Occurs worldwide and only selected localities are given here: Point of Rocks, Colfax Co., NM; Picture Gorge Basalt, Spray, OR; Sonoma Co., CA; Mt. St.-Hilaire, QUE, Canada; nearly end-member composition from the Red Wine alkalic complex, central Labrador, Canada; Ilimaussaq and Narssarsuk, Julianehaab district, Greenland; also at Tunliarfik and Naujakasik, Greenland; Vesteroya, Langesundfjord, Norway; Pantelleria Is., Italy; Lovozero, Khibiny, Kovdor, and other alkalic massifs, Kola Penin., Russia; eastern Sayan Mts., Siberia, Russia; Wonchi volcano, Ethiopia; Liruei complex, Nigeria; Mulanje complex, Malawi; Nandewar Mts., NSW, Australia. *EF DHZ IIA:640(1978)*, *MM 55:529(1991)*.

69.2.1a.2 Dorrite $\text{Ca}_2(\text{Mg}_2\text{Fe}_4^{3+})(\text{Al},\text{Fe}^{3+})_4\text{Si}_2\text{O}_{20}$

Named in 1988 by Cosca et al. for John A. Dorr (1922–1986), University of Michigan. Aenigmatite group. Chemically most similar to rhönite. *TRIC P1* or *P1̄*. $a = 10.505$, $b = 10.897$, $c = 9.019$, $\alpha = 106.26^\circ$, $\beta = 95.16^\circ$, $\gamma = 124.75^\circ$, $Z = 2$, $D = 3.959$. *45-1408(nat)*: 8.1_2 7.5_2 2.97_{10} 2.56_8 2.52_8 2.12_6 1.51_3 1.48_3 . *AM 73:1440(1988)*. Anhedral to prismatic grains to 0.1 mm long; twinning present producing pseudomonoclinic symmetry. Red-brown to brown, gray streak, submetallic luster. Cleavage is parallel to {010} and {001}, irregular fracture, brittle. $H \approx 5$. Analysis (wt %): SiO_2 , 10.4–12.0; Al_2O_3 , 8.6–24.85; Fe_2O_3 , 41.65–59.06; FeO , 2.8–3.4; TiO_2 , 0.4–1.04; MnO , 0.2–0.7; MgO , 4.3–5.6; CaO , 12.1–13.6; Na_2O , 0.0–0.2; K_2O , 0.0. In some samples Fe^{3+} is $> \text{Al}^{3+}$ in the tetrahedral site (to 75%). Biaxial (–); $N_x = 1.82$, $N_y = 1.84$, $N_z = 1.86$; $2V$ large, near 90° . In ultrathin section: X, red-orange brown; Y, yellowish brown; Z, greenish brown. Occurs in a paralava (pyrometamorphic melt-rock) formed from burning coal beds. Associated with esseneite or titanian andradite. Also from a basalt–limestone contact on Reunion Is. Occurs at the *Durham ranch, 25 km S of Gillette, WY (Powder River Basin)*; St.-Leu, Reunion Is. *EF BM 105:364(1982)*.

69.2.1a.3 Høgtuvaite $(\text{Ca},\text{Na})_2(\text{Fe}^{2+},\text{Fe}^{3+},\text{Ti},\text{Mg},\text{Mn},\text{Sn})_6(\text{Si},\text{Be},\text{Al})_6\text{O}_{20}$; simplified formula: $\text{Ca}_2\text{Fe}_4^{3+}\text{Fe}_2^{2+}\text{Si}_5\text{BeO}_{20}$

Named in 1994 by Grauch et al. for the locality. Aenigmatite group. See other members of the group. This mineral was also described under the name *makarochkinite* [*SPC 35:818(1990)*], but this name was not approved by the CNMMN IMA. *TRIC (pseudo-MON) P1*. $a = 10.317$ – 10.385 , $b = 10.724$ – 10.751 , $c = 8.855$ – 8.959 , $\alpha = 104.76$ – 105.77° , $\beta = 96.16$ – 97.03° , $\gamma = 124.77$ – 125.47° , $Z = 2$, $D = 3.92$ – 3.98 . *PD(nat)*: 8.05_9 3.12_5 2.92_6 2.68_5 2.53_{10} 2.10_6 2.07_5 1.62_3 . The structure is that of the aenigmatite group. *CM 32:439(1994)*. Bladed; to 4 cm long, 6 mm circumference maximum, striated parallel to axis of elongation; polysynthetic twinning, with the twin axis perpendicular to (010) (of monoclinic cell). Black; dark green streak; vitreous, nonmetallic luster. Two good cleavage directions at $\approx 55^\circ$; pronounced parting present approximately perpendicular to direction of elongation; uneven fracture; brit-

tle. $H = 5\frac{1}{2}$. $G = 3.85-3.88$. Mössbauer spectral data indicate that $Fe^{3+}/Fe^{2+} = 0.6$; TGA shows 0.25% weight loss at 100° and a minor weight gain (oxidation of Fe^{2+}) at 800°. Contains 2.65 wt % BeO, low Al. Inert to common acids and bases. Soluble in HF. Probably biaxial (-); $N_x = 1.78$, $N_z = 1.82$; 2V large; strongly pleochroic. X, green; Z, bronze. Occurs in peraluminous granitic gneiss. Also in a small metamorphic granitic pegmatite and granite pegmatite. Associated minerals include: quartz, albite, microcline, phenakite, biotite, zircon, fluorite, magnetite, and others. Formed in a second metamorphic event. Occurs as poikiloblasts. Found at *Høgtuva, Nordland Co., Norway*; mine 400, Ilmensky Natural Forest, Russia. EF

69.2.1a.4 Krinovite $NaMg_2CrSi_3O_{10}$

Named in 1968 by Olsen and Fuchs for Evgeny Leonidovich Krinov (1906-1984), Russian student of meteorites. Aenigmatite group. TRIC P1. $a = 10.238$, $b = 10.642$, $c = 8.780$, $\alpha = 105.15^\circ$, $\beta = 96.50^\circ$, $\gamma = 125.15^\circ$, $Z = 4$, $D = 3.46$. ZK 187:133(1989). 20-1123(nat): 7.92₆ 3.64₆ 3.10₆ 2.89₈ 2.65₉ 2.50₁₀ 2.08₇ 2.05₆. Largest grain is 200 μm . Emerald-green. $H = 6-7$. $G = 3.38$. IR data: GZ 36:76(1976). Analysis (wt %): SiO_2 , 48.1; Al_2O_3 , 0.6; Cr_2O_3 , 19.1; FeO, 1.8; TiO_2 , 0.5; MnO, 0.1; MgO, 19.7; CaO, 0.1; Na_2O , 9.1; K_2O , 0.0. Biaxial (+); OAP parallel to b (monoclinic cell); Na light: $N_x = 1.702$, $N_y = 1.725$, $N_z = 1.760$; 2V = 61°. X, yellow-green; Y, blue-green; Z, greenish black (anomalous reddish brown). Occurs in meteorite as subhedral grains in granitole nodules in octahedrites: *Canyon Diablo, AZ; Wichita Co., KA; and Younegin, Australia*; in association with olivine, roedderite, high albite, richterite, and other minerals. EF ZK 136:81(1972).

69.2.1a.5 Rhönite $Ca_2(Mg,Fe^{2+},Fe^{3+},Ti)_6(Si,Al)_6O_{20}$ and $Ca_4(Fe_3^2+Fe_3^3+Mg_{4.28}Ti_{2.84})_{12}(Si,Al)_{12}O_{40}$

Named in 1907 by Soellner for the locality. Aenigmatite group. For Fe-dominant material: $\Sigma Fe > Mg$. Need two names, one for Mg-dominant and one for Fe-dominant material. Several polytypes: polysomes—pyroxene + spinel slabs. TRIC P1. (Allende meteorite): $a = 10.367$, $b = 10.756$, $c = 8.895$, $\alpha = 105.98^\circ$, $\beta = 96.04^\circ$, $\gamma = 124.72^\circ$; (volcanic breccia): $a = 10.428$, $b = 10.807$, $c = 8.925$, $\alpha = 105.91^\circ$, $\beta = 96.13^\circ$, $\gamma = 124.80^\circ$; $Z = 2$ [EJM 2:203(1990)], $D = 3.72-3.79$. 23-607(nat): 8.14₂₅ 2.95₁₀ 2.78₃ 2.69₆₅ 2.55₇ 2.09₅₅ 1.99₂₅ 1.50₄. The structure consists of "octahedral" walls connected through tetrahedral chains with appendices and additional insular octahedra. OD (order-disorder) schemes present. EJM 2:203(1990). As prismatic or tabular crystals to several centimetres or more; also as skeletal to anhedral grains. Forms include {011}, {100}, {010}, {211} + others; polysynthetic twinning, with the twin axis perpendicular to (010) plane of the pseudomonoclinic cell. Brown, black; good {010} and {001} cleavage vitreous luster. $H = 5-6$, $G = 3.4-3.75$. Ti^{3+} and Ti^{4+} are present in the mineral from the Allende meteorite. Rhönite is of relatively wide compositional range. Aenigmatite is not. Thus a solubility gap exists. $Ca + Al - Na + Si$. Analysis (wt %): SiO_2 ,

19.1–30.7; Al_2O_3 , 12.3–28.9; Fe_4O_3 , 16.0–24.5; Fe_2O_3 , 6.9–11.7; FeO , 11.4–17.6; TiO_2 , 5.1–16.8; MnO , 0.1–0.4; CaO , 0.4–13.0; Na_2O , 0.7–3.1; K_2O , 0–0.6. Biaxial (+); Na light: $N_x = 1.79$ – 1.810 , $N_y = 1.80$ – 1.825 , $N_z = 1.83$ – 1.845 ; $2V = 47$ – 90° ; $X < Y < Z$; $r < v$, extreme. X, greenish brown to red-brown; Y, greenish brown–reddish brown or brownish yellow; Z, dark red, black, reddish brown. Occurs in volcanic breccia, the Allende meteorite, a mafic alkaline sill in Texas, in a nepheline basanite in Rhön, Germany, in nepheline–dolerites in Massif Central, France. Also in many other mafic rocks of the Rhön region. In an inclusion of pyroxenite in basalt in Haute-Loire, France. Principally found in silica-poor, mafic to intermediate rocks. Occurs with titanaugite and feldspathoids. Often an alteration product of amphiboles. Occurs at Big Bend National Park, Brewster Co., TX; north of Kalaheo, Kauai, Hawaii; Hobbs Land, Greenland; Puy Forestier, Haute-Loire, Puy de St.-Sandoux (Auvergne), and Puy de Barneire, Massif Central, France; *Scharnhausen, Platz, Bruckenau, Rhön District, Hessen*, Löbauer Berg, Saxony, Fe-dominant from Sattel volcano, Eich, East Eifel, *Germany*; Snababerg, Skåne, southern Sweden; St.-Leu, Reunion Is.; Hut Point Penin., Ross Is., Antarctica, and several other Antarctic localities; Fe-dominant from Pulling Point, Otago Harbor, Dunedin volcano, Morotu district, New Zealand; Dogo, Oki Islands, Japan, and Sakhalin Is., Russia; high Ti-bearing in the Allende meteorite. *EF TMPM 18:17(1972), AM 70:1211(1985), DA 40:391(1989)*.

69.2.1a.6 Serendibite $(\text{Ca},\text{Na})_2(\text{Al},\text{Mg},\text{Fe}^{2+},\text{Fe}^{3+})_6(\text{Si},\text{B},\text{Al})_6\text{O}_{20}$

Named in 1903 by Prior and Coomaraswamy, for the locality, Serendib, an old Arabic name for Ceylon. Aenigmatite group. See the other members of the group. *TRIC P1*. (Fe-poor, 2 wt % FeO): $a = 10.010$, $b = 10.393$, $c = 8.631$, $\alpha = 106.37^\circ$, $\beta = 96.10^\circ$, $\gamma = 124.38^\circ$ [*AM 78:195(1993)*]; (intermediate Fe, 5.8% FeO): $a = 10.043$, $b = 10.428$, $c = 8.662$, $\alpha = 106.37^\circ$, $\beta = 96.02^\circ$, $\gamma = 124.40^\circ$; (high Fe, 13% FeO): $a = 10.094$, $b = 10.478$, $c = 8.694$, $\alpha = 106.36^\circ$, $\beta = 96.00^\circ$, $\gamma = 124.40^\circ$; $Z = 2$, $D = 3.47$. *29-343(nat)*: 3.32_4 2.85_{10} 2.60_8 2.46_8 2.04_7 2.03_7 2.02_5 . Tetrahedral substitutions are constrained to B for Si and Si for Al. One tetrahedral site is nearly fully occupied by B, whereas the other has a B/Si ratio near 1.5. These two tetrahedra are the only ones in serendibite to share three vertices with other tetrahedra, resulting in B–O–B and B–O–Al bridges, as well as B–O–Si bridges. There is little or no Fe in the tetrahedral site. Fe^{3+} is in octahedral sites along with Fe^{2+} . No evidence for ordering of Fe was found. See *AM 78:195(1993)* and *PNAS 71:4348(1974)* for fundamental details. Oblique tablets or as anhedral grains to 2 cm; fine, polysynthetic twinning on {011} often present. Grayish blue-green, deep blue, sky-blue, dark green, to nearly black and also pale yellow; vitreous luster. Cleavage {010}, {001}, good. $H = 6\frac{1}{2}$ –7. $G = 3.42$ – 3.515 . Infusible, only slightly attacked by acids. Analysis (wt %): SiO_2 , 17.1–26.3; Al_2O_3 , 30.7–43.0; B_2O_3 , 4.2–8.4; Fe_2O_3 , 2.3–5.05; FeO , 2.8–6.1; TiO_2 , 0.1–0.3; MnO , 0.2; MgO , 8.45–15.4; CaO , 13.3–17.1; Na_2O , 0.0–0.5; K_2O , 0.2. B_2O_3 may be as

high as ≈ 9 wt %. Material from Johnsbury, NY, has 0.9–1.37% Na_2O . Usually biaxial (+); $Z \wedge c = 26\text{--}40^\circ$; $N_x = 1.700\text{--}1.738$, $N_y = 1.703\text{--}1.741$, $N_z = 1.706\text{--}1.743$; birefringence = 0.004–0.006; $2V = 78\text{--}90^\circ$, also large (–) $2V$; $r < v$ for optically (+) material; dispersion sometimes so strong as to produce anomalous interference colors. X, greenish blue–yellowish green; Y, pale blue, blue-green, pale yellow; Z, blue, indigo-blue, greenish yellow. Occurs typically in contact-metamorphosed calcisilicate rocks, particularly gneisses. Typical associated minerals include diopside, apatite, calcite, clinopyroxene, spinel, pargasite, phlogopite, and plagioclase, but quartz is conspicuously absent. Tourmaline, grandidierite, sinhalite, and other minerals may or may not be directly associated. Typically occurs in zoned metasomatic skarns between marble and feldspathic rock. Serendibite is rare because of the combination of Si-undersaturated skarns, metamorphosed at fairly high temperatures (1–9.5 kbar and $600\text{--}825^\circ$) during influx of B-bearing fluids. Associated with sinhalite at Johnsbury, Warren Co., Amity, Orange Co., NY; Russell, St. Lawrence Co. (northwestern Adirondacks), NY; New City quarry, Riverside, CA; Melville Peninsula, NWT, Canada; Bug River area, Ukraine; associated with uvite at the Tayozhnoye iron deposit, Aldan Shield, Yakutia, Russia; high-iron-containing (13.0 wt % FeO) from the Ozersk gabbroic massif, Priolkhon (western Pribaikal), Russia; 10 km SE of Ihosy, southern Madagascar (colorless to light green); Ianapera, southwestern Madagascar; Handeni district, Tanzania; in a granulite–limestone contact zone at *Gangapitiya, Sri Lanka (Ceylon)*. EF *MIN 3(1):532(1972)*; *NJBM:435(1974)*; *CM 15:108(1977)*; *MM 54:131(1990)*, *54:133(1990)*; *AM 76:1061(1991)*.

69.2.1a.7 Welshite $\text{Ca}_2\text{Mg}_4\text{Fe}^{3+}\text{Sb}^{5+}\text{O}_2[\text{Si}_4\text{Be}_2\text{O}_{10}]$ or $\text{Ca}_2\text{Sb}^{5+}\text{Mg}_4\text{Fe}^{3+}\text{Si}_4\text{Be}_2\text{O}_{20}$

Named by Moore in 1978 for Wilfred R. Welsh (b.1915), amateur mineralogist and teacher of the natural sciences, Upper Saddle River, NJ. Aenigmatite group. See the other members of the group. TRIC P1. $a = 10.167$, $b = 10.65$, $c = 8.787$, $\alpha = 106.5^\circ$, $\beta = 96.1^\circ$, $\gamma = 124.0^\circ$, $Z = 2$, $D = 3.67$. *29-1407(nat)*: 7.32₇ 4.73₆ 2.91₇ 2.67₆ 2.53₁₀ 2.10₆ 1.49₇ 1.46₇. Aenigmatite-type structure. Thick, prismatic crystals to 3 mm in maximum diameter; polysynthetic twinning on {010} (monoclinic setting). Reddish black to reddish brown, pale brown streak, subadamantine luster. No cleavage, conchoidal fracture. $H = 6$. $G = 3.77$. Insoluble in dilute to strong HCl. Analysis (wt %): SiO_2 , 19.6; Al_2O_3 , 2.1; BeO , 4.0; As_2O_5 , 3.6; Sb_2O_5 , 24.8; Fe_2O_3 , 9.1; MnO , 1.0; MgO , 15.3; CaO , 14.2; Na_2O , 0.0; K_2O , 0.0. $\text{Sb}^{5+} \leftrightarrow \text{Ti}^{4+}$ and $\text{Be}^{2+} \leftrightarrow \text{Al}^{3+}$ in rhönite. Biaxial; $N_x \approx 1.81$, $N_y = 1.81(?)$, $N_z \approx 1.83$; $2E = 45^\circ$; nonpleochroic, deep reddish brown to reddish black. Optical character uncertain. Occurs in dolomite, in fractures in hematite ore. Associated with roméite, adelite, and others. *Langban, Varmland, Sweden*. EF *MM 42:129(1978)*, *CM 32:439(1994)*.

69.2.1a.8 Wilkinsonite $\text{Na}_2\text{Fe}_2^{2+}\text{Si}_6\text{O}_{20}$

Named by Duggan in 1990 for John Frederick George Wilkinson (1927–1985), emeritus professor of geology, University of New England, NSW, Australia. Aenigmatite group. See the other members of the group. TRIC *P1*. $a = 10.355$, $b = 10.812$, $c = 8.906$, $\alpha = 105.05^\circ$, $\beta = 96.63^\circ$, $\gamma = 125.20^\circ$, $Z = 2$ [*AM 75:694(1990)*], $D = 3.89$. *PD(nat)*: 8.10₁₀ 4.82₃ 4.18₃ 3.702₄ 3.149₁₀ 2.935₆ 2.750₃ 2.696₈. Synthesized by Ernst. *JG 70:689(1962)*. Small, anhedral grains, < 50 μm in diameter. Black, brown streak, vitreous luster. Conchoidal fracture. $H = 5$. Forms a solid-solution series with aenigmatite and other members of the group. Substitution of MgO (5.5%), MnO (2.1%), and CaO (0.7%) for Fe^{2+} . Also substitution of minor K_2O (0.75%) for Na_2O . Contains as much as nearly 4% Nb_2O_5 . Analysis (wt %): SiO_2 , 39.1–41.5; Al_2O_3 , 0.03–0.85; Fe_2O_3 , 44–48; TiO_2 , 0–1.9; ZrO_2 , 0.0–0.5; MnO, 1.0–1.4; MgO, 0.0–0.2; CaO, 0.1–0.2; Na_2O , 7.1–7.4; K_2O , 0.0–0.1. Biaxial (+); $N_x = 1.79(1)$, $N_y = 1.79(1)$, $N_z = 1.90(1)$; $2V \approx 10^\circ$; $Z > Y > X$. X, olive-green; Y, gray-brown; Z, dark brown. With increasing contents of TiO_2 , the reddish-brown colors of aenigmatite are then observed. Occurs as anhedral groundmass grains associated with anorthoclase, clinopyroxene, sodalite, analcime, and traces of eudialyte and arfvedsonite in a fine-grained silica-undersaturated trachyte. In silica-undersaturated, mildly peralkaline hosts, with very low TiO_2 contents. In syenite ejecta at Wonchi volcano. Occurs as relics surrounded by riebeckite and biotite. Occurs in the Sierra Prieta nepheline–analcime syenite, Diablo Plateau, TX; Wonchi volcano, Ethiopia; *Warrumbungle volcano*, NSW, Australia. *EF CIWY 72:578(1973)*, *GSAB 88:1428(1977)*, *MM 55:529(1991)*.

69.2.1b.1 Sapphire $[\text{Mg}_{4-x}\text{Al}_{4+x}][\text{Al}_{4+x}\text{Si}_{2-x}]\text{O}_{20}$

Named in 1819 by Giesecke from *sapphire*, in allusion to its common sapphire-blue color. Most sapphire is monoclinic (2M polytype), followed by triclinic (1A polytype) and other rarer polytypes: 2A, 3A, 4M, and 5A. *AM 75:937(1990)*. A monoclinic 2C superstructure has $a = 11.320$, $b = 14.367$, $c = 19.794$, $\beta = 125.49^\circ$. *AM 73:1134(1988)*. MON *P2₁/n*. $a = 11.281$, $b = 14.425$, $c = 9.940$, $\beta = 125.49^\circ$, $Z = 4$, $D = 3.48$; TRIC *P1* or *P1*. $a = 9.97$ – 10.04 , $b = 10.34$ – 10.38 , $c = 8.62$ – 8.65 , $\alpha = 107.4$ – 107.55° , $\beta = 95.12$ – 95.2° , $\gamma = 123.8$ – 123.92° , $Z = 2$, $D = 3.57$. *19-750(nat, 2M polytype)*: 3.00₆₅ 2.84₆₅ 2.45₁₀ 2.35₆ 2.02₉ 1.44₈ 1.42₇ 1.41₆; *44-1430(nat, 1A polytype)*: 3.01₅ 2.85₄ 2.78₂ 2.58₃ 2.46₁₀ 2.36₃ 2.04₄ 2.02₇. An OD (order-disorder structure; “normal” 2M sapphire has a disordered arrangement of domains. There is a considerable scope for cation order-disorder. There are eight or nine octahedral sites and six tetrahedral sites in the average structures of the two most common polytypes. Sapphire is stabilized as a phase through a combination of short-range order in T_2 and T_3 and disorder on the remaining tetrahedral sites. It is still unknown if 1A and 2M polytypes differ only in the succession of the structural layers or if they differ in some degree in the structure layers themselves. Habit: Usually granular, also occurs as tabular plates, flattened on (010) (for

monoclinic); uncommon repeated twinning is present on {100} (monoclinic); in the triclinic case, the composition plane is (010). **Physical properties:** Light to medium blue, blue-green, gray, pale red or maroon (high Cr-containing: 7.5 wt % Cr_2O_3); white to pale blue streak; vitreous luster. Cleavage (monoclinic) {010} moderate; {001}, {100} poor; uneven fracture. $H = 7\frac{1}{2}$. $G = 3.40\text{--}3.60$. MAS-NMR studies on ^{27}Al and ^{29}Si and FTIR studies in *AM* 77:8(1992). Insoluble in acids; decomposed by fusion in Na_2CO_3 or KHSO_4 . **Chemistry:** There is substitution of Fe^{2+} for Mg and of Fe^{3+} or Cr for Al. Substitution of Fe^{2+} appears to be necessary for stability of the 2M structure. Tschermak substitution in the form $\text{R}^{2+}\text{Si} \leftrightarrow 2\text{R}^{3+}$ is common. This accounts for the deviation from the ideal 2:2:1 formula ratios. May contain as much as 2.2–2.5 wt % BeO; Cr_2O_3 to 7.5 wt % (Greenland); TiO_2 to 1.5 wt %; may also contain as much as 0.75 wt % B_2O_3 . **Optics:** Usually biaxial (–), but some are (+); $Z \wedge c = 6\text{--}12^\circ$, $Y = b$, OAP = (010); $N_x = 1.701\text{--}1.731$, $N_y = 1.703\text{--}1.741$, $N_z = 1.705\text{--}1.745$; $2V_x = 47\text{--}114^\circ$, most are $50\text{--}80^\circ$; $2V$ decreases as Fe content increases, and (+) sapphire is very low in total Fe; $r < v$, strong. Birefringence = 0.005–0.009. X, colorless, pale red or pink, yellowish green; Y, sky-blue, pale blue, lavender; Z, blue, dark blue, blue-green. **Occurrence:** Occurs in Mg- and Al-rich high-grade metamorphic rocks (e.g., granulites). Also occurs in upper mantle rocks (breccia pipes). Occurs at the contact zone of alpine peridotites, in metagabbros, and in kimberlites. Fine, large crystals occur in calcite–phlogopite rock at Itrongay. Occurs rarely in pegmatites. Characteristic of high-pressure, high-temperature environments. **Localities:** Salt Hill, Cortlandt complex, Peekskill, NY; from Stockdale kimberlite pipe, Riley Co., KA; magmatic in anorthosite from St. Urbain, Charlevoix Co., QUE, Canada; 1A sapphire from Wilson Lake, LAB, Canada; Cr-bearing from Bjørnesund area, Fiskenaesset region, and regular sapphire from the *Fiskenaesset Harbor, southwestern Greenland*; Snarum and Vikesa, Norway; Lerc, France; Val Codera, and Sondrio, Chiavenna, Italy; Waldheim, Saxony, Germany; Naxos, Greece; Aldan Shield, Yakutia, Russia; colorless sapphire with gem spinel from Kuk-i-Lal, southwestern Pamirs, Kazakhstan; Al-rich from Sar-i-sang, Afghanistan; yellow sapphire from Mautia Hill, Tanganyika; Fe-richest material from the Labwor Hills, Uganda; large crystals from the farms Blinkklip and Randjesfontein, near Messina, Transvaal, and near Okiep, Namaqualand, South Africa; Kakanuru area, eastern Ghats, India; Sitampundi complex, Gangurvapatti, Madura, India; Betroka, Itrongay, and Zahosy, Madagascar, and several other localities in Madagascar (e.g., low-Fe, well-developed sapphire crystals from the Bekily area); Strangway and Reynolds Ranges, NT, and Dangin, WA, Australia; MacRobertson Land, Be-rich material from Casey Bay, Enderby Land, and Ti-bearing sapphire (1A) from the Vestfold Hills, Antarctica [*EJM* 7:637(1995)]; Salvador, Bahia, Brazil. *EF CMP* 41:23(1973), 68:349,357(1979); *ZK* 151:91(1980); *MIN* 3(2):576(1981); *MM* 46:323(1982); *CMP* 103:211(1989).

69.2.1b.2 Surinamite (Mg,Fe,Mn)₃(Al,Fe)₄BeSi₃O₁₆

Named in 1976 by deRoever et al. for the locality. *MON P2/n.* (Syn): $a = 9.881$, $b = 11.311$, $c = 9.593$, $\beta = 109.52^\circ$, $Z = 4$, $D = 3.48$; (nat): $a = 9.916$, $b = 11.384$, $c = 9.631$, $\beta = 109.30^\circ$, $Z = 4$, $D = 3.48$. 38-433, 29-702(syn): 2.91₉ 2.89₈ 2.65₈ 2.43₇ 2.42₁₀ 1.993₁₀ 1.988₉ 1.42₈; (nat): 3.08₃ 2.91₈ 2.67₄ 2.635₄ 2.42₁₀ 2.00₈ 1.43₆ 1.395₆. *AM 66:1022(1981)*. $R = 4.7\%$. Nine octahedral cations and five tetrahedral cations incorporated in a CCP array of 16 independent oxygen atoms. *AM 68:804(1983)*. Colorless to white (syn) and blue (nat). Platy parallel to (010) with one well-developed cleavage perpendicular to (010); <0.2-mm crystals in Suriname; one well-developed cleavage perpendicular to (010), also (010). $G > 3.30$. Analyses (wt %): SiO₂, 30.9–32.1; Al₂O₃, 33.7–37.3; FeO, 9.1–13.4; MnO, 0.01–0.2; MgO, 16.4–18.4; Be, 0.5–1; H₂O, 0.66; end member: MgO, 22.8; Al₂O₃, 38.47; BeO, 4.72; SiO₂, 34.00. Biaxial (-); $Y = b$; (syn): $N_x = 1.7015$, $N_y = 1.7035$, $N_z = 1.7055$; (nat): $N_x = 1.738$, $N_y = 1.743$, $N_z = 1.746$; $2V = 68^\circ$. Y, violet for vibrations in the OAP(010); bright blue-green if parallel to the cleavage, but very light colored if perpendicular to it. X, pale yellow to pale yellow-green; Y, bluish, purple; Z, bright green-blue. Optically similar to sapphirine. Very strong dispersion; in (010) the extinction angle between Z and the trace of a cleavage perpendicular to (010) is 31° for violet and 44° for yellow light. Anomalous interference colors. Occurs in Suriname in a mesoperthite gneiss associated with charnockitic granulites. Granulite facies rocks in Australia; same in Antarctica. Forms as pseudomorphs after cordierite in Zambia. In most cases it is formed by alteration of cordierite (Be-bearing). In pegmatites in granulite-facies rocks—Be-rich in Casey Bay, associated with sillimanite. Occurs in the *Bakhuis Mts., western Suriname*; also found in the Chimwala area, near the Malawi border, Eastern Prov., Zambia; eastern Strangways Range, Central Australia; Christmas Point, Casey Bay, Enderby Land, Antarctica. *EF MIN 3(2):584(1981)*, *AM 70:710(1981)*, *CMP 92:113(1986)*.

69.2.1c.1 Magbasite KBa(Mg,Fe)₆(Al,Sc)Si₅O₂₀F₂

Named in 1965 by Semenov et al., for the composition: magnesium, barium, silicate. Possibly aenigmatite group. Probably ORTH *P* lattice. $a = 22.56(4)$, $b = 18.96(4)$, $c = 5.29(2)$, $Z = 6$, $D = 3.99$. 42-571(nat): 3.57₈ 3.13₅ 2.98₇ 2.84₆ 2.71₄ 2.56₁₀ 1.99₅ 1.61₄. Fine fibers. Colorless, light red-violet. $G = 3.41$. Analysis (wt %): SiO₂, 39.7; Al₂O₃, 4.0; Sc₂O₃, 2.1; FeO, 8.9; MgO, 21.4; CaO, 1.7; CaO, 14.8; K₂O, 4.9; F, 5.5. Biaxial (-); $N_x = 1.597$, $N_y = 1.609$, $N_z = 1.615$; $2V = 70^\circ$. Occurs in hydrothermal deposits. Occurs at an unspecified locality in the Asian part of Russia. *EF DAN SSSR 163:718(1965)*, *CA 93:171152(1980)*.

69.2.2.1 Saneroite Na₂(Mn²⁺, Mn³⁺)₁₀[VSi₁₁(OH)₂](OH)₂

Named in 1979 by Cortesogno et al. for Edoardo Sanero (b.1901), emeritus professor of mineralogy, University of Genova. *TRIC P1*. $a = 9.741$, $b = 9.974$,

$c = 9.108$, $\alpha = 92.70^\circ$, $\beta = 117.11^\circ$, $\gamma = 105.30^\circ$, $Z = 1$, $D = 3.49$. *35-484*: 3.06₁₀ 3.01₆ 2.98₆ 2.83₁₀ 2.70₁₀ 2.62₆ 2.20₆ 1.682₈. Structure: *NJMA 138:333(1980)*. The linear component, parallel to [110], of the chain has five tetrahedra; a sixth tetrahedron, statistically occupied by Si and V in a 1:1 ratio, is appended to the chain by one shared corner. Bright orange, resinous to greasy luster. Two perfect cleavages. $G = 3.47$. Biaxial (-); $2V = 40-48^\circ$; $N_x = 1.720$, $N_y = 1.740-1.745$, $N_z = 1.745-1.750$; extinction oblique (15° max). Pleochroic, $X > Z > Y$; deep orange to lemon yellow. Found with barite, cariopillite, and ganophyllite in veins in manganese ores at the *Gambatesa and Molinello mines, Chiavari, Val Greveglia, Liguria Apennines, Italy*. AR *NJMM:161(1981)*, *AM 66:1277(1981)*.

69.2.3.1 Howieite $\text{Na}(\text{Fe,Mg,Al})_{12}(\text{Si}_6\text{O}_{17})_2(\text{O,OH})_{10}$

Named in 1964 by Agrell et al. for Robert Andrew Howie (b.1923), British mineralogist and petrologist, King's College, London University. See taneyamalite (69.2.3.2). TRIC *P1*. $a = 10.170$, $b = 9.774$, $c = 9.589$, $\alpha = 91.22^\circ$, $\beta = 70.76^\circ$, $\gamma = 108.09^\circ$, $Z = 1$, $D = 3.35$. *19-571*: 9.02₁₀ 7.79₁₀ 3.21₈ 3.02₅ 2.76₅ 2.72₅ 2.63₈ 2.16₅. Structure: *AM 59:896(1974)*. The fundamental structural unit may be regarded as a hybrid single/double chain of tetrahedra, having the conformation of six-membered rings joined by oxygens of opposing pairs of tetrahedra. The resulting ribbons are parallel to one another and to {120}. Dark green, pale green streak, vitreous luster, translucent to opaque. Cleavage {010}, good; {100}, fair; conchoidal fracture. $G = 3.38$. Biaxial (-); $2V = 65^\circ$; $N_x = 1.701$, $N_y = 1.720$, $N_z = 1.734$; $r < v$, strong. Pleochroic; X, pale golden yellow; Y, dark lilac-gray; Z, dull green. Occurs as bladed crystals in blueschist metamorphic facies, metamorphosed ironstones, and mafic igneous rocks. In the Franciscan formation in the *Laytonville district, Mendocino Co., CA*, associated with glaucophane, lawsonite, deerite, zussmanite, and also at Ward Creek, Sonoma Co., and Panoche Pass, San Benito Co. At Pinchi Lake, BC, Canada; at Brezovica, Yugoslavia; at Maki, Kochi Pref., Shikoku, Japan. AR *AM 50:278(1965)*, *MM 43:363(1979)*, *CM 28:855(1990)*.

69.2.3.2 Taneyamalite $(\text{Na,Ca})(\text{Mn,Mg})_{12}[\text{Si,Al}]_6\text{O}_{17}]_2(\text{O,OH})_{10}$

Named in 1981 by Matsubara for the Taneyama mine. See howieite (69.2.3.1). TRIC *P1*. $a = 10.198$, $b = 9.820$, $c = 9.484$, $\alpha = 90.50^\circ$, $\beta = 70.53^\circ$, $\gamma = 108.57^\circ$, $Z = 1$, $D = 3.30$. *35-480*: 9.29₈ 7.99₃ 4.62₈ 3.65₄ 3.27₁₀ 3.08₅ 2.79₃ 2.22₃. Isostructural with howieite. Greenish gray-yellow, pale yellow streak, vitreous luster. Cleavage {010}, perfect. $H = 5$. Biaxial (-); $2V = 70^\circ$; $N_x = 1.646$, $N_y = 1.664$, $N_z = 1.676$; positive elongation. Pleochroic; X,Y, nearly colorless; Z, pale yellow. Found associated with bannisterite as small seams in caryopillite at the *Iwaizama mine, Saitama Pref., Honshu*, and earlier observed but not named at the Taneyama mine, Kumamoto Pref., Kyushu, Japan. AR *MM 44:51(1981)*, *MJ 10:385(1981)*.

69.2.3.3 Deerite $(\text{Fe,Mn})_6(\text{Fe,Al})_3\text{O}_3(\text{Si}_6\text{O}_{17})(\text{OH})_5$

Named in 1964 by Agrell et al. for William Alexander Deer (b.1910), British mineralogist and petrologist, Cambridge University. *MON* $P2_1/a$. $a = 10.786$, $b = 18.88$, $c = 9.564$, $\beta = 107.45^\circ$, $Z = 4$, $D = 3.82$. $19-421$: 9.45_2 9.03_{10} 3.22_2 3.01_7 2.64_5 2.54_2 2.37_2 2.26_2 . Structure: *AM* 62:990(1977). The silicate structural unit is a hybrid single/double chain, as in howieite, but the chains are not parallel to one another. Crystals acicular [001] with amphibole-like cross section. Black, transparent on thin edges. Cleavage {110}, good. $G = 3.84$. Biaxial (+ or -); $N_x = 1.81-1.84$, $N_z = 1.84-1.87$; $Z = c$. Found in metamorphosed shales, ironstones, and limestones of the Franciscan formation in the *Laytonville district, Mendocino Co., CA*, associated with howieite, zussmanite, and other blueschist facies minerals, and also at Ward Creek, Sonoma Co., and Panoche Pass, San Benito Co.; at Wild Horse Lookout, Curry Co. and the Powers quarry, Coos Co., Oregon. Found at Termignon, Haute-Savoie, France; Eskisehir Prov., Turkey; and Ouega Koumec, New Caledonia. *AR AM* 50:278(1965), *BM* 93:263(1970), *MM* 43:251(1979).

69.2.4.1 Liebauite $\text{Ca}_3\text{Cu}_5[\text{Si}_9\text{O}_{26}]$

Named in 1992 by Zoller and Tillmanns for Friedrich Karl Liebau (b.1926), Mineralogisch-Petrologisches Institut, Kiel, in recognition of work on silicate crystal chemistry. *MON* $C2/c$. $a = 10.160$, $b = 10.001$, $c = 19.973$, $\beta = 91.56^\circ$, $Z = 4$, $D = 3.62$. *PD*: 7.13_6 6.70_7 3.58_4 3.12_9 3.00_{10} 2.45_6 2.41_7 1.780_5 . Structure: *ZK* 200:115(1992). The silicate element is a loop chain with $P = 14$ and $N = 18$ consisting of six-membered rings linked by three tetrahedra. Bluish green, vitreous luster, transparent. $H = 5\frac{1}{2}$. Biaxial (+); $2V = 35^\circ$; $N_x = 1.722$, $N_y = 1.723$, $N_z = 1.734$ for Na(D). Found as minute (<0.03 mm) crystals with several copper minerals in an argillaceous xenolith in scoria of the *Sattelberg cone, near Kruff, Eifel district, Germany*; also in other scoria cones at Osteifel and Westeifel. *AR*

69.2.5.1 Johninnesite $\text{Na}_2\text{Mg}_9^{2+}(\text{Mg,Mn})_7(\text{OH})_8[\text{AsO}_4]_2[\text{Si}_6\text{O}_{17}]_2$

Named in 1986 by Dunn et al. for John Innes, senior mineralogist, Tsumeb Corp. *TRIC* $P1$. $a = 10.485$, $b = 11.065$, $c = 9.654$, $\alpha = 107.11^\circ$, $\beta = 81.17^\circ$, $\gamma = 111.86^\circ$, $Z = 1$, $D = 3.51$. $39-402(\text{nat})$: 9.8_6 5.99_4 4.06_3 3.38_4 3.23_6 2.68_{10} 2.48_4 1.54_4 . A layered structure with a tetrahedral layer consisting of independent AsO_4 and Si_6O_{17} chains, an octahedral layer of edge-sharing $(\text{Mn,Mg})\text{O}_6$ octahedra with one-sixth of the octahedral sites vacant, and a layer with single MnO_6 octahedral chains separated by NaO_6 distorted octahedra. Very friable aggregates; fibrous, elongate on [001]; flattened on {100}; to 2 cm long on type sample and to 4.5 cm long on others. Light yellow-brown, light brownish yellow streak, vitreous luster. Cleavage {100}, good; {010}, poor. $G = 3.48$. Analysis (wt %): SiO_2 , 35.5; FeO , 0.1; MgO , 8.2; MnO , 40.7; As_2O_5 , 10.6; Na_2O , 3.1; H_2O , 2.6. Biaxial (-); Na(D); $N_x = 1.6742$,

$N_y = 1.6968$, $N_z = 1.6999$; $2V = 42^\circ$; $r > v$, distinct. Occurs at the *Kombat mine, Otavi Valley, Namibia*, in late-stage, low-temperature hydrothermal veins cutting Mn ores. Associated with kentrolite, rhodonite, and richterite. In upper Proterozoic dolostones underlying slates and marls. EF *AM* 79:991(1994).

Column or Tube Structures

70.1.1.1 Litidionite $\text{KNaCu}[\text{Si}_4\text{O}_{10}]$

Named in 1880 by Scacci from the Greek *lithidion*, pebble, in allusion to the lapilli on which the mineral was found. Synonym: lithidionite. See fenaksite and manaksite. TRIC P1. $a = 9.80$, $b = 8.01$, $c = 6.97$, $\alpha = 114.12^\circ$, $\beta = 99.52^\circ$, $\gamma = 105.59^\circ$, $Z = 2$, $D = 2.85$. *Z9-1041*: 6.75₃ 4.05₂ 3.65₂ 3.37₁₀ 3.22₇ 2.84₂ 2.68₄ 2.41₈. Structure: *AM 60:471(1975)*. The silicate structural element consists of a pair of vlasovite-like double chains condensed to form a rod. Essentially isostructural with fenaksite (70.1.1.2). Blue, vitreous luster. $H = 5-6$. $G = 2.75$. Biaxial (-); $2V = 56^\circ$; $N_x = 1.548$, $N_y = 1.574$, $N_z = 1.582$. Found as crusts with tridymite on lapilli highly modified by fumarolic activity in the *Vesuvius crater, Campania, Italy*. AR *D6:1041(1892)*, BM *104:387(1981)*.

70.1.1.2 Fenaksite $(\text{K,Na,Ca})_4(\text{Fe}^{2+}, \text{Fe}^{+3}, \text{Mn}^{+2})_2 \text{Si}_8\text{O}_{20}(\text{OH}, \text{F})$, simplified formula: $\text{KNaFe}^{2+}[\text{Si}_4\text{O}_{10}]$

Named in 1959 by Dorfman et al. from its component cations: Fe, Na, K, and Si. Compare manaksite, the Mn-analogue. Litidionite group. TRIC P1. $a = 6.79-6.98$, $b = 8.18-8.24$, $c = 9.97-9.98$, $\alpha = 105.07^\circ$, $\beta = 98.96^\circ$, $\gamma = 114.66^\circ$, $Z = 1$ (*ZVMO 121:112(1992)*), $D = 2.78$; PD *13-520* (nat.): 3.50₇ 3.03₁₀ 2.88₆ 2.71₆ 2.46₇ 1.875₆ 1.835₆ 1.752₆ (note 0 assigned because $\delta 2\theta = 0.092$) and (*ZVMO 121:112(1992)*): 6.86₅ 4.67₅ 4.48₅ 3.55₇ 3.03₁₀ 2.88₆ 2.71₆ 2.46₇. Structure: (*DAN SSSR 194:818(1970)*) and *SPD 15:902(1970)*). Essentially isostructural with litidionite, although the unit cell is chosen differently. Light rose, rose, sometimes with brownish tint, transparent and translucent; white streak; 2-4 cm granular aggregates, some prismatic crystals found: $0.4 \times 0.8 \times 0.4$ cm; luster pearly; two good cleavages at an angle of 122° : $\{001\} + \{010\}$; when abraded, it gives tangled and matted fibrous masses; splintery fracture; brittle; $H = 5-5\frac{1}{2}$. $G = 2.73-2.744$. IR data = (*MIN 3(3):361(1981)*); Mössbauer spectral data for Fe in *TMMAN 26:198(1978)*; gelatinizes in acids, easily fusible. MgO to 1%, CaO to 0.7%, MnO to 2.5%, traces of Al_2O_3 . Biax. (+) but (-) from indices; $2V = 77^\circ-84^\circ$, $2V_{\text{calc}} = 62^\circ$; $N_x = 1.541$, $N_y = 1.560$, $N_z = 1.567$; colorless, $Z = b$, $Y \wedge c = 49^\circ$, (+) elongation. Occurs in central zones of ijolite and urtite pegmatites with canasite and lamprophyllite. In rischorrite on the Rasvumchorr Plateau. Associated with alkalic minerals: canasite, delhayelite, pecto-

lite, villaumite. Occurs on *Yukspor mountain, Mt. Rasvumchorr and Kukisvumchorr, Khibiny massif, Kola Peninsula, Russia*. Also in the dumps of the Central mine. AR and EF.

70.1.1.3 Manaksite $\text{NaKMnSi}_4\text{O}_{10}$

Named in 1992 by Khomyakov et al. for the composition: Mn–Na–K–Si. See litidionite and fenaksite, the Fe analog. TRIC *P1*. $a = 6.993$, $b = 8.219$, $c = 10.007$, $\alpha = 105.11^\circ$, $\beta = 100.76^\circ$, $\gamma = 114.79^\circ$, $Z = 2$, $D = 2.71$. *PD(nat)*: 6.89₇ 4.07₅ 3.45₁₀ 3.26₉ 3.05₈ 2.88₇ 2.71₇ 2.46₇. Structure not done, but probably like fenaksite (70.1.1.2). *DAN SSSR 194:818(1970)*. Disseminated, irregular grains, 1–3 mm, aggregates to 5 mm. Colorless, creamy, rosy; white streak; vitreous luster. Cleavage {001}, perfect; {010}, good; steplike and hackly fracture; brittle. $H = 5$. $G = 2.73$. IR data available; heating ($> 600^\circ$) produces serandite, readily soluble in cold 10% HCl, with production of a creamy residue. Analysis (wt %): Na_2O , 8.9; K_2O , 10.8; SrO , 0.2; CaO , 0.2; MgO , 0.3; MnO , 17.2; FeO , 0.8; SiO_2 , 62.0. ($\text{Na}_{11}\text{K}_{0.89}\text{Ca}_{0.01}$)₂ . . . Biaxial (-); white light: $N_x = 1.540$, $N_y = 1.551$, $N_z = 1.557$; $2V = 73^\circ$; $r > v$, moderate; detailed optical orientation given. Occurs on *Mt. Alluaiev, Lovozero massif, Kola Penin., Russia*, in ultra-agpaitic pegmatite, associated with K-feldspar, nepheline, sodalite, cancrinite, and rare accessory minerals. EF *ZVMO 121:112(1992)*.

70.1.1.4 Agrellite $\text{NaCa}_2[\text{Si}_4\text{O}_{10}]\text{F}$

Named in 1976 by Gittins et al. for Stuart O. Agrell, British mineralogist, Cambridge University. TRIC *P1*. $a = 7.759$, $b = 18.946$, $c = 6.986$, $\alpha = 89.88^\circ$, $\beta = 116.65^\circ$, $\gamma = 94.32^\circ$, $Z = 4$, $D = 2.887$. *33-1230*: 3.83₃ 3.44₈ 3.33₈ 3.19₁₀ 3.14₁₀ 2.58₈ 2.31₇ 2.04₅. Structure: *AM 64:563(1979)*. The silicate structural element consists of condensed double chains that form tubular or rodlike units parallel to [001]. White, grayish or greenish white; vitreous luster, pearly on cleavage; translucent. Cleavage {110}, {110}, excellent; {010}, poor. $H = 5\frac{1}{2}$. $G = 2.90$. Biaxial (-); $2V_{\text{calc}} = 47^\circ$; $N_x = 1.567$, $N_y = 1.579$, $N_z = 1.581$; REE_2O_3 (lanthanum dominant) may be present to ≈ 2.6 wt %. Found as laths up to 10 cm elongated [001] and flattened {010} or {110} in lenses in alkalic igneous rocks of the Sheffield Lake complex, *Kipawa R., Villdieu Twp., Temiscaming Co., QUE, Canada*; also from the Murun massif, Yakutia, Russia, and the Dara-i-Pioz massif, Alai Range, Tajikistan. AR *CM 14:120(1976)*, *MZ 9:73(1987)*.

70.1.2.1 Narsarsukite $\text{Na}_2(\text{Ti,Fe,Zr})[\text{Si}_4\text{O}_{10}](\text{OH,F})$

Named in 1990 by Flink for the locality. TET *I4/m*. $a = 10.726$, $c = 7.947$, $Z = 4$, $D = 2.77$. *11-478*: 7.61₃ 5.37₁₀ 3.98₅ 3.79₃ 3.39₈ 3.26₈ 2.58₆ 2.52₆. Structure: *AM 47:539(1962)*. The silicate element is a strip of tetrahedra forming four-membered rings successively turned approximately 90° to one another along the length. Crystals tabular {001} with {001}, {101}, {110} dominant, to prismatic [001] with {100} and {001} dominant. Yellow to brownish gray,

greenish yellow to dark green; vitreous luster; translucent. Cleavage {100}, {110}, perfect. $H = 6-7$. $G = 2.78$. Uniaxial (+); $N_O = 1.604-1.612$, $N_E = 1.625-1.660$. Weakly pleochroic: $O > E$; yellow to colorless. As small crystals with aegirine and quartz at Sage Creek and Halfbreed Creek, Sweet-grass Hills, MT; as tabular and prismatic crystals(l) at Mt. St.-Hilaire, PQ, Canada; in fine crystals(l) at Igdlutalik, Ilimaussaq, and Narsarsuk, Greenland; at Gjerdingen, Nordmark, Norway; Mt. Flora, Lovozero massif, Kola Penin., Russia; and at Gurē, Sudan. *AR AM* 59:269(1959), *MR* 21:324(1990), *EJM* 3:574(1991), *ZVMO* 123:58(1994).

70.1.2.2 Caysichite-(Y) $Y_2(Ca,Gd)_2Si_4O_{10}(CO_3)_3(H_2O,O,OH) \cdot 3H_2O$ Narsarsukite group.

Named in 1974 by Hogarth et al. for the composition, contains Ca, Y, Si, C, H. ORTH. *Ccm2*₁. $a = 13.27-13.283$, $b = 13.91-13.925$, $c = 9.724-9.73$, $Z = 4$, $D = 3.03$ (*CM* 12:293(1974) 26-1394 (nat.) 6.93₁₀ 4.87₄ 4.38₆ 4.22₆ 3.48₆ 3.32₉ 3.20₃ 2.32₄). See also *MA* 27:82(1972). Structure determined: *CM* 16:81(1978). Crystals are prismatic, elongated on c and terminated by {001}. Colorless to white, rarely pale yellow or pale green; white streak; vitreous luster; good {010} cleavage, $H = 4\frac{1}{2}$; $G = 2.9-3.03$; IR data = (*MA* 27:82(1972)); decomposed by cold HCl with evolution of CO_2 + formation of silica residue. Non-fluorescent, but has a faint green cathodoluminescence under the electron beam. Biaxial (-), for colorless material: $2V = 53^\circ$, $2V_{calc} = 54.5^\circ$, $N_x = 1.586$, $N_y = 1.614$, $N_z = 1.621$; for yellowish material: $2V = 73^\circ$, $2V_{calc} = 62^\circ$, $N_x = 1.589$, $N_y = 1.616$, $N_z = 1.626$. $XYZ = bac$. Occurs in granite pegmatite lining cavities as a dull, white pulverulent coating or as a stain. Also as incrustations, reniform masses and stalagmites to 1 cm long. Occurs in granite as spherulitic crusts and overgrowths assoc. with tenerite-(Y), opal and synchysite-(Y). *Evans-Lou feldspar mine, Portland West Township, Quebec, Canada; Kazakhstan.*

70.1.2.3 Charoite $K_5Ca_8(Si_6O_{15})_2(Si_2O_7)Si_4O_9(OH) \cdot 3H_2O$ and $(K,Na)_5(Ca,Ba,Sr)_8(Si_{12}O_{30})Si_6O_{16}(OH,F) \cdot nH_2O$ (KSTM, 100(1985) and GSAPA 26:A481(1994) find K 3.5-4.0, Na 1.3-1.7, Ca 6.8-7.1, Ba 0.3-0.4, Sr 0.05-0.1, Mn^{2+} 0.04-0.09, Si 18.01-18.28, F 0.17-0.59, Al, Ti, Fe, Mg, Zr, & Th are <0.01 wt %. Another composition given is: $(K_{2.88}Na_{1.03})(Ca_{5.58}Ba_{0.23}Sr_{0.11}Mn_{0.04})(Si_{14}Al_{0.02})O_{35}(OH)_2 \cdot 3H_2O$ (GSAAP 27(6):A440(1995).

Named by Rogova et al. in 1978 for the impression that it gives: "chary" in Russian means "charms" or "magic" and not for the Chara River, which is 70 km away, Murun Massif, NW Aldan, Yakutia, USSR. *MON P*/4*. $a = 19.61\text{\AA}$, $b = 32.12\text{\AA}$, $c = 7.20\text{\AA}$; $\beta = 93.76^\circ$; $Z = 4$, $D = 2.68$. 42-1402 (nat.) 32.0₆ 12.4₁₀ 9.39₂ 3.90₂ 3.35₆ 3.13₄₅ 2.98₂ 2.80₂. Structure: not done. Electron diffraction studies suggest that the mineral has an orthorhombic-shaped unit cell of dimensions: $a = 19.6\text{\AA}$, $b = 32\text{\AA}$, $c = 7.2\text{\AA}$, a second polymorph, intimately intergrown with the first (monoclinic), has a b -axis repeat of 64Å (*GSAAP* 27(6):A-

440(1995). The *c*-axis dimension is consistent with a structure based on linkage of wollastonite-type chains, forming sheets whose *b*-axis length is defined by two pyroxenoid and one pyroxene chain repeat. Violet-lilac; white; fibrous, elongate on *c*; vitreous to silky in aggregates; 3 cleavages present, good; $H \approx 5-6$ VHN = 412 Kg/mm² (50 g load); $G = 2.54-2.58$; IR and thermal data = (ZVMO 107:94(1978)); luminescence = very weakly fluorescent in SW & LWUV, bright orangish yellow cathodoluminescence; insoluble in common acids. Charoite does show cation exchange properties (GSAAP 27(6): A440(1995). Analysis (wt.%): SiO₂ 57.06, CaO 21.76, BaO 2.68, SrO 0.58, K₂O 9.23, Na₂O 2.00, MnO 0.16, H₂O 5.39, F 0.54; color is due to Mn³⁺. Analyses given in (Min 3(3):378(1981)). Biaxial (+); $2V = 29^\circ$, $N_x = 1.550$, $N_y = 1.553$, $N_z = 1.559$; colorless in section, (+) elongation, $X = b$, $Z \wedge c = 5^\circ$. Occurs in at least 25 areas within a syenite massif, in metasomatic rocks, formed between 200–250°C. Enriched in K at the contact of the massif, with limestone. Associated with canasite, tinaksite, aegirine and other minerals. *Murun massif, Chara River area, Aldan Shield, SW Yakutia (Sakha Republic)*. Alters to 'charoite asbestos', a white to cream-colored felt-like mass, which differs in OH-content from charoite. Extensively used as a semi-precious jewelry stone and for lapidary work; cabochons, vases, boxes, etc. The mineral occurs in a number of different textures (World of Stones, no. 7, 3(1995)).

70.2.1.1 Miserite $K(\text{Ca,Ce})_6[\text{Si}_8\text{O}_{22}](\text{OH,F})_2$

Named in 1950 by Schaller for Hugh Dinsmore Miser (1884–1969), geologist, U.S. Geological Survey. TRIC P1. $a = 10.100$, $b = 16.014$, $c = 7.377$, $\alpha = 96.42^\circ$, $\beta = 111.15^\circ$, $\gamma = 76.57^\circ$, $Z = 2$, $D = 2.646$. ρ_{2-806} : 15.6₆ 3.47₅ 3.36₅ 3.14₁₀ 2.83₆ 2.38₇ 1.845₆ 1.641₈. Structure: CM 14:515(1976). The structure is based on a tubular unit of four condensed wollastonite-type chains and isolated [Si₂O₇] dimers, but the formula given with the structure determination gives yttrium in place of cerium. Pink to lavender, reddish brown; vitreous or pearly luster; translucent. Cleavage {100}, perfect; {010}, imperfect. $H = 5\frac{1}{2}-6$ (but also given as $2\frac{1}{2}$). $G = 2.84-2.93$. Biaxial (+); $2V = 52-78^\circ$; $N_x = 1.580-1.586$, $N_y = 1.583-1.593$, $N_z = 1.590-1.600$; $XZ = ca$; negative elongation. Insoluble in acids. As fibers and bladed masses with wollastonite in metamorphosed shale at *Wilson Mineral Springs, AR*; at the Kipawa Lake area, Temiscamingue Co., in carbonatite, and at Mt. St.-Hilaire, QUE, Canada; in the Dara-Pioz alkalic massif, Alai Range, Tajikistan. AR AM 35:911(1950), CM 11:569(1972), MR 21:32(1990).

70.2.2.1 Penkvilksite $\text{Na}_4\text{Ti}_2[\text{Si}_8\text{O}_{22}] \cdot 5\text{H}_2\text{O}$

Named in 1974 by Bussen et al. from the Lapp *penk* and *vilkis*, white and curly, in allusion to its appearance. ORTH or MON Space group unknown. $a = 7.48$, $b = 8.77$, $\gamma \approx 90^\circ$ (derived from powder data). ρ_{2-1386} : 8.20₁₀ 3.42₆ 3.37₉ 3.32₇ 3.10₇ 3.07₇ 2.84₈ 1.713₇. White; porcelaneous; dull luster, pearly or silky on fracture. Perfect cleavage in one direction. $H = 5$. $G = 2.58$. Biaxial

(+); $2V = 42^\circ$; $N_x = 1.637$, $N_y = 1.640$, $N_z = 1.662$. Gelatinizes with acids. Rarely as clusters and rosettes of tabular crystals at Mt. St.-Hilaire, QUE, Canada; as "clotted" masses with mountainite, aegirine, and raitite in the *Jubilee pegmatite deposit, Mt. Karnarsut, Lovozero massif, Kola Penin., Russia*. AR AM 60:340(1975), MR 21:329(1990).

70.3.1.1 Ashcroftine-(Y) $K_{10}Na_{10}(Y,Ca)_{24}(Si_{56}O_{140})(CO_3)_{16}(OH)_4 \cdot 16H_2O$

Named in 1933 by Hey and Bannister for Frederick Noel Ashcroft (1878–1949), a prominent mineral collector of London. Originally described as kalithompsonite in 1924 by Gordon. TET $I4/mmm$. $a = 23.994$, $c = 17.512$, $Z = 2$, $D = 2.60$. $22-508$: 17.0₁₀ 12.0₉ 7.62₆ 7.10₂ 6.01₃ 5.38₃ 3.11₅ 2.69₅. Structure: AM 72:1176(1987). An unusual structure consisting of ball-like clusters of composition $(Si_{48}O_{128})$ joined to one another by four pairs of (SiO_4) tetrahedra to form columns parallel to [001]. Capillary to fibrous [001] up to 20 mm long with length/width $\approx 100:1$; often bent; powdery. Pale violet, pink, white; silky luster. Cleavage {100}, perfect; {001}, good. $H = 5(?)$, also stated to be soft. $G = 2.61$. Uniaxial (+); $N_O = 1.536$, $N_E = 1.545$; also biaxial (+); $2V$ small; $N_x = 1.535$, $N_y = 1.537$, $N_z = 1.545$. Distinguished from lorenzenite by lack of fluorescence in UV. In breccia zones andmiarolitic cavities in nepheline syenite at Mt. St.-Hilaire, QUE, Canada, often intergrown with lorenzenite, with which it is easily confused. Found in vugs in aegirine pegmatite in augite-syenite at Narssarsuk, Greenland. AR MM 23:305(1933), 37:515(1969); MR 21:296(1990).

70.4.1.1 Neptunite $KNa_2Li(Fe^{2+},Mn)_2Ti_2O_2[Si_8O_{22}]$

Named in 1893 by Flink for *Neptune*, the Roman god of the sea, because it was found with aegirine, which was named for the Scandinavian god of the sea. See manganneptunite (70.4.1.2). MON Cc. $a = 16.46$, $b = 12.50$, $c = 10.01$, $\beta = 115.43^\circ$, $Z = 4$, $D = 3.14$. $14-134$: 9.6₆ 3.52₄ 3.31₃ 3.19₁₀ 2.94₃ 2.90₃ 2.84₃ 2.48₃. Structure: AC 21:200(1966), PCM 18:199(1991). The structure consists of two interlaced cages built of linked chains parallel to [110] and $[\bar{1}\bar{1}0]$ such that each cage has two 18-tetrahedron rings and four 14-tetrahedron rings, resulting in an $[Si_{16}O_{44}]^{24-}$ element. Crystals prismatic [001], with dominant {110}, {100}, and terminated by {111}, $\{\bar{1}\bar{1}\bar{1}\}$, and {311}. Black with reddish-brown internal reflection, reddish-brown streak, vitreous luster, nearly opaque. Cleavage {110}, perfect; conchoidal fracture. $H = 5-6$. $G = 3.19-3.23$. Biaxial (+); $2V = 45-65^\circ$; $N_x = 1.697-1.711$, $N_y = 1.710-1.721$, $N_z = 1.735-1.744$; $Y = b$, $Z \wedge c = 16-20^\circ$; $r < v$, strong. Strongly pleochroic, $Z > Y > X$; yellow-orange to deep red. Insoluble in acids. Complete solid solution with manganneptunite; Mg may substitute for iron. Alters to brown crossite. Most commonly associated with syenitic rocks. Found at Point of Rocks, near Springer, Colfax Co., NM; with benitoite in natrolite at the Dallas Gem mine, San Benito Co., CA(1); at Mt. St.-Hilaire, QUE, Canada. Found with eudialyte in nepheline syenite at Narsarsuk, Julianehaab

district, Greenland; from the Khibiny and Lovozero massifs, Kola Penin., Russia; the Dara-i-Pioz massif, Alai Range, Tajikistain; at Weal Guk Ri, Dang Myun, Gang Weon Prov., Korea; in the Wood's Reef serpentinite, NSW, Australia. AR CM 7:679(1963), AM 57:85(1972).

70.4.1.2 Manganneptunite $\text{KNa}_2\text{Li}(\text{Mn},\text{Fe}^{2+})_2\text{Ti}_2\text{O}_2[\text{Si}_8\text{O}_{22}]$

Named in 1923 by Kurbatov for the composition and relationship to neptunite. See neptunite (70.4.1.1). MON *Cc*. $a = 16.38$, $b = 12.48$, $c = 10.01$, $\beta = 115.4^\circ$, $Z = 4$, $D = 3.26$. *29-823*: 2.95₅ 2.90₅ 2.84₆ 2.49₁₀ 2.17₈ 1.924₇ 1.506₁₀ 1.483₉. Isostructural with neptunite. Reddish black, red-brown streak, vitreous luster, translucent to opaque. Cleavage {110}, perfect; conchoidal fracture. $H = 5-6$. $G = 3.23$. Biaxial (+); $2V = 35-45^\circ$; $N_x = 1.691-1.697$, $N_y = 1.700-1.710$, $N_z = 1.725-1.735$; $Y = b$, $Z \wedge c = 16-20^\circ$; $r < v$, strong. Strongly pleochroic; $Z > Y > X$; yellow-orange to deep red. Fusibility 2.5. Insoluble in acids. Complete solid solution with neptunite. Found at Point of Rocks, Colfax Co., NM in syenites and syenite pegmatite at Mt. St.-Hilaire, QUE, Canada, and in the *Lovozero massif, Kola Penin., Russia. AR AM 12:96(1927), ZVMO 94:204(1965).*

70.5.1.1 Chiavennite $\text{CaMn}(\text{BeOH})_2\text{Si}_5\text{O}_{13} \cdot 2\text{H}_2\text{O}$

Named in 1983 by Bondi et al. and Raade et al. for the Italian locality. Related to zeolites and zeolite-like minerals. Compare tvedalite. ORTH *Pnab* (standard setting), $P2_1ab$ (for $c < a < b$). (Italy): $a = 8.729$, $b = 31.326$, $c = 4.903$; (Norway): $a = 8.866$, $b = 31.34$, $c = 4.787$, (Sweden): $a = 8.905$, $b = 31.229$, $c = 4.775$, $Z = 4$, $D = 2.63-2.66$; PD *35-602* (nat.): 15.7₁₀ 7.80₂ 4.15₃ 3.93₃ 3.82₃ 3.28₇ 2.90₁₀ 1.94₃. Structure consists of an interrupted framework of four-connected [SiO₄] and three-connected [BeO₄] tetrahedra, which consists of zig-zag chains to form a zeolite-like framework. Ca and Mn are in eight- and six-fold coordination respectively. The framework contains channels along [001] formed by 9-membered rings of O atoms, with free channel diameters of $3.9 \times 4.3\text{\AA}$: (*EJM 7:1339(1995), RSIMP 37:994(1981)*). The framework density classifies the mineral as a zeolite. Hemimorphic, spear-shaped crystals flattened on {010} with {161} pyramid, elongated on [100]. Also flat, pseudo-hexagonal, with perf. "basal" cleavage. Spherulites to 2 mm across, with individual crystals 10 μ thick. Crystals may be 1 mm long. Pale orange-yellow to reddish orange, or bright orange-orange red, translucent, white streak, vitreous, good to perf. cleavage on {100}, {010}, and {001}, $H = 3$, $G = 2.56-2.64$. IR and thermal data *AM 68:623(1983)* and *AM 68:628(1983)*. Insol. in H₂O, HCl, HNO₃ and H₂SO₄. Norwegian material contains Fe(1.5 wt % FeO) which is believed to be the chromophore. Al₂O₃ 3.6-6.0 wt % (substitutes for Be and Si), minor to trace Na, Mg, CO₂ and F. Utö material contains 1.0 wt. % B₂O₃ and 2.4 wt. % Fe₂O₃. Italian material is quite pure. There is some variation in T_{Si} (063-068). Biax.(+), $2V_z(\text{calc}) = 50^\circ$, (Italy) $N_x = 1.581$, $N_z = 1.600$, (Norway) $N_x = 1.596$, $N_y = 1.600$, $N_z = 1.618$. Faintly pleochroic, X = colorless to yel-

low, $Z =$ yellow orange. Norwegian material is pale yellowish brown, $X < Z$. $X = a$, $Y = b$, $Z = c$, OAP = (010), disper. $r \gg v$. In vugs in syenite pegmatite (Norway), fracture-fillings in massive microcline and analcime (Norway) and coating beryl in granitic pegmatite (Italy). A late-stage, low-temperature hydrothermal mineral. *Tanno, Valle di San Giacomo, Chiavenna, Lombardia, Italy*; Utö, Stockholm, Sweden; Vevja and Heia quarries, Tvedalen, 10 km W of Larvik, and twelve other localities in the Larvik-Oslo region including Langangen, Langesundsfjord, and Bakkane, Brunlanes, Vestfold County, Norway. AR, EF *AM 77:438(1992)* 16th IMA Gen. Meeting Abst., p. 232(1994).

70.5.2.1 Tvedalite $(\text{Ca},\text{Mn})_4\text{Be}_3\text{Si}_6\text{O}_{17}(\text{OH})_4 \cdot 3\text{H}_2\text{O}$

Named in 1992 by Larsen et al. for the type locality. Compare chiavennite – close in chemistry and cell dimensions. ORTH C face centered lattice. $a = 8.724\text{Å}$, $b = 23.14$, $c = 4.923$, $Z = 2$, $D = 2.55$. *PD 44-1465* (nat.): 11.64₉ 5.86₇ 4.20₅ 3.87₈ 3.16₇ 2.89₈ 2.84₁₀ 2.49₆. Structure: no single-crystal work was possible. Cream white, pale gray to pale beige, streak white; spherulites, radial platelets, always overgrown by a crust of chiavennite; vitreous; cleavage = {010} perfect. $H = 4\frac{1}{2}$. $G = 2.54$. IR, TGA and DTA data (*AM 77:438(1992)*); non-fluorescent in UV; slightly soluble in hot, concentrated HCl. Zoned: $\text{Ca}_{50}\text{Mn}_{46}\text{Fe}_4 - \text{Ca}_{80}\text{Mn}_{18}\text{Fe}_2$ (in % of divalent atoms). SiO_2 44.2–45.8, Al_2O_3 0.6–1.1, FeO 0.8–1.8, MnO 6.9–15.8, CaO 13.4–24.1, BeO 10.7, H_2O 11.8. Biax , $N_{\text{av}} = 1.604$, close to the average value for chiavennite. Occurs in vugs in a nepheline–syenite pegmatite. Occurs as minute tabular crystals in spherulitic aggregates up to 3 mm diameter in nepheline–syenite pegmatite at the *Vevja larvikite quarry, Tvedalen, Brunlanes, Vestfold Co., Norway*. AR, EF.

70.5.3.1 Bavenite $\text{Ca}_4\text{Be}_2\text{Al}_2\text{Si}_9\text{O}_{26}(\text{OH})_2$ to $\text{Ca}_4\text{Be}_3\text{Al}[\text{Si}_9\text{O}_{25}(\text{OH})_3]$

Named in 1901 by Artini for the locality. ORTH. *Cmcm* (*MM 47:87(1983)*); originally given as: $a = 9.72\text{Å}$, $b = 11.65\text{Å}$, $c = 4.94\text{Å}$ $Z = 16$; all other sources have a and b doubled: a 19.38–19.480 Å b 23.19–23.22 Å c 4.94–5.00 Å , $Z = 4$, $D = 2.77$; (nat.) (*MM 47:87(1983)*); *ICDD 13-535*: 4.86₈ 3.73₈ 3.46₅ 3.32₁₀ 3.24₁₀ 3.12₈ 3.05₆ 1.94₉. True symmetry is probably monoclinic or triclinic based on inclined and irregular extinction (optical) as being the result of twin formation, along with distinct extinctional dispersion (*NJBM 321(1995)*). Structure determined: (*AC 20:301(1966)*, *ZSK 12:87(1971)*). Structural formula can be given as: $\text{H}_n\text{Ca}_4\text{Be}_{2+n}\text{Al}_{2-n}(\text{SiO}_3)_9 \cdot x\text{H}_2\text{O}$ where n is between 0.1 and 0.8. White, colorless, pale green, pale rose or pink; crystals are fibrous, prismatic, as well as bladed habit; may also be chalk-like and massive; elongated on c , flattened on a , and in radial lamellar masses. Radiating groups to 6 cm; dominant forms (using $a = 23.19\text{Å}$, $b = 5.005\text{Å}$, $c = 19.39\text{Å}$ are: {001}, {100}, {010}, {101}, {201}, {310}, {510} and {111} with {100} dominating. {100} twins known. Streak white, earthy to vitreous or silky; cleavage: {001} excellent, {010} fair to good; brittle, $H = 5\frac{1}{2}$ –6, $G = 2.68$ –2.76; weakly piezo-

electric; IR data: Minerali 3(1) 564:1972. Magnetic properties: MZ 6:64(1984). Not soluble in common acids. DTA, TGA: Minerali 3(1) 564(1972) and RSMI 18:53(1962). Traces of Na_2O , MgO , and Fe_2O_3 are usually present. Bavenite from Ilimaussaq has SiO_2 58.5 wt. %, Al_2O_3 5.60, CaO 24.25, BeO 9.5, H_2O 1.8, $\Sigma = 99.70$, and is the Be-richest and Al-poorest bavenite yet reported. Biaxial (+); $2V = 26\text{--}60^\circ$, $N_x = 1.578\text{--}1.586$, $N_y = 1.579\text{--}1.589$, $N_z = 1.583\text{--}1.593$ (USGSB 1627(1984)); for Ilimaussaq bavenite which is Be-richest and Al-poorest (NJBM 321(1995)): $N_x = 1.5845$, $N_y = 1.5845$, $N_z = 1.5957$ with a $2V_z = 18^\circ$ and dispersion $r > v$ to $r \gg v$; colorless; optical orientation: positive elongation, OAP || to (100) and $XYZ = bac$. Occurs in granitic pegmatites and miarolitic cavities in such pegmatites; often pseudomorphous after beryl. Also found replacing emerald - Urals. In skarns, e.g. Baty-stau, Ilimaussaq and Thailand. In some greisens and zones of pneumatolytic alteration. Occurs in minor amounts in many localities. Only noteworthy or unusual occurrences are given here. In pegmatite at Waterville Valley, NH; and at Haddam, CT; at the Rutherford mine, Amelia, VA; Foote quarry, Kings Mountain, NC; coating on minerals in miarolitic cavities and as pseudomorphs after beryl in the Himalaya dike system, Mesa Grande district, San Diego Co., CA; Ilimaussaq complex, Kangerdluarssuk Fjord, Greenland; Val D'Ossola and *Baveno*, *Lago Maggiore*, *Piedmonte*, *Italy*; various locations in Switzerland (SMPM 50:445(1970); Striegau (Strzegom), Silesia, Poland; Marsikov, Drahonin and Jeclava, Moravia (after beryl), Czech Rep.; Akoudertia, Siberia; various emerald mines in the Malyshevo district, Urals, Russia: Batystau, central Kazakhstan; massive bavenite with epidote from Kalisay, Kyrgyzia; crystals to 5 cm long from Doi Mok mine, Wiang Pa Pao, north Thailand; Londonderry, W. Australia. *MAC SC 8:135(1982) NJBM 321(1995)*. EF

Sheets of Six-Membered Rings

KAOLINITE-SERPENTINE GROUP

The kaolinite-serpentine group of minerals are phyllosilicates with the general chemical formula:

where

A=Al, Fe³⁺, Mg, Ti, Mn.

The structure is based on a t-o (tetrahedral-octahedral) layer (also called a 1 : 1 layer). The t-o layer itself consists of an infinite sheet of Si-Al tetrahedra made up of linked hexagonal rings of composition Si₂O₅. The apical oxygens of the sheet all point in the same direction and provide the base for a set of octahedral sites. Hydroxyl groups complete the octahedral sites.

The t-o layers are electrically neutral. The entire exterior octahedral side of the t-o layer consists of hydroxyl groups, available for hydrogen bonding to the oxygen-covered exterior of the next "t" layer.

The dimensions of ideal trioctahedral sheets are slightly mismatched to the dimensions of ideal sheets of tetrahedra, and the dimensional mismatch [predicted by Linus Pauling, *PNAS* 16:578(1930)] is relieved by one of four mechanisms that form the basis for the division of the serpentine (trioctahedral) subgroup.

Polymorphism is extensive in the kaolinite-serpentine group. Successive layers may be translated $-(a/3)$, $\pm(b/3)$ and may be rotated $\pm 60^\circ$, $\pm 120^\circ$, or 180° . References to the polytypes are found in *Electron-Diffraction Analysis of Clay Mineral Structures*, Zvyagin(1967), *CCM* 17:355(1969), *AM* 53:14(1968), *CM* 14:314(1976).

KAOLINITE SUBGROUP, DIOCTAHEDRAL

Mineral	Formula	
Dickite*	$\text{Al}_2\text{Si}_2\text{O}_5(\text{OH})_4$	71.1.1.1
Kaolinite	$\text{Al}_2\text{Si}_2\text{O}_5(\text{OH})_4$	71.1.1.2
Nacrite*	$\text{Al}_2\text{Si}_2\text{O}_5(\text{OH})_4$	71.1.1.3
Halloysite	$\text{Al}_2\text{Si}_2\text{O}_2(\text{OH})_4 \cdot 2\text{H}_2\text{O}$	71.1.1.4
Odinite	$(\text{Fe}^{3+}, \text{Mg}, \text{Al}, \text{Fe}^{2+}, \text{Ti}, \text{Mn})_{2-42}(\text{Si}, \text{Al})_2\text{O}_5(\text{OH})_4$	71.1.1.5

*Named polytypes.

SERPENTINE-ANTIGORITE-RELATED SUBGROUP, TRIOCTAHEDRAL

Mineral	Formula	
Antigorite	$\text{Mg}_3\text{Si}_2\text{O}_5(\text{OH})_4$	71.1.2a.1

Strain relieved by an alternating wave of curved t-o sheets.

SERPENTINE-LIZARDITE-RELATED SUBGROUP, TRIOCTAHEDRAL

Mineral	Formula	
Caryopilite	$(\text{Mn}, \text{Mg}, \text{Zn}, \text{Fe})_3(\text{Si}, \text{As}), \text{O}_5(\text{OH}, \text{Cl})_4$	71.1.2b.1
Lizardite	$\text{Mg}_3(\text{Si}, \text{Al})_2\text{O}_5(\text{OH})_4$	71.1.2b.2
Nepouite	$\text{Ni}_3\text{Si}_2\text{O}_5(\text{OH})_4$	71.1.2b.3
Greenalite	$\text{Fe}_3^{2+}\text{Si}_2\text{O}_5(\text{OH})_4$	71.1.2b.4

Strain relieved by minor Al and/or Fe^{3+} substitution with the R^{3+} occupying a smaller polyhedron.

SERPENTINE-AMESITE-RELATED SUBGROUP, TRIOCTAHEDRAL

Mineral	Formula	
Amesite	$(\text{Mg}_2\text{Al})[\text{SiAl}]\text{O}_5(\text{OH})_4$	71.1.2c.1
Berthierine	$\text{Fe}_2^{2+}\text{Al}(\text{SiAl})\text{O}_5(\text{OH})_4$	71.1.2c.2
Brindleyite	$\text{Ni}_2\text{Al}(\text{SiAl})\text{O}_5(\text{OH})_4$	71.1.2c.3
Fraipontite	$(\text{Zn}, \text{Ca}, \text{Al})_3(\text{SiAl})_2\text{O}_5(\text{OH})_4$	71.1.2c.4
Kellyite	$\text{Mn}_2^{2+}\text{Al}[\text{SiAl}]\text{O}_5(\text{OH})_4$	71.1.2c.5
Manandonite	$\text{Li}_2\text{Al}_4[(\text{Si}_2\text{AlB})\text{O}_{10}](\text{OH})_8$	71.1.2c.6
Cronstedtite	$\text{Fe}_2^{2+}\text{Fe}^{3+}(\text{Si}, \text{Fe}^{3+})\text{O}_5(\text{OH})_4$	71.1.2c.7

Strain relieved by extensive Al substitution in both the t and o layers.

SERPENTINE-CHRYSOTILE-RELATED SUBGROUP, TRIOCTAHEDRAL

Mineral	Formula	
Clinochrysotile	$\text{Mg}_3\text{Si}_2\text{O}_5(\text{OH})_4$	71.1.2d.1
Orthochrysotile	$\text{Mg}_3\text{Si}_2\text{O}_5(\text{OH})_4$	71.1.2d.2
Parachrysotile	$\text{Mg}_3\text{Si}_2\text{O}_5(\text{OH})_4$	71.1.2d.3
Pecoraite	$\text{Ni}_3\text{Si}_2\text{O}_5(\text{OH})_4$	71.1.2d.4

Strain relieved by developing a cylindrically rolled structure.

Reference: *MIN 41:122(1992)*.

Kaolinites show only moderate chemical variations. There has been much discussion of the compositional differences of the Mg serpentines and the extent to which they are polymorphs or are compositionally different. *CM 13:227(1975)*, *AM 55:1025(1970)*. Excess silica is present in many analyses and is attributed to interstratified 2 : 1-layer phyllosilicate impurities or to Mg and OH vacancies. *CM 17:785(1979)*.

71.1.1.1 Dickite $\text{Al}_2\text{Si}_2\text{O}_5(\text{OH})_4$

71.1.1.2 Kaolinite $\text{Al}_2\text{Si}_2\text{O}_5(\text{OH})_4$

71.1.1.3 Nacrite $\text{Al}_2\text{Si}_2\text{O}_5(\text{OH})_4$

Kaolinite is named for the ancient Chinese locality Kauling, *high ridge*. Dickite was named by Ross and Kerr in 1930 for A. B. Dick, British mineralogist, and nacrite was named by Brongniart in 1807 in allusion to its pearly luster. Kaolinite-serpentine group. Polytypes known as kaolinite, dickite, nacrite, and halloysite. Anauxite = kaolinite + silica. Naorite: TRIC C1 (also P1). $a = 5.13\text{--}5.16$, $b = 8.89\text{--}8.95$, $c = 7.25\text{--}7.40$, $\alpha = 90\text{--}91.8^\circ$, $\beta = 104.5\text{--}105^\circ$, $\gamma = 89.8\text{--}90^\circ$, $Z = 1$; dickite: MON Cc. $a = 5.14\text{--}5.15$, $b = 8.94$, $c = 14.40\text{--}14.74$, $\beta = 96.7^\circ$, 103.58° , $Z = 2$; nacrite: MON Cc. $a = 8.909\text{--}8.96$, $b = 5.146\text{--}5.15$, $c = 14.35\text{--}15.70$, $\beta = (100^\circ)$, 113.70° , $Z = 2$, $D = 2.63$. 14-164(kaolinite-1A, nat): 7.17₁₀ 4 37₆ 4.19₄₅ 3.58₈ 2.49₄₅ 1.62₇ 1.59₆ 1.49₉; 29-1488(kaolinite-1Md, nat): 7.1₁₀ 4 41₆ 3.56₁₀ 2.55₂₅ 2.49₃ 2.37₅₂ 2.33₄ 1.49₃; 10-446(dickite-2M₁, nat): 7.15₁₀ 4.12₇ 3.80₆ 3.58₁₀ 2.51₅ 2.33₉ 1.97₅₅ 1.49₅; 16-606(nacrite-2M₂, nat): 7.18₁₀ 4.41₃ 4.36₈ 4.13₇ 3.59₈ 2.43₆ 2.40₄ 1 49₄. Kaolinite is a 7-Å phyllosilicate which consists of a sheet of silicate tetrahedra polymerized to form nearly hexagonal, ditrigonal openings, due to vacancies in the tetrahedral sheet. The tetrahedral sheet has an essentially coplanar surface of oxygen atoms with the unpolymerized tetrahedral apices directed toward, and forming part of, coordination polyhedra, which, together with additional oxygens and hydroxyls, constitute a layer of octahedral sites two-thirds occupied by Al. Hydroxyls are located below the center of the hexagonal openings of the tetrahedral sheet on the surface of the octahedral sheet and on the entire surface of the octahedral sheet opposite the tetrahedral sheet. Polyhedral distortions and rotations are present to minimize bond energies [*AM 58:471(1973)*] and the layer contains minor corrugations. Kaolinite is dioctahedral with $d_{060} \sim 1.49\text{--}1.50$ Å and has no layer charge. The structure is united by angled hydrogen bonds extending from hydroxyls of the octahedral sheet of one layer to oxygens of the adjacent tetrahedral sheet of the next layer. *CCM 29:316(1981)*, *31:352(1983)*, *32:483(1984)*. Structure of triclinic material: *CCM 36:225(1988)*. The stacking of kaolinite layers is frequently turbostratic, which can result in the loss of definition of XRD peaks in the range 20–24° 2θ, as well as loss of many otherwise permitted *hkl* reflections. This disordered material, which can be pseudomonoclinic, then gives a broad asymmetrical band-like peak, consisting of three coalescing peaks, which is steep at ~ 20° 2θ and which declines in intensity toward the base of d_{002} at

$\sim 29^\circ 2\theta$. Additional defects include $\pm^{nb}/3$ translations and $\pm^{2p}/3$ rotations of adjacent layers. Defects also increase with $^{IV}\text{Fe}^{3+}$. *BM 105:457(1982)*. The Hinckley Index [*CCM 11:229(1963)*] involves the ratio of X-ray diffraction peaks in the range $20\text{--}24^\circ 2\theta$ and is a measure of stacking order, but for low-defect kaolinites, $\text{HI} > 0.43$, the value represents the abundance of the low-defect kaolinite in the entire sample. *CCM 37:203(1989)*. In well-ordered kaolinite, these three peaks are more intense and are well resolved. In practice, however, relatively few peaks are observable, especially in mixtures. Kaolinite derived from plagioclase can have a higher crystallinity index than that derived from alkali feldspar. *DS 27:609(1979)*. Specimen grinding can induce additional disorder. Kaolinite has three polytypes which have historically been given separate names: kaolinite, dickite, and nacrite. **Habit:** Kaolinite is characterized by a stacking sequence of $-a/3$ translations and superimposed layer vacancies. Dickite is a polytype of kaolinite where each layer is shifted by $-a/3$, as in kaolinite proper, but with alternating superpositions of vacancies equivalent to $\pm 120^\circ$ relative rotation of adjacent layers. *CCM 37:297(1989)*. Nacrite was originally thought to be a six-layer polytype, but a two-layer stacking has been derived. The pattern of vacancies in nacrite shifts the symmetry and requires the interchange of a and b axis labels relative to kaolinite and dickite [*AM 48:1196(1963)*], but thus with $-a/3$ stacking sequence and $\pm 60^\circ$ relative rotation of adjacent layers. *CCM 37:297(1989)*. Kaolinite synthesis has been reviewed with temperatures ranging from surface conditions to 400° . *KZ 17:181(1986)*. Kaolinite polytypes are not yet systematically useful indicators of their mode of formation, and all three polytypes have been found in a single deposit. *CCM 29:451(1981)*. NMR studies have been made. *DAN SSSR 261:1169(1981)*, *JCSF I 84:117(1988)*. IR studies are numerous. Kaolinite has been intercalated with K-acetate, hydrazine, amines, urea, dimethyl sulfoxide, and others. Kaolinite polytypes are decomposed and become X-ray amorphous on heating to 550° . **Physical properties:** Usually white, also pale yellow to cream, pale green to pale blue, can be lightly to heavily stained yellow or red to brown. Usually earthy, also waxy to pearly; unctuous, can be plastic when wet and varies from freely slaking to flinty, nonslaking and has even been found as stream cobbles. Crystals pseudohexagonal platy, but usually $2\text{--}5\ \mu\text{m}$ visible crystals rare but may be more than 1 mm across. SEM photographs of kaolinite usually show hexagonal platelets or curved stacks of plates, but fibers and spheres have been observed. Mica-law pseudotwinning has been observed. *AM 57:411(1972)*. Cleavage $\{001\}$, perfect; flexible but inelastic. $H = 2\text{--}2\frac{1}{2}$, hardness may be affected by amorphous to crystalline silica impurities. G below 2.0 when porous, but can be up to $2.60\text{--}2.68$. Infusible. Insoluble in most acids, but can be attacked by HCl. Dickite can show distinct cathode luminescence. *CCM 29:451(1981)*. **Optics:** Kaolinite: biaxial (-); OAP perpendicular to (010), $Z = b$, $X \wedge c = 1\text{--}4^\circ$, also $X \wedge c = -10$ to -13° , and $Y \wedge a = 1\text{--}4^\circ$; $N_x = 1.553\text{--}1.565$, $N_y = 1.559\text{--}1.569$, $N_z = 1.560\text{--}1.570$; birefringence = $0.005\text{--}0.010$, usually ≈ 0.006 ; $2V = 24\text{--}50^\circ$; $r > v$, weak; rarely pleochroic, colorless to pale yellow. Dickite: biaxial (+); $Z = b$; $Y \wedge a = 14\text{--}20^\circ$; $N_x = 1.560\text{--}1.564$, $N_y = 1.561\text{--}1.566$, $N_z = 1.566\text{--}$

1.570; birefringence = 0.006; $2V = 55-80^\circ$; $r \gg v$. Nacrite: biaxial (-, +); $Z = b$, $X \wedge c = 10-12^\circ$; $N_x = 1.557-1.560$, $N_y = 1.562-1.563$, $N_z = 1.563-1.566$; birefringence = 0.006; $2V = 40-90^\circ$; $r > v$. **Chemistry:** Kaolinite does not have a large chemical variation, most of which can be attributed to a few elements; very minor quantities of other clay impurities, iron oxides, and others. Fine-grained detrital minerals such as quartz, feldspar, rutile, or anatase can therefore be significant chemical contributors. Very minor ^{IV}Al substitutes for ^{IV}Si , usually no more than 0.10 and normally no more than 0.02. Kaolinite has been thought rarely to have additional phyllosilicate interstratifications, such as micalike layers and sometimes much less than 1% of the total layers. *CCM 23:125(1975)*. Ferric iron, Mn^{2+} , and $(VO)^{2+}$ have been recognized in kaolinite using electron spin resonance. *CM 10:313(1975)*. Iron has been observed to be more common in disordered kaolinite than in well-ordered material. Dithionite treatment does not remove all iron oxides. *CCM 29:23(1981)*. Observed analyses (wt %): SiO_2 , 37.45-46.79 (higher values indicate free silica in the sample); Al_2O_3 , 33.09-43.50; TiO_2 , 0.09 (St. Austell) (higher values might be due to detrital Ti minerals); Fe_2O_3 , 4.69 (GA); MnO , 1.61 (Jundiai); SO_3 , 2.00 (GA); P_2O_5 , 1.33 (GA); Na_2O , 0.85 (GA); K_2O , 0.46 (GA); MgO , 0.35 (GA); CaO , 0.23 (Keokuk); H_2O^+ , 13.3-13.9. Lithian kaolinite has been synthesized (*CA 114:188488*). CEC is generally negligible to 10 meq per 100 g. Kaolinite has long been known for its small anion-exchange capacity with P and its importance in agriculture; also retains ^{137}Cs . Chromian kaolinite has been observed from three different localities: Urakawa Ni deposit, Shizuoka Pref., Japan; Sonoma region, CA; Takovo, Serbia. As much as 1.2 wt % Cr_2O_3 has been reported. *MIN 4(1):51(1992)*, *CCM 28:295(1980)*. **Occurrence:** Frequently, the result of alteration of plagioclase or alkali feldspars, also micas and smectites. Can be found replacing a variety of minerals, usually feldspars, but also leucite, quartz, sillimanite, tourmaline, and others. Can be associated with a variety of other clay minerals, including halloysite, micas, quartz and silica, feldspar, gypsum, pyrophyllite, rutile, or anatase, rarely alunite, boehmite, gibbsite, diaspore, and a host of detrital minerals. Found in a wide variety of freshwater and marine sedimentary environments, can be an important constituent in coal and, by extension, in coal and fly ash. Frequently, large residual deposits result from deep weathering of granites or feldspathic rocks, but also occur as nearly monomineralic sedimentary layers of economic significance. Abundant in some sandstones. Also may occur in vugs in hornfels. **Uses:** Kaolinite and its ore, kaolin, are consumed in millions of metric tons annually. Used in numerous industrial, agricultural, and other applications when raw, refined, or chemically treated: widely used as a filler and/or coater for paper, also as a pressure-sensitive paper coating for microencapsulated dyes for carbonless copies, used as an absorbant as in dye tracers, also as a pore-forming enhancer for dye uptake, ink retention enhancer, as a simple absorbant for liquid spills (e.g., oils), and as a stain preventive coating on lithographic plates; used in reinforced plastics or rubber, as a filler in some food (e.g., chocolate), as a filler in some talcum powders and paints; used in fireproofing, as a major compo-

nent of putty and some grouts, cements, glazes, and refractory mortars, in gas barriers for carbonated beverage containers, in a wide variety of gaskets, as a binder in zeolite absorbants and in pencil leads, as a foundry die coating, a nonsticking dispersant for agricultural granules, seeds, and so on, and flinty varieties used as an all-weather coating on primitive roads. Also as catalysts for oxidation or polymerization reactions, can be resin coated for electrolyte fixing, aids extrusion processes, smooths and provides antiabrasion properties for magnetic tape; used as a coagulant in water purification, also for benzene purification, widely used in soaps, cosmetics, and disinfectants, useful in desulfurizing and dedusting agents, as a filler in polyester fibers to improve surface appearance as well as resistance to piling and fibrillation, initially used in the manufacture of porcelain and fine china, also tiles, bricks, and terracotta, and used as a starting material in alumina ceramics manufacture and as a starting run material in the manufacture of some zeolites. **Kaolinite localities:** Brandon, Rutland Co., VT; Blandford, Hampden Co., MA; Chaudiere Falls, PA; Mt. Savage(!), MD; Richmond, Hanover Co., VA; Spruce Pine, Mitchell Co., and near Webster, Jackson Co., NC; hundreds of active and inactive deposits are located around Byron, Peach Co.; Butler, Taylor Co.; Gordon, Wilkinson Co.; Kathleen, Houston Co.; Dry Branch, Twiggs Co.; Griswoldville, Jones Co.; Carrs Station, Hancock Co.; Gibson, Glascock Co.; Hephzibah, Richmond Co.; Buffalo Creek, Washington Co.; and Andersonville, Macon Co., all in Georgia; many locations in SC, including the Dixie Clay Co. mine and the Lamar pit, near Bath, Aikin Co.; Longley and Edgefield, Edgefield Co., SC; Hackleburg, AL; Panola Co., MS; near Murfreesboro, Pike Co., and at Greenwood, Sebastian Co., AR; Blaxland, MO; in quartz geodes at Keokuk(!), Lee Co., IA; Silverton, San Juan Co., CO; Mesa Alta, Rio Arriba Co., NM; Rock Springs formation(!), WY; Lewistown, Fergus Co., MT; Ione, Amador Co., CA; Huberdeau, PQ, and near Walton, NS, Canada; Jacal, Villa Victoria, MICH; Noche Buena and Sombrete, ZAC; Etzatlan, JAL; Huayacocotla, SLP, Mexico; Almwch(!), Anglesey Is., Wales; exceptional deposits at St. Austell and elsewhere, Cornwall, also in Devon and Stourbridge, England; Ayrshire, Scotland; Yriex and the Limoges district, Haute-Vienne; St. Gilles, La Chartreuse, and Bagatelle, France; Guadalajara to Valencia, Spain; Locchera, Sardinia, Italy; Brand, Dresden, and Kemmlitz, Saxony; Wetrop deposit, Bautzen; Tirschenreuth, Diendorf, and elsewhere, Bavaria; also Caminau and Wiesa deposits, Lusatian massif, Germany; Karlovy Vary, Schlan, and elsewhere, Bohemia, Czech Republic; Horna Prievrana, Slovakia; Oldrzychow and Osiecznica, Lower Silesia, Poland; Prosyankovskoe, Donets Basin, and elsewhere, Ukraine; Elena deposit, Ural Mts., Russia; Jari River district, Amapa; Jundiai and Varinhas, SP, Brazil; Barker, Buenos Aires Prov.; Chubut Valley, Chubut Prov., and Santa Cruz Prov., Argentina; Wadi Kalabsha, also Nile delta, Egypt; Kuban delta; Pugu, Tanzania; Grahamstown and Fish Hoek district, Cape Prov.; Inanda, Natal; Koster and elsewhere, Transvaal, South Africa; Mehsana, Gujarat; Malti deposit, Purulia district, western Bengal, India; Guoshan deposit, Fujian Prov., Dapo deposit, Huazhou, Guangdong; Suzhou, Jingsu Prov.; *Kauling*

(*Jauchau*), *Kiangsi Prov., China*; Belitung and Banka Is., Indonesia; Moengo area, Suriname; Kanpaku, Tochigi Pref.; Itaya, Okayama Pref.; Amakusa Sarayama deposit, Kyushu, Japan; Weipa, Queensland; Gabbin, WA; Mt. Hope, Imbitcha, and Crawford deposits, SA; Gulgong, NSW; Egerton and Pittong, VIC, Australia; Maungaparerua, North Island, New Zealand. **Dickite localities:** St. Clair(1), Schuylkill Co., PA; Profitt, Albermarle Co.; Willis Mt., Buckingham Co.; Herbb No. 2 pegmatite, Powhatan Co.; Tiberville, Rockingham Co., VA; Rock Springs, WI; Silverton, San Juan Co., and Alma, Park Co.; Red Mt., Ouray, CO; St. George, Washington Co., UT; Bisbee, Cochise Co., AZ; Chon, Nayaret; San Juanito and Cusihiuriachio, Mexico; *Almwich, Anglesey, Wales*; Mas d'Aulry(1), Lodeve, and crystals to 4 mm from the Raberjac mine, Lodev, Herault, France; Crete Nere formation, Sicily; Scabiazza sandstone, Oltrepo Pavese area, Italy; Nowa Ruda, Lower Silesia, Poland; Kara-Chekv massif, Karkaralinsk, Kazakhstan; San Pablo mine, La Paz Dept., Bolivia; Hawksbury sandstone, Sydney Basin, NSW; Williamstown, SA, Australia; Makurasaki, Kagoshima Pref.; Itaya, Okayama Pref.; Syokozan mine, Shokozan; Amakusa Sarayama deposit, Kyushu, Japan. **Nacrite localities:** Middleville, Herkimer Co., NY; Lone Jack quarry, Glasgow, Rockbridge Co., VA; Tracy mine, Marquette Co., MI; Eureka tunnel, St. Peter's Dome, El Paso Co., CO; St. Eustache, QUE; Dresser mine(1), Walton, NS, Canada; Cerro de la Bufa and San Jose de Ranchos, Sombreerte, ZAC; and Xilosintla, OAX, Mexico; Groby, Leicestershire, England; Ottoschwanden, Schwartzwald, Bavaria; Huhnerse-del Mt. Baden; Brand and *Freiberg, Saxony, Germany*; Harvivaara, Finland; Eski-Orda, Simferopol, Crimea, Russia; Otege mine, Yamagata Pref.; Itaya, Okayama Pref., Japan. **VK, EF MIN 4(1):25(1992).**

71.1.1.4 Halloysite $\text{Al}_2\text{Si}_2\text{O}_2(\text{OH})_4 \cdot 2\text{H}_2\text{O}$

Named in 1826 by Berthier for Belgian Geologist Baron Omalius d'Hallo (1783–1875), the mineral's discoverer. Kaolinite–serpentine group. Halloysite-7 Å (metahalloysite), halloysite-10 Å (hydrated halloysite, endellite; European literature). **MON Cc** (also **TRIC**). Cell sometimes given on hexagonal coordinates. $a = 5.14\text{--}5.15$, $b = 8.90\text{--}8.95$, $c = 7.214\text{--}7.37$, $10.1\text{--}10.2$, $\beta = 96^\circ$, $99.7\text{--}101.9^\circ$, $Z = 2$; (hexagonal coordinates): $a = 5.118\text{--}5.133$, $c = 7.16\text{--}7.30$, 10.03 ; $Z = 1$, $D = 2.58\text{--}2.62$ (7 Å), $D = 2.14\text{--}2.15$ (10 Å). *9-453*(halloysite-7 Å, nat): 7.5_9 4.42_{10} 3.63_9 2.56_8 1.68_8 1.48_9 1.28_7 1.23_7 ; *29-1487*(halloysite-7 Å, nat): 7.3_{65} 4.42_{10} 3.62_6 2.56_{25} $2.37_{<1}$ 1.68_2 1.48_3 ; *9-451*(halloysite-10 Å): 10.1_9 4.42_{10} 3.34_9 2.56_8 1.68_8 1.48_9 1.28_7 1.23_7 ; *29-1489*(halloysite-10 Å): 10.0_{10} 4.36_7 3.35_4 2.54_{35} 1.67_1 1.48_3 1.28_1 . **PD 4:19(1989)**. Halloysite is a phyllosilicate that has a tubular morphology (generally less than 5 µm), with an average diameter of 0.04 µm, but apparently with the structural topology of kaolinite. Halloysite has a hydrated 10-Å as well as a dehydrated 7-Å modification. The dehydrated 7-Å halloysite is generally regarded as tubular halloysite that has unrolled to form laths or plates. The tube elongation is b , but a has been observed occasionally as the axis coincident with elongation.

CMB 2:133(1954), *AC 7:511(1954)*. The transition from 10 Å to 7 Å was early recognized to occur at about 105° [*ZK 86:340(1934)*], but the dehydration can occur at 70° [*B&B 153(1980)*], and the gentle heat treatment of halloysite-10 Å is therefore diagnostic. Rehydration is usually not possible, but intermediate hydrates might be restored to full hydration. Halloysite irreversibly becomes X-ray amorphous when heated to 550°. The additional disorder of halloysite compared with disordered kaolinite is useful in distinguishing the two, and tubular morphology has been suggested to be a primary feature of the mineral. *CCM 26:25(1978)*. SEM study generally reveals round tubular morphology for halloysite, but spheres and geometrical platelets have been observed. In Japan, halloysite morphology was related to origin: hydrothermal = tubular and altered pumice = rounded grains [*Proc. Int. Clay Conf. 257(1975)*], but the relationship may have been regional. Platy halloysite is often high in Fe³⁺. *CM 21:401(1986)*. Polygonal tubes (triangular, pentagonal, hexagonal, and octagonal) have sometimes been interpreted as precursors to round tubes, and spiral layering has been observed. *CCM 39:113(1991)*. The first-order peak of halloysite is generally less intense than the band of peaks observed at ≈ 20° 2θ (CuKα). Oriented X-ray diffraction shows considerable disorder for halloysite, with a coalescing of or broadening of peaks. Halloysite expands with ethylene glycol, dimethyl sulfoxide [*CCM 17:57(1978)*], formamide [*CCM 32:241(1984)*], and similar compounds. HWG (hydrazine, water, glycerol) intercalation sequences have been used to distinguish kaolinite, which is usually unaffected, from halloysite, which expands to 11 Å [*Proc. Int. Clay Conf., Tokyo v. 1:3(1969)*], but results can be ambiguous. *CCM 38:591(1990)*. Halloysites have been synthesized only at near-surface conditions. Halloysite is easily damaged by electron beams. **Habit:** Found as an earthy to waxy, rarely pearly, mineral; fine-grained (2–5 μm size common), clay-size particles are typically tubular but sometimes show spherical clustering with thin peel-like exfoliations; indistinct particle morphology may make visual identification (SEM) impossible, rarely rounded polyhedral. Many allophanes could be spherical halloysites. **Physical properties:** White to tan, also bluish and greenish gray, reddish to chocolate brown; pearly to waxy or dull luster. Cleavage {001} probable, conchoidal fracture. H = 1–2. G = 2.0–2.65. Can become translucent when immersed in water. **Optics:** Biaxial (–); N_x = 1.559, N_y = 1.564, N_z = 1.565 (for 7 Å), N_y = 1.490 (for 10 Å); 2V = 37°. **Chemistry:** Halloysite does not have a widely variable chemistry and some of the variation might be ascribed to detrital minerals such as anatase and rutile or to additional clays and micas. Analysis (wt %): SiO₂, 42.20–44.46; Al₂O₃, 36.58–38.46; Fe₂O₃, generally less than 0.36, but observed to 12.8; FeO, 0.07; MgO, 0.18; CaO, 0.32; Na₂O, 0.14; K₂O, 0.51; H₂O⁺, 13.38–14.59; H₂O[–], 2.58–4.05; TiO₂, 0.15; P₂O₃, 0.18. More effective than kaolinite in fixing soil Cu. Halloysites may have low SiO₂ values if [OH]₄ substitutes for [SiO₄] [*Proc. Int. Clay Conf., Jerusalem 1:11(1965)*], and 0.16^{IV}Al has been observed. CEC = 20–60 meq per 100 g, but smectite could be present in higher-CEC samples. **Occurrence:** Frequently found as an alteration of basaltic rocks or in hydrothermally altered fissures in mon-

zonite, for example; also derived from feldspars, chlorite, micas, rhyolite, granite, volcanic ash, tuffs, and pumice; rarely found in granite pegmatites, also in bauxite or laterite, and in some marine, glacial, or K-T boundary clays. Easily weathers to kaolinite, but can also be derived from it. Sometimes associated with allophane and may be derived from it. In many cases, halloysite is probably the result of low-temperature weathering below the water table but is also the result of hydrothermal alteration of feldspathic igneous rocks. Ongoing formation observed at hot springs. Associated with kaolinite, illite, smectite, allophane, volcanic glass, detrital minerals, and others. Uses are similar to those of kaolinite, especially in high-quality ceramics and high-strength concrete; also as a carrier for catalysts. Localities: Only selected occurrences can be listed here: Paris, Oxford Co., ME; Piney R. and (Bunker Hill pegmatite) Buena Vista, Amherst Co., VA; Gusher Knob, Spruce Pine, Alexander, and Corundum Hill mine, Macon Co., NC; Panola Mt. and Taylors Ridge, GA; Stanford and elsewhere, Lincoln Co., also Horse Cove, Hart Co., KY; Gardner mine, Bedford, Lawrence Co., IN; Lawrence Co., MO; Pruden mine, Saline Co., AR; Clayton and Dodge, and Gonzales, Gonzales Co., TX; Wagon Wheel Gap, Mineral Co., CO; San Lorenzo; Gila Hot Springs, Grant Co., NM; Bisbee, Cochise Co., Ray, Pinal Co., and other localities in AZ; Blue Star mine, Eureka Co.; Bullion, NV; New Park, Dragon mine, Eureka, Tintic district, Juab Co., and Wendover, UT; Brownie Butte, Garfield Co., MT; Clearwater Valley-Bitterroot Mts., ID; Cerro Gordo mine, Inyo Co.; Pala, San Diego Co.; Hackberry Mt., San Bernardino Co., CA; Koolau Mts., Oahu Is., also on Lanai and Molokai Is., HI; Vancouver Is., BC, Canada; Los Azufres, MICH, Mexico; Mt. Pelee, Martinique; Guadeloupe; Rosslund, Scotland; Bristol district, England; Vuotso-Tankavaara, Finland; with iron, zinc, and lead minerals in limestone at *Angleure, near Liège, Belgium* (now inaccessible); Dordogne; Armorican massif, Brittany, France; Haro, La Rioja, Spain; Valenca, Portugal; Vilco volcano, Rome; Scatola trough, Viterbo, Italy; Altenberg, Stolberg, and Bergnersreuth, near Wunsiedel, Bavaria, Germany; Stanzertal, Styria, Austria; Karlovy Vary, Bohemia, Czech Republic; Michalovce and Cervenica-Dubnik opal deposits, Slovakia; Kovagoors, Hungary; Kubno and Dunino, Lower Silesia; Tarnowitz, Silesia, Poland; Mt. Peres, Israel; Kara Oba and Tsager region, Caucasus Mts., Kazakhstan; Capivarita, RGS, and Chapada do Araripe, Pernambuco, Brazil; Barker, Buenos Aires Prov., Argentina; Copiapo, Chile; Adamwa Plateau and Cameroon Mt., Cameroon; Mt. Kenya, Kenya; Kivu Prov., Zaire; Andhra Pradesh; Panhala, Maharashtra; Colva, Goa, India; Ranong, Thailand; Hong Kong; coastal Guangdong Prov.; Guoshan, Fujian Prov., China; Nanju and Sancheong, South Korea; Talakag, Philippines; Kuantan, Malaysia; Beleitung and Banka Is., Indonesia; Darling Range bauxite, WA; Andamooka opal field and Moculta and other phosphate deposits, SA; Ardlethan mine, NSW; Trial Hill mine, Q, Australia; Maturi Bay, Te Puke, and Maungaparerua, North Island, New Zealand; Ambrym, Vanuatu; New Georgia Sound, Solomon Is.; Inage, Chiba Pref.; Iriki and Oguchi, Kagoshima Pref.; Kusatsu and Joshin, Gunma Pref.; Koganei and

Ina, Nagano Pref.; Yawata, Gifu Pref.; Gosammae, Iwate Pref.; Iki Is., Nagasaki Pref.; Imaichi and Mashiko, Tochigi Pref.; Shigaraki Pref., Japan; Kerguelen Is. *VK, EF ACP II 2:332(1826), AC 31:2851(1975)*.

71.1.1.5 Odinite $(\text{Fe}^{3+}, \text{Mg}, \text{Al}, \text{Fe}^{2+}, \text{Ti}, \text{Mn})_{2.42}(\text{Si}, \text{Al})_2\text{O}_5(\text{OH})_4$

Named in 1988 by Bailey for Gilles-Serge Odin, geologist, Paris, France. Kaolinite-serpentine group. Also called phyllite V; originally thought to be berthierine. Two polytypes exist: 1M and 1T, usually mixed in the same sample, with 1M being more abundant. *MON* and *HEX-R* Space groups unknown but probably *Cm* (1M) and *P31m* (1T). (1M): $a = 5.373$, $b = 9.326$, $c = 7.363$, $\beta = 104.0^\circ$; and (1T, orthogonal axes): $a = 5.366$, $b = 9.334$, $c = 7.161$, $\beta = 90.0^\circ$. *MSASC 19:169(1988)* gives (1M): $a = 5.369$, $b = 9.307$, $c = 7.17$, $\beta = 103.9^\circ$; (1T): $a = 5.371$, $b = 9.316$, $c = 7.361$, $\beta = 90.0^\circ$. X-ray diffraction lines are broad and frequently show a 14-Å peak due to partial conversion to chlorite. A 1 : 1 serpentine-type layer structure, intermediate between dioctahedral and trioctahedral. Ideally dioctahedral and therefore conceptually related to, and the Fe^{3+} analog of, kaolinite. End-member odinite should ideally be $(\text{Fe}^{3+})_2\text{Si}_2\text{O}_5(\text{OH})_4$, but when $\Sigma^{\text{VI}}\text{R}^{2+} > \Sigma^{\text{VI}}\text{R}^{3+}$, dioctahedral odinite grades into trioctahedral greenalite. Green, like glauconite; gray-green streak; silky to earthy luster. Mossbauer, IR, DTA data: *CM 23:237(1988)*. Odinite does not expand with ethylene glycol or similar compounds and becomes amorphous on heating to 490° . An Fe^{3+} -rich 1 : 1 clay mineral with 0–10% tetrahedral substitution of Al for Si. Structural formula of "purest" material yielded $\text{Fe}_{0.784}^{+}\text{Mg}_{0.772}\text{Al}_{0.556}\text{Fe}_{0.279}^{2+}\text{Ti}_{0.016}\text{Mn}_{0.15}\square_{0.443}$ ($\text{Si}_{1.788}\text{Al}_{0.212}$) $\text{O}_5(\text{OH})_4$ (Koukoure R. mouth); also $(\text{Fe}_{0.72}^{3+}\text{Al}_{0.70}\text{Mg}_{0.63}\text{Fe}_{0.25}^{2+}\square_{0.70})$ (Si_2) $\text{O}_5(\text{OH})_4$ (Guiana). $^{\text{IV}}\text{Fe}$ was not observed. The chemistry of odinite is difficult to interpret, due to its admixture with so much extraneous matter. Typical chemical ranges of odinite with Fe^{3+} greater than any other octahedral cation include (wt %): SiO_2 , 36.0–39.1*; Al_2O_3 , 10.8–12.2; Fe_2O_3 , 17.9–19.5**; FeO , 5.0–6.5*; TiO_2 , 0.4–0.5; CaO , 0.13–0.7***; MgO , 6.5–11.0*; MnO , 0.0–0.33; P_2O_5 , 0.0–0.17; N_2O , trace–0.3; K_2O , 0.35–1.40; H_2O , 2.0–4.10; $\text{H}_2\text{O}^+(\text{+CO}_2)$, 9.4–10.96. *Lower values reported but where $\Sigma\text{R}^{2+} > \Sigma\text{R}^{3+}$; **higher values reported but where $\Sigma\text{R}^{2+} < \Sigma^{3+}$; ***possible impurity. Widespread as infillings or replacements of microtests, bioclasts, fecal pellets, or mineral debris on shallow (15–60 m) marine shelves and reef lagoonal areas in tropical latitudes: e.g. New Caledonia; Ogooue R. prodelta, Congo Republic; the continental shelf between the Amazon and Orinoco rivers, Brazil; Niger R. prodelta, Nigeria; off Martinique Is.; and the *Los Is.*, in the mouth of the Koukoure R., Guinea. Authigenic. Associated with detrital quartz, carbonate bioclasts, clays (kaolinite, smectite, illite, etc.), chlorite, pyrite, goethite, and others. Not recognized in rocks older than Recent-Quaternary. Not yet found in oolites in contrast to berthierine. In shallow depths (< 15 m), odinite is usually oxidized yellow to red-brown and probably closer to the end member. Easily alters to chlorite. Informally reported from a wide variety of localities,

but chemical data indicate that some samples are ferrian greenalite rather than odinite. *vk, EF CR 301:105(1985), MIN 4(1):176(1992)*.

71.1.2a.1 Antigorite $\text{Mg}_3\text{Si}_2\text{O}_5(\text{OH})_4$

Named in 1840 by E. Schweizer for the locality. Kaolinite-serpentine group. Antigorite is frequently called serpentine and thus confounded with other members of the group; also called williamsite, bowenite, jenkinsite, picros mine, and picrolite in part. *MON Pm. a = 35.4–47.2* (commonly 43.4 Å, but 33–50 Å and 109 Å as extremes [*AM 42:133(1957)*], usually with a subcell 5.42–5.46 Å, but with a wide range, designated A), *b = 9.2–9.28, c = 7.24–7.28, β = 91.1–91.7°, Z = 7–10, 16, D = 2.52. 21-963: 7.29₁₀ 6.43₄ 5.82₄ 5.15₄ 4.64₄ 3.61₈ 2.53₁₀ 2.46₆*. Antigorite deviates from other serpentines in that its sheet-like structure consists of alternating curved layers or waves. The Mg-filled octahedral polyhedra are larger than the normally Si-filled tetrahedral polyhedra, and a curving of the layer relieves the bond-length mismatch with the apical coordinating oxygens, which constitute one side of the octahedral sheet. A plane of hydroxyls forms the remainder of the coordinating ions of the octahedral sheet. The structure is built of alternating up–down orientations of the serpentine layers, and defect structures are common. Antigorite has been observed as a distorted 1T polytype. The radius of curvature of most antigorite is 50–72 Å with a 61 Å average [*ZK 110:282(1958)*], but the tetrahedral–octahedral mismatch of 0.14 Å predicts a curvature with 190 Å radius. *CM 13:227(1975)*. TEM studies confirm the alternating wave structure of antigorite. *CM 17:679(1979), CMP 97:147(1987), AM 78:75(1993)*. Unlike chrysotiles and lizardites, antigorites can show a deficiency of 0.16–0.19 octahedral cations. *USGSPP:384-A(1962)*. The *a* dimension in antigorite is a large multiple (usually 7–10, ranging to 16 and rarely higher) of 5–5.7 Å, and various layer multiples have been modeled with differing chemical composition. *AC(B) 45:129(1989)*. Subcell X-ray diffraction reflections are usually weak. Due to the wavelike pattern of antigorite layers, the dimensional misfit can result in three fewer ^{VI}R for every eight tetrahedral ring units, and a specific formula for antigorite could be $\text{Mg}_{3m-3}\text{Si}_{2m}\text{O}_{5m}(\text{OH})_{4m-6}$, where *m* is the number of multiples of *a*. *CMP 97:147(1987)*. Large multiples of *a* are more stable at low temperatures. *FM 61:283(1983)*. A typical observed structural formula is: $(\text{Mg}_{2.87}\text{Al}_{0.04}\text{Fe}_{0.03}^{\text{II}}\text{Fe}_{0.02}^{\text{II}})(\text{Si}_{1.99}\text{Al}_{0.01})\text{O}_5(\text{OH})_4$. IR studies are numerous [e.g. *MJJ 12:299(1985)*]. Antigorite has been synthesized. *AM 58:915(1973)*. A plot of $\text{Fe}^{2+}/\text{Mg} + \text{Fe}^{2+}$ vs. cell edge shows a positive correlation with increasing *a* subcell and *b* and a negative correlation with increasing *c*. *MJJ 12:299(1985)*. Crystal structures have been solved [*MM 30:498(1954), FM 39:206(1961)*] which confirmed suggestions that the antigorite structure was due to regularly occurring distortions. *AM 21:463(1936)*. High ^{IV}Si values (> 4.0) are commonly calculated and are due to neglecting vacancies of Mg and OH. *CM 17:785(1979)*. **Physical properties:** Dark green ranging to many shades of green, including light shades and blue and yellow-greens; also brown to black, and bright yellow to nearly white. Cleavage {001}, perfect; {010},

{100}, good to poor; pseudocubic parting rare, can show some platyness, also splintery to fibrous as in picrolite. Smooth, but not unctuous. $H = 2.5\text{--}4$, rarely $5.5\text{--}6$ (polishing of antigorite reveals noticeably greater hardness than lizardite and very noticeably greater than chrysotile). *CM 17:785(1979)*. $G = 2.4\text{--}2.79$, slowly decomposed by acids or not at all (chromian varieties unaffected). Fusible with difficulty. **Optics:** Biaxial (-); $X = c$; $N_x = 1.557\text{--}1.595$, $N_y = 1.563\text{--}1.603$, $N_z = 1.564\text{--}1.604$; birefringence = $0.004\text{--}0.014$, $2V = 48\text{--}61^\circ$, decreasing with iron substitution; $r > v$; parallel extinction. RI increasing with iron substitution. Also chromian (Cr_2O_3 , 4.4 wt %): $X = c$; $N_x = 1.567$, $N_y = 1.577$, $N_z = 1.578$; birefringence = 0.011 ; $2V = 58^\circ$; $r \ll v$ and abnormal blue interference colors; positive elongation, platy to lathlike appearance common ($0.1\text{--}4$ mm), but not exclusive to antigorite, undulatory to patchy extinction common. $N_z = b$, $N_x \approx a$. Generally nonpleochroic. Fe^{2+} increases N_x and N_y faster than N_z . *MJJ 12:299(1985)*. OAP parallel to (100). **Chemistry:** Ranges of reported antigorite analyses include (wt %): SiO_2 , 36.19–45.69; Al_2O_3 , 0–5.00 (usually < 0.50); Fe_2O_3 , 0–5.47; Cr_2O_3 , 0–0.91; TiO_2 , 0–0.02; FeO , 0.07–22.73; NiO , 0–0.42; MgO , 21.08–43.45; MnO , 0–2.53; ZnO , 0.14 (Lowell); CaO , 0.02–1.15; Na_2O , 0–0.05; K_2O , 0–0.24; H_2O , 0–0.92; H_2O^+ , 10.48–13.30; Cl , 0–0.03; F , 0–0.31. Chemical heterogeneity within a single purified specimen has been noted. *MJJ 12:299(1985)*. **Occurrence:** Antigorite can be found with other serpentines, talc, clinocllore, amphiboles, pyroxenes, brucite, dolomite, magnesite, olivine, magnetite–magnesiochromite, and others. The reactions antigorite \rightarrow olivine + talc + H_2O [*MM 55:367(1991)*] and antigorite + brucite \rightarrow forsterite [*GSAB 88:1497(1977)*] have been proposed. Antigorite is stable in the association tremolite, forsterite, and diopside. *CM 17:729(1979)*. Antigorite is stable at $250\text{--}550^\circ$ [*CMP 97:147(1987)*] and may coexist with lizardite over most of that range. Many antigorites form under reducing prograde conditions contrary to many lizardites. *CM 17:785(1979)*. A major component of serpentinites and important in ophiolite sequences. Observed as a vein mineral. Also found with rodingite. The original antigorite specimen may have been an erratic boulder or was from nearby small valleys: Val Devero or Val Bognanco. *GSLQJ 64:152(1908)*. Extraordinary variety of pseudomorphs from Tilly Foster mine(l). Commonly associated with other serpentines, magnetite, talc, magnesite, and/or dolomite. Clinochrysotile may alter to antigorite. **Localities:** Selected localities include: Lowell, Lamoine Co., and elsewhere, VT; Conklin quarry(l), Smithfield, Providence Co., RI; Monroe, Orange Co.; Tilly Foster mine(l), Brewster, Putnam Co.; Staten Is., Richmond Co., NY; Turkey Mt., Montville, Morris Co., NJ; Lows and Cedar Hill mines, Texas, Lancaster Co., PA; Harford Co., Baltimore and Bare Hills, Baltimore Co., MD; Buck Creek, Clay Co., NC; Bisbee, Cochise Co., AZ; Shipton, QUE; Knee Lake, MAN; Tadmagouche Creek, YT, Canada; Tasiussarsuaq fjord, Greenland; Milton and elsewhere, Glen Urquhart, Inverness-shire, Scotland; Mornhausen–Amolose and Bottenhorn, Hesse-Nassau; Waldheim and Zobnitz, Saxony, Germany; Taberg, Sweden; Zermatt, Switzerland; Sterzing, Bolzano Prov.; Malenco Serpentinite, Bergell Aureole, Italy; Valsavaranche,

Aosta; Passo della Rossa and Domodossola, *Antigorio Valley, Novara Prov., Piedmont, Italy*; Steinbach, Burgenland, Austria; Kutna Hora, Bohemia, Czech Republic; Breznicka and elsewhere, Slovakia; Peloponnesus and Kythira Is., Greece; Caracas region, Venezuela; Cana Brava, Goias; Santa Rosa, Bahia, Brazil; Cyclops Mts., Hollandia, Suriname; Upsallata, Mendoza, Argentina; Zeber Kuh Mts., Iran; Karya magnesite deposit, Mysore, Karnataka; Shapur district, Punjab, India; Safed Koh, Kabul R. valley, Afghanistan; Shigar, Kashmir, Pakistan; Fengtien ophiolite, Taiwan; Khotan, Chinese Turkestan; Hsiu-Yen Hsien, Liaoning Prov., Manchuria; Heiluyu, Xichuan Co., Henan Prov.; Xiuyan district, China; Ryumon peridotite, Kii Penin.; Nishisonogi area, Nagasaki Pref.; Jin-Gatou and elsewhere; Sasaguri area, Fukuoka Pref., Japan; Kyongsangpuk Do, South Korea; Griffin Range, Hokitika, Westland; Cross River, Mikonui, New Zealand., **VK, EF MIN 4(1):126(1992)**.

71.1.2b.1 Caryopilite (Mn,Mg,Zn,Fe)₃(Si,As)₂O₅(OH,Cl)₄

Described in 1889 by Hamberg and named from the Greek for *nut* and *felt*, in allusion to its brown color and felted structure. Kaolinite-serpentine group. See greenalite (71.1.2b.4), the Fe analog. Two polymorphs exist: 1M and 1T. **MON** and **TET** *Cm* or *C2/m*. (1M): $a = 5.668\text{--}5.692$, $b = 9.811\text{--}9.858$, $c = 7.518\text{--}7.527$, $\beta = 104.52\text{--}104.6^\circ$, $Z = 2$, $D = 3.00$; (1T): $a = 5.692$, $c = 7.275$, $Z = 1$, $D = 3.00$. **38-422(nat)**: 7.3_8 3.64_5 2.82_6 2.52_{10} 2.10_{35} 1.73_{25} 1.64_{35} 1.60_{25} . Pattern for 1T (41-1446) is the same as for 1M, along with some other faint lines. Structure not solved in detail. **MJJ 14:165(1980)**. Massive, reniform, stalagtitic aggregates or rosettes of flattened crystals to 3-4 mm, pseudohexagonal plates. Reddish brown, yellow, greenish brown, orange-brown. Cleavage (001), good. $H = 3\text{--}4$. $G = 2.80\text{--}2.91$. IR data: **DAN SSSR 249:513(1979)**. Readily soluble in concentrated acids. Sterling Hill, NJ, material has as much as 6.9 wt % As_2O_3 and 3.4 wt % ZnO. MgO to 7.2 wt %, CaO to 3.6 wt %, FeO to 22.3 wt %. Very Fe-rich material from Primorye (22.3 wt % FeO). Al_2O_3 to 2.4 wt %. Biaxial (-); $Z = b$, X perpendicular to (001); (1T): $N_x = 1.603$, $N_y = N_z = 1.632$; (1M): $N_x = 1.606$, $N_y = N_z = 1.633$; range given as $N_x = 1.606\text{--}1.620$, $N_y = 1.632\text{--}1.65$. $2V \approx 0^\circ$; weak dispersion. Forms as an alteration product of primary manganese silicates such as rhodnite. In metamorphosed manganese deposits. Also occurs as granules in sediments. Occurs at Franklin, and Sterling Hill, Sussex Co., NJ; as 0.5-cm-diameter rosettes of radiating yellow-brown plates at Bald Knob, Sparta, Alleghany Co., NC; both 1M and 1T occur at the Hurricane claim, Olympic Penin., WA; Langban, Norbotten, Sweden, and the *Harstig mine, Pajsbjerg, Varmland, Sweden*; Fallota, Grisons, Switzerland; unspecified locality in Primorye (Russian Far East), Russia; Wessels and N'chwaning mines, Kalahari Mn field, Cape Prov., South Africa; the most Mn-rich known occurs at Tokusawa, Iwate Pref., Japan; Ichinomato mine, Kumamoto Pref., Japan; also Okutama mine, Tokyo; Sagadani mine, Ehime Pref., Niro mine, Shikoku, Japan. **VK, EF CM 20:1(1982), MIN 4(1):199(1992)**.

71.1.2b.2 Lizardite $Mg_3(Si,Al)_2O_5(OH)_4$

Named in 1956 by Whittaker and Zussman for the locality. Kaolinite-serpentine group. Frequently called serpentine and thus confounded with other members of the group; also baumite, bastite, marmolite, and serophite in part. A component of garnierite, picrolite, and retinalite in part. Synonym: orthoantigorite. ORTH Space group unknown. $a = 5.31$, $b = 9.20$, $c = 7.31$, $\beta = 90^\circ$, $Z = 2$. HEX $P31m$. (1T): $a = 5.325\text{--}5.338$, $c = 7.257\text{--}7.317$, $D = 2.56$; (syn): $a = 5.336$, $c = 7.239$, $Z = 1$, $D = 2.58$; (6T): $a = 5.31\text{--}5.33$, $c = 42.62\text{--}43.78$, $Z = 6$, $D = 2.57\text{--}2.67$. 18-779 (HEX 1T, nat): 7.4_{10} 4.6_8 3.9_5 3.67_8 2.51_{10} 2.16_8 1.538_8 $1.310_{6.5}$, 11-386 (HEX 1T, aluminian): 7.25_6 4.61_2 3.62_6 2.50_{10} 2.15_4 1.778_2 1.541_3 1.507_2 ; 9-444 (Unstable type, nat): 7.33_{10} 4.60_6 3.66_{10} 2.62_3 2.50_{10} 2.34_7 1.963_7 1.535_8 . Lesser quality data are listed on 13-4 for aluminian 6(2)T lizardite. 31-782 [6(3)T]: 7.12_{10} 4.59_3 4.48_3 3.56_8 2.63_4 2.38_9 2.00_4 $1.532_{5.5}$. $P6_3cm$. (2H₁): $a = 5.318$, $c = 14.541$. Lizardite, a trioctahedral 1 : 1 layer silicate, is perhaps the most common member of the serpentine group. Unlike antigorite, it has a "flat" layer structure. The minor substitution of Al might relieve some of the dimensional mismatch of the tetrahedral and octahedral sheets and result in more favorable bond lengths, leading to flat rather than curved layers. Various structural calculations predict that lizardite should have maximum stability at $^{IV}Al = 0.75$ or 0.6. AM 48:368(1963), 60:200(1975). A mechanism in one-layer polytypes which can relieve tetrahedral sheet dimensional mismatch with the octahedral sheet involves tetrahedral rotation, but which destroys the coplanar nature of the basal oxygens of that sheet, as well as introducing a minor wave-like modulation of the octahedral sheet (NJMM: 193(1995)). Two-layer lizardites have essentially planar layers. Structural formulas include $(Mg_{2.79}Fe_{0.12}Al_{0.07})(Si_{1.83}Al_{0.17})O_5(OH)_4$ (Val Sissone) and $(Mg_{2.74}Fe_{0.16}Al_{0.09})(Si_{1.93}Al_{0.07})O_5(OH)_4$ (Elba). Additional structural formulas include $(Mg_{2.76}Fe_{0.04}^{2+}Fe_{0.10}^{3+}Al_{0.07})(Si_{1.83}Al_{0.17})O_5(OH)_4$, while a low-Al lizardite with a particularly good X-ray pattern is $(Mg_{2.825}Ni_{0.10}Fe_{0.07}^{3+}Al_{0.03}Ti_{0.001})Si_{2.025}O_5(OH)_4$. $^{IV}Fe^{3+}$ can be present in place of Al in lizardite: for example, $(Mg_{2.756}Fe_{0.172}^{3+}Ni_{0.017}Ti_{0.02}Mn_{0.004}Cr_{0.003}^{3+})(Si_{1.906}Fe_{0.053}^{3+}Al_{0.041})O_5(OH)_4$ (Soroako). Lizardites with $^{IV}Al < 0.15$ are probably metastable with respect to antigorite above 400° at 2 kbar [CM 17:757(1979)], but nonaluminous lizardite has been synthesized. AM 60:200(1975). Lizardite can show translational and/or rotational disorder. AC 19:381(1965), CM 13:227(1975). Additional crystal structure determinations have been made. CM 14:314(1976); AM 72:943(1987), 79:194(1994). TGA, DTA data: IGR 17:1035(1975). One- and two-layer structures are common and have been synthesized [e.g., CM 17:757(1979)]. TEM studies verify the flat layering but show numerous defects [CM 24:775(1986)] as well as topotactic replacement orientations. AM 75:813(1990). Unst-type lizardite (6T₁), a six-layer polytype, also has been synthesized. MJJ 6:464(1972). Some polygonal serpentine, with or without chrysotile as a core filling in the texture, has the flat-layered lizardite structure [CM 14:307(1976)] and formerly has been called Povlen-type chry-

sotile. IR studies are few. *CM 17:719(1979)*. **Physical properties:** Green to yellow-green, bluish green, also nearly black, rarely yellow or white, can be platy [rarely with visible crystals (0.1–2 mm, Coli, Val Sissone, and Elba)], sometimes unctuous to greasy. $H = 2-3$ (by polishing, noticeably softer than antigorite and harder than chrysotile). $G = 2.55-2.61$. Cleavage $\{001\}$, perfect. More easily decomposed by 1 N HCl than antigorite, sometimes unaffected by acids. **Optics:** Uniaxial (-); $N_E = 1.545$, $N_O = 1.555$; biaxial (-); $N_x = 1.545-1.563$, $N_y = 1.555-1.568$, $N_z = 1.555-1.570$; birefringence = 0.006–0.010; 2V small or usually 37–61°; parallel extinction; can be nearly isotropic. Nickelooan lizardite can have $RI = 1.575-1.580$. *AM 48:1227(1963)*. Rarely biaxial (+); $N_x = 1.568$, $N_y = 1.569$, $N_z = 1.581$; birefringence = 0.013; 2V small. Optical data are few. Frequently shows hourglass, mesh, and other textures. Rosette or radial lizardite textures reported. Can be weakly pleochroic light green–light yellow. Bastitic replacements sometimes in antigorite groundmass. **Chemistry:** Observed compositional ranges include (wt %): SiO_2 , 31.3–47.8; Al_2O_3 , 0–4.5 (13.9–15.9, Stillwater); Fe_2O_3 , 0.21–5.68; Cr_2O_3 , 0–1.05; FeO , 0–1.81; MgO , 37.75–42.67 (18.5–30.8 when nickelooan; also 32.7, Stillwater); MnO , 0–0.22; NiO , 0–26.2; TiO_2 , 0–0.10; CaO , 0–0.24; Na_2O , 0–0.28; K_2O , 0–0.41; Cl , 0.32 (Lizard); H_2O^- , 0.36–1.26; H_2O^+ , 12.92–15.03. **Occurrence:** Field evidence suggests that lizardite serpentinization could occur at 75°, which can convert to antigorite at greenschist facies conditions (350°, 3–4 kbar) [*MM 47:301(1983)*], but antigorite and lizardite have been observed to coexist over a wide range of conditions. *CMP 97:147(1987)*. Serpentinization of dunite, peridotite, and ultramafic rocks is common. Can be found replacing olivine in basalt and so on, also as a microscopic replacement in amphibole and uraltite. *SCI 206:1398(1979)*. Pseudomorphs of lizardite after enstatite, diopside/augite, or tremolite have been called bastite, but thermal effects can convert lizardite to antigorite or talc + clinocllore. *CM 17:729(1979)*. The reaction lizardite → talc + forsterite + clinocllore + water has been investigated. *CM 17:757(1979)*. Contrary to many antigorites, many lizardites form under oxidizing retrograde conditions. Can be found with other serpentines, talc, chlorite, magnetite–magnesiocromite, dolomite, magnesite, brucite, and so on. **Localities:** Selected localities include: Jim Pond, Franklin Co., ME; Newburyport, Essex Co., MA; Bellows Falls, Windham Co., VT; Aboutville; Talcville, St. Lawrence Co.; Staten Is., Richmond Co., NY; Turkey Mt., Montville, Morris Co.; Franklin, Sussex Co.; Castle Point, Hoboken, Hudson Co., NJ; Mineral Hill, Media, Delaware Co., PA; Lone Mt., Norris, Union Co., TN; Webster, Jackson Co., NC; Burke Mt. complex, Columbia Co., GA; southern Organ Mts., NM; Stillwater complex, MT; New Almaden mine, Santa Clara Co., CA; Riddle, Douglas Co., OR; Sultan area, Cascade Mts., WA; Juan de Fuca submarine ridge; Asbestos, Coleraine, and Thompson Lake, PQ; Setting Lake, MAN; Somerset Is., NWT, Canada; Havana, Havana Prov.; Nicaro, Oriente Prov., Cuba; Loma Pagnerra, Dominican Republic; Mayaguez, Puerto Rico; Unst, Shetland Is., and Polmaily, Glen Urquhart, Inverness-shire, Scotland; *Kennack Cove, The Lizard, Cornwall, England*; Snarum,

Modum Canton, Norway; Kuhmo greenstone belt, Finland; Pernes Massif, Pyrenees Mts., France; Totalp, Davos, Switzerland; Todtmoos, Wehratal, Schwarzwald, Baden; Baste, Harz, Germany; Monte dei Abati(1), Mte. Fico, Elaba(1); Coli(1) and Val Sissone morraine(1), Italy; Tyrol, Austria; Kapaonik and Radusa mines, Korab Mt., Povlen Mts., Serbia; Dognacska and Ocna de Fier, Romania; Ijim, western Sayan, Russia; Morro do Niquel and Morro do Coriso, MG; Cana Brava complex, Goias, Brazil; Sipilou and Moyango massifs, Ivory Coast; Frank Smith kimberlite, South Africa; Valojoro, Madagascar; Hindubagh, Baluchistan; Soroako and Pomalaa, Indonesia; Kwanson, Taitung, Taiwan; Sasaguri, Fukuoka Pref., Japan; Nullagine, WA, Australia. Unst-type lizardite found at the Tracy mine, Negaunee, Marquette Co., MI; Thompson Lake, LAB, Canada; Unst, Scotland; Piz Lunghin, Maloja, Switzerland; Lord Brassy mine, Heazelwood R., Tasmania; Silversheen mine, WA, Australia. vk, EF *MM* 31:107(1956), *MIN* 4(1):126(1992).

71.1.2b.3 Nepouite $\text{Ni}_3\text{Si}_2\text{O}_5(\text{OH})_4$

Named in 1906 by Glasser for the locality. Kaolinite-serpentine group. Originally called genthite, also a component of garnierite; has been equated erroneously with nickel-bearing chlorite. ORTH *Ccm*2₁. $a = 5.31$, $b = 9.19$, $c = 14.50$, $Z = 2$, $D = 3.20$; $a = 5.27-5.31$, $b = 9.14-9.20$, $c = 7.24-7.27$, 14.50. 25-524(nat): 7.31₁₀ 4.55₅ 3.63₉ 2.89₆ 2.50₇ 2.31₄ 2.20₄ 1.53₆. Found in polytypes: 1T [*CM* 12:381(1974)]; 2Or, 2M2, 6H [*MM* 44:153(1981)]. IR data: *IGR* 17:1035(1975), *AM* 48:1227(1963). DTA data: *ZVMO* 102:143(1972). TGA data: *IGR* 17:1035(1975), *AM* 60:863(1975). Nickeliferous lizardites tend to be better crystallized than nepouites. Nepouites have been synthesized. *AM* 46:32(1961), *CMP* 34:84,346(1972). Bright green to slightly yellowish or brownish green (color intensity varying with Ni content), can be earthy to waxy < also pearly, also fibrous, pseudohexagonal crystals (to 0.5 μm). $H = 2-2.5$. $G = 3.18-3.24$. Cleavage {001}, perfect with possible secondary cleavages. Biaxial (-); $N_x = 1.60-1.63$, $N_z = 1.635-1.65$; birefringence = 0.036-0.038, 0.05; $N_{av} = 1.62-1.63$; pleochroic. X, green to yellow-green; Z, yellow-green. Optical variation diagram: *IGR* 17:1035(1975). A range of composition from nepouite to nickeliferous lizardite is probably found at a single locality and observed chemical ranges include (wt %): SiO_2 , 32.36-47.8; Al_2O_3 , 0-10.74; Fe_2O_3 , 0.10-2.42; Cr_2O_3 , 0.79 (Ba); FeO , 0-5.29; MgO , 1.11-11.80; MnO , 0.02 (Ba); NiO , 27.18-50.70; CaO , 0.05-1.07; TiO_2 , 0-0.01; Na_2O , 0.10-1.58; K_2O , 0.02-0.08; CO_2 , 1.24 (Ba); H_2O^+ , 9.7-11.9. A series to brindleyite is probable. Found in nickel-bearing laterites as a fracture filling in Ni-bearing serpentine or as a contact alteration in limestone. A component in some high-Ni garnierite, but much garnierite consists of nickeliferous lizardite. Can be found with willemseite-talc, falcondoite-sepiolite, pimelite-nontronite, goethite, quartz, calcite, halloysite, or others. Might be admixed with poorly crystalline to X-ray amorphous materials. Found at

Woods mine and elsewhere, Lancaster Co., PA; Piliken Chrome mine, El Dorado Co.; Pine Tree and Josephine mines, Mariposa Co.; Kalkar quarry, Santa Cruz Co.; Coyote Mt. Ni mine, Imperial Co.; Venice Hills, Tulare Co., CA; Hanna mine, Riddle, Douglas Co., OR; Rottis, Voigtland, Germany; Frankenstein, Silesia, Poland; Kremze, Bohemia, and Letovice, Czech Republic; Ba, Serbia; Pavlos, Bœotie, Greece; Tyulenevskoye and Ackerman deposits, Ural Mts., Russia; Nuggihalli schist belt, Mysore, India; Soroako, Indonesia; Kouaoua, Noumea, Nakety, Thio, and *Reis II mine, Nepoui, New Caledonia*. VK, EF CR 143:1173(1906), MIN 4(1):186(1992).

71.1.2b.4 Greenalite $\text{Fe}_3^{2+}\text{Si}_2\text{O}_5(\text{OH})_4$

Named in 1903 by Leith for its color. Kaolinite-serpentine group. Frequently erroneously called glauconite; tosalite. MON *Cm*. $a = 5.54\text{--}5.60$, $b = 9.55\text{--}9.70$, $c = 7.38\text{--}7.44$, $\beta = 104.2\text{--}104.33^\circ$, $Z = 2$, $D = 3.15$; HEX *P31m*. $a = 5.598$ (syn: 5.490 \AA), $c = 7.213$ (syn: 7.140 \AA), $Z = 1$, $D = 3.15$. 39-337 (1T): 7.2_{10} 3.61_5 2.78_3 2.61_6 2.49_3 2.21_4 1.62_6 1.58_5 ; 39-348(1M): 7.2_{10} 3.61_5 2.78_3 2.61_6 2.49_3 2.21_4 1.62_6 1.58_5 (identical patterns, but not all reflections are accepted by one space group); 45-1353(1T, syn): 7.16_{10} 4.76_1 $3.57_{6.5}$ 2.56_7 2.44_1 $2.18_{2.5}$ 1.80_2 $1.58_{5.2}$. Greenalite appears to be dominantly trigonal in some samples, but can be mixed with a minor monoclinic form. Found in polytypes: 1M and 1T. Forms a series with lizardite [*AM 47:783(1962)*], but once thought to be related to chamosite. *NAT 181:45(1958)*. Numerous defects occur in greenalite and the structure is organized into 21- to 23-A domains and a superlattice with $a = 279$ ($5a_0$), $b = 45.2$ ($4.67b_0$) has been proposed. CM 20:1(1982). Structural formulas include: $\text{Fe}^{2+}1.64\text{Al}_{0.75}\text{Mg}_{0.23}\square_{0.36}(\text{Si}_{1.96}\text{Al}_{0.04})\text{O}_5(\text{OH})_4$ [*CM 23:447(1988)*] and the nearest to end-member: $(\text{Fe}_{2.69}^{2+}\square_{0.275}\text{Mg}_{0.02}\text{Mn}_{0.01}(\text{Si}_2)\text{O}_5(\text{OH})_4$. Frequently as rounded granules with a fibrous texture even when indurated. Olive-green to dark green. $H = 3$. $G = 2.7\text{--}3.15$. Weakly magnetic. Isotropic; $N = 1.655\text{--}1.675$; anisotropic in strong light, yellow-green to blue-green. *AM 20:405(1935)*. Analysis (wt %): SiO_2 , 30.08–38.00; Al_2O_3 , 0–5.65; Fe_2O_3 , 8.40–34.85; FeO , 25.72–46.56; MgO , 0–4.16; MnO , 0–8.52; CaO , 0–0.22; Na_2O , 0–0.22; K_2O , 0–0.10; H_2O^+ , 7.04–9.35. Found in slate adjacent to banded iron formations, also as a deep ocean ooze. Ferrian greenalite is currently forming in shallow (15–60 m) tropical sediments. Alters to iron oxides. Can be associated with siderite, chert, iron oxides, and quartz. *Biwabik Iron M (Section 2, T.58N, R.16W)*, *Biwabik*, also Gilbert and Virginia, *Mesabi Range, MN*; Knob Lake, LAB; Gunflint Lake and Belcher Is., Hudson Bay, ONT; Blue Bell mine, Riondell, BC, Canada; Martinique Is. shelf; Arenig, Glenluce, Wigtownshire, Scotland; Mina Brunita, La Union, Murcia, Spain; Hjulsjoe, Bergslagen, Sweden; Amazon and Orinoco R. continental shelves; Congo R. mouth, Ivory Coast; Ogooue R. prodelta; Niger R. prodelta; Casamance estuary sediments and Cap Vert continental shelf, Senegal; east of Mayotte Is. lagoon, Comoro Is.; Toa and Matsua mines, Kochi

Prof., Japan; North Sarawak continental shelf; Weld Range and Dales Gorge member, Hamersley Group, WA, Australia. Found on the moon. *VK, EF USGSM:43(1903), MIN 4(1):169(1992)*.

71.1.2c.1 Amesite (Mg₂Al)[SiAl]O₅(OH)₄

Named in 1876 by C. U. Shepard for James Ames, owner of the Chester Emery mine. Kaolinite-serpentine group. TRIC C1. $a = 5.31\text{--}5.32$ (5.386*, Fe²⁺-rich), $b = 9.20\text{--}9.21$ (9.291*), $c = 14.06\text{--}14.07$ (14.124*), $\alpha = 90.01\text{--}90.09^\circ$, $\beta = 90.25\text{--}90.27^\circ$, $\gamma = 89.96\text{--}89.97^\circ$; also $a = 5.31$, $b = 9.21$, $c = 14.40$, $\alpha = 102.11^\circ$, $\beta = 90.2^\circ$, $\gamma = 90.1^\circ$; $Z = 4$. *37-429: 7.06₁₀ 4.63₂ 3.53₉ 2.64₆ 2.51₇ 2.33₃ 1.938₃ 1.549₂; 34-163: 7.03₁₀ 4.37₅ 3.52₆ 2.61₂ 2.48₆ 1.934₂ 1.930₂ 1.535₂*. HEX *P6₃*. $a = 5.31$, $c = 14.01$, $Z = 4$, $D = 2.83$. *9-493: 7.06₁₀ 3.52₁₀ 2.48₆ 2.32₅ 1.925₇ 1.749₅ 1.596₆ 1.531₆*. Amesite is a trioctahedral 1:1 layer hydrous silicate and belongs to the serpentine subgroup of the serpentine-kaolinite group. It shows nearly complete ^{IV&VI}R cation ordering, but the style of ordering can differ with the same kind of polytype [*AM 66:185(1981)*], and IR can falsely suggest extensive disorder. *AM 52:296(1977)*. Amesite is frequently triclinic but can be hexagonal. Occasional disorder has been observed. Mössbauer, IR, DTA, TGA data: *TA 64:83(1983)*. Some detailed studies have erroneously equated amesite with aluminian clinocllore or sudoite [e.g., *EJM 6:279(1994)*]. Found in polytypes: 2H₂ (most common), 9T [*MM 44:153(1981)*], 6R₂, 6R₁, and 2H₁ (rare). Several polytypes can be present at a single locality. *CCM 27:241(1976), AM 66:185(1981)*. Several crystal structure determinations have been made. *AC 15:510(1962); AM 66:185(1981), 76:651(1991)*. Proton positions have been calculated. *CCM 28:816(1980), 30:409(1982)*. At least one amesite has low ^{IV}Al (New Caledonia), but the distinction between amesite and lizardite lies in ^{IV}Al > 0.5. Due to charge balance considerations, ^{IV}Al \approx ^{VI}Al. Light green, pale bluish green, apple-green, also mauve to purple or violet (chromian), foliated, rarely in pseudo-hexagonal columnar crystals (to several millimeters) elongated parallel to [001]. Cleavage {001}, perfect, with pearly luster. $H = 2\frac{1}{2}\text{--}3$. $G = 2.71\text{--}2.80$. Slowly decomposed by HCl, infusible. Electronic absorption spectra of chromian amesite: *EJM 7:961(1995)*. Uniaxial (+); $N_O = 1.597$, $N_E = 1.612$; birefringence = 0.015; negative elongation; also biaxial (+); $Z \wedge c = 0\text{--}20^\circ$; $N_x = 1.597\text{--}1.612$, $N_y = 1.599\text{--}1.612$, $N_z = 1.615\text{--}1.630$, with N_x very close to N_y ; RI increases with Fe substitution; birefringence = 0.018; $2V = 18\text{--}20^\circ$; $r < v$; negative and positive elongation. Can show sector twinning on {001} or polysynthetic lamellae on {010} [*AM 66:185(1981)*] or hourglass texture. Optical properties of amesite can be confused with chlorites. *MM 46:469(1982)*. Chemistry is moderately variable with some minor element substitution (wt %): SiO₂, 20.11–24.00 (33.51, New Caledonia); Al₂O₃, 31.14–35.21 (21.30, New Caledonia); Fe₂O₃, 0.63 (Saranovsk); Cr₂O₃, 0–3.90; FeO, 0.60–22.48; MgO, 14.59–30.70; NiO, 0–0.31 (3.12, New Caledonia); MnO, 0–0.41; CaO, 0–0.58; Na₂O, 0.38 (Saranovsk); TiO₂, 0.26 (Saranovsk);

H_2O^+ , 10.54–13.02. Typical structural formulas include: $(\text{Mg}_{1.936}\text{Fe}^{2+}0.025\text{Cr}_{0.074}\square_{0.022})\text{Al}_{0.943}(\text{Si}_{1.027}\text{Al}_{0.973})\text{O}_5(\text{OH})_4$ (Ural Mts.), which can range to $(\text{Mg}_{1.132}\text{Fe}^{2+}0.979\text{Mn}_{0.94}\text{Ca}_{0.025})\text{Al}_{0.960}(\text{Si}_{1.047}\text{Al}_{0.953})\text{O}_5(\text{OH})_{3.76}$ (Black Lake). Rarely as an alteration of cancrinite and other minerals. At Black Lake, formed during calcium metasomatism of granite, particularly biotite. Found with clinocllore, magnetite, sometimes grossular, diopside, calcite, and clinozoisite; occasionally margarite. *Chester Emery mine, Chester, Hampden Co., MA*; Tracy mine, Negaunee, Marquette Co., MI; Tiger, AZ; Black Lake, PQ, Canada; Cr-bearing from Mt. Sobotka, Lower Silesia, Poland; St. Johns Is., Egypt; Saranovsk chromite deposits, Ural Mts., Russia; Col. de Mourange, New Caledonia; Dufek massif, Pensacola Mts., Antarctica. vk, EF

71.1.2c.2 Berthierine $\text{Fe}_2^{2+}\text{Al}(\text{SiAl})\text{O}_5(\text{OH})_4$

Named in 1832 by Beudant for Pierre Berthier (1782–1861), redefined by Orcel, Henin, and Caillere (1949). Kaolinite–serpentine group. At one time, erroneously believed to be chamosite and still easily confused with it. *MON Cm*. $a = 5.25\text{--}5.41$, $b = 9.10\text{--}9.33$, $c = 7.06\text{--}7.28$, $\beta = 104.5^\circ$, $Z = 2$. *ORTH* $a = 5.42$, $b = 9.38$, $c = 7.11$. *HEX* $a = 5.42$, $c = 7.11$, $Z = 1$, $D = 3.04$. *31-618*: 7.12₁₀ 4.68₅ 3.55₁₀ 2.53₁₀ 2.15₇ 1.779₆ 1.563₇ 1.481₆; *7-315*: 7.05₁₀ 3.52₁₀ 2.68₄ 2.52₉ 2.40₄ 2.14₆ 1.769₄ 1.555₇. Found in polytypes 1H and 1M, which might exist together in some samples. Structural formulas include: $(\text{Fe}_{1.84}^{2+}\text{Mg}_{0.23}\text{Al}_{0.84}\text{vacancy}_{0.09}\text{Fe}_{0.01}^{3+})(\text{Si}_{1.33}\text{Al}_{0.67})\text{O}_5(\text{OH})_4$ (Corby), $(\text{Fe}_{1.33}^{2+}\text{Mg}_{0.57}\text{Al}_{0.82})(\text{Si}_{1.28}\text{Al}_{0.72})\text{O}_5(\text{OH})_4$ (Kursk) [*CCM 30:153(1982)*], and $(\text{Fe}_{1.14}^{2+}\text{Zn}_{0.83}\text{Al}_{0.78}\text{Mg}_{0.10}\text{Ca}_{0.02})(\text{Si}_{1.49}\text{Al}_{0.51})\text{O}_5(\text{OH})_4$ (Air Mts.). Fe^{3+} in berthierines is usually originally absent and then Fe^{2+} is oxidized in place [*AC 74(1984)*] and ferric berthierines have reduced cell parameters. Heated berthierine (300°) shows collapsed d_{060} 1.548 Å → 1.513 Å and all reflections disappear at 600°. IR studies have been done and show similarities to iron-bearing chlorites. *CM 19:279(1981)*. Usually earthy, rarely foliated or in columnar pseudo-hexagonal crystals (to several millimeters at Mt. St.-Hilaire). Dark green, gray, brown, to black; white to light green streak. $H = 2\text{--}2.5$. Cleavage {001}, perfect. Decomposed by hot HCl. Probably biaxial; $N_{av} = 1.62\text{--}1.65$; pleochroic, yellow green–dark green. Observed chemical variation includes (wt %): SiO_2 , 18.50–26.9; Al_2O_3 , 10.99–28.02; Fe_2O_3 , 0–6.62, but oxidized specimens to 26.25; Cr_2O_3 , 0–0.05; TiO_2 , 0–3.63; FeO , 20.20–39.79; MgO , 0.97–8.15; MnO , 0–2.84; ZnO , 19.56 (Air Mts.); Nb_2O_5 , 0.78 (Mt. St.-Hilaire); CaO , 0–0.93; Na_2O , 0–0.21; K_2O , 0–0.21; H_2O_{tot} , 9.58–17.4. A “berthierine” with $^{VI}\text{Ti} \gg ^{VI}\text{Al}$ ($\text{TiO}_2 = 20.48$ wt %) (Picton) has been analyzed. *CM 23:213(1985)*. TGA, DTA, IR, Mossbauer data: *MM 30:57(1953)*, *TA 74:291(1984)*. Found in unconsolidated estuarine and marine sediments in iron reduction zones and in arctic soils. Can be found in phosphatic or sideritic sedimentary rocks, also laterites or coal beds, rarely found in granite pegmatite. In banded iron formations with andradite, diopside–hedenbergite,

babingtonite, magnetite, stilpnomelane, epidote, and other minerals, also in fault breccias and in fluorite–pyrrhotite veins. Can alter to chamosite. Can be found with kaolinite, chamosite, micas, pyrophyllite, siderite, quartz, or miscellaneous detrital minerals. Selected localities include: Rose Hill Formation, VA; Gunflint Formation, Ely, MN; Wabana, NF; Ruth shale, Howells R. area, LAB; Wakefield and Mt. St.-Hilaire(!), PQ; Gunflint formation; Kidd Creek mine, Timmins and Picton, ON; Clearwater Formation, Cold Lake, ALB; Ellef Ringnes and Ellsmere Is., NWT, Canada; Carnlough and Knowehead, County Antrim, Northern Ireland; Cambokeels mine and Redburn; North Wear tunnel, Weardale, Durham; Horsham, Sussex; Finedon, Stanion Lane mines, Northamptonshire; Corby; Frodingham Ironstone formation, Scunthorpe, England; Ayrshire, Scotland; Kongsberg, Norway; Visingsö Group, Sweden; Caradocian rocks, Crozon Penin.; Champagne, Bourgogne, and Lorraine; *Hayanges, Moselle, France*; Serra del Cadi, Pyrenees Mts., Spain; Windgalle, Switzerland; Hagendorf Süd, Bavaria, and Pegnitz, Germany; Kank mine, Kutna Hora, Czech Republic; Trojarova deposit, Male Karpaty Mts., Slovakia; Aladag, Turkey; Belgorod district, Kursk and Onega areas; Chara uplift, West Aldan Shield, Siberia, Russia; Orinoco R. delta; Del Corral Hill, Argentina; Niger R. delta and Taghouaji alkaline ring complex, Air Mts., Niger; Sarawak continental shelf; Chashan, Guangxi, China; Hirumatsu, Utatsu, Miyagi Pref.; Ohmine coal field, Yamaguchi Pref.; Kado, Iwate Pref.; Ishikari coal field, Hokkaido, Japan. *vk, EF ACP 35:258(1827), BTEM, MIN 4(1):175(1992)*.

71.1.2c.3 Brindleyite $\text{Ni}_2\text{Al}(\text{SiAl})\text{O}_5(\text{OH})_4$

Described in 1978 by Maksimovic and Bish and named for George William Brindley (1905–1983), English–American clay mineralogist, Pennsylvania State University. Kaolinite–serpentine group. A trioctahedral clay mineral. See berthierine (71.1.2c.2), the Fe–Al analog. Originally called nimesite. *BSCASA 17:224(1972)*. *MON C2/m* and *P31m* for 1M and 1T polymorphs. (1M): $a = 5.286$, $b = 9.133$, $c = 7.31$, $\beta = 104.15^\circ$, $Z = 2$, $D = 3.16$. *HEX* (1T): $a = 5.277$, $c = 7.09$, $Z = 1$, $D = 3.38$. *31-892(1M)*: 7.07₁₀ 4.54₁ 3.54₈ 2.65_{0.5} 2.62₂ 2.47₂ 2.37₂ 1.524₂; *42-1311(1T)*: (*P31m*) 7.07₁₀ 4.54₁ 3.54₈ 2.62₂ 2.47₂ 2.37₂ 2.01₇ 1.524₂. Structure unknown. Found in polytypes: 1M–3T, 1T assumed. *AM 63:484(1978)*. Disordered stacking observed. Dark yellowish green (color due to octahedrally coordinated Ni^{2+}), green coatings a few millimeters thick with sporadic thickening to 1.2 cm, on limestone. Has a clayey appearance, with schistosity and lustrous surface, earthy to waxy, microscopically fibrous to platy (generally < 1 μm). Cleavage not observed. $H = 2\frac{1}{2}$ –3. $G = 3.01$ –3.17. IR, DTA, TGA data: *AM 63:484(1978)*. Biaxial; $N_{av} = 1.635$. Few brindleyite analyses appear in the literature (wt %): SiO_2 , 23.61–27.45; Al_2O_3 , 23.39–32.18; Fe_2O_3 , 0–0.45; Cr_2O_3 , 0.05–0.26; REE_2O_3 , 0–0.35; TiO_2 , 0.99–1.04; FeO , 1.15–3.40; MgO , 2.81–3.54; NiO , 30.18–22.02; MnO , 0–0.18; ZnO , 0.24–0.25; CoO , 0–0.18; CuO , 0–0.72; CaO , 0.07–0.39; Na_2O , 0–0.10; K_2O , 0–0.20; H_2O^+ , 11.36–12.59; H_2O^- , 0.70–1.29; CO_2 , 0–0.58. $\text{CEC} = 36$

meq per 100 g. Brindleyite can be cation deficient: $(\text{Ni}_{1.75}\text{Al}_1\Box_{0.25})(\text{Si}_{1.5}\text{Al}_{0.5})\text{O}_5(\text{OH})_4$ or $(\text{Ni}_{1.81}\text{Mg}_{0.26}\text{Fe}_{0.05}^{2+}\text{Ti}_{0.04}\text{Al}_{1.03}\Box_{0.31})(\text{Si}_{1.49}\text{Al}_{0.51})\text{O}_5(\text{OH})_4$, but only one locality has published analyses. Found as veinlets in red kaolin and in limestone with bastnaesite-(Ce), malachite, bayerite, and calcite. Also in altered serpentine. Found at Victorio, Grant Co., NM; *Marmara Bauxite mine, Megara, Greece*. EF AM 58:1112(1973) MSASC 19:169(1988); MIN 4(1):197(1992).

71.1.2c.4 Fraipontite $(\text{Zn,Cu,Al})_3(\text{Si,Al})_2\text{O}_5(\text{OH})_4$; ideal: $[\text{Zn,Cu}]_{3-x}\text{Al}_x(\text{Si}_{2-x}\text{Al}_x)\text{O}_5(\text{OH})_4$

Described in 1927 by Cesaro and named for Julien Jean Fraipont (1857–1910) and Charles Fraipont, Belgian geologists and paleontologists. Kaolinite-serpentine group. Polytypes include 1H and 2M₁. Zn analog of berthierine. MSASC 19:169(1988) and MIN 4(1):202(1992) state that zinalsite is equivalent to fraipontite. MON C1 or C1̄ (Moresnet): $a = 5.372$, $b = 9.246$, $c = 7.273$, $\beta = 103.55^\circ$; (Defiance): $a = 5.331$, $b = 9.23$, $c = 9.275$, $\beta = 104.15^\circ$, $Z = 2$, $D = 3.44$; another cell for Moresnet material: $a = 5.34$, $b = 9.21$, $c = 14.12$, $\beta = 93.2^\circ$, $Z = 4$; supposedly, orthorhombic material from Laurion has $a = 5.325$, $b = 9.238$, $c = 7.075$, $\beta = 90.0^\circ$. 14-366(monoclinic): 7.0_{10} 3.52₇ 2.63₃ 2.48₂ 2.36₂ 2.25₁ 2.12₁ 1.53₂; 34-782(orthorhombic): 7.07_{10} 4.65₁ 3.54₆ 2.66₁ 2.49₂ 2.37₁ 2.12₁ 1.54₁. A hydrous phyllosilicate. Described as Zn-berthierine [BM 98:235(1975)] and as a septechlorite [NJBM 4:155(1977)] because of much higher Al content. Following Bailey (1980), the term *septechlorite* should be dropped and the Laurion fraipontite could be a high-Al serpentine. Usually earthy and massive, rarely occurs as pseudo-hexagonal platy crystals to 1 mm. White, yellowish white, light blue-green, bluish gray; white to pale blue or blue-green streak; earthy to silky luster, sometimes waxy. Cleavage {001}, perfect. H = 3½–4 (of aggregate). G = 3.08–3.54. Becomes amorphous on heating to 450°. IR, DTA, TGA data: BM 98:235(1975), MZ 14:89(1992). Soluble in HNO₃, gelatinizes upon evaporation; dissolves completely in 10% HCl and 30% solution of NaOH. About eight good analyses of fraipontite exist (wt %): CuO, 0.2–16.8; ZnO, 14.5–51.9; traces of MgO, CaO; Al₂O₃, 16.2–21.7; SiO₂, 19.5–32.8 and H₂O is about 14. Some fraipontites are Zn-bearing and some are cuprian. Solid solution between berthierine and fraipontite exists. AM 75:909(1990). Biaxial (–); 2V = 15–20°; indices of refraction not well measured, but the mean ranges from 1.61 to 1.62; positive elongation; OAP parallel to the length of the fibers. A low-temperature clay mineral found with secondary zinc and copper minerals. In slags at Laurion, Greece. On smithsonite at Moresnet. In hydrothermal Cu–Zn base metal deposits. Often associated with sauconite. Forms as pseudomorphs after azurite, cuprite, and other minerals. Coating fluorite, associated with gypsum, jarosite, and quartz in Turkmenia. Found at Sterling Hill, Ogdensburg, Sussex Co., NJ; the Silver Bill and Defiance mines, Gleeson district, Cochise Co., AZ; Bingham(I), Socorro Co., NM; also at the West adit, Mohawk mine, San Bernardino Co., CA; Wensleydale area, Yorkshire,

England; *Vielle Montagne, Moresnet, Belgium*; Altenberg, near Aachen, Germany; Laurion, Greece; Kugitang-Tau, Kugitang Mts., Turkmenistan; several deposits in Kazakhstan (Akdzhal, Achisai, Bazar-Tube, Maidanshak, Gulshad); Almalik deposit in Kirgizia; Taghouaji complex, Air Mts., Niger; Tsumeb, Namibia. *vk, EF MR 13:137(1982), 14:131(1983); MIN 4(1):202(1992).*

71.1.2c.5 Kellyite $(\text{Mn,Mg,Al})_3(\text{Si,Al})_2\text{O}_5(\text{OH})_4$

Described in 1974 by Peacor et al. for William Crowley Kelley (b. 1929), American geologist, University of Michigan. Kaolinite-serpentine group, Mn analog of amesite. Two polytypes are recognized: 2H_2 and 6R_2 . *HEX P6₃*. (2H polytype): $a = 5.348$, $c = 14.04$; (6R polytype): $a = 5.44$, $c = 42.13$; *MSASC 19:169(1988)*. $29-885(2\text{H}$ polytype, nat): 7.0_9 3.51_{10} 2.67_4 2.53_6 2.34_4 2.15_1 1.95_3 1.57_3 . See *MSASC 19:169(1988)* for X-ray data for the monoclinic cell. Structure unknown. Micaceous grains to 1 mm, laths and tablets. Golden yellow to lemon yellow; oily to vitreous luster, sometimes pearly. Cleavage $\{001\}$, perfect. $G = 3.07$. Analysis (wt %): SiO_2 , 17.6; Al_2O_3 , 28.55; Fe_2O_3 , 2.18; MnO , 38.84; MgO , 2.97; H_2O (by difference), 10.82. A structural formula is: $(\text{Mn}_{1.8}\text{Mg}_{0.25}\text{Fe}_{0.1}^{\text{III}})_{\Sigma 2.15}\text{Al}_{0.85}(\text{Si,Al})\text{O}_5(\text{OH})_4$. Biaxial (-); X perpendicular to (001); $N_x = 1.639$, $N_y = 1.646$, $N_z = 1.646$; $2V = 16-30^\circ$, sometimes as low as $5-6^\circ$; $r > v$, moderately pleochroic. X, colorless to greenish yellow; Y, Z, pale yellow to reddish brown. Irregular to undulatory extinction, possible sector twinning. Occurs in a metamorphic manganese deposit along with Mn-silicates, including alleghanyite, tephroite, sonolite, galaxite-jacobsite, and Mn-carbonates, including kutnahorite. *Bald Knob, Sparta, Alleghany Co., NC; Savoie Dept., French Alps. vk, EF AM 59:1153(1974), BM 101:514(1978), MR 12:167(1981), MIN 4(1):198(1992).*

71.1.2c.6 Manandonite $\text{Li}_2\text{Al}_4[(\text{Si}_2\text{AlB})\text{O}_{10}](\text{OH})_8$

Named in 1912 by Lacroix for the Manandona River in Madagascar. Serpentine-kaolinite group. An Al-, Li-, B-rich analog of amesite. Originally thought to be a chlorite related to cookeite, which it can physically resemble. *TRIC C1*. $a = 5.070$, $b = 8.776$, $c = 13.778$, $\alpha = 90.09^\circ$, $\beta = 90.12^\circ$, $\gamma = 89.97^\circ$, $Z = 2$, $D = 2.79$. $45-1464(\text{nat})$: 6.92_{10} $4.36_{2.5}$ 4.16_1 3.45_8 $2.49_{1.5}$ $2.38_{3.5}$ 2.295_1 $1.86_{1.5}$. *EJM 1:633(1989)*. A 1:1 layer silicate (7-A serpentine-kaolinite group). A two-layer polytype. Refined in space group *C1* to *R* = 5.7%. Tetrahedral Si, Al, and B are partly ordered. B has a greater tendency to order than do Si and Al. There is also partial ordering of the octahedral cations that decreases the ideal *P6₃* symmetry to *P1* (or *C1*, as used for refinement). Occurs as a 2H_2 polytype. Dull yellow globules or white isolated platy pseudohexagonal crystals, fanlike aggregates and globules most common. Frequently twinned on (001) as sixfold sectors and warped; white streak; pearly luster, otherwise greasy. Cleavage $\{001\}$, excellent. $H = 2\frac{1}{2}$. $G = 2.78-2.89$. IR, TGA, DTA data: *EJM 1:633(1989)*. Analysis (wt %): SiO_2 , 23.0; B_2O_3 , 7.7; Al_2O_3 , 47.85; Fe_2O_3 , 0.36; MnO , 0.02; MgO , 0.03; CaO , 0.07; Na_2O , 0.13;

Li_2O , 5.38; H_2O , 15.40. Biaxial (+); Z perpendicular to (001); $N_x \approx N_y = 1.604$; $2V = 10\text{--}15^\circ$; no dispersion. Sometimes pseudo-uniaxial (+). Frequently sector-twinned with undulatory extinction. Optics confirm true triclinic symmetry. Found in an Li- and B-rich granite pegmatite with spodumene, red elbaite, albite, quartz, beryl, spessartine, rhodizite, and danburite. Occurs in the *Antandrokomby pegmatite, Manandona R., Sahatany Valley, near Antsirabe, Madagascar*, as crusts in small vugs of albite, lined with elbaite and quartz. VK, EF CR 155:446(1912), MIN 4(2):172(1992).

71.1.2c.7 Cronstedtite $\text{Fe}_2^{2+}\text{Fe}^{3+}(\text{Si},\text{Fe}^{3+})\text{O}_5(\text{OH})_4$

Named in 1821 by J. Steinmann for Axel Cronstedt, Swedish pioneer mineralogist. Kaolinite-serpentine group. MON CC (three-layer): $a = 5.49$, $b = 9.51$, $c = 14.29$, $\beta = 82.63^\circ$; Cm (three-layer): $a = 5.49$, $b = 9.51$, $c = 7.32$, $\beta = 104.5^\circ$, $Z = 2$, $D = 3.59$. HEX; R3(six-layer): $a = 5.49$, $c = 42.5$; $P6_3$: $a = 5.49$, $c = 14.7$; $P31m$ (one-layer): $a = 5.49$, $c = 7.085$; $P6_3cm$ (two-layer): $a = 5.49$; $c = 14.7$; $P31$ (three-layer): $a = 5.49$, $c = 21.21$; 14-470(1M): 7.09₁₀ 3.54₉ 2.72₅ 2.44₄ 2.31₂ 2.04₂ 1.680₂ 1.586₄. Found in polytypes: 1M, 2M₁, 2T, 2H₁, 2H₂, 3T₁, 6R₃, 6H₂. AC 16:1(1963), 17:404(1964). A 9R polytype with large a (9.56 Å) has also been reported. AM 47:781(1962). Twinning is common in some polytypes and frequently occur intergrown in a single specimen and polytype style cannot be predicted by external morphology. AC 16:1(1963). A structural formula is: $\text{Fe}_{2.38}^{2+}\text{Fe}_{0.71}^{3+}(\text{Si}_{1.11}\text{Fe}_{0.81}^{3+}\text{Al}_{0.07})\text{O}_5(\text{OH})_4$ (Herja), while a general formula could be $(\text{R}_{3-x}^{2+}\text{Fe}_x^{3+})(\text{Si}_{2-x}\text{Fe}_x^{3+})\text{O}_5(\text{OH})_4$ with $x \approx 0.5\text{--}1$. AM 60:175(1975). Ordering of $^{\text{IV}}\text{R}^{3+}$ is present as in amesite, but not $^{\text{VI}}\text{R}^{3+}$. Mössbauer data: CCM 16:381(1968). Frequently in divergent groups of trigonal or hexagonal, striated, tapering crystals (rarely to 1 cm) forming hemispheres, with basal terminations forming the surface, sometimes showing interpenetrating twins, also smooth botryoidal, cylindrical, or massive. Black to brownish black, rarely green or brownish yellow in thin foliae; dark olive-green streak; vitreous. Cleavage {0001}, perfect. Foliae elastic. $H = 3\frac{1}{2}$. $G = 3.34\text{--}3.45$. Fusibility 4. Gelatinizes with acid. Uniaxial (-); $N_0 = 1.80$; birefringence large; pleochroic. E, dark reddish brown; O, almost opaque. Also biaxial; $N_y = 1.80$; $2V = 0^\circ\text{--small}$. Pleochroic, X, brown; Y,Z, black. Chemical analyses are few (wt %): SiO_2 , 16.42; Al_2O_3 , 0.90; Fe_2O_3 , 29.72; FeO, 41.86; CaO, 1.32; H_2O^+ , 10.17. Found associated in sulfide veins with limonite and calcite. Long Hill, Trumbull, Fairfield Co., CT; Cornucopia mine, Nye Co., NV; San Antonio and Potosi mines, Santa Eulalia, CHIH, Mexico; Wheal Jane, Kea (almost always three-layer, P31, also Cc and Cm) and Wheal Maudlin, Lanlivery (one-, two-, and six-layer polytypes, including P6₃ and P31c), Cornwall, England; Mina Brunita, La Union, Murcia, Spain; Eisleben, Thuringia, Germany; (Kuttenberg), Kutná Hora, Chyňava, and Příbram, Bohemia, Czech Republic; Anbruch, Reusengang, Hüttenberg, Carinthia, Austria; Herja(!) (Kisbanya), Transylvania, Romania; Llallagua and Huanuni(!), Bolivia; Conghonas do Campo, MG, Brazil;

Cold Bokkeved, Renazzo, and Cochabamba meteorites. VK, EF *JCP* 32:69(1821), *MIN* 4(1):183(1992).

71.1.2d.1 Clinochrysotile $Mg_3Si_2O_5(OH)_4$

71.1.2d.2 Orthochrysotile $Mg_3Si_2O_5(OH)_4$

71.1.2d.3 Parachrysotile $Mg_3Si_2O_5(OH)_4$

Chrysotile was named in 1834 by F. von Kobell from the Greek, in allusion to its golden fibers. Clinochrysotile and orthochrysotile were named in 1951 by Whittaker in allusion to their crystallographic relationship to chrysotile. Parachrysotile was named, but not described, by Whittaker in 1956 in allusion to its crystallographic relationship to chrysotile. Originally called amianthus; also the common asbestos; constitutes in part, aquacryptite, baltimorite, deweylite, jenkinsite, picrolite, retinalite, and other less common materials. Also variously important in schweizerite, metaxite, bastite, marmolite, and rarely, in mountain leather. Clinochrysotile: *MON* *Cc*, *C2/m*. $a = 5.30\text{--}5.34$, $b = 9.17\text{--}9.25$, $c = 14.31\text{--}14.65$, $\beta = 93.12\text{--}93.34^\circ$, $97.15^\circ(\text{syn})$, $106.4^\circ(1M_{cl})$; β can vary by up to 1° within a specimen. *CM* 17:679(1979). Orthochrysotile: *ORTH* $a = 5.32\text{--}5.34$, $b = 9.2$, $c = 14.6\text{--}14.63$. Parachrysotile: *ORTH* $a = 5.3$, $b = 9.2$, $c = 14.6$. *MM* 31:107(1956). Clinochrysotile (syn): *Cc*. $a = 5.32$, $b = 9.25$, $c = 14.31$, $\beta = 97.15^\circ$, $Z = 4$, $D = 2.63$. 22-1163: 7.1₉ 4.60₂ 4.40₂ 4.07₁ 3.55₆ 2.65₃ 2.39₁₀ 2.001₃; 21-1262, *C2/m*: 7.28₆ 4.54₁₀ 3.64₄ 2.62₄ 2.53₄ 2.45₄ 1.531₅ 1.501₅; 31-808, *C2/m*($2M_{cl}$): $a = 5.31$, $b = 9.12$, $c = 14.64$, $\beta = 93.17^\circ$, $Z = 4$, $D = 2.60$. *PD*: 7.31₁₀ 4.57₅ 3.65₇ 2.27₃ 2.21₃ 2.09₃ 1.827₃ 1.744₃. Orthochrysotile($2Or_{cl}$): $a = 5.34$, $b = 9.25$, $c = 14.20$, $Z = 4$, $D = 2.62$. 22-1162: 7.1₁₀ 4.63₂ 4.40₄ 3.88₃ 3.55₇ 2.50₅ 2.33₈ 1.615₃; 25-645($2Or_{cl}$): $a = 5.32$, $b = 9.2$, $c = 14.64$, $Z = 4$, $D = 2.57$. *PD*: 7.36₁₀ 4.56₅ 3.66₈ 2.60₄ 2.50₅ 2.45₇ 2.09₄ 1.531₇. Chrysotiles are based on a cylindrical development of curved sheets. Continuous curvature does not result entirely in optimum hydrogen bonds between layers. Chemical composition determines the degree of dimensional mismatch of a and b , and it has been suggested that 88 Å is the ideal radius of a chrysotile cylinder. *AC* 10:149(1957). The minimum radius of a chrysotile cylinder should be 35–40 Å, while the expected maximum radius would be ≈ 140 Å [*AC* 23:704(1971)], but 400-Å radius has been observed [*MM* 50:301(1986)]. In clinochrysotile and orthochrysotile, a is the fiber axis and c is the interlayer axis, while in parachrysotile b is the fiber axis. Ortho- and clinochrysotile have been observed in alternating overgrowth in a single fiber. *CCM* 32:429(1984). All the chrysotiles have been found in polygonal Povlen-type textures, sometimes with lizardite-2H overgrowths, but normal cylindrical morphology might also be found in parachrysotile. *CM* 17:693,699(1979), 26:991(1988). In some polygonal serpentines, the structure is flat-layered and thus is appropriately called lizardite [*CM* 14:308(1976)], but cores in Povlen-type texture may contain chrysotile. Small chrysotile fibers can transform to polygonal textures. *MM* 50:301(1986). All forms of chrysotile (clino-, ortho-, and para-) have been observed in a single specimen. Parachrysotile is a growth variety of orthochrysotile, not a polytype variation

of it, and powder XRD does not serve to distinguish it from orthochrysotile. Found in one- and two-layer polytypes and which are in the opposite sense of standard serpentine stacking. *CM 13:227(1975)*. Three forms of chrysotile have been given separate names (the subscript c was introduced to indicate cylindrical development): orthochrysotile, clinochrysotile, and parachrysotile. Clinochrysotile is the most abundant polytype and sometimes has orthochrysotile intergrown with it. The polytypes of chrysotile are visually indistinguishable, but ratios of polytypes can be calculated from XRD. *MM 31:107(1956)*. Two kinds of clinochrysotile have been distinguished: normal and Globe-type. *USGSPP:384-A(1962)*. Normal clinochrysotile has a strong $d = 2.456$ Å line with a diffuse band extending to 2.594 Å. Globe-type has two lines at $d = 2.456$ Å and 2.604 Å with a weak diffraction band in between, and there is no diffraction line at 2.500 Å. Globe-type might be a mixture of clinochrysotile and orthochrysotile polytypes. Polygonal cross-sectional morphology exists (Povlen-type) and appears to yield sharper X-ray diffraction results than those for fibrous cylindrical material. Disordered chrysotile has been given the symbol D_c . Mössbauer studies of chrysotile indicate $^{IV\&VI}Fe^{3+}$, but $^{VI}Fe^{3+}/^{IV}Fe^{3+} \approx 3 : 1$. *CM 17:713(1979)*. Chrysotile has been synthesized [*AM 39:957(1954)*, *CM 20:19(1982)*], and increasing Al was found to decrease chrysotile products. **Physical properties:** Green to pale green to yellowish green, also golden yellow to dark brown (WY), rarely ash gray; usually fibrous and weavable (pure orthochrysotile can have a "badly crimped appearance"), also compact or splintery (metaxite), silky to oily luster, but some chrysotile is not visibly fibrous, especially when mixed with other serpentines; sometimes unctuous. $H = 2-3$ (by polishing, noticeably softer than lizardite and very much softer than antigorite). $G = 2.53-2.55$. Infusible, insoluble in acids. **Optics:** Biaxial (-); $N_x = 1.545-1.569$, $N_y = 1.546-1.569$, $N_z = 1.553-1.570$; birefringence = 0.001-0.008; $2V = 50^\circ$. Fibrous, RI value increases with iron substitution. The refractive indices of the various chrysotiles overlap and are therefore indistinguishable by this method of identification. Can be weakly pleochroic. **Chemistry:** Reported ranges of chrysotile analyses (wt %) include: SiO_2 , 40.6-46.20; Al_2O_3 , 0-0.96; Fe_2O_3 , 0-1.34; Cr_2O_3 , 0-0.27; TiO_2 , 0-0.07; FeO , 0-1.57; MgO , 35.25-43.6; MnO , 0-0.15; NiO usually ≈ 0 , but a series can extend to nepouite; CaO , 0-0.85; Na_2O , 0-0.14; K_2O , 0-0.11; H_2O^- , 0.70-4.82; H_2O^+ , 12.53-14.04; F, 0-0.31. Aluminian chrysotiles ($^{IV}Al > 0.10$) are probably unstable. *CM 17:757(1979)*. **Occurrence:** Clinochrysotile and orthochrysotile are frequently intergrown in a sample, usually with a ratio of the former to the latter of 30-50 : 1, but some orthochrysotile contents range from 7% (Thetford) to 35% (Shabani) to 81% (Chuddapah) to the essentially pure orthochrysotile that occurs at an unknown locality in Silesia. Methods of establishing the ratio of clinochrysotile to orthochrysotile have been published. *MM 31:107(1956)*. Chrysotiles can be found with other serpentines, talc, chlorite, dolomite, magnesite, brucite, magnetite/magnesiocromite, and so on. Orthochrysotile and parachrysotile can be present mixed with the fibrous brucite called nemalite, and orthochrysotile can occur as cross fibers in dolomite. Clinochrysotile can be found as the major constituent in some

mountain leather. Found intergrown with uralite [*SCI 206:1398(1979)*] and rarely with carlosturanite or balangeroite. Parachrysotile can be formed during the incipient serpentinization of forsterite. Can recrystallize to antigorite or weather to smectite. Observed as an authigenic mineral. *CCM 35:43(1987)*. Oxygen isotopes have been used to model chrysotile formation at about 200°. *GI 16(1):170(1979)*. Localities: Selected clinochrysotile localities include: Lowell, Lamoine Co., and Eden, Orange Co., VT; Talcville and Balmat, St. Lawrence Co., NY; Castle Point, Hoboken, Hudson Co.; Turkey Mt., Montville, Morris Co., NJ; Woods mine, Cedar Hill mine, and elsewhere, Lancaster Co.; Sylmar West Nottingham Twp., Chester Co., PA; Forest Hill, Bare Hills, Baltimore Co.; Harford Co., MD; Webster, Jackson Co., NC; Prairie Creek, Murfreesboro, Pike Co., AR; Grand View, Grand Canyon, Coconino Co.; Globe, Gila Co., AZ; Current Creek deposit, White Pine Co., NV; Casper, WY; New Almaden mine, Santa Clara Co.; New Idria and Clear Creek Canyon, San Benito Co., CA; Sultan area, Cascade Mts., WA; Baie Verte, NF; Thetford, Black Lake, Asbestos, and elsewhere, QUE; Timmins, ONT; Pipe Lake, MAN; Clinton Creek, YT; Cassiar, BC, Canada; Nicaro and Moa, Oriente Prov., Cuba; The Lizard, Cornwall, England; Glen Urquhart, Scotland; Findeten Glacier, Zermatt, Switzerland; Balangero serpentinite, Lanzo massif; Franscia, Chiesa, and elsewhere, Malenco serpentinite, Bergell Aurole, Italy; *Reichenstein, Silesia, Poland*; Povlen Mts., Serbia; Ocna de Fier, Romania; Aktovrak deposit, Tuva; Bazhenovo, Ural Mts.; Sayan deposit, West Sayan, Russia; Krantzkop, Natal; Premier mine, Kimberley, Transvaal, South Africa; Port Macquarie, WA, Australia; Yamabe mine, Hokkaido, Japan. Orthochrysotile localities studied include: Balmat, St. Lawrence Co., NY; Turkey Mt., Montville, Morris Co., NJ; New Almaden mine, Santa Clara Co., CA; Cuicateco, OAX, Mexico; Unst, Shetland Is., and Milton, Glen Urquhart, Scotland; *Silesia, Poland*; Chuddapah, Andhra Pradesh, India; Shabani mine, Zimbabwe; Havelock mine, Swaziland; Kranskop, Natal; Premier mine, Kimberley and elsewhere, Transvaal, South Africa; Jilin, China; Nunyerry, WA, Australia. Parachrysotile localities studied include: East Broughton, Thetford, and Asbestos, QUE, Canada; Glen Urquhart, Inverness-shire, Scotland; Shabani mine, Zimbabwe; Havelock mine, Swaziland. vk, EF *JPC 2:297(1834)*, *MIN 4(1):126(1992)*.

71.1.2d.4 Pecoraite $\text{Ni}_3\text{Si}_2\text{O}_5(\text{OH})_4$

Named in 1969 by Faust et al. for William Thomas Pecora (1913–1972), former director of the U.S. Geological Survey and student of nickel silicate deposits. Kaolinite–serpentine group. Synonym: Ni-chrysotile. Dimorphous with nepouite. MON Space group unknown. $a = 5.26$, $b = 9.16$, $c = 14.7$, $\beta = 92^\circ$, $Z = 4$, $D = 3.57$. $22\text{-}754(\text{nat})$: 7.43_{10} 4.50_6 3.66_8 2.62_6 2.45_5 1.53_8 . Generally poorly crystalline. Found as polytype: $2M_{c1}$. *MM 44:153(1981)*. Synthesis: *AM 46:32(1961)*. Curved plates (to 70 Å), tubes and spirals to 0.4 μm ; granular, to 5 mm; also massive. Bright green, blue green to yellow green, earthy to waxy or vitreous luster; transparent to translucent. $G = 3.08$

(with adsorbed water). $N_{av} = 1.565\text{--}1.603$ (meteorite), 1.616; also $N_{av} = 1.65$ (dried). Analysis (wt %), Wolf Creek material: SiO_2 , 31.0; Al_2O_3 , 1.4; FeO , 0.7; MgO , 0.5; NiO , 51.5; CaO , 0.4; H_2O^+ , 9.7; H_2O^- , 4.1; Otway material: Ni , 44.0; Mg , 0.6; Fe^{2+} , 0.1; Si , 12.5; O , 20.7. Formed by weathering of Fe–Ni meteorite fragments in a desert environment (Wolf Creek meteorite) in association with goethite, maghemite, cassidyite, reevesite, and quartz. Also found in hydrothermally altered shear zones in serpentinite with millerite, polydymite, gaspeite, magnesite, and rare nickel minerals; also as a replacement of millerite in quartz geodes. Woods mine, Lancaster Co., PA; route 44 roadcut, St. Louis, MO; Hanna nickel mine, Riddle, Douglas Co., OR; Tscherschemskoye, Russia; Rockys Reward mine, Agnew and Otway prospects, near Spinnaway, Nullagine district, WA; *Wolf Creek meteorite, WA, Australia*. *VK, EF SCI 165:59(1969)*; *AM 54:1740(1969)*; *MM 39:113(1973)*, *USGSPP:384-C(1974)*; *GSAJ 26:61*; *CM 20:367(1982)*, *21:341(1983)*; *NJBM:513(1983)*; *AUSM 4:141(1989)*; *MIN 4(1):191(1992)*.

71.1.3.1 Bismutoferrite $\text{BiFe}_2^{3+}[\text{SiO}_4]_2(\text{OH})$

Named in 1871 by Frenzel in allusion to the composition. See chapmanite (71.1.3.2). *MON Cm*. $a = 5.21$, $b = 9.02$, $c = 7.74$, $\beta = 100.67^\circ$, $Z = 2$, $D = 5.092$. *11-714*: 7.63₁₀ 4.18₂ 3.87₁₀ 3.58₃ 3.18₅ 2.90₇ 2.59₃ 2.53₂. Structure: *SPC 22:419(1977)*. The structure consists of t-o layers similar to those found in kaolinite and having the composition $[(\text{Fe}_2^{3+}(\text{OH})\text{O}_3(\text{Si}_2\text{O}_5)]^{3-}$, with the iron in the octahedral sites and bismuth occupying the interlayer sites. Isostructural with its antimony analog, chapmanite. Compact, massive; sometimes powdery. Bright to dull yellow-green, waxy to adamantine luster, translucent to opaque. $H = 6$. $G = 4.47$. Biaxial (-); 2V large; $N_x = 1.93$, $N_y = 1.97$, $N_z = 2.01$; . Sb may substitute for Bi to a limited degree; Fe^{2+} may replace Fe^{3+} . Found at Ludi No. 4 Claim Plumas Co., CA; at the South Terras mine, St. Stephan-in-Brannel, Cornwall, and at Buckbarrow Beck, Carney Fell, Cumbria, England; with quartz at Ullersreuth and Gersdorff, and with quartz, bismuth and cobaltite in veins in shale at *Schneeberg, Saxony, Germany*; at Yinnietharra, WA, Australia. *AR AM 43:656(1958)*.

71.1.3.2 Chapmanite $\text{SbFe}_2^{3+}[\text{SiO}_4]_2(\text{OH})$

Named in 1924 by Walker for Edward John Chapman (1821–1904), Canadian geologist and mineralogist, University of Toronto. See bismutoferrite (71.1.3.1). *MON Cm*. $a = 5.19$, $b = 8.99$, $c = 7.70$, $\beta = 100.67^\circ$, $Z = 2$, $D = 4.29$. *11-135*: 7.63₉ 4.17₃ 3.88₈ 3.58₁₀ 3.19₉ 2.90₇ 2.59₇ 2.54₃. Structure: *SPC 22:419(1977)*. Isostructural with its Bi analog, bismutoferrite. Fine-grained aggregates; sometimes granular and microcrystalline to megascopic plates and prisms. Olive-green, yellow-green, yellow; greenish yellow to yellow streak; earthy to waxy, adamantine luster; translucent to opaque. Fracture conchoidal to irregular in masses. $H = 2\frac{1}{2}$. $G = 3.58\text{--}3.57$. Biaxial (-); 2V small; $N_x = 1.85$, $N_{y \text{ calc}} = 1.95$, $N_z = 1.96$; X perpendicular to laths and Z parallel to elongation. Limited substitution of Bi for Sb, Fe^{3+} for Sb, and Al

for Fe^{3+} . Slightly soluble in HCl and H_2SO_4 . On heating yields hematite and tripuhyite. Occurs as a hydrothermal or secondary mineral in Sb-As deposits and in gneisses with other Sb and As minerals. Found at the McDermitt mercury mine, Humboldt Co., NV; at Venesela Mt., AK; at the *Keeley mine, Timiskaming district, South Lorraine Twp., ON, Canada*; Velardeña, DGO, Mexico; La Bassade (Haute Loire) Vosges, France; at Freiberg, Braunsdorf, and Schneeberg, Saxony, Germany; Tafone, Tuscany, Italy; at Smilkov, Votice, and Borenov, Bohemia, Czech Republic; in the Kadamdzhai deposit, Kirgizia; Suzuyama mine, Kagoshima Pref., Japan. EF *AM* 43:656(1958), 49:1499(1964); *MIN* 3(1):503(1972).

ALLOPHANE GROUP

The allophanes are poorly crystallized or noncrystalline minerals with some ordering when viewed by electron microscopy. *CLM* 18:21(1983), *SRF*(1988), *MIN* 29(1994). Members of the group include the following:

ALLOPHANE GROUP

Mineral	
Allophane	71.1.5.1
Hisingerite	71.1.5.2
Imogolite	71.1.5.3
Neotocite	71.1.5.4

71.1.5.1 Allophane $\text{Al}_2\text{Si}_{1-2}\text{O}_{5-7}\cdot 2-3\text{H}_2\text{O}$

Named in 1816 by Stromeyer from the Greek *to appear [as] another*, in allusion to its change when blowpiped. Allophane group. Synonym: protoallophane. Amorphous or poorly crystalline. Space group unknown. $b = 9.0$, $c = 7.0$. 38-449(nat): 3.3₁₀ 2.25₂ 1.86_{<1} 1.40₁ 1.23_{<1}. Allophane is generally amorphous to X-rays, and is a mineral that has a variable chemical composition. As many as four wide diffraction bands are occasionally observed [*AM* 38:634(1953)] which can disappear on heating to 400° [*CCM* 29:124(1981)] and $^{\text{IV}}\text{Al}$ and $^{\text{VI}}\text{Al}$ have been determined [*CS* 2:1(1964)], both suggesting some ordering. Numerous TEM studies show that it frequently consists of hollow spheres (~ 35-55 Å with walls 7-10 Å thick and an external water monolayer [*AM* 56:465(1971)]), but which can quickly dehydrate and collapse in electron beams. The spheres might be composed of a phyllosilicate structure rolled to reduce bond distortions. *PICC* 2:29(1969). Spherical halloysite can be mistaken for allophane by TEM. *CCM* 11:169(1963) and others. A defect kaolinite structure has been proposed [*DS* 27:537(1979)], but MAS-NMR studies suggest an octahedral sheet similar to that of 2:1 phyllosilicates, but different

from that of kaolinite or gibbsite [CCM 42:276(1994)]. Dry grinding can affect allophane morphology [CM 18:101(1983)], as can electron beams [AM 61:379(1976)]. IR studies have been numerous [e.g., CCM 28:295,328(1980); 29:124(1981)] and are similar to those of imogolite. CCM 28:285(1980). **Habit:** Generally occurs as hyaline crusts, masses, and coatings; stalactites and rarely as flowstone. **Physical properties:** White to tan, also bright blue, green, or yellow; frequently stained brown; uncolored streak unless stained; waxy to earthy luster, can be unctuous; sometimes translucent. Conchoidal fracture and then showing a shining luster; brittle; sometimes stalactitic. $H = 3$. $G = 1.8\text{--}2.78$. Infusible. Gelatinizes in HCl. **Chemistry:** Chemistry is variable, in part due to impurities, and has been assigned a composition $\text{Al}_2\text{Si}_2\text{O}_7 \cdot 3\text{H}_2\text{O}$ to $\text{Al}_2\text{SiO}_5 \cdot 2\text{H}_2\text{O}$ [AM 52:690(1967)]: $\text{SiO}_2/\text{R}_2\text{O}_3 \approx$ to 2.0 but frequently near 1:1. Analysis (wt %): SiO_2 , 19.71–33.22 (34.80–41.29, Japan); Al_2O_3 , 28.24–50.5; Fe_2O_3 , generally 0.2–1.0 but to 5–6; MgO , 0–0.18; CaO , 0–2.86; P_2O_5 , 0–10.57 (Indiana); SO_3 , 0–0.44; H_2O^- , 19.26–22.52; H_2O^+ , 9.80–25.0. CEC 69–74 meq per 100 g, also 100 meq per 100 g and varies according to cation. PSSSA 23:210(1959). **Optics:** Isotropic; $N = 1.47\text{--}1.52$; RI increases with Fe_2O_3 . **Occurrence:** Principally a weathering product of volcanic ash; also a hydrothermal alteration product of feldspars. Allophane may be a precursor to halloysite, but halloysite has been observed to alter from allophane. CCM 9:315(1962). Citric and humic acids can inhibit the formation of allophane. PICC 221(1985). Frequently found with admixed halloysite, imogolite, limonite, opal, gibbsite, cristobalite, occasionally chrysocolla or evansite, but nearly pure material can occur in sulfide veins or as a coating. Found in sedimentary (sediments, laterites, weathered basalt, marl, chalk, limestone, coal beds, etc.) and hydrothermal (sulfide veins, replacement zones, etc.) environments. Various abundant or insignificant in soils. **Localities:** Selected localities include: Richmond, MA; Bristol, CT; Morgantown, Berks Co.; Friedensville and Allentown, Lehigh Co.; Rohrs Cave, Lancaster Co., Cornwall, Lebanon Co., PA; Polk Co., TN; Lawrence Co., IN; Alabama Street mine and elsewhere, Saline Co., AR; Kelly mine, Socorro Co., NM; Bisbee, and the Maid of Sunshine mine, Gleeson, Cochise Co., AZ; Cerro Gordo, Inyo Co., CA; Trail Bridge and Crescent Lake, OR; Maui Is., HI; Derbyshire; Wheal Hamblyn, Devon; New Charleton, Kent; Hawkswood mine, North Hill, Cornwall, England; Chessy copper mine, Lyons, Rhone, France; Rosas mine, Sulsis, Sardinia; Calabona mine, Alghero; Cerro del Tasca, Mt. Amiata, Italy; Vise, Belgium; Grafenthal, near Saalfeld, Thuringia; Schneeberg, and Schwarzenberg, Saxony; Dehrn; in marl at Grafenthal, Thuringia, Germany; Jachymov and Chotina, Bohemia; Petrov, Moravia, Czech Republic; Boleslaw mine, Olkusz, Poland; Vyshkovo region, Transcarpathia, Ukraine; Central Aldan and Podolsk district; Cis-Baikal, Yakutia, Russia; Mbobo Mkulu Cave, Transvaal, South Africa; Alotenango, Guatemala; Guoshan deposit, Fujian Prov., China; northwestern Taiwan; Shishigahana, Mt. Chokai; Fukazawa and Iijima, Nagano Pref.; Kakino pumice, Choyo, and Imogo soil, Hitoyoshi, Kumamoto Pref.; Kanuma and Hangadai, Tochigi Pref.; Oze, Gunma Pref.; Bihoro, Hokkaido Pref.; Kitikami, Iwate

Pref.; Kurayoshi, Tottori Pref.; Ando soil, Okamoto, Japan; Bandung, Java; Sulawesi, Celebes, Indonesia; Aoba, Vanuatu; Mt. Schank, South Australia, Australia; Bealey Spur, Silica Springs, and elsewhere, New Zealand. *VK, EF AM 59:1094(1974)*, *CMB 12:289(1977)*.

71.1.5.2 Hisingerite $(\text{Fe,Mn})\text{SiO}_3, \text{Fe}_2^{3+}\text{Si}_2\text{O}_7 \cdot 2\text{H}_2\text{O}$

Named in 1828 by Berzelius for the eminent chemist Wilhelm Hisinger (1766–1852). Allophane group. Synonyms: canbyite, scotiolite, sturtite. Amorphous or *MON* $a = 5.40$, $b = 9.0\text{--}9.30$, $c = 14.99$, $\beta = 98.32^\circ$, $Z = 4$, $D = 3.23$. *26-1140(nat)*: 4.23_{10} 2.71_8 2.46_{10} 2.25_8 2.20_8 1.72_{10} 1.57_8 1.55_8 . Hisingerite is generally an amorphous substance which frequently yields a small set of wide or diffuse X-ray diffraction peaks. TEM studies [*CCM 35:29(1987)*] reveal that hisingerite consists of hollow spherical particles, generally 100–200 μm but up to 1000 μm in diameter. As sphere size increases, so does smectite content. *NJBM: 321(1982)*. The weak X-ray diffraction peaks observed have been variously attributed to those of a smectite [*CUSSGM 19:1(1974)*], mica, or generalized phyllosilicate, but the longest basal spacings of smectite, micas, and so on, have been observed only rarely (Romania). Does not expand with ethylene glycol. Mossbauer and other more recent studies indicate that hisingerite does not have a layer structure. *CM 18:21(1983)*. IR, DTA, and TGA did not suggest the presence of hydroxyl. *CCM 32:272(1984)*. Hisingerite can be a mixture of amorphous and crystalline materials. *AM 9:1(1924)*. Hisingerite can recrystallize to a mixture of ferrian saponite or nontronite + hematite when heated to 180° . **Habit**: Commonly massive and compact. May be minutely spherical. **Physical properties**: Black to brownish black, amber-brown in thinnest slivers and a streak lighter than the massive material; rarely dark red or dark green and photosensitive; resinous to vitreous luster, rarely greasy. Conchoidal fracture but can have a platy parting. [Trace cleavage observed in canbyite (Brandywine).] $H = 3\text{--}3\frac{1}{2}$, $G = 2.3\text{--}3.0$. Decomposed by HCl. Infusible. Can be confused with ferrihydrite. Summary of IR, EPR, Mossbauer data: *MIN 4(2):620(1992)*. **Optics**: Isometric; $N = 1.44\text{--}1.73$; biaxial; $N_x = 1.562$ (maximum range 1.552–1.595), $N_y = 1.580$, $N_z = 1.582$; $2V(-)$ very small [also $N_x = 1.715$, $N_z = 1.730$, *PASP 44:279(1944)*]; birefringence = 0.020 (0.015); $r > v$, parallel extinction; $B \times O$ perpendicular to cleavage; orange to golden brown, generally nonpleochroic. **Chemistry**: Hisingerite is generally regarded to have $\text{SiO}_2/\text{Fe}_2\text{O}_3 = 2:1$ with minor substitutions [*CMB 2:294(1955)*], while attempts have been made at rationalizing the alkalis into exchangeable positions [*CCM 32:272(1984)*], frequently with the calculating of a smectite-like formula. Chemical analyses are variable [*DS 36:97(1981)*], but given some high values, such as MgO and/or Al_2O_3 , suggest that some materials, perhaps unrecognized as new to the group were included in the survey. Inability to distinguish X-ray amorphous mixtures (opal, etc.) and minor crystalline components could contribute to the uncertainty of some extreme analyses (wt %): SiO_2 , most commonly 40.35–49.90 ranging to 27.99–56.91; Fe_2O_3 , commonly 14.34–29.00, ranging to 4.80–

40.70; Al_2O_3 , ranging 0–22.65; TiO_2 , 0–1.88; FeO , 0–6.75 (24.64); MgO , 0–25.95; MnO , 0–3.72; CaO , 0–3.80; Na_2O , 0–2.90; K_2O , 0–1.44; H_2O^+ , 3.46–12.10; H_2O^- , 5.53–17.92. $\text{CEC}_{\text{meas}} = 20\text{--}74.5$ meq per 100 g. **Occurrence:** Originally occurring in large mammillary masses (to many centimeters) and frequently observed in obvious veins, coatings, or crusts. Increasingly observed as microscopic alterations of iron-bearing rocks, especially igneous rocks and ash or glass. Sometimes observed as a thin amber film or as amber globules in amygdules. Frequently veining fayalite, enstatite, and/or amphiboles, sometimes siderite or wollastonite; also alters from pyrrhotite and possibly from chalcopyrite. A component of chlorophaeite and probably in some iddingsite. Observed in recent sediments. Probably formed by meteoric water, also from hot springs. Alters to nontronite; large hisingerite spheres show nontronite alteration rims. *NJBM: 321(1982)*. Also occurs as pseudomorphs after hedenbergite. **Localities:** Found in a wide variety of occurrences frequently inconspicuous in quantity and due to its nearly amorphous character difficult to recognize. Selected occurrences include: Tilley Foster mine, Brewster, Putnam Co., NY; Gap nickel mine, Lancaster Co., PA; Brandywine quarry, Wilmington, DE; Alexander Co., NC; Montreal mine, Iron Co., WI; Hibbing, Beaver Bay, and Silver Bay, MN; Castle Dome mine, Gila Co., and on the Mildren and Steppe claims, Cababi district, Pima Co., AZ; Bellvue, Blaine Co., ID; Cardinal mine, Stevens Co., WA; Tetrault mine, Montauban-les-Mines and Hull, QUE; Wilcox mine, Parry Sound, ONT; Nicholson mine, Goldfields, SAS, Canada; Lostwithiel and Wheal Jane, Kea, Cornwall, England; Solberg mine, Elvestorp; Brunjo(1), Västmanland; Sjöström mine, Hofors, Gästrikland; Tunaberg, Langban, and Vestra Silfberg, Värmland; *Riddarhyttan, Västmanland, Sweden*; Helsingfors, and Orijärvi; Degerö mine, Helsinki, Finland; Limburg Sasbach, Kaiserstuhl, Germany; Gallego and Aragon rivers, Spain; Fagul Cetatii, Balan, and Masca, Iara Valley, Apuseni Mts., Romania; Atlantis II Deep, Red Sea, Israel; Mt. Karnasurt, Lovozero massif, and Mt. Rasvumchorr, Khibiny massif, Kola Penin.; Ilmen Mts., Urals; Terny Astrobleme, Krivoy Rog, Russia; Zaval'ye, Bug region, Ukraine; Dalnegorsk, Primorsky Krai; Talnakh, Kazakhstan; Gran Canaria, Canary Is.; Llallagua, Bolivia; Suzuyama mine, Kagoshima Pref.; Kawayama mine, Yamaguchi Pref.; Sano mine, Wakayama Pref., Japan; Geelong, VIC; Cobar and Broken Hill, NSW, Australia; Aoba, Vanuatu. Remotely sensed on Mars. *vk, EF SUBBSC 19:9(1974), MIN 4(2):620(1992)*.

71.1.5.3 Imogolite $\text{Al}_2\text{SiO}_3(\text{OH})_4$

Named in 1962 by Yoshinaga and Aomine for the locality. Allophane group. Space group unknown. *38-447(nat)*: 21.0_3 11.5_{10} 7.9_8 5.6_2 4.4_1 3.7_{15} 3.3_6 2.25_3 ; *MM 51:327(1987)*: 16_{10} 7.9_7 5.6_{35} 4.4_1 4.1_1 3.7_2 3.3_{65} 2.25_{25} . Imogolite gives relatively few X-ray diffraction peaks, has a tubular structure (17–21 Å outer diameter and 7–10 Å inner diameter) and can appear as partial webs composed of filaments, usually in bundles, in TEM. Imogolite is sometimes characterized by a sharp 19.7 Å peak and broad peaks at 13.3, 7.6, 5.5–5.7, 3.7, 3.3–3.45,

2.25, 2.1, and 1.40 Å. The main peak might be related to a close packing of tubes and the broad peaks relate to a scattering of single tubes. *DS 27:547(1979)*. MAS-NMR studies suggest that imogolite has an octahedral sheet similar to that of 2:1 phyllosilicates but different from that of kaolinite or gibbsite. *CCM 42:276(1994)*. Dry grinding can affect imogolite crystallinity. *CM 16:139(1981)*. Imogolite has been synthesized [*DS 27:547(1979)*] and might form naturally from allophane. The IR of imogolite is similar to allophane [*CCM 28:285(1980)*] and might represent the crystalline equivalent of allophane. *AM 61:379(1976)*. Earthy, composed of microscopic threadlike grains and bundles of fine tubes, each about 20 Å in diameter. Light brownish yellow, also tan to white, blue, green, brown. Conchoidal fracture, brittle. $H = 2-3$. $G = 2.7$. Isometric; $N = 1.47-1.51$ and similar to allophane. RI increases with Fe_2O_3 . Principally in soils derived from volcanic ash. Can be found with allophane, halloysite, vermiculite, goethite, gibbsite, quartz, and detrital minerals. Observed in cracks in weathered plagioclase. Citric and humic acids can inhibit the formation of imogolite. *PICC 221(1985)*. Selected localities include: Adirondack Mts., NY; Hawaii Is., HI; Plastic Lake, ONT, Canada; Roudado basalt, Aurillac, Cantal, France; Luochoan loess, Shensi Prov.; Guoshan deposit, Fujian Prov., China; Kitakami, Iwate Pref.; Kanto loam, Ibaroki Pref.; (Fukuwa) Kanumatsuchi ash bed, Kanuma and Hangadai, Tochigi Pref.; Kurayoshi, Tottori Pref.; Mitsutsuchi ash bed, Iijima, Nagano Pref.; Uemura, Choyo, and *Imogo soil, Hitoyoshi, Kumamoto Pref., Japan*; New Hebrides; Papua New Guinea; Tirau, Rangitaua, and Wharepaina, New Zealand. *VK, EF SSPN 8:6(1962)*; *AM 54:50(1969)*; *CM 8:87(1969)*, *12:289(1977)*; *PCM 12:342(1985)*.

71.1.5.4 Neotocite $Mn^{3+}SiO_3 \cdot H_2O$

Named in 1848 by Nordenskiöld from the Greek for *new origin*, in allusion to its paragenetic position. Allophane group. Synonyms: stratopeite, penwithite. Isostructural with hisingerite. Amorphous or *MON* Space group unknown. $b = 9.0-9.30$. *14-172(nat)*: 4.36_{10} 3.59_{10} 2.59_{-1} 1.54_{10} . Neotocite is generally an amorphous substance but has been observed to yield at least five X-ray diffraction reflections (6.4, 4.36-4.4, 3.5-3.59, 2.59-2.6, 1.54 Å). Neotocite forms 70- to 100-Å microspheroids as for hisingerite and allophane. *CM 18:21(1983)*. When heated to 1000° for 5 minutes, usually yields braunite and minor jacobsite-magnetite and rarely hausmannite; or pyroxmangite (Pajsberg). Brown, brownish black, rarely dark red, amber brown in thinnest slivers, with a brown to dark brown streak. Generally massive and compact; resinous to greasy luster, rarely vitreous to adamantine. Can be photosensitive, changing from red to brown shades on exposure. Conchoidal fracture, brittle. Rarely shows a platy parting (Klapperud). $H = 4$. $G = 2.04-2.8$. Decomposed by HCl. Sensitive to relative humidity. DTA, IRA data: *MM 42:279, M26(1978)*, *MIN 4(2):633(1992)*. Isometric; $N = 1.475-1.654$, usually pale yellow to reddish brown; sometimes birefringent. 2V to 20°. The composition of neotocite is variable [*MM 42:279, M26(1978)*], especially with respect

to iron, and a series might extend to hisingerite. Analysis (wt %): SiO₂, 30.0–43.8; Fe₂O₃, 0.01–18.7; Al₂O₃, 0.10–2.9; Mn₂O₃, 0–33.2; FeO, usually 0, also 9.6 (Gastrikland); MnO, 10.4–37.2; TiO₂, 0.01; MgO, 0.5–9.6; CaO, 0.1–2.3; Na₂O, 0.02–0.3; K₂O, 0.01–0.3; CO₂, 2.2–7.4; H₂O⁺, 8.2–11.8; H₂O⁻, 7.04 (WI). See also *MIN 4(2):633(1992)*. Associated with rhodonite, rhodochrosite, quartz, manganese phosphates, spessartine, bementite, tephroite, and others. Can have admixed birnessite. Frequently observed in obvious veins, coatings, or crusts. Observed as microscopic alterations of manganese-bearing rocks or minerals, also manganese-bearing ophiolite. Frequently veining weathered manganese-bearing pyroxenes, especially rhodonite, and spessartine. Found lining fractures in granite pegmatite and in association with manganese-bearing minerals or rocks, but due to its nearly amorphous character, difficult to recognize. Selected occurrences include: Plainfield, MA; Bald Knob, Alleghany Co.; Foote mine, Kings Mt., Cleveland Co., NC; Montreal mine, Gogebic Range, Iron Co., WI; Batesville, Independence Co., AR; Bromide district, OK; Aravaipa district, Graham Co. and Ajo, AZ; in several locations in CA, including Johe Ranch mine, San Luis Obispo Co., Lake Elsinore area, Riverside Co., and in the Charles Mt. deposit, Humboldt Co.; Anacortes and elsewhere, Olympic Penin., WA; El Fino mine, Pinar del Rio Prov.; Polaris mine, Candelaria district and elsewhere, Bueycito, Oriente Prov., Cuba; Bambolita mine, Moctezuma, SON, Mexico; Llanfaerhys, Rhiw, Wales; Wheal Owles, Penwith, and Geevor mine, St. Just, Cornwall, England; Brevik, West Gothland, Norway; Klapperud, Dalsland; Delecarlia; Gillinge mine, Svärta, Södermanland; at Långban, Jakobsberg, and the Harstig mine, Pajsberg, and Filipstad, Värmland; *Erik-Ers mine, Torsåker, Gästrikland, Sweden*; also in the Brunsjö mine, near Grythyttan, Örebro; Wittingi, Stor-kyro, Finland; Herborn, Dillenberg, Germany; Chiavari, Liguria, and Val Graveglia, Genoa, Italy; Litosice, Iron Mts., Czech Republic; Yakobeni, Romania; Malo-Sedelnikovsk, Middle Ural Mts., Russia; Tien Shan, Kirghizstan; Lafaiete district, MG, Brazil; Broken Hill, NSW, Australia; Shidara, Aichi Pref.; Kawazu mine, Shizuoka Pref., Noda-Tamagawa mine, Iwate Pref., Japan. *VK, EF AM 46:1412(1961), MIN 4(2):633(1992)*.

PYROPHYLLITE TALC GROUP

The pyrophyllite talc group minerals are phyllosilicates corresponding to the general formula

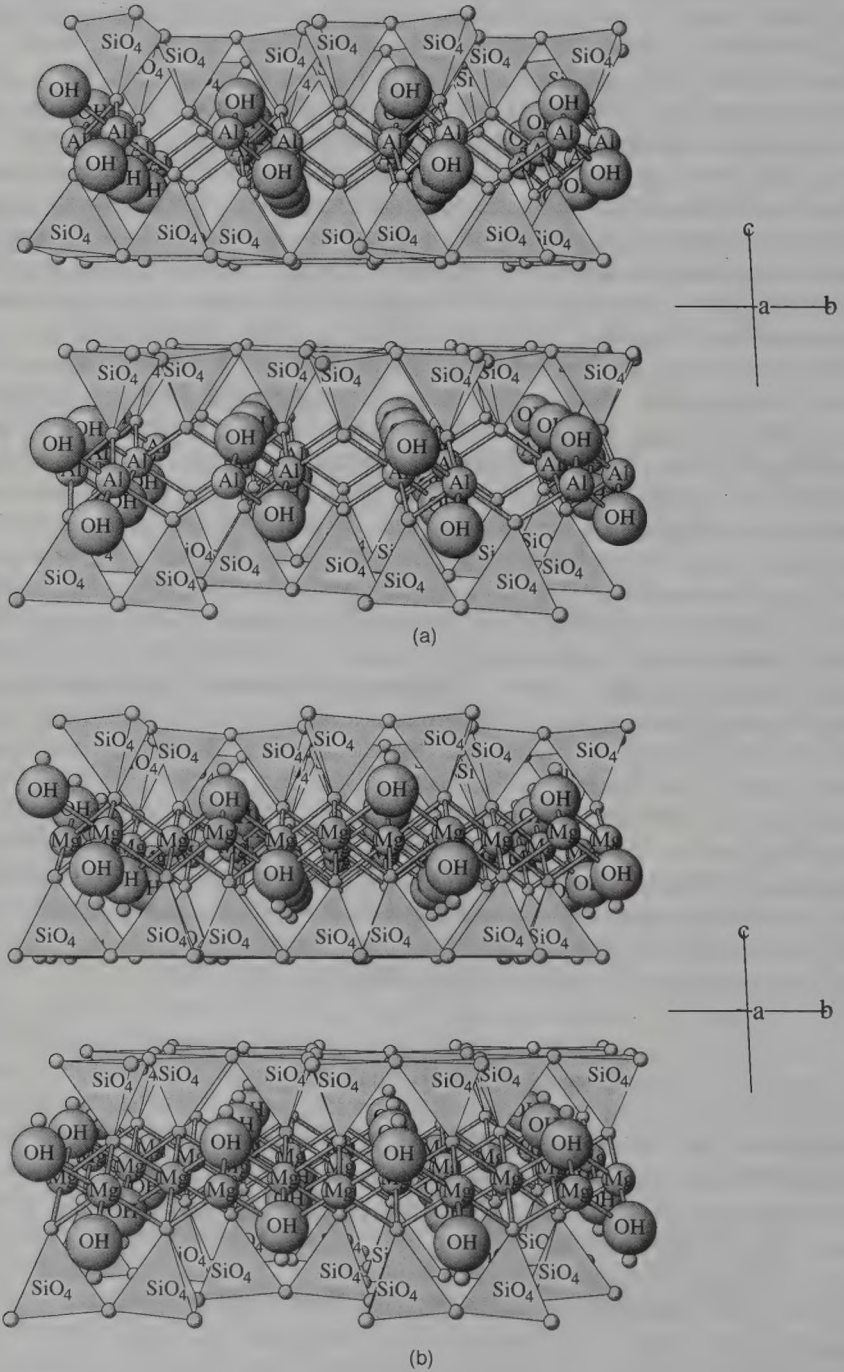

or

where

The structure of pyrophyllite (a) and talc (b) in perspective view along *a*, illustrating the difference between dioctahedral and trioctahedral phyllosilicates.

The structure is based on t-o-t (tetrahedral-octahedral-tetrahedral) layers (also called 2:1 layers). These layers are basically of the same type as in the mica group structures, several of the clay minerals, and in the chlorites.

The t-o-t layer is itself made up of two infinite sheets of six-membered rings of SiO_4 tetrahedra. The apical oxygens of two such layers, oppositely facing, together with (OH), make up the coordination sphere of the octahedral layer. The octahedral layer has one M1 site and two M2 sites per formula unit; layers may have trivalent (R^{3+}) cations in M2 and M1 vacant (dioctahedral), or all sites occupied by divalent (R^{3+}) cations (trioctahedral). These 2:1 composite layers form the basis for the species of this group, the mica group, several of the clay minerals, and are present in the chlorite group.

The t-o-t layers are ideally electrostatically neutral, and thus the bonding between successive t-o-t layers is due essentially to van der Waals forces. This is reflected in the low hardness of the species in the group. The stacking of successive t-o-t layers is shifted by approximately $0.3a$ along one of the pseudo-hexagonal axes, so that hexagonal rings in successive layers are not aligned, the shift being dictated by Si-Si repulsion. The structural details of the group show considerable variation, due in part to the several possible polytypes and the difficulty of obtaining undeformed crystals of these materials. *MSARM 19:225 (1988)*.

TALC GROUP

Mineral	Formula	Space Group	Space						
			a	b	c	α	β	γ	
Pyrophyllite-1A	$\text{Al}_2\text{Si}_4\text{O}_{10}(\text{OH})_2$	C1	5.160	8.966	9.347	91.18	100.46	89.64	71.2.1.1

Minnesotaita*	$(\text{Fe}^{2+},\text{Mg})_3\text{Si}_4\text{O}_{10}(\text{OH})_2$	P1	5.623	9.419	9.624	85.2	95.6	90.0	71.2.1.5

*Minnesotaita is included here but may be placed more appropriately with modulated layer structures.

71.2.1.1 Pyrophyllite-1A, 2M $\text{Al}_2\text{Si}_4\text{O}_{10}(\text{OH})_2$

The name was first used in 1829 by Hermann and derives from the Greek for *fire* and *leaf*, in allusion to its tendency to exfoliate on heating. Talc group. Some agalmatolite, from Greek, *agalma*, image, and *lithos*, stone, is compact, very fine-grained pyrophyllite, but other examples may be talc or muscovite of similar texture. *1A-polytype*: TRIC C1. $a = 5.160$, $b = 8.966$, $c = 9.347$, $\alpha = 91.18^\circ$, $\beta = 100.46^\circ$, $\gamma = 89.64^\circ$, $Z = 2$, $D = 2.814$. *25-22*: 9.20₉ 4.60₃ 4.42₁₀ 4.23₈ 4.06₅ 3.07₈ 2.53₄ 2.42₈. *2M-polytype*: MON C2/c. $a = 5.138$, $b = 8.910$, $c = 18.60$, $\beta = 100.02^\circ$, $Z = 4$, $D = 2.85$. *PD*: 9.21₁₀ 4.61₄ 4.42₆ 4.18₉ 3.07₁₀ 2.53₂ 2.42₄ 1.647₂. Structure: *AM 66:350(1981)*. The six-membered rings of the tetrahedral layers have a distinctly trigonal conformation. The octahedral sites (M2) occupied by Al are distorted and considerably

smaller than the more symmetrical and larger M1 site, which is vacant. Two polytypes are commonly encountered in nature; type 1A is triclinic with a single 2:1 layer per unit cell, and type 2M is monoclinic with two 2:1 layers per unit cell. Twenty-two hypothetical polytypes have been proposed for the idealized pyrophyllite structure, but only 14 of these would yield distinguishable X-ray diffraction patterns. Stacking disorder and mixed phases often make for difficulty in distinguishing the two polytypes described here.

Habit: Most commonly as granular masses of lamellae or laths flattened on {001}, but often so fine-grained as to be compact, textureless, and commonly incorporating other phases. Less commonly in very fine to coarse laths in radiating aggregates.

Physical properties: Colorless, white, cream, light blue, gray, brownish green, but also nonuniform and colored by other phases in compact varieties; luster pearly on cleavage to dull (massive); transparent to translucent. Cleavage {001}, perfect, yielding flexible but inelastic scales. $H = 1-2$. $G = 2.7-2.9$.

Optics: Biaxial (-); $2V = 53-62^\circ$; $N_x = 1.552-1.556$, $N_y = 1.586-1.589$, $N_z = 1.596-1.601$; pleochroism in colored examples is weak with $X < Y = Z$. Infusible; only slightly attacked by acids; closely resembles talc but distinguishable therefrom by spot test for Al, by abrasion pH (6 for pyrophyllite, 9 for talc), and by diffraction peak for (060) at ≈ 1.49 Å. Thermal decomposition endotherms occur at $\approx 500^\circ$ and 675° .

Chemistry: Published analyses for reasonably uncontaminated examples are very close to the ideal composition. Only traces of Fe^{2+} and Fe^{3+} are found in octahedral sites, and the existence of a series with ferripyrophyllite is doubtful. Large cations are present only in trace amounts. Some analyses suggest that some Al substitution for Si may take place, but this has not been substantiated by structure studies, and these may be due to impure material.

Occurrence: Forms by low-grade metamorphism of aluminum-rich sediments such as aluminous pelite, bauxites, and aluminous quartzites, and rocks enriched in aluminum by base metal leaching during hydrothermal alteration. It is rare in sedimentary rocks. In prograde metamorphism the sequence is usually kaolinite-pyrophyllite-kyanite, and it normally is unstable beyond the greenschist facies. Also forms in retrograde metamorphism at the expense of other Al-rich phases, such as diaspore and kyanite. Pyrophyllite is stable at temperatures below 130° and pressures of < 10 kbar but may occasionally form at temperatures of $250-300^\circ$.

Localities: Pyrophyllite may be of more widespread occurrence than is realized, it being easily overlooked because of its resemblance to talc and fine-grained muscovite. Some noteworthy occurrences are: in seams in coal at Mahoney City, Schuylkill Co., PA; at Crowder's Mt., Gaston Co., at Cottonstone Mt., Montgomery Co., and compact (agalmatolite) at Deep River, Guilford Co., NC; with lazulite and kyanite in Chesterfield Co., SC; 2M in masses of coarse, radial clusters(!) with kyanite and rutile at Graves Mt., Lincoln Co., GA; at Bisbee, Cochise Co., and the Dome Rock Mts., near Quartzsite, AZ; and as yellow, radiating needles at Tres Cerritos, Mariposa Co., at Blue Bird mine, Imperial Co., and Champion mine, Mono Co., CA. Found at Horrsjöberg, Varmland, and the Westna mine, Kristianstad, Sweden; at Liège, Belgium; in the Visp-St. Niklaus-Zermatt area, Valais, Switzer-

land; between Pyschminsk and Beresovsk, Yekaterinburg district, Ural Mts., Russia. Agalmatolite is found at numerous localities in China, as at Shaoshan, Minhou Co., Fujian Prov., and Quingtian, Zhejiang Prov. Light blue *2M* found at Hanami mine, Nagama Pref., Japan; *1A* near Coromandel, North Island, New Zealand; an impure, compact variety called "wonderstone" is found at Gestoptefontein, Transvaal, South Africa; found as 5- to 12-cm-long laths and similar-size radial sprays(!) of *1A* polytype at Ibitiara, BA, Brazil. Uses: Used as a filler in paints, rubber, and so on, and in cosmetics and other dusting powders in much the manner of talc, and some materials marketed as "talc" may in fact be pyrophyllite. It also finds application as a refractory material and as a thermal and electrical insulator. Compact varieties (agalmatolite) are used as ornamental carving materials, particularly in China. AR *DHZI* 3:115(1962); *MR* 16:451(1985), 20:465(1989).

71.2.1.2 Ferripyrophyllite $\text{Fe}_2^{3+}\text{Si}_4\text{O}_{10}(\text{OH})_2$

Named in 1979 by Chukhrov et al. for the composition and relationship to pyrophyllite. Talc group. Inadequate data. MON *C2/m*. $a = 5.26$, $b = 9.10$, $c = 19.1$, $\beta = 95.5^\circ$, $Z = 4$, $D = 3.05$. 45-569: 9.6₈ 4.54₁₀ 3.17₇ 2.62₄ 2.47₄ 1.725₃ 1.665₃ 1.518₈. The Fe^{3+} analog of pyrophyllite. Yellow-brown, transparent to translucent. Cleavage {001}, probably perfect. $H = 1\frac{1}{2}$ -2. $G = 2.99$. Biaxial (-); $2V = 76^\circ$; $N_x = 1.660$, $N_y = 1.676$, $N_z = 1.686$. German material contains 1.96 Fe^{3+} (octahedral), 0.11 Mg, 0.13 Al, 0.07 Fe^{3+} (tetrahedral), and 0.05 Ca per formula unit. Found in low-temperature hydrothermal deposits at *Strattenschacht, Germany*, and *Mt. Tologay, central Kazakhstan*. AR *CE* 38:324(1979), *MA* 31:355(1980), *MSARM* 19:226(1988).

71.2.1.3 Talc-1A $\text{Mg}_3\text{Si}_4\text{O}_{10}(\text{OH})_2$

The name has been in use since antiquity and is derived from the Arabic. The name *kerolite*, applied to a hydrated and layer-disordered variety, is from the Greek *keros*, wax, and *lithos*, stone, in allusion to its luster. Talc group. *Soapstone* and *steatite* are synonymous and used for massive material, often with admixed serpentine minerals and calcite, the former name in reference to the "soapy" feel, the latter from the Greek through the Latin *steatitis*, precious stone. TRIC $C\bar{1}$. $a = 5.290$, $b = 9.173$, $c = 9.460$, $\alpha = 90.46^\circ$, $\beta = 98.68^\circ$, $\gamma = 90.09^\circ$, $Z = 2$, $D = 2.798$. 24-1493: 9.31₁₀ 4.67₂ 4.55₆ 3.12₉ 2.59₂ 2.48₃ 2.23₁ 1.524₃. Structure: *ZK* 156:177(1981). Alternate space groups have been reported, and a *2M* polytype has been reported but not substantiated as occurring in nature. The six-membered rings of the tetrahedral layer have nearly hexagonal symmetry. The M1 and M2 sites are occupied by Mg in nearly ideal octahedral coordination, the average Mg-O bond length in M1 being nearly identical to that in M2. A total of 10 hypothetical polytypes have been proposed, but only seven would be distinguishable using powder diffraction. **Habit:** Rarely as pseudohexagonal tablets {001} or as free-standing, leafy crystals of irregular outline several square centimeters in area; more commonly in foliated or fibrous masses or stellate aggregates of laths; massive,

compact, fine-grained (agalmatolite in part). In extensive masses with serpentine, calcite, and so on (e.g., soapstone, steatite). Often pseudomorphous after forsterite, enstatite, and other Mg-rich silicates. **Physical properties:** Colorless, white, pale to dark green, yellowish to brown; pearly luster, waxy for massive material (kerolite); transparent to translucent. Cleavage {001}, perfect, yielding flexible but inelastic scales; uneven to subconchoidal (massive) fracture. $H = 1$ resulting in "soapy" feel. $G = 2.58\text{--}2.83$. **Optics:** Biaxial (-); $2V = 0\text{--}30^\circ$; $N_x = 1.539\text{--}1.550$, $N_y = 1.584\text{--}1.594$, $N_z = 1.588\text{--}1.602$; X approximately perpendicular to (001), $Y = b$, as expected for a one-layer polytype, but also reported as $Z = b$, possibly as a result of difficulty in identifying b ; $r > v$, weak; pleochroism evident in darker examples only, with $X < Y = Z$; refractive indices increase with iron content. Infusible and inert to acids. Often confused with pyrophyllite, but distinguishable from it by tests described under that species. **Chemistry:** Most talc is very close to the ideal composition, the only significant substitutions being Fe^{2+} and Fe^{3+} for Mg, and concomitant Al for Si to maintain charge balance. FeO may be present to ≈ 15 wt %, but reported higher values suggest a series with minnesotaite, formerly regarded as the ferrous analog of talc. Fluorine has been reported to ≈ 0.3 wt %. Dehydration of normal talc takes place as a single endothermic event at $\approx 900^\circ$. **Occurrence:** Most commonly found in Mg-rich rocks such as ultramafics and siliceous dolomites, although in the presence of high Al or K content, chlorite and phlogopite may be more likely, and with high Ca as in dolomite, the formation of tremolite may precede the formation of talc. Ferroan talc is not uncommon in meta-ultrabasics, but is less so in talcs derived from siliceous dolomite. Talc is unusual in sedimentary rocks, but Ni- and Fe^{3+} -rich varieties are found in laterites developed on serpentized ultramafics. Talc is stable at higher temperatures than is pyrophyllite. **Localities:** Talc is of very widespread occurrence, and only a few noteworthy localities are listed. Found at numerous localities in New England, as at Athens (steatite), and Bridgewater(1), Windsor Co., VT; at Chester, Hampton Co., MA(1); at Smithfield, RI. Fine fibrous material found at Edwards, St. Lawrence Co., and at Amity(1), Orange Co., and steatite on Staten Island, NY; formerly extensively quarried (including steatite) at Chestnut Hill, Philadelphia, PA; at Coop-town, MD; steatite quarried in Cherokee Co., NC; and at Bisbee, Cochise Co., AZ. Found at Mt. St.-Hilaire and in Brome Co., PQ, and Hastings Co., ON, Canada. Also found at Malangen, Norway; with serpentine at Lizard Head, Cornwall, England; at St. Gothard, Tecino, and Fiesch, Valais, Switzerland; at Parma, in the Apennines, Italy; steatite at Gröpfersgrün, Bavaria, Germany; at Mt. Grainer, Zillertal, Tyrol, Austria; and at Shabrov, Ural Mts., Russia. Steatite is abundant in Hyderabad, India, and at numerous localities in China; fine-grained, massive, translucent talc, sometimes partially replacing tremolite and rarely with embedded pale green beryl, is mined at Chungju, Chung Cheong N. Prov., South Korea; at Mt. Fittom, SA, Australia. Found in the Barberton district, Transvaal, and the Hotazel, Mamatwon, and Smartt mines, Cape Prov., South Africa. In excellent, free-standing, colorless, leafy crystals(1) of several square centimeters area, and as small, green,

pseudo-hexagonal crystals(l) in magnesite at several mines in the Brumado district, BA, Brazil. Uses: Steatite is used for its thermal and electrical insulating properties; as tabletop and tub material, but now largely replaced by synthetic products. Talc is extensively used as a filler in paints and rubber, in soaps and cosmetics and as a lubricating dusting powder. Fine-grained, compact material (agalmatolite in part) is used as an ornamental stone for carvings, particularly in China, and translucent, light green talc carvings are common in the crafts market, often lacquered to enhance hardness and improve luster. AR *DHZI* 3:121(1962), *AM* 53:751(1968), *MR* 9:196(1978).

71.2.1.4 Willemseite $(\text{Ni},\text{Mg})_3\text{Si}_4\text{O}_{10}(\text{OH})_2$

Named in 1970 by De Waal for Johannes Willemse (b.1909), geologist, University of Pretoria, South Africa. Talc group. The name *pimelite*, from the Greek *pimele*, fatness, in allusion to the greasy luster and feel, has been applied to Ni-rich talc or the Ni equivalent of kerolite. MON *C2/c* or *Cc*. $a = 5.316$, $b = 9.149$, $c = 18.994$, $\beta = 99.96^\circ$, $Z = 4$, $D = 3.348$. *22-711*: 9.4_{10} 4.57_2 3.12_3 2.50_2 2.25_1 1.524_1 . Light green, greasy to waxy luster, translucent. Cleavage {001}, perfect. $H = 2$. $G = 3.31$. Biaxial (-); $2V = 27^\circ$; $N_x = 1.600$, $N_y = 1.652$, $N_z = 1.655$. Pleochroic, X, yellow-green; Y,Z, blue-green. Mg is present in substitution for Ni, and excess water may be present (pimelite). When Mg is dominant, it is regarded as nickelian talc. Found as massive, fine-grained material at the *Scotia talc mine, Bon Accord, Barberton district, Transvaal, South Africa*. Pimelite is reported from Silesia, Poland. AR *AM* 55:31(1970).

71.2.1.5 Minnesotaite $(\text{Fe}^{2+},\text{Mg})_3\text{Si}_4\text{O}_{10}(\text{OH})_2$

Named in 1944 by Gruner for the state of Minnesota. Talc group. TRIC $P\bar{1}$. $a = 5.623$, $b = 9.419$, $c = 9.624$, $\alpha = 85.2^\circ$, $\beta = 95.6^\circ$, $\gamma = 90.0^\circ$, $Z = 2$, $D = 2.99$. *41-594*: 9.54_{10} 4.78_2 3.18_5 2.76_3 2.66_4 2.54_3 2.53_5 2.21_2 , the lines with spacing 2.54 and 2.53 commonly unresolved. Structure: *CM* *24:479(1986)*. The structure is reportedly a modulated layer of distinctive configuration. Alternate unit cells have been reported: (1) *P* with $a = 28 \text{ \AA}$ ($\approx 5 \times 5.6$) for Mg-rich material, and (2) *C* with $a = 50.6 \text{ \AA}$ ($\approx 9 \times 5.6$). Greenish gray to olive-green, dull to greasy luster, translucent. Cleavage {001}, perfect. $H < 3$. $G = 3.01$. Biaxial; $2V$ small; $N_x = 1.580-1.592$, $N_z = 1.615-1.632$; pleochroic with $X > Z$, pale green to colorless. Magnesium commonly present and may predominate over Fe^{2+} ; if the structure is indeed different from that of talc, Mg-dominant minnesotaite would constitute a distinct species. An alternative formulation is $(\text{Fe},\text{Mg})_{27}\text{Si}_{36}\text{O}_{86}(\text{OH})_{26}$. Found in low-grade metamorphosed banded iron formation deposits in association with quartz, stilpnomelane, siderite, etc. Found in the *Cuyuna and Mesabi Ranges, St. Louis Co., MN*; in the *Sokoman iron formation, Labrador, NF*, and at the *Blue Bell mine, Riondel, BC, Canada*; at *Tynagh, Co. Galway, Ireland*, and in *Cornwall, England*. In the Pb-Zn deposits at *Sierra de Cartagena, Murcia,*

Spain; at Hagendorf, Bavaria, Germany; in the Mara Mamba iron formation, Hamersley basin, Weld Range, WA, Australia; and at the Mamatwan mine, Kalahari manganese field, Cape Prov., South Africa. *AR AM* 29:363(1994), *MM* 47:229(1983).

MICA GROUP

The mica minerals comprise some 30 species of phyllosilicates with the general formula

where

A = a large monovalent or divalent cation, Na^+ , K^+ , $(\text{NH}_4)^+$, Cs^+ , Ca^{2+} , Ba^{2+} , or a partial vacancy

R = an octahedrally coordinated cation, Li^+ , Mg^{2+} , Fe^{2+} , Mn^{2+} , Zn^{2+} , Al^{3+} , Fe^{3+} , Mn^{3+} , V^{3+}

T = a tetrahedrally coordinated cation (dominantly Si^{4+} , with Al^{3+} commonly present, and also B^{3+})

X = an anion, most commonly $(\text{OH})^-$, but also F^- or O^{2-} and rarely S^{2-}

The structure is based on t-o-t layers (also called 2:1 layers) which carry a net negative charge. Most commonly, the net negative charge is the result of substituting Al^{3+} for one-fourth of the tetrahedrally coordinated silicons, but may also be accomplished by positive charge deficiency in the octahedral R sites, or by the substitution of oxygen or sulfur for hydroxyl ion.

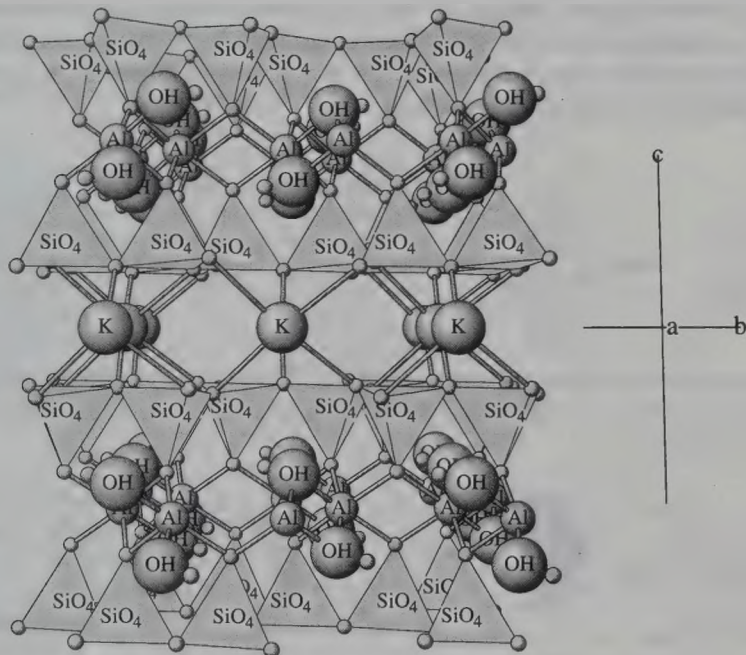

The t-o-t layers are of the same type found in the chlorite structures, and (except for the negative charge) in the pyrophyllite and talc structures. In the micas, the net negative charge is compensated by an interlayer of A cations. The octahedral R sites in the t-o-t layers may be either fully occupied, as in talc, to give the trioctahedral micas; or, they may be only two-thirds occupied, as in pyrophyllite, to give the dioctahedral mica series. Micas with R-site occupancy intermediate between 2 and 3 are rarely found: montdorite, whose species status is uncertain, would be a representative.

The t-o-t layers lie parallel to {001} in all the micas. The large interlayer A cations occupy 12-coordinated sites between the centers of six-membered rings of tetrahedra in adjacent t-o-t layers. The weak bonds of these cations and the strong intralayer bonding of the t-o-t layers account for the prominent perfect {001} cleavage of these species.

The octahedral t-o-t sheets contain two sites that are similar in size in the trioctahedral micas, but distinctly different in the dioctahedral species. In the latter, two sites (M2) are smaller and occupied by the trivalent cations, and one site (M1) is considerably larger and unoccupied.

The periodicity normal to the stacked sheets is approximately 10 Å or a multiple thereof. The stacking of t-o-t layers may occur in several ways, leading to a number of stacking sequences or polytypes. There is a certain

degree of composition dependence associated with the various stacking sequences so that they are not *sensu strictu* polytypes but, rather, intermediate between polytypes and polymorphs. There are six standard polytypes, only four of which occur commonly in nature, and several other sequences can be postulated. The stacking sequence may be described in terms of a shift of the layers by a shift of magnitude $\pm x$ accompanied by a rotation.

The structure of muscovite, a typical dioctahedral mica, viewed in perspective along a , and showing the t-o-t sequence parallel to $\{001\}$.

STANDARD POLYTYPES OF MICAS

Type	Shift*	$\approx a$	$\approx b$	$\approx c$	$\approx \beta$	Space Group
1M	0°	5.3	9.2	10	100	$C2/m$ or Cm
2O	180°	5.3	9.2	20	90	$Ccm2$
$2M_1$	$\pm 120^\circ$	5.3	9.2	20	95	$C2/c$
$2M_2$	$\pm 60^\circ$	9.2	5.3	20	98	$C2/c$
3T	$-120^\circ / +120^\circ$	5.3		30	90	$P3_122$ or $P3_222$
6H	$-60^\circ / +60^\circ$	5.3		60	90	$P6_122$ or $P6_522$

*Rotation angle between successive shifts.

Polytype $2M_1$ is dominant in muscovite and tends to be so in most aluminium-rich dioctahedral micas. Polytype $1M$ is also common in dioctahedral micas, particularly in those with considerable substitution of the octahedral aluminium. The $1M$ polytype is the most common in the trioctahedral micas. The micas are here divided into three subgroups: (1) the muscovite subgroup of dioctahedral micas, including the intermediate montdorite, and (2) the biotite subgroup of trioctahedral micas, and the brittle mica subgroup (3), which includes both dioctahedral and trioctahedral micas. In the brittle micas, the net negative charge of the t-o-t layer is high, and the interlayer A ions are usually alkaline earths. These micas tend to have a greater hardness and lesser flexibility than ordinary micas. Placement of a species in the brittle mica subgroup is sometimes uncertain.

Kinoshitalite	$(Ba,K)(Mg,Mn^{2+},Al)_3[Al_2Si_2O_{10}](OH)_2$	1M	71.2.2c.5

Morphology: Although characteristically tabular in habit, some common micas display short-to-long [001] prismatic crystals, the prism zone often poorly developed, tapering, or of variable diameter. Early morphological descriptions were based on an axial ratio $a/b/c \approx 0.58:1:3.33$ with $\beta \approx 90^\circ$ that corresponds roughly to the 3T polytype dimensions. The transformation matrix for old setting is 300/030/101 to the 1M cell, and 200/020/101 to the 2M₁ cell.

Notes:

1. Twinning according to the mica law is common, the twin axis being [310] and the composition plane {001}.
2. Optics: all the micas are optically negative, usually biaxial with small to medium 2V. The acute bisectrix (X) is approximately perpendicular to the {001} cleavage, with $Z = b$ in 2M₁ polytypes, and $Y = b$ in 1M polytypes. Extinction is parallel or nearly so relative to the cleavage trace, which is always the slow direction. *D6 611(1892)*, *DHZI 3:1(1962)*, *MSARM 13:1(1984)*.

71.2.2a.1 Muscovite-2M₁, 1M, 3T, 2M₂ KAl₂[AlSi₃O₁₀](OH,F)₂

The name muscovite was first used in 1850 by Dana without regard to polytype, and is derived from the term in common use at the time, *Muscovy glass*, from Muscovy Province, Russia. The 2M₂ polytype was first defined in 1973 by Zhoukilstov et al. Mica group, muscovite subgroup. Varietal names in common use are: *phengite*, from the Greek *phengites*, a term used by the ancients for transparent and translucent stones used as windows; *fuchsite* (chromian muscovite) is named in honor of Johann Nepomuk von Fuchs (1774–1856), German chemist and mineralogist; *sericite* is from the Greek for *silky*, in allusion to the luster. The 2M₁ polytype is the most frequently encountered; 1M and 3T are less common, and disordered 1Md also exists. Phengite is most commonly of the 1M, 1Md, or 3T polytype, with 2M₁ less common and 2M₂ rarer still. Mixed polytypes exist. For many, probably a majority, of occurrences, the polytype is unreported. 2M₁: MON C2/c. $a = 5.199$, $b = 9.027$, $c = 20.106$, $\beta = 95.78^\circ$, $Z = 4$, $D = 2.818$. PD: 10.01₁₀ 5.02₆ 4.48₆ 4.46₇ 3.35₁₀ 3.21₅ 2.59₅ 2.56₉; also 6-263: 9.95₁₀ 4.97₃ 3.34₃ 3.32₁₀ 3.19₃ 2.99₄ 2.57₆ 1.993₅; also 19-814 (vanadian): similar. 1M: MON C2/m. $a = 5.208$, $b = 8.995$, $c = 10.275$, $\beta = 101.6^\circ$, $Z = 2$, $D = 2.805$. 7-25(syn): 10.1₁₀ 5.04₄ 4.49₉ 3.66₆ 3.36₁₀ 2.58₅ 2.57₉ 1.499₃; also 21-993 (magnesian): 9.91₉ 4.50₁₀ 3.62₇ 3.33₈ 3.29₆ 3.06₂ 2.59₅ 2.56₈. 3T: HEX P3₁21 or P3₂31. $a = 5.196$, $c = 29.97$, $Z = 3$, $D = 2.831$. 7-42: 9.97₁₀ 4.99₅ 4.49₂ 4.46₂ 3.31₁₀ 2.88₂ 2.56₃ 1.999₅; the pattern is essentially like that of the 1M polytype. 2M₂: MON C2/c. $a = 9.017$, $b = 5.210$, $c = 20.437$, $\beta = 100.4^\circ$, $Z = 4$, $D = 2.80$. 34-175(calc): 9.98₁₀ 4.44₇ 3.66₇ 3.49₈ 3.18₈ 3.04₇ 2.57₉ 2.55₉; also 26-649(calcian), 10-490(barian). D6:611(1892), DHZI 3:1(1962), MSARM 13:1(1984). Structure: 2M₁, EJM 4:283(1992); 1M, SR 19: 468(1955); 3T, ZK 125:163(1957); 2M₂, CCM 21:465(1973). In muscovite, as in all dioctahedral micas, the vacant M1 site lies on the mirror plane and is larger than the occupied and distorted M2 sites. **Habit:** Tabular {001} crystals with rhombic to hexagonal outline, bounded most frequently by {221}, {111}, and {010}

Muscovite displaying rhombic cross-section (Harvard Mineralogical Museum).

(old setting); sometimes in large sheets or "books" of irregular outline; less commonly as pronounced prismatic [001] crystals of crude hexagonal cross section; stellate, fivelings composed of crystals with rhombic cross section. Concentric, curved aggregates; flakes, lamellar masses, plumose aggregates, and fine-grained aggregates. Twinning common according to the mica law; less commonly with composition perpendicular to {001}. **Physical properties:** Colorless, silvery white, pale yellow to light brown, light to medium green, pink to light raspberry-red; vitreous luster, pearly on cleavage, aggregates silky, glistening or dull; transparent to translucent. Cleavage {001}, perfect, yielding flexible elastic sheets; parting on {110} and {010} often well developed by percussion normal to sheet; brittle when torn across cleavage. $H = 2\frac{1}{2}$, parallel to cleavage, to $3\frac{1}{2}$, perpendicular to cleavage. $G = 2.77-2.88$. **Optics:** Common muscovite is biaxial (-); $2V = 28-47^\circ$; $N_x = 1.552-1.576$, $N_y = 1.582-1.615$, $N_z = 1.587-1.618$; $Z = b$, $Y \wedge a = 1-3^\circ$, OAP perpendicular to {010}; $r > v$; nonpleochroic to moderately so; $Z = Y > X$. 3T muscovites are uniaxial (-) with similar indices; chromian muscovites (fuchsites) indices lie within the foregoing range, with distinct pleochroism in light blue-green to green; lithian muscovites have indices as low as $N_x = 1.530$, $N_y = 1.552$, $N_z = 1.556$; vanadian muscovites have higher indices, increasing toward those of roscoelite and display a more pronounced pleochroism; phengites have $2V = 0-30^\circ$; $N_x = 1.547-1.580$, $N_y = 1.584-1.620$, $N_z = 1.587-1.623$; rose muscovites have indices lying in the normal range but often display a reverse pleochroism with X, brown-red; Y,Z, light pinkish orange. Refractive indices generally increase with increasing iron or manganese and decreasing tetrahedral aluminum. Insoluble in acids. Fusibility $5\frac{1}{2}$. **Chemistry:** Muscovites approaching the ideal composition are not uncommon, and anhydrous fluormuscovite has been synthesized. Extensive substitution occurs in tetrahedral, octahedral, and interlayer sites leading to partial or complete solid solution with other dioctahedral micas, and to some extent with trioctahedral ones. Sodium is usually low, rarely exceeding 12% but sometimes reaching near 35% of the interlayer cation site; rubidium and cesium may amount to 5% and 1%, respectively, of the interlayer sites; calcium and barium may also substitute here with nearly 10 wt % BaO (oellacherite); interlayer water and potassium deficiency, accompanied by other substitutions, leads to hydromuscovite. Tetrahedral sites ideally have Si : Al = 3:1, but excess Si is not uncommon, accompanied by substitution of Mg and Fe²⁺ (phengite) or Li (Li muscovite) in octahedral sites. Substitution of Fe²⁺ and Fe³⁺ in octahedral sites leads to light green and brown muscovites; up to about 3.5 wt % Li₂O may be present with retention of the 2M₁ polytype; MnO is usually < 1 wt % but may be double that resulting in purple-blue color. Rose muscovites are close to the ideal composition with significant Li and Rb content; the color, however, appears to be a function of a small amount of Mn³⁺, Fe³⁺ in the tetrahedral sites, or Fe³⁺ and Mn²⁺, which may result in an electron transfer couple. Chromium substitution in octahedral sites, up to 5 wt % Cr₂O₃, is not uncommon in fuchsite, but a Cr-dominant mica with 24.7 wt % Cr₂O₃ has been reported from Outokumpu, Finland. There is evidence of a miscibility

gap in the Cr-Al substitution, and a distinct species designation may be appropriate. Substitution of V³⁺ for Al results in olive-green tones, but when significant the 1M polytype predominates, and solid solution with roselite exists. Large "books" of muscovite often enclose in their cores, epitaxial, reticulated films of red-brown hematite and nearly black magnetite parallel to {001}; these are probably the result of exsolution. Occurrence: Muscovite, although generally less common than biotite, is an important constituent of granite and granodiorite, wherein it may have crystallized directly from the fluid at pressures in excess of 3.5 kbar or in the solid state over a wide range of pressure. Muscovite granites tend to be high in quartz. Less commonly it is found in rhyolites, where it is often fluorine-rich. Abundant in granite pegmatites, both simple and complex, where it is associated with biotite and lepidolite. Late-stage replacement of potash feldspars, spodumene, tourmaline, beryl, topaz, etc. by fine-grained muscovite (sericite) is common. Rose muscovites are confined to pegmatites, usually in Na-Li replacement zones, where it is associated with spodumene, topaz, beryl, and tantalum minerals. Muscovite is a common constituent of every progressive zone of regionally metamorphosed sediments, forming initially by recrystallization of the sericitic micas and illite of the original sediments to yield albite-chlorite-sericite schists. With progressive metamorphism, muscovite tends to become coarser-grained and segregated into bands; it may coexist with almandine, but the latter, with K-feldspar, may also be a product of the reaction of muscovite, biotite, and quartz. Fuchsites are found in hydrothermal carbonate replacement zones associated with sulfide-gold deposits, and also in corundum schists and staurolite-zone quartz conglomerates and quartzites. Muscovite is also characteristic of fluorine metasomatism (greisenization), and associated feldspars are often replaced by muscovite. Muscovite in *sensu strictu* is less common in sedimentary rocks than was once believed. Sericite, illite, and various mixed-layer phyllosilicates are the common micaceous minerals of sediments. Those micas that approach true muscovites in such environments are usually of the 1M or 1Md polytypes. Localities: As a rock-forming mineral, muscovite is of worldwide, common occurrence, and the same is true for well-crystallized material from pegmatites and metasomatic deposits. Only a sampling of localities for documented analyzed and polytype identified samples, commercially important, or well-crystallized occurrences are given. Unless otherwise noted, the polytype is in all probability 2M₁. The type locality for undifferentiated muscovite is lost in antiquity. Noteworthy U.S. localities are: Auburn, Androscoggin Co., and Buckfield and Hebron, Oxford Co., ME; fuchsite in staurolite-zone metamorphics at Acworth, Sullivan Co., NH; pink and rose-red at Chesterfield and Goshen, Hampshire Co., MA; large sheets and curved, concentric aggregates at Branchville, Fairfield Co., CT; pink, barian muscovite (oellacherite), 1M and 2M₂, at Franklin, Sussex Co., NJ; fuchsite at the Line pit, Lancaster Co., PA; Amelia C.T., Amelia Co., VA. In NC, transparent to translucent, green crystals with rutile at Boiling Spring, Cleveland Co.; in fine crystals at Henry, Lincoln Co.; mined commercially in Mitchell, Yancey, Jackson, and Macon Cos. Commercially

mined in pegmatites of the Black Hills, SD, the Etta mine, near Keystone, Pennington Co., having yielded large masses of coarse-grained, light yellow, lithian muscovite. Found at Mt. Antero, Chaffee Co., CO; rose muscovite, 2M₁, is abundant at the Harding pegmatite, near Dixon, Taos Co., NM, where it forms light raspberry-red disseminated scales and crude prismatic crystals to 10 cm long and a few millimeters in diameter embedded in albite, and also replaces K-feldspar in part. In pegmatites of San Diego Co., CA, particularly the Himalaya mine, where it is often epitactically encrusted with lepidolite; phengite, 2M₁, at Tiburon Peninsula, CA; a 3T polytype is found in the *Sunrise Cu prospect, Sultan Basin, Snohomish Co., WA*. In Canada, a nearly ideal end-member muscovite, 2M₁, in Methuen Twp., ON, and at Mt. St.-Hilaire, PQ; fuchsite at Pointe du Boise, MB. In Mexico, as well-crystallized material in pegmatites of Baja California. Rose muscovite at Varutrask, Sweden; fuchsite and Cr-dominant dioctahedral mica at Outokumpu, Finland; at the Penryn granite quarry and Wheal Lock Zawn, Cornwall, England; 2M₂ calcian muscovite from Albertsweiler, Germany; at numerous localities in the Swiss, Italian, and Austrian Alps, often with adularia, and sodian, 2M₁ muscovite at Alpe Sponda, Switzerland; magnesian 1M at Borza, Poland; in Russia, in pegmatites of the Ural Mts., particularly at Alabashka, near Mursinka; 1M phengite is reported from Transbaikalia, and 2M₂ phengite from northern Armenia. Important commercial deposits in India at Hazaribagh, Bihar, and the Inikurti mine, Madras(!), where crystals weighing as much as 85 tons have been found. Fuchsite, 2M₁, is found in the Harts Range, NT, Australia. 2M₁ polytype at Archer's Post, Kenya, and 2M₁ phengite at Bulautad, western (Spanish) Sahara. Abundant at numerous pegmatites of MG, Brazil. Particularly noteworthy are the commercial deposits at Lavra de Enio, Boa Vista; twinned crystals at Laranjeira, between Araçuaí and Itaobim; at the Cruzeiro mine, Santa Maria Suaçui, in part lithian; yellow, lozenge-shaped crystals and "star mica" twins at the Riacho Genipapo pegmatite, and as "fishtail" twins at the Urubu pegmatite, near Araçuaí; with brazilianite at Corrego Frio, between Linópolis and Mendes Pimentel; as superb reddish-brown tabular crystals(!), sometimes forming "roses," and associated with dark greenish-gray fluorapatite, at the Zé Pinto prospect (Fazenda Santa Elisa), east of Governador Valadares. Uses: The combined properties of perfect cleavage, elasticity, high dielectric constant, and low thermal conductivity make cleavage sheets ideal for many electrical, electronic, and thermal insulation applications. An early application, occasionally still encountered, is as windows, particularly of small size in furnaces. Ground mica (muscovite in large part) is used as a filler and dusting compound. Fine and coarsely ground muscovite finds use in the arts to produce special surface effects in prints and paintings. Scattered fuchsite flakes in quartzite result in one type of aventurine that is used ornamentally when cut into cabochons or beads. AR *DHZI* 3:11(1962), *MSARM* 13:274(1984), *MM* 51:594(1987), *CM* 29:481(1991).

71.2.2a.2 Paragonite-2M₁, 3T, 1M NaAl₂[AlSi₃O₁₀](OH)₂

Named in 1843 by Schafhautl from the Greek for *to mislead*, in allusion to its originally having been mistaken for talc. The 3T polytype described in 1956 by Dietrich and 1973 by Zvyagin et al. Mica group, muscovite subgroup. 2M₁: MON C2/c. $a = 5.128$, $b = 8.898$, $c = 19.278$, $\beta = 94.35^\circ$, $Z = 4$, $D = 2.893$. 12-165: 9.7₈ 4.9₆ 4.44₁₀ 4.06₆ 2.92₇ 2.83₇ 2.54₉ 2.48₈; also 42-602: 9.63₃ 4.44₄ 4.39₄ 3.21₁₀ 2.56₂ 2.53₅ 1.925₃ 1.481₃. The substitution of Na for K leads to a distinctly shorter c axis than that found in muscovite. 1M: MON C2/m. $a = 5.139$, $b = 8.885$, $c = 9.750$, $\beta = 98.87^\circ$, $Z = 2$, $D = 2.885$. 24-1047(syn): 9.67₈ 4.82₅ 4.44₄ 4.24₂ 3.21₁₀ 3.06₃ 2.52₂ 1.928₃. Usually found as massive, fine-grained to scaly aggregates. Colorless to pale yellow, pearly to dull luster, transparent to translucent. Cleavage {001}, perfect. $H = 2\frac{1}{2}$. $G = 2.78-2.90$. Biaxial (-); $2V = 0-40^\circ$; $N_x = 1.564-1.580$, $N_y = 1.594-1.609$, $N_z = 1.600-1.609$; $X \wedge c \approx 5^\circ$, $Y \approx a$, $Z = b$; $r > v$. Polytype 3T is uniaxial (-), but 2M₁ displays the foregoing range of $2V$. Contains ≈ 6 wt % Na₂O compared to muscovite, which is usually limited to < 2 wt %; thus complete solid solution is unlikely. Minor Mg and Fe³⁺ substitute for octahedral aluminum; K and Ca may replace Na to a limited extent. Occurs in a broad range of conditions in metamorphic regions in phyllite, schist, and muscovite-biotite gneiss, often associated with staurolite and kyanite. Also in quartz veins and in fine-grained sediments. In feldspar-mica assemblages, sodium has a tendency to enter the feldspar structure preferentially and paragonite is less likely to form than muscovite. Many "sericite" rocks contain significant paragonite. May be more abundant than commonly assumed, due to its association with and misidentification as muscovite. Probably of very widespread occurrence, the following being well documented: in schists of Glebe Mt., VT; in Campbell and Franklin Cos., VA; in the Leadville district, Lake Co., CO; with staurolite and kyanite at *Mte. Campione, Tessin, Switzerland*; at Borgofranco, Piemonte, Italy; and in the southern Ural Mts., Russia. AR *DHZI* 3:31(1962), *SPC* 22:557(1977), *AM* 69:122(1984), *EJM* 4:283(1992).

71.2.2a.3 Chernykhite-2M₁ (Ba,Na)(V³⁺,Al)₂[(Si,Al)₄O₁₀](OH)₂

Named in 1972 by Ankinovich et al. for V. V. Chernykh, professor, Leningrad Mining Institute. Mica group, muscovite subgroup. This species may also be considered a brittle mica. MON C2/c. $a = 5.29$, $b = 9.182$, $c = 20.023$, $\beta = 95.68^\circ$, $Z = 4$, $D = 3.07$. 25-76: 3.33₁₀ 3.01₅ 2.89₄ 2.80₄ 2.61₇ 1.996₆ 1.660₆ 1.530₅. Structure: *SPC* 19:70(1974). Olive-green, pearly luster, translucent. Cleavage {001}, perfect. $H = 3-3\frac{1}{2}$. $G = 3.14$. Biaxial (-); $2V = 11-12^\circ$; $N_x = 1.640-1.643$, $N_y = 1.686-1.691$, $N_z = 1.702-1.704$; $Z = b$. Contains, by weight, 9.5% BaO, 18.6% V₂O₃, 5.3% V₂O₄; the dominance of divalent cations in the interlayer sites makes this species transitional with the brittle mica subgroup. Occurs as veins in carbonate rocks in *Kara Tau, Zhambil, Kazakhstan*. AR *ZVMO* 101:451(1972), *AM* 58:966(1973).

71.2.2a.4 Roscoelite-1M $K(V^{3+},Al,Mg)[(Si,Al)_4O_{10}](OH)_2$

Named in 1876 by Blake in honor of Henry Enfield Roscoe (1833–1915), English chemist of Manchester, who first prepared pure vanadium. Mica group, muscovite subgroup. MON $C2/m$. $a = 5.26$, $b = 9.09$, $c = 10.25$, $\beta = 101.0^\circ$, $Z = 2$, $D = 3.08$. $10-496$: 10.0_{10} 4.54_8 3.66_5 3.35_8 3.11_5 2.70_3 2.60_8 1.520_6 ; also $19-933$ (syn). Minute scales, often in small stellate or spheroidal aggregates; occasionally in fine-grained masses. Clove-brown to greenish brown, dark green; pearly to dull, earthy luster; translucent to opaque in mass. Cleavage {001}, perfect. $H = 3$. $G = 2.97$. Biaxial (-); $2V = 24-40^\circ$; $N_x = 1.59$, $N_y \approx 1.63$, $N_z \approx 1.64$, but also reported with $2V = 10-15^\circ$, $N_x = 1.610$, $N_y = 1.685$, $N_z = 1.704$; $X \approx c$, $Y = b$; $r < v$, strong. Pleochroic; X, olive-green; Y, greenish brown. Interference colors display distinct green tones. Slowly decomposed by HCl. End-member roscoelite would contain ≈ 33.5 wt % V_2O_5 , whereas original type-material analyses report ≈ 28.5 wt %. Occurs in quartz veins with gold and as interstitial material in uranium-bearing sandstones. Found extensively in Jurassic sedimentary rocks of the Colorado Plateau, such as at Uravan, Montrose Co., CO, and similar occurrences in UT, AZ, and NM; associated with native gold at Red River, near Sutter's Mill, and at the *Stuckslacker (Sam Sims) mine, on Granite Creek, near Coloma, El Dorado Co., CA*, where several hundred pounds are said to have been found and discarded. Found in seams in porphyry at Kalgoorlie, WA, Australia; and in the uranium deposits at Mounana, Haut-Ogoue, Gabon. A minor but noteworthy ore of vanadium; worked extensively in Colorado Plateau deposits, often as a by-product of uranium recovery. AR $D6:635(1892)$, *AJS 39:253(1955)*, *MJJ 4:299(1965)*, *DHZI 3:11(1962)*, *MR 6:239(1975)*.

71.2.2a.5 Glauconite-1M $(K,Na)(Mg,Fe^{2+})_{0.33}(Fe^{3+},Al)_{1.67}[(Si,Al)_4O_{10}](OH)_2$

Named in 1828 by Keferstein from the Greek *glaukos*, blue-green, in allusion to its color, but the term *glauconie* was used in 1823 by Brongniart. Mica group, muscovite subgroup. The term *glauconite* has also been applied to green pellets in marine sediments that, although typical of the species, commonly incorporate other mineral species or may be entirely lacking in glauconite. Originally thought to be a $2M_1$ mica, the 1M polytype is now firmly established. Disordered (1Md) material and mixed-layer glauconite also exist. A 3T polytype may exist, but cannot be distinguished by X-ray powder diffraction. MON $C2/m$. $a = 5.234$, $b = 9.066$, $c = 10.16$, $\beta = 100.5^\circ$, $Z = 2$, $D = 2.90$. $9-439$: 10.1_{10} 4.53_8 3.63_4 3.33_6 3.09_4 2.59_{10} 2.40_6 1.511_6 . The powder pattern often resembles that of trioctahedral micas, but the species is truly dioctahedral. Structure: *AM 20:699(1935)*. **Habit:** Rounded aggregates and pellets of fine-grained, scaly particles; as casts of rhizopod shells; rarely as minute laths or platelets. **Physical properties:** Yellow-green, green, blue-green, rarely colorless; dull, earthy luster; translucent to opaque in mass. Cleavage {001}, perfect. $H = 2$. $G = 2.4-2.95$. Biaxial (-); $2V = 0-20^\circ$; $N_x = 1.585-1.610$, $N_y = 1.600-1.634$, $N_z = 1.610-1.641$, the indices increasing

with increasing total iron content; $X \wedge c \approx 10^\circ$; $Y = b$, $Z \approx a$; $r < v$, distinct; pleochroic, $X < Y = Z$, yellow-green to blue-green. The indices for aluminum-dominant ($\text{Al}_2\text{O}_3 \approx 18 \text{ wt } \%$) variety are $N_x = 1.559$, $N_y = N_z = 1.586$. Readily decomposed by HCl. **Chemistry:** The interlayer, large cation A sites, are usually not fully occupied or may contain water in place of potassium; in ordered 1M material the A-site occupancy by K^+ is 70–90%, decreasing to 40–70% in disordered, 1Md, glauconite, and further to 10–50% in mixed-layer glauconite that is similar to mixed-layer 2 : 1 clays. Minor Na_2O ($< 0.3 \text{ wt } \%$) and CaO ($< 1.0 \text{ wt } \%$) are present. In octahedral sites the Fe^{3+}/Al ratio is usually $> 3:1$; 1–5 wt % FeO is usually present, and 2–5 wt % MgO is usually present; Ni-bearing material has been reported; Mn is usually a minor constituent; Ti is present only in minor amounts. Silica content is usually high compared to muscovites. Water is usually present in amounts significantly in excess of that needed as $(\text{OH})^-$ in the octahedral layer, the amount increasing to as much as 13–14 wt %, being higher in disordered or mixed-layer types. The water may be adsorbed or in part occupy A sites as H_2O or H_3O^+ , this excess water being completely lost at 200° . **Occurrence:** The relatively narrow range of composition is consistent with the restricted conditions of formation in shallow-water marine environments under mildly reducing conditions during periods of low or no sedimentation. Association with iron sulfides suggests that the reducing conditions may be those associated with sulfate-reducing bacteria. In marine limestones, siltstones, and sandstones; greenstones are so named because of their color, due to a high glauconite content. The mechanism of formation is not wholly understood. In one hypothesis the proposed conditions are that a precursor 2:1 layer silicate be present, high iron and potassium be available, and a reducing condition exist. Glauconite, however, may form where a layer silicate precursor cannot be identified, so direct precipitation has also been proposed. **Localities:** Glauconite and glauconitic clays are of very widespread occurrence. Formation is presently taking place along many continental margins, particularly along the margins of eastern and western United States, northern Spain, southern Japan, southwestern Australia, eastern and southwestern Africa, and the southern areas of South America. A few well-documented occurrences are: as crystalline grains in dolomite at Bonnetterre, St. Francis Co., MO; at Woodburn, County Antrim, Northern Ireland; near Hrodna, Byelarus; aluminum-dominant material from Skole in the eastern Carpathians, Romania; Ni-bearing material is reported from Widgiemooltha(?), Australia; analyzed samples from Table Hill, Kakako Creek, Whare Flat, and the Otepopo tunnel, Otego, New Zealand; from the Vidono formation, Anzoategui, Venezuela. **Uses:** Glauconite has ion-exchange properties which have found it application as a water softener and decolorizer. **AR DHZI 3:35(1962), MSARM 13:545(1984).**

71.2.2a.6 Celadonite-1M $\text{K}(\text{Fe}^{3+}, \text{Al}, \text{Fe}^{2+}, \text{Mg})_2[\text{Si}_4\text{O}_{10}](\text{OH})_2$

Named in 1847 by Glocker from the French *celadon*, sea-green, in allusion to its common color. Mica group, muscovite subgroup. Formerly included under

glaucanite. *MON* *C2/m*. $a = 5.223$, $b = 9.047$, $c = 10.197$, $\beta = 100.43^\circ$, $Z = 2$, $D = 3.03$. *17-521*: 4.53₉ 3.64₈ 3.32₇ 3.09₈ 2.68₈ 2.60₇ 2.59₁₀ 2.40₈. Structure: *MZ* 8:32(1986). Disordered and mixed-layer varieties are common. Found as earthy aggregates and coatings, or as minute scales. Gray-green to blue-green; dull luster; translucent, opaque in mass. Cleavage {001}, perfect. $H = 2$. $G = 2.95\text{--}3.05$. Biaxial (-); 2V small; $N_x = 1.606\text{--}1.644$, $N_y = 1.630\text{--}1.662$, $N_z = 1.630\text{--}1.663$; $X \approx c$, $Y = b$; $r > v$; also uniaxial (-); $N_O = 1.643\text{--}1.663$, $N_E = 1.612\text{--}1.644$. Pleochroic; X, yellow-green; Y,Z, green to emerald-green. The hypothetical end member is nonaluminous and only Fe^{3+} occupies octahedral sites, but natural material contains $\approx 12\text{--}27$ wt % Fe_2O_3 , $\approx 1\text{--}7$ wt % Al_2O_3 , $\approx 2\text{--}10$ wt % FeO , and $\approx 0\text{--}6$ wt % MgO . Decomposed by HCl. Except for its distinctly different mode of occurrence, it is difficult to distinguish from glaucanite. Widespread as vesicle lining and coatings in altered volcanics of intermediate to basaltic composition, where it is associated with montmorillonite, quartz, chalcedonic silica, and zeolites. Some noteworthy localities are: at Bisbee, Cochise Co., Horseshoe Dam, Maricopa Co., and elsewhere in AZ; in the Porcupine Hills, Yellowstone National Park, WY; in the John Day Formation, OR; Wind R. area, WA; at Berufjordur, Iceland; Sandoy, Faroe Is., Denmark; at *Mt. Baldo, near Verona, Italy*; and numerous worldwide localities. *AR* *D6:683(1892)*, *MM* *42:373(1978)*, *MSARM* *13:545(1984)*.

71.2.2a.7 Tobelite-1M (NH₄K)Al₂[AlSi₃O₁₀](OH)₂

Named in 1982 by Higashi for the locality. Mica group, muscovite subgroup. *MON* *C2/m*. $a = 5.219$, $b = 8.986$, $c = 10.447$, $\beta = 101.31^\circ$, $Z = 2$, $D = 2.617$. *18-119*: 10.24₁₀ 5.12₇ 4.49₇ 4.36₃ 3.69₃ 3.41₆ 3.10₃ 2.57₄; also *42-1321(syn)*. Yellowish green, dull luster, translucent. Cleavage {001}, perfect. $G = 2.58$. Biaxial (-); 2V = 28°; $N_x = 1.555$, $N_y = 1.572$, $N_z = 1.581$; $Z = b$. The interlayer site occupancy for Tobe material is [(NH₄)_{0.53}, K_{0.19}, Na_{0.01}, □_{0.27}]. Found as clayey material consisting of minute flakes and crystals up to 0.1 mm in diameter, associated with quartz alone at the *Ohgidani deposit, Tobe, Ehime Pref., Shikoku*, and at the *Horo deposit, Toyosaka, Hiroshima Pref., Honshu, Japan*. *AR* *MJJ* *11:138(1982)*, *AM* *68:850(1983)*.

71.2.2a.8 Nanpingite-2M₁ Cs(Al,Mg,Fe²⁺,Li)₂[AlSi₃O₁₀](OH,F)₂

Named in 1990 by Yang et al. for the locality. Mica group, muscovite subgroup. *MON* *C2/c*. $a = 5.362$, $b = 8.86$, $c = 21.41$, $\beta = 97.77^\circ$, $Z = 4$, $D = 3.19$. *PD*: 3.62₅ 3.33₆ 2.99₅ 2.92₅ 2.66₁₀ 2.65₁ 2.13₉ 2.12₂. Colorless, white; vitreous luster, pearly on cleavage; transparent to translucent. Cleavage {001}, perfect; more brittle and less elastic than muscovite. $H = 2\text{--}3$. $G = 3.11$. Biaxial (-); 2V = 46°; $N_x = 1.551$, $N_y = 1.584$, $N_z = 1.588$; $Z = b$; $r > v$, weak. A cesium analog of muscovite. Occurs as scales and plates up to 10 mm in diameter in radiating aggregates and less commonly as pseudohexagonal crystals, associated with montbrasite, quartz, and apatite in veinlets in the pollucite-bearing middle zone of a muscovite-albite-spodumene pegmatite in the *Nanping area, Fujian Prov., China*. *AR* *AM* *75:708(1990)*.

71.2.2a.9 Boromuscovite-1M, 2M₁ KAl₂[BSi₃O₁₀](OH,F)₂

Named in 1991 by Foord et al. from the composition and relationship to muscovite. Mica group, muscovite subgroup. 1M: *C2/m*. $a = 5.077$, $b = 8.775$, $c = 10.061$, $\beta = 101.31^\circ$, $Z = 2$, $D = 2.90$. *PD*: 9.86₆ 4.24₄ 3.57₁₀ 3.29₄ 3.01₈ 2.51₈ 2.49₄ 2.20₄. 2M₁: *C2/c*. $a = 5.075$, $b = 8.775$, $c = 19.815$, $\beta = 95.59^\circ$, $Z = 4$, $D = 2.89$. *PD*: 9.86₈ 4.39₁₀ 4.01₅ 3.29₅ 2.52₅ 2.34₄ 2.10₄ 1.46₅. For the type material (mixed polytypes), *PD*: 9.86₆ 4.39₈ 4.24₄ 3.57₁₀ 3.29₄ 3.01₈ 2.49₄ 2.20₄. Structurally analogous to muscovite, the substitution of boron for aluminum in the tetrahedral sites leading to the smaller unit cell. White to cream; dull, earthy luster; translucent. Cleavage {001}, perfect; parting {010}, poor; subconchoidal fracture for masses. $H = 2\frac{1}{2}$ -3. $G = 2.81$. Biaxial (-); $2V_{\text{obs}} = 44^\circ$, $2V_{\text{calc}} = 47.5^\circ$; $N_x = 1.557$, $N_y = 1.587$, $N_z = 1.593$; $\text{Na}(D): Z = b; X \wedge c = -1^\circ$; $r > v$, weak. Analysis (wt %): B₂O₃, 7.0; MgO, 0.15; CaO, 0.10; Rb₂O, 0.52. Formed in the temperature range 350–400° as porcelaneous coatings up to 1+ cm thick consisting of minute scales and pseudo-hexagonal crystals of mixed 1M and 2M₁ polytypes in the *New Spaulding Pocket, Main Little Three dike, Little Three mine, Ramona, San Diego Co., CA*, where fragmented topaz, elbaite, and albite are included in the coatings. Reported from Rečice, Czech Republic. *AR AM 76:1998(1991)*.

71.2.2a.10 Montdorite-1M, 3T (K,Na)(Fe²⁺,Mn²⁺,Mg)_{2.5}[Si₄O₁₀](F,OH)₂

Named in 1979 by Robert and Maury for the locality. Mica group, muscovite subgroup. Species status uncertain. *MON C2/c*. $a = 5.310$, $b = 9.20$, $c = 10.18$, $\beta = 99.9^\circ$, $Z = 2$, $D = 3.159$. *33-1016*: 9.97₄ 3.41₄ 3.34₁₀ 3.14₃ 2.71₃ 2.52₄ 2.17₃ 1.669₃. No data are given for the 3T polytype. Structurally intermediate between di- and trioctahedral, 1M micas. Green to brownish green, translucent. $G = 3.15$. Biaxial (-); $2V < 1^\circ$. $N_x = 1.580$, $N_y \approx N_z = 1.605$; $\text{K}/\text{Na} \approx 0.82$, Fe²⁺ is dominant in the 2.5 octahedral sites occupied, and $\text{F}/(\text{OH}) \approx 1.65$. Occurs as 5- to 25- μm grains in peralkaline rhyolite of the *Mt. Dore stratovolcano, near La Bourboule, France*. *AR CMP 68:117(1979)*.

71.2.2b.1 Phlogopite-1M, 3T, 2M₁ KMg₃[AlSi₃O₁₀](F,OH)₂

Named in 1841 by Breithaupt from the Greek *phlogos*, firelike, in allusion to the reddish-brown color or internal reflections exhibited by some varieties. Mica group, biotite subgroup. The name *eastonite* applied in part to aluminous phlogopite is from the locality, and may be encountered in petrographic literature. *Manganophyllite*, named from composition and foliated habit, is applied to Mn-rich phlogopite and biotite. The 1M and 1Md polytypes are most common, followed in abundance by 3T and then 2M₁. Manganous phlogopite of polytype 3T has not been reported. 1M: *C2/m*. $a = 5.308$, $b = 9.190$, $c = 10.155$, $\beta = 100.08^\circ$, $Z = 2$, $D = 2.686$. *10-495*: 9.97₁₀ 3.39₂ 3.35₁₀ 2.61₃ 2.52₂ 2.43₂ 2.17₂ 2.01₃. 3T: *P3₁12/P3₂12*. $a = 5.317$, $c = 30.618$, $Z = 3$, $D = 2.629$. *10-492*: 10.1₁₀ 5.02₃ 3.41₅ 2.62₃ 2.51₅ 2.01₁₀ 1.673₄; taken *in toto* the 1M and 3T powder patterns are almost indistinguishable. 2M₁: *C2/c*.

$a = 5.347$, $b = 9.227$, $c = 20.252$, $\beta = 95.02^\circ$, $Z = 4$, $D = 2.670$. ~~10-493~~: 10.1₁₀ 3.54₄ 3.36₁ 3.28₄ 2.62₁₀ 2.18₅ 2.02₇ 1.677₅ 1.538₅. Structure: *AM 58:889(1973)*. **Habit:** Pseudohexagonal or rhombic, tabular {001}, short-to-long prismatic [001]; equant crystals bounded by {221}, {111}, and {010} (old setting); long prismatic crystals commonly tapering or of nonuniform cross section. **Twinning** common on {001} according to the mica law. **Physical properties:** Colorless, pale yellow, yellow-brown, reddish to dark brown, green; white to brown-tinted white streak; pearly to submetallic luster, on cleavage surface; transparent to translucent. Cleavage {001}, perfect, yielding flexible and commonly elastic sheets, may develop hexagonal percussion figures on cleavage plates. $H = 2-2\frac{1}{2}$. $G = 2.76-2.98$. Asterism by transmitted light perpendicular to cleavage is often displayed, and is probably due to inclusions of oxide minerals. **Optics:** Biaxial (-); $2V = 0-20^\circ$; $N_x = 1.530-1.590$, $N_y = 1.557-1.637$, $N_z = 1.558-1.637$, the values overlapping those for biotite; for 1M polytype, $X \approx c$, $Y = b$, $Z \wedge a = 0-5^\circ$; $r < v$. Pleochroism none to moderate; X, pale yellow; Y, Z, yellow to red-brown or green. Indices depth of color increases with increasing iron content. For Mn-rich material, $N_x = 1.575$, $N_y = 1.617$, $N_z = 1.621$; $2V = 30^\circ$. Synthetic, end-member fluor-phlogopite has $2V = 14^\circ$; $N_x = 1.522$, $N_y = 1.548$, $N_z = 1.549$. Fluorine-rich phlogopites have lower indices than otherwise corresponding OH-rich compositions. **Chemistry:** Phlogopite forms a complete isomorphous series with biotite, annite, and siderophyllite, but solid solution with muscovite appears to be very limited. Members of the series with Mg:Fe ratios of $> 2:1$ are generally regarded as phlogopites, but the boundary is arbitrary largely because substitutions other than Fe for Mg may also occur. Aluminum may substitute in octahedral sites with concomitant additional Al in tetrahedral sites yielding the variety eastonite. Fe_2O_3 may be present up to ≈ 6 wt %. Significant MnO may be present, and a variety with 7.5 wt % MnO and 5.5 wt % CuO has been reported (Japan). Minor Li and Ti may also be present in octahedral sites. The interlayer cation is predominantly potassium, but significant sodium may be present as well as minor calcium and barium. Examples from metamorphic environments are often F-dominant or F-rich, but those from ultrabasic rocks may contain almost no fluorine. Phlogopite from basic volcanic rocks may be OH and F deficient. **Occurrence:** Commonly occurs in regionally and thermally metamorphosed impure limestones, particularly dolomite marble, the potassium being derived from either detrital potash feldspar or muscovite; excess alumina from the latter may form associated spinel. Fluorine metasomatism at contact zones results in F-rich phlogopite. Phlogopite is also characteristic of ultrabasic rocks and is common in kimberlites, where it may rim pyroxenes and other minerals, and in leucite-rich rocks. **Localities:** Phlogopite is of widespread occurrence and only selected well-documented localities are given: found in many of the Grenville metamorphics in NY, such as at Port Henry, Essex Co., and at Gouverneur and as crystals to 60 cm long(!) at Clarke's Hill, St. Lawrence Co.; in marble at Franklin, Sussex Co., NJ; eastonite at Williams quarry, Easton, PA; in pyroxenite at Iron Hill, Gunnison Co., CO. In Canada it is found constituting 20-25% of kimberlite at Bachelor

Lake, PQ; with uraninite and molybdenite in cream-colored calcite at Gati-neau Park, PQ; as transparent brown and nearly black crystals of 7 cm average length at Yates mine, Pontiac Co., PQ; as large, F-rich, near-end-member crystals(!) at Burgess, ON. In crystals up to 50 cm across in the Gardiner Complex, Kangerdlugssuak Fjord, Greenland. The 2M₁ polytype occurs, although rarely, at Lake Gjerdenken, north of Oslo, Norway; formed in chondrodite-spinel marble by F-metasomatism at Manjšö Mt., Sweden; mangano-phyllite in manganese ores at Langban, Sweden; with monticellite, apatite, vesuvianite, and cuspidine in marble at Carlingford, Co. Louth, Ireland; disseminated and in lenses and bands in marble at contact with Querigut granite in the Pyrenees Mts., France; 1M polytype at Mte. Braccio, Val Malenco, Italy. Important economic deposits(*)(!), mined since the eighteenth century, occur at Slyudyanka, at south west end of Lake Baikal, Irkutsk region, Russia, where some crystals reach 1 m in length; mangano-phyllite in a pegmatitic ore band at Chikla, Bhandara district, India; cuprian and manganoan phlogopite occurs at Kamogawa, Boso Peninsula, Honshu, Japan; a constituent of host rock of large dravite crystals at Yinnietharra, WA, and titanian material (≈ 9 wt % TiO₂) at Howes Hill, WA, Australia; at Anxiety Point, Nancy Sound, New Zealand; the 2M₁ polytype occurs at Saharakara, and undifferentiated, presumably 1M phlogopite, is noted from many localities in Madagascar; (*) in kimberlite at Frank Smith mine, Cape Prov., South Africa; with dravite, magnesite, and talc at the Pedra Preta and Pirajá deposits, Brumado, BA, Brazil. Uses: Low- or iron-free phlogopite has dielectric and thermal conductivity properties akin to those of muscovite, and has application as an electrical and thermal insulating material and as a filler. AR *DHZI* 3:42(1962); MR 1:58(1970), 16:492(1985); AM 77:1099(1992).

71.2.2b.2 Biotite-1M, 3T, 2M₁ $K(Fe^{2+}, Mg)_3[AlSi_3O_{10}](OH, F)_2$

Named in 1847 by Hausmann for Jean Baptiste Biot (1774–1862), French physicist who studied the optical properties of the micas. Mica group, biotite subgroup. The term *lepidomelane*, from Greek for *scale* and *black*, is in common but superfluous use for black biotites, particularly those rich in Fe³⁺, and may encompass annite and ferriannite. Siderophyllite, now given species status, was formerly included as a variety of biotite. The 1M polytype is by far the most common, followed by 3T and then 2M₁. A polytype described as 4M₃ has been reported, but the documentation is poor. 1M: MON C2/m. $a = 5.343$, $b = 9.258$, $c = 10.227$, $\beta = 100.26^\circ$, $Z = 2$, $D = 2.81$. 24-867(syn): 10.2₁₀ 3.39₁₀ 2.64₃ 2.62₉ 2.44₅ 2.18₄ 2.03₄ 1.534₄; 42-1437: 10.05₁₀ 3.35₄ 2.63₃ 2.45₂ 2.18₁ 2.01₆ 1.678₁ 1.542₂. 3T: HEX P3₁21/P3₂21. $a \approx 5.3$, $c \approx 30$, $Z = 6$. The powder pattern is essentially equivalent to that of 1M. 2M₁: MON C2/c. $a = 5.315$, $b = 9.22$, $c = 19.95$, $\beta = 95.1^\circ$, $Z = 4$. 42-1339: 10.01₁₀ 3.53₁ 3.34₃ 3.27₂ 3.02₁ 2.62₄ 2.44₂ 2.43₂ 2.17₂. 4M₃: MON Space group unknown. $a = 5.535$, $b = 9.24$, $c = 40.03$, $\beta = 92.54^\circ$, $Z = 8$ (by electron diffraction). Structure: 1M, AM 75:305(1990); 2M₁, AM 60:1030(1975). Habit: Tabular {001} to short prismatic [001], with pseudo-hexagonal or rhombic cross section; dominant forms

BIOTITE

Biotite. Forms: b, {010}; c, {001}; r, {101}; o, {112}; μ, {111}; z, {132}.

in old morphological setting are {001}, {221}, {010}, { $\bar{1}11$ }, {112}, and {132}; prism faces often in repeated oscillatory combinations; crystals with well-developed {101}, {132}, and {132} are pseudorhomboidal. Disseminated grains, scales, and large "books" of irregular outline. Twinning according to the mica law, commonly with {001} composition or, less frequently, perpendicular to {001}. **Physical properties:** Brown, green grading to black, also pale yellow to tan, bronze; white to pale streak; vitreous, splendid luster and sometimes pearly to submetallic on cleavage surface. Cleavage {001}, perfect yielding flexible, commonly elastic but somewhat brittle sheets; six-ray percussion figures may develop on cleavage plates; pressure may develop fractures or pseudofaces on the glide planes {205} and {135} resulting in pseudotrigonal-pyramidal forms. $H = 2\frac{1}{2}$ -3. $G = 2.7$ -3.4. **Optics:** Biaxial (-); $2V = 0$ -25°; or uniaxial (-); $Z \wedge a = 0$ -9°; $Y = b(1M)$, $Z = b(2M_1)$; $N_x = 1.565$ -1.625, $N_y \approx N_z = 1.605$ -1.696, the indices overlapping the ranges of phlogopite and of annite and ferriannite; $r > v$ or $r < v$ (Mg-rich), $r < v$ (Fe-rich), weak. Strongly pleochroic; X, light yellow, brown, or green; Y, Z, dark brown to dark green. Pleochroic halos with more pronounced absorption surround included radioactive phases, particularly zircon. Interference colors strongly influenced by absorption. Color is strongly influenced by the ratio of Ti to $Fe^{3+}/(\text{total Fe})$ such that the lower the ratio, the greener the color. Readily decomposed by strong acids. **Chemistry:** Biotite forms a complete isomorphous series with phlogopite and annite, and at least in part with siderophyllite and ferriannite; solid solution with muscovite is limited. The biotite composition field is arbitrarily defined as that having Mg:Fe ratios between 2 : 1 and 1 : 4, but the division is obscured by substitution of other cations in the octahedral as well as tetrahedral sites. Al^{3+} , Fe^{3+} , and Ti^{4+} may account for up to a third of the octahedral site occupancy, with concomitant excess of Fe^{3+} over their usual limit of a fourth of the tetrahedral sites; the charge excess may also be balanced by lithium in octahedral substitution. Up to approximately 5 wt % TiO_2 and approximately 1 wt % Li_2O may be present. Mn^{2+} substitution is usually limited, although some manganophyllite is known near the phlogopite-biotite boundary. Interlayer potassium may be replaced by sodium (20%) or calcium (10%) as well as minor rubidium and cesium. Small amounts of barium may also be present, but larger amounts lead to ardenite. Fluorine may replace up to half the hydroxyl ions, but is rarely that abundant. In contrast to many phlogopites. **Alteration:** Alteration by hydrothermal fluids tends to leach iron and magnesium to yield sericite pseudomorphs; (

ducts are green biotite, due to early leaching of Ti, chlorites, illite, and kaolinite. Alteration by weathering processes to yield hydrated biotite, vermiculite, and ultimately, montmorillonite clays. **Occurrence:** Biotite is found in a greater variety of geological environments than other micas. It forms over a wide pressure-temperature range, and is common in igneous and metamorphic rocks of diverse composition, but only sparsely in sedimentary environments. It forms early in the thermal metamorphism of argillaceous sediments, and survives into successively higher-grade hornfelses. With increased metamorphism it is gradually replaced by assemblages such as K-feldspar/pyroxene/sillimanite or K-feldspar/cordierite. In regional metamorphism it is the indicator for the relatively low-grade "biotite zone," then giving way to somewhat more magnesian biotite in the "garnet zone," and persisting into still higher metamorphic grades. It may form from iron-rich amphiboles during potassium metasomatism. It is common over a wide range of plutonic rocks, from granites and granite pegmatites through intermediate composition and peralkalic rocks, particularly those which are leucite-rich. Less common in extrusive rocks, it is often partially or completely resorbed, especially in those of low silica content. The biotite of volcanics is commonly poorer in Fe²⁺ and richer in Fe³⁺ and TiO₂ than corresponding plutonics. **Localities:** Biotite is as widespread as the great diversity of rock types in which it is found; only a selection of localities of analyzed samples that exemplify its mode of occurrence is presented: common in the granites, pegmatites, schists, and gneisses of the metamorphic belts of the eastern United States from New England to the Carolinas; black biotite at West Balmat, and reddish-black biotite at Colton, northwestern Adirondack Mts., NY; Ba-rich at Franklin, Sussex Co., NJ; a Rb-Li biotite occurs at Kings Mt., NC, at the contact with spodumene pegmatite; at Rib Mt., Marathon Co., WI; in the Clear Creek pegmatite, Burnet and Llano Cos., TX; biotite and aluminum-rich biotite in granites and pegmatites of the Pikes Peak batholith, Crystal Park, CO; 2M₁, OH and F-deficient (oxybiotite) at Ruiz Peak, NM; biotite containing 0.15 per formula unit of chlorine in schist from Lemhi Co., ID; in pegmatites, granodiorites, tonalite, and norite of the southern California batholith, CA. Large books of lepidomelane at Davis Hill, Silver Crater, and other localities in the Bancroft area, and both 1M and 2M₁ polytypes in Burgess Twp., ON; at Pontiac, Litchfield Twp., and at Mt. St.-Hilaire, PQ, Canada. Biotite is found in nepheline syenite at Låven and in nepheline-syenite pegmatite at Brevik, Norway; in kyanite gneiss at Ross of Mull, Scotland; in volcanics of the Laacher See district, Germany. Polytype 4M₃ is reported from the Khlebodarov quarry, east of the Sea of Azov, Ukraine. Found in biotite schist at Ogawamati, Nakosa, Fukushima Pref., and elsewhere in Japan; in a pegmatite-like lens in gneiss at Charles Sound, New Zealand; lithian lepidomelane in biotite granite and lithian siderophyllite(?) at Liruei, northern Nigeria. *AR DHZI 3:55(1962), AM 76:302(1991).*

71.2.2b.3 Annite-1M $KFe_3^{2+}[AlSi_3O_{10}](OH,F)_2$

Named in 1868 by Dana for the locality. Mica group, biotite subgroup. MON $C2/m$. $a = 5.386$, $b = 9.324$, $c = 10.268$, $\beta = 100.63^\circ$, $Z = 2$, $D = 2.77$, for natural, magnesian material. *42-1413*: 10.07₁₀ 3.36₄ 3.15₂ 2.63₄ 2.44₃ 2.18₂ 1.680₂ 1.542₂; *33-1016*(manganoan): 9.97₅ 3.41₄ 3.34₁₀ 3.14₃ 2.91₄ 2.52₄ 2.17₃ 1.669₃. Structure: *AM 58:889(1973)*. Black, brownish streak, vitreous to subadamantine luster, translucent to opaque. Cleavage {001}, perfect. $H = 2\frac{1}{2}$ -3. $G = 3.17$. Biaxial (-); $2V = 0-5^\circ$; $N_x = 1.624$, $N_y = 1.672$, $N_z = 1.672$; $Y = b$; $r < v$. Pleochroic; $X < Y = Z$; brown to dark brown. For synthetic end-member composition $N_x = 1.631$, $N_z = 1.697$, $D = 3.334$. Forms solid solution with biotite and phlogopite and with siderophyllite and ferriannite; in the phlogopite-annite series, annite compositions have a Fe/Mg ratio of 4 : 1 or greater. Natural material contains 32 wt % FeO, 3.1 wt % Fe₂O₃, 3.6 wt % TiO₂. Attacked by strong acids. Found in granite at *Cape Ann, MA*; in the Homestake formation, Lead, SD; and at La Bourboule, France (manganoan); at Sludorudnik, Ural Mts. and at Katugin, Siberia, Russia; at the Kawai mine, Ena, Gifu Pref., Japan. AR *JP 3:82(1962)*, *AM 77:34(1992)*.

71.2.2b.4 Ferriannite-1M $K(Fe^{2+},Mg)[Fe^{3+}Si_3O_{10}](OH)_2$

Named in 1963 by Wones for the composition and relationship to annite. Mica group, biotite subgroup. MON $C2/m$. $a = 5.402$, $b = 9.237$, $c = 10.306$, $\beta = 99.27^\circ$, $Z = 2$, $D = 3.54$. *PD*: 10.16₁₀ 3.68₅ 3.38₅ 2.91₁ 2.67₁ 1.696₅ 1.660₃ 1.539₁; also *16-169*(syn): 10.2₁₀ 4.66₁ 3.46₁ 3.39₇ 2.67₅ 2.48₂ 2.21₁ 1.567₂. Structure: *AC 17:1369(1964)*. Brown to black, off-white to pale brown streak, vitreous to subadamantine luster; translucent to nearly opaque. Cleavage {001}, perfect. $H = 2\frac{1}{2}$ -3. Biaxial (-); $2V = 40^\circ$; $N_x = 1.653$, $N_y = N_z = 1.691$; also $N_x = 1.677$, $N_y = N_z = 1.721$, $2V = 0-10^\circ$; also $N_x = 1.660$, $N_y = 1.720$, $N_z = 1.728$. Pleochroic; $X > Y = Z$; X, reddish brown; Y,Z, pale yellow-green to pale greenish brown. The first of the optically described material having FeO, Fe₂O₃, Al₂O₃ equal to 24.5, 8.0, 5.5 wt %, respectively, and the last having those oxides equal to 29.9, 13.2, 1.4 wt %, respectively. Occurs as scales and massive aggregates of tabular grains in association with riebeckite, stilpnomelane, hematite, and magnetite in the banded iron formation of the *Dales George member, Hammersley group, Witte-noom, WA, Australia*. AR *AM 67:1179(1982)*.

71.2.2b.5 Siderophyllite-1M $KFe_2^{2+}Al[Al_2Si_2O_{10}](OH)_2$

Named in 1880 by Lewis from the Greek for *iron* and *leaf*, in allusion to the composition and foliated (micaceous) character. Mica group, biotite subgroup. MON $C2/m$. $a = 5.369$, $b = 9.297$, $c = 10.268$, $\beta = 100.06^\circ$, $Z = 2$, $D = 3.27$. *25-1355*: 9.99₁₀ 3.36₉ 3.27₉ 2.62₁₀ 2.43₈ 2.16₇ 1.979₇ 1.542₉; also *26-909*. Tabular crystals and sheets, scales, and flakes. Twinning common according to the mica law. Dark brown to black, also blue-green to gray-green; light tan streak in dark examples; vitreous luster, pearly on cleavage;

transparent to nearly opaque. Cleavage {001}, perfect. $H = 2\frac{1}{2}$, $G = 3.0$. Biaxial (-); 2V small; $N_x = 1.582-1.616$, $N_y \approx N_z = 1.625-1.670$; $Y = b$; dark varieties markedly pleochroic with $X < Y = Z$, brown to dark brown. Some materials designated as siderophyllite lie in or close to the biotite field. End-member siderophyllite as formulated above has not been reported in nature, but Al commonly exceeds one-fourth of the tetrahedral site occupancy and is also present as up to a third of the octahedral sites. Lithium and vacancies may constitute up to a sixth of the octahedral positions. Occurs in pegmatite zones and greisens. Dark brown to black examples found at *Pikes Peak, Park Co., CO.*; green-gray, lithian [biotite (?)] in pegmatite in marble in the Broos Range, AK. Lithium-free, blue-green [biotite (?)] is found with topaz in greisen at Newcastle, County Down, Northern Ireland; at Novara, Baveno, Italy; and at Altenburg in the Erzgebirge, Saxony, Germany. AR *DHZI 3:55(1962)*, *MR 14:165(1983)*, *MSARM 13:581(1984)*.

71.2.2b.6 Hendricksite-1M $K(\text{Zn,Mg,Mn}^{2+})_3[\text{AlSi}_3\text{O}_{10}](\text{OH})_2$

Named in 1966 by Frondel and Ito for Sterling Brown Hendricks (1902-1981), American chemist and crystallographer and student of the micas. Mica group, biotite subgroup. MON $C2/m$. $a = 5.340$, $b = 9.524$, $c = 10.25$, $\beta = 100.07^\circ$, $Z = 2$, $D = 3.28$. *19-544*: 10.20₁₀ 5.09₄ 3.40₆ 2.65₁ 2.55₃ 2.46₁ 1.696₂ 1.554₈. Structure: *TMPM 34:1(1985)*. Copper-brown, reddish brown, to reddish black; vitreous luster. Cleavage {001}, perfect. $H = 2\frac{1}{2}-3$. $G = 3.4$. Biaxial (-); 2V = 2-8°; $N_x = 1.598-1.624$; $N_y = 1.658-1.686$, $N_z = 1.660-1.686$ $Y = b$; . For the optical properties reported the compositions span 19.8-21.4 wt % ZnO, 12.5-13.9 wt % MnO, and ≈ 5 wt % Fe₂O₃. Occurs as rough tabular or short prismatic crystals and as anhedral plates to 30 cm in diameter at *Franklin, Sussex Co., NJ*. AR *AM 51:1107(1966)*.

71.2.2b.7 Lepidolite-1M, 2M₂, 3T, 3M₂, 2M₁(?)

$K(\text{Li,Al})_3[\text{AlSi}_3\text{O}_{10}](\text{F,OH})_2$

Named in 1792 by Klaproth from the Greek *lepidos*, scale, and *lithos*, stone, in allusion to its common habit of aggregates of platy crystals. Mica group, biotite subgroup. Although accorded species status, lepidolite actually represents a complex solid solution involving other Li-Al micas, either naturally occurring (polyolithionite) or hypothetical (trilithionite), as well as magnesian, ferroan, and manganoan lithium micas. The 1M and 2M₂ polytypes are most common, followed by 3T and then 2M₁ and 3M₂. Other polytypes have been proposed. The 2M₁ polytype is usually a lithian muscovite rather than a trioctahedral mica. Mixed sequences may occur, and the formation of a particular polytype may be composition dependent. 1M: MON $C2/m$. $a = 5.209$, $b = 9.011$, $c = 10.149$, $\beta = 100.77^\circ$, $Z = 2$, $D = 2.83$. *38-425*: 9.97₄ 4.50₅ 3.62₇ 3.33₇ 3.09₇ 2.59₈ 2.53₁₀ 1.501₅; also *14-565*(ferroan). 2M₂: MON $C2/c$. $a = 9.023$, $b = 5.197$, $c = 20.171$, $\beta = 99.48^\circ$, $Z = 4$, $D = 2.84$. PD: 10.01₇ 5.00₄ 4.64₇ 3.64₄ 3.50₄ 3.34₆ 3.21₄ 2.58_{10b}; also *14-11*. 3T: HEX $P3_121/P3_221$. $a = 5.200$, $c = 29.76$, $Z = 3$, $D = 2.85$. *42-612*: 9.93₃ 4.45₅ 3.85₃ 3.59₃ 3.32_{10b}

3.09₃ 2.59₈ 2.56₈. 2M₁: MON C2/c. $a = 5.199$, $b = 9.026$, $c = 19.969$, $\beta = 95.41^\circ$, $Z = 4$, $D = 2.87$. 24-594: 4.48₅ 3.73₅ 3.20₆ 2.98₆ 2.59₁₀ 2.56₁₀ 2.38₈ 1.504₁₀. 3M₂: MON C2. $a = 5.239$, $b = 9.070$, $c = 29.886$, $\beta = 92.58^\circ$, $Z = 6$, $D = 3.11$. PD: 9.97₈ 4.49₆ 3.35₇ 3.31₇ 3.17₃ 2.60₁₀ 1.989₃ 1.513₆. Structure: 1M, 2M₂, AM 66:1221(1981); 3T, AM 63:332(1978); 2M₁ CCM 29:81(1981); 3M₂, AM 72:1163(1987). Lithium often preferentially occupies the smaller M1 octahedral sites. Vacancies may exist in both M1 and M2 sites. Lithian muscovites are dioctahedral or intermediate between di- and trioctahedral structures, usually of the 2M₁ polytype. Habit: Pseudo-hexagonal or hexagonal, tabular {001} to short prismatic [001] crystals, the terminal faces often rounded and the [001] zone faces commonly rough or etched; also as concentric, curved plates. Most commonly as fine- to coarse-grained masses of interlocking scales and plates. Zonal or epitactic growths with muscovite. Twinning common according to the mica law. Physical properties: Gray, blue-gray, violet, lavender, violet-pink, also light yellow to brownish; vitreous to pearly luster on cleavage, often dull on [001] faces; transparent to translucent. Cleavage {001}, perfect, yielding flexible and elastic sheets. $H = 2\frac{1}{2}$ -3 $\frac{1}{2}$. $G = 2$ 8-2.9. Optics: Lepidolites are biaxial (-) or uniaxial (-) with $2V = 0$ -58°; indices are commonly in the range $N_x = 1.529$ -1.542, $N_y = 1.548$ -1.567, $N_z = 1.553$ -1.570, the lower part of the range overlapping the values for poly-lithionite; higher indices to $N_x = 1.548$, $N_y = 1.585$, $N_z = 1.587$ are also reported with increasing Fe or Mn content; $r > v$; $Y = b$, $Z \wedge a = 0$ -7°. Weakly pleochroic. $X < Y = Z$; pinkish violet for Mn- and Fe³⁺-bearing examples, and yellowish with Fe²⁺-bearing examples. Chemistry: The majority of lepidolites represent a solid solution of poly-lithionite, $K(Li_2Al)[Si_4O_{10}](F, OH)_2$, and a hypothetical end member, trilithionite represented by $K(Li_{1.5}Al_{1.5})[Si_3AlO_{10}](F, OH)_2$. There appears to be complete solid solution with muscovite, so that only part of the larger M2 sites may be occupied; the transition between true lepidolite of 2M₂ type and lithian muscovite of 2M₁ type occurs at about 3.3 wt % Li₂O. At least partial solid solution exists with the magnesian, ferroan, and manganous lithium micas, taeniolite, zinnwaldite, and masutomilite, and with ephesite, the sodium analog of lithian muscovite. In the absence of Fe²⁺, the increasing Mn : Fe³⁺ ratio results in the deeper purple colors, whereas ferrous iron leads to yellowish or brownish colors. FeO and Fe₂O₃ may each attain 1.5 wt %, MgO 0.5 wt %, and MnO 1.0 wt %; titanium is present only in trace amounts. Potassium is always the dominant large alkali cation, but Na₂O, Rb₂O, and Cs₂O have been reported up to ≈ 1.0 , ≈ 3.8 , and ≈ 2.0 wt %, respectively. Fluorine is markedly dominant, and only rarely is it equal to or less than the hydroxyl content. Occurrence: Occurs almost exclusively in granitic pegmatite, where it is associated with other lithium minerals, elbaite, topaz, beryl, quartz, etc. It forms by metasomatic replacement of biotite and/or muscovite, and often forms granular to well-crystallized overgrowths on the latter. Rose muscovite is often later than associated lepidolite, on which it may form overgrowths. Also reported from granite, aplite, and high-temperature hydrothermal veins that are often tin-bearing. Localities: Abundant in the lithian pegmatites of

New England, as at Auburn(!), Androscoggin Co., ME (1M); 2M₂ at *South Portland, Cumberland Co., ME*; ferroan lepidolite at Rockport, MA; as blue-gray to lavender, granular masses interstitial; to large spodumene laths, and often intergrown with microlite, at the Harding pegmatite, Dixon, Taos Co., NM; at the Brown Derby mine, Gunnison Co., CO; abundant in pegmatites of the Black Hills, SD; 2M₂ with 2M₁ lithian muscovite at the Stewart mine, Pala, and 1M at Himalaya mine, Mesa Grande, at the Little Three mine in the Ramona district, and other pegmatites of San Diego Co., CA; in the Tanco pegmatite, Bernic Lake, NB, Canada. 1M and 2M₂ at the Varutråsk pegmatite, and 3M₂ at *Skuleboda, Sweden*; 3T with lithian muscovite at Kimito, Finland; in pegmatites of the Isle of Elba, Italy; in large sheets at Penig, Saxony, Germany; massive material at Rožna, Moravia, and 2M₁ near *Bisupice, Czech Republic*; at Alabashchka, near Mursinka, Ural Mts., Russia; at Minagi, Okayama Pref., Honshu, Japan; 3T at *Londonderry pegmatite, Coolgardie, WA, Australia*; abundant, often as large sheets at Antsomgombato, south of Betafo, and at Ampangabé, near Miandrarivo, and also at Maharitra on Mt. Bity, and elsewhere in Madagascar; in short prismatic, somewhat rounded crystals(!) at the Xanda mine, Virgem da Lapa, and in botryoidal form at Itinga, MG, Brazil. Uses: An important source of lithium compounds, and used directly in the manufacture of glass and enamels, thereby increasing strength and lowering the coefficient of expansion. AR *DHZI 3:85(1962)*, *AM 63:203(1978)*, *MSARM 13:579(1984)*, *MR 20:109(1989)*.

71.2.2b.8 Polyolithionite-1M $\text{KLi}_2\text{Al}[\text{Si}_4\text{O}_{10}](\text{F},\text{OH})_2$

Named in 1884 by Lorenzen from the Greek for *many* and its high lithium content, the highest for any mineral known at the time. Mica group, biotite subgroup. MON *C2/m*. $a = 5.186$, $b = 8.968$, $c = 10.029$, $\beta = 100.40^\circ$, $Z = 2$, $D = 2.823$. $21\text{-}952(\text{syn})$: 4.93₉ 3.59₁₀ 3.31₁₀ 3.29₉ 3.07₁₀ 2.87₇ 2.58₇ 1.974₉. Colorless, pink, purple, amber; vitreous to pearly luster; transparent to translucent. Cleavage {001}, perfect. $H = 3\text{-}3\frac{1}{2}$, $G = 2.85$. Biaxial (-); 2V small- 30° ; $N_x = 1.524\text{-}1.537$, $N_y = 1.543\text{-}1.563$, $N_z = 1.545\text{-}1.566$, these indices overlapping the common range for lepidolite. Bright yellow-green fluorescence in UV distinguishes it from taeniolite, with which it may occur (Mt. St.-Hilaire). Found at Point of Rocks, near Springer, NM. Relatively abundant at Mt. St.-Hilaire, QUE, Canada, in pegmatite pipes and veins as thin and fairly loose lamellae or as pseudo-hexagonal books or plates of up to 4 cm in diameter(!), and rarely in marble xenoliths. Found in the syenite pegmatites of *Kangerdluarsuk, Ilimaussaq, Greenland*, as tablets up to 10 cm in diameter(!); in the Oslo region, Norway; and the Kola Penin., Russia. AR *AM 53:1490(1968)*, *MR 21:330(1990)*.

71.2.2b.9 Taeniolite-1M,2M, $\text{KLiMg}_2[\text{Si}_4\text{O}_{10}]\text{F}_2$

Named in 1900 by Flink from the Greek for *band* or *strip*, in allusion to the tabular habit of the crystals. Mica group, biotite subgroup. 1M: MON *C2/m*.

$a = 5.231$, $b = 9.065$, $c = 10.140$, $\beta = 99.86^\circ$, $Z = 2$, $D = 2.84$. 31-1045(syn): 9.95₉ 4.98₄ 4.51₃ 4.48₃ 3.33₁₀ 3.11₃ 2.40₄ 1.995₃. 2M₁: MON C2/c. $a \approx 5.2$, $b \approx 9.1$, $c \approx 20$, $\beta \approx 95^\circ$, $Z = 4$. 12-236(syn): 10.0₈ 5.01₈ 4.52₈ 4.48₆ 3.61₈ 3.11₈ 2.60₁₀ 2.40₈. Structure: ZK 146:73(1977). The 1M polytype, for which there are detailed structure data, appears to be the most abundant, and a 3T polytype is also said to occur. Greenish brown, colorless, silvery; vitreous luster, pearly on cleavage; transparent to translucent. Cleavage {001}, perfect; flexible, somewhat elastic. $H = 2\frac{1}{2}$ -3 $\frac{1}{2}$. $G = 2.82$ -2.90. Biaxial (-); $2V = 2-5^\circ$; $N_x = 1.522$ -1.540, $N_y \approx N_z = 1.553$ -1.570; $Z = b$, X perpendicular to cleavage; $r > v$, also $r < v$. Weakly pleochroic; Z, pale yellow; X, colorless. Also uniaxial (-). Fusibility 3. May be regarded as a lithian phlogopite or magnesian lepidolite. Higher indices and darker color due largely to Fe²⁺ substitution for Mg. Occurs in nepheline-syenite pegmatites as tabular, pseudohexagonal crystals up to 5 cm in diameter and 0.5 cm thick. Found at Magnet Cove, Hot Spring Co., AR, and at Coyote Peak, Humboldt Co., CA. Occurs as thin lamellae and also as tapering pseudohexagonal prisms in breccia pipes and marble xenoliths at Mt. St.-Hilaire, PQ, Canada; at Narsarsuk, Greenland(1); and in the Lovozero massif, Kola Penin., Russia. AR AM 47:1049(1962), MR 21:342(1990).

71.2.2b.10 Zinnwaldite-1M,2M,3T $\text{KLiFe}^{2+}\text{Al}[\text{AlSi}_3\text{O}_{10}](\text{F,OH})_2$

Named in 1845 by Haidinger for the former name of the locality. Mica group, biotite subgroup. 1M: MON C2/m. $a = 5.296$, $b = 9.140$, $c = 10.096$, $\beta = 100.83^\circ$, $Z = 2$, $D = 2.99$. 42-604: 9.90₁₀ 3.35₆ 3.30₆ 3.09₅ 2.59₆ 1.655₅ 1.640₅ 1.578₅; also 42-1399. Structure: AM 62:1158(1977). Ordering of cations may lead to a decrease in symmetry to Cm. Zonal growth of 1M and 3T polytypes has been reported. Occurs as pseudohexagonal tabular {001} or short prismatic [001] crystals, often in clusters or rosettes; also as disseminated scales. Twinning according to the mica law common. Gray-brown, yellowish brown, less commonly green or pale violet; vitreous to pearly luster; transparent to translucent. Cleavage {001}, perfect yielding elastic, flexible sheets. $H = 2\frac{1}{4}$. $G = 2.90$ -3.02. Biaxial (-) $2V = 0-40^\circ$; or uniaxial (-); $N_x = 1.535$ -1.558, $N_y = 1.570$ -1.589, $N_z = 1.572$ -1.590; $r > v$, weak; for 1M type, $Y = b$, $Z \wedge a = 0-2^\circ$. Weakly pleochroic; $X < Y < Z$; colorless to yellow-brown or gray-brown. The octahedral site occupancy may be represented as $[\text{Li}_{0.5-1.5}\text{Fe}_{1.5-0.5}^{2+}(\text{Al, Fe}^{3+})]$ with commensurate substitution in tetrahedral sites to maintain charge balance. As with lepidolite, the octahedral sites may not be fully occupied. In addition, significant Mn may be present (up to ≈ 2.0 wt %), as well as minor Ti. Potassium dominates the interlayer cation sites, and fluorine usually predominates over the hydroxyl ion. Occurs in granite pegmatites and high-temperature hydrothermal tin-bearing veins. It is associated with other lithium minerals, cassiterite, tourmaline, fluorite, topaz, etc. Found at Amelia Court House, VA; in growth-zoned crystals at Wigwam Creek and in other localities, in the Pikes Peak batholith, CO; the

White-Picacho district, Maricopa Co., AZ; with masutomilite in miarolitic cavities in the Sawtooth batholith, ID; the York district, Seward Penin., AK; in the Mourne Mts., Ireland, and in the tin deposits of Cornwall, England; at Altenburg, Saxony, Germany, and at *Cínovec (Zinnwald)*, *Krusné Hory (Erzgebirge)*, *Czech Republic*; at Novara, Baveno, Italy; in Japan at Kurobera, Yamanshi Pref., Naegi, Gifu Pref., Tanokamiyama, Shiga Pref., and the Takazawa mine, Okayama Pref. Also at Laouni, Algeria, and at Virgem da Lapa, MG, Brazil. AR *ZK 97:519(1937)*, *MJJ 15:73(1990)*.

71.2.2b.11 Norrishite-1M $\text{KLiMn}_2^+[\text{Si}_4\text{O}_{10}]\text{O}_2$

Named in 1989 by Eggleton and Ashley for Keith Norrish of the Division of Soils, Commonwealth Scientific and Industrial Organization (Australia), in recognition of his contribution to layer-silicate research. Mica group, biotite subgroup. MON *C2/m*. $a = 5.289$, $b = 8.914$, $c = 10.062$, $\beta = 98.22^\circ$, $Z = 2$, $D = 3.21$. *PD*: 10.01₁₀ 4.46₅ 3.57₆ 3.33₈ 3.16₇ 2.62₅ 2.55₅ 2.37₆. Structure: *AM 76:266(1991)*. Black to dark brown, opaque to translucent. Cleavage {001}, perfect; {010}, {100}, poor. $H = 2\frac{1}{2}$. $G = 3.25$. Biaxial (+); $2V = 74^\circ$; ($2V_{\text{blue}} = 71^\circ$, $2V_{\text{red}} = 75^\circ$) for NaD: $N_x = 1.636$, $N_y = 1.687$, $N_z = 1.785$; optic axis dispersion strong with $r > v$. Pleochroic; X, yellow; Y, lime- to olive-green; Z, yellow-brown; color zoning is evident for Y. The composition is close to the ideal; the water content is the lowest for all analyzed micas and is consistent with the high octahedral layer charge. Occurs as millimeter-size crystals in rock-forming amounts on the *dumps of the abandoned Hoskins mine, 3 km W of Grenfell, NSW, Australia*, where it is associated with manganoean alkali clinopyroxene, pectolite-serandite, braunite, Ca and Ba carbonates, albite, K-feldspar, quartz, and barite. AR *AM 74:1360(1989)*.

71.2.2b.12 Masutomilite-1M, 2M₁ $\text{K}(\text{Li,Al,Mn}^{2+})_3[(\text{Si,Al})_4\text{O}_{10}](\text{F,OH})_2$

Named in 1976 by Harada et al. for Kazunosuke Masutomi, Japanese pharmacist and prominent amateur mineralogist and mineral collector. Mica group, biotite subgroup. 1M: MON *C2/m*. $a = 5.262$, $b = 9.102$, $c = 10.094$, $\beta = 100.83^\circ$, $Z = 2$, $D = 2.94$. *29-822*: 10.10₇ 4.99₃ 3.64₄ 3.35₇ 3.32₁₀ 3.09₆ 2.90₃ 1.989₅. Structure: *MJJ 13:13(1986)*. Pale purplish pink, vitreous to pearly luster, transparent to translucent. Cleavage {001}, perfect. $H = 2\frac{1}{2}$. $G = 2.94$. Biaxial (-); $2V = 29-31^\circ$; $N_x = 1.534$, $N_y = 1.568$, $N_z = 1.570$; $Y = b$, $Z \wedge a = 3^\circ$; $r > v$, weak. Pleochroic; $Y > Z = X$; pale purple to colorless. Found with zinnwaldite in miarolitic cavities in the Sawtooth batholith, ID. Reported from a Li-pegmatite in western Moravia, *Czech Republic*. Occurs as druses and pseudo-hexagonal crystals up to 3 cm in diameter and 1 cm thick, associated with topaz, schorl, albite, and quartz in the *Tanokamiyama district, Shiga Pref.*, and at Tawara, Gifu Pref., *Honshu, Japan*. AR *MJJ 8:95(1976)*, *AM 63:594(1977)*.

71.2.2b.13 Sodium Phlogopite NaMg₃[AlSi₃O₁₀](OH)₂

Named in 1980 by Schreyer et al. from the composition and relationship to phlogopite. Mica group, biotite subgroup. An inadequately described species. MON Space group unknown, probably C2/m. No lattice constants or X-ray diffraction patterns are documented. Silvery. Cleavage {001}, perfect. The average composition of 10 microprobe analyses is very close to the ideal. Occurs as minute flakes, rimmed by normal phlogopite in a massive, sugary dolomite with albite, talc, mixed-layer talc-chlorite, pyrite, and rounded tourmaline grains in a metamorphic evaporite sequence at *Derug, Tell Atlas, Algeria*. AR *CMP* 74:223(1980).

71.2.2b.14 Wonesite-1Md (Na,K)_{0.5}□_{0.5}(Mg,Fe²⁺)_{2.5}Al_{0.5}[AlSi₃O₁₀](OH,F)₂

Named in 1981 by Spear et al. for David R. Wones (1932–1984), Professor of Geology, Virginia Polytechnique Institute. Mica group, biotite subgroup. Also referred to as sodium phlogopite, but distinct from it in having a deficiency of interlayer alkali ions. MON C2/m. $a = 5.312$, $b = 9.163$, $c = 9.825$, $\beta = 103.18^\circ$, $Z = 2$, $D = 2.875$. Partial structure data support the partial occupancy of the interlayer cation sites. Irregular cleavage plates; twinned on (001) with [310] twin axis; (001) epitactic intergrowths with phlogopite and talc. Brown, vitreous luster, transparent to translucent. Cleavage {001}, perfect. Biaxial (–) $2V = 0-5^\circ$; or uniaxial (–); $N_x = 1.544$, $N_y = N_z = 1.608$. Pleochroic; X, pale brown; Y,Z, dark brown. Closely resembles phlogopite in thin section, but distinguished in thin section by slightly lighter color where the two occur together. Occurs as a rock-forming component of metamorphosed Ordovician Post Pond volcanics in the southwestern corner of the *Mt. Cube quadrangle, VT*. AR *AM* 66:100(1981).

71.2.2b.15 Preiswerkite-1Md, 2M₁ NaMg₂Al[Al₂Si₂O₁₀](OH)₂

Named in 1980 by Keusem and Peters for H. Preiswerk (1876–1940), Basel, Switzerland. Mica group, biotite subgroup. 1Md: MON C2/m. $a = 5.227$, $b = 9.049$, $c = 9.804$, $\beta = 100.23^\circ$, $Z = 2$. 42:605: 9.65₈ 4.50₃ 3.22₉ 2.57₁₀ 2.46₃ 2.12₄ 1.508₈ 1.488₄. 2M₁: MON C2/c. $a = 5.22$, $b = 9.05$, $c = 19.42$, $\beta = 95.17^\circ$, $Z = 4$, $D = 2.94$. 33-1259: 9.64₅ 4.52₆ 3.22₅ 2.78₅ 2.57₁₀ 2.46₇ 2.15₆ 1.508₁₀. Structure: *IMA* 355(1990). Pale green, colorless; vitreous luster; transparent. Cleavage {001}, perfect. $H = 2\frac{1}{2}$. $G = 2.96$. Biaxial (–); $2V = 5-7^\circ$; $N_x = 1.560$, $N_y = 1.614$, $N_z = 1.615$. Found as platy grains up to 1 mm in nodular aggregates of Al-pargasite and zoisite in a rodingite dike in the *Geisspfad ultramafic complex, Binntal, Valais, Switzerland*. AR *AM* 65:1134(1980), *MSARM* 13:582(1984).

71.2.2b.16 Ephesite-2M₁,1M NaLiAl₂[Al₂Si₂O₁₀](OH)₂

Named in 1851 by Smith for the locality. Mica group, biotite subgroup. MON C2/c. $a = 5.120$, $b = 8.853$, $c = 19.303$, $\beta = 95.08^\circ$, $Z = 4$, $D = 2.97$. *PD*: 9.63₆ 4.40₈ 3.21₆ 2.54_{10b} 2.41₈ 2.09₅ 1.605₄ 1.479₁₀; also 19-1181; 35-423(syn): 9.61₈

4.38₇ 3.26₄ 3.20₁₀ 3.14₄ 2.52₉ 1.479₇ 1.473₅. Structure: *NJMM 275(1987)*. The 2M₁ polytype appears to be the more common, but most recent structure studies assign it to space group *P1*. $a = 5.123$, $b = 8.872$, $c = 19.307$, $\alpha = 89.97^\circ$, $\beta = 95.15^\circ$, $\gamma = 89.96^\circ$, which would properly be called a 2A polytype. Forms indistinct crystals up to 13 mm in diameter and 10 mm long, and as flakes up to 5 mm in diameter; often twinned by rotation about [310] or [310]. Pink to pinkish brown; vitreous luster, pearly on perfect {001} cleavage; translucent. Brittle. $H = 3\frac{1}{2}$ – $4\frac{1}{2}$. $G = 2.84$. Biaxial (-); $2V = 18$ – 28° ; $N_x = 1.592$ – 1.595 , $N_y = 1.624$ – 1.625 , $N_z = 1.625$ – 1.627 ; $Z = b$, $Y \wedge a = 7^\circ$; $r < v$. Although the brittleness and relatively high hardness suggest that the species should be grouped with the brittle micas, unlike them, the triple-layer charge is only 1^- and the alkaline earth content is low. Found in the Ilimaussaq complex, Greenland; in the emery deposit at *Gumuchdagh, Ephesus, near Izmir, Turkey*; with manganoan diaspore, braunite, and bixbyite in the Postmasburg district, South Africa. *AR AM 52:1689(1967)*, *MSARM 13:581(1984)*, *CMP 85:74(1984)*.

71.2.2c.1 Margarite-2M₁, CaAl₂[Al₂Si₂O₁₀](OH)₂

Named prior to 1823 by Fuchs, from the Greek for *pearl*, in allusion to the pearly luster of its platy aggregates. Mica group, margarite subgroup. *MON C2/c*. $a = 5.108$, $b = 8.844$, $c = 19.156$, $\beta = 95.48^\circ$, $Z = 4$, $D = 3.069$. *18-276*: 3.18₁₀ 3.12₁ 2.52₂ 2.51₂ 2.41₁ 1.908₃ 1.903₂ 1.466₂. Structure: *ZK 165:295(1983)*. Dioctahedral, the Ca analog of muscovite, but with some buckling of the basal oxygens of the sheets due to anion repulsion where the smaller interlayer cations bring oxygens of adjacent sheets into proximity. Rarely as tabular {001} pseudo-hexagonal crystals; more commonly as random platy aggregates or scaly masses. Twinning according to the mica law common. Light pink to grayish pink, pale yellow, pale green; pearly luster on cleavage; transparent to translucent. Cleavage {001}, perfect, yielding inflexible plates; brittle. $H = 3\frac{1}{2}$ – $4\frac{1}{2}$ on {001}, $H = 6$ perpendicular to {001}. $G = 3.0$ – 3.1 . Biaxial (-); $2V = 40$ – 67° ; $N_x = 1.630$ – 1.638 , $N_y = 1.642$ – 1.648 , $N_z = 1.644$ – 1.650 ; $Z = b$, $Y \wedge a = 6$ – 8° ; $r < v$; pleochroism very weak to absent. Fusible with great difficulty. Only partially decomposed by boiling acids. Most margarite is close to the end-member composition. Ca may be replaced by minor Ba, Sr, and K, and by significant Na. In the latter case the charge balance may be restored by replacing some tetrahedral Al by Si and thus forming a solid solution with paragonite, or by excess (OH)⁻ as suggested by some published analyses. Fluorine is rarely present. Typically occurs in metamorphic emery (corundum) deposits; also in chlorite and mica schists with staurolite and schorl. Noteworthy localities are at the Emery mines, Chester, Hampden Co., MA, with corundum, magnetite, and diaspore; at Corundum Hill, Chester Village Green, and Delaware Co., PA; chromian at Line pit, State Line district, MD; near Buck Creek, Clay Co., NC; with corundum near Meadow Valley, Plumas Co., CA. Found at *Zillertal, Tyrol, Austria*; sodian margarite at a pegmatite–amphibolite intrusion bound-

ary at Mt. Yatyrgvata, northern Caucasus, Russia; at the Shin-Kiura mine, Oita Pref., Japan; embedded in corundum at Gibraltar, WA, Australia. AR *DHZI* 3:95(1962), *AM* 63:186(1978).

71.2.2c.2 Clintonite-1M, 2M₁, CaMg₂Al[Al₃SiO₁₀](OH)₂

Named in 1843 by Mather for DeWitt Clinton (1769–1828), American lawyer and statesman who had an interest in the geological sciences. Mica group, margarite subgroup. Synonymous with xanthophyllite, although earlier use applied this term to material with OAP parallel to {010} (1M), and clintonite was reserved for that with OAP perpendicular to {010} (2M₁). 1M: MON C2/m. $a = 5.204$, $b = 9.013$, $c = 9.814$, $\beta = 100.26^\circ$, $Z = 2$, $D = 3.12$. 20-321: 9.68₅ 3.21₇ 2.56₁₀ 2.45₅ 2.37₄ 2.11₇ 1.505₆ 1.485₅. Structure: *AM* 73:365(1988). A trioctahedral mica; as with margarite there is considerable distortion of the layer units. Crystals tabular {001} and pseudohexagonal; lamellar, in foliated or radiating, massive aggregates. Twinning according to the mica law. Colorless, pale yellow to greenish yellow, orange to reddish brown; uncolored streak or pale tan for darker varieties; vitreous to pearly luster, sometimes submetallic; transparent to translucent. Cleavage {001}, perfect, yielding inflexible plates; brittle. $H = 3\frac{1}{2}$ parallel to {001}, $H = 6$ perpendicular to {001}. $G = 3.0$ – 3.1 . Biaxial (-); $2V = 0$ – 32° ; $N_x = 1.643$ – 1.649 , $N_y = 1.655$ – 1.662 , $N_z = 1.655$ – 1.663 ; $Y = b$ for 1M, $Z = b$ for 2M₁; $r < v$ weak. Pleochroism absent to weak, $X < Y = Z$, colorless to green or brown. Most clintonites have slightly less Si and more Al than the formula above, and thus represent a high degree of substitution of Al in tetrahedral sites. Aluminum is also present in about one-fourth to one-third of the octahedral sites. Fe²⁺ and Fe³⁺ also substitute in octahedral sites. Sodium may replace calcium, and fluorine is usually absent. Clintonite occurs with talc in chlorite schists and in metasomatized limestones with spinel, grossular, vesuvianite, diopside, and minerals of the humite group. Found at *Amity*, Orange Co., NY; in metamorphosed diorite at the Christmas mine, Gila Co., AZ; with blue calcite and monticellite at Crestmore, Riverside Co., CA; at Prince of Wales Is., AK. Found at Pargas, Finland; on Mt. Monzoni, Val di Fassa, Trentino, and Vacca Lake, Adamello, Italy; in the Shiskimskaya Mts., near Zlatoust, and near Achmatovsk, both in southern Ural Mts., Russia. AR *DHZI* 3:99(1962), *AM* 71:1194(1986).

71.2.2c.3 Bityite-2M₁, CaLiAl₂[BeAlSi₂O₁₀](OH)₂

Named in 1908 by Lacroix for the type locality. Mica group, margarite subgroup. MON C2/c. $a = 5.058$, $b = 8.763$, $c = 19.111$, $\beta = 95.39^\circ$, $Z = 4$, $D = 3.05$. 11-400: 4.29₆ 3.14₈ 2.48₁₀ 2.36₆ 2.04₉ 1.878₇ 1.570₆ 1.450₁₀. Structure: *AM* 68:130(1983). Colorless, white, yellow, brownish; vitreous luster; transparent. Cleavage {001}, perfect. $H = 5\frac{1}{2}$. $G = 3.02$ – 3.07 . Biaxial (-); $2V = 35$ – 52° ; $N_x = 1.643$ – 1.651 , $N_y = 1.652$ – 1.659 , $N_z = 1.654$ – 1.661 . X perpendicular to cleavage; cleavage plates commonly divided into six sectors, with lamellar twinning visible in each sector. Insoluble in acids. Easily fusible.

Occurs sparingly in lithium pegmatite as crusts and small scales sometimes with hexagonal outline. Found at Strickland quarry, Portland, CT; at the Foote mine, Kings Mt., Cleveland Co., NC, and the Harding pegmatite, Taos Co., NM; with albite, beryl, bavenite, columbite, and cassiterite at Londonderry, WA, Australia; at *Maharitra, Mt. Bity, Madagascar*, with pink tourmaline, albite, and lepidolite. AR DT: 657(1932), ZK 107:325(1956).

71.2.2c.4 Anandite-2M₁, 2O (Ba,K)(Fe²⁺,Mg,Fe³⁺)₃[(Si,Fe³⁺)₄O₁₀](OH,S)₂

Named (2M₁) in 1967 by Pattiaratchi et al. for Ananda Kentish Coomaraswamy (1877–1947), first director of the Mineral Survey of Ceylon (Sri Lanka). Polytype 2O described in 1972 by Giuseppetti and Tadini. Mica group, margarite subgroup. 2M₁: MON C2/c. $a = 5.412$, $b = 9.434$, $c = 19.953$, $\beta = 94.87^\circ$, $Z = 4$, $D = 3.97$. 19-78: 9.92₆ 4.99₉ 3.32₁₀ 2.72₅ 2.68₄ 2.49₈ 1.991₃ 1.660₃. 2O: ORTH Pnmm. $a = 5.439$, $b = 9.509$, $c = 19.878$, $Z = 4$, $D = 4.22$. 38-423: 3.43₄ 3.31₃ 3.04₄ 2.71₁₀ 2.64₄ 2.11₄ 1.607₄ 1.357₃. Structure: AM 70:1298(1985). Detailed structural data are available for the 2O polytype, the more common of the two. The usual Ccmm symmetry of the standard 2O polytype is reduced to Pnmm, due to the ordering of Fe³⁺ and Si in tetrahedral sites, Fe²⁺ and Mg in octahedral sites, and the (OH) and S anions. The 1M polytype has also been reported from the type locality. Black, nearly opaque. Cleavage {001}, perfect. $H = 3-4$, $G = 3.94$. Biaxial (+?); $N_y = 1.855$, $N_z > 1.88$; $Y = b$, $Z \wedge a = 12^\circ$. Pleochroic; Y, green; Z, brown. Sulfur occupies about one-half of the sites normally occupied by (OH), and significant chlorine and minor fluorine are also present; Fe³⁺ occupies approximately one-third of the tetrahedral positions as well as $\approx 10\%$ of the octahedral sites. Tentatively identified in the Rush Creek–Big Creek area, Fresno Co., CA. Both polytypes are found as 1- to 5-cm-thick bands and lenses in iron ore at the *Wilagedera prospect, North Western Prov., Sri Lanka*, where it is associated with magnetite, chalcopyrite, pyrite, and pyrrhotite. AR MM 36:1(1967), TPM 18:169(1972).

71.2.2c.5 Kinoshitalite-1M (Ba,K)(Mg,Mn²⁺,Al)₃[Al₂Si₂O₁₀](OH)₂

Named in 1973 by Yoshii et al. for Kameki Kinoshita (1896–1974), Japanese geologist at Kyushu University and investigator of ore deposits of Japan. Mica group, margarite subgroup. MON C2/m. $a = 5.345$, $b = 9.250$, $c = 10.256$, $\beta = 99.99^\circ$, $Z = 2$, $D = 3.33$. 29-180: 10.1₄ 5.05₅ 3.37₁₀ 3.16₁ 2.93₁ 2.52₅ 2.02₅ 1.684₁. Structure: MJJ 12:1(1984). The structure is of 1M polytype. Yellow-brown, vitreous luster, translucent. Cleavage {001}, perfect. $H = 2\frac{1}{2}-3$. $G = 3.30$. Biaxial (-); $2V = 23^\circ$; $N_x = 1.619$, $N_y = 1.633$, $N_z = 1.635$. Weakly pleochroic; X, very light yellow; Y, Z, yellow. Type material contains (wt %): BaO, 17.8; K₂O, 3.3; MnO, 7.4; Mn₂O₃, 3.2. Reported from Trumbull Peak, Mariposa Co., CA, and at Netra, Balghat district, Madhya Pradesh, India. Found at Hokkejino, Kyoto Pref., Honshu, and in the *Misago orebody, Noda-Tamagawa mine, Iwate Pref., Honshu, Japan*, where

it occurs as < 1-mm scales associated with celsian, quartz, spessartine, rhodinite, chalcopyrite, and pyrrhotite in hausmannite-tephroite ore. *AR AM* 60:486(1975), 74:200(1989).

71.2.2d.1 Hydrobiotite $[K(Mg,Fe)_3Si_3AlO_{10}(OH)_2]\{Mg_{0.35\pm}(H_3O_{16,12,8,3,o})\}(Mg,Fe)_3Si_3AlO_{10}(OH)_2]$

Named in 1882 by Schrauf for its relationship to biotite; redefined in 1980. Mica group. Synonyms: hydromica, jefferisite, vermiculite (71.2.2d.3). ORTH Space group unknown. $a = 5.2$, $b = 9.0$, $c = 23.3-25.5$. Also given as HEX $Z = 1?$. *PD*(oriented flake): 24.3₁ 12.23₆ 8.27_{<1} 4.91₃ 3.49₅ 3.07₁₅ 2.73₂ 2.04₂; *PD*(oriented powder): 23.6₂ 12.26₁₀ 8.18_{<1} 4.88₁₅ 3.50₅ 3.05₂ 2.73₁ 2.04₁₅. *AM* 68:420(1983). Hydrobiotite is a regularly interstratified 24- to 25-Å phyllosilicate with biotite and trioctahedral vermiculite layers. X-ray diffraction data nearly nonexistent except for basal reflections. **Habit:** Generally fine-grained, then earthy to indurated, sometimes 2–5 μm, but can be to several centimeters. **Physical properties:** Golden yellow to golden brown, rarely brownish black; white to tan streak, sometimes stained; dull to waxy luster, also pearly to bronzy on cleavages. Cleavage {001}, perfect; flexible, but inelastic, almost brittle. Partly decomposed by strong mineral acids. $H = 1-2$. **Chemistry:** The chemical distinction between hydrobiotite and biotite or vermiculite resides in the intermediate water contents and intermediate K_2O and Fe_2O_3 values compared with pure biotite or pure vermiculite. The mica layer is typically ferruginous phlogopite. *AM* 68:420(1983). The vermiculite layer is probably hypersilicic, as with vermiculite proper. CEC of hydrobiotite is about 50–75 meq per 100 g, ammonium is absorbed from soils. *MA* 78:4853(1977). The anion-exchange capacity should be about 2 meq per 100 g. Interlayer charge deficiency could be slightly compensated by conversion of OH^- to O^{2-} . Many of the data on “hydrobiotite” were collected on materials without demonstrating their 1:1 interstratification requirement. **Optics:** Biaxial (-); $N_y = 1.560-1.562$, $N_z = 1.565-1.567$; $2V \approx 10^\circ$; birefringence = 0.045–0.055; yellow-brown, brown, greenish brown, pleochroic in yellows, browns, or greens. Optical data on hydrobiotite are insufficient. **Occurrence:** Found in a wide variety of sedimentary environments and frequently coexisting with a variety of clay minerals, including biotite, vermiculite, smectites, chlorites, and so on. Hydrobiotite is frequently an important-to-exclusive component of commercial “vermiculite.” Hydrobiotite has been synthesized from vermiculite. *CCM* 41:580(1993). **Tests:** Hydrobiotite d_{001} collapses to 10 Å when heated to 500° with disappearance of 14- and 7-Å peaks. The d_{001} of hydrobiotite should not change more than negligibly upon glycolation, but smectite can be randomly present, giving false values. K-intersalination collapses d_{001} to 10 Å with loss of 14- and 7-Å peaks. The original locality does not contain a predominance of hydrobiotite as redefined, but contains mostly vermiculite and biotite mixed with a small quantity of hydrobiotite. **Localities:** Well-studied hydrobiotite localities include: Brintons quarry, West Chester, Chester Co., PA; Enoree, Spartan-

burg Co., SC; Rainy Creek deposit, Libby, Lincoln Co., MT; Chanon granite, Montebras, Creuse, France; Fosso Pisciareello and Fosso di Monte Acuto, Monti Ernici, Lazio, Italy; Haugabreen and Austerdalsbreen regions, Norway; Schoeninger Mt., Stupna near Kremza, Czech Republic; northwestern and northeastern Transvaal, South Africa. VK, EF

71.2.2d.2 Illite $[K,(H_3O^+)]Al_2[Si_3AlO_{10}](OH)_2$

Named in 1937 by Grim et al. for the locality. Synonyms: hydromuscovite, hydromica, gümbelilite. *MON* $C2/m$, $C2/c$, or Cc . $a = 5.19\text{--}5.225$, $b = 8.950\text{--}9.020$, $c = 9.95\text{--}10.447$, $\beta = 94.87\text{--}95.18^\circ$, $(101.47\text{--}101.68^\circ)$, $Z = 2, 4$, $D = 2.82\text{--}2.61$. $26\text{--}911(2M_1)$: 3.34_{10} 10.00_9 2.005_5 5.02_5 2.99_2 4.48_2 3.20_1 4.44_1 ; $29\text{--}1496(1M)$: 10.7_4 5.0_3 4.43_{10} 3.66_4 3.33_4 3.06_4 2.56_9 1.50_4 . Illite is characterized as a 10-A phyllosilicate and is generally a dioctahedral degradation product of muscovite, while trioctahedral "illites" are usually hydrobiotites; extensive alteration of illite can produce a dioctahedral vermiculite (HIV-vermiculite, 71.2.2d.3). *SSAJ* $52:1486,1808(1988)$, *CCM* $40:32(1992)$. The illite structure is essentially the same as muscovite: two infinite sheets of pseudo-hexagonal rings of silicon-aluminum tetrahedra with unpolymerized apices directed toward and forming the coordination of a central set of octahedral sites occupied by aluminum, but some structural Mg has been suggested to be helpful in the generation of illite. The 2:1 structure has a net negative charge that is compensated by interlayer cations—originally potassium, but subsequently partially replaced by H_3O^+ . The interlayer potassium prevents significant intercalation by water or hydrated cations; however, intercalation by organic liquids has been accomplished. *AM* $54:858(1969)$. Revised polytype determination methods exist. *CCM* $41:45\ 389(1993)$. The most common polytype is 1Md with $2M_1$ and $2M_2$ very much less common and 3T rare. Layer stacking is disordered and reflections are broadened, but basal reflections are strong to distinct. Illite crystallinity decreases with lower K_2O . Frequently interstratified with smectite, chlorite, and others. **Habit:** Generally fine-grained, sometimes 2–5 μm , earthy to indurated. **Physical properties:** Gray-white, silvery-gray, gray-green, sometimes stained; white streak; dull to waxy luster. Cleavage $\{001\}$, perfect; flexible, but inelastic. $H = 1\text{--}2$. $G = 2.79\text{--}2.8$. Decomposed by strong mineral acids. **Chemistry:** Illite is $X_zY_3[(Si_{4-z}Al_z)O_{10}](OH, O)_2$; z is generally 0.5–0.7 and therefore might be hypersilicic. X, the interlayer site, is generally partly occupied by K and H_3O^+ ; K_2O is generally in the range 6–8 wt % and therefore usually distinctly lower than normal muscovite, and very low values are suggestive of interstratification by nonillitic layers, while illitic muscovite with 11.00 wt % K_2O has been reported from a Texas shale. Y is virtually always occupied by Al, but Mg, Fe^{2+} , and Fe^{3+} have been reported. The cation-exchange capacity of illite is about 10–40 meq per 100 g, while the anion-exchange capacity is generally negligible. Cation ion-exchange values higher than 15 might indicate the presence of nonillite layers. Interlayer charge deficiency can be slightly compensated by conversion of OH^- to O^{2-} . A series probably extends, by Na

substitution, to brammalite. Minor substitutions* include (wt %): TiO_2 , 1.92 (Grès à Voltzia); Fe_2O_3 , 4.99 (Fithian); FeO , 2.15 (Fithian); MnO , 1.58 (Grès à Voltzia); MgO , 4.2 (Grès à Voltzia); CaO , 3.0 (Grès à Voltzia); Cr_2O_3 , 14.6 (Takova); $(\text{NH}_4)_2\text{O}$, 4.90 (calculated, Llewellyn). Trace elements found (in ppm, Grès à Voltzia) include: Sr, 198; Ba, 487; V, 178; Ni, 71; Co, 13; Cr, 126; B, 251; Zn, 6; Ga, 39; Cu, 87; Pb, 45; Li, 93; Rb, 221. Can be found naturally intercalated by small amounts of "humic" molecules. (*Many illite analyses represent whole-rock or whole-sediment compositions. Due to concerns of sample species purity, analyses of illites must be made on well-characterized materials. Many high- Fe_2O_3 or high- MgO samples could contain hydrobiotite, etc.). Optics: Biaxial (-); $N_x \approx$ perpendicular to (001), most have $N_x = 1.535\text{--}1.572$, $N_y = 1.555\text{--}1.600$, $N_z = 1.565\text{--}1.605$; $2V$ generally $< 10^\circ$ ranging to 25° ; birefringence = 0.025–0.037; colorless, nonpleochroic. Dehydrated illite has slightly higher RI. Occurrence: Found in a wide variety of environments and frequently coexisting with a wide variety of minerals, including other micas, smectites, kaolinities, chlorites, vermiculite, and so on. Illite appears to have been formed by weathering or hydrothermal alteration of muscovite–phengite, but some illite is authigenic or could be derived from alteration of K-feldspars or recrystallization of smectites. Common in sediments, underclays, marls, shales, some slates. Illite from oil well drill cuttings increases in proportion with depth, apparently at the expense of kaolinite, and so on. Interstratified illite–smectite converts to illite at depth. *CCM* 41:26,119,134(1993). Low-grade metamorphism can convert illite to true muscovite. Observed altered to smectite or dioctahedral HIV–vermiculite. Tests: Illite does not change d values when heated to 500° ; basal spacings can be broad with widths = $0.6\text{--}1^\circ 2\theta$, d_{100} is asymmetrical with a low-angle "tail"; a slight basal peak shift is detected with glycol solvation. Sometimes confused with muscovite, sericite, glauconite, phengite, and others. Localities: Abundant worldwide; only selected localities with well-characterized materials are given here. Found at State College, Centre Co., Llewellyn and Pottsville formations, PA; *Maquoketa shale*, *Gilead*, *Calhoun Co.*, Salt Fork Creek, Fithian, Vermilion Co., Illinois Clay Products mine, Goose Lake area, Grundy Co., IL; Ouachita Mts., OK; Point Chevreuil and Atchafalaya Bay, LA; Marblehead, Fond du Lac Co., WI; Glacier National Park, MT; St. Austell, Cornwall, England; Ballater, Aberdeenshire, Scotland; Ogofau, Wales; Grès à Voltzia sandstone, Vosges Mts., France; Göschwitz, Thuringia, Germany; Saraspatak, Hungary; *Takova*, *Yugoslavia*; Candeias formation, Bahia, Brazil; Eureka mine, Cordoba Prov. and Barker, Buenos Aires Prov., Argentina; Nile delta, Egypt; Al-Habbaniya Lake, Iraq; Dhauladhar Mts., Siwaliks, India; Ichinomiya, Hyogo Pref., Japan; Tengchong, Yunnan Prov., China; Bidor, Perak, Indonesia. VK, EF

71.2.2d.3 Vermiculite $[\text{Mg}_{0.35+}(\text{H}_2\text{O})_{16,12,8,3,0}](\text{Mg},\text{Fe}^{3+})_3$
 $[\text{Si}_3(\text{Al},\text{Fe}^{3+})\text{O}_{10}](\text{OH})_2$

Named in 1824 by Webb for *vermiculor*, in allusion to the swelling property of the mineral: "I breed or produce worms." Synonyms: hydromica, jefferisite, hydrobiotite (71.2.2d.1). MON $C2/m$, $C2/c$, $C2$, or Cc . $a = 5.326\text{--}5.358$, $b = 9.18\text{--}9.28$, c (for Mg hydrates) = 20.6, 14.81, 14.36, 13.82, 11.59, 9.02, $\beta = 96.56\text{--}97.12^\circ$; for 2M vermiculite: $a = 5.24$, $b = 9.17$, $c = 28.60$, $\beta = 94.6^\circ$, $Z = 2$, $D = 2.26$. 16-613(2M nat): 14.2₁₀ 4.57₆ 2.85₃ 2.61₅ 2.57₅ 2.52₅ 2.36 -- 2.38₄ 1.53₇. Vermiculite is virtually always a trioctahedrally occupied 2:1 mica structure with interlayer water and generally a divalent, cation-exchangeable interlayer ion, usually Mg, rarely Ca. The interlayer cation is increasingly shown to be Al, which is nonexchangeable. Due to the inadequacy of the definition of vermiculite to accommodate the nonexchangeable variety, the term *HIV-vermiculite* (hydroxy-interlayer vermiculite) is sometimes used. *CCM* 40:335(1992), *SSAJ* 52:1486,1808(1988). The two-layer hydrate provides octahedral coordination for the interlayer cation. Fine-grained dioctahedral "vermiculite" is known. Vermiculites have a 2:1 layer charge = -0.6 to -1.5 . The distinction between vermiculite and smectite has been placed at a layer charge of -0.6 , but the significance of layer charges between -0.5 and -0.7 is not obvious. *CCM* 36:184(1988). Vermiculite stacking sequences are usually, at least partially, disordered. Additionally, interlayer cations are less regularly ordered than in the presumed parent mica; interlayer cations are fewer than the available sites and are frequently situated asymmetrically in the clefts of opposing bases of tetrahedra (usually occupied by Al), with repulsion effects dictating that occupied sites be interspersed with vacancies. Interlayer cations do not appear to migrate upon dehydration, although several interlayer cation sites exist. Domain-ordered Mg-hydrate vermiculite has been recognized, while some linear regularity of interlayer Ca has been suggested. Intercalated organic molecules show ordering. *AM* 55:1550(1970); *CCM* 32:223(1984), 40:240(1992). Parent mica polytypes are usually 1M, rarely 2M₁, 2M₂, or 3T, with interlayer cations of the vermiculite partly controlling the derivative polytype or stacking mode. *AM* 69:237(1984). Mössbauer spectroscopy indicated Phalaborwa vermiculite has 70% of its total Fe tetrahedral: $^{IV}\text{Fe}_{1.24}^{3+}$ vs. $^{VI}\text{Fe}_{0.39}^{3+} + ^{VI}\text{Fe}_{0.08}^{2+}$. *CCM* 39:467(1991). Partial interlayer water is easily lost or gained due to low or high relative humidity, respectively. Rapid intense heating (300°) of hydrated vermiculite generates interlayer steam, resulting in enormous volume expansion of the aggregate sample; structural Fe^{3+} sometimes partly reduced by dithionite-citrate-bicarbonate treatment; and dry grinding of vermiculite induces disorder of stacking. Vermiculite d_{001} is usually sensitive to external relative humidity and thermal conditions (see HIV-vermiculite), but the water exchangeability is also inversely proportional to grain size ($d_{001} = 11.59$ Å dehydrates very rapidly in dry air). When in a water-saturated medium, $d_{001 \text{ max}} = 14.81$ Å (indicating 16-13 interlayer H_2O), while vermiculite in a dry medium is considered fully hydrated (12-9 H_2O) when $d_{001} = 14.36$ Å. At

lower relative humidity and/or higher temperature, vermiculite can dehydrate to $d_{001} = 13.82 \text{ \AA}$ (8–9 H_2O) with an ordered double water molecule interlayer sheet, then to $d_{001} = 11.59 \text{ \AA}$ (8–3 H_2O), indicating a single water molecule layer. Near dehydration (less than 3 H_2O), alternate layers contain single water molecule layers and water-free layers yielding $d_{001} = 20.6 \text{ \AA}$ before becoming exclusively dehydrated with $d_{001} = 9.02 \text{ \AA}$. The actual interlayer region occupied by water is 4.98 \AA . The double hydrate interlayer superficially resembles the interlayer of chlorites, but with only one-sixth, or less, of the cation sites and two-thirds of the anion sites occupied. Hydrogen bonds link water molecules to silicate ring bases. During dehydration, b changes in step-wise fashion as d_{001} collapse occurs. Cation-exchanged vermiculites show spacings related to the kind or absence of interlayer hydration associated with the exchanged cation: Mg, 14.33–14.39 \AA ; Ca, 15.07 \AA ; Sr, 15.0 \AA ; Ba, 12.3–12.56 \AA ; Li, 12.2–12.56 \AA ; Na, 14.8–12.56 \AA ; K, 10.6–10.42 \AA ; NH_4 , 10.8–11.24 \AA ; Rb, 11.24 \AA ; Cs, 11.97 \AA . *AM 33:655(1948)*. TGA data: e.g., *CM 14:399(1976)*. Vermiculites which show a resistance to d_{100} collapse are usually attributed to a propping effect of hydroxy-interlayer polymers (HIV; $[\text{Al}_{13}\text{O}_4(\text{OH})_{24}(\text{H}_2\text{O})_{12}]^{7+}$). Vermiculite sheets regularly interstratified with other structures are very common and have been treated as separate materials (e.g., vermiculite–biotite = hydrobiotite; vermiculite–smectite = HLC corrensite; vermiculite–chlorite = LLC corrensite). **Physical properties:** Generally foliated, crystals rare. Flaky (many centimeters) to fine-grained earthy, sometimes 2–5 μm . Gray-white, golden brown, green to olive-green to brownish black; white streak; oily to earthy luster, frequently bronzy. $H = 1\text{--}2$. $G = 2.28\text{--}2.77$. Cleavage $\{001\}$, perfect; flexible, but generally inelastic. **Chemistry:** Vermiculites can be chemically indistinguishable from some smectites or can range to hydrobiotite. A general formula for trioctahedral vermiculite is $\text{X}_{1-z}\text{Y}_3(\text{Si}_{4-z}[\text{Al}, \text{Fe}^{3+}]_z)\text{O}_{10}(\text{OH})_2$. z is generally 0.5–0.7. X, the interlayer site, is generally occupied by Mg plus a double (16–9 H_2O) or single water layer (8–3 H_2O). Y can be occupied by Mg, Fe^{2+} , Fe^{3+} , Al, and so on. The cation-exchange capacity of vermiculite is about 100–150, to 260 meq per 100 g, while the anion-exchange capacity is about 4 meq. While much vermiculite contains dominant interlayer Mg, the interlayer composition can vary due to exchange similar to smectites. Ferric iron is almost invariably present, several wt % to 19.22 (Ukraine), while FeO is generally small, generally < 1.0 to 8.61 wt % (Westcliffe). Leaching of original interlayer K^+ in micas is usually compensated by interlayer Mg and is additionally compensated by low-temperature conversion of ferrous to ferric iron and/or conversion of hydroxyl to O^{2-} . CaO can replace interlayer MgO, generally < 1 wt %, but to 2.70 wt % (Saskatchewan). Additional substitutions (wt %) include TiO_2 , 2.23 (Saskatchewan); NiO, 11.25 (Webster); MnO, 0.22 (Maaninka); Na_2O , 0.39 (Rohrenhof); K_2O , 0.43 (Westcliffe); F, 0.05 (Rohrenhof). Vermiculites with natural 0.45 interlayer Ba (Llano) and 0.30 Ca (Malawi) have been observed. **Optics:** RI of vermiculite increases rapidly with increasing iron contents. Biaxial to pseudo-uniaxial, X approximately perpendicular to (001), sometimes pleochroic, green-brown. RI has been related to total iron

(DHZ). Uniaxial (-); $N_O = 1.540\text{--}1.648$, $N_E = 1.517\text{--}1.622$; birefringence = 0.019–0.026 (rarely to 0.047). Biaxial (-); $N_x = 1.520\text{--}1.622$, $N_y = 1.530\text{--}1.648$, $N_z = 1.530\text{--}1.651$; $2V = 0\text{--}8^\circ$, up to 18° ; birefringence = 0.020–0.029 (rarely to 0.047) ($Fe_2O_3 = 4.2\text{--}19.2$ wt %). **Occurrence:** Found in a wide variety of environments and frequently coexisting with a wide variety of minerals. Potassium fixation by vermiculite in soils is common. Frequently found as alteration fringes on phlogopite or hydrobiotite. Vermiculite appears to have usually formed by weathering or hydrothermal alteration of iron-bearing phlogopite or annite at temperatures generally 300° or below and frequently at surface conditions, usually at acid pH. HIV-vermiculite appears to form directly from a muscovite precursor. *CCM 40:32(1992)*. Observed to form from amphibole, rarely clinochrysotile. Mg has been suggested to diffuse from octahedra in the 2:1 layer into the interlayer. *JG 65:603(1957)*. Also found in a contact zone near felsic intrusives, including pegmatites. Parent rocks include basic and ultrabasic rocks, including kimberlites, also gneisses, schists, or Mg skarns. In some carbonatites, meta-limestone, and others. Uncommon in marine sediments due to frequent K^+ in pore fluids. Observed to alter to chlorite or clinochrysotile. *CCM 7:135(1960)*, *18:213(1970)*. **Tests:** Stepwise dehydration 14.81–9.02 Å characteristic; d_{100} more intense than lower orders (unlike chlorite or HIV-vermiculite); $d = 7$ Å remains on heating to 110° ; vermiculite is not permanently affected by heating until about 550° ; intercalation with glycol generally does not expand Mg-rich vermiculite beyond 14.5 Å; generally contracts, almost irreversibly, to $d = 10^+$ Å with K^+ intercalation. HIV-vermiculite 14-Å peaks broaden and shift to ~ 12 Å upon heating. Intercalation of *n*-alkylammonium ions has been used to estimate interlayer charge. *CCM 40:240(1992)*. **Localities:** Only localities with well-characterized and/or abundant amounts of vermiculite are mentioned here. Found at *Millbury, Worcester Co., MA*; Kent, CT; Brintons quarry, West Chester, Chester Co., PA; Bare Hills and Pilot, MD; Culsagee mine, Macon Co., Webster, NC; Tigerville, Greenville Co., coastal plain sediments, FL; Magnet Cove, AR; Texas magnesite quarry, Llano Co., TX; Westcliffe, Custer Co., CO; Rainy Creek mine, Libby, Lincoln Co., MT; Gold Butte, Virgin Mts., Clark Co., NV; Santa Cruz mine, Pinal Co., AZ; Stanleyville, Lanark Co., ONT, gray luvisol profile, SAS, Canada; Cerro de Pedregosa, Coahuila, Mexico; Prayssac, Aveyron, France; La Garrenchosa, Santa Olalla, Huelva; Benahavis and Ojen massif, Serrania de Ronda, Malaga; Ronquillo and Real de la Jara, Seville, Spain; Maaninka, Posio, Finland; Junosuando, Pajala, Sweden; Röhrenhof, Fichtberg, Bavaria, Kropfmühl bei Passau, Germany; Nova Ves, Czech Republic; Batn El-Ghoul, Jordan; Kovdorsk, Murmansk Oblast, Russia; Paulistana, Piaui; Catalao Deposit, Goias; and Pernambuco, Brazil; Wadi as Shati' deposit, Fazzan, Libya; Kapirikamodzi, Malawi; Kibara Formation, Shaba, Zaire; Palabora mine, Phalaborwa and Loolekop, Transvaal, South Africa; Pauni mine, Pauni, Maharashtra; and Sevvattur, Tiruppattur Taluk, Tamil Nadu, India; Matsusaka, Japan; Mud Tank deposit, Strangways Mts., Australia. *vk, EF CCM 35:203(1987)*, *39:174(1991)*, *36:481(1988)*; *AM 60:175(1975)*.

71.2.2.d.4 Brammallite $[\text{Na}_2(\text{H}_3\text{O}^+)]\text{Al}_2[\text{Si}_3\text{AlO}_{10}](\text{OH})_2$

Named in 1943 by Bannister for Alfred Brammall (b.1879), British geologist and mineralogist. Synonyms: sodium hydromica, sodium illite, hydroparagonite. *MON C2/c*. $a = 5.12\text{--}5.2$, $b = 8.91\text{--}9.0$, $c = 19.2\text{--}19.26$, $\beta = 95.83^\circ$, $Z = 4$, $D = 2.83\text{--}2.88$. $27\text{-}0020(2M_1)$: 9.77₁₀ 4.78₈ 4.41₉ 3.17₁₀ 2.54₉ 2.41₆ 2.11₆ 1.485₁₀. Brammallite is believed to be a degradation product of paragonite. The structure has not been determined but is believed to be essentially the same as that of paragonite: two infinite sheets of pseudo-hexagonal Si/Al rings with the unpolymerized apices directed toward and forming the coordination of a central set of octahedral sites occupied by Al. This 2:1 structure has a net negative charge which is compensated by interlayer cations—mostly Na, but partially replaced by H_3O^+ . Interlayer Na prevents significant intercalation by water or hydrated cations, but brammallite should behave similarly to illite. Generally fine-grained to visibly fibrous, sometimes 2–5 μm , earthy to indurated, sometimes unctuous. White to pale greenish white, white streak, dull to waxy luster. Cleavage {001}, perfect; flexible. $H = 1\text{--}2$. $G = 2.69$. Brammallites are generally intermediate in chemical composition (wt %): Na_2O , 4.66–5.85; K_2O , 2.58–2.70 or less. Significant substitutions (wt %) are few: Fe_2O_3 , 2.17 (Missouri); P_2O_5 , 0.45 (Kazakhstan). Minor elements detected include: Mn, Ni, Co, Ti, V, Zr, Cu, Pb, and Ga (all < 0.001 wt %, Kazakhstan). Data for brammallite are few. CEC probably similar to illite and interlayer charge deficiency could be compensated by conversion of OH^- to O^{2-} . A series probably extends, by K substitution, to illite. A mineral attributed to brammallite (Pilot Knob) is given as $(\text{Na}_{0.66}, \text{K}_{0.23})(\text{Al}_{1.04}, \text{Fe}_{0.01}^{3+})[(\text{Si}_{3.07}\text{Al}_{0.94})\text{O}_{10}(\text{OH})_{2.51}]$. *AM 20:384(1935)*. DTA (Pilot Knob) shows 0.3–0.4 wt % H_2O loss at 100–120° and 0.6–0.7 wt % loss by $\sim 375^\circ$; similar results found at different temperature for Kazakhstan brammallite. Biaxial (-); $N_x = 1.561\text{--}1.567$, $N_y = 1.58$, $N_z = 1.579\text{--}1.585$; 2V large; birefringence = 0.018°; nonpleochroic, colorless. Found in crevices in shale or weathered conglomerate (Missouri). Brammallite could have been formed by weathering or hydrothermal alteration of paragonite. Occurs at Pittsburgh coal seam, Pursglove, Monongalia Co., WV; Pilot Knob, Ironton, MO; *Llandebie, Dyfed, Wales*; Ordovician mudstone, northern Kazakhstan. *VK, EF MM 26:304(1943)*, *DANS-ESS 208:157(1973)*.

71.2.3.1 Cuprorivaite $\text{CaCu}[\text{Si}_4\text{O}_{10}]$

Named in 1938 by Minguzzi for the composition and for Carol Riva (1872–1902), mineralogist. Equivalent to the synthetic pigment Egyptian blue. *TR P4/ncc*. (Syn): $a = 7.30$, $c = 15.12$, $Z = 4$, $D = 3.09$. $12\text{-}512(\text{syn})$: 7.63₄ 3.78₉ 3.36₈ 3.29₁₀ 3.19₅ 3.00₉ 2.27₅ 1.831₆. Structure: *AC 12:733(1959)*. Silicate sheets lie parallel to {001}. Synthetic material habit is tabular {001} modified by {110}, and {102}; only {001} observed, but rarely, on natural material. Blue, vitreous luster, translucent. Cleavage {001}, perfect; brittle. $H = 5$. $G = 2.87\text{--}3.08$. Uniaxial (-); $N_O = 1.627\text{--}1.633$, $N_E = 1.590$. Pleochroic; O, blue; E, pale rose to pale yellow. Insoluble in HCl. Natural material slightly

hydrated in part. Found at Summit Rock, Douglas Co., OR; at Wheal Edward, Cornwall England; as minute, crude crystals with quartz at *Mt. Vesuvius, Campania, Italy*; the Eifel district, Germany; at Messina, Transvaal, South Africa. *AR AM 47:409(1962)*.

71.2.3.2 Gillespite $\text{BaFeSi}_4\text{O}_{10}$

Named in 1922 by W. T. Schaller for Frank Gillespie, who found the first specimen near his mining claim in Alaska. At high pressure (18–45 kbar) transforms to an orthorhombic phase. See cuprorivaite (71.2.3.1), the Ca-Cu analog. *TET P4/ncc*. $a = 7.5164\text{--}7.522$, $c = 16.0768\text{--}16.082$, $Z = 4$, $D = 3.40$. *37-472(nat)*: 8.06_{10} 4.44_4 4.02_4 3.55_4 3.41_6 3.21_8 2.75_3 2.39_5 . A layer silicate with four-membered rings of SiO_4^{4-} tetrahedra forming the basic building blocks. *AM 59:1166(1974)*. Micaceous scales and in aggregates; aggregates to 6 cm at Big Creek, CA. Red, rose; vitreous luster. Cleavage {001}, good; {100}, poor; {110}, indistinct. $H = 4$. $G = 3.33\text{--}3.40$. Spectral data: *JCP 47:4240(1967)*. Readily decomposed by HCl. Traces of Mn + Ti. Uniaxial (-); $N_O = 1.619\text{--}1.621$, $N_E = 1.617\text{--}1.619$. O, colorless; E, red. Synthetic has $N_O = 1.620$ and $N_E = 1.617$. Associated with sanbornite and other Ba-silicates at five localities in California and elsewhere. In contact zones of granitic intrusives, and metasomatic rocks. From a moraine in Alaska. Occurs at Trumbull Peak, Incline, Mariposa Co., CA; Rush Creek, Fresno Co., CA; crystals to 6 cm or more at Big Creek, Fresno Co., CA; *Dry Delta, Alaska Range, Alaska (100 miles SE of Fairbanks)*; Ross R., Yukon, and Gunn claim, Itsi Mtns, deposit, YT, Canada; La Madrelena mine, Tres Pozos, and Rosario, Baja California Norte, Mexico. *EF AM 69:358(1984)*, *MIN 4(2):454(1992)*.

71.2.3.3 Effenbergerite $\text{BaCu}[\text{Si}_4\text{O}_{10}]$

Described in 1994 by Giester and Rieck and named for Herta S. Effenberger, (b. 1954), mineralogist, University of Vienna, Austria. See cuprorivaite (71.2.3.1), $\text{CaCu}[\text{Si}_4\text{O}_{10}]$, and gillespite (71.2.3.2), $\text{BaFe}[\text{Si}_4\text{O}_{10}]$. *TET P4/ncc*. $a = 7.422$, $c = 16.133$, $Z = 4$, $D = 3.52$. *PD*: 8.06_{10} 4.03_4 3.54_3 3.20_4 2.69_2 2.39_4 2.02_3 1.95_2 . The structure consists of silicate sheets $[\text{Si}_8\text{O}_{20}]^{8-}$ parallel to (001) formed by corner linkage of silicate four-membered rings. The copper(II) atom is nearly planar four-coordinated; the barium atom has a distorted cube-like environment of oxygen atoms. *MM 58:663(1994)*. The mineral occurs as transparent blue ditetragonal dipyramidal platelets with a perfect cleavage parallel to {001} in sizes up to 8.0 mm × 8.0 mm × 0.1 mm; one very poor cleavage parallel to {110}. Forms: {001}, {100}, {110}, {102}. No twinning observed. Pale blue streak, vitreous luster on cleavage planes, resinous on crystal faces, and subvitreous on fracture surfaces. Subconchoidal fracture, brittle. $H = 4\text{--}5$. $G = 3.57$. Nonfluorescent. Insoluble in all common acids except HF. IR absorption spectrum given contains minor amounts of Al_2O_3 : 0.4–0.7 wt %. Uniaxial (-); $N_O = 1.633$, $N_E = 1.593$, $r > v$, weak. Strongly pleochroic; O, intense blue; E, colorless. A hydrothermal mineral,

effenbergerite occurs in the central-eastern orebody of the *Wessels mine in the Kalahari manganese field, northwestern Cape Prov., South Africa*. A matrix of braunite, sugilite, and hausmannite is cut by pectolite veinlets containing effenbergerite. Associated minerals are native copper, calcite, quartz, clinozoisite and two unknown species. EF

71.2.4.1 Ferrisurite ideally $(\text{Pb,Ca})_{2-3}(\text{CO}_3)_{1.5-2}(\text{OH,F})_{0.5-1}[(\text{Fe,Al})_2\text{Si}_4\text{O}_{10}(\text{OH})_2] \cdot n\text{H}_2\text{O}$

Named in 1992 by Kampf et al. for the composition and as an analogue of surite. Compare: surite. MON (pseudo-ORTH). $P2$ or $P2_1/m$. $a = 5.241\text{Å}$, $b = 9.076\text{Å}$, $c = 16.23\text{Å}$, $\beta = 90.03^\circ$, $Z = 2$, $D = 3.89$ (nat.) 16.1_4 5.40_{25} 4.53_{10} $3.73_{3.5}$ 3.24_9 2.61_8 2.27_5 $1.71_{2.5}$ (AM 77:1107(1992)). **Structure:** consists of smectite layers between which are cerussite- and hydrocerussite-like regions of variable composition (interlayer). Forest green, transparent; greenish yellow to olive green; fibrous, {010} is prominent; occurs in quartz and cerussite, crystals to 2 mm long on a , 0.001 mm on $b \times 0.04$ on c ; no twinning observed, fibers are very flexible; silky; $H = 2-2\frac{1}{2}$; $G = 4.01$; IR data = (AM 77:1107(1992)); no fluorescence observed in SW or LW; effervesces in cold 1:1 HCL leaving a gelatinous residue, Analysis (wt. %) Na_2O 0.3, MgO 0.2, CaO 3.4, FeO 0.8, BaO 0.1, PbO 42.7, Al_2O_3 3.2, Fe_2O_3 10.5, SiO_2 26.6, F 0.8, CO_2 8.2, H_2O 3.5, = 100.3. Biaxial (+); $2V = 76^\circ_{\text{calc}}$; $N_x = 1.757$, $N_y = 1.763$, $N_z = 1.773$; $X = \text{yellow}$, $Y = \text{brown}$, $Z = \text{light green}$; XYZ = cba. Occurs in an oxidized lead deposit in contact metamorphosed and faulted shaly limestone. Associated with galena, pyrite, chalcopyrite, covellite, chalcocite, quartz, calcite, hematite, cerussite, mimetite, wulfenite and malachite. Early stage oxidation mineral. Occurs at the *Shirley Ann claim, Ubehebe district, Inyo Co., CA*. EF, VK.

71.2.4.2 Surite $(\text{Pb,Ca})_{2-3}(\text{CO}_3)_{1.5-2}(\text{OH,F})_{0.5-1}[(\text{Al,Fe})_2(\text{Si,Al})_4\text{O}_{10}\text{OH}_2] \cdot n\text{H}_2\text{O}$

Named in 1978 by Hayase et al. for the locality. Compare: ferrisurite. MON $P2_1$ or $P2_1/m$. $a = 5.241\text{Å}$, $b = 8.95$, $c = 16.20$, $\beta = 90.0$, $Z = 2$; $D = 3.99$; PD (no ICDD card data), (nat.): 16.2_7 5.4_7 4.48_2 4.05_{10} 3.24_6 2.70 2.59_2 2.31_5 (AM 77:1107(1992)). Cell reported in 1978 (AM 63:1175(1978)) was: $a = 5.22$, $b = 8.97$, $c = 16.3$, $\beta = 96.1^\circ$. **Structure:** heating to below 550°C causes little change, at 550°C all X-ray peaks are weakened without changes in spacings. At 650°C all peaks disappear. White to pale green; streak white; tabular, lath-shaped; compact aggregates; twinning-not stated; 1 cleavage parallel to elongation {001}; $H = 2-3$; $G = 4.0$; IR, DTA and TGA data (AM 63:1175(1978)); effervesces in 0.75% HCl at 25°C , leaves gel-like residue. Na_2O 0.77, MgO 1.29, CaO 4.75, CuO 0.07, PbO 45.3, Al_2O_3 11.27, Fe_2O_3 0.41, SiO_2 23.58, CO_2 9.45, H_2O 3.72, FeO -, BaO -, F -, $\Sigma 100.63$. HCl treatment removes PbO & CO_2 , leaving smectite component. Equivalent to a 2:1 dioctahedral smectite interlayered with PbCO_3 . Biaxial (+); $2V$ - not determined, $N_x = 1.693$, $N_z = 1.738$; birefringence - 0.045-0.047; parallel extinction. Occurs at the

Cruz del Sur mine, Rio Negro Prov., Argentina; in oxidation zone of Pb–Zn–Cu deposits (fissure-filling veins). Associated with common secondary ore minerals. EF

71.2.5.1 Macaulayite $\text{Fe}^{3+}_{24}\text{Si}_4\text{O}_{43}(\text{OH})_2$

Named by Wilson et al. in 1984 for the Macaulay Institute for Soil Research. MON [C] $a = 5.038\text{Å}$, $b = 8.726\text{Å}$, $c = 36.34\text{Å}$, $\beta = 92^\circ$, $Z = 2$, $D = 4.41\text{--}4.52$; PD 42-596 (nat.): 36.6_{10} 18.2_{10} 4.38_{15} 3.70_{25} 2.72_{35} 2.53_{10} 2.21_2 1.46_{35} . IR response has been studied. Contracts to 34Å on heating to 300°C and expands to 40–41Å with glycerol or ethylene glycol. "The ideal formula is consistent with an arrangement consisting of twelve Fe octahedral sheets bounded by two Si tetrahedral sheets, corresponding essentially to a double hematite unit terminated on both sides by silicate sheets. Adjacent basal oxygen surfaces of these sheets are only weakly bonded, allowing structural expansion and the introduction of a layer of water molecules in the interlamellar space." (MM 48:127(1984). Bright red, earthy (2 micron subangular platelets), decomposed by HF. $N > 1.734$, birefringent?, {001} cleavage probable, pleochroism uncertain, pale red to yellow. Chemistry of type material (anhydrous totals), in wt. %: FeO 84.67; Al_2O_3 4.01; SiO_2 11.32; H_2O (TGA) 7.4 (apportioned 2.5 absorbed, 3.7 edge hydroxyl and interstitial water, and 1.2 structural hydroxyl). CEC = < 6 meq/100g. Found in red patches intimately associated with kaolinite and illite derived from deeply weathered granite. *Bennachie car park, 7 km NW of Inverurie, Aberdeenshire, Scotland, UK*. EF, VK, VK, CM 16:261(1981) MM 48:127(1984) Minerali 4(2):607(1992).

SMECTITE GROUP

The smectite group minerals are phyllosilicate "clay" minerals corresponding to the general formula

where

A = interlayer cation = Na, Ca, K, Li

M = octahedral t-o-t site = Al, Mg, Fe^{3+} , Cr^{3+} , Zn, Cu^{2+}

As with all phyllosilicates, the basic structural element is a *t-o-t layer* (tetrahedral–octahedral–tetrahedral layer, also called a 2:1 layer). The t-o-t layer is made up of two infinite sheets of (Si, Al) O_4 tetrahedra, linked together in nearly hexagonal rings, with the apical oxygens of one sheet facing the apical oxygens of the other sheet, thus creating nearly close-packed octahedral sites between the sheets. Octahedral sites may be fully occupied by divalent cations (thus producing *trioctahedral layers*), or they may be 2/3 occupied by trivalent cations (which produces *dioctahedral layers*). Subgroup designations are based on this octahedral site occupancy.

By substituting Al^{3+} for Si^{4+} in the t-o-t layer tetrahedra, the oxygen atoms of the surfaces of the layer can acquire a net negative charge. Charge may also arise from other causes: substitution in the octahedral sites (e.g., $\text{Mg} \leftrightarrow \text{Al}$). In the smectite group minerals, total layer charge below -0.25 is rare, -0.3 to -0.35 is normal, and above -0.6 is again rare.

In the smectite group structures, the interlayer space between two t-o-t layers is occupied by water molecules and the A cations. The number of water molecules depends on the circumstances, and the spacing between the layers can vary from about 9.6 Å in the completely dehydrated situation, to about 12.5 Å for a single water molecule layer, to 14.5–15.5 Å for a two-water-molecule layer (normal air-dried), up to ≈ 18 Å for three water molecules.

SMECTITE GROUP: DIOCTAHEDRAL SUBGROUP

Mineral	Formula	
Beidellite	$(\text{Na}, \text{Ca}_{0.5})_{0.33} \text{Al}_2 [\text{Si}_{3.5} \text{Al}_{0.5} \text{O}_{10} (\text{OH})_2] \cdot n \text{H}_2\text{O}$	71.3.1a.1
Montmorillonite	$(\text{Na}, \text{Ca}_{0.5})_{0.33} (\text{Al}, \text{Mg})_2 [(\text{SiAl})_4 \text{O}_{10} (\text{OH})_2] \cdot n \text{H}_2\text{O}$	71.3.1a.2

Volkonskoite	$(\text{Ca}_{0.5})_{0.33} (\text{Cr}^{3+}, \text{Mg}, \text{Fe}^{3+})_2 [\text{Si}_{3.5} \text{Al}_{0.5} \text{O}_{10} (\text{OH})_2] \cdot 4 \text{H}_2\text{O}$	71.3.1a.4
Swinefordite	$(\text{Li}, \text{Ca}_{0.5} \text{Na})_{0.33} (\text{Li}, \text{Al}, \text{Mg})_2 [(\text{SiAl})_4 \text{O}_{10} (\text{OH}, \text{F})_2] \cdot 2 \text{H}_2\text{O}$	71.3.1a.5

SMECTITE GROUP: TRIOCTAHEDRAL SUBGROUP

Mineral	Formula	
Hectorite	$(\text{Na}, \text{Ca}_{0.5})_{0.33} (\text{Mg}_{2.67} \text{Li}_{0.33}) [\text{Si}_4 \text{O}_{10} (\text{F}, \text{OH})_2] \cdot n \text{H}_2\text{O}$	71.3.1b.1
Pimelite	$(\text{Ca}_{0.5}, \text{Na})_{0.33} \text{Ni}_3 [\text{Si}_4 \text{O}_{10} (\text{OH})_2] \cdot n \text{H}_2\text{O}$	71.3.1b.2
Saponite	$(\text{Ca}_{0.5}, \text{Na})_{0.33} (\text{Mg}, \text{Fe}^{2+})_3 [\text{Si}_{3.5} \text{Al}_{0.5} \text{O}_{10} (\text{OH})_2] \cdot 4 \text{H}_2\text{O}$	71.3.1b.3
Sauconite	$(\text{Na}, \text{Ca}_{0.5})_{0.33} \text{Zn}_3 [(\text{Si}_{3.5} \text{Al}_{0.5}) \text{O}_{10} (\text{OH})_2] \cdot 4 \text{H}_2\text{O}$	71.3.1b.4
Stevensite	$(\text{Ca}_{0.5})_{0.33} (\text{Mg}, \text{Fe}^{2+})_3 [\text{Si}_4 \text{O}_{10} (\text{OH})_2] \cdot 4 \text{H}_2\text{O}$	71.3.1b.5
Sobotkite	$(\text{Na}, \text{Ca}_{0.5})_{0.33} (\text{Mg}_2 \text{Al}) [\text{Si}_3 \text{Al} \text{O}_{10} (\text{OH})_2] \cdot 5 \text{H}_2\text{O}$	71.3.1b.6
Yakhontovite	$(\text{Ca}, \text{K})_{0.5} (\text{Cu}^{2+}, \text{Fe}^{3+})_{2.37} [\text{Si}_4 \text{O}_{10} (\text{OH})_2] \cdot 3 \text{H}_2\text{O}$	71.3.1b.7
Zincsilite	$\text{Zn}_3 [\text{Si}_4 \text{O}_{10} (\text{OH})_2] \cdot 4 \text{H}_2\text{O}$	71.3.1b.8

Note: Smectites constitute a major industrial mineral group, with consumption of millions of metric tons annually, principally montmorillonite and beidellite. Many uses take advantage of the thixotropic effects, where a stationary moist smectite is somewhat rigid but rapidly transforms to a low-viscosity fluid with vibration. Uses include drilling muds, oven cleaners, greases, lubricants, toothpaste, mold coating, mortars, plasters, caulking compounds, coatings to improve the pelletization of iron ores and animal feeds, fillers in paints, paper, and cosmetics, and as antistick coatings.

71.3.1a.1 Beidellite $\text{Na}_{0.50} \text{Al}_2 (\text{Si}_{3.50} \text{Al}_{0.50}) \text{O}_{10} (\text{OH})_2 \cdot n \text{H}_2\text{O}$

Named in 1925 by Larsen and Wherry for the locality. Last redefined in *AM 47:137(1962)*. Smectite group. Synonyms: montmorillonite, Ca-montmorillonite, Na-montmorillonite, bentonite. *MON* Probably $C2/m$ or *ORTH*, sometimes pseudo-*HEX* $a = 5.14\text{--}5.18$, $b = 8.93\text{--}9.00$, $c = 15.0\text{--}15.5$, $\beta = 99.54^\circ$, $Z = 1$. *19-150*(18 Å, glycerol): 17.6_{10} 4.42_{10} 3.95_{10} 3.54_{10} 2.57_8 2.50_{10} 2.36_8 1.50_{10} . Beidellite has the typical smectite structure with 15-Å spacing when divalent

cations are dominant in the interlayer region. While montmorillonite has its layer charge resulting from octahedral substitutions $^{VI}Al \leftrightarrow Mg$ and is essentially tetrasilicic with minor ^{IV}Al , beidellite, and beidellite-like smectites have considerable ^{IV}Al . Beidellites have net layer charges dominantly arising from tetrahedral substitutions, while net layer charge in montmorillonite is the result of octahedral substitutions. The pattern of ^{IV}Al vs. ^{VI}Al source of net layer charge is paralleled by other smectites and intermediate substitutional schemes are normal. IR data: e.g., *AM 70:1004(1985)*. Physical properties: White to buff, pale yellow, greenish yellow, light greenish gray, can be stained red or brown; white streak; earthy to waxy luster. Cleavage $\{001\}$, perfect. $H = 1-2$. $G = 2.06-2.3$. Decomposed or gelatinized by common acids. Stained blue-green by benzidine. An "average" beidellite, as generally used in the literature, was $(Ca/_{2.031}K_{0.04}Na_{0.01})(Al_{1.34-1.98}Fe_{0.02-0.39}^{3+}Fe_{-0.02}^{2+}Mg_{0.01-0.28})(Si_{3.26-3.73}Al_{0.27-0.74})O_{10}(OH)_2 \cdot nH_2O$. *DS 15:55(1973)*. An "end-member" formula proposed [*USGSP:205B (1945)*] was $Na_{0.33}Al_{2.22}(Si_3Al)O_{10}(OH)_2 \cdot nH_2O$, but the closest approximation to the end member observed by those authors was $Na_{0.33}Al_{2.17}(Si_{3.17}Al_{0.87})O_{10}(OH)_2 \cdot nH_2O$. The midpoint between beidellite and montmorillonite would be represented by $Na_{0.33}Al_{2.06}(Si_{3.5}Al_{0.50})O_{10}(OH)_2 \cdot nH_2O$ if only ^{IV}Al determined the net layer charge and which was kept constant at about -0.33 . Beidellite is midway between montmorillonite and sobotkite. Due to the uncertainty of how beidellite was defined, significant erosion of the beidellite definition occurred, eventually with only slightly aluminian montmorillonites being called beidellite. Beidellite was redefined [*AM 47:137(1962)*] with a layer charge arising from tetrahedral substitutions and with exactly dioctahedral occupancy. An end-member formula was proposed: $Na_{0.45}K_{0.01}(Al_{1.98}Fe_{0.02}^{3+}Mg_{0.01})(Si_{3.48}Al_{0.52})O_{9.98}(OH)_2 \cdot nH_2O$. The boundary between beidellite and montmorillonite was placed at the point where net layer charge had equal or greater contribution from the tetrahedral sheet than the octahedral sheet, but beidellite does not necessarily have a total layer charge higher than montmorillonite. *DS 15:55(1973)*. Additional Al behavior was noted: "Once the threshold value of 2.0-2.1 Al is exceeded, additional Al is divided between tetrahedral and octahedral sheets in the approximate proportion of 70% tetrahedral and 30% octahedral" and "When the total amount of Al in the structure is enough to fill more than two structural positions, the amount of octahedral Al decreases by approximately 0.25. These positions are filled by the larger Mg... and Fe... ions." Tests: Identical to montmorillonite (71.3.1a.2). Optics: Biaxial (-); $N_x = 1.493-1.503$, 1.530 (2.26 wt % Fe_2O_3), $N_z = 1.526-1.533$, 1.556 (2.26 wt % Fe_2O_3); 2V small, $10-15^\circ$; birefringence = 0.026-0.033; dehydration increases RI and birefringence; RI increases rapidly with increasing Fe_2O_3 ; positive elongation; generally non-pleochroic, but feruginous varieties can show red-brown pleochroism. Chemistry: The chemistry of beidellite is generally aluminous, but Al_2O_3 values of 16.07-31.30 wt % have given high enough tetrahedral Al occupancy to merit the name *beidellite*, but octahedral substitutions greatly affect the total Al. Silica has a smaller range, due to its appearing in only one coordination type:

44.02–50.72 wt %. A complete series extends to nontronite with increasing Fe_2O_3 , but normally ranges from a fraction to several wt %. Other substitutions observed (wt %) include: Cr_2O_3 , to 5.02 (Ural Mts.); FeO , 0–0.71, 7.83 (Gedmayshikh); MnO , 0–0.49; NiO , 3.83 (WI); TiO_2 , 0–1.01; NiO , 0–0.30; MgO , 0.18–6.99; CaO , 0–2.76; K_2O , 0–1.04; Na_2O , 0–1.17; P_2O_5 , 0–0.15 (2.16, Putnam); H_2O^- , to 16.66; H_2O^+ , to 12.90. CEC = 115–130 meq per 100 g. Occurrence: Major component of some altered ash flows and bentonite layers. Occurs as an alteration product in hydrothermal ore deposits. Found in a variety of sedimentary environments. Also found in some granitic pegmatites as “pocket clay.” Can be found with illite, kaolinite, and other clays, quartz, amorphous silica, detrital minerals, etc. Localities: Although it is not always clear how the identification was arrived at, the following have been seemingly reasonably called beidellite: Pontotoc, MS; Putnam, MO; Nashville, AR; South Bosque and Houston, TX; Dever Basin, Wagon Wheel Gap, Mineral Co.; *Esperanza mine, Beidell, Saguache Co., CO*; Black Jack mine, Carson district, Owyhee Co., ID; Candelaria, Mineral Co.; Fairview, Sanpete Co., UT; Carson district, NV; Embudo, NM; Himalaya dike system, Mesa Grande, San Diego Co.; Los Angeles, Los Angeles Co.; Castle Mt., Ivanpah, CA; Maniquipi, Mexico; Ancon, Canal Zone, Panama; Rothamstead, England; Gemmano, Italy; Unterrupsroth, Rhône, Germany; Takovaya and Cheget-Lakhran Valley, Ural Mts.; Gedmayshikh Valley, Russia; Velka Kopan, near Chust, Ukraine; Ropp, Nigeria; Akkar plain, Safita, Syria; Hathi-Ki-Dhani, India; Tottori, Japan. vk, EF *MIN* 4(2):44(1992).

71.3.1a.2 Montmorillonite $(\text{Na,Ca}_{0.5})_{0.33}(\text{Al,Mg})_2\text{Si}_4\text{O}_{10}(\text{OH})_2 \cdot n\text{H}_2\text{O}$

Named in 1847 by Salvétat for the locality. Smectite group. Synonyms: Namontmorillonite, Ca-montmorillonite, bentonite. May form random or regular interstratifications with other phyllosilicates (e.g., kaolinite, cookeite, illite, muscovite). MON (sometimes given as pseudo-*HEX*) *C*2/*m*. $a = 4.93$ – 5.21 , $b = 8.94$ – 9.02 , $c = 12.4$, 15.0 – 15.5 , $\beta = 99.54^\circ$, $Z = 1, 2$. *12-219*(18 Å, nat): 17.6_{10} 9.0_5 4.49_8 3.58_4 2.99_3 2.57_4 1.70_2 1.50_6 ; *13-135*(15 Å, nat): 15.0_{10} 5.01_6 4.50_8 3.77_2 3.02_6 1.70_3 1.50_5 1.49_5 ; *13-259*(14 Å, nat): 13.6_{10} 4.47_2 3.34_1 3.23_1 2.92_1 2.59 and $2.49_{0.5}$; *29-1498*(15 Å, nat): 13.6_{10} 5.16_1 $4.46_{6.5}$ 2.56_2 1.69_1 1.495_1 ; *29-1499*(21 Å, nat): 21.5_{10} 10.6_2 $4.45_{5.5}$ $2.56_{3.5}$ 1.69_1 $1.495_{2.5}$ 1.325_1 . Montmorillonite has the typical smectite structure. It has been suggested that true montmorillonite has its layer charge resulting from octahedral substitutions, while beidellites are not necessarily high in Al compared to montmorillonite, but have significant layer charges arising from tetrahedral Al substitution. Expands to 17–18 Å with glycerol and collapses to ~ 10 Å with heating to 550° . Physical properties: Individual crystals are typically 1–3 μm and are platy or scaly, tabular on {001}. White to buff, pale yellow, light greenish gray, also pink, rose red to deep terra-cotta; earthy, also compact, dense and waxy. Cleavage {001}, perfect. $H = 1$ – 2 . $G = 2.06$ – 2.3 (porous), but up to 2.7. Decomposed or gelatinized by common acids. Stained blue-green by benzidine. Optics: Biaxial (-); $X \sim c$, $Y = b$, $Z \sim a$; $N_x = 1.48$ – 1.503 ,

$N_y = 1.50-1.534$, $N_z = 1.50-1.534$; $2V$ small, $10-25^\circ$; birefringence = $0.018-0.031$; positive elongation. Generally colorless, can be slightly pleochroic with increasing Fe_2O_3 . **Chemistry:** A complete series extends to nontronite with increasing Fe_2O_3 and to beidellite with increasing ^{IV}Al . Chromian montmorillonite has been called volkonskoite, but true volkonskoite has $^{VI}Cr > ^{VI}Al$. Chemical analyses have been reviewed, and the mean of 101 analyses. Weaver and Pollard [*DS 15:55(1973)*] gave $(Na_{0.01}Ca_{0.007}K_{0.004})(Al_{1.492}Fe^{3+}0.187Fe^{2+}0.007Mg_{0.354})(Si_{3.837}Al_{0.158})O_{10}(OH)_2 \cdot nH_2O$. Two-thirds of the analyses chosen had $^{IV}Al < 0.2$, per four tetrahedral sites, and few had $^{IV}Al > 0.4$, with bimodal points at 0.10 and 0.30. Low-Mg montmorillonite (Wyoming-type; ~ 0.19 octahedral position) and high-Mg montmorillonite (Cheto-type; 0.55 octahedral position) have been distinguished [*AM 46:1329(1961)*] with no significant differences in tetrahedral occupancy, but with differing thermal behavior. The two types can be present in a single sample with the coarser size fraction more magnesian (Cheto type) than the finer fraction (Wyoming type), but observed MgO values do not show enough bimodal distribution to verify the high/low-Mg montmorillonite types as important features of the species unless the mixing of types within a sample is a common occurrence. Montmorillonites have also been subdivided into categories (Wyoming, Tatatilla and Chambers, and Otay types) based on their total layer charge and on their percentage contribution to net layer charge by tetrahedral substitutions. [*CCM 17:115(1969)*]. Mg may be helpful in the genesis of montmorillonite. [*USGSPP:205B(1945)*]. Frequently found with amorphous silica- and/or alumina-bearing material, can be impure and mixed with other clay minerals. Observed ranges of major elements (wt %) include: SiO_2 , 50.10-65.00; Al_2O_3 , 15.20-34.00; Fe_2O_3 , 0.00-13.61; FeO , 0.00-1.61; MgO , 0.09-7.38; MnO , 0-0.03; CaO , 0.00-4.23; Na_2O , 0.00-3.74; K_2O , 0.00-2.80; TiO_2 , 0.00-2.90; P_2O_5 , 0-0.09; also (ppm): Li_2O , 4-88; F, 7100 (Chambers); H_2O^+ , 5.21-13.75. CEC = 70-130 meq per 100 g. Interlayer cations to 0.465. Can alter to illite. **Occurrence:** A product of alkaline weathering conditions and poor drainage. Major component of altered ash flows and bentonite layers. Found in a wide variety of sedimentary environments. Also in replacement zones in some granite pegmatites, and in hydrothermal mineral deposits. Frequently noted with a mixture of clay minerals, also with detrital minerals, quartz, amorphous silica, and so on. **Localities:** Only selected occurrences can be listed here: Greenwood and Stoneham, Oxford Co., ME; Branchville, CT; Polkville, Aberdeen, and Armory, MS; Helms Park, Gonzales; Houston and San Saba, TX; Bayard and Santa Rita, Grant Co., NM; Pierre shale; Belle Fourche, Butte Co., SD; Bates Park, Casper; Clay Spur; J.C. Lane tract, Upton, Weston Co.; Newcastle, Crook Co., WY; Ely, NV; Chambers, Apache Co.; Cheto, AZ; Bearpaw shale, Garfield, Rosebud, and Horn Cos., MT; Plymouth, UT; Shoshone, Amargosa Valley; Otay, CA; Umiat, AK; Aina Haina, HI; Dorothy and Wayne, ALB; Pembina, MAN, Canada; Santa Rosa; Tatatilla, Vera Cruz, Mexico; Elliots, Antigua; Giants Causeway, County Antrim, Northern Ireland; Woburn, Bedfordshire; Red Hill, Surrey, England; *Montmorillon*, Vienne, Confolens, Charente Dept.; Plom-

bières, Ludes, Montjavoult, and Virolet, *France*; Vallortigara-Posina, Schio, Venezia; Castiglione, Livorno; Cala Aqua mine, Ponza Is., Italy; Groschlattengrün, Fichtelgebirge, Bavaria, Germany; Cilly, Untersteiermark, Austria; Stritez, Bohemia, Czech Republic; Barataka, Transylvania, Romania; Selongin Daura, Russia; Malka River area, Caucasus Mts., Kazakhstan; Nahal Ayalon and Hatrurim formations, Israel; Emilia, Calingasta and Burrera mine, Jachal and El Retamito and Mario Don Fernando mine, Retimito, San Juan Prov.; Tala, Heras and Santa Elena, Potrerillos and San Gabriel, Mendoza Prov., Argentina; Taourirt, Morocco; Marnia, Fadli-Mostaganem, and Camp Berteaux, Algeria; Thies, Senegal; Youe, Chad; Iriba, Cameroon; Ankaratra, Malagasy; Reunion Is.; Itoigawa, Niigata Pref.; Usui and Hojun Mts., Gumma Pref.; Yakote and Hanaoka Mts., Akita Pref., Rokkaku, Yamagata Pref.; Tottori, Japan. *vk, EF MIN 4(2):15(1992)*.

71.3.1a.3 Nontronite $(\text{Na}, \text{Ca}_{0.5})_{0.33}(\text{Fe}^{3+}, \text{Al})_2(\text{Si}, \text{Al})_4\text{O}_{10}(\text{OH})_2 \cdot n\text{H}_2\text{O}$

Named in 1827 by Berthier for the locality. Smectite group. Also originally called chloropal. *MON C2/m*. $a = 5.23\text{--}5.264$, $b = 9.06\text{--}9.18$, $c \sim 10, 14.80, 15.0\text{--}15.5$, $\beta = 90^\circ, 99^\circ$, $Z = 1, 2$, $D = 2.29\text{--}2.36$. *29-1497(nat)*: $15.2_{10} 4.48_{55} 3.58_2 3.05_2 2.564_{25} 2.560_{25} 1.51_1 1.34_1$; *34-842(nat)*: $14.6_{10} 4.53_{10} 3.67_2 3.01_3 2.60_5 1.52_8 1.31_3 1.27_3$. Typical smectite structure with air-dried basal spacings 13.6–15.0 Å normal. Rarely naturally found with collapsed spacings ~ 10 Å. Ethylene glycol causes expansion to 16.9–17.3 Å. Collapses on heating (550°) 9.6–10.4 Å. K-intersalination generally causes some collapse from air-dried spacings to 11.9–13.1 Å. Mössbauer studies show some $^{IV}\text{Fe}^{3+}$. *AM 73:1346(1988)*. Nontronites can contain significant ^{IV}Al and parallel beidellite-like smectites: $\text{Ca}_{0.18}(\text{Fe}^{3+}1.94\text{Mg}_{0.10}\text{Al}_{0.06}\text{Fe}^{2+}0.05)(\text{Si}_{3.55}\text{Al}_{0.45})_{\Sigma 4}\text{O}_{10}(\text{OH})_2 \cdot n\text{H}_2\text{O}$. *AM 31:294(1946)*. A pseudo-anhydrous nontronitelike mineral has been reported [Arkansas, *GSAPA 18(6):528(1986)*]. The Arkansas nontronite has a collapsed spacing (~ 10 Å), expands with glycol, but does not hydrate upon immersion in water, and has a near-end-member composition: one water molecule per formula is apparently ordered within the opening of the tetrahedral ring of the silicate layer, yet does not contribute to non-mica-like spacings, $(\text{Ca}, \text{Mg}, \text{Mn})_{0.135}(\text{Fe}^{3+}1.785\text{Fe}^{2+}0.185\text{V}^{5+}0.04)_{\Sigma 2.01}(\text{Si}_{3.8}\text{Fe}^{3+}0.18\text{Al}_{0.02})_{\Sigma 4}\text{O}_{10}(\text{OH})_2 \cdot \text{H}_2\text{O}$. **Physical properties:** Pale to dark yellow-green to olive, also bright yellow-green, resinous to waxy luster with conchoidal fracture to earthy, sometimes fibrous. $H = 1\text{--}2$. $G = 2.06\text{--}2.32$. Cleavage $\{001\}$, perfect. Decomposed or gelatinized by common acids. **Optics:** Biaxial (-); $Y = b$, $Z \sim c$, high RI material has $X \sim c$; $N_x = 1.545\text{--}1.625$, $N_y = 1.569\text{--}1.650$, $N_z = 1.570\text{--}1.655$; $2V$ moderate, $33\text{--}40^\circ$, ranges $25\text{--}70^\circ$; $r < v$; birefringence = $0.035\text{--}0.044$ (0.010 low Fe); very strong increase in RI with increasing Fe^{3+} ; positive elongation; usually pleochroic in yellowish $\wedge (001)$ to brownish greens parallel to (001) ; pleochroic. X, pale yellow; Y, olive-green; Z, yellow-green. **Chemistry:** Forms a series with montmorillonite by Fe^{3+} exchange with Al; most compositions yield < 1.0 wt % Al_2O_3 , SiO_2 ,

40.8–48.8; Fe₂O₃, 20.4–32.4; FeO usually < 0.50; MgO, 0.61–2.1; CaO, 0.77–2.2; Na₂O, 0–0.29; K₂O, 0–0.24; TiO₂, 0.08–1.72; P₂O₅, 0–0.02; H₂O⁺, 7.8–11.4; H₂O⁻, 7.1–14.75; H₂O (total), 14.5–23.0; CEC = 60 meq per 100 g. Can replace olivine, chlorite, or pyroxene or be replaced by chlorite. **Occurrence:** Found with other clay minerals, including kaolinite, glauconite, chlorite, and vermiculite. Found in weathered basalts, ophiolites, basic and ultrabasic rocks, and fractures therein, also in basalt vesicles. Abundant in vertisols, also in submarine sediments, usually authigenic. As a sediment on sea mounts, also around midocean-ridge hydrothermal vents. As a coating in fractures in some granite pegmatites. **Localities:** Topsham, Sagadahoc Co., ME; Lehigh Mt., Mountainville; Bethlehem(!), PA; Chevy Chase, MD; North Garden, Albemarle Co., VA; Sugar Grove, Pendleton Co., WV; Sandy Ridge; Spruce Pine, Mitchell Co., NC; Wilson mine, Potash Sulphur Springs, AR; Green River Fm, Shirley Basin, WY; Bingham, UT; Santa Rita, NM; Miami, Gila Co., AZ; Woody, Kern Co.; Crestmore, Riverside Co., CA; Garfield(!) and Colfax, Whitman Co., Spokane, Manito, Excelsior, and Valleyford, Spokane Co., WA; lower Cook Inlet, AK; Loihi submarine volcano, HI; Peace River deposit, ALB, Canada; Pinares de Mayari deposit, Oriente Prov., Cuba; Concepcion del Oro, ZAC; Santa Eulalia, CHIH, Mexico; Smallacombe, Devon, England; Isle MaGee, County Antrim, Northern Ireland; *Perigueux Mn mine, St. Pardoux, Nontron, Dordogne, France*; Froland, Norway; Starbo, Sweden; Tirschenreuth and Passau, Bavaria; Meenser Steinberg, Gottingen, Hanover; St. Andreasberg, Zwickau, and Wolkenstein, Saxony; Menzenberg, Siebengebirge, Rhineland, Germany; Uzhorod, Ruthenia (formerly Unghwar); Sitno complex, Pukanec; Sternberg, Moravia, Czech Republic; Urkut deposit, also Szekes-Fejevar, Hungary; Starog Cikatova, Kosovo; Goles, Yugoslavia; eastern Rhodopes Mt., Bulgaria; Troodos ophiolite, Cyprus; Suakin and Atlantis II deeps, Red Sea; Sary-Krym, near Mariupol; Petrovsk, Krivoi-Rog region; Kerch, Ukraine; Balkan mine, Ural Mts., Russia; Baltatarak, Kazakhstan; Galapagos Is., Ecuador; Niquelandia, Goias; Xanda mine, Virgem da Lapa, MG; Campo Formo, Bahia, Brazil; Lake Malawi, Malawi; Lake Chad, Chad; Black Rock and Hotazel, Cape Prov., South Africa; Faratsiho and Behenjy, Malagasy; Shulan, Jilin Prov., China; Yamashiro-cho, Saga Pref., Japan; Mururoa Atoll, French Polynesia; Mariana Trench; Kasuga and other Pacific sea mounts; Burra Burra, SA, Australia; Waipiate, New Zealand; remotely sensed at *Viking* land site on Mars. VK, EF

71.3.1a.4 Volkonskoite (Ca_{0.5})_{0.33}(Cr³⁺,Mg,Fe³⁺)₂(Si,Al)₄O₁₀(OH)₂ · 4H₂O

Named in 1830 by Volkov for A. Volkonsky, Russian nobleman. Smectite group. Synonyms: wolchonskoite, volchonskoite. *MON* Space group unknown. $a = 5.16$, $b = 8.94$, $c = 14.40$, $Z = 2$; also *HEX* $a = 5.172$, $c = 15.12$, $Z = 1$, $D = 2.29$. *42-619*(nat): 15.0₁₀ 5.02_{<1} 4.49₅ 3.05_{<1} 2.56₃₅ 2.51_{<1} 1.69₁ 1.50₃₅. Volkonskoite is defined as a dioctahedral smectite with Cr³⁺ ≥ ∑[Al, Fe³⁺, Mg, etc.]. A structural formula of volkonskoite based on type

material has been calculated: $(\text{Ca}_{0.11}\text{Mg}_{0.11}\text{Fe}^{2+}0.03\text{K}_{0.02})(\text{Cr}_{1.18}\text{Mg}_{0.78}, \text{Fe}^{3+}0.29\text{Ca}_{0.02})(\text{Si}_{3.50}\text{Al}_{0.51})\text{O}_{10}(\text{OH})_2 \cdot 3.64\text{H}_2\text{O}$. Essentially the Cr^{3+} analog of beidellite. Volkonskoite expands on glycolation (typically to 16–17 Å). *CCM 35:139(1987)*. Deep to bright green, sometimes deep blue-green or blackish green; bluish green to green streak; resinous to earthy luster, sometimes fibrous. Conchoidal fracture. $H = 2.5$. $G = 2.05\text{--}2.3$. Cleavage $\{001\}$, perfect. Slowly soluble in water. Decomposed or gelatinized by hot HCl. Infusible. Mossbauer and TGA data: *CCM 35:139(1987)*. Biaxial (–); $N_x = 1.551\text{--}1.569$, $N_z = 1.564\text{--}1.569$; $2V$ typically $30\text{--}40^\circ$, but can be very low; birefringence = $0.004\text{--}0.013$; sometimes slightly pleochroic in shades of green. Refractive indices are principally a function of the Cr content. Volkonskoite usually requires 15 wt % Cr_2O_3 to become the dominant octahedral cation in a smectite and thus satisfy nomenclature requirements, but the mineral from listed occurrences has 19.87–29.81 wt %. Due to the strong chromophoric effect of chromium, some bright green smectites containing relatively low amounts of chromium, and insufficient for volkonskoite, have been misidentified as volkonskoite. The only verified localities are listed below. Volkonskoites are usually magnesian 0.58–7.73 wt % MgO and Al_2O_3 is generally 4–5 wt %. An aberrant, high- Cr^{3+} , essentially dioctahedral smectite has been described where ${}^{\text{VI}}\text{Mg} \geq {}^{\text{VI}}\text{Cr}^{3+}$ [*CM 19:43(1984)*], but as the total trivalent elements exceed the total divalent elements, dioctahedral nomenclature should prevail. Iron is nearly completely Fe_2O_3 (90% or more) with a possible series to nontronite. Trace elements in volkonskoite include [*CCM 35:139(1987)*]: TiO_2 , 0.015 wt %; also (ppm): Ag, 3; B, 70; Ba, 300; Be, 3; Cu, 300; Ga, 30; Li, 30; Mn, 500; Sc, 200; Sr, 70; V, 300; Y, 50; Zr, 100; Yb, 3 (Okhansk). Sometimes has organic impurities [see ref. by Gudoshnikov (1968) in *CCM 35:139(1987)*]. CEC (values not given), TGA, Mossbauer studies: *CCM 35:139(1987)*. Other substitutions (wt %) include: V_2O_5 , 0.36 (Samosadka); MnO , 0.36 (Okhansk); P_2O_5 , 0.11 (Samosadka); SO_3 , 0.22 (Akkerman); NiO , 0.24 (Akkerman); CoO , 0.04 (Akkerman). The original volkonskoite was found in sedimentary red beds where it was the mineralizer of fossil plants. Well-characterized localities include: Nevrokop, Bulgaria; Akkerman area, northern Ural Mts., Uchtym and Udmurtia (Vyatka); Samosadka, Kama area; *Mount Efimyata, Efimyata, Okhansk region, middle Kama R. area, Perm Basin, Russia*; Daba area, Jordan. $\text{vk, EF MIN 4(2):68(1992)}$.

71.3.1a.5 Swinefordite $(\text{Li,Ca}_{0.5},\text{Na})_{0.72}(\text{Li,Al,Mg})_{2.66}(\text{Si,Al})_4\text{O}_{10}(\text{OH,F})_2 \cdot 2\text{H}_2\text{O}$

Named in 1975 by Tien et al. for Ada Swineford (1917–1993), clay mineralogist and professor of geology at Western Washington State College, Bellingham, WA. Smectite group. Probably ORTH or MON Space group unknown, probably $C2/m$. $a = 5.2$, $b = 9.0$, $c = 13.0$, $Z = 2$, $D = 2.21$. $29\text{--}809(13 \text{ \AA}, \text{nat})$: 12.96_{10} 6.27_4 4.53_9 3.09_8 2.62_6 1.71_6 1.51_9 1.30_6 . Swinefordite is a trioctahedral 13-Å smectite. When fully hydrated, the mineral has “large” d values, which on dehydration shift to a 40-Å spacing and which continue to

collapse on dehydration to 19.6 Å, then 16 Å, then 14.5 Å (at 60% relative humidity), and stably to 13 Å. The observed basal reflections of air-dried material are very much sharper than is usual for a smectite, although precession photographs indicate significant stacking disorder. The layer charge of swinefordite is probably near the upper limit allowed by a smectite. Swinefordite expands to 18 Å with glycerol and collapses to 9.8 Å on heating to 450°, but spontaneously rehydrates and expands to 11.3 Å within a few hours of returning to ambient temperature, while further spontaneous rehydration, to 13 Å, may take months. Heating to 575° postpones spontaneous rehydration expansion by 6 and 12 months, respectively. IR and DTA data: *AM 60:540(1975)*. Usually in leathery mats of fibrous, thin ribbons when dry. Gray-olive to greenish gray when dry, and greenish yellow to light olive when wet; white streak; also orange red scaly (China), tough when dry and greasy when wet, unctuous to gelatinous when wet and resembles a thick grease or petroleum jelly; glistening luster when wet and dull when dry. Cleavage {001}, perfect. H = 1. Biaxial (-); $X \sim c$, $Y = a$; $N_x \text{ calc} = 1.492$, $N_y = 1.524$, $N_z = 1.526$; $2V = 29-45^\circ$; birefringence = 0.034; pleochroic. Y, colorless; Z, light yellow-brown. Swinefordite is richer in Li_2O than hectorite: 1.22 wt % (Hector) vs. 4.6 (unheated) or 5.66 wt % (heated to 150°) (Kings Mt.) $(\text{Li}_{0.41}\text{Ca}_{0.17}\text{Na}_{0.07}\text{Mg}_{0.01}\text{K}_{0.06})(\text{Li}_{1.02}\text{Al}_{0.85}\text{Mg}_{0.66}\text{Fe}^{3+}0.10\text{Fe}^{2+}0.03)_{2.66}(\text{Si}_{3.81}\text{Al}_{0.19})\text{O}_{10}[(\text{OH})_{1.68}\text{F}_{0.32}] \cdot 2\text{H}_2\text{O}$. F 1.49 wt %. The ${}^{\text{VI}}\text{Li} : {}^{\text{VI}}\text{Al} \sim 1$ in swinefordite and the limit of Li contents is probably analogous to that of lepidolite: $(\text{Li}_{1.50}\text{Al}_{1.50})$. Type material contains (wt %): MgO, to 7.38; FeO, to 3.67; MnO, to 0.29. A high Al_2O_3 and low MgO (China) were indicated. *MA: 96(1995)*. CEC = 93–102 meq per 100 g. Found in greasy patches (wet) or thin mats or films (dry) lining fractures with fluorapatite and/or rare minerals in spodumene-bearing granite pegmatite. *Foote Quarry, Kings Mountain, Cleveland Co., NC*; Pegmatite No. 3, Keketuohai district, Xinjiang, China. *VK, EF MIN 4(2):51(1992), KY 14(1):1(1994)*.

71.3.1b.1 Sobotkite $(\text{K,Ca}_{0.5})_{0.33}(\text{Mg}_{0.66}\text{Al}_{0.33})_3(\text{Si}_3\text{Al})\text{O}_{10}(\text{OH})_2 \cdot 1-5\text{H}_2\text{O}$

Named in 1976 by Haranczyk and Prchazka for the locality. Smectite group. *MON* Space group unknown. $b = 9.16-9.21$, $c = 14.5$. *PD*: 14.5₇ 4.48₉ 2.61₆ 2.51₆ 2.41₅ 2.35₅ 1.527₆. Sobotkite is a trioctahedral smectite, but with ${}^{\text{IV}}\text{Al}$ equivalent to a mica. Part of the tetrahedral charge is balanced by corresponding ${}^{\text{VI}}\text{Al}$ or high interlayer cations. Structural formula of type material yields: $(\text{Ca}_{0.13}\text{K}_{0.015})(\text{Mg}_{1.91}\text{Al}_{0.95})(\text{Si}_{3.06}\text{Al}_{0.94})\text{O}_{10}(\text{OH})_2 \cdot 5.18\text{H}_2\text{O}$, while sobotkite from Caslav has a similar formula: $(\text{Ca}_{0.33}\text{Na}_{0.08}\text{K}_{0.06})(\text{Mg}_{2.42}\text{Fe}^{2-}0.32\text{Fe}^{3+}0.21\text{Al}_{0.10}\text{Mn}_{0.03})(\text{Si}_{3.16}\text{Al}_{0.84})\text{O}_{10}(\text{OH})_2 \cdot 1.97\text{H}_2\text{O}$ [*UC 1:177(1955)*], while sobotkite from Roseland gave $(\text{K,Ca,Na})_{0.19}(\text{Al}_{1.84}\text{Fe}^{3+}0.31\text{Mg}_{0.02})(\text{Si}_{3.18}\text{Al}_{0.82})\text{O}_{10}(\text{OH})_2 \cdot n\text{H}_2\text{O}$ [*USGSP:205-B(1945)*]. DTA data: *PMZ 22:3(1974)*. Sobotkite has a 14.5-Å spacing and “swells” with glycerol (data not given). Pale green, fine-grained, unctuous. H = 3. G = 2.31. Biaxial; $N_x = 1.513$, $N_{\text{av}} = 1.525$, $N_z = 1.536$. Analysis (wt %): SiO_2 , 39.68–44.23;

Al_2O_3 , 20.98–31.30; Fe_2O_3 , 5.77; MgO , 0.18–16.72; NiO , 0.014; CaO , 0.45–1.58; K_2O , 0.15–0.95; Na_2O , 0.19 (Roseland); TiO_2 , 1.01 (Roseland); $\text{H}_2\text{O}_{\text{tot}}$, 16.02–20.71. Type material was found with chrysotile, nickeloan lizardite, and pime-lite (willemseite) in serpentinite, Roseland, VA; *Mt. Sobotka, Godolow-Jordanow massif, Wiry, Lower Silesia, Poland*; Caslav, Czech Republic. *VK, EF MIN 4(2):83(1992)*.

71.3.1b.2 Saponite $(\text{Ca}_{0.5}\text{Na})_{0.33}(\text{Mg},\text{Fe}^{2+})_3(\text{Si},\text{Al})_4\text{O}_{10}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$

First recognized in 1758 by Axel Cronstedt and named in 1830 by Svanberg from the Greek word *sapo*, in allusion to its soapy feel. Smectite group. Synonym: griffithite. *MON* Space group unknown. $a = 5.232\text{--}5.314$, $b = 9.148\text{--}9.211$, $c = 12.4, 14.52\text{--}15.56$, $Z = 2$, $D = 2.10$. *6-2* (18 A, glycerol): $18.8_{10} 9.1_5 4.55_5 3.61_5 3.01_4 2.61_6 1.74_4 1.54_4$; *12-168* (17 A, glycol, syn): $17.0_{10} 8.5_5 5.69_4 4.58_5 3.37_8 2.81_3 2.58_4 1.535_7$; *13-86* (15 A, nat): $14.2_{10} 4.96_4 4.57_5 3.67_8 2.09_3 1.84_3 1.53_9 1.32_4$; *13-305* (15 A, ferroan): $15.4_{10} 7.9_5 5.28_1 4.6_5 3.13_5 2.65$ and $2.56_5 1.54_{6.5} 1.33_3$; *29-1491* (15 A, nat): $15.5_{10} 7.73_{<1} 5.11_{<1} 4.57_1 3.83_{<1} 3.07_1 2.61_{<1} 1.53_{<1}$; *30-789* (15 A, aluminian, also called sobotkite): $14.5_8 7.38_4 4.48_{10} 2.61_7 2.51_7 2.41_6 2.35_6 1.53_7$. Saponite has the normal trioctahedral smectite structure and frequently has a 15-A basal spacing with interlayer Ca or 12.5-A spacing with interlayer Na. Saponite can have a net layer charge arising from tetrahedral Al substitutions and can grade from saponite to sobotkite [see montmorillonite (71.3.1a.2) and beidellite (71.3.1a.1)] but $^{\text{IV}}\text{Al}$ is frequently 0.25–0.50 atom per formula unit and distinguished from the essentially Al-deficient stevensite. Expands with ethylene glycol to 17–18 A. DTA studies have been made [*CCM 32:147(1984)*] which show a shifting of basal spacings down to 12.5 A, with an abrupt shift to 9.85 A at 600°, indicating collapse due to dehydration, but the spacing spontaneously expands to 14 A by rehydration on cooling. IR has also been studied. *CCM 32:147(1984)*. **Physical properties:** White, pale yellow to dark brown, gray-green, bluish green, light blue; can be stained orange to terra-cotta; earthy to resinous, rarely fibrous, unctuous when wet. $H = 1$ or less or up to 2. $G = 2.10\text{--}2.30$ for porous material, but can be 2.79–2.87. Cleavage {001}, perfect. Fusibility 4 or with difficulty. Decomposed or gelatinized by common acids. Can be visually similar to fine-grained chlorite in mid-ocean basalts. **Optics:** Biaxial (-); $N_x = 1.479\text{--}1.53$, $N_y = 1.486^*$ (very low iron), $1.510\text{--}1.565$, $N_z = 1.50^*$ (low iron), $1.510\text{--}1.59$; 2V usually 20–38°, but can be nearly 0°; birefringence = 0.020–0.044, 0.003 (high iron), N_x perpendicular to (001); positive elongation; high-iron varieties are pleochroic in brownish greens. Also uniaxial (-); $N_O = 1.54\text{--}1.573$, $N_E = 1.560\text{--}1.593$; birefringence = 0.020–0.037. **Chemistry:** Can be nickeloan forming a series with pime-lite, also mistaken for volkonskoite when Cr-bearing. Chemical analyses (wt %) are variable: SiO_2 , 42.78–53.88; Al_2O_3 , 3.89–6.44; Fe_2O_3 , generally < 1%; MgO , 22.96–31.61; MnO , 0.06; TiO_2 , 0.37 (Irisugawa); FeO , 7.83 (Griffith Park); H_2O^+ , 7.25 (Ballarat); H_2O^- , 10.76 (Ballarat). Interlayer cations

can contain Mg and intersalination techniques are required to remove this Mg in order to have a rigorous understanding of its structural role. CEC = 76–109. **Occurrence:** Can be associated with other clays, quartz, chlorite, adularia, sepiolite, celadonite and other micas, calcite, chalcedony, zeolites, and so on. Saponite can be a major component of iddingsite alteration of olivine. *CCM 32:1(1984)*. Found lining cavities in basalt or as a pervasive alteration of olivine or plagioclase in submarine as well as continental basalts. Oxygen isotope analyses suggest that some saponite was derived from basalt while in equilibrium with seawater [*CMP 73:323(1980)*] and have demonstrated an authigenic reaction phlogopite → vermiculite → saponite. *CCM 33:214(1985)*. Found in lateritic profiles above, or as a hydrothermal alteration along fractures in basic or ultrabasic rocks. A component in some volcanic ash. **Localities:** Only selected saponite localities are listed here: Roaring Brook, New Haven, New Haven Co., CT; Sugar Grove, WV; Ahmeek and South Kearsarge mines and elsewhere, Keweenaw Penin., MI; Silver Bay; Pigeon Point to Fond du Lac, Lake Superior region, MN; Hills Pond peridotite, Woodson Co., KS; Italian and northern Italian Mts., Gunnison Co., CO; Ash Meadows; Trucker Canyon, Reno, NV; Milford, Beaver Co., UT; South Panamint Valley, Ballarat; Cahuenga Pass, Griffith Park, Los Angeles, Los Angeles Co., CA; Mt. St. Helens ash; Grand Rone Formation, WA; Georges Is., PEI, Canada; Faroe Is.; Orrock, Fife; Allt Ribhein, Fiskavaig Bay, Skye; Cathkin Hills, Carmunnock, Lanarkshire, Scotland; Lizard, Cornwall, England; Svärdsjö, Kopparberg, Dalarne, Sweden; Mormoiron, France; Sasbach, Kaiserstuhl, Germany; Kozakov, Czech Republic; Ksabi, Morocco; Krugersdorp, Transvaal, South Africa; Wakamatsu mine, Tari district, Totori Pref.; Irisugawa, Gunma Pref., Japan. VK, EF

71.3.1b.3 Sauconite $(\text{Ca}_{0.5}\text{Na})_{0.33}\text{Zn}_3(\text{Si}_{3.5}\text{Al}_{0.5})\text{O}_{10}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$

Named in 1875 by Frederick Genth for the locality. Smectite group. Synonym: tallow clay. MON Space group unknown. $a = 5.2\text{--}5.35$, $b = 9.1\text{--}9.32$, $c = 15.4\text{--}15.8$, $\beta = 90^\circ$, $D = 2.43\text{--}2.53$. $8\text{-}243(15 \text{ \AA}, \text{nat}): 15.4_{10} 7.9_6 4.55_6 3.94_1 3.16_5 2.67_6 1.55_8 1.33_4$; $8\text{-}444(17 \text{ \AA}, \text{nat}): 16 6_{10} 8.33_{10} 4.60_{10} 3.34_{7.5} 2.62_{7.5} 1.55_{10} 1.33_5 1.01_{2.5}$; $8\text{-}445(15 \text{ \AA}, \text{nat}): 15.4_{10} 7.77_9 4.60_9 3.87_5 3.09_5 2.67_{10} 1.54_{10} 1.33_{7.5}$; $29\text{-}1500(15 \text{ \AA}, \text{nat}): 15.5_{10} 5.0_1 4.53_5 3.14_1 2.59_1 1.52_1$. Sauconite has the normal trioctahedral smectite structure and shows 15.0- to 15.6-Å (air-dried) basal spacings and expands to 16.1–16.6 Å with ethylene glycol. *AM 36:795(1951)*. Untreated air-dried samples collapsed from 15.4 Å to 14.5 Å on heating to 327°. Sauconites usually have high $^{\text{IV}}\text{Al}$ and are analogous to beidellite or even sobotkite. Fine-grained, usually in dense clay-like masses of small micaceous plates in laminated to compact masses. Ideally white, but usually stained yellow to brownish yellow, red-brown; luster is usually dull to greasy. Cleavage {001}, perfect. Like other smectites, soluble in water, decomposed by HCl. $H = 1\frac{1}{2}\text{--}2$. $G = 2.61\text{--}2.71$ (for about 30 wt % ZnO); 2.76–2.80 (for about 40 wt % ZnO). DTA data: *AM 36:795(1951)*. May fluoresce bluish white in UV light. Biaxial (–); X perpendicular to (001),

$Y = b$; $N_x = 1.530, 1.550\text{--}1.575$, $N_y = 1.550, 1.59\text{--}1.614$, $N_z = 1.551, 1.592\text{--}1.615$; $2V = 0\text{--}20^\circ$; birefringence = $0.035\text{--}0.042$; positive elongation. Chemistry is variable (wt %): TiO_2 , 0.24; CuO , to 0.13; MgO , to 2.4; Fe_2O_3 , to 6.2; MnO , to 0.06; CaO , to 2.7; Na_2O , to 0.4; K_2O , to 0.65; Al_2O_3 , 6.4–17.0; ZnO , 22.5–42.5; SiO_2 , 29.6–38.7. Calculated formulas range from $(\text{Ca}_{0.13}\text{Na}_{0.09}(\text{Zn}_{2.40}\text{Al}_{0.22}\text{Mg}_{0.18}\text{Fe}_{0.17}^{\text{II}}))(\text{Si}_{3.47}\text{Al}_{0.53})\text{O}_{10}(\text{OH})_2 \cdot n\text{H}_2\text{O}$ to $\text{K}_{0.33}(\text{Zn}_{1.48}\text{Al}_{0.74}\text{Fe}^{3+}0.40\text{Mg}_{0.14})\text{Si}_{3.01}\text{Al}_{0.99}\text{O}_{10}(\text{OH})_2 \cdot n\text{H}_2\text{O}$. *AM 31:411 (1946)*. Frequently associated with hemimorphite. Found as small-to-large masses in rock or cavities in oxidized zones of zinc deposits, sometimes in considerable minable quantities. Also found with smithsonite, chrysocolla, and Fe-oxides. *Uberroth mine, Friedensville, Saucon Valley, Lehigh Co., PA*; Liberty mine, Meekers Grove, Lafayette Co., and at Platteville, WI; Coon Hollow mine, Zinc, Boone Co., AR; Lower Waterloo, New Discovery, and Yankee Doodle mines, Leadville, Lake Co., CO; Defiance mine, Gleason, Castle Dome, Globe–Miami district, and the 79 mine, Gila Co. and Magma mine, Superior, Pinal Co., AZ; Mohawk mine, San Bernardino Co., CA; Altenberge, Aachen, Germany; Moresnet, Liege, Belgium; Garperberg, Sweden; found in about 25 veins and dikes of pegmatite on Mts. Nepakh, Kuivchorr, Mannepakh, and others, Lovozero massif, Kola Penin., and central Tien-Shan, Russia; pink, Co-bearing ($\text{CoO} = 4.15$ wt %) from the Dashkesan Fe ore deposit, Azerbaijan. Well known from weathering zone of sulfide deposits of Kazakhstan; eastern Transbaikal, Siberia, and Yaroslav deposit, Primorye, Russia. *VK, EF MIN 4(2):96(1992)*.

71.3.1b.4 Hectorite $(\text{Na,Ca}_{0.5})_{0.33}(\text{Mg}_{2.67}\text{Li}_{0.33})\text{Si}_4\text{O}_{10}(\text{F,OH})_2 \cdot \text{H}_2\text{O}$

Found in 1936 [*AM 21:238(1936)*] and named in 1941 by Strese and Hofmann for the type locality. Smectite group. *MON C2/m*, also indexed as pseudo-*HEX*: $a = 5.2\text{--}5.274$, $b = 9.16\text{--}9.18$, $c = 15.93\text{--}16.13$, $Z = 1$. *9-31* (15 Å, nat): 15.8₈ 4.58₁₀ 2.66₈ 2.48₆ 1.72₆ 1.53₁₀ 1.32₈ 1.30₈; *25-1385* (15 Å, syn): 4.5₁₀ 2.6₁₀ 1.74₆ 1.53₁₀ 1.31₆ 1.28₄ 0.98₆ 0.875₆. Hectorite is a trioctahedral 12.4-Å smectite and is the lithium-bearing equivalent of stevensite: $(\text{Na}_{0.28}\text{Ca}_{0.02}\text{K}_{0.01})\text{Mg}_{2.65}\text{Li}_{0.33}\text{Al}_{0.02}\text{Si}_4\text{O}_{10}(\text{OH})_2 \cdot \text{H}_2\text{O}$. EPR data: *AM 70:996(1985)*. NMR data: *AM 72:935(1987)*, *GCA 54:1655(1990)*. Swells with ethylene glycol and untreated material collapses on heating to 550° . Pillaring with $[\text{Al}_{13}\text{O}_4(\text{OH})_{24}(\text{H}_2\text{O})_{12}]^{7+}$ has been produced experimentally. *AM 41:598(1993)*. Earthy aggregates, individual crystals, to several micrometers, are lathlike or brick-shaped, elongated parallel to a . White to buff, white streak, earthy or dull to waxy luster, unctuous when wet. Cleavage {001}, perfect; uneven fracture. $H = 1\text{--}2$. $G = 2.34\text{--}2.5$. Decomposed or gelatinized by common acids. IR, DTA, and other spectra data: *MIN 4(2):91(1992)*. Biaxial (–); $N_x = 1.485\text{--}1.489$, $N_y = 1.499$, $N_z = 1.510\text{--}1.524$; $2V$ small; birefringence = $0.021\text{--}0.031$ (optical data are few). Heating raises the refractive indices: (100°): $N_x = 1.524$, $N_z = 1.553$; (200°): $N_x = 1.555$, $N_z = 1.584$. Analyses of natural material are few. Hectorite is virtually a nonaluminous smectite with

Al_2O_3 to 1.40 wt %. Laponite is a synthetic hectorite transformed from other smectites. Hectorite from Hector, CA, frequently has 0.3–0.57 Li in trioctahedral sites, while that from Romania varies from 0.33 to 0.45 but has no F. Some Li-bearing stevensites have been called hectorite. Fourier analysis of California material yielded 0.71 Li. *CR(D) 274(2):149(1972)*. Other substitutions include (wt %): MgO, 24.00–28.68; SiO_2 , 49.3–59.76; Fe_2O_3 , to 1.82; Li_2O , 0.36–1.35; Na_2O , 0.07–3.37; CaO, 0.1–1.80; K_2O , to 0.43; B_2O_3 to 0.035 (Hector); H_2O^+ , 8.68; H_2O^- , 10.82; F, to 6.0 (Hector); Cl, to 0.31 (Hector). Some hectorite appears to contain very little F substituting for (OH). CEC = 40–115 meq per 100 g. Found as an alteration of clinoptilolite in bentonite in an alkaline lake environment and can be admixed with saponite; also by action of hot springs or relatively hot meteoric waters. *EG 53:22(1958)*. Usually contains minor fine-grained calcite. Also found in argillized skarn. Used in an enormous variety of industrial applications, particularly due to its high viscosity, absorbancy, and interesting rheology, with a correspondingly large research literature, sometimes as the synthetic equivalent called laponite (CEC = 71–75 meq per 100 g). Occurs at the Lyles mine, near Kirkland, Yavapai Co.; Date Creek basin, near Wickenburg, AZ; Disaster Peak, Montana Mts., Humboldt Co., NV; McDermitt caldera, NV–OR; 5 km S of Hector, Mojave desert, San Bernardino Co., CA; with calcite veins in acid tuffs at Puy Chalard near Verteson, Dept. Puy de Dôme, France; Ebro Basin and other Tertiary basins, Spain; Moldova Noua, Romania; Djebel-Gassul deposit, Central Atlas Mts., eastern Morocco; Balikesir borate deposit, Balikesir Prov., Turkey. vk, EF

71.3.1b.5 Pimelite $\text{Ni}_3\text{Si}_4\text{O}_{10}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$

Discovered in 1788 by Martin Klaproth and renamed in 1800 by Karsten from the Greek word for *fat*, in allusion to the mineral's appearance. Smectite group. Synonyms: röttisite, revdanskite, desaulsite. Apparently constitutes part of the mixtures called genthite, nickel-gymnite, garnierite, nepouite, and noumeite. HEX Space group unknown. $a = 5.256$, $c = 14.822$, $Z = 1$, $D = 2.68$. $43-664(\text{nat})$: 15.1_{10} 4.56_4 3.34_2 2.66_4 2.27_2 1.72_1 1.52_8 . In 1938, pimelite from an unstated locality, but probably not holotype material, was determined to be a smectite. *CMA:360(1938)*. Additional studies have shown that a nickel-rich smectite exists at the type locality. *AM 51:279(1966)*. Earlier, pimelite was studied by powder diffraction film methods, but large spacings may have been unrecorded. *BSFM 59:163(1936)*. Garnierite from Riddle was found to consist of a mixture of smectitic pimelite, nickeloan deweylite, and nickeloan serpentine. *EG 44:13(1949)*. Generally low in Al with consequent low layer charge. Air-dried material (Brazil) 14.4 Å expands to 17.35 Å₀₀₁ with glycol, and collapses to 9.83 Å at 490°. Noumea smectitic pimelite is apparently a mixture that expands on glycolation from naturally collapsed 10.2 Å up to 15.3 Å, leaving a 9.6-Å residual. *AM 70:549(1985)*. A confusion has arisen, as a nickel-rich talc also has been observed in specimens from the type locality [*AM 64:615(1979)*] which has variously been called pimelite or

kerolite. Smectitic pimelite has been synthesized (Macewan, 1961). It has been stated that a Ni-dominant smectite has never been found in nature, but these statements may have been made by workers studying Ni-dominant talc and not type specimens of pimelite. As röttisite, desaulsite, and revdanskite are also Ni-dominant smectites [AM 51:279(1966), but data not given], further systematic work is needed to establish the true nature of pimelite vs. kerolitic willemseite. An aberrant Ni-dominant smectite ($\text{Ca}_{0.01}\text{K}_{0.05}$) ($\text{Ni}_{1.47}\text{Fe}_{0.50}\text{Mg}_{0.48}\text{Al}_{0.17}\text{Cr}_{0.02}$)($\text{Si}_{3.92}\text{Al}_{0.08}$) $\text{O}_{10}(\text{OH})_2 \cdot n\text{H}_2\text{O}$ has been found at Niquelandia, Goias, Brazil. CCM 35:1(1987). The Ni-dominant smectite has high trivalent ion substitution (Fe^{3+} , Al, Cr) and so is dioctahedral. The Niquelandia clay sample contains Ni-rich and Ni-poor size fractions similar to Cheto- and Wyoming-type size fractions of montmorillonite. Physical properties: Bright green, apple-green, yellowish green, emerald-green; greenish white streak; usually waxy with conchoidal fracture, also fibrous. $H = 2-2\frac{1}{2}$. $G = 2.23-2.98$. Decomposed by acids. Optical absorption spectra: AM 70:549(1985). Optics: Biaxial (-); $N_y = 1.592-1.615$; $2V = 30-80^\circ$; birefringence = 0.014-0.025, but can appear isotropic due to fine grain size; pleochroic, pale green-colorless to light yellow green. Chemistry: Analyses are few; material from the type locality gave [AM 51:279(1966)] (wt %): SiO_2 , 47.20; Al_2O_3 , 0.22; Fe_2O_3 , 0.20; MgO , 11.42; NiO , 27.66; CaO , 0.16; H_2O^+ , 9.38; H_2O^- , 3.64. Type material is magnesian and pimelite could form a series with stevensite or saponite. Additional ranges of composition (wt %) include: NiO , 38.22 (Franklin); FeO , 12.15 (Revdansk); ZnO , 4.0 (Franklin); CaO , 0.70 (Franklin); As_2O_5 , 4.77 (Franklin). Occurrence: Found in lateritic profiles above serpentinites or dunites. Frequently admixed with nickeloan serpentinites or quartz. The color of chrysoprase has occasionally been attributed to pimelite inclusions. Localities: Reported pimelite occurrences that appear to be smectite include Wood's chrome mine, Texas, Lancaster Co., PA; Franklin, Sussex Co., NJ; Michipicoten, ID; Riddle, Douglas Co., OR; Wiley Well district, CA; Malaga, Spain; Saasthal, Walais, Switzerland; Röttis, Vogtland, Saxony; Kosemütz, near Frankenstein, Upper Silesia, Poland; Steinberg Mt., near Jordansmuhl, Silesia; Revdansk, Ural Mts., Russia; Sarykulbod and Karaganda, Kazakhstan; Jacuba mine, Niquelandia, Goias, Brazil; Marlborough Creek, Rockhampton district, Q, Australia; Noumea, and Poro, New Caledonia. VK, EF Karsten, *Mineralogische Tabellen* (1800), MIN 4(1):248(1992).

71.3.1b.6 Stevensite $(\text{Ca}_{0.5}\text{Na})_{0.33}(\text{Mg},\text{Fe}^{2+})_3\text{Si}_4\text{O}_{10}(\text{OH})_2 \cdot n\text{H}_2\text{O}$

Named in 1873 by A. R. Leeds for E. A. Stevens, founder of Stevens Institute of Technology, Hoboken, NJ. Smectite group. ORTH or MONO Space group unknown. $a = 5.26-5.4$, $b = 9.108-9.162$, $c = 15.3$, $Z = 2$, $D = 2.07$. 25-1498(15 Å, nat); 15.5₁₀ 5.0₁ 4.53₅ 3.10₁ 2.54₁ 2.27_{<1} 1.87₁ 1.52_{1.5}. Stevensite has the typical smectite structure and shows a 14-Å basal spacing. Expands to 15.1 Å, rarely to 16.9-18 Å, with ethylene glycol. Some "stevensites" show 24.5- to 26.5-Å spacings, suggesting they have a corrensite impurity. AM

44:342(1959). North Tyne stevensite might be naturally collapsed in part. *MM 32:218(1959)*. DTA and IR data: *AM 44:342(1959)*. Generally massive, individual crystals occur as platy aggregates to 2 μm . Pink, cream white, tan, buff, light brown; earthy or dull to resinous luster. Cleavage {001}, perfect; brittle when dry. Fusibility 3. $H = 2.5$. $G = 2.15\text{--}2.565$. Sometimes thermoluminescent. Decomposed by HCl. Stained by malachite-green/nitrobenzene deep emerald-green (natural) and very pale yellow (acid treated). *AM 38:973(1953)*. IR and DTA data: *MIN 4(2):85(1992)*. The chemical composition (wt %) is fairly constant: MgO, 23.7–27.9; CaO, to 2.2; MnO, 0.02–1.6; Al_2O_3 , 0.1–1.0; Fe_2O_3 , 0.3–1.75; SiO_2 , 51.2–57.3; H_2O^+ , 6.4–9.9; H_2O^- , 4.8–12.4; traces of Na_2O and K_2O . Isotropic; $N_{\text{av}} = 1.50\text{--}1.511$; birefringence = 0.0–0.02; also 2V and sign, not reported; $N_x = 1.515$ (white), 1.552(brownish green), $N_z = 1.509$, 1.535(white), 1.571(brownish green), birefringence = 0.012, 0.009. Optical variations might be due to water contents, also similar to sepiolite [*MM 32:218(1959)*], but the X-ray diffraction data are identical for the two types. A structural formula of stevensite (North Tyne) is $(\text{Ca}_{0.5}, \text{K}, \text{Na})_{0.273} (\text{Mg}_{2.896} \text{Fe}_{0.026}^{2+} \text{Mn}_{0.026}^{2+} \text{Fe}_{0.017}^{3+}) \text{Si}_{3.925} \text{Al}_{0.075} \text{O}_{10} (\text{OH})_2 \cdot n\text{H}_2\text{O}$. Stevensite is usually very low in Al_2O_3 usually < 1.0 wt % and hence is nearly tetrasilicic, unlike saponite, but frequently has minor substitutions (wt %) including: TiO_2 , 0.02 (Italy); Fe_2O_3 , 1.29 (Italy); MnO, 0.75 (Jersey City); FeO, 1.33 (Scotland); Li_2O , 0.33 (Romania); H_2O^+ , 9.9 (North Tyne); H_2O^- , 6.69 (Springfield). CEC = 36 meq per 100 g. Stevensite differs from saponite and hectorite by being low or deficient in Al_2O_3 , Li_2O , and/or F; however, lithian stevensites have been described. *CCM 38:171(1990)*. Sometimes these lithian stevensites (with $\sim 0.11\text{--}0.12$ Li) have been called hectorite. Originally found as earthy replacements of pectolite in basalt cavities with quartz, calcite, datolite, and so on. A component of some deweylite. *MM 41:443(1977)*. Also as hydrothermal alteration of dunite, skarn, or in oolitic iron ore. Rarely as a component of volcanic ash. Well-characterized stevensite localities include: Willsboro, Essex Co., NY; Harts-horn quarry, Springfield, Essex Co.; railway tunnel, Jersey City; railway tunnel, Bergen Hill, Hudson Co., and railway tunnel, Hoboken; New Street Quarry, Paterson, Passaic Co., NJ; Cedar Hill quarry, Texas, Lancaster Co., PA; Mine Creek, Bakersville, Mitchell Co., NC; Mayville, WI; Green River formation, WY; Holbrook mine, Cochise Co., AZ; Whin Sill, Gunnerton, North Tyne, Northumberland, England; Corstorphine Hill, Edinburgh, Scotland; Puy Chalard, Puy de Dome; Salinelles, France; pseudomorphous after periclase from Procida Is., Italy; Burg Herborn, Germany; Moldova Noua, Romania; pseudomorphous after wollastonite from the Balkan deposit, southern Ural Mts., Russia; Ghassoul, Morocco; Ohiri mine, Yamagata Pref.; Akatani mine, Niigata Pref.; Obori mine, Yamagata Pref., and Kamaishi mine, Iwate Pref., Japan. *EF NJBM:556(1983)*. VK, EF.

71.3.1b.7 Yakhontovite $(\text{Ca},\text{K})_{0.5}(\text{Cu}^{2+},\text{Fe}^{3+})_{2.37}\text{Si}_4\text{O}_{10}(\text{OH})_2 \cdot 3\text{H}_2\text{O}$

Named in 1986 by Postnikova et al. for Liia Konstantinovna Yakhontova (b.1926), Russian mineralogist, University of Moscow, a specialist in cobalt deposits. Smectite group. Probably *MON* Space group unknown. $a = 5.26$, $b = 9.108$, $c = 13.89$ ($c \times \sin \beta$), $Z = 1$, $D = 2.48$. $41-1447(\text{nat})$: 13.9_{10} 7.3_2 4.5_8 3.2_1 2.88_6 . Yakhontovite is an unusual smectite. The dominant cation is copper, which should yield a trioctahedral occupancy, but the abundance of Fe^{3+} decreases the occupancy to 2.37. Also, copper occupies less than half of the octahedral positions: $(\text{Ca}_{0.20}\text{K}_{0.01})(\text{Cu}_{0.84}\text{Fe}^{3+}_{0.83}\text{Mg}_{0.67}\text{Zn}_{0.02}\text{Al}_{0.01})\text{Si}_4\text{O}_{10}(\text{OH})_2 \cdot n\text{H}_2\text{O}$. As Yakhontovite is very nearly cuprian nontronite and as it was intimately associated with malachite and pseudomalachite, additional study should be directed at establishing all of the physical constants of the mineral. Yakhontovite d_{001} expands to 17.9 Å with glycerin and 17.6 Å with ethylene glycol. IR and DTA are similar to nontronite. *MZ* 8(6):80(1986). Pistachio-green, dull luster. Conchoidal fracture. $H = 2-3$. Biaxial; $Z \wedge c = 12-14^\circ$; $N_x = 1.530-1.547$, $N_z = 1.560-1.570$; positive elongation; pleochroic, dark to medium blue-green. Found as veinlets with malachite, pseudomalachite, chrysocolla, chalcopyrite, pyrrhotite, stannite, quartz, and so on. *Komsomolsk region, Far East Region, Russia*. vk, EF *MIN* 4(2):83(1992).

71.3.1b.8 Zincsilite $\text{Zn}_3\text{Si}_4\text{O}_{10}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$

Named in 1960 by Smol'yaninova et al. for the chemical composition. Smectite group. *MON* Space group not certain. $b = 9.17$, $c = 15.3$; expands to 17.6 Å after glycolation, and collapses to 10 Å after heating to 400° for 10 minutes. *PD*(nat): 15.3_{10} 7.56_2 4.56_2 4.09_4 2.56_5 1.53_7 ; (glycolated): 17.6_{10} 8.50_4 4.56_4 4.05_7 2.57_4 1.53_6 ; (heated to 400°): 10.0_{10} 4.56_6 3.95_7 2.57_7 1.53_{10} . Zincsilite is indistinguishable from sauconite, except for optical properties, which may depend on $\text{Zn} \leftrightarrow \text{Al}$ substitution. If tetrahedral Al were present, a layer charge would be developed and an interlayer cation would be necessary. Zincsilite would then represent an end member of the sauconites. Diagnostics are similar to dioctahedral smectite. Foliae to 2 mm. White to bluish white, pearly luster. Cleavage {001}, perfect. Decomposed by HCl. $H = 1\frac{1}{2}-2$. $G = 2.67-2.71$. Fusibility 5. IR and DTA data: *MIN* 4(2):101(1992). Chemical analyses (wt %) for white and green varieties, respectively: CuO, 0.60, 3.07; MgO, 4.62, 1.08; CaO, 6.40, 2.00; MnO, 0.40, none; ZnO, 26.64, 35.00; Al_2O_3 , 0.84, 0.70; Fe_2O_3 , 2.16, 1.55; SiO_2 , 47.6, 42.75; H_2O^+ , 6.35, 8.50; H_2O^- , 4.35, 6.00. Biaxial (-); $Z \wedge c = 3^\circ$, X approximately perpendicular to {001}, OAP parallel to (010); $N_x = 1.514$, $N_y = 1.559$, $N_z = 1.562$; $2V = 0-22^\circ$. Heating to 400° produces pleochroic material in shades of brownish green to pale green to colorless. After heating to 400°, $N_x = 1.512$ and $N_z = 1.570$. Found as pseudomorphs after diopside with chrysocolla, fluorite, opal, and manganese oxides in an oxide zone of a galena-sphalerite-chalcopyrite skarn. *Batystau, central Kazakhstan*; Gifu Pref., Japan. vk, EF

CHLORITE GROUP

The chlorite group minerals are phyllosilicates corresponding to the general formula

where

A = Al, Fe²⁺, Fe³⁺, Li, Mg, Mn, Ni (or a combination of two or more of these elements)

Z = Al, Si, Fe³⁺ (or a combination)

Allowing for substitution, the formula may be written somewhat more exactly as

or

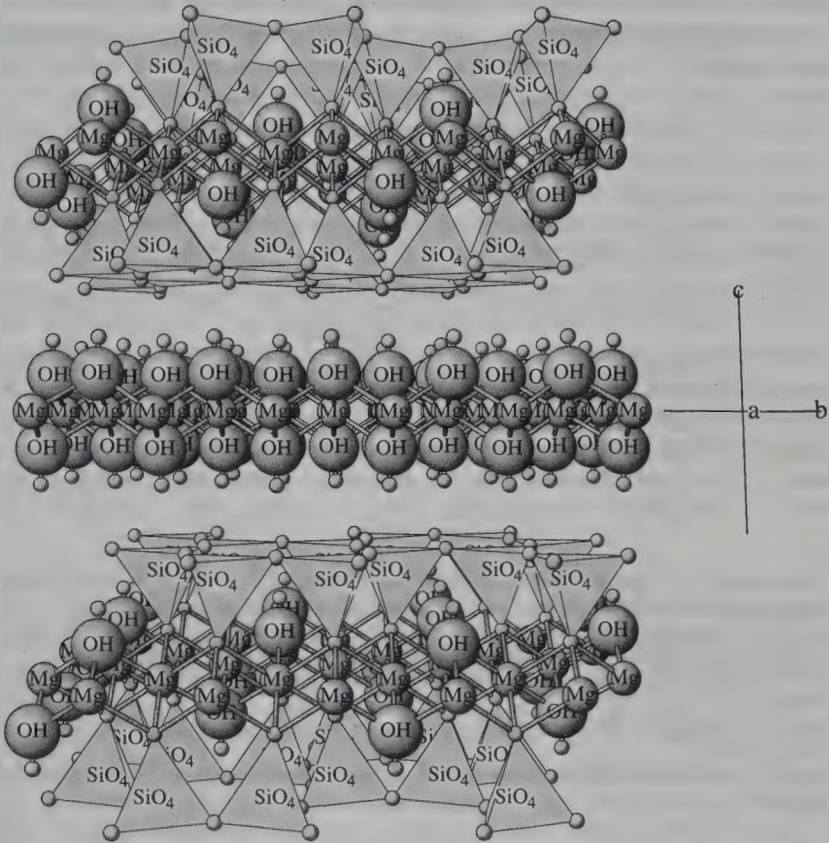

The structure consists of an alternation of layers of two distinctly different types. The first type is called the *tetrahedral-octahedral-tetrahedral* (t-o-t) layer (in the literature this layer is also sometimes called the *2:1 silicate layer*, *talc layer*, or *pyrophyllite layer*). The second type of layer we call the interlayer (in the literature it has sometimes been called the *gibbsite layer* or *brucite layer*).

The t-o-t layer is itself made up of two infinite sheets of six-membered rings of SiO₄ and AlO₄ tetrahedra. The two infinite sheets are oriented toward one another, apical oxygens and hydroxyl groups of one sheet facing the apical oxygens and hydroxyl groups of the other sheet, so that between the two sheets there is an interior set of octahedral sites, the X sites, for cations. The exterior sides of the t-o-t layer are generally oxygen only. The usual ratio of Si to Al in the tetrahedra is 3:1. As Si⁴⁺ is tetravalent and Al³⁺ is trivalent, the substitution of an aluminum for a silicon frees an electron, and the t-o-t layer can thus acquire a net negative charge. The overall chemical formula of the t-o-t layer can be given as, for example in the case of magnesium, Mg₃[(AlSi₃O₁₀)(OH)₂]⁻.

The interlayer is also made up of two infinite sheets, this time sheets of close-packed hydroxyl groups, with the interstices between the layers providing octahedral sites, Y sites, for cations. The interlayer generally has a net positive charge, an example of the formula being [Mg₂Al(OH)₆]¹⁺.

The interlayer and the t-o-t layer are bound together by electrostatic and hydrogen-bonding forces. Normal to the layers, in the *c* direction the usual repeat distance is 14 Å; that is, 14 Å is the usual thickness of one t-o-t layer plus one interlayer. The *a* and *b* directions of the t-o-t layer may be oriented relative to the *a* and *b* directions of the interlayer in 12 different ways, resulting in a series of 12 unique polytypes discussed in *AM* 46:819(1962), *CCM* 37:193(1989), *MJJ* 4:11(1963), *REVM* 19, *MSM* 1(5):86(1980).

CHLORITE: $Mg_3Si_4O_{10}(OH)_2 \cdot Mg_3(OH)_6$

This is a double sandwich structure, with talc layers alternating with $Mg(OH)_2$ (brucite) layers

The octahedral cation sites in both types of layers may be occupied by divalent or trivalent cations. When the cation is divalent, three of three adjacent cation sites may all be occupied, and this is electrostatically neutralized by $6OH^-$ ions (or by six O's from SiO_4 tetrahedra), leading to a group of zero net charge consisting of $[Mg_3^{2+}(OH^-)_6]^0$. A layer made up of such groups is referred to as *trioctahedral*, and each oxygen is surrounded by three divalent cations. Another contrasting situation exists when the cation is trivalent, such as Al^{3+} . The equivalent grouping consists of two trivalent cations plus an empty site: $[Al_2^+ \square (OH^-)_6]^0$. Sheets made up of this kind of group that involves vacancies are called *dioctahedral* since each oxygen is surrounded by only two octahedrally coordinated cations. With the chlorites the octahedral site occupancies are such that one can have two dioctahedral layers, two trioctahedral layers, or one of each. In the nomenclature of the group, the t-o-t

layer is mentioned first, so that in a *di-trioctahedral chlorite* the X sites in the t-o-t layer would be dioctahedral, and the Y sites in the interlayer would be trioctahedral.

CHLORITE GROUP

Mineral	Formula	Space Group	a	b	c	β	
Di-di-donbassite (Ia polytype)	$\text{Al}_2^{\text{3+}}[\text{Al}_{2/33}^{\text{3+}}]\text{Si}_3\text{AlO}_{10}(\text{OH})_8$	Monoclinic	5.16	8.94	14.15	93.83	71.4.1.1

Notes:

1. A wide variety of names have been proposed to account for major or minor elemental composition, crystal shapes, polytypes, and so on. These obsolete names include: aphrosiderite, brunsvigite, corundophilite, delessite, diabantite, daphnite, kammererite, leuchtenbergite, orthochamosite, orthochlorite, mennine, menninite, prochlorite, pseudothuringite, pycnochlorite, ripidolite, sheridanite, strigovite, talc-chlorite, and thuringite.
2. Franklinfurnacite is a related mineral with zinc in place of aluminum in the tetrahedra of the t-o-t layer.
3. Gonyerite is a related mineral with iron $\text{Fe}^{\text{3+}}$ in place of aluminum in the tetrahedra of the t-o-t layer.

71.4.1.1 Donbassite $\text{Al}_2^{\text{3+}}[\text{Al}_{2/33}^{\text{3+}}][\text{Si}_3\text{AlO}_{10}(\text{OH})_8$

Named in 1940 by Lazarenko for the location. Chlorite group. Not currently approved by the IMA-CNMMN. Originally called α -chloritite based on chemistry in 1906, but without physical data. MON C2/m, Cc, or C2. $a = 5.16\text{--}5.174$, $b = 8.94\text{--}8.956$, $c = 14.15\text{--}14.26$, $\beta = 93.83\text{--}97.83^\circ$ (two-layer polytype), $Z = 2$, $D = 2.66$. 45-1375(calc pattern): 14.1₆ 7.06₇ 4.71₁₀ 4.48₅ 3.98₉ 3.53₈ 2.52₅ 2.33₁₀. CCM 37:193(1989), SPC 17:456(1972). Structure generally Ia polytype. Ordering of Al into a specific tetrahedron has been observed with a partly vacant site above and below the Al ordered tetrahedron. SPC 17:456(1972). Generally fine-grained earthy, also flaky aggregates. White to slightly greenish or yellowish white, pearly luster. Cleavage {001}, perfect. $H = 2\text{--}2\frac{1}{2}$. $G = 2.63\text{--}2.64$. Slightly decomposed by HCl and H_2SO_4 , unaffected by HNO_3 . Flexible lamellae. Frequently near end member, but can grade to aluminian sudoite or cookeite. Total octahedral occupancy generally varies from 4.27 to 4.49, with $^{\text{IV}}\text{Al} = 0.6\text{--}1.3$. Minor substitutions (wt %) include: FeO, 0.54 (Novaya Zemlya); Fe_2O_3 , 3.34 (Kesselberg); MgO, 1.75 (Utrennyaia); MnO, 0.08 (Spain); CaO, 2.03 (Utrennyaia); TiO_2 , 1.2 (St-Paul-de-Fenouillet); Na_2O , 1.08 (Zhuravaka); K_2O , 3.95 (Kesselberg); Li_2O , 1.43 (Itaya). Biaxial (+); $Z \wedge c = 0^\circ$; $N_x = 1.560\text{--}1.578$, $N_y = 1.566\text{--}1.582$,

$N_z = 1.572\text{--}1.596$; $2V = 48\text{--}55^\circ$; birefringence = $0.006\text{--}0.018$; $r > v$; negative elongation; OAP parallel to (010). Probably a common mineral in high alumina, sedimentary, or altered wall or breccia-zone rocks of hydrothermal ore deposits (with hematite or arsenopyrite, etc.), fluorite veins, soils, sediments, and slickensides in coal. Frequently associated with kaolinite, muscovite or illite, pyrophyllite, interstratified phyllosilicates, and other minerals. Also occurs in granitic pegmatites. Observed as a hydrothermal alteration product of andalusite and spodumene. Major localities include: Alberni soils, BC, Canada; St-Paul-de-Fenouillet, eastern Pyrenees Mts., France; Cornberger sandstone, Hesse; Kesselberg, Schwarzwald, Germany; Zhuravaka and Nikitovsk ore field, and *Utrennyaia shaft and Uralskaya vein, Nagolyn area, Donbass region, Ukraine*; Karagand basin, Kazakhstan; Berezovskoye and Novaya Zemlya, Ural Mts., Russia; Kamp d'Atondo, Zaire; Namivu, Alto Ligonha, Mozambique; Itaya, Okayama Pref., Japan; Szabo Bluff, Scott Glacier, Antarctica. *VK, EF MS 21:40(1967), MM 52:396(1988), MIN 4(2):156(1992).*

71.4.1.2 Cookeite $\text{Al}_2[\text{LiAl}_2^{3+}][\text{Si}_3\text{AlO}_{10}](\text{OH})_8$

Named in 1866 by Brush for Josiah B. Cooke, Jr. (1827–1894), American chemist and mineralogist, Harvard University. Chlorite group. *MON C2/c* or *Cc*. $a = 5.13\text{--}5.17$, $b = 8.89\text{--}8.95$, $c = 14.09\text{--}14.35$, $\beta = 96.78\text{--}98.75^\circ$, $Z = 2$, $D = 2.68\text{--}2.70$. Rarely *TRIC C1*. *AM 60:1041(1975)*. $a = 5.14$, $b = 8.90$, $c = 14.15$, $\alpha = 90.58^\circ$, $\beta = 96.20^\circ$, $\gamma = 90^\circ$, $Z = 2$, $D = 2.65$. *38-416(1M_{Ia})*: 14.1_4 7.05_3 4.71_{10} 4.45_3 3.53_6 2.51_4 2.32_6 1.96_{35} ; *Ia(s)*: 14.1_{75} 7.05_6 4.68_{10} 4.44_3 3.51_6 2.50_5 2.32_9 1.49_5 ; *Ia(r)*: 14.1_9 4.70_6 3.52_6 2.81_{45} 2.56_6 2.505_8 2.32_{10} 1.49_{75} ; *Iib*: 14.1_8 4.70_8 4.45_{65} 2.47_{10} 2.37_8 1.96_{75} 1.49_9 . *CCM 37:193(1989)* and *45-1376*, *45-1377*, *45-1476*. Polytype is usually *Ia*, but *Iib* has been reported. *LIT 4:7(1971)*. Ordering of tetrahedral Si and Al has been suggested. Thin tabular crystals usually in radial rosettes; twinning sometimes present, around [310], with {001} composition plane. White or pale yellow or pale pink, frequently pale green, occasionally orange, rarely deep rose to purple; white streak; oily to subvitreous luster. Cleavage {001}, perfect; flexible, inelastic. $H = 2\frac{1}{2}\text{--}3\frac{1}{2}$. $G = 2.58\text{--}2.69$. Insoluble in common acids, soluble in HF. Cookeites generally have 4.9–5.35 octahedral sites occupied and can grade to lithian donbassite. Si is nearly constant at 3.0 Si atoms per four tetrahedral positions. Be and B may substitute for tetrahedral Al. The main octahedral substitution is $3(\text{Li, alkali})^+/\text{Al}^{3+}$. Total Li varies from 0.75 to 1.50 atoms per six octahedral positions. High- Al_2O_3 and lower- Li_2O cookeites could grade to donbassite, or with concomitant higher MgO, grade toward sudoite. Numerous minor substitutions (wt %) include: TiO_2 , 0.13 (Auburn); Fe_2O_3 , 1.72 (Allakurtti); B_2O_3 , 1.66 (Radkovice); FeO, 1.69 (Allakurtti); MnO, 0.86 (Vostoknoye); CaO, 1.63 (B.C.); MgO, 1.32 (Lipovka); BeO, 1.06 (Muiane); Na_2O , 1.12 (Lipovka); K_2O , 0.67 (Allakurtti); P_2O_5 , 0.11 (Varutrask); F, 0.46 (Hebron); B_2O_3 , 0.38 (Muiane). Biaxial (+); $Y = b$, $X \wedge a = 0\text{--}3^\circ$, $Z \wedge a = 90\text{--}87^\circ$, $Z \approx c$; $N_x = 1.572\text{--}1.585$, $N_y = 1.579\text{--}1.590$,

$N_z = 1.589-1.607$; $2V = 0-90^\circ$, usually $35-60^\circ$; $r < v$; birefringence = $0.014-0.031$; negative elongation; six twin sectors common and sometimes about a uniaxial core. May be pleochroic. $X = Y > Z$; X,Y, pale green to pink; Z, colorless to pale yellow. Most noted from late-stage mineralization in gem-pocket-bearing granite pegmatites associated with cleavelandite, elbaite, lepidolite, spodumene, and so on; also from some relatively simple quartz crystal-lined veins; increasingly recognized from sedimentary environments with kaolinite, diaspore, boehmite, illite, sandstones, bauxites (sometimes with fine-grained pyrophyllite), and others. Synthesized in the range $260-480^\circ$, $1-14$ kbar. *CMP 108:72(1991)*. Sometimes found among the corrosion products and as pseudomorphs of pegmatitic spodumene, petalite, and/or elbaite. Also noted as an alteration of kaolinite and diaspore, by Li-bearing solutions, releasing quartz. Notable localities include: Pulsifer mine, Auburn, Androscoggin Co., Bennett mine(!), Buckfield, Waisanen-Tamminen mine, Greenwood; *Mt. Rubellite mine, Hebron, and Mt. Mica mine(!), Paris, Oxford Co., ME*; Gillette mine, Haddam Neck, Middlesex Co., CT; Jeffrey mine, northern Little Rock, Pulaski Co., Stand on Your Head No. 2 mine(!), Saline Co., AR; Ozark Uplift, MO; Rib Mt., Marathon Co., WI; Tin Mountain mine, Custer, Custer Co., SD; Pala district, Himalaya mine, Mesa Grande, San Diego Co., CA; Wait-A-Bit Creek, BC, Canada; Ogofau mine, Carmarthenshire, Wales; northern Pennine ore field, England; Castelnau-de-Brassac, Tarn, Vanoise, Savoie, Pyrenees Mts., Haute Garrone, France; Batallero and Formigal mines, Tena Valley, Huesca, Spain; Richelsdorf Mts., Hesse, Germany; Dobrá Voda and Radkovice, Czech Republic; Varutrask, Västerbotten, Sweden; triclinic from Djalair bauxite deposit, Middle Asia, Allakurtti, Murmansk Oblast, Lipovka, Ural Mts., Vostoknoye, Siberia, and Kalbinski Mts., Ural Mts., Russia; Golconda mine(!), Governador Valadares, Lavra de Genipapo, Araçuaí, MG, Brazil; Carcota mine, Bolivia; Muiane pegmatite, Alto Ligonha district, Zambezia, Mozambique; Manono, Kivu, Zaire; Padar, Kashmir, Pakistan; Back Creek deposit, Pambula, NSW, Londonderry, WA, Australia. *VK, EF CM 10:636(1970), AM 60:1041(1975)*.

71.4.1.3 Sudoite $Al_2[Mg_2Al][Si_3AlO_{10}](OH)_3$

Named in 1962 by von Engelhardt, Müller, and Kromer for T. Sudo (b.1911), Japanese mineralogist. Chlorite group. *MON C2/m*. $a = 5.21-5.238$, $b = 9.02-9.080$, $c = 14.00-14.29$, $\beta = 97.03-97.45^\circ$. Or *C2/c*. $a = 5.225$, $b = 9.058$, $c = 14.19$, $\beta = 93.67^\circ$, $Z = 2$, $D = 2.65$. May also be *C1*. *19-751(1M_{IIb}, nat)*: 14.2_8 7.13_7 4.74_8 4.52_{85} 3.55_{65} 2.50_{10} 2.41_5 1.51_6 . Ia and IIb polytypes known. A di- or trioctahedral chlorite. IIb polytype: A characteristic feature of the one-level layers is the ordered distribution of the cations, in which two of the three independent positions are almost completely occupied by Mg, with one by Al. The interatomic distances show that the Al replaces the Si in an ordered fashion. Generally fine-grained earthy, sometimes $3-5$ μm , may form small plates (1 mm) in rosettes, or as scaly films. White to pale green, white streak, pearly luster. Cleavage $\{001\}$, perfect. $H = 2-2\frac{1}{2}$. $G = 2.67-2.70$. Sometimes

slowly decomposed by acids. Octahedral occupancy generally 4.5–5.1 per 6.0 sites, while $^{IV}Al = 0.4\text{--}1.1$ with $^{VI}Al = 2.5\text{--}3.4$ and $Mg = 1.2\text{--}2.5$. Can grade to magnesian donbassite, within a small distance. Intermediate compositions can grade to magnesian cookeite or aluminian clinochlore. Excess interlayer Mg commonly found. FeO, 6.27 wt % (Monticiano–Rocastrada) (“impure” specimens with $Fe > Mg$, Geco mine); Fe_2O_3 , 7.02 (Sivagli, Yakutia); TiO_2 , 0.34 (Rudnii Altai); MnO, 0.31 (Ardennes); CaO, 1.80 (Novo Zolotushinskoye); Na_2O , 1.41; K_2O , 1.52 (Furotobe); MnO, 0.28 (Ottre); Cr_2O_3 , 0.01 (Cigar Lake); BaO, 0.03 (Cigar Lake); Cu, 0.45 (Svagli, Yakutia); ZnO, 0.09 (Regnè); NiO, 0.09 (Ottre); F, 0.14 (Cigar Lake); Li_2O , 1.60 (Echassière), and could grade to cookeite. Biaxial (+); $Z \wedge c = 7^\circ$, Z perpendicular to (001); $N_x = 1.563\text{--}1.583$, $N_y = 1.569\text{--}1.589$, $N_z = 1.581\text{--}1.601$; $2V = 50\text{--}78^\circ$; birefringence = 0.018; negative elongation. Biaxial (–); $Z \wedge c \approx 90^\circ$; $N_x = 1.569$, $N_y = 1.579$, $N_z = 1.583$; $2V = 78^\circ$; birefringence = 0.014; $r < v$; negative elongation. Found in a wide variety of environments and frequently coexisting with a wide variety of minerals; can be found with and confused with pyrophyllite. Also sometimes associated with Mg-chlorites, kaolinite, dickite, nacrite, muscovite, illite, chloritoid, böhmite, and so on; often associated with metallic ore deposits, also in marine sediments, soils, low-grade metamorphic rocks, quartz veins, late-stage granite pegmatite alterations, hydrothermally altered sedimentary and igneous rocks, bentonites, diagenetic rocks. Can coexist with trioctahedral chlorites and may be a very common mineral. Observed to alter from andalusite. Only selected localities are given here: Chesapeake Bay, MD; Tracy mine, Negaunee, Marquette Co., MI; Colorado Plateau, CO; Geco mine, Manitouwadge, ONT; Cigar Lake Deposit, SAS, Canada; Anhee, Ottre and Regnè, Ardennes, Belgium; Echassières, Massif Central, France; Wippra Zone, Harz Mts., *Knollenmergel-Keuper, Lützelbach bei Plochingen, Württemberg, Germany*; Kaiserbach Valley, southern Pfalz, Germany; Monticiano–Rocastrada area, Apennine Mts., Italy; Sretnica Mt., Bosnia; Crete Is., Greece; Dneprovsk–Donetsk, Ukraine; Beresovsk, Ural Mts., Russia; Madneuli, Caucasus Mts., Novo Zolotushinskoye formation, and Orlovskoye, Rudnii Altai, Russia; Namivu, Mozambique; Kamikita mine, Honko deposit, Aomori Pref. and Hanaoka, Kosaka, Kamikita, and Furutobe mines and Niida mine, Odate, Akita Pref., and Shinyo, Japan; Welkom Goldfield, Witwatersrand Basin, South Africa; Chalmers, Q, Australia; Szabo Bluff, Scott Glacier, Antarctica. EF *JSP 27:355(1957)*, *AC 21(7):A172(1966)*, *AM 52:673(1967)*, *SPC 18:50(1973)*, *CM 16:365(1978)*, *CMP 86:409(1984)*, *MIN 4(2):161(1992)*.

71.4.1.4 Clinochlore $Mg_3^{2+}[Mg_2^{2+}Al][Si_3AlO_{10}](OH)_8$

Named in 1851 by Blake in allusion to its symmetry and relationship to chlorite. Chlorite group. MON *C2/m*. *Z* = 4. TRIC *P1*. *a* = 5.306–5.37, *b* = 9.203–9.40, *c* = 14.18–14.40, $\beta = 96.83\text{--}99.80^\circ$. Polytypes Ia, Ib, IIb, rarely IIA; *Z* = 2, *D* = 2.47–2.88. 16-362(ferroan clinochlore, $1M_{Ia}$); 16-351(ferroan clinochlore, $1M_{Ib}$); 12-242($1M_{IIb}$); 24-506($1M_{IIb}$); 7-160(chro-

mian $1M_{IIb}$); 7-78(ferrian $1M_{IIb}$); 29-701(ferroan $1M_{IIb}$); 20-671(chromian clinocllore, IIA); 45-1321(manganoan $1M_{IIb}$). Crystals usually only in vein cavities or fracture linings, tabular pseudo-hexagonal to blocky pseudorhombic, almost always horizontally grooved and almost always forming arcuate vermiform clusters. Generally green to very dark green or greenish black, rarely grading to white (low iron, high aluminum), rose to purple (> 2 wt % Cr_2O_3), or pinkish orange (Mn). $H = 2-3$. $G = 2.30-2.85$ (manganoan). Sector twinning common. Also twinned on {001} by mica and penninite twin laws. Cleavage {001}, perfect; flexible, but inelastic. Usually decomposed by acids, especially H_2SO_4 . Clinocllore forms a continuous series with chamosite and almost always has a small ferric iron content: $Fe_2O_3 = 8.42$ wt % (Chester Co.). Additional substitutions (wt %) include: Cr_2O_3 , 8.31 (Gümüşhane), 13.46 (northern Sweden); TiO_2 , 0.85 (Miask, Urals); MnO, 20.1 (Falotta, Graubunden, Switzerland); CaO, 1.24 (Deer Creek); Na_2O , 0.53 (Chester Co.); NiO, 7.60 (Ukraine). Biaxial (- or +), frequently uniaxial; $N_x = 1.555-1.670$, $N_y = 1.556-1.685$, $N_z = 1.558-1.685$; birefringence = 0.003-0.014, noticeable dispersion, frequently with anomalous blue interference colors, RI increases with increasing FeO or MnO and rises rapidly with increasing Fe_2O_3 . Uniaxial (+); $N_O = 1.562-1.587$, 1.618, $N_E = 1.576-1.594$, 1.621; birefringence = 0.003-0.014; negative elongation; low RI colorless, greenish gray to pleochroic. O, colorless; E, green. Sometimes $2V = 0-5^\circ$, usually resistant to H_2SO_4 decomposition. Uniaxial (-); $N_O = 1.579-1.619$, $N_E = 1.577-1.605$; birefringence = 0.002-0.014; positive elongation; sometimes $2V = 0-5^\circ$; pleochroic. O, green; E, pale green to colorless. Anomalous blue interference colors. Biaxial (+); $Z \approx c$; $N_x = 1.553-1.599$, $N_y = 1.554-1.601$, $N_z = 1.558-1.609$; $2V$ usually small $0-15^\circ$, but can be to 22° , and rarely to 50° ; $r < v$; birefringence = 0.005-0.010; negative elongation. Insoluble in H_2SO_4 . Biaxial (-); $X = c$; $N_x = 1.576-1.605$, $N_y = 1.578-1.619$, $N_z = 1.578-1.619$; $2V = 0^\circ$; $r > v$; birefringence = 0.003-0.014; positive elongation; anomalous blue interference colors. Pleochroic; X, colorless to pale green; Y, Z, green. Decomposed by H_2SO_4 . RI increases with FeO and more rapidly increases with Fe_2O_3 . Frequently, a product of contact or low-grade regional metamorphism. Found in fissure veins, soils, sediments, and amygdules in volcanic rocks. Frequently associated with feldspars, quartz, biotite, garnet, calcite group, dolomite group, magnetite, chromite, talc, serpentine, chloritoid, rutile, ilmenite, titanite, common sulfides, zircon, zeolites; rarely with corundum, diaspore, margarite, or spinel. Can be slightly to completely oxidized or replaced by other minerals. Found as a replacement of a variety of species, including garnet, pyroxene, amphibole, and so on. Found at Belvidere mine(!), Lowell, Orleans Co., Vermont; Acushnet, Bristol Co., MA; Tilly Foster mine(!), Brewster, Putnam Co., NY; Unionville, *Brinton mine*, West Chester, Chester Co., Cedar Hill mine(!), Texas, Wood's mine(!), Lancaster Co., PA; Culsagee mine, Macon Co., NC; Deer Creek, WY; Miles City, Custer Co., MT; Challis Custer Co., ID; Calaveras and San Benito Cos., and Sierra Nevada Mts., CA; Black Lake mine, Coleraine, Jeffrey mine(!), Asbestos, PQ, Canada; Banffshire, Scotland; Harstig mine, Pajsberg, Varmland,

Sweden; St. Christophe, Isère, France; St. Gotthard(I), Rimpfischwäge, Zermatt(I), Vallais, Switzerland; Marienberg, Saxony, Germany; Zillertal, Burgumer Alp, Pfisch, Tirol, Austria; Traversella(I), Ala, Aosta, Ossola, and Fassa valleys, Piedmonte, Italy; Frankenstein, Silesia, Poland; Kop Chrom mine(I) and elsewhere, Kop Doglari, Askale, near Erzurum, Erzincan, and Gümüşhane, Anatolia, Turkey; Saranovskii mine(I), Saranui, Bazhenovsk mine(I), Asbest, Akmatovsk(I), Zlatoust(I), Syssertsk, Karkadansk, and Nasiamsk, Ural Mts., Korshunovsk deposit, Siberia, Russia; [Ushkatin] Atasu deposits, central Kazakhstan; Pedra Preta mine, Brumado, Bahia, Brazil; Kumanohata mine, Shiga Pref., Japan; Nelson, New Zealand.SPC 18:50(1973), VK, EF *MIN* 4(2):179(1992).

71.4.1.5 Nimite (Mg,Ni)₃[Ni₂Al][Si₃AlO₁₀](OH)₈

Named in 1968 by De Waal for the acronym of the National Institute for Metallurgy, South Africa. Chlorite group. MON *C2/m*. $a = 5.320\text{--}5.346$, $b = 9.214\text{--}9.268$, $c = 14.302, 28.649$, $\beta = 97.10^\circ$, $Z = 2$ (I Ib) or 4 (Ia), $D = 3.20\text{--}3.21$. 22-712(1M_{I Ib}, nat): 14.2₃ 7.10₁₀ 4.74₂ 4.60_{<1} 3.55₅ 2.84₁ 2.58_{<1} 2.00_{<1}. 38-424(1M_{Ia}, nat): 7.11₁₀ 4.74₅ 3.56₆ 2.65₄ 2.55₃ 2.39₅ 2.01₃ 1.54₅. Nimite is mostly composed of the I Ib polytype. Fine-grained. Yellowish green, white streak, oily to vitreous luster. Cleavage {001}, perfect. $H = 3$. $G = 3.12\text{--}3.19$. IR data: *MIN* 4(2):223(1992). Type material is magnesian: MgO = 10.13. Minor substitutions (wt %) include: Fe₂O₃, 4.35; Cr₂O₃, <0.01; FeO, 2.78; MnO, 0.06; CaO, 0.38; CoO, 0.38. Biaxial (-); $N_x = 1.637$, $N_y = N_z = 1.647$; $2V = 15^\circ$; birefringence = 0.010. Weakly pleochroic; X, yellow-green; Y, Z, apple-green. Found in nickeliferous serpentinite with bonaccordite, bunsenite, gaspeite, goethite, liebenbergite, millerite, opal, reevesite, trevorite, violarite, and/or willemseite. 3+ km W of Scotia Talc mine, Bon Accord area, Barberton district, Transvaal, South Africa; Woodline Well, WA, Australia. VK, EF *AM* 55:18(1970), *MSM* 5:94(1980).

71.4.1.6 Baileychlore Zn₃[Fe²⁺Al][Si₃AlO₁₀](OH)₈

Named in 1988 by Rule and Radke for Sturges W. Bailey (b.1919), mineralogist, University of Wisconsin. Chlorite group. TRIC *C1* or *C1*. $a = 5.346$, $b = 9.257$, $c = 14.402$, $\alpha = 90^\circ$, $\beta = 97.12^\circ$, $\gamma = 90^\circ$, $Z = 2$, $D = 3.20$. *AM* 73:135(1988). 42-1335 gives MON *C2/m*. $a = 5.344$, $b = 9.249$, $c = 14.392$, $\beta = 97.06^\circ$. 42-1335: 14 3₉ 7.14₁₀ 4.60₃ 3.573₄ 2.66₅ 2.450₄ 1.542₆ 1.508₃. Type material contains 0.36 vacancy out of six octahedral sites and is the Ib polytype with broadened *hkl* reflections. A one-dimensional electron-density analysis and an asymmetry value of +1.29 suggest a composition ^{VI}(Zn_{2.50}Al_{0.14}vacancy_{0.36})^{0.58} for the 2:1 layer and ^{VI}(Fe²⁺1.20Al_{1.03}Mg_{0.76}Mn²⁺0.01)^{1.01+} for the interlayer sheet. *AM* 73:135(1988). Dark green fibrous veinlets. $G = 3.18$. Cleavage {001}, perfect. DTA-TGA. Type material is a ferroan baileychlore with FeO to 14.5 wt %. Additional substitutions (wt %) include: MgO, to 4.7; MnO, to 0.4; CaO, to 1.0. Biaxial (+); $N_x = 1.582$, $N_{av} = 1.59$, $N_z = 1.614$; weakly pleochroic green-yellow green. Type material

is optically zoned green to yellow-green along the fiber length. Found as selvages (to 1 mm) lining calcite veins in mineralized collapse karst-breccia, composed of altered andesite, garnet-vesuvianite skarn, sandstone, felite porphyry, and chert. Associated with chalcopyrite, zincian clinocllore, copper, cuprite, goethite, hematite, and malachite. *Red Dome deposit, Mungana, 15 km WNW of Chillagoe, Lynd Co., Q, Australia.* VK, EF

71.4.1.7 Chamosite $\text{Fe}_3^{2+}[\text{Fe}_2^{2+}\text{Al}][\text{Si}_3\text{AlO}_{10}](\text{OH})_8$

Named in 1820 by Berthier for the locality. Chlorite group. Synonyms: daphnite, delessite, brunsvigite. MON $C2/m$, $C2$, and ORTH. $a = 5.363\text{--}5.40$, $b = 9.286\text{--}9.375$, $c = 14.00\text{--}14.222$, $\beta = 90^\circ$, $97.43\text{--}97.88^\circ$, 99° ; $Z = 2$, $D = 3.10\text{--}3.13$. $21\text{--}1227(1M_{\text{Ib}})$: 14.1_7 7.05_{10} 3.52_{10} 2.60_9 2.55_7 2.45_7 2.39_8 1.55_9 ; $13\text{--}29(1O_{\text{Ib}})$: 14.1_4 7.05_{10} 4.71_4 3.53_8 2.84_3 2.52_5 2.15_4 1.56_4 . Crystals tabular pseudohexagonal to blocky pseudorhomboidal. Green to greenish black, oily to vitreous luster. $H = 2\frac{1}{2}\text{--}3$. $G = 2.95\text{--}3.30$. Cleavage $\{001\}$, perfect; foliated, flexible but inelastic. Decomposed by hot HCl. Grades toward clinocllore with increasing MgO and toward pennantite with increasing MnO; almost always contains ferric iron (wt %): Fe_2O_3 , 18.97 (Messina); 8.70 (Schmiedefeld). Additional substitutions (wt %) include: TiO_2 , 0.35 (NZ); MnO, 21.14 [Ushkatin] Atasui deposits, Kazakhstan; ZnO, 0.16 [Ushkatin]; CaO, 3.34 (Frodingham); Na_2O , 1.1 (Penzance); K_2O , 0.50 (Mourne). Displays a wide variety of optical behavior. Uniaxial (-); $N_O = 1.637\text{--}1.643$, $N_E = 1.615\text{--}1.649$; birefringence = 0.006–0.022; positive elongation. O, olive-green; E, pale yellow to brownish yellow. Biaxial (+); $Z \approx c$; $N_x = 1.620\text{--}1.630$, $N_y = 1.620\text{--}1.630$, $N_z = 1.625\text{--}1.635$; $2V = 0\text{--}5^\circ$; $r > v$; birefringence = 0.005; negative elongation; pleochroic. X, Y, deep green; Z, greenish brown. Not decomposed by acids. Biaxial (-); $X = c$; $N_x = 1.643\text{--}1.670$, $N_y = 1.649\text{--}1.685$, $N_z = 1.649\text{--}1.685$; $2V = 0\text{--}6^\circ$; birefringence = 0.006–0.015; positive elongation. X, pale yellow; Y, Z, olive-green. Decomposed by acids. Biaxial (-); $N_x = 1.615$, $N_y = 1.637$, $N_z = 1.638$; $2V = 15^\circ$; birefringence = 0.023, positive elongation. Pleochroic; X, olive; Y, Z, brownish yellow. Decomposed by acids. RI increases with increasing FeO and increases rapidly with Fe_2O_3 . Formed in low-grade regional and contact-metamorphosed rocks, granite pegmatites, also forms as a hydrothermal alteration of wall rock around sulfide deposits; amygdules in volcanic rocks. Abundant in soils and marine clays. Observed in coal deposits. Found variously associated with quartz, feldspars, garnet, muscovite, biotite, amphiboles, pyroxenes, dolomite group, chromite, talc, serpentine, chloritoid, ilmenite, titanite, common sulfides, zircon, zeolites, siderite, calcite, tourmaline, magnetite, hematite, rutile, and others. Observed as a replacement of a wide variety of silicates, including garnet. Alters by recrystallization and reaction with coexisting iron minerals, including siderite, to a fine-grained, more iron-rich chamosite. Also alters to limonite. Excellent quality or analyzed material found at: Rangeley formation, Byron, Oxford Co., Maple Mt., Aroostook Co., ME; State Line quarry, York Co., French Creek, Chester Co., PA; Harper's Ferry, Jefferson Co., WV; Hot Springs, Garland Co., AR; Michigamme, Marquette Co., MI; Climax, Lake Co., CO; Lis-

keard, Tolgus mine, Redruth, Coradon mine, St. Clear, and Penzance, Cornwall, Wickwar, Gloucestershire, Frodingham, Lincolnshire, England; Silent Valley quarry, Mourne Mts., Northern Ireland; Bas Vallon, Brittany, St. Christophe, Isère, France; Windgalle, Uri, *Chamoson, Valais, Switzerland*; Schmiedefeld, Saalfeld, Thuringen, Büchenberg, Harz, Germany; Grangesberg, Sweden; Nučič, Chrustenic, and Kank, Čechy, Czech Republic; Strzegom (Streigau), Wrocław, Poland; [Ushkatin] Atasui deposits, Kazakhstan; Messina, Transvaal, South Africa; Randalls and Kalgoorlie, WA, Australia; Tateyama Hot Springs, Jodojama, Toyama Pref., Kumano-hata mine, Shiga Pref., Japan; Great Is., New Zealand. VK, EF *MM* 25:441(1939), 30:277(1954); *MIN* 4(2):207(1992).

71.4.1.8 Pennantite $Mn_3^{2+}[Mn_2^{2+}Al][Si_3AlO_{10}](OH)_2$

Named in 1946 by Campbell et al. for Thomas Pennant (1726–1798), Welsh naturalist. Chlorite group. MON *C2/m*. $a = 5.41\text{--}5.51$, $b = 9.40\text{--}9.54$, $c = 14.25\text{--}14.40$, $\beta = 96.8\text{--}97.3^\circ$, $Z = 2$, $D = 3.18$. 42-594(1M_{IIb}, nat): 7.12₁₀ 3.56₉ 2.65₇ 2.60₅ 2.43₅ 2.30₅ 2.03₆ 1.58₁₀; 29-884(1M_{Ia}, nat): 14.3₄ 7.1₁₀ 4.75₃ 3.57₈ 2.70₄ 2.43₈ 2.03₄ 1.68₃. Known as Ia (“grovesite”) and IIb polytypes. Generally fine-grained or closely packed small rosettes, rarely platy. Orange-brown, blackish brown to dark red; waxy to oily luster. $H = 2\text{--}2\frac{1}{2}$. $G = 3.04\text{--}3.15$. Cleavage {001}, perfect. Grades toward magnesian clinocllore. Substitutions observed (wt %) include: Fe₂O₃, 6.67 (Ushkatin); MgO, 3.4 (Franklin); BaO, 1.33 (Benalt); ZnO, 15.9 (Franklin); minor Pb, Na, K, and Ge detected (Ushkatin). Uniaxial (–); $N_O = 1.667\text{--}1.673$, $N_E = 1.658\text{--}1.664$; birefringence = 0.009; positive elongation; pleochroic. O, dark brown; E, perpendicular to {001}, red-brown. For Ia: biaxial (–); X perpendicular to {001}; $N_x = 1.646\text{--}1.664$, $N_y = 1.661\text{--}1.673$; $2V = 0\text{--}1^\circ$; $r \ll v$; birefringence = 0.009–0.029; positive elongation. Pleochroic; X, red-brown; Y, Z, dark brown. Found in a variety of metamorphic or hydrothermally altered manganese- and zinc-bearing assemblages. Found associated with alleghanyite, analcime, banalsite, barite, calcite, kellyite, kutnahorite, paragonite, prehnite, rhodochrosite, and/or willemite. Mine Hill, Franklin, NJ; Bald Knob, Sparta, Alleghany Co., NC; *Ty Canol incline, Benalt mine, Rhiw, Carnarvonshire, Lleyn Peninsula, Gwynedd, Wales*; French Alps (Dept. Savoie); [Ushkatin] Atasui deposits, central Kazakhstan. VK, EF *MM* 27:217(1946), 30:645(1954); *CM* 21:545(1983); *MIN* 4(2):229(1992).

REGULARLY INTERSTRATIFIED PHYLLOSILICATE GROUP

The great abundance of clay minerals with superlattice (long period basal) reflections has led to the recognition of phyllosilicates composed of a mixture of layered structures. Although clay minerals are generally too small to be subjected to single-crystal structural analysis techniques, one-dimensional Fourier calculations have generally substantiated the belief that a portion

of the clay minerals consist of regular, 1:1 interstratifications of mica-like, talc/pyrophyllite-like, chlorite-like, vermiculite-like, serpentine-like or smectite-like layers: ". . . non-random interstratification involving a proportion of two types of layers different from 1:1 is less easily recognized, because it gives rise to a sequence of (00 l) reflections that is non-integral and is often mistakenly assumed to be random." (*CCM 18:25(1970)*). Trioctahedral serpentine-like layers have not been observed in regularly interstratified phyllosilicates, but dioctahedral kaolinite-like layers have not been well characterized. One dimensional Fourier methods of structure calculations have been summarized (*CCM 18:25(1970)*), Int. Clay Conf., Denver 1985:33). HRTEM and NMR studies are numerous enough that regular interstratification of phyllosilicates is verified, independent of XRD studies. These individual layers can be dioctahedral or trioctahedral, but are generally of the same type within a particular sample. (As the individual layers are not a true fragment of the mineral they represent, the suffix "like" is added to the layer name to clarify the use of smectite-like vs. smectite, for instance. Dioctahedral smectite is preferable to "montmorillonite" unless it was defined as a necessary component of a particular 1:1 interstratified mineral). Recent NMR analysis of the rectorite structure has broad implications as to the actual character of the "species-like" layers. NMR study has suggested that similar Al \leftrightarrow Si substitutions occur in the tetrahedral sheets facing the interlayer cations, rather than being on either side of the octahedral sites within a layer. Therefore, juxtaposed tetrahedral sheets might be both mica-like (Si₃Al) or both margarite-like (Si₂Al₂) about the fixed interlayer cation and both smectite-like (Si_{4-x}Al_x) tetrahedral sheets facing the exchangeable cation. The interstratifications could therefore be considered as hybrid layers where each and every layer was composed of smectite-like and mica-like or margarite-like tetrahedral sheets with alternation of "up-down" hybrid layer orientations (*AM 80:247(1995)*). Some regularly interstratified minerals appear more likely to be the result of constructive changes (e.g. LLC corrensite), while some may be more likely to be degradation products (hydrobiotite). Conjecture has been directed at interstratified phyllosilicates concerning their stability and whether or not they would spontaneously transform, through time, into inter-stratified phyllosilicates. Many interstratified clays are not 1:1 regular structures, but have random stacking and/or greater proportions of one layer compared to another. The regular interstratifications yield superlattice reflections equivalent to the sum of the thickness of the component layers, while semi-randomly or disproportionately (i.e. non-1:1) interstratified structures do not coherently diffract X-rays and so yield spacings only of their individual layers. Ordered interstratifications can be grouped in packets within otherwise non-interstratified or randomly interstratified clay particles. It is frequently possible that recognition of "regular" interstratifications to 2:1 is possible, but with diminished intensities and increasingly non-integral spacings. High ratios of interlayers do not provide sufficient intensities to be observed. Interstratified minerals are variously reported as hexagonal or orthorhombic, but few data have been presented to support these high symmetry categorizations. Not all interstra-

tified layers have similar elemental ratios. For example, the chemical variability of chlorite-like layers appears greater than their co-interstratified smectite-like layers (*CCM 32:391(1984)*). Major problems of studies with regularly interstratified phyllosilicates have been attempts to rationalize new kinds of interstratifications or chemical variations with pre-existing classifications instead of recognizing a new mineral species.

Definitions. The AIPEA (Associated Internationale Pour l'Etude des Argiles) has adopted a set of criteria by which they will approve newly named 1:1 regular interstratifications (*CM 17:243(1982)*, *CCM 30:76(1982)*). The most important criterion includes: "To merit a name, an interstratification of two layer types A and B should have sufficient regularity of alternation to give a well-defined series of at least ten 00- summation spacings $d^{AB} = d^A + d^B$, for which the suborders are integral and the even and odd suborders have closely similar diffraction breadths. If any odd 00- suborders are absent, calculations must be given to show that their intensities are too small to be observed. The coefficient of variation (CV) of the d(00-) values should be less than 0.75 to demonstrate adequate regularity of alternation." Additional details are considered. The limits of interstratification proportions have not been rigorously defined. Use of a species name suggests 1:1 proportions, but almost all natural samples deviate from this ratio slightly to significantly and still show characteristic long period spacings.

Types of Interstratification. The thickness of the various layers are constant: serpentine-like $\approx 7.3\text{\AA}$, talc/pyrophyllite-like $\approx 9.1 - 9.4\text{\AA}$, mica-like $\approx 10\text{\AA}$, vermiculite-like $\approx 12 - 14\text{\AA}$, chlorite-like $\approx 14\text{\AA}$, smectite-like $\approx 15 - 17\text{\AA}$. Therefore, hydrobiotite, 1:1 mica-like/vermiculite-like interstratifications should have a spacing $10\text{\AA} + 14\text{\AA} = 24\text{\AA} +/ -$. Observed basal spacings alone are not unambiguous, especially when a given layer can be variously hydrated. Various diagnostic tests have been devised to verify the swelling or collapsing characteristics of the various layers involved, including intersalination, intercalation by organic liquids, or dehydration by heat. Computer programs have been devised to analyse interstratified phyllosilicate data (*CM 28:445(1993)*). A number of observed regular interstratifications have not been proposed for species status for different reasons, including high CV, ambiguous data, etc. Multiple interstratifications have been proposed, such as tarasovite (mica-like/rectorite-like, chlorite-like/corrensite-like, etc., but these materials are not 1:1 regular interstratifications and the CV is usually unfavorable.

Regularly interstratified phyllosilicates assemblages and localities which have been extensively studied (e.g. rectorite and corrensite) show a tendency to have shorter period phyllosilicate assemblages with increased age or with subjection to increased temperature exposure. For example illite-like/smectite-like interstratifications disappear at depth. Also basin-wide patterns show corrensite distributed between non-interstratified smectite-bearing and chlorite-bearing zones. Some interstratifications are not predicted. For example, vermiculite is a trioctahedral mineral by definition, and a report of a

dioctahedral "vermiculite-like" layer would be a misnomer. Table xx is a summary of the 1:1 regularly interstratified phyllosilicates.

Kaolinite-like/smectite-like interstratifications have been occasionally reported (*CM 26:343(1991)*; Murray et al., *Kaolin Genesis and Utilization*, 1993). The interstratification is generally poorly crystalline, yielding too few peaks to allow characterization or is randomly interstratified, yielding nonintegral basal reflections.

TABLE 1. 1:1 REGULARLY INTERSTRATIFIED PHYLLOSILICATES

	mica-like	talc/pyrophyllite-like	smectite-like	vermiculite-like	serpentine-like	layer types
pyrophyllite	—		—	‡	—	di-, dioctahedral

	hydrobiotite	**	—	—	—	tri-, trioctahedral
smectite	Na-rectorite					di-, dioctahedral
	K-rectorite					
	—			di-, trioctahedral		
	—			tri-, trioctahedral		

* indicate that a material of this category has been reported without a specific proposal being made as to its nomenclature. *NJGPA 1988: 176 **sometimes has been called rectorite, but this interstratification is unknown.

‡ = not predicted [The octahedral site occupancies are designated for all layers. Whichever layer sequence is listed first, that layer has its site occupancy listed first. For chlorite-like interstratifications, the first designator is for the silicate layer, while the second designator is for the interlayer: di-, trioctahedral therefore signifies a dioctahedral silicate layer with a trioctahedral interlayer.]

71.4.2.1 Dozyite $[(Mg, Fe^{2+})_3SiAlO_5(OH)_4 \cdot (Mg, Fe^{2+})_3[(Mg, Fe^{2+}, Fe^{3+})_2Al](Si, Al)_4O_{10}(OH)_8]$

Named in 1995 by Bailey et al. for Jean Jacques Dozy, Dutch geologist. *MON Cm*. $a = 5.323$, $b = 9.215$, $c = 21.45$, $\beta = 94.44^\circ$, also 90° (Pennsylvania), $Z = 2$. Oriented basal reflections noted $d_{(001)}$, $21.4_{14 \text{ calc}}$; $d_{(002)}$, 10.71 ; $d_{(003)}$, 7.12_3 ; $d_{(004)}$, 5.31_2 ; $d_{(005)}$, 4.30_2 ; $d_{(006)}$, 3.56_{10} ; $d_{(007)}$, 3.06_2 ; $d_{(00.15)}$, 1.426_2 . *AM 80:65(1995)*. Powder diffraction results: 7.1_{10} , $d_{(003)}$; 4.61_3 , $d_{(02.11)}$; 3.56_2 , $d_{(006)}$; 2.61_8 , $d_{(201,13-2)}$; 2.56_5 , $d_{(132,20-3)}$; 2.43_4 , $d_{(203,13-4)}$; 1.536_6 , $d_{(060,33-1)}$; 1.501_7 , $d_{(332,063,33-4)}$. *AM 80:65(1995)*. Indonesian dozyite is a Iaa-2,4,6 polytype. Dozyite is a regularly interstratified 21-A phyllosilicate with alternating trioctahedral serpentine-like and trioctahedral chlorite-like layers, but stacking errors were detected and intergrowths with amesite noted. It is the first 1:1 layer with 2:1 layer phyllosilicate interstratification. HRTEM imaging confirmed the interstratification. *CMP 117:137(1994)*.

Random serpentine-like–chlorite-like interstratifications have frequently been observed. *AM 80:65(1995)*. Does not swell with organic fluids, does not collapse on heating to 400°: “Detection of interstratification thus depends on a detailed comparison of observed and calculated peak intensities and widths.” *AM 80:65(1995)*. Found as white to colorless foliae (to 2 mm) (Indonesia); also observed as pale purple or mauve fibers (chromian) (Pennsylvania); white streak; pearly luster. $H = 2.5$. $G = 2.66$. Cleavage (001), perfect. Biaxial (+); $2V < 5^\circ$; pseuduniaxial; OPA parallel to (010), $Y = b$, $Z \wedge c = 4^\circ$; $N_x = N_y = 1.575$, $N_z = 1.581$; weak dispersion. X, Y, colorless; Z, pale tan in thick crystals. Dozyite is difficult to distinguish optically from randomly interstratified serpentine-like–chlorite-like layers associated with it (Indonesia). Dozyite has the following formula: $(Mg_{2.00}Al_{0.85}Fe^{3+0.15})^{+1.00} 3.00 (Si_{1.00}Al_{1.00})^{-1.00} 2.00O_5(OH)_4 (Mg_{5.29}Al_{0.70}Fe_{0.04}^{++})^{+0.80} 6.03(Si_{3.18}Al_{0.82})^{-0.82} 4.00O_{10} (OH)_8$ and is thus an interstratified amesite-like–clinochlore-like mineral. Chemical analyses (Indonesia, wt %) gave: SiO₂, 29.69; Al₂O₃, 20.29; MgO, 43.74; FeO, 1.63; CaO, 0.04; Na₂O, 0.07; K₂O, ~ 0; Li₂O, ~ 0; B₂O₃, ~ 0; BeO, ~ 0; Cl, 0.18; H₂O, 12.20. Low Al in dozyite from Pennsylvania rules out the likelihood of its having amesite as its serpentine component. An iron-rich dozyite consisting of berthierine-like layer–chamosite-like layer interstratification has been described. *GSAPA: A-146(1993)*. Found in Si, Fe, and Al metasomatized and hydrothermally altered limestone resulting in a “skarn.” Associated minerals include lizardite, chrysotile pseudomorphic after forsterite, antigorite, amesite, clinochlore (IIBb, etc.), magnesite, dolomite, calcite, anhydrite, chalcopyrite, etc. (Indonesia). Also found with chromite, chromian clinochlore (IIBb), and chromian lizardite (Pennsylvania). *Wood’s chrome mine, Lancaster Co., Pennsylvania*; Archean granulite-facies ironstone, eastern border of Beartooth Mts., MT; *drill core in skarn near Ertsberg East mine, 4,200-m elevation, Carstenz Mts., central Irian Jaya, Indonesia*. VK, EF

71.4.2.2 Lunijianlaite $[Al_2(LiAl_2)Si_3AlO_{10}(OH)_8/Al_2Si_4O_{10}(OH)_2] = LiAl_5(Si_7Al)O_{20}(OH)_{10}$

Named in 1990 by Kong et al. for “chlorite alternating (interstratified) with pyrophyllite.” Probably MON Space group unknown. $a = 5.09$, $b = 8.97$, $c \sin \beta = 23.397$. *AMS 10:289(1990)*. On hexagonal axes: $a = 5.085$, $c = 23.367$, $D = 2.75$ – 2.80 . *PD(nat)*: 14.27₂ 11.79₂ 7.80₂ 4.70₁₀ 3.90₁ 3.54₅ 3.34₅ 2.92₄ 2.83₂; *45-1397*: 23.5₁ 11.79₂ 7.80₂ 4.70₁₀ 3.90₁ 3.34₅ 2.92₄ 1.95₁. Lunijianlaite is an interstratified cookeite-like–pyrophyllite-like interstratification with ≈ 23 – 24 Å basal spacing. Does not expand with glycol and does not collapse on heating to 500°. Colorless to white radial aggregates to 2 mm, pearly to vitreous luster, transparent. $H = 2$. $G = 2.75$. Cleavage (001), perfect. Biaxial (–); $N_x = 1.576$, $N_y = 1.583$, $N_z = 1.587$; $2V = 61^\circ$; birefringence = 0.011; extinction can be undulatory, extinction with cleavage can be parallel to 2–6°. Chemical analysis (wt %) of type material gave: SiO₂,

41.61; Al₂O₃, 44.80; Fe₂O₃, 0.60; Li₂O, 1.57; Na₂O, 0.063; K₂O, 0.012; H₂O⁺, 11.296. Occurs with blue corundum aggregates with pyrophyllite in hydrothermally altered rhyolite. Can be in contact with diaspore and intergrown with minor cookeite. Additional associated species include chlorite, illite, halloysite, svanbergite, zeolites, and specular hematite. *Qingtian, Zhejiang Prov., China*. VK, EF

71.4.2.3 Saliotite Al₂(LiAl₂)Si₃AlO₁₀(OH)₈/(Na,K)Al₂Si₃AlO₁₀(OH)₂

Named in 1994 by Goffé for Pierre Saliot (b.1941), geologist at l'Ecole Normale Supérieure de Paris. MON C2/m. $a = 5.158$, $b = 8.914$, $c = 23.83$, $\beta = 94.23^\circ$, 1M polytype, $Z = 4$, $D = 2.75$. PD (random orientation): 11.9₇ 4.75₅ 4.46₉ 4.32₉ 2.55₁₀ 2.48₇ 1.62₅ 1.49₉; (oriented): 23.8₆ 11.9₄ 7.9₃ 4.75₈ 3.40₁₀ 2.97₅. An ordered (1:1) 23.5- to 24-Å interstratification of cookeite (di-trioctahedral chlorite, 14 Å) and paragonite (dioctahedral mica, 9.5 Å). *EJM 6:897(1994)*. Should not expand with glycol or collapse with heating > 500°. Occurs as deformed lamellae 0.25–1 mm long and 0.05–0.1 mm thick. Sometimes in 0.5-mm-diameter rosettes included in quartz. White to colorless, nonfluorescent. Cleavage {001}, perfect. Low hardness and tenacity. Biaxial (-); $N_x = 1.58$ –1.59, $N_y = 1.58$ –1.59, $N_z = 1.59$ –1.60; $2V = 30$ –50°; birefringence = 0.007. Traces of FeO (0.4 wt %), CaO (0.3 wt %), K₂O (0.35 wt %) present. Saliotite occurs in schists as a high-pressure, low-temperature metamorphic rock-forming mineral. Associated with pyrophyllite, paragonite, cookeite, and calcite. Found in the Alpujarrides nappes in the Sierra Alhamilla (Betic chain; Andalusia), Spain. An illite-like-sudoite-like interstratification "saliotite" was found at the Hanaoka mine, Kuroko, Akita Pref., Japan [*CS 4:45(1972)*]. VK, EF

71.4.2.4 Tosudite Chlorite-like-smectite-like layers; three varieties have been distinguished:

Al-tosudite [Al₂(Al_{2.33})Si₃AlO₁₀(OH)₈/(Na,Ca)_{0.33}Al₂(Si,Al)₄O₁₀(OH)₂· n H₂O], **Mg-tosudite** [Al₂(Mg₂Al)Si₃AlO₁₀(OH)₈/(Na,Ca)_{0.33}Al₂(Si,Al)₄O₁₀(OH)₂· n H₂O], and **Li-tosudite** [Al₂(LiAl₂)Si₃AlO₁₀(OH)₈/(Na,Ca)_{0.33}Al₂(Si,Al)₄O₁₀(OH)₂· n H₂O]

Named in 1963 by Frank-Kamenetsky et al. for Toshio Sudo (b.1911), Japanese mineralogist and crystallographer, University of Tokyo. Interstratified phyllosilicate group. Synonym: alushtite. HEX (given on 12-231 and 22-956, varieties not stated) but probably ORTH, HEX cell: $a = 5.125$ –5.214, $c = 29.78$ –29.80, $Z = 1$. ORTH cell: $a = 5.0$, $b = 8.9$, $c = 29.8$, $Z = 2$. Some may be MON C2 [*MIN 4(2):271(1992)*], with $a = 5.15$ –5.21, $b = 8.94$ –9.03, $c = 24.2$ –25.1, $\beta = 94^\circ$ (desiccated material). D (for ORTH cell) = 2.46. 12-231(nat): 30.0₆ 15.0_{<9} 4.97₈ 4.53₁₀ 3.29₃ 2.60₃ 2.54₅ 1.51_{<5}; 22-956(nat): 30.4₁₀ 15.2₇ 10.0₁ 5.01₂ 4.48₃ 3.30₁ 2.56₁ 1.49₁. As currently defined, tosudite consists of three varieties. The original material (Al-tosudite) is an interstratified species that is di-, dioctahedral chlorite-like (donbassite-like) with dioctahedral smectite-like layers and is aluminum-rich, but also has significant, although minor, Mg.

Later discoveries include: di-, trioctahedral chloritelike "sудоite-like" with dioctahedral smectite-like layering (Mg-tosudite), and di-,trioctahedral chloritelike "cookeite-like" with smectite-like layering (Li-tosudite). Tosudites are 29.5- to 30.5-Å phyllosilicates with an X-ray powder pattern very similar to that of corrensite, tri-,trioctahedral chlorite-like with trioctahedral smectite-like layers, but with differences in peak intensities. Originally erroneously stated to be a pyrophyllite-like-hydroargillite-like interstratification. Octahedral occupancy for chlorites and chlorite smectites that do not contain lithium can be determined roughly from the position of the 060 reflection. A completely dioctahedral structure will give an 060 around 1.49 Å, a trioctahedral 060 is at about 1.54 Å, and a mixed di-,trioctahedral structure will give a peak about 1.51 Å (Bailey, 1975). Li-tosudite and cookeite, however, may give a dioctahedral 060 spacing around 1.49 Å, even though the hydroxide interlayer may be trioctahedral. The problem lies in the small *b* parameter of an (Al,Li)-hydroxide sheet. A chemical analysis is therefore required for identification. *CCM* 26:327(1978). Tests: Basal spacing expands to about 31.1–32.1 Å with ethylene glycol. Collapses on heating to 500° to 23.3–24.0 Å. After heating to 700°, collapses to 23.7 Å. Can be rehydrated to 29.5 Å after heating to 500°. Observed to collapse from 30.5 Å to 26.8 Å with K-intersalination. Physical properties: White, pale yellow, pale green, pale blue, or pale pink; white streak; earthy to waxy luster. Cleavage {001}, {010}, very good; {100}, poor; conchoidal fracture in masses. Fine-grained masses, often pulverulent. *H* ~ 1. *G* = 2.42–2.50. IR data: *CCM* 24:142(1976), 36:39(1988). Thermal data: *CCM* 23:337(1975). Not soluble in common acids or bases or only poorly soluble; soluble in HF. Optics: Biaxial (–) with moderate 2*V* (58–68°); *N*_x = 1.542–1.564, *N*_y about 1.57 (few data), *N*_z = 1.548–1.574. Rarely uniaxial (–). Variable optical orientations observed. Tosudites are always Al-rich (33–37 wt % Al₂O₃) with SiO₂ 39–47 wt %. May contain (wt %): TiO₂, 0.74 (Kamikita); Fe₂O₃, 1.82 (Toohe); FeO, 2.77 (Huy); Cr₂O₃, 1–3; MgO, to 8.2 (Mg-tosudite); CaO, to 2.56 (Hokuno); P₂O₅, 0.08 (Kamikita); S, 0.69 (Kamikita); Na₂O, 0.58 (Hokuno); K₂O, 1.40 (Takatama); Li₂O, to 1.7 (Li-tosudite), but Al-tosudite frequently has some Li. H₂O (total) 16–17 wt %. Occurrence: A hydrothermal alteration product of tuffs, andesites, sediments, and so on, and can occur with other clay minerals. Also occurs in altered granites, in granite pegmatites as late-stage cavity fillings and pseudomorphs after tourmaline or beryl. Occurs in some gold deposits as well. Also in conglomerate at two localities. May alter rarely to dickite. Localities: Occurs in more than 40 worldwide localities, only some of which are mentioned below. General tosudite localities include: Schasse, Hazle Twp., Luzerne Co., and at Delano, Schuylkill Co., PA; Geneva–Davis mine, Gogebic district, MI; Lisbon Valley, UT; Supai Group, Grand Canyon, AZ; Sespe formation, Santa Barbara, CA; Echassieres, Massif Central, and Montebas, Creuse, France; Ehrenfriedersdorf, Germany; Cr-bearing from Takovo, Yugoslavia; in Sakalinsk deposit, northern Caucasus, and at Borkut, Transcarpathians, Russia; Nikitovsk and Druzhkovsk–Konstantinovsk ore fields in the Donbass, Ukraine; Belogorsk Au deposit, Primorye, Russia; Dernberg pegmatite, Kar-

ibib, Namibia; Agades, Nigeria; in more than 20 "Kuroko" and "roseki" deposits in Japan: Makurazaki area, Kagoshima Pref., Japan; Bubsoo mine, Cheongsong-eup, Korea. Li-tosudite: Himalaya pegmatite-aplite dike system, Mesa Grande district, and Stewart mine, Pala district, San Diego Co., CA; Huy, Belgium; Tooho mine, Aichi Pref.; Hokuno mine, Gifu Pref., Japan. Al-tosudite: *Alushta, Crimea, Russia*; Takatama mine, Fukushima Pref., Uebi, Ehime Pref.; Uku and Kurata mines, Yamaguchi Pref.; Hanaoka mine, Akita Pref.; Izushi, Hyogo Pref.; Igashima mine, Niigata Pref.; Hiraki mine, Hyogo Pref.; Hokuno mine, Gifu Pref.; Amakusa, Kumamoto Pref.; Niida, Akita Pref.; Iwami mine, Shimane Pref., Japan. Mg-tosudite: *Kamakita mine, Aomori Pref., Japan.* vk, EF

71.4.2.5 Corrensite $(\text{Mg}, \text{Fe}^{2+}, \text{Fe}^{3+})_3 [(\text{Mg}, \text{Fe}^{2+}, \text{Fe}^{3+})_2 \text{Al}]$
 $[(\text{Si}_3\text{AlO}_{10}(\text{OH})_8) / (\text{Ca}, \text{Na}, \text{Mg})_{0.35\pm}, (\text{Mg}, \text{Fe}^{2+}, \text{Fe}^{3+})_3 (\text{Si}, \text{Al})_4 \text{O}_{10}(\text{OH})_2$
(HLC corrensite) or $(\text{Mg}, \text{Fe}^{2+}, \text{Fe}^{3+})_3 [(\text{Mg}, \text{Fe}^{2+}, \text{Fe}^{3+})_2 \text{Al}] [\text{Si}_3\text{AlO}_{10}$
 $(\text{OH})_8] / [(\text{Mg})_{0.35\pm}, (\text{H}_2\text{O})_{16,12,8,3,0}] (\text{Mg}, \text{Fe}^{3+})_3 [\text{Si}_3\text{AlO}_{10}(\text{OH})_2]$ **(LLC**
corrensite)

Originally recognized as long ago as 1938 [*AM 23:851(1938)*], but not named until 1954 by Lippmann for Carl Wilhelm Correns (1893–1980), German mineralogist and director of the Sedimentary Petrography Institute, University of Göttingen; redefined in 1980. Synonym: "swelling chlorite." ORTH Space group unknown. $a = 5.337$, $b = 9.215\text{--}9.26$, $c = 23.2\text{--}24.2, 28.5\text{--}29, 31\text{--}32$; or HEX P . $a = 5.337$, $c = 23.2\text{--}24.2, 28.5\text{--}29, 31\text{--}32$, $Z = 1$. ICDD 19-764 and 13-465 are older data. 31-794 (LLC corrensite): 29.0₃ 14.0₁₀ 7.83₃ 7.08₆ 4.72₃ 4.62₃ 3.53₆ 2.57₃; 42-620 (glycerol-treated): 31.6₁₀ 15.8₇ 7.99₂ 5.33₁ 4.59₁ 3.56₂ 2.91₁. HEX P . $a = 5.337$, $c = 28.56$. Corrensite is a 1:1 regularly interstratified tri-, trioctahedral chlorite-like–trioctahedral smectite-like layers (high layer charge corrensite, HLC) or tri-, trioctahedral chlorite-like–(trioctahedral) vermiculite-like (low-layer-charge corrensite, LLC) 29- to 31-Å interstratified phyllosilicate. (Di-, dioctahedral chloritelike–dioctahedral smectite-like layerings are Al-tosudite, while di-, trioctahedral chlorite-like–dioctahedral smectite-like layerings are Mg-tosudite or Li-tosudite.) Additional nomenclature could be considered. *AM 67:394(1982)*. Structure not precisely determined, but surmised from oriented XRD and one-dimensional Fourier calculations. *CCM 35:150(1987)*. Site occupancies (octahedral, tetrahedral, and interlayer) have been calculated. *USGSOF:84-165 (1984)*, *CMP 105:123(1990)*. HRTEM study of HLC corrensite shows regular interstratification. *CCM 34:155(1986)*, *CMP 105:123(1990)*. The interlayer cations in both high and low layer charge corrensite are exchangeable and therefore do not particularly distinguish the two types of corrensite. Fully hydrated corrensite can have $d_{100} = 31\text{--}32$ Å, while air-dried material is generally 28.5–29.2 Å. Cation-exchange treatment can result in 58-Å spacings. *CCM 33:123(1985)*. DTA studies of common and systematic intersalination of low-layer-charge corrensite shows double water layers with Li, Ca, Sr, and Ba and single layers with Na and absence of water layers with K. *AM*

49:556(1964). Tests: Untreated corrensite usually has $d_{100} = 28\text{--}31$ Å, which usually collapses to 21–28 Å, usually ≈ 24 Å, when heated to 500°; original spacings can be 24–28 Å, however. Intercalation with glycerol or ethylene glycol can increase d_{100} to 31–32 Å (HLC corrensite), while LLC corrensite should not expand. LLC corrensite can collapse from 28–30 Å to 24 Å on K-salination. HLC corrensite has relatively strong (003) while glycolated LLC corrensite has virtually undetectable (003). IR data: *CCM 33:458(1985)*, *35:150(1987)*. HLC corrensite is very common compared to true LLC corrensite. Many identifications are probably in error as to type of corrensite. Physical properties: Generally fine-grained to fibrous, typically 2–5 μm . Brown to light golden brown, gray-white, silvery gray, pale gray-green to yellow-green, sometimes stained; white streak; earthy to indurated, dull to waxy luster. Cleavage {001}, perfect; flexible, but inelastic. $H = 1\text{--}2$. Partly decomposed by strong HCl. Chemistry: Chemistry of corrensite is variable. *CCM 32:391(1984)*. Observed ranges in composition (wt %) are: HLC corrensite SiO_2 , 31–38; Al_2O_3 , 12–24 (high Al values might reflect sample purity or presence of tosudite); Fe_2O_3 , to 13; FeO, to 21.85; MgO, 12–32; TiO_2 , to 0.81; MnO, to 0.38; CaO, 0.18–3.49; Na_2O , 0.10–1.65; K_2O , 0.08–1.20; $\text{H}_2\text{O}(\text{tot.})$, to 15. Sedimentary corrensites are richer in silica, and hydrothermal corrensites are richer in Mg and Al. CEC of HLC corrensite is about 40–55 meq per 100 g, but data are few. Optics: Biaxial (–); $N_x = 1.560\text{--}1.585$, $N_y \approx N_z = 1.582\text{--}1.612$; $2V = 0\text{--}10^\circ$; birefringence = 0.010 up to 0.021–0.027; also $N_{av} = 1.59$, birefringence = 0.000, approximately parallel to extinction with (001); positive elongation; N_x approximately perpendicular to {001}; pleochroic. X, yellowish brown; Y,Z, brownish green. RI and pleochroism increase with Fe ($\approx 0.0015/\text{at } \% \text{ Fe}/\text{Fe} + \text{Mg}$). RI between tri-trioctahedral chlorite and trioctahedral smectite. Corrensite (unspecified) birefringence = 0.01–0.03 similar to vermiculites (cf. random interstratifications < 0.01 and trioctahedral smectite > 0.03). Corrensites can have first-order pale yellow to orange yellow in thin section. Occurrence: Found in a variety of sedimentary environments, especially pelitic sediments, and frequently coexist with a wide variety of clay minerals almost universally, including illite, frequently found with chlorite, also found with smectite, micas, talc, and so on, as well as gypsum, dolomite, or zeolites. Corrensite not reported with kaolinite, but tosudites are. Both HLC and LLC corrensite have been found in the same sample area. Frequently found in evaporite sequences. Basin-wide zonation of clays observed with dioctahedral clays on basin margins, corrensite intermediate zone, and a chlorite zone at the basin center. *CCM 41:240(1993)*. Found as vesicle linings in volcanic rocks, also replacing volcanic glass in ash deposits. Noted as a hydrothermal alteration of phlogopite in marble [*CM 26:957(1988)*], also noted with talc, anthophyllite, antigorite, zeolites, and/or clinochrysotile. Corrensite has been suggested to form from the chloritization of smectite and from the hydrothermal alteration of phlogopite or as a hydrothermal alteration of amphibole in dolomite. Direct formation of corrensite from chlorite is debated. *CM 26:962(1988)*, *CCM 32:391(1984)*. Corrensite can form diagenetically at 90–100°, ranging

to 200° at low pressures [*Bull. Centre Rech. Pau, Soc. Nat. Petroles d'Aquitaine* 7:543(1973), *CS* 6:103(1984)] or deuterically. Localities: Only selected localities are given here: Hartford Basin, MA-CT; West Rock Sill, New Haven, New Haven Co., CT; Hamilton, Adams Co., Hamburg Klippe, PA; Jordan No. 5 mine, Murphy, Durham, Durham Co., NC; Florida Keys, FL; Cumberland Plateau, TN; Valmeyeran carbonate, IL; Cary mine, Wellington formation, Lyons Co., KS; Brazer limestone, Juniper Canyon, Moffat Co., CO; DeMoines shale, OK; Ordovician limestone and Guadaloupe formation, TX; Salado formation, Delaware Basin, NM; Goldfield, NV; Gilson Dome, Paradox Basin and Hermosa formation, San Juan Co., UT; Dearborn River locality(1), MT; Point Sal, CA; Sherbot Lake and Carleton, Frontenac, Lanark, Leeds, and Renfrew Cos., ON, Shawinigan and Gaspé Peninsula, PQ, Canada; Iberian Mts., Saragossa Prov., Spain; Veitsivaara, Finland; Thones syncline, Haute Savoie, and Sancerre-Couy drill hole, Paris Basin, France; Keuper Marl, England; Caithness and Orkney, Scotland; *Zaiserweiher bei Maulbronn, Baden-Württemberg*, and *Hüntstollen* and Coburg, Keuper Basin, *Lower Saxony, Germany*; Taro and Ceno valleys, Italy; Zerevta asbestos deposits, Ural Mts., and Bugety-Say, Russia; abyssal basalt near St. Paul's Rocks; Cassiope, Parana, and Sergipe-Alagoas basins, Brazil; Sirban limestone, Riasi, Jammu, and Kashmir states, India; eastern Otago, NZ; Green Tuff formation, Yamana area, Ishikawa Pref.; Ohyu caldera, Aikita Pref.; Tsunemi, Fukuoka Pref.; Yamakata area, Ibaraki Pref.; Niigata oil field, and Matsukawa area, Japan. VK, EF *MIN* 4(2):281(1992).

71.4.2.6 Kulkeite $(\text{Mg,Fe}^{2+},\text{Fe}^{3+})_3[(\text{Mg,Fe}^{2+},\text{Fe}^{3+})_2\text{Al}]\text{Si}_3\text{AlO}_{10}(\text{OH})_8/(\text{Mg,Fe}^{2+})_3\text{Si}_4\text{O}_{10}(\text{OH})_2$

Named in 1980 by Abraham et al. for Holger Kulke, geologist, Essen, Germany. MON Space group unknown. $a = 5.319$, $b = 9.195$, $c = 23.897$, $\beta = 97^\circ$, $Z = 2$; also HEX $a = 5.304$, $c = 23.70$, $D = 2.70$. 42-584: 11.9₈ 7.9₁₀ 4 74₆ 3.38₈ 2.96₅ 2.55₆ 2.46₅ 1.53₁₀. Kulkeite is a regularly interstratified 23.5- to 23.7-Å trioctahedral chlorite-like-(trioctahedral) talc-like layer phyllosilicate. Unaffected by ethylene glycol or heating to 500° for 1 hour. Diagnostic peaks at $2\theta = 7.4^\circ$, 11.2° , 26.4° , while peak at 3.7° is weak. The structure was verified by TEM and indicated numerous defects. *CMP* 80:103(1982). The talc-like layer in kulkeite appears to be sodian while the talc-like layer in the chlorite does not appear to contain alkalis and considered with ^{IV}Al, the two talc-like layers are compositionally different. *CMP* 80:103(1982). Kulkeite might not be a stable phase. Occurs as several millimeter-size porphyroblasts in dolomite or talc and usually intimately intergrown with clinocllore as a thin selvage between talc and kulkeite; platy to subhedral crystals. Colorless, white streak, pearly luster, transparent. Cleavage (001), perfect. $H \approx 2$. Biaxial (-); $Z = b$, $Y \approx a$, OAP perpendicular to (010); $N_x = 1.552$, $N_y = 1.5605$, $N_z = 1.5610$; $2V_{\text{obs}} = 24^\circ$; $r > v$; birefringence = 0.009; positive elongation. RI not directly intermediate between pure components. Distinguishable from talc by having lower birefrin-

gence and from chlorite by sign of elongation. Chemical analysis (wt %) of type material gave: SiO₂, 41.44, 40.53; Al₂O₃, 12.42, 12.64; MgO, 33.05, 33.19; CaO, 0.07, 0.06; Na₂O, 0.94, 1.20; K₂O, 0.20, 0.07; Li₂O, 0.09; H₂O_{calc}, 9.39, 9.24; total_{determined} 88.12, 87.69. Associated with dolomite, albite, sodian-aluminian talc, quartz, dravite-uvite, clinocllore, phlogopite, sodium phlogopite, rutile, and pyrite in a meta-evaporite sequence probably subjected to less than 400°. *El Mourdur Hill, near Derrag, 35 km W of Ksar El Boukhari, Tell Atlas Mountains, Algeria*. VK, EF *FM* 58:4(1980), *MIN* 4(2):250(1992).

71.4.2.7 Rectorite (Na,K)Al₂Si₃AlO₁₀(OH)₂/(Na,K,Ca)_{0.33}Al₂(Si,Al)₄O₁₀(OH)₂ · nH₂O

Named in 1891 by Brackett and Williams for E. W. Rector (b.1849), legislator and lawyer of Hot Springs, AR. Synonyms: Na-rectorite; K-rectorite; Ca-rectorite; illite-smectite (I/S); allevardite. Redefined by Brown and Weir in 1963 [also *CCM* 30:76(1982)] as paragonite-like-montmorillonite-like layer (= Na-rectorite), increasingly recognized as K-rectorite (illite-like or muscovite-like-dioctahedral smectite-like layers), also glauconite-like-dioctahedral smectite-like; earlier commonly thought to be a pyrophyllite-like-vermiculite-like interstratification. MON Space group unknown. $a = 5.12\text{--}5.13$, $b = 8.88\text{--}8.92$, $c = 23.77\text{--}26.4$, $\beta = 96.3^\circ, 99^\circ$; after heating to 600°, $d_{(001)} = 19.3$ Å; after ethylene glycol treatment, $d_{(001)} = 26.8$ Å; $Z = 2$, $D = 2.34\text{--}2.39$. 29-1495(K-rectorite): 26.4₃ 12.2₄ 4.99₃ 4.45₁₀ 3.15₃ 2.55₇ 2.44₁ 1.492₄; 25-0781(Na-rectorite): 23.8₁₀ 11.9₆₅ 4.75₁ 3.96_{<1} 3.40₂ 2.54_{<1} 2.91₂ 1.97₁. The structure of rectorite features a mica-like sheet that has tetrahedral aluminum and a strongly bonded interlayer cation alternating with a smectite-like sheet, which may or may not have tetrahedral aluminum, and does have an exchangeable interlayer cation with interlayer water. NMR study has suggested that similar Al → Si substitutions occur in the tetrahedral sheets facing the interlayer cations, rather than on either side of the octahedral sites within a layer. Therefore, juxtaposed tetrahedral sheets might be both mica-like (Si₃Al) or both margarite-like (Si₂Al₂) about the fixed interlayer cation and both smectite-like (Si_{4-x}Al_x) tetrahedral sheets facing the exchangeable cation. The interstratifications could therefore be considered as hybrid layers where each and every layer was composed of smectite-like and mica-like or margarite-like tetrahedral sheets with alternation of "up-down" hybrid layer orientations. *AM* 80:247(1995). Interstratification model B: *CS* 4:191(1974). Mica layers of rectorite have been compared to muscovite, paragonite, and margarite spacings. Rectorite is a ~24- to 27-Å (usually ~25 Å) interstratified phyllosilicate which expands by intercalation (ethylene glycol = 26.4–28.8 Å, 29.5 Å [*CCM* 28:241(1980), *CM* 16:91(1981)] with low spacings 23.7–24.84 Å for K-rectorite); glycerol = 27.2–27.6 Å, also 28.8 Å, with smaller spacings, 23.48–23.72 Å for K-rectorite) and collapses to 19.2–19.8 Å on heating to 550°. Na-saturated rectorite can show $d_{001} = 22.0\text{--}22.5$ Å, Mg-saturated rectorite can show 24.6–25 Å, Ca-saturated rectorite can show 24.65–24.86 Å, and K-saturated can be 21.83–22.10 Å. *CM* 7:63(1967), 16:91(1981). Rectorite has been

rehydrated after being heated $> 500^\circ$. *CCM 40:92(1992)*. HRTEM verification of mica-like-smectite-like layer interstratification has been published [*CCM 34:155(1986)*] and shows dehydrated spacings. Illite-like-smectite-like interstratifications can be found outside the 1:1 rectorite definition, with loss of the 24- to 27-Å peak with increasing randomness of the interstratification. *CCM 28:401(1980)*. Mixtures of illite and smectite and randomly interstratified illite-like-smectite-like layers do not develop long period spacings, but near 1:1 interstratifications do yield diffractograms which appear to be mixtures of 27- and 17-Å layers ($> 50\%$ smectite) or 27- and 10-Å layers ($< 50\%$ smectite). Proportion diagnostics of illite to smectite layers have been presented. *AM 50:990(1965)*; *CCM 28:401(1980)*. Intermediate angle peak shifts have been used to determine the proportion of smectite layers in an "ordered" illite-like-smectite-like interstratification as well as nonintegral basal reflections that might split into two peaks when glycerated, indicating randomness in the interstratification. *CM 6:261(1966)*. "Only the relatively weak 002/003 and 002 serve to distinguish glauconite-smectite from illite-montmorillonite diffraction patterns." Many supposed "rectorites" do not show long-period X-ray diffraction peaks and these identifications can be questioned. Non-1:1 illite-smectite interstratifications are among the most abundant of the clay minerals observed, and the proportion of illite/smectite layers is open to calculation. *CCM 18:25(1970)*, *28:401(1980)*. Rectorite "ordering," presumably in packets, has been invoked for samples with as little as 20% illite/smectite layer proportions. "Kalkberg ordering" (ISII order) can show 47° peaks. DTA data: *AM 51:1035(1966)*, *CM 16:91(1981)*. IR data: *CCM 19:61(1971)*, *32:154(1984)*. **Physical properties:** White to tan, sometimes pale green or brown, earthy; also thick leathery mats resembling "mountain leather," formed by aggregates of microscopic crystals; waxy luster (in mat form), infusible, unctuous, plastic and greasy when wet. Cleavage {001}, perfect; flexible and elastic (some sources say not elastic); heated ($> 500^\circ$) material is brittle. Decomposed by hot HCl. $H < 1$. G about 2.2. **Optics:** Biaxial (-); $N_x = 1.519$, $N_y = 1.550$, $N_z = 1.559$; $2V = 5-20^\circ$ (Arkansas), range $0-39^\circ$, also $49-63^\circ$ [*USGSB:1627 1984*]; $r > v$; birefringence = 0.040; cleavage traces can show nearly parallel extinction. Optical data are few. **Chemistry:** The chemistry of rectorites is variable, but truly monomineralic samples are probably very rare. Interlayer water has been modeled with one-, two-, and three-layer hydrates. *AM 41:91(1956)*. CEC = 53-57 meq per 100 g (Pakistan and Makurazaki) to 62 meq per 100 g (Surges Bay). Shinzan rectorites had exchangeable Na and fixed K. *CCM 31:401(1983)*. Studies have suggested that the smectite-like component was beidellite-like. *AM 51:1035(1966)*, *CCM 32:154(1984)*. Low- Na + K rectorites might seem chemically more like pyrophyllite-like-dioctahedral smectite-like or pyrophyllite-like-dioctahedral "vermiculite-like" layers and 22-Å "rectorite" has been reported. Due to the wide variety of possible mica-like-smectite-like interstratifications allowed by AIPEA definitions, chemical analyses of "rectorite" can be difficult to interpret without full X-ray diffraction characterization, including intercalation, even with one-dimensional Fourier modeling. Chemical analyses

of rectorites are few and some analyses (wt %) have been calculated to "anhydrous" totals: SiO₂, 44.62–55.2 (generally 51–54); Al₂O₃, 23.95–41.00; Fe₂O₃, 0.65–2.83; FeO, 0.16–0.97; MnO, 0.03–0.35; MgO, 0.07–1.46; TiO₂, 0.12–1.81; CaO, 0.33–1.61 (3.99, Ca-rectorite, Sano); K₂O, 0.10+ (K-rectorite, to 4.94); Na₂O, 0.10+ (Na-rectorite, to 5.31); SrO, 0.13 (Pakistan); Li₂O, 0.05 (Sano); P₂O₅, 0.15; total H₂O, 6.04–15.76 (not frequently determined). Rectorite has been synthesized from gels and smectite starting materials [CCM 26:327(1978)], as well as from sericite [CCM 26:209(1978)] and kaolinite [PICC:303(1973)]. Occurrence: Rectorite is one of the most common interstratified clay minerals and is found in a wide variety of sedimentary environments associated with quartz, carbonates, chlorite, and a wide variety of detrital minerals; usually found with mixtures of clays, including sericite, illite, montmorillonite, pyrophyllite, corrensite, tosudite, and so on. [Tosudite and other minerals might be present in some rectorite with a persistent 24-Å peak after heating to 550°. CCM 28:241(1980).] Rectorite appears to be formed through diagenesis through the reaction: smectite + K⁺ + Al³⁺ = illite + Si⁴⁺ over the temperature range ±100–175°. Temperature also seems to increase the order of interstratified illite-like–smectite-like layers. Noted in shales. Observed to replace volcanic glass shards. Rectorite has been frequently suggested to have altered to uninterstratified illite and sometimes to pyrophyllite. Found in a few bentonites. Also as a component in coal seams. Found in hydrothermal veins with quartz crystals and cookeite. As replacements of plagioclase in dacite, tuffs, and so on. Found in some Roseki clays in Japan. Various reported in drill core samples in the eastern United States from the Cincinnati Arch through the Atlantic and Gulf of Mexico coastal plains, but much of the material is composed of non-1:1 interstratified mica-like–smectite-like layers. Localities: Selected localities include: *Blue Mt. district, Marble, Garland Co.*, Jeffrey quarry(1), northern Little Rock, Pulaski Co., AR; Cañon City, Fremont Co., and Buckeye Gulch, near Leadville, Lake Co., CO; Manning Canyon shale, UT; Tulameen, BC, Canada; Cala Abajo deposit, Puerto Rico; Woodbury; Alston block and Northumberland trough, England; Abersoch and Nanhoron, Llyn; Nantlle and Tremadog, Snowdonia, Wales; Allevard(1), Isère, Sibert, Rhône, France; Kinnekulle, Sweden; Király Hill, Mad, Hungary; Rhodope Mts., Bulgaria; Troodos ophiolite, Cyprus; Cufra, Libya; Berghersdorp, Cape Prov., Beatrix mine, South Africa; Muluti, Transkei; Donets Basin, Ukraine; Dagestan; Samara bend of Volga R., Russia; Brunjkaki, Fort Sandeman district, Baluchistan, Pakistan; Dafang Co., Guizhou Prov.; Longzhong, Hubei Prov., China; Ohira mine, Mitsuisi, Okayama Pref.; Makurazaki, Kawanabe, and Iwato, Kagoshima Pref.; Goto mine, Goto Is., Nagasaki Pref.; Sano mine, Kakuma, also Honami and Yonago mines, Nagano Pref.; Takatama mine, Fukushima Pref.; Shinzan, Aikita Pref.; Tooho mine, Aichi Pref., Japan; Maitland, NSW; Surges Bay, TAS, Australia; Wairaki geothermal field, New Zealand. 71.4.2.8 Allietite $(\text{Mg}, \text{Fe}^{2+})_3\text{Si}_4\text{O}_{10}(\text{OH})_2(\text{Ca}, \text{Na})_{0.2-0.3}(\text{Mg}, \text{Fe}^{2+})_3(\text{Si}, \text{Al})_4\text{O}_{10}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$

Named in 1969 by Veniale and van der Marel for Andrea Alietti (b.1923), clay mineralogist, University of Modena, Italy. *HEX* Space group unknown. $a = 5.216$, $c = 24.6$, $Z = 1$; *07-0357*: 24.0_2 $12.0-11.2_{10}$ 4.54_x $3.50-3.00_6$ 2.62_9 1.725_4 1.520_9 1.314_7 ; oriented basal reflections noted (Greece, natural and *glycolated): $d_{(001)}$, $24.9, *27.1$; $d_{(002)}$, $12.3, *13.4$; $d_{(003)}$, $8.27, *8.90$; $d_{(005)}$, $4.92, *5.32$; $d_{(007)}$, 3.54 ; $d_{(008)}$, $*3.32$; $d_{(004,006)}$, absent. *CR 314(II):483(1992)*. Allietite is a regularly interstratified 24- to 25-Å phyllosilicate with alternating talc-like and trioctahedral smectite-like layers, but significant deviation from 1:1 interstratification is the norm. X-ray diffraction data virtually nonexistent except for basal reflections, for which structure factors have been calculated. *CCM 28:388(1980)*. Diagnostics: d_{001} untreated 24.8 Å; glycerol solvated 27.1 Å; natural, heated to 600° d_{001} collapses to 9.34 Å (Monte Chiaro), also heated to 490° d_{001} collapses to 9.6 Å (Greece). DTA data: *PICC 233(1969)*, *CCM 28:388(1980)*, *CR 314(II):483(1992)*. IR data: *CCM 28:388(1980)*, *PICC 1:233(1969)*. Also described as a kerolite-like–stevensite-like or disordered talc-like–Mg-trioctahedral smectite-like interstratification. *CCM 30:321(1982)*. Found as the clay-size fraction of rocks or sediments, also as “small, soft green plates which can be easily separated under the microscope.” *CCM 28:388(1980)*. Buff to gray, to dark green, depending on the host’s coloration. Cleavage (001), perfect. Other physical data not reported. IR data: *MIN 4(2):248(1992)*. $N = 1.556-1.567$; other optical properties not reported. Allietite is difficult to distinguish chemically from pure noninterstratified trioctahedral smectite. A calculated structural formula (Greece) gave: $(\text{Mg}_{0.15}\text{K}_{0.02}, \text{Na}_{0.02}, \text{Ca}_{0.02}) (\text{Mg}_{2.62}, \text{Fe}^{2+} 0.38) [\text{Si}_{3.62}\text{Al}_{0.23} \text{Fe}^{2+} 0.15\text{O}_{10}(\text{OH})_2]$. “Allietite” from Amargosa desert region can have saponitelike or stevensitelike layers as the smectite component. Monte Chiaro material gave (wt %): Na_2O , 1.15; K_2O , 0.01; CaO , 1.02; MgO , 27.74; FeO , 1.71; MnO , 0.03; Al_2O_3 , 2.95; Fe_2O_3 , 3.90; TiO_2 , 0.06; SiO_2 , 55.43; H_2O^+ , 6.00 (Amargosa desert region “anhydrous” analyses gave: Na_2O , 0.31–3.86, 0.31* (*for 50% expandable layers, i.e., 1:1 interstratification); K_2O , 1.00–1.68, 1.27*; Li_2O , 0.27–0.60, 0.32*; CaO , 0.01–3.22, 3.22*; MgO , 27.47–31.46, 31.46*; Al_2O_3 , 1.44–3.76, 2.66*; Fe as Fe_2O_3 , 0.69–1.76, 1.05*; TiO_2 , 0.05–0.08, 0.08*; SiO_2 , 59.64–63.15, 59.64*). CEC (Nevada) = 46–67, 53* meq per 100 g. Probably formed at low temperatures, 105–107°. *CR 314(II):483(1992)*. Found with talc in serpentinites, dolomites; as a clay-size fraction in metasediments with saponite, illite–smectite, illite, HLC corrensite, orthochrysotile, and so on; also in ancient lake sediments with authigenic dolomite or calcite, sepiolite, or other minerals. Amargosa desert, Nye Co., NV; Hectorite–Whiting pit, Inyo Co., CA; Monte Chiaro and other localities, Taro Valley, Parma Prov., Ferriere, Nure Valley, Piacenza Prov., Frassinoro, Modena, Italy; Beotian flysch, eastern Parnassus Mts., Hellenides, Greece; Kinsasha region, Shaba Prov., Zaire; Obori mine, Yamagata Pref., Japan. vk, EF *PICC 1:233(1969)*, *MIN 4(2):248(1992)*.

71.4.3.1 Franklinfurnaceite $\text{Ca}_2[\text{Mn}^{2+}\text{Fe}^{3+}][\text{Mn}_2^{2+}\text{Mn}^{3+}][\text{Zn}_2\text{Si}_2\text{O}_{10}](\text{OH})_8$

Named by Dunn et al. in 1987 for an old name for the locality. Chlorite group. MON C2. $a = 5.483$, $b = 9.39$, $c = 14.51$, $\beta = 97.05^\circ$, $Z = 2$, $D = 3.74$. $41-1412(\text{nat})$: 14.4_5 3.60_4 3.35_5 3.20_4 2.71_8 2.60_7 2.305_{10} 1.58_4 . Franklinfurnaceite is the only chlorite-related mineral with the IIa polytype. The interlayer has vacant sites over the Ca site. The overall structure is essentially that of a chlorite, but with unusual chemistry. The octahedral sheet of the 2:1 layer is trioctahedrally occupied with a pattern of six-membered Mn^{2+} (with minor Mg and Zn) octahedral "rings" with a centrally occupied Mn^{3+} octahedron. The tetrahedral sheets are nearly triangular, true six-membered rings with alternating large Zn and small Si tetrahedra. Outer oxygens of the tetrahedral sheets and hydroxyls of the interlayer sheet form a regular sixfold coordination of a Ca site with these sites above and below an interlayer octahedral vacancy. The dioctahedral interlayer consists of six-membered "rings" of alternatingly small Fe^{3+} (with minor Al) and large Mn^{2+} (with minor Mg, Zn) octahedra. Dark brown to black, opaque to subtranslucent crystals (to several millimeters) tabular triangular to pseudo-hexagonal, also plumose and in rosettes; brown streak; waxy to subvitreous luster. $H = 3$. $G = 3.66$. Cleavage $\{001\}$, perfect; brittle. Minor substitutions observed include MgO to 4.3 wt % and Al_2O_3 to 1.3 wt %. Biaxial (-); $Z = b$, $Y \wedge c = 29^\circ$; $N_x = 1.792$, $N_y = 1.798$, $N_z = 1.802$; $2V = 79^\circ$; $r < v$; birefringence = 0.010; $X \gg Z > Y$; pleochroic. X, very dark brown; Z, deep brown; Y, brown. Usually found associated with hodgkinsonite, including clinohedrite, franklinite, hetaerolite, or willemite. (*Franklin mine*) Franklin, Sussex Co., NJ. VK, EF AM 72:812(1987), 73:876(1988).

71.4.4.1 Gonyerite $\text{Mn}_5^{2+}[\text{Mn}_2^{2+}\text{Fe}^{3+}][(\text{Si},\text{Fe}^{3+})_4\text{O}_{10}](\text{OH},\text{O})_8$

Named in 1955 by Frondel for Forest A. Gonyer (1899–1971), chemist-analyst and mineralogist, Harvard University. Chlorite group. ORTH (pseudo-HEX) Space group unknown. $a = 5.47$, $b = 9.46$, $c = 28.8$, $Z = 4$, $D = 3.03$. $10-378(\text{nat})$: 14.6_3 7.23_{10} 4.79_5 3.61_8 2.88_2 2.70_3 1.63_3 1.57_5 . Originally described as a trioctahedral chlorite; however, X-ray powder data of the mineral show that it is not a true chlorite. CM 13:179(1975). Gonyerite is a modulated phyllosilicate structure commonly interleaved with 14-Å chlorite units. REVM 19:707(1988). Found in radially splayed plates. Dark brown to brownish black, or bright green; brown streak; waxy to subvitreous luster. Cleavage $\{001\}$, perfect; flexible, but inelastic. $H = 2\frac{1}{2}$. $G = 3.01$. Quickly soluble in concentrated HCl and insoluble in H_2SO_4 . Gonyerite shows several unusual aspects involving charge balance, but about 5.9 octahedral sites are occupied. Type material is a magnesian gonyerite ($\text{MgO} = 12.22$). Gonyerite is a manganese-rich mineral; it is essentially aluminum deficient. A small quantity of ferric iron substitutes for $^{\text{IV}}\text{Si}$. AM 40:1090(1955). Oxygen substitutes for a small amount of hydroxyl: $(\text{Mn}^{2+}, \text{Mg})_3[(\text{Mn}^{2+}, \text{Mg})_2\text{Fe}^{3+}][\text{Si}_{4-x}(\text{Fe}^{3+}, \text{Al})_x\text{O}_{10}](\text{OH}_{8-y}\text{O}_y)$. Minor substitutions (wt %) from the type locality include:

CaO, 0.07; PbO, 0.56; ZnO, 0.42; Al₂O₃, 0.58; Na₂O + K₂O, 0.31. Biaxial (-); N_x = 1.646, N_y = 1.664, N_z = 1.664; 2V = 0°; birefringence = 0.018; pleochroic. X, dark brown; Y,Z, light brown. Or N_O = 1.646, N_E = 1.664, pleochroic. O, light brown; E, dark brown. Found in veinlets in manganese-rich skarn. Associated with alleghanyite, barite, bementite, berzeliite, garnet, jacobsite, and so on. Karnes mine near Brinnon, Jefferson Co., WA; *Långban, Varmland, Sweden*; fairly common in Wessels mine, Kalahari manganese field, Cap Prov., South Africa, as thin brown bands in siliceous areas, and as small bright green crystals on hematite. VK, EF *MIN* 4(2):234(1992).

71.5.1.1 Kegelite $\text{Pb}_8\text{Al}_4\text{Si}_8\text{O}_{20}(\text{SO}_4)_2(\text{CO}_3)_4(\text{OH})_8$

Named in 1975 by Medenbach and Schmetzer for Friedrich Wilhelm Kegel, director of the Tsumeb mine from 1922 to 1938. *MON* A2/m, A2, or Am. $a = 21.04$, $b = 15.55$, $c = 8.986$, $\beta = 91.0^\circ$, $Z = 3$, $D = 4.76$. *PD*: 21.0₁₀ 7.01₅ 4.49₃ 3.82₈ 3.74₄ 3.01₅ 2.59₉ 2.34₅; also 29-790. The suggested structure consists of a stacking of pyrophyllite-1A layers and leadhillite layers. White; pearly luster. Biaxial (-); 2V small; N in plane of plates = 1.81. Found intergrown with hematite and mimetite in the deep oxidation zone at *Tsumeb, Namibia*. AR *AM* 61:175(1976), 75:702(1990); *MM* 55:121(1991).

Two-Dimensional Infinite Sheets with Other Than Six-Membered Rings

72.1.1.1 Ekanite $\text{Ca}_2(\text{Th,U})\text{Si}_8\text{O}_{20}$

Named in 1961 by Anderson et al. for F. L. D. Ekanayake, who first found the mineral in Sri Lanka. See steacyite (63.1.1.1), iraqite-La (63.1.1.2). Metamict or TET I422. $a = 7.483$, $c = 14.893$, $Z = 2$, $D = 3.36$. 35-532(Yukon, crystal-line): 7.45₆ 6.70₆ 4.14₁₀ 3.34₁₀ 3.27₆ 2.77₂ 2.64₅ 1.796₃; PD(Ceylon, 1250°C): 7.31₉ 5.21₉ 3.45₁₀ 3.30₆ 2.63₉ 2.50₆ 2.16₇ 1.820₇; PD(E. Siberia, metamict, 800°C): 4.18₅ 3.32₈ 3.26₅ 2.64₁₀ 1.704₄ 1.627₅ 1.385₆ 1.224₇. Structure: CM 20:65(1982). Structure determined on naturally crystalline Yukon material indicates two-dimensionally infinite, puckered sheets, perpendicular to c , made up of four-membered rings. The unit cell is dimensionally equivalent to steacyite (63.1.1.1) and iraqite-La (63.1.1.2), that have four-membered double rings and a different space group. Tetragonal bipyramidal habit with {101} dominant and modified by {100}, {110}, and {001}; also anhedral, rounded masses in gem gravel. Yellow, green, red; white streak; vitreous luster; transparent to translucent. Cleavage {101}, distinct; irregular fracture; brittle. $H = 4\frac{1}{2}$. $G = 3.05-3.25$ (some reported physical properties may actually apply to steacyite). Uniaxial (-), sometimes biaxial (-); $2V = 10-15^\circ$; $N_0 = 1.570-1.597$, $N_E = 1.545-1.568$, Sri Lanka metamict gems 1.59-1.596. The composition is quite variable; Yukon and eastern Siberian material contains up to 11.5 wt % H_2O at least in part zeolitic; potassium is often present, calcium varies from 4-14 wt %, and uranium may replace up to 20% of the thorium. Found in syenite in the Tombstone Mts., YT, Canada; uranoan, in volcanic alkaline xenoliths at Pitigliano, Tuscany, Italy; the Murun massif, near Olkeminisk, Yakutia, Russia; in the Ratnapura gem district, Eheliyagoda, Sri Lanka. Sometimes faceted as a collector's gem (not to be worn due to high radioactivity), a handful of stones, one nearly 44 ct, have been reported. AR NAT 190:997(1961), MS 33:68(1979), RSIMP 41:3(1986).

72.1.2.1 Thornasite $(\text{Na,K})\text{ThSi}_{11}(\text{O,F,OH})_{25} \cdot 8\text{H}_2\text{O}$

Named in 1987 by Ansell and Chao as a composite of element names and symbols: thorium, Na and Si. HEX-R R32. $a = 29.08$, $c = 17.30$, $Z = 18$, $D = 2.627$. 40-506: 14.54₂ 8.17₃ 7.27₁₀ 5.09₂ 4.17₇ 3.24₃ 2.96₂ 2.89₂. Structure undetermined; metamict in part. Colorless to pale green, vitreous to waxy

luster. $G = 2.62$. Uniaxial (+); $N_O = 1.510$, $N_E = 1.512$. Bright green fluorescence in LWUV and SWUV. Found as anhedral grains, < 1 mm, embedded in brockite and associated with yofortierite, eudialyte, albite, serandite, etc., at the *DeMix quarry, Mt. St.-Hilaire, QUE, Canada*. AR *CM 25:181(1987)*, AM *73:931(1988)*, MR *21:342(1990)*.

72.1.3.1 Prehnite $\text{Ca}_2\text{Al}_2\text{Si}_3\text{O}_{10}(\text{OH})_2$

Named in 1789 by Werner for its discoverer, Hendrik von Prehn (1733–1785), Dutch military officer. ORTH $P2cm$. $a = 4.65$, $b = 5.49$, $c = 18.52$, $Z = 2$, $D = 2.91$. 29–290: 3.54₄ 3.48₉ 3.31₆ 3.28₄ 3.08₁₀ 2.81₃ 2.56₇ 2.36₄. Structure: *EJM 2:731(1990)*. The structure consists of sheets parallel to {001} consisting of four-membered rings whose tetrahedra share all oxygens, linked to tetrahedra that share only two oxygens with other tetrahedra. Al^[4] is disordered with respect to Si in the ring-forming tetrahedra. The silicate sheets are interlayered with isolated AlO_6 octahedra and Ca polyhedra. **Habit:** Uncommon as individual crystals, and then short prismatic [001] to tabular {001}, often with curved faces; more commonly as fanlike, globular, spherical, or stalactitic forms of coarse to very fine crystals; in columnar, polycrystalline groups with a “bowtie” or “hourglass” morphology; granular to compact and, less commonly, fibrous. Lamellar twinning, probably of more than one type, is common. **Physical properties:** Pale to medium green, pinkish tan to tan, pale yellow, gray, white; vitreous luster to somewhat pearly {001}; translucent to nearly transparent. Cleavage {001}, good; {110}, poor; brittle with uneven fracture. $H = 6-6\frac{1}{2}$. $G = 2.90-2.95$. **Optics:** Biaxial (+); $2V = 65-69^\circ$; $N_x = 1.611-1.632$, $N_y = 1.615-1.642$, $N_z = 1.632-1.655$; $XYZ = abc$; $r > v$; birefringence = 0.022–0.035; the refractive indices generally increasing with Fe content. Optical anomalies are common, with wavy or incomplete extinction, anomalous interference figures, and occasional crossed dispersion. These properties probably due to complex twinning or intergrowths of lamellae both parallel to and perpendicular to {001}. **Chemistry:** Little variation in composition is noted; FeO and Fe_2O_3 may total as much as 1.5 wt %; Mg and Mn are minor, as are K and Na. H_2O is lost in two endothermic steps at 787° and 868°C . Slowly gelatinized by HCl. **Occurrence:** Found as a late-forming mineral in veins and cavities in mafic volcanics, where it is associated with pectolite, quartz, and zeolite species; less commonly in veins in granite, monzonite, granite gneiss, etc; as pseudomorphs after laumontite, axinite, and clinzoisite. Found in contact-metamorphosed impure limestones, and in rocks subjected to calcium metasomatism; stable in the zeolite and greenschist facies. Shown to be a product of incipient metamorphism in schistose greywackes. Prehnite-bearing rocks may be of regional extent in a zone characterized by pumpellyite and/or prehnite. **Localities:** Common as light green botryoidal masses and encrustations(!) in Triassic basalts of the Newark series as at Hampden quarry, West Springfield, Hampden Co., MA; the Roncari quarry, East Granby, Hartford Co., CT; Bergen Hill, Hudson Co., and Pater-son, Passaic Co., NJ; and the Fairfax quarry, Centreville, Fairfax Co., VA. At

Cornog, PA; with copper in the basalts of the Upper Peninsula, MI; at Bisbee, AZ; pinkish-tan to brown material in zoned pegmatite in quartz monzonite cutting magnesian limestone at Crestmore, Riverside Co., CA. Pale tan, somewhat curved crystals of several centimeters(1) at the Jeffrey quarry, Asbestos, QUE; colorless crystals in a fissure in peridotite on the east side of Bonaparte R., Ashcroft, BC, Canada. In the Kilpatrick Hills, Dunbarton, the Campsie Hills, Stirling, Scotland; at Bourg d'Oisans, Isere, France; at the Monte Redondo quarry, Portugal; at the Rauschermule quarry, Niederkirchen, and at Radauthal, Harzburg, Harz Mts., Germany; at Habachtal, Salzburg, Austria; at St. Gotthard, Tecino, Switzerland, and Val di Fassa, Italy; in pillow lava at Komiza Bay on Vis Island, Yugoslavia. With phlogopite at Emel'dzhak, southern Yakutia, Siberia, Russia; white fibrous prehnite in rodingite at Pastoki, Hindubagh, Pakistan; in numerous localities in the Deccan traps, as at Poona, and at the Bombay and Khandilavi quarries, Maharashtra, India. At numerous localities in Japan, as at Tokura, Okuzure, and Naoki, Shizuoka Pref., and Hiradani, Shiga Pref. In cavities in dolerite at the Emu quarry, Prospect Hill, near Sydney, NSW, Australia. Found at *Cradock, Cape Prov., South Africa*; well-crystallized(1) on the western slope of Tafelkop, Gobabusberg (also given as Brandberg), and as spherules to 1 cm about 70 km SE of Marienthal, Namibia; from North Victoria Land, Antarctica. Uses: Finds occasional use as a cabochon material and some chatoyant stones are known; faceted collector stones have been produced from Australian and Scottish material, and possibly from other sources. AR *D6:530(1892)*, *DHZI 3:263(1963)*, *MR 14:224(1983)*.

72.1.4.1 Amstallite $\text{CaAl}[(\text{Si,Al})_4\text{O}_8](\text{OH})_4 \cdot (\text{H}_2\text{O,Cl})$

Named in 1987 by Quint for the locality. MON *C2/c*. $a = 18.83$, $b = 11.52$, $c = 5.19$, $\beta = 100.86$, $Z = 4$, $D = 2.38$. $d_{111} 9.75_{10}$ $d_{110} 5.43_7$ $d_{100} 4.71_6$ $d_{010} 4.07_4$ $d_{001} 3.82_9$ $d_{111} 3.60_{10}$ $d_{110} 3.18_6$ $d_{100} 2.63_4$. Structure: *NJMM: 253(1987)*. Structurally related to but distinct from prehnite; sheets lying parallel to {100} contain four-membered rings and are three tetrahedrons thick; tetrahedral Al is fully disordered with respect to Si. Al octahedra and $\text{Ca}^{[7]}$ polyhedra form edge-sharing ribbons parallel to [001]. Prismatic or acicular unterminated crystals, striated and elongated [001] up to 1 cm long and 0.5 mm in diameter, with a rhombic to hexagonal cross section displaying {100} and/or {110}. Colorless, vitreous luster, transparent to translucent. Cleavage (100), good; conchoidal fracture. $H \approx 4$. $G = 2.90$. Biaxial (+); $2V_{\text{obs}} = 57^\circ$; $N_x = 1.533$, $N_y = 1.534$, $N_z = 1.538$; $Y \wedge c \approx +10^\circ$, $Z = b$; $r < v$. $\text{Al}^{[4]}:\text{Si} \approx 0.8:3.2$ and $(\text{H}_2\text{O}):\text{Cl} \approx 4:1$. Occurs in pegmatoid schlieren of low-pressure, low-temperature origin in a graphite deposit, and is associated with apatite, rutile, siderite, albite, laumontite, calcite, and rarely vivianite at the *Amstall quarry, Amstall, Austria*. AR *AM 73:1492(1988)*.

72.1.5.1 Eakerite $\text{Ca}_2\text{SnAl}_2\text{Si}_6\text{O}_{18}(\text{OH})_2 \cdot 2\text{H}_2\text{O}$

Named in 1970 for Mr Jack Eaker (1930–) of Kings Mtn., NC who discovered the mineral (MR 1:92(1970). MON $P2_1/a$. $a = 15.829\text{\AA}$, $b = 7.21\text{\AA}$, $c = 7.438\text{\AA}$, $\beta = 101.34^\circ$, $Z = 2$, $D = 2.93$; 24-0218 (nat.) 7.31₈ 6.905₅ 5.94₅ 5.29₉ 4.81₁₀ 4.00₅ 3.88₅ 3.40₄ 3.35₆ 3.30₅ 3.02₈. The structure consists of crankshaft-like chains, similar to those in feldspars, of composition $\text{AlSi}_3\text{O}_9(\text{OH})$, which are cross-linked to form a kinked sheet. Al is ordered, and the OH is bonded to it. Ca + Sn ions lie in sheets between the kinked aluminosilicate network. The Ca ions are coordinated by 4O, 2OH and 2H₂O in a square antiprism; these are edge-linked into chains which run across the aluminosilicate chains and are cross-linked by Sn octahedra. The OH and H₂O are bonded to Ca and by H bonds, and to other O; this strong bonding prevented their being distinguished by TGA. (AM 61:956(1976)). Colorless to milky white; prismatic, [001] prism zone is striated; elongated on c , with {001}, {201}, {201, {210}}, {410}, {11}, and {100}; to 5 mm long; no cleavage; conchoidal fracture; $H = 5\frac{1}{2}$; $G = 2.83\text{--}2.93$; TGA shows no loss of wt. below 350°C, 3% to 725°C, 6.5% to 775°C, 10.5% to 1175°C; mineral fuses at $\approx 1075^\circ\text{C}$, not dissolved by acids or bases. SiO₂ 46.75, Al₂O₃, 14.07, SnO₂ 18.59, CaO 14.2, H₂O 6.70, total = 100.3. Biaxial (+); $2V = 35^\circ$, $N_x = 1.584$, $N_y = 1.586$, $N_z = 1.660$; colorless; $X \wedge c = +23\frac{1}{2}^\circ$; disper. = $r > v$ marked. Occurs as a hydrothermal mineral in seams in spodumene pegmatite. Associated with quartz, albite and bavenite. Also occurs as an exsolution product from garnet (Russia). Occurs at *Kings Mountain, NC*; Kitelskoye skarn-tin deposit, north of Lake Laguda, Russia, probably also at the Staroye Ora deposit, Pitkyaranta, Finland. EF ZVMO 101(5):286 (1972), DAN SSSR ESS 250:151(1982) Minerali 4(2):508(1992).

72.2.1.1 Dalyite $(\text{K},\text{Na})^2\text{ZrSi}_6\text{O}_{15}$

Named in 1952 by Van Tassel for Reginald Adsworth Daly (1871–1957), American geologist, Harvard University. See davanite (72.2.1.2). TRIC $P1$. $a = 7.371$, $b = 7.730$, $c = 6.912$, $\alpha = 106.23^\circ$, $\beta = 111.45^\circ$, $\gamma = 100.0^\circ$ (for $\text{K}_{1.7}\text{Na}_{0.3}$), $Z = 1$, $D = 2.798$. 23-1376(syn): 5.90₅ 4.17₇ 3.59₈ 3.34₁₀ 3.08₉ 2.85₄ 2.62₁₀ 2.13₅. Structure: ZK 121:349(1965). The silicate unit is a sheet composed of four-, six-, and eight-tetrahedron rings. Isostructural with davanite. Short prismatic crystals, 0.5 mm, displaying {101}, {100}, {110}, {110}, and {111}. Twinned with composition plane (100). Colorless, vitreous luster, transparent to translucent. Cleavage {101}, {010}, good. $H = 7.5$. $G = 2.84$. Biaxial (-); $2V = 72^\circ$; $N_x = 1.575$, $N_y = 1.590$, $N_z = 1.594$; $X \wedge c = 7^\circ$; $r > v$, weak. Gelatinizes with acids. Fusibility 3. Limited Na substitution for K; Ti may substitute for Zr. Found as an accessory mineral (0.2%) in an alkali granite with aegirine, arfvedsonite, and aenigmatite at *Green Mountain, Ascension*; at Dalsfjorden, Sunnifjord, and associated with pyrophanite, elpidite, and kupletskite at Gjerdingen, Oslo area, Norway; in lamproite at Cancarix, Albacete, Spain; in the Murun massif and elsewhere in the Aldan

shield, Yakutia, Russia; in the Straumsvola complex, Dronning Maud Land, Antarctica. AR *MM* 29:850(1952), 47:93(1983).

72.2.1.2 Davanite $K_2TiSi_6O_{15}$

Named in 1984 by Lazebnick et al. for the locality. See dalyite (72.2.1.1). TRIC $P\bar{1}$. $a = 7.272$, $b = 7.480$, $c = 6.910$, $\alpha = 105.55^\circ$, $\beta = 112.82^\circ$, $\gamma = 99.42^\circ$, $Z = 1$, $D = 2.725$. 40-483: 5.87₅ 4.10₇ 3.49₈ 3.35₈ 3.18₇ 3.02₁₀ 2.79₅ 2.62₅. Isostructural with dalyite. Colorless, vitreous luster, transparent to translucent. Subconchoidal fracture. $H = 5$. $G = 2.76$. Biaxial (-); $2V_{\text{calc}} = 53^\circ$; $N_x = 1.660$, $N_y = 1.684$, $N_z = 1.690$; also reported, biaxial (+)?; $N_x = 1.623$, $N_z = 1.668$. Minor Fe may be present. In lamproite from Smokey Butte, Garfield Co., MT; as pseudo-hexagonal grains to 5 mm diameter, with aegirine, pectolite, and titanite in the *Murun alkaline massif, near Davan Spring, Yakutia, Russia*, and possibly in platinum metals in the Inagli pluton, central Aldan. AR *AM* 7:214(1985), 71:1473(1986), 72:1014(1987); *DANS* 309:690(1989).

72.2.1.3 Sazhinite-(Ce) $Na_2Ce[Si_6O_{14}(OH)] \cdot nH_2O$ ($n \geq 1.5$)

Named in 1974 by Eskova et al. for Nikolai Petrovich Sazhin (1898-1969), founder of the Russian rare earth industry. See dalyite (72.2.1.1). ORTH $Pmm2$. $a = 7.50$, $b = 15.62$, $c = 7.35$, $Z = 2$, $D = 2.80$. 30-1176(nat): 7.25₄ 5.23₆ 3.37₈ 3.30₄ 3.23₁₀ 2.55₄ 2.00₄ 1.95₃. Structure: *SPC* 25:419(1980). Structure is based on infinite corrugated networks formed by four-, six-, and eight-membered rings of Si tetrahedra. Tabular, platy prisms to 5 mm × 5 mm × 1 mm, also as irregular grains, and as dense fine-grained aggregates; striated prisms to 1.7 cm × 1 cm × 6 mm from Mt. St.-Hilaire. White to pale yellowish gray, cream; white streak; vitreous to pearly luster. Cleavage {100}, perfect; {010}, {001}, very good. $H = 2\frac{1}{2}$. $G = 2.61$. IR and DTA data: *ZVMO* 103:338(1974). Probe data have shown La-dominant zones in crystals from Mt. St.-Hilaire. The La analog of sazhinite-(Ce) occurs in the 10-m-thick St.-Amable trachyphonolite sill, Varennes, Quebec. Analysis (wt %), Mount Karnasurt: SiO₂, 46.28; TiO₂, 1.06; Nb₂O₅, 0.65; Al₂O₃, 0.80; CaO, 0.50; Na₂O, 11.20; K₂O, 1.21; ThO₂, 1.30; Lu₂O₃, 21.15; P₂O₅, 1.05; H₂O⁺, 9.58; H₂O⁻, 4.46; Fe₂O₃, 0.26; MnO, 0.06. Ce > La = 54%/21%. Biaxial (+); XYZ = cba; $N_x = 1.525$, $N_y = 1.528$, $N_z = 1.544$; $2V = 47^\circ$. Occurs in cavities in sodalite xenoliths with vuonnemite, serandite, ussingite, sodalite, aegirine, and so on, at Mt. St.-Hilaire, QUE, Canada. Found in the central zone of the Jubilee pegmatite with natrolite, neptunite, and steenstrupine at *Mt. Karnasurt, Lovozero massif, Kola Penin., Russia*. EF

72.3.1.1 Fluorapophyllite $KCa_4[Si_8O_{20}]F \cdot 8H_2O$

72.3.1.2 Hydroxyapophyllite $KCa_4[Si_8O_{20}(OH)] \cdot 8H_2O$

The term *apophyllite* from the Greek *away from* and *leaf*, in allusion to its tendency to exfoliate on heating, was probably first used by Haiüy in 1800.

FLUORAPOPHYLLITE

Apophyllite, common habits. Forms: $a \{100\}$; $c \{001\}$; $p \{111\}$; $y \{310\}$.

The names of the chemically differentiated end members were coined in 1978 by Dunn and Wilson. The nonspecific term is retained for members of the series whose chemical composition has not been established. An orthorhombic polymorph of fluorapophyllite has been proposed. $TET P4/mnc$. (Fluor-): $a = 8.969$, $c = 15.706$, $Z = 2$, $D = 2.347$; (hydroxy-): $a = 8.985$, $c = 15.875$, $Z = 2$, $D = 2.322$. $19-82$: 7.81_{10} 4.51_4 3.90_5 3.57_6 3.17_4 2.95_5 2.49_9 2.10_3 ; $30-920(\text{calc})$: 7.81_{10} 4.55_4 3.89_4 3.58_6 3.17_4 2.99_5 2.50_6 2.49_5 . Structure: $AC(B) 43:517(1987)$. The lattice dimensions and axial ratio increase linearly with increasing (OH) for F substitution. The silicate element is a two-dimensionally infinite sheet, perpendicular to $[001]$, made up of four-tetrahedron rings with fourfold symmetry linked to one another to form intervening eight-tetrahedron rings with twofold symmetry; apical oxygens of alternate four-membered rings point in opposite directions. Calcium ions link the sheet via two oxygens each, as well as one (F,OH) and two waters. Potassium is eight-coordinated to water molecules. Crystals equant, to prismatic $[001]$, to tabular $\{001\}$. The dominant forms are $\{100\}$, $\{001\}$, and $\{111\}$ in the traditional morphological setting. Faces of prism zone are commonly striated parallel to $[001]$. The X-ray setting is rotated 45° ; the transformation matrix, morphology to X-ray, is $110/110/002$. Less commonly massive or lamellar aggregates. Colorless, gray, cream, pale yellow, pale to bright green, pink to reddish; vitreous luster, pearly on cleavage; transparent to translucent. Cleavage $\{001\}$, highly perfect; $\{110\}_{\text{morph}}$, imperfect; uneven fracture; brittle. $H = 4\frac{1}{2}-5$. $G = 2.33-2.37$. Uniaxial (+); $N_O = 1.534-1.542$, $N_E = 1.536-1.543$, the indices increasing with increased (OH); strong dispersion; higher-index material may be isotropic or uniaxial (-); occasionally in biaxial sectors, (+) for red, (-) for blue with crossed axial planes. Soluble in acids leaving a silica residue. May undergo natural leaching to yield material of lower refractive index. The green color of some apophyllites has been attributed to vanadium. Found chiefly as a late mineral in amygdules and druses in basalts, where it is associated with pectolite, calcite, and zeolites. Less frequently found in cavities in granites and syenites, in metamorphic rocks and limestones and calc-silicate rocks, sometimes as an alteration of wollastonite, and as late product in hydrothermal ore deposits. Members of this series are found worldwide, but most have not been differentiated by chemical analysis. Fluorapophyllite crystals of excellent quality have been found in the

traprocks at Bergen Hill, West Paterson, Prospect Park, and others in the vicinity of Paterson, NJ; high-hydroxyl material in large crystals at Cape Blomidon, NS, Canada, and as pale red crystals at Guanajuato, GTO, Mexico; as colorless crystals at St. Andreasberg, Harz, Germany. Light to deep green prismatic crystals(1) are found at several quarries near Khadakvasla, Pashan Hills, near Poona, and at several occurrences at Nasik and Ahmed Nagur, Maharashtra, India. Hydroxyapophyllite is found as thick druses of white crystals on chalcopyrite-pyrrhotite ore at the *Ore Knob mine, Jefferson, Ashe Co., NC*; as opaque, chalky crystals at Bergen Hill and Prospect Park, NJ; with fluorapophyllite at Mt. St.-Hilaire, QUE, Canada; at Guanajuato, GTO, Mexico, where it is more abundant than the fluorine end member. Found at Storr Mt., Isle of Skye, Scotland; at the Giken mine, Sulitjela, Nordland, Norway; at Khandivali and the Parvati Hills, near Bombay, Maharashtra, India; and at Kimberley, Transvaal, South Africa. Apophyllite (undifferentiated) is found at the Upper New Street quarry, Paterson, NJ; white, tabular crystals at Cornwall, Lebanon Co., PA; tabular, white to pale tan tabular crystals and rosettes(1) found at Centreville, Fairfax Co., VA, are a physical mixture of the two end members; at the Clarke mine, Keweenaw Co., MI. Found at the Jeffrey mine, Asbestos, QUE, Canada; in basalts at numerous localities in Iceland and at several localities in the Faeroe Is., Denmark. Found at numerous localities in Maharashtra, India, in excellent colorless, pale green, and white crystals, particularly Aurangabad, Malegaon, Nasik(1), Poona, Bombay, and the Jewel Tunnel; at the Pahua R., South Island, New Zealand; at the Wessels mine, Cape Prov., South Africa. Colorless to light green tabular crystals to 20 cm are found at Bento Gonsalves, RS, Brazil. Numerous other localities are known. An allegedly orthorhombic modification is reported from the Christmas mine, Gila Co., AZ. Colorless and green material from India has been faceted as a collector gem. AR *MR* 9:95(1978); *AM* 63:196(1978), 77:1119(1992); *MM* 54:567(1990).

72.3.1.3 Natroapophyllite $\text{NaCa}_4[\text{Si}_8\text{O}_{20}]\text{F} \cdot 8\text{H}_2\text{O}$

Named in 1981 by Matsueda et al. for the composition and structural relation to apophyllite. ORTH *Pnmm* or *Pnn2*. $a = 8.875$, $b = 8.881$, $c = 15.79$, $Z = 2$, $D = 2.30$. 41-1371(potassian): 7.9₂ 7.79₄ 4.54₄ 3.97₇ 3.57₃ 2.98₁₀ 2.49₃ 2.48₃. Distortion of the tetragonal apophyllite structure due to substitution of Na for K. Colorless, brownish yellow to yellow-brown; vitreous luster, pearly on cleavage; transparent to translucent. Cleavage {001}, perfect; {110}, poor. $H = 4-5$. $G = 2.5$. Biaxial (+); $2V = 32^\circ$; $N_x = 1.536$, $N_y = 1.538$, $N_z = 1.544$. Significant potassium may replace sodium. Dissolved by HCl with separation of silica. Potassian material is found at Rancheria Palo Verde, SLP, Mexico; apophyllite from Boliden, Sweden, is, at least in part, natroapophyllite; as pyramid-truncated, prismatic crystals alternately zoned with fluorapophyllite and associated with zeophyllite, cuspidine, and calcite in skarn at the *Sampo mine, Okayama, Honshu, Japan*. AR *DHZI* 3:260(1962), *AM* 66:410(1981).

72.3.1.4 Carletonite $\text{KNa}_4\text{Ca}_4[\text{Si}_8\text{O}_{18}](\text{CO}_3)_4(\text{OH},\text{F}) \cdot \text{H}_2\text{O}$

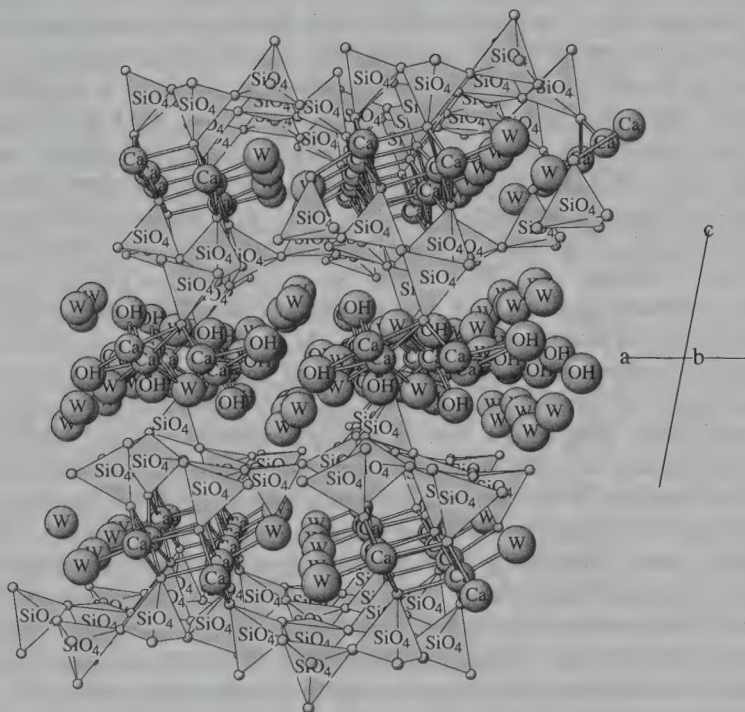

Named in 1971 by Chao for Carleton University, Ottawa, Canada, where it was first recognized. TET $P4/mbm$. $a = 13.178$, $c = 16.695$, $Z = 4$, $D = 2.426$. $25-628$: 16.7_4 8.35_{10} 4.82_4 4.17_{10} 4.05_5 3.34_4 2.90_9 2.38_6 . The silicate structural element consists of two apophyllite silicate layers condensed by sharing apical oxygens to form a layer of double thickness lying parallel to {001}; potassium occupies the voids in the layer. Blue to light pink, colorless in thin section or small grains; vitreous luster, pearly on cleavage. Cleavage {001}, perfect; {110}, distinct; conchoidal fracture. $H = 4-4\frac{1}{2}$. $G = 2.45$. Uniaxial (-); $N_O = 1.521$, $N_E = 1.517$ for Na(D); blue crystals weakly pleochroic; O, very pale blue; E, very pale pinkish brown. IR spectrum much more complex than for apophyllites due to lower site symmetries. No significant compositional difference noted for the several colors. Occurs in marble xenoliths in nepheline syenite as square prisms, {100} and {001} dominant, sometimes with color zoning or color phantoms, at *Mt. St.-Hilaire, QUE, Canada*, where crystals up to 6 cm long have been found. A few small gems (< 1 ct) have been cut for collectors. AR *AM* 56:1855(1971), 57:763(1972); *MR* 21:301(1990).

TOBERMORITE GROUP

The tobermorite group minerals are hydrated Ca-Si, Ca-Al-Si, or Ca-B-Si minerals that are structurally heterogeneous but nevertheless appear to be somewhat related. All the minerals are rare, and for some complete structural information is lacking. A recent study and structural models are found in *ZVMO* 124:36(1995).

TOBERMORITE GROUP

Mineral	Formula	Space Group	Crystallographic Data						
			a	b	c	α	β	γ	
Tobermorite	$\text{Ca}_5\text{Si}_6\text{O}_{16}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$	C222 ₁	11.283	7.372	22.56				72.3.2.1

OKENITE: $\text{Ca}_{10}\text{Si}_{18}\text{O}_{46} \cdot 18\text{H}_2\text{O}$

This has two different types of silicate layer: (tobermorite group) a true sheet with five- and eight-membered rings, and a layer containing double chains with four- and six-membered rings. Ca atoms link the sheets, and water molecules occupy cavities in the larger rings. Other members of the tobermorite group have different layer structures.

72.3.2.1 Tobermorite $\text{Ca}_5\text{Si}_6\text{O}_{16}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$

Named in 1880 by M. F. Heddle for the locality. Tobermorite group. See plombierite (72.3.2.3) and riversideite (72.3.2.4). Polymorph: clinotobermorite. ORTH C222₁. $a = 11.233\text{--}11.255$, $b = 7.372\text{--}7.375$, $c = 22.56\text{--}22.760$, $Z = 4$, $D = 2.58$ (syn). 45-1480(nat): *JJMPE* 84:374(1989) (Fuka): 11.3₁₀ 5.45₄ 3.51₃ 3.08₉ 2.97₇ 2.81_{7b} 2.00₂ 1.84_{2b}; 19-1364(syn): 11.3₈ 5.48_{2.5} 3.53₂ 3.08₁₀ 2.98_{6.5} 2.82₄ 2.00₂ 1.84₄. Structure: *NAT* 177:390(1956), *ZK* 154:189(1981). At 140°, 11.3-A tobermorite has double chains of SiO₄ tetrahedra. Partial dehydration of plombierite at 100° yields 11.3-A tobermorite with single chains of SiO₄ tetrahedra. Porcelaneous, massive, also finely fibrous bundles, rosettes or sheaves, granular or {001} plates, acicular parallel to [010], platy crystals to 3 mm across. Colorless-white, pinkish white; white streak; vitreous-silky luster. Cleavage {001}, {100}, distinct. $H = 3$. $G = 2.40\text{--}2.48$ (Fuka). Material from Crestmore is sometimes weakly fluor-

escent white to yellow in SWUV and LWUV. IR data: *MM 42:229(1978)*, *56:353(1992)*; *ZVMO 124:36(1995)*. DTA and TGA data: *MM 42:229(1978)*, *ZVMO 124:36(1995)*. Heating to 300° yields 9.3-Å (002) spacing, with eventual conversion to wollastonite at about 800°. From three analyses of Japanese material (wt %): SiO₂, 45.1–49.0; TiO₂, 0.00–0.03; Al₂O₃, 1.0–3.3; B₂O₃, 0.0–0.23; MgO, 0.0–0.04; CaO, 35.2–37.9; Na₂O, 0.01–0.24; K₂O, 0.02–0.23; H₂O, 11.5–15.5; Eynort: SiO₂, 46.2; Al₂O₃, 4.3; MgO, trace; CaO, 35.2; Na₂O, 0.6; K₂O, 0.3; H₂O, 13.5. Clinotobermorite has 0.4% Al₂O₃, tobermorite has 1–>3% Al₂O₃. Heguri tobermorite (wt %): BaO, 1.7; Al₂O₃, 4.55; Na₂O, 0.45; K₂O, 0.52; H₂O⁺, 12.2; H₂O⁻, 3.7. Chemical analyses also given in *ZVMO 124:36(1995)*. Biaxial (+); XYZ = cba; N_x = 1.570, N_y = 1.571, N_z = 1.575; 2V small; colorless; positive and negative elongation. *MM 30:293(1954)*. *DA 25:613(1974)* gives biaxial (-); N_x = 1.554, N_y = 1.566, N_z = 1.567; 2V = 26–33°. Pseudomorphous after wilkeite, associated with blue calcite, monticellite, and vesuvianite at Crestmore. Cavity fillings at Tobermory, Island of Mull. With apophyllite, thomsonite, calcite, and plombierite in 1-cm veins that cut skarn. Also present in some soils as a secondary mineral. Generally occurs in gabbros and basalts. With minerals such as gyrolite, natrolite, zeolites, ettringite, and calcite. Localities for true tobermorite (11 Å) include *Pier, and Bloody Bay, near Tobermory, Isle of Mull, Scotland*; both tobermorite and plombierite occur at Ballycraigy near Larne, Co. Antrim, Northern Ireland; from the Mokraya Sinya R. (Voikaro–Sininsky ultrabasic massif), Polar Ural Mts., Russia; Okur-Tau Range, Kansaisk district, Uzbekistan; on inesite and as beautiful fans of platy yellow crystals up to 15 mm associated with xonotlite and datolite from Wessels mine, Kuruman, Kalahari manganese field, Cape Prov., South Africa; Ba-bearing tobermorite occurs at Heguri, Chiba Pref., Japan, and tobermorite, plombierite, and clinotobermorite occur at Fuka, Kawakami Twp., Okayama Pref., Japan. Other localities for “tobermorite,” not clearly specified, from the literature include: Durham, NC; Bingham, UT; Goldfield, NV; Concepcion de Oro and the Noche Buena mine, Mazapil, ZAC, Mexico; Portree, Scotland; Loch Eynort, Skye, Scotland; Castle Hill, Kilbirnie, Ayrshire, Scotland; Höwenegg, Hegau, Germany; Arensberg near Zilsdorf, Eifel, Germany; Zeilberg quarry, Maroldswisach, Franconia, Bavaria, Germany; Mont Alto di Castro (Viterbo), Italy; Pia de la Stua, and Monte Biaena, Trento, Italy; Klösch, southeastern Styria, Austria; Bazhenovskoye, Russia; Hatrurim Fm., Nahal Ayalon, Israel; Taiwan. *EF MIN 3(3):322(1981)*, *ZK 154:268(1981)*, *MM 56:353(1992)*, *ZVMO 124:36(1995)*.

72.3.2.2 Clinotobermorite $\text{Ca}_5\text{Si}_6(\text{O},\text{OH})_{18} \cdot 5\text{H}_2\text{O}$

Described in 1989 by Henmi and Kasache and named in 1992 for the locality. Tobermorite group. The monoclinic polymorph of tobermorite. *MON Cc* or *C2/c*. $a = 11.331$, $b = 7.353$, $c = 22.67$, $\beta = 96.59^\circ$, $Z = 2$, $D = 2.69$. *45-1479(nat)*: 11.25_{10} 3.74_4 3.30_5 3.07_4 3.03_6 3.01_4 2.81_4 2.79_6 . *JJMPE 84:374(1989)*. Clinotobermorite is the low-temperature form of tobermorite. Upon heating at 300°, the (002) spacing is reduced from 11.3 Å to 9.3 Å.

Crystals are platy {001}, acicular [010], or tabular. Microtwinning is always observed on {011}, along with stacking disorder on {001}. Colorless–white, tabular crystals to 5 mm wide and acicular crystals to 2 mm long, white streak, vitreous luster. Cleavage {001}, perfect; {100}, poor. $H = 4.5$. $G = 2.51\text{--}2.58$. Thermal data: *JJMPE* 84:374(1989), *MM* 56:353(1992). Trace to minor amounts of Al, B, Mg, K, F and traces of Ti, Fe, Na, and Mn. No 2V measured because of microtwinning. $2V_{\text{calc}} = 90^\circ$. $N_x = 1.575$, $N_y = 1.580$, $N_z = 1.585$, colorless. A vein-forming mineral in gehlenite–spurrite skarns. In hybrid rocks and in retrograde garnet-bearing rocks. Associated with tobermorite, calcite, apophyllite, plombierite, and oyelite. *Fuka, Bitchu-cho, Okayama Pref., Japan.* EF

72.3.2.3 Plombierite $\text{Ca}_5\text{Si}_6\text{O}_{16}(\text{OH})_2 \cdot 6\text{H}_2\text{O}$

Described in 1858 by Daubree and named for the locality; redefined in 1954 by McConnell. Tobermorite group. Formerly called 14-A tobermorite, redefined on material from Ballycraigy, Larne, County Antrim, Northern Ireland. Deposited from thermal waters on brick and mortar of an old Roman aqueduct. See riversideite (72.3.2.4) and tobermorite (72.3.2.1). ORTH *Imm*2. $a = 11.250$, $b = 7.344$, $c = 27.99$, $Z = 4$, $D = 2.31$. 29–331: 14.0₁₀ 5.50₂₅ 3.08₆₅ 3.00₄₅ 2.81₃ 2.80₁ 2.72₁ 1.835₃₅. Also amorphous. Gelatinous masses (that harden in air) may be powdery, massive and compact to 5 cm, also as white fibers, radial aggregates, or lenses; sometimes elongated on b . Pinkish white, white; white streak; silky luster. Cleavage {001}, excellent; {100}, very good; brittle; masses have conchoidal fracture. $H = 2\frac{1}{2}\text{--}4$; $G = 2.02\text{--}2.25$ with some as high as 2.42. Material from Crestmore fluoresces weak pink-white in SWUV and weak to medium yellow-white in LWUV. IR data: *ZVMO* 124:36(1995). Progressive heating (at 90°C) produces tobermorite and then riversideite (at 300°C). Essentially a hydrated calcium silicate that sometimes contains traces of K, Mg, Fe, and Al. Biaxial (+); $2V = 15^\circ$; variable optics are reported in the literature. $N_x = 1.570$, $N_y = 1.571$, $N_z = 1.575$, and $N_y = 1.552$ (Israel) and 1.550(syn); length-slow or length-fast, OAP is perpendicular to length, $X = c$. Occurs in skarns and as deposits from thermal waters. Occurs at Bingham, Utah; in skarn at Crestmore, Riverside Co., CA; in skarn at Ballycraigy and Scawt Hill, near Larne, and at Carneal, County Antrim, Northern Ireland; at *Plombieres, Vosges, France*; Klöch, Styria, Austria; in the Ozersk gabbro massif, West Baikal area, Siberia, Russia; Bazhenovskoye deposit, Russia; in the “mottled zone” in the Hatrurim area and Beersheba valley, northern Negev, Israel; in association with tobermoreite and oyelite in skarn that is mostly gehlenite and spurrite; Arimao Norte, Cuba; some parts of the skarns were retrogressively altered and cut by numerous veins of tobermorite, oyelite, bultfonteinite, scawtite, xonotlite, afwillite, and jennite at *Fuka, Bitchu, Okayama Pref., Japan.* EF *MIN* 3(3):327(1981); *MM* 56:353(1992); *ZVMO* 123:111(1992), 124:36(1995).

72.3.2.4 Riversideite $\text{Ca}_5\text{Si}_6\text{O}_{16}(\text{OH})_2 \cdot 2\text{H}_2\text{O}$

Named in 1917 by Eakle for the locality. Tobermorite group. ORTH P^{***} . (29-329): $a = 5.571$, $b = 3.641$, $c = 18.79$, $Z = 1$; true cell is C centered: $2a = 11.142$, $2b = 7.282$, $c = 18.79$, $Z = 4$, $D = 2.87$. 29-329(nat, heated plombierite from Crestmore): 9.4_2 4.82_1 3.59_2 3.15_2 3.01_{10} 2.78_2 2.74_1 1.82_1 . Structure: *DAN SSSR 123:163(1958)*. White, white streak, fibrous precipitate, also massive length to 1 cm elongate on b . Cleavage {001}, excellent; {100}, less so. G given as 2.38 and 2.6–2.7. Material from Crestmore fluoresces a weak white in LWUV and SWUV. Biaxial (+); $XYZ = cba$; $N_x = 1.600$, $N_y = 1.601$, $N_z = 1.605$; $2V_{\text{calc}} = 53^\circ$; length-fast or length-slow. Occurs as white fibrous precipitate from a gel, associated with tobermorite and wilkeite at *Crestmore, Riverside Co., CA*; also occurs at Ballycraigy, Larne, County Antrim, Northern Ireland; in xenoliths in basalt at Maroldswisach, northern Bavaria, Germany; in the Hatrurim Fm., Israel. *EF MM 30:155(1953)* *30:293(1954)* *42:229(1978)*, *MIN 3(3):328(1981)*, *DA 46:69(1995)*.

72.3.2.5 Okenite $\text{Ca}_3[\text{Si}_6\text{O}_{15}] \cdot 6\text{H}_2\text{O}$

Named in 1828 by Von Kobell for Lorenz Oken (1779–1851), naturalist, Munich, Germany. Tobermorite group. TRIC $P\bar{1}$ or $P1$. $a = 9.69$ – 9.80 , $b = 7.28$ – 7.29 , $c = 22.0$, $\alpha = 87.5$ – 92.7° , $\beta = 100.1$ – 102.0° , $\gamma = 110.9$ – 112.6° , $Z = 9$. *AM 68:614(1983)* and *33-305*. The true cell (superstructure) has: (for $P\bar{1}$) $a = 9.81$, $b = 14.56$, $c = 22.02$, $\alpha = 87.3^\circ$, $\beta = 106.0^\circ$, $\gamma = 112.8^\circ$; maintaining the same orientation as the subcell requires a C -centered cell ($C1$): $a = 19.38$, $b = 14.56$, $c = 22.02$, $\alpha = 97.7^\circ$, $\beta = 100.1^\circ$, $\gamma = 110.9^\circ$; $Z = 1$; another cell from a structure solution is: $a = 18.50$, $b = 7.29$, $c = 22.45$, $\alpha = 87.7^\circ$, $\beta = 102.6^\circ$, $\gamma = 91.5^\circ$; $Z = 3$ [*ZK 159:37(1982)*], $D = 2.24$. *33-305*(nat): 21.0_{10} 8.84_8 3.11_6 3.00_6 2.95_6 2.92_6 2.80_5 1.82_7 . A SOCOS layer is formed of infinite tetrahedral sheets S characterized by five- and eight-membered rings, double tetrahedral chains C , and double octahedral chains O . First example of a tetrahedral chain and sheet silicate. $R = 13\%$. *AM 68:614(1983)*. Structure solution in *ZK 159:37(1982)* yielded $R = 8\%$. Fibrous, bladed or lath-like crystals, elongate on [010], also radial aggregates of curved crystals, "balls" to 4 cm in diameter; repeated lamellar twinning across the cleavage plane {001} – $011[010] + 011\{001\}$. Colorless, white, pale yellow, or blue; white streak; pearly luster. Cleavage {001}, perfect; flexible fibers. $H = 4\frac{1}{2}$ – 5 . $G = 2.2$ – 2.4 . IR data: *MMS II 6:199(1966)*. DTA and TGA data: *MM 43:677(1980)*. Gelatinizes with acids; okenite transforms to β - CaSiO_3 (parawollastonite) on heating. The presence of tetrahedral ribbons in its structure instead of the octahedral layers in gyrolite appears to be a determining factor for its stability. May have trace to minor Na, K, Mg, Al, Fe. Na_2O to 1.2%. Biaxial (-); $Z \approx c$; $N_x = 1.512$ – 1.532 , $N_y = 1.514$ – 1.535 , $N_z = 1.515$ – 1.542 ; $2V = 60^\circ$; length-fast. In cavities in basalt or related eruptive rocks. In limestone at Crestmore. Often associated with zeolites, apophyllite, calcite, prehnite, quartz and others. In carbonatites. Occurs at the Fairfax Quarry, Centreville, Fairfax Co., VA; Crestmore, Riverside Co.,

CA; Skookumchuck Dam, near Bucoda, Thurston Co., WA; Nova Scotia, and Jeffrey mine, Asbestos, QUE, Canada; Bordo, Faroe Is. (Denmark); *Disko Is.*, Greenland; Kutdlisat, Ritenbenk district, Greenland; Scawt Hill, County Antrim, Northern Ireland; Isle of Mull and on Morven Peak, Grampian Highlands, Scotland; Branburg, Germany; Brézno nad Labem, and Ústí nad Labem-Krásné Brézno, Bohemia, Czech Republic; in carbonatite at Vuorijarvi, Kola Penin., Russia; Kerch and Taman Penin., Crimea, Ukraine; Ale-shinsk deposit, Turgai, Russia; southern Mugodzhar, Kazakhstan; Poona and Deccan traps, Syhadree Mts., Bombay, MAH, Naskik, and Kolhapur district, MAH, India; Rio Putagan, Chile. *EF MM 31:5(1956) MIN 3(3):330(1981)*.

72.3.2.6 Tacharanite Formula given variously as:

$\text{Ca}_{12}\text{Al}_2\text{Si}_{18}\text{O}_{33}(\text{OH})_{36}$; $\text{Ca}_{12}\text{Al}_2\text{H}_6\text{Si}_{18}\text{O}_{54} \cdot 15\text{H}_2\text{O}$; sodium-bearing from Japan: $\text{NaCa}_{12}\text{Al}_2\text{H}_6\text{AlSi}_{17}\text{O}_{54} \cdot 12\text{H}_2\text{O}$

Named in 1961 by Sweet et al. from the Gaelic *tacharan*, a changeling, because on standing in air the mineral breaks down to form other compounds (note that later investigators did not find this to be the case). Tobermorite group. **MON** A centered, pseudo-cell: $a = 17.05\text{--}17.11$, $b = 3.65$, $c = 27.8\text{--}28.04$, $\beta = 114.1^\circ$, $Z = 1$, $D = 2.28$. A cell with b doubled has been reported [*BNSMTC 9:85(1983)*]: $a = 17.07$, $b = 7.276$, $c = 27.96$, $\beta = 114.0^\circ$, $Z = 2$. $29\text{--}287(\text{nat})$: 12.7_{10} 5.19_7 3.05_9 2.89_7 2.85_7 2.77_8 2.43_7 1.82_8 . Unknown structure. Fine acicular, massive, porcelaneous masses and crusts, elongate laths, b parallel to fiber length. White, porcelaneous, cryptocrystalline; white streak. Conchoidal fracture. $H \approx 5$. $G = 2.21\text{--}2.36$. IR data: *MM 40:113(1975)*, very similar to tobermorite. DTA data: *MM 42:383(1978)*. TGA data: *MM 40:113(1975)*, very similar to tobermorite. Can heat to 700° before changes occur in the powder pattern; production of wollastonite at $900\text{--}1000^\circ$. Analysis (wt %): SiO_2 , 48.4; Al_2O_3 , 5.0, CaO , 30.4; Na_2O , 0.25; K_2O , 0.8; H_2O , 14.9; Japanese material: Fe_2O_3 , 0.1; MgO , 0.6; Na_2O , 1.26; K_2O , 0.14; H_2O^+ , 12.50; H_2O^- , 1.76. Substitution of (Na, Al) for (\square , Si) occurs. Isotropic to biaxial (+) with large 2V; $N = 1.537$ (Portree cryptocrystalline), 1.530 (Carneal), 1.54 (Bramberg, variable crystallinity); 1.530 parallel to fiber direction and 1.518 perpendicular to fiber direction. For Tasmanian material, $N = 1.535$ parallel to the fiber direction and 1.525 perpendicular to the fiber direction. Colorless. Positive elongation of fibers. Occurs in vesicles of an olivine dolerite with zeolites and other hydrated Ca-silicates: tobermorite, xonotlite, gyrolite, and others. In Italy, in fractures in metagabbros with zeolites; in vesicular olivine nephelinite in Tasmania; in glassy pillow lava, Japan. A low-temperature ($< 250^\circ$) mineral. Alteration: tacharanite altered to tobermorite, gyrolite, and xonotlite [*MM 32:745(1961)*], but no alteration was reported later [*MM 40:113(1975)*]. Alteration to tobermorite \pm saponite also reported. Doe Hill, Highland Co., VA; Ritter Hot Springs, Oregon; *Portree, Isle of Skye, Scotland*; also Isle of Mull, and at the Binbill quarry, Cairnie, Huntley, Aberdeenshire, Scotland; Carneal, County Antrim, Northern Ireland; at Espalion, Aveyron,

France; Bramburg, near Göttingen, Lower Saxony, and at Arensburg, near Zilsdorf, Eifel district, Germany; Gruppo di Voltri, and along the Olbirella, near Tiglieto, Ligurian Alps, Italy; Scottsdale, Marrawah-Redpa, Brittons Swamp, and several other areas in Tasmania, Australia; Noaki, Yaizu city, Shizuoka Pref., Japan. EF *MM* 42:383(1978), 51:467(1987); *MIN* 3(3):329(1981).

72.3.2.7 Nekoite $\text{Ca}_3\text{Si}_6\text{O}_{15} \cdot 7\text{H}_2\text{O}$

Named in 1956 by Gard and Taylor from *okenite* by reversing the first four letters; the minerals are very similar. Tobermorite group. See *okenite* (72.3.2.5). TRIC *P1*. $a = 7.588$, $b = 9.793$, $c = 7.339$, $\alpha = 111.77^\circ$, $\beta = 103.50^\circ$, $\gamma = 86.53^\circ$, $Z = 1$, $D = 2.21$. 31-303(nat): 9.1₁₀ 6.64₇ 3.38₆ 3.32₉ 3.30₆ 2.83₆ 2.80₆ 1.83₈. *PM* 48:5(1979): 9.09₅ 7.38₈ 3.69₄ 3.45₆ 3.38₁₀ 2.83₆ 2.82₆ 2.19₇. The structure consists of tetrahedral sheets interlayered with octahedral chains. The tetrahedral Si_6O_{15} sheets are obtained by interconnecting a "dreierkette" so as to form alternating bands of five- and eight-membered rings. Ca-octahedral chains, which cross-link the tetrahedral sheets, are formed by a double strand of octahedra, of which three out of four are occupied and the fourth is empty. $R = 6.8\%$. *AM* 65:1270(1980). Radial-fibrous nodular aggregates of fine acicular prismatic crystals to 5 mm long (Brazil); elongated parallel to c , polysynthetic twinning on {001} and {100}. Colorless, white streak, vitreous luster. Cleavage {001}, perfect. $H = 5$ or less. $G = 2.21$ –2.24. Material from Crestmore fluoresces weak to medium white-yellow in SWUV and medium white-yellow in LWUV. IR, DTA, and TGA data: *PM* 48:5(1979). Biaxial (+); Z perpendicular to (001), $X \wedge a = 26^\circ$; $N_y = 1.535$; $2V = 70^\circ$; birefringence is very low; length-slow. Occurs at the Iron Cap mine, Landsman's Camp, Arivaipa District, Graham Co., AZ; in a contact metamorphosed limestone deposit, assoc. with apophyllite at *Crestmore quarry, Crestmore, Riverside Co., CA*; in cavities in basaltic rock at Caxias do Sul, Rio Grande do Sul, Brazil, along with heulandite and apophyllite. EF *MIN* 3(3):335(1981).

72.3.2.8 Oyelite $\text{Ca}_{10}\text{B}_2\text{Si}_8\text{O}_{29} \cdot 12\text{H}_2\text{O}$

Named in 1984 by Kusachi et al. for Jiro Oye (1900–1968), professor of mineralogy, Okayama University, Japan. Tobermorite group. Previously reported and described as 10-Å tobermorite. ORTH Space group B^{***} . $a = 11.23$ –11.25, $b = 7.24$ –7.252, $c = 20.42$ –20.46, $Z = 2$, $D = 2.64$. 41-1386(nat): 10.29₉ 4.92₂ 3.78₂ 3.06₅ 2.92₁₀ 2.81₄ 2.56₂ 2.04₂. *JJMPE* 81:138(1986). Acicular crystals 1–3 mm long, sprays and coatings. White, vitreous luster. $H = 5$. $G = 2.62$. IR, DTA, and TGA data: *JJMPE* 81:138(1986). Analysis (wt %): SiO_2 , 35.3; B_2O_3 , 4.8; Al_2O_3 , 0.3; CaO , 41.2; H_2O^+ , 16.7; H_2O^- , 0.7; CO_2 , 0.4. Biaxial (+); $N_x = 1.602$, $N_y = 1.606$, $N_z = 1.613$; $2V_{\text{calc}} = 74^\circ$; colorless. Occurs at Crestmore Quarry, Riverside Co., CA, in association with bultfonteinite, scawtite, xonotlite, and calcite. In a vein cutting a spurrite zone of a spurrite-gehlenite skarn at *Fuka, Bitchu, Okayama Pref., Japan*. Also occurs at Suisho-dani, Ise

City, Mie Pref., Japan, where it is in a serpentinite body, in rodingitic rock derived from a gabbro pegmatite. Occurs associated with bultfonteinite at the N'chwane II mine, Kalahari manganese field, Cape Prov., South Africa. *EF JMMPE* 79:267(1984), *MR* 22:279(1991).

PYROSMALITE GROUP

The pyrosmalite group consists of several isostructural, polytypic, and derivative species conforming to the formula

where

The structure is characterized by a silicate layer built up of six-tetrahedron rings, each of which is joined by two tetrahedra to three adjacent rings whose apical oxygens point opposite to that of the central ring. The resultant layers, about 7.15 Å thick, have one 12-tetrahedron ring surrounding a large void, for every two six-tetrahedron rings.

Perspective view approximately along c.

The several species differ from one another on the basis of the cation (Mn^{2+} or Fe^{2+}), the stacking sequence of the layers, the ordering of chlorine and hydroxyl, and the occupancy of silicate-layer voids by $[As^{3+}O_2(OH)]$. The stacking sequence appears not to be entirely independent of ordering and void occupancy, so that similar compositions of different symmetry may not be polytypes in *sensu strictu*. *AM* 66:1054(1981); *CM* 21:1(1983), 21:7(1983).

PYROSMALITE GROUP

Mineral	Formula	Space Group	a	b	c	β
Ferropyrosmalite	$(Fe, Mn)_8[Si_6O_{15}](OH, Cl)_{10}$	P3m1	13.33		7.11	72.4.1a.1

72.4.1a.1 Ferropyrosmalite $(Fe, Mn)_8[Si_6O_{15}](OH, Cl)_{10}$

Named in 1987 by Vaughan for the composition and from the Greek *fire* and *odor*, in allusion to the odor produced on heating. Pyrosmalite group. Equivalent in part to undifferentiated pyrosmalite described in 1808. See isomorphous manganpyrosmalite (72.4.1a.2). *HEX* P3m1. $a = 13.33$, $c = 7.11$, $Z = 2$, $D = 3.10$ for $Fe/(Fe + Mn) = 0.92$. *12-268*: 7.13₈ 3.58₅ 2.69₁₀ 2.25₇ 1.84₅ 1.672₅ 1.629₄ 1.521₅. The lattice constants increase slightly with increased substitution of Mn for Fe. Crystals tablets to stout hexagonal prisms {1010} terminated by {0001} and occasionally modified by rhombohedral faces; massive. Yellow-green to tan, rarely pinkish; surface often gray, dark green, or brown due to alteration; vitreous luster, pearly on perfect {0001} cleavage; translucent, rarely transparent. $H = 4-5$. $G = 3.06-3.19$. Uniaxial (-); $N_O = 1.664-1.682$, $N_E = 1.634-1.650$ for undifferentiated pyrosmalite, Fe-rich material having the higher indices; darker varieties pleochroic in brown, $O > E$. Early analyses of Swedish material lie on either side but close to $Fe/Mn = 1:1$; reported values for $Fe/(Fe + Mn) = 0.15-0.92$. Found at the Geco and Willroy mines, Manitouwadge, ON, at the Mattagami Lake mine, Mattagami, QUE, and Thompson mine, Thompson, MB, Canada; at the New Broken Hill Consolidated mines, Broken Hill, NSW, and in the *Pegmont deposit*, Q, Australia. Undifferentiated pyrosmalite: in transparent, pink microcrystals on silver at the El Bonanza mine, Port Radium, NWT, Canada; at Naut Francon, Wales, and the Treburland mine, Altarnum, Cornwall, England; in the iron ores of Dannemora, Uppsala, and Nordmark, Varmland, Sweden(!),

near midway toward Mn end member. See also manganpyrosmalite (72.4.1a.2). AR *D6:465(1892)*; *MM 50:527(1986)*, *51:174(1987)*; *CM 31:695(1993)*.

72.4.1a.2 Manganpyrosmalite $(\text{Mn,Fe})_2[\text{Si}_6\text{O}_{15}](\text{OH,Cl})_{10}$

Named in 1953 by Frondel and Bauer for the composition and from the Greek for *fire* and *odor*, in allusion to the odor produced on heating. Pyrosmalite group. Equivalent in part to undifferentiated pyrosmalite described in 1808. See isomorphous ferropyrosmalite (72.4.1a.1). HEX *P3m1*. $a = 13.442$, $c = 7.165$, $Z = 2$, $D = 3.03$ for $\text{Fe}/(\text{Fe} + \text{Mn}) = 0.18$. *12-249*: 7.16_{10} 3.58_8 3.42_4 2.68_9 2.25_7 1.843_4 1.672_5 1.523_5 . Structure: *CM 21:1(1983)*. The lattice constants increase slightly with increased substitution of Mn for Fe. Brown, translucent. Cleavage $\{0001\}$, perfect. $H = 4\frac{1}{2}$. $G = 3.13$. Uniaxial (-); $N_O = 1.669$, $N_E = 1.631$. Weakly pleochroic; $O > E$; light brown. Indices increase with increasing Fe substitution. Complete solid solution with ferropyrosmalite. Found at *Sterling Hill, Sussex Co., NJ*, with friedelite, bementite, and willemite in veinlets cutting franklinite ore. In Varmland and Uppsala, Sweden (!) (Mn/Fe near 1:1); in the Dzhumart and Ushkatyn deposits, Kazakhstan; Primorye Kray, Russia; Wafangzi, Liaoning, China; at the Kyurazawa mine, Tochigi Pref., Honshu, Japan; large composite crystals at Broken Hill mine, NSW, Australia; Lar mine, Tierra Amarilla, Chile. See also ferropyrosmalite AR *D6:465(1892)*, *AM 38:755(1953)*, *CM 31:695(1993)*.

72.4.1a.3 Schallerite $\text{Mn}_{16}[\text{As}^{3+}\text{O}_2\text{OH}]_3[\text{Si}_{12}\text{O}_{30}](\text{OH})_{14}$

Named in 1925 by Gage et al. in honor of Waldemar Theodore Schaller (1882–1967), mineralogist, U.S. Geological Survey. Pyrosmalite group. HEX Space group unknown, probably *P3m1(?)*. $a = 13.40$, $c = 14.28$, $Z = 2$, $D = 3.45$. *12-253*: 3.55_4 2.83_3 2.67_6 2.47_5 2.02_5 1.975_4 1.688_{10} 1.511_6 . $[\text{As}^{3+}\text{O}_2\text{OH}]^{2-}$ probably occupy the large voids in the 12-membered rings of the silicate sheets. Dimorphous with nelenite. Light brown to reddish brown; waxy luster, pearly on $\{0001\}$ cleavage; translucent. $H \approx 5$. $G = 3.37$. Uniaxial (-); $N_O = 1.704$, $N_E = 1.679$. Ideally, As_2O_3 should be 12.87 wt %, but samples with as little as 1.2–6.9 wt % are known, suggesting a complex relationship to pyrosmalite and friedelite. Fe substitution for Mn appears to be limited. Found massive and as small (to 2 mm) hemimorphic pyramidal crystals with calcite in fractures perpendicular to banded willemite–franklinite ore at the 700-ft level at the *Franklin mine, Sussex Co., NJ*, and as spherical and rectangular aggregates in massive rhodonite; also in the Ködnitz Valley, Tyrol, Austria. AR *USGSP 180:90(1935)*, *AM 66:1054(1981)*.

72.4.1b.1 Friedelite $\text{Mn}_2[\text{Si}_6\text{O}_{15}](\text{OH,Cl})_{10}$

Named in 1876 by Bertrand for Charles Friedel (1832–1899), French chemist and mineralogist. Pyrosmalite group. The name once applied to the manganese end member of pyrosmalite. MON *C2/m*. $a = 23.33$, $b = 13.396$, $c = 7.447$, $\beta = 105.08^\circ$, $Z = 4$, $D = 3.06$. *35-572*: 7.17_9 3.60_7 2.88_6 2.56_{10} 2.41_3 2.12_4

1.731₃ 1.676₆. May be described as HEX-R with a supercell, $a = 13.40$, $c = 21.57 \approx (3 \times 7.15)$. Structure: *CM 21:7(1983)*. Crystals tabular, pseudohexagonal, and often hemimorphic; rarely slender needles; fibrous and lamellar aggregates; massive. Pale pink to dark red, brown to red-brown, rarely yellow; vitreous to pearly luster; transparent to translucent. Cleavage {001}, perfect; brittle. $H = 4-5$. $G = 3.04-3.14$. Uniaxial (-); $N_O = 1.654-1.664$, $N_E = 1.625-1.629$; also biaxial (-); 2V very small; $N_y = 1.623$, $N_x = 1.650$, $N_z = 1.651$; positive elongation to parallel cleavage. Pleochroic; X, colorless; Y,Z, greenish yellow. Decomposed by HCl; fusibility 4. The chlorine content appears to be $Cl/OH < 1:9$; Fe^{2+} is low, as is Mg. Associated with franklinite and willemite at Franklin and Sterling Hill, Sussex Co., NJ; at the American tunnel, San Juan Co., CO. At *Adervielle, Louron Valley, Haute Pyrenees, France*; the Sjö mines, near Orebro, and the Harstig mine, Pajsberg, Sweden. At Broken Hill, NSW, Australia; Kalahari manganese field, Cape Prov., South Africa. AR *D6:465(1892)*; *AM 38:755(1953)*, *66:1054(1981)*.

72.4.1b.2 McGillite $Mn_8[Si_6O_{15}](OH)_8Cl_2$

Named in 1980 by Donnay et al. for McGill University, Montreal, Canada. Pyrosmalite group. MON $C2/m$. $a = 23.312$, $b = 13.459$, $c = 7.423$, $\beta = 105.17^\circ$, $Z = 4$, $D = 3.08$, *38-891*: 11.7₂ 7.16₇ 3.57₄ 2.89₆ 2.56₁₀ 2.41₂ 2.12₄ 1.683₄. Also regarded as HEX-R $R3m$ with a supercell of $a = 13.459$, $c = 85.97 \approx (12 \times 7.16)$. An apparent polytype of friedelite but not in *sensu strictu*, the stacking sequence possibly may be compositionally dependent with regard to ordered site occupancy by Cl. Structure: *CM 21:7(1983)*. Possibly twinned on a micro scale by 120° about [110]. Light to dark pink, vitreous to pearly luster, translucent. Cleavage {001}, perfect. $H \approx 4$. $G = 2.98$. Uniaxial (-); $N_O = 1.667-1.670$, $N_E = 1.640-1.643$. Decomposed by HCl. The chlorine content is close to that of the ideal formula. Found associated with sphalerite and minor boulangerite, jamesonite, galena, and quartz at the *Sullivan mine, Kimberley, BC, Canada*, and the Kyurazawa mine, Tochigi Pref., Honshu, Japan. AR *CM 18:31(1980)*.

72.4.1b.3 Nelenite $(Mn,Fe)_{16}[As^{3+}O_2OH]_3[Si_{12}O_{30}](OH)_{17}$

Named in 1984 by Dunn and Peacor for Joseph Aloysius Nelen (b.1923), Dutch-American chemist, Smithsonian Institution, Washington, DC. Pyrosmalite group. Equivalent to the name used earlier: ferroschallerite. MON $C2/m$. $a = 23.240$, $b = 13.418$, $c = 7.832$, $\beta = 105.21^\circ$, $Z = 2$, $D = 3.45$; an HEX-R supercell has $a = 13.42$, $c = 85.5$. *38-355*: 7.10₄ 3.55₆ 2.88₇ 2.55₁₀ 2.40₄ 2.10₄ 1.723₅ 1.677₆. Dimorphous (polytypic) with schallerite (72.4.1a.3). Light to medium brown, vitreous to resinous luster. Cleavage {001}, perfect. $H \approx 5$. $G = 3.46$. Uniaxial (-); $N_O = 1.718$, $N_E = 1.700$; occasionally biaxial (-) with 2V very small. With actinolite, tirodite, albite, garnet, willemite, rhodonite, apatite, lennilenapeite, and stilpnomelane from the *Trotter shaft, Franklin, Sussex Co., NJ*. AR *MM 48:271(1984)*.

RHODESITE GROUP

The rhodesite group comprises silicates of composition near

where

and where there is possible substitution of $(OH)^-$ for O^{2-} . The structures of rhodesite and macdonaldite have been determined and are characterized by corrugated sheets having, in rhodesite, the composition $[Si_8O_{19}]^{6-}$. The assigned axial orientation is not self-consistent, but all have an edge of 23–25 Å.

RHODESITE GROUP

Mineral	Formula	Space Group	Crystallographic Data				β
			a	b	c		
Rhodesite	$H(K,Na)Ca_2[Si_8O_{19}] \cdot 5H_2O$	Pm3m	23.416	6.555	7.050		72.5.1.1
Monteregianite-(Y)	$K_2Na_4Y_2[Si_{16}O_{38}] \cdot 10H_2O$	P2 ₁ /n	9.512	23.956	9.617	93.85	72.5.1.2
Macdonaldite	$BaCa_4[Si_{16}O_{36}](OH)_2 \cdot 10H_2O$	Cmcm	14.081	13.109	23.560		72.5.1.3
Delhayelite	$(Na,K)_{10}Ca_5Al_6[Si_{32}O_{80}](Cl_2,F_2,SO_4)_3 \cdot 18H_2O$	Pnmm	13.06	24.65	7.04		72.5.1.4
Hydrodelhayelite	$KCa_2[AlSi_7O_{17}](OH)_2 \cdot 6H_2O$	Pnm2 ₁	6.648	23.846	7.073		75.5.1.5

72.5.1.1 Rhodesite $H(K,Na)Ca_2[Si_8O_{19}] \cdot 5H_2O$

Named in 1957 by Gard et al. for Cecil John Rhodes (1853–1902), British financier and colonial statesman who founded the DeBeers Mining Company. Rhodesite group. ORTH Pm3m. $a = 23.416$, $b = 6.555$, $c = 7.050$, $Z = 2$, $D = 2.41$. 2θ -1253: 6.55₁₀ 6.30₃ 5.90₄ 5.03₃ 4.39₅ 3.38₂ 2.86₃ 2.76₃. Structure: *ZK 199:25(1992)*. Matted silky [001] fibers and rosettes up to 2 mm in diameter. White, silky luster. Cleavage {100}, good. $H = 4$. $G = 2.36$. Biaxial (+); $2V_{obs}$ small, $2V_{calc} = 68$ – 71° . $N_x = 1.501$ – 1.504 , $N_y = 1.505$ – 1.508 , $N_z = 1.513$ – 1.518 ; $XYZ = bac$. Found with magadiite and montmorillonite in altered silicic lava 35 miles NW of Redding, Trinity Co., CA; with natrolite at Zeilberg, Unterfranken, Germany; San Venanzo, Rieti, Italy; with mountainite at Bultfontein mine, Kimberley, South Africa. AR *MM 31:607(1952)*.

72.5.1.2 Monteregianite-Y $K_2Na_4Y_2[Si_{16}O_{38}] \cdot 10H_2O$

Named in 1978 by Chao for the Monteregian Hills, which include the type locality. Rhodesite group. Synonym: monteregianite. MON (pseudo-ORTH).

$P2_1/n$. $a = 9.512$, $b = 23.956$, $c = 9.617$, $\beta = 93.85^\circ$, $Z = 2$, $D = 2.41$. 31-1087: 12.0₁₀ 7.03₁₀ 6.55₄ 6.02₅ 4.42₁₀ 3.41₅ 3.03₅ 2.87₈. Radiating clusters of acicular [100] crystals, mostly 1–5 mm long, but known up to 25 mm, displaying {100}, {010}, {001}, and occasionally {101}; also parallel groups of laths, elongated [100] and flattened on {010}. All indices are in the original morphological setting, the transformation matrix, morphological to structure being $/10\bar{1}/010/101/$. Colorless, white, gray, rarely mauve or green; vitreous luster when transparent to silky or greasy; transparent to opaque. Cleavage {010}, perfect; {001}, very good; {100}, fair. $H = 3\frac{1}{2}$. $G = 2.42$. Biaxial (+); $2V = 87^\circ$; $N_x = 1.510$, $N_y = 1.513$, $N_z = 1.517$; $XYZ = cab$ in morphological setting. Bright green fluorescence in SWUV. Widespread in small amounts at *Mt. St.-Hilaire, QUE, Canada*, most commonly in igneous breccias and marble xenoliths, rarely in carbonate-richmiarolitic cavities, and very rarely in pegmatites. AR *CM 16:561(1978)*, *MR 21:323(1992)*.

72.5.1.3 Macdonaldite $BaCa_4[Si_{16}O_{36}(OH)_2] \cdot 10H_2O$

Named in 1965 by Alfors et al. for Gordon Andrew Macdonald (1911–1978), American volcanologist, University of Hawaii. Rhodesite group. ORTH *Cmcm*. $a = 14.081$, $b = 13.109$, $c = 23.560$, $Z = 4$, $D = 2.36$. 18-163: 8.90₄ 6.50₁₀ 6.30₅ 5.90₃ 4.36₈ 3.36₅ 3.02₄ 2.74₄. Structure: *SR 33A:489(1968)*. As acicular [100] crystals, 1–6 mm in length, displaying the three pinacoids. Colorless to white, satiny to vitreous luster. Cleavage {010}, perfect; {001}, good; {100}, poor. $H = 3\frac{1}{2}$ –4. $G = 2.27$. Biaxial (+, –); $2V \approx 90^\circ$; $N_x = 1.518$, $N_y = 1.524$ –1.525, $N_z = 1.530$; $XYZ = cba$. Insoluble in cold acids but decomposed by boiling HCl. Fusibility 5.5. Found in sanbornite-bearing metamorphic rocks near a granodiorite contact, exposed in a narrow zone $2\frac{1}{2}$ miles long near *Big Creek, eastern Fresno Co., CA*. AR *AM 50:314(1965)*.

72.5.1.4 Delhayelite $(Na, K)_{10}Ca_5Al_6[Si_{32}O_{80}](Cl_2, F_2, SO_4)_3 \cdot 18H_2O$

Named in 1959 by Sahama and Hytonen for Fernand Delhaye (1880–1946), Belgian geologist. Rhodesite group. ORTH *Pnmm*. $a = 13.06$, $b = 24.65$, $c = 7.04$, $Z = 1$, $D = 2.48$. 12-286: 12.3₃ 6.16₂ 3.48₁ 3.08₁₀ 2.96₁ 2.79₁ 1.760₁ 1.541₁. Colorless to light gray-green. Cleavage {010}, distinct. $H \approx 4$. $G = 2.517$ –2.615 (impure). Biaxial (–); $2V = 88^\circ$; $N_y = 1.532$. Fluoresces orange in UV. Found at *Mt. St.-Hilaire, QUE, Canada*; at *Yukspor Mt. and Mt Rasvumchorr, Khibiny massif, Kola Penin., Russia*; and as platy crystals in kalsilite–melilite–nepheline lava at *Mt. Shaheru, Kivu, Zaire*. AR *MM 32:6(1959)*, *MR 10:108(1979)*.

72.5.1.5 Hydrodelhayelite $KCa_2[AlSi_7O_{17}(OH)]_2 \cdot 6H_2O$

Named in 1979 by Dorfman and Chiragov for its composition and relationship to delhayelite. Rhodesite group. ORTH *Pnm2₁*. $a = 6.648$, $b = 23.846$, $c = 7.073$, $Z = 2$, $D = 2.24$. 41-611: 6.79₄ 4.89₃ 4.15₃ 3.32₄ 3.07₈ 2.92₁₀ 2.80₆ 2.67₂. Grayish-white, vitreous luster, translucent. Cleavage {010}, perfect;

{100}, {001}, less so. $H = 4$. $G = 2.17$. Biaxial; $N_x = 1.503$, $N_z = 1.518$. Found as a supergene alteration product of delhayelite at *Mt. Rasvumchorr, Khibiny massif, Kola Penin., Russia*. AR AM 72:1024(1987).

72.5.2.1 Leucosphenite $\text{Na}_4\text{BaTi}_2\text{O}_2[\text{B}_2\text{Si}_{10}\text{O}_{28}]$

Named in 1901 by Flink from the Greek for *white* and *wedge*, in allusion to its color and morphology. MON $C2/m$. $a = 9.814$, $b = 16.851$, $c = 7.210$, $\beta = 93.35^\circ$, $Z = 2$, $D = 3.090$. 25-784: 8.45₉ 4.22₁₀ 3.57₃ 3.37₇ 3.31₅ 3.25₃ 3.19₃ 2.89₆. Structure: SPD 26:372(1981). The structural unit consists of four-tetrahedron rings of two types. Two rings, $[\text{Si}_4\text{O}_{10}]$, share their apical oxygens with a ring, $[\text{B}_2\text{Si}_2\text{O}_8]$, in which B and Si are disordered; these are linked to form a layer, $[\text{B}_2\text{Si}_{10}\text{O}_{28}]^{14-}$. The individual rings lie perpendicular to the layer, which is parallel to {001}. Crystals prismatic [100] with wedge-shaped terminations; {001}, {010}, {130} dominant and lesser {101} and {110}. Also tabular to equant with the same dominant forms, yielding short, striated, pseudo-hexagonal prisms. Twinning with {001} composition plane common. Colorless, lemon yellow to brown, also pale blue; vitreous luster; transparent to translucent. Cleavage {010}, perfect; {001}, fair. $H = 6-6\frac{1}{2}$. $G = 3.05-3.09$. Biaxial (+); $2V \approx 76^\circ$; $N_x = 1.643-1.649$, $N_y = 1.657-1.664$, $N_z = 1.681-1.691$; $X \approx a$, $Y \wedge c = -3^\circ$, $Z = b$; $r > v$, weak. Fluoresces yellowish white in SWUV. Insoluble in acids. Calcium may replace sodium with concomitant additional boron replacement of silicon. Found with shortite and analcime in crystals in the Tertiary Green River formation, UK and WY; as blocky, prismatic [001] crystals(1), less commonly long [100] prisms, at *Mt. St.-Hilaire, QUE, Canada*. Occurs as [100] prisms at *Narsarsuk, Julianehaab district, Greenland*; in the Alaiski massif, Turkestan, and in the Inaglia alkaline massif, Yakutia, Russia. AR AM 57:1801(1972), CM 11:851(1972), MR 21:319(1990).

72.5.2.2 Nordite-(Ce) $(\text{Ce},\text{La},\text{Ca})(\text{Sr},\text{Ca})\text{Na}_2(\text{Na},\text{Mn})(\text{Zn},\text{Mg})\text{Si}_6\text{O}_{17}$

Named in 1958 by Semenov and Barinsky by analogy to the La-dominant analogue, nordite-(La). ORTH. *Pcca*. No cell data available. $Z = 4$. No powder data available. A metamict mineral. Recrystallized at 800°C for 10 hours. Structure not determined. Light brown, dark brown, nearly black, white; streak light brown; to 1 cm long, lamellar parallel to b ; sometimes radial, fibrous aggregates of curved and lamellar crystals to 2.0 cm diameter; vitreous, greasy on fracture; cleavage = {010}; $H = 5$; $G = 3.43-3.49$; decomposes in acids. Biaxial (-); $2V = 30^\circ$ or less, $N_\alpha = 1.619-1.621$, $N_\beta = 1.63-1.64$, $N_\gamma = 1.642-1.655$. Occurs associated with lueshite at *Mont Saint-Hilaire, Quebec*; on the *Chinglusuai River and Motchusuai River, Lovozero Massif, Kola Peninsula, Russia*; in sodalite syenite pegmatite. Also occurs in vuggy natrolite in the central zone of the Jubilee pegmatite and other locations on Mount Karnasurt, Lovozero Massif. Unspecified locality in the Khibiny Massif. Alteration: weathers readily to ochers of hydrous REE minerals and ancy-

lite-(Ce). AM 55:1167(1970) Minerali 3(3):336(1981) New data on the mineralogy of rare elements of the Kola Peninsula, Apatity, p. 60–65(1991).

72.5.2.3 Nordite-(La) (La,Ca)(Sr,Ca)Na₂(Na,Mn)(Zn,Mg)Si₆O₁₇

Named in 1941 by Gerasimovsky from the word for North because of its northern origin in the Lovozero Massif, Kola Pen, Russia. Compare: Nordite-(Ce). ORTH. Pcca a 14.468 b 5.203 c 19.88 (DAN, VMU 4:97(1992)) $Z = 4$ $D = 3.51$ a 14.369 b 5.180 c 19.766 (ICDD 41-584); PD 41-584 (nat.): 7.2₁₀ 4.69₅ 4.20₈ 3.46₇ 3.31₇ 2.95₆ 2.86₈ 2.78₅. Structure: (AM 55:1167(1970) and DAN VMU 4:97(1992)). Light brown, dark brown to black; H 5–6; G 3.43–3.48. SiO₂ 45.5, Fe₂O₃ 1.84, Ce₂O₃ 8.77, La earths 10.48, Y earths 0.95, MnO 6.04, SrO 7.40, CaO 4.46, MgO 2.00, Na₂O 11.70, K₂O 0.08, Cl trace, total 99.27. Another REE analysis La₂O₃ 8.55, Ce₂O₃ 8.1, Pr₂O₃ 1.6, Nd₂O₃ 1.85. Biax. (–), $2V = 31^\circ$; N_α 1.619 N_β 1.630–1.640 N_γ 1.642; XYZ = abc. Sometimes uniaxial due to square distribution of heavy atoms on the yz plane. Occurs in Ne-syenite near the Chinglusuai River, Lovozero Massif, Kola Peninsula, Russia. Also at several localities in the Khibiny Massif, Kola Peninsula, Russia. EF MIN 3(3):336(1981).

72.5.2.4 Semenovite-(Ce) (Ca,Ce,La,Na)_{10–12}

(Fe⁺², Mn)(Si,Be)₂₀(O, OH, F)₄₈ or Ce₂Na_{0–2} (CSRE Mins. 1993) III

Named in 1972 by Petersen and Ronsbo for Yevgeny Ivanovich Semenov (1951–) Russian mineralogist, IMGRE, Moscow. ORTH *Pmnm*. $a = 13.879A$, $b = 13.835$, $c = 9.942$, $Z = 2$, $D = 3.17$; PD 25-699 (nat.): 8.08₇ 6.95₄ 5.25₄ 3.28₁₀ 3.18₄ 3.10₄ 2.84₁₀ 2.73₁₀. Structure: R = 5% {110} twinning, always present, is responsible for pseudotetragonal symmetry. Structure related to miliphanite, leucophanite, gadolinite, nordite and hellandite. Aminoffite shows little similarity with regards to crystal structure (AM 64:202(1979)). Fresh – transparent brown, rarely orange-brown altered – dull gray and reddish brown to gray with brown hue, also colorless; streak white to pale brown; pseudotetragonal, bipyramidal crystals 0.1–1 mm usual, largest are 1 cm; twinning complex, interpenetrant, always twinned, TP = (110), twin after {110}, with composition plane = (120); vitreous; cleavage = none; fracture = uneven; H = 3½–4; G = 3.14; TGA data (LIT 5:163(1972)). The chemistry is complex. Biaxial (–); $2V = 0$ to 55° , $N_\alpha = 1.595$, $N_\beta = 1.614$, $N_\gamma = 1.614$; OAP parallel to {010}, X parallel to [001]. Occurs on the Taseq slope, in the Ilimaussaq complex, South Greenland. Occurs in border zone of the only epididymite-eudidymite-bearing albitite, in cavities and fractures.

72.5.3.1 Kvanefjeldite Na₄(Ca,Mn)[Si₃O₇(OH)]₂

Named in 1984 by Petersen et al. for the locality. ORTH *Pcab*. $a = 10.213$, $b = 15.878$, $c = 9.058$, $Z = 4$, $D = 2.53$. 37-433: 4.45₆ 4.36₇ 3.88₇ 3.67₄ 3.39₆ 3.31₅ 3.11₁₀ 2.58₅. Structure: NJMM:505(1983). The structure is built of highly corrugated layers of composition [Si₃O₇(OH)]^{3–} containing eight-membered rings. Violet-pink; vitreous luster, pearly on {010}. Cleavage {010},

good; {101}, imperfect. $H = 5\frac{1}{2}$ -6. $G = 2.55$. Biaxial (+); $2V = 0-9^\circ$; $N_x = 1.522$, $N_y = 1.522$, $N_z = 1.543$. Occurs as tabular {010} anhedral grains in veinlets and streaks in arfvedsonite-nepheline syenite with villiauminites and analcime in the *Ilimaussaq complex, Kvanefjeld Plateau, Greenland*. *AR CM 22:465(1984)*.

72.5.4.1 Armstrongite $\text{CaZrSi}_6\text{O}_{15} \cdot 3\text{H}_2\text{O}$

Named in 1973 for Neil Alden Armstrong (b.1930), American astronaut, first human being on the moon's surface, *Apollo 11* Lunar Mission. Not a lunar mineral. May form a series with elpidite, $\text{Na}_2\text{ZrSi}_6\text{O}_{15} \cdot 3\text{H}_2\text{O}$. *MON* I_2/m , $I2$, or Im . $a = 13.599$, $b = 14.114$, $c = 7.833$, $\beta = 103.41^\circ$, $Z = 4$, $D = 2.70-2.71$. $40-490$: 7.37₄ 7.09₅ 6.61₉ 4.58₄ 4.28₁₀ 3.81₇ 3.05₉ 3.00₃. Subhedral crystals are 2-7 mm long and 2 mm wide (Strange Lake), with poikilitic crystals to 2 cm and aggregates to 50 cm \times 50 cm from Mongolia; bladed habit with {100}, {010}, and {001} prominent; most crystals are twinned polysynthetically (patch twinned) by rotation about [100]. Colorless to brown (with iron), white streak, vitreous luster. Cleavage {001}, perfect; {100}, average; very brittle. $H = 4\frac{1}{2}$. $G = 2.56-2.59$. DTA data on Mongolian material: *DANS 209:1185(1973)*. Dull blue cathodoluminescence. Can heat to 500° and remove the H_2O . If rehydrated, the H_2O is absorbed. Not attacked by HCl or HNO_3 . Decomposed by HF. Mongolian material has 1.31 wt % Fe_2O_3 and 0.60 wt % Al_2O_3 . Trace and minor elements in Strange Lake material are 0.4% Al_2O_3 , 0.6% SnO_2 , and 1.0% HfO_2 with a maximum content of 0.27% Na_2O . Biaxial (-); $Z = b$, $X \wedge c = +4^\circ$ in obtuse β ; $N_x = 1.563-1.567$, $N_y = 1.569-1.576$, $N_z = 1.573-1.577$; $2V = 39^\circ$; colorless; $r < v$, weak. Intimately associated with gittinsite at Strange Lake; crystals are veined by turbid alteration minerals, predominantly gittinsite. In schlieren of alkali granite pegmatite at contact of arfvedsonite granite with xenoliths of acid volcanic rocks. Strange Lake alkalic complex, QUE-LAB, Canada; *Khan-Bogdin massif, Mongolia*. *EF DANS 209:1185(1973)*, *PD 2:2(1987)*, *CM 30:191(1992)*.

72.5.4.2 Elpidite $\text{Na}_2\text{ZrSi}_6\text{O}_{15} \cdot 3\text{H}_2\text{O}$

Named in 1894 by Lindstrom and Nordenskiöld from the Greek for *hope*, because there was expectancy of finding other interesting minerals from the same locality. See armstrongite (72.5.4.1), $\text{CaZrSi}_6\text{O}_{15} \cdot 3\text{H}_2\text{O}$, with which it may form a series. "Titanoelpidite" is labuntsovite. *ORTH Pbm2*. (Syn): $a = 7.297$, $b = 14.302$, $c = 7.032$; (nat): $a = 7.111-7.31$, $b = 14.68-14.70$, $c = 7.13$, $Z = 2$, $D = 2.61-2.65$. From structure refinement, cell also given as: $a = 7.14$, $b = 14.68$, $c = 14.65$, with $Z = 4$. $29-1294$ (syn): 7.08₁₀ 6.52₅ 5.11₈ 4.77₄ 4.13₅ 3.24₁₀ 3.10₉ 2.94₄. Structure: *K 25:620(1980)*, *AM 58:106(1973)*. Usually massive, fine fibrous or columnar, with good prismatic cleavage. Dominant forms: {110}, {120}, {010}, {011}, {001}, and {100}. Elongated on c , rhombic. Polysynthetic twinning present, striated parallel to c . Fine crystals 1-3 cm, but some to 10 cm \times 1 cm from Mt. St.-Hilaire. Crystals to 30 cm from Kazakhstan. Many colors: colorless, white, yellowish,

tan, greenish gray, brick-red to red-brown; white streak; vitreous-greasy, sometimes silky luster. Two good cleavages parallel to c ; $\{110\}$, good; splintery to uneven fracture; brittle. $H = 6\frac{1}{2}$ -7. $G = 2.5$ -2.8. IR and thermal data: *MIN 3(3):317(1982)*. Sometimes has a dull blue cathodoluminescence. Decomposes only in HF. At Strange Lake, may have as much as 3.2 wt % CaO, indicating 33 mol % of the armstrongite end member. Mongolian material has to 3.5 wt % CaO. K_2O to 0.2 wt %. Dalyite is the anhydrous K analog. Burpala massif sample has 4.7 wt % HfO_2 . Mt. Karnasurt, Lovozero, massif sample has 3.7 wt % TiO_2 . Biaxial (+) in nearly all cases, but rarely (-); OAP parallel to (010), $Z = a$, $X = c$; $N_x = 1.54$ -1.563, $N_y = 1.568$ -1.570, $N_z = 1.572$ -1.578; $2V$ ranges from 89° (-) to 71° (+); $r > v$, distinct, to $r < v$, distinct; negative elongation; pleochroic, colorless to yellow. In alkaline granites, aplite dikes, and pegmatites. Sometimes a rock-forming mineral. Also in nepheline syenites and their cogenetic pegmatites. Sometimes forms as a pseudomorph after eudialyte and calcite. Found as pseudomorphs after serandite at Mt. St.-Hilaire. May also form epitactic intergrowths with labuntsovite. Found in the Bearpaw Mountains, MT; authigenic from the Green River formation, UT; Golden Horn batholith, Okanogan Co., WA; Strange Lake complex, QUE-LAB; best material known is from the Desourdy quarry, Mt. St.-Hilaire, and St. Amable phonolite sill, Varennes, QUE, Canada; *Igalik, Harsarsuk, southern Greenland*; Kangerdlugsuak, Greenland; Lake Gjerdingen, Normarka, 30 km N of Oslo, Norway; Yumegot Pass, Mt. Yukspor, Khibiny massif, and Mt. Alluaiev, Mt. Allnayo (to 6 cm long), Mt. Karnasurt, and several other locations in the Lovozero massif, Kola Penin., Russia; to 30 cm in aegirine-quartz-feldspar pegmatites at Tarbagatai, eastern Kazakhstan, and Ulan-ERGE, southeastern Tuva region, Russia; Maygunda R., Burpala massif, northern Pribaikal, Russia; Khan-Bogdin massif, Mongolia. *EF CM 9:286(1967)*, *30:191(1992)*; *BM 97:433(1974)*.

72.5.5.1 Varennesite $Na_8Mn_2Si_{10}O_{25}(OH,Cl)_2 \cdot 12H_2O$

Described in 1995 by Grice and Gault, and named for the type locality. ORTH. *Cmcm* $a = 13.447\text{\AA}$, $b = 15.022\text{\AA}$, $c = 17.601\text{\AA}$, $Z = 4$, $D = 2.32$; *PD* 10.05₁₀ 8.82₅ 5.025₂ 4.14₁ 3.81₂ 3.66₁ 3.15₁ 2.72₅. The structure consists of alternating, undulating layers of silicate tetrahedra and Na and Mn octahedra. The structure has similarities to the monophyllosilicate structures of manganpyrosomite, bementite, and apophyllite, but is unique in topology. Contains layers of unbranched tetrahedra of the type $[Si_2O_5]^{2-}$. Pale brownish yellow to orange, white streak, tabular crystals to 4 mm in length, showing the pinacoids $\{100\}$, and $\{010\}$ and a set of $\{101\}$ prism faces; the basal pinacoid $\{001\}$ is also present. No fluorescence, $G = 2.31$, $H = 4$, brittle, good $\{010\}$ cleavage and conchoidal fracture. Biaxial (+), (Na_D): $N_\alpha = 1.532$, $N_\beta = 1.540$, $N_\gamma = 1.550$; $2V_{meas} = 89^\circ$, $2V_{calc} = 84^\circ$; dispersion is weak, with $r < v$. Pleochroic; $Z > Y > X$; $Z =$ yellow green; $X =$ very pale yellow. X parallel to c , Y parallel to a , Z parallel to b . Na_2O 19.25 wt. %, CaO 0.11, K_2O 0.21, SrO 0.15, MnO 6.50, FeO 3.25, TiO_2 2.56, MgO 0.03, SiO_2 48.26, Al_2O_3 0.48, SO_3 1.02, Cl 2.20, H_2O

18.47 (calc. from stoichiometry), total 102.00. Occurs in a peralkaline sill called the Saint-Amable sill, in the *Demix-Varennes quarry, between Varennes and Saint-Amable, Varennes Twp., Vercheres Co., Quebec, Canada*. A primary, late-stage mineral most common associated with eudialyte, aegirine, natrolite, serandite, mangan-neptunite, microcline, albite, and zackarovite. Other associated species include astrophyllite, villiaumite, makatite and vuonnemite. *CM 33:1073(1995)*.

72.6.1.1 Petalite $\text{LiAlSi}_4\text{O}_{10}$

Named in 1800 by d'Andrea from the Greek for *leaf*, in allusion to its perfect cleavage. Lithium was first discovered in this mineral. *MON P2/a*. $a = 11.754$, $b = 5.139$, $c = 7.630$, $\beta = 113.01^\circ$, $Z = 2$, $D = 2.398$. *35-463*(calc, 1M polytype): 3.73_{10} 3.72_{10} 3.67_7 3.65_7 3.51_3 2.57_1 2.06_1 1.934_2 . Structure: ZK 197:27(1991). The silicate structural element is a layer of tetrahedra, $[\text{Si}_4\text{O}_{10}]^{4-}$, lying parallel to $\{001\}$; the layers are linked by AlO_4 tetrahedra to form a three-dimensional framework, leading to its sometimes being regarded as a tektosilicate. A 2M polytype having a nearly identical X-ray powder pattern is known. Euhedral crystals are rare, usually small with $\{001\}$, $\{201\}$, $\{010\}$ dominant; usually massive, as large, cleavable, blocky segregations. Polysynthetic twinning on $\{001\}$. Colorless to grayish white, less commonly light pink or light green; vitreous luster, on cleavage sometimes pearly; transparent to translucent. Cleavage $\{001\}$, perfect; $\{201\}$, distinct. $H = 6-6\frac{1}{2}$. $G = 2.3-2.5$. Biaxial (+); $2V = 83^\circ$; $N_x = 1.504-1.507$, $N_y = 1.510-1.513$, $N_z = 1.516-1.523$; $Z = b$, $X \wedge a$ (cleavage trace) = $2-8^\circ$; $r > v$ weak. Composition is usually close to ideal with but minor Na or K substitution for Li; Fe^{3+} may replace Al in very small amount. Insoluble in acids. Alters to montmorillonite. Characteristically found in granite pegmatites associated with albite (cleavelandite), quartz, and lepidolite. Widespread worldwide; notable localities are: at Peru, Oxford Co., ME; at Bolton, Worcester Co., MA; at Pala and Rincon, San Diego Co., CA; in the Tanco pegmatite, Bernic lake, MB, Canada. Found in the Varutråsk pegmatite and at *Uto, Stockholm, Sweden*; in the pegmatites of San Piero in Campo, Elba, Italy; and at a number of localities in the former USSR; at Nagatareyama, Fukuoka Pref., Japan. At the Londonderry quarry, Coolgardie, WA, Australia. In the Karibib district, Namibia, as massive, pink material; at Bikita, Zimbabwe; at Araçuaí and other localities, MG, Brazil. A source of lithium. Brazilian material has been faceted into collector gems up to 50 ct. *AR D6:311(1892)*, *VLA 2:35(1966)*, *TMPM 27:129(1980)*.

Condensed Tetrahedral Sheets

73.1.1.1 Naujakasite $(\text{Na,K})_6(\text{Fe,Mn})[\text{Al}_4\text{Si}_8\text{O}_{26}]$

Named in 1933 (Bøggild) for the type locality. MON $C2/m$, Cm or $C2$. $a = 15.039$, $b = 7.991$, $c = 10.487$, $\beta = 113.7^\circ$, $Z = 2$, $D = 2.661$. 20-1113: 3.99₁₀ 3.69₆ 3.56₇ 3.44₆ 3.06₆ 2.79₆ 2.61₆ 2.26₇. Structure: BGGU 116:11(1975). The structure has sheets of double-layer tetrahedra, each with 4- and 6-membered rings, lying perpendicular to c ; aluminum shares two of the three tetrahedral sites with silicon. Crystals are tabular {001} and modified by {110} and $\{\bar{1}11\}$. Silver-white to grey, greenish when fresh; vitreous luster, pearly on {001}. Cleavage {001} perfect; {401} and {010} distinct; brittle. Biaxial (-); $2V_{\text{calc}} = 68^\circ$; $2V = 52-71^\circ$ ($2V_{\text{calc}} = 68^\circ$); $N_x = 1.536-1.538$, $N_y = 1.548-1.551$, $N_z = 1.555-1.557$. Found as an aggregate of micaceous plates, < 1 mm thick and 1-5 mm in diameter, intimately associated with arfvedsonite at Naujakasik, Tunugdliarfik Fjord, Greenland. AR AM 20:138(1935), 53:1780(1968).

73.1.2.1 Latiumite $(\text{Ca,K})_8(\text{Al,Mg,Fe})[(\text{Si,Al})_{10}\text{O}_{25}](\text{SO}_4)$

Named in 1953 by Tilley and Henry for the locality. See tuscanite (73.1.2.2). MON $P2_1$. $a = 12.06$, $b = 5.08$, $c = 10.81$, $\beta = 106^\circ$, $Z = 2$, $D = 2.90$. 8-174: 4.60₅ 4.50₅ 3.83₅ 3.38₅ 3.28₅ 3.06₉ 2.96₈ 2.86₁₀; 25-1212(calc): 3.82₄ 3.29₃ 3.08₆ 2.95₅ 2.90₄ 2.86₆ 2.84₁₀ 2.54₅. Structure: AM 58:466(1973). The principal structural element is a double layer of ordered Si and Al tetrahedra lying parallel to the {100} cleavage, and joined to one another by the cations and sulfate groups. Each half of the double layer is made up of six- and eight-membered rings and the two halves are related by glide symmetry. Essentially dimorphous with tuscanite. Elongated tabular crystals; massive. Simple and multiple twinning on {100} common. Colorless to white, vitreous luster, transparent to translucent. Cleavage {100}, perfect. $H = 5\frac{1}{2}-6$. $G = 2.93$. Biaxial (+, -); $2V = 83^\circ-90^\circ$; $N_x = 1.600-1.603$, $N_y = 1.606-1.609$, $N_z = 1.614-1.615$; $Z = b$, $X \wedge c = 16-28^\circ$; $r > v$, distinct; also biaxial (-); $2V = 40^\circ$; $N_x = 1.582$, $N_y = 1.590$, $N_z = 1.591$; extinction commonly mottled. Occurs with hedenbergite, Ca-garnet, melilite, leucite, and kaliophilite in two ejecta blocks in the Alban Hills, Albano, Lazio (Latium), Italy; also at Pitigliano, northern Grosseto, Tuscany, Italy. AR MM 30:39(1953).

73.1.2.2 Tuscanite $\text{K}(\text{Ca},\text{Na})_6(\text{Si},\text{Al})_{10}\text{O}_{22}(\text{SO}_4,\text{CO}_3,(\text{OH})_2) \cdot \text{H}_2\text{O}$

Named in 1977 by Orlandi et al. for the locality. See latiumite (73.1.2.1). *MON P2₁/a*. $a = 24.04$, $b = 5.11$, $c = 10.89$, $\beta = 106.96^\circ$, $Z = 2$, $D = 2.77$. *PD*: 11.51₁₀ 5.75₂ 3.83₂ 3.07₅ 3.00₁ 2.96₂ 2.87₁₀ 2.55₁. Structure: *AM 62:1114(1977)*. The structure is similar to that of latiumite except that the two halves of the tetrahedral double sheet are related by an inversion. Essentially dimorphous with latiumite. Colorless, vitreous to pearly luster, transparent. Cleavage {100}, distinct. $H = 5\frac{1}{2}$ -6. $G = 2.83$. Biaxial (-); $2V = 40^\circ$; $N_x = 1.581$, $N_y = 1.590$, $N_z = 1.591$. Found in ejecta in a pumice deposit near the *Latera caldera, Pitigliano, Tuscany, Italy*, associated with vesuvianite, grossular, andradite, pyroxene, wollastonite, anorthite, brandisite, and latiumite. *AR AM 62:1110(1977)*.

73.1.3.1 Fedorite $(\text{K},\text{Na})_{25}(\text{Ca},\text{Na})_7\text{Si}_{16}\text{O}_{38}(\text{OH},\text{F})_2 \cdot \text{H}_2\text{O}$

Named in 1965 by Kukharenko et al. for E. S. Fedorov (1853-1919), noted Russian mineralogist. *TRIC P1*. $a = 9.650$, $b = 16.706$, $c = 13.153$, $\alpha = 93.42^\circ$, $\beta = 114.92^\circ$, $\gamma = 90.0^\circ$, $Z = 2$, $D = 2.46$. *19-466*: 11.7₈ 6.00₈ 4.21₇ 4.00₆ 3.13₈ 2.97₉ 2.93₁₀ 1.826₉. Structure: *SPC 33:763(1988)*. The structure, sparsely described, consists of double tetrahedral layers made up of two types of six-membered rings. Colorless to pink, vitreous luster, transparent to translucent. Cleavage {001}, perfect. $G = 2.43$. Biaxial (-); $2V = 32^\circ$; $N_x = 1.522$, $N_y = 1.530$, $N_z = 1.531$; $XY \approx cb$; $r < v$. Insoluble in acids. Easily fusible. The formula above is based on the structure determination; composition also given as $\text{KNa}_4\text{Ca}_4(\text{Si},\text{Al})_{16}\text{O}_{36}(\text{OH})_4 \cdot \text{H}_2\text{O}$. Found as pseudohexagonal, tabular crystals resembling muscovite at *Tur'yii Peninsula, Kola Penin., Russia*, and in the Murun massif, Chana R. area, Yakutia. *AR AM 52:561(1967)*.

73.1.4.1 Zeophyllite $\text{Ca}_{13}\text{Si}_{10}\text{O}_{28}(\text{OH})_2\text{F}_8 \cdot 6\text{H}_2\text{O}$

Named in 1902 by Pelikan from the Greek for *to boil* and *leaf*, in allusion to the hemispherical, micaceous aggregates. *TRIC* Space group unknown. $a = 9.34$, $b = 9.34$, $c = 13.2$, $\alpha = 90^\circ$, $\beta = 110^\circ$, $\gamma = 120^\circ$; pseudo-*HEX-R R3*. $a = 9.36$, $c = 36.48$; $Z = 3$, $D = 2.79$. *35-715*: 12.3₁₀ 6.13₅ 3.71₅ 3.20₄ 3.05₈ 2.55₄ 2.34₅ 1.770₇. Structure: *AC(B) 28:2726(1968)*. The silicate element consists of a pair of centrosymmetrically related sheets containing 12-tetrahedron rings, the tetrahedra sharing two or three oxygens. The pair of sheets are joined to one another by a sheet of six-coordinated Ca^{2+} , and the voids within these rings are occupied by three Ca^{2+} . Water lies between these t-o-t composite layers which are perpendicular to *c*. Platy crystals, in radiating spherical aggregates. White; translucent; tips of crystals often opaque. Cleavage {0001}, perfect. $H = 3$. $G = 2.8$. Uniaxial (-); $N_O = 1.565$, $N_E = 1.560$; or biaxial (-); $2V$ small; $N_x = 1.560$, $N_y = 1.565$, $N_z = 1.566$; uniaxial and biaxial segments. Gelatinizes in acids and exfoliates on heating. The formula above is based on the structure determination; the original formula given as $\text{Ca}_4\text{Si}_3\text{O}_8(\text{OH},\text{F})_4 \cdot 2\text{H}_2\text{O}$. Found in the Salmon River district, Idaho Co., ID; at Mont St. Hilaire, PQ, Canada; in the Oslo region, Norway; from

Gobnehall Yuglingarum, Skåne, Sweden; from the Lacher See volcanics, Rhineland, Germany; with apophyllite and zeolites in basalt at Brezno and Lbem (*Gross-Priesen*), *Cechy (Bohemia)*, *Czech Republic*, and at Radicin and at Teplice; in recent lavas of Mte. Somma, Campania, Italy. AR *D6(Supp)* 2:113(1909), *MM* 47:397(1983).

73.1.5.1 Kanemite $\text{NaHSi}_2\text{O}_4(\text{OH})_2 \cdot 2\text{H}_2\text{O}$ or $\text{NaH}[\text{Si}_2\text{O}_5] \cdot 3\text{H}_2\text{O}$

Named in 1972 by Johan and Maglione for the locality. ORTH *Pnmb*. $a = 7.282$, $b = 20.507$, $c = 4.956$, $Z = 4$, $D = 1.933$. 25-1309: 10.3₁₀ 4.01₁₀ 3.44₉ 3.16₇ 3.09₇ 2.48₈ 2.39₆ 2.00₅. Said to have a double tetrahedral layer structure. Colorless to white, translucent. Cleavage {010}, perfect; {100}, good. $H = 4$. $G = 1.93$. Biaxial (-); $2V = 46^\circ$; $N_x = 1.451$, $N_y = 1.470$, $N_z = 1.478$; $XYZ = bac$; $r > v$. Decomposed by acids. Large dehydration endotherms at 160° and 220° . Found as spherulitic aggregates, 1–2 mm in diameter, associated with gaylussite in trona at *Lake Chad, Kanem region, Adaija, Chad*, and *Lake Bogoria, Kenya*. AR *AM* 59:210(1974), 62:763(1977).

73.1.6.1 Vertumnite $\text{Ca}_8\text{Al}_4(\text{Al}_4\text{Si}_5)\text{O}_{12}(\text{OH})_{36} \cdot 10\text{H}_2\text{O}$

Named in 1977 by Passaglia and Galli for the Etruscan god Vertumnus. MON (pseudo-HEX) *P2₁/m*. $a = 5.744$, $b = 5.766$, $c = 25.12$, $\beta = 119.72^\circ$, $Z = 1$, $D = 2.15$. 29-291: 12.6₇ 6.28₆ 4.28₂ 4.19₁₀ 2.87₂ 2.49₁ 2.44₁ 2.08₁; this pattern as well as the bulk chemistry bears a strong resemblance to that of stratlingite (77.2.5.1) and may be regarded as a polytype thereof. Structure: *TMPM* 25:33(1977). The structure is described as having a double tetrahedral layer. Occurs as pseudo-hexagonal tablets {001} and bounded by {100} and {010}. Twinned but twin law undefined. Colorless, vitreous luster, transparent. Conchoidal fracture, very brittle. $H = 5$. $G = 2.15$. Biaxial (+); $2V = 62^\circ$; $N_x = 1.531$, $N_y = 1.535$, $N_z = 1.541$. Found in a "geode" in phonolite at *Campomorto, Montalto di Castro, Viterbo, Italy*. AR *TMPM* 24:57(1977), *AM* 62:1061(1977), *EJM* 2:841(1990).

73.2.1.1 Jagoite $(\text{Pb,Na})_3(\text{Fe}^{3+},\text{Mg})\text{Si}_3\text{O}_{10}(\text{Cl,OH})$

Named in 1957 by Blix et al. for John Bernard Jago Trelawny (b.1909), American lawyer and mineral collector of Palo Alto, CA. HEX *P62c*. $a = 8.528$, $c = 33.33$, $Z = 6$, $D = 5.34$. 36-417: 6.16₅ 5.56₇ 4.13₆ 3.38₁₀ 3.07₅ 2.98₈ 2.78₉ 2.05₅. Structure: *AM* 66:852(1981). Structurally related to naujakasite, with alternating double and single tetrahedral sheets perpendicular to c , the latter being discontinuous with the missing tetrahedron replaced by an Fe^{3+} octahedron. Yellow-green, vitreous luster. Cleavage {0001}, perfect. $H = 3$. $G = 5.43$. Uniaxial (-); $N \approx 2.0$; birefringence = 0.025. The formula given is considerably simplified; Pb is, in part, four-coordinated, and in its larger coordination sites is replaced by both Na and Ca; Fe^{3+} is six-coordinated but also four-coordinated; and Be may also be present in tetrahedral sites. Occurs as fine-grained, micaceous aggregates, commonly surrounded by

black melanotekite, in hematite ore at the *Canberra stope, Langban, Sweden*. AR *AM* 43:387(1958).

73.2.2a.1 Reyerite $(\text{Na,K})_2\text{Ca}_{14}\text{Al}_2\text{Si}_{22}\text{O}_{58}(\text{OH})_8 \cdot 6\text{H}_2\text{O}$

Named in 1907 by Cornu and Himmelbauer for the Austrian geologist Eduard Reyer (1849–1914), but the first samples were collected by Giesecke in 1811. See minehillite (73.2.2b.1) and truscottite (73.2.2a.2). HEX $P\bar{3}$ or $P3$. $a = 9.764$, $c = 19.07$, $Z = 1$, $D = 2.59$. 29-1039: 19.0₄ 4.23₆ 3.51₇ 3.15₁₀ 3.03₄ 2.85₉ 2.65₆ 1.84₆, also 17-760. Structure: *MM* 52:247(1988). The structure consists of alternating single, $[\text{Si}_8\text{O}_{20}]^{8-}$, and double, $[\text{Si}_{14}\text{Al}_2\text{O}_{58}]^{14-}$, tetrahedral sheets having six-membered rings and lying parallel to {0001}, with intervening layers of edge-sharing calcium octahedra. Al is ordered in one of the connecting tetrahedra of the double layer. Massive or as micaceous, spherical aggregates; sometimes tabular {0001} with {1010}. Colorless, white; vitreous luster pearly on cleavage; transparent to translucent. Cleavage {0001}, perfect; brittle, uneven fracture. $H = 3-4$. $G = 2.54-2.578$. Uniaxial (-); $N_O = 1.563-1.568$, $N_E = 1.558-1.563$. Found in chlorite-containing amygdules in diabase at the Rawlins quarry, Brunswick Co., VA; in a Triassic sill near Durham, NC; in tuff at *Niaqornat, Nuussuaq, Greenland*; and in basalt at 'S Airde Beinn, Mull, and at Alet Coir'a'Ghobainn, Skye, Scotland. AR *D6(Supp)* 2:88(1909), *AM* 58:517(1973).

73.2.2a.2 Truscottite $(\text{Ca,Mn}^{2+})_{14}\text{Si}_{24}\text{O}_{58}(\text{OH})_8 \cdot 2\text{H}_2\text{O}$

Named in 1914 by Höving for Samuel John Truscott (1870–1950), English mining geologist. See minehillite (73.2.2b.1) and reyerite (73.2.2a.1). HEX $P3$ or $P\bar{3}$. $a = 9.731$, $c = 18.836$, $Z = 1$, $D = 2.51$. 29-382: 18.8₆ 4.21₇ 3.85₃ 3.50₅ 3.14₁₀ 2.84₈ 2.64₆ 1.839₇. Isostructural with reyerite. Massive or as micaceous, spherical aggregates. White, pearly luster on cleavage, translucent. Cleavage {0001}, perfect. $G = 2.35$. Uniaxial (-) or biaxial (-); 2V very small; $N_O = 1.552$, $N_E = 1.530$. Found in a drill hole in the Lower Geyser Basin, Yellowstone National Park, WY; in the *Hatrumim Formation, Israel*; at the *Leong Donok gold mine, Benkulen, Sumatra, Indonesia*; and at the Toi mine, Tagata-gun, Shizuoka Pref., Japan. AR *MM* 30:450(1954), 43:333(1979); *AM* 44:470(1959).

73.2.2b.1 Minehillite $(\text{K,Na})_{2-3}\text{Ca}_{26}\text{Zn}_4\text{Al}_4\text{Si}_{40}\text{O}_{112}(\text{OH})_{16}$

Named in 1984 by Dunn et al. for Mine Hill, the hill on which the Franklin deposit cropped out. See reyerite (73.2.2a.1) and truscottite (73.2.2a.2). HEX $P6_3/mmc$, $P6_3mc$, or $P62c$. $a = 9.77$, $c = 33.01$, $Z = 1$, $D = 2.94$. 38-371: 16.1₇ 3.35₉ 3.14₆ 3.07₇ 2.97₅ 2.88₄ 2.76₁₀ 1.847₉. Dimensionally similar to reyerite, but space group has hexagonal symmetry. Colorless, white to grayish black; vitreous luster; transparent to translucent. Cleavage {0001}, perfect. $H \approx 4$. $G = 2.93$. Uniaxial (-); $N_O = 1.607$, $N_E = 1.604$. Fluoresces a medium violet in UV. Found as aggregates of plates up to 5 mm in diameter, associated with

diopside, calcite, grossular, vesuvianite, microcline, and wollastonite at the *Franklin mine, Franklin, Sussex Co., NJ. AR AM 69:1150(1984)*.

73.2.2b.2 Orlymanite $\text{Ca}_4\text{Mn}_3\text{Si}_8\text{O}_{20}(\text{OH})_6 \cdot 2\text{H}_2\text{O}$

Named in 1990 by Peacor et al. for Orlando P. Lyman (1903–1986), founder of Lyman House Memorial Museum, Hilo, Hawaii. See gyrolite (73.2.2c.1), truscottite (73.2.2a.2), minehillite (73.2.2b.1), reyerite (73.2.2a.1), and fedorite (73.1.3.1). **HEX-R** *P3* or *P3*. $a = 9.60$, $c = 35.92$, $Z = 5$ [*AM 75:923(1990)*], $D = 2.93$. *PD*(nat): 7.15₇ 4.18₇ 3.60₁₀ 3.13₈ 2.54₄ 2.47₄ 1.84₉ 1.62₂. Detailed structure not yet done; see *AM 75:923(1990)*. A possible link between the gyrolite family and conventional phyllosilicate minerals. Spheres to 2- to 3-mm, tightly packed rosettes, fibrils elongated on *a* rather than *c*. Dark brown, light brown streak, vitreous luster. Cleavage {001}, perfect. $H = 4-5$. $G = 2.7-2.8$. Analysis (wt %): SiO_2 , 46.8; Al_2O_3 , 0.2; Fe_2O_3 , 0.8; MgO , 1.6; CaO , 21.6; MnO , 19.7; Na_2O , 0.6; H_2O , 8.68. Uniaxial (-); $N_O = 1.598$, N_E not determined because of extreme fibrous shape. Pleochroic; *O*, pale brown; E' , dark brown. Occurs at *Wessels mine, Kalahari manganese field, Cape Prov., South Africa*; part of a vein assemblage 1.5–2.0 cm thick. Associated with inesite and hematite. One specimen known. **EF**

73.2.2c.1 Gyrolite $\text{NaCa}_{16}\text{Si}_{23}\text{AlO}_{60}(\text{OH})_8 \cdot 14\text{H}_2\text{O}$

Named in 1851 by Anderson from the Greek for *round*, in allusion to its form as crystalline spherical concretions. Note that water content is from structure determination, may be more H_2O to 17 H_2O . See truscottite (73.2.2a.2), minehillite (73.2.2b.1), reyerite (73.2.2a.1), and orlymanite (73.2.2b.2). Converts to $\alpha\text{-CaSiO}_3$, wollastonite, when heated (pseudowollastonite). **TRIC** *C1* or *P1* [*MM 52:377(1988)*]. $a = 9.74$, $b = 9.74$, $c = 22.40$ $\alpha = 95.7^\circ$, $\beta = 91.5^\circ$, $\gamma = 120.0^\circ$, $Z = 1$, $D = 2.39-2.46$. *42-1452* [combination of Guinier and Debye-Scherrer data, $\text{Ca}_4(\text{Si}_6\text{O}_{15})(\text{OH})_2 \cdot 3\text{H}_2\text{O}$, $Z = 4$]: 22.0₁₀ 11.1₇ 4.21₆ 3.16₁₀ 3.10₈₅ 2.81₆ 2.77₅ 1.84₈; *9-449*(nat): 22.0₁₀ 11.0₈ 8.4₄ 4.20₈ 3.65₆ 3.12₁₀ 2.80₆ 1.82₈; *12-217*(syn): 22.0₉ 11.1₇ 4.20₇, 3.72₅ 3.16₁₀ 3.10₉ 2.83₇ 1.83₆. Structure is built up of the structural units found in the crystal structure of reyerite, namely tetrahedral sheets S_1 and S_2 and octahedral sheets *O*. The tetrahedral and octahedral sheets are connected by corner-sharing to give rise to the complex layer which can be schematically described as $S_2\text{OS}_1\text{OS}_2$ where S_2 and S_2 as well as *O* and *O* are symmetry-related units. Successive complex layers with composition $[\text{Ca}_{14}\text{Si}_{23}\text{AlO}_{60}(\text{OH})_8]^{5-}$ are connected through an interlayer sheet made up of Ca and Na cations and H_2O molecules. There is appreciable disorder present in stacking of the structural layers. Disorder in stacking accounts for the high R factor (13.5%). *ZK 159:34(1982)*, *MM 52:377(1988)*. For additional details on the structure, see *AM 80:173(1995)*. Crystals to 5–6 mm, flakes to 3–4 cm, massive lamellar-radiating structure, concretionary. Colorless–white, rarely green, brown, gray; white streak; vitreous–pearly luster. Cleavage {0001}, perfect; uneven fracture; brittle. $H = 3-4$. $G = 2.36-2.45$. IR data: *AM 46:913(1961)*, *NBSM*

43:297(1960). DTA data: *SIMP* 39:695(1984). Decomposed by acids. The crystal chemical formula that accounts for most gyrolite samples is $\text{Ca}_{16}\text{Si}_{24}\text{O}_{60}(\text{OH})_8 \cdot (14 + x)\text{H}_2\text{O}$ where $0 \leq x \leq 3$. Biaxial (-); 2V small; sometimes uniaxial; $N_x = 1.537$, $N_y = 1.547$, $N_z = 1.549$ (perpendicular to perfect cleavage) and $N_O = 1.545\text{--}1.551$, $N_E = 1.534\text{--}1.539$. Occurs in basalt or diabase in amygdules. Secondary mineral; a stable phase under saturated steam conditions from 120 to 200°. Occurs in many worldwide localities; only the most notable are given here: Fort Point, San Francisco, New Almaden, Santa Clara Co., and Crestmore, Riverside Co., CA; Port George, Cape Blomidon, Black Rock, NS, Canada; Qarusait, Greenland; Faeroe Is.; *Portree*, *Skye*, and *s'Airde*, Tobermory, Mull, *Scotland*; Collinward, Belfast, County Antrim, Northern Ireland; Ortano, Elba, Monte Biaena, and Trento, Italy; Bramburg, Germany; Arsului and Korii valleys, Romania; Lower Tunguska R., Yakutia; Angara R., Siberia, Russia; Bombay and Pune (Poona), India (fine crystals); Ueda, Irakawa, and Sayama Lake, Japan; Mogy Guassu, São Paulo, Brazil; Mururoa, South Pacific. EF *SIMP* 39:695(1984), *MIN* 4(2):311(1992).

Modulated Layers

74.1.1.1 Stilpnomelane $(K,Ca,Na)(Fe^{2+},Mg,Fe^{3+})_8(Si,Al)_{12}(O,OH)_{27} \cdot nH_2O$

Named in 1827 by Glocker from the Greek for *shining* and *black*, in allusion to the color and luster. See lennilenapeite (74.1.1.2), franklinphilitite (74.1.1.3), and bannisterite (74.1.1.4). The name *ferristilpnomelane* has been applied to high- Fe^{3+} varieties, but such are called stilpnomelane by some, and *ferrostilpnomelane* is applied to Fe^{3+} -poor varieties. TRIC P1. $a = 21.995$, $b = 21.955$, $c = 17.619$, $\alpha = 124.83^\circ$, $\beta = 95.96^\circ$, $\gamma = 120.00^\circ$, $Z = 6$, $D = 2.62$ also reported as MON. 25-174: 12.1_{10} 4.04_8 3.03_7 2.72_4 2.57_{10} 2.35_7 1.585_6 1.571_5 ; also 15-48, 29-703. Structure: MM 38:693(1972). The structure is a modulated layer structure consisting of islands of 24 tetrahedra having roughly coplanar bases. These islands are joined to one another within a layer, and cross-linked to a second layer of oppositely facing islands by way of a double ring of approximately ditrigonal symmetry consisting of 12 tetrahedra; the resultant modulated layer is thus four tetrahedrons thick. The apical oxygens of the islands form the octahedral coordination of the smaller cations, and the larger cations lie between the facing basal oxygens of the islands within the modulated layer. Both tetrahedral and octahedral layers are warped, and successive modulated layers are shifted with respect to one another. Occurs as scales, foliated masses and coatings, and as fibrous druses, often spherulitic and with velvety surface. Golden brown, dark reddish brown to black, also dark green; pearly to vitreous luster, often submetallic and velvety on druses; translucent to nearly opaque. Cleavage {001}, perfect; {010}, imperfect; brittle. $H = 3\frac{1}{2}$. $G = 2.59-2.96$. Biaxial (-); $2V \approx 0^\circ$; $N_x = 1.543-1.634$, $N_y = N_z = 1.576-1.745$; X nearly perpendicular to {001}, $Y = b$; the indices increasing with increasing total Fe and increasing Fe^{3+}/Fe^{2+} . Strongly pleochroic with increasing Fe^{3+} ; X, pale yellow to bright gold; Y,Z, deep green to very dark red-brown. Soluble in warm 1:1 H_2SO_4 . Substitution of cations is highly complex; Ca and Na may replace K with Na frequently exceeding it. In octahedral sites, Fe^{3+} exceeds Fe^{2+} in many published analyses thus supporting the concept of two iron end members; the ratio of the two oxidation states is probably a function of oxidation-reduction conditions at the time of formation rather than the result of oxidation of earlier formed ferroan material. Manganese and aluminum may also enter octahedral sites, and vacancies exist. H^+ or hydro-

nium ion as well as excess water may be present. Stilpnomelane occurs in iron-rich, low-grade regionally metamorphosed sediments and in associated ore veins with magnetite, goethite, pyrite, etc. It may also be an abundant constituent in chlorite schists. When occurring in small flakes it is easily dismissed as biotite, and many occurrences may thus be overlooked. Found in ores at the Sterling mine, Antwerp, Jefferson Co., NY, often in velvety druses; near Rockyhill, Somerset Co., NJ; manganoan at Bald Knob, NC; in ferruginous slate at Crystal Falls, MI; and in the Animikian iron formation of MN; at Rib Mt., Marathon Co., WI; and in glaucophane and chlorite schists at the San Juan Bautista mine, Santa Clara Co., CA. Occurs in vesicles in a granophyre inclusion in olive gabbro at Kangerdlugssuaq, Greenland; at Nordmark, Värmland, Sweden; *Obergrund, near Zuckmantel, Silesia, Poland Beroun na Morave, Beroun, Czech Republic*; in a polymetallic skarn deposit at Tetukhe in far-eastern Russia; in glaucophanic rocks at several localities in Japan; at the Great Cobar Mine, NSW, and the Hamersley Range, WA, Australia; ferroan and ferrian varieties in chlorite schists of Otago, New Zealand. AR *DHZI 3:103(1962)*, *MM 42:361(1978)*.

74.1.1.2 Lennilenapeite $K_{6-7}(Mg, Mn^{2+}, Fe^{2+}, Zn)_{48}(Si, Al)_{72}(O, OH)_{216} \cdot 16H_2O$

Named in 1984 by Dunn et al. for the Lenni Lenape Native American tribe, who first inhabited the type locality region. See stilpnomelane (74.1.1.1), franklinphillite (74.1.1.3), and bannisterite (74.1.1.4). TRIC (pseudo-HEX) Space group unknown. $a = 21.9$, $d_{001} = 12.18$, $Z = 1$. $34-403$: 12.11_{10} 4.07_2 3.04_2 2.73_3 2.58_4 2.37_3 1.593_3 1.578_3 . Black; vitreous/resinous luster, translucent to opaque. Cleavage {001}, perfect; also imperfect perpendicular to {001}. $H \approx 3$. $G = 2.72$. Biaxial (-), $2V = 0^\circ$; pseudo-uniaxial; $N_x = 1.553$, $N_y = N_z = 1.594$. Strongly pleochroic; $Z = Y > X$; Z, dark brown; X, pale brown to colorless. Found as druses at *Franklin, Sussex Co., NJ*, associated with tirodite, willemite, and nelenite, or with sphalerite. AR *CM 22:259(1984)*, *MSARM 19:675(1988)*.

74.1.1.3 Franklinphillite $K_4(Mn^{2+}, Mg, Fe^{3+}, Zn)_{48}(Si, Al)_{72}(O, OH)_{216} \cdot 6H_2O$

Named in 1992 by Dunn et al. for the type locality and from the Greek *philos*, friend. See stilpnomelane (74.1.1.1), lennilenapeite (74.1.1.2), and bannisterite (74.1.1.4). TRIC $P1$ or $P1$. A pseudo-HEX cell has $a = 22.08$, $d_{001} = 12.19$, $Z = 1$; an ortho-HEX subcell has $a = 5.521$, $b = 9.560$, $c = 36.57$, $Z = \frac{3}{8}$, and $D = 2.66$. PD : 12.3_{10} 4.79_2 4.08_2 3.06_2 2.58_4 2.36_3 1.59_3 1.58_3 . Dark brown to black, light brown streak, vitreous to slightly resinous luster, translucent to opaque. Cleavage {001}, imperfect; brittle. $H \approx 4$. $G = 2.6-2.8$ (impure). Biaxial (-); $2V_{obs} = 10^\circ$, $2V_{calc} = 0^\circ$; $N_x = 1.545$, $N_y = 1.583$, $N_z = 1.583$; $X \wedge (001) = 6^\circ$. Strongly pleochroic; $Z = Y > X$; dark brown to pale yellow. The manganese dominant analog of stilpnomelane and lennilenapeite, the holotype material having 56% of the end-member component; Na replaces

K in part, and minor Fe^{3+} may substitute in tetrahedral sites. Water determined by difference. Found as radial aggregates of platy crystals intimately associated with friedelite in a centimeter-wide vein cross-cutting a breccia of aegirine, calcite, chamosite and interlayered phyllosilicates, and in a second assemblage with nelenite, rhodonite, and tirodite, on the *Buckwheat dump, Franklin, Sussex Co., N.J.* AR *CM* 22:259(1984), *MR* 23:465(1992).

74.1.1.4 Bannisterite $\text{KCa}(\text{Mn}^{2+}, \text{Fe}^{2+}, \text{Mg}, \text{Zn})_{20}(\text{Si}, \text{Al})_{32} \text{O}_{76}(\text{OH})_{16} \cdot 4-12\text{H}_2\text{O}$

Named in 1936 by Foshag for Frederick Allen Bannister (b.1901), former keeper of minerals, British Museum (Natural History). See stilpnomelane (74.1.1.1), lennilenapeite (74.1.1.2), and franklinphilite (74.1.1.3). *MON A2/a*. $a = 22.27$, $b = 16.37$, $c = 22.67$, $\beta = 94.3^\circ$, $Z = 4$, $D = 2.84$. 21-57: 12.3₁₀ 4.10₁ 3.44₂ 3.36₁ 3.08₁ 2.64₁ 2.61₁ 2.41₁. Structure: *CCM 40:129(1992)*. Prismatic, bladed crystals and aggregates to 20 cm; as anhedral, cleavage-bounded plates to 5 cm in diameter. Brown to nearly black, resinous luster, translucent to opaque. Cleavage {001}, perfect. $H = 4$. $G = 2.83-2.84$. Biaxial (-); 2V small to medium; $N_x = 1.544-1.574$, $N_y = 1.586-1.611$, $N_z = 1.589-1.612$; $r < v$, weak to moderate. Pleochroic; $X < Y = Z$; colorless to pale yellow or brown. Mn/Fe is $\approx 6:5$ in Broken Hill material and $\approx 4:1$ in Franklin material; Broken Hill material is reported as Zn-free and contains but minor Mg, whereas Franklin material contains 4.6 wt % ZnO and 3.1 wt % MgO; significant Na is present. Found in association with manganoan and zincian amphiboles, rhodonite, sphalerite, and calcite at Franklin, Sussex Co., NJ; at the *Bennalt mine, Rhiw, Lleyn Peninsula, Wales*; at Nyberget, Sweden; at the Tanohata mine, Iwate Pref., Honshu, and the Ananai mine, Koci Pref., Shikoku, Japan; and with rhodonite, sphalerite, fluorite, and apophyllite at Broken Hill, NSW, Australia. AR *MM* 36:893(1968), *AM* 66:1063(1981).

74.1.2.1 Ganophyllite $(\text{K}, \text{Na})_2(\text{Mn}, \text{Al}, \text{Mg})_8[(\text{Si}, \text{Al})_{12}\text{O}_{29}](\text{OH})_7 \cdot 8-9\text{H}_2\text{O}$

Named in 1890 by Hamberg from the Greek for *luster* and *leaf*, in allusion to its physical properties. See eggletonite (74.1.2.2). *MON A2/a*. $a = 16.60$, $b = 27.04$, $c = 50.34$, $\beta = 94.2^\circ$, $Z = 24$, $D = 2.92$ (a slightly different formula, with approximately tripled subscripts, is given in the structure determination with $Z = 8$ and $D = 2.875$). 21-359: 12.5₁₀ 5.12₁ 4.18₁ 3.97₁ 3.46₁ 3.14₃ 2.98₁ 2.70₁. Structure: *MM* 50:307(1986). The structure has modulated tetrahedral layers consisting of sixfold rings forming three-ring-wide strips. Brown to orange-red with paler streak, vitreous to greasy luster, transparent to translucent. Cleavage {001}, perfect. $H = 4-4\frac{1}{2}$. $G = 2.84-2.88$. Biaxial (-); 2V small; $N_x = 1.563-1.573$, $N_y = 1.593-1.611$, $N_z = 1.593-1.612$; $r < v$; positive elongation. Weakly pleochroic, $X > Y = Z$ ($X < Y = Z$ also reported), pale yellow to colorless. Gelatinizes with acids. Occurs as short prismatic to acicular crystals with rectangular cross section. Found at Franklin, Sussex Co., NJ; Alum Rock Park, Santa Clara Co., CA; with astrophyllite and labuntso-

vite which it closely resembles at Mt. St.-Hilaire, QUE, Canada; at the Sjö mine, near Grythyttan, and at the *Harstig mine, Pajsberg, Varmland, Sweden*. AR *USGSPP 180:114(1935)*, *MM 36:893(1968)*, *MR 21:311(1990)*.

74.1.2.2 Eggletonite $\text{Na}_2\text{Mn}_8[\text{Si}_{11}\text{AlO}_{29}](\text{OH})_7 \cdot 11\text{H}_2\text{O}$

Named in 1984 by Peacor et al. in honor of R. A. Eggleton, Australian National University. see ganophyllite (74.1.2.1). MON *Ia* or *I2/a*. $a = 5.554$, $b = 13.72$, $c = 25.00$, $\beta = 93.95^\circ$, $Z = 2$, $D = 2.76$. 29-909: 12.4₁₀ 3.45₁ 3.13₃ 2.85₁ 2.69₂ 2.60₂ 2.46₂ 2.39₁. Undetermined structure, but probably isostructural or nearly so with ganophyllite. Occurs as radiating groups of acicular to prismatic, [100], crystals up to 1.5 mm long. Dominant forms are {110} and {001}. Twinned on (001). Dark golden brown with lighter streak, vitreous luster. Cleavage {001}, perfect; brittle. $H = 3-4$. $G = 2.76$. Biaxial (-); $2V = 9^\circ$; $N_x = 1.566$, $N_y = 1.606$, $N_z = 1.606$. Found in mirolitic cavities in nepheline syenite at the 3M and *Big Rock quarry, Little Rock, Pulaski Co., AR*. AR *MM 48:93(1984)*.

74.1.3.1 Parsettensite $(\text{K},\text{Na},\text{Ca})(\text{Mn},\text{Al})_7\text{Si}_8\text{O}_{20}(\text{OH})_8 \cdot 2\text{H}_2\text{O}(?)$

Named in 1923 by Jakob for the locality. ORTH or MON Space group unknown. $a = 39.1$, $b = 22.6$, $c = 12.6$, $\beta \approx 90^\circ$, $Z = 1(?)$, $D = 2.58$. 25-8: 12.1₁₀ 4.2₆ 3.84₅ 3.70₅ 2.79₈ 2.65₁₀ 1.634₈ 1.617₆. The structure is a modulated 2:1 layer structure related to, but probably distinct from, stilpnomelane and ganophyllite. Copper-red, somewhat metallic luster, translucent. Cleavage {001}, perfect. $H \approx 1\frac{1}{2}(?)$. $G = 2.59$. Uniaxial (-) or biaxial (-); $2V = 0-8^\circ$; $N_z = 1.546$, $N_y \approx N_x = 1.576$. Pleochroic; X, colorless; Y,Z, greenish yellow. Decomposed with hot acids. Fuses readily with intumescence. Found at the Foote mine, Kings Mt., Cleveland Co., NC; as somewhat micaceous masses in manganese deposits at *Val d'Err, Alp Parsettens, Sursass, Grischun, Switzerland*. Reported from the Molinella manganese mine, near Chiavari, Liguria, Italy; at the Noda-Tamagawa mine, Iwate Pref., Japan; at the N'Chwaning mine, Kuroman district, Cape Prov., South Africa. AR *SMPM 3:227(1923)*, *MSARM 19:675(1985)*, *AM 77:673(1990)*.

74.1.4.1 Zussmanite $\text{K}(\text{Fe}^{2+},\text{Mg},\text{Mn})_{13}[\text{AlSi}_{17}\text{O}_{42}](\text{OH})_{14}$

Named in 1964 by Agrell et al. for Jack Zussman (b.1924), crystallographer and emeritus professor of geology, Manchester University, England. HEX-R *R3*. $a = 11.66$, $c = 28.69$, $Z = 3$, $D = 3.14$. 19-1500: 9.60₁₀ 4.78₁₀ 3.78₅ 3.69₅ 3.19₈ 2.74₅ 2.20₅ 1.908₅. Structure: *MM 37:49(1969)*. The tetrahedral layer consists of six-membered rings to which are joined three-membered rings akin to those of benitoite; these composite sheets are joined to a trioctahedral layer of the divalent cations. Pale green, vitreous luster, translucent. Cleavage {0001}, perfect. $G = 3.146$. Uniaxial (-); $N_O = 1.643$, $N_E = 1.623$. Weakly pleochroic; O, pale green; E, colorless. Found as tabular, {0001}, crystals in blueschist facies metamorphosed shale, ironstone, and impure limestone of the Francis-

can formation at the *Laytonville quarry, Mendocino Co., CA*, and elsewhere in the Laytonville district. AR *AM* 50:278(1965), *MM* 43:605(1980).

74.2.1.1 Wickenburgite $\text{CaPb}_3\text{Al}_2\text{Si}_{10}\text{O}_{27} \cdot 3\text{H}_2\text{O}$

Named in 1968 by Williams for the locality. *HEX* *P31c*. $a = 8.560$, $c = 20.190$, $Z = 2$, $D = 3.88$. *21-148*: 10.08_{10} 5.96_3 5.04_3 3.93_6 3.36_4 3.26_8 2.79_3 2.64_4 . Structure: *CM* 32:525(1994). The structure has layers of composition $[\text{AlSi}_5\text{O}_{15}]$, with ordered Al and Si tetrahedral sites, linked to layers of composition $[\text{CaSi}_5\text{O}_{17}]$, with octahedral Ca sites, to form thick slabs parallel to $\{0001\}$. Colorless to white, rarely pink; vitreous luster. Cleavage $\{0001\}$, indistinct. $H = 5$. $G = 3.85$. Uniaxial (-); $N_{\text{O}} = 1.692$, $N_{\text{E}} = 1.648$. Fluoresces dull orange under SWUV. Occurs abundantly as 0.2- to 1.5-mm tabular crystals, associated with phoenicochroite, mimetite, cerussite, and willemite in oxidized zone of several prospects including the *Cramer claim, near Wickenburg, Maricopa Co., AZ*. AR *AM* 53:1433(1968).

PALYGORSKITE-SEPIOLITE GROUP

The palygorskite-sepiolite group minerals are "clay" minerals that have typical phyllosilicate stoichiometry with the (Si,Al)/O ratio of 2:5. A general formula is

where

and the structure is layered but different from that of the micas and with certain characteristics of the amphiboles.

In the micas the layers may be viewed as being made up of parallel, cross-linked amphibole ribbons, thus extending the structure infinitely in two dimensions; all apical oxygens point in the same direction. In palygorskite the layers are also built of cross-linked amphibole ribbons, but the apical oxygens of alternate ribbons point in opposite directions, resulting in a layer with a superimposed one-dimensional component. The layers, parallel to (001), are stacked so that apical oxygens of adjacent sheets point toward one another and are bonded to the remaining cations so as to form amphibole-like I-beam units. The linear component of these layers (parallel to c in the table below) has the characteristic $\approx 5\text{-\AA}$ periodicity of the amphiboles. Hydroxyl ions are involved in the octahedral coordination of the I-beam cations. Water, both bonded and zeolitic, occupies the channels formed by the base-to-base facing portions of the layers. The structure of the sepiolite subgroup is similar except that the ribbons joined to form layers are three tetrahedra wide, as in the jimthompsonite ribbons.

Species in this group are fibrous or lath-like rather than lamellar, with fiber length rarely exceeding a few μm , and having a thickness or width of no more than a few hundred Å. Palygorskite and sepiolite commonly form matted aggregates of fibers to which terms such as “mountain leather”, “mountain cork”, “cardboard”, “paper”, “wool”, etc. have been applied. The measured density is commonly less than the calculated value due to the highly porous nature of the fiber aggregates.

Adsorbed and zeolitic water is lost at $\approx 120^\circ\text{C}$ (sepiolite) and $\approx 150^\circ\text{C}$ (palygorskite). Palygorskite loses bound water in the range $450\text{--}500^\circ\text{C}$; in sepiolite the bound water is lost in two stages at $\approx 350^\circ\text{C}$ and $500\text{--}550^\circ\text{C}$. About half of the bound water is lost at the first stage and the structure “folds” to close up the now unsupported channels.

Although relatively rare “clay” minerals, palygorskite and sepiolite have found considerable application due to their sorptive capabilities.

SEPIOLITE: $\text{Mg}_8\text{Si}_{12}\text{O}_{30}(\text{OH})_4 \cdot n\text{H}_2\text{O}$

Perspective view along *c* of modulated layers formed of ribbons of composition $[\text{Si}_6\text{O}_{15}]$. Palygorskite is similar but the narrower ribbons have composition $[\text{Si}_4\text{O}_{10}]$.

74.3.1a.1 Palygorskite (Mg,Al)₂Si₄O₁₀(OH) · 4H₂O

Named in 1862 by Savchenkov for the locality, but almost certainly known since the time of Theophrastus (≈ 300 B.C.). Palygorskite-sepiolite group. Synonym: attapulgitite, named in 1935 by Lapparent for the Georgia locality. Several space group assignments have been made, some of them may represent distinct polytypes. Aluminum-free palygorskite, if it exists, is polymorphous with sepiolite. Most samples are a mixture of a monoclinic and orthorhombic phase. MON C2/m. $a = 12.78$, $b = 17.89$, $c = 5.24$, $\beta = 105.2^\circ$. ORTH Pbnm. $a = 12.78$, $b = 17.89$, $c = 5.21$, $Z = 4$, $D = 2.31$. Other space groups have also been proposed. 21-958: 10.4₁₀ 6.36₂ 5.38₂ 4.46₂ 4.14₂ 3.23₁ 3.18₁ 2.51₁; PD(calc, MON): 10.4₁₀ 4.47₁ 4.38₁ 4.07₁ 3.28₁ 3.19₂ 2.60₁ 2.57₁; PD(calc, ORTH): 10.4₁₀ 4.47₁ 4.25₁ 3.68₁ 3.20₂ 3.09₁ 2.68₁ 2.54₁; observed lines at 4.25, 3.09, and 2.51 Å are indicative of the orthorhombic polymorph, while a pair of lines close to 3.20 Å are indicative of the monoclinic form. Structure: CM 30:61(1992). The structure model will be found in the group description. Habit: Aggregate masses of lath-shaped crystals up to 300 μm long, [001] and flattened on {100}, commonly in matted forms resembling leather or cardboard and very porous; rarely in millimeter-length laths. Physical properties: White, gray, greenish, tan; dull to earthy luster; opaque in mass, but microscopically transparent. Cleavage {110}, good. $H = 2-2\frac{1}{2}$. $G = 2.29-2.36$ but often found lower due to high porosity. Biaxial (-); $2V = 61-36^\circ$; $N_x = 1.522-1.528$, $N_y = 1.530-1.546$, $N_z = 1.533-1.548$; the highest indices and smallest $2V$ for a sample with 6.6 wt % F₂O₃. Insoluble in acids. Infusible. Sometimes fluorescent, cream to bluish gray in SWUV, white in LWUV.

Chemistry: Aluminum substitution lies in the range 0.01–0.69 of the eight tetrahedral sites. Usually contains some iron and minor calcium; manganese is often present as well as minor sodium and potassium; fluorine may reach ≈ 5000 ppm. Its paucity in older than Tertiary sedimentary rocks suggests metastability. **Occurrence:** Found in hydrothermal veins; in basalts; in syenites and granites; and in granitic pegmatites. In deep-sea sediments and associated with active ridge and fracture zones in the Atlantic; in continental slope or margin deposits; in lacustrine sediments. Develops in soils of arid and semiarid regions. Formed as an alteration product in a diversity of rocks, including serpentinites. **Localities:** Found at the Lone Jack quarry, Rockbridge Co., VA; important commercial deposits at Attapulcus, Decatur Co., GA, and Quincy, Gadsden Co., FL; Sapillo, San Miguel Co., NM; at the New Cornelia mine, Ajo, AZ; in granite pegmatite at Mesa Grande, San Diego Co., and at the New Melones Lake Spillway, Calaveras Co., CA; Pend Oreille mine, Stevens Co., WA(!); Gustavus, Alexander Archipelago, AK; at Saucillo, CHIH, the Refugio mine, Concepcion del Oro, ZAC, and near Saculum village, northern Yucatan Penin., Mexico. In England at South Petherwin, Cornwall; Seaton, Devon; Endersby, Leicestershire; in Scotland at Cabrach, Aberdeenshire; and at Bakkasetter in the Shetland Is. At Torrejón, Cáceres, Spain; Schneeberg, Saxony, Germany; Idria, Venezia, Italy; Klesovo, Volyn, and Chekassk S of Kiev, Ukraine; *Palygorskaya, Ural Mts., Russia*; Jezda, Kazakhstan; Hyderabad, Andhra Pradesh, India; the Kuzuu district, Tochigi Pref., Japan; in the Flinders Range, Q, Australia; Taguenout-Hagueret, Algeria, and Tafout, Morocco. **Uses:** Filtering and sorptive agent; as a thermal and acoustic insulator. Yucatan palygorskite, mixed with indigo, was used to form the highly prized “Maya blue” pigment in pre-Columbian times; the same material was used by local potters well into historic times. AR AM 54:198(1969), SPC 16:183(1971), CM 28:329(1990).

74.3.1a.2 Tuperessuatsiaite $\text{Na}_{1-2}\text{Fe}_3\text{Si}_8\text{O}_{20}(\text{OH})_2 \cdot 5\text{H}_2\text{O}$

Named in 1985 by Karup-Møller and Petersen for the locality. Palygorskite-sepiolite group. MON $C2/m$ (material from Namibia reported as $C2/c$ or Cc). $a = 13.729$, $b = 18.000$, $c = 4.828$, $\beta = 104.28^\circ$, $Z = 2$, $D = 2.468$. 38-372(Greenland): 10.82_{10} 4.14_2 3.40_3 2.64_4 2.54_3 2.51_3 2.38_2 2.24_3 . Fan-shaped aggregates to several centimeters in size, rosettes, or fibers, elongated on [001] and twinned on (001). Red-brown, vitreous luster, translucent. Cleavage {100}, good. Biaxial (+); 2V large; for Greenland material: $N_x \approx 1.54$, $N_y \approx 1.56$, $N_z \approx 1.58$; for Namibian material: $2V = 76.5^\circ$; $N_x = 1.539$, $N_y = 1.560$, $N_z = 1.595$; $Y = b$, $Zc = 5-7^\circ$. Pleochroic, $Z > Y > X$ dark red-brown to colorless. Greenland material contains NaFe_3^{II+} , whereas Namibian material approaches Na_2Fe_3 , requiring part of the iron in the ferrous state. Manganese is present as a substituent for iron. A zinc-rich material is noted but not described further. Found in late, low-temperature veinlets associated with natrolite and aegirine in natrolite-albite rocks at *Tuperessuatsiait Bay*,

Ilimausaq, Greenland, and better crystallized material from the Aris phonolite, Windhoek, Namibia. AR *NJMM:501(1984)*, *145(1992)*; *AM 70:1332(1985)*.

74.3.1a.3 Yofortierite $(\text{Mn}^{2+}, \text{Mg})_5\text{Si}_8\text{O}_{20}(\text{OH})_2 \cdot 8-9\text{H}_2\text{O}$

Named in 1975 by Perrault et al. in honor of Yves Oscar Fortier (b.1914), director of the Geological Survey of Canada, 1964–1972. Palygorskite–sepiolite group. MON Space group uncertain, probably *Pn*. $a = 12.759$, $b = 18.369$, $c = 5.024$, $\beta = 94.98^\circ$, $Z = 2$, $D = 2.81$. d_{hkl} : 10.5₁₀ 4.41₂ 3.68₁ 3.30₉ 2.62₃ 2.53₁ 2.51₂ 1.564₁. Pink to violet, silky to dull luster. $H = 2\frac{1}{2}$. $G = 2.18$. Biaxial; $N_x = 1.530$, $N_z = 1.539$; $X \wedge$ fiber = 8° . Pleochroic; maximum absorption perpendicular to fiber. Found as radiating fibers up to 3 cm in length, associated with analcime, serandite, eudialyte, polyolithionite, aegirine, microcline, and albite in pegmatite veins in nepheline syenite at the *DeMix quarry, Mt. St.-Hilaire, QUE, Canada*. AR *CM 13:68(1975)*.

74.3.1b.1 Sepiolite $\text{Mg}_4\text{Si}_6\text{O}_{15}(\text{OH})_2 \cdot 6\text{H}_2\text{O}$

Named in 1847 by Glöcker from the Greek for *cuttlefish*, whose “bone” is light and porous, as is the mineral, but the mineral was probably known nearly a century earlier. Palygorskite–sepiolite group. Synonym: meerschaum, German for *sea foam*, coined in 1788 by Werner. ORTH *Pncn*. $a = 13.43$, $b = 26.88$, $c = 5.281$, $Z = 4$, $D = 2.25$; alternate settings transpose a and c yielding *Pnan*. *13-595*: 12.1₁₀ 4.31₄ 3.75₃ 3.37₃ 3.20₃ 2.62₃ 2.56₅ 2.26₃. The structure model is presented in the group description. Usually as nodular masses of very fine, matted fibers and laths; aggregates commonly highly porous; rarely in laths to several millimeters long [001]. White, gray, and variously tinted in yellows, browns, and greens; dull, earthy luster; opaque in mass. Tough due to interlocking fibers. Cleavage {110}, good, but rarely discernible. $H = 2-2\frac{1}{2}$ but easily indented by pressure due to porous nature. $G = 2.0-2.2$ but often much lower in mass with dry pieces floating in water. Biaxial (-); $2V = 50-83^\circ$; $N_x = 1.498-1.522$, $N_y = 1.507-1.553$, $N_z = 1.527-1.579$, the indices increasing with increased iron content; $Z = c(\text{elongation})$. *Meerschaum* is reported as isotropic with $N = 1.517$. Decomposed by HCl. Infusible. Compact varieties tend to adhere to tip of tongue when thus touched. Aluminum commonly replaces up to a few percent of the tetrahedral sites; Ca and alkalis are present only in small amount; Fe^{2+} and Fe^{3+} are commonly present with Fe_2O_3 up ≈ 10 wt % (Strunz has proposed the *Fedominant ferrisepiolite*); nickeliferous material is known, and a series with *falcondoite* is likely; fluorine is commonly present in the range 0.5–1.3 wt %. Occurs in a wide variety of environments as described for palygorskite with which it is commonly associated. Forms as an authigenic mineral in lacustrine deposits; an important alteration product of several rock types particularly serpentinites and magnesite. Found in Chester and Delaware Cos., PA; as an authigenic mineral at Mound Lake, Lynn and Terry Cos., TX; at Sapillo, San Miguel Co., NM; at the Cole shaft and Southwest mine, Bisbee, Cochise Co., AZ; in Duchesne and Tooele Cos., UT; in small veins in calcite and as pellets

in limestone at Crestmore, Riverside Co., CA; at the Cardiff mine, Wilberforce, ON, Canada. Important economic deposits occur at Vallecas-Vicalvaro, Madrid, Spain. The alleged type locality is at *Baldissero Canavese, Piemonte, Italy*; also in Moravia, Czech Republic; and at Thebes, Greece. Fine nodular masses (*meerschaum*) occur on the plains of Eskişehir, Turkey(1). Found at Liling, Hunan, China; in the Kuzuu district, Tochigi Pref., Japan; at Tintinara, SA, Australia (aluminian); as crystals(1) to several millimeters at Ampandradara, Madagascar; at Amboseli, Kenya; and in Morocco. Fine, compact meerschaum has been used extensively as a carving material, particularly in the manufacture of smoking pipes that were often executed in very ornate designs. Material from Spain is an important lightweight building stone and is also used in ceramic wares. AR *D6:680(1892)*, *DT:679(1932)*, *MSARM 19:631(1988)*.

74.3.1b.2 Falcondoite $(\text{Ni,Mg})_4\text{Si}_6\text{O}_{15}(\text{OH})_2 \cdot 6\text{H}_2\text{O}$

Named in 1976 by Springer for the contraction, Falcondo, of Falconbridge Dominica C. por A., the company mining at the type locality. Palygorskite-sepiolite group. The nickel analog of sepiolite. ORTH *Pncn*. $a = 13.5$, $b = 26.9$, $c = 5.24$, $Z = 4$, $D = 2.54$. *29-1433*: 12.2₁₀ 3.33₃ 3.19₂ 2.62₃ 2.53₃ 2.44₃ 2.39₂ 2.26₂. Whitish green, translucent. Friable; cleavage described as "slightly schistose." $H = 2-3$. Biaxial; $N \approx 1.55$; positive elongation; extinction approximately parallel. The Ni/Mg ratio varies from 0.75 to 2.33 with an average of 1.38. DTA endotherms occur at 180° (zeolitic water), 360° and 540° (bound water), and 840° (hydroxyl). Occurs as tangled masses of 10- μm fibrous particles in 2-cm-wide fissures at a depth of 3 m below the surface in the *Loma Peguera laterite deposit at Bonao, Dominican Republic*. AR *CM 14:407(1976)*.

74.3.1b.3 Loughlinite $\text{Na}_2\text{Mg}_3[\text{Si}_6\text{O}_{15}](\text{OH})_2 \cdot 7\text{H}_2\text{O}$

Named in 1960 by Fahey et al. for Gerald Francis Loughlin (1880-1946), chief geologist, U.S. Geological Survey. Palygorskite-sepiolite group. Probably ORTH Space group unknown. *13-310*: 12.8₁₀ 7.60₃ 4.80₅ 4.45₁₀ 3.79₁₀ 3.65₁₀ 2.90₇. White, silky to pearly luster. $G = 2.165$. Biaxial (+); $2V_{\text{calc}} = 60^\circ$; $N_x = 1.500$, $N_y = 1.505$, $N_z = 1.525$. Decomposed by HCl; prolonged immersion in water produces sepiolite(?). Minor ferric and ferrous iron are present. Found as massive to fibrous fillings in veins up to 3 cm long and 1 cm thick, in dolomitic oil shale at three locations *18 to 20 miles W of Green River, Sweetwater Co., WY*. AR *AM 45:270(1960)*.

74.3.2.1 Chrysocolla $\text{Cu}_2\text{H}_2[\text{Si}_2\text{O}_5](\text{OH})_4$

The name was first used by Theophrastus in 315 B.C., and derives from the Greek for *gold glue*, in allusion to its use, with other mineral materials as well,

in the soldering of gold. The name often is used very broadly for any massive, globular, glassy, blue to green copper-bearing mineral whose specific identity is undetermined. Probably ORTH Space group unknown. $a = 5.7$, $b = 8.9$, $c = 6.7$. *27-188*: 17.9₈ 7.9₆ 4.45₂ 4.07₆ 2.90₈ 2.56₇ 1.602₄ 1.486₁₀, weaker lines often diffuse; also *PD*: 4.39₁₀ 2.80₅ 2.60₄ 2.42₁ 2.32₁ 1.600₃ 1.482₈ 1.321₂. Structure: *CR D271:1837(1970)*. For "well-crystallized" acicular material a structure is proposed that is related to that of palygorskite, with sheets made up of amphibolelike ribbons joined to one another with apical oxygens pointing in opposite directions in alternating ribbons. This superimposed linear component within the sheets accounts for the fibrous habit. **Habit**: As very fine acicular crystals to 5 mm in length in radiating clusters; fibrous; in botryoidal aggregates; cryptocrystalline. Often in glassy, opaline, or porcellaneous encrustations coating or replacing other phases. **Physical properties**: pale to deep blue, blue-green, green, brown to black due to impurities; pale blue to tan or gray streak; vitreous, waxy, porcellaneous, to earthy luster, translucent to opaque. Brittle, and in part, somewhat sectile. $H = 2-4$. $G = 1.93-2.40$. **Optics**: Biaxial (-); 2V small: $N_x = 1.575$, $N_y = 1.587$, $N_z = 1.600$; but optical properties highly variable. **Chemistry**: Al and Fe^{3+} may substitute for Cu^{2+} with Al_2O_3 reported up to 5.9 wt % and Fe_2O_3 up to 5.7 wt %; water content is variable. A formula written as $Cu_{2-x}(Al,Fe^{3+})_xH_{2-x}[Si_2O_5](OH)_4 \cdot nH_2O$ takes the substitutions into account. Endothermic water loss is reported at 60° and 120°C, and approximately half of the water is lost by 200°C and the balance between 200° and 700°C. Many materials designated as chrysocolla are mixtures of such materials as several copper silicate species, amorphous material, cryptocrystalline quartz, and opaline silica. **Occurrence**: A ubiquitous phase in oxidized zones of copper deposits, often encrusting or replacing earlier secondary minerals, and commonly associated with malachite, azurite, tenorite, and clay minerals. **Localities**: Of worldwide occurrence. Some notable localities are: at the Chino pit, Santa Rita, Grant Co., and replacing hemimorphite and various copper minerals in the Hansonburg district, S of Bingham, Socorro Co., NM; in the Tintic district, UT; an important component of some large Cu orebodies in the Globe-Miami district, Gila Co., the Ray pit and San Manuel mine, Pinal Co., Morenci, Greenlee Co., and other deposits in AZ; at Cananea, SON, Mexico. Known from several copper deposits of Cornwall, England; at Lubietova (Libethen), Czech Republic; rich deposits from Nizhne Tagil, Ural Mts., Russia; "Eilat Stone" from Timna, southern Negev, Israel; at Broken Hill, Zambia; at Tsumeb, Namibia; at Lubumbashi, Likasi, Zaire; at the Pinnacles mine, Flinders range, SA, Broken Hill, NSW, and the Chillagoe district, Q, Australia. At Chuquicamata and Copiapo, Chile. **Uses**: A minor and incidental ore of copper from oxidized zones. A popular ornamental material fashioned in various decorative forms; chrysocolla, sometimes intergrown with malachite, azurite, and/or cuprite is often fashioned into cabochons ("Eilat Stone" in part). The ancient use as a component of soldering flux is no longer practiced. *AR D6:699(1892)*; *AM 48:649(1963)*; *AM 54:993(1969)*; *IANS 6:29(1968)*.

74.3.3.1 Altsite $\text{Na}_3\text{K}_6\text{Ti}_2[\text{Al}_2\text{Si}_8\text{O}_{26}]\text{Cl}_3$

Named by Khomyakov et al. in 1994 for the principal high valence cations in the chemical formula: Al, Ti, Si. *MON* $C2/m$, $a = 10.363\text{Å}$, $b = 16.310\text{Å}$, $c = 9.132\text{Å}$, $\beta = 105.34^\circ$ at 20°C , $Z = 2$, $D = 2.67$; *PD* (ZVMO 123:82(1994)) (nat.): 8.22₇ 3.50₄ 3.16₃₅, 3.05₁₀, 2.90₇, 2.835₈, 2.00₃, 1.97₃. The structure ($R = 2.5\%$) consists of parallel (001) layers of Si and Al tetrahedra joined with Ti octahedra. Each infinite sheet of tetrahedra is grouped in 6 (two types) and 10-fold rings with an ordered distribution of Al and Si. In the structure, there are three types of channels filled with Na, K and Cl. Structure is related to that of lemoynite which has $2 \times c$ of altsite and $Z = 4$ (EJM 7:537(1995)). Colorless, transparent, occurs as anhedral grains to 3 mm diameter, in the interstices of pectolite crystals; conchoidal fracture, vitreous luster, greater than that of nepheline, $H = 6$, $G = 2.64$. Not luminescent in UV light. Heated to 1000°C , then gives an X-ray pattern of KCl. Na_2O 9.3 wt. %, K_2O 20.7, BaO 1.0, Al_2O_3 , 8.7, SiO_2 40.3, ZrO_2 0.1, TiO_2 13.1, Nb_2O_5 0.5, Cl 8.6, O for Cl 1.9, $\Sigma 100.4$. Biaxial (+), $2V = 85^\circ$ (calc. 86°); $N_\alpha = 1.601$, $N_\beta = 1.625$, $N_\gamma = 1.654$, weak dispersion, $r < v$. IR, DTA, TGA, and DTG data available (ZVMO 123:82(1994)). A hydrothermal mineral, formed late in the period of formation of ultra-agpaitic pegmatites. Found in core from a 470 m drill hole in pegmatitic rocks in the SW part of the Khibiny Massif in the region of the Olen Brook apatite deposit. Principal minerals are sodalite, nepheline, K-feldspar, and pectolite. Also associated with aegirine, shcherbakovite, tinaksite, Mg-astrophyllite, nefedovite, villiaumite, natrite, and rasvumite. *EF*.

74.3.3.2 Lemoynite $(\text{Na},\text{K})_2\text{CaZr}_2[\text{Si}_{10}\text{O}_{28}] \cdot 5-6\text{H}_2\text{O}$

Named in 1969 by Perrault et al. for Charles Lemoyne (1625–1685), prominent in the history of Canada. *MON* $C2/c$. $a = 10.384$, $b = 15.947$, $c = 18.601$, $\beta = 104.59^\circ$, $Z = 4$, $D = 2.38$. $24-1072$: 9.0₄ 8.01₁₀ 4.39₃ 3.96₂ 3.56₅ 3.48₃ 3.03₃ 2.81₅. Structure: *CM* 14:132(1976). A pseudocell with c halved can be assigned to $C2/m$. The silicate structural element consists of double-width ribbons lying in (010) and parallel to [100]; these are condensed to form sheets parallel to (001) that, in turn, are linked by Zr octahedra to form an open framework. Prismatic to bladed crystals in spherical aggregates with the dominant forms {100}, {010}, {001}, and {011}; fine, almost fibrous. White to tan, rarely colorless, greenish-gray, yellowish white; dull luster but colorless crystals are vitreous. Cleavage {100}, {010}, perfect. $H = 4$. $G = 2.29$. Biaxial (+); $2V = 80^\circ$; $N_x = 1.540$, $N_y = 1.553$, $N_z = 1.570$; $Y = b$, $Z \wedge a = 5^\circ$; $r < v$, weak. As compact 3- to 8-mm spheres and spherical aggregates of bladed crystals in interstices of large microcline crystals in pegmatite at *Mt. St.-Hilaire, PQ, Canada*. *AR* *CM* 9:585(1969), *MR* 21:318(1990).

74.3.4.1 Sanbornite BaSi_2O_5

Named in 1932 for Frank B. Sanborn (1862–1936), mineralogist, California Department of Natural Resources. β - BaSi_2O_5 , α - BaSi_2O_5 is the high-tempera-

ture form. ORTH *Pmnb*. (Syn): $a = 7.692$, $b = 13.525$, $c = 4.634$; *ZK 153:33(1980)(nat)*: $a = 7.688$, $b = 13.523$, $c = 4.629$, $Z = 4$, $D = 3.774$. α -form, *B2/b*, has $a = 23.195$, $b = 13.613$, $c = 4.658$, $Z = 12$. *26-176(syn)*: 6.77_4 3.97_9 3.42_5 3.34_7 3.10_{10} 2.73_4 2.71_4 2.28_4 . Structure: *ZK 153:33(1980)*. Platy to 2–3 cm; polysynthetic twinning on (010). White, colorless; pearly luster. Cleavage (001), perfect; {010}, imperfect. $H = 5$. $G = 3.70$ – 3.77 . May fluoresce cream, gray, or bluish in SWUV and LWUV light. Decomposed by acids. Biaxial (–); $Z \approx c$; $N_x = 1.597$, $N_y = 1.616$, $N_z = 1.624$; $2V = 66^\circ$. Occurs as a major component of Ba-silicate assemblages at or near fringes of large granite intrusives. Associated with witherite and taramellite. Occurs at *Trumbull Peak, Incline, Mariposa Co., CA*; Rush Creek and Big Creek, Fresno Co., CA; Chicken Coop Canyon, Tulare Co., CA; Ross River, YT, Canada; La Madralena mine, Tres Pozos, Baja Norte California, Mexico. EF

74.3.4.2 Krauskopfite $\text{BaSi}_2\text{O}_4(\text{OH})_2 \cdot 2\text{H}_2\text{O}$

Named in 1965 by Alfors et al. for Konrad Bates Krauskopf (1910–). American geologist and geochemist, Stanford University. *MON P2_{1/a}* $a = 8.460$ – 8.608 $b = 10.602$ – 10.622 $c = 7.831$ – 7.837 $\beta = 94.53$ – 94.79° $Z = 4$ $D = 3.06$; *PD 18-192 (nat.)*: 6.7_3 6.36_5 5.34_5 3.94_3 3.84_{10} 3.66_3 3.01_4 2.88_3 . Structure has been solved (*Acad. Naz. dei Lincei 42:859(1967)*). Colorless-white; streak white; equidimensional to short prismatic (on a), subhedral to anhedral grains to 6 mm; subvitreous, pearly on cleavage plates; cleavage = 2 perfect {010} and {001} at 90° , a third poor cleavage or fracture at a high angle to the other two; H 4; G 3.14; readily decomposed by cold acids (dilute) leaving a white to transparent silica residue. Not affected by weak bases. Traces of Ca, Mg and Fe present. Biax. (–), $2V = 88^\circ$, $N_\alpha 1.574$, $N_\beta 1.587$, $N_\gamma 1.599$; colorless; $X = b$, $Y = 10\frac{1}{2}^\circ$, fragments elongated on Y, thus can be either length fast or length slow. Dispersion = $R > V$ distinct. Occurrence: A secondary mineral along with macdonaldite occurring in veinlets or lining cracks with Ba silicates in metasomatic rocks. Assoc. with opal and witherite, also replaces sanbornite. *Rush Creek, Fresno Co., CA*, Chickencoop Canyon, Tulare Co., CA. EF *AM 50:314(1965)*, *MIN 3(2):531(1981)*, *AM 69:358(1984)*.

74.3.5.1 Natrosilite $\text{Na}_2\text{Si}_2\text{O}_5$

Named in 1975 by Timoshenkov et al. from the composition: sodium (natrium) and silicon. *MON P2_{1/a}*. $a = 12.30$, $b = 4.88$, $c = 8.27$, $\beta = 104.23^\circ$, $Z = 4$, $D = 2.51$; (syn): $a = 12.329$, $b = 4.848$, $c = 8.133$, $\beta = 104.24^\circ$. *29-1261(nat)*: 6.06_{10} 4.28_5 4.17_6 3.97_8 3.64_7 2.98_9 2.44_8 1.83_8 ; *23-529(syn)*: 5.98_4 4.13_3 3.94_5 3.77_3 3.62_4 2.97_5 2.43_{10} 1.83_3 . Structure: β -form of $\text{Na}_2\text{Si}_2\text{O}_5$. *AC(B) 24:1077(1968)*. Pseudohexagonal thick tabular crystals to 6 cm \times 6 cm \times 4 cm; twins on {100} noted on synthetic material, but not in natural material. Colorless; silky luster on micaceous cleavage, also pearly; transparent—thin, translucent—thick. Cleavage {100}, micaceous; {001}, distinct; {011}, poor; even fracture. $G = 2.48$. IR data: *ZVMO 104:317(1975)*. Decomposed by water and weak acids, melts at $850 \pm 20^\circ$ to a transparent

yellowish glass. $N = 1.505$. Analysis (wt %): SiO_2 , 66.03, 66.32; Na_2O , 33.96, 33.74; trace of K_2O . Biaxial (-); $X \approx$ perpendicular to (100), $Z = b$, $Y \wedge c$ at $484 \text{ nm} = -12^\circ$, $Y \wedge c$ at $645 \text{ nm} = 1-2^\circ$; $N_x = 1.507$, $N_y = 1.517$, $N_z = 1.521$; $2V = 63-64^\circ$ (484 nm), $49-50^\circ$ (645 nm); $r < v$; anomalous optical properties include undulatory extinction; anomalous blue interference colors. Occurs in pegmatite segregations of nepheline-syenites with microcline, analcime, natrolite, lomonosovite, ussingite, and vuonnemite. Occurs at Mt. St.-Hilaire, QUE, as white, elongated crystals to 0.5 mm, with good cleavage, associated with revdite in sodalite xenoliths; *Mt. Karnasurt, Lovozero massif, Kola Penin., Russia*; also in the Khibiny massif. EF

74.3.5.2 Makatite $\text{Na}_2\text{Si}_4\text{O}_8(\text{OH})_2 \cdot 4\text{H}_2\text{O}$

Named in 1970 by Shepard et al. from the Masai *emakat*, soda, in allusion to the high sodium content. MON $P2_1/c$. $a = 7.388$, $b = 18.094$, $c = 9.523$, $\beta = 90.64^\circ$, $Z = 2$, $D = 2.05$; originally reported as ORTH with a different cell. 23-703: 9.04₅ 8.42₃ 5.09₁₀ 4.22₃ 3.42₄ 3.13₃ 2.99₆ 2.88₄. Structure: ZK 159:203(1982). The structure determined on synthetic material is made up of sheets, $[\text{Si}_2\text{O}_4(\text{OH})]_n^{n+}$, parallel {010} and containing six-membered rings. Crystals acicular, 5-30 μm long and 0.05-2.0 μm wide; also in radiating aggregates and spherulites 0.05-0.3 mm in diameter; also as striated prisms of 3 mm length. White, dull vitreous luster, translucent. Cleaves into thin flakes presumably {010}. $G = 2.072$. Russian material is biaxial (+); $2V = 70^\circ$; $N_x = 1.472-1.475$, $N_y = 1.48$, $N_z = 1.487-1.490$; also reported as biaxial (-). Often forms spongy pseudomorphs after bladed trona (Lake Magadi); possibly a pseudomorph after natrosilite (Kola). Found in sodalite xenoliths with vuonnemite at Mt. St.-Hilaire, QUE, Canada; at Howenegg, Hegau, Germany; at Mt. Alluaiv, Lovozero alkalic massif, Kola Penin., Russia; in cores of trona from *Lake Magadi, Kenya*; at the Aris mine, S of Windhoek, Namibia. AR AM 55:358(1970), DANS 255:181(1980).

74.3.5.3 Silinaite $\text{NaLiSi}_2\text{O}_5 \cdot 2\text{H}_2\text{O}$

Named in 1991 by Chao et al. for the composition: Si-Li-Na. MON $A2/n$. $a = 5.061$, $b = 8.334$, $c = 14.383$, $\beta = 96.67^\circ$, $Z = 4$, $D = 2.22-2.23$. PD(nat): 7.14₁₀ 4.24₈ 4.14₁₀ 4.02₈ 2.85₁₀ 2.70₅ 1.61₄ 1.58₄. Structure: CM29:363(1991). Tabular crystals show {001}, fibrous clusters, poorly formed prismatic crystals, cloudy to earthy or powdery patches; crystals to 2 mm: twinning present, CP is parallel to (001), $[110]_{180^\circ} =$ twin axis. Clear, colorless to white; white streak; vitreous to earthy luster; opaque to translucent. Cleavage {001}, perfect; {010}, good; {110}, distinct; conchoidal fracture; brittle. $H = 4\frac{1}{2}$. $G = 2.24$. Dissolves slowly in concentrated HCl and HNO_3 , more slowly in H_2SO_4 , and leaves a gel residue. Analysis (wt %): SiO_2 , 58.5; Al_2O_3 , 0.0; CaO, 0.1-0.4; Na_2O , 15.0-13.7; Li_2O (calc), 7.25-7.28; H_2O (calc), 17.5-17.6. Biaxial (+); $X = b$, $Y \wedge c = 16^\circ$ in acute $> \beta$; Na(D): $N_x = 1.515$, $N_y = 1.516$, $N_z = 1.518$; $2V = 64^\circ$; strong, $r > v$, inclined; nonpleochroic. Occurs at the *Poudrette quarry, Mt. St.-Hilaire, QUE, Canada* in sodalite syenite xenoliths

in nepheline syenite. Associated with many rare species, such as erdite, kogarkoite, tugtupite, and vitusite-(Ce). *EF CM 29:359(1991)*.

71.3.5.4 Searlesite $\text{NaBSi}_2\text{O}_5(\text{OH})_2$

Named in 1914 for John W. Searles (1828–1897), an early California resident of the Searles Lake area, or possibly for his son (1865–1938). *MON P2₁. APK 194*, $a = 7.972$, $b = 7.049$, $c = 4.895$, $\beta = 93.93^\circ$, $Z = 2$, $D = 2.46$. *AM 61:123(1976)*. $a = 7.981$, $b = 7.066$, $c = 4.905$, $\beta = 93.95^\circ$, $Z = 2$, $D = 2.45$. *6-37(nat)*: 8.01_{10} 4.31_3 4.06_5 3.54_3 3.48_4 3.24_4 3.21_4 2.92_3 . Also *29-1181* (not in latest book). Structure: *AM 61:123(1976)*. Elongated on [001], striated, xls to 15 cm. White, colorless; white streak; vitreous luster; translucent. Cleavage (100), micaceous; (010), (001), average. $G = 2.46\text{--}2.49$. IR data: *ZSGD: 301(1977)*. DTA data: *USGSB: 1036-K(1957)*, *ZSGD:301(1977)*. Sometimes fluoresces orange in LWUV. Decomposed by HCl. Biaxial (-); $Z = b$, $X \wedge c = 30^\circ$; $N_x = 1.515\text{--}1.524$, $N_y = 1.531\text{--}1.533$, $N_z = 1.535$; $2V = 55\text{--}73^\circ$. Occurs in alkaline saline lakes, alkaline sedimentary rocks, and in alkalic rocks and their cogenetic pegmatites. Occurs in the Green River formation in Wyoming and Utah and at Coaldale, Esmeralda Co., NV; *Searles Lake, San Bernardino Co., CA*; also at China Lake, Owens Lake, and Lake Tecopa, Inyo Co., CA; Kramer borate deposit, Boron, CA; Nuka formation, Brooks Range, AK; Lopore, Bosnia; Kemna, Yugoslavia; Lovozero massif, Kola Penin., Russia; West Azzir, near Caspian Sea, Russia; Miyang depression, Henan Prov., China. *EF*

74.3.6.1 Revdite $\text{Na}_{16}[\text{Si}_4\text{O}_6(\text{OH})_5]_2[\text{Si}_8\text{O}_{15}(\text{OH})_6](\text{OH})_{10} \cdot 28\text{H}_2\text{O}$

Named in 1980 by Khomyakov et al. for the locality, the nearby village of Revda. Compare natrosilite – revdite is the hydrous analogue. *MON. C2*. $a = 53.83\text{\AA}$, $b = 9.972$, $c = 6.907$, $\beta = 96.78^\circ$, $Z = 2$, $D = 1.93$; *PD 33-1279* (nat.): 13.4_9 4.46_{10} 3.79_4 3.34_7 3.12_2 2.88_4 2.50_5 2.23_3 . Structure: main elements consist of bands of $[\text{Si}_4\text{O}_6(\text{OH})_5]$, and the second type is a combination of two bands of the first type, displaced relative to one another (*SPC 37:632(1992)*). Colorless-white, transparent; acicular, spherical masses 1–2 cm diameter, irregular shaped; at Mont Saint-Hilaire, crystals are 1–2 mm long, to 2 mm at Lovozero; vitreous-pearly; cleavage = excellent, micaceous on (001) and one other nearly as good; $H = 2$; $G = 1.94$; IR and DTA data in *ZVMO 109:566(1980)*; dissolves slowly in H_2O at 20°C , giving an alkaline reaction to phenolphthalein; dissolves quickly in cold dilute acids. SiO_2 , 45.21; Na_2O , 22.25; H_2O , 32.50; K_2O trace. Biaxial (-); $2V = 30\text{--}75^\circ$, Khibiny: $N_\alpha = 1.460$, $N_\beta = 1.478$, $N_\gamma = 1.481$ and Lovozero: $N_\alpha = 1.469$, $N_\beta = 1.482$, $N_\gamma = 1.490$; dispersion = $r > v$. Occurs at Mont Saint-Hilaire in cavities and fractures in sodalite xenoliths; at Lovozero it occurs in ussingite veinlets cutting nepheline syenites. Mont Saint-Hilaire, Quebec, Canada; from deep workings on *Mount Karnasurt, Lovozero Massif, Kola Peninsula, Russia*; Mount Rasvumchorr, Khibiny Massif.

74.3.7.1 Cavansite $\text{Ca}(\text{V}^{+4}\text{O})(\text{Si}_4\text{O}_{10} \cdot 4\text{H}_2\text{O})$

Named in 1973 for the composition Ca-V-Si. Polymorphous with pentagonite. ORTH. *Pcmm* $a = 10.298$, $b = 13.99$, $c = 9.601$, $Z = 4$ (AM 58:412(1973)). $D = 2.34$, 25-182 (nat) 7.96₁₀ 6.85₅ 6.13₃ 4.53₁ 3.93₃ 3.42₃ 3.06₁ 2.78₃ A layer silicate: contains zig-zag chains of $(\text{SiO}_3)_N$. Blue to greenish blue; elongate on c , prismatic aggregates with {110} & {101} dominant, rosettes to 5 mm from Oregon; India, crystals to >8 mm long; both prismatic & platelike xls, elongate parallel to b with {001}, {100}, {011} & {001}; vitreous; good cleavage parallel to b ; $H = 3-4$; $G = 2.21-2.31$; difficulty soluble in acids; in HNO_3 - blue color bleaches out and turns olive brown; a fine white precipitate forms when heated in dil. H_2SO_4 . Biaxial (+), $2V_z = 51-52^\circ$; (India) $N_\alpha = 1.540$; $N_\beta = 1.545$; $N_\gamma = 1.550$; ($2V_{\text{calc}} = 90^\circ$); pleochroic from very light blue to deep blue. (Oregon) $N_\alpha = 1.542$, $N_\beta = 1.544$, $N_\gamma = 1.551$; $N_x = \text{colorless}$, $N_y = \text{blue}$, $N_z = \text{colorless}$. $X = b$, $Y = b$, $Z = c$. OAP perpendicular a , Bxa parallel to c . Dispersion $r < v$ extreme. Occurs in basalts with zeolites, also in tuffs. Occurs in fractures in palagonitic tuff, association with zeolites and calcite at *Lake Owyhee State Park, Malheur Co., OR and Goble, Columbia Co., OR*; in tholeiitic basalt tuff breccia at Abanagur, near Pune (Poona), Maharashtra, India. !! (best material in the world). AM 58:405(1973); MN 7:8(1991); Minerali 4(2):479(1992); AC B:1593(1975); LAP 14:39(1989).

74.3.7.2 Pentagonite $\text{Ca}(\text{V}^{+4}\text{O})\text{Si}_4\text{O}_{10} \cdot 4\text{H}_2\text{O}$

Named in 1973 by Staples et al. from the Greek words meaning 5 and angle. It occurs in prismatic crystals twinned to form fivelings with star-shaped cross sections. Polymorph: cavansite-dimorph. ORTH. *Ccm2₁*, $a = 10.298\text{A}$, $b = 13.99$, $c = 8.891$, $Z = 4$, $D = 2.34$; PD 25-181 (nat.): 8.30₇, 6.07₁₀ 4.45₃ 3.92₁₀ 3.76₁₀ 3.50₄ 2.64₃ 2.57₄. Structure: A sheet structure. Both cavansite and pentagonite have silicate layer structures in which the layers are held together by VO^{2+} groups, and Ca^{2+} ions, but they differ in the way the SiO_4 tetrahedra link to form the layers (AM 58:412(1973)). Blue; streak light blue; prismatic, elongated parallel to c ; twinning: yes, fivelings with star-shaped cross-section. Forms: {110}, {201} and {001}, twinned by reflection across the prism (110) which is the composition plane; vitreous; cleavage = 1 good, parallel to {010}; brittle; $H = 3-4$; G not done. Biaxial (-). $2V = 50^\circ$; $N_\alpha = 1.533$, $N_\beta = 1.544$, $N_\gamma = 1.547$; pleochroic with $X = \text{colorless}$, $Y = \text{blue}$, $Z = \text{colorless}$; OAP perpendicular to a , Bxa perpendicular to b , $X = b$, $Y = a$, $Z = c$. Dispersion = $r > v$, strong. Occurs at *Lake Owyhee State Park, Malheur Co., Oregon*; in fractures in palagonitic tuff. Associated with analcime, stilbite, chabacite, thomsonite, heulandite, calcite and apophyllite. AM 58:405(1973).

Si Tetrahedral Frameworks

75.1.1.1 Cristobalite SiO_2

Named in 1887 by vom Rath for the locality. The term *lussatite* has been used for a fibrous variety. Polymorphous with quartz, tridymite, coesite, and stishovite. The cristobalite structure proper has low-temperature (α) and high-temperature (β) configurations. β -Cristobalite is the stable form of SiO_2 from 1470°C to the melting point (1728°C). It exists as a metastable phase below 1470°C because of the sluggish nature of the reconstructive transition to tridymite. The transformation to quartz is further inhibited by the

CRISTOBALITE

The structure of tetragonal α -cristobalite; Perspective along c .

presence of foreign ions in the open framework of the cristobalite. The displacive transformation, β to α , takes place at 268°C for highly ordered, pure cristobalite but may be as low as 175°C where a high level of impurities exists.

Low(α)-cristobalite: TET $P4_12_12$ or $P4_32_12$. $a = 4.969$, $c = 6.926$, $Z = 4$, $D = 2.331$. *39-1425(syn)*: 4.04₁₀ 3.14₁ 2.84₁ 2.49₁ 2.47₁ 2.12₁ 1.929₁ 1.612₁.

High(β)-cristobalite: ISO $P2_13$ or $Fd3m$. $a = 7.16$ at 500°C, $Z = 8$, $D = 2.17$. *PD(500°C)*: 4.15₁₀ 2.53₈ 2.07₃ 1.639₆ 1.409₅ 1.379₂ 1.265₃ 1.209₃. Structure: *ZK 201:125(1992)*. The structure is a three-dimensional framework of cross-linked, spiral chains of tetrahedra. In an idealized structure of β -cristobalite the silicon atoms form an array not unlike that of the carbons in diamond except that an oxygen lies at the midpoint between each pair of adjacent silicons resulting in a very open structure. Furthermore, the oxygens of β -cristobalite and β -tridymite, although not close packed, are related to one another in the manner of cubic and hexagonal close packing. **Habit:** Crystals, usually under 1 mm in diameter, are dominantly octahedral, rarely cubic; {110} and {331} have been reported, and all are paramorphs after high-cristobalite; the octahedra often skeletal and elongated on cell axes. β -Cristobalite occurs as simple (spinel type) or multiple twins on {100}. Oriented overgrowths on tridymite with cristobalite [110](111) parallel to tridymite [1120](0001). More commonly as spherulitic aggregates with radial-fibrous structure, often as the result of devitrification of natural and synthetic high-silica glass; microcrystalline aggregates; botryoidal and stalactitic forms; massive. **Physical properties:** Colorless to white, pale gray, yellowish, and brownish white; vitreous to dull luster; transparent to translucent. Conchoidal to splintery fracture, brittle. $H = 6\frac{1}{2}$. $G = 2.2-2.33$. Uniaxial (-); $N_O = 1.487$, $N_E = 1.484$ for α -cristobalite; inverted material is often so fine grained or complexly twinned as to appear isotropic. **Chemistry:** Substitution of aluminum for silicon and the very open structure permit the incorporation of alkali or alkaline earth ions in the voids of the framework. Published analyses all show less than 100% SiO₂, although the reported low value of 91% may be due to presence of impurities. The extreme case of substitution of half the Si sites by Al with half the voids being occupied by Na leads to the synthetic phase carnegieite that has corresponding high- and low-temperature modifications. The preparation of cristobalite from amorphous silica in the laboratory is facilitated by the presence of water and alkalis, although the latter are not necessary. **Occurrence:** Occurs as both α and β forms as a component of opal (75.2.1.1), the inversion of the latter apparently being inhibited by its being embedded in a colloidal matrix. Crystalline material occurs in siliceous volcanic rocks, apparently initially as the β form formed at relatively high temperatures but frequently as a metastable phase at lower temperatures (300°C). Characteristic in vesicles in rhyolite, andesite, and trachyte, where it is associated with tridymite, quartz, sanidine, pyroxene, fayalite, and magnetite, and also in basalts. Similarly, it occurs as thick-fibered, spherulitic aggregates in the groundmass of siliceous volcanics, and as large spherulites to several centimeters in diameter as devitrification products of obsidian, where it is often associated with tridymite and sanidine. Also found in ther-

mally metamorphosed sandstones and sandstone xenoliths at the contact with basaltic and other basic rocks. Quartz grains in the fused walls of fulgurites may contain cristobalite. Localities: Of widespread occurrence throughout the world; see also under opal (75.2.1.1). Some noteworthy localities are: in the Tertiary lavas of the western United States, particularly in the San Juan Mts., CO, Yellowstone Park, WY, at Crater Lake, OR, and in the Columbia River basalts; as large spherulites in obsidian ("snowflake obsidian") at Glass Mt., Little Lake, and Sugarloaf Mt. near Coso Hot Springs, Inyo Co., CA. Found as octahedra to 4 mm associated with tridymite at *Cerro San Cristobal, near Pachuca, HGO, Mexico*; with cassiterite in veinlets in rhyolite at the Santin mine, Santa Caterina, GTO, Mexico; as a component of a metamorphosed block in olivine-dolerite at Tievebulliagh, Northern Ireland; in trachyandesite from Puy de Clerzou, France, where it constitutes up to 10% of the rock; in basalts and other volcanics in the Mayen and Niedermendig region, Eifel district, Germany; in good crystals at Nezdenice, Cechy, Czech Republic; as twin crystals in rhyolite at Sárosptak, Hungary. In thermally metamorphosed sandstone at Arkhara, Transcaucasia, and in Quaternary volcanics of the Kamchatka Penin., Russia. As sharp octahedra and twinned octahedra perched on mordenite in basalt from Ellora, Hyderabad, India, where the temperature of formation is estimated at no more than 300°C. Found at numerous localities in Japan, some devitrification spherulites reaching up to 10 cm in diameter; at Tokatoka, New Zealand, where it makes up some 60% of a 10- to 15-cm-thick grossular-cristobalite contact zone between limestone and andesite. Uses: Snowflake obsidian is used as an ornamental stone. AR D7 3:273(1962), DHZI 4:177(1963), ZK 138:274(1973).

75.1.2.1 Tridymite SiO_2

Named in 1868 by vom Rath from the Greek for *three* and *twin*, in allusion to the twinned crystals, which are often trillings. Polymorphous with quartz, cristobalite, coesite, lutcite, and stishovite. Tridymite occurs in a variety of polymorphs and polytypes. At 25°, α -tridymite (low form) is MON or rarely TRIC. With an increase in temperature, there are two ORTH (ORTH I and ORTH II, respectively) forms (now considered part of β -tridymite) and then finally two HEX forms (β -tridymite or high tridymite). All of the transformations between these structures are displacive (second order) but show variable degrees of hysteresis. The transitions from quartz to tridymite and from tridymite to cristobalite are reconstructive (first order). The latter transformation is topotactic, where {111} of cristobalite is parallel to {0001} of tridymite. Tridymite is the stable phase of SiO_2 between 867 and 1470° and its stability field is greatly reduced with increasing pressure. Due to the reconstructive nature of transformations to other polymorphs (i.e., quartz and cristobalite), tridymite tends to persist metastably upon rapid cooling. At 25°C, three coexisting polymorphs of tridymite (MC, PO-10, MX) have been found together along with lamellae of cristobalite. AM 72:167(1987), MM

53:89(1989). The temperatures of transition for the different structures of tridymite are variable, chiefly because of substitution of variable amount of trace and minor elements such as Al, K, Na, Ti, and others. Transitions are reversible by slow heating or cooling. Microchemical data and the wide range of structural states occurring in tridymite crystals (and in cristobalite as well) even in the same rock sample indicate nonequilibrium during formation. Rapid growth rates also favor formation of tridymite. Terrestrial tridymites are generally triclinic or orthorhombic at 25° and sometimes monoclinic (e.g., Plumas Co., CA). Most synthetic and meteoritic tridymites are monoclinic. This is probably due to the amount of impurity elements present. Cell data for the most common structures are given below:

Name	Mc	TRIC PO- <i>n</i>	ORTH II OP	ORTH I OC	HEX	HEX HC
a	18.494	9.932	26.171	8.74	5.05	5.05

Z	48	320	24	8	4	4
Temp. range	to about 105°C	to 70°C	105–180°C	180–350°C	350–465°C	465°C to transit. to β-cr.

Note: A slightly different sequence and temperatures of transition were observed upon heating and cooling a single crystal of synthetic monoclinic tridymite. *AM 63:1252(1978)*. Transformation of the Mc structure to an orthorhombic phase occurs at about 5 kbar. *AM 65:1283(1980)*. Additional details of the various phase transitions are given in *AM 79:606(1994)*. A review of the structural modifications of tridymite and the various cells for meteoritic and terrestrial tridymite are given in *RIM 29:1(1994)*. ICDD cards: 18-1170(monoclinic, *Cc*); 42-1401(orthorhombic, F-centered lattice); 18-1169(hexagonal, *P6₃/mmc*); 14-260(hexagonal, P-lattice). Monoclinic: 4.33₉ 4.11₁₀ 3.87₂ 3.82₅ 2.98₃ 2.50₂ 2.49₁ 2.31₂; orthorhombic: 4.28₉ 4.08₁₀ 3.80₇ 3.24₅ 2.48₄ 2.38₂ 2.30₂ 1.96₁; hexagonal (20H): 4.27₁₀ 4.08₉ 3.83₅ 3.80₉ 2.96₆ 2.49₆ 2.48₆ 2.30₅. See also *AM 52:536(1967)* for powder data. *D* = 2.20–2.45. High tridymite is made up of layers of SiO₄ tetrahedra that are parallel to the {0001} plane. The mineral shows polytypism, and considerable variation occurs in the weak reflections. No evidence has been found for ordering of Al into particular tetrahedral sites. Natural low tridymite (orthorhombic, monoclinic, and triclinic) has up to 12 crystallographically distinct layers and the six-membered rings of tetrahedra which form these layers are all “oval,” while meteoritic-synthetic low tridymite has only two crystallographically distinct layers and the layers contain one-third “oval” and two-thirds ditrigonal rings. High tridymite contains only

ditrigonal rings. PO (pseudo-orthorhombic) tridymites are designated PO- n , where $n = 1, 1.5, 2, 5, 6, 10,$ and 12 (multiple of 4.07 \AA). Structural channels are present in tridymite running parallel to $[001]$, which contain variable amounts of Na, K, and other cations. **Habit:** Crystals are generally flabelliform, thin to thick, tabular flattened on $\{0001\}$. Pseudo-hexagonal, as inversion pseudomorphs after β -tridymite. The pyramid $\{1013\}$ is commonly present. Also as rosettes or in spherical and fan-shaped aggregates. Plates, often triplets. Twinning on $\{1016\}$ is extremely common, contact and penetration; wedge-shaped, sheaflike, or as trillings. Twinning on $\{3034\}$ is uncommon. Untwinned crystals are very rare. **Physical properties:** Generally white, or colorless; vitreous luster, pearly on $\{0001\}$. Cleavage $\{0001\}$, $\{10\bar{1}0\}$, imperfect; a parting parallel to c is sometimes observed; conchoidal fracture; brittle. $H = 6.5\text{--}7$. $G = 2.26\text{--}2.33$. Soluble in HF and boiling Na_2CO_3 . Cathodoluminescent in shades of blue. *CLGM:49(1989)*. NMR spectroscopy: *NAT 303:223(1983)*. IR data: *MP 14:3(1983)*. Raman spectra: *AM 71:694(1986)*, *79:269(1994)*. **Chemistry:** May be pure but generally contains minor amounts of Na, K, Al, and Ti. Typical contents (wt %) are: Na, 0.1–0.7, Al, 0.2–0.7; K, 0.03–0.3; Ti, 0.03–0.1. Large cations substitute in the structural channels and charge compensation is accomplished by substitution of Al for Si (tetrahedral). **Optics:** High tridymite is uniaxial (+) with negative elongation. Low tridymite has a range of reported optical properties: (meteoritic and synthetic): biaxial (+); $XZ = bc$; $N_x = 1.468\text{--}1.472$, $N_y = 1.470\text{--}1.473$, $N_z = 1.474\text{--}1.475$; $2V = 40\text{--}75^\circ$; negative elongation; [natural (Transcarpathia)]: biaxial (+); $N_x = 1.482$, $N_y = 1.484$, $N_z = 1.486$; $2V = 86^\circ$; same orientation as given. Indices increase with an increase of Na, K, Al, and so on. Colorless, nonpleochroic. **Occurrence:** Chiefly found in magmatic rocks, especially felsic volcanic rocks. Occurs as phenocrysts to several centimeters across and as euhedral crystals in lithophysal cavities. Also occurs in meteorites. Occurs rarely as a constituent of xenoliths in lavas. Also a constituent of some opals and cherts. Often alters to quartz (i.e., quartz paramorphs after both cristobalite and tridymite). **Localities:** Because tridymite is such a common mineral, only some of the more notable occurrences are mentioned here: abundant in groundmass and as phenocrysts in andesite–rhyolite, San Juan Mountains, CO; in lithophysal rhyolite at Topaz Mountain, Juab Co., UT; in lithophysae of rhyolite and obsidian, Yellowstone Park, MT; Mt. Rainier, WA; Johnstown meteorite, Weld Co., CO; Drachenfels and Perlenhardt, Siebengebirge, Germany; Mts. Dore, Puy Capuchin, Puy de Dome, France; Steinbach meteorite (Germany); Vesuvius, Mt. Aetna, Colli, and Euganei, Italy; crystals to 1 cm from Kremnicka and Vechec, Czech Republic; *Cerro San Cristobal, Pachuca, Mexico*; Mt. Pele, Martinique; crystals to 1.5 cm from Ishigayama, Japan; Niutoushan, southeastern China. *EF DS 7(III):259(1962)*; *AC 23:617(1967)*; *AC(B) 32:2486(1976)*, *33:2615(1977)*, *34:391(1978)*; *ZK 148:237(1978)*, *195:31(1991)*; *SMPM 64:335(1984)*; *EJM 5:605(1993)*; *IMAMA 16:203*.

75.1.3.1 Quartz SiO_2

Known since antiquity, but the current name is apparently from the Saxon word *querklufertz*, cross-vein ore, which became condensed to *querertz* and then to *quartz*. Clear, transparent, well-crystallized quartz is also referred to as *rock crystal* or derivatives thereof in various languages (e.g., Bergkristall). The Greeks and Romans used *crystallos* and *crystallus*, respectively, to refer to this type of quartz, and it is from these words that our word *crystal* is derived. Polymorphs include coesite, cristobalite, tridymite, and stishovite (not a tectosilicate). **HEX-R** (α -quartz) $P3_121$ (right-handed) or $P3_221$ (left-handed). **HEX** (β -quartz) $P6_422$ or $P6_222$, (α -quartz): $a_{\text{synth}} = 4.9133$, $c_{\text{synth}} = 5.4053$, $Z = 3$, $D = 2.66$. $33\text{-}1161$: 4.257_2 3.342_{10} 2.457_1 2.282_1 2.127_1 1.8179_1 1.5418_1 , 1.3718_1 . (β -quartz, at 575°): $a = 4.999$, $c = 5.457$, $Z = 3$. α -quartz is stable at low pressures and up to about 573°C , and β -quartz, also stable at low pressures, is stable from about 573°C to 870°C . It can exist metastably above 870°C . Enantiomorphic. High (β) quartz is made up of SiO_4 tetrahedra, with Si atoms at the center of each tetrahedron. Tetrahedra are grouped to form regular hexagonal and trigonal helices, and their heights (referred to their Si atoms) are expressed as fractions of the c repeat distance. The helices of Si—O—Si—O... atoms are either all right-handed or all left-handed in each of the enantiomorphous forms of quartz. Upon cooling, β -quartz undergoes a displacive (second order) transformation to the familiar α -form. The structure of α -quartz is similar to that of β -quartz but the SiO_4 tetrahedra are less regular and are rotated from their ideal positions. The α -to- β transition was formerly thought to be a simple second-order transformation. It now appears that α -quartz undergoes a first-order transformation to an incommensurately modulated phase that is stable over a 1.3° interval. The intermediate phase is an ordered mosaic of Dauphiné microtwins that occur as triangular prisms elongate along c . The prisms grow finer with increasing temperature. The subsequent transition is probably second order. *AM 76:1018(1991)*. **Habit**: Commonly anhedral, equant grains. When in crystals, commonly prismatic to short prismatic with the $m\{1010\}$ m faces horizontally striated; terminated commonly by the two rhombohedrons $r\{1011\}$ and $z\{01\bar{1}1\}$. When one rhombohedron predominates, it is in almost all cases, r . Often in double six-sided pyramids or quartzoids through equal development of r and z . When r is relatively large, the crystal then appears pseudocubic. Occasionally distorted, twisted or bent. Twinning is fairly common and the commonest twin laws observed in α -quartz are: Dauphiné, sometimes called electrical twinning because the electrical polarity of the piezoelectric a axes is reversed in the twinned parts (twin axis c , twin plane $\{10\bar{1}0\}$), in which two right- or left-handed crystals interpenetrate; Brazil, sometimes called optical twinning because it can be easily detected between crossed polaroids (twin plane $\{1120\}$), in which right- and left-handed crystals interpenetrate; $\{10\bar{1}1\}$ and more rarely $\{0111\}$ serve as the composition planes in Brazil twins formed during growth. Japanese (twin = composition plane $\{1122\}$), and combined Dauphiné-Brazil. All four possible types of Japan twinning are contact twins

of two individuals, with the c axes inclined at $84^{\circ}33'$. Secondary Dauphiné twinning – Dauphiné twinning may be produced artificially in various ways: inversion from β -quartz when cooled through the α - β inversion point, by thermal shock produced by quenching from temperatures as low as 200°C , by the application of an intense electric field, by local pressure at room temperature or higher, by putting a thermal gradient in a cut plate as it cools through the inversion point, and by pure bending or torsion applied to cut plates at temperatures from 573° down to at least 300° . Dauphiné twinning disappears when quartz is heated over the 573° inversion temperature because the twin operation around the threefold axis of low quartz becomes an operation to identity in the sixfold axis of high-quartz. On cooling, Dauphiné twinning may or may not reappear. More than fifteen additional inclined-axis twin laws have been reported (*DS III:1962*). A number of twin laws of the {hohl} type are known in β -quartz, including the Sardinian {1012}, Esterel {10 $\bar{1}$ 1}, Belowda {3032}, Cornish {2021}, and doubtful {3021} laws. All can have geometrical equivalents in low-quartz. Of these only the Sella (Sardinian) {1012} and Reichenstein-Grieserthal {1011} laws have hitherto been described. The high-quartz Belowda {3032} law was recognized [*MM 21:368(1928)*] in a number of specimens from Belowda Beacon and Wheal Coates in Cornwall, England, and from the Esterel Mts., France. For β -quartz, twinning on {1011}, Esterel law, is very common; on {1122}, Verespatak law, less common; other twin laws are rare. So-called 'gwindels' are a growth phenomena where a series of quartz crystals joined with a prism face in common and parallel to one another have the c axis of each succeeding crystal in the stack slightly offset from the one under it. The result is the appearance that the composite crystal is a single crystal "twisted" about an a axis. They were first described by Kennegott in 1866 and are best known from the Swiss Alps, especially from many sites in the central Aar massif (e.g. the Grimsel region, Göschener Tal and Val Giuf). Other fine examples have been found in the region of Mont Blanc, France. **Physical properties:** Usually white or colorless. Also shades of gray, yellow to orange-yellow (citrine), purple and/or violet (amethyst), pink (rose quartz), and gray-brown, to brown, to nearly black (smoky quartz). May be colored by submicroscopic to visible inclusions of other minerals [e.g., chlorite (green), hematite (red-brown)]. Color-zoning commonly observed and may be patchy, irregular, or regular. Streak is white or may be faintly tinted in colored varieties. Luster is vitreous, sometimes greasy or waxy. Cleavage is rare on the positive rhombohedron (r) {1011} and negative rhombohedron (z) {0111}. Other rarely observed cleavages are on {1010}, {0001}, {1120}, {1121}, and {5161}. *AM 48:821(1963)*. Fracture is conchoidal, to a degree structurally controlled to produce flat conchoidal, uneven, splintery (massive varieties) and uneven, hackly or splintery (fibrous varieties). Brittle, cryptocrystalline varieties are tough. $H = 7$. $G = 2.65$ – 2.66 . Gravity of chalcedonic quartz is less and is variable (2.59–2.63) because of porosity, admixed impurities, and a content of nonessential water. Pyroelectric and piezoelectric. Color centers in quartz are best studied by EPR and optical absorption spectroscopy EPR has proven to be the most informative

method. Miscellaneous properties are discussed in *DS 7:116(1962)*. The hardness of β -quartz is also 7, and the specific gravity is about 2.35 (at 600°). Good {1011} cleavage and a {1010} parting is present in β -quartz. Fracture is conchoidal and the mineral is brittle. Crystals of β -quartz are always α -quartz paramorphs; typically dipyramidal; often rounded and rough. Enantiomorphous.

A list of the varieties of quartz in common use is as follows:

Crystalline varieties:

- Rock crystal—colorless, transparent.
- Amethyst—various shades of purple or violet; transparent to translucent.
- Citrine—pale yellow, yellow-brown, reddish brown. Transparent to translucent; often erroneously called smoky topaz.
- Smoky quartz—pale smoky brown to almost black. Transparent to nearly opaque; also called cairngorm or morion (black or very dark brown); often combined with amethyst.
- Rose quartz—pale pink to deep rose-red, occasionally with a purplish tinge; usually translucent, rarely clear; rarely in euhedral crystals; color may fade upon exposure to light or heat.
- Milky quartz—milky white to grayish white; translucent to nearly opaque; luster often greasy.
- Blue quartz—pale blue, grayish blue to lavender blue; translucent; somewhat chatoyant.

Crystalline varieties with inclusions:

- Rutilated quartz—contains distinct acicular rutile crystals in sprays or random orientation.
- Aventurine—spangled with glistening scales of micaceous minerals such as mica or hematite.
- Tiger-eye—finely fibrous, chatoyant; formed by complete or partial replacement of asbestos, especially crocidolite; yellow, yellow-brown, brown, reddish brown, bluish; also grayish green, green; cat's-eye quartz is closely related (shows opalescence).
- Ferruginous quartz—contains inclusions of goethite, hematite or other hydrous iron oxides; brown to red.

A variety of other minerals are found as inclusions in quartz crystals, including tourmaline, various amphiboles, stibnite, pyrite, scheelite, gold, copper, and epidote. Sagenitic quartz. May or may not produce asteriated quartz.

Cryptocrystalline varieties:

- Chalcedony—composed of microscopic fibers. Often mammillary, botryoidal, stalactitic, concretionary; as geodes; in veinlets; as pseudomorphs after other minerals; as a replacement of organic materials. Color white, grayish, blue, brown, black. Luster waxy. Transparent to translucent. Often fluorescent in various shades of green (due to incorporation of uranyl ion). Enhydros are nodules of chalcedony containing water. May be

intergrown with leuctecite (moganite). Some is optically (-), unlike true quartz. Structural water, as (OH), is present in Chalcedony (*AM 67:1248(1982)*).

- Agate—distinctly banded chalcedony with successive layers differing in color.
- Onyx—banded agate with layers in parallel straight lines; often used for cameos.
- Moss agate—gray, bluish, or milky transparent to translucent chalcedony containing dendritic inclusions.
- Sard—uniformly colored light brown to dark brown transparent chalcedony; sardonyx is banded sard.
- Carnelian—uniformly colored blood-red, flesh-red to reddish-brown translucent chalcedony.
- Chrysoprase—apple-green, Ni-bearing, translucent variety of chalcedony.
- Plasma—microgranular or microfibrous variety of quartz colored various shades of green.
- Prase—leek-green translucent variety of quartz.
- Heliotrope = bloodstone—greenish variety of chalcedony or plasma containing red spots of iron oxide.
- Flint—compact microcrystalline variety of quartz commonly found as nodules in chalk or marly limestone (e.g., White Cliffs of Dover).
- Chert—compact microcrystalline variety of quartz commonly found in bedded deposits or as lenses.
- Jasper—impure, opaque colored quartz; commonly red, also yellow, dark green, and grayish blue.
- Novaculite—compact microcrystalline variety of quartz of uniform texture frequently used for whetstones.
- Pseudomorphs of quartz, generally fine-grained, exist as replacements of minerals such as calcite, barite, fluorite, and siderite.
- Lechatelierite—naturally occurring fused quartz such as fulgarites from lightning strikes.

Various explanations have been given for the origin of the various colored varieties of quartz [e.g., *ANCH 12:283(1973)*]: (1) ions of transition metals or rare-earth metals that are incorporated in a state of atomic dispersion into the crystal structure, and cause selective absorption in the visible region of the spectrum because of their ligand field or electron transfer bands; (2) electronic defects, which are preferentially formed at structural faults (impurities, vacancies, or interstitial atoms) by ionizing radiation; by transfer of electrons, producing hole centers; (3) heterogeneous inclusions, which can cause selective absorption and scattering of light; in many cases these simply produce turbidity in the crystals. Color in SiO_2 has been summarized recently (*RIM v.29, Ch13:433(1994)*). Iron can occupy both substitutional (S sites) and interstitial (I sites) sites in quartz. The substitutional site is the tetrahedral, oxygen-coordinated silicon site. At least two interstitial positions exist.

Citrine—submicroscopic distribution of colloidal ferric hydroxide and oxides, as well as Fe^{3+} substituting for Si.

Rose quartz—Tyndall scattering by tiny oriented rutile needles and/or the presence of Ti^{3+} in channels and voids. Al^{3+} is usually also present. *MM 49:709(1985)*. Asterism in rose quartz is due to rutile needles. Massive rose quartz from pegmatites is colored by the above mentioned mechanisms. Transparent, single-crystals of pegmatitic rose quartz are colored by substitutional phosphorous (e.g. Sapucaia pegmatite, MG, Brazil).

Amethyst—color is produced by Fe^{3+} substituting for Si in tetrahedral coordination, and then the action of natural irradiation producing Fe^{4+} . The role of Fe-activated color centers was demonstrated conclusively. *PL 12:310(1964)*, *S 144:289(1964)*, *PCM 8:128(1982)*. Heating changes the color from blue-violet to gray-violet, to clear and sometimes to yellow (citrine). Heat-bleached material may be restored to its original color by X-radiation. Amethyst usually has both Fe and Al present in about equal amounts (Al is usually > Fe), to as much as 200 ppm. Heating of amethyst with ferrous iron present rather than ferric produces a transparent green quartz that has been called “praseolite” or “greened amethyst.” The color of amethyst is usually unevenly distributed in natural crystals. It is usually concentrated under the major rhombohedral face $r\{1011\}$ and often consists of a series of thin, dark bands which parallel the r and occasionally the $z\{0111\}$ faces.

Smoky quartz—color is related to the presence of Al^{3+} in the tetrahedral site. If Fe^{3+} is present in greater concentration than Al^{3+} , irradiation of clear quartz produces smoky quartz at first but further irradiation further ionizes the iron and causes charge transfer between Fe^{4+} and a trapped hole on an oxygen atom of the Al^{3+} tetrahedron producing amethyst. *AM 70:1180(1985)*, *71:589(1986)*, *60:338(1975)*. Heating (to $>225^\circ$) will decolorize smoky quartz.

Blue quartz—blue quartz phenocrysts such as those from the Llano rhyolite, Llano Co., TX, are colored by submicron-size inclusions of ilmenite which produce Rayleigh scattering. Other examples of blue quartz owe their color to submicron-size inclusions of rutile, tourmaline, or amphibole, and in rare cases to incorporation of Co. *ANCH 12:283(1973)*.

Ametrine is the trade name for unusual crystals of quartz that show amethyst and citrine sectors. *AM 71:1186(1986)*, *GG 30:4(1994)*. Major rhombohedral $r\{1011\}$ sectors are purple-bluish violet and the minor rhombohedral $z\{0111\}$ sectors are orange-yellow. The r sectors are invariably Brazil-twinned with both right- and left-handed quartz. The orange-yellow sectors show no twinning. Orange-yellow sectors have 68–125 ppm Fe, while the purple sectors have 19–40 ppm Fe. Al contents are low; otherwise, the samples would be smoky. Citrine also has more water than the purple. Amethyst sectors are pleochroic. Most citrine available is heat-treated amethyst from Maraba or Rio Grande do Sul, Brazil and Uruguay. Heating citrine causes a loss of color ($450\text{--}500^\circ$). The same is true for the amethyst (400°). The color of most amethyst fades upon exposure to sunlight. Some extremely dark Uruguayan

amethyst does not seem to be affected by sunlight. Irradiation restores the color.

Various cathodoluminescent colors (CL) have been reported for quartz: red, blue, violet, gray, rust, and brown. *CLGM: 37-56(1989), MM 52:669(1988)*. The intensity of quartz CL is weak compared to that of feldspars and carbonates and many other minerals. The CL of authigenic quartz is dull or nonexistent. Quartz CL is apparently often controlled by defects and crystal damage effects rather than by activators. CL color may change with time under electron bombardment. "Long-lived" red, blue, and violet CL displayed by igneous and metamorphic quartz remains stable or changes only slightly during electron bombardment. "Short-lived" blue, bottle-green, and violet CL exists in hydrothermal quartz. Reddish to bluish-brown CL that increases in intensity during excitation by electrons occurs in quartz of igneous, metamorphic, hydrothermal, or diagenetic origin. Response to SWUV and LWUV light is usually nil. Cryptocrystalline varieties may fluoresce green due to the presence of uranyl ions. **Optics:** α -Quartz is uniaxial (+); refractive indices show little variation from $N_O = 1.544$ and $N_E = 1.553$. Accurate measurements of optical-grade quartz of known purity (Na light) gave $N_O = 1.544258$ and $N_E = 1.553380$ (at 18°). Quartz that has been shocked at high pressures, such as those from meteorite impact structures, has somewhat reduced refractive indices (as low as $N_O = 1.476$, $N_E = 1.481$) as well as one or more sets of characteristic deformation lamellae parallel to crystallographic directions in quartz with or without accompanying diaplectic glass ($N = 1.460$ – 1.466). In some metamorphic and igneous rocks quartz develops undulatory extinction due to strain, and in such quartz fine curvilinear lamellae (Bohm lamellae) may occur. These lamellae are not to be confused with true shock lamellae resulting from the sudden application of high pressures. Some quartz, particularly rose quartz, is distinctly biaxial, with a $2V$ value as high as 8 or 10° . The development of anomalous $2V$ generally results from strain and may be removed by heating or recrystallization. The color centers (Fe^{4+}) in amethyst are responsible for the biaxial character. The presence or absence of twinning can be determined only in thick/thin sections. Absorption is normally $N_E < N_O$ but $N_E > N_O$ has been observed. β -Quartz is uniaxial (+) with $N_O = 1.5329$ and $N_E = 1.5405$ (Na light at 580°). **Tests:** Insoluble in all acids except HF. Soluble in molten Na_2CO_3 . **Chemistry:** Quartz is usually quite pure, but careful analytical studies have shown the presence of various trace elements in natural quartz. Ordinary clear and colorless quartz contains very few trace elements. Variable amounts (as much as 0.2% Al) of Al are present in all colored varieties of quartz and sometimes play a role in the development of color. Iron is usually very low in smoky quartz but is present to as much as 0.3% in rose quartz. Li, Mg, Ti, and Ca are other elements that have been detected in quartz. As much as 500 ppm Ti is present in rose quartz. Fluid inclusions are often present and result in the presence of water, halides, and other daughter products. **Occurrence:** β -Quartz occurs mainly in cavities or as phenocrysts in rhyolite and other acidic rocks. Next to the feldspars, quartz is the most abundant mineral

in the Earth's crust. α -Quartz occurs in most geological environments and in most igneous, metamorphic, and sedimentary rocks. It also occurs in veins and in graphic granite. Quartz may be of multiple generations (e.g., authigenic overgrowths on detrital grains). **Localities:** Because quartz is one of the most common minerals, only those localities that yield unusual crystals or exceptionally fine specimens can be mentioned here. Brazil is the world's premier producer of the principal varieties of crystallized quartz (i.e. rock crystal, amethyst, citrine, rose, smoky, and rutilated), and is also the major producer of agate. The largest well-formed quartz crystal (20 ft long, 5 ft across each prism face, and weighing >44 tons) is from Manchao Felipe, Itapore, Goias, Brazil. Individual crystals weighing more than 800 lb were found in Alpine quartz veins in Switzerland. *Rock crystal and clear quartz:* Fine pseudo-cubic crystals occur at the Tamminen quarry, Greenwood, ME; "Herkimer diamonds" are found near Herkimer, Little Falls, Fonda, and Middleville, NY. The crystals occur in the Little Falls (Cambrian) Dolomite; they are highly perfect, transparent, usually equant, and range from 1 mm up to about 4cm, although larger ones are occasionally found. They are commonly single and usually show no point of attachment ("floaters"); associated minerals are normally lacking, except for occasional masses and included blebs of bitumen. Clear quartz occurs at Ellenville, Lake George, Diamond Point, and Diamond Isle, Warren Co., NY. Some of the most famous and prolific localities in the world for fine, clear, and beautifully shaped clear quartz crystal are near Hot Springs, Jessieville, and other areas in Garland Co., AR; also in Saline and Montgomery Counties, AR; Mt. Antero and Mt. White, Chaffee Co., CO; White Queen, Elizabeth R, and Tourmaline Queen mines, Pala district, Little Three mine, Ramona, and Himalaya dike system, Mesa Grande, San Diego Co., CA. "Lake County Diamonds" occur in rhyolite, Clear Lake region, Lake Co., CA; one of the most familiar occurrences to the public of generally colorless but rarely amethystine quartz are the linings of walls of hollow "coconut" concretions formed in an altered volcanic ash deposit in north-central Chihuahua about 120 km north of Chihuahua City; in England fine crystals come from Frizington, Cleator Moor, and Alston Moor, Cumberland; in Switzerland at the Zingenstock, Canton Bern and large crystals to 625 kg (1,400 pounds) from alpine clefts between M \ddot{u} nster and Laax in Oberwallis (upper Valaise); in Austrak in the Pinzgau district, Salzburg; in the Stubachtal in the Oberpinzbau in the Gross Glockner where the largest crystal found (in 1962) was 618 kg (1360 pounds); also in alpine veins at Gastein, Rauris, Kaprun, Zillertal, Gelbernbachtal, Habachtal, Untersulzbachtal, and Pragraaten; from alpine veins in the Austrian Tyrol (e.g. Laperwitzkees); white, opaque exteriors on clear quartz at Suttrop in Westphalia, Germany; fine quality, limpid, equant crystals occur in the famous Carrara marble quarries, Tuscany, Italy; limpid crystals known as Paphos diamonds have been known since ancient times from the vicinity of Paphos, western tip of Cyprus; the gem-bearing pegmatites of the Nuristan district, Laghman Prov., Afghanistan often yield large quartz crystals in addition to the more famous spodumene, tourmaline, topaz and beryl crystals for which they are noted; "Kaysumah

diamonds" occur at Al Quasumah, Saudia Arabia; at Sakangyi, Katha District, Burma, a 700 kg flawless crystal was recovered, from which a sphere nearly 33 cm in diameter and weighing more than 48 Kg was made, and is now at the Smithsonian Institution, Washington, D.C. For many centuries, Madagascar was the world's premier source of rock crystal, used almost exclusively in the arts; the crystals occur in cavernous veins in quartzite in the northern part of the island, and to a lesser extend from pegmatites, much of the latter being smoky. Occurs at a number of localities in Australia including: Stonyfell and Ashton near Adelaide; also in veins in Pre-Cambrian quartzite at the White Rock quarry at Horsnell Gulley, Magill, in the Giles Range, 30 km east of Adelaide; Newstead tin mines, New England, NSW; Maldon and Bendigo, northeast of Melbourne, VIC. The largest well-formed quartz crystal on record (6.1 m long, 1.5 m across each prism face, and weighing >44 tons) is from Manchao Felipe, Itapore, GO., Brazil. Two major districts for crystals, from veins in quartzite, are at Diamantina and Corinto, MG, and a further one at Cristalina, GO. Much of this quartz is used to make "lasca" (fragments of quartz crystals used as a raw material in the manufacturing of synthetic quartz crystals or for fusing); the production amounts to hundreds of tons/year. In addition, very large quantities of slightly less pure quartz are used for electric furnace production of silicon metal. Additional applications for clear crystals are for the electronics industry, and for optical purposes. Other Brazilian localities for fine crystals are Brumadao, BA (superb Japan law twins); the Morro Velho gold mine, Nova Lima, MG; Novo Horizonte (formerly Ibitiara) BA where fine gwindels have been found; and many of the pegmatites in eastern MG. In Chile from La Serena, 700 km north of Santiago and from Inca de Oro, 8 km north of Copiapo. *Smoky quartz*: from pegmatites in Oxford Co., and Androscoggin Co., ME; Moat Mountain, and Sugarloaf Mtn., NH; Lake George ring, Devils Head and other localities in the Pikes Peak batholith, CO; Sawtooth batholith, Salmon, Idaho; 19-mile district (Pipestone district), Jefferson Co., MT; Sierra Blanca, Otero Co., NM; Little Three mine, Ramona, San Diego Co., CA; Cairngorm Mtns., Banffshire, Scotland, and the Mourne Mountains, Ireland; with pink octahedrons of fluorite from the Mont Blanc region, near Chamonix, France; the Swiss Alps, including St. Gotthard, Ticino (Grimsel region); Val Tavetsch, Grisons; Val Cavradi, Graubunden; Göschener Alp, Uri, and others such as Zinkenstock near Grimsel Pass and Tiefen Glacier in Uri which produced fine material in the last century. In Italy from Aosta, and other localities in Prov. Piemonte; from the Carrara marble quarries in Tuscany; from Poretta, Emilia; the island of Elba; classic localities in Austria include: Knappenwand, Salzburg; Saualpe, Carinthia; Schwemmhoisl quarry, Stiermark (Styria), and huge crystals from the Eiskögele, Salzburg; in Russia from the Ilmen Mtns., Urals; at Mursinka, Alabashka, Sherlova Gora, and other pegmatite fields; at Kingsgate mines, NSW, Australia; Alto Ligonha district, Mozambique; fine crystals from several localities in Madagascar. In Brazil many pegmatites produce fine smoky quartz, especially in MG: Arassuai, Itinga, Coronel Murta, Barra de Salinas, Galileia, São Geraldo do Baixio, Divino da Laranjeiras, Consel-

heiro Pena; and in ES: Baixo Guandu, Mimoso do Sul, and Fundão. Also from Conselheiro Pena, Corrego do Urucum, Corrego Frio, Cruzeiro, Arussuai area, Campo do Boa, Lavra da Ilha, near Taquaral, the Morro Velho gold mine at Nova Lima; Korea). *Rose quartz*: Discrete crystals of rose quartz are rare but have been found at a number of world localities: in ME from Dunton quarry (rough crystals to 1 cm), Nevel Quarry and Rose Quartz Crystal area, Newry, Oxford Co., also from the Red Hill quarry, Rumford; massive rose quartz (many tons) occurs at the Bumpus quarry and Scribner's Ledge, near Albany; also at the Whispering Pines quarry, Paris, Oxford Co.; rose quartz masses to 25 cm suitable for gem purposes and of the deepest rose red found anywhere at the Hibbs quarry, Hebron, Oxford Co. (including Antsirabê, Madagascar; the Sapucaia pegmatite, Conselheiro Peña, Lavra da Ilha on the Rio Jequitinhonha near Itinga, Taquaral, Pitorra quarry, Linopolis and several localities in Galileia; all in Minas Gerais, Brazil) in NH at the Charles Davis quarry, North Groton; also at Acworth; Williamsburg, MA; in pegmatite at La Grange, Troup Co., GA; the Scott Rose Quartz Quarry, French Creek, Custer Co., SD is one of the largest deposits of rose quartz in North America (reserves have been estimated at 600,000 tons); Rabenstein, near Zwiesel, at Hühnerkobel near Bodenmais, and at Schwarzenberg, in Bavaria, Germany; top quality rose quartz with saturated color occurs in beryl-bearing pegmatites near Sahanivotry, and Samiresy, Madagascar; in large amounts from Rössing, Swakopmund, Namibia; reported from Warangal, Hyderabad, and Chindwara, India. In Brazil, large amounts are produced at Alto Feio, Rio Grande do Norte, PB; Riberao do Largo, 45 km from Vitoria da Conquista, and Macarani in BA. Brazil has at least four major localities for crystalized rose quartz, the least of which is superior to any other known locality worldwide. All are in MG: Sapucaia do Norte, Municipio Divino de Laranjeiras; Piabanha and Pitorra, Mun. do Galileia; Lavra de Ilha (island in the Jequitinhonha River), Mun. do Itinga; and Coronel Murta. Other localities such as Taquaral and Sapucaia have also produced fine material. Superb, deep-colored massive material is also found at Joaima, MG (Jour. of Gemmology 22:273(1991)). *Amethyst*: In ME very fine material is found in pegmatite at the Intergalactic pit, Deer Hill, Stow, Oxford Co., ME; very fine material occurs at the Warren farm, Pleasant Mountain, Denmark, Plumbago quarry, Sweden, Oxford Co., ME; Green's ledge, Milan Twp., and Diamond ledge, Stark Twp., Coos Co., NH; Hopkinton, RI; from PA at Media, Upper Providence Twp., and other localities in Delaware Co., and also from Chester Co.; in Va. from Amherst and Nelson Cos.; in NC at localities in Alexander, Iredell and Macon Cos. and at Iron Station, Lincoln County; Keweenaw peninsula, MI; Pohndorf pegmatite, 19-mile district, Jefferson Co., MT; Yellowstone Park, WY; in Colorado, at the Crystal Hill mine near La Garita, Saguache Co; massive amethyst occurs in the Creede district, Mineral Co., also at Red Feather Lakes area (Rainbow Lode mine or Pennoyer amethyst mine), Larimer Co.; Amethyst Queen claim, Unaweep Canyon, south of Grand Junction, in Mesa Co. Amethyst crystals line vugs in quartz veins and other voids in a brecciated zone in the Four Peaks area, Mazatzal Mountains, Maricopa Co., AZ; about

45 mi. NE of Phoenix (found about 1900); the Four Peaks amethyst is unique because of having well-developed "c" pinacoid faces; also heat-treatment turns the crystals green rather than citrine colored; amethyst and smoky quartz occurs at Peterson Mtn., Hallelujah Junction, NV-CA border. Some of the most spectacular and valuable amethyst specimens (sharp, lustrous scepters to 5-6 cm long) ever found in North America have come from Denny Mountain, King County, SE of Seattle, WA; in Canada at Thunder Bay, Ontario one of the largest amethyst occurrences in the world (associated minerals include fluorite, calcite, barite and minor amounts of the common sulfide minerals). Amethyst at Thunder Bay was mentioned as far back as 1846. Amethyst also occurs at the Dzuba mine at pass Lake-Elbow Lake, Ontario; Bay of Fundy, Nova Scotia; in Mexico at Mina la Veronica, Piedra Parada, Las Vigas, Ver.; Guanajuato, Gto.; royal purple crystals to 40 cm long at Amatitlan, Guerro; unlike most amethyst occurrences, the color is usually concentrated near the base, and the crystals often show a Dauphine habit; deposits are found in France in the Auvergne, around Puy-de-Dome, near Vernet-la-Varenne, Condat, Chateauneuf, Champagnat, and Escout, and at Bansat, near Lamontgie; Teiser Kugele (geodes) occur in the Italian Tyrol near Teis (Tiso) and at Zillertal, in the Austrial Tyrol; at Schemnitz, Slovakia; and at Pokura near Nagy-Ag in Transylvania, Romania. Pokura, Hungary; occurrences in Russia include: in pegmatites at Mursinka, middle Ural Mtns., Chassawarka in the southern Polar urals; Sanarka River area, southern Urals; Nerchinsk (now Chita) district, Transbaikal region and in Yakutia; at the Onyang mine, Onyang-Myon, Ulson-Gun, Korea; Madras, India; also from Sri Lanka. In Madagascar (particularly in pegmatites) at such localities as Vatomandry, Mahasolo, Broiziny, Tsaratanana, Soavinandriana, and Ambatofinahdrahana; large geodes (to two feet in diameter) lined with fine dark crystals that can be "burnt" to a fine "Madeira" citrine color occur on the Skeleton Coast, 65 km from Cape Fria, Namibia; spectacular material with clear, smoky and amethyst zones occur at Brandberg, about 160 km north of Swakopmund in NW Namibia; the most important amethyst deposit in Africa was discovered in 1956 in southern Zambia in the Kalomo district where it occurs in hydrothermal veins in granulite gneisses. The amethyst occurs in large crystals up to 1 foot long with zones of dark color from which stones called "Siberian" can be cut; amethyst localities in Australia include: Corona, near Broken Hill, NSW; Culladilla, near Mt. Isa, Q; the area of Beechworth in northeast VIC, 40 km southwest of Wodonga; the most important amethyst mine in Australia is at Wyloo Station in WA, about 985 miles north of Perth; In RS, Brazil, amethysts occurs around Ametista do Sul (formerly Planalto); Iraí and Frederico Westphalen are nearby districts that produce smaller quantities, as well as from the San Eugenio district, Dept. Artigas, Uruguay. The amethyst occurs in geodes which can measure up to 3 m in length and weigh 1800 kgs. Individual crystals are up to 10 cm in length and the druses may be thinly studded with white to yellow calcite crystals. This is by far the world's largest source of amethyst geodes, both in quantity and quality; the total production in 1994 was in excess of 500

tons. Amethyst is also found as veins in quartzites and arenites at Maraba and Pau d'Arco, PA; at the former, very large crystals up to $40 \times 40 \times 80$ cm have been produced; the latter produces the best cutting-grade amethyst in Brazil. Other Brazilian localities are Brejinho das Ametistas and Jacobina, Bahia; Santa Quitéria, CE; and as late-stage crystallization products around the quartz cores of pegmatites at Ataleia and Fernandes Tourinho, MG; and Fundão and Mimoso do Sul, ES where fine bicolor "scepters" over milky quartz are found. Amethyst-citrine combination (ametrine) occurs along faults in dolomitic limestone at the Anahí mine, in the Irma Bush Province of Santa Corazon Canton in the Dept. of Santa Cruz, eastern Bolivia, near the Brazilian border. Since 1989 more than 100 metric tons of rough crystals have been produced; most crystals are highly etched (G&G 30:4(1994)). Occurs in Brazil as geodes and cavity fillings in intermediate to acid flows in flood basalt provinces e.g., Parana Basin, RGS; at Brejinho das Ametistas, southwestern BA; also occurs as veins in quartzites and quartz arenites e.g. Maraba, near Alto Bonita, PB; Jacobina, Vitoria da Conquista, BA, and as a late-stage crystallization product around the quartz cores of pegmatites, e.g., MG and ES. *Citrine*: Natural citrine is rarer than amethyst and smoky quartz. It occurs chiefly at localities for amethyst, and principally as zones of citrine in amethyst: Isle of Arran, Scotland; Salamanca Prov., Spain; Dauphiné, France; Mursinka, Urals, Russia; Hyderabad, India; Madagascar; Anahí mine, Bolivia; excellent natural dark orange-brown citrine crystals were found at the Morro do Cristal, Campo Belo, MG Brazil, and at the Morro Redondo mine, Coronel Murta, large quantities of excellent dark citrine have been found since 1992, mostly broken pieces rather than well-formed crystals. *Blue quartz*: blue quartz is found in the Milford granite, Rhode Island; Cornog, PA; Nelson, Amherst, and Stafford Counties, VA; Llano, Llano Co., TX; and other world-wide localities. *Japan law twins*: rare, but fine-quality twins occur in the Hot Springs district, AR; at Capitan Mountain, Otero Co., NM; King County, WA; in AZ at Hamburg Cochise Co., and at the Holland mine, Washington Camp, Santa Cruz Co., which has produced thousands of twins, some of which may reach the size of 30 cm from tip to tip; also from the Cooper and Green Monster mines on Prince of Wales Island, AK; In France, fine twinned crystals from the La Gardette mine, near Bourg d'Oisans, Isere (Dauphiné), was the first locality noted for Japan-law twins which were known as La Gardette twins in 19th century literature; from Val Bedretto, Ticino Canton, Switzerland; in cavities in quartz porphyry at Saubach, Saxony; a Japan twin 26 cm high and 6 kg in weight was found at Gudzhivass in the Pamir Mountains, Tadzhikistan. The most famous locality for these twins is at Otomizaka, Yamanashi Prefecture, where beautiful twins up to half a meter across occur in granite pegmatite and quartz pegmatite. Also at Narushima Island, Shimo-goto, Nagasaki Pref.; from the Siglo XX mine at Llalagua, Dept. Oruro, Bolivia, in sulfide veins; some quite large twins and often showing virtually no re-entrant angle are found at Brumado, Bahia State, Brazil. A perfect quartz twin on {3032} was found at the Ariranha mine, Teofilo Otoni, MG, Brazil. *Quartz with inclusions*: The finest locality for ruti-

lated quartz is Novo Horizonte (formerly called Ibitiara), BA, Brazil. Here the rutile is a bright golden yellow color, sometimes radiating outward epitaxially in a six-rayed star from a crystal of hematite embedded in the quartz. Most rutile in quartz is brownish-red to red, and the gold color from this locality is due to an abnormally low iron content (around 0.5 wt. %); a more normal content would be at least double that. The needles may be curved, suggesting that the rutile was in place before the quartz began to crystallize. Another prolific producer of rutilated quartz is Oliveira dos Brejinhos, BA. Other minerals included in Brazilian quartz are anatase, schorl, various amphiboles, pyrite, and others. Anatase in quartz crystals is found at Diamantina and also at Novo Horizonte, BA; it can be caramel to brown colored, sometimes with delicate thin rutile, a dramatic combination. Well-formed, bright pyrite crystals in clear quartz crystals come from Serra do Cabral, MG; the crystals are usually pyritohedrons, and reach a size of 2 cm. Quartz with schorl needles is abundant at Jaguaracū, MG and was mined there for decorative uses; minasgeraisite and milarite were found in the same deposit. *Quartz phantoms*: Blue "phantoms" quartz, from Morro do Serrote, Regisitro, SP is caused by a light coating of fine-grained riebeckite growing on the crystal termination at various stages of growth. White (etched or frosted surface), grey (sandy inclusions), green (chlorite), or reddish-brown (ferruginous matter) phantoms are found at Diamantina, also at Serra do Cipo, MG. The phantoms may be repeated several times, revealing successive stages in the growth of the crystal. Fantastic emerald-green phantoms come from Pakistan. *Shocked quartz*: Shocked quartz from the Cretaceous-Tertiary boundary occurs at numerous world-wide sites (e.g. Brownie-Butte, MT; Haiti, Stevns Klint, Denmark; Gubbio, and Pontedazzo, Italy; Caravaca, Spain; Woodside Creek, NZ ((S 224:867(1984), S 236:705(1987))). Such quartz also exists in the fallout ejecta and in impactite materials from meteorite impact structures (e.g. Ries crater, Germany). *Cryptocrystalline varieties*: Novaculite (used for sharpening stones), in the form of metaquartzite, occurs in the Novaculite mountains, Hot Springs Co., AR. Occurrences of carnelian, agate, chalcedony, jasper, and other cryptocrystalline forms of quartz are exceedingly numerous world-wide. Chrysocolla-stained chalcedony occurs in the Globe district, Gila Co., AZ and is especially prized because of its vibrant blue color. "Sweetwater agates" characterized by fine black dendrites occur scattered over the surface in an area north of the Sweetwater River in Fremont Co., WY. "Montana agate" occurs in gravel bars and river terraces along the course of the Yellowstone River in the central and eastern part of the state. The original source has never been located. Fine quality blue chalcedony comes from near Mojave, Mojave Co., CA; The Priday Ranch of the Richardson Recreational Ranch, near Prineville, central Oregon, is one of the best known localities for "thundereggs" (agate fillings of lithophysae in air-fall welded rhyolitic tuffs, or vitrophyres). Fine fire agate occurs at various localities in San Luis Potosi and north of Guadalajara, Jal., Mexico. Unusual chalcedony stalactites are found near Camborne, Cornwall, England. Colorful banded agate occurs near Fofarshire and Perthshire, Scotland; stalactites from

amygdaloidal cavities are found in the Faeroe Islands. Fine carnelians and agates are found in India. Agate and carnelian were formerly found at and around Idar-Oberstein, Rhineland, Germany; the cutting and polishing of these stones started at least 700 years ago and resulted in the founding of this large community almost exclusively devoted to the lapidary arts. A famous locality for jasper for lapidary purposes is at Orsk, Ural Mountains, Russia; so-called Botswana agate, which is beautifully banded comes from unspecified localities in Botswana; fine (\$2.00/gram wholesale) blue chalcedony, known since the 1930's, comes from Namibia; important agate and jasper deposits are associated with the Deccan basalt flows in India; chalcedony and agate has been known for hundreds of years from near San'a, Yemen; fine agate and chalcedony occurs at Agate Creek, on the north slope of the Gregory Range, in northern Q, 350 miles inland from Cairns, Australia, "mookite", a colorful type of jasper occurs at Mooka Station, WA; in Brazil, enormously prolific agate deposits are found in the Parana Basin, RS, particularly on the outskirts of Salto Grande on the banks of the Jacui River. The basalt flows from which these chalcedony and agate nodules are derived extend for 1200 km, from SP to PR, SC and RS states and are up to 1000 m thick. Most of the agate/chalcedony comes from the Salto do Jacui district, RS. In 1994, the production totaled about 2000 mt.; this is the world's main agate producer. In addition, fine jasper and bloodstone are produced in the district. Agate and carnelian are found in the provinces of Corrientes and Entre Rios, Argentina; Fine chrysoprase occurred at Exeter, Porterville, Visalia and Lindsay, Tulare Co., CA; deposits of fine chrysoprase occur near Frankenstein, Silesia, Poland, but they are now nearly exhausted. What many consider to be the world's best chrysoprase occurs at Marlborough, a small town some 100 km northwest of Rockhampton, Queensland, Australia. "Tigereye", a silica replacement of "crocidolite" asbestos, occurs in several world-famous localities including: the area of Griquatown in the Doornbergen (Asbestos Mountains) north of the Orange River, South Africa, is the most important occurrence of yellow tigereye and hawkeye (colored blue due to the less altered crocidolite); mostly yellow-brown tigereye also occurs in iron ore deposits, near Wittenoom Gorge, WA, Australia. Petrifications (replacements of organic material) of quartz are also numerous world-wide. Petrified wood replaced by silica is abundant. More famous localities include: perhaps the world's best known petrified forest is preserved in the Arizona Petrified Forest National Monument which is located northeast of Holbrook and straddles Navajo and Apache Counties, AZ; fossil dinosaur bone from numerous Mesozoic deposits in the western USA is replaced by silica; petrified forests are preserved in Yellowstone Nat. Park, Wyoming; at Hilbersdorf, a suburb of Chemnitz, Germany; another petrified forest occurs on the island of Mytilene in the northeastern part of the Aegean Sea, Greece; a petrified forest is preserved in the Cerro Cuadrado Petrified Forest, Neuquen Prov., Patagonia, Argentina. Uses: Quartz in its many forms, is one of the most important of all mineral commodities on a world-wide basis, and is exceeded in tonnage and value by only a few others such as iron ore, coal, or limestone. The principal uses in the U.S.

are, in decreasing order of value, the glass industry; foundry sand; abrasive sand; and hydraulic fracturing sand (used in the petroleum industry), with a total value of about \$400,000,000. The manufacturing of silicon metal, ferro-silicon, and silicon alloys also consumes about a million tons/year of high purity quartz. This type of quartz, usually >99.6% SiO₂, is found in the quartz cores of pegmatites, pure quartzites, and other related geological formations. Even larger quantities of less pure quartz, >90% SiO₂, is used as a flux in making steel and in other metallurgical processes.

The first synthetic crystals of quartz of appreciable size and quality were produced in 1905. Crystals are grown hydrothermally, using as the raw material "lasca" (fragments of highly pure quartz crystals). These artificial crystals are preferred because they are free from twinning, to which most natural crystals are subject; twinning renders the crystals unsuitable for piezoelectric applications. The piezoelectric property of quartz has resulted in its use for oscillator plates for controlling and stabilizing the frequency of electronic oscillator circuits, e.g. for radio transmission or reception, or for time keeping (mostly satisfied by synthetic material).

Of all of the minerals used as gems, none compares with quartz in its diversity of occurrence and in abundance of varieties. There are two groups: coarsely crystalline varieties (which many refer to as quartz) and fine-grained, microcrystalline to cryptocrystalline varieties (chalcedony, agate, etc.). EF *D6:183(1892)*, *DIII(1962)*, *MIN II(2):143(1965)*.

75.1.4.1 Coesite SiO₂

Named in 1954 by Sosman for Loring Coes, Jr. (1915–1973), American chemist, Norton Company, who first synthesized the phase. Polymorphous with quartz; tridymite, cristobalite, and stishovite. MON pseudo-*HEX C2/c*. $a = 7.135$, $b = 12.372$, $c = 7.174$, $\beta = 120.36^\circ$, $Z = 16$, $D = 2.92$ (also reported as dimensionally hexagonal with $a = c$ and $\beta = 120^\circ$). *14-654*: 3.44₇ 3.10₁₀ 2.77₅ 2.71₇ 2.30₅ 2.19₅ 2.04₇ 1.717₇. Structure: *ZK 167:287(1984)*. The structure is dominated by four-tetrahedron rings linked into a three-dimensional tetrahedral framework, distinct from other tetrahedral silica structures but related to the framework of feldspars. Irregular grains 5–50 μm in diameter. Synthetic material forms minute, lathlike {010}, dominant crystals with a morphology reminiscent of gypsum. Twinning on {001} and {021}. Colorless to white, vitreous luster, transparent to translucent. Subconchoidal fracture. $H = 7-8$. $G = 3.01$. Biaxial (+); $2V = 54-64^\circ$; $N_x = 1.594$, $N_y = 1.595$, $N_z = 1.599$; $X = b$; $r < v$, weak; in aggregate may appear isotropic with $N \approx 1.595$. Chemical analyses indicate >99 wt% SiO₂. Formed at elevated temperature (500–800°C and $\approx 30-35$ kbar). Pseudomorphs of quartz after coesite are commonly encountered. Coesite forms in high-pressure, high-temperature environments such as shocked materials of impact craters, crustal eclogite facies, and possibly high-grade blueschist facies metamorphics. Found in fossil impact craters at Sinking Springs, OH, and at Kentland, Newton Co., IN; as a fine-grained, nearly isotropic groundmass in shocked Permian Coco-

COESITE

Coesite: Perspective view approximately along c.

nino sandstone at *Meteor Crater, Coconino Co., AZ*; as inclusions in clinopyroxenes at *Grytting, Norway*; in stressed granite at the *Rieskessel meteorite crater, Bavaria, Germany*; in eclogite in the western Alps, Italy; at the *Wabar meteorite crater, Al Hadida, Rub'-al-Khali, Saudi Arabia*. Found as inclusions in zircon in diamond-bearing gneiss of the *Kokchatov massif, Kazakhstan*, and in diamond from the *Anabar alluvial deposits, Yakutia, Russia*; in eclogite near *Xinxian, Henan, and Dhonghai Co., Jiangsu, China*; as inclusions in omphacite in an impure marble at the northeastern edge of the *Gourma Basin, Mali*; and in the *Roberts Victor kimberlite, Cape Prov., South Africa*. 75.2.1.1 Opal $\text{SiO}_2 \cdot n\text{H}_2\text{O}$

Known as a gemstone since antiquity. The oldest known source of the word *opal* is from the Sanskrit *upala*, stone or precious stone. The Romans used the word *opalus* and the word *opal* is clearly derived from this. Amorphous (some opal) or more often disordered crystalline, for most common opal, possessing the structure (as disordered interlayers) of low-temperature cristobalite and/or low-temperature tridymite. Opals consist of structural units of amorphous SiO_2 and crystalline cristobalite (and/or tridymite). Gem opals are the least crystalline type (opal-AG) of opal. Precious opal (especially that from sedimentary deposits) is a mixture of amorphous and crystalline silica (low tridymite), with the former being dominant. The extent of crystallinity varies between samples from different localities. 38-448: 4.08₁₀ 3.14₁ 2.86₁ 2.51₃ 2.13_{0.5} 2.03_{0.5} 1.94_{0.5} 1.88_{0.5}. ICDD card has schematic patterns for the three main types of opal: CT (cristobalite-tridymite), C (cristobalite), and A (amorphous). Information regarding the distinction between well-ordered

opal-CT and opal-C from high-temperature β -cristobalite by X-ray diffraction is given in *ACA 286:107(1994)*. The characteristic play of colors present in precious opal is due to optical diffraction from a randomly faulted, close-packed ordered array of minute (typically $0.25 \mu\text{m}$) transparent silica spheres. The diameter of the spheres is of the order of one-half the wavelength of visible light, and the play of colors depends on the size, uniformity, and uniformity of packing of the spheres and the extent of faulting. *AC(A) 24:427(1968)*, *MR 2:261(1971)*. In potch opal, often associated with precious opal, the spheres are not uniform in size or shape. Opal has been divided into a number of types and subcategories [*JGSA 18:57(1971)*, *FM 52:17(1974)*, *NJBM:81(1990)*]: Opal-A is amorphous with one diffuse diffraction band. Opal-AN (amorphous network) has a glasslike network (including hyalite), and opal-AG (amorphous gel) has a gel-like structure (precious and potch opal) due to H_2O and OH incorporation. Opal-C has a sharp X-ray pattern for low cristobalite and sometimes minor tridymite is present. The mineral is not true cristobalite because when heated it does not transform to high cristobalite. Opal-CT has a broadened X-ray pattern but with well-defined peaks for low cristobalite. Variable degrees of stacking disorder are present, leading to maxima attributable to low tridymite. Opal-CT typically occurs as lenticles and also as fibers. Opal-CT includes common opal and some precious opal. Opal-CT has been further subdivided by some investigators, and a simple classification seems preferable: opal-CT_M, referred to as massy opal, shows no texture resolved with a polarizing microscope. Opal-CT_P is platy in habit. Opal-CT_L (L = lussatite) is fibrous with positive elongation, fiber axis [101] using indices of tetragonal low cristobalite. It can vary from opal-C_L to opal-CT. Opal-CT has also been interpreted as showing long-range ordering of oxygen atoms followed by short-range ordering of Si atoms. *AM 72:1195(1987)*. Opal-CT has a ^{29}Si MAS NMR spectrum much more like that of amorphous SiO_2 than that of cristobalite or tridymite. In volcanic rocks, one gets opal-AN or opal-CT_L. Opal-C occurs as horizontal layers on the bottom part of agate nodules and geodes of the Uruguay type, associated with chalcedony. Opal-C_M and opal-CT_M are massive in texture. All opal-CT will have $\bar{N} = 1.43\text{--}1.46$. Opal C_L and opal-CT_L are birefringent. Massive and platy varieties are isotropic or nearly so. Some opal in fossil wood is all high tridymite (\pm quartz) or more rarely low cristobalite, along with variable water content. Chalcedony, on the other hand, is a fine-grained, fibrous variety of quartz with little or no water content. It has a negative optical character of fiber elongation (length-fast). The fiber axis is one of the trigonal a axes. The quartz fibers are composed of submicroscopic {1011} lamellae, polysynthetically twinned left- and right-handed according to the Brazil law. It may have 1–2 wt % H_2O . The water is present in open porosity on crystal surfaces and in closed micropores on inner surfaces. Water is also present in regions of accumulated defects. Quartzine is a length-slow chalcedony and has positive elongation, with the fiber axis being c . Opal-C may occur as horizontal layers in the lower part of agate nodules and geodes of the Uruguay type, associated with chalcedony. It can also occur in cavities in volcanic rocks, possibly

formed by later recrystallization by further heating. Opal-CT is widespread and may be found as accretions in both volcanic and sedimentary rocks. It is also common in some earthy materials such as some deep-sea sediments and some forms of opal claystone, tripoli, and opoka (Russian). Opal-A is widespread in deep-sea deposits as the remains of diatoms and radiolaria, and on land as large deposits such as diatomite. It also occurs as potch opal, with which may be associated gem-quality material. Both opal-A and opal-CT may be found replacing wood, with remarkably detailed preservation of the cellular structures. Opal occurs as coatings, stalactites, nodules, concretions, crusts, pseudomorphs, after other minerals, such as ikaite ("opal pineapples"), gypsum, calcite, aragonite, apatite, siderite, and others. It occurs as botryoidal, reniform and globular masses, and various earthy aggregates or massive material. Numerous names have been given to opaline materials of differing morphology: geyserrite and siliceous sinter—opal associated with volcanic activity and hot springs, forming terraces, basins, and cones; (diatomite) diatomaceous earth—earthy to soft deposits made up of the remains of tiny organisms such as diatoms, tripolite—a variety of diatomaceous earth, usually opal-A; opoka, opal claystone—earthy material often showing little evidence of biogenic remains; commonly opal-CT; fire opal—vitreous, transparent to semi-transparent with yellow, orange, red, or brown body color, with or without play of color, sometimes cut as a gemstone; precious opal (= noble opal)—opal showing play of color caused by optical diffraction from the regular packing of silica spheres, with white and black subtypes being distinguished based on the body color; girasol opal—transparent opal showing some play of color, relatively transparent, with a rather uniform bluish or reddish floating or wavy type of internal light; common—a general term for any type of vitreous opal showing no play of color and is not associated with precious opal; hyalite (= water opal)—colorless and transparent opal that looks like congealed droplets of glass. Much of this type of opal is believed to have been deposited from an aqueous vapor phase ($> 100^\circ$). Hyalite is thus genetically distinct from most opal. Regular opal is deposited from aqueous solutions or as a colloid (gel); moss—common opal patterned with dendritic growths of metal oxides; milk—translucent to opaque common opal with a milk white, pale bluish white, or greenish white color; wood opal—wood replaced by opal, with or without preservation of the woody structure; plant opal—opal particles formed in many types of plant growth, especially in grasses and eucalypts; cacholong—chalky white and completely opaque opal; hydrophane—a type of cacholong that has an affinity for water. Turns from opaque to highly transparent when placed in water; tabasheer—a milky white opaline silica deposited in the joints of bamboo plants; potch opal—a term applied to non-precious opal, usually gray to black in color, associated with gem material, especially in the Australian opal fields. Other terms, such as cherry opal, pinfire opal, harlequin or mosaic opal, contra-luz opal, boulder opal, and jelly or water opal, are used to further describe precious opal. **Physical properties:** Opal is generally white or colorless but may also be just about any other color: yellow, red, orange, green, brown, blue, black, and others. They also

show multicolored opalescence or pearly luster in the same sample. Opal ranges from perfectly transparent to nearly opaque. Luster ranges from vitreous, to dull, waxy, or greasy. Cleavage is absent. Fracture is conchoidal, uneven, irregular to splintery. Brittle to very brittle. $H = 5\frac{1}{2}$ – $6\frac{1}{2}$. $G = 1.9$ – 2.3 (depends partly on water content). Often luminescent and colors include white, yellow, yellow-green, green, or light blue. Fluorescent yellow to yellow-green due to presence of uranyl ions, especially hyalite opal. Black opal is inert to LWUV and SWUV. White opal may phosphoresce. Fire opal may be inert or may fluoresce a moderate greenish brown to LWUV and SWUV, and may also phosphoresce. IR data: *FM 52:17(1974)*. DTA and TGA data (precious opal): *MM 35:429(1965)*. Thermoluminescence data on synthetic and natural opals: *AM 63:737(1978)*. XAS studies: *AM 79:622(1994)*. Opal is both heat- and humidity-sensitive. Soluble in HF and KOH. Sometimes attacked by HCl. **Chemistry:** The presence of >1 wt % H_2O in opal is considered essential for the mineral. *JGSA 18:57(1971)*. Most opal has 3–9 wt % H_2O but it may have as much as 15–20 wt %, there being no clear distinction between opal-A and opal-CT on this basis. Opal-AN, however, usually contains around 3 wt % H_2O , while opal-AG contains 5–8 wt %, but sometimes contains much less. The water is present as (1) SiOH and as (2) H_2O (molecular). Opal-CT contains (1) 0.2–0.4 wt % and (2) widely varying amounts. Two types of molecular water are present: single, almost non-hydrogen-bonded molecules in small 0.35-nm cages of the SiO_2 matrix, and liquidlike, H-bonded water as films on inner surfaces. For additional details, see *FM 52:17(1974)* and for opal-C and chalcedony, *PCM 12:300(1985)*. At least five types of water occur in opal-A (Monterey diatomite). *AM 67:510(1982)*. Some opal contains trace to minor amounts of Fe, Al, Mg, Ca, alkalis, and sometimes Ni (prase opal). A wide variety of rare to common elements occur in variable amounts. As Fe can be precipitated at a low pH, it is sometimes present in significant amounts (up to 23% Fe_2O_3 reported). Unlike for cristobalite and tridymite, opal with high amounts of cristobalite is “dirty” (e.g., 0.25–3.5 wt % Al) and opal with tridymite is “clean” with 0.008–1.5 wt % Al. *AM 58:717(1973)*. **Optics:** Generally isotropic or with weak birefringence. Wood opal has a range of refractive indices between 1.410 and 1.453. The higher the water content, the lower the indices of refraction. All opal-CT has refractive indices between 1.43 and 1.46, with most being <1.44 . Opal-AG and opal-AN usually have refractive indices between 1.45 and 1.46. **Occurrence:** Most opal is formed in a variety of low-temperature environments, generally in near-surface deposits. Precious opal and the associated potch (opal-AG) are deposited by colloidal processes in an aqueous environment. Geyselite (siliceous sinter) may be formed by deposition (in hot springs) from hot-water solutions containing 100–200 ppm SiO_2 in true solution. Opal-AG can be stable for long periods; unaltered sponge spicules, for example, have been found in Eocene opal claystone. Opal-AN in the form of hyalite is found mainly in volcanic rocks, at least in part having been formed by vapor-phase deposition. It occurs in sedimentary (e.g., siliceous shales) and diagenetic environments. It sometimes replaces organic matter and occurs as a fossil. Common in volcanic rocks, filling cavities and

fractures. The main constituent of diatomite. Most is deposited by Si-bearing waters at low temperatures ($<100^{\circ}$) that evaporate. SiO_2 concentrations may be no greater than 100-200 ppm. The diagenetic alteration process in sediments generally involves opal-A \rightarrow opal-CT (porcellanite) \rightarrow chalcedony or cryptocrystalline quartz (chert). Under conditions of unrestricted growth, opal-CT usually forms spherical aggregates (lepispheres) consisting of opal-CT blades intergrown according to twinning laws of tridymite [i.e., (3034) and (1016)]. Precious opal in Australia is chiefly in sedimentary host rocks, in the Andamooka, Coober Pedy, and Lightning Ridge fields. Elsewhere in the world, precious opal mostly occurs with volcanic rocks (e.g., Mexico). Localities: Opal, of varying types and quality, occurs worldwide. Only localities that have produced or are producing fine-quality, noteworthy, or otherwise unusual opal are mentioned here. Hyalite is present in Mitchell Co., NC; fine-quality precious opal in sandstone has recently been found at Cedar Grove, Houlton Parish, and near the Toledo Bend Reservoir, Sabine Parish, LA; opaline sinters occur in hot springs in Yellowstone National Park, WY; good-quality common opal and hyalite occur at Mt. Blackmore and Mt. Hyalite, Gallatin Co., MT; opaline sinters also occur in hot springs at Steamboat Springs, NV. Perhaps the most famous U.S. locality for precious opal is that of Virgin Valley, Humboldt Co., NV. The Rainbow Ridge, Royal Peacock, and Bonanza mines have produced fine black opals, including the 3.2-kg Hodson opal, the 3-kg Bonanza opal, and the 2402-ct Roebbling black opal, all of which are opalized limb sections. One 130-lb log estimated to be $> 30\%$ precious opal was found at the Northern Lights mine. Most material from Virgin Valley is unstable and tends to crack and dehydrate. However, the Roebbling opal has shown no degradation in more than 75 years. Milk opal occurs east of Spencer, ID. Hyalite is present in the Columbia R. basalts in the northwestern United States, and hyalite and other varieties of opal occur at Opal Butte, Morow Co., OR. Fine wood-opal occurs along Clover Creek, Bliss, Lincoln Co., ID, in the form of oak logs with well-preserved textures. Excellent wood opal also occurs in the Latah formation, in south-central Washington. Opal-CT occurs in the porcellanites of the Monterey Shale in California. Diatomites contain opal-A. Some fire opal occurs at the Okanagan opal mine, near Vernon, BC, Canada. Some of the world's best fire-opal and cherry-opal occurs near San Juan del Rio, QUE, Mexico. Good material also occurs near Magdalena, JAL, and Zimapan, HID, Mexico. Several areas in Honduras are producing good-quality opals. Before discovery of the Australian opal fields, the best known localities for precious opals were near Cervenica and Dubnik, now in Slovakia (formerly Hungary) on Mts. Simonka and Libanka in the Carpathian Mts. These localities have been known since the time of the Romans. Mining was discontinued in 1923, due to the competition from Australia. Fine hyalite occurs at Waltsh, Bohemia, and Puy de Dôme, France. Fire opal occurs at Aleksevskoye in Kazakhstan. Fine hyalite occurs at Tateyama and Sankyō, Japan. Other notable occurrences of opaline sinters are in Iceland and at Wairaki, New Zealand. A relatively little known but potentially significant brown fire opal occurs in Ethiopia. There are records of precious opal being

found in and exported from India in ancient times, but the localities are not now known. Brazilian agate consists of chalcedony and opal-C. The world's finest precious opals occur in Australia: Mintabie, Coober Pedy, and Andamooka fields, South Australia; White Cliffs, and Lightning Ridge fields in New South Wales. The White Cliffs fields produce opal "pineapples" (to 700 g, 4.5 in. \times 3.5 in.), which are pseudomorphs after ikaite(?). Lesser production comes from areas in Queensland, the best of which are the Opalton, Eromanga, Quilpie, and Yowah areas. In most areas the opal occurs in sandy clays of Cretaceous age. Precious opal also occurs in altered volcanic rocks in several areas in eastern NSW and Q but has never been commercial. Some 90% of the world's production of precious opal comes from the Australian opal fields, where it occurs as thin bands, nodules ("nobbies") or in ironstone concretions. Since 1960, the estimated total value of opal mined in Australia is about 2.2 billion (1988 Australian dollars). Uses: The chief use of opal, since antiquity, is as a gemstone. Usually cut *en cabachon*, but thin layers may also be used as doublets and triplets; larger pieces may be carved. Australia is by far the world's largest producer. For the past 20 years it has produced just about all of the world's precious opal. Coober Pedy is the single largest gem opal producer in the world. Mintabie is now ranked first. Australia currently accounts for 95% of the world's production of opal. The only other significant commercial sources at present are Mexico, where it occurs in volcanic rocks, and in Piauí State, Brazil, where although associated with volcanic rocks, it may have been formed by sedimentary processes; the opal is similar to that found in some of the Australian localities. Opal is also used in ceramics, chemical industries, and in insulating and acid-proof materials. Large quantities of opaline silica such as diatomite are used as filter insulating materials, as absorbents, and in refractory manufacture. More compact materials such as opal claystones are calcined for use as a grog for refractories and as pet litter. Small amounts of opal in aggregate can cause damage to concrete structures by reaction with alkali elements in the cement. Early examples of this were concrete roads in California and in the Parker Dam. Opal simulants (synthetics) are now known, such as Slocum stone, a glass product. The most convincing simulants are opalite and opal essence, a plastic material produced in Japan. Synthetic opal has been available commercially since the 1970s [*JG* 14:215(1975)] and was first marketed by Pierre Gilson, Saint Sulpice, Switzerland. Black opal and crystal opal types are sold by Inamori in Japan. *EF GSNA* I:105(1959), II:49(1976); *D7 III:287(1962)*; *TOB(1961)*; *LJ* 47:36(1993).

75.2.2.1 Melanophlogite SiO_2 + (organic compounds)

Named in 1876 by Lasaulx from the Greek for *black* and *to be burned*, in allusion to the mineral blackening when heated in the blowpipe flame. *TET* (pseudo-iso) $P4_2/nbc$. $a = 26.79$, $c = 13.395$ (pseudoisometric subcell with $a = 13.395$), $Z = 4$ ($Z = 128$ for SiO_2), $D = 2.06$. Structure: *SCI* 148:232(1965). A three-dimensional, pentagonal dodecahedral framework of

silica tetrahedra is proposed, the organic components within the voids being essential to maintaining the open framework. Crystals rarely as simple pseudocubes up to 4 mm on edge; more commonly as complex, rounded intergrowths forming crusts. Colorless, pale yellow to reddish brown; turbid white when altered; white streak; transparent to translucent. Brittle. $H = 6\frac{1}{2}$ -7. $G = 2.005$ -2.052. Isotropic; $N = 1.423$ -1.467, but occasionally weakly birefringent. The organic components are somewhat variable, 7-12 wt %. A formula based on Cechy material is given as $Si_{46}O_{92} \cdot C_2H_{17}O_5$; Sicilian material often contains significant sulfur. Insoluble in acids; blackens on heating. Found at Mount Hamilton, Santa Clara Co., CA; at Fortunillo, Livorno, Tuscany, and associated with sulfur at Caltanissett and at the *Giona mine, Racalmuto (Agrigento), Sicily, Italy*; as fine crystals on lussatite (fibrous cristobalite) in a vein cavity in a pyrite-rhodochrosite deposit at Chvaletice, Cechy (Bohemia), Czech Republic. *AR D7 3:283(1962)*; *AM 48:854(1963)*, *57:779(1972)*.

75.2.3.1 Lutecite SiO_2

Originally described in 1892 by Michel-Levy and Munier-Chalmas. Synonyms: lutecine and moganite. The CNMMN IMA has not formally approved a name for this species. The name *moganite* was assigned in 1984, but *lutecite* has priority. Compare chalcedony (75.1.3.1). Polymorphous with the other forms of SiO_2 : quartz, tridymite, cristobalite, and coesite. MON with many crystallites showing a TRIC superstructure. $I12/a1 = C2/c$. $a = 8.758$, $b = 4.876$, $c = 10.715$, $\beta = 90.09^\circ$, $Z = 12$, $D = 2.617$. $38-360$: 4.45_1 3.39_5 3.33_{10} 3.11_1 2.29_1 1.83_1 1.38_1 1.37_1 ; also *DAN SSSR 320(2):428(1991)*: 4.26_5 3.33_{10} 2.44_4 2.27_5 1.80_8 1.54_4 1.37_6 1.18_5 [also *DAN ESS 320:169(1993)*]. Triclinic superstructure has: $a = 10.024$, $b = 9.752$, $c = 10.715$, $\alpha = 90.00^\circ$, $\beta = 90.07^\circ$, $\gamma = 119.11^\circ$. The structural relationship to quartz is: $2a + b$, b , $2c$ (for a, b, c of quartz). The structure consists of corner-linked SiO_4 tetrahedra with six-, eight-, and four-membered rings. The tetrahedra are only slightly distorted. The structure can be thought of as consisting of alternating layers resembling (1011) slices through right- and left-handed quartz, which form a three-dimensional network of corner-sharing SiO_4 tetrahedra. The structural principle is thus a periodic twinning according to the Brazil law on a cell-dimension scale. **Habit**: The concentration of lutecite is dependent on depositional environment. Formation of the metastable polymorph is promoted by the substitution of $[Fe^{3+} + Na^+]$ for Si^{4+} . *IMAMA 16:170(1994)*. Occurs as microcrystalline fibrous silica fillings of cavities, fissures, and cooling cracks in ignimbrite flows (Gran Canaria); as weirdly shaped crusts, pockets, amygdules, and veinlets, in vesicles, in fractures, and in voids at intersection of joints in basalt (Gobi desert, Mongolia). Some pure lutecite occurs in masses 40 cm or more across. Often exhibit a typical and distinctive morphology: regular intergrowth of pseudohexagonal, strongly flattened individual crystals. Individual crystals have $\{1010\}$ (of quartz), = $\{110\}$ (monoclinic cell) dominant, lathlike, fibrous, and radiating plates. They are approximately 100

A thick. Also in much agate and chalcedony throughout the world. *SCI* 255:441(1992). Indistinguishable from chalcedony in hand specimens. **Physical properties:** Translucent gray to chalky white, cream. $G = 2.52\text{--}2.58$ (because of water that is present). NIRS and IR data: *EJM* 4:693(1992). Raman spectra [*AM* 79:269(1994)] confirms that lutecite is a structurally distinct polymorph of SiO_2 . **Optics:** Optically length-slow (rather than length-fast as for quartz), $N = 1.524\text{--}1.531$. Inclined extinction angle of $29\text{--}45^\circ$. **Chemistry:** Contains variable amounts of water (1.5–3.0 wt %) that is not a constituent of the structure. Also may contain traces of Mg, Mn, Ca, K, Na, and others. **Occurrence:** Occurs as veins, fillings, and crusts in rhyolitic ignimbrite flows, in Magadi-type chert (evaporite-type regimes), most microcrystalline quartz varieties contain some lutecite (agate, chert, flint, chalcedony, etc.). Formed at low temperature and pressure. Coatings on nodules may be $>80\%$ pure lutecite. **Localities:** *Gran Canaria, Canary Islands*; Lake Magadi, Kenya; Arts Bogdo range, NW Gobi desert, Mongolia. Fairly abundant and occurs worldwide. Most work has been done on material from Gran Canaria and Mongolia. *EF NJBA* 149:325(1984), 163:19(1991).

75.2.4.1 Silhydrite $\text{Si}_3\text{O}_6 \cdot \text{H}_2\text{O}$

Named from the composition: a silica hydrate. ORTH *P* lattice. $a = 14.519$, $b = 18.80$, $c = 15.938$, $Z = 28$ (on three Si's) or 32 (on six O's), $D = 2.116$. 25-1332(nat): 14.5₁₀ 7.31₂ 7.07₂ 5.31₂ 3.63₃ 3.54₃ 3.42₈ 3.14₄. White; in masses, single pieces to 3–4 cm in longest dimension, but most are <5 mm across. Crystals are <4 μm long; earthy. Rough and subconchoidal fracture. $H \approx 1$. $G = 2.141$. DTA and TGA data: *AM* 57:1053(1972). Treatment with Na_2CO_3 produces a magadiitelike material; however, magadiite leached with dilute HCl yields a silica hydrate that differs from silhydrite. Analysis (wt %): SiO_2 , 88.9; H_2O^+ , 3.13; H_2O^- , 6.65; traces of Al, Fe, Mg, Ca, Na, and K. Biaxial; sign unknown; $N_{\text{avg}} = 1.466$. Occurs in a magadiite deposit as crystals remaining after Na has been leached from magadiite by spring water. Occurs east of *Trinity Center, Trinity Co., CA*. *EF*

75.3.1.1 Virgilite $\text{Li}_x[\text{Al}_x\text{Si}_{3-x}\text{O}_6]$

Named in 1978 by French et al. for Virgil Everett Barnes (b.1903), University of Texas, who pioneered the study of tektites and other natural glasses. Dimorphous with spodumene. HEX $P6_222$ or $P6_422$. $a = 5.132$, $c = 5.454$, $Z = 1$, $D = 2.399$. 31-707: 4.44₁ 3.44₁₀ 2.57₁ 2.24₂ 1.870₁ 1.605₁ 1.429₁ 1.408₁. Structure: *ZK* 127:327(1968). The structure is a stuffed derivative of β -quartz, with Al–Si substitution disordered. Colorless, vitreous luster, transparent. $H = 5\frac{1}{2}\text{--}6$. Uniaxial (–); $N_{\text{av}} = 1.520$; birefringence = 0.005. Al substitutes for Si such that $x = 0.5\text{--}1.0$. Found as hexagonal prisms and bipyramids, up to 50 μm , and as fibers on quartz associated with K-feldspar, biotite, and spinel in a stream cobble of volcanic glass at *Macusani, Peru*. *AR AM* 63:461(1978).

Al-Si Framework

FELDSPAR GROUP

The feldspar group minerals are tectosilicates with similar framework configuration, whose compositions lie between

where

R^{1+} = Na, K, or occasionally (NH_4)

R^{2+} = Ca, but also Ba and Sr

and where aluminum is sometimes replaced by boron (reedmergnerite).

Most naturally occurring feldspars are made up of three principal chemical components:

where

Or = orthoclase = KAlSi_3O_8

Ab = albite = $\text{NaAlSi}_3\text{O}_8$

An = anorthoclase = $\text{CaAl}_2\text{Si}_2\text{O}_8$

The *alkali feldspars* are composed primarily of Or and Ab, while the *plagioclase series* feldspars are those containing primarily Ab and An. These two feldspar subgroups collectively constitute the dominant minerals of the upper lithosphere, being almost ubiquitous in igneous rocks, as well as important components of many metamorphic rocks, and also exist, although far less commonly, in sedimentary environments. Within these subgroups varying degrees of substitution and Al-Si ordering are found. Albite is common to the two subgroups but is usually included as a plagioclase, there being a discontinuity in the alkali feldspar series at low temperature.

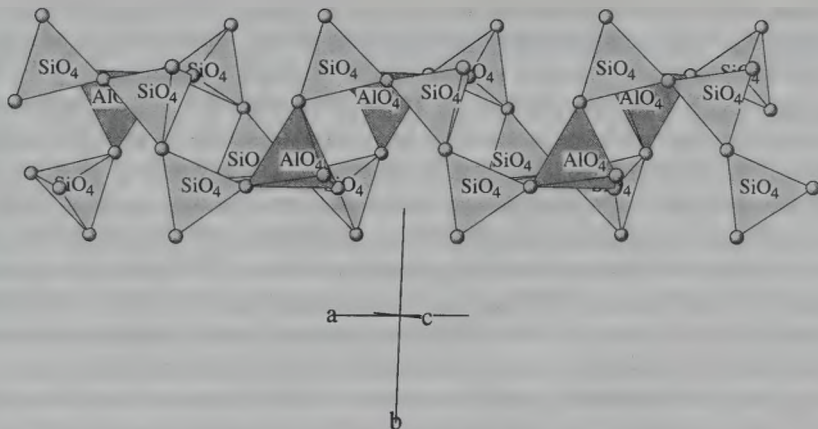

The structural framework may be described in terms of its component structural elements. The fundamental building block is a ring of four tetrahedra. These four-membered rings are linked through common oxygens to form a chain, commonly described as a "double crankshaft" lying parallel to [100] with the rings alternately nearly perpendicular to [010] and somewhat inclined to [100]. The chains are cross-linked in a plane parallel to {201} to

Nomenclature for the plagioclase feldspar series and the high-temperature alkali feldspars. (after Deer, Howie, and Zussman, 1963, *Rock Forming Minerals*, v. 4. Longman Group Ltd., p. 2.)

form puckered sheets. All feldspars display two cleavages, {001} perfect and {010} good, which represent severing of bonds that cross-link the double-crankshaft chains. The chain and sheet elements make up the framework, which has large “cages” accommodating the cations.

The conformation of apical oxygens within the rings comprising the puckered sheets is consistent in all feldspars; however, different conformations appear in similar sheets of some feldspar polymorphs and zeolites.

Feldspar Group

Partial structure of low-albite; the feldspar "crankshaft" extending parallel to *a* and made up of four-membered tetrahedral rings.

TRUE FELDSPARS: ALKALI FELDSPAR SUBGROUP

Order-disorder. Aluminum and silicon may be completely disordered to fully ordered in the tetrahedral sites, this being one cause of the complexity of polymorphic subspecies possible for a feldspar of a given composition.

Composition. The following elements may be encountered in addition to the essential chemical components of the feldspar group. Other than in reedmergnerite, boron does not usually exceed 1000 ppm, but may reach 1 wt % B_2O_3 in authigenic K-feldspars. Titanium is usually present in amounts less than 0.1 wt %, and even these levels may be suspect because of possible contamination with ilmenite. Tin is normally present only to the extent of a few ppm, but may be higher in feldspars from greisens. Iron, usually as Fe^{3+} replacing Al^{3+} , reaches a maximum of about 4 wt%. Rubidium varies from about 1 ppm in anorthite to 100 ppm in granitic oligoclase to over 1000 ppm in granitic or pegmatitic K-feldspars. Although less abundant than rubidium, cesium follows a similar distribution. Strontium and barium form feldspars or feldspar polymorphs, wherein they may be the dominant divalent cation.

Temperature-composition phase relations. Albite (Ab) and orthoclase (Or) show a large miscibility gap at temperatures below approximately 650° and an extensive region of solid solution above that temperature. The rate of cooling can be the essential factor in determining the phase preserved in the cooled

Experimentally determined extent of solid solution in the system Or-Ab-An at $P_{H_2O} = 1$ kbar (After Ribbe, *Reviews in Mineralogy*, v. 2, Mineralogical Society of America, 1975)

product. Sanidine, for example, can be quenched into the sanidine structure, or when cooled more slowly can result in either the monoclinic orthoclase or the triclinic microcline phase.

Exsolution. Many feldspars undergo exsolution resulting from decreased solubility at lower temperatures and order-disorder transformations. This may result in a variety of intergrowth textures and optical phenomena (schiller, adulescence, labradorescence, etc., as discussed under the individual species). The exsolved phase may occur as stringers, rods, blebs, interlocking masses, or other forms, and the size of its particles tends to increase with lower temperature of formation and time. However, the single phase domains are often beyond resolution by optical methods or by powder X-ray diffraction. (In such cases the concept of "average structure" may sometimes be introduced.) Exsolution commonly results in perthite (exsolved Na-rich feldspar in K-spar host) and antiperthite (exsolved K-spar in Na-rich feldspar host). Perthite (named for Perth, ONT, Canada) may thus occur as "sub-X-ray-perthite," "X-ray-perthite," cryptoperthite," and "microperthite," with sizes from $< 15 \text{ \AA}$ to $100 \mu\text{m}$, to "perthite," with exsolved regions exceeding $100 \mu\text{m}$.

Twinning. Twinning in feldspars is very common and may arise in primary crystal growth, through deformation, or during thermal transformation. There are numerous twin laws, divided into (1) *normal twins*, with the twin axis normal to the composition plane that is a possible face; (2) *parallel twins*, with the twin axis being a zone axis and the composition plane including the twin axis; and (3) *combined twins*, involving a combination of a normal and a parallel twin law. Repeated (polysynthetic) twinning is common for some laws, and some laws apply only to triclinic phases. The most commonly observed twin laws are indicated in the table.

COMMON FELDSPAR TWIN LAWS

Name	Twin Axis	Composition	
Albite	$\perp(010)$	(010)	Triclinic only; repeated
Baveno (R,L)	$\perp(021),(021)$	(021),(021)	Contact; simple; rare in plagioclase
Carlsbad	[001]	(010), ($hk0$)	Contact and penetration; simple
Manebach	$\perp(001)$	(001)	Contact; simple
Pericline	[010]	($h0l$)	Triclinic only; repeated
Albite-Carlsbad		(010)	Triclinic only; repeated

In triclinic system pericline twins, the composition plane lies in zone [010], but its orientation is a function of the geometry of the cell; this composition plane is referred to as the "rhombic section." The orientation of the rhombic section relative to cleavage planes is useful in identification of the feldspar.

Notes:

1. The group name, feldspar, derives from the Swedish *fält spat*, through the German *feld spath*, meaning field spar, *spar* being a term used for a nonmetallic, often cleavable, lustrous stone. The usage is of mid-eighteenth-century origin, often attributed to Wallerius and/or Cronstedt, but probably first used in 1742 by Daniel Tillis.
2. The nomenclature of the feldspar minerals is highly complex, involving elements of composition, structure, order-disorder, exsolution, texture, and optical phenomena. An extensive discussion is presented in *JVS Ch 9*.
3. Polymorphism is common, and many of the true feldspars have structurally and chemically related polymorphic phases. These are classified in the Dana system after the true feldspars.

References: *DHZI* 4:1(1963), *MSASC* 2:R1(1975).

76.1.1.1 Orthoclase KAlSi_3O_8

Named in 1823 by Breithaupt from the Greek for *straight fracture*, in allusion to the perpendicular cleavages. Feldspar group. The varieties valencianite from the Valenciana mine, GTO, Mexico, and adularia from the Adular Mts., Switzerland, an erroneous placement of the St. Gotthard locality. Moonstone is sometimes included as an orthoclase microperthite but is more likely sanidine or anorthoclase. The term *K-spar* or *K-feldspar* for undifferentiated K-rich feldspars includes orthoclase. Dimorphous with microcline. *MON* $C2/m$. $a \approx 8.56$, $b \approx 12.94$, $c \approx 7.21$. $\beta \approx 116.3^\circ$, $Z = 4$, $D = 2.54$. *31-966*: 4.22₇ 3.77₈ 3.45₅ 3.31₁₀ 3.29₆ 3.24₇ 2.99₅ 2.90₃. Fully ordered orthoclase is considered by some to represent twinning of a triclinic cell on a submicroscopic scale. Adularia is reported to be triclinic in part, making it more appropriately a microcline, but some samples may have domains of the two symmetries. **Habit:** The habit is usually short prismatic, [100], with dominant {001}, {010}, {110}, and {201} or short prismatic [001] and somewhat tabular {010} with similar forms. The habit of adularia is commonly prismatic, with {110} dominant and modified by {001} and {101}. Massive, coarsely crystalline to granular; compact to cryptocrystalline. Usually anhedral or subhedral rock-bound grains, with euhedral crystals being found as phenocrysts in volcanic rocks and in pegmatites and fissure fillings. Twins are common on the *Carlsbad law*, the *Baveno Law*, and the *Manebach law*. **Physical properties:** Colorless to white, cream, pale yellow, pink, to brownish red; streak uncolored to very pale in dark varieties; vitreous luster, somewhat pearly on {001}; transparent to translucent; a pale blue to white Schiller effect, moonstone, is evident in some orthoclase microperthites. Cleavage {001}, perfect; {010}, less so; parting may occur on {110}, {100}, and {201}; subconchoidal to uneven fracture; brittle. $H = 6-6\frac{1}{2}$. $G = 2.55-2.63$. **Optics:** Biaxial (-); $2V = 12-84^\circ$; $N_x = 1.518-1.528$, $N_y = 1.521-1.533$, $N_z = 1.524-1.537$ increasing with Ab content; $X \wedge a = 3-14^\circ$, OAP perpendicular to {010} and \approx parallel to {001}; $r > v$; for $\text{Or}_{85}\text{Ab}_{14}\text{An}_1$, $2V = 46^\circ$, $N_x = 1.519$, $N_y = 1.524$,

Orthoclase

Typical habits of orthoclase. a) Short prismatic [100]. b) Prismatic [001]. c) Variety adularia. Forms: b, {010}; c, {001}; m, {110}; x, {101}, y, {201}.

Orthoclase twin laws. a) Carlsbad penetration twin. b) Baveno twin. c) Manebach twin.

$N_2 = 1.525$. **Chemistry:** Orthoclase has been reported with compositions from $Or_{>90-25}$, the balance being Ab and usually less than 4 mol % An, but some examples reported may in fact be sanidine or anorthoclase, the high-sodium examples having fine-scale perthitic textures. Adularia is always high in Or (>80). Silicon appears to be consistently shy of the ideal 3:1 Si:Al ratio. TiO_2 is generally low (0.1 wt %), and Fe_2O_3 is generally < 1 wt %, but may reach 3 wt % (Madagascar). BaO and SrO may be present in small amounts, but high-Ba analogs exist [see hyalophane (76.1.1.3)]. Alkali metal content, other than Na and K, is low. **Alteration:** Common alteration products are muscovite and clay minerals, particularly kaolin that may form pseudomorphs. Talc, chlorite, leucite, cassiterite, and calcite are known to form pseudomorphs after orthoclase. **Occurrence:** Typical of acidic and alkaline igneous rocks of plutonic and volcanic origin and in granitic pegmatities. In alpine-cleft environments (adularia) and in hydrothermal veins. Found in high-grade metamorphic environments; as porphyroblasts in contact zones. Found as weathered grains in arkosic sediments, often with authigenic overgrowths. **Localities:** Orthoclase is of common worldwide occurrence, and but a sampling of noteworthy localities is given. Found at Acworth, NH; as large crystals coated with clinocllore(1) at Acushnet, Bristol Co., MA; large crystals at Barre, Worcester Co., MA, and throughout the pegmatites of New

England; as reddish, divergent columnar masses at French Creek, Chester Co., PA; Mt. Antero, Chaffee Co., CO (adularia, fine crystals); large crystals at Barringer Hill, Llano Co., TX; crystals up to 5 cm, simple, Carlsbad twins and Manebach twins, found in weathered porphyritic granodiorite at West Maroon Pass, Pitkin Co., CO; as near ideal crystals(!) up to 4 cm long at Oro Grande, NM; at Goodsprings, NV; adularia at Denny Mt., King Co., WA; with epidote, quartz, and chlorite on Prince of Wales Island, AK. Valencianite at Valenciana mine, GTO, Mexico. Found at Stokō, Langesundsfjord, also as Baveno twins in the Drammen granite \approx 40 km SW of Oslo, and at Fredricksvårn, near Larvik, Vestfold, Norway; at St. Agnes and elsewhere in Cornwall, England, often as Carlsbad twins sometimes replaced by cassiterite; adularia at Bourg d'Oisans, Dauphiné, France. Excellent crystals of adularia(!) at Val Tavetsch, Disentis, and elsewhere, Grisons, at St. Gotthard, Tessin, and at Unseren Thal, Uri, Switzerland. In vugs in gneiss with clinocllore, quartz, and sphene at Mt. Forno, Val Devero, Piemonte; type Baveno twins at Baveno, Novara, Piemonte; at Val di Flemm, (red), Trentino, Italy; at La Colta, St. Piero in Campo, and elsewhere, Elba. Adularia at Zillertal, Tyrol, Austria; at Karlovy Vary, (Carlsbad) (type *Carlsbad twins*), Becov and elsewhere, Cechy, Czech Republic. Fine crystals were found at Albaschka, northern Mursinska, Ural Mts.; Carlsbad twins to 8 cm long at Belokurikha, Altai; prisms to 18 cm and Manebach twins at Udacha, Kabarovskii Kray; and as fine crystals in the Stanovoi Range, Russia. Colorless ($\text{Or}_{90}\text{Ab}_7\text{An}_{25}$) found at Sinkwa, Mogok, Myanmar, as well as *moonstone* ($\text{Or}_{20}\text{Ab}_{73}\text{An}_{65}$), but the latter may be a sanidine. Adularia found at Su Gu Myun, Su An Gun, and Hwang Hae Do, North Korea, and as white, 2-cm crystals heavily encrusting 20-cm quartz crystals at Nae Gun Gang Myun, Jun Yang Gun, Gang Weon Do, South Korea; adularia as drusy crystals in Alpine-type cavities in quartz veins in schist at Kukutzu, Taiwan; Baveno twins at Tanokamiyama, Shiga Pref., Japan; as fine, large, transparent yellow (2.56 wt % Fe_2O_3) crystals at Itron-gay and elsewhere in northern Betroka, Madagascar. Uses: Orthoclase, together with other K-rich feldspars, is an important component of ceramic bodies. With other feldspars is used as a mild abrasive in cleaning compounds. Transparent yellow material from Madagascar has been fashioned into quite large faceted gems. If truly orthoclases, moonstone varieties are fashioned into cabochon and carved gems. *AR DHZI 4:1(1963)*, *MSASC 2:R-1,ST-23,Sm-18(1975)*, *MR 8:363(1977)*.

76.1.1.2 Sanidine (K,Na) AlSi_3O_8

Named in 1808 by Nose from the Greek *sanis*, tablet, in allusion to the crystal habit. Feldspar group. An earlier used term is *soda-orthoclase*. Much moonstone is cryptoperthitic sanidine. High- and low-sanidine modifications exist. High-sanidine forms a series with high-albite. *MON C2/m*. $a = 8.60$, $b = 13.04$, $c = 7.18$, $\beta = 116.0^\circ$, $Z = 4$, $D = 2.54$. *19-1227*($\text{Or}_{54}\text{Ab}_{38}\text{An}_8$): 4.16₇ 3.76₈ 3.45₅ 3.27₇ 3.26₁₀ 3.25₈ 3.22₉ 2.98₄; also *25-618*(disordered): 4.24₆ 3.79₆ 3.46₃ 3.33₁₀ 3.28₆ 3.23₅ 3.00₃ 2.54₄. Structure: *CM 29:543(1991)*. Of all the feldspars, the

structure of high sanidine is the best understood, and displays the double-crankshaft structural unit described earlier. High sanidine is fully disordered with respect to both Al/Si and Na/K. **Habit:** Crystals usually short prismatic, somewhat flattened on {010}, the prominent forms being {010}, {110}, {001}, and {201}; {010} sections may attain 50 cm. Also anhedral grains and cleavable masses. Twinning on Carlsbad law is common; Manebach and Baveno law twins, less so. **Physical properties:** Colorless, white, gray, other pale tints; white to light blue schiller is often present (moonstone); vitreous luster, somewhat pearly on cleavage; transparent to translucent. Cleavage {001}, perfect; {010}, good; {001} parting; conchoidal to uneven fracture; brittle. $H = 6$. $G = 2.56-2.62$. High: $Biax(-)$; $2V = 0-40^\circ$; $Y = bX \wedge a \approx 5^\circ$; $r > v$ weak. Low: $Biax(-)$; $2V = 0-40^\circ$; $Z = bX \wedge a = 5-9^\circ$; $r < w$ weak. High and low: $N_X = 1.518-1.527$ $N_Y = 1.523-1.532$ $N_Z = 1.524-1.534$; slightly higher indices are found in barian sanidines. **Chemistry:** Most published analyses lie in the range $Or_{40-80}Ab_{60-20}An_{0-10}$. Minor Ba and Sr may be present. Fe and Ti are each present at < 0.1 atom per 32 oxygens. Exsolution lamellae are common and not restricted to low-temperature forms. **Alteration:** Commonly alters to sericite and clay minerals. **Occurrence:** Sanidine is typical of silicic volcanic rocks such as rhyolite, phonolite, and trachyte, and in shallow intrusives. It is commonly cryptoperthitic. In highly silicic volcanics such as obsidian and rhyolite it may occur in spherulites intergrown with cristobalite and as acicular clusters. In metamorphic rocks formed at high temperature and low pressure (sanidinite facies). Less common than orthoclase and microcline in clastic sediments. **Localities:** Widespread worldwide; noteworthy localities are: Thomas Range, UT; in the Mitchell Mesa rhyolite, TX ($Or_{41.5}Ab_{57.7}An_{0.8}$); at Rabb Canyon, Grant Co., NM; as masses in trachybasalt at Black Point, near Huntingdon Lake, CA; Summit Rock, Klamath Co., OR; in Canada at Bernic Lake, MB, and Mt. St.-Hilaire, PQ. In blocky, somewhat tabular crystals(1) at Mina de la Pilio, La Cruz, CHIH, Mexico (cryptoperthitic moonstone, $Or_{38-40}Ab_{59-62}An_{0-1}$), the composition range overlaps that of anorthoclase, and that term has been applied to its descriptions. Mt. Dore, Auvergne, and Puys de Dome, France; Mte. Somma, Campania, in the Alban Hills, near Rome, and at Mt. Cimino, near Viterbo, Lazio, Italy ($Or_{80}Ab_{17}An_3$); at Mendig, Mayen, and elsewhere, near Laacher See, Eifel, Germany ($Or_{78}Ab_{22}$); Mt. Somlyod, near Vegardo, Slovakia (twinned, $Or_{63}Ab_{35.5}An_{1.5}$); phenocrysts of zoned, barian sanidine in dacite at Zvečan, Yugoslavia. *Moonstone* is found at a number of localities in southern India and Sri Lanka. Meisen Gun, Kanchin Prov., North Korea (idiomorphic, colorless, moonstone). **Uses:** May find use in porcelain bodies. The moonstone variety is cut into cabochon gems. AR *DHZI* 4:6,40,56(1963), AM 63:1264(1978), MR 26:222(1995).

76.1.1.3 Hyalophane (K,Ba)(Al,Si)₄O₈

Named in 1855 by von Walterhausen from Greek for *glass* and *to appear*, in allusion to its transparent crystals. Feldspar group. MON *C2/m*. $a - 8.56$,

$b = 13.04$, $c = 7.20$, $\beta = 115.7^\circ$, $Z = 4$, $D = 2.88$. 19-2: 3.78₅ 3.46₅ 3.31₉ 3.24₁₀ 3.00₇ 2.91₄ 2.57₅ 2.17₄. Structure: *AC(B) 33:3073(1977)*. Habit often prismatic [001] with dominant {110}, similar to adularia, or equant to short prismatic as with ordinary orthoclase. Simple Carlsbad, Manebach, and Baveno law twins; also composite and multiple twins. Colorless, white, pale yellow, pale to deep pink; vitreous luster; transparent to translucent. Cleavage {001}, perfect; {010}, good; conchoidal fracture; brittle. $H = 6-6\frac{1}{2}$. $G = 2.58-2.82$. Biaxial (-); $2V = 70-85^\circ$, decreasing with increasing Ba content; $N_x = 1.522-1.542$, $N_y = 1.526-1.547$, $N_z = 1.528-1.551$; $X \wedge a = 0-19^\circ$, $Z = b$; $r > v$, weak. Intermediate in composition between orthoclase and celsian, but with discontinuity in the series; sodium may be present to Ab₂₅, but only minor amounts of calcium are found. The celsian content is generally < 50 mol %. Typically in metamorphosed manganese deposits with Mn-epidote, rhodonite, spessartine, and so on. Found at Franklin, Sussex Co., NJ; high-Na (barium-sanidine) phenocrysts in analcite phonolite at Highwood Mts., MT; at Jakobsberg, Värmland, and the Sjö mines, near Örebro, Sweden; in dolomite marble with barite at the *Lengenbach quarry, Binn, Valais, Switzerland*; as large, complex twins(1) at Zogradski Creek, near Busovaca, Bosnia and Herzegovina; at Slyudyanka, Transbaikalia, Russia; at the Kaso mine, Tochigi Pref., Japan; at Broken Hill, NSW, Australia, and Pahau River, South Island, New Zealand; at Otjosondu, Namibia. *AR DHZI 4:166(1963)*, *MR 16:306(1985)*.

76.1.1.4 Celsian BaAl₂Si₂O₈

Named in 1895 by Sjogren for Anders Celsius (1701-1744), Swedish astronomer and naturalist. Feldspar group. Kasoite, from the locality, has been applied to K-rich material. Dimorphous with paracelsian (76.1.5.1). *MON I2/c*. $a = 8.62$, $b = 13.08$, $c = 14.41$, $\beta = 115.1^\circ$, $Z = 8$, $D = 3.389$. 38-1450(syn): 6.52₆ 3.56₅ 3.47₇ 3.36₁₀ 3.28₅ 3.03₆ 2.61₄ 2.59₆; also 21-812, 19-9. Structure: *AM 61:414(1976)*. The structure is similar to orthoclase but with a doubled c axis. Crystals are usually short prismatic, often similar to adularia in habit, with prominent {110} prism faces; also massive, cleavable. Twinning according to Carlsbad, Manebach, and Baveno laws common. Colorless, white, yellow; vitreous luster; transparent to translucent. Cleavage {001}, perfect; {010}, good; {110}, poor; uneven fracture; brittle. $H = 6-6\frac{1}{2}$. $G = 3.10-3.45$. Biaxial (+, -); $2V_z = 83-92^\circ$; $N_x = 1.579-1.587$, $N_y = 1.583-1.593$, $N_z = 1.588-1.600$; birefringence = 0.009-0.013; the highest indices being for the synthetic end member; $X \wedge a = 3-5^\circ$, $Y = b$; . Occurs in amphibolite-grade metamorphic rocks, rich in Mn and Ba. Found in quartzite near Rush Creek and Big Creek, Fresno Co., CA, with quartz, diopside, witherite, and sanbornite; with sanbornite and gillespite near Incline, Mariposa Co., and at the Kalkar quarry, Santa Cruz, Santa Cruz Co., CA; in the Alaska Range, AK; at *Jakobsberg, Värmland, Sweden*; with paracelsian at the Benallt Mn mine, Rhiw, Lleyl Penin., Caernarvonshire, England; at Burutlas, W of Lake Balkhash, Kazakhstan; at the Kaso mine, Tochigi Pref., Japan; "The Pig-

gery," Broken Hill, NSW, Australia; Otjosondu, Namibia, in Mn deposit. *AR DHZI* 4:166(1963).

76.1.1.5 Microcline KAlSi_3O_8

Named in 1830 by Breithaupt from the Greek for *small angle* or *inclination*, in allusion to the slightly oblique intersection of the cleavage planes. Amazonite is named for the Amazon River. Feldspar group. Dimorphous with orthoclase (76.1.1.1). **TRIC** C1. $a = 8.53$, $b = 12.95$, $c = 7.19$, $\alpha = 90.4^\circ$, $\beta = 116.0^\circ$, $\gamma = 87.80^\circ$, $Z = 4$, $D = 2.59$. 19-926 (fully ordered, $\text{Or}_{96} \text{Ab}_{35}$): 4.22₁₀ 3.70₄ 3.49₃ 3.37₄ 3.29₆ 3.26₈ 3.25₈ 3.24₄; 19-932 (intermediate, $\text{Or}_{84.4} \text{Ab}_{15.0} \text{An}_{0.6}$): 4.22₅ 3.80₂ 3.74₁ 3.48₂ 3.31₁ 3.29₅ 3.24₁₀ 2.98₁; also 22-675, 22-687. Microcline lattice constants vary from nearly monoclinic to a maximum obliquity for "maximum microcline." The structure is similar to that of low albite. Structure: *BM* 107:401(1984). **Habit**: Commonly as short prismatic, {001} or {100}, crystals with dominant forms {001}, {010}, {110}, {110}, plus minor modifying faces. Crystals from granite pegmatites may attain lengths measured in tens of meters and weights of several thousand metric tons. Twinning on the Carlsbad, Manebach, and Baveno laws are common; twinning on the albite and pericline laws are commonly observed in thin section. Perthitic textures formed by exsolution of albite are very common and distinctive for the species. Epitactic albite may be found, particularly on {001}. Cleavable masses, granular. **Physical properties**: Colorless, white, cream to pale yellow, salmon-pink to red, bright green to blue-green, generally colorless in thin section; vitreous luster, somewhat pearly on dominant cleavage; transparent to opaque. Cleavage {001}, perfect; {010}, good; parting may develop on {100}, {110}, {110}, and {201}; conchoidal to uneven fracture; brittle. $H = 6-6\frac{1}{2}$. $G = 2.54-2.57$. **Optics**: Biaxial (-); $2V = 65-85^\circ$, but may be as low as 35° ($2V_x = 103^\circ$ has been reported but this may be due to exsolved albite lamellae); $N_x = 1.518$, $N_y = 1.522$, $N_z = 1.525$ for fully ordered microcline, sodic cryptoperthites have indices intermediate to those of low albite; $X \wedge a \approx Y \wedge c \approx Z \wedge b \approx 18^\circ$; $r > v$, weak. On {001} in thin section, "Scotch plaid" albite-pericline twinning is usually coarser than in {100} sections of anorthoclase. **Chemistry**: True, fully ordered microcline is near the

Microcline; "scotch-plaid" appearance in thin section due to combined albite and pericline twinning.

ideal composition, but most examples are actually perthitic on micro- to megascopic scale, and the bulk composition may reach $\text{Or}_{35}\text{Ab}_{65}$, although such Na-rich examples may indeed be antiperthites. The An content rarely reaches 4 mol %. Phosphorus content in feldspars of complex pegmatites may be as high as 1.2 wt %; in peraluminous feldspars Al^{3+} and P^{5+} may replace 2Si^{4+} . Rb_2O may be present (3+ wt %) in the microcline of complex pegmatites, as may be Li_2O and Cs_2O but to a significantly lesser extent. Total iron oxides may reach ≈ 1 wt %, but only trace amounts of Ti are found. The green color of amazonite, which is lost at temperatures in excess of 250°C , is not fully understood; it has been attributed to the presence of Pb^{2+} , it is not uncommon in rubidian examples, but may be due to color centers caused by fluorine substitution for oxygen. Occurrence: The common feldspar of plutonic, felsic rocks such as granite, granodiorite, syenite, and in simple and complex granite pegmatites; in metamorphic rocks of greenschist and amphibolite facies; as a detrital component in sedimentary rocks wherein it may have authigenic overgrowths. Commonly associated with quartz, sodic plagioclase, muscovite, biotite, and hornblende amphiboles. Localities: A widespread mineral, but a few noteworthy localities are given. Government pit, Carroll Co., NH; at the Gillette quarry, Haddam, Middlesex Co., CT, and elsewhere in pegmatites of New England; at the Buckwheat open pit, Franklin, Sussex Co., NJ; Poorhouse quarry, Chester Co., PA, as white crystals, low Na, on dolomite; Amelia C.T., Amelia Co., VA, amazonite; at Magnet Cove, Hot Springs Co., AR, having nearly ideal composition; amazonite at Rib Mt., Marathon Co., WI; in pegmatites of the Black Hills, SD. Fine specimens at numerous localities in Colorado, as on Mt. Antero, Chaffee Co.; amazonite(!) in pegmatites of the Pikes Peak granite in El Paso Co. and Teller Co. with large (to 25 cm) crystals, and Baveno and Manebach twins, with thin albite overgrowths(!) at the Ten-Percenter mine; large crystals with thick albite "caps" at Lake George, at Stevens Ranch, and at the Yucca Hill claim, Park Co., CO. In the Harding pegmatite, near Dixon, NM, as large cleavable masses often in pinkish tones due to partial replacement by manganoan muscovite. At the Blue Chihuahua, Hercules, and Himalaya mines, San Diego Co., CA. In Canada at Davis Hill, Bancroft, (antiperthite); Hybla; Smart mine, Eganville; Perth, Lanark Co., (perthite); Kuel Lake, Renfrew Co.; and Tory Hill, ONT; Yates mine, Pontiac Co., and at Mt. Saint Hilaire as euhedral crystals to 30 cm and Baveno twins to 15 cm, QUE. White to tan (8 cm) crystals with scheelite, dravite, and fluorapatite at the Guadalupeña mine, Santa Cruz, SON, Mexico. Carlsbad and Manebach twins at Narsarsuk, and amazonite (10 cm) at Torsukattak Fjord, Greenland. Found as cleavable masses in zircon syenite at *Fredriksvårn, Norway*; maximum microcline in pegmatite at Norra Karr, and Rb microcline perthite in pegmatite at Varuträsk, Sweden; at Vigo, Galicia, Spain; at Baveno, Lago Maggiore, Piemonte, Italy; amazonite(!) in the Ilmen Mts., Ural Mts., and as large crystals at Naryn-Kunta, Irkutsk, Russia; in the pagmatites of the Mawi and Laghman

districts, Afghanistan; 6- to 8-cm white crystals at Wae Gum Gang Myun, Go Sung Gun, Gang Weon Prov., South Korea; in the Ishikawa district, Fukushima Pref., Tadachi, Nagano Pref., and elsewhere in Japan; at Broken Hill, NSW, Australia; at Ambositra and Anjanbonoina, Madagascar. Widespread in the pegmatite of MG, Brazil, as at Fazenda do Bananal, Fazenda do Funil (amazonite), Taquaral district, and Virgem da Lapa. Uses: Used, as are other feldspars, in ceramics and mild abrasives. The amazonite variety is a popular ornamental stone. AR *DHZI* 4:6,38(1963), AM 69:440(1989), CM 28:771(1990).

76.1.1.6 Anorthoclase (Na,K)AlSi₃O₈

Named in 1885 by Rosenbusch from the Greek for *not straight fracture* or *not orthoclase*, in allusion to the lower symmetry than that of orthoclase. Feldspar group. Much material displays a bluish schiller and may thus be included under the term *moonstone*. The name is often applied to multiphase material found in slightly alkalic lavas. The composition range slightly overlaps that of Na-rich sanidine, but true polymorphism may not exist as the overlap region may be a multiphase one. TRIC C1. $a = 8.252$, $b = 12.936$, $c = 7.139$, $\alpha = 92.11^\circ$, $\beta = 116.31^\circ$; $\gamma = 90.22^\circ$, $Z = 4$, $D = 2.60$. 9-478(Or₃₂Ab₆₆An₂) 6.49₁ 6.42₁ 4.11₂ 3.77₁ 3.73₁ 3.24₉ 3.21₁₀ 2.16₂. Structure: AM 67:975(1982). **Habit:** Crystals commonly prismatic [001] with dominant {110} and {110} resembling somewhat those of adularia, or tabular {010}; massive, granular. Twinning occurs according to the Carlsbad, Manebach, and Baveno laws; albite and pericline law twins also occur, as is the case with microcline, but the pericline composition plane is different, and the reticulated pattern formed by these two laws is seen in thin section on {100}. **Physical properties:** Colorless, white, light to dark gray, cream, pale yellow, pink, green; may display a pale to deep blue, greenish, or gold Schiller; vitreous luster to somewhat pearly on cleavage; transparent to translucent. Cleavage {001}, perfect; {010}, good; parting may develop on {100}, {110}, {110}, and {201}; conchoidal to uneven fracture; brittle. $H = 6-6\frac{1}{2}$, $G = 2.57-2.60$. Biaxial (-); $2V = 0-55^\circ$; $N_x = 1.519-1.529$, $N_y = 1.524-1.534$, $N_z = 1.527-1.536$, the indices increasing with Na content; $X \wedge a \approx 10^\circ$, $Y \wedge c \approx 20^\circ$, $Z \wedge b = 5^\circ$; $r > v$ weak. On {100} in thin section, "Scotch plaid" albite-pericline twinning is usually finer than in {001} sections of microcline. **Chemistry:** The usual composition range of anorthoclase is Or₁₀₋₄₀Ab₆₀₋₉₀An₀₋₂₀, overlapping to some extent that of high-Na sanidine but distinguished therefrom by its lower symmetry. Total Fe may reach 0.2 atom per 32 oxygens. Substitution of Ti is low, as is that for Sr and Ba (<1 wt %). Exsolution lamellae of high-K and high-Na phases is common, yielding cryptoperthite intergrowths frequently displaying schiller effects. **Occurrence:** Found in sodian volcanic and hypabyssal rocks formed at elevated temperature. As phenocrysts intergrown with oligoclase in alkalic syenite (larvikite) in association with minor augite, titanian augite, apatite, ilmenite, etc. **Localities:** Found at Cripple Creek, Teller Co., CO; as

Manebach and Baveno twins at Obsidian Cliff, Yellowstone National Park, WY. A major component of larvikite at Larvik, near Oslo, Norway (blue schiller due to exsolution to oligoclase and orthoclase); phenocrysts ($\text{Or}_{17-22}\text{Ab}_{76-81}\text{An}_{1-2}$) in volcanic neck Brownhills, Fife, Scotland; Caldeira Grande, Azores ($\text{Or}_{30-36}\text{Ab}_{63-68}\text{An}_{0.1-1.7}$); on Ustica Island and in andesite of *Pantelleria Island, Sicily, Italy*. Found at Ogaya, Toyama Pref., Japan; in Australia, as massive white crystals ($\text{Or}_{0.7}\text{Ab}_{98}\text{An}_2$) at Tingha, NSW, and as phenocrysts ($\text{Or}_{19}\text{Ab}_{72}\text{An}_9$) at Mt. Anakie and ($\text{Or}_{21-22}\text{Ab}_{75-77}\text{An}_{2-3}$) at Camperdown, VIC; as large xenocrysts ($\text{Or}_{12-14}\text{Ab}_{83-84}\text{An}_{2-4}$) in the Deborah volcanic sequence Kakanui, New Zealand; loose cryptoperthitic crystals ($\text{Or}_{17-22}\text{Ab}_{63-72}\text{An}_{5-20}$) at Mt. Erebus crater, Antarctica. Rhomb-shaped cryptoperthitic phenocrysts ($\text{Or}_{19-22}\text{Ab}_{70-76}\text{An}_{4-8}$) in soda-trachyte at Ropp, Nigeria; at Mt. Kenya, Kenya, both lacking and displaying Schiller; and at Mt. Kilimanjaro, Tanzania. Uses: Material displaying Schiller may be cut en cabochon as a gemstone; coarse-textured larvikite containing Schillerized phenocrysts of anorthoclase is used as an ornamental building or facing stone. AR *DHZI* 4:6,42,57(1963), *MM* 33:949(1964).

76.1.2.1 Buddingtonite $(\text{NH}_4)\text{AlSi}_3\text{O}_8 \cdot 0.5\text{H}_2\text{O}$

Named in 1964 by Erd et al. for Arthur Francis Buddington (1890–1980), American petrologist, Princeton University. Feldspar group. *MON* $P2_1$ or $P2_1/m$. $a = 8.571$, $b = 13.032$, $c = 7.187$, $\beta = 112.7^\circ$, $Z = 4$, $D = 2.38$. *17-517*: 6.52_{10} 5.91_4 4.33_7 3.81_{10} 3.38_7 3.26_6 3.23_7 3.01_4 . Crystals similar to orthoclase in habit and of small size; more commonly as anhedral grains and cryptocrystalline. Colorless, vitreous luster, transparent. Cleavage {001}, good; {010}, distinct; subconchoidal fracture; brittle. $H = 5\frac{1}{2}$. $G = 2.32$. Biaxial (+); $2V_{\text{calc}} = 60^\circ$; $N_x = 1.530$, $N_y = 1.531$, $N_z = 1.534$; $X' \wedge a = 0^\circ$ on {001} and 4° on {010}, $Y \wedge c = 19^\circ$. Found in compact masses pseudomorphous after plagioclase and as minute crystals lining cavities in Quaternary rocks altered by ammonia-bearing waters below the water table at the *Sulphur Bank mercury mine, Lake Co., CA*; also, widespread in the Meade Peak member of the Phosphoria formation, ID; at Tōshichi spa, Iwate Pref., Japan; and in the Condor oil shale, Q, Australia. AR *AM* 49:831(1964), *MA* 35:425(1984).

76.1.3.1 Albite $\text{NaAlSi}_3\text{O}_8$ $\text{An}_0\text{--An}_{10}$

76.1.3.2 Oligoclase $\text{An}_{10}\text{--An}_{30}$

76.1.3.3 Andesine $\text{An}_{30}\text{--An}_{50}$

76.1.3.4 Labradorite $\text{An}_{50}\text{--An}_{70}$

76.1.3.5 Bytownite $\text{An}_{70}\text{--An}_{90}$

76.1.3.6 Anorthite $\text{CaAl}_2\text{Si}_2\text{O}_8$ $\text{An}_{90}\text{--An}_{100}$

The term *plagioclase* is from the Greek *plagios*, oblique and fracture, in allusion to the slightly oblique intersection of the cleavage planes. Albite was named in 1815 by Gahn and Berzelius from the Latin *albus*, white, in allusion

to its usual color; the variety pericline from the Greek for *sloping on all sides*; the variety cleavelandite was named for Parker Cleaveland (1780-1858), American mineralogist, Bowdoin College, Maine; peristerite, which may encompass other species, is from the Greek *peristera*, pigeon, in allusion to the play of colors as on the neck feathers of a pigeon; oligoclase was named in 1826 by Breithaupt from the Greek for *little fracture*, again in reference to the small obliquity of the cleavage planes. Andesine was named in 1841 by Abich for the Andes Mountains; labradorite was named in 1780 by Werner for the locality; bytownite was named in 1835 by Thomson for Bytown, now Ottawa, Canada; anorthite was named in 1823 by Rose from the Greek *anorthos*, not straight, in allusion to the triclinic symmetry. Feldspar group. The compositional boundaries for names within the series are arbitrary, although there may be structurally valid boundaries that are not in use. Anorthite is polymorphous with dmisteinbergite (76.1.7.1) and svyatoslavite (76.1.6.4). Low- and high-temperature forms in the series are a function of the degree of ordering in the structure, and generally correspond to plutonic and volcanic occurrences, respectively. Structure: ZK 133:43(1971), 169:35(1984); AM 65:81(1980), 75:135(1990); AC(B) 44:344(1988); CMP 104:471(1990). The structures of the series end members have been determined with reasonable accuracy, but those of intermediate members of the series are not fully understood, commonly involve exsolution phenomena, and often only "average structures" are reported. The space group is either $C1$ or $P1$, the latter with a doubled c axis; additionally, an I-cell with doubled c axis occurs in bytownites. The trend in lattice constants with increasing anorthite content is for a and b to increase, and for c or $c/2$ to decrease slightly. Albite: Low- TRIC $C1$. $a = 8.14$, $b = 12.79$, $c = 7.16$, $\alpha = 94.3^\circ$, $\beta = 116.6^\circ$, $\gamma = 87.7^\circ$, $Z = 4$, $D = 2.62$. 9-466: 6.39₂ 4.03₂ 3.78₃ 3.68₂ 3.66₂ 3.51₁ 3.20₁₀ 2.93₂; also 20-554, 20-572, 41-1480. High- TRIC $C1$. $a = 8.16$, $b = 12.87$, $c = 7.11$, $\alpha = 93.5^\circ$, $\beta = 116.4^\circ$, $\gamma = 90.3^\circ$, $Z = 4$, $D = 2.62$. 20-528, 41-1481. Oligoclase: Low- TRIC $C1$. $a = 8.15$, $b = 12.82$, $c = 7.14$, $\alpha = 94.0^\circ$, $\beta = 116.5^\circ$, $\gamma = 88.6^\circ$, $Z = 4$, $D = 2.65$. PD: 4.03₈ 3.76₇ 3.69₅ 3.66₅ 3.18₁₀ 2.98₅ 2.93₇ 2.84₅. High- TRIC $C1$. $a = 8.16$, $b = 12.88$, $c = 7.11$, $\alpha = 93.4^\circ$, $\beta = 116.3^\circ$, $\gamma = 90.3^\circ$, $Z = 4$, $D = 2.65$. Andesine: TRIC $P1$ (also $C1$). $a = 8.15$, $b = 12.83$, $c = 14.21$, $\alpha = 93.6^\circ$, $\beta = 116.2^\circ$, $\gamma = 89.7^\circ$, $Z = 8$, $D = 2.68$. PD(low): 4.04₈ 3.76₇ 3.65₇ 3.21₁₀ 3.18₉ 3.14₇ 2.93₇ 2.53₇. Labradorite: TRIC $C1$. $a = 8.18$, $b = 12.87$, $c = 7.10$, $\alpha = 93.46^\circ$, $\beta = 116.09^\circ$, $\gamma = 90.5^\circ$, $Z = 4$, $D = 2.70$. 9-465: 4.04₈ 3.75₈ 3.64₇ 3.29₈ 3.20₁₀ 3.18₉ 3.14₇ 2.95₇. Bytownite: TRIC $P1$ (also $I1$). $a = 8.19$, $b = 12.88$, $c = 14.20$, $\alpha = 93.4^\circ$, $\beta = 116.0^\circ$, $\gamma = 90.9^\circ$, $Z = 8$, $D = 2.73$. PD: 4.03₈ 3.75₈ 3.62₇ 3.36₅ 3.20₁₀ 3.17₈ 2.95₇ 2.52₇. Anorthite: TRIC $P1$. $a = 8.18$, $b = 12.87$, $c = 14.18$, $\alpha = 93.2^\circ$, $\beta = 115.9^\circ$, $\gamma = 91.1^\circ$, $Z = 8$, $D = 2.76$. 20-20: 4.04₅ 3.78₂ 3.62₃ 3.26₅ 3.21₆ 3.19₁₀ 3.18₉ 3.12₄; also 41-1486. Habit: Albite and anorthite occur as well-crystallized examples more commonly than the intermediate members of the series. Albite commonly forms equant to {010} tabular crystals with {010}, {110}, {110}, and {001} dominant, the tabular or lamellar habit being pronounced in cleavelandite. The variety pericline is elongated on [010] with {001}, {101}, and {010} domi-

Striations appearing on {001} cleavage plane of polysynthetic twinning on the albite law.

nant and commonly twinned on the pericline law. Well-crystallized intermediate plagioclases have similar habit, but are more commonly euhedral to anhedral, rock-bound grains. Anorthite is commonly short prismatic, elongated on either [001] with {110} and $\{1\bar{1}0\}$ dominant or elongated on [010] with {001}, {101} (equivalent to {201} in the older morphological setting), and {010} dominant. Commonly polysynthetically twinned on the albite law, with the twin lamellae appearing as striations on the {001} cleavage due to their slightly different orientations. Pericline and Carlsbad law twins are also common, and combined twins are commonly seen in thin section. **Physical properties:** Colorless, white to gray in mass, also yellow, pink, brown, black, pale blue, pale green; vitreous luster; transparent to translucent. Cleavage {001}, perfect, {010}, good, the two intersecting at $93\text{--}94^\circ$; {110}, imperfect; conchoidal to uneven fracture; brittle. $H = 6\text{--}6\frac{1}{2}$. G increases with Ca content [2.60–2.65(albite), 2.63–2.66(oligoclase), 2.66–2.68(andesine), 2.68–2.74(labradorite), 2.72–2.75(bytownite), 2.74–2.76 (anorthite)]. **Optics:** Plagioclases are biaxial (+ or –); $2V_z$ large to moderate; for low-plagioclase $2V_z$ rises from $\approx 88^\circ$ at An_0 to $\approx 95^\circ$ at $An_{\sim 25}$, then decreases to $\approx 88^\circ$ at $An_{\sim 50}$ and rises to $\approx 104^\circ$ at An_{100} ; for high-plagioclase $2V_z$ varies from $\approx 132^\circ$ for An_0 to a minimum of 76° at $An_{\sim 60}$ and rises again to $\approx 103^\circ$ at An_{100} . The refractive indices of low- and high-plagioclase are nearly equal, the significant difference appearing in the albite–oligoclase range and in the bytownite range lie between 1.528 and 1.589; birefringence = 0.007–0.014 being least at $An_{40\text{--}45}$ and greatest at An_{100} ; the dispersion is weak, usually $r < v$. Extinction angles may be measured relative to either of the two cleavages or to twin composition planes; most useful for purposes of identification is the maximum extinction, $X' \wedge (010) = 0\text{--}57^\circ$, measured in sections cut perpendicular to (010) (the Michel–Levy method), or the pair of extinction angles observed in similar sections for combined albite–Carlsbad twins. **Chemistry:** The plagioclase series was one of the first mineralogical solid-solution series to be described, and was initially represented as an ideal, simple, two-component series. In fact, the series is very complex with space group changes, order–disorder phenomena,

Approximate value of $2V_z$ for low and high-plagioclase

Approximate value of low and high-plagioclase

and exsolution phenomena. Plagioclases, particularly those of volcanic and intermediate igneous rocks, are commonly zoned with the cores being Ca-richer, but the reverse is also known. Peristerite intergrowths occur in the An_2 – An_{16} range and commonly consist of alternating lamellae of albite and An_{25} ; Bøggild intergrowths of $\approx An_{45}$ and $\approx An_{60}$ occur in the range An_{47} – An_{58} ; and Huttenlocher intergrowths of $\approx An_{67}$ and An_{95} occur in the range An_{67} – An_{90} . These intergrowths are on a very fine scale and are only rarely visible in thin section, although they are responsible for many of the schiller phenomena displayed by plagioclases. Significant potassium enters the structure only in Na-rich members; at high temperatures there is more extensive solid solution, which often undergoes exsolution on cooling to form antiperthites (albite with K-feldspar blebs and stringers); exsolution is generally not evident in plagioclases of volcanic origin, but may be present on a sub-microscopic scale. Cleavelandite occurs essentially free of calcium in many pegmatites and may then be associated with oligoclase (peristerite). Minor Ti may be present; Fe^{2+} and Fe^{3+} may be present, often as exsolved material in pinkish feldspars. Only minor Sr and Ba are present, and Mg has been reported in some high-Ca examples. The color of rare green and more common red labradorites of Oregon is alleged to be due to extremely fine to colloidal metallic copper inclusions. Plagioclases alter to sericite (fine-grained white mica), saussurite (sericite, epidote, albite), scapolite, prehnite, pyrophyllite,

Schematic phase diagram for the plagioclase series showing almost complete solid solution at elevated temperatures and miscibility gaps at lower temperatures. (After Smith & Brown, *Feldspar Minerals*, v. 1, Springer Verlag, 1988).

and various clay minerals. **Occurrence:** Plagioclases are widespread components of almost all types of igneous and metamorphic rocks, and in some sediments. Albite and oligoclase are common in acid igneous rocks, such as granite, granodiorite, rhyolite, syenite, and granite and syenite pegmatites, with cleavelandite being common in complex granite pegmatites. Intermediate igneous rocks are characterized by andesine; gabbros and basalts commonly contain labradorite and, less commonly, bytownite, either or both being the dominant constituents of anorthosites. Anorthite is much less common and is usually restricted to unusual mafic and ultramafic environments. In metamorphic rocks, plagioclase compositions are usually $<An_{50}$, the calcium content usually being higher with higher-grade metamorphism. Anorthite is sometimes found in metamorphosed carbonate rocks. In sedimentary rocks plagioclase is usually restricted to detrital grains, but authigenic albites may form by diagenesis of the detrital plagioclase. **Localities:** With the exception of anorthite, members of the plagioclase series are found worldwide, and but a few localities can be noted. Albite is particularly noteworthy for well-crystallized specimens. *Albite:* Found at Granville, Washington Co., NY (transparent); at the Gillette Quarry and others, Haddam Neck, CT; Topsham, MA; Amelia C. T., VA (cleavelandite); at various localities in the Pikes Peak granite, CO (cleavelandite, and as caps on green microcline); in the Green River formation, WY, CO, UT; Tip Top Mine, Custer, SD; in the Harding pegmatite, northern Dixon, Taos Co., NM (cleavable, massive cleavelandite with rose muscovite); in San Diego Co., CA (cleavelandite) (Cota, Hercules, Himalaya, Little Three, Mack, Stewart, Tourmaline King, Vandenberg, and White Queen mines). Albite antiperthite at Davis Hill and Silver Crater, northern Bancroft, ON; northern Sherbrooke (alpine cleft environment:albite and Carlsbad twins); at Mt. St.-Hilaire, QUE, Canada. Crystals to 4 cm at Ojos Negros, Ensenada, BCN, Mexico. Large crystals at Skarvebergbukten, Seeland, Norway; at Meylan, northern Grenoble, Isere, and Col du Bonhomme, near Madone, Savoie, France (in granular limestone); pericline in many of the same localities as adularia in Switzerland; near Mursinsk, Ural Mts. (cleavelandite with topaz), also near Miask, Ilmen Mts., and (iridescent) along the Bezymyannaya R., Slyudyanka, Irkutsk, Russia; cleavelandite in pegmatites of the Lagham and Jegdalek areas, Afghanistan. Cleavelandite is abundant in pegmatites of MG, Brazil, as at Campo do Boaitatiaia mine, Palmital, Corrego Frio mine, Cruzeiro mine, Galileia, Xanda mine, Jonas mine(!), the Pederneira mine, São Jose da Safira, and at the Morro Velho mine. *Oligoclase:* Found at the Palermo No. 1 mine, North Groton, NH; at Chester Emery mines, Hampton Co., MA; Macomb, St. Lawrence Co., NY; Mineral Hill, Delaware Co., PA (sunstone); at the Hawk Mine and others, Bakersville, Mitchell Co., NC ($Ab_{72.7}An_{24.8}Or_{2.5}$, gemmy fragments); in Scandinavia at Tredestvard, Kragero, and Arendal, Norway; at Kimito, Finland; at *Danviken, near Stockholm, Sweden*; and at the Monte Redondo quarry, 155 km N of Lisbon, Portugal. *Andesine:* Found at St. Raphael, Mt. Esterel, near Cannes (Carlsbad and Baveno twins), and northern Chagney, Haute-Saone, France; at Zabkowicz, Poland

(Frankenstein, Silesia); in Japan at Hishishiota, Shinano Pref., at Kaneda, Miyagi Pref., at Kuzuhara, Toyama Pref., and elsewhere; at *Marmato, Cauca, Colombia*, and elsewhere in the Andes Mts. of South America. *Labradorite*: An important component of anorthosites of the Adirondack Mts, NY, and northern MN; gemmy yellow, red, green material is mined in Lake Co., OR (in part bytownite), and in crystals N of Plush. In Canada at Taher Is., northern Nain, Labrador ($\text{Ab}_{47}\text{An}_{52}\text{Or}_{0.8}$); *Paul Is., Labrador, NF; and elsewhere*; at Santo Domingo, Puerto Peñasco, SON, Mexico (anhedral to 6 cm in Pinacate volcanic field). Found on Surtsey Is., S of Iceland; at Langesundfjord, Norway; at Lappeenranta, Finland; and at Etna, Sicily, and Mt. Vesuvius, Campania, Italy. Beautiful, nearly transparent material with a delicate labradorescence is mined in southern India. *Bytownite*: Found at Phoenixville, Chester Co., and Cornwall, Lebanon Co., PA; a major component of anorthosites and gabbros as at Crystal Bay and Duluth area, MN ($\text{Ab}_{70-75}\text{An}_{30-25}$), and in the Stillwater Complex, MT; gemmy material at Lakeview, Lake Co., OR (see also *labradorite*); in anorthosite in Foleyet Co., and at *Ottawa (Bytown), ONT, Canada*; E of Nueva Casas Grandes, CHIH, Mexico (8 cm, light yellow, transparent gems to 80 ct). Found at Fiskeneset, Greenland; Rhum Is., Scotland; and in the Bushveld Complex, South Africa. *Anorthite*: Found at Grass Valley, Nevada Co., CA, and Great Sitkin Is., AK; on Amitok Is., Labrador, NF, Canada. Found at Tunaberg, Sweden; in older lavas of *Mte., Somma, Campania, Italy*; northern Bogoslovsk and Barsovka, Ural Mts., Russia. In Japan at Miyakejima, Tokyo Pref. (pseudomonoclinic to $1.5, \text{An}_{97}\text{Ab}_3$); at Otaru-shi (1.5 cm in andesite tuff) and Tarumae volcano, Hokkaido (tabular {001} and asymmetric); at Za volcano, Yamagata Pref., (2 cm in andesite breccia); at Hakone, Kanagawa Pref. Japan and elsewhere. Uses: Sodrian plagioclases find such applications as in ceramics and cleaning compounds, much as for orthoclase. Various intermediate-plagioclase-rich rocks are utilized as building and ornamental stones, especially those displaying a prominent labradorescence, and the latter are also cut en cabochon and marketed under the names "fabulite" and "rainbow moonstone." Albite and oligoclase displaying adularescence and/or chatoyancy make up part of the moonstone gem feldspars; oligoclase with distinct orange-red schiller is known as sunstone and is cut en cabochon; transparent labradorite and bytownite are cut into faceted gems, as are the green and red varieties (Oregon), the latter also being designated as sunstone. AR *MM 30:306(1954)*, *AM 43:1179(1958)*, *DHZI 4:94(1963)*, *BM 107:467(1984)*, *FELD 1:14(1988)*.

76.1.4.1 Reedmergnerite NaBSi_3O_6

Named in 1960 by Milton et al. for Frank S. Reed (b.1894) and John L. Mergner (b.1894), laboratory technicians, U.S. Geological Survey. Feldspar group. TRIC C1. $a = 7.839$, $b = 12.373$, $c = 6.808$, $\alpha = 93.32^\circ$, $\beta = 116.38^\circ$, $\gamma = 92.01^\circ$, $Z = 4$, $D = 2.77$. 18-1201: 6.08₅ 3.88₇ 3.56₉ 3.23₉ 3.08₉ 3.04₁₀ 2.96₅ 2.84₆; also PD: 3.87₁₀ 3.65₃ 3.23₂ 3.14₃ 3.08₇ 3.03₂ 2.84₄ 2.38₂. Structure: *AM 77:76(1992)*. Isostructural with low-albite, ordered with boron ideally in

the T1 site. Order-disorder transformation for synthetic boron-albite occurs at 1 kbar H₂O pressure in the range 500–550°C. Isolated, short prisms up to 2 mm long, with wedge-shaped terminations; untwinned. Colorless, vitreous luster, transparent. Cleavage {001}, perfect; brittle. $H = 6-6\frac{1}{2}$. $G = 2.78$. Biaxial (-); $2V = 80^\circ$; $N_x = 1.554-1.558$, $N_y = 1.565$, $N_z = 1.573-1.573$; An authigenic mineral in black oil shale and brown dolomitic rock at the *Joseph Smith No. 1 well, Duchesne Co., UT*, and elsewhere in the Greenriver formation in CO, UT, and WY. Also found in peralkaline pegmatite, Dar-i-Pioz, Tien Shan, southern Tajikistan. AR *AM 45:188(1960)*, *DANT 10:51(1967)*, *EJM 5:971(1993)*.

76.1.5.1 Paracelsian BaAl₂Si₂O₈

Named in 1905 by Tacconi from the Greek *para*, akin to, and for its compositional identity to celsian. See slawsonite (76.1.5.2). Again described in 1942 by Spencer, the earlier description having been interpreted erroneously as being identical to celsian. Dimorphous with celsian (76.1.1.4). MON $P2_1/a$. $a = 9.065$, $b = 9.568$, $c = 8.578$, $\beta = 90.01^\circ$, $Z = 4$, $D = 3.351$. *10-352: 4.00*₁₀ *3.80*₇ *3.59*₄ *2.99*₅ *2.73*₅ *2.56*₅ *2.37*₄ *2.19*₄. Structure: *AC 6:613(1953)*. The structure is pseudo-ORTH $Pnam$. The tetrahedral framework is similar to that of the feldspars but with a different cross-linkage of the double-crankshaft chains. Aluminum and silicon appear to be disordered or only partially ordered. The structure is closely related to that of danburite, which has symmetry $Pnam$, but in which the tetrahedral framework is ordered with the presence of distinct Si₂O₇ and B₂O₇ dimers. Isostructural with slawsonite. Prismatic crystals often well formed and resembling topaz; granular massive. Multiple, complex twinning. Colorless, white, pale yellow; vitreous luster. Cleavage {110}, poor; uneven fracture; brittle. $H = 5\frac{1}{2}-6$. $G = 3.29-3.32$. Biaxial (-); $2V = 52.5^\circ$; $N_x = 1.570$, $N_y = 1.582$, $N_z = 1.587$. Found with celsian in a band in shale and sandstone associated with manganese ore at the Benallt mine, Rhiw, Lleyn Penin., Caernarvonshire, Wales; and as pale yellow granules in schist at *Candoglia, Piemonte, Italy*. AR *MM 26:231(1942)*, *DHZI 4:172(1963)*, *AM 70:969(1985)*.

76.1.5.2 Slawsonite (Sr,Ca)Al₂Si₂O₈

Named in 1977 by Griffen et al. for Chester Baker Slawson (1898–1964), mineralogist and professor, University of Michigan. See paracelsian (76.1.5.1). MON $P2_1/a$. $a = 8.888$, $b = 9.344$, $c = 8.326$, $\beta = 90.33^\circ$, $Z = 4$, $D = 3.08$. *37-462(Oregon): 3.93*₈ *3.71*₈ *3.22*₁₀ *2.94*₄ *2.92*₅ *2.68*₄ *2.67*₅ *2.55*₄. Structure: *AM 62:31(1977)*. Isostructural with paracelsian. Aluminum and silicon are reported as being ordered; the difference in intensity distribution of the two samples may be due to different degrees of ordering. Fibrous to tabulate prisms. Colorless, gray; vitreous luster; transparent to translucent. Cleavage {001}, good; {110}, fair-good. $H = 5\frac{1}{2}-6\frac{1}{2}$. $G = 3.0$. Biaxial (-); Oregon material: $2V = 82^\circ$; $N_x = 1.573$, $N_y = 1.581$, $N_z = 1.585$; $Y \wedge c = 11^\circ$; $r > v$, weak; Japan material: $2V = 55^\circ$; $N_x = 1.570$, $N_y = 1.582$, $N_z = 1.586$;

$Y \wedge c = 5^\circ$; $r < v$, moderate. Japan material fluoresces pink to purplish red in SWUV. Up to 1.5 wt % BaO. In metamorphosed limestone of the *Martin Bridge formation, Wallowa Co., OR*; associated with celsian, cymrite, grossular, diopside, and others in veinlets cutting a rhodinite xenolith in chloritized serpentine at Sarusaka, Kagami, Kochi Pref., Japan. AR *AM* 72:225(1987).

76.1.6.1 Banalsite $\text{BaNa}_2\text{Al}_4\text{Si}_4\text{O}_{16}$

Named in 1944 by Campbell Smith et al. from a contraction of the component cation symbols: Ba, Na, Al, and Si. ORTH *Ibam*. $a = 8.496$, $b = 9.983$, $c = 16.755$, $Z = 4$, $D = 3.045$. 23-651: 8.50₈ 5.20₉ 4.20₆ 3.77₇ 3.53₁₀ 3.21₈ 2.90₈ 2.09₈; also 33-401: 6.48₆ 3.52₈ 3.24₁₀ 3.10₄ 3.02₅ 2.91₈ 2.09₆ 2.08₆, the latter for a sample from Japan with $\text{Ba}_{0.81}\text{Sr}_{0.25}\text{Na}_{1.98}$. Structure: *MJ* 7:262(1973). The structure is a framework of linked four-tetrahedron rings whose apical oxygens point alternately up and down, whereas in the feldspars the apical oxygen sequence is up–up–down–down. Within the framework the tetrahedra form layers parallel to (001). Al and Si are disordered in the tetrahedral sites; Ba and Na are 10- and six-coordinated, respectively. Isostructural with stronalsite. White, vitreous luster, translucent to transparent. Cleavage {110}, {001}, good. $H = 6$. $G = 3.065$. Biaxial (+); $2V = 41^\circ$; $N_x = 1.5695$, $N_y = 1.5710$, $N_z = 1.5775$; $\text{Na}(D)$: $XYZ = cab$, OAP parallel to {100}. Strontium substitutes for barium, and a solid solution with stronalsite is likely. Found in a vein in manganese ore at the *Benallt mine, Rhiw, Llyn Penin., Caernarvonshire, Wales*; at Langban, Varmland, Sweden; and at the Shiromaru mine, Tokyo Pref., Honshu, Japan. AR *NAT* 154:336(1944), *MR* 1:163(1970).

76.1.6.2 Stronalsite $\text{SrNa}_2[\text{Al}_4\text{Si}_4\text{O}_{16}]$

Named in 1987 by Hori et al. from a contraction of the names and symbols of the component cations: strontium, Na, Al, and Si. ORTH *Ibam* or *Iba2*. $a = 8.415$, $b = 9.901$, $c = 16.729$, $Z = 4$, $D = 2.943$. 40-1451: 3.77₄ 3.50₈ 3.18₅ 3.20₁₀ 3.07₄ 2.99₄ 2.88₇ 2.07₅. Isostructural with banalsite. White, colorless; vitreous luster; transparent to translucent. Cleavage not given but presumably like that of banalsite. $H = 6\frac{1}{2}$. $G = 2.95$. Biaxial (+); $2V = 32^\circ$; $N_x = 1.563$, $N_{y \text{ calc}} = 1.564$, $N_z = 1.574$. Minor barium is present. Found with jadeite in serpentinite at Mt. Ohsa, Okayama Pref., and with pectolite and slawsonite in veinlets in basic tuff xenoliths at *Rendai, Kochi City, Japan*. AR *MJ* 13:368(1987), *AM* 72:226(1987).

76.1.6.3 Lisetite $\text{CaNa}_2\text{Al}_4\text{Si}_4\text{O}_{16}$

Named in 1986 by Smith et al. for the locality. ORTH *Pbc2*₁. $a = 8.260$, $b = 17.086$, $c = 9.654$, $Z = 4$, $D = 2.73$. *PD*: 4.16₄ 3.53₃ 3.47₄ 3.20₁₀ 3.16₂ 3.10₂ 3.01₁ 2.95₃. Structure: *AM* 71:1372(1986). The tetrahedral framework, with disordered Al and Si, is the same as that of banalsite, but cation occupancy and coordination is different (Na in two six-coordinated sites; Ca in seven-coordination). Dimensionally, $a_{\text{lis}} = c/2_{\text{ban}}$, $b_{\text{lis}} = 2a_{\text{ban}}$, and $c_{\text{lis}} = b_{\text{ban}}$.

Colorless, transparent. No cleavage noted. Refractive indices and birefringence similar to that of plagioclase, from which it is distinguished by micrometer-size inclusions and a corona texture. Chemically it is midway between anorthite and pure sodium nepheline. Found as anhedral, untwinned, 100- μ m grains in a retrograde metamorphic environment in the *Liset eclogite pod, Selje district, Western Gneiss region, Norway*. AR

76.1.6.4 Svyatoslavite $\text{CaAl}_2\text{Si}_2\text{O}_8$

Named in 1989 by Chesnokov et al. for Svyatoslav Nestorovich Ivanov (b.1911), Russian geologist. Polymorphous with anorthite (76.1.3.6) and dmisteinbergite (76.1.7.1). ORTH $P2_12_12$ or $P2_12_12_1$. $a = 8.232$, $b = 8.606$, $c = 4.852$, $Z = 2$, $D = 2.687$. PD: 4.16₈ 3.75₆ 3.22₁₀ 2.94₆ 2.71₇ 2.09₈ 1.967₇ 1.670₇. Undetermined structure, but having some dimensional correspondence to banalsite and lisetite; possibly $a_{\text{svy}} = c/2_{\text{ban}}$, $b_{\text{svy}} = a_{\text{ban}}$, $c_{\text{svy}} = b/2_{\text{ban}}$. Dimensionally equivalent orthorhombic and monoclinic anorthite compositions have been synthesized. As prismatic [100] crystals with dominant {011} and {100}. Colorless, white; vitreous luster; transparent to translucent. Cleavage {100}, poor. $H \approx 6$. $G = 2.695$. Biaxial (-); $2V_{\text{calc}} = 37^\circ$; $N_x = 1.552$, $N_y = 1.578$, $N_z = 1.581$; XYZ = *cba*. Weak yellow fluorescence in SWUV. Formed in a burning coal dump as a sublimate (700–900°C) on fracture walls in coal at *Kopeysk, Chelyabinsk coal basin, southern Ural Mts., Russia*, where it is associated with anorthite, troilite, cohenite, fayalite, titanite, and graphite. AR *ZVMO 118(2):111(1989)*, *AM 76:300(1991)*.

76.1.7.1 Dmisteinbergite $\text{CaAl}_2\text{Si}_2\text{O}_8$

Named in 1990 by Chesnokov et al. for Dmitri Sergeievich Steinberg (1910–1992), Russian petrographer, Institute of Geology, Ekaterinburg. Feldspar group. Polymorphous with anorthite (76.1.3.6) and svyatoslavite (76.1.6.4). HEX $P6/mmm$. $a = 5.122$, $c = 14.781$, $Z = 2$, $D = 2.747$. PD: 4.48₆ 3.83₆ 3.73₁₀ 2.85₇ 2.57₈ 2.14₃ 1.847₇ 1.481₄. Structure: *AC 12:465(1959)*. The structure has been determined on synthetic material. Colorless, vitreous luster. Cleavage {0001}, perfect. $H = 6$. $G = 2.73$. Uniaxial (+); $N_O = 1.575$, $N_E = 1.580$. Occurs as hexagonal tablets with well-developed {0001} and poorly developed {1010} on fractures in blocks from burned coal dumps from the *Chelyabinsk coal basin, southern Ural Mts., Russia*, where it is associated with cordierite, mullite, anorthite, wollastonite, tridymite, graphite, iron carbides, and fayalite. AR *ZVMO 119:43(1990)*, *AM 77:446(1992)*.

NEPHELINE GROUP

The nepheline group minerals are tectosilicates of high aluminum content with structures that are derivatives of the β -tridymite silica structure. The nepheline minerals are, however, not isostructural. The general formula is

where

$R = K, Na, Ca, \text{ or } \square$

The formula may be restated in terms of the end members

where

Ne = soda nepheline = $NaAlSiO_4$

Ks = kalsilite = $KAlSiO_4$

An = anorthite = $CaAl_2Si_2O_8$

Q = silica

$x, y, z = \text{fractional percentages}$

The structures are layered, and the idealized structure of a single layer of each of the phases is illustrated along with the β -tridymite structure for comparison. Ignoring the orientation of the apical oxygens, the hexagonal six-

NEPHELINE: $KNa_3Al_4Si_4O_{16}$

Perspective view approximately along c of the hexagonal structure.

tetrahedron rings of tridymite are distorted to lower-symmetry ditrigonal and/or oval rings, alkali cations occupying the various voids. The resultant different ratio of ring types and accompanying voids is directly related to the limited solid solution among the several phases involved. Not all the voids need be occupied. Those that are may contain K, Na, and Ca. The tetrahedral site occupancy may have varying degrees of ordering, leading to polymorphs that may or may not exist in natural systems. *DHZI* 4:231(1963), *FF* 444(1984), *AM* 77:19(1992).

76.2.1.1 Kalsilite $K(\text{AlSiO}_4)$

Named in 1942 by Bannister for the symbols of the constituent elements K, Al, and Si and from the Greek *lithos*, stone. Nepheline group. Dimorphous with kaliophilite. *HEX* $P6_3$ or $P6_322$. $a = 5.161$, $c = 8.693$, $Z = 2$, $D = 2.619$. *11-579*(syn): 4.35₁ 3.97₄ 3.12₁₀ 2.58₅ 2.47₁ 2.43₁ 2.22₁ 2.18₂. Structure: *MM* 35:588(1965). Colorless, white, gray; vitreous to greasy luster; transparent to translucent. Cleavage {1010}, {0001}, poor; subconchoidal fracture; brittle. $H = 6$. $G = 2.59-2.63$. Uniaxial (-); $N_O = 1.538-1.543$, $N_E = 1.532-1.537$, reported slightly higher indices may be due to Na and/or Fe^{3+} substitution. Fusibility 3. Gelatinizes with acids. Excess silica is commonly present in the range $Q_{0.5-2.0}$, and soda nepheline up to Ne_{10} ; calcium is present in very minor amount. Found as embedded grains in the groundmass of lavas and as phenocrysts of nepheline-kalsilite with a perthitic texture. Found in the Colima graben 50 km SSW of Guadalajara, JAL, Mexico; intergrown with K-feldspar the ultramafic Batbjerg intrusion, eastern Greenland; in lavas at San Venanzo, Umbria, Italy; in syenite in the Yakshinsk pluton, Russia; at *Kyam-bogo crater, Bunyaruguru field, Uganda*; as nepheline-kalsilite phenocrysts at Baruta crater, Nyiragongo area, Zaire. *AR* *AJS* 255:282(1957), *DHZI* 4:231(1963), *AM* 77:19(1992).

76.2.1.2 Nepheline $(\text{Na},\text{K})(\text{AlSiO}_4)$

Named in 1800 by Haüy from the Greek for *cloud*, in allusion to its becoming cloudy or milky when immersed in strong acids. Nepheline group. For polymorphs see the nepheline group discussion. *HEX* $P6_3$. $a = 9.989$, $c = 8.380$, $Z = 8$, $D = 2.63$. *35-424*(syn): 4.32₄ 4.17₈ 3.83₁₀ 3.27₇ 3.00₁₀ 2.88₄ 2.57₅

2.34₄; 12-198(syn, potassian): 4.25₈ 4.02₇ 3.35₆ 3.07₁₀ 2.56₆ 2.39₃ 2.36₄ 2.13₅, the unit cell for this sample being $a = 10.237$, $c = 8.508$. Structure: *BM 107:499(1984)*. Many nephelines show satellite reflections in single-crystal diffraction patterns, indicating that the true unit cell is larger than reported here; these have been interpreted as indicating an ordering of Al and Si in tetrahedral sites. **Habit:** Commonly as hexagonal prisms {1010} terminated by the pinacoid {0001} and pyramids {1011}, but often with other prism and pyramid forms; faces, especially on large crystals, often rough and pitted; as rock-bound euhedral, often tabular, to anhedral grains; massive. Twinning on {10 $\bar{1}$ 0}, {11 $\bar{2}$ 2}, and {3365}. **Physical properties:** White, often with yellow or greenish tint, gray, red-brown, the color often due to microscopic inclusions; vitreous to greasy luster; transparent to nearly opaque. Cleavage {10 $\bar{1}$ 0}, distinct; {0001}, imperfect; subconchoidal fracture; brittle. $H = 5\frac{1}{2}$ -6. $G = 2.55$ -2.67. **Optics:** Uniaxial (-); $N_O = 1.529$ -1.546, $N_E = 1.526$ -1.542; birefringence = 0.003-0.004. Substitution of K for Na increases the indices, as does excess silica. For synthetic material, introduction of Ca tends to reduce birefringence, but this is not borne out by natural examples; excess silica accompanied by cation vacancies reduces the indices. **Chemistry:** Pure sodium nepheline, NaAlSiO_4 , has not been found in nature but has been prepared in the laboratory. At 1254°C it inverts to an isometric dimorph, carnegieite, which is also unknown in natural systems. Published analyses indicate a range of Ne/Ks from $\approx 3.5:0.5$ to $\approx 3:1$; a few reported lower ratios may actually represent trikalsilite. Although experimental data show that the nepheline structure may accommodate up to 35 mol % anorthite, calcium substitution in natural nepheline is no more than 0.03 Ca per formula unit, and usually much less. The Si/Al ratio is usually > 1 ; the excess silica can be represented as quartz and is accompanied by cation vacancies. On the basis of these observations the ideal unit cell formula of nepheline can be represented by $\text{Na}_6\text{K}_2[\text{Al}_8\text{Si}_8]\text{O}_{32}$, and that for the encountered substitutions by $\text{Na}_x\text{K}_y\text{Ca}_z\text{O}_{8-x-y-z}[\text{Al}_{x+y+2z}\text{Si}_{16-x-y-2z}\text{O}_{32}]$. Excess silica lies between $Q_{0.5-12.0}$. Nepheline-kalsilite "perthites" may arise from exsolution of phases formed at elevated temperatures, possibly "tetrakalsilite" (panunzite). **Occurrence:** A characteristic phase in alkaline igneous plutonic, hypabyssal, and volcanic rocks of quite varied bulk composition. It occurs in nepheline syenites and related rocks, where it is associated with aegirine-augite, aegirine, and alkali amphiboles, through basic and ultrabasic alkaline rocks, where it may occur with forsterite, spinel, and perovskite. Where crystallized early it forms euhedral crystals, but it may also form poikilitic masses of later crystallization. It forms textural intergrowths with K-feldspar and less often with plagioclase. The earlier formed nepheline usually contains less excess silica than that formed later. In volcanic rocks, the composition range of nephelines is broader than in those of plutonic origin. Nepheline may be of metasomatic origin, the "nephelinization" occurring through the actions of fluids from alkaline intrusives on country rock of varying composition, as in the Haliburton-Bancroft area, ON, Canada, and at Alno, Sweden. Nepheline-bearing rocks may also form at the contact of Ca-rich sediments and basic

intrusives. Localities: The following noteworthy and well-documented localities illustrate the widespread distribution. Found at Litchfield, Kennebec Co., ME; in the Magnet Cove area, Hot Springs, Co., AR; in the Highwood, Bearpaw, and Judith Mts., MT. Of numerous occurrences in Canada, that at Davis Hill, Dungannon Twp., Hastings Co., ON, is particularly noteworthy for large, though crude, 20-cm-diameter crystals(1) with biotite and albite-antiperthite; also at Mt. St.-Hilaire, QUE, sometimes as good, simple tabular crystals(1) to 3.5 cm; at the Lomo del Toro mine, Zimapán, HDG, Mexico. Abundant in the syenitic complexes of the Julianehaab district, Greenland; at Bratholmen, Langesundfjord, Norway; at Alnå, Sweden; with cancrinite at Iivaara, Finland; nepheline-syenite at Assynt, Sutherland, Scotland; at Scawt Hill, Northern Ireland; in leucite-nepheline diabase at Meiches, Hessen, and in the Laacher See district, Eifel, Germany; at Capo di Bove, Rome, and at Mte. Somma, Campania, Italy; at Ditro, Romania; near Miask, Ilmen Mts., Russia; in jacupirangite at Chaunggyi, and in ijolitic nepheline-syenite at Sinkwa, Moguk district, Myanmar; in Ul Len Co., Gyong Sang North Prov., and elsewhere in South Korea; at Nagahama, Shimane Pref., Japan; in phonolite at Abbot's Hill, Dunedin, New Zealand; nephelinite at Etinde, Cameroons; at Lake Kivu and Mt. Nyiragongo, Zaire; in phonolite at Nairobi, Kenya; in foyaite at Pilansberg and the Vaal River, Transvaal, South Africa; with analcime as pseudomorphs after leucite at Rio das Ostras, RJ, Brazil. Use: A component in ceramic bodies. AR *AJS* 255:282(1957); *DHZI* 4:231(1963); *MR*20:439(1989), 21:235(1990).

76.2.1.3 Trikalsilite $K_2Na(AlSiO_4)_3$

Named in 1957 by Sahama and Smith for its similarity to kalsilite and the tripling of the empirical formula of the tetrahedral framework to account for the potassium/sodium ratio. Nepheline group. *HEX* $P6_3$. $a = 15.339$, $c = 8.501$, $Z = 6$, $D = 2.636$. $12-197(\text{syn})$: 4.27₃ 3.93₃ 3.38₂ 3.08₁₀ 3.05₉ 2.66₂ 2.56₄ 2.41₃. Structure: *NJMM*:559(1988). Colorless, vitreous luster, transparent. Subconchoidal fracture, brittle. $H = 6$. Occurs in parallel intergrowth with nepheline in the *Kabfumu lavas, North Kivu, Zaire*. AR *AM* 42:286(1957), *JG* 65:515(1957).

76.2.1.4 Panunzite $(K,Na)(AlSiO_4)$

Named in 1988 by Benedetti et al. for Achille Panunzi, University of Naples. Nepheline group. Possible synonym: tetrakalsilite. *HEX* $P6_3$. $a = 20.513$, $c = 8.553$, $Z = 32$, $D = 2.62$. $31-1081$: 4.28₂ 3.93₇ 3.07₁₀ 2.91₃ 2.56₄ 2.38₂ 2.27₂ 2.18₂. X-ray powder data show sufficient difference from synthetic tetrakalsilite to make equivalence of the two uncertain. Structure: *NJMM*:322(1985). Prismatic [0001]. Colorless, vitreous luster, transparent. $H = 5\frac{1}{2}$. $G = 2.59$. Uniaxial (-); $N_O = 1.540$, $N_E = 1.535$. Distinguished from associated nepheline by its greater transparency. Occurs as short, up to 4 mm, hexagonal prisms with nepheline, green augite, and biotite in ejected, pyrox-

ene-rich blocks associated with the latest volcanic activity at *Mte. Somma-Vesuvius, Campania, Italy*. AR *AM* 42:286(1957), 64:658(1979), 73:420(1988).

76.2.1.5 Kaliophilite $K(\text{AlSiO}_4)$

Named in 1886 by Mierisch from the Latin *kalium*, potassium, and the Greek *philos*, friend, in allusion to the prominence of potassium. Nepheline group. Dimorphous with kalsilite. HEX $P6_3$ or $P6_322$. $a = 27.011$, $c = 8.557$, $Z = 54$, $D = 2.65$. 11-313: 4.26₂ 3.91₁ 3.76₁ 3.50₁ 3.09₁₀ 3.02₁ 2.81₁ 2.59₃. Structure: *EJM* 4:1209(1992). Colorless to white, vitreous to silky luster, transparent to translucent. Cleavage {1010}, distinct. $H = 6$. $D = 2.49$ – 2.67 . Uniaxial (–); $N_0 = 1.530$ – 1.532 , $N_E = 1.526$ – 1.527 . Fusibility 3₂. Gelatinized by acids. Occurs in volcanic ejecta of biotite pyroxenite and augite–melilite–calcite rock at *Mte. Somma, Campania, Italy*, and in ejecta with leucite and hauyne at Albano, Lazio, Italy. AR *D6*:427(1892), *AJS* 255:282(1957).

76.2.1.6 Yoshiokaite $\text{Ca}_{1-x/2}\square_{x/2}(\text{Al}_{2-x}\text{Si}_x\text{O}_4)$

Named in 1990 by Vaniman and Bish for T. Yoshioka (1935–1983), who synthesized the phase. Nepheline group. HEX $P3$, pseudo- $P3c1$ due to twinning. $a = 9.939$, $c = 8.245$, $Z = 8$, $D = 2.74$. *PD*: 8.54₅ 4.94₃ 3.71₁ 3.02₂ 2.97₁₀ 2.86₂ 2.30₅ 2.06₂. Structure: *AM* 75:1186(1990). The unit cell and structure are similar to those of nepheline except that the distortion of the parent tridymite structure has opposite senses of rotation in successive layers. Colorless, vitreous luster. Cleavage(?) {100}, poor. Uniaxial or biaxial with $2V < 5^\circ$ due to strain; $N_{av} = 1.61$; birefringence ≈ 0.02 . The value of x in the formula as given is 2.0–5.3. A lunar mineral occurring as a metastable phase due to devitrification in glassy, shocked grains in *Apollo 16* and *17*, and *Luna 24* soil samples, and in *Apollo 14* regolith, Luna. AR *AM* 75:676(1990).

76.2.2.1 Leucite $K(\text{AlSi}_2\text{O}_6)$

Named in 1791 by Werner from the Greek *leukos*, white, in allusion to its usual color. See ammonioleucite (76.2.2.2). *Low leucite* and *high leucite* refer to the low (tetragonal) and high (isometric/tetragonal) structures, respectively. **Low**: TET $I4_1/a$. $a = 13.09$, $c = 13.75$, $Z = 16$, $D = 2.461$. 15-47: 5.54₅ 5.39₈ 3.44₉ 3.27₁₀ 2.92₇ 2.84₇ 2.81₆ 2.37₇. **High**: ISO $Ia3d$ or TET $I4_1/acd$. $a = 13.4$, $Z = 16$. 31-967(syn): 5.48₆ 4.75₁ 3.36₁₀ 3.00₁ 2.86₃ 2.63₁ 2.37₁ 1.706₁. Structure: *AM* 61:108(1976). The tetrahedral framework in both high- and low-temperature forms is made up of rings of six and four tetrahedra; the four- and six-membered rings are normal to the four- and threefold symmetry axes, respectively, of the high form. In the low form the four-membered rings, somewhat distorted, are normal to the c and a axes. The structure is closely related to the hydrous minerals analcime and pollucite. The transition from low to high form is gradual, but appears to be complete at $\approx 625^\circ$. Euhedral crystals with trapezohedron {112} dominant in the high form, becoming {211}, {121}, and {112} on inversion to tetragonal low form; {110} may also be present. Upon inversion, multiple twinning is common on {110} and {101}, leading to

a retention of the pseudoisometric morphology. Crystals may attain a diameter of 8–9 cm. As disseminated grains, granular and massive. White, colorless, gray; vitreous luster; transparent to translucent. Cleavage {110}, very poor; brittle. $H = 5\frac{1}{2}$ –6. $G = 2.45$ –2.50. Uniaxial (+); sometimes anomalously biaxial (+); $2V$ very small; $N_O = 1.508$, $N_E = 1.509$. **Chemistry:** Most leucite is close to its ideal composition, with Al/Si near 1:2. TiO_2 is usually low, but reaches ≈ 1.4 wt % in material from Lake Kariya, Uganda. Na_2O may reach ≈ 2 wt %, but is usually lower; the presence of excess albite in the system is unfavorable to the formation of leucite. As cooling reaches $1020^\circ C$, leucite may react with liquid to form a mixture of nepheline and K-feldspar (pseudoleucite). Minor CaO may also be present, as well as FeO and MgO. Leucite is decomposed by HCl. **Occurrence:** Found as phenocrysts and in the matrix of K-rich mafic and ultramafic volcanics and hypabyssal rocks. Often associated with K-feldspar, analcime, nepheline, kalsilite, natrolite, and others. **Localities:** Of worldwide distribution; some important occurrences are: at Magnet Cove, Hot Springs Co., AR; as gray to white phenocrysts in volcanics from the Leucite Hills, Sweetwater Co., WY; in the Bearpaw Mts., Hill Co., MT; in the Sierra Nevada Range, CA. In Germany at the Laacher See, Eifel District; at Mte. Somma, Roccamonfina, and *Mt. Vesuvius, Campania, Italy*, and on Vulcano on Lipari Is. In Uganda, at Ruwenzori and Kariya; Mt. Kilimanjaro, Tanzania; and from Mt. Nyiragongo, Kivu, Zaire. AR *DHZI 4:276(1963)*, *ZK 127:213(1968)*, *PCM 16:298(1988)*.

76.2.2.2 Ammonioleucite $(NH_4,K)(AlSi_2O_6)$

Named in 1986 by Hori et al. from the composition and relationship to leucite. See leucite (76.2.2.1). TET (pseudo-ISO) $I4_1/a$. $a = 13.214$, $c = 13.713$, $Z = 16$, $D = 2.24$. 4.0 – 4.74 : 5.53_5 5.43_{10} 3.54_1 3.43_4 3.30_8 2.96_2 2.86_2 2.84_1 . Isostructural with leucite. White, vitreous to resinous luster, translucent. $G = 2.29$. Uniaxial (+); $N = 1.518$; birefringence very low. The electron microprobe-based analysis shows a deficiency of Al compared to the ideal formula, and a concomitant deficiency in ammonium and potassium $[(NH_4)_{0.68}K_{0.19}]$. Found with dolomite and analcime in veinlets and cavities in hydrothermally altered schist as powdery replacements of analcime at *Fujioka, Tatarazawa, Sanbagawa, Gumma Pref, Japan*. AR *AM 71:1022(1986)*.

SODALITE GROUP

Species of the sodalite group proper have aluminum–silicon tetrahedral framework structures and a formula corresponding to

where

SODALITE: $\text{Na}_4(\text{Al}_3\text{Si}_3\text{O}_{12})\text{Cl}$

Perspective view along a_1 .

In the structure, 24 tetrahedra (alternately occupied by Al and Si in a fully ordered scheme), and all shared by adjacent unit cells, make up a series of linked cages having cubo-octahedral configuration. The large cations, predominantly Na and Ca, and the anions Cl , $(\text{SO}_4)^{2-}$, $(\text{OH})^{-1}$, S^{2-} and to a lesser extent, water, are located within the large voids of the cage. The exact position of these larger anionic groups is dependent on the particular combination encountered. The $P\bar{4}3n$ space group may represent an averaged structure, particularly for intermediate phases in which the substitutions are not wholly random or fully ordered and thus leading to domains of lower symmetry.

SODALITE MINERALS

Mineral	Formula	Space Group	a		
Sodalite	$\text{Na}_4(\text{Al}_3\text{Si}_3\text{O}_{12})\text{Cl}$	$P\bar{4}3n$	8.882	76.2.3.1	
Nosean	$\text{Na}_8(\text{Al}_6\text{Si}_6\text{O}_{24})(\text{SO}_4) \cdot \text{H}_2\text{O}$	$P\bar{4}3n$	9.084	76.2.3.2	
Häuyne	$\text{Na}_3\text{Ca}(\text{Al}_3\text{Si}_3\text{O}_{12})(\text{SO}_4)$	$P\bar{4}3n$	9.116	76.2.3.3	
Lazurite	$\text{Na}_3\text{Ca}(\text{Al}_3\text{Si}_3\text{O}_{12})\text{S}$	$P\bar{4}3n$	9.105	76.2.3.4	

In addition to the sodalite group, there are four related minerals with structures based on the fundamental sodalite framework.

SODALITE-RELATED MINERALS

Mineral	Formula	Space Group	a	b	c	
Bicchulite	$\text{Ca}_2(\text{Al}_2\text{SiO}_6)(\text{OH})_2$	I43m	8.825			76.2.3.5
Kamaishilite	$\text{Ca}_2(\text{Al}_2\text{SiO}_6)(\text{OH})_2$	I4(?)	8.850		8.770	76.2.3.6
Tugtupite	$\text{Na}_4(\text{BeAlSi}_4\text{O}_{12})\text{Cl}$	I4	8.640		8.873	76.2.3.7
Tsargorotsevit	$\text{Na}(\text{CH}_3)_4(\text{Si}_{2.5}\text{Al}_{0.5}\text{O}_6)_2$	I222	8.984	8.937	8.927	76.2.3.8

Solid solution between sodalite and nosean, haüyne and lazurite, appears to be complete at elevated temperatures (approximately 1000°C and higher for increased pressure) but is limited at lower temperatures.

76.2.3.1 Sodalite $\text{Na}_4(\text{Al}_3\text{Si}_3\text{O}_{12})\text{Cl}$

The name was coined by Thomson in 1811 in allusion to the high sodium content. Sodalite group. The varietal name, hackmanite, honors Victor Axel Hackman (1866–1941), Finnish petrologist. ISO *P43n*. $a = 8.882$, $Z = 2$, $D = 2.30$. *37-476*: 6.28_4 4.44_1 3.62_{10} 2.81_1 2.56_2 2.37_2 2.09_2 1.570_1 . Structure: *AC(B) 40:6(1984)*. **Habit**: Dodecahedra, sometimes elongated, cubo-dodecahedra, octahedra, well formed and sharp to crude, from microcrystals to 10 cm in diameter; also as embedded grains and massive, sometimes crudely cleavable. Twinned on {111}, often as penetration twins and complex multiple twins. **Physical properties**: Gray, white, greenish or yellowish white, light to medium blue or violet blue, pink; white or very pale blue streak; transparent to translucent. Cleavage {110}, poor to distinct; uneven to conchoidal fracture; brittle. $H = 5\frac{1}{2}$ –6. $G = 2.14$ –2.30. **Optics**: Isotropic; $N = 1.483$ –1.487. The color of yellow, pink, and violet varieties (hackmanite) tends to fade on exposure to visible light, but returns after storage in the dark for a few weeks or exposure to UV or X-radiation; these also display an intense orange to orange-red fluorescence in LWUV and SWUV, often with a short-lived yellowish-white phosphorescence. Deep violet and blue varieties appear to be color stable. Fusibility $3\frac{1}{2}$ –4; gelatinized by HCl. Massive blue material is usually distinguished from lazurite by the absence of associated pyrite and its almost white streak. **Chemistry**: Substitutions for components of the ideal formula are very limited, but may strongly influence color. Al and Si are always close to a 1:1 ratio, with only minor Fe^{3+} substitution for aluminum; minor substitution of K^- and Ca^{2+} is also possible. Other than the related tugtupite, sodalite is the only member of the group in which chlorine is important, but $(\text{OH})^-$ may substitute for it and S^{2-} is almost invariably present in small amounts. The color and fluorescence phenomena have been attributed, in part, to the presence of sulfide or sodium polysulfide clusters. Complete solid solution between sodalite and the sulfate- or sulfide-rich members of the group exists only at elevated temperatures ($>1000^\circ\text{C}$). **Occurrence**: Most frequently encountered

Scapolite, Monte Somma, Italy. Forms: a, {100}; m, {110}; p, {101}; z, {131}

in nepheline syenites and associated pegmatitic rocks, and in volcanic ejecta. Less commonly it may be found in metasomatized calcareous rocks at the contact with alkaline igneous bodies. **Localities:** Only a sampling of noteworthy or well-documented occurrences is given. Massive blue sodalite with distinct cleavage associated with zircon and cancrinite at Litchfield and West Gardiner, ME; at Red Hill, NH; violet-blue in syenite with orthoclase, biotite, and zircon at Salem, Essex Co., MA; blue and white (hackmanite) at Magnet Cove, Hot Springs Co., AR; at Cripple Creek, Teller Co., CO. Sodalite, including hackmanite, is abundant at Mt. St.-Hilaire, QUE, sometimes in exceptional crystals(!), transparent, colorless to deep pink and pale violet, and up to several centimeters in diameter; hackmanite at the Davis quarry, east of Bancroft, and blue massive(!) at the Princess quarry, 4 km E of Bancroft, ON; in the Ice River complex, Ottertail Range, BC, Canada. Found on both sides of the *Kangerdluarssuk and Tunugdliarfik fjords, Greenland*; in the Langesundfjord area, Norway; in volcanic ejecta as white translucent dodecahedra with haüyne and sanidine, and rarely, as green cubododecahedra with vesuvianite and nepheline in limestone at Mte. Somma, and with sanidine in sodalite-trachyte at Scarrupata, Ischia, Campania, Italy; with nepheline and analcime at Val di Noto, Sicily; in the Laacher See area, Eifel, Germany; at several localities in the Kola Penin., and at Miask, Ilmen Mts., Russia. Blue and white (hackmanite) sodalite found at Kishengar, Rajputana, India; blue and white massive in Gil Ju Co., Ham Gyong North Prov., North Korea; dark blue in dike in nepheline syenite at Cerro Sapo, Cochabamba, and, of uncertain origin, in the ruins at Tiahuanaco, Bolivia. **Uses:** Massive blue material has been used as an ornamental stone and a carving material. Transparent Mt. St.-Hilaire material has been faceted into collector gems up to 15+ ct. AR *D6:429(1892)*, *DHZI 4:289(1963)*, *CM 21:549(1983)*, *MR 21:339(1990)*, *ZK 199:75(1992)*.

76.2.3.2 Nosean $\text{Na}_8(\text{Al}_6\text{Si}_6\text{O}_{24})(\text{SO}_4) \cdot \text{H}_2\text{O}$

Named in 1815 by Klaproth for Karl Wilhelm Nose (1753?–1835), mineralogist, Brunswick, Germany. Sodalite group. Synonym: noselite. iso *P43m*. $a = 9.084$, $Z = 1$, $D = 2.21$. *17-538(syn)*: 9.09₆ 6.45₇ 3.71₁₀ 2.87₅ 2.63₇ 2.27₂ 2.14₄ 1.781₃. Structure: *CM 27:165(1989)*. The centrosymmetric space group is for an averaged structure made up of *P23* domains occupied by $\text{Na}_4(\text{SO}_4)$ and $\text{Na}_4(\text{H}_2\text{O})$; Al and Si are fully ordered. Dodecahedral crystals; twinned on {111}; usually massive, granular. Colorless, white, gray, brown, blue; vitreous luster; transparent to translucent to opaque due to inclusions. Cleavage {110}, poor. $H = 5\frac{1}{2}$ –6. $G = 2.3$ –2.4. Isotropic; $N = 1.470$ –1.495. Gelatinizes in acids without liberation of H_2S . Forms discontinuous solid solution with haüyne. The formula is commonly given without the H_2O , but it is almost invariably present in natural examples. Typically in alkali-rich, silica-deficient volcanic rocks, particularly phonolites, and in volcanic bombs. Found in phonolite and tinguaitite in Lawrence Co., SD, in the Cripple Creek area, Teller Co., CO, and in the La Sal Mts., UT. Occurs as phenocrysts in phonolite in the Canary and

Cape Verde Is.; at Wolf Rock, Cornwall, England; at Cantal, France; from the Schellkopf quarry, Laacher See, Eifel, Germany; at Alban Hills, S of Rome, Italy; and elsewhere. It has been reported in syenites from northern China. *AR DHZI* 4:289(1963), *AM* 74:394(1989).

76.2.3.3 Haiüyne $\text{Na}_3\text{Ca}(\text{Al}_3\text{Si}_3\text{O}_{12})(\text{SO}_4)$

Named in 1807 by Brunn-Neergard for Rene Just Haiüy (1743–1822), French pioneer in crystallography. Sodalite group. iso $P43n$. $a = 9.116$, $Z = 2$, $D = 2.41$. $37\text{--}474$: 6.47_2 3.72_{10} 2.87_1 2.62_2 2.43_1 2.14_1 1.936_1 1.781_1 ; also $20\text{--}1087$, $25\text{--}802$. Structure: *CM* 29:123(1991). Al and Si in the tetrahedral framework are fully ordered. The centrosymmetric space group is for an averaged structure made up of domains with $P23$ symmetry populated with either $\text{Na}_3\text{Ca}(\text{SO}_4)$ or $\text{K}_2\text{Ca}(\text{OH})$, significant K being present in almost every case. Dodecahedral or octahedral; commonly in rounded grains. Twinning, contact, penetration, and polysynthetic, on {111} common. Blue, white, gray, yellow, green, pink; pale blue to white streak; vitreous to greasy luster; transparent to translucent. Cleavage {110}, distinct; uneven to conchoidal fracture; brittle. $H = 5\frac{1}{2}\text{--}6$. $G = 2.44\text{--}2.50$. Isotropic; $N = 1.496\text{--}1.505$. Fusibility $4\frac{1}{2}$. Gelatinizes with acids. As much as 5 wt % K_2O may be present; H_2O is also present (although not as much as in nosean), as well as Cl. Forms a discontinuous solid solution with nosean and with sodalite. Most commonly found in phonolites and related rocks, and less commonly in metamorphic rocks (marble). Haiüyne of metamorphic origin at the Edwards mine, Edwards, St. Lawrence Co., NY; in nepheline alnöite with melilite, phlogopite, and apatite at Winnett, Petroleum Co., MT; in Lawrence Co., SD; the Cripple Creek district, Teller Co., CO. Also found at Aruca, Canary Is.; in the Auvergne, France; variously colored at Mte. Vulture, SW of Melfi, in the Alban Hills, Lazio and at *Mte. Somma, Campania, Italy*; at Niedermendig and Laacher See, Eifel, Germany; at Malaya Bistraya, Siberia, Russia; near Nanjing, Jiangsu Prov., China; and at Jebel Tourguejid, Morocco. *AR D6:431(1892)*, *CM* 27:173(1989).

76.2.3.4 Lazurite $\text{Na}_3\text{Ca}(\text{Al}_3\text{Si}_3\text{O}_{12})\text{S}$

Named in 1890 by Brøgger from the Persian *lazhward*, blue, from the earlier-used lapis lazuli, which owes its color to lazurite but may incorporate several other phases. Sodalite group. The name is easily confused with the blue phosphate species lazulite of similar etymology. Equivalent to the *sapphiros* of Pliny (77a.d.). Ultramarine, the blue pigment now produced synthetically, was originally applied to powdered lazurite. iso $P43n$. $a = 9.105$, $Z = 2$, $D = 2.39$. $17\text{--}749$: 6.43_4 3.71_{10} 2.87_5 2.62_8 2.27_3 2.14_4 1.782_3 1.606_2 ; Also $41\text{--}1392$ for TRIC $P1$. $a = 9.09$, $b = 12.86$, $c = 25.71$, $\alpha = \beta = \gamma = 90^\circ$; and $41\text{--}1393$ for MON $P2/a$. $a = 36.36$, $b = 51.40$, $c = 51.40$, $\beta = 90^\circ$; the four strongest lines of these patterns are identical, and the cell edges are either direct multiples of a of the $P43n$ cell or multiples of $2\frac{1}{2}a$ thereof. Structure: *AC(C)* 41:827(1985). When well-crystallized form dodecahedra or cubododecahedra up to 5 cm;

more commonly compact, massive incorporating more or less of other minerals, primarily pyrite and calcite. Multiple contact or penetration twins on {111}, common but generally not apparent. Deep blue to lighter shades, violet blue, greenish blue, colorless; bright blue streak; dull to vitreous luster. Cleavage {110}, distinct; uneven fracture; brittle. $H = 5-5\frac{1}{2}$. $G = 2.38-2.45$. Isotropic; $N = 1.500-1.522$. Fusibility 3. Gelatinizes with acids with liberation of H_2S . As in nosean, Ca substitution is limited. Complete solid solution with nosean may exist, but is very limited with regard to sodalite. The low-symmetry, large-volume cells proposed for triclinic and monoclinic lazurites may reflect a nonrandom occupancy of anions in the framework cages. Occurs in metamorphosed limestones and dolomitic limestones and at pegmatite-limestone contacts. It has been reported from the Green River formation, CO, UT, and WY; at Ontario Peak, San Bernardino Co, CA; in ejected masses at Mte. Somma and Latium, Italy. At Lyadzhuar-Darinsk in the Pamir Mts., Tajikistan; and in dolomitic marble on the Slyudyanka, Malaya Bystraya, and Talaya Rivers, Sayan Mts., near Lake Baikal, Irkutsk, Russia. Massive lapis lazuli(!) has been mined since antiquity at *Sar-e-Sang, on the Kowkcheh R., Badakshan, Afghanistan*, where it occurs in white calcite marble, often enclosing pyrite, and sometimes in octahedral and cubo-octahedral crystals(!) to 5 cm in diameter; lapis lazuli of lighter color and less pyrite than Afghan material, associated with granite, at the headwaters of the Cazadero and Vias rivers, near Ovalle, Coquimbo, Chile. Long used as an ornamental stone in cabochons and small to large carvings, particularly the deep blue Afghan material. Crushed, it forms the artist's pigment, ultramarine, but now largely replaced by synthetic ultramarines of several blue to violet hues. Material of lesser or less uniform color has been dyed to enhance its appeal. AR *D6:432(1892)*, *DHZI 4:289(1963)*, *BM 89:333(1966)*, *ZVMO 119:110(1990)*, *PD 8:202(1993)*.

76.2.3.5 Bicchulite $Ca_2(Al_2SiO_6)(OH)_2$

Named in 1973 by Henmi et al. for the Japanese locality. Sodalite group. Dimorphous with kamaishilite. iso *I43m*. $a = 8.825$, $Z = 4$, $D = 2.824$. *PD*: 3.60₉ 3.04₄ 2.96₄ 2.79₁₀ 2.75₉ 2.60₅ 2.46₄ 1.559₅; also 27-66(syn). Structure: *ZK 146:35(1977)*. Colorless, vitreous to dull luster, translucent. Cleavage not determined. $G_{syn} = 2.75$. Isotropic; $N = 1.625$. Found in skarns at *Carneal, County Antrim, Northern Ireland*, and at *Tuka, Bicchu, Okayama Pref., Japan* and at the Alkagane mine, Iwate pref. AR *MJJ 7:243(1973)*, *AM 59:1330(1974)*.

76.2.3.6 Kamaishilite $Ca_2(Al_2SiO_6)(OH)_2$

Named in 1981 by Uchida and Iiyama for the locality. Sodalite group. Dimorphous with bicchulite. TET *I*-lattice. $a = 8.850$, $c = 8.770$, $Z = 4$, $D = 2.83$. *35-673*: 3.61₁₀ 2.80₈ 2.78₄ 2.55₄ 2.36₂ 2.35₂ 2.09₃ 2.08₂. Colorless, transparent. Uniaxial but nearly isotropic with $N = 1.629$ and no interference figure

observed. Occurs as 0.1-mm grains associated with vesuvianite, garnet, perovskite, calcite, magnetite, and chalcopyrite in vesuvianite skarn at the *Kamaishi mine, Kamaishi, Iwate Pref., Honshu, Japan*. AR AM 67:855(1982).

76.2.3.7 Tugtupite $\text{Na}_4(\text{BeAlSi}_4\text{O}_{12})\text{Cl}$

Named in 1962 by Sørensen for the locality, but discovered in 1957. Sodalite group. TET I4. $a = 8.640$, $c = 8.873$, $Z = 2$, $D = 2.34$. 38-472: 6.19₄ 6.11₁ 4.43₁ 3.59₄ 3.54₁₀ 2.52₂ 2.06₁ 2.04₁. Structure: CM 29:385(1991). The structural framework is intermediate between that of sodalite and helvite. Tugtupite involves an ordered substitution of BeAl for AlAl, thus reducing the symmetry. Most commonly as massive, granular material; as small globular aggregates; rarely in millimeter-size crystals sometimes in complex penetration trillings of pseudocubic habit with twin plane {101}, and also as pseudotrigonal contact twins on {101} and {011}. White, light pink, rose red; vitreous to greasy luster; transparent to translucent. Cleavage bipyramidal distinct; conchoidal fracture, brittle. $H \approx 4$. $G = 2.3$. Uniaxial (+) sometimes biaxial (+); $2V < 10^\circ$; $N_O = 1.496$, $N_E = 1.502$. The color tends to deepen on exposure to light, and fade when stored in darkness. Intensely fluorescent, dark crimson in SWUV and bright to pale crimson in LWUV. Found rarely as millimeter-size globular aggregates and crude pseudo-octahedra at Mt. St.-Hilaire, QUE, Canada; in hydrothermal veins associated with albite, analcime, aegirine, neptunite, and pyrochlore at several sites in the Ilimaussak Complex, as at Kangerdluarssuk, Kvanefjeld, and in the cliffs of *Tugtup agatakorfia, Tunugdliarfik, Greenland*; also, but very sparsely, at Mt. Pengisschorr and Mt. Punkaruiv. Lovozero massif, Kola Penin., Russia. As a lapidary material it has produced cabochon gems, and small (<2.0 ct) faceted gems, principally for the collector. AR AM 48:1178(1963); MR 21:343(1990), 24:26(1993).

76.2.3.8 Tsargorodtsevit $\text{N}(\text{CH}_3)_4[\text{Si}_2(\text{Si}_{10}\text{Al}_5)\text{O}_6]_2$

Named in 1993 by Pautov et al. for Sergei Vasilievich Tsargorodtsev (1953–1986), mineral collector. ORTH (pseudocubic). I222. $a = 8.984$, $b = 8.937$, $c = 8.927$, $Z = 2$, $D = 2.01$. PD(nat): 6.33₆ 4.50₁ 4.46₃ 3.66₁₀ 3.16₁ 2.83₁ 2.59₂ 2.23₁. Powder pattern is very close to ammonian sodalite. Structure: R = 4.7%, first mineral known with isolated polyatomic organic groups: $[\text{N}(\text{CH}_3)_4]$. A tetramethyl ammoniated aluminosilicate. Transforms to TET I422, at 870° , $a = 8.908$, $c = 8.925$, and then to cubic, I432, at 970° , $a = 8.817$. DAN SSSR 317:884(1991), DAN RAN 332:309(1993). Pseudoisometric, pseudocubic habit with {100}, {001}, {101}, {011}, {110}, {010}; {100}, {001}, and {010} faces are dull, but others are lustrous; crystals to 10 mm across; sector twinning present. Colorless, very pale yellowish to opaque white; vitreous luster. No cleavage observed, conchoidal fracture, brittle. $H \approx 6$. $G = 2.04$. IR data resemble those for sodalite. ZVMO 122:128(1993). Raman spectral data and DTA and TGA data also given. No response to UV. Insoluble in boiling H_2SO_4 , HNO_3 , or HF. Partly dissolves with prolonged

boiling in H_3PO_4 . Analysis (%): Si, 31.0; Al, 6.45, N, 3.2; O, 45.6; need $\approx 2.8\%$ H + 11.1% C as well. Biaxial (-); ($2V = 76^\circ$; $N_x = 1.528$, $N_z = 1.531$; colorless; birefringence = 0.002; $r < v$, weak. Sector zoning is present in crystals, details given in *ZVMO 122:128(1993)*. Occurs in friable material filling tectonic fractures in muscovite-chlorite schist which occurs in the *Man'-Khambo Mts., Khanty-Mansiysk region, northern Ural Mts., Russia*. Description was done from specimens in the museum of the Ilmen State Preserve. Recorded as sodalite. On a sample of mica schist. Also on another specimen in the state museum in Yekaterinburg. Fluid inclusion homogenization temperature of 185° . *Man-Khambo Range, Polar Urals, Khanti-Mansi Autonomous Area*. EF MK 1:28(1994).

76.2.4.1 Helvite $Mn_4[Be_3Si_3O_{12}]S$

Named in 1817 by Werner from the Greek *helios*, sun, in allusion to its color. See danalite (76.2.4.2) and genthelvite (76.2.4.3). iso *P43n*. $a = 8.291$, $Z = 2$, $D = 3.23$. *29-217*: 3.38_{10} 2.62_6 2.22_7 1.955_8 1.692_6 1.510_5 1.466_5 1.422_5 . Structure: *AM 70:186(1985)*. The structural framework is similar to that of sodalite; Be and Si are completely ordered. The cell-edge length is related to the larger cations being greatest for Mn, intermediate for Fe, and least for Zn. The habit is markedly tetrahedral with $\{111\}$ dominant, and modified by $\{\bar{1}\bar{1}\bar{1}\}$, $\{101\}$, and $\{211\}$, up to several centimeters in diameter; less commonly pseudo-octahedral; also in rounded aggregates. Yellow, yellow-green, red-brown to brown, gray, darkens with weathering; vitreous to resinous luster; transparent to translucent. Cleavage $\{111\}$, distinct; conchoidal to uneven fracture; brittle. $H = 6$. $G = 3.17-3.37$. Isotropic; $N = 1.728-1.747$. Strong, deep red fluorescence (Mt. St-Hilaire) in LWUV and SWUV. Gelatinizes with acids. Forms complete solid solution with danalite and genthelvite. Found in granite and nepheline-syenite pegmatites, magnetite-fluorite skarns, and in hydrothermal environments. Found at Cumberland, RI; at Amelia, VA; at the Lexington and East Moulton mines, Butte, MT; at the Sunnyside mine, Silverton district, San Juan Co., CO; in skarn of banded fluorite, magnetite, and garnet at Iron Mt., Cuchillo Range, Sierra Co., NM; in tactite in the Dragoon Mts., Cochise Co., AZ; at the Miller mine, Beaver Co., UT; in the sawtooth batholith, ID, sometimes enclosed in topaz; and at Pala and Rincon, San Diego Co., CA. Rarely as small, sharp tetrahedra at Mt. St.-Hilaire, QUE, Canada; as sharp tan-yellow crystals to 4 mm with rhodochrosite and ilvaite at the Potosi mine, Santa Eulalia, CHIH, Mexico. At Langesundfjord and elsewhere in Norway; with magnetite and fluorite at Lupikko, Finland; at Breitenbrunn and *Schwarzenberg, Saxony, Germany*; at Kapnik, Hungary; as large spherical masses with topaz, phenakite, and monazite in the Ilmen Mts., near Miask, Russia. Abundant near Shantou, Guangdong, China, in quartz veins carrying nearly pure helvite-beryl intergrowth; massive at Saiya, Ladimi Bouchi, Nigeria; as sharp, lustrous tetrahedra to 12 cm(!) at the

Chingolo mine, Cosquin, Cordoba, Argentina. AR *D6:434(1892)*, *MM 40:627(1976)*.

76.2.4.2 Danalite $\text{Fe}_4[\text{Be}_3\text{Si}_3\text{O}_{12}]\text{S}$

Named in 1866 by Cook for James Dwight Dana (1813–1895), American mineralogist, Yale University. See helvite (76.2.4.1) and genthelvite (76.2.4.3). iso *P43n*. $a = 8.218\text{--}8.232$, $Z = 2$, $D = 3.40$. *11-491: 3.68_4 3.35_{10} 2.19_5 1.932_7 1.451_4 1.118_5 1.043_5 1.012_6*. Structure: *AM 70:186(1985)*. Isostructural with helvite and genthelvite. The habit is commonly pseudo-octahedral or dodecahedral; also in rounded aggregates. Yellow, pink, red-brown to brown, gray; darkens with weathering; vitreous to resinous or greasy luster; transparent to translucent. Cleavage {111}, trace; conchoidal to uneven fracture; brittle. $H = 6$. $G = 3.31\text{--}3.46$. Isotropic; $N = 1.753\text{--}1.771$. Gelatinizes with acids. Forms complete solid solution with helvite and genthelvite. Found in granite pegmatites, gneiss, and contact-metasomatic and hydrothermal environments. Found at Bartlett, Carroll Co., NH; in the *Rockport granite, Cape Ann, Essex Co., MA*; at Grants Mills, RI; in the Pikes Peak district and St. Peter's Dome, El Paso Co., CO; and near Jerome, Yavapai Co., AZ. Found at Needlepoint Mt., McDame area, BC, Canada; near Redruth, St. Just, Falmouth, and Lanivet, Cornwall, England; Sweden; Russia; at the Mihara fluorite mine, Hiroshima Pref., Honshu, Japan; and at Coolgardie, WA, Australia. AR *D6:435(1892)*, *CM 6:68(1957)*.

76.2.4.3 Genthelvite $\text{Zn}_4[\text{Be}_3\text{Si}_3\text{O}_{12}]\text{S}$

Named in 1944 by Glass et al. for its relationship to helvite and for Fredrick August Ludwig Karl Wilhelm Genth (1820–1893), German–American chemist and mineralogist. See danalite (76.2.4.2) and helvite (76.2.4.1). iso *P43n*. $a = 8.149$, $Z = 2$, $D = 3.64$. *38-467: 3.32_{10} 2.57_6 2.17_7 1.916_8 1.657_6 1.483_5 1.435_5 1.393_5*. Isostructural with helvite and danalite. Crystals commonly tetrahedral, up to 5 cm in diameter; as large rounded masses. Colorless, white, yellow, green, pink to red; darkens to brown to black on weathering; vitreous luster; transparent to translucent. Uneven fracture, brittle. $H = 6\text{--}6\frac{1}{2}$. $G = 3.62$. Isotropic; $N = 1.742\text{--}1.745$. Strong green fluorescence in LWUV and SWUV; occasionally, short-lived phosphorescence. May form complete solid solution with helvite and danalite. Gelatinizes with acids. Found in granite and syenite pegmatites. Found at *Rockport, MA*; *Cheyenne Canyon, near Cookstove Mt., El Paso Co., CO*, and several nearby localities; at Iron Mt., Cuchillo Range, Sierra Co., NM. In excellent crystals associated with analcime at Mt. St.-Hilaire, QUE, Canada(!); in the Cairngorm Mts., Scotland; the Lovozero massif, Kola Penin., Russia; in the Air Mts., Niger; and in columbite-bearing granites of the Jos–Bukuru complex, Nigeria. AR *AM 29:163(1944)*, *73:1384(1988)*; *VLA 2:119(1966)*.

CANCRINITE GROUP

The cancrinite group minerals are feldspathoids, tectosilicates characterized by an aluminosilicate framework. The general formula is

where

A = Na, K, Ca

B = SO₄, CO₃, OH, Cl

and a structure based on a common framework of sixfold rings of tetrahedra.

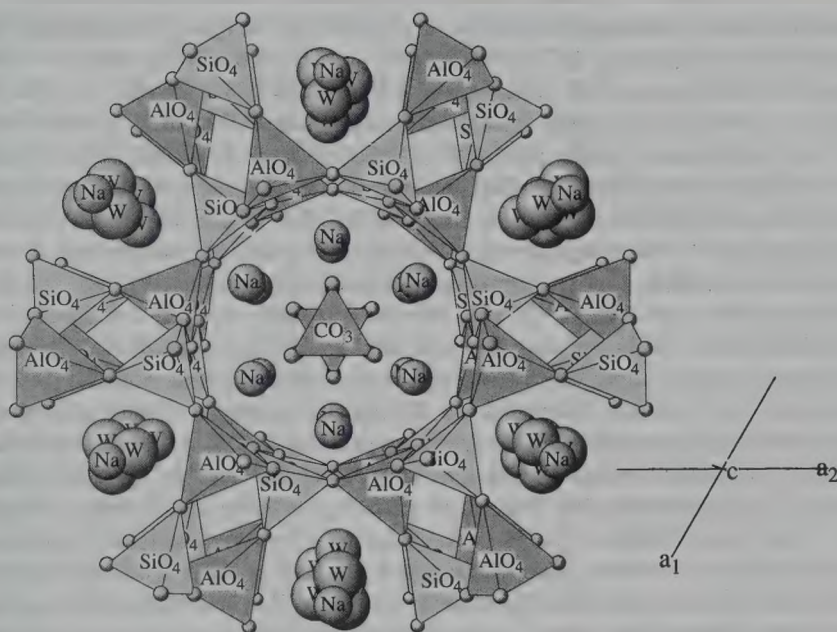

The structure of the cancrinite minerals is based on a sixfold ring of tetrahedra: each ring is linked to three rings in the preceding layer and to three other rings in the succeeding one, resulting in a three-dimensional framework. The layers succeed each other along *c* according to the stacking sequence ABAB. Weak and diffuse reflections exist, indicating that superstructures exist with values of *c* equal to 5*c*, 8*c*, 11*c*, 16*c*, and 21*c*, where *c* = 5.13 Å.

The aluminosilicate framework is constant for the various members of the group, and they differ only in the ordering of the cations outside the tetrahedral framework, which leads to the appearance of satellite reflections.

Most of the cancrinite minerals have Na as the dominant A-site cation, except for liottite, which has Ca dominant. A potassium-dominant vishnevitte also exists. The Si/Al ratio is ideally 1:1 and is usually this value, but may be somewhat greater and is rarely less.

CANCRINITE GROUP

CANCRINITE: $\text{Na}_8\text{Al}_6\text{Si}_6\text{O}_{24} \cdot 2\text{CO}_3 \cdot 5\text{H}_2\text{O}$

A framework with strictly alternating Al and Si tetrahedra forms 6- and 12-membered rings. Na atoms at the center of the six-membered rings are coordinated by disordered oxygen, and Na_2 atoms in the 12-membered rings are coordinated partially by disordered CO_3 groups—less than half of the oxygen sites in the interring cavities are occupied.

CANCRINITE GROUP

Mineral	Formula	Space Group	a	c	
Microsommite	$(\text{Na}, \text{Ca}, \text{K})_{7-8}(\text{Si}, \text{Al})_{12}\text{O}_{24}(\text{Cl}_{2.5}, \text{SO}_4, \text{CO}_3)_{2-3}$	P6_322 or P6_3	22.15	5.28	76.2.5.10

Note: Wenkite (76.2.5.16) is a related structure.

76.2.5.1 Afghanite $(\text{Na,Ca,K})_8(\text{Si,Al})_{12}\text{O}_{24}(\text{SO}_4,\text{Cl,CO}_3)_3 \cdot \text{H}_2\text{O}$

Named in 1968 by Bariand et al. from the country of origin. Cancrinite group. HEX-R P31c according to *EJM 9:21(1997)*. $a = 12.770$, $c = 21.350$, $\gamma = 120^\circ$, $Z = 4$, $D = 2.65$; other cell data: $a = 12.796\text{--}12.847$, $c = 21.361\text{--}21.464$. *20-1086* ($a = 12.786$, $c = 21.436$); (nat): 6.0_5 4.82_8 4.00_6 3.69_{10} 3.30_{10} 2.68_6 2.46_5 2.13_6 ; *PD 9:68(1994)*: 4.83_3 4.00_1 3.69_{10} 3.65_6 2.77_1 2.75_1 2.68_3 2.13_2 . Structure like that of cancrinite. The 8-layer member of the cancrinite group, Si and Al are ordered, with an Si/Al ratio equal to 1. *DAN SSSR 320:882(1991)* and *L-JMG:21(1997)*. Tabular, also massive anhedral grains; crystals show several orders of dipryamids, penetration turning sometimes present. Bluish, or colorless transparent. Cleavage $\{1010\}$, perfect. $H = 5\frac{1}{2}\text{--}6.0$. $G = 2.55\text{--}2.65$ or $2.44\text{--}2.53$ (Italy). Uniaxial (+); $N_O = 1.522\text{--}1.528$, $N_E = 1.528\text{--}1.533$; colorless. Occurs in lapis lazuli deposits associated with nepheline, sodalite, pyrite, phlogopite, and olivine. Forms cores in lazurite crystals. Pseudomorphs of lazurite and afghanite after quartz from Sar-e-Sang. In ejected metasomatized blocks of carbonate rocks in alkalic lavas. Occurs at the Edwards mine, Edwards, St. Lawrence Co., NY; Lake Harbour, Baffin Is., Canada; Volcan Vico Ventralla, Viterbo, Italy; Mte. Somma-Vesuvius volcanic complex, Italy; Pitigliano, Tuscany, Italy; Sacrafano, Latium, Italy; Tultuisk deposit, Lake Baikal, Siberia, Russia; Lyadzhuar-Darinsk, Pamirs, Russia; *Sar-e-Sang lapis mine, Badakshan Prov., Afghanistan*. EF *CM 17:47(1979)*, *RSIMP 35:713(1980)*.

76.2.5.2 Bystrite $\text{Ca}(\text{Na,K})_7\text{Si}_6\text{Al}_6\text{O}_{24}(\text{S}^{2-})_{15} \cdot \text{H}_2\text{O}$

Named in 1991 by Sapozhnikov et al. for the locality. Cancrinite group. See the other members of the group. HEX Originally stated to be $P6_3/mmc$ or $P62c$ or $P6_3mc$ (all from powder data); however, data from the structure refinement indicates HEX-R P31c. $a = 12.855$, $c = 10.700$, $Z = 2$, $D = 2.45$. *45-1373*(nat): 4.82_7 3.92_8 3.72_{10} 3.38_9 2.78_3 2.69_4 2.68_7 2.47_4 . Structure: $R = 8.7\%$. *DAN SSSR 319:873(1991)*. Prismatic to flat plates to 5 mm long; $\{10\bar{1}0\}$ dominant; no twinning. Yellow, transparent; white streak; vitreous luster; after heating at 800° , becomes dark green. Cleavage $\{10\bar{1}0\}$, good; weak pinacoidal cleavage or parting. $H = 5\text{--}5\frac{1}{2}$. $G = 2.43$. Nonfluorescent. Readily soluble in dilute acids, producing H_2S . Analysis (wt %): SiO_2 , 33.4; Al_2O_3 , 26.7; CaO , 5.10; Na_2O , 14.4; K_2O , 7.6; S, 12.0; SO_3 , 0.50; CO_2 , 0.32; Cl, 0.25; H_2O , 1.62. Uniaxial (+); $N_O = 1.584$, $N_E = 1.660$; birefringence = 0.076; negative elongation; $O > E$. O, dense yellow; E, nearly colorless. Found at the *Malo-Bystrinskoye lazurite deposit, western Pribaikal, Siberia, Russia*; in close association with lazurite in lazurite-bearing metasomatite—two generations, the second with lazurite, diopside, and calcite. It sometimes replaces lazurite. EF *ZVMO 120:97(1991)*.

76.2.5.3 Cancrinite $\text{Na}_6\text{Ca}_2[\text{Al}_6\text{Si}_6\text{O}_{24}](\text{CO}_3)_2 \cdot 2\text{H}_2\text{O}$

Named by Rose in 1839 for Georg Cancrin (1774–1845), German-Russian, minister of finance of Russia. Cancrinite group. See vishnevite (76.2.5.15),

microsommitite (76.2.5.10), davyne (76.2.5.5), and the other members of the group. $HEX-R P6_3$. $a = 12.590\text{--}12.75$, $c = 5.117\text{--}5.193$, $Z = 1$, $D = 2.38\text{--}2.56$. (25-776 nat): 10.92_4 4.64_9 3.64_7 3.21_{10} 2.73_4 2.10_7 1.49_5 1.45_5 (superstructure present, $c = 11c$); 34-176: 6.30_5 4.63_9 3.63_5 3.21_{10} 2.73_3 2.60_2 2.56_3 2.41_2 . AlO_4 and SiO_4 tetrahedra. The Al and Si atoms are completely ordered. Tetrahedra are corner-linked to form a framework of a chain of cages parallel to the Z axis. The cages are bounded at the top and bottom by parallel six-membered rings consisting of alternating AlO_4 and SiO_4 tetrahedra. Basic cancrinite (hydroxyl) is stoichiometric with respect to the interframework Na cations; in particular, the Na_2 site is fully occupied by Na atoms. Therefore, the Na atoms on the Na_2 site do not contribute to the satellite reflections, which arise from ordering of the (OH) and H_2O groups in the channels. The OH and H_2O atoms are in positions similar to those of the oxygen atoms of the CO_3 group in cancrinite. Another superstructure has $8 \times c$ axis. *CM 30:49(1992)*. In regular CO_3 -rich cancrinite, superstructures are explained by ordering of cations, anions, and vacancies that occur in the channels. Fine-grained and commonly massive, also {0001} fibrous columnar masses and prisms with {1010} and {1120}, {1011} pyramid, {1110} elongated parallel to [0001]; crystals to several centimeters across. Lamellar twinning rare. Pale to dark yellow and pale orange, gray, green, small crystals are pale violet, pink to purple; sometimes colorless or white and also light blue to grayish blue; white streak; vitreous to subvitreous luster. Cleavage {1010}, perfect; {001}, poor; uneven fracture; brittle. $H = 5\text{--}6$. $G = 2.40\text{--}2.45$. Nonfluorescent. IR, DTA, TG, TGA data: *ZVMO 118:78(1989)*. Gelatinizes with acids. Heating to 900° does not appreciably change the cell dimensions. Uniaxial (-); $N_0 = 1.498\text{--}1.528$, $N_E = 1.492\text{--}1.503$. Has been synthesized many times [e.g., *26:822(1981)*, *SPC 26:33(1981)*]. Occurs as a primary mineral in alkaline rocks (plutonic and volcanic), in sodalite syenite at Mt. St.-Hilaire. Often in nepheline syenites. Also in skarn-zone silicate lavas and alkalic pegmatites. Only localities for fine specimens of cancrinite are given here: occurs as an alteration product of nepheline, in masses to 10 cm associated with sodalite at Litchfield, Kennebec Co., ME; York R., Bancroft, and Dungannon Twp., ONT, Canada; Mt. St.-Hilaire, QUE, Canada; Laacher See, Eifel, Germany; Val Malenco, Italy; Mt. Alluaiev and Mt. Karnasurt, Lovozero massif, Kola Penin., Russia. *EF NJBM 3:97(1990)*, *CM 20:239(1982)* *28:341(1990)*.

76.2.5.4 Cancrisilite $Na_7[Al_5Si_7O_{24}]CO_3 \cdot 3H_2O$

Named in 1991 by Khomyakov et al. for the composition: silica-rich cancrinite. Cancrinite group. Formerly called carbonate-vishnevite. $HEX P6_3mc$. $a = 12.575$, $c = 5.105$, $Z = 1$, $D = 2.39$. $PD(nat)$ (*ZVMO 120:30(1991)*): 6.30_7 4.61_5 3.65_9 3.22_{10} 2.72_5 2.60_2 2.40_2 2.10_2 . Structure is as for other members of the cancrinite group. Symmetry is higher than that of cancrinite ($P6_3$). In cancrisilite, the 12 formula atoms of Si and Al are distributed as 7.2 Si and 4.8 Al, so that $Si/Al = 1.5$. Xenomorphic grains, anhedral, euhedral crystals to 1–3 mm across and aggregates to 10–15 mm. Lilac colored, clear to turbid; white

streak; vitreous luster. Conchoidal fracture, brittle. $H = 5$. $G = 2.40$. IR data: *ZVMO 120:80(1991)*. In UV light, fluoresces bright yellow, characteristic of feldspathoids containing S^{2-} or SO_4^{2-} ions. Dissolves readily with effervescence of CO_2 at 25° in 10% HCl, HNO_3 , and H_2SO_4 . Analysis (%): Na_2O , 21; K_2O , 0.3; CaO , 0.6; MnO , 0.1; Fe_2O_3 , 0.35; Al_2O_3 , 24.5; SiO_2 , 43.4; CO_2 , 4.4; SO_3 , 0.2; H_2O , 5.5. Uniaxial (-); $N_O = 1.509$, $N_E = 1.490$; colorless. Occurs in ultra-agpaitic pegmatites on *Mt. Alluaiev and along the Chinglusuai R., Lovozero massif, Kola Penin., Russia*. EF *RSIMP 35:713(1979)*.

76.2.5.5 Davyne $Na_4K_2Ca_2(Si_6Al_6O_{24})(Cl,SO_4,CO_3)_{2-3}$ (ideal formula)

Named in 1825 by Monticelli and Covelli for Sir Humphry Davy (1778–1829), English chemist. Cancrinite group. HEX $P6_3/m$ [*NJBM 3:97(1990)*] and $P6_3$ [*CM 28:341(1990)*]. $a = 12.705$ – 12.854 , $c = 5.357$ – 5.368 , $Z = 1$, $D = 2.43$. 20 – 379 (nat): 4.80_{10} 3.67_{10} 3.28_{10} 2.76_5 2.67_6 2.48_5 2.12_6 . Structure details given in two papers: Ca–Cl–Ca–Cl chains along the threefold axes; Ca cations in center of sixfold rings of tetrahedra (references as above). Na and K together with sulfate groups and chlorine anions are located in the large channels along the sixfold axis. Ordering is present. Colorless, white; vitreous to pearly luster. Cleavage {1010}, {0001}, excellent. Conchoidal to uneven fracture, brittle. $H = 5\frac{1}{2}$. $G = 2.4$. Gelatinizes with acids. Summary of analyses given in *NJBM 3:97(1990)* (wt %): SiO_2 , ≈ 32 ; Al_2O_3 , ≈ 28 ; Na_2O , ≈ 10 ; K_2O , ≈ 7 ; CaO , ≈ 14 ; SO_3 , ≈ 4 ; Cl, ≈ 7 ; CO_3 , ≈ 7 ; O for Cl, $\approx 2\%$. Uniaxial (+); $N_O = 1.518$ – 1.519 , $N_E = 1.520$ – 1.521 . Also isotropic and uniaxial (-). Occurs in volcanic ejecta and blocks from *Mte. Somma–Vesuvius*. Associated with leucite, orthoclase, garnet, vesuvianite, scapolite, and others. *Mte. Somma and Mt. Vesuvius, Napoli, Campania, Italy. Pitigliano, Tuscany, Italy*. EF *AM 60:435(1975)*.

76.2.5.6 Franzinite $(Na,Ca)_7(Si,Al)_{12}O_{24}(SO_4,CO_3,OH,Cl)_3 \cdot H_2O$

Named in 1977 by Merlini and Orlandi for Marco Franzini (b.1938), Italian mineralogist, University of Pisa. Cancrinite group. HEX $P3m1$ or $P321$. $a = 12.861$ – 12.906 , $c = 26.45$ – 26.62 , $Z = 5$, $D = 2.52$. 30 – 1170 (nat): 3.81_4 3.72_{10} $3.59_{4.5}$ 3.56_4 3.30_2 3.05_2 2.66_2 2.15_3 . Squat prisms to 1 cm in diameter. Pearly white to colorless. Cleavage {0001}, excellent. $H = 5$. $G = 2.46$ – 2.52 . Analysis (wt %): SiO_2 , 32.44; Al_2O_3 , 25.21; CaO , 12.08; Na_2O , 11.50; K_2O , 4.24; SO_3 , 10.65; CO_2 , 1.54; H_2O , 1.88; minor components: Fe_2O_3 , 0.04; MgO , 0.14; Cl, 0.36. Uniaxial (+); $N_O = 1.504$ – 1.510 , $N_E = 1.506$ – 1.512 . Occurs in a pumice deposit with afghanite and liottite in ejected blocks. Associated with diopside and vesuvianite. *Pitigliano, Tuscany; Ariccia, Tuscany; Sacrofano, Latium, Italy*. EF *NJBM 4:163(1977)*, *RSIMP 35:713(1979)*.

76.2.5.7 Giuseppettite $(Na,K,Ca)_{7-8}(Si,Al)_{12}O_{24}(SO_4,Cl)_{1-2}$

Named in 1981 by Mazzi and Tadini for Giuseppe Guiseppetti, the University of Pavia. Cancrinite group. HEX $P6_3mc$, $P62c$, or $P6_3/mmc$. $a = 12.850$,

$c = 42.22$, $Z = 8$, $D = 2.37$. $35\text{-}479(\text{nat})$: 6.42_6 4.32_{55} 3.71_{10} 3.45_8 3.28_5 3.13_7 2.64_6 2.14_{65} . Detailed structure not yet done. Si/Al ratio is 0.99 and is a strong indication for an ordered distribution of Si and Al in the octahedral framework. Anhydrous, allomorphic masses, no crystals. Light violet-blue. No cleavage. $H = 6\text{-}7$. $G = 2.35$. IR data: confirmed no H_2O , OH, or CO_3 . *NJBM 3:103(1981)*. Analysis (wt %): SiO_2 , 33.25; Al_2O_3 , 28.56; Fe_2O_3 , 0.03; CaO, 4.85; H_2O , 14.37; K_2O , 8.00; SO_3 , 9.92; Cl, 0.78. Uniaxial (+); Na(D): $N_{\text{O}} = 1.491$, $N_{\text{E}} = 1.507$. Occurs in fragmented, pale violet-blue veinlets a few millimeters thick in an ejected sanidinite block at *Sacrofano, Biachella Valley, Latium, Italy*. EF

76.2.5.8 Hydroxycancrinite $\text{Na}_8[\text{Al}_6\text{Si}_6\text{O}_{24}](\text{OHCO}_3)_2 \cdot 2\text{H}_2\text{O}$

Named in 1993 by Khomyakov et al. for the composition and cancrinite. Cancrinite group. See the other members of the group. *HEX-R P3*. $a = 12.664\text{-}12.740$, $c = 5.159\text{-}5.187$, $Z = 1$, $D = 2.26$. *PD(nat)*: 6.43_{25} 4.70_6 4.17_2 3.68_7 3.26_{10} 2.76_5 2.59_2 2.43_3 . Structure: *ZVMO 121:100(1993)*. $R = 3.9\%$. Massive aggregates 10–15 mm. Blue, light blue; white streak; vitreous luster. Cleavage {1010}, excellent; steplike fracture; brittle. $H = 6$. $G = 2.32$. IR, DTA, TGA data: *ZVMO 121:100(1993)*. Lost 8.4 wt % to 1000° . Non-fluorescent under UV. Dissolves easily at room temperature in HCl, HNO_3 , and H_2SO_4 with slight effervescence. Analysis (wt %): Na_2O , 23.4; K_2O , 0.45; CaO, 0.92; MgO, 0.11; MnO, 0.03; Fe_2O_3 , 0.18; Al_2O_3 , 31.15; SiO_2 , 36.32; CO_2 , 1.59; H_2O , 5.41. Uniaxial (+); $N_{\text{O}} = 1.494$, $N_{\text{E}} = 1.501\text{-}1.503$; colorless. Occurs in the northern part (Mt. Karnasurt) of the *Lovozero massif, Kola Penin., Russia*; in pegmatoid veins (1–5 cm wide), in ultra-agpaitic rocks (urtite-lujavrite-foyaite), associated with other alkalic minerals such as Natrolite, Steenstrupine, Vuonnemite, Epistolite, and others. EF *AC(B) 38:893(1982)*, *MZ 6:50(1984)*, *SPC 36:325(1991)*.

76.2.5.9 Liottite $(\text{Ca,Na,K,Fe})_8(\text{Si,Al})_{12}\text{O}_{24}[(\text{SO}_4),(\text{CO}_3),(\text{Cl,OH})]_4 \cdot \text{H}_2\text{O}$

Named in 1977 by Merlino and Orlandi for Luciano Liotti (b.1932), Italian mineral collector, who supplied the original specimen from Tuscany. Cancrinite group. *HEX P6*. $a = 12.870$, $c = 16.096$, $Z = 3$ [*CM 34:1021(1996)*], $D = 2.61$ also $a = 12.8575$ and $c = 16.0905$; $29\text{-}1187(\text{nat})$: 4.84_{35} 3.72_{10} 3.32_{75} 2.79_1 2.69_1 2.47_1 2.14_{25} 1.80_1 . Improved powder data in *JPD 10:13(1995)*. The 6-layer member of the cancrinite group. It has a perfectly (Si, Al)-ordered framework. Transparent, colorless crystals to 1 cm in diameter, flattened hexagonal prisms with dominant {0001}, {1010}, {1110}. $H = 5$. $G = 2.56$. Analysis (wt %): SiO_2 , 30.51; Al_2O_3 , 24.92; Fe_2O_3 , 0.36; CaO, 16.71; Na_2O , 7.97; K_2O , 4.98; SO_3 , 8.68; CO_2 , 2.1; Cl, 2.57; H_2O , 1.8. Uniaxial (+); $N_{\text{O}} = 1.530$, $N_{\text{E}} = 1.528$. Occurs at *Pitigliano, Tuscany, Italy*; in ejecta blocks in pumice. The blocks are a product of syntexis between carbo-

nate rocks and trachytic magma associated minerals include melilite, latiumite, clintonite, anorthite, vesuvianite, grossular and andradite. EF *AM* 62:321(1977).

76.2.5.10 Microsommite $(\text{Na,Ca,K})_{7-8}(\text{Si,Al})_{12}\text{O}_{28}(\text{Cl}_{2.5},\text{SO}_4,\text{CO}_3)_{2-3}$

Named in 1872 by Scacchi from the Greek for *small*, in allusion to the minute prismatic crystals, and for the locality. Cancrinite group. See the other members of the group. HEX $P6_322$. $a = 22.08\text{--}22.156$, $c = 5.237\text{--}5.337$, $Z = 3$, $D = 2.34$. $20\text{--}743(\text{nat})$: 4.81_{10} 3.69_{10} 3.29_{10} 2.765_6 2.67_8 2.66_8 2.455_6 2.13_6 . Detailed structure not yet done. Hexagonal prisms; crystals to 14 cm long and 2 cm wide from St. John's Island (may be davyne). Colorless. $\{1010\}$ perfect and imperfect $\{0001\}$ cleavage. Vitreous, silky to brilliant luster on $\{0001\}$, $G = 2.37\text{--}2.45$. Analysis (wt %): SiO_2 , 31; Al_2O_3 , 28; CaO , 13.4; K_2O , 6.1; SO_3 , 8.7; Cl , 8. Six wet analyses given in *BM* 91:34(1968). St. John's Island complete analysis (wt %): Na_2O , 14.9; CaO , 10.4; K_2O , 0.17; SO_3 , 6.60; Cl , 5.70; Al_2O_3 , 29.4; SiO_2 , 32.50; O for Cl , 1.36. This may be davyne because single-crystal work was not done to determine the cell dimensions. Uniaxial (+); $N_{\text{O}} = 1.521$, $N_{\text{E}} = 1.529$; positive elongation. Occurs from ejecta and leucite lavas. Also in fractures in metabasalt. *Mte. Somma, Vesuvius, Naples, Catania, Italy*; Pitigliano, southern Tuscany, Italy; possibly at St. John's Island, Red Sea. St. John's Is. material is extensively altered to a mixture of spinel, anorthite, calcite, corundum and amesite. EF *RSIMP* 35:713(1979), *NJBM* 8:345(1980), *CM* 28:341(1990).

76.2.5.11 Pitiglianoite $\text{Na}_6\text{K}_2\text{Si}_6\text{Al}_6\text{O}_{24}(\text{SO}_4) \cdot 2\text{H}_2\text{O}$

Named in 1991 by Merlino et al. for the locality. Cancrinite group. Discovered in 1979, and called microsommite. *RSIMP* 35:713(1979). Structurally very similar; however, the chemical composition is different. $\text{Na}^+ + \text{H}_2\text{O}$ (pitiglianoite), $\text{Ca}^{2+} + \text{Cl}^-$ (microsommite). HEX $P6_3$. $a = 22.121$, $c = 5.211$, $Z = 3$, $D = 2.394$. $PD(\text{nat})$: 6.39_{str} $4.77_{\text{v str}}$ 3.69_{med} $3.27_{\text{v str}}$ 2.77_{med} 2.65_{med} . (8 lines not given). *AM* 76:2003(1991). A three-dimensional framework of alternating $[\text{SiO}_4]$ and $[\text{AlO}_4]$ tetrahedra with alkali cations, H_2O molecules, and sulfate groups in the channels and cages. Detailed structure not yet done. Hexagonal prisms to 4 mm long, 1 mm in diameter. Elongate parallel to $[001]$. Dominant forms are $\{0001\}$ and $\{1010\}$; twinning present. Colorless, transparent; white streak; vitreous luster. Subconchoidal fracture, brittle. $H \approx 5$. $G = 2.37$. Analysis (wt %): SiO_2 , 35.0; Al_2O_3 , 29.05; CaO , 0.07; Na_2O , 17.10; K_2O , 9.4; SO_3 , 7.58; Cl , 0.01; H_2O , 3.46* (assuming two molecules of H_2O). Uniaxial (-); $\text{Na}(\text{D})$: $N_{\text{O}} = 1.508$, $N_{\text{E}} = 1.506$. Occurs at *Casa Collina, Pitigliano, Tuscany, Italy*, in a pumice quarry, in ejected blocks showing metasomatic effects. Associated with apatite, diopside, and grossular. A product of reaction between trachytic magma and carbonate and sulfate rocks of the volcanic vent. EF

76.2.5.12 Quadridavyne (Na,K)₆Ca₂(Al₆Si₆O₂₄)Cl₄

Named in 1994 by Bonaccorsi et al. from its relationship to and quadruple cell volume of davyne. Cancrinite group. HEX $P6_3/m$. $a = 25.771$, $c = 5.371$, $Z = 4$, $D = 2.354$. PD : 4.85_s 3.71_{vs} 3.31_{vs} 2.79_s 2.68_m 2.47_m 2.15_m 1.80_m. The structure is topologically equivalent to that of davyne, the only difference being the long-range ordering of the alkali metals, and the chlorine in open channels parallel to [0001] resulting in the doubling of the a parameter. As hexagonal prisms, {1010}, to 2 mm in length terminated by {0001}; twinning on {1010} common. Colorless, vitreous luster, transparent. Cleavage {0001}, perfect; {1120}, distinct; brittle. $H \approx 5$. $G = 2.335$. Analysis (wt. %): SiO₂ 33.1; Al₂O₃ 27.6; CaO 11.35; Na₂O 11.21; K₂O 5.93; SO₃ 1.08; Cl 12.13. Uniaxial (+); $N_O = 1.529$, $N_E = 1.532$. In altered ash of the 1906 eruption of Vesuvius at Ottaviano, near Naples, Campania, Italy. EF, AR *EJM* 6:481(1994).

76.2.5.13 Sacrofanite (Na,Ca,K)₉Si₆Al₆O₂₄(OH,SO₄,CO₃,Cl)₄ · nH₂O

Named in 1980 by Burrigato et al. for the locality. Cancrinite group. See the remainder of the cancrinite group. HEX Probably $P6_3/mmc$. $a = 12.865$, $c = 74.240$, $Z = 14$, $D = 2.446$. Also $a = 12.8945$ and $c = 74.213$. 35-653(nat): 11.1₁ 3.74₂₅ 3.73₁₀ 3.69₃ 3.48₄ 2.90₁ 2.65₃ 2.15₂. improved powder data *JPD* 10:13{1995}. Detailed structure not yet done. Flattened hexagonal prisms to 2 cm. Colorless, pearly luster, transparent. Cleavage {0001}, very perfect; {0110}, perfect probably {1010}. $H = 5\frac{1}{2}$ -6. $G = 2.42$. IR data: *NJBA* 140:102(1980). Analysis (wt %): SiO₂, 33.06; Al₂O₃, 24.94; Fe₂O₃, 0.35; CaO, 8.76; Na₂O, 16.50; K₂O, 5.56; H₂O, 2.47; CO₂, 1.00; SO₃, 7.77; Cl, 0.59. Uniaxial (-); $N_O = 1.505$, $N_E = 1.486$. Occurs on Mt. Sabatini, Sacra-fano volcano area, Latium, Italy; in a cavity of an ejecta block associated with sanidine, andradite, fassaite, pyroxene, leucite, and hauyne. EF

76.2.5.14 Tounkite (Na,Ca,K)₈(Al₆Si₆O₂₄)(SO₄)₂Cl · H₂O

Named in 1992 by Ivanov et al. for the locality. Cancrinite group. See the other members of the group. HEX $P6_22$. $a = 12.843$, $c = 32.239$, $Z = 6$, $D = 2.60$. PD (nat): 4.84₄ 3.71₁₀ 3.31₈ 3.04₂ 2.99₂ 2.69₃ 2.47₂ 2.14₃. Detailed structure not yet done. Columnar crystals to 1 cm at Tultui. Bottle green with yellowish or dark blue shade (tint), white streak, vitreous luster. Cleavage (1010), medium. $H = 5$ -5 $\frac{1}{2}$. $G = 2.557$. Mineral is readily soluble in dilute common acids, at the same time losing color. Analysis (wt %): SiO₂, 30.7; Al₂O₃, 25.4; CaO, 10.8; Na₂O, 10.25; K₂, 6.5; SO₃, 13.3; Cl, 2.90; H₂O, 0.77. Uniaxial (+); $N_O = 1.528$, $N_E = 1.543$; colorless or pleochroic in yellow-green to colorless, $E > O$; birefringence = 0.15. Associated with lazurite metasomites. At Malo-Bystri it is associated with diopside-lazurite rocks. At Tultui it is at contact with lazurite calciphyres, associated with calcite, diopside, pyrite, and apatite. *Malo-Bystri and Tultui lazurite deposits, Tounka Valley, southern Pribaikal, Russia*. EF *ZVMO* 121:92(1992).

76.2.5.15 Vishnevite $(\text{Na,Ca,K})_6(\text{Si}_6\text{Al}_6\text{O}_{24})(\text{SO}_4,\text{CO}_3,\text{Cl})_{2-4} \cdot 2\text{H}_2\text{O}$
 or $(\text{Na,K})_8(\text{Si}_6\text{Al}_6\text{O}_{24})(\text{SO}_4) \cdot 2\text{H}_2\text{O}$ (ideal)

Named in 1931 by Belyankin for the locality. Cancrinite group. Synonym: sulfatic cancrinite. See the other members of the group. *HEX* $P6_3$. $a = 12.685$ – 12.789 , $c = 5.179$ – 5.236 , $Z = 1$, $D = 2.40$; for high-K vishnevite: $a = 12.839$, $c = 5.272$. *25-1499* and *25-1500* (drastically overexposed film, 7 lines = 100 Int.). *25-1499*(nat): 3.20_5 2.96_9 1.97_{10} 1.61_8 1.49_6 1.44_6 1.40_6 1.25_8 ; *ZVMO 118:78(1989)*: 6.4_{25} 4.74_5 4.19_2 3.70_9 3.27_{10} 2.77_{65} 2.65_3 2.13_3 ; *ZVMO 119:72(1989)*(K-rich vishnevite): 6.42_6 4.79_9 3.72_8 3.29_{10} 2.68_7 2.14_7 1.34_6 . The observed superstructure in vishnevite is attributed to ordering of the SO_4 group. A unit subcell in vishnevite contains two symmetry-unrelated orientations of the SO_4 group (apical oxygen atom pointing either up or down). Equal occurrences of each SO_4 orientation would give a random pattern and no superstructure. Ordering of the SO_4 groups together with a sympathetic ordering of the cations (Na,K, and Ca) on the Na_2 site within the channels give rise to the observed satellite reflections in vishnevite. The superstructure features a doubling of c . *CM 22:333(1984)*, *30:49(1992)*. Crystal structure of high-K vishnevite: *SPC 34:37(1989)*. Cell parameters for vishnevite decrease upon heating to 1100° . Crystals prismatic to tabular, usually massive; lamellar twinning, rare. Blue, white, yellow, orange, pink, colorless; white streak; vitreous to pearly luster. Cleavage $\{1010\}$, perfect; $\{0001\}$, poor; uneven fracture; brittle. $H = 5$ – 6 ; $G = 2.46$ – 2.48 . IR, TG, DTA, TGA data: *ZVMO 118:78(1989)*. High-K vishnevite has $G = 2.39$. Analysis (wt %): SiO_2 , 33.38; Al_2O_3 , 28.84; Fe_2O_3 , 0.14; MgO , 0.31; CaO , 2.77; Na_2O , 20.56; K_2O , 1.29; SO_3 , 6.36; CO_2 , 1.10; Cl , 0.02; H_2O^+ , 5.25; H_2O^- , 0.22. High K-containing vishnevite from Synnyrsky massif, northern Pribaikal, has 12.7 wt % K_2O . Uniaxial (–); $N_0 = 1.501$, $N_E = 1.495$; sometimes biaxial with $2V = 5$ – 10° . For high-K vishnevite, $N_0 = 1.491$, $N_E = 1.490$. Occurs as a primary mineral in certain alkalic rocks and as an alteration product of nepheline. Occurs at Beaver Creek, Iron Hill, Gunnison Co., CO; Allt a' Mhuillin, Loch Borolan, Assynt, Scotland; Alno Is., Sweden; Iivaara, Kuusamo, Finland; *Kurochkin Valley, Vishnevye Mts., Ural Mts.*, Urusai, and Chekindy, Altai Ridge, *Russia*; high-K material from Synnyr massif, northern Pribaikal, *Russia*; Oldoinyo Lengai volcano, Tanzania. *EF CM 22:333(1984)*, *30:49(1992)*.

76.2.5.16 Wenkite $\text{Ba}_4\text{Ca}_6(\text{Si,Al})_{20}\text{O}_{39}(\text{OH})_2(\text{SO}_4)_3 \cdot n\text{H}_2\text{O}$ (?)

Named in 1962 by Papageorgakis for Eduard Wenk (b.1907), Swiss mineralogist and petrologist, University of Basel. Cancrinite group. *HEX* $P31m$. $a = 13.512$ – 13.528 , $c = 7.462$ – 7.471 , $Z = 1$, $D = 3.23$. *19-1418*(nat): 3.54_7 3.46_{10} 3.38_8 3.25_7 3.15_6 2.70_6 2.69_9 2.23_3 ; also *27-31*. An interrupted framework silicate with six- and eight-fold Al/Si tetrahedral ring channels linked by lone Al/Si tetrahedra that have either $+c$ or $-c$ orientations. *AC(B) 30:1262(1974)* has $(\text{Ba,K})_4(\text{Ca,Na})_6(\text{Si,Al})_{20}\text{O}_{41}(\text{OH})_2(\text{SO}_4)_3 \cdot \text{H}_2\text{O}$. Prismatic to 5 cm long and 1 cm wide, dominant forms: $\{0001\}$, $\{1011\}$, $\{1010\}$.

Light gray; vitreous to pearly luster, greasy on fractures. Prismatic cleavage is very poor, parting is pinacoidal, brittle. $H = 6$. $G = 3.13\text{--}3.19$. IR data: *SMPM* 42:269(1962). DTA data: *ZVMO* 100:492(1971). Nonluminescent. Analysis (wt %): SiO_2 , 31.0; Al_2O_3 , 19.8; CaO , 10.0; SrO , 0.8; BaO , 27.6; Na_2O , 0.6; K_2O , 2.3; SO_3 , 6.7; Cl , trace. Unaxial (-); Na(D) : $N_O = 1.595\text{--}1.604$, $N_E = 1.589\text{--}1.594$; birefringence = $0.006\text{--}0.008$, colorless; sometimes anomalously biaxial, $2V$ to 10° . Occurs between barite layers and calc-silicate rock as a product of strong metamorphism of marbles. In a barite-polymetal deposit in Kazakhstan. *Cava Mergozzoni, Candoglia, Val d'Ossola, Piedmonte, Italy*; Karagaila deposit, Kazakhstan. *EF ZK* 137:113(1973), *AM* 59:1135(1974).

76.3.1.1 Marialite $\text{Na}_4[\text{Al}_3\text{Si}_5\text{O}_{24}]\text{Cl}$

76.3.1.2 Meionite $\text{Ca}_4[\text{Al}_6\text{Si}_6\text{O}_{24}](\text{CO}_3, \text{SO}_4)$

The name *scapolite*, now applied to the series as a whole, was introduced in 1800 by d'Andrade and derives from the Greek *skapos*, shaft, in allusion to the prismatic habit; marialite (Ma) was named in 1866 by vom Rath in honor of his wife, Maria Rosa vom Rath (1830–1888); meionite (Me), named in 1801

MARIALITE

Perspective view along c.

by Haüy, is from the Greek *meion*, less, in allusion to its being distinguished from vesuvianite by its less steep pyramidal faces. Wernerite, applied to the "common" scapolite, and honoring Abraham Gottlob Werner, was also named in 1800 by d'Andrade; mizzonite is from the Greek *meizon*, greater, in reference to its greater *c* axis relative length than for other members of the series; dipyre, a synonym for Na-rich intermediate members of the series but also used for some mizzonite, is from the Greek for *twice* and *fire*, in allusion to the two effects of heat, fusion and phosphorescence. The names *wernerite*, *dipyre*, and *mizzonite* have generally been discarded but are retained here because of evidence of space group variation within the series. **Marialite:** TET $P4_2/n$. $a = 12.059$, $c = 7.587$, $Z = 2$, $D = 2.543$. **Meionite** ($\text{Ma}_{16}\text{Me}_{84}$): TET $I4/m$. $a = 12.179$, $c = 7.571$, $Z = 2$, $D = 2.76$. *31-1279*($\text{Ma}_{65}\text{Me}_{35}$): 3.82₅ 3.56₂ 3.47₁₀ 3.06₇ 3.02₃ 2.73₁ 2.69₃ 1.914₁; *29-1036*($\text{Ma}_{48}\text{Me}_{52}$): 6.04₂ 3.82₆ 3.46₁₀ 3.07₇ 3.03₆ 2.70₃ 2.69₃ 1.912₃. Structure: *NJMA 149:309(1984)*. The structure is made up of four-tetrahedron rings with alternating up-down apical oxygens linked into columns parallel to [001]; the columns are cross-linked by additional four-tetrahedron rings to form the framework of disordered Al and Si tetrahedra. The large anions occupy a central location between the cross-linking rings and are surrounded by coplanar sodium and calcium. The proposed *P* and *I* structures differ in the manner of linkage of columns to rings. Scapolites in the range $\text{Me}_0\text{--Me}_{75}$ crystallize in $P4_2/n$ except that pure end-member marialite is reported to crystallize in $I4/m$. Scapolites in the range $\text{Me}_{75}\text{--Me}_{100}$ have the $I4/m$ structure. Thus it may be appropriate to consider the common soda- and chlorine-rich scapolites (*wernerite*) as a distinct species, and that $\text{Ma}_{25}\text{Me}_{75}$ (*mizzonite*) may be a valid end member of the body-centered, high-calcium end of the series. **Habit:** The usual morphological setting is rotated 45° from the structure cell, the transformation matrix, morphological to structure cell, being 110/110/002. Indexing on the morphological cell, the dominant habit is short-to-medium [001] prismatic crystals with either {100} or {110} dominant, modified by the first-order bipyramid {111}, the second-order bipyramid {101}, and less commonly, the third-order bipyramid {311}, all in the morphological setting. The pinacoid {001} and other pyramidal forms are often present, commonly with holosymmetric morphology; sometimes acicular [001]. Also granular, massive, often columnar to somewhat fibrous. **Physical properties:** Colorless, white, gray, yellow, orange, brown, pink, purple; vitreous luster; transparent to nearly opaque. Cleavage {100}, {110}, good. $H = 5\frac{1}{2}\text{--}6$. $G = 2.55\text{--}2.72$. **Optics:** Uniaxial (-); marialite: $N_O = 1.546\text{--}1.550$, $N_E = 1.540\text{--}1.541$; meionite: $N_O = 1.590\text{--}1.600$, $N_E = 1.556\text{--}1.562$; birefringence = 0.004–0.037, increasing with Ca content; biaxial (-) with $2V < 10^\circ$ has been reported. Oriented inclusions may lead to a distinct chatoyancy. Some varieties display strong yellow fluorescence in LWUV. Ca-rich material is attacked by HCl, but Na-rich material is not. **Chemistry:** Although end-member compositions have been synthesized, they have not been reported in nature, and examples within 80 mol % of either end member are very rare. The principal cation substitution is the Na–Ca couple accompanied by commensurate Si–Al substitution in tetrahedral sites. Minor

potassium may substitute for sodium. Other cations, such as Mg, Fe^{2+} , and Fe^{3+} , are not significant. Anionic substitution, however, is significant, with the Cl-CO₃ couple generally following the Na-Ca substitution. Fluorine is a common substituent for Cl, and SO₄ may substitute for CO₃; hypothetical sulfate-marialite and sulfate-meionite have been proposed. **Alteration:** Commonly becomes cloudy and subsequently alters to a mixture of calcite, plagioclase, and sericitic mica. Alteration to aggregates of epidote, plagioclase, and vesuvianite has been reported, as well as alteration to harmotome and clay minerals as a result of barium metasomatism. **Occurrence:** Scapolites are usually confined to metamorphic and metasomatic environments. They form in regionally metamorphosed rocks such as marble, calcareous gneiss, and greenschists, most commonly in the amphibolite facies but spanning a wide range, perhaps from the zeolite to eclogite facies. In marbles they are often associated with pyroxene (augite), apatite species, sphene, phlogopite, and zircon. Large crystal size is common in the marble environments. Scapolites also form in metasomatic environments (scapolitization) at intrusive contacts, often those of feldspathic pegmatites and gabbros or pyroxenites. They may form at the expense of calcic plagioclase or in place of it in systems high in calcium and CO₂ partial pressure. Chlorine and carbon dioxide may derive from components of original sedimentary rocks. Less commonly, they may form by direct crystallization from pegmatitic fluids. **Localities:** Found as large crystals at Bolton and Boxborough, and massive at Westfield, MA; massive at Marlborough, VT; white, massive, somewhat fibrous at Monroe, CT; as good crystals near Ticonderoga, Essex Co., and Cl-rich, SO₄-poor in the contact zones of marble in the Amity, Orange Co., NY, area, where crystals(!) may reach up to 25 cm in length; similarly at Franklin and Ogdensburg, Sussex Co., NJ; at the Elizabeth mine, French Creek, Chester Co., with magnetite and pyrite in cavities in corroded grossular, and in scapolite-metagabbros (Me_{~63}) interbanded with scapolite-free metagabbro in Bucks Co., PA; of primary crystallization in pyroxene aplite of the Phillipsburg Quadrangle, MT; from the Holbrook Shaft, Bisbee, Cochise Co., AZ. In Canada it is common throughout the Grenville Province, often with phlogopite and fluorapatite, and occurring as large (>10 cm) crystals(!), as at Bobs Lake mine, Bedford Twp., Frontenac Co., at Highland Grove, Haliburton Co., at the Craigmont mine, Raglan Twp., Renfrew Co., and mauve-colored at Gooderham, Glamorgan Twp., ONT; and Bear Lake and Leslie Lake, Pontiac Co., QUE. Found with augite and zircon in coarse marble at La Panchita mine, Ayoquezco, OAX, Mexico. Found at numerous localities in Scandinavia, as at Ødergarden, Norway, the metasomatic deposits of the Kiruna region, northern Sweden, and marialite, Me_{~14}, on Pezh Is., Karelia, Finland. Found at Wehrer Kessel, Laacher See district, Eifel, Germany; Ma_{~80} at *Pianura, Napoli*, and Me_{~90} at *Mte. Somma-Vesuvius, Campania, Italy*, in "geodes" in limestone; at Zdar Mt., Ruda, Moravia, Cecy, Czech Republic; in iron deposits of the Ural Mts., with Cl-rich amphibole in Tuva, K-rich scapolite from southern Yakutia, and associated with phlogopite at Slyudyanka, Lake Baikal, southern Irkutsk, Russia. Gemmy, chatoyant in part,

reddish purple, Na-rich "scapolite" reported from western Xinjiang Prov., China. Gem material from the Ratnapura stone tract, Sri Lanka; pink and yellow, chatoyant, gemmy material in the Mogok stone tract, Myanmar; $Me_{\sim 57}$ at Milendella, Mt. Lofty Ranges, SA, Australia. In Africa, $Me_{\sim 55}$ at Tsarasaotra, Madagascar; yellow, orange, white, and violet transparent, frequently etched, terminated crystals(1) in the Uмба Valley and nearby tracts near Arusha, Tanzania; yellow and pink, gemmy crystals from pegmatite east of Entre Rios, Mozambique; $Me_{\sim 65}$ in garnet-hornblende-pyroxene-scapolite gneiss at Shai Hills, Ghana. Yellow, gemmy scapolite found in ES, Brazil; at the Llanca mine, Coquimbo, Chile. Uses: Transparent material of various colors is fairly plentiful and is cut into faceted gems. Translucent chatoyant material produces attractive cat's-eye cabochons. AR *D6:466(1892)*, *DHZI 4:321(1963)*, *AC(B) 29:1272(1973)*, *MR 13:78(1982)*, *CGEM 1:12(1992)*, *ZVMO 123:90(1993)*.

76.3.2.1 Sarcolite $NaCa_5Al_4Si_6O_{24}F(?)$

Named in 1807 by Thompson from the Greek for *flesh* and *stone*, in allusion to its pink-red color. TET $I4/m$. $a = 12.343$, $c = 15.463$, $Z = 4$, $D = 2.93$, the formula for the determined structure being given as $Na(Na,K,Fe,Mg)_{<1}Ca_6[Al_4Si_6O_{23}](OH,H_2O)_{<2}(SiO_4,SO_4,CO_3,Cl)$. *42-1367*: 4.85₅ 3.91₃ 3.35₈ 3.28₅ 2.95₉ 2.86₈ 2.76₁₀. Structure: *TMPM 24:1(1977)*. Although morphologically similar to the scapolites, and having a dimensionally related unit cell ($a_{sar} \approx a_{scp}$ and $c_{sar} \approx 2c_{scp}$), the structure is unique in being composed of eight-membered rings of alternating Al and Si tetrahedra that are cross-linked to form a framework, and further joined to Si_2O_7 dimers. The structural cell is rotated 45° from the older morphological cell, the transformation matrix, morphological to structural, being 110/110/002. The habit, in morphological setting, is as equant to short prismatic [001] with {100} dominant crystals, and highly modified by other prisms, bipyramids of all three orders and the basal pinacoid. Simpler crystals often resembling cubo-octahedrons. Also as irregular masses. Pink, red, pinkish white; vitreous luster; transparent to translucent. $H = 6$. $G = 2.545$. Uniaxial (+); $N_O = 1.604$, $N_E = 1.615$; but also reported as biaxial (+); 2V small; $N_x = N_y = 1.640$, $N_z = 1.657$; $r > v$, strong. Gelatinized by acids. Fusibility 3(?). Found in volcanic ejecta at *Mte. Somma, Campania, Italy*. AR *MM 48:107(1984)*, *CM 25:731(1987)*.

76.3.3.1 Ussingite $Na_2[AlSi_3O_8](OH)$

Named in 1915 (Bøggild) in honor of Prof. Niels Viggo Ussing (1864–1911), Copenhagen, Denmark. TRIC $P1$. $a = 7.256$, $b = 7.686$, $c = 8.683$, $a = 90.75$, $\beta = 99.75$, $\gamma = 122.48$, $Z = 2$, $D = 2.51$. *14-426* 6.88₇ 6.35₉ 4.92₇ 4.18₇ 3.84₇ 3.47₇ 2.95₁₀ 2.69₁₀. Structure: *AM 59:335(1974)*. The structure is a unique alumino-silicate framework with ordered Al. Occurs as subparallel tabular to blocky crystals with {100}, {010}, and {001} dominant; more commonly as

fine-grained masses and aggregates. Twinning on (010) common. Pale reddish violet; vitreous luster; transparent to translucent. Cleavage {001} and {110} perfect. $H = 6-7$. $G = 2.48$. Biaxial (+); $2V = 32-39^\circ$; $N_x = 1.504$, $N_y = 1.508-1.509$, $N_z = 1.543-1.545$; $Z \wedge b = 3^\circ$; pleochroic. Easily fusible. Gelatinizes with acids. Distinguished from similar appearing sodalite (St. Hilaire) by its lack of fluorescence in UV. Found in syenite pegmatites. In good crystals, 5 mm, and masses in sodalite xenoliths at Mont. St Hilaire, QUE, Canada; at *Kangerdluarsuk, Ilimaussaq, Greenland*; in the Khibiny and Lovozero massifs, Kola Peninsula, Russia. *DT 551(1932)*, *MR 21:284(1990)*.

Zeolites

ZEOLITE GROUP

The zeolites are a very large group of minerals. They may be defined as crystalline, hydrated aluminosilicates of alkali and alkaline earth cations having infinite, three-dimensional structures. They are further characterized by an ability to lose and gain water reversibly and to exchange constituent cations without major changes in structure. *MASCN:4(1977)*. The general formula is

The structure is based on an arrangement of SiO_4 and AlO_4 tetrahedral groups positioned to create an open, three-dimensional framework of channels. In all zeolites, if a tetrahedral site forms after an alkali ion occupies the channel, an Al^{3+} ion will preferentially occupy the tetrahedral site. If a tetrahedral site forms before an alkali ion occupies the channel, an Si^{4+} ion will occupy the tetrahedral site. If the growth steps are inclined to the mirror or glide plane, the two symmetry-related sites will not be equivalent, and thus ordering will occur and the space group symmetry will be reduced; therefore the mirror plane changes into a twin plane. Indeed, during crystal growth various degrees of Al-Si ordering are produced by electron charge balance between alkali or alkaline cations and the Si-Al atoms on the crystal surface. Optical phenomena inconsistent with the apparent external or even the x-ray symmetry suggest the presence of complicated optical sectors with various symmetries, and no truly single crystals are produced during growth.

Because of the variety and complexity, commercial importance, practical utility, and beauty of the zeolite structures, the field has been very well studied and published reports include: *NZ:18(1985)*, *ZW (1992)*, *AM 77:685(1992)*, *EJM 7:501(1995)*, and many others.

77.1.1.1 Analcime $\text{Na}(\text{AlSi}_2)\text{O}_6 \cdot \text{H}_2\text{O}$

Named in 1801 by Haüy from the Greek for *weak*, in allusion to its weak electrical property when heated or rubbed. Zeolite group. See pollucite (77.1.1.2) and wairakite (77.1.1.3). ISO, TET, ORTH, MON, and TRIC; reported space groups include: *Ia3d*, *I4₁/acd* or *I4₁a*, *Ibca*, *I2/a*, and *P1*. Monoclinic cell: $a = 13.72\text{--}13.73$, $b = 13.71\text{--}13.73$, $c = 13.69\text{--}13.74$, $\beta = 90.0\text{--}90.5^\circ$,

$Z = 16$, $D = 2.27$. Orthorhombic cell: $a = 13.720\text{--}13.733$, $b = 13.715\text{--}13.729$, $c = 13.709\text{--}13.740$. Z 8:247(1988). 41-1478(ISO): 5.59₆ 4.84₁ 3.43₁₀ 2.92₄ 2.69₁ 2.50₁ 2.22₁ 1.74₂; also 42-1378(magnesian), 19-1180(ORTH). Analcime has a wide variation in Ca, Na, Cs, and Mg, along with order-disorder of Si-Al in the framework, which causes it to be classified in several crystal systems. The Al-Si framework is the same as for pollucite and wairakite. The framework is composed of four-ring chains wrapped around square prisms that are interconnected to form cages. Cubic analcime has disordered Al and Si in the framework. Ordering of Al and Si in the tetrahedra and related Na-Ca occupancy results in lower symmetries. *NZ:321(1985)*, *ZK 184:63(1988)*. Neutron-diffraction study: *ZK 135:240(1972)*. **Habit:** Trapezohedral {211} common with small cube {100} faces. Rare: {110}, {112}, {233}, {345}, {210}, and {421}. Noncubic analcime is polysynthetically twinned. Pseudomorphohedral twins with two sets of twin lamellae at 90° are common (contact plane {101}?). Crystals may be 25 cm across or more (e.g., Mt. St.-Hilaire). **Physical properties:** Generally white or colorless, but may be yellow, pink, orange, red, green, blue, brown, or black; white streak; vitreous luster. Cleavage {100}, poor; subconchoidal fracture; brittle. $H = 5\text{--}5\frac{1}{2}$. $G = 2.22\text{--}2.63$. Soluble in HCl. IR and Raman data: *PCM 7:96(1981)*. Thermal data: *NZ(1985)*. **Chemistry:** Si/Al ratio ranges from 1.5 to 3. T_{Si} varies widely 0.60-0.73. The terms *low-silica analcime* and *high-silica analcime* may be used where T_{Si} is significantly less or greater than the common value of approximately 0.67. Series between analcime and pollucite and wairakite are well established; most are Na-dominant. Mg-rich analcime (23 at .7%) has been found. **Optics:** $N = 1.479\text{--}1.493$. Isotropic or biaxial with a small (-) 2V. Birefringence to 0.001. **Occurrence:** In a variety of geologic environments: continental and marine sedimentary rocks (deep-sea sediments, saline alkaline lakes), altered and unaltered pegmatites, veins andmiarolitic cavities. Occurs in igneous rocks as phenocrysts, but there is still controversy as to their primary or secondary (formed from leucite) origin. *AM 78:225,230(1993)*. Some may be primary in basaltic magmas. **Localities:** Many worldwide localities. Display-quality specimens are known from the following: Watchung basalts at Paterson and Bergen Hill, NJ, particularly the Upper and Lower New Street quarries and the Prospect Park quarry; also at Chimney Rock and Bound Brook quarries, Somerset Co., NJ; Cornwall, Lebanon Co., PA; Copper Falls mine, Eagle Harbor, Keweenaw Co., MI; twinned crystals from the Phoenix mine, Houghton, MI; North and South Table Mts., Golden, CO; Skookumchuck Dam, near Tenino and Bucoda, Thurston Co., and 3-cm crystals at Kalama, Cowlitz Co., WA; fine, transparent crystals to 6 cm at the Dek and Two Hug quarries, Price Creek, Kings Valley, Benton Co., OR; also at the Springfield Butte quarry, Springfield, Lane Co., OR; Mt. St.-Hilaire, QUE (to 25 cm across), Wasson's Bluff and Cape Blomidon, Bay of Fundy, NS, and deep red phenocrysts at Crowsnest Pass, Coleman, ALB, Canada; Dumbarton, and Salisbury Crags, Edinburgh, Scotland; to 4.5 cm at the Dean quarry, Keveerne, Lizard Penin., Cornwall, England; in the Faroe Is. at Eysteroy, Mykines, and Stremoy Is.; *Cyclope Is., Catania, Sicily, Italy*; pinkish-

white crystals to 8 cm with apophyllite at Val di Fassa, Trento, Italy; white well-formed crystals to 18 cm at Tura and along the Nidym R. area, Tunguska R. region, Yakutia, Siberia, Russia; and crystals to 4 cm from along the Amudikha R., Tunguska R. region, near Mirny; 2-cm crystals with gmelinite at Cairns Bay, Flinders, Victoria, and Cape Grim, TAS, Australia; with natrolite at Pahau River, Culverden, North Canterbury, New Zealand. *EF INDM* 6:127(1965); *AM* 63:448(1978), 66:403(1981), 76:189(1991); *PT* 1:1-22(1979); *MR* 21:284(1990); *ZW* (1992).

77.1.1.2 Pollucite (Cs > Na > Rb > Li)_xAl_xSi_{3-x}O₆ · nH₂O

Described by Breithaupt in 1846, and named for Pollux, one of the twin brothers (Gemini) of Greek and Roman mythology, when two new minerals were found together that resembled one another. Zeolite group. Castor (= castorite), the associated mineral, is now known as petalite. Isostructural with analcime, wairakite, leucite, and ammonioleucite. Most pollucite is cubic and is isotropic but is not completely disordered. Single-phase primary pollucite reequilibrates with decreasing temperature. Na-Si-enriched and Cs-Al-enriched domains (usually less than 200 μm) form. Quartz may exsolve, leading to Si-poor but cation-Al-rich pollucite. Forms a complete solid-solution series with analcime. *iso Ia3d* (nat) and *TET I4₁/a* (syn anhydrous equivalents of MAlSi₂O₆, where M = K, Rb, Cs). Isometric: *a* = 13.64–13.71, *Z* = 16, *D* = 3.25 (for pure end member). *25-194*(nat): 3.65₃ 3.42₁₀ 2.91₄₅ 2.42₂ 2.22₂ 1.86₂ 1.74₂ 1.71₁; *29-407*(syn): 5.58₁ 3.66₅ 3.42₁₀ 2.91₄₅ 2.42₃ 2.20₂ 1.86₂ 1.74₂. Significant changes in peak intensities occur in X-ray diffraction patterns between pollucite and analcime. *CM* 12:334(1974). Pollucite has the same aluminosilicate framework as analcime and wairakite. Four-ring chains are wrapped around square prisms and interconnected to form cages that are occupied by Cs. Large voids in the framework exist that are occupied by water molecules and Cs. Na is located between water molecules, in the same position as in analcime, but in randomly distributed clusters. Si/Al varies from about 2.1 to 2.6. High-Cs-containing samples have Si/Al approaching 2.0. Complete disorder (i.e., totally cubic) was not observed even in pollucite. *CM* 32:69(1994). **Physical properties:** Commonly massive or as rounded, corroded crystals. Sharp, euhedral crystals are rare. Forms {100}, {211}, common; {110}, {210}, rare. Crystals to 10 cm or more in diameter. Colorless, white, gray, pink, blue, or violet; white streak; vitreous to greasy luster. No cleavage, conchoidal to uneven fracture. *H* = 6½–7. *G* = 2.67–3.03. NMR and MAS study of Al–Si order in pollucite–analcime series: *CM* 32:69(1994). X-ray luminescence spectra: *MS* 36:116(1982). Dissolves with difficulty in hot HCl, but is readily soluble in HF. **Chemistry:** As the Na content increases, so does the H₂O content. Traces of K, Li, Mg, Fe, and Mn may be present. Ca is found in trace amounts only in sodian pollucite. Rb₂O to 3.0 wt %, Li₂O to 0.4 wt %, P₂O₅ to 1.5 wt % (Al³⁺ + P⁵⁺ = 2Si⁴⁺). Specimens from Poll₅₀ to Poll₁₀₀ have been found. There is no solid solution toward wairakite or leucite. CRK = 100(Cs + Rb + K)/Σ cations = 69 to 89, with a mean of 81 for pollucite from

about 70% of known localities. Si/Al ratios for primary pollucite are usually 2.31–2.57, mean 2.48. **Optics:** Isotropic or very weakly anisotropic; $N = 1.508$ – 1.527 . One can determine the Cs content from the refractive index. **Occurrence:** Restricted to highly fractionated rare-element, complex Li-Cs-bearing, evolved, granitic pegmatites. Forms at 300 – 400° and 2 – 4 kbar. Associated with quartz, feldspars, spodumene, lepidolite, elbaite, petalite, eucryptite, and apatite. **Alteration:** Quartz pseudomorphs to 23 cm across have been found. Also alters to quartz, analcime, adularia, lepidolite, spodumene, and clays. **Localities:** Approximately 100 worldwide localities are known. Only noteworthy localities are given here: gem-quality material from Dudley's Ledge, Bennett quarry at Buckfield, Oxford Co., ME; also Mt. Mica, Mt. Marie(!), Paris; Tamminen quarry, Greenwood; Dunton gem mine at Newry and other locations in Oxford Co., ME; Portland and Haddam, Middlesex Co., CT; Tin Mountain mine, Custer Co., SD; Himalaya dike system, Mesa Grande district, San Diego Co., CA; major reserves (350,000 tons) at the Tanco pegmatite, Bernic Lake, MAN, Canada, where crystals are 1 – 2 m across and bodies and pods are as much as 180 m \times 75 m \times 12 m(!); sharp, colorless crystals to 2.5 cm across from the La Speranza dike, *San Piero di Campo, Elba, Italy*; additional localities on Elba exist; sodian pollucite from the Varutrask pegmatite, near Skellefteå, Västerbotten, Sweden; Luolamaki, Viitaniemi, Haapaluoma, and Oriselka pegmatites in Finland; in pegmatites from Shmakat, Alingar, Sorkh Rud, Darya-i-Pech, and Kurgai pegmatite fields, Afghanistan; also from Nilaw-Kulam and Parown fields, Nuristan, Laghman Prov., and crystals to 60 cm across at the Paprock prospect, Kamdesh, Nuristan, Kunar Prov., Afghanistan. Crystals to 8 cm from Shingus, Gilgit Division, NWF, Pakistan; Bikita, Zimbabwe; Karibib, Namibia; Taquaral district, Itinga, MG, Brazil. **Uses:** Is used as a minor gemstone and as a source for Cs. *EF ZK 129:280(1969), MS 29:28(1975), NZ(1985), ZW(1992), IMA (Pisa, Italy):125(1994).*

77.1.1.3 Wairakite (Ca,Na₂)[Al₂Si₄O₁₂] · 2H₂O

Named in 1955 by Steiner for the locality. Zeolite group. See analcime (77.1.1.1), the Na end of the series. **MON**, **ISO**, **TET**, **ORTH**, and **TRIC** I^*/a , $I2/a$, $Ia3d$, $I4_1/acd$, and $Ibca$. $a = 13.69$ – 13.70 , $b = 13.64$ – 13.58 , $c = 13.56$ – 13.58 , $\beta = 90.0$ – 90.5° , $Z = 8$, $D = 2.27$ – 2.28 ; 42 – 1451 : $a = 13.695$, $b = 13.638$, $c = 13.550$, $\beta = 90.33^\circ$. **PD** 42 – 1451 (nat, monoclinic): 6.83_3 5.56_8 3.42_4 3.41_5 3.39_{10} 2.92_4 2.91_3 2.89_3 ; 11 – 156 (syn, cubic): 6.81_4 5.57_9 4.83_4 3.41_{10} 2.90_8 2.675_4 2.49_5 1.73_4 . Aluminosilicate framework is the same as for analcime and pollucite. Isometric wairakite has a disordered Si and Al framework, while those with **TET**, **ORTH**, **MON**, and **TRIC** symmetry are partially or fully ordered. The Al is preferentially located in two tetrahedra sites near the Ca. Ca is located in one site with two sites empty or containing Na. Commonly forms trapezohedra with {211}, rarely modified by {100} and the dodecahedron {110}; most crystals <1 mm in diameter, some to 15 mm in diameter; lamellar twinning on {110} is commonly seen in monoclinic varieties. Colorless

or white, white streak, vitreous to dull luster. Cleavage {100}, distinct; conchoidal fracture; brittle. $H = 5\frac{1}{2}$ –6. $G = 2.26$. A complete Ca–Na series between wairakite and analcime exists. A chemical series between warakite and pollucite has not been found. Analysis (wt %), Japan (Toi): SiO_2 , 54.5; Al_2O_3 , 23.9; Fe_2O_3 , 0.1; MgO , 0.1; CaO , 12.4; Na_2O , 0.25; K_2O , 0.34; H_2O , 8.51. Biaxial (+) and (–); $\text{XYZ} \approx \text{bac}$; $N_x = 1.498$ – 1.500 , $N_z = 1.502$; $2V = 70$ – 105° ; birefringence = 0.00–anisotropic. Has been synthesized from stilbite and heulandite at low pressure and 300° . *PJA* 42(8):925(1966). Occurs in geothermal wells and metamorphosed volcanics. 60– 300° , 72–1600 m. Occurs in the deepest and hottest geothermal wells in Iceland. Occurs at a number of localities; among them: Spanish Peaks, CO; Lower Geyser Basin, Yellowstone National Park, WY; The Geysers, Sonoma Co., and near Rosamond, Kern Co., CA; Mt. Rainier National Park, Pierce Co., WA; St. Thomas and St. Croix, U.S. Virgin Is.; Buttle Lake area, Vancouver Island, BC, Canada; western and northern Iceland; *Wairakei geothermal field, North Island, New Zealand*; also in the Ngatamariki geothermal field, NE of Wairakei; Tui mine, Te Aroha, Auckland; a number of localities in Japan, in geothermal areas and past geothermal areas, including Nishi-Iburi district, Hokkaido; Seigoshi mine, Toi, and at Kawazu, Shizuoka Pref.; Onikobe, Miyagi Pref., Koriyama, Fukushima Pref., Yugami district, Fukui Pref., and Hikihara, Hyogo Pref. *EF AM* 57:924(1972), 64:993(1979), 65:1212(1980); *NZ* (1985), *ZW* (1992).

77.1.1.4 Laumontite $\text{CaAl}_2\text{Si}_4\text{O}_{12} \cdot 4\text{H}_2\text{O}$

Initially described in 1801 as “zeolithe efflorescente” by Haüy, but the mineral was considered as an independent species by Werner who named it lomonite for François Pierre Nicolas Gillet de Laumont (1747–1834), who collected the sample studied by Haüy. Haüy (1809) changed the spelling to “laumonite”; finally, the name *laumontite* was proposed by Leonhard (1821) and is now currently used. *NZ* (1985). *Leonhardite* is a now discredited term that is still used occasionally in the literature for a partially dehydrated laumontite. The transition *laumontite* to *leonhardite* is normally reversible. Zeolite group. *MON* $C2/m$. For fully hydrated material with 16– $18\text{H}_2\text{O}$ for $Z = 1$: $a = 14.82$ – 14.90 , $b = 13.10$ – 13.19 , $c = 7.54$ – 7.565 , $\beta = 110.2$ – 110.7° , $Z = 4$, $D = 2.12$. For *leonhardite* with $14\text{H}_2\text{O}$: $a = 14.77$, $b = 13.09$, $c = 7.58$, $\beta = 112.0^\circ$; for $12\text{H}_2\text{O}$: $a = 14.71$, $b = 13.09$, $c = 7.46$, $\beta = 112.1^\circ$. 45-1325(nat): 9.48₁₀ 6.87₄ 4.51₁ 4.16₂ 3.68₂ 3.51₅ 3.28₁ 3.04₁; 26-1047(syn): 9.5₆ 6.84₄ 4.16₁₀ 3.66₃₅ 3.51₈ 3.36₃ 3.27₅₅ 3.20₃. Fully deuterated ($18\text{D}_2\text{O}$) laumontite has $a = 14.863$, $b = 13.169$, $c = 7.537$, $\beta = 110.18^\circ$. *EJM* 5:851(1993). The aluminosilicate framework is composed of singly connected four-ring chains in TTTT configuration, linked by Al–O tetrahedra. Si–Al distribution is perfectly ordered. Ca is present in the larger channel (parallel to c) connected to H_2O molecules and four framework oxygens of the Al-bearing tetrahedra. Four water sites are present in the structure: two are coordinated to Ca, the other two act as bridges between the Ca-coordinated waters through hydrogen bonding. All water sites are disordered to some degree and are

essentially fully occupied in fully hydrated laumontite. Crystal structure determinations for fully hydrated laumontite: *Z 13:249(1993)*, *NJBM: 385(1992)*. Additional structure determination: *SPC 30:624(1985)*. The number of water molecules in laumontite changes from $12\text{H}_2\text{O}$ at 0–5% relative humidity, to $14\text{H}_2\text{O}$ at 10–70%, and to $16\text{--}18\text{H}_2\text{O}$ at 80–100%. **Habit:** Often occurs as simple prisms, elongate on *c*. Square cross section, equant crystals are less common. Crystals to 15 cm long, shorter crystals to 5 cm long are 1–2.5 cm wide. Common forms include {110}, {201}, {100}, {010}. Twinning is present on {100} to form “swallowtail” reentrant twins. **Physical properties:** White, sometimes stained by Fe or Mn oxides; colorless, pink, or white when hydrated; gray, pink, yellow when partially dehydrated; white streak; vitreous luster, pearly on cleavages, and chalky (when dehydrated). Cleavage {010}, {110}, perfect; {100}, imperfect; uneven fracture. $H = 3\text{--}4$. $G = 2.20\text{--}2.41$. Laumontite sometimes fluoresces white to cream or yellow in LWUV and SWUV light. May be piezoelectric. **Chemistry:** Always very Ca-rich. Some Na (to 2.6 wt % Na_2O) and K (to 1.75 wt % K_2O). So-called “primary leonhardite” has 4.36 wt % K_2O and 2.58 wt % Na_2O , and this chemistry may be the cause, being unable to get a fully hydrated phase. Dehydrated or partly dehydrated crystals crumble readily. **Optics:** Biaxial (–); $Z \wedge c = 8\text{--}32^\circ$, $X \wedge a = 10\text{--}26^\circ$, $Y = b$; $N_x = 1.501\text{--}1.514$, $N_y = 1.508\text{--}1.522$, $N_z = 1.512\text{--}1.525$; $2V = 26\text{--}82^\circ$ (most are $30\text{--}50^\circ$; $r < v$, distinct, weakly inclined. **Occurrence:** Found in a wide range of geologic conditions. Occurs in the weathering environment, to zeolite-grade (facies) metamorphic rocks. Occurs in hydrothermal ore deposits, volcanics, pegmatites, intrusive rocks, and hot springs. Rarely in deep-sea sediments. May be an authigenic cement in sandstones. **Localities:** Occurs in many worldwide localities, and only selected localities are given here: Paterson, Passaic Co., NJ; Centerville, Fairfax Co., VA; crystals to 15 cm long and 15 mm wide from the Pine Creek tungsten mine, near Bishop, Inyo Co., CA; to 1 cm from the Himalaya pegmatite–aplite dike system, Mesa Grande District, San Diego Co., CA; pink crystals to 6 cm long and 3 cm wide from the Bear Creek quarry, Drain, Douglas Co., OR; prisms to 4–10 cm long from Tum Tum Mountain, Clark Co., WA; *Bleigrube (lead mine)*, Huelgoët, Finistere, Brittany, France; to 4 cm long from the Gall quarry, Frassgraben, Koralpe, Carinthia, Austria; colorless to white prisms to 5 cm long (common) to >20 cm long and 3 cm wide are found at the “Bombay quarry” near Khandivali, Bombay district, MAH, India. Also at Nasik and Pune (Poona). Crystals to 4–6 cm long from Alamos, SON, Mexico. *EF NZ (1985)*, *CS 8:79(1991)*, *ZW(1992)*.

77.1.1.5 Hsianghualite $\text{Ca}_3\text{Li}_2\text{Be}_3(\text{SiO}_4)_3\text{F}_2$

Named in 1958 by Huang et al. for the locality, whose name means *fragrant flower*. iso $I2_13$ (originally reported as $I4_132$). $a = 12.879$, $Z = 8$, $D = 2.965$. $36\text{--}412$: 3.44_6 3.22_4 2.75_{10} 2.35_4 2.21_{10} 2.09_9 1.753_7 1.691_5 . Structure: *DANS 316:624(1991)*. The structure is reported to be analogous to that of analcime, with Be and Si in tetrahedral coordination forming a three-dimensional frame-

work, but no reference is made as to the possible ordering of these two elements. The observed and calculated densities are high for a phase of such structure and composition. White, vitreous luster, transparent to translucent. $H = 6\frac{1}{2}$. $G = 2.90$, also $2.97-3.00$. Isotropic; $N = 1.613$. Minor iron, magnesium, and sodium are present. The interpretation of the chemical analysis is subject to some question. Occurs as dodecahedral and trapezohedral crystals, and as granular masses in phlogopite veins in a light-colored band in green- and white-banded, metamorphosed Devonian limestone at *Hsianghualing*, in the *Nanling Range, Linwu Co., Hunan Prov., China*, associated with fluorite, liberite, chrysoberyl, taaffeite, and nigerite. AR AM 44:1327(1959), 46:244(1961).

77.1.2.1 Chabazite-Ca ($\text{Ca,Na}_2,\text{K}_2,\text{Sr,Mg}$)[$\text{Al}_2\text{Si}_4\text{O}_{12} \cdot 6\text{H}_2\text{O}$]

Named in 1792 by Bosc d'Antic from the Greek *chabazios* or *chalazios*, an ancient name of a stone. The name of the last of the 20 stones celebrated for their virtues and mentioned in a poem ascribed to Orpheus. Zeolite group. Chabazite-(Na) and chabazite-K also exist and are approved by the CNMMN IMA. Chabazite-Na includes "herschelite." Synonyms include "phacolite," a bean or lens-shaped variety, which is repeatedly twinned about {0001}. Often intergrown with gmelinite. TRIC [pseudo-HEX (TRIG, $R3m$)] $P\bar{1}$. $a = 9.41$, $b = 9.42$, $c = 9.42$, $\alpha = 94.18^\circ$, $\beta = 94.27^\circ$, $\gamma = 94.35^\circ$. On a hexagonal cell, dimensions range from $a = 13.71-13.86$ and $c = 14.83-15.42$. $Z = 6$, $D = 2.05-2.16$. $34-137$ (rhombohedral axes): 9.34_5 5.55_3 5.00_3 4.32_{10} 3.87_2 3.58_4 2.93_9 2.88_{45} . Patterns for three different chabazites are given in *NZ:333(1985)*. Significant variations in intensities exist. (Rhombohedral axes): strontian chabazite, $45-1427$: 9.43_{10} 5.56_5 5.12_5 4.33_8 3.97_3 3.64_5 2.93_{10} 2.53_5 . Al-Si tetrahedra are linked to form parallel double six-membered rings stacked in three different positions (A,B,C) in the repeat arrangement AABCCAAABCC ..., forming large cages. The maximum symmetry compatible with this framework is $R3m$, the highest symmetry which has been attributed to chabazite. Si and Al in the tetrahedra are disordered, but some areas show regular (1:1) ordering. Complete order of Al and Si tetrahedra is found in the variety [*ZW (1992)*] or species (according to the IMA at present) willhendersonite. If the amount of ordering in a mineral is not a basis for a separate species, the name *willhendersonite* should be discontinued. The structure of a K-exchanged chabazite ($R3m$) was reported. *Z 3:205(1983)*. **Habit:** Basic crystals are distorted cubes or pseudorhombohedrons that are actually composed of six triclinic twins. Crystals may also be prismatic parallel to $[001]_{\text{hex}}$, tabular on $\{001\}_{\text{hex}}$. Twinning is common, often along several different planes or axes. Contact twins on the dominant rhombohedral face $\{101\}$ are relatively rare. Penetration twins are very common. Twinning around c results in bean- or lens-shaped crystals, which are said to have a "phacolitic" habit. Detailed morphological and twin drawings are given in *ZW (1992)*. **Physical properties:** Colorless, white, cream, yellow, pink, red, green, or brown; white streak; vitreous luster. Cleavage is parallel to the pseudorhom-

bohedron. Brittle. $H = 3-5$. $G = 1.97-2.20$. Thermal and optical spectral data: NZ (1985). Decomposed by HCl with separation of silica gel. Mostly non-fluorescent, but sometimes is fluorescent green under SWUV (probably uranyl ions). Fluorescent material occurs at Bancroft, ONT, and the New Street quarry, West Paterson, NJ. A complete series exists between Na and Ca members, but most chabazites are Ca-dominant. K-dominant and ordered (willhendersonite) material is also known. K-dominant chabazite may exist [NZ:191(1985)]. The old variety herschelite was defined as Na-dominant. Sr (to >8 wt % SrO) and Mg (to >0.5 wt % MgO) may be present. Si/Al ranges from about 1.5 to 4.1. T_{Si} varies from 0.6 to 0.8. Optics: Optical properties are variable. May be uniaxial (-) or (+), but very often are biaxial (+). As expected, high Na-chabazite has lower indices than Ca-rich chabazite, and Sr-bearing chabazite has the highest reported indices. Range: $N_O = 1.461-1.517$, $N_E = 1.460-1.514$; for biaxial chabazite: $N_x = 1.485$, $N_y = 1.485$, $N_z = 1.486$; $2V (+) = 67-75$. Occurrence: Occurs in volcanic rocks, altered volcanic ash deposits in both fresh and saline lakes, pegmatites, and granitic and metamorphic rocks. Localities: Exceptional display-quality material occurs: crystals to 4.5 cm in Triassic basalts at Paterson, Passaic Co., NJ, particularly the Upper and Lower New Street quarries and the Prospect Park quarry; also Laurel Hill, Secacus, NJ; numerous localities in Oregon: the best (twinned phacolite crystals to 5 cm) is the Springfield Butte quarry, Springfield, Lane Co., OR; Oxbow Dam on the Snake R., near Copperfield, Baker Co., OR; rhombohedra to 3 cm at Goble, Columbia Co., and Burnt Cabin Creek, Wheeler Co.; also Two Hug quarry, Price Creek, Kings Valley, Benton Co.; salmon-orange crystals to 2.5 cm in diameter at Parrsboro, and Wasson's Bluff, Bay of Fundy, NS, Canada; in the Faroe Is.: colorless to white crystals to 4 cm across from Vidoy, Eysteroy, and Sandoy Is.; colorless, twinned phacolite crystals to 3 cm from the Craigahulliar quarry, Portrush, Northern Ireland; (some deep amber crystals to 2 cm fluoresce cream under LWUV); Kilmalcolm, Renfrewshire, Scotland; colorless rhombohedra to 2 cm across occur at *Idar Oberstein, Germany*; strontian (8% SrO) material from Alba, Ardeche, France, and at Kaiserstuhl, Baden, Germany; 2-cm crystals from Vogelsberg, Hessen, Germany; deep red crystals to 2 cm from Striegau, Poland; Rubendorf, Czech Republic; twinned phacolite crystals to 8 cm at Csodi Mt., Dunabogdany, near Budapest, Hungary; white, colorless, or pink crystals to 4 cm across from the No. 10 Bombay quarry, Khandivali, MAH, India; also from Panvil; colorless, twinned phacolite crystals to 3 cm across from Fairy Mount, Kyogle, NSW, Australia. Sodium-rich crystals from the Bundoora quarry, Whittesea and Clifton Hill, Melbourne, VIC, Australia; also Sutherlands Bluff, Phillip Is., VIC, and twinned phacolite crystals from Gads Hill, Leina, TAS, Australia. *EF AM 55:1278(1970)*, *LIT 14:17(1981)*, *NJBM:461(1983)*, *BM 111:671(1988)*, *ZW (1992)*.

77.1.2.2 Herschelite (Na,Ca,K)AlSi₂O₆ · 3H₂O

Described by Levy in 1825 and named for John Frederick William Herschel (1792–1871), British astronomer. Zeolite group. The status of this zeolite is now considered questionable. It is the Na analog of chabazite. $\text{HEX-R } R3m$. $a = 13.799$, $c = 15.102$, $Z = 12$, $D = 2.05$; actually triclinic, $P\bar{1}$ (based on optics and detailed X-ray diffraction studies). $19-1178(\text{nat}): 9.4_5 \ 6.89_2 \ 5.03_4 \ 4.32_{6.5} \ 3.88_{2.5} \ 3.60_2 \ 2.93_{10} \ 2.90_3$. Structure is the same as that of chabazite (77.1.2.1). Heating to only 300° produces structural changes (i.e., lines weaken and disappear). Ca–Sr–K-rich material is most unstable (chabazite). Clean, Ca-rich material is very resistant to heating, and is stable to 650° . It appears that the rate of crystal growth governs whether herschelite or chabazite results. If growth is slow, Na can be excluded, and one gets chabazite; if fast, Na is incorporated within the chabazite structure, and herschelite results. Some K-dominant samples exist (e.g., Vallerano quarry, Rome, Italy) and are willhendersonite. Hexagonal plates that are either flat or biconvex, with prominent $\{1010\}$, $\{0001\}$, and $\{10\bar{1}1\}$; the predominant prism and c -pinacoid give herschelite a distinctive morphology. Also occurs as aggregates of plates, composed of stacked individuals; rarely occurs as minute spherules. Gmelinite at Boron, CA, is epitaxially overgrown by herschelite, attached by respective $\{0001\}$ faces. All herschelite is twinned, and several types of twinning exist. $\{0001\}$ sectors show rotation twins around the c axis. $\{1010\}$ sectors are polysynthetic twins of platy crystals parallel to $\{0001\}$. Generally colorless or white, white streak, vitreous luster. Cleavage $\{10\bar{1}1\}$, distinct; uneven fracture; brittle. $H = 4-5$. $G = 2.08-2.16$; most are $2.0-2.08$. Gelatinizes readily in common acids. There is a range of Na and Ca contents between the two end members; K_2O is variable, from 0.1 to 3.2 wt %. Uniaxial (+) or (–); $N_0 = 1.471-1.479$, $N_E = 1.470-1.481$; $\bar{N} = 1.472$, and some are even lower: $1.460-1.462$. Chabazite has $\bar{N} = 1.485$. Birefringence is $0.003-0.004$. A low-temperature zeolite found in basalts through rhyolites (basic to acid rocks). Si-rich in rhyolite glass and tuff and in lacustrine saline lake environments, and Si-poor in mafic rocks. Associated with other zeolites such as chabazite, phillipsite, analcime, clinoptilolite, and stilbite. Occurs in many worldwide localities and only selected localities are given here: near Bowie, Cochise Co., and Horseshoe Dam area, Maricopa Co., AZ; Saddleback basalt, Boron, Inyo Co., CA; Fossil Canyon, San Bernardino Co., CA; Vaalvo, and Dalsnipa, on Sandoy, Faeroe Is.; Ilimaussaqa intrusion, southern Greenland; flanks of Mt. Aetna, *Aci Castello, Sicily, Italy*; also at Aci Reale and Aci Trezza, Sicily, Italy; Cyclopean Is., Italy; at Richmond, Melbourne, VIC, Australia; Tokatoka district, about 150 km N of Auckland, New Zealand; Hayata, Saga Pref., Japan. It should be noted at this point that the material from near Bowie, Cochise Co., AZ, and Fossil Canyon, CA, is Na-rich but the habit is not that of herschelite. The term *herschelite* should be abandoned, as it is just a morphological variety of chabazite. *EF AM 51:909(1966)*, *55:1278(1970)*, *74:1337(1989)*; *NZ(1985)*; *CCM 36:131(1988)*; *ZW (1992)*.

77.1.2.3 Willhendersonite $\text{KCa}[\text{Al}_3\text{Si}_3\text{O}_{12}] \cdot 5\text{H}_2\text{O}$

Named in 1984 by Peacor et al. for research chemist and mineral collector William A. Henderson, Stamford, CT. Zeolite group. See chabazite (77.1.2.1), isostructural, $(\text{Ca}, \text{Na}_2)[\text{Al}_2\text{Si}_4\text{O}_{12}] \cdot 6\text{H}_2\text{O}$. Ordered chabazite. TRIC $P1$. $a = 9.206\text{--}9.23$, $b = 9.21\text{--}9.216$, $c = 9.500\text{--}9.52$, $\alpha = 92.34\text{--}92.7^\circ$, $\beta = 92.4\text{--}92.70^\circ$, $\gamma = 90\text{--}90.12^\circ$, $Z = 2$, $D = 2.17\text{--}2.20$. *35-0643(nat)*: 9.16_{10} 5.18_3 4.09_4 3.93_2 3.82_2 3.71_3 2.91_6 2.80_5 . Isostructural with chabazite, but with complete Si–Al ordering. The tectosilicate (SiO_4 and AlO_4) tetrahedral frameworks of both minerals are topologically similar and consist, in part, of double six-membered rings of tetrahedra, although the coordinations of Ca are very different. *ZK 159:125(1982)*, *NJBM 547(1984)*. “Trellis-like” twinned aggregates (San Venanzo), forms {001}, {100}, and {010} and tabular crystals, flattened on {001} (Ettringer Bellerberg, Mayen, Germany); Mayen crystals are $60 \mu\text{m} \times 30 \mu\text{m} \times 10 \mu\text{m}$; twinning by rotation about [111], additional complex twinning of two types is also present; Mayen, Germany, material is untwinned. Colorless, white streak, vitreous luster, transparent. Cleavage parallel to {100}, {010}, and {001}, perfect; these three cleavages are equivalent to the rhombohedral cleavage of chabazite; brittle. $H = 3$. $G = 2.10\text{--}2.18$. Nonfluorescent. Analysis (wt %): K_2O , 6.8–8.0; Na_2O , trace; CaO , 10.7–11.6; Al_2O_3 , 28.1–30.1; SiO_2 , 34.8–35.5; H_2O , 16.0–18.4. The most common ratio of Si/Al in willhendersonite is 1:1, while it is 2:1 in chabazites. Biaxial (+); $2V = 87^\circ$; Mayen: $N_x = 1.503$, $N_y = 1.511$ (calc.) for $2V = 80^\circ$ (+), $N_z = 1.517$; for Terni crystals, optical properties not determined because of complex polysynthetic twinning, small size, and so on. Formed by low-temperature hydrothermal alteration. Occurs in cavities (Terni, Italy) of quaternary lavas and basic potassic lavas. Associated with phillipsite and other minerals. At Mayen, crystals are in cavities in a limestone xenolith in basalt. Associated with other zeolites. *San Venanzo quarry, Terni, Umbria, Italy*; Ettringer Bellerberg volcano, Mayen, Eifel, Germany; Stradnerkogel, Wilhelmsdorf, Styria, Austria. *EF AM 55:1278(1970)*, *69:186(1984)*; *NJBM:547(1984)*; *NZ (1985)*; *ZW (1992)*.

77.1.2.4 Offretite $(\text{Ca}, \text{K}_2, \text{Mg})_2[\text{Al}_5\text{Si}_{13}\text{O}_{36}] \cdot 15\text{H}_2\text{O}$

Named in 1890 by Gonnard for Albert Jules Joseph Offret (b.1857), professor, Lyon, France. Zeolite group. *HEX P6m2*. $a = 13.29\text{--}13.32$, $c = 7.56\text{--}7.61$, $Z = 1$, $D = 1.91\text{--}2.06$. *22-803*: 11.5_{10} 6.64_2 5.76_{35} 4.35_6 3.84_{45} 3.32_2 2.88_{65} 2.51_2 ; *25-1186(nat, calc pattern)*: 11.5_{10} 7.58_{15} 6.65_1 5.76_1 4.35_{15} 3.77_2 3.60_1 2.86_2 . Structure done on $(\text{K}_{11}\text{Ca}_{11}\text{Mg}_{07})_{\Sigma 29}[\text{Si}_{12.8}\text{Al}_{5.6}\text{O}_{36}] \cdot 15.2\text{H}_2\text{O}$. Aluminosilicate framework is based on double six-membered rings and single six-membered rings in two positions (A and B), linked in a regularly repeating stacking sequence AAB. The exchangeable cations are in three positions: K in cancrinite cages, Ca in double six-membered rings in wide channels, and Mg in gmelinite-type cavities. Similarity of structural units of offretite and erionite with levyne account for their epitaxial overgrowth on levyne. *AC(B) 28:825(1972)*. Usually simple hexagonal prisms with {1010} terminated by

{0001} pinacoid, bundles of parallel crystals and radiating groups, sometimes barrel-shaped, offretite is commonly epitaxial on levyne or on erionite. Colorless, white, yellow, golden; white streak; vitreous, silky luster. $H = 4$, $G = 2.10\text{--}2.13$. Pure synthetic offretite, phase "O," has been produced by Aiello and Barrer (1970). *ZW* (1992). Both Ca- and Mg-dominant varieties are known; $\text{Ca} + \text{Mg} > \text{K} + \text{Na}$. Ca is commonly more abundant than K. One example of Mg-dominant offretite is known (Sasbach, Germany). Material from Philip Is., and Flinders, VIC, Australia, also have $\text{Ca} + \text{Mg} + \text{Ba} + \text{Sr} \ll \text{K} + \text{Na}$. Uniaxial (-); $N_O = 1.489\text{--}1.493$, $N_E = 1.486\text{--}1.491$; negative elongation, elongated parallel to c . Intergrown with erionite, most offretite crystals should be considered an intergrowth of both offretite and erionite. *Offretite* = $\text{Ca} + \text{Mg} > \text{K} + \text{Na}$, $\text{Si}/\text{Al} = 1.99\text{--}2.80$, uniaxial (-), $\text{RI} > 1.485$, simple X-ray diffraction pattern; and *Erionite* = $\text{K} + \text{Na} > \text{Ca} + \text{Mg}$, $\text{Si}/\text{Al} = 2.85\text{--}3.60$, uniaxial (+), $\text{RI} < 1.485$, complex X-ray diffraction pattern. Occurs in veins and fractures in basaltic rocks. Not found in Si-rich volcanics, pegmatites, or altered volcanic ash tuffs (where erionite is abundant). May be intergrown with other zeolites. Of hydrothermal origin. Display specimens are rare, principally micromounts. Crystals to several millimeters have been found. From Queen Creek, AZ, CA, CO, NJ, Beech Creek, OR, and WA; 2–3-mm long needles on plates of levyne from Westwold, BC, Canada; several localities in County Antrim, Northern Ireland; barrel-shaped crystals to 0.3 mm long from *Mt. Semiol, Montbrison, Loire, France*; chabazite-offretite epitaxial overgrowths from Passo Forcel Rosso, Adamello, Brescia, Italy; Zezice, Czech Republic; on plates of levyne from Hunter Valley, NSW, Australia; Merriwa district, also Flinders, Jindivick, and Philip Is., VIC, Australia. *EF NZ* (1985), *EJM* 6:397(1994).

77.1.2.5 Erionite $(\text{K}_2\text{Na}_2\text{Ca,Mg})_2[\text{Al}_4\text{Si}_{14}\text{O}_{36}] \cdot 15\text{H}_2\text{O}$

Named in 1898 by A. S. Eakle from the Greek for *wool*, in allusion to its white, fibrous, wool-like appearance. Zeolite group. *HEX* $P6_3/mmc$. $a = 13.186\text{--}13.34$, $c = 15.041\text{--}15.13$, $Z = 2$, $D = 2.09\text{--}2.13$. $39\text{--}1379(\text{nat})$: 11.56_8 4.35_8 3.84_6 3.77_9 3.59_6 2.88_8 2.85_{10} 2.83_{65} . Aluminosilicate framework is based on double six-membered rings and single six-membered rings in three positions (A, B, and C) linked in a regularly repeating stacking sequence (AABAAC). Structures of erionite, offretite, and levyne all have hexagonal layers A, B, and C. Errors in the stacking sequences for erionite and offretite (AAB) produce an intergrowth of these two species. Exchangeable cations are in three positions: K in cancrinite cages, double six-membered rings are empty or contain some Ca, and a large erionite cage containing Ca, Na, and Mg in several sites. {1000}, {0001} and rare {1012}, may be wool-like masses, for which named, frequently striated parallel to c , sometimes hexagonal pyramid developed, simple hexagonal prisms, terminated by {0001}, may be epitaxial on levyne, or vice versa, commonly intergrown with offretite; generally small, <3 mm long, some hairs to 15 mm long, radiating aggregates to 8 mm in diameter; no twinning. Colorless, white, green, gray, orange; white streak; vitreous, silky luster. Cleavage is

parallel to *c* axis; fracture is splintery. $H = 3\frac{1}{2}$ –4. $G = 2.02$ – 2.13 . K-, Mg-, and Ca-dominant members exist. Commonly $K + Na > Ca + Mg$, although some varieties have considerable Ca. Cape Lookout, Tillamook Co., Oregon: Ca-rich. Mg-rich from Sasbach, Kaiserstuhl, Germany, also Ca-dominant from Montresta, Nuovo, Sardinia, Italy, and Nidym R., Siberia, Russia. T_s ranges from 0.71–0.79. Uniaxial (+); $N_O = 1.455$ – 1.483 , $N_E = 1.457$ – 1.485 ; generally positive elongation, but may show negative elongation as well (e.g., Faedo, Italy); often intergrown with offretite; erionite: $K + Na > Ca + Mg$, $Si/Al = 2.78$ – 3.60 , uniaxial (+), $RI < 1.485$, complex X-ray diffraction pattern and offretite: $Ca + Mg > K + Na$, $Si/Al 1.99$ – 2.80 , uniaxial (–), $RI > 1.485$; simple X-ray diffraction pattern; has been synthesized, with intergrowths of offretite. Occurs in volcanic and sedimentary rocks. Common in altered silicic tuffs, especially in saline lacustrine deposits. Hydrothermal erionite in cavities in volcanic rocks. Known from more than 40 localities; only noteworthy localities are mentioned here and only for pure or relatively pure material. Occurs at several areas in Arizona; *Durkee opal mine, Swayze Creek, near Durkee, Baker Co., OR*; best specimens come from Cape Lookout, Tillamook Co., and Agate Beach, Lincoln Co., OR; Lake Tecopa, Inyo Co., CA; Rock Island Dam, WA; excellent specimens without any intergrown offretite at Chase Creek, N of Falkland, BC, Canada; aggregates to 15 mm on the Nidym R., Siberia, Russia. Other localities include: Eastgate, Churchill Co., Reese R., Lander Co., Jersey Valley, Pershing Co., and Pine Valley, Eureka Co., NV; Hvalstod and Berufjord, Iceland; Parkgate quarry, Templepatrick, County Antrim, Northern Ireland; Mazi, Niigata Pref., Japan; Moeraki, Otago, South Island, New Zealand. *EF MM 32:261(1959)*; *AM 54:875(1969)*, *61:853(1976)*; *MGNZ (1977)*; *AC(B) 33:3265(1977)*; *NZ (1985)*; *ZW (1992)*; *NJBM:185(1995)*.

77.1.2.6 Gmelinite $(Na_2,Ca)Al_2Si_4O_{12} \cdot 6H_2O$

Described by Brewster in 1825 and named for Christian Gottlob Gmelin (1792–1860), professor of chemistry and mineralogist, Tübingen, Germany. Zeolite group. $HEX P6_3/mmc$. Regular Na–Ca-dominant gmelinite: $a = 13.737$ – 13.805 , $c = 9.974$ – 10.077 ; $a = 13.621$ – 13.696 , $c = 10.203$ – 10.254 ; K-dominant gmelinite: $Z = 4$, $D = 2.07$. *38-435(nat)*: 11.9_6 7.68_3 5.02_3 4.11_{10} 3.28_4 2.98_{55} 2.86_4 2.69_4 ; *NJBM:504(1990)* (K-rich gmelinite): 11.9_3 5.14_5 4.11_{10} 3.29_4 2.96_8 2.85_6 2.72_8 2.59_2 . The aluminosilicate framework is composed of tetrahedra linked to form parallel double six-membered rings stacked in two different positions (A and B) in the repeating arrangement AAB-BAABB. The framework has no Al–Si order although Na-rich gmelinite has better order and is more stable than gmelinite containing dominant Ca. Two cation sites, C1 and C2, contain either Na or Ca. In K-dominant gmelinite, C2 is nearly empty (3% occupancy). Stretching along *c* occurs because of K substitution. Structure of Na- and Ca-rich gmelinite: *NJBM:145(1982)*; K-rich gmelinite: *SPC 29:256(1984)*, *NJBM:504(1990)*. Has been synthesized at temperatures less than 95°. *CR 272:ser. D:181(1971)*. Crystals intergrown with

Gmelinite

chabazite and may reach 4 cm across. Hexagonal plates, or short prisms, showing hexagonal dipyrramids, pyramids, and basal pinacoid: {1010}, {1011}, {0001} dominant. May also be tabular or rhombohedral in habit. Striated parallel to (0001) or less commonly parallel to [0001]. Twinning is rare, on (1011); interpenetrant twins consist of four individuals; three are at 90° to the other and at 60° to each other. Colorless, white, pale yellow, lemon-yellow, greenish white, orange, pale green, pink, salmon, red, brown, and gray(!); white streak; dull to vitreous luster. Cleavage {1010}, good; {0001} parting; uneven to conchoidal fracture; brittle. $H = 4\frac{1}{2}$. $G = 2.04\text{--}2.17$. Piezoelectric. Thermal data: *NJBM:310(1978)*, *NZ(1985)*; for K-rich: *NJBM:504(1990)*. Soluble in cold 10% HCl, and gelatinizes with a residue. Na-rich variety occurs at Boron, CA; is also richer in Si than other gmelinites. The mineral is generally Na-dominant; however, considerable Ca, K (may be dominant), and Sr may be present (to 0.35 atom). Mg is very low and Ba is absent. Usually uniaxial (-) or (+); may be anomalously biaxial (-) or (+) with a small 2V; for Na-Ca gmelinite: $N_O = 1.476\text{--}1.494$, $N_E = 1.474\text{--}1.480$; birefringence = 0.002-0.008; for K-dominant gmelinite: $N_O = 1.470$, $N_E = 1.474$; colorless. Generally occurs in Si-poor volcanic rocks, marine basalts, and breccias. Also in Na-rich pegmatites in alkalic rocks. No sedimentary gmelinite has been found. A product of diagenetic reactions, hydrothermal activity, or deuteric alteration of basalt. Occurs in 55-75° geothermal wells. K-dominant samples have probably undergone cation exchange after deposition. Associated with other zeolites, quartz, aragonite, calcite, and so

on. A widespread zeolite but occurring in small amounts. Localities for well-characterized material include: Bergen Hill, Hudson Co., and Great Notch, Paterson, and Prospect Park, Passaic Co., NJ; Na- and Si-richest gmelinite from Boron, San Bernardino Co., CA; Springfield, Lane Co., OR; Mt. St.-Hilaire, QUE, and at Pinnacle Rock, Five Is., and Two Is., Bay of Fundy, NS, Canada; Ilimaussaq intrusion, southern Greenland; *Little Deer Park, Glenarm, and elsewhere in County Antrim, Northern Ireland; Isle of Skye, Scotland; Montecchio Maggiore, Vicenza, Italy*; K-dominant from Cava Fortelongo, Fara Vicentina, Vicenza, Italy, and from Mt. Alluiav, Lovozero massif, Kola Penin., Russia; Bekiady, Madagascar; exceptional display specimens, to 4 cm in diameter, from the Mornington Penin., between Flinders and Cape Schank, VIC, Australia. EF ZW (1992).

77.1.2.7 Faujasite $(\text{Na}_2, \text{Ca}, \text{Mg})_3 \cdot 5(\text{Al}, \text{Si}_{17}\text{O}_{48}) \cdot 32\text{H}_2\text{O}$, or $(\text{Na}_2, \text{Ca})\text{Al}_2\text{Si}_4\text{O}_{12} \cdot 8\text{H}_2\text{O}$

Named in 1842 by Damour for Barthelemy Faujas de Saint Fond (1741–1819), French geologist and writer on origin of volcanoes. Zeolite group. iso $Fd\bar{3}m$. $a = 24.64\text{--}24.78$, $Z = 8$, $D = 1.94$. $39\text{--}1380(\text{nat})$: 14.28_{10} 5.67_8 4.75_4 4.37_5 3.76_{9_5} 3.30_7 2.91_4 2.85_8 . Has the most open structure of all the zeolites.

FAUJASITE

Structure: *NJBM:193(1958)*, *AM 49:697(1964)*. {111}, rare {100}, and {556}, aggregates to 10 mm across; small, single octahedra 1–4 mm in diameter common; contact and penetration twinning on spinel law {111} is common. Colorless–white or pale brown, white streak, vitreous luster, transparent to translucent. Cleavage {111}, perfect; conchoidal to uneven fracture; brittle. $H = 4\frac{1}{2}$ –5. $G = 1.92$ –1.93. NMR studies of Al, Si distribution: *ACS 104:4859(1982)*, *JPC 86:3489(1982)*. Na and Ca may both be dominant, but Na is dominant at most locations. Mg and K are present in most specimens. Isotropic; $N = 1.47$ –1.48. Usually occurs in basaltic volcanics; metapyroxenite; also alteration product of volcanic tuff. Found at Cima Dome, near Valley Wells, San Bernardino Co., CA; at several localities on Oahu, Hawaii; Davis Hill and Khartoum, ONT; Hincks Bridge, Laurel, and Notre-Dame-de-la-Salette, and the Daisy Mica mine, Ottawa Co., QUE, Canada; *Sasbach, Kaiserstuhl, Baden, Germany* (principal source since 1842) and other localities in Baden–Württemberg; Pflasterkaute, near Eisenach, Thuringia; at Annerod, near Giessen, and at a number of localities around the Vogelsberg volcano, Hesse, Germany; Aci Reale, and Aci Castello, Catania, Sicily; several other worldwide localities are known. Synthetic counterparts are used for sorbents and catalysts. *EF AM 67:794(1982)*, *NZ (1985)*, *ZW (1992)*.

77.1.2.8 Levyne $(Ca,Na_2,K_2)Al_2Si_4O_{12} \cdot 6H_2O$

Named in 1825 by Brewster for Armand Levy (1794–1841), French mineralogist and crystallographer, Paris University. Zeolite group. **HEX-R** *R3m*. $a = 13.34$ –13.43, $c = 22.69$ –23.01, $Z = 1$, $D = 2.12$. *26-1381(nat)*: 8.15₂ 6.69₂ 4.25₁₅ 4.08₁₀ 3.85₂ 3.16₂ 2.80₆. Aluminosilicate framework is based on double and single six-membered rings in three positions (A, B, C), linked in a regularly repeating sequence AABCCABBC. No Si–Al ordering is present in the tetrahedra. The exchangeable cations are aligned along the threefold axis at the center of the cage and distributed in five sites. Similarity to offretite–erionite results in epitaxial overgrowths on levyne. Sometimes occurs as rhombohedra, forms {1011}, {0112}, {3032}, {0001}; thin hexagonal plates 2–5 mm across, rarely to 3 cm across, each simple-appearing hexagonal plate is composed of six twinned {1011} rhombohedra terminated by a large {0001} pinacoid; penetration twins around the c axis are universally present. Colorless, white, gray, yellow, red; white streak; vitreous luster. Cleavage {1011}, uneven fracture, brittle. $H = 4$ –4 $\frac{1}{2}$. $G = 2.09$ –2.16. Usually Ca-dominant with $Ca \gg Na > K$. Some Na-dominant levyne have been found. Two such examples are Is. Magee and Dunseverick, both in County Antrim, Northern Ireland. Most Na-rich samples are from the seashore, where cation exchange with seawater probably occurred. Also Na dominant from Choja-baru, and Iki Is., Nagasaki Pref., Japan. Uniaxial (–); $N_O = 1.489$ –1.510, $N_E = 1.487$ –1.502; birefringence very low, nearly isotropic; levyne-na has $N_O = 1.481$, synthetic material was produced by Wirsching (1981). Occurrences are most common in low-silica volcanic rocks (e.g., olivine basalt and rarely in andesite). Often with other zeolites, especially offretite and erionite.

Occurs at numerous worldwide localities; only localities for fine-quality and/or unusual specimens are given here. Best display specimens are from Burnt Cabin Creek, Spray, Wheeler Co., OR (to 12-mm-diameter colorless hexagonal plates); Beech Creek, Grant Co., OR(!) (to 1 cm); largest crystals (to 2 cm) are from Goble, Columbia Co., OR; twinned crystals without {0001} are found at Elk Mountain, WA, and Green Peter Dam, OR; hexagonal plates to 2 cm from near Berufjordur, Dyrafjord, Onundarfjord, and Mjoadalsa, Iceland; *Dalsnipa*, *Sandoy Is.*, *Faroe Is.*; crystals to 3 cm are found at Rossafelli and Nesvik on Stremoy Is., Faroe Is. Other localities include North and South Table Mts., Golden, Jefferson Co., CO; Is. Magee and the Parkgate quarry, Templepatrick, County Antrim, Northern Ireland; Matgilligan and Dungen, County Londonderry, Ireland; Cinchwad, Pune district, MAH, India; Flinders and Victoria Is., VIC, Australia. *EF AM 59:837(1974)*, *61:853(1976)*; *TMPM 22:117(1975)*; *NZ (1985)*; *ZW (1992)*.

77.1.3.1 Gismondine $\text{Ca}_2[\text{Al}_4\text{Si}_4\text{O}_{16}] \cdot 9\text{H}_2\text{O}$

Named in 1817 by Leonhard for Carlo Giuseppe Gismondi (1762–1824), Italian mineralogist, who previously discovered a similar mineral, zeagonite, a mixture of gismondine and phillipsite. Zeolite group. The oldest and best established member of the gismondine group [see amicitite (77.1.3.2), garronite (77.1.3.3), and gobbinsite (77.1.3.4)]. Has been divided by chemistry and amount of disorder in the framework. *MON* (pseudo-TET) $P2_1/c$. $a = 10.021$, $b = 10.637$, $c = 9.836$, $\beta = 92.5^\circ$, $Z = 2$, $D = 2.22\text{--}2.28$. *39-1373(nat)*: 7.3_6 4.91_5 4.27_{10} 4.21_5 3.19_9 2.74_8 2.71_6 2.69_8 2.66_7 ; *20-452*: 7.28_2 4.91_2 $4.27_{3.5}$ 3.34_{10} 3.19_2 3.13_1 2.70_2 1.82_2 ; also *21-840* (preferred orientation may affect intensities). Single four-membered rings stacked in two-dimensional arrays of double-crankshaft chains parallel to [100] and [010]. Gismondine has perfect Si–Al ordering in the framework with alternation of Si and Al at the centers of the tetrahedra. Ca is in a fourfold position bound by two framework oxygens on one side and H_2O molecules. Gismondine is the ordered equivalent of garronite, the Ca equivalent of amicitite, and the ordered Ca equivalent of gobbinsite. Appear to be pseudotetragonal dipyramids with {111}; in reality, they are interpenetration twins of two individuals with four faces of the form {232} and four faces of its twin, with twinning perpendicular to {100}, with twin plane approximately parallel to (100) and (001); commonly intergrown with phillipsite (epitaxial); aggregates to >15 mm across, individual crystals to >6 mm across; also in radiating spherulitic aggregates; rare twinning on {110} around a or b . Colorless–white, very pale pink; white streak; vitreous luster. Two poor cleavages parallel to form {232}, conchoidal fracture. $H = 4.5$. $G = 2.12\text{--}2.28$. IR data: *CMG 26:143(1981)*. Nonluminescent. Piezoelectric. Has a narrow range of composition, small amounts of Na, K, or Sr with no Ba, Fe, or Mg. Tsi ranges from 0.50–0.60 Biaxial (–); X perpendicular to [010], $Y = b$, $Z \wedge c = 42^\circ$; $N_x = 1.512\text{--}1.538$, $N_y = 1.516\text{--}1.544$, $N_z = 1.523\text{--}1.549$; $2V = 60\text{--}90^\circ$, but as low as 15° ; length-fast; $r < v$, weak. Has been synthesized. *CCM 29:171(1981)*. Occurs in olivine basalt (most

common), less commonly in nepheline basalt, and palagonite tuffs, schist, or pegmatites, also in metapyroxenite. Best localities for display-quality specimens: Italy, Germany, Oregon, Northern Ireland, and New Zealand. Also found in Australia, Austria, Canada, Canary Islands, Czech Republic, Faroe Is., France, Hungary, Iceland, Japan, Mexico, Poland, Russia, Senegal, South Africa, and Switzerland. Type locality is *Capo di Bove, Lazio, Italy*. Selected detailed localities include: Round Top volcano, Oahu, and Alexander Dam, Kauai, HI; Reydarfjord, Faskrudsford, and Fagridalur, Iceland; Ballyclare, County Antrim, Northern Ireland; Montalto di Castro, Viterbo, Italy; Gorner glacier, near Zermatt, Switzerland; in Germany from the Eifel district (e.g., Schellkopf near Brenk); Schlauroth, Gorlitz, Saxony; Hohenberg near Bühne, Westphalia; Frauenberg, Fulda, Hesse; Arensberg, Zilsdorf; Zalezly, Czech Republic; Concepcion del Oro, ZAC, Mexico. EF *MM 33:187(1962)*, *43:841(1980)*; *BM 107:805(1984)*; *NZ (1985)*; *Z6:361(1986)*; *ZW (1992)*.

77.1.3.2 Amicite $K_2Na_2(Al_4Si_4)O_{16} \cdot 5H_2O$

Named in 1979 for Giovan Battista Amici (1786–1863), physicist, optician, and inventor of the Amici lens. Zeolite group. *MON I2*. $a = 10.23\text{--}10.26$, $b = 10.42\text{--}10.44$, $c = 9.88\text{--}9.92$, $\beta = 91.50\text{--}91.68^\circ$, $Z = 2$, $D = 2.18$. *33-1273: 7.30₆ 5.11₄ 4.22₉, 4.18₄ 3.24₅ 3.14₈ 2.72₁₀ 2.70₅*. Characterized by untwisted double-crankshaft chains developed in two perpendicular directions, as in gismondine and the disordered phases gobbinsite and garronite, but with the symmetry and distribution of cations and water molecules being completely different. The Si–Al and Na–K distributions are perfectly ordered. Amicite can be considered as the ordered equivalent of gobbinsite. Na replaces Ca in gismondine sites and occupies another site as well. K occupies sites that are filled by H₂O in gismondine. *AC(B) 35:2866(1979)*. Rhombic prisms most common. {110} and {011} dominant, with {111}, {101}, and {010} uncommon. Lamellar twinning on {011} or {110}. Pyramidal crystals to 3 mm and rarely to 1 cm in length. Colorless, white streak, vitreous luster. No cleavage, conchoidal fracture. $H = 4\frac{1}{2}$. $G = 2.06\text{--}2.23$. Thermal data: *NZ (1985)*. Slowly decomposed by cold 10% HCl. Minor Ca and traces of Fe may be present. Biaxial (–); $Y = b$, $Z \wedge c = 12^\circ$; $N_x = 1.485$, $N_y = 1.490$, $N_z = 1.494\text{--}1.498$; $2V = 82^\circ$. A low-temperature zeolite in veins cutting alkalic volcanic rocks (Hegau) and as veins several centimeters thick cutting alkalic pegmatites (Khibiny massif). Found at *Howenegg, near Hegau, Eifel, Germany*, sometimes with merlinoite, in the S.M. Kirov mine, Mt. Kukisvumchorr, Khibiny massif, Kola Penin., Russia; also in cavities in basalt south of Ciudad Real, Ciudad Real Prov., Spain. EF *NJBM 11:481(1979)*, *DANS-ESS 263:135(1982)*, *NZ (1985)*; *ZW (1992)*.

77.1.3.3 Garronite $Na_2Ca_5Al_{12}Si_{20}O_{64} \cdot 27H_2O$

Described in 1962 by Walker and named for the locality. Zeolite group. ORTH (pseudo-TET) *I4m2*. $a = 9.871\text{--}9.93$, $b = 9.871\text{--}9.893$, $c = 10.292\text{--}10.303$, $Z = 0.5$, $D = 2.19$. *39-1374(nat): 7.15₇₅ 4.95₆ 4.15₈ 4.07₃ 3.24₅ 3.14₁₀ 2.67₇*

2.57₁ 16-905(syn); 7.13₈ 4.95₆ 4.15₇ 4.07₅ 3.24₄ 3.14₁₀ 2.71₁ 2.67₆. The mineral has an aluminosilicate framework that is the same as that of gismondine but with disordered Si-Al distribution. Probably grew as a disordered phase that later underwent a partial ordering with four differently oriented domains. Deviations from the maximum framework symmetry can be explained in terms of cation and water arrangements in the zeolitic cavities. *AM* 77:189(1992). Generally compact, massive, sometimes fibrous, radiating. Rare single crystals to 4 mm; prismatic, rarely dipyrarnidal. Forms: {101}, {011}, and {112}. Often covered by or associated with phillipsite and as epitaxial overgrowths on phillipsite. Internal twinning on {110}, and further twinning on {011} leads to characteristic groups. Various colors, including pale yellow, orange-yellow, yellowish brown, colorless, white, and tan; white streak; dull to greasy-vitreous luster. Two good cleavages: {100}, {010}; series of concentric fractures perpendicular to the length of the fibers (elongate on *c*). $H = 4\frac{1}{2}$ -5. $G = 2.13$ -2.18. Always Ca dominant. Na and K contents vary considerably. Garronite can be considered the Ca equivalent of gobbinsite and may have been the precursor that was altered by Na-K-rich solutions to gobbinsite. Some garronite has very little Na (about 0.2 atom). Biaxial (-) and (+), $2V = 25$ -30°; also uniaxial (+) and (-); $N_x = 1.500$ -1.512, $N_y = 1.502$ -1.511, $N_z = 1.512$ -1.515; $N_O = 1.500$ -1.515, $N_E = 1.502$ -1.512; length slow and fast; parallel or inclined extinction; $Y = c$ (elongation). Most common in vesicles in basalts and diabases; some metamorphic rocks, and in sodalite xenoliths at Mt. St.-Hilaire. North and South Table Mts., Golden, Jefferson Co., CO; Neer Road pit, Goble, Columbia Co., OR; Pete's Point, Aneroid Lake, Joseph, Wallowa Co., OR; Capitol Peak, Thurston Co., WA; Davis Hill, ONT; Mt. St.-Hilaire, QUE, Canada; at numerous localities in Iceland, between Berufjord and Seydisfjord (e.g., Skessa, Reydarfjord); *Glenariff Valley, Garron Plateau, and many other localities, County Antrim, Northern Ireland*; Storr, Isle of Skye, Scotland; Fara Vicentina, and San Giorgio di Perlana, Vicenza, Italy; Gignat, Puy de Dôme, France; Höwenegg quarry, Hegau, Baden-Württemberg, Germany. *EF MM* 33:173(1962), 47:567(1983); *NZ* (1985); *NJBM*(2):91(1994).

77.1.3.4 Gobbinsite $Na_4(Ca,Mg,K_2)Al_6Si_{10}O_{32} \cdot 12H_2O$

Named in 1982 by Nawaz and Malone for the Gobbins escarpment, near Hills Port, Island Magee, County Antrim, Northern Ireland. Zeolite group. See garronite (77.1.3.3), phillipsite (77.1.3.6), gismondine (77.1.3.1), amicite (77.1.3.2), and merlinoite (77.1.3.11). ORTH (pseudo-TET) $Pmn2_1$. $a = 10.10$ -10.15, $b = 9.77$ -9.80, $c = 10.10$ -10.17, $Z = 1$, $D = 2.15$. 35-459(nat): 7.11₁₀ 5.06₅ 4.89₃ 4.12₁₀ 3.20₁₀ 3.11₈ 2.70₈ 2.65₄. Tetragonal cell is $P4_22_12$, with $a = 10.115$ and $c = 9.766$. The framework (Al-Si) is the same as gismondine. It is composed of stacked two-dimensional arrays of double-crankshaft chains parallel to [100] and [010], with Na and Ca ions located in more than half of the eight-membered rings perpendicular to *a*, where K ions alternate in eight-membered rings perpendicular to *b*. Distribution of Al and Si in the framework

is disordered. *ZK 171:281(1985)*, *MM 58:615(1994)*. Rietveld refinement. Terminated crystals are very rare, pyramidal crystals have external morphology and twinning of phillipsite, also steep and spikelike to about 2 mm, elongated on *c*; masses to 2 cm in diameter; twinning like phillipsite, on {110}. White to tan, cream; white streak; dull to greasy (chalky) luster. No cleavage observed, brittle, poor parting perpendicular to length of fibers. *H* probably ≈ 4 . *G* = 2.19. Always Na dominant. *K* varies from being \approx Na, to only a trace. *Ca* is present in considerable amounts in some samples. *Mg* present in small amounts. *Tsi* ranges from 0.62–0.68 Uniaxial (-); $N_O = 1.494$ perpendicular to length, $N_E = 1.489$ parallel to length; or biaxial, with small 2*V*; negative elongation, parallel extinction; *c* parallel to direction of elongation. Occurs at Mt. St.-Hilaire, found in small cavities in a eudialyte-rich pegmatite layer in nepheline syenite. Has overgrowth of phillipsite. Gobbinsite appeared to form as a replacement of garronite during a late Na–K-rich phase. In olivine basalt and sodalite syenite (Ireland). Occurs at the Poudrette quarry, Mt. St.-Hilaire, QUE, Canada; this was the first locality for well-crystallized specimens, and most have thin, epitaxial overgrowths of phillipsite. *Gobbins escarpment, near Hills Port, Island Magee, County Antrim, Northern Ireland*; K-rich gobbinsite occurs near Two-Mouth Cave, Portmuck, Island Magee, and at Dunseverick, near the Giant's Causeway, County Antrim, also at Maghera Morne, Larne, Northern Ireland; Aranga, North Island, New Zealand. This may be gismondine or an intergrowth of garronite–gobbinsite. *EF MM 46:365(1982)*, *47:567(1983)*; *NZ (1985)*; *ZK 171:281(1985)*; *ZW (1992)*.

77.1.3.5 Harmotome $(Ba,K)_{1-2}(Si,Al)_8O_{16} \cdot 6H_2O$

Described in 1801 by Haüy and named from the Greek for *joint cutting*; defined as “that which divides on the joints,” in allusion to the morphology of twinned crystals. Zeolite group. See phillipsite (77.1.3.6), the Ca-, Na-, or K-dominant analog. *MON P2₁/m*. *a* = 9.86–9.91, *b* = 14.12–14.17, *c* = 8.67–8.72, $\beta = 124.43$ – 124.74° , *Z* = 2, *D* = 2.45. *39-1377(nat)*: 8.12₆ 7.16₅ 6.39₅ 4.08₇ 3.24₆ 3.17₇ 3.13₁₀ 2.67₆. The framework consists of layers of tetrahedra forming chains of doubly connected four-membered rings (double-crankshaft chains) on planes where two nearby chains have been alternately rotated 180° and mirrored between successive planes. Two sets of intersecting channels are present, one parallel to *a* and the other parallel to *b*. Partial Si–Al ordering exists as determined by X-ray diffraction and optics. Ordering of Ba causes deviations from orthorhombic to monoclinic symmetry, while Si–Al order causes deviation, up to 2°, from monoclinic to triclinic symmetry. The topological orthorhombic symmetry (*Cmcm*) that reduces to monoclinic (*P2₁/m*) from cation ordering and finally to triclinic (*P1*) because of Si–Al ordering. *AC(B) 30:2426(1974)*; *AM 63:960(1978)*, *70:822(1985)*; *EJM 2:861(1990)*. May be blocky, equant, or radiating. Pseudo-orthorhombic, twinned, prismatic crystals, elongate on *a* or *b*. Crystals to about 4 cm long. All crystals are repeatedly twinned on {001}, {021}, and {110}, with a multitude of twin types. Harmotome appears to nucleate as twins. The major twin types are:

Morvenite: fourling twin present in all crystals; Marburg; a cruciform twin; Perrier: a cruciform twin; Stempl: a multiple twin of Morvenite, Marburg, or Perrier types and twinned around two or three axes. Three double twins may further twin to simulate a pseudotetragonal prism or dodecahedron. Dominant forms include {010}, {001}, {110}, {100}, {520}, {410}. Colorless, white, gray, red, yellow, orange, brown; white streak; vitreous luster. Cleavage {010}, good; {100}, fair; uneven to conchoidal fracture; brittle. $H = 4\frac{1}{2}$ –5. $G = 2.38$ –2.50. IR data: *MPOL 16:3(1985)*, *CMG 26:143(1981)*. Soluble in common acids. A continuous solid-solution series exists between harmotome and phillipsite. Harmotome commonly contains little Sr, K, and Ca. However, considerable and dominant amounts of K and Na have been found in some crystals. $T_{si} = 0.70$ –0.72 Biaxial (+); $Z = b$, $X \wedge a = 62$ –67°; $N_x = 1.498$ –1.508, $N_y = 1.503$ –1.509, $N_z = 1.506$ –1.514; $2V = 75$ –85°; weak, crossed dispersion. For triclinic material: $Z \wedge b = 0$ –2°, $X \wedge c = -52$ to -58 °, $Z = b$, $Y \wedge c = 27$ –34° in the acute angle. A low-temperature zeolite. Most occurrences are in late-stage hydrothermal veins. Some are in volcanics (e.g., basalts, phonolites, and trachytes), due to hydrothermal alteration of Ba-containing feldspars or other Ba-containing minerals. Harmotome is rarely found in altered tuffs and deep-sea sediments. Associated with such minerals as other zeolites, quartz, calcite, barite, pyrite, galena, hyalophane, clay minerals, and leucite. Occurs in many worldwide localities, but only localities for display-quality specimens and unusual specimens are given here. Crystals to 2 cm from Sing Sing, near Ossining, Westchester Co., NY; Glen Riddle, Delaware Co., PA; Beaver mine, Thunder Bay, ONT, Canada; crystals to 2.5 cm from several mines, most from the Bellsgrove mine, Strontian, Argyllshire, Scotland; crystals to 2.5 cm across, elongated on b , from the Korsnas lead mine, south of Vaasa, Finland; Sarrabus, Sardinia, Italy; *Andreasburg, Harz Mts. and at Idar-Oberstein, Rhineland-Palatinate*, and Silberberg, near Bodenmais, Bavaria, Germany; Příbram, Czech Republic; Kupferberg-Rudelstadt, Silesia, Poland; crystals to 3 cm from Bukan, Kotui R. basin, Taimir, Russia; Batopilas, CHI, Mexico. *EF MM 36:444(1967)*, *NZ (1985)*, *ZW (1992)*.

77.1.3.6 Phillipsite $(K,Na,Ca,Ba)_{1-2}(Si,Al)_8O_{16} \cdot 6H_2O$

Described in 1825 by Levy and named for William Phillips (1775–1829), British mineralogist and founder of the Geological Society of London. Zeolite group. Forms a series with harmotome. Wellsite is a barian phillipsite. *MON P2₁/m*. $a = 9.84$ –10.02, $b = 13.85$ –14.32, $c = 8.64$ –8.73, $\beta = 124.3$ –125.07°, $Z = 2$, $D = 2.17$. *39-1375(nat)*: 7.18₆ 7.16₇ 4.13₄ 4.12₄ 3.28₄ 3.21₁₀ 2.75₄ 2.70₄; *CCM 37:243(1989)(sedimentary)*: 7.10₈ 5.35₂ 5.01₃ 4.97₅ 3.25₄ 3.17₁₀ 2.73₂ 2.68₃. Structure is like that of harmotome (77.1.3.5). X-ray diffraction shows no Si–Al ordering. However, optics show fine-scale ordering. Ordering occurs when cations bond to the framework oxygens at Al-populated sites. If the cation is completely surrounded by water molecules, the Si–Al structure is disordered. Ordering of the exchangeable cations causes deviations from

orthorhombic to monoclinic symmetry, while ordering of Al and Si causes deviations (up to 2°) from monoclinic to triclinic symmetry. Topologically orthorhombic ($Cmcm$) \rightarrow monoclinic ($P2_1/m$) — triclinic ($P1$). Occurs as pseudo-orthorhombic, twinned, prismatic crystals, commonly elongated on a . Also, blocky, equant crystals and radiating aggregates and spherulites are common. Common forms are $\{010\}$, $\{001\}$, $\{110\}$, $\{100\}$, $\{520\}$, $\{410\}$. Always forms complex penetration twins. Untwinned phillipsite has not been found. Four types of penetration twins: Morvenite, Marburg, Perrier with $\{021\}$ twin plane, and Stempl. May be single- or double-penetration twins. Twin plane can be $\{001\}$ and $\{110\}$ as well. The Perrier and Marburg twins are also cruciform twins. Colorless, white, pink, red, light yellow; white streak; vitreous luster. Cleavage $\{010\}$, distinct; $\{100\}$, indistinct; uneven fracture; brittle. $H = 4-4\frac{1}{2}$. $G = 2.19-2.20$. Gelatinizes with common acids. Synthesized: *CCM 29:171(1981)*. IR and Raman data: *CPMG 26:143(1981)*, *CRT 16:917(1981)*. Thermal data: *NZ (1985)*. Dominant cations may be K, Na, Ca, or Ba, but Ba may not exceed 50% of the total exchangeable cations. Sr-bearing phillipsite is known. Most phillipsite has Ca as the dominant cation, but others are often dominant. Sedimentary phillipsites are generally very siliceous and alkalic [$Si/(Al + Fe^{3+}) = 3.08-3.37$]. Tsi varies from 0.56–0.77, may be biaxial (+) or (-); $N_x = 1.483-1.505$, $N_y = 1.484-1.511$, $N_z = 1.486-1.514$; $2V_z = 60-90^\circ$ or $2V_x 60-90^\circ$; sedimentary phillipsites have a much lower average N than for other phillipsites because of their high Si and alkali content; dispersion is $r < v$ moderate in optically positive phillipsite and $r > v$ in negative phillipsites. $X = b$, $Z \wedge c = 19^\circ$ ($11-30^\circ$) in the acute angle, positive elongation for optically positive phillipsite. For triclinic phillipsite: $Z \wedge b = 2^\circ$, $X \wedge c = (-)52-58^\circ$, $Y \wedge c = 27-34^\circ$ in the acute β . Phillipsite is a common zeolite in volcanic rocks (e.g., in cavities in basalts); ore veins; is a common constituent in diagenetically altered rhyolitic vitric tuffs of Cenozoic saline, alkaline lake deposits; on the ocean floor. A low-temperature zeolite. May be associated with other zeolites, apophyllite, calcite, celadonite, and other minerals. Display-quality specimens of phillipsite are rare. A Na-dominant (11.0 wt% Na_2O) of phillipsite occurs at Boron, Mojave Co., CA; display-quality specimens: crystals to 2 cm long from Wall Creek, N of Monument, Grant Co., OR; also Mt. Vernon, Grant Co., Oregon; Cape Lookout, Tillamook Co., and Spray, Wheeler Co., and other localities in Oregon; Mt. St.-Hilaire, QUE, Canada; at a number of localities, including the Giant's Causeway, County Antrim, Northern Ireland; with natrolite at *Aci Castello, Sicily, Italy*; Capo di Bove and other localities around Rome, Lazio, Italy; Asbach, Westerwald, and at Annerod, near Giessen, Hesse, Germany; to 8 mm long from Sumeg, Hungary; on heulandite to 12 mm long from Quebrada Grande, Costa Rica; water-clear to orange crystals to 4 mm long from near Melbourne, and other localities in VIC and at Gads Hill, near Liena, TAS, Australia; Maze, Niigata Pref., Japan. *EF AM 49:1366(1964)*, *57:1125(1972)*, *70:822(1985)*; *AC(B) 30:2426(1974)*; *CCM 36:131(1988)*; *NZ (1985)*; *ZW (1992)*.

77.1.3.8 Perliaite $K_9Na(Ca,Sr)[Al_{12}Si_{24}O_{72}] \cdot 15H_2O$

Named in 1984 by Menshikov for Lilliya Alekseevna Perekrest, instructor of mineralogy, Kirov Mining School. Zeolite group. *HEX P6/mmm*. $a = 18.490$ – 18.535 , $c = 7.51$ – 7.535 , $Z = 1$, $D = 2.15$. *38-0395(nat)*, *ZVMO 113:607(1984)*: 16.0_{10} 6.0_7 4.62_{10} 3.94_7 3.20_9 2.67_8 1.54_8 1.31_{10} ; Murun massif, *ZVMO 115:200(1986)*: 16.1_8 6.07_3 4.64_{10} 3.95_5 3.21_{10} 3.19_3 2.68_9 2.21_3 . Not related structurally to any of the other natural zeolites but similar to synthetic zeolites L, K, and Ba-G-g. X-ray diffraction patterns resemble synthetic zeolites L and K. Fibrous, radiating needles 2–5 mm long or opal-like masses to 2 cm in diameter; curved, flexible, and elastic needles. White, white streak, pearly luster. $H = 4$ – 5 . $G = 2.14$ – 2.18 . IR, DTA, TGA, DTG data: *ZVMO 115:200(1986)*. Kola Penin. = $K_{9.07}Na_{0.91}Ca_{0.49}Sr_{0.46}Fe_{0.08}Mg_{0.05}[Al_{11.35}Fe_{0.33}Si_{24.27}O_{71.12}] \cdot 15.2H_2O$ and Murun = $K_{8.48}Na_{1.04}Ca_{0.61}Ba_{0.37}Mg_{0.17}Sr_{0.15}Mn_{0.02}[Al_{12.64}Si_{23.47}O_{72}] \cdot 18H_2O$. Uniaxial (+); $N_O = 1.479$ – 1.483 , $N_E = 1.488$ – 1.489 ; parallel extinction; positive elongation. Occurs as radiating fibrous aggregates in nepheline–microcline and sodalite–microcline pegmatites, associated with pectolite, kalsilite, aegirine, wadeite, and yuksporite. *Mt. Eveslogchorr and Mt. Yukspor, Khibiny massif, Kola Penin., Russia*; also at Chioiny, Kola Penin.; Murun massif, Transbaikalia, Russia. *EF ZW (1992)*.

77.1.3.9 Paulingite $(K_2,Ca,Na_2Ba)_5[Al_{10}Si_{32}O_{84}] \cdot 34$ – $44H_2O$ or $(Ca_{2.6}K_{2.3}Ba_{1.4}Na_{0.8})(Al_{11.5}Si_{30.6}O_{84}) \cdot 33H_2O$ [IMA 16th Meet.: 238(1994)]

Named in 1960 by Kamb and Oke for Linus Carl Pauling (1901–1994), professor of chemistry, California Institute of Technology, Pasadena, CA. Zeolite group. *ISO Im3m*. $a = 35.049$ – 35.114 ; $Z = 16$, $D = 2.10$ – 2.22 . *39-1378(nat)*: 8.28_6 6.89_7 4.78_8 3.58_6 3.35_7 3.26_9 3.13_6 3.08_{10} . Has been synthesized. Extremely complex aluminosilicate framework composed of large polyhedral cages consisting of double eight-membered rings; gmelinite cages, and truncated cubo-octahedra, where the gmelinite cage is completely surrounded by H_2O molecules. No Al–Si order was detected. The size of the unit cell is the largest for any inorganic compound. *SCI 154:1004(1966)*, *JSSC 46:265(1983)*. Small, 0.1–0.8 mm usual, dodecahedra {110} dominant, very small cube {100} and trapezohedral {211} modifications are present, a few crystals are 3–4 mm across; no twinning. Colorless, light yellow, orange, red; white streak; vitreous to greasy luster. No cleavage, conchoidal fracture. $H = 5$. $G = 2.085$ – 2.24 . A K–Ca–Ba–Na-rich zeolite. K is commonly the dominant cation, with considerable variation in the amounts of the exchangeable cations Ca, Ba, Na. A Ca-dominant variety has been found. When large cations are present, $D = 2.24$ and water is $44H_2O$, while the smaller cations produce a cell with $D = 2.08$, and $34H_2O$. Isotropic; $N = 1.472$ – 1.484 . Some lamellae seen optically may indicate the presence of twinning. Occurs in tholeiitic basalt and sandstone xenoliths in basalt (melilite–nephelinite–basalt). Associated with erionite and pyrite. Occurs at the *Rock Island Dam, on the Columbia R., Wenatchee, Douglas Co., WA*; Paulingite-Ca at Three Mile School, NW of Ritter, Grant Co., OR;

Riggins, Idaho Co., ID; Chase Creek, N of Falkland, and Twig Creek, Monte Hills, BC, Canada; on the northern coast of County Antrim, particularly at Port Ganny, Giant's Causeway, and Craigahulliar, Portrush, Northern Ireland; Howenegg quarry, Hegau, and Ortenberg quarry, Vogelsberg, Hesse, Germany; Vinarice, near Kladno, Bohemia, Czech Republic. EF *AM* 45:79(1960), 67:799(1982); *NZ* (1985); *CMG* 33:109(1988); *ZW* (1992); *IMAMA* 238(1994).

77.1.3.10 Mazzite

Named in 1974 by Galli et al. for Fiorenzo Mazzi (b.1924), professor of mineralogy, University of Pavia, Italy. Zeolite group. *HEX* Probably $P6_3/mmc$ (other possible space groups are $P62c$ and $P6_3mc$). $a = 18.38\text{--}18.39$, $c = 7.64\text{--}7.65$, $Z = 1$, $D = 2.11$. $38\text{--}426(\text{nat})$: 9.20_6 6.02_5 4.73_5 3.82_{9_5} 3.65_5 3.53_9 3.19_{10} 2.94_{10} . The Al–Si framework consists of doubly connected four-membered ring chains that form gmelinite-type cages, stacked to form columns parallel to c . Adjacent columns are shifted by one-half the c -axis length and cross-linked to form two different types of channels parallel to c ; the large channels are composed of 12-membered rings surrounded by six cages, while smaller channels are formed by distorted eight-membered rings between adjacent pairs of cages. Exchangeable cations are found in three positions. The Si–Al in the framework is disordered. *RSIMP* 31:599(1975). Radiating groups of crystals, simple hexagonal prisms, with $\{100\}$ and $\{0001\}$; needles to 15 mm known. Colorless, white streak, vitreous luster. Monte Semiol, France: $K_{2.5}Mg_{2.1}Ca_{1.4}Na_{0.3}[Al_9Si_{26.5}O_{72}] \cdot 28.03H_2O$. Uniaxial (–); $N_O = 1.5062$, $N_E = 1.4990$; birefringence: looks similar to other hexagonal zeolites and morденite; negative elongation. Occurs in basalt, associated with phillipsite, chabazite, and offretite. Of hydrothermal origin. Nearly pure Na member to 1.5 cm long from Boron, Kern Co., CA; at *Mte. Semiol, Montbrison, Loire, France*, with other zeolites, calcite, and siderite. EF *AC(B)* 31:1603(1975), *CMP* 45:99(1974).

77.1.3.11 Merlinoite $(K,Na)_5(Ca,Ba)_2[(Al_9Si_{23})O_{64}] \cdot 22H_2O$

Described in 1977 by Passaglia et al. and named for Stefano Merlino (b.1938), professor of crystallography, University of Pisa. Zeolite group. *ORTH* *Immm*. $a = 14.05\text{--}14.116$, $b = 14.10\text{--}14.25$, $c = 9.946\text{--}9.99$, $Z = 1$, $D = 2.19\text{--}2.23$. $29\text{--}0989(\text{nat})$: 7.12_9 7.08_9 5.36_4 4.48_4 3.26_4 3.24_4 3.23_4 3.18_{10} . Structure consists of a framework with doubly connected eight-ring chains. Double octagonal rings that deviate from regularity. Deviation from tetragonal symmetry is due to the different arrangement of two (K, Ba) sites that would otherwise be equivalent to the tetragonal space group. Four double-crankshaft chains around a tetrad. Topological symmetry = I_4/mmm . Al and Si are completely disordered. *NJBM*:1(1979). Because of isostructural similarity in structure, epitaxial intergrowths of phillipsite and merlinoite are common. Crystals to 4 mm long, in radial aggregates; pseudotetragonal, with $\{001\}$, $\{101\}$, $\{011\}$, and $\{100\}$, prismatic to fibrous, elongate on c ; 90° rotation twinning about c

and interpenetrant twinning. Colorless to white, white streak, vitreous-dull luster. Cleavage {010}, good; steplike fracture. $G = 2.14-2.27$. Thermal data: *NZ (1985)*. Na or K may be dominant in the A site, and Ba or Ca may be dominant in the B site. BaO to 15.9 and SrO to 7.3 wt % (Khibiny). Traces of iron (0.72 wt % Fe_2O_3) are present in Cupaello merlinoite. Biaxial (-); $\text{XYZ} = bca$; $N_x = 1.494-1.499$, $N_y = 1.500$, $N_z = 1.501$; $2V = 56^\circ$; $r > v$. A secondary mineral occurring in cavities in basalt; at contact between basalt and marine sediments; from nepheline melilitite and other silica-undersaturated volcanic rocks; in cataclastic pegmatitic rocks, in pyroxene-rich volcanic ejecta; in manganese nodules and as a diagenetic alteration product of mafic to intermediate composition volcanic ash falls. Searles Lake, San Bernardino Co., CA; Tjornes Penin., northern Iceland; *Cupaello, Santa Rufina, Rieti*, and Valle Biachella, Sacrofano, Rome, *Italy*; twinned crystals from a sandstone xenolith in basalt at Ortenberg quarry, Vogelsberg, Hessen, also at Höwenegg, Hegau, Germany; Vuonemiok R., Khibiny massif, Kola Penin., Russia; in manganese nodules on the south Indian Ridge, Indian Ocean. *EF NJBM:355(1977), 481(1979); MM 51:749(1987); DA 41:295(1990); ZW (1992)*.

77.1.3.12 Montessonmaite $(\text{K},\text{Na})_9\text{Al}_9\text{Si}_{23}\text{O}_{64} \cdot 10\text{H}_2\text{O}$

Named in 1990 by Rouse et al. for the locality. Zeolite group. ORTH (pseudotet) *Fdd2*. $a = 10.099$, $b = 10.099$, $c = 17.307$, $Z = 1$, $D = 2.30$. *PD(nat): 6.59₇₅ 4.33₄ 3.30₁₀ 3.13₁₀ 2.80₃ 2.51₂ 2.35₂ 1.78₂*. *AM 75:1415(1990)*. Related to gismondine group and to merlinoite. Very nearly tetragonal *I42d* or *I4₁md*. It probably has disordered intergrowths in an otherwise ordered arrangement of Si and Al in the framework. K is coordinated with two H_2O molecules and six oxygen atoms in the center of eight-membered ring channels. *AM 75:1415(1990)*. Crystals to 2 mm long, dipyrmidal, {001 + 00 $\bar{1}$ }, {*hkl*} + {*hKl*}, {504}, {50 $\bar{4}$ }, {054}, {05 $\bar{4}$ }; to 0.1 mm in size; twinning not observed. Colorless, white streak, vitreous luster. No cleavage. $G = 2.34$. Nonluminescent. Analysis (wt %): K_2O , 16.7; Na_2O , 0.2; Al_2O_3 , 19.8; SiO_2 , 55.7; H_2O (7.6) by difference = 100%. Biaxial (-); $X = c$, $Y, Z = a$ or b ; $N_x = 1.498$, $N_y = 1.506$, $N_z = 1.507$; $2V = 35^\circ$ ($2V_{\text{calc}} = 39^\circ$); no dispersion. Occurs in a 3-mm vesicle in scoria. Associated minerals are dolomite, calcite, chabazite, and natrolite. Additional specimens were later found. Occurs at *Pollena in the Mte. Somma-Vesuvius volcanic complex, Naples, Italy*. *EF ZW (1992)*.

77.1.4.1 Heulandite-Ca $(\text{Ca},\text{Na},\text{K})_{2-3}\text{Al}_3(\text{Al},\text{Si})_2\text{Si}_{13}\text{O}_{36} \cdot 12\text{H}_2\text{O}$

Described by Brooke in 1822 and named for John Henry Heuland (1778-1856), a British mineral collector and dealer. Zeolite group. Heulandite-(Na) and heulandite-(K) also approved by the CNMMN IMA. Clinoptilolite is considered by some authors [e.g., *KL:793(1980), ZW (1992)*] to be a high-silica variety of heulandite. See clinoptilolite (77.1.4.2) for a discussion of the thermal stability of the two minerals and the differentiation between the two. Three methods (cation ratios, Si/Al ratio, and thermal behavior) have been

used to differentiate the two minerals, but there is a great lack of consistency between the three methods. *MON C2/m*. $a = 17.498\text{--}17.74$, $b = 17.816\text{--}18.025$, $c = 7.396\text{--}7.529$, $\beta = 116.07\text{--}116.60^\circ$; K-rich material (Denmark): $a = 7.405$, $b = 17.885$, $c = 15.821$, $\beta = 91.39^\circ$ (on a pseudo-orthorhombic cell); $Z = 2$, $D = 2.16$. *41-1357(nat)*: 8.96_{10} 4.65_3 3.98_{65} 3.90_4 3.82_2 2.99_3 2.97_9 2.81_2 . There have been at least five structural studies on untreated material [summarized in *AM 76:1872(1991)*]. There are four metal sites. Al and Si in the framework have some ordering. Low-Si heulandite contains two additional sites containing water molecules that are not present in silica-rich heulandite. All of the exchangeable cations are in two sites within channels parallel to c . One site contains Ca, and the other site contains all of the other cations (Na, K, Mg, Sr). Neutron diffraction studies of the structure: *JSSC 54:1(1984)*. Structure of K-exchanged heulandite: *AC(B) 39:189(1983)*. Heulandite has been synthesized [e.g., *JCSSJ 30:31(1990)*]. Synthetic heulandite tends to change morphologically from prismatic to platy habit with an increase of Ca. The thermal stability of heulandite increases gradually with an increase of the Na-K or Si contents. **Habit**: Crystals to 3 cm long relatively common, as much as 14 cm long (elongated on a). Commonly tabular parallel to $\{010\}$, and elongated on a , as well as widest at the center—thus the common “coffin-shaped” crystals. Also platy, trapezoidal crystals with $\{010\}$ dominant. Some crystals may be elongated on b or c . May be granular to massive. Common forms (pseudo-orthorhombic cell): $\{100\}$, $\{010\}$, $\{011\}$, $\{101\}$, $\{\bar{1}01\}$, $\{110\}$. Twinning sometimes present with $\{100\}$ as the twin and contact plane. **Physical properties**: Colorless, white, gray, yellow, pink, red, brown, green, and black; white streak; vitreous to pearly luster (on $\{010\}$). Uneven fracture, brittle. $H = 3\frac{1}{2}\text{--}4$. $G = 2.10\text{--}2.29$. Soluble in HCl. May show photoluminescence. *CRT 18:213(1983)*. **Chemistry**: The mineral has a wide range in exchangeable cations, and Al-Si in the framework. Most large heulandite crystals are Ca-dominant, with a relatively low Si content. There is a continuous series between heulandite and Ca-clinoptilolite with $R^{2+} + 2Al \rightarrow 2Si$ substitution, where monovalent cations (Na, K) are contained in the range one to two in a unit formula based on 72 oxygens. Clinoptilolite is usually dominant in Na or K and is Si-rich. However, a K-dominant heulandite from Denmark contained 14.5 wt % K_2O . *MM 54:91(1990)*. An Na-rich heulandite from Boron, CA, contains 8.2 wt % Na_2O . Sr and Mg are present in small amounts and rarely are the dominant cations (SrO to 8.7 wt % from Campegli, Italy). *NJBM: 541(1982)*. Ba may be present as well (to 6.9 wt % BaO). *CM 12:188(1973)*. T_{Si} varies widely from 0.71 to 0.83. H_2O content varies over a wide range. Low Si: $(Ca, Na_2, K_2, Mg)_9[Al_9Si_{27}O_{72}] \cdot 24H_2O$; high Si: $(Na_2, K_2, Ca, Mg)_6[Al_6Si_{30}O_{72}] \cdot 20H_2O$ (= clinoptilolite). In general, the exchangeable cations have a profound effect on the dehydration behavior. It is more appropriate to speak of a continuum of H_2O -molecule binding energies than to refer to loosely bound or tightly bound zeolitic water. Material with univalent cations dominant dehydrate more easily than those with dominant divalent cations. **Optics**: Biaxial (+); $N_x = 1.476\text{--}1.506$, $N_y = 1.479\text{--}1.510$, $N_z = 1.479\text{--}1.517$; $2V = 10\text{--}48^\circ$; OAP perpendicular to $\{010\}$. **Occurrence**: A

low-temperature (< 60–200°) zeolite found in a wide variety of geological environments: volcanic rocks, metamorphic rocks, pegmatites, tuffs, and deep-sea sediments. Occurs in vesicles and cavities in basaltic and andesitic rocks; in weathered andesites and diabases; as a devitrification product of silicic volcanic glasses and tuffs. Associated with other zeolites, calcite, apophyllite, datolite, and feldspars. **Localities:** Occurs in many worldwide localities; only the most important in terms of quality, amount, and unusual character are given here. Best display specimens are from India, Russia, Iceland, Brazil, New South Wales, New Jersey, Washington, and Oregon. Many different colors and crystals to >5 cm long from Paterson, Passaic Co., NJ, particularly the Upper and Lower New Street quarries and the Prospect Park quarry; also from Bergen Hill, Hudson Co., NJ; 6.5-cm crystals from Lookout Point Dam, Dexter, Lane Co. and 3.5-cm crystals from Dorena Dam, Cottage Grove, Lane Co., OR; also from Rickreal Creek quarry, Dallas, Polk Co., Mitchell, Wheeler Co., and Succor Creek, Malheur Co., OR; pink crystals to 2.5 cm long from Skookumchuck Dam, near Tenino and Bucoda, Thurston Co., WA; also on South Fork of the Toutle R., Mt. St. Helens, Cowlitz Co., and Kosmos, Lewis Co., WA; exceptional crystals to 5 cm long from Minas Basin and Bay of Fundy, Nova Scotia; excellent crystals to 10 cm long from Teigarhorn, Berufjord, and at Fassarfell and Randafell, Iceland; deep red crystals from around *Glasgow, Dumbartonshire, Scotland*; K-dominant from Sangstrup Klint, Denmark; crystals to 7 cm from the Tunguska R. area, Krasnoyarsk Kray, Yakutia, Russia; in India, exceptional crystals to 12 cm long (blocky) from the Poona (Pashan Hills and Lonavala) and Nasik districts (Pathardy, Pandulena, and Sayad Pimpri quarries); pink to maroon crystals to 12 cm with quartz and apophyllite from Jalgaon and 4-cm crystals on mordenite from Aurangabad, MAH, India; reddish-orange crystals to 2 cm at Tambar Springs, near Gunnedah, NSW, Australia; crystals to 4 cm from the Rio das Antas railway tunnel; Bento Goncalves, Rio Grande do Sul, and brown crystals from Pato Branco, Parana, Brazil. *EF AM 57:1448(1972), 57:1463(1972); TPM 31:259(1983); NZ (1985); CCM 36:131(1988); ZW (1992).*

77.1.4.2 Clinoptilolite $(K,Na,Ca)_{2-3}Al_3(Al,Si)_2Si_{13}O_{36} \cdot 12H_2O$

Named in 1932 by Schaller for its inclined optics, from the Greek for *wing* or *down*, in allusion to the light, downy nature of aggregates of the mineral, and for ptilolite (mordenite). Zeolite group. Some authors consider this mineral to be a high-silica variety of heulandite. *KL:793(1980), ZW (1992)*. However, clinoptilolite is distinct from heulandite, particularly in thermal behavior. *AM 45:351(1960)*. Upon heating to about 450°, the structure of heulandite is destroyed, whereas that of clinoptilolite persists to about 700°. At a temperature below 450°, heulandite is transformed to a phase called heulandite-B; the temperature needed to start the transformation was reported to be 230° to about 400°. The structure of heulandite, which is thus sensitive to temperature compared to clinoptilolite, can be stabilized by replacement of Ca by K.

CLINOPTILOLITE: $(\text{Ca}, \text{Na}_2)\text{Al}_2\text{Si}_7\text{O}_{18} \cdot 6\text{H}_2\text{O}$ (variable)

There are two types of large channels running down the *c* direction shown in this view. There are also channels in the *a* direction.

On the contrary, Ca-exchanged clinoptilolite behaves thermally similarly to heulandite. Clinoptilolite and heulandite have also been distinguished from one another on the basis of the ratio of divalent to monovalent cations: clinoptilolite has $(\text{Na} + \text{K}) > 2\text{Ca}$, and heulandite has $(\text{Na} + \text{K}) < 2\text{Ca}$. *AM 45:341(1960)*. An additional definition [*AM 57:1463(1972)*] has clinoptilolite with $\text{Si}/\text{Al} > 4.0$ and heulandite with $\text{Si}/\text{Al} < 4.0$. The Zeolite Subcommittee of the IMA will probably recommend that this name be retained because it is so entrenched in the literature and in use by industry. *MON C2/m*. $a = 17.622\text{--}17.688$, $b = 17.895\text{--}17.941$, $c = 7.399\text{--}7.410$, $\beta = 116.37\text{--}116.50^\circ$, $Z = 2$, $D = 2.17\text{--}2.29$. *39-1383(nat)*: 8.95_{10} 4.65_2 3.98_6 3.96_6 3.91_5 3.42_2 3.00_2 2.97_5 . *PD* for K-clinoptilolite [*EJM 2:819(1990)*] is somewhat different: 8.93_{10} 4.67_2 3.98_4 3.955_4 3.90_3 3.125_4 3.07_2 2.80_{25} . Structure solutions have been done on material from four localities: Agoura, CA; Alpe di Siusi, Italy; Kuruma Pass, Japan; and Richardson Ranch, OR. *AM 75:522(1990)*, *78:260(1993)*. The crystal structure of clinoptilolite at 350° is triclinic, probably *C1* rather than monoclinic. Cell dimensions are: $a = 17.698$, $b = 17.511$, $c = 7.392$, $\alpha = 90.21^\circ$, $\beta = 116.76^\circ$, $\gamma = 90.19^\circ$. The potassium atom located at the M3 site at room temperature is still preserved at the same site, while those located at the cation sites other than M3 are missing. The occupancy of cations at the M3 site is even higher than that observed at room temperature. This occupancy and nearly even coordination by six framework oxygen atoms is responsible for the thermal stability of clinoptilolite. *AC(B) 39:189(1983)*, *MJJ*

11:392(1983). **Habit:** Platy crystals to 1 cm; also tabular, elongated on *a*, flattened on *b*; commonly fine-grained and massive. Common forms include: {010}, {001}, {101}, and {201}. **Physical properties:** Colorless to white, vitreous to pearly luster, transparent to translucent. Cleavage {010}, perfect. $H = 3\frac{1}{2}$ –4. $G = 2.10$ –2.17. Readily decomposed by HCl. **Chemistry:** A wide range in chemistry has been reported for clinoptilolite. Sodium, potassium, or calcium may be the dominant extraframework cation. Sodium is the dominant cation in most sedimentary clinoptilolites. However, deep-sea clinoptilolites are predominantly potassic. K-dominant clinoptilolite also occurs in vitric tuffs and in alkali saline lake deposits. *AM 50:244(1965)*. The most Na-rich clinoptilolite reported is that from Boron, CA, with 7.9 wt % Na_2O . Clinoptilolite with as much as 9.6 wt % K_2O occurs in deep-sea sediments adjacent to the Japanese islands. Minor amounts of SrO (to 1.4 wt %), and trace to minor levels of Fe and Mg may be present. Ca-dominant clinoptilolite, such as that from Australia, contains as much as 5.0 wt % CaO. *NZ 93':15(1995)*. Clinoptilolite and heulandite may be found together in chemically zoned crystals, such as clinoptilolite cores and heulandite rims on single crystals from a deep bore hole off Japan. **Optics:** Biaxial (–) or (+); $Y = b$, $Z \wedge a = 30$ – 45° (optically positive material); $X = b$, $Z \wedge a = 15^\circ$ (optically negative material); $N_x = 1.476$ – 1.491 , $N_y = 1.479$ – 1.493 , $N_z = 1.479$ – 1.497 ; $2V = 31$ – 48° ; birefringence = 0.003–0.006; $r > v$ (optically positive material), $r < v$, strong (for optically negative material). **Occurrence:** Occurs in a variety of geologic environments. Most commonly formed as a devitrification product of silicic volcanic glass from tuffs (air fall and ash flow). Also occurs in cavities in rhyolites and more-mafic rocks such as andesites and basalts. Often present in saline, alkaline lake sedimentary deposits derived from volcanic material. K-rich material is present in deep-sea sediments. *AM 57:1448(1972)*. As much as 5.0 wt % CaO occurs in clinoptilolite. *93:15(1995)*. Commonly associated with other zeolites, montmorillonite, hectorite, quartz, opal, calcite, and potassium feldspar. Other minerals that may be associated are halite, celadonite, gaylussite, and thenardite. **Localities:** Occurs in many worldwide localities, and only localities with fine crystals, large amounts, or special characteristics are given here. It is especially abundant, with some deposits being exploited commercially, in the western United States. Examples of large sedimentary deposits currently being mined include: near Fort La Clede, Sweetwater Co., WY; Cuchillo deposit, near Winston, Sierra Co., NM; near Wikieup, Mohave Co., AZ; near Oreana, Owyhee Co., ID; near Succor Creek, Malheur Co., OR; Owens Lake and China Lake, Inyo Co., CA; near Barstow and Hector, San Bernardino Co., CA; and near Tilden, McMullen Co., TX. Two large sedimentary provinces, Drummond and New England, occur in eastern Australia (NSW and central Q). In moderate to large crystals from Agate Beach, Lincoln Co., Succor Creek, Malheur Co., and at Richardson Ranch, near Bend, Jefferson Co., OR; Agoura, Los Angeles Co., CA; at Kamloops Lake, near Kamloops, BC, Canada; Kapfenberg, Styria, Austria; Vogelsberg, Hesse, Germany; Val di Fassa and Alpe di Siusi, Trentino-Alto Adige, Italy. **Uses:** An economically important zeolite because of its cation-

exchange properties. Used for removal of radioactive Cs and Sr from low-level waste streams of nuclear installations and ammonium extraction from sewage and agricultural effluents. Also used as a soil conditioner, odor absorber, stock-feed additions, and heavy metal extraction and filtration. *EF AM* 54:887(1969), *ZK* 145:216(1977), *NZ* (1985), *SSAJ* 50:1618(1986), *CCM* 36:131(1988), *ZW* (1992).

77.1.4.3 Stilbite-(Ca) $\text{NaCa}_4[\text{Al}_8\text{Si}_{28}\text{O}_{72}] \cdot n\text{H}_2\text{O}$ to $\text{NaCa}_4[\text{Al}_{10}\text{Si}_{26}\text{O}_{72}] \cdot n\text{H}_2\text{O}$ ($n = 28\text{--}32$)

Described in 1801 by Haiüy and named from the Greek for *to shine*, in allusion to the pearly to vitreous luster. Zeolite group. Stilbite-(Na) also approved by the CNMMN IMA. See barrerite (77.1.4.5), an Na-rich, orthorhombic variety, and stellerite (77.1.4.4), a Ca-rich, orthorhombic variety. TRIC and MON C1 and C2/m. Orthorhombic cell: $a = 13.595\text{--}13.69$, $b = 18.197\text{--}18.31$, $c = 17.775\text{--}17.86$, $\beta = 90.00\text{--}90.91^\circ$; monoclinic cell: $a = 13.595\text{--}13.69$, $b = 18.197\text{--}18.31$, $c = 11.265\text{--}11.30$, $\beta = 127.94\text{--}128.1^\circ$; $Z = 2$, $D = 2.20\text{--}2.23$. 24-894(nat), 26-584(calc. pattern), 44-1479(nat): 9.14₁₀ 4.67₂ 4.63₂ 4.06₉ 3.40₂ 3.20₂ 3.03₅ 2.78₂. Structure is related to heulandite. Stilbite, stellerite, and barrerite have the same tetrahedral framework, differing only in symmetry, due to minor differences from cation positioning. With an increase in the Na content, β increases from 90.0° to 90.91° (triclinic). There is a continuous series between stellerite and stilbite. Therefore, the change from orthorhombic to triclinic is gradual. Repulsion between Na and Ca pushes the Ca atoms from the mirror planes and forces the framework to rotate, thus reducing the symmetry to C1 (triclinic). Also, Al-Si ordering occurs, producing triclinic symmetry, not detected by X-ray diffraction but is detected by optics. There is also a continuous series between stilbite and barrerite. Recent work [*EJM* 5:839(1993)] has shown that the {001} growth sector is orthorhombic with respect to X-rays, whereas the {101} sector is monoclinic. Thus natural stilbite crystals consist of monoclinic and orthorhombic sectors rather than single monoclinic or orthorhombic crystals. **Habit:** Generally tabular, flattened on {010} and elongated on a . Crystals may be flat-topped or pointed. Aggregates may be sheaflike or in "bowties." Morphology is described in the monoclinic system: {010} broad, smaller, striated {001}; sometimes {101} termination. Twinning, which is ubiquitous on {001}, produces four equivalent {110} faces, due to twinning on (010), (001), (101), and (101). If indexed in the orthorhombic system: {010}, {001}, {111}, and flat {100}. The sector twinning is explained by growth ordering. **Physical properties:** Many colors, usually colorless or white, but may be yellow, brown, pink, salmon, red, green, blue, or black; white streak; vitreous luster, pearly on {010}. Cleavage {010}, perfect; uneven and brittle fracture. $H = 3\frac{1}{2}\text{--}4$. $G = 2.12\text{--}2.22$. **Chemistry:** Shows a wide variation in exchangeable cations: Ca, Na, K, Sr, Ba, and Mg are essentially absent. Most stilbites are very rich in Ca, but some are Na- or K-dominant. The natural pure Na equivalent to stellerite has not been found. A continuous Ca-Na series between stellerite and barrerite is not possible

because that compositional area is occupied by triclinic stilbite. T_{Si} ranges from 0.73 to 0.78. Biaxial (-); $X \wedge a = 5^\circ$, $Y \wedge b = 2-8^\circ$, $Z \wedge c = 5^\circ$, elongate on a ; $N_x = 1.479-1.492$, $N_y = 1.485-1.500$, $N_z = 1.489-1.505$, $2V = 22-79^\circ$; inclined (wavy) extinction angle of $2-9^\circ$; $r < v$, weak. Occurrence: Occurs in many geologic environments: in basic igneous rocks, other volcanic rocks, granitic pegmatites, gneisses and schists, sedimentary tuffs, hot-spring deposits, and deep-sea sediments. Localities: A common zeolite; only noteworthy localities are mentioned here. Very fine crystals to 10 cm long from Paterson, Passaic Co., and Summit, Union Co., NJ; to 8 cm long at the Kibblehouse quarry, Perkiomenville, Montgomery Co., PA; at many localities in Oregon, but the best are Roadside quarry, Goble, Columbia Co., Rickreall Creek quarry, Dallas, Polk Co., Calapooya R., near Dollar, Linn Co., Roadside quarry, Goble, Columbia Co., Lookout Point Dam, Dexter, Lane Co., Mitchell, Wheeler Co., and Ritter, Grant Co.; fine bowties to 10 cm long in Washington at Skookumchuck Dam, near Tenino and Bucoda, Thurston Co.; Poison Creek, Skamania Co.; Mossyrock Dam, Lewis Co., South Fork of the Toutle R., near Mt. St. Helens, Cowlitz Co., and Kalama, Cowlitz Co.; on chabazite from Minas basin and Bay of Fundy, NS, Canada; bowties to 6 cm from the Teigarhorn in Beruffjord, Iceland; Faroe Is.; four places are mentioned by Haüy as type localities: (1) Helgusta (Helgustadir) calcite mine, Reydarfjord, Iceland; (2) Andreasburg, Harz, Germany; (3) Dauphine Alps, France; and (4) Mt. Abildgaard, Arendal, Norway; numerous places in the United Kingdom, such as the Glasgow district, Dumbartonshire, Scotland, and the Isle of Skye; deep yellow-brown crystals from Striegau, Poland; golden-yellow crystals to 10 cm long associated with other zeolites occur in basalt along the Amudikha R., from the lower Tunguska R. area, near Mirny (several localities), Yakutia, Russia; gray, flat-topped crystals near Lake Baikal, Siberia, Russia; from numerous localities in Kazakhstan; localities in India within the Deccan Trap basalts are the most prolific in the world, most abundant at Nasik and Poona, decreasing toward the coast at Bombay, MAH; in the Nasik district, pink to salmon-orange bowties to 14 cm long occur at the Pandulena, Pathardy, and Syed Pimpri quarries; in the Pune (Poona) district, 12-cm-long white bowties and fanlike groups, up to 12 cm long, are found at Pashan Hills, Hadspar, and Lanavala; quarries near Jalgaon produce light pink crystals with quartz and colorless apophyllite, orange flat-topped crystals are found on mordenite at Aurangabad; to 5 cm long with 20-cm apophyllite crystals from Rio de Antas, Bento Gonsalves, Rio Grande do Sul, Brazil; also bowties from Volta Grande, in Santa Catarina; large orange crystals near Gunnedah, and Tanbar Springs, NSW, and Arkaroola, SA, Australia; Guanajuato, Mexico. EF *BM 101:368(1978)*, *AM 70:814(1985)*, *NZ (1985)*, *ZW (1992)*.

77.1.4.4 Stellerite $\text{CaAl}_2\text{Si}_7\text{O}_{18} \cdot 7\text{H}_2\text{O}$

Described by Morozewicz in 1909 and named for Georg Wilhelm Steller (1709-1746), German explorer and zoologist. Zeolite group. See barrerite

(77.1.4.5), the Na-dominant analog of stellerite. ORTH *Fmmm*. $a = 13.599$, $b = 18.222$, $c = 17.683$, $Z = 8$, $D = 2.12$. 25-124(nat): 9.03₁₀ 4.66_{1.5} 4.06_{4.5} 3.40₁ 3.18₁ 3.03_{2.5} 3.00₁ 2.77₁. The X-ray pattern for barrerite is very similar to that of stellerite, and it may be difficult to tell them apart. The structure is like that of stilbite, with no Si-Al order, but a higher symmetry, *F2/m 2/m 2/m*, which coincides with the topological symmetry for the framework. In stilbite, electrostatic repulsive forces between extra-framework cations are strong enough to push the Ca atoms out of the mirror planes, so allowing only symmetry *C2/m*. In stellerite there is no Na present, and its site is partially occupied by water, so Ca can remain on the mirror planes. Lamellar to tabular crystals with dominant forms {010}, {100}, {001}, {111}. Commonly in spheres to 14 cm, of radiating crystals; also crystal aggregates. Ideally no twinning, but some are optically sector-twinned, indicating triclinic symmetry. Usually white, but may be pink, salmon-orange, brown, or red; white streak. Cleavage {010}, perfect. $H = 4\frac{1}{2}$. $G = 2.13$. Typical analysis (wt %): SiO₂, 59.15; Al₂O₃, 14.21; CaO, 7.45; Na₂O, 0.19; K₂O, 0.23; Fe₂O₃, 0.17; H₂O, 17.79; traces of other elements (Sr, Ba, Mg) present. Biaxial (-); $XYZ = abc$; $N_x = 1.485$, $N_y = 1.496$, $N_z = 1.498$; $2V = 47^\circ$. Occurs principally in veins and geodes in basalts and other basic volcanic rocks; on fracture surfaces as well. Also occurs in mica schist, skarns, gneisses, and graniodiorites. Occurs in geothermal fields. Associated with other zeolites, tridymite, prehnite, apophyllite, and others. An increasingly recognized zeolite that occurs in numerous worldwide localities; only selected localities are given here: various quarries in the Paterson area, Passaic Co., NJ; Fanwood quarry, Fanwood, Somerset Co., NJ; Ritter Hot Springs, Grant Co., OR; Villanova, Monte Leone, Sassari, Sardinia, Italy; Gelbe Birke, Furstenberge bei Schwarzenberg, Erzgebirge, Germany; Kongsberg, Norway; Szob, Malomvolgy, and Nadap, Hungary; orange stellerite from the Sarbayskaya quarry, near Rudny, Kusteni Oblast, northern Kazakhstan; on Copper Island in the Commander Islands (Kommandorskiye Ostrova), Bering Sea, Russia; Franca, São Paulo, Brazil; Chinchwad, NW of Pune (Poona), and in the Nasik district, MAH, India; Girrawaillie Creek, and Mitchells Creek, Garrawilla, NSW, Australia; also from near Gunnedah, NSW, and at Harcourt, Dookie, and Corop, VIC, Australia. EF *LIT* 6:83(1973); *BM* 98:11(1975), 101:368(1978); *NZ* (1985); *ZW* (1992).

77.1.4.5 Barrerite $\text{Na}_8(\text{Al}_8\text{Si}_{28}\text{O}_{72}) \cdot 26\text{H}_2\text{O}$

Named in 1975 by Passaglia and Pongiluppi for Richard Maling Barrer (b.1910), British chemist, Imperial College, London, who has contributed greatly to the investigation of zeolites and to the chemistry of molecular sieves. Zeolite group. *ZW* (1992) considers this to be an orthorhombic variety of stilbite. See stilbite (77.1.4.3) and stellerite (77.1.4.4). Stellerite is Ca-dominant. ORTH *Amma*. $a = 13.643$, $b = 18.200$, $c = 17.842$, $Z = 2$, $D = 2.11$. 29-1185(nat): 9.1₁₀ 4.66₂ 4.05₁₀ 3.19₂ 3.03₈ 3.00_{2.5} 2.77₂ 1.82₂. Structure same as for stellerite (77.1.4.4). (010) lamellae to 5 cm diameter, (010) platy crys-

tals with {001} and {111} are rare. White to slightly pink, vitreous luster, transparent to translucent. Cleavage {010}, perfect. $G = 2.13$. Analysis (wt %): SiO_2 , 58.8; Al_2O_3 , 14.75; Fe_2O_3 , 0.04; MgO , 0.24; CaO , 1.66; Na_2O , 5.97; K_2O , 1.76; H_2O , 16.40. Biaxial (-); $XYZ = abc$; $N_x = 1.479$, $N_y = 1.485$, $N_z = 1.489$; $2V_{\text{calc}} = 78^\circ$. Occurs in a monomineralic vein in lava (andesitic to rhyolitic). Seams in altered calc-silicate rock. Associated with heulandite. Occurs at Tosenvegen, Vefsn, Nordland, Norway; *Capo Pula, Nora, Sardinia, Italy*. EF LIT 7:69(1974), MM 40:208(1975), BM 98:331(1975), NZ (1985).

77.1.5.1 Natrolite $\text{Na}_2\text{Al}_2\text{Si}_3\text{O}_{10} \cdot 2\text{H}_2\text{O}$

Described by Klaproth in 1803 and named from the Greek *natrium*, soda, in allusion to the Na content of the mineral. Zeolite group. Dimorphous with tetranatrolite. ORTH $Fdd2$. $a = 18.27\text{--}18.354$, $b = 18.587\text{--}18.67$, $c = 6.56\text{--}6.608$, $Z = 8$, $D = 2.25$. A study of 38 natrolites [CE 49:297(1989)] showed a range of: $a = 18.26\text{--}18.48$, $b = 18.52\text{--}18.70$, $c = 6.35\text{--}6.66$. For monoclinic natrolite, a to 19.00, b to 19.04, c to 6.60, β to 90.52° . 39-226(calc. pattern), 45-1413(nat): 6.54₅ 5.89₁₀ 4.40₄ 4.36₄ 3.20₃ 2.94₃ 2.87₅ 2.85₅. Earlier cards (19-1185 and 20-759) show preferred orientation effects. The aluminosilicate framework is the same as that of mesolite and scolecite. Long chains of tetrahedra are rotated by 24° . Cations are in four sites in the channels, parallel to c . The channels are occupied by two Na and two H_2O molecules. Si and Al in an ideal natrolite framework are highly ordered into three independent tetrahe-

NATROLITE: $\text{Na}_2\text{Al}_2\text{Si}_3\text{O}_{10} \cdot 2\text{H}_2\text{O}$

Al tetrahedra green; Na atoms magenta; H_2O cyan. This is a view down the large zeolitic channels, which contain Na and H_2O .

dral sites. There appears to be a complete series between fully ordered natrolite and completely disordered tetranatrolite [i.e., Na-rich gonnardite according to ZW (1992)]. Tetranatrolite has from 17.5 to 0 Å (>50% disorder); $b - a = 0.35$ Å (fully ordered natrolite), $b - a = 17.5$ Å (disordered natrolite, with 50% disorder). Truly completely ordered natrolite has not been found thus far and should be referred to as strongly ordered rather than fully ordered. As much as 30% disorder (30% of the Al site is occupied by Si and about 20% of the Si sites are occupied by Al) in Si and Al has been found for some natrolite. *AC(B)* 37:781(1981), *EJM* 2:799(1990). **Habit:** Most commonly occurs as long, slender needles, striated parallel to elongation, prismatic (pseudotetragonal) on *c*; crystals to more than 1 m long; in stellate or jack-straw groups, radial aggregates, and compact masses. Frequently epitaxially intergrown with mesolite, tetranatrolite, gonnardite, paranatrolite, thomsonite, and rarely scolecite. Sometimes flattened, with {111} dominant. Common forms are {110} and {111}, with complex terminations. Also {100}, {010}, {101}, {331}, and {551}. Twinning is common, on {110}, {011}, and {031}. **Physical properties:** Pale pink, colorless, white, gray, red, yellow, green, or brown; white streak; vitreous to silky luster but may be greasy or dull. Cleavage {110}, perfect; {010} parting; uneven fracture; brittle. $H = 5-5\frac{1}{2}$. $G = 2.20-2.27$. IR data: *CMG* 25:239(1980). Natrolite dehydrates to "metanatlrolite," monoclinic, $a = 16.0$, $b = 16.73$, $c = 6.40$, $\beta = 90^\circ$. *NJBM*:135(1983). Gelatinizes with common acids. Pyroelectric and piezoelectric. Sometimes fluorescent orange to yellow in LWUV and SWUV. **Chemistry:** A very Na-rich zeolite. Contains very small amounts of Ca and K, traces of Mg, Sr, Ba. Chemically, natrolite differs from mesolite by an ordered substitution of $2\text{Na} \leftrightarrow \text{Ca} + \text{H}_2\text{O}$, which causes a tripling of b for mesolite. With an increase in the content of Si atoms, the tetragonal form is obtained; with an increase in H_2O , the monoclinic structural form is obtained. The monoclinic form may also form from ion exchange, $\text{Ca}^{2+} \leftrightarrow 2\text{Na}^+$, in a hydrothermal altering solution. **Optics:** Biaxial (+); $\text{XYZ} = abc$; $N_x = 1.473-1.483$, $N_y = 1.476-1.486$, $N_z = 1.485-1.496$; $2V = 57-64^\circ$; length-slow, $r < v$, weak. Some natrolite is optically monoclinic [*AM* 73:613(1988)]: $X \wedge b = 0.5^\circ$, with slightly inclined optical axis (Markovice, Bohemia); $X \wedge b = 1^\circ$ but still showing optically parallel extinction with direction of elongation (Puy de Dôme, Auvergne, France). **Occurrence:** Occurs in cavities in amygdaloidal, silica-poor basalt, Ne-syenite complexes, their co-genetic pegmatites, and rarely in volcanic ash deposits. Also in veins in gneisses, granite, and other rock types. Associated with other zeolites, nepheline, quartz, calcite, and alkalic minerals. **Alteration:** Fresh crystals are translucent to transparent. They often develop a white, opaque, flaky overgrowth of tetranatrolite. The coating results from dehydration of paranatrolite, a common epitactic overgrowth on natrolite. **Localities:** Occurs in many worldwide localities; only noteworthy localities are given here: Bergen Hill, Hudson Co., and Prospect Park, Paterson, Passaic Co., NJ; truly orthorhombic (by optics) crystals to 18 cm long and 3 cm wide from the Chimney Rock quarry, Bound Brook, Passaic Co., NJ; to 4.5 cm long from the Dallas gem mine (Benitoite mine), and other

nearby areas, San Benito Co., CA; new and old Springfield quarries, Springfield Butte, Lane Co., OR; to 4 cm long from Robertson quarry, near Dayton, Mason Co., WA; natrolite capped by mesolite from the Imnaha basalt, on the Snake R., 10 km W of Clarkston, WA; to 2.5 cm from Pinnacle Island, Bay of Fundy, NS; to 15 cm long and 2 cm wide from Mt. St.-Hilaire, and large crystals from the Johnston asbestos mine, near Thetford, QUE, Canada; to 25 cm long from the Ice River complex, near Golden, BC, Canada; coarse 2-cm needles from White Head, and to 4 cm at Larne, County Antrim, Northern Ireland; Dean quarry, St. Keverne, Lizard Penin., Cornwall, England; from the Langesundfjord and Tvedalen areas, Norway; at Puy de Marman, near Veyre, Puy de Dome, Auvergne, France; *Hohentwiel, Hegau, Baden-Württemberg, Germany*; also from the Howenegg quarry; gemmy, colorless crystals to 30 cm long and 13 cm in diameter in pegmatites at the Jubilee mine, Lovozero massif, Kola Penin., Russia; also from the Khibiny massif; exceptional groups of milky crystals 10 cm long forming groups 15 cm across with a thin natrolite overgrowth on mesolite and scolecite at Khandivali, Maharashtra state, India; at Jacupiranga, Sao Paulo, Brazil; crystals to 7 cm long and 5 mm diam. from Culverden, Canterbury, South Island, New Zealand; thin needles at Ardglen, NSW; Cairns Bay, Flinders, Victoria; groups of needles 2 cm across at Cape Grim, Tasmania, and on gonnardite at Bundoora, Victoria, Australia. *ZK 164:19(1983), 185:619(1988); NZ (1985); AM 77:685(1992).*

77.1.5.2 Tetranatrolite $\text{Na}_2\text{Al}_2\text{Si}_3\text{O}_{10} \cdot 2\text{H}_2\text{O}$ and $(\text{Na}_{1-5}\text{Ca}_0-5)_2\text{Al}_2\text{Si}_3\text{O}_{10} \cdot 2\text{H}_2\text{O}$

Named in 1980 by Chen and Chao for the symmetry (tetragonal) and natrolite (same formula). Zeolite group. A tetragonal dimorph of natrolite. Ranite is a calcian variety; natrolite does not contain Ca. Tetranatrolite is interpreted as the result of partial dehydration of paranatrolite. *EJM 7:501(1995)*. TET *I42d*. $a = 13.02\text{--}13.25$, $c = 6.615\text{--}6.704$, $Z = 4$, $D = 2.22\text{--}2.23$. *33-1205(nat)*: 6.55₅ 5.91₄ 4.63₄ 4.39₅ 4.14₄ 3.19₅ 2.87₁₀ 2.44₄; *42-1381(calcian)*: 6.62₆ 5.90₉ 4.68₆ 4.41₈ 3.21₈ 3.11₆ 2.96₇ 2.90₁₀. Structure: *SPC 31:254(1986), ZK 189:191(1989)*. Prismatic crystals and fine-grained coatings up to 1 mm, silky, fibrous, thick coatings on natrolite. White, rarely pale pink; white streak; silky to dull luster. No cleavage. $H \approx 5$. $G = 2.21\text{--}2.28$. IR and TGA data: *CM 18:77(1980)*. Dissolves readily in 1:1 HCl, slowly in 1:1 HNO₃ with gelatinous residues. Shows large deviations from ideal stoichiometry. Analysis (wt %), calcian: SiO₂, 39.36; Al₂O₃, 30.73; Fe₂O₃, 0.33; CaO, 6.34; SrO, 0.04; BaO, 0.02; Na₂O, 11.94; K₂O, 0.04; H₂O, 11.2; regular, Mt. St.-Hilaire: SiO₂, 46.9; Al₂O₃, 25.6; CaO, 1.48; Na₂O, 14.0; K₂O, 1.12; H₂O⁺, 9.59; H₂O⁻, 1.31; minor TiO₂ and FeO. The Si/Al ratio is ≥ 1.5 in tetranatrolite. Uniaxial (+); 589 nm; $N_O = 1.480\text{--}1.481$, $N_E = 1.493\text{--}1.496$. Occurs in all mineralogical environments at Mt. St.-Hilaire. Associated with natrolite. Forms coatings and crusts on natrolite. Also epitactic overgrowths. Also occurs in phonolite and basalt and in hydrothermal veins. Alteration: the end product of dehydration of paranatrolite, which forms epitactic over-

growths on natrolite. Point of Rocks Mesa, Springer, Colfax Co., NM; *Mt. St.-Hilaire*, and *St.-Amable* sill, Varennes, QUE, Canada; Tugtup Agtakorfia, Ilimaussaq, southern Greenland; Hills Port, Island Magee, County Antrim, Northern Ireland; Tvedalen, and Lamo, Langesundsfjord, Norway; Klöch, Austria; Schellkopf, Brenk, Eifel district, Germany; Marianberg, Bohemia, and Usti nad Labem, Czech Republic; *Mt. Kukisvumchorr*, Khibiny massif, and Lovozero intrusion, Kola Penin., Russia. EF *MGR* 181:1(1969), *NZ* (1985), *MM* 52:207(1988), *CE* 49:297(1989), *AM* 77:685(1992).

77.1.5.3 Paranatrolite $\text{Na}_2\text{Al}_2\text{Si}_3\text{O}_{10} \cdot 3\text{H}_2\text{O}$

Named in 1980 by Chao for the mineral's epitaxial relationship with natrolite and similarity in chemical composition to natrolite. Zeolite group. Considered a doubtful species by the CNMMN IMA. Polymorphous with natrolite. *MON* (pseudo-ORTH) *Fmm*2, *Fm*2*m*, *F2mm*, *F222*, or *Fmm* for the pseudo-orthorhombic cell. $a = 19.07$, $b = 19.13$, $c = 6.580$, $Z = 8$, $D = 2.20$; *42-1386*: $a = 18.93$, $b = 19.21$, $c = 6.589$. *35-458*(nat): 6.76₂ 5.92₆ 4.78₃ 4.44₄ 3.26₁₅ 3.12₁₅ 2.94₁₀ 2.65₁₅; *42-1386*: 6.75₁₀ 4.79₃ 4.74₃ 2.95₇ 2.92₄ 2.90₅ 2.64₃ 2.51₂ (O assigned because of poor agreement of cell to data). Crystals must be kept in H₂O from the time of removal. All tetranatrolite crystals are probably pseudomorphs after paranatrolite. Aluminosilicate framework is the same as natrolite, mesolite, scolecite, gonnardite, and tetranatrolite. It is an overhydrated monoclinic polymorph of natrolite that is unstable in air. Dehydrates irreversibly to tetranatrolite. *EJM* 7:501(1995). Si and Al are disordered. Extra H₂O molecules warp the natrolite structure to monoclinic symmetry. Radial fibrous, sheaflike, parallel columnar aggregates; habit is the same as natrolite and tetranatrolite, {110} dominant, commonly terminated by {111} dipyrmaid or rarely {001}; most occurs as epitaxial overgrowth to 1 mm thick on natrolite; composite crystals to 5 cm, pure crystals to 2 mm long have been found, identical in appearance to natrolite. White, colorless, grayish, pale pink, yellow; white streak; greasy-vitreous luster. No cleavage, conchoidal fracture. H undetermined, ≈ 5 . $G = 2.21-2.29$. Natrolite inverts to paranatrolite at $>360^\circ$. *Acta Mont.* 63:87(1983). *Mt. St.-Hilaire*: $(\text{Na}_{1.75}\text{Ca}_{0.10}\text{K}_{0.09})[\text{Al}_{1.95}\text{Fe}_{0.01}\text{Si}_{3.02}\text{O}_{10}] \cdot 2.98\text{H}_2\text{O}$; natrolite has 2H₂O rather than 3. Analysis (wt %), Khibiny massif: SiO₂, 40.07; Al₂O₃, 28.14; CaO, 0.30; Na₂O, 15.19; K₂O, 2.54; H₂O, 13.6. Biaxial (-) wet and (+) dry; 2V small (under 10°); $N_x = 1.479$, $N_y = 1.481$, $N_z = 1.493$; Khibiny massif: $N_x = 1.493$, $N_y = 1.499$, $N_z = 1.505$, 2V (\pm) 90°, undulating inclined extinction, to 21°. Occurs at *Mt. St.-Hilaire* in epitaxial overgrowths on natrolite crystals and in miarolitic cavities, pegmatite veins, sodalite syenite, uncommon in igneous breccia, very rare in marble and sodalite xenoliths. In pegmatites and basic volcanics. On aegirine at Point of Rocks Mesa, near Springer, Colfax Co., NM; originally found at *Mt. St.-Hilaire*, QUE, Canada; small amounts from Gobbins Cliff, Hillsport, Is. Magee, County Antrim, Northern Ireland; small amounts from Aci Castello, Sicily, Italy; from Schellkopf, near Brenk, Eifel, also at Teichelberg, near Pechbruun, Bavaria, Germany; *Mt. Kukisvumchorr*,

Khibiny massif, and Mt. Alluaiv, Lovozero massif, Kola Penin., Russia. *EF CM* 18:85(1980), *NZ* (1985), *DAN-ESS* 288:136(1986), *CRT* 23:467(1988), *ZW* (1992).

77.1.5.4 Mesolite $\text{Na}_2\text{Ca}_2[\text{Al}_6\text{Si}_9\text{O}_{30}] \cdot 8\text{H}_2\text{O}$

Described in 1816 by Fuchs and Gehlen and named from the Greek for *middle* and *stone*, because it was intermediate in chemical composition between natrolite and scolecite. Zeolite group. *ORTH Fdd2*. $a = 18.39\text{--}18.47$, $b = 56.45\text{--}56.84$, $c = 6.53\text{--}6.58$, $Z = 8$, $D = 2.30$. $24\text{--}1064(\text{nat})$: 6.6_6 5.9_{65} 4.72_{45} 4.41_{55} 4.37_{45} 2.94_{45} 2.89_{10} 2.87_7 . Is isostructural with natrolite and scolecite. Structure has long Si–Al ordered chains, rotated by 24° , with Na–Ca cations and water molecules in four ion sites in the channels parallel to c . Mesolite can be visualized as sheets of natrolite-type channels (two Na and two H_2O) alternated with two sheets of scolecite-type channels (one Ca and three H_2O) that result in a b -axis dimension three times that of natrolite. Asymmetry with regard to the (100) plane causes mesolite to be monoclinic. Disorder in the structure (cation) causes it to be monoclinic. Disordered Si–Al varieties have not been recognized. *AC(C)* 42:937(1986); *AM* 1988:613(1988), 73:613(1988). Best identified by optical methods because X-ray diffraction patterns of natrolite–scolecite–mesolite are very similar. Normally long, slender needles, elongate on c ; may be in hairlike tufts and aggregates of fibers; divergent, radiating groups to 20 cm in diameter; less commonly as compact masses, fibrous stalactites, or massive, porcelaneous habit; epitaxial intergrowths with natrolite and scolecite in single needles is common; dominant forms: {110}, {111}, with less development of {100}, {010}, {101}, and {011}. Typically twinned on {010} or {100}, crystals consist of {111} sectoral twins without {110} growth sectors. Colorless, white, pink, red, yellowish, or green; white streak; vitreous–silky luster. Cleavage {110}, $\{1\bar{1}0\}$, perfect; uneven fracture; brittle with compact masses being tough. $H = 5$. $G = 2.25\text{--}2.26$. Gelatinizes with common acids. May show a small pyroelectric effect and is also piezoelectric. The atomic percentages of Ca and Na are nearly equal. Sometimes Na is slightly greater and sometimes Ca is greater. Traces of K are present. Sr, Ba, and Mg are not present. The ordering of the cations makes mesolite a unique member intermediate between natrolite and scolecite. A continuous chemical series does not exist between natrolite (Na), mesolite (1:1), and scolecite (Ca). Biaxial (+); $X \wedge a = 10^\circ$, $Y - c$, $Z = b$; $N_x = 1.504\text{--}1.505$, $N_y = 1.505\text{--}1.506$, $N_z = 1.505\text{--}1.507$; $2V = 80\text{--}87^\circ$; nearly isotropic; length-slow, some are length-fast; parallel extinction with elongation direction; $r > v$, strong; 10° inclination extinction angle can only be observed looking down the end of a needle. Commonly found in basaltic rocks, but also in andesites, porphyries, and hydrothermal veins. Occurs in many worldwide localities; dominant localities having exceptional display specimens are given here: Table Mts., Golden, Jefferson Co., CO; to 4 cm long from Bear Creek quarry, Drain, Douglas Co., OR; also from Goble, Columbia Co., near Dollar, and on Shotgun Creek, Linn Co; Springfield,

Lane Co.; Ritter Hot Springs, Grant Co., OR; to 10 cm long from Skookumchuk Dam, near Tenino, Thurston Co., WA; western Bay of Fundy, Nova Scotia, Canada, including Gates Mt., North Mt., and Cape Blomiden; to 10 cm long from Naalsoy, Stremoy, the Faroe Is.; Neubauerberg, Bohemia, Czech Republic; to 10 cm long from the Pune (Poona) district, MAH, India; sprays to 20 cm from Ahmadnagar; also large crystals, 15% mesolite, 85% scolecite, from the No. 2 quarry at Khandivali, Bombay, India; to 10 cm long from Westhaven Nunatak, Darwin Glacier, Victoria Land, Antarctica. EF *NJBA* 143:231(1982), *NZ* (1985), *ZW* (1992), *AM* 77:685(1992).

77.1.5.5 Scolecite $\text{CaAl}_2\text{Si}_3\text{O}_{10} \cdot 3\text{H}_2\text{O}$

Described in 1813 by Gehlen and Fuchs and named from the Greek for *worm* because of scolecite's tendency to curl up in a wormlike fashion when heated in a blowpipe. Zeolite group. *MON Cc*. $a = 6.516\text{--}6.517$, $b = 18.948\text{--}18.956$, $c = 9.761\text{--}9.765$, $\beta = 108.86\text{--}108.98^\circ$, $Z = 4$, $D = 2.275$. *41-1355(nat)*: 6.63_{10} 5.87_6 4.74_7 4.62_5 2.90_4 2.89_5 2.88_5 2.86_4 . Cell may also be expressed as: $a = 18.48\text{--}18.508$, $b = 18.891\text{--}18.96$, $c = 6.527\text{--}6.548$, $\beta = 90.64\text{--}90.75^\circ$ with $Z = 8$ (pseudotetragonal). The structure of the aluminosilicate framework is the same as for natrolite and mesolite. Long, ordered chains, rotated 24° , with a small distortion caused by a slight rotation of the center of the silicon tetrahedron of the chains around the chain axis. One Ca cation and three H_2O are in four ion sites in the channels parallel to c . It is monoclinic with no indication of Si–Al disorder. Scolecite with a disordered Si–Al framework similar to gonnardite should be possible. Optical studies [*AM* 73:613(1988)] indicate that scolecite has some disorder on Al and Si positions because growth sectors are present with triclinic symmetry. There is also a symmetrical extinction angle of 3° from the b axis. Occurs commonly as thin, prismatic needles, frequently flattened on $\{010\}$, elongated on c , and striated parallel to c , and crystals appear to be pseudo-orthorhombic or pseudotetragonal. Crystals are as much as 35 cm long. Also occurs as radiating groups and fibrous masses. May be nodular and massive. Epitaxial intergrowths with mesolite are common. Natrolite does not directly form epitaxial overgrowths on scolecite. May have all three minerals developed in the same crystal. Crystals are commonly twinned on $\{100\}$, producing “v” or fishtail terminations. Rare twinning on $\{001\}$ and $\{110\}$ also occurs. Scolecite crystals consist of $\{110\}$, $\{010\}$, and $\{111\}$ growth sectors with triclinic symmetry (by optics) and appear to be monoclinic by X-ray analysis. Common forms include $\{111\}$, $\{111\}$, $\{101\}$, $\{110\}$, $\{010\}$. Colorless, white, pink, salmon, red, or green; white streak; vitreous–silky luster. Cleavage $\{110\}$, $\{110\}$, perfect; uneven fracture; brittle. $H = 5\text{--}5\frac{1}{2}$. $G = 2.24\text{--}2.31$. Pyroelectric and piezoelectric. Sometimes fluorescent yellow to brown in SWUV and LWUV. IR data: *CMG* 25:239(1980). Synthesized: *JG* 68:41(1960), *CCM* 29:171(1981). Soluble in common acids. Because of an ordered Si–Al framework, scolecite has a

narrow range of composition. Only minor amounts of Na and traces of K substitute for Ca. There is an absence of Ba, Sr, Fe, and Mg. Scolecite is isostructural with mesolite and natrolite but does not form a continuous chemical series with them. There is not much deviation from ideal stoichiometry. Biaxial (-); $N_x = 1.507\text{--}1.513$, $N_y = 1.516\text{--}1.520$, $N_z = 1.517\text{--}1.521$; $2V = 35\text{--}56^\circ$; $r < v$, strong; negative elongation, inclined extinction. For triclinic material: $X \wedge c = 16\text{--}18^\circ$, $Y \wedge a = 3^\circ$ (also reported as -14 to -17° , $Z \wedge b = 3^\circ$). For monoclinic optics, $Z = b$. A common zeolite, widely found with low-Si zeolites. Occurs in basalts, andesites, gneisses, and amphibolites, and in contact-metamorphic zones. Also in laccoliths and dikes of gabbroic to syenitic composition. A hydrothermal mineral. Associated with other zeolites, calcite, quartz, and prehnite. No type locality is known for this mineral. Many worldwide localities; only selected localities are given here: coarse prisms 4–15 mm wide and 9–14 cm long from the south fork of the Toutle R., near Mt. St. Helens, Cowlitz Co., WA; fine sprays to 8–10 cm long from Teigarhorn, Berufjord, Iceland; Ben More, Isle of Mull, and Talisker Bay, Isle of Skye, Scotland; from Val Giuf-Fallital area, Graubunden, Switzerland; most of the world's finest scolecite is from Nasik and Pune (Poona), also Bombay, MAH, India, where crystals are as much as 2 cm wide and 35 cm long; Charcas, San Luis Potosi, Mexico; fine, large crystals associated with other zeolites from Rio Pelotas and Bento Goncalves, Rio Grande do Sul, Brazil. *EF MM 38:72(1971)*, *NJBA 143:231(1982)*, *ZK 166:219(1984)*, *P6IZC:842(1984)*, *ZK 171:141(1985)*, *NZ (1985)*, *ZW (1992)*.

77.1.5.6 Edingtonite (Ba,Ca)Al₂Si₃O₁₀ · 4H₂O

Named in 1825 by Haidinger for James Edington (1787–1844), Glasgow, Scotland, who discovered the mineral. Zeolite group. Three structural varieties: tetragonal, orthorhombic, and triclinic (from optics). *TET P42₁m*. $a = 9.581\text{--}9.585$, $c = 6.524\text{--}6.530$. *ORTH P2₁2₁2₁*. $a = 9.537\text{--}9.583$, $b = 9.651\text{--}9.680$, $c = 6.509\text{--}6.530$, $Z = 2$, $D = 2.82\text{--}2.83$. *25-60*: 6.51₁₀ 5.37₆ 4.82.5 4.70₇ 3.59₆₅ 3.57₅₅ 2.76₅₅ 2.74₅₅; *25-61(nat)*: 6.51₈ 5.38₆ 4.79₃ 4.69₅ 3.58₁₀ 2.74₇₅ 2.59₄₅ 2.28₃. Chains of SiO₄ and AlO₄ tetrahedra parallel to c . Each chain is linked through oxygen bridges to four neighboring chains, at the same level, to form a three-dimensional network. Seven of eight water positions are located in the zeolite channels (planes perpendicular to c). Ba atoms are surrounded by framework oxygen and H₂O molecules. Orthorhombic edingtonite has a framework with nearly perfect Al–Si order. Tetragonal varieties have a disordered Si–Al distribution. Triclinic material also exists. Material from the Ice River Complex, Canada, described as tetragonal [*NJBM 8:373(1984)*], has an orthorhombic core and a triclinic rim. Bipyramidal, pseudotetragonal, also prismatic, equant to elongate, elongate on c ; common forms include {111}, {110}, {001}, {121}, {100}, {010}; 1–10 mm long with exceptional prisms as much as 10 cm long and 2.5 cm wide; penetration twinning (rotated 90° about

EDINGTONITE: $\text{BaAl}_2\text{Si}_3\text{O}_{10} \cdot 4\text{H}_2\text{O}$

This zeolite has eight- and four-membered rings and the framework is the same as that of natrolite—the only differences is in the channels where there is one Ba in place of two Na, but twice as many water molecules, and the orientation is quite different.

the *c* axis), and twins on {110} are rare. Doubly terminated crystals display hemimorphic morphology and rare forms. Colorless, white, gray, pink, brown, and yellow; white streak; vitreous luster. Cleavage {110}, perfect; uneven fracture. *H* = 4–5. *G* = 2.27–2.82. Pyroelectric and piezoelectric. IR data: *CMG 25:239(1980)*. DTA data: *NZ(1985)*. Gelatinizes with acids. Ba dominant. Varying smaller amounts of Na, K, Ca. A Ca-dominant variety was found in Russia. *DAN-ESS 234:170(1977)*. Biaxial (–); $N_x = 1.535\text{--}1.546$, $2V = 10\text{--}63^\circ$, $N_y = 1.542\text{--}1.558$, $N_z = 1.545\text{--}1.562$; $2V$ increases with degree of Si–Al order; tetragonal material has $2V = 10\text{--}22^\circ$; orthorhombic and triclinic material has $2V = 50\text{--}63^\circ$; positive elongation; parallel or inclined extinction of $1\text{--}10^\circ$ (for triclinic only); $r < v$, weak to moderate. For orthorhombic material: $XYZ = cba$. In hydrothermal ore veins, late hydrothermal stages of syenite complexes and volcanics. Carbonatites, alkaline igneous rocks. In dolerite in England. A relatively uncommon zeolite. In Franciscan greywacke at Ash Creek, Mendocino–Sonoma Co. line, CA; to 14 mm diameter and 4.5 cm long from Bathhurst, Gloucester Co., NB, very rare and inmiarolitic cavities at Mt. St.-Hilaire, QUE, and zoned crystals (orthorhombic and triclinic) from Ice River, BC, Canada; *Old Kilpatrick, Dumbartonshire, Scotland*, and other localities in the Kilpatrick Hills; Squilver Quarry, Disgwylfa Hill, Shropshire, England; to 10 cm long and 3 cm wide from Bohlet, Västergötland, Sweden; Stare Ranski, eastern Bohemia, Czech Republic; Tululukht Bay, Khibiny massif, Kola Penin., and Ca-dominant variety from

pyrite deposits at Podolskoye, southern Ural Mts., Russia; in carbonatite at Jacupiranga, SW of São Paulo, SP, Brazil. *EF JCP* 79:2356(1983); *NJBM* 8:373(1984), 541(1986); *NZ* (1985); *AM* 71:1510(1986); *ZW* (1992); *MM* 57:349(1993).

77.1.5.7 Gonnardite $(\text{Na,Ca})_{12-15}(\text{Al,Si})_{40}\text{O}_{80} \cdot n\text{H}_2\text{O}$

Described in 1896 by Lacroix and named for Ferdinand Gonnard, French mineralogist, who described gonnardite in 1871 as "mesole." Zeolite group. Described as ORTH and TET *I42d*. Orthorhombic axes: $a = 13.04\text{--}13.45$, $b = 13.04\text{--}13.42$, $c = 6.22\text{--}6.67$, $Z = 0.5$, $D = 2.25\text{--}2.33$. *AM* 77:685(1992) gives for a possible orthorhombic pseudocell: $a = 18.56$, $b = 18.64$, $c = 6.62$ ($Z = 1$). Gonnardite may well be a mixed structure, composed of slabs of natrolite and thomsonite. According to *AM* 77:685(1992), the structure of gonnardite is still unknown. However, the crystal structures of four natural gonnardite samples were refined by full-profile Rietveld techniques. *MSF* 79-82:845(1991). The Al-Si framework is the same as natrolite, mesolite, scolecite, tetranatrolite, and paranatrolite. Si and Al are disordered in both gonnardite and tetranatrolite, where $\text{Si/Al} < 1.5$ in gonnardite and ≥ 1.5 in tetranatrolite. *EJM* 7:501(1995). Some of the water sites in the disordered natrolite structure of gonnardite are empty. A series, based on the disorder of the Si-Al in the framework, appears to exist between Na-rich gonnardite (i.e., tetranatrolite) and natrolite. Crystals are prismatic, bound by {110} and {111}, as well as {100} and {001}. Also occurs as radial hemispheres to 3 cm. Gonnardite and tetranatrolite form overgrowths on natrolite. Commonly found as zoned prisms or aggregates with thomsonite, natrolite, and paranatrolite. Colorless, white, yellow, pink to salmon-orange; white streak; vitreous to silky or dull luster. Cleavage not determined. $H = 4\frac{1}{2}$. $G = 2.21\text{--}2.36$. IR and thermal data: *JJMPE* 77:78(1982), *NZ* (1985). Gonnardite and tetranatrolite have the same disordered Al-Si framework and differ only by the amount of Ca and Na present. *NJBM*:219(1986) showed the existence of a complete solid-solution series between tetranatrolite and gonnardite. Tetranatrolite is considered as Na-rich gonnardite by *ZW* (1992). *MM* 52:207(1988) further showed the existence of a complete series but divided it into tetranatrolite-ranite-gonnardite, based on chemistry, optics, and X-ray diffraction patterns. Small amounts of Mg, Sr, Ba, and K may be present (0-2 wt % of each oxide). Uniaxial (-) and (+), also biaxial (-) or (+); $N_x = 1.480\text{--}1.513$, $N_z = 1.480\text{--}1.515$; 2V to 50°; Na-rich material is length-slow, Ca-bearing is length-fast or length-slow, with parallel extinction. Occurs in silica-poor volcanic rocks and pegmatites; rarely in skarn. Often intergrown with thomsonite, with cores of gonnardite and rims of thomsonite. Found in Crestmore, Riverside Co., CA; Table Mts., Golden, Jefferson Co., CO; Honolulu, Oahu, HI; Connecticut, New Mexico, Oregon, and Washington; Na-rich gonnardite (originating as paranatrolite) from Mt. St.-Hilaire, QUE, Canada; Hillsport, Is. Magee, County Antrim, Northern Ireland; *Chaux de Bergonne, Gignat, Puy de Dome, France*; Capo di Bove, Lazio, near Rome; Aci

Castello, Aci Trezza, Osilo, and other localities on Sardinia; Arendahl, Tvedalen, and Brevik in the Langesund district, Norway; Schellkopf, near Brenk, Eifel district, and in the Höwenegg quarry, Hegau, Baden-Württemberg, and Arensburg, Zilsdorf, Eifel, Germany; Klöch, Styria, Austria; best display specimens are from Austria, Mt. St.-Hilaire, Germany, and Australia. Bundoora, near Melbourne, VIC, Australia; Maze, Niigata Pref., Japan. *EF MM 31:265(1956), NJBM 5:219(1986)*.

771.5.8 Cowlesite $\text{Ca}[\text{Al}_2\text{Si}_3\text{O}_{10}] \cdot 5\text{-}6\text{H}_2\text{O}$

Named in 1975 by Wise and Tschernich for John George Cowles (1907–1985), American amateur mineralogist and zeolite collector. Zeolite group. ORTH Space group unknown, probably $P222_1$. Cell data commonly given as $a = 11.27\text{-}11.29$, $b = 15.24\text{-}15.25$, $c = 12.61\text{-}12.68$, $Z = 6$, $D = 2.05$; however, new data from *MM 48:565(1984)* and *MM 56:575(1992)* indicate a cell with all axes doubled: $a = 23.3$, $b = 30.6$, $c = 25.0$, $Z = 52$. *29-286(nat)*: 15.2_{10} 7.62_{15} 5.08_2 $3.81_{3.5}$ $3.75_{1.5}$ 3.05_2 $2.96_{3.5}$ $2.93_{2.5}$; *MM 56:575(1992)*: 15.2_{10} $7.64_{1.5}$ 3.83_1 3.06_1 2.98_1 2.94_1 $2.83_{0.5}$. Because of extreme thinness of single crystals, structure has not been determined. Thus cowlesite is the only natural zeolite whose crystal structure has not been described. Cell data derived from powder data. Structure now being attempted on synchrotron data. Probably an ordered (Si,Al) distribution in the tetrahedral framework. Pointed, blade-shaped laths; broad {010}, extremely narrow {100}, terminated by {101}; 0.1 mm wide, only 2 μm thick, 0.2–2 mm long, ball-like aggregates are 2–3 mm across, some to 8 mm; twinning not observed. Colorless, gray, white, yellow; white streak; variable luster: vitreous, greasy, pearly. Cleavage (010), perfect. $H = 2$. $G = 2.05\text{-}2.14$. TGA data: *AM 60:951(1975)*. Very little variation from the ideal formula. Small amounts of Na present. Traces of K and Mg locally, also Sr, Ba, and Fe in trace levels. $\text{Si}/(\text{Si} + \text{Al} + \text{Fe}) = 0.603\text{-}0.622$. H_2O ranges from 30.2 to 32.8, ideal = 36. Biaxial (-); $\text{XYZ} = abc$; $N_x = 1.505\text{-}1.513$, $N_y = 1.509\text{-}1.516$, $N_z = 1.509\text{-}1.518$; $2V = 30\text{-}53^\circ$; positive elongation; colorless; no dispersion. Occurs only in low-silica volcanic rocks (e.g., olivine basalts). A low-silica zeolite from hydrothermal solutions. A low-temperature zeolite (70–110°C). Occurs 8 km S of Superior, Pinal Co., AZ; Table Mt., Jefferson Co., CO; *Neer Road, N of Goble, Columbia Co., OR(!)*; also at Burnt Cabin Creek, Spray, Wheeler Co., OR(!); Beech Creek, Grant Co., OR(!); Capitol Peak, Thurston Co., WA; Monte Lake, BC, Canada; other localities in ONT and QUE, Canada; Dalsnipa, on Sandoy and Satan, on Streymoy, Faroe Is.; Mjoadalsa Canyon, Hvammur, Iceland; Dunseverick and Bally Clare quarry, County Antrim, Northern Ireland (10 localities total in Northern Ireland); Kingsburgh, Skye, Scotland; North and South Islands, New Zealand; Cairns Bay, Flinders, and Jindivick, VIC, Australia; Kuniga tunnel, Nishi-no-Shima, Dozen, Oki Is., Japan. *EF AM 60:951(1975), NZ (1985), ZW (1992)*.

77.1.5.9 Thomsonite $(\text{Ca,Sr})_2\text{NaAl}_5\text{Si}_5\text{O}_{20} \cdot 6\text{H}_2\text{O}$

Named in 1820 by Brooke for Thomas Thomson (1773–1852), professor of chemistry at Glasgow, Scotland, who analyzed the mineral. Zeolite group. ORTH (pseudo-TET); some is MON based on optics. *Pcnn* (many weak *hkl* reflections suggest that the space group may be *Pcmm* or *Pcn2*). $a = 13.00\text{--}13.15$, $b = 13.01\text{--}13.09$, $c = 13.20\text{--}13.26$; and at 13 K: $a = 13.0569$, $b = 13.1043$, $c = 13.2463$, $Z = 4$, $D = 2.38$ at 13 K. *35-498*(nat): 6.57_7 5.90_6 4.62_{10} 3.50_7 3.19_7 2.94_{10} 2.86_{10} 2.67_{10} . Synthesized: *CCM 29:171*(1981). The aluminosilicate framework is long chains of tetrahedra rotated by 23° (similar to natrolite), but are cross-linked at two levels. Ideal thomsonite has an ordered framework. There is some Si–Al disorder in high-Si thomsonite. Degree of disorder is measured by the difference between the length of b vs. a . This is 5–10%. Two sets of channels parallel to c are present. The first set is fully occupied by equal amounts of Na and Ca, where the second channel is only partly occupied by (up to 50%) Ca or Sr. Four fully occupied H_2O sites are present. Two with two H_2O molecules (along with Ca and Sr) in the channels, and the other two sites with $2\text{H}_2\text{O}$ molecules between the channels. At 13 K, there is no cation ordering. Common forms are: {100}, {010}, {001}, {110}, has a wide range of habits: thin, rectangular, blades to blocky prismatic, rarely long, coarse, acicular prisms, elongated on c ; twinning = {110} and {041} common. Colorless, white, pink, red, green, orange, yellow, blue; white streak; vitreous to pearly luster. Cleavage {100}, perfect; {010}, good; uneven to subconchoidal fracture; brittle. $H = 5\text{--}5\frac{1}{2}$. $G = 2.25\text{--}2.44$; IR data: *CMG 25:239*(1980). Gelatinizes with acids. Most is Ca-dominant, with considerable Na. Rarely, small amounts of Sr (to 10% of cations). Na-dominant thomsonite (Tyamyr, Russia) has been reported. Well ordered, $\text{Si}/\text{Al} = 1.00$. Si-rich, $\text{Si}/\text{Al} = 1.18\text{--}1.3$ has greatest disorder. High SrO ($\approx 6.6\%$ SrO) in specimens from Honshu, Japan. Also 6.65% SrO in material from eclogite in western Norway. Biaxial (+); $\text{XYZ} = bca$, sometimes $\text{XYZ} = acb$; $N_x = 1.497\text{--}1.530$, $N_y = 1.513\text{--}1.536$, $N_z = 1.518\text{--}1.544$; $2V = 42\text{--}75^\circ$; $r > v$, distinct. Thomsonite is a common zeolite found in low-Si basalts and hypabyssal rocks. Less common in contact-metamorphic zones, pegmatites, and rarely in Si-rich tholeiitic basalt. Also in some alkalic igneous rocks. Not found in altered volcanic ash deposits. Occurs as an authigenic cement in some sandstones. Many worldwide localities, only notable localities are mentioned here. Scarce at Paterson, Passaic Co., NJ, but some exceptional aggregates to 8 cm occur; aggregates to 5 cm from Prospect Park, NJ; thomsonite is the most prominent zeolite at North and South Table Mts., Golden, Jefferson Co., CO; Jaquish Road and Neer Road, Goble, Columbia Co., Ritter Hot Springs, Grant Co., Springfield, Lane Co., and Drain, Douglas Co., OR; Stremoy, Nolsoy, and Essuroy Is., Faroe Is.; *Old Kilpatrick, Dumbartonshire, Scotland*; to 10 cm long and 3–10 cm wide from Boyleston quarry, Barrhead, Glasgow, Scotland; Mt. Monzoni, Val di Fassa, Trentino–Alto Adige, Italy; in the Eifel volcanics, Germany; also at Rossberg, near Darmstadt; Mettweiler, Rhein–Preussen, Germany; Eulenberg, Vinaricka Hill, Kladno, Bohemia, Usti nad

Labem, and Kadan, Czech Republic; Krasnoyarsk region, Yakutia, Russia; high SrO-containing (6.6 wt % SrO) from Honshu, Japan. *EF CM 16:487(1978)*; *MM 44:231(1981)*; *Z1:91(1981)*, *5:74(1985)*; *NZ (1985)*; *AC(C) 46:1370(1990)*; *AM 77:685(1992)*.

77.1.6.1 Mordenite $(\text{Na}_2, \text{Ca}, \text{K}_2)\text{Al}_2\text{Si}_{10}\text{O}_{24} \cdot 7\text{H}_2\text{O}$

Described in 1864 by How and named for the locality. Zeolite group. Old synonym: ptilolite. *ORTH Cmc2₁*. $a = 18.09\text{--}18.17$, $b = 20.40\text{--}20.58$, $c = 7.49\text{--}7.54$, $Z = 4$, $D = 2.09\text{--}2.13$. *6-239(nat)*: 9.1₉ 6.6₉ 4.53₈ 4.00₉ 3.84₆ 3.48₁₀ 3.39₉ 3.22₁₀; *29-1257(nat)*: 9.06₁₀ 4.53₃ 4.00₇ 3.48_{4,5} 3.39_{3,5} 3.22₄ 3.20_{3,5} 13.6₂. The aluminosilicate framework is made up of complex chains of five-membered rings of SiO₄ tetrahedra and single AlO₄ tetrahedra cross-linked by four-membered rings that form twisted 12-membered rings around nearly cylindrical channels parallel to c . Si occupies 80–85% of the tetrahedra with Al in the remaining tetrahedra. Al–Si distribution is partly ordered. Cations are on two sites. Many other K and Na ions are not localized. Some mordenite needles have an inclined extinction of 3–5° and are monoclinic. *ZK 175:249(1986)*. Ion-exchanged mordenite is *Cmcm*. *CSJB 58:3035(1985)*. Slender needles elongated on c , and striated parallel elongation. Crystals to 5 cm long. Also radiating needles, cottony masses. Compact porcelaneous masses, and smooth radiating hemispheres. Forms: {100}, {010}, {110} in the prism zone; {101}, {001}, {111} terminal forms. Twinning present, parallel to c . Colorless, white, yellow, pink, orange, red; white streak; vitreous to silky luster, pearly on {010}. Cleavage {100}, perfect; {010}, distinct; brittle. $H = 4\text{--}5$. $G = 2.10\text{--}2.15$. Gelatinizes in common acids. Most mordenite is Na-dominant, but some is K-dominant or Ca-dominant. Mordenite derived from volcanic ash has the highest Si content. Biaxial (+) or (–); $XYZ = cab$; $N_x = 1.471\text{--}1.483$, $N_y = 1.475\text{--}1.485$, $N_z = 1.476\text{--}1.487$; $2V_z = 76\text{--}104^\circ$; always negative elongation; length-fast, parallel to 3–5° inclined extinction, $r < v$, weak. Occurs in silica-rich (e.g., rhyolitic) volcanics and as a hydration product of volcanic glasses; volcanic ash beds, tuffs, and rarely in olivine–basalt. Of hydrothermal or sedimentary authigenic (mostly saline lake) origin. A widespread zeolite, and only notable occurrences are given here: Table Mts., Golden, Jefferson Co., CO; to 2 cm long from Wolf Creek Pass, Mineral Co., CO; Roadside quarry and Jaquish Road, Goble, Columbia Co., OR; Rickreall Creek quarry, Dallas, Polk Co., OR; to 5 cm long from South Point quarry, Jefferson Co., WA; also from near Stevenson, Skamania Co., WA; Crestmore, Riverside Co., CA; *Morden, King's Co., Nova Scotia, Canada*, and elsewhere along the Bay of Fundy; high-K-containing (5.3 wt % K₂O) from Mydzk, Volniya, Ukraine; to 5 cm long and spheres to 5 cm diameter at Chinchwad, Pune (Poona) district, MAH, India. Crystals in 5-cm groups occur at Kawazu, Shizuoka Pref., Japan. Only a few applications for natural mordenite, but synthetic material is widely used for adsorbers and catalysts. *EF CMP 50:65(1975)*, *NZ (1985)*, *ZW (1992)*.

77.1.6.2 Epistilbite $(\text{Ca}, \text{Na}_2)[\text{Al}_2\text{Si}_6\text{O}_{16}] \cdot 5\text{H}_2\text{O}$

Named in 1826 by Rose from the Greek for *near* and *stilbite*, a mineral that is similar in many respects. Zeolite group. See goosecreekite (77.1.7.3), the dimorph. TRIC and MON $C1$, $C2$, Cm ; $a = 8.92\text{--}9.12$, $b = 17.73\text{--}17.77$, $c = 10.21\text{--}10.25$, $\beta = 124.57\text{--}124.65^\circ$, and $\alpha = 9.083$, $b = 17.738$, $c = 10.209$, $\alpha 89.95^\circ$, $\beta 124.58^\circ$, $\alpha 90.00^\circ$, $Z = 3$, $D = 2.27\text{--}2.31$. 39-1381(nat): 8.9₁₀ 6.9₃ 4.92₅ 3.92₂ 3.87₇ 3.45₉ 3.21₈ 2.92₅. Aluminosilicate framework contains chains of four-membered rings joining sheets parallel to (010). The cation sites, coordinating three oxygens of the four-membered rings plus six H₂O molecules lay on the mirror plane. Si and Al in the framework are highly ordered, although streaking of single-crystal photos indicates some disorder. Si-Al ordering differs in each sector of the crystal. Structure has two tetrahedral modifications ($R = 1.82\%$, 2.18%), resulting in $C2$ symmetry. Atomic ordering that is apparent in optical analysis is too small to be detected by X-ray diffraction. ZK 173:257(1985), AM 73:1434(1988). {110} is dominant, also {001}, {011}, {010}, {013}, {101}, prismatic, commonly elongated on c , with a diamond-shaped cross section; frequently 3–10 mm long, exceptional aggregates to 3 cm long; twinning = rarely on {110} to form penetration twins; all are twinned on {100} to form a pseudo-orthorhombic crystal. Two kinds of sectoral twins are observed; one is that of structure with symmetry $C2/m$, and the other is due to (Al,Si) order. Colorless, white, orange fresh or red; white streak; vitreous luster. Cleavage {010}, very good; uneven fracture; brittle. $H = 4\text{--}4\frac{1}{2}$. $G = 2.22\text{--}2.28$. Piezoelectric. Very little variation in exchangeable cations. Always Ca dominant. Moderate Na, K is scarce or absent. Mg, Ba, and Sr are generally not present. Ratio $\text{Ca}/(\text{Na} + \text{K}) = 9$ to 2. Biaxial (-); $Y = b$, $Y \wedge b = 2^\circ$, $Z \wedge c = 5\text{--}10^\circ$, $X \wedge a = -24^\circ$, also $Z \wedge c = -10^\circ$, and $X \wedge a = 11^\circ$; $N_x = 1.485\text{--}1.505$, $N_y = 1.497\text{--}1.515$, $N_z = 1.497\text{--}1.519$; $2V = 44\text{--}46^\circ$; colorless; length-slow; $r < v$, strong. Has been synthesized. Occurs in geothermal wells in basalt in Iceland (80–160°). Generally found in silica-rich tholeiitic basalt, olivine basalt, also in gneisses. No diagenetic epistilbite has been reported. A relatively rare zeolite, but it has been reported from more than 25 localities. Localities for fine-quality material include 1 to 2.5-cm crystals from Riffe Lake, Kosmos, Lewis Co., WA; crystals from 1 to 2.8 cm long associated with quartz and high-Si zeolites from *Berufjord, Iceland*; Fonte del Prete, San Piero in Campo, Elba, Italy; “Bombay quarry” at Khandivali and near Nasik, Bombay, MAH, India; also from the Pune district, India. Lesser-quality material occurs at Goble, Columbia Co., OR; Giebelsbach, Fiesch, Valais, Switzerland; Kuroiwa, Niigata Pref., and Yugawara, Kanagawa Pref., Japan. EF AM 59:1055(1974), GNZ (1977), NZ (1985), ZW (1992).

77.1.6.3 Maricopaite $\text{Pb}_7\text{Ca}_2\text{Al}_{12}\text{Si}_{36}(\text{O},\text{OH})_{100} \cdot 32(\text{H}_2\text{O},\text{OH})$

Named in 1988 by Peacor for the locality. Zeolite group. See mordenite (77.1.6.1). ORTH $Cm2m$, $Cmmm$, $C2mm$, $Cmm2$, or $C222$. $a = 19.65\text{--}19.713$, $b = 19.385\text{--}19.40$, $c = 7.522\text{--}7.531$, $Z = 1$. $D = 2.96$. PD(nat): 13.7₁₀₀ 9.86₄₀

4.79₂₀ 4.35₃₀ 3.357₄₀ 3.216₅₀ 2.978₄₀ 2.845₄₀. *CM 26:309(1988)*. Structure is similar to mordenite and other zeolites. Based on an interrupted mordenite-like framework. Maricopaite is not a true tetrasilicate because of the interrupted T-O-T linkages; one of a small group of natural and synthetic compounds having interrupted octrahedral framework structures. *AM 79:175(1994)*. Pb atoms form Pb₄(O,OH)₄ clusters with Pb₄ tetrahedra within channels. Acicular, sprays of crystals, elongated on [001]; radial sprays to 1 mm in diameter. Translucent white, white streak, silky to vitreous luster. Cleavage {010}, imperfect. Soft and friable. G = 2.94. IR and TGA. Analysis (wt %): SiO₂, 42.0; Al₂O₃, 11.4; CaO, 2.4; PbO, 30.8; H₂O, 11.0. Biaxial (-); N_x = 1.563, N_y = 1.582, N_{z calc} = 1.592; 2V = 70°; XYZ = acb; r > v, strong. Occurs with mimetite on quartz matrix. A secondary mineral in a single calcite-fluorite vein at the *Moon Anchor mine, Tonopah, Maricopa Co., AZ.* EF.

77.1.6.4 Dachiardite (Ca,Na₂K₂)₅Al₁₀Si₃₈O₉₆ · 25H₂O

Described in 1906 by D'Achiardi and named for Antonio D'Achiardi (1839–1902), an Italian mineralogist. The mineral was investigated by his son. A second occurrence of the mineral was not reported until 1964, from Japan; in 1975, the Na-dominant analog was found in Italy. Zeolite group. Svetlozarite is twinned and highly faulted dachiardite. *MON C2/m*. $a = 18.625\text{--}18.69$, $b = 7.489\text{--}7.52$, $c = 10.239\text{--}10.30$, $\beta = 107.58\text{--}108.35^\circ$, $Z = 0.5$ (for 96 O), $D = 2.14\text{--}2.17$. *18-467(nat)*: 8.90₅ 6.91₅ 4.97₅ 4.88₅ 3.93₅ 3.80₅ 3.45₁₀ 3.20₁₀. The structure consists of sheets of six-membered rings (Al-free) connected with four-membered rings (which are Al-rich), while the exchangeable cations are distributed between the six-ring sheets. Dachiardite from Elba and Hokiya-dake shows (Al,Si) order, while bladed dachiardite from other localities (most) shows irregular {001} twinning and {100} stacking faults that indicate disorder. Sharp patterns for samples from Elba, Hokiya-dake, and Yellowstone Park. Most others are diffuse or show streaks indicating some disorder. *ZK 166:63(1983)*. Domain structure was shown to exist in dachiardite. *ZK 185:620(1988)*. More recently, structural studies of dachiardite show the coexistence of domains of "modified" dachiardite and "normal" dachiardite. *EJM 2:187(1990)*. Two acentric framework configurations are present with the same frequency, so that the statistical symmetry *C2/m* is maintained. Crystals are fibers or blades, to 5 mm long; also radiating aggregates; Cs-bearing material from Elba forms cyclic-twinned eightlings; twinned on {110} at nearly 45°. Blades are elongated on *b* or *c*. Twinning on {001} is also common, rarely on {100}. Simple, untwinned crystals are also found with the "eightlings." Repeated parallel twins on {001} with {100} as the twin axis. Also, polysynthetic twinning on [100] twin planes. Colorless, white, pink, or orange-red; white streak; vitreous to silky luster. Cleavage {100}, {001}, perfect; conchoidal to uneven fracture; brittle. $H = 4\text{--}4\frac{1}{2}$. $G = 2.14\text{--}2.21$. Decomposed by common acids. Calcium is the dominant exchangeable cation in dachiardite, but Na may be dominant (sodium-dachiardite) as well as K (Yellowstone Park). A high-silica zeolite. Cs₂O-bearing dachiardite from

Elba has about 1 wt % Cs_2O and is nonfibrous in habit. It is bladed and has an ordered Al-Si framework. Na-rich occurrences (sodium-dachiardite) are about 2× those of Ca-rich dachiardite. $\text{Si}/(\text{Al} + \text{Fe}) = 3.6\text{--}5.7$, $\text{R}^{2+}/(\text{R}^+ + \text{R}^{2+}) = 0.98\text{--}0.01$ for the complete series dachiardite-Na-dachiardite. Biaxial (+); $X = b$, $Z \wedge c = -32$ to -38° ; $N_x = 1.488\text{--}1.494$, $N_y = 1.490\text{--}1.496$, $N_z = 1.494\text{--}1.499$; $2V = 58\text{--}73^\circ$; $r > v$, moderate to strong. $\text{Si}/(\text{Al} + \text{Fe}) = 3.66\text{--}3.81$ and $\text{R}^{2+}/(\text{R}^+ + \text{R}^{2+}) = 0.53\text{--}0.84$. *CM 25:475(1987)*. A hydrothermal zeolite that generally occurs in silica-rich environments; in late stages of pegmatites and Si-rich volcanoes, but also occurs in basalts. Yellowstone Park drill holes show temperatures of $100\text{--}200^\circ$. Also in hydrothermally altered pumiceous tuffaceous sediments. May be associated with mordenite, ferrierite, and heulandite. Only selected localities are given here: Hassayampa, AZ; Ca-richest dachiardite from Lower Geyser Basin, Yellowstone National Park, WY; Agoura Hills, Los Angeles Co., Ca; Yuquina Head, Lincoln Co., OR; Cape Lookout, Tillamook Co., OR; Altoona, Wahkiakum Co., WA; *Filone della Speranza, Mte. Capanne, San Piero di Campo, Elba, Italy*; Alpe di Siusi, Trentino-Alto Adige, Italy; Zeilberg quarry, Maroldsweisach, Franconia, Bavaria; Zvezdel, Rhodope Mts., Bulgaria; Onoyama mine, Kagoshima Pref., Hatsuneura, Ogasawara Is., Hokiya-dake, Nagano Pref., Japan. *EF MM 43:548(1979)*, *MJJ 10:371(1981)*, *NZ(1985)*, *JCSSJ 30:45(1990)*, *ZW(1992)*.

77.1.6.5 Sodium Dachiardite $(\text{Na}_2, \text{Ca}, \text{K}_2)_{4-5}\text{Al}_8\text{Si}_{40}\text{O}_{96} \cdot 26\text{H}_2\text{O}$

Described in 1977 by Yoshimura and Wakabayashi and named as the Na-dominant analog of dachiardite. Zeolite group. *MON C2/m*. $a = 18.639\text{--}18.666$, $b = 7.506\text{--}7.512$, $c = 10.277\text{--}10.299$, $\beta = 108.35\text{--}108.68^\circ$, $Z = 0.5$ (for 96 oxygens), $D = 2.14\text{--}2.17$. *30-1149(nat)*: 9.77_2 $8.66_{7.5}$ 4.88_9 $3.96_{2.5}$ 3.79_4 3.45_{10} 2.97_3 $2.86_{2.5}$. See dachiardite (77.1.6.4) for a description of the structure. Divergent bundles of bladed and acicular crystals to 1.5 cm long, twinning as for dachiardite. Colorless, white, reddish orange; white streak; vitreous to greasy luster, silky on cleavage surfaces. Two perfect cleavages parallel to [010], uneven fracture, brittle. $H = 4\text{--}4\frac{1}{2}$. $G = 2.14\text{--}2.17$. Na is the dominant exchangeable cation. $\text{R}^{2+}/(\text{R}^+ + \text{R}^{2+}) = 0.00\text{--}0.20$, $\text{Si}/(\text{Al} + \text{Fe}^{3+}) \geq 4.46$. The K-dominant equivalent of dachiardite has not yet been named. Material from near the Belogorskoye gold mine in the northern Sikote-Alin Range, Russia, has K dominant. *ZVMO 105:449(1976)*. Some dachiardite from Yellowstone Park is also K-dominant. Biaxial (-); $X = b$, $Z \wedge c = -8$ to -20° , $Y \approx a$; $N_x = 1.471\text{--}1.480$, $N_y = 1.475\text{--}1.481$, $N_z = 1.476\text{--}1.484$; $2V = 52\text{--}80^\circ$; $r < v$, moderate. Distinct from dachiardite, which is optically (+), sodium dachiardite has higher indices of refraction and an opposite sense of dispersion. Occurs in veins and cavities in basic to acid volcanic rocks, and alkalic rocks (e.g., silicocarbonatite). A hydrothermal mineral. Associated with other zeolites such as mordenite, analcime, heulandite, ferrierite, and clinoptilolite, as well as carbonates and quartz. Localities include: Yaquina Head, near Agate Beach, Lincoln Co., OR; strongly Na-Ca zoned crystals from Altoona, Wahkiakum Co., WA; Francon quarry, St. Michel, Montreal Is., QUE, Canada;

Alpe di Siusi and Val di Fassa, Trentino-Alto Adige, Italy; Tanzenberg, Kapfenberg, Styria, Austria; Zielberg, near Maroldsweisach, Bavaria, Germany; Yanagi-Shiden, Tsugawa district, Niigata Pref., Japan; Chichijima, Ogasawara (Bonin) Is., Japan. EF *CMP* 49:63(1975), *SRNU* E4:49(1977), *NZ* (1985), *JCSSJ* 30:45(1990), *ZW* (1992).

77.1.6.6 Ferrierite $(\text{Na}_2, \text{K}_2, \text{Mg}, \text{Ca})_{3-5}[\text{Al}_{5-7} \text{Si}_{27.5-31} \text{O}_{72} \cdot 18\text{H}_2\text{O}]$

Named in 1918 by Graham for Walter Frederick Ferrier (1865–1950), Canadian geologist and mining engineer. Zeolite group. Found in 1918 and then not reported again until 1967! The monoclinic polymorph was first reported in 1976. *AM* 61:60(1976). Orthorhombic and monoclinic polymorphs. The monoclinic polymorph is rarer than the orthorhombic form. Three to five exchangeable cations (1^+ and 2^+) per 72 oxygen atoms. The univalent cations range from 21 to 85%; the Si–Al framework varies from $(\text{Al}_7 \text{Si}_{27.5} \text{O}_{72})$ to $(\text{Al}_5 \text{Si}_{31} \text{O}_{72})$. The a cell dimension varies linearly with SiO_2 content: high SiO_2 , smaller a ; low SiO_2 , larger a . ORTH *Immm*. $a = 18.90\text{--}19.45$, $b = 14.12\text{--}14.28$, $c = 7.43\text{--}7.53$, $Z = 1$, $D = 2.10$. 39-1382(nat): 9.60₁₀ 5.84₂ 3.97₄ 3.89₁ 3.71₃ 3.56₁ 3.53₃ 3.49₂. MON $P2_1/m$. $a = 18.89$, $b = 14.18$, $c = 7.47$, $\beta = 90.0^\circ$, $Z = 1$; no PD for the monoclinic polymorph. A Si-rich zeolite characterized by $(\text{Si}, \text{Al})\text{O}_4$ tetrahedra forming five-membered rings linked in complex chains parallel to c . Between the chains in each unit cell are two large cation cages, which contain hydrated cations, commonly Mg, and two channels containing the loosely bound and highly disordered remaining cations and H_2O molecules. Orthorhombic structure; *AC* 21:983(1966), *ZK* 178:249(1987); monoclinic structure: *AM* 70:619(1985). Structure of both polymorphs is the same but with slight deviations in the monoclinic form. The amounts of Mg and Na appear to control the structure. Orthorhombic crystals are elongated on c , platy on $\{100\}$, commonly $\{100\}$ dominant, with small $\{010\}$ and $\{110\}$, terminated by $\{101\}$, rare $\{010\}$ dominant variety has small $\{100\}$ and $\{101\}$; usually 5–10 mm long, rarely to 8 cm long. Colorless, white, pink, orange, and red (due to Fe^{3+}); white streak; vitreous–silky luster. Cleavage $\{100\}$, perfect; $\{001\}$, imperfect; uneven fracture. $H = 3\text{--}3\frac{1}{2}$. $G = 2.06\text{--}2.23$. Specimens of the mineral from Agoura, CA, fluoresce and phosphoresce a moderately strong blue-white under SWUV and LWUV. They phosphoresce for about 10 seconds. IR data (orthorhombic): *NZ* (1985). Monoclinic crystals are thin, diamond-shaped, tablets with $\{010\}$ dominant, showing $\{201\}$, $\{100\}$, and $\{010\}$. Highest BaO (2.5%) and SrO (0.4) in Silver Mt. ferrierite. May have Mg, Na, or K dominant. A high Si-zeolite. Biaxial (+) and (–); $XYZ = abc$ and material from Tapu has $XYZ = bca$; $N_x = 1.473\text{--}1.489$, $N_y = 1.474\text{--}1.489$, $N_z = 1.477\text{--}1.492$, and Tapu (Ba-Mg rich) $N_x = 1.487$, $N_y = 1.489$; 2V ranges from 50° about Z to 55° about X ; positive elongation. Monoclinic material generally has $N_x = 1.473\text{--}1.478$, $N_y = 1.474\text{--}1.479$, and $N_z = 1.477\text{--}1.482$. Occurs in cavity fillings in basaltic rocks and as a diagenetic mineral in rhyolitic tuffaceous sediments. Also in metamorphic rocks. In rhyolitic pyroclastic rocks as a result of hydration reactions. Occurs at more than 30 worldwide

localities; only selected localities are mentioned here. Minable amounts of K-dominant ferrierite in tuffaceous lake sediments at Lovelock, Pershing Co. NV; both orthorhombic and monoclinic polymorphs occur in vesicles and open spaces in brecciated basalt at *Altoona, Wahkiakum Co., WA* (for monoclinic polymorph); Na-dominant and both forms probably occur and are fluorescent and phosphorescent from the Canwood Mall site at Agoura in the Agoura Hills, CA; Leavitt Park, Sonora Pass, Tuolumne Co., CA; good display specimens from *Kamloops Lake* (orthorhombic polymorph), Monte Lake, and Pinaus Lake, near Westwold, BC, Canada; the Kamloops Lake locality is still the best and most prolific locality for ferrierite. Monoclinic polymorph and Mg-rich from Albergo Basso and Val Timonchio, Vicenza, Italy. Ba-Mg-rich from Tapu, Thames, Coromandel Penin., North Island, New Zealand. Occurs at several localities in Japan. EF NZ (1985), MM 50:63(1986), ZW (1992), AM 77:314(1992).

77.1.6.7 Boggsite (Ca,Na,K,Mg)₁₁(Fe,Al,Si)₉₆O₁₉₂ · 70H₂O

Described in 1990 and named for Robert Maxwell Boggs (b.1918) and Russell Calvin Boggs (b.1952), father and son, who discovered the mineral. Zeolite group. ORTH *Imma.* $a = 20.236\text{--}20.25$, $b = 23.798\text{--}23.82$, $c = 12.78\text{--}12.789$; also $a = 20.21$, $b = 23.77$, $c = 12.80$; $Z = 1$, $D = 1.994$. AM 75:1200(1990). PD: 11.80₃ 11.30₁₀ 10.2₃ 4.43₇ 3.86₈ 3.63₃ 3.37₁₀; 42-1379(calc. pattern). A high-silica zeolite with the first reported three-dimensional channel system bounded by both 12- and 10-membered rings of tetrahedra. AM 75:501(1990). Chisel-shaped blades elongated on *b*. Radiating hemispheres 0.5–2 mm in diameter. Individuals crystals to 0.5 mm long and 0.2 mm wide. No twinning observed. Prominent forms are {102}, {010}, and {011}. {001}, {010}, and {100} are poorly developed. Morphology is similar to thomsonite. Colorless–white, white streak, vitreous to dull luster. No cleavage, conchoidal fracture, brittle. $H = 3\frac{1}{2}$. $G = 1.98$. White zones fluoresce a weak blue-white in LWUV and SWUV. Highly resistant to acids. 6 N HCl for 1 hour leaves it unaffected. $\text{Si}/(\text{Al} + \text{Fe}) = 4.2$. The ratio of monovalent/divalent extra-framework cations ranges from 0.39 (Goble) to 1.03 (Mt. Adamson). Biaxial (–); $XYZ = cab$; $N_x = 1.480$, $N_y = 1.481$, $N_z = 1.487$; $2V_x = 25^\circ$; nonpleochroic; length-slow, parallel extinction; $r > v$, strong. Some material has a lower average refractive index (1.46–1.47). In one area (3 mm × 2 mm × 1 m) of a basalt flow, associated with tschernichite. Very early stage of zeolite growth. Other minerals include chalcedony, heulandite, apophyllite, levyne, chabazite, calcite, aragonite, and opal. Neer Road pit, Goble, Columbia Co., OR; Mt. Adamson, northern Victoria Land, Antarctica. EF ZW (1992), EJM 7:1029(1995).

77.1.7.1 Brewsterite (Sr,Ba,Ca)Na₂Al₂Si₆O · 5H₂O

Discovered and named by H. J. Brooke in 1822 for David Brewster (1781–1868), Scottish physicist, who studied the optical properties of crystals. Zeolite group. See Ba analog of brewsterite (77.1.7.5). TRIC *P1* (pseudomonoclinic) or MON *P2₁/m*. $a = 6.75\text{--}6.82$, $b = 17.46\text{--}17.51$, $c = 7.73\text{--}7.76$, $\beta = 94.27\text{--}$

94.47°, $Z = 2$, $D = 2.38$. *41-1356*: 8.78₃ 4.66₇ 3.27₄ 3.11₂ 2.92₁₀ 2.73₂ 2.72₂ 2.19₄; also 15-0582(nat). Ordering of Al and Si in the framework causes a slight distortion of only 0.5° from the c axis, producing a triclinic framework. A sheet-type structure composed of chains of parallel four-membered rings. *AC 17:857(1964)*, *AC(C) 41:492(1985)*, *AM 72:645(1987)*, *AC(B) 33:2907(1977)*. Common forms are: {010}, {001}, {100}, {011}, and {610}; tabular on (010) striated parallel to a , often flattened along c , blocky to prismatic, pseudomonoclinic, elongated on a ; large crystals are 1–2 mm in diameter, 4 mm long common; microscopic twinning frequent, and parallel to the dominant {010} cleavage; mineral is piezoelectric (i.e., noncentric), triclinicity of brewsterite is too slight to be detected by XRD or neutron diffraction. Colorless, white, pink, light yellow, and brown; white streak; vitreous luster, pearly on (010). Cleavage {010}, perfect; {001}, poor; uneven fracture; brittle. $H = 4\frac{1}{2}$ –5 $\frac{1}{2}$. $G = 2.32$ –2.45. Si and Al contents varied: Strontian (Scotland) = $\text{Sr}_{0.58}\text{Ba}_{0.30}\text{Ca}_{0.14}[\text{Al}_{1.99}\text{Si}_{6.04}\text{O}_{16}] \cdot 4.9\text{H}_2\text{O}$. Yellow Lake = $\text{Sr}_{0.85}\text{Na}_{0.24}\text{K}_{0.02}\text{Ca}_{0.02}[\text{Al}_{2.17}\text{Si}_{5.84}\text{O}_{16}] \cdot x\text{H}_2\text{O}$. Burpala massif = $\text{Sr}_{0.75}\text{Ba}_{0.13}\text{Na}_{0.04}\text{K}_{0.02}[\text{Al}_{2.06}\text{Si}_{5.94}\text{O}_{16}] \cdot 5.04\text{H}_2\text{O}$. Biaxial (+); $X \wedge a = 22$ –28° in obtuse β , $Y \wedge c = 0.5^\circ$, $Z = b$; $N_x = 1.506$ –1.510, $N_y = 1.510$ –1.512, $N_z = 1.522$ –1.523; $2V = 55$ –65°; $r > v$; positive elongation. See also *MM 52:416(1988)* for a discussion of morphology and optics of brewsterite; not tied to X-ray orientation. A hydrothermal mineral; occurs in vugs of massive volcanic rocks. Also in hydrothermal veins. Occurs at Yellow Lake, Ollala, BC, Canada; in the Whitesmith, Middleshop, and Bellsgrrove mines at *Strontian, Argyleshire, Scotland*; St. Cristophes, Bourg d'Oisans, Val d'Isere, France; at several localities in the high Pyrenees (e.g., in the Riou Maou Mountains between Gararie and Luz, and others). *EF MGNZ (1977)*, *NZ (1985)*, *ZW (1992)*, *MM 54:654(1990)*.

77.1.7.2 Yugawaralite $\text{CaAl}_2\text{Si}_6\text{O}_{16} \cdot 4\text{H}_2\text{O}$

Described in 1952 by Sakurai and Hayashi and named for the locality. Zeolite group. *MON Pc* (by X-ray analysis), *TRIC P1* (by optics). $a = 6.70$ –6.730, $b = 13.95$ –14.008, $c = 10.03$ –10.54, $\beta = 111.07$ –111.50°, $Z = 2$, $D = 2.22$. *39-1372(nat)*: 7.01₃ 5.82₅ 4.67₁₀ 4.30₃ 3.24₄ 3.05₉ 2.94₂ 2.72₂. This and other zeolites showing metastable crystal growth, may show noncentrosymmetry, but be centrosymmetric by X-ray analysis. The electrostatic charge is balanced on the growth surface (two-dimensional) of the crystal rather than the three-dimensional structure. The Al–Si framework consists of singly connected four-membered rings, linked to form five- and eight-membered rings, with a single Ca cation in the main channel that runs parallel to a , and is coordinated by four framework oxygens on one side and four H₂O molecules on the other side. Two of the water sites are fully occupied, whereas the other two have an occupancy of <20%. Perfect Al–Si order is found for Iceland samples, and only partial ordering is found for Yugawara, Japan, material. *MM 51:615(1987)* correlated optical symmetry to Si–Al ordering and found three possible variations: (1) crystals are monoclinic, (2) crystals are triclinic, and (3) crystals are monoclinic and triclinic (sectors alternate). Low-tempera-

ture hydrothermal yugawaralite is monoclinic–triclinic because unstable atom positions are frozen in place during growth. At higher temperature, atoms can reach a stable position and homogeneous structure. Thin, tabular, lathlike blades, elongate on c ; broad $\{010\}$ pinacoid, $\{001\}$, $\{010\}$, $\{100\}$, $\{011\}$, $\{120\}$, $\{110\}$, and $\{\bar{1}11\}$ all common; usually less than 10 mm long, exceptional crystals to 6 cm long. Colorless, white, pink; white streak; vitreous luster, pearly on $\{010\}$. Cleavage $\{104\}$, $\{001\}$, distinct; $\{101\}$, imperfect; $\{010\}$, parting; conchoidal fracture; brittle. $H = 4\frac{1}{2}$ – $5\frac{1}{2}$. $G = 2.19$ – 2.25 . IR, DTA, TGA data: *AM 56:1699(1971)*, *MJJ 8:456(1977)*, *NZ (1985)*. Insoluble or nearly so in hot concentrated HCL, HNO_3 , H_2SO_4 , aqua regia, and water. Only slightly attacked by concentrated hot KOH. Soluble in HF. Decomposes readily in KOH and Na_2CO_3 fusions. Is piezoelectric and pyroelectric (i.e., no center of symmetry). Nonmagnetic and nonfluorescent. Always Ca-rich, with trace to minor amounts of Na, K, Mg, Fe, and Sr. Biaxial (–) and (+), has anomalous optical properties; type material has: $N_x = 1.496$, $N_y = 1.497$, $N_z = 1.504$; $2V = 78^\circ(+)$; $r > v$, weak; other samples of Yugawara material have: $N_x = 1.493$, $N_y = 1.499$, $N_z = 1.503$; $2V = 72^\circ(-)$. Dispersion $r < v$ distinct (horizontal dispersion). Total range of indices is: $N_x = 1.492$ – 1.500 , $N_y = 1.497$ – 1.505 , $N_z = 1.501$ – 1.512 ; $2V_x = 65$ – 82° ; $Y \wedge c = -6$ to -14° ; $X \wedge a = -9$ to $+7^\circ$; $Z = b$ or $Z \wedge b = 1^\circ$. Occurs in natural geothermal systems (active or past). Hosts can be rhyolite, dacite, or basalt. Associated with other zeolites, such as wairakite and calcite. In drill core from Lower Geyser Basin, Yellowstone National Park, WY; Chena Hot Springs, Chena R., E of Fairbanks, AK; Yellow Lake, near Olalla, BC, Canada; at least three localities in Iceland, two are Heinabergsjökull and Hvalsgod, Hvalfjord; at least two localities on Sardinia: Osilo, Sassari, Sardinia, Italy; Khandivali quarry, near Bombay, MAH, India; Takitimu Mountains, South Island, New Zealand's Nukabira district; central Hokkaido, Japan; Shimoda district, and in the Toi and Seikoshi mines, Shizuoka Pref., Japan; *Yugawara Hot Springs, Kanagawa Pref., Honshu, Japan*; also at Onikobe, Miyagi Pref., in the Tanzawa Mts. in Shizuoka Pref., also at Kakkonda Hot Springs, and Takinoue, Iwate Pref. *EF AC(B) 25:1183(1969)*, *ZK 130:88(1969)*, *NZ (1985)*, *ZK 174:265(1986)*, *ZW (1992)*.

77.1.7.3 Goosecreekite $Ca[Al_2Si_6O_{16}] \cdot 5H_2O$

Named in 1980 by Dunn et al. for the locality. Zeolite group. MON (pseudorth) $P2_1$. $a = 7.401$ – 7.52 , $b = 17.439$ – 17.56 , $c = 7.293$ – 7.35 , $\beta = 105.73^\circ$, $Z = 2$, $D = 2.23$. *35-469(nat)*: 7.19_5 5.59_5 4.91_5 4.53_{10} 3.53_{25} 3.35_4 3.28_{25} 3.07_{25} . Al–Si framework has (010) layers that resemble those of brewsterite but are cross-linked by Si tetrahedra (sharing two vertices with each adjacent layer) to form a three-dimensional framework. Si and Al are ordered in the framework, with only a few sites showing an exchange of Al and Si. Details given in *AM 71:1494(1986)*. Crystals equant or elongated on b , similar to epistilbite, distinguished by the presence of highly curved and twisted faces, $\{100\}$, $\{010\}$, $\{001\}$; crystals to 4 cm long, aggregates from India to 6 cm long,

10 cm in diameter; no twinning shown. Colorless, milky white; white streak; vitreous-pearly luster. Cleavage {010}, perfect. $H = 4\frac{1}{2}$. $G = 2.16-2.23$. Insoluble in HCl or HNO₃. Only material from VA has been analyzed. No other exchangeable cations besides Ca. Uniaxial (-); Y parallel to b , $c \wedge Z = 46^\circ$, X and Z lie in the cleavage plane; $N_x = 1.495$, $N_y = 1.498$, $N_z = 1.502$; $2V = 82^\circ$. Occurs in basalt-dabase and granitic pegmatites, associated with minerals such as actinolite, chlorite, epidote, quartz, prehnite, stilbite, albite, and apophyllite. *Goose Creek quarry, Leesburg, Loudon Co., VA*; *Jensen quarry, Riverside, Riverside Co., CA*; *Oberbaumühle quarry, Windischeschenbach, Bavaria, Germany*; *Pandulena quarry, Nasik, MAH, India* (crystals to more than 4 cm long and hemispheres to 8 cm in diameter); also from several other nearby localities. *EF CM 18:323(1980)*, *NZ (1985)*, *ZW (1992)*.

77.1.7.4 Roggianite $\text{Ca}_2[\text{Be}(\text{OH})_2\text{Al}_2\text{Si}_4\text{O}_{13}] \cdot 2.5\text{H}_2\text{O}$

Named in 1969 by Passaglia for Aldo G. Roggiani, teacher of natural sciences, who found the mineral. Zeolite group. Previously called ginzburgite. *TER I4/mcm*. $a = 18.366-18.377$, $c = 9.164-9.187$, $Z = 1$, $D = 2.12$. *39-366 [MZ 8(4):85(1986)]* (nat): 12.96₁₀ 9.16₄₅ 6.12₁ 5.80₁ 3.60₁ 3.41₄ 3.20₂ 3.15₂; *MM 52:201(1988)*: 12.99₁₀ 9.18₅ 6.12₄ 5.81₂ 3.60₄ 3.41₇ 3.20₃ 3.15₄. $R = 6\%$. Characterized by an interrupted (Si,Al) framework with some OH vertices unshared by two tetrahedra; Ca cations and H₂O molecules lie in cavities where the framework is interrupted and in the largest channels, respectively. Be in Al tetrahedra. *NJBM: 307(1991)*. Elongated prisms with {100} {010}, {110}; long laths, 70-600 nm wide and 40-120 nm thick. Whitish yellow, colorless; white streak. Cleavage {100}, perfect. $G = 2.02$ (certainly too low) and 2.30. *MZ 8(4):85(1986)*. DTA data: *CLM 8:107(1969)*. TGA data: *MM 52:201(1988)*. Breaks down at $> 850^\circ$ to a feldspar. Analysis (wt %): SiO₂, 41.0; Al₂O₃, 18.7; CaO, 19.6; SrO, 0.02; Na₂O, 0.29; K₂O, 0.64 (Σ 80.34; Alpe Rosso, Italy) + 18.1H₂O and 3.2BeO; Pizzo Marcio: SiO₂, 44.1; Al₂O₃, 18.5; Fe₂O₃, 0.05; CaO, 20.0; SrO, 0.04; BaO, 0.09; K₂O, 0.02; H₂O, 17.2 (by difference). Roggianite is the first and, up to now, only zeolite with many tetrahedral sites occupied by Be. Uniaxial (+) and (-); $N_O = 1.527$, $N_E = 1.535$ (+) and $N_O = 1.526$, $N_E = 1.519$ (-) [*MZ 8(4):85(1986)*]; elongation = c . Occurs in coating fractures in a sodium feldspar dike cutting gneiss at *Alpe Rosso, Val Vigizzo, Novara Prov., Italy*. Also in another albitite dike 1 km away at Pizzo Marcio. Hydrothermal origin. Also occurs in desilicated pegmatites in the Ural Mts., Russia. *EF PM 48:15(1979)*, *P5ICZ: 205(1980)*, *NZ (1985)*.

77.1.7.5 Ba Analog of Brewsterite Ideally, $\text{BaAl}_2\text{Si}_6\text{O}_{16} \cdot 5\text{H}_2\text{O}$

Described in 1993 by Cabella et al. [*EJM 5:353(1993)*] and subsequently in the same year by Robinson and Grice [*CM 31:687(1993)*], but not named. Zeolite group. See brewsterite (77.1.7.1). *MON P2₁/m*. New York: $a = 6.780$, $b = 17.599$, $c = 7.733$, $\beta = 94.47^\circ$, $Z = 2$; Italy: $a = 6.790$, $b = 17.581$, $c = 7.735$, $\beta = 94.50(3)^\circ$, $D = 2.52$. *PD(nat)*: 2.93₁₀ 4.68₈ 6.31₈ 3.27₆ 5.07₃

4.53₃ 2.02₃ 1.66₃. R = 5.1%. Structure like brewsterite (77.1.7.1). Platy aggregates of flattened pinacoidal crystals to 1 mm across (NY) and subparallel, tabular crystals to 3 mm and (Italy) colorless to pale pink prismatic crystals to 0.2 mm long, also radiating and parallel aggregates; prismatic to tabular on {010}, showing forms {100}, {010}, and {001}; twinning on {010}. Pale yellow to colorless, transparent. Cleavage {010}, perfect; conchoidal fracture; brittle. H = 4. G = 2.50. IR data: FTIR spectrum is like that of brewsterite; NY material fluoresces bright yellow-green in SWUV. New York material is zoned with respect to Ba and Sr. Analysis (wt %), most Ba-rich zone: BaO, 19.1; SrO, 1.99; CaO, 0.06; K₂O, 0.08; Na₂O, 0.06; Al₂O₃, 15.49; SiO₂, 52.48; Σ = 89.28 with empirical formula of: (Ba_{0.85}Sr_{0.13}Ca_{0.01}K_{0.01})_{Σ1.01}(Al_{2.07}Si_{5.95})O₁₆ · 5H₂O. Italian material has: (Ba_{1.80}Mg_{0.08}Na_{0.07}K_{0.04}Ca_{0.03}Sr_{0.02})_{Σ2.04}(Si_{11.78}Al_{4.29}Fe_{0.02})_{Σ12.09}O₃₂ · 9.82H₂O. Biaxial (+); Na(D) (New York): N_x = 1.513, N_y = 1.517, N_z = 1.527; nonpleochroic, 2V = 57°, 2V_{calc} = 64°; (Italy): N_x = 1.514, N_y = 1.516, N_z = 1.528; 2V = 45°, 2V_{calc} = 44°, X ∧ c = 36° (β obtuse) and Z parallel to b; no dispersion. A late-stage hydrothermal mineral that occurs in New York in cavities in massive prehnite at a wollastonite mine. Also associated with quartz, diopside, calcite, and microcline. In Italy, occurs in fractures in radiolarian metacherts and schistose metapelite. *Gouverneur Talc Co. No. 4 wollastonite quarry (Valentine property), Harrisville, Diana, Lewis Co., NY; Cerchiara mine, Faggiona, La Spezia, eastern Liguria, Italy.* EF

77.1.8.1 Bellbergite (K,Ba,Sr)₂Sr₂Ca₂(Ca,Na)₄Al₁₈Si₁₈O₇₂ · 30H₂O

Named in 1993 by Rüdinger et al. for the locality. Zeolite group. HEX Space group unknown, possibly *P6₃/mmc*, *P6₂c*, or *P6₃mc*. *a* = 13.244, *c* = 15.988, Z = 1, D = 2.19. 45-1482(nat); 9.25₄ 6.58₈ 3.80₁₀ 2.95₇ 2.70₅ 2.50₅ 2.21₇ 1.83₅. *MP 48:147(1993)*. Zeolite structure type EAB. Not completely ordered. Six-fold rings of TO₄-tetrahedra form layers perpendicular to *c*. The stacking sequence of the layers is ABBACC. *MP 48:147(1993)*. Dipyrramids to 0.3 mm, elongate on [0001], {1012} dipyrramid; no twinning. Colorless-white, white streak, vitreous luster. No cleavage observed, conchoidal fracture. H = 5. G = 2.20. Analysis (wt %): SiO₂, 34.4; Al₂O₃, 27.9; BaO, 1.22; Na₂O, 0.70; K₂O, 1.95; SrO, 7.63; CaO, 9.31 (Σ 83.12). Uniaxial (-); N_O = 1.522, N_E = 1.507; colorless, nonpleochroic. Occurs in Ca-rich xenoliths in leucite tephrite lava. In thin marginal contact zones. *Bellberg volcano, Mayen, Laacher See area, Eifel, Germany.* EF

77.1.8.2 Tschernichite Ca[Al₂Si₆O₁₆] · 8H₂O to (Ca,Na,K,Mg)Al_{1.67}Si_{6.33}O₁₆ · 4H₂O

Named in 1991 by Smith et al. for Rudy Warren Tschernich (b.1945), mineralogist and zeolite specialist, who found the mineral in 1971. Zeolite group. TET [or pseudo-TET (some is MON from optics)]. *P4/mmm* (most probable). *a* = 12.880, *c* = 25.020, Z = 8, D = 2.12. *PD(nat)*: 12.5₁ 11.6₃ 4.03₁₀ 3.57₁ 3.16₂ 3.06₁ 2.73₁ 2.11₂. *AM 78:882(1993)*. The aluminosilicate framework is

the natural analog of synthetic zeolite beta. The distribution of Al and Si in tschernichite is disordered in two different arrangements, in approximately equal amounts, that correspond to the ordering in the polymorphs A + B of zeolite β . An intergrowth of an enantiomorphic pair having the tetragonal space groups $P4_122$ and $P4_322$, with $a = 12.447$ and $c = 26.56$ (polymorph A) and a triclinic polymorph (B) with space group $P1$, with $a \approx b = 12.4$, $c = 14.5$, $\alpha \approx \beta = 73^\circ$, and $\gamma = 90^\circ$. *JCS* 6:363(1991). A tschernichite-type mineral has been reported from Antarctica and the mineral shows significant differences in the X-ray diffraction pattern from Goble tschernichite, mainly in the low 2θ region, suggesting a different ratio of the two frameworks found in the Goble tschernichite and/or the highly probable presence of at least one other distinct beta-type framework in the Antarctic tschernichite. Generally elongate on c , steep, lustrous, tetragonal dipyrramids, radiating to blocky or stout; forms: {302}, {502}, {101}, {001}, sometimes terminated with {001}, 0.1- to 1-mm hemispheres to drusy linings 1–2 mm thick, largest crystal was 1 cm long, single crystals from <0.1 mm to 1 cm, most are <3 mm in length; twinning on {302}, {101}, {304}, multiple twins on {101}. White–colorless, white streak, vitreous luster, transparent–translucent. No cleavage, no parting, conchoidal fracture, brittle. $H = 4\frac{1}{2}$. $G = 2.02$. Sometimes fluorescent, a very pale yellow under LWUV and SWUV. Analysis (wt %): SiO_2 , 54.1, 65.8; Al_2O_3 , 15.4, 14.4; CaO , 8.3, 6.6; FeO , 0.3, N.D.; MgO , 0.5, N.D.; Na_2O , 0.2, N.D.; H_2O , 22.7, 13.15. $\text{Ca}_{0.97}\text{Na}_{0.05}\text{Mg}_{0.08}\text{Al}_2\text{Si}_6\text{O}_{16} \cdot 8\text{H}_2\text{O}$ (large crystal) and $\text{Ca}_{0.73}\text{Na}_{0.11}\text{K}_{0.02}\text{Al}_{1.69}\text{Si}_{6.33}\text{O}_{16} \cdot 4\text{H}_2\text{O}$ (druse). Uniaxial (–), also biaxial (–); $N_0 = 1.484$, $N_E = 1.483$; $2V = 0\text{--}35^\circ$; length-fast, and commonly twinned. First zeolite to form in its paragenesis. Occurs in vesicular olivine basalt only in an area 2 m \times 3 m and 1 m thick. Associated with other zeolites. May be associated with boggsite. A drusy coating. *Neer Road pit, Goble Creek, N of Goble, Columbia Co., OR*; Santiago de Puriscal, SW of San Jose, Costa Rica; Mt. Adamson, northern Victoria Land, Antarctica. *EF ZW* (1992), *MP VII6:4*(1992), *EJM* 7:1029(1995).

77.2.1.1 Bikitaite $\text{LiAlSi}_2\text{O}_6 \cdot \text{H}_2\text{O}$

Named in 1957 by Hurlbut for the locality. Zeolite group. tric $P1$ (pseudomon). $a = 8.607$, $b = 4.954$, $c = 7.597$, $\alpha = 89.90^\circ$, $\beta = 114.44^\circ$, $\gamma = 89.99^\circ$ [*Z* 9:303(1989)], $Z = 2$, $D = 2.28$. *14-168*: 7.87₈ 6.93₅ 4.37₄ 4.20₉ 3.46₁₀ 3.37₁₀ 3.28₄ 2.48₉. Originally stated to be monoclinic but recent work (both X-ray and neutron diffraction) has shown the mineral to be triclinic. Complete Al–Si order results in triclinic symmetry. If only partial Al–Si order is shown to exist, the space group would be $P2_1$. Al–Si framework consists of five-membered rings linked by Al tetrahedra. The framework contains channels parallel to [010] which are occupied by tetrahedrally coordinated Li atoms and water molecules. Several millimeters to 6 cm long, pseudo-orthorhombic prisms flattened on {001}, {100}, or {101}, flattened blades are elongate along b , and highly striated parallel to b . Colorless to cream colored, vitreous luster. Cleavage {100}, perfect; {001}, good; conchoidal fracture; brittle. $H = 6$. $G = 2.29\text{--}$

2.34. DTA, TGA data: *AM 59:71(1974)*. Biaxial (-); $X \wedge c = 28^\circ$ in the obtuse angle, $Z = b$; $N_x = 1.509\text{--}1.510$, $N_y = 1.520\text{--}1.521$, $N_z = 1.522\text{--}1.523$; $2V = 45^\circ$; positive elongation. The only lithium-bearing zeolite known at this time. It is like spodumene with the addition of water. Occurs in Li-rich pegmatites and forms prior to stilbite. Foote mine, Kings Mt., Cleveland Co., NC; *Bikita mine, Zimbabwe*. Also occurs at the El Hayat mine and Nolan mine at Bikita. *EF AM 53:1202(1968)*, *NZ (1985)*, *NJBM 6:241(1986)*, *ZW (1992)*.

77.2.2.1 Lithosite $K_8Al_4Si_8O_{25} \cdot H_2O$

Named in 1983 by Khomyakov et al. from the Greek *lithos*, stone, because it contains the most abundant components of Earth's crust. Zeolite group. MON (pseudo-ORTH) $P2_1$. $a = 15.197$, $b = 10.233$, $c = 8.435$, $\beta = 90.21^\circ$, $Z = 2$, $D = 2.54$. $37\text{--}457(\text{nat})$: 3.46₉ 3.26₉ 3.16₉ 3.07₁₀ 2.82₈ 2.10₉ 2.05₅ 1.99₅. Structure: *DAN SSSR 291(6):1370(1986)*. Irregular grains to 3 mm across. Colorless, clear; white streak; vitreous luster. Conchoidal fracture. $H = 5\frac{1}{2}$. $G = 2.51$. IR data indicate presence of H_2O ; under X-rays acquires a bright rose color which persists for at least 8 months, and then is pleochroic. X, Y, colorless; Z, bright rose. Easily decomposed by cold 10% HCl. Analysis (wt %): SiO_2 , 50.0, 49.6; Al_2O_3 , 20.7, 20.4; K_2O , 28.4, 28.0; H_2O LOI, 2.34. Biaxial (+); $Z = b$, Y near a , X near c ; $N_x = 1.510$, $N_y = 1.513$, $N_z = 1.527$; $2V = 47^\circ$. XY, nearly colorless; Z, pale rose. Occurs in veins of ultra-agpaitic pegmatite cutting nepheline syenite. In cavernous parts of drill cores. Associated with other alkalic minerals. *Vuonemiok R., southern Khibiny massif, Kola Penin., Russia. EF ZVMO 112:218(1983)*, *NZ (1985)*, *ZW (1992)*.

77.2.3.1 Mountainite $KNa_3Ca_2Si_8O_{20} \cdot 8H_2O$ or $(Ca,Na_2K_2)_2Si_4O_{10} \cdot 3H_2O$

Described in 1957 by Gard et al. and named for Edgar Donald Mountain (1901–1985), British mineralogist and geologist, Rhodes University, Grahamstown, South Africa. MON $P2_1/a$. $a = 13.51\text{--}13.6$, $b = 13.10\text{--}13.2$, $c = 13.51\text{--}13.6$, $\beta = 104^\circ$, $Z = 4$ or 8 (depending on formula), $D = 2.37\text{--}2.49$. $25\text{--}676$: 13.1₈ 6.69₄ 4.67₈ 4.18₆ 2.94₁₀ 2.80₇ 1.97₇ 1.72₆. Structure has not yet been solved in detail. The true b might be 6.55 Å rather than 13.1 Å. White, matted silky fibers in rosettes up to 2 mm, flattened prisms to 2 mm long (Lovozero), elongated on b ; segregations to 2 cm; white streak; silky to vitreous luster. Cleavage (001), good. $H = 3$. $G = 2.36\text{--}2.38$. IR data: *DAN-ESS 210:337(1974)*. DTA data: *MM 31:611(1957)*. Analysis (wt %), Lovozero: SiO_2 , 51.6; Na_2O , 10.15; K_2O , 4.43; CaO , 10.1; Al_2O_3 , 2.3; H_2O , 17.8; South Africa: SiO_2 , 58.5; CaO , 13.4; MgO , 0.2; Na_2O , 7.9; K_2O , 6.0; H_2O , 13.4. Biaxial (+); $Y = b$, $Z \wedge c = 18^\circ$; $N_x = 1.500\text{--}1.509$, $N_y = 1.505\text{--}1.513$, $N_z = 1.513\text{--}1.519$; $2V$ medium to large. Occurs with rhodesite in serpentinized kimberlite; also as a late hydrothermal mineral in natrolite and aegerine in alkaline pegmatite, and with zeolites in vugs of a melilite–nephelinite. May form pseudomorphs after eudialyte and lomonosovite. Occurs in volcanics at Howenegg, Hegau, Germany; in the Jubilee pegmatite body on Mt. Karna-

surt, Lovozero massif, Kola Penin., Russia; and in the *Bultfontein kimberlite pipe, Kimberley, South Africa*. EF *DA 25:613(1974)*, *DAN-ESS 260:134(1983)*.

77.2.4.1 Partheite $\text{Ca}_2\text{Al}_4\text{Si}_4\text{O}_{15}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$

Named in 1979 by Sarp et al. for Erwin Parthe (b.1928), crystallographer at the University of Geneva. Zeolite group. See gismondine (77.1.3.1), a similar cell. Dimorph of lawsonite. MON *C2/c*. *SMPM 59:5(1979)*. $a = 21.59$, $b = 8.78$, $c = 9.31$, $\beta = 91.47^\circ$, $Z = 8$, $D = 2.37$ and $a = 21.555$, $b = 8.761$, $c = 9.304$, $\beta = 91.55^\circ$. *36-378[SMPM 59:5(1979)](nat)*: 10.79₁₀ 8.12₈ 6.10₇ 3.74₅ 3.60₄ 3.19₄ 3.05₃ 2.90₃. Structure: *AC(A) 40:247(1984)*, *ZK 169:165(1984)*. Radial, fibrous crystals to 0.1–0.3 mm; no twinning observed. Colorless to white, colorless to white streak, vitreous luster. Cleavage {100}, {110}, distinct. $H = \text{ca.}4$. $G = 2.39\text{--}2.45$. IR data: *ZVMO 111:209(1984)*, *SMPM 65:129(1985)*. Traces of Na_2O to 0.3% and $\text{K}_2\text{O} = 0.2\%$. Biaxial (+); $Y = b$, 23–30° extinction angle between X and c; $N_x = 1.547\text{--}1.550$, $N_y = 1.549\text{--}1.552$, $N_z = 1.559\text{--}1.565$; $2V = 48^\circ$; $r > v$, moderate; negative elongation. Occurs about 7 km SE of the village of Doganbaba in the *Taurus Mts., Burdur Prov., southwestern Turkey*, in an ophiolite zone, in rodingitic rocks with prehnite, thomsonite, and augite. In a gabbro pegmatite at Denezhkin Kamen, Ural Mts., Russia. EF

77.2.5.1 Strätlingite $\text{Ca}_2\text{Al}_2\text{SiO}_2(\text{OH})_{10} \cdot 2.25\text{H}_2\text{O}$

Named in 1976 by Hentschel and Kuzel for W. Strätling, who synthesized the compound in 1938. HEX-R *R3m*. $a = 5.745$, $c = 37.77$, $Z = 3$, $D = 1.98$. *29-285*: 12.5₁₀ 6.20₇ 4.90₃ 4.16₁₀ 2.87₇ 2.61₄ 2.49₄ 2.12₄; this pattern as well as the bulk chemistry bears a strong resemblance to that of vertumnite (73.1.6.1). Structure: *EJM 2:841(1990)*. The structure is reported to be related to the zeolite chabazite. Colorless to pale green, translucent. Cleavage {0001}, perfect; brittle. $G = 1.9$. Uniaxial (-); $N_0 = 1.534$. Occurs as hexagonal plates < 1 mm in diameter, with nepheline, melilite, thomsonite, gismondine, and ettringite in a limestone inclusion in basalt at *Bellerberg Volcano, 2 km N of Mayen, Eifel, Germany*, and with tobermorite, ettringite, and vertumnite at Campomorto, Montalto di Castro, Lazio, Italy. AR *NJMM 326(1976)*, *AM 62:395(1977)*.

77.2.6.1 Gaultite $\text{Na}_4\text{Zn}_2\text{Si}_7\text{O}_{18} \cdot 5\text{H}_2\text{O}$

Named in 1994 for Robert Allen Gault (b.1943), Canadian Museum of Nature. ORTH *F2dd*. $a = 10.211$, $b = 39.88$, $c = 10.304$, $Z = 8$, $D = 2.52$. *PD(nat)*: 6.35₁₀ 5.36₂ 4.96₃ 3.24₆ 3.17₄ 3.14₄ 3.00₂ 2.82₃. Structure shows no chemical disorder. There are five tetrahedral sites, four with Si, one with Zn. Structure is similar to that of lovdarite. A zeolitelike mineral, because Zn is a framework cation. Euhedral, equant crystals to 0.5 mm in diameter, predominant forms are {010}, {110}, {110}, {021}, {151} + {151}. Colorless–pale mauve, white streak, vitreous luster. Cleavage {101} + {010}, perfect; {021}, poor; conchoidal fracture on some surfaces. $H = 6$. $G = 2.52$. IR data are similar to stilbite. *CM 32:855(1994)*. Bright apple-green fluorescence

under SWUV. Does not readily dissolve in 1:1 HCl, but it is etched after prolonged exposure. Analysis (wt %): Na₂O, 16.6; ZnO, 19.2; SiO₂, 52.6; H₂O calc., 11.3. Biaxial (+); XYZ parallel to *acb*; Na light: 2V = 61°, 2V_{calc} = 60°; N_x = 1.520, N_y = 1.521, N_z = 1.524; nonpleochroic; r > v, weak to moderate for all directions except B×a. Occurs in a sodalite inclusion within Ne-sodalite syenite. Many associated alkaline minerals. *Poudrette quarry, Mt. St.-Hilaire, Rouville Co., QUE, Canada.* EF

77.2.7.1 Kalborsite K₆Al₄Si₆O₂₀(OH)₄Cl

Named in 1980 by Khomyakov et al. for the composition. TET P421c. *a* = 9.851, *c* = 13.060, Z = 2, D = 2.48 (DAN SSSR ESS 252:131(1982)); PD 33-0999 (nat.): 3.44₈ 3.26₅ 3.08₁₀ 2.94₈ 2.79₉ 2.24₅ 2.08₅ 1.17₅. The structure is a three-dimensional backbone of SiO₄ and AlO₄ tetrahedra. Channels are along *c* in which K atoms are separated from each other by Cl atoms and isolated B(OH)₄ tetrahedra (DAN SSSR 252:611(1980)). Faint pinkish brown, transparent; 1–2 mm grains; vitreous luster, pearly on (110) cleavage planes; perfect {110} cleavage; H = 6; G = 2.5; IR data (DAN SSSR ESS 252:131(1982)); does not decompose in cold H₂O or 10% HCl. When heated to 600°C, the mineral becomes semitransparent and the R.I. decreases but XRD pattern is about the same. Uniaxial (+); N_o ≈ N_c = 1.525; colorless, birefringence = < 0.001. Occurs on *Mount Rasvumchorr, Khibiny Massif, Kola Peninsula, Russia* in veins of rischorrite pegmatite associated with pectolite which forms 2–5 mm thick rims around circular segregations of lomonosovite. May have formed as a result of reaction of eudialyte and zirsinalite with hydrothermal solutions. In a lovozerite-rich pegmatite.

77.2.8.1 Verplanckite Ba₁₂(Mn²⁺Ti,Fe²⁺)₆(OH,O)₂[Si₄O₁₂]₃Cl₉(OH,H₂O)₇

Named in 1965 by Alfors et al. for William E. VerPlanck (1916–1963) American geologist, California Division of Mines & Geology. HEX P6/*mmm*. *a* = 16.398A, *c* = 7.200, Z = 1, D = 3.46 or 3.33; PD 18-175 (nat.): 13.8₇ 5.39₅ 3.95₁₀ 3.58₃ 2.97₇ 2.86₃ 2.74₇ 2.65₃. Structure: AM 58:1103(1973) and AC 29:2019(1973). R = 10%. Brownish orange, brownish yellow; streak pale orange; elongate parallel to *c*, radial masses of prismatic crystals to 3 mm long, also as disseminated grains in sanbornite-qtz rock, dominant forms are {1010} and {1120}; vitreous; cleavage = 1 good on (1120) plus a poor cleavage or fracture parallel to (0001); H = 2½–3; G = 3.52; IR data (MZ 1:3(1979)); no fluorescence; completely but slowly soluble in dil. HCl, quickly bleached and the white or transparent fragments are dissolved. Reacts the same in other acids, but the bleached fragments do not dissolve completely; no change in NaOH. Uniaxial (–); N_o = 1.683, N_c = 1.672; pleochroic with N_o = orange-yellow, and N_c = colorless; length fast. Occurs at or near the fringes of large granitic intrusives – metasomatic rocks; in metasediments surrounded by late Jurassic biotite-quartz diorite. *Esquire no. 7 mine, Big Creek and Rush Creek, Fresno Co., CA. Minerali 3(2):41(1981); AM 69:358(1984).*

Unclassified Silicates

78.1.1.1 Cebollite $\text{Ca}_5\text{Al}_2(\text{SiO}_4)_3(\text{OH})_4$

Named in 1914 by Larsen and Schaller for the locality. Probably ORTH Space group unknown. *PD*: 3.29₈ 3.08₉ 2.90₁₀ 2.73₅ 2.58₅ 2.28₆ 1.753₇ 1.464₆. Structural data, composition, and classification uncertain. Fibrous masses. Colorless, white to reddish brown; vitreous luster; translucent. $H = 5$. $G = 2.96$. Biaxial (+); $2V = 58^\circ$; $N_x = 1.595$, $N_y = 1.60$, $N_z = 1.628$; parallel extinction, length-slow. Formed by deuteric alteration of melilite, with natrolite as an alteration of plagioclase-rich xenoliths and as a late-stage primary mineral in kimberlites. Found at *Iron Hill, Cebolla Creek, Gunnison Co., CO*; at Scawt Hill, County Antrim, Northern Ireland; in kimberlites at Letseng-La-Terai, Lesotho, and at the DeBeers mine, Kimberley, Cape Prov., South Africa. *AR DT:607(1932)*, *MM 43:583(1980)*.

78.1.2.1 Chantalite $\text{CaAl}_2(\text{SiO}_4)(\text{OH})_4$

Named in 1977 by Sarp et al. for Chantal Sarp (b.1944), Swiss wife of its discoverer, Halil Sarp. *TET* $I4_1/a$. $a = 4.952$, $c = 23.275$, $Z = 4$, $D = 2.97$. *29-1410*: 5.81₂ 4.83₄ 4.17₇ 3.35₆ 2.60₁₀ 2.24₅ 2.20₃ 1.453₆. Structure: *ZK 150:53(1950)*. Colorless to white, vitreous luster. $G = 2.8-2.9$. Uniaxial (-); $N_0 = 1.653$, $N_E = 1.642$. Found as anhedral, 0.1- to 0.3-mm grains with vuagnatite, prehnite, hydrogrossular, chlorite, and calcite in rodingitic dikes of the ophiolite zone at *Doganbaba, Burdur, Taurus Mts., southwestern Turkey*. *AR SMPM 57:149(1977)*, *MA 78:3469(1978)*.

78.1.3.1 Cymrite $\text{BaAl}_2\text{Si}_2\text{O}_8 \cdot \text{H}_2\text{O}$

Described and named in 1949 for Cymru, the old Welsh name for Wales. *MON* (pseudo-*HEX*) $P2_1$. $a = 5.33-5.35$, $b = 36.6-37.0$, $c = 7.67-7.71$, $\beta = 90.0^\circ$, $Z = 8$, $D = 3.45$. *CA 97:58727(1982)*, *K 20:280(1975)*. *PD*(nat, *PDF 17-507*): 7.71₅ 3.96₉ 2.96₁₀ 2.67₇ 2.24₄ 2.21₄ 1.925₃ 1.85₄; *PD*(syn): 3.96₁₀ 2.95₄ 2.67₇ 2.31₂ 2.24₃ 2.19₂ 1.92₂ 1.59₂. Platy, with {001} dominant; {010}, {100}, {140}, and {120} also present. Often twinned. Structure: *K 20:280(1975)*, *CA 97:58727(1982)*. As much as 2 mm across. Usually white, but may be colorless, green, or brown; satiny-vitreous luster. Cleavage {001}, good; perpendicular to {001}, fair; irregular fracture. $H = 2-3$. $G = 3.41$. IR data: *MM 46:63(1982)*; *AM 49:158(1964)*. Slightly soluble in HCl and other acids.

Usually fairly pure with traces of Ti, Fe, Na, K present. Minor to trace amounts of Ca substitute for Ba. Uniaxial or biaxial (-); $2V = 0-5^\circ$; $N_x = 1.611$, $N_y = 1.619$, $N_z = 1.621$, $N_O = 1.619-1.622$, $N_E = 1.611-1.616$; positive elongation; colorless. Most occurrences of this mineral are in bedded manganese ore deposits that have undergone low- and medium-grade (amphibolite facies) metamorphic rocks, often as part of Ba-Mn mineralization and associated with other Ba silicates and Mn minerals. It is stable at high pressures. Alters by dehydration to celsian. $\text{Celsian} + \text{H}_2\text{O} = \text{cymrite}$. Occurs at Pacheco Pass, San Benito Co., CA; Bonanza Creek, Brooks Range, and Ruby Creek, Bornite, AK; Navarana Fjord, Greenland; Aberfeldy, Scotland; *Bennalt mine, Rhiw, Carnarvonshire, Scotland*; Ireland; Arrens, Långban, Värmland, Sweden; High Pyrenees, France; La Zarza, Huelva, Spain; Blazna Valley, Romania; Andros Island, Greece; Pribaikal, and Saureyskoye deposit, Polar Ural Mts., Russia; Shiromaru mine, Tokyo, and Omiya mine, Saitama Pref.; Sarusaka, Kagami, and Niro mines, Tosayamada, Kochi Pref., Shikoku, Japan; Kalahari manganese field, N of Shishen, Cape Prov., South Africa; northwestern Nelson, South Island, New Zealand. *EF MM 28:676(1949)*.

78.1.4.1 Dellaite $\text{Ca}_6\text{Si}_3\text{O}_{11}(\text{OH})_2$

Named in 1965 by Agrell for Della M. Roy (b.1926), Pennsylvania State University geochemist, who synthesized the phase. *TRIC P1*. $a = 6.815$, $b = 6.934$, $c = 12.882$, $\alpha = 90.67^\circ$, $\beta = 97.70^\circ$, $\gamma = 98.14^\circ$, $Z = 2$, $D = 2.97$. *29-376(syn)*: 6.90₂ 3.44₇ 3.35₂ 3.26₂ 3.07₅ 2.99₄ 2.82₃ 2.29₁₀. The natural phase is not well characterized. Structure: *AM 43:1009(1958)*. Found as minute elongated [100] grains twinned on {010}. Colorless, vitreous luster, transparent. Biaxial (-); $2V < 30^\circ$; $N_x = 1.650$, $N_y = 1.661$, $N_z = 1.664$; $Z' \wedge [100] = 20^\circ$; also $2V = 65^\circ$; $N_x = 1.650$, $N_y = 1.657$, $N_z = 1.660$. Found in late-stage veins cutting a metamorphic assemblage at *Kilchoan, Ardnamurchan, Scotland*. *AR MM 34:1(1965)*.

78.1.5.1 Jinshajiangite $(\text{Na,K})_5(\text{Ba,Ca})_4(\text{Fe,Mn})_{15}(\text{Ti,Fe}^{3+}\text{Nb,Zr})_8(\text{SiO}_4)_{15}(\text{F,O,OH})_{10}$

Named in 1982 for the locality. According to *CM 29:355(1991)*, the mineral is the Fe-dominant analog of perraultite (78.1.5.2). A recalculation of the formula yields $\text{Na}_2\text{KBaCa}(\text{Fe,Mn})_8\text{Ti}_4\text{Si}_8\text{O}_{32}(\text{OH,F,H}_2\text{O,OH})_6$. $\text{Mn}^{2+} \leftrightarrow \text{Fe}^{2+}$, and $2\text{Nb} \leftrightarrow 2\text{Ti} + \text{Ca}$ are the main substitutions. *MON C2/m, Cm, or C2*. $a = 10.732$, $b = 13.847$, $c = 20.817$, $\beta = 95.05^\circ$, $Z = 2$, $D = 3.56$. *35-722(nat)*: 10.2₇ 4.4₄ 3.44₁₀ 3.15₈ 2.85₇ 2.63₇ 2.57₈ 1.72₅. Thin tabular prismatic crystals to 2×20 mm, elongation [001]. Blackish red, brownish red, or golden red; light yellow streak; vitreous luster. Cleavage {010}, {100}, perfect. $H = 430$ kg/mm^2 . $G = 3.61$. Infrared, Mossbauer, DTA, and TGA data: *G(C) 1:458(1982)*. Analysis (wt %): SiO_2 , 27.10; TiO_2 , 15.90; $(\text{Zr,Hf})\text{O}_2$, 0.70; Fe_2O_3 , 1.64; Nb_2O_5 , 1.03; BaO , 9.80; FeO , 19.07; MnO , 12.93; CaO , 2.94; K_2O , 2.30; Na_2O , 3.15; F , 2.65; minor: Al_2O_3 , 0.36; Ln_2O_3 , 0.30; Ta_2O_5 , 0.07; SrO , 0.08; MgO , 0.28; H_2O^+ , 0.33; H_2O^- , 0.36. Biaxial (+); $c \wedge X$

= 13°; $N_x = 1.729$, $N_y = 1.802$, $N_z = 1.852$; $2V_{\text{rep}} = 72^\circ$, $2V_{\text{calc}} = (-)76^\circ$; $r < v$; pleochroic. X, light golden yellow; Y, brownish yellow; Z, brownish red. Occurs in an albite dike, associated with arfvedsonite and other alkalic minerals at a locality on the *Jinshajiang R., Sichuan Prov., China.* EF

78.1.5.2 Perraultite $\text{Na}_2\text{KBaMn}_8(\text{Ti,Nb})_4\text{Si}_8\text{O}_{32}(\text{OH})_5 \cdot 2\text{H}_2\text{O}$

Named in 1991 by Chao for Guy Perrault (b.1937) of the Ecole Polytechnique, Montreal. See jinshajiangite (78.1.5.1); these two minerals are probably analogs. MON $C2/m$, Cm , or $C2$. $a = 10.820$, $b = 13.843$, $c = 20.93$, $\beta = 95.09^\circ$, $Z = 4$ [*CM 29:355(1991)*], $D = 3.81$. $45\text{-}1346(\text{nat})$: 10.4_4 3.47_{10} 3.19_2 2.87_1 2.79_1 2.61_4 2.08_2 1.73_1 . Bound by $\{001\}$, $\{010\}$, $\{100\}$, and possibly $\{101\}$; elongate $[100]$, flattened on $\{010\}$, prismatic to tabular, wedge-shaped terminations; to 1 mm; "swallowtail" contact twins common, twin plane and contact plane = $\{001\}$; has a pronounced subcell with $A2/m$, $A2$, or Am . Has $a' = a/2$, $b' = b/2$, $c' = c$, $\beta' = \beta$, $Z = 1$. Orange-brown; vitreous, slightly waxy luster; transparent to translucent. Cleavage $\{001\}$, perfect; uneven to irregular fracture; very brittle. $H = 4$. $G = 3.71$. IR and TGA data: *CM 29:355(1991)*. Analysis (wt %): Na_2O , 3.52; K_2O , 2.68; MgO , 0.06; MnO , 31.14; FeO , 1.12; BaO , 8.88; Al_2O_3 , 0.03; SiO_2 , 27.32; TiO_2 , 9.44; ZrO_2 , 0.12; Nb_2O_5 , 13.35; H_2O , 3.49; F , 0.84; $\text{O} = \text{F}$, 0.35. Biaxial (-); $X = b$, $Z \wedge c = 9.6^\circ$ in acute angle β , $Y \wedge a = 19^\circ$ in obtuse angle β ; $\text{Na}(D)$: $N_x = 1.785$, $N_y = 1.81$, $N_z = 1.82$; $2V = 66^\circ$; $r \ll v$, strong; pleochroic. X, Y, light yellow; Z, dark orange-brown. Occurs at the *DeMix quarry, Mt. St.-Hilaire, QUE, Canada*; in pegmatite dikes with microcline, aegirine, albite, astrophyllite, analcime, rhodochrosite, catapleiite, natrolite, tetranatrolite, ancyllite-(Ce), pyrochlore, and kupletskite. EF *MR 21:284(1990)*.

78.1.6.1 Kurumsakite $(\text{Zn,Ni,Cu})_8\text{Al}_8\text{V}_2^{5+}\text{Si}_5\text{O}_{35} \cdot 27\text{H}_2\text{O}$

Named in 1954 by Ankinovich for the locality. An inadequately described mineral. Probably ORTH Space group unknown. $29\text{-}571(\text{nat})$: 4.91_{25} 3.91_{75} 2.61_5 2.42_1 2.28_4 1.99_1 1.53_{10} 1.42_{25} . *IANKSG 19:116(1954)*. Greenish to bright yellow, radiating fibrous to felted masses; vitreous-silky luster. $G = 4.03$. Biaxial (+); $N_x = 1.616$, $N_y = 1.617$, $N_z = 1.622\text{-}1.623$; $2V = 35^\circ$; birefringence = 0.006; parallel extinction; positive elongation. Analysis of type material [*AM 42:583(1957)*, *MA 13:207(1957)*] (wt %) SiO_2 , 13.82; Al_2O_3 , 20.51; Fe_2O_3 , 2.15; V_2O_5 , 8.50; ZnO , 17.55; CuO , 3.05; NiO , 7.33; MgO , 0.92; CaO , 1.24; H_2O , 23.25; SO_3 , 1.15. Found in fractures in bituminous schists. *Kurumsak, near Dzhabul, Karatau Mts., Kazakhstan.* EF

78.1.7.1 Plumbotsumite $\text{Pb}_5\text{Si}_4\text{O}_8(\text{OH})_{10}$

Named in 1982 for the composition and the locality. ORTH $C222_1$. $a = 15.875$, $b = 9.261$, $c = 29.364$, $Z = 10$, $D = 5.56$. $35\text{-}0858$: 14.7_7 7.99_6 4.63_5 3.65_{10} 3.12_8 2.47_7 1.633_6 1.476_6 . Thick tabular $\{001\}$; irregular skeletal grains up to 1 mm \times 1 mm \times 0.5 mm. Twinned. Cleavage $\{001\}$, perfect. Colorless, adamantine luster, transparent. $H \approx 2$. $G = 5.6$. Biaxial (-); $2V = 32^\circ$; $N_x = 1.922$,

$N_y = 1.933$, $N_z = 1.938$; XYZ = *cba*; $r > v$. On alamosite and encrusted by melanotekite at *Tsumeb mine, Namibia*. AR *CE* 41:1(1982); *AM* 67:1075(1982).

78.1.8.1 Poldervaartite $\text{Ca}(\text{Ca}_5\text{Mn}_5)[\text{SiO}_3(\text{OH})](\text{OH})$

Named in 1993 by Dai et al. for Arie Poldervaart (1918–1964), Professor of Petrology, Columbia University, New York City. ORTH *Pbca*. $a = 9.398$, $b = 9.139$, $c = 10.535$, $Z = 8$, $D = 2.90$. *PD*: 4.18₅ 3.23₁₀ 2.85₄ 2.79₄ 2.62₃ 2.58₈ 2.39₄ 2.04₃. Structurally akin to $\text{Ca}_2(\text{SiO}_3\text{OH})(\text{OH})$ found in cement materials. Wheat-sheaf groups to euhedral prismatic crystals with {110}, {100}, {010}, and {001}. Milky white rims with colorless cores; translucent-transparent (cores); subvitreous luster, vitreous on fracture. Very brittle. $H = 5$. $G = 2.91$. Deep red fluorescence in SWUV. Biaxial (+); $2V = 65^\circ$; $N_x = 1.634$, $N_y = 1.640$, $N_z = 1.656$; XYZ = *bac*; $r < v$, weak. Weakly pleochroic, $Z > Y > X$; colorless to bluish gray. Found in association with henritermierite and calcite, and coated with bultfonteinite and hematite in a pocket in massive braunite–hausmannite at the *Wessels mine, Kalahari manganese field, NW of Kuroman Hill, Cape Prov., South Africa*. AR *AM* 78:1082(1993).

78.1.9.1 Stringhamite $\text{CaCuSiO}_4 \cdot \text{H}_2\text{O}$

Named in 1976 by Hindman for Bronson F. Stringham (1907–1968), University of Utah. MON *P2₁/c*. $a = 5.030$, $b = 16.135$, $c = 5.343$, $\beta = 102.96^\circ$, $Z = 4$, $D = 3.359$. 29-318: 8.05₁ 4.88₂ 4.69₂ 3.93₃ 3.24₄ 2.77₁₀ 2.52₇ 1.614₂. Structure: *TMPM* 34:15(1985). Flattened, pseudorhombohedral (0.1 mm) with {011}, {101} dominant, {010}, and {111}. Deep azure blue, light blue streak, vitreous luster, translucent to transparent. Cleavage {001}, good; {100}, imperfect. Biaxial (+); $2V = 80^\circ$; $N_x = 1.709$, $N_y = 1.717$, $N_z = 1.729$. $X = b$, $Y \wedge c = 2.5^\circ$. Pleochroic in blues; $Z > Y > X$. Occurs with other secondary and primary copper minerals in diopside–magnetite skarn at *Bawana mine, near Milford, Beaver Co., UT*; at the Christmas mine, Hayden, Gila Co., and in Pinal Co., AZ; at the Crestmore quarry, Riverside, CA; and the El Bronce mine, Tierra Amarilla, Chile. AR *AM* 61:189(1976).

78.1.10.1 Vistepite $\text{Mn}_5\text{SnB}_2\text{Si}_5\text{O}_{20}$

Named in 1992 by Pautov et al. for Viktor Ivanovich Stepanov (1924–1988), Russian mineralogist and mineral collector. MON *P2/m*. $a = 28.77$, $b = 7.01$, $c = 13.72$, $\beta = 96.6^\circ$, $Z = 7$, $D = 3.70$. *PD*(nat): 6.82₄ 3.41₈ 3.22₈ 2.83₁₀ 2.81₁₀ 2.24₇ 1.75₆ 1.70₅. Structure not done. Radial aggregates to 15 mm, elongated on *b*; polysynthetic twinning parallel to elongation. Orange-yellow, vitreous luster, transparent. Three perfect cleavages, brittle. $H = 4\frac{1}{2}$. $G = 3.67$. IR and DTA data: *ZVMO* 121:107(1992). Nonfluorescent. Traces of Al, Ca, Fe as well. Biaxial (-); $N_x = 1.696$, $N_y = 1.711$, $N_z = 1.715$; $2V = 57^\circ$; nonpleochroic; OAP perpendicular to length; $r > v$, strong. Occurs in a rhodonite (plus quartz and galena) in biotite–quartz-bearing hornfels at the exocontact

of the Inylchek Sn-bearing granite massif, at the northern end of the Inylchek Range, Kirgizia. EF

78.2.1.1 Ganomalite $\text{Ca}_5\text{Pb}_9\text{MnSi}_6\text{O}_{33}$

Named in 1876 by Nordenskiöld from the Greek *ganoma*, luster, in allusion to its vitreous to resinous appearance. HEX *P3*. $a = 9.82$, $c = 10.13$, $Z = 1$, $D = 5.69$. 25-150: 4.92₇ 4.43₇ 3.53₉ 3.38₈ 3.06₁₀ 2.71₇ 1.985₇ 1.797₇. The empirical $[\text{Si}_9\text{O}_{33}]$ silicate unit can be rendered as $[(\text{SiO}_4)_3(\text{Si}_2\text{O}_7)_3]$. Originally described as tetragonal. If the space group is given correctly, Mn must play the same role as Ca. Simple tabular crystals bounded by the prism $\{1010\}$; usually granular, massive or in curved plates. Colorless, white, gray; resinous to vitreous luster, somewhat pearly on plates; transparent to translucent. Cleavage $\{1010\}$, perfect; $\{0001\}$, less so. $H = 3$. $G = 5.74$. Uniaxial (+); $N_O = 1.910$, $N_E = 1.945$; or biaxial (+); 2V small. Easily fusible; gelatinized by HNO_3 . Previously interpreted as the hydroxyl analog of nasonite. Found in tabular, colorless crystals at Franklin, Sussex Co., NJ; crystals of uncertain habit and massive at the Långban mine, Varmland, and at the Jakobsberg mine, N of Nordmarken, Sweden. AR *D6:422(1892)*, *MR 10:47(1979)*, *MM 49:579(1985)*.

78.3.1.1 Mathewrogersite $\text{Pb}_7(\text{Fe}^{2+}, \text{Cu}^{2+})\text{Al}_1\text{GeSi}_{12}\text{O}_{36}(\text{OH}, \text{H}_2\text{O})_6$

Named in 1986 by Keller and Dunn in honor of Mathew Rogers, first European prospector at Tsumeb, Namibia. HEX-R *R3*, *R $\bar{3}$* , *R32*, *R3/m*, or *R32/m*. $a = 8.457$, $c = 45.970$, $Z = 3$, $D = 4.68$. 40-476: 15.3₇ 7.68₆ 4.08₅ 3.26₁₀ 2.86₅ 2.77₆ 2.03₇ 1.762₆. Colorless, white, to pale greenish yellow; pearly luster; translucent. $H = 2$. $G = 4.7$. Uniaxial (-); $N_O = 1.810$, $N_E = 1.745$. The composition is close to that of the formula. Found at Tsumeb, Namibia, associated with queitite, alamosite, melanotekite, kegelite, schaurteite, etc. in corroded Pb-Zn ores of the lower oxidation zone. AR *AM 72:1025(1987)*.

78.3.2.1 Shafranovskite $(\text{Na}, \text{K})_6(\text{Mn}, \text{Fe})_3\text{Si}_6\text{O}_{24} \cdot 6\text{H}_2\text{O}$

Named in 1982 by Khomyakov et al. for Ilarion Ilarionovich Shafranovskii (b.1907), professor of mineralogy and crystallography, Leningrad Mining Institute. HEX *P3m1* or *P31m*. $a = 14.58$, $c = 21.01$, $Z = 6$, $D = 2.78$. 37-453: 10.8₃ 10.5₁₀ 3.60₄ 3.51₇ 3.16₃ 2.98₅ 2.79₆ 2.67₃. Dark green, olive-green, yellow-green; vitreous luster. $H = 2-3$ (for grain aggregate). Uniaxial (-); $N_O = 1.587$, $N_E = 1.570$. Decomposed by dilute HCl; reacts with H_2O to give alkaline solution. Found as granular aggregates associated with thermnatrite, nacaphite, olympite, sidorenkite, and rasvumite in alkalic pegmatite at several localities in the Lovozero massif, and at Mt. Rasvumchorr, Khibiny massif, Kola Penin., Russia. AR *ZVMO 111:475(1982)*, *AM 68:644(1983)*.

78.3.3.1 Zakharovite $\text{Na}_4\text{Mn}_2^{2+}\text{Si}_{10}\text{O}_{24}(\text{OH})_6 \cdot 6\text{H}_2\text{O}$

Named in 1982 by Khomyakov et al. for E. E. Zakharov (1902-1980), director of the Moscow Geological Exploration Institute. HEX *P31m*. $a = 14.58$,

$c = 37.71$, $Z = 9$, $D = 2.67$. *39-405*: 12.6₁₀ 3.99₁ 3.43₁ 3.16₄ 3.06₁ 2.82₁ 2.63₁ 2.39₁. Yellowish to bright yellow, pearly to waxy luster. Cleavage {0001}, perfect; conchoidal fracture. $H = 2$. $G = 2.58$, 2.64. Uniaxial (-); $N_O = 1.565$, $N_E = 1.535$. Found as platy aggregates with ussingite in veinlets cutting foyaite at *Mt. Karnarsut, Lovozero massif, and in the Yukspor and Koashva Mts., Khibiny massif, Kola Penin., Russia*, the several localities reported simultaneously. *AR ZVMO 111:491(1982)*, *AM 68:1040(1983)*.

78.4.1.1 Apachite $Cu_9Si_{10}O_{29} \cdot H_2O$

Named in 1980 by Cesbron and Williams for the Apache Indians, whose reservation is near the locality. Probably *MON* Space group unknown. $a = 12.89$, $b = 6.055$, $c = 19.11$, $\beta = 90.42^\circ$, $Z = 2$, $D = 3.27$. *35-467*: 12.9₁₀ 10.6₄ 9.56₄ 7.66₅ 4.49₄ 4.17₄ 3.17₇ 2.89₄. Blue, translucent. $H = 2$. $G = 2.80$ (in poor agreement with D). Biaxial (-); $2V \approx 15^\circ$; $N_x = 1.610$, $N_y \approx N_z = 1.650$; Y approximately parallel to elongation. Spherules of radiating fibers associated with gilalite, kinoite, and apophyllite in a garnet diopside tactite zone at the *Christmas mine, Gila Co., AZ*. *AR MM 43:639(1980)*, *AM 65:1065(1980)*.

78.4.2.1 Ashburtonite $HPb_4Cu_4Si_4O_{12}(HCO_3)_4(OH)_4Cl$

Named in 1991 for the locality. *TET I4/m*. $a = 14.234$, $c = 6.103$, $Z = 2$, $D = 4.69$. *PD*: 10.2₁₀ 5.64₇ 4.50₁₀ 3.33₁₀ 3.01₉ 2.81₃ 2.61₅ 2.01₃. Prismatic, elongated on [001] with {110}, {100}, {001}, and {301} present. $30 \times 400 \mu m$, in aggregates to 20 mm in diameter. Blue, pale blue streak, vitreous luster, transparent. No cleavage, conchoidal fracture, very brittle. $G > 4.09$. *IR data: AM 76:1701(1991)*. The mineral reacts in index liquids > 1.785 , leaving an opaque residue. Decomposes rapidly in concentrated HCl, slowly in 0.2 M HCl, 1:1 HNO₃, and concentrated H₂SO₄. Uniaxial (+); $N_O = 1.786$, $N_E = 1.800$ (sodium light). In a secondary Pb-Cu mineral assemblage in a weathered shear zone that cuts a series of shales and greywackes. *Anticline prospect, Ashburton Downs, WA, Australia*. *EF AM 76:1701 (1991)*.

78.4.3.1 Fukalite $Ca_4Si_2O_6CO_3(OH,F)_2$

Named in 1977 for the locality. *ORTH* Space group unknown. $a = 5.48$, $b = 3.78$, $c = 23.42$, $Z = 2$, $D = 2.78$. *29-308(nat)*: 5.86₃ 3.90₂ 3.60₂ 3.08₉ 2.93₇ 2.85₁₀ 2.34₃ 1.76₃. Crystals to 0.2 mm long. Light brown, white, translucent. Analysis (wt %): SiO₂, 20.1; Al₂O₃, 0.55; CaO, 54.4; H₂O⁺, 4.4; CO₂, 10.3; minor Fe₂O₃, 0.1; MgO, 0.14; Na₂O, 0.17; K₂O, 0.01; H₂O⁻, 0.23; P₂O₅, 0.01; F, 0.32. H of aggregate is ≈ 4 . $G = 2.77$. Biaxial (\pm); $N_x = 1.595$, $N_y = 1.605$, $N_z = 1.626$; colorless, $2V = 90^\circ$; negative elongation. Occurs as an alteration product of spurrite, and is associated with calcite \pm xonotlite. In spurrite-gehlenite skarns. *Bicchu, Fuka, Okayama Pref., Mihara, Okayama Pref., and Kushiro, Hiroshima Pref., Japan*; Cerro Mazahua, Zitacuaro, MICH, Mexico. *EF MJJ 8:374(1977)*.

78.4.4.1 Gilalite $\text{Cu}_5\text{Si}_6\text{O}_{17} \cdot 7\text{H}_2\text{O}$

Named in 1980 by Cesbron and Williams for the locality. MON $a = 13.38$, $b = 19.16$, $c = 9.026$, $\beta = 90^\circ$, $Z = 4$, $D = 2.54$. 35-468: 13.4₁₀ 11.0₃ 7.79₅ 6.68₃ 4.79₅ 3.90₄ 3.32₃ 3.15₃. Green to blue-green, translucent. $H = 2$. $G = 2.82$ (in poor agreement with D). Biaxial (-); 2V small; $N_x = 1.560$, $N_y \approx N_z = 1.635$. Found abundantly as spherules of radiating fibers (0.2 mm) with apachite, kinoite, and apophyllite in a garnet-diopside tactite zone at the *Christmas mine, Gila Co., AZ*. AR MM 43:639(1980).

78.4.5.1 Grumantite $\text{NaHSi}_2\text{O}_5 \cdot \text{H}_2\text{O}$

Named in 1987 by Khomyakov et al. from the old Russian name for the Spitzbergen Archipelago, Arctic Ocean. ORTH *Fdd2*. $a = 15.979$, $b = 18.25$, $c = 7.16$, $Z = 16$, $D = 2.264$. 41-1331: 6.20₅ 6.05₅ 4.46₅ 3.51₁₀ 3.35₂ 3.09₅ 3.01₁₀ 2.23₂. The poorly described structure is stated to have four-tetrahedron spiral chains parallel to [001], suggesting that the formula be rendered as $\text{Na}_2[\text{Si}_4\text{O}_6](\text{OH})_6$. White, silky to vitreous luster, translucent. Cleavage {110}, perfect. $H = 4\frac{1}{2}$. $G = 2.21$. Biaxial (+); 2V = 85°; $N_x = 1.494$, $N_y = 1.507$, $N_z = 1.523$; XYZ = acb; $r > v$, weak. Weak, blue-white fluorescence in UV. Found as fine-grained compact to porous veins with ussingite margins, and as 2- to 5-mm irregular crystals replacing makatite in veins containing kazakovite, tisinalite, nordite, and sodalite at *Mt. Alluaiev, Lovozero massif, Kola Penin., Russia*. AR ZVMO 116:244(1987), AM 73:440(1988), ZK 185:612(1988).

78.5.1.1 Ajoite $(\text{K},\text{Na})\text{Cu}_7\text{AlSi}_9\text{O}_{24}[\text{OH}]_6 \cdot 3\text{H}_2\text{O}$

Named in 1958 for the locality. TRIC *P1* or *P1*. AM 66:201(1981). $a = 13.637$, $b = 14.507$, $c = 13.620$, $\alpha = 107.45^\circ$, $\beta = 105.45^\circ$, $\gamma = 110.57^\circ$, $Z = 3$. Also reported as MON *P2₁/m* or *P2₁*. $a = 15.218$, $b = 24.712$, $c = 13.632$, $\beta = 92.91^\circ$ [MJJ 8:234(1976)], but $Z = 7$, which is unlikely; $D = 2.951$. 35-0477(nat): 12.3₁₀ 4.08₁ 3.38₁ 3.06₁ 2.52₁ 2.46₁ 2.26₁. Laths, plates or massive; bladed 0.01 mm × 0.1 mm × 0.4 mm elongated on c , flattened on (010); dominant form is {010}; {110} and {100} much less prominent. Bluish green, translucent. Cleavage {010} for triclinic cell. $G = 2.96$. TGA data: AM 66:201(1981). Readily decomposed by acids such as HCl and HNO₃, leaving a coherent white mass of hydrated silica; no reaction in NH₄OH. Contains minor MnO, FeO, CaO. Biaxial (+); $X = b$, $Z \wedge c = 15^\circ$; $N_x = 1.550$ (Na light), 1.565, $N_y = 1.583$ (Na light), 1.590, $N_z = 1.641$ (Na light), 1.650; 2V = 68–80°. X, very light bluish green; Y, Z, brilliant bluish green. Occurs in massive fracture coatings, vein fillings, and in vugs, associated with shattuckite, quartz, sericite, pyrite, and others. Alteration: may form from shattuckite and also is replaced by shattuckite. Occurs at the *New Cornelia mine, Ajo, Pima Co., AZ*; fine specimens also as inclusions in quartz crystals in the Messina mining district, South Africa. EF AM 43:1107(1958); MR 14:283(1983), 22:187(1991).

78.5.2.1 Bementite $Mn_5^{2+}Si_6O_{15}(OH)_{10}$ (?)

Named in 1887 by Koenig for Clarence Sweet Bement (1843–1923), manufacturer of machine tools and a collector of minerals, Philadelphia, PA. Possibly related to and confused with caryopilite. **MON** Space group unknown. $a = 7.5$, $b = 9.8$, $c = 5.65$, $Z = 1$ (?), but also reported as **ORTH** $P2_12_12_1$. $a = 14.5$, $b = 17.5$, $c = 29.1$, $Z = 18$ (?), $D = 3.06$. *25-546*: 7.25₉ 3.66₁₀ 3.58₉ 3.43₁ 3.30₅ 2.44₁ 2.11₁ 2.10₁. Structure not determined but suggested to be related to serpentine or friedelite. (Calculated Z for an assumed $G \approx 3.0$ and using any of the various formulations, does not agree well with the values reported above. **AR**). Fibrous to lamellar, in radiating or stellate masses; granular, massive. Gray, pale yellow to brown, darkening on exposure to light; waxy luster, pearly on cleavage; translucent. Cleavage {001}, perfect; {100}, {010}, less so. $H = 4-6$ (?), also reported as soft. $G = 2.9-3.1$. Uniaxial (–) or biaxial (–); $2V \approx 0^\circ$; $N_x = 1.602, 1.624$, $N_y = N_z = 1.632, 1.650$; $X = c$. Weakly pleochroic. X , colorless; Y, Z , pale yellow. The composition has been variously formulated as $Mn_8Si_7O_{17}(OH)_{10}$, $Mn_8Si_6O_{15}(OH)_{10}$, and $Mn_5Si_4O_{10}(OH)_6$. Minor Mg, Zn, and Fe^{2+} are present. Found at *Franklin, Sussex Co., NJ*; at various localities in CA; the Olympic Mts., WA; at Pajsberg, Värmland, Sweden (caryopilite?); and at Broken Hill, NSW, Australia. **AR** *D6:704(1892)*, *DT:685(1932)*, *AM 56:416(1971)*.

78.5.3.1 Burckhardtite $Pb_2(Fe^{3+}, Mn^{3+})Te^{4+}(AlSi_3O_{10})O_2(OH)_2 \cdot H_2O$

Named in 1979 by Gaines et al. for Carlos (Carl) Burckhardt (1869–1935), Swiss geologist working in Mexico. **MON** (pseudo-**HEX**) Cm or $C2/m$. $a = 5.21$, $b = 9.04$, $c = 12.85$, $\beta = 90^\circ$, $Z = 2$, $D = 4.96$. *33-0730*: 12.8₉ 3.78₉ 3.11₁₀ 2.60₇ 2.26₃ 2.24₃ 1.840₆ 1.590₅. Pseudohexagonal tabular {001} crystals. Violet-red to pale pink, pale red streak, adamantine/pearly luster. Cleavage {001}, perfect. $H \approx 2$. $G = 3.2$ for impure sample. Biaxial (–); $2V \approx 0^\circ$; $N_x = 1.82$, $N_y \approx N_z = 1.85$; $X = c$ Pleochroic; X , pale magenta; Y, Z , carmine. A secondary mineral intergrown with dickite and often with cores of the latter. *Moctezuma mine, Moctezuma, SON, Mexico*, often accompanied by moctezumite. **AR** *AM 64:355(1979)*.

78.5.4.1 Canasite $K_3Na_2Ca_4(Na,Ca)_2[Si_{12}O_{30}]F(OH)_3$ (mon) and $K_3NaCa(Na,Ca)_6[Si_{12}O_{30}]F_3(OH) \cdot H_2O$ (tric)

Described in 1959 by Dorfman et al. and named for the composition: Ca–Na–Si. **MON** $C2/m$. $a = 18.836$, $b = 7.244$, $c = 12.636$, $\beta = 111.76^\circ$, $Z = 2$, $D = 2.67$. **TRIC** $P1$. $a = 10.094$, $b = 12.691$, $c = 7.240$, $\alpha = 90.0^\circ$, $\beta = 111.02^\circ$, $\gamma = 110.2^\circ$, $Z = 1$, $D = 2.69$. *13-553(mon)*: 4.81₆ 4.69₇ 4.27₄ 4.20₅ 3.08₁₀ 2.91₈ 2.36₆ 1.64₈; *45-1398* and *MZ 14:71(1992)* (tric): 8.74₄ 4.70₅ 4.21₄ 3.08₂ 3.01₂₅ 2.92₁₀ 2.35₃ 2.31₂. Additional powder data in *ZVMO 123:104(1994)*. Structure done three times on Khibiny material. A threefold increase in F in triclinic canasite is accompanied by changes in ordering of Ca and Na. *MZ 14:71(1992)*. Subhedral to anhedral grains to 3 cm or more across. Polysynthetic twinning; twin

plane is at an angle of 8° to (100). Greenish yellow, gray, lilac-gray, greenish brown; triclinic material is lilac-gray, blue-gray, rarely greenish; white streak; vitreous luster. Cleavage (mon) (001), excellent; (100), perfect; (tric) (010), excellent; (100), perfect; 118° between cleavages. Splintery fracture, brittle. $G = 2.68\text{--}2.71$. IR and thermal data: *ZVMO 123:104(1994)*. Variations in chemistry cause a variation in symmetry. Contains minor Al_2O_3 (to 0.6 wt %), Fe_2O_3 (to 1.1 wt %), MnO (to 0.5 wt %), and MgO (to 0.4 wt %). Biaxial (-) or (+); (mon): $Y = b$; $N_x = 1.533\text{--}1.534$, $N_y = 1.538\text{--}1.539$, $N_z = 1.541\text{--}1.543$; $2V_x = 58^\circ$; (tric): $X \wedge a = 34^\circ$, $Y = c$, $Z \wedge b = 5^\circ$; $N_x = 1.536$, $N_y = 1.539$, $N_z = 1.542$; $2V_z = 65\text{--}76^\circ$, colorless. Occurs in alkalic pegmatites with fenaksite and lamprophyllite (Khibiny massif), in the Lilac Stone deposit of charoitite rocks, associated with tinaksite, charoite, and aegirine, in the alkalic Murun massif (Yakutia). Several generations of canasite occur. *Khibiny massif, Kola Penin., Russia*; Murun massif, Chary R., southern Yakutia (now Sakha Republic). *EF TMMAN 9:158(1959)*, *MIN 3(3):376(1981)*, *L&L:32-36(1981)*.

78.5.5.1 Erlianite $(\text{Fe}^{2+}, \text{Mg})_4(\text{Fe}^{3+}, \text{V}^{3+})_2[\text{Si}_6\text{O}_{15}](\text{O}, \text{OH})_8$

Named in 1986 by Feng and Yang for the locality. ORTH $Pm2_1n$ or $Pmnm$. $a = 23.2$, $b = 9.2$, $c = 13.2$, $Z = 6$, $D = 3.11$. *PD: 11.5*₁₀ *3.05*₅ *2.89*₆ *2.61*₆ *2.52*₅ *2.42*₃ *2.31*₃ *1.56*₅. Black, brown streak, silky luster, nearly opaque. Cleavage {001}, {100}, perfect. $H = 3\frac{1}{2}\text{--}4$. $G = 3.11$. Biaxial (-); $2V = 56\text{--}59^\circ$; $N_x = 1.667$, $N_y = 1.674$, $N_z = 1.679$. Occurs as 1- to 2-cm lathlike aggregates of fibrous to platy crystals associated with quartz, magnetite, siderite, albite, stilpnomelane, minnesotaite, and deerite at the *Harhada iron deposit, near the Jining-Erlian railway, Inner Mongolia, China*. *AR MM 50:285(1986)*.

78.5.6.1 Karpinskite $(\text{Mg}, \text{Ni})_2\text{Si}_2\text{O}_5(\text{OH})_2$ (?)

Named in 1956 by Rukavishnikova for Alexander Petrovich Karpinsky (1846-1936), Russian geologist and president of the Russian Academy of Sciences. An inadequately described mineral. Probably MON Space group unknown. *42-1313(nat): 11.0*₁₀ *7.71*₄ *4.76*₄ *3.75*₄ *3.32*₂ *2.72*₂ *2.55*₃ *1.555*₄. *KV 2:124(1956)*. Apparently an 11-Å phyllosilicate. DTA has been reported. *AM 42:584(1957)*. Fine-grained veinlets to massive, microscopic plates or prisms (to 0.8 mm long). Greenish blue or blue to white, dull to greasy luster. Trace cleavage parallel to c . $H = 2\frac{1}{2}\text{--}3$. $G = 2.53\text{--}2.63$. Visually similar to nepouite, dyed deep blue by benzadine. Biaxial (-); $Z \wedge c = 12^\circ$, $0\text{--}12^\circ$ (second data set for nickeloan material with $\text{NiO} = 28.07$ wt %); $N_x = 1.553$, 1.570 , $N_z = 1.569$, 1.594 ; birefringence = 0.016, 0.024; nonpleochroic; positive elongation. Analysis of type material (wt %): SiO_2 , 47.55; Al_2O_3 , 0.48; MgO , 17.56; NiO , 21.12 (also 28.07); CaO , 0.80; CuO , 0.01; H_2O^- , 3.50; H_2O^+ , 6.50; LOI, 2.30. Found in veinlets in kerolitized serpentinite from the *Nizhne Tagilsk massif, Ural Mts., Russia*.

78.5.7.1 Molybdophyllite $\text{Pb}_9\text{Mg}_9\text{Si}_9\text{O}_{24}(\text{OH})_{24}$ (14 Å) or $\text{Pb}_3\text{Mg}_2\text{Si}_2\text{O}_7(\text{OH})_4$ (18 Å)

Named in 1901 by Flink from the Greek for *lead* and *leaf*, in allusion to its composition and foliated habit. There are two structural forms of the mineral: 14 Å and 18 Å. *HEX* *P6₃22*. (14 Å): $a = 9.371$, $c = 27.44$, $Z = 2$, $D = 4.98$. (18 Å): $a = 9.34$, $c = 36.79$, $Z = 10$, $D = 5.41$. *42-1384* (14 Å, nat): 14.2₈ 8.16₄ 4.69₄ 3.07₆ 2.70₇ 2.68₇ 2.41₇ 1.77₁₀; *42-1385* (18 Å): 18.6₁₀ 4.32₆ 4.18₆ 4.05₆ 3.29₆ 3.07₇ 2.70₉ 2.34₆. No structural information available. Irregular foliated masses. Light green, pale yellow to colorless; white streak; pearly luster; vitreous luster; transparent. Perfect basal cleavage. $H = 3-4$. $G = 4.72$. Analysis (wt %), 14 Å: SiO₂, 18.25; Al₂O₃, 0.32; MgO, 11.94; MnO, 0.18; CaO, 0.01; PbO, 59.47; BaO, 0.25; 18 Å: SiO₂, 12.4; Al₂O₃, 0.35; MgO, 7.98; MnO, 0.03; CaO, 0.01; PbO, 70.9; BaO, 0.13; Cl, 0.07; F, 0.05. Uniaxial (-); $N_O = 1.815$, $N_E = 1.761$. Occurs with calcite and hausmannite at *Langban, Filipstad, Värmland, Sweden*. G. Charalampides, Ph.D. thesis, Dept. Geology, Stockholm Univ., Sweden, 1988. *EF*

78.5.8.1 Raite $(\text{Na,Ca})_4(\text{Mn,Ti,Fe})_3\text{Si}_6(\text{O,OH})_{24} \cdot 9\text{H}_2\text{O}$

Named in 1973 by Me'kov et al. for the participants in the 1969-1990 voyage of the papyrus ship *RA* under the leadership of Thor Hyerdahl. *ORTH C222*. $a = 30.6$, $b = 5.31$, $c = 18.20$, $Z = 4$, $D = 2.32$. *25-1318*: 11.4₁₀ 4.50₈ 2.94₁₀ 2.65₁₀ 2.48₆ 1.640₆ 1.575₆ 1.514₆. Red, reddish brown, brown, gold. Cleavage {100}, {010}, {001}, perfect. $H = 3$. $G = 2.39$. Biaxial (+); $2V = 53^\circ$; $N_x = 1.540$, $N_y = 1.542$, $N_z = 1.550$; $Z = c$. Pleochroic; $Z > Y > X$; golden brown to colorless. Occurs as radiating fiber aggregates. Rare in pegmatite with rhodochrosite, serandite, nenadkevichite, natrolite, etc., and in sodalite xenoliths with villiauminite, eudialite, serandite, ussingite, steenstrupine, vuonnemite, and lovozerite at *Mt. St.-Hilaire, QUE, Canada*. Found in alkali syenite pegmatite of the Lovozero massif with zorite, aegerine, mountainite, and natrolite at *Mt. Karnarsut, Kola Penin., Russia*. *AR ZVMO 102:54(1973)*, *ZM 58:1113(1973)*, *MR 10:99(1979)*.

78.5.9.1 Tungusite $\text{Ca}_4\text{Fe}_2\text{Si}_6\text{O}_{15}(\text{OH})_6$

Named in 1966 by Kudryasheva for the locality. An inadequately described mineral. System and space group unknown. *19-231*: 4.17₈ 3.58₆ 3.12₈ 3.01₈ 2.79₂ 1.818₁₀ 1.605₃ 1.570₃. Yellow-green to grass-green, somewhat pearly luster. Separable into very fine, elastic platelets. $H \approx 2$. $G = 2.59$. Uniaxial (-) or biaxial (-); $2V = 0^\circ$; $N_O(?) = 1.586$. Found as plates up to 0.5 cm, forming crusts of radiating structure, associated with analcime, apophyllite, gyrolite, "zeolites," calcite, and quartz on the walls of amygdules in lava from the *right bank of the Tunguska R., 2 km above Tura, Siberia, Russia*. *AR AM 52:927(1967)*.

78.6.1.1 Hyalotekite

Named in 1877 by Nordenskiöld from the Greek for *glass* and *to melt*, in allusion to its easy fusion to a clear glass. TRIC *I1*. $a = 11.310$, $b = 10.995$, $c = 10.317$, $\alpha = 90.43^\circ$, $\beta = 90.02^\circ$, $\gamma = 90.16^\circ$, $Z = 2$, $D = 3.829$. 19-572: 7.70₆ 4.32₅ 3.81₇ 3.53₈ 3.45₁₀ 2.94₈ 2.30₆ 2.14₆. Structure: *AM 67:1012(1982)*. The structure is an incomplete tetrahedral framework related to layer-structured gillespite. White to gray, vitreous luster, translucent. Two cleavages at $\approx 90^\circ$, brittle. $H = 5 - 5\frac{1}{2}$. $G = 3.80 - 3.82$. Biaxial (+); $2V = 15^\circ$; $N_x = 1.963$, $N_y = 1.963$, $N_z = 1.966$; OAP perpendicular to cleavage zone axis; $r < v$, strong. Easily fusible. Insoluble in acids. Found as coarsely crystalline masses associated with barylite at *Långban mine, near Filipstad, Värmland, Sweden*, and in the Dara-i-Pioz massif, Alai Range, Tajikistan. *D6 422(1892)*, *MM 58:285(1994)*.

78.6.2.1 Lovdarite $K_2Na_6[Be_4Si_{14}O_{36}] \cdot 9H_2O$

Named in 1973 by Men'shikov et al. from the Russian for *gift of Lovozero*. ORTH *Pma2* (also reported as *P2₁2₁2₁*, and as *P2₁22* with doubled *a* axis). $a = 39.576$, $b = 6.931$, $c = 7.153$, $Z = 2$, $D = 2.34$. 12-1305: 6.56₆ 4.96₉ 3.52₄ 3.29₁₀ 3.14₁₀ 2.48₆ 2.29₆ 1.785₅. Structure: *EJM 2:809(1990)*. The structure is a three-dimensional framework of Be and Si tetrahedra with the beryllium ordered; the framework is unusual in that it contains 5-tetrahedron components consisting of 3-membered rings sharing a common tetrahedron to form a 5-tetrahedron element. Colorless, white to yellowish; vitreous luster; translucent. Cleavage {100}, {010}, {001}, distinct; {110}, poor. $H = 5 - 6$. $G = 2.33$. Biaxial (+, -); $2V \approx 90^\circ$; $N_x = 1.513$, $N_y = 1.515 - 1.516$, $N_z = 1.518$. Readily fusible. Insoluble in acids. Occurs as a late hydrothermal phase replacing chkalovite and, rarely, as 1- to 2-mm prisms lining cavities in alkalic pegmatite at *Mt. Karnarsut, Lovozero massif, Kola Penin., Russia*. *AR DANES 213:130(1973)*, *AM 68:474(1983)*.

78.6.3.1 Pellyite $Ba_2Ca(Fe,Mg)_2 \cdot Si_6O_{17}$

Named in 1972 by Montgomery et al. for the locality. ORTH *Cmcm*. $a = 15.677$, $b = 7.151$, $c = 14.209$, $Z = 4$, $D = 3.62$. 25-95(nat): 3.83₅ 3.46₆ 3.43₁₀ 3.19₇ 3.17₅ 3.15₅ 2.31₆ 2.11₅. Fe^{2+} (and minor substituting Mg, Zn, and Mn) occur in tetrahedral coordination. Ca is octahedrally coordinated. A nearly continuous framework of Si and Fe tetrahedra with Ba occupying a large void of 10-fold coordination within the tetrahedral framework. *AM 61:67(1976)*. Average grain size is 2 mm, massive. Colorless, light yellow; white streak; vitreous luster. Cleavage poor prismatic; conchoidal fracture. $H = 6$. $G = 3.51$. Decomposes slowly in dilute HCl, leaving a white residue. Probe analysis (wt %): BaO, 36.00; CaO, 6.02; FeO, 12.18; MgO, 0.98; ZnO, 1.20; MnO, 1.54; Al₂O₃, 0.28; SiO₂, 40.86; wet analysis: SiO₂, 40.5; BaO, 34.16; CaO, 6.25; FeO, 12.46; MnO, 0.57; MgO, 1.46; ZnO, 1.05; Al₂O₃, 3.53. Biaxial (+); Na(D): $N_x = 1.643$, $N_y = 1.645$, $N_z = 1.649$; $2V = 47^\circ$; rhombic dispersion, $r > v$, very strong. Occurs in a contact-metasomatic deposit adjacent to

a porphyritic quartz monzonite stock. With other Ba-silicates, sanbornite, quartz, and so on, in metamorphic rocks. Big Creek, Fresno Co., and Trumbull Peak area, Mariposa Co., CA; headwaters of the *Pelly R. and Ross R.*, YT, Canada; La Madrelena mine, Tres Pozos, northern Baja California, Mexico. EF *CM* 11:444(1972), *AM* 69:358(1984).

78.6.4.1 Tiettaite $(\text{Na,K})_{17}\text{Fe}^{3+}\text{TiSi}_{16}\text{O}_{29}(\text{OH})_{30} \cdot 2\text{H}_2\text{O}$ (Koashva) and $(\text{Na,K,Ca})_{20}\text{Fe}^{3+}(\text{Ti,Fe}^{3+})_2\text{Si}_{16}\text{O}_{32}(\text{OH})_{28.5} \cdot 8\text{H}_2\text{O}$ (Rasvumchorr)

Named in 1993 by Khomyakov et al. from the Finnish *tietta*, science or knowledge, for the first science station in Khibiny. ORTH *Cmcm*, *Cmc2₁*, or *C2cm*. $a = 29.77$, $b = 11.03$, $c = 17.111$, $Z = 4$, $D = 2.39$. *PD*(nat): 14.79₅ 10.38₁₀ 4.96₆ 4.52₈ 3.70₆ 3.41₅ 3.22₇ 3.10₈. In aggregate grayish white, sometimes dark gray; masses (spheres) to 1 cm, grains 0.3–0.5 mm; rounded, friable aggregates to 1 cm, containing acicular hairs elongate [001] and flattened on (100); vitreous to silky luster. Cleavage {100}, {010}, excellent; steplike fracture. $H = 3$. $G = 2.42$ for both localities. IR, DTA, and TGA data: *ZVMO* 122:121(1993). Decomposes between 200 and 300°. Tarnished with prolonged exposure in air; soluble in weak HCl and HNO₃. 15.4% weight loss to 1000°. H₂O analysis gave 14.73%. Biaxial (-); XYZ = *acb*; (Koashva): $N_x = 1.532$, $N_y = 1.548$, $N_z = 1.559$; (Rasvumchorr): $N_x = 1.530$, $N_y = 1.549$, $N_z = 1.559$; $2V = 79^\circ$; colorless; $r < v$, moderate. Occurs on *Mt. Rasvumchorr* and *Mt. Koashva*, *Khibiny massif*, *Kola Penin.*, *Russia*; in ultra-agpaitic pegmatites associated with other alkalic minerals. EF

78.7.1.1 Bostwickite $\text{CaMn}_6^{2+}\text{Si}_3\text{O}_{16} \cdot 7\text{H}_2\text{O}$

Named in 1983 by Dunn and Leavens for Richard C. Bostwick (b.1943), technician with SPEX Industries, and collector and compiler of data on Franklin and Sterling Hill, NJ mineralogy, particularly fluorescent species. A corresponding but impure phase has been known since 1874. ORTH *35-616*: 11.30₁₀ 3.55₃ 2.90₃ 2.57₄ 2.48₂ 2.26₂ 2.24₂ 1.470₂. Dark red, vitreous to sub-metallic luster. $H = 1$. $G = 2.93$. Biaxial (-); $2V = 25^\circ$; $N_x = 1.775$, $N_y = 1.798$, $N_z = 1.800$; $r < v$, strong. Strongly pleochroic; X, Y, red-brown; Z, yellow-brown. Found as divergent sprays of bladed, prismatic crystals and as hemispherules up to 3 mm in diameter, associated with franklinite, calcite, fluorite, and minor willemite at the *Franklin mine*, *Franklin*, *Sussex Co.*, *NJ*. AR *MM* 47:387(1983).

78.7.2.1 Creaseyite $\text{Cu}_2\text{Pb}_2(\text{Fe,Al})_2\text{Si}_5\text{O}_{17} \cdot 6\text{H}_2\text{O}$

Named in 1975 by Williams and Bideaux for S. C. Creasey (b.1917) in recognition of his studies of the Mammoth–St. Anthony mine. ORTH *mmm*. $a = 12.483$, $b = 21.395$, $c = 7.283$, $Z = 4$, $D = 4.01$. *29-566*: 10.7₁₀ 6.02₅ 5.35₄ 4.07₅ 3.56₅ 3.01₅ 2.98₅ 2.70₅. Fibers [001] up to 0.5 mm; also spherules and matted aggregates. Yellow-green, pale green streak. $H = 2\frac{1}{2}$. $G = 4.1$. Biaxial (+); $2V = 69^\circ$; $N_x = 1.737$, $N_y = 1.747$, $N_z = 1.768$; XYZ = *abc*. Pleochroic; $Z = X > Y$ in yellow-greens. Found in oxidized zones with wulfenite, willemite,

mimetite, and other copper silicates at *Mammoth mine, Tiger, Pinal Co., AZ*, and at *Wickenburg, Maricopa Co.*, with fluorite and ajoite. Mostly replaced by chrysocolla at *Caborca, SON, Mexico*. AR *MM* 49:227(1975).

78.7.3.1 Ertixiite $\text{Na}_2\text{Si}_4\text{O}_9$

Named in 1985 for the locality. iso *Pa*3. $a = 5.975$, $Z = 1$, $D = 2.35$. 39-382(nat): 3.44₂ 2.99₂ 2.67₂ 2.19₂ 2.00₈ 1.80₁₀ 1.60₂ 1.49₂. Structure not yet done, no single-crystal work done. *CJG* 4(2):192(1985). Granular, 0.1–0.5 mm. Colorless, white streak, vitreous luster, transparent. No cleavage, poor subconchoidal fracture. $H = 5.8$ –6.5. $G = 2.35$. IR data: bands at 1050 and 475 cm^{-1} due to $(\text{SiO}_4)^{4-}$ vibrations and a band at 775 cm^{-1} resulting from Al–O–Al vibrations. Na loss occurred under the electron beam. $(\text{Na}_{1.75}\text{Ca}_{0.15})_{1.90}(\text{Al}_{0.09}\text{Si}_{3.92})_{4.01}\text{O}_9$. Analysis (wt %): Na_2O , 17.97; CaO , 2.82; SiO_2 , 77.86; Al_2O_3 , 1.45; FeO , 0.05. Isotropic; $N = 1.502$; colorless. Occurs in miarolytic cavities in a complex Ta–Nb–Be-bearing granitic pegmatite. Associated with topaz, albite, muscovite, quartz, apatite, and garnet. *Altai No. 3 pegmatite, Ertixi R., Fuyun Co., Xinjiang Autonomous Region, China*. EF

78.7.4.1 Ilimaussite-(Ce) $\text{Ba}_2\text{Na}_4(\text{Ce},\text{La})\text{Fe}^{3+}\text{Nb}_2\text{Si}_8\text{O}_{28} \cdot 5\text{H}_2\text{O}$

Named in 1968 for the locality. *HEX* Space group and unit cell data not certain. *DANS-ESS* 182:139(1968). Superstructure appears to be present with $a = 10.72$ and $c = 60.54$. If C centered, possible space groups are *C6/mcm*, *C6cm*, and *C62c*. If P cell, possible space groups are *P6₃mmc*, *P6₃mc*, or *P62c*. $a = 10.72$ –10.80, $c = 20.31$ or 60.54, $Z = 1$ or 3 [*MGR* 181:3(1968)], $D = 3.70$. 21-399: 3.25₆ 3.12₅ 2.98₄ 2.67₁₀ 2.50₂ 2.24₃ 2.02₂ 1.82₂. Structure not yet determined. Polysynthetic twinning sometimes present; forms lamellar and flaky {0001} aggregates to 15 × 10 × 3 mm. Brownish yellow, vitreous to resinous luster. Conchoidal fracture, very brittle. $H = 4$. $G = 3.6$ –3.7. IR data: *DANS-ESS* 182:139(1968), *GZ* 36:54(1976). Ilimaussaq material contains 3.80% K_2O and 1.64 wt % TiO_2 . Khibiny material contains 6.3 wt % TiO_2 . Substitution: $\text{Ba} + \text{Ti} \leftrightarrow (\text{K},\text{Na}) + \text{Nb}$. Uniaxial (+); $N_0 = 1.686$ –1.689, $N_E = 1.695$ –1.698; negative elongation; pleochroic. O, pale yellow; E, bright yellow. Occurs in a hydrothermal ussingite–analcine vein cutting a nepheline–sodalite syenite, *Nakalaq, Ilimaussaq massif, southern Greenland*. Associated minerals are chkalovite and epistolite. Alters readily, becoming dull and non-transparent. Also occurs in the Material'naya adit, on Mt. Yukspor, Khibiny massif, Kola Penin., Russia, in a cavity in nepheline–aegirine–feldspar pegmatite. EF

78.7.5.1 Ilmajokite $(\text{Na},\text{Ce},\text{La},\text{Ba})_2\text{TiSi}_3\text{O}_5(\text{OH})_{10} \cdot n\text{H}_2\text{O} (?)$

Named in 1972 by Bussen et al. for the locality. *MON* C2/c or *Cc*. $a = 39.80$, $c = 29.83$, $\beta = 96.63^\circ$, $G = 2.20$. 25-0783(nat): 11.5₁₀ 10.9₇ 10.2₉ 4.3₁₀ 3.7₇ 3.1₉ 2.48₇ 2.44₁₀. Hydrous salt of metasilicic acid of the type $\text{MRO}_3 \cdot 3\text{M}^{2+} \text{---}$ Na_2Ti . Prismatic and platy; granular deposits, crusts, and aggregates of crystals to 2 mm long. Very unstable and decomposes in both damp and dry

atmospheres. It dries and cracks in air, then becomes turbid and disintegrates. Bright yellow, transparent, vitreous luster. Perfect cleavage on the rhombic prism and pinacoid, intersecting at 72° ; brittle. $H = 1$. $G = 2.20$. IR, DTA, and TGA data: *ZVMO 101:75(1972)*. Contains $\text{OH} + \text{H}_2\text{O}$; in H_2O at 20° it increases in volume and disintegrates into quartzine fibers with $N_x = 1.541$ and $N_z = 1.543$; in 1:1 HCl at 20° it effervesces and dissolves; decomposed by cold water or by acids, it fuses readily to a white enamel. Biaxial (+); $N_x = 1.573$, $N_y = 1.576$, $N_z = 1.579$; $2V = 90^\circ$. Symmetrical extinction with respect to cleavage. Occurs in cavities in the central (natrolitic) zone of the Jubilee stratified pegmatite and along the border layers of lujavrite and ijolite (foyaite) on Mt. Karnarsut in the Lovozero alkaline massif, Kola Penin., Russia. In one of the other mines of Mt. Karnarsut, ilmajokite forms granular deposits on the walls of cavities in white natrolite apophyses, associated with aegirine, cleiophane, halite, and mountainite. EF *MU (1990)*.

78.7.6.1 Juanite $\text{Ca}_{10}\text{Mg}_4\text{Al}_2\text{Si}_{11}\text{O}_{39} \cdot 4\text{H}_2\text{O} (?)$

Named in 1932 by Larsen and Goranson for the San Juan Mountains, Colorado. An inadequately described species. Probably ORTH Space group unknown. *29-335*: 3.58₅ 3.41₅ 3.40₅ 3.27₁₀ 2.98₁₀ 290₉ 1.97₈ 1.93₁₀. White to pistachio-green to brown, translucent. $G = 3.01$. Biaxial (+); $2V = 50^\circ$; $N_x = 1.640$, $N_y = 1.642$, $N_z = 1.647$; positive elongation. Decomposed by acids. Formula given for Kuznetzk material is $\text{Ca}_9(\text{Mg},\text{Fe})_3(\text{Si},\text{Al})_{12}(\text{O},\text{OH})_{36} \cdot 7\text{H}_2\text{O}$, and includes 5.18 wt % Fe_2O_3 . A fibrous alteration product of melilite found at *Iron Hill, Powderhorn-Cebolla district, Gunnison Co., CO*; in the Kiya-Shatyrsk massif, Kuznetsk Ala-Tau, Kazakhstan. AR *AM 17:343(1932)*, *GG 12:62(1971)*.

78.7.7.1 Kenyaite $\text{Na}_2\text{Si}_{22}\text{P}_{41}(\text{OH})_8 \cdot 6\text{H}_2\text{O}$

Named in 1967 by Eugster for the country of origin. *MON P*. $a = 7.79$, $b = 19.72$, $c = 6.91$, $\beta = 95.9^\circ$, $Z = 1$, $D = 2.46$; *20-1157(nat)*: 19.68₁₀ 9.93₅ 4.97₄ 4.69₃ 3.53₂ 3.43₉ 3.32₅ 3.20₆; *AM 68:818(1983)*(syn, air-dried): 19.8₁₀ 9.88₃ 4.89₁ 4.24₁ 3.79₁ 3.43₈ 3.19₈ 2.93₂. X-ray patterns for both natural and synthetic kenyaite can be sensitively changed by variations in the amount of interlayer water, and partial or complete exchange of the interlayer Na by protons if exposed to H_2O . Nodular concretions, sometimes with cores of chert. White, white streak. $G \approx 3.18$. DTA data: *AM 53:2061(1968)*. Material from New Mexico fluoresces very pale yellow to white in SWUV. Biaxial (+), $N = 1.48$, small $2V$. Occurs in saline playa evaporite alkaline lake deposits. Formed by leaching of magadiite, and from saline brines. Point of Rocks Mesa, Colfax Co., NM; Alkali Lake, Oregon; Trinity Co., CA; *Lake Magadi, Kenya, and vicinity (e.g., High Natron Beds)*; Lake Tchad, Africa; Lake Natron, Tanzania; Kaffi Basin, Niger. EF *CMP 22:1(1969)*, *MIN 4(2):437(1992)*.

78.7.8.1 Kuliokite-(Y) (Y,REE)₄Al(SiO₄)₂(OH)₂F₅

Named in 1984 by Voloshin et al. for the locality. TRIC *P1*. $a = 8.606$, $b = 8.672$, $c = 4.317$, $\alpha = 102.79^\circ$, $\beta = 97.94^\circ$, $\gamma = 116.66^\circ$, $Z = 1$, $D = 4.24\text{--}4.28$. $40\text{--}467(\text{nat})$: 3.71₉ 3.49₉ 3.31₆ 2.79₁₀ 2.46₈ 2.14₇ 1.86₆ 1.70₈. Structure: *SPD 31:601(1986)*. Crystals to 0.5 mm in maximum dimension; crystals from Norway are intimately and complexly twinned, centimeter-size crystals from Norway, largest to 3 cm, pseudomonoclinic. Norwegian material recognized as a new species in 1961, but twinning prevented description. Colorless, transparent (Norway: light pink); white streak; vitreous to greasy luster. One good cleavage parallel or nearly parallel to the OAP, two other more or less perfect cleavages or partings present. $H = 4\text{--}5$. $G = 4.2\text{--}4.3$. IR data: *MZ 8:94(1984)*. Yellow-green cathodoluminescence. Analysis (wt %): Y₂O₃, 56.4; Yb₂O₃, 2.71; Er₂O₃, 2.24; Dy₂O₃, 1.38; Lu₂O₃, 0.11; Gd₂O₃, 0.39; Tm₂O₃, 0.10; Ho₂O₃, 0.19; Al₂O₃, 7.36; SiO₂, 17.75; F, 13.45; H₂O, 3.58. Chemistry of Norwegian material is similar. Biaxial (-); $X \wedge a = 7^\circ$, $Y \wedge b = 28^\circ$, $Z = c$; $N_x(D)$: $N_x = 1.656$, $N_y = 1.700$, $N_z = 1.703$; $2V = 10\text{--}19^\circ$; $r > v$. Occurs in fissure fillings in pegmatites, also inclusions in fluorite. Associated with thalenite-(Y), xenotime-(Y), kainosite-(Y), and bastnaesite. In amazonite-bearing pegmatite at Hoydalen, Tordal, Norway; the mineral alters to kamphaugite-(Y) and other carbonate-bearing species [e.g., kainosite-(Y) and tengerite-(Y)]; *unspecified pegmatite near the Kuliok R., Kola Penin., Russia*. EF *EJM 5:691(1993)*.

78.7.9.1 Laplandite-(Ce) (Na,K,Ca)₄(Ce,Th)(Ti,Mg,Al,Nb)PSi₇O₂₂ · 5H₂O

Named in 1974 by Eskova et al. for the locality, the area called Lapland in the northern part of Fennoscandia at Mt. Karnasurt. ORTH *Pmmm*. $a = 7.27$, $b = 14.38$, $c = 22.25$, $Z = 4$, $D = 2.71$. $27\text{--}673(\text{nat})$: 7.27₁₀ 6.47₇ 3.76₁₀ 3.36₈ 3.35₁₀ 3.03₁₀ 2.80₈ 2.01₇. Structure not done because of lack of suitable single crystals. Radiating fibrous groups (to 1 cm in diameter) of crystals 0.5–1 mm in diameter, also fan-shaped platy aggregates ≈ 0.01 mm thick, crystals flattened on c . Light gray to yellowish, rarely bluish; vitreous or silky to greasy luster. Splintery fracture. $H = 2\text{--}3$. $G = 2.83$. IR and thermal data: *ZVMO 103:571(1974)*. Analysis (wt %): SiO₂, 40.9; P₂O₅, 9.6; TiO₂, 4.1; Nb₂O₅, 1.9; Al₂O₃, 0.64; MgO, 1.02; MnO, 0.20; CaO, 0.56; ThO₂, 1.32; REE₂O₃, 16.8; Na₂O, 9.81; K₂O, 1.88; H₂O⁺, 8.96; H₂O⁻, 0.37, for yellowish sample; bluish sample has 4.15 wt %. A poorly studied P-free analog of laplandite-(Ce) also occurs in the Jubilee pegmatite. Biaxial (-); $X = c$; $N_x = 1.568$, $N_y = 1.584$, $N_z = 1.585$; $2V_{\text{calc}} = 28^\circ$; colorless. Laplandite may form pseudomorphs after steenstrupine, along with vitusite, belovite, and others. Occurs on *Mt. Karnasurt, Lovozero massif, Kola Penin., Russia*; in the central natrolite zone of an alkalic pegmatite (Jubilee pegmatite), associated with belovite, nordite, serandite, thermonatrite, steenstrupine, leucosphenite, sphalerite, ilmajokite, raite, and zorite. EF

78.7.10.1 Lelfite $\text{Na}_6\text{Be}_2\text{Al}_2\text{Si}_{16}\text{O}_{39}(\text{OH})_2 \cdot 1.5\text{H}_2\text{O}$

Named in 1915 by Bøggild for the tenth-century Norse mariner and explorer Leif Ericson. *HEX P3m1*. $a = 14.352$, $c = 4.852$, $Z = 1$, $D_c = 2.59$. $27-1$: 12.4_2 4.70_4 4.52_2 4.14_2 3.59_2 3.38_7 3.15_{10} 2.46_2 . Hexagonal prisms {1010} terminated by {1121}, {0001}, fine needles to fibrous, 1 mm to 5 cm long; radiating aggregates and rosettes. Penetration trillings with {1010} as twin plane (Ilimaussaq). White, colorless to pale violet; vitreous luster; translucent. Prismatic cleavage {1010}, distinct; brittle. $H = 6$. $G = 2.57$. Uniaxial (+); $N_0 = 1.516-1.518$, $N_E = 1.520-1.521$. In cavities in alkali-pegmatite veins. At Mt. St-Hilaire, QUE, Canada, in crystals(1) up to 5 cm long and as disk-shaped aggregates and radially fibrous spheres with albite, natrolite, serandite, and catapleiite; at Ilimaussaq and *Narssarsuk, Greenland*, with microcline, calcite, zinnwaldite, and acmite; Lovozero massif, Kola Penin., Russia. *AR DT:535(1932)*, *BGSD 20:134(1970)*, *AC(B) 30:396(1974)*, *MR 24:45(1993)*, *NJMM 2:83(1994)*.

78.7.11.1 Luddenite $\text{Cu}_2\text{Pb}_2\text{Si}_5\text{O}_{14} \cdot 14\text{H}_2\text{O}$

Named in 1982 by Williams for Raymond W. Ludden, chief geologist for western exploration, Phelps-Dodge Corporation. *MON Space group unknown*. $a = 7.85$, $b = 20.06$, $c = 14.72$, $\beta = 90.78^\circ$ (from powder data), $Z = 6$ (originally reported as 4), $D = 4.98$. $35-560$: 7.36_{10} 5.22_7 4.23_5 3.52_5 3.41_5 3.17_{10} 2.92_8 2.89_5 . Green, translucent. Cleavage in one unspecified direction. $H = 4$. $G = 4.45$. Biaxial; $2V = 40^\circ$; $N_x = 1.852$, $N_z = 1.867$. Pleochroic; Y, X, yellow-green; Z, emerald-green. Soluble with difficulty in acids. Found as rosettes and fan-shaped aggregates with galena, chalcopyrite, fluorite, alamosite, melenotekite, and hyalotekite in a Pb-Cu-Ag prospect near *Artillery Peak, Mohave Co., AZ*. *AR MM 46:363(1982)*.

78.7.12.1 Magadiite $\text{NaSi}_7\text{O}_{13}(\text{OH})_3 \cdot 4\text{H}_2\text{O}$

Named in 1967 by Eugster for the locality. *MON P. (nat)*: $a = 7.25$, $b = 7.25$, $c = 15.69$, $\beta = 96.8^\circ$, $Z = 2$; (*syn*): $a = 7.30$, $b = 7.28$, $c = 15.71$, $\beta = 96.4^\circ$ for $Z = 1$ ($\text{Na}_2\text{Si}_{14}\text{O}_{29} \cdot 10\text{H}_2\text{O}$), $D = 2.17-2.25$. $24-698$ (nat): 15.6_{10} 5.19_2 5.01_1 4.47_2 3.54_2 3.43_8 3.30_4 3.15_6 ; $42-1350$ (syn): 15.46_8 5.18_2 3.64_2 3.56_2 3.45_{10} 3.31_7 3.15_{10} 1.82_2 . Dehydrated form is stable to 500°C and can be completely rehydrated; $500-700^\circ$ produces quartz with or without cristobalite; $>700^\circ$ produces tridymite. Structure not determined. Thin rectangular plates $\approx 1 \times 1 \mu\text{m}$, a white powder; when put in vacuum, the (001) spacing decreases to 13.5 Å but recovers the original spacing when exposed again to H_2O vapor. White, white streak, usually earthy in texture, dull to vitreous luster. IR and NMR data: *AM 54:1034(1969)*, *ZAAC 597:183(1991)*. DTA and TGA data: *AM 53:2061(1968)*, $60:642(1975)$. In dilute acids at 20° , a hydrous form of silica results; composition near $6\text{SiO}_2 \cdot \text{H}_2\text{O}$. May contain traces of K, Al, Fe, Mg, and Ca in addition to Na, Si, and water. Biaxial; $N \approx 1.48$; positive elongation. At Mt. St.-Hilaire, occurs in cavities in marble xenoliths. Usually occurs in alkaline lakes, particularly those of the sodium carbonate-bicarbon-

nate variety. Brines with high pH and silica content. Magadiite has not been reported from lacustrine deposits older than late Pleistocene. Occurs as white puttylike laminae in silts. In veins at Alkali Lake, Oregon. Evaporites. Alteration to chert with loss of water and alkalis. Trinity R. area, Trinity Co., CA; Alkali Lake, Lake Co., OR; Mt. St.-Hilaire, QUE, Canada; the Ca analog of magadiite occurs in cavities to several centimeters across in the St.-Amable 10-m-thick sill of trachytic phonolite at Varennes, QUE. Associated with other rare alkalic minerals [*RMS:8-9(1993)*]; *Lake Magadi*, Olduvai Gorge, and Kanem, Lake Chad, *Kenya*; El Fraile Municipio de Huajuapán de León, OX, Mexico. *EF CPM 22:1(1969)*.

78.7.13.1 Maufite $(\text{Mg,Ni})\text{Al}_4\text{Si}_3\text{O}_{13} \cdot 4\text{H}_2\text{O}$ (?)

Very poorly described mineral. *TGSSA 32:103(1930)*, *AM 15:275(1930)*.

78.7.14.1 Spadaite $\text{MgSiO}_3 \cdot 2\text{H}_2\text{O}$ or $\text{MgSiO}_2(\text{OH})_2 \cdot \text{H}_2\text{O}$ (?)

Named in 1843 by von Kobell for Lavino Spada (de Medici)(1801–1863), Italian politician and amateur mineralogist. Probably ORTH Space group unknown. Dense massive to microscopic platy or columnar. Cream white to pink, pearly to greasy luster. Conchoidal fracture when dense, sometimes splintery. Decomposed by HCl. $H = 2.5$. $G = 2.2-2.32$. Fusible at 5 to a white enamel, decomposed by HCl with separation of sandy silica. Superficially resembles a light-colored serpentine. Biaxial (+); $N_x = 1.521$, $N_y = 1.525-1.53$, $N_z = 1.545$; $2V = 37-61^\circ$; birefringence = 0.024; negative and positive elongation; parallel extinction to slightly inclined; colorless and nonpleochroic in thin section. Type material and Utah [dehydrated and corrected, *AM 16:231(1931)*] spadaite gave (wt %), respectively: SiO_2 , 56.00, 53.96; Al_2O_3 , 0.66, —; FeO , 0.66, 0.35; MgO , 30.67, 32.08; H_2O , 11.34, 13.64. Loses half its H_2O [Utah, *AM 16:231(1931)*] at 110° . Found replacing tactite minerals, and associated with quartz, chalcopyrite, bornite, garnet, diopside, calcite, wollastonite, and gold. Also in dolerite–diabase and leucite-bearing lava. Spadaite is observed to replace wollastonite. Cane Springs, Alvarado, and Midas mines, Gold Hill, Tooele Co., UT; Sasbach, Kaiserstuhl, Baden–Württemberg, Germany; *Capo di Bove*, near Rome, Lazio, Italy. *EF*

78.7.15.1 Terskite $\text{Na}_4\text{ZrSi}_6\text{O}_{15}(\text{OH})_2 \cdot \text{H}_2\text{O}$

Named in 1983 by Khomyakov et al. for Terskii berreg, the southern shore of the Kola Peninsula. ORTH *Pnc2*. $a = 14.195$, $b = 14.750$, $c = 7.511$, $Z = 4$ [*DAN SSSR 316:645(1991)*], $D = 2.74$. $35-712(\text{nat})$: 4.09_6 3.32_{10} 3.30_{10} 3.26_{10} 3.19_8 3.13_6 2.62_7 2.56_6 . Structure: *DAN SSSR 316:645(1991)*. White, pink, and rarely light cream to light violet-lilac to dark brown; at Mt. St.-Hilaire, powdery to porcelaneous; in Russia, plates, 1–3.5 mm, pseudotetragonal, vitreous to porcelaneous. $H \approx 5$. $G = 2.71$. IR, DTA, TGA data: *ZVMO 112:226(1983)*. Weak yellowish-white fluorescence under SWUV and LWUV, which shows bright green photoluminescence. Insoluble in 10% HCl or HNO_3 . Analysis (wt %): SiO_2 , 56.3; ZrO_2 , 17.8; Na_2O , 19.0; H_2O , 6.37.

Biaxial (-); $N_x = 1.576$, $N_y = 1.582$, $N_z = 1.584$; $2V = 53^\circ$; $r > v$, weak. Occurs at Mt. St.-Hilaire in sodalite xenoliths. Occurs in syenites at Mt. Alluaiev and in the Jubilee pegmatite on Mt. Karnarsut. In pegmatite veins in syenites. Associated with alkalic minerals. Alteration: hollow pseudomorphs replacing lovozerite. Crude, twinned dodecahedra. Replaces eudialyte. Mt. St.-Hilaire and St.-Amable sill, Varennes, QUE, Canada; Ilimaussaq, Greenland; Mt. Alluaiev and Mt. Karnarsut, Lovozero massif, Kola Penin., Russia. EF

78.7.16.1 Tranquillityite $\text{Fe}_8^{2+}\text{Ti}_3(\text{Zr},\text{Y})_2\text{Si}_3\text{O}_{24}$

Named in 1971 for the locality. HEX Primitive lattice. $a = 11.69$, $c = 22.25$, $Z = 3$ or 6 , $D = 4.70$. Alternative cell data given in *GCA Suppl., Proc. 8th Lunar Sci. Conf., 2, 1831(1977)*: rhombohedral cell with $a_{rh} = 4.743$ and $\alpha_{rh} = 88.57^\circ$. A number of weak reflections could be indexed with $a_{rh} = 9.486$ ($2\times$) and $D = 4.83$. If the original hexagonal cell is transformed to rhombohedral coordinates, the results are $a_{rh} = 10.83$ and $\alpha_{rh} = 71.31^\circ$, which do not agree well with the subsequently proposed rhombohedral cell. Probably, two different minerals are involved. *26-1143(nat)*: 4.04_5 3.34_4 3.23_{10} 3.18_4 3.13_4 2.92_4 2.16_6 1.78_7 . Nearly opaque, dark red, black. Thin laths, from a few microns to $65 \times 15 \mu\text{m}$. Reported as being metamict. *GCA Suppl., Proc. 8th Lunar Sci. Conf., 2, 1831(1977)*. Analysis (wt %): SiO_2 , 14.0; TiO_2 , 19.5; Al_2O_3 , 1.1; FeO , 42.5; CaO , 1.3; ZrO_2 , 17.2; Y_2O_3 , 2.8; traces of Gd_2O_3 , Cr_2O_3 , MnO , HfO_2 , Nb_2O_5 , Pr_2O_3 , Nd_2O_3 . Biaxial; $N = 2.12$ (calculated from r values); $2V = 40^\circ$ (*Proc. Apollo 11 Lunar Science Conference, GCA Suppl. 1(1):315(1970)*); reflectance at 546 nm = 12.9%. Occurs in lunar basalts, associated with interstitial phases such as troilite, pyroxferroite, cristobalite, and alkali feldspar. Found at *Tranquility Base, Moon*, and other sites with mare and non-mare basalts. *AR Proc. Second Lunar Sci. Conf., GCA Suppl. 2(1):39(1971)*, *NAT 236:215(1972)*.

78.7.17.1 Umbozerite $\text{Na}_3\text{Sr}_4\text{ThSi}_8(\text{O},\text{OH})_{24}$

Named in 1974 by Es'kova et al. for the locality. Amorphous. *26-1384*(heated to 1100°): 3.38_6 3.29_{10} 2.98_5 2.82_5 2.09_4 2.00_6 1.70_{18} 1.29_{94} . Green to greenish brown, vitreous luster. Conchoidal fracture. $H \approx 5$. $G = 3.60$. Isotropic; $N = 1.640$; metamict. Occurs as crude crystals of apparent tetragonal morphology up to 3 mm and as irregular masses associated with sphalerite, belovite, schizolite, and niobium minerals of the lomonosovite group in ussingite veinlets cutting alkalic rocks at *Umbozero (Lake Umba), Kola Penin., Russia*. *AR AM 60:341(1975)*.

78.7.18.1 Vyuntspakhkite-(Y) $(\text{Y},\text{Yb},\text{Er})_4\text{Al}_2\text{AlSi}_5\text{O}_{18}(\text{OH})_5$

Named in 1983 by Voloshin et al. for the locality. *MON P21/a*. $a = 5.830$, $b = 14.763$, $c = 6.221$, $\beta = 123.05^\circ$, $Z = 1$, $D = 4.04$. *35-0708(nat)*: 7.4_6 4.98_6 4.92_6 3.47_{10} 2.95_5 2.86_6 2.60_8 2.27_5 . Structure: *SPC 29:141(1984)*. Slender prismatic crystals 0.5–0.7 mm long and 0.05–0.2 mm wide; vacancies exist

in the two Al positions because of the short distances between the two sites (1.68 Å), cannot be occupied simultaneously. Colorless, white streak, adamantine luster, transparent. No cleavage, brittle. H = 6–7. G = 4.02. IR data: *SPC 29:141(1984)*. Nonfluorescent, very pale yellow-green cathodoluminescence; not soluble in HCl. Average of four probe analyses (wt %): Y₂O₃, 24.18; Yb₂O₃, 15.71; Er₂O₃, 5.74; Dy₂O₃, 3.02; Lu₂O₃, 2.22; Tm₂O₃, 1.57; Al₂O₃, 13.14; SiO₂, 28.69; H₂O, 4.29; Gd₂O₃, ≈ 0.4, Ho₂O₃, ≈ 0.4, Tb₂O₃, ≈ 0.3. Biaxial (+); Z \wedge a = 68°, X \wedge c = 40°, OAP = (010); N_x = 1.680, N_y = 1.692–1.695, N_z = 1.720–1.722. Occurs on *Mt. Vyuntspakh, Kola Penin., Russia*, from amazonite pegmatites. In cavities within fluorite in amazonite pegmatite. Varieties rich in Y give faint yellow-green luminescence in cathode ray. Two generations; chemistry varies widely: Y₂O₃, 17.8–34.7; associated with fluorite, xenotime, and bastnaesite. *EF MZ 5:89(1983)*.

78.7.19.1 Wawayandaite Ca₁₂Be₁₅Mn₄B₂Si₁₂O₄₆(OH,Cl)₃₀

Named in 1990 by Dunn et al. from the Lenni Lenape Native American *wawayanda*, many or several windings, in allusion to the grossly curved and winding habit of its crystals. *MON Pc* or *P2/c*. *a* = 15.59, *b* = 4.87, *c* = 18.69, β = 101.84°, Z = 1, D = 2.98. *PD*: 15.1₉ 9.20₃ 3.16₁₀ 3.00₇ 2.72₆ 2.63₇ 2.58₃ 2.25₅. Usually as very thin plates, curved and warped in all dimensions. Rarely as minute (0.1 mm) sharp and thin crystals tabular {100} and twinned on (100); other forms are not discernible. Colorless and transparent; fine-grained aggregates white and opaque; pearly luster is obvious on curved crystals, but less so on aggregates. Cleavage {100}, perfect. Flexible. G ≈ 3.0. Biaxial (-); 2V = 85.2°; N_{x calc} = 1.619, N_y = 1.631, N_z = 1.641 for Na(D); X \wedge a = 11.5° in obtuse β, YZ = bc; r < v strong. Observed on a museum specimen from the *Franklin mine, Franklin, Sussex Co., NJ*, associated with superb willemite crystals and with calcite, hodgkinsonite, cahnite, and friedelite. *AR AM 75:405(1990)*.

Appendix

NEW MINERALS FOR 1996

Mineral Name	Formula	Reference
1. Androsite-(La)	(Mn,Ca) (REE)AlMn ³⁺ Mn ²⁺ (SiO ₄)(Si ₂ O ₇)O(OH)	AM 81:735(1996)
2. Babkinites	Pb ₂ Bi ₂ (S,Se) ₃	DAN 346(5):656(1996), and AM 81:1513(1996)
3. Baksanite	Bi ₆ (Te ₂ S ₃)	DAN 347(6):787(1996)
4. Bechereite	(Zn,Cu) ₆ Zn ₂ (OH) ₁₃ (S,Si)(O,OH) ₄ 2	AM 81:244(1996)
5. Belovite-(La)	Sr ₃ Na(La,Ce)[PO ₄] ₃ (F,OH)	PRMS 125(3):101(1996)
6. Benavite	HSrFe ³⁺ ₃ (PO ₄) ₂ (OH) ₆	Chemie der Erde 56:171(1996)
7. Calcioaravaipaite	PbCa ₂ Al(F,OH) ₉	MR 27:293(1996)
8. Christelite	Zn ₃ Cu ₂ (SO ₄) ₂ (OH) ₆ ·4H ₂ O	NJBM 188(1996)
9. Clerite	MnSb ₂ S ₄	PRMS 125(3):95(1996)
10. Clinoatacamite	Cu ₂ (OH) ₃ Cl	CM 34:61(1996) and CM 34:73(1996)
11. Deloneite-(Ce)	NaCa ₂ SrCe(PO ₄) ₃ F	PRMS 125(5):83(1996)
12. Dusmatovite	K(K,Na)(Mn ²⁺ ,Y,Zr) ₂ (Zn,Li) ₉ Si ₁₂ O ₃₀	Vestnik Moscow U. Sreies 4, Geology Z, pp54-60 and DAN344 (5)1607-610(1996)
13. Fettelite	Ag ₂₄ HgAs ₅ S ₂₀	NJBM 313(1996)
14. Fianelite	Mn ₂ V(V,As)O ₇ ·2H ₂ O	AM 81:1270(1996)
15. Fluor-cannilloite	CaCa ₂ (Mg ₄ Al)(Si ₅ Al ₃)O ₂₂ F ₂	AM 81:995(1996)
16. Fluor-ferro-leakeite	NaNa ₂ (Fe ²⁺ ₂ Fe ³⁺ ₂ Li)Si ₅ O ₂₂ F ₂	AM 81:226(1996)
17. Frankamenite	K ₃ Na ₃ Ca ₆ (Si ₁₂ O ₃₀)(F ₃ OH)H ₂ O	crystal structure MM 60:897(1996) and PRMS 125(2):106(1996)
18. Galloebudantite	PbGa ₃ (AsO ₄) ₂ (OH) ₆	CM 34:1305(1996)

25. Kukharenkoite-(Ce)	Ba ₂ Ce(CO ₃) ₃ F	EJM 8:1327(1996)
26. Malinite	Cu(Pt,Ir) ₂ S ₄	MP 56:25(1996) and Acta Geologica Sinica 70(4):309(1996)
27. Mahmertite	(Na,Ca)Cu ₃ (AsO ₄) ₂ Cl·5H ₂ O	Archives de Science Geneve 49(2):119(1996)
28. Leisingite	Cu(Mg,Cu,Fe,Zn) ₂ Te ⁶⁺ O ₆ ·6H ₂ O	MM 60:653(1996)
29. Medenbachite	Bi ₂ Fe(Cu,Fe)(O,OH) ₂ (OH) ₂ (AsO ₄) ₂	AM 81:505(1996)
30. Meurigitite	KFe ³⁺ ₇ (PO ₄) ₅ (OH) ₇ ·8H ₂ O	MM 60:787(1996)
31. Natroxalate	Na ₂ C ₂ O ₄	PRMS 125(1):126(1996)
32. Nezilovite	PbZn ₂ (Mn ⁴⁺ ,Ti ⁴⁺) ₂ Fe ₈ O ₁₉	CM 34:1287(1996)
33. Noelbensonite	BaMn ³⁺ ₂ [Si ₂ O ₇](OH) ₂ ·H ₂ O	MM 60:369(1996)
34. Oulankaite	(Pd,Pt) ₅ (Cu,Fe) ₄ SnTe ₂ S ₂	EJM 8:311(1996)
35. Penobskisite	Ca ₂ FeCl[B ₃ O ₁₃ (OH) ₆]·4H ₂ O	CM 34:657(1996)

36. Piretite	$\text{Ca}(\text{UO}_2)_3(\text{SeO}_3)_2(\text{OH})_4 \cdot 4\text{H}_2\text{O}$	CM 34:1317(1996)
37. Pyatenkoite-(Y)	$\text{Na}_5(\text{Y}, \text{Dy}, \text{Gd})\text{TiSi}_5\text{O}_{18} \cdot 6\text{H}_2\text{O}$	PRMS 125(4):72(1996)
38. Rosiaite	PbSb_2O_6	EJM 8:487(1996)
39. Shkatulkalite	$\text{Na}_{10}(\text{Mn}, \text{Ca}, \text{Sr})\text{Ti}_3\text{Nb}_3(\text{Si}_2\text{O}_7)_6(\text{OH})_2\text{F} \cdot 12\text{H}_2\text{O}$	PRMS 125(1):120(1996)
40. Sigismundite	$(\text{Ba}, \text{K}, \text{Pb})\text{Na}_3(\text{Ca}, \text{Sr})(\text{Fe}, \text{Mg}, \text{Mn})_{14}\text{Al}(\text{OH})_2(\text{PO}_4)_{12}$	CM 34:827(1996)
41. Smrkovecite	$\text{Bi}_2\text{O}(\text{OH})(\text{PO}_4)$	NJBM 97(1996)
42. Vianeite	$(\text{Fe}, \text{Pb})_4\text{O}_9\text{O}$	EJM 8:93(1996)
43. Wesselsite	$\text{SrCu}[\text{Si}_4\text{O}_{10}]$	MM 60:795(1996)
44. Zajacite-(Ce)	$\text{Na}[\text{REE}_x\text{Ca}_{1-x}][\text{REE}_y\text{Ca}_{1-y}]\text{F}_6$ where x is not equal to y	CM 34:1299(1996) NJBM 103(1996)

Index of Mineral Names in Numerical Order

1.1.1.1	Gold	2	1.1.22.1	Perryite	16
1.1.1.2	Silver	3	1.1.23.1	Suessite	16
1.1.1.3	Copper	4	1.1.23.2	Gupeiite	16
1.1.1.4	Lead	5	1.1.23.3	Xifengite	16
1.1.1.5	Aluminum	5	1.2.1.1	Platinum	17
1.1.2.1	Auricupride	5	1.2.1.2	Iridium	17
1.1.2.2	Tetraauricupride	6	1.2.1.3	Rhodium	18
1.1.2.3	Yuanjiangite	6	1.2.1.4	Palladium	18
1.1.3.1	Maldonite	6	1.2.2.1	Osmium	19
1.1.4.1	Anyuuite	6	1.2.2.2	Ruthenium	19
1.1.5.1	Zinc	6	1.2.4.1	Tetraferroplatinum	21
1.1.5.2	Cadmium	7	1.2.4.2	Tulameenite	22
1.1.6.1	Danbaite	7	1.2.4.3	Ferronickelplatinum	22
1.1.6.2	Zhanghengite	7	1.2.4.4	Potarite	22
1.1.7.1	Mercury	7	1.2.5.1	Isoferroplatinum	24
1.1.8.1	Moschallandsbergite	7	1.2.5.2	Rustenbergitte	24
1.1.8.2	Schachnerite	8	1.2.5.3	Atokite	24
1.1.8.3	Paraschachnerite	8	1.2.5.4	Zvyagintsevitte	24
1.1.8.4	Luanheite	8	1.2.5.5	Chengdeite	24
1.1.8.5	Eugenite	8	1.2.6.1	Paolovite	25
1.1.8.6	Weishanite	8	1.2.7.1	Taimyrite	25
1.1.9.1	Kolymite	8	1.2.8.1	Cabriite	25
1.1.9.2	Belendorffite	9	1.2.9.1	Stannopalladinitte	25
1.1.10.1	Leadamalgam	9	1.2.10.1	Nigglitte	25
1.1.11.1	Kamacite	10	1.2.11.1	Plumbopalladinitte	26
1.1.11.2	Taenite	10	1.3.1.1	Arsenic	26
1.1.11.3	Tetrataenite	10	1.3.1.2	Antimony	27
1.1.11.4	Awaruite	12	1.3.1.3	Stibarsen	28
1.1.11.5	Nickel	12	1.3.1.4	Bismuth	28
1.1.11.6	Wairauite	12	1.3.1.5	Stistaite	29
1.1.12.1	Chromium	12	1.3.2.1	Arsenolamprite	29
1.1.12.2	Chromferide	13	1.3.3.1	Paradocrasite	29
1.1.12.3	Ferchromide	13	1.3.4.1	Selenium	30
1.1.13.1	Tin	13	1.3.4.2	Tellurium	30
1.1.14.1	Indium	13	1.3.5.1	Sulfur	30
1.1.15.1	Cupalite	13	1.3.5.2	Rosickyite	31
1.1.15.2	Khatyrkite	13	1.3.6.1	Diamond	32
1.1.16.1	Cohenite	14	1.3.6.2	Graphite	33
1.1.16.2	Haxonite	14	1.3.6.3	Lonsdaleite	35
1.1.17.1	Tongbaite	14	1.3.6.4	Chaoite	35
1.1.18.1	Siderazot	14	2.1.1.1	Algodonite	37
1.1.18.2	Roaldite	14	2.1.2.1	Horsfordite	37
1.1.19.1	Osbornite	15	2.1.3.1	Telargpalite	37
1.1.19.2	Khamrabaevite	15	2.1.4.1	Duranusite	37
1.1.20.1	Carlsbergite	15	2.1.5.1	Bezmertnovite	38
1.1.21.1	Barringerite	15	2.1.6.1	Billibinskite	38
1.1.21.2	Schreibersite	15	2.2.1.1	Dyscrasite	38

- 2.2.1.2 Allargentum 38
