MONOGRAPH

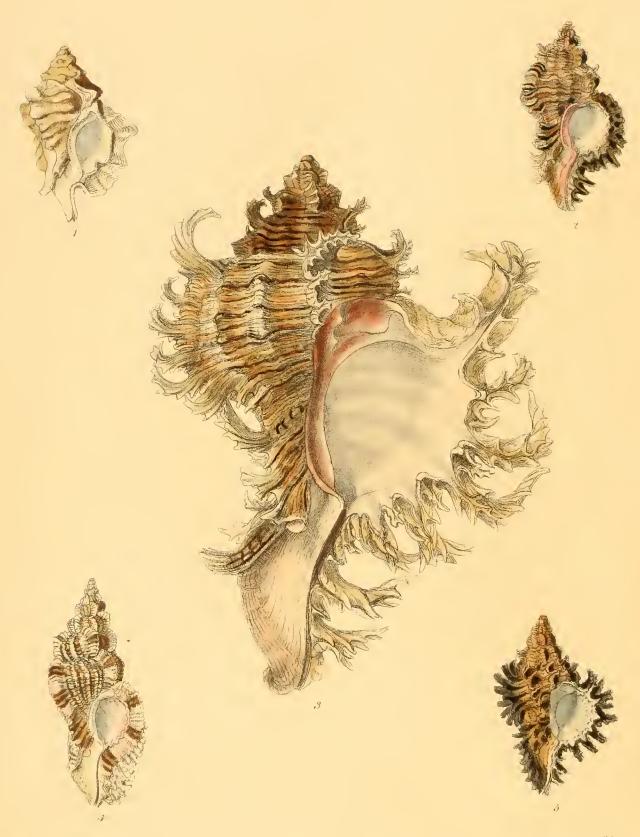

OF THE GENUS

MUREX.

"For Nature here
Wanton'd as in her prime, and play'd at will
Her virgin fancies, wild above rule or art."—Millon.

Reeve Brothers cupro-lith

PLATE I.

Genus MUREX, Linnæus.

Testa ovata vel oblonga, sæpissimè pyriformis, aut plus minusve fusiformis, spirá subangulato-turritá; anfractibus
leviter ventricosis, varicosis, varicibus tribus aut pluribus, frondibus ramosis vel foliatis vel spinosis ornatis;
columellá lævi, arcuatá, in canatem nunc brevissimum
recurvum, nunc longissimum tubulosum desinente; aperturá suborbiculari, labro externo plerumque denticulato
aut crenato, dente unico prominulo erecto infra medium
interdum armato. Operculum corneum.

Shell ovate or oblong, generally pyriform, or more or less fusiform, spire somewhat angularly turreted; whorls slightly ventricose, varicose, varices three or more in number, ornamented with branched, foliated, or spinose fronds; columchla smooth, arched, ending in a canal which is sometimes very short and recurved, sometimes very long and tubulous; aperture nearly orbicular, outer lip generally denticulated or crenated, and sometimes armed beneath the middle with an erect prominent tooth. Operculum horny.

The genus Murex, as at present constituted, contains but a very limited number of the species referred to it by its founder. After having been liberally dismembered by Bruguière and Lamarck for the formation of the genera Cerithium, Turbinella, Cancellaria, Fasciolaria, Fusus, Pleurotoma and Pyrula, there yet remained a considerable portion that were characterized by their different varieties of varicose growth; and of these Lamarck established the genera Ranella, Triton and Murev. The first for the reception of the species in which exactly two varices are deposited on a whorl, the second for those having a smaller number, and the third for such as have a larger number. The genns therefore under consideration includes all the varicose Canaliferous Gastropods which deposit a marginal varix at three or more intervals during every volution of increase round their columellar axis. As, in all arbitrary varieties of classification, however, there is great difficulty in determining the limit of the genus. The Murex, with numerous light and immaturely formed varices, is scarcely to be generically distinguished from the Fusus with its successive layers or ridges. The Murices Magellanicus, salebrosus and Belcheri are of this anomalous character; although, I consider the last-mentioned species, described by Mr. Hinds in the 'Zoology of the Sulphur,' to present many more characters in common with those of Pyrula than of Murex, and do not hesitate to refer it to that genus.

The Murices are greatly distinguished by the ornamental and varied structure of the varices; and when it is considered what an impediment the numerous spines and frondose ramifications must offer to their revolving process of growth, it becomes interesting to notice in what manner this emergency is provided for. The animal inhabitant has the power of removing these obstacles to its growth by the use of a powerful solvent. In the *Murex cornutus*, for example, may be commonly observed, on the left of the upper portion of the columella, the remains of a spine which has been abraded and removed at its base to make way for the approaching deposit of the increasing whorl.

The genus Murex has been so recently illustrated by Mr. Sowerby in his 'Conchological Illustrations,' and by M. Kiener in his 'Iconographie des Coquilles vivantes,' that I have not many new species to be added; there are, however, some important errors to be emended in the works of both authors.

Species 1. (Mus. Cuming.)

Murex emarginatus. Mur. testá ovatá, spirá breviusculá, acuminatá, suturis rudis, undatis; anfractibus senis, supernè angulatis, læviusculis, inter varices conspicuè tuberculatis, transversim obsoletè costatis; trifariam varicosá, varicibus obtuso-fimbriatis, solidiusculis; albidá, ferruginco-fuscescente tinctá; labro externo dente unico parvo, planulato, anticè armato; canali brevi, clauso, obliquè recurvo.

The emarginated Murex. Shell ovate, spire rather short, acuminated, sutures rude, waved; whorls six in number, angulated at the upper part, rather smooth, conspicuously tuberculated between the varices, transversely obsoletely ribbed; three-varicose, varices obtusely fimbriated, rather solid; whitish, stained with pale rusty brown; outer lip armed anteriorly with a single small flattened tooth; canal short, closed, obliquely recurved.

Sowerby, Pro.Zool.Soc.,1840; Conch.Illus. f.98 and 100. *Hab.*

The entire surface of this shell has the appearance of being very minutely indented. The oblique turn of the canal is characteristic, and so also is the prominent developement of the tubercles between the varices.

Species 2. (Mus. Cuming.)

Murex laciniatus. Mur. testā oblongo-ovatā, subfusiformi, basem versus contractā, spirā mediocri, suturis subimpressis; anfractibus senis, inter varices bituberculatis, transversim biratis, liris parvis, subscabrosis, distantibus, tribus basalibus fortioribus; trifariam varicosā, varicibus creberrime crispifoliatis, folios basem versus frondiformibus, subspinosis; rosaceo-fuscescente, varicibus castaneo-maculatis, columellá apice canalique purpureo-roseis; aperturá rotundá, labro externo crenulato.

The laciniated Murex. Shell oblong-ovate, somewhat fusiform, contracted towards the base, spire midding, with the sutures somewhat impressed; whorls six in number, with two tubercles between each varix, transversely ridged, ridges small, somewhat scabrous, distant, the three basal ridges stronger than the rest; three-varicose, varices very closely crisply foliated, the foliations being frond-like and somewhat spinous towards the base; pinkish brown, variees spotted with chesmit brown, columella apex and canal purple rose; aperture rounded, onter lip cremidated.

Sowerby, Conchological Illustrations, f. 59.

Eadem. Murex scabrosus, Sowerby, Conch. Illus. f. 73. Hab. Island of Ticao, Philippines; Cuming.

This is a very interesting species; the varices appear to consist of a number of foliated laminæ closely pressed together, and the ridges which on the body of the shell are very small, on the varices are developed with peculiar force. The three basal ridges are, however, much stronger throughout than any of the rest. Mr. Sowerby has erroneously described a mutilated example of his Murex laciniatus for a new species, under the name of Murex scabrosus.

Species 3. (Mrs. Saul.)

Murex ramosus. Mur. testá trigono-ovalá, ventricosá, spirá breviusculá; anfractibus senis, tuberculis pluvimis inter varices armatis, transversim obsoletè livatis et eveberrimè elevato-lineatis; trifariam varicosá, varicibus conspicuè frondosis, frondibus maximis, curvis, canaliculatis, inciso-serratis; albá, fusco pallidè nebulosá, lineis transversis elevatis fuscis, columellá labrique externi limbo rosaccis; canali breviusculo, plannlato, recurvo.

The branched Murex. Shell triangularly ovate, ventricose, spire rather short; whorls six in number, armed between the variess with several tubercles, transversely obsoletely ridged and elevately lineated; three-varicose, variese conspicuously frondose, fronds very large, curved, canaliculated, deeply serrated; white, faintly clouded with brown, transverse raised lines brown, columella and edge of the outer lip rosepink; canal rather short, tlattened, recurved.

LANN.EUS, Mus. Ludovicæ Ulricæ reginæ.

Murex inflatus, Lamarck.

Hab. Eastern Seas.

Lamarck distinguished this large and well-known species by the new title of *Murev inflatus*, because, judging from the various references which Linnaeus quoted in illustration of his *Murex ramosus* in the 'Systema Nature,' he appeared

to have confounded several species together. This is, however, without doubt, the shell he had under consideration; and the original name should be preserved, especially when we learn, upon the testimony of M. Deshayes, that in the 'Mus. Lud. Uhricæ reginæ' the references and synonymy are correct.

Species 4. (Mus. Cuming.)

Murex triqueter. Mur. lestá elongato-ovalá, subfusiformi, spirá turritá; anfractibus octonis, longitudinaliter plicatis, transversim liratis, liris augustis, subacutis, basem versus rotundatis, impresso-striatis; trifariam varicosá, varicibus posticè obtuso-rotundatis,
anticè, propè ad canalem, egregiè laminato-frondosis;
albidá, roseo tinctá, fusco maculatá et nebulosá; canali
brevi.

THE THREE-ANGLED MUREX. Shell clongately ovate, somewhat fusiform, spire turreted; whorls eight in number, longitudinally plicated, transversely ridged, ridges narrow, rather sharp, rounded towards the base, impressly striated; three-varicose, varices posteriorly obtusely rounded, anteriorly, near the canal, eminently laminately frondose; white, tinged with rose, spotted and clouded with brown; canal short.

BORN, Mus. Cæs. p. 291. pl. 11. f. 1, 2.

Murex trigonulus, Enc. Méth.; Kiener.

Hab. Philippine Islands; Cuming.

The Murices triqueter and trigonulus are figured in the 'Encyclopèdic Mèthodique' and in Kiener's 'lcon. Coq. viv.' one for the other, and vice versû.

Species 5. (Mus. Cuming.)

Murex angularis. Mur. testá ovatá, subventricosá, spirá parvá, acuminatá; anfractibus senis, transversim elevato-striatis, striis leviter scabrosis; octofariam varicosá, varicibus regulariter obtuso-frondosis, frondibus erectis, subdistantibus; nigricante-fuscá, apicem versus pallidiore; canali brevi.

The angular Murex. Shell ovate, rather ventricose, spire small, acuminated, whorls six in number, transversely elevately striated, striæ scabrous; eight-varicose, varices regularly obtusely frondose, fronds erect, somewhat distant; dark brown, paler towards the apex; canal short.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol. ix. p. 595. Hab. Senegal.

In this species the variees are extremely variable, and when only few in number impart an angular structure to the shell; in one of the specimens before me, for example, in which there are only five variees on a whorl, it assumes the form of a pentagon.

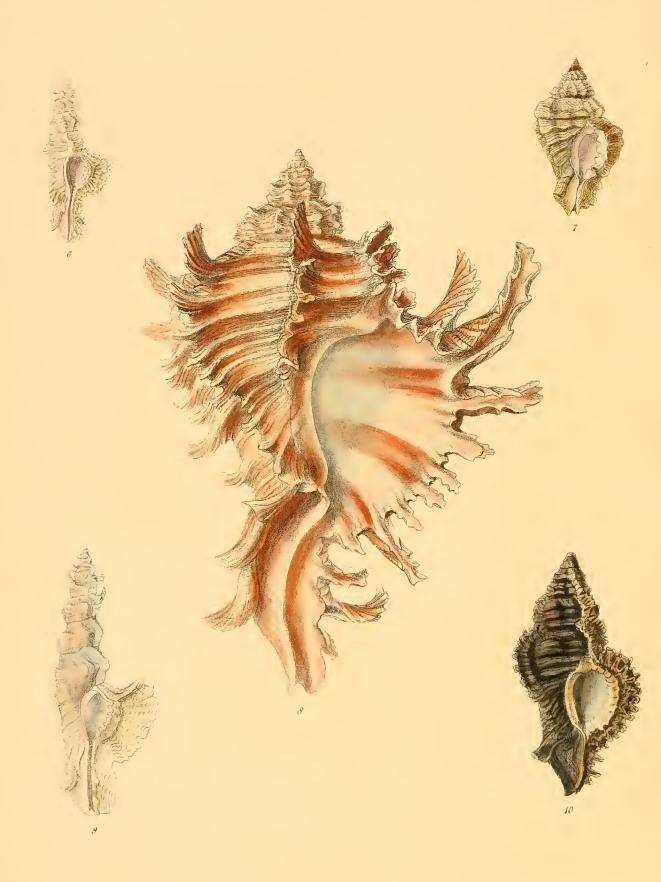

PLATE II.

Species 6. (Mus. Taylor.)

Murex bipinnatus. Mur. testa elongato-fusiformi, spira acuminato-turrită; unfractibus septenis, transversim eximiè liratis, et elevato-striatis, liris striis et interstitiis subtilissimè scabroso-crenulatis, anfractibus primis senis tuberculato-nodosis, ultimo trivaricoso, varicibus ultimis duobus pulcherrimè fimbriato-pinnatis; nivea, rosaceo tincta, columella pallidè rosea; apertura parva, labri externi limbo minutè denticulato; canali latius-culo, subelongato.

The two-winged Murex. Shell elongately fusiform, spire acuminately turreted; whorls seven in number, transversely delicately ridged and elevately striated, ridges striae and interstices very finely seabrously crenulated, first six whorls tuberculously noduled, last whorl three-varicose, last two varices very beautifully fimbriately winged; snowy white, tinged with rose, columella pale rose; aperture small, edge of the outer lip minutely denticulated; canal rather broad, a little elongated.

REEVE, Pro. Zool. Soc., 1845. *Hab.* —— ?

I am much indebted to Mr. Taylor for the loan of this very interesting shell, and readily adopt a name which that gentleman kindly suggests, as indicating the peculiarity of there being no appearance of frill structure except upon the last two varices. The spire exhibits a mass of prominent nodules, each whorl taking the form of a heptagon with as many as seven on its circumference. In general form the *Murex bipinnatus* approaches the *Murex clavus*; it will, however, be observed on reference to that species that the detail of structure and sculpture is distinct throughout.

Species 7. (Mus. Cuming.)

Murex Monogeros. Mur. testá subtrigono-ovatá, spirá breviusculá, acutá, suturis impressis; anfractibus senis, inter varices tuberculato-nodosis, transversim elevato-striatis, striis scabrosis; trifariam varicosá, varicibus obtuso-rotundatis, nodiferis, posticè anticèque laminatis; albidá, glauco-fuscescente tinctá, aperturæ fauce pallidissimè purpurascente-roseá; canali brevi; aperturá ovatá, labro intus fortiter tuberculato-dentato, timbo minutè denticulato, denticulo uno aut pluribus conspicuè erectis.

The Monoceros-like Murex. Shell somewhat triangularly ovate, spire rather short, sharp, with the sutures impressed; whorls six in number, tubercularly noduled between the varices, transversely elevately striated, striæ scabrons; three-varicose, varices obtusely rounded, nodiferous, posteriorly and anteriorly laminated; whitish, stained with glaucous brown, interior of the aperture very faintly tinged with purple rose; canal short; aperture ovate, lip strongly tubercularly toothed within, edge minutely denticulated, one or more of the teeth being conspicuously erect.

Sowerby, Pro. Zool. Soc., 1840.

Murex Nuttallii? Conrad.

Hab. California.

The minute scabrous sculpture of this shell is very characteristic, and so is also the obtuse stunted tubercular structure of the varices. The marginal tooth is unusually prominent.

Species 8. (Mus. Cuming.)

Murex saxatilis. Mur. testā subpyriformi, ventricosā, spirā mediocri; anfractibus transversim liratis et elevato-striatis, striis subundulatis et granosis; sexfariam varicosā, varicibus frondosis, frondibus posticis anticisque grandibus simplicibus foliaceis, canaliculatis, erectocurvatis, medianis multo brevioribus; fuscā vel aurantio-rubrā, columellā canalique vividè roseo-rubentibus, aperturæ fauce radiatā; canali compresso, recurvo.

The Rock-inhabiting Murex. Shell somewhat pyriform, ventricose, spire middling; whorls transversely ridged and elevately striated, striæ slightly waved and granose; six-varicose, varices frondose, posterior and anterior fronds large, simple, foliaceous, canaliculated, erectly curved, middle fronds much shorter; brown or orange-red, columella and canal bright pinkish red, aperture radiated with the same colour; canal compressed, recurved.

Linnæus, Syst. Nat. (Gmelin's edit.) p. 3529. *Hab.* Eastern Seas.

The shell which I have selected for the illustration of this beautiful and well-known species, is one of the rich orange-red variety. The ordinary colour of the outer surface is a light fulvous brown. Species 9. (Mus. Cuming.)

Murex clavus. Mur. testá elongato-fusiformi, spirá trigono-turritá, squamis erecto-recurvis ad angulos apicem versus uncinatá; anfractibus octonis, trigonis, lævibus, aut obsoletè liratis et striatis, inter varices tuberculato-plicatis; trivaricosá, varice ultimo marginali latissimè fimbriato-pinnato; niveá, roseo tinctá, columellá pallidè roseá; canali subelongato; aperturá parvá, labro externo denticulato.

THE RUDDER MUREX. Shell elongately fusiform, spire triangularly turreted, armed at the angles towards the apex with erectly recurved hook-like scales; whorls eight in number, three-sided, smooth or obsoletely ridged and striated, tubercularly plicated between the varices; three-varicose, the last marginal varix very broadly fimbriately winged; snowy white, tinged with rose; eanal rather elongated; aperture small, outer lip denticulated.

Kiener, Ieon. Coq. viv. p. 111. pl. 37. f. 2.

Murex uncinarius, Sowerby (not of Lamarck).

Hab. Island of Masbate, Philippines; Cuming.

A characteristic figure of this remarkable species was published by Martini nearly seventy years since, in the 'Conchylien Cabinet,' but no further illustration of it appeared until it was recently figured in the 'Conchological Illustrations.' Mr. Sowerby there describes it as the Murex uncinarius of Lamarek, but as M. Kiener has since shown that species to be another and of very different character, I feel much pleasure in adopting his name. The error into which Mr. Sowerby had fallen was, no doubt, occasioned by Lamarck's referring his Murex uncinarius to Martini's figure of this shell; and eleven lines being the measurement given of it, Mr. Sowerby, and even Lamarck himself,

may have suspected that the *Murex uncinarius* was merely an example of the shell under consideration in a very early stage of growth.

The nearest allied species to the *Murex clavus* is that which I have just described under the new title of *Murex bipinnatus*; in that species the whorls are tuberculated, not hooked, and of a heptagonal form; in this, they are distinctly three-sided and conspicuously hooked at the angles; the laminated frills of the two species are also different.

Species 10. (Mus. White.)

Murex Capucinus. Mur. testá elongalo-ovatá, fusiformiturritá, crassiusculá; anfractibus transversim subirregulariter liratis; trifariam varicosá, varicibus multilamellatis, lamellis brevibus, compressis, externá foliatá, recurvá; atro-fuscá, columellá albidá; canali depresso, breviusculo; labro externo intus denticulato.

THE CAPUCHIN MUREX. Shell elongately ovate, fusiformly turreted, rather thick; whorls transversely somewhat irregularly ridged; three-varicose, varices many-lamellated, lamellæ short, compressed, the outer lamella foliated, recurved; black-brown, columella whitish; canal depressed, rather short; outer lip denticulated within.

CHEMNITZ, Conch. Cab. vol. xi. pl. 192. f. 1849-50.

An cadem. Murex quadrifrons, Lamarek.

Hab. Philippine Islands (found at the root of Mango trees on the shore); Cuming.

This species may be recognised by the peculiar compressed laminated structure of the variees. There is little doubt, I think, but that Lamarck's *Murex quadrifrons* is merely an accidental four-varieose variety of this species.

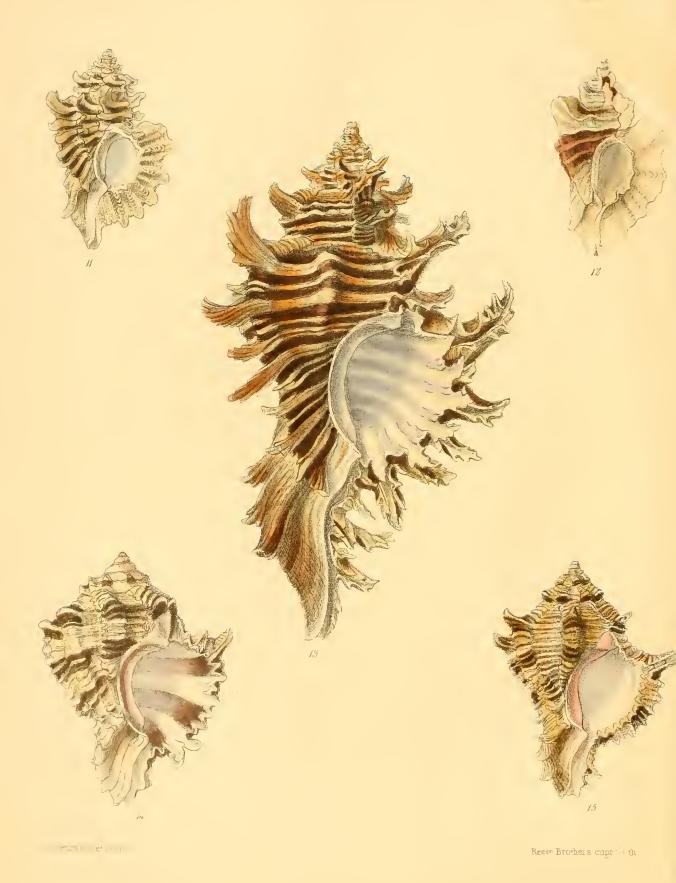

PLATE III.

Species 11. (Mus. Cuming.)

Murex erinaceus. Mur. testá subfusiformi-ovatá, spirá mediocri; anfractibus supernè angulatis, inter varices tuberculatis, transversim fortiter costatis, costis rotundato-tumidis, teviter undatis, interstitiis minutissimè squamuloso-rugosis, lirá parvá squamulosá sæpè interveniente; quadrifariam ad septifariam varicosá, varicibus valdè irregularibus, nunc frondosis, nunc fimbriatolamellatis; albido-fulvá; canali brevi, clauso, subrecurvo.

The hedge-hog Murex. Shell somewhat fusiformly ovate, spire middling; whorls angulated at the upper part, slightly tuberculated between the varices, transversely strongly ribbed, ribs rotundately swollen, slightly waved, interstices very minutely squamulously rugose, with a small squamulous ridge running through; four- or seven-varicose, varices very irregular, sometimes frondose, sometimes fimbriately lamellated; white, stained with pale fulvous brown; canal short, closed, a little recurved.

LINNÆUS, Syst. Nat. (Gmelin's edit.), p. 3530.

Variety β .

Testa varicibus incrassatis, solidis; costis transversis angustis, valdė obscurioribus.

Shell with the varices thickened, solid; transverse ribs narrow, much more obscure.

Murex Tarentinus, Lamarck, Anim. sans vert. (Deshayes' edit.), vol. ix. p. 593. Kiener, Iconographie des Coquilles vivantes, pl. 44. f. 2.

Variety y.

Testa nunc varicosa, nunc evaricosa; anfractibus supernè albicingulatis.

Shell sometimes varicose, sometimes without varices; whorls encircled with a white belt round the upper part

Murex cinguliferus, Lamarck, Anim. sans vert. (Deshayes' edit.), vol. ix. p. 597. Kiener, Iconographie des Coquilles vivantes, pl. 30. f. 2.

Hab. Mediterrancan, and coast of France and Britain, (found at low water and at depths varying to four-teen fathoms).

This species, like the Murices trunculus and brandaris, which inhabit the same sea, is extremely variable in growth,

some examples having as many as seven varices, whilst others exhibit nothing more than a row of almost obsolete plicated laminæ. In the variety β , which Lamarck distinguished as the Murex Tarentinus, the laminæ of each varix, instead of being raised like a festooned frill, as in the type of the species, are pressed down and, as it were, solidified between the ribs; whilst the ribs are narrower and more obscure. The variety γ is chiefly distinguished by a conspieuous white belt encirching the ribs at the angle, the sculpture being in most respects like that of the variety β . This is much the scarcest state of the species; it is very well represented by M. Kiener as the Murex cinguliferus, and I have a small but equally characteristic specimen from the collection of Thomas Norris, Esq.

Species 12. (Mus. White.)

Murex foliatus. Mur. testá ovato-oblongâ, spirá breviusculá; anfractibus transversim costatis, costis parvis, compressis, subdistantibus, interstitiis lævibus; trifariam varicosâ, varicibus tenuibus, erecto-foliatis; albidâ, castaneo-fusco fasciatá; aperturâ parvâ, labro columellari simplici, externo denticulato, dente unico planato infernè armato; canali brevi, plano-compresso, clauso.

The foliated Murex. Shell ovately oblong, spire rather short; whorls transversely ribbed, ribs small, compressed, somewhat distant, interstices smooth; three-varicose, varices thin, erectly foliated; whitish, banded with chesnut brown; aperture small, columellar lip simple, outer lip denticulated, armed at the lower part with a small flattened tooth; canal short flatly compressed, closed.

GMELIN, Syst. Nat. p. 3529.

Purpura foliata, Martyn, Univ. Conch. pl. 66.
Murex purpura alata, Chemnitz, Conch. Cab. vol. x.
p. 250. pl. 160. f. 1538-9.

Hab. Island of Sitka, north-west coast of America (found in rocky places); Escholtz.

Lamarck committed a grand error in referring to Chemnitz's admirable figure of this species for the illustration of the *Murex tripterus* of Born; and Kiener, confiding with his usual fidelity in the purity of Lamarck's labours, has not failed to repeat it. M. Deshayes has, however, published the *Murex foliatus* in his recent edition of the 'Animaux sans vertèbres,' with an accurate citation of its synonymes, and the species is no longer veiled with any obscurity.

Species 13. (Mus. Taylor.)

Murex calcitraya. Mur. testă trigono-fusiformi, crassă, solidiusculă, spiră turrită; anfractibus superne depressinsculis, transversim striatis et sulcatis, inter varices tuberculatis; trifariam varicosă, varicibus biseriatim frondosis frondium serie alteră minută, alteră prominente, frondibus crassiusculis, irregularibus, duabus anticis majoribus; rufescente-castaneă, lineis balteisve angustis nigerrimo-fuscis cingulată; canali subelongato, compresso, leviter recurvo.

The Caltrop Murex. Shell triangularly fusiform, thick, rather solid, spire turreted; whorls rather depressed at the upper part, transversely striated and grooved, tuberculated between the varices; three-varicose, varices composed of a double row of fronds, one of which is minute, the other prominent with the fronds rather thick and irregular, the two most anterior being larger than the rest; reddish-chesnut, encircled with narrow blackish-brown lines or narrow belts; canal rather elongated, compressed, slightly recurved. Lamarck, Anim. sans vert. (Deshayes'edit.), vol.ix.p.573. Hab. Red Sea (found on the coral reefs); Rüppell.

Variety β .

Testa plerumque brevior; albá, lineis rubido-fuscis cincta.
Shell generally shorter; white, cheircled with reddish brown lines.

Murex brevifrons, Lamarck, Anim. sans vert. vol. ix. p. 573.

Purpura frondosa fasciata, Martini.

Hab. West Indies (found on the coral rccfs).

There can be little doubt but that Lamarck's Murex brevifrons is a white variety of his Murex calcitrapa, inhabiting a different locality; although their close affinity is not commented upon by M. Deshayes. It is a thick, rather ponderous looking species, well characterized by the brown lines and belts which cross the interstices between the variees. Some specimens are thin, and more frondose.

It may be interesting to know that the caltrop was an instrument of war, which the ancients scattered on the field of battle in order to wound the feet of the enemies' horse. It was a small iron weapon constructed of three sides, with a row of sharp spikes down each angle, such as may be suggested by the three-varicose structure of the shell under consideration. If thrown with skill over the enemies quarters, a shower of caltrops must have proved very annoying,

because, upon whatever side the instrument fell, a row of spikes would stand uppermost.

Species 14. (Mus. Cuming.)

Murex Rosarium, Var. β. For description of which see Plate VIII.

Species 15. (Mus. Cuming.)

Murex turbinatus. Mur. testă ovato-turbinată, spiră brevi, conică; anfractibus superne angulatis, transversim liratis, liris impresso-striatis, alternis majoribus; sexfariam varicosă, varicibus obtuso-rotundatis, ad angulum conspicue spinoso-tuberculatis, basem versus submuricato-tuberculatis; albidă, fasciis rufescente-fuscis tribus interruplis varices super tinctă, columellă pallide rosaceă; canali breviusculo.

The turbinated Murex. Shell ovately turbinated, spire short, conical; whorls angulated at the upper part, transversely ridged, ridges impressly striated, alternate ridges the larger; six-varicose, varices obtusely rounded, conspicuously spinosely tubercled at the angle, somewhat prickly tubercled at the base; whitish, stained, upon the varices only, with three interrupted reddish brown bands, columella faintly tinged with pink; canal rather short.

Lamarck, Anim.sans vert. (Deshayes' edit.) vol.ix. p. 586. Kiener, Icon. Coq. viv. pl. 22. f. I.

Hab. Mouth of the Gambia, East coast of Africa.

The variees of this somewhat rare species are probably rather variable in number; in the specimen before me there are only six on a whorl, Lamarck mentions seven, and Kiener, who transcribes Lamarck's Latin diagnose of the species, enumerates eight in his summary of the specific characters. The aperture of this shell is lined with pure white, and the columella with pink enamel.

Mr. Sowerby, jun., has unfortunately published a serious category of errors in attempting to illustrate this species; having figured three different shells, of which neither has any reference to it. The shell represented at Fig. 30. of the 'Conchological Illustrations' is an indifferent specimen of the *Murex spinicostata*; that represented at Fig. 90 I have decided, after a long and patient examination of the specimen, to be a worn, curiously stained, tubercled variety of the *Murex trunculus*; and Fig. 91 represents an obscure example of the *Murex endicia*.

Reeve Brothers cupro-11th

PLATE IV.

Species 16. (Mus. Cuming.)

Murex Maurus. Mur. testā trigono-oblongā, utrinque attenuatā, crassiusculā, ponderosā, spirā acuminatoturritā; anfractibus inter varices unduloso-tuberculatis, transversim granuloso-liratis et impresso-striatis, liris alternis majoribus; trifariam varicosā, varicibus incrassatis, rotundatis, basem versus subobsoletē frondosis, frondibus parvis, perpancis; fuscescente, liris nigricantibus, labrorum limbo roseo, labro externo denticulato; canali breviusculo.

The moor Murex. Shell triangularly oblong, acuminately turreted at both ends; whorls undulately tubercled between the varices, transversely granulously ridged and impressly striated, alternate ridges the larger; three-varicose, varices thickened, rounded, somewhat obsoletely frondose towards the base, fronds small, very few in number; pale brown, ridges blackish, edge of the columellar and outer lips tinged with rose, outer lip denticulated; canal rather short. Broderip, Pro. Zool. Soc., 1832.

Hab. Island of Annaa, Pacific Ocean (found on the reefs); Cuming.

M. Deshayes very properly reprimands M. Kiener for asserting that the *Murices maurus* and *rubescens* Broderip, are merely specimens of the *Murex adustus* in a bad state of preservation. "Cela prouve," very truly says the learned editor of the 'Animaux sans vertèbres," que M. Kiener n'a pas eu sous les yeux ces espèces du naturaliste anglais." The *Murex maurus* has more the appearance of a stunted immature *Murex palmarosæ* than a *Murex adustus*, from which it differs too manifestly to render any comparison necessary.

Mr. Cuming and Miss Saul both possess specimens of the *Murex maurus* in the finest possible condition, and I feel much pleasure in being enabled to add my testimony to its specific importance. M. Kiener disposes in like manner, of a vast number of the many valuable and characteristic new species of shells collected by Mr. Cuming, and described, from time to time, by Messrs. Broderip and Sowerby, in the 'Proceedings of the Zoological Society,' 1832—12.

Species 17. (Mus. Cuming.)

MUREX OXYACANTIIA. Mur. testa pyriformi, spira brevi,

obtusă, suturis cavernosis; anfractibus transversim liratis et impresso-striatis, liris alternis minimis; niveă, spinis fuscescente tinctis; apertură parvă, rotundă; canali breviusculo, ad extremitatem recurvo.

The sharp-spined Murex. Shell pear-shaped, spire short, obtuse, sutures cavernons; whorls transversely ridged and impressly striated, alternate ridges very small; seven-varicose, varices spined throughout, spines long, erect, canaliculated, alternate spines very small; snowy white, spines stained with pale brown, aperture small, round; canal rather short, recurved at the extremity.

Broderip, Pro. Zool. Soc., 1832.

Hab. Real Llejos, Central America (found in sandy mud at the depth of eight fathoms); Cuming.

Each transverse ridge terminates upon the following varix in a lofty erect canaliculated spine, the minute alternate ridges terminating in spines of the same proportion of size.

Miss Saul possesses several specimens of a dwarf variety of this species.

Species 18. (Mus. Cuming.)

Murex spinicostata. Mur. testâ pyriformi, nunc oblongă, nunc breviore, ventricosă; anfractibus superne biangulatis, transversim liratis et striatis, liris minutis, angustis, subsuperficialibus; sexfariam vel septifariam varicosă, varicibus undique spinosis, spinis canaliculatis, subcurvatis, duabus anticis angulos superantibus et duabus tribusve basalibus, longioribus, mucronatis; albă, liris rufo-fuscis, maculis parvis saturatioribus lunute-formibus hic illic tinctis, aperturæ fance albā, rubido sparsim maculată; canali subelongato, interdum breviore, recurvo.

The spine-ribbed Murex. Shell pear-shaped, sometimes oblong, sometimes shorter and ventricose; whorls bi-angulated at the upper part, transversely ridged and striated, ridges minute, narrow, rather superficial; six- or seven-varicose, varices armed with frond-like spines throughout, spines canaliculated, slightly curved, the basal and those upon the posterior angles, longer, sharp-pointed; white, ridges reddish brown, stained here and there with small crescent-shaped spots of a deeper colour, interior of the aperture white,

stained in places with ruddy spots; canal rather clongated, sometimes shorter, recurved.

VALENCIENNES, Kiener, Icon. Coq. viv. p. 49. pl. 41. f. 1. *Hab.* Gulf of Mexico.

This very interesting shell, of which a worn stunted example is represented in the 'Conchological Illustrations,' fig. 30, under the erroneous title of *Murex turbinatus*, was, I believe, originally distinguished by Mr. Sowerby by the name of *Murex fulvescens*; no description, however, appeared, and as the name was subsequently cancelled from the catalogue, I am obliged to yield to M. Valenciennes the honour of having first introduced the species.

The frond-like spines of the *Murex spinicostata* are of a sharp simple structure, exhibiting no indication of being foliated; but are singularly characterised in being armed with a small prickle on each side at about one-third of their entire length from the top. This character can, however, only be recognised in such specimens as have the spines well developed.

Species 19. (Mus. Taylor.)

Murex rufus. Mur. testá trigono-ovatá, subfusiformi, spirá mediocri; anfractibus transversim leviter liratis, et granoso-striatis, inter varices tuberculatis; trifariam varicosis, varicibus, uniseriatim frondosis, frondis planocompressis, regularibus, elegantissimè foliatis; rufofuscá: aperturá parvá rotundatá, sub-impressá.

The Red Murex. Shell triangularly ovate, somewhat fusiform, spire middling; whorls transversely ridged and granosely striated, tuberculated between the varices; three-varicose, varices surmounted by a single row of flatly compressed, regular, very elegantly foli-

ated fronds; reddish-brown; aperture small, rounded, somewhat impressed.

LAMARCK, Anim. sans vert. (Deshayes'edit.), vol.ix. p. 574. Hab. Indian Seas.

This species is chiefly distinguished by its three single rows of elegant leaf-like fronds, some of which seem to be coated internally with one or more peculiar laminæ of enamel. There is a very delicate small white variety of this shell with a pink apex.

Species 20. (Mns. Cuming.)

Murex palmiferus. Mur. testâ fusiformi-oblongâ, spirâ subelongatâ, acuminato-turritâ; anfractibus transversim liratis et striatis, tuberculis duobus prominentibus inter varices armatis; trifariam varicosâ, varicibus subincrassatis, uniseriatim frondosis, frondis brevibus, subcompressis, sæpè lateraliter fimbriato-connexis; roseofuscescente aut albidâ; canali breviusculo, recurvo; tabro externo denticulato.

The Branch-bearing Murex. Shell fusiformly oblong, spire rather elongated, acuminately turreted; whorls transversely ridged and striated, armed between the varices with two prominent tubercles; three-varicose, varices somewhat thickened, furnished with a single row of short rather compressed fronds, often fimbriately connected at the side; pinkish brown or white; canal rather short, recurved; outer lip denticulated.

Sowerby, Pro. Zool. Soc., 1840.

Hab. North Australia.

This species may be recognised by its short compressed fronds, which range for the most part so closely side by side as often apparently to form a connected leaf-like frill.

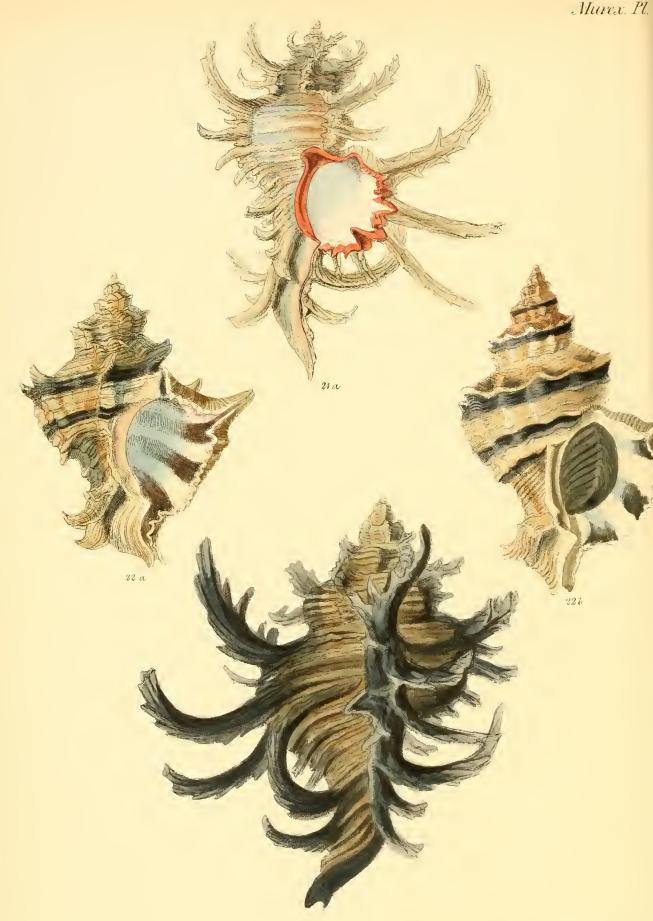

PLATE V.

Species 21. (Fig. a, Mus. Cuming; Fig. b, Mus. Saul.)

Murex Monodon. Mur. testá ovato-fusiformi, tenui, spiræ suturis excavato-impressis; anfractibus transversim liratis et striatis; trifariam varicosá, varicibus pulcherrimè frondosis, frondibus elongatis, curvatis, penultimá longissimá, peculiariter recurvá; rufescente-fuscá, frondibus nigricantibus, columellá labrique limbo rosaceis; cauali breviusculo; labro infra medium dente valido erecto instructo.

The single tooth Murex. Shell ovately fusiform, thin, sutures of the spire excavately impressed; whorls transversely ridged and striated; three-varicose, varices very beautifully frondose, fronds elongated, curved, the last but one from the base much the longest, and peculiarly curved back; reddish brown, fronds blackish, columclla and edge of the lip tinged with rose; canal rather short; lip furnished just beneath the middle with a strong raised tooth.

Variety β . (Fig. 21 a.)

Testa alba, columellá labrique limbo vividè coccineo-roseis.
Shell pure white, columella and edge of the outer lip bright scarlet rose.

Sowerby, Tankerville Catalogue, App. p. 19.

Murex aranea, Blainville (Kiener).

Hab. Dupuch's Island, Torres Straits (found on the reefs at low water); Dring, H. M. S. Beagle.

I have much pleasure in being enabled to illustrate the varieties of this fine species, by two most magnificent specimens from the cabinets of Mr. Cuming and Miss Saul; the one exhibiting the front structure, in the white variety, with the delicate contrast of the pink lip and columella, the other showing the graceful curvature of the fronds, of

which the lowest but one assumes such a remarkable spurlike form.

The Murices monodon and imperialis, though figured by Martini in his Conchylien Cabinet, in the year 1777, were unknown to Lamarck, whose monograph of the genus, in the 'Animaux sans vertèbres,' was not published until five and forty years afterwards.

Species 22. (Mus. Cunning.)

Murex trunculus. Mur. testa orato-fusiformi, subventricosa, spira angulato-turrita; anfractibus transversim impresso-striatis et obtusè nodutiferis, supernè angulatis; sexfariam varicosa, varicibus ad angulum nunc obtusonodosis, nunc squamato-tuberculatis; purpureo-fusco alboque fasciata; canali brevi, compresso, recurvo; aperturæ fauce zonis purpureis et atbis vividè radiata,

The banded Murex. Shell ovately fusiform, slightly ventricose, spire angularly turreted; whorls transversely impressly striated, and obtusely nodiferous, angulated at the upper part; six-varicose, sometimes obtusely nodose at the angle; sometimes squamately tubercled; banded with purple-brown and white; canal short, compressed, recurved; interior of the aperture vividly rayed with purple and white zones.

LINNÆUS, Syst. Nat. (Gmelin's edit.) p. 3527.

Hab. Mediterranean.

The figures given in illustration of this well-known species are selected to show the variable character of its growth, some examples being merely slightly nodiferons, whilst others are coronated with a prominent row of scale-like tubercles. A variation of structure analogous to this occurs in the genus $\Gamma oluta$, which presents both smooth and tubercled varieties of the greater portion of the species.

Reeve Brother .up. .uth

PLATE VI.

Species 23. (Mus. Cuming.)

Murex princeps. Mur. testá subpyriformi-ovatá, hexagoná, spirá brevi; anfractibus supernè angulatis; transversim subobsoletè liratis et striatis; sexfariam varicosá, varicibus frondosis, frondibus subrudibus, erectis; albá, fasciis lineisque ferrugineo-fuscis transversis tinctá; canali brevi.

The prince Murex. Shell somewhat pyriformly ovate, six-angled, spire short; whorls angulated at the upper part, transversely somewhat obsoletely ridged and striated; six-varicose, varices frondose, fronds somewhat rude, erect; white, stained with transverse rusty brown lines and bands; canal short.

Broderip, Pro. Zool. Soc., 1832.

Hab. Puerto Portrero, Central America (found on coral reefs at low water); Cuming.

The fronds of this species are of a peculiarly rude erect character, and that upon the angle is in each varix much stouter at the base than any of the rest. The style of colouring, which is of a reddish rusty brown, reminds one of the *Murex radix* though quite unlike.

Species 24. (Mus. Cuming.)

Murex megacerus. Mur. testá fusiformi-ovatá, quadrangulari, spirá subacuminatá; anfractibus supernè leviter angulatis, inter varices nodoso-plicatis, transversim liratis et striatis, liris parvis, acutangulis; quadrifariam varicosá, varicibus frondosis, frondibus peculiariter erectis, ad apicem leviter foliatis, fronde superá longissimá; fulvo-albicante, ferrugineo-fusco plus minusve pallidè tinctá; canali subelongato.

The large-horned Murex. Shell fusiformly ovate, four-angled, spire somewhat asuminated; whorls slightly angulated at the upper part, nodosely plieated between the variees, transversely ridged and striated, ridges small, sharp-angled; four-varieose, variees frondose, fronds peculiarly erect, slightly foliated at the top, uppermost frond the longest; fulvous white, stained more or less with rusty brown; canal slightly elongated.

SOWERBY, Pro. Zool. Soc., 1845. Hab. West Indies.

This species, though presenting no peculiarity of colour, may be readily distinguished by its four-varicose and quad-

rangular structure, and by the straight erect character of the fronds.

Species 25. (Mns. Cuming.)

Murex Sinensis. Mur. testá elongato-ovatá, subfusiformi, tenui, spiræ suturis subimpressis; anfractibus transversim liratis et striatis, inter varices nodiferis; trifariam varicosá, varicibus frondosis, frondibus regularibus, curvatis, pulcherrimè floridis, inciso-serratis; albicante, fusco tinctá, lineis transversis fuscis; labro infra medium fortiter erecto-dentato.

THE CHINESE MUREX. Shell clongately ovate, somewhat fusiform, thin, sutures of the spire rather impressed; whorls transversely ridged and striated, nodiferous between the varices; three-varicose, varices frondose, fronds regular, curved, beautifully flowered, deeply serrated; whitish, stained with brown, transverse lines brown; lip strongly erectly toothed beneath the middle.

REEVE, Pro. Zool. Soc., 1845.

Murex elongatus, var., Sowerby, Coneh. Illus. f. 88. Hab. China.

The species which I here distinguish by the new title of *Murex Sinensis* appears to have been confounded for some time past with the *Murex elongatus*, or the young of the *Murex inflatus*. It is uniformly of a thin structure, and the fronds are of a delicate open flowery growth.

Species 26. (Mus. Cuming.)

Murex elongatus. Mur. testâ fusiformi-elongatâ, tenuiculâ, subventricosâ; anfractibus transversim elevatostriatis, inter varices tuberculatis; trifariam varicosâ, varicibus frondosis, frondibus curvatis, inciso-serratis; rubido-fuscâ, columellâ et aperturæ fauce nigricanteviolascentibus; canali subelongato.

The elongated Murex. Shell fusiformly elougated, rather thin, somewhat ventricose; whorls transversely elevately striated, tuberculated between the variees; three-varicose, variees frondose, fronds eurved, deeply serrated; dark reddish brown; columella and interior of the aperture blackish violet; canal rather elongated.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol.ix. p. 571. *Hab.* Gulf of Mexico.

There is not so much novelty in the elongated structure of this species as in its uniform dark reddish-brown colour, and the blackish-violet enamel of the aperture.

PLATE VII.

Species 27. (Fig. a, b, c, d, Mus. Cuming.)

Murex endivia. Mur. testá subgloboso-ovatá, ventricosá, spirá subturritá; anfractibus transversim liratis et striatis; sexfariam vel septifariam varicosis, varicibus frondosis, frondibus floridi-foliaceis, laciniato-muricatis; pallidè ferrugineo-fuscá, frondibus nigricante-fuscis, vel albá, nigricante-fusco zonatá, frondibus alternatim nigricante-fuscis et albis, columellá et aperturæ fauce albis, rubro marginatis, varicibus rubromarginatis; canali brevi, ascendente; umbilico plerumque amplo.

The endive Murex. Shell somewhat globosely ovate, ventricose, spire slightly turreted; whorls transversely ridged and striated; six- or seven-varicose, variees frondose, fronds flowery foliaeeous, laciniately mmicated; pale rusty brown, fronds blackish brown, or white, zoned with blackish brown, fronds alternately white and blackish brown, columella and interior of the aperture white, edged with red, variees edged with red; canal short, ascending; umbilicus frequently large.

Variety β . (Fig. 27 a.)

Testa octofariam vel nonafariam varicosa, anfractibus su-

pernè declivibus, infernè contractis, varicibus octonis vel novenis, frondibus minoribus.

Shell eight- or nine-varicose, with the whorls bending downwards at the upper part, and contracted at the lower; fronds smaller.

Lamarck, Anim. sans vert. (Deshayes'edit.), vol. ix. p. 253. Variety β, Murex saxicola, Broderip.

Hab. Philippine Islands (found in great abundance in rocky places at low water); Cuming.

The leading colour of this magnificent species is a rusty or blackish brown, and it is so differently distributed in different examples, that it would be useless to establish any specific varieties upon so extremely variable a character. The Murex endivia presents, however, a variety of form which is of much greater importance, so much so, that Mr. Broderip described it in the Zoological Journal as a new species, Murex saxicola. The numerous specimens collected by Mr. Cuming at the Philippine Islands, abundantly testify that the remarkable declination which characterises the upper portion of the whorls in this variety, is no other than that structure of which we find a similar modification in the common Murex trunculus of the Mediterranean. The red marginal colouring of the columella and outer lips forms a characteristic feature in this species.

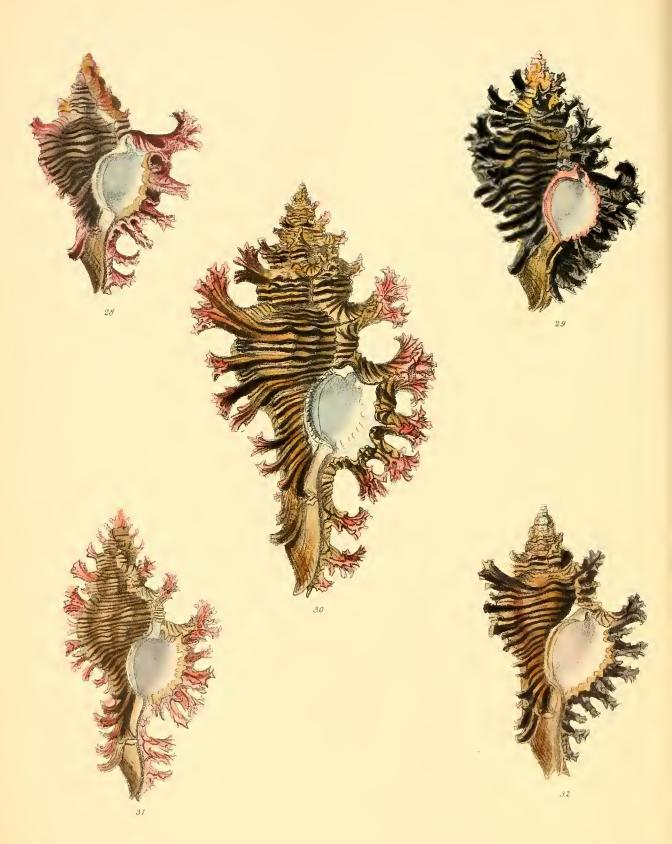

PLATE VIII.

Species 28. (Mus. Saul.)

Murex Steerie. Mur. testa abbreviato-fusiformi, crassa, transversim granoso-tirata, inter varices fortiter tubercutata; trifariam varicosa, varicibus incrassatis, frondosis, frondibus crispato-ramosis, subcompressis, brevinscutis, fronde parva interveniente; fusca, tiris nigricantibus, frondibus purpureo-roseis, columella et apertura fauce albis; labro externo incrassato, intus denticulato; canali breviusculo.

STEERE'S MUREX. Shell abbreviately fusiform, thick, transversely granosely ridged, strongly tuberculated hetween the varices; three-varicose, varices thickened, frondose, fronds crispately branched, somewhat compressed, rather short, with a small frond intervening; brown, ridges blackish, fronds purple-rose, columella and aperture white; outer lip thickened, denticulated within; canal rather short.

Reeve, Pro. Zool. Soc., 1845. *Hab.* ——?

This shell might easily be mistaken for an accidental stunted growth of the *Murex palma-rosæ*, were it not for the constancy and marked peculiarity of its characters. The fronds are short and somewhat erect, with a row of small fronds sprouting up at their base, they are also laterally pinched, as it were, and do not spread in the same flowery bifurcate manner as in the *Murex palma-rosæ*. There is another exactly similar example in the collection of Miss Steere, whose name deserves to be recorded in testimouy of her honourable zeal for the science.

Species 29. (Mus. Cuming.)

Murex adustus. Mur. testa abbreviato-fusiformi, crassiuscula, transversim conspicue lirata et striata, intervarices maxime tuberculata; trifariam varicosa, varicibus densissime frondosis, frondibus foliaceis, dentatomuricatis; fuscescente-alba nigro tincta, liris frondibusque aterrimis; columella rosea, interdum lutea, aperturæ fauce alba, roseo marginata; canati brevi.

THE BURNT MUREX. Shell shortly fusiform, rather thick, transversely conspicuously ridged and striated, very largely tuberculated; three-varicose, variees very thickly frondose, fronds foliaceous, dentately muri-

cated; brownish-white stained with black, ridges and frouds jet black; columella rose-colour, sometimes yellow, interior of the aperture white, edged with rose; caual short.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol.ix. p.573. Hab. Philippine Islands; Cuming.

This species may be easily recognised by its jet black colour, and the profuse clustered character of the fronds.

Species 30. (Mus. Cuming.)

Murex Palma-rosæ. Mur. testá obtongo-fusiformi, crassiusculá, transversim granoso-liratá, inter varices leviter bituberculatá; trifuriam varicosá, varicibus frondosis, frondibus foliaceo-ramosis, bifurcatim expansis; castaneo-fuscescente, liris nigricante-fuscis, frondibus roseo marginatis, columellá et aperturæ fauce albis; labro cotumellari denticutato; canali subelongato.

THE ROSE-BRANCH MUREX. Shell oblong-fusiform, rather thick, transversely granosely ridged, with two slight tubercles between the varices; three-varicose, varices frondose, fronds foliaeeously branched, expanded in a bifurcate manner; pale chesnut brown, ridges blackish brown, fronds edged with pink, columella and interior of the aperture white; columellar lip denticulated; canal rather clongated.

LAMARCK, Anim. sans vert. (Deshayes'edit.), vol. ix. p. 572. *Hab.* Ceylon.

The beautiful pink branched character of the fronds of this species has always rendered it one of peculiar admiration to the collector.

Species 31. (Mus. Saul.)

Murex Sauliæ. Mur. testå elegantissimè fusiformi, transversim eximiè granoso-tiratå, intervarices teviter tuberculatå; trifariam varicoså, varicibus frondosis, frondibus suberectis, foliaceo-muricatis, fronde minutå interveniente; pallidè luteo-fuscescente rosaceo tinctå, liris castaneo-fuscis, frondibus intus rosaceis, columellå canali et aperturæ fauce albis, rosaceo marginatis; tabro columetlari simplici, lævi; canali subelongato, recurvo.

Saul's Murex. Shell very elegantly fusiform, transversely delicately granosely ridged, slightly tuberculated between the varices; three-varicose, varices frondose, fronds rather erect, foliaceously muricated, with a minute frond intervening; pale yellowish brown stained with pink, ridges chesnut brown, fronds pink within, columella canal and interior of the aperture white, edged with pink; columellar lip simple, smooth, canal rather elongated, recurved.

Sowerby, Pro. Zool. Soc., 1840.

Murex palma-rosæ var., Kiener.

Hab. Philippine Islands; Cuming.

There can be no difficulty in distinguishing this species from the *Murex palma-rosæ*; it is of an uniform paler colour, the canal, and columellar and outer lips being edged with pink, whilst the columellar lip presents no indication of being denticulated, and the fronds have here and there a small frond sprouting up at their base.

Species 32. (Mus. Cuming.)

Murex rubiginosus. Mur. testå subabbreviato-fusiformi, transversim granoso-liratå et striatå, inter varices fortiter tuberculatå; trifariam varicoså, varicibus frondosis, frondibus foliaceis, brevibus, alternis parvis, recumbentibus; pallidè rubiginoså, liris frondibusque nigricante-fuscis; columellå rubiginoso-luteå, aperturæ fauce albå.

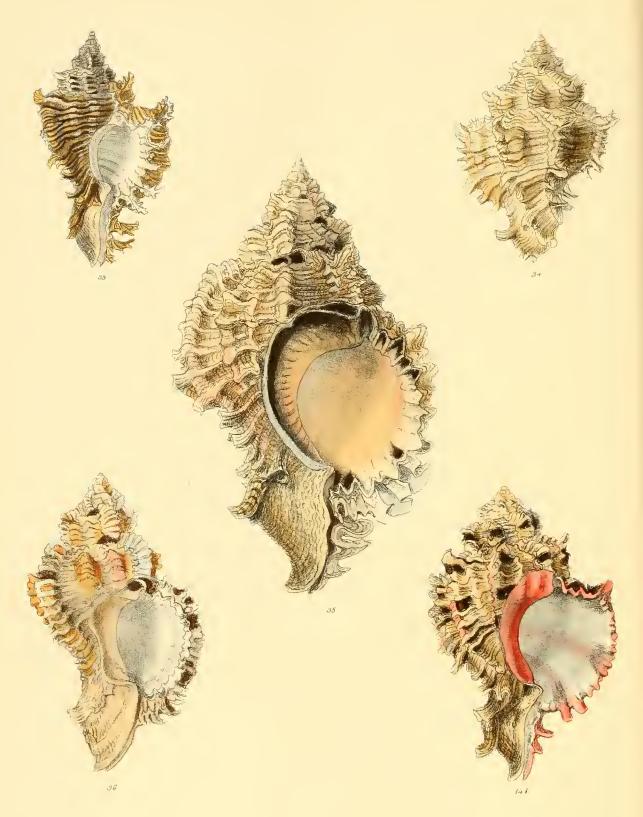

THE RUSTY MUREX. Shell somewhat abbreviately fusiform, transversely granosely ridged and striated, strongly tuberculated between the varices; threevaricose, varices frondose, fronds foliaceous, short, the alternate small, recumbent; pale rusty brown, ridges and fronds blackish brown; columella rustyyellow, interior of the aperture white.

REEVE, Pro. Zool. Soc., 1845.

Hab. Philippine Islands.

This shell, of which both Mr. Cuming and Mr. Taylor possess specimens, is quite distinct from any species hitherto described.

Sowerby del et sculp

PLATE IX.

Species 33. (Mus. Saul.)

Murex crassivaricosa. Mur. testá subabbreviato-fusiformi, crassiusculá; transversim granoso-liratá et striatá trifariam varicosá, varicibus incrassatis, rotundatis, frondosis, frondibus parvis, foliaceis, alternis minoribus; livido-ferrugineá, aperturæ fauce albá.

THE THICK-VARICOSE MUREX. Shell somewhat abbreviately fusiform, rather thickened, transversely granosely ridged and striated; three-varicose, varices thickened, rounded, frondose, fronds small, foliaceous, alternate ones smaller; livid rusty brown, interior of the aperture white.

REEVE, Pro. Zool. Soc., 1845. Hab. ——?

A new species of which I have seen several characteristic examples, including an interesting white variety from the collection of Thomas Norris, Esq.

Species 34. (Mus. Cuming.)

Murex varius. Mur. testů subrhomboideă, fusiformi, transversim granoso-lineată et striată, post varices sæpè tuberculată; anfractibus supernè angulatis, infra rotundatis; quinquevaricosă, varicibus ad angulum et infernè squamato-tuberculatis, squamis tribus minutis interdum intervenientibus; albidă, fulvo tinctă, lineis extantibus fuscescentibus; columellă et aperturæ fauce albis; canali breviusculo.

The Changeable Murex. Shell subrhomboidal, fusiform, transversely granosely lineated and striated, often tuberculated behind the varices; whorls angulated at the upper part, rounded beneath; five-varicose, varices squamately tubercled at the angle and towards the base, with three minute scales sometimes coming hetween; whitish, stained with fulvous brown, raised lines light reddish-brown, columella and interior of the aperture white; canal rather short.

SOWERBY, Pro. Zool. Soc., 1840.

Hab. Mouth of the Gambia, west coast of Africa; Lieut. Shaw.

There is a smaller variety of this species in which the tubercles are much fuller and more obtuse, and which exhibits no indication of the minute intermediate scales noticed above.

Species 35. (Mus. Steere.)

Murex Pomum. Mur. testá fusiformi-oblongá, crassá, solidá, undiquè scaberrimá; transversim conspicuè liratá, inter varices tuberculatá; trifariam varicosá, varicibus lamellis brevibus complicatis tuberculatis; fulvá aut rufo-fuscescente; columellá et aperturæ fauce ochraceis, labro columellari subrugoso, margin ecrecto, nigerrino-fusco, præcipuè supernè, vividè tincto, labro externo fortiter dentato, maculis tribus nigerrimo-fuscis ornato; canali breviusculo, compresso, recurvo.

The apple Murex. Shell fusiformly oblong, thick, solid, very rough throughout, transversely conspicuously ridged, tuberculated between the varices; three-varicose, varices tuberculated with a complicated mass of laminæ; fulvous or reddish brown, columella and interior of the aperture ochraceous yellow, columellar lip slightly wrinkled, edge erected, vividly stained, especially at the upper part, with very black brown; outer lip strongly toothed, ornamented with three black-brown spots; canal rather short, compressed, recurved.

GMELIN, Syst. Nat., p. 3527, no. 6.

Murex asperrimus, Lamarck.

Hab. West Indies (found on coral reefs at the Island of St. Vincents); Guilding. Mediterranean, &c.

A well-known species which appears to be very widely and abundantly distributed.

Species 36. (Mus. Cuming.)

Murex oculatus. Mur. testá fusiformi-oblongá, crassiusculá, undique leviter scabrosá, transversim liratá et
striatá, inter varices bituberculatá; trifariam varicosá,
varicibus lamellis brevibus subcomplicatis tuberculatis;
albidá, rufo-fuscescente tinctá, varicibus maculis quadratis rubentibus alternatim pictis, columettá rubenteluteá, aperturæ fauce albá, labro nigerrimo-fusco supernè
pracipuè, maculato, apice rubente; canali breviusculo,
compresso, recurvo.

The Eyed Murex. Shell fusiformly oblong, rather thick, slightly scabrous throughout, transversely ridged and striated, with two tubercles between the varices; three-varicose, varices tuberculated with short rather complicated lamellæ; whitish, stained with reddish brown,

varices painted alternately with square red spots, columella reddish yellow, interior of the aperture white, lip spotted with black-brown, especially at the upper part, apex red, canal rather short, recurved.

Reeve, Pro. Zool. Soc., 1845. Hab. ——?

Although this shell has so many characters in common with the *Murex pomum*, it exhibits a constant peculiarity of sculpture, form, and colour. In sculpture it is smoother and presents two tubercles between each varix; in form it is more graceful and slender; and in colour it is peculiarly tinged and spotted with red, with a red apex. I have seen numerous examples of this species, and can distinguish them at a glance from any variety of the *Murex pomum*.

Species 14. (Fig. 14. Plate III. Mus. Taylor; Fig. 14 b. Plate IX. Mus. Cuming.)

Murex rosarium. Mur. testá globoso-turbinatá, ventricosá, spirá breviusculá; anfractibus supernè rotundatoangulatis, transversim crebriliratis, liris crispato-rugosis, subsquamosis; sexfariam vel septifariam varicosá,
varicibus obtusis, angulum super squamato-tuberculatis,
busem versus crassisquamatis; ferrugineo-fuscescente,
fasciis tribus nigricante-fuscis interruptis ornatá, varicibus roseo marginatis, columellá vividè roseá, aperturæ
fauce roseo trifasciatá; canali breviusculo, latiusculo,
umbilicato.

The rose-bed Murex. Shell globosely turbinated, ventricose, spire rather short; whorls rotundately angulated at the upper part, transversely closely ridged, ridges wrinkled in a crisped manner, and somewhat squamose; six- or seven-varicose, varices obtuse, squamately tubercled upon the angle, thick-scaled towards the base; rusty brown, ornamented with three interrupted dark brown bands, varices edged with rose, columella deep rose colour, interior of the aperture stained with three rose bands; canal rather short, somewhat broad, umbilicated.

Variety β (Plate III. Fig. 14).

Testa globosior, albida, fasciis purpureis, columellá citrinoluteá.

Shell more globose, whitish, with the bands purple, and the columella citron yellow or salmon-colour.

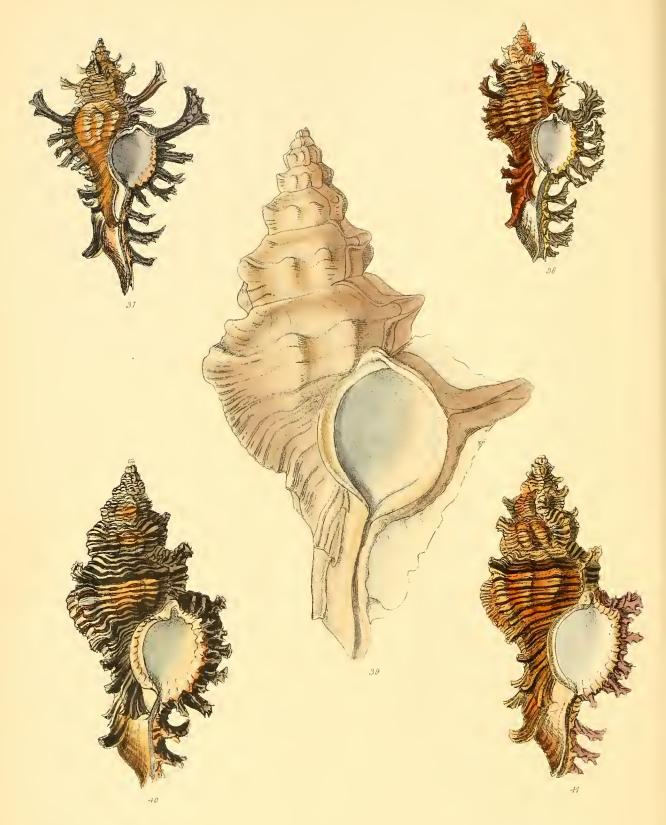

CHEMNITZ, Conch. Cab. vol. x. pl. 161. f. 1528, 1529.

Murex melonulus, Lamarck.

Hab. Fernando Po. Variety β, Senegal.

Although this species presents such a striking display of characters it is one of the most variable of the genus. No two shells, for example, are apparently more distinct from each other than the varieties here figured, yet upon examination they will be found to approximate in their plan of sculpture and distribution of colour with the minutest exactness. In form and structure the variations are really extraordinary; in one richly-coloured example before me, from the collection of Thomas Norris, Esq., the aperture is so large and widely expanded that the shell almost assumes the form of a *Pyrula*, in another the structure is that of a heavy solid shell like the *Murex imperialis* (though, of course, having no relation with that species).

recept del et sculp Reeve Brothers cupro-lut.

PLATE X.

Species 37. (Mus. Saul.)

MUREX AXICORNIS. Variety β . For description of this species, see Plate XV.

Species 38. (Mus. Cuming.)

Murex Banksii. Mur. testá subelongato-fusiformi, transversim granoso-liratá et striatá, inter varices trituberculatá; trifariam varicosá, varicibus frondosis, frondibus laciniato-foleaceis, recurvis, fronde minutá basi interveniente; castaneo-fuscescente, frondibus nigricantefuscis, apice rosaceo; aperturá rotundatá, labro pulcherrimè denticulato; canali longiusculo.

Banks' Murex. Shell somewhat elongately fusiform, transversely granosely ridged and striated, with three tubereles between the varices; three-varicose, variees frondose, fronds laciniately foliaceous, recurved, with a minute frond intervening at the base; light chesmut brown, fronds blackish brown, apex pink; aperture rounded, lip very beautifully denticulated; canal rather long.

SOWERBY, Pro. Zool. Soc., 1840; Coneh. Illus. f. 82. Hab. Moluccas.

The sculpture of this species is of a character somewhat similar to that of the *Murex axicornis*; it agrees with it also in the rounded aperture, closed canal, and finely denticulated lip. Here, however, the resemblance ceases, for its form and the growth of the fronds are totally different.

Species 39. (Mus. Cuming.)

Murex alabaster. Mur. testă trigono-fusiformi, spiră testæ longitudinem æquante; anfractibus transversim liratis et striatis, liris lævibus, supernè angulatis, nodulis duobus tribusve subconspicuis ad angulum armatis; trifariam varicosă, varicibus laminato-alatis, tuberculo erecto, profundè canaliculato, ad angulum munitis; intus extusque eburneă; canali brevinsculo.

THE ALABASTER MUREX. Shell triangularly fusiform, spire equal to the length of the shell, whorls transversely ridged and striated, ridges smooth, angulated at the upper part, armed at the angle with two or three rather conspicuous nodudes; three-varicose, varices laminately winged, furnished at the angle with an erect deeply canaliculated tubercle; ivory white within and without; canal rather short.

Reeve, Pro. Zool. Soc., 1845.

Hab. Island of Cagayan, Province of Misamis, Island of Mindanao (found on the beach); Cunning.

Mr. Sowerby referred this extraordinary shell with some doubt to the *Murex acanthropterus*; its proportions are, however, so utterly different that I venture to describe it as a new species. No other specimen has been seen.

Species 40. (Mus. Cuming.)

Murex microphyllus. Mur. testá subfusiformi, crassiusculá, inter varices bi-trituberculatá, transversim granoso-liratá et striatá, liris extantibus, nodiferis; trivaricosá, varicibus frondosis, frondibus superioribus brevibus, subobscuris, inferioribus foliaceis; columella margine deutato-corrugato; ferrugineo-fuscá, liris conspicuè nigris, apertura fauce albá, columellá luteoaurantiá; labro denticulato.

The small-leaf Murex. Shell somewhat fusiform, rather thick, with two or three elongated tubereles between the variees; transversely granosely ridged and striated, ridges prominently standing out, nodiferous; three-varieose, variees frondose, upper fronds short, somewhat obscure, lower fronds foliaceous; edge of the columella dentately wrinkled; rusty brown, with the ridges conspicuously black, interior of the aperture white, columella yellowish orange; lip denticulated.

LAMARCK, Anim. sans vert. (Deshayes'edit.), vol. ix. p. 575. *Hab.* Ceylon (found in rocky places); Dr. Siebald.

This species is distinguished from the following by the prominent nodulous structure of the ridges, and by their very dark colour; by the obscure blunted growth of the fronds and absence of any pink colouring; and by the dentately wrinkled peculiarity of the edge of the columella.

Species 41. (Mus. Saul.)

Murex torrefactus. Mur. testá subfusiformi, transversim eximiè granoso-liratá et striatá, inter varices bituberculatá; trifariam varicosá, varicibus frondosis, frondibus brevibus, expanso-foliaceis, frondibus alternis parvis, decumbentibus; pallidè ustulato-fuscá, liris saturatioribus, frondibus intus rosaceis; columellá lævi, luteo-aurantiá.

The scorched Murex. Shell somewhat fusiform, transversely delicately granosely ridged and striated, with two tubercles between the varices; three-varicose, varices frondose, fronds short, expandedly foliated, alternate fronds small, bending downwards; pale burnt brown, ridges darker brown, fronds pink within; columella smooth, yellowish orange.

Sowerby, Pro. Zool. Soc., 1840.

Murex microphyllus, var., Kiener.

Hab. Island of Ticao, Philippines; Cuming.

None but a Kiener could fail to discover the specific differences between this shell and the *Murex microphyllus*, as detailed in my observations on that species.

English authors may justly feel indignant at the unceremonious manner in which their new species are disposed of by this author, merely because he has not the discrimination to appreciate them.

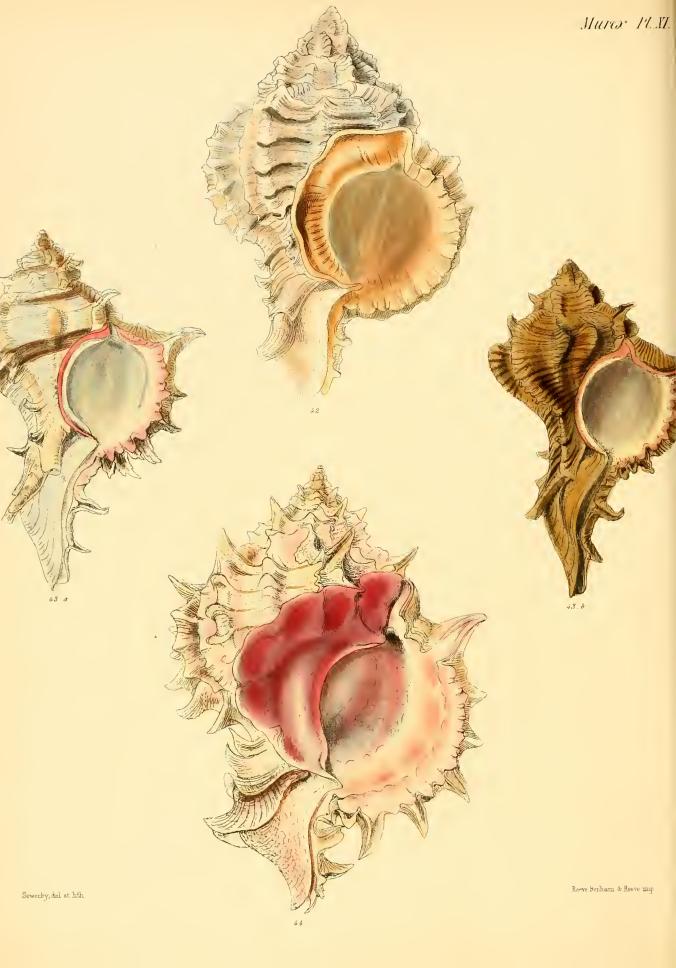

PLATE XI.

Species 42. (Mus. Cuming.)

Murex imperialis. Mur. testá ovato-ventricosá, crassá, ponderosá, transversim costatá et striatá, interstitiis peculiariter puncturatis, tuberculo subelongato variciformi inter varices armatá; quadrifariam varicosá, varicibus crassis, tuberculiferis; albidá, columellá corrugatá; labro externo dentato; canali brevi.

The imperial Murex. Shell ovately ventricose, thick, ponderous, transversely ribbed and striated, interstices peculiarly punctured, armed between the varices with a rather elongated varix-shaped tubercle; fonr-varicose, varices thick, tuberculiferous; whitish, columella wrinkled; outer lip toothed; canal short.

SWAINSON, Zool. Illus. 2nd Series, vol. ii. pl. 67.

Hab. Isabella Island, California (found on mud banks); Captain Belcher, R.N.

The mouth of this species is sometimes yellow, sometimes deep pink. Of the latter variety there is a beautiful example in the collection of Colonel Drummond.

Species 43. (Fig. a, Mus. Cuming; Fig. b, Mus. Taylor.)

Murex anguliferus. Mur. testá pyriformi-fusiformi,
trigonulari, crassiusculá, transversim striatá, rugosá
et leviter corrugatá, tuberculo magno in plicam sæpe
terminato inter varices; trifariam varicosá, varicibus
subincrassatis, squamis brevibus solidiusculis recurvis
muricatis armatis; albá, fasciá fuscá interdum cingulatá, columellá et aperturæ fauce albis, roseo marginatis; canali breviusculo, ascendente.

The anguliferous Murex. Shell pyriformly fusiform, triangular, rather thick, transversely striated, rough and slightly wrinkled, with a large tubercle between the varices which sometimes terminates in a fold; three-varicose, varices somewhat thickened, and armed with short solid recurved sharp-pointed scales; white, sometimes encircled with a brown band, columella and interior of the aperture white, edged with pink; canal rather short, ascending.

Variety β . (Fig. 43 b,)

Testa omnino fusca.

Shell entirely brown.

Murex ferrugo, Wood.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol.ix. p. 588.

Hab. Ceylon (found on the reefs); Miller, R.N.

This species, which may easily be distinguished by its peculiarly triangular pyriform shape, is certainly not *Le Sirat* of Adanson (see Plate XXIV.) as Lamarck supposed. The *Murex ferrugo* of Wood, which I at one time thought to be a distinct species, is unquestionably a variety only of this.

Species 44. (Mus. Steere.)

Murex bicolor. Mur. testa yloboso-oblonga, tenuiuscula, inflata, ventricosa, transversim striata, rugosa et leviter corrugata; lira magna elongata variciformi, tuberculiferi, inter varices; quinquefariam varicosa, varicibus rotundatis, squamis plus minusve solidis supernè et infernè, tuberculis compressis in medio, armatis; roseo-albicante, fuscescente pallidissimè tincta, columella et aperturæ fauce vividè roseis; labro columellari latissimè expanso, margine erecto, labro externo dentato; canali breviusculo, compresso, ascendeute.

The two-coloured Murex. Shell globosely oblong, thin, inflated, ventricose, transversly striated, rough and slightly wrinkled, with a large elongated, tuberculiferous varix-like ridge between the varices; five-varicose, varices rounded, armed at the upper and lower parts with more or less solid scales, in the middle with compressed tubercles; pinkish white, faintly stained with light brown, columella and interior of the aperture bright pink; columella lip very widely expanded, erect at the edge, outer lip toothed; canal rather short, compressed, ascending.

Valenciennes. Zoology of Humboldt and Bonpland's Voyage, vol. ii. 1821.

Murex erythrostoma, Swainson.

Murex regius, Schubert and Wagner (not of Swainson).

Murex hippocastanum, Philippi (not of Linnæus).

Hab. Gulf of California (found on mud banks at low water); Lieutenant Babb, R.N.

Dr. Philippi appears to have described and figured in the eighth Part of his 'Abbild. und Besch. Conch.' under the new title of *Murex hippocastanum*, a small variety of this species in which the columella is white and the light brown colouring rather predominates.

PLATE XII.

Species 45. (Mus. Cuming.)

Murex rubescens. Mur. testâ fusiformi, crassâ, transversim striatâ et costatâ, inter varices fortiter tuberculatâ; trifariam varicosâ, varicibus incrassatis, tuberculis obtusis rudibus canaliculatis irregulariter armatis; vividè rubescente, tuberculis castaneo-fuscis; aperturâ parvâ.

The PINK-RED MUREX. Shell fusiform, thick, transversely striated and ribbed, strongly tuberculated between the varices; three-varicose, varices thickened, armed with irregular rude obtuse canaliculated tubercles; bright pink-red, tubercles chesnut brown; aperture small.

BRODERIP, Pro. Zool. Soc., 1832.

Hab. Taheite (found on the coral reefs); Cuming.

A solid shell of rude irregular structure.

Species 46. (Mus. Cuming.)

Murex digitatus. Mur. testă subpyriformi, spiră brevi, snturis cavernosis; transversim scabroso-lirată et striată; octofariam varicosă, varicibus frondosis, frondibus parvis, numerosis, erecto-dilatatis, ad summitatem leviter palmatis; aurautio-fuscescente, frondibus castaneis; apertură parvă; canati subelongato.

THE DIGITATED MUREX. Shell somewhat pyriform, spire short, sutures cavernous; transversely roughly ridged and striated; eight-varicose, varices frondose, fronds small, numerous, erectly dilated, slightly pahuated at the summit; orange-brown, fronds dark ehesnut; aperture small; canal rather elongated.

SOWERBY, Pro. Zool. Soe., 1840; Coneh. Illus. f. II4.

Hab. Island of Massoua, Red Sea (found in rocky places);

Rüppell.

There are eight variees to a whorl in this beautiful species, each consisting of a row of numerous palmated fronds.

Species 47. (Mus. Steere.)

Murex nigritus. Mur. testá ovato-pyriformi, ventricosá, spirá brevi; anfractibus supernè angulatis, transversim planiliratis, liris alternis latioribus; octofariam vel nonafariam varicosá, varicibus frondosis, fronde ad angulum grandi, tuberculato-squamată, frondibus tribus vel quaternis basalibus longioribus fortibus corniformibus, cæteris parvis, subobsoletis; albā, ferrugineo tinctā, frondibus lirisque aterrimis; umbilico amplo.

The blackened Murex. Shell ovately pyriform, ventricose, spire short; whorls angulated at the upper part, transversely flatly ridged, alternate ridges the broader; eight-ornine-varieose, variees frondose, frond upon the angle large tubercularly squamate, the three or four basal fronds longer, strong, horn-shaped, the rest small and rather obsolete; white, stained with rusty brown, fronds and ridges jet black; umbilicus large.

Philippi, Abbild. und Besch., Conch. Part VIII. Murex, p. 1. pl. 1. fig. 1.

Hab. Paeific Islands.

I quite agree with Dr. Philippi in distinguishing this shell from the *Murex radix*; three species have been confounded together, in my opinion, under that name.

Species 48. (Mus. Saul.)

Murex melanomathos. Mur. testá globoso-pyriformi, spirá brevi, transversim eterato-striatá; octofariam varicosá, varicibus squamato-spinosis, spinis solidiusculis, canaliculatis, confertis, peculiariter erectis; albá, varicibus aterrimis; aperturá parvá; canali subcompresso; clauso.

THE BLACK-SPINED MUREX. Shell globosely pyriform, spire short, transversely elevately striated, eight-varicose, varices squamately spined, spines rather solid, eanalieulated, close-set, peculiarly erect; white, varices jet-black; aperture small, canal rather compressed, closed.

GMELIN; Lamarck, Anim. sans vert. (Deshayes' edit.), vol. ix. p. 584.

Hab. ——?

This interesting little shell may be recognised by the tall, solid, ereet, jet-black character of its spines, in which respect it differs from the *Murex angularis*, a species I have often seeu mistaken for it by collectors.

Species 49. (Mus. Cuming.)

Murex varicosus. Mur. testá subelongato-pyriformi, transversim squamato-liratá, spiræ suturis profundè cavernosis; septifariam varicosá, varice ultimo marginati planifrondoso, frondibus canaliculatis ad summitatem palmatis, extus crispato-squamatis, varicibus cæteris frondibus irregularibus plus minusve confragosis; albá, frondibus nigricante-fuscis; aperturá peculiariter parvá.

THE VARICOSE MUREX. Shell somewhat elongately pyriform, transversely squamately ridged, sutures of the

spire deeply cavernous; seven-varicose, the marginal varix flatly frondose, fronds eanaliculated, palmated at the summit, crisply scaled on the outside, the rest of the varices with the fronds irregular and more or less obscurely broken away; white, fronds blackish brown; aperture peculiarly small.

Sowerby, Pro. Zool. Soc., 1840.

Hab. ----?

An interesting species established by Mr. Sowerby, approximating, in some degree, to the Murex secundus.

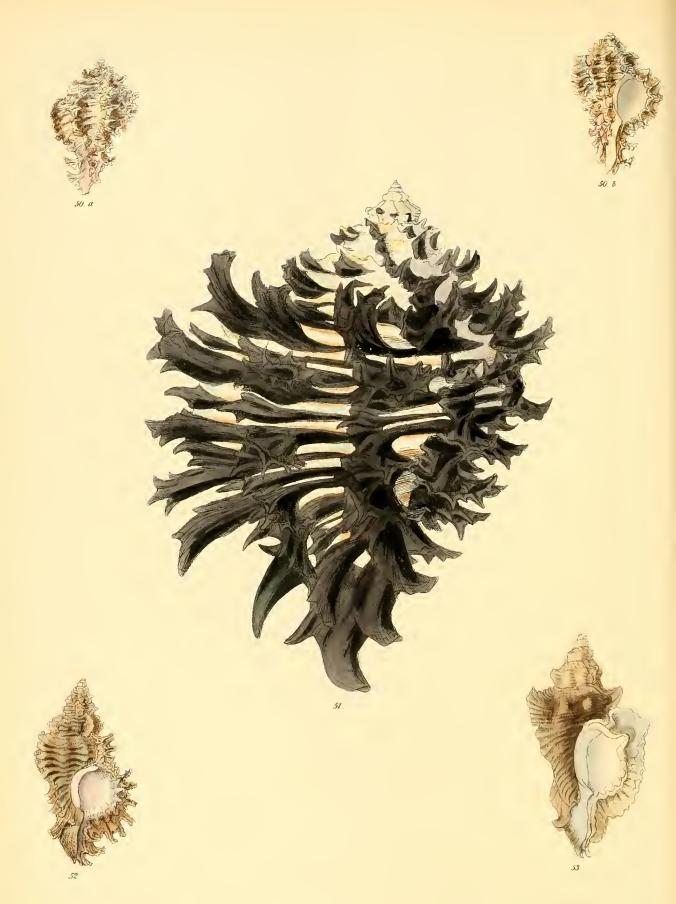

PLATE XIII.

Species 50. (Fig. a and b, Mus. Saul.)

Murex humilis. Mur. lestá ovato-pyriformi, spirá brevi, angulato-turritá, anfractibus supernè plonulatis, infra contractis, transversim liratis, liris pone varices conspicuis; octofariam varicosá, varicibus medio seriatim duplicato-squamatis, squamis brevibus, recurvis, basi frondosis, frondibus subramosis, spinosis; albido-fuscescente, aurantio-rufescente profusè tinctá et maculatá; operturá parvá; canali subelongatá.

The humble Murex. Shell ovately pyriform, spire short, angularly turreted, whorls depressed round the upper part, contracted below, transversely ridged, ridges conspicuous behind the varices; eight-varicose, varices consisting in the middle of a double row of scales, peculiarly curved back, at the base of a single row of slightly branched spinous fronds; whitish brown, profusely stained and spotted with orange red; aperture small, canal slightly elongated.

BRODERIP, Pro. Zool. Soc., 1832; Sowerby, Couch. Illus. f. 46 and 47.

Hab. St. Elena, western coast of South America (dredged from sandy mud at the depth of seven fathoms); Cuming.

This species has been but imperfectly described and figured hitherto for want of a good specimen. It is a species of very peculiar character, its pyriform growth, the curiously recurved bi-squamate structure of the varices, and its orange-red colouring are features of considerable specific interest.

Species 51. (Mus. Saul.)

Murex ambiguus. Mur. testá globosá, subpyriformi, transversim liralá, liris irregularibus, interruptis; octofariam varicosá, varicibus frondosis, frondibus alternis vel paucioribus elato-ramosis, spinosis, basalibus longioribus; albá, frondibus lirisque aterrimis, labri columellari parte superiorá nigro tinctá; canali breviusculo.

The ambiguous Murex. Shell globose, slightly pyriform, transversely ridged, ridges irregular, interrupted; eight-varicose, varices frondose, the alternate fronds, or fewer, elevately branched, spinous, basal fronds longer; white, fronds and ridges jet black, upper part

of the columellar lip stained with black; canal rather short.

REEVE, Pro. Zool. Soc., 1845.

Three species appear to me to have been confused hitherto under the common title of Murex radix, which though closely approximating may be separated without difficulty by any person possessing a tolerable share of conchological discrimination. The true Murex radix is a round particularly solid heavy shell with a short, though sharply acuminated, spire, with not less than ten varices, in which the fronds are numerous, somewhat laterally compressed, comparatively short, and sharp pointed; the species described by Dr. Philippi under the title of Murex nigritus (for which see Pl. 12. Sp. 47), has but eight or nine varices and the fronds are not branched, those on the upper angle of the whorls being tubercularly squamate, those in the middle flat and very obscure, whilst those at the base are long and horn-shaped. In the species under consideration the shell is of somewhat light structure and the fronds are large, open, and flowery. It certainly presents a modification of character intermediate between the Murices radix and nigritus, but it is always easy to be distinguished; and any modification of structure may, I apprehend, be considered of specific importance when it is not immediately approached on either side.

Species 52. (Mus. Metcalfe.)

Murex corrugatus. Mur. testű ovato-fusiformi, inter varices bituberculatű, transversim liratű et striatű, liris subconspicuis, obsoletè nodosis; trifariam varicosű, varicibus obliquis, peculiariter laminato-squamatis; ferrugineo-fuscá, aperturæ fauce violaceű.

The Wrinkled Murex. Shell ovately fusiform, with two tubercles between the varices, transversely ridged and striated, ridges somewhat conspicuous, obsoletely noduled; three-varicose, varices oblique, peculiarly laminately squamate; rusty-brown, interior of the aperture tinged with violet.

Sowerby, Pro. Zool. Soc., 1840. *Ilab*. North Australia; H.M.S. Beagle.

This shell has very much the aspect of the Murex palmiferus, the varices are nevertheless of very different structure. Instead of being furnished with a row of distinct leaf-like fronds, they are ornamented throughout with a counceted lamina forming festoons of open seales.

Species 53. (Mus. Metcalfe.)

Murex triformis. Mur. testå trigono-ovatå, crassiusculå, transversim liratå et corrugatå, tuberculis duobus aut pluribus inter varices; trifariam varicoså, varicibus laminato-fimbriatis, supernè excavato-sinuatis; ferrugineo-fuscå; aperturá ovatå, supernè sinuatå.

THE THREE-SHAPED MUREX. Shell triangularly ovate, ra-

ther thick, transversely ridged and wrinkled, with two or more tubercles between the variees; three varicose, variees laminately frilled, excavately sinnated at the upper part; rusty-brown; aperture ovate, sinuated at the upper part.

Murex acanthropterus, var., Sowerby, Conch. Illus., f. 51.

Hab. New Holland.

Several specimens of this shell have been lately received from New Holland, and it is now generally regarded as a species quite distinct from the *Murex acanthropterus*. It is of a more rude and solid structure, and of a dark rusty brown colour.

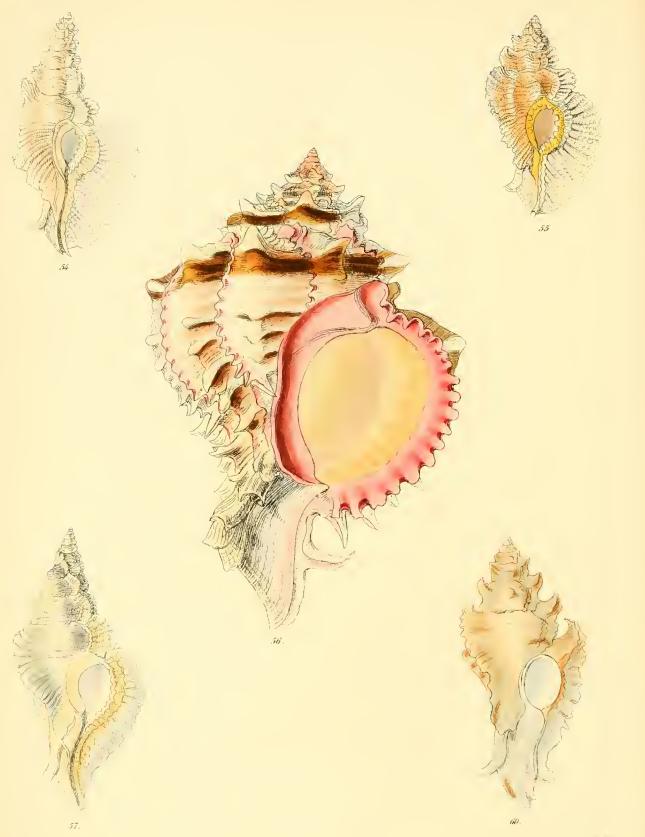

PLATE XIV.

Species 54. (Mus. Cnming.)

Murex pellucidus. Mur. testá trigono-fusiformi, tenui, transversim liratá, pulcherrimè squamatá, inter varices tuberculatá; trivaricosá, varicibus obliquis, latissimè et eximiè alatis; pellucido-albá; aperturá parvá, labro intus nodoso.

The transparent Murex. Shell triangularly fusiform, thin, transversely ridged, very beautifully scaled, tuberculated between the varices; three-varicose, varices oblique, very widely and delicately winged; transparent white; aperture small, lip nodose within.

Murex trigonularis, Sowerby (not of Lamarck).

Hab. Island of Bantayan, Philippines (found upon a coral bottom at the depth of seven fathoms); Cuming.

Mr. Sowerby somewhat incautiously refers this shell to the Murex trigonularis of Lamarck, with whose description of which it certainly does not agree. Instead of this shell being rather smooth "lavinscula" it is covered with small scales; the winged varices are not very narrow "perangustis," but, on the contrary, very wide, and instead of their being two tubercles in the interstices between the varices "tuberculis interstitiorum geminis" there is but one. The sculpture is in most respects like that of the following species.

I therefore distinguish it by a new name, and consider Lamarck's *Murex trigonularis* to be either (with Mr. Gray) a worn *M. acanthropterus* or (with M. Kiener) a worn *M. phyllopterus*.

Species 55. (Mus. Cuming.)

Murex tripterus. Mur. testá ovato-fusiformi, transversim liratá, pulcherrimè squamatá, inter varices tuberculatá; trivaricosá, varicibus valdè obliquis, latè alatis; albá, columellá et aperturæ fauce luteo-aurantiis; columellá labroque intus conspicuè nodosis.

The three-sided Murex. Shell ovately fusiform, transversely ridged, very bcautifully scaled, tuberculated between the varices; three-varicose, varices very oblique, widely winged; white, columella and interior of the aperture yellowish orange; columella and lip conspicuously nodose within.

Born, Mus. Cæs., p. 291. pl. 10. f. 18, 19. Murex trialatus; Kiener. Hab. Island of Ticao, Philippines (found on the reefs); Cuming.

This species differs from the preceding in having a much less acuminated spire, and in the columella being strongly nodose as well as the outer lip.

Species 56. (Mus. Taylor.)

Murex Brassica. Mur. testâ subgloboso-ovatâ, ventricosissimâ, transversim striatâ, striis confertis, peculiariter minutissimè crispato-nodulosis: prope varices, præcipuè supernè, tuberculatâ, tuberculis brevibus, solidis;
sexfariam vel octofariam varicosâ, varicibus planis, decumbentibus, lamellæformibus, margine serratis, basem
versus spinoso-squamatis; fuscescente, fasciis castaneis,
interdum interruptis, cingulatâ; columellâ, labro, varicumque marginibus vividè purpureo-roseis, aperturæ
fauce subaurantiâ.

The cabbage Murex. Shell somewhat globosely ovate, very ventricose, transversely striated, striæ close-set, peculiarly very minutely crisply nodulous, tuberculated near the varices, especially round the upper portion of each whorl, tubercles short, solid; six- or eight-varicose, varices flat, lying down, lamella-like, serrated at the edge, spinosely squamate towards the base; light brown, encircled, with sometimes interrupted, chesnut-brown bands; columella, lip, and edges of the varices rich purple-pink, interior of the aperture tinged with orange.

LAMARCK, Anim. sans vert. (Deshayes' cdit.), vol.ix. p.581.

Murex ducalis, Broderip and Sowerby.

Hab. Gulf of California (found in rocky places at a depth of from four to six fathoms); Cuming.

This beautiful and very distinct species grows to more than twice the size of the example selected for representation in the accompanying plate.

The figure in Martini, Conchylien Cab., vol. iii. pl. 104. f. 986, to which M. Kiener refers for an illustration of the species, is not the *Murex brassica*, but may be quoted as affording an excellent representation of the *Murex calcitrapa var* β , (for which see Pl. III. Sp. 13.), *Murex brevifrons*, Lamarck.

Species 57. (Mus. Cuming.)

Murex pinnatus. Mur. testa elongato-fusiformi, inter varices tuberculata, transversim lirata et striata, longitudinaliter squamato-striata; trivaricosa, varicibus obliquis, alatis; alba; apertura parva.

THE WINGED MUREX. Shell elongately fusiform, tuber-culated between the varices, transversely ridged and striated, longitudinally squamately striated; three-varicose, varices oblique, winged; white, aperture small.

Wood, Index Testaeeologicus Supp., pl. 5. f. 20. *Hab.* China.

The sculpture of this well-known Chinese species is very similar to that of the *Murex tripterus*.

Species 73. (Fig. 60, Mus. Saul.)

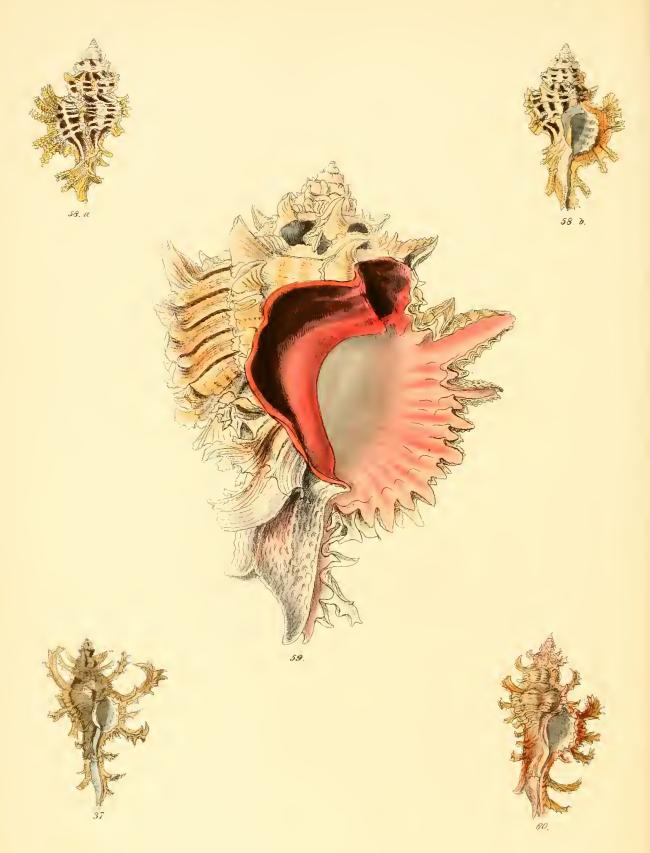

Murex osseus. Mur. testá oblongo-ovalá, subfusiformi, læviusculá, inter varices fortiter tuberculatá; trivaricosá, varicibus fimbriato-laminatis, supernè falcatis; albá, castaneo-fusco hic illic, tinctá; aperturá peculiariter parvá, ovatá.

THE BONY MUREX. Shell oblong-ovate, somewhat fusiform, rather smooth, strougly tubercled between the variees; three-varicose, varices fimbriately laminated, hooked at the upper part; white, stained here and there with chesnut-brown; aperture peculiarly small, oval.

REEVE, Pro. Zool. Soc., 1845. Hab. ——?

The Murex pinniger is perhaps the nearest allied species to this, though of very different form.

Sowerby del at lith

PLATE XV.

Species 58. (Mus. Saul.)

Murex fenestratus. Mur. testâ fusiformi-ovatâ, superne subangulatâ, inferne contractâ, inter varices longitudinaliter unicostatâ, liris angustis pulcherrime squamatis cingulatâ, superne tribus vel quaternis, in medio duabus, deinde ad basem duabus; lirarum interstitiis quadratis, excavatis; quadrifariam varicosâ, liris transversis varices super erecto-fimbrialis; albidâ, lirarum interstitiis castaneo- aut rubido-fuscis, varicibus vivide fuscoaurantiis; aperturâ parvâ, columellâ labroque leviter nodulosis.

The window-sculptured Murex. Shell fusiformly ovate, somewhat angulated at the upper part, contracted at the lower, longitudinally single-ribbed between the varices, encircled with narrow very beautifully squamate ridges, three or four round the upper part, two round the middle, and two round the base, interstices between the ridges square, excavated; four-varicose, transverse ridges erectly fimbriated upon the varices; whitish, interstices between the ridges dark chesnut or reddish brown, varices bright fuscous orange; aperture small, lip and columella slightly nodulous.

CHEMNITZ, Coneh. Cab. vol. x. pl. 161. f. 1536-1537. *Hab.* —— ?

I think M. Deshayes has erred in excluding the figures of Sowerby and Kiener from the synonymy of this remarkable species. This is undoubtedly the shell figured by Chemnitz, and not the violet-mouth shell of which M. Deshayes speaks. The figures hitherto published of it have all unfortunately been drawn from worn imperfect specimens, none of them exhibiting that beautifully scaled sculpture as seen on the back of the fimbriated digitations in the example here represented.

Species 59. (Mus. Cuming.)

Murex regius. Mur. testá globoso-ovatá, crassiusculá, transversim peculiariter corrugato-striatá, et funiculatá, funicutis angustis, subdistantibus; sexfariam varicosá, varicibus duplicato-squamatis, squamis profundè canaliculatis, spinoso-serratis; fuscescente-albá, roseo tinctá, varicum squamis intus roseis, suluris piceo-ni-

gris; labro columellari erecto-expanso, intus et infernè vividè roseo, supernè conspicuè piceo-nigro; canali planiusculo, corrugato; labro fortiter denticulato.

The royal Murex. Shell globosely ovate, rather thick, transversely peculiarly corrugately striated and corded, eords narrow, rather distant; six-varicose, varices consisting of a double row of deeply canabiculated, spinosely serrated scales; bight brownish white, tinged with pink, interior of the scales pink, sutures pitchblack; columellar lip creetly expanded, bright pink towards the interior and lower part, pitch-black at the upper; canal rather flat, curiously wrinkled or indented; lip strongly denticulated.

Wood, Ind. Test. Supp., pl. 5. f. 13. *Phyllonotus regius*, Swainson.

Hab. Panama (found on mud banks at low water); Cuming.

No one eau fail to recognise this magnificent and well-known species.

Species 37. (Plates X. and XV. Fig. 37.)

Murex axicornis. Mur. testá ovato-fusiformi, transversim striatá, striis minutissimè nodulosis, scabrosis; trifariam varicosá, varicibus conspicuè frondosis, frondibus rariusculis, elongatis, dilatato-ramosis, spinosis; roseo-fuscescente; aperturá parvá, subrotundá.

THE AXIS' HORN MUREX. Shell ovately fusiform, transversely striated, striæ very minutely noduled, scabrous; three-varicose, varices eonspicuously frondose, fronds rather few in number, elongated, dilately branched, spinous; pinkish brown; aperture small, nearly round.

Variety & (Plate X. Fig. 37. Mus. Saul.)

Testa grandior, elongatior, frondibus brevioribus, minus dilatato-ramosis, purpureo-nigricantibus.

Shell larger, more elongated, with the fronds shorter, less dilately branched, and of a purple-black colour.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol.ix. p.574. Hab. Island of Bohol, Philippines (dredged from the depth of twelve fathoms); Cuming.

I had selected the variety β for illustration in Plate X. Fig. 37, with the view of describing it as a new species; upon

mature examination, however, I am obliged to concede to the opinion held by Mr. Sowerby as to its being a variety of the *Murex axicornis*.

Axis was a name given by the ancients to an animal of the deer tribe, recorded by Pliny as being held sacred to Bacchus.

Species 60. (Mus. Cuming.)

Murex aculeatus. Mur. testá fusiformi, transversim striatá, inter varices subobsolete bituberculatá; trifariam varicosá, varicibus frondosis, frondibus rariusculis, dilatato-ramosis, spinosis; roseo-fuscescente, varicibus, columella, apice basique vividè rosaceis ; apertura parva, tabro minutè denticulato.

The prickly Murex. Shell fusiform, transversely striated, somewhat obsoletely tuberculated between the varices; three-varicose, varices frondose, fronds rather few, dilately branched, spinous; pinkish brown, varices, columella, apex and base deep pink; aperture small, less minutely denticulated.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol. ix. p. 575. Hab. Moluccas.

A beautiful little species, richly suffused throughout with a delicate pink tinge.

Murex Pl XVI.

R.B&R mg

PLATE XVI.

Species 61. (Fig. a, Mus. Cuming; Fig. b, Mus. Norris.)

Murex falcatus. Mur. testá abbreviato-fusiformi, spirá brevi, angulato-turritá, liris parvis longitudinalibus et transversis apicem versus clathratis; quinquevaricosá, varicibus laminato-alatis, supernè falcatis, margine involuto; albá, rubido-fusco tinctá; aperturá parvá; canali subelongato.

The hooked Murex. Shell abbreviately fusiform, spire short, angularly turreted, latticed towards the apex with small longitudinal and transverse ridges; five-varicose, varices laminately winged, hooked at the upper part, with the edge turned inwards; white, stained with reddish-brown; aperture small; canal rather elongated.

Sowerby, Pro. Zool. Soc., 1840.

Eadem. Murex aduncus, Sowerby.

Hab. Japan.

By permission of Thomas Norris, Esq., 1 have represented at Fig. 61 a, the specimen described by Mr. Sowerhy under the name of *Murex aduncus*. It appears merely to exhibit a slight modification of growth without any variation of specific importance.

Species 62. (Mus. Cuming.)

Murex Pinniger. Mur. testá fusiformi, supernè obsoletè liratá, tuberculo solido prominulo inter varices; tricaricosá, varicibus alæformibus, supernè laciniato-fulcatis, ad basem alatis; purpurascente-albá, fusco hic illic tinetá et punctatá; aperturá peculiariter parvá.

The wing-bearing Murex. Shell fusiform, obsoletely ridged at the upper part, with a solid prominent tubercle between the varices; three-varicose, varices wing-like, laciniately hooked at the upper part, winged at the base; purplish white stained and spotted here and there with brown.

BRODERIP, Pro. Zool. Soc., 1832.

Murex cristatus, Gray (not Broeehi).

Hab. Xipixapi, West Columbia (dredged from sandy mud at the depth of eight fathoms); Cuming.

The variees of this species are peculiarly thin and flattened though a little waved and serrated at the edge; and they are developed in a curious winged manner at the base. Species 63. (Mus. Saul.)

Murex phyllopterus. Mur. testá trigono-oblongá, subfusiformi, inter varices obtuse tuberculutá, transversim liratá, liris latiusculis, subobsoletis, distantibus; trivaricosá, varicibus radiatim laminatis, alæformibus; albá, fasciis latiusculis castaneo-fuscis inter varices conspicue pictá; canali breviusculo.

The leaf-winged Murex. Shell triangularly oblong, somewhat fusiform, obtusely tuberculated between the varices, transversely ridged, ridges rather broad, somewhat obsolete, distant; three-varicose, varices radiately laminated, wing-like; white, conspicuously painted between the varices with rather broad ehesnut brown bands; canal rather short.

LAMARCK, Anim. sans vert. (Deshayes'edit.), vol.ix.p. 577.

Murex trialatus, Sowerby.

Hab. ——?

This shell may probably be a dark handed variety, and not the type, of Lamarek's species; it is, however, the only specimen at present known in this country, and the only one I remember to have seen.

Species 64. (Mus. Cuming.)

Murex acanthropterus. Mur. testá trigono-fusiformi, anfractibus supernè angulatis, transversim liratis et striatis; trivaricosá, varicibus laminato-alatis, membranaceis, supernè canaliculato-falcotis; albá, interdum fuscescente sparsim tincta; canali longiusculo.

The spine-winged Murex. Shell triangularly fusiform, whorls angulated at the upper part, transversely ridged and striated; three-varicose, varices laminately winged, membranaceous, canaliculately hooked at the upper part; white, sparingly stained with light brown; canal rather long.

Lamarck, Anim. sans vert. (Deshayes'edit.), vol.ix. p. 577. Hab. ——?

The variees of this species exhibit a very peculiar canaliculated structure at the upper part, which ranges on the spire in rows of prominent spine-like hooks.

Species 65. (Mus. Cuming.)

Murex Gambiensis. Mur. testá fusiformi, infernè attenuatá, solidiusculá, transversim obsoletè striatá, tuberculo magno prominulo inter varices; trivaricosá, varicibus plicato-laminatis, supernè falcatis, ad basem alatis; utbá, fusco hic illic punctatá; aperturá parvá; canali longiusculo.

The Gambia Murex. Shell fusiform, attenuated at the lower part, rather solid, transversely obsoletely striated, with a large prominent tubercle between the varices; three-varicose, varices plicately laminated, hooked at the upper part, winged at the base; white, dotted here and there with brown; aperture small; canal rather long.

REEVE, Pro. Zool. Soc., 1845.

Hab. Mouth of the Gambia, west coast of Africa.

Closely allied to the *Murex pinniger*, but of a more elongated structure, and different style of colouring.

Species 66. (Mus. Cuming.)

Murex cervicornis. Mur. testá fusiformi, transversim liratá et striatá; trifariam varicosá, varicibus frondosis, frondibus erectis, superioribus bifurcatim elongatis; albá; aperturá subrotundá; canali longiusculo, recurvo.

THE STAG'S HORN MUREX. Shell fusiform, transversely ridged and striated; three-varicose, varices frondose, fronds erect, upper ones bifurcately elongated; white, aperture nearly round; canal rather long, recurved.

LAMARCK, Anim. sans vert. (Deshayes' cdit.), vol. ix. p. 575. Hab. ——?

A rare and elegantly formed species, well distinguished by the curious two-forked growth of the upper fronds of the varices.

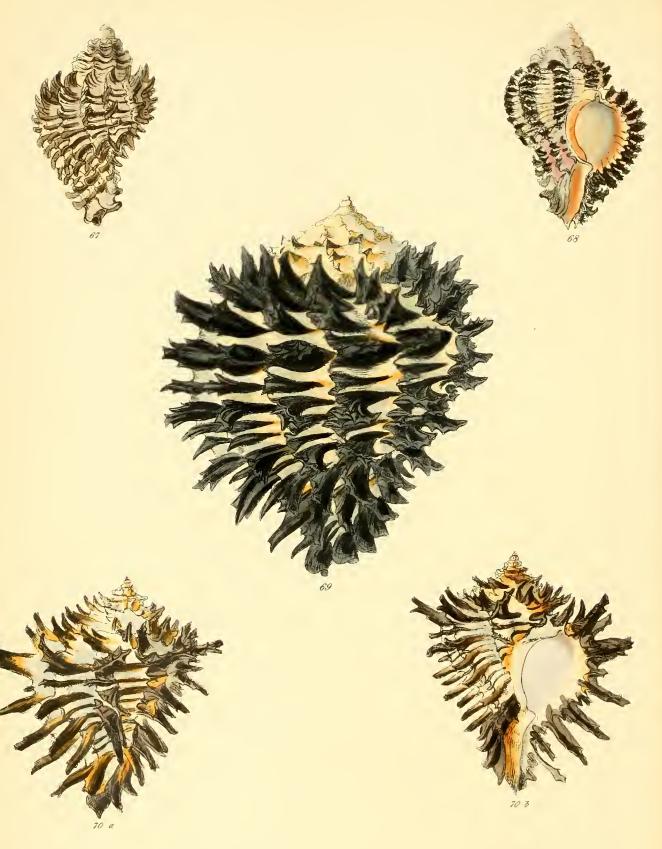

PLATE XVII.

Species 67. (Mus. Norris.)

Murex crispus. Mur. testá ovato-pyriformi, transversim liratá, liris prominentibus, alternis majoribus, spiræ suturis plano-depressis; multivaricosá, varicibus ad decenis, confertis, squamis subobtusis brevibus compressis undique armatis; virescente-albá, squamis lirisque nigricante-fuscis; canali breviusculo.

The CRISPED MUREX. Shell ovately pyriform, transversely ridged, ridges prominent, alternate ridges the larger, sutures of the spire flatly depressed; many-varicose, varices about ten to a whorl, close-set, armed throughout with short rather obtuse compressed scales; greenish white, scales and ridges blackish brown; canal rather short.

BRODERIP, Pro. Zool. Soc., 1832.

Hab. Pacasmayo, coast of Peru (found on a reef at a depth of about twenty-five fathoms, twelve miles from the shore); Cuming.

Only two or three specimens of this very rare and remarkable species appear to have been yet discovered.

Species 68. (Mus. Taylor.)

Murex Stainforthii. Mur. testá globoso-ovatá, subpyriformi, transversim liratá, liris angustis, granosis, interstitiis corrugatis; septifariam varicosá, varicibus densissimè frondosis, frondibus brevibus confertis, acutissimè muricato-ramosis; albidá vel aurantio-fuscescente, frondibus lirisque nigricante-fuscis, columellá et aperturæ fauce vividè aurantiis; aperturá ovatá, labro crenato; canali breviusculo.

STAINFORTH'S MUREX. Shell globosely ovate, somewhat pyriform, transversely ridged, ridges narrow, granose, interstices wrinkled; seven-varicose, varices unusually thickly frondose, fronds short, close-set, very sharply prickly branched; white or orange-brown, fronds and ridges blackish brown, columella and interior of the aperture bright orange; aperture ovate, lip crenated; canal rather short.

REEVE, Pro. Zool. Soc., 1842.

Hab. North coast of New Holland; H.M.S. Beagle.

I had the pleasure of describing this very characteristic species about three years since from a specimen in the cabinet of Mr. Inwood, now in the possession of Mr. Burt, the only one at that time known. Several examples have been since brought from New Holland by H.M.S. Beagle, but none with the beautiful ramose structure of the varices more fully developed than in the original specimen. Each varix is composed of a number of very close-set prickly fronds, sometimes one or two successive layers of them,

which from their delicate structure appear to become very soon eroded. No specimens of this shell have yet been seen without the back varices being more or less destroyed.

Species 69. (Mus. Cuming.)

Murex radix. Mur. testá globosá, crassissimá, solidá, spirá brevi, acuminatá, transversim liratá, liris inæqualibus; multivaricosá, varicibus ad decenis muricatosquamatis, squamis brevibus, solidis, atternis majoribus; albá, squamis aterrimis; canali brevi.

The root Murex. Shell globose, very thick, solid, spire short, acuminated, transversely ridged, ridges uncqual; many-varicose, varices about ten to a whorl, prickly squamate, scales short, solid, alternate ones the larger; white, scales jet black; canal short.

GMELIN, Syst. Nat., p. 3527.

Hab. Bay of Caraccas, West Colombia (found on mud banks at low water); Cuming.

This species may be distinguished by its massive structure, round globose form, and by the numerous varices characterised by the compressed stunted growth of the scales.

Species 70. (Mus. Cuming.)

Murex nitidus. Mur. testá ovato-pyriformi, transversim liratá, liris valdè inæqualibus; septifariam vel octofariam varicosá, varicibus squamatis, squamis elongatis, erectis, muricatis; albá, squamis nigerrimo-fuscis, basi fuscis, liris nigris et fuscis; aperturá subparvá.

The neat Murex. Shell ovately pyriform, transversely ridged, ridges very unequal; seven- or eight-varicose, varices squamate, scales elongated, erect, prickly; white, scales very black brown, brown at the base, ridges black and brown; aperture rather small.

BRODERIP, Pro. Zool. Soc., 1832.

Hab. Guacomayo, Central America (found on the coral reefs at low water); Cuming.

This species was originally described by Mr. Broderip from a young prettily filleted specimen, of which there is a representation in Sowerby's 'Conchological Illustrations,' *Murex*, Fig. 4. It was considered at that time to be unique, though Mr. Sowerby pronounced it to be "probably a variety of the *Murex princeps* in a young state.

The fine full grown shell here figured was obtained by Mr. Cuming in nearly the same locality as the small specimen; other examples since come to hand show their specific connection, and the species now proves to be distinct from the *Murex radix* in all stages of growth.

R B & R, imp.

PLATE XVIII.

Species 71. (Mus. Cuming.)

Murex cornutus. Mur. testá clavaformi, tenui, ventricosá, transversim subtiliter sulcatá et striatá, spirá
subdepressá, suturis profundis; septifariam varicosá,
varicibus planulatis, spinis duabus tribusve canaliculatis
longissimis recurvis armatis; cinereo-fuscá, interdum
rufo zonatá; canali longissimo, spiraliter longispinoso;
labro columellari tenui, erecto-expanso.

The horned Murex. Shell club-shaped, thin, ventricose, transversely finely grooved and striated, spire somewhat depressed, sutures deep; seven-varicose, varices flattened, each armed with two or three very long canaliculated spines; ashy brown, sometimes zoned with fulvous red; canal very long, armed with spiral rows of long spines; columellar lip thin, erectly expanded.

Variety \(\beta.\)

Testa laclea.

Shell eream-coloured.

LINNÆUS, Syst. Nat., p. 1214.

Hab. Mouth of the Gambia, western coast of Africa (found in rocky places); Lieut. Babb.

I have figured the cream-coloured variety of this well-known species for the sake of novelty.

Species 72. (Mus. Taylor.)

Murex Martinianus. Mur. testâ trigono-clavæformi, transversim liratâ, liris nodulosis, inæqualibus; trifariam varicosă, varicibus rarispinosis, spinis breviusculis; luteo- vel griseo-carulescente, canali fuscescente; apertură ovată, labro dente planulato, erecto, munito; canali longissimo, recto, supernè spinoso.

Martini's Murex. Shell triangularly club-shaped, transversely ridged, ridges nodulous, unequal; three-varicose, varices few-spined, spines rather short; yellowish or greyish blue, canal brownish; aperture ovate, lip furnished with an erect flattened tooth; canal very long, straight, spined towards the upper part.

Reeve, Pro. Zool. Soc., 1845; Martini, Conch. Cab., vol. iii. pl. 113. f. 1056.

Murex rarispina, Sowerby (not of Lamarck.)

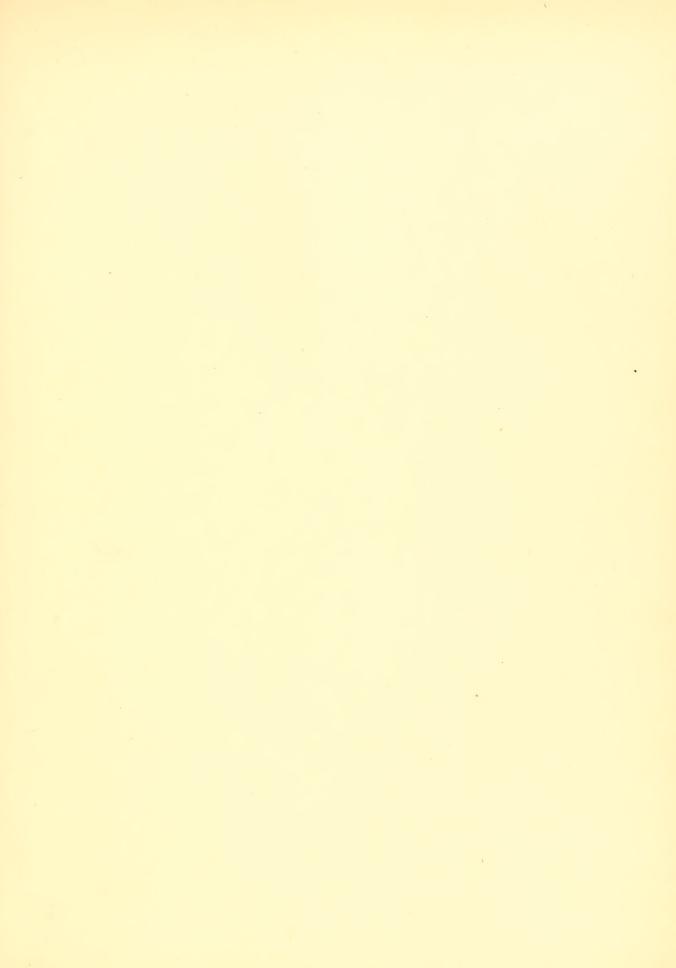

Hab. ---?

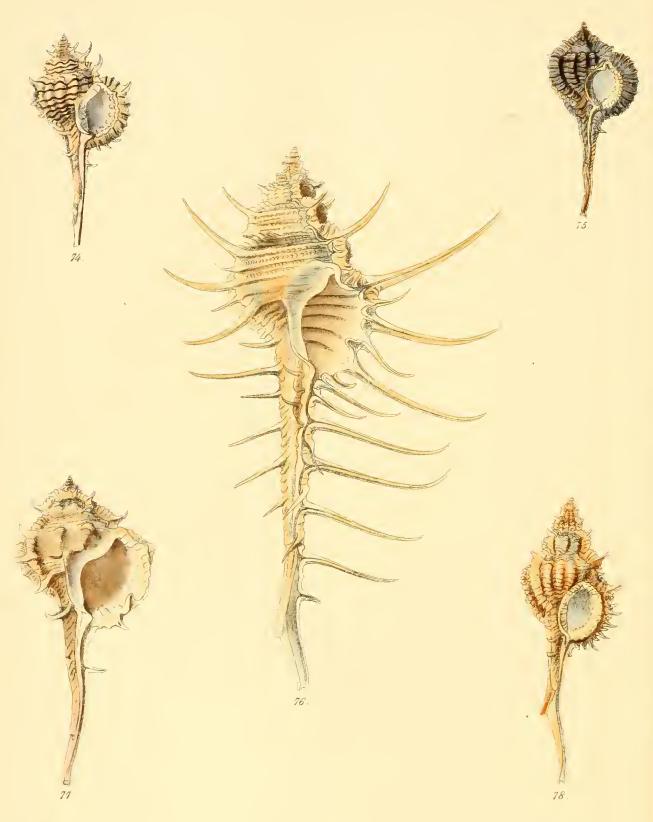

A careful examination of the description of Lamarek's Murex rarispina has now led me to believe with MM. Kiener and Deshayes that it more correctly applies to the shell described by Mr. Sowerby under the name of Murex formosus. The figure, however, in Martini's 'Coneh. Cab.' to which Lamarek refers for the illustration of that species, affords a characteristic representation of this; and it is innquestionably distinct from the Murex tribulus or any species hitherto described.

For account of Fig. 73, see the following plate, Species 76; and for Species 73, see Plate XIV. Fig. 60.

June 1845.

F. B & R, imp

PLATE XIX.

Species 74. (Mus. Metealfe.)

- Murex funiculatus. Mur. testá clavæformi, transversim liratá, liris ad summitatem funiculatis, costis tribus vel quaternis plicæformibus longitudinalibus inter varices; trivaricosá, varicibus spinosis, spinis brevibus, acutis, sursum inclinatis; fuscescente-albá, funiculis transversis castaneis; aperturá ovatá, columellá labroque intus noduliferis; canali elongato.
- THE CORDED MUREX. Shell club-shaped, transversely ridged, ridges corded at the summit, with three or four longitudinal plait-like ribs between the varices; three-varicose, varices spinous, spines short, sharp, inclined upwards; brownish white, transverse cords dark chesnut brown; aperture ovate, columella and lip noduliferous within; canal clongated.

REEVE, Pro. Zool. Soc., 1845.

Hab. --- ?

An interesting species, well characterised by the fine dark chesnnt brown cords with which it is encircled throughout at equal distances.

Species 75. (Mus. Cuming.)

- Murex recurvirostris. Mur. testá clavaformi, transversim liratá, costis tribus plicaformibus longitudinatibus inter varices; trivaricosá, varicibus grandibus rotundis, spinis paucis brevissimis minutis muricatis; cinereo-nigricante, fuscescente zonatá; canali elongato, recurvo,
- The recurved beak Murex. Shell club-shaped, transversely ridged, with three plait-like longitudinal ribs between the varices; three-varicose, varices large, round, muricated with a few very short minute spines; ashy black, zoned with light brown; canal elongated, recurved.

BRODERIP, Pro. Zool. Soc., 1832.

Hab. Gulf of Nicoiyo, Central America (found in sandy mud at the depth of about nine fathoms); Cuming.

The varices of this species are unusually large and swollen, with a minute spine sprouting up here and there.

Species 76. (Fig. 76. Mus. Saul; and Fig. 73, Pl. XIX Mus. Cuming.)

- Murex ternispina. Mur. testa elongato-ctavæformi, transversim lirata, liris parvis, inæqualibus, interstitiis corrugatis; trifariam varicosa, varicibus spinosis, spinis gracilibus, ternis prælongis, intermediis breviusculis; canali longissimo, spinoso, spinis alternis prælongis, horizontalibus, alternis breviusculis, erectis; lutescenteaut cinereo-grisea; apertura ovata, labro dente planulato erecto munito.
- The triple-spine Murex. Shell elongately club-shaped, transversely ridged, ridges small, unequal, interstices wrinkled; three-varicose, varices spinous, spines slender, three very long, alternate ones rather short; canal very long, spinous, spines alternately very long and rather short, the long spines being horizontal, the short ones erect; yellowish or ashy grey; aperture ovate, lip furnished with a flattened erect tooth.

Lamarck, Anim. sans vert. (Deshayes' edit.), vol.ix.p.567. *Hab.* Island of Negros, Philippines; Cuming.

This shell I conceive to be the true Murex ternispina of Lamarck, and not that figured for it by Kiener.

Species 77. (Mus. Taylor.)

- Murex brevispina. Mur. testá clavaformi, tenuiculá, transversim striatá, inter varices nodosá; trifariam varicosá, varicibus spinis brevibus obesiusculis armatis; fuscescente-albá; canali elongato, supernè brevispinoso; aperturá ovatá, labro dente planutato erecto munito.
- The short-spine Murex. Shell club-shaped, rather thin, transversely striated, nodose between the varices; three-varicose, varices armed with rather stout short spines; brownish white; canal elongated, short-spined; aperture ovate, furnished with an erect flattened tooth.

Lamarck, Anim. sans vert. (Deshayes'edit.),vol.ix. p.567. *Hab.* Coast of Arabia.

This species has generally a double row of nodules between the varices.

Species 78. (Mus. Cuming.)

Murex Mindanensis. Mur. testá elonyato-clavaformi, transversim tiratá, costis tribus plicaformibus inter varices; trifariam varicosá, varicibus rotundis, spinis brevibus acutis canaliculatis muricatis; lutescente-albá, varicibus aurantio-fusco pallide maculatis; canali elongato, inferne sinuato-recurvo.

THE MINDANAO MUREX. Shell elongately club-shaped, transversely ridged, with three plait-like ribs between the varices; three-varicose, varices round, muricated

with short sharp canaliculated spines; yellowishwhite, varices spotted with pale orange brown; canal elongated, sinuately recurved at the lower part.

SOWERBY, Pro. Zool. Soc., 1840.

Hab. Cagayan, Island of Mindanao, Philippines (dredged from sandy mud at the depth of twenty-five fathoms); Cuming.

This species has somewhat the appearance of an elongated Murex rarispina (Murex formosus, Sowerby), divested of its three long anterior spines.

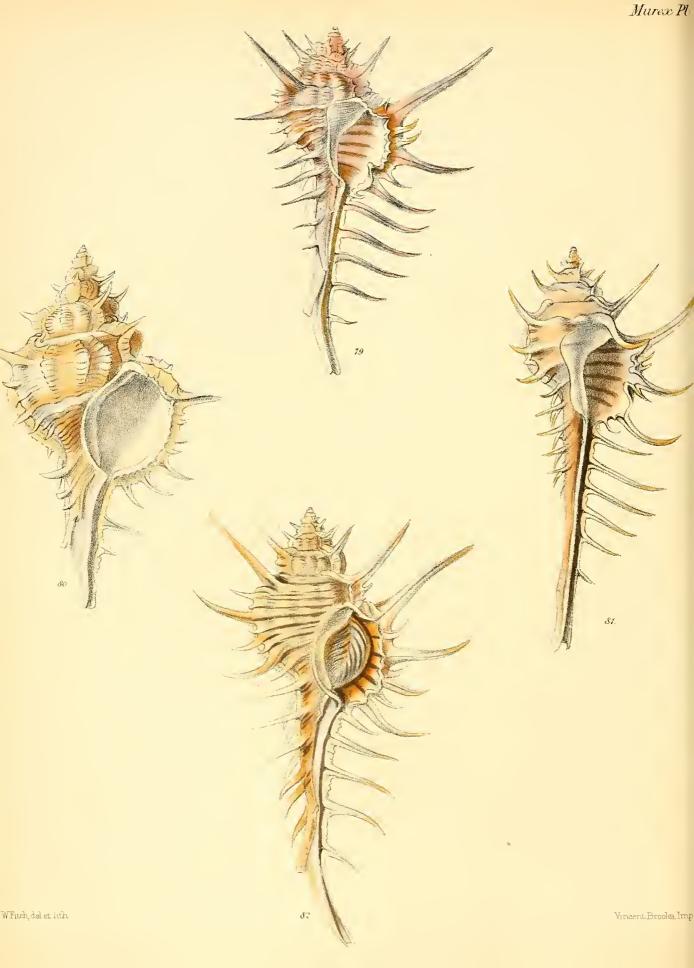

PLATE XX

Species 79 (Mus. Saul.)

Murex nigrispinosus. Mur. elongato-clavaformi, transversim lirată et striată, liris inaqualibus, subnodosis, spirai breviusculă; trifariam varicosă, varicibus spinosis, spinis erecto-elongatis; canali elongato, ad extremitatem leviter recurvo, spinoso, spinis longis, subcurvatis, purpurascente-albă, fasciis tribus vel quaternis fuscescentibus subindistincte cingulată, spinis purpureonigricantibus.

The black-spined Murex. Shell elongately club-shaped, transversely ridged and striated, ridges unequal, slightly nodose; spire rather short; three-varicose, varices spinous, spines erectly elongated; canal elongated, slightly curved back at the extremity, spined, spines long, a little curved; purplish white, somewhat indistinctly encircled with three or four light brown bands, spines purple-black.

REEVE, Pro. Zool. Soc., 1845

This shell should, I think, be distinguished from the *Murex tribulus*, to which it is most nearly allied. Its characters throughout present an agreable modification which is constant in all the examples I have seen.

Species 50. (Mus. Cummg.)

Murex pliciferus. Mur. testő ovato-fusiformi, medio ventricosá, transversim subtiliter liralá, liris augustis, numerosis, rugis minutis longitudinalibus undique granoso-decussatis; tuberculis duobns plicato-elongatis inter varices; trivaricosá, varicibus spinis canaliculatis brevibus inæqualibus, quarum uná anticá subconspicuá, armatis; albá, aurantio-fuscescente pallidè tinctá; canali subelongato, recurvo.

The plicated Murex. Shell ovately fusiform, ventricose in the middle, transversely finely ridged, ridges narrow, numerous, granosely decussated throughout with minute longitudinal wrinkles, with two plicately elongated tubercles between the varices; three-varicose, varices armed with short unequal canaliculated spines one anterior of which is conspicuous; white, faintly tinged with orange-brown; canal rather elongated, recurved.

SOWERBY, Pro. Zool Soc., 1840. Hab. —— : A fine species, of which I do not remember to have seen any other specimen. The back of it is well figured in Sowerby's 'Conchological Illustrations,' *Murex*, f. 101.

Species 81. (Mus. Saul.)

Murex occa. Mur. testă clavæformi, lævi, aut obsolete striată; anfractibus superne angulatis, nodis duobus inter varices ad angulum armatis; trifariam varicosai, varicibus spinosis, spinis longiusculis, sursum inclinatis; luteo- aut cinereo-cærulescente; canali longissimo, recto, trifariam spinoso; apertură ovată, labro dente planulato erecto munito.

The harrow Murex. Shell club-shaped, smooth or obsoletely striated; whorls angulated at the upper part, armed upon the angle between the varices with two nodules; three-varicose, varices spinous, spines rather long, bent upwards, yellowish or ashy blue; canal very long, straight, armed with three rows of spines; aperture ovate, lip furnished with an erect flattened tooth.

SOWERBY, Pro. Zool. Soc., 1840; Conch. Illus., Mnrex, f. 45.
Hab. Island of Nicobar (found in sandy mud); Commodore Ludlin.

An excellent species which may be recognised by the smooth, angular structure of the spire, and the upward inclination of the spines.

Species 82. (Mus. Metcalfe.)

Murex tribulus. Mur. testá trigono-claraformi, transversim obtuso-liratá, liris alternis majoribus, interstitiis rugosis; trifariam varicosá, varicibus spinosis, spinis longiusculis, validis, infernè crassis; pallidè fulvá, liris fusco alboque plus minusve distinctè articulatis; canali longissimo, recurvo.

The Bramblex Mure. Shell triangularly club-shaped, transversely obtusely ridged, alternate ridges the larger, interstices wrinkled; three-varicose, varices spinous, spines rather long, strong, thick at the base; pale fulvous white, ridges more or less distinctly articulated with brown or white; canal very long, recurved.

LINNÆUS, Syst. Nat., 12th edit., p. 1214.

Murex crassispina, Lamarek (not of Kiener).

Murex ternispina, Kiener (not of Lamarek).

Hab. Eastern Seas.

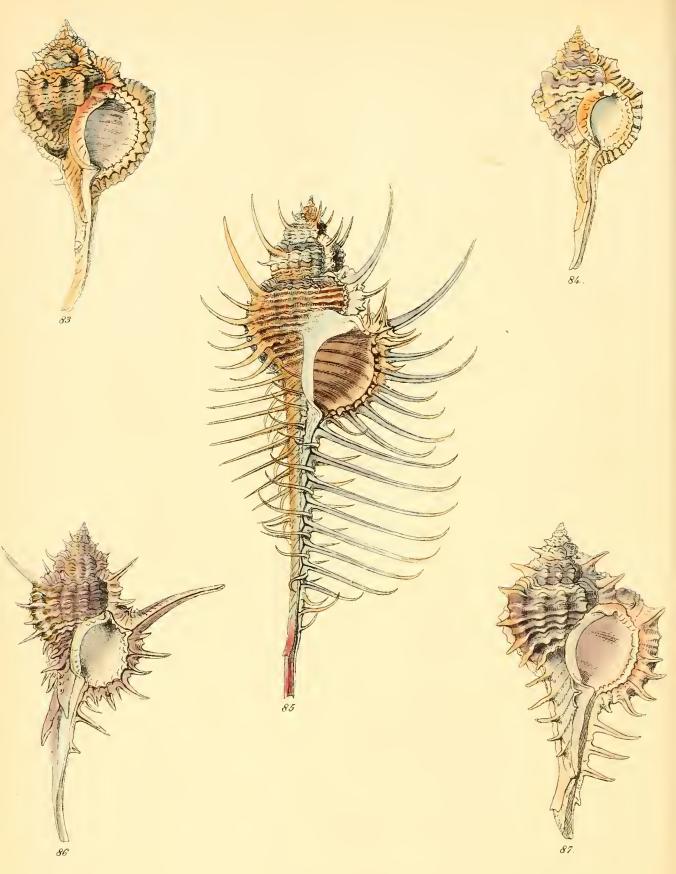

M. Deshayes' note on this species in his edition of Lamarck's 'Anim. sans vert.' so admirably exposes the complicated series of errors connected with it, that I cannot do better than give a free translation:—

"It is very certain that this species (Murex crassispina, Lamarck), is the same as that named Murex tribulus by Linneus. Lamarck recognised it himself in citing the Linneus name at the commencement of his synonymy; and should have restored to the species a name which it ought never to have lost. It is true that Linnæus refers, amongst others, to some figures of the Murex tenuispina for the illustration of his Murex tribulus; but this confusion, easy to rectify, does not authorise a change of name." "It should be observed that Lamarck confounded two very distinct species in his synonymy of Murex crassispina; one, the true Murex tribulus of Linnæus,—Martini, Conch. Cab. vol. iii. pl. 113. f. 1053, 1350, which name should be adopted; the other, the Murex tribulus maximus of Chem-

nitz,—Conch. Cab. vol. xi. pl. 189. f. 1819, 1820, (for which see Pl. XXII. Fig. 89.), described by Dillwyn under the new title of *Murex scolopax*. This Murex had been already figured by Martini, Conch. Cab. vol. iii. pl. 113. f. 1052, as a variety of *M. tribulus*; and a further error arises on the part of Mr. Sowerby, in his 'Catalogue of Murices' in the 'Conchological Illustrations.' For the *Murex crassispina*, Lamarck, he refers to Martini's, f. 1052; and for the *Murex scolopax*, Dillwyn, to Chemnitz's, f.1819, 1820, without perceiving that they represent exactly one and the same species. M. Kiener falls into a similar error, and neither author having searched for the origin of these species, they have both committed themselves in not having figured the true *Murex tributus* at all."

In reference to the latter part of this remark 1 may observe, that the shell figured by Kiener for the *Murex ternispina* is in my opinion the *Murex tribulus*; the true *Murex ternispina* being correctly figured by Sowerby, Conch. Illus. f. 110, and by myself, Pl. XVIII. f. 73, and Pl. XIX. f. 76, in my account of which the differences between these two so closely approximating species are detailed.

GBS del et lith.

RB&R mp

PLATE XXI.

Species \$3. (Mus. Cnming.)

Murex chrysostoma. Mur. testá abbreviato-clavæformi, transversim noduloso-striatá, tuberculis tribus aut pluribus inter varices; trifuriam varicosá, varicibus rotundis, tuberculato-liratis, spiná validá breviusculá curvatá ad basem; olivaceo-cinereá, luteo tinctá et maculatá; columellá corrugatá, rufo-aurantio tinctá; canali subelongato, recurvo.

The golden mouth Murex. Shell abbreviately elubshaped, transversely nodulously striated with three or four tubereles between the varices; three-varicose, varices round, tuberculately ridged, with a strong rather short curved spine at the base; olive-ash colour, stained and spotted with yellow; columella wriukled, stained with rufous orange; canal somewhat clongated, recurved.

Gray; Sowerby, Conch. Illus. Cat., Murex, no. 8. f. 1. Hab. Gulf of Mexico.

This shell is of a peculiar dark obve ash colour, tinged and irregularly stained with yellow; the edge of the lip and of the variees is festooned, in a manner, with reddish brown; and the columellar lip is coloured in places with rich rufous orange.

Species 84. (Mus. Cuming.)

Murex bellus. Mur. testá clavæformi, transversim liratis, liris tuberculato-nodosis; trivaricosá, varicibus rotundis, tuberculato-liratis, spiná brevi acutá ad basem; albicante, castaneo-fusco supra et infra maculatá, liris castaneo conspicuè funiculatis, columellá labroque rufo-aurantio tinctis; conali subelongato.

The pretty Murex. Shell elub-shaped, transversely ridged, ridges tubereularly noduled throughout; three-varicose, variees round, tubercularly ridged, with a short sharp spine at the base; whitish, spotted above and below with chesnut brown, ridges conspicuously corded with chesnut-brown, lip and columella stained with rufous-orange; canal rather elongated.

REEVE, Pro. Zool. Soc., 1845.

Hab. --- ?

Allied to the preceding species in respect to its rufous orange mouth, but of a different colour and sculpture throughout.

Species 85. (Mus. Cuming.)

Murex tenuispina. Mur. testă elongato-clavæformi, transversim noduloso-lirată, interstitiis rugis longitudinalibus clathratis; trifariam varicosă, varicibus parvis, planiusculis, longispinosis; canali elongato, sexfariam spinoso, spinarum seriebus alternis longissimis tenuibus horizontalibus ad extremitatem aduncis, alternis parvis intermediis erectis; cinereo- aut cærulescente-fuscă, aperturæ fance nigricante-fusco lineată.

The thin-spine Murex. Shell elongately club-shaped, transversely nodulously ridged, interstices latticed with longitudinal wrinkles; three-varicose, varices small, rather flattened, long-spined; canal elongated, armed with six rows of spines, three rows of very long thin horizontal spines bent inwards at the end, alternating with three rows of small erect intermediate spines; ashy or blueish brown, interior of the aperture lineated with blackish brown.

Lamarck, Anim. sans vert. (Deshayes' edit.), vol.ix. p. 566. *Hab.* Eastern Seas.

No one can fail to admire the very delicate and beautiful structure of this well-known species.

Species 86. (Mus. Cuming.)

Murex rarispina. Mur. testá trigono-clavæformi, transversim nodoso-liratá; trifariam varicosá, varicibus spinosis, spiná anticá prælongá, subcurvá, cæteris brevissimis irregularibus; fuscescente, roseo-violascente tinctá; canali subelongato, ascendente.

The rare-spine Murex. Shell triangularly elub-shaped, transversely nodosely ridged; three-varieose, varices spinous, the anterior spine of each very long, a little eurved, the rest very short, irregular; pale brown, tinged with pinkish violet; canal somewhat clongated, asceuding.

Lamarck, Anim. sans vert. (Deshayes' edit.),vol.ix. p.567.

Murex formosus, Sowerby.

Hab. ---- ?

I quite agree with MM. Kiener and Deshayes in assigning this shell to Lamarck's *Murex rarispina*; but the mischievous tendency of an observation in reference to it by M. Kiener must be exposed. It it stated by that author

that "the varieties of the Murex rarispina are very numerous, and have served for the establishment of several species which cannot be preserved, such as the M. plicatus, pliciferus, and Mindanensis." It is only necessary to refer my readers to the descriptions and figures of those species to show that M. Kiener must have been totally unacquainted with them, for their specific characters are really determinable at a glance.

Species 87. (Mus. Cuming.)

Murex plicatus. Mur. testů, abbreviato-clavaformi, crassiusculá, transversim nodoso-liratů, longitudinaliter plicatů; trifariam varicosů, varicibus rotundis, spinosis, spinis brevibus, obtusis; canali subelongato, recto, trifariam spinoso, spinis obesis, longioribus; fuscescente, purpureo-cinereo tinctů et fasciatů.

THE PLICATED MUREX. Shell abbreviately club-shaped, rather thick, transversely nodosely ridged, longitudi-

nally plicated, three-varicose, varices round, spinous, spines short, obtuse; canal somewhat elongated; straight, armed with three rows of stout longer spines; pale brown, tinged and banded with purple ash colour.

SOWERBY, Pro. Zool. Soc., 1840.

Hab. Gulf of Nicoiyo (found in coarse sand at the depth of twelve fathoms); Cuming.

No two species of a group could be pronounced to be more truly distinct than this and the *Murex rarispina*. The latter is a light delicately formed shell, distinguished by the prominent developement of the extreme anterior spine of each varix over the rest which are very short, irregular, and scale-like; the latter is a shell of rather rude obtuse structure, in which the spines are stout and solid, and exhibit this peculiarity of distribution,—that whilst upon the varices they are extremely short and in some cases almost obsolete, upon the canal they are comparatively long.

PLATE XXII.

Species 97. (Fig. 87, H.M. The King of Denmark.)

Murex trigonulus. Mur. testá trigono-fusiformi, curvatá, transversim nodoso-liratá, ad basem striatá et costatá, longitudinaliter plicatá; trifariam varicosá, varicibus tuberculiferis, ad basem plicato-laminatis; canali subelongato-recurvo; lutescente-albá, roseo tinctá et nebulosá, macularum quadratarum fuscescentium seriebus duabus ornatá.

The triangular Murex. Shell triangularly fusiform, curved, transversely nodosely ridged, striated and ribbed at the base, longitudinally plicated; three-varicose, varices tuberculiferous, plicately laminated at the base; canal somewhat elongately recurved; yellowish white, stained and clouded with pink, ornamented with two rows of square pale brown spots.

LAMARCK, Anim. sans vert. (Deshayes'cdit.), vol. ix. p. 581. *Hab.* Red Sea.

This important shell, from the private collection of H.M. The King of Denmark at Copenhagen, is the only example of the species that I have seen with the canal properly developed. Those figured by Sowerby, Kiener, and in the 'Encyclopédie Mèthodique,' being worn specimens, and all having the delicate recurved canal positively broken off. It may be recognised by the characteristic plicated lamina into which the varices terminate at the base, and by its strong scarlet-pink colouring.

It may be as well to repeat that the Murices triqueter and trigonulus are figured in the 'Encyclopédie Mèthodique' and by Kiener, the one for the other.

Species 88. (Mus. Cuming.)

Murex motacilla. Mur. testá clavæformi, crassiusculá, transversim liratá, liris angustis, subnodosis, tuberculis prominentibus inter varices; trifariam varicosá, varicibus rotundis, spiná brevi acutá anticè armatá, posticè laminatá et spinoso-squamatá; canali attenuato, lateraliter recurvo; albicante, maculis fasciisque rufo-fuscis profusè tinctá.

The wagtail Murex. Shell elub-shaped, rather thick, transversely ridged, ridges narrow, slightly nodose, with two prominent tubereles between the varices; three-varicose, varices round, armed anteriorly with a sharp short spine, posteriorly laminated and spinosely scaled; canal attenuated, laterally recurved; whitish,

profusely stained with reddish brown bands and blotches.

Снемхітz, Conch. Cab., vol. х. pl. 163. f. 1563.

Murex motacilla, var. b, Lamarek.

Hab. Senegal.

The shell which Lamarck describes for the *Murex mota-cilla* of Chemnitz, is one of very opposite character, now known to conchologists as the *Murex elegans*; his var. b. is the true species.

Mr. Sowerby described the Murex elegans in the 'Proceedings of the Zoological Society' for 1840, and figured it in his 'Conchological Illustrations,' f. 84, without discovering it to be Lamarck's Murex motacilla. He moreover published a drawing of another shell at Fig. 69, as a variety of Murex motacilla, which has little or no affinity with it, and which I propose to distinguish by the new title of Murex articulatus.

M. Kiener very properly distinguishes, and correctly figures, the *Murices elegans* and *motacilla*, confounded together by Lamarck; but ludicrously applies to his *M. motacilla* the description which Lamarck drew up from the now called *M. elegans*.

Species 89. (Mus. Brit.)

Murex scolopax. Mur. testá elongato-clavæformi, lævi, aut transversim obsoletè striatá et liratá, liris distantibus; trifariam varicosá, varicibus spinosis, spinis solidiusculis, subdistantibus, sursum inclinatis; canali sexfariam spinoso, seriebus alternis spinis fortibus longissimis, horizontalibus, alternis spinis minutis erectis; albicante, liris transversis conspicuè aurantio-fuscis.

The woodcock Murex. Shell elongately club-shaped, smooth or transversely obsoletely striated and ridged, ridges distant; three-varicose, varices spinous, spines rather solid, somewhat distant, bent upwards; canal armed with six rows of spines, one row with the spines strong, very long, and horizontal, alternating with the other, having the spines minute and erect; whitish, transverse ridges conspicuously coloured with orange-brown.

DILLWYN, Descriptive Catalogue of Shells, vol. ii. p. 681, *Murex*, no. 3.

Hab. Persian Gulf.

This species may be distinguished, amongst other characters, by the narrow transverse orange-brown bands.

Species 90. (Mus. Cuming.)

Murex messorius. Mur. testá clavaformi, transversim tuberculatá et nodosá, interstitiis leviter corrugatis; trifariam varicosá, varicibus rotundis, tuberculato-liratis, spinis tribus acutissimis armatis, uná anticá brevi, duabus posticis longioribus curvatis; canali subelongato; olivaceá, rufo-fusco minutissimè et densissimè undatá; columellá labroque intus dentato-corrugatis.

The reaping-hook Murex. Shell club-shaped, transversely tuberculated and noduled, interstices slightly wrinkled; three-varicose, varices round, tubercularly ridged, armed with three very sharp spines, one anterior, short, two posterior, longer, curved; canal rather elongated; olive, very minutely and thickly waved with reddish brown; columella and lip dentately wrinkled within.

SOWERBY, Pro. Zool. Soc., 1840; Conch. Illus. f. 93. Hab. ——?

The painting and sculpture of this species approximates very closely to that of the *Murex chrysostoma*, except in the absence of the bright rufous-orange colour of the

columella. In form it is smaller, more erect, and angulated.

Species 91. (Mns. Cuming.)

Murex rectirostris. Mur. testá clavaformi, spira suturis excavatis; transversim elevato-striatá, longitudinaliter noduloso-costatá; trifariam varicosá, varicibus rotundis, pone excavatis, spiná unicá, brevi, acutá, anticè armatis; canali elongato, recto; fuscescente, fusco maculáto-fasciatá.

The straight-beak Murex. Shell club-shaped, sutures of the spire excavated, transversely elevately striated, longitudinally nodulously ribbed; three-varicose, varices round, excavated behind, armed anteriorly with a single short sharp spine; canal elongated, straight; pale brown, banded in a blotchy manner with darker brown.

Sowerby, Pro. Zool. Soc., 1840.

Hab. Xipixapi, West Colombia (dredged from sandy mud at the depth of eleven fathoms); Cuming.

Well characterised by its straight erect growth, pale brown colouring, and other minor peculiarities.

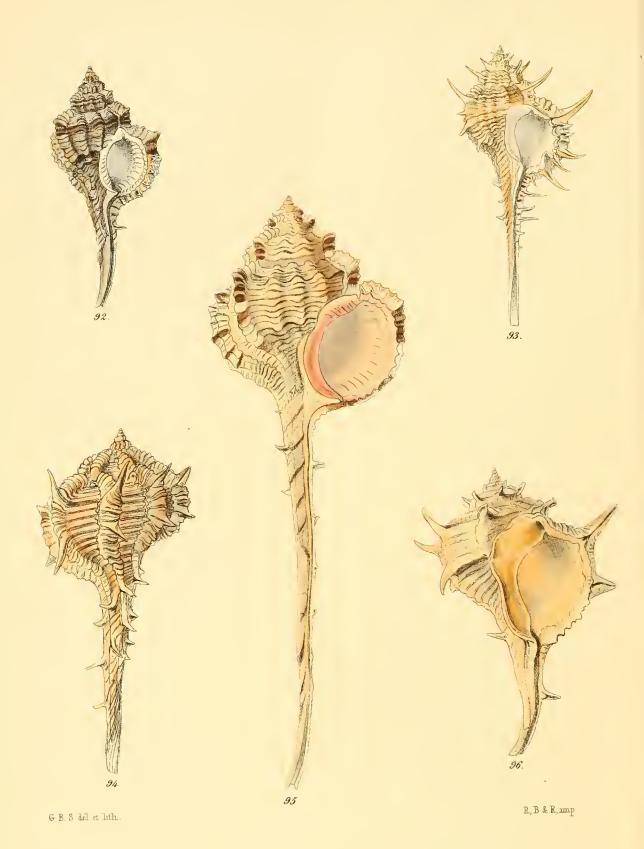

PLATE XXIII.

Species 92. (Mns. Cuming.)

Murex nigrescens. Mar. testâ clavæformi, transversim liratâ, liris angustis, prominentibus, longitudinaliter nodoso-costatis; trifariam varicosâ, varicibus rotundis, sotidis, nodiferis, spinis perpaucis minutis subobscuris infernè munitis; nigrescente-olivaceâ, fasciis duabus nigris pictâ; canali elongato.

The blackish Murex. Shell club-shaped, transversely ridged, ridges narrow, prominent, longitudinally nodosely ribbed; three-varicose, varices round, solid, nodiferous, with a very few rather obscure minute spines at the lower part; blackish-olive, painted with two black bands; canal elongated.

SOWERBY, Pro. Zool. Soc., 1840.

Hab. Xipixapi, West Columbia (found in sandy mud at the depth of eleven fathoms); Cuming.

This species, although closely approximating to the *Murex recurrinostris*, exhibits differences which may be recognised by careful comparison; it it more ventricose, and the spire more elevated.

Species 93. (Mus. Cuming.)

Murex adunco-spinosus. Mur. testá clavæformi, transversim fortiter liratá, longitudinaliter plicato-costatá; trifariam varicosá, varicibus rotundis, spinis fortibus breviusculis leviter aduncis, spinis minutis intervenientibus, armatis; lutescente-fuscá; canali elongato, supernè spinoso.

The hooked-spine Murex. Shell club-shaped, transversely strongly ridged, longitudinally plicately ribbed; three-varicosc, variees round, armed with rather short, strong, slightly hooked spines, with minute spines intervening; yellowish-brown; canal elongated, spinous at the upper part.

BECK; Marex ternispina, var., Sowerby, Conch. Illus. Cat., Murices, no. 2. f. 68.

Hab, Philippine Islands; Cuming.

The leading characteristic features of this shell are so peculiar and constant that I am induced to follow Dr. Beck in arranging it as a species distinct from the *Murex ternispina*. The spines are shorter, the ridges are much more strongly nodulous, and all the examples I have seen are of a certain brownish yellow colour.

Species 94. (Mus. Saul.)

Murex tumulosus. Mur. testá elongato-clavaformi, transversim subgranoso-liratá et striatá, spirá depressá, suturis profundè excavatis, subcavernosis, apice acuminato; septifariam varicosá, varicibus rotundis, pone excavatis, tribus vel quaternis ultimis spinis squamæformibus duabus breviusculis divergentibus armatis; lutescente, aurantio-fusco hic illic tinctá et macutatá; canali longissimo, recto, spiraliter spinoso.

The tumulous Murex. Shell elongately club-shaped, transversely somewhat granosely ridged and striated, spire depressed, sutures deep, excavated, somewhat cavernous, apex acuminated; seven-varicose, variees round, excavated behind, the three or four last variees armed with a diverging pair of rather short scale-like spines; yellowish, stained and spotted here and there with orange-brown; canal very long, straight, spirally spinous.

Sowerby, Pro. Zool. Soc., 1840. Hab. ——?

I quite agree with Mr. Sowerby in his estimation of this unique and valuable species; a hybrid, as it were, between the *Murices cornutus* and *brandaris*, but presenting an assemblage of peculiarities distinct from either.

M. Kiener asserts that this shell is merely a variety of the *Murex cornutus*, but I cannot see what right he has to question the validity of any of those species described in the "Proceedings of the Zoological Society," which he has never had an opportunity of seeing.

Species 95. (Mus. Cuming.)

Murex haustellum. Mur. testā elongato-clavæformi, transversim striatā, longitudinaliter nodoso-plicatā; trivaricosā, varicibus rotundis, muticis; fuscescente, lineis spadiceis cingulatā; varicibus maculis quadratis nigricante-fuscis ornatis, columellā labroque rubentibus; canali longissimo, gracili, spinis squamæformibus brevibus perpaucis supernè munito; aperturā rotundatoovatā.

The snipe's head Murex. Shell elongately club-shaped, transversely striated, longitudinally nodosely plicated; three-varicose, varices round, spineless; pale brown, encircled with rusty-brown lines, varices ornamented

with square blackish-brown spots, lip and columella red; canal very long, slender, furnished at the upper part with a very few short scale-like spines; aperture rotundately ovate.

Linnæus, Syst. Nat., 12th edit., p. 1214. *Hab.* Ceylon, Mauritius, &e.

This well-known species is found abundantly throughout the regions of the East. The magnificent specimen here figured was collected by Mr. Cuming at the Philippine Islands.

Species 96. (Mus. Taylor.)

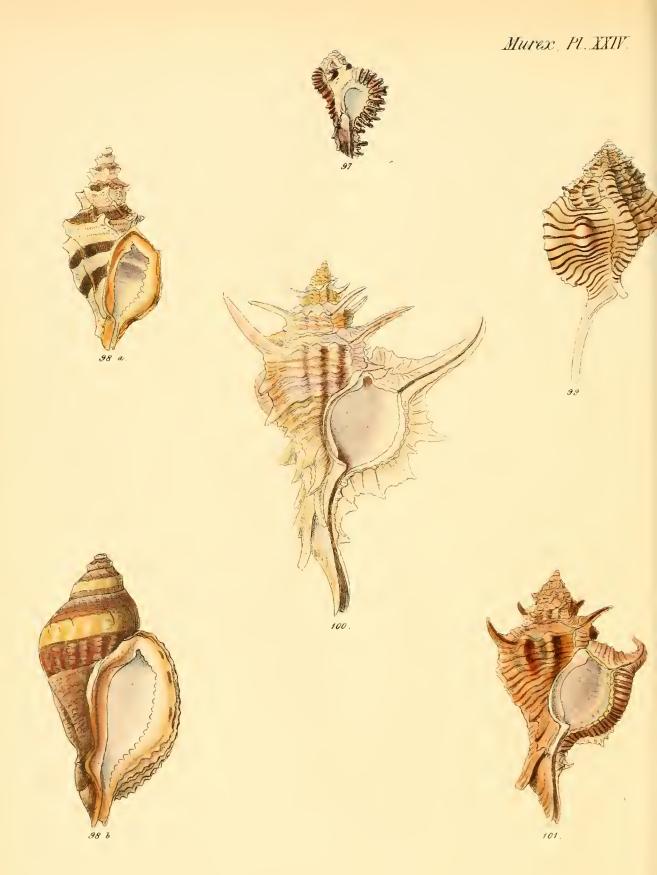

Murex brandaris. Mur. testá clavæformi, transversim subirregulariter liratá et striatá; sexfariam varicosá, varicibus planulatis, nunc muticis et tuberculatis, nunc spinis squamæformibus duabus breviusculis divergentibus armatis ; luteo-fuscescente, columellá et aperturæ fauce lutescentibus ; columellá sæpe latissimè inflatá ; canali subelongato.

The strait-spined Murex. Shell club-shaped, transversely somewhat irregularly ridged and striated; sixvaricose, variees flattened, spineless and tubercled, sometimes armed with two rather short diverging scale-like spines; yellowish-brown, columella and interior of the aperture yellowish; columella often very widely inflated; canal rather elongated.

Linnæus, Syst. Nat., 12th edit., p. 1214. *Hab.* Mediterranean.

This well-known Mediterranean species, like its fellow-inhabitant the *Murex trunculus*, is extremely variable in its growth, examples being frequently seen without a single spine.

GBS del et lith.

RB & R imp

PLATE XXIV.

Species 97. (Mus. Cuming.)

Murex secundus. Mur. testá subpyriformi-ovatá, transversim liratá, scabrosá, spirá brevi, cavernosá; quinquefariam varicosá, varice ultimo dilatato, plauifrondoso, frondibus namerosis, conferlis, canaliculatis; albá, nigricante-fusco tinctá; canali breviusculo, planulato.

The Next-Allied Murex. Shell somewhat pyriformly ovate, transversely ridged, scabrous, spire short, cavernous; five-varicose, last varix dilated, flatly frondose, fronds numerous, close-set, canaliculated; white, stained with blackish brown; canal rather short, flattened.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol.ix.p. 586. Hab. Island of Masbate, Philippines (found on the sands); Cuming.

This is the "next-allied" species to the *Murex scorpio*; from which it differs in the spire not being deeply sntured, more like that of the *Murex rota*, and in the marginal varix having none of the large palmated fronds.

Species 98. (Fig. a and b, Mus. Cuming.)

Murex salebrosus. Mur. testá elongato-ovatá, sub-Pyrulæformi, scabrosá, spirá interdum brevi, interdum elatá, angulato-turritá; sexfariam varicosá, varicibus undato-laminatis, nonnullis sæpè obsoletis; anfractibus supernè plus minusve angulatis, ad angulum irregulariter obtusè nodosis; fuscescente, fusco fusciatá; aperturá subangustá, albá, columellá labroque aurautio-rubris, labro dentato; canali brevi.

The Rugged Murex. Shell elongately ovate, somewhat Pyrula-shaped, rough, spire sometimes short, sometimes elevated, angularly turreted; six-varicose, varices undulately laminated, some often obsolete; whorls more or less angulated at the upper part, irregularly obtusely noduled at the angle; pale brown, banded with dark brown, aperture rather narrow, white, lip and columella orange-red, lip toothed; canal short.

KING, Zool. Journal, vol. v. p. 347.

Sowerby, Conch. Illus., f. 48.

Murex vitulinus, var., Gray. Beechey's Voyage, p.108. pl. 33. f. 4 and 6.

Hab. Panama (found under stones); Cuming.

I cannot agree with Mr. Gray in regarding this shell, of which numerous specimens are to be found, as a variety of the *Murex vitulinus*. It is of extremely variable growth, as the specimens selected for illustration show, but they all exhibit one uniform peculiarity of character.

Species 99. (Mns. Cuming.)

Murex elegans. Mur. testă contorto-clavaformi, crassiusculă, transversim lirată, liris angustis, ad summitatem minute granoso-funiculatis; trifariam varicosă, varicibus rotundis, hic illic obscure spinoso-plicatis; albă, funiculis transversis nitide castaneo-fuscis; canali longinsculo, gracili, oblique contorto.

The elegant Murex. Shell contortly club-shaped, rather thick, transversely ridged, ridges narrow, minutely granulously corded; three-varicose, varices round, here and there obscurely spinously plicated; white, transverse cords bright clusnut brown; canal rather long, slender, obliquely contorted.

Beck; Sowerby, Conch. Illus. Cat. Murices, no. 19. f. 84. *Hab.* Island of St. Domingo, West Indies.

Easily distinguished by its peculiarly contorted growth, and the neat appearance of its entire surface being crossed by a series of equi-distant fine brown thread-like cords.

Species 100. (Mus. Brit.)

Murex calcar. Mur. testá trigono-fasiformi, transversim liratá, liris alternis majoribus, interstitiis, subscabrosis, costis nodoso-plicatis tribus longitudinalibus inter varices; trifariam varicosá, varicibus peculiariter fimbriato-laminatis, spiná longinsculá recurvá supernè armatis; albá, ferrugineo-fusco hic illic pallidè tinclá; canali mediocri.

The spur Murex. Shell triangularly fusiform, transversely ridged, alternate ridges the larger, interstices somewhat scabrous; with three longitudinal nodosely plicated ribs between the varices; three-varicose, varices peculiarly fimbriately laminated, armed at the upper part with a rather long recurved spine; white, palely tinged here and there with rusty brown; canal middling.

Kiener, Icon. Coq. vivantes, p. 107. pl. 36. f. 2.

Murex Senegalensis, var., Sowerby, Conch. Illus. f. 61.

Hab. ——?

This shell approximates very closely to the *Murex Sene-galensis*, but I still think with M. Kiener that it may be distinguished as a species; the horn-like spines are longer, and they are webbed at the base with a delicate lamina, which in the *Murex Senegalensis* is folded down, as it were, upon the varix.

Species 101. (Mus. Cuming.)

Murex Senegalensis. Mur. trigono-fusiformi, transversim lirată, liris numerosis confertis, interstitiis minute scabrosis, tuberculis duobus grandibus inter varices; trifariam varicosá, varicibus rolundis, spiná breviusculá recurvá ad angulum armatis; livido-fuscá; canali mediocri.

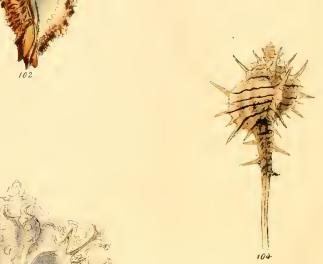

The Senegal Murex. Shell triangularly fusiform, transversely ridged, ridges numerous, close-set, interstices minutely seabrons, with two large tubercles between the varices; three-varicose, varices round, armed with a rather short recurved spine at the angle; livid brown; canal middling.

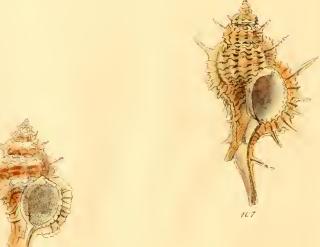

GMELIN, Syst. Nat., p. 3537.

Le Sirat, Adanson, Voy. en Sénégal, pl. 8. f. 19. Hab, Senegal; Brazil.

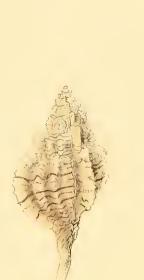

Lamarck appears to have omitted mention of this species, and referred to Adanson's figure of it for the illustration of his *Murex anguliferis*.

Murer Pl. XXV.

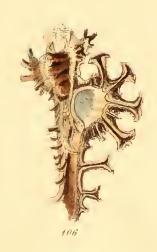

(7 B. 8 de) (47)

PLATE XXV.

Species 102. (Mus. Cuming.)

Murex Purpura. Mur. testa ovato-oblonga, basem versus attenuata, scabra; septifariam vel octofariam varicosa, varicibus obtuso-nodosis; aurantio-lutescente, varicum partibus inferioribus nodisque nigricantibus; apertura pyriformi-ovata; labro intus denticulato.

The Purpura Murex. Shell ovately oblong, attenuated towards the base, rough; seven- or eight-varicose, variees obtusely nodose; orange-yellow, nodules and lower parts of the variees blackish; aperture pyriformly ovate; lip denticulated within.

CHEMNITZ, Conchylien Cab., vol. x. pl. 161. f. 1552-5.

Murex miliaris, Gmelin.

Murex vitulinus, Lamarck.

Hab. West Coast of Africa.

The entire surface of this shell is peculiarly rough and scabrous, and the varices are distinguished by their large blunt rounded nodides.

Species 103. (Mus. Cuming.)

Murex trilineatus. Mur. testā abbreviato-fusiformi, utrinque attenuatā, solidiuscutā, transversim regulariter liratā, longitudinaliter plicato-costatā; trifariam varicosā, varicibus rotundis, spinis brevissimis squamæformibus hic illic armatis; albā, filis castaneo-fuscis tribus distantibus transversim lineatā; aperturā rotundā, labro intus denticulato-striato; canali longiusculo, gracili, ascendente.

THE TRILINEATED MUREX. Shell abbreviately fusiform, attenuated at both ends, rather solid, transversely regularly ridged; longitudinally plicately ribbed; three-varieose, variees round, armed here and there with very short scale-like spines; white, encircled with three distant chesnut-brown thread-like lines; aperture round, lip denticulately striated within, canal rather long, slender, ascending.

Reeve, Pro. Zool. Soc., 1845.

Hab. Gulf of Mexico.

 Λ white shell, distinguished by three brown thread-like cords crossing it at rather distant intervals.

Species 104. (Mus. Metealfe.)

Murex concinnus. Mur. testá elongato-clavæformi, longi-

tudinaliter subobsoletè plicato-costată, transversim eximie lirată, tirarum interstitiis minutissime squamatis; trivaricosă, varicibus spinosis, spinis breviusculis grucilibus erectis acutis; pallide fuscescente, filis castaneofuscis, quarum tribus saturatioribus, cingulată; canali gracili, longissimo, recto, superne spinoso.

The Neat Murex. Shell elongately club-shaped, longitudinally rather obsoletely plicately ribbed, transversely delicately ridged, interstices between the ridges very minutely scaled; three-varieose, variees spinous, spines rather short, slender, creet, sharp; pale light brown, encircled with chesnut-brown thread-like lines, three of which are of deeper colour than the remainder; canal slender, very long, straight, spinous at the upper part.

REEVE, Pro. Zool. Soc., 1845.

Hab. ---?

An extremely delicate and elegantly formed shell in which the coloured thread-like lines, as in the preceding species, of another form, are very characteristic.

Species 105. (Mus. Cuming.)

Murex rota. Mur. testá oblongo-ovatá, lærigatá aut obsoletè scabrosá, spirá brevi, cavernosá; septifariam varicosá, varicibus quaternis quinisve ultimis frondibus planis canaliculatis, ad apicem dilatatis et peculiariter palmatis, ornatis; niveá; canali breviusculo.

The water-wheel Murex. Shell oblong-ovate, smooth or obsoletely scabrous, spire short, cavernous; seven-varicose, last four or five varices ornamented with flat canaliculated fronds, dilated and peculiarly palmated at the summit; snowy white; canal rather short.

Sowerby, Conch. Illus. Cat. Murices, no. 73. f. 119. *Hab.* Molucca and Philippine Islands.

It is strange that this well-known species should not have been distinguished either by Lamarck or Deshayes. It differs from the *Murex scorpio* not only in having four or five of the varices handsomely palmated, but is of a different form; the body whorl being fuller and not separated from the penultimate whorl by so deep a suture; the canal moreover is shorter

Species 106. (Mus. Cuming.)

Murex scorpio. Mur. testá elongato-ovatá, gracili, subfusiformi, spirá brevi, suturis profundis et latis; quinquefariam varicosá; varice ultimo frondibus planis canaliculatis, ad apicem dilatatis et peculiariter palmatis, ornato; nigricante-fuscá, interdum albá; aperturá parvá; canali longiusculo, frondoso.

The scorpion Murex. Shell elongately ovate, slender, somewhat fusiform, spire short, sutures very deep and broad; five-varicose, last whorl ornamented with flat canaliculated fronds, dilated and peculiarly palmated at the summit; blackish-brown, sometimes white; aperture small; canal rather long, frondose.

Linnæus, Syst. Nat., 12th edit., p. 1215. *Hab.* Molucca and Philippine Islands.

It cannot be denied that a very close affinity exists between this and the preceding species; but it may be asserted without hesitation, that the differences are positive and constant. In addition to those already enumerated, it may be observed, that the varices are always fewer in number, and the last two or three are entirely separated from the penultimate whorl by the deep wide suture.

Species 107. (Mus. Cuming.)

Murex nodatus. Mur. testá abbreviato-fusiformi, subclavatá, utrinque attenuatá, longitudinaliter subplicatá, transversim liratá, liris nodiferis; trifariam varicosá, varicibus rotundis, spinis brevibus acutis armatis; luteofuscescente, lineis fuscis inter nodos cingulatá; canali longiusculo, gracili, obliquè ascendente.

The knotted Murex. Shell abbreviately fusiform, elavate, attenuated at both ends, longitudinally subplicated, transversely ridged, ridges nodiferous; three-varicose,

varices round, armed with sharp small spines; yellowish-brown, encircled between the nodules with brown lines; canal rather long, obliquely ascending. Reeve, Pro. Zool. Soc., 1845.

Hab.—?

This shell was figured in the Conchological Illustrations by Mr. Sowerby, as a variety of the *Murex motacilla*, with which species he was probably not at the time acquainted, as it bears little or no affinity with it.

Species 108. (Mus. Saul.)

Murex similis. Mur. testa abbreviato-fusiformi, spira subturrită, anfractibus superne subangulatis, transversim obsolete striatis, tuberculis tribus nodiferis inter varices; trifariam varicosă, varicibus spinis brevissimis acutis armatis; luteo-albicante, fasciis duabus aurantio-fuscescentibus latiusculis distantibus cingulată; apertură rotundato-ovată, labro columellari subconspicuo; canali longiusculo, oblique ascendente.

The similar Murex. Shell abbreviately fusiform, spire somewhat turreted, whorls a little angulated at the upper part, transversely obsoletely striated, with three nodiferous tubercles between the varices; three-varicose, varices armed with very short sharp spines; yellowish white, encircled with two rather wide orange-brown bands; aperture rotundately ovate, columellar lip rather conspicuous; canal rather long, obliquely ascending.

SOWERBY, Pro. Zool. Soc., 1840. *Hab.* ——?

This is a very excellent species, and perfectly distinct from the preceding, a comparison with which is recorded by Mr. Sowerby in the Pro. Zool. Soc., 1840, p. 140, under the impression of its being the *Murex motacilla*.

Murer, Pl. XXVI.

PLATE XXVI.

Species 109. (Mus. Belcher.)

Murex gyratus. Mur. testá fusiformi, costis transversis minutis, numerosis, eleganter crenatis, undique sculptá; spirá acuminato-turritá; anfractibus supernè depressis, medio carinatis, cariná promiuente, plano-convexá, crenatá; albicante; canali subrecurvo.

The turned Murex. Shell fusiform, sculptured throughout with numerous minute elegantly crenated transverse ribs; spire asuminately turreted; whorls depressed at the upper part, keeled round the middle, keel prominent, flatly convex, crenated; whitish; canal a little curved

Trophon gyratus, Hinds, Mollusca Voy. II. M. S. Sulphur, p. 14, pl. 1, f. 14, 15.

Hab. Straits of Macassar (found in course sand at the depth of seventeen fathoms); Cuming.

The entire surface of this shell is crossed with fine delicately crenulated ribs.

Species 110. (Mus. Cunning.)

Murex Blainvilli. Mur. testá subcylindraceo-ovatá, transversim elevato-striatá; sexfariam vel septifariam varicosá, varicibus obscurè squamatis aut nodulosis; fuscá aut fusco-rubente, interdum albifasciatá, aperturæ fauce violascente; columellá basem versus leviter plicatá, labro intus noduloso; canali brevissimo.

BLAINVILLE'S MUREX. Shell somewhat cylindrically ovate, transversely elevately striated; six- or seven-varicose, varices obscurely scaled or noduled; brown or brownish-red, sometimes banded with white, interior of the aperture violet; columella slightly plaited towards the base, lip noduled within; canal very short.

PAYRANDEAU, Cat. Moll. de la Corse, pl. 7. f. 17, 18.

Murex cristatus, var., Philippi.

Hab. Sicily.

It is true that this species presents merely a modified growth of the *Murex cristatus*, but that modification is of so marked a character that I have maintained Payrandeau's distinction.

Species 111. (Mus. Cuming.)

Murex dipsacus. Mur. testá fusiformi, spirá angulatoturritá, septifariam vel octofariam varicosá, varicibus frondosis, frondibus squamæformibus, brevibus, numerosis, varicum interstitiis, elevato-liratis, quasi cancellatis; albidá, fasciá unicá fuscescente indistinctè pictá; canali breviusculo. The teasle Murex. Shell fusiform, spire angularly turreted; seven- or eight-variouse, various frondose, fronds scale-like, short, numerous, interstices between the various elevately ridged, as if cancellated; whitish, indistinctly painted with a single light brown band; canal rather short.

Broderip, Pro. Zool. Soc., 1832, p. 194.

Hab. St. Elena, West Columbia (from a rocky bottom at the depth of twelve fathoms); Cuming.

A beautifully formed shell in which the sculpture is laid in most symmetrical order.

Species 112. (Mus. Cuming.)

Murex cristatus. Mur. testá oblongo-ovatá, transversim liratá; anfractibus supernè subdepresso-angulatis, septifariam varicosis, varicibus squamosis, squamis prominentibus solidiusculis; albicante, roseo aut rubente tinctá; columellá basem versus leviter plicatá; labro intus noduloso; canali brevissimo.

The crested Murex. Shell oblong-ovate, transversely ridged; whorls somewhat depressly angulated at the upper part, seven-varicose, varices squamate, scales prominent, rather solid; whitish, stained with pink or red; columella slightly plicated towards the base; lip nodulous within; canal very short.

Вкосені, Conch. Foss., p. 394. pl. 7. f. 15. *Hab.* Sieily.

The main distinction between this species and the *Murex Blainvilii* consists in the npper portion of the whorls being more angularly turreted, and the fronds much more prominently developed.

Species 113. (Mus. Cuming.)

Murex lepidus. Mur. testá oblongo-ovatá, transversim liratá, tiris convexis, subirregularibus, confertis; octofariam varicosá, varicibus frondosis, frondibus brevibus confertis; albidá, frondibus nigricantibus; canali breviusculo.

The pretty Murex. Shell oblong-ovate, transversely ridged, ridges convex, somewhat irregular, close-set; cight-varicose, varices frondose, fronds short, delicate, close-set; whitish, fronds blackish; canal rather short.

Reeve, Pro. Zool. Soc., 1845.

Hab. ---- ?

The fronds are of a blackish-brown colour, whilst the remaining parts of the shell are pale greenish or blueish white.

Species 114. (Mus. Cuming.)

Murex festivus. Mur. lestá oblongo-fusiformi, crassiusculá, transversim lineari-sulcatá, interstitiis lirisque intervenientibus minutè granulatis; trivaricosá, varicibus, incrassato-laminatis, recurvis, supernè cristatis; fulvescente, lineis fuscis subgeminis cingulatá; aperturá parvá; canali breviusculo.

The festive Murex. Shell oblong-fusiform, rather thick, transversely linearly-grooved, grooves and intervening ridges minutely granulated; three-varicose, varices forming a recurved thickened lamina, crested at the upper part; pale fulvous brown, encircled with fine brown thread-like lines; aperture small; canal rather short.

Hinds, Mollusca, Voy. II. M.S. Sulphur, p. 9. pl. 3. f. 13, 14. *Hab.* Bay of Magdalena, California (dredged from a sandy floor at the depth of seven fathoms); Hinds.

This species may be easily known by the peculiarly recurved structure of the varices.

Species 115. (Mus. Saul.)

Murex laqueatus. Mur. testa trigono-ovata, utrinque attenuata, transversim undique costata, costis lævigatis, tuberculo magno inter varices; trivaricosa, varicibus fimbriato-laminatis, quasi laqueatis; alba, roseo tincta; apertura parva, canali breviusculo.

THE CHANNELLED MUREX. Shell triangularly ovate, attenuated at both ends, transversely ribbed throughout, ribs smooth, with a large tubercle between the varices; three-varicose, varices fimbriately laminated, as if channelled; white, tinged with pink; aperture small, canal rather short.

SOWERBY, Pro. Zool. Soc., 1840. Hab. ——?

The variees of this shell are composed of a regularly channelled frill to which I know of no similar structure in any other species. It has little or no affinity with the *Murex tripterus*.

Species 116. (Mns. Cuming.)

Murex dubius. Mur. testá oblongo-ovatá, transversim subtiliter elevato-striatá; anfractibus supernè angulalis, septifariam varicosis, varicibus squamatis, squamis solidiusculis, ad angulum grandibus prominentibus, infra gradatim minoribus; atbidá, nigricante-fusco variá; tabro intus noduloso, canali brevissimo. The doubtful Murex. Shell oblong-ovate, transversely finely elevately striated; whorls angulated at the upper part, seven-varicose, varices squamate, scales rather solid, large and prominent at the angle, gradually smaller beneath; whitish, variegated with blackish brown; lip nodulous within, canal very short. Sowerby, Conch. Illus., f. 23.

Murex aculeatus, Wood (not of Lamarck.)
Hab. Panama; Cuming.

An aberrant species of *Murex* scarcely coming within the generic limit of the group.

Species 117. (Mus. Cuming.)

Murex laminiferus. Mur. testă ovată, spiră angulatoturrită; anfractibus ventricosis, superne angulatis, octofariam varicosis, varicibus simplicibus laminatis, interstitiis costatis, quasi cancellatis; albicante, balteo angusto unico fuscescente superne cingulată; canali brevi.

The laminiferous Murex. Shell ovate, spire angularly turreted; whorls ventricose, angulated round the upper part; eight-varicose, varices simple, laminated, interstices ribbed, as if cancellated; whitish, encircled round the upper part with a single narrow brown belt; canal short.

Reeve, Pro. Zool. Soc., 1845.

Hab. —— ?

The ventricose growth of this shell is a little peculiar.

Species 118. (Mus. Cuming.)

Murex tetragonus. Mur. testá subrotundato-ovatá, spirá interdum subpyramidali; tranversim costatá, costis foraminatis, interstitiis confertim cancellatis; quadrifariam varicosá, varicibus solidis, rotundatis, pone cavernosis; albá; canali brevi, ascendente, peculiariter abruptè recurvo.

The Quadrangular Murex. Shell somewhat rotundately ovate, spire sometimes pyramidal; transversely ribbed, ribs pierced with holes, interstices closely cancellated; four-varicose, varices solid, rounded, cavernous behind; white; canal short, ascending, peculiarly abruptly curved back.

Broderip, Pro. Zool. Soc., 1832.

Eadem. Murex breviculus, Sowerby, Conch. Ill., f. 37.

Hab. ——?

I cannot discover any specific difference between the *Murices tetragonus* and *breviculus*; it is a species in which the growth is more pyramidal in some examples than in others, but the sculpture is invariable the same.

Murex . Pl XXIII.

- s = del et lith

RB&R,mp

PLATE XXVII.

Species II9. (Mus. Belcher.)

Murex hamatus. Mur. testã ovatã, basem versus subattenuatã, anfractibus supernè angulatis, sexfariam varicosis, varicibus alatis, laciniis retrorsum hamatis, interstitiis transversim costatis, areis quadratis formantibus; pallidè luteo-fuscescente; labro dente parvo infernè munito; canali breviusculo.

The hooked Murex. Shell ovate, somewhat attenuated towards the base, whorls angulated at the upper part, six-varicose, variees winged, lappets hooked backwards, interstices transversely ribbed, forming square areas; pale yellowish brown; lip furnished at the lower part with a small tooth; canal rather short.

Ilinds, Mollusca Voy. II. M. S. Sulphur, p.8. pl.3. f.11,12.Hab. Bay of Guayaquil (dredged from a muddy floor at the depth of twenty-one fathoms); Hinds.

An interesting new species bearing some distant affinity with the *Murex monoceros*.

Species 120. (Fig. a and b, Mus. Cuming.)

Murex hexagonus. Mur. testá fusiformi-ovatá, hexagoná, anfractibus supernè subangulatis, serfariam varicosis, varicibus spinis aculeiformibus armatis, varicum interstitiis transversim tiratis, areis concavis oblongoquadratis formantibus; lutescente, spinis interdum roseo-purpurascentibus; canali subelongato.

THE HEXAGONAL MUREX. Shell fusiformly ovate, six-sided, whorls slightly angulated at the upper part, six-varieose, varices armed with priekle-like spines, interstices between the varices transversely grooved, forming obloug-quadrate concave areas; yellowish, spines sometimes rose-purple; eanal rather elongated. LAMARCK, Anim. sans vert. (Deshayes'edit.), vol.ix. p. 585. *Hab.* Island of St. Thomas, West Indies.

In some examples of this excellently defined species the prickle-like spines are of a beautiful rose-purple colour.

Species 121. (Mus. Cuming.)

Murex lingua-vervecina. Mur. testá subpyriformiovatá, lævigatá, aut peculiariter scabrosá, infernè contractá, spirá brevi, acutá; anfractibus supernè depressocavernosis, trivaricosis, varicibus laminatis, varicum interstitiis obtuso-costatis, tuberculo magno rotundato; alba, nigricante-fusco sæpè tincta et variegata; canali breviusculo, attenuato.

The sheep's tongue Murex. Shell somewhat pyriformly ovate, smooth, or peculiarly seabrous, contracted at the lower part; spire short, sharp; whorls depressly cavernous at the upper part, three-varicose, varices laminated, interstices between the varices obtusely ribbed, with a large rounded theorete; white, often stained and variegated with blackish brown; canal rather short, attenuated.

Спемкітz, Conch. Cab. v. 10. pl. 161. f. 1540-1.

Le Jaton, Adanson.

Murex gibbosus, Lamarck.

Murex lingua, Dillwyn.

Hab. Island of Goree, West Africa (dredged from sandy mud at a depth of about thirty fathoms); Belcher.

This is truly *Le Jaton* of Adanson; the shell figured by Sowerby, under the corrupt name *Jatonus*, in the Conchological Illustrations, Fig. 60, is the *Murex hemitripterus*, a species perfectly distinct, as will be seen by the description following this, and the figure to which it refers.

I adopt Chemnitz's name for *Le Jaton* in full, because I see no objection to the introduction of compound specific names when they involve one idea; and we have already several acknowledged precedents, ex. gr. auris-Midæ, caput-serpentis, pellis-serpentis, &c.

Species 122. (Mus. Saul.)

Murex hemitripterus. Mur. testa trigono-pyriformi, basem versus gradatim attenuată, crassiusculă, transversim obtuso-costată, tuberculo magno inter varices, spiră brevi, angulato-turrită; anfractibus superne angulato-depressis, trivaricosis, varicibus solidiusculis, obtuso-costatis; albidă, carneo-fuscescente variă; canali breviusculo.

The hemitripterous Murex. Shell triangularly pyriform gradually attenuated towards the base, thick, transversely obtusely ribbed, with a large tubercle between the varices; spire short, angularly turreted; whorls angularly depressed at the upper part, three-varicose, variees rather solid, obtusely ribbed; whitish, variegated with flesh-tinted brown; canal rather short.

Lamarck, Anim. sans vert. (Deshayes' edit.), vol.ix.p.579.

Murex gibbosus, young, Kiener.

Murex Jatonus, Sowerby (not Le Jaton, Adanson).

Hab. ——?

Mr. Sowerby and M. Kiener have greatly erred in confounding this with the preceding species; they are well distinguished by Lamarck, Deshayes, and also in the accompanying figures.

Species 123. (Mus. Saul).

MUREX MACROPTERON. Mur. testá elongato-fusiformi, solidiusculá, transversim obsoletè striatá, tuberculo prominente inter varices, spirá trigono-acuminato, trivaricosá, varicibus alatis, ultimo latissimè plano-expanso, quadrilobato, superficie interná undato-scabrosá; corneo-fuscescente; aperturá ovatá, margine producto; canali longo, clauso.

The Expanded-Winged Murex. Shell elongately fusiform, rather solid, transversely obsoletely striated, with a prominent tubercle between the variees, spire triangularly acuminated; three-varicose, variees winged, last varix very widely flatly expanded, four-lobed, inner surface undately scabrous; horny brown; aperture ovate, edge produced all round; canal long, closed.

Deshayes, Guerin's Mag. de Zoologie, 1841. pl. 38. *Hab.* ——?

This is certainly a most interesting and remarkable species; the example here figured from the collection of Miss Saul, is, I believe, the only one in this country.

For a more elaborate description I refer the reader to M. Deshayes's account of it, in his edition of Lamarck's Anim, sans vert. v. ix. p. 606-7.

Species 124. (Mus. Cuming.)

Murex fiscellum. Mur. testå ovato-oblongå, crasså, spirå breviusculå; anfractibus supernè subangulatis, octofariam varicosis, varicibus rotundatis incrassatis, costis striis longitudinalibus clathratis; albidå, violaceo-nigricante tinetå, aperturæ fauce vividè violaceå; canali brevi.

The Little Basket Murex. Shell ovately oblong, thick, spire rather short; whorls somewhat angulated at the upper part; eight-varieose, variees rounded, thickened, close-set, transversely ribbed, ribs latticed with longitudinal striæ; whitish, stained with blackish-violet, interior of the aperture bright violet; canal short.

CHEMNITZ, Conch. Cab. v. x. pl 160. f. 1524-5.

Hab. Island of Masbate, Philippines (found under stones at low water); Cuming.

The variees are so closely developed in this species as almost to fall one upon the other.

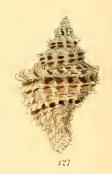

PLATE XXVIII.

Species 125. (Mus. Cuming.)

Murex carduus. Mur. testá ocatá, utrinque acutè attenuatá, spirá mucronatá; aufractibus supernè angulatis, squamurum varicibus numerosis confertis ornatis, squamis supremis prominentibus erectis; albá; canali brevi, umbilicato.

The thistle Murex. Shell ovate, sharply attenuated at both ends, spire pointed; whorls angulated at the upper part, ornamented with numerous close-set variees of scales, the uppermost of which are prominent and erect; white, canal short, umbilicated.

BRODERIP, Pro. Zool. Soc., 1832.

Hab. Pacasmayo, Coast of Peru (dredged from a coral reef twelve miles from shore at the depth of twenty-five fathoms); Cuming.

An interesting species, belonging to that section of the *Murices* which De Montford distinguished by the generic title of *Trophon*.

Species 126. (Mus. Cuming.)

Murex fasciatus. Mur. testa ovata, crassa, transversim lirata, interstitiis subtilissime granoso-striatis, tuberculo magno inter varices; trifariam varicosa, varicibus convexis, solidiusculis, costatis; livido-fuscescente, obscure fasciata; columelta callositate parva superne munita; canali brevi, clauso.

THE BANDED MUREX. Shell ovate, thick, transversely ridged, interstices very finely granosely striated, with a large tubercle between the varices; three-varicose, varices convex, rather solid, ribbed; livid brown, obscurely banded; columella furnished at the upper part with a small callosity; canal short, close.

Sowerby, Pro. Zool. Soc., 1840; Conch. Illus. f. 86. Hab. Month of the Gambia, west coast of Africa.

A solid Buceinum-like shell, of a dull livid brown colour.

Species 127. (Mus. Cuming.)

Murex luculentus. Mur. testú ovato-fusiformi, spirá angutato-turritá; anfractibus supernè angulatis, transversim costatis, lamettis fimbriatis frequentibus erectis lougitudinaliter ornatis; lutescente, fusco tinctá et fasciatá; canali breviusculo, umbilicato.

The beautiful Murex. Shell ovately fusiform, spire angularly turreted; whorls angulated at the upper part, transversely ribbed, longitudinally ornamented with frequent erect fimbriated lamelle; yellowish, stained and banded with brown; canal rather short, umbilicated.

Trophon fimbriatus, Hinds, Mollusca Voy. H.M.S. Sulphur, p. 14. pl. 1. f. 18, 19.

Hab. Straits of Maeassar (found among sand and gravel at the depth of eleven fathoms); Hinds.

The growth of this shell is marked by a beautiful succession of erect lamine, thrown up, as it were, one from under the other. The name *fimbriatus* is occupied by Lamarck in reference to a species of which we have no knowledge.

Species 128. (Mus. Cuming.)

Murex horridus. Mur. testá oblonyo-ovatá, anfractibus supernè concavo-depressis, decemfariam varicosis, varicibus rudibus simplicibus, interstitiis costis clathratis, areis elevato-striatis; albá, ferrugineo-fusco circa varices tinctá; canali brevi.

The rough Murex. Shell oblong-ovate, whorls concavely depressed round the upper part, ten-varicose, varices rude, simple, interstices latticed with ribs, the areas between which are sculptured with raised striæ; white, stained about the varices with pale rusty brown; canal short.

Broderip, Pro. Zool. Soc., 1832.

Fusus horridus, Sowerby, Conch. Illus., f. 29.

Murex Boivinii, Kiener.

Hab. St. Elena and Panama (found in sandy mud at the depth of from eight to twelve fathoms); Cuming.

I regret extremely that M. Kiener should have been doubly unfortunate in his complimentary endeavours to record the name of M. Boivin, a distinguished amateur of Paris, whose courtesy and conchological zeal I have on more than one oceasion experienced;—the Murex Boivinii is the Murex horridus, and the Cypræa Boivinii is a well-known variety of the Cypræa gangrenosa.

Species 129. (Fig. a and b, Mus. Cuming.)

Murex Norrisii. Mur. testâ subpyriformi-ovatâ, basem versus peculiariter attennatû et recurvâ, transversim conspicuè costatâ et subtilissimè elecato-striatâ, spirâ breviusculá; anfractibus supernè paululum depressis, sexfariam varicosis, varicibus frondosis, frondibus gracilibus, elegantissimè muricato-ramosis; albá, frondibus medianis fuscis; aperturá parvá; canali longiusculo, ascendente.

NORRIS'S MUREX. Shell somewhat pyriformly ovate, peeubarly attenuated and curved back towards the base, transversely conspicuously ribbed and very finely elevately striated, spire rather short; whorls a little depressed at the upper part, six-varicose, varices frondose, fronds slender, very elegantly prickly branched; white, middle fronds brown; aperture small; canal rather long, ascending.

Reeve, Pro. Zool. Soc., 1845.

Hab. ---?

I have much pleasure in dedicating this important species to Thomas Norris, Esq., in whose cabinet there is another equally characteristic specimen. The shell is most peculiarly attenuated and curved back towards the base, and the fronds are branched and ramified with remarkable sharpness and delicacy.

Species 130. (Mus. Belcher.)

Murex centrifuga. Mur. trigono-fusiformi, gracili, ba-

sem versus attenuată, spiră acuminată; anfractibus supernè subangulatis, transversim creberrime striatis, tuberculo unico, et in anfractu ultimo costis tribus quaternisve, inter varices; trivaricosă, varicibus subalatis, in spinis fortibus latiusculis compressis laciniatis, spină supremă multo maximă, elongată, rectă; corneo-fuscă; apertură parvă; canali longiusculo, extremitate paululum obliquo-recurvo.

The centrifugal Murex. Shell triangularly fusiform, slender, attenuated towards the base, spire acuminated, whorls slightly angulated at the base, transversely very closely striated, with a single tubercle, and in the last whorl three or four ribs, between the varices; three varieose, varices subwinged, laciniated into rather wide strong compressed spines, the uppermost of which is much the largest, clongated and straight; horny brown; aperture small; canal rather long, a little obliquely recurved at the extremity.

HINDS, Mollusea Voy. H. M. S. Sulphur, p. 8. pl. 3. f. 7, 8. *Hab.* West coast of Veragua (dredged from a sandy floor at the depth of fifty-two fathoms); Hinds.

A species which may be easily recognised by the three horn-like protuberances with which each whorl is surmounted at the angle.

Murer Pl XXIX.

PLATE XXIX.

Species 131. (Mus. Cuming.)

Murex nucula. Mur. testã oblongo-ovatá, crassiusculá, sexfariam varicosá, varicibus solidis, costatis, costis prominentibus, interstitiis concellatis; albidá; operturá ovatá, canali breviusculo, ascendente recurvo.

THE LITTLE NUT MUREX. Shell oblong-ovate, rather thick, six-varieose, varices solid, ribbed, ribs prominent, interstices cancellated; whitish, aperture ovate, canal rather short, ascending, recurved.

REEVE, Pro. Zool. Soc., 1845.

Hab. Island of Capul, Philippines; Cuming.

Murex cyclostoma var, Sowerby.

Very intimately allied to the *Murex cyclostoma* but is of a more oblong form, and has a recurved ascending canal.

For Species 132 see Plate XXXIII; the shell here figured proving, upon further examination, to be a variety of the *Murex cristatus*.

Species 133. (Mus. Belcher.)

Murex gravious. Shell globosely fusiform, solid, transversely ribbed, ribs approximated, lamellated, a little divergent upon the varices; five-varicose, varices prominent, pierced with holes posteriorly; white, banded round the upper part with brown; aperture oval; canal rather long, a little ascending, recurved to the left.

Ilinds, Mollusca Voy. H.M.S. Sulphur, p. 9. pl. 3. f. 19, 20.Hob. Cape Blanco, west coast of Africa (dredged from the depth of sixty fathoms); Hinds.

This interesting species may be known by its solid globose form, its close ribbed seulpture, and the sinistral prolongation of the canal.

Species 134. (Mus. Cuming.)

Murex octogonus. Mur. testá ovato-fusiformi, spirá acuminatá; anfractibus supernè concavo-depressis, octofariam vel nonafariam varicosis, varicibus acuteatis, aclueis eleganter recurvis, duobus basalibus valdè prominentibus, areis inter varices concavis, subtiliter liratis; albidá ant fuscescente, liris undique castaneofuscis; aperturá subviolaceá.

The octangular Murex. Shell ovately fusiform, spire acuminated, whorls concavely depressed at the npper part; eight- or nine-varicose, varices prickly, prickles elegantly recurved, two very prominent on each varix at the base, the areas between the varices concave, finely ridged; whitish or pale brown, ridges throughout dark chesnut brown; aperture faintly tinged with violet.

Quoy and Gaimard, Voy. de l'Astrolabe Zool. v.iii. p. 521. pl. 36. f. 8, 9.

Murex Peruvianus, Sowerby.

Hab. Bay of Islands, New Zealand; Quoy and Gaimard. Paeasmayo, coast of Peru; Cuming.

An extremely pretty species, encircled throughout with fine dark brown ridges, which curl up upon the varices in the form of prickly spines.

Species 135. (Fig. 135. Mus. Saul; and Fig. 136. Mus. Cuming.)

Murex balteatus. Mur. testa ovata, subventricosa, anfractibus supernè leviter angulatis, infra angulum costatis, costis fortibus, subdistantibus, per summitatem
obsoletè sulcatis; septifariam varicosa, varicibus frondosis, frondibus eximiè ramosis, anticè squamis minutis
peculiariter calamistratis; alba, rosaceo pulcherrimè
tincta, frondibus supernè aurantio-vel nigricante-rubentibus; apertura parva, producta; canali brevi, planulato, recurvo.

THE BELTED MUREX. Shell ovate, rather ventricose, whorls slightly angulated at the upper part, ribbed below the angle, ribs strong, rather distant, obsoletely grooved along the top; seven-varicose, varices frondose, fronds delicately branched, peculiarly frizzled on the anterior side with minute scales; white, beautifully tinged with pink, fronds orange or blackish brown at the upper part; aperture small, produced; canal short, flattened, recurved.

Beck; Sowerby, Pro. Zool. Soc., 1840.

Hab. Island of Musbate, Philippines (found on the coral reefs); Cuming.

The name of "balteatus" was suggested for this beautiful species, Mr. Sowerby informs us, by Dr. Beck, but for what reason I am at a loss to imagine.

The curious frizzled sculpture on the anterior side of the varices is peculiarly worthy of remark.

For Species 136 see Plate XXXIII.

Species 137. (Mus. Cuming.)

Murex pudicus. Mur. testá oblongo-ovatá, solidiusculá medio ventricosá, utrinque attenuatá, transversim costatá, costis varices super minutissimè squamatis, lirá parvá interveniente; septifariam varicosá, varicibus solidis, leviter tuberculatis; intus extusque niveá; canali brevi.

The chaste Murex. Shell oblong ovate, ventricose in the middle, attenuated at both ends, transversely ribbed, ribs very minutely scaled upon the varices, with a small ridge intervening; seven-varicose, varices solid, slightly tuberculated; snowy white within and without; canal short.

REEVE, Pro. Zool. Soc., 1845.

Hab. Island of St. Domingo.

A solid white shell, very much attenuated from the middle.

Species 138. (Mns. Belcher.)

Murex cirrosus. Mur. testá ovatá, ventricosá, spirae suturis profundis; nonafariam varicosá, varicibus laciniis senis fistulosis recurvis ornatis, areis inter varices costatis, costis laciniis intercurrentibus; pallidè carneá, varicum laciniis albis; aperturá ovali; canali breviusculo, gracili, recurvo, dorso bifariam laciniato.

The cirrous Murex. Shell ovate, ventricose, sutures of the spire deep; nine-varicose, varices ornamented with six recurved fistulous laciniæ, areas between the varices ribbed, ribs running from the lacinia of one varix to that of the other; pale flesh-colour, laciniæ of the varices white; aperture oval; canal rather short, slender, recurved, with two rows of laciniæ at the back.

HINDS, Mollusca Voy. H. M. S. Sulphur, p. 9. pl. 3. f. 17, 18.Hab. Straits of Macassar (found among sand and fine gravel at the depth of fifteen fathoms); Hinds.

Distinguished by the very beantiful curl-like laciniated structure of the varices.

Species 139. (Mus. Belcher.)

Murex peritus. Mur. testá subtrigono-ovatá, anfractibus supernè angulatis, transversim striatis; sexfariam varicosá, varicibus tenuibus, laciniatis, laciniis acuminatis, uncinatis, supremá præcipnè; varicum parte anticá inter lacinias crenatá; albidá, ferrugineo-fuscescente tinctá et fasciatá; canali subelongato, planato, recurvo.

THE EXPERT MUREX. Shell somewhat triangularly ovate, whorls angulated at the upper part, transversely striated; six-varicose, varices thin, laciniated, laciniae acuminated, hooked, the uppermost especially; anterior part of the varices crenated between the laciniae; whitish, stained and banded with faint rusty brown; canal a little clongated, flattened, recurved.

HINDS, Mollusca, Voy. H. M. S. Sulphur, p. 9. pl. 3. f. 23, 24.Hab. Bay of Magdalena, California (dredged from a sandy floor at the depth of seven fathoms); Hinds.

This species may be known by the curious hooked termination of the laciniæ.

Species 140. (Mus. Cuming.)

Murex vittatus. Mur. testá subfusiformi-ovatá, transversim sulcatá, septifariam varicosá, varicibus latiusculis, solidis, approximatis, brevispinosis; albá, nigro tessellato-vittatá; canali breviusculo.

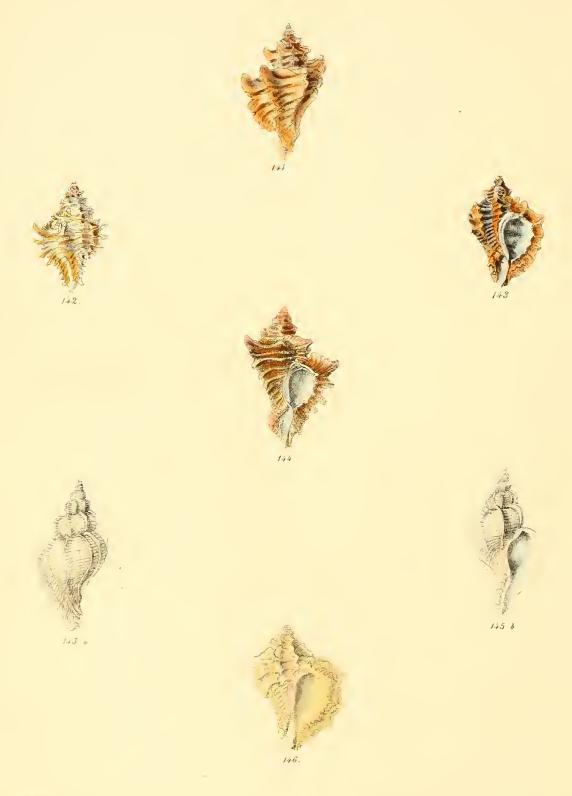

The filletted Murex. Shell somewhat fusiformly ovate, transversely grooved, seven-varicose, varices rather broad, solid, approximated, armed with short spines; white, tessellately filleted with black; canal rather short.

BRODERIP, Pro. Zool. Soc., 1832.

Hab. Isle of Muerte, Bay of Gnayaquil (from sandy mud at the depth of eleven fathoms); Cuming.

Easily to be recognised by the marked contrast of its painting.

RB&Rimp

PLATE XXX.

Species 141. (Mus. Cuming.)

- Murex caliginosus. Mur. testã ovatã, spirā angulatoturritā, basem versus contractā, anfractibus supernè depresso-angulatis, transversim costatis, costis latis, planiusculis, subdistantibus; sexfariam varicosā, varicibus tenuibus, plicato-laminatis; sordidè fuscā, costis saturatioribus; canali breviusculo.
- The obscure Murex. Shell ovate, spire angularly turreted, contracted towards the base; whorls depressly angulated round the upper part, transversely ribbed, ribs broad, rather flat, somewhat distant; six-varicose, varices thin, plicately laminated; dull brown, ribs of a darker colour; canal rather short.

REEVE, Pro. Zool. Soc., 1845.

Hab. ——?

The varices of this shell resemble those of the *Murex falcatus*, though not lapped over at the edge as in that species; the ribs are very different, and more in the style of those of the *Murex torosus*.

Species 142. (Mus. Cuming.)

- Murex lappa. Mur. testá ovatá, utriuque attenuatá, sexfariam varicosá, varicibus latis, incrassatis, solidis, approximatis, frondibns numerosis spinosis erectis armatis, varicibus utriuque fortiter costatis, costis sulcatis, minutissimè scabrosis; albá, rufo-fuscescente bifasciatim maculatá; aperturá parvá, productá, intus elevatostriatá.
- THE BUR MUREX. Shell ovate, attenuated at both ends, six-varicose, varices broad, thickened, solid, approximated, armed with numerous erect spinous fronds, varices strongly ribbed on both sides, ribs grooved, minutely scabrous; white, stained with two bands of pale reddish brown spots; aperture small, produced, elevately striated within.

BRODERIP, Pro. Zool. Soc., 1832.

Hab. St. Elena, West Columbia (found on a rocky bed at the depth of twelve fathoms); Cuming.

A stout shell with solid, sharp, prickly varices.

Species 143. (Mus. Cuming.)

MUREX LUGUBRIS. Mur. testa ovata, spira breviuscula,

transversim liratá et striatá; anfractibus supernè depressis, sexfariam varicosis, varicibus laciniatis, laciniis brevibus, recurvis; atro-purpureá, varicibus ferrugineo-fuscis; aperturá subamplá; canali brevi.

THE MOURNFUL MUREX. Shell ovate, spire rather short, transversely ridged and striated; whorls depressed at the upper part, six-varicose, variees laciniated, laciniae short, recurved; blackish purple, varices rusty brown; aperture rather large; caual short.

BRODERIP, Pro. Zool. Soc., 1832.

Hab. Puerto Portrero, Central America (found in the coral rocks); Cuming.

The lacinize in all but the last one or two varices are for the most part worn and blunted.

Species 144. (Mus. Cuming.)

- Murex Californicus. Mur. testá trigono-oblongá, subfusiformi, spirá angulato-turritá; anfractibus supernè angulato-depressis, tuberculo prominulo inter varices, transversim costatis, costis distantibus, interstitiis liris minutis pulcherrimè squamatis exsculptis; trifuriam varicosá, varicibus laciniatis, laciniis subrecurvis; ferrugineo-fuscá; aperturá ovatá; canali brevi, clauso, recurvo.
- THE CALIFORNIAN MUREX. Shell triangularly oblong, slightly fusiform, spire angularly turreted; whorls angularly depressed at the upper part, with a rather prominent tubercle between the varices, transversely ribbed, ribs distant, engraved with minute very beautifully scaled ridges; three-varicose, varices laciniated, laciniæ a little recurved; rusty brown; aperture ovate, canal short, closed, recurved.

Hinds, Mollusca Voy., H. M.S. Sulphur, p.8. pl.3. f.9, 10. *Hab.* California.

An interesting species with respect to form and seulpture, but of dull colour; the interstices between the cross ribs are scaled with extreme delicacy and beauty.

Species 145. (Mus. Cuming.)

Murex borealis. Mur. testå subelongato-fusiformi, gracili, subpellucidå, transversim obsoletè liratå; septifariam varicoså, varicibus simplicibus, lamelliferis; intus extusque niveã, roseo pallidissimè tinctá; aperturá subamplá.

The northern Murex. Shell somewhat elongately fusiform, slender, slightly transparent, transversely obsoletely ridged; seven-varicose, varices simple, lamel-liferous; snowy white within and without, very palely tinged with pink; aperture rather large.

REEVE, Pro. Zool. Soc., 1845.

Hab. Iccland.

An elegant semitransparent laminiferous shell partaking very much of the generic character of *Fusus*.

Species 146. (Mus. Cuming.)

Murex crassilabrum. Mur. testá ovatá, spirá brevi, acutá, transversim fortiter costatá, costis perpaucis,

grandibus; multifariam varicosa, varicibus simplicibus, laminiferis; intus extusque nivea; labro peculiariter incrassato.

The thick-lip Murex. Shell ovate, spire short, acute, transversely strongly ribbed, ribs very few in number, large; many-varicosc, varices simple, laminiferous, snowy white within and without; lip peculiarly thickened.

GRAY, MSS. British Museum.

Purpura crassitabrum, Sowerby.

Hab. Valparaiso (found in crevices of rocks at low water); Cuming.

Mr. Sowerby has questioned the propriety of placing this shell in the genus *Murex*, but I am inclined to think Mr. Gray is correct in so doing.

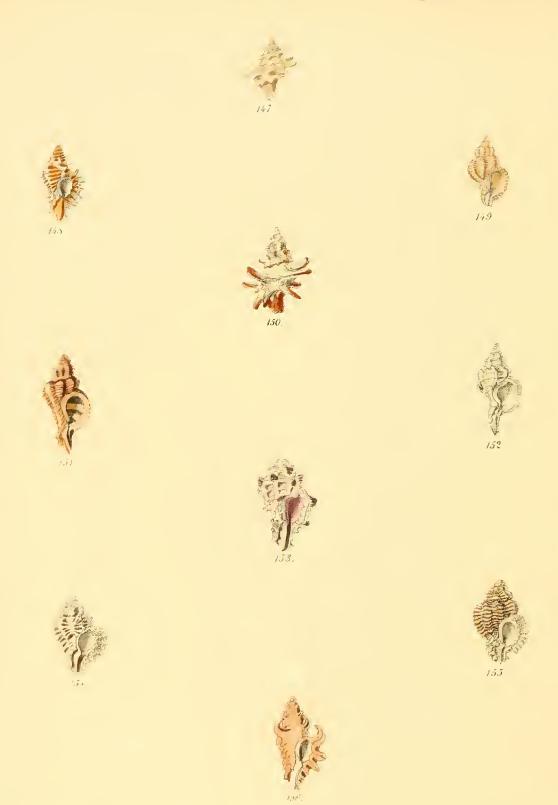

PLATE XXXI.

Species 147. (Mus. Belcher.)

- Murex muricatus. Mur. testa ovato-fusiformi, anfractibus supernè depressis, squamarum compressarum horizontalium seriebus duabus spiraliter ornatis; albicante; apertura subampla; canali brevi.
- THE PRICKLY MUREX. Shell ovately fusiform, whorls depressed at the upper part, spirally adorned with two rows of compressed horizontal scales; whitish, aperture rather large: canal short.
- Trophon muricatus, Hinds, Mollusca Voy. Sulphur, p. 14. pl. 1. f. 16, 17.
- Hab. Panama (found in mud at the depth of about nineteen fathoms); Hinds.

Only one example of this singular species was found.

Species 148. (Mus. Belcher.)

- Murex radicatus. Mur. testú ovatú, quinquefariam varicosú, varicibus laciniatis, antice abruptis, laciniis compressis, subquadratis, medio lineú duplicatis, postice interstitiorum medio exsilientibus; aperturá parcú, productú; canali ferè clauso, ad basin leviter recurro.
- The rooted Murex. Shell ovate, five-varicose, varices laciniated, anteriorly abrupt, laciniae compressed, subquadrate, divided in the middle by a line, extending back on the posterior side to the middle of the interstices; aperture small, produced; canal almost closed, slightly recurved at the base.
- HINDS, Mollusca Voy. Sulphur, p. 9. pl. 3. f. 21, 22.

Hab. San Blas, west coast of Mexico (found in mud at the depth of cleven fathoms).

Mr. Hinds describes the lacinize of this species as taking root in a peculiar manner near the centre of the interstices.

Species 149. (Mus. Cuming.)

- Murex Planiliratus. Mur. testá oblongo-ovatá, transversim undique pulcherrimè liratá, liris angustis numerosis confertis, ad summitatem peculiariter planulatis; sexfarium varicosá, varicibus plicatis; luteo-fuscescente; aperturá amplá.
- The flat-ridged Murex. Shell oblong-ovate, transversely very beautifully ridged throughout, ridges narrow, numerous, close-set, peculiarly flattened along the summit; six-varieose, varices plicated; yellowish brown; aperture large.

REEVE, Pro. Zool. Soc., 1845.

Hab. Swan River.

The entire surface of this beautiful little species is eovered with very prominent close-set narrow ridges, which are peculiarly flattened along the summit.

Species 150. (Mus. Cuming.)

- Murex noduliferus. Mur. testa cylindraceo-ovata, crassa, transversim elevato-striata, spira acuminata; sexfarium varicosa, varicibus noduloso-squamatis, anfractiis ultimi varicibus squamis duabus longissimis erectis; alba, squamis rubido-fuscis aut nigricantibus; canali brevissimo.
- The Noduliferous Murex. Shell cylindrically ovate, thick, transversely elevately striated, spire acuminated; six-varicose, varices nodudously squamate, varices of the last whorl with the scales very long and erect; white, scales reddish-brown or blackish; canal very short.

Sowerby, Pro. Zool. Soc., 1840.

Hab. Island of Masbate, Philippines (found on coral reefs); Cuming.

A remarkable species reminding one very forcibly of the *Pleurotoma anriculifera*.

Species 151. (Mus. Belcher.)

- Murex foveolatus. Mur. testű fusiformi, crassű, transversim creberrimè sulcatű, unfractibus supernè subangulatis, laminis minimis longitudinalibus foveolatis; septifariam varicosű, varicibus simplicibus, posticè rotundatis, anticè acutis; rubido-fuscű, atro-purpureo pallidè bifasciatű; labro externo intus obtusè dentato, columellari producto; canali breviusculo, subrecurvo.
- THE FURROWED MUREX. Shell fusiform, thick, transversely very closely grooved, whorls slightly angulated at the upper part, furrowed with very small longitudinal laminæ; seven-varieose, variees simple, posteriorly rounded, anteriorly sharp: ruddy brown, with two blackish purple bands; outer lip obtusely denticulated within, columellar lip produced; canal rather short, a little recurved.

HINDS, Mollusea Voy. Sulphur, p. 9. pl. 3. f. 15, 16.

Hab. Bay of Magdalena, California (dredged from a sandy floor at the depth of seven fathoms); Hinds.

A shell of somewhat uncouth growth, though presenting good distinguishing characters.

Species 152. (Mns. Cuming.)

Murex inermis. Mur. testâ eleganter fusiformi, semi-

pellucida, transversim obsolete lirata; anfractibus rotundatis, sexfariam varicosis, varicibus parvis, annuliformibus; nivea; apertura rotundata, labro columellari producto; canali subelongato, recurvo.

The unarmed Murex. Shell elegantly fusiform, semi-transparent, transversely obsoletely ridged; whorls rounded, six-varicose, varices small, ring-like; snowy-white; aperture rounded, columellar lip produced; canal slightly clongated, recurved.

Sowerby, Pro. Zool. Soc., 1840.

Hab. Japan; Dr. Siebald.

A delicately formed species in which the varices bear some resemblance to the rings of the Scalaria pretiosa.

Species 153. (Mus. Cuming.)

Murex decussatus. Mur. testá ovatá, basem versus contractá, spirá brevi, angulato-turritá; anfractibus supernè angulatis, sexfariam varicosis, varicibus angustis, solidis, nodosis, subdistantibus, areis intermediis in anfractu ultimo costis duabus distantibus decussatis; violascente-albidá, varicum nodis atro-purpureis, aperturæ fauce violascente; labro intus noduloso.

The Cross-barred Murex. Shell ovate, contracted towards the base, spire short, angularly turreted; whorls angulated at the upper part, six-varicose, varices narrow, solid, nodose, rather distant, intermediate areas on the last whorl cross-barred with two distant ribs; violet-tinged white, nodules of the varices jet-purple; interior of the aperture violet; lip noduled within.

Murex fiscetlum var., Sowerby.

Hab. Island of Bohol, Philippines.

The cross-barred sculpture of this shell, dividing its surface into regular square compartments, distinguishes it from the *Murex fiscellum* to rank as a separate species. Several examples were collected by Mr. Cuming at the above Island without any particular variation in character.

Species 154 (Mus. Cuming.)

Murex cyclostoma. Mur. testá ovatá, gibbosá, spirá breviusculá; sex-varicosá, varicibus prominentibus, anticè foraminatis et cancellatis, varicum interstitiis transversim costatis, costis pone varices fortioribus, divergentibus; livido-fuscescente, costis albicantibus; aperturá parvá, rotundá, margine producto.

The round-mouth Murex. Shell ovate, gibbons, spire rather short; six-varicose, varices prominent, anteriorly cancellated and pierced with holes, interstices between the varices transversely ribbed, ribs divergent and stronger behind the varices; livid-brown, ribs whitish; aperture small, round, edge produced. Sowerby, Pro. Zool. Soc., 1840.

Hab. Island of Bohol, Philippines.

The variety mentioned by Mr. Sowerby is a distinct species to which I have given the name of *Murex nucula*, Pl. XXIX. f. 131.

Species 155. (Mus. Cuming.)

Murex incisus. Mur. testá globoso-ovatá, crassá, spirá brevi, subobtusá; septifariam varicosá, varicibus rotundatis, incrassatis, approximatis, transversim carinatocostatis et striatis, costis striisque pulcherrimè squamatocrenulatis; albá, costis castaneis; aperturá parvá.

The carved Murex. Shell globosely ovate, thick, spire short, rather obtuse; seven-varicose, varices rounded, thickened, approximated, transversely carinately ribbed and striated, ribs and striæ very beautifully squamately crenulated; white, ribs chesnut-brown; aperture small.

BRODERIP, Pro. Zool. Soc., 1832.

Hab. St. Elena, West Columbia (dredged from a rocky bottom at the depth of eight fathoms); Cuming.

A species well distinguished by the narrow crenulated keel-like ribs which cross the varices at regular and frequent intervals throughout.

Species 156. (Mus. Cuming.)

Murex uncinarius. Mur. testā trigono-ovatā, subfusiformi, spirā subacuminatā, læviyatā, tuberculo fere obsoleto inter varices; trifariam varicosā, varicibus squamā plano-compressā uncinatā superne armatis, infra
plano-fimbriatis; fulvo-albicante; aperturā parvā;
canoli brevi, clauso.

THE HOOKED MUREX. Shell triangularly ovate, somewhat fusiform, spire rather acuminated, smooth, with a nearly obsolete tubercle between the variees; three-varicose, variees armed at the upper part with a flatly compressed hooked scale, below flatly fimbriated; fulvous white; aperture small; canal short, closed.

LAMARCK, Anim. sans vert. (Deshayes' edit.),vol.ix. p.579.

Murices Capensis and Mitriformis, Sowerby.

Hab. Cape of Good Hope.

Lamarck referred in doubt to Martini's figure of the Murex clavus thinking, probably, that this was the young of that species; and hence arose the confusion of Martini's shell (Murex clavus) being taken for Lamarck's Murex uncinarius.

I ought, perhaps, to notice an error into which M. Deshayes has fallen in stating that this shell is a species of *Typhis*. The distinguishing character of that genus is the presence of an erect fistulous tube between the varices in place of a tubercle; of which there is no indication in the *Murex uncinarius*.

GB.S. del et Lu

PLATE XXXII.

(Specimens slightly magnified.)

Species 157. (Fig. 157 and 163, Mus. Cuming.)

Murex alveatus. Mur. testā pyramidali-oblongā, transversim costatā, costis angustis, peculiariter elevatis, utrinque minutissime nodulosis, varicibus reticutatis, interstitiis alveatis; quadrifariam vel octofariam varicosā, varicibus pulcherrime cancellatis, pone cavernosis; albidā; aperturā parvā; canali brevi.

The nollowed Murex. Shell pyramidally oblong, transversely ribbed, ribs narrow, peculiarly elevated, very minutely noduled along each side, reticulated with the varices, interstices hollowed; four- to eight-varicose, varices very beautifully cancellated, cavernous behind; whitish; aperture small, canal short.

Kiener, Iconographie coq. viv., p. 24. pl. 46. f. 2.

Hab. Panama (found under stones at low water); Cuming.

A pretty deeply reticulated species, partaking somewhat of the characters of *Triton*.

Species 158. (Mus. Gruner, Bremen.)

Murex Purpuroides. Mur. testá ovatá, subventricosá, spirá brevi; anfractibus supernè subangulatis, costis parvis angustis longitudinalibus et transversis infra angulum reticulatis, costis transversis confertioribus; albicante, fasciá fuscescente interdum cingulatá; aperturá amplá, patulá.

The Purpura-like Murex. Shell ovate, rather ventricose, spire short; whorls slightly angulated at the upper part, reticulated below the angle with small narrow transverse and longitudinal ribs of which the transverse are the closer together; whitish, sometimes encircled with a pale brown band; aperture large, wide open.

DUNKER, MSS. (Cassel).

Hab. Cape of Good Hope.

A small open-mouth shell, with no regular indication of varices.

Species 159. (Mus. Cuming.)

Murex badius. Mur. testá obeso-fusiformi, solidiusculá, transversim elevato-striatá, striis conspicuis, regularibus; septifariam varicosá, varicibus incrassatis, subrolundis; rubido-castaneá; canali paululum recurvo. The brown Murex. Shell ovately fusiform, rather solid, transversely elevately striated, striæ conspicuous, regular; seven-varicose, varices thickened, somewhat round; reddish chesnut; canal a little recurved.

Reeve, Pro. Zool. Soc., 1845.

Hab. ----?

A solid dark brown shell, certainly distinct from any species that I have seen.

Species 160. (Mus. Cuming.)

Murex erosus. Mur. testa pyramidali-oblonga, transversim lirata, liris angustis, confertis, planiusculis, utrinque crenatis, interstitiis profundis; basi cavernoso-sulcata, sulco septis duobus decussato; irregulariter varicosa, anfractu ultimo varicibus duobus fortibus, cæteris obsoletè varicosis; cæruleo-nigricante, varicibus albicantibus; apertura minuta; canali brevi.

The eroded Murex. Shell pyramidally oblong, transversely ridged, ridges narrow, close-set, rather flattened, crenated on both sides, interstices deep; cavernously grooved at the base, groove crossed by two septa; irregularly varicose, two strong varices upon the last whorl, the rest obsoletely varicose; blueish black, varices white; aperture very small, canal short.

Broderip, Pro. Zool. Soc., 1832.

Hab. Panama (found under stones); Cuming.

This is rather a questionable species of *Murex*, partaking so much as it does of the characters of *Triton*. It differs in its sculpture throughout from the *Murex alveatus*, but especially in being encircled with a deep broad cavernous groove at the base.

Species 161. (Mus. Cuming.)

Murex distinctus. Mur. testá fusiformi-turriculatá, transversim striatá aut exiliter liratá, spiræ suturis subprofundis; anfractibus rotundatis, sexfariam varicosis, varicibus incrassatis, noduliferis; albidá aut flavescente; aperturá parvá, rotundá; canali brevi, subascendente.

The divided Murex. Shell fusiformly turriculated, transversely striated or faintly ridged, sutures of the spire rather deep; whorls rounded, six-varicose, va-

rices thickened, noduliferous; white or yellowish; aperture small, round; canal short, slightly ascending.

DE CRISTOFORIS and JAN, Cat. rerum nat., pl. 11. f. 82.

Murex scalarinus, Bivon.

Murex Scalarioides, De Blainville.

Hab. Mediterranean. Palermo; Philippi.

Very closely approximating to the *Murex inermis* brought from Japan by Dr. Siebald, and which might be regarded as the eastern analogue of it.

Species 162. (Mus. Cuming.)

Murex bæticus. Mur. testá fusiformi-ovatá, longitudinaliter tuberculato-costatá, transversim elevato-striatá; trivaricosá, varicibus eminentibus, muricato-nodosis; bæticá, indistinctè fasciatá, aperturæ fauce subpurpurascente; labro intus dentato; canali brevi.

The swarthy Murex. Shell fusiformly ovate, longitudinally tuberculously ribbed, transversely elevately striated; three-varicose, varices eminent, prickly nodose; dark brown, indistinctly banded, interior of the aperture tinged with purple; lip toothed within; canal short.

REEVE, Pro. Zool. Soc., 1845.

Hab. --- ?

The nodules of this interesting little dark brown shell are peculiarly prickly.

Species 164. (Mns. Cuming.)

Murex inconspicuus. Mur. testä oblongo-ovatä, crassä, transversim creberrimè obtuso-liratä, longitudinaliter costatá, costis rudibus, incrassatis, varicibus indistinctis; sordidè fuscá; labro intus dentato; canali brevissimo.

The inconspicuous Murex. Shell oblong-ovate, thick, transversely very closely obtusely ridged, longitudinally ribbed, ribs rude, thickened, varices indistinct; dirty brown; lip toothed within; canal very short.

SOWERBY, Conch. Illus., f. 81 and 117.

Murex corallinus, Scaechi.

Fusus corattinus, Philippi.

Hab. English Channel, Jersey; Sowerby.

A small rude thickened species, some examples of which are much more elongated than others.

For Species 165 see Plate XXXIII; Fig. 165 proving to be the young of *Murex balteatus*.

Species 166. (Mus. Cuming.)

Murex exiguus. Mur. testá ovatá, crassiusculá, transversim obtuso-liratá, quinquefariam varicosá, varicibus eminentibus, angilaciniatis, laciniis interstitiisque cancellatis; albá; aperturá parvá, productá; canali breci, recurvo.

The little Murex. Shell ovate, rather thick, transversely obtusely ridged, five-varicose, varices eminent, narrow-laciniated, laciniæ and interstices between them cancellated; white, aperture small, produced; canal short, recurved.

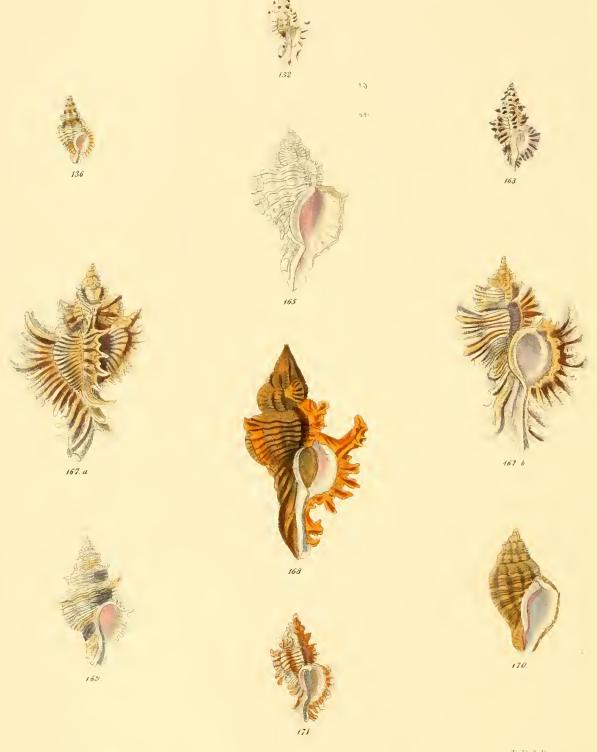

REEVE, Pro. Zool. Soc., 1845.

Hab. Saint Nicolas, Island of Zebu, Philippines; Cuming.

The laciniæ of the varices of this species are peculiar in that they assume a narrow, almost fistulose, structure.

Murex Pl.XXXIII.

RB.&R mp

PLATE XXXIII.

Species 132. (Mns. Saul.)

Murex cancellatus. Mur. testá trigono-ovatá, spirá breviusculá, anfractibus transversim liratis, lirarum interstitiis peculiariter cancellatis; trivaricosá, varicibus compresso-fimbriatis, fronde clausá subfistulosá superne ornatis; eburneá, aperturá parvá; canali clauso, b isi aperto, uncinato-recurvo.

The cancellated Murex. Shell triangularly ovars, spire rather short, whorls transversely ridged, interstices between the ridges peculiarly cancellated; three-varieose, variees compressly fimbriated, ornamented at the top with a closed, fistulous-like frond; ivorywhite; aperture small; canal closed, open at the base, curved back in a hooked manner.

SOWERBY, Pro. Zool. Soc., 1845.

Hab. ----?

An extremely eurious and characteristic species, in which a compressed fistulose-like frond is developed on the upper extremity of each varix, though not in any way analogous to the fistulose tube which rises from the area between the variees in the genus *Typhis*.

Species 136. (Mus. Cuming.)

Murex maculatus. Mur. testa ovata, subpyramidali, anfractibus brevibus, tuberculato-varicosis, varicibus interstitiisque subtiliter liratis, liris, lirarum interstitiis quoque pulcherrimè fimbriato-cancellatis; albida, macula rubido-fusca inter varices conspicuè tincta, columella et apertura fauce pallidè rosacea; canali breviusculo, recurvo.

The spotted Murex. Shell ovate, somewhat pyramidal, whorls short, tubercularly varieose, variees and interstices finely ridged, ridges and their interstices also very beautifully cancellated; whitish, conspicuously stained between the variees with a reddish brown spot, columella and interior of the aperture tinged with pink; canal rather short, recurved.

REEVE, Pro. Zool. Soc., 1845.

Hab. ----?

The whorls of this species are strongly tubercled by the variess which are very delicately cancellately ridged across.

Species 163. (Mus. Saul.)

Murex rusticus. Mur. testá ovatá, spirá acuminato-turritá, aufractibus medio tumidis, transversim subobscurè liratis, tuberculato-varicosis, varicibus frondosis, frondibus brevibus, interstitiis minutissime squamatis; lutescente-alba, varicibus nigricante-fuscis; apertura parva, limbo producto; canali breviusculo.

The Rustic Murex. Shell ovate, spire acuminately turreted, whorls swollen in the middle, transversely rather obscurely ridged, tubercularly varicose, variees frondose, fronds short, interstices minutely scaled; yellowish-white, variees dark brown; aperture small, bp produced; canal rather short.

Reeve, Pro. Zool. Soc., 1845.

Hab. ----?

A rather solid shell with an elevated tubercled spire.

Species 165. (Fig. Kiener.)

Murex polygonulus. Mur, testa ovata, subfusiformi, ventricosa, transversè sulcata et striata, nonafariam varicosa, alba; anfractibus supernè angulatis, supra planulatis, ad angulum tuberculato-coronatis; spira prominente.

THE MANY-ANGLED MUREX. Shell ovate, somewhat fusiform, ventricose, transversely grooved and striated, mine-varieose, white; whorls angulated at the upper part, flat above, tubereularly coronated at the angle; spire prominent.

LAMARCK, Anim. sans vert. (Deshayes' edit.) vol.ix. p. 594. KIENER, 1con. Coq. viv. p. 75. pl. 41. f. 2. Hab. ——?

Knowing nothing of this species I have copied Kiener's figure, and Lamarek's description verbatim.

Species 167. (Fig. a and b, Mus. Cuming.)

Murex territus. Mur. testă trigono-ovată, liris convexis subnodosis irregularibus confertis undique cingulată, tuberculo unico inter varices; trifariam varicosă, varicibus peculiariter laminato-frondosis, frondibus erectis, lateraliter connexis; lutescente, livido-olivaceo hic illic saturatiore tinctă.

The terrified Murex. Shell triangularly ovate, encireled throughout with close-set, slightly nodose, irregular convex ridges, with a single tubercle between the variees; three-varieose, variees peculiarly laminately frondose, fronds erect, connected and entangled together; yellowish, stained with livid orange, in patches here and there of a deeper colour. REEVE, Pro. Zool. Soc., 1845. Hab. ——?

A decidedly new species, reminding one at first sight of the *Murex Sinensis*, but quite distinct on examination. The entire shell is encircled with very close-set convex ridges, each terminating on the variees in an erect frond, connected together at the side so as to form a continuous laminated frill extending from the suture to the base.

Species 168. (Mus. Norris.)

Murex crocatus. Mur. testá trigono-fusiformi, transversim tiratá, liris parvis, granoso-squamatis, tuberculo inter varices; trivaricosá, varicibus frondosis, frondibus obtuso-ramosis; canali subelongato, frondoso; fuscescente, frondibus rubido-crocatis.

The saffron-tinged Murex. Shell triangularly fusiform, transversely ridged, ridges small, granosely sqamate, with a tubercle between the varices; three-varicose, varices frondose, fronds obtusely branched; canal rather elongated, frondose; brownish, fronds reddish saffron colour.

Reeve, Pro. Zool. Soc., 1845.

Hab. ——?

This might be regarded as a species of somewhat doubtful character, but after eareful comparison I am unable to refer it to any hitherto described. The varices of fronds in the specimen before me, from the collection of Thomas Norris, Esq., which, with its operculum, is in excellent condition, are of a bright scarlet saffron colour.

Species 169. (Fig. Kiener.)

Murex cariniferus. Mur. testá ovato-conicá, turbinalá; longitudinaliter costatá, transversim striatá; fulvescente; spirá acutá, spinis coronatá; anfractibus convexis, carinatis; striis sublamellosis, decurrentibus rugosis; aperturá albá; labro dextro sulcato, denticulato; canali brevi; columellá basi umbilicatá.

The keeled Murex. Shell ovately conical, turbinated, longitudinally ribbed, transversely striated; yellowish, spire sharp; with sublamellar, decurrent, wrinkled striæ; aperture white, right lip grooved, denticulated; canal short; columella umbilicated at the base.

Kiener, 1con. Coq. viv. p. 100. pl. 18. f. 2.

Fusus cariniferus, Sowerby, Conch. Illus., f. 58.

Hab. ——?

This shell is unknown to me, but, rather than omit the species, I have copied Kiener's figure and description.

Species 170. (Mus. Cuming.)

Murex buxeus. Mur. testá fusiformi-ovatá, anfractibus supernè subangulatis, multifariam unduloso-varicosis, varicibus obtusis liratis, liris creberrimis minutè rugosis; aperturá patulá, cunali brevi; lutescente-fuscá, zonulis lutescente-albidis numerosis cingulatá, columellá et aperturæ fauce niveá, prope marginem denticulatá.

The Box-wood Murex. Shell fusiformly ovate, whorls a little angulated round the npper part, multifariously varicose, varices waved, obtuse, transversely ridged, ridges very close-set, minutely wrinkled; aperture wide open, canal short; yellowish-brown, encircled with numerous small yellowish white zones; columella and interior of the aperture snowy white, denticulated near the margin.

BRODERIP, Pro. Zool. Soc., 1832.

Pollia buxea, Sowerby.

Hab. Iquiqui, Peru (found on a sandy bottom at the depth of eighteen fathoms); Cuming.

A most aberrant form of the genus.

Species 171. (Mus. Gruner, Bremen.)

Murex pudoricolor. Mur. abbreviato-fusiformi, obtiquè trigoná, transversim liratá, liris singulis tuberculis duobus basem versus evanidis inter varices, lineá minutá elevatá inter liras; trivaricosá, varicibus rotundatis, prominentibus, squamis frondibusque prototomis basem versus præcipuè pulcherrimè ornatis; eximiè rubente.

THE BLUSH-COLOURED MUREX. Shell abbreviately fusiform, obliquely triangular, transversely ridged, each
ridge with two tubercles, fading towards the base of the
shell, between the variees, and a minute clevated line
between the ridges; three-varieose, variees rounded,
prominent, beautifully ornamented with scales and,
especially towards the base, with small sprouting
fronds; bright delicate blush-red.

Reeve, Pro. Zool. Soc., 1845.

Hab. Island of St. Thomas, West Indies; Gruner.

To Mr. Gruner, of Bremen in Germany, my thanks are most justly due for the loan of this new and extremely interesting shell. It reached me just at the moment in which I was arranging my last two plates of Murices for the artist; and I take no little pleasure in recording, as a noble example of disinterestedness in the pursuit of science, the circumstance of his having forwarded it through the post, suspended at imminent risk from a letter, in order to be in time for insertion: an offering the more acceptable, because coming from a gentleman to whom I had not the honour of being personally known.

Mures, Pl XXXIV.

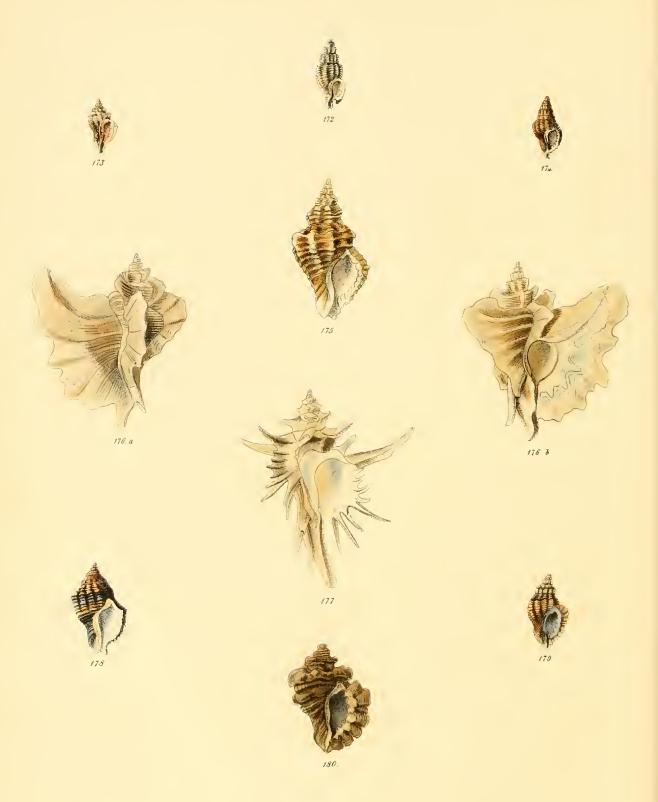

PLATE XXXIV.

Species 172. (Fig. Kiener.)

Murex Kieneri. Mur. testá parvâ, elongatâ, turriculatâ, varicosâ, transversim striatâ, fulvâ aut flavescente; spirâ acutâ; anfractibus convexis; suturâ profundâ, flavo maculatâ; labro dextro intus sulcato; canuti subelongato, supra rotundato, angusto.

Kiener's Murex. Shell small, elongated, turriculated, varicose, transversely striated, fidvous or yellowish; spire sharp; whorls convex; suture deep, spotted with yellow; right lip grooved within; canal rather elongated, rounded above, narrow.

Murex exiguus, Kiener (not of Broderip), Icon. Coq. viv., p. 97. pl. 46. f. 3.

11ab. ----?

An interesting looking species with which I am unacquainted. The name *exiguus* being already occupied I have the pleasure of attaching M. Kiener's name to it.

Species 173. (Mus. Cuming.)

Murex Pleurotomoides. Mur. testá pyriformi-ovatá, anfractibus supernè depressis, transversim liratis et minutissimè crispato-squamatis, multifariam varicosis, varicibus muricato-squamatis; canali subelongato, patulo; columellá labroque intus dentatis, labro supernè sinuato; albidá aut flavicante.

THE PLEUROTOMA-LIKE MUREX. Shell pyriformly ovate, whorls a little depressed at the upper part, transversely ridged and very minutely crisply scaled, multifariously varicose, variees priekly scaled; canal rather clongated, wide open; lip and columella toothed within, lip sinuated at the upper part.

REEVE, Pro. Zool. Soc., 1845.

Пав. ——?

A small pyriform prickly shell having a sinus in the upper part of the lip after the manner of a *Pleurotoma*.

Species 174. (Mus. Cuming.)

Murex Pistacia. Mur. testá ovatá, subfusiformi, solidiusculá, aufractibus rotundatis, sulco subobsoleto prope suturam cinctis, transversim crebriliratis, longitudinaliter subobliquè unduloso-varicosis, varicibus oblusis; castaneo-fuscescente, columellá et aperturæ fauce subrosaceis: canali brevi. The Pistachio-nut Murex. Shell ovate, somewhat fusiform, rather solid; whorls rounded, encircled with a rather obsolete groove near the suture, transversely closely ridged, longitudinally a little obliquely varicose, varices waved obtuse; light chesnut-brown, columella and interior of the aperture faintly tinged with pink; canal short.

REEVE, Pro. Zool. Soc., 1845.

Hab. —— ?

A true and well-defined species which has not been hitherto noticed.

Species 175. (Mus. Cuming.)

Murex vibex. Mur. testá ovato-fusiformi, turritá, transversim liratis, lirarum interstitiis concavo-sulcatis; septifariam varicosá, varicibus rotundatis, prominentibus, subnodosis; columellá subindistinctè pticatá; canali brevissimo; labro crenulato, intus radiatim sulcato; albá, ferrugineo-fusco tinctá, epidermide fuscá, rugosá.

THE STRIPE-MARKED MUREX. Shell ovately fusiform, turreted, transversely ridged, interstices between the ridges, concavely grooved; seven-varicose, variecs rounded, prominent, subnodose, columella somewhat indistinctly plaited; canal very short; lip erenulated, radiately grooved within; white, stained with rusty brown, epidermis brown, rough.

BRODERIP, Pro. Zool. Soc., 1832.

Hab. St. Elena and Panama (found in sandy mud at a depth of from six to twelve fathoms); Cuming.

An aberrant species which might be referred with equal propriety to *Turbinellus*.

Species 176. (Fig. a and b, Mus. Crotch.)

Murex eurypteron. Mur. testa ovato-oblonga, basem versus contracta, spira breviuscula, acuminato-turrita, suturis subexcavatis; anfractibus supernè depressis, transversim obscurè obtuso-liratis et punctato-striatis, tuberculo superficiario inter varices; trivaricosa, varicibus tenuibus, erecto-alatis, ultimo latissimè expanso, supernè falcato-recurvo; apertura parva ovata; canali breviusculo.

THE WIDE-WING MUREX. Shell ovately oblong, contracted towards the base, spire rather short, acuminately tur-

reted, sutures slightly exeavated; whorls depressed at the upper part, encircled with obscure transverse obtuse ridges and punctured striæ, with a superficial tubercle between the variecs; three-varieose, variees thin, erectly winged, the last very widely expanded and falcately recurved at the upper part; aperture small; canal rather short.

REEVE, Pro. Zool. Soc., 1845. Hab. Japan?

For this new and extraordinary shell 1 am indebted to the kindness of the Rev. W. R. Crotch, whose manuscript name eurypteron, (from $\epsilon i \rho i s$, widely extended, and $\pi \tau \epsilon \rho o v$, wing), I feel great pleasure in adopting as being peculiarly expressive of its remarkable alate growth. It approaches nearest to the Murex falcatus, but in that species there are five variees on a whorl, whilst in this there are but three, and the winged expansions of the Murex falcatus are folded over at the superior margin. The specimen here figured, and which is I believe unique, was received from Holland, and is supposed to have come from Japan.

Species 177. (Fig. Kiener.)

Mure Zelandicus. Mur. testá globosá, anterius ventricosá, subfragili; albidá; longitrorsum quinquies spinosá, transversim leviter sulcatá, spinis ultimis anfractüs longioribus, recurvatis; spirá longá, acutá; aperturá ovali et albá; canali brevi, contorto, squamoso.

The New Zealand Murex. Shell globose, ventricose anteriorly, somewhat fragile; whitish, armed longitudinally with five varices of spines, transversely slightly grooved, the last spines of the whorl longer, recurved; spire long, sharp; aperture oval, white; canal short, twisted, squamose.

Quoy and Gaimard, Zool. Voyage de l'Astrolabe, vol. iii. p. 529. pl. 36. f. 5-7.

Hab. Cook's Straits, New Zealand.

As I have not had the pleasure of seeing this interesting species I am unable to give an original figure or description. There is, I believe, a small specimen of it in this country figured some years since by Mr. Sowerby, in his 'Conchological Illustrations,' but he cannot recollect in whose possession it is.

Species 178. (Mus. Cuming.)

Murex margariticola. Mur. testa ovata, squamarum liris augustis undique cincta, anfractibus superne leviter angulatis, multifariam varicosis, varicibus obtuso-rotundatis ad angulum compresso-nodosis; alba, squamarum liris purpureo-nigricantibus, aperturæ fauce violaceā, prope marginem dentatá; canati brevi.

THE PEARL-SHELL-INHABITING MUREX. Shell ovate, encircled throughout with narrow ridges of seales, whorls slightly angled at the upper part, multifariously varicose, varices obtusely rounded, compressly nodose at the angle; white, ridges purple-black, interior of the aperture violet, toothed near the margin; eanal short.

BRODERIP, Pro. Zool. Soc., 1832.

Hab. Lord Hood's Island, Pacific Ocean (found adhering to the Meleagrina margaritifera).

A shell of very interesting sculpture, consisting of a succession of narrow purple-black ridges of fine scales upon a white ground.

Species 179. (Mus. Cuming.)

Murex Edwardsii. Mur. testå ovatå, crassiusculå, transversim irregulariter crebriliratå, longitudinaliter plicato-tuberculatå, varicibus interdum duobus vel tribus, interdum nullis; viridi-fuscå, aperturæ fauce violaceå, prope marginem dentatå; canali brevi.

Edwards' Murex. Shell ovate, rather thick, transversely irregularly closely ridged, longitudinally plicately tubercled, sometimes two or three varices, sometimes none; greenish-brown, interior of the aperture violet, toothed near the margin; canal short.

Menke, Syn. p. 65; Philippi, Ennm. Moll. Sicil. p. 210. Purpura Edwardsii, Payrandeau.

Purpura Lasseignei, Basterot.

Hab. Mediterranean.

The varices are so irregular in their appearance that the generic character of the species appears to oscillate between that of *Murex* and *Purpura*.

Species 180. (Mus. Norris.)

Murex torosus. Mur. testá globoso-ovatá, ventricosá, costis grandibus tumulosis, interstitiis profundè excavatis, lirá squamatá percurrente, cingulatá; varicibus tribus aut pluribus, obtusis; fuscá; spirá brevissimá.

The lusty Murex. Shell globosely ovate, ventricose, cheircled with large tunnulous ribs, the interstices between which are deeply hollowed, with a squamate ridge running along; varices three or more in number, obtuse; brown; spire very short.

Lamarck, Anim. sans vert. (Deshayes'edit.) vol.ix. p. 598. Hab. ——?

A very unsatisfactory species having much the appearance of a monstrous variety of the *Murex erinaceus*.

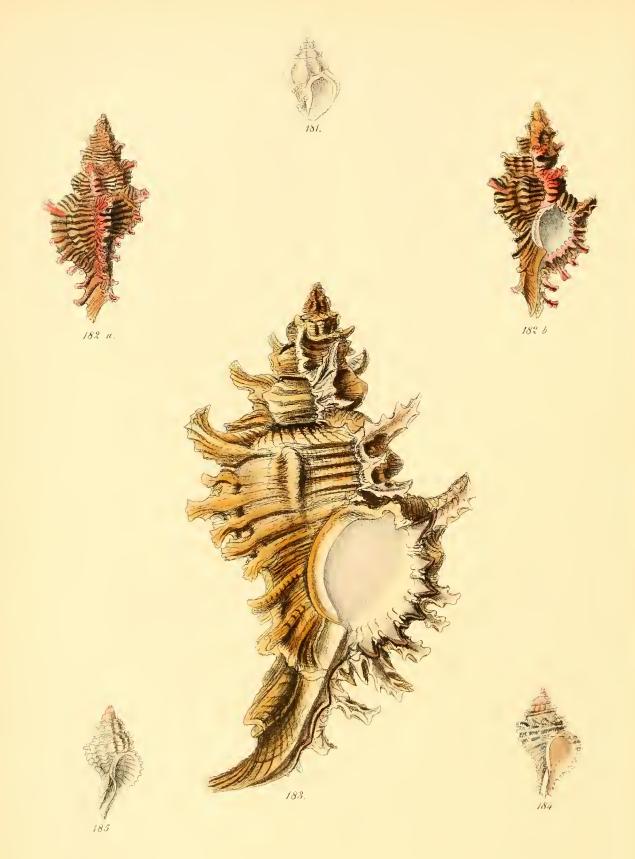

PLATE XXXV.

Species 181. (Mus. Cuming.)

Murex nux. Mur. testa abbreviato-ovata, crassiuscula, transversim obsoletè striata, basi umbilicata, spira brevi, acuminata; septifariam varicosa, varicibus crassis, solidis, supernè subnodosis, canali brevissimo; intus extusque alba.

The Nut Murex. Shell abbreviately ovate, rather thick, transversely obsoletely striated, umbilicated at the base, spire short, acuminated; seven-varieose, variees thick, solid, slightly nodose at the upper part, canal rather short, white within and without.

REEVE, Pro. Zool. Soc., 1847.

Hab. --- ?

A short gibbous shell with very stout obtuse variees.

Species 182. (Mus. Cuming.)

Murex affinis. Mur. testā fusiformi, transversim pulcherrime crebriliratā, liris subtiliter scabrosis, tuberculis duobus approximatis, quorum uno subobsoleto, inter varices; trivaricosā, varicibus frondosis, frondibus breribus subobtusis; fuscescente, liris castaneis, apice frondibusque rosaceis.

The allied Murex. Shell fusiform, transversely very beautifully closely ridged, ridges finely scabrous, with two tubereles, one of which is somewhat obsolete, between the variees; three-varicose, variees frondose, fronds short and rather obtuse; light brown, ridges chesnut, apex and fronds pink.

Reeve, Pro. Zool. Soc., 1845.

Hab. ----?

This species might easily be taken for a young Murex palma-rosæ of stunted growth, or a variety of the Murex maurus; it will, however, be found on examination to be distinct from both; and its peculiarities of character are perfectly uniform in several specimens that have come under my notice.

Species 183. (Mus. Cuming.)

Murex purpuratus. Mur. testá ovato-fusiformi, subdistortá, liris obtusis lineisque elevatis cingulatá, tuberculo prominulo inter varices; trivaricosá, varicibus frondosis, frondibus brevibus, submuricatis, labro intus couspicuè denticulato, denticulis binis; fusco-albicante, castaneo-fusco hic illic tinctá, margine labri collumellaris rufescente, labri externi limbo vividè purpureoviolaceo.

THE PURPLE-STAINED MUREX. Shell ovately fusiform, rather distorted, encircled with raised lines and obtuse ridges, with a rather prominent tuberele between

the variees; three-varieose, variees frondose, fronds short, slightly muricated, lip conspicuously toothed within, teeth ranged two and two; brownish white, stained here and there with chesnut brown, edge of columellar lip reddish, edge of the outer lip deep purple violet.

Reeve, Pro. Zool. Soc., 1846.

Hab. ——?

I have not described this shell without some hesitation, because there is a glimpse of some affinity with the *Murex calcitrapa* in it. It, nevertheless, exhibits a great peculiarity of form and colouring, and though I have carefully compared it with many different examples of that species, I cannot identify it with satisfaction.

Species 184. Mus. Cuming.)

Murex squamulosus. Mur. testa Pyrulaformi, anfractibus supernè planulatis, longitudinaliter plicato-costatis, costis liris elevatis transversis, alternatim majoribus, pulcherrimè fornicato-squamatis, clathratis, canali longiusculo; pellucidè rosaceo-albá..

THE SQUAMULOUS MUREX. Shell Pyrula-shaped, whorls flattened round the upper part, longitudinally plicately ribbed, ribs latticed with raised ridges, alternately larger, beautifully ornamented with vaulted seales; canal rather long; transparent pink white.

Fusus squamulosus, Philippi, Enum. Moll. Sieil. vol. i. p. 204. pl. xi. f. 31.

Hab. Mediterrrancan.

This is one of those abnormal species of the genus which might with equal propriety be referred to *Fusus*. The squamiferous sculpture of the transverse ridges, which are alternately larger and smaller, is extremely delicate and beautiful.

Species 185. (Mus. Cuming.)

Murex clathratus. Mur. testá subfusiformi-ovatá, basi umbilicatá, anfractibus rotundatis, longitudinaliter crebricostatis, costis crassiusculis, liris angustis squamigeris conspicuè clathratis, canali subrecurvo; albá, apice pallidè rosaceo.

The Latticed Murex. Shell somewhat fusiformly ovate, umbilicated at the base, whorls rounded, longitudinally closely ribbed, ribs rather thick, conspicuously latticed with narrow squamiferous ridges, eanal a little recurved; white, apex pale pink.

Reeve Pro. Zool. Soc., 1846.

Hab ----?

Well characterized by its rounded whorls, and the sharp elevated squamiferous structure of the transverse ridges.

R.B. & R mp

PLATE XXXVI.

Species 186. (Mus.Cuming.)

Mure rubridentatus. Mur. testá trigono-fusiformi, transversim obtuso-liratá, tuberculis duobus approximatis inter varices; trivaricosá, varicibus unululatolaminatis, erectis, e apice obliquè fluentibus, aperturá parvá, labro intus conspicuè dentato; lacteá, aurantiofusco hic illic sparsim tinctá, dentibus rubris.

THE RED-TOOTHED MUREX. Shell triangularly fusiform, transversely obtusely ridged, with two approximating tubercles between the varices; three-varieose, variees undulately laminated, erect, flowing obliquely from the apex, aperture small, lip eonspicuously toothed within; cream-eoloured, sparingly stained here and there with orange-brown, teeth red.

Reeve, Pro. Zool. Soc., 1846. *Hab.* —— ?

A truly interesting species, quite distinct from any hitherto described. It is of a triangular fusiform structure, and each varix consists of an erect plaited lamina flowing obliquely from the apex. The inner side of the lip is strongly toothed, and the teeth being tipped with red upon a milk-white ground have a very chaste and characteristic appearance. Mr. Cuming possesses two examples of this species, both in equally fine condition.

Species 187. (Mus. Cuming.)

Murex spectrum. Mur. testá erecto-fusiformi, transversim tiratá, liris irregularibus, nodosis et tuberculatis, spiræ suturis subexcavatis; trivaricosá, varicibus incrassatis, frondosis, frondibus subelongatis, ramosis et muricatis, canali longiusculo; lutescente, frondibus lirisque castaneo-fuscis.

THE SPECTRE MUREX. Shell ereetly fusiform, transversely ridged, ridges irregular, nodose and tuberculated, sutures of the spire rather excavated; three-varicose, varices thickened, frondose, fronds rather elongated, branched and muricated, canal rather long; yellowish, fronds and ridges chesnut-brown.

Reeve, Pro. Zool. Soc., 1846.

Hab. ---- ?

This new and somewhat remarkable species approximates to the *Murex palma-rosæ* in form, though perfectly distinct throughout in its various details of character. Mr. Cuming possesses no information as to its locality, and has not heard of any other specimen.

Species 188. (Mus. Cuming.)

Murex florifer. Mur. testā trigono-ovatā, subfusiformi, transversim liratā, liris subdistantibus, interstitiis subtilissime funiculatis, funiculis frondes super scabrosis, tuberculo grandi elongato inter varices; trivaricosā, varicibus pulcherrime frondosis, frondibus erectis, floriferis, muricatis; albicante, ferrugineo-fusco plus minusve tinctā, frondibus saturatioribus, extremitatibus muricatis intus extusque albis, apice rosaceo.

The flower-bearing Murex. Shell triangularly ovate, somewhat fusiform, transversely ridged, ridges rather distant, interstices very finely corded, cords seabrous over the back of the fronds, with a large elongated tuberele between the variees; three-varieose, variees very beautifully frondose, fronds creet, floriferous, muricated; whitish, more or less stained with rusty brown, frouds darker brown, muricated extremities of the fronds white within and without, apex pink.

Reeve, Pro. Zool. Soc. 1846.

Hab. Honduras.

A fine new species approximating in general appearance to the *Murex rufus*, from which it may easily be distinguished by the forcible character of the ribs and tubercles, by its white ground colour and pink apex, and the striking effect which is produced by the white-tipped extremities of the fronds.

Species 24. (Mus. White).

MUREX MEGACERUS.—A specimen from the collection of H. H. White, Esq., illustrating a peculiar state of this species (for the normal form of which see Plate VI.), in which the fronds are of a short stunted growth, and the body of the shell particularly stout and gibbous.

SUPP. PLATE I.

Species 189. (Mus. Gubba.)

Murex strigatus. Mur. testá trigono-fusiformi, transversim graniliratá et striatá, tubercutis duobus, quorum uno multo majore inter varices; trivaricosá, varicibus regulariter frondosis, frondibus floriferis, æqualibus, aperturá parvá, canali clauso; ustulato-fuscescente, castaneo transversim undique strigatá.

THE STRIPED MUREX. Shell triangularly fusiform, transversely granulately ridged and striated, two tubercles between the varices, one of which is much the larger; three-varicose, varices regularly frondose, fronds floriferous, equal, aperture small, canal closed; light burnt brown, transversely striped throughout with dark chestnut.

Hab. ---- ?

An interesting new species from the collection of M. Gubba of Havre.

Species 190. (Mus. Taylor.)

Murex rorifluus. Mur. testă fusiformi, subventricosă, anfractibus transversim obscure liratis, rugosis, quadrivaricosis, varicibus rudibus, simplicibus, planulatis, obscure denticulatis, aperturæ margine dentato; sordide cinerascente, intus nigricante-castaneă, varicibus albidis.

The bedewed Murex. Shell fusiform, slightly ventricose, whorls transversely obscurely ridged, rugose, four-varicose, varices rude, simple, flattened, obscurely denticulated, margin of the aperture toothed; dull ash-colour, blackish chestnut within, varices white.

Adams and Reeve, Moll. Voy. Samarang, pl. 8. f. 2. a, b. Hab. Korean Archipelago; Belcher.

Of a very dark chestnut colour interiorly, the outer surface being of a dull ash, with the lip and varices white.

Species 191. (Mus. Taylor.)

Murex plorator. Mur. testá trigono-ovatá, anfractibus lævibus, trivaricosis, varicibus compresso-alatis, aperturá parvá, rotundalá, canali clauso; castaneo-fuscá, medio transversim albizonatá.

The Mourner Murex. Shell triangularly ovate, whorls smooth, three-varicose, varices compressly winged, aperture small, rounded, canal closed; chestnut-brown, transversely white-zoned in the middle.

Adams and Reeve, Moll. Voy. Samarang, pl. 8. f. 3. a, b. Hab. Korean Archipelago; Belcher.

Belonging to the same division of the genus as the M, eurypteron.

Species 192. (Mus. Taylor.)

Murex Burnettii. Mur. testá trigono-ovatá, crassiusculá, aufractibus transversim obsotetè costatis, trivaricosis, varicibus latè fimbriatis, dente unico marginali prominente, aperturá ovali, canali clauso; albidá, castaneo-fusco plus minusve tinctá.

Burnett's Murex. Shell triangularly ovate, rather thick, whorls transversely obsoletely ribbed, three-varicose, varices broadly fimbriated, with a single prominent marginal tooth, aperture oval, canal closed; whitish, more or less stained with chestnut-brown.

Adams and Reeve, Moll. Voy. Samarang, pl. 8. f. 4. a, b. Hab. Korean Archipelago; Belcher.

A fine species, very distinct from any hitherto described of which only one or two specimens were collected in a more or less mutilated condition. The canal is closed over, and each varix is furnished with a remarkably prominent tooth.

Species 193. (Mus. Gubba.)

Murex Gubbi. Mur. testá trigono-fusiformi, basin versus contractá, anfractibus supernè depresso-concavis, granoso-striatis et liratis, liris irregulariter nodulosis, trivaricosis, varicibus frondosis, frondibus angustis, irregularibus, unicá medianá bifurcatá, superná multo majore, peculiariter falcatá; labro intus conspicuè dentato; adustá, prope basin anticè fuscescente, apertura fauce carulescente-albá.

Gubba's Murex. Shell triangularly fusiform, contracted towards the base, whorls depressly concave round the upper part, transversely granosely striated and ridged, ridges irregularly nodulous, three-varicose, varices frondose, fronds narrow, irregular, a single middle one bifurcated, the uppermost frond much the larger, peculiarly hooked; lip conspicuously toothed; cinder-black, fulvous in front near the base, interior of the aperture bluish-white.

Hab. ---- ?

M. Gubba possesses two specimens of this very intercsting new species, to which I have the pleasure of attaching his name.

Species 194. (Mus. Cuming.)

Murex unicornis. Mur. testá subfusiformi-oblongá, crassá, obliquè trigoná, transversim obscurè costatá, tuberculo magno inter varices, varicibus incrassatis, obtusis, ultimo intus denticulato, dente unico conspicuo erecto etongato, canali brevissimo, clauso; albá, castaneo tinctá.

The unicorn Murex. Shell somewhat fusiformly oblong, thick, obliquely triangular, transversely obscurely ribbed, with a large tubercle between the varices, varices thickened, obtuse, last whorl deuticulated within, one tooth conspicuous, erect, elongated, canal very short, closed: white, stained with chestnut.

Hab. ——?

This approaches very near to the *M. monoceros*, but is of a different form and of more solid growth.

MONOGRAPH

OF THE GENUS

CYPRÆA.

"What wonder then if with one virtuous touch
The arch-chimic sun, so far from us remote,
Produces, with terrestrial humour mixed,
Here in the dark so many precious things
Of colour glorious and effect so rare."—Milton.

PLATE I.

Genus CYPR.EA, Linnæns.

Testa ovata vel oblongo-ovata, ventricosa, polita, interdum nodifera aut costellata, extremitatibus canaliferis aut emarginatis, spirá brevissimá, partim vel omninò occultá; aperturá subcentrali, longitudinali, angustá; columellá labroque per totam longitudinem plus minusve denticulatis, interdum at rarò edentulis.

Shell ovate or oblong-ovate, ventricose, polished, sometimes nodiferons or ribbed, with the extremities channeled or emarginated; spire very short, partially or entirely concealed; aperture nearly central, longitudinal, narrow; lip and columella more or less toothed throughout their entire length, sometimes, but rarely, without teeth.

There is perhaps no group in the series whose shells have excited more admiration than those of the *Cyprææ*; the Cowry is generally the first to attract the attention of the amateur, and its physiological history offers matter of no less interest to the man of more abstruse habits of enquiry.

The Cypræa is a mollusk of very peculiar character: first, on account of the different phases presented by its shell at different periods of growth; and, secondly, on account of the curious property which the animal possesses of dissolving and renewing its shell. The original growth of the Cowry is, undoubtedly, a process of time; but the re-calcification of a shell at maturer age appears to be the work of a few days only.

The first stage of advancement produces a simple convolution of shell around a columella axis in the form of a long drawn out Bulla, the columella being smooth, the outer lip thin, and the colour usually diffused in bands of waves. In the second epoch of growth the shell solidifies, the lip and columella begin to thicken, and present gradual indications of teeth, the teeth become more and more perfectly developed, and the dorsal surface is overlaid with a strong coat of livid colouring matter also diffused in obscure bands or waves. The calcifying energies of the mantle, which, extending in two unequal lobes one from either side of the shell's aperture, have been chiefly excreised during the second epoch of growth upon the dorsal surface, are now more particularly directed to the base

and sides. The teeth are strengthened, the sides become thickened with a rich coating of enamel, and the growth of the shell is completed by a light fabric of colouring matter deposed in lines, blotches, waves, or reticulations, of various hues and patterns.

The re-calcification of a shell at maturer age has been a subject of some difference of opinion amongst naturalists. Bruguière first introduced the fact, and Lamarck says "I possess observations which tend to prove that the Cowry, arrived at the power of forming a complete shell, has still the faculty of enlarging its habitation, and is then obliged to quit the shell in order to form a new one. It results from this that the same individual has the power of forming a successive number of shells during both the second and third stages of growth; and which accounts for our often meeting with so many different sizes of the same species"!

M. Deshayes, after furnishing us with an excellent account of the zoological characters of Cypræa, derived mainly from the observations of M. M. Quoy and Gaimard, argues against the possibility of any re-modelling of the shell taking place, and regards the statement of Lamarek as a theory opposed to the common laws of organization. To the supposition of Bruguière that the Cowries east their shells after the manner of Crabs, M. Deshayes very properly replies that there can be no analogy between them. The new shell of the Crustacea is formed by a secretion of equal consistency from every part of the body, whereas the Mollusca have a muscidar attachment to the columella, and increase the growth of their shell by an exudation, not from the whole body, but from a particular organ;the mantle being the sole agent charged with that faculty. It is further argued by the same distinguished naturalist that the Cowry must lose the power of forming the inner chambers of the columella anew, after having once passed that early process of development which induces their formation. "How is it possible," asks M. Deshayes, "that the animal can, under the circumstances of its nature, secrete a new shell from all parts of the body at once, and with all the different phases of colour exhibited in the original, when it has reached to an advanced condition of its existence?"

It is, however, certain that the Cowry is enabled to effect a very important change in the shell during one or more periods of its life; and I think the fact may be fully established without prejudice to the excellent arguments of my illustrious contemporary. From the testimony of a gentleman, who worthily employs the opportunities afforded him as a Naval Officer to the advancement of science, whose veracity is beyond all question, and whose communication (given verbatim) * contains nothing more than a simple narrative of the phenomena of which he was himself an eye-witness, it may, I think, be deduced that it is the outer wall of the shell only which is re-constructed, the columella with its spiral compartments remaining undisturbed. The animal does not quit the shell as Lamarck supposed, but dissolves the outer portion with its acetose jinces. All visible trace of the shell may be thus removed without weakening M. Deshayes' proposition founded on the circumstance of the mantle being the only organ charged with the secretive fluid. The mantle is always capable of extension over the shell; and the same power which furnishes the adult with its last coating of enamel can be exerted to the formation of as many superincumbent layers as may be necessary to replace all that has been decomposed. That a dissolution takes place there can be no doubt:-"the shell gradually swells," says Lieut. Hankey, "and cracks, becomes thinner, and duller in colour, and finally disappears;" a circumstance which may be easily credited when it is remembered that the Murex possesses the faculty of removing spines or any similar obstacles to its advancement of growth, and that the Pholades, and other terebrating mollusks, exercise a power of absorbing which enables them to penetrate the hardest limestone rock. The microscopical structure of the Cowry shell is, moreover, of a nature peculiarly tenacious of absorption; it is composed of a large quantity of carbonate of lime in proportion to the amount of membranous substance; and this accounts for its surface becoming vitrified, as it were, to such a highly polished state of enamel when in contact with the acidity of the soft parts.

There is another circumstance in Lieut. Hankey's narrative to which attention should be given, respecting the formation of the new shell:—the glutinous matter which has the appearance of shell-lac, and is so fragile that it yields to the touch, does not assume the narrow cylindrical Bulla form, it does not follow the original plan of revolving round a columellar axis, but is of the wide, ventricose shape of a Cymba, and rapidly consolidates into the adult shell.

With these generalizations I think it may be assumed that the Cowry possesses the faculty of decomposing, during one or more periods of its existence, any portion of the shell that is liable to resist its advancement of growth; that the renewal of the shell is accomplished within a comparatively short space of time; and that the columella with its internal spiral partitions remains undisturbed. It may, however, be inferred that it is an operation of extremely rare occurrence, and one which only happens under peculiar conditions.

The Cyprææ present two very distinct groups;—the larger species in which the surface of the shell is highly enamelled, and the smaller species in which it is disposed in grooves and ridges of a lighter character and of more delicate colouring. In the first division there are two or three species from South Africa of a peculiar opake white structure, of which the C. Algoensis and Capensis may be quoted as being the types of Mr. Gray's genera Luponia and Cypræovula; the second division is the genus Trivia of the same writer.

The genus Cypræa presents little variety of form but a diversity of colouring; it contains several very distinct and characteristic species of unusual rarity, and which our country can alone boast of possessing. Of these the Cyprææ princeps and leucodon, in our national collection,

* LIEUT. J. B. HANKEY, R.N., to LOVELL REEVE.

My dear Sir.

H.M.S. Collingwood, August 6th, 1844.

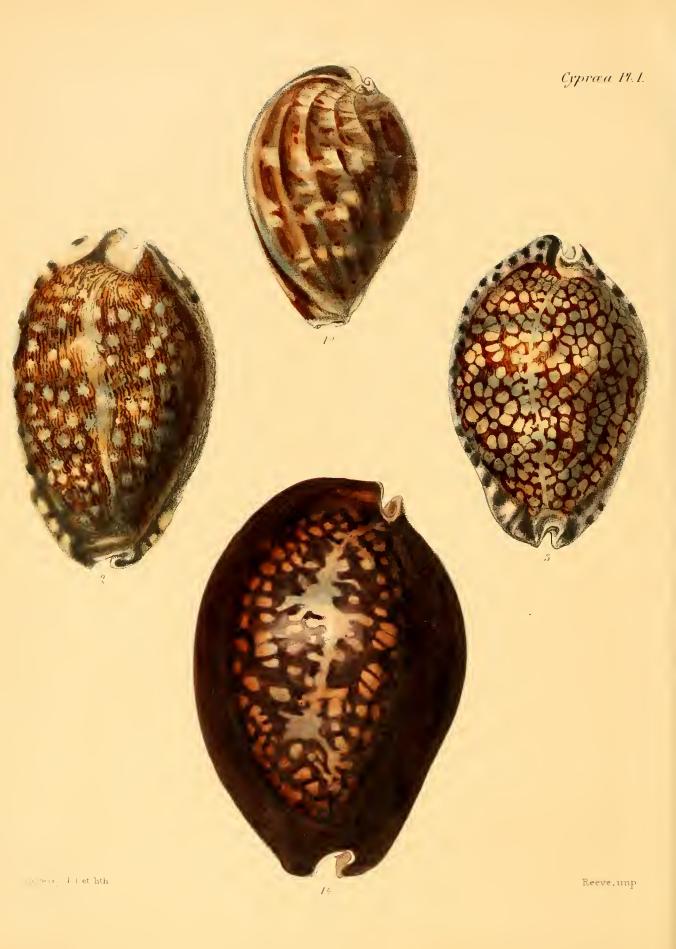

Will you allow me to offer you a few remarks on the habits of the Cypræa as regards the fact of its making a new shell, at an advanced age, of which process I have been myself in more than one instance an eye-witness. I have seen the Cowry crawl into some hollow or sheltered place, evidently for some predetermined purpose. The growth of the animal appears to increase too large for its cell; it gradually swells and cracks the shell, and I think that some powerful solvent or decomposing fluid is distributed over the outer surface by the mantle of the fish, for it gets thinner in substance, and the colours duller in appearance. The shell then entirely disappears, the Cowry becomes, to all appearance a naked mollusk, with no other covering than its membranous mantle, and in a short time secretes a thin layer of glutinous matter which in a few days obtains the fragile consistency of shell-lac. From this step its growth is more rapid, and it becomes more and more consolidated into the adult shell. When in the first stage of renewal it has the appearance of shell-lae it is always of the Cymba form, but I have never succeeded in preserving any specimens in this state on account of their extreme fragility.

Trusting that you may make some use of these notes, and that (as I have a good dredge with me) I may, like Mr. Cuming, succeed in hringing home something worthy of notice, I shall conclude myself, my dear sir,

Yours very truly,

JOHN B. HANKEY.

are perfectly unique; it seems curious that Nature should not have exercised her accustomed prodigality in the perpetuation of these species, for instead of being the solitary living witnesses of an extinct period of the world's history whose fauna only remains to us in a fossil state, they are a new creation, framed with an exuberance of character quite unapproached by any other species. They are both in the finest possible condition, and may certainly be regarded as the most valuable shells yet discovered. The next in value are the *C. Broderipii* and *guttata*; of the former, three specimens are known, two of which are in this country; of the latter, five, of which we possess four. Of distinguished rarities of smaller size may be mentioned *C. Cumingii*, *Sauliæ*, *xanthodon*, *similis*, *contaminata* and *teres*, all in our collections.

There is little to be said on the geographical distribution of the Cowries except that they are strictly tropical. Only one or two very small grooved species are found on our own coast, and none larger than the *C. lurida* in the Mediterranean. The *C. Scottii* may be quoted as a fine example of the New Holland region, and the *C. aurora*, which is now a shell of frequent occurrence, of the Pacific. The *C. pantherina* is brought in extraordinary abundance from the Red Sea, but the great portion of the species are from Mauritius, Ceylon, and other parts of the castern world.

The genus Cypræa has been so fully and ably investigated hy Mr. Gray and Mr. Sowerhy, that scarcely a species is to be found which has not already been described and figured; I have only, therefore, in the absence of any novelty in kind, to contribute such observations as may appear to be worthy of recording.

Species 1. (Fig. a Mus. Saul. and b. Mus. Cuming.)

Cypr. testá subovatá, crassissimá, dorso gibboso-elevato, lateribus angulatis, basi concavo-planulatá, aperturá valdè sinuosá, dentibus prominulis; basi lateribusque nigricante-fuscis, dorso fulvo-fusco, subfasciato, reticulá irregulari nigricante-fuscá supertecto, columellá albicante.

The Mauritius Cowry. Shell snboyate, very thick, back elevated into a kind of hump, sides angulated, base concavely flattened, aperture very sinuous, teeth rather prominent; hase and sides blackish brown, back light fulvous brown, obscurely banded, covered over with a reticulated coating of blackish-brown, columella whitish.

Testa junior. (Fig. a.)

Fulvo-fusca, maculis luteis flammeolis triangularibus promiscuè aut subirregulariter trifasciatim ornatá. Fulvous brown, ornamented with triangular yellowish flame-like spots arranged either promiseuously or in three irregular bands.

Testa juvenis.

Fulva, fusco fusciatim undata.
Yellow, with bands of waved brown.
Linnæus. Syst. Nat. (12th edit.) p. 1176.
Hab. Island of Mauritius, Ceylon, &c.

The form of this shell is chiefly distinguished by the hump-like elevation of the back, and concavity of the base. Its primitive colouring in the Bulla form is a pale yellow, over which the fulvous brown spreads in bands of waves; in an intermediate state the waves become agglomerated, and leave the yellow in triangular flame-like spots; and when the teeth are fully developed, the sides become thickened with a rich dark blackish-brown coating which is thinly spread over the dorsal surface, opening into irregular reticulations just as if its flow had been disturbed by the intermixture of some oily liquid.

Such a variation of colour as is exhibited in this shell at different stages of growth, has naturally given rise to many errors among early writers which it is scarcely necessary to enumerate. Gmelin describes it in its earliest state as a Bulla, (Bulla cypræa,) and in its intermediate state as a species (Cypræa trifasciata,) distinct from the adult. Chemnitz figured a fine example of the middle stage of growth, such as I have represented at fig. a, as "The Queen of Cowries" (Cypræarum regina,) and other names have been introduced of which no notice need be taken.

The Cypræa Mauriliana must be a mollusk of great muscular power, for its shell is truly the heaviest and most solid of the series; the enamel round the sides is deposited with remarkable thickness, and its appearance altogether indicates a considerable degree of energy in the testaceous properties of its inhabitant.

Species 2. (Mus. Saul.)

CYPRÆA ARABICA. Cypr. testå oblongo-ovatå, basi subplanulatå, lateribus plus minusve incrassatis; dorso
livido-fusco indistinctè fasciato, lineis brevibus hieroglyphicis hic illic interruptis, vacuis orbicularibus formantibus, longitudinaliter ornato; basi albicante, plus
minusve rubido-fusco tinctå, lateribus maculis fusco-nigricantibus promiscuè pictis; dentibus rubido-fuscis,
extremitatibus nigricantibus.

The Arabic Cowry. Shell oblong-ovate, base rather flattened, sides more or less thickened; back livid-brown, indistinctly banded, longitudinally ornamented with short hieroglyphical lines, interrupted here and there so as to form round vacant areas, base whitish; more or less tinged with reddish brown, sides promiscuously painted with brownish black spots, teeth reddish brown, extremities blackish.

Testa junior.

Livido-cærulescens, fusco undato-fasciata. Livid-blue, banded with brown waves. Variety Cypræa eglantina Duclos. LINNÆUS, Syst. Nat. (12th edit.) p. 1173. Hab. Eastern Seas.

The Cypræa Arabica is well distinguished by the lines of hieroglyphical character which cross the dorsal surface from one extremity to the other, leaving a greater or less number of circular vacancies showing the under coating; the sides are ornamented with a number of promiscuous blackish spots, some of which are often partially obscured by the overflowing of the brown-tinged milky enamel of the base.

The young of this species appears to have been described by Linnæus in different states under the names of *Cyprææ fragilis* and *amethystea*; and an oblong livid-green variety in which the Arabic lines are fine and rather close-set has been named by Duclos *Cypræa eglantina*.

Species 3. (Mus. Cuming.)

Cypr. A reticulata. Cypr. testá ovatá, lateribus dorsoque gibbosis, lateribus valdè incrassatis; dorso lividocærulescente, fuscescente obscurè fasciato, reticulá consummatá fuscá undique picto; basi lacteá, maculis purpureo-nigricantibus promiscuè et creberrimè pictá; dentibus nigricante-fuscis.

The reticulated Cowry. Shell ovate, sides and back gibbous, sides very much thickened; back livid-blue, obscurely banded with very pale brown, and painted throughout with elaborate net-work; base milky white, promiscuously and very closely painted with purple-black spots; teeth blackish brown.

Martyn, Universal Conchology, pl. 15.

Martyn, Universal Conchology, pl. 15. Cypræa histrio, Gmelin, Lamarck. Cypræa arlequina, Chemnitz.

Cypræa Arabica var., Gray.

Hab. Eastern Seas.

I quite agree with Lamarck in the propriety of distinguishing this shell from the Cyprea Arabica; it is true they run very closely into each other, but we must judge of their typical difference. The Cypraa Arabica is of an obloug form, marked with lines of hieroglyphical character running from one extremity to the other, but interrupted in such a manner here and there as to leave an irregular display of vacancies showing the under layer of colouring matter. In the Cypraea reticulata the under layer of colouring matter is much more exposed, the dorsal surface having merely a fine net-work thrown over it, the vacancies in which are clear and definite. This peculiarity of pattern in the Cownies has not been correctly represented by the term "spots"; it is only a deposite of colouring matter such as characterizes the Cypræa tigris, and the sides of these shells, that can be termed spots. These spot-like appearances are merely that visible portion of the under layer of colouring matter which the light fabric of the adult does not affect.

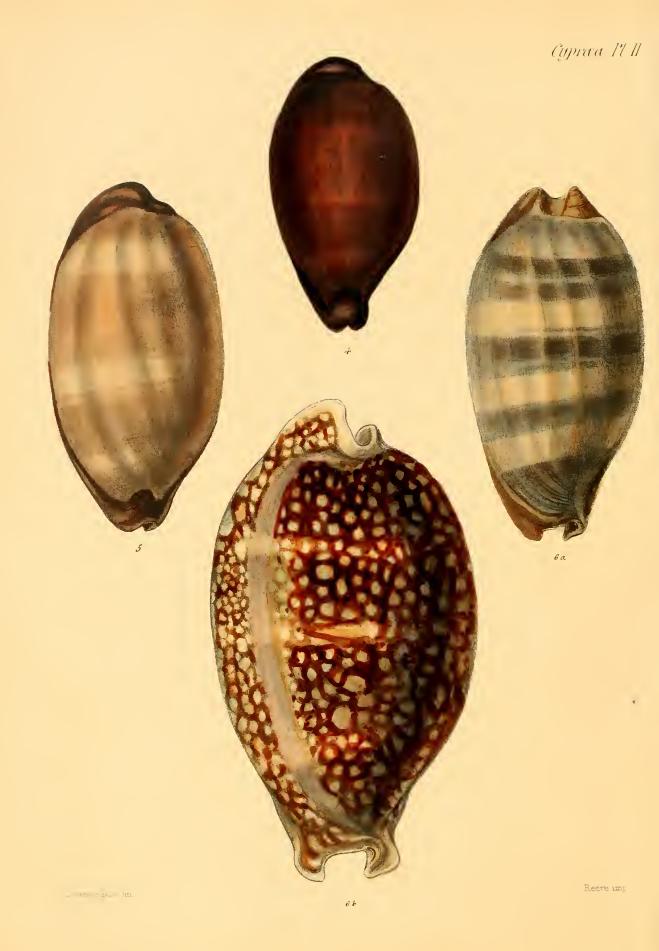

PLATE II.

Species 4. (Mus. Saul.)

Cypr. Exusta. Cypr. testá pyriformi-ovatá, anticè contractá, basi lateribusque rotundis, aperturá subsinuosá, extremitate posticá productá; dentibus subtilibus numerosis brevibus, interioribus plus minusve tritis; columeltæ parte interná cum concavitate anticá lævigatis; dorso exusto-fusco, obscurè fasciato, interdum flavescente, extremitatibus lateribus basique piceo-nigris, dentum interstitiis albidis, columeltæ parte anticá albidá,

The scorched Cowry. Shell pyriformly ovate, contracted anteriorly, base and sides rounded, aperture subsinuous, posterior extremity produced; teeth fine, numerous, short, inner teeth more or less worn, internal portion of the columella, together with the anterior coneavity, smooth, back dark burnt brown, obscurely banded, sometimes yellowish, extremities sides and base pitch-black, interstices between the teeth whitish, anterior portion of the columella whitish.

Sowerby, Conch. Illus. Cat. Cypræadæ, No. 25. f. 2 *.

Cypræa talpa exusta, Gray.

Hab. Red Sea.

Although the differences between the Cyprææ tałpa and exusta are of so nice a character, they are nevertheless uniform and constant. The distinguishing features of the C. exusta consist in its rounded pyriform shape, peculiarly pinched, as it were, at the anterior end, with the posterior extremity more than usually produced under similar influence. The teeth are fine and merely marginal in the outer lip whilst in the anterior concavity of the columella, which is destitute of any colouring matter, and on the inner portion, they are completely absorbed or abraded. Another peculiarity in this species is that the dorsal smface is usually of a rich dark burnt brown colour.

The Cypræa exusta first made its appearance among a large importation of Cypræa pantherina. Some merchants of Alexandria traded to some considerable extent, a few years since, in the Panther Cowry of the Red Sea; a number of cases were sent to this country, containing from three to four hundred pounds weight of them, and they were publicly sold in the produce market. Amongst these a few of the Cyprææ exusta and pulchra were found, but none of the Cypræa talpa.

Species 5. (Mus. Saul.)

Cypr. talpa. Cypr. testá cylindraceo-ovatá, oblongá, lateribus angulato-rotundatis, basi subdepressá; dentibus parvis, numerosis, interioribus columellam subobliquè et irregulariter transcurrentibus; dorso flavescente, obscurè bi-trifasciato, extremitatibus lateribus basique exusto-vel nigricante-fuscis, dentum interstitiis albidis.

THE MOLE COWRY. Shell cylindrically ovate, oblong, sides angularly rounded, base rather depressed; teeth running somewhat obliquely and irregularly across the columella; dorsal surface pale yellow, obscurely two or three-banded, extremities sides and base dark burnt or blackish brown, interstices between the teeth whitish.

LINNEUS, Syst. Nat. (12th edit.) p. 1174. Hab. Eastern Seas.

This species will be found upon comparison to differ materially from the preceding in form. The Cypræa exusta is of a rounded pyriform shape, contracted towards the anterior extremity; the Cypræa talpa is of an oblong cylindrical form with the base just sufficiently flattened to give a slight angular character to the sides. The outer teeth are not worn away, but very neatly developed across the entire surface of the columella; the spire of the Cypræa talpa is less concealed by the superposition of the basal coat of enamel; the enamelling is altogether lighter, and there are many appearances in the shell which seem to indicate that the calcifying properties of its inhabitant are of a less energetic character than those of the Cypræa exusta.

It may be as well perhaps to notice that in the young of this species, the shell is entirely yellow, with obscure brown-tinged bands; the rich basal coating of dark enamel is the last deposit in its formation.

Species 6. (Fig, a and b Mus. Cuming.)

Cypr. Lestá oblongo-ovatá, tenuiculá, ventricosá, aperturá latinsculá, auticè patentiore, extremitatibus anticis peculiariter plano-productis; fulvo-fusca, maculis parviusculis numerosis, rarò ocellatis, ornatá; dentibus nigricante-fuscis, internis confertis, subirregularibus; intus violaceá.

THE STAG COWRY. Shell oblong-ovate, rather thin, ven-

tricose, aperture rather wide, more open anteriorly, anterior extremities peculiarly flatly produced; fulvous brown, ornamented with uumerous rather small white spots, rarely ocellated; teeth blackish brown, the inner close-set and rather irregular; interior violet.

Testa junior. (Fig. 6. a.)

Testa junior fasciis quaternis latiusculis cæruleo-plumbeis transversim radiata.

Younger shell transversely radiated with four rather broad blueish lead-coloured bands.

LINNÆUS Mautissa, p. 548.

Cypræa cervina, Lamarck.

Cyprææ cervina and cervinetta Kiener, Doshayes.

Hab. Pacific Islands (under stones); Cuming.

This species is, as Chemnitz truly calls it, the "Cypræarum maxima", peculiarly distinguished from its congener

the Cypræa exanthema by a light inflated growth, smaller inocellated spots, and wider separation of the lip and columella anteriorly; it has, however, a diminutive variety as the name cervinetta, adopted by Kiener and Deshayes implies. In this the colours are of a deeper hue, the bands of the younger shell are of a leaden blue colour and the basal coating of enamel in the adult is of a rich dark brown.

The Cypraa cervus and exanthema were frequently confounded together by early writers; Gmelin and Schreiber have even made four species of the different phases which they exhibit at different periods of growth,—Cypr. plumbea, dubia, bifasciata and oculata. These synonymes are, however, best left in obscurity; in the present state of our knowledge, with the means of figuring examples of all the different stages of growth in the finest possible condition, any errors that may have arisen from a less perfect state of things, once exposed, had better remain unrecorded.

PLATE III.

Species 7. (Mus. Saul.)

Cypr. Está subpyriformi-ovatá, ventricosiusculá, extremitatibus subattenuatis, aperturá anticè paululum hiante, dentibus parviusculis, præcipuè columellaribus; albidá, flavo rufove inquinatá, dorso guttis nigricante-fuscis, interdum cæruleo-nebulatis aut intensè castaneis, profusè picto, tineá dorsali ferrugineo-rufá, lateribus sæpè rufo aut violaceo tinctis.

THE PANTHER COWRY. Shell somewhat pyriformly ovate, rather ventricose, extremities slightly attenuated, aperture a littly gaping at the anterior end, teeth rather small, especially the columellar; whitish, besmeared with red and yellow, back profusely painted with intensely chesnut or blackish-brown spots, sometimes clouded with blue, dorsal line rusty red, sides often tinged with red or violet.

Testa junior.

Testa junior cinereo-viridescens, fulvo rufoque nebulata. Younger shell ashy green, mottled with red and yellow. SOLANDER, Dillwyn, Cat. of Shells, v. 1. p. 449.

Cyprææ guttata and tigrina, Lamarck.

Monstrosity. Cypræa umbilicata, Sowerby. Hab. Red Sea.

This shell, which has been received in extraordinary abundance from the Red Sea, varies in colour from a pale sickly white to a very deep chesnut red, profusely adorned with small blackish-brown spots clouded with blue.

The shell, described and figured by Mr. Sowerby in the Tankerville Catalogue, under the name of *Cypræa umbilicata*, has been subsequently acknowledged a monstrosity.

The name tigrina, given to this species by Lamarck, would certainly have been adopted had it not been previously used, though erroneously, by Gmelin. The names given to shells by Dr. Solander are of no authority unless adopted and printed by any subsequent naturalist; although they appear in a manuscript to which all the world may have access, yet, they have never been strictly published.

Species 8. (Mus. Said.)

Cypr. EA Argus. Cypr. testá ovato-oblongá, subcylindraceá, medio teviter contractá, aperturá subangustá, dentibus mediocris, numerosis; lacteo-fuscescente, dorso trifasciato, fusciis latis, diametrorum variorum annulis deformibus fulvo-fuscescentibus, plus minusve numerosis, quorum nonnullis impletis, promiscuè picto, basi maculis quaternis nigricante-castaneis ornată, quarum duabus columellaribus multò majoribus; dentibus fusco-marginatis.

The Argus Cowry. Shell ovately oblong, somewhat cylindrical, slightly contracted in the middle, aperture rather narrow, teeth middling, numerous; pale milky brown, back three-banded, bands broad, promiscuously painted with a greater or less number of misshapen fulvous brown rings of different diameters, some of which are filled in, base ornamented with four large blackish chesnut spots, two on each side the aperture, of which the columellar are much the larger; teeth edged with brown.

Testa juvenis.

Testa juvenis fulvescente-fusca, fasciis plurimis angustis, maculis castaneis perpaucis irregularibus interruptis, cingulata.

Young shell pale fulvous brown, encircled with several narrow bands, interrupted with a very few irregular chesnut blotches.

LINN.EUS, Syst. Nat. (12th edit.) p. 1173.

Hab. Ceylon, &c.

It is difficult to conceive from what peculiar modification of the mautle, this shell receives its curious deposite of rings. They are of very irregular size, and much more numerous in some specimens than in others, one here and there being filled up with colour. I have two or three very young examples of this species in the Bulla form collected by Mr. Cuming, but never remember to have seen' it in the stage of growth, before the rings are diffused.

The Cypræa Argus is well named after the hundred-eyed Arestorides, although its imaginary eyes vary in different specimens from one to at least five hundred in number.

Species 9. (Fig. a. Mus. Saul, Fig. b. Mus. Cuming.)

Cypr.ex testudinaria. Cypr. testá elongato-ovatá, subcylindraceá, crassá, extremitatem versus utrinque declivibus, aperturá angustá, dentibus parviusculis, numerosis; lacteo-fuscescente, dorso fulvo castaneoque nebulato et maculato, punctulis albis furfuraceis profusè adsperso, basi incarnato-fuscá. THE TORTOISE-SHELL COWRY. Shell elongately ovate, somewhat cylindrical, thick, inclining steeply down each side towards the extremity, aperture narrow, teeth rather small, numerous; milky brown, back clouded and spotted with fulvous and chesnut brown, and profusely sprinkled with minute white scurf-like dots, base desh-tinged brown.

Testa junior.

Testa junior lacteo-fusca uniusmodi obscurè fasciata, fusciis circa columellam maculis castaneis irregutaribus interruptis.

Young shell uniform pale milky brown, obscurely banded, bands interrupted about the columella with irregular chesnut blotches.

LINNÆUS, Syst. Nat. (12th edit.) p. 1173. *Hab.* Mauritius.

This is certainly a most characteristic species, unlike any other of the genus both in form and colouring, which latter, as its name implies, is of a rich tortoise-shell pattern. The chief peculiarity of the shell consists in its being sprinkled with a fine scurf of promiseuous white speeks, which may be observed to be imbedded at different depths in the enamel; and it is only in the last coating of enamel that this scurf occurs.

In the young shell there are several bands of interrupted chesnut-brown blotches, very irregular in size, and more or less obscure in appearance; they begin to change as the second stage of growth is proceeding, and entirely disappears during the progress of the third.

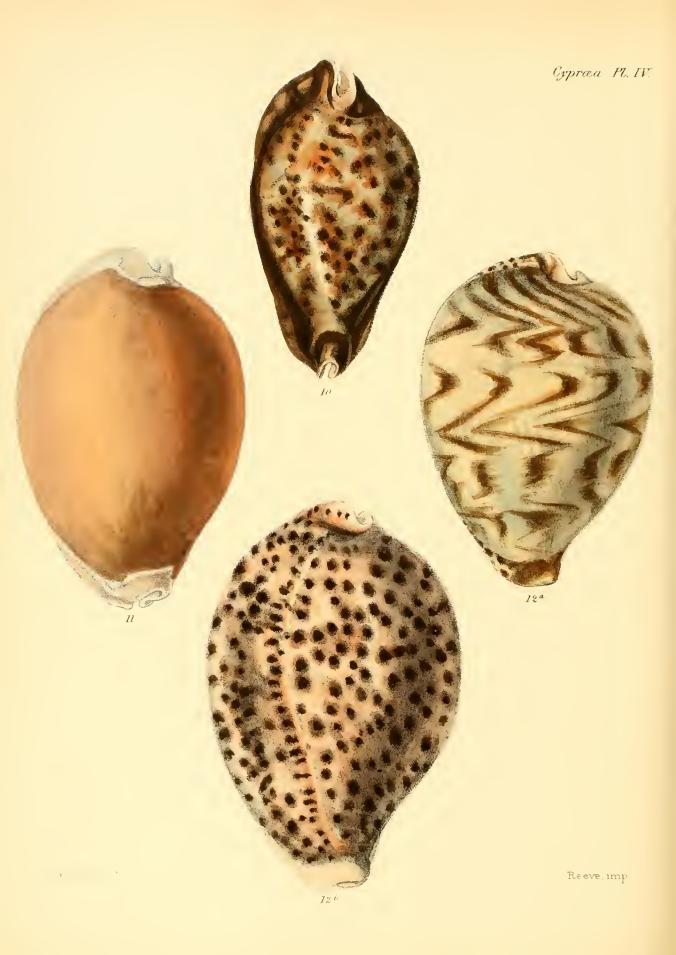

PLATE IV.

Species 10. (Mus. Saul.)

Cypr. As Scottii. Cypr. testá oblongo-naviformi, extremitatibus contractis et erecto-recurvis, aperturá angustá, sinuatá, dentibus parxis, numerosis, interioribus plus minusre obsoletis, exterioribus, quorum nonnullis medianis bipartitis, brevibus; dorso cinereo-cærulescente, flavescente-fusco promiscuè maculato et nebulato, basi lateribusque piceo-fuscis.

Scott's Cowry. Shell oblong-boat-shaped, extremities contracted and erectly recurved, aperture narrow, sinuated, teeth small, numerous, the inner more or less obsolete, the outer, some of the middle of which are bipartite, short; back pale ashy blue, promiscuously blotched and clouded with yellowish brown, base and sides dark pitchy brown.

Variety β.

Testa brevior, dorso gibboso-elevato, maculis omninò nebulatis; dentibus exterioribus basem super transcurrentibus.

Shell shorter, back gibbously elevated, with the spots wholly clouded into each other; outer teeth running across the base.

Testa junior.

Testa junior cæruleo-lactea, obscurè fasciata, maculis flavescente-fuscis hic illic ornata, columellæ basi albicaute.

Younger shell blueish milky colour, obscurely banded, ornamented here and there with pale yellowish-brown blotches; base of the columella whitish.

Testa juvenis.

Testa juvenis uniusmodi lacteo-aurantia, columella basi nivea.
Young shell uniform milky orange colour, base of the columella snowy white.

Broderip, Zool. Journal, vol. v. p. 330. pl. 14. f. 1. and 2.

Cypræa Friendii, Gray.

Hab. Swan River, New Holland. Variety β . Port Lincoln, New Holland.

This very striking species was introduced about fourteen years since, by Mr. Broderip, in the Zoological Journal, from two eroded specimens, brought by the Rev. Archdeacon Scott, from Angia, in the Island of Java. Since then, several examples in the finest possible condition have been received from Swan River, New Holland, with a very

eharacteristic variety from Port Lincoln of the same contitinent; and I am now enabled to give an amended description of it in different states of growth. The shell in its first Bulla, or rather Cymba, form, is of an uniform pure clear milky orange colour, it then assumes a blueish tinge disposed in obscure bands, and begins to show a few bright tortoise-shell brown blotches, which rapidly accumulate, as exhibited in the adult, long before there is any indication of teeth. This is an arrangement different to that of most Cowries, in which the teeth are chiefly developed before the last layer of colouring matter is deposited. The sides and base then become thickened with an extremely rich pitchy brown coating of enamel, and the extremities compressed and turned upwards.

The variety from Port Lincoln differs most conspicuously both in form and colour; it is much shorter, the back is swollen and elevated almost into a hump, the extremities are blunted, and the outer teeth, which in the Swan River variety are scarcely more than marginal, extend across the base, especially the anterior portion, in grooved prominent ridges. The inner teeth of this species are very obscure; indeed, the columella is mostly edentulate.

The young of this species and several others will be figured together at the close of the monograph.

Species 11. (Mus. Cuming.)

Cypr. testå oblongo-ovatå, ventricoså, immaculatå, dorso dentibus interstitiisque vividè aurantiis, basi lateribus et extremitatibus lacteis.

THE ORANGE COWRY. Shell oblong-ovate, ventricose, unspotted, back, teeth, and interstices bright orange, base, sides, and extremities milk-white.

Testa junior.

Testa junior columellá vivide aurantiá.

Younger shell with the columella bright orange.

Martyn, Universal Conchology, vol. 2. f. 59.

L'Orange, Favanne.

Cypræa aurora, Solander, MSS. Chemnitz.

Hab, Taheite, Pacific Islands.

The history of this rare and beautiful species has been so often described, that it only remains to call attention to an interesting example in the British Museum, not quite arrived at maturity, in which the columella is of the same rich orange as the back, prior to the layer of white enamel being deposited.

Species 12. Fig. a. and b. (Mus. Cuming.)

Cypr. Ea tigris. Cypr. testá ovatá, ventricosá, basi planoconcavá, dentibus majusculis; dorso albido ant flavescente, guttis nigricantibus majusculis, cæruleo nebulatis, promiscuè picto, basi niveá, immaculatá.

The tiger Cowry. Shell ovate, ventrieose, base flatly coneave, teeth rather large; back whitish or yellowish, promiscuously painted with rather large blackish blue-clouded spots; base snowy white, unspotted.

Testa junior.

Testa junior albida, flanmis ferrugineis undatis subdistantibus ornata.

Younger shell whitish, ornamented with rather distant zigzag rusty brown flames.

Testa juvenis.

Testa juvenis uniusmodi castanea, albido-flavicante interdum interrupta et fasciata.

Young shell uniform chesnut, sometimes interrupted and banded with pale yellow.

LINNÆUS, Syst. Nat. (12th edit.) p. 1176.

Hab. Eastern Scas.

Testa junior, Cypræa flammea, Gmelin.

The progress of this shell exhibits a curious variety in the style of colouring:—first, it is a uniform chesnut bay, the colour then breaks up, as it were, into bands of closeset waved blotches of a richer line, a coating of white is then superimposed, and upon that is deposited a series of rather distant zigzag flames, such as are represented at fig. a. The rich colouring of the first state is now, therefore, concealed, and nothing is seen but a few zigzag

flames upon a white ground; the teeth are forming in the mean time, and a few spots of colour make their appearance round the outer side. In the next state of the shell, a second layer of white enamel is superimposed, a thinner and more delicate stratum than the preceding, through which the zigzag flames may be seen of a milky huc; and, upon this surface a number of dark spots are deposited. These are again overspread by a third white coating, intermixed with numerous rich black and brown spots, showing, for the first time, a narrow dorsal hiatus, mostly edged with reddish brown with the first deposite of dark spots, thus overspread, of a blueish milky bue.

I cannot resist inserting the following interesting observations on the habits of this species by Mr. Broderip. "Mr. Samuel Stutehbury, who had an opportunity of examining many individuals of C. tigris at the Pearl Islands, informed me that these cowries lived there in very shallow water, and always under rolled masses of Madrepore. They never were to be seen exposed to the sun's On lifting one of these masses, a Tiger Cowry was generally observed with its shell entirely covered by the large mantle which was mottled with dark colours, the intensity of which the animal seemed to have the power of ehanging; for the colour varied in the same light and in the same medium, after the manner of the spots on the Cephalopodous Mollusca, or, to use a more familiar instance, somewhat in the same way that the hues of a turkey-cock's wattle vary. On touching the mantle, it was immediately withdrawn within the shell, which became exposed in all its brilliancy. So firmly did the soft parts adhere to the shell, that, in no instance, (and the experiment was often made) did Mr. Stutchbury succeed in extracting them by force, either during life, or before decomposition took place. He was obliged to let the animal die, and suffer the soft parts to decay, in order to remove them."—Zool. Journal, vol. iv. p. 163.

PLATE V.

Species 13. (Mus. Cuming.)

Cypr. está ovatá, ventricosá, crassiuscula, dentibus numerosis, conspicuis, cotumellaribus longiuscutis, regularibus; dorso roseo et flavido-albicante obscurè fasciato, reticulá irregulari aurantio-fuscescente maculisque niveis latera versus ornato, lateribus et extremitatibus fuscescentibus, basi fuscescente, roseo-aurantio tinctá; dentibus albidis.

BRODERIP'S COWRY. Shell ovate, ventricose, rather thick, teeth numerous, rather long and regular; back obseurely banded with yellowish white and rose-pink, and ornamented with a pale orange-brown net-work, with snow-white spots towards the sides, sides and extremities drab-brown, base of the same colour tinged with a warm glow of rose-orange; teeth white.

GRAY, Descriptive Catalogue (inedit).

Sowerby, Conchological Illustrations, Cat. Cypræadæ, no. 20. f. 2.

Hab. Island of Madagascar (found on the reefs); Rev. W. V. Hennah.

Of this beautiful and very characteristic species only three specimens have yet been discovered, two, now before me, from the collections of Mr. Cuming and Miss Saul, and one in some private collection, I believe, in the United States. Although it partakes in some measure, of the characters of the Cypraa vitellus and nivosa, it is perfectly distinguished from both by its fine columellar teeth, delicate rose-pink and rose-orange colouring, and superincumbent deposite of brown net-work. As in most highly enamelled Cowries the base is radiated with fine hair-like scratches.

It is a beautiful species, and honours the name of a gentleman highly estcemed in the conchological world, and to whose princely zeal our national collection is indebted for the great treasures of the genus.

Species 14. (Mus. Saul.)

Cypr. Está ovatá, ventricosá, crassá, anticè teviter attenuatá, dentibus fortiusculis, dorso futvo-spadiceo, guttis niveis variæ magnitudinis adsperso, lateribus olivaceo-fuscis, arenaceis, striatis; basi, extremitatibus, dentibus, interstitiisque roseo-albicantibus, THE LITTLE CALF COWRY. Shell ovate, ventricose, thick, anteriorly slightly attenuated, teeth rather strong, back fulvous bay colour, sprinkled with snowwhite spots of various sizes, sides olive-brown, arenaceous, striated; base, extremities, teeth, and the interstices between them pinkish white.

Testa junior.

Testa junior otivaceo-cinerea, obscurè fasciata, immaculata. Younger shell olive-ash colour, obscurely handed, unspotted. LINNÆUS, Syst. Nat. (12th edit.) p. 1176. Hab. Eastern Seas.

This species is strongly characterized by the curious sand-like striæ with which the sides are colonred, and the miniature firmament of spots, of different degrees of magnitude, which adorn the whole of the dorsal surface.

Whether Linnaus named this shell from vitellus, a little calf, or vitellus, the yolk of an egg, I am unable to determine, for it resembles one as much as the other.

Species 15. (Mus. Cuming.)

Cypræa stercoraria. Cypr. testá ovatá, subventricosá, anticè contractà, tateribus angulatis, basi concavo-depressa, apertura sinuosa, anticè hiante, columellæ concavitate antica ampla, profunda; undique livido-olivaceá, dorso castaneo-fusco maculato et nebulato; dentibus albidis.

THE SOILED COWRY. Shell ovate, rather ventricose, contracted anteriorly, sides angulated, base concavely depressed, aperture sinuous, gaping anteriorly, anterior concavity of the columella large, deep; livid olive colour throughout, back spotted and clouded with chesnut brown, teeth whitish.

Testa junior.

Testa junior cinereo-fusca, fasciis olivaceo-fuscis quinis senisve picta, immaculata.

Younger shell ashy brown, painted with five or six olive brown bands, unspotted.

LINNÆUS, Syst. Nat. (12th edit.) p. 1176.

Cyprææ stercoraria and rattus, Lamarck.

Cyprææ olivacea, gibba, and conspurcata, Gmelin.

Testa antiquata, Cypræa cauteriata, Chemnitz.

Testa junior, Cypræa fasciata, Chemnitz.

Hab. Persian Gulf; coast of Africa.

The sinuous character of the aperture, and the anterior concavity of the columella are curiously exaggerated in this species; its uniform olivaceous east of colour is also peculiar. The younger shell has a kind of hump-like elevation on the back, and is of an ashy or greyish brown with five olive bands upon, and auterior to, the dorsal elevation, and one of more indistinct character round the spire.

Species 16. (Mus. Saul.)

Cypr. testá elongato-ovatá, crassiusculá, extremitatibus subtruncatis, dorso fulvo-fusco, maculis albidis rotundis, quarum nonnullis, præcipuè ad latera, ocellatis, ornato; basi pallidè fulvá, dentibus castaneo-fuscis. The Measled Cowry. Shell elongately ovate, rather thick, extremities slightly truncated, back fulvous brown, ornamented with round white spots, some of which, especially at the sides, are occllated, base pale fulvous, teeth chesnut brown.

Testa junior.

Testa junior fasciis cœruleo-plumbeis ornata. Younger shell ornamented with blueish lead colour. Linnæus, Syst. Nat. (12th cdit.) p. 1172. Testa junior, Cypræa zebra, Linuæus.

Hab. West Indies; on the reefs.

The chief peculiarities of distinction between this and the *Cypræa cervus*, are its more elongated form, solid and heavier growth, more contracted aperture and, ocellated character of the spots.

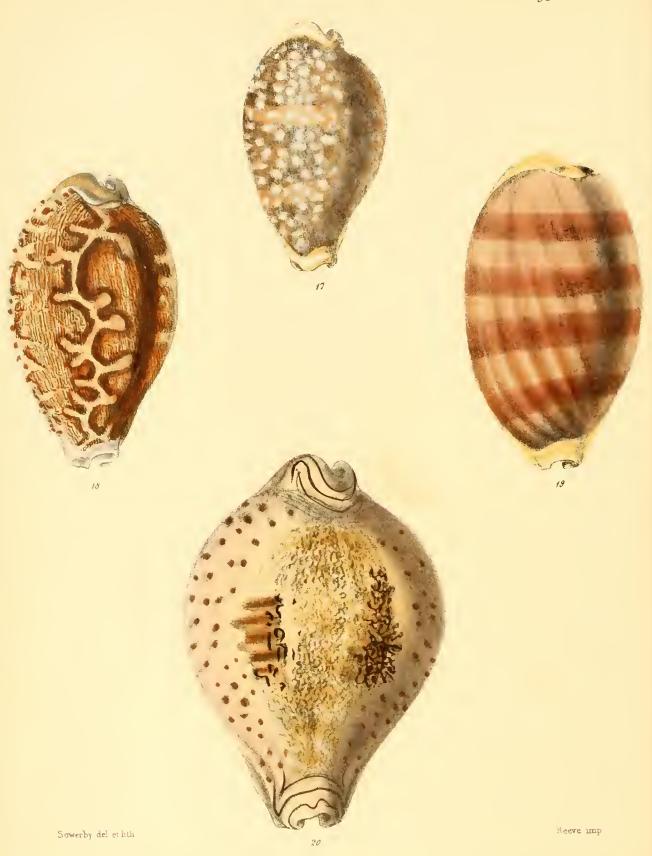

PLATE VI.

Species 17. (Mus. Cuming.)

CYPRÆA MELANOSTOMA. Cypr. testå oblongo-ovatå, extremitatibus prominentibus, utrinque subfoveolatis; dorso cæruleo-aut cinereo-fusciato, floccis niveis elevatinsculis adsperso, extremitatibus basique lacteis, dentum columellarium interstitiis purpureo-nigricantibus.

THE BLACK-MOUTH COWRY. Shell oblong-ovate, extremities prominent, indented on both sides; back blueish or ashy brown, very faintly banded, sprinkled with slightly elevated snow-like flakes, base and extremities milk-white, interstices of the columellar teeth purple-black.

Leathes, MSS. Sowerby, Tankerville Cat. App. p. xxxi. and Zool. Journal, vol. 2. p. 495. pl. 18. f. 3. and 4. *Cypræacameleopardalis*, Gray; (Perry haudreeognitus). *Hab.* Red Sea.

It is not easy to conceive any two shells with such an apparent resemblance as the Cyprææ melanostoma, and vitellus, eapable of differing more essentially on examination. In the former, the extremities are prominently up-turned, the white flakes are of a blueish enamel-like tinge and slightly raised, the interstices between the columellar teeth stained with purple-black, and there is no indication of those peculiar lateral sand-lines which constitute so striking a peculiarity in the latter. The younger shell of the C. melanostoma differs from the adult in being unspotted, in the base and extremities not being thickened, and in the absence of the purple-black colouring of the columellar grooves.

Since Mr. Sowerby described this species in the Tankerville Catalogue, under Mr. Leathes' manuscript name of Cypræa melanostoma, it has been published by one or two authors under that of Cyprae cameleopardalis, from its having been thus originally named by one Mr. Perry; the writings of this person have, however, been eensured a mass of buffoonery wholly unworthy of credit. So much has been already said on this subject by Mr. Sowerby, (Zoological Journal vol. iv. p. 218.) that it only remains to state how fully I concur in the opinion there recorded. If every charlatan who sets himself up for a naturalist, with brush in one hand, and writing-tool in the other, is to be regarded as an authority on scientific matters; all the zoological sign-boards in the kingdom might be quoted as figures of reference. For my own part, I consider that the "Cameleopard of Perry" should no more enter the nomenclature of zoology, than the "Red Lion of Brentford."

Species 18. (Mus. Saul.)

Cypræa Mappa. Cypr. testá oblongo-ovatá, crassá, extremitatibus subobtusis, dectivibus, dentibus numerosis, columellaribus hic illic bifurcatis, dorso pallidè violaceofuscescente, lineis rubido-fuscis hieroglyphicis longitudinalibus confertis consummate picto; hiatu dorsali angusto, peculiariter ramoso, lateribus violaceo-fusco guttatis, basi violascente, maculá grandi violaceo-fuscá sinistrorsum ornatá; dentibus vivide crocato-rubris.

The Map Cowry. Shell oblong-ovate, thick, extremities rather obtuse, inclined downwards, teeth numerous, the columellar teeth here and there bifurcated, back violet brown, elaborately painted with close-set reddish brown lines of hieroglyphical character; dorsal opening narrow, peculiarly branched, sides dotted with violet brown, base tinged with violet, ornamented with a large violet brown blotch on the left side; teeth bright saffron-red.

Variety β .

Tesla brevior, gibbosiuscula, extremitatibus basique sanguineo-tinetis, basi immaculată, dentibus pallide incarnatis. Shell shorter, more gibbous, extremities and base bloodred tinged, base unspotted, teeth pale flesh-colour.

Testa junior.

Testa junior violaceo-fuscescens, pallidè nebulata, lineis fulvofuscescentibus hieroglyphicis ad latus sinistrorsum picta.

Younger shell elouded or mottled with pale violet brown, and painted on the left side with fulvous-brown hicroglyhical lines.

LINNÆUS, Syst. Nat. (12th edit.) p. 1173.

Hab. Island of Annaa, Pacific Ocean (found on the reefs); Cuming.

There is a peculiarity in the progressive arrangement of the colouring matter of this species which I believe has not been hitherto noticed; namely, that there are two layers of ornamental pattern, one over the other.

The ornamental character with which the dorsal surface of the Cowries is mostly painted, appears to be the last effort in the formation of the shell. The previous infusions of colour rarely exhibit anything more than a dull confusion of waves, clouds, or bands; no ornamental device appears until the shell is on the eve of maturity;—the beauty of the architecture is reserved for the final decoration of the building. In the Cypræa mappa, we have an exception to this order of arrangement; a layer of pale hieroglyphical painting, greatly resembling, except in colour, that of the Cypræa Arabica, is deposited by the animal on the left side chiefly, while yet in a very immature state of growth, and on arriving at maturity, another and richer layer is superimposed upon the former, which in most specimens may be faintly seen beneath it.

The two varieties of this species above noted are very distinct, especially in regard to colour; one has a violet base, bright saffron-red teeth, and a large dark blotch upon the left base; the other is of a warm hue with blood-red tinged base and extremities, no spot, and teeth of

faint flesh-colour. The curious ramifications of the dorsal line indicate corresponding jagged edges to the lobes of the mantle.

Species 19. (Mus. Saul.)

Cypr. testá oblongo-ovatá, crassá, extremitatibus subobtusis, dorso carneolo, fasciis quaternis quinisve saturatioribus ornato, basi lateribusque pallidè futvis, tateribus plus minusve arenaceis, dentibus interstitiisque vividè viotaceis.

The Carnellon Cowry. Shell oblong-ovate, thick, extremities rather obtuse, back pale flesh-colour, ornamented with four or five bands of a deeper flesh tint, base and sides pale fulvous, sides more or less arenaceous, teeth and interstices deep violet.

Linneus, Syst. Nat. (12th edit.) p. 1174.

Hab. Isle of Annaa, Pacific Ocean, (on the reefs); Cuming.

This species is, perhaps, more variable in size than any other of the genus; there is no change of colour on the dorsal surface throughout its entire growth, but the archaecous deposite round the sides, and the bright violet colouring of the teeth, both of which peculiarities are extremely characteristic, do not appear until the shell arrives at maturity.

Species 20. (Mus. Brit.)

CYPRÆA PRINCEPS. Cypr. testá orbiculato-ovatá, tenuiculá, ventricosissimá, dorso vatdè etevato, utrinque declivi; aperturá subangustá, sinuosá, dentibus numerosis, extremitatibus subretusis, basi plano-convexá; dorso luteolo, roseo-purpurascente, basem versus paltidiore, tincto, medio characteribus rha-coloreis undulatis profuse picto, maculá grandi saturatiore, characteribus perpaucis hieroglyphicis, utrinque nebulato; extremitatibus lineis fuscis tribus irregularibus, quarum medianâ fortissina, concentrice ornatis, extremitate postica striis concentricis plurimis fuscescentibus subtilibus supra spiræ apicem occultam; linea dorsali subcentrali, recta, tateribus guttis caruleis et fuscis ornatis, quarum nonnullis fortibus distinctis, nonnultis nebulatis indistinctis; dentibus niveis, per cotumetlam paltide rufo-fuscescentibus.

The Prince Cowry. Shell orbicularly ovate, rather thin, extremely ventricose, back considerably elevated, steep on each side, aperture rather narrow, sinuous, teeth numerous, extremities rather blunt, base flatly convex; back yellowish, tinged with rose-purple, fainter towards the base, profusely painted in the middle with waved rhubarb-colour characters, clouded on each side with a squarish spot of darker colour on

which there are a few dark hierogly phical characters; extremities concentrically adorned with three irregular brown lines, of which the middle is the strongest, the posterior extremity having several finer light brown concentric strice beyond the concealed spire; dorsal line straight, nearly central; sides ornamented with blue and brown spots of which some are strong and distinct, some clouded and indistinet; teeth snowy white, pale reddish brown across the columella.

Gray, Zoological Journal. vol. 1. p. 75.

Cypræa Valentia, Perry (haud recognitus).

Hab. Persian Gulf.

Having already spoken of the exceeding value and rarity of this remarkable shell, in my introductory observations to the genus, it only remains to add a more detailed history of its specific character.

The Cypræa princeps presents an association of character of which we find no approximation in any other species. It is of a rather light thinnish structure, swelling out on both sides with peculiar rotundity and rising in the middle to a lofty obtuse hump forming a steep incline anteriorly and posteriorly to the extremities. (I now regret not having decided upon a lateral view of this shell; as it is impossible to convey an accurate notion of this dorsal hump-like elevation by its position in the accompanying figure, which was selected in order to obtain a more correct representation of its makings than has hitherto appeared.) The general tone of colour is a pale yellow at the top, changing into a purple-pink wash at the sides, and thence into white at the base. The middle is painted with a close-set profusion of small waved rhubarb-yellow characters, with a central straight dorsal line, and a large rhomboidal dark clouded blotch on each side the dorsal acclivity, the left of which is the more diffused. Both of these blotches are painted with strong hieroglyphical marks of a very decided character. Around the extremities are three irregular concentric brown lines a little raised, or apparently so, the middle of which is the strongest; and on the posterior end of the shell are from six to seven concentric faint brown strice immediately above the three dark lines just spoken of. The teeth are rather small, numerous, and white, except on crossing the columella, where they are reddish-brown. The sides are white, marked with small scattered spots of which the uppermost are brown, partaking of the upper region of colour, and distinct, whilst those towards the base receive a blue-clouded appearance from the overflowing of the milk-white enamel of the base.

The only record we have of this shell's history is, that it was in "Old Humphrey's" collection under the name of "The Brindled Cowry of the Persian Gulf," and it remains in our national collection a curious exception to the favourite axiom of Linnæus,—"Natura non facit saltum."

owerny del et lith

Reeve imp

PLATE VII.

Species 21. (Mus. Saul.)

Cypr. Ea Spadicea. Cypr. testa ovato-oblonga, subpyriformi, antice attenuata, apertura angusta, dentibus crassiusculis, brevibus; dorso spadiceo, latera versus ustulato-fusco nebulato, guttis nigricantibus seriatim undatomarginato, lateribus rosaceo-albis, obscurissime nigroguttatis, dentibus basique albis.

The Chesnut-Bay Cowry. Shell ovately oblong, somewhat pyriform, attenuated anteriorly, aperture narrow, teeth rather thick, short; back chesnut-bay, elouded towards the sides with burnt brown, edged with a waved row of eonfused blackish spots, sides pinkish white, showing very obscure dark spots, teeth and base white.

SWAINSON, Phil. Mag. vol. lxi. p. 370. Zool. Illus. pl. 182. Hab. ——?

This species may be recognised by its peculiar burnt-brown colouring, which looks at first sight as if it had been artificially obtained by the action of acid. It is still one of great rarity, in fine condition, and I have not seen it in any other state than the adult. The dorsal area of burnt-brown clouding is edged on both sides by a row of confused blackish spots; and I am inclined to think, that during the intermediate state of growth the right side is entirely tessellated with these spots, regular in size, and neatly equidistant from each other, on a burnt-brown ground; a faint indication of this style of colouring may be seen through the white coating of the sides, which has, in consequence, a dull pinky appearance.

Species 22. (Fig. a and b. Mus. Cuming.)

Cypr. testá depresso-ovatá, crassá, basi turgidá, extremitatibus posterioribus incrassatis, sinistrá præcipuè, aperturá subangustá, columellá edentulá, labro externo anticè obsoletissimè dentato; dorso cinereo-fusco, maculá castaneá elongatá, lineá dorsali pallidá ramosá percurrente, medio picto; luteribus albidis, guttis numerosis cinereo-fuscis fulvo-nebulatis profusè aspersis, basi albá.

THE WHITE-MOUTH COWRY. Shell depressly subovate, thick, swollen at the base, posterior extremities thickened, especially the left, aperture rather narrow, columella destitute of teeth, outer lip very faintly

toothed anteriorly; ashy brown, painted along the middle with an elongated chesnut blotch, through which runs a pale branched dorsal opening; sides whitish, profusely sprinkled with ash-brown fulvous-clouded spots, base white.

GASKOIN, Pro. Zool. Soc. 1845.

Cypræa mus. var. Sowerby, Coneh. Illus. f. 157. Hab. Mocha; Sowerby.

The Cypræa leucostoma has been very properly distinguished, by Mr. Gaskoin, from the Cypræa mus, on aecount of the following peculiarities. The base is white, the columella is entirely destitute of teeth, and only the faintest indication of teeth is to be found on the outer lip. The sides are more distinctly spotted, and the dorsal line has a peculiar branched character. Out of ten or a dozen examples of this shell which I have seen within the last few days, there is not the slightest modification of any of these features into those of the Cypræa mus. I have not seen the shell in an intermediate state of growth, but the columella mostly exhibits a portion of its colouring at that age;—a close series of concentric brown festoons npon a yellowish-white ground.

Species 23. (Mus. Brit.)

Cypr. Leucodon. Cypr. testá subpyriformi-ovatá, dorso gibboso, elevato, basi convexá, aperturá posticè sinuosá, extremitatibus prominentibus, leviter recurvis, dentibus utrinque fortibus, elongatis, insterstitiis profundè sulcatis; dorso rufescente aut flavescente-fusco, guttis rotundis albidis subamplis hic illic asperso, basi pallidiore, striis subtilissimis transversè notatá; dentibus eburneis; hiatu dorsali latiusculo, ad dextrum latus approximante.

The white-tooth Cowry. Shell somewhat pyriformly ovate, back gibbous, elevated, base convex, aperture sinuous posteriorly, extremities prominent, slightly recurved, teeth strong on both sides, elongated, interstices deeply grooved; back reddish or yellowish-brown, sprinkled here and there with rather large round white spots, base paler, marked transversely with fine striæ, teeth ivory white; dorsal hiatus rather broad, approaching the right side.

BRODERIP, Zool. Journal, vol. iv. p. 163. pl. 6.

This is another species of Cowry which our national collection can alone boast of possessing. The dorsal surface, of which I have given a more characteristic view than has yet been published, is of a yellowish reddish-brown, sprinkled with rather large round white spots, clouded, two and two, one refracting upon the other, like floating particles of oil. The base is thickly crossed with fine strialike scratches, and the teeth are developed with remarkable intensity,—an exaggeration, as it were, of those of the Cypræa sulcidentata. The posterior margin of the shell exhibits on the right side a number of wart-like protuberances; and there is a pale concentric mark over each extremity.

Species 24. (Fig. a. and b. Mus. Saul.)

Cypr. A Mus. Cypr. testå ovatå, lateribus gibbosiusculis, basi plano-depresså, aperturå subsinuoså, dentibus brevissimis, columellaribus plus minusve obsoletis, medianis præcipuè, extremitate posticå dextrå prominente; dorso interdum verrucis nonnullis posticè munito, cinereo-vel olivaceo-fusco marmorato, latera versus præcipuè, hiatu dorsali pallido, marginibus rufo-fuscescentibus, guttis deformibus aterrimo-fuscis, interdum in viciniå aspersis, utrinque irregulariter pictis, maculå intenså ad extremitatem posticam, basi cinereo-fuscå, dentibus alro-fuscis, columellå ustulato-fusco tinctå.

The Mouse Cowry. Shell oval, sides rather gibbous, base rather flatly depressed, aperture a little sinnous, teeth very short, the columellar teeth more or less obsolete, especially the middle, the right posterior extremity obsolete; back sometimes firmished posteriorly with a few wart-bike protuberances, olive-brown, marbled, especially towards the side, dorsal hiatus pale, edges faint reddish brown, irregularly painted on both sides with very black-brown variously shaped spots, sometimes sprinkled in the vicinity, and an intense blotch of the same colom at the posterior end, base olive ash-brown, teeth black-brown, colnmella stained with burnt brown.

Testa junior.

Testa junior ventricosissima, paltidè cinereo-fusca, longitudinaliter peculiariter undatu, maculá atro-fuscá supra extremitatem posticam. Younger shell very ventricose, pale ash-brown, longitudinally peculiarly waved, with a black brown blotch above the posterior extremity.

LINNEUS, Syst. Nat. (12th edit.) p. 1176.

It will be seen by the foregoing description how materially this shell varies from the *Cypræa leucostoma*, which might at first sight be easily mistaken for it. The base of the *Cypræa mus* is of an olive ash-brown colour without any appearance of spots, there are always a few short teeth in the columella, and the outer teeth are very much more defined; there is also a great peculiarity in the general colouring of the shell which is distributed into waves like a rippled cloud.

Species 25. (Mns. Cnming.)

Cypræa nivosa. Cypr. testű oblongo-ovatű, crassiusculű, extremitatibus brevibus, subrecurvis, dentibus columellaribus subtilibus, dorso fulvo-fuscescente, floccis punctisque variæ magnitudinis promiscue adsperso, dentibus basique lutescente-albis, hiatu dorsali latiusculo, interdum confuse ramoso, ad latus dextrum approximante.

The snow-flecked Cowry. Shell oblong-ovate, rather thick, extremities short, a little recurved, columellar teeth fine; back pale fulvous-brown, promisenously flecked with snow spots, and specks of various size, teeth and base yellowish white, dorsal hiatus rather wide, sometimes confusedly branched, approximating to the right side.

Broderip, Zool. Journal, v. 3. p. 84. pl. 4. f. 1.

Cypræa dama, Kiener (Perry hand recognitus.)

Hab. ——?

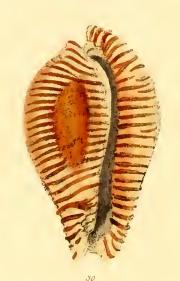

An excellent species, and admirably figured in the Zoological Journal. From Cypræa vitellus, with which it might be confounded, it differs by its more oblong form, more irregular and confused assemblage of spots and specks, and entire absence of arenaceous striæ; the columellar teeth are also longer and finer, and the colour a peculiar fulvous bay. From Cypræa melanostoma, which is also destitute of arenaceous striæ, it differs materially in form, and the spots, which in that species are raised, are of a totally different colour and character.

Cypraa Pl VIII

PLATE VIII.

Species 26. (Mns. Saul.)

Cypr. Ea Pyrum. Cypr. testâ pyriformi-ovatâ, postice umbilicatâ, extremitate postică dextră subproductă, dentibus brevibus, subexilibus; dorso fulvo-lutescente, obscure quadrifasciato, castaneo-fusco copiose marmorato, basi, extremitatibus lateribusque aurantio-rufis, dentibus pallidis, interstitiis subrosaceis, lateribus interdum castaneo-fuscis, fusco suturatiore obscure punctatis.

The Pear Cowry. Shell pyriformly ovate, posteriorly umbilicated, right posterior extremity somewhat produced, teeth short, rather faint; back fulvous yellow, obscurely four-banded, copiously marbled with rich chesnut brown; base, extremities, and sides deep orange-red, teeth pale, interstices tinged with pink, sides sometimes chesnut brown, obscurely dotted with darker brown.

Testa junior.

Testa junior lutescens, incarnato-fuscescente quadrifasciata, luteo-fusco subtilissimè marmorata, basi lucteo-aurantiâ.

Younger shell yellowish, crossed with four broad fleshbrown bands, very finely marbled with yellowish brown, base milky orange.

GMELIN, Syst. Nat. 3411.

Cypræa flavescens, Born. Cypræa rufa, Lamarek.

Hab. African shores of the Mediterranean.

This is the most northern species of *Cypræa* with such a brilliant display of colouring; the base and sides are of a deep orange-red, and the back is richly marbled with chesnut brown upon a yellowish four-banded ground. The teeth are somewhat faintly developed, and do not make their appearance until the shell is on the eve of maturity.

Species 27. (Fig. a. and b. Mus. Cuming.)

Cypr. testů orbiculari-ovatů, crassissimů, subdepressů, lateribus turgidis, aperturů angustů, extremitatibus retusis, basi convexů, dentibus minutis, numerosis, columellaribus subtilissimis elongatis, exterioribus brevibus; dorso cæruleo-cinereo, fasciis quaternis carneolo-fuscis ornato, lateribus cinereo-fuscis, supra arenaceo-striatis, basi eburneů.

THE SANDY COWRY. Shell orbicularly ovate, very thick,

somew at depressed, sides swollen, aperture narrow, extremities blunt, base convex, teeth minute, numerous, the columellar very fine and elongated, the outer short; back blueish ash-colour, ornamented with four carnelion-brown bands, sides ash-brown, arenaceously striated above, base ivory-white.

Testa junior.

Testa junior oblongo-ovata, fuscescens, fasciis quaternis carneolis cingulata.

Young shell oblong-ovate, pale brown, encircled with four carnelion bands.

Gray, Zool. Journal, vol. 1. p. 148. pl. 7. and 12. f. 6. *Hab.* 1sle of Annaa, Pacific Ocean (found on the reefs); Cuming.

The plan of colouring in this species, and the two which follow, offers an exception to the general rule:—
in the dorsal surface of the shell receiving no new ornamental distribution of colour on arriving at maturity. The calcifying energies of the mantle at an advanced stage of growth are exclusively directed, and with more than usual force, to the thickening of the sides, accompanied in the present species by a dull brown deposite of colour, throwing up a number of fine arenaceous striæ.

The banded layer of enamel in the *Cyprææ arenosa*, ventriculus, and sulcidentata, is therefore analogous to the intermediate banded layer of most Cowries, and to the dorsal hiatus, of which the *Cypræa talpa*, carneola, and pulchra exhibit still more exaggerated modifications.

Species 28. (Mus. Cuming.)

Cypr. Está ovatá, crassissimá, lateribus turgidis, subangulatis, extremitatibus retusis, busi subconcavo-depressá; dorso cæruleo aut livido-cinereo, fasciis quaternis carneolis ornato, lateribus nigricante-castaneis, supra rubidis, infra fumeo-albicantibus, striis subtilissimis copiosè exorientibus; basi albicante.

The ventricle Cowry. Shell ovate, very thick, sides swollen, rather angulated, extremities blunted, base somewhat concavely depressed; back blueish or livid ash, ornamented with four caruelion bands, sides blackish chesnut, red above, smoky white beneath, with a number of very fine striæ rising; base whitish.

Testa junior.

Testa junior pallidè fulvescens, fasciis qualernis carneolis cingulata.

Younger shell pale fulvous, encircled with four carnelion bands.

LAMARCK, Ann. du mus. p. 452.

Cypræa achatina, Solander MSS. Dillwyn.

Cypræa carneota, Martyn.

Hab. Island of Annaa, Pacific Ocean (found on the reefs); Cuming.

Lamarck appears to have published this species under the above title before Dr. Solanders's manuscript name was recorded by Dillwyn. The shell is a truly solid mass of enamel, the sides of which are profusely striated with a number of extremely fine scratch-like striæ. The observations on the arrangement of the colours in the preceding species apply specially to this.

Species 29. (Fig. a. and. b. Mus. Saul.)

Cypr. testa ovata, crassissima, lateribus turgidis, basi convexa, apertura angusta, dentibus elongatis, valdè prominentibus, interstiis profundè excavatis; dorso cæruleo-cinereo, fasciis quaternis fuscescentibus subdistantibus ornato, lateribus granuloso-arenaceis, basi fumeo-albicante.

The grooved-toothed Cowry. Shell ovate, very thick, sides swollen, convex at the base, aperture narrow, teeth elongated, interstices deeply excavated; base blueish ash-colour, ornamented with four rather distant pale brown bands, sides brown granulously arenaceous, base smoky-white.

Gray, Zool. Journal, vol. 1. p. 148. f. 5. *Hab.* South Seas.

The deeply excavated interstices of the teeth which are like those of the *Cypræa leucodon*, amply distinguish this species from the *Cypræa arenosa* to which it so closely approximates in general appearance; the colours are of a duller brown, and the base is of a dull smoky white. Another peculiarity by which it differs from that species is, that the sandy border round the sides does not rise in striæ but subsides in sediment-like granules.

Species 30. (Mns. Brit.)

Cypr. testã, oblongo-ovatã, subpyriformi, lateribus margine recurvis, basi depressiusculā, aperturā sinuosā, dentibus parvis, in liris per basem continuatis, liris subirregularibus, rugiferis, hic ittic bifurcatis, supra marginem et ad latera exorientibus; columellā lævi; dorso flavescente-fusco, guttis albis variæ magnitudinis asperso, hiatu dorsali latiusculo, dentibus lirisque vividè crocato-rufis

The spotted Cowry. Shell oblong-ovate, somewhat pyriform, sides recurved round the margin, base rather depressed, aperture sinuous, teeth small, continued across the base in ridges, ridges rather irregular, wrinkled, bifurcated here and there, passing over the margin and rising upon the sides; back yellowish-brown, sprinkled with white spots of various sizes, dorsal hiatus rather wide, teeth and ridges rich saffron-red.

Gray, Zool. Journal, vol. 1. p. 511. pl. 18. f. 1 and 2. *Hab.* ——?

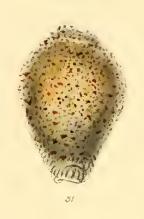

This very rare and remarkable shell is the largest species of that division of the genus to which the Cyprææ erosa and Lamarckii belong. Its chief peculiarity consists in the teeth extending across the base in bright saffron-red ridges, each of which passes over the edge and a little way up the side, terminating in a point; they have a somewhat irregular wrinkled appearance, and are here and there forked. The white spots on the back are extremely variable in size, and, as in the Cypræa vitellus, have the appearance of a miniature firmament of stars of different degrees of magnitude. The back of the shell is not, however, so highly enamelled as in that species, nor are the spots of the same round definite character.

I have seen three specimens of the Cypræa guttata, one, from which the accompanying figure is taken, in the British Museum, one in the Leyden Museum, and one in Mr. Norris's collection, at Preston. There are also two which I have not had the pleasure of seeing; one lately received from Amsterdam, in the collection of Mr. Dennison of Liverpool, and another (I am told) in that of Mr. Johnston, of Berwick-on-Tweed. It appears to have been well-known to Martini, as it is figured by that author in the first volume of his "Conchylien Cabinet," Pl. 25. f. 252. and 253., published in 1769, under the title of "Argus flavus tenuis occillis lacteis."

Reeve m.

PLATE 1X.

Species 31. (Mus. Cuming.)

Cypr. A Turdus. Cypr. testá depresso-ovatá, turgidá, basi subplanulatá, extremitatibus productis, aperturá latiusculá, anticè dilatatá, dentibus brevibus, subdistantibus; albidá, dorso guttis punctisque fulvis inæqualibus profusè asperso.

The thrush Cowrey. Shell depressly ovate, swollen, rather flattened at the base, extremities produced, aperture rather wide, dilated anteriorly, teeth short, somewhat distant; whitish, profusely sprinkled with unequal small fulvons spots and dots.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol. x. p. 520.

Hab. ——?

The dots of this species on the anterior extremity, which is slightly creudlated, assume a dash-like character.

Species 32. (Mus. Cuming.)

Cypr. Ex Lurida. Cypr. testá oblongo-ovatá, extremitatibus plano-productis, basi subdepressá, dentibus brevibus; dorso cincreo- ant cærulescente-olivaceo, subobscurè trifasciato, extremitatibus croceo-incarnatis, maculá conspicuá nigricante utrinque tinctis, basi albicante.

THE LURID COWREY. Shell oblong-ovate, extremities flatly produced, base a little depressed, teeth short; back ash or blueish olive, somewhat obscurely three-banded, extremities saffron-flesh colour, stained on each side with a conspienous blackish blotch; base whitish.

Linnæus, Syst. Nat. (12th edit.), p. 1175. *Hab.* Adriatic and Mediterranean Seas.

There are two very distinct varieties of this well-known species, one a greenish-olive colour as figured, the other of a more blueish east of colour, which is more elevated at the back, and more contracted at the extremities.

Species 33. (Mus. Gaskoin.)

Cypr. Exit. Cypr. testá oblongo-ovatá, crassá, extremitatibus retusis, aperturá subangustá, dentibus interioribus per columellam elongatis; dorso albido, fulco et cærulescente profusè nebulato et guttato, maculis nigerrimo-fuscis inæquatibus hic illic interspersis, hiatu dorsali angusto lineari, lateribus dentibus basique albicantibus, dentium interstitiis conspicuè sanguineo-rufis.

THE LYNX COWREY. Shell oblong-ovate, thick, extremities blunt, aperture rather narrow, inner teeth extended across the columella; back whitish, profusely spotted and clouded with fulvous brown and blue, interspersed here and there with unequal dark blackish-brown spots, dorsal hiatus narrow, linear, sides teeth and base whitish, interstices between the teeth bright blood-red.

Testa junior.

Testa junior alba, fulvo profuse guttata.

Younger shell white, profusely spotted with yellowish brown.

LINNEUS, Syst. Nat. (12th edit.), p. 1177.

Testa junior.

Cypræa vunelli, Linnæns.

Cypræa squalina, Gmelin.

Hab. Ceylon, Mauritius, Paeific Islands, &c.

The first coat of colouring matter, in which there is no dorsal opening, is one of pale fulvous brown spots on a white ground, the second is blueish and of a more clouded character, and the third consists of a scattered deposite of blackish-brown spots, round, but of very unequal size. The teeth are mostly developed simultaneously with the first deposite of colour, and the bright red colouring of the interstices between the teeth begins to make its appearance at the same time.

Species 34. (Mus. Saul.)

Cypr. Ex Pulchra. Cypr. testá cylindraceo-oblongá, extremitatibus subcontractis, aperturá rectiusculá, angustá, dentibus parvis, numerosis, linearibus, subobsoletis, columellá lævigatá, concavitate subamplá, lateribus basique rotundatis; dorso olivaceo, subobscurè trifasciato, extremitatibus maculá conspicuá nigerrimo-fuscá utrinque tinctis, basi pallidissimè olivaceo-rubidá, dentibus lacco-fuscescentibus, interioribus medianis interdum bifurcatis, per basem partim fluentibus.

THE BEAUTIFUL COWREY. Shell cylindrically oblong, extremities a little contracted, aperture rather straight, narrow, teeth small, numerous, linear, somewhat obsolete, columella smooth, with a rather large concavity, sides and base rounded; back olive, rather obscurely three-banded, extremities stained on each side with a rich blackish-brown blotch, base with a warm ruddy olive tinge, teeth lake-brown, inner middle teeth sometimes bifurcated, flowing partially over the base.

Gray, Zool. Journal, vol. i. p. 143. Hab. Red Sea.

Although there is so close an approximation between the painting of the back of this species and the Cypræa lurida, they are eminently distinct at the base. The teeth of the Cypræa pulchra are of a curious half-obsolete character, and peculiarly coloured, and the middle of the inner row are extended in lines a little way over the base, which just at that point has a slight concave depression.

The name *pulchella*, originally given to this species by Mr. Gray, at page 143 of the 'Zoological Journal,' vol. i. having been pre-occupied by Mr. Swainson, it was altered to *pulchra* at page 379 of the same volume.

Species 35. (Mus. Cuming.)

Cypr. Eburna. Cypr. testâ depresso-ovatâ, turgidâ, anticè contractâ, marginibus subobscurè foveolatis, aperturâ latiusculâ, anticè dilatatâ, dentibus brevibus, fortibus, subdistantibus; extus undique eburneâ, intus fulvo-fuscescente.

The Ivory Cowrey. Shell depressly ovate, swollen, contracted anteriorly, margins somewhat obscurely pitted, aperture rather wide, dilated anteriorly, teeth short; strong, rather distant; outside ivory-white, inside fulvous brown.

Barnes, Annals Lyceum Nat. Hist., New York, vol. i. p. 133. pl. 9. f. 2.

Hab. Philippine Islands; Cuming.

This shell has so much the form of the *Cypræa Lamarckii* that it has been regarded as a white variety of that species. It is, however, constantly distinct, a pure highly polished ivory white shell, fulvous brown within.

many del et ath

Reeve imp

PLATE X.

Species 36. (Mus. Cuming.)

Cypr. Ea Miliaris. Cypr. testá oblongo-ovatá, antice attenuatá, extremitatibus productis, subreflexis, lateribus foveolatis; dorso citrino-flavescente, ocellis albis profuse asperso, tateribus basique albis.

The MILLET COWREY. Shell oblong-ovate, attenuated anteriorly, extremitics produced, a little reflexed, sides pitted; back eitron-yellow, profusely sprinkled with white eyes of various sizes, sides and base white.

GMELIN, Syst. Nat. p. 3420.

Hab. Japan (under stones); Dr. Siebald.

Notwithstanding what has been said of this species by M. Deshayes, I am inclined to think with M. Kiener that it is really the *C. miliaris* of Gmelin; and that the following, university regarded by collectors as *C. Lamarckii*, is distinct from it.

Species 37. (Mus. Gaskoin.)

Cypr.æa Lamarckii. Cypr. testá ovatá, ventricosá, extremitatibus subobtuso-productis, reflexis, utrinque foveolatis; dentibus brevibus, fortibus, subdistantibus; dorso aurantio-flavescente, ocellis atbis, quorum nonnullis pupillatis, profusè asperso, tateribus punctis, extremitatibus lineis aurantio-castuneis, notatis, basi albi.

LAMARCK'S COWREY. Shell ovate, ventricose, extremities somewhat obtusely produced, reflected, pitted on both sides; teeth sbort, strong, rather distant; back orange-yellow, profusely sprinkled with white eyes, some of which are pupilled, sides marked with orange-brown spots, extremities with lines, base white.

GRAY, Zool. Journal, vol. 1. p. 506.

Hab. Mozambique (under stones); W. V. Hennah.

The growth of this species, in which the former is included by Mr. Gray as a variety, seems to differ constantly in being less obese, whilst the extremities are more produced and the outer teeth more in number. The difference in the colouring is most conspicuous; the sides and extremities are dashed and dotted with orange-brown, whilst the ground colour of the back is darker, and the eyes more or less pupilled.

Species 38. (Mus. Cuming.)

CYPRÆA CRUENTA. Cypr. testå oblongo-ovatá, extremita-

tibus subrectis, tateribus plus minusce incrassatis, dentibus fortibus, subelongatis; albidú, dorso lutescente, fusco murmorato, lateribus guttis inæquatibus purpureotaccis ornatis, dentium interstitiis crocato-cocceis.

The blood-spot Cowrey. Shell oblong-ovate, extremities rather blunt, sides more or less thickened, teeth strong, rather clongated; whitish, back marbled with yellowish brown, sides ornamented with unequal purple-lake spots, interstices between the teeth saffronscarlet.

GMELIN, Syst. Nat. p. 3420 (?).

Cypræa variolaria, Lamarck.

Hab. ---- ?

Although M. Deshayes urges the propriety of following Lamarck's name of this species on account of its doubtful identity with the description published by Gmelin, he does not show that description to refer to anything else. Mr. Dillwyn, Gray, Sowerby and all who have written upon the genus in this country have united in referring the species under consideration to the Cypræa cruenta of Gmelin.

Species 39. (Fig. a. and b. Mus. Saul. Fig. c. Mus. Cuming.)

Cypr. Está ovato-pyriformi, posticè umbiticatá, aperturá tatiuscutá; dorso albicante, zonis binis obscuris, extremitatibus, basi, tateribusque aterrimis, aurantio-fusco supra marginatis, dentibus aterrimis.

The onyx Cowrey. Shell ovately pyriform, umbilicated posteriorly, aperture rather wide; back whitish, with two obscure zones, extremities base and sides jet black, edged above with orange-brown, teeth jet black.

Variety β (Fig. 39 a.)

Testa undique castaneo-fusca, extremitatibus basi lateribusque saturatioribus, dentibus crocato-rubris.

Shell chesnut-brown throughout; extremities, base, and sides the deeper colour, teeth saffron red.

Variety v. (Fig. 39 b.)

Testa undique aurantio-lactea, extremitatibus basi lateribusque saturatioribus.

Shell of an orange cream-colour throughout; extremities, base, and sides the darker.

LINNÆUS, Syst. Nat. (12th edit.), p. 1177.

Cypræa adusta, Lamarck.

Hab. San Diego, California.

This species presents three remarkably distinct varieties all of which, represented in the accompanying plate, are well known to collectors.

Species 40. (Mus. Saul.)

Cypr. Lesta oblongo-oveta, depressiuscula, subumbilicata, dorso cærulescente, obscurissimè quadrifasciato, maculis inæqualibus castaneo-fuscis creberrimè et confusè picto, extremitatibus basi lateribusque aurantio-fuscis, lateribus et extremitatibus nigro-punctatis dentibus albidis.

Sowerby's Cowrey. Shell oblong-ovate, rather depressed, slightly umbilicated, back blueish, very obscurely fourbanded, very closely and confusedly painted with unequal chesnut-brown spots, extremities, base, and sides orange-tinged brown, sides and extremities dotted with black, teeth whitish.

KIENER, Icon. coq. viv. p. 38. pl. 7. f. 3.
 Cypræa zonata, Gray, (not of Chemnitz).
 Eadem, Cypræa ferruginosa, Kiener.
 Hab. Mouth of the Gambia, Africa.

The Cypræa Sowerbyi has been confounded with another very distinct species, Cypræa zonata (for which see Plate X111. Fig. 58.), and great confusion has resulted from the different interpretation put upon a very obscure figure published under that name by Chemnitz (Conch. Cab. vol. x. pl. 145. f. 1342), and copied in an absurdly embellished style into Wood's 'Index Testaceologicus'.

After a careful examination of figures, and the comparison of an extensive series of specimens 1 am inclined to think that the shell above described, and of which the accompanying figure is a rich characteristic example, was correctly introduced for the first time by Mr. Gray in the Zoological Journal, vol. iv. pl. 7. f. 8, as a new shell, but the name intended to distinguish it, maculata, was not employed, because the author subsequently determined to refer it to the Cypræa zonata of Chemnitz; and, curious enough, the word maculata was at about the same period (September 1824) used by Mr. Barnes in the 'Ann. Lyc. Nat. Hist. New York,' in reference to a shell, which, though

only figured in outline, is clearly a *C. reticulata*. We have, however, another extremely variable species of a shorter and more pyriform shape (vide *Cypræa zonata*, pl. 13. f. 58.), of which the figure above alluded to in Chemnitz is, in my opinion, either an uncoated, or immature specimen.

The following history may assist in the determination of these species, and, I wish I might say, put an end to the confusion attending them.

In the year 1788, before the different phases of colour which the Cowries exhibit at different periods of growth were fully understood, Chemnitz (Conch. Cab. vol. x. pl. 145. f. 1342.), published the figure of an African species in an incomplete state, showing the zones of hunar spots ("zonis maculis lunaribus") characteristic of an intermediate stage of growth. Lamarek in 1822 confirmed the propriety of regarding this shell as new, by the discovery of an adult specimen of the same, not otherwise described (" mais parmi celles du Muséum se trouve un invidu complet"); but his testimony not being accompanied by any figure it is difficult to say with which of the two species (Sp. 40, or Sp. 48, of the present monograph), he had in his own mind identified it. Mr. Gray in 1824 published a figure of the former of these (and I think correctly), as a new species, with a name which he abandoned in the text, referring it to Chemnitz's Cypræa zonata; and subsequently to that, as if desirous of returning to the opinion which I now hope to maintain, inserted a note to the following effect; "The reference to Chemmitz is doubtful," (Zool. Journ. vol. iv. p. 81.), Mr. Sowerby follows Mr. Gray in referring this species to the C. zonata without allusion to the doubt expressed in the note above alluded to; and no figure appeared of the true Cypræa zonata (such at least as I hold to be the true one), until M. Kiener figured both species under the same name (Icon. Coq. viv. pl. 7. f. 3. and pl. 48. f. 1.). After the publication of these figures he appears to have discovered their specific difference, and in the text distinguished that under consideration by the new name of C. Sowerbyi. Unfortunately, however, M. Kiener did not stop here; for an inferior example of the very same shell is reproduced in a subsequent plate as a new species under the title of Cypræa ferruginosa.

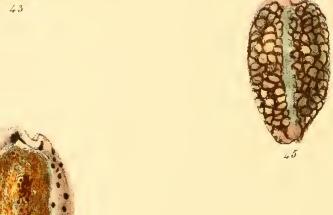

Had it not been for the misapplication of the word maculata by Barnes, I should certainly have adopted it, as having been proposed, though not adopted by Mr. Gray.

PLATE XI.

Species 41. (Mus. Cuming.)

CYPRÆA REEVEL. Cypr. testá ovatá, tenui, ventricosá, spiræ apice subprominente, dentibus parvis tenuibus numerosis, per columeltam, præcipuè concavitatem anticam, subconspicuis; dorso flavicante- aut lavendulofusco, obscurè quadrifasciato, basi albida, spiræ apice extremitatibusque roseis.

REEVE'S COWREY. Shell ovate, thin, ventricose, apex of the spire rather prominent, teeth small, thin, numerous, rather conspicuous across the columella; back vellowish- or lavender-brown, obscurely four-banded, base whitish, extremities and apex of the spire pink.

GRAY; Sowerby, Cat. Cypræadæ, Coneh. Illus. no. 15.f. 52. Hab. Garden Island, mouth of the Swan River.

The back of this shell in a fine state of preservation is of a blueish layender colour; and in this and the delicate pink colouring of the extremities the species is peculiarly eharacteristic.

Species 42. (Mus. Saul.)

CYPRÆA PULCHELLA. Cypr. testå eleganter pyriformi, antice contracta et producta, dentibus elongatis, interioribus in liris basem percurrentibus; albida, dorso futvo minutissime punctato, maculis futvis semilunaribus bifasciato, lateribus guttis circularibus nigricante-fuscis irregulariter aspersis, dentibus lirisque rubidis.

THE PRETTY COWREY. Shell elegantly pear-shaped, anteriorly contracted and produced, teeth elongated, the inner teeth running over the base in ridges; whitish, back minutely dotted with fulvous speeks, with two bands of semilunar blotches, sides irregularly sprinkled with round blackish brown spots, teeth and ridges dark red.

SWAINSON, Exotie Coneh. p. 25. pl. 35.

Hab. China.

The colouring of the back of this species is exceedingly variable, being sometimes banded with semilunar spots as in the specimen here figured, sometimes ornamented with a large irregular splash of ehesnut-brown. markable for the novel and characteristic extension of the teeth.

Species 43. (Mus. Saul.)

Cypr. Ea erosa. Cypr. testá ovatá, plus minusve depresso-

plana, lateribus incrassatis, margine circa extremitate reflexo, foveolato et crenato, dentibus fortibus, exterioribus basem interdum percurrentibus; dorso citrinofulvo, punctis minutis albis profusè notato, guttis fuscescentibus obscuris asperso, lateribus albis, maculá quadratá fusco-nigricante in medio tinctis, castaneo-fusco lineatis et punctatis.

THE ERODED COWRY. Shell ovate, more or less depressly flattened, sides thickened, edge reflected, pitted and erenated, teeth strong, outer teeth sometimes running aeross the base; back citron-fulvous, profusely marked with minute white specks, and sprinkled with obscure brownish ones, sides white, stained in the middle with a square brownish black spot lineated and dotted with chesnut brown.

LINN.EUS, Syst. Nat. (12th edit.), p. 1179. Hab. Ceylon, Mauritius, &c.

An abundant and extremely variable species of which the specimen here figured may be regarded as the type.

Species 44. (Mus. Cuming.)

Cypræa caput-serpentis. Cypr. testå subquadrato-oratá, depresso-planá, crassá, solidá, dorso subacuminato, dentibus conspicuis, subelongatis; nigricante-fusca, dorso anttis niveis circularibus inæquatibus asperso, extremitatibus albicantibus, dentibus et aperturæ fauce fumeoallidis.

The snake's-head Cowrey. Shell somewhat squarely ovate, depressly flat, thick, solid, back a little acuminated, teeth conspicuous, rather elongated; blackish brown, back sprinkled with unequal round snow-white speeks, extremities whitish, teeth and aperture smokywhite.

Testa junior.

Testa junior cinereo-cærulescens fasciá unicá fuscá tatiusculá

Younger shell ashy-blue, with a single rather broad central band.

Linnæus, Syst. Nat. (12th edit.), p. 1175.

Hab. Tahcite, Pacific Ocean (on the reefs); Cuming.

I take especial notice of the younger state of this wellknown species on account of the great difference in its colour and appearance.

Species 45. (Mus. Cuming.)

Cypr. Está cylindraceo-oblongâ, extremitatibus declivibus, subretusis, aperturá angustá, dentibus tenuibus numerosis, columellæ concavitate subamplá; dorso cinereo-cærulescente, obscurè quadrifasciato, reticulá fuscá gracili latiusculá obtecto, hiatu lineari, lateribus basique flavicante-fuscis, guttis fumeo-nigricantibus aspersis, dentibus fusco-rubidis.

The Jester Cowrey. Shell cylindrically oblong, extremities steep, rather blunt, aperture narrow, teeth fine, numerous, coneavity of the columella rather large; back ashy blue, obscurely four-banded, covered over with rather open slender net-work of brown, with a linearhiatus, sides and base yellowish-brown, sprinkled with smoky black spots, teeth brownish red.

CHEMNITZ, Coneh. Cab. vol. x. p. 103. pl. 144. f. 1338. Eadem. *Cypræa Indica* Gmelin.

Hab. Isle of Annaa, Pacific Ocean (on the reefs); Cuming.

Distinguished from any varieties of the *C. Arabica*, to which it is in most respects allied, by its straight cylindrical form.

Species 46. (Mus. Sanl.)

Cypr. testá ovatá, vel oblongo-ovatá, plus minusve depressá, lateribus plerumque incrassatis, dentibus fortibus, basem utrinque percurrentibus; dorso albido, punctis minutissimis flavicante-fuscis confusè et creberrimè picto, lateribus fulvo-albidis, guttis nigerrimis conspicuis hic illic ornatis, basi subaurantio-fulvis, dentibus albidis.

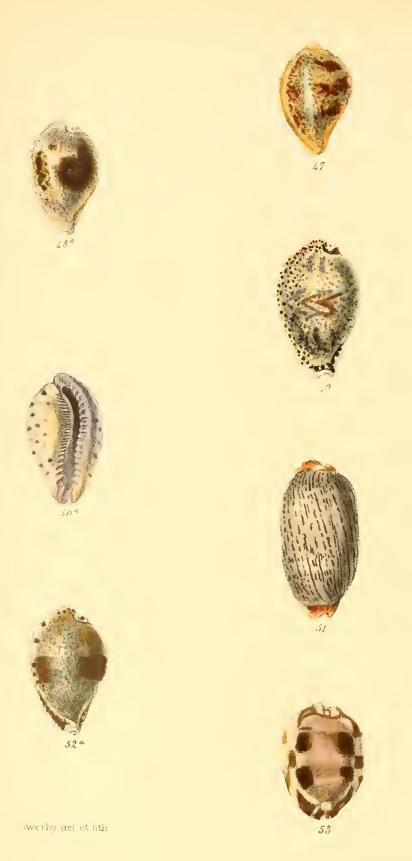

The thick-edged Cowrey. Shell ovate, or oblong-ovate, more or less depressed, sides generally thickened, teeth strong, running partially over the base on each side; back whitish, confusedly and very closely painted with minute yellowish brown specks, sides fulvous white ornamented here and there with very dark conspicuous spots, base orange-tinged fulvous, teeth whitish.

LINNÆUS, Syst. Nat. (12th cdit.), p. 1179. Hab. Eastern Seas.

This species is most abundant, varying from long and rounded forms with thin sides, to short and depressed with thickened sides.

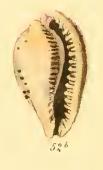

Cypraea Pl. XII.

Reeve imp

PLATE XII.

Species 47. (Mus. Cuming.)

Cypr. Lesta subpyriformi, tenui, inflata, apertura latiuscula, dentibus tenuibus minutis, interioribus ferè obsoletis; dorso cærulescente, zonis duabus fuscescentibus ornata, flavescente-fusco confusè picta, lateribus et extremitatibus fulvo-aurantiis, basi albida.

The swollen Cowrey. Shell somewhat pyriform, thin, inflated, aperture rather broad, teeth fine minute, inner teeth almost obsolete; back blueish, ornamented with two light brown zones, yellowish, confusedly painted with yellowish-brown dashes, sides and extremities fulvous orange, base whitish.

Brocchi (in ætate fossili), Conch. Foss. Subap. vol. ii. p. 284. pl. 2. f. 3.

Cypræa achatidea, Sowerby.

Cypræa Grayi, Kiener.

Hab. Sicily (found under stones); Capt. Mott.

A species comparatively new to collectors of recent shells, which M. Deshayes first identified with one that has been known for some time in a fossil state. It is of light inflated growth, with very fine teeth, the inner row of which is almost obsolete, the sides and extremities are fulvous orange, and the back is profusely splashed with yellowish brown.

Species 48. (Mus. Saul.)

Cypr. A subviridis. Cypr. testá ovatá, turgidá, subpyriformi, extremitatibus leviter productis, dentibus brevibus,
fortibus, subdistantibus, interioribus posterioribus plus
minusve obsoletis; dorso subviridis obscurè latifusciato,
punctis pallidis minutissimis lentiginoso, maculá peramplá castaneo-fuscá picto, dentibus basi lateralibusque
subviridescente-albis, extremitatibus incarnato-fuscescentibus.

The Greenish Cowrey. Shell ovate, turgid, somewhat pyriform, extremities slightly produced, teeth short, strong, rather distant, the inner posterior teeth more or less obsolete; back greenish, obscurely broadly banded, painted with a very large chestnut-brown blotch, and freckled with minute pale specks; teeth base and sides greenish white, extremities flesh-tinged brown.

Reeve, (mendâ typographicâ Lake), Pro. Zool. Soc., 1835. Cypræa errones var., Sowerby, Conch. Illus.

Hab. Dupuch's Island, North west coast of Australia (found under stones at low water); Dring R. N.

This is the first shell I ever ventured, as a youth, to describe; like most collectors my attention was first at-

tracted by the Cowries, and the specimen which struck me as being specifically distinct from any other that I had seen is now in the collection of Mr. Cuming. The species has been entirely disregarded by naturalists; one noticing it as a variety of *C. errones*, another omitting mention of it altogether. M. Kiener has certainly adopted the species, but as his figure is copied from Mr. Sowerby's, and his comparison with the *C. physis* is one of figures only, it cannot be estimated as a record of opinion.

Several specimens of the *Cypræa subviridis* have fortunately arrived from the locality above mentioned within the last twelvemonth, and the species is now universally esteemed by collectors in this country as one totally distinct from any hitherto known.

Species 49. (Mus. Gaskoin.)

CYPRÆA LENTIGINOSA. Cypr. testå oblongo-ovatå, extremitatibus subproductis, dentibus magnis, subdistantibus; dorso cærulescente-albo maculis undatis obscurè trifasciato, punctis minutis fuscescentibus undique lentiginoso, extremitatibus nigricante-fuscis, lateribus guttis nigricante-fuscis aspersis, basi albidå.

THE FRECKLED COWREY. Shell oblong-ovate, extremities a little produced, teeth large, somewhat distant; back blueish-white, with three obscure bands of waved blotches, freekled over with small light brown specks; extremities blackish-brown, sides sprinkled with blackish-brown spots; base whitish.

Gray, Zool. Journal, vol. i. p. 489. pl. 7 and 12. f. 1. Hab. Ceylon.

Although a shell of great rarity there are several specimens in our different collections; the one here figured from the eabinet of J. S. Gaskoin, Esq. which is by far the finest I have seen, is already well known to the public by the figures of Mr. Sowerby and M. Kiener.

Species 50. (Mus. Saul.)

Cypr. EA Walkeri. Cypr. testā oblongo-ovatā, depressiusculā, extremitatibus subretusis, dentibus parvis, tenuibus, numerosis, præcipuè interioribus; dorso cæruleo-albicante, trifasciato, fasciis latissimis fuscis, centrali saturatiore, in juniore undato-maculatis, punctis minutissimis flavido-fuscis undique lentiginoso; lateribus subflavis, guttis nigro-fuscis sparsim notatis, dentium interstitiis basique purpureo-violaceis.

Walker's Cowrey. Shell oblong-ovate, rather depressed, extremities somewhat blunt, teeth small, fine,

numerous, especially the inner; back blueish-white, three-banded, bands unusually broad, brown, central band darker than the others, marked in the younger shell with waved spots, freekled throughout with minute yellowish-brown specks; sides yellowish, marked here and there with round blackish brown spots; base and interstices between the teeth purple-violet.

Gray, Sowerby Conch. Illus. Cat. Cypræadæ, no. 70. f. 22.*

Hab. New Holland.

An extremely well-defined species named by Mr. Gray after a zealous and intelligent collector of shells, now no more, to whom I am indebted with many kind remembrances for my first introduction to conchological pursuits.

Species 51. (Mus. Cuming.)

Cypr. testá cylindraceo-oblongá, extremitatibus declivibus, retusis, aperturá angustá, dentibus tenuissimis numerosis, dorso cinereo aut cinereofulvo, obsurè trifasciato, punctis lineisque interruptis atris, longitudinaliter plus minusve notato; extremitatibus crocato-rubris, basi niveá.

The fawn-coloured Cowrey. Shell cylindrically oblong, extremities steep, blunt, aperture narrow, teeth very fine and numerous; back ashy or ashy fulvous, obscurely three-banded, more or less marked longitudinally with inky black dots and dashes, extremities saffron-red, base snowy white.

Linnæus, Syst. Nat. (12th edit.) p. 1177. Eadem, *Cypræa controversa*, Gray. *Hab.* Mauritius.

A well-known species of the same oblong cylindrical form as the *C. scurra*.

Species 52. (Mus. Gaskoin.)

Cypr. testa pyriformi, tenuicula, subumbilicata, extremitatibus productis, præcipuè antica, dentibus subirregularibus præcipuè interioribus, basi anticè depressiuscula; dorso subciridi, fascia centrali interrupta fuscescente, punctis minutissimis fulvo-fuscis undique lentiginoso, lateribus albidis, guttis fulvo-fuscescentibus notatis, basi albida, dentibus interioribus rubidis.

The Pear-Shaped Cowrey. Shell pear-shaped, rather thin, a little umbilicated, extremities produced, the anterior especially, teeth somewhat irregular, particularly the interior, base rather depressed anteriorly;

back greenish, with a central interrupted pale brown band, freckled throughout with very minute fulvous brown dots, sides whitish, marked with fulvous brown spots, base whitish, inner teeth red.

Gray, Zool. Journal, vol. 1. p. 371. Hab. Ceylon.

Having two magnificent specimens of this very rare species before me from the collections of Mr. Gaskoin and Miss Saul, I am enabled to fill up the characters that were unwillingly omitted by Mr. Gray at the time of its introduction. The back is of a delicate sea-green, freckled with very minute yellowish brown specks, having a broad interrupted band of the same colour across the centre. The teeth are deep red, and of the same remarkable character, on a small scale, as those of the *C. pulchella*. M. Kiener's figure gives a most inadequate idea of the species, being a wretched copy of a rather indifferent figure in Sowerby's 'Conchological Illustrations'.

Species 53. (Mus. Saul.)

Cypr.æa tessellata. Cypr. testá crassissimá, solidá, subquadrato-ovatá, lateribus incrassatis, dorso paululum acuminato, extremitatibus retusis, anticá callositate subobscurá munitá, aperturá angustá, dentibus parvis, gracilibus; dorso ferruginoso-cinereo, trifasciato, fasciis latissimis, lateribus maculis quadratis fuscis et albis tessellatis, maculis duabus superioribus ad utrumque latus vividè nigerrimo-castaneis, callositate albá, basi fusco alboque tessellatim variegatá, dentibus aurantiofuscis.

The tessellated Cowrey. Shell very thick and solid, somewhat squarely ovate, sides thickened, back a little acuminated, extremities blunt, the anterior furnished with a somewhat obscure callosity, aperture narrow, teeth small, slender, back ferruginous ash-colour, three-banded, bands very broad, sides tessellated with square brown and white spots, the two upper spots on both sides very dark bright chesnut, callosity white, base tessellately variegated with brown and white, teeth orange-brown.

SWAINSON, Zool. Illustrations, 1st Series, vol. ii. pl. 3. *Hab.* New Zealand.

This species, like the preceding, has been but imperfectly described hitherto for want of a specimen in adequate condition. The shell here figured from the collection of Miss Saul is in the finest state imaginable, and quite a gem to look upon.

Cypræa.Pl.M

heeve Broth rs my

Sowerty del et scul

PLATE XIII.

Species 54. (Mus. Saul.)

Cypræa Pallida. Cypr. testå ovatå, subpyriformi, turgidå, dentibus subgrandibus; dorso viridescente-stramineo, fulvo-fusco minutissimè lentiginoso, lateribus fusco sparsim guttatis, basi albicante.

The Pale Cowrey. Shell ovate, somewhat pear-shaped, swollen, teeth rather large; back greenish straw-colour, very minutely freekled with fulvous brown, sides spotted here and there with brown, base whitish.

Gray, Zool. Journal, vol. 1. p. 387. Hab. ——?

The *C. pallida* approximates rather closely to the *C. punctulata*, but is perfectly distinct on examination; it is of a more pear-shaped form, and less thickened, the tone of colour always paler, whilst the inner teeth do not extend across the columella, which wants the anterior concavity.

Species 55. (Mus. Saul.)

CYPRÆA XANTHODON. Cypr. testå oblongo-ovatå, anticè attenuatå, basi subdepresså, extremitatibus leviter productis, tateribus subincrassatis, dentibus brevibus, interioribus superioribus subobsoletis, columellå anticè medio sulcatå; dorso cæruleo-viridescente, obscurè trifasciato, punctis minutis fulvo-olivaceis undique lentiginoso, lateribus flavicantibus, guttis nigerrimo-fuscis conspicuis ornatis, dentibus basique fulvo-flavicantibus.

The Yellow-tooth Cowney. Shell oblong-ovate, attenuated anteriorly, base a little depressed, extremities slightly produced, sides rather thickened, teeth short, the inner upper teeth somewhat obsolete, columella grooved down the middle anteriorly; back blueish green, obscurely three-banded, freekled throughout with minute fulvous orange specks, sides yellowish, ornamented with conspicuous blackish-brown spots, teeth and base fulvous yellow.

GRAY; Sowerby, Conch. Illus. Cat. Cypræadæ no. 88, f. 18, *Hab.*—?

Through the kindness of Miss Saul, I am cnabled to figure the only adult specimen of this Cowrey that has been seen in fine condition; Mr. Gaskoin has a well-preserved specimen in an intermediate stage of growth, and besides these I have seen none but what are decorticated.

Species 56. (Mus. Cuming.)

Cypr.æA errones. Cypr. testá oblongo-ovali, dentibus brevibus; dorso cæruleo-viridescente, punctis fulvis minutissimis lentiginoso, maculá castaneá grandi centrali plerumque picto, lateribus basique flavescentibus immaculatis.

The erroneus Cowrey. Shell oblong-oval, teeth short; back blueish green, freekled with very minute fulvous specks, generally painted with a large chesnut blotch in the centre.

LINNEUS, Syst. Nat. (10th edit.), p. 723.

Cyprææ ovum and subflava, Gmelin.

Cypræa olivacea. Lamarck.

Hab. Eastern Seas.

This, unlike most other species of the genus, is not spotted at the sides.

Species 57. (Mus. Cuming.)

Cypr. A Picta. Cypr. testá oblongo-ovatá, antice attenuatá, lateribus subangulatis, basi depresso-planá, dentibus brevibus; dorso cæruleo, fasciá centrali subobscurá, purpureo-fusco undique peculiariter nebulatopicto, hiatu dorsali centrali, lateribus fumeo-fuscis, guttis conspicuis nigricantibus ornatis, basi fumeoalbidá.

The painted Cowrey. Shell oblong-ovate, attenuated anteriorly, sides somewhat angulated, base depressly flattened, teeth short; back blue, with a rather obscure central band, painted throughout with peculiarly clouded purple-brown, with a central dorsal opening, sides smoky brown, ornamented with conspicuous blackish spots, base smoky white.

Gray, Zool. Journal, vol. i. p. 389. pl. 7. f. 10. *Hab.* Mouth of the Gambia.

Distinguished from the following species, to which it is the next allied, by its reddish-purple tinged painting and dorsal opening, by its angular form, the base being more depressed, and the back more steeply elevated.

Species 58. (Mus. Saul.)

CYPRÆA ZONATA. Cypr. testå ovatå, lateribus basique convexis, dentibus fortibus, subelongatis; dorso cæruleo

aut viridescente, maculis semilunaribus undatis plus minusve distinctis medio zonato, fulvo-fusco sparsim undique nebuloso-picto, lateribus basique fumeo-fuscis, nigriguttatis.

The zoned Cowrey. Shell ovate, sides and base convex, teeth strong, a little elongated; back blueish or greenish, zoned across the middle with more or less distinct waved semilunar spots, sparingly painted throughout with clouded fulvous brown, sides and base dark smoky brown, spotted with black.

CHEMNITZ, Coneh. Cab. vol. x. pl. 145. f. 1342. Eadem, *Cypræa nebulosa*, Kiener. *Hab.* Mouth of the Gambia.

I quite agree with M. Kiener in regarding this shell as the *Cypræa zonata* of Chemnitz, for a full history of which I refer to my observations on the *Cypræa Sowerbyi*. The *Cypræa nebulosa* of M. Kiener is, however, an obscure variation of colouring, which may be easily identified with the typical examples by a careful comparison.

Species 59. (Mus. Saul.)

CYPRÆA NIGRO-PUNCTATA. Cypr. testâ oblongo-ovatâ, anticè attenuatâ et contractâ, lateribus marginatis et cum extremitatibus productis, dentium interstitiis subprofundè sulcatis; dorso cærulescente, fulvo pallidè lentiginoso, lateribus creberrimè nigripunctatis, basi flavicante.

THE BLACK-DOTTED COWREY. Shell oblong-ovate, attenuated and contracted anteriorly, sides marginated and produced with the extremities, interstices between the teeth rather deeply grooved; back blueish, freckled with pale fulvous brown, sides very closely dotted with black, base yellowish.

Gray, Zool. Journal, vol. iv. p. 11.

Eadem, Cypræa irina, Kiener.

Hab. Gallapagos Islands, Pacific Ocean (found under stones); Cuming.

M. Kiener has been singularly unfortunate in his lucubrations of this and two other allied species; an uncoated example of that under consideration is figured at Pl. II. with its proper name Cypræa nigro-punctata, and a fine specimen with its last coating of enamel is introduced at Plate LVI., as a new species, under the name of Cypræa irina. The Cypræa Sowerbyi is unconsciously reproduced at Plate LVI. under that of Cypræa ferruginosa. A variety of Cypræa zonata is introduced at Pl. XXXII. as a new spe-

cies under the name of Cypræa nebulosa; and to complete the category it may be added that his C. Boivinii is a well-known variety of C. gangrenosa, his C. fabula one of C. felina, his C. Grayi the C. physis, already named C. achatidea by Sowerby, and his C. rotunda the C. quadripunctata.

Species 60. (Mus. Cuming.)

Cypræa Arabicula. Cypr. testá ovatá, dorso elevato, lateribus marginatis, extremitatibus angulato-productis, basi depresso-planá, dentibus numerosis, angustis, acutis, interstitiis profundè incisis; dorso cæruleo-viridescente, obscurè fasciato, fusco creberrimè subreticulatim picto, lateribus fumeo-fuscis, guttis grandibus nigricantibus ornatis, basi albicante.

THE LITTLE ARABIC COWREY. Shell ovate, back elevated, sides marginated, with the extremities angularly produced, base depressly flat, teeth numerous, narrow, sharp, interstices deeply cut; back blueish green, obscurely banded, very closely reticulately painted with brown, sides smoky brown, ornamented with large black spots, base whitish.

Lamarck, Anim. sans vert. (Deshayes'edit.), vol. x. p. 534. Hab. St. Elena, West Columbia (under stones); Cuming.

There is something very peculiar in the form of this species, the base being flattened, the sides produced into a rim all round, whilst the teeth are very deeply cut in the interstices.

Species 61. (Mus. Cuming.)

Cypr.æA punctulata. Cypr. testá subgloboso-ovatá, crassá, solidá, lateribus rotundatis, basi couvexá, dentibus fortiusculis; dorso cæruleo-viridescente, olivaceo-fusco creberrimè lentiginoso, lateribus fumeo-nigricantibus, interdum aurantio tinctis, gnttis nigris aspersis.

The five dotted Cowrey. Shell somewhat globosely ovate, thick, solid, sides rounded, base convex, teeth rather strong; base blueish green, very closely freekled with olive-brown, sides smoky black, sometimes brightened with a warm orange tinge, sprinkled with black spots.

Gray, Zool. Journal, vol. i. p. 387.

Hab. Panama (found under stones), Cuming.

Intermediate between the *C. pallida* and *Arabicula*, but perfectly distinct from both.

Cypraa. PLXIV.

Sowerby, del. et sculp.

Reeve Brothers ump

PLATE XIV.

Species 62. (Mus. Cuming.)

Cypr. Ea Saul. E. Cypr. testá oblongo-ovatá, postice umbilicatá, antice attenualá, lateribus antice marginatis, extremitatibus productis, subreflexis, aperturá leviter flexuosá, dentibus prominulis; dorso lacteo, maculá grandi conspicuá centrali, punclisque paucis minutissimis vivide aurantio-castaneis picto, lateribus guttis perpaucis nigricante-fuscis ornatis, basi albicante, dentibus albidis, interstitiis aureo-flavescentibus.

Saul's Cowrey. Shell oblong-ovate, umbilicated posteriorly, attenuated anteriorly, sides marginated at the anterior end, extremities produced, a little reflexed, aperture slightly flexuous, teeth rather prominent, bold; back clear cream-colour, painted with a large conspicuous central spot of bright orange chestnut, surrounded with a few very minute dots of the same colour, sides ornamented with a very few dark brown spots, base whitish, teeth whitish, interstices pale golden yellow.

GASKOIN, Pro. Zool. Soc. 1843.

Hab. Island of Corregidor, Bay of Manila (found among coarse sand and gravel at the depth of seven fathoms); Cuming.

This is one of the most distinct and pleasing species to look upon of any in the genus; the beautiful economy and delicacy of the bright sienna painting upon a clear cream-coloured ground, render it an object of peculiar admiration.

Species 63. (Mus. Cuming.)

Cypr.ea erythræensis. Cypr. testá subcylindraceo-ovatú, anticè attenuatá, lateribus rotundatis, extremitatibus subproductis, dentibus parvis, numerosis, per busem subelongatis; dorso viridi-cærulescente, punctis perpancis minutissimis maculáque grandi centrali deformi aurantio-castaneá picto, extremitatibus guttá unicá aurantio-castaneá utrinque ornatis; lateribus, dentibus, basique cæruleo-albidis.

THE RED-SPOTTED COWREY. Shell somewhat cylindrically ovate, attenuated anteriorly, sides rounded, extremitics a little produced, teeth small, numerons, elongated partially across the base; back greenish blue, painted with exceedingly minute orange-ches-

nut dots and a large central mis-shapen blotch of the same colour, extremities ornamented on each side with a single reddish chesnut spot, sides, teeth and base blueish white.

Beck, MSS. (Mus. Cuming.)

Hab. Red Sea; Rüppell. Zanzibar; Thorn.

The Cypraa erythraensis exhibits without doubt a close approximation to the Cypraa stolida; but the differences, though minute, are constant, and determinable at a glance. In the first place it is uniformly smaller in size; the specimen here figured being rather above the average, and the largest I have seen. In form it varies in being less clevated, more cylindrically lengthened, and attenuated at the anterior end, without that sudden declivity which is so characteristic of its ally. There is moreover a marked variation in the colouring :- in all the specimens I have seen, probably some twenty or more, the central dorsal blotch is of a different style, it is more open and irregular, and has no symmetry of squareness; I find no indication, either, of the angles of colour which characterize the four corners of the Cypræa stolida, nor are the teeth or edge of the extremities coloured.

Species 64. (Mus. Gaskoin.)

Cypr. testá elongato-ovatá, subcylindraceá, anticè declivi, lateribus cum extremitatibus marginatis, reflexis, basi depresso-planá, aperturá antice dilatatá, dentibus exterioribus grandibus subdistantibus, interioribus tenuibus per basem subelongatis; dorso cærulescente punctis maculáque grandi centrali deformi fulvo-castaneis lentiginoso, extremitatibus maculá conspicuá nigro-castaneá utrinque pictis, latere sinistro punctis perpaucis; dentibus busique albicantibus.

The cylindrical Cowrey. Shell elongately ovate, somewhat cylindrical, steep anteriorly, sides with the extremities marginated, reflexed, base depressly flat, aperture anteriorly dilated, outer teeth large, rather distant, inner fine and elongated partially across the base; back blueish, freckled with very minute fulvous chesnut specks and a large mis-shapen central blotch, extremities painted on each side with a conspicuous blackish chesnut spot, the left side with one or two dots; teeth and base whitish.

Born, Mus. p. 184. pl. 8. f. 10. *Hab.* Ceylon; Pacific Islands; New Holland.

The New Holland examples of this species are rounder and less elongated, approaching more to the form of the *Cypræa errones*.

Species 65. (Mus. Cuming.)

Cypr. testá subpyriformi-ovatá, ventricosá, aperturá flexuosá, dentibus brevibus fortius-culis; dorso violaceo-castaneo, zonis duabus aut pluribus undulato-albis ornatis, lateribus basique albis, punctis perpaucis fuscis notatis, extremitatibus nigricante-castaneo-marginatis.

The day-break Cowrey. Shell somewhat pyriformly ovate, ventricose, aperture flexuous, teeth short, rather strong; back violet-chesnut, ornamented with two or more zones of zigzag white, sides and base white, marked with a very few brown dots, extremities edged with dark chesnut.

Cypræa ziczac (pars), Linnæus, Martini. Cypræa undata, Lamarck (not of Chemnitz.) Hab. Philippine Islands; Cuming.

This ancient and well-known species requires to be distinguished by a new name in consequence of the word undata, applied to it by Lamarck, having been already used by Chemnitz in reference to a shell which proves to be the young of the C. Mauritiana (Conch. Cab. vol. x. p. 102). It was confounded by Linneus and Martini with the C. ziczae, and is extremely well figured by the latter in the first volume of his 'Conchylien Cabinet,' published in 1769.

Species 66. (Fig. a, Mus. Cuming. Fig. b, Mus. Saul.)

TPREA TABESCENS. Cypr. testã oblongã vel ovată, umbilicată, lateribus incrassatis, dentibus parviusculis; dorso albicante, flavido-fuscescente pallide lentiginoso, maculis semilunaribus medio subobscure trizonato, lateribus fusco-guttatis, dentibus basique albicantibus.

The consumptive Cowrey. Shell oblong or ovate, umbilicated, sides thickened, teeth rather small; back whitish, freckled with pale yellowish brown, and rather obscurely three-zoned across the middle with semilunar spots of the same colour, sides spotted with brown, teeth and base whitish.

Solander, MSS., Dillwyn Cat. vol. i. p. 463.

Cypræa teres, Gmelin (?).

Hab. Ceylon; Taheite, Pacific Ocean (on the reefs); Cuming.

The figures in Martini's 'Conch. Cab.' f. 294 and 295, to which Mr. Gray and M. Deshayes refer for this species, are intended to represent, without doubt, the Cypræa cy-

lindrica; the Cypræa tabescens may be recognised in Fig 295 and 296 of the same plate. I have figured a curious broad growth of this species from Mr. Cuming's collection, because it is one of extremely rare occurrence.

Species 67. (Mus. Saul.)

Cypr. A Stolida. Cypr. testá oblongo-ovatá, dorso elevato, extremitates versus utrinque declivi, lateribus cum extremitatibus marginatis, subreflexis, aperturá flexuosá, dentibus numerosis, per basem elongatis, interstitiis subprofundè incisis; dorso cærulescente, punctis minutissimis, maculá grandi quadratá centrali, maculáque semiquadratá ad utrumque angulum aurantio-castaneis vividè picto, basi albicante, dentibus et extremitatibus aurantio-castaneis.

The foolish Cowrey. Shell oblong-ovate, back elevated, steep down each side to the extremities, sides with the extremities marginated, a little reflexed, aperture flexuous, teeth numerous, clongated across the base, interstices rather deeply cut; back blueish, brightly painted with very minute orange-chesnut dots, with a large central square spot, and with a half-square spot at each corner, of the same colour, base whitish, teeth and extremities orange-chesnut.

LINNEUS, Syst. Nat. (12th edit.), p. 1180.

Rubigo, Martini.

Cypræa rubiginosa, Gmelin.

Hab. Ceylon.

A careful comparison of the above description with that of the *Cypræa crytleræensis*, will show that there is a very characteristic specific difference between them, and one of which 1 find no intermediate modification.

Species 68. (Mus. Saul.)

Cypr. Está ovatá, lateribus cum extremitatibus marginatis, foveolatis, dentibus fortiusculis; dorso luteo nebulato et ocellato, lateribus flavicantibus, foveolis fuscis, basi albicante.

The dirty Cowrey. Shell ovate, sides with the extremities marginated, pitted, teeth rather strong, back clouded and ocellated with fulvous yellow, pits brown, base whitish.

LINNEUS, Syst. Nat. (12th edit.) p. 1179.

Cypræa acicularis, Gmelin.

Cypræa flareola, Lamarck, (not of Linnæus).

Hab. Mediterranean.

There is a curious variety of this well-known shell, in which the base has a large dark splash upon it.

Cypraa PLAT.

PLATE XV.

Species 69. (Mns. Saul.)

Cypr. Ea Obvallata. Cypr. testá orbiculari-ovatá, depressá, dorso angusto, elevato, lateribus valdè incrussato-marginatis, aperturá angustá, dentibus fortibus, subelongatis: dorso cæruleo, unnulo sanguineo interdum circumcincto, lateribus basique fumeo-albicantibus.

THE INTRENCHED COWREY. Shell orbicularly ovate, depressed, back narrow, elevated, sides very much thickened and puffed out, aperture narrow, teeth strong, rather elongated; back bine, sometimes encircled with a blood-red ring, sides and base smoky white.

Lamarck, Anim. sans vert. (Deshayes' edit.) vol. x. p. 538. Cypræa moneta, var., Dillwyn.

Hab. Taheite, Pacific Islands (found on the reefs); Cuming.

I use the term obvallata instead of obvelata, believing it to be the word which Lamarek intended to characterize the peculiar growth of this shell. Those who think with me that such was the case, will adopt it without prejudice to the authenticity of the species.

Species 70. (Mus. Cuming.)

Cypr. A nucleus. Cypr. testã ovatã, extremitatibus productis et rostratis, dorso noduloso, nodulis, præcipué lateralibus, liris coadunatis, basi convexã, dentibus parvis, in liris augustis per basem utrinque extensis; sordidè albã, nodulis lirisque pallidè ferruginosis.

THE UARD-CRUSTED COWREY. Shell ovate, extremities produced and beaked, back nodulous, nodules, particularly the lateral ones united together by ridges, base convex, teeth small, extending across the base on both sides in ridges; dull white, nodules and ridges pale rusty brown.

LINNÆUS, Syst. Nat. (12th edit.), p. 1181.

The dorsal line of this species is represented by a rather deep longitudinal groove.

Species 71. (Mus. Cuming.)

Cypræa annulus. Cypr. testå ovatå, basi concavo-depresså, lateribus incrassatis, declivibus, dentibus, fortibus, subdistantibus; fumeo-albidå, dorso annulo sanguineo circumcincto.

THE RING COWREY. Shell ovate, base concavely depressed,

sides thickened, steep, teeth strong, rather distant; smoky white, back encircled with a blood-red ring.

Linneus, Syst. Nat. (12th cdit.) p. 1179.

Hab. Eastern Seas.

There is no indication in this species of the oval intrenehment which characterizes the growth of the *Cypræa* obvallata.

Species 72. (Mus. Cuming.)

Cypr. Ea Melvola. Cypr. testã ovatã, depressã, lateribus incrassatis, medio turgidis, marginatis, foveolatis, dentibus fortibus, latiusculis, exterioribus per basem partim elongatis; dorso olivaceo-fuscescente, ocellis numerosis atbis, maculisque stellaribus fulvo-rubidis spursim ornato, lateribus basique fusco-rubidis, colore supra marginem saturatiore, extremitatibus violaceis.

THE RED COWREY. Shell ovate, depressed, sides thickened, swollen in the middle, marginated, pitted, teeth strong, rather broad, the outer partially elongated across the base; back pale olive-brown, ornamented with numerous white eyes and fulvous brown starry spots, sides and base brownish red, colour darker above the edge, extremities violet.

LINNEUS, Syst. Nat. (12th edit.), p. 1180. *Hab.* Ceylon.

A common species but one of the most richly and beautifully coloured of the series.

Species 73. (Mus. Cuming.)

Cypr. Está ovatá, basi subdepressá, lateribus turgidis, submarginatis, obscurè foveolatis, dentibus fortibus; dorso rufescente-flavo, ocellis numerosis albis, quorum nounullis hic illic nigro-pupillatis, ornato, basi lateribusque albidis, fusco-puuctatis.

THE OCELLATED COWREY. Shell ovate, base a little depressed, sides swollen, submarginated, obscurely pitted, teeth strong; back reddish-yellow, ornamented with numerous white eyes, some of which are pupilled with black, base and sides whitish, dotted with brown.

LINNEUS, Syst. Nat. (12th edit.), p. 1180.

Hab. Eastern Seas.

Another abundant and beautifully marked species well-known to collectors.

Species 74. (Mus. Saul.)

Cypr. Está trigono-ovatá, depressá, lateribus incrassato-marginatis, tuberculatis, dentibus subobtusis, basi tuberculatá; albá, pallidè stramineá, aut flavá, dorso annulo tenui sanguineo-rufo interdum circumcincto.

The Money Cowrey. Shell triangularly ovate, depressed, sides thickly marginated, tuberculated, teeth rather obtuse, base tuberculated; white, pale straw-colour or deep yellow, back sometimes encircled with a faint blood-red ring.

LINNÆUS, Syst. Nat. (12th edit.) p. 1178.

Hab. Taheite, Pacific Ocean (on the reefs); Cuming.

The colour of this species varies from white to a very deep yellow.

Species 75. (Mus. Saul.)

Cypr. testá ovatá, peculiariter depressá, dorso noduloso, nodulis liris coadunatis, sulco dorsali impresso, lateribus marginatis, extremitatibus obtusis, aperturá angustá, dentibus tenuibus, basem super in liris extensis, quarum alternis præcipuè ad latus sinistrum, minoribus; lacteá, dorso rosaceo-fuscescente pallidissimè tincto, liris basalibus rufo-fuscescente tenuiter marginatis.

The Madascar Cowrey. Shell ovate, peculiarly depressed, back noduled, nodules connected together by ridges, impressed by a dorsal groove, sides marginated, extremities obtuse, aperture narrow, teeth fine, extending over the the base in ridges, the alternate of which, on the left side more particularly, are smaller; cream-colour, back tinged with pinkish-brown, basal ridges edged with reddish-brown.

GMELIN. Syst. Nat. p. 3419.

Cypræa nucleus, var. b. Lamarck.

Hab. Madagascar.

This species is uniformly larger in size than the *C. nu-cleus*, much more depressed, and of a peculiarly soft pinkish cream-colour. The extremities are more obtuse, and the ridges across the left base are alternately larger and smaller.

Species 76. (Mus. Cuming.)

Cypræa pustulata. Cypr. testå ovatå, antice attenuatå, basi depresså, dentibus in liris conspicuis per basem utrinque extensis, columellå cum concavitate antica lævigatå, dorso striis elevatiusculis longitudinalibus et transversis, quarum transversis fortioribus, subtilissime cancellato, verrucis numerosis prominentibus, quarum medianis majoribus, munito; dorso cinereo-plumbeo, verrucis vivide corallo-rubris, ad basem nigro-annulatis, basi nigricante-fuscå, liris albidis.

The pustular Cowrey. Shell ovate, somewhat attenuated anteriorly, depressed at the base, teeth extending across the base on each side in conspicuous ridges, columella with the anterior concavity smooth, back very finely cancellated with slightly clevated longitudinal and transverse striæ, of which the transverse are the stronger, and armed with numerous prominent pimples of which the middle are the largest; back ashy lead-colour, pimples bright coral-red ringed with black, ribs whitish.

Testa junior.

Testa junior dorso cancellato, verrucis nullis

Younger shell with the back cancellated, but destitute of pimples.

Lamarck, Anim. sans vert. (Deshayes' edit.) vol.x. p. 535. *Hab*. Isle of Plata and Panama, west coast of America (found under stones); Cuming.

It is a circumstance worth noting in the growth of this shell that the teeth become considerably developed before there is any indication of dorsal pimples.

Sowerby del et hith

Reeve Brothers imp

PLATE XVI.

Species 77. (Mus. Cuming.)

Cypr. testá oblongo-ovatá, anticè attenuatè extensá, lateribus marginatis, extremitatibus productis et reflexis, aperturá flexuosá, dentibus tenuibus, præcipuè interioribus; dorso fulvo-stramineo, ocellis albidis fusco annulatis parviusculis sparsim ornato, lateribus castaneo-punctatis, basi albá.

CUMING'S COWREY. Shell oblong-ovate, attenuately drawn out anteriorly, sides marginated, extremitics produced and reflected, aperture flexuous, teeth fine, especially the inner; back fulvous straw-colour, sparingly ornamented with rather small white eyes tinged with pale brown, sides dotted with dark chesnut brown, base white.

GRAY; Sowerby, Conch. Illus. Cat. Cypræadæ, no. 77. f. 5 and 181.

Hab. Island of Rietea, Society Islands (found under coral on the reefs at low water); Cuming.

This beautiful species may be distinguished from the *Cypræa cribraria* by its attenuated and elegant growth, by the clearness and delicacy of its colouring, and by the spots being smaller, fewer in number, and ringed with pale brown.

Species 78. (Mus. Saul.)

Cypr. testá globoso- vel oblongo-ovatá, ventricosá, lateribus marginatis et foveolatis, aperturá latiusculá, dentibus brevibus; dorso olivaceo-rubido maculis inæqualibus rotundis albidis irregulariter asperso, subtus cinerascente, obscurè fasciato, hiatu dorsali latiusculo, lateribus extremitatibus basique citrino-rubidis, basi castaneo tinctá.

THE CITRON COWREY. Shell globosely or oblong-ovate, ventricose, sides marginated, pitted, aperture rather wide, teeth short; back olive ruddy colour, irregularly sprinkled with unequal round white spots, ash-colour underneath, obscurely banded, dorsal hiatus rather wide, sides extremities and base citron-red, base stained with chesnut.

GRAY, Zool. Journal, vol. i. p. 509.

Hab. ---?

The specimen here figured from the collection of Miss Saul is the only one I know in really fine condition. The species varies in form from a swollen globose to an oblong shape.

Species 79. (Mus. Saul.)

Cypr. Está ovato-oblongá, lateribus submarginalis, obscurè foceolatis, extremitatibus subrostratis, callositate plus minusve conspicuá munitis, aperturá flexuosá, dentibus fortibus, per basem subelongatis, interstitiis profundè excavatis; rubido-crocatá, dorso castaneo variè maculato et nebulato.

The two-callus Cowrey. Shell ovately oblong, sides slightly marginated, obscurely pitted, extremities somewhat beaked, furnished with a more or less conspicuous callus, aperture flexuous, teeth strong, a little elongated across the base, interstices deeply excavated; reddish saffron colour, back variously clouded and mottled with chesnut.

Gray; Sowerby, Conch. Illus. Cat. Cypræadæ. no. 50.f. 10. Hab. Island of St. Vincent, West Indies; Guilding.

An extremely rare and interesting species, distinguished from all others not only by its callosities, but by its general form and colouring.

Species So. (Mns. Cuming.)

Cypr. Lestá ovato-oblongá, subumbilicatá, solidiusculá, lateribus incrassatis, marginatis, dentibus fortibus; dorso luteo vel pallidè cinnamomeo, maculis rotundis numerosis subamplis ornato, lateribus basique eburneis, lateribus cinnamomeo punctatis.

The Keeled Cowrey. Shell ovate-oblong, rather solid, slightly umbilicated, sides thickened, marginated, teeth strong; back yellowish or pale cinnamon-brown, ornamented with numerous rather large white spots, sides and base ivory white, sides dotted with cinnamon-brown.

Duclos, Magasin de Zoologie 1833, pl. 36.

Hab. Philippine Islands; Cuming.

Distinguished from the following species to which it is so nearly allied, by its thickened growth, by its larger and more contiguous spots, and by the dotted colouring of the sides; characters which appear to be of uniform constancy.

Species 81. (Mus. Saul.)

Cypr. Ea Cribraria. Cypr. testå ovato-oblongå, subumbilicatå, tenuiculå, lateribus marginalis cum extremitatibus plerumque reflexis, dentibus subnumerosis; dorso luteo vel cinnamomeo, maculis rotundis albis plus minusve numerosis ornato, basi lateribusque eburneis.

The Sieve-Like Cowrey. Shell ovate-oblong, rather thin, sides marginated generally with the extremities reflexed, teeth rather numerous; back yellow or cinnamon-brown, ornamented with more or less numerous round white spots, base and sides ivory white.

Testa junior.

Testa junior flavescente-lacteo latifasciata, immaculata.

Yonnger shell encircled with broad bands of yellowish cream-colour, without spots.

Linneus, Syst. Nat. (12th edit.), p. 1178. Hab. Ceylon.

It is not literally correct to say that the back of this species is spotted; there is no deposite of spots, the last coat of cinnamon-brown colour being perforated, like a sieve, the white or cream coloured ground of the intermediate state is seen through each orifice. The two different shades generally observable in the colour, shows that the left mantle of the animal must be of unusually large proportion, whilst the right is small and feeble.

Species 82. (Fig. a and b, Mns. Saul.)

Cypr. testá ovatá, dorso multigranoso, granis latera versus prominentioribus, lateribus et extremitatibus foveolatis, dentibus per basem utrinque extensis; dorso lavendulo aut cinereo-violaceo, granis albidis, dentibus et extremitatibus vroceo-fuscescentibus, extremitatibus interdum purpureis, basi albicante.

The Grape-shot Cowrey. Shell ovate, back many-grained, grains more prominent towards the sides, sides and extremities pitted, teeth extended across the base on each side; back lavender or ashy violet, grains whitish, teeth and extremities yellowish brown, extremities sometimes purple, base whitish.

Variety β , Fig. 82 α .

Testa grandior, tenuior, dorso lævigato, maculis granorum locis.

Shell larger, thinner, smooth, with spots instead of grains. Linneus, Syst. Nat. (12th edit.), p. 1181.

Variety \(\beta\), Cypræa interstincta, Wood.

Varietas intermedia, Cypræa limacina, Lamarck.

Hab. Philippine Islands (all varieties); Cuming.

This I consider, without exception, the most variable species of the genus, so much so that I can only particularize the two extremes through which all the variations range. The typical variety (Fig. b.) is small and granulous, the opposite variety (Fig. a.) is smooth, the grains being replaced by spots, and larger, confirming with peculiar accuracy an observation in my Monograph of the Cones to the effect that all those varieties of shells in which the surface is raised in granules, are proportionally more diminutive in size. One of the most constant character throughout the varieties of this species is the yellowish-brown colouring of the teeth and extremities, indeed it is hard to distinguish some of the white varieties from the *C. nucleus* except by this peculiarity.

Species \$3. (Mus. Cuming.)

Cypr. Esta ovată, depressinsculă, lateribus extremitatibusque marginatis et foveolatis, dentibus fortiusculis, interstitiis profunde excavatis; dorso pallide olivaceo, punctis perpaucis albidis, guttis olivaceo-fuscis sparsis inæqualibus ornato; lateribus basique purpurascente-violaceis, purpureo lineatis et punctatis.

Lister's Cowrey. Shell ovate, rather depressed, sides and extremities marginated and pitted, teeth rather strong, interstices deeply excavated; hack pale olive, ornamented with a very few white dots, and a few scattered unequal olive-brown spots; sides and base pale purple-violet, dashed and dotted with purple.

GRAY, Zool. Journal, vol. 1. p. 507.

Hab. Philippine Islands; Cuming.

A beautiful species, and one of great rarity, well distinguished by its peculiarity of colouring.

90 a.

PLATE XVII.

Species 84. (Mus. Gaskoin.)

Cypr. EA Pulicaria. Cypr. testá subcylindraceo-oblongá, antice subdectivi, latere dextro marginato, leviter contracto, aperturá angustá, dentibus minutis; pellucidoalbá, vel luteá, lateribus dorsoque punctis rubido-fuscis subconspicuis aspersis.

THE FLEA-SPOTTED COWREY. Shell somewhat cylindrically oblong, somewhat steep anteriorly, right side marginated, slightly contracted, aperture narrow, teeth minute; transparent white or yellowish, sides and back sprinkled with rather conspicuous reddish-brown dots.

Reeve, Pro. Zool. Soc., 1845.

Hab. ---?

This is quite a distinct species from the *Cypræa piperata* with which I have frequently seen it mingled in collections; it is of a smaller and more cylindrically oblong form and is not banded, whilst the dots are more conspicuous.

Species 85. (Mns. Saul.)

Cypr. testå subpyriformi-ovatå, inflatå, spirå plano-depresså, latere dextro marginato, posticè producto, aperturå latiusculå, columellå labroque edentulis; albidå, dorso rubido-castaneo profusè picto, lateribus punctatis.

The TOOTILESS COWREY. Shell somewhat pyriformly ovate, inflated, spire flatly depressed, right side marginated, produced posteriorly, aperture rather wide, lip and columella toothless; white, back profusely painted with reddish-chesnut, sides dotted.

Sowerby, Conch. Illus. Cat. Cypræadæ, no. 102.
Cypræa (Luponia) Algoensis, var. Gray.

Hab. Southern Africa.

This shell, of which I have examined numerous examples, is specifically distinct from the *Cypræa Algoensis* without reference to the absence of teeth; it is of a shorter and more inflated growth, and the back is more conspicuously bedanbed with chesnnt colour.

Species 86. (Mus. Saul.)

CYPREA CAPENSIS. Cypr. testa ocata, profunde umbilicata, basi peculiariter depressa, lateribus conspicue marginalis, extremitalibus præcipue posticis productis, apertură semicirculari, columellă dorsoque liris rugaformibus parvis numerosissimis confertis superficiariis, labri dentes versus convergentibus tectis; sordide tuteo-fuscescente.

The Cape Cowrey. Shell ovate, deeply umbilicated, peculiarly depressed, sides conspicuously marginated, extremities, especially the posterior, produced, aperture crescent-shaped, columella and back covered with very numerous close-set small superficial wrinkle-like ridges, converging towards the teeth of the lip; dirty light yellowish-brown.

Gray, Wood Index Testaceologicus Supp. pl. 3. f. 18.
Cypræovula Capensis Gray.

Hab. Cape of Good Hope.

The ridges of this remarkable and, now, well-known species are of a curious superficial epidermal character, though converging round the lip with some solidity.

Species 87. (Mus. Saul.)

Cypræa Piperata. Cypr. testâ subpyriformi-ovatâ, latere dextro marginato, dentibus parvis; lutescente, dorso fusciis quaternis pallidè castaneis interruptis ornato, obscurè minutè punctato, lateribus punctatis.

The peppered Cowrey. Shell somewhat pyriformly ovate, right side marginated, teeth small; yellowish, back ornamented with four interrupted pale chesnut bands, obscurely minutely dotted, sides dotted.

SOLANDER, MSS.; Gray, Zool. Journal vol. i. p. 498. Cypræa angustala var. (f. 2. b.) Kiener.

Hab. New Holland.

The two central bands of this species are sometimes amalgamated into one of double width. It is of a more pyriform shape than that which I have distinguished by the new title of *Cypræa pulicaria*, and the painting and dotting are of quite a different character.

Species 88. (Mns. Sanl.)

Cypræa fusco-dentata. Cypr. testå subpyriformi-ovatå, posticè plano-depresså, subumbilicatå, marginibus sub-incrassatis, dentibus basem super rugoso-liratis, columellå lævigatå; lutescente aut sordidè albå, dentibus fuscis.

THE BROWN-TOOTH COWREY. Shell somewhat pyriformly ovate, posteriorly flatly depressed, slightly umbilicated, margins rather thickened, teeth rugose, ridged across the base, columella smooth; yellowish or dirty white, teeth brown.

Gray, Zool. Journal, vol. 1. p. 499. Hab. Cape of Good Hope.

No examples of this species appear to have come to hand in any better condition than that described more than twenty years ago by Mr. Gray, with the back entirely decorticated, but amply distinguished from any other at the base.

Species 89. (Mus. Cuming.)

Cypr. testá subpyriformi-ovatá, ventricosá, posticè plano-obtusá, crassiusculá, lateribus submarginatis, aperturá latiusculá, dentibus exterioribus
subdistantibus, basem versus partim elongatis, interioribus parvis numerosis irregularibus confertis; sordidè
albá, fuscescente spiram versus indistinctè sparsim maculato.

The similar Cowrey. Shell somewhat pyriformly ovate, ventricose, posteriorly flatly obtuse, rather thick, sides slightly marginated, aperture rather broad, outer teeth somewhat distant, partially elongated across the base, inner small, numerous, irregular, close-set; dead white, back indistinctly spotted here and there around the spire with pale brown.

Gray, Zoological Miscellany p. 36. *Hab.* Cape of Good Hope.

This is another remarkable shell from South Africa of which no other specimen has been seen. Like all the species from that locality figured in the accompanying plate, it is of an opake white, tinged with brown, without any porcellanous enamel.

Species 90. (Mus. Gaskoin.)

Cypr. testá oblongo-ovatá, postice depressiusculá, latere dextro marginato, postice producto, aperturá latiusculá, dentibus exterioribus subelongatis, interioribus parvis brevissimis; lutescente-lacteá, lateribus dorsoque rubido-fusco punctatis.

The Algoa Cowrey. Shell oblong-ovate, rather depressed posteriorly, right side marginated, produced posteriorly, aperture rather wide, onter teeth slightly elongated, inner small, very short; yellowish cream-colour, sides and back dotted with reddish brown.

Hab. Algoa Bay, South Africa.

The inner teeth of this species are rarely represented by anything more than a row of granular nodules.

Species 91. (Mus. Gaskoin.)

Cypr. testá ovatá, incrassatá, lateribus tumidiusculis, submarginatis, basi depressá, dentibus parvis, præcipuè interioribus: dorso cinereo-fusco, lateribus albicantibus, punctis grandibus castaneis conspicuè notatis, extremitatibus maculá castaneá utrinque pictis, basi albá.

The straightened Cowrey. Shell ovate, thickened, sides rather swollen, slightly marginated, base depressed, teeth small, especially the inner; back ashy brown, sides whitish, conspicuously marked with large chesnut brown dots, extremities painted on each side with a chesnut brown spot, base white.

Hab. New Holland.

Although a species comparatively not uncommon, the specimen here figured from the collection of Mr. Gaskoin is the only one I know that is not more or less worn, or uncoated. It has a bright enamelled porcellanous surface consisting of a layer of dark brown colouring matter, overlaid with a thin filmy coating of semi-opake cream colour.

Cspræa Pl.XVIII.

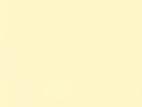

PLATE XVIII.

Species 92. (Mus. Saul.)

Cypr. FA FIMBRIATA. Cypr. testá oblongo-ovalá, lateribus submarginatis, medio leviter contractis, basi pluno-de-pressá, aperturá anticè hiante, dentibus parviusculis; albicante, dorso olivaceo-fusco minutissimè lentiginoso, maculá grandi centrali indistinctá, extremitatibus maculá conspicuá nigricante-violaceá utrinque ornalis.

The fimbriated Cowrey. Shell oblong-ovate, sides somewhat marginated, slightly contracted in the middle, base flatly depressed, aperture gaping anteriorly, teeth rather small; whitish, back very minutely freekled with olive brown, with a large indistinct central blotch, extremities onamented on both sides with a conspicuous dark violet spot.

GMELIN Syst. Nat. p. 2423.? Gray, Zool. Journal vol. 1. p. 383,

Hab. Japan (under stones) Dr. Siebold.

A species which is extremely variable in size, but always distinguishable by the dark violet spots on each side of the extremities.

Species 93. (Mus. Gaskoin.)

Cypr. Ea teres. Cypr. testá elongato-ovatá, latere dextro conspicuè marginato, basi peculiariter depresso, extremitatibus prominulis subrostratis, aperturá angustá, dentibus minutis; albicante, dorso maculis fuscescentibus undatis.

THE TAPERING COWREY. Shell elongately ovate, right side conspicuously marginated, peculiarly depressed at the base, extremities prominent, somewhat beaked, aperture narrow, teeth minute; whitish, back painted with three bands of waved pale brown spots, right side dotted with brown.

GMELIN; Sowerby Conch. Illus. Cat. Cypræadæ, no. 72. f. 56.

Cypræa tabescens, var. Gray.

Hab. ---?

I take this shell as the *Cypræa teres* of Gmelin on the authority of Mr. Sowerby, though it is somewhat doubtful; it is, however, a species distinct from the *C. tabesceus*, and one of great rarity. There are two specimens in the collection of Mr. Gaskoin.

Species 94. (Mus. Saul.)

Cypr. Ea Albuginosa. Cypr. testá oblongo-ovatá, extremitatibus subobtusis, dentibus brevibus; dorso fulvo, violaceo-fusco picto, occllis, numerosis albis, fusco-annulatis, ornato, lateribus violaceis, purpureo punctatis, basi violaceo-albá,

The white-eyed Cowrey. Shell oblong-ovate, extremities rather obtuse, teeth short; back fulvous, painted with violet-brown, ornamented with numerous white eyes encircled with brown rings, sides violaceous, dotted with purple, base violet-tinged white.

Mawe; Gray, Zool. Journal. vol. 1. p. 510. *Hab.* Califormia.

A richly painted violet and brown shell, closely studded with white eyes encircled with brown rings which are mostly thicker on one side than the other.

Species 95. (Mus. Cuming.)

Cypræa flaveola. Cypr. testå oblongå, lateribus marginatis et foveolatis, basi depresså, dentibus subelongatis; dorso luteo-fusco, ocellis albis variis profusè ornatis, marginibus atro-fusco tinctis et punctatis, basi albå.

The Yellowish Cowrey. Shell oblong, sides margined and pitted, base depressed, teeth somewhat elongated; back yellowish brown, profusely ornamented with white eyes of various sizes, margins stained and dotted with blackish brown, base white.

LINNEUS, Syst. Nat. p. 1179. (not of Born, or Lamarck.) Hab. ——?

Very closely allied to the following species, but differing by its more straightly oblong form, and absence of black rings. Care must be taken not to confound this shell with the *C. flaveola* of Lamarck, which is the *C. spurca*, or the *C. flaveola* of Born, which is the *C. rufa*.

Species 96. (Fig. a Mus. Cuming, Fig. b. Mus. Gaskoin.)

Cypr. Ea Gangrenosa. Cypr. testá subpyriformi-ovatá, lateribus marginatis et foveolatis, basi subplanidatá, dentibus subelongatis; dorso olivaceo, ocellis minutis albis, annulisque perpaucis fuscis ornato, extremitatibus atrofusco tinctis, basi albá. Species 97. (Mus. Cuming.)

Cypr. Lestá subpyriformi-ovatá, umbilicatá, dentibus subelonyatis; dorso albicante, lineis flavescentibus undatis longitudinaliter ornato, lateribus basique rufo-aurantiis nigro vividè punctatis.

The zigzag Cowrey. Shell somewhat pyriformly ovate, umbilicated, teeth rather elongated; back whitish, ornamented with longitudinal zigzag yellow lines, sides and base reddish orange brightly dotted with black.

Linneus, Syst. Nat. (12th edit.) p. 1177. Hab. Mozambique (under stones); Hennah.

There is a beautiful variety of this ancient, though not abundant, species, in which the zigzag lines resolve themselves into distinct bands. The base is very similar to that of the *Cypræa lutea*.

Species 98. (Mus. Cuming.)

Cypr. Está oblongo-ovatá, lateribus vix marginatis, dentibus subelongatis; eburneá, dorso fasciis tribus latis uigro-fuscis ornato.

The LITTLE ASS COWREY. Shell oblong-ovate, sides very slightly margined, teeth a little clongated; ivory white, back ornamented with three broad blackish-brown bands.

Linneus, Syst. Nat. (12th edit.) p. 1178. *Hab.* West Indies.

It is eurious to observe that the very characteristic dark bands of this species are not deposited at the last; they appear in all the earlier stages of growth winding round the columella, and in the adult are ent off, as it were, on each side by the superposition of a layer of ivory white.

Species 99. (Mus. Cuming.)

Cypr. A Poraria. Cypr. testá subabbreviato-ovatá, crassiusculá, lateribus subindistinctè foveolatis, dentibus subelongatis; extremitatibus obtusis; fulvá, dorso punctis albis numerosis, quibusdam fusco-annulatis, ornato, lateribus basique purpureo-violaceis.

The porous Cowry. Shell shortly ovate, thick, sides rather indistinctly pitted, teeth a little elongated, extremities obtuse; fulvous, back ornamented with numerous white dots some of which are encircled with brown rings, sides and base purple-violet.

LINNEUS, Syst. Nat. (12th edit.) p. 1180.

Hab. Taheite, Paeific Ocean (on the reefs); Cuming.

The painting of this species is very similar to that of the *Cypræa albuginosa*, but it may always be distinguished by its more diminutive and stunted form.

CypræPlAIX.

W = 12

PLATE XIX.

Species 100. (Mus. Saul)

Cypr. Ea Neglecta. Cypr. testá oblongo-ovatá, ad extremitates subdeclivi, lateribus submarginatis, dentibus elongatis; dorso cæruleo obscurè fasciato, punctis minutis fuscis maculáque grandi centrali, subquadratá, ornato, extremitatibus macula nigrá utrinque pictis, lateribus albis, nigro-punctatis, basi albá.

THE NEGLECTED COWREY. Shell oblong-ovate, steep at the extremities, sides slightly margined, teeth elongated, back blue, obscurely banded, ornamented with minute brown dots and a large central square spot, extremities painted with a black spot on each side, sides white, dotted with black, base white.

Sowerby, Conch. Illus. Cat. Cypræadæ no. 66, f. 12*. Hab. Mauritius.

Curiously intermediate between the *Cyprææ stolida* and *hirundo*, but quite distinct from either.

Species 101. (Mus. Saul.)

Cypr. La punctata. Cypr. testá ovatá, dentibus parvis, interdum brevibus, interdum per busem subelongatis : lacteá, dorso punctis fuscis asperso, extremitatibus et dentibus aureo-flavescentibus.

THE DOTTED COWREY. Shell ovate, teeth small, sometimes a little elongated across the base; cream-colour, back sprinkled with brown dots, teeth and extremities golden yellow.

LINNEUS Mantissa p. 54S.

Hab. Philippine Islands; Cuming.

Cypræa atomaria, Gmelin.

Cypræa stercus-muscarum, Lamarck.

There appears to be two very distinct states of this species, one in which the teeth are yellow and extend partially across the base, as represented in the accompanying figure: the other in which the teeth are very fine, short and colourless.

Species 102. (Mus. Cuming.)

Cypr. está oratá, dentibus brevibus, interioribus subobscuris; dorso cinereo-purpurascente fasciato, olivaceo parcè lentiginoso, maculá

fuscá grandi centrali irregulari, lateribus purpureo punctatis.

THE BLOOD-SPOTTED COWREY. Shell ovate, teeth short, the inner somewhat obscure; back banded with ashy purple, sparingly freckled with olive, with a large irregular brown blotch in the centre, sides dotted with purple.

GMELIN, Syst. Nat. p. 3406.

Hab. Mouth of the Gambia, Africa (under stones); Hennah.

A well-defined species which, though not uncommon, is rarely found in fine condition.

Species 103. (Mus. Cuming.)

Cypr. Está oblongo-ovatá, dentibus parvis; dorso olivaceo-viridi lentiginoso, maculis ni-gricante-olivaceis subquadratis trifasciatim ornato, lateribus basique albis.

THE INTERRUPTED COWREY. Shell oblong-ovate, slightly umbilicated, teeth small: back freckled with olive green, and ornamented with three bands of square dark olive spots, sides and base white.

GRAY, Zool. Journal, vol. i. p. 376.

Hab. Ceylon.

 $\cal A$ species well distinguished by three interrupted bands of oblong-square spots.

Species 104. (Mus. Cuming.)

Cypr. Es Hirundo. Cypr. testá oblongo-ovatá, dentibus subconspicuis; dorso viridescente-cæruleo nebulato et fasciato, punctis fuscis minutis asperso, lateribus fuscopunctatis, extremitatibus maculá nigricante-fuscá utrinque pictis, basi albidá.

The swallow Cowrey. Shell oblong-ovate, teeth rather conspicuous; back clouded and banded with greenish blue, sprinkled with minute brown dots, sides dotted with brown, extremities painted on each side with a blackish-brown spot, base whitish.

LINNEUS, Syst. Nat. (12th edit.) p. 1178.

Hab. Eastern Seas.

According to M. Deshayes, Lamarck confounded the Cypræa felina, and probably one or two other species,

with this. There is a marked variety of the *C. hirundo* in which the blue painting is obsolete and the brown dots more conspicuous and numerous; the *C. Owenii* Sowerby, which name he afterwards cancelled. The *C. ursellus* of Gmelin is thought to be a worn specimen of the *C. hirundo*.

Species 105. (Mus. Cuming.)

Cypr. testá oblongo-ovatá, lateribus submarginatis, basi depressiusculá, dentibus fortiusculis, subdistantibus; dorso viridi-cæruleo, latè trifasciato, punctis olivaceis ubique lentiginoso, lateribus flavicantibus, maculis nigris conspicuè ornatis, basi flavicante.

The CAT Cowrey. Shell oblong-ovate, sides slightly margined, base somewhat depressed, teeth rather strong; back greenish-blue, disposed in three broad bands, freckled all over with olive dots, sides yellowish, conspicuously ornamented with black spots, base yellowish.

Variety β (Fig. b.)

Testa abbreviala, gibbosa, dorso clevato.
Shell shortened, gibbous, back elevated.
GRAY. Zool. Journal, vol. 1. p. 384.

Variety β. Cypræa fabula, Kiener. Hab. — ?

The Variety β was specially noticed by Mr. Gray on his first introduction of the species in the Zoological Journal. It is a variation of growth common to many other species of the genus.

Species 106. (Fig. a Mns. Cuming; Fig. b Mns. Saul.)

Cypræa clandestina. Cypr. testâ ovatâ, umbilicatâ, dentibus fortibus subconspicuis; dorso incarnato-lacteo, obsoletè trifasciato, lineis rufis exilissimis, luc illic angulatim convergentibus, transversim ornato, lateribus basique eburneis.

THE CLANDESTINE COWREY. Shell ovate, umbilicated, teeth strong, rather conspicuous; back fleshy cream-colour, obsoletely three-banded, ornamented transversely with extremely faint red lines converging here and there to a point, sides and base ivory-white.

Linneus, Syst. Nat. (12th edit.) p. 1177.

Cypræa moniliaris, Lamarck.

Hab. Ceylon.

The faint transverse red hair-lines, converging here and there to a point, form an extremely characteristic feature in this species.

Species 107. (Mus. Saul,)

Cypr. testâ subcylindraceoovatâ, utrinque attenuato-rostratâ, dentibus subprominulis; dorso pallidè cærulescente, olivaceo minutissimè lentiginoso, extremitatibus macutâ nigricante-fuscâ conspicuè ornatis, basi albâ.

The four-spotted Cowrey. Shell cylindrically ovate, attenuately beaked at each end, teeth rather prominent; back pale blue, very minutely freekled with olive, extremities conspicuously ornamented with a blackish brown spot on each side, base white.

Gray, Zool. Journal. vol. 1. p. 377.

Hab. ——?

Although the *Cypraæ lirundo*, *cylindrica*, and a few others are characterized by the appearance of two dark spots at each extremity, they have not the same conspicuous aspect as in the species under consideration, on account of the pale delicate colouring of the shell. The *Cypræa quadrimaculata* is moreover peculiarly distinguished by the attenuated growth of its extremities.

Çrpræa PU

PLATE XX.

Species 108. (Mus. Cuming.)

Cypr. Lestâ globoso-inflatâ, tenui, subpellucidá, striis subtilibus elevatis, hic illic bifurcatis, creberrimè ornatâ; aperturâ amplâ, latâ, labro denticulato, denticulis subdistantibus; pallidè pellucidocarneâ.

The vesiculated Cowrey. Shell globosely inflated, thin, somewhat transparent, very closely ornamented with fine raised striæ, bifurcated here and there; aperture large, wide, lip finely toothed, teeth rather distant; pale transparent flesh-colour.

GASKOIN, Pro. Zool. Soc. 1835.

Hab. Cape of Good Hope.

Lest this interesting little species may be taken for the young of the *Cypræa oniscus*, it may be observed that the dorsal striæ are much more numerous and regular, whilst the denticulations of the outer lip are comparatively fewer in number. There is, moreover, no dorsal impression, and the striæ terminate less abruptly on the columella.

Species 109. (Mus. Cuming.)

Cypr. Es Costata. Cypr. testá globoso-oblongá, tenui, inflatá, subpellucidá, latere dextro subincrassato; striis subtilibus numerosis elevatis, raro interruptis, undique ornatá; aperturá amplá, latá; pallidè roseá, apice labroque albicantibus.

The Ribbed Cowrey. Shell globosely oblong, thin, inflated, rather transparent, right side slightly thickened; ornamented thronghout with numerous fine raised striæ, rarely interrupted; aperture large, broad; pale rose, lip and apex whitish.

GMELIN, Syst. Nat. p. 3418. no. 94. Cypræa (Trivia) carnea, Gray.

Cypræa rosea, Wood, Kiener.

Hab. --- ?

I follow M. Deshayes in referring this species to the *Cypræa costata* of Gmelin; but he has erred in stating that M. Kiener has taken it for a variety of the *Cypræa oniscus*.

Species 110. (Fig. α and b Mns. Walton. Fig. c Mus. Saul.)

CYPREA LUTEA. Cypr. testá subpyriformi-ovatá, umbilicatá,

lateribus marginatis, extremilatibus paululum reflexis; dorso lacteo-cæruleo, punctis luteo-fuscis irregulariter nebulatis, profusè inquinato, lateribus extremitatibus basique luteis aurantiisve, nigricante-fusco punctatis, dentibus pallidioribus.

The Yellow Cowrey. Shell somewhat pyriformly ovate, umbilicated, sides margined, extremities a little reflexed; back milky blue, profusely bedaubed with irregularly clouded yellowish-brown dots, sides, extremities, and base, yellow or orange, dotted with dark brown, teeth paler.

Variety β Fig. 110 c.

Testa parva, dorso olivaceo-fuscescente, zonis duabus angustis lacteo-cæruleis.

Shell small, back olive-brown, with two narrow milky blue zones.

Gronovius, Zoophylacium, fasc. 3. pl. xix. f. 17.

Cypræa Humphreysii, Gray.

Hab. ——?

l quite agree with M. Deshayes in identifying this interesting and rare species with the Cypræa lutea of Gronovius; the figure in the 'Zoophylacium' is perhaps a little obscure for want of colour, but the description, though short, is sufficiently characteristic;—"testa umbilicata, supra fuscescente albo-fasciata, subtus Intea punctis fuscis."

This well-known state of the shell must, however, be regarded as a variety, as we have it, in the collection of Mr. Walton, as represented at Fig. 110 a and b, of larger size and in a much more perfect and elaborately painted condition. The whole of the dorsal surface is a clear milky blue profusely bedaubed with light brown splashes, clouding one with the other.

An intermediate state has been represented by Sowerby in the Conchological Illustrations f. 55, copied so inaccurately by Kiener as to exhibit a dot-banded character entirely foreign to the species.

Species 111. (Mus. Saul.)

Cypr.ea oniscus. Cypr. testá globoso-ovatá, valdè inflatá, latere dextro incrassalo; striis elevalis aut vesiculis bifurcatis et rugatis ornatá, impressione lævi dorsali centrali; aperturá amplá, latissimá; columellá lævi; dorso rosaceo-carneo, basi albicante.

The wood-louse Cowrey. Shell globosely ovate, very much inflated, right side thickened; ornamented with bifurcated and wrinkled raised strize or vesicles, with a smooth central dorsal impression; aperture large, very wide; columella smooth, back pinkish flesh-colour, base whitish.

LAMARCK, Anim. sans vert. (Deshayes' edit.) vol. x. p. 541.

Cypræa (Trivia) aperta, Gray.

Hab. Cape of Good Hope.

Neither of the figures in Lister and Martini to which Lamarck refers for the illustration of this species can be possibly identified with his description. The former, as M. Deshayes has already shown, represents the C. radians, and there is very little doubt but that the latter is intended for the same species, to which the terms "globosâ, inflatâ, albido-carneâ, immaculatâ, ventre convexâ, aperturâ latissimâ" do not apply. They apply on the other hand with such peculiar accuracy to the species under consideration, it is strange the confusion has never been detected by Euglish writers on the genus.

Species 112. (Mus. Cuming.)

Cypræa ovula. Cypr. testå ovato-ventricoså, inflatå, labro dextro incrassato; undique tævigatå, dentibus interioribus minimis, aperturå latissimå; niveå, aut rosaceo pallidè tinctå.

The oval Cowrey. Shell ovately ventricose, inflated, right lip thickened; smooth throughout, inner teeth very small, aperture very wide; snowy white, or faintly tinged with pink.

LAMARCK, Anim. sans vert. (Deshayes' edit.) vol. x. p. 533. Cypræa carnea var, Gray.

Hab. —— ?

Cypræa ovulata was the name first given to this shell by Lamarck, but finding, probably, that it had been already used by Gmelin in reference to the C. cervus, he dropped the last syllable for the sake of distinction, though both terms are sufficiently corrupt. The species is a very characteristic one, and may be easily recognised by its smooth surface.

Cypræa Pl. XII

PLATE XXI.

Species 113. (Mus. Cuming.)

Cypr. Está ovatá, subventricosá, basi lateribusque rotundatis, dorso medio impresso, utrinque nodoso, costis e nodis divergentibus, dentibus exterioribus minutissimis; cinereo-fuscá.

Solander's Cowrey. Shell ovate, rather ventricose, base and sides rounded, back impressed down the middle, noduled on each side, with ribs diverging from the nodules, outer teeth very minute; ashbrown.

Gray; Sowerby, Conch. Illus. Cat. Cypræadæ, no. 128.

Hab. California.

This species may be easily distinguished from the Cypræa radians by its minute row of outer teeth, there being an intermediate one between each of those terminating the ribs: it is, moreover, distinct in form, being uniformly smaller and more rounded at the base. Mr. Sowerby says "it is impossible to know which of the two is the radians of Lamarck"; but I think Lamarck's expression "lateribus dilatatis depressis, ventre plano" fully decisive.

Species 114. (Mus. Cuming.)

Cypræa annulata. Cypr. testå oblongo-ovatå, crasså, solidå, extremitatibus subrostratis, lateribus basique rotundatis, aperturå subflexuoså, angustå, dentibus minutissimis, eburneå, dorso maculis rotundis luteis saturatè annulatis, irregulariter picto.

The RINGED Cowrey. Shell oblong-ovate, thick, solid, extremities somewhat rounded, aperture slightly flexuous, narrow, teeth very minute, concavity of the columella deep; ivory-white, back irregularly painted with round yellow spots encircled with rings of a deeper yellow.

GRAY, Zool. Journal, vol. iv. p. 88.

Hab. Isle of Annaa, Pacific Ocean (on the reefs); Cuming.

Distinguished from all other species by its solid obesity and very characteristic style of painting.

Species 115. (Mus. Cuming.)

Cypr. Estű cylindraceo-oblonyá, undique transversim crebricostatá, basi subdepressá, aperlurá angustá, dentibus minutis, dorso medio exiliter impresso, extremitatibus rostratis, infra carinato-alatis; pallidè luteo-fuscescente, costis saturatioribus.

CHILDREN'S COWREY. Shell cylindrically oblong, transversely closely ribbed throughout, base a little depressed, aperture narrow, teeth minute, back faintly impressed down the middle, extremities beaked, carinately winged beneath; pale yellowish brown, ribs darker.

Gray, Zool. Journal, vol. i. p. 518.

Hab. 1sle of Annaa, Pacific Ocean (on the reefs); Cuming.

This is the only species at present known with the peculiar wing-like appendages, above described, at the base of the extremities.

Species 116. (Mus. Cuming.)

Cypr. Está ovatá, turgidá, dorso peculiariter elevato, granuloso, medio sulco lineari impresso, aperturá augustá, dentibus subelongatis, extremitatibus rostratis, productis; luteá aut fulco-albicante, dorso fusco irregulariter maculatá, lateribus fusco-punctatis, basi muculis quaternis castaneis conspicuê pictá.

The chick-pea Cowrey. Shell ovate, turgid, back peculiarly clevated, granulous, impressed with a linear groove down the middle, aperture narrow, teeth rather clongated, extremities beaked, produced; yellow or fulvous white, back irregularly blotched with brown, sides dotted with brown, base conspicuously painted with four chesnut spots.

LINNÆUS, Syst. Nat. (12th edit.) p. 1181.

Hab. Isle of Annaa, Pacific Ocean (on the reefs); Cuming.

The back of this species is peculiarly elevated and granulous, whilst the base presents a characteristic feature in the four chesnut spots.

Species 117. (Mus. Cuming.)

CYPRÆA RADIANS. Cypr. testá rotundato-ovatá, tateribus dilatutis, basi depressá, extremitatibus retusis, dorso medio latiusculè impresso, utrinque nodoso, costis e nodis divergentibus; cinereo-fuscá, dorso maculá nigricante tincto.

THE RADIATING COWREY. Shell rotundately ovate, sides

dilated, base depressed, extremities blunt, back rather broadly impressed down the middle, nodose on each side, with ribs diverging from the nodules; ash-brown, back stained with a blackish blotch.

LAMARCK, Anim. sans vert. vol. x. p. 540.

Hab. St. Elena, West Columbia (under stones); Cuming. Characterized by its depressed growth and dilated margin.

Species 118. (Mus. Cuming.)

Cypr. Está cylindraceo-oblongá, dorso lævi, sulco obsoleto aut nullo, aperturá angustá, dentibus subclongatis, extremitatibus rostratis, productis; dorso fulvo-luteo, fusco subobscurè punctato, lateribus extremitatibusque rufo-aurantiis.

The LITTLE GLOBE COWREY. Shell cylindrically oblong, back smooth, dorsal groove obsolete or entirely wanting, aperture narrow, teeth rather elongated, extremities beaked, produced; back fulvous yellow, rather obscurely dotted with brown, sides and extremities reddish orange.

LINNÆUS, Syst. Nat. (12th edit.) p. 1181. Hab. East Indies.

Fully distinguishable from the Cypræa cicercula, to

which it so nearly approximates in general appearance, by the absence of the dorsal groove, the granules, and the four chesnut spots of the base; it is also of a more oblong cylindrical form.

Species 119. (Mns. Saul.)

Cypr.æa Maugeriæ. Cypr. testå subpyriformi-ovatå, latere dextro marginato, posticè subproducto, undique transversim creberrimè costatå, costis subirregulariter flexuosis, interstitiis scabriusculis, dorso medio lineari-impresso; fulvo-rosaceå, dorso maculå grandi fuscescente obscurè tincto, latere dextro rosaceo.

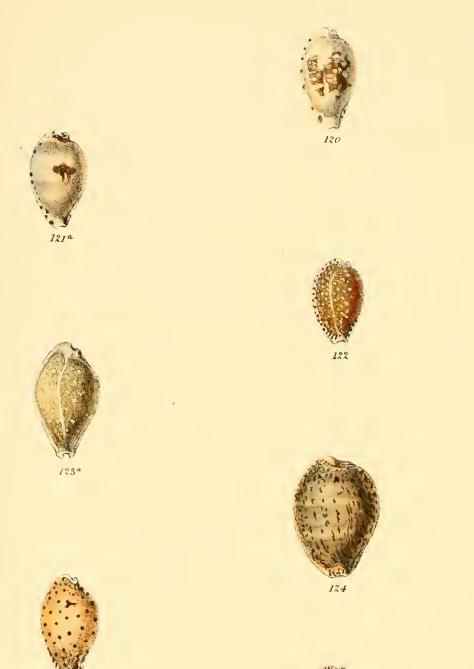

MAUGER'S COWREY. Shell somewhat pyriformly ovate, right side margined, a little produced posteriorly, transversely very closely ribbed throughout, ribs somewhat irregularly flexuous, interstices roughish, back impressed down the middle with a narrow groove; fulvous rose colour, back obscurely stained with a large faint brown blotch, right side pink.

Gray; Sowerby, Conch. Illus. Cypræadæ, no. 111. f. 30. *Hab.* Gallapagos Islands; Cuming.

An extremely delicate species of which the fine example here figured from the collection of Miss Saul is larger than any other specimen 1 have seen.

Cypriew, PLXXII.

reve Jir thers, imp

PLATE XXII.

(All magnified to twice their length except Fig. 122 and 124.)

Species 120. (Mus. Cuming.)

Cypr. £A Goodalli. Cypr. testá oblongo-ovatá, lateribus submarginatis, basi depressá, dentibus parvis; niveá, dorso maculá grandi irregulari aurantio-fuscá picto, lateribus fusco-punctatis.

margined, base depressed, teeth small; snowy white, painted with a large irregular orange-brown blotch, sides dotted with brown.

FRAY; Sowerby, Conch. Illus. Cypræadæ. no. 76. f. 16.
Hab. Lord Hood's Island, Pacific Ocean (on the sands);
Cuming.

A delicate snowy white shell conspicuously stained on he back with a large square irregularly reticulated bright range-brown blotch.

Species 121. (Mus. Gaskoin.)

YPRÆA CONTAMINATA. Cypr. testá subpyriformi-ovatá, lateribus submarginatis, dentibus parvis, extremitatibus subproductis, reflexis; dorso carneo-fuscescente subobscurè fasciato, minutissimè pallidè fusco-punctato, maculá fuscá centrali, lateribus basique fusco conspicuè punctatis.

HE DISTAINED COWREY. Shell somewhat pyriformly ovate, sides slightly margined, teeth small, extremities rather produced, reflexed; back fleshy brown, obscurely banded, dotted with pale brown, with a central brown spot, base and sides conspicuously dotted with dark brown.

RAY; Sowerby, Conch. Illus. Cypræadæ no. 96. f. 21.

An interesting well-defined species in the collection of r. Gaskoin of which Mr. Cuming also possesses an exple.

Species 122. (Mus. Brit.)

(Natural size.)

YPRÆA GASKOINI. Cypr. testá subabbreviato-ovatá, solidiusculá, lateribus incrassatis, marginatis, dentibus fortiusculis; dorso fulvo-stramineo, ocellis albidis. fusco annulatis, parviusculis, sparsim ornato, lateribus castaneo-punctatis, basi albá.

Gaskoin's Cowrey. Shell somewhat shortly ovate, rather solid, sides thickened, margined, teeth rather strong; back yellowish straw-colour, sparingly ornamented with rather small white eyes, encircled with pale brown rings, sides dotted with chesnut, base white.

Reeve, Pro. Zool. Soc. 1846. Hab.——?

This interesting species of which I have seen two specineus, one in the British Museum and one in the collection of Mr. Gaskoin, partakes of the characters of the Cyprea Cumingii and esontropia, bearing such a relation to the former as the latter does to the C. cribraria. The sides are stoutly thickened and spotted like the C. esontropia, and the back is covered with the same kind of small clear ringed eyes as the C. Cumingii. As the accompanying figure has rather a diminutive appearance in comparison with the surrounding species, it may be as well to call attention to the circumstance of the outer figures of this plate being considerably magnified, whilst the two in the centre are of the natural size. I dedicate it with a great deal of pleasure to J. S. Gaskoin Esq., a gentleman to whom we are much indebted not only for the liberal use of a collection of Cyprææ exhibiting almost every imaginable variety of growth and colour of each species, but for his essential services in working out the small ribbed kinds which constitute Mr. Gray's genus Trivia.

Species 123. (Mus. Cuming.)

Cypr. A Margarita. Cypr. testá pyriformi-ovatá, lateribus submarginatis et foveolatis, extremitatibus rostratis, productis, aperturá subflexosá, angustá, dentibus parvis; pallidè stramineá; dorso ocèllis albis grandibus parvisque, lineá dorsali pallidá flexuosá, profusè ornato, basi eburneá, immaculatá.

The pearl Cowrey. Shell pyriformly ovate, sides slightly margined and pitted, extremities beaked, produced, aperture rather flexuous, narrow, teeth small; pale straw-colour, back profusely ornamented with large and small white eyes, with a pale flexuous dorsal line, base ivory white, unspotted.

Solander; Gray, Zool. Journal vol. iv. p. 87.

Hab. Isle of Annaa, Pacific Ocean (on the reefs); Cuming.

This extremely delicate and graceful species appears to have been known to 'old Humphrey' as 'The pearl-porcelain Cowrey'. The peculiarity in its style of painting is that there are two distinct systems of spots of different magnitude, which are not cucircled with rings.

Species 124. (Mus. Gaskoin.)

(Natural size.)

Cypr. está ovato-ventricosá, interdum oblongá, lateribus subincrassatis, dentibus breviusculis; dorso cinereo-fusco, trifasciato, punctis oblongis atris interdum longitudinaliter picto, lateribus carneis, punctis atris numerosis peculiariter confusè inquinatis, basi flavicante, dentium interstitiis roseo-carneis.

The ash Cowrey. Shell ovately ventrieose, sometimes oblong, sides rather thickened, teeth rather short; back ash-brown, three-banded, sometimes longitudinally painted with jet black oblong dots, sides flesh-tinged, peculiarly confusedly stained with numerous jet black dots, base yellowish, interstices between the teeth pinkish flesh-colour.

GMELIN, Syst. Nat. p. 3402.

Eadem, Cypræa sordida Lamarek.

Hab. West Indies (under stones); Guilding.

The black-dotted painting which so strongly characterthis species is perhaps less constant than the pinkish fleshcolouring between the columellar teeth, of which I have invariably noticed indications where the first-mentioned character was wanting.

Species 125. (Mus. Cuming.)

Cypr. Ea Beckii. Cypr. testá subpyriformi-ovatá, lateribus submarginatis et foveolatis, extremitatibus subrostratis et reflexis, aperturá subflexuosá, dentibus parvis, fortiusculis; fulvá, dorso ocellis grandibus parvisque albis ornato, ocellis grandibus castaneo pupillatis, late ribus castaneo-punctatis, basi ad dentes exteriores cas taneo lineo-punctatá.

BECK'S COWREY. Shell somewhat pyriformly ovate, side slightly margined and pitted, extremities a little beaked and reflexed, aperture rather flexuous, teetl small, rather strong; fulvous yellow, back orna mented with large and small white eyes, of which the large are pupilled with chesnut, sides dotted with chesnut, linearly dotted at the outer teeth with chesnut brown.

Gaskoin, Pro. Zool. Soc. 1835.

The C. Beckii approximates very closely in form to the C. margarita, and like that species it has two distinct size of white eyes; it differs, however, in having the range of larger spots pupilled with chesnut brown, the sides dotted with chesnut-brown, and the outer teeth each marked of the base with a chesnut-brown linear dot. In a specime kindly remitted to me by M. Deshayes the form is less pear-shaped and the extremities more obtuse.

Species 126. (Mus. Cuming.)

Cypr.ea irrorata. Cypr. testá ovato-oblongá, lateriba submarginatis, basi depresso-planá; dorso pallidè pur pureo-cærulescente, obscurè fasciato, punctis numeros fulvo-fuscis, latera versus saturatioribus, copiosè au sperso, basi albidá, immaculatá.

The bedewed Cowrey. Shell ovately oblong, side slightly margined, base depressly flattened; bac pale purple-blue, obscurely banded, eopiously sprint led with fulvous brown spots which are darker in colour towards the sides, base whitish, unspotted.

Solander; Gray, Zool. Journal, vol. iv. p. 80. Hab. Elizabeth Island (on the sands); Cuming.

It would be difficult to confound this with any oth species, so peculiar is it both in form and style of colouring.

PLATE XXIII.

(All magnified to twice their natural length).

Species 127. (Mus. Cuming.)

Cypr. Es Anguinea. Cypr. testá ovatá, dorso elevato, lateribus dilutatis, radiatim costatá, impressione dorsali vix nullá; nigricante-purpureo-fuscá, dorso maculá sauguineá, ntrinque albidá, medio tincto.

The blood-stained Cowrey. Shell ovate, back elevated, sides dilated, radiately ribbed, with scarcely any dorsal impression, blackish purple-brown, back stained in the middle with a blood-red spot, whitish on each side.

Gray; Sowerby, Conch. Illus. Cypræadæ, no. 115. f. 32.

Trivia sanguinea, Gray.

Hab. St. Elena, West Columbia (under stones); Cuming.

A very dark purple-brown shell with a blood-stain, whitish at each end, in the middle.

Species 128 (Mus. Cuming.)

Cypr. E. Californica. Cypr. testa ovata, subglobosa, lateribus vix dilatatis; undique costata, costis subdistantibus, impressione dorsali vix nulla; purpureo-fusca, dorso medio pallido, dentibus albidis.

The Californian Cowrey. Shell ovate, rather globose, sides scarcely dilated; ribbed throughout, ribs rather distant, with scarcely any dorsal impression; purple-brown, back pale in the middle, teeth whitish.

GRAY, Zool. Journal, vol. iii. p. 365.

Trivia Californica, Gray.

Hab. California.

Distinguished from the preceding species by its smaller and more rounded form, whilst the ribs are stouter and wider apart.

Species 129. (Mus. Cuming.)

Cypr. Europ.ea. Cypr. testá ovatá, subventricosá, tatere dextro submarginato; transversim undique crebricostatá, impressione dorsali nullá; carneo-fulvá, fusco, præcipuè prope apicem, sparsim maculatá, busi allá.

THE EUROPEAN COWREY. Shell ovate, somewhat ventricose, right side slightly margined; transversely closely ribbed throughout, with no dorsal impression,

flesh-tinged fulvous, sparingly spotted, especially near the apex, with brown, base white.

Montagu, Testacea Britannica, Supp. p. 88.

Cypræa coccinella, Lamarek.

Trivia Europæa, Gray.

Varietas pallida immaculata.

Cypræa arctica, Montagu.

Testa juvenis pellucida.

Cypræa bullata, Montagu.

Hab. Shores of Britain, &c.

The spots of this well-known species are very undefined; it may, however, be observed, that it is generally most deeply stained in the vicinity of the apex.

Species 130. (Mus Gaskoin.)

Cypr. Labiosa. Cypr. testa rotundato-ovata, subdepressa, lateribus dilatatis et marginatis, extremitatibus retusis; dorso medio sulcato, utrinque nodoso, costis fortiusculis, subdistantibus, e nodis divergentibus; dorso carueo-fuscescente, maculis senis nigricantibus ornato, lateribus basique cinereo-fuscis, costis albicantibus.

The full-lipped Cowrey. Shell rotundately ovate, rather depressed, sides dilated and margined, extremities retuse, back grooved down the middle, noduled on each side, with rather strong and somewhat distant ribs diverging from the nodules; back fleshy brown, ornamented with six dark spots, sides and base ash-brown, ribs whitish.

Gaskoin, Pro. Zool. Soc. 1835.

Hab. ——?

I am rather inclined to think, with M. Gaskoin, that this shell is distinct from the *C. pediculus*; without reference to its more depressly dilated form and difference of colour, the ribs are much fewer in number, and developed with greater force and regularity.

Species 131. (Mus. Cuming.)

Cypr. Lesta ovata, subventricosa, lateribus submarginatis, dorso medio sulcato, utrinque noduloso, costis subtiliusculis numerosis e nodulis divergentibus; carueo-albicante, facescente, præcipuè ad

latera, marmoratá et punctatá, dorso maculis senis nigricantibus ornato.

THE LOUSE COWREY. Shell ovate, rather ventricose, sides slightly margined, back grooved down the middle, nodulous on each side, with numerous rather fine ribs diverging from the nodules; fleshy white, marbled and dotted, especially towards the sides, with pale brown, back ornamented with six black blotches.

LINNEUS, Syst. Nat. (12th edit.) p. 1180.

Cypræa sulcata, Dillwyn.

Trivea pediculus, Gray.

Hab. West Indies.

Linnæus may have confounded two or three species under this head, but I think his specific name should be reserved for that which is without doubt the type of the group.

Species 132. (Mus. Cuming.)

Cypr. testá globosá, tenui, subinflatá, latere dextro submarginato, undique transversim creberrimè tenuicostatá; roseo-albicante, sericeo-nitente, dorso carneo-fuscescente pallidissimè tincto, basi albá.

THE BEAUTIFUL COWREY. Shell globose, thin, rather inflated, right side slightly margined, transversely very closely finely ribbed throughout; pinkish white,

shining like silk, back very faintly stained with fleshy brown, base white.

GASKOIN, Pro. Zool. Soc. 1835.

Hab. Cape of Good Hope.

A very characteristic species distinguished from the C. Europxa by its globose and more inflated growth and finer ribs, whilst there is a marked peculiarity in the delicacy of its colouring.

Species 133. (Mus. Saul.)

Cypræa depauperata. Cypr. testá suborbiculari, depressá, lateribus dilatatis, subincrassatis, extremitatibus retusis, dentibus subtilibus, dorso medio lineari-sulcato, costis subdistantibus utrinque divergentibus; pallidè cinereo-fuscá, immaculatá, basi carneo-tinctá.

THE IMPOVERISHED COWREY. Shell nearly orbicular, depressed, sides dilated, rather thickened, extremities retuse, teeth fine, back linearly grooved down the middle, with rather distant ribs diverging on each side; pale ash-brown, unspotted, base flesh-tinged.

Sowerby, Conch. Illus. Cypræadæ, no. 130. f. 49. Hab. ——?

Allied to the *C. radians*, but differing in that the dorsal groove is perfectly linear, without nodules on either side; and it is of a paler ash colour.

Cypraea, Pl. XAIV.

136

137 a.

140.

PLATE XXIV.

(All magnified to twice their natural length.)

Species 134. (Mus. Gaskoin.)

Cypr. A fusca. Cypr. testâ ovatâ, latere dextro subincrassato, transversim undique costutâ, costis tenuibus impressione dorsali obsoletâ; undique fuscâ.

THE BROWN COWREY. Shell ovate, right side slightly thickened, transversely ribbed throughout, ribs fine, with an obsolete dorsal impression; brown throughout.

Gray: Sowerby, Conch. Illus. Cypræadæ, no. 120. f. 37.

Trivea fusca, Gray.

Hab. Gallapagos Islands, and Bay of Guayaquil; Cuming.

There is some character in the colouring of this species, it being of an uniform dull brown without any tinge of that dark crimson which is so conspicuous in the *C. sanguinea*.

Species 135. (Mus. Cuming.)

Cypr. EA Adamsonii. Cypr. testă Ovuliformi, solidiusculă, tatere dextro crasso, marginato; transversim undique crebricostată, costis lævibus, extremitatibus subrostratis, productis; albă, aurantio-fusco conspicue maculată.

Adamson's Coursey. Shell Ovulum-shaped, rather solid, right side thick and margined; transversely closely ribbed throughout, ribs smooth, extremities slightly beaked, produced; white, conspicuously blotched with orange-brown.

GRAY; Sowerby, Conch. Illus. Cypræadæ, no. 107. f. 7. Hab. Isle of Capul, Philippines; Cuming.

An extremely characteristic species and the nearest approach in form to the genus *Ovulum*.

Species 136. (Mus. Cunning.)

Cypr. Ea nivea. Cypr. testá globosá, extremitatibus valde obtusis, transversim undique costatá, costis angustis, corrugatis, subprominentibus, dorso sulco lineari impresso; pellucido-albá.

The snow-white Cowrey. Shell globose, extremities very obtuse, transversely ribbed throughout, ribs narrow, wrinkled, rather prominent, back impressed with a linear groove; transparent white.

GRAY; Zool. Journal. vol. iii. p. 369.

Hab. --- ?

This species has a peculiar globose form, very like that of a coffee-berry. M. Kiener has figured a C. nivea for the C. scabriuscula of Gray, which is Lamarck's C. oryza.

Species 137. (Mus. Gaskoin.)

Cypr. Estú ovatá, lateribus subdilatatis, extremitatibus peculiariter productis, basi depressá, columellá acutangulá; transversim undique tenuicostatá, impressione dorsali nullá; albá.

The produced Cowrey. Shell oyate, sides a little dilated, extremities peculiarly produced, base depressed, columella sharp-angled; transversely finely ribbed throughout, with no dorsal impression; white.

Gaskoin, Pro, Zool. Soc., 1835, p. 200.

Hab. ---- ?

A white shell of very peculiar form, approximating nearest to that of the brown *Cypræa sanguinea*.

Species 138. (Mus. Saul.)

Cypr. testá obtongo-ovatá, tenuiculá, paululum inflatá, apice subconspicuo, latere dextro marginato; transversim undique tenuissimè costatá, costis supra lævibus, subobsoletis, impressione dorsati nullá, aperturá subamplá; albidá, dorso maculis fuscescentibus grandibus duabus vel tribus subirregulariter picto, extremitatibus roseis.

The southern Cowrey. Shell oblong-ovate, rather thin, a little inflated, apex rather conspicuous, right side marginated; transversely very finely ribbed throughout, ribs smooth above, rather obsolete, with no dorsal impression, aperture rather wide; whitish, somewhat irregularly painted with two or three light brown blotches, extremities tinged with rose.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol.x. p. 545.

Trivia australis, Grav.

Hab. New Holland.

Distinguished by its colouring and light inflated growth.

Species 139. (Mus. Gaskoin.)

Cypr. Lestá subelongato-ovatá, planoumbilicatá, anticè subattenuatá et rostratá, lateribus marginatis, basi depressá, aperturá flexuosá, dentibus brevibus minutis; albá, dorso lineis undatis aurantiofuscis concinnè trifusciato, extremitatibus utrinque roseis.

The small-tooth Cowrey. Shell somewhat elongately ovate, flatly umbilicated, anteriorly rather attenuated and beaked, sides margined, base depressed, aperture flexuous, teeth minute; white, encircled with three

ing.

CYPRÆA.—PLATE XXIV.

neat bands of waved orange-brown lines, extremities tipped on each side with pink.

Gray, Zool. Journal, vol. iv. p. 71.

Hab. Isle of Ticao, Philippines; Cuming.

Care should be taken not to confound a small variety of the *C. fimbriata* with this species, which is distinguished from it by its attenuated form, minute teeth and peculiarity of colouring.

Species 140. (Mus. Gaskoin.)

Cypr. Está ovatá, latere dextro vix marginato, transversim undique tennissimè costatá, costarum interstitiis peculiariter scabris, impressione lineari dorsali ; niveã.

THE RICE-GRAIN COWREY. Shell ovate, right side scarcely margined, transversely very finely ribbed throughout, interstices between the ribs peculiarly rough, with a linear dorsal impression; snowy white.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol. x. p. 543. Cypræa scabriuscula, Gray.

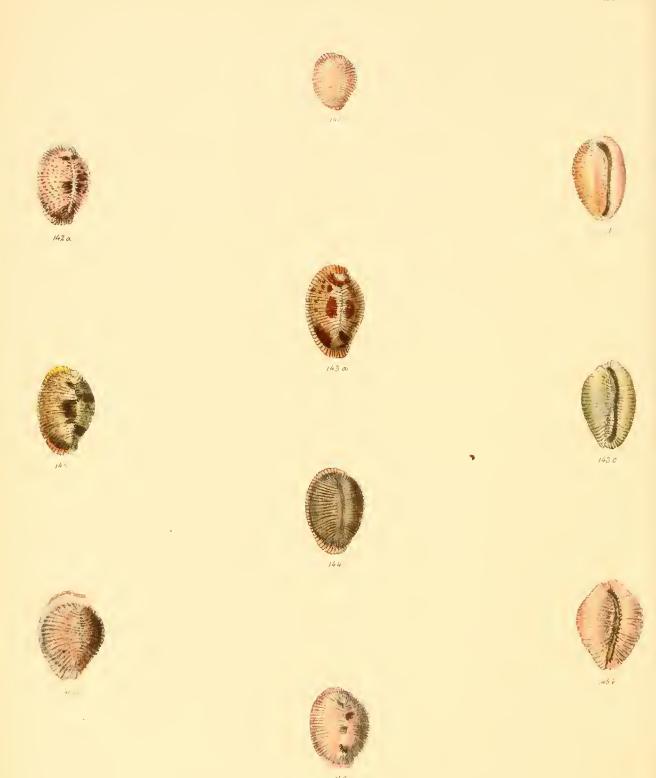

Varietates?

Cypræa hordacea and intermedia, Kiener.

Hab. Isle of Ticao, Philippines; Cuming.

Of a rounded oblong oval form, the rihs being very fine, and the interstices of a peculiarly roughish character.

Sowerby delethth

PLATE XXV.

(All magnified to two and a half times their natural length.)

Species 141. (Mus. Gaskoin.)

Cypr. Lestá globoso-ovatá, latere dextro incrassato, marginato, transversim undique tenui-costatá, columellá concavá, acutangulá, impressione dorsali nullá; rubescente vel pallidè roseá, basi albicante.

The Reddish Cowrey. Shell globosely ovate, right side thickened, margined, transversely finely ribbed throughout, columella hollow, sharp-angled, with no dorsal impression; pale red or pink, base whitish.

GRAY; Pro. Zool. Soc., 1832, p. 185.

Hab. Galapagos Islands (under stones); Cuming.

The C. rubescens is rather a solid shell than otherwise.

Species 142. (Mus. Cuming.)

Cypr.æa suffusa. Cypr. testá oblongo-ovatá, latere dextro extremitatibusque marginatis, transversim undique tenuicostatis, costis vix yranosis, sulco dorsali conspicuo; roseo-albicante, costis fusco promiscuè variegatis et punctatis, extremitatibus roseis, basi albidá.

The sprinkled Cowrey. Shell rather oblong-ovate, right side and extremities slightly thickened and margined, transversely finely ribbed throughout, ribs scareely granose, with a conspicuous dorsal groove; pinkish-white, ribs promisenously variegated and dotted with brown, extremities pink, base whitish.

Gray; Sowerby, Conch. Illus. Cypræadæ, no. 126. f. 41. Cypræa armandina, Duclos.

Hab. Gallapagos Islands; Cuming.

Distinguished by the sprinkled brown painting of the ribs.

Species 143. (Mus. Cuming.)

Cypr.æa Pacifica. Cypr. testű oblongo-ovatá, latere dextro submarginato, extremitatibus leviter productis, basi depressá; transversim undique costatá, costis tenuibus subcorrugatis, sulco dorsali conspicuo; dorso pallidè cinereo aut fuscescente, punctis maculisque fuscis ad utrumque latus sulci dorsalis alternantibus suffuso, extremitatibus roscis, basi albicante.

The Pacific Cowrey. Shell oblong-ovate, right side slightly margined, extremities a little produced, base depressed, transversely ribbed throughout, ribs fine, rather wrinkled, with a conspicuous dorsal groove; pale ash or very light brown, back suffused with brown dots and spots alternating on each side the dorsal groove, extremities pink, base whitish.

GRAY, Pro. Zool. Soc., 1832.

Hab. Gallapagos Islands (under stones); Cuming.Well characterized by the alternating spots.

Species 144. (Mus. Gaskoin.)

Cypr. testá ovalá, latere dextro submarginato, transversim undique subtilissimè costatá, costis supra lævibus vel obsoletis, impressione dorsali vix nullá; dorso cinereo-fusco, lateribus basique albis.

The flea Cowrey. Shell ovate, right side a little margined, transversely very finely ribbed throughout, ribs smooth or obsolete at the top with scareely any dorsal impression; back ashy brown, sides and base white.

Solander, MSS.; Gray, Zool. Journ., vol. iii. p. 368. *Hab.* Mediterranean.

This well-known species exhibits a great deal of character in the smoothness of the dorsal ribs.

Species 145. (Mus. Gaskoin.)

CYPR.EA RUBINICOLOR. Cypr. testá globoso-ovatá, crassiusculá, latere dextro incrassato marginato, extremitatibus obtuso-productis, transversim undique costatá, costis tenuissimis impressione dorsali nullá; roseo-carneá, extremitatibus pulchrè roseo-rubris.

The Red-Coloured Cowrey. Shell globosely ovate, rather thick, right side thickened, margined, extremities obtusely produced, transversely ribbed throughout, ribs very fine, with no dorsal impression; pinkish flesh-colour, extremities prettily tinged with rose-red. Gaskoin, Pro. Zool. Soc., 1835.

Hab. —— ?

This is without doubt a very distinct species; it may have somewhat the form of the *C. sanguinea*, but in colour and in the structure of the ribs it is quite dissimilar.

Species 146. (Mus. Cuming.)

CYPRÆA QUADRIPUNCTATA. Cypr. testå rotundato-ovatå, extremitatibus obtusis, transversim undique subtilissimè costatå, sulco lineari dorsali; pellucido-roseå, dorso punctis rubidis quaternis conspicuis, quarum duabus ad utrumque latus sulci dorsalis alternantibus, ornato.

The four-dotted Cowrey. Shell rotundately ovate, extremities obtuse, transversely very finely ribbed, with a linear dorsal groove; transparent rose, back ornamented with four conspicuous red dots, two on each side the dorsal groove, alternating one with the other.

Gray, Zool. Journal, vol. iii. p. 368.

Cypræa rotunda, Kieuer.

Hab. Philippine Islands; Cuming.

Easily distinguished by the four dorsal red dots.

PLATE XXVI.

Species 147. (Mus Gaskoin.)

Cypr. estâ rotundato-ovatâ, tatere dextro marginato, extremitatibus obtuso-rostratis; transversim subtitissimè costată, sulco dorsali subconspicuo; undique nigricante-fusca.

THE SLIGHTLY-BEAKED COWREY. Shell rotundately ovate, right side margined, extremities obtusely beaked; transversely very finely ribbed, with a rather conspienous dorsal groove; blackish brown throughout.

Gray, Zool. Journal, vol. iii. p. 363.

Hab. - ?

A dark chocolate-brown species distinguishable by its rounded form and slightly beaked extremities.

Species 148. (Mus. Gaskoin.)

Cypr.ea tremeza. Cypr. testá ovatá, extremitatibus subattenuatis et rostratis; transversim subtiliter costată; albâ, roseo vivide variegatâ et maculatâ.

THE ROSE-SPOTTED COWREY. Shell ovate, extremities, somewhat attenuated and beaked; transversely finely ribbed; white, stained and variegated with bright

Duclos, Magasin de Zoologie, 1833.

Cypræa exigua, Grav.

Hab. West Indies; Duclos.

An extremely characteristic species, delicately painted with rieh rose-pink.

Species 149. (Mus. Gaskoin.)

Cypræa napolina. Cypr. testâ ovatâ, latere dextro incrassato, marginato, extremitatibus subproductis; transversim undique costată, costis crebris, subobesis, sulco dorsali nutlo; alba, dorso pallidissimè fuscescente, maculis duabus tribusve cinereo-nigricantibus exilissimè

THE FAINTLY-SPOTTED COWREY. Shell ovate, right side thickened, margined, extremities a little produced, transversely ribbed throughout, ribs close-set, rather stout, without any dorsal groove; white, back very pale brown, stained with two or three faint ashy-black spots.

Duclos; Kiener, Icon. Coq. viv. pl. 53. f. 3. Hab. Senegal.

There is a peculiarity in the colouring of this species which, carefully observed, serves amply to distinguish it from the C. Europæa, with which it is nearly allied.

Species 150. (Mus. Saul.)

Cypr. testå rotundo-ovatå, subventricoså, extremitatibus subobtusis; transversim subtiliter costată, sulco dorsali nullo; nigricante-fusca.

THE BROWN-COLOURED COWREY. Shell ovate, slightly ventricose, extremities, a little obtuse, transversely finely ribbed, with no dorsal groove; dark reddish brown.

Gaskoin, Pro. Zool. Soc. 1846. Hab. - ?

more transparent character.

Very like the C. subrostrata, but upon examination it will be found to be rather more oblong in form, and without any distinct dorsal groove; the colour is also of a

Spectes 151. (Fig. 151 and 154, Mus. Gaskoin.)

Cypr. Ea Candidula. Cypr. testá globoso-ovatá, lateribus subdilatatis, margine incrassatis; transversim undique costatá, costis fortibus, subconspicuis; niveá.

THE LITTLE WHITE COWREY. Shell globosely ovate, sides somewhat dilated, thickened at the edge; transversely ribbed throughout, ribs strong, rather conspieuous; snowy white.

GASKOIN, Pro. Zool. Soc., 1835. Hab. Mexico.

This interesting little species may be distinguished by the foreible character of the ribs; as a proof of its specific importance Mr. Gaskoin relates the circumstance of it having been almost simultaneously described in two other eities of Europe, in Paris by M. Duclos under the name of C. olorina, and in Copenhagen by Dr. Beck under that of C. approximans.

Species 152. (Mus. Cnming.)

Cypr. A Globosa. Cypr. testá peculiariter globosá, transversim costatá, sulco lineari dorsali conspicuo; niveá.

The globose Cowrey. Shell peculiarly globose, transversely ribbed, with a conspicuous dorsal groove; snowy white.

Gray; Sowerby, Conch. Illus. Cypræadæ, no. 117. Cypræa pilula, Kiener.

Hab. —— ?

The globose pea-like form of this species, the smallest of the genns, is truly characteristic.

Species 153. (Mus. Gaskoin.)

Cypr. Es a pellucidula. Cypr. testa ovata, extremitatibus subattennatis et rostratis, transversim undique costatis, costis tenuibus, subirregularibus, sulco dorsali nullo; nivea.

THE RATHER-PELLUCID COWREY. Shell ovate, extremities somewhat attenuated and beaked, transversely ribbed throughout, ribs fine, rather irregular, with no dorsal groove; snowy white.

GASKOIN, Pro. Zool. Soc., 1846.

Hab. South Pacific.

A new snowy white species approximating in form to the *C. tremeza*; it differs, however, in being rather more gibbous, and in having a greater number and finer ribs, without any dorsal impression

Species 154. (Mus. Gaskoin.)

Cypr. A Pisum. Cypr. testá globosá, ventricosá, latere dextro subincrassato; transversim undique costatá, costis numerosis, angustis, prominentibus, sulco dorsali subconspicuo; carneo-fuscescente.

The pea Cowrey. Shell globose, ventricose, right side rather thickened, transversely ribbed throughout, ribs numerous, narrow, prominent, with a rather conspicuous dorsal groove; pale fleshy brown.

GASKOIN, Pro. Zool. Soc., 1846.

Hab. East Indies.

A very distinct and characteristic species, approaching nearest in general aspect to the *C. formosa*, for which I have been indebted to Mr. Gaskoin since the accompanying plate was engraved. The shell represented at *Fig.* 154 is the *C. candiduta*.

Vincent Breck.

PLATE XXVII.

So different is the appearance presented by the Cypræa in an early stage of growth to that which they assume at a more advanced period, that 1 have thought it necessary to figure a few of the most interesting species during the Bulla-like state of their existence; that is, when the columella shows itself most distinctly to be the axis of growth, and before the outer lip is inflexed or exhibits any indication of teeth. As of form, so also are there differences of colour and design; and the changes in both instances are very dissimilar. The following series includes some of the most remarkable.

- CYPREA MAURITIANA. Fig. 1 c. Pale buff brown, encircled with three broad bands of darker brown elouded waves, the waves of the posterior band striking out of the suture; columella white; interior pale purple. Spire acuminated.
- CYPREA ARGUS. Fig. 8 b. Pale yellowish fawn eolour, encireled with three or four narrow enlarging bands, very irregularly stained here and there with oblong-square spots of which there are no traces in the adult; columella white. Spire peculiarly flattened.
- Cypr.ea Scottii. In its first state (Fig. 10 b and c) a pure bright uniform milky orange, with the columella ivory-white; it then assumes a blueish tinge disposed

in obscure bands, and begins to show (Fig. 10 d) a few bright tortoise-shell brown blotches, as exhibited in the adult, before there is the slighest inflexion of the lip, or any indication of teeth. This is an arrangement different to that of most of the Cowries, in which the teeth are chiefly developed before there is any appearance of the spotted pattern with which the adult is ornamented. Spire prominent.

- CYPR.EA TIGRIS. In its first state (Fig. 12 c) a clear rather dark chesnut brown, eneireled with faintly shaded bands, with the columella white; the chesnut coating then disappears by a superincumbent layer of cream colonred enamel, encircled with five bands of close set oblong blueish-brown spots (Fig. 12 d), splashed irregularly with clouded stains of yellowish brown. Spire rather depressed.
- Cypr.ea exanthema. Fig. 16 b. An uniform fawn brown, eneircled with five broad bands of a darker colour, no appearance of spots, waves, or any description of marking; interior rich purple; columella white. Spire acuminated.
- CYPR.EA CARNEOLA. Fig. 19 b. Colour and bands exactly as in the adult; columnla white.

March 1846.

ERRATA.

Plate 1. p. 2,—for C. aurora, read C. aurantium.

Species 3, C. RETICULATA, -add as synonyme C. maculata, Barnes.

Species 20, C. PRINCEPS.—A report has just reached me from Lyons that a second specimen of this remarkable shell has been received from the Red Sea, and deposited in the Museum of that city; I cannot, however, vouch for the correctness of it at present.

Species 90, C. Algoensis,—add authority, Gray, Zool. Journal, vol. i. p. 498.

Species 91, C. Angustata,—add authority, Gray, Zool. Journal, vol. i. p. 497.

Species 96, C. gangrenosa,—add authority, Solander, MSS., Gray, Zool. Journal, vol. i. p. 503.

MONOGRAPH

OF THE GENUS

HALIOTIS.

"In all the liveries deck'd of summer's pride,
With spots of gold and purple, azure and green;
Or in their pearly shells at ease, attend
Moist nutriment, or under rocks their food."—Milton.

HALIOTIS.

PLATE I.

Genus Haliotis, Linnæus.

Testa ovala, auriformis, planata, spirā parvā, brevissimā, laterali, peculiariter depressā; intus margaritacea, pulcherrimè prismatica, extus rugoso-costata aut corrugata, raro tævi, latere sinistro ptus minusve angulato, foraminum serie regulari ad angulum perforato, nonnullis perviis; labro sinistro inflexo, planulato, dextro simplici; aperturā amplissimā, propatulā.

Shell ovate, ear-shaped, flat, spire small, very short, lateral, peculiarly depressed; pearly and very beautifully prismatic within, roughly ribbed or wrinkled without, rarely smooth, left side more or less angulated, perforated along the angle by a regular series of holes, some of which are open; left lip inflexed, flattened, right lip simple; aperture very large and wide open.

The genus *Haliotis* affords an unusual abundance of novelty from the circumstance of it never having been selected for the subject of an illustrated monograph; the species are, moreover, well defined, and may be easily determined by a careful examination of the variations of sculpture and arrangement of colours.

The Haliotides are interesting in form as being the most evolved and depressed of spiral shells, and they have been arranged with the Chitons and Limpets as exhibiting the nearest apparent affinity with the non-spiral Gastropods. They present also a singularity of structure in great measure analogous to the orifice in the shell of Fissurella or to the fissure in Emarginula. On the left side of the shell, in a direct curve parallel to the inflexed edge, is a row of equidistant perforations, made by the animal in its progress of growth for conveying the water to the breathing organs; the mantle is slit in that direction to a certain extent, and the water passes into the respiratory cavity through a tubular filament protruding from each hole. The number of pallial filaments being alike in the same individual throughout its several stages of growth, the shell mostly presents the same number of holes at all ages, filling up the hindmost orifice as a new one becomes formed at the margin. The Siliquaria presents a similar modification of structure, and it has been also considered that the slit in Pleurotoma is in some measure analogous.

The internal surface of the 'Ear Shells' is lined with a bright pearly nacre, which in most species is of remarkable irridescent brilliancy, glowing with all the colours of the rainbow; the attention must, however, be directed to the outer coating of the shell, for the discrimination of species, and it is with this view that the figures in the foregoing monograph are devoted mainly to external sculpture. There is certainly a striking variation of character in the nacre of different species, but the pattern of the inner surface is merely an indentation of the outer. The number of perforations varies in different species, but may be said to correspond in different individuals of the same species; where an exception occurs, it is that there is sometimes one, or at most two, less in the adult than in the young state; that is, when the animal arrives at maturity it continues to stop up one or two of the perforations in advance of any new one.

It is a curious circumstance in the geographical distribution of the Haliotides that few, if any, are to be found where Chitons abound; as if they exchanged places to a certain extent in the two hemispheres There are a few species from California, but along the western eoast of Sonth America, where Chitons are most abundant, not any are found, and only one small species, the H. pulcherrima, at any of the Islands of the Pacific. They inhabit the coasts of China, Japan, Ceylon, Mozambique, Cape of Good Hope, Borneo, and the Philippine Islands; but the greater number of species, and the most remarkable, are from New Zealand, and the continent of New Holland, displaying all the peculiarity of design which invariably characterizes the fauna of those isolated regions. With the well-known Haliotis tuberculata of the Channel islands, all are familiar. It is, however, a circumstance worth noting, that although such near neighbours, and comparatively abundant, especially at the island of Jersey, it is rarely collected on the eoast of England.

The *Haliotides* are found at low water, attached to the under surface of masses of stone, and they fix themselves with great force to the rocks, by suction, on the least alarm.

Although the genus *Haliotis* was described by Lamarek as being "assez nombreux en espèces," only fifteen species appear to have been known to that illustrious naturalist; six were added to that number by M. Deshayes, in his new edition of the 'Animaux sans vertèbres,' and a few have been described by Mr. Gray and others in seattered memoirs.

With the rich and beautiful materials now before me, chiefly from the collection of Mr. Cuming, I shall probably be enabled to determine about eighty species; only a limited portion of them, however, were taken by that eminent traveller alive, as his researches have been chiefly confined to the Western Hemisphere.

Species 1. (Mus. Cuming.)

Haliotis pulcherrima. Hal. testá orbiculari-ovatá, convexiusculá, radiatim costatá, costis fortibus, latiuscutis, nodoso-corrugatis, interstitiis rugosis; spirá subamplá; foraminibus senis perviis; lutescente-albá, castaneo-rubente maculatá et variegatá, intus aureo-albicante.

The very beautiful Haliotis. Shell orbicularly ovate, rather convex, radiately ribbed, ribs strong, rather wide, nodosely wrinkled, interstices rough; spire rather large; six perforations open; yellowish white, spotted and variegated with chesnut red; nacre golden white.

Martyn, Universal Coneh. vol. ii. pl. 62.

Hab. Lord Hood's and Grimwood Islands, Pacific Ocean; Cuming.

There is no green or blue either in the outer coat or naere of this species. The ribs are of a soft yellowish white, stained here and there with chesnut-red, and the pearly interior exhibits a faint golden hue.

Species 2. (Mus. Cuming.)

Haliotis glabra. Hal. testá oblongo-ovatá, convexoplanulatá, spirá parvá; glabrá, striis perpaucis exsculptis radiantibus, latere sinistro tenuilirato, foraminibus senis perviis, parviusculis; labro sinistro latiusculo; olivaceo-viridi, luteo-viridescente angulato-reticulatá et variegatá.

The smooth Haliotis. Shell oblong-ovate, convexly flattened, spire small; smooth, with a few radiating engraved striæ, left side finely ridged, six perforations open, rather small, left lip rather broad; dark olive green, angularly reticulated and variegated with pale yellowish green.

Chemnitz, Conch. Cab. vol. x. p. 311. pl. 166. f. 1602, 3. *Hab.* Australia; Dring, R.N.

M. Deshayes is perfectly correct in his views of this species, so admirably portrayed by Chemnitz. Figures 1607 and 8 of the 'Conchylien Cabinet' represent a species,

hereafter to be described, unquestionably distinct both in form and colour from that under consideration; and the shell represented by Schubert and Wagner in the Supplement of that work, Fig. 3086, 7, as a variety of *H. glabra*, is also a very distinct species, subsequently described by Mr. Swainson under the name of *Haliotis Californiensis*.

Species 3. (Mus. Cuming.)

Haliotis Cunninghamii. Hal. testű ovatű, tenni, maximű, concavo-depressű, latere sinistro angutato, ad angulum perforato, foraminibus subtubutosis, senis, (in testű juveni septenis vel octonis) perviis; oblique undato-plicatű, striis elevatis minute corrugatis undique sculptű, margine sinistro latiusculo, planato; extus rubro-ferrugineű, viridi fuscoque variegatű, intus albicante.

CUNNINGHAM'S HALIOTIS. Shell ovate, thin, very large, concavely depressed, left side angulated, perforated at the angle, perforations somewhat tubulous, six (in the young shell seven or eight) open, obliquely undulately plicated, sculptured throughout with minutely wrinkled striæ, left margin rather broad, flattened; outside reddish brown, variegated with green and darker brown, inside whitish.

Gray, Appendix to King's Voyage (Narrative of a Survey of the Coast of Australia, 1827), vol. ii. p. 494.

Hab. Australia and New Zealand.

Three excellent figures of this magnificent species have been recently publised by Dr. Phillippi in his valuable work on Species of Shells 'Abbild, und Besch, Conch,' for the Haliotis nævosa of Martyn, Univ. Conch. vol. ii. pl. 63, from which it differs materially both in form and colour. It was described by Mr. Gray nearly twenty years ago in the work above quoted, and I have had the pleasure of identifying the splendid shell here figured, with a young specimen in that gentleman's private cabinet, having the name of Mr. Allan Cunningham, the indefatigable Botanist of that Expedition, attached to it in Mr. Gray's handwriting. It is a very large thinnish concavely flattened shell, with the left side rather sharply angulated, and the outer surface finely sculptured throughout with wrinkled striæ, a good distinctive character to which I attach some importance, and which is conspicuously developed in spccimens of different stages of growth now before mc. The colour is a light rusty red, variegated with flame-like patches of dark brown, with a little green intermingled, the naero of the interior being of a rather pallid hue.

Tialiotis. Pl.II.

HALIOTIS.

PLATE II.

Species 4. (Mus. Cuming.)

Haliotis varia. Hal. testű ovato-oblongű, depresso-convexű, spirá humili ; obliquè tumido-nodosá, spiraliter crebiliratű, liris valdè irregularibus, foraminibus senis perviis ; viridi aut olivaceo-fusco luteoque diversimodo radiatim variegatű, intus argenteű.

THE VARIEGATED HALIOTIS. Shell ovately oblong, depressly convex, spire low, obliquely tunnidly nodose, spirally closely ridged, ridges very irregular, six holes open; diversely radiately variegated with greenish or olive-brown and yellow; nacre silvery.

LINNÆUS, Syst. Nat. (12th edit.) p. 1256. *Hab.* Philippine Islands; Cuming.

A good distinguishing mark in this species are the curious swollen nodules, ranging across the shell in oblique waves, though sometimes a little obscure. The variegated yellow and olive-green colour is mostly disposed in alternate enlarging stripes striking out from the nucleus of the spire. Mr. Cuming found the *H. varia* abundantly distributed throughout the Philippine Islands.

Species 5. (Mus. Cuming.)

Haliotis Rubicunda. Hal. testá suborbiculari-ovatá, tenniculá, medio concavo-depressá, latere sinistro tricostato, costá externá tuberculatá, scabrosá, medianá tubiferá, perforatá, foraminibus quinis senisve perviis, interná tumidá, conspicuá, rugoso-striatá, lamellis tennibus undato-striatis erectis inter spiram et costam internam concentricè dispositis; extus rufescente aut olivaceo viridique variegatá, intus pulcherrimè irridescente.

The Red-Tinged Haliotis. Shell somewhat orbicularly ovate, rather thin, concavely depressed in the middle, left side three-ribbed, the outer rib tuberculated and scabrous, the middle rib tubiferous and perforated, six to seven of the perforations open, the inner rib swollen, conspicuous, roughly striated, with

thin lamellæ concentrically arranged between the spire and the inner rib; exterior reddish or variegated olive and green, interior very beautifully irridescent.

LAMARCK, Anim. sans. vert. (Deshayes' edit) vol. ix. p. 30. Gray, App. King's Voyage, p. 494.

Padollus rubicundus, De Montford.

Padollus scalaris, Leach.

Haliotis tricostalis, Lamarek.

Haliotis canaliculata, Schubert and Wagner.

Hab. Rotten Nest Island, Swan River Settlement; Lieut. Preston, R.N.

The structure and symmetrical arrangement of this species is truly elegant; and highly characteristic of the beautiful natural productions of the country of which it is an inhabitant.

Species 6. (Mus. Cuming.)

Haliotis rufescens. Hal. testá ovatá, convexo-depressá, crassiusculá, spiraliter liratá, liris minutis irregularibus; obliquè undato-plicatá, plicis grandibus tumidis; foraminibus subamplis, tubulosis, quaternis tantum perviis; extus corallo-rubrá saturatá, intus irridescente, labri dextri limbo intus corallo-rubro.

The coral-red Haliotis. Shell ovate convexly depressed, rather thick, spirally ridged, ridges minute, irregular; obliquely wave-plicated, plaits large, swollen; perforations rather large, tubulous, four ouly open; outside deep coral-red, inside irridescent, inner edge of the right lip coral red.

SWAINSON, Appendix to Bligh Catalogue, p. 2.

Hab. Ceylon; Dr. Sibbald.

A fine dark coral-red species growing in large oblique swollen undulating waves. "In proportion as the back of this species is worn down," says Mr. Swainson "the colour becomes of a bright red," an observation very significant of its real character.

PLATE III.

Species 7. (Mns Taylor.)

Haliotis rugoso-plicata. Hal. testá oblongo-ovatá, anticè subattenuatá, valdè convexá, spiraliter elevatostriatá, obliquè rugoso-plicatá, foraminibus septenis perviis; olivaceo-viridescente, rufo pallidè radiatá.

The Rough-Plaited Haliotis. Shell oblong-ovate, a little attenuated anteriorly, very convex, spirally elevately ridged, obliquely roughly plicated, seven of the perforations open; pale olive green, faintly radiated with red.

CHEMNITZ, Conch. Cab. vol. x. p. 311. pl. 116. f. 1604. and 1604. a.

Haliotis australis, Gmelin, Lamarck.

Hab. New Holland; Capt. King.

Although a compound specific name is not quite in accordance with the modern rules of nomenclature, I cannot think that any hitherto given should be abandoned.

Species 8. (Mus. Cuming.)

Haliotis Kamtschatkana. Hal. testā ovato-oblongā, spiraliter striatā et liratā, liris plano-oblusis subdistanibus, transversim oblique tumulosis, tumoribus conspicuis, subundatis, latere sinistro latisulcato, foraminibus tumidinsculis amplis, quaternis tantum perviis, extus rufo-viridique vivide tessellatim variegatā, liris spiralibus rufo-alboque promiscue articulatis.

THE KAMTSCHATKA HALIOTIS. Shell ovately oblong, spirally striated and ridged, ridges flatly obtuse, rather distant, transversely obliquely full of conspicuous waved swellings, left side rather broadly grooved, perforations rather swollen, large, four only open; exterior tessellately variegated with bright red and green, spiral ridges articuted with red and white.

ONAS, Menke, Zeitschrift für Malak. Nov. 1845.

Hab. Oonalaska, near Kamtschatka, Northern Archipelago; Jonas.

This very beautifully painted shell has more the appearance of a tropical than a northern species, for it presents the brightest display of colours of any of the genns. The entire surface consists of wavy swellings, variegated in a somewhat tessellated style with dark coral red and bright verdigris green, over which the spiral ridges pass here and there articulated with red and white.

Species 9. (Mus. Cuming.)

Haliotis splendens. Hal. testã ovatã, convexo-depressã, undique spiraliter liratã, liris crebris regularibus subobtusis, nonnullis aliis latioribus, foraminibus quinis perviis; extus ærugini-viridescente, articulis albicantibus spiram prope interdum notatã, epidermide fibroso fusco indutã, intus cæruleo viridique, nigricante nebulatã, pulcherrimè irridescente.

The splendid Haliotis. Shell ovate, convexly depressed, spirally ridged throughout, ridges close-set, regular, rather obtuse, some broader than others, five of the perforations open; outer surface of the shell verdigris green, sometimes marked near the spire with whitish articulated markings, covered with a brown epidermis, inner surface very beautifully irridescent with blue and green clouded with black.

Reeve. Pro. Zool. Soc. 1846. Hab. California

This is the large species imported from California, the richly coloured polished surface of which is used for the ornamental work of various articles of manufacture. It is not referable to any of the species mentioned by Lamarck, and although familiarly known to collectors by the above name I cannot learn upon what authority it has been used.

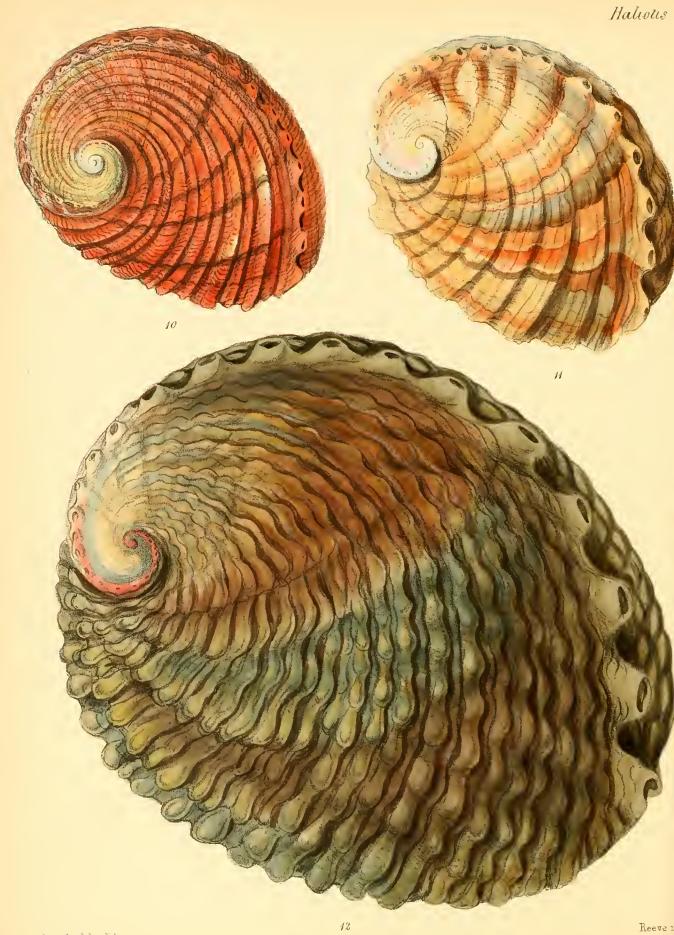

PLATE IV.

Species 10. (Mus. Cuming.)

Haliotis Roei. Hal. testă suborbiculari-ovată, depressoplană, spiraliter costată et lirată, costis lirisque alternantibus, peculiariter crebriscabrosis, foraminibus parviusculis, octonis novenisque perviis; extus vividè coccineo-rubră aut olivaceo-fuscă, radiatim albimarmorată, intus spiraliter sulcată, pulchrè irridescente.

Roe's Haliotis. Shell somewhat orbicularly ovate, depressly flattened, spirally ribbed and ridged, ribs and ridges alternating, peculiarly closely scabrous, perforations rather small, eight or nine open; exterior bright searlet red, radiately marbled with white, interior spirally grooved, beautifully irrideseent.

Gray, Appendix to King's Voyage (Narrative of a Survey of the coast of Australia, 1827), vol. ii. p. 493.

Haliotis scabricosta, Menke.

Hab. New Holland; King, Menke.

This very interesting species was originally collected during Capt. King's Survey of the coast of Australia, and named by Mr. Gray in honour of Lieut. Roe of that Expedition in his Appendix to the 'Narrative of the Voyage' above referred to. M. Menke not being cognizant of this book described the species in his Moll. Novæ Hollandiæ under the name of *H. scabricosta*, and Dr. Philippi has reproduced it under the same name in his 'Abbild. und Besch. Conch'.

The external sculpture of the *Haliotis Roei* consists of a number of alternating ribs and fine ridges, composed of irregular scales closing immediately one upon the other.

Species II. (Mus. Cuming.)

Haliotis Mariæ. Hal. testå ovatå, depressiusculå, spirå sublaterali; spiraliter costatå, costis depressis, perlatis, oblique vix plicatis, supra uni-bi-sulcatis, interstitiis excavatis, foraminibus subamplis, quinis perviis; extus aurantio-spadiceo variegatå, intus subargenteå.

Maria's Haliotis. Shell ovate, rather depressed, spire nearly lateral; spirally ribbed, ribs depressed, very broad, slightly obliquely plicated, upper surface engraved with one or two grooves, interstices between the ribs hollow, holes rather large, five open; exterior tinged with orange fawn, interior rather silvery.

GRAY, Wood Index Test. Supp. 1825. pl. 8. f. 6.

Haliotis dentata, Jonas.

Hab. ---- ?

This interesting species was named some twenty years since by Mr. Gray in honour of his kind-hearted and accomplished lady, so well-known to conchologists by her spirited etchings of the Mollusca. It is so unlike any other species of the genus that no one can fail to admire it. The surface between the row of perforations and the spire, is characterized by about half a dozen peculiarly broad depressed ribs, the interstices between which are excavated into as many hollow channels; and down the flattened summit of each rib are one or two faintly indented grooves.

I have not as yet heard of more than three specimens, that in the possession of Mr. Cuming here figured; one in Mr. Gray's collection; and one in the collection of Dr. Jonas of Hamburgh, to whom my thanks are due for the trouble he has taken in forwarding mc drawings of it. Although I am unable to adopt that gentleman's name for this species, I feel equally indebted to him for his kind services; and I can only say that if all my continental friends would be equally prompt in putting mc in possession of their new unfigured species of shells by the same means, it would avoid a great deal of confusion, and enable me to do justice alike to all authors.

Species 12. (Mus. Cunning.)

Haliotis corrugata. Hal. testă ovată, convexă, spiraliter crebrilirată, liris undique tumido-corrugatis, plicis undatis interdum oblique decussatis, foraminibus perpaucis, amplis, tubiferis, tribus tantum perviis; extus rubido-castaneo viridique, nigro marginato, pulcherrime irridescente.

The wrinkled Haliotis. Shell ovate, convex, spirally closely ridged, ridges prominently raised throughout in swollen wrinkles, sometimes obliquely crossed with waved folds, perforations few in number, large, tubiferons, three only open; exterior rayed with dark green and reddish chesnut, edged with black, very beautifully irridescent.

Gray, Wood, Index Test. Supp. pl. 8. f. 5. *Hab.* California.

This fine large species, which is not uncommon in collections, may be recognized by the conspicuous nodulous wrinkles with which its entire surface is covered; it is a thick heavy shell, rather more convex than usual.

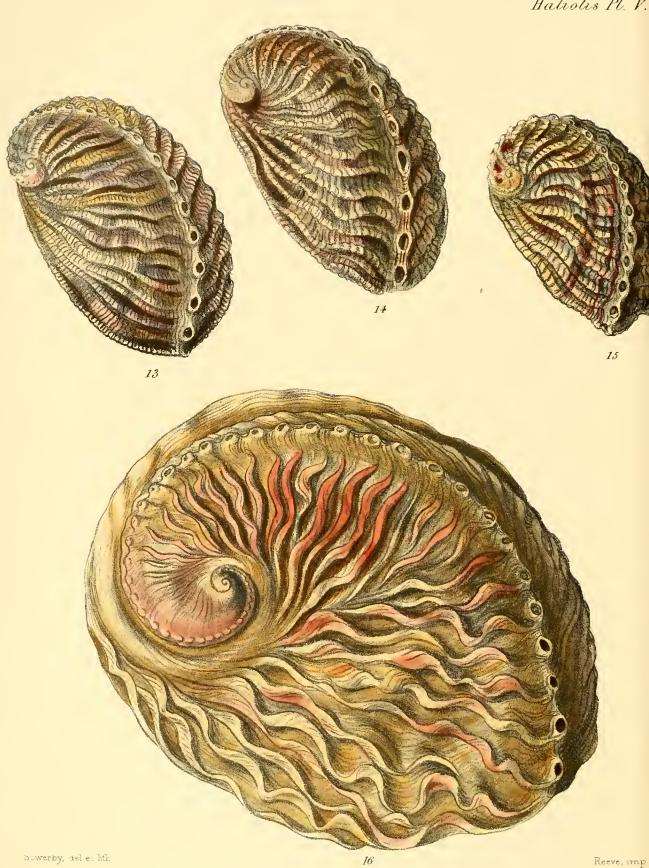

PLATE V. ·

Species 13. (Mus. Cuming.)

Haliotis Japonica. Hal. testa ovato-oblonga, subplanulato-convexa, liris tenuibus æqualibus spiraliter funiculata, concentricè ruguso-plicata, plicis conspicuis lamellæformibus irregularibus, foraminibus quinis senisve perviis; tuteo, olivaceo-fusco, viridique undique pulcherrimè variegata.

The Japan Haliotis. Shell ovately oblong, rather flatly convex, spirally corded with fine equal ridges, concentrically rugosely plicated, plaits conspicuous, lamella-like, irregular; five to six holes open, beautifully variegated with yellow, olive-brown and green.

REEVE, Pro. Zool. Soc., 1846.

Hab. Japan; Dr. Siebold.

This beautiful species from Japan might easily be mistaken for the following, from the coast of Gibraltar, the shell being developed in stout concentric ridges in a nearly similar manner; the detail of sculpture will, however, be found on examination, to differ materially. In the H. Japanica the surface is engraved throughout with fine cords, equidistant from each other, and extremely regular in their arrangement; in the H. lamellosa the ridges are very irregular, though mostly alternately broad and narrow; and the interstices are not so distinctly grooved. Coming from such a different locality these variations may be regarded of ample specific importance.

Species 14. (Fig. 14 and 15, Mus. Cuming.)

Haliotis lamellosa. Hal testá oblongo-ovatá, subplanulato-convexá, spiraliter tenuiliratá, liris obtusis, irregularibus, foraminibus quinis senisve perviis; luteo, olivaceo-fusco, viridique, vel aurantio-rubente, undique pulcherrimè variegatá.

The Lamellated Haliotis. Shell oblong-ovate, rather flatly convex, spirally finely ridged, ridges obtuse, irregular, with the alternate mostly the larger, concentrically obliquely plaited, plaits conspicuous lamell like, irregular, five to six holes open; beautifully variegated with yellow, olive brown and green, or with orange red.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol. ix. p.29. Hab. Gibraltar.

Having already described the specific peculiarities of this shell in treating of the preceding species, it only remains to notice that the oblique lamella-like folds are very irregularly developed, the most constant character being displayed in the style of the spiral grooving.

For Species 15, see Plate IX.

Species 16. (Mus. Cuming.)

Haliotis Midæ. Hal. testa rotundato-ovata, depressoplana, circa apicem minutissimè et creberrimè spiraliter
sulcata, obliquè obsoletè undata, concentricè plicata,
plicis peculiariter undulatis, et retrorsum crispatis, valdè
irregularibus; marginibus postica sinistraque latis,
plano-reflexis; foraminibus parvis numerosis confertis,
ad novenis perviis; extus luteo-albicante, apice plicisque
sæpissimè corallo-rubris, epidermide tuteo-fusca indutis,
intus cæruleo-viridi sanguineoque irridescente.

MIDAS'S HALIOTIS. Shell rotundately ovate, depressly flattened, very minutely and closely spirally grooved around the apex, obliquely obsoletely waved, concentrically plaited, plaits peculiarly waved and curled backwards, very irregular, posterior and left margins broad and flatly reflexed, holes small, very numerous, close-set, about nine open; outside yellowish white, apex and folds more or less tinged with coral red, covered with a light yellowish-brown epidermis, inside irridescent with blueish green and faint blood tinge.

LINNÆUS, Syst. Nat. (10th edit.), p. 779.

Testa juvenis.

Haliotis Capensis, Dunker.

Hab. Cape of Good Hope.

In order to appreciate the characters of this beautiful species, it should be examined in different stages of growth; in a very young state there is no indication of the wavy curled plaits with which the shell is so remarkably characterized in a maturer condition. The entire surface of the primitive whorls is very minutely spirally grooved or elevately striated; the plaits begin to develope themselves at the commencement of the last whorl, originating from a point in its centre, and gradually spreading in light lamella-like wrinkles like a concentric flow of ripples on the bosom of a calm lake. In this state it is of an oblong form, rather acuminated anteriorly, and constitutes the H. Capensis of Dunker, Philippi, Abbild. und Besch. Conch. Hal. Pl. 1. Fig. 4. As the shell advances in growth the plaits become more thickened and irregular, and wind round the spire in such a manner as to form a flattened reflexed rim. The spire, generally more or less worn, has a peculiar coppery red irridescence, and the plaits, though covered naturally with a pale yellowish brown epidermis, are coral-red beneath, and mostly exhibit their colour from the effects of friction.

PLATE VI.

Species 17. (Mus. Cuming.)

Haliotis sanguinea. Hal. testã oblongo-ovatã, anticè flexuoso-contractá et attenuatã, parte spirali subelevatã, concentricè obliquè corrugatá et striatá; foraminibus creberrimis, ad novenis perviis; fuscá (in ætate juveni albivariegatá), spirá intus sanguineo peculiariter tinctá.

The blood-stained Haliotis. Shell oblong-ovate, anteriorly flexuously contracted and attenuated, spiral portion of the shell rather elevated, concentrically obliquely wrinkled and striated, holes very close together, about nine open; brown (varigated with white in a young state), spire peculiarly tinged within with blood red.

HANLEY, Young Conchologist's Book of Species (1841), p. 60. Frontispiece, f. 5.

Haliotis ficiformis, Menke.

Hab. Cape of Good Hope.

This species may be easily recognised by its obliquely wrinkled and dark chocolate brown exterior, and by an irridescent blood stain within the winding cavity of the spire; the holes are very numerous and unusually close together, and the anterior portion of the shell is peculiarly flexuous and attenuated. It was originally described and figured by Mr. Hanley, in a little work called 'The Young Conchologist's Book of Species'.

Species 18. (Mus. Cuming.)

Haliotis asinina. Hal testá elongato-ovatá, subcurvatá, postice flexuoso-acuminatá, spirá terminali, oblique irregulariter striatá, parte posticá liris subtilibus subdistantibus e apice radiantibus, deinde evanidis; foraminibus parviusculis, numerosis, ad octonis perviis; olivaceo-viridi, maculis fuscis perpaucis subtrigonis, flammis lutescentibus, lincisque fuscis numerosis brevibus interruptis pulcherrime variegatá, radiis viridibus et rufo-flavis undatis prope apicem alternatim pictá.

THE ASS'S HALIOTIS. Shell elongately ovate, slightly curved, posteriorly flexuously acuminated, spire terminal, obliquely irregularly striated, posterior portion of the shell with fine rather distant ridges radiating from the apex, then fading away; holes rather small, numerous, about eight open; olive green, beautifully

variegated with a few triangular brown spots, yellowish flames and numerous short interrupted brown lines, and painted with alternate green and reddish yellow zigzag rays next the apex.

LINNÆUS, Syst. Nat. (10th edit.), p. 780.

Hab. China; Belcher, Dr. Sibbald. Philippine Islands; Cuming.

This very prettily variegated species, the most elongated of the genus, is remarkable for the extra-terminal convolution of the spire.

Species 19. (Mus. Cuming.)

IIALIOTIS GIGANTEA. Hal. testa ovata, spiraliter costata, costis parvis crebris irregularibus obtusis, interdum subobsoletis, obliquè nodoso-undatis; foraminibus amplis, peculiariter tubulosis, tribus quaternisve perviis; extus spadiceo-rubente, intus albicante pallidè viridique irridescente.

The gigantic Haliotis. Shell ovate, spirally ribbed, ribs small close irregular obtuse, sometimes somewhat obsolete, obliquely nodosely waved; holes large, peculiarly tubular, three to four open; exterior fawn red, interior irridescent with white and pale green.

CHEMNITZ, Conch. Cab., vol. x. pl. 167. f. 1610, 1611.

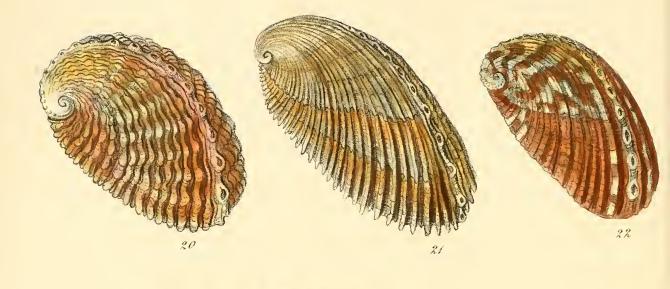

Haliotis tubifera, Lamarck.

Hab. Japan; Dr. Siebold.

The word gigantea is a much less appropriate term for this species than tubifera, for there are four or five others of larger size, but none in which the orifices are so peculiarly tubular; the rule of priority nevertheless requires that it should be adopted in preference. It was wrong of Chemnitz to introduce this shell under the name of gigantea, when he considered it to be identical with the H. nævosa of Martyn; it happens, however, that these are two distinct species, and both names, therefore, must be maintained. The H. gigantea is a peculiar light fawn-coloured red shell from Japan, well distinguished by the tubular structure of the holes; the H. nævosa (for which see Plates VIII. and 1X., Fig. 27), is of a deep coral red, sometimes green, variegated, from Van Dieman's Land, and of smaller size.

Sowerby, de eighth

Reeve imp

PLATE VII.

Species 20. (Mus. Cuming.)

Haliotis squamosa. Hal. testá oblongo-ovatá, transversim obliquè rugosá, spiraliter tuberculato-costatá, tuberculis squamæformibus, costis nunc confertis, nunc tirá parvá intercurrente; foraminibus subamplis, septenis perviis; extus aurantio-fusco luteoque maculatá et variegatá, intus albicante, irridescente.

The scaly Haliotis. Shell oblong-ovate, transversely obliquely wrinkled, spirally tuberenlarly ribbed, tubercles scale-like, ribs sometimes close, sometimes with a fine ridge running between them; perforations rather large, seven open; exterior spotted and variegated with yellow and orange-brown, interior whitish, irridescent.

Gray, Appendix to King's Voyage (Narrative of a Survey of the Coast of Australia, 1827), vol. ii. p. 495.

Haliotis Rodingii, Philippi.

Hab. Australia; King.

An extremely interesting species, well characterized by its close ribs of scale-like tubercles, ranging across the shell in oblique waves; in the middle portion of the shell there is a fine ridge running between the ribs; the colour is also peculiar, a kind of burnt-umber-stained orange.

Dr. Jonas of Hamburgh informs me that there is another specimen in the collection of Dr. Roding of that city.

Species 21. (Mus. Cuming.)

Haliotis elegans. Hal. testá elongato-ovatá, subflexuosá, convexá, apice terminali; spiraliter costatá, costis tenuibus, angustis, elevatis, lamellaformibus, per summitatem subobsoletè crebrisquamatis, costarum interstitiis subprofundè sulcatis, striatis; foraminibus parvis, remotis, ad octonis perviis; aurantio-lacteá, aurantio-rufescente strigatá et variegatá; intus albicante, margaritaceá.

THE ELEGANT HALIOTIS. Shell elongately ovate, rather flexuous, convex, apex terminal; spirally ribbed, ribs thin, narrow, elevated, lamella-like, somewhat obsoletely closely scaled along the summit, interstices between the ribs rather deeply grooved and striated, holes small, distant, about eight open; orange cream colour, streaked and variegated with orange red, interior whitish, pearly.

Kocn, Philippi, Abbild. und Besch. Conch. *Haliotis*, Pl. 1. Fig. 1 and 2.

Hab. l'ort Adelaide, New Holland.

This is a truly elegant species and very distinct from any hitherto known; its form is that of a gracefully enrved elongated oval, covered with ercet close-set lamellalike ribs, spirally radiating from the apex, the summits of which are swollen and bent over with scales fitting closely one upon the other. Its general tinge is that of an orange cream colour.

Species 22. (Mus. Cuming.)

Haliotis coccinea. Hal testá oblongo-ovatá, spiraliter tiratá, liris creberrimis inæqualibus, interstitiis transversim minutissimè striatis; foraminibus confertiusculis, quinis senisve perviis; extus coccineo-rufá, lutescentealbo maculatá et variegatá, intus argenteo-albicante.

The scarlet-clad Haliotis. Shell oblong-ovate, spirally ridged, ridges very close, unequal, interstices transversely finely striated; holes rather close, five or six open; exterior scarlet-red, spotted and variegated with yellowish white, interior silvery white.

Reeve. Pro. Zool. Soc. 1846.

Hab. Cape de Verd Islands.

The ridges have a tendency to range alternately singly and in pairs, but are very irregular.

Species 23. (Mus. Cunning.)

Haliotis Cracherodii. Hal. testă ovată, convexă, spiră suboccultă; lavigată aut radiatim striată, foraminibus parvis, senis ad octonis perviis, extus caruleo-nigricante, intus albicante, margaritaceă.

Cracherode's Haliotis. Shell ovate, convex, spire somewhat concealed; smooth or radiately striated, holes small, about six to eight open; exterior blueish black, interior whitish, pearly.

Leach, Zoological Miscellany, 1814, vol. i. p. 131. *Haliotis glaber*, Schubert and Wagner.

Hab. California.

It may perhaps be as well to mention that the fine specimen of *H. Cracherodii* here figured from Mr. Cuming's collection, is of unusually large size; it is of a peculiar bottle-blue black colour externally, and has never more than eight of the perforations open.

PLATE VIII.

Species 24. (Mus. Cuming.)

Haliotis ziczac. Hal. testá ovatá, planulato-convexá, spiraliter subtilissimè sulcatá, foraminibus parviusculis, senis perviis; olivaceo-viridi, luteo-viridescente obliquè flammeo-undatá, apice luteo-aurantio tinclo, intus argenteá, irridescente.

THE ZIGZAG HALIOTIS. Shell ovate, rather flatly convex, spirally very finely grooved, perforations rather small, six open; dark olive green, obliquely marked with light yellowish green zigzag flames, apex tinged with orange yellow, interior silvery, irridescent.

REEVE, Pro. Zool. Soc., 1846.

Hab. Calipan, Island of Mindoro, Philippines (found on smooth stones); Cuming.

The colour, form, and general aspect of this shell very much resembles those of the *H. glabra*; it differs chiefly in having the entire surface finely radiately grooved. The zigzag design of the colouring is very characteristic.

Species 25. (Mus. Cuming.)

Haliotis excavata. Hal. testă subrotundă, convexissimă, spiră elevată; spiraliter subtiliter lirată, liris striis radiantibus decussatis, rugis brevibus obliquis circa spiram concentrice dispositis; viridi-albicante, olivaceofusco radiatim strigată et variegată, intus profunde excavată, albicante, pulchre irridescente.

THE EXCAVATED HALIOTIS. Shell nearly round, very convex, spire elevated; spirally finely ridged, ridges crossed with radiating striæ, with short oblique wrinkles concentrically ranged round the spire; greenish white, radiately streaked and variegated with olive brown, interior deeply excavated, whitish, beautifully irridescent.

Lamarck, Anim.sans vert. (Deshayes' edit.), vol. ix. p.25. Hab. Kangaroo Island, Australia.

An interesting and well-known species, fully distinguished from any other hitherto recorded by its rounded convex growth.

Species 26. (Mus. Cuming.)

Haliotis Californiensis. Hal. testâ ovatâ, spirâ suboccultâ, lævigatâ aut decussatim striatâ, margine sinistro latiusculo, concavo-plano; foraminibus minutis, numerosissimis, duodecenis perviis, extus cæruleo-nigricante, intus albidâ, margaritaceâ.

THE CALIFORNIAN HALIOTIS. Shell ovate, spire rather concealed, smooth or decussately striated, left margin rather broad, concavely flattened; holes very small and numerous, twelve open; exterior blueish black, interior whitish, pearly.

SWAINSON, Zool. Illustrations, vol. ii. pl. 80. *Hab.* California.

This species has been separated with excellent discrimination by Mr. Swainson from the H. Cracherodii, from which it exhibits little intelligible difference beyond the unusual number and smallness of the holes; in the specimen here figured there are as many as twelve open; Mr. Swainson does not enumerate the perforations of the specimen he described, but in comparing it with the H. Cracherodii he sufficiently explains that they are "half as large and doubly numerous."

The distinction above noted between the *II. Cracherodii* and *Californiensis*, appears to have escaped the critical attention of M. Deshayes; the shell described by him, first, as the *H. glabra*, after Schubert and Wagner, and secondly, as the *H. Californiensis*, is the *H. Cracherodii*, which, though commonly of similar dimensions, is often much larger. The marked difference in the arrangement and number of the perforations in these two Californian species is certainly important; it is not a character of the genus to present so great a variation in different individuals of the same species.

Species 27. (Mus. Cuming.)

Haliotis Nævosa.—For description and further illustration of this extremely variable species see Plate IX.

PLATE IX.

Species 27. (Fig. a, Plate viii, and Fig. c, Mus. Cuming; Fig. b, Mus. Metcalfe.)

Haliotis nævosa. Hal. lestá ovatá, spiraliter liratá, liris granoso-squamosis, sæpè alternatim majoribus, obliquè undato-rugosá, rugis plus minusve tumidis, foraminibus senis perviis; aut vividè rubrá aut coccineorubrá, lutescente radiatá, aut olivaceo-rufescente viridi radiatá.

The knotted Haliotis. Shell ovate, spirally ridged, ridges granosely scaled, often alternately the larger, obliquely undately wrinkled, wrinkles more or less swollen, six holes open; deep red or scarlet red, radiated with yellowish white, or light olive red radiated with green.

MARTYN, Universal Conch. v. ii. f. 63.

Haliotis ruber, Leach.

Hab. New Holland, New Zealand, and Van Dieman's Land.

This is the most variable species I have met with, and appears to have been greatly misunderstood by authors; Lamarck confounded it with the *H. gigantea*, his *H. tubifera*; Philippi with the *H. Cunninghamii*, whilst Dr. Leach described it in his 'Zoological Miscellany' Pl. 23, as a new species, under the name of *H. ruber*. The variations chiefly consist in the spiral ridges being more or less prominently developed, and in the obliquely waved wrinkles being more or less swollen; in colour the species varies from an uniform deep coral red to a reddish olive, radiated with pale green, as represented in Fig. 27 of the preceding and accompanying plates.

Species 15. (Mus. Cuming.)

Haliotis multiperforata. Hal. testå oblongo-ovatå, subflexuoså, anfractuum parte spirali subelevatå; spiraliter lineari-sulcată, sulcis subundatis irregularibus; foraminibus parviusculis numerosis, decenis perviis, extus nigricante-fusco viridique variegată, intus albicante.

The many-perforated Haliotis. Shell oblong-ovate, rather flexuous, spiral portion of the whorls somewhat elevated; spirally linearly grooved, grooves a little waved, irregular; holes rather small, numerous, ten open; exterior dark-brown, variegated with green, interior whitish.

Hab. --- ?

This darkly variegated species, the surface of which is smooth, engraved with fine waved spiral lines, has somewhat the form of the *H. sanguinea*; the spiral portion of the shell being more than usually raised. The holes are numerous and close set.

Species 28. (Mus. Cuming.)

Haliotis ovina. Hal. testá suborbiculari-ovatá, convexodepressá, spirá plano-depressá, anfractibus rugis tumidis plicato-radiatis, foraminibus tubiferis, quinis senisve perviis; rubro aut viridi pulcherrimè marmoratá, intus argenteá.

The sheep Haliotis. Shell somewhat orbicularly ovate, convexly depressed, spire flatly depressed, whorls plicately rayed with swollen wrinkles; holes tubiferous, five or six open; exterior very beautifully marhled with orange-red or green, interior silvery.

CHEMNITZ, Conch. Cab. vol. x. p. 315. pl. 166. f. 1609. *Hab.* New Holland and the Philippine Islands.

An extremely characteristic species, an orange-red marbled example of which is very correctly represented by Chemnitz; neither Lamarck nor Deshayes appear to have been acquainted with it.

PLATE X.

Species 29. (Mus. Brit.)

Haliotis Emm.e. Hal. testá suborbiculari-ovatá, tenuiculá, convexá, spiraliter subtilissimè granoso-liratá, medio leviter obtuso-carinatá, circa spiram radiatim plicatá, spirá conspicuá subcentrali; foraminibus tubiferis, senis perviis; vividè rubrá, zonis albis undatis obliquè radiatá.

EMMA'S HALIOTIS. Shell somewhat orbicularly ovate, rather thin, convex, spirally very finely granosely ridged, slightly obtusely keeled in the middle, radiately plicated around the spire, spire conspicuous, subcentral; perforatious tubiferous, six open; bright red, obliquely rayed with white waved zones.

GRAY, MSS. British Museum.

Hab. New Holland.

A very striking, brightly coloured species, allied in structure to the *H. rubicundus*, and belonging to the genus *Padollus* of De Montford.

Species 30. (Mus. Cuming.)

Ilaliotis albicans. Hal. testă suborbiculari-ovată, convexă, lævigată aut spiraliter obsolete lirată; foraminibus parvis, numerosis, decenis perviis; extus luteo-coccineă, flammulis albidis radiată intus argenteă.

The whitish Haliotis. Shell somewhat orbicularly ovate, convex, smooth or spirally obsoletely ridged; perforations small, numerous, ten open; exterior yel-

lowish scarlet, rayed with whitish flames, interior silvery white.

Quoy and Gaimard, Voyage de l'Astrolabe, vol. iii. p. 311. pl. 68. f. 1, 2.

Hab. New Zealand.

No one can fail to distinguish this species by its delicate rayed style of colouring; the perforations are more than usually small, and the silvery interior is characterized by a kind of minute wavy pattern.

Species 31. (Mus. Cuming.)

Haliotis discus. Hal testá oblongo-ovatá, elevato-convexá, hic illic tumidá et rugosá, latere sinistro lato, peculiariter erecto; foraminibus amplis, subdistantibus, tubiferis, quaternis tantum perviis; castaneo-fuscá, viridi aut rufescente radiatim tinctá.

The quoit Haliotis. Shell oblong ovate, clevately convex, here and there swollen and wrinked, left side broad, peculiarly creet; perforations large, rather distant, tubiferous, four only open; chesnut brown, faintly radiated with red or green.

Reeve, Pro. Zool. Soc., 1846.

Hab. Japan; Dr. Siebold.

Chiefly distinguished from any species hitherto recorded by its oblong form, and erect growth of the perforated side of the shell.

Halietis Pt. Y

Sowerby, del et lith

Reeve, imp

PLATE XI.

Species 32. (Mus. Cuming.)

Haliotis Sieboldii. Hal. testá suboblique ovatá, subpeclinată, valde convexă, apice terminali, vix spirali; radialim liratā, liris obtusis, subdistantibus; foraminibus subamplis, quinis perviis; extus aurantio-rubra, intus albicante, irridescente.

SIEBOLD'S HALIOTIS. Shell somewhat obliquely ovate, a little pectinated, very convex, apex terminal, scarcely spiral; radiately ridged, ridges obtuse, rather distant; holes rather large, five open; exterior orange-red. interior white, irridescent.

REEVE, Pro. Zool. Soc., 1846. Hab. Japan; Dr. Siebold.

This very remarkable species, which is at present unique in the collection of Hngh Cuming, Esq., has very much the form of a Concholepas or the left valve of a Cardium; its resemblance to the latter is, however, probably the more striking. It is of a hollow ventricose growth, the apex with scarcely any spiral, terminating on the margin, like the umbone of a Cockle.

Species 33. (Mus. Cuming.)

Haliotis bistriata. Hal. testá oblonyo-ovatá, subplanulata, spiraliter lirata, liris valde irregularibus nunc latis, nunc angustis, interstitiis incisis; latere sinistro latiuscula, foraminibus senis perviis; rubido-fusco viridique variegată, maculis albidis irregularibus interdum aspersá.

THE DOUBLE-STRIATED HALIOTIS. Shell oblong-ovate,

rather flattened spirally ridged, ridges very irregular, sometimes broad, sometimes narrow, interstices engraved; left side rather broad, six holes open; variegated with green and reddish brown, sometimes sprinkled with irregular white spots.

GMELIN, Syst. Nat. p. 3691. Hab. Mozambique.

This species may be recognised by the very irregular width of the ridges and sharply engraved interstices; it is sometimes very prettily variegated with red and green, but a dark reddish brown sprinkled with whitish spots is the predominating colour.

Species 34. (Mus. Saul.)

Haliotis tuberculata. Hal. testã ovatã, convexo-depressá, spiraliter inciso-striatá, radiatim tuberculatoplicata, plicis inæqualibus, plus minusve tumidis; rubido-fuscă, viridi aut rufescente variegală.

THE TUBERCULATED HALIOTIS. Shell ovate, convexly depressed, spirally deeply striated, radiately tubercularly plicated, plaits unequal, more or less swollen; reddish brown, variegated with red and green.

LINNÆUS. Syst. Nat. 10th. edit. p. 780.

Hab. Guernsey &e.

Extremely variable in its colouring, which is sometimes a dull mixture of red and green, at other times a reddish brown ornamented with light green zigzag waves, as in the specimen selected for illustration.

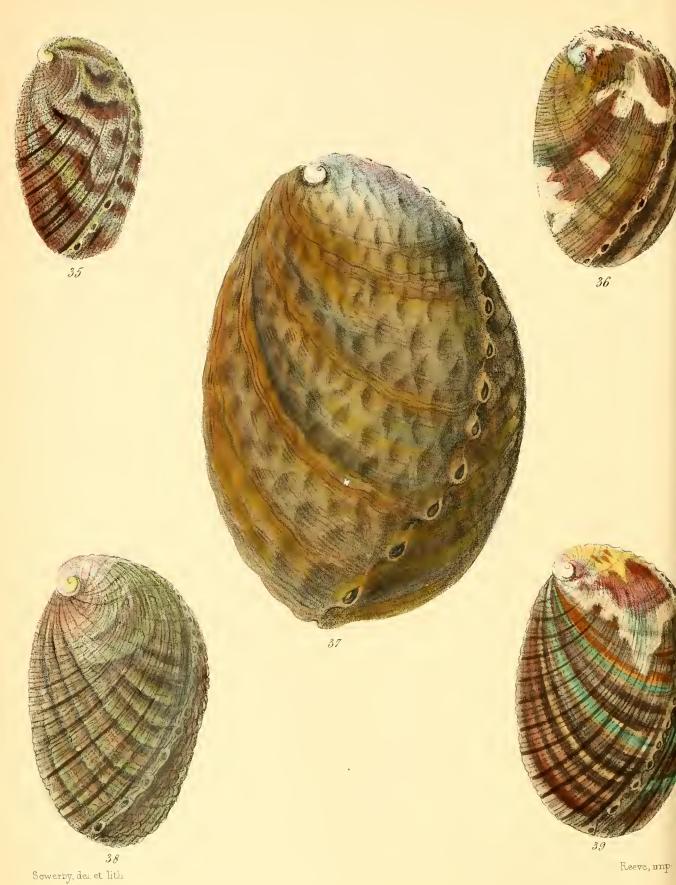

PLATE XII.

Species 35. (Mus. Cuming.)

Haliotis squamata. Hal. testá oblongo-ovatá, convexá, spiraliter liratá, liris creberrimis, squamatis, alternis majoribus; foraminibus octonis perviis; fuscá et rubrofuscá, flammulis lutescentibus undatis ornatis, intus vividè irridescente.

The squamate Haliotis. Shell oblong-ovate, convex, spirally ridged, ridges very close-set, squamate, the alternate the larger; eight perforations open; brown and reddish brown, ornamented with yellowish waved flames.

REEVE, Pro. Zool. Soc., 1846.

Hab. North West Coast of Anstralia; Dring, H.M.S. Beagle.

The form of this shell is rather more than usually convex, and the surface is closely set throughout with fine ridges of scales, the colouring being a rich red-brown ornamented with waved yellowish flames.

Species 36. (Mus. Cuming.)

Haliotis virginea. Hal. testâ ovată, depressă, spiraliter tenuè sulcată, tiris intermediis sæpissime duplicatis; foraminibus senis perviis; fuscă, rubro viridique plus minusve tinctă, maculis grandibus albis irregulariter notată.

The virgin Haliotis. Shell ovate, depressed, spirally grooved, intermediate ridges very often duplicate; six perforations open; brown, more or less stained with red and green, irregularly marked with large white blotches.

CHEMNITZ, Conch. Cab. vol. x. p. 314. pl. 166. f. 1607, and 1608.

Distinguished among other characters by the irregular scattered white blotches.

Species 37. (Mus. Saul.)

Haliotis iris. Hal. testă ovato-oblongă, convexă, postice attenuată, spiră terminali, peculiariter decussatim corrngată et plicată, latere sinistro lato, erecto; foraminibus quinis perviis; extus luteo viridique variegată, intus cæruleo viridique vivide irridescente.

The rainbow Haliotis. Shell ovately oblong, convex, attenuated posteriorly, spire terminal, peculiarly decussately plicated and wrinkled, left side broad, erect;

five perforations open; exterior variegated with green and yellow, interior blue and green, brightly irridescent.

GMELIN, Syst. Nat. p. 3691.

Hab. Kangaroo Island, Australia.

This well-known species may be recognised by its oblong hollow form, and flat inflexion of the margin in the vicinity of its terminal spire; the indented surface of the shell is also peculiar.

Species 38. (Mus. Cuming.)

Haliotis funebris. Hal. testá ovatá, subdepresso-convexá, spiraliter liratá, liris subsquamatis, hic illic majoribus, transversim peculiariter rugoso-plicatá; foraminibus octonis aut novenis perviis; rubido-castaneá, interdum viridi tinctá, flammis perpaucis indistinctis circa spiram.

The mourning Haliotis. Shell ovate, somewhat depressly convex, spirally ridged, ridges slightly squamate, here and there larger, transversely peculiarly rugosely plicated; perforations eight or nine open; reddish chesnut sometimes tinged with green, with a few indistinct light flames around the spire.

REEVE, Pro. Zool. Soc. 1846.

Hab. New Holland.

This is a larger and flatter species than the *H. squamata*, and the ridges are more widely separated and less squamate.

Species 39. (Mus. Hudson.)

Haliotis diversicolor. Hal. testá ovatá, subplanulatá, spiraliter liratá, liris obtusis irregularibus, transversim teviter plicatá; foraminibus octonis vel novenis perviis; castaneo-fusco coccineo-rufo viridique radiatá, maculis undatis lutescentibus variegatá.

The divers-coloured Haliotis. Shell ovate, rather flattened, spirally ridged, ridges obtuse, irregular, transversely slightly plicated; perforations eight or nine open, rayed with chesnut brown, scarlet-red and green, and more or less variegated with zigzag yellowish blotches.

REEVE, Pro. Zool. Soc., 1846.

Hab. New Holland.

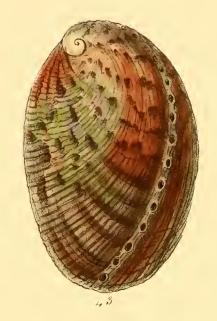

This species may be distinguished amongst other characters by the brightness and variety of its colours.

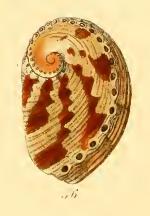

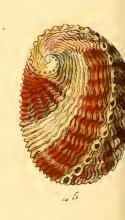

Haliotis

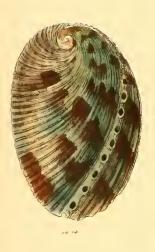

PLATE XIII.

Species 40. (Mus. Cuming.)

Haliotis viridis. Hal. testá ovatá, depresso-convexá, obliquè undato-rugatá, spiraliter liratá, lirarum interstitiis subtilissimè striatis; foraminibus quinis perviis; extus albicante, viridi pulcherrimè tinctá et marmoratá, intus argenteá.

The Green Haliotis. Shell ovate, depressly convex, obliquely undately wrinkled, spirally ridged, interstices between the ridges very finely striated; five perforations open; exterior whitish, beautifully stained and marbled with green, interior silvery.

REEVE, Pro. Zool. Soc., 1846.

Hab. ---- ?

Very closely allied to the *II. varia*, from which it differs only in the depression of the spire, and a slight though characteristic variation in the sculpture.

Species 41. (Mus. Cnming.)

Plaliotis astricta. Hal, testá ovatá, convexá, spiraliter liratá, liris laminis striisque elevatis irregularibus rudiatim decussatis; foraminibus quaternis perviis; extus albido olivaceo-viridique marmoratá, intus irridescente.

The tied Haliotis. Shell ovate, convex, spirally ridged, radiately crossed with irregular raised strice and laminæ; four perforation open; exterior marbled with white and olive green, interior irridescent.

REEVE, Pro. Zool. Soc., 1846.

Hab. ---- ?

Distinguished by the strong decussating sculpture of the cross ridges.

Species 42. (Mus. Hanley.)

Ilaliotis gibba. Hal. testá oblongo-ovatá, peculiariter convexá aut gibbá, spiraliter liratá, liris irregularibus, crebriusculis; spirá subterminali; foraminibus quinis perviis; extus fusco- et cæruleo-viridi, strigis albidis, rufo-punctatis, undutis, interdum ornatá, intus peculiariter irridescente.

The gibbous Haliotis. Shell oblong-ovate, peculiarly convex or gibbous, spirally ridged, ridges irregular, rather close-set, spire nearly terminal; five perforations open; exterior brownish or blueish green,

sometimes ornamented with white, red-dotted, waved streaks, interior peculiarly irridescent.

Philippi, Abbild. und Besch. Conch. *Haliotis*, Pl. ix. f. 2, a and b.

Hab. --- ?

The inner surface of this very characteristic species is disposed in minute wrinkles, from which the refraction of light throws off a peculiar degree of irridescence.

Species 43. (Mus Taylor).

Haliotis tayloriana. Hal. testá oblongo-ovatá, sotidiusculá, convexá, spirá subterminali; spiraliter obtusè et irregulariter liratá; foraminibus septenis ad novenis perviis; extus coccineo-fuscá, fluvido, coccineo-fusco, maculato, prope spiram nebulatá, intus albicante.

Taylor, S Haliotis. Shell oblong-ovate, rather solid, eonvex, spire nearly terminal; spirally obtusely and irregularly ridged; seven to nine perforations open; exterior searlet-brown, clouded near the spire with yellow spotted with searlet-brown, interior white.

Reeve, Pro. Zool. Soc., 1846.

Hab. ---- ?

I have the pleasure of describing this comparatively rare species from specimens in the collection of Thos. Lombe Taylor, Esq. It is of a dull scarlet-brown, the posterior portion of the shell being clouded with pale yellow, peculiarly mottled with dashes of the darker colour.

Species 44. (Mus. Cuming.)

Haliotis marmorata. Hali testă depresso-ovată, dextrorsum postice effusă, spiră subterminali; spiraliter planicostată, sulcis intermediis subexeavatis; foraminibus senis vel septenis perviis, extus viridi, rufo marmorată, intus albicante.

THE MARBLED HALIOTIS. Shell depressly ovate, effused posteriorly on the right side, spire nearly terminal, spirally flatly ribbed, intermediate ridges rather excavated; six or seven perforations open; dark green, marbled with red, interior whitish.

GRAY, MSS. (private cabinet)

There is a peculiarity in the growth of this shell, in the right posterior extremity being so prominently effused round the spire. Species 45. (Mus. Cuming.)

Haliotis Rubiginosa. Hal. testá ovatá, subdepressoconvexá, radiatim plicato-rugosá, spiraliter liratá, liris obtusè squamatis, foraminibus subapproximatis, senis perviis; extus rubiginoso-aurantiá, spiraliter albistrigatá, intus argenteá.

The rusty Haliotis. Shell ovate, rather convex, raditely plicated wrinkled, spirally ridged, ridges obtusely scaled; perforations rather approximated, six open; exterior rusty orange, spirally streaked with white.

REEVE, Pro. Zool. Soc., 1846.

Hab. ——?

Besides the peculiarity of sculpture, it is very fairly characterized by its rusty orange painting and silvery interior.

Species 46. (Mus. Cuming.)

Haliotis coccoradiata. Hal. testá suborbiculari-ovatá, plano-convexá, medio leviter depressá, spiraliter subtiliter liratá, liris striis minutis elevatis decussatis; foraminibus senis perviis; flavidá, strigis lalis vividè coccineis radiatim pictá.

The scarlet-rayed haliotis. Shell somewhat orbicularly ovate, flatly convex, slightly depressed in the middle, spirally finely ridged, ridges crossed with minute raised striæ; yellowish, radiately painted with broad, bright scarlet streaks.

Reeve, Pro. Zool. Soc., 1846.

Hab, —— ?

No one can fail to recognize this delicate and very striking scarlet-rayed species. The ridges are minutely beaded, as it were, with transverse striæ, and the surface of the shell is peculiarly indented.

1/ mile

PLATE XIV.

Species 47. (Mus. Cuming.)

Haliotis speciosa. Hal. testá oblongo-ovatá, planoconvexá, medio depressá, spiraliter elevato-stiatá, striis confertis; foraminibus senis perviis; coccineo-rufá, albo, nigricante marginatá, pulcherrimè variegatá.

THE HANDSOME HALIOTIS. Shell oblong-ovate, flatly convex, depressed in the middle, spirally elevately striated, striæ closc-set; six perforations open; scarlet-red, beautifully variegated with black-edged white.

REEVE, Pro. Zool. Soc., 1846.

Hab. —— ?

This is a very gay species, the colour being a rich scarlet red, variegated with broad zigzag flames, edged along the front with black.

Species 48. (Mus. Cuming.)

Haliotis reticulata. Hal. testá oblongo-ovalá, anticè subattenualá, plano-convexá, medio depressá, latere sinistro latiusculo, erecto, spiraliter vix striatá; foraminibus quaternis perviis; sordidè fuscá, maculis albidis reticulatis, subtriangularibus, ornatá.

The reticulated Haliotis. Shell oblong-ovate, somewhat attenuated, flatly convex, depressed in the middle, left side rather broad, erect, spirally slightly striated; four perforations open; dull dark brown, ornamented with somewhat triangular reticulated white spots.

REEVE, Pro. Zool. Soc., 1846.

Hab. ——?

May be recognized by the triangular reticulated style of the painting.

Species 49. (Mus. Cuming.)

Haliotis nebulata. Hal. testá oblongo-ovatá, convexá, spirá subelevatá, spiraliter sulcatá, sulcis parvis, undatis; foraminibus subapproximatis, septenis perviis; fusco roseoque undique nebulatá.

THE CLOUDED HALIOTIS. Shell oblong-ovate, convex, spire rather elevated, spirally grooved, grooves small,

waved; perforations rather approximated, seven open; clouded throughout with brown and red.

REEVE, Pro. Zool. Soc., 1846.

Hab. ---- ?

Very distinct, both in form and in its style of painting.

Species 50. (Mus. Cuming.)

Haliotis sepiculata. Hal. testá ovatá, spiraliter peculiariter liratá, liris angustis, erectis, valdè irregularibus, radiutim undato-plicatá; foraminibus amplis, senis perviis; olivaceo-viridi, hic illic albipunctatá.

The hedged Haliotis, Shell ovate, spirally peculiarly ridged, ridges narrow, erect, very irregular, radiately undately plicated; perforations large, six open; dark olive green, here and there dotted with white.

REEVE, Pro. Zool. Soc., 1846.

IIab. ——?

A finc species, well-characterized by the erect development of the ridges.

Species 51. (Fig. a, Mus. Hanley, b, Mus. Cuming, c, Mus. Metcalfe.)

Haliotis semistriata. Hal. testá ovatá, spiraliter subtiliter tiratá, radiatim undato-plicatá et plus minusve tuberculosá; foraminibus subtubiferis, quinis perviis; fuscá aut coccineo-rufá, albimaculatá.

The Half-striated Haliotis. Shell ovate, spirally finely ridged, radiately undately plicated, and more or less tuberculated; perforations a little tubiferous, five open; brown or scarlet red, spotted or streaked with white.

Reeve, Pro. Zool. Soc., 1846.

Hab. Ceylon; Dr. Sibbald.

A well-marked species, though extremely variable in its colouring and sculpture, some specimens being covered with swoollen tubercles, whilst others are comparatively smooth; as a general rule it may be observed that the spiral half of the shell is the more distinctly striated or finely ridged. Care should be taken not to confound this species with the *Haliotis varia*, to which it has some slight resemblance, though differing in colour.

Halious. 17 XV.

PLATE XV.

Species 52. (Mus. Metcalfe.)

Haliotis pustulata. Hal. testá oblongo-ovatá, spiraliter obscurè liratá et tuberculis parvis pustulatá, radiatim plicatá; foraminibus senis perviis; albidá viridique pulcherrimè marmoratá.

THE PUSTULATED HALIOTIS. Shell oblong-ovate, spirally obscurely ridged, and pustulated with small tubercles, radiately plicated, six perforations open; beautifully marbled with green and white.

REEVE, Pro. Zool. Soc., 1846.

Hab. ——?

A prettily variegated species, distinguished by its obscure tubular sculpture.

Species 53. (Fig. a, Mus. Metcalfe, Fig. b, Mus. Cuming.)

Haliotis parva. Hal. testá orbiculuri-ovatá, spiraliter crebristriatá, medio subdepressá, costá unicá conspicuá rotundatá notatá; foraminibus tubiferis, senis perviis; viridè coccineo-rufá.

The small Haliotis. Shell orbicularly ovate, spirally closely striated, a little depressed in the middle, and marked with a single conspicuous rounded rib; perforations tubiferous, six open, bright scarlet red.

Variety β . (Fig. 53, δ .)

Testá viridescente-albidá, purpureo-rufo pulcherrimè variegatá et strigatá.

Shell beautifully variegated and streaked with greenish white and purple-red.

LINNÆUS, Syst. Nat. (12th edit.) p. 1256.

Haliotis canaliculata, Lamarck.

Hab. --- ?

The varieties of this species above noted are so very distinct and characteristic, that I was strongly tempted, at one time, to regard them of specific importance; the distinction is not, however, supported by the slightest variation in form or sculpture. Another circumstauce in testimony of their specific relation, is, that both varieties are frequently more or less covered with a peculiar kind of deposit, probably coralline, which I have not observed on any other species.

Species 54. (Mus. Cuming.)

HALIOTIS AQUATILIS. Hat, testa oblongo-ovata, plano-

convexá, medio depressá, lævigatá, prope marginem peculiariter plicatá; foraminibus senis perviis; pallidè viridi, albido aut flavicante undato-variegatá, intus albicante.

THE RIPPLED HALIOTIS. Shell oblong-ovate, flatly convex, depressed in the middle, smooth, peculiarly plicated near the margin; six perforations open; light green, undately variegated with yellowish white, interior whitish.

REEVE, Pro. Zool. Soc., 1846.

Hab. Kurile Islands, south of Kamtschatka.

There is a marked peculiarity in the form and colouring of this species, independently of the rippled plications near the margin.

Species 55. (Mus. Cuming.)

Hallotis Janus. Hal. testá oblongo-ovatá, spiraliter liratá, liris subtilibus angustis, interstitiis excavatis; foraminibus senis perviis; luteo-anrantiá, fasciá latá albidú, fusco grandimaculatá, prope foramines ornatá.

The two-faced Haliotis. Shell oblong-ovate, spirally ridged, ridges fine, narrow, interstices excavated, six perforations open; yellowish orange, ornamented next the perforations with a broad white band, coloured with large broad spots.

Reeve, Pro. Zool. Soc., 1846.

Hab. ---- ?

The curious double style of painting which this shell exhibits is peculiar to the species, and not, as one might be led to imagine, a mere casual variety.

Species 56. (Mus. Cuming.)

IIALIOTIS CRUENTA. Hal. testá ovatá, antice subattenuatá, spirá etevatius vutá, spiraliter peculiariter undato- et corrugato-striatá; foraminibus subapproximatis, octonis perviis; sanguineo albipunctato et atbido sanguineo-punctato pulcherrime variegatá.

The blood-smeared Haliotis. Shell ovate, a little attenuated anteriorly, spire rather clevated, spirally peculiarly striated in a waved and wrinkled manner; perforations somewhat approximated, eight open; beautifully variegated with white-dotted searlet and scarlet-dotted white.

REEVE, Pro. Zool. Soc., 1846.

Hab. New Zealand.

A very pretty species, perfectly distinguished from any other in form, sculpture, and colonring.

Species 57. (Mus. Cuming.)

Haliotis incisa. Hal. testa ovata, medio subdepressa, spiraliter incisa, subtuberculifera; foraminibus amplis, quaternis perviis; albida et purpureo-viridi marmorata, albido minutissimè rufo-punctato. The engraved Haliotis. Shell ovate, a little depressed in the middle, spirally engraved, slightly tuberculiferous; perforations large, four open; marbled with white and purple-green, the white very minutely dotted with red.

REEVE, Pro. Zool. Soc., 1846.

Hab. ——?

Almost the entire surface of this shell is minutely speekled with red, over the green and white marbling.

Haliotis Pl A

PLATE XVI.

Species 58. (Mus. Cuming.)

Haliotis striata. Hal. testá oblongo-ovatá, convexodepressá, spirá subprominulá; spiraliter crebristriatá, radiatim leviter rugosá; foraminibus senis perviis; intus striatá, irridescente, extus ferrugineo, rufo, alboque marmoratá.

The striated Haliotis. Shell oblong-ovate, convexly depressed, spire rather prominent; spirally closely striated, radiately lightly wrinkled; six perforations open; interior striated, irridescent, exterior marbled with rusty brown, red, and white.

Linneus, Syst. nat. (12th edit.) p. 1256.

Hab. ---- ?

I refer this shell to the *H. striata* of Linnæus, as being the nearest to accord with his description; it is quite impossible to identify the species with any degree of certainty.

Species 59. (Mus. Cuming.)

Haliotis Rugosa. Hal. testa ovata, convexa, medio leviter depressa, radiatim plicato-rugosa, spiraliter tirata, liris obtusis, hic illic majoribus; foraminibus subamphis, quaternis perviis; extus olivaceo-fusco viridique marmorata.

THE ROUGH HALIOTIS. Shell ovate, convex, slightly depressed in the middle, radiately plicately wrinkled, spirally ridged, ridges obtuse, here and there larger; perforations rather large, four open; exterior marbled with olive-brown and green.

REEVE, Pro. Zool. Soc., 1846.

Hab. —— ?

The ridges of this species are somewhat irregular near the apex, but in the middle they are arranged alternately one broad and three narrow.

Species 60. (Mus. Cuming.)

Haliotis rosacea. Hal. testá ovatá, convexo-depressá, spiraliter crebriliratá, liris striis exsculptis undique decussatis; foraminibus peculiariter oblongo-ovatis, quaternis perviis; extus corallo-rubro et roseo-albicante marmoratá, rubro viridi punctato.

THE ROSE-TINTED HALIOTIS. Shell ovate, convexly depressed, spirally closely ridged, decussated throughout with engraved striæ; perforations peculiarly oblong ovate, four open; exterior marbled with deep coral red punctured with green.

Reeve, Pro. Zool. Soc., 1846.

Hab. --- ?

It is impossible to give any other than a very faint conception of this beautiful shell in a figure, the entire surface has a most delicate beaded appearance, and the colouring is extremely rich; there is also a marked peculiarity in the oblong shape of the perforations which very nearly approximate.

Species 61. (Mus. Cuming.)

Haliotis pertusa. Hal. testa oblongo-ovata, spiraliter posticè subtilissimè sulcata, sulcis pertusis, anticè exiliter lirata, sulcis lirisque subirregularibus et undatis; foraminibus senis perviis; extus rufo-fusca, strigis perpaucis lutescentibus undatis prope spiram, intus vividè irridescente.

The pricked Haliotis. Shell oblong-ovate, spirally posteriorly very finely grooved, grooves pricked, anteriorly faintly ridged, grooves and ridges rather irregular and waved; six perforations open; exterior ruddy brown, with a very few yellowish zigzag streaks near the spire, interior brightly irridescent.

REEVE, Pro. Zool. Soc., 1846.

Hab. —— ?

One half of the shell, next the spire, is sculptured with faint pricked grooves, the other with fine waved ridges.

Species 62. (Mus. Metcalfe.)

Haliotis planilirata. Hal. testá ovatá, plano-convexá, spiraliter liratá, liris planulatis, irregularibus; foraminibus quinis perviis; olivaceo- et cæruleo-viridi.

THE FLAT-RIDGED HALIOTIS. Shell ovate, flatly convex, spirally ridged, ridges flattened, irregular; five holes open; olive and blueish green.

REEVE, Pro. Zool. Soc., 1846.

Hab. —— ?

May be recognised by its dark blue-green flattened growth.

Species 63. (Mus. Hanley.)

Haliotis scutulum. Hal. testá convexá, spirá depressá

suboccultá, spiraliter exiliter liratá, liris planulatis, undulatis, his iltic majoribus; foraminibus senis perviis; olivaceo-fuscá, viridi pulcherrimè articulatá, punctatá, et maculatá.

The shield Haliotis. Shell convex, spire depressed, rather concealed, spirally faintly ridged, ridges flattened, waved, here and there larger; six holes open; olive-brown, very beautifully articulated, dotted and spotted with green.

Reeve, Pro. Zool. Soc., 1846.

Hab. ---- ?

The ridges of this species have a peculiar undulating character, and towards the middle of the shell are arranged one broad and three narrow alternately. Species 64. (Mus. Cuming.)

Haliotis Zealandica. Hal. testá oblongo-ovatá, subdepressá, spiraliter irregulariter sulcatá. liris intermediis obtusis, nunc latis, nunc angustis, foraminibus senis perviis; rufo-castaneo et albicante peculiariter marmoratá.

The New Zealand Haliotis. Shell oblong, rather depressed, spirally irregularly grooved, intermediate ridges obtuse, now broad, now narrow; six holes open; exterior peculiarly marbled with reddish chesnut and red-tinged white.

REEVE, Pro. Zool. Soc., 1846.

Hab. New Zealand.

Distinguished by the curious irregularity of the grooves, and its style of painting.

PLATE XVII.

Species 65. (Mus. Cuming.)

Haliotis Dringii. Hal. testá orbiculari-ovatá, spiraliter striatá, radiatim plicatá et tuberculosá; foraminibus subtubiferis, quaternis perviis; extus pallidè viridescente-luteá, medio conspicuè coccineo-tinctá, intus argenteá.

Dring's Haliotis. Shell orbicularly ovate, spirally striated, radiately plicated and tuberculated; perforations a little tubiferous, four open; exterior pale greenish yellow, conspicuously stained in the middle with scarlet, interior silvery.

REEVE, Pro. Zool. Soc., 1846.

Hab. North coast of Australia; Dring.

I dedicate this interesting little species to Mr. Dring, of H. M. S. Beagle, in remembrance of the many beautiful new species of shells for which we are indebted to him, from the comparatively unexplored region above noted.

Species 66. (Mns. Cuming.)

Haliotis concinna. Hal. testâ suboblongo-ovatâ, spiraliter striatâ, medio leviter tuberculatâ, obliquè subobscurè plicatâ; foraminibus quaternis perviis; carneoalbicante, coccineo-roseo profusè variegatâ.

THE NEAT HALIOTIS. Shell somewhat oblong-ovate, spirally striated, slightly tuberculated in the middle, obliquely rather obscurely plicated; four perforations open; fleshy white, profusely variegated with scarletrose

REEVE, Pro. Zool. Soc., 1846.

Hab. Zamboanga, Island of Mindanao, Philippines; Cuming.

Another gaily-coloured species of similar style of painting, but of a totally different form.

Species 67. (Mus. Cuming.)

(Magnified double.)

Haliotis gemma. Hal. testa suborbiculari-ovata, planoconvexa, latere sinistro latiusculo; spiraliter tuberculata, radiatim pulcherrime minute plicato-squamata; foraminibus subtubiferis, quaternis quinisve perviis; flavescente, coccineo viridique tincta.

THE GEM HALIOTIS. Shell somewhat orbicularly ovate, flatly convex, left side rather broad; spirally tuber-culated, radiately very beautifully minutely plicately

scaled; perforations a little tubiferous, four or five open; yellowish, stained with scarlet and green.

Reeve, Pro. Zool. Soc., 1846.

Hab. ----

The surface of this beautiful little species, besides being tuberculated, is covered with minute scales, which present a rather more prominent character on the left side beneath the perforations.

Species 68. (Mus. Cuming.)

HALIOTIS LAUTA. Hal. testá ovatá, anticè attenuatá, undato-tumidá, spiraliter liratá, liris subtilibus, confertis, striis minutis decussatis; foraminibus subamplis, quinis perviis; rubido et flavescente-albidá irregulariter marmoratá.

THE SHOWY HALIOTIS Shell ovate, anteriorly attenuated, undately swollen, spirally ridged, ridges very fine, close-set, decussated with minute strize; perforations rather large, five open; irregularly marbled with red and yellowish-white.

REEVE, Pro. Zool. Soc., 1846.

Hab. Swan River Settlement, New Holland; Lieut. Preston.

In form, and in the character of the perforations, this species bears some resemblance to the *H. sanguinea*, though its relation is very remote in other respects.

Species 69. (Mus. Cuming.)

Haliotis papulata. Hal testá suborbicutari-ovatá, spiraliter obtuso-liratá, liris subdistantibus, conspicuè tuberculatis; foraminibus subtubiferis, quaternis perviis; corallo-rubidá, flavescente variá.

THE PIMPLED HALIOTIS. Shell somewhat orbicularly ovate, spirally obtusely ridged, ridges rather distant, conspicuously tuberculated; perforations a little tubiferous, four open; dark eoral-red, variegated here and there with patches of yellow.

Reeve, Pro. Zool. Soc., 1846.

Hab. North coast of Australia; Dring.

The pimpled sculpture of this shell is of a much more prominent character than that of the first three species of the plate. Fig. 70.

The shell here figured from the cabinet of Mr. Gray, proves, on further examination, to be the young of *H. san-quinea*.

Species 70. (Fig. 71, Mus. Cuming.)

Haliotis ancile. Hal. testá ovatá, regulariter convexá, spiraliter exiliter noduloso-striatá, nodulis interdum subobscuris, interruptis; foraminibus numerosis, parvis, octonis perviis; olivaceo-viridi, nodulis et circa spiram cupro-roseis.

THE MARTIAN BUCKLER HALIOTIS. Shell ovate, uniformly convex, spirally faintly nodulously striated, nodules sometimes nearly obscure, interrupted; perforations numerous, small, eight open; olive-green, nodules and around the spire coppery rose-red.

REEVE, Pro. Zool. Soc., 1846.

Hab. -- ?

An uniform convex shell striated with faint, interrupted, irregular, nodulous striæ of a coppery rose hue, with the perforations very small and numerous.

Species 71. (Fig. 72 Mus. Cuming.)

Haliotis clathrata. Hal. testă semicirculari-ovată, spiraliter crebrilirată, interstitiis striis subtilissime clathratis, radiatim plicată; foraminibus subamplis, quinis perviis; viridi et vivide rufo variegată.

The Latticed Haliotis. Shell semicircularly ovate, spirally closely ridged, interstices very finely latticed with striæ, radiately plicated; perforations rather large, five open; variegated with green and bright red.

Reeve, Pro. Zool. Soc., 1846.

Hab. Baclayon, Island of Bohol, Philippines; Cuming.

An interesting little species finely latticed between the ridges, and strongly plicated immediately around the spire.

Species 72. (Mus. Cuming.)

Haliotis Jacnensis. Hal. testá oblongo-ovatá, spiraliter peculiariter rudè liratá, liris valdè irregutaribus, subsquamosis, prope foramines sublævigatá; foraminibus subtubiferis, distantibus; rufescente-aurantiá, intus argenteá.

The Jacka Haliotis. Shell oblong-ovate, spirally peculiarly rudely ridged, ridges very irregular and rather scaly, somewhat smooth next the perforations, which are slightly tubiferous and distant; reddish-orange, interior silvery.

Reeve, Pro. Zool. Soc., 1846.

Hab. Jacna, Island of Bohol, Philippines; Cuming.

A very characteristic species, to which there is little or no approximation in any other.

Species 73. (Fig. 74, Mus. Cuming.)

Haliotis Stomatiæformis. Hal. testá oblongo-ovatá, valdè convexá, spiraliter striatá, radiatim subtiliter plicatá, spirá subterminali, elevatá; foraminibus quinis perviis; olivaceo viridique marmoratá.

The Stomatia-shaped Haliotis. Shell oblong-ovate, very convex, spirally striated, radiately finely plicated, spire nearly terminal, elevated; five perforations open; marbled with olive and green.

REEVE, Pro. Zool. Soc., 1846.

Hab. New Zealand.

Well distinguished by its conspicuously convex oblong form, resembling in great measure that of some of the *Stomatiæ*

MONOGRAPH

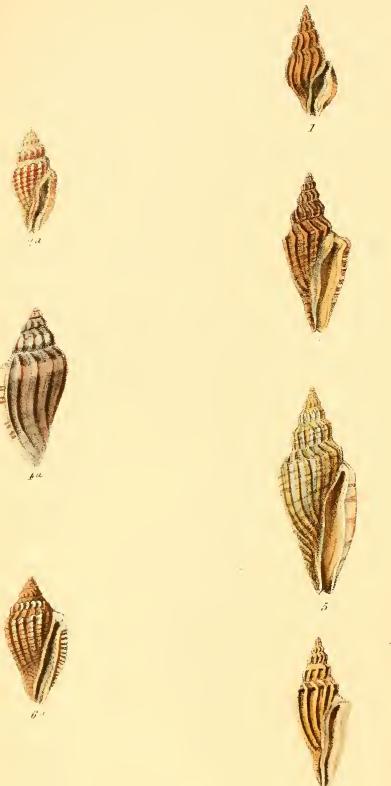

OF THE GENUS

MANGELIA.

I named them as they passed, and understood
Their nature, with such knowledge God endued
My sudden apprehension: but in these
I found not what methought I wanted still."—Milton.

c rerby del et hth

MANGELIA.

PLATE I.

(Figures magnified to two and a half times their natural size.)

Genus Mangelia, Leach.

Testa Marginellæformis aut fusiformis, plerumque longitudinaliter costata, spirå nunc brevi, nunc acuminatoturritå; columetlå labroque intus subtilissimè rugosodenticulatis, labro incrassato, supernè leviter sinuato; canali brevissimo, plus minusve truncato.

Shell Marginella-shaped or fusiform, mostly longitudinally ribbed, spire sometimes short, sometimes acuminately turreted; lip and columella very finely rugosely denticulated, lip thickened, slightly sinuated at the upper part; canal very short, more or less truncated.

M. Deshayes passes a severe and somewhat merited reprimand upon M. Kiener, for having, in genus Cancellaria of his 'leonographie', which professes to illustrate the shells contained in the Lamarckian collection, omitted mention of the C. thiarella of that illustrious author, notwithstanding the authority "mon cabinet" attached to that species in the 'Animanx sans vertèbres'.* It would certainly have been desirable if M. Kiener had published his reasons for this omission, for they were probably founded on the discovery that the shell in question is not only no Cancellaria at all, but that it is not referable to any genus hitherto established. Mr. Sowerby had already intimated that this shell belongs to another genus; and M. Deshayes erroneonsly imagines, from Martini's figure, that it may be the young of Strombus plicatus.

This "Fusus ad formam citharæ compositus" of Martini, Cancellaria citharella of Lamarck, has been collected in various states by Mr. Cunning, at the Philippine Islands, together with upwards of fifty other closely allied species, the whole of which are new and display a very striking association of character. In addition to these I have a new one from Australia, one from Sicily, some from the West Indies collected by the Rev. Lansdowne Guilding, and five collected by Capt. Belcher during the surveying expedition of the 'Sulphur', described and figured by Mr. Hinds in the Zoology of that Voyage; all of which I now propose to assemble under the head of Mangelia, a genus proposed some years since in manuscript, by the late Dr. Leach of the British Museum, of which I find no published record.

The Mangeliæ are nearest allied to those aberrant species of Pleurotoma in which the predominant character of that genus, the fissure in the upper extremity of the lip, becomes modified into a somewhat obscure sinus. Their general aspect is that of a more or less fusiform Marginella, without plaits or polished exterior; distinguished, on the other hand, by a row of faint wrinkle-like denticulations on the inner surface of the lip and columella, and a gutter-like sinus in the lip at its junction with the body-whorl, in a manner similar to that of the Pleurotome above referred to.

It is rarely an author has the pleasure of introducing a whole genus of seventy new species, but such is the opportunity which the indefatigable exertions of Mr. Cuming have afforded me, with the exception of the one included by Lamarck with the Cancellariæ, and the five published by Mr. Hinds in the 'Zoology of the Sulphur'. They were found by that eminent traveller under various circumstances, some on the reefs, some in concealed situations under stones, and some at depths varying from three to twenty five fathoms.

Species 1. (Mus. Cuming.)

Mangelia Sicula. Mang. testá subfusiformi, spirá acuminatá, anfractibus rotundatis, gibbosiusculis, concentricè costatis, læcibus; aperturá brevi, ovatá, sinu subconspicuo; intus extusque castaneo-fuscá, labro flavicante, fusco-lineato.

The Sicilian Mangelia. Shell somewhat fusiform, spire acuminated, whorls rounded, rather gibbous, concentrically ribbed, smooth, aperture short, ovate, sinus rather conspicuous; dark chesnut-brown within and without, lip yellowish, crossed with fine brown lines

REEVE, Pro. Zool. Soc., 1846. Hab. Sicily.

I place this species at the commencement of the series as indicating the nearest approach to *Pleurotomu*; oscillating in character between that of the two genera, it might be referred with equal propriety to either.

* Il y a une autre coquille, la Cancellaria citharella de Lamarck, et dont M. Kieuer ne parle pas dans sa Monographie. Une telle lacune est fâcheuse dans un ouvrage aussi spécialement consacré à l'illustration de la partie conchyliologique des animaux sans vertèbres. M. Sowerby suppose que cette coquille appartient à un autre genre, et si l'on s'en rapporte à la figure citée de Martini, elle ne serait en effet qu'un jeune Strombe. Il appartenait donc à M. Kieuer d'éclairer la science à ce sujet."

And again, "M. Kiener nous laisse dans l'ignorance la plus complète à l'égard de cette espèce de Lamarek. Nous avons toujours eru que l'un des buts que se proposait l'auteur du Species des coquilles, était de donner des reuseignemens positifs sur les espèces de Lamarek, mises à sa disposition. En s'abstenaut, M. Kiener ote gratuitement à sou ouvrage ce qui lui aurait donné le plus d'intéret, non-seulement aux yenx des simples amateurs, qui tous consident les travaux de Lamarek, mais aussi à ceux des personnes qui font de la science d'une manière sérieuse et qui rechercheut avec avidité tout ce qui pent les éclairer sur les espèces de Lamarek. Cette Cancellaria citharella, d'apres la figure de Martini, nous semble une jeune Strombus plicatus de Lamarek."—Deshayes, Animaux sans vertèbres, vol. ix. p. 401 and 407.

Species 2. (Mus. Cuming.)

Mangelia vexillum. Mang. testá oblongo-ovatá, anfractibus supernè depressis, nodosis, costis e nodis descendentibus, superficie totá decussatim striatá, quasi subtilissimè decussatá; aurantio-luteá, fasciis albicantibus angustis undique cingulatá.

THE FLAG MANGELIA. Shell oblong-ovate, whorls depressed round the upper part, noduled, with ribs descending from the nodules, entire surface of the shell decussately striated, as if very finely granulated; orange-yellow, encircled throughout with narrow whitish bands.

Reeve, Pro. Zool. Soc., 1846.

Hab. Ilo Ilo, Isle of Panay, Philippines (found under stones); Cuming.

A prettily marked species of a bright orange-yellow colour, banded with white like a miniature Orange-flag Volnte; the minute decussated sculpture of the surface is also characteristic.

Species 3. (Mus. Cuming.)

Mangelia lyra. Mang. testá trigono-fusiformi, anfractibus supernè angulatis, longitudinaliter costatis, costis subobliquis, ad angulum incrassatis; castaneo-fuscá, lineis albicantibus decussatis, labro albicante.

The Lyre Mangelia. Shell triangularly fusiform, whorls angulated at the upper part, longitudinally ribbed, ribs rather oblique, thickened at the angle; chesnutbrown, crossed with whitish lines, lip whitish.

Hab. Island of Ticao, Philippines (found on the sands); Cuming.

The white lines which encircle this dark chesnut-brown shell are most conspicuous on the ribs.

Species 4. (Mns. Cuming.)

Mangelia Antillarum. Mang. testá subpyriformi-ovatá, lævigatá, lougitudinaliter concentricè costatá, costis fortibus, subobtusis, distantibus; cinereo-carneá, costis fasciá rubidá tinctis, labro albicante, rubido fasciatim tincto.

The West India Mangelia. Shell somewhat pyriformly ovate, smooth, longitudinally concentrically ribbed, ribs strong, rather obtuse, distant; ashy flesh-colour, ribs stained with a reddish band, lip whitish, stained with reddish bands.

Reeve, Pro. Zool. Soc., 1846.

Hab. West Indies.

This is a fine species, and one highly typical of the genus.

Species 5. (Mus. Cuming,)

MANGELIA CITHARELLA. Mang. testá fusiformi-ovatá,

anfractibus supernè angulato-depressis, longitudinaliter costatis, costis e suturis descendentibus, ad angulum nodosis, lævibus, interstitiis subtilissimè elevato-striatis, albidå, costis luteo-rufo lineatå et fasciatå.

THE LITTLE HARP MANGELIA. Shell fusiformly ovate, whorls angular, depressed at the upper part, longitudinally ribbed, ribs descending from the sutures, nodose on the angle, smooth, interstices very finely elevately striated; whitish, ribs lineated and banded with yellowish-red.

Cancellaria citharella, Lamarck.

Icon. Martini, Conch. Cab. vol. ix. pl. 142. f. 1330. *Hab.* Island of Siquijor, (found on the sands); Cuming.

Having already spoken of this species in my introductory observations, at the commencement of the genus, it only remains to notice that it was figured by Martini, in 1780 under the head of " Fusi ad formam citharæ compositi", and referred by Lamarck to the genus Cancellaria under an impression that the faint wrinkle-like denticulations of the columella, which are only developed in the mature shell, are indentical with the plaits which wind round the columella of the Cancellaria throughout its entire growth. To make his shell accord with the generic character of Cancellaria Lamarck described the columella as being "multiplicata, plicis tenuissimis;" it will be found however, on examination, that they are not plaits at all, but one of several characteristic peculiarities of growth and sculpture which are more or less variably developed throughout the whole of the species here associated under the title of Mangelia.

Species 6. (Fig. a and b Mus. Cuming.)

MANGELIA MARGINELLOIDES. Mang. testá pyriformiovatá, spirá brevi, acutá; anfractibus supernè angulatis, longitudinaliter multicostatis, costis tenuibus, crebris, suturis descendentibus; lacteo-cærulæá aut cinereo-fuscá, lineis rubidis cingulatá, anfractüs ultimi parte supra angulum maculá grandi nigricante conspicué tinctá.

The Marginella-like Mangelia. Shell pyriformly ovate, spire short, acute; whorls angulated at the upper part, longitudinally many-ribbed, ribs thin, close-set, descending from the sutures,; milky blueish colour, or ashy brown, encircled with ruddy lines, portion of the last whorl above the angle conspicuously stained with a blackish blotch.

REEVE, Pro. Zool. Soc. 1846.

Hab. Island of Burias, Philippines (found in sandy mud at the depth of seven fathoms); Cuming.

This is an extremely interesting species having the typical form of a *Marginella*, and almost as highly polished in front from the abundant sceretion of enamel which paves the vicinity of the aperture.

For species 7, see Plate II.

Mangelia Pl. II.

MANGELIA.

PLATE II.

(Specimens magnified to two and a half times their natural size.)

Species 7. (Mns. Cuming.)

- Mangelia funiculata. Marg. testá trigono-fusiformi, subelongatá, anfractibus supernè depressis, longitudina-liter tenuicostatis, lævibus; cinereo-fuscá, costis labroque albicantibus.
- The corded Mangelia. Shell triangularly fusiform, rather elongated, whorls depressed at the upper part, longitudinally, finely ribbed, smooth; ashy brown, ribs and outer hip whitish.
- REEVE, Pro. Zool. Soc., 1846.
- Hab. Islands of Tieao and Masbate, Philippines (found on the sands); Cuming.

The fine smooth white ribs of this species, on a dark ground, give the shell the appearance of being strung with longitudinal cords.

(Species 8. (Mus. Cuming.)

- Mangelia cavernosa. Mang. testá oblongo-ovatá, spirá angulato-turritá; anfractibus supernè angulatis, intra costis cavernosis, costis fortibus, obtusis, e suturis descendentibus; albá, aurantio-fusco hic illic sparsim maculatá
- The cavernous Mangelia. Shell oblong-ovate, spire angularly turreted; whorls angulated at the upper part, cavernous between the ribs, ribs strong, obtuse, descending from the sutures; white, sparingly spotted here and there with orange-brown.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Ticao, Philippines (found on the sands); Cuming.

The orange-brown spotting is mostly on the cavernous portion of the whorls above the angle.

Species 9. (Mus. Cuming.)

- Mangelia cylindrica. Mang. testá cylindraceo-fusiformi, apice acutá, longitudinaliter subtiliter costatá, transversime levato-striatá; pellucido-albú, fuscescente tinctá, aurantio-fusco infra suturas maculatá.
- THE CYLINDRICAL MANGELIA. Shell eylindrically fusiform, sharp at the apex, longitudinally finely ribbed, transversely elevately striated; transparent white, stained with pale brown, spotted beneath the sutures with orange-brown.

Reeve, Pro. Zool. Soc., 1846.

Hab. Cagayan, Island of Mindanao, Philippines (found in sandy mud at the depth of twenty-five fathoms); Cuming.

The orange-brown spots, as in the former species, are arranged round the upper portion of the whorls beneath the sutures.

Species 10. (Mus. Cuming.)

- Mangelia capillacea. Mang. testă ovalo-fusiformi, spiræ suluris profundis; anfractibus supernè depressis, transversim subtilissimè et creberrimè elevato-striatis, longitudinaliter costatis, costis angustis, suberectis, supernè leviter mucronatis; fuscescente, lineis subtilibus fuscescentibus zonată.
- The hair-girt Mangelia. Shell ovately fusiform, sutures of the spire deep; whorls depressed at the upper part, transversely very finely and closely elevately striated, longitudinally ribbed, ribs narrow, somewhat ereet, a little pointed at the top; light brown, zoned with fine brown lines.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Burias, Philippines, (found among coarse sand at the depth of seven fathoms); Cuming.

Encircled with fine brown lines which on the summit of the raised striæ have the appearance of hair.

Species II. (Mns. Cuming).

- Mangelia gracilis. Mang. testá gracili-fusiformi, transversim subtitissimè striatá, longitudinaliter costatá, costis angustis; albá, castaneo-fusco indistinctè zonatá et maculatá.
- The slender Mangelia. Shell slenderly fusiform, transversely very finely striated, longitudinally ribbed, ribs narrow; white, indistinctly zoned and blotched with chesnut-brown.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Ticao, Philippines (found under stones at low water); Cuming.

The peculiarities of this shell are very briefly defined, hut they are not, on that account, less characteristic of a very distinct and elegantly formed species. The brown zoned painting is most conspicuous on the back of the last whorl, where it forms a rude blotch.

Species 12. (Mus. Cuming.)

MANGELIA LAMELLATA. Mang. testá fusiformi-ovatá, spiræ suturis profundis, subcavernosis, anfractibus transversim elevato-striatis, striis fortibus, subdistantibus, longitudinaliter costatis, costis angustis, erectis, lamellæformibus, supernè leviter mucronatis; albidá, fusco pallidissimè zonatá.

THE LAMELLATED MANGELIA. Shell fusiformly ovate, sntures of the spire deep, a little cavernous; whorls transversely elevately striated, striæ strong, rather distant, longitudinally ribbed, ribs narrow, erect, lamella-like, slightly pointed at the top; white, zoned with very pale brown.

REEVE, Pro. Zool. Soc., 1846.

Hab. Isle of Burias, Philippines (found among coarse sand at the depth of seven fathoms); Cuming.

Chiefly distinguished by the narrow elevated lamella-like character of the ribs.

Fig. 13. (Mus. Cuming.)

MANGELIA GRACILIS. Var. β. I had figured this shell

as a species distinct from the *M. gracilis*, but upon further examination, am inclined to think that it is merely a variety, with the transverse striæ more strongly developed, and the longitudinal ribs less so.

For Species 13 see Plate V.

Species 14. (Mus. Cuming.)

Mangelia vittata. Mang. testá oblongo-ovatá, subconicá, spirá brevi, obtusá; anfractibus longitudinaliter costatis, costarum interstitiis striis fortibus clathratis; albidá, olivaceo-fusco latifasciatá, costarum parte olivaceo-fuscá albipunctatá,

THE RIBAND-BOUND MANGELIA. Shell oblong-ovate, somewhat conical, spire short, obtuse; whorls longitudinally ribbed, interstices between the ribs latticed with strong striæ; whitish, encircled with broad olive-brown bands, the coloured portion of the ribs being dotted with white.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Ticao, Philippines (found on the sands); Cuming.

An interesting species so distinct from any other I have met with, that it may be recognised without difficulty.

Mangelia Pl.III.

PLATE III.

(Figures magnified to two and a half times their natural length.)

Species 15. (Mus. Cuming.)

Mangelia zonata. Mang. testá abbreviato-fusiformi, spirá breviusculá, turritá, suturis profundis; anfracti-bus longitudinaliter costatis, coslis e suturis descendentibus; lævigatá; albá, zoná conspicuá aurantio-fuscá cingulatá.

The zoned Mangelia. Shell shortly fusiform, spire rather short, turreted, sutures deep; whorls longitudinally ribbed, ribs descending from the sutures; smooth; white, encircled with a conspicuous zone of orange brown.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Ticao, Philippines (found on the sands); Cuming.

A delicate white shell, encircled throughout with a dark orange-brown zone.

Species 16. (Mus. Cuming.)

Mangelia interrupta. Mang. testá oblongo-ovatá, spirá brevi, anfractibus supernè nodosis, costis e nodis descendentibus; albá, lineis nigris subtilissimis transversis interruptis, creberrimè dispositis, inter costas ornatá.

THE INTERRUPTED MANGELIA. Shell oblong-ovate, spire short, whorls nodose round the upper part, with ribs descending from the nodules; white, ornamented between the ribs with very fine interrupted transverse black lines, ranging very close to one another.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Ticao, Philippines (found on the sands); Cuming.

A very significant character is here displayed, in the interstices between the ribs being painted with short black hair lines.

Species 17. (Mus. Cuming.)

Mangelia reticulata. Mang. fusiformi-ovatā, spirā breviusculā, apice acuminatā; anfractibus supernè perpendiculariter compressis, deinde tumidiusculis et longitudinaliter costatis, costarum interstitiis exiliter obliquè reticulatis; albidā, cinereo pallidè zonatā, costis exiliter fusco-punctatis. The reticulated Mangelia. Shell fusiformly ovate, spire rather short, acuminated at the apex; whorls perpendicularly compressed round the upper part, then a little swollen and longitudinally ribbed, interstices between the ribs faintly obliquely reticulated; whitish, zoned with pale ash, ribs faintly dotted with brown.

Reeve, Pro. Zool. Soc., 1846.

Hab. Island of Ticao, Philippines (found on the reefs); Cuming.

This species is distinguished by a peculiar perpendicular depression of the upper portion of the whorls, together with the faint reticulated sculpture of the interstices between the ribs. The colouring is also characteristic.

Species 18. (Mns. Cuming.)

MANGELIA FULCHELLA. Mang. testa fusiformi-ovatá, subcylindraceá, spirá breviusculá, apice acuminatá; anfractibus supernè rotundatis, longitudinaliter multicostatis, costis tenuibus, gracilibus, concentricè dispositis, anfractuum superficie totá exilissimè reticulatá; luteoalbicante, maculis quadratis parvis rufis costarum interstitiis fasciatim cinqulatá.

The pretty Mangelia. Shell fusiformly ovate, somewhat cylindrical, spire rather short, acuminated at the apex; whorls rounded at the upper part, longitudinally many-ribbed, ribs thin, slender, arranged concentrically; entire surface of the whorls very faintly reticulated; yellowish-white, encircled throughout in the interstices between the ribs, with bands of small square red spots.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Ticao, Philippines (found on the sands); Cnming.

An extremely pretty species, strikingly tessellated throughout with bright square red spots.

Species 19. (Mus. Cuming.)

Mangelia fusiformis. Mang. testá fusiformi, anfractibus supernè subangulutis, ad angulum nodosis, costis tenuibus subsuperficiariis e nodis descendentibus, transversim creberrime, striatis; luteo-albicante, punctis perpaucis aurantio-fuscis tincta.

The fusiform Mangelia. Shell finiform, whorls slightly angulated round the upper part, nodose at the angle, with thin rather superficial ribs descending from the nodules, transversely very closely striated; yellowish white, stained with orange brown.

Reeve, Pro. Zool. Soc., 1846.

Hab. Isle of Corrigidor, Philippines (found among coarse sand at the depth of ten fathoms); Cuming.

The orange-brown spots which characterize this species, are few in number, and very faintly indicated.

Species 20. (Mus. Cnming.)

MANGELIA LYRICA. Mang. testâ fusiformi, utrinque acuminatâ, anfractibus longitudinaliter concentricè costatis, transversim elevato-striatis; fuscescente, aurantio-fusco pallidè et indistinctè fasciatâ.

THE LYRICAL MANGELIA. Shell fusiform, acuminated at both ends, whorls longitudinally concentrically ribbed, transversely elevately striated; light brown, palely and indistinctly banded with orange-brown.

REEVE, Pro. Zool. Soc., 1846.

Hab. Islc of Burias, Philippine Islands (found among coarse sand at the depth of seven fathoms); Cuming.

Lightly ribbed and more asuminated at the base than any of the former species of this plate.

Species 21. (Mus. Cuming.)

Mangelia gibbosa. Mang. testá ovato-conicá, spirá brevissimá; anfractibus supernè gibbosis et nodulosis, longitudinaliter costatis, lævigatis; cinereo-albicante, lineis aurantio-fuscis exilibus cingulatá, dorso supernè nigricante tincto.

The hunch-backed Mangelia. Shell ovately conical, spire very short; whorls gibbous and nodulous round the upper part, longitudinally ribbed, smooth; ashy white, encircled with faint orange-brown lines, back stained with pale black at the upper part.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Ticao, Philippines (found on the reefs); Cuming.

A short conical shell characterized by very faint brown hair lines, and a dark neutral tint blotch on the back at the summit of the last whorl.

Mangelia Pl.IV.

24a

PLATE IV.

(Figures magnified to two and a half times their natural length.)

Species 22. (Mus. Cuming.)

Mangelia maculata. Mang. testá subfusiformi, basi truncatá, longitudinaliter costatá, costis, tennibus subdistantibus, concentricè dispositis; sinu latiusculo; albá, maculis subquadratis aurantio-fuscis inter costas.

The spotted Mangelia. Shell somewhat fusiform, truncated at the base, longitudinally ribbed, ribs thin, rather distant, concentrically arranged; sinus rather broad; white, with somewhat square orange-brown spots between the ribs.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Tieao, Philippines (found under stones at low water); Cuming.

The orange-brown spots which constitute one of the distinguishing features of this species are very characteristic on the last whorl, but on the upper whorls only the upper portion of them remain visible.

Species 23. (Mus. Cuming.)

Mangelia turricula. Mang. testá fusiformi-turritú, suturis profundis; anfractibus plano-depressis, longitudinaliter concentricè costatis; albicante, lineis subtilissimis aurantio-fuscis obsoletè cingulatú.

The Little tower Mangelia. Shell fusiformly turred, sutures deep; whorls flatly depressed, longitudinally concentrically ribbed; whitish, obsoletely encircled with very fine orange-brown lines.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Ticao, Philippines (found on the sand); Cuming.

The orange-brown lines above described are too faintly indicated to be represented in the figure, indeed they are but just discernible with the lens.

Species 24. (Mus. Cuming.)

Mangelia Columbelloides. Mang. testá ovatá, spirá brevi, acutá; anfractibus supernè leviter rotundatis, transversim elevato-striatis, longitudinaliter tenuicostatis, labro medio tumido, intus fortiter denticulato; niveá, costis eximiè aurantio-fusco punctatis.

The Columbella-like Mangelia. Shell ovate, spire short, acute; whorks slightly rounded at the upper part, tranversely elevately straited, longitudinally finely ribbed, hip swollen in the middle, strongly denticulated within; snowy white, ribs delicately dotted with orange-brown.

Reeve, Pro. Zool. Soc., 1846.

Hab. Baelayon, Island of Bohol, Philippines (found on mud banks); Cuming.

An extremely interesting species distinguished by its Columbella-like structure, and faint dotted colouring of the ribs.

Species 25. (Mns. Cuming.)

Mangelia Conohelicoides. Mang. testá ovato-conicá, spirá brevissimá, acutá; anfractibus transversim elevato-striatis, longitudinaliter multiliratá, liris tenuibus, ante suturas evanidis; tuteo-albicante, dorso maculá grandi aurantio-fuscá interdum tincto.

The Conohelix-like Mangelia. Shell ovately comical, spire very short, acute; whorls transversely clevately striated, longitudinally many-ridged, ridges thin, fading before the sutures; yellowish-white, back sometimes stained with a large orange-brown blotch.

REEVE, Pro. Zool. Soc., 1846.

Hab. Dalegnete, Isle of Zehu, Philippines (found under stones); Criming.

Distinguished by that peculiar conical form, which is typified in the Mitres, separated by Mr. Swainson under the title of *Conohelix*.

Species 26. (Mus. Cuming.)

Mangelia tenebrosa. Mang. testă subfusiformi, spiră acuminato-turrită; anfractibus superne plano-depressis, suturis profundis, transversim striatis, longitudinaliter costatis, costis distantibus; intus extusque castaneo-fuscă.

THE DARK MANGELIA. Shell somewhat fusiform, spire acuminately turrited; whorls flatly depressed at the top, sutures deep; transversely striated, longitudinally ribbed, ribs distant; dark chesnut brown within and without.

REEVE, Pro. Zool. Soc., 1846.

Hab. Cagayan, Island of Mindanao (found in sandy mud at the depth of twenty-five fathoms); Cuming.

A dark brown sharply turreted deep-water species.

Species 27. (Mus. Cuming.)

MANGELIA NOVÆ HOLLANDIÆ. Mang. testå ovatå, infernè attenuatå, subconicå, spirå brevi; anfractibus supernè rotundatis, longitudinaliter obliquè costatis; livido-cinereå, apice basique nigricantibus, labro albido, aperturæ fauce fuscå.

THE NEW HOLLAND MANGELIA. Shell ovate, attenuated at the lower part, somewhat conical, spire short; whorls rounded at the upper part, longitudinally obliquely ribbed; livid ash-colour, base and apex blackish, lip whitish, interior of the aperture brown.

Reeve, Pro. Zool. Soc., 1846.

Hab. Swan River.

A very characteristic species exhibiting a curious variety of dingy colouring.

Species 28. (Mus. Cuming.)

Mangelia livida. Mang. testá subfusiformi-ovatá, apice acuminatá; anfractibus longitudinaliter concentricè costatis, costis tenuibus; livido-carneá.

THE LIVID MANGELIA. Shell somewhat fusiformly ovate, acuminated at the apex, whorls longitudinally concentrically ribbed, ribs thin; livid flesh-colour.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Ticao, Philippines (found on the reefs): Cuming.

A livid flesh-coloured shell, simply longitudinally ribbed.

Mangelia Pl.1

PLATE V.

(Specimens magnified to two and a half times their natural length.)

Species 13. (Mus. Cuming.)

Mangelia pyramidalis. Mang. testā pyramidali, turrilā, longitudinaliler coslatā, costarum interstitiis striatis; aperturā parvā, brevi; albā.

THE PYRAMIDAL MANGELIA. Shell pyramidal, turreted, longitudinally ribbed, interstices between the ribs striated; aperture small, short; white.

Hab. Island of Mindoro, Philippines; Cuming.

Of a somewhat hexagonal form, arising from the ribs following one under the other.

Species 29. (Mus. Cuming.)

Mangelia Dysoni. Mang. testa ovata, spira breviuscula, anfractibus supernè rotundatis, longitudinaliter creberrimè tenuicostatis, striis transversis decussatis; albida, aurantio-fusco pallidè bifasciata.

Dyson's Mangelia. Shell ovate, spire rather short, whorls rounded at the upper part, longitudinally very closely finely ribbed, decussated with transverse striæ; whitish, encircled with two faint bands of orange-brown.

Hab. Honduras (found on the sands); Dyson.

The ribs being decussated with striæ have a slightly granular appearance.

Species 30. (Mus. Cuming.)

M/ sgelia abyssicola. Mang. testá oblongo-ovatá, ntrinque conspicuè attenuatá, longitudinaliter costatá, lineis elevatis cingulatá; albidá, fusco zonatá.

The deep-dwelling Mangelia. Shell oblong-ovate, conspicuously attenuated at both ends, longitudinally ribbed, encircled with raised lines; whitish, zoned with brown.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Mindanao, Philippines (found in sandy mud at the depth of twenty-five fathoms); Cuming.

Peculiarly attenuated at both ends, and corded throughout with raised strice.

Species 31. (Mus. Cuming.)

MANGELIA BICOLOR. Mang. lestá oblongá, concentricè

costatá, costarum interstitiis subtilissimè striatis; supra atbidá, infra plumbeá.

THE TWO-COLOURED MANGELIA. Shell oblong, concentrically ribbed, interstices between the ribs very finely striated; white above, lead colour below.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Ticao, Philippines; Cuming.

Distinguished in some measure by its conspicuous contrast of colour.

Species 32. (Mus. Cuming.)

Mangelia funebris. Mang. testá oblongá, concentricè costatá, costarum interstitiis lævibus; albidá, fasciá plumbeá latá cingulatá.

The mourning Mangelia. Shell oblong, concentrically ribbed, interstices between the ribs smooth; whitish, encircled with a broad lead-coloured band.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Ticao (found under stones at low water); Cuming.

The spire is rather more elevated than in the former species, and the shell has altogether a different aspect.

Species 33. (Mus. Cuming.)

Mangelia Stromboides. Mang. testă fusiformi-ovată, spiră subturrită; anfractibus superne angulatis, longitudinaliter costatis, costis ad angulum nodosis, interstitiis subtilissime striatis; albidă.

The Strombus-like Mangelia. Shell fusiformly ovate, spire somewhat turreted; whorls angulated round the upper part, longitudinally ribbed, ribs nodose at the angle, interstices very finely striated; whitish.

Reeve, Pro. Zool. Soc., 1846.

Hab. Island of Bohol, Philippines.

Mr. Cuming possesses a specimen of this shell from the Red Sea, collected by Dr. Rüppell.

Species 34. (Mus. Cnming.)

Mangelia Pallida. Mang. testá ovatá, concentricè costatá, costis subotusis; albá.

THE PALE MANGELIA. Shell ovate, concentrically ribbed, ribs rather obtuse; white.

Reeve, Pro. Zool. Soc., 1846. *Hab.* Island of Ticao, Philippines; Cuming.

A small white species with stout concentric ribs.

Species 35. (Mus. Cuming.)

Mangelia tæniata. Mang. testa oblongo-fusiformi, lævissimå, longitudinaliter plicato-coslatå; albidå aut lutescente, lineis fuscis conspicuè cingulatå.

The filletted Mangelia. Shell oblong-fnsiform, very smooth, longitudinally plicately ribbed; whitish or yellowish, conspicuously encircled with brown lines. *Pleurotoma tæniata*, Deshayes, Expèd Morée p. 178. pl. xix. f. 37–39.

Pteurotoma eburneum, Bivon.

Hab. Mediterranean.

A smooth yellowish species encircled with fine brown lines.

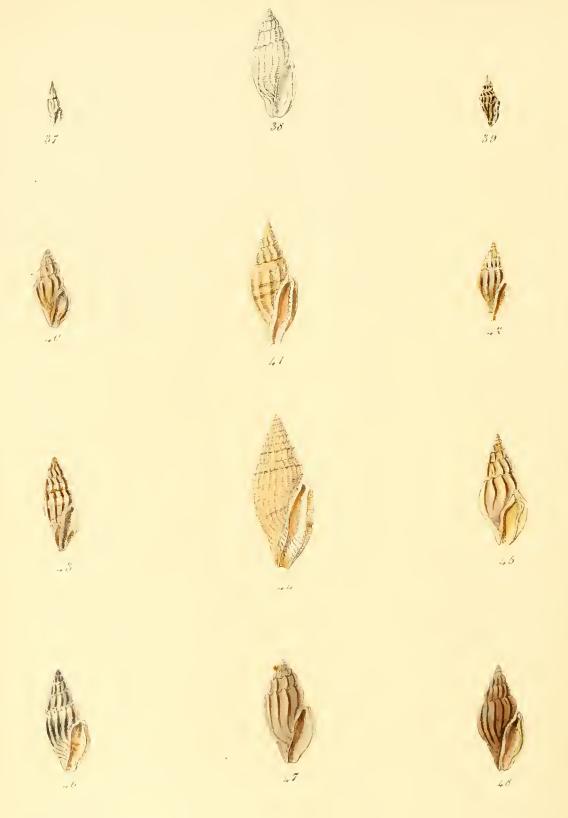

Species 36. (Mus. Cuming.)

Mangelia crassilabrum. Mang. testá oblongá, spirá brevi, subturritá, anfractibus supernè rotundatis, longitudinaliter crebricostatis; labro valdè incrassato; plumbeo-fasciatá, obscurè subtilissimè albilineatá.

THE THICK-LIPPED MANGELIA. Shell oblong, spire short, a little turreted, whorls rounded at the upper part, longitudinally closely ribbed; lip more than usually thickened; lead colour or banded with lead colour, crossed with numerous obscure fine white liues.

Hab. Islands of Ticao and Bohol, Philippines; Cuming.Distinguished by its swollen lip.

, werby del et hth.

Reeve, imp

PLATE VI.

(Specimeus, except Figs. 37 and 39, magnified to two and a half times their natural length.)

Species 37. (Mus. Beleher.)

Mangelia oryza. Mang. testá atlenuatá, acuminatá, lævigatá, nitidá, hexagonè plico-costulatá; anfractibus septenis; albidá.

THE RICE-GRAIN MANGELIA. Shell attenuated, aenminated, smooth, shining, hexagonally plicately ribbed; whorls seven in number; whitish.

HINDS, Moll. Voy. Sulphur, p. 20. pl. 9. f. 4.

Hab. North coast of New Guinea (from twenty-two fathoms, mud); Hinds.

The figure of this species is of the natural size.

Species 38. (Mus. Cuming.)

Mangelia pessulata. Mang. testá cylindraceo-oblongá, spirá breviusculá, longitudinaliter eximiè subobliquè costatá, costarum interstitiis subtilissimè striatis; niveá.

The barred Mangelia. Shell rather cylindrically oblong, spire rather short; longitudinally delicately rather obliquely ribbed, interstices between the ribs very finely striated; snowy white.

REEVE, Pro. Zool. Soc., 1846.

Hab. Philippine Islands; Cuming.

The sculpture of this shell is of a most delicate character.

Species 39. (Mus. Belcher.)

Mangelia cinnamomea. Mang. testá attenuatá, nitidá, cinnamomeá, albifasciatá; anfractibus senis, plico-costulatis, transversim lævissimè striatis.

THE CINNAMON MANGELIA. Shell attenuated, smooth, cinnamon-coloured, white-banded; whorls six in number, plicately ribbed, transversely obsoletely striated. HINDS, Moll. Voy. Sulphur, p. 25. pl. 9. f. 1.

Hab. North coast of New Guinea, Straits of Macassar, and Malacca (from five to tweuty-two fathoms, mud);

Of the natural size, from Mr. Hinds' figure.

(Species 40. Mus. Forbes.)

Mangelia rigida. Mang. testã ovatã, longitudinaliter fortiter tuberculato-costatã, transversim subtilissimè striatã; fuscescente.

THE RIGID MANGELIA. Shell ovate, longitudinally strongly tubercularly ribbed, transversely very finely striated; light brown.

Reeve, Pro. Zool. Soc., 1846.

Hab. Ægean Sea; Forbes.

I cannot identify this with any of the Mediterranean species of *Pleurotoma* hitherto described.

Species 41. (Mus. Cuming.)

Mangelia elegans. Mang. testă oblongă, spiră breviusculă, acuminată, anfractibus superne angulatis, tongitudinaliter costatis, costis angustis, ad angulum mucronatis, costarum interstitiis pulcherrime elevato-striatis; lutescente-albă, exilissime fusco-zonată.

The elegant Mangelia. Shell oblong, spire rather short, acuminated, whorls angulated at the upper part, longitudinally ribbed, ribs narrow, pointed at the angle, interstices between the ribs very beautifully elevately striated; yellowish white, very faintly zoned with brown.

REEVE, Pro. Zool. Soc., 1846.

Hub. Island of Mindoro, Philippines; Cuming.

Au interesting species most delicately sculptured.

Species 42. (Mus. Cumiug.)

Mangelia lineata. Mong. testá ovatá, spirá acuminatá; concentricè obtuso-costatá, lævigatá; carneo-fuscescente, lineis saturatioribus undique cingulatá.

The lineated Mangelia. Shell ovate, spire acuminated; conceutrically obtusely ribbed, smooth; fleshy brown, cucircled throughout with lines of a darker tint.

REEVE, Pro. Zool. Soc., 1846.

Hab. ----?

The transverse lines which characterize this species are somewhat faintly indicated.

Species 43. (Mus. Cuming.)

Mangelia Planilabrum. Mang. testă fusiformi, utrinque acuminată, lævissimă, anfractibus superne depressis, longitudinaliter costatis; labro planulato, supra subangulato; cinereo-purpurascente, albi-zonată.

The flat-lipped Mangelia. Shell fusiform, acuminated at both ends, very smooth, whorls depressed round the upper part, longitudinally ribbed; lip tlattened, slightly angulated above; ashy purple, zoned with white.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Ticao, Philippines; Cuming.

An extremely pretty and characteristic species.

Species 44. (Mus. Cuming.)

- Mangelia ponderosa. Mang. testá ovatá, spirá breviusculá, acuminatá, anfractibus convexis, tiris eximiis tongitudinatibus striisque transversis eleganter clathratis; tabro valdè incrassato; albicante, macutis perpancis fuscis tinctá.
- The ponderous Mangelia. Shell ovate, spire rather short, asuminated, whorls convex, latticed with transverse striæ and delicate longitudinal ridges; lip very much thickened; whitish, stained with a very few brown spots.
- *Hab*. Island of Burias, Philippines (found among coarse sand at the depth of seven fathoms); Cuming.

A fine species with the surface delicately latticed with ridges and raised striæ.

Species 45. (Mus. Cuming.)

- Mangelia Ginnannia. Mang. testá pyramidali-acuminatá, concentricè tuberculato-costatá, lævigatá, aperturá breviusculá; lutescente-carneá.
- THE GINNANNIA MANGELIA. Shell pyramidally acuminated, concentrically tubercularly ribbed, smooth, aperture rather short; yellowish flesh-colour.
- Risso, Hist. Nat. Europe mèrid. p. 220. pl. 7. 99.

 Pleurotoma Ginnannianum, Scacchi.

Hab. Mediterranean.

Sometimes of a dull leaden colour.

Species 46. (Mus. Cuming.)

Mangelia Bertrandi. Mang. testá oblongů, subturritâ, lævigatå, nitidå, longitudinaliter costatå; purpureofuscå, costis labro basique albidis. Bertrand's Mangelia. Shell oblong, somewhat turreted, smooth, shining, longitudinally ribbed; purple-brown, ribs base and lip white.

Pleurotoma Bertrandi, Payrandcau, Cat. Moll. Corse p. 144. pl. 7. f. 12 and 13.

Hab. Mediterranean.

It is scarcely necessary to observe that this species is quite distinct from the *Pleurotoma Vauquelini*, which should also be referred to this genus.

Species 47. (Mus. Cuming.)

- Mangelia Hornbeckii. Mang. testâ ovatâ, spirâ breviusculâ, acutâ, suturis profundis, subcavernosis, longitudinaliter costatâ, costis prominentibus, transversim subtitissimè striatâ, albâ.
- Hornbeck's Mangelia. Shell evate, spire rather short, acute, sutures deep, somewhat cavernous, longitudinally ribbed, ribs prominent, transversely very minutely striated; white.

Reeve, Pro. Zool. Soc., 1846.

Hab. Island of St. Thomas, West Indies; Dr. Hornbeck.

Distinguished by the prominent character of the ribs, and the depth of the sutures.

Species 48. (Mns. Mctealfe.)

- Mangelia castanea. Mang. testã oblongã, spirá acuminatã, concentrice tenuicostatã, costarum interstitiis striatis; castaneo-fuscã.
- The Chesnut Mangelia. Shell oblong, spire acuminated; concentrically finely ribbed, interstices between the ribs striated; chesnut-brown.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Burias, Philippines; Cuming.

An ovate subfusiform shell of a bright chesnut colour.

Mangelia Pl. V.

PLATE VII.

(Specimens, except Figs. 49 and 51, magnified to twice their natural length.)

Species 49. (Mus. Belcher.)

Mangelia celebensis. Mang. testá attenuatá, lævigatá, pallidá, fusco latè fasciatá; anfractibus senis, plicocostulatis; costulis subdistantibus.

THE PRETTY MANGELIA. Shell attenuated, smooth, pale, broadly handed with brown, whorls six in number, plicately ribbed; ribs rather distant.

Hinds, Moll. Voy. Sulphur, p. 26. pl. 9. f. 5. Hab. New Guinea.

Represented of the natural size.

Species 50. (Mus. Cuming.)

Mangelia pusilla. Mang. testá fusiformi-ovatá, lævigatá, longitudinaliter costatá, costis solidinsculis obtusis; albidá, castaneo copiosè tinctá et lineatá.

THE SMALL MANGELIA. Shell fusiformly ovate, smooth, longitudinally ribbed, ribs rather solid, obtuse; whitish, copiously stained and lineated with chesnut-brown.

REEVE, Pro. Zool. Soc., 1846.

Hab. --- ?

The ribs are mostly of lighter colour than the ground of the shell.

Species 51. (Mus. Belcher.)

Mangelia coronata. Mang. testá attenuatá, acuminatá; anfractibus senis plico-costulatis, transversim striatis; costulis supernè subacuminatis.

THE CORONATED MANGELIA. Shell attenuated, acuminated; whorls six in number, plicately ribbed, transversely striated, ribs somewhat acuminated at the upper part.

HINDS, Moll. Voy. Sulphur, p. 26. pl. 9. f. 1.

Hab. Straits of Macassar; Hinds.

From Mr. Hinds' figure of the natural size.

Species 52. (Mus. Gray.)

Mangelia fasciata. Mang. testá ovatá, utrinque altennatá, anfractibus supernè rotundatis, longitudinaliter costatis, striis conspicuis transversim clathratis; albidá aut lutescente, fasciá rubidá angustá cingulatá. The banded Mangelia. Shell ovate, attenuated at both ends, whorls rounded above, longitudinally ribbed, latticed with conspicuous transverse striæ; whitish or yellowish, encircled with a narrow reddish band.

GRAY, MSS. (Private cabinet.)

Hab. Africa.

Characterized by its short attenuated growth at the base,

Species 53. (Mus. Cuming.)

Mangelia vittata. Mang. testá fusiformi-ovatá, utrinque peculiariter attenuatá, longitudinaliter eximiè costellatá, transversim subtilissimè funiculatá; albidá, fusco aut rubido-fusco lineatá et fasciatá.

The filletted Mangelia. Shell fusiformly ovate, peculiarly attenuated at both ends, longitudinally delicately ribbed, transversely very finely corded; whitish, lineated and banded with brown or reddish brown.

HINDS, Moll. Voy. Sulphur. p. 26. pl. 9. f. 3.

Hab. Island of Luzon, Philippines (found in sandy mud at the depth of seven fathoms); Cuming.

An elegantly formed species, distinguished by the peculiar debeacy of the ribs and transverse striæ.

Species 54. (Mus. Cuming.)

Mangelia marmorosa. Mang. testá ovatá, solidiusculá, spirá breviusculá; longitudinaliter costatá, costis obesis, striis elevatis, decussatis; sinu amplo, albá, aurantiofusco perparce maculatá.

THE MARBLE MANGELIA. Shell ovate, rather solid, spire rather short; longitudinally ribbed, ribs stout, crossed with raised striæ; white, very sparingly spotted with orange brown.

REEVE, Pro. Zool. Soc., 1846.

Hab. ——?

A solid white marble-like shell, with one or two scattered orange-brown spots on the back.

Species 55. (Mus. Cuming.)

Mangelia casta. Mang. testá ovato-turritá, longitudinaliter costatá, costis tenuibus subdistantibus, lævigatá; aperturá brevi, basi truncatá; carneo-fuscá, obscurè fasciatá, costis albicantibus.

The chaste Mangelia. Shell ovately turreted, longitudinally ribbed, ribs fine, rather distant, smooth, aperture short, base truncated; fleshy brown, obscurely banded, ribs whitish.

REEVE, Pro. Zool. Soc., 1846.

Hab. --- ?

Peeuliarly truncated at the base.

Species 56. (Mns. Cuming.)

Mangelia obeliscus. Mang. testá subulatá, hexagoná, basi truncatá, striis pulcherrimis elevatis undique creberrimè cingulatá, longitudinaliter costatá, costis distantibus, sequentibus; aperturá minutá, ovatá; sordidè albá, aperturæ fauce lutescente.

The obelisk Mangelia. Shell subulate, six-sided, truncated at the base, very closely encircled throughout with beautiful raised striæ, longitudinally ribbed, ribs following one under the other; aperture minute, ovate; dull white, interior of the aperture yellowish.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Corrigidor, Philippines (found among coarse sand at the depth of ten fathoms); Cuming.

An interesting species remarkably characterized by its erect obelisk-like growth.

Species 57. (Mus. Metcalfe.)

Mangelia Balteata. Mang. lestá elongatá, subfusiformi, longitudinaliter costatá, costis angustis, distantibus; albá, coná fuscá conspicuá cingulatá.

THE BELTED MANGELIA. Shell elongated, somewhat fusiform, longitudinally ribbed, ribs narrow, distant; white, encircled with a conspicuous brown zone.

Reeve, Pro. Zool. Soc., 1846.

The brown zone which forms so conspicuous a character in the specimen here figured, is but faintly indicated in others.

Species 58. (Mus. Gray.)

Mangelia Goodalii. Mang. testá oblongo-ovatá, spiræ suturis subprofundis; longitudinaliter costatá, costurum interstitiis striis conspicuis clathratis; albá, striis pallidè fuscescentibus.

Goodall's Mangelia. Shell oblong-ovate, sutures of the spire rather deep; longitudinally ribbed, interstices between the ribs latticed with conspicuous striæ; white, striæ pale brown.

GRAY, MSS. (Private cabinet).

Hab. —— ?

Named some years since by Mr. Gray in manuscript, after the late venerable Provost of Eton.

Species 59. (Mus. Metcalfe.)

Mangelia astricta. Mang. testá subfusiformi-ovatá, spirá breviusculá, suturis profundis; longitudinaliter costatá, costis crebriusculis; albidá, zoná fuscá angustá cingulatá.

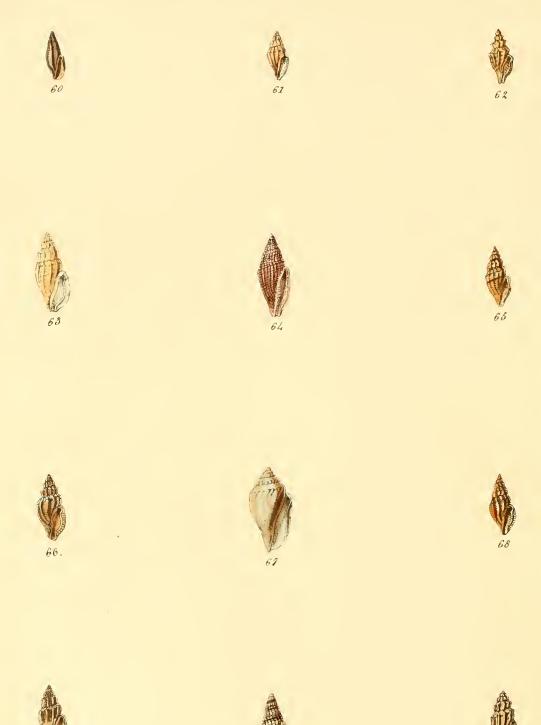

The tied Mangelia. Shell somewhat fusiformly ovate, spire rather short, sutures deep; longitudinally ribbed, ribs rather close-set; whitish, encircled with a narrow brown zone.

REEVE, Pro. Zool. Soc., 1846.

Hab. --- ?

The ribs of this species present an unusually numerous aspect on the spire.

Reeve mup

PLATE VIII.

(Specimens magnified to two and a half times their natural length.)

Species 60. (Mus. Cuming.)

Mangelia Badia. Mang. testâ fusiformi-ovatâ, concentricè plicato-costatâ, transversim fortiter striatâ; castaneo-fuscâ.

The brown Mangelia. Shell fusiformly ovate, concentrically plicately ribbed, transversely strongly striated; chesnut-brown.

REEVE, Pro. Zool. Soc., 1846.

Hab. ----?

Of an uniform dark brown colour.

Species 61. (Mus. Cuming.)

Mangelia pellucida. Mang. testá ovatá, utrinque attenuatá, lævigatá, pellucidá, nitidá, longitudinaliter crebricostatá; albidá, basi fuscá.

THE TRANSPARENT MANGEMIA. Shell ovate, attenuated at both ends, smooth, transparent shining, longitudinally closely ribbed, whitish, brown at the base.

REEVE, Pro. Zool. Soc., 1846.

Hab. —— ?

A delicate transparent shell, swollen in the middle.

Species 62. (Mus. Cuming.)

Mangella angulata. Mang. testá fusiformi-ovatá, anfractibus medio peculiariter angulatis, suturis profundis, longitudinaliter costutis, costis angulos super mucronatis; albidá, fuscescente lineatá.

THE ANGULATED MANGELIA. Shell fusiformly ovate, whorls peculiarly angulated in the middle, sutures deep, longitudinally ribbed, ribs pointed over the angles; whitish, lineated with pale brown.

REEVE, Pro. Zool. Soc., 1846.

Hab. Bay of Manila (found in sandy mud at the depth of four fathoms); Cuning.

An interesting form, distinguished by the very peculiar angularity of the whorls.

Species 63. (Mus. Metcalfe.)

Mangelia pura. Mang. testá oblongo-ovatá, spirá subturritá, suturis profundis; anfractibus concentricè costatis; albidá, maculis perpaucis aurantio-fuscis. The pure Mangelia. Shell oblong-ovate, spire somewhat turreted, sutures rather deep; whorls concentrically ribbed; whitish, with a very few orange-brown spots.

REEVE, Pro. Zool. Soc., 1846.

Hab. ——?

There is merely a faint row of dots on the back of the last whorl.

Species 64. (Mus. Cuming.)

Mangelia solida. Mang. testá cylindraceo-ovatá, utrinque attenuatá, solidá, undique creberrimè granoso-clathratá; aperturá longiusculá; purpurascente.

The solid Mangelia. Shell cylindrically ovate, attenuated at both ends, solid, very closely granosely latticed throughout; aperture rather long; purplish.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Burias, Philippines (among sand at the depth of seven fathoms); Cuming.

A peculiarly solid, finely granulated shell.

Species 65. (Mus. Cuming.)

This shell proves, on a second examination, to be a Mangelia vittata.

Species 66. (Mus. Cuming.)

Mangelia derilicta. Mang. lesta ovata, longitudinaliler fortiter concentricè costata, transversim subobsoletè striata; fuscescente.

THE FORSAKEN MANGELIA. Shell ovate, longitudinally strongly concentrically ribbed, transversely rather obsoletely striated; light brown.

REEVE, Pro. Zool. Soc., 1846.

Hab. --- ?

A strong ribbed species of ordinary form.

Species 67. (Mus. Gray.)

Mangelia Coniformis. Mang. testá ovato-conicá, tenui, subpellucida, spirá brevissimá; anfractibus transversim subtilissimè striatis, supernè exiliter plicato-crenatis; albá.

The cone-shaped Mangelia. Shell ovately eomical, thin, rather transparent, spire very short, whorls transversely very finely striated, faintly plieately crenated round the upper part; white.

GRAY, MSS. (Private cabinet).

Hab. --- ?

An interesting species, which may readily be distinguished by its conical form.

Species 68. (Mus. Cuming.)

Mangelia Zebuensis. Mang. testá ovato-oblongá, spirá acuminatá, basi subattenuatá, concentricè fortiter costatá, transversim creberrimè striatá; fuscescente.

The Zebu Mangelia. Shell ovately oblong, spire acminated, a little attenuated at the base, concentrically ribbed, transversely very closely striated; pale brown. Reeve, Pro. Zool. Soc., 1846.

Hab. Island of Zebu, Philippines (found in sandy mud at the depth of four fathoms); Cuming.

Of simple structure, but specifically distinct from any of the former.

Species 69. (Mus. Cuming.)

Mangelia cincta. Mang. testá subfusiformi-ovatá, spirá turritá, suturis subprofundis; anfractibus supernè angulatis, longitudinaliter costatis, costis distantibus; albidá, anfractibus fasciá latá fuscescente supernè cinctis.

The Girdled Mangelia. Shell somewhat fusiformly ovate, spire turreted, sutures rather deep; whorls encireled round the upper part with a broad light brown band.

Reeve, Pro. Zool. Soc., 1846.

Hab. Island of Bohol, Philippines (found under stones at low water); Cuming.

The ribs are unusually distant, and impart a hexagonal character to the shell.

Species 70. (Mus. Metealfe.)

Mangelia digitale. Mang. testă fusiformi-ovată, solidă, undique creberrime granoso-clathratis; albicante, zonis duabus purpureis angustis cingulată.

THE THIMBLE MANGELIA. Shell fusiformly ovate, solid, very closely granosely latticed throughout; whitish, encircled with two narrow purple zones.

Reeve, Pro. Zool. Soc., 1846.

Hab. ---- ?

The sculpture of this species is very similar to that of the M. solida, represented at Fig. 64.

Species 71. (Mus. Cuming.)

Mangelia nana. Mang. testá ovatá, spirá brevi, turritá, apice acutá; anfractibus supernè angulatis, longitudinaliter obliquè costatis, interstitiis cavis, subtiliter striatis.

The DWARF Mangelia. Shell ovate, spire short, turreted, sharp at the apex; whorls angulated round the upper part, longitudinally obliquely ribbed, interstices hollow, finely striated.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Mindanao, Philippines (found in sandy mud at the depth of twenty five fathoms); Cuming.

The spire is of a peenliar short dwarf-like character, though sharp at the apex.

MONOGRAPH

OF THE GENUS

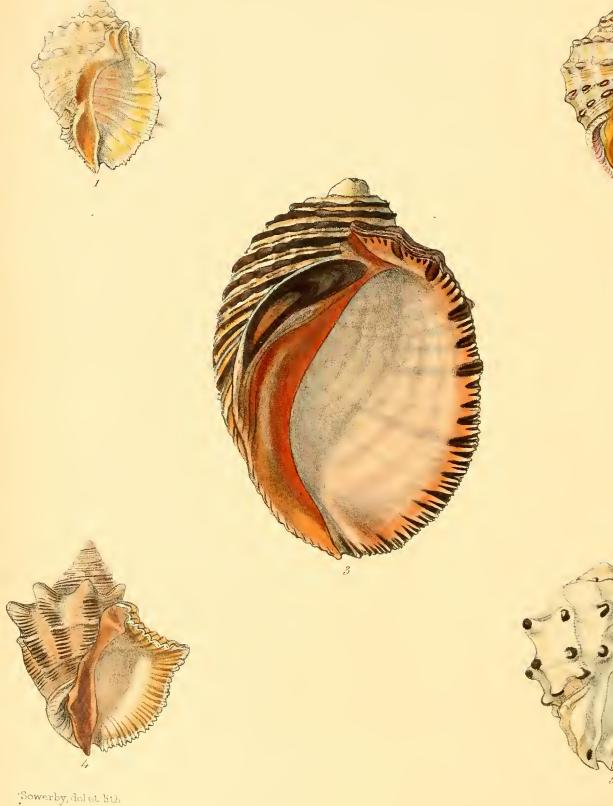

PURPURA.

"Is not the sea
With various living creatures, and the air
Replenished, and all these at thy command?"—Millon.

Purpura

Reeve, imp

PURPURA.

PLATE I.

Genus Purpura, Lamarck.

Testa ovata vel oblongo-ovata, plerumque nodulosa vel tuberculata, spirá brevi, anfractu ultimo tumido, plus minusve inflatá, aperturá dilatatá, fauce sæpissimè sulcatá; basi emarginatá; columeltá plus minusve depresso-planá; labro plerumque denticulato.

Shell ovate, or oblong-ovate, generally nodulous or tuberculated, spire short, last whorl swollen, more or less inflated, aperture dilated, interior most frequently grooved; base emarginated; columella more or less depressly flattened; lip generally denticulated.

The terms Κήρυξ, Murex, and Πορφύρα, Purpura, were used indiscriminately by ancient Greek writers in reference to all mollusks yielding a purple juice, and they became objects of especial interest in that remote age, on account of the limited sources then known of obtaining colour. Who has not heard of the purple dye produced by the 'Tyrius murex' of Ovid, (Murex trunculus Linn.)? which no doubt abounded on the shores of the ancient Phænician eity of Tyros.

The purple juice of the mollusk affords, however, no assistance to the systematist; it abounds alike in animals of very dissimilar character; in Scalaria and Ianthina, as well as in Murex and Purpura; hence the term Purpura was adopted by Lamarek to distinguish the genus under consideration, regardless of any property with which the animal might be endowed of secreting a purple juice. The most striking feature in the soft parts of Purpura is that of the head being a little flattened, and prolonged at each extremity into the tentacles, without any prominence in the centre; approximating in this respect to Buccinum. The tentacles are pedunculated to generally two thirds of their extent, and at the summit of the pedanculated portion are the eyes. The operculum which the animal carries on the hind extremity of its disk, is invariably horny, and fits closely to the aperture of the shell.

The shell of *Purpura* is mainly distinguished by an ovate dilated growth, emarginated at the base, with a more or less flattened columella, the spire being sometimes extremely short, sometimes a little acuminated. There are three closely allied genera, *Concholepas*, *Monoceros*, and *Ricinula*, which the French authors propose to fuse into the present; I have not considered it prudent, however, to follow this course, as they afford good typical distinctions, whilst their amalgamation under the head of

Purpura would only tend to confusion by involving a change of names.

The *Purpuræ* vary exceedingly in their detail of sculpture, but are somewhat constant in colour; the well-known *P. lapillus* of Europe varies, however, in both respects to an almost inconceivable degree; indeed, no one who has not thoroughly examined a numerous series of specimens can form an adequate idea of its Protean character.

Species 1. (Mus. Cuming.)

Purpura echinulata. Purp. testá ovatá, subventricosá, spirá brevi, transversim tenuissimè striatá et squamosotuberculatá, tuberculis subechinulatis; columellá latiusculá, concavá; aperturá amplá, dilatatá, supernè canaliculatá, fauce tiratá, liris distantibus; luteo-albicante, columellá et aperturæ fauce aurantio-lutescentibus, liris albidis.

THE PRICKLY PURPURA. Shell ovate, rather ventricose, spire short, transversely very finely striated and squamosely tuberculated, tubercles somewhat priekly; columella rather broad, concave; aperture large, dilated, canaliculated at the upper part, interior ridged, ridges distant; yellowish white, columella and interior of the aperture orange yellow, ridges whitish.

Lamarck, Anim. sans vert. (Deshayes' edit.) vol. x. p. 84. Eadem, (fide Deshayes), *Purpura mancinelloides* De Blainville.

Hab. Philippine Islands, Cuming.

The aperture of this species is larger and more dilated than that of the P. mancinella.

Species 2. (Mus. Cuming.)

Purpura Mancinella. Purp. testá ovatá, crassiusculá, spirá brevi, transversim tenuissimè striatá et costatá, costis distantibus, angustis, compresso-nodosis; aperturá supernè canaliculatá, fauce lineatá, lineis elevatis, confertis; luteo-albicante, nodis interdum rufo-fuscis, columellá lutescente, aperturæ fauce rufo-aurantiá, lineis saturatioribus.

THE PIMPLED PURPURA. Shell ovate, rather thick, spire short, transversely very finely striated and ribbed, ribs distant, narrow, compressly noduled; aperture canaliculated at the upper part, interior lineated, lines elevated and close-set; yellowish white, nodules

sometimes reddish-brown, columella yellowish, interior of the aperture reddish-orange, lines of a darker colour.

Murex mancinella, Linnæns, Syst. Nat. (12th edit.) p. 1219.

Purpura gemmulata, Enc. Mèth.

Hab. Philippine Islands; Cuming.

Distinguished by its lineated aperture.

Species 3. (Mus. Cuming.)

Purpura patula. Purp. testá ovatá, depressá, spirá brevissimá, transversim liratá et costatá, costis rudè et irregutariter tuberculatá; columellá latá, plano-concavá, aperturá amplissimá patuláque, supernè canaliculatá, labro intus sulcato et crenato; cæruleo-fuscescente, costis lirisque nigricantibus, columellá rufá, maculá fuscá ellipticosemilunari supernè pictá, labri sulcis nigricante-fuscis.

The open-mouthed Purpura. Shell ovate, depressed, spire very short, transversely ridged and ribbed, ribs rudely and irregularly tubercled; columella broad, flatly concave, aperture very large and open, canaliculated at the upper part, lip grooved and crenated within; blueish brown, ribs and ridges blackish, columella red, painted at the upper part with an ellipticosemilunar brown spot, grooves of the lip blackish brown.

Buccinum patulum, Linnæus, Syst. Nat. (12th edit.) p. 1262.

Hab. Philippine Islands; Cuming.

This well-known species is a most characteristic example of the patulous series of the genus.

Species 4. (Mus. Cuming.)

Purpura Consul. Purp. testá abbreviato-ovatá, spirá conico-acutá, anfractibus transversim tenuissimè sulcatis et striatis, supernè concavo-depressis, tuberculis grandibus, erectis, ad angulum uniseriatim armatis; aperturá parviusculá, fauce lubrum versus sulcatá; albido-

fuscescente, nigrilineată, columellă et aperturæ funce aurantio-rufis.

The Consul Purpura. Shell shortly ovate, spire conically acute, whorls transversely very finely grooved and striated, concavely depressed round the upper part, armed at the angle with a row of large erect tubercles; aperture rather small, interior grooved towards the lip; whitish brown, crossed with black lines, columella and interior of the aperture orange-red.

Lamarck, Anim. sans vert. (Deshayes' edit.) vol. x. p. 63.

Murex Consul, Chemnitz.

Hab. Island of Corrigidor, Philippines (on the reefs); Cuming.

The difference between the *P. Consul* and *gigantea*, which have been confounded together, is sufficiently apparent in Chemnitz's figures of them, cited by Lamarck, under the head of the former.

Species 5. (Mus. Cuming.)

Purpura bimaculata. Purp. testá ovatá, crassá, solidá, spirá brevi, anfractibus supernè depressis, transversim tenuissimè sulcatis et striatis, tuberculorum seriebus duabus tribusve seriutim armatis; albidá, fuscescente tinctá, columellá et aperturæ fauce niveis, tuberculis intus peculiariter nigricante-fuscis.

THE DOUBLE-SPOTTED PURPURA. Shell ovate, thick, solid spire short, whorls depressed round the upper part finely grooved and striated, and armed with two or three rows of tubercles; white, stained with light brown, columella and interior of the aperture snowy white, tubercles blackish-brown within.

Jonas. (Hamburgh), MSS.

Hab, Zanzibar.

This species exhibits a curious black-spotted appearance from the tubercles being of a blackish brown colour within they are covered by a superimposed layer of white, during the growth of the shell, but it becomes more or less worn off by friction or crosion.

PURPURA.

PLATE II.

Species 6. (Mus. Cuming.)

Purpura Haustrum. Purp. testá ovatá, basi subattenuatá, spirá brevissimá; transversim irregulariter incisostriatá; aperturá peramplá, columellá latá, obliquè planatá, labro tenui, minutè denticulato; extus cinereonigricante, columellá intusque carulescente-albá.

The scoop Purpura. Shell ovate, somewhat attenuated at the base, spire very short; transversely irregularly engraved with striæ; aperture very large, columella broad, obliquely flattened, hip thin, finely deuticulated; exterior ashy-black, columella and interior blueish white.

Quoy and Gaimard, Voy. de l'Astrolabe, Zoologic, v. ii. p. 554. pl. 37. f. 4 to 8.

Buccinum haustrum, Martyn.

Buccinum hauritorium, Chemnitz.

Buccinum haustorium, Gmelin.

Hab. New Zealand.

We are indebted to M. Quoy, the enterprising naturalist of the Astrolabe, for having rescued this species from the obscurity into which it had fallen in the hands of Lamarck. It was first described and admirably figured, during the last century, by our countryman Martyn in his 'Universal Conchology,' under the name of Buccinum haustrum, or 'Water Scoop Whelk, from New Zealand'; Chemnitz afterwards published an excellent figure and description of the species with the name of Buccinum hauritorium, making a needless change in its specific appellation. Lamarck, who was evidently unacquainted with the Purpura haustrum, confounded it with the Purpura persica, quoting the foregoing names as synonymes of that species; a glance at the accompaning figures will, however, show that it is unecessary to institute a comparison.

Species 7. (Mus. Cuming.)

Purpura bufo. Purp. testá suborbiculari-ovatá, crassá, spirá brevissimá, plus minusve depressá, transversim inciso-striatá et tuberculis subdistantibus, nunc prominentibus, nunc ferè obsoletis, seriatim armatá; columellá subconcavá, callositate insigni supernè munitá, labro minutè denticulato, supernè conspicuè sinuato; extus nigricante-fusco lineatá, columellá et aperturæ fauce rufescente-luteis.

THE TOAD PURPURA. Shell somewhat orbicularly ovate, thick, spire very short, more or less depressed, trans-

versely deeply striated, and ornamented with rows of rather distant tubercles, which are sometimes prominent, sometimes almost obsolete; columella rather concave, furnished at the upper part with a remarkable callosity; lip minutely denticulated, conspicuously sinuated at the upper part; exterior lineated with blackish brown, columella and interior of the aperture reddish yellow.

LAMARCK, Anim. sans vert. (Deshayes' edit.), v.x. p. 69.

Variety β .

Testa spirá depressiore, tuberculorum seriebus supremá et infimá prominentibus, callositate crassiore.

Shell with the spire more depressed, the uppermost and lowest row of tubercles more prominent, and the callosity thicker.

Purpura callosa, Lamarck.

Purpura tumida, Schubert and Wagner.

Hab. Island of Corrigidor, mouth of the Bay of Manila (on rocks at low water); Cuming.

M. Deshayes charges M. Kiener, in a note at page 70 of his edition of the 'Animaux sans vertebres', of having confounded Lamarck's *Purpura callosa* with his *P. bufo*; I cannot, however, agree with the learned editor on this subject. After a careful comparison of the shells with Lamarck's description, coupled with an examination of the figures of Petiver and Seba, I am forced to the conclusion that they are the same species in different states.

M. Kiener describes the *Purpura centiquadrata*, Duclos, as being the young of this species, whilst M. Deshayes, on the other hand, considers it distinct; not having as yet obtained access to the work in which M. Duclos' monograph occurs, I am unable at present to offer an opinion.

Species 8. (Mus. Cuming.)

Purpura persuca. Purp testã ovatã, basi leviter attenuată, spirâ brevi, transversim inciso-striată, striis regularibus, liris intermediis subplanulatis, anfractibus parte superiori obsoletè biseriatim nodulosă; columellă medio longitudinaliter excavată, apertură peramplă, labro simplici, subtiliter denticulato, supernè latè sinuato; cinereo-fuscă, zonis albidis fusco-articulatis angustis subdistantibus cingulată, columellă rubido-luteă, apertură fauce rufo-albicante, rufo-lineală.

The princely Purpura. Shell ovate, slightly attenuated at the base, spire short, transversely deeply striated, striæ regular, intermediate ridges rather flattened, upper part of the whorls encircled with two rows of obsolete nodules; columella longitudinally excavated, aperture very large, lip simple, finely denticulated, broadly sinuated at the upper part; ashy brown, encircled with narrow distant white zones articulated with brown, columella reddish yellow, interior of the aperture pinkish white, ornamented with numerous radiating red lines.

Lamarck, Anim. sans vert. (Deshayes edit.) v. x. p. 59.

Buccinum persicum, Linnæus.

Hab. Island of Bohol, Philippines (on the reefs at low water); Cuming.

The narrow articulated brown and white zones which constitute so characteristic a feature in this well-known species, seem to have a tendency to become nodulous throughout; although nodules are only apparent in the two uppermost zones which encircle the spire.

Species 9. (Mus. Cuming.)

Purpura columellaris. Purp. testá suboblongo-ovatá, crassá, spirá breviusculá; transversim costatá et liratá, costis rudè nodulosis; columellá latá, leviter excavatá, medio obsoletè uniplicatá, labro denticulato et sutcato, dentibus interioribus binis; nigricante-fuscá, columellá et aperturæ margine rufescentibus, fauce rufescente, interdum liratá.

The columellar Purpura. Shell rather oblong-ovate, thick, spire rather short; trausversely ribbed and ridged, ribs rudely noduled; columella broad, slightly excavated, with a single almost obsolete plait in the middle, lip denticulated and grooved, inner teeth in pairs; blackish brown, columella and edge of the

aperture reddish, interior reddish-white, sometimes ridged.

Lamarck, Anim. sans vert. (Deshayes' edit.) v. x. p. 62. Hab. Gallapagos Islands (on exposed rocks at low water); Cuming.

Distinguished by its solid nodulous structure, and strongly grooved and denticulated lip.

Species 10. (Mus. Cuming.)

Purpura Rudolphi. Purp. testá suboblongo-ovatá, basem versus attenuatá, spirá breviusculá; anfractibus supernè subangulatis, transversim inciso-striatis, zonis obtusè nodiferis subdistantibus infra angulum cingulatis; columellá longitudinaliter sulcatá, labro simplici, supernè sinuato, minutè denticulato; fusco-nigricante, maculis luteo-albicantibus irregulariter aspersá; columellá rufescente, aperturæ fauce albidá, rufescente lineatá.

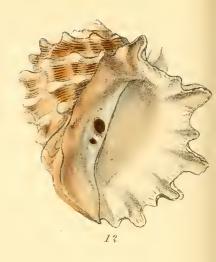

Rudolph's Purpura. Shell rather oblong-ovate, attenuated towards the base, spire rather short; whorls slightly angulated round the upper part, transversely deeply striated, encircled beneath the angle with rather distant obtusely nodiferous zones; columella longitudinally grooved, lip simple, sinuated at the upper part, minutely denticulated; brownish black, irregularly sprinkled with yellowish-white spots, columella reddish, interior of the aperture whitish, bineated with red.

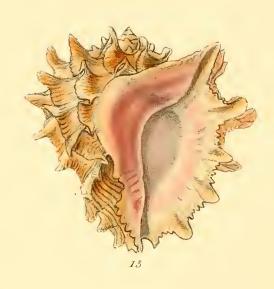

Lamarck, Anim. sans vert. (Deshayes edit.) v. x. p. 60. *Hab.* Matnog, Province of Albay, Island of Luzou, Philippines (on exposed rocks at low water); Cuming.

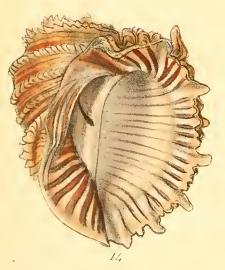

The characters of this species present a sort of confused modification of those of the *Purpura persica*; the transverse zones are broader and most irregularly articulated, and the nodules are of a rude blunted growth.

Soverby del at lith

.Re ze mn

PLATE III.

Species 11. (Mus. Cuming.)

Purpura Ascensionis. Purp. testá globosá, crassá, persolidá, spirá plano-depressá; lævigatá aut subtiliter
striatá; columellá latissimá, plano-concavá, labro minutè denticulato, supernè canaliculato; extus transversim subtilissimè castaneo-striatá, intus eburneá, columellá eburneá, maculis atris tribus aut pluribus aut
minoribus conspicuè notatá.

The Ascension Purpura. Shell globose, thick, very solid, spire flatly depressed; smooth or finely striated; eolumella very broad, flatly concave, lip minutely denticulated, channelled at the upper part; exterior transversely very finely striated with chesnut brown, interior ivory white, columella ivory white, conspicuously with three, more or less, jet black spots.

Quoy and GAIMARD, Voy. de l'Astrolabe, Zool. vol. ii. p. 559, pl. 37. f. 20 to 23.

Murex Mæga (pars), Martini.

Hab. Island of Ascension, Atlantic (on rocks at low water).

I am not surprised that Martini should have represented this, and the following species, under one name; it may be more convenient to preserve the distinction assigned to them by M. Quoy, but, that they are extreme modifications of the same thing I have no doubt; I attach greater importance to the brown hair-like lines which characterize these species, than to the presence or absence of tubercles.

Species 12. (Mus. Cuming.)

Purpura Neritoidea. Purp. testá, suborbiculari, ventricosá, crassiusculú, spirá brevissimá, depressá; transversim striatá, tuberculis solidis prominentibus seriatim cinctá; columellá tatá, concavo-planatá; albidá, lineis subtilibus castaneis plus minusve pictá, aperturæ fauce eburneá, maculis atris tribus aut pluribus aut minoribus notatá.

The Nerite-like Purpura. Shell nearly orbicular, ventricose, rather thick, spire very short, depressed; transversely striated, encircled with rows of prominent solid tubercles; columella broad, concavely flattened; white, more or less painted with fine chesnut lines, interior of the aperture ivory white, columella ivory white, marked with three, more or less, jet black spots.

Deshayes, Anim. sans vert. v. x, p. 70. note Purpura Neritoides, Lamarck. Murex Neritoideus, Linnæus (12th. ed. Syst. Nat.). Nerita nodosa, Linnæus (10th. edit. Syst. Nat.). Murex Mæga, (pars altera), Martini. Murex fucus, Gmelin. Purpura fucus, Sowerby, De Blainville.

Hab. Island of St. Vincent, Cape de Verds.

The confusion indicated by the above synonymes arises mainly from the circumstance of Linnæus having referred, for the illustration of his Murex Neritoideus, to figures of the Ricinula horrida, as well as of the shell under consideration; M. Deshayes clearly shows, however, that Gmelin and his followers are in error, the character "columetta planinscuta" used by Linnæus, being quite inapplicable to that species.

Species. 13. (Mus. Cuming.)

Purpura hystrix. Purp. testá ovato-globosá, subventricosá, umbilicatá, spirá breviusculá, acuminatá; squamis grandibus spiniformibus fornicatis seriatim ornatá; subtiliter tiratá, liris minutissimè squamatis, columellá convexá, basi exiliter rugatá, labro intus denticulato; lutescente, columellá et aperturæ fauce roseis.

THE PORCUPINE PURPURA. Shell ovately globose, slightly ventricose, umbilicated, spire short, acuminated; ornamented with rows of large prominent spiniform vaulted scales, transversely finely ridged, ridges very minutely scaled; columella convex, faintly wrinkled at the base, lip toothed within; yellowish, columella and interior of the aperture rich pink.

LAMARCK, Anim. sans vert. (Deshayes' edit.) v. x. p. 85.

Murex hystrix, Linnæus.

Eadem *Purpura spathulifera*, De Blainville (according to M. Kiener).

Hab. Island of Annaa, south Pacific Ocean (on the coral recfs at low water); Cuming.

This species is one of those intermediate states between *Purpura* and *Ricinula*, which have induced some of the continental naturalists to combine the two genera in one. Although it may be referred with equal propriety to either, I think it convenient to perpetuate the generic appellations of Lamarck; all limitations of genera become less defined, as the links which are wanting in the chain of affinity become revealed to observation; if this system of fusion were followed out, the nomenclature would be completely overthrown.

Species 14. (Mus. Cuming.)

Purpura planospira. Purp. testá orbiculari-ovatá, spirá plano-depressá; transversim squamicostalá, costis subdistantibus, interstitiis obtuso-liratis, columellá medio profundè excavatá, labri margine sulcato; extus pallidè rubido-fuscá, columellá albá, maculá oblongá nigrá medio notatá, infra rugis rufis conspicuè tinctá, aperturæ fauce albicante, rufo-lineatá, lineis marginem versus saturatioribus.

The flat-spire Purpura. Shell orbicularly ovate, spire flatly depressed; transversely scale-ribbed, ribs rather distant, interstices obtusely ridged, columella deeply excavated in the middle, edge of the lip grooved; exterior pale reddish-brown, columella white, marked in the centre with an oblong black spot, conspicuously stained beneath with red wrinkles, interior of the aperture whitish, lineated with red, lines deeper red towards the margin.

Lamarck, Anim. sans vert. (Deshayes cdit.) v. x. p. 71. Purpura lineata, Enc. Méth.

Hab. James Island, Gallapagos (on exposed rocks); Cuming.

Several specimens of this remarkable shell were collected by Mr. Cuming at the island above noted; and he never met with it in the course of his researches at any other locality. Species 15. (Mus. Cuming.)

Purpura aperta. Purp. testá orbiculari-ovatá, basem versus subattenuatá, transversim tuberculatá, tuberculis
squamæformibus, prominentibus, in seriebus subdistantibus, interstitiis subtiliter liratis; columellá concavoplanatá, rugis perpaucis brevibus notatá, labro sulcato,
intus tenuidenticulato; albicante, punctis castaneis
obscurè tinctá, columellá et aperturæ fauce albis, columellæ rugarum interstitiis labrique sulcis pallidè rubidoluteis.

The open Purpura. Shell orbicularly ovate, a little attenuated towards the base, transversely tuberculated, tubercles, scale-like, prominent, in rather distant rows, the interstices between which are finely ridged; columella concavely flattened, marked with a very few short wrinkles, lip grooved, finely denticulated within; whitish, insterstices between the wrinkles of the eolumella, and grooves of the lip, palely stained with reddish yellow.

DE BLAINVILLE, Nouv. Ann. du mus. Purpura macrostoma (?), Conrad.

Hab. San Carlos, Central America.

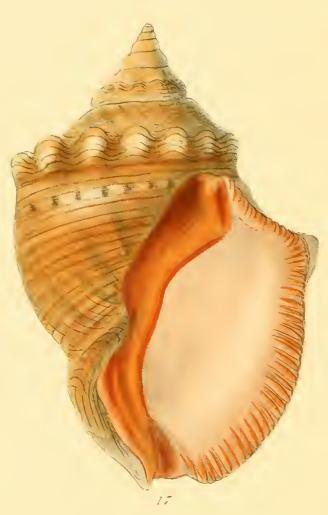

A very characteristic and well-defined species, which does not appear to have been known to Lamarek. The shell described and figured by M. Kiener as a variety, is merely the same thing in a bad state of preservation.

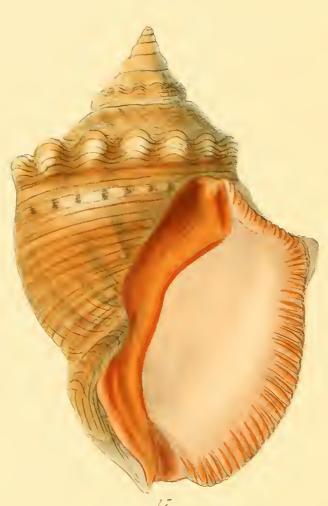

Purpura. P

16 b

the relet ath

PLATE IV.

Species 16. (Fig. a and b Mus. Cuming.)

Purpura Buccinea. Purp. testá suboblongo-fusiformi, tongitudinaliter obsoletè costatá, costis latis, transversim undique tiratá, tiris angustis, acutis, hic illic, subaquidistanter, majoribus, columellá obtusè uniplicatá, apertura fauce subtiliter radiatim tiratá; fuscá, tiris majoribus fusco saturatiore alboque nitidè articulatis, aperturá fuscescente-albidá.

THE BUCCINOID PURPURA. Shell somewhat oblong, fusiform, longitudinally obsoletely ribbed, ribs broad, transversely ridged throughout, ridges narrow, acute, here and there, nearly equidistantly, larger, columella obtusely one-plaited, interior of the aperture finely radiately ridged; brown, larger ridges neatly articulated with white and darker brown, aperture brownish white.

DESHAYES, Anim. sans vert. vol. x. p. 92.

Purpura striata, Quoy and Gaimard.

Hab. New Guinca.

An aberrant species of the genus, but possessing an abundance of character. The columella has a strong obtuse plait upon it, and the shell is encircled round the upper part by three narrow articulated fillets.

Species 17. (Mus. Cuming.)

Purpura Gigantea. Purp. testă subquadrato-ovată, spiră peculiariter acuminată, transversim irregulariter subtilissime sulcată, anfractibus superne uni-vel bi-seriatim tuberculatis, tuberculis peculiariter rotundatis et obtusis, apertură peramplă, margine intus inciso-sulcato; olivaceo-fuscescente, sulcis saturatioribus, rolumellă et apertura fance aurantio-rufis.

The GIGANTIC PURPURA. Shell somewhat squarely ovate, spire peculiarly acuminated, transversely irregularly very finely grooved, whorls encircled round the upper part with one or two rows of blunt peculiarly rounded tubereles, aperture very large, edge sharply grooved within; pale olive brown, grooves of a dark tinge, columella and interior of the aperture orange-red.

Buccinum hæmustoma, Chemnitz (not of Linnæus), vol. xi. pl. 187. f. 1796-7.

Purpura consul, Kiener (not of Lamarck).

Hab. ----

It will be seen by the above arrangement of synonymes, that this magnificent species is neither the Buccinum hamastoma of Linnæus, as supposed by Chemnitz, nor the Purpura consul of Lamarck, as propounded by Kiener;

the former (Pl. V. Fig. 21.) is an oval shell, encircled throughout with rows of blunt tubercles, and fine dark flattened striæ, the spire being only moderately elevated; the latter (Pl. I. Fig. 4.) is a broad abbreviated shell, with a strong radiating series of prominent tubercles, and a curiously acuminated conical spire. The shell under consideration, differs from both these in being of a more oblong-square form, with a peculiarly elevated acuminated spire, the tubercles though prominent, are of a rounded pimple-like character, and one of the most characteristic features of the species, consists in the surface being encircled throughout with finely engraved grooves, which are the most prominently developed on the summit of the tubercles.

Species 18. (Mus. Cuming.)

Purpura delitoidea. Purp. testá abbreviato-ovatá, crassá, ponderosá, transversim impresso-striatá, tuberculis solidis subdistantibus coronatá; castaneo-nigricante, basi albicante, tuberculis albizonatis, columellá patlidè purpureá.

THE DELTOID PURPURA. Shell shortly ovate, thick, ponderous, transversely impressly striated, coronated with solid, rather distant, tubercles; dark chesnut black, base whitish, tubercles marked with a white zone, columella faintly stained with purple.

LAMARCK, Anim. sans vert. vol. x. p. 85.

Hab. Jamaica; Dr. Adams.

Distinguished from the following species with which we are more familiar, by its spiral ridge of tubercles.

Species 19. (Mus. Cuming.)

Purpura melones. Purp. testá abbreviato-ovatá, crassá, ponderosá, spirá brevissimá, transversim impresso-striatá, muticá; castaneo-nigricante, alto variá, columeltá lutescente, purpureo tinctá, aperturá lutescente.

The Melon Purpura. Shell shortly ovate, thick, ponderous, spire very short, transversely impressly striated, smooth; dark chesnut-black, variegated with white, columella yellowish, stained with purple, aperture yellowish.

Duclos, Annales Sci. Nat. 1832, Pl. 1, fig. 2.

Purpura crassa, De Blainville.

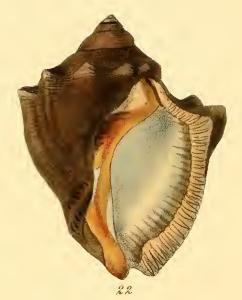

Hab. Monte Christi, West Columbia (under stones at low water); Cuming.

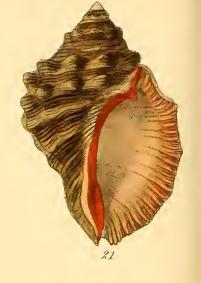

One of the few species of the genus which are destitute of tubercles.

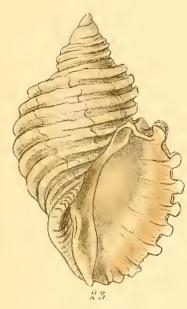

Reeve, m

PLATE V.

Species 20. (Mus. Cuming.)

Purpura inerma. Purp. testá rotundato-ovatá, ventricosá, spirá acutá, transversim creberrimè subtilissimè liratá, liris striis longitudinalibus decussatis, aperturá subamplá, labro tenuiculo, intus inciso-sulcato; cinereo-olivaceá, liris maculis albis hic illic sparsim ornatis, columellá et aperturæ fauce rufescente-aurantiis.

The unarmed Purpura. Shell rotundately ovate, ventricose, spire sharp, transversely very closely and finely ridged, ridges decussated with longitudinal striæ, aperture rather large, lip rather thin, sharply grooved within; ashy olive, ridges sparingly ornamented here and there with white spots, columella and interior of the aperture reddish orange.

REEVE, Pro. Zool. Soc., 1846.

Hab. ---- ?

This is probably one of those species which M. Kiener has confounded together, under the title of Purpura cataracta, neither of which have the slightest reference to the Buccinum cataracta of Chemnitz. I cannot identify it with any species hitherto recorded, and am unable to say whether it is ever tuberculated; there is no indication of tubercles in the specimen before me, and it has a very peculiar style of colouring, the ridges being marked here and there in a very irregular manner, with oblong white spots.

Species 21. (Mus. Cuming.)

Purpura Hæmastoma. Purp. testă ovată, spiră conică, anfractibus superne concavis, transversim planistriatis et quadriseriatim tuberculatis, tuberculis rotundatis obtusis, basem versus obsoletioribus, columellă lævigată, apertură oblongă, superne subconspicue sinuată, labro intus inciso-sulcato; olivaceo-fuscă, striis nigricantibus, columellă et aperturæ fauce vivide aurantio-rufis.

The Red-Mouth Purpura. Shell ovate, spire conical, whorls concave round the upper part, transversely flatly ridged and encircled with four rows of tubercles, which are blunt, rounded, and more obsolete as they approach the base, columella smooth, aperture oblong, rather conspicuously sinuated at the upper part, lip sharply grooved within; olive-brown, striæ blackish, columella and interior of the aperture bright orangered.

Buccinum hæmastoma, Linnæus, Syst. Nat. (12th edit.) p. 1202.

Eadem? Purpura cornuta, Menke.

Hab. Mediterranean.

I am inclined to think with M. Deshayes, that this species is confined to the Mediterraneau and Atlantic shores of Europe, concluding that where a more southern locality is quoted, as in the 'Iconographie des Coquilles vivantes,' the author has, probaby, had some allied species before him, (such as the *P. ochrostoma*, for example) the specific peculiarities of which he has failed to discriminate.

Species 22. (Mus. Cuming.)

Purpura chocolatum. Purp. testá subabbreviato-ovatá, turgidá, anfractibus supernè concavo-depressis, undique creberrimè et subtilissimè inciso-striatis, tuberculis grandibus, subdistantibus, ad angulum armatis, columellá concavá, labro tenui, intus inciso-sulcato; extus chocolato-fuscá, columellá aurantio-rufá, labro intus chocolato-fusco.

The chocolate-brown Purpura. Shell somewhat shortly ovate, swollen, whorls concavely depressed at the upper part, very closely and finely deeply striated throughout, armed with large rather distant tubereles at the angle, columella concave, hip thin, sharply grooved within; exterior dark chocolate brown, columella orange-red, hip chocolate brown within.

Duclos, Annales Sci. Nat. vol. xxvi. pl. 2. f. 7.

Hab. Bay of Callao, Peru (found in sandy mud at the depth of six fathoms); Cuming.

An extremely characteristic species, and so distinct from any other yet described that it is impossible to find any difficulty in recognizing it.

Species 23. (Mus. Cuming.)

I'urpura succincta. Purp. testă ovată, spiră plus minusve elevată, anfractibus sic plus minusve intrusis, transversim undique costată, costis prominentibus, rugosis, obsolete squamatis, interstitiis profunde excavatis, striatis, costă minore raro interveniente; sordide lutescente-albă.

THE ENCIRCLED PURPURA. Shell ovate, spire more or less elevated, whorls accordingly more or less thrust

inwards, transversely ribbed throughout, ribs prominent, rugose, obsoletely squamate, interstices deeply excavated, striated, with rarely a small intervening rib; dull yellowish white.

Buccinum succinctum, Martyn, Univ. Conch. vol. 2. pl. 45.

Buccinum orbita, Chemnitz.

Buccinum lacunosum, Bruguière.

Buccinum bicostatum, Bruguière.

Variety 3.

Testa parva, elongatior, costarum interstitiis laminis tenuibus peculiariter decussatis.

Shell small, more elongated, with the interstices between the ribs peculiarly crossed with thin laminæ.

Buccinum striatum, Martyn.

Purpura rugosa, Lamarck.

Purpura striata, Deshayes.

Hab. Cape of Good Hope.

The *Purpura rugosa*, Lamarck, of which M. Kiener has omitted mention, is, I think, without doubt, a modified state of the *P. succincta*, the extremes of which are beautifully represented by Martyn, in the 'Universal Conchology.'

Species 24. (Mus. Cuming.)

Purpura xanthostoma. Purp. testa pyriformi-ovata, ven-

tricosá, basi subelongatá et recurvá, anfractibus supernè angulatis, ad angulum plus minusve tuberculiferis, lougitudinaliter obtusè plicato-costatis, transversim subtiliter costatis, costis angustis, subdistantibus, interstitiis liris minutis, vel obsoletè, vel conspicuè squamatis, creberrimè cingulatis, labro sæpissimè intus denticulato; albá, columellá et aperturæ fauce lutescente-lacteis.

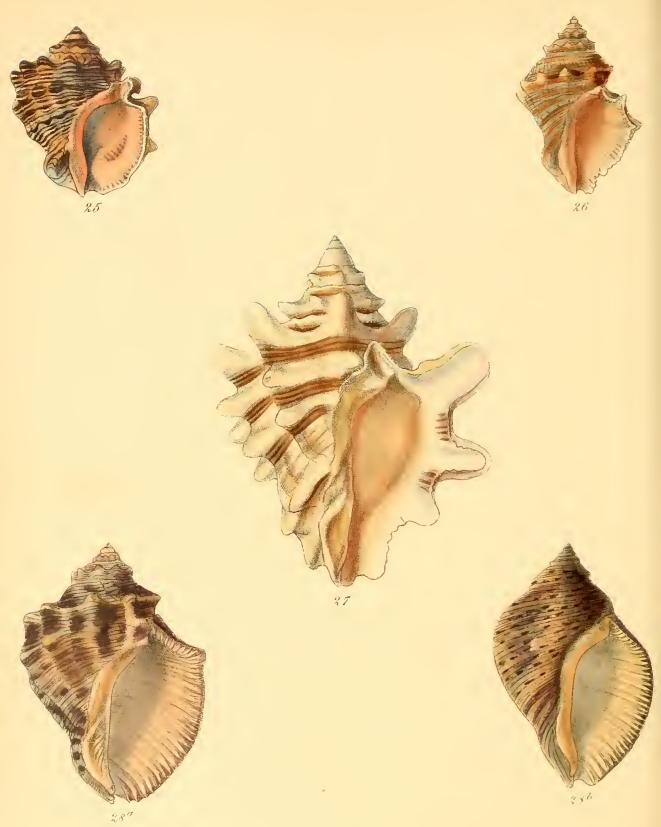

The yellow-mouth Purpura. Shell pyriformly ovate, ventricose, rather elongated and recurved at the base, whorls angulated at the upper part, more or less tubercled at the angle, longitudinally obtusely plicately ribbed, transversely finely ribbed, ribs narrow, rather distaut, interstices closely encircled with minute ridges sometimes obsoletely, sometimes conspicuously scaled, lip frequently denticulated within; white, columella and interior of the aperture yellowish cream colour.

BRODERIP, Pro. Zool. Soc., 1833.

Hab. Valparaiso (dredged from gravel and saud at various depths, from seven to twenty-five fathoms); Cuming.

This is a most variable species both in form and sculpture, and might be referred in its different states, with the same propriety, either to the genera Pyrula or Fusus. However unlikely it may appear, an affinity may certainly be traced to the Fusus squamulosus of Philippi, inhabiting the Mediterranean, the Purpura xanthostoma in a young and highly sculptured condition, being of exactly similar form, and almost as thickly beset with imbricating scales.

Sowerby del at hth

PLATE VI.

Species 25. (Mus. Cuming.)

Purpura coronata. Purp. testá subglobosá, ventricosá, basi umbilicatá, anfractibus triseriatim nodosis, supernè squamis callosis gibbosis ascendentibus coronatis; albicante, lineis transversis fuscis conspicuè pictá, columellá et aperturæ fuuce rufo-aurantiis.

THE CORONATED PURPURA. Shell somewhat globose, ventricose, umbilicated at the base, whorls encircled with three rows of nodules, coronated round the upper part with callous swollen ascending scales; whitish, conspicuously painted with transverse brown lines, columella and interior of the aperture reddish orange.

LAMARCK, Anim. sans vert. (Deshayes' edit.) vol. x. p. 72.
Eadem. Purpura callifera, Lamarck.

Purpura Guinensis, Schubert and Wagner.

Hab. ---- 9

The main feature of distinction in this species, consists in the curious vaulted seales which are formed over the suture. Frequently they are increased by a callous deposit of semitransparent matter, having almost the appearance of wax; which state is the *Purpura callifera* of Lamarck.

Species 26. (Mus. Cuming.)

Purpura carinifera. Purp. ovată, spiră acuminatoturrită, anfractibus transversim carinatis et striatis, medio angulato-tumidis et tuberculatis, apertură superne sinuată; cinereo-fuscescente, carinis striisque, columellă et apertură funce rufo-aurantiis.

The Keeled Purpura. Shell ovate, spire acuminately turreted, whorls transversely keeled and striated, angularly swollen and tuberculated in the middle, aperture sinnated at the upper part; ashy brown, keels, striæ, columella and interior of the aperture reddish orange.

LAMARCK, Anim. sans vert. (Deshayes' edit.) vol. x. p. 73.

Hab. ——?

It is the distinguishing feature of this species to have two keels of a more prominent character than the rest, on the middle and upper half of the whorls, each of which, particularly the lower, is more or less tuberculated.

Species 27. (Mus. Cuming.)

Purpura armigera. Purp. testá ovatá, spirá conico-

acuminată, anfractibus superne depressiusculis, tuberculorum seriebus tribus aut pluribus cingulatis, tuberculis grandibus, crassis, obtusis, valde prominentibus, columellă et aperturæ fauce rosaceo-luteis.

The armed Purpura. Shell ovate, spire conically acuminated, whorls rather depressed round the upper part, encircled with three or more rows of tubercles, tubercles large, thick, obtuse, very prominent, columella slightly wrinkled; white, encircled with yellowish-brown bands between the rows of tubercles, columella and interior of the aperture pinkish-yellow.

Lamarck, Anim. sans vert. (Deshayes' edit.) vol. x. p. 64.

Buccinum armigerum, Chemnitz.

Hab. --- ?

A well-known species, distinguished by its stout prominent tubercles and elevated conical spire; the banded painting is also peculiar.

Species 28. (Mus. Cuming.)

Purpura bicostalis. Purp. testá ovatá, spirá subacuminatá, anfractibus transversim undique impresso-striatis, supernè depressiusculis, costis duabus subobsoletis, plus minusve tuberculiferis, cingulatis, columellá obliquè plicato-rugosá, labro intus fortiter inciso-sulcato; fuscescente, strigis flexuosis cinereo-olivaceis longitudinaliter nebulatá, areis inter strias concinnè fusco arliculatis, columellá et aperturæ fauce aurantio-rugis.

The two-ribbed Purpura. Shell ovate, spire a little acuminated, whorls transversely impressly striated throughout, rather depressed at the upper part, encircled with two obsolete ribs, which are more or less tuberculiferous, columella obliquely plicately wrinkled, lip strongly sharply grooved within; light brown, clouded longitudinally with ashy olive streaks, spaces between the strice prettily articulated with brown, columella and interior of the aperture orange-red.

LAMARCK, Anim. sans vert. (Deshayes' edit.) vol. x. p. 82. *Hab.* St. Elena, West Columbia (found on the rocks at low water); Cuming.

This species, which is probably often confounded with the P. hæmastoma, may be distinguished in great measure by its neat articulated painting.

PLATE VII.

Species 29. (Mus. Cuming.)

Purpura lineata. Purp. testā ovatā, tenui, ventricosā, spirā breviusculā, acutā; anfractibus transversim undique striatis, supernè acutè angulatis, ad angulum plicato-nodosis, nodis subcompressis, infra funiculis obsoletè nodiferis, subirregulariter distantibus, cingulatis; aperturā amplā, fauce subtiliter liratā, labro tenui; luteoalbicante; faniculis castaneis, columellā labrique margine internā aurantio-rufis.

The LINEATED PURPURA. Shell ovate, thin, ventricose, spire rather short, acute; whorls transversely striated throughout, sharply augulated, plicately noduled at the angle, nodules rather compressed, eucircled beneath with rather irregularly distant cords, which are obsoletely nodiferous; aperture large, interior finely ridged, lip thin; yellowish white, cords chesnut brown, columella and inner side of the lip orange-red.

Kiener, Icou. coq. viv. p. 115. pl. 33. f. 80.

Buccinam tineatum, Lamarck.

Hab. ——?

This remarkable shell which is admirably figured in the 'Encyclopèdie Méthodique ' Pl. 400 f. 6. a, b. was included by Lamarck in the genus *Buccinum*; M. Kiener has, however, very properly removed it to *Purpura*.

Species 30. (Mus. Cuming.)

Purpura imperialis. Purp. testá ovatá, basi ampliter umbilicatá, spirá acutè turritá; anfractibus transversim undique striatis, supernè angulatis, spinis squamæformibus prominentibus subrecurvis conspicuè biseriatim cinctis, spinis apicem versus obsoletis; luteo-albicante, aperturæ fauce cæruleo-fusco subindistinctè fasciatá.

The imperial Purpura. Shell ovate, largely umbilicated at the base, spire sharply turreted; whorls transversely striated throughout, angulated at the upper part, conspicuously encircled with two rows of prominent scale-like spines a little recurved, spines obsolete towards the apex; yellowish white, interior of the aperture somewhat indistinctly banded with blueish brown.

De Blainville, Nouv. Ann. du Mus. vol. i. p. 227. pl. 11. f. 6.

Hab. ---- ?

How M. Kiener can possibly discover any specific rela-

tion between the shells which he has figured as varieties under the above title, I cannot imagine. The P imperialis, which he correctly figures at Fig. 39. is allied rather to the P carinifera, the keels of that species being developed in this into a diadem of recurved spines; the shell represented at Fig. 39. α , is of a different form, and exhibits quite another design of sculpture.

Species 31. (Mus. Cuming.)

Purpura kiosquiformis. Purp. testâ fusiformi-ovată, subscalariformi, transversim undique elevato-striatis, anfractibus medio uni- vel biseriatim carinatis et tuberculatis, spiræ suturis profundis, lamellis crispatis erectis concentrice decussatis, labro superne sinuato; olivaceoviridi, albo vel cærulescente zonatâ, aperturæ fauce interdum fasciatâ.

The Kiosk-shaped Purpura. Shell fusiformly ovate, somewhat scalariform, transversely elevately striated throughout, whorls encircled round the middle with one or two keels and rows of tubercles, sutures of the spire deep, concentrically crossed with creet crisped lamellæ, lip sinuated at the suture; olive-green, zoned with white or pale blue, interior of the aperture sometimes banded with black-brown.

Duclos, Annales Sei. Nat. vol. xxvi. pl. 1. f. 5.

Hab. Bay of Panama (on rocky places at low water); Cuming.

The locality of New Holland cited by M. Kiener for this species, is, I think, a very doubtful one; it was collected by Mr. Cuming at the Bay of Panama.

Species 32. (Mus. Cuming.)

Purpura D'Orbignyi. Purp. testá fusiformi-ovatá, basi umbilicatá, anfractibus transversim liratis, liris prominentibus subdistantibus, supernè convexo-angulatis, ad angulum biseriatim tuberculatis, tuberculis compressis, superioribus prominentioribus; albá, ferrugineo-fusco, apicem versus saturatiore, plus minusve tinctá, epidermide crassá fibrosá indutá, aperturá albá.

D'Orbigny's Purpura. Shell fusiformly ovate, umbilicated at the base, whorls transversely ridged, ridges promineut, rather distant, convexly angulated at the upper part, encircled at the angle with two rows of compressed tubercles, of which the upper are the

more prominent; white, more or less stained with rusty brown which is darker towards the apex, and covered with a thick fibrous epidermis, aperture white.

Fusus Purpuroides, D'Orbigny, Voyage dans l'Amérique Méridionale, Pl. 63. Fig. 1.

Hab. St. Elena, West Columbia (in the crevices of rocks at low water); Cuming.

I include this species under the head of *Purpura*, in conquence of its unquestionable generic affinity with the *P. kiosquiformis*, and dedicate it to the illustrious traveller and naturalist, the adoption of whose specific name would involve an inconsistent tantology.

Species 33. (Mus. Cuming.)

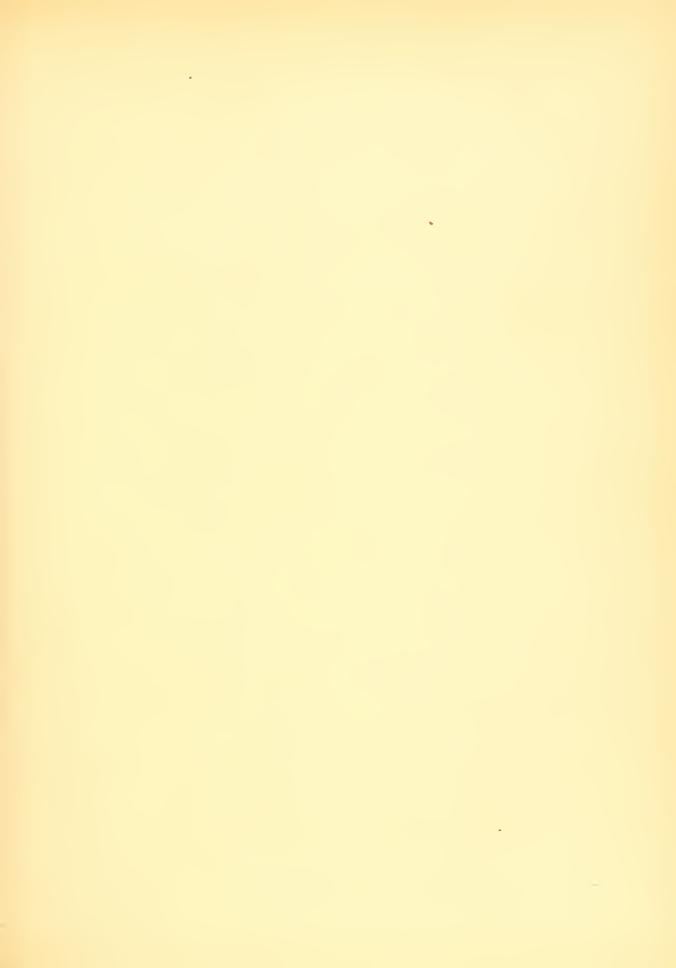

Purpura echinata. Purp. testá ovatá, basi umbilicatá,

anfractibus transversim undique elevato-striatis, striis subtilissimè squamatis, supernè subangulatis, infra angulum quadriseriatim tuberculatis, tuberculis parvis, nodiformibus; extus pallidè rubiginoso-fusca, intus alba.

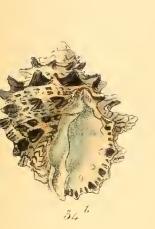

THE PRICKLY PURPURA. Shell ovate, umbilicated at the base, whorls transversely elevately striated throughout, striæ very finely scaled, slightly angulated at the upper part, encircled beneath the angle with four rows of small nodule-like tubercles; exterior pale rusty brown, interior white.

DE BLAINVILLE, Nouv. Ann. du Mus. pl. 11 f. 2. Hab. ——?

A very characteristic and well-defined species, quite distinct from the *P. echinulata* of Lamarck, of which M. Deshayes appears to have omitted mention.

Purpura Pl. VIII

Reeve unp

PLATE VIII.

Species 34. (Fig. a, b, and c, Mus. Cuming.)

Purpura hippocastanum. Mur. testá ovatá spirá breviusculá, interdum subelevatá, anfractibus supernè leviter angulatis, serialim tuberculatis, tuberculis fortibus, nunc obtusis, nunc prominentibus, interareis impresso-striatis, labro intus noduloso; extus albidá, nigerrimo plus minusve tinctá vel articulatá, columella et aperturæ fance purpureo-fusco radiatis.

The horse-chesnut Purpura. Shell ovate, spire rather short, sometimes a little elevated, whorls slightly angulated round the upper part, encircled with rows of tubercles, tubercles strong, sometimes obtuse, sometimes prominent, the interspaces being impressly striated, lip noduled within; exterior whitish, more or less stained and articulated with jet black, columella and interior of the aperture radiated with purple-brown.

Murex hippocastanum, Linnæus.

Hab. Eastern Seas, South Seas, Zanzibar, &c.

I cannot agree with the principle advanced by my estcemed friend, M. Deshayes, in his observations on the Purpura hippocastanum, to the effect that any species of Linnæan origin should be abandoned that cannot be satisfactorily identified. The author of the 'Systema Naturæ' had but a meagre range of antiquated figures to refer to for the illustration of his species, and he lived in a time when not only comparatively few shells had been discovered, but when the greater portion were collected dead upon the shore, and in very imperfect condition. The case before us is merely one of those instances in which Liunæus, from the miscellaneous character of his materials, included several species under one specific head. It was his misfortune, in the present case, to refer to figures which have proved to be the representatives of different species, one of which in Rumphius' 'Thesaurus Imaginum' Pl. 24. Fig. C. a Purpura hystrix, is an error which appears to have escaped even the penetration of Lamarck. The reference made by Linnæus to Gualter's great figure of the Pyrula galeodes (Pl. 31. Fig. F.) is probably a typographical error, for a figure resembling the shell under consideration, occurs at Pl. 43. Fig. V. of the same work, as corrected by Lamarck; it is a serious reflection on the genius and discrimination of the learned Professor of Upsal to imply that he could have simultaneously regarded the figures above cited in Rumphius and Gualter as the representatives of one and the same species. I think it is tolerably apparent from the references of Linneus, that he included the Purpuræ hippocastanum, bitubercularis, and pica under one specific head (Murex hippocastanum), and confounded them with a dorsal figure of the P. hystrix; of these names the first has been assigned by Lamarck to the shell under review, and, although some confusion has arisen amongst naturalists, through one taking one type, and another selecting another, it is manifest that to abandon all on the principle advanced by M. Deshayes, would only lead to confusion worse confounded.

The *P. hippocastanum* is, perhaps, the most readily distinguished by a peculiarity in the arrangement of the colouring matter, which is for the most part articulated in small tessellated squares ranging between the engraved striæ; there is, however, a dark variety represented at Fig. 34. *a*, in which the articulation is lost in the overwhelming deposit of black colouring, in broad close concentric stripes.

Species 35. (Mus. Metealfe.)

Purpura luteostoma. Purp. testá oblongo-ovatá, transversim undique striatá, anfractibus supernè angulatis, infra seriatim tuberculatis, tuberculis obtusis, interdum fere obsoletis; luteo-fuscescente, cinereo-nigricante longitudinaliter undatim pictá, columellá et aperlura fauce rufo-aurantiis.

THE YELLOW-MOUTH PURPURA. Shell oblong-ovate, transversely striated throughout, whorls angulated at the upper part, encircled with rows of tubercles beneath, which are obtuse, and sometimes nearly obsolete; yellowish brown, painted with longitudinal waves of ashy black, columella and interior of the aperture reddish orange.

DESHAYES, Anim. sans vert. vol. x. p. 98.

Buccinum luteostoma, Chemnitz, vol. xi. p. 83. pl. 187. f. 1800, 1.

Hab. ---- ?

An interesting species, distinguished by its clevated spire and blueish tinge of colour.

Species 36. (Mus. Cuming.)

Purpura pica. Purp. testá ovatá, crassiusculá, subventricosá, anfractibus supernè angulatis, infra biseriatim tuberculatis, tuberculis solidis, prominentibus, subdistantibus, aperturæ fauce striatá; nigro alboque conspicuè variegată, columellă lutescente, rufo-fusco tinctă, apertură lutescente, margine nigro tessellată.

The Magpie Purpura. Shell ovate, rather thick, somewhat ventricose, whorls angulated at the upper part, encircled beneath with two rows of rather distant prominent tubercles, interior of the aperture striated with reddish brown, aperture yellowish, tessellated with black at the margine.

DE BLAINVILLE; Kiener, Icon. Coq. viv. p. 48. pl. 11. fig. 31.

Hab. Island of Luzon, Philippines (under stones at low water); Cuming.

The comparison of affinities which M. Kiener draws between this species and the *P. armigera*, is quite uncalled for, the two species being far removed from each other; it approaches rather to the *P. bitubercularis*, but may be distinguished by its broader and more ventricose shape, and by the more solid and obtuse growth of the tubercles, the aperture also differing in being striated.

Species 37. (Mus. Cuming.)

Purpura bitubercularis. Purp. testá oblongo-ovatá, transversim impresso-striatá, anfractibus supernè subangulatis, infra biseriatim tuberculatis, tuberculis acuminatis, muricatis, labro intus denticulato; extus cinereo-nigricante, et luteo-albido csnspicuè variegatá, aperturá rufescente-aurantiá.

The double-tubercled Purpura. Shell oblong-ovate, transversely impressly striated, whorls slightly angulated at the upper part, encircled beneath with two rows of asuminated prickly tubercles, denticulated

within; exterior conspicuously variegated with ashy black and yellowish-white, aperture reddish-orange. LAMARCK, Anim. sans vert. (Deshayes' edit.) vol. x. p. 64.

Purpura Kienerii, Deshayes.

Hab. Philippine Islands; Cuming.

I consider M. Kiener perfectly correct in his illustration of this species, and that his figure is in every respect identical with that of Seba.

Species 38. (Mns. Cuming.)

Purpura intermedia. Purp. testá oblongo-ovatá, spirá brevi, subacuminatá, anfractibus supernè leviter depressis, transversim impresso-striatis, seriatim obsoletè tuberculatis, aperturá subamplá, labro plano-incrassato, intus noduloso; nigerrimá, areis inter tuberculos albimaculatis, columellá labrique margine purpureo-fusco tinctis

The intermediate Purpura. Shell oblong-ovate, spire short, a little acuminated, whorls slightly depressed at the upper part, transversely impressly striated, encircled with rows of obsolete tubercles, aperture rather large, lip flatly thickened, nodulous within; very black, spaces between the tubercles blotched with white, columella and edge of the lip stained with purple-brown.

KIENER, Icon. Coq. viv. p. 51. pl. 12. f. 34. *Hab.* —— ?

An interesting well-defined species, quite distinct from either of those between which M. Kiener has considered it intermediate.

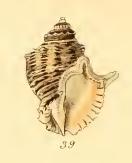

PLATE IX.

Species 39. (Mus. Cuming.)

Purpura thiarella. Purp. testá ovatá, subincrassatá, spirá breviusculá, angulato-acuminatá, anfractibus transversim subtiliter liratis, longitudinaliter subplicatis, supernè concavo-angulatis, ad angulum tuberculato-coronatis; cinereo-griseá, columellá albidá, aperturæ fauce lutescente.

The Little crown Purpura. Shell ovate, somewhat thickened, spire rather short, angularly acuminated, whorls transversely ridged, longitudinally subplicated, concavely angulated round the upper part, tubercularly coronated at the angle; asby grey, columella whitish, interior of the aperture yellowish.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol. x. p. 83. Hab. Island of Vanikoro; Quoy.

Approaching very closely to the *P. imperialis*, but constantly distinguishable by its more solid growth and stouter and ruder form.

Species 40. (Mus. Cuming.)

Purpura cataracta. Purp. testá oblongo-ovatá, Bucciniformi, scabrá, transversim subobsoletè sulcatá, striis longitudinalibus obliquè decussantibus; columellá planodepressá, aperturá inflatá; griseo-albicante, strigis nigricantibus, irregulariter undulatis, longitudinaliter pictá, columellá et aperturæ fauce purpureo-fuscis.

The Cataract Purpura. Shell oblong-ovate, Buccinum-shaped, rough, transversely obsoletely grooved, with longitudinal striæ crossing obliquely; columella flatly depressed, aperture inflated; greyish-white, painted longitudinally with irregularly undulating black streaks, columella and interior of the aperture purplebrown.

Buccinum cataracta, Chemnitz, Conch. Cab. vol. x. p. 188, pl. 152, f. 1455.

Hab. ——?

No author appears to have yet succeeded in identifying the mysterious *Buccinum cataracta* of Chemnitz; it is easy to frame a description referring to it, as did Lamarck, or to criticise the illustrations of others, as M. Deshayes has very properly done, but the test of an author's researches is to produce the shell. M. Kiener in attempting this, has unfortunately added to the confusion; in his monograph of *Purpura*, he has figured at least two, if not three,

species for P. cataracta and varieties, not one of which exhibits the slightest approach to Chemnitz's figure, and all presenting the ordinary character of a grooved aperture, the absence of which in the Buccinum cataracta is one of its distinguishing features. Again, on referring to M. Kiener's monograph of Buccinum, it will be found that he has figured another totally different shell under the name of B. Delalandi, referring, for the sake of illustration, to Chemnitz's figure of B. cataracta. If M. Kiener regarded that shell as the species now under investigation, why not have adopted Chemnitz's name, instead of complimenting M. Delalande in opposition to the ordinary rules of nomenclature? we are all hable to error, and to avoid it is impossible, but the necessity for such a reiteration of critical correction as the labours of this author invoke, becomes irksome.

The specimen here described and figured for the *P. cataracta* does not accord so intimately with Chemuitz's figure as could be wished, but I believe it to be the shell intended, and leave others to form their own opinion of the accuracy of my views. It is a rough shell, obscurely grooved and striated, conspicuously and most irregularly undulated with black upon a white ground, the columella and interior of the aperture being perfectly smooth, and of a chocolate or purple-brown colour.

Species 41. (Mus. Cuming.)

Purpura Blainvilli. Purp. testá ovatá, spirá subacuminatá, anfractibus transversim nodoso-costatis, interstitiis subtiliter liratis; columellá subangustá, labro intus sulcato, margine denticulato; aperturá subinflatá; fuscá, columellá albá, ferrugineo-rufo marginatá.

DE BLAINVILLE'S PURPURA. Shell ovate, spire a little acuminated, whorls transversely nodosely ribbed, interstices finely ridged; columella rather narrow, lip grooved within, denticulated at the margin; aperture a little inflated; brown, columella white, edged with ferruginous red.

Deshayes, Anim. sans vert. vol. x. p. 93.

Purpura Callaoensis, De Blainville, Kiener, (not of Gray).

Hab. Bay of Callao, Peru.

A light, rather delicately formed shell, in which the columella is edged with dark red.

Species 42. (Mus. Cuming.)

Purpura Ægrota. Purp. testá oblongo-ovatá, transversim nodoso-costatá et liratá, columellá depressá, aperturæ fauce conspicuè sulcatá; sordidè lacteá, liris fuscescentibus, labro intus croceo-rufescente.

The Sickly Purpura. Shell oblong-ovate, transversely modosely ribbed and ridged, columella depressed, interior of the aperture conspicuously grooved; dingy cream colour, ridges tinged with light brown, lip saffron-red within.

Hab. New Holland.

A very characteristic species, from New Holland, of which several specimens have been recently collected by Mr. Jukes, during the surveying expedition of H. M. S. 'The Fly.' It approaches nearest to the *P. hæmastoma*, but is of a different style of seulpture, and always characterized by a pallid tone of colouring.

Species 43. (Mus. Cuming.)

Purpura undata. Purp. testá oblongo-ovatá, utriuque subattenuatá, spirá angulato-acuminatá; anfractibus transversim subtiliter granoso-liratis, supernè depressis, transversim costatis, costis peculiariter compresso-tuberculatis; albo et cinereo-fusco longitudinaliter undatim pictá, costis hic illic lutescentibus, columellá et aperturæ fauce luteis.

The waved Purpura. Shell oblong-ovate, a little attenuated at each end, spire angularly acuminated; whorls transversely ribbed, ribs peculiarly compressly tubereled; painted longitudinally with waved ashybrown and white, ribs here and there yellowish, columella and interior of the aperture yellow.

LAMARCK, Anim. sans vert. (Deshayes' edit.) vol. x. p. 67.
Hab. Monte Christi, West Columbia (under stones at low water); Cuming.

Another example in which M. Kiener has figured different species as varieties; easily determined, however, by its waved painting, and the compressed character of the tubercles.

Species 44. (Mus. Cuming.)

Purpura Floridana. Purp. testá oblongo-ovatá, utrinque conspicuè attenuatá, spirá ucutá; anfractibus supernè

depressis et subtiliter nodosis, transversim undique creberrimè liratis et sulcatis; aperturæ fauce fortiter sulcatű; cæruleo-griseű, zonis luteis angustis indistinctè et irregulariter cingulatű, undulis nigricantibus longitudinaliter subindistinctè pictű, columellű et aperturæ fauce aurantio-luteis.

The Florida Purpura. Shell oblong-ovate, conspicuously attenuated at both ends, spire sharp; whorls depressed and finely noduled round the upper part, transversely very closely ridged and grooved throughout, interior of the aperture strongly grooved; blueishgrey, indistinctly and irregularly encircled with narrow yellow zones, and rather indistinctly painted with blackish longitudinal waves, columella and interior of the aperture orange-yellow.

CONRAD, Journ. Acad. Nat. Sci. Philadelphia, vol. vii. pl. 20. f. 21.

Hab. Florida.

A shell of elongated growth with a row of fine nodules round the upper portion of the whorls; of a blueish grey colour, waved longitudinally with black streaks.

Species 45. (Mus. Cuming.)

Purpura fasciata. Purp. testa oblongo-ovata, spira acuminata, exserta, transversim subtiliter lirata et sulcata, labro minutè denticulato; cærnleo-albicante, fasciis tribus angustis lutescentibus cingulata, interstitiis nigricante longitudinaliter undulatis, aperturæ fauce albicante, prope marginem purpureo-radiata.

The banded Purpura. Shell oblong-ovate, spire acuminated, exserted, transversely finely ridged and grooved; aperture rather short, a little inflated, interior grooved, lip minutely denticulated; blueishwhite, eneircled with three narrow yellowish bands, interior of the aperture whitish, rayed near the edge with purple.

Hab. ——?

There is a marked peculiarity of form as well of eolouring in this shell; the spire is acuminated whilst the aperture is short and almost rounded; the three equidistant yellow bands which encircle the last whorl are characteristic, and so also is the purplish-white tinge of the aperture, in which there is no indication of yellow or orange-red.

Purpur

PLATE X.

Species 46. (Mus. Cuming.)

Purpura emarginata. Purp. testá ovatá, crassá, spirá brevi, unfractibus oblique plicatis et corrugatis, transversim costatis, costis rugosis, compressis, acute nodosis; columellá excavatá, ampliter dilatatá; rubido-fuscá, aperturæ fauce fuscá, columellá labroque albicantibus.

THE EMARGINATED PURPURA. Shell ovate, thick, spire short, whorls obliquely plaited and wrinkled, transversely ribbed, ribs rugose, compressed, sharply noduled; columella excavated, largely dilated; reddishbrown, interior of the aperture brown, lip and columella whitish.

Deshayes, Rev. Zool. Soc. Chv., 1839. Magasin de Zool. 1841, Moll. Pl. 25.

Purpura Conradi, Nuttall.

Hab. California? New Zealand?

There is a considerable degree of uncertainty attending his species, which I am not able to clear up. M. Deshayes lescribed and figured a shell in the Magasin de Zoologie, under the name of *P. emarginata*, in an immature state, emarginated at the lip, said to be brought from New Zealand by M. Chiron; in the British Museum are several well-authenticated specimens, answering in their minutest particulars with M. Deshayes' description and figure above referred to, collected by Mr. Nuttall in California, and named by him, in manuscript *P. Conradi*.

The emargination noticed by M. Deshayes becomes almost obliterated with age, and the species differs exceedingly in its growth, the transverse ribs varying from smooth to roughly noduled.

Species 47. (Fig. a and b, Mus. Cuming.)

Purpura lapillus. Purp. testá ovatá, spirá acutá, anfractilus læcibus, aut transversim crebrè liratis, liris obsoletè squamatis; columellá excavatá, aperturá dilatatá; albidá, aurantio-luteo conspicuè fasciatá, aut ferrugineo-fuscá.

THE LITTLE STONE PURPURA. Shell ovate, spire sharp, whorls smooth, or transversely closely ridged, ridges obsoletely scaled; columella excavated, aperture dilated; whitish, conspicuously banded with orange-yellow, or rusty brown.

Variety β .

Testa creberrime fimbriato-laminata.

Shell very elosely fimbriately laminated.

Buccinum lapillus, Linnæus, Syst. Nat. (12th edit.), p. 1202.

Eadem. Buccinum filosum, Gmelin.

Hab. Shores of Europe.

To particularize every discriminable variety of this Protean species would occupy more space than the limits of the present work will allow; suffice it to illustrate the ordinary yellow-banded and lamellated states, and to observe by way of caution, that its modifications of colour and sculpture are infinite. M. Kiener has figured twenty-one different varieties of the *Purpura lapillus*.

Species 48. (Mus. Cuming.)

Purpura squamosa. Purp. testã oblongo-ovatã, subventricosã, spirã prominulã, suturis profundis; anfractibus rotundatis, transversim crebricostatis, costis angustis, obscurê squamosis, interstitiis concinnè striatis; rubido-castaneã, aperturæ funce albã.

The squamose Purpura. Shell oblong-ovate, somewhat ventricose, spire prominent, sutures deep; whorls rounded, transversely closely ribbed, ribs narrow, obscurely scaled, interstices neatly striated; reddish chesnut, interior of the aperture white.

Lamarck, Anim. sans vert. (Deshayes' edit.), vol. x. p. 74. Hab. Tigre Bay, Abyssinia.

Approaching rather in form to the Whelk division of the Buccina.

Species 49. (Mus. Cuming.)

Purpura attenuată, Purp. testă oblongo-ovată, basi peculiariter attenuată, anfractibus superne rotundatis, transversim creberrime carinatis, carinis irregularibus, augustis, lateraliter excavutis, interdum oblique subtilissime laminatis; intus extusque fuscă.

The attenuated Purpura. Shell oblong-ovate, peculiarly attenuated at the base, whorls rounded at the upper part, transversely very closely ridged, ridges irregular, narrow, excavated at the sides, sometimes obliquely very finely laminated; brown within and without.

Hab. --- ?

Although partaking somewhat of the character of *P. lapillus*, I believe it to be nevertheless distinct.

Species 50. (Mus. Cuming.)

Purpura septentrionalis. Purp. testá subfusiformiovatá, crassá, ponderosá; basi subcanaliculatá et recurvá; anfractibus lævibus, transversim obsoletè liratis; aperturá parvá, labro intus obscurè denticulato; castaneo-fuscá, intus albá.

THE NORTHERN PURPURA. Shell somewhat fusiformly ovate, thick, ponderous, slightly channelled and recurved at the base; whorls smooth, transversely obsoletely ridged; aperture small, lip obscurely denticulated within; chesnut brown, interior white.

Hab. Sitka, north-west coast of America

A solid ponderons shell, attenuately produced at the base.

Species 51. (Mns. Cuming.)

Purpura Freycinetii. Purp. testâ ovatâ, tenui, inflatâ, basem versus attenuatâ, spirâ brevissimâ, acutâ; an-

fractibus obscurè subtiliter multicarinatis; columella excavata, angusta, infernè peculiariter compressa; apertura ampla; pallidè fusca, obscurè fasciata, apertura fauce tabroque albicantibus.

FREYCINET'S PURPURA. Shell ovate, thin, inflated, attenuated towards the base, spire very short, sharp; whorls obscurely finely many-keeled; columella excavated, narrow, peculiarly compressed at the lower part; aperture large, pale brown, obscurely banded, lip and interior of the aperture whitish.

Deshayes, Revue Zool. Soc. Cuv., 1839. Magasin de Zool. 1841, Moll. Pl. 26.

Hab. Kamtschatka.

M. Deshayes describes this species as approximating to the *Purpura Rudolphi*, I fear however that this observation has rather a tendency to mislead; it is much more closely allied to the *Purpura haustrum*, having the same light attenuated form, although sufficiently remote in general character.

PLATE XI.

Species 52. (Mus. Cuming.)

Purpura musiva. Purp. testá subfusiformi-ovatá, medio angulatá, transversim subtiliter striatá, seriatim tuber-culatá, tuberculis ad angulum prominentibus, labro intus denticulato; albidá, tuberculorum seriebus alternatim aterrimis et rufo-fuscis, aperturæ fauce cærulescente.

FHE MOSAIC PURPURA. Shell somewhat fusiformly ovate, angulated in the middle, transversely finely striated, encircled with rows of tubercles, which are prominent on the angle, lip denticulated withiu; whitish, rows of tubercles alternately jet black and reddish brown, interior of the aperture blueish.

KIENER, Icon. Coq. vivantes, p. 38. pl. ix. f. 22.

Hab. Island of Ticao, Philippines (on the reefs); Cuming.

An interesting species, which may be easily recognized by the alternating colour of the tubercles, those on the angle being reddish or light chesnut brown, and of a more prominent structure than those next in order, which are black.

Species 53. (Mus. Cuming.)

Purpura trigona. Purp. testá ovatá, crassiusculá, medio gibbosá, utrinque attenuatá, spirá brevi; anfractibus supernè angulatis, transversim sulcatis et liratis; aperturá subelongatá; cæruleá et albá, fusco irregulariter strigatá, columellá et aperturæ fauce lutescente-albis.

THE TRIANGULAR PURPURA. Shell ovate, rather thick, gibbous, attenuated at both ends, spire short; whorls angulated round the upper part, transversely grooved and ridged; aperture somewhat elongated; blue and white, irregularly streaked with reddish brown, columella and interior of the aperture yellowish-white.

Hab. China and Malacca (under stones at low water).

Chiefly distinguished by its stout triangular form.

Species 54. (Mus. Cuming.)

Purpura rustica. Purp. testá ovatá, spirá acutá, transversim liratá et striatá, liris plus minusve tuberculatis, longitudinaliter subobscurè plicatá, labro intus denticulato et sulcato; longitudinaliter fusco strigatá, interstitiis plumbeis, liris interdum pallidè fluvescentibus, tuberculis semper coccineo-rufis; columellá et aperturæ fauce aurantio-luteis.

The Rustic Purpura. Shell ovate, spire sharp, transversely ridged and striated, ridges more or less tuber-culated, longitudinally streaked with brown, interstices

lead-colour, ridges sometimes tinged with pale yellow, tubercles always deep scarlet-red; columella and interior of the aperture orange-yellow.

Lamarck, Anim. sans vert. vol. x. p. 83.

Hab. Island of Luzon, Philippines (under stones at low water); Cuming.

M. Kiener, whose natural acuteuess of perception seems somewhat inferior to that of his predecessor Lamarck, has figured an example of this species for an immature variety of the *P. undata*; it is, however, constantly distinct.

The Purpura rustica is uniformly smaller than the P. undata, and throughout all its variations of form between the little tuberculated example represented by Kiener (Pl. 34. f. 81 c.), and the nearly smooth specimen figured in the accompanying plate, is forcibly characterized by the scarlet-red colouring of the ridges on the tubercles.

Species 55. (Mus. Cuming.)

Purpura tumulosa. Purp. testá ovatá, subventricosá, spirá breviusculá, anfractibus quadriseriatim tuberculatis, tuberculis rotundatis, tumidis, lævigatis, interstitis subtiliter sulcatis; albidá, tuberculis nigricantefuscis, columellá et aperturæ fuuce flavicantibus.

The tumulous Purpura. Shell ovate, somewhat ventricose, spire rather short, whorls encircled with four rows of smooth round swollen tubercles, interstices finely grooved; whitish, tubercles blackish-brown, columella and interior of the aperture yellowish.

Hab. Zanzibar (on the reefs).

Easily distinguished by its prominent smooth rounded tubercles, which have a curious swollen appearance.

Species 56. (Mus. Cuming.)

Purpura speciosa. Purp. testá ovatá, spirá brevissimá; anfractibus supernè depressis, triseriatim tuberculatis, tuberculis mucronatis, acutis; albidá, quadris pareis castaneo-fuscis undique tessellatá, zonis albidis inter tuberculos, columellá et aperturæ fauce aurantio-luteis.

THE BEAUTIFUL PURPURA. Shell ovate, spire very short; whorls depressed round the upper part, encircled with three rows of sharp-pointed tubercles; whitish, tessellated throughout with small chesuut-brown squares, with white zones between the tubercles, columella and interior of the aperture orange-yellow.

VALENCIENNES, Zool. Humboldt's Voyage.

Purpura centiquadra, Duclos.

Hab. Acapideo; Humboldt.

M. Kiener is evidently unacquainted with the *P. speciosa*; it is quite distinct from the young of the *P. bnfo*, to which he refers it; and may be recognised by the peculiar exactness of the little squares into which its colour is distributed.

Species 57. (Mus. Cuming.)

Purpura Carolensis. Purp. testá orbiculari, spirá brevissimá, depressá, anfractibus transversim fortiter biseriatim tuberculatis, subtiliter inciso-lineatis, areis intermediis minutissimè regulariter striatis; spadiceofuscescente, intus niveá.

The Charles Island Purpura. Shell orbicular, spire very short, depressed; whorls encircled with two rows of very prominent tubercles, and finely engraved lines, the interstices between which are very minutely regularly striated; light bay colour, interior snowy white.

Hab. Charles Island, Gallapagos (under stones at low water); Cuming.

Care must be taken not to confound this species with the *P. Callaoensis*; it is rounder and of more ventricose proportions, is much more strongly tuberculated, and the minute engraved detail is different, the areas between the fine grooves being more numerously and regularly striated.

Species 58. (Mus. Cuming.)

Purpura sacellum. Purp. testá fusiformi-ovatá, spirá acuminatá; anfractibus supernè angulatis, ad angulum et infra seriatim squamatis, squamis erectis, submuricatis, peculiariter compressis, interstitiis minutissimè squamutatis; luteo-albicante, squamis fuscescentibus.

The temple Purpura. Shell fusiformly ovate, spire acuminated, whorls angulated round the upper part, encircled with rows of erect somewhat prickly peculiarly compressed scales on and below the angle, the interstices between which are very minutely scaled; yellowish white, scales light brown.

Murex sacellum, Chemnitz, Conch. Cab. vol. x. p. 267.

Hab. ——?

The shell figured by M. Kiener for the Purpura sacel-lum, accords distinctly with Lamarck's description of the species, but it is not the Murex sacellum of Chemnitz; neither Lamarck nor Kiener have identified it. M. Deshayes notices the discrepancy between the figures of Kiener and Chemnitz, and it is peculiarly gratifying to me to be enabled to produce the true species. The accompanying figure may appear somewhat dissimilar from the antiquated drawing in the 'Conchylien Cabinet,' at first sight, but a comparison with the original description removes all doubt on the subject:—"testa umbilicata, flavescente, costis muricato-spinosis circumcineta, anfractibus supra late planiusculis et margine acuto, imbricato,

a parietibus distinctis, spinis costarum ex fusco maculatis, subulatis, labro crenato, caude recta adscendente".

The shell figured by M. Kiener Pl. 14, Fig. 39 a, as a variety of the *P. imperialis*, is, I think, a *P. sacellum*.

Species 59. (Fig. a and b. Mus. Cuming.)

Purpura Muricina. Purp. testá ovatá vet oblongo-ovatá, anfractibus supernè depressis, longitudinaliter plicato-costatis, costis interdum duplicatis, superficie totá minutissimè et creberrimè squamatá; sordidè fuscá vel nigricante, albo articulatá et tessellatá, columellá labroque chocolato-fuscis, aperturæ fauce cærnlescente.

The little mouse Purpura. Shell ovate or oblongovate, whorls depressed round the upper part, longitudinally plicately ribbed, ribs more or less tuberculated, transversely ribbed, ribs sometimes duplicated, entire surface of the shell very minutely and closely scaled; dun brown or blackish, articulated and tessellated with white, lip and columella chocolatebrown, interior of the aperture blueish.

DE BLAINVILLE. Nouv. Ann. du Mus. pl. 10. Fig. 2 to 5.

Purpura tessellata. Sowerby, Genera of Shells.

Hab. Philippine Islands, (under stones); Cuming.

This extremely variable, yet well-defined, species, was introduced by M. De Blainville, under three heads, P.muricina, Muricoides, and Turbinoides; and in M.Kiener's 'Iconographie', it will be found that the shells represented in his group of 'Pourpres semi-ricinules' Fig. 13 and 17, are clearly identical with that figured among his 'Pourpres buccinoides' at Fig. 82. The species is subject to a remarkable degree of modification, but may be recognized in all its phases, amongst other characters, by the surface being closely bestudded with minute scales.

Species 6.9 (Mus. Cuming).

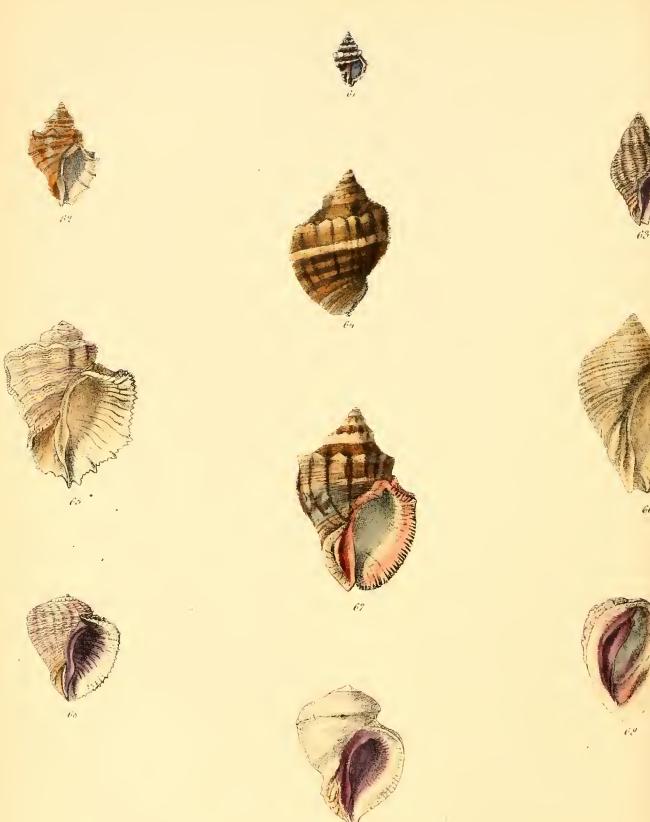

Purpura alveolata. Purp. testá subfusiformi-ovatá, transversim obscurè costatá, undique inciso-striatá, costis obsoletè tuberculatis, tuberculis obtusis, superficiariis, columellá subdepressá, labro intus dentato; albidá, tuberculis nigris, areis inter strias maculis nigris oblongis interruptis, columellá et aperturæ fauce aurantio-luteis.

The checkered Purpura. Shell somewhat fusiformly ovate, transversely obscurely ribbed, encircl throughout with engraved striæ, ribs obsoletely tuber-culated, tubercles black, spaces between the striæ interrupted with oblong black spots, columclia and interior of the aperture orange yellow.

Hab. Panama (under stones); Cuming.

A very characteristic species easily recognized by its style of colouring above described.

PURPURA.

PLATE XII.

Species 61. (Mus. Cuming.)

Purpura anaxares. Purp. testá ovatá, subfusiformi, transversim inciso-striatá et fortiter tuberculato-nodosá, labro intus denticulato; purpureo-nigrá, nodis albis, aperturæ fance purpureá.

The diminutive Purpura. Shell ovate, somewhat fusiform, transversely deeply striated and strongly tubercularly noduled, lip denticulated within; purple-black, nodules white, interior of the aperture dark purple.

Duclos; Kiener, Icon. Coq. viv. p. 26. pl. 7. f. 17. Hab. Lord Hood's Island (on the reefs); Cuming.

Distinguished by its conspicuous white nodules.

Species 62. (Mus. Cuming.)

Purpura diadema. Purp. testá subfusiformi-ovatá, spirá acuminatá; anfractibus supernè depressis, subtiliter impresso-striatis, striis obsoletè punctatis; spiraliter bicarinatis, carinis tuberculatis, tuberculis compressis, erectis; pallidè spadiceá, intus atbá.

THE DIADEM PURPURA. Shell somewhat fusiformly ovate, spire acuminated; whorls depressed round the upper part, finely impressly striated, strice obsoletely punctured; spirally double-keeled, keels tuberculated, tubercles compressed, erect; light bay colour, interior white.

Hab. Payta (on the reefs); Cuming.

Easily recognized by its compressly tubercled keels.

Species 63. (Mus. Cuming.)

Purpura costularis. Purp. testá fusiformi, longitudinaliter plicato-costatá, transversim creberrimè et subtilissimè liratá, liris minutissimè squamatis; aperturá parvá, labro serrato; viotascente-albá, columeltá et aperturæ fauce vividè viotaceis.

The small-ribbed Purpura. Shell fusiform, longitudinally plicately ribbed, transversely very closely and finely ridged, ridges very minutely scaled; aperture small, lip serrated; violet-tinged white, columella and interior of the aperture deep violet.

DE BLAINVILLE, Nouv. Ann. du Mus. pl. 11, f. 9.

Murex costularis, Lamarek.

Hab. Isle of Masbate, Philippines (under stones at low water); Cuming.

I include this shell in the present genus on account of its affinity with the P. galea, violacea, &c.

Species 64. (Mus. Taylor.)

Purpura unifascialis. Purp. testá ovatá, tenui, ven-

tricosá, anfractibus transversim tenuissimè striatis, biseriatim nodosis, supernè depressis; columellá angustá, aperturá dilatatá, subtiliter sulcatá; spadiceofuscá, fasciá albidá angustá medio cingulatá, aperturæ sulcis prope labrum rufescentibus.

THE SINGLED-BANDED PURPURA. Shell ovate, thin, ventricosc, whorls transversely very finely striated, encircled with two rows of nodules, depressed round the upper part; columella narrow, aperture dilated, finely grooved; light bay colour, encircled round the middle by a narrow whitish band, grooves of the aperture red near the lip.

LAMARCK, Anim. sans. vert. (Deshayes edit.) vol. x. p. 86. Hab. ——?

This is not a variety of the *P. hæmastoma*, as M. Kiener supposes, but a very excellent species, distinguished, without reference to the bauded style of colouring, by its light inflated growth and other peculiarities of detail; it approaches very closely to the *P. Blainvillii*, but the aperture is proportionably larger and more dilated, the columella is not, moreover, edged with red. The shell before me answers with peculiar accuracy, irrespective of the band, both with Lamarck's description, and the figure cited by him in the 'Encyclopédie Méthodique.'

Species 65. (Mus. Cuming.)

Purpura galea. Purp. testă abbreviato-ovată, Pyrulæformi, ampliter umbilicată, spiră brevi; anfractibus,
longitudinaliter plicatis, superne plano-depressis, transversim costatis, et creberrime subtiliter tiratis, liris
minutissime squamatis; albă, coccineo pallidissime
tinctă.

The Helmet Purpura. Shell abbreviately ovate, Pyrula-shaped, largely umbilicated, spire short; whorls longitudinally plicated, flatly depressed round the upper part, transversely ribbed and very closely finely ridged, ridges very minutely scaled; white, very faintly tinged with scarlet.

Murex galea, Chemnitz, Conch. Cab., vol. x. p. 237. pl. 160. fig. 1518, 1519.

Pyrula abbreviata, Lamarek.

Purpura abbreviata, Kiener.

Hab. Island of Luzon, Philippines (under stones at low water); Cuming.

This remarkable species is very closely allied, generically, to the *Pyrula Mawæ*, but its affinity with the *Purpura violacea* and others, renders the present the most appropriate genus for its reception.

Species 66. (Mus. Taylor.)

Purpura textiliosa. Purp. testá ovatá, ventricosá, transversim undiquè obsoletè costatá, costis superficiariis, irregularibus, confertis, interstitiis subindistinctè pertusis, aperturá amplá; sordidè albá, labro intus pallidè aurantio tincto.

The interwoven Purpura. Shell ovate, ventricose, transversely obsoletely ribbed throughout, ribs superficial, irregular, close-set, interstices rather indistinctly punctured, aperture large; dull white, lip palely tinged within with orange.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol. x. p. 77. *Hab.* New Holland.

Amply distinguished from the *P. succincta* by the superficial character of the encircling ribs, the *P. textiliosa* yet passes into that species through a succession of intermediate states.

Species 67. (Mns. Hanley.)

Purpura biserialis. Purp. testá oblongo-ovatá, spirá conico-acutá, anfractibus transversim tenuissimè inciso-striatis, supernè depressis, biseriatim tuberculatis; pallidè griseá, striis fuscis, fusco irregulariter strigatá, columellá vividè rufá, aperțuræ fauce pallidá, rufo prope labrum tinctá.

The double row purpura. Shell oblong-ovate, spire conically acute, whorls encircled with fine engraved striæ, depressed round the upper part, beneath which are two rows of tubercles; pale gray colour, striæ brown, irregularly streaked with brown, columella bright red, interior of the aperture pale, tinged with red towards the lip.

DE BLAINVILLE, Nouv. Ann. du Mus. Pl. 11. Fig. 11, Hab. ——?

I venture to refer this shell to *P. biserialis* of De Blainville; it answers with peculiar accuracy to his description, and is quite distinct from any other species of the present monograph.

Species 68. (Mus. Cuming.)

Purpura squamulosa. Purp. testá globoso-ovatá, basem versus attenuatá, spirá brevissimá, depressá; anfractibus supernè rotundatis, liris subtitibus minutè squamulosis undique creberrimè cinctis; albá, columellá et aperturæ fauce pallidè violaceis.

THE FINELY SCALED PURPURA. Shell globosely ovate, attenuated towards the base, spire rather short, depressed; whorls rounded at the upper part, very closely encircled throughout with fine minutely scaled ridges; white, columella and interior of the aperture pale violet.

Hab. Island of Ticao, Philippines (on the reefs at low water); Cuming.

This delicately sculptured species has very much the form of the *P. violacea*, from Taheite, but it is perfectly distinct; the entire surface is encircled with minutely scaled ridges similar in pattern to those of the beautiful little *Murex squamulosus* of Philippi, and the colour of the mouth is a pale violet of a different tint.

Species 69. (Mus. Cuming.)

Purpura Madreporakum. Purp. testá depresso-ovatá, spirá brevissimá, interdum oculatá; transversim tenuissimè striatá, scabrá; aperturá amplá, marginibus latissimè dilatatis, columellá, plano-depressá; albá, columellá vividè purpureo-violaceá, aperturæ fauce purpureo-violaceo partim tinctá.

THE MADREPORE PURPURA. Shell depressly ovate, spire very short, sometimes concealed; transversely very finely striated, rough; aperture large, margins very widely dilated, columella flatly depressed; white, columella rich purple-violet, interior of the aperture partially stained with purple violet.

Sowerby, Genera of Shells, Purpura.

Purpura monodonta Quoy and Gaimard.

Hab. Eastern Seas (upon madrepores).

I adopt Mr. Sowerby's name for this interesting parasite, first, because he introduced it simultaneously if not prior to that of M M. Quoy and Gaimard, and secondly because the name assigned to it by those naturalists is a very inappropriate one, there being nothing in the structure of the shell that can be designated a tooth.

Species 70. (Mus. Cuming.)

Purpura violacea. Purp. testá ovatá, crassá, ponderosá, basi attenuatá, subcanaliculatá, spirá, brevissimá; transversim obsoletè striatá, scabrá; albá, columellá et aperturæ fauce vividè purpureo-violaceis

The violet Purpura. Shell pyriformly ovate, thick, ponderous, attenuated and somewhat channelled at the base, spire very short, transversely obsoletely striated, rough; white, columella and interior of the aperture rich purple violet.

KIENER, Icon. Coq. viv. p. 77. pl. 19. f. 57.

Murex Neritoideus, Chemnitz (not of Linnæus).

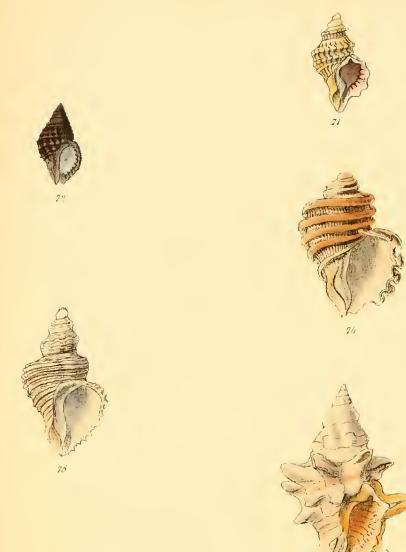

Fusus Neritoideus, Enc. Méth. Pyrula Neritoidea, Lamarck.

Purpura Neritoidea, Quoy and Gaimard.

Hab. Taheite (on the reefs at low water); Cuming.

This well-known shell may be easily distinguished from the *Purpura squamulosa*, by its rude structure and deep purple violet colouring.

7.9

PURPURA.

PLATE XIII.

Species 71. (Mus. Brit.)

Purpura Quoyi. Purp. testå subfusiformi, utrinque productå, aufractibus supernè concavo-depressis, longitudinaliter subtilissimè laminatis, costis lirisque rugosis aut scabrosis cinctis; columellå parcå, labro intus crenato; albidå aut fuscescente, aperturæ fauce purpureo-fuscå.

Quoy's Purpura. Shell somewhat fusiform, produced at each end, whorls concavely depressed round the upper part, longitudinally very finely laminated, encircled with rough and scabrous ribs and ridges; columella excavated, aperture small, lip crenated within; whitish or light brown, interior of the aperture purple brown.

Purpura rugosa, Quoy, Zool. Voy. de l'Astrolabe, pl. 38. f. 19 to 21.

Hab. New Zealand.

M. Kiener appears to have confounded this interesting little species with the following.

Species 72. (Mns. Cuming.)

Purpura scobina. Purp. testá oblongo-ovatá, anfractibus convexis, liris transversis et longitudinalibus creberrimè clathratis; nigricante-fuscá, liris transversis interdum albis, columellá purpureo-fuscá, aperturæ fauce cærulescente.

THE FILE PURPURA. Shell oblong-ovate, whorls convex, very closely latticed with transverse and longitudinal ridges; blackish-brown, transverse ridges sometimes white, columella purple-brown, interior of the aperture blueish.

Quoy, Zool. Voy. de l'Astrolabe, pl. 38. f. 12 and 13. Hab. New Zealand.

An extremely variable species, but one whose different phases exhibit a good specific affinity.

Species 73. (Mns. Cuming.)

Purpura nux. Purp. testá ovatá, crassinsculá, subventricosá, anfractibus convexis, transversim irregulariter multiliratis, lirarum interstitiis laminis decussatis, labro intus dentato; olivaceo-fusco variá, hic illic albipunctatá, columellá et aperturæ fauce albis.

THE NUT PURPURA. Shell ovate, rather thick, somewhat ventricose, whorls convex, encircled with numerons irregular ridges, the interstices between which are crossed with minute laminæ, lip toothed within; varicgated with olive brown, dotted with white, columella and interior of the aperture white.

Hab. ---- ?

An interesting species, not immediately allied with any hitherto described,

Species 74. (Mns. Brit.)

Purpura spiralis. Purp. testú ovatú, tenui, inflatú, costis quinis prominentibus conspicuè spiraliter cinctú, interstitiis longitudinaliter striatis, costis latis, planatis, lævibus, lateribus excavatis; albido-fuscescente, costis rufo-fuscis.

The spiral Purpura. Shell ovate, thin, inflated, conspicuously spirally encircled with five prominent ribs, smooth and flattened at the summit, excavated at the sides, with the interstices striated longitudinally; whitish-brown, ribs reddish brown.

Purpura trochlea, var. Kiener, Icon. Coq. viv. pl. 28. f. 75 and 75 a.

Hab. ——?

"It is very possible," says M. Deshayes, "that this shell may constitute a species distinct from the *P. cingulata* (*P. trochlea*, Lam)." There cannot, I think, be a doubt of it, it is uniformly larger, more inflated, and has a larger number of ribs,

Species 75. (Mus. Cuming.)

Purpura Scalariformis. Purp. testà acuminato-turrità, anfractibus supernè angulatis, suturis depressis, infru angulum carinatis et striatis, carinis irregularibus, acutis; extus intusque albà.

THE SCALARIA-SHAPED PURPURA. Shell acuminately turreted, whorls angulated round the upper part, depressed at the sutures, keeled and striated beneath the angle, keels irregular, sharp; white within and without.

LAMARCK, Anim. sans vert. (Deshayes' edit) vol. x. p. 73. Hub. Juan Fernandez (in rocky places at low water); Cuming.

The sculpture and general tone of this shell so far resembles the *P. yalea*, that it has been considered an elongated growth of that species. The *P. deformis* of Lamarck, according to Kiener, is a monstrosity of the *P. yalea*; and the *P. brevis* of De Blainville, the young of the same.

October, 1846.

Species 76. (Mus. Cuming.)

PURPURA CINGULATA. Purp. testá oblongo-oratá, costis tribus aut minoribus spiraliter cingulata, costis valdè prominentibus, planatis, lævibus, utrinque excavatis, costarum interstitiis subtilissime striatis; cinereo-albicante, aperturæ fauce fusco tinctå.

THE BELTED PURPURA. Shell oblong-ovate, spirally encircled with three, or fewer, ribs, which are peculiarly prominent, smooth and flattened at the summit, and excavated at the sides, interstices between the ribs very finely striated; ashy-white, interior of the aperture stained with brown.

DESHAYES, Anim. sans vert. vol. x. p. 86. note.

Buccinum cinqulatum, Linnæus.

Purpura trochlea, Lamarek.

Hab. Cape of Good Hope.

The prominence and regularity of the ribs impart a peculiar screw-like appearance to the shell, the effect of which is increased by the depression of the sutural portion of the spire.

Species 77. (Mus. Cuming.)

Purpura Affinis. Purp. testá recto-fusiformi, crassá, solida, spira acute acuminata, anfractibus tuberculis solidis prominentibus biseriatim cinctis, interstitiis striatis; cotumella obsolete plicata; apertura parva, labro intus dentato; alba, aperturæ fauce crocato-fuscescente.

THE ALLIED PURPURA. Shell straightly fusiform, thick, solid, spire sharply acuminated, whorls eneircled with two rows of prominent solid tubercles, interstices striated; columella obsoletely plaited, aperture small, lip toothed within; white, interior of the aperture saffron-brown.

Hab. Elizabeth Island, South Seas, (on exposed rocks at half-tide); Cuming.

I have examined several examples of this species, and find it uniformly distinct from the P. armigera to which it is so closely allied.

Species 78. (Mus. Cuming.)

Purpura gibbosa. Purp. testá, subventricosá, spirá brevi, anfractibus concentrice plicato-costatis, costis tumidis, si bnodosis, transversim subtilissimè et creberrimè carinatis, carinis acutis, irregutaribus, minute squamatis; albá, violaceo tinctá, aperturæ fauce vividè violaceá.

THE GIBBOUS PURPURA. Shell ovate, somewhat ventricose, spire rather short, whorls concentrically pheately ribbed, ribs swollen, somewhat nodose, transversely very finely and closely keeled, keels sharp, irregular, minntely scaled; white, tinged, with violet, interior of the aperture deep violet.

A small gibbous species approximating in general character to some of the Murices.

Species 79. (Mns. Cuming.)

Purpura Callagensis. Purp. testá ovatá, subdepressá, spirâ brevissimă; anfractibus lævibus aut obsoletè nodosis, transversim tenuissime sulcatis, areis inter sulcos minutissimè regulariter striatis; columella excavatá, aperturá amplá, labro crenulato; sordide albá, fuscescente subindistincte longitudinaliter undulatá, columella et aperturæ fauce albis.

THE CALLAO PURPURA. Shell ovate, a little depressed, spire very short; whorls smooth or obsoletely nodose, transversely very finely grooved, areas between the grooves very minntely regularly striated; columella excavated, aperture large, hip cremulated; dull white, rather indistinctly longitudinally festooned with light brown, columella and interior of the aperture white.

Gray, Spicilegia Zoologica p. 4. pl. 6. f. 11.

Hab. Callao Bay; Hennah, Cuming.

An interesting little species, described some years since by Mr. Gray, of which there are several examples in the British Museum.

Species 80. (Mus. Brit.)

Purpura Janellii. Purp. testá ovatá, medio obesá, basi contracta, spira brevi; anfractibus transversim striatis, superne declivibus, infra tuberculis rotundatis obtusis seriatim armatis; columella arcuata, lubro intus denticulato et lirato; albida, epidermide olivaceo-fusca induta, columella rubro-nigricante, aperturæ fauce cærulescente.

JANELLE'S PURPURA. Shell ovate, stout in the middle, contracted at the base, spire short; whorls transversely striated, sloping round the top, armed beneath with rows of blunt rounded thbereles; columella arched, lip denticulated and ridged within; whitish, covered by an olive-brown epidermis: columella reddish black, interior of the aperture blueish.

KIENER, Icon. Coq. viv. p. 122. pl. 31. f. 89.

Hab. Payta; Kiener.

A very rare and characteristic species of which there are two specimens in the British Museum.

PURPURA.

MONOGRAPH

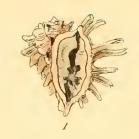

OF THE GENUS

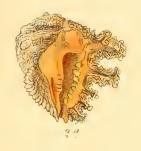

RICINULA.

"These are thy glorious works, Parent of good, Almighty!"—Milton.

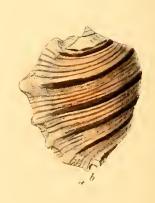

PLATE I.

Genus RICINULA, Lamarck.

Testa suborbiculari- vel fusiformi-ovata, sapissimè tuberculata aut spinosa, spirá nunc brevissimá, depressá, nunc acuminatá; aperturá subangustá, columellá subexcavatá, interdum corrugatá aut dentatá, labro intus dentato, dentibus nodulosis aut plivaformibus, labri margine interdum, autem raro, digitato. Operculum corneum, tenue, semilunare.

Shell somewhat orbicularly or fusiformly ovate, most frequently tuberculated or spined, spire sometimes very short and depressed, sometimes acuminated; aperture rather narrow, columella a little excavated, sometimes wrinkled or toothed, lip toothed within, teeth nodulous or plait-like, edge of the lip sometimes, but rarely, digitated. Operculum horny, thin, semilunar.

In adopting the genus Ricinula, I propose to include a much wider range of species than has been hitherto referred to it; namely, that fusiform series distinguished from Buccinum and Purpura by the nodulous dentition of the inner lip, arranged by M. Kiener as a section of the latter genus, under the significant title of "Les Pourpres semiricinnles;" and of which the Purpura fiscellum of authors may be regarded as the type. It cannot be disputed that there are species in the genera Ricinula, in its limited acceptation, and Purpura, in which it is difficult to define any generic difference; as for example, between the P. hystrix and the R. arachnoides, or between the P. aperta and certain varieties of the R. cluthrata; but the alteration of names in familiar usage should, as far as possible, be avoided. A large proportion of the species I am about to characterize as Rivinulæ, have not been hitherto described, and their connection with the Purpuræ proper, is one of such very remote affinity, that I prefer elevating the genus under consideration into one of more importance, to the creation of a new genus, or to the fusion of the whole into one, after the manner of the French naturalists.

The soft parts of the typical species of *Ricinula* differ in no respect from those of *Purpura*, and, in both genera, are furnished with a thin horny operculum.

Species 1. (Mus. Cuming.)

RICINULA ELEGANS. Ricin. testā rotundato-ovatā, basi attenuatā, brevissimā; transversim regulariter spinosā, spinis squamæformibus, prominentibus, marginem versus gradatim longioribus, interstitiis minutissimè et pulcherrimè squamatis, columella labroque intus conspicuè dentatis; albicante, apertura eburnea, linea vividè rufa concinnè circumdata.

The elegant Ricinula. Shell rotundately ovate, attenuated at the base, spire very short; transversely regularly spinous, spines scale-like, prominent, gradually longer towards the margin, interstices very minutely and beautifully scaled, lip and columella conspicuously toothed within; whitish, aperture ivory white, very prettily encircled with a bright red line.

Broderip and Sowerby, Zool. Journ. vol. iv. p. 376.
Beechev's Voyage, Moll. pl. 36. f. 4.

Hab. Lord Hood's Island (on reefs at low water); Cuming.

No one can fail to recognize this very rare and delicate species by the bright red line which encircles the aperture; in other respects it mostly resembles the *R. arachnoides*.

Species 2. (Mus. Cuming.)

RICINULA DIGITATA. Ricin. testá obovatá, peculiariter depressá, spirá brevissimá; transversim obtuso-costatá, minutissimè crispato-squamatá, costis spiram versus nodosis aut tuberculatis, frondibus depresso-palmatis, supernè majoribus, ad marginem desinentibus; albidá aut lutescente, aperturá vividè luteo-aurantiá.

The fingered Ricinula. Shell obovate, peculiarly depressed, spire rather short; transversely obtusely ribbed, very minutely crisply scaled, ribs nodose or tuberculated towards the spire, ending on the margin in depressly palmate fronds, the upper of which are the larger; whitish or yellowish, aperture bright yellowish orange.

LAMARCK, Auim. sans vert. (Deshayes edit.) vol. x. p. 50, d., Ricinula (Purpura) lobata, De Blainville.

Hab. Lord Hood's Island (on the reefs at low water); Cuming.

Variety β .

Testa fusca, apertură vivide nigricante-castaneă.

Shell brown, with the aperture bright dark chesnut.

Ricinula (Purpura) lobata, Deshayes.

Hab. Seehelle Islands (on the reefs at low water); Ronsseau.

I am sorry to be obliged to differ from two such authorities as M. M. De Blainville and Deshayes in regard to the specific rank of the Sechelle Island variety; there cannot be a doubt, in my estimation, of the immediate

affinity of the shells here represented; they exhibit no difference except in colour; and I think, with Mr. Sowerby, that they cannot be regarded otherwise than as varieties of one and the same species. The arrangement of synonymes above recorded, show that M. De Blainville erroneously considered the dark variety as the Lamarckian type.

Species 3. (Mus. Cuming.)

RICINULA HORRIDA. Ricin. testá ovato-globosá, spirá brevissimá, transversim tuberculatá, tuberculis brevibus, squamæformibus, acutis, columellá labroque fortiter dentatis; albidá aut lutescente, tuberculis nigricantibus, aperturá violaceá.

The rough Ricinula. Shell ovately globose, spire very short, transversely tuberculated, tubereles short, scale-like, sharp, lip and columella strongly toothed; whitish or yellowish, tubercles blackish, aperture violet.

Lamarck, Anim. sans vert. (Deshayes' edit.) vol. x. p. 47.

Murex neritoideus, Gmelin, (not of Linnæus).

Ricinella violacea, Schumacher.

Hab. Philippine and Society Islands (on the reefs at low water); Cuming.

This well-known species is distinguishable from all others by its black tubercles and violet aperture.

Species 4. (Mus. Cuming.)

RICINULA IODOSTOMA. Ricin. testå suborbiculari-ovatå, crasså, ponderoså, subdepresså, spirå brevissimå, transversim striatå, et obtusè vel obsoletè costatå, costis ad marginem prominentioribus, aperturå fortiter dentatå, supernè calloså; albicante, costis fusco-nigricantibus, striis intermediis fuscescentibus, aperturå vividè roseopurpureå.

The violet mouth Ricinula. Shell somewhat orbicularly ovate, thick, ponderous, rather depressed, spire very short, transversely striated and obtusely, or rather obsoletely, ribbed, ribs more prominent at the margin, aperture strongly toothed, thickened at the upper part; whitish, ribs brownish-black, intermediate striæ brown, aperture bright pinkish pupple.

Lesson, Magasin de Zoologie, 1842. Moll. pl. 58. *Hab.* New Zealand, Lesson; Straits of Macassar; Rohr.

An interesting species, introduced by M. Lesson, and forming a valuable addition to the typical portion of the genus; it may be readily distinguished from the *R. horrida* by the absence of tubercles, in place of which it is encircled with conspicuous dark bands, and the more pinky tinge of the purple which characterizes the aperture.

Species 5. (Mus. Cuming.)

RICINULA ARACHNOIDES. Ricin. testá obovatá, spirá brevissimá, transversim costatá, costis spinis squamæformibus muricatis, spinis marginem versus longioribus, costarum interstitiis striatis, striis interdum minutissimè squamatis; lutescente, costis albidis, spinis partim vel omnino nigricantibus, aperturá interdum maculis luteis circumdatá.

The spider-like Ricinula. Shell obovate, spire very short, transversely ribbed, ribs muricated with scale-like spines, spines longer towards the margin, interstices between the ribs striated, striæ sometimes minutely scaled; yellowish, ribs white, spines partially or entirely blackish, aperture sometimes encircled with yellow spots.

Lamarck, Anim. sans vert. (Deshayes edit.) vol. x. p. 49.

Murex ricinus, Linnæus.

Unspotted variety, *Ricinula albolabris*, De Blainville. *Hab.* Philippine and Society Islands; Cuming.

Here again I must be allowed to differ from M. M. De Blainville and Deshayes. There can be no doubt of the specific affinity between R. albolabris of the former, and the R. arachnoides of Lamarek; the "stries subcealleuses" to which M. Deshayes refers, as distinguishing the former, are but a modification of growth, the striæ being sometimes smooth, sometimes, and especially in young individuals, developed in minute scales, characteristic of the normal state. The spines of this species are more or less coloured black, sometimes altogether white, and the presence or absence of yellow spots at the aperture is subject to the same law of variety.

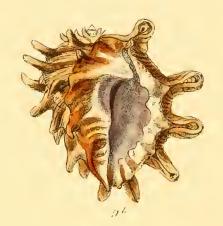

PLATE 11.

Species 6. (Mus. Cuming.)

- RICINULA MUTICA. Ricin. testá ovato-globosá, crassisimá, basi subattenuatá, spirá brevissimá, obtusá; transversim inciso-striatá, muticá, columetlá subexcavatá, tævigatá, labro intus conspicuè dentato; fusco-nigricante, aperturá albá, aut pallidè viotuceo-albá.
- THE SMOOTH RICINULA. Shell ovately globose, very thick, a little attenuated at the base, spire very short, obtuse; transversely deeply striated, smooth, columella slightly exeavated, smooth, lip conspicuously toothed within; brownish black, aperture white, or pale violet-tinged white.

LAMARCK, Anim. sans vert. (Deshayes edit.) vol. x. p. 51. Testa junior, *Ricinula pisolina*, Lamarck.

Hab. Mozambique (on coral reefs at low water); Hennah.

A very distinctly characterized species, and one that is rarely met with; the *R. pisolina* of Lamarck is referred to the young state, on the testimony of M. Kiener.

Species 7. (Mus. Cuming.)

- RICINULA PORPHYROSTOMA. Ricin. testá oblongo-ovatá, utrinque attenuatá, spirá subprominente, acutá; longitudinaliter concentricè costatá, transversim peculiariter liratá, liris numerosis augustis, confertis, inter costas profundè excavatis, aperturá utrinque denticulatá; livido-olivaceá, liris cinereo-albicantibus, aperturá vividè purpureo-laccá.
- The purple-mouth Richnula. Shell oblong-ovate, attenuated at both ends, spire rather prominent, sharp; longitudinally concentrically ribbed, transversely peculiarly ridged, ridges numerous, uarrow, close-set, deeply exeavated between the ribs, aperture denticulated on both sides; livid olive colour, ridges ashywhite, aperture deep purple-lake.

REEVE, Pro. Zool. Soc., 1846.

Hab. Marquesas Islands (on the reefs at low water); Rohr.

An interesting new species distinguished by the erect character of the transverse ridges, especially across the interstices between the ribs, which, however, become somewhat obsolete with age; the rich purple-lake colouring of the aperture is also worthy of notice.

Species 8. (Mus. Cuming.)

RICINULA MENDICARIA. Ricin. testa ovatá. medio obesá.

ntrinque subattenuată, anfractibus basi subindistincte livatis, superne vel lævigatis, vel tongitudinaliter obsolete nodoso-costatis, columellă superne excavată, labro intus medio denticulato; plerumque atro luteoque alternatim transversim couspicue tæniată, interdum atră, tæniă luteă unică angustă cinctă, apertură cinnamomeo-purpureă.

The patch-work Ricinula. Shell ovate, stout in the middle, attenuated at each cud, whorls rather indistinctly ridged at the base, either smooth or longitudinally obsoletely nodosely ribbed above, columella excavated at the upper part, lip deuticulated within in the middle; generally alternately filleted with black and yellow, sometimes black, encircled by a single narrow yellow fillet, aperture cinnamon-purple. Columbella mendicaria, Lamarck.

Hab. Philippine Islands; Cuming. Zanzibar (for the dark single-zoned variety); Thorne.

The well-known Columbella mendicaria of Lamarek, which has been already discarded from that genus by Mr. Sowerby, in his recent admirable monograph in the 'Thesaurus Conchyborum', belongs to that interesting group of species, distinguished by M. Kiener under the characteristic title of "Les Pourpres semi-ricinules", and which I propose to include under the Lamarekian head of Ricinula.

Species 9. (Fig. a and b Mus. Cuming.)

- Ricinula clathrata. Ricin. testá rotundato-ovatá, spirá breviusculá; longitudinaliter crebrivaricosá, varicibus costis spiniferis decussatis, spinis squamæformibus, prominentibus, marginem versus longioribus, interstitiis striatis, striis minutissimè squamatis; columellá supernè subexcavatá, infra plicato-rugosá; extus ferrugineo-fuscá et albá, intus cæruleo-violaceá.
- The latticed Richaula. Shell rotundately ovate, spire rather short; longitudinally closely varieose, varieose erossed with spiniferons ribs, spines scale-like, prominent, longer towards the margin, interstices striated, striae very minutely scaled; columella a little excavated at the upper part, plicately wrinkled beneath; exterior white and rusty brown, interior blueish violet.

 LAMARCK, Anim. sans vert. (Deshayes' edit.) vol. x. p. 49.
 Hab. Elizabeth Island (on the reefs at low water); Cuming Testa junior Ricinula miticula, Lamarck.

Variety β . (Fig. 9. α .)

Testa parva, spinis brevioribus; albida, intus vividè purpureo-lacca.

Shell small, with the spines rather short; white, interior rich purple-lake.

Hab. Island of Annaa (on the reefs at low water); Cuming. The very beautiful and characteristic variety of this species, represented at fig. 9 a, does not appear to have been hitherto noticed.

Species 10. (Mus. Cuming.)

RICINULA MORUS. Ricin. testá ovatá, crassá, obesá, spirá breviusculá, transversim costatá, costis tuberculatis, lirá augustá, interstitiis utrinque minutissimè squamatis, interveniente; cærulescente-albá, tuberculis plerumque anthracinis, aperturá vividè violaceá.

The Mulberry Richards. Shell ovate, thick, stout, spire rather short, transversely ribbed, ribs tuberculated, and a narrow ridge running between them with the interstices very minutely sealed; blueish white, tubercles generally coal-black, aperture rich violet.

LAMARCK, Anim. sans vert. (Deshayes' edit.); vol. x. p. 51. Purpura sphæridia, Duclos.

Hab. Lord Hood's Island (on the reefs at low water); Cuming.

The Ricinula morus is sometimes entirely white, though of much more common occurrence with the tubercles black. The R. aspera which M. Kiener has confounded with this species, is distinct, as M. Deshayes affirms, but it requires an acute eye to detect the difference.

Species 11. (Mus. Cuming.)

RICINULA TUBERCULATA. Ricin. testá oblongo-ovatá, spirá breviusculá; transversim seriatim tuberculatá, tuberculis subquadratis, interstitiis subtiliter inciso-striatis; cæruleo-albá, tuberculis anthracinis, interdum omnino anthraciná, aperturá violaceo-nigricanle, denticulis albis.

The tubercled Ricinula. Shell oblong-ovate, spire rather short; encircled with rows of tubercles, tubercles somewhat square, interstices finely deeply striated; blueish-white, tubercles coal-black, sometimes altogether coal-black, aperture violet-black, teeth white.

DE BLAINVILLE, Nouv. Ann. du Mus. pl. 9. f. 3. Eadem. *Purpura marginalba*, De Blainville. *Purpura granulata*, Duelos.

Hab. Lord Hood and Elizabeth Islands (on the reefs at low water); Cuming.

The leading feature of distinction between this and the preceding species, is, that in the former the interstices be-

tween the tubercles are simply engraved with striæ, whilst in the latter, they are characterized by a distinct ridge, the hollow on either side of which is crossed at frequent intervals by minute scales; the tubercles are also uniformly larger and more obtuse.

Species 12. (Mus. Cuming.)

RICINULA CHRYSOSTOMA. Ricin. testå oblongå, spirå nunc abbreviutå; transversim undique inciso-striatå, striis subdistantibus, longitudinaliter varicoså, varicibus squamis vel obtusis vel spiniferis et erectis ornatis; ferrugineo-fuscå, striis saturatioribus, zonis albis interruptis interdum cinctå, aperturå violaceå interdum aurantiå.

The golden-mouth Richnula. Shell oblong, spire sometimes acuminated, sometimes abbreviated; transversely deeply striated throughout, strice rather distant, longitudinally variouse, varices ornamented with scales which are either obtuse or spiniferous; rusty brown, strice darker, sometimes encircled with interrupted white zones, aperture violet, sometimes orange.

Deshayes, Magasin de Zool., 1844. Moll. pl. 86.

Hab. Islands of Bohol and Ticao, Philippines (on the reefs at low water); Cuming.

An extremely variable species in form, sculpture, and colour; the shell is sometimes elongated, sometimes short, and the squamate varices above described in the typical specimens become modified into mere noduled ridges. The colour of the aperture varies from purple-violet to bright golden-yellow, as in the specimen described and figured by M. Deshayes.

Species 13. (Mus. Cuming.)

RICINULA ASPERA. Ricin. testá obtusè ovatá, spirá brevi; transversim et longitudinaliter forticostatá, lirá unicá obesá, vel duabus angustis utrinque minutissimè squamatis, inter costas cingulatá; albidá, costarum tongitudinalium latere sinistro fusco-nigricante, aperturá vividè violaceá.

THE ROUGH RICINULA. Shell obtusely ovate, spire short; transversely and longitudinally strongly ribbed, encircled between the ribs with a single stout ridge or two narrow ones; whitish, left side of the longitudinal ribs brownish-black, aperture bright purple.

Lamarck, Anim. sans vert. (Deshayes' edit.) vol. x. p. 51. Hab. Island of Masbate, Philippines (on the reefs at low water); Cuming.

The sculpture of this shell is very similar to that of the R. morus, and M. Kiener has published it as a variety of that species; I am, however, inclined to think with M. Deshayes that it is distinct, there is a peculiarity in the form, painting, and general aspect, by which it may always be recognised.

PLATE III.

Species. 14. (Mus. Cuming.)

RICINULA SIDEREA. Ricin. testá fusiformi-ovatá, basi subcontractá, transversim striatá, longitudinaliter subobsoletè nodoso-costatá; albá, maculis parvis rubido-fuscis quadratis hic illic irregulariter pictá.

The Starry Ricinula. Shell fusiformly ovate, gibbous in the middle, a little contracted at the base, transversely striated, longitudinally rather obsoletely nodosely ribbed; white, irregularly painted here and there with reddish-brown square spots.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Burias and Masbate, Philippines (on the reefs and under stones at low water); Cuming.

A pure white shell miscellaneously sprinkled with eonspieuous small square reddish-brown spots.

Species 15. (Mus. Cuming.)

RICINULA BELLA. Ricin. testá subcylindraceo-fusiformi, utrinque attenuatá, basi contractá et paululum recurvá, longitudinaliter concentricè costatá, costis suboblusis, confertis, transversim liratá, liris angustis, interstitiis striatis; pallidè roseá, fusciis duabus castaneis, liris costas super roseis, cingulatá.

THE PRETTY RICINULA. Shell evlindrically fusiform, attenuated at both ends, contracted and a little recurved at the base, longitudinally concentrically ribbed, ribs rather obtuse, close-set, transversely ridged, ridges narrow, interstices striated; pale rose, encircled by two chesnut bands, on which the ridges are rose on crossing the ribs.

REEVE, Pro. Zool. Soc., 1846.

Hab. Island of Capul, Philippines (on the reefs at low water); Cuming.

An extremely pretty species of a pale rose colour, encircled with two rather broad bright chesnut bands, each band having two ridges passing through them, exhibiting a particularly neat appearance, from their being light on crossing the ribs.

Species 16. (Mus. Cuming.)

RICINULA FUNICULATA. Ricin. testá obtongo-ovatá, obliquè costatá, costis latis, solidis, subobscuris, transversim alternatim liratá et lineatá, liris obtusè nodosis; cæruleo-albicante, liris lineisque aterrimis, aperturá vividè violaceá.

The corded Ricinula. Shell oblong-ovate, obliquely ribbed, ribs broad, solid, rather obscure, transversely alternately ridged and lineated, ridges obtusely nodose; blueish white, ridges and lines jet black, aperture deep violet.

REEVE, Pro. Zool. Soc., 1846.

Hab. --- ?

A blueish white shell eneircled with conspicuous black ridges, the lower of which have a fine cord running between them; and with a rich violet mouth.

Species 17. (Mus. Cuming.)

RICINULA HEPTAGONALIS. Ricin. testá fusiformi-ovatá, basi paululum recurvá, anfractibus transversim liratis et squamistriatis, supernè angulatis, longitudinaliter obtusè costatis, liris costas super compresso-nodosis; fusco-albicante, nigricante-fusco tinctá et fasciatá, aperturá albá.

The seven-sided Ricinula. Shell fusiformly ovate, a little recurved at the base, whorls eneireled with ridges and squamate striæ, angulated round the upper part, longitudinally obtusely ribbed, ridges compressly noduled over the ribs; brownish-white, stained and banded with blackish-brown, aperture white.

REEVE, Pro. Zool. Soc., 1846.

Hab. Panama (under stones at low water); Cuming.

An extremely interesting species, though scarcely coming within the generic range of *Ricinula*; it may, however, be readily distinguished as such by the characteristic row of nodulous denticles within the lip.

Species 18. (Fig. a and b, Mus. Cuming.)

RICINULA CONCATENATA. Ricin, testá subfusiformi-ovatá, anfractibus supernè leviter concavis, transversim seriatim tuberculatis, tuberculis confertis subquadratis et mucronatis, interstitiis striatis, striis minutissimè squamatis; lutescente-albá, tuberculis ferrugineo-nigricantibus, aperturá purpureo-violaceá, vel aurantio-rufá.

THE ENCHAINED RICINULA. Shell somewhat fusiformly ovate, whorls slightly eoneave round the upper part,

transversely ornamented with rows of tubercles, which are close-set somewhat square and pointed, interstices striated, striæ very minutely scaled; yellowish-white, tubercles rusty-black, aperture purple-violet or orange-red.

Murex concatenatus, Lamarck, Anim. sans vert. vol. ix. p. 599.

Purpuræ fragum, and concatenata, De Blainville.

Hab. Swan Point, North Australia (under stones at low water).

The species above cited from De Blainville's monograph, are evidently varieties of the same; I have specimens of each before me from the collection of Mr. Cuming, and can observe no other difference than a change of colour in the aperture.

Species 19. (Mus. Cuming.)

RICINULA SPECTRUM. Ricin. testá oblongo-ovatá, spirá acuminatá, longitudinaliter obliquè costatá, costis sub-obtusis, tuberculatis, tuberculis compressis, interstitiis striatis; intus extusque albá.

The spectre Ricinula. Shell oblong-ovate, spire acuminated, longitudinally obliquely ribbed, ribs rather obtuse, tuberclated, tubercules compressed, interstices striated; pure white within and without.

REEVE, Pro. Zool. Soc., 1846.

Hab. Isle of Capul, Philippines (on the reefs at low water); Cuming.

A stont solid tuberculated shell, which appears to be naturally colourless, the shell here represented being in the finest possible condition.

Species 20. (Mus. Cuming.)

RICINULA PULCHRA. Ricin. testá cylindraceo-ovatá, medio obesá, utrinque attenuatá, basi recurvá, anfractibus rotundatis, concentricè crebricostatis, transversim liratis, liris confertis, costas super compresso-nodulatis;

luteo-aurantia, lirarum interstitiis fusco-lineatis, apertura, apice basique pulcherrimè roseis.

THE BEAUTIFUL RICINULA. Shell cylindrically ovate, stout in the middle, attenuated at both ends, recurved at the base; whorls rounded, concentrically closely ribbed, transversely ridged, ridges close-set, compressly noduled across the ribs; yellowish orange, interstices between the ridges lineated with brown; aperture, base, and apex, prettily stained with pink. Reeve, Pro. Zool. Soc., 1846.

Hab. Island of Capul, Philippines (on the reefs at low water); Cuming.

Both the sculpture and colouring of this species are developed with peculiar neatness; the former consists of a regular concentric succession of compressed nodules, ranging somewhat obliquely, the latter of an uniform yellow or light orange brown, encircled in the interspaces of the ridges by a fine cord of a darker brown, whilst the base, apex, and aperture, are either white, or delicately pink.

Species 21. (Mus. Cuming.)

RICINULA CHAIDEA. Ricin. testã ovatã, crassã, ponderosá, spirá subacuminatá, anfractibus tumidiusculis, obliquè concentricè costatis, costis rudis, obtusè tubercutatis, transversim sulcatis; albidá aut lutescente, aperturá albã.

The consumed Ricinula. Shell ovate, thick, ponderous, spire a little acuminated, whorls rather swollen, obliquely concentrically ribbed, ribs rude, obtusely tuberculated, transversely grooved; whitish or yellowish, aperture white.

Purpura chaidea, Duclos, Annales, Sci. Nat. 1832. Purpura Nassoides, Quoy and Gaimard.

Hab. Island of Masbate, Philippines (on the reefs at low water); Cuming.

A short stout ponderous shell, having very much the aspect of a Nassa.

PLATE IV.

Species 22. (Mus. Cuming.)

RICINULA CARBONARIA. Ricin. testú ovatá, utrinque attenuatá, transversim striatá, longitudinaliter fortiter costatá, costis distantibus, liris transversis decussatis; nigerrimo variá, aperturæ fauce cærulescente-albá.

THE COAL-BLACK RICINULA. Shell ovate, attenuated at both ends, transversely striated, longitudinally strongly ribbed, ribs distant, crossed with transverse ridges; variegated with jet black, interior of the aperture blueish-white.

Hab. --- ?

Mainly distinguished by its gibbous growth, and the stout swollen character of the ribs.

Species 23. (Mus. Cuming.)

RICINULA ALVEOLATA. Ricin. testá subfusiformi, longitudinaliter conspicuè costatá, costis sulcis transversis decussatis; lutescente-albá, costis rufo-fusco pulcherrimè tessellatis.

THE CHECKERED RICINULA. Shell somewhat fusiform, longitudinally conspicuously ribbed, ribs crossed with transverse grooves; yellowish white, ribs beautifully tessellated with red-brown.

Purpura alveolata, Kiener, Icon. coq. viv. p. 42. pl. 9. f. 23.

Hab. Panama; Cuming.

The ribs of this pretty species have a kind of beaded appearance.

Species 24. (Mus. Cuming.)

RICINULA LAUTA. Ricin. testá subfusiformi, medio gibbosiusculú, solidá, longitudinaliter costatá, costis sulcis transversis decussatis; cærulescente-albá, costis nigro minioque alternatim vividè pictis; columellá labroque intus purpureo-rufis.

THE GAY RICINULA. Shell somewhat fusiform, rather gibbous in the middle, solid, longitudinally ribbed, ribs crossed with transverse grooves; blueish white alternately brightly painted with black and vermilion, lip and columella purple-red.

Hab. —— ?

The colouring of the ribs exhibits a striking contrast.

Species 25. (Mus. Cuming).

RICINULA ELONGATA. Ricin. testa fusiformi, spira acuminata, anfractibus medio augulatis, longitudinaliter costatis, costis ad augulum nodosis, liris transversis decussatis, interstitiis peculiariter covernosis; extus intusque aurantio-lacteis.

The elongated Ricinula. Shell fusiform, spire acuminated, whorls angulated in the middle, longitudinally ribbed, ribs nodose at the angle, crossed with transverse ridges, the interstices being peculiarly cavernous; orange cream-colour within and without.

Purpura etonguta, De Blainville.

Hab. Island of Burias Philippines (under stones at low water); Cuming.

Characterized by the cavernous excavations between the ridges.

Species 26. (Mus. Cuming.)

RICINULA DEALBATA. Ricin. testá ovatá, solidiusculá, transversim striatá et seriatim tenuinodosá, striis incisis, subobscurè punctatis; extus intusque albá.

THE BLEACHED RICINULA. Shell ovate, rather solid, transversely striated and finely noduled, strike engraved, somewhat obscurely punctured; white within and without.

IIab. --- ?

Encircled with fine nodules and engraved strize in a manner somewhat peculiar

Species 27. (Mus. Cuming.)

RICINULA ELATA. Ricin. testá ovatá, crassá, solidá, tongitudinaliter plicato-costatá, costis subobscuris, tuberculis echinalis seriatim armatis, extus intusque albá.

The elevated Ricinula. Shell ovate, thick, solid longitudinally plicately ribbed, ribs somewhat obscure, armed with rows of prickly tubercles; white within and without.

Purpura elata, De Blainville, Nouv. Ann. du mus. pl. 11.f.1. Hab. New Holland.

Some of the prickly tubercles which characterize this species, have a faint indication of brown painting upon them.

Species 28. (Mus. Cuming).

RICINULA FISCELLUM. Ricin. testà ovatà, spirà acutà, anfractibus supernè subangulatis, ad angulum compresso-nodosis, liris angustis minutè squamatis undique creberrimè cingulatis; albidà, liris purpureo-atris, columellà et aperturæ fauce purpureo-violaceis.

The Little basket Ricinula. Shell ovate, spire sharp, whorls somewhat angulated round the upper part, compressly noduled at the angle, very closely encirled throughout with fine minutely scaled ridges; whitish, ridges purple-black, columella and interior of the aperture purple violet.

Murex fiscellum. Chemnitz, Conch. Cab. vol. x. pl. 160. f. 1524-5.

Murex margariticola. Broderip.

Hab. Australia and the Pacific Islands.

It will be seen on reference to genus Murex of this work, that a most unhappy state of confusion has attended this species on the part of Mr. Broderip, Mr. Sowerby, and myself. Named Murex margariticola by Mr. Broderip from the circumstance of Mr. Cuming having found it adhering to the Pearl Oyster (Conch. Icon. Murex Sp. 178.), another shell was fixed upon by Mr. Sowerby, and adopted by myself, as representing the M. fiscellum of Chemnitz (Conch. Icon. Murex Sp. 124.). The former is however the true M. fiscellum, and the latter an extremely variable species, again described by me in a different state under the name of M decussatus (Conch. Icon. Murex Sp. 153); though introduced by Mr. Sowerby also in different states under the names of M. violacea and Ricinuloides, which he afterwards cancelled.

It is determined beyond doubt that the *Murex margariticola* of Broderip, of which the specimen here figured is a fine large tubercled variety, is the *Murex fiscellum*; it only remains to enquire of M. Kiener whether the shell mistaken for it, and which has received so many names in different states, is not the *Murex fimbriatus* of Lamarck.

Species 29. (Mns. Cuming.)

RICINULA FORTICOSTATA, Ricin testá ovatá, medio gibbosá,

longitudinaliter conspicuè costatá, costis fortibus, vald prominentibus, sulcis decussatis; albidá, costis fuscis liris decussantibus albidis.

The strong-ribbed Ricinula. Shell ovate, gibbous in the middle, longitudinally conspicuously ribbed ribs strong, very prominent, crossed with grooves whitish, ribs brown, the cross ridges white.

Hab.—?

The prominent character of the ribs, coupled with their conspicuous style of painting, give an appearance to the shell which is very characteristic.

Species 30. (Mus. Cuming.)

Ricinula astricta. Ricin. testá ovatá, medio obesá, solidá, utrinque attenuatá, longitudinaliter plicatocostatá; lutescente-albá, liris transversis angustis fuscis undique peculiariter astrictá.

The corded Ricinula. Shell ovate, stout in the middle, solid, attenuated at both ends, longitudinally plicately ribbed; yellowish-white peculiarly corded throughout with brown narrow transverse ridges.

Hab. ---- ?

Easily distinguished by the fine dark brown cord-like ridges with which it is encircled throughout.

Species 31. (Mus. Mctcalfe).

RICINULA OCHROSTOMA. Ricin. testá ovatá, crassá, concentricè plicato-costatá, costis liris nodosis decussatis, interstitiis minutè squamatis; albá, aperturæ fauce croceo-aurantiá.

The Yellow Mouth Ricinula. Shell ovate, thick, concentrically plicately ribbed, ribs crossed with noduled ridges, the interstices between which are minutely scaled; white, interior of the aperture saffron-orange.

DE BLAINVILLE, (fide Kiener). Icon. Coq. viv. p. 44. pl. 10. f. 29.

Hab. ----?

A solid sharply tubercled shell, having the areas between the ribs finely scaled.

PLATE V.

(Specimens magnified to twice their natural length.)

Species 32. (Mus. Cuming.)

- RICINULA CONTRACTA. Ricin. testá subfusiformi-ovatá, utrinque attenuatá, basi contractá, tongitudinaliter obliquè plicato-costatá, transversim liratá et striatá; luteofuscescente, aperturæ fauce albá.
- THE CONTRACTED RICINULA. Shell fusiformly ovate, attenuated at both ends, contracted at the base, longitudinally obliquely plicately ribbed, transversely ridged and striated; yellowish brown, interior of the aperture white.
- Hab. Panama, and St. Elena, West Columbia (under stones); Cuming.

Rather more than usually produced and contracted at the base.

Species 33. (Mus. Cuming.)

- RICINULA ZONATA. Ricin. testá abbreviato-ocatá, solidá, utrinque longitudinaliter nodoso-plicatá; albá, zonis cæruteo-nigris pulcherrimè cingulatá, columellá labrique margine interno lacco-purpureis.
- The zoned Ricinula. Shell shortly ovate, solid, attenuated at both ends, longitudinally nodosely plicated throughout; white, very prettily encircled with blueblack zones, columella and inner edge of the lip lakepurple.
- Hab. Charles Island, Gallapagos (under stones at low water); Cuming.

Easily distinguished by the marked style of its painting.

Species 34. (Mus. Cuming.)

- RICINULA OCELLATA. Ricin. testá ovatá, ventricosá, undique subtilissimè cancellatá, anfractibus supernè angulatis, longitudinaliter costatis, costis fortibus, distantibus, compresso-tuberculatis; albidá, lineis nigris, costas super ocellatis, cingulatá.
- The occllated Ricinula. Shell ovate, ventricose, very finely cancellated throughout; whorls angulated round the upper part, longitudinally ribbed, ribs strong, distant, compressly tubercled; whitish, encircled with black lines, which are occllated on crossing the ribs.

Hab. --- ?

The detail of sculpture and disposition of colour are extremely characteristic in this species.

Species 35. (Mus. Cuming.)

- RICINULA CONCINNA. Ricin. testá subfusiformi-ovatá, basi contractá, spirá acuminatá; anfractibus concentricè plicato-costatis, costis tenuissimè nodiferis; albá, fasciis fuscis, nodis albis, conspicuè cinctá, labri limbo aurantiorufo.
- THE PRETTY RICINULA. Shell somewhat fusiform, ovate, contracted at the base, spire acuminated; whorls concentrically flatly ribbed, ribs very finely noduled; white, conspicuously encircled with brown bands, in which the nodules are white, edge of the lip orange-red.
- Hab. Cagayan, Island of Mindanao, Philippines (under stones at low water); Cuming.

Alternately encircled with brown and white bands, in the former of which the nodules are white, and have a very striking appearance.

Species 36. (Mus. Cuming.)

- RICINULA HISTRIO. Ricin. testá ovatá, medio gibbosá et tuberculatá, transversim subtilissimè striatá et obtusoliratá; luteá, lineis rufescentibus, maculisque nigris cingulatá et variegatá, columellá labrique margine interno lacco-purpureis.
- THE HARLEQUIN RICINULA. Shell ovate, gibbons and tuberculated in the middle, transversely very finely striated and obtusely ridged; yellowish, encircled and variegated with faint red lines and conspicuous black spots, columella and inner edge of the lip lake-purple.
- Hab. Island of Burias, Philippines (under stones at low water); Cuming.

A stont hump-backed shell, strongly tuberculated, and strikingly variegated in colour.

Species 37. (Mus. Adamson.)

- RICINULA IOSTOMA. Ricin. testá ovatá subobesá, longitudinaliter concentrice plicato-costatá, costis nodulis obtusis decussatis; albidá, costarum nodulis atris, columellá et aperturæ fauce violaceis.
- THE VIOLET-MOUTH RICINULA. Shell ovate, rather stout, longitudinally concentrically plicately ribbed, ribs crossed with obtuse nodules; whitish, nodules of the

ribs jet black, columella and interior of the aperture violet.

Hab. --- ?

Distinguished by its violet mouth and the concentrie rows of black nodules.

Species 38. (Mus Cuming).

- RICINULA CAVERNOSA. Ricin. testá ovatá, gibbosá, costis fortibus longitudinalibus lirisque compressis transversis conspicuè clathratá, areis interstitialibus subexcavatis; albá, areis medianis rufo-fuscis, colomellá et aperturæ fauce croceis.
- The Cavernous Ricinula. Shell ovate, gibbous, eonspicuously latticed with strong longitudinal ribs, and transverse ridges, interstitial areas rather excavated; white, the middle row of areas red-brown, columella and interior of the aperture saffron yellow.

Hab. Island of Burias, Philippines (on the reefs at low water); Cuming.

A remarkable species very accurately represented on an enlarged scale in the accompanying plate.

Species 39. (Mus. Cuming).

- RICINULA MURICATA. Ricin. testá ovatú, spirá acutá, anfractibus supernè concavo-depressis, infra conspicuè muricato-tuberculatis; intus extusque albá.
- THE PRICKLY RICINULA. Shell ovate, spire sharp, whorls concavely depressed round the upper part, conspicuously prickly tubercled beneath; white within and without.

Hab. --- ?

Distinguished by its sharp priekly seulpture.

Species 40. (Mus. Cuming).

RICINULA CROCOSTOMA. Ricin. testá subpyriformi-ovatá, medio gibbosá, anfractibus supernè depressis, longitudinaliter nodoso-costatis, costis subdistantibus, interstitiis lævibus; lutescente, costis nigerrimo-fuscis, columellá labrique margine interno rufo-croceis.

THE SAFFRON-MOUTH RICINULA. Shell pyriformly ovate,

gibbous in the middle, whorls depressed round the upper part, longitudinally nodosely ribbed, ribs rather distant, interstices smooth; yellowish, ribs very dark brown, columella and inner edge of the lip reddish saffrou.

Hab. Isle of Capul, Philippines (on the reefs at low water); Cuming.

Very characteristic both in form and colouring.

Species 41. (Mus. Cuming).

- RICINULA TRIFASCIATA. Ricin. testâ ovatú, crassâ, solidá, spirá acutá; longitudinaliter nodoso-costatá, aperturá angustá; albá, fasciis tribus cæruleo-atris conspicuiis cingulatá; columellá labrique margine interno lacco-purpureis.
- The three-banded Ricinula. Shell ovate, thick, solid, spire sharp, longitudinally nodosely ribbed, aperture narrow; white, encircled with three conspicuous blueblack bands; columella and inner edge of the lip lake-purple.

Hab. Island of Bohol, Philippines (on stones at low water); Cuming.

Resembling the *R. zonata* somewhat in its style of painting, but quite distinct on comparison.

Species 42. (Mus. Cuming).

- RICINULA TURBINELLA. Ricin. testá ovatá, spirá acuminatá, transversim tennissimè striatá, et liratá, anfractibus supernè declivibus, medio nodulosis; fusconigricante, nodulorum serie medianá albá.
- THE LITTLE TOP RICINULA. Shell ovate, spire acuminated, transversely very finely striated and ridged, whorls sloping round the upper part, nodulous in the middle; brownish black, middle row of nodules white

Purpura turbinella, Kiener, Icon. Coq. viv. p. 29. pl. 9. f. 25.

Hab. --- ?

This appears to me to be identical with M. Kiener's Purpura turbinella.

Ricinula Pe

PLATE VI.

Species 43. (Mus. Cuming.)

- conula parva. Ricin. testá subpyramidali-ovatá, liris nodulosis longitudinalibus et transversis decussatá, aperturá parvá; albidá, nodulorum seriebus alternatim aurantio-rufis et nigris.
- ovate, crossed with nodulous longitudinal and transverse ridges, aperture small; whitish, rows of nodules alternately orange-red and black.
- ab. Island of Luzon, Philippines (under stones at low water); Cuming.

The smallest of the group hitherto observed.

Species 44. (Mus. Cuming.)

- ACINULA DEFORMIS. Ricin. testá ovatá, basi attenuatá, spirá peculiariter abbreviatá, longitudinaliter plicatá, transversim nodoso-tiratá, labro incrassato; liris transversis interstitiisque alternalim rufescente-luteis et fuscis.
- The Deformed Ricinula. Shell ovate, attenuated at the base, spire peculiarly shortened; longitudinally plicated, transversely nodosely ridged, lip thickened; transverse ridges and interstices alternately reddish yellow and brown.

Hab. ——?

Peculiarly characterized by the depressed obesity of the pire.

Species 45. (Mus. Cuming.)

- RICINULA EXIMIA. Ricin. testá fusiformi, spirá acuminatá; anfractibus rotundatis, concentricè tennicostatis, liris subtilibus eleganter cancellatis; lutescente-albá, liris inter costas seriatim fuscescentibus.
- The delicate Ricinula. Shell fusiform, spire acuminated, whorls rounded, concentrically finely ribbed, elegantly cancellated with delicate ridges; yellowish white, ridges brown in zones between the ribs.
- Hab. Island of Corrigidor, Bay of Manila (among coarse sand at the depth of six fathoms); Cuming.

A species of very elaborate sculpture.

Species 46. (Mus. Cuming.)

- RICINULA ROSEA. Ricin. testű ovatű, basi productű, spirű peculiariter abbreviatű; anfractibus longitudinaliter nodoso-costatis, labro incrassato, aperturű parvű; rosaceű, fusco zonatű.
- The Rose Ricinula. Shell ovate, produced at the base, spire peculiarly shortened; whorls longitudinally nodosely ribbed, lip thickened, aperture small; rose-colour, zoned with brown.
- Hab. Island of Masbate (in sandy mud at the depth of five fathoms); Cuming.

Somewhat akin in form to the R. deformis.

Species 47. (Mus. Cuming.)

- RICINULA ARMILLATA. Ricin. testá pyramidali-ovatá, spirá acutè acuminatá; anfractibus cariná unicá nodosá supernè cingulatis, infra nodoso-costatis, interstitiis lævibus; albidá, nodis zonatim nigris et albis, carinæ nodis lutescentibus.
- The Beaded Ricinula. Shell pyramidally ovate, spire sharply acuminated, whorls eneircled round the upper part with a single nodolous keel, nodosely ribbed beneath, interstices smooth; whitish, nodules alternately black and white in zones, nodules of the keel yellowish.

Hab. Island of Tieao, Philippines (under stones at low water); Cuming.

A prettily beaded shell with rather a sombre arrangement of colours.

Species 48. (Mus. Cuming.

- RICINULA BICATENATA. Ricin. testá subtrigono-fusiformi, longitudinaliter costatá, transversim tenuissimè liratá, liris duabus centralibus prominentioribus muricatosquamatis; fuscá, liris prominentibus centralibus albis.
- The double-chained Ricinula. Shell somewhat triangularly fusiform, longitudinally ribbed, transversely very finely ridged, the two central ridges more prominent, prickly scaled; brown, the two central ridges white.

Hab. ---- ?

Somewhat of a triangularly fusiform shape.

Species 49. (Mus. Cuming.)

RICINULA RUTILA. Ricin. testá ovatá, basi subproductá, spiræ apice subobtusá; anfractibus rotundatis, concentricè nodoso-costatis; rufo undique zonatá, nodis albis.

THE RED RICINULA. Shell ovate, a little produced at the base, apex of the spire rather obtuse; whorls rounded, concentrically nodosely ribbed; zoned throughout with red, nodules white.

Hab. --- ?

A prettily beaded shell.

Species 50. (Mus. Cuming.)

Ricinula ferruginosa. Ricin. testä subfusiformi-ovatä, liris obtuso-nodulosis undique clathratä; ferrugineofusco, zonis duabus albidis inter nodulis cingulalä.

The rusty Ricinula. Shell somewhat fusiformly ovate, latticed throughout with obtnsely noduled ridges; rusty-brown, encircled with two zones white between the nodules.

Hab. ——?

Characterized by two narrow white zones, the nodules upon which are of the same dark rusty brown as the rest of the shell.

Species 51. (Mus. Cuming.)

RICINULA LINEATA. Ricin. testá ovatá, obesá, solidá, tongitudinaliter nodoso-plicalá; albá, lineis plumbeonigris cingulatá.

THE LINEATED RICINULA. Shell ovate, stout, solid, longitudinally nodosely plicated; white, encircled with lead-black lines.

Hab. Island of Ticao, Philippines (under stones at low water); Cuming.

Easily recognised by its style of painting.

Species 52. (Mus. Cuming.)

RICINULA ACUMINATA. Ricin. testá ovatá, spirá acuminatá; anfractibus longitudinaliter obsoletè plicato-costatis, supernè unicarinatis, infra tenuiliratis; luteo-fuscescente. The acuminated Ricinula. Shell ovate, spire ac minated; whorls longitudinally obsoletely plicate ribbed, with a single keel round the upper part, fine ridged beneath; yellowish brown.

Hab. ---- ?

A cross-beaded shell of an uniform yellowish brov colour.

Species 53. (Mns. Cuming.)

RICINULA RECURVA. Ricin. testá abbreviato-ovatá, med gibbosú, utrinqae attenuatá, basi recurvá, anfractib concentricè plicato-costatis, costis latiusculis, confert supernè unicarinatis, infra tenuiter liratis; luteo-aura tiá, fasciá albidá medio cingulatá.

THE RECURVED RICINULA. Shell shortly ovate, gibbo round the middle, attenuated at each end, recurve at the base; whorls concentrically plicately ribbe ribs rather broad, close-set, a single keel round to upper part, finely ridged beneath; yellowish orang encircled round the middle with a white band.

Hab. Lord Hood's Island, Pacific Ocean; Cuming.

Species 54. (Mus. Cuming.)

Ricinula echinata. Ricin testá ovatá, utrinque atter uotá, longitudinaliter plicato-costatá transversim pece liariter liratá, liris angustis tubulosis, costas super pu cherrimè echinato-squamatis, lirarum interstitiis exce vatis; albidá, punctis crocato-rufis seriatim pictá.

The prickle-armed Ricinula. Shell ovate, attenuate at both ends, longitudinally plicately ribbed, transversely peculiarly ridged, ridges narrow, tubulou beautifully prickly scaled upon the ribs, interstice between them excavated; whitish, painted with row of faint saffron red dots.

Hab. --- ?

Of a character totally distinct from that of any species that have preceded it; the varieties of sculpture and ar rangement of colour in the semi-Ricinuloid series of this genus are truly interesting.

MONOGRAPH

OF THE GENUS

MONOCEROS.

"Then were they known to men by various names."-Milton.

Riceve im

PLATE I.

Genus Monoceros, Lamarek.

Testa ovata, spirá nunc elatá, nunc subdepressá, anfractu ultimo inflato, basi emarginato; columellá amplá, depressiusculá, interdum subindistinctè plicalá; labro processu dentiformi, acutissimo, elongato, prope basin armato. Operculum corneum.

Shell ovate, spire sometimes elevated, sometimes a little depressed, last whorl inflated, emarginated at the base; columella large, rather depressed, sometimes indistinctly plaited, lip armed near the base with a very sharp elongated dentiform process or tooth.

The genus *Monoceros* of Lamarck, introduced almost simultaneously by De Montford under the title of *Unicornus*, is characterized solely by the conspicuous tooth which becomes developed towards the base of the lip; the genus is not, however universally admitted, the animals of *Monoceros* and *Purpura* are the same, and there are many of the *Purpura* which exhibit indications of a tooth.

The species are very limited in number, and no additions have been made to the catalogue during the last few years.

Species 1. (Mus. Cuming.)

Monoceros unicarinatum. Mon. testá orato-oblongá, subfusiformi, anfractibus supernè angulatis, ad angulum subobsoletè carinatis, transversim impresso-striatis, aperturæ fauce denticulatá: cinereo-albicante, areis inter strias fusco-nigricante articulatis, aperturá albicante, rufo interdum exiliter tinctú.

The one-keeled Monoceros. Shell ovately oblong, somewhat fusiform, whorls angulated round the upper part, rather obsoletely keeled at the angle, transversely impressly striated, interior of the aperture denticulated; ashy white, spaces between the striæ articulated with brownish black, aperture whitish, sometimes faintly tinged with red.

Sowerby, Conch. Illus. Monoceros, fig. 5.

Purpura spicata, De Blainville.

Purpura engonata, Conrad.

Hab. Santa Barbara, California (under stones at low water); Nuttall.

This is unquestionably a true *Monoceros*; M. Kiener, who includes the species among his 'Pourpres buceinoides,' under De Blainville's name of *P. spirata*, has represented a specimen in an early stage of growth before the tooth is developed.

Species 2. (Mns. Cuming.)

Monoceros punctatum. Mon. testá subglobosá, crassá, lævigatá, labro intus denticulato, lutescente-albá, fasciis tribus nigripunctatis cinctá, aperturá rufo pallidè tinctá.

THE DOTTED MONOCEROS. Shell somewhat globose, thick, smooth, lip denticulated within; yellowish-white, encircled with three black-dotted bands, aperture faintly stained with red.

Gray, Zoology of Beechey's Voyage, p. 124. Purpura lapilloides, Conrad.

Hab. Isle of Cocos, north-west coast of Mexico (on the rocks); Capt. Colnett. Santa Barbara; Nuttall.

This species, although found in the same locality with the preceding, is perfectly distinct, and may be recognized by its more solid globose structure and dotted bands.

Species 3. (Mus. Cuming.)

Monoceros giganteum. Mon. testű oblongo-fusiformi, medio ventricosű, basi attennatá, lævigatá, transversim obsoletè costatá, columellá infernè subplanulatú, labro simplici, integro, aperturú amplá; pallidè luteo-fuscescente, costis saturatioribus, aperturæ fauce croceú.

The gigantic Monoceros. Shell oblong fusiform, ventricose in the middle, attenuated at the base, smooth, transversely obsoletely ribbed, columella a little flattened towards the lower part, lip simple, entire; aperture large; pale yellowish brown, ribs darker, interior of the aperture yellow.

Lesson, Voy. de la Coquille, (1826), Moll. p. 405. p. 11. f. 4.

Monoceros Fusoides, King, Zool. Journ. (1830).

Hab. Conception, Chili (in rocky places at a depth of from three to five fathoms); King.

Very few examples of this fine species have yet been found in good condition; M. Lesson appears to have preceded Capt. King in the discovery of it by three or four years.

Species 4. (Mus. Cuming.)

Monoceros brevidentatum. Mon. testű ovatű, crassá, spirá brevi, subacuminatá, transversim impresso-striatá, obsoletè triseriatim nodoso-costatá; cinereo-nigricante, maculis albis cinetá, aperturá albá.

MONOCEROS .- PLATE I.

THE SHORT-TOOTHED MONOCEROS. Shell ovate, thick, spire short, somewhat acuminated, trausversely impressly striated, encircled with three obsolete noduled ribs; ashy blackish, encircled with white spots, aperture white.

GRAY, Wood's Index Test. Supp. pl. 4. f. 10.

Purpura cornigera, De Blainville.

Testa junior, Purpura ocellata, Kiener.

Hab. Xipixapi and Monte Christi, West Columbia (in crevices of rocks at low water); Cuming.

The tooth, though perfectly developed, is rather minute in this species.

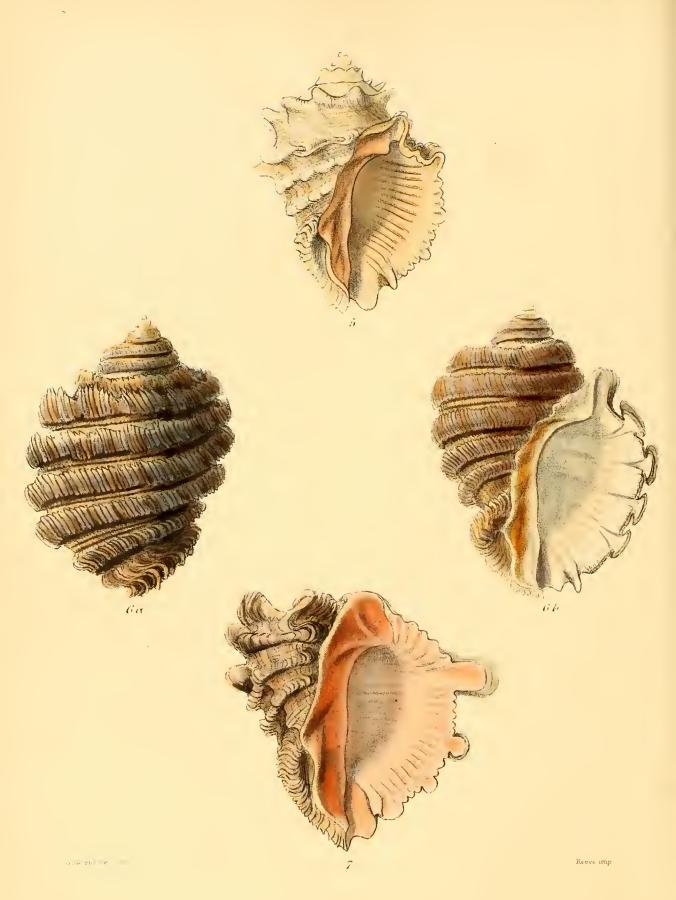

PLATE II."

Species 5. (Mus. Cuming.)

Monoceros tuberculatum. Mon. testá ovatá, basi umbilicatá, spirá brevi, plus minusve exsertá, anfractibus supernè depressiusculis, transversim plicato-costatis, costis angustis tuberculatis, tuberculis compressis, superioribus valdè prominentioribus, costarum interstitiis sulcatis, aperturá oblongá, fauce lineatá; lutescentealbá, aperturá carneá.

The tuberculated Monoceros. Shell ovate, umbilicated at the base, spire short, more or less exserted, whorls narrow, tuberculated, tubercles compressed, upper ones very prominent, interstices between the ribs grooved, aperture oblong, interior lineated; yellowish white, aperture flesh-tinted.

GRAY; Sowerby, Conch. Illus. Monoceros, fig. 9.

Hab. St. Elena, West Columbia (in the crevices of rocks); Cuming.

Chiefly distinguished by the narrow compressed tubercled structure of the ribs.

Species 6. (Mus. Cuming.)

Monoceros grande. Mon testá ovatá, crassá, spirá breviusculá, acutá, anfractibus supernè concavis, transversim costatis, costis grandibus peculiariter crebrisquamatis, squamis utrinque depresso-fornicatis, subiude latioribus, interstitiis profundè excavatis, liris minutè squamatis ornatis, aperturá ovatá, fauce lineatá, labro laqueato, dente subelongato, conspicuo; purpureo-fuscá, aperturá albá, columellá rufo tinctá.

THE GREAT MONOCEROS. Shell ovate, thick, spire rather short, sharp, whorls concave round the upper part, transversely ribbed, ribs large, peculiarly closely scaled, scales depressly vaulted on either side, now and then wider, interstices deeply excavated, ornamented with minutely scaled ridges; aperture ovate, interior lineated, lip fluted, tooth rather elongated, conspicuous; purple brown, aperture white, columella tinged with red.

Gray, Zool. Beechey's Voyage, p. 124.

Purpura Grayi, Kiener.

Hab. James Island, Gallapagos, (in the elefts of rocks at low water); Cuming.

M. Kiener appears to be unacquainted with the beauty and grandeur of this magnificent species, having questioned the propriety of Mr. Gray's generic arrangement of it merely from the circumstance of his having no other than a young specimen, in which the tooth was scarcely developed.

Species 7. (Mus. Cuming.)

Monoceros muricatum. Mon. testá ovatá, spirá peculiariter depresso-truncatá, anfractibus supernè planatis, transversim costatis, costis, quarum superioribus valdè majoribus, tuberculatis et creberrimè squamatis, costarum interstitiis sulcatis et squamatis; columellá planiusculá; aperturá semi-ovatá, fauce lineatá; carneofuscá, columellá labroque rufescentibus.

The prickly Monoceros. Shell ovate, spire peculiarly depressly truncated, whorls flattened round the upper part, transversely ribbed, ribs, the upper of which are much the largest, tuberculated and closely scaled, interstices between the ribs grooved and scaled; columella rather flattened; aperture semi-ovate, interior lineated; fleshy brown, lip and columella reddish.

Purpura muricata, Broderip, Pro. Zool. Soc., 1832, p. 125.

Purpura truncata, Duelos, Magazin de Zool., 1833, pl. 22. f. 2.

Hab. St. Elena, West Columbia (in the crevices of rocks); Cuming.

The *M. muricatum* is chiefly distinguished from the *M. tuberculatum* by its more depressed form, and by the peculiarly broad squamate structure of the ribs; there is a close affinity between them, but the series of each species in various stages of growth, in Mr. Cuming's collection, sufficiently demonstrate the difference in their specific character. M. Duclos' figure, like M. Kiener's of the preceding species, is evidently drawn from an immature toothless specimen.

PLATE III.

Species 8. (Mus. Cuming.)

Monoceros plumbeum. Mon. testá globoso-ovatá, crassá, ponderosá, spirá brevissimá, acutá; anfractibus supernè tumidis; columeltá arcuatá, basi mucronatá, supernè callosá, labro tenui, simplici, dente parvo basem versus munito; aurantio-tuteá, epidermide crassá olivaceofuscá indutá.

THE LEADEN MONOCEROS. Shell globosely ovate, thick, ponderous, spire very short, sharp; whorfs swollen round the upper part; columella arched, pointed at the base, callous at the top, lip thin, simple, furnished towards the base with a small tooth; orange-yellow, covered with a thick olive-brown epidermis.

Buccinum plumbeum, Chemnitz, Conch. Cab. vol. xi. p. 86. pl. 188. f. 1806, 1807.

Buccinum plumbeum, (Sect. Les Monodontes), Deshayes. Eburna plumbea, Sowerby.

Hab. --- ?

This appears to be the most natural situation for this *vexata species*; its generic character is far removed from the type of *Buccinum*.

Species 9. (Mus. Cuming.)

Monoceros lugubre. Mon. testa ovata, subventricosa, anfractibus costis tribus vel quaternis rudis cingulatis, costis hic illic tumidis, inciso-striatis, interstitiis lacunosis, aperturæ fauce denticulata, dente marginali longissimo incurvo; fusca, maculis flammulisve nigris variegata, columella et aperturæ fauce purpureo-fuscis.

The Mourning Monoceros. Shell ovate, somewhat ventricose, whorls encircled with three or four rude ribs, ribs swollen here and there, engraved with striæ, interstices guttered, interior of the aperture denticulated, marginal tooth very long, curved inwards; brown, variegated with black blotches or flames, columella and interior of the aperture purple-brown.

Sowerby, Genera of Shells, Monoceros. f. 3.

Buccinum cymatum, Solander MSS.

Monoceros cymatum, Sowerby, Tankerville Catalogue. Monoceros armatum, Gray, Wood Ind. Test. Supp.

Hob. California (on rocks); Belcher.

This species originally received the name of *Buccinum* cymatum from Dr. Solander, and the manuscript in which

it occurs is accessible to all who desire to consult it among the records in the library of the British Museum; it cannot however, in justice to foreign authors, be regarded of any authority, and the word *cymatum* has never been published except in an equally inauthentic inventory of species in the Tankerville Catalogue. If Mr. Sowerby, to whom this confusion of names is incidentally due, had issued a description or figure of the species, under its original title, in his valuable appendix to that Catalogue, it would have been duly established; but, as this is not the case, the species becomes entitled to the new name of *lugubre*, somewhat indiscreetly introduced by the same author in his 'Genera of Shells.'

Species 10. (Mus. Cuming.)

Monoceros imbricatum. Mon. testá oratá, rentricosú, liris subangustis undique cingulatá, liris interstitiisque densissimè imbricato-squamosis, aperturá, dilatatá, dente longissimo, erecto; rufescente-fuscá cotumeltá et apertura fauce albis.

The imbricated Monoceros. Shell ovate, ventrieose, cheireled throughout with rather narrow ridges, which, together with the interstices are very thickly imbricately scaled; aperture dilated, tooth very long, straight; reddish-brown, columella and interior of the aperture white.

Variety β . (Fig. 10. b.)

Testa lævigata.

Shell smooth.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol.x. p. 119.

Buccinum monoceros, Chemnitz.

Buccinum monodon, Gmelin.

Rudolpha monodon, Schnmacher.

Variety B, Monoceros striatum? Lamarck.

Hab. Cape Horn.

It would scareely be supposed that there are states of this species in which the imbricating scales almost wholly disappear; in the specimen represented at Fig. 10 b, there is only just sufficient indication of the squamate sculpture at the lip to identify it.

Species 11. (Mus. Cuming.)

Monoceros cingulatum. Mon. testá ovatá, spirá subprominulá, anfractibus supernè concavo-depressis, liris planis, subobsoletis, undique cingulatis, interstitiis striatis, lirá minutá labrum versus medio decurrente, cotumellá uniplicatá, aperturá breviusculá, dente aculo, incurvo; intus extusque albá, liris nigerrimo-fuscis, epidermide luteo-fuscá indutá.

The Girdled Monoceros. Shell ovate, spire rather prominent, whorls concavely depressed round the upper part, girdled throughout with rather obsolete flattened ridges, interstices striated, with a minute ridge running through the middle towards the lip; columella one-plaited; aperture rather short; tooth sharp, incurved; white within and without, ridges very dark brown, covered with a yellowish-brown epidermis.

Lamarck, Anim. sans vert. (Deshayes' edit.), vol. x. p. 118.

Turbinella cingulata, Kiener.

Buccinum pseudodon, Burrows.

Hab. Pauama (in clefts of rocks at low water); Cuming. Quite inseparable from the present group, although distinguished, like *Tubinellus*, by a winding plait upon the columella.

Species 12. (Mus, Cuming.)

Monocebos calcar. Mon. testá suborbiculari-ovatá, concavo-depressá, spirá brevissimá, anfractibus ventricosis, liris interstitiisque densissimè imbricato-squamatis, aperturá ampliter dilatatá, dente longissimo, erecto; rufescente-fuscá, columellá et aperturæ fauce albis.

THE SPUR MONOCEROS. Shell somewhat orbicularly ovate, concavely depressed, spire rather narrow, ridges and interstices between them very thickly imbricately scaled, aperture largely dilated, tooth very long and erect; reddish brown, columella and interior of the aperture white.

DESHAYES, Anim. sans vert. vol. x. p. 122.

Buccinum calcar, Martyn, Universal Conchology, vol. 2. pl. 50.

Monoceros breve, Sowerby.

Hab. Cape Horn.

This only differs from the *M. imbricatum* in respect o form; the sculpture is the same.

Monocer

Reeve imp

PLATE IV.

Species 13. (Mus. Cuming.)

[ONOCEROS ACUMINATUM. Mon. lesta oblongo-ovala, spira peculiariter acuminata; spiraliter lirata, liris parvis, subdistantibus, liris interstiliisque tenuissimè squamatis, squamis interdum in laminis continuiter decurrentibus; albida, ferrugineo-fusco varia, apertura alba, labri margine intus purpureo-fusca.

Shell oblong-ovate, spire particularly acuminated, spirally ridged, ridges small, rather distant, ridges together with the interstices very finely scaled, the scales sometimes running down continuously in laminæ; white, variegated with rusty brown, aperture white, edge of the lip tinged within with purple-hrown.

SOWERBY, Conch. Illustrations, Monoceros, Fig. 10.
Hab. Valdivia, Chili (on rocks at low water); Cuming.

Approximating very closely in general character to the *M. crassilabrum*, but so widely removed from it in form, that it is impossible to be reconciled to the propriety of maintaining the *M. calcar* and *imbricatum*, as distinct species without adopting the distinction in the present case.

Species 14. (Fig. a, b, c, d, Mns. Cuming.)

Monoceros crassilabrum. Mon. testá ovatá, crassissimá, ponderosá, aut lævigatá aut squamiliratá; aperturá parvá, labro valdè plano-incrassato, margine interno, obsoletè denticulato, dente acuto, erecto; citrino vel rubente-fusco, columellá labroque lacteis.

The thick-lip Monoceros. Shell ovate, very thick, ponderous, either smooth or scaly ridged; aperture small, lip very flatly thickened, inner edge obsoletely denticulated, tooth sharp, creet; citron yellow or reddish brown, lip and columella milk-white.

Lamarck, Anim. sans vert. (Deshayes' edit.) vol. x. p. 120 Fig. 14 c. Monoceros globulus, Sowerby.

Fig. 14 d. Monoceros citrinum, Sowerby.

Hab. Valparaiso, Chili (under stones at low water); Cuming.

Chiefly distinguished by its broad flattened lip.

Species 15. (Mus. Cuming.)

Monoceros glabratum. Mon. testá oblongo-ovatá, crassiusculá, spirá subacuminatá; anfractibus convexis, glabratis, labro obliquè planato, dente acuto, erecto; rubente-fusco variá, labro et aperturæ fauce albis.

The smooth Monoceros. Shell oblong-ovate, rather thick, spire somewhat acuminated; whorls convex, smooth, lip obliquely flattened, tooth sharp, erect; variegated with reddish brown, lip and interior of the aperture white.

Lamarck, Anim. sans vert. (Deshayes' edit.) vol. x. p. 120.

Hab. Island of Chiloe (on rocks at low water); Cuming.

Little more, apparently, than an acuminated growth of the preceding species.

MONOGRAPH

OF THE GENUS

BULLIA.

"Well hast thou taught the way that might direct Our knowledge, and the scale of Nature set From center to circumference."—Mitton.

PLATE I.

Genus Bullia, Gray.

Testa ovalo-lurrita, spiră subulato-acuminată, spira suturis nunc impressis, nunc callosis; columeltă plus minusve callosă, labro sapissime simplici, apertură basi late emurginată; lutescente aul pallide lividă.

Shell ovately turreted, spire subulately acuminated, sutures of the spire sometimes impressed, sometimes callous; columella more or less callous, lip mostly simple, aperture widely emarginated at the base; yellowish or pale livid colour.

The genus Bullia was founded by Mr. Gray for the purpose of distinguishing a very natural group of species, intermediate between Buccinum and Terebru, and of which the Buccinum lævissimum and Terebru vittatu of Lamarck, may be regarded as typifying a peculiarity of character fully borne out by a difference in the animal, which, according to the representations of MM. Quoy and Gaimard, is remarkably characterised by the wide expansion of its ventral disc.

Of the multifarious genera enumerated by Mr. Gray in his 'Synopsis of the Collection of the British Museum', few are more deserving of attention than the present, introduced in his 'Zoology of Beechey's Voyage of the Blossom'; not only are the shells distinguished by a subulate turreted growth, different from that of any *Terebra*, and are for the most part of a curious callous formation, but they possess a livid peculiarity of colouring and texture which assumes a certain degree of generic importance.

The species at present known are about two- or threeand twenty in number, several of which have been confounded together, for want of investigation, under similar names. They do not appear to be confined to any particular locality; in respect to their habits, the author notices that they "are found crawling on the sand in bays; they generally remain at the bottom of the water, and are easily caught alive with a bit of meat tied at the end of a stringas they immediately attach themselves to it."

Species 1. (Mus. Cuming.)

Bullia tenuis. Bul testă tenuiculă, acute turrită, basem versus ventricosă, spiræ suturis subimpressis; anfructibus lævigatis, supra sulcă unică minută, infra sulcis sublilibus plurimis cingulatis, apertură latiusculă; sordide albă. The thin Bullia. Shell rather thin, sharply turreted, ventricose towards the base, sutures of the spire rather impressed; whorls smooth, encircled with several fine grooves below and a single minute one above, aperture rather wide; dull white.

Gray, MSS., British Museum.

Hab. —— ?

A thin delicate species, comparatively smooth, and white.

Species 2. (Mus. Cuming.)

Bullia armata. Bul. testá turritá, spiræ suluris callosis; anfractibus supernè anguluto-declivibus, nodis prominentibus submucronatis irregularibus ad ungulum armatis; columellá supernè callosá; albidá, fasciis duabus rufo- vel cæruleo-fuscis latiusculis ornatá.

The armed Bullia. Shell turreted, sutures of the spire callous; whorls angularly slanting round the upper part, armed at the angle with irregular prominent pointed nodules; columella callous at the upper part; whitish, ornamented with two rather broad reddish or blueish-brown bands.

Gray, Zoology of Beechey's Voyage, p. 26 Buccinum moniliferum, Valenciennes.

Hab. --- ?

Easily distinguished from any other species at present known, by the armature of elevated nodules with which the whorls are coronated.

Species 3. (Mus. Cuming.)

Bullia Gradata. Bul. lestá ovatá, crassiusculá, spirá exsertá, suturis callosis; anfractibus supernè depresso-planis, subgrundá rotundutá marginatis undique lævigatis, columellá supra callosá; pallidè luteo-spadiceá, rufo-fusco hic illic longitudinaliter flammatá.

The step Bullia. Shell ovate, rather thick, spire exserted, sutures callous; whorls depressly flattened round the upper part, margined with a rounded ledge, smooth throughout; columella callous above; pale yellowish bay, longitudinally flamed here and there with reddish-brown.

DESHAYES, Auim. sans vert. vol. x. p. 186.

Hab. ---- ?

This shell was referred by Mr. Gray in his 'Zoology of

Beechey's Voyage', and by M. Kiener in his 'Ieonographie', to the Buccinum cochlidium of Chemnitz, until M. Deshayes, with his usual aeumen, observed a marked dissimilarity between the shell here represented and the figure in the 'Conchylien Cabinet'. Upon the discovery of this want of resemblanee he introduced the species under consideration with the name here adopted, and I am happy to bear testimony to the value of his discrimination by publishing in Plate IV. a figure of the true Buccinum cochlideum of Chemnitz, taken from a worn and rather mutilated specimen in the British Museum, the only one I have seen.

Fig. 4 proves to be merely a contracted belted growth of the *B. lævigata*, Sp. 6. For Sp. 4 see Plate 1V.

Species 5. (Mus. Cuming.)

Bullia globulosa. Bul. testá ovatá, ventricosá, spirá brevi; anfractibus supernè rotundatis, undique lævigatis, columellá subcallosá, aperturá subamplá; purpureo- aut fuscescente-albá, columellá luteo-aurantiá.

The globular Bullia. Shell ovate, ventricose, spire short; whorls rounded at the upper part, smooth throughout, columella somewhat callous, aperture rather large; purple- or brownish-white, columella yellowish orange.

Buccinum globulosum, Kiener, Icon. eoq. viv.p. 2. pl.10. f.3. Hab. ———?

Distinct from the following, the globose variety of which it approximates in general aspect; the sutures of the spire are not filled up with any eallous deposit of enamel, the shell is of a more rude obtuse growth, and it is distinguished by a different system of colouring.

Species 6. (Fig. 4 and 6, Mus. Cuming.)

Bullia Levigata. Bul. testá ovato-turrită, basem versus inflată, spiră acută, suturis callosis, anfractibus undique lævigatis, sulco parvo subobsoleto supernè cingulatis; apertură subamplă; purpureo-albidă, rubiginoso apicem versus tinctă, columellă albă, maculă purpureo-fuscă ornată.

The smooth Bullia. Shell ovately turreted, inflated towards the base, spire sharp, sutures callous, whorls smooth throughout, encircled round the upper part with a small rather obsolete groove; aperture rather large; purple-white, stained towards the apex with rusty brown, columella white, ornamented with a purple-brown blotch.

Gray, Zoology of Beechey's Voyage, p. 127.

Buccinum lævigatum, Martini.

Buccinum lævissimum, Gmelin, Lamarck.

Nassa lævissima, Deshayes.

Hab. —— ?

This species, as shown by the examples represented at Fig. 4 and 6, varies exceedingly in its growth, some specimens being very much contracted and belted, whilst in others the spire is sharply acuminated; a character, too, which appears to be worth noticing as of constant occurrence, is the purple brown blotch on the columella.

PLATE II.

Species 7. (Mns. Cuming.)

- Bullia Grayi Bul. testű ovalo-turritű, spirű peculiariter atlenuatű, et ucutè aciculalá; anfractibus lævigatis, transversim superficialiter sulcatis, costá callosű planű spirali juxta suturam; livido-fuscescente, costá spirali livido-albidű, columellű albű, apertura fance rubiginosű.
- GRAY'S BULLIA. Shell ovately turreted, spire peculiarly attenuated and sharply accounted; whorls smooth, transversely superficially grooved, with a flattened callous spiral rib next the suture; livid brown, spiral rib livid-white, columella white, interior of the aperture rust-brown.

Hab. --- ?

There is a magnificent specimen of this sharply acculated species in the British Museum, nearly twice the size of the one here figured, and which I regret not having observed until after the accompanying plate was engraved. I consider it distinct from the smaller *B. Mauritiana*, and dedicate it to the founder of the genus.

Species 8. (Mus. Cuming.)

- Bullia Belangeri. Bul. testá turritá, spiræ suturis subprofundis, unfractibus lævigatis, basi profundè sulcatis, lirá planá supernè juxta suturam cingulatis; aperturá parviusculá; pallidè lividá, lineis rufis exilibus undulatis longitudinaliter tinctá.
- Belanger's Bullia. Shell turreted, sutures of the spire rather deep, whorls smooth, deeply grooved at the base, encircled with a flattened ridge round the upper part next the suture; aperture rather small; pale livid colour, stained longitudinally with waved faint red lines.

Buccinum Belangeri, Kiener, Icon. coq. viv. pl. 14. f. 48.
Buccinum politum, Deshayes (not of Lamarck) in
Bélanger's Voyage.

Hab. Ceylon.

This species which may be easily recognised by its undulating faint red lines, was figured by Martini, Conch. Cab. vol. iv. pl. 155. f. 1463; and is one of many instances of species published in that important work between sixty and seventy years since, which escaped the observation of Lamarck, and have since remained in obscurity.

Species 9. (Mus. Cuming.)

- Bullia vittata. Bul. testá elongato-turritá, spiræ suturis subimpressis, anfractibus lævigatis aut concentricè sulcatis, supernè juxta suturam tenuipticatis; albidá, aperturæ fauce croceá.
- The riband Bullia. Shell elongately turreted, sutures of the spire rather deep, whorls smooth or concentrically striated, spirally delicately grooved, finely plaited round the upper part next the suture; whitish, interior of the aperture yellowish.

Buccinum vittatum, Linnæus, Syst. Nat. (12thedit.)p.1206.
Terebra vittata, Lamarck.

Hab. Ceylon.

Two species appear to have been confounded under this head by Linnæus and subsequent authors; that which I retain to represent it, answers best with the Linnæan diagnose, and is the one figured in the 'Encyclopédie Méthodique', and by Kiener; the other species which follows under the name B. lividu, is that figured by Martini and De Blainville.

Species 10. (Mus. Cuming.)

- Bullia livida. Bul testá elongato-turritá, spiræ suturis impressis, anfractibus lævibus politis, spiraliter obsoletè impresso-striatis, supernè juxta suturam fortiter crenulato-plicatis, labro incrassato, varicoso, aperturá brevi; livido-cærulescente, columellá albá, aperturæ fauce rubiginosú.
- The Livid Bullia. Shell elongately turreted, sutures of the spire impressed, whorls smooth, polished, spirally obsoletely impressly striated, strongly crenulately plicated round the upper part next the suture, lip thickened, varicose, aperture short; livid-blue, columella white, interior of the aperture rust-brown.

Hab. Zanzibar.

This species may be readily distinguished from the former with which it has been hitherto confounded; the plicated crenulations round the summit of each whorl are much more strongly developed, whilst there are no concentric strize, the lip has a thickened varix, sometimes two or three upon it, the uniform livid colouring of the shell is characteristic, and it is from a very different locality.

Species 11. (Mns. Cuming.)

Bullia Taheitensis. Bul. testă turrită, anfractibus rotundatis, transversim planiliratis, liris confertissimis, duabus tribusve juxta suturam quam cateris distantioribus, granosis, late aliter excavatis; flavido-cinereă, aurantio-fusco hic illic punctată, apertura fauce rubiginosă.

The Taheite Bullia. Shell turreted, whorls rounded, transversely flatly ridged, ridges very close-set, two or three next the suture more distant than the rest, granose, excavated at the sides; yellowish ash colour, dotted here and there with orange brown, interior of the aperture rust-brown.

GRAY, MSS. British Museum. Hab. Taheite.

The only species at present known in which the shell is disposed in spiral ridges,

Species 12. (Mns. Cuming.)

Bullia Mauritiana. Bul. testå subulato-ovatå, spiræ suturis subimpressis; anfractibus lævigatis, politis, subohsoletè spiraliter impresso-striatis, lirå planå calloså juxta suturam; pallidè lividå.

The Mauritus Bullia. Shell subulately ovate, sutures of the spire somewhat impressed; whorls smooth, polished, rather obsoletely spirally impressly striated, with a flattened eallous ridge next the suture; pale livid eolour.

Gray, Zoology of Beechey's Voyage p. 126. Hab. Madagascar.

Closely approximating to the *B. Grayi*, but is less ventricose towards the base, whilst the spire is less accounted at the apex; it is also uniformly smaller, although the specimens represented in the accompanying plate do not exhibit that comparative difference of proportion.

Species 13. (Mus. Cuming.)

Bullia annulata. Bul. testá ovato-turritá, spiræ suturis callosis, anfractibus supra plano-depressis, anguli margine rotundato, annulato, infra creberrimè impressostriatis; pallidè luteo-spadiceá, columellá albá.

The annulate Bullia. Shell ovately turreted, sutures of the spire eallous, whorls flatly depressed round the upper part, edge of the angle rounded, annulate, very closely impressly striated beneath; light yellowish bay, columella white.

Buccinum annulatum, Lamarck, Anim. sans vert. (Deshayes' edit.) vol. x. p. 156.

Nassa annulata, Deshayes.

Hab. — ?

This and the *B. gradata* and *cochlidium*, are the only species at present known in which the whorls are depressly flattened with a ledge round the summit.

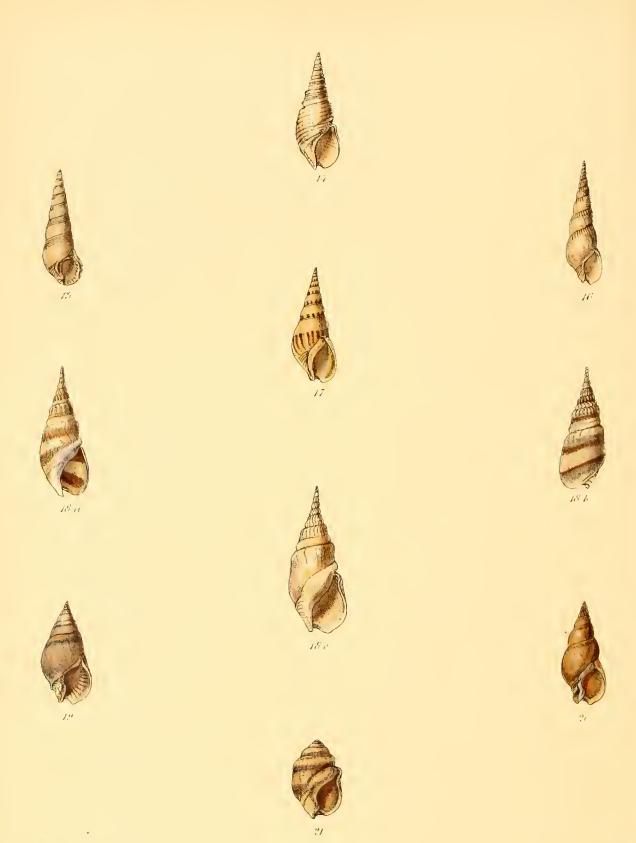

PLATE III.

Fig. 14 proves to be a variety of the *Bullia Mauritiana* Sp. 12. For Sp. 14 see Plate IV.

Species 15. (Mus. Cuming.)

Bullia truncata. Bul. testá subulatá, basi peculiariter truncatá, unfractibus minutissimè spiraliter striatis, striis numerosis, creberrimis; columellá subobsoletè corrugatá et verrucosá, callosá supernè munitá, aperturá brevi, parvá, fauce sulcatá, labro incrassato, marginato; lutescente-albá.

The truncated Bullia. Shell subulate, peculiarly truncated at the base, whorls very minutely spirally striated, striæ numerous, very close set; columella rather obsoletely wrinkled and warty, furnished with a callosity at the upper part, aperture short, small, interior grooved, lip thickened marginated; yellowish white.

Hab. --- ?

Of very peculiar structure at the aperture.

Species 16. (Mus. Cuming.)

Bullia turrita. Bul. testă angustă, subulată, anfractibus lævibus, e suturis subtilissime et irregulariter plicatis; columellă sulcută, subcontortă, apertură parvă, labro tenui; lutescente-albă, fusco basi exiliter tinctă.

THE TURRETED BULLIA. Shell narrow, subulate, whorls smooth very finely and irregularly plaited from the sutures; columella grooved, somewhat twisted, aperture small, lip thin; yellowish-white, faintly stained round the base with brown spots,

Gray, Zoology of Beechey's Voyage, p. 126.

Hab. ——?

The form of this shell at the base approaches that of *Terebra*, but it is of lighter growth and readily distinguised as belonging to the present group.

Species 17. (Mus. Cuming.)

Bullia semiflammea. Bul. testá ovato-turritá, lævigatá, aut striis minutissimè decussatá, basi sulcatú; columellá callosá, basi mucronatá; lutescente-albá, maculis rubidis quadratis longitudinaliter flammatis medio cingulatá.

The Half-Flamed Bullia. Shell ovately turreted, smooth, or very minutely decussated with striæ, grooved round the base; columella callous, pointed at the base; yellowish white, encircled round the middle with a row of ruddy square spots which are flamed downwards.

Hab. ---- ?

This species is strongly characterized by its spiral chain of longitudinally flamed ruddy spots.

Species 19. (Fig. a, b and c. Mus. Cuming.)

Bullia semiplicata. Bul. testă ovato-turrită, spiră acutè aciculată, anfractibus longitudinaliter fortiter plicatis, costă callosă spirali subconspicuă juxta suturam, anfractu ultimo lævigato, plicis evanidis; columellă callosă; albidă aut Intescente, fasciis duabus, rufo- aut violaceo-fuscis interdum cingulată.

The Half-plaited Bullia. Shell ovately turreted, spire sharply accounted, whorls longitudinally strongly plaited, with a rather conspicuous spiral callous rib next the suture, last whorl smooth, the plaits fading away; columella callous; whitish or yellowish, sometimes encircled with two reddish or violet-brown bands.

 $\operatorname{Gray},$ Zoology of Beechey's Voyage, p. 127.

Hab. — ?

Distinguished by the strongly plaited growth of the first few whorls, and prominent spiral callous rib next the suture; the spire is also peculiarly acculated.

Species 19. (Mus. Cuming.)

Bullia polita. Bul. testá ovato-oblongá, subventricosá, spirá brevinsculá, acutá; anfractibus lævigalis, vitreis, nitidis, ad apicem exiliter plicatis; columellá brevi, excavatá, basi contortá, uperturæ fauce peculiariter corrugatá, labro tenui, acuto; livido-olivaceá, fasciá nigricante-fuscá obscurá prope suturam cingulatá.

The polished Bullia. Shell ovately oblong, rather short, sharp; whorls smooth, vitreous, shining, faintly plaited at the apex; columella short, excavated, twisted at the base, interior of the aperture peculiarly wrinkled, lip thin, sharp; livid olive colour, encircled with an obscure blackish-brown band near the suture. Buccinum politum, Lamarck, Anim. sans vert. vol. x. p. 126.

Nassa polita,, Deshayes.

Hab. ---- ?

One of the least acuminated of the genus, and presenting characters intermediate with those of Nassa.

Species 20. (Mus. Cuming.)

Bullia vitrea. Bul. testá ovato-obtongá, spirá acutá, anfractibus tævigatis, nitidis, aut minutissimè concentricè striatis, ad apicem teviter plicatis; cotumellá excavatá, subcontortá, aperturæ fauce lævi, labro tenui, acuto; livido-fuscá, apicem versus rubiginosá, longitudinatiter subtilissimè rufo-lineatá.

The vitreous Bullia. Shell ovately oblong, spire sharp, whorls smooth, shining, or very minutely concentrically striated, slightly plaited at the apex; columclia excavated, somewhat twisted, interior of the aperture smooth, lip thin, sharp; livid-brown or yellowish, rust-colour towards the apex, marked with very fine longitudinal red lines.

Hab. ---- ?

Very similar to the preceding, but certainly distinct.

Species 21. (Mus. Cuming.)

Bullia deformis. Bul. testá subquadrato-ovatá, crassá, ponderosá, spirá brevissimá; anfractibus supernè valdè callosis, lævibus, medio concavis; columeltá callosá, aperturá parvá, labro acuto; lutescente, fasciá violaceo-fuscá obscurá medio cingulatá.

THE DEFORMED BULLIA. Shell somewhat squarely ovate, thick, ponderous, spire very short; whorls very callous round the upper part, smooth, hollow round the middle; columella callous, aperture rather small, lip sharp; yellowish, encircled round the middle with an obscure violet brown band.

Buccinum deforme, King, Zool. Journal, vol. v. p. 349. Hab. Rio de la Plata; King.

Remarkable on account of its short ponderous callous growth.

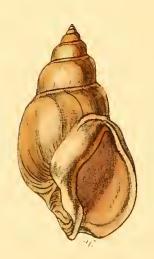

В

PLATE IV.

Species 4. (Mns. Gray.)

Bullia digitalis. Bul. testă acuminato-turrită, basem versus gradatim effusă, truncată, spiræ suturis subcallosis, lineă spirali incisis; anfractibus lævibus, ultimo sulco spirali prope basem; ferrugineă, columellă albidă, aperturæ fauce purpureo-fuscescente.

The finger-shaped Bullia. Shell acuminately turreted, gradually effused towards the base, truncated, sutures of the spire rather callous and engraved with a spiral line; whorls smooth, last whorl with a spiral groove towards the base; rust colour, columella whitish, interior of the aperture purple-brown.

Buccinum digitale, Meuschen, Mus. Gevers. p. 296.

Buccinum achatinum, Lamarek.

Nassa achatina, Deshayes.

Bullia achatina, Grav.

Hab. --- ?

We are indebted to the accuracy of Mr. Dillwyn for showing this to be the *Buccinum digitale* of Meuschen, though it is probable one or two of its congeners were confounded with it under the same title. The specific name attachedto it by Lamarck is doubly inapplicable, on account of the term *Buccinum achatinum* having been already given by Muller and others to the type of his genus *Achatina* (A. perdix).

Species 14. (Brit. Mus.)

Bullia sulcata. Bul. testú acuminato-turritá, basi subeffusá, anfractibus concentrice creberrime undulato-sulcatis; cæruleo-plumbeá.

The grooved Bullia. Shell acuminately turreted, somewhat effused at the base, whorls concentrically very closely undulately grooved; blueish lead colour.

Hab. --- ?

A peculiarly dark blueish lead-coloured shell of rather solid structure, very closely concentrically grooved throughout

Species 22. (Mns. Cuming.)

Bullia semiusta. Bul. testá acuminalo-lurritá, basi truncatá, tævigatá, politá; anfractibus supra albidis, infra ustulato-fuscis, columella eburneá. The half-scorched Bullia. Shell acuminately thrreted, truncated at the base, smooth, polished; whorls white above, burnt brown below, columella ivorywhite.

Hαb. —— ?

Distinguished in form, as well as by its peculiar contras of colouring.

Species 23. (Mus. Brit.)

Bullia cochlidium. Bul. testá ovato-turritá, tenuiculá, anfractibus supernè rotundatis et subcanaliculatis, lævibus, columellá arcuatá; pallidè fulvá.

The winding-stair Bullia. Shell ovately turreted, rather thin, whorls rounded and somewhat channelled round the upper part, smooth; columella arched, pale fulvous yellow.

Buccinum cochlidium, Chemnitz, Conch. Cab. v. 11. p. 275. pl. 209. f. 2053, 4.

Hab. ——?

It may be observed that a considerable portion of the shell here represented is broken away, but I value it as enabling me to confirm the view taken by M. Deshayes, that the *Buccinum cochlidium* of Chemnitz, with whose figure this specimen accords, is specifically distinct from the *Bullia gradata* with which it has been hitherto confounded.

Species 24. (Mus. Gray.)

Bullia callosa. Bul. testă acuminată, basem versus gibbosă et effusă, spiræ suturis subprofundis, anfractibus læcibus, columellă arcuată, truncată, callositate amplă munită; cæruleo-fuscescente, callositate eburneâ, purpureo-fusco tinctă.

The callous Bullia. Shell acuminated, gibbons and effused towards the base, sutures of the spire rather deep, more or less callous; whorls smooth, columella arched, truncated, furnished with a large callosity; blueish-brown.

Buccinum callosum, Wood. Ind. Test. Supp.

IIab. --- ?

Remarkable for the callous deposit of enamel which overspreads the columella and a considerable portion of the body-whorl.

Species 25. (Mus. Gray.)

Bullia rhodostoma. Bul. acuminată, subventricosă, spiræ suturis subprofundis, anfractibus lævibus, fasciă callosă supra suturas ornatis; lacteă, aperturæ funce rufo-fuscă.

The Red-Mouth Bullia. Shell acuminated, somewhat ventricose, sutures of the spire rather deep, whorls smooth, ornamented above the sutures with a callous band; cream white, interior of the aperture reddish brown.

GRAY, MSS. (private cabinet).

Hab. ——?

Of a peculiar cream colour and characterised by a band of enamel deposited above the sutural line. Species 26. (Mus. Gray.)

Bullia squalida. Bul. testá ovato-oblongá, ventricosá, tævi, basi subcontortá et recurvá, columellá arcuatá; fulvo-fuscá, columellá et aperturæ fauce aurantio-luteis.

THE DIRTY BULLIA. Shell ovately oblong, ventricose, smooth, somewhat twisted and recurved at the base, columella arched; fulvous brown, columella and interior of the aperture orange-yellow.

Buccinum squalidum, King, Zool. Journ. v. 5. p. 349.

Buccinum Paytense, Valenciennes, Kiener.

Hab. Payta.

I have not seen any example of this species with the dark brown epidermis, represented by M. Kiener.

BULLIA.

MONOGRAPH

OF THE GENUS

BUCCINUM.

⁶ Endued with various forms, various degrees Of substance, "—*Milton*,"

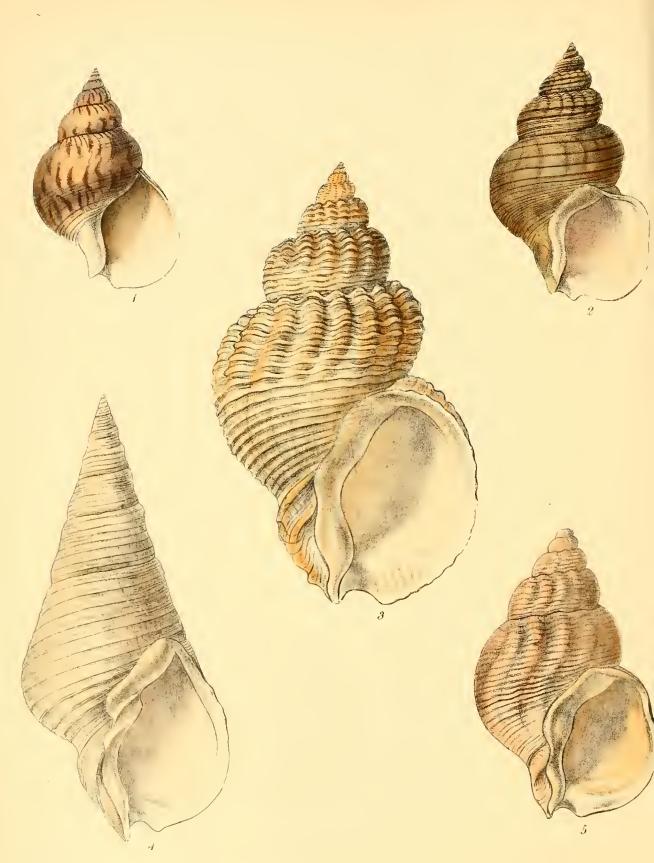

PLATE I.

Genus Buccinum, Linnœus.

Testa cvata vel fusiformi-obtonga, basi emarginata, interdum subcanaliculata et plus minusve recurva; columellá plerumque laxigata; apertura callositate aut denticulis sæpissime superne munita; labro tenuiculo, nunc simplici, nunc crenulato.

Shell ovate or fusiformly oblong, base emarginated, sometimes channelled and more or less recurved; columella generally smooth; aperture most frequently furnished with a callosity or denticles; lip rather thin, sometimes simple, sometimes erenulated.

The Latin word Buccinum, a trumpet, was applied iadiscriminately by the ancients to any sort of spiral univalve shell; Linnæus adopted the term in a more restricted sense, yet his genus of that name included a multitude of very anomalous character. Lamarck divided the Linnæan Buccina into several excellent acknowledged genera, the chief portion of which constitute his family Purpurifera; and it has been considered necessary to institute a still further subdivision of those species distinguished by the titles Nassa, Bullia, Cyllene and Phos.

The Buccinum undatum and its congeners, though mostly retained as the typical series, are separated by M. Deshayes under the title of Tritonium, once assigned to them by Müller; they are mostly of northern origin, and it cannot be disputed that they present a particular uniformity of character, still there is a transition from this characteristic group to an extensive and varied series, mostly of smaller size, inhabiting the tropical regions, which are of more solid growth, of brighter colours, and of which the aperture is mostly distinguished by the presence of a callosity or denticles. With these I include Lamarck's Purpuræ sertum, Francolina and lagenaria, also Fusus articulatus of the same author, and numerous species distinguished as a new genus by Mr. Gray with the name of Pollia.

A number of interesting new species have now to be added, collected by Mr. Cuming at the Philippine Islands, exhibiting an extremely interesting variety of form colour and sendpture.

Species 1. (Fig. Kiener.)

Buccinum ciliatum. Buc. testá ovato-conicá, tenui, ventricosa, spira acuta; anfractibus rotundatis, transver-

sim creberrimè striatis; columellà brevi, subcontortà; apertură amplă; carneo vel cinereo-fuscescente, obscurè fasciatá, flammulis fuscis longitudinaliter variegatá.

THE HAIRY BUCCINUM. Shell ovately conical, thin, ventricose, spire acute; whorls rounded, transversely very closely striated; columella short, a little twisted, aperture large; fleshy or ashy brown, obscurely banded, variegated longitudinally with brown flames.

Fabricius, O. Fauna Grænlandica p. 401.

Buccinum ventricosum, Kiener.

An Buccinum Humphreysianum? Bennett.

Hab. Newfoundland; Sowerby. Northern Seas; Kiener. Massachusetts, United States, (taken from fishes caught for the most part at the banks); Gould.

This species I regret to say I have not seen; there can however be no fear of mistaking it from the striking figure here copied from M. Kiener's (though probably a little exaggerated) and that of Dr. Gould in his invaluable Report of the Invertebrates of Massachusetts. Of the Buccinum Humphreysianum described by Mr. Bennett in the Zoological Journal, specimens are said to have been taken by some fishermen alive in Cork Harbour, perfectly identical with some received from Newfoundland by Mr. Sowerby.

Species 2. (Mus. Cuming.)

BUCCINUM DONOVANI. Buc. testá ovato-conicá, tenuiculá, spirá acutá; anfractibus rotundatis, transversim lineatis et obscurè carinatis, apicem versus concentricè plicatis; columellá brevi, aperturá subquadrato-ovatá; albidá aut fuscescente, epidermide indutá.

Donovan's Buccinum. Shell ovately conical, rather thin, spire sharp; whorls rounded, transversely lineated and obscurely ridged, concentrically plicated towards the apex; columella short, aperture somewhat squarely ovate; whitish or light brown, covered with an epidermis.

Gray, Zoology of Beechey's Voyage, p. 128.

Buccinum glaciale, Donovan.

Hab. Massachusetts, United States (inhabits the Bank fishing grounds); Gould.

The shell here represented, it will be observed, does not agree very accurately either with the figures of Donovan or Dr. Gould; still, I believe it to be the species, whose most constant character is retained in the short square-like effusion of the aperture; the thickness and plicated structure of this group varies, as will be noticed in the following species, according to circumstances of habitation.

Species 3. (Mus. Cuming,)

Buccinum undatum. Buc. testá ovato-conicá, spirá subacuminatá, suturis profundis; anfractibus rotundatis, transversim lineatis et liratis, concentricè plicatis, plicis e suturis descendentibus; albidá aut pallidè ferrugineá epidermide sæpissimè indutá.

The waved Buccinum Shell ovately conical, spire somewhat acuminated, sutures deep; whorls rounded, transversely lineated and ridged, concentrically plicated, folds descending out of the sutures; whitish, or pale rusty colour, most frequently covered with an epidermis.

Linnæus, Syst. Nat. (12th edit.) p. 1204. Varietates,

> Buccinum vulgare, Da Costa. Buccinum striatum, Pennant. Buccinum solutum. Dillwyn.

Hab. Shores of Europe and the United States.

This well known species, the common Whelk of our market, varies in growth according to the situation it inhabits; in a rocky gravelly soil the shell is stout and strongly plicated, on mud and in a soft bottom it is thin, comparatively smooth and covered with a soft epidermis.

Species 4. (Mus. Brit.)

Buccinum acuminatum. Buc. testâ conico-subulatâ, basi contractâ, anfractibus medio leviter concavis, transversim regulariter liratis, interstitiis subtilissime granoso-striatis; columellâ uniplicatâ, plicâ subamplâ; albâ, epidermide tenui partim indutâ.

THE ACUMINATED BUCCINUM. Shell conically subulate, contracted at the base, whorls slightly concave in the middle, transversely regularly ridged, interstices very finely granosely striated; columella one-plaited, plait rather large; white, partially covered with a thin epidermis.

Broderip, Zool. Journ. vol. v. p. 44. pl. 3. fig. 1 and 2. Hab. Torquay, south coast of England.

This remarkable light Terebra-like species, of which there are in the British Museum two other smaller specimens, was taken alive some twenty years since by a fisherman off Torquay, on the coast of Devonshire; the original proprietor of the shell, Lord Kilcoursie, being in the boat at the time. It is of light structure and of singularly acuminated growth, approaching very much in these respects to a specimen in the possession of John Bates, Esq., R.N., Sec. Royal Yacht Society, thought to be a variety of the B. glaciale, recently taken alive by a fisherman off Cowes in one of the basket pots laid along shore in about two or three fathoms water for catching Whelks.

Species 5. (Mus. Brit.)

Buccinum Labradorense. Buc. testă conico-ovată, ventricosă, tenuiculă, anfractibus rotundatis, transversim tenuissime striatis, e suturis subobsolete plicatis; albă, epidermide corneă partim indută, aperturæ fauce pallide croceă.

THE LABRADOR BUCCINUM. Shell conically ovate, ventricose, rather thin, whorls rounded, transversely very finely striated, rather obsoletely plicated from the sutures; white, partially covered with a horny epidermis, interior of the aperture pale saffron colour.

Hab. Labrador; Lady K. Douglas.

This species, of which there are four or five specimens in the British Museum, collected by Lady Katherine Douglas, appears to be quite distinct from any hitherto recorded.

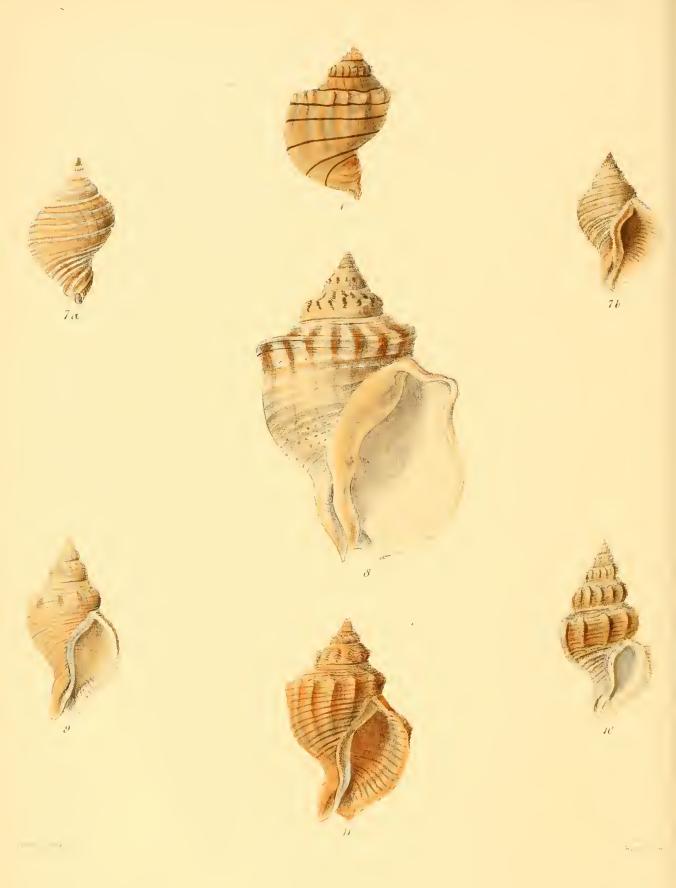

PLATE II.

Species 6. (Mus. Cuming.)

- Buccinum signum. Buc. testá ovatá, subventricosá, sub-Pyrulaformi, contortá, basi productá et obliquè recurvá; aufractibus transversim peculiariter minutissimè undulato-striatis, supernè angulatis, ad angulum plicatonodosis, nodis prominentibus; aperturá amplá; cinereá, luteo-fuscescente tinctá, lineis castaneis subdistantibus cingulatá.
- The flag Buccinum. Shell ovate, ventricose, somewhat Pyrula-shaped, contorted, produced and obliquely recurved at the base; whorls transversely peculiarly very minutely striated in a waved manner, angulated round the upper part, plicately noduled on the angle, nodules prominent, aperture large; ash-colour stained with yellowish brown, eneircled with rather distant chesnut brown lines.

Hab.---?

A remarkable shell having somewhat the aspect of the *Purpura lineata*, but of quite a different form; the general character of this species, and of those which accompany it in the present plate, has almost tempted me to introduce them in a new and separate genus.

Species 7. (Mus. Cuming.)

- Buccinum trochulus. Buc. testá oblongo-ovatá, basi contortá, canaliculatá et recurvá, spirá acutá; anfractibus rotundatis, undique creberrimè tenuiliratis, prope apicem nodosis; aperturá oblongá, fauce irregulariter et interruptè liratá; luteo-spadiceá, lineis albis distantibus cingulatá.
- THE LITTLE TOP BUCCINUM. Shell oblong-ovate, twisted, channelled and recurved at the base, spire sharp; whorls rounded, very closely finely ridged throughout, noduled near the apex; aperture oblong, interior irregularly and interruptedly ridged; yellowish bay colour, encircled with distant white lines.

Hab. --- ?

Another characteristic species of rarity which does not appear to have been hitherto recorded.

Species S. (Mus. Brit.)

Buccinum imperiale. Buc. testá ovatá, tenuiculá, inflatá; anfractibus transversim striatis et obscurè

liratis, supernè concavo-angulatis, ad angulum obtusè carinatis; aperturá peramplá; sordidè albidá, aurantio-fusco, præcipuè ad angulum, maculatá et punctatá.

The imperial Buccinum. Shell ovate, rather thin, inflated; whorls transversely striated and obsurely ridged, concavely angulated round the upper part, obtusely keeled at the angle; aperture very large; dull white, blotched and dotted, especially at the angle, with orange-brown.

Hab. ——?

A species of very peculiar form and colouring, unique, as far as I can ascertain, in our national collection.

Species 9. (Mns. Cuming.)

- Buccinum Fusoides. Buc. testá fusiformi, basi canaliculatá et recurvá, transversim undique liratis, liris angustis, confertiusculis, interstitiis longitudinaliter striatis; aperturá oblongá, funce liratá; fuscesceute, liris maculis parcis saturatioribus profusè tinctis.
- The Fusus-like Buccinum. Shell fusiform, channelled and received at the base, transversely ridged throughout, ridges narrow, rather close-set, interstices longitudinally striated; aperture oblong, interior ridged; light brown, ridges profusely stained with small spots of a deeper colour.

Hab. ---- ?

If it were not that this species falls into the present series, distinguished by the recurvature of the channelled base, it might be referred with propriety to the genus Fusus.

Species 10. (Mus. Cuming.)

- Buccinum varicosum. Buc. testá subfusiformi-turritá, basi canaliculatá et recurvá, spiræ suturis subimpressis, aufractibus subrotundis, transversim conspicuè elevatostriatis, longitudinaliter costatis, costis obtusis, subdistantibus; aperturá parvá; sordidè fuscescente.
- THE VARICOSE BUCCINUM. Shell somewhat fusiformly turreted, channelled and recurved at the base, sutures of the spire rather impressed; whorls nearly round, transversely conspicuously elevately striated, longitudinally ribbed, ribs obtuse, rather distant; aperture small; dull brown.

Murex varicosus, Chemnitz, Conch. Cab. vol. x. p. 256. pl. 162. f. 1546, 7.

Hab. ——?

The Murex varicosus of Chemnitz falls so peculiarly into this novel group of recurved-channelled Buccina, that I included it in the scries, before noticing that M. Kiener had described it under the head of Fusus, and M. Deshayes observed that it has as much the appearance of Buccinum as of Fusus, ("coquille qui a antant l'apparence d'un Buccin que d'un Fuseau"), and I incline to think the situation to which I have here assigned it is the more appropriate. Lamarck does not appear to have noticed the species.

Species 11. (Mus. Cuming.)

Buccinum Cassidariæforme. Buc. testá ovatá, subventricosá, basi canaliculatá et recurvá; anfractibus transversim undique subirregulariter sulcatis, supernè declivibus et angulatis, ad angulum conspicuè nodosis; aperturâ oblongâ, fauce liratâ; intus extusque fusco-aurantiâ.

THE CASSIDARIA-SHAPED BUCCINUM. Shell ovate, rather ventricose, channelled and recurved at the base; whorls transversely somewhat irregularly grooved throughout, sloping and angulated round the upper part, conspicuously nodose at the angle; aperture oblong, interior ridged; brownish-orange within and without.

Hab. ----?

None of the rarc and interesting species of this plate from Mr. Cuming's cabinet and the British Museum were collected by him, nor does he possess any information as to their locality or circumstances of habitation.

PLATE III.

Species 12. (Mus. Cuming.)

Buccinum Nassoides. Buc. testă pyramidali-ovată, apice acuminată; anfractibus superne concavis, concentrice nodoso-plicatis, transversim obsolete lirutis et subtilissime striatis; auruntio-fuscescente, nodulis tirisque albidis.

The Nassa-like Buccinum. Shell pyramidally ovate, acuminated at the apex; whorls concave round the upper part, concentrically nodosely plicated, transversely obsoletely ridged and very finely striated; orange-brown, nodules and ridges whitish.

Hab. ——?

Mr. Cuming possesses no information relative to this new and interesting species.

Species 13. (Mus. Cuming.)

Buccinum spirale. Buc. testã ovatá, spirá acuminatá, suturis profundis; anfractibus supernè plano-augulatis, tongitudinaliter obsoletè tuberculato-plicatis, transversim liratis, liris prominentibus, interstitiis excavatis et striatis; apertura fauce sulcatá et crenatá; albá, fusco hie illic sparsim tinctá.

The spiral Buccinum. Shell ovate, spire acuminated, sutures deep; whorls flatly angulated round, the upper part, longitudinally obsoletely tubercularly plicated, transversely ridged, ridges prominent, interstices excavated and striated; interior of the aperture grooved and crenated; white, sparingly tinged here and there with brown.

Pollia spiralis, Gray, Zoology of Beechey's Voyage,p. 111. Hab. Mauritius.

Though not uncommon I find no mention of this species, except in the work above quoted; some collectors possess it, named in manuscript *B. fuscatum*, but it is obviously not the *B. fuscatum* of Brugniére.

Species 14. (Mus. Cuming.)

Buccinum erythrostoma. Buc. testű ovatá, spirá acuminatá, anfractibus concentricè tuberculatis, transversim subtiliter et creberrimè liratis; aperturæ fauce sulcatá et crenatá; lutescente, epidermide sericeá indutá, tuberculis nigricante-fuscis, aperturæ fauce albá, columellá labrique limbo interno rufis. The red-mouth Buccinum. Shell ovate, spire acuminated, whorls concentrically tuberculated, transversely finely and closely ridged; interior of the aperture grooved and crenated; yellowish, covered with a silken epidermis, tubercles blackish brown, interior of the aperture white, columella and inner margin of the lip red.

Hab. Ceylon.

Easily distinguished by the characteristic blood red colouring of the mouth.

Species 15. (Mus. Cuming.)

Buccinum melanostoma. Buc. testã oblongo-ovată, subventricosă, anfractibus superne rotundato-a gulatis, suturis profundis, longitudinaliter plicato-undatis, transversim irregulariter tiratis et striatis, apertură ovată, fauce sulcată et crenată; aurantio-fuscă, maculis saturatioribus hic illic tinctă, columellă nigricante-fuscă, apertura fauce albă.

The black-mouth Buccinum. Shell oblong-ovate, somewhat ventrieose, whorls rotundately angled round the upper part, sutines deep, longitudinally plicately waved, transversely irregularly ridged and striated, aperture ovate, interior grooved and crenated; orange brown, stained here and there with spots of a darker brown, columella blackish brown, interior of the aperture white.

Sowerby, Tankerville Catalogue, Appendix, p. 21. *Hab.* Ceylon.

M. Deshayes arranges this species together with the B. sepimentum and plumbeum (Monoceros plumbeus, mihi), in a separate section, under the title of "Les Monodontes"; 1 do not, however, see that it has any such affinity with them. It may be easily distinguished from the B. Tranquebaricum with which species M. Kiener has confounded it, under an impression that they are the same in different ages.

Species 16. (Mus. Cuming.)

Buccinum Maculatum. Buc. testá gibboso-ovatá, spirá breviusculá, anfractibus supernè leviter concavis, medio turgilis, lævibus, ad apicem tuberculato-nodosis; columellá excavatá, supernè callosá et canaliculatá, basi ampliter emarginutá; griseo-flavá, tæniis fusco-articulatis undique cingulatá.

The spotted Buccinum. Shell gibbonsly ovate, spire rather short, whorls slightly coneave at the upper part, swollen at the apex; columella excavated, callous and channelled at the upper part, base largely emarginated; greyish yellow, encircled throughout with brown-articulated fillets.

Martyn, Universal Conchology, vol. ii. pl. 49.

Buccinum adspersum, Chemnitz. Buccinum turgidum, Dillwyn.

Buccinum testudineum, var. Kiener.

Hab. New Zealand.

I quite agree with M. Deshayes in the propriety of distinguishing this from the *B. lestudineum*, independent of the specific difference which he notices in the animal.

Species 17. (Mns. Cuming.)

Buccinum Tranquebaricum. Buc. testá ocatá, subventricosá, anfractibus supernè rotundato-angulatis, longitudinaliter fortiter plicato-costalis, transversim undique liratis; aperturæ fance sulcatá et crenatá; flavescente, zoná angustá albá interdum cingulatá, liris rufescentibus, columellá et aperturæ fauce albis.

THE TRANQUEBAR BUCCINUM. Shell ovate, somewhat ventricose, whorls rotundately angled round the upper part, longitudinally strongly plicately ribbed, transversely ridged throughout; interior of the aperture ridged and crenated; pale bright yellow, sometimes encircled with a narrow white zone, ridges reddish,

columella and interior of the aperture white.

Nassa Tranquebarica Martini, Conch. Cab. vol. 4. p. 35. pl. 123. f. 1146, 7.

Hab. Tranquebar.

Not often so brightly coloured as the specimen here figured, which is moreover distinguished by a central white band.

Species 18. (Mus. Cuming.)

Buccinum glaciale. Buc. testă subulato-ovută, spirae suturis profundis, anfractibus subplanatis longitudinaliter oblique plicatis, transversim bi-tri-carinatis, carinarum interstitiis regulariter elevato-striatis; apertură brevi, labro conspicue effuso; sordide flavido-fuscă, labro albo.

The icy Buccinum. Shell subulately ovate, sutures of the spire deep, whorls somewhat flattened, longitudinally obliquely plicated, transversely two-three-keeled, interstices between the keels regularly elevately striated; aperture short, lip conspicuously effused; dull yellowish brown, lip white.

LINNÆUS, Syst. Nat. (12th. edit.) p. 1204.

Tritonium glaciale, Muller.

An eadem? *Buccinum angulosum*, Gray, Zool. Beechey's Voyage, p. 127. pl. 36. f. 6.

Hab. Northern Seas.

I have not seen the fractured specimen from Iey Cape described by Mr. Gray under the above mentioned name, but fear nevertheless it is a variety of the present species.

PLATE IV.

Species 19. (Mus. Cuming.)

Buccinum modestum Buc. testå ovato-fusiformi, basi sulcatå, supra subtiliter striatå; aperturå oblongå, labro incrassato, marginato; albidå aut lutescente, rufescente-castaneo tinctå, in strigis juxta suturas disposito, unfractu ultimo zonå angustå albidå cingulatå.

THE MODEST BUCCINUM. Shell ovately fusiform, grooved at the base, finely striated above; aperture oblong. lip thickened, marginated; whitish or yellowish, stained with reddish chesnut, arranged in streaks next the sutures, last whorl enercled by a narrow white zone.

Powis, Pro. Zool. Soc. 1835, p. 94.

Hub. Bay of Montija, Central America (dredged from muddy gravel at a depth of from seven to seventeen fathoms); Cuming.

Species 20. (Mus. Cuming.)

Buccinum costatum. Buc. testá pyramidali-ovatá, anfractibus transversim undique creberrimè sulcatis, supernè concavo-angulatis, ad angulum nodosis, infra obsotetè plicato-costatis: columellá excavatá, aperluræ fauce liratá; albidá ant vinereá, areis inter sulcos transversos rufo-fusco articulatis, columellá aurantio-fuscá, aperturæ fauce albá.

The Ribbed Buccinum. Shell pyramidally ovate, whorls transversely very closely grooved throughout, concavely angled round the upper part, nodose at the angle, obsoletely plicately ribbed beneath, columella excavated, callous and channelled at the upper part, interior of the aperture ridged; whitish or ash colour, areas between the transverse rows articulated with reddish brown, columella orange-brown, interior of the aperture white.

Quoy & Gaimard. Voy. de l'Astrol. Zool. vol. ii. p. 417, pl. 30. f. 17, to 20.

Hab. South Australia.

The name selected for this species is a very inappropriate one, there being little or no appearance of ribs.

Species 21. (Mus. Cuming.)

Buccinum acutinodosum. Buc. testá ovatá, spirá breviusculá, turritá, anfractibus supernè angulatis, ad angulum acutè nodosis, transversim undique creberrimè sulcatis; columellá excavatá et supernè canaliculatá; cinereo- vel cæruleo-albicante, arcis inter sulcos nigricante-fusco articulatis, aperturæ funce purpureo-nigricante.

THE SHARPLY NODULED BUCCINUM. Shell ovate, spire rather short, turreted, whorls augulated round the

upper part, sharply noduled at the angle, transversely very closely grooved throughout; columella exeavated and channelled at the upper part; ashy or blueish white, areas between the transverse grooves articulated with blackish brown, interior of the aperture purple-black.

Hab. South Australia.

Closely approximating to the preceding species and from the same locality; its more gibbous and shortened growth cannot be estimated of any specific importance, but the columella is rather different, and the interior of the aperture deep purple-black. Mr. Cuming possesses specimens of each without any intermediate modification of these characters.

Species 22. (Mus. Cmning.)

Buccinum porcatum. Buc. testá ocuto-oblongá, anfractibus supernè concavis, liris plano-convexis, subdistantibus regulariter cinctis, lirarum interstitiis tenuiter striatis; columellá supernè lirá callosá munitá, supra canaliculatá; labro tenui, simplici; ferrugineo-fusco, liris saturatioribus, columellá albá, aperturæ fauce curneo tinctá.

THE RIDGED BUCCINUM. Shell ovately oblong, whorls concave round the upper part, régularly encircled with rather distant flatly convex ridges, interstices between the ridges finely striated; columella furnished at the upper part with a callous ridge, channelled above; lip thin, simple; rusty brown, ridges darker, columella white, interior of the aperture tinged with flesh-colour.

GMELIN, Syst. Nat. p. 3494.

Buccinum usperius striatum, &c., Martini.

Buccinum Mexicanum, Bruguière.

Purpura ligata, Lamarck.

Buccinum ligatum, Kiener.

Hab. ---- ?

I refer this species to the *Purpura ligata* of Lamarck solely on the authority of M. Kiener.

Species 23. (Mus. Cuming.)

Buccinum Anglicanum. Buc. testá oblongá, tenuiculá, anfractibus supernè leviter concavis, liris parvis confertiusculis striisque cinctis, columellá supernè lirá vallosá munitá, suprá canaliculatá; labro simplici; ferrugineo-fuscá, columellá et aperturæ fauce albidis.

THE ENGLISH BUCCINUM. Shell oblong, rather thin, whorls slightly concave round the upper part, encircled with close-set small ridges and striæ, columella furnished at the upper part with a callous ridge,

channelled above; lip simple; rusty brown, columella and interior of the aperture whitish.

MARTINI, Conch. Cab. vol. iv. p. 70. pl. 196. f. 1212. Buccinum Norvegicum, Enc. Méth.

Hab. Coasts of England and Norway.

Very like the preceding species, differing only in having the ridges more frequent and less strongly developed, and the whorls less elevated one upon each other at the sutures.

Species 24. (Mus. Cuning.)

Buccinum papyraceum. Buc. testá ovatá, subfusiformi, tenui, anfractibus transversim tenuissimè striatis; columellá subexcavatá, lirá callosá supernè munitá, suprá canaliculatá; ferrugineo-fuscá, columellá et aperturæ fauce albis.

The paperaceous Buccinum. Shell ovate, somewhat fusiform, thin, whorls transversely very finely striated; columella somewhat excavated, furnished at the upper part with a callous ridge, channelled above; light rusty brown, columella and interior of the aperture white.

Bruguiere, Enc. Mèth. Dict. no. 22. Hab. ——?

So closely do this and the two preceding species approximate to one another, that they may prove to be nothing more than different states of the same.

Species 25. (Mus. Cuming.)

Buccinum ovum. Buc. testá ovatá, spirá breviusculá, anfractibus rotundatis, ventricosis, lævigatis, labro tenui; eburneá, epidermide tenui lutescente indutá.

THE EGG BUCCINUM. Shell ovate, spire rather short, whorls round, ventricose, smooth, hip thin; ivory white, covered with a thin yellowish epidermis.

Turton, Zool. Journal, vol. ii. p. 366. pl. 13. f. 9.

An Buccinum fusiforme, Kiener (not of Broderip)? Hab. Britain.

I have no shell that comes so near to M. Kiener's figure, B. fusiforme, as the present; it is of rather a more elongated form, and if on comparison it should prove distinct must be re-named.

Species 26. (Mus. Cuming.)

Buccinum tenebrosum. Buc. testá tenui, subinflatá, spirá mediocri, ad apicem subplicatá; anfractibus rotundis, aut supernè leviter depressis, spiraliter indistinclè carinatis, carinis ferè obsoletis, labro acuto; intus extusque violaceo- aut livido-fuscá, columellá supra nigricante.

THE DARK BUCCINUM. Shell thin, somewhat inflated, spire middling, slightly plaited at the apex, whorls

round or a little depressed round the upper part, spirally indistinctly keeled, keels almost obsolete, lip sharp; violet or livid brown within and without, columella blackish above.

HANCOCK, Ann. and Mag. Nat. Hist. vol. xviii. p. 327. pl. 5. f, 1, 2.

Hab. West coast of Davis's Strait, between Greenland and North America (dredged from a blue clay bottom at a depth of from fifteen to twenty fathoms); Warham and Harrison.

An interesting species of which there are several examples in Mr. Cuming's collection, described almost simultaneously with the present by Mr. Hancock, one of the accomplished authors of the 'British Nudibranchiate Mollusca' issuing under the auspices of the Ray Society. The new species of shells just described in the Magazine above quoted, were dredged in a deep bay on the west coast of Davis's Strait, through the zeal of Messrs. Warham and Harrison, masters of whaling vessels belonging to the port of Newcastle-on-Tyne.

Species 27. (Mus. Cuming.)

Buccinum tenue. Buc. testá fusiformi-oratá, tenui, spirá subacuminatá, anfractibus subrotundis, lævibus aut minutissimè spiraliter striatis, concentricè plicatocostatis, labro tenui; sordidè albá.

The thin Buccinum. Shell fusiformly ovate, thin, spire rather acuminated; whorls somewhat round, smooth, or very minutely spirally striated, concentrically plicately ribbed, lip thin; dead white.

Gray, Zool, of Beechey's Voyage, p. 128, pl. 36, f. 19, Hab. Icy Cape.

Well characterized by its concentric scalariform ribs.

Species 28. (Mns. Cuming.)

Buccinum Zealandicum. Buc, testá conico-ovatá, subventricosá, anfractibns spiraliter striatis, e suturis concentricè fortiter obliquè semiplicatis, labro subincrassato; albidá aut Intescente, maculis rubidis transversim oblongis inter plicas vittatá, aperturæ fauce aurantioluteá.

The New Zealand Buccinum. Shell conically ovate, somewhat ventricose, whorls spirally striated concentrically, strongly half-plicated from the sutures, lip rather thickened, whitish or yellowish, filleted between the folds with transversely oblong red spots, interior of the aperture orange-yellow.

Hab. New Zealand.

The rows of oblong red spots which encircle the upper portion of the whorls in the interstices between the folds, constitute a character by which this species may be easily recognised.

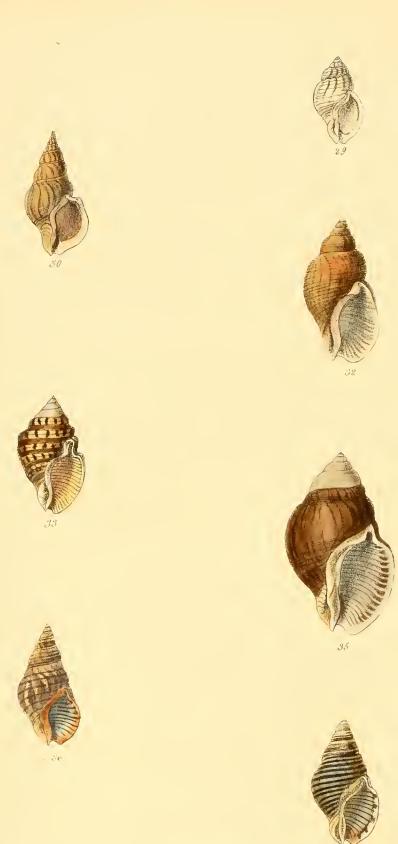

PLATE V.

Species 29. (Mus. Brit.)

Buccinum ciliatum. Buc. testă ovată, spiră brevi, anfractibus rotundatis, transversim subtilissime striatis, concentrice e suturis fortiter plicato-costatis; intus extusque albă.

THE CILIATED BUCCINUM. Shell ovate, spire short, whorls rounded, transversely very finely striated, concentrically strongly plicately ribbed from the sutures; white within and without.

MOLLER, Index Moll, Grænl.

Hab. Greenland.

A small ovate white shell very strongly concentrically plicately ribbed.

Species 30. (Mus. Cuming.)

Buccinum Antarcticum. Buc. testá ovato-fusiformi, basi truncatá, anfractibus apicem versus fortiter plicatocostatis, costis anfractüs ultimi evanidis; extus epidermide crassá olivaceá indutá, intus purpureo-fuscá, columellá labrique margine interno albis.

The Antarctic Buccinum. Shell ovately fusiform, truncated at the base, whorls strongly plicately ribbed towards the apex, ribs of the last whorl fading away; exterior covered with a thick olive epidermis, interior purple-brown, columella and inner edge of the lip white.

Hab. Falkland Islands; Ross.

One of the few species brought home by the Antarctic Expedition of H.M. Ships 'Erebus' and 'Terror,' under the command of Captain Sir James Clarke Ross.

Species 31. (Mus. Brit.)

Buccinum fusiforme. Buc. testá fusiformi, spirá acuminatá, anfractibus transversim creberrimè liratis et concentricè costatis, costis subgranosis; albá, epidermide fuscescente indutá.

The fusiform Buccinum. Shell fusiform, spire acuminated, whorls transversely very elosely ridged and concentrically ribbed, ribs subgranose; white, covered by a brownish epidermis.

BRODERIP, Zool. Journal, vol. v. p. 45. pl. 3. f. 3. Hab. Cork, Ireland.

Partaking very much of the character of Fusus.

Species 32. (Mus. Cuming.)

Buccinum intinctum. Buc. testá oblongo-ovatá, tenuiculá anfractibus supernè leviter depressis, transversim undique creberrimè striatis, columellá lævi, callositate supernè munitá, aperturæ fauce radiatim subtiliter liratá; castaneo-rufá epidermide tenui indutá, intus albá.

THE DYED BUCCINUM. Shell oblong-ovate, rather thin, whorls slightly depressed round the upper part, transversely very closely striated throughout, columella smooth, furnished with a callosity at the upper part, interior of the aperture radiately finely ridged; chesnut red, covered with a thin epidermis, interior white.

Hab. ——?

This species has, I fear, been confounded with the *B.* papyraceum, from which it is constantly distinguished by its less elongated form and deep red colour.

Species 33. (Fig. 33 and 34. Mus. Cunning.)

Buccinum lagenarium. Buc. testá ovatá, transversim tenuissimè striatá, anfractibus supernè compresso-planatis et lacunatis; lutescente, lineolis strigisque spadiceo-fuscis longitudinaliter undulatis variè pictá.

The calabash-shaped Buccinum. Shell ovate, transversely very finely striated, whorls compressly flattened and guttered round the upper part; yellowish, variously painted with longitudinally waved brown lines and streaks.

Variety 3. (Fig. 33 and 34.)

Testa obsoletè plani-lirata, liris maculis quadratis aurantiofuscis articulatis.

Shell obsoletely flatly ridged, ridges articulated with square orange-brown spots.

DESHAYES, Anim. sans vert. vol. x. p. 81. note.

Purpura lagenaria, Lamarek.

Variety a. Purpura cucurbita, Duclos.

Variety \(\beta \). an Purpura zebra? Kiener.

Hab. Cape of Good Hope.

By some unfortunate mistake two examples of Var. β have been figured in place of one of each variety; Var. α has been, however, well represented by M. Duclos in the 'Magasin de Zoologie' for 1833, and it is a shell of very common occurrence.

Species 35. (Mus. Brit.)

Buccinum limbosum. Buc. testá conico-ovatá, anfractibus supernè concavo-depressis, transversim subtilissimè et creberrimè striatis, aperturæ fauce radiatim tenuiliratá; purpureo-nigricante, columellá et aperturæ fauce albis, fusco-purpureo tinctis.

The collared Buccinum. Shell conically ovate, whorls concavely depressed round the upper part, transversely very finely and closely striated, interior of the aperture radiately finely ridged; purple-black, columella and interior of the aperture white, tinged with brownish purple.

Purpura limbosa, Lamarck, Anim. sans vert. (Deshayes' edit.) vol. x. p. 78.

Hab. ——?

A species not often met with, of which there are two or three fine examples in the British Museum; it was only known to Lamarck in a young state.

Species 36. (Mus. Cuming.)

Buccinum lineolatum. Buc. testá conico-ovatá, spirá elevatiusculá, lævigatá; griseo-fuscescente lineis nigris æqualibus nunc interruptis, nunc integris, cingulatá, aperturæ fauce cærulescente, columellá labrique margine interno rufo-aurantiis.

The Lineated Buccinum. Shell conically ovate, spire rather elevated, smooth; greyish brown, encircled with equal black lines sometimes interrupted, sometimes entire, interior of the aperture blueish, columchla and inner edge of the lip stained with orange.

LAMARCK, Anim. sans vert. (Deshayes' edit.) p. 164. and p. 186.

Hab. New Zealand.

M. Deshayes has published this as a new species of M. Quoy, without observing it to have been already described by Lamarck under the same name; should M. Quoy's entire-lined shell prove eventually to be distinct from the

interrupted-lined species of Lamarck (figured by M. Kiener at pl. 8. f. 25. as a variety of B. maculatum), I may here suggest that it be named Buccinum Quoyi, in honour of the indefatigable naturalist of the 'Astrolabe.'

Species 37. (Mus. Cuming.)

Buccinum alveolatum. Buc. testă conico-ovată, spiră elevatiusculă, lævigată; griseo- aut cærulescente-albidă, maculis cæruleo-nigris transverse oblongis creberrime seriatim cinctă.

THE TESSELLATED BUCCINUM. Shell conically ovate, spire rather elevated, smooth; greyish or blueish white, closely encircled with transversely oblong blue-black spots.

Kiener, Icon. coq. viv. p. 32. pl. x. f. 34. Hab. New Holland.

This is little more than a variety of the interrupted-lined B. lineolalum, in which the lines assume the width of interrupted bands; an argument however in favour of its being regarded as a species, is, that it never occurs with entire bands.

Species 38. (Mus. Brit.)

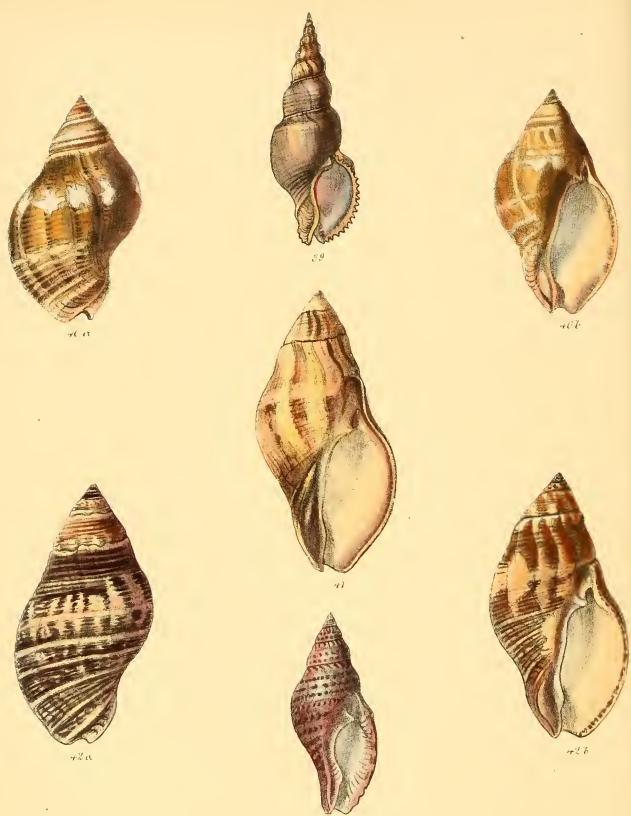

Buccinum plurianulata. Buc. testá conico-ovatá, anfractibus supernè concavo-depressis, lævigatis, aperturæ fauce subtiliter liratá; griseo-albidá, lineis nigris undique creberrimè cingulatá, aperturæ fauce nigricante, labri margine interno albicante.

THE MANY-RINGED BUCCINUM. Shell conically ovate, whorls concavely depressed round the upper part, smooth, interior of the aperture finely ridged; greyish-white, very closely encircled throughout with black lines, interior of the aperture blackish, inner edge of the lip whitish.

Hab. Swan River.

Perfectly distinguished from the *B. lineolatum* both in form and colouring.

Howerby del et lith

Reev

PLATE VI.

Species 39. (Mus. Cuming.)

Buccinum pristis. Buc. testá elongato-turritá, acuminatá, basi subcontortá; anfractibus supernè declivibus, apicem versus subobsotetè plicatis et striatis, cæteris lævibus, politis; aperturá brevi, labri timbo pulcherrimè et conspicuè serrato; intus extusque livido-olivaceá.

The elongated Buccinum. Shell elongately turreted, acuminated, somewhat twisted at the base; whorls depressly slanting round the upper part, somewhat obsoletely plicated and striated, the rest smooth, polished; aperture short, edge of the lip very beautifully and conspicuously serrated; livid olive within and without.

DESHAYES, Anim. sans vert. vol. x. p. 192.

Buccinum serratum Dufresne.

Hab. St. Elena, West Columbia.

The name pristis has been given to this singular species by M. Deshayes in consequence of that of serratum introduced by Dufresne being pre-occupied in reference to a fossil species; it was originally dedicated by Mr. Gray in manuscript to Lady North, Buccinum Northiæ, but I cannot learn that this name ever reached publicity.

Species 40. (Mus. Cuming.)

Buccinum situla. Buc. testá oblongo-ovatá, spirá brevi, anfractu ultimo amplo, inflato; lævigatá aut obscurissimè elevato-striatá; aperturá amplá, callositatibus duabus supernè munitá, labro simplici; fulvo-rubidá, maculis violascente-albis seriatim aspersá, aperturæ fauce rufescente-aurantiá.

THE LITTLE WATER-SCOOP BUCCINUM. Shell oblongovate, spire short, last whorl large, inflated, smooth or very obscurely clevately striated; aperture large, furnished at the upper part with two callosities, lip simple; fulvous rcd, sprinkled with rows of violetwhite blotches, interior of the aperture reddish-orange.

Hab. Isle of Annaa, Pacific Ocean (on the reefs at low water); Cuming.

An interesting new species abundantly distinguished from the two which follow by its shorter and more inflated growth, smooth surface and peculiar style of painting.

Species 41. (Mus. Cuming.)

Buccinum Francolinus. Buc. testá ovato-oblongá, cras-

siusculá, spirá brevi, subobtusá; anfractibus supernè depresso-concavis, transversim exilissimè et creberrimè elevato-striatis, interstitiis minutissimè cancellatis, anfractu ultimo inflato; aperturá amplá, callositatibus duabus supernè munitá; luteo-aurantiá, fusco-rubido hic illic strigatá et reticulatá, aperturæ fauce luteo-albidá.

The Francoline Buccinum. Shell ovately oblong, rather thick, spire short, somewhat obtuse, whorls depressly concave round the upper part, transversely very faintly and closely elevately striated, the interstices being very minutely cancellated, last whorl inflated; aperture large, furnished at the upper part with two callosities; yellowish orange, streaked and reticulated here and there with brownish-red, interior of the aperture yellowish white.

BRUGUIERE, Enc. Méth. Dict. no. 24.

Purpura Francolinus, Lamarek.

Hab. Isle of Annaa, Pacific Ocean (on the reefs at low water); Cuming.

This may easily be distinguished from the foregoing and following species, by its minutely cancellated sculpture and delicate tone of colouring.

Species 42. (Mus. Cuming.)

Buccinum sertum. Buc. testá ovato-oblongá, spirá brevi, subobtusá, anfractibus supernè leviter concavis, transversim granoso-striatis, striis nunc rudis nunc tenuibus, anfractu ultimo inflato; aperturá amplá, callositatibus duabus supernè munitá; luteo-aurantiá, rufo-castaneo tinctá et variegatá, apertura fauce luteo-albidá.

The Garland Buccinum. Shell ovately oblong, spire short, rather obtuse, whorls slightly concave round the upper part, transversely granosely striated, striæ sometimes rude sometimes fine, last whorl inflated; aperture large, furnished at the upper part with two callosities; yellowish orange, stained and variegated with red-chesnut, interior of the aperture yellowish-white.

BRUGUIERE, Enc. Méth. Dict. no. 25.

Purpura sertum, Lamarek.

The painting of this species is mostly darker than that of the preceding; the sculpture sometimes coursely, sometimes delicately engraved.

Species 43. (Mus. Cuming.)

Buccinum pusio. Buc. testá fusiformi, anfractibus supernè leviter concavis, tævigatis aut transversim tenuissimè striatis; columettá excavatá, aperturá oblongá, supernè catlositatibus munitá, fauce sulcatá; purpureoplumbeá, tæniis fusco-articulatis undique cingulatá, aperturæ fauce cærulescente, aurantio margine tinctá.

The young Buccinum. Shell fusiform, whorls slightly concave round the upper part, smooth or transversely very finely striated; columella excavated, aperture oblong, furnished at the upper part with callosities, interior grooved; purple-lead colour, encircled throughout with brown-articulated fillets, interior of the aperture blueish, stained at the edge with orange.

LINNÆUS, Syst. Nat. (12th edit.) p. 1223.

Buccinum plumatum, Gmelin.

Fusus pusio Enc. Méth.

Fusus articulatus, Lamarek.

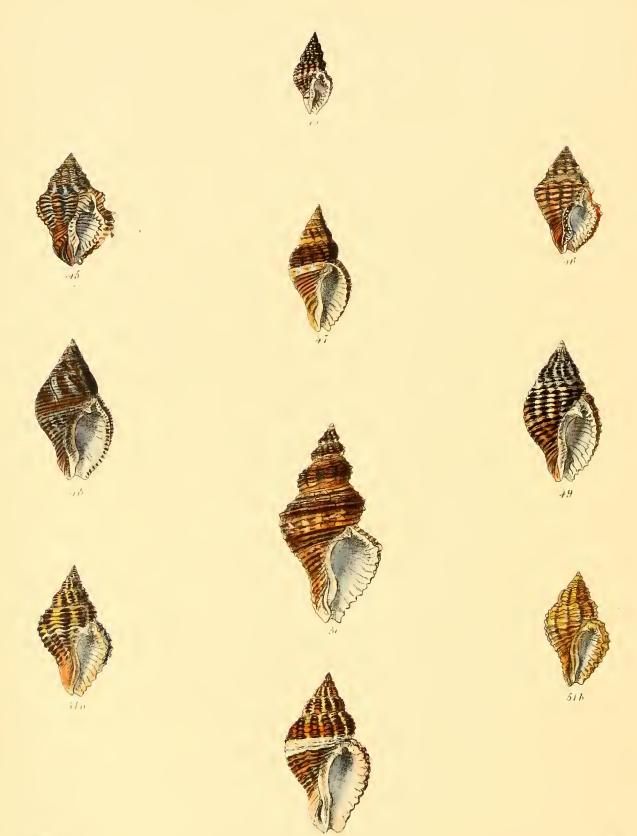

Hab. Honduras, California.

A great deal of confusion has arisen in regard to the origin of this species, in consequence of Linuæus having formed his description from an immature specimen (suggestive of the name pusio) "about the size of a hazel-nut," in which the dark spots range in longitudinal streaks, as he describes, instead of forming articulated bands; and in quoting the Mediterranean Sea as its habitat, thereby leading Philippi and others to confound it with the B. maculosum, of that locality.

Thanks, however, to Mr. Hanley for calling my attention to it, we possess in the collection of our Linnæan Society the very shell from which the diagnose in the 'Systema Naturæ' was drawn up, with the number referring to it on the shell, in Linnæus's handwriting; and the specimen agrees precisely with the immature representations of the species in Gnalter and Bonanni to which he refers.

So many of Linnæus' shells were in young or bad condition, that his descriptions scarcely apply to the same of mature age and in finer state of preservation.

Reeve

PLATE VII.

Species 44. (Mus. Cuming.)

Buccinum D'Orbignyi. Buc. testá fusiformi-ovatá, basem versus paululum contractá; anfractibus concentrice plicato-costatis, transversim striatis et sulcatis; labro intus plicato-dentato; luteo nigroque pulcherrime variá, zoná angustá albidá cingulatá.

D'Orbigny's Buccinum. Shell fusiformly ovate, a little contracted towards the base; whorls concentrically plicately ribbed, transversely striated and grooved; lip plicately toothed within; beautifully variegated with black and yellow, encircled with a narrow white zone.

PAYRANDEAU, Cat. Moll. de. Corse. p. 159. pl. 8. f. 4 to 6. Cancellaria D'Orbignyi, De Blainville.

Hab. Mediterranean.

The colouring of this shell is extremely characteristic; the plicated ribs are divided, as it were, by the transverse grooves into nodules which are bright yellow on the front side and black at the back.

Species 45. (Mus. Cuming.)

Buccinum ringens. Buc. testá ovatá, solidá, gibbosiusculá, spirá brevi, acutá; anfractibus fortiter turberculatoplicatis, transversim subtilissimè liratis et striatis, columellá labroque profusè sulcatis et corrugatis, supernè canaliculatis; fusco viridique variá, liris fusco articulatis, columellá et aperturæ fauce albis.

The Grinning Buccinum. Shell ovate, solid, rather gibbous, spire short, acute; whorls strongly tubercularly plicated, transversely very finely ridged and striated, lip and columella profusely grooved and wrinkled, channelled at the upper part; variegated with green and brown, ridges articulated with brown, columella and interior of the aperture brown.

Hab. Panama (on the rocks at low water); Cuming.

Of a dark blue-green colour, varied with fine spiral cord-like ridges articulated with rusty brown.

Species 46. (Mus. Cuming.)

Buccinum hæmastoma. Buc. testá ovatá, solidiusculá, spirá brevi, anfractibus medio tuberculato-plicatis, transversim subtilissimè liratis et striatis, columellá margine minutè verrucosá, supernè lirá callosá munitá, supra canaliculatá; viridi, liris transversis hic illic

sanguineis, columellæ labrique limbis vividè sanguineis, columellæ verrucis albis, aperturæ fauce albû.

The blood-red-mouth Buccinum. Shell ovate, rather solid, spire short, whorls tubercularly plicated in the middle, transversely very finely ridged and striated, edge of the columella minutely warty, furnished at the upper part with a callous ridge, channelled above; dark green, transverse ridges here and there dark blood-red, warts of the columella white, interior of the aperture white.

Pollia hæmastoma, Gray, Zool. of Becchey's Voyage, p. 112.

Hab. Panama (under stones at low water); Cuming.

Easily recognised by the blood-red colouring of the lip and columella, the latter sprinkled with minute white warts.

Species 47. (Mus. Cuming.)

Buccinum rubiginosum. Buc. testá oblonyá, ovato-fusiformi, concentricè subobsoletè plicatá, transversim subirregulariter liratá et striatá; aperturæ fauce sutcatá; ferrugineo-aurantiá, fusco hic illic tinctá, zoná unicá albá cinquiatá.

The rusty Buccinum. Shell ovately fusiform, concentrically somewhat obsoletely plicated, transversely somewhat irregularly ridged and striated; interior of the aperture grooved; rusty-orange, stained here and there with brown, encircled with a single white zone.

Hab. Red Sea.

This species has a very strong resemblance with the *B. Proteus* which follows at Sp. 51, but is more elongated and constantly distinct.

Species 48. (Mus. Cuming.)

Buccinum variegatum Buc. testá oblongo-ovatá, spirá acutá, anfractibus supernè depressiusculis, liris subtilibus superficiariis undique cingulatis; cotumellá, excavatá, lirá callosá supernè munitá, supra canaliculatá; cinereo-fuscá, maculis viridibus variegatá, liris nigris interdum viridi interruptis, aperturæ fuuce cærulescente-albá.

THE VARIEGATED BUCCINUM. Shell oblong-ovate, spire sharp, whorls rather depressed at the upper part,

encircled with fine superficial ridges; columella excavated, furnished with a callous ridge at the upper part, channelled above; ashy brown, variegated with blotches of light green, ridges black, sometimes interrupted with green, interior of the aperture pale blueish white. Le Tafon, Adanson.

Potlia variegata, Gray, Zool. Beechey's Voyage p. 112. Buccinum viverratum, Kiener.

Hab. Senegal.

I cannot recognise with M. Deshayes the propriety of naming this species Buccinum Tafon; the french word Tafon, given to it by Adanson, will not assist the Latin binomial in a grammatical sense.

Species 49. (Mns. Cuming.)

Buccinum gemmatum. Buc. testá ovatá, crassá, spirá breviusculá, acutá; anfractibus longitudinaliter subobsoletè plicatis, supernè depressiusculis, transversim striatis, liris peculiariter interruptis undique cingulatis; columella, subverrucosa, excavata, lirá callosa supernè munitá, supra canaliculatá, aperturæ fauce sulcatá et crenatů; ferrugineo-fusců, maculis albis variegatů, liris interruptis conspicuè atris, columella et apertura fauce

THE JEWELLED BUCCINUM. Shell ovate, thick, spire rather short, sharp; whorls longitudinally obsoletely plicated, slightly depressed round the upper part, tranversely striated, encircled throughout with peculiarly interrupted ridges; columella a little warty, excavated, furnished with a callous ridge at the upper part, channelled above, interior of the aperture grooved and crenated; rusty brown, variegated with blotches of white, interrupted ridges conspicuously jet black, columella and interior of the aperture

Hab. Monte Christi, West Columbia (in clefts of the rocks); Cuming.

A very striking species of which the transverse jet beads remind one of the irridiscent Turbinella prismatica. M. Kiener figures it for the female B. undosum.

Species 50. (Mus. Cuming.)

Buccinum pagodus. Buc. testá orato-fusiformi, spirá acuminata, anfractibus supernè depressè rotundatoangulatis, apicem versus concentricè tuberculatis, liris irregularibus undique cingulatis; columellá subexcavatá, lirá callosá parvá supernè munitá, aperturæ fauce sulcatá et crenatá; castaneo-fusco undique tinctá et variegatá, columellá et aperturæ fauce cærulescentealbis.

THE PAGODA BUCCINUM. Shell ovately fusiform, spire acominated, whorls depressly rotundately angulated round the upper part, concentrically tubercled towards the apex, encircled throughout with irregular ridges; columclla a little excavated, furnished at the upper part with a small callous ridge, interior of the aperture grooved and crenated; stained and variegated throughout with chesnut-brown, columella and interior of the aperture pale blueish white.

Hab. Island of Taboga, Bay of Panama (in clefts of the rocks at low water); Cuming.

An elegantly formed species of which Mr. Cuming only collected one or two specimens.

Species 51. (Fig. a, b, c. Mus. Cuming.)

BUCCINUM PROTEUS. Buc. testá subfusiformi-ovatá, spirá subacutá, anfractibus longitudinaliter plicato-costatis, transversim creberrime liratis et striatis; columella subexcavatá, supernè callositate parvá munitá, aperturæ fauce sulcatá et crenatá; albidá aut lutescente, fusco tinctá, zoná albidá medio formante, tiris costas super fusco saturatioribus.

THE PROTEAN BUCCINUM. Shell somewhat fusiformly ovate, spire sharp, whorls longitudinally plicately ribbed, transversly very closely ridged and striated; columella a little excavated, furnished with a small callosity at the upper part, interior of the aperture grooved and crenated, whitish or yellowish, stained with brown so as to leave a central white band, ridges stained with darker brown on crossing the ribs; lip tinged with orange.

Hab. Ceylon and the Philippine Islands.

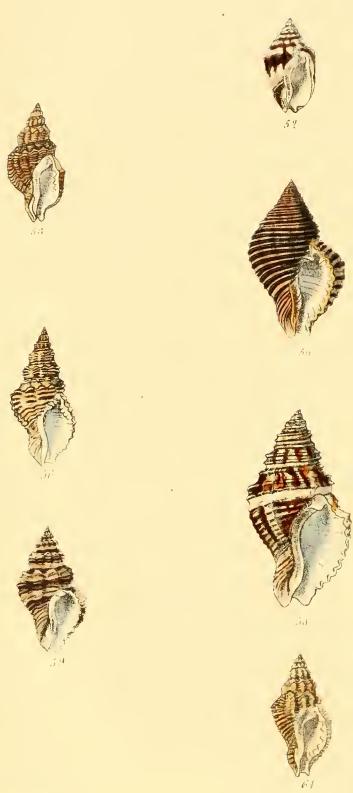

Variety B. Fig. 51. b.

Testa undique vividè crocea. Shell bright yellow throughout.

Hab. Australia.

The brown colouring of Var. α is much darker in some specimens than in others; in Var. 3. from Anstralia the colour is one uniform delicate bright yellow

 $\theta \epsilon$

PLATE VIII.

Species 52. (Mus. Cuming.)

Buccinum avellana. Buc. testú subabbreviato-ovatá, crassá, solidá, spirá brevi, anfractibus supernè rudè plicato-nodosis; columellá subexcavatá, labro simplici; albidá, castaneo nigroque irregulariter tinctá et fasciatá, columellá et aperturæ fauce albis.

The filbert-nut Buccinum. Shell somewhat abbreviately ovate, thick, solid, spire short, whorls rudely plicately noduled round the upper part; columella a little excavated, lip simple; whitish, irregularly stained and banded with chesnut and black, columella and interior of the aperture white.

Hab. North Coast of New Holland; Dring.

A heavy solid shell of rude structure and somewhat irregular style of painting.

Species 53. (Mus. Cuming.)

Buccinum contractum. Buc. testá subjusiformi, basi contraclá et canaliculatá, canali subrecurvo; anfractibus transversim conspicuè elevato-striatis, longitudinaliter plicato-costalis, supernè angulatis, costis ad angulum nodosis, labro intus noduloso; ferrugineofusco variá, columellá et apertura fauce albis.

The contracted Buccinum. Shell somewhat fusiform, contracted and canaliculated at the base, canal slightly recurved; whorls transversely conspicuously elevately striated, longitudinally plicately ribbed, ribs nodose at the angle, lip nodose within; variegated with rusty brown, columella and interior of the aperture white.

Hab. Island of Samar, Philippines (in sandy mnd at the depth of eight fathoms); Cuming.

On the left side of the last whorl is a fully developed varix, imparting a *Ranella*-like appearance to the shell which I have not noticed in the description fearing it may be of inconstant occurrence.

Species 54. (Mus. Cuming.)

Buccinum anomalum. Buc. testa gracili-fusiformi, spira acuta, anfractibus longitudinaliter costatis, costis angustis, numerosis, tranversim liratis, liris acutis, tenuibus, regularibus, labro intus minute noduloso; rosaceo-

albá, fuscescente fasciatim tinctá et maculatá, aperturæ fauce rosuceo-albá.

The anomalous Buccinum. Shell slenderly fusiform, spire sharp, whorls longitudinally ribbed, ribs narrow, numerous, transversely ridged, ridges sharp, thin, regular, lip minutely noduled within; pink-white, stained and spotted in bands with light brown, aperture pink-white.

Hab. — ?

Partaking also of the character of both Murex and Fusus.

Species 55. (Mus. Cuming.)

Buccinum undosum. Buc. testá ovatá, crassá, spirá acutá, anfractibus longitudinaliter subobsoletè plicatis, liris undosis conspicuis undique creberrimè cingulatis; columellá subexcavatá, apertura fance sulcatá et crenatá; aurantio-albidá, liris olivaceo-nigris, columellá et apertura fance ulbis, margine vividè aurantio-luteis.

The waved Buccinum. Shell ovate, thick, spire sharp, whorls longitudinally somewhat obsoletely plicated, very closely encircled throughout with conspicuous waved ridges; columella a little excavated, interior of the aperture grooved and crenated; orange-white, ridges olive-black, columella and interior of the aperture white, edge bright orange yellow.

Buccinum undosum, Linnæus, Syst. Nat. (12th. edit.) p.

Nassa undosa, Martini.

Triton undosum, Lamarck.

Variety, Buccinum affine, Gmelin.

Hab. Straits of Malacca; Australia; Philippine and Society Islands; Cuming.

The errors which M. Kiener has committed in reference to this ancient and well known species, have been so fully exposed by M. Deshayes, that it is unnecessary here to recur to them, except for the sake of noticing that the shell figured by him, under some new dogma, as a sexual variety characteristic of the female, appears to be the B. gemmatum, Sp. 49. found in a locality which the B. undosum does not inhabit. Lamarck referred the B. undosum to the genus Triton in consequence of having incidentally met with a specimen in which a varix had been deposited on the last whorl, in a manner similar to that just spoken of in the B. contractum, Sp. 43.

Species 56. (Mus. Cuming.)

Buccinum ustulatum. Buc. testá subfusiformi-ovatá, spira acuminata; anfractibus transversim undique creberrimè liratis, liris angustis, acutis, longitudinaliter rude plicatis, leviter tuberculatis; alba, aurantio-fusco tinctá et maculatá, aperturæ fauce albá.

THE SINGED BUCCINUM. Shell somewhat fusiformly ovate, spire acuminated; whorls transversely very closely ridged throughout, ridges narrow, sharp, longitudinally rudely plicated, slightly tubereled; white stained and spotted with orange brown, interior of the aperture white.

Hab. ----?

An interesting species of new form and colouring.

Species 56. (Mus. Metcalfe.)

Buccinum ligneum. Buc. testá ovatá, anfractibus transversim tenuè funiculatis, longitudinaliter varicosis, varicibus solidis, tuberculatis; aperturæ fauce sulcatá et crenatá; luteo-fuscescente, castaneo-fusco fasciatim maculată, funiculis fuscis.

THE WOODEN BUCCINUM. Shell ovate, whorls transversely finely eorded, longitudinally varicose, varices solid, tuberculated; interior of the aperture grooved and crenated; yellowish brown, stained with bands of brown blotches, cords brown.

Hab. ---- ?

The longitudinal plicated growth of this shell is deposited in varices throughout the last whorl, partaking very much in this respect of the generic character of Murex.

Species 58. (Mus. Cuming.)

Buccinum insignis. Buc. testá fusiformi-ovatá, subventricosa, anfractibus supernè leviter depressis, transversim undique irregulariter liratis et sulcatis; columellá supernè lirá callosá munitá, supra canaliculatá, aperturæ fauce sulcatá; albá, castaneo-fusco variegatá.

THE REMARKABLE BUCCINUM. Shell fusiformly ovate, somewhat ventricose, whorls slightly depressed round the upper part, transversely irregularly ridged and grooved throughout; columella furnished at the upper part with a callous ridge, channelled above, interior of the aperture grooved; white, variegated with chesnut-brown.

Hab. St. Elena, West Columbia (in the elefts of rocks at low water); Cuming.

A fine species eneireled throughout hy grooves and ridges of a peculiar style of carving.

Species 59. (Mus. Cuming.)

Buccinum Balteatum. Buc. testá subfusiformi-ovatá, spira acuta, anfractibus transversim liratis, longitudinaliter creberrimè tuberculato-costatis, aperturæ fauce sulcatá; lutescente-albá, nigricante-fusco balteatá, costarum interstitiis supernè fusco tinctis.

THE BELTED BUCCINUM. Shell somewhat fusiformly ovate, spire sharp, whorls transversely ridged, longitudinally very closely tubereularly ribbed, interior of the aperture grooved; yellowish-white, belted with blackish brown, interstices between the ribs stained with brown.

Hab. Torres Straits.

Distinguished by the frequency of the broad longitudinal ribs and characteristic style of painting.

Species 60. (Mus. Cuming.)

Buccinum amygdala. Buc. testá oblongo-ovatá, crassá, solidá, spirá brevi, acutá; anfractibus longitudinaliter obtuse costatis, transversim creberrime incisis, liris intermediis obtusis, subtilissime squamatis; columella superne callosa et canaliculata; aurantio-fuscescente, castaneo basi tinctà, columellà et aperturæ fauce aurantio-lacteis.

THE ALMOND BUCCINUM. Shell obloug-ovate, thick, solid, spire short, acute; whorls longitudinally obtusely ribbed, transversely very closely cut, intermediate ridges obtuse and very finely sealed; eolumella callous and channelled at the upper part, orange brown, stained at the base with chesnut, columella and interior of the aperture orange eream colour.

Purpura amygdala, Kiener, Ieon. eoq. viv. pl. x. f. 26.

Hab. North coast of New Holland.

Very peculiar in form and general appearance, and easily distinguished by its minute squamate sculpture.

Species 61. (Mus. Metcalfe.)

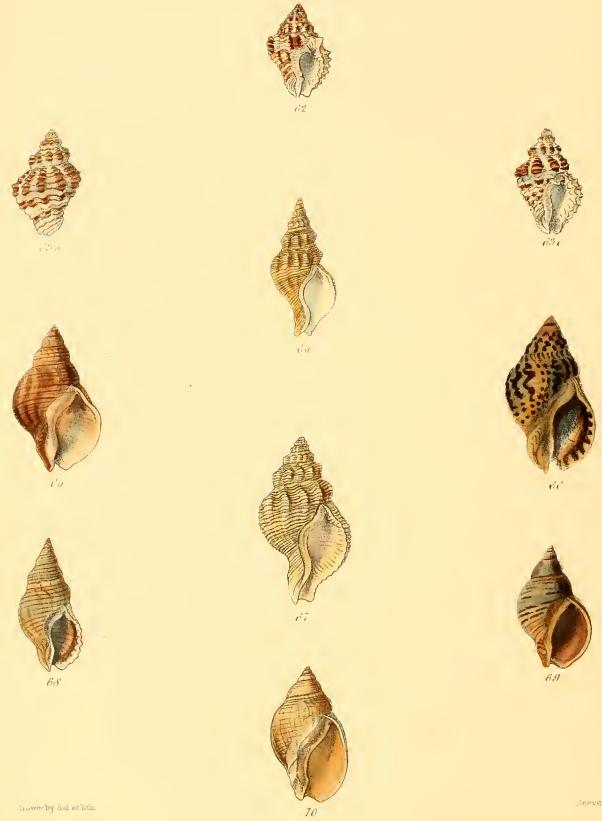

BUCCINUM FUNICULATUM. Buc. testá fusiformi, basi recurvá, anfractibus supernè subangulatis, longitudinaliter rudè costatis, costis ad angutum nodosis, transversim undique funiculatis: albida, funiculis fuscescentibus, pone costas nigris.

THE CORDED BUCCINUM. Shell fusiform, recorved at the base, whorls slightly angulated at the upper part, lougitudinally rudely ribbed, ribs nodose at the angle, transversely corded throughout; whitish, eords brown, black behind the ribs.

Hab. ---- ?

Peculiar in having the corded ridges scarcely coloured except at the back of the ribs, where they are jet black.

deevenip

PLATE IX.

Species 62. (Mus. Taylor.)

Buccinum Coromandelianum. Buc. testă ovată, crassă, subcompressă, spiră breviusculă; anfractibus superne depressis, infra nodoso-plicatis, transversim subtiliter liratis et striatis, columellă labroque intus sulcatis et corrugatis; albidă, aurantio-fusco tinctă et maculată.

THE COROMANDEL BUCGINUM. Shell ovate, thick, somewhat compressed round the upper part, nodosely plicated beneath, transversely ridged and striated, lip and columella grooved and wrinkled within; whitish, stained and blotched with orange-brown.

LAMARCK, Anim. sans vert. (Deshayes' edit.) vol.x. p. 169. Hab. Coromandel; Panama; Cuming.

The specimen here figured is remarkable for its bright blotches of colouring, the species generally having a much more sombre appearance.

Species 63. (Mus. Taylor.)

Buccinum lautum. Buc. testá ovatá, anfractibus transversim liratis, liris conspicuis, angustis, subdistantibus, longitudinaliter fortiter costatis, costis nodosis; columellá labroque corrugatis et sulcatis; albá, rubroaurantio costas super vivide maculatá.

THE GAY BUCCINUM. Shell ovate, whorls transversely ridged, ridges conspicuous, narrow, rather distant, longitudinally strongly ribbed, ribs nodose; lip and columella wrinkled and grooved; white, vividly blotched with red-brown upon the ribs.

Hab. ——?

A prettily coloured species, in which the sculpture is developed with peculiar force.

Species 64. (Mns. Cuming.)

Buccinum Fusoides. Buc. testá fusiformi, basi contortá et recurvá, spirá acuminatá; anfractibus medio obtusè angulatis, ad angulum eleganter nodosis, transversim creberrimè liratis, liris subtilibus, leviter undulatis; fuscescente, fusco hic illic flammulatá.

The Fusus-like Buccinum. Shell finiform, twisted and recurved at the base, spire acuminated; whorls obtusely angled in the middle, elegantly noduled at the angle, transversely very closely ridged, ridges fine, slightly undulated; light brown, stained here and there with brown flames.

Hab. —— ?

Of a character similar to that of the group figured in Plate II.

Species 65. (Mus. Taylor.)

Buccinum effusum. Buc. testá ovato-conicá, tenui, inflatá, spirá breviusculá autem elevatá; anfractibus obscurè planiliratis et minutè striatis, labro simplici, effuso; castaneo-fuscá,

THE EFFUSED BUCCINUM. Shell ovately conical, thin, inflated, spire rather short but clevated, whorls obscurely flatly ridged and minntely striated; lip simple, effused; chesnut-brown.

Hub. ---- ?

The ridges of this species are of quite a superficial character.

Species 66. (Mus. Taylor.)

Buccinum testudineum. Buc. testá ovatá, basi subcontortá, spirá subobtusá, anfractibus supernè depressiusculis, lævigalis; cinereá, nigerrimo-fusco tessellatá et flammatá; columellá rufescente-aurantiá, aperturæ fauce purpureo-nigricante.

The tortoise-shell Buccinum. Shell ovate, somewhat twisted at the base, spire rather obtuse, whorls rather depressed at the upper part, smooth; ash-colour, tessellated and flamed with black-brown; columella reddish orange, interior of the aperture purple-black.

Martyn, Universal Conch. vol. i. pl. 8. Hab. New Zealand.

The *B. maculatum* has been regarded by most writers as a variety of this species, but M. Deshayes considers that the animals vary sufficiently with the shells to allow of their being separated.

Species 67. (Mus. Cuming.)

Buccinum modificatum. Buc. testá subobeso-fusiformi, basi contortá et recurvá, anfractibus supernè subangulatis, ad angulum eleganter plicato-nodosis, transversim creberrimè liratis, liris parvis, angustis, leviter undulatis; pallidè luteo-fuscescente.

THE MODIFIED BUCCINUM. Shell somewhat stoutly fusiform, contorted and recurved at the base, whorls slightly angulated towards the upper part, elegantly plicately noduled at the angle, transversely very

December, 1846.

closely ridged, ridges small, narrow, slightly waved; pale yellowish brown.

Hab. ——?

This is another species of the peculiar form of that figured above it, and of those represented in Plate II.; the detail of sculpture is the same in a modified form.

Species 68. (Mus. Taylor.)

Buccinum obscurum. Buc. testá pyramidali-ovatá, anfractibus supernè depressiusculis, tævigatis aut transversim obscurè liratis; plumbeo-albicante, aperturæ fauce purpureo-fuscá.

The obscure Buccinum. Shell pyramidally ovate, whorls rather depressed round the upper part, smooth or transversely obscurely ridged, leaden white, interior of the aperture purple-brown.

Hab. ——?

Having somewhat the general aspect of a Planaxis.

Species 69. (Mus. Cuming.)

Buccinum cyaneum. Buc. testá oratá, tenui, subinflatá, spirá breviusculá, lævigatá aut obscurè incisá, labro

simplici, subeffuso; plumbeá, maculis perpaucis fuscis oblongis tinctá, aperturæ fauce castaneo-fuscá.

THE AZURE BUCCINUM. Shell ovate, thin, somewhat inflated, spire rather short, smooth or obsoletely engraved, lip simple, effused; lead colour, stained with a very few transversely oblong spots, interior of the aperture chesnut brown.

MULLER; Gray MSS. British Museum.

Hab. ----?

A light thin shell of a dull leaden colour exteriorly, and of a deep chesnut interiorly.

Species 70. (Mus. Taylor.)

Buccinum citrinum. Buc. testá ovatá, basi truncatá et latè emarginatá, spirá breviusculá, anfractibus convexis, lævigatis, ætate rugosis; columellá brevi, labro tenui, simplici; pallidè luteo-aurantiá.

THE CITRON-COLOURED BUCCINUM. Shell ovate, truncated and widely emarginated at the base, spire rather short, whorls convex, smooth, rough with age, columella short, lip thin, simple; pale yellowish orange.

Hab. ----?

Of rather an aberrant form, and which M. D'Orbigny has, I believe, proposed for the type of a new genus.

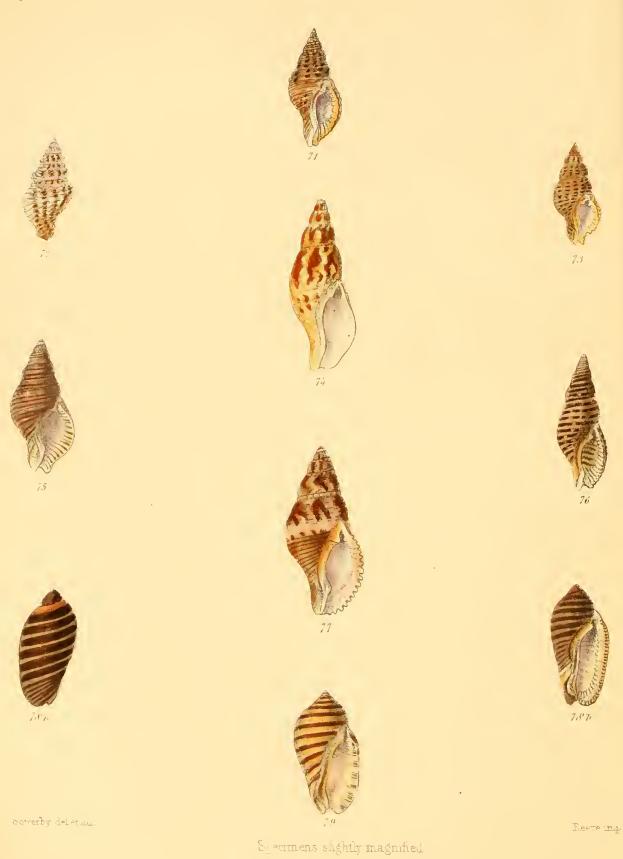

PLATE X.

Species 71. (Mus. Cuming.)

- Buccinum biuratum. Buc testá fusiformi, basi subcontractá, leviter recurvá; anfractibus liris subtilibus binis undique cingulatis, interstitiis minutè cancellatis; labro crenato; lutescente, castaneo marmoratá.
- THE DOUBLE RIDGED BUCCINUM. Shell fusiform, somewhat contracted and a little recurved at the base; whorls encircled throughout by pairs of fine ridges, the interstices between which are minutely cancellated; lip crenated; yellow, marbled with chesnut.

Hab. Gallapagos Islands; Cuming.

An elegantly sculptured fusiform species with a varicose lip like the small Tritons.

Species 72. (Mus. Cuming.)

- Buccinum concentricum. Buc. testâ fusiformi, basi contortă, anfractibus crebrè concentrice costatis, costis liris acutis striisque decussatis, liris costas super mucronatis; carulescente-albâ, rufo-fusco variegatâ.
- THE CONCENTRIC BUCCINUM. Shell fusiform, a little twisted at the base, whorls closely concentrically ribbed, ribs crossed with sharp ridges and strice, ridges pointed on the ribs; blueish white, variegated with red-brown.

Hah ----- 2

The red-brown colouring is mostly in the interstices between the ribs.

Species 73. (Mus. Cuming,)

- Buccinum nigricostatum. Buc. testá subfusiformi, basi recurvá, spirá acuminatá; anfractibus concentricè costatis, funiculis subtilibus undique cingulatis; aperturá parvá; olivaceo-luteá, costis nigris.
- THE BLACK-RIBBED BUCCINUM. Shell nearly fusiform, recurved at the base, spire acuminated; whorls concentrically ribbed, encircled throughout with fine cords; aperture small; olive yellow, ribs black.

Hab. Panama (under stones at low water); Cuming.

Easily to be recognized by its dark concentric ribs.

Species 74. (Mus. Cuming.)

Buccinum pictum. Buc. testá elongato-ovatá, basi truncatá, tenuiculá, lævigatá, labro simplici, subeffuso; luteoalbicante, rufo-castaneo maculatá et flammatá. THE PAINTED BUCCINUM. Shell clongately ovate, truncated at the base, rather thin, smooth, lip simple, slightly effused; yellowish white, spotted and flamed with reddish chesnut.

Tritonium buccinulum, Martini Conch. Cab. vol. iv. p. 72. pl. 127. f. 1217.

Hab. Island of Capul, Philippines (on the reefs); Cuming.A smooth handsomely painted species, described by Martini in 1780, and since left in obscurity.

Species 75. (Mus. Cuming.)

- Buccinum cingulatum. Buc. testå acuminato-ovatå, basi leviter recurvå, lævigatå, aperturå parvå, labro subeffuso; plumbeo-fuscå, lineis nigris undique cingulatå.
- The encircled Buccinum. Shell acuminately ovate, slightly recurved at the base, smooth, aperture small, lip a little effused; leaden-brown, encircled throughout with black lines.

Hab. — ?

The lines which encircle this shell exist only in colour, but are nevertheless seen within the lip.

Species 76. (Mus. Cuming.)

- Buccinum fasciculatum. Buc. testá elongato-ovatá, basi truncatá, lævigatá, politá, obsoletè liratá, liris apicem versus distinctioribus; labro subincrassato, minutè crenulato; aurantiá, tæniis nigris angustis hic illic albipunctatis regulariter cingulatá.
- The finely-banded Buccinum. Shell elongately ovate, truncated at the base, smooth, polished, or obsoletely ridged, ridges more distinct towards the apex; lip rather thickened, minutely crenulated; orange, regularly encircled with narrow black fillets, dotted here and there with white.

Hab. Island of Mindanao, Philippines; Cuming.

The dark fillets of this beautiful species are clevated in ridges on the first one or two whorls, and gradually become obsolete towards the margin.

Species 77. (Mus. Cuming.)

Buccinum Tritonoides. Buc. testá elongato-ovatá, subventricosá, basi truncatá, anfractibus lævibus, aut obsoletè transversim incisis, labro subeffuso, crenulato; rufo undique maculatá et variegatá. The Triton-shaped Buccinum. Shell clongately ovate, rather ventricose, truncated at the base, whorls smooth or obsoletely transversely engraved, lip somewhat effused, crenulated; blotched and variegated throughout with dark red.

Hab. Island of Ticao, Philippines; Cuming.

Allied in form to the species figured above it, but quite distinct in detail.

Species 78. (Mus. Cuming.)

Buccinum tæniatum. Buc. testá oblongo-ovatá, spirá brevissimá, anfractu ultimo peroblongo, transversim tenuissimè elevato-striato, columellá plano-excavatá, callositate parvá supernè munitá, labro intus minute denticulato; castaneo-fuscá, tæniis angustis fulvo-aurantiis regulariter cingulatá.

The filleted Buccinum. Shell oblong-ovate, spire very short, last whorl very oblong, transversely very finely elevately striated, columella flatly excavated, furnished at the upper part with a small callosity, lip minutely denticulated within; chesnut brown, regularly encircled with narrow fulvous orange fillets. Purpura taniata, Powis, Proceedings Zool. Soc., 1835. p. 96. IIab. Maldon Island, Pacific Ocean; Frembly.

I refer this species to *Buccinum* on account of the callosity and denticles at the upper extremity of the aperture.

Species 79. (Mus. Cuming.)

Buccinum vexillum. Buc. testá oblongo-ovatá, spirá brevissimá, acutá, anfractu ultimo peroblongo, lævigatá aut transversim minutissimè incisá; columellá plano-excavatá, callositate parvá supernè munitá, labro intus minutè denticulato; rufo-aurantiá, fasciis angustis nigris regulariter cingulatá.

The flag Buccinum. Shell oblong-ovate, spire very short, sharp, last whorl very oblong, smooth or very minutely transversely engraved; columella flatly excavated, furnished at the upper part with a small callosity, lip minutely denticulated within; reddishorange, regularly encircled with narrow black bands.

Strombus vexillum, Chemnitz, Conch. Cab. vol. x. p. 222. pl. 157. f. 1504, 1505.

Purpura vexillum, Lamarck. Cassidaria vexillum, Kiener.

Hab. Island of Ticao, Philippines; Cuming.

Anthors have been somewhat divided as to the generic situation of this singular species, which I have referred to *Buccinum* for the same reason given in reference to the preceding. M. Kiener's appropriation of it is inconsistent.

PLATE XI.

Species 80. (Mus. Cuming.)

Buccinum pulchrum. Buc. testa ovata, medio gibbosa, utrinque attenuata, anfractibus longitudinaliter fortiter tuberculato-costatis, transversim striatis, costas super liratis, labro intus denticulato; cæruleo-olivacea.

The pretty Buccinum. Shell ovate, gibbous in the middle, attenuated at both ends, whorls longitudinally strongly tubercularly ribbed, transversely striated, ridged across the summit of the ribs; lip denticulated within; blueish olive, banded with black, short ridges white, interior of the aperture violet.

Hab. Gallapagos Islands; Cuming.

The colouring of this species is very characteristic; a livid olive or green crossed by narrow black bands passing between short white ridges surmounting the ribs.

Species 81. (Mus. Metcalfe.)

Buccinum solidum. Buc. testā ovatā, crassā, solidā, basi leviter recurvā, spirā acuminatā; anfractibus rotundatis obscurē plicato-costatis, transversim subobsoletē liratis, interstitiis minutissimē incisis; aperturā parvā, fauce sulcatā; sordidē albā, maculis quadratis nigris inter costas uniseriatim cinctā, aperturæ fauce tuteā.

The solid Buccinum. Shell ovate, solid, slightly recurved at the base, spire acuminated; whorls rounded, obscurely plicately ribbed, transversely rather obsoletely ridged, interstices very minutely engraved; aperture small, interior grooved; dead white, encircled with a single row of square black spots between the ribs, interior of the aperture yellow.

Hab. Island of Capul, Philippines; Cuming.

Easily recognised by the central row of square black spots; the columella is obscurely plaited, presenting a link with *Turbinellus*.

Fig. 82 proves on further examination to be identical with Sp. 54. For Sp. 82 see Plate XIII.

Species 83. (Mus. Cuming.)

Buccinum rapulum. Buc. testá oblongo ovatá, solidiusculá, basi contractá, contortá et recurvá, lævigatá, basi striatá; albá, epidermide lutescente indutá.

THE LITTLE TURNIP BUCCINUM. Shell oblong-ovate,

rather solid, contracted, twisted and recurved at the base, smooth, striated at the base; white, covered with a yellowish epidermis.

Hab. Malacea.

A stout smooth shell of a form rather foreign to the present genus, though irreferable to any other.

Species 84. (Mus. Cuming.)

Buccinum cinis. Buc. teslá pyramidali-ovatá, basi leviter recurvá, anfractibus granulis rugosis undique seriatim decussatis, aperturæ fance sulcatá, supernè callositatibus munitá; cærulescente-albá, granulis atris.

THE CINDER BUCCINUM. Shell pyramidally ovate, slightly recurved at the base, whorls decussated throughout with rows of rough granules, interior of the aperture grooved, furnished with eallosities at the upper part; blueish white, granules jet black.

Hab. Gallapagos Islands (under stones); Cuming.

The granules of this shell impart a rough touch to it, resembling that of a coal einder.

Species 85. (Mus. Cuming.)

Buccinum maculosum. Buc. testá ovatá, crassá, lævigatá, transversim tenuissimè et creberrimè incisá; columeltá minutè denticulatá, supernè callosá, labro intus denticulato; olivaceo-fuscá, albo profusè et irregulariter striuatá et maculatá.

The spotted Buccinum. Shell ovate, rather thick, smooth, transversely very finely and closely engraved; columella minutely denticulated, callous at the upper part, lip denticulated within; olive-brown, profusely and irregularly streaked and spotted with white.

LAMARCK, Anim. sans vert. (Deshayes' edit.), vol. x. p. 164. Voluta striata, Gmelin.

Purpura variegata, Schubert and Wagner.

Purpura Gualtieri, Scaeelii.

Purpura maculosa, De Blainville, Kiener.

Eadem, varietas fasciolata.

Purpura fasciolaris, Lamarek.

Hab. Mediterranean.

Dr. Philippi has expressed his opinion in 'Wiegman's Archives', that this species is without doubt (absque ullo dubio) the *Buccinum pusio* of Linnæus; I have, however,

through the kindness of Mr. Hanley in drawing my attention to it, identified that species with Lamarek's Fusus articulatus by an examination of the very specimen, in the collection of our Linnæan Society, from which the diagnose in the 'Systema Naturæ' was drawn up. It is a specimen of immature growth, in which the dark spots are disposed in longitudinal streaks, in a manner very similar to a figure of the species in Bonanni, to which Linnæus refers. Gmelin appears to have been the first to notice the B. macutosum under the title of Votuta striata, a name which cannot be used as a specific with the present genus, in consequence of its having been already made use of by his predecessors Martyn and Gronovius. M. Deshayes quotes the Voluta Syracusana of Gmelin as synonymous with the present species; but this is unsatisfactory inasmuch as Gmelin refers to the same figure in Bonanni, beyond doubt Lamarck's F. articulatus, as Linnæus does for the B. pusio, and his description agrees with that species although it is equally unfavourable in respect of locality.

Species 86. (Mus. Cuming.)

Buccinum distortum. Buc. testá ovatá, crassissimá, ponderosá, spirá brevi, desessá; anfractibus lævibus, apicem versus sulcatis et nodosis, ultimo basi inciso, supernè rotundato, distortè elevato, ad aperturam in alam sinuatam extenso; cotumellá subexcavatá, corrugatá, labro intus sulcato; albá, castaneo-fusco profusè tinctá et variegatá.

The distorted Buccinum. Shell ovate, very thick, ponderous, spire short, sunken; whorls smooth, grooved and noduled towards the apex, last whorl engraved, rounded at the upper part, distortedly elevated, extended at the aperture into a kind of sinuated wing; columella alittle excavated, wrinkled, lip grooved within; white, profusely stained and variegated with chesnut brown.

Gray, Wood's Index Test. Supp. pl. 4. f. 7.

Hab. Punto, St. Elena, West Columbia; Cuming.

A species of enriously distorted growth, reminding one very much of the remarkable *Turbinella*-like shell described by Mr. Hinds in the 'Zoology of the Sulphur' as the type of a new genus, under the name of *Cyrtulus*.

Species 87. (Mns. Cuming.)

Buccinum lividum. Buc. testá subfusiformi-ovatá, an-

fractibus transversim creberrimè elevato-striatis, medio angulatis, ad angulum compressè nodosis; labro intus denticulato; livido-fuscá, variegatá, aperturæ fauce fuscá

The LIVID BUCCINUM. Shell somewhat fusiformly ovate, whorls transversely very closely elevately striated, angulated in the middle, compressly nodose at the angle; lip denticulated within, livid brown, variegated, interior of the aperture brown.

Hab. Island of Negros, Philippines; Cuming.

This and the following species belong rather to the denticulated group which I have introduced under the head of *Ricinula*.

Species 88. (Mus. Cuming.)

Buccinum bimucronatum. Buc. testá ovatá, subfusiformi, anfractibus transversim rudè liratis, medio angulatis, ad angulum biseriatim nodosis, nodis acutè mucronatis; labro intus denticulato; cinereo-fuscá.

THE DOUBLE-POINTED BUCCINUM. Shell ovate, somewhat fusiform, whorls transversely rudely ridged, angulated in the middle, encircled with two rows of sharp pointed nodules at the angle; lip denticulated within; ashy brown.

Hab. Philippines; Cuming.

A stouter shell than the preceding, and more sharply noduled.

Species 89. (Mus. Cuming.)

Buccinum pastinaca. Buc. testá ovatá, crassiusculá, spiræ suturis excavatis, anfractibus rotundatis, longitudinaliter creberrimè plicato-costatis, costis latiusculis, liris transversis acutis decussatis; columeltá minute corrugatá, aperturá subrotundá, fauce sutcatá; albá, epidermide flavescente indutá.

THE PARSNIP BUCCINUM. Shell ovate, rather thick, sutures of the spire excavated, whorls rounded, longitudinally very closely plicately ribbed, ribs rather broad, crossed with sharp transverse ridges; columella minutely wrinkled, aperture nearly round; white covered with a yellowish epidermis.

Hab. Bay of Montija, West Columbia; Cuming.

A distinct varix is formed at the lip of this shell after the manner of some of the *Tritons*.

PLATE XII.

Species 90. (Mus. Cuming.)

Buccinum assimile. Buc. testá ovatá, parvá, transversim creberrimè liratá, longitudinaliter subobsoletè concentricè costatá; lutescente, purpureo-fusco variegatá.

The similar Buccinum. Shell ovate, small, transversely very closely ridged, longitudinally rather obsoletely concentrically ribbed; yellowish, variegated with purple-brown.

Hab. ——?

Very closely allied to the B. D'Orbignyi of the Mediterranean, but seemingly distinct.

Species 91. (Mus. Cuming.)

Buccinum obliquicostatum. Buc. testá fusiformi, basi subrecurvá, longitudinaliter obliquè et creberrimè costatá, costis liris parvis decussalis; labro incrassalo; fusco-rufá, liris transversis subalbidis.

The obliquely ribbed Buccinum. Shell fusiform, recurved at the base, longitudinally obliquely and very closely ribbed, ribs crossed with small ridges; lip thickened; brown-red, transverse ridges whitish.

Hab. Island of Ticao, Philippines; Cuming.

The first of a peculiar fusiform group of which the species represented at Fig. 95, 96 and 97 also belong.

Species 92. (Mus. Cuming.)

Buccinum dirum. Buc. testá fusiformi, basi leviter recurrá, anfractibus rotundatis, striis rugosis conspicuis elevatis undique cingulatis, aperturæ fauce sulcalá; intus extusque sordidè fuscá.

The dismal Buccinum. Shell fusiform, slightly recurved at the base, whorls rounded, encircled throughout with conspicuous elevated rough striæ, interior of the aperture grooved; dull brown within and without.

Hab, ---- ?

The strize with which the entire surface of this species is engraved almost assume the character of fine ridges.

Species 93. (Mus. Taylor.)

Buccinum eburneum. Buc. testá pyramidali-ovatá, spirá acutá, anfractibus supernè concavis, ad angulum nodosis, infra obscurè liratis, aperturá breviusculá; intus extusque eburneá, epidermide viridi-luteá indutá. THE IVORY BUCCINUM. Shell pyramidally ovate, spire sharp, whorls concave round the upper part, nodose at the angle and obscurely ridged hencath, aperture rather short; ivory white within and without, covered with a greenish yellow epidermis.

Hab. ——?

A pure white pyramidal shell.

Species 94. (Mus. Taylor.)

Buccinum Littorinoides. Buc. testâ fusiformi, basi subrecurvâ, lævigatâ, labro simplici; olivaceo-fuscâ, obscurè lineatâ, aperturæ fance pallidè carneâ.

THE PERIWINKLE-LIKE BUCCINUM. Shell fusiform, a little recurved at the base, smooth, lip simple; olive-brown, obscurely lineated, interior of the aperture pale flesh-colour.

Hab. New Zealand; Earl.

A smooth sombre looking shell eneircled with faint lines.

Species 95. (Mus. Cuming.)

Buccinum marmoratum. Buc. testú subelongato-fusiformi, basi recurvá; anfractibus convexis, liris subtilibus obtusis granosis longitudinalibus et transversis decussatis; rosaceo-albá, rubido-fusco conspicuè marmoratú.

THE MARBLE BUCCINUM. Shell somewhat elongately fusiform, recurved at the base; whorls convex, crossed throughout with fine obtuse granulated ridges; piukish white, conspicuously marbled with reddish-brown.

Hab Island of Capul, Philippines; Cuming.

An interesting species constituting the type of a section of the genus, of which the two following form part.

Species 96. (Mus. Cuming.)

Buccinum gracile. Buc. testá gracili-fusiformi, basi canaliculatá et recurvá; anfractibus medio subangulatis, liris granosis obtusis longitudinalibus et transversis decussatis, labro intus minutè denticulato; albidá, granorum seriebus longitudinalibus aurantio-fuscis.

THE SLENDER BUCCINUM. Shell slenderly fusiform, channelled and recurved at the base; whorls a little angulated in the middle, crossed by longitudinal and

December, 1846.

transverse obtuse granose ridges, lip minutely denticulated within; whitish, longitudinal rows of granules orange-brown.

Hab. Island of Masbate, Philippine Islands, (under stones at low water); Cuming.

The granules at the angle are more prominent than the rest, and of rather darker colour.

Species 97. (Mus. Cuming.)

Buccinum crocatum. Buc. testá subelongato-fusiforni, basi canaliculatá et recurvá, longitudinaliter creberrimè plicatá, transversim granoso-liratá, labro intus minutè denticulato; croceo-aurantiá, hic illic albipunctatá, striis inter liras aurantio-fusco saturatiore.

The saffron-coloured Buccinum. Shell somewhat elongately fusiform, channeled and recurved at the base, longitudinally very closely plicated, transversely granosely ridged, lip minutely denticulated within; saffron-orange, specked here and there with white, striæ between the ridges of a darker orange brown.

Hab. Island of Capul, Philippines; Cuming.

More deeply coloured than either of the preceding species of this form.

Species 98. (Mus. Cuming.)

Buccinum trilineatum. Buc. testá abbreviato-fusiformi, basi subrecurvá, aufractibus apicem versus plicato-no-dosis, ultimo lævigato, aperturá subcontractá, fauce sulcatá; albidá, fasciis duabus, utráque lineis tribus cinereo-nigris compositá, cingulatá,

THE THREE-LINED BUCCINUM. Shell shortly fusiform, a little recurved at the base, whorls plicately noduled towards the apex, last whorl smooth, aperture somewhat contracted, interior grooved; whitish, encircled by two bands each of which is composed of three ashy-black lines.

Hab. ——?

Easily recognised by the bands of lines which are scareely sufficiently distinguished in the figure.

Buccinum PlXIII.

PLATE XIII.

Species 47. (Fig. Kiener.)

Buccinum discolor. Buc. testá parvá, Olivaformi, violaceo-griseá, transversim tennissimè striatá, spirá acutá, supernè plicis longitudinalibus distinctá; anfractibus convexiusculis; aperturá cinereá, ovatá; columellá lavi; labro dextro denticulato, intus plicato.

THE DISCOLOURED BUCCINUM. Shell rather small, Olive-shaped, voilet grey, transversely very finely striated, spire sharp, distinguished at the upper part by longitudinal plaits; whorls rather convex; aperture ash-colour, ovate; columella smooth; right lip denticulated, plaited within.

Quoy, and Gaimard, Voy. de l'Astrol. pl. 30. f. 23, 25. Hab. Island of Tonga-Tabou.

As this species has a characteristic appearance I venture to copy M. Kiener's figure and description of it; it is quite unknown to me.

Species 100. (Fig. Kiener.)

Buccinum Blainvillii. Buc. testá ovatá, elongatá, albescente; spirá acutá, cancellutá, costulis longitudinalibus et striis transversis decussatá; anfractibus angustis, in medio carinatis; aperturá ovatá, violascente; columellá rufescente; lubro dextro intus tenuè striato.

BLAINVILLE'S BUCCINUM. Shell ovate, clongated, whitish, spire sharp, cancellated, decussated with fine longitudinal ribs and transverse striæ; whorls narrow, keeled in the middle; aperture ovate, pale violet; columella reddish; right lip finely striated within.

Deshayes, Voy. Bellanger aux Indes Orientales.

Buccinum textum, Wood.

Buccinum cancellatum, Quoy and Gaimard.

Hab. Malabar.

This species I insert also on the authority of M. Kiener.

Species 101. (Mus. Cuming.)

Buccinum cingillum. Buc. testá ovatá, spirá breviusculá, spiræ suturis subprofundis; anfractibus convexis, creberrimè undiquè tenuisulcatis, aperturá oblongá; labro intus denticulato; rufo-castaneá, zonulá angustá albá medio cinctá.

THE LITTLE GIRDLE BUCCINUM. Shell ovate, spire

rather short, sutures of the spire rather deep, whorls convex, very closely finely grooved throughout; aperture oblong, lip denticulated within; reddish chesnut, encircled round the middle with a narrow white zone.

It should perhaps be observed that there is a small callosity at the upper part of the columella.

Species 102. (Mus. Cuming.)

Buccinum ferreum. Buc. testá acuminato-turritá, subfusiformi, anfractibus rotundatis, supernè leviter sulcatis; columellá subcoutortá, aperturæ fauce radiatim tenniliratá; cinereo-fuscá, nigro obscurè spiraliter lineatá.

The Iron Buccinum. Shell acuminately turreted, somewhat fusiform, whorls rounded, slightly grooved round the upper part; columella slightly twisted, interior of the aperture rayed with fine ridges; ashybrown, obscurely spirally lineated with black.

Hab. ---- ?

A smooth polished shell of an ashy slate colour, obscurely lineated throughout.

Species 103. (Mus. Cuming.)

Buccinum hydrophanum. Buc. testá oblongo-ovatá, tenui, subhyaliná, epidermide tenui virescente partim indutá; spirá productá, anfractibus rotundatis, lævibus aut tenuissimè concentricè striatis; columellá brevi, subtruncatá; cinereá uut livido-cærulescente, intus vividè ferrugineo-castaneá.

The hydrophanous Bucchum. Shell oblong-ovate, thin, somewhat hyaline, partially covered with a thin pale green epidermis; spire produced, whorls rounded, smooth or very finely concentrically striated; columella short, somewhat truncated; ash colour or livid blue, bright ferruginous chesnut within.

Hancock, Ann. and Mag. Nat. Hist. vol. xviii. p. 325. Hab. West Coast of Davis's Strait; Warham and Harrison.

A thin bright ferruginous brown shell more or less enveloped with that livid chalky coating, permeable to water, which is in a manner peculiar to Arctic species.

Species 104. (Mus. Cuming.)

Buccinum pyramidale. Buc. testå acuminato-turritá, spirá valdè productá; anfractibus supernè fortiter obliquè plicatis et corrugatis, aperturá breviusculá; albidá, ferrugineo-luteo tinctá.

The Pyramidal Buccinum. Shell acuminately turreted, spire very much produced; whorls strongly obliquely plicated and wrinkled round the upper part; aperture rather short; whitish, stained with rusty yellow.

Hab. --- ?

This appears to be distinct from any of the numerous varieties of *B. undatum*.

Species 105. (Mus. Cuming.)

Buccinum tubulosum. Buc. testá ovato-turritá, spirá acuminatá, valdè productá; anfractibus rotundatis, e suturis fortiter plicatis, transversim creberrimè tenuiliratis; aperturá brevi, rotundatá; luteo-fuscá, aperturæ fauce albidá, aurantio tinctá.

The tubulous Buccinum. Shell ovately turreted, spire acuminated, very much produced; whorls rounded, strongly plaited from the sutures, transversely very closely finely ridged; aperture short, rounded; yellowish-brown, interior of the aperture whitish, tinged with orange.

Hab. --- ?

Distinguished by the rounded tubular structure of the whorls.

Species 106. (Fig. Kiener.)

Buccinum Delalandii. Buc. testá ovato-oblongá, subturriculatá, cinereá, transversim tenuissimè striatá, fasciis longitudinalibus undulatis; spirá acutá; aperturá ovato-oblongá; labro lævi, albo, dilatato, intus striato, rubescente; epidermide virescente.

Delaland's Bucchum. Shell ovately oblong, somewhat turriculated, ash colour, transversely very finely striated, with waved longitudinal bands; spire sharp, aperture ovately-oblong; lip smooth, white, dilated,

striated within, reddish; covered with a greenish epidermis.

KIENER, Icon. coq. viv. p. 15. pl. 5. f. 15.

Hab. Cape of Good Hope.

This is another species described and figured by M. Kiener as here represented, which is unknown to me; his reference to Chemnitz however is certainly incorrect.

Species 107. (Fig. Kiener.)

Buccinum Quoyi. Buc. testá ovato-oblongá, fulvá, transversim plurimum longitudinaliter tenuissimè striatá; spirá acutá; columellá prominulá; aperturá ovaliformi, rubescente; labro arcuato, internè striato.

Quoy's Buccinum. Shell ovately oblong, fulvous, transversely very numerously and finely longitudinally striated; spire sharp; columella prominent; aperture oval-shaped, reddish; lip arched, striated internally. Kiener, Icon. coq. viv. p. 16. pl. 5. f. 13.

Hab. New Zealand.

Also transcribed and illustrated from M. Kiener's 'Iconographie', as a characteristic looking species with which I am not acquainted.

Species 108. (Mus. Cuming.)

Buccinum Æthiops. Buc. testá ovatá, spirá breviuscula, anfractibus supernè latè plano-depressis, regulariter costatis, costis grandibus convexis interstitiis latiusculis, excavatis; columellá et aperturæ fauce subcorrugatis aut tiratis; albá, epidermide corneá anthraciná indutá.

The blackamoor Buccinum. Shell ovate, spire rather short, whorls broadly flatly depressed round the upper part, regularly ribbed, ribs large, convex, interstices rather broad, excavated; columella and interior of the aperture somewhat wrinkled and ridged; white, covered with a coal-black horny epidermis.

Hab. ——?

A remarkable species approximating in form and general character to the *Purpura trochlea* and its congeners.

PLATE XIV.

Species 109. (Mus. Cuming.)

Buccinum Glandiforme. Buc. testá abbreviato-ovatá, anfractibus supernè concavo-depressis, deinde conspicuè nodosis, infra undique striatis; albidá, cæruleo-plumbeo tinctá, zonulá angustá cinereo-nigricante prope nodulos, columella et aperturæ fauce cinereo-purpureis.

THE ACORN-SHAPED BUCCINUM. Shell abbreviately ovate, whorls coneavely depressed round the upper part, then conspieuously noduled, striated throughout beneath; whitish, stained with blueish lead-colour, with a uarrow ashy black zone near the nodules, columella and interior of the aperture ashy purple.

Hab. - 9

The edge of the lip is slightly sinuated on the nodulous angle.

Species 110. (Mus. Cuming.)

Buccinum corrugatum. Buc. testá oblongo-ovatá, anfractibus transversim striatis, striis basem versus fortioribus, supernè oblique corrugatis; pallide spadicea.

THE WRINKLED BUCCINUM. Shell oblong-ovate, whorls transversely striated, striæ stronger towards the base, obliquely wrinkled round the upper part; light bay colour.

Hab. --- ?

Peculiarly characterized by the oblique concentric wrinkles.

Species 111. (Mus. Cuming.)

Buccinum Rugatum. Buc testá fusiformi-ovatá, spirá acutá, transversim undique elevato-striatá, longitudinaliter irregulariter varicosa; albida aut fuscescente.

THE WRINKLED BUCCINUM. Shell fusiformly ovate, spire transversely elevately striated throughout, longitudinally irregularly varieose; whitish or light brown. Hab. --- ?

A peculiarly formed species in which the varicose growth does not appear to be of accidental occurrence.

Species 112. (Mus. Cuming.)

Buccinum cretaceum. Buc. lestá acuminato-pyramidali,

subfusiformi, anfractibus rotundatis, lævibus concentricè plicatis; cretaceo-alba, fuscescente tincta.

THE CHALKY BUCCINUM. Shell acuminately pyramidal, somewhat fusiform, whorls rounded, smooth, concentrically plicated; ehalky-white, tinged with pale brown Hab -___ 9

Of simple structure, but clearly distinct from any previously described species.

Species 113. (Mus. Cuming.)

Buccinum Cancellarioides. Buc. testá ovato-fusiformi, tennicula, anfractibus superne rotundatis, concentrice plicato-costatis, transversim incisis; lutescente.

THE CANCELLARIA-LIKE BUCCINUM. Shell ovately fusiform, rather thin, whorls rounded at the upper part, eoneentrically plicately ribbed, transversely engraved; yellowish.

Hab. - ?

Peculiar in form and neatly sculptured.

Species 114. (Mus. Hancock.)

Buccinum sericatum. Buc. testá globoso-ovatá, tenuiculá, spirá brevi; anfractibus rotundatis, spiratiter striatis, columella arcuata, labro subeffuse; pallidè castaneã, epidermide sericeâ virescente partim indutâ.

THE SILK-CLAD BUCCINUM. Shell globosely ovate, rather thin, spire short; whorls rounded, spirally striated, eolumella arched, lip somewhat effused; pale chesnut, partially covered with a light green silken epidermis.

Hancock, Ann. and Mag. Nat. Hist. vol. xviii. p. 328 pl. 4. f. 7.

Hab. West Coast of Davis's Strait; Warham and Harrison.

This species is unknown to me, but I can have no hesitation in inserting it on the authority of Mr. Hancock.

Species 115. (Mus. Cuming.)

Buccinum tortuosum. Buc. testá fusiformi, subtubulosá, tenni, lævi, concentricè indistinctè et irregulariter plicatá, basi peculiariter canaliculatá et contractá; aperturá parvá, lutescente-albá.

THE TWISTED BUCCINUM. Shell fusiform, somewhat tubulous, thin, smooth, concentrically indistinctly and

February, 1847.

irregularly plicated, peculiarly channelled and contracted at the base; aperture small; yellowish white.

Hab ———?

A light delicate species in which the whorls are of a tubulous Scalaria-like growth.

Species 116. (Mus. Cuming.)

Buccinum lineare. Buc. testá ovatá, crassiusculá, lævigatá, spirá brevi, acutá; anfractibus supernè subcompressis; columellá arcuatá, supernè callosá; cinereoaut viridescente-fuscá, lineis nigris inæqualibus undique conspicuè cingulatá, columellá albidá, aperturæ fauce purpureo-cinereá.

The Line-drawn Buccinum. Shell ovate, rather thick, smooth, spire short, acute; whorls somewhat compressed round the upper part; columella arched, callous above; ash or greenish brown, conspicuously encircled throughout with unequal black lines, columella whitish, interior of the aperture purple ash.

Hab. ---- ?

A very characteristic species of solid growth not much unlike the common periwinkle in general aspect.

Species 117. (Mus. Cuming.)

Buccinum lacteum. Buc. testá oblongo-ovatá, spirá acutá, anfractibus supernè concavo-impressis; columellá arcuatá, aperturæ fauce radiatim liratá; lacteo-cæruteá, lineis nigricantibus obscurè notatá, aperturæ fauce luteá, purpureo-fusco tinctá, liris radiantibus albis.

THE MILKY BUCCINUM. Shell oblong-ovate, spire sharp, whorls concavely impressed round the upper part;

columella arched, interior of the aperture radiately ridged; milky-blue, marked with obscure black lines, interior of the aperture yellow, stained with purple-brown, radiating ridges white.

Hab. ——?

This shell is enveloped by a milky coating through which a dark layer of colouring is discovered; the aperture exhibits a great deal of character, being of a pale yellow ground, distinguished by a rich purple-brown stain over which the radiating ridges are white.

Species 118. (Mus. Hancock.)

Buccinum Grænlandicum. Buc. testá oblongo-ovatá, tenni, subventricosá, anfractibus supernè leviter angulatis, bicarinatis, longitudinaliter subobscurè plicatis, plicis carinas super nodulosis; columellá subindistinctè plicatá, labro subeffuso; rufescente-spadiceá, epidermide viridi-flavá partim indutá.

THE GREENLAND BUCCINUM. Shell oblong-ovate, thin, somewhat ventricose, whorls slightly angulated round the upper part, two-keeled, longitudinally somewhat obscurely plicated, plaits nodulous in crossing the keels; columella somewhat indistinctly plaited, lip slightly effused; pale reddish fawn colour, partially covered with a greenish yellow epidermis.

HANCOCK, Ann. and Mag. Nat. Hist. vol. xviii. p. 322. pl. 5. f. 8, and 9.

Hab. West Coast of Davis's Strait; Warham and Harrison.

Another of the interesting additions made to this genus by Mr. Hancock through the dredging exertions of Messrs. Warham and Harrison of Newcastle on Tyne, in the locality above quoted.
