Native Elements and Alloys

Class 1 Native Elements and Alloys	1
------------------------------------	---

Sulfides and Related Compounds

Class 2 Sulfides, Including Selenides and Tellurides	37
Class 3 Sulfosalts	150

Oxides

Class 4 Simple Oxides	204
Class 5 Oxides Containing Uranium, and Thorium	255
Class 6 Hydroxides and Oxides Containing Hydroxyl	266
Class 7 Multiple Oxides	292
Class 8 Multiple Oxides Containing Niobium, Tantalum, and Titanium	332

Halogenides

Class 9 Anhydrous and Hydrated Halides	373
Class 10 Oxyhalides and Hydroxyhalides	391
Class 11 Halide Complexes; Alumino-fluorides	407
Class 12 Compound Halides	419

Carbonates

Class 13 Acid Carbonates	422
Class 14 Anhydrous Carbonates	426
Class 15 Hydrated Carbonates	462
Class 16 Carbonates Containing Hydroxyl or Halogen	475
Class 17 Compound Carbonates	519

Nitrates

Class 18 Nitrates	526
Class 19 Nitrates Containing Hydroxyl or Halogen	528
Class 20 Compound Nitrates	530

Iodates

Class 21 Anhydrous and Hydrated Iodates	531
Class 22 Iodates Containing Hydroxyl or Halogen	532
Class 23 Compound Iodates	533

Borates

Class 24 Anhydrous Borates	534
Class 25 Anhydrous Borates Containing Hydroxyl or Halogen	542
Class 26 Hydrated Borates Containing Hydroxyl or Halogen	551
Class 27 Compound Borates	565

Sulfates

Class 28 Anhydrous Acid and Sulfates	568
Class 29 Hydrated Acid and Sulfates	583
Class 30 Anhydrous Sulfates Containing Hydroxyl or Halogen	623
Class 31 Hydrated Sulfates Containing Hydroxyl or Halogen	639
Class 32 Compound Sulfates	666

Selenates and Tellurates; Selenites and Tellurites

Class 33 Selenates and Tellurates	672
Class 34 Selenites, Tellurites and Sulfites	677

Chromates

Class 35 Anhydrous Chromates	692
Class 36 Compound Chromates	696

Phosphates, Aresenates, and Vanadates

Class 37 Anhydrous Acid Phosphates, etc.	697
Class 38 Anhydrous Phosphates, etc.	700
Class 39 Hydrated Acid Phosphates, etc.	735
Class 40 Hydrated Phosphates, etc.	814
Class 41 Anhydrous Phosphates, etc., Containing Hydroxyl or Halogen	815
Class 42 Hydrated Phosphates, etc., Containing Hydroxyl or Halogen	882
Class 43 Compound Phosphates, etc.	957

Antimonates, Antimonites, and Arsenites

Class 44 Antimonates	971
Class 45 Acid and Normal Antimonites and Arsenites	977
Class 46 Basic or Halogen-Containing Antimonites, Arsenites	981

Vanadium Oxysalts

Class 47 Vanadium Oxysalts	985
----------------------------	-----

Molybdates and Tungstates

Class 48 Anhydrous Molybdates and Tungstates	993
Class 49 Basic and Hydrated Molybdates and Tungstates	1005

Organic Compounds

Class 50 Salts of Organic Acids	1011
---------------------------------	------

Nesosilicates: Insular SiO_4

Class 51 Insular SiO_4 Groups Only	1020
Class 52 Insular SiO_4 Groups and O, OH, F, and H_2O	1061
Class 53 Insular SiO_4 Groups and Other Anions or Complex Cations	1106
Class 54 Borosilicates and Some Beryllsilicates	1116

Sorosilicates: Isolated Tetrahedral Noncyclic Groups, N:1

Class 55 Si_2O_7 Groups, Generally with No Additional Anions	1133
Class 56 Si_2O_7 with Additional O, OH, F and H_2O	1149
Class 57 Insular Si_3O_{10} and Larger Noncyclic Groups	1188
Class 58 Insular, Mixed, Single, and Larger Tetrahedral Groups	1193

Cyclosilicates

Class 59 Three-Membered Rings	1220
Class 60 Four-Membered Rings	1231
Class 61 Six-Membered Rings	1238
Class 62 Eight-Membered Rings	1267
Class 63 Condensed Rings	1269
Class 64 Rings with Other Anions and Insular Silicate Groups	1281

Inosilicates: Two-Dimensionally Infinite Silicate Units

Class 65 Single-Width Unbranched Chains, $W = 1$	1288
Class 66 Double-Width Unbranched Chains, $W = 2$	1335
Class 67 Unbranched Chains with $W > 2$	1376
Class 68 Structures with Chains of More Than One Width	1379
Class 69 Chains with Side Branches or Loops	1381

Class 70 Column or Tube Structures	1397

Preface

Mineralogy is as old as humankind. From antiquity, people have known and highly valued minerals, with a fascination for their utility and beauty. The names of many of the 3700 minerals we know today derive from the ancient past.

However, a systematic approach, or a science of mineralogy, dates only from the late eighteenth and early half of the nineteenth century, when Linnaeus, better known for usurping Adam's role in naming the plants and animals, also showed an interest in classifying the minerals. His natural history collection contained some 2500 mineral specimens, and even today, individual minerals (as distinct from rocks) are referred to as species.

The period 1830–1859 saw a huge expansion of both popular and professional interest in natural history and great advances in the systematic classification of the many diverse parts of our environment. The first edition of Dana's *A System of Mineralogy* appeared in 1837, before *On the Origin of Species* (Darwin, 1859), a time of flux in understanding both the physical and biological history of the earth. Similarly, this eighth edition is presented against a background of changing ideas of the nature, properties, relationships, genesis, and uses of mineral species. It appears at a time when mineralogy has close affiliation with solid-state physics, materials science, and inorganic chemistry, biology, and other more wide ranging fields of science and technology.

Historical Perspective

Publication of Dana's *New Mineralogy*, the eighth Edition of Dana's *System of Mineralogy*, culminates a long series of books begun by James Dwight Dana when he wrote the first edition of *A System of Mineralogy* in 1837. Sparked by the chemical discoveries of Lavoisier and Berzelius and the crystallographic findings of Haüy, mineralogical investigators had begun to systematize the science. James D. Dana, newly appointed assistant in the chemistry laboratory at Yale University, completed his *System* at the age of 24 in 10 months. He used the Linnean principles for the classification, following and modifying those published by Friedrich Mohs. His description of individual species is basically that of Mohs' *Treatise on Mineralogy*, the English translation (1825) of Mohs' German-language book published two years earlier. The first edition of Dana's book was privately published, but the second edition (1844) and all but one other have been published by John Wiley. The *System* was the first book Wiley (then known as Wiley & Putnam) published in the sciences. Dana's mineral descriptions were considerably condensed, and he added to the localities listed for each mineral those in the United States where such were known.

The original system contained 352 minerals which can be identified with species we know today, although actual names of about 50% of them are from slightly to entirely different now; for example, gray antimony is now called stibnite, spathic iron is now known as siderite, and blue vitriol is now called chalcantite.

The general chemistry of individual species was discussed, but no chemical formulas were presented, even though Berzelius had proposed a system of chemical notation in 1814 that introduced one- and two-letter abbreviations for the Latin names of the elements (K, Na, Fe, etc.) By the third edition of the *System* (1850), Dana adopted the Berzelian system of writing formulas, but today's reader would find them difficult to understand since the notation today was not codified until about 1880. Mineral formula presentation probably aided the systematization.

The early recognition of mineral species was entirely dependent on a knowledge of physical properties such as crystal morphology, color, luster, hardness, cleavage, streak, and specific gravity, plus simple chemical tests and blowpipe analysis. Today, the physical properties are still important, but definitive identification requires analyses developed and refined in this century such as x-ray and electron diffraction, optical and electron microscopy, and spectrographic and microprobe examination. The number of minerals we recognize

as of the writing of this book has increased by a factor of 10 since 1837 and grows by about 50 new species per year. In contrast to former times, only a few milligrams of the substance is needed for complete characterization.

Dana continued to revise *A System of Mineralogy* and produced other books, many of which continue today, such as the *Manual of Mineralogy* (first edition 1848; twenty-first edition 1993), *Manual of Geology*, *Manual of Mineralogy and Petrography*, *Minerals and How to Study Them*, and other titles. Edward Salisbury Dana, the son of J.D. Dana, prepared *Dana's Textbook of Mineralogy* (first edition 1877; fourth edition 1932), as well as the sixth edition of *A System of Mineralogy* in 1892. In that edition, all of the interfacial angles from the crystal elements were recalculated, the Miller–Bravais symbols were introduced, mineral varieties were critically evaluated, and synonymy was improved and extended. The work became an international classic for over 50 years, due to the meticulous care with which it was prepared, the wonderful freedom from errors, the extraordinary detail through the author's personal knowledge of the mineralogical literature, and the inclusive scope of the work.

The desirability of having a successor to the sixth edition of the *System* became evident as early as 1915. Efforts to produce a seventh edition began in 1927 and by 1941, a partial manuscript for the first volume was nearly complete. However, World War II interrupted publication, so that the first volume of the seventh edition of the *System of Mineralogy* (elements, sulfides, sulfosalts, and oxides) by Charles Palache, Harry Berman, and Clifford Frondel, did not appear until 1944.

By then so many new minerals had been added and old ones discredited, and the methodology of mineral identification had become so much more rigorous, with new structural data leading to more scientific classification of mineral groups, that the need for completing the new edition was sorely felt. Work on volume 2 (halogenides and all oxysalts except the silicates) started in 1942, was interrupted by World War II, and was completed in 1951. Harry Berman (1902–1944) had been killed in a plane crash while on war work and Charles Palache (1869–1954) had retired, so the work was essentially completed by Clifford Frondel (1907–). Volume 3 (silica minerals) was completed by Frondel in 1962. The level of detail and complexity required by the format of the seventh edition of *System* was too daunting to attract volunteers to do the silicates, and thus the last volume, the systematic description of the most common silicate minerals, was never undertaken.

The present eighth edition, with five co-authors and a considerably less detailed format than the 7th Edition of the *System*, has been many years in preparation. During the years since it was started, the number of minerals to be covered has about doubled.

Acknowledgments

In compiling and selecting the data for this edition we have consulted the *Powder Diffraction File* published by the International Center of Diffraction Data (Newtown Square, PA 19073-3273) who have generously granted permission for reproduction of portions of their data sets; *The Mineral Data Base* by Ernest H. Nickel, CSIRO, Wembley, WA, Australia, and Monte C. Nichols published by Aleph Enterprises, Box 213, Livermore, CA 94551; and *GEOREF* the bibliographical reference compilation of the American Geological Institute, 4220 King St., Alexandria, VA, 22302-1502. However, without the contributions of colleagues and associates no effort of this magnitude could have been undertaken.

The initial stages of this project were undertaken by the late Horace Winchell of Yale University, Department of Geology and Geophysics, and Brian J. Skinner, also at Yale, was a co-author. We are grateful and wish to publically acknowledge and thank the following individuals for reviewing substantial portions of the manuscript, supplying bibliographical data on the individuals for whom minerals have been named, and offering suggestions and information on the mineral species covered in this volume.

Jay Ague: Dept. of Geology/Geophysics, Yale University.

Eugene Alexandrov: Hamden, Connecticut.

Eric Asselborn, M.D.: Montrevel-en-Bresse, Ain, France.

F. John Barlow: Appleton, Wisconsin.

Peter Bayliss: Mineralogy, Australian Museum, Sydney, NSW, Australia.

We also wish to acknowledge our present editor, Philip Manor, without whom this project would never have seen the light of day. Finally, we take unto ourselves the responsibility for any errors or omissions and urge readers to write to us through John Wiley and Sons, Inc., 605 Third Avenue, New York, N.Y. 10158-0012.

Introduction: Criteria for Inclusion and Definition of a Mineral

Just as the first edition of Dana's *A System of Mineralogy*, this eighth edition also attempts to describe, catalog, and classify all known and recognized minerals reported in the literature up to December 31, 1995. It presents the results of nature's own experiments in chemical synthesis. However, since human beings are now a major factor in our global environment, some anthropogenic minerals are included, along with some data from synthetic equivalents of minerals.

CRITERIA FOR INCLUSION

The criteria for including a mineral in this book require not only that the mineral be discovered and be recognized, but also that the discovery be reported in the generally accessible literature. For minerals discovered after 1959, **recognized** means that the name of the species is approved by the Commission on New Minerals and Mineral Names (CNMMN) of the International Mineralogical Association. For minerals reported before 1959, **recognized** means generally accepted by professionals today as unique, valid species.

The International Mineralogical Association, founded in 1958 to further international cooperation in the mineralogical sciences, currently consists of representatives from 33 countries, and sponsors some 14 commissions, one of which is the Commission on New Minerals and Mineral Names (CNMMN). Proposals for a new mineral should include (1) the name and its significance; (2) geographic and geologic occurrence, source or generation of the mineral, and associated minerals, particularly those in apparent equilibrium with the proposed new mineral; (3) composition and method of analysis; (4) chemical formula, empirical and simplified; (5) crystallographic data, including single-crystal and powder diffraction results, the morphology, and crystal structure determination; (6) general appearance and physical properties; (7) the optical properties; (8) locality of the type material; and (9) relationship to other species. Acceptance as a new species requires a vote of at least 50% of the

international members and an affirmative response of at least two-thirds of those voting. Once accepted, the information must be published in an appropriate journal within two years or the CNMMN would be willing to accept a proposal from anyone else. The name proposed for the mineral is voted on separately: it must not be too similar to any existing name, must be a single word, and must follow usage guidelines if it is derived from the chemical composition, physical properties, or if it is named for a country or individual. The CNMMN reviews 50 to 90 proposals a year, adding about 50 new mineral species each year.

DEFINITION OF A MINERAL

The definition of a mineral as used in this work is a pragmatic, functional one. "A mineral is an element or chemical compound that is normally crystalline and that has been formed as a result of geological processes" E. H. Nickel, *CM* 33:689(1995). A more formal and precise definition of what is or is not a mineral has been and continues to be debated.

The term *crystalline* in this context means that the material possesses atomic ordering on a scale that can produce an indexable diffraction pattern when the material is examined with x-rays, electrons, neutrons, or other radiation of suitable wavelength. There are, however, some naturally occurring materials that have traditionally been included among minerals even though they are noncrystalline. These include (1) a few amorphous substances that have never been crystalline to the extent of producing diffraction patterns (e.g., opal), (2) metamict materials that were crystalline at one time but whose crystallinity has been disrupted by ionizing radiation, (e.g., zircon) and (3) certain naturally occurring liquids (H_2O , as ice but not as water, and liquid mercury are both considered minerals). Petroleum and its noncrystalline bituminous forms are not regarded as minerals. The term *geological processes* in this context is expanded to include extraterrestrial substances (meteorites, moon rocks, etc.) apparently produced by processes similar to those on Earth. Secondly, deliberately synthesized materials, if substantially identical to naturally occurring minerals, may be called *synthetic equivalents*. Chemical compounds formed by the action of geological processes on anthropogenic substances have, on occasion, been accepted as minerals. Examples include the laurium minerals formed by the action of seawater on ancient metallurgical slags. However, many exotic materials are produced today with the possibility that such substances in a geological environment may have reaction products which could qualify as new minerals. Current policy of the CNMMN holds that such substances are not considered minerals.

Thirdly, strictly biogenic substances, inorganic chemical compounds produced entirely in the biological sphere such as the calcium phosphates (apatite) of bones and teeth, the carbonate species typical of mollusc shells, the iron compounds found in bacteria, and oxalate crystals in plant tissues, are all

discussed in this volume as minerals because they also form under strictly geological conditions.

Apart from the named mineral species there is a rapidly growing category of potential minerals, those compounds found in minute quantities along with, or within, known minerals. The quantity is often too small to establish all the requisite characteristics to qualify as a new species, or perhaps the investigator will not deem it worthy of following the procedure to obtain a species name. At present there are about 700 of such compounds, or roughly 16% of naturally occurring mineral substances. Some are mentioned in the mineralogic literature, e.g., annual summary of compounds and new minerals in the *Canadian Minerologist*, but most are to be found in *Chemical Abstracts*.

The potential number of naturally occurring compounds that might be named as minerals is extremely large (see *Skinner and Skinner MR 11:333(1980)*) so continuity of the present rate of 50 to 60 new mineral species per annum seems assured.

Descriptions of Mineral Species: Format of Presentation

1. DANA CLASSIFICATION NUMBER

The first entry for each mineral species is a number containing four parts separated by periods. It represents a hierarchical system parallel to that of Linnaeus but based on a combination of chemistry and crystal structure of the minerals. These numbers facilitate insertion and addition of a new species into a list emphasizing close chemical and structural affiliations, an advantage since each mineral is known by a different, and not necessarily related, name.

The hierarchical numbering system was developed for the seventh edition but covered only nonsilicates. That portion has been updated by James Ferriolo (*A Systematic Classification of Nonsilicate Minerals*, Bull. Am. Mus. of Nat. Hist., Vol. 172, 1982, and Supplements) and is generally followed in this edition. The many and often very complex silicate minerals are here classified for the first time according to a structural-chemical system developed by authors Abraham Rosenzweig and Eugene Foord. The work of H. Strunz (*Mineralogische Tabellen*, 1970, Classe der Silikate, pp.359-493) was incorporated with modification. The silicates are covered in classes 51 to 78.

The first consideration in generating the numbers was division into classes based on composition or, in the case of silicates, on dominant structural elements. The table of contents lists and numbers each of these classes. Species containing more than one anion or anion group may be assigned to a separate class or may be assigned according to dominant chemical entity. The first number indicating class is followed by a number for **type**, which in some cases specifies the atomic (cation to anion, or to anion group) ratio for the mineral. This and the remaining numbers assigned to each species relate to structural similarity considerations. Mineral species with similar structures within their class and type are listed together.

2. NAME

The currently accepted name of the mineral is given next, complete with all appropriate diacritical marks, and is followed by the chemical formula. The derivation of the name, if known, opens the body of the description.

3. CHEMICAL FORMULA

All of the chemical formulas we present approach an ideal composition, that is, the formula includes the elements that are essential or usually found in the natural occurrences of the mineral and describe the proper atomic ratios among the constituent elements and moieties. We generally follow the presentation of M. Fleischer and J. A. Mandarino, *Glossary of Mineral Species*, seventh edition (The Mineralogical Record, Tucson, Arizona, 1995), which accurately describes the stoichiometry but does not necessarily incorporate structural characteristics even though they may be known. An appropriate formula that would uniquely describe a mineral species both chemically and structurally is currently under debate in the mineralogical community [AC(A)46:1(1990)]. In some mineral presentations important relationships are indicated by the way in which the formulas are written.

3A. Isostructural Substitution

Isostructural substitution* is shown by the use of commas to separate two or more elements within parentheses. Such a presentation implies that the elements are similar enough in their structural behavior that they may occupy the same site in the crystal structure of the species. This is a common option for elements with similar charge, ionic size, and bonding character; that is, for example, more than one element can occupy a site with octahedral coordination (C. Klein and C. Hurlbut, *John Wiley & Sons, Inc.*, New York 1985, p.136). The individual elements (with or without parentheses), define an end-member species. A multiple element presentation (within parentheses) suggests that the structure is not grossly altered by the substitution of one element by the other.

When there is a continuum between end member compositions, substitution may be complete defining a mineral series, but often there is only partial substitution.

3B. Vacancies

Vacancies or voids at certain sites in the structure are indicated in the chemical formula by the symbol \square . It is a useful and appropriate way to express the substitution of ions with different charges; for example, $3\text{Mn}^{2+} \Leftrightarrow 2\text{Fe}^{3+}$

* Isostructural substitution is also known as "isomorphous" substitution. We have avoided the term "isomorphic" as it may refer to materials of the same crystal structure, or of the same morphology (habit), or both, according to context. We have also used the term "isostructural" in preference to the synonymous term "isotypic".

□ allows the interchange of divalent and trivalent cations while preserving both the equivalence of overall charge balance and the number and disposition of sites occupied in the structures.

4. NAME DERIVATION

The body of the presentation begins with details on the name, such as the date of the initial description, sometimes the author to whom the name is attributable, and the source of the name, whether it be based on composition, physical properties, geographic discovery site, or person honored. When the name is derived from the initial occurrence (the *type locality*), that locality will be shown in italics in the subsequent section on localities. For names deriving from languages other than English, the foreign language term or, at least its meaning, is given.

At the urging of the CNMMN, an effort is being made to reduce the proliferation of species names by appending chemical or crystallographic criteria to a root name. For example, the Levinson Rule, introduced in 1966, for mineral containing rare earth isostructurals with other rare earth species appends the R.E.E. cation to a root name, the root name being the name of the first member of the series discovered: for example, tritomite-(Ce) and tritomite-(Y) are end members [Ce+Y] in the tritomite series [AM 51:152(1966)]. Chemical prefixes are also employed. However, the chemical prefix does not always mean that the two species have the same crystal structure: for example, sklodowskite and cuprosklodowskite.

5. GROUPS, DIMORPHS AND POLYMORPHS, SYNONYMS AND VARIETIES, AND POLYTYPES

The relationship between the species being described and other species follows the derivation of the name. Here, other members of an isostructural series, polymorphs, or closely related species are mentioned, with cross-references to the appropriate Dana number. When recognized, membership in a group is noted. Occasionally, the phrase "an inadequately characterized species" may occur when the species is accepted, but the data are either incomplete or seem internally contradictory.

5A. Groups

The term *group* refers to an aggregate or multiple (usually three or more) species that have identical or closely similar structure and chemistry. A group may be named when there are several end members of isostructural series (e.g., the calcite group; see 14.1.1.1) or when several species have chemical identity and are structurally related through the multiplicity of one or more lattice parameters. The term *subgroup* is used when many species exhibit

the same basic structural and chemical components but there are discrete ranges for some of the chemical constituents (see the pyroxene group and subgroups).

5B. Dimorphs and Polymorphs

Some chemical compositions have more than one three-dimensional structural configuration. **Dimorphs** are two, and **polymorphs** are three or more, species with the same chemical composition but distinct crystalline structures. Each species is given a different name and number. For example, calcite CaCO_3 (14.1.1.1) has a polymorph aragonite (14.1.3.1), while vaterite (14.1.2.1) has yet another configuration.

5C. Synonyms and Varieties

Many minerals show variations in color or morphology usually due to trace amounts of certain elements. Especially when the mineral species is common, such as quartz (75.1.3.1), many varieties (jasper, onyx) are known. These names are **varieties** but in another sense are **synonyms** as the basic chemistry and structure are identical to those of quartz.

5D. Polytypes

Materials whose basic structural components are layers often exhibit different layer superposition or different periodicity. These variations give rise to distinct but related structures called **polytypes** rather than dimorphs or polymorphs. The micas (71.2.2.X) are sheet silicates which offer examples of stacking sequences, and different polytypes are named by appending an appropriate shorthand notation denoting the structural consideration.

6. CRYSTALLOGRAPHY

The term crystal as used in this volume implies a solid with long-range internal order detectable by diffraction techniques, whether or not the material exhibits external faces, but its unqualified use here generally implies at least a partial development of faces. The text context serves to make any necessary distinctions. A very few materials are included here that lack this long-range order (e.g., opal). Lattice constants are generally derived by X-ray diffraction studies carried out on small single crystals, but may sometimes be derived from powder diffraction of fine grained samples.

Any crystalline substance is characterised by a distinct chemical composition whose components are arranged in a distinctive three-dimensional array or structure. In the majority of minerals species, the composition is not fixed but varies within defineable limits because of substitution of ions (atoms) of similar size and coordination number. This combination of composition and structure constitutes the distinction among mineral species.

The explanation of terms in the following paragraphs are intentionally brief; their meaning and use are well developed in numerous texts, a few of which are given below; abbreviations used in the subsequent text precede each entry.

6A. Crystallographic Principles

1) Crystal Systems (KH, Ch. 2; P, pp. 34-51)

Crystal systems as used here are based on the symmetry of the internal structure rather than on the traditional equality/non-equality of axial ratios and interaxial angles. It follows that coincidental dimensional equality of two axes of an orthogonal set does not require that the third axis have 4-fold symmetry, but rather that the existence of a 4-fold axis requires that the remaining two axes be orthogonal and dimensionally equal.

Some confusion arises when the unique symmetry is of order three (3) or six (6). The former is a subset of the latter, and it follows that such crystals may be divided into a trigonal system and a hexagonal system, or they may be combined into a single system (hexagonal) with subdivisions. In this work, the only distinction made within the composite hexagonal systems for which rhombohedral symmetry exists.

2) Crystal Classes, Point Group Symmetry, and Symmetry Notations (KH, Ch. 2; P. pp. 338-340)

The symmetry elements defining a system may combine with additional symmetry elements to yield thirty-two combinations known as **crystal classes** or **crystallographic point groups**, those combinations constrained by the requirement of spacial repetition to symmetries of order 1, 2, 3, 4, or 6. Point groups

with other than the above rotational symmetries may apply to such subjects as molecular symmetry, spectroscopic data, etc.

The Hermann-Mauguin notation is generally used in presentation of crystallographic data, and consists of a combination of numerals (1, 2, 3, 4, 6) denoting the order of rotational symmetry and "barred" numerals ($\bar{1}$, $\bar{2}$, $\bar{3}$, $\bar{4}$, $\bar{6}$) denoting the order of rotary-inversion symmetry. The $\bar{2}$ axis is equivalent to reflection normal to that axis, and is usually replaced by the symbol *m*. A slash denotes perpendicularity of a rotational element and a reflection.

The Schoenflies notation is commonly used by spectroscopists and for most representation of non-crystallographic symmetry.

4) Miller Indices and Zone Symbols (KH, Ch. 2)

The Miller indices of a crystallographic plane or face represents the coordinates of the plane-normal in reciprocal space. (*N.B.* For a face or form "indices" is often replaced by "index" without a change in meaning. The four-term Miller-Bravais indices, (hkil), are used relative to hexagonal crystals. The third term, however, is a function of the first two such that $i = -(h + k)$.)

Zone symbols, enclosed in square brackets, [uvw], are the coordinates of a line in direct space with respect to the crystallographic axes.

5) Crystal Forms (KH, Ch. 2)

A crystal form is a set of faces generated from a given face by the symmetry elements present. The Miller indices of a face are enclosed in parentheses, i.e., (123), those of a form in braces, i.e., {123}.

The form {hkl} where *h*, *k* and *l* are positive or negative, unequal integers is the general form whose individual faces are acted upon by all symmetry elements present; it has the maximum possible number of faces for a form in the given point group and is distinctive for it. A face for which *h*, *k*, and *l* are no longer unequal or have a value of zero, may shift to a position perpendicular to a symmetry element, and that symmetry element no longer duplicates the face. The resultant special form will have the same number or fewer faces than the general form. The most commonly encountered forms are those with relatively simple Miller indices (corresponding to planes with a high density of lattice nodes); consequently, the correct assignment of crystal class can not always be deduced from the crystal morphology.

6) Space Groups (ITXC, v. 1: P. pp. 241–301)

In the internal crystal structure the rotation and reflection elements of the point group may combine with translational components yielding centered cells, screw axes and glides. These translational components are generate the 230 possible space groups.

7) Choice of Settings (ITXD, v.1, pp. 542-553)

In the mineralogical and crystallographic literature there are followed a number of different conventions, often conflicting, that dictate the assignment of unit cell edges to the axes, *a*, *b*, and *c*. Space groups may be set in a "standard" orientation but alternative settings are possible. The reasons for choosing an alternate setting are varied, but usually depend on the organization of data or the comparison of related structures.

8) Twinning and Epitaxy (KH, pp. 100-105; P, pp. 171-193)

Twinning is the crystallographically rational, non-parallel intergrowth of two or more individual crystals of the same species.

Epitactic relationships are those in which the structure of two species have certain features in common such that the substrate or primary phase acts as a template or nucleation site for the overgrowth or secondary phase.

6B. Order of Presentation of Crystallographic Data

1) **Crystal System** - Denoted by the abbreviations: **TRI** = triclinic; **MON** = monoclinic; **ORTH** = orthorhombic; **TET** = tetragonal; **HEX** = hexagonal including trigonal; **HEX-R** = hexagonal with a rhombohedral lattice; **ISO** = isometric.

2) **Space Group and Point Group** - The next entry is the space group or the possible space groups, and generally corresponds to the space group for the referenced structure determination, but may have been reset to emphasize correspondence with related species. The Hermann-Mauguin point group is nowhere stated *per se*, but an abbreviated H-M notation may be derived from the space group by dropping the lattice type symbol, deleting all subscripts from screw axis symbols, and replacing all glide symbols by an *m*. Thus, *Pnma* becomes *mmm*.

3) **Lattice Constants** - The unit cell edges, if known, are given in Angstrom units, followed by the interaxial angles in decimal degrees, either as fixed value or ranges.

4) **Cell Contents and Calculated Density** - The cell contents, *Z*, is the number of formula units per unit cell as defined by the lattice constants. The calculated density in gms/cm³, *D*, is obtained by the equation $D = (ZM)/(NV)$, where *M* is the formula weight, *N* is Avogadro's number, and *V* is the cell volume in cm³. This numerical value should be close to that of the measured Specific Gravity, *G*, reported as a physical property of the species.

5) **Powder Diffraction Pattern** - (*AZ*) Next is the X-ray powder diffraction pattern consisting of the eight strongest lines, unindexed, arranged in decreasing order of spacing, and subscripted by the relative intensity from 10 down to 1. The pattern is preceded by the ICDD number in italics (**International Center for Diffraction Data Mineral Powder Diffraction File**), or the letters **PD** if the

data was taken directly from the literature. Where appropriate, several diffraction patterns may be given. It should be kept in mind that relative intensity and even the lines included in the strongest eight may vary due to compositional variation within the species and sample preparation artifacts.

6) **Structure** - (GL, GT) A literature reference to a structure determination may appear next, and may be followed by a statement of the salient features of the structure. For important or larger mineral groups, this information will appear in the group description.

If a crystal structure drawing is present, the following criteria apply to them: (a) **Radii** - Atomic radii are nominally one-half the standard ionic radii. For labeling and other reasons, however, it is necessary in many cases to modify these radii. The minimum radius shown is 0.45 Å, meaning that many smaller cations are not shown at true relative size. Anion radii may also be modified downward. Corners of polyhedra, almost always occupied by oxygen atoms, are shown at 0.2 Å, as are unlabeled hydrogen atoms.

(b) **Projection and Extent of Structure** - The structures are in perspective except where noted, and the perspective distance is usually about 50 Å, although it may be less for simple structures or more for complex ones. Typically, the projection is down the shortest crystal axis, although this is by no means a rule. The drawing may show only a portion of the unit cell; constraints of space do not always allow showing the true cell repeats or symmetry.

(c) **Crystal Axes** - Crystal axes are shown at one-half the true relative length end to end, except where noted. Labels on the axes have a white background, and when axes point toward the observer the labels are drawn over the ends of the axes and *vice versa*. The axes are shown in true perspective for their position as shown. Thus they do not show the exact orientation of the center of the structure.

(d) **Atom Labels** - In most cases all atoms and polyhedra are labeled, but in complex structures this may not be true. The label refers to the predominant species in a site. Hydrogen atoms are not labeled, but may be identified by their 0.2 Å radius, that is otherwise used only for oxygen at polyhedra corners. Due to space constraints, "C" is used for the carbonate group and "W" for water. The "W" label is also used for tungsten but appears only in the anhydrous species scheelite and huebnerite.

7) **Habit and Twinning** - There follows a statement of the dominant morphological habit of the species expressed as the Miller indices of the forms present. Where morphological description differ from the structural setting, this fact is noted and a transformation matrix may be given. Furthermore, a verbal description of the gross features of the morphology (acicular, tabular, etc.) and/or a statement of the texture of crystalline aggregates. These terms are generally self-explanatory but may be found in any standard dictionary or DT, pp. 204–206. Included here is a statement of any observed twinning including the twin law and its frequency of occurrence.

7. PHYSICAL PROPERTIES

7A. Morphology and Habit

A brief description of the distinct morphology exhibited by euhedral crystals of a species follows. This includes the following information: When planar faces are observed, they are described relative to the crystal symmetry by the Miller indices. In a crystal drawing, faces are identified by letters, and possibly other symbols, that are identified in the legend to the figure in terms of Miller indices. General shapes of minerals and mineral aggregates are also described.

7B. Twinning

Twinning is the crystallographically rational intergrowth of two or more individual crystals of the same species. The intergrowth generally occurs along a layer or zone of atoms that are common to the two orientations at the boundary of the individuals, but in many cases this site has not been elucidated and only the morphological relationships of the individuals may be described.

Twinning commonly involves a 180° rotation about a zone axis or face-normal having no even-order symmetry, or a reflection across a plane that is not a mirror plane of the individual crystals. If the individual crystals are centrosymmetric, the morphological appearance of the twin displays both the rotation and reflection aspects of the twinning process. The twins may be contact or penetration twins, and may be designated as twins, trillings, four-lings, and so on, in accordance with the number of individuals observed.

Polysynthetic twinning is repeated, usually small-scale twinning that results in parallel slabs in alternating orientation. The usual boundary between the individuals is called the **composition plane**. It often but not always coincides with the twin plane. An irregular composition surface between individuals is common in penetration twins.

The description of twinning may appear in a group description when it applies to all members of a mineral group, or it may be stated as part of the habit description of an individual species. The Miller(-Bravais) index of the twin plane or the zone symbol of the twin axis is stated, as is the frequency of that type of twin. If the twinning relationship has been assigned a specific name, that is stated as the twin law.

7C. Color

Color, an important but variable mineral property, may be due to a variety of factors, including not only the presence of intrinsically colored constituents but also small amounts of foreign substances as well as physical but nonchemical factors such as crystal lattice defects. Consequently, many minerals are found in a wide variety of colors. Unlike soils, there is no widely accepted system for describing the color of minerals in standardized terms. Gemstones, especially diamonds, are of course an exception and are evaluated by color as well as other criteria, although there is no universally accepted system for describing the colors of colored gemstones.

7D. Streak

Particularly with opaque and nearly opaque minerals, color is difficult to distinguish. Producing a streak by, for example, rubbing a sample across an abrasive porcelain or glass surface may allow characteristic colors of the powdered material to be recognized.

7E. Luster

The luster of minerals depends on the appearance of its surfaces in reflected light. It is a complex property that depends on a mineral's reflectivity; index of refraction; and the propensity to cleave, giving flat or rough surfaces; and its response to polarized light. Luster is described by terms such as those listed in Table 1.

TABLE 1 LUSTER

Luster	Description	Examples
Metallic	The luster of metals, applies only to opaque materials	Gold, copper, tin
Sub-Metallic	imperfectly metallic	Columbite, wolframite
Adamantine	The luster of diamond, other materials of high index of refraction, and usually of high density; Index of refraction approximately 1.9 to 2.5.	Diamond
Vitreous	Like broken glass; Index of refraction approximately 1.3 to 1.8.	Quartz
Sub-Vitreous	Imperfectly vitreous	
Resinous	Like amber	Opal, some yellow varieties of sphalerite
Greasy	The luster of oily glass, nearly as lustrous as 'resinous'	Nepheline
Pearly	Like a pearl, or like the luster of a stack of glass plates.	Talc, brucite
Silky	Like silk, used only with fibrous minerals	Sillimanite

The degree or intensity of luster may be described by such terms as **splendent**, **shining**, **glistening**, or **glimmering**. **Dull** is used to describe a mineral totally lacking in luster.

7F. Cleavage and Parting

Cleavage is the planar fracture along a crystallographically rational plane that is structurally controlled. It represents a plane of weaker (but not necessarily weak) bonding within the crystal structure, and consequently can occur everywhere and anywhere within the mineral sample.

If present, cleavage is stated in terms of the indices of the form to which it is parallel, with a modifying adjective denoting the ease of propagation and/or the perfection of the cleavage surface. The self-explanatory terms are in approximate diminishing order of perfection: **perfect** or **excellent**, **good**, **fair**, **poor**. Other self-explanatory terms used are: **easy**, **difficult**, **interrupted**.

Parting is the development of planar fractures that tend to be widely spaced relative to cleavage and which do not occur everywhere within a specimen. Parting may be related to structural features in some degree but develops as a result of nonuniform forces such as external stress, twin boundaries, oriented mechanical inclusions, and so on, and is thus not characteristic of all samples of the species.

7G. Fracture

Fracture is the way in which crystalline substances break when not conforming to cleavage or parting. Some fracture patterns are distinctive. Conchoidal fracture, typical of quartz, gives a fracture similar to the interior of a seashell. Fracture may also be described as hackly, jagged, fibrous, uneven, or irregular. Fibrous materials show distinctive elongate fracture.

7H. Tenacity

Tenacity depends on the nature of the chemical bonding in a mineral species and is described by terms such as those in Table 2.

TABLE 2 TENACITY

Tenacity	Description	Examples
Malleable	Can be flattened with a hammer blow without breaking or crumbling into fragments. A property only of metals.	Gold, silver
Ductile	Can be changed in shape by pressure, especially when it can be drawn out into a wire.	Gold, silver, copper
Sectile	Can be cut with a knife like cold wax, so that shavings may be turned, yet the mineral may break with a sharp blow.	Chlorargylite, chalcocite
Flexible	Bends easily, and stays bent after the pressure is removed.	Talc
Elastic	May be bent or pulled out of shape, but returns to its original form when the pressure is removed	Mica
Brittle	Separates into fragments with a sharp blow, or when cut by a knife	Characteristic of most minerals

7I. Hardness

Hardness can be related to Mohs scale, or measured quantitatively with Vickers hardness tester. Mohs scale assigns numbers to reference minerals, which correspond to simple tests (Table 3).

TABLE 3 MOHS' SCALE OF HARDNESS

Hardness	Reference Mineral	Description and Feel
1	Talc	Soft, greasy feel like talc and graphite, and flakes of the mineral will be left on the fingers
2	Gypsum	Scratched easily with the fingernail, as gypsum
3	Calcite	Just scratched by a copper coin, but not normally scratched by the fingernail
4	Fluorite	Scratched by a knife without difficulty
5	Apatite	Scratched with a knife, but with difficulty
6	Orthoclase	Not scratched with a knife, but is scratched by a file, and will scratch ordinary glass
7	Quartz	Scratches glass easily, but is scratched by topaz and a few other minerals
8	Topaz	Hard
9	Corundum	Harder
10	Diamond	The hardest known mineral

Hardness is an easily measured and valuable property of appropriately sized samples. Microscopic samples require the Vickers hardness tester, which is more quantitative. Results are presented as VHN_n, where *n* represents the amount of loading of the device used to test the sample.

7J. Density/Specific Gravity (KC, p203)

The density *D* (grams/cm³) may be calculated from the lattice parameters as follows:

$$D = \frac{Z \times M}{N \times V}$$

where *Z* is the number of formula units in the unit cell, *M* the formula weight of the compound, *N* is Avogadro's number, and *V* the volume of the unit cell. It is presented with the lattice parameter information.

It may be compared with the measured specific gravity, *G* (weight of a substance relative to the weight of an equal volume of water at 4°C) which serves to confirm the number of formula units, or composition, of the unit cell. A variety of techniques have been developed to measure the specific gravity, depending on the size of the sample and its chemical composition (C. Klein and C. S. Hurlbut, John Wiley & Sons, New York 1985, p. 203).

7K. Infrared, Raman, and Mössbauer Spectroscopic Data, and Differential Thermal Analysis

Spectroscopic and differential thermal analysis data are indicated when reported in the literature and referenced.

7L. Fluorescence/Phosphorescence

Materials may luminesce on direct exposure to different wavelengths of ultra-violet light, x-rays or cathode rays, emitting light of a different and distinctive wavelength. This fluorescence is the result of the excitation of specific electrons, often from transition metal elements included in the mineral. If the luminescence persists after illumination of the sample ceases, the sample is said to be phosphorescent (see WARR and ROBB). Some minerals also react to heat by giving off visible light and are notably thermoluminescent. Fluorite, ideally CaF_2 , is the classic fluorescent species. There are some famous mineral localities, such as Franklin, New Jersey, where many of the mineral species are fluorescent when exposed to UV light.

7M. Optical Properties

The optical properties presented in this work are those that can usually be determined by use of the petrographic microscope appropriately equipped for transmitted or reflected light observations, and by use of appropriate immersion media. The reader is referred to the cited references or to similar texts for additional information regarding any of the reported phenomena and the theory and practice of their determination.

7M(1) Opaque Minerals

Opaque materials are those that do not transmit visible spectrum light or do so only in the very thinnest of fragments. Details of the methods and principals involved may be found in Craig, J. R., and D. J. Vaughn, *Ore Microscopy and Ore Petrography*, John Wiley & Sons, New York, 1994, and extensive descriptions for various species may be found in Uytendogaardt, W., and E. A. J. Burke, *Tables for Microscopic Identification of Ore Minerals*, 2nd ed., Elsevier-North Holland, New York, 1971.

The word "opaque" may also be used in the description of other species; in such cases the reference is to diaphaneity in a bulk sample.

7M(2) Non-opaque Minerals

The optical properties of transparent crystalline substances can be described in terms of the basic equations of electromagnetism as may be found in numerous text such as Slater, J. C., and H. H. Frank, *Electromagnetism*, McGraw-Hill, New York, 1947.

The optical properties of mineral species as well as other light-transmitting substances differ with direction in the crystal as a function of the symmetry of the internal structure. Detailed discussions of these optical properties can be

found in any college-level text on the subject of optical crystallography (e.g. Nesse, W. D., *Introduction to Optical Mineralogy*, 2nd ed., Oxford University Press, New York, 1991; Hartshorn, N. H., and A. Stuart, *Crystals and the Polarizing Microscope*, 3rd ed., Edward Arnold Publishers, London, 1960; and Wahlstrom, E. E., *Optical Crystallography*, 3rd ed., John Wiley & Sons, New York, 1960 listed above).

The optical properties of concern may be described by reference to a geometrical construct known as the **indicatrix**, generally a triaxial ellipsoid in which any axis (line passing through the origin) of the indicatrix is proportional in length to the refractive index of light vibrating in that particular direction. A section passing through the origin of the ellipsoid is an ellipse whose axial lengths correspond to the refractive indices of the two polarized rays propagated normal to the section.

A triaxial ellipsoid indicatrix has two sections that are circular; the normals to these are the two optic axes, and hence the material is said to be **biaxial**. If the indicatrix is an ellipsoid of revolution, there is but one circular section the normal to which is the optic axis, and the material is **uniaxial**. If the indicatrix is a sphere, all sections are circular and geometrically equivalent, and the material is **isotropic**.

Orthorhombic, monoclinic, or triclinic crystals are biaxial; tetragonal and hexagonal crystals are uniaxial; isometric crystals and amorphous substances are isotropic. The constraints regarding orientation of optical vibration directions relative to crystallographic axes will be found in any text on optical mineralogy or optical crystallography.

Optical properties are very sensitive to mechanical stress, and the strain produced may result in observed optical character of lower symmetry than is expected for the crystal's ideal symmetry. Such situations result in an anomalous double refraction manifested as a weak (very low) birefringence.

TABLE 4. ALTERNATIVE NOTATION FOR REFRACTIVE INDICES

n_{α}	or	n_x	or	$n_{ }$
n_{β}	or	n_y	or	n_{\perp}
n_{γ}	or	n_z	or	n_{\parallel}
		n_e	or	n_e
		n_{ω}	or	n_o

7M3. Order of Data Entry

- a) For opaque species: Optical character, isotropic or anisotropic, and reflectivity data for various wavelengths are given.
- b) For non-opaque species: The initial property reported is the optical character and sign (Biaxial+, Biaxial-, Uniaxial+, Uniaxial-, or Isotropic). In situations where either wavelength dispersion or compositional variation leads to a change in the sign, the sign may be given as (+, -). This is particularly true for biaxial species with an optic axial angle close to 90 degrees.

The order of entry for remaining optical properties may vary slightly from entry to entry, but the following are included where relevant and known:

1) For biaxial species the axial angle, $2V$. When the optic axial angle measured over a particular indicatrix axis varies to either side of 90° , $2V$ may be subscripted with an X or Z to indicate which axes is being referred to, as for example: Biax (+, -) $2V_2 = 82-94^\circ$.

2) The refractive indices either as fixed values or ranges. The indices are to be assumed as being for white light, unless a reference is made to a specific wavelength. Dispersion follows in the format $r > v$ or $r < v$ in accordance with whether the indices are greater for red or violet light, but the notation may also refer to dispersion of the optic axis or orientation of the indicatrix.

3) For biaxial species a statement of the indicatrix orientation is given. The correspondence between X, Y and Z with crystallographic axes a, b, and c for orthorhombic crystals; for monoclinic crystals, an identification of the vibration direction, X, Y, or Z coinciding with the b crystallographic axis, and a statement of the angle (extinction angle) between at least one other vibration direction and some crystallographic axis or other observable property such as cleavage (i.e., $Y = b$, $Z \wedge c = 11^\circ$); for triclinic crystals the orientation, when known, of the indicatrix relative to the crystallographic axes is given in the form of one or more extinction angles.

4) Pleochroism/dichroism are stated if that phenomenon is recognizable. The format varies, but will consist of a statement of the color or color range associated with each vibration direction, i.e. X = colorless, Y = yellow, Z = pink, or as a statement of optical density, i.e., $X < Y < Z$. Color and optical density may be combined in the statement.

Variations in any of these properties, particularly those that are composition dependent will be found in the accompanying discussion. Other special optical properties such as pronounced changes in indicatrix orientation, and optical activity will also be found here. Optical activity, the rotation of the polarization plane of light passing through the crystal, is a phenomenon associated with crystals that lack both a center of symmetry and reflection symmetry. There are few minerals for which this rotation is large enough to be observed even in relatively thick sections.

8. COMPOSITION AND PHASE RELATIONSHIPS

Observations concerning the range in composition or substitutions of ions or elements in the formula given are discussed where appropriate, as are any unusual aspects of the composition. Full chemical analyses of the species are generally not provided. Phase relationships relative to other species, and stability fields of the species in question, with or without phase diagrams, are also given here.

9. OCCURRENCE

The overwhelming majority of mineral species we know come from the crust of the earth. A relatively few species have been found uniquely in meteorites, and two are found only in lunar samples. With the exception of a very low content of H_2O , lunar rocks so far examined are very similar to some rock types known on earth.

The crust of the earth consists of igneous, metamorphic, and sedimentary rocks, plus in some regions vast amounts of ice, which in the form of glaciers and ice caps may be considered a monomineralic rock. Nearly 99% of the composition of these rocks consists of only nine chemical elements: oxygen, silicon, aluminum, iron, calcium, sodium, potassium, magnesium, and titanium. Another 0.8% includes chlorine, carbon, phosphorus, sulfur, manganese, and hydrogen. The remaining elements altogether constitute less than 0.3% of the crust. These rarer elements are scattered through the rocks in accessory minerals, as substitutions in more common minerals, or as localized concentrations. The latter account for the ore deposits of many of the less common elements.

The bulk mineral composition of the crust consists mostly of common minerals: quartz, feldspars, micas, amphiboles, pyroxenes, olivines, garnets, clays, calcite, dolomite, apatites, rutile, hematite, magnetite, pyrite, and others. Such minerals constitute at least 98% of the crust but probably less than 200 of the approximately 3600 recognized species. The remainder of species are found in rather special circumstances, where conditions favoring the formation of minerals containing the rarer elements, or rare combinations of the common elements, obtain. These special circumstances include principally the geologic bodies listed in Table 5.

TABLE 5 - GEOLOGIC BODIES

-
1. Granite pegmatites, including their oxidized and/or hydrothermally altered phases
 2. Syenitic pegmatites
 3. Massive sulfide deposits
 4. Oxidized sulfide deposits

 6. Carbonates
 7. Evaporites
 8. Volcanic exhalates
 9. Special metamorphic situations, such as Franklin, NJ and Langban, Sweden
 10. Sedimentary, having mineral concentrations
-

10. LOCALITIES

Each mineral description in this book includes a selection of the best known localities, and the number of localities listed is proportional to the general importance of the mineral. For minerals of special interest to collectors, the number of localities listed has been expanded considerably, especially for calcite and quartz. Many rare minerals are known from only one place, and for other rare minerals all known localities are listed.

The localities are usually listed in a sequence depending on geographic location (Table 6).

TABLE 6 - ORDER OF PRESENTATION OF LOCALITIES INFORMATION

-
1. The United States, from east to west
 2. Canada
 3. Mexico
 4. Central America and the Caribbean
 5. Greenland
 6. Iceland
 7. European countries, from west to east
 8. Asia, including Siberia
 9. China and Japan
 10. India
 11. South east Asia
 12. Middle East
 13. African Countries, from north to south
 14. Oceania
 15. Australia
 16. Antarctica
 17. South America
-

The localities section includes a description of the geological occurrence for important, abundant minerals as well as for rare minerals and, where possible, for the type locality.

The type locality, the locality where the mineral was first discovered, is italicized. In a very few instances there may be more than one type locality, whenever a mineral was found and studied in more than one place before being formally described and named. For some older minerals, mostly for those described before 1850, the type locality is unknown.

Localities providing economically important deposits or specimens of unusual quality may be indicated by an asterisk (*), and those for truly exceptional, museum-quality specimens by an exclamation point (!).

Abbreviations of geographic place names used in this book are given in Table 7.

TABLE 7 - GEOGRAPHICAL ABBREVIATIONS

States, (as in postal usage)		Washington	WA

Native Elements and Alloys

GOLD GROUP

The members of the gold group are elements or intermetallic compounds that share the same basic cubic close-packed structure: $Fm\bar{3}m$.

CCP: cubic closest-packed (gold, copper, platinum, nickel, taenite)

Space group $Fm\bar{3}m$. In this view the $[111]$ direction is vertical, showing the horizontal layers of atoms. Adopted by gold, silver, copper, platinum, and related metals.

CUBIC CLOSE-PACKED ELEMENTS

Mineral	Formula	Space Group	a	D	
Gold	Au	<i>Fm3m</i>	4.079	19.28	1.1.1.1
Silver	Ag	<i>Fm3m</i>	4.085	10.50	1.1.1.2
Copper	Cu	<i>Fm3m</i>	3.615	8.94	1.1.1.3
Lead	Pb	<i>Fm3m</i>	4.951	11.34	1.1.1.4
Aluminum	Al	<i>Fm3m</i>	4.049	2.697	1.1.1.5

Note: Taenite (1.1.11.2) and nickel (1.1.11.5) are isostructural with the gold group.

1.1.1.1 Gold Au

Known since antiquity. Gold group. iso *Fm3m*. $a = 4.079$, $Z = 4$, $D = 19.28$. $4-78.4(\text{syn})$: 2.36_{10} 2.04_5 1.44_3 1.23_4 1.18_1 0.936_2 0.912_2 0.833_2 . Physical properties: octahedral and dodecahedral crystals, often in parallel groups or dendritic and arborescent forms; also massive, and as scales and rounded grains in alluvium. Golden yellow color and streak, inclining to silver-white with increasing substitution by Ag, or to orange-red with substitution by Cu; metallic luster. No cleavage, hackly fracture, very malleable and ductile. $H = 2\frac{1}{2}-3$, $VHN_{10} = 30-58$. $G = 15.2-19.3$. Tests: Insoluble in acids except aqua regia. Gold is readily distinguished from other metallic minerals and from scales of golden mica by its malleability and high G; from pyrite and chalcopyrite since they are harder, brittle, and soluble in HNO_3 . Chemistry: A complete substitution series exists between Au and Ag, and nearly all gold contains some Ag; beyond 20 wt% Ag the mineral is commonly termed *electrum*. Up to 20% Cu, 20% Hg, 10% Pd, and minor Bi have been recorded. Optics: $R = 63.4$ (540 nm); isotropic. Occurrence: Gold is commonly found in hydrothermal quartz veins associated with pyrite, arsenopyrite, and other sulfide minerals, and in placers resulting from the weathering of these deposits and subsequent concentration of gold with other heavy resistant minerals. Gold in quartz veins is usually fine grained and tends to be irregularly distributed in stringers, scales, and plates; large polycrystalline masses are found occasionally. The transformation from gold in veins to gold in placers involves abrasion and mechanical deformation, and placer gold grains tend to be small, flattened or rounded. Placer deposits, especially the fossil placers of the Witwatersrand in South Africa, have produced most of the world's gold. Localities: Gold is so widespread and so readily concentrated in placers that almost every country has some recorded production. It is therefore possible to list only the more important localities. In the United States, gold occurs in small amounts in MD, VA, NC, SC, and GA; fine specimens in quartz were found in White Hall mines, Spotsylvania Co., and Partridge mine, Orange Co., VA, and at Dahlonga, GA; Homestake mine, Lawrence Co., SD; Silver Bow, Madison, and Broadwater Cos., MT; Leadville, Lake Co., Breckenridge(*), Summit Co., Ground Hog mine(*), Gilman Co., Silverton and Telluride, San Juan Co., CO; Bingham and Tintic, Salt Lake Co., UT; Mohave and Cochise Cos., AZ; Elmore, Idaho, and Valley Cos., ID; Goldfield, Esmer-

alda Co., Tonopah, Nye Co., Carlin and Cortez, Eureka Co., Winnemucca(*), Humboldt Co., NV; many localities in CA, especially in the Mother Lode belt in Mariposa, Tuolumne, Calaveras, Amador, and El Dorado Cos.—exceptional crystallized specimens from Placerville, El Dorado Co., Greenville, Plumas Co., Red Ledge mine, Nevada Co., Jamestown, Tuolumne Co., Colorado quartz mine, Mariposa Co., Bonanza mine, Trinity Co., Michigan Bluff district, Placer Co., in AK, placers at Fairbanks, Iditarod, and Nome, and quartz veins at Juneau. In Canada, Noranda district, PQ; Porcupine, Kirkland Lake, and Larder Lake deposits, ON; Atlin and Caribou, BC; and Klondike district, YT. In Mexico, Altar and Magdalena, SON; Parral, CHIH; and localities in GTO and ZAC. In Europe, minor occurrences in the Alps; major occurrences in Transylvania, Romania, especially Rosia Montana (Verespantik). In Russia, gold is found on the eastern slope of the Ural Mts. for a distance of 500 miles, from Nizhne Tagilsk in the north to Orsk in the south; in Siberia important placer deposits near Tomsk, Yeniseisk, Lena R., and upper Amur R. In India the chief producer is the Kolar field in Mysore. In Africa, Ashanti, Ghana; Kilo and Moto, Zaire; Bulawayo and Hartley, Zimbabwe; Witwatersrand, South Africa, a belt of fossil placers about 120 miles long that has been mined to depths exceeding 2 miles. Many important gold mining districts in Australia, including Hill End, Hillgrove, and Mt. Boppy, NSW; Mt. Morgan and Cooktown, Q; Bendigo and Ballarat, VIC; Kalgoorlie, Coolgardie, and Norseman, WA; Tennant Creek, NT. In New Zealand, Hauraki Peninsula, North Island, and placer deposits in Nelson, Westland, Otago, and Southland. Emperor mine, Vatukuola, Fiji. Mt. Kare, Papua New Guinea. In South America, Antioquia and Cauca, Colombia; Santa Elena, Venezuela; the coastal ranges of northern Chile and scattered localities in Peru, Bolivia, and Ecuador; Morro Velho mine, Nova Lima, MG, Brazil. *BM DI:90, R:321, P&J:281, ABI:189, MR 13:323(1982).*

1.1.1.2 Silver Ag

Known since antiquity. Gold group. iso $Fm\bar{3}m$. $a = 4.085$, $Z = 4$, $D = 10.50$ (Silver 3C). Hexagonal polytypes 2H and 4H are known. $4-783(\text{syn})$: 2.36_{10} 2.04_4 1.45_3 1.23_3 1.18_1 0.938_2 0.914_1 0.834_1 . **Physical properties:** Cubic and octahedral crystals, but commonly as reticulated, arborescent, and wiry forms; twinning common on {111}. Silver-white, usually tarnishing to gray to black, silver-white streak, metallic luster. No cleavage, hackly fracture, malleable and ductile. $H = 2\frac{1}{2}$ -3, $VHN_{100} = 61-65$. $G = 10.5$. **Tests:** Soluble in HNO_3 ; color, malleability, and G usually diagnostic. **Chemistry:** A complete solid solution series exists between Ag and Au. Mercurian (kongsbergite, up to 37 at % Hg), cuprian, arsenian (huntelite), antimonian (animitite), and bismuthian (chilenite) varieties have been reported. **Optics:** $R = 80.8$ (540 nm); isotropic. **Occurrence:** Native silver is widely distributed in small amounts, principally in the oxidized zone of ore deposits. The larger deposits, however, are probably the result of the deposition of silver from hydrothermal solutions of primary origin. Deposits of this kind are of three main types: silver asso-

ciated with various silver minerals, sulfides, and zeolites in a gangue of calcite, barite, fluorite, and quartz (Kongsberg); silver with arsenides and sulfides of nickel and cobalt in a calcite or barite gangue (Cobalt); with uraninite and nickel-cobalt minerals (Great Bear Lake, Jachymov). **Localities:** Only some of the more important localities can be given. Prospect Park, Paterson, NJ, with zeolites; Keweenaw Peninsula(*), MI, as fine crystallized aggregates and "half-breeds" (crystallized together with native copper); Butte and Elkhorn districts, MT; Georgetown(*), Crested Butte(*), Creede(*), Aspen(*), and other localities, CO; Bunker Hill, Shoshone Co., and Poorman mine, Owyhee Co., ID; Tombstone(*), Globe(*), Bisbee, and other localities, AZ; Calico district, San Bernadino Co., Cerro Gordo(*), Inyo Co., Bodie district, Mono Co., and other localities in CA. In Canada, at Cobalt(*) and Thunder Bay district, ON, Highland Bell mine(*), Beaverdell, BC, and Great Bear Lake, NWT. Many localities in Mexico, especially Batopilas(*), CHIH, Guanaquato(*), GTO, and localities in SON, DGO, and ZAC. Kongsberg(!), Norway (large specimens of crystallized and wire silver); Ste.-Marie-aux-Mines, Alsace, France; Andreasberg, Freiberg(*), and Schneeberg(*), Germany; Příbram(*), Jachymov, and Schemnitz, Czech Republic; Monte Narba, Sardinia, Italy; Smeingorsk, Semenowsky, and Altai, Siberia, Russia; Rudnui(*) and Dhezkazgan(*), Kazakhstan; Salida and Mangani, Sumatra; Broken Hill(*) and Cobar, NSW, Australia; Huancavelica, Peru; Potosi(*), Oruro(*), and other localities in Bolivia; Copiapo, Huantaya(*), Chanarcillo(*), and Chanca, Chile; Tsumeb, Namibia. *BM DI:96, R:313, P&J:71, ABI:475.*

1.1.1.3 Copper Cu

Known since antiquity. Gold group. ISO $Fm\bar{3}m$. $a = 3.615$, $Z = 4$, $D = 8.94$. $4-836(\text{syn}): 2.09_{10} 1.81_5 1.28_2 1.09_2 1.04_1 0.904_1 0.829_1 0.808_1$. **Physical properties:** Cubic and dodecahedral crystals, often flattened or elongated; also arborescent, platy, and as masses weighing many tons. Light rose, tarnishing to copper-red and brown, metallic streak and luster. No cleavage, hackly fracture, highly malleable and ductile. $H = 2\frac{1}{2}-3$, $VHN_{100} = 77-99$. $G = 8.95$. **Tests:** Soluble in HNO_3 ; color malleability and G usually diagnostic. **Chemistry:** Usually remarkably pure, containing only traces of other elements. Arsenian copper (whitneyite) is reported with more than 11% As, but most arsenian specimens are mixtures with algodonite, so analyses are questionable. **Optics:** $R = 47.6$; isotropic. **Occurrence:** Probably all native copper is of secondary origin, formed by the reduction of copper-bearing solutions by iron minerals. Rarely an ore mineral, but large deposits of Keweenaw Peninsula, MI, are exceptions; here copper is associated with native silver, chalcocite, bornite, epidote, zeolites, and calcite, and is found as a cement in interstices of sandstone and conglomerate, filling amygdaloidal openings in interbedded lavas, and in veins traversing the country rocks. **Localities:** In traprocks and associated Triassic sandstones in MA, CT, NJ, PA, and VA. In MI a narrow belt 200 miles long in the Keweenaw Peninsula(*), which was for many years the major copper district of the world: huge masses were found there, the

largest about 420 tons, and large groups of crystals. Santa Rita, Grant Co., NM; Ajo(*), Pima Co., Bisbee(*), Cochise Co., and Ray, Gila Co., AZ; Copper R. district, AK. Cap d'Or, NS, Kamloops, BC, and Upper White R., YT, Canada. Cananea, SON, and Mapimi, DGO, Mexico. Cornwall, England, in many mines. Rheinbreitenbach and Friedrichsseggen, Rheinland-Pfalz, Germany. Bogoslovsk(*), Nizhne-Tagilsk, and Sverdlovsk, Ural Mts., Russia. Broken Hill(*), NSW, Mt. Isa, Q, and Wallaroo and Burra-Burra, SA, Australia; Aniseed Valley, near Nelson, New Zealand. Shaba, Zaire; Broken Hill mine, Zambia; Onganja mining district, Namibia. Andacolla, near Coquimbo, and Chuquicamata, Chile; Corocoro(*), Bolivia. Alteration: Alteration of native copper first produces a thin cuprite film over the surface, which gives it a characteristic copper-brown color; weathering may produce malachite, azurite, atacamite, and other secondary minerals. Copper pseudomorphs have been observed after cuprite, aragonite, calcite, azurite, chalcocite, and antlerite. *BM DI:99, R:308, P&J:138, ABI:108, MR 23(2):1(1992).*

1.1.1.4 Lead Pb

Known since antiquity. Gold group. iso *Fm3m*. $a = 4.951$, $Z = 4$, $D = 11.34$. $4-686(\text{syn}): 2.86_{10} 2.48_5 1.75_3 1.49_3 1.43_1 1.14_1 1.11_1 0.837_1$. Rarely as octahedral, cubic, and dodecahedral crystals; commonly as rounded masses and plates; recorded as pellets in alluvium, but probably artificial. Gray-white, tarnishing to dull lead-gray, metallic luster. No cleavage, sectile and malleable. $H = 1\frac{1}{2}$, $VHN_{100} = 5$. $G = 11.37$. $R = 48.9$ (540 nm). Franklin, NJ; Shafter district, Presidio Co., TX; Wood R. district, ID; Keno Hill, YT, Canada; Ilimaussaq, Greenland; *Långban*(*), *Värmland*, Sweden (crystallized masses up to 60 kg); Red Cap mine, Chillagoe, Q, Australia; El Dorado, Gran Sabana, Venezuela. *BM DI:102, R:337, P&J:304, ABI:292.*

1.1.1.5 Aluminum Al

Identified as a mineral in 1978. Gold group. iso *Fm3m*. $a = 4.049$, $Z = 4$, $D = 2.697$. $4-787(\text{syn}): 2.34_{10} 2.02_5 1.43_2 1.22_2 1.17_1 0.929_1 0.906_1 0.827_1$. Flat platelets and scaly masses. Gray-white, metallic luster. $H = 2-3$. $G = 2.707$. Tsepochechnyi intrusive, Siberia, and Tolbachik volcano, Kamchatka, Russia. *BM DANS 243:191(1978), 313:433(1990); ZVMO 113:210(1984); AM 65:205(1980).*

1.1.2.1 Auricupride Cu_3Au

Named in 1950 for the composition. See isoferroplatinum group. May contain up to 8% Pd. iso *Pm3m*. $a = 3.753$, $Z = 1$, $D = 12.2$. $35-1357(\text{syn}): 3.75_2 2.65_1 2.17_{10} 1.87_4 1.33_2 1.13_2 0.860_1 0.838_1$. Platy aggregates and anhedral grains. Yellow with a reddish tint, metallic luster. No cleavage, ductile and malleable. $H = 3\frac{1}{2}$, $VHN_{10} = 54$. $G = 11.5$. $R = 63$ (580 nm). Occurs in serpentinites as a product of low-temperature unmixing of Au-Cu alloys. Steinmauern, Baden, Germany; Laksia and Pefkos, Cyprus; *Karabash and Talnakh deposits, Ural*

Mts., Russia; El Indio mine, east of Coquimbo, Chile. BM FM 28:69(1950), AM 62:595(1977), R:334, ABI:36.

1.1.2.2 Tetraauricupride CuAu

Named in 1982 for the composition and symmetry. See the tetraferroplatinum group. TET. $P4/mmm$. $a = 3.960$, $c = 3.670$, $Z = 2$, $D = 15.03$. 25-1220(syn): 3.67₃ 2.80₂ 2.23₁₀ 1.98₃ 1.84₁ 1.74₁ 1.35₁ 1.19₁. Microscopic anhedral grains. Golden yellow, metallic luster. Malleable. $H = 4\frac{1}{2}$, $VHN_{20} = 288$. $R = 61.2$ (546 nm); weakly anisotropic. *Sardala, Xinjiang, China*, in serpentinite. BM AM 68:1250(1983), ABI:523.

1.1.2.3 Yuanjiangite AuSn

Named in 1994 for the locality. HEX $P6_3/mmc$. $a = 4.316$, $c = 5.510$, $Z = 2$, $D = 11.78$. AM 80: 3.73₃ 3.09₄ 2.22₁₀ 2.16₆ 1.55₃. Granular aggregates. Silver-white, black streak, metallic luster. Slightly ductile. $VHN_{25} = 172-274$. $G = 11.7-11.9$. $R = 74-76$ (540 nm); distinctly anisotropic, pale yellow to brown. In placers, *Yuanjiang R., near Yuanlin, Hunan Prov., China*. BM APM 13:232(1994), AM 80:1330(1995).

1.1.3.1 Maldonite Au₂Bi

Named in 1870 for the locality. ISO. $Fd3m$. $a = 7.971$, $Z = 8$, $D = 15.70$. 12-734: 2.82₄ 2.41₁₀ 2.30₅ 1.63₃ 1.54₆ 1.41₅ 1.20₃ 1.04₄. Octahedral crystals and massive, granular. Silver-white, tarnishing to copper-red and black, metallic luster. Cleavage {001}, {110}, distinct; conchoidal fracture; malleable and sectile. $H = 1\frac{1}{2}-2$, $VHN_{100} = 147-264$. $G = 15.46$. $R = 55.8$ (540 nm). Ingram, ON, Canada; Salsigne deposit, Aude, and Scoufour, Cantal, France; Baita, Romania; Tyrnyauz district, Caucasus Mts., Russia; Syrymbet, Kazakhstan; Maldon, VIC, Australia. BM DI:95 R:336, P&J:254, ABI:310.

1.1.4.1 Anyuuite Au(Pb,Sb)₂

Named in 1989 for the locality. TET $I4/mcm$. $a = 7.338$, $c = 5.658$, $Z = 4$, $D = 13.33$. 25-365(syn): 2.84₁₉ 2.48₃ 2.32₅ 2.24₄ 1.70₂ 1.54₂ 1.48₂ 1.32₁. Detrital grains. Silver-gray, tarnishing to dull lead-gray, metallic luster. $H = 3$, $VHN_{20} = 146$. $R = 63.9$ (540 nm); weakly anisotropic. *Bolshoi Anyui R., Kolyma region, Russia*, in gold-bearing alluvium. BM MZ 11(4):88(1989), AM 76:299(1991).

1.1.5.1 Zinc Zn

Known since antiquity. See the osmium group. HEX $P6_3/mmc$. $a = 2.665$, $c = 4.947$, $Z = 2$, $D = 7.14$. 4-831(syn): 2.47₅ 2.31₄ 2.09₁₀ 1.69₃ 1.34₃ 1.33₂ 1.17₂ 1.12₂. Microscopic grains. Blue-white, metallic luster. Cleavage {0001}, perfect; brittle. $H = 2$. $G = 6.9-7.2$. Keno Hill, YT, Canada, precipitated from cold brines; Syrymbet, Kazakhstan; Dulcinea de Llampos mine, near Copiapo, Chile, an oxidation product of sphalerite. Other reported occur-

rences doubtful and need confirmation. BM *DI:127*, *CM 6:692(1961)*, *AM 55:1019(1970)*, *ABI: 585*.

1.1.5.2 Cadmium Cd

Identified as a mineral in 1979. See the osmium group. HEX *P6/mmc*. $a = 2.979$, $c = 5.618$, $Z = 2$, $D = 8.64$. $5-674(\text{syn})$: 2.81_7 2.58_3 2.35_{10} 1.90_3 1.52_3 1.49_2 1.32_2 1.26_1 . Microscopic grains. Tin-white, metallic luster. *Ust-Khannin intrusive, Vilyui R., Russia*, in heavy concentrate from a gabbro. BM *DANS 248:1426(1979)*, *AM 65:1065(1980)*, *ABI:75*.

1.1.6.1 Danbaite CuZn₂

Named in 1983 for the locality. iso Space group unknown. $a = 7.762$, $Z = 12$, $D = 7.36$. $39-400$: 2.36_5 2.16_4 2.08_{10} 1.59_3 1.37_4 1.23_3 1.22_3 1.16_3 . Microscopic spherulitic aggregates. Silver-white to gray-white, metallic luster. $H = 4$, $VHN_{20} = 234-288$. *Danba, Sichuan Prov., China*, in a Cu-Ni deposit. BM *KT 22:1383(1983)*, *AM 69:566(1984)*, *ABI: 126*.

1.1.6.2 Zhanghengite CuZn

Named in 1986 for Zhang Heng (78-139), a famous astronomer in ancient China. iso *Pm3m*. $a = 2.95$, $Z = 1$, $D = 8.32$. $2-1231(\text{syn})$: 2.96_1 2.08_{10} 1.47_2 1.20_3 1.04_1 0.932_1 0.851_1 0.788_1 . Microscopic grains. Golden yellow, bronze streak, metallic luster. No cleavage. $VHN_{10} = 140-150$. $R = 81.1$ (549 nm). Occurs in the Boxian meteorite that fell in *Boxian Co., Anhui Prov., China*, on October 20, 1977. BM *AM 75:244(1990)*.

1.1.7.1 Mercury Hg

Known since antiquity. HEX-R *R3m*. $a = 3.46$, $c = 6.71$, $Z = 3$, $D = 14.40$. $9-253(\text{syn})$: 2.74_{10} 2.23_8 1.73_5 1.46_6 1.37_6 1.12_5 0.937_6 0.865_6 . Liquid globules, solid below -40° . Tin-white, metallic luster. $G = 13.6$. Volatile, fumes highly toxic. Occurs in cinnabar or associated with it in mercury deposits. Terlingua, TX; New Almaden, Santa Clara Co., and in mercury deposits in Sonoma, Napa, and Lake Cos., CA; Almaden, Spain; Landsberg, near Obermoschel, Germany; Idrija, Slovenia; Mt. Avala, near Belgrade, Serbia. BM *DI:103*, *R:337*, *ABI:323*.

1.1.8.1 Moschallandsbergite Ag₂Hg₃

Named in 1938 for the locality. iso *Im3m*. $a = 10.04$, $Z = 10$, $D = 13.41$. $11-67$: 2.67_4 2.36_{10} 1.97_4 1.67_4 1.45_4 1.37_7 1.28_5 1.24_6 . Dodecahedral crystals commonly modified by the cube and trapezohedron, also massive, granular. Silver-white, metallic luster. Cleavage $\{011\}$, $\{001\}$, distinct; conchoidal fracture; somewhat brittle. $H = 3\frac{1}{2}$, $VHN_{100} = 153$. $G = 13.5-13.7$. Sala mine, Vastmanland, Sweden; *Landsberg(*) (Moschallandsberg), near Obermoschel, Pfalz, Germany*; Chalanches mine, Allemont, Isere, France. BM *DI:103*, *R:337*, *P&J:275*, *ABI:341*.

1.1.8.2 Schachnerite $\text{Ag}_{11}\text{Hg}_{10}$

Named in 1972 for Doris Schachner (1904–1989), German mineralogist. *HEX* $P6_3/mmc$. $a = 2.978$, $c = 4.842$, $Z = 2$, $D = 13.4$. $27-618(\text{syn})$: 2.58_3 2.42_5 2.27_{10} 1.49_4 1.27_5 0.954_5 0.937_4 0.860_6 . Crystals to 1 cm. Cream-white, metallic luster. $H = 3\frac{1}{2}$, $\text{VHN}_{100} = 148$. $G = 12-15$. $R = 72$ (589 nm); very weakly anisotropic. Sala mine, Västmanland, Sweden; *Landsberg, near Obermoschel, Pfalz, Germany*. *BM NJMA 117:1(1972)*, *AM 58:347(1973)*, *R:338*, *ABI:463*.

1.1.8.3 Paraschachnerite Ag_3Hg_2

Named in 1972 for its relationship to schachnerite. *ORTH* $Cmcm$. $a = 2.961$, $b = 5.13$, $c = 4.83$, $Z = 2$, $D = 12.98$. $27-617$: 2.56_3 2.40_6 2.27_{10} 1.76_3 1.48_4 1.36_5 1.26_6 0.831_4 . Small pseudo-hexagonal crystals. Gray, metallic luster. $H = 4$, $\text{VHN}_{100} = 87$. $R = 70.9-73.7$ (589 nm); weakly anisotropic. Sala mine, Västmanland, Sweden; *Landsberg, near Obermoschel, Germany*; Kremikovci, Bulgaria. *BM NJMA 117:1(1972)*, *AM 58:347(1973)*, *R:338*, *ABI:288*.

1.1.8.4 Luanheite Ag_3Hg

Named in 1984 for the locality. *HEX* Space group unknown. $a = 6.61$, $c = 10.98$, $Z = 6$, $D = 12.57$. $41-1417$: 2.83_7 2.45_5 2.00_6 1.74_5 1.50_{10} 1.20_9 1.13_7 1.11_6 . Microscopic grains and spherical aggregates. White, tarnishing to black, black streak, metallic luster. Malleable. $H = 2\frac{1}{2}$, $\text{VHN} = 44-75$. $G = 12.5$. $R = 64-71$ (540 nm). *Luan He R., Hebei Prov., China*, in a gold placer. *BM AM 73:192(1988)*, *ABI:303*.

1.1.8.5 Eugenite $\text{Ag}_{11}\text{Hg}_2$

Named in 1986 for Eugen F. Stumpfl (b.1931), Austrian mineralogist. *iso* $I43m$. $a = 16.02$, $Z = 4$, $D = 10.45$. *AM 80*: 2.37_{10} 2.10_8 1.46_7 1.24_7 1.19_6 1.03_5 0.950_8 0.925_8 . Grains up to 4 mm. White. $\text{VHN}_{15} = 96$. $G = 10.75$. $R = 80.1$ (546 nm); isotropic. Bisbee, AZ; *Lubin mine, Poland*, in Zechstein Cu deposit. *BM AM 80:845(1995)*.

1.1.8.6 Weishanite $(\text{Au,Ag})_3\text{Hg}_2$

Named in 1984, derivation not given. *HEX* $P6_3/mmc$. $a = 2.927$, $c = 4.818$, $Z = 2$, $D = 18.17$. $4-808(\text{syn})$: 2.52_5 2.40_5 2.23_{10} 1.74_6 1.46_7 1.35_8 1.24_8 1.22_7 . Microscopic aggregates. Pale yellow, metallic luster. Ductile and malleable. $H = 2\frac{1}{2}$, $\text{VHN} = 51$. $R = 76.3$ (534 nm); weakly anisotropic. *Poshan mining district, Tongbai, Henan Prov., China*, in an Au–Ag deposit. *BM AM 73:196(1988)*, *ABI:571*.

1.1.9.1 Kolymite Cu_7Hg_6

Named in 1980 for the locality. Dimorphous with belendorffite. *iso* $I43m$. $a = 9.418$, $Z = 4$, $D = 13.11$. $33-470$: 2.98_3 2.52_4 2.22_{10} 2.09_3 2.01_3 1.52_2 1.39_2 1.28_3 . Microscopic cubo-octahedral crystals. Tin-white, tarnishing to brown-black, metallic luster. Brittle. $H = 4$, $\text{VHN}_{20} = 220-267$. $G = 13.0$. $R = 72.1$

(540 nm). Comstock Lode, NV; *Krokhalin antimony deposit, Kolyma R., Russia*. BM *ZVMO* 109:206(1980), *AM* 66:218(1981), *ABI*:270, *EM* 1:719(1989).

1.1.9.2 Belendorffite Cu_7Hg_6

Named in 1992 for Klaus Belendorff (b.1956), German mineral collector. Dimorphous with kolymite. *HEX-R R3m*. $a = 9.408$, $\alpha = 90.47^\circ$, $Z = 4$, $D = 13.15$. *22-241*(syn): 6.66₅ 3.31₅ 2.98₈ 2.97₈ 2.52₁₀ 2.23₁₀ 2.22₁₀ 2.01₅. Globule. Silver-white, tarnishing to brown-black, silver-white streak, metallic luster. $\text{VHN}_{25} = 125$. $G = 13.2$. $R = 71.9$ (540 nm); weakly anisotropic. *Landsberg, near Obermoschel, Pfalz, Germany*. BM *NJMM* 21(1992), *AM* 77:1305(1992).

1.1.10.1 Leadamalgam Pb_2Hg

Named in 1981 for the composition. *TET I4/mmm*. $a = 3.545$, $c = 4.525$, $Z = 0.667$ (*sic*), $D = 11.98$. *39-395*: 2.78₁ 2.49₄ 2.25₄ 1.78₄ 1.68₄ 1.49₁₀ 1.40₁₀. Microscopic grains. Silver-white, metallic luster. $H = 1\frac{1}{2}$, $\text{VHN}_{100} = 12$. *Shiaonanshan, Inner Mongolia, China*, in heavy concentrates from a Cu-Ni sulfide deposit. BM *AM* 70:215(1985), *ABI*:293.

IRON-NICKEL GROUP

The iron-nickel group consists of six nonisostructural species that reflect the various proportions of

that are stable at various temperatures. Fe and Ni form a complete series of solid solutions at high temperatures, but at lower temperatures the relationships are more complex. The names *kamacite* and *taenite*, corresponding to α -Fe and γ -Fe, were originally introduced to describe meteoritic forms of Fe-Ni. Both are perfectly good mineral names and are preferred to the terms *iron* and *nickel iron* used by some authorities.

On cooling through 900° , pure Fe inverts from the face-centered structure to the body-centered structure. The inversion temperature decreases with increasing Ni content. In the slowly cooled meteorites, the nickel-iron exsolves kamacite along the octahedral planes, giving rise to Widmanstätten structure typical of most iron meteorites. At about 500° kamacite containing 7.5% nickel is in equilibrium with taenite containing about 30% Ni. *GCA* 52:617(1988).

IRON-NICKEL GROUP

Mineral	Formula	Space Group	a	c	D
Kamacite	α -(Fe,Ni)	<i>Im3m</i>	2.859		7.90
Taenite	γ -(Fe,Ni)	<i>Fm3m</i>	3.596		8.14
Tetrataenite	FeNi	<i>P4/mmm</i>	2.533	3.582	8.275
Awaruite	Ni ₃ Fe	<i>Fm3m</i>	3.560		8.32
Nickel	Ni	<i>Fm3m</i>	3.524		8.91
Wairauite	FeCo	<i>Im3m</i>	2.86		8.32

1.1.1.1 Kamacite α -(Fe,Ni)

Named in 1861 from the Greek for *bar*. Iron-nickel group. Contains up to 7.5% Ni. iso *Im3m*. $a = 2.859$, $Z = 2$, $D = 7.90$. *18-645*: 3.03_1 2.95_1 2.03_{10} 1.97_6 1.48_1 1.44_3 1.17_7 1.02_1 . Terrestrial kamacite occurs as disseminated grains or rounded masses; meteoritic kamacite as exsolved lamellae or in hexahedrites (5–7% Ni) as single crystals weighing many kilograms. Steel-gray, metallic luster. Cleavage {001}, hackly fracture. $H = 4$, $VHN_{100} = 110$ –155. $G = 7.84$ –7.92. $R = 45$ (546 nm). Magnetic. Easily soluble in dilute HCl. Terrestrial kamacite is rare; most occurrences are in basalts in which the iron has been reduced by the assimilation of carbonaceous material. The most important occurrence is on Disko Is., Greenland, where masses of up to 20 tons are present in basalts that have broken through coal seams. Other significant localities include Bühl, Kassel, Germany, and Putorana plateau, Taimyr Penin., Russia. Kamacite is a major component of most iron meteorites and is a minor mineral in most chondrites. It occurs as microscopic grains in some lunar rocks. BM *DI:114*, *R:353*, *P&J:161*, *ABI:256*.

1.1.1.2 Taenite γ -(Fe,Ni)

Named in 1861 from the Greek for *band*. Iron-nickel group. Contains 25–50% Ni. iso *Fm3m*. $a = 3.596$, $Z = 4$, $D = 8.14$. *23.297*(syn): 2.08_{10} 1.80_8 1.27_5 1.08_8 1.04_5 0.900_3 . Small grains and exsolved lamellae; also massive. Silver-white to steel-gray, metallic luster. Malleable. $H = 5$ – $5\frac{1}{2}$, $VHN_{100} = 350$ –500. $G = 8.01$ –8.08. Magnetic. Slowly soluble in dilute HCl. Occurs in iron meteorites containing more than 7% Ni and is a major component of Ni-rich ataxites. An accessory mineral in many chondrites and in some lunar rocks. BM *DI:117*, *R:353*, *ABI:510*.

1.1.1.3 Tetrataenite FeNi

Named in 1980 for the tetragonal ordered form of taenite. Iron-nickel group. Contains 48–57% Ni. TET *P4/mmm*. $a = 2.533$, $c = 3.582$, $Z = 1$, $D = 8.275$. Microscopic grains, and rims on taenite. Cream-white, metallic luster. $H = 3\frac{1}{2}$, $VHN_{25} = 170$ –200. Weakly anisotropic. An accessory mineral in many

CCP: cubic closest-packed (gold, copper, platinum, nickel, taenite)

Space group $Fm\bar{3}m$. In this view the $[111]$ direction is vertical, showing the horizontal layers of atoms. Adopted by gold, silver, copper, platinum, and related metals.

BCC: body-centered cubic (iron, kamacite)

Space group $Im\bar{3}m$. Each atom is coordinated by eight others instead of 12 as in closest packing. Adopted by iron and related metals.

meteorites, most abundant in mesosiderites and slowly cooled chondrites; forms below 350°. BM *AM 65:624(1980)*, *ABI: 527*.

1.1.11.4 Awaruite Ni₃Fe

Named in 1885 for the locality. Iron–nickel group. Synonyms: josephinite, souesite, bobrovskite. iso *Fm3m*. $a = 3.560$, $Z = 4$, $D = 8.32$. *38-419*: 2.04₁₀ 1.77₆ 1.25₃ 1.07₄ 1.02₁ 0.814₁ 0.792₁. Rounded pebbles or grains. Silver-white, often tarnishing to brown, metallic luster. Malleable. $H = 5\frac{1}{2}$ -6, $VHN_{100} = 346$. $G = 7.9$ -8.2. $R = 64.2$ (540 nm). Strongly magnetic. Found in or derived from serpentinite masses; formed during the serpentinization of nickel-bearing olivine. Josephine Co., OR; Fraser R., BC, and Muskox intrusion, NWT, Canada; in many serpentinites in the European Alps; Bobrovka R., Ural Mts., Russia; Lord Brassey mine, TAS, Australia; *Gorge R., near Awarua Bay, New Zealand*. A rare accessory in meteorites. BM *DI:117*, *R:356*, *P&J:82*, *ABI:38*, *MM 43:647(1980)*.

1.1.11.5 Nickel Ni

Recognized as a mineral in 1967. Iron–nickel group. iso *Fm3m*. $a = 3.524$, $Z = 4$, $D = 8.91$. *4-850(syn)*: 2.03₁₀ 1.76₄ 1.25₂ 1.06₂ 1.02₁ 0.881₁ 0.808₁, 0.788₂. Microscopic cubic grains and flakes. Silver-white, metallic luster. $H = 4\frac{1}{2}$, $VHN_{50} = 172$ -184. $G = 8.90$. $R = 52.8$ (548 nm). Occurs in serpentinized basic rocks as a result of low-temperature hydrothermal activity. Grasshopper Mt., Tulameen, BC, Canada; Kaltenberg, Valais, Switzerland; *Bogota, near Canala, New Caledonia*; Mt. Clifford, near Agnew, WA, Australia; Jerry R., South Westland, New Zealand. BM *MM 40:247(1975)*, *R:362*, *EG 76:1686(1981)*, *ABI:349*.

1.1.11.6 Wairauite FeCo

Named in 1964 for the locality. Iron–nickel group. iso *Im3m*. $a = 2.86$, $Z = 1$, $D = 8.32$. *44-1433*: 2.02₁₀ 1.43₁ 1.17₃ 1.01₁ 0.904₂ 0.825₁. Microscopic grains showing cube and octahedron forms. Silver-white, metallic luster. $H = 4\frac{1}{2}$, $VHN = 255$. $R = 54$ (510 nm). Formed during serpentinization of ultrabasic rocks. Muskox intrusion, NWT, Canada; Selva, near Poschiavo, Switzerland; Oko, near Koti, Japan; *Red Hills, Wairau R., New Zealand*; and in some meteorites. BM *MM 33:948(1964)*, *R:357*, *ABI:566*.

1.1.12.1 Chromium Cr

Recognized as a mineral in 1981. iso *Im3m*. $a = 2.884$, $Z = 2$, $D = 7.20$. *6-694(syn)*: 2.04₁₀ 1.44₂ 1.18₃ 1.02₂ 0.912₂ 0.833₁. Spherulic and rounded grains. White, metallic luster. $H = 9$, $VHN = 1875$ -2000. $G = 7.17$. $R = 67.9$ (540 nm). Yakutia, Russia, as inclusions in diamond; *Sichuan Prov., China*, in heavy concentrate from sand. BM *KT 26:959(1981)*, *AM 67:854(1982)*, *ABI:98*.

1.1.12.2 Chromferide $\text{Fe}_3\text{Cr}_{1-x}(x = 0.6)$

Named in 1986 for the composition. ISO $Pm\bar{3}m$. $a = 2.859$, $Z = 1$, $D = 6.69$. $d_{111} = 2.87_2$, $d_{200} = 2.02_{10}$, $d_{110} = 1.66_1$, $d_{112} = 1.43_8$, $d_{113} = 1.28_5$, $d_{114} = 1.16_{10}$, $d_{115} = 1.01_7$. Microscopic grains. Pale gray, metallic luster. No cleavage. $H = 4$, $VHN_{100} = 260$. $R = 55.3$ (540 nm). Magnetic. *Kumak region, Southern Ural Mts., Russia*, in quartz veins with ferchromide, graphite, and halite. BM *ZVMO 115:355(1986)*, *AM 73:190(1988)*.

1.1.12.3 Ferchromide $\text{Cr}_3\text{Fe}_{1-x}(x = 0.6)$

Named in 1986 for the composition. ISO $Pm\bar{3}m$. $a = 2.882$, $Z = 1$, $D = 6.18$. *ZVMO 115:2.88_1*, $d_{111} = 2.04_{10}$, $d_{110} = 1.66_5$, $d_{112} = 1.44_6$, $d_{113} = 1.29_5$, $d_{114} = 1.17_9$, $d_{115} = 1.02_7$, $d_{116} = 0.77_8$. Microscopic grains. Pale gray, metallic luster. No cleavage. $H = 6-6\frac{1}{2}$, $VHN_{100} = 900$. $R = 58.8$ (540 nm). Magnetic. *Kumak region, Southern Ural Mts., Russia*, in quartz veins with chromferide, graphite, and halite. BM *ZVMO 115:355(1986)*, *AM 73:190(1988)*.

1.1.13.1 Tin Sn

Known since antiquity. TET $I4_1/amd$. $a = 5.831$, $c = 3.182$, $Z = 4$, $D = 7.286$. $d_{111} = 2.92_{10}$, $d_{112} = 2.79_9$, $d_{113} = 2.06_3$, $d_{114} = 1.66_2$, $d_{115} = 1.48_2$, $d_{116} = 1.44_2$, $d_{117} = 1.21_2$. Rounded grains or aggregates. Tin-white, metallic luster. Ductile and malleable. $H = 2$, $VHN_{10} = 7-9$. $G = 7.31$. $R = 82-88$ (540 nm); moderately anisotropic. *Nesbitt LaBine mine, Beaverlodge, SK, Canada*, associated with pitchblende; *Elkiaidan R., Uzbekistan*; *Oued Berkou, Algeria*, in greisen; *Clarence R., near Oban, NSW, Australia*, in placers. BM *DI:126, R:362, ABI: 531*.

1.1.14.1 Indium In

Recognized as a mineral in 1964. TET $I4/mmm$. $a = 3.252$, $c = 4.946$, $Z = 2$, $D = 7.29$. $d_{111} = 2.72_{10}$, $d_{112} = 2.47_2$, $d_{113} = 2.30_4$, $d_{114} = 1.68_2$, $d_{115} = 1.62_1$, $d_{116} = 1.47_2$, $d_{117} = 1.40_2$, $d_{118} = 1.36_1$. Grains to 1 mm. Gray with yellow tint, metallic luster. $H = 3$, $VHN = 130-159$. $R = 92.3$; weakly anisotropic. *Eastern Transbaikal, Russia*, in albitized granite in association with native lead. BM *AM 52:299(1967)*, *ABI:234*.

1.1.15.1 Cupalite (Cu,Zn)Al

Named in 1985 for the composition. ORTH Space group unknown. $a = 6.95$, $b = 4.16$, $c = 10.04$, $Z = 10$, $D = 5.18$. $d_{111} = 5.07_{10}$, $d_{112} = 4.12_8$, $d_{113} = 3.59_2$, $d_{114} = 2.83_1$, $d_{115} = 2.61_1$, $d_{116} = 2.32_1$, $d_{117} = 2.02_1$. Microscopic grains. Yellow, metallic luster. $H = 4-4\frac{1}{2}$, $VHN_{50} = 272-318$. $R = 62.9$ (540 nm); weakly anisotropic. *Listvenitovii R., Koryak Mts., Kamchatka, Russia*, in weathered serpentinite. BM *ZVMO 114:90(1985)*, *AM 71:1278(1986)*, *ABI:118*.

1.1.15.2 Khatyrkite (Cu,Zn)Al₂

Named in 1985 for the locality. TET $I4/mcm$. $a = 6.063$, $c = 4.872$, $Z = 4$, $D = 4.357$. $d_{111} = 4.30_{10}$, $d_{112} = 3.04_4$, $d_{113} = 2.37_7$, $d_{114} = 2.15_4$, $d_{115} = 2.12_9$, $d_{116} = 1.92_7$, $d_{117} = 1.90_6$, $d_{118} = 1.29_2$. Prismatic crystals and microscopic grains. Yellow-gray, metallic luster. Cleavage {100}. $H = 5$, $VHN_{50} = 540$. $R = 76.1$ (540 nm); strongly anisotropic. *Kha-*

tyrka R., Koryak Mts., Kamchatka, Russia, in weathered serpentinite of the Khatirskii ultramafic zone. *BM ZVMO 114:90(1985)*, *AM 71:1278(1986)*, *ABI:263*.

1.1.16.1 Cohenite (Fe,Ni)₃C

Named in 1889 for Emil W. Cohen (1842–1905), German mineralogist and meteorite researcher. Synonym: Cementite is Fe₃C in steel. Contains 0.7–2.3% Ni and up to 0.3% Co. *ORTH Pnma*. $a = 5.091$, $b = 6.743$, $c = 4.526$, $Z = 4$, $D = 7.675$. *35-772(syn)*: 2.39₄ 2.38₄ 2.11₆ 2.07₇ 2.03₆ 2.01₁₀ 1.98₅ 1.85₄. Platy crystals or rounded grains. White, tarnishing to yellow, gray streak, metallic luster. Cleavage {100}, {010}, {001}; very brittle. $H = 7$, $VHN_{50} = 1100$. $G = 7\ 20-7.65$. Strongly magnetic. Insoluble in dilute HCl. Disko Is., Greenland, and Putorana plateau, Taimyr Penin., Russia, in terrestrial iron; an accessory mineral in some iron meteorites and enstatite chondrites. Recorded in metallic particles in lunar rocks, probably of meteoritic origin. *BM DI:122*, *GCA 31:143(1967)*, *LAP 18(4):32(1993)*.

1.1.16.2 Haxonite (Fe,Ni)₂₃C₆

Named in 1974 for Howard J. Axon (1924–1992), English metallurgist. Contains 3.5–5.6% Ni and up to 0.4% Co. *ISO Fm3m*. $a = 10.55$, $Z = 4$, $D = 7.70$. *25-405*: 2.36₁₀ 2.15₁₀ 1.86₆ 1.76₅ 1.24₆ 1.22₅ 1.16₄ 1.06₅. Microscopic grains. Tin-white, metallic luster. $H = 7$, $VHN = 850$. A minor accessory in some iron meteorites, often in association with cohenite. *BM AM 59:209(1974)*.

1.1.17.1 Tongbaite Cr₃C₂

Named in 1983 for the locality. *ORTH Pnma*. $a = 5.57$, $b = 11.47$, $c = 2.816$, $Z = 4$, $D = 6.657$. *35-804(syn)*: 2.31₁₀ 2.24₆ 1.95₄ 1.87₄ 1.82₃ 1.78₃ 1.70₄ 1.19₇. Microscopic prismatic crystals. Pale yellow-brown, dark gray streak, metallic luster. $H = 8\frac{1}{2}$, $VHN_{50} = 1931$. $R = 55$ (546 nm); distinctly anisotropic. *Liu Zhuang, Tongbai Co., Henan Prov.*, and Hong district, Tibet, *China*, in ultrabasic rocks. *BM AM 70:218(1985)*.

1.1.18.1 Siderazot Fe₅N₂

Named in 1876 for the composition. *HEX P6₃22*. $a = 4.678$, $c = 4.369$, $Z = 1$, $D = 3.08$. *3-925(syn)*: 2.34₁₀ 2.19₁₀ 2.06₁₀ 1.59₁₀ 1.34₁₀ 1.24₁₀ 1.15₁₀ 1.13₁₀. Thin coating on lava. Tin-white, metallic luster. $G = 3.147$. Mt. Etna and Mt. Vesuvius, Italy. *BM DI:126*, *ZK 74:511(1930)*.

1.1.18.2 Roaldite (Fe,Ni)₄N

Named in 1981 for Roald Nielsen (b.1928), Danish metallurgist. Contains 5.6–6.4% Ni and 0.5% Co. *ISO Pm3m*. $a = 3.79$, $Z = 1$, $D = 7.168$. *6-627(syn)*: 2.19₁₀ 1.90₈ 1.70₂ 1.34₇ 1.14₉ 1.05₂ 0.949₅. Micron-size platelets. Tin-white, metallic luster. $H = 5\frac{1}{2}-6\frac{1}{2}$, $VHN = 600-900$. An accessory mineral in a few iron meteorites. *BM AM 66:1100(1981)*.

1.1.19.1 Osbornite TiN

Named in 1870 for George Osborne, who provided the original material. ISO *Fm3m*. $a = 4.242$, $Z = 4$, $D = 5.39$. Halite structure. *33-1420*(syn): 2.45₇ 2.12₁₀ 1.50₅ 1.28₂ 1.22₂ 1.06₁ 0.948₂ 0.865₁. Minute octahedra. Golden yellow, metallic luster. $H = 8-9$. $G = 5.25$. A trace constituent in meteorites, in some enstatite chondrites and achondrites. BM *DI:124*, *MM 26:36*(1941).

1.1.19.2 Khamrabaevite (Ti,V,Fe)C

Named in 1984 for Ibrahim K. Khamrabaev (b.1920), Uzbek mineralogist. ISO *Fm3m*. $a = 4.319$, $Z = 4$, $D = 4.91$. Halite structure. *32-1383*(syn): 2.50₈ 2.16₁₀ 1.53₆ 1.31₃ 1.25₂ 1.08₁ 0.993₁ 0.968₃. Skeletal cubic crystals. Dark gray, metallic luster. No cleavage, fracture irregular. $H = 9$, $VHN_{100} = 2230-2290$. $R = 47.5$ (580 nm). *Chaktal Range, Arashan Mts., Uzbekistan, in basaltic porphyrite*. BM *ZVMO 113:697*(1984), *AM 70:1329*(1985).

1.1.20.1 Carlsbergite CrN

Named in 1971 for the Carlsberg Foundation, Denmark, which supported the research. ISO *Fm3m*. $a = 4.13$, $Z = 4$, $D = 6.18$. Halite structure. *11-65*(syn): 2.39₈ 2.07₁₀ 1.46₈ 1.25₆ 1.20₃ 0.950₅ 0.926₆ 0.846₆. Micron-size laths and irregular grains. Pale gray, metallic luster. $H > 7$, $VHN > 1000$. $G = 5.9$. $R = 41.5$ (546 nm). A minor accessory in many iron meteorites. BM *AM 57:1311*(1972).

1.1.21.1 Barringerite (Fe,Ni)₂P

Named in 1969 for Daniel M. Barringer (1860-1929), U.S. mining engineer, who established the meteoritic origin of Meteor Crater, Arizona. HEX *P62m*. $a = 5.877$, $c = 3.437$, $Z = 3$, $D = 6.91$. *33-670*(syn): 2.23₁₀ 2.05₇ 1.92₄ 1.72₂ 1.70₂ 1.68₁ 1.28₂ 1.11₁. Micron-size grains. Tin-white, metallic luster. A trace constituent in the *Ollague pallasite*, possibly a product of artificial reheating. BM *SCI 165:169*(1969), *AM 55:317*(1970).

1.1.21.2 Schreibersite (Fe,Ni)₃P

Named in 1847 for Karl von Schreibers (1775-1852), Austrian meteorite researcher. Synonym: rhabdite. The Ni content ranges from 7.0 to 65.1%. TET *I4̄*. $a = 9.056$, $c = 4.471$, $Z = 8$, $D = 7.13$. *19-617*(syn): 2.20₁₀ 2.14₅ 2.11₄ 2.03₈ 1.98₁₀ 1.79₄ 1.76₆ 1.69₃. Thin plates (rhabdite) or rounded crystals. Tin-white, tarnishing to brass-yellow, gray streak, metallic luster. Cleavage {001}, perfect; very brittle. $H = 6\frac{1}{2}-7$, $VHN = 800-950$. $G = 7.0-7.3$. Strongly magnetic. An accessory mineral in most iron meteorites and many stony ones; has been observed in lunar samples, possibly of meteoritic origin. A trace constituent in terrestrial iron from Disko Is., Greenland. BM *DI:124*, *R:361*, *GCA 29:513*(1965).

1.1.22.1 Perryite (Ni,Fe)₈(Si,P)₃

Named in 1965 for Stuart H. Perry (1874–1957), U.S. newspaper publisher and researcher on iron meteorites. *HEX-R R3c*. $a = 6.640$, $c = 37.98$, $Z = 12$, $D = 7.63$. *17-222*(syn): 2.61_4 2.59_4 2.15_7 2.10_7 2.06_3 1.98_{10} 1.92_{10} 1.78_4 . Microscopic platelets. Tin-white, metallic luster. Twinned on {0001}. Occurs in association with kamacite in the *Horse Creek iron meteorite* and in some enstatite chondrites and achondrites. *BM MM 36:850(1968)*, *37:905(1970)*; *AM 77:452(1992)*.

1.1.23.1 Suessite (Fe,Ni)₃Si

Named in 1982 for Hans E. Suess (1909–1993), Austrian–U.S. geochemist. Contains up to 4.5% Ni. iso *Im3m*. $a = 2.841$, $Z = 0.5$, $D = 7.083$. *35-519*(syn): 2.01_{10} 1.42_1 1.16_3 . Microscopic blebs and elongated grains. Cream-white, metallic luster. $R = 51.6$ (546 nm). Magnetic. An accessory mineral in the *North Haig ureilite meteorite*, Kurama ridge, Uzbekistan. *BM AM 67:126(1982)*.

1.1.23.2 Gupeite Fe₃Si

Named in 1984 for the Gupeikou gateway in the Great Wall of China. iso *Fm3m*. $a = 5.670$, $Z = 4$, $D = 7.15$. *11-616*(syn): 3.25_4 2.83_4 1.99_{10} 1.70_4 1.62_2 1.41_{10} 1.15_{10} 0.995_{10} . Cores of microscopic spheres. Steel-gray, black streak, metallic luster. Brittle. $H = 5$, $VHN_{50} = 494-514$. $R = 53.5$ (546 nm). Strongly magnetic. *Yanshan area, Hebei, China*, in placers. *BM AM 71:228(1986)*.

1.1.23.3 Xifengite Fe₅Si₃

Named in 1984 for the Xifengkou gateway in the Great Wall of China. *HEX P6₃/mcm*. $a = 6.757$, $c = 9.440$, $Z = 2$, $D = 7.15$. *11-615*(syn): 2.35_5 2.18_6 2.00_{10} 1.94_8 1.92_9 1.37_6 1.27_9 1.24_8 . Cores of microscopic spheres. Steel-gray, black streak, metallic luster. Brittle. $H = 5$, $VHN_{50} = 633-694$. $R = 44$ (546 nm). Strongly magnetic. *Yanshan area, Hebei, China*, in placers. *BM AM 71:228(1986)*.

PLATINUM GROUP

The members of the platinum group are elements sharing a cubic close-packed structure, space group $Fm\bar{3}m$. They are isostructural among themselves and with the gold group.

CUBIC CLOSE-PACKED ELEMENTS

Mineral	Formula	Space Group	a	D	
Platinum	Pt	$Fm\bar{3}m$	3.924	21.46	1.2.1.1
Iridium	Ir	$Fm\bar{3}m$	3.839	22.56	1.2.1.2
Rhodium	(Rh, Pt)	$Fm\bar{3}m$	3.803	12.43	1.2.1.3
Palladium	Pd	$Fm\bar{3}m$	3.890	12.01	1.2.1.4

Note: Platinum, palladium, rhodium, and iridium form solid solutions among themselves. Many were separately named as minerals, but with the advent of the electron microprobe analyzer, most of the introduced names have been discarded as superfluous [CM 29:231(1991)].

1.2.1.1 Platinum Pt

Named in 1748 from the Spanish *platina*, diminutive of *plata*, silver. Platinum group. Natural occurrences always alloyed with other Pt-group elements and with Fe. iso $Fm\bar{3}m$. $a = 3.924$, $Z = 4$, $D = 21.46$. 29-717(syn): 2.24₁₀ 1.94₆ 1.37₆ 1.17₈ 0.890₉ 0.867₈ 0.792₁₀. Cubic crystals rare, usually as grains or flakes, rarely as sizable nuggets. Tin-white to steel-gray, dark gray to black in Fe-rich varieties; metallic luster. No cleavage, hackly fracture, malleable and ductile. $H = 4-4\frac{1}{2}$. $VHN_{100} = 297-339$. $G = 14-19$. Nonmagnetic to magnetic, magnetism increasing with Fe content. Insoluble except in hot aqua regia. Platinum is usually found in or associated with mafic and ultramafic igneous such as olivine gabbro and pyroxenite (Urals) and peridotite and dunite (Urals and Transvaal). Also found in quartz veins associated with hematite, chlorite, and pyrolusite. Commonly concentrated in placers. Platinum is widely distributed in placers throughout the world, but most commercial production is from primary deposits such as the Merensky Reef of the Bushveld Igneous Complex in South Africa and the Stillwater complex in Montana, and as a by-product from nickel ores as at Sudbury, ON, Canada; Norilsk, Russia; and Kambalda, WA, Australia. In the United States, placer deposits occur at Cape Blanco, Curry Co., OR, at several localities in CA, and at Platinum Creek, Goodnews Bay, AK. Also at Riviere-du-Loup, Beauce Co., PQ, near Edmonton, AB, Kamloops, Similkameen district, and Tulameen R., BC, Canada; Nizhni Tagil district, Ural Mts., and Konder(*), near Nelkan, Khabarovsk Oblast, Russia; near Papayan, Cauca, Colombia; Bom Sucesso, near Serro, MG, Brazil. BM DI:106, R:340, P&J:302, ABI:410.

1.2.1.2 Iridium Ir

Named in 1804 because its salts are of varied colors. Platinum group. Always alloyed with other Pt-group elements; platinumiridium is a rejected name for

platinian iridium, osmiridium a rejected name for osmian varieties. iso $Fm\bar{3}m$. $a = 3.839$, $Z = 4$, $D = 22.56$. $6-598(\text{syn}): 2.22_{10} 1.92_5 1.36_4 1.16_5 1.11_2 0.881_4 0.859_4 0.784_5$. Cubic habit, usually as rounded grains. Silver-white, metallic luster. Cleavage $\{001\}$, indistinct; hackly fracture. $H = 6-7$, $VHN_{100} = 867$. $G = 19-21$. Occurs in Pt-bearing ultrabasic rocks and in placers derived from them. Salmon Creek, Siskiyou Co., and other localities in CA; Goodnews Bay, AK; Tulameen, Spruce Creek, and Atlin, BC, Canada; Nizhni Tagil district, Ural Mts., Russia; Ava, near Mandalay, Burma; Ioma area, Papua New Guinea; Pieman R., TAS, Australia. BM *DI:110, R:339, ABI:239, CM 29:231(1991)*.

1.2.1.3 Rhodium (Rh,Pt)

Identified as a mineral in 1974. Platinum group. iso $Fm\bar{3}m$. $a = 3.803$, $Z = 4$, $D = 12.43$. $5-685(\text{syn}): 2.20_{10} 1.90_5 1.35_3 1.15_3 1.10_1 0.951_1 0.872_2 0.850_1$. Microscopic subhedral grain. Silver-white, metallic luster. $H = 3\frac{1}{2}$, $VHN_{30} = 136-194$. $R = 72.6$ (546 nm). *Stillwater Complex, MT*, a single grain with composition $Rh_{0.57}Pt_{0.43}$ in heavy-mineral concentrates. BM *CM 12:399(1974), AM 61:340(1976), ABI:439*.

1.2.1.4 Palladium Pd

Named in 1803 for the asteroid Pallas, discovered in 1802. Platinum group. iso $Fm\bar{3}m$. $a = 3.890$, $Z = 4$, $D = 12.01$. $5-681(\text{syn}): 2.25_{10} 1.95_4 1.38_3 1.17_2 1.12_1 0.972_1 0.892_1 0.870_1$. Rarely as octahedra; commonly in grains, sometimes with a radial fibrous texture. White to pale steel-gray, metallic luster. No cleavage, malleable and ductile. $H = 4\frac{1}{2}-5$. $G = 11.9$. $R = 67.8$ (540 nm). Easily confused with platinum but has a much lower density and is soluble in HNO_3 . Occurs as a primary phase in platinum deposits and as an oxidation product of palladium-bearing sulfides. Ural Mts., Russia; Merensky Reef, Transvaal, South Africa; Choco, Cauca, Colombia; Potaro R., Guyana; *Bom Sucesso, near Serro, MG, Brazil*. BM *DI:109, R:338, P&J:286, ABI:376, MR 23:471(1992)*.

OSMIUM GROUP

The members of the osmium group share a hexagonal close-packed structure.

HEXAGONAL CLOSE-PACKED ELEMENTS

Mineral	Formula	Space Group	a	c	D	
Osmium	(Os,Ir,Ru)	$P6_3/mmc$	2.733	4.319	22.59	1.2.2.1
Ruthenium	(Ru,Ir,Os)	$P6_3/mmc$	2.704	4.326	12.36	1.2.2.2
Rutheniridosmine	(Ir,Os,Ru)	$P6_3/mmc$	2.726	4.326	20.6	1.2.2.3
Rhenium	Re	$P6_3/mmc$	2.760	4.458	21.0	1.2.2.4

HCP: hexagonal closest-packed (osmium, iridium)

Space group $P6_3/mmc$. This shows the true symmetry with all atoms alike. No common minerals have this structure, but the arrangement is adopted by oxygen and sulfur atoms in many.

Notes:

1. Osmium and ruthenium form alloys with iridium, one of which is found as the mineral rutheniridosmine.
2. Zinc (1.1.5.1) and cadmium (1.1.5.2) are isostructural with osmium.

1.2.2.1 Osmium (Os,Ir,Ru)

Named in 1804 from the Greek for *smell*, because of the odor of its volatile oxide. Osmium group. May contain up to 50% Ir, 20% Ru, and minor amounts of the other platinum group elements. *Iridosmine*, *siserskite*, and *nevyanskite* are obsolete names for iridian osmium. $HEX P6_3/mmc$. $a = 2.733$, $c = 4.319$ $Z = 2$, $D = 22.59$. $6-662(\text{syn})$: 2.37_4 2.16_4 2.08_{10} 1.60_2 1.37_2 1.23_2 1.16_2 1.14_2 . Crystals tabular {0001}, also as flattened grains. Tin-white to steel-gray, metallic luster. Cleavage {0001}, perfect but difficult; slightly malleable. $H = 7$, $VHN_{25} = 1206-1246$. $G = 17.6-21.2$. $R = 55$ (540 nm); strongly anisotropic. Occurs with other platinoid minerals, usually in placers. American R., Sacramento Co., Salmon Creek, Siskiyou Co., and other localities in CA; Similkameen, Atlin, and Quesnel, BC, Canada; several localities in the Ekaterinburg Oblast, Ural Mts., and in Yakutsk and Transbaikalia, Russia; Anduo, Tibet, China; Guma Water, Sierra Leone; Birbir R., Ethiopia; Rustenberg area, Transvaal, South Africa; Pieman R., TAS, Australia; Lee R., Nelson, New Zealand. *BM DI:111*, *R:350*, *P&J:284*, *AB:369*, *CM 29:231(1991)*.

1.2.2.2 Ruthenium (Ru,Ir,Os)

Identified as a mineral in 1974. Osmium group. $HEX P6_3/mmc$. $a = 2.704$, $c = 4.326$, $Z = 2$, $D = 12.36$. $6-663(\text{syn})$: 2.34_4 2.14_4 2.06_{10} 1.58_3 1.35_3 1.22_3

1.14₃ 1.13₂. Microscopic grains. Silver-white, metallic luster. $H = 6\frac{1}{2}$, $VHN_{100} = 872$. $R = 60.1$ (530 nm); weakly anisotropic. Occurs in placers. Yuba R., Nevada Co., CA; Tennessee Pass, Josephine Co., OR; Nizhni Tagil, Ural Mts., Russia; Nuanquanzi Au deposit, northern China; *Horakanaï*, *Hokkaido*, Japan. BM *MJJ* 7:438(1974), *AM* 61:177(1976), *ABI*:454, *TMPM* 43:137(1990).

1.2.2.3 Rutheniridosmine (Ir,Os,Ru)

Named in 1973 for the composition. Osmium group. Its compositional field is restricted to hexagonal Ir–Os–Ru alloys in which Ir is the dominant element. $HEX P6_3/mmc$. $a = 2.726$, $c = 4.326$, $Z = 2$, $D = 20.6$. 41-601: 2.36₈ 2.07₁₀ 1.59₄ 1.36₆ 1.15₅ 1.14₄ 0.914₄ 0.870₅. Rounded grains. Silver-white, metallic luster. $H = 6-7$, $VHN_{100} = 1100$. $R = 72.0$ (556 nm). Occurs in placer deposits derived from ultrabasic rocks. Spruce Creek and Tulameen R. areas, BC, Canada; Ural Mts. and Yakutia, Russia; Witwatersrand, South Africa; Massif du Sud, New Caledonia; Heazlewood district, TAS, Australia; Ironstone Creek, Parapara, Nelson, New Zealand. BM *CM* 12:104(1973), 29:231(1991), *AM* 60:946(1975), *ABI*:453.

1.2.2.4 Rhenium Re

Identified as a mineral in 1976. Osmium group. $HEX P6_3/mmc$. $a = 2.760$, $c = 4.458$, $Z = 2$, $D = 21.0$. 5-702(syn): 2.39₃ 2.23₃ 2.11₁₀ 1.63₁ 1.38₂ 1.26₂ 1.17₂ 1.15₂. Microscopic grains. Silver-white, metallic luster. *Transbaikal*, *Russia*, in wolframite; Allende meteorite, in Ca,Al-rich inclusions (97% Re, 3% Ru). BM *AM* 63:1283(1978).

1.2.3.1 Hongshiite PtCu

Named in 1974 for the locality. $HEX-R R3m$. $a = 10.703$, $c = 13.197$, $Z = 48$, $D = 15.75$. 42-1326: 4.35₃ 2.20₁₀ 1.90₈ 1.35₅ 1.33₅ 1.15₈ 1.10₃ 0.856₅. Microscopic grains. Lead-gray, black streak, metallic luster. $H = 4$, $VHN_{50} = 204-277$. $G = 15.00$. $R = 60.5-62.8$ (540 nm); weakly anisotropic, red-brown to gray. Goodnews Bay, AK; *Hong district*, *China*; Merensky Reef, Transvaal, South Africa. BM *AM* 61:185(1976), 69:411(1984), *ABI*:223.

TETRAFERROPLATINUM GROUP

The five members of the tetraferroplatinum group are intermetallic compounds sharing the general formula

where

A = Pt, Pd

B = Cu, Fe, Ni, Hg

and sharing the tetragonal $P4/mmm$ structure. The structure is related to that of the isoferroplatinum group.

TETRAFERROPLATINUM: PtFe

TETRAFERROPLATINUM GROUP

Mineral	Formula	Space Group	D			
			a	c		
Tetraferroplatinum	PtFe	$P4/mmm$	3.84	3.72	15.07	1.2.4.1
Tulameenite	Pt ₂ FeCu	$P4/mmm$	3.902	3.585	15.21	1.2.4.2
Ferronickelplatinum	Pt ₂ FeNi	$P4/mmm$	3.871	3.635	15.39	1.2.4.3
Potarite	PdHg	$P4/mmm$	3.026	3.702	15.03	1.2.4.4

Note: Tetraauricupride (1.1.2.2) is isostructural with these minerals.

1.2.4.1 Tetraferroplatinum PtFe

Named in 1975 for the composition and crystal system. Tetraferroplatinum group. Composition somewhat variable around PtFe; may contain minor amounts of Cu, Rh, Ir, Sb. TET $P4/mmm$. $a = 3.84$, $c = 3.72$, $Z = 2$,

$D = 15.07$. $26-1139(\text{syn})$: 2.20_{10} 1.34_5 1.16_9 1.13_6 1.10_6 1.04_5 1.02_6 0.918_6 . Rounded grains or flakes. Silver-white, metallic luster. $\text{VHN}_{100} = 384$. $G = 14.3$. $R = 61.3$ (546 nm); weakly anisotropic. Ferromagnetic. Occurs in Pt-bearing placers; probably more common than reported because of confusion with ferroan platinum. *Tulameen* and *Similkameen R.*, *BC, Canada*; *Talnakh, Norilsk, Russia*; *Pirogues R., New Caledonia*; *Mooihoek and Witwatersrand, Transvaal, South Africa*. *BM CM 13:117(1975)*, *AM 61:341(1976)*, *TMPM 36:175(1987)*, *ABI: 525*.

1.2.4.2 Tulameenite Pt_2FeCu

Named in 1973 for the locality. Tetraferroplatinum group. Contains minor Ir, Ni, Sb; forms a series with ferronickelplatinum. $\text{TET } P4/mmm$. $a = 3.902$, $c = 3.585$, $Z = 1$, $D = 15.21$. $42-1359$: 2.19_{10} 1.95_5 1.32_6 1.17_{10} 1.09_9 1.02_8 0.976_6 0.941_7 . Microscopic grains. White, metallic luster. $H = 5$, $\text{VHN}_{50} = 420-456$. $G = 14.90$. Ferromagnetic. R_{60-66} (546 nm); very weakly anisotropic. Stillwater Complex, MT; *Tulameen* and *Similkameen R.*, *BC, Canada*; *Nizhni Tagil, Ural Mts., Russia*; *Guma Water, Sierra Leone*; *Yubdo, Ethiopia*. *BM CM 12:21(1973)*, *AM 59:383(1974)*, *ABI: 542*.

1.2.4.3 Ferronickelplatinum Pt_2FeNi

Named in 1983 for the composition. Tetraferroplatinum group. Forms a series with tulameenite. $\text{TET } P4/mmm$. $a = 3.871$, $c = 3.635$, $Z = 1$, $D = 15.39$. $35-702$: 3.66_1 2.75_1 2.19_{10} 1.94_5 1.70_3 1.32_4 1.16_3 1.09_2 . Microscopic grains. Silver-white, metallic luster. $H = 5$, $\text{VHN}_{50} = 481$. $R = 59.0$ (540 nm); weakly anisotropic. Occurs in placers derived from ultrabasic rocks. Goodnews Bay, AK; *Koryak Mts., Kamchatka, Russia*. *BM ZVMO 112:487(1983)*, *AM 69:1190(1984)*, *ABI: 155*.

1.2.4.4 Potarite PdHg

Named in 1926 for the locality. Tetraferroplatinum group. $\text{TET } P4/mmm$. $a = 3.026$, $c = 3.702$, $Z = 2$, $D = 15.03$. $13-149(\text{syn})$: 2.34_{10} 2.14_5 1.40_6 1.27_8 1.17_5 1.14_5 0.928_5 0.850_8 . Small grains or nuggets. White to steel-gray, metallic luster. Brittle. $H = 3\frac{1}{2}$, $\text{VHN}_{100} = 132$. $G = 13.5-16.1$. $R = 61.0$ (540 nm). *Musonoi and Mindingi, Zaire*; *Merensky Reef, Transvaal, South Africa*; *Potaro R., Guyana*, in placers. *BM DI:105, AM 45:1093(1960)*, *R:362, ABI:418*.

ISOFERROPLATINUM GROUP

The members of the isoferroplatinum group are intermetallic compounds sharing the general chemical formula

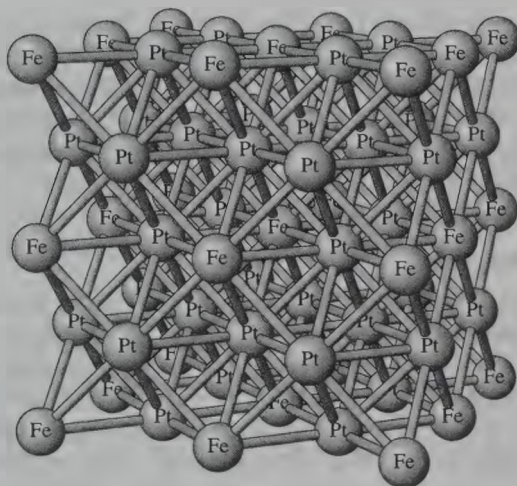

where

A = Pt, Pd

B = Fe, Sn, or Pb

and sharing the same cubic structure in space group $Pm\bar{3}m$.

ISOFERROPLATINUM: Pt₃Fe

ISOFERROPLATINUM GROUP

Mineral	Formula	Space Group	a	D	
Isoferroplatinum	Pt ₃ Fe	$Pm\bar{3}m$	3.866	18.42	1.2.5.1
Rustenbergite	(Pt,Pd) ₃ Sn	$Pm\bar{3}m$	3.988	15.08	1.2.5.2
Atokite	(Pd,Pt) ₃ Sn	$Pm\bar{3}m$	3.991	14.19	1.2.5.3
Zvyagintsevite	(Pd,Pt,Au) ₃ (Pb,Sn)	$Pm\bar{3}m$	4.024	13.41	1.2.5.4
Chengdeite	Ir ₃ Fe	$Pm\bar{3}m$	3.792	19.30	1.2.5.5

Notes:

1. Auricupride (1.1.2.1) is isostructural with these minerals.
2. See the tetraferroplatinum group for related tetragonal structures.

1.2.5.1 Isoferroplatinum Pt₃Fe

Named in 1975 for the composition and crystal system. Isoferroplatinum group. Contains minor amounts of Ir, Pd, Ru, and Rh. iso *Pm3m*. $a = 3.866$, $Z = 1$, $D = 18.42$. *29-1423*: 2.22₆ 1.93₁₀ 1.72₂ 1.57₁ 1.36₇ 1.17₁₀ 1.11₅ 1.07₁. Microscopic cubic crystals, and rounded grains and flakes. Silver-white, metallic luster. $VHN_{100} = 503-572$. Occurs in Pt-bearing placers; probably more common than reported because of confusion with ferroan platinum. Stillwater Complex, MT; Goodnews Bay, AK; *Tulameen* and *Similkameen R.*, BC, Canada; Norilsk and Kondor, Russia; Witwatersrand and Merensky R., Transvaal, South Africa; Round Hill, near Orepuki, New Zealand. BM *CM 13:117(1975)*, *AM 61:341(1976)*, *ABI:243*.

1.2.5.2 Rustenbergite (Pt,Pd)₃Sn

Named in 1975 for the locality. Isoferroplatinum group. Forms a series with atokite (1.2.5.3). iso *Pm3m*. $a = 3.988$, $Z = 1$, $D = 15.08$. *29-968*: 2.30₁₀ 1.99₈ 1.41₉ 1.20₁₀ 1.15₄ 0.915₉ 0.892₈ 0.815₉. Microscopic grains. Cream-white, metallic luster. $H = 4\frac{1}{2}$, $VHN_{25} = 365$. $R = 59.8$ (546 nm). Stillwater Complex, MT; Norilsk, Russia; *Rustenberg mine* and *Atok mine*, Transvaal, South Africa. BM *CM 13:146(1975)*, *AM 61:340(1976)*, *ABI:451*.

1.2.5.3 Atokite (Pd,Pt)₃Sn

Named in 1975 for the locality. Isoferroplatinum group. Forms a series with rustenbergite (1.2.5.2). iso *Pm3m*. $a = 3.991$, $Z = 1$, $D = 14.19$. *29-967*: 2.30₁₀ 1.99₈ 1.41₉ 1.20₁₀ 1.15₄ 0.915₉ 0.892₈ 0.815₉. Microscopic grains. Cream-white, metallic luster. $H = 4\frac{1}{2}$, $VHN_{25} = 357$. $R = 59.2-65.1$ (546 nm). Stillwater Complex, MT; Norilsk, Russia; *Atok mine* and *Rustenberg mine*, Transvaal, South Africa. BM *CM 13:146(1975)*, *AM 61:340(1976)*, *ABI:35*.

1.2.5.4 Zvyagintsevite (Pd,Pt,Au)₃(Pb,Sn)

Named in 1966 for Orest E. Zvyagintsev (1894-1967), Russian geochemist. Isoferroplatinum group. May contain up to 4% Au. iso *Pm3m*. $a = 4.024$, $Z = 1$, $D = 13.41$. *20-827(syn)*: 2.32₁₀ 2.01₈ 1.42₇ 1.22₉ 1.16₄ 1.01₃ 0.923₆ 0.900₅. Microscopic grains. Cream-white, metallic luster. $H = 4\frac{1}{2}$, $VHN_{15} = 241-318$. $R = 65.5$ (540 nm). Stillwater Complex, MT; *Talnakh*, Norilsk, Russia. BM *GRM 8:94(1966)*, *AM 52:299(1967)*, *R:363*, *ABI:588*.

1.2.5.5 Chengdeite Ir₃Fe

Named in 1995 for the locality. iso *Pm3m*. $a = 3.792$, $Z = 1$, $D = 19.30$. *MR 27*: 2.18₈ 1.89₆ 1.34₇ 1.26₂ 1.20₁ 1.14₁₀ 1.09₈. Microscopic grains. Black, black streak, metallic luster. No cleavage. $H = 5$, $VHN_{50} = 452$. Strongly magnetic. In reflected light white with a yellow tint; isotropic; $R = 69.3$ (546 nm). *Luan*

R., Chengde Co., China, in placer deposits. *BM AGS* 69(3):215(1995), *MR* 27:202(1996), *AM* 81:516(1996).

1.2.6.1 Paolovite Pd₂Sn

Named in 1974 for the composition: palladium and olovo (Russian = tin). *ORTH Pbnm*. $a = 8.11$, $b = 5.662$, $c = 4.234$, $Z = 4$, $D = 11.32$. *26-1297*: 3.19₃ 2.36₄ 2.28₁₀ 2.16₇ 1.96₅ 1.40₄ 1.34₃ 1.32₄. Microscopic grains. Lilac-rose, metallic luster. $H = 4\frac{1}{2}$, $VHN_{50} = 380$. $R = 48-53$ (540 nm). Geordie Lake, ON, Canada; *Oktyabr mine, Talnakh, Norilsk, Russia*; Atok and Western mines, Transvaal, South Africa. *BM GRM* 16:98(1974), *AM* 59:1331(1974); *ABI*:380, *CM* 28:489(1990).

1.2.7.1 Taimyrite (Pd,Cu,Pt)₃Sn

Named in 1982 for the locality (Taimyr Peninsula). *ORTH* Space group unknown. $a = 16.11$, $b = 11.27$, $c = 8.64$, $Z = 22$, $D = 10.20$. *41-1409*: 2.36₅ 2.29₅ 2.16₁₀ 2.04₂ 1.44₄ 1.30₃ 1.22₄ 1.14₂. Microscopic grains. Bronze-gray, metallic luster. $H = 5$, $VHN_{50} = 480$. $R = 45-50$ (550 nm); anisotropic, yellow-gray to dark gray. *Talnakh, Norilsk, Russia*. *BM ZVMO* 111:78(1982), *AM* 68:1252(1983), *ABI*:511.

1.2.8.1 Cabriite Pd₂SnCu

Named in 1983 for Louis J. Cabri (b.1934), Canadian mineralogist. *ORTH Pmmm*. $a = 7.88$, $b = 7.88$, $c = 3.94$, $Z = 4$, $D = 10.73$. *37-418*: 2.29₁₀ 2.17₉ 1.84₃ 1.43₃ 1.23₈ 1.22₄ 1.18₃ 1.09₂. Microscopic grains. White, metallic luster. $H = 4$, $VHN_{50} = 258-282$. $G = 11.1$. $R = 45.0-52.0$ (540 nm); strongly anisotropic, gold to gray-brown. Thetford mines, PQ, Canada; *Oktyabr mine, Talnakh, Norilsk, Russia*. *BM CM* 21:481(1983), *AM* 69:1190(1984), *ABI*:74.

1.2.9.1 Stannopalladinite Pd₃Sn₂

Named in 1947 for the composition. *HEX P6₃/mmc*. $a = 4.390$, $c = 5.655$, $Z = 1$, $D = 9.79$. *4-801(syn)*: 2.27₁₀ 2.20₁₀ 1.58₇ 1.42₅ 1.19₇ 0.988₆ 0.944₆ 0.834₇. Microscopic crystals. Pale brown-rose, metallic luster. $H = 4\frac{1}{2}-5$, $VHN = 387-452$. $R = 53-54$ (540 nm); strongly anisotropic, red to blue. *Monchegorsk, Kola Penin.*, and *Talnakh, Norilsk, Russia*; Merensky Reef, Transvaal, South Africa. *BM DANS* 58:1137(1947), *MA* 10:453(1949), *CM* 19:599(1981), *ABI*:492.

1.2.10.1 Niggliite PtSn

Named in 1937 for Paul Niggli (1888-1953), Swiss mineralogist. *HEX P6₃/mmc*. $a = 4.100$, $c = 5.432$, $Z = 2$, $D = 13.18$. Nickelium structure. *25-*

614(syn): 3.55₆ 2.97₇ 2.16₁₀ 2.05₈ 1.49₈ 1.20₉ 1.13₆ 0.927₆. Microscopic grains. Silver-white, metallic luster. $H = 5\frac{1}{2}$, $VHN_{25} = 590$. $R = 45-57$ (540 nm); strongly anisotropic, cream-pink to dark blue or black. Sudbury, ON, Canada; Monchegorsk, Kola Penin., and Talnakh, Norilsk, Russia; *Waterfall Gorge, Insizwa, South Africa*. BM *DI:347*, *MM 38:794(1972)*, *R:363*, *P&J:407*, *ABI:352*.

1.2.11.1 Plumbopalladinite Pd₃Pb₂

Named in 1970 for the composition. HEX $P6_3/mc$. $a = 4.465$, $c = 5.709$, $Z = 1$, $D = 12.36$. 4-797(syn): 3.21₇ 2.30₁₀ 2.24₁₀ 1.76₆ 1.60₈ 1.42₆ 1.30₈ 1.21₈. Microscopic grains. White with a rose tint, metallic luster. $H = 5$, $VHN_{50} = 407-441$. $R = 51-54$ (540 nm); strongly anisotropic, orange-brown to dark brown. Stillwater Complex, MT; *Mayak mine, Talnakh, Norilsk, Russia*; Merensky Reef, Transvaal, South Africa. BM *GRM 5:63(1970)*, *AM 56:1121(1971)*, *ABI:413*.

ARSENIC GROUP

Four semimetal minerals are isostructural with arsenic and crystallize in a rhombohedral lattice with space group $R\bar{3}m$. Each atom is bonded to six of its neighbors, but more closely to three than the other three. The shorter of the bonds, which are due to a degree of covalency bonding within As₄ groups, eliminates simple sphere packing and results in a puckered sheet of atoms, which is connected to the next sheet by the longer bonds. The sheets extend in the (0001) plane, resulting in perfect basal cleavage.

ARSENIC GROUP

Mineral	Formula	Space Group	a	c	D	
Arsenic	As	$R\bar{3}m$	3.76	10.56	5.78	1.3.1.1
Antimony	Sb	$R\bar{3}m$	4.307	11.273	6.70	1.3.1.2
Stibarsen	SbAs	$R\bar{3}m$	4.02	10.80	6.48	1.3.1.3
Bismuth	Bi	$R\bar{3}m$	4.546	11.860	9.75	1.3.1.4

Notes:

1. The tsumoite, tetradymite, and joseite group minerals are very similar to the arsenic group: they have the same space group, with a in the range 4.1–4.5 Å, and c a multiple of 2, 3, and 4.
2. Arsenolamprite (1.3.2.1) is an orthorhombic form of arsenic.
3. Paradoctasite (1.3.3.1) is a semimetal of antimony and arsenic but crystallizes in a monoclinic space group.

1.3.1.1 Arsenic As

Known since antiquity. Arsenic group. Usually contains small amounts of Sb in solid solution. Dimorphous with arsenolamprite. HEX-R $R\bar{3}m$. $a = 3.76$, $c = 10.56$, $Z = 6$, $D = 5.78$. 5-632(syn): 3.52₃ 3.11₁ 2.77₁₀ 2.05₂ 1.88₃ 1.77₁

ARSENIC

Arsenic is in cubic close-packed arrangement. However, layers are squeezed together in pairs, and the bonds between As atoms in these two layers (thick) are much shorter than those to the next layer (thin).

1.76₁ 1.56₁. Crystals rare; usually massive, reniform, stalactitic, often in concentric layers. Tin-white, tarnishing to dark gray, tin-white streak, metallic luster. Cleavage {0001}, perfect; {1014}, fair; uneven fracture; brittle. $H = 3\frac{1}{2}$, $VHN_{100} = 72-173$. $G = 5.6-5.8$. $R = 47.4-53.2$ (540 nm); distinctly anisotropic. On heating, sublimes without melting, giving dense white fumes with a garlic odor (poisonous). Widely distributed. Sterling Hill, NJ, and Washington Camp(*), Santa Cruz Co., AZ; near Port Alberni, Vancouver Is., and Watson Creek, Fraser R., BC, Canada; Ste.-Marie-aux-Mines, Haut-Rhin, France; Wolfsberg and Andreasberg(*), Harz, and Freiberg, Schneeberg, Marienberg, and Annaberg(*), Saxony, Germany; Jachymov and Příbram, Czech Republic; Sacaramb, Hunyad, and Cavnic, Romania; Akatani mine(*), Fukui Pref., Japan; Bidi, Sarawak; Forbes, NSW, Australia; Kaponga mine, near Coromandel, New Zealand; Huallapon mine, Pasta Bueno, Peru; Copiapo, Chile. *BM DI:128, R:365, P&J.76, ABI:24.*

1.3.1.2 Antimony Sb

Known since antiquity, identified as a mineral in 1748. Arsenic group. Usually contains a little As. *HEX-R R3m*. $a = 4.307$, $c = 11.273$, $Z = 6$, $D = 6.70$. *35-732(syn)*: 3.75₃ 3.11₁₀ 2.25₇ 2.15₆ 1.88₄ 1.42₆ 1.37₇ 1.26₄. Rarely as pseudocubic or thick tabular crystals, usually massive, foliated, or granular; tin-white, gray streak, metallic luster. Cleavage {0001}, perfect and easy; less distinct on {1011}, {1014}, {1120}; twins on {1014} common,

often polysynthetic or in complex groups; very brittle. $H = 3-3\frac{1}{2}$, $VHN_{100} = 50-69$. $G = 6.6-6.7$. $R = 70.0-71.6$ (540 nm); weakly pleochroic and anisotropic. Occurs in veins with silver, antimony, and arsenic minerals, often with stibnite or stibarsen. Surcease mine, near Las Plumas, Butte Co., and Antimony Peak deposit and Tom Moore mine(*), Kern Co., CA; Lake George mine(*), York Co., NB, Canada; Moctezuma, SON, Mexico; Allemont, Isere, France; *Sala, Västmanland, Sweden*; Seinäjoki, Finland; Andreasberg(*), Harz, Germany; Příbram, Czech Republic; Sarawak, Borneo; Consols mine(*), Broken Hill, NSW, Australia; Huasco, Atacama, Chile; Quime, La Paz, Bolivia. *BM DI:132, R:373, P&J:69, ABI:16, MR 22:263(1991)*.

1.3.1.3 Stibarsen SbAs

Named in 1941 for the composition. Arsenic group. Allemontite is stibarsen intergrown with either arsenic or antimony. *HEX-R R3m*. $a = 4.02$, $c = 10.80$, $Z = 3$, $D = 6.48$. *31-80*: 3.60₃ 2.92₁₀ 2.13₆ 2.01₇ 1.66₄ 1.47₂ 1.28₄ 1.01₂. Usually massive, reniform or mammillary, or fine granular. Tin-white, tarnishing to gray, metallic luster. Cleavage {0001}, perfect. $H = 3-4$. $G = 5.8-6.2$. $R = 61.6-66.3$ (540 nm). Occurs in hydrothermal veins and granite pegmatites. Ophir mine, Comstock Lode, NV; Bernic Lake, MB, and Atlin and Alder Is., BC, Canada; *Varutrask, Västerbotten, Sweden*; Mine des Chalanches, near Allemont, France; Andreasberg, Harz, Germany; Příbram, Czech Republic; Broken Hill, NSW, Australia. *BM DI:130, AM 26:456(1941), R:371, P&J:352, ABI:496*.

1.3.1.4 Bismuth Bi

Known since the Middle Ages. Arsenic group. *HEX-R R3m*. $a = 4.546$, $c = 11.860$, $Z = 6$, $D = 9.75$. *5-519(syn)*: 3.95₁ 3.28₁₀ 2.37₄ 2.27₄ 1.97₁ 1.87₂ 1.49₁ 1.44₂. Indistinct crystals, often in parallel groupings; also arborescent, foliated, or granular. Silver-white with a reddish hue, iridescent tarnish; silver-white streak, metallic luster. Cleavage {0001}, perfect and easy; {1011}, good; {1014}, poor; sectile; brittle. $H = 2-2\frac{1}{2}$, $VHN_{100} = 16-18$. $G = 9.7-9.8$. $R = 62.6-63.8$ (540 nm); distinctly anisotropic. Easily fusible, $MP = 270^\circ$. Occurs in hydrothermal veins and in pegmatites. Monroe, CT; Chesterfield district, SC; French Creek and Las Animas mines, Boulder Co., CO; Pala, San Diego Co., CA; Cobalt, ON, and Great Bear Lake, NWT, Canada; Dolcoath and other mines, Cornwall, England; Meymac, Correze, France; Altenberg, Schneeberg(*), and Annaberg, Saxony, Germany; Jachymov, Czech Republic; Ikuno(*), Hyogo Pref., Japan; Wolfram Camp(*), Q, and Kingsgate(*), NSW, Australia; Uncia, Chorolque, Llallagua, Tazna(*), Colquechaca(*), and Potosi(*), Bolivia; Bogueiraa(*), Parelhas, RN, Brazil. *BM DI:134, R:374, P&J:91, ABI:55*.

BISMUTHINITE: Bi_2S_3

Bi is in very irregular 5- and 6-coordination.

1.3.1.5 Stistaite SbSn

Named in 1970 for the composition: stibium (antimony) and stannum (tin). HEX-R $R\bar{3}m$. $a = 8.648$, $c = 10.675$, $Z = 12$, $D = 6.91$. $33-118(\text{syn})$: 3.07_{10} 2.18_3 2.16_3 1.78_1 1.77_1 1.53_1 1.38_1 1.37_1 . Microscopic pseudocubic crystals. Gray, metallic luster. $H = 3$, $\text{VHN} = 103-127$. $G = 6.91$. $R = 81.6$ (540 nm). *Elkai-dan R., Uzbekistan*; Rio Tamana, Colombia, in heavy-mineral concentrates from placer deposits. BM *ZVMO 99:68(1970)*, *AM 56:358(1971)*, *NJMM:117(1981)*, *ABI:501*.

1.3.2.1 Arsenolamprite As

Named in 1886 for the composition and the Greek for *brilliance*, in allusion to its luster. Dimorphous with arsenic. Contains up to 3% Bi. ORTH $Bmab$. $a = 3.65$, $b = 4.47$, $c = 11.0$, $Z = 8$, $D = 5.55$. $30-100$: 5.49_1 3.47_2 2.74_{10} 2.24_2 1.88_1 1.74_3 1.69_1 1.52_1 . Needles, radial aggregates of plates, or massive. Gray-white, tarnishing to black, black streak, metallic luster. Perfect cleavage in one direction. $H = 2$. $G = 5.3-5.5$. $R = 44.0-49.6$ (540 nm); weakly anisotropic. Ste.-Marie-aux-Mines, Alsace, France; Machenheim and Wittichen, Black Forest, and *Marienberg, Saxony, Germany*; Lengenbach, Binn, Switzerland; Jachymov, Czech Republic; Mina Alacran, Copiapo, Chile. BM *DI:130*, *CE 20:71(1959)*, *R:370*, *P&J:77*, *ABI:26*.

1.3.3.1 Paradocrasite $\text{Sb}_2(\text{Sb,As})_2$

Named in 1971 from the Greek for *unexpected alloy*. MON $C2$. $a = 7.252$, $b = 4.172$, $c = 4.431$, $\beta = 123.13^\circ$, $Z = 1$, $D = 6.44$. $25-48$: 3.72_4 3.06_{10} 2.21_6 2.09_7 1.73_4 1.52_4 1.39_4 1.33_4 . Microscopic stubby prisms. Silver-white, black streak, metallic luster. Perfect $\{010\}$ parting. $H = 3$, $\text{VHN}_{100} = 118$.

$G = 6.52$. $R = 70.0$ (546 nm); strongly anisotropic, white to gray. Polysynthetically twinned. Atlin, BC, Canada; Moctezuma, SON, Mexico; *Consols mine, Broken Hill, NSW, Australia*. BM AM 56:1127(1971), ABI:282.

1.3.4.1 Selenium Se

Discovered in 1818, recognized as a mineral in 1828. Named from the Greek for *moon*, because it is often associated with tellurium (from Latin *tellus*, earth). HEX-R $P3_121$. $a = 4.366$, $c = 4.954$, $Z = 3$, $D = 4.81$. 6-362(syn): 3.78₆ 3.01₁₀ 2.18₂ 2.07₄ 2.00₂ 1.77₂ 1.65₁ 1.64₁. Acicular crystals up to 2 cm long, frequently hollow and tubular, occasionally in sheetlike clusters, also as glassy droplets. Gray, red streak, metallic luster. Cleavage {0112}, good; crystals flexible. $H = 2$. $G = 4.80$. $R = 24.1-34.1$ (540 nm); strongly anisotropic. Formed by the sublimation of fumarolic vapors and by the oxidation of Se-bearing material in sandstone U-V deposits. Glen Lyon, Luzerne Co., PA, on old burning coal-waste heaps, as a surface fumarolic product (!). Occurs in many U-V mines in the Colorado Plateau; United Verde mines, Jerome, AZ, in a fire zone; Kladno, Czech Republic, on burning heaps of pyritic sediments; Pacajake mine, Colquechaca, Chile, with selenide minerals. BM DI:136, R:382, P&J339, ABI:468.

1.3.4.2 Tellurium Te

Recognized as a mineral in 1802. Named from Latin *tellus*, earth. HEX-R $P3_121$. $a = 4.457$, $c = 5.929$, $Z = 3$, $D = 6.23$. 4-554(syn): 3.86₂ 3.23₁₀ 2.35₄ 2.23₃ 2.09₁ 1.84₂ 1.62₁ 1.48₁. Prismatic crystals up to 3 cm; usually massive, columnar to fine granular. Tin-white, gray streak, metallic luster. Cleavage {1010}, perfect; {0001}, imperfect; brittle. $H = 2-2\frac{1}{2}$. $VHN_{10} = 48-66$. $G = 6.1-6.3$. $R = 57.1-68.7$ (540 nm); strongly anisotropic. A hydrothermal vein mineral, associated with gold and silver tellurides. Cripple Creek, Teller Co., Magnolia, Goldhill, Ballarat, and Central districts, Boulder Co., and Vulcan(*), Gunnison Co., CO; Wilcox district, NM; Delamar(*), Lincoln Co., NV; Frood mine, Sudbury, ON, Canada; Moctezuma(*), SON, Mexico; *Facebaj, Transylvania, Romania*; Balia, Turkey; Kochbulak(*), Uzbekistan; Teine mine, near Sapporo, and Kawazu mine, near Simoda, Japan; Shimian mine, Sichuan Prov., China; Empress mine, Vatukoula, Fiji; Kalgoorlie, WA, Australia. BM DI:138, R:383, P&J:364, ABI:516.

1.3.5.1 Sulfur α -S

Known since antiquity. Dimorphous with rosickyite. ORTH *Fddd*. $a = 10.45$, $b = 12.84$, $c = 24.46$, $Z = 128$, $D = 2.08$. 8-247(syn): 3.85₁₀ 3.44₄ 3.33₃ 3.21₆ 3.11₃ 3.08₂ 2.84₂ 2.62₁. Structure: The atoms are bonded into puckered rings of eight atoms that can be regarded as S_8 molecules; each atom is bonded to two neighbors in its ring by homopolar bonds; the distance between S atoms in adjacent rings is much greater than the distance within the ring. Physical properties: Dipyramidal crystals, also thick tabular and disphenoidal; at least 56 crystal forms are known; also massive, reniform, and stalactitic.

SULFUR

Each S atom is bonded to two others to form puckered eight-membered rings.

Pale yellow to yellow-brown, white streak, resinous to greasy luster. Cleavage {001}, {110}, {111}, imperfect; parting {111}; conchoidal to uneven fracture; brittle. $H = 1\frac{1}{2}$ – $2\frac{1}{2}$. $G = 2.07$. Tests: MP = 113° ; burns in air, giving choking fumes of SO_2 . Chemistry: Usually pure; Se and Te may be present in trace amounts. Optics: Biaxial (+); $N_x = 1.958$, $N_y = 2.038$, $N_z = 2.245$; $XY = ab$; $2V = 69^\circ$; $r < v$. Occurrence: Widely distributed in regions of recent volcanic activity, as a sublimate in fumaroles and by the oxidation of H_2S . Most commercial deposits are in salt domes, where it has been formed by the bacterial decomposition of calcium sulfate. Localities: LA and TX, in salt domes; Yellowstone Park, WY, in fumaroles; Sulphur Bank, Lake Co., Leviathan mine, Alpine Co., Mt. Shasta, Siskiyou Co., and other localities in CA; Mauna Loa and Kilauea, HI; San Felipe(*), BC, Mexico; Conil(*), near Cadiz, Spain; Agrigento(*), Sicily; Shor Su(*), Fergana, Uzbekistan; numerous localities in Japanese volcanic regions; White Is., New Zealand. Uses: The principal source of sulfur compounds, widely used in industry and agriculture. BM *DI:140*, *ABI:506*.

1.3.5.2 Rosickyite γ -S

Named in 1931 for Vojtech Rosicky (1880–1942), Czech mineralogist. Dimorphous with α -sulfur. MON $P2/n$. $a = 8.50$, $b = 13.16$, $c = 9.29$, $\beta = 124.86^\circ$,

$Z = 32$, $D = 2.02$. *13-141*(syn): 6.65₃ 3.79₁ 3.74₂ 3.29₁₀ 3.04₁ 2.49₁ 1.45₂. Microscopic equant crystals. Colorless to pale yellow, white streak, adamantine luster. $G = 2.19$. High-temperature form unstable at room temperature, inverting slowly to α -sulfur. Point Rincon, Ventura Co., CA, deposited by gases from shales; *Havirna, near Letovice, Czech Republic*, in well-developed crystals; Vulcano, Lipari Is., Italy, in fumaroles. *BM DI:145, ACB 30:1396(1974), ABI:446*.

1.3.6.1 Diamond C

Known since antiquity. Polymorphous with graphite, chaoite, and lonsdaleite. iso *Fd3m*. $a = 3.567$, $Z = 8$, $D = 3.515$. *6-675*: 2.06₁₀ 1.26₃ 1.08₂ 0.892₁ 0.818₂. **Structure:** Each carbon atom is linked to four neighboring C atoms in a face-centered cubic unit cell; the close three-dimensional covalent linking completing the outer electron shell of each atom is manifested in the great hardness of diamond. **Physical properties:** Crystals commonly octahedral, also dodecahedral, tetrahedral, and cubic; usually rounded. Spherical aggregates with radial structure rare; massive, fine-grained (carbonado), rare. Colorless to yellow, brown, gray; less commonly pink, red, green, blue; sometimes black due to inclusions; adamantine to greasy luster. Cleavage {111}, perfect but rather difficult; conchoidal fracture; brittle. Twins {111}, common, often flattened parallel to the twin plane; tetrahedral crystals twinned on {001}. $H = 10$, greater than any other substance; slightly variable with orientation. $G = 3.50-3.53$. Some specimens fluorescent and phosphorescent (usually blue) under UV and X-rays. Triboelectric; some crystals triboluminescent. **Tests:** Easily recognized by its hardness and luster. **Chemistry:** Pure C in

DIAMOND

Space group *Fd3m*. Each atom is coordinated by four others. Also adopted by silicon.

colorless material, but dark varieties yield up to 20% ash, consisting mainly of SiO_2 , Fe_2O_3 , MgO , Al_2O_3 , CaO , TiO_2 . **Optics:** Isotropic; $N = 2.418$; dispersion strong. **Occurrence:** Diamond is the product of deep-seated crystallization of ultrabasic igneous magmas, intruded as dikes or pipes of kimberlite or lamproite. Erosion of these primary deposits has concentrated diamonds in placers of various geologic ages; these include stream deposits, wave-concentrated deposits along present and ancient shorelines, and old conglomerates. World production of diamond in 1990 was approximately 100 million carats (equivalent to 20 metric tons). Most of this was from primary deposits, as follows (in parentheses, production in 10^3 carats). Argyle, WA, Australia (34,662); Botswana (17,352); Yakutia, Russia (15,000); South Africa (8,708); Tanzania (85). Significant producers from secondary deposits were Zaire (19,427); Brazil (1,500); Angola (1,300); Namibia (761); Ghana (637); Central African Republic (381); Venezuela (333); Guinea (135); Liberia (100); Sierra Leone (78). **Localities:** In addition to these producing localities, diamonds have been found in many places throughout the world. In the United States, alluvial diamonds have been recorded from the Appalachians in VA, WV, NC, TN, GA, AL, and in the Great Lakes region from WI, IL, IN; many diamonds have been found in placers in CA. One primary deposit is the Prairie Creek lamproite pipe near Murfreesboro, Pike Co., AR, where many thousands of stones have been collected, mostly less than 1 carat, but one weighed 40.2 carats. Small diamonds have been found in kimberlite pipes of the State Line Group, CO-WY. Numerous kimberlites, some diamondiferous, have been found in SK, AB, and NWT, Canada. India was the only source of diamonds until 1729, when the Brazilian deposits were discovered; three principal localities are known, the Golconda region in Mysore and Hyderabad, Sambalpur, and Wairarh, near Nagpur, and the Panna district, Central Provinces. The diamonds are in secondary deposits, and current production is small, 15,000 carats in 1990. There is some production of alluvial diamonds in Borneo, 30,000 carats in 1990. Diamond-bearing deposits have been found in northern Hunan Prov., Liaoning Prov., and Shandong Prov., China; 1990 production is estimated at 1 million carats. Microscopic diamonds have been recorded from a few meteorites. **Uses:** In 1954 the General Electric Co. succeeded in synthesizing diamond; since then this material has taken a large share of the market for abrasives and other nongem uses. *BM DI:146, ABI:131, G&G 28:234(1992).*

1.3.6.2 Graphite C

Known since antiquity. Polymorphous with diamond, chaoite, and lonsdaleite. $\text{HEX } P6_3/mmc$. $a = 2.463$, $c = 6.714$, $Z = 4$, $D = 2.26$. $23-64$: 3.36_{10} 2.03_5 1.68_8 1.23_3 1.16_5 1.12_2 0.994_4 0.829 . **Structure:** Planes of atoms linked in hexagons, the planes being stacked so that half the atoms in the *B* layer are over atoms in the *A* layer, and the others are over the centers of the hexagons; the *C* layer is then exactly over the *A* layer. A rhombohedral polytype has been described in which the *C* layer is shifted in the same direction as

GRAPHITE

Each carbon is bonded to only three others, forming a sheet with hexagonal rings. The sheets are stacked to form rhombohedral symmetry, but they are only held together with van der Waals forces.

B, with the *D* layer over *A*. **Physical properties:** Hexagonal crystals, tabular on {0001}; also scaly, columnar, radiating, granular, compact, or earthy. Black, black streak, metallic or earthy luster. Cleavage {0001}, perfect and very easy; glides readily on {0001}; flexible; inelastic. $H = 1$, $VHN_{10} = 7-11$. $G = 2.1-2.2$. Conducts electricity. **Tests:** Insoluble in acids. Distinguished by color, softness (soapy feel), and black streak. **Chemistry:** Pure carbon. **Optics:** $R = 7.4-20.5$ (540 nm); strongly pleochroic and anisotropic. **Occurrence:** Formed by metamorphism of sedimentary carbonaceous material, by the oxidation of hydrocarbons, and by the reduction of CO and CO₂. Found as disseminated scales in igneous and metamorphic rocks, and massive in metamorphosed coal beds. Major commercial deposits are mined in China, Korea, Siberia, India, Mexico, Brazil, and Czech Republic; minor deposits in Madagascar, Turkey, Romania, Germany, Austria, and Sri Lanka. Occurs as nodules in iron meteorites. **Localities:** Some localities for good specimens are Ticonderoga, Essex Co., NY; Franklin and Sterling Hill, Sussex Co., NJ; Crestmore, Riverside Co., CA; Buckingham, PQ, and National mine, Hastings Co., ON, Canada; Morodillas mine, SON, Mexico; Egalugssuit and Disko Is., Greenland; Barrowdale, Cumbria, England; Kongsberg, Norway; St. Michel and Pargas, Finland; Passau, Bavaria, Germany; Valle Risagliardo, Piedmont, Italy; Nizhni Tunguski, Siberia, and Botogol, East Sayan, Russia; Arumanaloir, Travancore, India; Sabaragamuwa, Sri Lanka. *BM DI:152, R:384, P&J:184, ABI:192.*

1.3.6.3 Lonsdaleite C

Named in 1967 for Kathleen Lonsdale (1903–1971), English crystallographer. Polymorphous with diamond, graphite, and chaoite; lonsdaleite has a hexagonal close-packed structure, in contrast to the cubic close-packed structure of diamond. HEX $P6_3/mmc$. $a = 2.52$, $c = 4.12$, $Z = 4$, $D = 3.52$. 19-268(syn): 2.19₁₀ 2.06₁₀ 1.92₅ 1.50₃ 1.26₈ 1.17₅ 1.08₅ 1.06₃. Microscopic cubes and cubo-octahedra, also polycrystalline aggregates, mixed with diamond. Pale yellow to gray, adamantine luster. $H = 3$. $G > 3.20$. $N \sim 2.41$. Associated with diamond in the *Canyon Diablo*, *Goalpara*, and *Allan Hills 77283* meteorites; in diamond-bearing placers, *Yakutia*, and in soil at the *Tunguska* impact site, *Russia*. BM *NAT 214:587(1967)*, *AM 52:1579(1967)*, *MZ 7:27(1985)*, *ABI:301*.

1.3.6.4 Chaoite C

Named in 1969 for Edward C. T. Chao (b.1919), Chinese–U.S. petrologist. Polymorphous with diamond, graphite, and lonsdaleite. HEX $P6/mmm$. $a = 8.948$, $c = 14.078$, $Z = 168$, $D = 3.43$. 22-1069: 4.47₁₀ 4.26₁₀ 4.12₈ 3.71₄ 3.22₄ 3.03₆ 2.55₆ 2.28₆. Thin microscopic lamellae, alternating with graphite. Black. $H = 1-2$. Occurs in shock-metamorphosed graphite gneisses, and in ureilite meteorites. *Ries Crater, Bavaria, Germany*; *Goalpur* and *Dyalpur* meteorites. BM *SCI 161:363(1968)*, *AM 54:326(1969)*, *55:1067(1970)*, *ABI:93*.

1.3.7.1 Silicon Si

Identified as a mineral in 1989. iso $Fd3m$. $a = 5.431$, $Z = 8$, $D = 2.33$. 27-1402(syn): 3.14₁₀ 1.92₆ 1.64₃ 1.36₁ 1.25₁ 1.11₁ 1.05₁ 0.918₁. Microscopic dodecahedral and cubo-octahedral crystals. *Nuevo Potosi, Cuba*, enclosed in gold grains from an ophiolite complex; *Kola Penin.*, in gneisses from the super-deep drill hole, and *Yakutia*, in kimberlites, and *Tolbachik, Kamchatka*, in volcanic exhalations, *Russia*. BM *DANS 309:1182(1989)*, *AM 76:668(1991)*.

1.3.8.1 Moissanite α -SiC

Named in 1905 for Henri Moissan (1852–1907), French chemist. Carborundum is the synthetic product, widely used as an abrasive. HEX $P6_3mc$. $a = 3.081$, $c = 5.031$, $Z = 2$, $D = 3.22$ (2H polytype); 5H, 6H, 15R, 33R polytypes are known; β -SiC is isometric, $a = 4.359$. 29-1126(syn): 2.67₈ 2.52₅ 2.36₁₀ 1.83₂ 1.54₄ 1.42₃ 1.31₂ 1.29₁. Small hexagonal platy crystals. Colorless to blue or green, metallic luster. Cleavage {0001}, poor. $H = 9\frac{1}{2}$. $G = 3.22$. Uniaxial (+); $N_0 = 2.654$, $N_E = 2.967$; weakly pleochroic in blue. Originally described from the *Canyon Diablo* meteorite, but probably a contaminant. *Bridger, WY* (β -SiC); *Yakutia, Russia*, in kimberlite; many localities in alluvium in the former USSR, but contamination with carborundum is a possibility; *Fuxian, Liaoning, China*, in kimberlite. Recorded as a rare accessory in lunar samples. BM *DI:123*, *NAT 346:352(1990)*, *MZ 12(3):17(1990)*, *AM 77:208(1992)*.

1.3.9.1 Sinoite $\text{Si}_2\text{N}_2\text{O}$

Named in 1964 for the composition. ORTH $Cmc2_1$. $a = 8.843$, $b = 5.473$, $c = 4.835$, $Z = 4$, $D = 2.84$. 18-1171(syn): 4.68₈ 4.44₁₀ 3.36₁₀ 2.60₅ 2.42₈ 2.38₈ 1.39₈ 1.37₈. Microscopic plates. Colorless, white streak, vitreous luster. $G = 2.80$ – 2.85 . Biaxial (-); $N_x = 1.740$; $N_y, N_z = 1.855$; $Z = c$; 2V small. Occurs as an accessory in some enstatite chondrites. BM *SCI* 146:256(1964), *AM* 50:521(1965).

1.3.10.1 Nierite Si_3N_4

Named in 1995 for Alfred O. A. Nier (1912–1994), professor of physics, University of Minnesota, a pioneer in mass spectrography. HEX-R $P31c$. $a = 7.758$, $c = 5.623$, $Z = 4$, $D = 3.184$. A hexagonal polymorph was also observed. 9-250(syn): 4.32₅ 3.88₃ 3.37₃ 2.89₉ 2.60₈ 2.55₁₀ 2.32₆ 2.08₅. Micron-size laths elongated in the c direction. Colorless. $H = 9$. $G_{\text{syn}} = 3.17$ – 3.18 . Uniaxial (-); $N_O = 2.03$, $N_E = 2.02$. Occurs in trace amounts in a few chondritic meteorites. BM *Meteoritics* 30:387(1995).

Sulfides, Including Selenides and Tellurides

2.1.1.1 Algodonite Cu_6As

Named in 1857 for the locality. HEX $P6_3/mmc$. $a = 2.600$, $c = 4.228$, $Z = 2$, $D = 8.75$. $9-429$: 2.25_2 2.11_4 1.30_2 1.19_2 1.11_2 1.09_1 1.06_1 0.837_2 . Massive granular, or incrustations of minute crystals. Silver-white to steel-gray, tarnishing to dull bronze, metallic luster. No cleavage, conchoidal fracture. $H = 4$, $\text{VHN}_{100} = 245-302$. $G = 8.38$. $R = 62.8$ (540 nm); weakly anisotropic. Occurs in hydrothermal deposits, intimately associated with other copper arsenides. Numerous mines in Houghton, Keweenaw, and Baraga Cos., MI; Långban, Varmland, Sweden; Mechernich and Bruckenberg Shaft, near Zwickau, Germany; Tsumeb, Namibia; Corocoro, Bolivia; *Algodones mine*, *Coquimbo*, and Cerro de los Sequas, Rancagua, Chile. BM *DI:171*, *R:393*, *P&J:63*, *ABI:8*.

2.1.2.1 Horsfordite Cu_5Sb

Named in 1888 for Eben N. Horsford (1818-1893), U.S. chemist. Massive. Silver-white, easily tarnished, metallic luster. Uneven fracture, brittle. $H = 4-5$. $G = 8.81$. *Mytilene*, *Lesbos Is.*, *Greece*. BM *DI:173*, *R:399*, *ABI:224*.

2.1.3.1 Telargpalite $(\text{Pd,Ag})_3\text{Te}$

Named in 1974 for the composition. iso Space group unknown. $a = 12.60$, $Z = 16$, $D = 7.378$. $26-1453$: 3.05_4 2.74_3 2.42_{10} 2.22_2 2.10_5 1.82_2 1.48_3 1.34_2 . Microscopic grains. Light gray, metallic luster. $H = 2-2\frac{1}{2}$, $\text{VHN}_{10} = 62$. $R = 50.1$ (540 nm). Stillwater Complex, Nye Co., MT; *Oktyabr mine*, *Talnakh area*, *Norilsk*, and *Lukkulaisvaara massif*, *Karelia*, *Russia*. BM *ZVMO 103:595(1974)*, *AM 60:489(1975)*, *66:1103(1981)*, *ABI:514*.

2.1.4.1 Duranusite As_4S

Named in 1973 for the locality. ORTH Space group unknown. $a = 3.576$, $b = 6.759$, $c = 10.074$, $Z = 2$, $D = 4.53$. $25-1479$: 5.62_9 5.04_9 3.02_7 2.92_{10} 2.81_7 2.68_8 1.97_9 1.79_9 . Microscopic grains and wiry aggregates. Red, metallic luster. $H = 2$, $\text{VHN}_{25} = 58$. $R = 30.4-31.5$ (540 nm). Mt. Washington Cu mine, Vancouver Is., BC, Canada; *Duranus*, *Alpes-Maritimes*, *France*. BM *BM 96:131(1973)*, *AM 60:945(1975)*, *ABI:141*.

2.1.5.1 Bezsmertnovite $Au_4Cu(Te,Pb)$

Named in 1979 for Marianna S. Bezsmertnaya (1915–1991) and Vladimir V. Bezsmertny (b.1912), Russian geologists. ORTH $Pmmn$. $a = 24.215$, $b = 4.025$, $c = 16.245$, $Z = 16$, $D = 15.17$. $41-579$: 3.30_7 2.61_8 2.33_{10} 1.74_9 1.43_3 1.41_4 1.14_4 1.07_4 . Microscopic grains. Golden yellow, metallic luster. $H = 4\frac{1}{2}$, $VHN_{20} = 353$. $R = 37.5$ (540 nm); weakly anisotropic. An undisclosed locality in Kamchatka, Russia. BM *DANS* 249:185(1979), *AM* 66:878(1981), *ABI*:52.

2.1.6.1 Bilibinskite $Au_3Cu_2PbTe_2$

Named in 1978 for Yuri A. Bilibin (1901–1952), Russian geologist. iso Space group unknown. $a = 4.095$, $Z = 0.5$, $D = 14.27$. $29-544$: 3.29_1 3.06_4 3.00_1 2.37_{10} 2.05_7 1.45_6 1.23_8 1.18_2 . Massive. Rose-brown, brown streak, submetallic luster. No cleavage. $H = 4\frac{1}{2}$, $VHN_{20} = 329-419$. $G = 12.7$. $R = 21.5-23.2$ (540 nm). Far Eastern region, Russia, and Kazakhstan, in weathering zone of gold-telluride deposits. BM *ZVMO* 107:310(1978), *AM* 64:652(1979), *ABI*:53.

2.2.1.1 Dyscrasite Ag_3Sb

Named in 1832 from the Greek for a bad alloy. ORTH $Pm2m$. $a = 2.996$, $b = 5.235$, $c = 4.830$, $Z = 1$, $D = 9.76$. $10-452$: 2.61_3 2.42_4 2.29_{10} 1.77_3 1.51_3 1.37_4 1.28_3 1.26_2 . Usually massive, foliated, or granular; pseudo-hexagonal crystals rare, usually poor. Silver-white, tarnishing to lead-gray, metallic luster. Cleavage $\{001\}$, $\{011\}$, distinct; $\{110\}$, imperfect; multiple twinning common on $\{110\}$, forming hexagonal aggregates. $H = 3\frac{1}{2}$, $VHN_{100} = 153-179$. $G = 9.71$. $R = 60.1-62.7$; weakly pleochroic and anisotropic. Decomposed by HNO_3 with a white precipitate of Sb_2O_3 . Occurs in a few silver deposits, and then, often abundant. Poughkeepsie Gulch, Silverton, CO, and Reese River mining district, NV; Ste.-Marie-aux-Mines, Alsace, France; Hiendelaencina, Spain; Andreasburg(*), Harz, and Wolfach, Baden, Germany; Příbram(*), Czech Republic; Kongsberg and Sulitjelma, Norway; Consols mine(*), Broken Hill, NSW, Australia, in large masses; Chanarcillo, Chile; Colquechaca, Bolivia. BM *DI*:173, *R*:407, *P&J*:153, *ABI*:142.

2.2.1.2 Allargentum $Ag_{1-x}Sb_x(x = 0.09-0.16)$

Named in 1949 from the Greek for another and the Latin *argentum*, silver. HEX $P6_3/mmc$. $a = 2.945$, $c = 4.780$, $Z = 2$, $D = 10.12$. $25-54$ (syn): 2.55_7 2.40_7 2.25_{10} 1.74_4 1.47_4 1.35_6 1.25_5 1.23_4 . Microscopic grains and lamellae, intergrown with silver. Silver-white, metallic luster. $H = 3\frac{1}{2}$, $VHN = 172-203$. $G_{syn} = 10.0$. $R = 69.5-70.4$ (540 nm); weakly anisotropic. Occurs in high-grade Ag-Sb ores. Many mines in the Cobalt area, ON, Canada; Wasserfall, Vosges, France; Wenzel mine, Oberwolfach, Baden, and Hartenstein, Saxony, Germany; Hallefors, Bergslagen, Sweden; Consols mine, Broken Hill, NSW, Australia. BM *FM* 28:69(1950), *CM* 10:163(1970), *BM* 101:563(1978), *ABI*:9.

2.2.2.1 Domeykite Cu_3As

Named in 1845 for Ignacio Domeyko (1802–1889), Chilean mineralogist. iso *I43d*. $a = 9.62$, $Z = 16$, $D = 7.93$. *9-333*: 3.95_4 3.05_4 2.15_4 2.05_{10} 1.97_5 1.89_7 1.31_5 1.22_4 . Massive, reniform, botryoidal. Tin-white to steel-gray, tarnishing to orange-brown, metallic luster. No cleavage, uneven fracture. $H = 3-3\frac{1}{2}$, $\text{VHN}_{100} = 213-235$. $G = 7.2-7.9$. $R = 51.9$ (540 nm). Inverts above 90° to β -domeykite (HEX, $a = 7.02$, $c = 7.25$). Soluble in HNO_3 . Commonly intergrown with algodonite or β -domeykite. Franklin, NJ; Portage Lake, Houghton Co., and Mohawk and other mines in Keweenaw Co., MI; Cashin mine, Paradox Valley, CO; Michipicoten Is., Lake Superior, ON, Canada; near Helstone, Cornwall, England; Zwickau, Saxony, Germany; near Nachod, Bohemia, Czech Republic; Talmessi, Iran; Corocoro, Bolivia; Calabazo, Coquimbó, many other localities in Chile. BM *DI:172*, *EG 66:135(1971)*, *R:393*, *P&J:149*, *ABI:138*.

2.2.2.2 Kutinaite Cu_2AgAs

Named in 1970 for Jan Kutina (b.1924), Czech mineralogist. iso Space group unknown. $a = 11.76$, $Z = 28$, $D = 8.86$. *23-957(syn)*: 2.70_9 2.41_8 2.27_{10} 2.08_{10} 1.99_6 1.96_7 1.78_7 1.39_6 . Microscopic grains. Silver-white, metallic luster. $H = 4\frac{1}{2}$, $\text{VHN}_{25} = 237-270$. $G = 8.38$. $R = 42.6$ (540 nm). Associated with other arsenides from Černý Dul, Czech Republic; Wasserfall, Vosges, France; Niederbeerbach, Odenwald, Germany; Meskani mine, Anarak district, Iran. BM *AM 55:1083(1970)*, *R:398*, *P&J:230*, *TMPM 34:167(1985)*.

2.2.2.3 Dienerite Ni_3As

Named in 1921 for Karl Diener (1862–1928), Austrian paleontologist, who discovered the mineral. iso A single cubic crystal, about 5 mm. White, with a gray tinge, metallic luster. Near Radstadt, Salzburg, Austria. BM *DI:175*, *ABI:133*.

2.2.3.1 Bogdanovite $(\text{Au,Te,Pb})_3(\text{Cu,Fe})$

Named in 1979 for Aleksei A. Bogdanov (1907–1971), Russian geologist. iso (pseudocubic; optics show probable ORTH symmetry) *Pm3m*. $a = 4.088$, $Z = 1$, $D = 13.72$. *34-1302*: 2.36_{10} 2.15_1 2.05_6 1.45_6 1.23_8 1.18_3 1.09_3 0.992_2 . Massive. Rose-brown to bronze brown, tarnishing to blue-black, semimetallic luster. No cleavage. $H = 4\frac{1}{2}$, $\text{VHN}_{20} = 235-270$. $R = 5.6-29.5$ (540 nm); anisotropic, yellow to gold to purple. Cu and Fe vary reciprocally from $\text{Cu}_3\text{Fe}_0\text{As}$ to $\text{Cu}_0\text{Fe}_2\text{As}$. Bisbee, AZ; Dalnii Vostok, Kazakhstan, and Ago Kamchatka, Russia, in oxidation zone of Au–Te deposits. BM *AM 64:1329(1979)*, *ABI:58*, *CM 28:751(1990)*.

2.2.4.1 Atheneite $(\text{Pd,Hg})_3\text{As}$

Named in 1974 for the Greek goddess Pallas Athene, in reference to the Pd content. HEX *P6/mmm*. $a = 6.798$, $c = 3.483$, $Z = 2$, $D = 10.16$. *26-889*: 2.42_{10}

2.25₉ 2.22₆ 1.87₇ 1.37₈ 1.30₈ 1.26₈ 1.03₇. Irregular alluvial grains. Cream-yellow, metallic luster. $H = 5$, $VHN_{100} = 419-442$. $G = 10.2$. $R = 54.0-56.7$ (540 nm); weakly pleochroic, distinctly anisotropic. Near Zlatoust, Ural Mts., Russia; Merensky Reef, Transvaal, South Africa; *Itabira, MG, Brazil*, in gold washings. *BM MM 39:528(1974)*, *AM 59:1330(1974)*, *ABI:34*.

2.2.5.1 Vincentite (Pd,Pt)₃(As,Sb,Te)

Named in 1974 for Ewart A. Vincent (b.1919), professor of mineralogy, Oxford University. *TET I4*. $a = 9.974$, $c = 4.822$, $Z = 8$, $D = 11.27$. *26-1452*: 4.18₁₀ 3.95₁₀ 3.24₁₀ 2.75₁₀ 2.00₁₀ 1.75₁₀ 0.944₁₀. Microscopic grains. Brown-gray, metallic luster. $H = 6$, $VHN_{15} = 494$. $R = 51.8-52.8$ (546 nm); weakly anisotropic. Talnakh, Norilsk, Russia; *Riam Kanan R., Borneo*, in Pt-Au alluvial concentrates. *BM MM 39:525(1974)*, *AM 59:1332(1974)*.

2.2.6.1 Keithconnite Pd_{3-x}Te ($x = 0.14-0.43$)

Named in 1979 for Keith Conn (b.1923), U.S. geologist who investigated the Stillwater Complex. *HEX-R R3*. $a = 11.45$, $c = 11.40$, $Z = 7$, $D = 10.16$. *34-1461*: 2.26₁₀ 2.22₂ 2.16₉ 1.40₂ 1.37₂ 1.32₃ 1.27₂ 0.791₄. Microscopic grains. Cream to gray, metallic luster. $H = 4\frac{1}{2}-5$, $VHN_{15} = 394-424$. $R = 44.4-44.9$ (540 nm); moderately to strongly anisotropic. *Stillwater Complex, MT*, in heavy-mineral concentrates; Shinkolobwe, Shaba, Zaire. *BM CM 17:589(1979)*, *AM 66:1275(1981)*, *ABI:259*.

2.3.1.1 Koutekite Cu₅As₂

Named in 1958 for Jaromir Koutek (1902-1983), Czech mineralogist. *HEX P6₃/mmc*. $a = 11.51$, $c = 14.54$, $Z = 18$, $D = 8.38$. *29-534(syn)*: 2.45₈ 2.16₅ 2.09₁₀ 2.02₁₀ 2.00₁₀ 1.79₄ 1.75₄ 1.15₄. Microscopic grains. Blue-gray, metallic luster. $H = 3\frac{1}{2}$, $VHN_{25} = 136-157$. $G = 8.48$. $R = 39.7-43.1$ (540 nm); strongly anisotropic. Occurs in arsenical copper deposits. Mohawk, Keweenaw Co., MI; Daluis, Vallee du Var, and Wasserfall, Vosges, France; *Cerný Dul, Czech Republic*; Talmessi and Meskani deposits, Anarak district, Iran. *BM NAT 181:1553(1958)*, *R:399*; *P&J:227*, *ABI:274*, *AM 78:677(1993)*.

2.3.2.1 Orcelite Ni_{5-x}As₂ ($x = 0.23$)

Named in 1959 for Jean Orcel (1896-1978), French mineralogist. *HEX P6₃cm*. $a = 6.70$, $c = 12.39$, $Z = 6$, $D = 8.11$. *35-493*: 3.25₂ 3.09₂ 2.95₄ 2.14₆ 1.99₁₀ 1.93₁₀ 1.76₆ 1.64₂. Microscopic grains. Yellow-white, metallic luster. $G = 7.25$. $R = 49.1$ (540 nm); weakly pleochroic, noticeably anisotropic. Occurs as inclusions in pentlandite in ultramafic rocks. Nipissing mine, Cobalt, ON, and Table Mt., NF, Canada; Ronda massif, Malaga, Spain; Vourinos, Greece; Zolotaya Gora, Ural Mts., Russia; Beni Bousera, Morocco; *Tiebaghi massif, New Caledonia*. *BM AM 45:753(1960)*, *BM 103:198(1980)*, *CM 22:553(1984)*, *ABI:363*.

2.3.3.1 Stibiopalladinite Pd₅Sb₂

Named in 1929 for the composition. HEX $P6_3/cm$. $a = 7.606$, $c = 14.21$, $Z = 6$, $D = 10.85$. 25-597: 3.35₅ 2.84₅ 2.48₅ 2.27₁₀ 2.19₁₀ 2.02₅ 1.58₆ 1.28₅. Massive and as minute grains. Silver-white to steel-gray, metallic luster. No cleavage, uneven fracture. $H = 6$, $VHN_{100} = 610$. $G = 9.5$. $R = 52.5-54.2$ (540 nm); weakly pleochroic, distinctly anisotropic. Occurs in platinum deposits. Goodnews Bay, AK; Lac des Iles Complex, ON, Canada; Morozova mine, Norilsk, and near Zlatoust, Ural Mts., Russia; Pirogues R., New Caledonia; *Farm Tweefontein, near Potgieterstust, Transvaal, South Africa*. BM *DI:175*, *AM 61:1249(1976)*, *R:414*, *P&J:354*, *ABI:497*.

2.3.3.2 Palarstanide Pd₅(Sn,As)₂

Named in 1981 for the composition. HEX $P6_322$. $a = 6.784$, $c = 14.80$, $Z = 6$, $D = 10.27$. 17-223(syn): 2.36₄ 2.33₄ 2.26₂ 2.20₁₀ 2.11₈ 1.97₃ 1.95₃ 1.52₃. Hexagonal prisms and rounded grains. Steel-gray, metallic luster. Cleavage {0001}, perfect. $H = 5$, $VHN_{50} = 470$. $R = 53.2-54.5$ (540 nm); weakly anisotropic in gray. *Talnakh, Norilsk, Russia*. BM *ZVMO 110:487(1981)*; *AM 67:858(1982)*, *74:1219(1989)*; *ABI:375*.

2.3.4.1 Parkerite Ni₃Bi₂S₂

Named in 1937 for Robert L. Parker (1893-1973), professor of mineralogy, ETH, Zurich, Switzerland. MON $C2/m$. $a = 11.066$, $b = 8.085$, $c = 7.965$, $\beta = 134.0^\circ$, $Z = 8$, $D = 8.53$. 26-1283(syn): 5.73₂ 4.04₃ 3.98₃ 2.86₇ 2.84₁₀ 2.34₆ 2.28₂ 1.99₃. Microscopic grains and irregular masses. Bronze, black streak, metallic luster. Cleavage {001}, perfect; lamellar twinning on {111}. $H = 3$, $VHN_{15} = 125$. $G = 8.4$. $R = 45.8-50.5$ (540 nm); strongly anisotropic, green-gray to yellow brown. Gaspé Cu mine, PQ, and Sudbury and Cobalt-Gowganda, ON, Canada; Zinkwand mine, Styria, Austria; Karik'yavr and the Allarechensk region, Kola Penin., and Norilsk area, Ural Mts., Russia; Rakha deposit, Bihar, India; *Waterfall Gorge, Insizwa, South Africa*. BM *AM 28:343(1943)*, *59:296(1974)*; *R:404*; *P&J:289*; *ABI:339*.

2.3.5.1 Shandite Pb₂Ni₃S₂

Named in 1950 for Samuel J. Shand (1882-1957), professor of petrology, Columbia University. HEX-R $R\bar{3}m$. $a = 5.576$, $b = 13.658$, $Z = 3$, $D = 8.87$. 26-494: 4.55₂ 3.94₇ 2.79₁₀ 2.28₇ 1.97₄ 1.76₂ 1.61₂ 1.39₂. Microscopic grains. Tin-white, metallic luster. Rhombohedral cleavage. $H = 4$. $G = 8.72$. Jeffrey mine, Asbestos, PQ, Canada; Isua belt, Godthab region, Greenland, in serpentine; *Trial Harbour, TAS*, in serpentine, and Nullagine, WA, *Australia*. BM *AM 35:425(1950)*, *59:296(1974)*; *R:405*; *ABI:473*.

2.3.5.2 Rhodplumsite Pb₂Rh₃S₂

Named in 1983 for the composition. HEX-R $R\bar{3}m$. $a = 5.73$, $c = 14.00$, $Z = 3$, $D = 9.85$. 35-720: 4.64₂ 4.02₃ 2.86₁₀ 2.44₃ 2.33₆ 2.01₆ 1.81₃ 1.22₂. Microscopic

grains. Gray, metallic luster. Strongly anisotropic. *Umutnaya R., Ural Mts., Russia*, in Pt placer. BM *MZ* 5:87(1983), *MA* 35:88(1984), *ABI*:441.

2.3.6.1 Vozhminite (Ni,Co)₄(As,Sb)₂S₂

Named in 1982 for the locality. HEX Space group unknown. $a = 17.46$, $c = 7.20$, $Z = 18$, $D = 6.20$. $35-667$: 8.7_{10} 3.07_9 2.72_6 2.30_7 2.11_9 1.94_5 1.82_5 1.78_{10} . Probably massive. Yellow-brown, black streak, metallic luster. One distinct cleavage. $H = 4-5$, $VHN_{100} = 376-480$. $R = 47.5-50.9$ (540 nm). *Vozhmin serpentinite, Karelia, Russia*. BM *ZVMO* 111:480(1982), *AM* 68:645(1983), *ABI*:562.

2.4.1.1 Acanthite Ag₂S

Named in 1855 from the Greek for *thorn*, referring to the shape of the crystals. Much acanthite is paramorphic after the isometric phase *argentite* stable only above 177°. MON $P2_1/n$. $a = 4.229$, $b = 6.931$, $c = 7.862$, $\beta = 99.61^\circ$, $Z = 4$, $D = 7.24$. $14-72(\text{syn})$: 3.08_6 2.84_7 2.61_{10} 2.58_7 2.46_7 2.44_8 2.42_6 2.38_8 . Pseudocubic or pseudo-octahedral crystals up to 8 cm, also massive. Black, black streak, metallic luster. Indistinct cleavage, subconchoidal fracture, very sectile. $H = 2-2\frac{1}{2}$, $VHN_{50} = 21-25$. $G = 7.2-7.4$. $R = 31.2$ (540 nm); weakly anisotropic. Occurs worldwide in silver ores. The following localities have provided fine specimens: Butte, MT; Comstock Lode, Virginia City, and Tonopah, NV; Cobalt, ON, Highland Bell mine, BC, and El Bonanza mine, near Port Radium, NWT, Canada; Santa Eulalia and Batopilas, CHIH, Arizpe, SON, Zacatecas, ZAC; and Guanajuato, GTO, Mexico; Liskeard, Cornwall, England; Kongsberg, Norway; Andreasberg, Harz, and Freiberg, Saxony, Germany; Jachymov, Czech Republic; Sarrabus, Sardinia, Italy; Broken Hill, NSW, Australia; Chanarcillo, Atacama, Chile; Colquechaca, Bolivia. BM *DI*:176, 191; *CM* 12:365(1974); *R*:471; *P&J*:72; *ABI*:1.

2.4.1.2 Naumannite Ag₂Se

Named in 1845 for Karl F. Naumann (1797-1873), German mineralogist. ORTH $P2_12_12_1$. $a = 4.333$, $b = 7.062$, $c = 7.764$, $Z = 4$, $D = 7.87$. $24-1041(\text{syn})$: 2.74_2 2.67_{10} 2.58_9 2.43_3 2.25_3 2.12_3 2.08_4 2.01_3 . Pseudocubic crystals, also massive and in thin plates. Black, metallic luster. Cleavage {001}, perfect; sectile and malleable. $H = 2\frac{1}{2}$, $VHN_{25} = 33-84$. $G = 7.4-7.8$. $R = 35.7-37.3$ (540 nm); distinctly anisotropic. Widely distributed in seleniferous silver ores. Silver City district, Owyhee Co., ID, L-D mine, Wenatchee, WA; Kidd Creek mine, near Timmins, ON, Canada; *Tilkerode* and *Andreasberg, Harz Mts., Germany*; Kongsberg, Norway; Sacaramb, Romania; Sanru mine, Hokkaido, Japan; Colquechaca, Bolivia; Cachueta, Mendoza, Argentina. BM *DI*:179, *CM*12:365(1974), *R*:478, *P&J*:277, *ABI*:345.

2.4.1.3 Aguilarite Ag₄SeS

Named in 1891 for Ponciano Aguilar (1853-1935), superintendent of the San Carlos mine, Guanajuato, where the mineral was first found. ORTH $P2_12_12_1$.

$a = 4.33$, $b = 7.09$, $c = 7.76$, $Z = 2$, $D = 7.56$. 27-620: 2.88₅ 2.67₂ 2.59₂ 2.43₁₀ 2.23₃ 1.73₃ 1.60₂ 1.48₄. Skeletal pseudododecahedral crystals, also massive. Black, metallic luster. No cleavage, hackly fracture, sectile. $H = 2\frac{1}{2}$, $VHN_{25} = 23$. $G = 7.40-7.53$. $R = 31.9$ (540 nm); very weakly anisotropic. A relatively low-temperature mineral in silver deposits rich in selenium. Silver City, Owyhee Co., ID, Comstock Lode, Virginia City, NV, L-D mine, Wenatchee, WA; *San Carlos mine*(*) and other mines, GTO, Mexico; Sanru mine, Hokkaido, Japan; Maritoto mine, near Paeroa, New Zealand. BM *DI:178*, *CM 12:365(1974)*, *P&J:60*, *ABI:2*.

2.4.2.1 Hessite Ag_2Te

Named in 1843 for Henri Hess (1802-1850), Swiss-Russian chemist of St. Petersburg. MON $P2_1/n$. $a = 8.13$, $b = 4.48$, $c = 8.09$, $\beta = 112.9^\circ$, $Z = 4$, $D = 8.40$. 12-695: 4.53₁ 3.19₂ 3.01₆ 2.87₈ 2.31₁₀ 2.25₇ 2.20₂ 2.14₆. Pseudocubic crystals up to 1.7 cm, also massive. Steel-gray to lead gray, metallic luster. Cleavage {001}, indistinct; even fracture; somewhat sectile. $H = 2-3$, $VHN_{100} = 22-24$. $G = 7.9-8.4$. $R = 38.4-41.1$ (540 nm); distinctly anisotropic, dark orange to dark blue. Widely distributed in Te-rich Ag-Au ores. Mines in Boulder, Eagle, and San Juan Cos., CO; Bisbee and Tombstone, Cochise Co., AZ; Calaveras, Tuolumne, and Nevada Cos., CA; numerous localities in ON, PQ, and BC, Canada; San Sebastian, JAL, Mexico; Loch Duich, near Kyle of Lochalsh, Scotland; *Sacaramb*, Baita, and Botes, Romania; Savodinski mine, Altai Mts., Russia; Chugu mine, Ishikawa Pref., Japan; Kalgoorlie and Norseman, WA, Australia; Condorriaco mine, near Coquimbo, Chile. BM *DI:184*, *AM 34:342(1949)*, *R:421*, *P&J:199*, *ABI:216*.

2.4.2.2 Cervelleite Ag_4TeS

Named in 1989 for Bernard Cervelle (b.1940), French mineralogist. ISO Space group unknown. $a = 14.03$, $Z = 24$, $D = 8.53$. *EM 1*: 6.29₈ 5.74₂ 5.00₁₀ 4.64₄ 4.29₉ 3.77₆ 2.60₂ 2.45₂. Microscopic grains. Black, metallic luster. $VHN_{10} = 26$. $R = 34.7-38.3$ (540 nm). *La Bambolla (Mina Moctezuma) mine*, Moctezuma, SON, Mexico, rimming acanthite; Chadak, Uzbekistan. BM *EM 1:375(1989)*, *AM 75:1431(1990)*.

2.4.3.1 Uyténbogaardtite Ag_3AuS_2

Named in 1978 for Willem Uyténbogaardt (b.1918), Dutch mineralogist. TET $P4_122$. $a = 9.75$, $b = 9.85$, $Z = 8$, $D = 8.30$. 33-587(syn): 6.98₈ 4.38₆ 3.09₆ 2.81₆ 2.73₁₀ 2.61₉ 2.12₈ 1.99₅. Microscopic grains. Gray-white, metallic luster. $H = 2$, $VHN_{15} = 20$. $R = 30.3-34.6$ (546 nm); distinctly pleochroic and anisotropic. Occurs in hydrothermal Au-Ag quartz veins, with acanthite. New Bullfrog mine, Nye Co., and Comstock Lode, Virginia City, NV; Smeino-gorski, Altai Mts., Russia; Cerotan, Java, and *Tambang Sawah, Benkoelen district*, Indonesia. BM *CM 16:651(1978)*, *AM 65:209(1980)*, *ABI:552*.

2.4.3.2 Fischesserite Ag_3AuSe_2

Named in 1971 for Raymond Fischesser (1911–1991), French mineralogist. ISO $I4_132$. $a = 9.967$, $Z = 8$, $D = 9.10$. $25\text{--}367$: 7.08_6 2.66_{10} 2.23_8 2.04_8 1.95_6 1.82_8 1.33_6 1.27_7 . Microscopic grains. Gray-white, metallic luster. $H = 2$, $\text{VHN}_{10} = 47\text{--}55$. $R = 29.7$ (540 nm); light pink in reflected light. De Lamar mine, Owyhee Co., ID; Kidd Creek mine, near Timmins, ON, Canada; Hope's Nose, Torquay, England; *Predborice, Czech Republic*, in calcite vein; Flamenco, Atacama, Chile. BM *BM 94:381(1971)*, *AM 57:1554(1972)*, *P&J:163*, *ABI:157*.

2.4.3.3 Petzite Ag_3AuTe_2

Named in 1845 for W. Petz, who first described the mineral. ISO $I4_132$. $a = 10.38$, $Z = 8$, $D = 9.22$. $12\text{--}424$: 7.31_5 3.66_3 2.77_{10} 2.44_6 2.32_6 2.12_8 2.03_7 1.89_5 . Massive, fine granular to compact. Steel-gray to iron-black, often tarnished, metallic luster. Cleavage $\{001\}$, subconchoidal fracture, slightly sectile to brittle. $H = 2\frac{1}{2}\text{--}3$, $\text{VHN}_{10} = 48$. $G = 8.7\text{--}9.1$. $R = 38.2$ (540 nm); anisotropic in part. Widely distributed in Te-rich Ag–Au deposits. Mines in Boulder, Hinsdale, and Lake Cos., CO; Tuolumne and Calaveras Cos., CA; many localities in PQ and ON, Canada; Botes, *Sacaramb*, and Baia Sprie, *Romania*; Zhanatyube deposit, Kazakhstan; Kalgoorlie, WA, Australia; Emperor mine, Vatukoula, Fiji. BM *DI:186*, *AM 34:350(1949)*, *R:424*, *P&J:298*, *ABI:402*.

2.4.4.1 Jalpaite Ag_3CuS_2

Named in 1858 for the locality. TET $I4_1/amd$: $a = 8.673$, $c = 11.756$, $Z = 8$, $D = 6.78$. $12\text{--}207(\text{syn})$: 6.93_4 4.32_6 2.80_{10} 2.75_{10} 2.48_6 2.43_{10} 2.35_{10} 2.12_6 . Massive, granular. Lead-gray, tarnishing to black, metallic luster. Cleavage prismatic, good; sectile and malleable. $H = 2\text{--}2\frac{1}{2}$, $\text{VHN}_{25} = 29$. $G = 6.7\text{--}6.8$. $R = 30.7\text{--}33.3$ (540 nm); distinctly pleochroic and anisotropic. A low-temperature mineral in Ag deposits. Mines in Clear Creek, Mineral, Park, and Boulder Cos., CO; Mogollon, Catron Co., NM; Bisbee, AZ; *Jalpa*, ZAC, Queretaro, QRO, and La Mesa, CHIH, *Mexico*; Kongsberg, Norway; Bohutin, near Příbram, Czech Republic; Savodinski mine, Altai Mts., Russia; Sado mine, Niigata Pref., Japan; Broken Hill, NSW, Australia. BM *AM 53:1530(1968)*, *R:486*, *P&J:216*, *ABI:246*.

2.4.5.1 Mckinstryite $(\text{Ag,Cu})_2\text{S}$

Named in 1966 for Hugh E. McKinstry (1896–1961), U.S. economic geologist. ORTH $Pnam$. $a = 14.043$, $b = 15.677$, $c = 7.803$, $Z = 32$, $D = 6.57$. $19\text{--}406$: 3.51_6 3.06_6 2.86_6 2.61_{10} 2.57_4 2.41_4 2.07_7 1.95_5 . Granular aggregates of microscopic crystals. Steel-gray, tarnishing to black, dark steel-gray streak, metallic luster. One poor cleavage, subconchoidal fracture. $\text{VHN}_{25} = 43\text{--}45$. $G = 6.61$. $R = 24.0\text{--}27.9$ (540 nm); strongly anisotropic, light tan to gray. A low-temperature mineral in Ag deposits. Colorado Central mine, near Georgetown, and Bulldog Mt. mine, near Creede, CO; Mogollon, Catron Co., NM; *Foster mine, Cobalt, ON*, and Echo Bay mine, Great Bear Lake, NWT,

Canada; Jalpa, ZAC, Mexico; Godejord, Grong dist., Norway; Příbram, Czech Republic; Sedmochislenitsi mine, Vratsa district, Bulgaria; Tort Kudak deposit, Kazakhstan; Sado mine, Niigata Pref., Japan; Broken Hill, NSW, Australia. BM *EG* 61:1383(1966), *AM* 53:1530(1968), *R*:484, *P&J*:263, *ABI*:320.

2.4.6.1 Stromeayerite AgCuS

Named in 1832 for Friedrich Stromeayer (1766–1835), German chemist, who first analyzed the mineral. ORTH *Cmcm*. $a = 4.06$, $b = 6.66$, $c = 7.99$, $Z = 4$, $D = 6.26$. 9-499: 3.46₇ 3.33₈ 3.07₆ 2.61₁₀ 2.55₆ 2.07₈ 1.99₇ 1.89₆. Pseudohexagonal prismatic crystals, also massive. Steel-gray, bluish tarnish, dark steel-gray streak, metallic luster. No cleavage, conchoidal fracture, brittle. $H = 2\frac{1}{2}$ –3, $VHN_{25} = 70$ –72. $G = 6.2$ –6.3. $R = 27.7$ –31.0 (540 nm); strongly anisotropic, blue to violet. An accessory mineral in Ag–Cu deposits. Many mines in CO; Butte, MT; Silver King and Magma mines, Superior, AZ; Cobalt-Gowganda district, ON, and Silver King mine, near Nelson, BC, Canada; Příbram, Czech Republic; Rudelstadt and Kupferberg, Silesia, Poland; Godejord, Grong Dist., Norway; Agdarinsk deposit, Azerbaijan; *Smeinogorski, Altai Mts., Russia*; Mt Lyell, TAS, and Broken Hill, NSW, Australia; Tsumeb, Namibia. BM *DI*:190, *EG* 61:1(1966), *R*:481, *P&J*:355, *ABI*:502.

2.4.6.2 Eucalrite AgCuSe

Named in 1818 from the Greek for *opportunity*, because it was discovered shortly after the discovery of selenium. ORTH *Pmmn*. $a = 4.105$, $b = 4.070$, $c = 6.310$, $Z = 2$, $D = 7.89$. 25-1180: 3.42₃ 3.16₃ 2.89₅ 2.63₆ 2.49₁₀ 2.05₃ 2.04₃ 1.58₃. Massive, granular. Silver-white to lead-gray, metallic luster. No cleavage, somewhat sectile. $H = 2\frac{1}{2}$, $VHN_{25} = 27$ –31. $G = 7.6$ –7.8. $R = 37.1$ –37.2 (540 nm); strongly anisotropic. Widely distributed in Cu–Se deposits. Cougar mine, San Miguel Co., CO; Kidd Creek mine, near Timmins, ON, and Martin Lake mine, near Lake Athabasca, SK, Canada; Hope's Nose, Torquay, England; *Skrikerum, near Kalmar, Sweden*; Lerbach, Harz Mts., Germany; Jachymov, Czech Republic; Kletno, Poland; Kalgoorlie, WA, Australia; Aguas Blancas, Copiapó, Chile; Sierra de Umango, La Rioja Prov., Argentina. BM *DI*:183, *AM* 35:337(1950), *R*:484, *P&J*:158, *ABI*:152.

CHALCOCITE GROUP

Copper and sulfur combine according to the formula

where $0 \leq x \leq 0.6$ to give seven separately named minerals. Chalcocite, Cu_2S appears in two polymorphs. One polymorph is based on a hexagonal close-packed framework of sulfur atoms containing a complex arrangement of copper atoms, mostly in triangular coordination but some in a tetrahedral coordination. Above 103° , chalcocite appears as a hexagonal polymorph, $P6/mmc$,

CHALCOCITE

and the lower-temperature polymorph has been characterized in the lower-symmetry space group $P2_1/c$.

COPPER SULFIDES

Mineral	Formula	Space Group	<i>a</i>	<i>b</i>	<i>c</i>	β	<i>Z</i>	
Chalcocite	Cu_2S	$P2_1/c$	15.235	11.885	13.496	116.26	48	2.4.7.1
Chalcocite*	Cu_2S	$P6/mmc$	3.95		6.75		2	2.4.7.1
Djurleite	$\text{Cu}_{1.97}\text{S}$	$P2_1/c$	26.896	15.745	13.565	90.13	128	2.4.7.2
Digenite	$\text{Cu}_{1.80}\text{S}$	$Fm\bar{3}m$	5.57				4	2.4.7.3
Roxbyite	$\text{Cu}_{1.78}\text{S}$	$C2/m$	53.79	30.90	13.36	90.0	64	2.4.7.4
Anilite	$\text{Cu}_{1.75}\text{S}$	$Pnma$	7.89	7.84	11.01		16	2.4.7.5
Geerite	$\text{Cu}_{1.60}\text{S}$	$F43m$	5.410				4	2.4.7.6
Spionkopite	$\text{Cu}_{1.40}\text{S}$	$P3m1$	22.962		41.429		504	2.4.7.7

*High-temperature polymorph.

Note: See also pyrrhotite (2.8.10.1), which is commonly Fe_7S_8 and which is also based on close-packed sulfur atoms with Fe in octahedral coordination. See also the nickeline group. Pyrrhotite is a nickeline structure but with ordered vacant sites.

2.4.7.1 Chalcocite Cu_2S

Named in 1832 from the Greek for *copper*. Chalcocite group. *MON* $P2_1/c$. $a = 15.235$, $b = 11.885$, $c = 13.496$, $\beta = 116.26^\circ$, $Z = 48$, $D = 5.79$; above 103° inverts to a hexagonal polymorph, $P6/mmc$; $a = 3.95$, $b = 6.75$, $Z = 2$, $D = 5.80$. *ZK 150:299(1979)*. *33-490: 3.28₄ 2.73₄ 2.41₅ 2.40₇ 2.33₃ 2.21₄ 1.97₇ 1.88₁₀*. Crystals rare, pseudo-hexagonal tabular or prismatic; usually massive, compact, sometimes with a sooty coating. **Structure:** Based on a hexagonal close-packed sulfur framework containing a complex arrangement of Cu

atoms, mostly in triangular coordination, some in tetrahedral coordination. **Physical properties:** Black, dark gray to black streak, submetallic luster. Cleavage {110}, indistinct; conchoidal fracture; brittle to somewhat sectile. $H = 2\frac{1}{2}$ -3, $VHN_{100} = 84$ -87. $G = 5.5$ -5.8. $R = 31.8$ (540 nm); weakly anisotropic. **Tests:** Soluble in HNO_3 . Easily reduced to metallic copper. **Occurrence:** A common and widely distributed ore mineral of copper. The principal occurrence is in the supergene-enriched zone of sulfide deposits. Oxidizing surface waters attack the primary sulfides, such as chalcopyrite, forming soluble sulfates, which react with the primary sulfides at greater depth to precipitate chalcocite, forming a blanketlike deposit at the water-table level. This contains a considerably greater content of copper than the primary ore, and it has yielded important amounts of copper at Bingham Canyon, UT, Morenci, AZ, Ely, NV, Rio Tinto, Spain, and several other localities. Chalcocite also occurs in hydrothermal sulfide veins with bornite, enargite, chalcopyrite, and pyrite, as at Butte, MT. **Localities:** The following localities are known for fine specimens. Bristol, CT; Flambeau mine, Rush Co., WI; Butte, MT; Bisbee and Miami, AZ; Kennecott, Copper R., AK; St. Just and Redruth, Cornwall, England; Jachymov, Czech Republic; Dognacska, Romania; Bogolovsk, Ural Mts., Russia; Dzhezkazgan, Kazakhstan; Mindouli, Congo Republic; Khan mine, near Arandis, and Tsumeb, Namibia; Messina, Transvaal, and Nababiep West mine, Cape Province, South Africa. **Uses:** An important ore of copper. *BM DI:187, EG 61:1(1966), R:441, P&J:116, ABI:88.*

2.4.7.2 Djurleite $Cu_{1.97}S$

Named in 1962 for Seved Djurle (b.1928), Swedish chemist, who first synthesized the compound. Chalcocite group. *MON P2₁/c*. $a = 26.896$, $b = 15.745$, $c = 13.565$, $\beta = 90.13^\circ$, $Z = 128$, $D = 5.77$. *34-660(syn)*: 3.76_2 3.19_2 3.04_2 2.65_2 2.42_2 2.39_9 1.96_{10} 1.87_{10} . Hexagonal and tabular crystals, usually massive, compact. Black, black streak, submetallic luster. No cleavage, twinning common on {110}, conchoidal fracture. $H = 2\frac{1}{2}$ -3, $VHN_{100} = 65$ -85. $G = 5.7$. $R = 29.6$ -30.2 (540 nm); weakly anisotropic. A widely distributed ore mineral of copper; present in many of the large porphyry copper deposits of the western United States, as in Butte, MT; Bisbee and Globe-Miami, AZ; as crystals up to 1 cm at the benitoite mine, San Benito Co., CA; *Barranca de Cobre* and *Salvadora* mine, *CHIH, Mexico*; Wheal Owles, Cornwall, and Seathwaite Tarn, Cumbria, England; Bandakslí, Norway; Osarizawa and Kawazu mines, Honshu, Japan; Bagacay, Samar Is., Philippines; Mt. Gunson mine, SA, Australia; Tsumeb, Namibia. Often confused with chalcocite, with which it is closely associated. *BM AM 47:1181(1962), R:441, P&J:116, ABI:137.*

2.4.7.3 Digenite $Cu_{1.80}S$

Named in 1844 from the Greek for *two kinds*, referring to the presumed presence of both cuprous and cupric copper. Chalcocite group. Contains about 1% Fe, which may be an essential component. *ISO (> 75°) Fm3m*. $a = 5.57$,

$Z = 4$, $D = 5.63$. $23-692(\text{syn})$: 3.21_4 3.01_1 2.78_5 2.14_1 1.97_{10} 1.75_1 1.68_2 1.39_1 . Octahedral crystals rare, usually massive. Blue to black, black streak, sub-metallic luster. Cleavage $\{111\}$, fracture conchoidal, brittle. $H = 2\frac{1}{2}$ -3, $VHN_{100} = 86$ -106. $G = 5.5$ -5.7. $R = 21.6$ (540 nm); distinctly blue in polished section. Widely distributed in copper deposits. Butte(*), MT; Bisbee, Jerome, and Superior, AZ; Kennecott, AK; Cananea, SON, Mexico; Botallack mine, Cornwall, England; *Sangerhausen, Thuringia, Germany*; Tsumeb, Namibia. *BM DI:180, AM 56:1889(1971), R:441, P&J:147, ABI:134.*

2.4.7.4 Roxbyite $\text{Cu}_1\text{7}_8\text{S}$

Named in 1988 for the locality. Chalcocite group. *MON C2/m*. $a = 53.79$, $b = 30.90$, $c = 13.36$, $\beta = 90.0^\circ$, $Z = 64$, $D = 5.56$. $23-958(\text{syn})$: 3.35_6 3.00_5 2.86_8 2.63_7 2.37_9 1.94_{10} 1.86_9 1.68_4 . Microscopic crystals and powdery aggregates. Blue-black. Cleavage $\{100\}$, poor. $H = 2\frac{1}{2}$, $VHN_{50} = 83$. $R = 24.5$ -29.8 (546 nm); anisotropism very weak. *Roxby Downs, SA, Australia*; El Teniente mine, Chile. *BM MM 52:323(1988), ABI:448.*

2.4.7.5 Anilite $\text{Cu}_1\text{7}_5\text{S}$

Named in 1969 for the locality. Chalcocite group. *ORTH Pnma*. $a = 7.89$, $b = 7.84$, $c = 11.01$, $Z = 16$, $D = 5.68$. $24-53$: 3.35_5 3.33_4 2.78_6 2.70_4 2.69_3 2.54_5 2.17_4 1.96_{10} . Prismatic or platy crystals, up to 5 mm. Blue-gray, black streak, metallic luster. $H = 3$. Yarrow Creek, AB, Canada; Neudorf, Harz, Germany; Lubin mine, Silesia, Poland; Bor, Serbia; *Ani mine, Akita, Japan*; Wallaroo, SA, Australia; Estrella mine, Atacama, Chile. *BM AM 54:1256(1969), R:441, ABI:14.*

ANILITE: $\text{Cu} \cdot 7\text{S}$ (chalcocite group)

Sulfur atoms are in approximately body-centered cubic arrangement, with copper 3- and 4-coordinated. Not closely related to the ideal chalcocite (CuS) structure, in which S is HCP.

2.4.7.6 Geerite Cu_{160}S

Named in 1980 for Adam Geer (1895–1973), of Utica, NY, who collected the mineral. Chalcocite group. iso $F43m$. $a = 5.410$, $Z = 4$, $D = 5.61$. $33\text{-}491$: 3.13_{10} 2.71_1 1.92_5 1.87_1 1.68_1 1.64_3 1.25_1 1.11_2 . Microscopic platelets. Black, metallic luster. $H = 3$, $\text{VHN}_{25} = 75\text{-}96$. Moderately anisotropic. *DeKalb Twp., St. Lawrence Co., NY*; Cuchillo, Sierra Co., NM; Grube Clara, Black Forest, Germany; near Eretria, Othris Mts., Greece. *BM CM 18:519(1980)*, *NJMM:489(1981)*, *ABI:175*.

2.4.7.7 Spionkopite Cu_{140}S

Named in 1980 for the locality. Chalcocite group. HEX-R Space group uncertain, probably $P3m1$. $a = 22.962$, $c = 41.429$, $Z = 504$, $D = 5.13$. $36\text{-}380$: 3.28_2 3.08_9 2.78_3 2.39_2 2.30_3 1.91_{10} 1.82_3 1.62_2 . Black, metallic luster. $H = 2\frac{1}{4}$, $\text{VHN}_{10} = 120\text{-}162$. $R = 19.0\text{-}27.4$ (540 nm); pleochroic in blue to blue-white [like yarrowite, formerly called “blaubleibender Covellit” (blue-remaining covellite) for this reason]. In a red-bed copper deposit at *Spionkop Creek, AB, Canada*; *DeKalb Twp., NY*; *Bisbee, AZ*; *Schulenberg, Harz, Germany*; near Eretria, Othris Mts., Greece. *BM CM 18:511(1980)*, *R:676*, *ABI:489*.

2.4.8.1 Weissite Cu_{2-x}Te

Named in 1927 for Louis Weiss, owner of the Good Hope mine. $\text{HEX } P3m1$. $a = 8.342$, $c = 21.69$, $Z = 24$, $D = 6.44$. $10\text{-}421(\text{syn})$: 3.61_7 3.24_6 2.55_3 2.17_3 2.09_{10} 2.01_7 1.80_5 1.45_3 . Dark blue-black, tarnishing to deep black, black streak, metallic luster. $H = 3$, $\text{VHN}_{100} = 145\text{-}158$. $G = 6$. $R = 33.7\text{-}34.9$ (540 nm); distinctly pleochroic and anisotropic. Occurs in hydrothermal veins with other tellurides. *Good Hope and Mammoth Chimney mines, Vulcan, Gunnison Co., CO*; near Winston, Sierra Co., NM; Teine mine, Hokkaido, and Kawazu, Honshu, Japan; Kalgoorlie, WA, Australia. *BM DI:199*, *R:419*, *P&J:388*, *ABI:573*.

2.4.9.1 Bellidoite Cu_2Se

Named in 1975 for Eleodoro Bellido Bravo (1918–1992), director of Servicio de Geología y Minería, Peru. Dimorphous with berzelianite. $\text{TET } P4_2/n$. $a = 11.52$, $c = 11.74$, $Z = 32$, $D = 7.03$. $29\text{-}575$: 6.8_3 3.5_1 3.38_8 2.32_1 2.26_5 2.06_{10} 1.76_7 1.52_1 . Microscopic anhedral grains. Silver-white, metallic luster. $H = 1\frac{1}{2}\text{-}2$, $\text{VHN}_{100} = 33\text{-}41$. $R = 28.5$ (589 nm); very weakly anisotropic. Occurs with other selenides in calcite at *Habri, near Tisnov, Moravia, Czech Republic*. *BM EG 70:384(1975)*, *R:468*, *ABI:43*.

2.4.10.1 Berzelianite Cu_2Se

Named in 1850 for Jöns J. Berzelius (1779–1848), Swedish chemist. Dimorphous with bellidoite. iso $Pm3m$. $a = 5.739$, $Z = 4$, $D = 6.90$. $6\text{-}680$: 3.33_9 2.03_{10} 1.73_8 1.43_3 1.32_2 1.17_4 1.01_1 . Fine-grained powdery and as dendritic

crusts. Lead-gray, black streak, metallic luster. No cleavage, uneven fracture, brittle. $H = 2$, $VHN_{100} = 21-24$. $G = 6.71$. $R = 25.8$ (540 nm). Occurs with other selenides in hydrothermal veins. Aurora, Mineral Co., NV; Pinky Fault uranium deposit, Lake Athabaska, SK, Canada; *Skrikerum, near Tryserum, Kalmar, Sweden*; Lerbach, Tilkerode, Zorge, and Clausthal, Harz, Germany; Habri, near Tisnov, Moravia, Czech Republic; Kalgoolie, WA, and El Sharana, NT, Australia; Sierra de Umango, La Rioja, Argentina. *BM DI:182, AM:351(1950), R:467, P&J:88, ABI:50.*

2.4.11.1 Cuprostibite $Cu_2(Sb,Tl)$

Named in 1969 for the composition. *TET P4/nmm*. $a = 3.990$, $c = 6.09$, $Z = 2$, $D = 8.42$. *22-601*: 3.33_2 2.82_4 2.56_5 2.07_{10} 1.99_4 1.67_2 1.42_3 1.17_4 . Fine-grained aggregates. Steel-gray with violet-red tint on fresh fractures, metallic luster. Cleavage in one direction, uneven fracture. $H = 4$, $VHN_{50} = 216-249$. $R = 38.7-45.5$ (540 nm); strongly pleochroic and anisotropic. Franklin, NJ; *Mt. Nakalak, near Narssaq, Greenland*, in vein in sodalite syenite; Langban and Långsjön, Sweden, in mineralized dolomite; Zolotaya Gora, Urals, Russia. *BM AM 55:1810(1970); NJMM:201(1982), 145(1988); ABI:123.*

2.4.12.1 Crookesite Cu_7TlSe_4

Named in 1866 for William Crookes (1832-1919), English chemist, who discovered thallium. May contain up to 5% Ag. *TET I4*. $a = 10.40$, $c = 3.93$, $Z = 2$, $D = 7.44$. *6-280*: 5.21_1 3.30_{10} 3.01_8 2.60_{10} 2.32_3 2.11_5 1.84_4 1.78_4 . Finely granular. Lead-gray, black streak, metallic luster. Two cleavages at right angles, brittle. $H = 2\frac{1}{2}-3$, $VHN_{100} = 92-123$. $G = 6.90$. $R = 31.5-36.5$ (540 nm); distinctly anisotropic. Occurs in hydrothermal deposits with other selenides. Pinky Fault uranium deposit, Lake Athabaska, SK, Canada; *Skrikerum, near Tryserum, Kalmar, Sweden*; Bukov, near Tisnov, Czech Republic. *BM DI:183, AM 35:347(1950), R:481, P&J:135, ZK 181:241(1987).*

2.4.12.2 Sabatierite Cu_4TlSe_3

Named in 1978 for Germain Sabatier (b.1923), French mineralogist. *TET P4/mmm*. $a = 3.977$, $c = 9.841$, $Z = 1$, $D = 7.42$. *41-1458(syn)*: 3.09_{10} 2.71_6 2.53_2 2.44_3 1.99_7 1.85_3 1.67_4 1.41_2 . Microscopic polycrystalline aggregates. Gray, metallic luster. $H = 2$, $VHN_{15} = 54$. $R = 27.9-30.6$ (540 nm); strongly anisotropic. *Bukov deposit, Rožná district, Czech Republic*. *BM BM 101:557(1978), AM 64:1331(1979), P&J:410, ZK 181:241(1987), ABI: 456.*

2.4.13.1 Carlinite Tl_2S

Named in 1975 for the locality. *HEX-R R3*. $a = 12.12$, $c = 18.175$, $Z = 27$, $D = 8.55$. *29-1344(syn)*: 3.03_{10} 2.29_1 2.02_1 1.75_1 1.51_1 1.20_1 1.08_1 0.916_1 . Microscopic anhedral grains. Dark gray, black streak, metallic luster. Cleavage $\{0001\}$, perfect; hackly fracture. $H = 1$, $VHN_{50} = 23.5$. $G = 8.1$. $R = 38.8-40.1$ (546 nm); moderately anisotropic. Occurs in carbonaceous

limestone in the *Carlin mine, Eureka Co., NV*. BM *AM 60:559(1975)*, *R:467*, *ABI:81*.

2.4.14.1 Palladoarsenide Pd₂As

Named in 1974 for the composition. MON *P2/m*. $a = 9.24$, $b = 8.47$, $c = 10.45$, $\beta = 94.00^\circ$, $Z = 18$, $D = 10.54$. *17-227(syn)*: 2.89₃ 2.60₇ 2.35₅ 2.31₅ 2.22₁₀ 2.15₁₀ 2.13₄ 1.96₄. Microscopic grains. Steel-gray, metallic luster. Cleavage perfect in two directions, brittle. $H = 5$, $VHN_{100} = 390$. $R = 52.5-54.8$ (540 nm); moderately anisotropic. Stillwater Complex, MT, in heavy-mineral concentrates; Lac des Iles Complex, ON, Canada; *Oktyabr mine, Talnakh, Norilsk, Russia*; *Merensky Reef, Transvaal, South. Africa*. BM *ZVMO 103:104(1974)*, *AM 60:162(1975)*, *CM 13:321(1975)*, *ABI:377*.

2.4.15.1 Palladobismutharsenide Pd₂(As,Bi)

Named in 1976 for the composition. ORTH *Pmcn* or *P2₁cn*. $a = 7.467$, $b = 18.946$, $c = 6.797$, $Z = 20$, $D = 10.8$. *29-962(syn)*: 2.59₈ 2.49₉ 2.38₄ 2.26₄ 2.23₁₀ 2.20₈ 2.13₅ 2.08₉. Microscopic grains. Cream-white, metallic luster. $H = 6$, $VHN_{25} = 429-483$. $R = 52.1-53.0$ (546 nm); weakly to distinctly anisotropic. *Stillwater Complex, MT*, in heavy-mineral concentrates. BM *CM 14:410(1976)*, *ABI:378*.

2.4.16.1 Majakite PdNiAs

Named in 1976 for the locality. HEX Space group unknown. $a = 6.066$, $c = 7.20$, $Z = 6$, $D = 10.42$. *29-965*: 3.04₄ 2.65₁₀ 2.40₄ 2.30₅ 2.19₇ 1.19₁₀ 1.80₄ 1.75₃. Microscopic grains. Gray-white, metallic luster. $H = 6$, $VHN_{50} = 520$. $G_{syn} = 9.33$. $R = 52.8$ (540 nm); weakly anisotropic. *Majak mine, Talnakh, Norilsk, Russia*, intergrown with chalcopyrite and platinum-group minerals. BM *ZVMO 105:698(1976)*, *AM 62:1260(1977)*, *ABI:307*.

2.4.17.1 Petrovskaita AuAgS

Named in 1984 for Nina Petrovskaya (b.1910), Russian mineralogist. Contains up to 1.3% Se. MON Space group unknown. $a = 4.943$, $b = 6.670$, $c = 7.221$, $\beta = 95.68^\circ$, $Z = 4$, $D = 9.44$. *38-396*: 7.25₃ 3.87₃ 2.77₁₀ 2.63₅ 2.39₄ 2.25₄ 1.80₃ 1.47₄. Microscopic rims on gold. Dark gray to black, dark gray streak, dull metallic luster. $H = 2-2\frac{1}{2}$, $VHN = 40-48$. Occurs with gold in the *Maikain gold deposit, Kazakhstan*. BM *ZVMO 113:602(1984)*, *AM 70:1331(1985)*, *ABI:401*.

2.4.18.1 Novakite (Cu,Ag)₂As₁₀

Named in 1961 for Jiri Novak (1902-1971), Czech mineralogist. MON Space group uncertain, probably *C2/m*. $a = 16.269$, $b = 11.711$, $c = 10.007$, $\beta = 112.7^\circ$, $Z = 4$, $D = 8.01$. *39-370*: 3.15₆ 2.52₇ 2.38₅ 2.00₉ 1.96₈ 1.91₇ 1.88₁₀ 1.18₈. Granular aggregates or veinlets. Steel-gray, tarnishing to black, black streak, metallic luster. $H = 3-3\frac{1}{2}$. $R = 50.6-55.6$ (540 nm);

anisotropic, blue-gray to light brown. *Černý Dul mine, near Berghaus, Czech Republic*, in calcite veins. *BM AM 46:885(1961)*, *TMPM 34:167(1985)*, *P&J:279*, *ABI:356*.

2.5.1.1 Umangite Cu_3Se_2

Named in 1891 for the locality. *TET* $P\bar{4}_2m$. $a = 6.406$, $c = 4.282$, $Z = 2$, $D = 6.59$. *19-402(syn)*: 3.55_{10} 3.20_5 3.11_6 2.26_5 2.03_4 1.91_4 1.83_8 1.78_6 . Small grains. Blue-black with reddish cast, tarnishing to iridescent purple, black streak, metallic luster. Poor rectangular cleavage, uneven fracture, brittle. $H = 3$, $\text{VHN}_{100} = 88-100$. $G = 6.44-6.49$. $R = 13.6-16.5$ (540 nm); strongly pleochroic and anisotropic. Occurs with other selenides in hydrothermal veins. From Lodge Bay, Lake Athabaska to Ato Bay, Beaverlodge Lake, SK, Canada; Skrikerum, Sweden; Andreasberg, Tilkeroede, Zorge, and other localities in Harz, Germany; Chameau mine, Puy-de-Dome, France; Habri, near Tisnov, Moravia, Czech Republic; Kalgoorlie, WA, Australia; Tsumeb, Namibia; *Sierra de Umango* and *Sierra de Cachueta, La Rioja, Argentina*. *BM DI:194*, *AM 35:354(1950)*, *R:469*, *P&J:379*, *ABI:549*.

2.5.2.1 Bornite Cu_5FeS_4

Known as a mineral since 1725. Named in 1845 for Ignaz von Born (1742-1791), Austrian mineralogist. *ORTH* (pseudo-*TET*) $Pbca$. $a = 10.950$, $b = 21.862$, $c = 10.950$, $Z = 16$, $D = 5.09$; above 228° *ISO* $Fm\bar{3}m$, $a = 5.50$, $Z = 2$. *CM 16:397(1978)*. *14-323*: 3.31_4 3.18_6 2.74_5 2.50_4 1.94_{10} 1.65_3 1.26_5 1.12_5 . *Habit*: Crystals rare, pseudocubic, dodecahedral, rarely octahedral; usually massive. *Twin plane* $\{111\}$; often as penetration twins. *Structure*: Based on

BORNITE: Cu_5FeS_4

Copper and iron are 4-coordinated by S and S is 4-coordinated by Fe and S. The Cu and Fe tetrahedra share edges, with the metals only 2.75 Å apart.

cubic close-packed sulfur framework with Cu atoms in a complex arrangement in triangular and tetrahedral coordination. **Physical properties:** Copper-red to brown on fresh surfaces, tarnishes rapidly to iridescent purple (peacock ore), gray-black streak, metallic luster. Cleavage {111} in traces, conchoidal or uneven fracture brittle. $H = 3$, $VHN_{100} = 92$. $G = 5.06-5.09$. $R = 21.1$ (540 nm); weakly pleochroic and anisotropic. **Tests:** Easily fusible to a brittle magnetic globule. Soluble in HNO_3 with the separation of sulfur. **Occurrence:** A common and widespread mineral present in many important copper deposits throughout the world. Also occurs in dikes, in basic intrusives, in contact-metamorphic deposits, in pegmatites, and in quartz veins. **Localities:** Bristol(*), CT; Butte(*), MT; many mines in AZ, including Bisbee, Globe, Ajo, Magma; many localities in CA; Kennecott, AK; Marble Bay mine, Texada Is., BC, Canada; Carn Brea(*) and other mines near Redruth, Cornwall, England; Freiberg and other localities in Saxony, Germany; near Praggratten, Austria; Talnakh, Norilsk, Russia; Dzhezkazgan(*), Kazakhstan; N'ouva mine, Talate, Morocco; Kipushi(*) and Kambove(*), Zaire; Mangula mine(*), Zimbabwe; Ookiep, Cape Prov., and Messina, Transvaal, South Africa; Mt. Lyell, TAS, Australia; Morococha, Peru; Braden mine, Chile. **Uses:** An important ore of copper. *BM DI:195, AM 63:1(1978), R:487, P&J:98, ABI:62.*

2.5.3.1 Heazlewoodite Ni_3S_2

Named in 1896 for the locality. **HEX-R** $R32$. $a = 5.741$, $c = 7.139$, $Z = 3$, $D = 5.87$. $8-126$: 4.11_5 2.89_9 2.38_4 2.03_5 1.83_{10} 1.66_8 1.29_2 1.08_3 . Massive, fine-grained; rarely in minute crystals. Pale bronze, light bronze streak, metallic luster. $H = 4$, $VHN_{100} = 230-254$. $G = 5.82$. $R = 57.0$ (540 nm); strongly anisotropic, brown to blue-gray. Widely distributed as an accessory mineral in serpentinite. Cedar Hill quarry, Lancaster Co., PA; Josephine Co., OR; White Creek, Fresno Co., and Dorleska mine (minute crystals), Trinity Co., CA; Jeffrey mine, Asbestos, PQ, and Miles Ridge, YT, Canada; Poschiavo, Grisons, Switzerland; Cap Corse, Corsica, France; Hirt, near Friesach, Carinthia, Austria; Kop Krom mine, near Askale, Turkey; Talnakh, Norilsk, Russia; near Rabad Sefid, Iran; *Heazlewood* and *Trial Harbour*, *TAS, Australia*; *Barberton*, Transvaal, South Africa. *BM AM 32:484(1947), 62:341(1977); R:405, P&J:196; ABI:210.*

2.5.4.1 Oregonite Ni_2FeAs_2

Named in 1959 for the state of Oregon. **HEX** Space group unknown. $a = 6.083$, $c = 7.130$, $Z = 3$, $D = 6.92$. $13-368$: 3.57_4 2.95_4 2.31_{10} 2.12_{10} 1.99_7 1.79_7 1.76_7 1.74_7 . Fine-grained pebbles with smooth brown crust. White, metallic luster. $H = 5$. $R = 48.0$ (540 nm); weakly anisotropic. *Josephine Creek, Josephine Co., OR*; *Alexo mine*, near *Timmins*, ON, Canada; near *Skouriotissa*, Cyprus, in serpentinite. *BM NJMM:239(1959), AM 45:1130(1960), R:400, P&J:282, ABI:364.*

2.5.5.1 Thalcusite $Tl_2Cu_3FeS_4$

Named in 1976 for the composition. TET $I4/mmm$. $a = 3.882$, $c = 13.25$, $Z = 1$, $D = 6.51$. 29-580(syn): 3.73₆ 3.31₄ 2.92₁₀ 2.54₉ 2.19₄ 1.72₈ 1.61₆ 1.07₅. Microscopic grains. Gray, metallic luster. $H = 2\frac{1}{2}$, $VHN_{10} = 88$. $G = 6.15$. $R = 28.4-29.9$ (540 nm); moderately anisotropic, light yellow to very dark gray. Mont Saint-Hilaire, PQ, Canada; Ilimaussaq intrusion, near Narsaq, Greenland; Talnakh, Norilsk, Russia; Rajpura-Dariba, Rajasthan, India. BM ZVMO 105:202(1976), AM 62:396(1977), ABI:528.

2.5.5.2 Bukovite $Tl_2Cu_3FeSe_4$

Named in 1971 for the locality. TET $I4/mmm$. $a = 3.976$, $c = 13.70$, $Z = 1$, $D = 7.45$. 25-312: 3.43₅ 3.00₁₀ 2.60₉ 2.26₇ 1.99₇ 1.77₈ 1.71₅ 1.66₆. Microscopic crystals and massive. Gray-brown, metallic luster. Cleavage {001}, good; {100}, imperfect. $H = 2$, $VHN_{20} = 64$. $R = 27.7-29.4$ (540 nm); weakly pleochroic. Occurs in calcite veins with other selenides at Bukov, Petrovice, and Predborice, Czech Republic. BM BM 94:529(1971), AM 57:1910(1972), NJMA 138:122(1980), P&J:109.

2.5.5.3 Murunskite $K_2Cu_3FeS_4$

Named in 1981 for the locality. TET $I4/mmm$. $a = 3.88$, $c = 13.10$, $Z = 1$, $D = 3.81$. 33-1005: 6.52₁₀ 3.29₂ 2.90₆ 2.53₈ 2.31₁ 2.10₃ 1.94₅ 1.72₄. Microscopic grains. Copper-red to brown, iridescent tarnish, oxidizes rapidly to give a black sooty coating, metallic luster. Imperfect cleavage, brittle. $H = 3$, $VHN = 109$. $R = 18.9$ (540 nm); moderately anisotropic. Khibeny massif, Kola, and Murun alkaline massif, Yakutia, Russia. BM ZVMO 110:468(1981), AM 67:624(1982), ABI:342.

2.5.6.1 Argyrodite Ag_8GeS_6

Named in 1886 for the Greek for silver-containing. Forms a series with canfieldite (2.5.6.2). ORTH $Pna2_1$. $a = 15.149$, $b = 7.476$, $c = 10.589$, $Z = 4$, $D = 6.25$; above 223°: ISO $Im3m$, $a = 21.11$, $Z = 32$, $D = 6.49$. 14-356: 3.14₃ 3.02₁₀ 2.66₄ 2.44₃ 2.03₃ 1.86₅ 1.78₂ 1.17₂. Pseudocubic crystals up to 18 cm, also as radiating aggregates and botryoidal crusts. Steel-gray, gray-black streak, metallic luster. No cleavage, crystals twinned on the spinel law {111}, conchoidal or uneven fracture, brittle. $H = 2\frac{1}{2}$. $G = 6.1-6.3$. $R = 25.0$ (540 nm); weakly anisotropic. Rico, Dolores Co., CO; Vipont mine, Box Elder Co., UT; Dolly Varden mine, Alice Arm, BC, Canada; Silvermines, Co. Tipperary, Eire; Himmelfürst and other mines, Freiberg, Saxony, Germany; Fournial mine, Cantal, France; Wolyu mine, Youngdong district, South Korea; Aullagas, Colquechaca(*), Potosi(*), Porco, and other localities, Bolivia. BM DI:356, NJMM:269(1978), R:479, P&J:75, ABI:23.

2.5.6.2 Canfieldite Ag_8SnS_6

Named in 1894 for Frederick A. Canfield (1849–1926), U.S. mining engineer and mineral collector. May contain up to 20% Te, 4% Se, and 2% Ge. Forms a series with argyrodite (2.5.6.1). ORTH $Pna2_1$. $a = 15.298$, $b = 7.548$, $c = 10.699$, $Z = 4$, $D = 6.31$; above 175° ISO $Im3m$. $a = 21.54$, $Z = 32$, $D = 6.24$. $38\text{--}434(\text{syn})$: 3.25_5 3.23_3 3.11_5 3.08_{10} 3.02_3 2.73_5 2.51_2 2.07_2 . Pseudocubic crystals up to 1 cm, also botryoidal, massive. Steel-gray with a reddish tinge, tarnishing to black, gray-black streak, metallic luster. No cleavage, crystals twinned on the spinel law $\{111\}$, conchoidal or uneven fracture, brittle. $H = 2\frac{1}{2}$, $\text{VHN}_{50} = 109$. $G = 6.2\text{--}6.3$. $R = 25.1$ (540 nm). Leadville, Lake Co., CO; Bisbee, AZ; Himmelsfürst mine, Freiberg, Saxony, Germany; Příbram and Kutna Hora, Czech Republic; Belukhinsk deposit, Transbaikalia, Russia; Ikuno, Omidani, and Ashio mines, Japan; Cirtan, Java; Aullagas(*), near Colquechaca, Bolivia. BM *DI*:356, *NJMM*: 269(1978), *R*:479, *P&J*:75, *ABI*:79.

2.5.7.1 Daomanite CuPtAsS_2

Named in 1974 for the locality. ORTH $Ama2$. $a = 5.875$, $b = 15.79$, $c = 3.761$, $Z = 4$, $D = 7.57$. $42\text{--}1327$: 8.0_8 4.71_5 3.25_7 3.06_{10} 2.91_5 2.10_8 1.87_5 1.83_8 . Microscopic tabular crystals. Steel-gray with a yellow tint, metallic luster. Cleavages $\{100\}$, $\{001\}$, $\{010\}$, $\{110\}$, from most to least perfect. $H = 3\frac{1}{2}$, $\text{VHN}_{15} = 169\text{--}175$. $R = 37\text{--}43$ (544 nm); strongly pleochroic and anisotropic. Dao and Ma districts, Yanshan, China. BM *AM* 61:184(1976), 65:408(1980); *ABI*:128.

2.5.8.1 Imiterite Ag_2HgS_2

Named in 1985 for the locality. MON $P2_1/c$. $a = 4.039$, $b = 8.005$, $c = 6.580$, $\beta = 107.12^\circ$, $Z = 2$, $D = 7.85$. $39\text{--}328$: 4.88_3 3.47_5 3.14_3 2.92_3 2.77_{10} 2.75_{10} 2.46_8 1.47_4 . Anhedral grains up to 1 mm. Gray, metallic luster. $H = 2\frac{1}{2}$, $\text{VHN}_{100} = 86$. $R = 29.5\text{--}32.1$ (540 nm); strongly anisotropic, blue to red-brown. Golden Rule mine, Tuolumne Co., CA; Imiter mine, Jbel Sarhro, Anti-Atlas, Morocco. BM *BM* 108:457(1985), *AM* 71:1277(1986), *ABI*:230, *MR* 21:500(1990).

2.5.9.1 Chvilevaite $\text{Na}(\text{Cu,Fe,Zn})_2\text{S}_2$

Named in 1988 for T. N. Chvileva (b.1925), Russian mineralogist. HEX-R $P3m1$. $a = 3.873$, $c = 6.848$, $Z = 1$, $D = 3.94$. $42\text{--}1366$: 6.85_6 3.40_9 3.02_{10} 2.40_{10} 1.87_9 1.48_5 1.19_5 . Microscopic grains. Bronze, tarnishing rapidly to a sooty black coating, metallic luster. Cleavage $\{001\}$, perfect; brittle. $H = 3$, $\text{VHN}_{20} = 110\text{--}153$. $R = 17.5\text{--}21.6$ (540 nm); strongly pleochroic and anisotropic. Occurs in sphalerite at the Akatuya deposit, Transbaikalia, Russia. BM *ZVMO* 117:204(1988), *AM* 74:946(1988), *ABI*:99.

2.6.1.1 Dimorphite As_4S_3

Named in 1850 from the Greek for two forms, I and II. I: ORTH $Pnma$; $a = 9.07$, $b = 8.01$, $c = 10.30$, $Z = 4$, $D = 3.51$; II: ORTH $Pnma$; $a = 11.24$, $b = 9.90$, $c = 6.56$, $Z = 4$, $D = 3.60$. $26-125$: 6.27_5 5.16_{10} 4.16_4 3.87_3 3.13_3 3.12_6 2.96_5 2.91_3 (I). $26-126$: 5.64_3 4.89_{10} 3.91_4 3.07_3 2.94_3 2.84_3 2.14_5 1.62_5 (II). Dipyramidal crystals. Orange-yellow, yellow streak, adamantine luster. $H = 1\frac{1}{2}$. $G = 2.58$. *Solfatarra, Italy*, in a fumarole; Alacran sulfide deposit, Copiapo, Chile. BM *DI:197*, *NJMM:423(1972)*, *ZK 138:161(1973)*, *R:890*, *ABI:135*.

JOSÉITE GROUP

The Joséite group of structures are bismuth minerals corresponding to the formula

where

Bi may be partially replaced by Pb

$X = S, Se, Te$

$m + p = 7$

The structures are all similar rhombohedral lattices, $R\bar{3}m$, and they are similar to the arsenic group, but with a $4c$ -axis repeat. *AM 76:257(1991)*.

JOSÉITE GROUP

Mineral	Formula	Space Group	a	c	D	
Joséite	Bi_4TeS_2	$R\bar{3}m$	4.24	39.69	8.23	2.6.2.1
Joséite-B	Bi_4Te_2S	$R\bar{3}m$	4.34	40.83	8.44	2.6.2.2
Ikunolite	Bi_4S_3	$R\bar{3}m$	4.15	39.19	7.97	2.6.2.3
Laitakarite	Bi_4Se_2S	$R\bar{3}m$	4.225	39.93	8.28	2.6.2.4
Pilsenite	Bi_4Te_3	$R\bar{3}m$	4.451	41.888	8.45	2.6.2.5
Poubaite	$Bi_2PbSe_2Te_2$	$R\bar{3}m$	4.252	40.10	7.88	2.6.2.6
Rucklidgeite	$(Bi,Pb)_3Te_4$	$R\bar{3}m$	4.422	41.49	8.06	2.6.2.7

Notes:

1. Related minerals sharing the composition and the threefold-inversion axis are: protojoseite (2.6.3.1), kochkarite (2.6.3.2), aleksite (2.6.3.3), and hedleyite (2.6.3.4).
2. See also the tsumoite group for bismuth minerals with formula BiX .

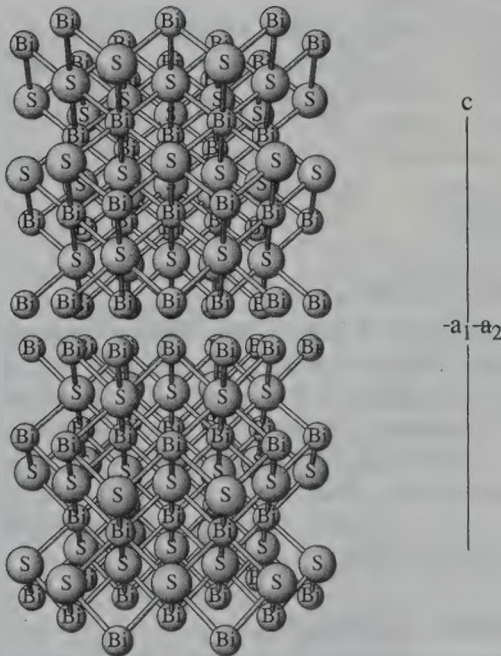

2.6.2.1 Joséite Bi_4TeS_2

Named in 1853 for the locality. Joséite group. Three varieties are recognized (A,B,C), differing in Te:S ratio; Joséite-C is questionable. HEX-R $R\bar{3}m$. $a = 4.24$, $c = 39.69$, $Z = 3$, $D = 8.23$. $12-735$: 4.4_2 3.62_2 3.08_{10} 2.24_5 2.11_5 1.75_3 1.54_3 1.54_3 . Platy crystals. Silver-white, tarnishing to lead-gray, gray streak, metallic lus-

ter. Cleavage {0001}, perfect; flexible. $H = 2$, $VHN_{25} = 29-43$. $G = 8.1-8.3$. $R = 56.2-60.0$ (540 nm); moderately anisotropic. Glacier Gulch, near Smithers, and Good Hope claim, near Hedley, BC, Canada; Carrock Fell and Coniston, Cumbria, England; Serrania de Rondo, Spain; Smolotely, Czech Republic; Bihot Mts., Romania; Stepnyak gold deposit, Kazakhstan; Koshbulak, Uzbekistan; Sosukchan deposit, Yakutia, Russia; Tsumo mine, Akita Pref., Japan; Kingsgate, NSW, Australia; *San José, MG, Brazil*. *BM DI:166; AM 34:342(1949); 56:1839(1971); R:439; P&J:367; ABI:252*.

2.6.2.2 Joséite-B Bi_4Te_2S

Named in 1949 for its relationship to jositite. Joséite group. $HEX-R R\bar{3}m$. $a = 4.34$, $c = 40.83$, $Z = 3$, $D = 8.44$. $9-435$: 4.53_2 3.16_{10} 2.30_4 2.17_5 1.95_2 1.78_3 1.57_2 1.38_2 . Platy crystals. Silver-white, tarnishing to lead-gray, gray streak, metallic luster. Cleavage {0001}, perfect; flexible; inelastic. $H = 2$, $VHN_{25} = 46$. $G = 8.3$. $R = 51.0-53.7$ (546 nm); distinctly anisotropic. *Glacier Gulch, near Smithers*, and Good Hope claim, near Hedley, BC, Canada; Tuna-berg, Sweden; Smolotely, near Příbram, Czech Republic; Stepnyak deposit, Kazakhstan; Sosukchan deposit, NE Yakutia, Russia; Tsumo mine, Akita Pref., Japan; *San José, MG, Brazil*. *BM AM 34:367(1949), 76:257(1991); EM 5:165(1993)*.

IKUNOLITE: Bi_4S_3 (jositite group)

Multiple-layer sandwich structure with the sequence Bi-S-Bi-S-Bi-S-Bi. Sulfurs are in hexagonal closest-packed arrangement.

2.6.2.3 Ikonolite Bi_4S_3

Named in 1959 for the locality. Joseite group. HEX-R $R\bar{3}m$. $a = 4.15$, $c = 39.19$, $Z = 3$, $D = 7.97$. $12\text{-}730$: 6.56_2 4.34_5 3.54_2 3.02_{10} 2.21_3 2.08_2 1.87_2 1.51_1 . Foliated massive, plates to 3 cm. Lead-gray, dark gray streak, metallic luster. Cleavage $\{0001\}$, perfect; flexible. $H = 2$, $\text{VHN}_{100} = 45$. $G = 7.8$. $R = 45.0\text{--}48.9$ (540 nm); moderately anisotropic. *Ikuno mine, Hyogo Pref., Japan*; Kingsgate, NSW, Australia. BM *MJJ* 2:397(1959); *AM* 45:477(1960), 47:1431(1962); *P&J*:207; *ABI*:228.

2.6.2.4 Laitakarite $\text{Bi}_4\text{Se}_2\text{S}$

Named in 1959 for Arne Laitakari (1890–1975), director of the Geological Survey of Finland. Joseite group. HEX-R $R\bar{3}m$. $a = 4.225$, $c = 39.93$, $Z = 3$, $D = 8.28$. $14\text{-}220$: 4.43_6 3.59_6 3.07_{10} 2.25_8 2.11_8 1.74_7 1.54_6 1.41_6 . Foliated plates and sheets. Gray-white, metallic luster. Cleavage $\{0001\}$, perfect; flexible; inelastic. $H = 2\text{--}2\frac{1}{2}$, $\text{VHN}_{100} = 54\text{--}78$. $G = 8.12$. $R = 45.0\text{--}53.0$ (540 nm); moderately anisotropic. Kidd Creek mine, near Timmins, ON, Canada; Falun mine, Sweden; *Orijarvi mine, Finland*; La Creusaz, Valais, Switzerland; Nevskoe, Magadan region, Russia; Akenobe mine, Hyogo Pref., Honshu, Japan. BM *AM* 44:308(1959), 47:806(1962); *P&J*:232; *ABI*:283.

2.6.2.5 Pilsenite Bi_4Te_3

Named in 1853 for the locality. Joseite group. Synonym: wehrlite. HEX-R $R\bar{3}m$. $a = 4.451$, $c = 41.888$, $Z = 3$, $D = 8.45$. $33\text{-}216$ (syn): 4.65_1 3.24_{10} 2.36_4 2.23_3 1.83_2 1.49_1 1.42_1 1.31_1 . Foliated masses. Tin-white to steel-gray, metallic luster. Cleavage $\{0001\}$, perfect. $H = 2$, $\text{VHN}_{25} = 53$. $G = 8.4\text{--}8.6$. Sylvanite, Hidalgo Co., NM; Sudbury, ON, Canada; *Deutsch-Pilsen (Borzonny), Hungary*; Koronuda Au-Cu deposit, Macedonia, Greece. BM *DI*:167, *R*:438, *AM* 69:215(1984), *ABI*:405.

2.6.2.6 Poubaitte $\text{Bi}_2\text{PbSe}_2\text{Te}_2$

Named in 1978 for Zdenek Pouba (1902–1971), Czech economic geologist. Joseite group. HEX-R $R\bar{3}m$. $a = 4.252$, $c = 40.10$, $Z = 3$, $D = 7.88$. $29\text{-}762$: 3.63_4 3.09_8 2.25_5 2.13_6 2.02_{10} 1.83_4 1.75_5 1.35_5 . Microscopic euhedral to subhedral lathlike crystals. Silver-white to lead-gray, metallic luster. Cleavage $\{0001\}$, perfect. $H = 2\frac{1}{2}$, $\text{VHN}_{25} = 74\text{--}122$. $R = 48.5\text{--}53.3$ (540 nm); strongly anisotropic. Otish Mts. uranium deposit, PQ, Canada; *Oldrichov, near Tachov, Czech Republic*. BM *NJMM*:9(1978), *AM* 63:1283(1978), *CM* 25:625(1987), *ABI*:421.

2.6.2.7 Rucklidgeite $(\text{Bi,Pb})_3\text{Te}_4$

Named in 1977 for John C. Rucklidge (b.1938), Canadian mineralogist. Joseite group. Contains up to 3% Sb and 2% Ag. HEX-R $R\bar{3}m$. $a = 4.422$, $c = 41.49$, $Z = 3$, $D = 8.06$. $29\text{-}234$: 3.22_{10} 2.34_9 2.21_4 1.98_5 1.82_4 1.61_4 1.47_6 1.38_4 . Foliated aggregates and microscopic grains. Silver-white, lead-gray streak,

metallic luster. Perfect basal cleavage, brittle. $H = 2$, $VHN_{10} = 52-63$. $G = 7.74$. $R = 62.1-65.3$ (540 nm); distinctly anisotropic. Hesperus mine, La Plata Co., CO; Campbell mine, Bisbee, AZ; *Robb-Montbray mine*, *Montbray Twp., PQ*, and Ashley deposit, Bannockburn Twp., ON, *Canada*; Ilomantsi, Finland; Oldrichov, near Tachov, Czech Republic; Zod, Armenia; Kochkar Au deposits, Ural Mts., Russia; Yanahara mine, Okayama Pref., Japan; Kam-balda, WA, Australia. *BM ZVMO 106:62(1977), AM 63:599(1978), ABI:450, CM 31:99(1993)*.

2.6.3.1 Kochkarite Bi_4PbTe_7

Named in 1989 for the locality. $HEX-R P\bar{3}m1$. $a = 4.416$, $c = 79.20$, $Z = 3$, $D = 7.89$. $44-1439$: 3.23_{10} 2.36_6 2.21_2 2.01_3 1.98_2 1.82_2 1.61_1 1.48_2 . Tabular crystals. Silver-gray, lead-gray streak, metallic luster. Perfect basal cleavage; fragments flexible, inelastic. $H = 2-2\frac{1}{2}$, $VHN_{15} = 28-80$. $G = 7.94$. $R = 59.0-63.2$ (540 nm); strongly anisotropic. *Kochkar deposit, southern Ural Mts., Russia*. *BM GRM 31:98(1989), AM 76:1434(1991)*.

2.6.3.2 Aleksite $Bi_2PbTe_2S_2$

Named in 1978 for the locality. $HEX-R P\bar{3}m1$. $a = 4.238$, $c = 79.76$, $Z = 6$, $D = 7.59$. $29-765$: 3.63_3 3.09_{10} 2.25_4 2.12_6 1.97_3 1.35_4 1.31_4 1.21_3 . Platy grains to 1 mm. Pale gray, metallic luster. Cleavage {0001}, perfect. $H = 2$. $VHN_{20} = 40-65$. $R = 53.2$ (540 nm); weakly anisotropic. Near Tybo, Nye Co., NV; Barringer mine, Timmins, ON, *Canada*; St. David's mine, near Dolgellau, Wales; *Alekseev mine, Sutemskii region, Stanovoi Mts., Russia*. *BM ZVMO 107:315(1978), AM 64:652(1979), ABI:7*.

2.6.3.3 Hedleyite Bi_7Te_3

Named in 1945 for the locality. $HEX-R R\bar{3}m$. $a = 4.47$, $c = 119.0$, $Z = 6$, $D = 8.93$. $12-719$: 3.25_{10} 2.37_5 2.24_4 1.99_3 1.85_3 1.63_4 1.48_4 1.42_3 . Platy masses. Tin-white, tarnishing iron-black, gray streak, metallic luster. Cleavage {0001}, perfect; flexible lamellae. $H = 2$, $VHN_{25} = 31-42$. $G = 8.91$. $R = 66.2-66.7$ (540 nm); weakly anisotropic. *Good Hope claim and Oregon mine, near Hedley, BC*, and Burwash Creek placer, Kluane Lake district, YT, *Canada*; Vaddas-Rieppe area, Norway; Kumbel skarn deposit, Kyrgyzstan; Ugat, Uzbekistan; Vostok-2, Maritime Territory, Russia. *BM AM 30:644(1945), 34:364(1949); R:438; P&J:365; ABI:211*.

2.6.4.1 Genkinite $(Pt,Pd)_4Sb_3$

Named in 1977 for Alexandr D. Genkin (b.1919), Russian mineralogist. $TET P4_12_12$. $a = 7.736$, $c = 24.161$, $Z = 8$, $D = 9.26$. $29-133$: 3.47_3 3.02_9 2.27_{10} 2.15_4 2.12_4 1.93_6 1.91_5 1.27_4 . Microscopic grains. Pale brown, metallic luster. $H = 5\frac{1}{2}$, $VHN_{25} = 578-612$. $R = 50.8-51.1$ (540 nm); moderately to strongly anisotropic. Fox Gulch, Goodnews Bay, AK; Unst and Fetlar, Shetland Is., Scotland; Birbir R., Ethiopia; *Onverwacht mine* and Driekop mine, *Transvaal, South Africa*. *BM CM 15:389(1977), 26:979(1988); AM 64:654(1979); P&J:404*.

2.6.5.1 Temagamite Pd_3HgTe_3

Named in 1973 for the locality. ORTH Space group unknown. $a = 11.608$, $b = 12.186$, $c = 6.793$, $Z = 6$, $D = 9.36$. 26-881(syn): 2.91₁₀ 2.64₄ 2.19₉ 2.09₄ 1.96₇ 1.66₅ 1.62₅ 1.46₅. Microscopic grains. White, metallic luster. $H = 2\frac{1}{2}$, $\text{VHN}_{25} = 92$. $G = 9.5$. $R = 52.9\text{--}53.9$ (546 nm); weakly anisotropic. Stillwater Complex, MT; New Rambler mine, Albany Co., MT; *Temagami Cu deposit, Temagami I., ON, Canada*; Merensky Reef, Transvaal, South Africa. BM CM 12:193(1973), AM 60:947(1975), R:440, ABI:520.

2.6.6.1 Donharrisite $\text{Ni}_8\text{Hg}_3\text{S}_9$

Named in 1989 for Donald C. Harris (b.1936), Canadian mineralogist. MON C2/m. $a = 11.66$, $b = 6.91$, $c = 10.92$, $\beta = 97.43^\circ$, $Z = 2$, $D = 5.18$. CM 27: 5.75₇ 5.09₇ 3.71₅ 3.33₆ 2.68₆ 2.61₃ 2.55₁₀ 2.22₃. Microscopic micalike flakes. Brown, gray-brown streak, metallic luster. Cleavage {001}, perfect; conchoidal fracture; brittle. $H = 2$, $\text{VHN}_5 = 47$. $R = 44.2\text{--}47.1$ (540 nm); distinctly anisotropic. *Erasmus mine, Leogang, Salzburg Prov., Austria*. BM CM 27:257(1989).

PENTLANDITE GROUP

The pentlandite group consists of isostructural sulfides and selenides corresponding to

where

A = Ag, Cd, Mn, Fe, Ni, Co, Pb

B = Fe, Ni, Co, Cu

X = S, Se

The structures are all cubic, $Fm\bar{3}m$, based on a cubic close packing of sulfur atoms with iron or nickel in a tetrahedral coordination forming a highly condensed B_8S_{14} group.

PENTLANDITE GROUP

Mineral	Formula	Space Group	D		
			a		
Pentlandite	$(\text{Fe},\text{Ni})_9\text{S}_8$	$Fm\bar{3}m$	10.042	5.08	2.7.1.1
Argentopentlandite	$\text{Ag}(\text{Fe},\text{Ni})_8\text{S}_8$	$Fm\bar{3}m$	10.50	5.05	2.7.1.2
Cobalt pentlandite	Co_9S_8	$Fm\bar{3}m$	9.973	5.22	2.7.1.3
Shadlunite	$(\text{Pb},\text{Cd})(\text{Fe},\text{Cu})_8\text{S}_8$	$Fm\bar{3}m$	10.91	4.72	2.7.1.4
Manganese-shadlunite	$(\text{Mn},\text{Pb})(\text{Cu},\text{Fe})_8\text{S}_8$	$Fm\bar{3}m$	10.73	4.56	2.7.1.5
Geffroyite	$(\text{Cu},\text{Fe},\text{Ag})_9(\text{Se},\text{S})_8$	$Fm\bar{3}m$	10.889	5.39	2.7.1.6

PENTLANDITE: $(\text{Ni}, \text{Fe})_9\text{S}_8$

One type of Ni atom is in octahedral coordination and the other is tetrahedral. The tetrahedral Ni atoms share three edges with other tetrahedra and there is probably Ni–Ni bonding. S atoms are 4r- and 5-coordinated.

Notes:

1. Compare also with the chalcocite structures based on a hexagonal close packing of sulfur atoms.
2. Compare with the sphalerite structures based on an arrangement of cubic close-packed sulfur atoms.
3. Godlevskite (2.7.4.1) and kharaelakhite (2.7.5.1) fulfill the chemical formula, but they are reported in lower-symmetry orthorhombic space groups.

2.7.1.1 Pentlandite $(\text{Fe}, \text{Ni})_9\text{S}_8$

Named in 1856 for Joseph B. Pentland (1797–1873), Irish scientist, who first noted the mineral. Pentlandite group. iso $Fm\bar{3}m$. $a = 10.042$, $Z = 4$, $D = 5.08$. $30-657$: 5.79_3 3.03_{10} 2.90_3 1.93_3 1.77_{10} 1.31_1 1.25_1 1.02_2 . **Habit:** Massive, typically in granular aggregates; large grains show well-developed $\{111\}$ parting planes. **Structure:** Based on cubic close-packed S atoms, with (Fe,Ni) in tetrahedral coordination forming highly condensed B_8S_{14} groups joined at corners about an octahedrally coordinated (Fe,Ni) atom. **Physical properties:** Bronze-yellow, bronze-brown streak, metallic luster. No cleavage, conchoidal fracture. $H = 3\frac{1}{2}-4$, $VHN_{100} = 210$. $G = 4.9-5.2$. $R = 49.2$ (540 nm). Nonmagnetic. **Tests:** Insoluble in 1:1 HCl. Fuses readily to a steel-gray bead. **Chemistry:** Most analyses show Fe/Ni ratio near 1:1, but Fe ranges from 25 to 43%, and Ni from 19 to 34%; Co may be present, up to 11%. **Occurrence:** Pentlandite occurs in basic igneous rocks along with iron and nickel sulfides and arsenides. It is nearly always intimately associated with pyrrhotite. It is an accessory in some stony meteorites. **Localities:** The most abundant nickel mineral, pentlandite is widely distributed throughout the world. Lick Fork, Floyd Co., VA;

Stillwater, MT; Sudbury, ON, and Thompson, MB, Canada; *Espedalen, near Lillehammer, Norway*; Outokumpu, Finland; Pechenga, Kola, and Norilsk, Russia; Kambalda, Agnew, Spargoville, and Windaira, WA, Australia; Rustenburg, Transvaal, South Africa. Uses: The principal ore of nickel. *BM DI:242, CM 12:169(1973), MM 41:345(1977), R:497, P&J:293, ABI:396.*

2.7.1.2 Argentopentlandite $\text{Ag}(\text{Fe,Ni})_5\text{S}_8$

Named in 1977 for the relationship to pentlandite. Pentlandite group. iso *Fm*3*m*. $a = 10.50$, $Z = 4$, $D = 5.05$. *25-406*: 6.06₂ 5.25₂ 3.71₂ 3.17₁₀ 3.02₂ 2.02₄ 1.86₁₀ 1.07₃. Octahedral crystals and massive. Bronze-brown, metallic luster. Cleavage {111}, good. $H = 3-3\frac{1}{2}$, $\text{VHN}_{50} = 132-154$. $R = 28.8$ (540 nm). Silver City, Ontonagon Co., MI; Agassiz Au deposit, Lynn Lake, MB, Canada; Talnotry mine, Dumfries, Scotland; Vuonos, Miihkali, Hietajärvi, and Outokumpu deposits, Finland; Bottino, Tuscany, Italy; *Oktyabr mine, Norilsk, Russia*; Windaira, WA, Australia. *BM AM 57:137(1972), ZVMO 106:688(1977), ABI:20.*

2.7.1.3 Cobalt Pentlandite Co_9S_8

Named in 1959 for the composition and relationship to pentlandite. Pentlandite group. Contains some Fe and Ni replacing Co. iso *Fm*3*m*. $a = 9.973$, $Z = 4$, $D = 5.22$. *12-723*: 5.75₆ 3.01₁₀ 2.88₆ 2.29₅ 1.92₈ 1.76₁₀ 1.30₅ 1.02₆. Microscopic crystals and exsolved lamellae. Yellow-brown, metallic luster. Cubic cleavage. $H = 4-4\frac{1}{2}$, $\text{VHN}_{100} = 278-332$. $R = 57.0$ (540 nm). Vauze mine, Noranda, PQ, and Langis mine, Cobalt, ON, Canada; Erglodd mine, central Wales; *Varislahti deposit* and Savonranta and Outokumpu deposits, Finland; Talmessi mine, near Anarak, Iran; Shimokaua mine, Hokkaido, Japan; Amianthus mine, Barberton, South Africa. *BM AM 44:897(1959), CM 9:597(1969), ABI:104.*

2.7.1.4 Shadlunite $(\text{Pb,Cd})(\text{Fe,Cu})_8\text{S}_8$

Named in 1973 for Tatyana Shadlun (b.1912), Russian mineralogist. Pentlandite group. iso *Fm*3*m*. $a = 10.91$, $Z = 4$, $D = 4.72$. *25-1426*: 5.42₃ 3.84₄ 3.29₁₀ 3.16₂ 2.11₄ 1.93₉ 1.67₂ 1.42₂. Microscopic grains and veinlets. Yellow-gray, metallic luster. Polysynthetic twinning seen in polished section. $H = 3\frac{1}{2}-4$, $\text{VHN}_{20} = 210$. $R = 24.5$ (540 nm). In Cu ore, *Majak mine* and *Oktyabr mine, Norilsk, Russia*. *BM ZVMO 102:63(1973), AM 58:1114(1973), R:592, ABI:472.*

2.7.1.5 Manganese Shadlunite $(\text{Mn,Pb})(\text{Cu,Fe})_8\text{S}_8$

Named in 1973, the Mn analog of shadlunite. Pentlandite group. iso *Fm*3*m*. $a = 10.73$, $Z = 4$, $D = 4.56$. *25-1425*: 3.78₂ 3.23₁₀ 3.08₃ 2.46₂ 2.07₃ 1.89₉ 1.64₂ 1.10₄. Microscopic grains and veinlets. Yellow-gray, metallic luster. Polysynthetic twinning seen in polished section. $H = 3\frac{1}{2}$, $\text{VHN}_{20} = 195$. $R = 29.0$

(540 nm). *Oktyabr deposit, Norilsk, Russia*. BM *ZVMO* 102:63(1973), *AM* 58:1114 (1973), *ABI*:311.

2.7.1.6 Geffroyite $(\text{Cu,Fe,Ag})_9(\text{Se,S})_8$

Named in 1982 for Jacques Geffroy (b.1918), French metallurgist. Pentlandite group. ISO *Fm3m*. $a = 10.889$, $Z = 4$, $D = 5.39$. 35-523: 3.28₉ 3.15₉ 2.44₄ 2.09₆ 1.93₁₀ 1.82₄ 1.66₅ 1.11₆. Microscopic grains. Cream-brown, metallic luster. $H = 4$, $\text{VHN}_{15} = 68-72$. $R = 30.1$ (540 nm). *Chameane, Puy-de-Dôme, France*; San Miguel mine, Moctezuma, SON, Mexico. BM *TMPM* 29:151(1982), *AM* 67:1074(1982), *P&J*:404, *ABI*:176.

2.7.2.1 Mackinawite $(\text{Fe,Ni})\text{S}_{0.9}$

Named in 1962 for the locality. May contain up to 9% Cu and 8% Co. TET *P4/nmm*. $a = 3.676$, $c = 5.032$, $Z = 2$, $D = 4.29$. 15-37: 5.03₁₀ 2.97₈ 2.31₈ 1.84₄ 1.81₈ 1.73₄ 1.24₄ 1.06₆. Microscopic pyramidal crystals or anhedral grains. Bronze-gray, black streak, metallic luster. Cleavage {001}, good; soft. $\text{VHN}_{15} = 63-89$. $R = 21.6-45.3$ (540 nm); strongly pleochroic and anisotropic. Widely distributed in small amounts; formed by hydrothermal activity in ore deposits, during serpentinization of ultrabasic rocks, and in the reducing environment of sediments and sedimentary rocks; an accessory in meteorites and lunar rocks. Howard Montgomery quarry, Howard Co., MD; *Mackinaw mine, Snohomish Co., WA*; Kramer borate deposit, Kern Co., CA; Muskox intrusion, NWT, Canada; Kynance Cliff, Lizard, Cornwall, England; Outokumpu mine, Finland; Talnakh area, Norilsk, Russia; Broken Hill, NSW, and Scotia nickel deposit, WA, Australia; and many other localities. BM *AM* 48:511(1963), *R*:683, *P&J*:247, *ABI*:305.

2.7.3.1 Yarrowite Cu_9S_8

Named in 1980 for the locality. HEX-R Space group uncertain, probably *P3m1*. $a = 3.800$, $c = 67.26$, $Z = 3$, $D = 4.89$. *CM* 18:514: 5.96₂ 5.03₃ 3.68₃ 3.06₆ 2.85₃ 2.77₄ 2.51₂ 1.90₁₀. Black, metallic luster. Cleavage {0001}. $H = 2\frac{1}{2}$, $\text{VHN}_{15} = 93-98$. $R = 10.7-25.6$ (540 nm); pleochroic in blue to blue-white [formerly called "blaubleibender Covellit" (blue-remaining covellite) for this reason]. In red-bed copper deposit at *Yarrow Creek, AB, Canada*; High Rolls district, Otero Co., NM; Cannington Peak, Somerset, England. BM *CM* 18:511(1980), *R*:676, *ABI*:583.

2.7.4.1 Godlevskite Ni_9S_8

Named in 1969 for Mikhail N. Godlevsky (1902-1984), Russian economic geologist. May contain up to 3% Fe. ORTH *C222*. $a = 9.180$, $b = 11.263$, $c = 9.457$, $Z = 4$, $D = 5.273$. 22-1193: 3.28₅ 2.85₁₀ 2.33₄ 2.18₄ 2.10₅ 1.80₉ 1.79₈ 1.65₈. Microscopic grains. Yellow, metallic luster. Complexly twinned. $H = 4\frac{1}{2}-5$, $\text{VHN}_{50} = 383-415$. $R = 50.5-52.2$ (540 nm); strongly anisotropic. Near Moapa, Clark Co., NV; Orford mine, PQ, Texmont mine, south of Timmins, ON, Canada; *Zapolyarnyi mine, Norilsk, Russia*; Mt. Clifford,

near Leonora, WA, Australia; Bou Azzer, Morocco; Amianthus mine, Barberton, South Africa. *BM GRM 11:115(1969)*, *AM 55:317(1970)*, *R:505*, *P&J:182*, *CM 26:283(1988)*.

2.7.5.1 Kharaelakhite (Pt,Cu,Pb)₉S₈

Named in 1985 for the locality. Contains up to 6% Fe and 5% Ni. ORTH *Pmmm*. $a = 9.713$, $b = 8.333$, $c = 14.52$, $Z = 4$, $D = 7.66$. *39-411*: 6.30₂ 3.04₄ 2.80₁₀ 2.67₂ 2.59₂ 1.85₃ 1.81₅ 1.73₃. Thin rims on braggite-cooperite. Gray, metallic luster. $R = 37.1-42.2$ (540 nm); distinctly anisotropic. *Talnakh deposit, Kharaelakh Plateau, Norilsk, Russia*. *BM MZ 7:78(1985)*, *AM 74:1215(1989)*.

GALENA GROUP

The galena group minerals consist of isostructural species having the chemical formula

where

A = Pb, Mn, Ca, Mg

B = S, Se, Te

and the structure is the halite structure, *Fm3m*, a face-centered cubic close-packed association of two different elements.

GALENA GROUP

Mineral	Formula	Space Group	a	D	
Galena	PbS	<i>Fm3m</i>	5.94	7.60	2.8.1.1
Clausthalite	PbSe	<i>Fm3m</i>	6.12	8.28	2.8.1.2
Altaite	PbTe	<i>Fm3m</i>	6.44	8.31	2.8.1.3
Alabandite	MnS	<i>Fm3m</i>	5.22	4.05	2.8.1.4
Oldhamite	CaS	<i>Fm3m</i>	5.69	2.59	2.8.1.5
Niningerite	(Mg,Fe,Mn)S	<i>Fm3m</i>	5.17	2.66	2.8.1.6

Notes:

1. The halite, periclase, and galena groups are all essentially isostructural.
2. Borovskite (2.8.1.7) and crerarite (2.8.1.8) are possible members of this group.
3. See the periclase (4.2.1.1) group for other halite structures, with oxygen in place of S, Se, or Te.

2.8.1.1 Galena PbS

Name is the Latin word for *lead ore* or *dross from melted lead*. Galena group. ISO *Fm3m*. $a = 5.94$, $Z = 4$, $D = 7.60$. *5-592(syn)*: 3.43₈ 2.97₁₀ 2.10₆ 1.79₄ 1.71₂ 1.48₁ 1.33₂ 1.21₁. **Habit**: Cubes and cubo-octahedral crystals; commonly massive, coarse to very fine granular. Twinned on {111}, penetration or contact

twins; on {114}, with lamellae giving diagonal striations on cleavages. **Physical properties:** Lead-gray, lead-gray streak, metallic luster. Cleavage {100}, perfect; parting or cleavage on {111}. $H = 2\frac{1}{2}$, $VHN_{100} = 79-104$. $G = 7.58$. $R = 42.4$ (540 nm). **Tests:** On heating, emits SO_2 fumes and yields a globule of metallic lead. Decomposed by HNO_3 with the formation of $PbSO_4$ and the separation of S. **Chemistry:** Usually pure PbS ; the silver reported in some analyses is usually due to admixed silver minerals. Bi, Ag, Sb, Hg, and Cu have been found in amounts greater than 1 wt%. **Occurrence:** Galena is the commonest lead mineral and occurs in many types of deposits. Extensive deposits of galena (and sphalerite) occur as irregular masses in solution cavities in limestone. Hydrothermal vein deposits of galena frequently contain significant silver values. Some important deposits are of contact or regional metamorphic origin. **Localities:** Some localities for outstanding specimens are: Balmat, St. Lawrence Co., NY; Tri-State mining district, MO-KS-OK; Breckenridge, Creede, and Leadville, CO; Coeur d'Alene, ID; Admiralty Is., AK; Bathurst, NB, Kidd Creek, ON, Kimberley, BC, Pine Point, NWT, Canada; Naica and Santa Eulalia, CHIH, Mexico; Mogul mine, Tipperary, Eire; Alston Moore and Weardale, Cumberland, England; Andreasberg, Neudorf and Clausthal, Harz, and Freiberg, Saxony, Germany; Příbram, Czech Republic; Bottino, Tuscany, Italy; Trepca, Serbia; Madan, Rhodope Mts., Bulgaria; Dalnegorsk, eastern Siberia, Russia; Tsumeb, Namibia; Mt. Isa, Q, and Broken Hill, NSW, Australia; Huanzala mine, Dept. Ancash, Peru. **Uses:** The principal ore of lead. *BM DI:200, R:646, P&J:171, CM 27:363(1989), ABI:170.*

2.8.1.2 Clausthalite $PbSe$

Named in 1832 for the locality. Galena group. iso $Fm\bar{3}m$. $a = 6.12$, $Z = 4$, $D = 8.28$. $6-354(\text{syn}): 3.54_3 3.06_{10} 2.17_7 1.85_2 1.77_2 1.53_1 1.37_3 1.25_2$. Massive, commonly fine granular. Lead-gray, lead-gray streak, metallic luster. Cleavage {100}, good. $H = 2\frac{1}{2}-3$, $VHN_{100} = 44-49$. $G = 8.0-8.2$. $R = 51.3$ (540 nm). Widely distributed in small amounts. Rifle and Garfield mines, Garfield Co., CO; Corvusite mine, Grand Co., UT; Kidd Creek and Hemlo mines, ON, and Goldfields dist., SK, Canada; *Clausthal*, Tilkerode, Lerbach, and Zorge, *Harz, Germany*; Lasovice, Bohemia, Czech Republic; El Sharana, NT, Australia; Pacajake, Colquechaca, Bolivia; Sierra de Umango and Sierra de Cachueta, La Rioja, Argentina. *BM DI:204, AM 44:166(1959), R:659, P&J:123.*

2.8.1.3 Altaite $PbTe$

Named in 1845 for the locality. Galena group. iso $Fm\bar{3}m$. $a = 6.44$, $Z = 4$, $D = 8.31$. $8-28(\text{syn}): 3.23_{10} 2.28_8 1.86_3 1.61_2 1.44_5 1.31_4 1.07_2 1.02_2$. Cubic crystals rare; usually massive, fine-grained. Tin-white with a yellow tinge, tarnishing to bronze-yellow, metallic luster. Cleavage {100}, perfect. $H = 3$, $VHN_{25} = 51$. $G = 8.1-8.3$. $R = 69.7$ (540 nm). Widely distributed, usually in hydrothermal Au deposits. Kings Mt. mine, Gaston Co., NC; Red Cloud mine, Boulder Co., CO; Hilltop mine, Dona Ana Co., NM; Stanislaus mine,

Calaveras Co., CA; Mattagami Lake mine, Mattagami, PQ, Kirkland Lake mines and Sudbury, ON, Canada; Adervielle, Hautes-Pyrenees, France; Sacaramb, Stanija, and Herja, Romania; Merisi Cu deposit, Georgia; *Savodinsky mine, Zyryanovsk, Altai Mts., Kazakhstan*; Nojori mine, Japan; Kalgoorlie and Norseman, WA, Australia; Condorriaco mine, Coquimbo, Chile. BM *DI:205, AM 34:361(1949), R:661, P&J:66, ABI:11.*

2.8.1.4 Alabandite MnS

Named in 1832 for the locality. Galena group. Composition usually near MnS, but may contain up to 22% Fe and 7% Mg. iso *Fm3m*. $a = 5.22$, $Z = 4$, $D = 4.05$. *6-518(syn)*: 3.02_1 2.61_{10} 1.85_6 1.58_1 1.51_2 1.31_1 1.17_2 1.07_2 . Usually massive or granular. Black, tarnishing to brown, green streak, submetallic luster. Cleavage {100}, perfect. $H = 3\frac{1}{2}$ –4, $VHN_{100} = 240$ –251. $G = 4.0$ –4.1. $R = 22.8$ (540 nm). Occurs in low-temperature vein deposits, and as an accessory mineral in some enstatite chondrites. Schellbourne, White Pine Co., MT; Manhattan mine, Park Co., CO; Bisbee, and Lucky Cuss mine(*), Tombstone, AZ; McDame Creek, BC, Canada; Mina La Preciosa, Tlalchichuca, PUE, Mexico; Litosice, Bohemia, Czech Republic; Molinello mine, Liguria, Italy; Sacaramb and other localities, Romania; Ruen, Bulgaria; *Alabanda, Caria, Turkey*; Dastakert deposit, Armenia; Solongo and Norilsk, Russia; Noda-Tamagawa, Kaso, and other Mn mines, Honshu, Japan; Broken Hill(*), NSW, Australia; Uchucchacua mine, Peru. BM *AM 56:1269(1971), R:642, P&J:62, ABI:5.*

2.8.1.5 Oldhamite CaS

Named in 1862 for Thomas Oldham (1816–1878), director of the Geological Survey of India. Galena group. May contain up to 2% Mg and 6% Fe. iso *Fm3m*. $a = 5.69$, $Z = 4$, $D = 2.59$. *8-464(syn)*: 2.85_{10} 2.01_7 1.64_2 1.42_1 1.27_2 1.16_1 0.95_1 0.90_1 . Microscopic grains. White to pale brown, white streak. Cleavage {100}, perfect. $H = 4$. $G = 2.58$. Isotropic; $N = 2.14$. Occurs in enstatite chondrites and enstatite achondrites. *Bustee meteorite, India*. BM *DI:208, R:642, GCA 46:2083(1982), ABI:360.*

2.8.1.6 Niningerite (Mg,Fe,Mn)S

Named in 1967 for Harvey H. Nininger (1887–1986), U.S. meteorite researcher. Galena group. Contains up to 37% Fe, 12% Mn, 3% Ca, and 2% Cr. iso *Fm3m*. $a = 5.17$, $Z = 4$, $D = 2.66$ (MgS). *35-730(syn)*: 3.00_1 2.60_{10} 1.84_6 1.50_2 1.30_1 1.16_1 1.06_1 0.87_1 . Microscopic grains. Gray. An accessory mineral in enstatite chondrites. BM *SCI 155:451(1967), AM 56:1269(1971), R:642, GCA 46:2083(1982).*

2.8.1.7 Borovskite Pd_3SbTe_4

Named in 1973 for Igor B. Borovski (1909–1985), Russian chemist. Possibly galena group. ISO $Fm\bar{3}m$. $a = 5.79$, $Z = 1$, $D = 8.12$. ρ_{calc} : 3.34₃ 2.90₁₀ 2.04₆ 1.60₃ 1.55₅ 1.30₄ 1.24₃ 1.18₄. Microscopic grains. Dark gray, metallic luster. $H = 2\frac{1}{2}$, $\text{VHN}_{10} = 88$. *Khautovaarsk deposit, Karelia, Russia*. BM *ZVMO 102:427(1973)*, *AM 59:873(1974)*, *ABI:63*.

2.8.1.8 Crerarite $\text{Bi}_3(\text{Pb,Pt})(\text{S,Se})_{4-x}$ ($x = 0.1-0.2$)

Named in 1994 for David Crerar (1945–1994), professor of geochemistry, Princeton University. Possibly galena group. ISO $Fm\bar{3}m$. $a = 5.86$, $Z = 1$, $D = 7.75$. *NJMM*: 3.37₅ 2.94₁₀ 2.07₃ 1.77₂ 1.69₂ 1.47₅ 1.35₁ 1.20₁. Microscopic grains. White-gray. $R = 50$ (540 nm). Found in amphibolite boulders, *Lac Sheen, near Belleterre, PQ, Canada*. BM *NJMM:567(1994)*.

SPHALERITE GROUP

The sphalerite group consists of six minerals with the formula

where

A = Zn, Fe, Hg, Cd

B = Se, Te

and a structure in space group $F\bar{4}3m$. The structure is based on cubic close-packed sulfur atoms, with A atoms in tetrahedral coordination.

SPHALERITE GROUP

Mineral	Formula	Space Group	a	D	
Sphalerite	(Zn,Fe)S	$F\bar{4}3m$	5.406	4.10	2.8.2.1
Stilleite	ZnSe	$F\bar{4}3m$	5.667	5.27	2.8.2.2
Metacinnabar	HgS	$F\bar{4}3m$	5.903	7.86	2.8.2.3
Tiemannite	HgSe	$F\bar{4}3m$	6.085	8.24	2.8.2.4
Coloradoite	HgTe	$F\bar{4}3m$	6.460	8.09	2.8.2.5
Hawleyite	CdS	$F\bar{4}3m$	5.818	4.87	2.8.2.6

Notes:

1. Polhemusite (2.8.3.1) is a tetragonal (Zn,Hg)S structure with a cubic pseudocell with $a = 5.33$.
2. See the pentlandite group for other structures based on closed-packed arrangements of sulfur atoms.
3. See wurtzite (2.8.7.1) for a hexagonal polymorph of ZnS.
4. See the tetrahedrite group for similar structures accommodating additional elements.

SPHALERITE: ZnS

Space group $F\bar{4}3m$. Each atom is coordinated by four of the other type. Each type of atom forms a cubic closest-packed arrangement. See also WURZITE.

2.8.2.1 Sphalerite (Zn,Fe)S

Named in 1847 from the Greek for *treacherous*, the mineral sometimes being mistaken for galena but yielding no lead. The old German miners' name *Blende* for sphalerite means *blind* or *deceiving*. Sphalerite group. iso $F43m$. $a = 5.406$, $Z = 4$, $D = 4.10$. $5-566(\text{syn})$: 3.12_{10} 2.71_1 1.91_5 1.63_3 1.35_1 1.24_1 1.10_1 1.04_1 . **Habit**: Tetrahedral or dodecahedral crystals, often distorted and complex; frequently as cleavable masses, coarse to fine granular, fibrous, concretionary, or botryoidal. Twinning common on $\{111\}$, as simple or multiple contact or penetration twins. **Physical properties**: Yellow, brown, black, less commonly red or green; white or colorless when iron-free; white to yellow or brown streak, resinous to adamantine luster. Cleavage $\{011\}$, perfect. $H = 3\frac{1}{2}-4$, $VHN_{100} = 208-224$. $G = 3.9-4.1$, decreasing with Fe content. Pyroelectric. Sometimes triboluminescent. **Tests**: Soluble in HCl with evolution of H_2S . **Chemistry**: The Fe content ranges up to about 26%, corresponding to nearly 50 mol % FeS; Mn may be present up to 6%, and Cd up to 1.7%. **Optics**: $R = 16.6$ (540 nm); isotropic; $N = 2.37-2.47$, increasing with Fe content. **Occurrence**: Sphalerite has been reported in small amounts as a primary constituent of granite and in pegmatites. It is often found in contact-metamorphic deposits and in veins. Large deposits (Mississippi valley type) occur along solution channels in limestone and dolomite. It is an accessory mineral in some meteorites and lunar rocks. **Localities**: Sphalerite is the commonest zinc mineral and occurs widely throughout the world; only a few localities for fine specimens can be cited. Thomasville quarry, York Co., PA; Franklin, NJ; Elmwood mine, Carthage, TN; many localities of the Mississippi valley type

in WI, IL, MO, KS, and OK; Hanover, NM; Butte, MT; Big Four mine, Kremmling, CO; Bingham and Park City, UT; Coeur d'Alene, ID; Sullivan mine, Kimberley, BC, and Watson Lake(*), YT, Canada; Cananea, SON, Santa Eulalia and Naica, CHIH, Charcas, SLP, Mexico; Alston Moor and Egremont, Cumberland, England; Picos de Europa(*), Santander, Spain; Lengenbach(*), Binn, Switzerland; Bottina, Tuscany, Italy; Rodna and Baia Sprie, Romania; Trepca, Serbia; Madan, Rhodope Mts., Bulgaria; Dalnegorsk, eastern Siberia, Russia; Chichibu mine, Saitama Pref., Japan; Mt. Isa, Q, and Broken Hill, NSW, Australia; Huaron, Casapalca, and Huancaavelica, Peru. Uses: The principal ore of zinc. *BM DI:210, AC(A) 36:482(1980), R:506, P&J:95, ABI:488.*

2.8.2.2 Stilleite ZnSe

Named in 1956 for Hans Stille (1876–1966), German geologist. Sphalerite group. iso *F43m*. $a = 5.667$, $Z = 4$, $D = 5.27$. *5-522(syn): 3.27₁₀ 2, 00₇ 1.71₄ 1.42₁ 1.30₁ 1.16₂ 1.09₁ 0.96₁*. Microscopic grains. Gray, gray streak, metallic luster. $H = 5$. $G = 5.3$. *Shinkolobwe, Shaba Prov., Zaire; Santa Brigida mine, La Rioja Prov., Argentina. BM AM 42:584(1957), R:520, ABI:499.*

2.8.2.3 Metacinnabar HgS

Named in 1870 for its relationship to cinnabar. Sphalerite group. Synonyms: onofrite (selenian), saukovite (cadmian). May contain up to 12% Cd, 9% Zn, 10% Se. iso *F43m*. $a = 5.903$, $Z = 4$, $D = 7.86$. *22-729: 3.41₁₀ 2.95₄ 2.09₈ 1.78₇ 1.70₂ 1.36₃ 1.20₃ 1.14₃*. Usually massive, rarely as small tetrahedral crystals. Gray-black, black streak, metallic luster. Shows lamellar twinning, subconchoidal to uneven fracture, brittle. $H = 3$. $G = 7.5-7.7$. $R = 25.6$ (540 nm). Widely distributed in Hg deposits. Terlingua, Brewster Co., TX; Marysvale, Piute Co., UT; Reward mines, King Co., WA; New Almaden, Santa Clara Co., New Idria, San Benito Co., Redington mine, Lake Co., and other Hg deposits in CA; Read Is., BC, Canada; San Onofre, ZAC, Almoloya, GRO, and Guadalcazar, SLP, Mexico; Leogang, Salzburg, Austria; Levigliani, Tuscany, Italy; Idria, Slovenia; Baia Sprie, Romania; Uland deposit, Gornyi Altai, Russia; Wen-Shan-Chang, Kweichow, China. *BM DI:215, AM 44:471(1959), R:521, P&J:267, ABI:327.*

2.8.2.4 Tiemannite HgSe

Named in 1855 for W. Tiemann, who discovered the mineral in 1829. Sphalerite group. iso *F43m*. $a = 6.085$, $Z = 4$, $D = 8.24$. *8-469(syn): 3.51₁₀ 3.04₂ 2.15₅ 1.84₃ 1.76₁ 1.52₁ 1.40₁ 1.24₁*. Tetrahedral crystals and massive. Dark gray to black, black streak, metallic luster. No cleavage, twinned on {111}, uneven to conchoidal fracture, brittle. $H = 2\frac{1}{2}$, $VHN_5 = 22-26$. $G = 8.2-8.5$. $R = 29.8$ (540 nm). Marysvale, Piute Co., UT; New Idria, San Benito Co., and San Joaquin Ranch, Orange Co., CA; Nicholson Bay, Lake Athabaska, SK, Canada; Tilkerode, Lehrbach, Zorge, and *Clausthal, Harz, Germany; Lasovice, Bohemia, Czech Republic; El Sharana mine, NT, Australia; Paca-*

jake, near Colquechaca, Bolivia; Sierra de Umango, La Rioja Prov., Argentina. BM *DI:217*, *AM 35:358(1950)*, *R:523*, *P&J:370*.

2.8.2.5 Coloradoite HgTe

Named in 1877 for the state of Colorado. Sphalerite group. iso *F43m*. $a = 6.460$, $Z = 4$, $D = 8.09$. *32-665(syn)*: 3.73_{10} 3.23_1 2.28_6 1.95_3 1.62_1 1.48_1 1.32_1 1.24_1 . Massive, granular. Dark gray to black, black streak, metallic luster. No cleavage, brittle, friable. $H = 2\frac{1}{2}$, $VHN_{100} = 25-28$. $G = 8.0-8.1$. $R = 35.4$ (540 nm). *Keystone area*, *Boulder Co.*, and *Good Hope mine*, *Gunnison Co.*, *CO*; *Norwegian mine*, *Tuolumne Co.*, *CA*; *Robb-Montbray mine*, *PQ*, and mines in the *Kirkland Lake area*, *ON*, *Canada*; *Uzel'ginsk deposit*, *Ural Mts.*, *Russia*; *Emperor mine*, *Vatukoula*, *Fiji*; *Kalgoorlie*, *WA*, *Australia*. BM *DI:218*, *AM 34:342(1949)*, *R:524*, *P&J:127*.

2.8.2.6 Hawleyite CdS

Named in 1955 for James E. Hawley (1897-1965), Canadian mineralogist. Sphalerite group. Dimorphous with greenockite. iso *F43m*. $a = 5.818$, $Z = 4$, $D = 4.87$. *10-454*: 3.36_{10} 2.90_4 2.06_8 1.75_6 1.45_2 1.34_3 1.19_3 1.12_3 . Fine-grained powdery coatings: Orange, orange streak, earthy luster. Isotropic; $N = 1.78$. Occurs as coatings on sphalerite. *Franklin*, *NJ*; *Eureka Co.*, *NV*; *Crestmore*, *Riverside Co.*, *CA*; *Hector-Calumet mine*, *Galena Hill*, *YT*, *Canada*; *Tynagh*, *Galway*, *Eire*; *Los Blancos mine*, *Sierra de Cartagena*, *Spain*; *Komna*, *Moravia*, *Czech Republic*; *Norilsk area*, *Ural Mts.*, *Russia*; *Tui mine*, *Te Aroha*, *New Zealand*; *Mina Coquimbana*, *Atacama*, *Chile*. BM *AM 40:555(1955)*, *NJMM:205(1971)*, *507(1974)*, *ABI:208*.

2.8.3.1 Polhemusite (Zn,Hg)S

Named in 1978 for Clyde Polhemus Ross (1891-1965), U.S. geologist. $TET P4/n$. $a = 8.71$, $c = 14.74$, $Z = 24$, $D = 4.23$. *31-870*: 3.63_6 3.16_7 3.08_{10} 1.89_8 1.61_7 1.22_6 1.09_6 1.02_6 . Microscopic tetragonal crystals. Black, resinous to adamantine luster. Knee-shaped twins with {605} as composition plane. $H = 4$, $VHN_{25} = 262$. $R = 17.1-18.3$ (546 nm); moderately to strongly anisotropic. *B and B deposit*, *Big Creek district*, *Valley Co.*, *ID*; *Getchell mine*, *Humboldt Co.*, *NV*. BM *AM 63:1153(1978)*, *ABI:415*.

2.8.4.1 Xingzhongite (Ir,Cu)S

Named in 1974, presumably for the locality. iso *Fd3m*. $a = 9.970$, $Z = 16$, $D = 7.94$. *29-551*: 5.80_8 3.00_8 2.88_5 2.49_6 1.77_{10} 1.34_4 1.21_8 1.17_5 . Microscopic grains. Steel-gray, metallic luster. $H = 6$, $VHN_{50} = 753$. $R = 38.9$ (544 nm). *Fox Gulch*, *Goodnews Bay*, *AK*; *China*, locality not given; *Tiebaghi*, *New Caledonia*. BM *AM 61:184(1976)*, *69:412(1984)*, *CM 26:177(1988)*, *ABI:582*.

2.8.5.1 Cooperite PtS

Named in 1928 for Richard A. Cooper (1890–1972), South African metallurgist, who described the mineral. May contain up to 6% Pd. Dimorphous with braggite. TET $P4_2/mmc$. $a = 3.47$, $c = 6.10$, $Z = 2$, $D = 10.27$. 26-1302: 3.05₂ 3.02₁₀ 2.45₂ 1.91₃ 1.75₁ 1.74₁ 1.51₁ 1.50₂. Crystal fragments and microscopic grains. Steel-gray, metallic luster. Cleavage {011}, conchoidal fracture. $H = 4-5$, $VHN_{100} = 743-1018$. $G = 9.5$. $R = 39.4-47.2$ (540 nm); strongly anisotropic. Stillwater Complex, MT; in gravels, Trinity, Merced, and Stanislaus rivers, CA; Lac des Iles Complex, PG, and Tulameen district, BC, Canada; Gusevogorskii and Norilsk deposits, Russia; Round Hill, near Orepuki, New Zealand; at several localities along the Merensky Reef, Bushveld Complex, Transvaal, South Africa. BM DI:258, AM 63:832(1978), R:696, P&J:129, ABI:107.

2.8.5.2 Vysotskite PdS

Named in 1962 for N. K. Vysotskii, Russian geologist, discoverer of platinum at Norilsk. Contains up to 17% Ni and 14% Pt. Forms a series with braggite. TET $P4_2/m$. $a = 6.371$, $c = 6.540$, $Z = 8$, $D = 6.40$. 15-151: 2.91₁₀ 2.86₁₀ 2.64₇ 2.61₈ 2.15₆ 1.86₇ 1.73₆ 1.72₈. Microscopic grains. Silver-white, metallic luster. $VHN_{100} = 830$. $G = 8.4$. $R = 45.1-45.8$ (540 nm); moderately anisotropic. Stillwater Complex, MT; near Moapa, Clark Co., NV; Yuba R., Nevada Co., CA; Lac des Iles Complex, ON, Canada; Konttijärvi Intrusion, Finland; Norilsk, Russia; Merensky Reef, Transvaal, South Africa. BM ZVMO 91:718(1962); AM 48:708(1963), 63:832(1978); R:695; P&J:102; ABI:565.

2.8.5.3 Braggite (Pt,Pd)S

Named in 1932 for W. H. (1862–1942) and W. L. (1890–1971) Bragg, pioneers in the X-ray investigation of crystals. Contains up to 5% Ni. Forms a series with vysotskite. TET $P4_2/m$. $a = 6.38$, $c = 6.59$, $Z = 8$, $D = 8.90$. 9-421: 2.93₃ 2.86₁₀ 2.64₃ 1.85₃ 1.71₂ 1.60₂ 1.42₃ 1.39₂. Prisms to 2 cm and rounded grains. Steel-gray, metallic luster. $H = 5$, $VHN_{100} = 981$. $G = 8.9$. $R = 42.6-44.2$ (540 nm); distinctly anisotropic. Stillwater Complex, MT; Norilsk, Russia; Round Hill near Orepuki, New Zealand; Merensky Reef, Bushveld Complex, Transvaal, South Africa. BM DI:259, AM 63:832(1978), R:695, P&J:102, ABI:67.

2.8.6.1 Polarite Pd(Bi,Pb)

Named in 1969 for the locality (Polar Ural Mts.). ORTH $Ccm2_1$. $a = 7.191$, $b = 8.693$, $c = 10.681$, $Z = 16$, $D = 12.51$. 23-1298: 3.33₂ 2.65₁₀ 2.50₃ 2.25₅ 2.16₉ 1.64₅ 1.40₃ 1.22₃. Microscopic grains. White with yellow tint, metallic luster. $H = 4$, $VHN_{50} = 168-232$. $R = 59.2$ (540 nm); slightly anisotropic. Goodnews Bay, AK; Talnakh, Norilsk, Russia; Union mine, Merensky Reef, Transvaal, South Africa. BM ZVMO 98:708(1969), AM 55:1810(1970), R:364, ABI:414.

WURTZITE GROUP

Wurtzite minerals have the formula

where

A = Cd, Zn

B = S, Se

and the structure is hexagonal, $P6_3mc$.

WURTZITE: ZnS

Space group $P6_3mc$. Each atom is coordinated by four of the other type. Each type of atom forms a hexagonal closest-packed arrangement.

WURTZITE GROUP

Mineral	Formula	Space Group	a	c	D	
Wurtzite	ZnS	$P6_3mc$	3.820	6.260	4.09	2.8.7.1
Greenockite	CdS	$P6_3mc$	4.136	6.713	4.82	2.8.7.2
Cadmoseelite	CdSe	$P6_3mc$	4.299	7.010	5.66	2.8.7.3

Notes:

1. The common 2H polytype of wurtzite is described above. Other polytypes with larger C repeats are known.
2. See also the nickeline group, $P6_3/mmc$.

2.8.7.1 Wurtzite ZnS

Named in 1861 for Charles A. Wurtz (1817–1884), French chemist. Wurtzite group. Trimorphous with sphalerite and matraite. May contain up to 8% Fe

and 4% Cd. $HEX P6_3mc$. $a = 3.820$, $c = 6.260$, $Z = 2$, $D = 4.09$ (the common 2H polytype; several polytypes with larger c -axis repeats are known). $5-492(\text{syn})$: 3.31_{10} 3.13_9 2.93_8 2.27_3 1.91_7 1.76_5 1.63_5 1.30_1 . Hemimorphic pyramidal crystals up to 1.5 cm; also massive and as botryoidal banded crusts. Brown to black, brown streak, resinous to submetallic luster. Cleavage $\{1120\}$, easy; $\{0001\}$, difficult. $H = 3\frac{1}{2}-4$. $G = 4.0-4.1$. $R = 16.6$ (540 nm). Uniaxial (+); $N_O = 2.356$, $N_E = 2.378$. Occurs in hydrothermal veins and on concretions in sedimentary rocks. Thomaston Dam, Litchfield Co., CT; Sterling Hill mine, Sussex Co., NJ; Union Bridge quarry, Frederick, MD; Witmer(*), Allegheny Co., PA; Joplin, MO; Butte, MT; Gladenbach, Odenswald, Germany; Bleischarley mine, Brzeziny, Giesche Spolka, Poland; Příbram, Czech Republic; Mezica, Slovenia; Baia Sprie, Romania; Beregovsk, Ukraine; Hercules mine, Mt. Read, TAS, Australia; Tsumeb, Namibia; Animas mine(*), Potosi, and Colquechaca, Llallagua, Oruro, and other localities, Bolivia. *BM DI:226, AM 35:29(1950), AC(B) 26:1192(1970), R:577, P&J:395, ABI:579.*

2.8.7.2 Greenockite CdS

Named in 1840 for Charles Murray Cathcart (1783–1859), Lord Greenock. Wurtzite group. Dimorphous with hawleyite. $HEX P6_3mc$. $a = 4.136$, $c = 6.713$, $Z = 2$, $D = 4.82$. $6-314(\text{syn})$: 3.58_8 3.37_6 3.16_{10} 2.45_3 2.07_6 1.90_4 1.79_2 1.76_5 . Hemimorphic pyramidal crystals up to 3 cm and earthy coatings. Yellow to red color and streak, resinous to adamantine luster. Cleavage $\{1122\}$, distinct; $\{0001\}$, imperfect. $H = 3-3\frac{1}{2}$, $VHN_{25} = 98$. $G = 4.8-4.9$. $R = 19.6$ (540 nm). Uniaxial (+), $N_O = 2.506$, $N_E = 2.529$. Paterson(*), Passaic Co., and Franklin and Sterling Hill, Sussex Co., NJ; Arlington quarry, Leesburg, VA; Friedensville, Lehigh Co., PA; Joplin, MO; Cerro Gordo, Inyo Co., CA; *Bishopton*(*), *Renfrewshire, Scotland*; Pierrefitte, Hautes-Pyrenees, France; Los Blancos mine, Sierra de Cartagena, Spain; Příbram, Czech Republic; Kti-Teberda deposit, Caucasus Mts., Russia; Tsumeb, Namibia; Asunta mine(*), Potosi, and Llallagua mines, Bolivia. *BM DI:228; AM 42:184(1957), 46:1382(1961); R:582; P&J:187; ABI:194.*

2.8.7.3 Cadmosellite CdSe

Named in 1957 for the composition. Wurtzite group. $HEX P6_3mc$. $a = 4.299$, $c = 7.010$, $Z = 2$, $D = 5.66$. $8-459(\text{syn})$: 3.72_{10} 3.51_7 2.55_4 2.15_9 1.98_7 1.83_5 1.80_1 1.46_2 . Microscopic hexagonal pyramids. Black, black streak, resinous to adamantine luster. Perfect cleavage, apparently prismatic. $H = 4$, $VHN = 203-222$. $G = 5.47$. *Tuva, Russia*. *BM ZVMO 86:626(1957), AM 43:623, R:582, ABI:76.*

2.8.8.1 Hypercinnabar HgS

Named in 1978 for its trimorphous relationship with cinnabar and metacinnabar. HEX Space group unknown. $a = 7.01$, $c = 14.13$, $Z = 12$, $D = 7.54$. $19-798(\text{syn})$: 3.70_7 3.43_8 3.08_{10} 2.97_6 2.80_9 2.24_6 1.98_{10} 1.89_{10} . Micro-

scopic grains in metacinnabar. Black with purple cast, dark purple streak, adamantine luster. No cleavage. $H = 3$, $VHN_{25} = 51$. $G = 7.43$. $R = 25$ (540 nm); distinctly anisotropic. Manhattan, Nye Co., NV; *Mt. Diablo mine, Contra Costa Co., CA*; Gravelotte, northern Transvaal, South Africa. *BM AM 63:1143(1978)*, *ABI:226*.

2.8.9.1 Troilite FeS

Named in 1863 for Domenico Troili (1722–1792), Italian Jesuit, who observed the mineral in the Albareto meteorite in 1766. *HEX P62c*. $a = 5.968$, $c = 11.740$, $Z = 12$, $D = 4.84$. *24-80(syn)*: 4.73₁ 2.98₆ 2.94₁ 2.66₄ 2.09₁₀ 1.72₃ 1.33₁. Rounded nodules in iron meteorites and anhedral grains in stony meteorites. Bronze, gray streak, metallic luster. $H = 4$, $VHN_{100} = 250$. $G = 4.7$ –4.8. An accessory mineral in most meteorites and in some lunar rocks. Terrestrial occurrences rare: Alta mine, Del Norte Co., CA; Disko Is., Greenland, with native iron in basalt. *BM DI:231*, *SCI 167:621(1970)*, *GCA 39:1457(1975)*.

2.8.10.1 Pyrrhotite $Fe_{1-x}S$ ($x = 0-0.2$)

Named in 1835 from the Greek for redness, in reference to its color. *MON A2/a*. $a = 12.811$, $b = 6.870$, $c = 11.885$, $\beta = 117.3^\circ$, $Z = 32$, $D = 4.62$ (the commonest polytype, Fe_7S_8). *29-723*: 2.98₉ 2.64₁₀ 2.07₆ 2.06₉ 2.05₁₀ 1.72₈ 1.60₁ 1.43₃. **Habit**: Pseudohexagonal crystals rare; usually massive, granular; twinned on {101̄2}. **Structure**: A modified nickeline structure, based on hexagonal close-packed S atoms with Fe atoms in octahedral coordination. In the monoclinic type, one in every eight Fe atoms is omitted ($x = 0.125$). **Physical properties**: Bronze to brown, tarnishing on exposure, gray-black streak, metallic luster. No cleavage, basal parting, subconchoidal to uneven fracture, brittle. $H = 3\frac{1}{2}$ –4 $\frac{1}{2}$, $VHN_{100} = 373$ –409. $G = 4.6$ –4.7. Magnetic, varying inversely with Fe

PYRRHOTITE: Fe_7S_8

Sulfur is in hexagonal closest-packed arrangement, as are potential iron sites (see NICCOL). Iron in pyrrhotites is always deficient from the ideal 1 : 1 ratio, and several different symmetries are shown, depending in part on the size of the deficiency.

content. **Tests:** Magnetism. Dissolves in HCl with evolution of H₂S. **Chemistry:** Usually pure iron sulfide; many analyses report minor Ni, but this is due to admixed pentlandite. **Optics:** R = 30.3–31.0 (540 nm); distinctly anisotropic. **Occurrence:** Mainly in mafic igneous rocks, frequently as magmatic segregations; also in pegmatites, in high-temperature hydrothermal and replacement veins, and as an accessory in metamorphic rocks. **Localities:** Widely distributed throughout the world. Tilly Foster mine, Brewster, NY; Franklin, NJ; Gap mine, Lancaster Co., PA; Galax, Carroll Co., VA; Ducktown, TN; Butte, MT; Crestmore, CA; Sudbury, ON, and Bluebell mine(*), Riondell, BC, Canada; Potosi and San Antonio mines(*), Santa Eulalia, CHIH, Mexico; Falun, Sweden; Outokumpu, Finland; Andreasberg, Harz, Germany; Botтино, Tuscany, Italy; Herja(*), Romania; Trepca(*), Serbia; Dalnegorsk(*), eastern Siberia, Russia; many mines in Japan; Kambalda, WA, Australia; Morro Velho(*), Nova Lima, MG, Brazil. *BM DI:231, EG 70:824(1975), R:592, P&J:315, ABI:428.*

2.8.10.2 Smythite Fe₉S₁₁

Named in 1957 for Charles H. Smyth, Jr. (1866–1937), U.S. economic geologist. May contain minor Ni. **HEX-R R3m.** $a = 3.47$, $c = 34.50$, $Z = 3$, $D = 4.09$. *25-1182*: 11.5₁₀ 5.75₂ 2.99₃ 2.57₃ 2.27₂ 2.17₂ 1.99₁ 1.74₂. Microscopic hexagonal plates. Bronze-yellow, dark gray streak, metallic luster. Cleavage {0001}, perfect. VHN = 388. $G = 4.06$. Strongly magnetic. Strongly pleochroic and anisotropic. *Bloomington, Monroe Co., IN*, inclusions in calcite crystals; near Helena, Boulder Co., MT; Boron, Kern Co., CA; Silverfields mine, Cobalt, and Nicopor mine, north of Schreiber, ON, and Bird River mines, Lac du Bonnet, MB, Canada; Clara mine, Black Forest, and Hartenstein, Saxony, Germany; Lengenbach quarry, Binn, Switzerland; Kerch Peninsula, Ukraine; Kamaishi mine, Iwate Pref., Japan; Wadi Kamal, Saudi Arabia. *BM AM 42:309(1957), R:612, P&J:345, ABI:482.*

NICKELINE GROUP

The nickeline structure minerals have the general formula

where

A = Ni, Co, Pt, Pd

X = As, Sb, Bi, Se, Te

and the structure is hexagonal, $P6_3/mmc$. In this structure, each X atom is surrounded by six metal atoms in the corners of a trigonal prism. Each metal atom is surrounded by six X atoms in an octahedral coordination. Even when the ratio of atoms differs considerably from 1:1, most compounds will form the structure. Nonstoichiometric compositions often result from vacant cation sites. The vacant sites may be disordered; if they are ordered, superstructures

NICCOLITE (nickelite, nickeline): NiAs

Space group $P6_3/mmc$. Each atom is coordinated by six of the other type. Each is the arrangement of hexagonal closest packing. Trolite, FeS, found in extraterrestrial rocks, has essentially the same structure, and pyrrhotites, $Fe_{1-x}S$, have the same basic structure with Fe vacancies in various locations.

may be formed with lower symmetry. Pyrrhotite (2.8.10.1) is a monoclinic variation on the nickeline structure due to regular vacancies in the metal position.

NICKELINE GROUP

Mineral	Formula	Space Group	a	c	D	
Nickeline	NiAs	$P6_3/mmc$	3.609	5.019	7.84	2.8.11.1
Breithauptite	NiSb	$P6_3/mmc$	3.926	5.138	8.74	2.8.11.2
Sederholmitite	NiSe	$P6_3/mmc$	3.624	5.228	7.11	2.8.11.3
Hexatestibio-panickelite	(Ni,Pd)(Sb,Te)	$P6_3/mmc$	3.98	5.35	8.94	2.8.11.4
Sudburyite	PdSb	$P6_3/mmc$	4.079	5.587	9.41	2.8.11.5
Kotulskite	Pb(Te,Bi)	$P6_3/mmc$	4.19	5.67	8.26	2.8.11.6
Sobolevskite	PdBi	$P6_3/mmc$	4.23	5.69	11.88	2.8.11.7
Stumpflite	Pt(Sb,Bi)	$P6_3/mmc$	4.175	5.504	13.52	2.8.11.8
Langisite	(Co,Ni)As	$P6_3/mmc$	3.538	5.127	8.17	2.8.11.9
Freboldite	CoSe	$P6_3/mmc$	3.632	5.301	7.56	2.8.11.10

Note: Many binary compounds of V, Cr, Mn, Fe, Co, Ni, Pd, and Rh with S, Se, Te, As, Sb, and Bi have this structure or a related one. See, for example, the wurtzite structure group.

2.8.11.1 Nickeline NiAs

Named in 1832 for the composition. Nickeline group. Synonym: niccolite. $HEX P6_3/mmc$. $a = 3.609$, $c = 5.019$, $Z = 2$, $D = 7.84$. $31-900$: 2.66_{10} 1.96_9 1.81_8 1.50_2 1.48_2 1.33_3 1.07_4 1.03_3 . Crystals rare, pyramidal and often malformed; usually massive, also reticulated and arborescent. Pale copper-red, tarnishing

to gray or black, black streak, metallic luster. No cleavage, may be twinned on {1011} producing fowlings, conchoidal to uneven fracture, brittle. $H = 5-5\frac{1}{2}$. $G = 7.78$. $R = 47.0-51.6$ (540 nm); strongly pleochroic and anisotropic. Alters to annabergite. Soluble in aqua regia. Occurs in ore deposits with other Ni and As minerals, with pyrrhotite and chalcopyrite in ore deposits derived from norites, and in vein deposits with Co and Ag minerals. Chatham, CT; Franklin, NJ; Keweenaw Penin., MI, in Cu deposits; Copper King mine, Boulder Co., and Gem mine, Fremont Co., CO; Stanislaus mine, Calaveras Co., and Long Lake, Inyo Co., CA; Cobalt, Gowganda, Sudbury, and Thunder Bay, ON, and Great Bear Lake, NWT, Canada; Alistos, SIN, Mexico; Chalcanches, Isere, France; Andreasberg, Mansfeld, and Eisleben, Harz, and Freiberg, Annaberg, Schneeberg, and Sangerhausen, Saxony, Germany; Jachymov, Czech Republic; Schladming, Styria, Austria; Talmessi mine, near Anarak, Iran; Ait Ahmane mine, near Bou-Azzer, Morocco; Cochabamba, Cercado, Bolivia. *BM DI:236, R:615, P&J:278, ABI:350.*

2.8.11.2 Breithauptite NiSb

Named in 1845 for Johann F. A. Breithaupt (1791–1873), German mineralogist. Nickeline group. $HEX P6_3/mmc$. $a = 3.926$, $c = 5.138$, $Z = 2$, $D = 8.74$. *41-1439*: 2.84_{10} 2.06_7 1.97_7 1.61_2 1.53_3 1.42_2 1.25_2 1.07_3 . Tabular crystals rare, usually massive. Light copper-red, red-brown streak, metallic luster. No cleavage, brittle. $H = 5\frac{1}{2}$. $G = 7.59-8.23$. $R = 41.0-48.6$ (540 nm); distinctly pleochroic and anisotropic. Occurs in hydrothermal veins associated with Co–Ni Ag ores. Coyote Peak, Humboldt Co., CA; many mines in the Cobalt area, ON, Canada; Sulitjelma, Norway; *Andreasberg, Harz Mts., Germany*; Sarrabus, Sardinia, Italy; Tunaberg, Saxberget, and Langsjön, Sweden; Norilsk, Russia; Broken Hill, NSW, Australia. *BM DI:238, R:623, P&J:107, ABI:69.*

2.8.11.3 Sederholmite NiSe

Named in 1964 for Jakob J. Sederholm (1863–1934), director of the Geological Survey of Finland. Nickeline group. $HEX P6_3/mmc$. $a = 3.624$, $c = 5.288$, $Z = 2$, $D = 7.11$. *18-888*: 2.70_{10} 2.02_8 1.81_6 1.54_4 1.50_4 1.35_3 1.16_3 1.08_3 . Microscopic grains. Brass yellow, metallic luster. Strongly anisotropic. Occurs with other nickel selenides in calcite veins at *Kuusamo, northeastern Finland*. *BM AM 50:519(1965), R:625, P&J:339, ABI:466.*

2.8.11.4 Hexatestibiopanickelite (Ni,Pd)(Sb,Te)

Named in 1974 for the crystal system and composition. Nickeline group. $HEX P6_3/mmc$. $a = 3.98$, $c = 5.35$, $Z = 2$, $D = 8.94$. *29-932*: 2.89_{10} 2.11_8 1.99_7 1.64_4 1.58_5 1.45_3 1.34_3 1.11_6 . Brown-gray, metallic luster. $H = 2$, $VHN = 75-108$. $R = 58.2-62.3$ (590 nm); weakly anisotropic. *Southwestern China*, in Cu–Ni sulfide deposit. *BM AM 61:182(1976), ABI:218.*

2.8.11.5 Sudburyite PdSb

Named in 1974 for the locality. Nickel line group. Contains up to 8% Ni. $HEX P6_3/mmc$. $a = 4.079$, $c = 5.587$, $Z = 2$, $D = 9.41$. $26-888(\text{syn})$: 2.98_7 2.18_{10} 2.03_7 1.49_6 1.30_5 1.20_8 1.15_6 1.08_4 . Microscopic grains. White, metallic luster. $H = 4-4\frac{1}{2}$, $VHN_{25} = 281-311$. $G_{\text{syn}} = 9.37$. $R = 59.3-62.8$ (540 nm); moderately anisotropic, yellow-gray to dark gray. Blue Lake, PQ, and *Frood and Copper Cliff South mines, Sudbury, ON, Canada*, as tiny inclusions in cobaltite and maucherite, and in heavy-mineral concentrates; Danba, Sichuan Prov., China; Witwatersrand, South Africa. *BM CM 12:275(1974)*, *AM 61:178(1976)*, *P&J:411*, *ABI:505*.

2.8.11.6 Kotulskite Pd(Te,Bi)

Named in 1963 for Vladimir K. Kotulskii (1879–1951), Russian geologist. Nickel line group. $HEX P6_3/mmc$. $a = 4.19$, $c = 5.67$, $Z = 2$, $D = 8.26$. $15-394$: 3.05_{10} 2.24_9 2.09_9 1.53_7 1.33_7 1.24_8 1.21_7 1.17_8 . Microscopic grains. Steel-gray, metallic luster. No cleavage. $VHN_{100} = 222$. $R = 59.6-67.4$ (540 nm); strongly anisotropic. An accessory mineral in many Pt deposits. Stillwater Complex, MT; New Rambler mine, Albany Co., WY; Key West mine, Clark Co., NV; Sudbury, Lac des Iles Complex, and Thierry mine, ONT, Canada; *Monchegorsk deposit, Kola*, and *Norilsk, Russia*; Shiaonanshan, Inner Mongolia, and Danba, Sichuan, China; Merensky Reef, Transvaal, South Africa. *BM ZVMO 92:33(1963)*, *AM 48:1181(1963)*, *EG 71:1159(1976)*, *R:838*, *P&J:406*.

2.8.11.7 Sobolevskite PdBi

Named in 1975 for Petr G. Sobolevski (1781–1841), Russian mineralogist. Nickel line group. $HEX P6_3/mmc$. $a = 4.23$, $c = 5.69$, $Z = 2$, $D = 11.88$. $29-238$: 3.07_{10} 2.26_{10} 2.11_9 1.74_4 1.69_5 1.34_4 1.24_4 1.18_5 . Microscopic grains. Gray-white, metallic luster. $H = 4$, $VHN_{50} = 236$. $R = 52.4-57.7$ (540 nm); strongly anisotropic, pale cream to red-brown. *Oktyabr mine, Talnakh, Norilsk, Russia*, in chalcopyrite ore; Lubin copper mine, Zechstein, Poland. *BM ZVMO 104:568(1975)*, *AM 61:1054(1976)*, *TMPM 28:1(1981)*, *ABI:483*.

2.8.11.8 Stumpflite Pt(Sb,Bi)

Named in 1972 for Eugen F. Stumpfl (b.1931), Austrian mineralogist. Nickel line group. $HEX P6_3/mmc$. $a = 4.175$, $c = 5.504$, $Z = 2$, $D = 13.52$. $25-1482$: 3.62_6 3.03_{10} 2.19_{10} 2.09_8 1.72_4 1.51_5 1.22_4 1.15_5 . Microscopic grains. Cream-white, metallic luster. $H = 5$, $VHN_{50} = 385$. $R = 59.3-63.0$ (540 nm); pleochroic and anisotropic, cream to yellow-brown. *Driekop mine, Transvaal, South Africa*, in platinum concentrates; near Nizhni Tagil, Russia. *BM BM 95:610(1972)*, *AM 59:211(1974)*, *P&J:356*, *ABI:503*.

2.8.11.9 Langisite (Co,Ni)As

Named in 1969 for the locality. Nickeline group. HEX $P6_3/mmc$. $a = 3.538$, $c = 5.127$, $Z = 2$, $D = 8.17$. 2θ - 333 : 3.07_2 2.63_{10} 1.97_9 1.77_8 1.49_4 1.47_3 1.32_3 1.14_3 . Microscopic grains. Pink-buff, metallic luster. $H = 6$, $VHN_{50} = 780$ – 857 . $R = 46.1$ – 47.4 ; moderately anisotropic, blue-gray to light brown. *Langis mine, Cobalt, ON, Canada*, in Co ore. BM *CM 9:597(1969)*, *AM 57:1910 (1972)*, *ABI:284*.

2.8.11.10 Freboldite CoSe

Named in 1957 for Georg Frebold (b.1891), German mining engineer. Nickeline group. HEX $P6_3/mmc$. $a = 3.632$, $c = 5.301$, $Z = 2$, $D = 7.56$. 15 - 464 : 2.4_5 2.05_{10} 1.71_5 1.08_5 1.07_{10} 0.99_5 0.96_{10} . Microscopic grains. Copper-red, metallic luster. Temple Mt., Emery Co., UT; Pinky Fault U deposit, SK, Canada; *Trogtal quarry* and *Andreasberg, Harz*, and *Hartenstein, Saxony, Germany*. BM *NJMM:133(1955)*; *AM 41:164(1956)*, $44:907(1959)$; *R:614*; *ABI:161*.

2.8.12.1 Covellite CuS

Named in 1832 for Niccolo Covelli (1790–1829), who described the mineral from Vesuvius. Isostructural with klockmannite (2.8.12.2). HEX $P6_3/mmc$. $a = 3.7938$, $c = 16.341$, $Z = 6$, $D = 4.68$. 6 - 464 (syn): 3.22_3 3.05_7 2.81_{10} 2.72_6 1.90_9 1.74_4 1.57_2 1.56_4 . Hexagonal plates, also massive or spheroidal. Based on a hexagonal framework of sulfur atoms with copper in triangular and tetrahedral coordination. Indigo-blue to black, sometimes highly iridescent in brass-yellow and deep red, lead-gray to black streak, submetallic luster inclining to resinous. Cleavage $\{0001\}$, perfect; flexible in thin leaves. $H = 1\frac{1}{2}$ – 2 , $VHN_{100} = 128$ – 138 . $G = 4.6$ – 4.7 . $R = 6.8$ – 21.9 (540 nm); pleochroic, deep blue to blue-white; strongly anisotropic. Easily fusible; when heated burns with a blue flame and fuses to a globule. Covellite is associated with other copper minerals in the zone of secondary enrichment; it is a primary mineral in a few places. Rarely as a volcanic sublimate (*Vesuvius*). Franklin, NJ; Summitville(*), Rio Grande Co., CO; Butte(*), MT; many localities in AZ, including Bisbee, Ajo, Mammoth, Globe-Miami, and Clifton-Morenci; Darwin mines, Inyo Co., CA; Kennecott, AK; Copper Mountain mine, BC, Canada; Dillenburg, Hesse, Germany; Alghero(*), Sardinia, Italy; Bor(*), Serbia; Moonta, SA, Australia. BM *DI:248*, *R:676*, *P&J:132*, *ABI:112*.

2.8.12.2 Klockmannite CuSe

Named in 1928 for Friedrich Klockmann (1858–1937), German mineralogist. HEX $P6_3/mmc$. $a = 3.94$, $c = 17.25$, $Z = 6$, $D = 6.12$. Isostructural with covellite (2.8.12.1). 6 - 427 : 3.35_6 3.18_9 2.88_{10} 2.19_8 2.00_4 1.97_8 1.82_6 1.62_5 . Granular aggregates. Slate-gray, tarnishing to blue-black, metallic luster. Perfect basal cleavage. $H = 3$, $VHN_{100} = 82$ – 104 . $G_{syn} = 5.99$. $R = 15.8$ – 37.4 (540 nm); strongly anisotropic. Montreal R., ON, and Beaverlodge Lake, SK, Canada; Moctezuma, SON, Mexico; Lehrbach and Tilkerode, Harz, Germany; Skrikerum, Kalmar, Sweden; Bukov and Petrovice, Czech Republic; *Sierra de*

Umango and Sierra de Cacheuta, La Rioja, Argentina. BM DI:251, AM 34:435(1949), R:681, P&J:224, ABI:267.

2.8.13.1 Vulcanite CuTe

Named in 1961 for the locality. ORTH *Pmmn*. $a = 3.16$, $b = 4.08$, $c = 6.93$, $Z = 2$, $D = 7.11$. 2θ - 25θ (syn): 3.50_7 2.87_8 2.34_5 2.31_5 2.02_{10} 1.66_7 1.52_5 1.44_5 . Microscopic prismatic grains. Light bronze to yellow-bronze, metallic luster. Two cleavages, probably pinacoidal. $H = 1-2$, $VHN_{50} = 34-40$. $R = 15.2-67.8$ (540 nm); strongly pleochroic and anisotropic. *Good Hope mine, Vulcan, Gunnison Co., CO*; Bryngovsk Au-Te deposit, Ural Mts., Russia; Iriki mine, Kagoshima Pref., Japan. *BM AM 46:258(1961), R:419, P&J:385, ABI:564.*

2.8.14.1 Cinnabar HgS

Name is from medieval Latin *cinnabaris*, probably derived from Persian *zinjifrah*, apparently meaning dragon's blood, in allusion to its red color. Trimorphous with metacinnabar and hypercinnabar. *HEX-R P3₁21*. $a = 4.149$, $c = 9.595$, $Z = 3$, $D = 8.19$. $6-25\theta$ (syn): 3.36_{10} 3.17_3 2.86_9 2.07_3 1.98_4 1.77_2 1.74_3 1.68_3 . **Habit:** Crystals rhombohedral or thick tabular on {0001} to short prismatic; commonly in crystalline incrustations, granular, massive, or as an earthy coating. Twinning common with {0001} as twin plane, simple and penetration. **Structure:** Consists of helical —Hg—S—Hg—S— chains parallel to the hexagonal c axis. **Physical properties:** Scarlet-red, darkening on exposure to light, scarlet streak, adamantine to submetallic luster. Cleavage {1010}, perfect; somewhat sectile. $H = 2-2\frac{1}{2}$, $VHN_{10} = 82-156$. $G = 8.1-8.2$. **Tests:** Heated in an open tube gives Hg vapor, which condenses to a silvery coating. **Chemistry:** Pure HgS. **Optics:** Uniaxial(+); $N_O = 2.905$, $N_E = 3.256$. $R = 28.4-29.2$ (540 nm); strongly anisotropic. **Occurrence:** Cinnabar is the most abundant mercury mineral. It occurs in veins or impregnations formed at relatively low temperatures near recent volcanic rocks or in hot-spring areas. **Localities:** Cinnabar is widely distributed and only the more significant localities can be given. Terlingua, Brewster Co., TX; Poverty Peak, Humboldt Co., and near Lovelock, Pershing Co., NV; New Idria(*), New Almaden, and other localities, CA; Almaden(*), Spain; Monte Amiata, Italy; Idria(*), Slovenia; Mt. Avala(*), Serbia; Nikitova, Ukraine; Hydercahn(*), Ferghana Basin, Uzbekistan; Tsar Tien mine(*), Hunan Prov., China; Kilkivan, near Gympie, Q, Australia; Bau(*), Sarawak; Huancavelica(*), Peru. **Uses:** The principal source of mercury and its compounds. *BM DI:251, R:673, P&J:122, ABI:100.*

2.8.15.1 Matraite ZnS

Named in 1958 for the locality. Trimorphous with sphalerite and wurtzite. *HEX-R R3m*. $a = 3.8$, $c = 9.4$, $Z = 3$, $D = 4.13$. Pyramidal crystal aggregates. Yellow-brown, vitreous luster. Telluride, San Miguel Co., CO; *Matra Mts., Hungary. BM AM 45:1131(1960), ABI:316.*

2.8.16.1 Millerite NiS

Named in 1845 for William H. Miller (1801–1880), English mineralogist, who first studied the crystals. *HEX-R R3m*. $a = 9.620$, $c = 3.149$, $Z = 9$, $D = 5.37$. $12\text{-}41$: 4.81_6 2.95_4 2.78_{10} 2.51_7 2.23_6 1.86_9 1.82_5 1.74_4 . Needlelike crystals, commonly in radiating groups, also massive. Brass-yellow, often with an iridescent tarnish, green-black streak, metallic luster. Cleavage $\{1011\}$, $\{0112\}$, perfect. $H = 3\text{-}3\frac{1}{2}$, $VHN_{20} = 179$. $G = 5.3\text{-}5.5$. $R = 52.9\text{-}54.8$ (540 nm); strongly anisotropic. Normally, a mineral of low-temperature origin, it occurs rather commonly as tufts of capillary crystals in cavities in limestone or dolostone; also as a late mineral in nickel sulfide deposits. Sterling mine(*), Antwerp, NY; Gap mine(*), Lancaster Co., PA; Keokuk(*), IA, many localities in Paleozoic limestones in the Mississippi valley; Temagami(*), ON, Marbridge mine, La Motte Twp., PQ, and Thompson mine(*), MB, Canada; Müsen(*) and Wissen(*), North Rhine-Westphalia, Germany; Kotalahti, Finland; Jachymov, Czech Republic; Kambalda and Black Swan, WA, Australia; Mina Carlote, Cuba. *BM DI:239*, *CM 12:248(1974)*, *EG 69:391,1335(1974)*, *R:626*; *P&J:270*, *ABI:333*.

2.8.16.2 Mäkinenite NiSe

Named in 1964 for Eero Mäkinen (1886–1953), Finnish geologist. *HEX-R R3m*. $a = 10.01$, $c = 3.28$, $Z = 9$, $D = 7.23$. $18\text{-}887$: 4.99_6 2.88_{10} 2.63_{10} 2.33_{10} 1.95_{10} 1.81_4 1.71_4 1.67_4 . Microscopic grains. Yellow, metallic luster. $H = 3$. $R = 47.4\text{-}48.8$ (540 nm); strongly pleochroic and anisotropic. Occurs with other nickel selenides in calcite veins at *Kuusamo, northeastern Finland*. *BM AM 50:519(1965)*, *R:630*, *P&J:252*, *ABI:308*.

2.8.17.1 Ruthenarsenite RuAs

Named in 1974 for the composition. Contains minor amounts of Ir, Os, Rh, Pd, and Ni. *ORTH Pnma*. $a = 5.628$, $b = 3.239$, $c = 6.184$, $Z = 4$, $D = 9.81$. $26\text{-}947$: 2.89_3 2.70_7 2.12_5 2.06_{10} 1.78_4 1.75_4 1.34_4 1.30_4 . Microscopic grains. Pale brown, metallic luster. $H = 6$, $VHN_{100} = 743\text{-}933$. $R = 47.5\text{-}49.5$ (546 nm); distinctly pleochroic and anisotropic. *Papua New Guinea*, in nuggets of rutheniridosmine; Anduo, Tibet, China; Onverwacht mine, Witwatersrand, South Africa. *BM CM 12:280(1974)*, *AM 61:177(1976)*, *ABI:452*.

2.8.17.2 Cherepanovite RhAs

Named in 1985 for Vladimir A. Cherepanov (1927–1983), Russian mineralogist. *ORTH Pnma*. $a = 5.70$, $b = 3.59$, $c = 6.00$, $Z = 4$, $D = 9.72$. $38\text{-}407$: 3.01_{10} 2.10_6 2.01_1 1.91_5 1.81_2 1.77_2 1.73_2 1.50_2 1.35_2 . Microscopic grains. Gray-white, gray-black streak, metallic luster. One distinct cleavage. $H = 6$, $VHN_{50} = 726\text{-}754$. $R = 43.6\text{-}45.5$ (540 nm); weakly pleochroic and anisotropic. *Koryak-Kamchatka ophiolite belt, Russia*. *BM ZVMO 114:464(1985)*, *AM 71:1544(1986)*, *ABI:95*.

2.8.18.1 Modderite CoAs

Named in 1924 for the locality. Contains up to 9% Fe. ORTH *Pmcm*. $a = 3.458$, $b = 5.869$, $c = 5.292$, $Z = 4$, $D = 8.28$. 9-9₄(syn): 2.59₉ 2.55₆ 2.06₅ 1.97₁₀ 1.70₅ 1.44₅ 1.21₅ 1.05₆. Microscopic grains. Black, metallic luster. $H = 4$, $VHN = 26$. *Modderfontein mine, Witwatersrand, South Africa*, in heavy-mineral concentrate; Dashkesan deposit, Azerbaijan. BM *DI:242, ZVMO 106:347 (1977), R:625, ABI:334*.

2.8.19.1 Westerveldite (Fe,Ni)As

Named in 1972 for Jan Westerveld (1905–1962), Dutch mineralogist. ORTH *Pnam*. $a = 5.436$, $b = 6.024$, $c = 3.372$, $Z = 4$, $D = 7.86$. 12-799(syn): 2.64₆ 2.59₁₀ 2.12₂ 2.08₄ 2.02₄ 2.00₆ 1.73₃ 1.69₂. Microscopic grains. Gray, metallic luster. $H = 6-7$, $VHN_{25} = 707-798$. $G = 8.13$. $R = 43.4-47.9$ (540 nm); distinctly pleochroic and anisotropic. Birchtree mine, near Thompson, MB, Canada; Ilimaussaq intrusion, near Narssaq, Greenland; *La Gallega mine, near Ojen, Malaga, Spain*; Tunaberg, Sweden; Seinäjoki, Finland. BM *AM 57:354(1972), CM 12:137(1973), P&J:389, ABI:574*.

TSUMOITE GROUP

The tsumoite group is a rhombohedral group of bismuth minerals with the general formula

where

and the mineral is isostructural with tsumoite in space group *P3m1*. The structure is similar to that of the arsenic, josëite, and tetradymite group minerals.

TSUMOITE GROUP

Mineral	Formula	Space Group	a		
			a	c	
Tsumoite	BiTe	<i>P3m1</i>	4.422	24.050	2.8.20.1
Sulphotsumoite	Bi ₃ Te ₂ S	<i>P3m1</i>	4.316	23.43	2.8.20.2
Nevskite	BiSe	<i>P3m1</i>	4.18	22.8	2.8.20.3
Ingodite	Bi ₂ TeS	<i>P3m1</i>	4.248	23.075	2.8.20.4

Note: The poorly characterized mineral platynite (2.8.21.1), (Bi,Pb)(Se,S) may belong to the group.

2.8.20.1 Tsumoite BiTe

Named in 1978 for the locality. Tsumoite group. HEX-R *P3m1*. $a = 4.422$, $c = 24.050$, $Z = 6$, $D = 8.23$. 31-200(syn): 3.23₁₀ 2.36₄ 2.21₃ 2.00₁ 1.82₂ 1.61₁

TSUMOITE: BiTe

According to the published structure, this has layers Bi-Te-Bi-Te-Bi-Te Te-Bi-Te-Bi-Te-Bi, that is, a 12-layer repeat.

1.48₁, 1.41₁. Tabular crystals. Silver-white, steel-gray streak, metallic luster. Cleavage {0001}, perfect. $H = 2-2\frac{1}{2}$, $VHN_{100} = 59$. $G = 8.16$. $R = 58.1-59.6$ (546 nm); moderately anisotropic. Sylvanite, Hidalgo Co., NM; Tunaberg, Sweden; Tyrnauz, Caucasus Mts., and Magadan region, eastern Siberia, Russia; *Tsumo mine, Shimane Pref., Japan*. BM *AM* 63:1162(1978), 76:257(1991); *ABI*:540; *EM* 5:165(1993).

2.8.20.2 Sulphotsumoite Bi₃Te₂S

Named in 1982 for its relationship to tsumoite. Tsumoite group. $HEX-R P\bar{3}m1$. $a = 4.316$, $c = 23.43$, $Z = 2$, $D = 8.03$. 38-442: 4.67₃ 3.16₁₀ 2.32₆ 2.16₅ 1.96₃ 1.78₄ 1.58₃ 1.37₄. Microscopic aggregates. Gray-white, metallic luster. Perfect basal cleavage. $H = 2$, $VHN_5 = 64-66$. $R = 53.6-57.3$ (540 nm). *Egerlyakh deposit, Yakutia*, and Magadan region, *Russia*. BM *ZVMO* 11:316(1982); *AM* 68:1250(1983), 76:257(1991); *ABI*:507.

2.8.20.3 Nevskite BiSe

Named in 1984 for the locality. Tsumoite group. $HEX-R P\bar{3}m1$. $a = 4.18$, $c = 22.8$, $Z = 6$, $D = 8.31$. 29-246(syn): 22.8₂ 4.56₁ 3.58₂ 3.06₁₀ 2.24₄ 2.09₃ 1.90₁ 1.73₂. Microscopic grains. Lead-gray, metallic luster. Perfect basal clea-

vage. $H = 2-3$, $VHN = 60-114$. $R = 50.5-55.5$ (540 nm); distinctly anisotropic. *Nevskii Sn deposit, Magadan district, Russia*. BM *ZVMO 113:351(1984)*, *AM 70:875(1985)*, *ABI:347*.

2.8.20.4 Ingodite Bi_2TeS

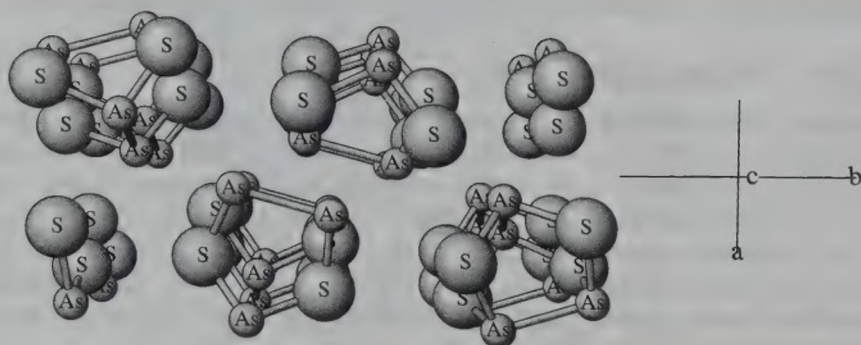

Named in 1981 for the locality. Tsumoite group. Synonym: grünlingite. *HEX-R P3m1*. $a = 4.248$, $c = 23.075$, $Z = 3$, $D = 7.98$. *41-1408*: 4.59_2 3.10_{10} 2.27_5 2.13_4 1.93_3 1.65_5 1.25_3 1.22_3 . Lamellar masses. Steel-gray, metallic luster. Perfect basal cleavage. $H = 2$, $VHN_{25} = 60$. $R = 52.4-57.8$ (540 nm); moderately pleochroic and anisotropic. Bluebird mine, Cochise Co., AZ; Brandy Gill, Cumbria, England; Baita Bihor, Romania; *Ingoda deposit, Transbaikal, Russia*. BM *ZVMO 110:594(1981)*; *AM 67:855(1982)*, *76:257(1991)*; *ABI:235*.

2.8.21.1 Platynite $(\text{Bi,Pb})(\text{Se,S})$

Named in 1910 from the Greek *to broaden*, in allusion to its platy habit. *HEX-R R3m*. $a = 8.49$, $c = 20.80$, $Z = 12$, $D = 7.45$. *ZVMO 118*: 5.45_2 3.97_{10} 3.39_2 2.97_4 2.93_2 2.60_2 2.55_2 1.98_2 . Thin plates to 3 cm and aggregates of anhedral grains. Silver-gray to steel-gray, black streak, metallic luster. Cleavage $\{0001\}$, perfect; $\{1011\}$, fair. $H = 2-3$, $VHN = 70-100$. $G = 7.98$. $R = 45-52$ (540 nm). *Falun, Sweden*; Baltic Shield, Russia. BM *DI:474*, *NJMM 154(1963)*, *ZVMO 118(3):22(1989)*, *AM 76:305(1991)*, *ABI:411*.

2.8.22.1 Realgar AsS

Named in 1747 from the Arabic for *powder of the mine*. Dimorphous with pararealgar. *MON P2₁/n*. $a = 9.324$, $b = 13.534$, $c = 6.585$, $\beta = 106.43$, $Z = 16$, $D = 3.57$. *24-77(syn)*: 6.03_4 5.73_6 5.41_{10} 3.16_8 3.05_6 2.98_5 2.93_6 2.72_7 . **Habit**: Crystals uncommon, generally short prismatic and striated parallel to c ; usually coarse to fine granular or as an incrustation. Contact twins on $\{100\}$. **Structure**: Consists of separate cagelike As_4S_4 molecules. **Physical properties**: Red to orange-yellow color and streak, resinous to greasy luster. Cleavage $\{010\}$, good; $\{101\}$, $\{100\}$, $\{120\}$ indistinct; sectile. $H = 1\frac{1}{2}-2$. $G = 3.5-3.6$. Disintegrates on long exposure to light to a red-yellow orpiment-bearing powder. **Tests**: Characteristic color and hardness; emits a garlic odor on heating. **Chemistry**: Pure AsS . **Optics**: Biaxial (-); $N_x = 2.538$, $N_y = 2.684$, $N_z = 2.704$; $2V = 40^\circ$. Pleochroic, nearly colorless to pale golden yellow. **Occurrence**: As a minor constituent in hydrothermal sulfide veins with orpiment and other As minerals; also sporadically in limestones, dolostones, and claystones, and as a sublimate in fumaroles. **Localities**: Only the more significant are listed. Norris Basin, Yellowstone, WY; Mercur(*), Tooele Co., UT; Getchell mine(*), Humboldt Co., and White Caps mine(*), Nye Co., NV; Franklin(*), King Co., and Monte Cristo(*), Snohomish Co., WA; Boron, Kern Co., CA; Noche Buena, ZAC, Mexico; Matra, Corsica, France; Andreasberg, Harz, and Freiberg, Saxony, Germany; Lengenbach, Binn, Switzerland; Baia Sprie, Cavnic(*), and Sacaramb(*), Romania; Allchar(*), Macedonia;

REALGAR: AsS

Each As is bonded to one other As and two S atoms, and each S to two As atoms, forming As_4S_4 molecular cages. This view shows one layer of the molecules.

Shimen(*), Hunan, China; Nishinomaki mine, Gumma Pref., Japan. BM *DI:255*, *AC 5:775(1952)*, *R:889*, *P&J:324*, *ABI:436*.

2.8.22.2 Pararealgar AsS

Named in 1980 for its relationship to realgar. MON $P2_1/c$. $a = 9.909$, $b = 9.655$, $c = 8.502$, $\beta = 97.29^\circ$, $Z = 16$, $D = 3.50$. *33-127*: 5.56₉ 5.14₁₀ 4.90₃ 3.75₈ 3.30₅ 3.11₄ 3.03₅ 2.80₇. Powdery to granular aggregates. Yellow to orange-brown, bright yellow streak, vitreous to resinous luster. No cleavage, uneven fracture. $H = 1-1\frac{1}{2}$. $G = 3.52$. $N > 2.02$. Golconda mine, Humboldt Co., NV; Hemlo Au deposit, near Marathon, ON, and *Mt. Washington* and *Gray Rock*, BC, Canada; Lengenbach, Binn, Switzerland. Probably occurs with realgar at other localities. BM *CM 18:525(1980)*; *AM 66:1277(1981)*, *80:400(1985)*; *ABI:387*.

2.8.22.3 Uzonite As₄S₅

Named in 1985 for the locality. MON $P2_1/m$. $a = 7.94$, $b = 8.08$, $c = 7.10$, $\beta = 100.1^\circ$, $Z = 2$, $D = 3.41$. *39-331*: 5.81₁₀ 5.31₆ 3.60₈ 3.10₆ 2.91₈ 2.82₆ 2.75₅ 2.03₅. Microscopic prismatic crystals. Yellow, pearly luster. Cleavage {001}, distinct. $H = 1\frac{1}{2}$, $VHN_8 = 66-71$. $R = 19.4-20.0$ (550 nm). *Uzon caldera*, Kamchatka, Russia. BM *ZVMO 114:369(1985)*, *AM 71:1280(1986)*, *ABI:553*.

2.8.22.4 Alacranite As₈S₉

Named in 1986 for the locality. MON $C2/c$. $a = 9.92$, $b = 9.48$, $c = 8.91$, $\beta = 100.83^\circ$, $Z = 2$, $D = 3.46$. *25-57*: 5.75₈ 5.01₄ 3.93₇ 3.20₈ 3.08₇ 3.01₁₀ 2.82₆ 2.53₃. Microscopic prismatic crystals. Orange-yellow, orange-yellow streak, greasy or adamantine luster. Cleavage {100}, imperfect; conchoidal fracture. $H = 1\frac{1}{2}$, $VHN_{20} = 69$. $G = 3.43$. $R = 13.2-14.5$ (550 nm). Biaxial (+);

$N_x = 2.39$, $N_z = 2.52$. Uzon caldera, Kamchatka, Russia; *Mina Alacran, Chile*. BM *ZVMO* 115:360(1986); *AM* 55:1338(1970), 73:189(1988); *ABI*:6.

2.8.23.1 Herzenbergite SnS

Named in 1934 for Robert Herzenberg (b.1885), German chemist. ORTH *Pbnm*. $a = 4.328$, $b = 11.190$, $c = 3.978$, $Z = 4$, $D = 5.20$. *14-620*(syn): 3.42₁ 3.24₂ 2.83₃ 2.79₁₀ 2.31₂ 2.02₁ 1.99₁ 1.40₇. Fine-grained aggregates. Black, black streak, metallic luster. Cleavage {001}. $H = 2$. $G = 5.16$. $R = 43.2-49.9$ (540 nm); strongly anisotropic. Järkvissle, Västernorrland, Sweden; Golub deposit, Primorskiy Krai, Russia; Hoi Sn mine, Oita Pref., Japan; Stiepelmann mine, near Arandis, Namibia; *Maria-Teresa mine, Huari, Bolivia*. BM *DI*:259, *R*:669, *P&J*:405, *ABI*:215.

2.8.24.1 Empressite AgTe

Named in 1914 for the locality. ORTH Space group uncertain, probably *Pmnm*. $a = 8.90$, $b = 20.07$, $c = 4.62$, $Z = 16$, $D = 7.58$. *16-412*: 4.02₄ 3.81₆ 3.33₆ 3.18₅ 2.70₁₀ 2.23₈ 2.14₅ 2.04₅. Granular and compact masses. Pale bronze, gray-black to black streak, metallic luster. No cleavage, uneven to subconchoidal fracture, brittle. $H = 3\frac{1}{2}$, $VHN_{25} = 139$. $G = 7.5-7.6$. *Empress Josephine mine, Saguache Co.*, and *Red Cloud mine, Boulder Co., CO*; *Tombstone, AZ*; *Grotto deposit, near Pitman, BC, Canada*; *Kochbulak deposit, Uzbekistan*; *Kawazu mine, Shizuoka Pref., Japan*; *Emperor mine, Vatakuola, Fiji*; *Kalgoorlie, WA, Australia*. BM *DI*:260, *AM* 49:325(1964), *R*:425, *ABI*:146.

2.8.25.1 Muthmannite (Ag,Au)Te

Named in 1911 for Friedrich W. Muthmann (1861-1913), German chemist and crystallographer. ORTH Space group unknown. $a = 7.211$, $b = 4.425$, $c = 5.100$, $Z = 4$, $D = 11.43$. *42-1377*: 5.09₂ 3.03₁₀ 2.94₅ 2.11₈ 1.95₃ 1.70₃ 1.32₃ 1.04₃. Tabular crystals. Brass-yellow, gray-white on fresh fracture, metallic luster. Perfect cleavage in zone of elongation. $H = 2\frac{1}{2}$. *Sacaramb, Romania*. BM *DI*:260, *ABI*:343.

CHALCOPYRITE GROUP

The chalcopyrite minerals are isostructural sulfides and selenides with the formula

where

B = Fe, Ga, In

X = S, Se

and the structure is related to that of sphalerite, with a doubled c spacing.

CHALCOPYRITE: CuFeS_2

The chalcopyrite structure can be derived from that of sphalerite by replacing alternate Zn atoms with Cu and Fe.

CHALCOPYRITE GROUP

Mineral	Formula	Space Group	a	c	D	
Chalcopyrite	CuFeS_2	$\bar{I}42d$	5.289	10.423	4.18	2.9.1.1
Eskebornite	CuFeSe_2	$\bar{I}42d$	5.518	11.048	5.45	2.9.1.2
Gallite	CuGaS_2	$\bar{I}42d$	5.351	10.484	4.37	2.9.1.3
Roquesite	CuInS_2	$\bar{I}42d$	5.523	11.141	4.74	2.9.1.4

Notes:

1. See also the chalcocite group for a discussion of other copper sulfides.
2. The stannite group minerals have essentially the same structure, adjusted for a greater diversity of elements.

2.9.1.1 Chalcopyrite CuFeS_2

Named in 1747 from the Greek for *brass and pyrite*. Chalcopyrite group. TET $\bar{I}42d$. $a = 5.289$, $c = 10.423$, $Z = 4$, $D = 4.18$. $35-75\%$: 3.04_{10} 2.64_1 1.87_2 1.86_4 1.59_3 1.57_1 1.21_1 1.08_1 . **Habit:** Equant tetrahedral crystals often modified by scalenohedral faces, up to 10 cm; often massive, compact. Twinned on $\{112\}$ and $\{012\}$, penetration or cyclic. **Structure:** The structure is very similar to that of sphalerite. The ordered distribution of Cu and Fe atoms results in a tetragonal unit cell with c double the pseudocube edge. **Physical properties:** Brass-yellow, often with an iridescent tarnish, green-black streak, metallic luster. Cleavage $\{011\}$, sometimes distinct; uneven fracture, brittle. $H = 3\frac{1}{2}-4$, $VHN_{100} = 187-203$. $G = 4.1-4.3$. **Tests:** On charcoal fuses to a magnetic globule. Soluble in HNO_3 with separation of S, and gives a green solution. **Chemistry:** Usually pure CuFeS_2 , but Se may replace S to a minor extent. **Optics:** $R = 35.1-36.4$ (540 nm); weakly anisotropic. **Occurrence:** The most widespread copper mineral and the most important source of that metal,

formed under a great variety of conditions. It is a primary mineral in hydrothermal veins, disseminations, and massive replacements. It is the primary mineral in most porphyry-copper deposits. It is often associated with large masses of pyrite. **Localities:** Only a few outstanding localities can be mentioned. French Creek, Chester Co., PA; Tri-State mining district, MO-KS-OK; Idaho Springs, Clear Creek Co., CO; Santa Rita and Bayard, Grant Co., NM; Bisbee, Tombstone, Globe-Miami, and Clifton-Morenci, AZ; Darwin mines, Inyo Co., and many other localities in CA; Noranda mine, Rouyn district, PQ, and Sudbury and Kidd Creek, ON, Canada; Cananea, SON, and Concepcion del Oro, ZAC, Mexico; Redruth, Carn Brea, Liskeard, and other localities in Cornwall, England; Falun, Sweden; Outokumpu, Finland; Siegen and Neunkirchen, Westphalia, Germany; Bourg d'Oisans, Isere, France; Rio Tinto, Spain; Cavnic, Herja, and Baia Sprie, Romania; near Chenzu, Hunan, China; Ani mine, Akita, and Ashio mine, Taguchi, Japan; Nababiep mine, Cape Prov., and Messina, Transvaal, South Africa; Cobar, NSW, Moonta, SA, and Mt. Lyell, TAS, Australia; Casapalca, Peru; Braden mine, Chile. *BM DI:219, AC(B) 29:579(1973), R:526, P&J:118, ABI:89.*

2.9.1.2 Eskebornite CuFeSe_2

Named in 1949 for the locality. Chalcopyrite group. *TET I42d*. $a = 5.518$, $c = 11.048$, $Z = 4$, $D = 5.45$. $14\text{-}312$: 5.53_8 3.19_9 2.48_6 1.96_{10} 1.67_8 1.39_5 1.27_5 1.13_6 . Microscopic tabular crystals. Brass-yellow, tarnishing to dark brown to black, metallic luster. Cleavage $\{001\}$, perfect. $H = 3\text{-}3\frac{1}{2}$, $\text{VHN}_{100} = 116$. $G = 5.35$. $R = 29.4\text{-}35.0$ (540 nm); markedly anisotropic. Martin Lake mine, Lake Athabaska, SK, Canada; *Eskeborn adit, Tilkerode, Harz, Germany*; Chameane, Puy-de-Dome, France; Nove Mesto, Moravia, Czech Republic; Habri, Peru; Sierra de Cachueta and Sierra de Umango, Argentina. *BM FM 28:69(1949), CM 10:786(1971), R:612, P&J:156, NJMM:337(1988).*

2.9.1.3 Gallite CuGaS_2

Named in 1958, the first gallium mineral. Chalcopyrite group. *TET I42d*. $a = 5.351$, $c = 10.484$, $Z = 4$, $D = 4.37$. $25\text{-}279(\text{syn})$: 3.06_{10} 1.89_5 1.87_8 1.61_6 1.34_2 1.23_2 1.22_3 . Microscopic grains and exsolution lamellae. Gray, gray streak, metallic luster. $H = 3\text{-}3\frac{1}{2}$. $G = 4.2$. $R = 19.2$ (540 nm); weakly anisotropic. Pinal del Rio Prov., Cuba; Radka and Chelopech deposits, Bulgaria; Prince Leopold mine, Kipushi, Zaire; *Tsumeb, Namibia*. *BM NJMM: 241(1958), R:542, P&J:173, ABI:173.*

2.9.1.4 Roquesite CuInS_2

Named in 1963 for Maurice Roques (b.1911), French geologist. Chalcopyrite group. *TET I42d*. $a = 5.523$, $c = 11.141$, $Z = 4$, $D = 4.74$. $27\text{-}159(\text{syn})$: 4.95_1 3.20_{10} 2.79_1 2.76_1 1.96_3 1.95_1 1.68_1 1.67_1 . Microscopic grains. Gray with a bluish tint, metallic luster. $H = 4$, $\text{VHN}_{100} = 241$. $R = 22.2\text{-}22.5$ (540 nm); very weakly anisotropic. Mt. Pleasant, NB, Canada; Geevor mine, Penzance,

Cornwall, England; Langban, Värmland, Sweden; *Charrier, Allier, France*; Syrymbet, Kazakhstan; Tosham Sn prospect, Haryana, India; Akenobe and Ikuno mines, Hyogo Pref., Japan; Ulsan mine, Korea. *BM BM 86:7(1963)*, *AM 54:1202(1969)*, *R:544*, *P&J:329*, *ABI:445*.

2.9.1.5 Llenaite AgFeS_2

Named in 1995 for the locality. TET Space group uncertain, probably $P4_2mc$. $a = 5.64$, $c = 10.34$, $Z = 4$, $D = 4.63$. *ZVMO 124*: 3.43₁ 3.15₁₀ 2.82₁ 2.59₁ 2.45₂ 2.34₂ 1.91₄ 1.69₂. Microscopic granular aggregates. Creamy color in reflected light. $H = 4\frac{1}{2}$, $VHN = 310$. $R = 32-36$ (546 nm); moderately anisotropic. *Khachakchansky Ag deposit, Lena R., Russia. BM ZVMO 124(5):85(1995)*.

STANNITE GROUP

The stannite group includes tetragonal sulfides with the general formula

where

A = Cu, Ag

B = Fe, Cd, Cu, Zn, Hg

C = Sn, Ge, In

and the structure is essentially identical with that of chalcopyrite.

STANNITE GROUP

Mineral	Formula	Space Group	a	c	
Stannite	$\text{Cu}_2\text{FeSnS}_4$	$I42m$	5.453	10.747	2.9.2.1
Cernyite	$\text{Cu}_2\text{CdSnS}_4$	$I42m$	5.487	10.845	2.9.2.2
Briartite	$\text{Cu}_2\text{FeGeS}_4$	$I42m$	5.325	10.53	2.9.2.3
Kuramite	$\text{Cu}_2\text{CuSnS}_4$	$I42m$	5.542	10.908	2.9.2.4
Sakuraiite	$\text{Cu}_2\text{CuInS}_4$	$I42m$	5.455	10.9	2.9.2.5
Hocartite	$\text{Ag}_2\text{FeSnS}_4$	$I42m$	5.74	10.96	2.9.2.6
Pirquitasite	$\text{Ag}_2\text{ZnSnS}_4$	$I42m$	5.786	10.829	2.9.2.7
Velikite	$\text{Cu}_2\text{HgSnS}_4$	$I42m$	5.554	10.911	2.9.2.8
Kesterite	$\text{Cu}_2\text{ZnSnS}_4$	$I\bar{4}$	5.44	10.88	2.9.2.9
Ferrokesterite	$\text{Cu}_2(\text{Fe,Zn})\text{SnS}_4$	$I4$	5.427	10.871	2.9.2.10

2.9.2.1 Stannite $\text{Cu}_2\text{FeSnS}_4$

Named in 1832 from the Latin for *tin*. Stannite group. May contain up to 2% In and Zn. TET $I42m$. $a = 5.453$, $c = 10.747$, $Z = 2$, $D = 4.47$. *35-582*: 3.13₁₀ 2.73₈ 1.93₃ 1.91₃ 1.64₂ 1.63₁ 1.24₁ 1.11₁. Rarely as pseudo-octahedral crystals, usually massive. Steel-gray to iron-black, black streak, metallic luster. Clea-

vage {110} and {001}, indistinct; uneven fracture. $H = 4$, $VHN_{25} = 216-265$. $G = 4.3-4.5$. $R = 27.4-28.6$ (540 nm); distinctly anisotropic. Occurs widely in tin-bearing veins of hydrothermal origin; an important ore mineral in some deposits. Etta mine, Keystone, SD; Lost River, Seward Penin., AK; Brunswick tin mines, NB, and Snowflake mine, BC, Canada; *Wheal Rock mine* and other mines, *Cornwall, England*; Kutna Hora, Czech Republic; Norilsk, Russia; Chenzhou, Hunan, China; Zeehan, TAS, Australia; Llallagua, Potosi, and other mines, Bolivia. BM *DI:224*, *CM 17:125(1979)*, *R:548*, *P&J:349*, *ABI:490*.

2.9.2.2 Černýite Cu_2CdSnS_4

Named in 1978 for Petr Černý (b.1934), Czech-Canadian mineralogist. Stannite group. TET $I42m$. $a = 5.487$, $c = 10.845$, $Z = 2$, $D = 4.95$. $29-537$: 5.39_3 3.15_{10} 2.73_3 1.94_5 1.93_5 1.65_4 1.64_4 1.12_5 . Microscopic grains. Steel-gray, black streak, metallic luster. $H = 4$, $VHN_{50} = 189-210$. $R = 23.4-25.6$ (546 nm); weakly anisotropic. *Hugo mine, Keystone, SD*; Tanco mine, MB, Canada. BM *CM 16:139*, *147(1978)*, *AM 64:653(1979)*, *ABI:85*.

2.9.2.3 Briartite Cu_2FeGeS_4

Named in 1965 for Gaston Briart, who studied the Kipushi deposit. Stannite group. Some of the Fe is replaced by Zn, and the Ge by Ga. TET $I42m$. $a = 5.325$, $c = 10.53$, $Z = 2$, $D = 4.27$. $25-282$: 3.06_{10} 2.66_8 2.63_4 1.88_{10} 1.87_{10} 1.60_{10} 1.59_5 1.53_4 . Microscopic grains. Gray, metallic luster. $H = 4$. $R = 27.6$ (540 nm); weakly anisotropic. *Prince Leopold mine, Kipushi, Zaire*; Tsumeb, Namibia. BM *BM 88:432(1965)*, *AM 51:1816(1966)*, *R:575*, *P&J:108*, *ABI:71*.

2.9.2.4 Kuramite Cu_2CuSnS_4

Named in 1979 for the locality. Stannite group. TET $I42m$. $a = 5.542$, $c = 10.908$, $Z = 2$, $D = 4.56$. $30-494$: 3.13_{10} 2.70_2 2.44_1 1.91_8 1.64_6 1.24_3 1.11_4 1.04_2 . Microscopic grains. Gray, metallic luster. $H = 4\frac{1}{2}$, $VHN_{100} = 353$. $R = 26.5$ (540 nm); distinctly anisotropic. Bisbee, AZ; *Kuramin Mts., Uzbekistan*, in gold-sulfide-quartz ores. BM *ZVMO 108:564(1979)*, *AM 65:1067(1980)*, *ABI:280*.

2.9.2.5 Sakuraiite Cu_2CuInS_4

Named in 1965 for Kin-ichi Sakurai (1912-1993), Japanese mineral collector. Stannite group. Contains Zn, Fe, Ag replacing Cu, and Sn replacing In. TET $I42m$. $a = 5.455$, $c = 10.9$, $Z = 2$, $D = 4.45$. $21-882$: 5.47_1 3.85_1 3.15_{10} 2.73_1 2.44_1 1.93_4 1.65_2 1.57_1 . Microscopic grains. Steel-gray, lead-gray streak, metallic luster. No cleavage. $H = 4$, $VHN_{100} = 243-282$. $R = 22.7$ (540 nm). *Ikuno mine, Hyogo Pref., Japan*. BM *AM 52:1421(1968)*, *73:934(1988)*; *ABI:459*.

2.9.2.6 Hocartite $\text{Ag}_2\text{FeSnS}_4$

Named in 1968 for Raymond Hocart (1896–1983), French mineralogist. Stannite group. Contains up to 7% Zn replacing Fe. TET $I42m$. $a = 5.74$, $c = 10.96$, $Z = 2$, $D = 4.77$. $21-1337$: 5.08₂ 3.26₁₀ 2.87₄ 2.74₃ 2.03₅ 1.98₈ 1.72₇ 1.67₃. Microscopic grains. Yellow-brown, metallic luster. $H = 4$, $\text{VHN}_{100} = 209-221$. $R = 24.5-25.4$ (540 nm); distinctly anisotropic. Dean mine, Lander Co., NV; Bisbee, AZ; *Fournial, Cantal, France*; *Tacama tin mine*, and *Hocaya and Chocaya tin mines, Bolivia*; Pirquitas deposit, Jujuy, Argentina. BM *BM 91:383(1968)*, *AM 54:573(1969)*, *R:548*, *P&J:202*, *ABI:220*.

2.9.2.7 Pirquitasite $\text{Ag}_2\text{ZnSnS}_4$

Named in 1982 for the locality. Stannite group. TET $I42m$. $a = 5.786$, $c = 10.829$, $Z = 2$, $D = 4.82$. $35-544$: 3.27₁₀ 2.90₄ 2.72₃ 2.05₆ 1.98₈ 1.74₈ 1.29₄ 1.17₄. Microscopic anhedral grains, polysynthetically twinned. Gray-brown, metallic luster. $H = 4$, $\text{VHN}_{25} = 218$. $R = 22.2-24.1$ (540 nm); strongly anisotropic, brick-red to pale green. *Pirquitas deposit, Jujuy Prov., Argentina*. BM *BM 105:229(1982)*, *P&J:408*, *AM 68:1249(1983)*.

2.9.2.8 Velikite $\text{Cu}_2\text{HgSnS}_4$

Named in 1977 for A. S. Velikiy (1913–1970), Russian geologist. Stannite group. TET $I42m$. $a = 5.554$, $c = 10.911$, $Z = 2$, $D = 5.42$. $30-494$: 3.92₁ 3.18₁₀ 2.77₁ 2.47₁ 1.96₂ 1.94₃ 1.67₂ 1.65₁. Microscopic grains. Dark gray, gray streak, metallic luster. $\text{VHN} = 215-305$. $G = 5.59$. $R = 26.4$ (540 nm); distinctly anisotropic. Bisbee, AZ; *Khaidarkan Sb-Hg deposit, Kyrgyzstan*. BM *DANS 300:432(1988)*, *AM 75:933(1990)*.

2.9.2.9 Kesterite $\text{Cu}_2\text{ZnSnS}_4$

Named in 1958 for the locality. Stannite group. TET $I4$. $a = 5.44$, $c = 10.88$, $Z = 2$, $D = 4.50$. $21-883$: 4.85₂ 3.15₁₀ 2.73₃ 1.93₇ 1.65₅ 1.25₃ 1.11₄ 1.05₃. Massive. Green-black, black streak, metallic luster. $H = 4\frac{1}{2}$, $\text{VHN}_{100} = 328-348$. $G = 4.5-4.6$. $R = 23.4-24.3$ (540 nm). Hugo mine, Custer Co., SD; Bisbee, AZ; Brunswick tin mine, NB, Kidd Creek mine, Timmins, ONT, Snowflake mine, Revelstoke, BC, Canada; St. Michael's Mount and Cligga mine, Cornwall, England; Chizeuil, Saone-et-Loire, France; Kirki, Thrace, Greece; *Kester deposit, Yakutia, Russia*; Oruru, Bolivia; Pirquitas deposit, Jujuy, Argentina. BM *ZVMO 88:165(1958)*, *AM 44:1329(1959)*, *R:560*, *P&J:226*, *ABI:261*.

2.9.2.10 Ferrokesterite $\text{Cu}_2(\text{Fe,Zn})\text{SnS}_4$

Named in 1989 for its relationship to kesterite. Stannite group. TET $I4$. $a = 5.427$, $c = 10.871$, $Z = 2$, $D = 4.51$. $31-463$: 4.86₁ 3.13₁₀ 2.71₁ 1.92₅ 1.64₃ 1.25₁ 1.11₁ 1.04₁. Massive. Steel-gray, black streak, metallic luster. Cleavage {110}, distinct. $H = 4$, $\text{VHN}_{100} = 228-255$. $R = 26.0-27.0$ (546 nm). *Cligga mine, Cornwall, England*. BM *CM 27:673(1989)*.

2.9.3.1 Mawsonite $\text{Cu}_6\text{Fe}_2\text{SnS}_8$

Named in 1965 for Douglas Mawson (1882–1958), Australian geologist and Antarctic explorer. May contain minor Zn, Ge, As, and Se. TET $P4m2$. $a = 7.603$, $c = 5.358$, $Z = 1$, $D = 4.65$. $30\text{--}486$: 5.38_1 4.38_1 3.10_{10} 2.87_1 2.69_1 1.90_6 1.62_2 1.10_1 . Microscopic grains. Bronze, metallic luster. $H = 3\frac{1}{2}$. $R = 20.6\text{--}23.0$ (540 nm); strongly pleochroic and anisotropic. Magnetic. Usually occurs in association with bornite. Bisbee, AZ; Kidd Creek mine, Timmins, ON, and Maggie Cu deposit, BC, Canada; Chizeuil, Saone-et-Loire, France; Neves-Corvo, Portugal; Khayragatsch deposit, Kuramin Mts., Uzbekistan; Akenobe, Tada, and Ikuno mines, Hyogo Pref., and other localities in Japan; *Mt. Lyell, TAS, and Tingha, NSW, Australia*; Cholquijirca, Peru; Vila Apacheta, Bolivia; Tsumeb, Namibia, Kipushi, Shaba, Zaire. BM *AM 50:900(1965)*, *CM 17:125(1979)*, *R:575*, *P&J:262*, *ABI:319*.

2.9.3.2 Chatkalite $\text{Cu}_6\text{FeSn}_2\text{S}_8$

Named in 1981 for the locality. TET $P4m2$. $a = 7.61$, $c = 5.373$, $Z = 1$, $D = 4.97$. $35\text{--}683$: 3.11_8 2.87_3 2.70_2 2.55_2 1.90_{10} 1.63_4 1.57_4 1.06_3 . Microscopic grains. Pale rose, metallic luster. $H = 4$, $\text{VHN}_{20} = 274$. $R = 27.2\text{--}27.6$ (540 nm); weakly anisotropic. Cove Au deposit, Lander Co., NV; *Chatkalokuramin Mts., Uzbekistan*. BM *MZ 3:79(1981)*, *AM 67:621(1982)*, *ABI:94*.

2.9.3.3 Stannoidite $\text{Cu}_8\text{Fe}_3\text{Sn}_2\text{S}_{12}$

Named in 1969 for its similarity to stannite. Contains up to 4% Zn. ORTH $I222$. $a = 10.76$, $b = 5.40$, $c = 16.09$, $Z = 2$, $D = 4.29$. $22\text{--}237$: 5.4_1 4.83_1 4.13_1 3.11_{10} 2.70_2 2.39_1 1.91_7 1.62_2 . Massive. Brass-brown, dark brown-gray streak, metallic luster. Subconchoidal to uneven fracture. $H = 4$, $\text{VHN}_{100} = 258$. $R = 23.4\text{--}25.2$ (540 nm); strongly anisotropic, orange-red to yellow-gray. Campbell mine, Bisbee, AZ; Maggie deposit, BC, Canada; St. Michael's Mount, Cornwall, England; Langban, Värmland, Sweden; Vaultry, Haute-Vienne, and Chizeuil, Saone-et-Loire, France; Chelopech, Bulgaria; Maikan deposit, Kazakhstan; *Konjo mine, Okayama Pref.*, and other localities in Japan; Tingha, NSW, Australia; Colquijirca, Peru; Vila Apacheta, Bolivia. BM *AM 54:1495(1969)*, *R:562*, *P&J:350*, *ABI:491*.

2.9.4.1 Renierite $\text{Cu}_{11}\text{GeAsFe}_4\text{S}_{16}$

Named in 1948 for Armand Renier (1876–1951), Belgian geologist. May contain up to 4% Zn and 2% Ga. TET $P4_2m$. $a = 10.622$, $c = 10.551$, $Z = 2$, $D = 4.40$. $9\text{--}424$: 7.50_1 4.31_2 3.06_{10} 2.82_1 2.65_3 1.87_8 1.60_6 1.21_3 . Microscopic equant crystals and granular aggregates. Bronze, black streak, metallic luster. $H = 3\frac{1}{2}$, $\text{VHN}_{100} = 328$. $G = 4.38$. Moderately magnetic. $R = 24.3\text{--}25.7$ (540 nm); strongly pleochroic and anisotropic. Originally known as "orange bornite" because of its similarity to that mineral. Inexo No. 1 mine, Jamestown, CO; Ruby Creek deposit, Brooks Range, AK; Pinar del Rio, Cuba; San Giovanni mine, Sardinia, Italy; Celopech and Radka deposits, Bulgaria; Akhtala, Armenia; Vaygach, Arkhangelsk, Russia; Shakanai mine,

Akita Pref., Japan; *Prince Leopold mine, Kipushi, Zaire*; Tsumeb, Namibia. BM *AM* 35:136(1950), 71:210(1986); *R*:574; *P&J*:325; *ABI*:438.

2.9.4.2 Germanite $\text{Cu}_{26}\text{Ge}_4\text{Fe}_4\text{S}_{32}$

Named in 1922 for the germanium content. May contain minor amounts of Zn, As, and Ga. iso *P43n*. $a = 10.586$, $Z = 1$, $D = 4.47$. 36-395: 3.05₁₀ 2.65₁ 1.87₇ 1.60₄ 1.32₁ 1.21₂ 1.08₂ 1.02₁. Minute cubic crystals rare, usually massive. Reddish gray, tarnishing to dull brown, dark gray to black streak, metallic luster. No cleavage, brittle. $H = 4$. $G = 4.4-4.6$. $R = 20.6$ (540 nm). A primary source of germanium. Inexco No. 1 mine, Jamestown, CO; Ruby Creek deposit, Brooks Range, AK; Pinar del Rio, Cuba; Bancairoun mine, Alpes-Maritimes, France; Radka deposit, Bulgaria; Vaygach, Archangelsk, and Norilsk, Urals, Russia; Shakanai mine, Akita Pref., Japan; Tsumeb, Namibia. BM *DI*:385, *EG* 52:612(1954), *R*:572, *P&J*:177, *AM* 69:943(1984), *ABI*:179.

2.9.5.1 Morozeviczite $(\text{Pb,Fe})_3\text{Ge}_{1-x}\text{S}_4$

Named in 1975 for Josef Morozevicz (1865-1941), Polish mineralogist. Forms a series with polkovicite. iso. $a = 10.61$, $Z = 8$, $D = 6.62$. 44-1466: 3.08₁₀ 2.80₆ 2.15₉ 2.05₆ 1.79₅ 1.57₅ 1.47₅ 1.11₅. Massive. Brown-gray, dark gray streak, metallic luster. $H = 3$, $\text{VHN}_{50} = 119-124$. $R = 43.0-44.0$ (535 nm). *Polkovicite mine, Silesia, Poland*. BM *AM* 66:437(1981), *ABI*:340.

2.9.5.2 Polkovicite $(\text{Fe,Pb})_3(\text{Ge,Fe})_{1-x}\text{S}_4$

Named in 1975 for the locality. Forms a series with morozeviczite. iso Space group unknown. $a = 10.61$, $Z = 8$. 39-410: 3.56₉ 3.47₁₀ 3.08₁₀ 2.18₁₀ 2.15₉ 1.83₇ 1.67₇ 1.39₇. Massive. Brown-gray, dark gray streak, metallic luster. $H = 3$, $\text{VHN}_{50} = 119-124$. $R = 43.0-44.0$ (535 nm); distinctly anisotropic. *Polkovicite mine, Silesia, Poland*. BM *AM* 66:437(1981), *ABI*:416.

2.9.6.1 Hemusite $\text{Cu}_6\text{SnMoS}_8$

Named in 1965 after an ancient name for the Balkan Mts. iso Space group unknown. $a = 10.82$, $Z = 4$, $D = 4.47$. 25-300: 3.61₂ 3.11₁₀ 2.87₂ 2.55₂ 2.09₂ 1.92₅ 1.86₃ 1.63₃. Microscopic grains and aggregates. Gray, metallic luster. $H = 4$, $\text{VHN}_{25} = 166$. $R = 24.2$ (589 nm). *Chelopech, Bulgaria*; Kochbulak deposit, Uzbekistan. BM *AM* 56:1847(1971), *ABI*:213.

2.9.6.2 Kiddcreekite Cu_6SnWS_8

Named in 1984 for the locality. iso Space group unknown. $a = 10.856$, $Z = 4$, $D = 4.88$. 37-427: 6.29₁₀ 5.41₃ 3.27₃ 3.14₅ 2.71₂ 2.49₂ 1.92₆ 1.84₃. Microscopic grains. Gray, metallic luster. $H = 3\frac{1}{2}$, $\text{VHN}_{100} = 183$. $R = 22.5$ (540 nm). Campbell mine, Bisbee, AZ; Kidd Creek mine, near Timmins, ON, Canada. BM *CM* 22:227(1984), *AM* 70:437(1985), *ABI*:264.

2.9.7.1 Putoranite $\text{Cu}_{11}\text{Fe}_{12}\text{S}_2$

Named in 1980 for Putoran Mts., Siberia. iso $Pn\bar{3}m$. $a = 5.30$, $Z = 2$, $D = 6.14$. d_{1-1404} : 3.05_{10} 2.65_2 1.87_9 1.60_6 1.33_2 1.22_3 1.08_5 1.02_2 . Single crystals rare, usually as coarse-grained aggregates. Yellow, metallic luster. Polysynthetically twinned. $H = 4$, $\text{VHN}_{50} = 263$. $R = 38.0$ (540 nm). *Oktjabr mine, Talnakh, Norilsk, Russia*. BM *ZVMO 109:335(1980)*, *AM 66:638(1981)*, *ABI:424*.

2.9.8.1 Talnakhite $\text{Cu}_9\text{Fe}_8\text{S}_{16}$

Named in 1968 for the locality. Contains up to 1% Ni. iso $I\bar{4}3m$. $a = 10.591$, $Z = 2$, $D = 4.83$. d_{25-287} : 3.75_4 3.06_{10} 2.64_5 1.87_9 1.60_7 1.21_5 1.08_6 1.02_5 . Microscopic laths. Brass-yellow, metallic luster. $\text{VHN}_{50} = 261-277$. $G = 4.29$. $R = 39.4$ (540 nm). Stillwater Complex, Sweetwater Co., MT; Strachimir, Bulgaria; Filizchai deposit, Azerbaijan; *Talnakh, Norilsk, Russia*. BM *ZVMO 97:63(1968)*, *AM 57:380(1972)*, *P&J:360*, *ABI:512*.

2.9.8.2 Haycockite $\text{Cu}_4\text{Fe}_3\text{S}_8$

Named in 1972 for Maurice H. Haycock (b.1900), Canadian mineralogist. ORTH $P222$. $a = 10.71$, $b = 10.71$, $c = 31.56$, $Z = 12$, $D = 4.35$. d_{25-289} : 3.07_{10} 2.67_4 1.89_6 1.88_8 1.61_6 1.59_4 1.21_5 1.09_6 . Microscopic grains. Brass-yellow, metallic luster. $H = 4$, $\text{VHN}_{100} = 206-231$. $R = 33.3-34.5$ (540 nm); moderately anisotropic. Duluth Gabbro Complex, MN; near Madera, SON, Mexico; Krzemianka, Poland; *Talnakh, Norilsk, Russia*; *Mooihoek Farm, Lydenburg, Transvaal, South Africa*. BM *AM 57:689(1972)*, *AC(B) 31:2105(1975)*, *ABI:209*.

2.9.8.3 Mooihoekite $\text{Cu}_9\text{Fe}_9\text{S}_{16}$

Named in 1972 for the locality. TET $P\bar{4}2m$. $a = 10.585$, $c = 5.383$, $Z = 1$, $D = 4.37$. $d_{25-286(\text{syn})}$: 3.77_3 3.07_{10} 1.89_8 1.87_4 1.60_6 1.32_4 1.22_5 1.08_6 . Microscopic grains. Brass-yellow, metallic luster. $H = 4$, $\text{VHN}_{100} = 240-246$. $G = 4.36$. $R = 35.2$ (540 nm). Duluth Gabbro Complex, MN; *Talnakh, Norilsk, Russia*; *Mooihoek Farm, Lydenburg, Transvaal South Africa*. BM *AM 57:689(1972)*, *CM 16:23(1978)*, *ABI:339*.

2.9.9.1 Ragunitite TlFeS_2

Named in 1969 for Eugene Raguin (b.1900), French geologist. ORTH Space group unknown. $a = 12.40$, $b = 10.44$, $c = 5.26$, $Z = 8$, $D = 6.33$. $d_{22-1468}$: 4.70_2 4.17_6 3.35_6 2.89_{10} 2.83_2 2.64_4 2.35_3 2.07_1 . Microscopic pseudo-hexagonal plates. Bronze, metallic luster. $G = 6.4$. $R = 25.4-32.1$ (540 nm); strongly pleochroic and anisotropic. *Allchar, Macedonia*. BM *BM 92:38,237(1969)*, *AM 54:1495,1741(1969)*, *R:562*, *P&J:319*, *ABI:430*.

2.9.10.1 Teallite $PbSnS_2$

Named in 1904 for Jethro J. H. Teall (1849–1924), director of the Geological Survey of Great Britain. ORTH *Pbnm*. $a = 4.258$, $b = 11.447$, $c = 4.103$, $Z = 2$, $D = 6.48$. *14-189*: 3.41₆ 3.27₄ 2.84₁₀ 2.33₄ 2.03₄ 1.80₃ 1.42₅ 1.09₄. Thin tabular crystals, usually massive aggregates of thin foliae. Black, black streak, metallic luster. Cleavage {001}, perfect; flexible; inelastic. $H = 1\frac{1}{2}$. $G = 6.36$. $R = 43.4-47.2$ (540 nm); distinctly anisotropic. Ivigtut, Greenland; Sinantscha, Sikhote-Alin, and Smirnovsk, Transbaikalia, Russia; *Santa Rosa mine* and many other tin mines in *Bolivia*, sometimes as an important ore mineral. BM *DI:439*, *R:670*, *P&J:362*, *ABI:513*.

2.9.11.1 Rasvumite KFe_2S_3

Named in 1970 for the locality. ORTH *Cmcm*. $a = 9.035$, $b = 11.022$, $c = 5.426$, $Z = 4$, $D = 3.04$. *33-1017*: 6.98₆ 5.51₁₀ 3.49₂ 3.40₅ 2.94₁ 2.91₁ 2.33₁ 1.78₁. Microscopic grains. Steel-gray, metallic luster. Cleavage {110}, perfect. $H = 4\frac{1}{2}$, $VHN = 243-433$. $G = 3.1$. Slightly magnetic. $R = 17.7-23.8$ (540 nm); strongly pleochroic and anisotropic. Point of Rocks, NM; Coyote Peak, Humboldt Co., CA; Mont Saint-Hilaire, PQ, Canada; *Rasvumchorr apatite deposits* and *Kikusvumchorr apatite deposits*, *Kola, Russia*. BM *ZVMO 99:712(1970)*; *AM 64:776(1979)*, *65:477(1980)*; *P&J:322*; *ABI:433*.

2.9.12.1 Sternbergite $AgFe_2S_3$

Named in 1828 for Count Caspar Sternberg (1761–1838), Czech botanist. Dimorphous with argentopyrite. ORTH *Ccmb*. $a = 6.625$, $b = 11.558$, $c = 12.750$, $Z = 8$, $D = 4.30$. *11-61*: 4.29₁₀ 3.42₂ 3.22₅ 2.79₇ 2.63₄ 1.94₃ 1.90₃ 1.79₅. Thin pseudohexagonal plates, forming rosettes or fanlike aggregates. Brown to black, black streak, metallic luster. Cleavage {001}, perfect; flexible cleavage lamellae. $H = 1-1\frac{1}{2}$, $VHN_{50} = 31-44$. $G = 4.1-4.2$. $R = 32.3-37.2$ (540 nm); distinctly pleochroic and anisotropic. Leroy mine, Cochise Co., AZ; Highland Bell mine, Beaverdell, BC, Canada; Andreasberg, Harz, and Freiberg(*), Saxony, Germany; *Jachymov*, Pribram, and in the *Krusnehozy Mts., Czech Republic*; Ruen Pb–Zn deposit, Bulgaria. BM *DI:246*, *R:639*, *P&J:73*, *NJMM:458(1987)*, *ABI:494*.

2.9.12.2 Picotpaulite $TiFe_2S_3$

Named in 1970 for Paul Picot (b.1931), French mineralogist. ORTH *C222*. $a = 5.40$, $b = 10.72$, $c = 9.04$, $Z = 4$, $D = 5.23$. *25-953*: 5.4₅ 4.53₅ 4.26₉ 3.80₇ 3.33₇ 2.91₁₀ 2.56₅ 2.51₅. Microscopic pseudohexagonal plates. Gray, metallic luster. $H = 2$, $VHN_{15} = 41$. $R = 24.2-31.0$ (540 nm); strongly pleochroic and anisotropic. *Allchar, Macedonia*. BM *BM 93:545(1970)*, *AM 57:1909(1972)*, *P&J:299*, *ABI:403*.

2.9.13.1 Cubanite CuFe_2S_3

Named in 1843 for the locality. Dimorphous with isocubanite. ORTH $Pcmm$. $a = 6.46$, $b = 11.117$, $c = 6.233$, $Z = 4$, $D = 4.03$. $9-324$: 3.49_4 3.22_{10} 3.00_4 2.79_4 1.87_8 1.75_7 1.28_4 1.17_5 . Thick tabular and elongated prismatic crystals, commonly twinned on $\{110\}$; usually massive. Brass- to bronze-yellow, gray-black streak, metallic luster. No cleavage, conchoidal fracture. $H = 3\frac{1}{2}$, $G = 4.0-4.2$. Strongly magnetic. $R = 36.3-41.0$ (540 nm); distinctly anisotropic. Widely distributed; occasionally an important ore mineral. Fierro, Grant Co., NM; Christmas mine, Gila Co., AZ; Mackinaw mine, Snohomish Co., WA; Landlocked Bay, Prince William Sound, AK; Chibougamau(*), PQ (exceptional crystals) and Sudbury, ON, Canada; *Barracanao, Cuba*; Kaveltorp, Örebro, Sweden; Pitkaranta, Karelia, and Norilsk, Russia; Kohmori mine, Kyoto Pref., Japan; Broken Hill, NSW, Australia; Beni Bousera, Morocco; Morro Velho mine, Nova Lima, MG, Brazil. A rare accessory in meteorites and lunar rocks. BM *DI:243*, *ZK 140:218(1974)*, *R:630*, *P&J:136*, *ABI:117*.

2.9.13.2 Argentopyrite AgFe_2S_3

Named in 1868 for its composition and similarity to pyrite. Dimorphous with sternbergite. ORTH $Pmmn$. $a = 6.64$, $b = 11.47$, $c = 6.45$, $Z = 4$, $D = 4.27$. $7-347$: 5.81_3 3.62_5 3.34_{10} 3.32_{10} 3.11_4 1.93_5 1.91_4 1.81_7 . Pseudo-hexagonal prismatic crystals. Bronze-brown, tarnishing to lead-gray, gray streak, metallic luster. No cleavage, uneven fracture. $H = 3\frac{1}{2}-4$, $VHN_{100} = 225-242$. $G = 4.0-4.3$. $R = 26.8-34.7$ (540 nm); strongly pleochroic. Andreasberg, Harz, and Freiberg and other Saxony localities, Germany; *Jachymov*, Příbram, and Medenec, *Czech Republic*; Omidani mine, Hyogo Pref., Japan; Broken Hill, NSW, Australia; Colquechaca, Bolivia. BM *DI:248*; *AM 39:475(1954)*, *54:1198(1969)*; *R:639*; *P&J:73*; *ABI:21*.

2.9.13.3 Isocubanite CuFe_2S_3

Named in 1988 as a dimorph of cubanite, stable above 250° . iso $Fm3m$. $a = 5.303$, $Z = 4/3$, $D = 4.075$. $27-166$: 3.05_{10} 2.64_3 1.87_8 1.59_7 1.32_4 1.21_5 1.08_6 1.02_5 . Microscopic cubo-octahedral crystals. Bronze, metallic luster. $H = 3\frac{1}{2}$, $VHN_{100} = 175$. $R = 34.8$ (540 nm). Described from submarine "black smokers," East Pacific Rise and Red Sea. Recorded in some ore deposits as chalcopyrrhotite. Sudbury, ON, Canada; Tunaberg, Sweden; Talnakh deposit, Norilsk, Russia; Mooihoek Farm, Lydenburg, Transvaal, South Africa. BM *R:545*, *MM 52:509(1988)*, *AM 74:503(1989)*, *ABI:242*.

2.9.14.1 Idaite Cu_5FeS_6

Named in 1958 for the locality. HEX $P6_3/mmc$. $a = 3.90$, $c = 16.95$, $Z = 1$, $D = 4.21$. Covellite structure. $13-161(\text{syn})$: 3.14_{10} 2.82_{10} 2.70_8 1.89_{10} 1.85_{10} 1.56_{10} 1.32_8 1.08_8 . Microscopic grains and exsolution lamellae. Copper-red to brown, metallic luster. $H = 2\frac{1}{2}-3\frac{1}{2}$. $G = 4.20$. $R = 26.1-29.4$ (540 nm); strongly anisotropic. White Canyon, San Juan Co., UT; Algoma, Jarvis Twp., ON, Canada; Radka deposit, Pazardzhik, Bulgaria; Kaikita mine,

Aomori Pref., and other localities in Japan; *Ida mine, Khan, and Tsumeb, Namibia*; several mines in the Copiapo district, Chile. BM *NJMM:142(1958), 241(1976)*; *MM 43:193(1979)*; *R:692*; *P&J:206*; *ABI:227*.

2.9.15.1 Nukundamite (Cu,Fe)₄S₄

Named in 1979 for the locality. HEX-R $P\bar{3}m1$. $a = 3.782$, $c = 11.187$, $Z = 1$, $D = 4.53$. *34-1409*: 3.73₁ 3.27₃ 3.14₁₀ 2.83₇ 2.80₅ 1.89₆ 1.85₅ 1.57₃. Microscopic hexagonal crystals and massive. Copper-red, dark gray to black streak, metallic luster. Perfect basal cleavage. $H = 3$, $VHN_{20} = 103-110$. $D = 4.30$. $R = 15.8-23.7$ (540 nm); strongly pleochroic and anisotropic. *Undu mine, Nukundamu, Fiji*. BM *MM 43:193(1979)*, *AM 66:398(1981)*, *ABI:359*.

2.9.16.1 Mohite Cu₂SnS₃

Named in 1982 for Gunter Moh (1929-1993), German mineralogist. TRIC $P1$. $a = 6.64$, $b = 11.51$, $c = 19.93$, $\alpha = 90.0^\circ$, $\beta = 109.75^\circ$, $\gamma = 90.0^\circ$, $Z = 12$, $D = 4.75$. *35-684*: 3.66₁ 3.34₁ 3.13₁₀ 2.82₁ 2.72₂ 2.63₁ 2.44₂ 1.92₇. Microscopic grains. Gray, metallic luster. $H = 4\frac{1}{2}$, $VHN_{20} = 179$. $R = 25.5$ (540 nm); distinctly anisotropic. April Fool mine, Lincoln Co., NV; *Kochbulak deposit, Uzbekistan*. BM *ZVMO 111:110(1982)*, *AM 68:281(1983)*, *ABI:335*.

2.9.17.1 Caswellsilverite NaCrS₂

Named in 1982 for Caswell Silver (b.1916), U.S. geologist. HEX-R $R\bar{3}m$. $a = 3.541$, $c = 19.35$, $Z = 3$, $D = 3.30$. *10-292*: 2.58₁₀ 1.89₉ 1.76₉ 1.46₈ 1.29₈ 1.20₈ 1.13₁₀ 1.04₁₀. Microscopic anhedral grains. Yellow-gray tarnishing brown, metallic luster. $H = 2$, $VHN_{15} = 17-45$. $R = 21.8-32.8$ (540 nm); strongly pleochroic and anisotropic. *Norton County enstatite achondrite* and *Quizhen enstatite chondrite*. BM *AM 67:132(1982)*, *GCA 49:1781(1985)*, *ABI:83*.

2.9.17.2 Schöllhornite Na₃CrS₂·H₂O

Named in 1985 for Robert Schöllhorn, German chemist. HEX-R Space group uncertain, probably $R\bar{3}m$. $a = 3.32$, $c = 26.6$, $Z = 3$, $D = 2.77$. *39-322(syn)*: 8.85₁₀ 4.43₁ 2.81₅ 2.53₅ 2.21₁ 1.66₅. Microscopic grains. Gray, metallic luster. Perfect basal cleavage. $H = 2$, $VHN_{15} = 80$. $G_{syn} = 2.70$. $R = 16.0-19.3$ (540 nm); distinctly pleochroic and anisotropic. A weathering product of caswellsilverite in the *Norton County enstatite achondrite*. BM *AM 70:638(1985)*, *ABI:465*.

2.9.18.1 Petrukite (Cu,Fe,Zn)₃SnS₄

Named in 1989 for William Petruk (b.1930), Canadian mineralogist. Contains up to 6% In and 1% Ag. ORTH $Pmn2_1$. $a = 7.667$, $b = 6.440$, $c = 6.276$, $Z = 2$, $D = 4.61$. *CM27*: 3.13₁₀ 2.71₄ 2.42₂ 1.92₆ 1.64₅ 1.24₅ 1.11₆ 10.04₃. Microscopic

grains. Brown to gray, metallic luster. Cleavage {110}, {100}, {010}, distinct; parting parallel to {001}. $H = 4\frac{1}{2}$, $VHN_{100} = 319$. $R = 27.7-27.8$ (546 nm). Mt. Pleasant mine, Charlotte Co., NB, and *Herb claim, Turnagain R., BC, Canada*; Ikuno mine, Hyogo Pref., Japan. *BM CM 27:673(1989)*.

2.9.19.1 Bartonite $K_3Fe_{10}S_{14}$

Named in 1981 for Paul B. Barton (b.1930), U.S. mineralogist. *TET I4/mmm*. $a = 10.424$, $c = 20.626$, $Z = 4$, $D = 3.286$. *35-476*: 9.31₃ 5.99₈ 3.14₃ 3.00₁₀ 2.39₂ 2.38₃ 1.84₃ 1.83₄. Brown-black masses, black streak, submetallic luster. Cleavage {112}, distinct; conchoidal fracture. $H = 3\frac{1}{2}$, $VHN_{15} = 94-120$. $G = 3.305$. $R = 20.9-21.8$ (540 nm); distinctly anisotropic. *Coyote Peak, Humboldt Co., CA*, in an alkalic diatreme. *BM AM 66:369(1981)*, *ABI:41*.

LINNAEITE GROUP

The linnaeite group minerals are sulfides and selenides conforming to the general formula

where

A = Fe, Co, Ni, Cu, Zn

B = Fe, Co, Ni, Cr, In, Rh, Ir, Pt

X = S, Se

and the minerals are cubic, space group *Fd3m*, isostructural with one another and with the spinel group.

LINNAEITE GROUP

Mineral	Formula	Space Group	a	D	
Linnaeite	$CoCo_2S_4$	<i>Fd3m</i>	9.43	4.83	2.10.1.1
Carrollite	$CuCo_2S_4$	<i>Fd3m</i>	9.48	4.83	2.10.1.2
Fletcherite	$CuNi_2S_4$	<i>Fd3m</i>	9.520	4.76	2.10.1.3
Tyrrellite	$(Cu, Co, Ni)_3Se_4$	<i>Fd3m</i>	10.005	6.59	2.10.1.4
Bornhardtite	$CoCo_2Se_4$	<i>Fd3m</i>	10.2	6.17	2.10.1.5
Siegenite	$(Ni, Co)_3S_4$	<i>Fd3m</i>	9.387	4.89	2.10.1.6

2.10.1.1 Linnaeite CoCo₂S₄

Named in 1845 for Carolus Linnaeus (1707–1778), Swedish taxonomist. Linnaeite group. May contain minor amounts of Cu, Ni, and Fe. iso *Fd3m*. $a = 9.43$, $Z = 8$, $D = 4.83$. $11-121: 3.34_4$ 2.83_{10} 2.36_7 1.93_3 1.82_6 1.67_8 1.09_4 1.06_4 . Octahedral crystals, also massive, granular, or compact; crystals twinned on {111}. Light gray to steel-gray, gray streak, metallic luster. Cleavage {001}, imperfect, subconchoidal to uneven fracture. $H = 4\frac{1}{2}-5\frac{1}{2}$, $VHN_{50} = 492$. $G = 4.5-4.8$. $R = 43.6$ (540 nm). Fuses to a magnetic globule; soluble in HNO₃ with the separation of sulfur. Widely distributed in hydrothermal veins with other cobalt and nickel sulfides. Springfield and Mineral Hill mines, Carroll Co., MD; Mine La Motte, Madison Co., MO; Gladhammar, Kalmar, and *Bastnäs, Västmannland, Sweden*; Müsen, Littfeld, and Altenberg, Westphalia, Germany; Kladno, Czech Republic; Musonoi mine, Shaba, Zaire; N'Kana mine, Kitwe, Zambia. BM *DI:262, R:697, P&J:238, ABI:297*.

2.10.1.2 Carrollite CuCo₂S₄

Named in 1852 for the locality. Linnaeite group. May contain minor amounts of Ni and Fe. iso *Fd3m*. $a = 9.48$, $Z = 8$, $D = 4.83$. $9-425: 3.35_4$ 2.86_{10} 2.37_5 1.83_6 1.67_8 1.23_3 1.19_3 1.10_3 . Octahedral crystals, often twinned on {111}; also massive, granular, or compact. Silver-white to steel-gray, gray streak, metallic luster. Cleavage {011}, imperfect; subconchoidal to uneven fracture. $H = 4\frac{1}{2}-5\frac{1}{2}$, $VHN_{100} = 507-586$. $G = 4.5-4.8$. $R = 41.8$ (540 nm). *Patapsco mine, Carroll Co., MD*; Mine La Motte, Madison Co., MO; Gladhammar, Kalmar, Sweden; Kohlenbach mine, Westphalia, Germany; Neves-Corvo, Portugal; Chernomorets, Bulgaria; Sazare mine, Ehime Pref., Japan; Kambalda, WA, Australia; Kambove and Kolwezi mines(*), Shaba, Zaire; Rokana mine, Kitwe, Zambia; Tsumeb, Namibia; Carrizal Alto deposit, Atacama, Chile. BM *DI:262, AM 59:302(1974), R:697, P&J:238, ABI:82*.

2.10.1.3 Fletcherite CuNi_2S_4

Named in 1977 for the locality. Linnaeite group. Contains up to 17% Co. iso *Fd3m*. $a = 9.520$, $Z = 8$, $D = 4.76$. *29-540*: 3.36_5 2.87_6 2.39_6 1.83_8 1.68_{10} 1.37_6 1.24_6 1.19_6 . Microscopic crystals. Steel-gray, metallic luster. $H = 4\frac{1}{2}$, $\text{VHN}_{25} = 446\text{--}464$. $R = 43.4$ (546 nm). *Fletcher mine, Reynolds Co., MO*; *New Rambler mine, Medicine Bow Mts., WY*. BM *EG 72:480(1977)*, *AM 62:596(1977)*, *ABI:159*.

2.10.1.4 Tyrrellite $(\text{Cu},\text{Co},\text{Ni})_3\text{Se}_4$

Named in 1952 for Joseph B. Tyrrell (1858–1957), Canadian geologist. Linnaeite group. iso *Fd3m*. $a = 10.005$, $Z = 8$, $D = 6.59$. *8-1*: 5.78_4 3.54_4 3.02_6 2.89_7 2.50_9 1.93_6 1.77_{10} 1.51_4 . Microscopic subhedral to anhedral grains. Pale bronze, black streak, metallic luster. Poor cubic cleavage, conchoidal fracture. $H = 3\frac{1}{2}$, $\text{VHN}_{100} = 343\text{--}368$. $G = 6.6$. $R = 47.3$ (540 nm). *Eagle shaft, Beaverlodge Lake, SK, Canada*; *Bukov, Moravia, Czech Republic*. BM *AM 37:542(1952)*, *CM 10:731(1970)*, *R:703*, *P&J:376*, *ABI:546*.

2.10.1.5 Bornhardtite CoCo_2Se_4

Named in 1955 for Wilhelm Bornhardt (1864–1946), German geologist. Linnaeite group. iso *Fd3m*. $a = 10.2$, $Z = 8$, $D = 6.17$. *15-463*: 2.7_{10} 2.4_{10} 2.3_{10} 2.18_{10} 2.00_{10} 1.96_{10} 1.42_{10} . Microscopic crystals. Pink-white, metallic luster. $H = 4$. $R = 42.4$ (540 nm). *Pinky Fault deposit, SK, Canada*; *Trogtal quarry and Tilkerode, Harz, Germany*; *Sierra de Cachueta, Mendoza Prov., Argentina*. BM *NJMM:133(1955)*, *AM 41:164(1956)*, *R:702*, *P&J:97*, *ABI:61*.

2.10.1.6 Siegenite $(\text{Ni},\text{Co})_3\text{S}_4$

Named in 1850 for the locality. Linnaeite group. iso *Fd3m*. $a = 9.387$, $Z = 8$, $D = 4.89$. *20-782(syn)*: 3.32_4 2.83_{10} 2.35_5 1.81_4 1.66_8 1.22_2 1.08_2 1.05_3 . Octahedral crystals, often twinned on {111}; also massive, granular or compact. Silver-white to steel-gray, gray streak, metallic luster. Cleavage {001}, imperfect; subconchoidal to uneven fracture. $H = 4\frac{1}{2}\text{--}5\frac{1}{2}$, $\text{VHN}_{100} = 459\text{--}540$. $G = 4.5\text{--}4.8$. $R = 46.2$ (540 nm). *Mine la Motte, Madison Co., and Miliken mine(*)*, *Reynolds Co., MO*; *Langis mine, near Cobalt, ON, Canada*; *Siegen district(*)*, *Westphalia, Germany*; *Kladno, Czech Republic*; *near Brestovsko, Bosnia*; *Etropole and Mladenovo, Bulgaria*; *Kamaishi mine, Iwate Pref., Japan*; *Kambalda, WA, Australia*; *Kilembe, Uganda*; *Shinkolobwe mine, Shaba, Zaire*. BM *DI:262*, *CM 9:597(1968)*, *R:697*, *P&J:238*; *ABI:474*.

2.10.1.7 Polydymite NiNi_2S_4

Named in 1876 from the Greek for *many* and *twin*, because the mineral often occurs in twinned crystals. Linnaeite group. iso *Fd3m*. $a = 9.48$, $Z = 8$, $D = 4.74$. *8-106*: 2.85_9 2.36_9 1.82_9 1.67_{10} 1.37_6 1.23_8 1.19_7 1.10_7 . Octahedral crystals, twinned on {111}; also massive, granular, or compact. Steel-gray,

black streak, metallic luster. Cleavage {001}, imperfect; subconchoidal to uneven fracture. $H = 4\frac{1}{2}$, $VHN_{100} = 379\text{--}427$. $G = 4.5\text{--}5.8$. $R = 45.4$ (540 nm). Hamilton, Hancock Co., IL; Miliken mine, Reynolds Co., MO; *Grunau mine, near Siegen, Westphalia, Germany*; Kunratice and Rozany, Czech Republic; Saint Marina, Khaskovo district, Bulgaria; Novo-Aidyrlinsk, Ural Mts., Russia; Kambalda, WA, Australia; Dry Nickel mine, Bindura, Zimbabwe. *BM DI:262, R:697, P&J:238, ABI:418.*

2.10.1.8 Violarite $FeNi_2S_4$

Named in 1924 for its color. Linnaeite group. Contains minor amounts of Co and Cu. iso *Fd3m*. $a = 9.46$, $Z = 8$, $D = 4.72$. *11-95*: 3.35_3 2.85_{10} 2.36_5 1.82_6 1.67_8 1.18_4 1.12_4 1.06_5 . Massive. Violet-gray, black streak, metallic luster. Cleavage {001}, perfect; brittle. $H = 4\frac{1}{2}\text{--}5\frac{1}{2}$, $VHN_{100} = 455\text{--}493$. $G = 4.6$. $R = 42.5$ (540 nm). Gap mine, Lancaster Co., PA; Lick Fork deposit, Floyd Co., VA; Key West mine, Clark Co., NV; Friday mine, Julian, CA; Marbridge mine, Malartic, PQ, *Sudbury, ON, English Lake, MB, Canada*; Praborna mine, St. Marcel, Italy; Kambalda, WA, Australia; Dry Nickel mine, Bindura, Zimbabwe. *BM DI:262, R:697, P&J:238, ABI:560.*

2.10.1.9 Trüstedtite $NiNi_2Se_4$

Named in 1964 for Otto Trüstedt (1866–1929), Finnish mining engineer. Linnaeite group. Contains 6.4% Co. iso *Fd3m*. $a = 9.94$, $Z = 8$, $D = 6.65$. *18-889*: 5.75_4 3.52_4 3.00_8 2.87_8 2.48_{10} 1.91_6 1.76_{10} 1.50_2 . Microscopic euhedral crystals. Yellow, metallic luster. $H = 3$. $R = 50.3$ (540 nm). *Kuusamo, Finland*. *BM AM 50:519(1965), R:703, P&J:373, ABI:539.*

2.10.1.10 Greigite $FeFe_2S_4$

Named in 1964 for Joseph W. Greig (1895–1977), U.S. mineralogist. Linnaeite group. Synonym: melnikovite (part). iso *Fd3m*. $a = 9.876$, $Z = 8$, $D = 4.08$. *16-713*: 3.50_3 2.98_{10} 2.47_6 2.02_1 1.90_3 1.75_8 1.56_1 1.51_1 . Microscopic octahedral grains and powdery coatings. Black, metallic luster. $H = 4$, $VHN_{50} = 401\text{--}423$. Strongly magnetic. $R = 30.7$ (540 nm). Widely distributed in lacustrine clays and in hydrothermal sulfide deposits. *Boron, Kern Co.*, and Coyote Peak, Humboldt Co., CA; near Zacatecas, ZAC, Mexico; Treore mine, Cornwall, England; Montemesola, Taranto, Italy; Lojane deposit, Macedonia; Kerch Peninsula, Ukraine; Hanoaka mine, Akita Pref., Japan. *BM AM 49:543(1964), R:697, P&J:238, ABI:195.*

2.10.1.11 Daubréelite $FeCr_2S_4$

Named in 1876 for Gabriel A. Daubree (1814–1896), French meteorite researcher. Linnaeite group. iso *Fd3m*. $a = 9.995$, $Z = 8$, $D = 3.83$. *4-651(syn)*: 3.53_8 3.01_{10} 2.50_8 2.04_6 1.92_8 1.77_{10} 1.30_8 1.25_8 . Exsolution lamellae in troilite, and microscopic grains. Black, black streak, metallic luster. Distinct cleavage, brittle. $H = 5$, $VHN_{100} = 260\text{--}303$. $G = 3.81$. $R = 33.0$

(540 nm). An accessory mineral in many meteorites. BM *DI:265, R:703, ABI:129*.

2.10.1.12 Indite FeIn_2S_4

Named in 1963 for its indium content. Linnaeite group. iso *Fd3m*. $a = 10.618$, $Z = 8$, $D = 4.59$. *33-613*: 3.75_4 3.20_{10} 2.65_2 2.17_1 2.04_4 1.88_5 1.62_1 1.38_1 . Microscopic grains. Iron-black, metallic luster. $H = 4\frac{1}{2}$, $\text{VHN} = 309$. $R = 27.0$ (540 nm). *Dzhalindin deposit, Little Khingan Ridge, eastern Siberia, Russia*. BM *ZVMO 92:445(1963), AM 49:439(1964), R:703, P&J:211, ABI:233*.

2.10.1.13 Kalininite ZnCr_2S_4

Named in 1985 for Pavel V. Kalinin (1905–1981), Russian mineralogist. Linnaeite group. iso *Fd3m*. $a = 9.974$, $Z = 8$, $D = 4.04$. *16-507(syn)*: 3.53_4 3.00_8 2.50_5 1.76_{10} 1.30_2 1.25_2 1.02_5 . Microscopic aggregates. Black, black streak, metallic luster. $H = 5$, $\text{VHN}_{50} = 468$. $R = 35.2$ (540 nm). *Slyudyanka complex, Baikal region, Russia*. BM *ZVMO 114:622(1985), AM 72:223(1987), ABI:255*.

2.10.1.14 Florensovite $\text{Cu}(\text{Cr,Sb})_2\text{S}_4$

Named in 1989 for Nikolai A. Florensov (1909–1986), Russian geologist. Linnaeite group. iso *Fd3m*. $a = 10.005$, $Z = 8$, $D = 4.28$. *43-1468*: 3.53_5 3.01_{10} 2.50_8 1.92_8 1.77_{10} 1.30_6 1.16_5 1.02_3 . Microscopic grains. Black, adamantine to metallic luster. $H = 5$, $\text{VHN}_{50} = 477-541$. Strongly magnetic. $R = 26.5$ (540 nm). *Slyudyanka complex, Baikal region, Russia*. BM *ZVMO 118:57(1989), AM 75:1209(1990)*.

2.10.1.15 Cuproiridisite CuIr_2S_4

Named in 1985 for the composition. Linnaeite group. Contains minor amounts of Pt, Rh, and Fe. iso *Fd3m*. $a = 9.92$, $Z = 8$, $D = 7.84$. *39-329*: 3.01_{10} 2.49_7 1.92_8 1.76_9 1.29_6 1.15_5 1.11_5 1.01_8 . Microscopic grains. Iron-black, metallic luster. Very brittle. $H = 5\frac{1}{2}$, $\text{VHN}_{30} = 578$. $R = 33.6-37.2$ (540 nm). *Finero, Italy; Konder massif, Yakutia, Russia*. BM *ZVMO 114:187(1985), AM 71:1277(1986), ABI:120*.

2.10.1.16 Cuprorhodisite CuRh_2S_4

Named in 1985 for the composition. Linnaeite group. Contains minor amounts of Ir, Pt, and Fe. iso *Fm3m*. $a = 9.88$, $Z = 8$, $D = 5.48$. *38-405*: 5.7_4 3.0_{10} 2.48_7 1.90_8 1.76_{10} 1.29_5 1.10_5 1.01_9 . Microscopic grains. Iron-black, metallic luster. Very brittle. $H = 5$, $\text{VHN}_{50} = 498$. $R = 36.7-39.2$ (540 nm). *Finero, Italy; Konder massif, Yakutia, Russia*. BM *ZVMO 114:187(1985), AM 71:1277(1986), ABI:122*.

2.10.1.17 Malanite $\text{Cu}(\text{Pt},\text{Ir})_2\text{S}_4$

Named in 1974, presumably for the locality. Linnaeite group. iso $Fd3m$. $a = 9.92$, $Z = 8$, $D = 7.92$. 38-406: 5.8₅ 3.01₁₀ 2.49₉ 1.92₉ 1.76₁₀ 1.29₆ 1.11₇ 1.01₉. Microscopic grains. Silver-white, metallic luster. $\text{VHN}_{20} = 462$. Ojen, Spain; Konder massif, Yakutia, Russia; *undisclosed locality, China*; Merensky Reef, Transvaal, South Africa. BM *AM 61:185(1976)*, *67:1081(1982)*; *ZVMO 114:187(1985)*; *ABI:309*.

2.10.2.1 Wilkmanite Ni_3Se_4

Named in 1964 for Wanold W. Wilkman (1872–1937), Finnish geologist. *MON I2/m*. $a = 6.22$, $b = 3.63$, $c = 10.52$, $\beta = 90.53^\circ$, $Z = 2$, $D = 6.88$. 18-890: 5.25₄ 2.70₁₀ 2.02₁₀ 2.00₈ 1.82₈ 1.80₁₀ 1.53₆ 1.50₆. Probably massive. Yellow-gray, metallic luster. Distinctly pleochroic and anisotropic. *Kuusamo, Finland*. BM *AM 50:519(1965)*, *ABI:375*.

2.10.2.2 Brezinaite Cr_3S_4

Named in 1969 for Aristides Brezina (1848–1909), Austrian meteoriticist. *MON I2/m*. $a = 5.96$, $b = 3.425$, $c = 11.27$, $\beta = 91.53^\circ$, $Z = 2$, $D = 4.11$. 24-310: 5.67₇ 5.23₄ 2.98₇ 2.64₁₀ 2.61₆ 2.06₇ 2.03₄ 1.72₇. Microscopic anhedral grains. Gray, metallic luster. $\text{VHN} = 400$. $R = 37\text{--}40$; strongly anisotropic. *Tucson iron meteorite* and New Baltimore iron meteorites. BM *AM 54:1509(1969)*, *ABI:70*.

2.10.2.3 Heideite $(\text{Fe},\text{Cr})_{1+x}(\text{Ti},\text{Fe})\text{S}_4$ ($x = 0.15$)

Named in 1974 for Friedrich Heide (1891–1973), German geochemist. *MON I2/m*. $a = 5.929$, $b = 3.426$, $c = 11.46$, $\beta = 90.10^\circ$, $Z = 2$, $D = 3.99$. 20-1303(syn): 5.72₂ 5.26₃ 2.96₃ 2.63₉ 2.06₁₀ 1.71₄ 1.61₃ 1.44₂. Microscopic anhedral grains. Black, metallic luster. $H = 3\frac{1}{2}\text{--}4\frac{1}{2}$. $G_{\text{syn}} = 3.94$. An accessory mineral in the *Bustee enstatite achondrite*. BM *AM 59:465(1974)*, *ABI:212*.

2.10.3.1 Rhodostannite $\text{Cu}_2\text{FeSn}_3\text{S}_8$

Named in 1968 for its reddish color compared to stannite. *TET I4_{1/a}*. $a = 7.29$, $c = 10.31$, $Z = 2$, $D = 4.82$. 29-558(syn): 5.96₅ 3.65₄ 3.11₉ 2.58₈ 1.99₇ 1.83₁₀ 1.35₄ 1.06₄. Microscopic grains. Reddish gray, metallic luster. $H = 4$, $\text{VHN} = 243\text{--}266$. $R = 28.8\text{--}30.4$ (540 nm); distinctly anisotropic. Dean mine, Lander Co., NV; Bisbee, AZ; *Vila Apacheta, Bolivia*; Pirquitas deposit, Jujuy, Argentina. BM *MM 36:1045(1968)*, *NJMM:166(1975)*, *P&J:326*, *ABI:440*.

2.10.3.2 Toyohaite $\text{Ag}_2\text{FeSn}_3\text{S}_8$

Named in 1991 for the locality. *TET I4_{1/a}*. $a = 7.464$, $c = 10.80$, $Z = 2$, $D = 4.94$. 44-1440: 6.10₃ 3.77₂ 3.72₄ 3.21₁₀ 2.64₃ 2.03₄ 1.88₄ 1.86₃. Microcrystalline aggregates. Gray-brown, metallic luster. $R = 24.1\text{--}26.1$ (546 nm); dis-

tinctorily anisotropic. *Toyoha mine, Sapporo, Japan*. BM *MJJ* 15:222(1991), *AM* 77:1117(1992).

2.10.4.1 Konderite $\text{PbCu}_3(\text{Rh,Pt,Ir})_6\text{S}_{16}$

Named in 1984 for the locality. HEX $P6/m$. $a = 7.024$, $c = 16.48$, $Z = 1$, $D = 4.09$. 38-393: 5.1₂ 2.98₁₀ 2.85₅ 2.46₉ 2.25₂ 1.76₁₀ 1.72₅ 1.29₃. Microscopic grains. Steel-gray, metallic luster. Cleavage in two directions, brittle. $\text{VHN}_{50} = 372\text{--}793$. $R = 42.5\text{--}44.8$ (520 nm). *Konder massif, Yakutia, Russia*. BM *ZVMO* 113:703(1984), *AM* 71:229(1986), *ABI*:271.

2.10.4.2 Inaglyite $\text{PbCu}_3(\text{Ir,Pt})_6\text{S}_{16}$

Named in 1984 for the locality. HEX $P6/m$. $a = 7.03$, $c = 16.44$, $Z = 1$. 37-441: 5.7₉ 2.98₁₀ 2.84₆ 2.44₈ 2.00₄ 1.90₄ 1.75₇ 1.70₅. Microscopic grains. Steel-gray, metallic luster. Cleavage in two directions, brittle. $\text{VHN}_{50} = 347\text{--}726$. $R = 41.6\text{--}42.8$ (520 nm). *Inagli massif, Yakutia, Russia*. BM *ZVMO* 113:712(1984), *AM* 71:228(1986), *ABI*:231.

2.11.1.1 Orpiment As_2S_3

Named in 1747 from the Latin *auripigmentum*, golden paint, in allusion to its color. MON $P2_1/n$. $a = 11.49$, $b = 9.59$, $c = 4.25$, $\beta = 90.45^\circ$, $Z = 4$, $D = 3.49$. 19-84: 4.85₁₀ 4.02₅ 3.22₃ 2.79₃ 2.72₃ 2.47₄ 2.09₃ 1.76₄. **Habit:** Crystals uncommon; typically small, short prismatic on c with pseudo-orthorhombic appearance; commonly in foliated, columnar, or fibrous masses; also granular or powdery. **Structure:** Consists of As and S atoms bonded together in complex sheets parallel to the ac plane, giving rise to perfect $\{010\}$ cleavage. **Physical**

ORPIMENT: As_2S_3

As is bonded to three S and S to two As—an essentially covalent arrangement—forming corrugated sheets.

properties: Lemon yellow to brownish yellow, pale yellow streak, pearly luster on cleavage surfaces, resinous elsewhere. Cleavage {010}, perfect; lamellae flexible but not elastic; sectile. $H = 1\frac{1}{2}$ -2. $G = 3.49$. Tests: Easily recognized by its color and cleavage. **Chemistry:** Usually pure As_2S_3 ; may contain up to 1.5% Sb and 0.4% Tl. **Optics:** Biaxial (-); $N_x = 2.4$, $N_y = 2.81$, $N_z = 3.02$; $2V = 76^\circ$; pleochroic in shades of yellow. $R = 20.5$ -27.7 (540 nm). **Occurrence:** A low-temperature hydrothermal mineral, occurring in veins and in hot-spring deposits; also as an alteration product of realgar. **Localities:** Widely distributed; fine specimens from the following places: Mercur, Tooele Co., UT; Getchell mine, Humboldt Co., and White Caps mine, Nye Co., NV; Tajov, Czech Republic; Baia Sprie, Romania; Allchar, Macedonia; Jelamerk, Kurdistan, Turkey; Lukum, Georgia; Zarehchuran mine, Takab, Iran; Elbrozka, Caucasus, and Menkule, Yakutia, Russia; Guizhou, Hunan Prov., China; Jozankei, Hokkaido, Japan; Quirivilca mine, La Libertad, Peru. *BM DI:266, ZK 136:48(1972), R:890, P&J:283, ABI:366.*

2.11.1.2 Getchellite $AsSbS_3$

Named in 1965 for the locality. *MON P2₁/a*. $a = 11.85$, $b = 8.99$, $c = 10.16$, $\beta = 116.5^\circ$, $Z = 8$, $D = 4.02$. *18-142*: 4.92₅ 4.58₅ 4.44₈ 3.61₇ 2.88₁₀ 2.53₇ 2.32₅ 2.24₆. Subhedral crystals and massive. Dark blood-red, sometimes with a purple to green iridescent tarnish; orange-red streak; pearly to vitreous luster on cleavage surfaces, resinous elsewhere. Cleavage {001}, perfect; cleavage flakes flexible but inelastic; splintery fracture; sectile. $H = 1\frac{1}{2}$ -2. $G = 3.92$. $R = 28.1$ -30.6 (540 nm). *Getchell mine, Humboldt Co., NV; Zarehchuran mine, Takab, Iran; Kaidarkan, Kyrgyzstan; Gal-Khaya deposit, Yakutia, Russia; Toya mine, Hokkaido, Japan. BM AM 50:1817(1965), AC(B) 29:2536(1973), R:704, P&J:179, ABI:182.*

STIBNITE GROUP

The stibnite group consists of antimony and bismuth sulfides and selenides corresponding to the general formula

where

A = Sb, Bi

B = S, Se

and the space group is monoclinic, *Pbnm*. The structure of stibnite consists of a zigzag chain parallel to the *c* axis of S and Sb atoms. The long prismatic crystals are parallel to these structural chains, and the perfect {010} cleavage occurs between them.

STIBNITE: Sb_2S_3

Bond lengths are highly variable. This view shows the complex chains which are isolated, ignoring bonds over 3.2 Å. With this limit, all Sb is 5-coordinated.

STIBNITE GROUP

Mineral	Formula	Space Group	a	b	c	D	
Stibnite	Sb_2S_3	<i>Pbnm</i>	11.229	11.310	3.839	4.63	2.11.2.1
Antimonselite	Sb_2Se_3	<i>Pbnm</i>	11.593	11.747	3.398	5.88	2.11.2.2
Bismuthinite	Bi_2S_3	<i>Pbnm</i>	11.149	11.304	3.981	6.81	2.11.2.3
Guanajuatite	Bi_2Se_3	<i>Pbnm</i>	11.37	11.55	4.054	7.54	2.11.2.4

2.11.2.1 Stibnite Sb_2S_3

Named in 1832 from the Latin *stibium*, an old name for the mineral. Stibnite group. ORTH *Pbnm*. $a = 11.229$, $b = 11.310$, $c = 3.839$, $Z = 4$, $D = 4.63$. $6-474(\text{syn})$: 5.05_6 3.57_7 3.56_7 3.05_9 2.76_{10} 2.68_5 2.53_5 1.94_5 . **Habit**: Crystals common, prismatic along c , typically striated or grooved parallel to c ; often appear bent or twisted as a consequence of translation gliding; commonly in complex aggregates of acicular crystals; also in radiating or columnar masses, or granular. **Structure**: Consists of Sb and S atoms bonded together in a complex sheet structure parallel to the ac plane, giving rise to perfect $\{010\}$ cleavage. **Physical properties**: Lead-gray, commonly with a black to iridescent tarnish, lead-gray streak, metallic luster. Cleavage $\{010\}$, perfect; cleavage flakes flexible, inelastic; slightly sectile. $H = 2$, $VHN_{100} = 71-86$. $G = 4.63$. **Tests**: Easily fusible. Soluble in HCl. **Chemistry**: Usually pure Sb_2S_3 . **Optics**: $R = 32.6-48.2$ (540 nm); strongly anisotropic. **Occurrence**: Occurs most commonly in hydrothermal vein and replacement

deposits of low-temperature origin. Under surface and near-surface conditions stibnite may oxidize to white or yellow stibiconite, often as pseudomorphs. **Localities:** Stibnite is the commonest antimony mineral and is very widely distributed; the following localities are known for fine specimens. White Caps mine, Nye Co., NV; Antimony Peak, Kern Co., Ambrose mine, San Benito Co., Rand mines, San Bernardino Co., and many other localities in CA; Prince William mine, York Co., NB, Canada; San Martin, ZAC, Wadley mine, Wadley, SLP, Los Tejocotes, OAX, and other localities in Mexico; Wolfsberg and Andreasberg, Harz, Germany; Pribram and Kremnica, Czech Republic; Herja, Stiavnica, and Baia Sprie, Romania; Allchar, Macedonia; Nerchinsk, Siberia, Russia; Kadamdzhai, Tajikistan; Xikuandshan, Hunan, China; Ichinokawa mine, Shikoku, Japan; Kusa mine, near Bau, Sarawak; San Jose and La Salvadora mines, Oruro, Amigos mine, Potosi, and other localities in Bolivia. **Uses:** The principal ore of antimony. *BM DI:270, ZK 135:308(1972), R:705, P&J:353, ABI:498.*

2.11.2.2 Antimonelite Sb_2Se_3

Named in 1993 for the composition. Stibnite group. Contains up to 4.8% Hg and 2.4% Cu. *ORTH Pbnm. a* = 11.593, *b* = 11.747, *c* = 3.398, *Z* = 4, *D* = 5.88. *AM 79: 3.70₇ 3.17₅ 2.87₁₀ 2.63₆ 1.75₄*. Microscopic acicular crystals and anhedral grains. Black, black streak, metallic luster. $VHN_{30} = 120$. *R = 39.0–42.0 (546 nm)*. Occurs in a polymetallic deposit at *Kaiyang, Guizhou Prov., China*. *BM AM 79:387(1994)*.

2.11.2.3 Bismuthinite Bi_2S_3

Named in 1832 for the composition. Stibnite group. May contain minor amounts of Sb and Se. *ORTH Pbnm. a* = 11.149, *b* = 11.304, *c* = 3.981, *Z* = 4, *D* = 6.81. *17-320(syn): 3.97₄ 3.57₁₀ 3.53₆ 3.12₈ 2.81₅ 2.72₃ 2.52₄ 1.95₄*. Prismatic to acicular crystals, elongated and striated parallel to *c*; usually massive with fibrous or foliated texture. Lead-gray, lead-gray streak; metallic luster. Cleavage {010}, perfect; {100}, {110}, imperfect; flexible and somewhat sectile. *H = 2, VHN₅₀ = 170. G = 6.8. R = 37.7–50.0 (540 nm)*; strongly anisotropic. Occurs in hydrothermal veins and granite pegmatites. Haddam, CT; Wickes, Jefferson Co., MT; Clear Creek mines, Chaffee Co., Breckenridge district, Summit Co., and other localities in CO; Midnight Owl mine, Yavapai Co., AZ; Pala, San Diego Co., CA; Glacier Gulch, BC, Canada; Nacozari, SON, and Guanajuato, GTO, Mexico; Carrock Fell, Cumbria, and Redruth district, Cornwall, England; Spind, Farsum, Norway; Schneeberg and Altenberg, Saxony, Germany; Bresso, Piedmont, Italy; Smolotely, Czech Republic; Moravicza and Baita, Romania; Zidarova, Bulgaria; Strezhen deposit, Altai, Russia; Horobetsu mine, Hokkaido, Japan; Kingsgate, NSW, and Mt. Biggenden mine, Q, Australia; Fefena, Madagascar; Llallagua, Potosi, and other localities in Bolivia. *BM DI:275, TMPM 14:55(1970), R:710, P&J:92, ABI:56.*

2.11.2.4 Guanajuatite Bi_2Se_3

Named in 1873 for the locality. Stibnite group. May contain up to 7% S. ORTH *Pbnm*. $a = 11.37$, $b = 11.55$, $c = 4.054$, $Z = 4$, $D = 7.54$. $10\text{-}475$: 5.16_4 3.65_9 3.19_{10} 2.88_6 2.58_5 2.31_5 1.99_7 1.77_4 . Acicular crystals, elongated parallel to c ; also massive, fibrous or foliated. Lead-gray, lead-gray streak, metallic luster. Cleavage $\{010\}$, distinct; $\{001\}$, indistinct; somewhat sectile. $H = 2\frac{1}{2}\text{-}3$, $\text{VHN}_{10} = 53\text{-}82$. $G = 6.3\text{-}7.0$. $R = 43.1\text{-}52.0$ (540 nm); strongly pleochroic and anisotropic. Near Salmon, Lemhi Co., ID; Thomas and Essex mines, Darwin, Inyo Co., CA; *Santa Catarina mine, Guanajuato, GTO, Mexico*; Andreasberg, Harz, Germany. BM *DI:278, R:714, P&J:188, ABI:197*.

2.11.3.1 Metastibnite Sb_2S_3

Named in 1888 as a dimorph of stibnite. May contain up to 9% Pb. Amorphous. Powdery coatings. Red, red streak, submetallic luster. $H = 2\text{-}3$. Occurs in fumaroles and as coatings on stibnite. *Steamboat Springs, Washoe Co., NV*; The Geysers, Sonoma Co., CA; Lac Nicolet mine, South Ham, PQ, Canada; Rujevac Sb-Zn-Pb deposit, Serbia; Alacran mine, Copiapó, Chile; San Jose mine, Oruro, Bolivia. BM *DI:275, AM 55:2104(1970), R:709, P&J:267, ABI:328*.

2.11.4.1 Wakabayashilite $(\text{As,Sb})_{11}\text{S}_{18}$

Named in 1970 for Yaichiro Wakabayashi (1874-1943), Japanese mineralogist. MON $P2_1/m$. $a = 29.128$, $b = 6.480$, $c = 29.128$, $\beta = 120.0^\circ$, $Z = 8$, $D = 4.06$. $29\text{-}1406$: 6.28_{10} 4.78_7 3.49_8 3.24_4 3.08_4 2.54_3 2.42_4 1.59_4 . Prisms or fibers up to 2 cm. Golden to lemon yellow, orange-yellow streak, silky luster. Cleavage $\{100\}$, $\{010\}$, $\{101\}$, perfect. $H = 1\frac{1}{2}$. $G = 3.96$. $R = 22.0$ (540 nm); strongly pleochroic. White Caps mine(*), Manhattan, Nye Co., NV; Jas Roux, Hautes-Alpes, France; Khaidarkan(*), Kyrgyzstan; Gal-Khaya deposit, Yakutia, Russia; Shuiluo deposit, Guangxi Autonomous Region, China; *Nishinomaki mine, Gumma Pref., Japan*. BM *AM 57:1311(1972), CM 13:418(1975), R:891, P&J:386, ABI:567*.

2.11.5.1 Pääkkönenite Sb_2AsS_2

Named in 1981 for Viecko Pääkkönen (1907-1980), Finnish geologist. MON Space group unknown. $a = 5.372$, $b = 3.975$, $c = 11.41$, $\beta = 89.71^\circ$, $Z = 2$, $D = 5.21$. $33\text{-}92$: 3.9_4 3.13_4 2.87_{10} 2.68_6 2.27_3 2.08_2 1.99_2 1.75_3 . Microscopic anhedral grains. Dark gray, gray streak with brown tint, metallic luster. Cleavage in one direction, brittle. $H = 2\frac{1}{2}$, $\text{VHN}_{10} = 87$. $R = 37.2\text{-}47.8$ (540 nm); strongly anisotropic. *Kalliosalo deposit, Seinäjoki region, Finland*; Příbram, Czech Republic. BM *ZVMO 110:480(1981), AM 67:858(1982), ABI:373*.

2.11.6.1 Laphamite $As_2(Se,S)_3$

Named in 1986 for Davis M. Lapham (1931–1974), U.S. mineralogist. *MON* $P2_1/n$. $a = 11.86$, $b = 9.756$, $c = 4.265$, $\beta = 90.17^\circ$, $Z = 4$, $D = 4.60$. $26-123(\text{syn})$: 4.98_8 2.95_5 2.91_{10} 2.87_9 2.82_7 1.80_6 1.77_5 1.72_7 . Prismatic crystals up to 5 mm; dark red, orange-red streak, resinous luster. Cleavage $\{010\}$, perfect; flexible; inelastic; soft. $G = 4.5$. $R = 29.5-34.0$ (540 nm); moderately pleochroic and anisotropic. *Burnside, Northumberland Co., PA*, deposited from a burning coal-waste dump. *BM MM 50:279(1986)*, *AM 72:1024(1987)*, *ABI:285*.

TETRADYMITE GROUP

The tetradymite structures are rhombohedral selenides and tellurides having the chemical formula

where

$A = \text{Bi or Sb}$

$B = \text{Te, Se, S}$

**KAWAZULITE: Bi_2Te_2Se**

Layer structure with the sequence Te-Bi-Se-Bi-Te. Te atoms in successive layers face each other.

and the structure is in space group $R\bar{3}m$, based on layers of successive planes composed entirely of A or X atoms [AM 76:257(1991)]. The structure is similar to that of the arsenic, joseite, and tsumoite groups.

TETRADYMITÉ GROUP

Mineral	Formula	Space Group	a	c	D	
Tetradymite	$\text{Bi}_2\text{Te}_2\text{S}$	$R\bar{3}m$	4.238	29.59	7.27	2.11.7.1
Tellurobismuthite	Bi_2Te_3	$R\bar{3}m$	4.43	29.91	7.86	2.11.7.2
Tellurantimony	Sb_2Te_3	$R\bar{3}m$	4.262	30.45	6.51	2.11.7.3
Paraguanajuatite	$\text{Bi}_2(\text{Se},\text{S})_3$	$R\bar{3}m$	4.140	28.64	7.68	2.11.7.4
Kawazulite	$\text{Bi}_2(\text{Te},\text{Se},\text{S})_3$	$R\bar{3}m$	4.240	29.66	8.11	2.11.7.5
Skippenite	$\text{Bi}_2\text{Se}_2\text{Te}$	$R\bar{3}m$	4.183	29.12	7.94	2.11.7.6

2.11.7.1 Tetradymite $\text{Bi}_2\text{Te}_2\text{S}$

Named in 1831 for the fourfold twinned crystals. Tetradymite group. HEX-R $R\bar{3}m$. $a = 4.238$, $c = 29.59$, $Z = 3$, $D = 7.27$. 19-1330: 3.10₁₀ 2.29₁₀ 2.11₈ 1.97₈ 1.93₈ 1.64₈ 1.35₈ 1.30₈. Rarely as acute rhombohedral crystals, commonly as foliated to bladed masses. Steel-gray, steel-gray streak, metallic luster. Cleavage {0001}, perfect; flexible, inelastic laminae. $H = 1\frac{1}{2}$, $\text{VHN}_{25} = 30-44$. $G = 7.1-7.4$. $R = 53.2-56.4$ (540 nm); weakly anisotropic. Widely distributed in small amounts, commonly in hydrothermal gold-quartz veins. Whitehall mines, Spotsylvania Co., VA; Sylvanite dist., Hidalgo Co., NM; Trail Creek, Blaine Co., ID; Bisbee, AZ; Melones and Morgan mines, Calaveras Co., CA; Eureka mine, Abitibi Co., PQ, White Elephant mine, near Vernon, BC, Discovery Fork, Carmacks dist., YT, and many other localities in Canada; Narverud, Telemark, Norway; Boliden, Västerbotten, Sweden; Zahkov, Slovakia; Ciclova, Romania; Ergelyatch deposit, Yakutia, Russia; Dashuigou, Sichuan, China; Tsushima Is., Japan; Nanima, NSW, Australia. BM DI:161, AM 34:370(1949), R:436, P&J:367, ABI:524.

2.11.7.2 Tellurobismuthite Bi_2Te_3

Named in 1863 for the composition. Tetradymite group. HEX-R $R\bar{3}m$. $a = 4.43$, $c = 29.91$, $Z = 3$, $D = 7.86$. 8-27: 3.23₁₀ 2.36₇ 2.21₅ 2.00₃ 1.82₃ 1.61₂ 1.49₃ 1.41₄. Irregular plates and foliated masses. Pale lead-gray color and streak, metallic luster. Cleavage {0001}, perfect; flexible, inelastic laminae. $H = 1\frac{1}{2}-2$, $\text{VHN}_{25} = 51$. $G = 7.6-7.9$. $R = 59.6-61.5$ (540 nm); weakly anisotropic. Tellurium mine, Fluvanna Co., VA; Field's vein, Dahlonega, Lumpkin Co., GA; Whitehorn, Fremont Co., Mt. Chipeta, Chaffee Co., and other localities in CO; Little Mildred mine, Grant Co., NM; Bisbee, AZ; Horne mine, Noranda, PQ, Lucky Jim mine, Quadra Is., BC, Canada; Boliden, Västerbotten, Sweden; Kaler deposit, Armenia; Uzelga Cu deposit, Ural Mts., Russia; Zhana-tube deposit, Kazakhstan; Oya mine, Miyage Pref., Kiura mine, Oita Pref.,

and other localities in Japan. *BM DI:160, ACB 30:1307(1974), R:436, P&J:365, ABI:517.*

2.11.7.3 Tellurantimony Sb_2Te_3

Named in 1973 for the composition. Tetradymite group. *HEX-R R3m*. $a = 4.262$, $c = 30.45$, $Z = 3$, $D = 6.51$. *15-874(syn)*: 3.38₁ 3.16₁₀ 2.35₄ 2.13₃ 1.77₁ 1.58₁ 1.47₁ 1.36₁. Microscopic laths. Gray, gray streak, metallic luster. $H = 2$, $\text{VHN}_{25} = 50$. $R = 64.1-64.3$ (540 nm); moderately anisotropic. *Mattagami Lake mine, Galinee Twp., PQ, Canada; Kobetsuzawa mine, Sapporo, Japan. BM CM 12:55(1973), P&J:363, ABI:515.*

2.11.7.4 Paraguanajuatite $\text{Bi}_2(\text{Se,S})_3$

Named in 1948 as a dimorph of guanajuatite. Tetradymite group. *HEX-R R3m*. $a = 4.140$, $c = 28.64$, $Z = 3$, $D = 7.68$. *33-124(syn)*: 4.78₂ 3.56₂ 3.04₁₀ 2.24₃ 2.11₁ 2.07₃ 1.91₁ 1.71₁. Intergrown with guanajuatite. Lead-gray, lead-gray streak, metallic luster. $H = 2$, $\text{VHN}_{10} = 27-50$. $R = 51.0-55.0$ (540 nm); distinctly pleochroic and anisotropic. *Santa Catarina mine, Guanajuato, GTO, Mexico; Falun, Sweden. BM AM 34:619(1949), R:714, P&J:188, ABI:383.*

2.11.7.5 Kawazulite $\text{Bi}_2(\text{Te,Se,S})_3$

Named in 1970 for the locality. Tetradymite group. *HEX-R R3m*. $a = 4.240$, $c = 29.66$, $Z = 3$, $D = 8.11$. *29-248*: 4.92₄ 3.64₃ 3.12₁₀ 2.61₂ 2.31₅ 2.12₅ 1.76₂ 1.65₁. Thin plates. Silver-white to tin-white, light steel-gray streak, metallic luster. Cleavage {0001}, perfect; flexible; inelastic. $H = 1\frac{1}{2}$, $\text{VHN}_{15} = 38$. $R = 60.0$ (547 nm); strongly anisotropic. Lone Pine mine, Grant Co., NM; Ward mine, White Pine Co., NV; Dianne Cu-U claims, Mazenod Lake, NWT, Canada; *Kawazu mine, Shizuoka Pref., and Sutttsu mine, Hokkaido, Japan. BM AM 57:1312(1972), CM 19:341(1981), ABI:258, NJMA 169:305(1995).*

2.11.7.6 Skippenite $\text{Bi}_2\text{Se}_2\text{Te}$

Named in 1987 for George Skippen (b.1936), Canadian geologist. Tetradymite group. *HEX-R R3m*. $a = 4.183$, $c = 29.12$, $Z = 3$, $D = 7.94$. *42-1373*: 9.71₅ 4.85₆ 3.58₆ 3.07₁₀ 2.27₇ 2.13₅ 2.09₈ 1.42₅. Massive aggregates of lamellar crystals. Steel-gray, black streak, metallic luster. Cleavage {0001}, perfect. $H = 2$, $\text{VHN}_{25} = 52-74$. $R = 49.0-50.3$ (540 nm); moderately anisotropic. *Otish Mts. uranium deposit, PQ, Canada. BM CM 25:625(1987), AM 74:947(1989), ABI:479.*

2.11.8.1 Montbrayite Au_2Te_3

Named in 1946 for the locality. May contain up to 3% Bi, 2% Pb, and 1% Ag and Sb. *TRIC P1*. $a = 12.11$, $b = 13.44$, $c = 10.80$, $\alpha = 104.38^\circ$, $\beta = 97.50^\circ$, $\gamma = 107.93^\circ$, $Z = 12$, $D = 9.70$. *25-364(syn)*: 9.30₁ 7.36₂ 4.43₄ 3.81₁ 2.98₈ 2.92₆ 2.12₄ 2.09₁₀. Microscopic grains and small masses. Yellow-white,

metallic luster. One perfect cleavage. $H = 2\frac{1}{2}$, $VHN_{100} = 238$. $G = 9.94$. $R = 63.5$ (540 nm); weakly anisotropic. April Fool mine, Lincoln Co., NV; *Robb-Montbray mine, Montbray Twp., PQ, Canada*; Kalgoorlie, WA, Australia. *BM AM 31:515(1946), 57:146(1972), R:435, ABI:338*.

2.11.9.1 Ottemannite Sn_2S_3

Named in 1966 for Joachim Ottemann (b.1914), German mineralogist. ORTH *Pnam*. $a = 8.864$, $b = 14.020$, $c = 3.747$, $Z = 4$, $D = 4.76$. $14-619(\text{syn})$: 7.0_4 5.5_8 4.13_{10} 3.74_4 3.26_3 2.75_4 2.67_5 2.26_3 . Microscopic crystals. Gray, metallic luster. $H = 2$. $G_{\text{syn}} = 4.87$. *Cerro Rico de Potosi*, and *Maria Teresa mine, near Huari, Bolivia*; Stiepelmann mine, Arandis, Namibia. *BM AM 51:1551(1966), CE 33:243(1974), R:704, ABI:370*.

2.11.10.1 Nagyagite $Pb_{13}Au_2Sb_3Te_6S_{16}$

Named in 1845 for the locality. ORTH (pseudo-TET). $a = 8.336$, $b = 30.20$, $c = 8.288$, $Z = 2$, $D = 7.51$. $8-3(\text{syn})$: 3.02_{10} 2.81_6 2.43_4 2.08_3 1.82_3 1.70_3 1.51_6 1.46 . Platy {010} with rectangular striations; also massive, granular. Blackish lead-gray color and streak, metallic luster. Cleavage {010}, perfect; {101}, good; flexible cleavage flakes. $H = 1\frac{1}{2}$, $VHN_{100} = 60-94$. $G = 7.4-7.5$. $R = 38.8-42.8$ (540 nm); distinctly anisotropic. Widely distributed in Au-Te deposits. Gold Mill, Boulder Co., and Cripple Creek, Teller Co., CO; Dorleska mine, Trinity Co., CA; Muronian mine, Moss Twp., ON, and Olive Mabel claim, Gainer Creek, BC, Canada; Schellgadener, Austria; Jilovc, Czech Republic; *Sacarimb (Nagyag), Romania*; Rendaiji mine, Shizuoka Pref., Japan; Tarua goldfield, Fiji; Sylvia mine, Tararu Creek, New Zealand; Kalgoorlie, WA, Australia; Farallon Negro, Catamarca Prov., Argentina. *BM DI:168, R:433, P&J:276, ABI:344, MM 58:479(1994)*.

2.11.11.1 Buckhornite $AuPb_2BiTe_2S_3$

Named in 1992 for the locality. ORTH *Pmmm* or *P222*. $a = 9.374$, $b = 12.326$, $c = 4.073$, $Z = 2$, $D = 8.35$. *CM 30*: 3.74_8 3.11_8 2.76_{10} 2.46_8 2.39_{10} 2.04_6 1.82_4 1.71_6 . Euhedral to subhedral blades to 1.5 mm. Black, gray streak, metallic luster. One good cleavage, sectile, flexible. $VHN_{10} = 54$. $R = 41.0-47.8$ (540 nm); distinctly anisotropic. *Buckhorn mine, near Jamestown, Boulder Co., CO*; Jilovc, Czech Republic; Megradzor deposit, Armenia. *BM CM 30:1039(1992), CR 318:1225(1994)*.

2.11.12.1 Bowieite $(Rh, Ir, Pt)_2S_3$

Named in 1984 for Stanley H. U. Bowie (b.1917), Scottish mineralogist. ORTH *Pbcn*. $a = 8.462$, $b = 5.985$, $c = 6.138$, $Z = 4$, $D = 6.45$. $35-736(\text{syn})$: 3.07_7 3.01_{10} 2.99_7 2.14_7 1.76_6 1.73_8 1.16_8 1.15_{10} . Microscopic anhedral grains. Gray, metallic luster. $H = 6-7$, $VHN_{100} = 1288$. $R = 46.2-47.8$ (540 nm); weakly anisotropic. *Salmon R., Goodnews Bay, AK*; Gusevogorskii massif, Ural Mts., Russia; Gaositai, Hebei Prov., China; Pirogues R., New Caledonia. *BM CM 22:543(1984), ABI:66*.

2.11.12.2 Kashinite (Ir,Rh)₂S₃

Named in 1985 for S. A. Kashin (1900–1980), Russian geologist. ORTH *Pbcn*. $a = 8.469$, $b = 6.001$, $c = 6.143$, $Z = 4$, $D = 10.23$. d_{1-1416} : 3.07_8 3.01_{10} 2.99_7 2.15_5 1.74_5 1.19_6 1.14_8 1.03_5 . Microscopic subhedral crystals. Gray-black, metallic luster. $H = 7\frac{1}{2}$, $VHN_{50} = 1529$. $R = 45.8-47.5$ (540 nm); distinctly anisotropic. Goodnews Bay, AK; *Nizhni Tagil, Ural Mts., Russia*, in placers. *BM ZVMO 114:617(1985)*, *AM 72:223(1987)*, *ABI:257*.

PYRITE GROUP

Many metal disulfides share the pyrite structure

where

A = Au, Co, Cu, Fe, Mn, Ni, Os, Pd, Pt, Ru

X = As, Bi, S, Sb, Se, Te

and structure is in the cubic space group *Pa3*. In the pyrite structure, metal atoms occupy the face-centered cubic lattice positions, and the S atoms lie in dumbbell-like pairs (S_2^{2-} groups) parallel to the four cube diagonals of the lattice. Each Fe is surrounded by six S atoms in octahedral coordination. Each pair of S atoms is coordinated to six Fe atoms.

**PYRITE: FeS₂**

Fe and S₂ groups are in an NaCl arrangement.

PYRITE GROUP

Mineral	Formula	Space Group	D		
			a		
Pyrite	FeS ₂	Pa3	5.417	5.01	2.12.1.1
Vaesite	NiS ₂	Pa3	5.670	4.47	2.12.1.2

Note: See also the cobaltite and marcasite groups.

2.12.1.1 Pyrite FeS₂

Named in antiquity from the Greek for *fire*, since sparks can be struck from it. Pyrite group. Dimorphous with marcasite. iso Pa3. $a = 5.417$, $Z = 4$, $D = 5.01$. 6-710(syn): 3.13₄ 2.71₉ 2.43₇ 2.21₅ 1.92₄ 1.63₁₀ 1.45₃ 1.04₃. **Habit:** Crystals common, typically cubic, also pyritohedral or octahedral; pyritohedral and cubic faces commonly striated; also massive, granular, in some cases radiated, reniform, or globular. Twins with twin axis [110], interpenetrating (Iron Cross Law). **Structure:** The metal atoms occupy the face-centered cubic lattice positions, and the S atoms lie in dumbbell-like pairs (S₂²⁻ groups) parallel to the four cube diagonals of the lattice. The S atoms are in octahedral coordination about each Fe atom, and the S₂ pairs are, in turn, coordinated to six Fe atoms. **Physical properties:** Pale brass-yellow, sometimes with iridescent tarnish, greenish black to brownish black streak, metallic luster. Cleavage {001}, indistinct; conchoidal to uneven fracture. $H = 6-6\frac{1}{2}$. $VHN_{100} = 1505-1520$. $G = 4.8-5.0$. Paramagnetic. **Tests:** Insoluble in HCl, soluble in strong HNO₃. **Chemistry:** Usually pure FeS₂, but Ni (var. bravoite) and Co may substitute for Fe. **Optics:** $R = 53.8$ (540 nm); may show anisotropism. **Occurrence:** The most widespread and commonest sulfide mineral, pyrite occurs in almost all geological environments: an accessory mineral in igneous rocks; as a magmatic segregation; in pegmatites; in contact-metamorphic deposits; in

hydrothermal veins and replacement deposits; as a sublimation product; and in sediments and sedimentary rocks. **Localities:** Only a few localities for large or fine crystals can be mentioned. Chester, VT; Franklin, NJ; French Creek, Chester Co., PA; Amex mine, Boss, MO; Butte, MT; Rico and Leadville, CO; Park City and Bingham, UT; Holland mine, Santa Cruz Co., and Magma mine, Superior, AZ; Spruce Peak, King Co., WA; Prince of Wales I., AK; Nanisivik mine, NWT, Canada; Cananea, SON, Naica and Santa Eulalia, CHIH, Noche Buena and Concepcion del Oro, ZAC, Mexico; Panasquero, Portugal; Ambasaguas and Navajun, Logroño Prov., Spain; Rio Marina, Elba, and Brosso, Piedmont, Italy; Kassandra, Greece; Kovdor, Kola, Russia; Akchitau, Kazakhstan; Mt. Stewart mine, Leadville, NSW, Australia; Quiruvilca, La Libertad, Huancala, Huanoco, Morococha, and San Cristobal, Junin, Peru; Lapiana mine, Chicote Grande, Tacna, and Llallagua, Bolivia; Serra do Cabral, MG, Brazil. **Alteration:** Alters readily to iron sulfates and iron oxides. Pseudomorphs of brown limonite after pyrite crystals are common. **Uses:** A source of sulfur for the manufacture of sulfuric acid. *BM DI:281, R:791, P&J:311, ABI:426.*

2.12.1.2 Vaesite NiS₂

Named in 1945 for Johannes Vaes (1902–1978), Belgian mineralogist. Pyrite group. iso *Pa*3. $a = 5.670$, $Z = 4$, $D = 4.47$. *11-99*: 2.83₁₀ 2.54₄ 2.32₄ 2.00₅ 1.71₈ 1.57₃ 1.09₆ 1.00₄. Small octahedral and cubic crystals. Silver-gray, black streak, metallic luster. Cubic cleavage. $H = 5$, $VHN_{100} = 743-837$. $G = 4.45$. $R = 31.6$ (540 nm). Miliken (Sweetwater) mine, Reynolds Co., MO; Orphan mine, Grand Canyon, AZ; Schneeberg, Nentershausen, and Iserlohn, Germany; Carmenes district, Leon Prov., Spain; St. Marina, Khaskovo district, Bulgaria; Kosaka mine, Japan; Scotia mine, Kalgoorlie, WA, Australia; *Kasompi mine* and Shinkolobwe mine, *Shaba, Zaire*; San Santiago mine, La Rioja Prov., Argentina. *BM AM 30:483(1945), R:809, P&J:105, MM 43:950(1980), ABI:554.*

2.12.1.3 Cattierite CoS₂

Named in 1945 for Felicien Cattier (1869–1946), chairman of the board, Union Miniere du Haut-Katanga. Pyrite group. iso *Pa*3. $a = 5.534$, $Z = 4$, $D = 4.82$. *19-362(syn)*: 2.77₇ 2.48₄ 2.26₄ 1.96₄ 1.67₁₀ 1.48₄ 1.06₁₀ 1.03₄. Cubic crystals and granular. Silver-gray with a pink tinge, black streak, metallic luster. Cubic cleavage. $H = 5$, $VHN_{100} = 1018-1114$. $G = 4.82$. $R = 36.7$ (540 nm). Bald Knob, Alleghany Co., NC; Gansberg and Hohensachsen, Black Forest, Germany; near Filipstad, Varmland, Sweden; *Shinkolobwe mine, Shaba, Zaire*. *BM AM 30:483(1945), ZK 150:163(1979), R:809, P&J:105, ABI:84.*

2.12.1.4 Penroseite NiSe₂

Named in 1926 for Richard A. F. Penrose (1863–1931), U.S. geologist. Pyrite group. Dimorphous with kullerudite. Contains up to 9% Co and 6% Cu. iso *Pa*3. $a = 5.991$, $Z = 4$, $D = 6.70$. *6-507*: 3.02₃ 2.68₁₀ 2.45₁₀ 1.81₉ 1.66₃ 1.60₄

1.30₂ 1.15₃. Reniform masses with radiating columnar structure. Steel-gray, black streak, metallic luster. Cleavage {001}, perfect; {011}, distinct; sub-conchoidal fracture; brittle. $H = 3$, $VHN_{100} = 500-583$. $G = 6.6-6.7$. $R = 41.1$ (540 nm). Hope's Nose, Devon, England; Kuusamo, Finland; Tilkeroode, Harz, Germany; Shinkolobwe mine, Shaba, Zaire; *Pacajake mine*(*), *Hiaco, Bolivia*. BM *DI:294*; *AM 35:360(1950)*, *74:1171(1989)*; *R:818*; *P&J:293*; *ABI:395*.

2.12.1.5 Trogtalite $CoSe_2$

Named in 1955 for the locality. Pyrite group. Contains 9% Cu and 5% Pd. Dimorph of hastite. iso $Pa\bar{3}$. $a = 5.931$, $Z = 4$, $D = 7.20$. *25-253*: 2.95₇ 2.64₁₀ 2.42₉ 1.79₈ 1.64₅ 1.59₇ 1.30₅ 1.14₆. Microscopic grains. Iron-gray, black streak, metallic luster. $R = 41.3$ (540 nm). *Trogtal quarry, near Lautenthal, Harz, Germany*; Musonoi mine, Shaba, Zaire. BM *NJMM:133(1955)*, *AM 41:164(1956)*, *R:819*, *P&J:372*, *ABI:537*.

2.12.1.6 Villamaninite CuS_2

Named in 1920 for the locality. Pyrite group. Contains considerable Ni, Co, and Fe. iso $Pa\bar{3}$. $a = 5.694$, $Z = 4$, $D = 4.50$. *29-556*: 3.29₂ 2.85₁₀ 2.55₃ 2.33₃ 2.01₃ 1.72₄ 1.58₁ 1.10₂. Cubic and octahedral crystals and massive. Black, black streak, metallic luster. Perfect cubic cleavage, uneven fracture. $H = 4\frac{1}{2}$, $VHN_{20} = 535-710$. $G = 4.4-4.5$. $R = 23.4$ (540 nm). *Providencia mine, near Villamanin, Leon Prov., Spain*; Lubin mine, near Legnica, Poland. BM *NJMM:174(1968)*, *AM 74:1173(1989)*, *R:816*, *P&J:383*, *ABI:558*.

2.12.1.7 Fukuchilite $(Cu,Fe)S_2$

Named in 1969 for Nobuyo Fukuchi (1877-1934), Japanese mineralogist. Pyrite group. iso $Pa\bar{3}$. $a = 5.604$, $Z = 4$, $D = 4.66$. *24-365(syn)*: 3.24₆ 2.80₁₀ 2.50₆ 2.29₆ 1.98₆ 1.69₈ 1.14₆ 1.08₈. Microscopic grains. Gray, gray streak, submetallic luster. $H = 6$. $G = 4.86$. *Hanawa mine, Akita Pref., Japan*. BM *MJJ 5:399(1969)*; *AM 55:1811(1970)*, *74:1173(1989)*; *ABI:167*.

2.12.1.8 Krutaite $CuSe_2$

Named in 1972 for Tomas Kruta (b.1906), Czech mineralogist. Contains minor Ni and Co. Pyrite group. iso $Pa\bar{3}$. $a = 6.116$, $Z = 4$, $D = 6.62$. *25-309*: 3.02₉ 2.71₁₀ 2.48₈ 1.83₆ 1.68₄ 1.62₃ 1.32₃ 1.17₄. Microscopic subhedral crystals. Gray, gray streak, metallic luster. $H = 4$, $VHN_{100} = 317$. $R = 34.9$ (540 nm). *Petrovice mine, Moravia, Czech Republic*; El Dragon mine(*), Potosi, Bolivia. BM *BM 95:475(1972)*, *AM 59:210(1974)*, *R:820*, *P&J:229*, *ABI:277*.

2.12.1.9 Hauerite MnS_2

Named in 1846 for Josef von Hauer (1778–1863) and his son Franz von Hauer (1822–1899), Austrian geologists. Pyrite group. iso $Pa3$. $a = 6.100$, $Z = 4$, $D = 3.48$. $25-549(\text{syn})$: 3.05_{10} 2.73_7 2.49_7 2.16_7 1.84_8 1.25_7 1.18_8 1.08_7 . Octahedral crystals and globular aggregates. Red-brown to brown-black, red-brown streak, adamantine to submetallic luster. Perfect cubic cleavage. $H = 4$. $G = 3.46$. $R = 24.8$ (540 nm); isotropic, $N = 2.69$. Salt domes in Texas; *Kalinka, Slovakia*; Jeziorko and Grzybow, Poland; Raddusa(*), Sicily, Italy; Yazovsk and Podgornensk deposits, Aktyubinsk, Ural Mts., Russia. *BM DI:293, R:826, P&J:194, ABI:207*.

2.12.1.10 Laurite RuS_2

Named in 1866 for Laura R. Joy, wife of C. A. Joy (1823–1891), U.S. chemist. Pyrite group. Forms a series with erlichmanite, OsS_2 . iso $Pa3$. $a = 5.610$, $Z = 4$, $D = 6.22$. $19-1107(\text{syn})$: 3.24_8 2.81_{10} 2.51_2 2.29_2 1.98_6 1.69_{10} 1.62_2 1.08_4 . Small cubic, octahedral, and pyritohedral crystals and rounded grains. Iron-black, dark gray streak, metallic luster. Cleavage $\{111\}$, perfect. $H = 7\frac{1}{2}$, $VHN_{25} = 2760-2898$. $G = 6.2-7.0$. $R = 40.2$ (540 nm). Stillwater Complex, MT; Yuba R., Nevada Co., and Trinity R., Trinity Co., CA; Goodnews Bay, AK; Tulameen area, BC, Canada; Konder massif, Yakutia, Russia; *Pontijn, Tanah Laut, Borneo*; Pirogues R., New Caledonia; Maud Creek, Howard R., New Zealand; Guma Water, Sierra Leone; Merensky Reef, Transvaal, South Africa. *BM DI:291, R:820, P&J:233, MM 47:465(1983), ABI:289*.

2.12.1.11 Aurostibite $AuSb_2$

Named in 1952 for the composition. Pyrite group. iso $Pa3$. $a = 6.659$, $Z = 4$, $D = 9.91$. $8-460(\text{syn})$: 3.85_3 3.33_7 2.98_8 2.72_6 2.36_6 2.01_{10} 1.78_3 1.28_3 . Microscopic grains. Gray, metallic luster. $H = 3$, $VHN = 280-292$. $G_{\text{syn}} = 9.98$. $R = 61.8$ (540 nm). Occurs in hydrothermal quartz veins. Tonawanda mine, Cadillac Twp., PQ, Chesterville mine, Larder Lake, ON, and *Giant Yellowknife mine, NWT, Canada*; Suliteljema, Norway; Krasna Hora, near Milesov, Czech Republic; Bestyube goldfield, Kazakhstan; Mobale mine, Kivu, Zaire; Sebaque area, Que-Que, Zimbabwe; Hillgrove, NSW, and Costerfield, VIC, Australia. *BM AM 32:461(1952), R:824, ABI:37, NJMM:537(1990)*.

2.12.1.12 Krutovite $NiAs_2$

Named in 1976 for Georgi A. Krutov (1902–1989), Russian mineralogist. Pyrite group. iso $Pa3$. $a = 5.794$, $Z = 4$, $D = 6.93$. $29-928$: 2.90_6 2.59_{10} 2.37_8 2.05_5 1.75_8 1.61_5 1.55_6 1.02_6 . Microscopic grains. Gray-white, metallic luster. $H = 5\frac{1}{2}$, $VHN = 630$. $R = 65.0$ (540 nm). *Geshiber vein, Jachymov, Czech Republic*; Kohmahs deposit, Tuva ASSR, Russia. *BM ZVMO 105:59(1976), AM 62:173(1977), ABI:278*.

2.12.1.13 Sperrylite PtAs₂

Named in 1889 for Francis L. Sperry (1861–1906), U.S. chemist, who found the mineral. Pyrite group. iso *Pa*3. $a = 5.967$, $Z = 4$, $D = 10.78$. *9-452*: 3.43₄ 2.98₆ 2.11₅ 1.80₁₀ 1.33₄ 1.22₄ 1.15₇ 1.05₄. Cubic and cubo-octahedral crystals, up to 3 cm. Tin-white, black streak, metallic luster. Cleavage {100}, indistinct; conchoidal fracture, brittle. $H = 6\frac{1}{2}$, $VHN_{100} = 960-1277$. $G = 10.6$. $R = 55.2$ (540 nm). The commonest Pt mineral. Rambler mine, Encampment, and Mouat mine, Stillwater, MT; *Vermilion mine*, and other mines in the *Sudbury district*, ON, Fraser R., BC, Canada, in placers; Hitura Cu–Ni deposit, Finland; Talnakh(*), Norilsk (centimeter-sized crystals), and in alluvial deposits, Yakutia, Russia; Kambalda Ni-mine, WA, Australia; Merensky Reef mines(*), Transvaal, South Africa. BM *DI:292*, *EG 71:1299(1976)*, *R:821*, *P&J:346*, *ABI:487*.

2.12.1.14 Geversite PtSb₂

Named in 1961 for Traugott W. Gevers (1900–1991), South African geologist. Pyrite group. iso *Pa*3. $a = 6.44$, $Z = 4$, $D = 10.91$. *14-141(syn)*: 2.92₃ 1.94₈ 1.72₅ 1.31₅ 1.24₁₀ 1.19₆ 1.17₅ 1.14₈. Microscopic grains. Gray, metallic luster. $H = 4\frac{1}{2}-5$, $VHN_{50} = 726-766$. $R = 58.9$ (540 nm). Occurs in concentrates of Pt minerals. Fox Gulch, Goodnews Bay, AK; Morozova mine, Norilsk, and Vozhmin massif, Karelia, Russia; *Driekop mine*, eastern Transvaal, South Africa. BM *MM 32:833(1961)*, *ABI:183*.

2.12.1.15 Insizwaite Pt(Bi,Sb)₂

Named in 1972 for the locality. Pyrite group. iso *Pa*3. $a = 6.691$, $Z = 4$, $D = 13.59$. *25-512*: 2.96₈ 2.70₈ 2.34₅ 2.00₁₀ 1.77₇ 1.44₅ 1.28₆ 1.17₆. Microscopic grains. White, metallic luster. $H = 5$, $VHN_{25} = 488-540$. $R = 54.0$ (540 nm). Fox Gulch, Goodnews Bay, AK; Coleman mine, Sudbury, ON, Canada; Norilsk region, Russia; *Waterfall Gorge*, Insizwa, South Africa. BM *MM 38:794(1972)*, *AM 58:805(1973)*, *ABI:236*.

2.12.1.16 Erlichmanite OsS₂

Named in 1971 for Josef Erlichman (b.1935), U.S. chemist. Pyrite group. Forms a series with laurite, RuS₂. iso *Pa*3. $a = 5.620$, $Z = 4$, $D = 9.52$. *19-882(syn)*: 3.24₁₀ 2.81₉ 1.99₆ 1.69₉ 1.62₂ 1.29₃ 1.26₃ 1.08₃. Small pyritohedral crystals and microscopic grains. Gray, metallic luster. $VHN_{100} = 1730-1950$. $G = 8.28$. $R = 42.9$ (540 nm). *MacIntosh mine*, *Trinity R.*, *Humboldt Co.*, and *American R.*, Sacramento Co., CA; Tulameen R., BC, Canada; Ural Mt. placers, and Konder massif, Yakutia, Russia; Tiebaghi, and Pirogues R., New Caledonia; Maud Creek, Howard R., New Zealand; Guma Water, Sierra Leone; Joubdo stream, Birbir R., Ethiopia; Merensky Reef, Transvaal, South Africa. BM *AM 56:1501(1971)*, *MM 47:465(1983)*, *R:821*, *ABI:149*.

2.12.1.17 Dzarkenite FeSe₂

Named in 1995 for the locality. Pyrite group. Dimorphous with ferroselite. iso *Pa*3. $a = 5.783$, $Z = 4$, $D = 7.34$. *ZVMO 124*: 2.89₅ 2.59₁₀ 2.36₈ 2.05₄ 1.74₅ 1.55₆ 1.26₃ 1.11₄. Microscopic octahedral crystals. Black, black streak, metallic to adamantine luster. No cleavage. $H = 5$. $R = 42.6$ (546 nm); isotropic, rosy yellow in reflected light. *Suluchekinskoye Se deposit, Dzarkenskaya depression, SE Kazakhstan*. BM *ZVMO 124(1):85(1995)*.

2.12.1.18 Gaotaiite Ir_{1-x}Te₂ (x = 0.25)

Named in 1995 for the locality. Pyrite group. iso *Pa*3. $a = 6.413$, $Z = 4$, $D = 10.0$. *AM 81*: 2.86₇ 2.60₆ 1.93₁₀ 1.71₆ 1.24₈ 1.13₉ 1.04₈ 0.978₈. Microscopic subhedral grains and veinlets. Black, black streak, metallic luster. Brittle. $H = 3$, $VHN_{20} = 117$. $R = 46.3$ (540 nm); in reflected light white with bluish tint, isotropic to weakly anisotropic. In placer concentrates and chromite ore near the village of Gaotai, 200 km NNE of Beijing, China. BM *AMS 15(1):1(1995)*, *AM 81:249(1996)*.

2.12.1.19 Mayingite IrBiTe

Named in 1995 for the locality. Pyrite group. iso *Pa*3. $a = 6.502$, $Z = 4$, $D = 12.77$. *AM 81*: 2.89₇ 1.96₁₀ 1.74₈ 1.25₈ 1.21₇ 1.15₇ 1.05₇ 0.991₇. Massive aggregates and veinlets to 1 mm. Black, black streak, metallic luster. Brittle. $H = 4$, $VHN_{50} = 178$. $R = 50.7$ (540 nm); in reflected light white with a yellow tint, moderately anisotropic. In placer concentrates and chromite ore near Maying, 230 km NNE of Beijing, China. BM *AMS 15(1):5(1995)*, *AM 81:251(1996)*.

MARCASITE GROUP

Marcasite group minerals have the general formula

where

A = Fe, Co, Ni, Ru, Os

X = S, Se, Te, As, Sb

and the minerals crystallize in the orthorhombic space group *Pnmm*. In the marcasite structure the metal atoms occupy the lattice points of an orthorhombic body-centered lattice, and the sulfur atoms surround each metal atom in sixfold coordination. The structure is related to that of pyrite (pyrite and marcasite are dimorphous) but with the S_2^{2-} pairs lying in the *a-b* plane. Reference: B. J. Wuensch, Sulfide Mineralogy, *Reviews in Mineralogy*, Vol. 1, Mineralogical Society of America, Washington, DC, 1974.

MARCASITE: FeS_2

Marcasite has the same octahedral coordination of iron by sulfur and disulfide ions as pyrite, but arranged differently into orthorhombic symmetry.

MARCASITE GROUP

Mineral	Formula	Space Group	a	b	c	D
Marcasite	FeS_2	<i>Pnmm</i>	4.436	5.414	3.381	4.91
Ferroselite	FeSe_2	<i>Pnmm</i>	4.815	5.808	3.599	7.05

Rammelsbergite	NiAs_2	<i>Pnmm</i>	4.759	5.797	3.539	7.09
Nisbite	NiSb_2	<i>Pnmm</i>	5.178	6.319	3.832	8.01

Notes:

1. The structure of arsenopyrite is a derivative of the marcasite structure.
2. Many of the marcasite minerals have dimorphs in the pyrite group.
3. The stability relations between marcasite and pyrite are unclear.

2.12.2.1 Marcasite FeS_2

Named in 1845 from an Arabic or Moorish word applied to pyrite and similar minerals. Dimorphous with pyrite. ORTH *Pnmm*. $a = 4.436$, $b = 5.414$, $c = 3.381$, $Z = 2$, $D = 4.91$. ρ_4-74 : 3.43_7 2.71_3 2.69_{10} 2.41_4 2.31_3 1.91_3 1.75_5 1.59_2 . **Habit:** Crystals common, typically tabular {010}, also pyramidal;

faces commonly curved; also stalactitic, globular, or reniform, with radiating internal structure. Twinning common on {101}, producing swallowtail contact twins, and repeated to form stellate fivelings. **Structure:** Consists of S_2^{2-} pairs as in pyrite but with the dumbbell groups lying in the a - b plane in the orthorhombic structure; the Fe atoms are in octahedral coordination with S. **Physical properties:** Pale brass-yellow, tending toward light green on exposure, tin-white on fresh fracture, gray to black streak, metallic luster. Cleavage {101}, distinct; uneven fracture. $H = 6-6\frac{1}{2}$, $VHN_{200} = 915-1099$, $G = 4.89$. Tends to decompose in moist conditions to iron sulfates. **Tests:** Reacts like pyrite but is more readily decomposed. **Chemistry:** Usually pure FeS_2 . **Optics:** $R = 48.6-55.5$ (540 nm); strongly anisotropic. **Occurrence:** Most marcasite occurs in near-surface deposits, where it has formed at low temperatures from acid solutions; pyrite, the more stable form, is deposited under conditions of higher temperature and alkalinity or low acidity. It is frequently found in sedimentary rocks and coal, often as concretions or replacing fossils. **Localities:** Only a few of the more significant can be given. Hackerville, OH; Pleasant Ridge, IN; the Pb-Zn deposits of the Mississippi Valley and the Tri-State mining district, MO-KS-OK; Temple, Bell Co., TX; Algoma mines, Wawa, ON, and Nanisivik mine, Baffin I., NWT, Canada; Santa Eulalia, CHIH, Mexico; Tavistock, Devon, and between Folkestone and Dover, Kent, England; Herne, Westphalia, Clausthal, Harz, and Freiberg, Saxony, Germany; Duchov, Vinitrov, Most, and other places in Czech Republic; Angren coalfield, Uzbekistan; Oppu mine, Akita Pref., Japan; Llallagua, Bolivia. *BM DI:311, AM 44:685(1959), R:839, P&J:257, ABI:312.*

2.12.2.2 Ferroselite $FeSe_2$

Named in 1955 for the composition. ORTH *Pnmm*. $a = 4.815$, $b = 5.808$, $c = 3.599$, $Z = 2$, $D = 7.05$. $12-291(\text{syn}): 3.07_2$ 2.89_5 2.59_{10} 2.49_9 1.89_8 1.80_4 1.71_3 1.46_3 . Small prismatic crystals and stellate and cruciform twins. Tin-white to steel-gray, black streak, metallic luster. $H = 6-6\frac{1}{2}$, $VHN_{25} = 858-933$. $G = 7.20$. $R = 45.6-51.4$ (540 nm); strongly anisotropic. An accessory mineral in Colorado Plateau uranium deposits; Kuusamo, Finland; Petrovice and Predborice deposits, Czech Republic; *Tuvinsk Autonomous Territory, Russia*. *BM DANS 105:812(1955), AM 41:671(1956), GCA 16:296(1959), R:845, P&J:162, ABI:156.*

2.12.2.3 Frobergite $FeTe_2$

Named in 1947 for Max H. Froberg (1901-1970), Canadian geologist. Marcasite group. ORTH *Pnmm*. $a = 5.29$, $b = 6.27$, $c = 3.86$, $Z = 2$, $D = 8.07$. $14-419: 3.29_3$ 2.81_{10} 2.71_7 2.07_5 1.94_3 1.85_4 1.58_3 1.11_3 . Microscopic grains. White, metallic luster. $H = 3-4$, $VHN = 250-297$. $R = 50.0-52.4$ (540 nm); strongly anisotropic. Gold Hill, north of San Simon, Cochise Co., AZ; *Robb-Montbray mine* and *Noranda mine*, PQ, and *Lindquist Lake*, BC, Canada; *Bodenec*, Finistere, France; *Sacaramb* and *Fata Baii*, Romania; *Jabal Sayid*, Saudi Arabia. *BM AM 32:310(1947), R:858, P&J:169, ABI:165.*

2.12.2.4 Hastite CoSe_2

Named in 1955 for P. F. Hast, German mining engineer. Marcasite group. Dimorphous with trogtalite. ORTH $Pn\bar{m}$. $a = 4.84$, $b = 5.72$, $c = 3.60$, $Z = 2$, $D = 7.23$. $10\text{-}408$: 2.9_3 2.58_{10} 2.47_{10} 1.90_{10} 1.61_3 1.44_3 1.02_{10} . Small idiomorphic grains and radiating aggregates. Red-brown, metallic luster. $H = 6$. $R = 46.9\text{-}52.2$ (540 nm); strongly pleochroic and anisotropic. La Sal mine, Montrose Co., CO; Trogtal quarry, near Lauenthal, Harz, Germany; San Francisco mine, La Rioja Prov., Argentina. BM *NJMM:133(1955)*, *AM 41:164(1956)*, *R:845*, *P&J:192*, *ABI:204*.

2.12.2.5 Mattagamite CoTe_2

Named in 1973 for the locality. Marcasite group. ORTH $Pn\bar{m}$. $a = 5.312$, $b = 6.311$, $c = 3.889$, $Z = 2$, $D = 8.00$. $11\text{-}553(\text{syn})$: 3.14_8 2.82_{10} 2.71_{10} 2.07_{10} 1.94_8 1.86_8 1.58_8 1.55_8 . Microscopic grains. Gray-violet, metallic luster. $H = 4\frac{1}{2}\text{-}5\frac{1}{2}$, $\text{VHN}_{25} = 383\text{-}404$. $R = 47.9\text{-}53.9$ (540 nm); weakly pleochroic and anisotropic. Mattagami Lake mine, Galinee Twp., PQ, Canada. BM *CM 12:55(1973)*, *AM 59:382(1974)*, *P&J:260*, *ABI:317*.

2.12.2.6 Kullerudite NiSe_2

Named in 1964 for Gunnar Kullerud (1921–1989), Norwegian–U.S. mineralogist. Marcasite group. Dimorphous with penroseite (2.12.1.4). ORTH $Pn\bar{m}$. $a = 4.89$, $b = 5.96$, $c = 3.67$, $Z = 2$, $D = 6.73$. $18\text{-}886$: 3.12_2 2.94_8 2.64_{10} 2.55_{10} 1.93_8 1.84_8 1.69_4 1.65_6 . Massive, fine-grained. Lead-gray, metallic luster. *Kuusamo, Finland*. BM *AM 50:519(1965)*, *R:846*, *ABI:279*.

2.12.2.7 Omeiite OsAs_2

Named in 1978 for the locality. Marcasite group. ORTH $Pn\bar{m}$. $a = 5.409$, $b = 6.167$, $c = 3.021$, $Z = 2$, $D = 11.19$. $34\text{-}336(\text{syn})$: 4.07_9 3.09_8 2.69_3 2.63_{10} 2.01_4 1.93_3 1.91_6 1.70_3 . Microscopic tabular crystals. Steel-gray, metallic luster. Cleavage parallel to elongation. $R = 39.2$ (546 nm); distinctly anisotropic. *Omeishan, Sichuan Prov., China*, in a Cu–Ni sulfide deposit. BM *AM 64:464(1979)*, *ABI:361*.

2.12.2.8 Anduoite RuAs_2

Named in 1979 for the locality. Marcasite group. Forms a series with omeiite. ORTH $Pn\bar{m}$. $a = 5.41$, $b = 6.206$, $c = 3.01$, $Z = 2$, $D = 8.25$. $33\text{-}1144$: 2.00_5 1.92_{10} 1.50_9 1.21_7 1.19_7 1.13_8 1.10_9 1.08_4 . Microscopic grains and granular aggregates. Lead-gray, gray-black streak, metallic luster. One cleavage, brittle. $H = 6\frac{1}{2}\text{-}7$, $\text{VHN}_{50} = 1078$. *Anduo, Tibet, China*. BM *AM 65:808(1980)*, *ABI:13*.

2.12.2.9 Löllingite FeAs_2

Named in 1845 for the locality. Marcasite group. Minor substitution of Co for Fe (up to 6.5%) and S (up to 6.7%) and Sb (up to 5.6%) for As has been

recorded. ORTH *Pnmm*. $a = 5.300$, $b = 5.983$, $c = 2.882$, $Z = 2$, $D = 7.47$. 25-249: 2.62₃ 2.57₁₀ 2.40₈ 1.97₄ 1.87₇ 1.85₃ 1.66₇ 1.64₃. Prismatic crystals, or massive; twinned on {011}, sometimes trillings. Silver-white to steel-gray, gray-black streak, metallic luster. Cleavage {010} and {101}, sometimes distinct; uneven fracture; brittle. $H = 5-5\frac{1}{2}$, $VHN_{100} = 859-920$. $G = 7.4-7.5$. $R = 53.1-53.6$ (540 nm); strongly anisotropic. Occurs with calcite and sulfides of Fe and Cu in veins; also in pegmatites. Auburn, ME, and Center Strafford, NH, in pegmatites; Franklin and Sterling Hill, NJ, in skarn; Black Hills, SD, in many pegmatites (300-kg masses at Ingersoll mine); Gunnison Co., CO, in several mines; Pala, CA, in pegmatites; Cobalt, ON, Canada, in many mines; Andreasberg, Harz Mts., Germany; *Lolling, Carinthia, Austria*; Varuträsk, Sweden, in pegmatite; Guadalcanal, Sierra Morena, Spain; Broken Hill, NSW, Australia. BM *DI:303*, *AM 53:1856(1968)*, *R:854*, *P&J:242*, *ABI:300*.

2.12.2.10 Seinäjokite FeSb₂

Named in 1976 for the locality. Marcasite group. Contains up to 6% Ni and 8% As. ORTH *Pnmm*. $a = 5.810$, $b = 6.490$, $c = 3.190$, $Z = 2$, $D = 8.27$. 29-129: 2.81₁₀ 2.59₉ 2.03₈ 1.79₆ 1.63₂ 1.52₂ 1.21₃ 1.17₃. Small grains. Light gray, metallic luster. $H = 4\frac{1}{2}$, $VHN_{30} = 332$. $R = 60.8$ (540 nm). *Seinäjoki, Vaasa, Finland*, in native antimony; Ilimaussaq intrusion, near Narssaq, Greenland; Zolotaya Gora, Urals, Russia. BM *ZVMO 105:617(1976)*, *AM 62:1059(1977)*, *ABI:467*.

2.12.2.11 Safflorite (Co,Fe)As₂

Named in 1835 from *Zaffer*, a German term for cobalt pigments. Marcasite group. Contains up to 16% Fe. ORTH *Pnmm*. $a = 5.173$, $b = 5.954$, $c = 2.999$, $Z = 2$, $D = 7.46$. 23-88: 2.96₁ 2.60₆ 2.57₈ 2.38₁₀ 1.86₅ 1.85₂ 1.65₂ 1.64₂. Prismatic crystals but commonly massive with radiating fibrous structure. Cyclic fiveling twins with {011} as twin plane, also cruciform twins with {101} as twin plane. Tin-white, tarnishing to dark gray, black streak, metallic luster. Cleavage {100}, distinct; uneven to conchoidal fracture. $H = 4\frac{1}{2}-5$, $VHN_{100} = 792-882$. $G = 7.1-7.4$. $R = 53.5-54.5$ (540 nm); strongly anisotropic. Quartzburg district, Grant Co., OR; Cobalt and South Lorrain, ON, Eldorado mine, Great Bear Lake, NWT, Hedley, BC, Canada; Batopilas, CHIH, Mexico; *Schneeberg* and Annaberg, *Saxony*, Bieber, Hesse, Wittichen, Baden, *Germany*; Tunaberg, Sweden; Sarrabus, Sardinia, Italy; Almalyk, Uzbekistan; Broken Hill, NSW, Australia; Bou Azzer, Morocco. BM *DI:307*, *AM 53:1856(1968)*, *R:347*, *P&J:332*, *ABI:457*.

2.12.2.12 Rammelsbergite NiAs₂

Named in 1854 for Karl F. Rammelsberg (1813-1899), German mineral chemist. Marcasite group. Trimorphous with krutovite and pararammelsbergite. ORTH *Pnmm*. $a = 4.759$, $b = 5.797$, $c = 3.539$, $Z = 2$, $D = 7.09$. 15-441: 2.82₁₀ 2.52₉ 2.42₆ 2.00₃ 1.84₇ 1.75₃ 1.66₃ 1.21₁₀. Prismatic crystals rare, usually mas-

sive. Tin-white with a reddish tint, black streak, metallic luster. Cleavage {101}, distinct; uneven fracture. $H = 5\frac{1}{2}$ -6, $VHN_{100} = 630$ -758. $G = 7.0$ -7.2. $R = 56.0$ -58.2 (540 nm); strongly anisotropic. Occurs with other Ni and Co minerals in vein deposits of the Co-Ni-Ag type. Mohawk and other copper mines, Keweenaw Co., MI; Cobalt, ON, and El Dorado mine, Great Bear Lake, NWT, Canada; *Schneeberg, Saxony*, Richeldorf, Hesse, Eisleben, Thuringia, *Germany*; Lölling, Carinthia, Austria; Sarrabus, Sardinia, Italy; and a number of other worldwide occurrences. BM *DI:309, R:352, P&J:320, ABI:432*.

2.12.2.13 Nisbite $NiSb_2$

Named in 1970 for the composition. Marcasite group. ORTH $Pnmm$. $a = 5.178$, $b = 6.319$, $c = 3.832$, $Z = 2$, $D = 8.01$. *25-1083*(syn): 3.08_5 2.76_{10} 2.69_9 2.03_8 1.84_7 1.56_6 1.17_6 1.10_6 . Microscopic grains. White, metallic luster. $H = 5$, $VHN_5 = 420$ -513. $R = 59.4$ (546 nm); weakly anisotropic. *Red Lake mines, Kenora district, ON, Canada*; Gruvåsen, Geton, and Tunaberg, Bergslagen, Sweden; Zolotaya Gora, Urals, and Festilvanoe mine, Magadan region, Russia. BM *CM 10:232(1970), 18:165(1980)*; *R:863; ABI:354*.

COBALTITE GROUP

The cobaltite group consists of sulfides and selenides corresponding to

ABX

where

A = Co, Ni, Pt, Ir, Rh, Pd

B = As, Sb, Bi

X = S, Se, Te

and the structure is cubic, or pseudocubic, and related to that of pyrite. The structure is similar to that of pyrite but with the S_2 pairs of pyrite replaced by As-S, Sb-S, As-Se, Bi-Se, or Bi-Te pairs.

COBALTITE GROUP

Mineral	Formula	Space Group	a	D	
Cobaltite	CoAsS	$Pca2_1$	5.582	6.34	2.12.3.1

Testibiopalladite	Pd(Sb,Bi)Te	$P2_13$	6.572	8.93	2.12.3.13

2.12.3.1 Cobaltite CoAsS

Named in 1832 for the composition. Cobaltite group. ORTH pseudo-ISO $Pca2_1$. $a = 5.582$, $Z = 4$, $D = 6.34$. *18-431*: 2.77₈ 2.49₁₀ 2.27₉ 1.97₆ 1.68₁₀ 1.49₈ 1.22₅ 1.07₈. Cubic and pyritohedral crystals, often in combination; also massive, granular. Silver-white to steel-gray, gray-black streak, metallic luster. Cleavage {001}, perfect; uneven fracture. $H = 5\frac{1}{2}$, $VHN_{200} = 1171-1346$. $G = 6.3$. $R = 50.3$ (540 nm). Occurs in high-temperature hydrothermal deposits, and as veins in contact-metamorphic deposits. Cobalt district, ON, Canada; Botallack, Cornwall, England; Skutterud, near Modum, Norway; Tunaberg(*), Sodermanland, and Riddarhyttan(*) and Håkanboda(*), Västmanland, Sweden; Mt. Cobalt, Q, Torrington and Broken Hill, NSW, and Bimbowrie, SA, Australia; Bou Azzer, Morocco. *BM DI:296*, *AM 67:1048(1982)*, *R:827*, *P&J:124*, *ABI:103*.

2.12.3.2 Gersdorffite NiAsS

Named in 1843 for Johann von Gersdorff (1781-1849), owner of the nickel mine at Schladming, Styria, Austria. Cobaltite group. May contain minor amounts of Co, As, Bi. iso $P2_13$ (other polytypes are known). $a = 5.688$, $Z = 4$, $D = 5.98$. *24-519*: 4.02₂ 2.84₇ 2.54₁₀ 2.32₆ 2.01₃ 1.72₆ 1.58₂ 1.52₂. Octahedral and pyritohedral crystals; also massive, granular. Silver-white to steel-gray, gray-black streak, metallic luster. Cleavage {001}, perfect; uneven fracture. $H = 5\frac{1}{2}$, $VHN_{100} = 657-767$. $G = 5.9$. $R = 45.0$ (540 nm). Snowbird mine, Mineral Co., MT; Sudbury and Cobalt, ON, Canada; Craignure mine, Strathclyde, Scotland; Müsen, Wissen, and Ramsbeck, Westphalia, Rammelsberg and Wolfsberg, Harz, Lobenstein, Thuringia, Germany; *Schladming, Styria, Austria*; Dobsina, Czech Republic; Ait Ahmane mine, Bou Azzer, Morocco; Cochabamba, Bolivia. *BM DI:298*, *R.833*, *P&J:178*, *CM 24:27(1986)*, *ABI:180*.

2.12.3.3 Ullmannite NiSbS

Named in 1843 for Johan C. Ullman (1771-1821), German chemist and mineralogist, who discovered the mineral. Cobaltite group. May contain up to 10% As, 5% Bi, and 3% Co. iso $P2_13$. $a = 5.886$, $Z = 4$, $D = 6.85$. *30-861*: 4.16₃ 2.94₁ 2.63₁₀ 2.40₆ 1.77₄ 1.63₂ 1.57₃ 1.28₁. Cubic crystals, twinned on [110]. Silver-white to steel-gray, gray-black streak, metallic luster. Cleavage

{001}, perfect; uneven fracture; brittle. $H = 5-5\frac{1}{2}$, $VHN_{100} = 592-627$. $G = 6.5-7.0$. $R = 46.1$ (540 nm). Kerr Addison mine, Timiskaming dist., ON, and Nicholson mine, near Goldfields, SK, Canada; Settlingstones mine, Northumberland, England; Tunaberg, Sweden; Siegen, Müsen, and *Freussberg, Westphalia*, Neudorf, Harz, and Lobenstein, Thuringia, *Germany*; Ar mine, Basses-Pyrenees, France; Monte Narba and Masaloni, Sardinia, Italy; Lölling, Carinthia, Austria; Roznava, Slovakia; Talnakh, Norilsk, Russia; Tsushima Is., Japan; Broken Hill, NSW, Australia. BM *DI:301, R:337, P&J:377, CM 24:27(1986), ABI:548*.

2.12.3.4 Willyamite CoSbS

Named in 1896 for the locality. Forms a series with ullmannite. Cobaltite group. Trimorphous with costibite and paracostibite. iso $Pca2_1$. $a = 5.860$, $Z = 4$, $D = 7.02$. *26-1106*: 4.14₃ 2.62₁₀ 2.39₇ 1.77₆ 1.63₄ 1.57₅ 1.28₄ 1.09₄. Small zoned crystals. Tin-white to steel-gray, gray-black streak, metallic luster. Perfect cubic cleavage. $H = 5-5\frac{1}{2}$. $G = 6.76$. Espeland, Norway; Tunaberg, Sweden; *Consols mine, Broken Hill (Willyama), NSW, Australia*. BM *DI:301, AM 56:361(1971), CM 24:27(1986), ABI:576*.

2.12.3.5 Tolovkite IrSbS

Named in 1981 for the locality. Cobaltite group. iso $P2_13$. $a = 6.027$, $Z = 4$, $D = 10.50$. *35-656*: 3.49₆ 2.99₉ 2.13₈ 1.81₁₀ 1.23₇ 1.15₉ 1.07₉ 1.01₈. Microscopic anhedral grains. Steel-gray, metallic luster. Conchoidal fracture, brittle. $H = 6$, $VHN_{10} = 1431-1703$. $R = 42.9$ (586 nm). Fox Gulch, Goodnews Bay, AK; Similkameen R., BC, Canada; *Ust-Belskii massif, Tolovka R., Russia*. BM *ZVMO 110:474(1981); AM 67:1076(1982), 74:1173(1989); ABI:534*.

2.12.3.6 Platarsite PtAsS

Named in 1977 for the composition. Cobaltite group. Contains up to 13% Rh, 12% Ru, and 18% Ir. iso $Pa3$. $a = 5.790$, $Z = 4$, $D = 8.41$. *29-974*: 3.35₈ 2.90₉ 2.59₅ 2.36₅ 2.05₆ 1.75₁₀ 1.18₅ 1.11₇. Crystals to 1 mm. Gray, metallic luster. $H = 7-7\frac{1}{2}$, $VHN_{100} = 1177-1343$. $G = 8.0$. $R = 48.0$ (540 nm). Fox Gulch, Goodnews Bay, AK; *Onverwacht mine* and Driekop, Union, and Western mines, *Transvaal, South Africa*. BM *CM 15:385(1977), 17:117(1979); P&J:408; ABI:408*.

2.12.3.7 Irsarsite IrAsS

Named in 1966 for the composition. Cobaltite group. Forms a series with hollingworthite. iso $Pa3$. $a = 5.777$, $Z = 4$, $D = 11.92$. *19-591*: 3.32₁₀ 2.87₁₀ 2.57₈ 2.04₉ 1.74₁₀ 1.29₇ 1.11₉ 1.02₈. Small grains. Iron-black, metallic luster. $H = 6\frac{1}{2}$, $VHN_{100} = 1546$. $R = 40.6$ (540 nm). American R., Sacramento Co., and Stanislaus R., Stanislaus Co., CA; Fox Gulch, Goodnews Bay, AK; Werner Lake and Sudbury, ON, and Pipe mine, MB, Canada; Cliff and Harold's Grave quarries, Shetland Is.; Hitura Ni-Cu deposit, Finland; Pletene deposit, Bulgaria; Vourinos, Greece; Pirogues R., New Caledonia; *Onverwacht mine*

and Driekop mine, *Transvaal, South Africa*. BM *ZVMO* 95:700(1966), *AM* 52:1580(1967), *R*:874, *P&J*:212, *ABI*:237.

2.12.3.8 Hollingworthite RhAsS

Named in 1965 for Sidney E. Hollingworth (1899–1966), English geologist. Cobaltite group. Forms a series with irarsite. iso *Pa*3. $a = 5.769$, $Z = 4$, $D = 7.91$. 30-1037: 3.31₁₀ 2.87₁₀ 2.57₈ 2.35₇ 2.04₉ 1.74₁₀ 1.29₈ 1.11₉. Microscopic euhedral to anhedral grains. Gray, metallic luster. $VHN_{100} = 650-700$. $R = 50.8$ (540 nm). Stillwater Complex, MT; Yuba R., Nevada Co., CA; Goodnews Bay, AK; Werner Lake and Sudbury, ON, Canada; Cliff and Harold's Grave quarries, Shetland Is.; Hitura Cu–Ni deposit, Finland; Norilsk, Russia; Pirogues R., New Caledonia; *Driekop mine* and Onverwacht mine, *Transvaal, South Africa*. BM *AM* 50:1068(1965), *R*:838, *MD* 22:178(1987), *ABI*:222.

2.12.3.9 Jolliffeite NIASe

Named in 1991 for Alfred W. Jolliffe (1907–1988), Canadian geologist. Cobaltite group. iso *Pa*3. $a = 5.831$, $Z = 4$, $D = 7.10$. *CM* 29: 2.92₅ 2.60₁₀ 2.38₈ 2.06₃ 1.76₈ 1.62₄ 1.56₅ 1.46₁. Microscopic anhedral grains. Gray, metallic luster. $R = 51.1$ (540 nm). *Shirley Penin., Lake Athabasca, SK, Canada*. BM *CM* 29:411(1991).

2.12.3.10 Padmaite PdBiSe

Named in 1991 for the locality. Cobaltite group. iso Space group uncertain, probably *P*2₁3. $a = 6.448$, $Z = 4$, $D = 9.86$. *ZVMO* 120: 2.89₁₀ 2.63₉ 2.28₃ 1.94₉ 1.72₅ 1.41₃ 1.38₄ 1.20₃. Microscopic anhedral grains. Pale yellow, metallic luster. $H = 3-4$, $VHN_{20} = 260-272$. $R = 48.6$ (540 nm). *Padma R., Karelia, Russia*, in metashales. BM *ZVMO* 120(3):85(1991), *AM* 78:450(1993).

2.12.3.11 Michenerite PdBiTe

Named in 1958 for Charles E. Michener (b.1907), Canadian geologist. Cobaltite group. iso *P*2₁3. $a = 6.651$, $Z = 4$, $D = 10.00$. 25-92(syn): 2.97₁₀ 2.72₈ 2.00₉ 1.77₈ 1.45₇ 1.28₆ 1.23₇ 1.17₆. Microscopic grains. Silver-white to gray-white, black streak, metallic luster. $H = 4$, $VHN_{25} = 306-317$. $G = 9.5$. $R = 58.2$ (540 nm). A principal Pd mineral in Cu–Ni sulfide deposits. Stillwater Complex, MT; New Rambler mine, Albany Co., WY; *Sudbury, ON*, and Pipe mine, MB, *Canada*; Hitura, Finland; Monchegorsk deposit, Kola, and Oktyabr mine, Norilsk, Russia; Danba, Sichuan Prov., China; Kambalda, WA, Australia; Merensky Reef, *Transvaal, South Africa*. BM *CM* 6:200(1958), 11:903(1973); *R*:825; *P&J*:269; *ABI*:331.

2.12.3.12 Maslovite PtBiTe

Named in 1979 for G. D. Maslov (1915–1968), Russian mineralogist. Cobaltite group. iso *Pa*3. $a = 6.687$, $Z = 4$, $D = 11.81$. 39-1389: 3.01₁₀ 2.71₈ 2.36₂

2.02₆ 1.85₂ 1.79₃ 1.29₂ 1.18₂. Microscopic grains. Gray-white, metallic luster. $H = 4$, $VHN_{20} = 262-388$. $R = 56.1$ (540 nm). *Oktyabr mine, Norilsk, Russia*. BM *GRM 21:94(1979)*; *AM 65:406(1980)*, *74:1171(1989)*; *ABI:314*.

2.12.3.13 Testibiopalladite Pd(Sb,Bi)Te

Named in 1974 for the composition. Cobaltite group. iso $P2_13$. $a = 6.572$, $Z = 4$, $D = 8.93$. $29-961: 3.28_5 2.94_{10} 2.68_8 1.98_9 1.76_7 1.27_6 1.16_6 1.07_7$. Microscopic grains. Gray-white, metallic luster. Cleavage imperfect in two directions, brittle. $H = 3\frac{1}{2}-4$, $VHN = 165$. $R = 53.9$ (540 nm). *Danba, Sichuan Prov., China*; *Kambalda, WA, Australia*. BM *AM 61:182(1976)*, *ABI:522*.

ARSENOPYRITE GROUP

Arsenopyrite minerals are arsenides or sulfides with the general formula

where

$A = \text{Fe, Co, Ru, Os, Ir}$

$B = \text{As, Sb}$

and a monoclinic (pseudo-orthorhombic) structure with space group $P2_1/c$. The structure is a derivative of the marcasite structure in which one-half of the S is replaced by As.

ARSENOPYRITE: FeAsS

ARSENOPYRITE GROUP

Mineral	Formula	Space Group	Space				β	
			a	b	c			
Arsenopyrite	FeAsS	$P2_1/c$	5.744	5.675	5.785	112.3	2.12.4.1	
Gudmundite	FeSbS	$P2_1/c$	10.02	5.94	6.74	90.0	2.12.4.2	
Osarsite	(Os,Ru)AsS	$P2_1/c$	5.933	5.916	6.009	112.35	2.12.4.3	
Ruarsite	RuAsS	$P2_1/c$	5.945	5.920	6.025	112.92	2.12.4.4	
Iridarsenite	IrAs ₂	$P2_1/c$	6.060	6.071	6.158	113.3	2.12.4.5	
Clinosafflorite	CoAs ₂	$P2_1/c$	5.916	5.872	5.960	116.4	2.12.4.6	

2.12.4.1 Arsenopyrite FeAsS

Named in 1847 for the composition, a contraction of the older term *arsenical pyrites*. Arsenopyrite group. MON $P2_1/c$. $a = 5.744$, $b = 5.675$, $c = 5.785$, $\beta = 112.3^\circ$, $Z = 4$, $D = 6.20$. $14-218$: 2.68₁₀ 2.66₁₀ 2.44₉ 2.42₉ 2.41₉ 1.96₅ 1.82₇ 1.81₉. **Habit**: Pseudo-orthorhombic prismatic crystals, frequently twinned on {012} to produce cruciform twins or star-shaped trillings; also granular or compact. **Structure**: Closely related to that of marcasite; each Fe atom is surrounded by a somewhat distorted octahedron, of which one face is a triangle of three As atoms, the other a triangle of three S atoms. **Physical properties**: Silver-white to steel-gray, gray-black streak, metallic luster. Cleavage {001}, distinct; uneven fracture. $H = 5\frac{1}{2}-6$, $VHN_{100} = 1081$. $G = 6.0-6.2$. **Tests**: Garlic odor when ground or hammered; decomposed by HNO_3 with separation of sulfur. **Chemistry**: May contain some Co substituting for Fe. **Optics**: $R = 49.7-52.0$ (540 nm); strongly anisotropic. **Occurrence**: The most abundant arsenic mineral, it typically occurs as an early formed mineral in moderate- to high-temperature conditions. Occurs most commonly in high-temperature gold-quartz veins, in high-temperature cassiterite deposits, and in some contact-metamorphic deposits. **Localities**: Only a few localities can be mentioned: Franconia, Grafton Co., NH; Franklin, Sussex Co., NJ; Cobalt district, ON, Canada; Santa Eulalia(*) and Santa Barbara(*), CHIH, Mexico; many mines in Cornwall, England; Sala, Tunaberg, and Boliden, Sweden; Altenberg, Ehrenfriedersdorf, and Freiberg(*), Saxony, Germany; Panasqueira(*), Portugal; Trepca(*), Serbia; Ashio mine, Togichi Pref., and Ohira mine(*), Miyazaki Pref., Japan; Torrington and Broken Hill, NSW, Australia; Llallagua(*), Bolivia. BM *DI:316*, *AM 46:1448(1961)*, *R:863*, *P&J:271*, *ABI:28*.

2.12.4.2 Gudmundite FeSbS

Named in 1928 for the locality. Arsenopyrite group. MON $P2_1/c$. $a = 10.02$, $b = 5.94$, $c = 6.74$, $\beta = 90.0^\circ$, $Z = 8$, $D = 6.94$. $8-104$: 4.10₅ 3.00₄ 2.93₄ 2.56₁₀ 1.91₈ 1.62₆ 1.46₆ 1.41₇. Pseudo-orthorhombic prismatic crystals, twinned on {101} forming penetration and contact twins, with cruciform and butterfly shapes. Silver-white to steel-gray, gray-black streak, metallic luster. No cleavage, uneven fracture. $H = 6$, $VHN_{100} = 572-673$. $G = 6.72$. $R = 49.9-55.3$

(540 nm); distinctly pleochroic and anisotropic. Lac Nicolet mine, South Ham, PQ, Hemlo Au deposit and near Red Lake, ON, Canada; *Gudmundstorp*, near Sala, and other localities in Sweden; Waldsassen, Bavaria, Germany; Kalliolampi, near Nurma, Finland; Pezink, Saxova, and Vlastejovice, Czech Republic; Askot, Pithoragarh, India; Broken Hill, NSW, Australia. BM *DI:325*, *R:872*, *P&J:189*, *ABI:198*.

2.12.4.3 Osarsite (Os,Ru)AsS

Named in 1972 for the composition. Arsenopyrite group. May contain minor amounts of Ir, Ni, Fe, Co. MON $P2_1/c$. $a = 5.933$, $b = 5.916$, $c = 6.009$, $\beta = 112.35^\circ$, $Z = 4$, $D = 8.44$. $25-595$: 3.79₁₀ 2.96₅ 2.78₆ 2.74₇ 2.01₆ 1.89₁₀ 1.87₈ 1.83₆ 1.70₆. Microscopic grains. Gray, metallic luster. *Gold Bluff*, *Humboldt Co.*, CA, in placer; Vourinos, Greece; Kola Peninsula, and near Zlatoust, Ural Mts., Russia; Anduo, Tibet, China; Witwatersrand, Transvaal, South Africa. BM *AM 57:1029(1972)*, *EG 71:1399(1976)*, *R:875*, *ABI:367*.

2.12.4.4 Ruarsite RuAsS

Named in 1979 for the composition. Arsenopyrite group. MON $P2_1/c$. $a = 5.945$, $b = 5.920$, $c = 6.025$, $\beta = 112.92^\circ$, $Z = 4$, $D = 7.08$. $27-568(\text{syn})$: 3.79₁₀ 2.78₆ 2.74₇ 2.01₆ 1.89₁₀ 1.87₈ 1.83₆ 1.70₆. Microscopic grains. Lead-gray, gray-black streak, metallic luster. $H = 6-6\frac{1}{2}$, $VHN_{50} = 734-893$. $R = 44.1$ (546 nm); distinctly pleochroic and anisotropic. *Anduo*, *Tibet*, *China*, in heavy-mineral concentrates; Merensky Reef, Transvaal, South Africa. BM *AM 65:1068(1980)*, *ABI:449*.

2.12.4.5 Iridarsenite IrAs₂

Named in 1974 for the composition. Arsenopyrite group. MON $P2_1/c$. $a = 6.060$, $b = 6.071$, $c = 6.158$, $\beta = 113.3^\circ$, $Z = 4$, $D = 10.92$. $14-411(\text{syn})$: 3.90₁₀ 3.03₄ 2.83₅ 2.78₅ 2.05₄ 1.91₅ 1.88₄ 1.73₅. Microscopic grains. Gray, metallic luster. $H = 5\frac{1}{2}$, $VHN_{100} = 540$. $R = 45.4-46.1$ (540 nm); weakly anisotropic. Occurs as inclusions in Os-Ir-Ru nuggets. Fox Gulch, Goodnews Bay, AK; near Zlatoust, Ural Mts., Russia; Tibet, China; *Papua New Guinea*; Witwatersrand and Merensky Reef, Transvaal, South Africa. BM *CM 12:280(1974)*, *AM 61:177(1976)*, *ABI:238*.

2.12.4.6 Clinosafflorite CoAs₂

Named in 1971 as the monoclinic analog of safflorite. Arsenopyrite group. MON $P2_1/c$. $a = 5.916$, $b = 5.872$, $c = 5.960$, $\beta = 116.4^\circ$, $Z = 4$, $D = 7.48$. $14-412(\text{syn})$: 2.67₅ 2.65₅ 2.54₁₀ 2.43₆ 2.41₅ 1.87₃ 1.86₃ 1.66₄. Massive. Tin-white. metallic luster. No cleavage. $H = 4\frac{1}{2}-5$, $VHN_{100} = 719-875$. $R = 52.0-54.7$ (540 nm). *Cobalt*, ON, Canada, in Co-Ni ores; Nord mine, Värmland, Sweden; Aghbar mine, near Bou Azzer, Morocco. BM *CM 10:877(1971)*, *21:129(1983)*; *ABI:102*.

2.12.5.1 Pararammelsbergite NiAs₂

Named in 1940 for its polymorphism with rammelsbergite. ORTH *Pbca*. $a = 5.770$, $b = 5.838$, $c = 11.419$, $Z = 8$, $D = 7.20$. 18-876(syn): 2.86₅ 2.83₅ 2.56₁₀ 2.52₁₀ 2.37₇ 2.36₇ 1.82₅ 1.74₇. Crystals tabular {001}, usually massive. Tin-white, metallic luster. Cleavage {001}, perfect; uneven fracture. $H = 5$, $VHN_{100} = 681-830$. $G = 7.0-7.1$. $R = 59.9$ (540 nm); strongly anisotropic, yellow, brown, gray. Occurs in Ni-Co deposits. Franklin, NJ; Cobalt, Gowganda, South Lorrain, and Kerr Lake, ON, Camsell R., NWT, Canada; Cerny Dul, near Berghaus, Czech Republic; Talmessi and Meskani mines, Iran; Bou Azzer, Morocco. BM *DI:310, R:862, P&J:288, TMPM 34:167(1985), ABI:386*.

2.12.5.2 Paxite CuAs₂

Named in 1961 from the Latin *pax*, peace. MON *P2₁/c*. $a = 5.839$, $b = 5.111$, $c = 8.084$, $\beta = 99.7^\circ$, $Z = 4$, $D = 5.96$. 39-369: 3.60₇ 3.30₅ 3.14₁₀ 2.62₁₀ 2.50₉ 1.99₄ 1.80₇ 1.69₆. Massive. Steel-gray, metallic luster. Cleavage perfect in one direction. $H = 3\frac{1}{2}-4$, $VHN_{25} = 146$. $G = 5.4$. $R = 44.2-49.5$ (540 nm); strongly anisotropic, gray-green to dark brown. Cerny Dul, Czech Republic, in hydrothermal calcite veins; Mohawk, Keweenaw Co., MI; Niederbeerbach, Odenwald, Germany. BM *AM 47:1484(1962), TMPM 34:167(1985), ABI:392*.

2.12.6.1 Glaucodot (Co,Fe)AsS

Named in 1849 from the Greek for *blue*, for its use in making blue glass. Dimorphous with alloclasite. ORTH *Cmmm*. $a = 6.64$, $b = 28.39$, $c = 5.64$, $Z = 24$, $D = 6.16$. 5-643: 2.72₁₀ 2.45₈ 2.42₇ 1.83₉ 1.64₄ 1.38₄ 1.13₆ 1.01₆. Prismatic crystals, twinned on {012}, forming cruciform penetration twins; also massive. Silver-white to gray-white, black streak, metallic luster. Cleavage {010}, perfect; {101}, distinct; uneven fracture; brittle. $H = 5$. $G = 5.9-6.1$. $R = 50.2-51.1$ (540 nm); distinctly pleochroic and anisotropic. Franconia, Grafton Co., NH; Standard Consolidated mine, Sumpter, Grant Co., OR; Cobalt-Gowganda district, ON, Canada; Tynebottom mine, near Alston, Cumbria, England; Skutterud, Norway; Hakansbo(*), Vastmanland, and Tunaberg(*), Sodermanland, Sweden; Gosenbach, Westphalia, Germany; Oravita, Romania; Dashkesan deposit, Azerbaijan; Abakan deposit, Siberia, Russia; Simokuzukawa, Japan; Carcoar, NSW, Australia; Witwatersrand, Transvaal, South Africa; Huasco, Atacama, Chile. BM *DI:322, R:871, P&J:181, ABI:187*.

2.12.6.2 Alloclasite (Co,Fe)AsS

Named in 1866 from the Greek for *another* and *fracture*, because of its cleavages. Dimorphous with glaucodot. MON *P2₁*. $a = 4.641$, $b = 5.606$, $c = 3.415$, $\beta = 90.03^\circ$, $Z = 2$, $D = 6.00$. 25-246: 3.58₃ 2.80₃ 2.75₁₀ 2.47₉ 2.40₅ 1.82₇ 1.71₃ 1.64₃. Prismatic crystals, commonly in columnar or radiating aggregates. Steel-gray, black streak, metallic luster. Cleavage {101}, perfect; {010}, distinct; subconchoidal to uneven fracture; brittle. $H = 5$, $VHN_{100} = 818-940$. $G = 5.95$. $R = 49.3-51.5$ (540 nm). Kibblehouse quarry, Perkiomenville, PA;

Silverfields mine, Cobalt, and Siscoe Metals mine, Gowganda, ON, Canada; Scar Crag mine, Keswick, England; Lautaret Pass, Hautes-Alpes, France; *Elizabeth mine, Oravita, Romania*; Dogatani mine, Japan; Mt. 2.12.8.1 Lautite CuAsS

Named in 1881 for the locality. ORTH $Pna2_1$. $a = 11.350$, $b = 5.456$, $c = 3.749$, $Z = 4$, $D = 4.88$. *25-1179*: 3.11_{10} 3.09_9 2.98_2 1.91_4 1.89_2 1.87_1 1.61_1 1.60_1 . Short prismatic crystals and massive. Black, black streak, metallic luster. Cleavage {001}, brittle. $H = 3-3\frac{1}{2}$, $VHN_{100} = 239-259$. $G = 4.9$. $R = 30.2-31.4$ (540 nm); weakly pleochroic and anisotropic. *Lauta, near Marienberg, Saxony*, and Niederbeerbach, Odenwald, Germany; Gabe Gottes mine, Raenthal, Haut-Rhin, France. BM *DI:327*, *AC 19:543(1965)*, *R:525*, *P&J:234*, *ABI:290*.

2.12.9.1. Bambollaite Cu(S_e,Te)₂

Named in 1972 for the locality. TET $I4_1/amd$. $a = 3.865$, $c = 5.632$, $Z = 1$, $D = 4.95$. *25-313*: 3.19_{10} 1.96_7 1.93_4 1.69_3 1.65_5 1.41_1 1.27_2 1.12_2 . Granular aggregates. Gray, gray streak, metallic luster. *Moctezuma mine* (also known as *La Bomballa*), near *Moctezuma, SON, Mexico*. BM *CM 11:738(1972)*, *ABI:40*.

2.12.10.1 Molybdenite MoS₂

Named in 1807 from the Greek *molybdos*, lead. HEX (a 3R polytype is known) $P6_3/mmc$. $a = 3.160$, $c = 12.295$, $Z = 2$, $D = 5.00$. *6-97*: 6.15_{10} 2.74_2 2.67_1 2.28_5 2.05_1 1.83_3 1.58_1 1.54_1 . **Habit**: Hexagonal crystals, thin-to-thick tabular on

MOLYBDENITE: MoS_2

There is no strong bonding between MoS_2 sandwich layers. Mo is coordinated by six S atoms in each layer, but the sulfur atoms layers lie over one another (not in closest-packed arrangement), and the coordination polyhedron is a trigonal prism rather than an octahedron. Sulfurs are in hexagonal closest packed arrangement.

{0001}; commonly foliated, massive, or in scales. **Structure:** MoS_2 has two polytypes: molybdenite-2H (hexagonal), molybdenite-3R (rhombohedral), and polymorph jordisite (amorphous). When molybdenite is referred to with no suffix, it refers to the 2H polymorph. In this polymorph, MoS_6 trigonal prisms are linked together by sharing edges to form sheets parallel to {0001}. The sheets are linked by weak bonds between sulfurs of adjoining sheets, in hexagonal stacking sequence, resulting in perfect basal cleavage. **Physical properties:** Color and streak lead-gray with a bluish tint, metallic luster. Cleavage {0001}, perfect; flexible, inelastic lamellae. $H = 1-1\frac{1}{2}$. $G = 4.6-4.7$. **Tests:** Decomposed by HNO_3 , leaving a residue of MoO_3 . **Chemistry:** Usually pure MoS_2 . **Optics:** $R = 21.3-45.5$ (540 nm); extremely pleochroic and anisotropic. **Occurrence:** The commonest molybdenum mineral. Occurs as an accessory in some granites and pegmatites, and in high-temperature veins with scheelite, wolframite, topaz, and fluorite, and in contact-metamorphic deposits. **Localities:** Only the more significant are listed. Climax, Lake Co., CO; Childs-Aldwinkle mine(*), Pinal Co., and Santo Nino mine(*), Santa Cruz Co., AZ; Crown Point mine(*), Chelan Co., WA; Cosumnes mine(*), El Dorado Co., Pine Creek mine, Inyo Co., and other localities in CA; Alford Twp. and Temiskaming district, ON, and Con mine, Yellowknife, YT, Canada; Carrock Fell and Caldbeck Fell, Cumberland, England; Knaben(*), Vest-Agder, Norway; Altenberg, Saxony, Germany; Miass, Ural Mts., and Adunchilon Mts., Transbaikal, Russia; Tae Hwa mine(*), S. Korea; Hirase mine(*), Gifu Pref., and Busshoji mine(*), Hyogo Pref., Japan; Azegour, Morocco; Onganja mine(*), Namibia; Wolfram Camp(*), Q, Deepwater(*) and Kingsgate(*), NSW, and Moina district, TAS, Australia. **Alteration:** Frequently alters to ferrimolybdate

in the zone of oxidation; also occasionally to powellite. Uses: The principal ore of molybdenum. BM *DI:328*, CM *7:524(1963)*, R:*874*, P&J:*273*, ABI:*336*.

2.12.10.2 Drysdallite MoSe_2

Named in 1973 for A. R. Drysdall (b.1933), director, Geological Survey of Zambia. Contains 3.4% S. HEX $P6_3/mmc$. $a = 3.287$, $c = 12.925$, $Z = 2$, $D = 6.97$. *29-914*: 6.46₈ 2.85₆ 2.37₁₀ 2.15₃ 1.91₆ 1.64₄ 1.62₄ 1.35₂. Microscopic pyramidal crystals. Gray-black, brown-black streak, metallic luster. Cleavage {0001}, perfect; flexible; inelastic. $H = 2$, $VHN_8 = 46-58$. $G = 6.90$. $R = 21.6-37.8$ (540 nm); strongly pleochroic and anisotropic. *Kapijimpanga uranium deposit, near Solwezi, Zambia*. BM *NJMM:433(1973)*, *AM 59:1139(1974)*, R:*880*, P&J:*150*, ABI:*139*.

2.12.10.3 Tungstenite WS_2

Named in 1917 for the composition. HEX (an R polymorph is known) $P6_3/mmc$. $a = 3.154$, $c = 12.362$, $Z = 2$, $D = 7.73$. *8-237(syn)*: 6.18₁₀ 3.09₁ 2.73₃ 2.67₃ 2.28₄ 1.83₂ 1.58₂ 1.53₁. Scaly or feathery aggregates. Dark lead-gray, metallic luster. Cleavage {0001}, sectile. $H = 2\frac{1}{2}$. $G = 7.4$. $R = 18.2-36.0$ (540 nm); strongly pleochroic and anisotropic. *Emma mine, Little Cottonwood district, UT*; Kidd Creek mine, near Timmins, ON, and near Chase, BC, Canada; Crevola d'Ossola, Piedmont, Italy; Lyangar, Uzbekistan; Angokitsk deposit, Buryat ASSR, and Tamvatnei deposit, Kamchatka, Russia; Tsumeb, Namibia. BM *DI:331*, R:*880*, P&J:*374*, CM *10:729(1970)*, ABI:*543*.

2.12.11.1 Jordisite MoS_2

Named in 1909 for Eduard F. Jordis (1868-1917), colloid chemist. Dimorphous with molybdenite. Amorphous. Massive. Black, gray-black streak, sub-metallic luster. Sectile. Ambrosia Lake, McKinley Co., NM; Kiggins mercury mine, Clackamas Co., OR; Sun Valley mine, Coconino Co., AZ; *Himmelsfürst mine, near Freiberg, Saxony, Germany*; Bleiberg, Carinthia, Austria; Carrizal Alto, Atacama, Chile; Campo do Agostinho, Brazil. BM *DI:331*, R:*878*, *AM 56:1832(1971)*, ABI:*251*.

2.12.12.1 Jeromite As(S,Se)_2

Named in 1928 for the locality. Amorphous. Black coatings, a sublimate from burning sulfide ores. *United Verde mine, Jerome, AZ*. BM *AM 13:227(1928)*, *DI:144*, ABI:*249*.

2.12.13.1 Krennerite AuTe_2

Named in 1877 for Joseph Krenner (1839-1920), Hungarian mineralogist. May contain up to 6% Ag. Dimorphous with calaverite. ORTH $Pma2$. $a = 16.54$, $b = 8.82$, $c = 4.46$, $Z = 8$, $D = 8.86$. *8-20*: 3.03₁₀ 2.94₆ 2.23₅ 2.11₇ 2.07₄ 1.78₄ 1.69₄ 1.52₄. Short prismatic crystals. Silver-white to pale brass-yellow, gray streak, metallic luster. Cleavage {001}, perfect; subconchoidal to

uneven fracture; brittle. $H = 2-3$, $VHN_{100} = 166-186$. $G = 8.4-8.6$. $R = 60.4-62.4$ (540 nm); strongly anisotropic. Occurs in hydrothermal Au-Te deposits. Cripple Creek, Teller Co., and Smoky Hill mine, Boulder Co., CO; Campbell mine, Bisbee, and Tombstone, Cochise Co., AZ; Bencourt mine, Louvricourt, PQ, Canada; *Sacaramb* and *Facebanya*, Romania; Zhanatyube deposit, Kazakhstan; Konstatin-Ovkoye deposit, Krasnoyarsk region, Russia; Emperor mine, Vatukoula, Fiji; Kalgoorlie and Mulgabbie, WA, Australia. BM *DI:333*, *R:430*, *P&J:228*, *TMPM 33:253(1984)*, *ABI:275*.

2.12.13.2 Calaverite $AuTe_2$

Named in 1868 for the locality. May contain up to 4% Ag. Dimorphous with krennerite. MON $C2/m$. $a = 8.76$, $b = 4.410$, $c = 10.15$, $\beta = 125.2^\circ$, $Z = 4$, $D = 9.31$. $7-344$. 2.99_{10} 2.91_7 2.19_5 2.09_9 2.06_6 1.50_5 1.32_5 1.20_5 . Bladed crystals, stout or slender prisms, also massive, granular. Silver-white to pale brass-yellow, yellow- to green-gray streak, metallic luster. No cleavage, subconchoidal to uneven fracture, very brittle. $H = 2\frac{1}{2}-3$, $VHN_{100} 197-213$. $G = 9.1-9.4$. $R = 61.3-65.9$ (540 nm); weakly pleochroic and anisotropic. Widespread in Au-Te deposits. Cripple Creek(*), Teller Co., Central City, Gilpin Co., Gold Hill, Boulder Co., and other localities in CO; Spotted Horse mine, Marden, MT; *Stanislaus mine*, Calaveras Co., CA; Robb-Montbray mine, PQ, Kirkland Lake and Hemlo gold deposit, ON, Canada; Zhanatyube deposit, Kazakhstan; Koshbulak, Uzbekistan; Klyuchi, eastern Siberia, Russia; Nishizaki, Gifu Pref., and Date mine, Hokkaido, Japan; Emperor mine, Vatakoula, Fiji; Kalgoorlie, WA, Australia. BM *DI:335*, *R:431*, *P&J:111*, *ZK 169:227(1984)*, *ABI:77*.

2.12.13.3 Sylvanite $(Au,Ag)_2Te_4$

Named in 1835 for Transylvania, where it was first found. MON $P2/c$. $a = 8.96$, $b = 4.49$, $c = 14.62$, $\beta = 145.4^\circ$, $Z = 2$, $D = 8.11$. $9-477$: 5.09_1 3.05_{10} 2.98_2 2.25_3 2.14_5 1.99_3 1.80_2 1.52_2 . Complex prismatic, tabular, or bladed crystals, also columnar to granular. Contact, lamellar, or penetration twins give arborescent forms resembling written characters (graphic tellurium). Silver-white, tarnishing to pale yellow, gray streak, metallic luster. Cleavage $\{010\}$, perfect; uneven fracture; brittle. $H = 2$, $VHN_{100} = 154-172$. $G = 8.1-8.2$. $R = 50.6-61.1$ (540 nm); strongly pleochroic and anisotropic. Occurs in minor amounts in many Au-Ag deposits. Cripple Creek(*), Teller Co., and Magnolia, Gold Hill, and Sunshine districts, Boulder Co., CO; Cornucopia district, Baker Co., OR; Melones and Stanislaus mines, Calaveras Co., CA; Dome mine, Porcupine, ON, Canada; Glava, Värmland, Sweden; *Sacaramb*(*) and *Facebanya*, Romania; Zhanatyube deposit, Kazakhstan; Emperor mine(*), Vatukuola, Fiji; Thames district, New Zealand; Kalgoorlie and Norseman, WA, Australia; Arakara goldfields, Guyana. BM *DI:338*, *R:426*, *P&J:359*, *TMPM 33:203(1984)*, *ABI:509*.

2.12.13.4 Kostovite CuAuTe_4

Named in 1966 for Ivan Kostov (b.1913), Bulgarian mineralogist. ORTH $Pma2$. $a = 16.50$, $b = 8.84$, $c = 4.42$, $Z = 4$, $D = 7.94$. $35-521$: 3.03_{10} 2.23_8 2.10_9 1.97_7 1.77_5 1.34_6 1.06_5 1.04_5 . Microscopic grains. Gray-white, metallic luster. One good cleavage, brittle. $H = 2-2\frac{1}{2}$, $VHN = 180-186$. $R = 50.5-61.7$ (540 nm); distinctly anisotropic. Buckeye Gulch, near Leadville, CO; Campbell mine, Bisbee, AZ; *Chelopech, Bulgaria*; Kochbulak deposit, Uzbekistan; Ashanti mine, Ghana. *BM AM 51:29(1966)*, *R:430*, *ABI:272*, *MM 54:617(1990)*.

MELONITE GROUP

The melonite group minerals are rhombohedral sulfides, selenides, and tellurides with the general formula

where

A = Ni, Sn, Pd, Pt, Ir

X = S, Se, Te, and minor Bi

and the space group is $P3m1$. The minerals have a layer-lattice structure similar to that of brucite, $\text{Mg}(\text{OH})_2$.

**BERNDTITE: SnS_2**

This has sandwich layers of S-Sn-S. The sulfur atoms are in hexagonal closest packing, unlike molybdenite.

MELONITE GROUP

Mineral	Formula	Space Group	a			c			D		
			a	c	D	a	c	D	a	c	D
Melonite	NiTe ₂	P3m1	3.843	5.265	7.74	2.12.14.1

Shuangfengite	IrTe ₂	P3m1	3.933	5.390	10.14	2.12.14.6					

2.12.14.1 Melonite NiTe₂

Named in 1866 for the locality. Melonite group. HEX-R P3m1. $a = 3.843$, $c = 5.265$, $Z = 1$, $D = 7.74$. $8\text{-}4\text{:} 2.82_{10}$ 2.64_3 2.06_5 1.92_5 1.59_2 1.55_6 1.23_2 1.08_2 . Hexagonal plates and small grains. Reddish white, tarnishing brown, dark gray streak, metallic luster. Cleavage {0001}, perfect. $H = 1\text{-}1\frac{1}{2}$. $VHN_{50} = 46\text{-}59$. $G = 7.4\text{-}7.7$. $R = 57.7\text{-}59.8$ (540 nm); moderately to strongly anisotropic. Cripple Creek, Teller Co., and Magnolia district, Boulder Co., CO; Bisbee, AZ; *Melones mine* and Stanislaus mine, *Calaveras Co., CA*; Robb-Montbray mine, Montbray Twp., PQ, and Sudbury and Hemlo gold deposit, ON, Canada; Monchegorsk deposit, Kola, Russia; Zhanatyube deposit, Kazakhstan; Yokozuru mine, Kyushu, Japan; Emperor mine, Vatakuola, Fiji; Kalgoorlie and Kambalda, WA, Australia; O'Okiep, Namaqualand, South Africa. BM *DI:341*, *R:420*, *P&J:265*, *ABI:321*.

2.12.14.2 Kitkaite NiTeSe

Named in 1965 for the locality. Melonite group. HEX-R P3m1. $a = 3.716$, $c = 5.126$, $Z = 1$, $D = 7.19$. $18\text{-}896\text{:} 5.13_2$ 2.73_{10} 2.57_3 2.01_5 1.86_3 1.54_2 1.51_4 1.36_1 . Small platy crystals and massive. Pale yellow, metallic luster. Cleavage {0001}, good. $H = 3$, $VHN_{100} = 137$. $G = 7.22$. $R = 52.3\text{-}57.9$ (540 nm); distinctly anisotropic. *Kuusamo, Kitka R., Finland*. BM *AM 50:581(1965)*, *R:421*, *P&J:223*, *ABI:266*.

2.12.14.3 Moncheite (Pt,Pd)(Te,Bi)₂

Named in 1963 for the locality. Melonite group. Forms a series with merenskyite. HEX-R P3m1. $a = 4.049$, $c = 5.288$, $Z = 1$, $D = 7.08$. $15\text{-}392\text{:} 5.32_6$ 2.93_{10} 2.11_8 2.02_7 1.66_6 1.58_5 1.46_7 1.28_7 . Small euhedral to subhedral crystals and microscopic grains. Steel-gray, metallic luster. Basal cleavage. $H = 3\frac{1}{2}$, $VHN_{10} = 146$. $R = 56.0\text{-}56.9$ (540 nm); strongly anisotropic. Stillwater Complex, MT; New Rambler mine, Albany Co., WY; San Joaquin R., Fresno Co., CA; Sudbury and Lac des Isles Complex, ON, Canada; *Monchegorsk deposit, Monche Tundra, Kola*, and Oktyabr mine, Norilsk, *Russia*; Tao and Ma districts, China; Merensky Reef and Witwatersrand, Transvaal,

South Africa. *BM ZVMO 92:33(1963)*, *AM 48:1181(1963)*, *R:838*, *P&J:407*, *ABI:337*.

2.12.14.4 Merenskyite $\text{Pd}(\text{Te},\text{Bi})_2$

Named in 1966 for Hans Merensky (1871–1952), South African geologist. Melonite group. Forms a series with moncheite. *HEX-R P3m1*. $a = 4.036$, $c = 5.132$, $Z = 1$, $D = 8.29$. *29-970(syn)*: 2.87_{10} 2.06_9 2.01_9 1.65_8 1.53_7 1.44_7 1.28_8 1.17_7 1.08_7 . Microscopic grains. Tin-white, metallic luster. $H = 3\frac{1}{2}$, $\text{VHN}_{10} = 82\text{--}128$. $R = 66.6\text{--}68.2$ (540 nm); strongly anisotropic. Stillwater Complex, MT; New Rambler mine, Albany Co., WY; near Moapa, Clark Co., NV; Lac des Iles Complex, Temagami Lake, Sudbury, and other localities, ON, Canada; Norilsk, Russia; Shiaoanshan, Inner Mongolia, China; *Rustenburg mine*, *Merensky Reef*, and *Messina*, *Transvaal*, *South Africa*. *BM MM 35:815(1966)*, *R:838*, *P&J:267*, *ABI:324*.

2.12.14.5 Berndtite SnS_2

Named in 1964 for Fritz Berndt, German mineralogist. Melonite group. *HEX-R* (a 4H polytype is known) *P3m1*. $a = 3.639$, $c = 5.868$, $Z = 1$, $D = 4.46$. *23-677(syn)*: 5.89_{10} 3.16_3 2.78_6 2.16_3 1.82_3 1.74_2 1.67_1 1.53_1 . Tabular hexagonal crystals. Pale yellow, yellow streak, adamantine luster. Cleavage {0001}, good. $H < 2$. $G = 4.5$. Uniaxial (-); $N_O > 1.93$, $N_E = 1.705$. Forestville, Northumberland Co., PA; Lagares-do-Estanho pegmatite, and Panasqueira, Portugal; Stiepelmann mine, Arandis, Namibia; *Cerro de Potosi*, *Bolivia*. *BM NJMM:94(1964)*, *AM 51:1551(1966)*, *R:880*, *ABI:47*.

2.12.14.6 Shuangfengite IrTe_2

Named in 1994 for the locality. Melonite group. *HEX-R P3m1*. $a = 3.933$, $c = 5.390$, $Z = 1$, $D = 10.14$. *AM 80: 2.85_{10}* 2.10_8 1.95_6 1.58_7 1.16_6 . Microscopic aggregates and veinlets. Black, black streak. Cleavage {0001}, perfect; brittle. $H = 3$, $\text{VHN}_{20} = 108$. $R = 40\text{--}48$ (540 nm); weakly anisotropic in blue and yellow tints. In placer concentrates, *Shuangfeng*, *190 km NNE of Beijing*, *China*. *BM AMS 14:322(1994)*, *AM 80:1329(1995)*.

2.12.15.1 Froodite PdBi_2

Named in 1958 for the locality. *MON C2/m*. $a = 12.75$, $b = 4.29$, $c = 5.67$, $\beta = 102.9^\circ$, $Z = 4$, $D = 11.52$. *11-251: 2.97_7* 2.77_{10} 2.48_7 2.21_7 2.14_5 1.64_6 1.56_8 1.42_6 . Flat cleavage fragments and rounded grains. Gray, tarnishing rapidly, black streak, metallic luster. Cleavage {100}, perfect; {001}, less perfect; uneven fracture; brittle. $H = 2\frac{1}{2}$, $\text{VHN}_{15} = 136$. $G = 12.5\text{--}12.6$. $R = 56.1\text{--}58.4$ (540 nm); anisotropic, light to dark gray. Occurs in mill concentrates of Pb–Cu ores. Fox Gulch, Goodnews Bay, AK; *Frood mine*, *Sudbury*, *ON*, and *Pipe mine*, *MB*, *Canada*; Oktyabr mine, Talnakh area, Norilsk, Russia; Merensky Reef, Transvaal, South Africa. *BM CM 6:200(1958)*, *11:903(1973)*; *R:826*; *ABI:166*.

2.12.15.2 Urvantsevite Pd(Bi,Pb)₂

Named in 1976 for Nikolai N. Urvantsev (1893–1985), Russian geologist, who discovered the Norilsk deposits. The high-temperature polymorph of froodite. TET $I4/mmm$. $a = 3.358$, $c = 12.949$, $Z = 2$, $D = 11.93$. $13\text{-}160(\text{syn})$: 3.26_7 2.65_{10} 2.37_8 2.05_4 1.91_3 1.62_5 1.42_4 1.11_4 . Microscopic grains. Gray-white, metallic luster. Perfect cleavage in one direction. $H = 2$, $VHN_{10} = 47\text{--}68$. $R = 54.0\text{--}55.2$ (540 nm); weakly pleochroic and anisotropic. Tilkerode, Harz, Germany; *Majak mine, Talnakh, Norilsk, Russia*. BM *ZVMO 105:704(1976)*, *AM 62:1260(1977)*, *ABI:550*.

2.12.16.1 Borishanskiite Pd(As,Pb)₂

Named in 1975 for Serafima S. Borishanskaya (1907–1988), Russian mineralogist. Possibly identical with polarite. ORTH $Ccm2_1$. $a = 7.18$, $b = 8.62$, $c = 10.66$, $Z = 16$, $D = 10.2$. *ZVMO 104*: 2.65_{10} 2.50_6 2.25_6 2.16_9 1.68_6 1.39_6 1.17_6 . Microscopic grains. Steel-gray, metallic luster. $H = 3\frac{1}{2}\text{--}4$, $VHN_{20} = 241$. $R = 57.3\text{--}57.8$ (580 nm); moderately anisotropic. *Oktyabr mine, Talnakh, Norilsk, Russia*, in Cu-Ni sulfide ores. BM *ZVMO 104:57(1975)*, *AM 61:502(1976)*, *ABI:60*.

2.12.17.1 Skutterudite CoAs₂₋₃

Named in 1845 for the locality. Synonym: smaltite (an As-deficient variety). ISO $Im\bar{3}$. $a = 8.204$, $Z = 8$, $D = 6.82$. $10\text{-}328(\text{syn})$: 5.80_2 3.35_2 2.59_{10} 2.19_4 1.84_4 1.68_2 1.61_3 1.41_2 1.21_2 . Cubes and cubo-octahedra, also massive; twinned on {112} to produce sixlings. Tin-white, tarnishing to gray, black streak, metallic luster. Cleavage {001}, {111}, distinct; {011}, poor; conchoidal to uneven fracture; brittle. $H = 5\frac{1}{2}\text{--}6$, $VHN_{100} = 810\text{--}915$. $G = 6.5\text{--}6.9$. $R = 54.0$ (540 nm). An important Co ore. Chatham, CT; Franklin, NJ; Silver City, NM; Horace Porter mine, Gunnison Co., CO; Cobalt(*), Gowganda, and Sudbury, ON; Hazelton, BC, and Eldorado mine, Great Bear Lake, NWT, Canada; *Skutterud, Modum, Norway*; *Tunaberg*(*), Sweden; *Andreasberg, Harz, Witichen, Black Forest, Schneeberg*(*), *Annaberg, and Freiberg, Saxony, Germany*; *Lolling, Austria*; *Khovu-Akay*(*), Tuva, Russia; *Bou Azzer*(*), Morocco; *Gashani, Zimbabwe*; *Punta Brava, Copiapo, Chile*. BM *DI:342, CM 9:559(1971)*, *R:881, P&J:343, ABI:480*.

2.12.17.2 Nickel-Skutterudite NiAs₂₋₃

Named in 1892 for its relationship to skutterudite. Synonym: chloanthite. ISO $Im\bar{3}$. $a = 8.17$, $Z = 8$, $D = 6.40$. $25\text{-}566$: 5.87_4 3.39_4 2.62_{10} 2.22_7 1.86_7 1.77_4 1.70_6 1.63_8 . Cubes and cubo-octahedral crystals, also massive; twinned on {112} as sixlings. Tin-white to silver gray, black streak, metallic luster. Cleavage {001} and {111}, distinct; conchoidal to uneven fracture; brittle. $H = 5\frac{1}{2}\text{--}6$, $VHN_{100} = 690$. $G = 6.5$. Franklin, NJ, *Bullards Peak, Grant Co., NM*; *Cobalt, ON, Canada*; *Bieber, Hesse, Andreasberg, Harz Mts., Schneeberg*(*) and *Annaberg, Saxony, Germany*; *Dobsina, Czech Republic*; *Kovuakhsin deposit, Ural Mts., Russia*. BM *DI:342, ABI:351*.

2.12.17.3 Kieftite CoSb_3

Named in 1994 for Cornelis Kieft (b.1924), Dutch mineralogist. iso $Im\bar{3}$. $a = 9.041$, $Z = 8$, $D = 7.63$ (Skutterudite group). $CM32$: 2.86₁₀ 2.42₆ 2.02₈ 1.77₆ 1.55₆ 1.33₇ 1.05₆ 0.933₈. Microscopic euhedral to subhedral grains. Tin-white, gray streak, metallic luster. No cleavage, conchoidal fracture, brittle. Crystal forms {100}, {110}, {111}. $VHN_{100} = 464$. $G = 7.2$. $R = 58.7$ (546 nm); isotropic. *Tunaberg, Sweden*, in Cu-Co sulfide ores. *BM CM 32:179(1994)*.

2.13.1.1 Kermesite $\text{Sb}_2\text{S}_2\text{O}$

Named in 1843 from *kermes*, an old chemical name for red amorphous antimony sulfide. TRIC $P1$. $a = 10.84$, $b = 4.07$, $c = 10.25$, $\alpha = 90.0^\circ$, $\beta = 101.53^\circ$, $\gamma = 90.0^\circ$, $Z = 4$, $D = 4.85$. $30-92$: 5.30₁₀ 4.32₅ 4.08₆ 3.14₄ 2.92₅ 2.70₁₀ 2.50₃ 2.26₁. Platy and acicular crystals, often in radiating clusters. Cherry-red, red-brown streak, adamantine to submetallic luster. Cleavage {001}, perfect; {100}, good; sectile; flexible thin splinters. $H = 1-1\frac{1}{2}$, $VHN_5 = 30-90$. $G = 4.68$. $R = 25.2-30.6$ (540 nm). Widely distributed as an alteration product of stibnite. Boron, Kern Co., and Kalkar quarry, Santa Cruz Co., CA; Lac Nicolet mine, South Ham Twp., PQ, and other localities in Canada; Sombrerete, ZAC, Mexico; Braunsdorf, near Freiberg, Saxony, Germany; Pernek(*), Pezinok(*), and Příbram, Czech Republic; Cetine mine, near Siena, Italy; Kadamja, Kirgizstan; Taratu Creek, Thames, New Zealand; Rivertree and Broken Hill, NSW, Australia; Globe and Phoenix mine(*), Que Que, Zimbabwe; Santa Cruz and San Francisco mines, Poopo, Bolivia. *BM DI:279, R:715, P&J:222, ABI:260*.

2.13.2.1 Sarabauite $\text{CaSb}_{10}\text{O}_{10}\text{S}_6$

Named in 1978 for the locality. MON $C2/c$. $a = 25.37$, $b = 5.654$, $c = 16.87$, $\beta = 117.58^\circ$, $Z = 4$, $D = 4.99$. $29-293$: 4.46₃ 4.23₄ 3.47₈ 3.22₁₀ 3.18₆ 3.16₅ 2.82₉ 2.58₄. Small tabular crystals. Carmine-red, orange streak, resinous luster. No cleavage, somewhat sectile. $H = 4$, $VHN_{20} = 272$. $G = 4.8$. Biaxial (-); $2V$ near 90° ; pleochroic, red-yellow to brown-red. *Sarabau mine, Sarawak*. *BM AM 63:715(1978), AC(B)34:3569(1978), ABI:461*.

2.13.3.1 Cetineite $(\text{K},\text{Na})_3(\text{Sb}_2\text{O}_3)_3(\text{SbS}_3) \cdot 3\text{H}_2\text{O}$

Named in 1987 for the locality. HEX $P6_3$. $a = 14.230$, $c = 5.579$, $Z = 2$, $D = 4.29$. $40-1458$: 12.41₈ 4.67₅ 4.11₆ 3.58₄ 3.42₄ 3.00₇ 2.92₁₀ 2.69₆. Microscopic acicular crystals. Orange-red, orange streak, resinous luster. $H = 3$, $VHN_{20} = 127-156$. Uniaxial (+); $N > 1.74$; weakly pleochroic, orange to orange-brown. *Cetine mine, near Siena, Italy*. *BM NJMM:419(1987); AM 73:398(1988), 74:1399(1989); ABI:86*.

2.14.1.1 Valleriite $4(\text{Fe,Cu})\text{S} \cdot 3(\text{Mg,Al})(\text{OH})_2$

Named in 1870 for Johan G. Wallerius (1709–1785), Swedish chemist and mineralogist. HEX-R $R\bar{3}m$. $a = 3.792$, $c = 34.10$, $Z = 6$, $D = 3.21$. 29-554: 11.4₁₀ 5.71₁₀ 3.80₅ 3.27₆ 3.23₅ 2.85₅ 1.89₅ 1.86₅. The structure consists of alternate layers of brucite-like $(\text{Mg,Al})(\text{OH})_2$ sheets and trigonal $(\text{Cu,Fe})\text{S}$ sheets [double S layer with (Cu,Fe) in tetrahedral coordination]. The unit cell given corresponds to the sulfide portion of the structure. Massive, nodular, and platy. Bronze-yellow, black streak, dull metallic luster. Cleavage $\{0001\}$, perfect. $H = 1$. $G = 3.14$. $R = 10.2\text{--}16.2$ (540 nm); strongly pleochroic and anisotropic. Widely distributed in small amounts. Elizabeth mine, South Strafford, VT; Continental mine, Fierro, Grant Co., NM; Pima mine, Pima Co., and Christmas mine, Gila Co., AZ; Marbridge mine, Malartic, PQ, Sudbury, ON, and Little Chief mine, near Whitehorse, YT, Canada; *Aurora mine*, Ljusnarsberg, and Kaveltorp, *Kopparberg*, Sweden; near Pefkos, Cyprus; Monchegorsk, Kola, and Norilsk, Russia; Alnalyk, Uzbekistan; Akagane mine, Iwate Pref., Japan; Loolekop, Palabora, Mooihoek, and Onverwacht, Transvaal, South Africa; Atacocha, Peru. BM *DI:235*, *ZK 127:73(1968)*, *R:683*, *P&J:382*, *ABI:555*.

2.14.2.1 Tochilinite $6\text{Fe}_9\text{S} \cdot 5(\text{Mg,Fe})(\text{OH})_2$

Named in 1971 for Mitrofan S. Tochilin (1910–1968), Russian scientist. MON Space group unknown. $a = 5.35$, $b = 15.54$, $c = 10.89$, $\beta = 94.81^\circ$, $Z = 2$, $D = 3.03$. 41-590: 10.84₄ 5.41₁₀ 2.63₂ 2.23₅ 2.05₂ 1.86₄ 1.75₃ 1.53₂. Radiating aggregates of cylindrical acicular crystals, and as felted masses. Bronze-black, black streak, dull metallic luster. Cleavage $\{001\}$. $H = 1\text{--}2$, $\text{VHN}_5 = 15\text{--}49$. $G = 2.96$. $R = 10.2\text{--}14.9$ (546 nm); strongly pleochroic and anisotropic. Cornwall mine, Lebanon Co., PA; Jeffrey mine, Asbestos, Cross and Maxwell quarries, Wakefield, and Amos area, PQ, near Bancroft, ON, and Muskox Intrusion, NWT, Canada; Lizard ultramafic body, Cornwall, England; *Mamonovo deposit*, Voronezh, and diamond pipes, Yakutia, Russia; Kamaishi mine, Iwate Pref., Japan; Mt. Keith, WA, Australia; Jacupiranga mine, São Paulo, Brazil; an accessory mineral in carbonaceous chondrite meteorites. BM *ZVMO 100:477(1971)*; *AM 57:1552(1972)*, *71:1201(1986)*; *R:692*; *ABI:533*.

2.14.3.1 Haapalaite $2(\text{Fe,Ni})\text{S} \cdot 1.6(\text{Mg,Fe})(\text{OH})_2$

Named in 1973 for Paavo Haapala (b.1906), Finnish geologist. HEX-R Space group uncertain, probably $R\bar{3}m$. $a = 3.64$, $c = 34.02$, $Z = 3$, $D = 3.57$. 26-1135: 11.3₁₀ 5.67₉ 3.18₈ 2.84₄ 2.59₄ 2.27₄ 1.84₇ 1.82₇. Thin scales. Bronze-red, metallic luster. $H = 1$, $\text{VHN}_3 = 9\text{--}11$. Strongly anisotropic. *Kokka serpentinite*, near *Outokumpu*, Finland. BM *AM 58:1111(1973)*, *R:692*, *ABI:201*.

2.14.3.2 Yushkinite $\text{V}_{0.6}\text{S}_{0.6}(\text{Mg,Al})(\text{OH})_2$

Named in 1984 for Nikolai P. Yushkin (b.1936), Russian mineralogist. HEX-R $P\bar{3}m1$. $a = 3.20$, $c = 11.3$, $Z = 2$, $D = 3.31$. 38-432: 11.4₃ 5.68₁₀ 2.76₈ 2.36₂ 1.60₄ 1.58₆ 1.53₃ 1.39₃. Scaly aggregates. Pink-violet, metallic luster. $H < 1$.

$G = 2.94$, $R = 18.7$ (540 nm); strongly anisotropic. In quartz-carbonate veins. *Pay-Khoy, Silova-Yakha R., Russia*. BM *MZ* 6:91(1984), *AM* 71:846(1986), *ABI*:584.

2.14.4.1 Vyalsovite $\text{FeS} \cdot \text{Ca}(\text{OH})_2 \cdot \text{Al}(\text{OH})_3$

Named in 1992 for Leonid N. Vyalsov (b.1939), Russian mineralogist. ORTH Space group uncertain, probably *Cmmm*. $a = 14.20$, $b = 20.98$, $c = 5.496$, $Z = 8$, $D = 1.96$. $44\text{-}1452$: 5.40₁₀ 4.76₄ 2.88₂ 2.16₅ 1.97₃ 1.89₃ 1.85₃ 1.68₄. Microscopic grains and veinlets. Crimson. $R = 8.2\text{-}11.4$ (540 nm); strongly anisotropic. In skarn, *Talnakh, Norilsk, Russia*. BM *AM* 77:201(1992).

2.14.5.1 Erdite $\text{NaFeS}_2 \cdot 2\text{H}_2\text{O}$

Named in 1980 for Richard C. Erd (b.1924), U.S. mineralogist. MON *C2/c*. $a = 10.693$, $b = 9.115$, $c = 5.507$, $\beta = 92.17^\circ$, $Z = 4$, $D = 2.22$. $33\text{-}1253$: 6.94₁₀ 5.34₈ 4.56₄ 3.47₂ 2.97₂ 2.90₅ 2.31₂ 2.01₁. Small bladed crystals and granular masses. Copper-red, black streak, metallic luster. Cleavage {110}, good. $H = 2$, $\text{VHN}_{15} = 22\text{-}67$. $G = 2.30$. $R = 8.8\text{-}20.7$ (540 nm); extremely pleochroic. *Coyote Peak, Humboldt Co., CA*, in a mafic alkalic diatreme; *Mont St.-Hilaire, PQ, Canada*; *Lovozero massif, Kola, Russia*, in pegmatite. BM *AM* 65:509(1980), *ABI*:148.

2.14.6.1 Coyoteite $\text{NaFe}_3\text{S}_5 \cdot 2\text{H}_2\text{O}$

Named in 1983 for the locality. TRIC *P1* or *P1*. $a = 7.409$, $b = 9.881$, $c = 6.441$, $\alpha = 100.42^\circ$, $\beta = 104.62^\circ$, $\gamma = 81.48^\circ$; $Z = 2$, $D = 2.88$. $35\text{-}565$: 9.6₆ 7.13₉ 5.60₆ 5.12₁₀ 3.91₅ 3.08₇ 3.03₈ 1.90₈. Small clots. Black, black streak, metallic luster. Cleavage {111}, perfect. $H = 1\frac{1}{2}$. $G = 2.5\text{-}2.6$. Moderately magnetic. Strongly anisotropic. *Coyote Peak, Humboldt Co., CA*, in a mafic alkalic diatreme. BM *AM* 68:245(1983), *ABI*:113.

2.14.7.1 Orickite $\text{CuFeS}_2 \cdot \text{H}_2\text{O}$

Named in 1983 for the locality. HEX Space group unknown. $a = 3.695$, $c = 6.16$, $Z = 4$, $D = 4.21$. $37\text{-}412$: 10.78₈ 6.92₃ 5.41₂ 4.35₁₀ 3.66₉ 3.60₇ 3.45₅ 2.52₂. Small clots. Brass-yellow, black streak, metallic luster. Cleavage {001}, good. $H = 3\frac{1}{2}$. Weakly magnetic. Strongly anisotropic. *Coyote Peak, near Orick, Humboldt Co., CA*, in a mafic alkalic diatreme. BM *AM* 68:245(1983), *ABI*:365.

2.15.1.1 Ardaite $\text{Pb}_{10}\text{Sb}_{13}\text{S}_{35}\text{Cl}_7$

Named in 1981 for the locality. MON Space group unknown. $a = 22.09$, $b = 21.11$, $c = 8.05$, $\beta = 103.02^\circ$, $Z = 2$, $D = 6.11$. $42\text{-}585$: 3.71₂ 3.39₁₀ 3.36₈ 3.28₂ 2.87₆ 2.82₄ 2.78₃ 2.10₄. Microscopic acicular aggregates. Green-gray, metallic luster. $R = 32.3\text{-}35.1$ (520 nm); distinctly pleochroic and anisotropic. *Madjarovo, Arda R., Bulgaria*; *Dressfall mine, Gruvåsen, near Filipstad, Sweden*. BM *CM* 19:419(1981), *MM* 46:357(1982), *ABI*:19.

2.15.2.1 Djerfisherite $K_6(\text{Fe,Cu,Ni})_{25}\text{S}_{26}\text{Cl}$

Named in 1966 for D. Jerome Fisher (1896–1988), U.S. mineralogist. iso $Pm\bar{3}m$. $a = 10.41$, $Z = 1$, $D = 3.90$. 25-635: 10.4₆ 3.33₇ 3.17₇ 3.03₇ 2.38₆ 2.01₄ 1.84₁₀ 1.30₅. Microscopic anhedral grains. Yellow-green, submetallic luster. $H \sim 3$, $VHN_{20} = 172$. $R = 22.9$ (540 nm). *Kota-Kota enstatite chondrite* and other meteorites; Coyote Peak, Humboldt, CA; Ilimaussaq Intrusion, Greenland; Lovozero and Khibina massifs, Kola, Norilsk, and Yakutian kimberlites, Russia. BM *SCI 153:166(1966)*, *R:1046*, *P&J:148*, *AM 64:776(1979)*, *ABI:136*.

2.15.2.2 Thalfenisite $Tl_6(\text{Fe,Ni,Cu})_{25}\text{S}_{26}\text{Cl}$

Named in 1979 for the composition. iso $Pm\bar{3}m$. $a = 10.29$, $Z = 1$, $D = 5.26$. 33-1401: 4.16₅ 3.42₉ 3.24₇ 2.96₁₀ 2.35₆ 2.09₃ 1.97₄ 1.81₇. Microscopic grains. Brown, metallic luster. $H = 3$, $VHN_{10} = 130-164$. $R = 25.6$ (560 nm). *Oktyabr mine, Norilsk, Russia*. BM *ZVMO 108:696(1979)*, *AM 66:219(1981)*, *ABI:529*.

2.15.2.3 Owensite $(\text{Ba,Pb})_6(\text{Cu,Fe,Ni})_{25}\text{S}_{27}$

Named in 1995 for DeAlton R. Owens (b.1934), Canadian mineralogist. iso $Pm\bar{3}m$. $a = 10.349$, $Z = 1$, $D = 4.78$. *CM 33*: 3.46₄ 3.28₄ 3.12₂ 3.00₉ 2.38₉ 1.84₁₀ 1.78₄ 1.73₂. Microscopic anhedral grains. Black, black streak, metallic luster. $H = 3\frac{1}{2}$, $VHN_{10} = 137$. $R = 24.7$ (540 nm); in reflected light pale brown-gray, isotropic. *Wellgreen deposit, Kluane district, YT, Canada*, associated with magnetite, chalcopyrite, and pentlandite. BM *CM 33:665(1995)*.

2.15.3.1 Kolarite PbTeCl_2

Named in 1985 for the locality. ORTH Space group unknown. $a = 5.93$, $b = 3.25$, $c = 3.89$, $Z = 1$, $D = 8.99$. 39-323: 3.91₄ 3.27₁₀ 2.35₅ 2.00₄ 1.86₃ 1.79₃ 1.50₃ 1.35₃. Microscopic aggregates. Gray, metallic luster. $R = 27.7-28.6$ (540 nm). *Champion Reef mine, Kolar Gold Fields, Karnataka, India*. BM *CM 23:501(1985)*, *AM 71:1545(1986)*, *ABI:269*.

2.15.4.1 Radhakrishnaite $\text{PbTe}_3(\text{Cl,S})_2$

Named in 1985 for B. P. Radhakrishna (b.1918), Indian mineralogist. TET Space group unknown. $a = 5.71$, $c = 3.77$, $Z = 1$, $D = 8.93$. 39-324: 3.78₆ 3.16₁₀ 2.73₄ 2.29₄ 2.04₃ 1.92₅ 1.78₅ 1.59₄. Microscopic aggregates. Brown-gray, metallic luster. $R = 31.1-31.8$ (540 nm); distinctly anisotropic. *Champion Reef mine, Kolar gold fields, Karnataka, India*. BM *CM 23:501(1985)*, *AM 71:1545(1986)*, *ABI:429*.

2.15.5.1 Perroudite $\text{Hg}_6\text{Ag}_4\text{S}_5(\text{Cl,I,Br})_4$

Named in 1987 for Pierre Perroud (b.1943), Swiss mineralogist. ORTH $P2_12_1$. $a = 17.43$, $b = 12.24$, $c = 4.35$, $Z = 2$, $D = 6.60$. 42-1336: 5.01₂ 3.94₆ 3.69₃ 3.01₁₀ 2.97₈ 2.74₃ 2.64₄ 2.45₃. Fibrous aggregates of microscopic prismatic crystals. Red, orange-red streak, vitreous to adamantine luster. Cleavage

{100}, perfect; irregular fracture. Biaxial (+); $N = 2.3\text{--}2.4$; $2V = 70^\circ$; pleochroic, yellow to red-brown. *Cap-Garonne, Var, France*; Broken Hill, NSW, and Coppin Pool, WA, Australia. *BM AM 72:1251(1987), ABI:399.*

2.15.6.1 Capgarronite $\text{HgAg}(\text{Cl}, \text{Br}, \text{I})\text{S}$

Named in 1992 for the locality. Synonym: tocornalite. ORTH $P2_12_12_1$. $a = 6.803$, $b = 12.87$, $c = 4.528$, $Z = 4$, $D = 6.19$. $44\text{--}1451$: 6.43_4 3.76_6 3.64_6 3.28_3 2.66_{10} 2.27_4 2.05_2 1.70_1 . Small prismatic crystals. Black, gray-black streak, subadamantine to submetallic luster. $N > 2.1$; pleochroic, purple to dark brown. *Cap-Garonne, Var, France*; Broken Hill, NSW, Australia; Chancillo, Chile. *BM DII:25, AM 77:197(1992).*

2.16.1.1 Mertieite-I $\text{Pd}_{11}(\text{Sb}, \text{As})_4$

Named in 1973 for John B. Mertie (1888–1980), geologist, U.S. Geological Survey. HEX Space group unknown. $a = 15.04$, $c = 22.41$, $Z = 18$, $D = 10.6$. $25\text{--}598$: 2.28_{10} 2.23_7 2.17_9 2.02_6 1.92_6 1.20_6 1.10_6 1.09_6 . Small grains. Brass-yellow, metallic luster. $\text{VHN}_{50} = 561\text{--}593$. $R = 51.3$ (546 nm); weakly pleochroic, distinctly anisotropic. *Goodnews Bay, AK*, in placer concentrates; Talnakh, Norilsk, Russia. *BM AM 58:1(1973), CM 13:321(1975), ABI:325.*

2.16.2.1 Isomertieite $\text{Pd}_{11}\text{Sb}_2\text{As}_2$

Named in 1974 for its relationship to mertieite. iso $Fd3m$. $a = 12.283$, $Z = 8$, $D = 10.33$. $26\text{--}833$: 2.36_9 2.17_{10} 1.53_7 1.45_6 1.29_6 1.25_7 1.19_7 1.00_7 . Microscopic grains. Pale yellow-white, metallic luster. $H = 5\frac{1}{2}$, $\text{VHN}_{100} = 587\text{--}597$. $R = 54.8$ (540 nm); weakly anisotropic in shades of brown. Occurs in heavy-metal concentrates with gold and other Pd minerals. Lac des Iles Complex, ON, Canada; Hope's Nose, Torquay, England; Konttijarvi intrusion, northern Finland; near Zlatoust, Ural Mts., Russia; Waiiau R., Southland, New Zealand; *Itabira, MG, Brazil*. *BM MM 39:528(1974), 46:371(1982), ABI:244.*

2.16.3.1 Mertieite-II $\text{Pd}_8(\text{Sb}, \text{As})_3$

Named in 1973 as for mertieite-I. HEX-R $R3c$. $a = 7.601$, $c = 42.904$, $Z = 12$, $D = 11.29$. $30\text{--}93(\text{syn})$: 2.48_4 2.28_9 2.19_{10} 2.02_4 1.93_4 1.49_4 1.28_5 1.27_5 . Small grains. Brass-yellow, metallic luster. $H = 6$, $\text{VHN}_{50} = 561\text{--}593$. $R = 50.1$ (540 nm); distinctly anisotropic, dark blue-gray to dark brown. Occurs as small grains in precious-metal concentrates. Stillwater Complex, MT; *Goodnews Bay, AK*; Hope's Nose, Torquay, England; Oktyabr mine, Norilsk, and near Zlatoust, Ural Mts., Russia; Merensky Reef, Transvaal, South Africa. *BM AM 58:1(1973), CM 13:321(1975), MM 46:371(1982), ABI:326.*

2.16.4.1 Stillwaterite Pd_8As_3

Named in 1975 for the locality. HEX $P3$. $a = 7.426$, $c = 10.316$, $Z = 3$, $D = 10.88$. $30\text{--}880(\text{syn})$: 2.36_{10} 2.21_5 2.14_7 2.13_8 1.99_3 1.76_4 1.36_5 1.21_4 . Microscopic grains. Cream-gray, metallic luster. $H = 4\frac{1}{2}$, $\text{VHN}_{50} = 384$. $G = 10.4$.

$R = 52.5\text{--}53.2$ (546 nm); weakly anisotropic. *Stillwater Complex, MT*, in Banded and Upper zones, associated with gold and other Pd-arsenides; Roby zone, Lac des Iles Complex, ON, Canada. *BM CM 13:321(1975)*, *AM 62:1060(1977)*, *ABI:500*.

2.16.5.1 Arsenopalladinite $\text{Pd}_8(\text{As,Sb})_3$

Named in 1974 for the composition. Contains up to 6% Sb. TRIC $P1$. $a = 7.43$, $b = 13.95$, $c = 7.35$, $\alpha = 92.88^\circ$, $\beta = 119.5^\circ$, $\gamma = 87.85^\circ$, $Z = 4$, $D = 11.03$. $29\text{--}959$: 2.34_6 2.28_2 2.19_2 2.13_{10} 1.41_4 1.39_2 1.24_3 1.21_3 . Rounded alluvial grains. White with a cream tint, metallic luster. $H = 4$, $\text{VHN}_{100} = 379\text{--}449$. $G = 10.4$. $R = 52.1\text{--}53.9$; strongly anisotropic, red-brown to blue-gray. *Stillwater Complex, MT*; Merensky Reef, Transvaal, South Africa; *Itabira, MG, Brazil*, in gold concentrates. *BM MM 39:528(1974)*, *CM 15:70(1977)*, *ABI:27*.

2.16.6.1 Telluropalladinite Pd_5Te_4

Named in 1979 for the composition. MON $P2_1/c$. $a = 7.45$, $b = 13.95$, $c = 8.82$, $\beta = 91.9^\circ$, $Z = 4$, $D = 10.64$. $35\text{--}699$: 2.54_2 2.24_{10} 2.13_3 2.09_4 1.98_3 1.96_3 1.40_3 1.31_5 . Microscopic grains. Cream-yellow, metallic luster. $H = 4\text{--}4\frac{1}{2}$, $\text{VHN}_{15} = 376\text{--}399$. $G_{\text{syn}} = 10.25$. $R = 50.0$ (540 nm); moderately to strongly anisotropic. *Stillwater Complex, MT*. *BM CM 17:589(1979)*, *ABI:519*.

2.16.7.1 Balkanite $\text{Cu}_9\text{Ag}_5\text{HgS}_8$

Named in 1973 for the locality. ORTH Space group uncertain, probably $P222$. $a = 10.62$, $b = 9.42$, $c = 3.92$, $Z = 1$, $D = 6.64$. $25\text{--}299(\text{syn})$: 3.14_7 3.01_8 2.98_{10} 2.70_8 2.61_9 2.55_{10} 1.99_8 1.96_9 . Microscopic prismatic crystals and small grains. Steel-gray, metallic luster. No cleavage. $H = 3\frac{1}{2}$, $\text{VHN}_{100} = 79\text{--}92$. $G_{\text{syn}} = 6.32$. $R = 28.0\text{--}34.0$ (540 nm); strongly anisotropic. *Manhattan, Nye Co., NV*; near *Agua Prieta, SON, Mexico*; *Sedmochistenitsi mine, Vratsa district, Balkan Mts., Bulgaria*. *BM AM 58:11(1973)*, *ABI:39*.

2.16.7.2 Danielsite $(\text{Cu,Ag})_{14}\text{HgS}_8$

Named in 1987 for John L. Daniels (b.1931), who collected the mineral. ORTH Space group unknown. $a = 9.644$, $b = 9.180$, $c = 18.156$, $Z = 4$, $D = 6.54$. $40\text{--}500$: 4.44_2 3.65_2 3.02_2 2.83_3 2.62_{10} 2.39_5 1.96_6 1.88_6 . Microscopic grains. Gray, metallic luster. $H = 2\text{--}2\frac{1}{2}$, $\text{VHN}_{10} = 38$. $R = 30\text{--}31$ (546 nm); moderately anisotropic. *Coppin Pool, WA, Australia*. *BM AM 72:401(1987)*, $73:187(1988)$; *ABI:127*.

2.16.8.1 Betekhtinite $\text{Cu}_{10}(\text{Pb,Fe})\text{S}_6$

Named in 1955 for Anatolii G. Betekhtin (1897–1962), Russian mineralogist. ORTH $Immm$. $a = 14.693$, $b = 22.72$, $c = 3.861$, $Z = 4$, $D = 6.14$. $25\text{--}1223$: 5.65_5 4.77_5 3.08_8 2.94_{10} 2.52_5 2.35_7 1.93_6 1.83_9 . Prismatic crystals to 2 cm and massive. Black, black streak, metallic luster. Cleavage in three directions. $H = 3\text{--}3\frac{1}{2}$. $G = 5.96\text{--}6.05$. $R = 32.1\text{--}32.5$ (540 nm); strongly anisotropic. *St.*

Cloud mine, Sierra Co., NM; near Laird, Sutherland, Scotland; *Mansfeld Kupferschiefer, Eisleben, Germany*; Mürtchenalp, Switzerland; Radka deposit, Pazardzik, Bulgaria; Bulancak deposit, Giresun, Turkey; Dzhezkazgan(*), Kazakhstan; Yoshino mine, Yamagata Pref., Japan; Mt. Lyell, TAS, Australia; Kipushi(*), Shaba, Zaire; Tsumeb, Namibia; La Leona mine, Santa Cruz Prov., Argentina. *BM AM 41:371(1956), NJMM:121(1960), P&J:89, ABI:51.*

2.16.9.1 Larosite $(\text{Cu,Ag})_{21}(\text{Pb,Bi})_2\text{S}_{13}$

Named in 1972 for Fred LaRose, a discoverer of silver ore at Cobalt. ORTH Space group unknown. $a = 22.15$, $b = 24.03$, $c = 11.67$, $Z = 10$, $D = 6.18$. $25\text{-}311: 3.21_5$ 2.92_9 2.85_6 2.56_4 2.50_2 2.47_6 2.16_4 1.98_{10} . Microscopic acicular crystals. Black, metallic luster. $H = 3$, $\text{VHN}_{100} = 124$. $R = 29.7\text{--}31.7$ (546 nm); moderately anisotropic. *Foster mine, Cobalt, ON, Canada. BM CM 11:886(1972), AM 59:382(1974), R:486, ABI:287.*

2.16.10.1 Sopcheite $\text{Ag}_4\text{Pd}_3\text{Te}_4$

Named in 1982 for the locality. ORTH Space group unknown. $a = 9.645$, $b = 7.906$, $c = 11.040$, $Z = 4$, $D = 9.95$. $35\text{-}671: 4.12_4$ 3.33_{10} 2.70_5 2.56_6 2.30_5 2.15_4 2.03_4 1.81_7 . Microscopic grains. Gray, metallic luster. $H = 3\frac{1}{2}$, $\text{VHN}_{10} = 134\text{--}209$. $R = 41.6\text{--}43.1$ (540 nm); weakly anisotropic. Lac des Iles Complex, and Levack West mine, Sudbury, ON, Canada; *Sopcha massif, Monchegorsk pluton, Kola, Russia. BM ZVMO 111:114(1982), AM 68:472(1983), CM 22:233(1984), ABI:484.*

2.16.11.1 Henryite $\text{Cu}_4\text{Ag}_3\text{Te}_4$

Named in 1983 for Norman F. M. Henry (1909–1983), English mineralogist. iso Space group unknown. $a = 12.20$, $Z = 8$, $D = 7.96$. $37\text{-}423: 7.03_6$ 3.04_8 2.35_6 2.16_{10} 1.36_6 1.25_6 1.08_8 1.02_6 . Microscopic anhedral grains. Gray, metallic luster. $H = 3$, $\text{VHN}_{100} = 109\text{--}115$. $R = 33.1$ (540 nm). *Campbell mine, Bisbee, AZ; Ashanti mine, Ghana. BM BM 106:511(1983), AM 70:216(1985), ABI:214.*

2.16.12.1 Furutobeite $(\text{Cu,Ag})_6\text{PbS}_4$

Named in 1981 for the locality. MON Space group uncertain, probably *Cm*. $a = 20.025$, $b = 3.963$, $c = 9.705$, $\beta = 101.57^\circ$, $Z = 4$, $D = 6.74$. $35\text{-}534: 3.43_5$ 2.95_9 2.78_3 2.61_5 2.55_7 2.50_{10} 2.14_4 2.09_4 . Microscopic grains. Gray, metallic luster. $H = 3$, $\text{VHN}_{25} = 100\text{--}108$. $R = 34.6\text{--}36.2$ (540 nm); moderately anisotropic. Erasmus mine, Leogang, Austria; *Furutobe mine, Akita Pref., Japan; Tsumeb, Namibia. BM BM 104:737(1981), AM 67:1075(1982), ABI:169.*

2.16.13.1 Stützite $\text{Ag}_{5-x}\text{Te}_3$ ($x = 0.24\text{--}0.36$)

Named in 1878 for Andreas Stütz (1747–1806), Austrian mineralogist. HEX *C6/mmm*. $a = 13.49$, $c = 8.48$, $Z = 7$, $D = 8.02$. $18\text{-}1187: 3.58_4$ 3.53_5 3.37_4

3.05₆ 2.63₆ 2.57₇ 2.55₆ 2.18₁₀. Highly modified hexagonal crystals, usually massive, granular. Lead-gray, lead-gray streak, metallic luster. $H = 3\frac{1}{2}$, $VHN_{25} = 73-90$. $G = 8.00$. $R = 40.7-40.8$ (540 nm); moderately anisotropic. Empress Josephine mine, Saguache Co., and other localities in CO; Campbell mine, Bisbee, AZ; Linnquist Lake, PQ, and Temagami Lake, ON, Canada; Moctezuma, SON, Mexico; Glava, Varmland, Sweden; *Sacaramb, Romania*; Kochbulak deposit, Uzbekistan; Kawazu mine, Shizuoka Pref., Japan. *BM DI:167, R:425, P&J:357, ABI:504*.

2.16.14.1 Gortdrumite $Cu_6Hg_2S_5$

Named in 1983 for the locality. Contains up to 3% Fe. ORTH Space group unknown. $a = 14.958$, $b = 7.900$, $c = 24.10$, $Z = 12$, $D = 6.80$. *34-184: 6.03₄ 4.58₁₀ 3.38₇ 3.08₃ 3.02₃ 2.88₅ 2.78₅ 2.67₃*. Microscopic anhedral grains. Lead-gray, metallic luster. $H = 3\frac{1}{2}-4$, $VHN_{10} = 186-230$. $R = 26.7-30.5$ (540 nm); strongly anisotropic. *Gortdrum deposit, Co. Tipperary, Eire. BM MM 47:35(1983), AM 69:407(1984), ABI:191*.

2.16.15.1 Rickardite Cu_7Te_5

Named in 1903 for Thomas A. Rickard (1864-1953), U.S. mining engineer. ORTH Space group unknown. $a = 4.003$, $b = 19.893$, $c = 12.220$, $Z = 4$, $D = 7.39$. *26-1117: 6.12₆ 3.35₉ 3.34₁₀ 3.06₈ 2.56₆ 2.07₁₀ 2.04₉ 1.99₅*. Massive. Purple-red tarnishing to brown, metallic luster. $H = 3\frac{1}{2}$, $VHN_{50} = 72-85$. $G = 7.54$. $R = 13.0-18.4$ (540 nm); strongly pleochroic and anisotropic. *Good Hope mine, Gunnison Co., and Empress Josephine mine, Saguache Co., CO; Bisbee and Tombstone, Cochise Co., AZ; Horne mine, Noranda, PQ, Canada; Sebastian mine, San Salvador; Chatkal Ridge, Kirghizstan; Darasun deposit, Transbaikalia, Russia; Teine mine, Hokkaido, and Kawazu mine, Shizuoka Pref., Japan; Kalgoorlie, WA, Australia; O'Okiep, Namaqualand, South Africa. BM DI:198, R:416, P&J:327, ABI:442*.

2.16.15.2 Oosterboschite $(Pd,Cu)_7Se_5$

Named in 1970 for M. R. Oosterbosch (b.1908), Belgian mining engineer. ORTH Space group unknown. $a = 10.42$, $b = 10.60$, $c = 14.43$, $Z = 8$, $D = 8.48$. *24-371: 4.48₆ 2.74₇ 2.65₁₀ 2.60₈ 2.49₅ 2.24₇ 1.90₇ 1.85₈*. Microscopic anhedral grains, polysynthetically twinned. Black, black streak, metallic luster. $H = 4\frac{1}{2}-5$, $VHN_{100} = 340$. $R = 46.0-51.8$ (540 nm); anisotropic, blue-gray to brown-gray. *Musonoi mine, Shaba, Zaire. BM BM 93:476(1970), AM 57:1553(1972), R:468, P&J:280, ABI:362*.

2.16.16.1 Maucherite $Ni_{11}As_8$

Named in 1913 for Wilhelm Maucher (1879-1930), German mineral dealer. TET $P4_12_1$. $a = 6.872$, $c = 21.821$, $Z = 4$, $D = 8.05$. *8-85: 2.69₉ 2.01₁₀ 1.71₁₀ 1.45₅ 1.21₆ 1.13₄ 1.11₅ 1.08₅*. Tabular or pyramidal crystals, also massive, radiating, or granular. Gray, gray-black streak, metallic luster. No cleavage, uneven fracture. $H = 5$, $VHN_{100} = 623-723$. $G = 8.00$. $R = 48.4-50.8$ (540

nm); weakly anisotropic. Occurs in hydrothermal veins with other nickel arsenides and sulfides. Mohawk mine, Keweenaw Co., MI, Gem mine, Fremont Co., CO, Mackinaw mine, Snohomish Co., WA; Cobalt district, ON, in several mines, Jeffrey mine, Asbestos, PQ, Canada; *Eisleben, Saxony*, and Mansfeld, Thuringia, *Germany*; Los Jarales and Vimbodi, Spain; Bou Azzer, Morocco; Talmessi mine, near Anarak, Iran. BM *DI:192, AM 56:203(1973), R:400, P&J:261, ABI:318.*

2.16.17.1 Athabascaite Cu_5Se_4

Named in 1970 for the locality. ORTH Space group unknown. $a = 8.227$, $b = 11.982$, $c = 6.441$, $Z = 4$, $D = 6.63$. *21-1016*: 3.44_3 3.24_{10} 3.02_6 2.00_8 1.89_5 1.82_3 1.66_4 1.37_3 . Microscopic laths and anhedral grains. $H = 2\frac{1}{2}$, $\text{VHN}_{15} = 78$. $R = 17.8\text{--}25.5$ (540 nm); strongly anisotropic. *Martin Lake mine, Uranium City, Lake Athabasca, SK, Canada*; Skrikerum, Kalmar, Sweden; Chameane, Puy-de-Dôme, France; Petrovice and Predborice deposits, Czech Republic. BM *CM 10:207(1970), R:505, P&J:80, ABI:33.*

2.16.18.1 Penzhinite $\text{Ag}_4\text{Au}(\text{S},\text{Se})_4$

Named in 1984 for the locality. Contains 3% Cu. HEX $P6_322$. $a = 13.779$, $c = 16.980$, $Z = 18$, $D = 8.35$. *38-398*: 3.38_5 3.04_2 2.71_9 2.59_{10} 2.14_9 2.11_9 1.99_6 1.78_5 . Microscopic grains. $R = 31.2\text{--}34.5$ (540 nm); anisotropic, cream-yellow to green-gray. *Penzhina R., Kamchatka, Russia*. BM *ZVMO 113:356(1984), AM 70:375(1985), ABI:397.*

2.16.19.1 Palladseite $\text{Pd}_{17}\text{Se}_{15}$

Named in 1977 for the composition. Contains 4% Cu and 2% Hg. ISO $Pm3m$. $a = 10.606$, $Z = 2$, $D = 8.33$. *29-1437(syn)*: 3.35_5 3.20_{10} 2.84_6 2.57_7 2.50_4 2.04_8 1.88_{10} 1.77_4 . Small detrital grains. White, metallic luster. $H = 4\frac{1}{2}\text{--}5$, $\text{VHN}_{100} = 390\text{--}437$. $G_{\text{syn}} = 8.30$. $R = 45.7$ (540 nm). *Itabira, MG, Brazil*. BM *MM 41:123(1977), AM 62:1059(1977), ABI:379.*

2.16.20.1 Cameronite $\text{Cu}_7\text{AgTe}_{10}$

Named in 1986 for Eugene N. Cameron (b.1910), U.S. economic geologist. TET $P4_2/mmc$. $a = 12.695$, $c = 42.186$, $Z = 16$, $D = 7.15$. *40-471*: 3.46_{10} 2.96_2 2.12_{10} 1.82_3 1.80_6 1.38_4 1.22_4 1.15_3 . Microscopic anhedral grains. Black, black streak, metallic luster. No cleavage, subconchoidal fracture, brittle. $H = 3\frac{1}{2}\text{--}4$, $\text{VHN}_{100} = 151\text{--}172$. $R = 32.1\text{--}33.8$ (540 nm); distinctly anisotropic. *Good Hope mine, Vulcan, CO*. BM *CM 24:379(1986), AM 72:1023(1987), ABI:78.*

2.16.21.1 Patronite VS_4

Named in 1906 for Antenor Rizo-Patron (1866–1948), Peruvian engineer, who discovered the Minasragra deposit. MON $I2/a$. $a = 12.110$, $b = 10.420$, $c = 6.780$, $\beta = 100.8^\circ$, $Z = 8$, $D = 2.83$. *14-179*: 6.3_3 5.47_6 5.15_{10} 3.92_5 3.82_4

3.02₅ 2.72₄ 1.98₄. Massive, finely granular. Gray-black, metallic luster. $H = 2$, $G = 2.81$. $R = 20.0\text{--}32.8$ (540 nm); strongly pleochroic. A major ore of vanadium. *Minasragra, near Cerro de Pasco, Peru*. BM *DI:347, R:887, P&J:290, ABI:390*.

2.16.22.1 Vasilite (Pd,Cu)₁₆(S,Te)₇

Named in 1990 for Vasil Atanasov (b.1933), Bulgarian mineralogist. iso *I43m*. $a = 8.922$, $Z = 2$, $D = 8.796$. *CM 28*: 3.64₈ 2.58₆ 2.39₁₀ 2.23₆ 2.10₈ 1.45₈ 1.21₇ 1.01₇. Small detrital grains. Gray, black streak, metallic luster. No cleavage, uneven fracture, brittle. $H = 4\frac{1}{2}\text{--}5$, $VHN_{20} = 467\text{--}506$. $R = 37.7$ (540 nm). In heavy-mineral concentrates, near *Novoseltsi, Bourgas region, Bulgaria*. BM *CM 28:687(1990)*.

2.16.23.1 Luberoite Pt₅Se₄

Named in 1992 for the locality. MON *P2₁/c*. $a = 6.584$, $b = 4.602$, $c = 11.10$, $\beta = 101.6^\circ$, $Z = 2$, $D = 13.02$. *31-950(syn)*: 5.45₇ 3.27₇ 2.93₁₀ 2.78₉ 2.64₆ 2.47₆ 1.88₉ 1.87₁₀. Small prismatic crystals and rounded grains. Dark bronze, metallic luster. $VHN_{15} = 461$. $G_{\text{syn}} = 12.79$. $R = 46.3\text{--}52.8$ (540 nm); strongly anisotropic. In placers, *Lubero region, Kivu Prov., Zaire*. BM *EM 4:683(1992), AM 78:450(1993)*.

Sulfosalts

COLUSITE GROUP

The colusite group consists of complex sulfosalts of copper with the general formula

where

B = As, Ge, Sn, Sb

and where the space group is *P43n*. The structure is closely related to that of sphalerite.

COLUSITE GROUP

Mineral	Formula	Space Group	a	D	
Colusite	$\text{Cu}_{26}\text{V}_2\text{As}_6\text{S}_{32}$	<i>P43n</i>	10.62	4.44	3.1.1.1
Germanocolusite	$\text{Cu}_{26}\text{V}_2(\text{Ge}, \text{As})_6\text{S}_{32}$	<i>P43n</i>	10.57	4.55	3.1.1.2
Nekrasovite	$\text{Cu}_{26}\text{V}_2(\text{Sn}, \text{As})_6\text{S}_{32}$	<i>P43n</i>	10.73	4.62	3.1.1.3
Stibicolusite	$\text{Cu}_{26}\text{V}_2(\text{Sb}, \text{Sn}, \text{As})_6\text{S}_{32}$	<i>P43n</i>	10.71	4.66	3.1.1.4

3.1.1.1 Colusite $\text{Cu}_{26}\text{V}_2\text{As}_6\text{S}_{32}$

Named in 1933 for the locality. Colusite group. May contain minor Fe, Sb, Sn, and Ge. iso *P43n*. *a* = 10.62, *Z* = 1, *D* = 4.44. *9-10*: 3.07₁₀ 2.65₂ 1.88₆ 1.60₄ 1.32₂ 1.22₃ 1.09₃ 1.02₂. Tetrahedral crystals rare; usually massive, granular. Bronze-brown, black streak, metallic luster. No cleavage, brittle. *H* = 4½, *VHN*₁₀₀ = 322–379. *G* = 4.4–4.5. *R* = 30.0 (540 nm). *Colusa claim* and other mines in *Butte, MT*; Red Mountain Pass, Ouray Co., and Buffalo Boy mine, near Silverton, CO; Magma mine, Gila Co., and Campbell mine, Bisbee, AZ; Kidd Creek mine, near Timmins, ON, Canada; Chiseuil, Saone-et-Loire, France; Lorano, near Carrara, Italy; Bor, Serbia; Chelopech, Bulgaria; Gay Cu–Zn deposit, southern Ural Mts., Russia; Cerro de Pasco, Peru; Chuquicamata, Antofagasta, Chile. *BM DI:386, R:562, P&J:129, ABI:106, AM 79:750(1994)*.

3.1.1.2 Germanocolusite $\text{Cu}_{26}\text{V}_2(\text{Ge}, \text{As})_6\text{S}_{32}$

Named in 1992 for its relationship to colusite. Colusite group. ISO $P43n$. $a = 10.57$, $Z = 1$, $D = 4.55$. *AM* 79: 3.05₁₀ 2.64₄ 1.87₅ 1.60₃ 1.32₃ 1.21₃ 1.08₃ 1.02₃. Microscopic grains, usually in bornite. No cleavage. $\text{VHN}_{40} = 280\text{--}370$. $R = 27.3\text{--}29.5$ (546 nm); color yellow, isotropic; no internal reflections. Chelopech, Bulgaria; *Urup, northern Caucasus, Russia*; Maykain, northeastern Kazakhstan; Tsumeb, Namibia. BM *AM* 79:387(1994).

3.1.1.3 Nekrasovite $\text{Cu}_{26}\text{V}_2(\text{Sn}, \text{As})_6\text{S}_{32}$

Named in 1984 for Ivan Y. Nekrasov (b.1929), Russian mineralogist. Colusite group. Contains minor Fe and Sb. ISO $P43n$. $a = 10.73$, $Z = 1$, $D = 4.62$. *41-1410*: 3.41₁ 3.09₁₀ 2.68₂ 1.89₈ 1.62₆ 1.23₅ 1.10₃ 1.03₃. Microscopic grains. Pale brown, metallic luster. $H = 4\frac{1}{2}$, $\text{VHN}_{20} = 314$. $R = 26.4$ (540 nm). Campbell mine, Bisbee, AZ; Neves-Corvo, Portugal; *Kairagach deposit, Kuramin Mts., Uzbekistan*. BM *MZ* 6:88(1984), *AM* 70:437(1985), *ABI*:346.

3.1.1.4 Stibiocolusite $\text{Cu}_{26}\text{V}_2(\text{Sb}, \text{Sn}, \text{As})_6\text{S}_{32}$

Named in 1992 for its relationship to colusite. Colusite group. ISO $P43n$. $a = 10.71$, $Z = 1$, $D = 4.66$. *DANS* 324: 3.10₁₀ 1.89₉ 1.61₇ 1.23₄ 1.09₆ 1.03₄. Microscopic anhedral grains. Dark gray, gray streak, metallic luster. No cleavage, conchoidal fracture. $H = 4\frac{1}{2}$, $\text{VHN}_{50} = 273$. $R = 29.5$ (580 nm). *Kairagach deposit, Kuramin Mts., Uzbekistan*, in tetrahedrite ore. BM *DANS* 324:411(1992), *AM* 79:186(1994).

3.1.2.1 Vinciennite $\text{Cu}_{10}\text{Fe}_4\text{Sn}(\text{As}, \text{Sb})\text{S}_{16}$

Named in 1985 for Henri Vincienne (1898–1965), French mineralogist. *TET* $P4_122$. $a = 10.697$, $c = 10.697$, $Z = 2$, $D = 4.25$. *39-327*: 4.37₃ 3.09₁₀ 2.68₅ 1.90₉ 1.61₇ 1.34₃ 1.23₄ 1.09₄. Small grains. Orange, metallic luster. Conchoidal fracture, very brittle. $H = 4$, $\text{VHN}_{100} = 321$. $R = 26.5\text{--}27.7$ (540 nm); weakly anisotropic. Maggie Cu deposit, near Ashcroft, BC, Canada; *Chizeuil, Saone-et-Loire, France*; Neves-Corvo, Portugal; Huaron, Peru. BM *BM* 108:447(1985), *AM* 71:1280(1986), *CM* 25:227(1987), *ABI*:559.

3.1.3.1 Levyclaudite $\text{Pb}_8\text{Sn}_7\text{Cu}_3(\text{Bi}, \text{Sb})_3\text{S}_{28}$

Named in 1990 for Claude Levy (b.1924), French mineralogist. *MON* Space group uncertain, probably $A2$. $a = 11.84$, $b = 5.825$, $c = 5.831$, $\beta = 92.6^\circ$, $Z = 1$, $D = 6.04$. *EM* 2: 5.9₃ 3.95₁₀ 3.72₁ 3.17₁ 2.96₈ 2.81₂ 2.37₂ 2.07₂. Microscopic lamellae in thin veinlets. Gray, black streak, metallic luster. Cleavage $\{100\}$, good. $H = 2\frac{1}{2}\text{--}3$, $\text{VHN}_{25} = 80\text{--}87$. $R = 32.5\text{--}34.0$ (546 nm); strongly anisotropic. *Aghios Philippos Pb-Zn deposit, Kirki district, Greece*. BM *EM* 2:711(1990), *AM* 76:2022(1991).

3.1.4.1. Cylindrite $Pb_3Sn_4FeSb_2S_{14}$

Named in 1893 for its cylindrical form. TRIC $P\bar{1}$. $a = 11.73$, $b = 5.79$, $c = 5.80$, $\alpha = 90.0^\circ$, $\beta = 92.38^\circ$, $\gamma = 93.87^\circ$, $Z = 2$, $D = 5.43$. 27-246: 3.9₉ 3.85₁₀ 3.47₆ 3.06₇ 2.89₁₀ 2.85₇ 2.04₇ 2.03₇. Concentric tubular shells and aggregates up to 3 cm, also massive. Dark lead-gray, black streak, metallic luster. Cleavage {100}, perfect. $H = 2\frac{1}{2}$, $VHN_{100} = 54-93$. $G = 5.4-5.5$. $R = 32.0-36.4$ (540 nm); distinctly anisotropic. Smirnovsk, Transbaikalia, Russia: *Mina Santa Cruz, Poopo*, and other mines in *Bolivia*. BM *DI:482*, *R:748*, *P&J:143*, *ABI:124*.

3.1.4.2 Franckeite $FePb_5Sn_3Sb_2S_{14}$

Named in 1893 for Carl and Ernest Francke, German mining engineers. TRIC $P1$. $a = 46.9$, $b = 5.82$, $c = 17.3$, $\alpha = 90.0^\circ$, $\beta = 94.68^\circ$, $\gamma = 90.0^\circ$, $Z = 8$, $D = 5.88$. 15-25: 4.30₅ 3.44₁₀ 3.11₅ 2.91₁₀ 2.86₁₀ 2.82₁₀ 2.36₅ 2.05₈. Thin tabular crystals; usually massive, radiating or foliated. Dark gray-black color and streak; metallic luster. Cleavage {010}, perfect; flexible, inelastic cleavage flakes. $H = 2\frac{1}{2}-3$. $G = 5.9$. $R = 36.4-38.2$ (540 nm); weakly anisotropic. Thompson mine, Inyo Co., and Kalkar quarry, Santa Cruz Co., CA; Coal R., YT, Canada; Vens Haut, Cantal, France; Smirnovsk, Transbaikalia, and Sinantscha deposit, Sikote-Alin, Russia; Dachang, Guangxi Prov., China; Hoei mine, Oita Pref., Japan; Renison Bell mine, TAS, and Walla Walla mine, Rye Park, NSW, Australia; *Poopo*, Oruro, Llalagua, Huanuni, and other localities in *Bolivia*. BM *DI:448*, *R:747*, *P&J:166*, *ABI:160*.

3.1.4.3 Incaite $Pb_4Sn_4FeSb_2S_{13}$

Named in 1974 for the original inhabitants of the locality. TRIC Space group uncertain, probably $P1$. $a = 17.29$, $b = 5.79$, $c = 5.83$, $\alpha = \beta = \gamma = 90.0^\circ$, $Z = 1$, $D = 5.75$. 39-1362: 4.31₆ 3.83₄ 3.43₇ 3.23₄ 3.12₄ 2.86₁₀ 2.06₄ 2.03₈. Microscopic lamellae. Lead-gray, metallic luster. Cleavage {100}, perfect. $R = 29.0-33.2$ (540 nm); distinctly anisotropic. Near Mejillones, Antofagasta, Chile; *Poopo*, *Bolivia*. BM *NJMM:235(1974)*, *AM 60:486(1975)*, *R:748*, *ABI:232*.

3.1.4.4 Potosiite $Pb_6Sn_2FeSb_2S_{14}$

Named in 1981 for the locality. TRIC Space group uncertain, probably $P\bar{1}$. $a = 5.915$, $b = 5.938$, $c = 17.239$, $\alpha = 91.63^\circ$, $\beta = 91.02^\circ$, $\gamma = 90.84^\circ$, $Z = 1$, $D = 6.20$. 35-726: 5.76₁ 4.32₃ 3.45₉ 2.94₁ 2.88₁₀ 2.16₁ 2.07₁ 1.92₁. Microscopic crystals in felted masses. Metallic luster. Cleavage {001}, perfect; {010}, good. $H = 2\frac{1}{2}$, $VHN_{100} = 105$. $R = 34.4-35.1$ (589 nm); moderately anisotropic. Herb claim, Turnagain R., BC, Canada; *Andacaba deposit*, *Potosi*, *Bolivia*. BM *AM 68:1249(1983)*, *CM 24:45(1986)*, *ABI:420*.

3.1.5.1 Miharaite $\text{Cu}_4\text{FePbBiS}_6$

Named in 1980 for the locality. ORTH $Pb2_1/m$. $a = 10.854$, $b = 11.985$, $c = 3.871$, $Z = 2$, $D = 6.06$. $33\text{-}461$: 3.25_3 3.11_3 3.03_{10} 3.00_7 2.70_3 2.64_3 2.18_5 1.94_7 . Microscopic grains. Gray, metallic luster. $H = 4$, $VHN_{25} = 190\text{-}230$. $R = 31.7\text{-}32.6$ (589 nm); moderately anisotropic. Neves-Corvo, Portugal; Ulsan mine, Kyongsangnam Prov., Korea; *Mihara mine* and *Imooka mine*, *Okayama Pref., Japan*. BM *AM 65:784(1980)*, *ABI:332*.

3.1.6.1 Billingsleyite $\text{Ag}_7(\text{As}, \text{Sb})\text{S}_6$

Named in 1968 for Paul Billingsley (1887–1962), U.S. geologist, who collected the material. ISO $P2_13$. $a = 10.481$, $Z = 4$, $D = 5.90$. $21\text{-}1334(\text{syn})$: 6.06_4 3.49_4 3.16_4 3.03_{10} 2.91_5 2.80_7 2.47_7 1.85_5 . Fine-grained aggregates. Dark lead-gray, metallic luster. $H = 2\frac{1}{2}$. $G = 5.92$. *North Lily mine, East Tintic district, UT*. BM *AM 53:1791(1968)*, *R:726*, *ABI:54*, *CM 28:751(1990)*.

3.1.7.1 Arsenopolybasite $(\text{Ag}, \text{Cu})_{16}\text{As}_2\text{S}_{11}$

Named in 1963 as the As analog of polybasite. Contains up to 1% Sb. MON $C2/m$. $a = 26.08$, $b = 15.04$, $c = 23.84$, $\beta = 90^\circ$, $Z = 16$, $D = 6.08$. $37\text{-}428(\text{syn})$: 6.38_3 6.02_3 3.68_3 3.08_4 3.01_{10} 2.09_3 1.84_6 . Thin pseudo-hexagonal plates. Black, black streak, metallic luster. Cleavage {001}, imperfect. $H = 2\text{-}3$. $G = 6.2$. Biaxial (-); $N > 2.72$; $2V = 22^\circ$. Creede, Mineral Co., CO; *Neuer Morgenstern mine, Freiberg, Saxony, Germany*; Quespisiza, Peru. BM *AM 43:565(1963)*, *52:1311(1967)*; *CM 8:172(1965)*; *ABI:30*.

3.1.7.2 Polybasite $(\text{Ag}, \text{Cu})_{16}\text{Sb}_2\text{S}_{11}$

Named in 1829 from the Greek for *many* and *base*, in allusion to the many metallic bases present. Forms a series with pearceite (3.1.8.1). MON $C2/m$. $a = 26.17$, $b = 15.11$, $c = 23.89$, $\beta = 90.0^\circ$, $Z = 16$, $D = 6.36$. $36\text{-}391$: 3.19_4 3.15_{10} 2.98_{10} 2.91_7 2.86_9 2.67_8 2.52_8 2.42_6 . Pseudo-hexagonal plates and massive. Black, black streak, metallic luster. Cleavage {001}, imperfect; uneven fracture. $H = 2\text{-}3$. $G = 6.1\text{-}6.2$. $R = 30.8\text{-}32.8$ (540 nm); moderately anisotropic. Occurs in silver-bearing veins, occasionally an important ore mineral. Leadville, Ouray, Rico(*), and other localities, CO; Tonopah, Goldfield, and the Comstock Lode, NV; Las Chispas mine(*), Arizpe, SON, Guanajuato, GTO, and other localities, Mexico; Sabana Grande(*), Honduras; Andreasberg(*), Harz, and Freiberg(*), Saxony, Germany; Příbram, Czech Republic; Broken Hill, NSW, Australia. BM *DI:351*, *R:729*, *P&J:306*, *ABI:417*.

3.1.8.1 Pearceite $(\text{Ag}, \text{Cu})_{16}\text{As}_2\text{S}_{11}$

Named in 1896 for Richard Pearce (1837–1927), U.S. chemist and metallurgist. Forms a series with polybasite (3.1.7.2). MON $C2/m$. $a = 12.64$, $b = 7.29$, $c = 11.90$, $\beta = 90.0^\circ$, $Z = 2$, $D = 6.07$. $8\text{-}130$: 2.97_{10} 2.80_9 2.47_6 2.34_5 2.30_6 2.16_3 1.99_5 1.83_6 . Pseudo-hexagonal plates. Black, black streak,

metallic luster. No cleavage, conchoidal to irregular fracture, brittle. $H = 3$, $VHN_{100} = 130-142$. $G = 6.15$. $R = 29.3-32.3$ (540 nm); moderately anisotropic. *Molly Gibson mine, Aspen, Pitkin Co.*, and *Rico, Dolores Co., CO*; *Neihart, Cascade Co., Flathead mine, Flathead Co.*, and *Drumlummon mine, Marysville, MT*; *Lakeview district, Bonner Co., ID*; *Morrison and Ross mines, Holtyre, ON*, and *Husky mine, YT, Canada*; *Arizpe, SON*, and *Veta Rica mine, Sierra Mojada, COAH*, and *Guanajuato, GTO, Mexico*; *Sark's Hope mine, Channel Is.*; *Clara mine, Black Forest, Germany*; *Francoli, Tarragona Prov., Spain*; *Seikoshi, Shizuoka Pref., Japan*; *Arqueros, Chile*. *BM DI:353, R:729, P&J:306, ABI:393*.

3.1.8.2 Antimonpearcelte $(Ag, Cu)_{16}Sb_2S_{11}$

Named in 1963 as the Sb analog of pearceite. *MON C2/m*. $a = 12.81$, $b = 7.41$, $c = 11.91$, $\beta = 90.0^\circ$, $Z = 2$, $D = 6.40$. *36-392(syn)*: 3.11₇ 2.96₉ 2.83₁₀ 2.49₆ 2.38₅ 2.31₄ 2.18₄ 1.86₅. Pseudohexagonal plates. Black, black streak, sub-metallic luster. No cleavage, conchoidal to irregular fracture, brittle. $H = 3$. $G = 6.34$. *North Lily mine, East Tintic district, UT*; *Guanajuato, GTO, Mexico*; *Clara mine, Black Forest, Germany*; *Sarrabus, Sardinia, Italy*; *Seikoshi mine, Shizuoka Pref., Japan*; *Taltal, Chile*. *BM AM 48:565(1963), CM 8:172(1965), ABI:15*.

3.1.9.1 Petrovicite $Cu_3HgPbBiSe_5$

Named in 1976 for the locality. *ORTH Pnam*. $a = 16.176$, $b = 14.684$, $c = 4.331$, $Z = 4$, $D = 7.76$. *29-567*: 3.62₇ 3.55₈ 3.19₈ 3.12₁₀ 2.96₁₀ 2.72₅ 2.26₅ 2.11₅. Microscopic tabular crystals. Metallic luster. One imperfect cleavage. $H = 3$, $VHN_{25} = 102$. $R = 45.2-46.5$ (540 nm); weakly anisotropic. *Petrovice deposit, Czech Republic*. *BM BM 99:310(1976), AM 62:594(1977), P&J:297, ABI:400*.

3.1.10.1 Benleonardite $Ag_6(Sb, As)Te_2S_3$

Named in 1986 for Benjamin F. Leonard (b.1921), U.S. geologist. *TET* Space group unknown. $a = 6.603$, $c = 12.726$, $Z = 2$, $D = 7.79$. *40-511*: 12.7₇ 3.19₃ 2.94₁₀ 2.86₃ 2.61₄ 2.33₂ 2.16₄ 2.12₂. Microscopic laths and anhedral grains. Black, metallic luster. $H = 3$, $VHN_{25} = 105-125$. $R = 32.2-34.7$ (540 nm); moderately to strongly anisotropic. *Moctezuma mine, Moctezuma, SON, Mexico*; *Rotgulden, Salzburg, Austria*. *BM MM 50:681(1986), AM 73:439(1988), ABI:46, LAP 18(5):18(1993)*.

3.1.11.1 Aschamalmite $Pb_6Bi_2S_9$

Named in 1983 for the locality. *MON C2/m*. $a = 13.71$, $b = 4.09$, $c = 31.43$, $\beta = 91.0^\circ$, $Z = 4$, $D = 7.33$. *35-612*: 3.53₄ 3.43₁₀ 3.38₉ 3.00₄ 2.94₆ 2.93₆ 2.86₅ 2.07₄. Laths up to 5 cm. Lead-gray, lead-gray streak, metallic luster. Cleavage {001}, perfect. $H = 3\frac{1}{2}$, $VHN_{25} = 150-181$. $R = 43.4-46.3$ (546 nm); moderately anisotropic. *Granite Gap, Hidalgo Co., NM*; *Ascham Alm, Untersulz-*

bachtal, Austria; Val Basso, Novara, Italy. BM NJMM:433(1983), AM 69:810(1984), ABI:32.

3.1.12.1 Tsnigriite $\text{Ag}_3\text{SbTe}_3(\text{S, Se})_3$

Named in 1992 from the initials of the Russian name for the Central Scientific-Research Institute of Geological Prospecting in Moscow. *MON P2/m* or *Pm*. $a = 8.89$, $b = 8.292$, $c = 19.50$, $\beta = 97.02^\circ$, $Z = 4$, $D = 7.38$. *ZVMO 121: 4.26₅ 3.78₇ 2.89₄ 2.85₄ 2.29₄ 2.20₁₀ 2.10₄ 2.00₄*. Microscopic anhedral grains, gray. $\text{VHN}_{20} = 125$. $R = 32.2\text{--}36.6$ (546 nm); weak bireflectance, anisotropic in brown and gray. Occurs in the Au–Ag deposit of *Vyskovol'noye, Tian Shan, Uzbekistan*, and in polymetallic ore of Bethumy, Rajasthan, India. *BM ZVMO 121(5):95(1992), AM 79:389(1994)*.

3.2.1.1 Enargite Cu_3AsS_4

Named in 1850 from the Greek for *distinct*, referring to the cleavage. Dimorphous with luzonite. *ORTH Pnm2₁*. $a = 6.431$, $b = 7.402$, $c = 6.149$, $Z = 2$, $D = 4.47$. *35-580(syn): 3.22₄ 3.21₈ 3.07₉ 2.84₈ 1.85₆ 1.73₁₀ 1.59₅ 1.26₄*. Crystals tabular on {001} or prismatic and typically striated parallel to c ; also massive and granular. Twinning common on {320}, sometimes as star-shaped cyclic trillings. Based on hexagonal close-packed S atoms with Cu and As atoms in tetrahedral coordination. Gray-black to iron-black, black streak, metallic luster. Cleavage {110}, perfect; {100}, {010}, distinct; uneven fracture; brittle. $H = 3$. $G = 4.4\text{--}4.5$. Striated crystals and cleavage are distinctive. Soluble in aqua regia. May contain up to 6% Sb and 3% Fe. $R = 25.0\text{--}26.4$ (540 nm); strongly anisotropic in violet-red and olive-green tones. In vein and replacement deposits, apparently formed at moderate temperatures, in some places in

ENARGITE: Cu_3AsS_4

The enargite structure is derived from that of wurzite by replacing one-fourth of the Zn atoms with As and three-fourths with Cu.

sufficient quantity to be an important copper ore. Butte(*), MT; Red Mountain district(*), Ouray and San Juan Cos., CO; Tintic, UT; Magma mine, Superior, AZ; Alghero and Calabona, Sardinia, Italy; Matzenkopfl, Brixlegg, Austria; Bor, Serbia; Chinkuashi mine, Keelung, Taiwan; Mancayan, Luzon, Philippines; Tsumeb, Namibia; Mina Luz Angelica, Quiruvilca(*), Morococha(*), and Cerro de Pasco(*), Peru; Sierra de Famatina, La Rioja Prov., Argentina. *BM DI:389, MD 4:72(1969), R:583, P&J:155, ABI:147.*

3.2.2.1 Luzonite Cu_3AsS_4

Named in 1874 for the locality. Dimorphous with enargite; forms a series with famatinite (3.2.2.2). *TET I42m. a = 5.290, c = 10.465, Z = 2, D = 4.47. 10-450 (syn): 3.05₁₀ 1.86₉ 1.59₇ 1.58₆ 1.32₅ 1.20₆ 1.08₆ 1.07₅.* Small equant crystals twinned on {112}, usually massive, granular. Deep pink-brown, black streak, metallic luster. Cleavage {101}, good; {100}, distinct; conchoidal to uneven fracture; brittle. $H = 3\frac{1}{2}$. $G = 4.4-4.6$. $R = 24.4-27.0$ (540 nm); strongly anisotropic. Butte, MT; Summitville, Rio Grande Co., CO; Goldfield, Esmeralda Co., NV; Bisbee, AZ; Calabona, Sardinia, Italy; Chelopech, Bulgaria; Kadzharan Cu-Mo deposit, Armenia; Teine mine, Hokkaido, Kasuga and Akeshi mines, Kagoshima Pref., and other localities in Japan; Chinkuashi mine(*), Keelung, Taiwan; *Mancayan, Luzon, Philippines*; Cerro de Pasco and Huaron, Peru; *Sierra de Famatina, La Rioja Prov., Argentina. BM AM 42:766(1957), MD 4:72(1969), R:588, P&J:246, ABI:304.*

3.2.2.2 Famatinite Cu_3SbS_4

Named in 1873 for the locality. Forms a series with luzonite (3.2.2.1). *TET I42m. a = 5.385, c = 10.748, Z = 2, D = 4.70. 35-581 (syn): 3.11₁₀ 2.69₂ 1.90₇ 1.62₄ 1.35₁ 1.23₂ 1.20₁ 1.10₃.* Massive, granular, or reniform. Deep pink-brown, black streak, dull metallic luster. Cleavage {101}, good; {100}, distinct; conchoidal to uneven fracture; brittle. $H = 3\frac{1}{2}$. $G = 4.5-4.7$. $R = 23.8-25.0$ (540 nm); strongly anisotropic. Butte, MT; Red Mountain, Ouray Co., CO; Campbell mine, Bisbee, Magma mine, Superior, and Tombstone, AZ; Goldfield, Esmeralda Co., NV; Darwin, Inyo Co., CA; Cananea, SON, Mexico; Calabona, Sardinia, Italy; Hokuetsu, Japan; Chinkuashi mine(*), Keelung, Taiwan; Isk Amellal, Morocco; Cerro de Pasco and Morococha, Peru; *Sierra de Famatina, La Rioja, Argentina. BM DI:387, AM 42:766(1957), R:588, P&J:160, ABI:153.*

3.2.2.3 Permingeatite Cu_3SbSe_4

Named in 1971 for François Permingeat (1917-1988), French mineralogist. *TET I42m. a = 5.63, c = 11.23, Z = 2, D = 5.86. 25-263: 5.04₄ 3.25₁₀ 1.99₉ 1.70₈ 1.41₅ 1.29₆ 1.15₇ 1.08₅.* Microscopic grains. Brown, metallic luster. $H = 4-4\frac{1}{2}$, $VHN_{50} = 234$. $R = 26.2-26.3$ (540 nm); strongly anisotropic. *Predborice, Czech Republic. BM BM 94:162(1971), AM 57:1554(1972), R:592, P&J:295, ABI:398.*

3.2.3.1 Sulvanite Cu_3VS_4

Named in 1900 for the composition. Forms a series with arsenosulvanite (3.2.3.2). iso $P43m$. $a = 5.393$, $Z = 1$, $D = 3.91$. $11-104$: 5.4_{10} 3.12_5 2.40_4 1.91_8 1.80_3 1.63_4 1.35_3 1.10_4 . Cubes to 2.5 cm; usually massive. Gray, sometimes with a bronze tint, black streak, metallic luster. Perfect cubic cleavage. $H = 3\frac{1}{2}$. $\text{VHN}_{100} = 135-157$. $G = 3.9-4.0$. $R = 31.0$ (540 nm). Thorpe Hills and near Mercur, UT; Ponte Castiola, Corsica, France; near Carrara, Italy; Bor, Serbia; Pay-Khoy, northern Ural Mts., Russia; Karatau Mts., Kazakhstan; *Edelweiss mine*, south of *Burra*, SA, Australia; Kipushi, Shaba, Zaire; Tsumeb, Namibia. BM *DI:384*, *R:576*, *P&J:358*, *ABI:508*.

3.2.3.2 Arsenosulvanite $\text{Cu}_3(\text{As}, \text{V})\text{S}_4$

Named in 1941 for its relationship to sulvanite (3.2.3.1), with which it forms a series. iso $P43m$. $a = 5.271$, $Z = 1$, $D = 4.33$. $25-265$: 3.04_{10} 2.77_{10} 1.87_{10} 1.67_1 1.59_5 1.32_1 1.26_1 1.08_3 . Microscopic grains. Bronze-yellow, metallic luster. $H = 3\frac{1}{2}$. $G = 4.0-4.2$. $R = 31.7$ (540 nm). Bisbee, AZ; Bor, Serbia; Kapan deposit, Armenia; Osarizawa mine, Akita Pref., Japan. BM *ZVMO 70:161(1941)*; *AM 40:368(1955)*, *46:465(1961)*, *79:750(1994)*.

3.2.4.1 Stephanite Ag_5SbS_4

Named in 1845 for Archduke Victor Stephan (1817-1867), former mining director of Austria. ORTH $Cmc2_1$. $a = 7.793$, $b = 12.295$, $c = 8.506$, $Z = 4$, $D = 6.43$. $11-108$: 3.56_3 3.08_{10} 2.89_6 2.78_3 2.58_9 2.19_4 2.13_5 1.83_4 . Short prismatic to tabular crystals; also massive. Iron-black, iron-black streak, metallic luster. Cleavage {010} and {021}, imperfect; subconchoidal to uneven fracture; brittle. Crystals twinned on {110}, often repeated to form pseudohexagonal groups. $H = 2-2\frac{1}{2}$. $G = 6.2-6.5$. $R = 27.6-29.0$ (540 nm); strongly anisotropic. Widely distributed as a late-stage mineral in hydrothermal silver deposits. Comstock Lode, NV; Cobalt, ON, and United Keno Hill mines, YT, Canada; Arizpe(*), SON, Fresnillo(*), ZAC, and Guanajuato, GTO, Mexico; Wheal Boys, Endellion, Cornwall, England; Espedalen, Norway; Andreasberg(*), Harz, and *Freiberg*(*), Schneeberg, and Marienberg, Saxony, Germany; Příbram(*), Hodrusa, and Jachymov(*), Czech Republic; Sarrabus(*), Sardinia, Italy; Lengenbach, Binn, Switzerland; Ozernoe deposit, Transbaikal, Russia; Altyn-Topkan, Tadjikstan; Broken Hill, NSW, Australia; Azegour, Morocco; San Cristobal, Peru; Colquechaca(*), Bolivia; Chanarcillo, Atacama, Chile. BM *DI:358*, *R:727*, *P&J:351*, *ABI:493*.

3.2.4.2 Selenostephanite Ag_5SbSe_4

Named in 1985 as the Se analog of stephanite. ORTH $P2_12_12_1$. $a = 7.86$, $b = 11.84$, $c = 8.92$, $Z = 4$, $D = 7.82$. $39-334$: 3.45_6 2.96_{10} 2.64_9 2.52_7 2.28_9 2.23_9 1.92_9 1.89_9 . Microscopic laths. Gray, metallic luster. $H = 3$, $\text{VHN}_{20} = 95-116$. $R = 32.6-34.8$ (580 nm); moderately anisotropic. *Chukotskiy*, Siberia, Russia. BM *ZVMO 114:627(1985)*, *AM 72:225(1987)*, *ABI:469*.

HAUCHECORNITE GROUP

The hauchecornite group minerals are complex nickel sulfides with general formula

where

B = As, Sb, Bi, Te

and the structure is tetragonal, $P4/mmm$. The structure consists of double Ni-S ribbons linked by Bi-Ni chains, all parallel to [001].

HAUCHECORNITE GROUP

Mineral	Formula	Space Group	a	c	D	
Hauchecornite	$\text{Ni}_9\text{BiSbS}_8$	$P4/mmm$	7.29	5.40	6.58	3.2.5.1
Bismutohauchecornite	$\text{Ni}_9\text{Bi}_2\text{S}_8$	$P4/mmm$	7.37	5.88	6.25	3.2.5.2
Tellurohauchecornite	$\text{Ni}_9\text{BiTeS}_8$	$P4/mmm$	14.64	10.87	6.50	3.2.5.3
Arsenohauchecornite	$\text{Ni}_{18}\text{Bi}_3\text{AsS}_{16}$	$I4/mmm$	10.271	10.807	6.52	3.2.5.4
Tucekite	$\text{Ni}_9\text{Sb}_2\text{S}_8$	$P4/mmm$	7.174	5.402	6.14	3.2.5.5

HAUCHECORNITE: $\text{Ni}_9\text{BiSbS}_8$

3.2.5.1 Hauchecornite $\text{Ni}_9\text{BiSbS}_8$

Named in 1893 for William Hauchecorn (1828–1900), German geologist. Hauchecornite group. $TET P4/mmm$. $a = 7.29$, $c = 5.40$, $Z = 1$, $D = 6.58$. $6-457$: 4.35_5 3.65_4 3.26_4 2.80_{10} 2.39_6 2.30_6 1.87_5 1.82_3 . Small tabular and prismatic crystals. Pale bronze-yellow, gray-black streak, metallic luster. No cleavage,

conchoidal fracture. $H = 5$, $VHN_{50} = 447\text{--}655$. $G = 6.4\text{--}6.5$. $R = 45.2\text{--}48.2$ (540 nm); distinctly anisotropic. Zimmer Lake, SK, Canada; *Friedrich mine, Hamm, Westphalia, Germany*; Talnakh, Norilsk, Russia. BM AM 35:440(1950), R:403, P&J:193, ABI:206.

3.2.5.2 Bismutohauchecornite $Ni_9Bi_2S_8$

Named in 1980 as the Bi analog of hauchecornite. Hauchecornite group. TET $P4/mmm$. $a = 7.37$, $c = 5.88$, $Z = 1$, $D = 6.25$. Tabular crystals, also massive. Bronze-yellow, metallic luster. $VHN = 360\text{--}392$. Weakly anisotropic. Near Zimmer Lake, SK, Canada; *Oktyabr mine, Norilsk, Russia*; Mihara mine, Okayama Pref., and Tsumo mine, Shimane Pref., Japan. BM MM 43:873(1980), AM 66:436(1981), ABI:57.

3.2.5.3 Tellurohauchecornite Ni_9BiTeS_8

Named in 1980 as the Te analog of hauchecornite. Hauchecornite group. TET $P4/mmm$. $a = 14.64$, $c = 10.87$, $Z = 8$, $D = 6.50$. 34-566: 5.2₃ 4.35₄ 3.66₄ 3.28₄ 2.80₁₀ 2.41₅ 2.31₆ 1.87₄. Microscopic grains. Bronze-yellow, metallic luster. $VHN_{50} = 812\text{--}825$. $R = 43.9\text{--}47.7$ (546 nm). *Strathcona mine, Sudbury, ON, Canada*. BM MM 43:877(1980), AM 66:436(1981), ABI:518.

3.2.5.4 Arsenohauchecornite $Ni_{18}Bi_3AsS_{16}$

Named in 1980 as the As analog of hauchecornite. Hauchecornite group. TET $I4/mmm$. $a = 10.271$, $c = 10.807$, $Z = 2$, $D = 6.52$. 38-346: 4.33₇ 3.63₇ 3.24₇ 2.77₁₀ 2.38₉ 2.28₈ 1.85₈ 1.81₇. Small tabular crystals, also massive. Bronze, gray-black streak, metallic luster. No cleavage, conchoidal fracture. $H = 5\frac{1}{2}$, $VHN_{50} = 516\text{--}655$. $G = 6.35$. $R = 46.2\text{--}47.1$ (546 nm). *Vermilion mine, Sudbury, ON, Canada*; Karagaily, Kazakhstan; Tsumo mine, Shimane Pref., Japan. BM MM 43:877(1980), AM 66:436(1981), CM 27:137(1989), ABI:25.

3.2.5.5 Tučekite $Ni_9Sb_2S_8$

Named in 1978 for Karel Tuček (1906–1990), Czech mineralogist. Hauchecornite group. TET $P4/mmm$. $a = 7.174$, $c = 5.402$, $Z = 1$, $D = 6.14$. 29-927: 4.33₇ 3.58₅ 3.21₆ 2.76₁₀ 2.38₈ 2.28₈ 1.85₈ 1.79₇. Microscopic grains. Pale brass-yellow, metallic luster. No cleavage, conchoidal fracture, brittle. $H = 5\text{--}6$, $VHN_{20} = 718$. $R = 45.4\text{--}48.0$ (540 nm); strongly anisotropic. Rocheservieres, Vendee, France; Vozhmin massif, Karelia, Russia; *Kanowna and Whim Creek, WA, Australia*; Witwatersrand, South Africa. BM MM 42:278(1978), AM 64:465(1979), ABI:541.

3.2.6.1 Arcubisite Ag_6CuBiS_4

Named in 1976 for the composition. Microscopic grains; gray, metallic luster. $R = 32.1\text{--}33.7$ (540 nm); distinctly anisotropic. *Ivigut, Greenland*. BM LIT 9:253(1976), AM 63:424(1978), ABI:18.

3.2.7.1 Chalcocallite (Cu,Fe)₆Tl₂SbS₄

Named in 1967 for the composition. TET $I4/mmm$. $a = 3.827$, $c = 34.280$, $Z = 2$, $D = 6.74$. d_{2-557} : 3.80_7 3.63_5 3.02_7 2.70_5 2.58_5 2.45_{10} 1.91_{10} 1.62_5 . Lamellar aggregates to 2 cm. Lead-gray to iron-black, iridescent tarnish, black streak, metallic luster. Cleavage {001}, perfect; {100}, {010}, indistinct. $H = 2-2\frac{1}{2}$, $VHN_{50} = 68-76$. $G = 6.6$. $R = 25.4-29.1$ (540 nm); distinctly anisotropic. Near *Taseq Lake, Ilimaussaq Intrusion, Greenland*. BM *AM 53:1775(1968)*, *NJMA 138:122(1980)*, *P&J:402*, *ABI:91*.

3.2.8.1 Chameanite (Cu,Fe)₄AsSe₄

Named in 1982 for the locality. Possibly identical with mgriite (3.4.7.2). ISO $I4mmm$. $a = 11.039$, $Z = 8$, $D = 6.17$. d_{35-524} : 3.19_{10} 1.95_9 1.67_8 1.38_4 1.27_6 1.13_7 1.06_5 0.975_3 . Microscopic grains. Gray, metallic luster. $H = 4$, $VHN_{25} = 247-292$. $R = 27.1$ (540 nm). *Chameane, Puy-de-Dome, France*. BM *TMPM 29:151(1982)*, *AM 67:1074(1982)*, *P&J:403*, *ABI:92*.

3.2.9.1 Fangite Tl₃AsS₄

Named in 1993 for Jen-Ho Fang (b.1929), U.S. crystal chemist. ORTH $Pnma$. $a = 8.894$, $b = 10.855$, $c = 9.079$, $Z = 4$, $D = 6.185$. *AM 78: 3.98_6* 3.36_7 3.24_5 2.81_5 2.71_9 2.68_5 2.54_{10} 2.27_6 . Subhedral to anhedral grains to 1 mm. Deep red to maroon, orange streak; vitreous to submetallic luster. $H = 2-2\frac{1}{2}$, $VHN_{100} = 61$. $G_{syn} = 6.20$. $R = 24$ (546 nm). BM *Mercur deposit, Tooele Co., UT*; Allchar, Macedonia. *AM 78:1096(1993)*.

3.3.1.1 Jordanite Pb₁₄As₆S₂₃

Named in 1864 for H. Jordan (1808-1887), German doctor, who provided the original material. MON $P2_1/m$. $a = 8.92$, $b = 31.88$, $c = 8.457$, $\beta = 117.7^\circ$, $Z = 2$, $D = 6.38$. d_{21-466} : 3.70_6 3.53_7 3.50_4 3.37_5 3.18_{10} 3.06_5 3.05_6 2.88_5 . Tabular pseudo-hexagonal crystals to 4 cm, commonly twinned on {001}; also massive. Lead-gray, iridescent tarnish, black streak, metallic luster. Cleavage {010}, perfect; {001} parting; conchoidal fracture; brittle. $H = 3$, $VHN_{50} = 106-141$. $G = 6.4$. $R = 38.6-42.2$ (540 nm). Edwards mine, Balmat, NY; Keystone mine, Birmingham, PA; Zuni mine, near Silverton, CO; Penberthy Croft mine, St. Hilary, Cornwall, England; Sala, Sweden; Wiesloch, near Heidelberg, Germany; *Lengenbach, Binn, Switzerland*; Beuthen, Upper Silesia, Poland; Horni Benesov, Czech Republic; Carrara, Italy; Sacaramb, Romania; Yunosawa and Okoppe mines, Aomori Pref., Japan; Sidi Bou Aouane and Djebel Hallouf, Tunisia. BM *DI:398*, *R:754*, *P&J:218*, *ABI:250*.

3.3.1.2 Geocronite Pb₁₄(Sb,As)₆S₂₃

Named in 1839 from the Greek for *Earth* and *Saturn*, the alchemical names for antimony and lead. MON $P2_1/m$. $a = 8.96$, $b = 31.85$, $c = 8.48$, $\beta = 118.0^\circ$, $Z = 2$, $D = 6.56$. d_{30-691} : 3.71_6 3.54_{10} 3.39_8 3.19_9 3.06_{10} 2.99_7 2.89_{10} 2.24_6 . Crystals rare, usually massive, granular. Lead-gray, lead-gray streak, metallic

luster. Cleavage {011}, distinct; uneven fracture. $H = 2\frac{1}{2}$, $VHN_{100} = 144-160$. $G = 6.3-6.5$. $R = 38.8-40.1$ (540 nm); distinctly anisotropic. Inexco mine, Jamestown, CO; Park City and Tintic, UT; Darwin, Inyo Co., CA; Hemlo deposit, Thunder Bay, ON, Canada; Noche Buena, ZAC, Mexico; Kilbricken mine, Co. Clare, Eire; Treore mine, St. Treath, Cornwall, England; *Sala*, Sweden; Bayerland mine, Oberpfalz, Germany; Pietrasanta, Tuscany, and Salafossa, Tyrol, Italy; Uzunzhai, Kazakhstan; Smirnovsk, Transbaikal, Russia; Rajpura, Rajasthan, India; Huachocolpa, Peru; Xanda mine(*), Virgem de Lapa, MG, Brazil. *BM DI:395, AM 61:963(1976), R:774, P&J:175.*

3.3.2.1 Gratonite $Pb_9As_4S_{15}$

Named in 1939 for Louis C. Graton (1880-1970), U.S. economic geologist. *HEX-R R3m*. $a = 17.701$, $c = 7.792$, $Z = 3$, $D = 6.23$. *13-446: 5.45₂ 3.78₆ 3.72₆ 3.43₁₀ 2.85₄ 2.73₅ 2.05₃ 1.75₃*. Hexagonal prisms to 15 mm, also massive. Dark lead-gray, black streak, metallic luster. No cleavage, brittle. $H = 2\frac{1}{2}$, $VHN_{100} = 130-146$. $G = 6.22$. $R = 34.2-34.8$ (540 nm). Pinal del Rio, Cuba; Wiesloch, near Heidelberg, Germany; Blei-Scharley mine, Upper Silesia, Poland; Rio Tinto, Spain; Zvezdel, Bulgaria; *Excelsior mine(*)*, Cerro de Pasco, Peru. *BM DI:397, R:757, P&J:186, ABI:193.*

3.3.3.1 Heyrovskyite $Pb_{10}AgBi_5S_{18}$

Named in 1971 for Jaroslav Heyrovsky (1890-1967), Czech chemist. *ORTH Cmcm*. $a = 4.110$, $b = 13.600$, $c = 30.485$, $Z = 2$, $D = 7.11$. *25-1404(syn): 3.75₂ 3.54₃ 3.41₁₀ 3.35₃ 2.94₃ 2.85₃ 2.18₂ 2.09₄*. Acicular to prismatic crystals, to 20 mm. Tin-white, gray-black streak, metallic luster. Cleavage {001}, poor; conchoidal fracture; brittle. $H = 3\frac{1}{2}-4$, $VHN_{50} = 166-234$. $G = 7.17$. $R = 40.6-44.6$ (540 nm); strongly anisotropic. Idarado mine, Ouray Co., CO; near Austin, Lander Co., NV; near Castlegar, BC, Canada; Clara mine, Black Forest, Germany; Rauris Goldberg, Salzburg, Austria; Furka Pass and Goppenstein, Switzerland; near Hurky, Czech Republic; Balikesir Balya deposit, Turkey; Spokoinoe and Shumilovsk deposits, Transbaikal, Russia; Juno mine, Tennant Creek, NT, Australia. *BM MD 6:133(1971), R:781, NJMA 127:62(1976), ABI:219, CM 29:553(1991).*

3.3.4.1 Nuffieldite $Pb_2Cu(Pb,Bi)Bi_2S_7$

Named in 1968 for Edward W. Nuffield (b.1914), Canadian mineralogist. *ORTH Pbnm*. $a = 4.61$, $b = 21.38$, $c = 4.03$, $Z = 4$, $D = 7.04$. *19-675: 4.00₉ 3.66₁₀ 3.54₁₀ 3.16₈ 2.87₃ 2.54₇ 1.87₆ 1.35₄*. Small prismatic to acicular crystals. Lead-gray, gray-black streak, metallic luster. Cleavage {001}, perfect; uneven fracture; very brittle. $H = 3\frac{1}{2}$, $VHN = 149-178$. $G = 7.01$. $R = 39.0-43.1$ (546 nm). *Lime Creek stock, Alice Arm, BC, Canada*; Les Houches, Haute-Savoie, France; Maleevskoe, Rudny Altai, Russia; Akchatau, Kazakhstan. *BM CM 9:439(1968), 32:359(1994); ABI:358.*

3.3.5.1 Meneghinite $Pb_{13}CuSb_7S_{24}$

Named in 1852 for Giuseppe Meneghini (1811–1889), Italian mineralogist. ORTH $Pn2_1m$. $a = 11.343$, $b = 24.028$, $c = 4.126$, $Z = 1$, $D = 6.47$. 29-559: 4.13₅ 3.74₈ 3.49₆ 3.27₁₀ 3.08₃ 2.92₉ 2.77₃ 2.74₄. Slender prismatic crystals, also massive, fibrous to compact. Dark lead-gray, black streak, metallic luster. Cleavage {010}, perfect; conchoidal fracture; brittle. $H = 2\frac{1}{2}$. $G = 6.36$. $R = 40.0-46.0$ (540 nm); strongly anisotropic. Kalkar quarry, Santa Cruz Co., CA; Marble Lake, Barrie Twp., ON, and Bluebird–Mayflower mine, Trail Creek, BC, Canada; Pengenna mine, St. Kew, Cornwall, and Shallowford Bridge, near South Moulton, Devon, England; Vallon de Merlier, Alpes-Maritimes, and Longerey, Savoie, France; Hallefors, Sweden; Aijala, Finland; Ochsenkopf, Saxony, and Goldkronach, Bavaria, Germany; *Bottino mine, near Seravezza, Italy*; Saki and Gouskhalat, Iran; Pundung, Korea; Pingtoushan, Kiangsi, China; Broken Hill, NSW, Australia. VM *DI:402*, *R:772*, *P&J:266*, *ABI:322*.

TETRAHEDRITE GROUP

The tetrahedrite group is made up of isometric sulfides, selenides, and tellurides with the general formula

where

A = Cu, Ag, Fe, Hg, Zn

B = As, Sb, Te

X = S, Se

and the structure is cubic, space group $I43m$. The structure is closely related to that of sphalerite.

Tetrahedrite Group

Mineral	Formula	Space Group	a	D	
Tetrahedrite	$(Cu,Fe)_{12}Sb_4S_{13}$	$I43m$	10.327	5.07	3.3.6.1
Tennantite	$(Cu,Fe)_{12}As_4S_{13}$	$I43m$	10.186	4.61	3.3.6.2
Freibergite	$(Ag,Cu,Fe)_{12}Sb_4S_{13}$	$I43m$	10.554	5.22	3.3.6.3
Hakite	$(Cu,Hg)_{12}Sb_4S_{13}$	$I43m$	10.88	6.30	3.3.6.4
Giraudite	$(Cu,Zn)_{12}Sb_4S_{13}$	$I43m$	10.578	5.75	3.3.6.5
Goldfieldite	$Cu_{12}(Te,As)_4S_{13}$	$I43m$	10.304	4.95	3.3.6.6
Argentotennantite	$(Ag,Cu)_{12}(As,Sb)_4S_{13}$	$I43m$	10.584	5.05	3.3.6.7

3.3.6.1 Tetrahedrite $(Cu,Fe)_{12}Sb_4S_{13}$

Named in 1845 for its crystal form. Tetrahedrite group. Forms a series with tennantite and freibergite. ISO $I43m$. $a = 10.327$, $Z = 2$, $D = 5.07$. 24-

TETRAHEDRITE: $\text{Cu}_{12}\text{Sb}_4\text{S}_{13}$

Tetrahedrite has basically the sphalerite arrangement, with one-fourth of the Cu replaced by Sb. However, one-fourth of the sulfurs are missing from their normal positions, and there are a smaller number of interstitial sulfurs in the Cu-Sb layer—these are at the corners and center of the cell in this view.

1318(syn): 3.65_2 2.98_{10} 2.76_1 2.58_3 2.43_1 2.03_1 1.83_4 1.56_3 . **Habit:** Crystals uncommon, typically tetrahedral; usually massive, granular to compact. Contact and penetration twins on {111}. **Structure:** Based on cubic close-packed S atoms with Cu and Fe in octahedral coordination and Sb in tetrahedral coordination. **Physical properties:** Gray to black, brown to black streak, metallic luster. No cleavage, subconchoidal to uneven fracture. $H = 3-4$, $\text{VHN}_{100} = 312-351$. $G = 4.6-5.1$. **Tests:** Decomposed by HNO_3 with the separation of sulfur. Crystal form and lack of cleavage typical. **Chemistry:** Forms a series with tennantite and with the Ag analog freibergite. May contain up to 8% Zn, 2% Cd, 17% Hg, and 4% Bi. **Optics:** Isotropic; $N > 2.72$. $R = 32.8$ (540 nm). **Occurrence:** Widely distributed in hydrothermal veins and contact-metamorphic deposits; probably the commonest sulfosalt mineral. **Localities:** Only the most significant are given. Butte(*), MT; Park City(*), UT; Tombstone, Globe, and other localities, AZ; Naica(*), CHIH, Noche Buena and Concepcion del Oro, ZAC, Mexico; Herodsfoot mine, Cornwall, England; Allevard(*), Isere, and Irazain, Ariège, France; Dillenberg(*), Hesse, and Freiberg, Saxony, Germany; near Brixlegg(*), Tyrol, Austria; Cavnic(*) and Botes, Romania; Tenes and Mouzaia, Algeria; Mt. Isa, Q, Broken Hill, NSW, and Renison Bell, TAS, Australia; Mercedes mine(*), Huanoco, and Casapalca, Junin, Peru; Oruro, Bolivia; El Teniente mine(*), near Santiago, Chile. **Uses:** An important copper ore, and may carry significant silver values. BM *DI:374*, *R:562*, *P&J:139*, *AM 73:389*(1988), *ABI:526*.

3.3.6.2 Tennantite (Cu,Fe)₁₂As₄S₁₃

Named in 1819 for Smithson Tennant (1761–1815), English chemist. Tetrahedrite group. Forms a series with tetrahedrite; may contain minor amounts of Zn, Ag, Hg, and Bi. iso *I43m*. $a = 10.186$, $Z = 2$, $D = 4.61$. *11-102*: 2.94₁₀ 2.55₃ 2.40₂ 1.80₈ 1.54₅ 1.27₂ 1.17₃ 1.04₃. Cubic and tetrahedral crystals; also massive, granular to compact. Contact and penetration twins on {111}. Black, black streak, metallic luster. No cleavage, subconchoidal to uneven fracture, brittle. $H = 4$, $VHN_{100} = 294-380$. $G = 4.6-4.7$. $R = 28.5$ (540 nm). Widely distributed in hydrothermal veins and contact-metamorphic deposits. Butte, MT; Freeland mine(*), Clear Creek Co., Central City district, Aspen, and other localities, CO; Globe–Miami district, Cerbat Mts., and other localities, AZ; El Cobre(*), El Bote(!), and Concepcion del Oro, ZAC, Mexico; Redruth–Camborne district, Cornwall, England; Freiberg, Saxony, Germany; Lengenbach(*), Binn, Switzerland; Dzhezkazgan(*), Kazakhstan; Tsumeb(*), Namibia; Morococha and Quiruvilca, Peru; Rancagua(*), Chile. *BM DI:374*, *R:563*, *P&J:139*, *ABI:521*.

3.3.6.3 Freibergite (Ag,Cu,Fe)₁₂Sb₄S₁₃

Named in 1853 for the locality. Tetrahedrite group. Forms a series with tetrahedrite. iso *I43m*. $a = 10.554$, $Z = 2$, $D = 5.22$. *27-190*(syn): 3.73₄ 3.05₁₀ 2.64₅ 2.07₄ 1.86₇ 1.71₄ 1.59₅ 1.08₄. Tetrahedral crystals and massive. Gray to black, black streak, metallic luster. No cleavage. $H = 4$, $VHN_{100} = 263-340$. $R = 32.6$ (540 nm). An important source of silver. Hi-Ho mine, Cobalt, ON, and Keno Hill area, YT, Canada; Tyndrum, Perthshire, Scotland; Sladekarr and Vena, Sweden; Espedalen, Norway; *Freiberg, Saxony, Germany*; Kutna Hora, Czech Republic; Knappenstube mine, Salzburg, Austria; Vratsa region, Bulgaria; Yukhondzha, Yakutia, Russia; Inakuraishi, Koryu, and Sanyu mines, Hokkaido, Japan; Mt. Isa, Q, Australia. *BM DI:374*, *MD 9:117(1974)*, *MM 50:717(1986)*, *ABI:162*.

3.3.6.4 Hakite (Cu,Hg)₁₂Sb₄Se₁₃

Named in 1971 for Jaroslav Hak (b.1931), Czech mineralogist. Tetrahedrite group. iso *I43m*. $a = 10.88$, $Z = 2$, $D = 6.30$. *25-297*: 3.14₁₀ 2.91₇ 2.57₆ 2.13₅ 1.99₇ 1.93₉ 1.76₆ 1.64₈. Microscopic anhedral grains. Gray-brown, metallic luster. $H = 4\frac{1}{2}$, $VHN_{40} = 306$. $R = 33.4$ (540 nm). Moctezuma, SON, Mexico; *Predborice* and *Bukov, Czech Republic*. *BM BM 94:45(1971)*, *AM 57:533(1972)*, *R:571*, *P&J:190*, *ABI:202*.

3.3.6.5 Giraudite (Cu,Zn)₁₂Sb₄Se₁₃

Named in 1982 for Roger Giraud (b.1936), French microprobe expert. Tetrahedrite group. iso *I43m*. $a = 10.578$, $Z = 2$, $D = 5.75$. *35-525*: 3.05₁₀ 2.83₃ 2.50₅ 2.08₄ 1.93₆ 1.87₉ 1.71₄ 1.59₇. Microscopic anhedral grains. Pale gray, metallic luster. $VHN_{25} = 233-333$. $R = 31.7$ (540 nm). *Chameane, Puy-de-Dome, France*. *BM TMPM 29:151(1982)*, *AM 67:1074(1982)*, *P&J:404*, *ABI:185*.

3.3.6.6 Goldfieldite $\text{Cu}_{12}(\text{Te,As})_4\text{S}_{13}$

Named in 1909 for the locality. Tetrahedrite group. iso $I43m$. $a = 10.304$, $Z = 2$, $D = 4.95$. $29-531$: 5.15_1 3.64_3 2.97_{10} 2.77_1 2.58_2 2.43_2 1.82_6 1.55_3 . Massive crusts. Lead-gray to iron-black, black streak, metallic luster. No cleavage. $H = 3-3\frac{1}{2}$, $\text{VHN}_{100} = 291-342$. $R = 30.1$ (540 nm). Butte, MT; Lucky Cuss mine, Tombstone, and Bisbee, AZ; *Mohawk mine* and Claremont mine, *Goldfield, NV*; Kuramin Mts., Uzbekistan; Kawazu mine, Shizuoka Pref., Japan. BM *DI:384, R:571, ABI:190*.

3.3.6.7 Argentotennantite $(\text{Ag,Cu})_{12}(\text{As,Sb})_4\text{S}_{13}$

Named in 1986 as the Ag analog of tennantite. Tetrahedrite group. iso $I43m$. $a = 10.584$, $Z = 2$, $D = 5.05$. *DANS 290*: 3.06_{10} 2.65_3 2.07_2 1.87_8 1.60_4 1.23_2 1.21_2 1.08_2 . Microscopic grains. Gray-black, red-brown to black streak, resinous luster. Conchoidal fracture. $H = 3\frac{1}{2}$, $\text{VHN} = 285-320$. $R = 30.4$ (540 nm). *Kvartsitoviye Gorky deposit, Kazakhstan*. BM *DANS 290:206(1986), AM 73:439(1988), ABI:22*.

3.3.7.1 Lengenbachite $\text{Pb}_{37}\text{Ag}_7\text{Cu}_6\text{As}_{23}\text{S}_{78}$

Named in 1905 for the locality. TRIC $P1$ or $P1$. $a = 36.92$, $b = 11.51$, $c = 70.20$, $\alpha = \gamma = 90.0^\circ$, $\beta = 92.58^\circ$, $Z = 2$, $D = 5.78$. $14-418$: 9.31_1 7.69_1 6.28_1 4.60_3 3.06_{10} 2.93_2 2.84_9 2.04_2 . Thin blades to 4 cm. Lead-gray to gray-black, frequently with blue tarnish, black streak, metallic luster. Cleavage $\{100\}$, perfect; flexible; inelastic. $H = 1\frac{1}{2}-2$, $\text{VHN} = 35$. $G = 5.80-5.85$. $R = 35.9-37.4$ (540 nm); weakly anisotropic. *Lengenbach, Binn, Switzerland*. BM *DI:398, R:754, ABI:294, NJMA 166:169(1994)*.

3.4.1.1 Proustite Ag_3AsS_3

Named in 1832 for Joseph L. Proust (1754-1826), French chemist. Dimorphous with xanthoconite (3.4.2.1). HEX-R $R3c$. $a = 10.79$, $c = 8.69$, $Z = 6$, $D = 5.63$. $11-470(\text{syn})$: 5.4_4 3.27_8 3.17_7 3.11_7 2.74_{10} 2.55_8 2.48_9 2.22_4 . Pyramidal, rhombohedral, and scalenohedral crystals, commonly twinned on $\{1014\}$ and $\{10\bar{1}1\}$; also massive, compact. Scarlet-red, darkening on exposure to light, vermilion streak, adamantine luster. Cleavage $\{10\bar{1}1\}$, distinct; conchoidal to uneven fracture; brittle. $H = 2-2\frac{1}{2}$, $\text{VHN}_{25} = 70-105$. $G = 5.6$. $R = 30.0-32.3$ (540 nm); strongly anisotropic. Widely distributed, occasionally an important silver ore. Georgetown and Red Mountain district, CO; Poorman mine, Owyhee Co., ID; Keeley mine(*), Cobalt, ON, Canada; Batopilas(*), CHIH, and Sombrerete, ZAC, Mexico; Ste.-Marie-aux-Mines(*), Haut-Rhin, France; Freiberg(*) and Niederschelma(*), Saxony, Germany; Lengenbach, Binn, Switzerland; Sarrabus(*), Sardinia, Italy; Jachymov(*) and Příbram, Czech Republic; Sacaramb, Romania; Nishizawa mine, Japan; Broken Hill(*), NSW, Australia; Chanarcillo(*), Atacama, Chile. BM *DI:366, R:783, P&J:309, ABI:423*.

PYRARGYRITE: Ag_3SbS_3

3.4.1.2 Pyrargyrite Ag_3SbS_3

Named in 1831 from the Greek for *fire* and *silver*, referring to its color and composition. Dimorphous with pyrostilpnite (3.4.2.2). **HEX-R** $R\bar{3}c$. $a = 11.047$, $c = 8.719$, $Z = 6$, $D = 5.86$. $d_{1-1173}(\text{syn})$: 3.34_6 3.22_7 3.19_6 2.78_{10} 2.57_6 2.54_6 2.27_{22} 1.96_3 . Prismatic and scalenohedral crystals; often twinned on $\{10\bar{1}4\}$ and $\{1011\}$; also massive, compact. Deep red, darkening on exposure to light, red streak, adamantine luster. Cleavage $\{1011\}$, distinct; conchoidal to uneven fracture; brittle. $H = 2\frac{1}{2}$. $G = 5.8-5.9$. $R = 28.2-34.0$ (540 nm); strongly anisotropic. An important ore of silver. Poorman mine, Owyhee Co., ID; Comstock Lode(*) and Reese R. district, NV; Cobalt(*), ON, and Beaverdell, BC, Canada; Las Chispas mine(*), Arizpe, SON, Fresnillo(*), ZAC, Guanajuato(*), GTO, and other localities, Mexico; Hiendelaencina(*), Guadalajara, Spain; Espedalen, Norway; Andreasberg(*), Harz, and Freiberg(*), Saxony, Germany; Jachymov and Příbram(*), Czech Republic; Strezhen deposit, Altai, Russia; Broken Hill(*), NSW, Australia; San Cristobal(*), Peru; Colquechaca(*), Bolivia; Chanarcillo(*), Atacama, Chile. **BM** *DI:362*, *NJMM:181(1966)*, *R:785*, *P&J:309*, *ABI:425*.

3.4.2.1 Xanthoconite Ag_3AsS_3

Named in 1840 from the Greek for *yellow* and *powder*, in allusion to its streak. Dimorphous with proustite (3.4.1.1). **MON** $C2/c$. $a = 12.00$, $b = 6.21$, $c = 17.08$, $\beta = 110.0^\circ$, $Z = 8$, $D = 5.45$. d_{1-1455} : 5.47_2 4.01_3 3.35_2 3.13_6 3.07_3 3.01_8 2.97_{10} 2.82_7 . Tabular crystals twinned on $\{001\}$, also reniform and hemispheric aggregates. Dark red to brown, orange-yellow streak, adamantine luster. Cleavage $\{001\}$, distinct; subconchoidal fracture; brittle. $H = 2-3$, $VHN_{25} = 71-93$. $G = 5.5-5.6$. $R = 23.7-27.3$ (540 nm). Flathead mine, San-

ders Co., MT; General Petite mine, Elmore Co., ID; Cobalt, ON, Canada; Batopilas, CHIH, Mexico; Ste.-Marie-aux-Mines, Haut-Rhin, France; Andreasberg, Harz, *Freiberg*, Schneeberg, and other localities in *Saxony, Germany*; Lengenbach, Binn, Switzerland; Jachymov and Příbram, Czech Republic; Baia Sprie, Romania; Nishizawa mine, Japan. *BM DI:371, R:789, P&J:396, ABI:580.*

3.4.2.2 Pyrostilpnite Ag_3SbS_3

Named in 1868 from the Greek for *fire* and *shining*, in allusion to its color and luster. Dimorphous with pyrargyrite. *MON P2₁/c. a = 6.84, b = 15.84, c = 6.24, $\beta = 117.15^\circ$, Z = 4, D = 5.98. 25-1187: 3.33₄ 3.22₁₀ 3.12₉ 2.86₃ 2.84₇ 2.64₄ 2.62₅ 2.42₃*. Tabular crystals and sheaflike aggregates. Red, orange-yellow streak, adamantine luster. Cleavage {010}, perfect; conchoidal fracture. *H = 2, VHN₁₀₀ = 107. G = 5.94. Biaxial (+); N very high. Bulldog mine, Creede, CO; Silver City district, Owyhee Co., ID; Randsburg, San Bernardino Co., CA; Cobalt, ON, Canada; Hiendelaencina, Guadalajara Prov., Spain; Andreasberg, Harz, Freiberg, Saxony, Germany; Příbram and Trebsko, Czech Republic; Kushikino mine, Kagoshima Pref., Japan; Broken Hill, NSW, and Long Tunnel, Heazlewood, TAS, Australia; Chanarcillo, Atacama, Chile. BM DI:369, R:789, P&J:396, ABI:427.*

3.4.3.1 Seligmanite PbCuAsS_3

Named in 1902 for Gustav Seligman (1849–1920), German mineral collector. Forms a series with bournonite (3.4.3.2). *ORTH Pmmn. a = 8.134, b = 8.710, c = 7.634, Z = 4, D = 5.43. 11-92: 5.72₆ 4.70₄ 3.85₈ 2.72₁₀ 2.56₅ 1.91₅ 1.75₇ 1.41₅*. Prismatic to tabular crystals, usually twinned on {110}. Black, black streak, metallic luster. Cleavage very poor on {001}, {100}, and {010}; conchoidal fracture; brittle. *H = 3, VHN₁₀₀ = 168–181. G = 5.38. R = 32.4–33.6 (540 nm); strongly anisotropic. Balmat–Edwards mine, Balmat, NY; Butte, MT; Bingham, UT; Hemlo gold deposit, near Marathon, ON, and Whisky Creek mines, near Woodcock, BC, Canada; Wiesloch, near Heidelberg, Germany; Lengenbach, Binn, Switzerland; Tsumeb, Namibia; Cerro de Pasco, Peru; Desierto mine, near Iquique, Chile. BM DI:411, R:754, P&J:340, ABI:470.*

3.4.3.2 Bournonite PbCuSbS_3

Named in 1805 for Jacques L. de Bournon (1751–1825), French mineralogist. Forms a series with seligmanite (3.4.3.1). *ORTH Pn2₁/m. a = 8.168, b = 8.712, c = 7.811, Z = 4, D = 5.84. 12-94: 3.91₃ 3.84₄ 2.74₁₀ 2.69₅ 1.99₃ 1.95₃ 1.85₃ 1.77₅*. Crystals short prismatic to tabular, commonly twinned on {110} forming cruciform or cogwheel aggregates; also massive, granular, or compact. Steel-gray to black color and streak, metallic luster. Cleavage {010}, imperfect; subconchoidal to uneven fracture; brittle. *H = 2 $\frac{1}{2}$ –3, VHN₁₀₀ = 176–205. G = 5.83. R = 34.5–36.3 (540 nm); weakly anisotropic. Widely distributed, sometimes in fine crystals. Park City(*), UT; Mineral King mine, BC,*

Canada; Naica, CHIH, and Noche Buena(*), ZAC, Mexico; Herodsfoot mine(*), Liskeard, and *Wheal Boys mine, Endellion, Cornwall, England*; Georg mine(*), near Horhausen, Westerwald, and Clausthal, Neudorf(*), and Wolfsberg(*), Harz, Germany; Pontgibaud, Puy-de-Dôme, and St. Laurent Le Minier(*), Gard, France; Rimska Jama, Bosnia; Trepca, Serbia; Rodna(*), Baia Sprie, Cavnic, and Sacaramb, Romania; Stratonii, Greece; Chichibu mine(*), Saitama, Japan; Broken Hill, NSW, Australia; Zancudo mine, near Medellín, Colombia; Quiruvilca mine(*), La Libertad, Peru; Huanacacha, Colquechaca, Machacamamarca(*), and Oruro(*), Bolivia. BM *DI:406, ZK 131:397(1970), R:734, P&J:101, AM 62:1097(1977), ABI:65.*

3.4.3.3 Součekite PbCuBi(S,Se)_3

Named in 1979 for Frantisek Souček (1911–1989), Czech mineral collector. ORTH $Pn2_1/m$. $a = 8.153$, $b = 8.498$, $c = 8.080$, $Z = 4$, $D = 7.60$. *33-197: 4.25₆ 4.04₈ 3.77₅ 2.76₁₀ 2.72₁₀ 2.02₆ 1.83₅ 1.78₅*. Microscopic anhedral grains and veinlets. Lead-gray, metallic luster. $H = 3\frac{1}{2}$, $VHN_{25} = 179$. Otish Mts. uranium deposit, PQ, Canada; *Oldrichov, near Tachov, Czech Republic*. BM *NJMM:289(1979), AM 65:209(1980), CM 25:625(1987), ABI:486.*

3.4.4.1 Lapieite CuNiSbS_3

Named in 1984 for the locality. ORTH $P2_12_12_1$. $a = 7.422$, $b = 12.508$, $c = 4.900$, $Z = 4$, $D = 4.97$. *37-436: 3.18₉ 2.96₁₀ 2.77₂ 2.64₂ 2.23₂ 1.86₆ 1.84₉ 1.60₃*. Microscopic subhedral grains. Gray, metallic luster. Cleavage $\{100\}$, fair. $H = 4\frac{1}{2}$ –5. *Lapie R., St. Cyr Ranges, YT, Canada*. BM *CM 22:561(1984), AM 70:1329(1985), ABI:286.*

3.4.4.2 Mückeite CuNiBiS_3

Named in 1989 for Arno Mücke (b.1937), German mineralogist. ORTH $P2_12_12_1$. $a = 7.509$, $b = 12.551$, $c = 4.877$, $Z = 4$, $D = 6.07$. *NJMM: 3.18₈ 2.98₁₀ 2.90₄ 2.23₃ 2.16₃ 2.09₆ 1.86₅ 1.84₇*. Tabular euhedral or subhedral crystals to 1 mm. Pale gray, gray-black streak, metallic luster. Cleavage $\{010\}$, very good; $\{001\}$, good. $H = 3\frac{1}{2}$, $VHN = 136$ –165. $G = 5.88$. $R = 34.1$ –39.0 (546 nm); moderately anisotropic. *Grüne Au mine, Schutzbach, near Siegen, Germany*. BM *NJMM:193(1989), AM 75:708(1990).*

AIKINITE GROUP

The members of the aikinite group are isotypic Cu–Pb–Bi sulfosalts and have closely related orthorhombic structures derived from that of bismuthinite, Bi_2S_3 , $Pbnm$, $a = 11.23$, $b = 11.27$, $c = 3.91$. *NJMM:56(1990)*. The general formula is

AIKINITE: PbCuBiS_3

All coordinations are irregular: Pb 5, Cu 4, and Bi 5 by sulfur.

3.4.5.1 Aikinite PbCuBiS_3

Named in 1843 for Arthur Aikin (1773–1854), English geologist. Aikinite group. ORTH *Pbnm*. $a = 11.32$, $b = 11.64$, $c = 4.04$, $Z = 4$, $D = 7.19$. ρ_s – ρ_l : 4.06₅ 3.67₁₀ 3.62₅ 3.59₉ 3.18₃ 3.16₇ 2.86₉ 2.68₅. Prismatic to acicular crystals, also massive. Black, black streak, metallic luster. Cleavage {010}, indistinct; uneven fracture. $H = 2-2\frac{1}{2}$. $G = 7.07$. $R = 46.3-47.3$ (540 nm); distinctly anisotropic. Widely distributed in small amounts. Chantilly quarry, Loudoun Co., VA; Ouray, San Juan Co., and Sunnyside mine, Eureka Co., CO; Sells mine, Alta, Salt Lake Co., UT; Bisbee, AZ; near Cucomungo Spring and Sylvania Mts., NV; Owen Lake, BC, Canada; Taxco and Huitzucó, GRO, Mexico; Gardette mine, near Bourg d'Oisans, France; Dobsina, Czech Republic; Pilica, Poland; Zidarova, Bulgaria; Kirki mine, Greece; *Beresovsk*, Ural Mts., and Inkur, Transbaikal, *Russia*; Karagaily, Kazakhstan; Huancavelica, Peru. BM *DI*:412, *R*:738, *P&J*:61, *AM* 61:15(1976), *ABI*:3.

3.4.5.2 Krupkaite $PbCuBi_3S_6$

Named in 1974 for the locality. Aikinite group. ORTH $Pb2_1m$. $a = 11.15$, $b = 11.51$, $c = 4.01$, $Z = 2$, $D = 6.98$. 29-563: 3.65₃ 3.59₂ 3.55₃ 3.16₃ 3.14₁₀ 2.84₄ 2.66₃ 1.97₃. Microscopic fibrous aggregates. Steel-gray, metallic luster. $H = 3\frac{1}{2}$, $VHN_{100} = 165$. $R = 46-49$ (546 nm). Ball's mine, Little Cottonwood district, Salt Lake Co., UT; Cucumungo Canyon, Esmeralda Co., NV; Temiskaming, PQ, Canada; Krupka and Dobsina, Czech Republic; Inkur, Transbaikal, Russia; Juno mine, Tennant Creek, NT, Australia. BM *NJMM:533(1974)*, *AM 60:300,737(1975)*, *ABI:276*.

3.4.5.3 Gladite $PbCuBi_5S_9$

Named in 1924 for the locality. Aikinite group. ORTH $Pbnm$. $a = 33.66$, $b = 11.45$, $c = 4.02$, $Z = 4$, $D = 6.88$. 25-1422: 3.56₁₀ 3.10₇ 2.81₇ 1.95₇ 1.92₇ 1.31₉ 1.10₉ 1.08₉. Prismatic crystals to 2 cm. Lead-gray, black streak, metallic luster. Cleavage {010}, good; {100}, fair. $H = 2-3$, $VHN_{100} = 166$. $G = 6.96$. Comstock mine, Dos Cabezas, Cochise Co., AZ; Tanco pegmatite, Bernic Lake, MB, Canada; Bleka, Telemark, Norway; Gladhammar, Kalmar, Sweden; Krupka, Czech Republic; Baita Bihor, Romania. BM *DI:483*, *AKMG 4:377(1968)*, *ABI:186*.

3.4.5.4 Hammarite $Pb_2Cu_2Bi_4S_9$

Named in 1924 for the locality. Aikinite group. ORTH $Pbnm$. $a = 33.45$, $b = 11.58$, $c = 4.01$, $Z = 4$, $D = 7.05$. 30-179: 4.03₆ 3.65₁₀ 3.57₁₀ 3.16₈ 3.14₁₀ 2.85₁₀ 2.67₅ 2.57₅. Prismatic or acicular crystals. Steel-gray with red tint, black streak, metallic luster. Cleavage {010}, good; flat conchoidal fracture. $H = 3-4$, $VHN_{100} = 243$. $G = 6.73$. $R = 39.3-47.5$ (540 nm). Victoria district, Dona Ana Co., NM; Gladhammar, Kalmar, Sweden; Baita, Romania; Inkur deposit, Transbaikal, Russia. BM *DI:442*, *P&J:191*, *AM 61:15(1976)*, *ABI:203*.

3.4.5.5 Friedrichite $Pb_5Cu_5Bi_7S_{18}$

Named in 1978 for Otmar M. Friedrich (1902-1991), Austrian mineralogist. Aikinite group. ORTH $Pb2_1m$. $a = 33.84$, $b = 11.65$, $c = 4.01$, $Z = 2$, $D = 7.13$. 29-561: 4.05₄ 3.64₁₀ 3.58₁₀ 3.16₁₀ 2.85₈ 2.68₃ 2.58₄ 1.98₄. Prismatic crystals to 1.5 mm, or granular aggregates. Black, metallic luster. $H = 4$, $VHN_{50} = 224$. $G = 6.98$. $R = 40.1-46.2$ (546 nm); distinctly anisotropic. Fremont mine, east of Hachita, Grant Co., NM; near Panguitch, Garfield Co., UT; Sedl, east of the Habachtal, Salzburg, Austria; Inkur, Transbaikal, Russia. BM *CM 16:127(1978)*, *AM 64:654(1979)*, *ABI:164*, *NJMM:56(1990)*.

3.4.5.6 Pekoite $PbCuBi_{11}S_{18}$

Named in 1976 for the locality. Aikinite group. ORTH $Pb2_1m$. $a = 33.50$, $b = 11.32$, $c = 3.99$, $Z = 2$, $D = 6.80$. 29-560: 3.62₃ 3.59₂ 3.56₃ 3.14₁₀ 3.03₄ 2.55₂ 2.33₂ 1.97₃. Prismatic crystals to 2 mm. Lead-gray, lead-gray streak,

metallic luster. Cleavage {010}, good. Comstock mine, Dos Cabezas, Cochise Co., AZ; Germania Consolidated mine, Fruitland, Stevens Co., WA; Tanco pegmatite, Bernic Lake, MB, Canada; Baita, Romania; near Narechen, Rhodope Mts., Bulgaria; Kochbulak deposit, Uzbekistan; *Peko mine, Tennant Creek, NT, Australia*. BM *CM 14:322,578(1976)*, *ABI:394*.

3.4.5.7 Lindströmite $Pb_3Cu_3Bi_7S_{15}$

Named in 1924 for Gustav Lindström (1838–1916), Swedish mineral chemist. Aikinite group. ORTH *Pbnm*. $a = 56.07$, $b = 11.57$, $c = 4.01$, $Z = 4$, $D = 7.03$. $42-543$: 4.03_5 3.65_{10} 3.58_6 3.56_8 3.16_7 3.14_9 2.84_9 2.66_4 . Striated prismatic crystals to 1 cm. Lead-gray, black streak, metallic luster. Cleavage {100} and {010}, good. $H = 3-3\frac{1}{2}$. $G = 7.01$. $R = 41.1-45.4$ (540 nm). Beaver Mts., Beaver Co., UT; Manhattan, Nye Co., NV; Silver Miller mine, Cobalt, ON, Canada; Yecora, near Iglesia, SON, Mexico; *Gladhammar, Kalmar, Sweden*; Beresovsk district, Ural Mts., and Inkur, Transbaikal, Russia. BM *DI:459*, *P&J:237*, *CM 15:527(1977)*, *ABI:296*.

3.4.6.1 Marrite $PbAgAsS_3$

Named in 1904 for John E. Marr (1857–1933), English geologist. MON $P2_1/a$. $a = 7.291$, $b = 12.68$, $c = 5.998$, $\beta = 91.22^\circ$, $Z = 4$, $D = 5.82$. $21-1338$: 3.45_{10} 3.15_3 3.00_7 2.91_4 2.75_{10} 2.05_5 2.01_4 1.00_4 . Equant to tabular crystals. Lead-gray to gray-black, brown-black streak, metallic luster. No cleavage, conchoidal fracture, brittle. $H = 3$, $VHN = 168$. $R = 31.5-34.0$ (546 nm); distinctly anisotropic. *Lengenbach, Binn, Switzerland*. BM *DI:487*, *SMPM 45:711(1965)*, *R:750*, *ABI:313*.

3.4.6.2 Freieslebenite $PbAgSbS_3$

Named in 1845 for Johann K. Freiesleben (1774–1846), German mining commissioner. MON $P2_1/a$. $a = 7.54$, $b = 12.82$, $c = 5.89$, $\beta = 92.23^\circ$, $Z = 4$, $D = 6.22$. $10-468$: 3.48_8 3.25_3 2.98_7 2.83_{10} 2.08_4 2.01_3 1.78_5 1.73_3 . Prismatic striated crystals to 2 cm. Lead-gray to black, gray streak, metallic luster. Cleavage {110}, imperfect; subconchoidal to uneven fracture. $H = 2-2\frac{1}{2}$. $G = 6.2$. $R = 37.0-42.3$ (540 nm); weakly anisotropic. Garfield mine, Gunnison Co., CO; Castle Dome Mts., Yuma Co., AZ; Cobalt, ON, and Mt. Nansen mines, YT, Canada; Pontgibaud, Puy-de-Dôme, Ussel, Correze, and Vialas, Lozère, France; Hiendelaencina(*), Guadalajara Prov., Spain; Hällefors, Sweden; *Himmelfurst mine*(*), *Freiberg*, and *Marienberg, Saxony, Germany*; *Pribram*, Czech Republic; *Dossena*, Bergamo, Italy; *Baia Sprie*(*), Romania; *Bakadzhik* deposit, Bulgaria; *Oruro*(*), Bolivia. BM *DI:416*, *R:744*, *P&J:168*, *ABI:163*.

3.4.7.2 Mgrite Cu_3AsSe_3

Named in 1982 from the initial letters of the Moscow Geological Exploration Institute. Possibly identical with chameanite (3.2.8.1). iso $Fd3m$. $a = 5.530$, $Z = 1$, $D = 5.87$. $35-675$: 3.18_{10} 1.95_{10} 1.67_5 1.38_3 1.27_4 1.13_4 1.06_3 0.978_4 .

Massive. Gray, metallic luster. No cleavage. $H = 4\frac{1}{2}$, $VHN_{20} = 287-379$. $R = 26.9$ (540 nm). *Erzgebirge, Saxony, Germany*. BM *ZVMO 111:215(1982)*, *AM 68:280(1983)*, *ABI:329*.

3.4.8.1 Wittichenite Cu_3BiS_3

Named in 1853 for the locality. ORTH $P2_12_12_1$. $a = 7.68$, $b = 10.33$, $c = 6.70$, $Z = 4$, $D = 6.20$. $9-488$: 4.55_4 3.83_3 3.19_3 3.08_8 2.85_{10} 2.66_4 2.39_3 1.90_3 1.82_3 . Acicular crystals and massive. Gray to black, black streak, metallic luster. Conchoidal fracture, brittle. $H = 3$, $VHN_{100} = 170-187$. $G = 6.0-6.2$. $R = 33.5-35.2$ (540 nm); weakly anisotropic. Widely distributed in small amounts. Fairfax quarry, Centerville, VA; Butte, MT; Bisbee, AZ; Cobalt, ON, and Maid of Erin mine, Rainy Hollow district, BC, Canada; Seathwaite Tarn, Cumbria, England; Tjøstulflaten, Telemark, Norway; *Wittichen, Black Forest, Germany*; Mangualde, Portugal; Musomiste, Bulgaria; Akavan deposit, Armenia; Chumauk deposit, Uzbekistan; Strezhan deposit, Transbaikal, Russia; Mt. Gunson mine, Pernatty Lagoon, SA, Australia; Colquijirca, Peru. BM *DI:373*, *R:721*, *P&J:391*, *ABI:577*.

3.4.8.2 Skinnerite Cu_3SbS_3

Named in 1974 for Brian J. Skinner (b.1928), Australian-U.S. economic geologist. MON $P2_1/c$. $a = 7.815$, $b = 10.252$, $c = 13.270$, $\beta = 90.35^\circ$, $Z = 8$, $D = 5.11$. $26-1110(\text{syn})$: 3.91_8 3.21_7 3.19_7 3.05_7 2.83_{10} 2.63_9 2.62_9 1.81_9 . Microscopic grains. Gray, metallic luster. $H = 3$, $VHN_{50} = 148-166$. Distinctly anisotropic. Belmont, Nye Co., NV; *Ilimaussaq Intrusion, Greenland*; Grube Clara, Black Forest, Germany; Kosice, Czech Republic. BM *AM 59:889(1974)*, *ABI:478*.

3.4.9.1 Ellisite Tl_3AsS_3

Named in 1979 for Albert J. Ellis (b.1929), New Zealand geochemist. HEX-R $R3m$. $a = 12.324$, $c = 9.647$, $Z = 7$, $D = 7.18$. $35-723$: 5.33_4 3.56_2 3.21_6 2.85_1 2.76_1 2.67_{10} 2.33_3 1.78_2 . Rhombohedral crystals to 1.3 mm and small masses. Dark gray, pale brown streak, metallic luster. Good rhombohedral cleavage, hackly fracture. $H = 2$, $VHN_{50} = 36-44$. $G_{\text{syn}} = 7.10$. $R = 29.2$ (546 nm); strongly anisotropic. *Carlin gold deposit, Eureka Co., NV*. BM *AM 64:701(1979)*, *ABI:144*.

3.4.10.1 Christite $TlHgAsS_3$

Named in 1977 for Charles L. Christ (1916-1980), U.S. mineralogist. MON $P2_1/n$. $a = 6.113$, $b = 16.188$, $c = 6.111$, $\beta = 96.71^\circ$, $Z = 4$, $D = 6.37$. $29-1337(\text{syn})$: 4.04_5 3.63_9 3.49_6 3.37_3 2.98_{10} 2.80_3 2.70_5 2.21_4 . Subhedral grains to 1 mm. Orange to deep red, orange streak, adamantine luster. Cleavage $\{010\}$, perfect; $\{100\}$, $\{001\}$, $\{101\}$, good. $H = 1-2$, $VHN_{10} = 28-35$. $G_{\text{syn}} = 6.2$. *Carlin gold deposit, Eureka Co., NV*; Allchar, Macedonia. BM *AM 62:421(1977)*, *ABI:96*.

3.4.10.2 Laffittite AgHgAsS_3

Named in 1974 for Pierre Laffitte (b.1925), French geologist. *MON Aa*. $a = 7.732$, $b = 11.285$, $c = 6.643$, $\beta = 115.16^\circ$, $Z = 4$, $D = 6.07$. *35-566*: 5.30₁ 3.63₂ 3.51₁₀ 3.20₈ 3.02₇ 2.69₆ 2.14₂ 1.90₃. Anhedronal grains to 1 mm. Dark red, red-brown streak, adamantine luster. $H = 3$, $\text{VHN}_{25} = 92\text{--}138$. $G_{\text{syn}} = 6.11$. $R = 30.7\text{--}32.5$ (540 nm); strongly anisotropic. Getchell mine, Humboldt Co., NV; *Jas Roux mine, Hautes-Alpes, France*; Chauvai, Kyrgyzstan. *BM BM 97:48(1974)*, *AM 68:235(1983)*, *R:783*, *P&J:231*, *ABI:282*.

3.4.11.1 Routhierite $\text{TiCuHg}_2\text{As}_2\text{S}_6$

Named in 1974 for Pierre Routhier (b.1916), French economic geologist. *TET I4mm*. $a = 9.977$, $c = 11.290$, $Z = 4$, $D = 6.81$. *29-1338*: 4.15₁₀ 3.53₈ 2.99₁₀ 2.50₉ 1.87₇ 1.83₆ 1.76₇ 1.52₆. Anhedronal grains and veinlets. Violet-red, metallic luster. Two perpendicular cleavages. $H = 3\frac{1}{2}$, $\text{VHN}_{25} = 148$. $R = 28.2\text{--}29.3$ (540 nm); weakly anisotropic. Hemlo gold deposit, near Marathon, ON, Canada; *Jas Roux mine, Hautes-Alpes, France*. *BM BM 97:48(1974)*; *AM 60:947(1975)*, *75:935(1990)*; *P&J:330*; *ABI:447*.

3.4.11.2 Stalderite $\text{TiCu}(\text{Zn}, \text{Fe}, \text{Hg})_2\text{As}_2\text{S}_6$

Named in 1993 for Hans-Anton Stalder (b.1925), Swiss mineralogist. *TET I42m*. $a = 9.865$, $c = 10.938$, $Z = 4$, $D = 4.97$. *SMPM 75*: 4.09₅ 3.42₃ 2.94₁₀ 2.65₂ 2.54₂ 2.44₄ 1.81₂ 1.74₂. Microscopic pseudoisometric crystals. Black, red-brown streak, metallic luster. No cleavage; uneven to conchoidal fracture. $H = 3\frac{1}{2}\text{--}4$, $\text{VHN}_{10} = 135$. In reflected light gray-white, very weakly anisotropic, $R = 27\text{--}28$ (540 nm). *Lengenbach, Binn, Switzerland*. *BM LAP 18(10):40(1993)*, *AM 78:845(1993)*, *SEPM 75:337(1995)*.

3.4.12.1 Samsonite $\text{Ag}_4\text{MnSb}_2\text{S}_6$

Named in 1910 for the locality. *MON P2₁/n*. $a = 10.92$, $b = 8.082$, $c = 6.682$, $\beta = 92.79^\circ$, $Z = 2$, $D = 5.51$. *11-74*: 6.4₃ 5.54₃ 3.20₁₀ 3.01₉ 2.86₅ 2.59₆ 2.51₄ 2.43₅. Prismatic crystals to 1 cm. Steel-black, dark red streak, metallic luster. Conchoidal fracture, brittle. $H = 2\frac{1}{2}$, $\text{VHN}_{100} = 187\text{--}212$. $G = 5.51$. $R = 30.0\text{--}31.2$ (540 nm); weakly anisotropic. Silver Miller mine(*), Cobalt, ON, Canada; *Samson vein*(*), *Andreasberg, Harz, Germany*. *BM DI:393*, *R:790*, *P&J:334*, *ABI:460*.

3.4.13.1 Nowackiite $\text{Cu}_6\text{Zn}_3\text{As}_4\text{S}_{12}$

Named in 1965 for Werner Nowacki (1909–1989), Swiss mineralogist. *HEX-R R3*. $a = 13.44$, $c = 9.17$, $Z = 3$, $D = 4.38$. *25-323*: 3.13₆ 1.89₇ 1.61₆ 1.22₅ 1.09₈ 1.04₂ 1.02₁₀. Small equant crystals. Dark gray to black, metallic luster. *Lengenbach, Binn, Switzerland*. *BM AM 51:532(1966)*, *ZK 124:352(1967)*, *R:571*, *ABI:357*.

3.4.13.2 Aktashite $\text{Cu}_6\text{Hg}_3\text{As}_4\text{S}_{12}$

Named in 1968 for the locality. Forms a series with gruzdevite (3.4.13.3). **HEX-R** *R3*. $a = 13.72$, $c = 9.32$, $Z = 3$, $D = 5.47$. 25-298: 4.04_2 3.10_{10} 2.69_7 1.90_{10} 1.62_{10} 1.55_2 1.35_3 1.24_4 . Microscopic euhedral to anhedral grains. Gray-black, black streak, metallic luster. Conchoidal to uneven fracture, brittle. $H = 4\frac{1}{2}$, $\text{VHN}_{50} = 300\text{--}346$. $G = 5.5$. Hemlo gold deposit, near Marathon, ON, Canada; Moctezuma, SON, Mexico; Jas Roux mine, Hautes-Alpes, France; *Gal-Khaya deposit, Yakutia, and Aktash deposit, Altai, Russia*; Chauvai, Kyrgyzstan. **BM** *AM 56:358(1971)*, *58:562(1973)*; *DANS 251:96(1980)*; *ABI:4*.

3.4.13.3 Gruzdevite $\text{Cu}_6\text{Hg}_3\text{Sb}_4\text{S}_{12}$

Named in 1981 for V. S. Gruzdev (1938–1977), Russian mineralogist. Forms a series with aktashite (3.4.13.2). **HEX-R** *R3*. $a = 13.902$, $c = 9.432$, $Z = 3$, $D = 5.85$. 35-659: 3.16_{10} 2.12_3 1.93_9 1.65_8 1.36_3 1.25_5 1.11_6 1.05_5 . Possibly massive. Gray-black, metallic luster. $H = 4$, $\text{VHN}_{30} = 295$. $R = 32.8$ (540 nm); weakly anisotropic. Moctezuma, SON, Mexico; *Chauvai deposit, Kyrgyzstan*. **BM** *DANS 261:971(1981)*, *AM 67:885(1982)*, *ABI:196*.

3.4.14.1 Galkhaite $(\text{Cs, Tl})(\text{Hg, Cu})_6\text{As}_4\text{S}_{12}$

Named in 1972 for the locality. **ISO** *I43m*. $a = 10.365$, $Z = 2$, $D = 5.36$. 35-533: 7.33_6 4.23_9 2.99_{10} 2.77_8 2.59_4 1.89_2 1.83_5 1.56_3 . Cubic crystals to 1 cm, also massive. Dark orange-red, orange-yellow streak, vitreous to adamantine luster. No cleavage; conchoidal to uneven fracture, brittle. $H = 3$, $\text{VHN}_{100} = 186\text{--}202$. $G = 5.4\text{--}5.7$. $R = 24.6$ (540 nm). Getchell mine, Humboldt Co., and Carlin mine, Elko Co., NV; Hemlo gold deposit, near Marathon, ON, Canada; *Gal-Khaya, Yakutia, Russia*; Khaidarkan, Kyrgyzstan. **BM** *DANS 205:1194(1972)*, *AM 59:208(1974)*, *CM 20:575 (1982)*, *ABI:172*.

LILLIANITE GROUP

The lillianite group minerals are sulfosalts with the general formula

where

A = Pb, Ag, Mn

B = Sb, Bi

The structures of these rare minerals are complex (see figure). *NJMA 165:331(1993)*.

LILLIANITE: $\text{Pb}_3\text{Bi}_2\text{S}_6$

The Pb–Bi sites (Pb and Bi are indistinguishable by X-ray methods) are irregular and may be anywhere from 2- to 8-coordinated, depending on the length cutoff. Pb and Bi must be at least partially disordered and could be completely disordered.

LILLIANITE GROUP

3.4.15.1 Lillianite $\text{Pb}_3\text{Bi}_2\text{S}_6$

Named in 1889 for the Lillian mine, Leadville, CO, the discredited type locality. Lillianite group. Dimorphous with xilingolite. ORTH *Bbmm*. $a = 13.522$, $b = 20.608$, $c = 4.112$, $Z = 4$, $D = 7.14$. 29-763(syn): 3.52₁₀ 3.42₇ 3.01₆ 2.91₈ 2.78₆ 2.16₅ 2.07₆ 1.78₇. Prismatic crystals rare; usually granular

massive or radiating fibers. Steel-gray, black streak, metallic luster. Cleavage {100}, good; conchoidal fracture. $H = 2-3$. $G = 7.0-7.2$. $R = 51.5$ (540 nm); distinctly anisotropic. Near Minersville, Beaver Co., UT; Twin Lakes, Fresno Co., CA; Yecora, near Iglesia, SON, Mexico; Montenem, Galicia, Spain; Jilijärvi, near Orijärvi, Finland; Buvinsk deposit, Czech Republic; Oberpinzgau, Salzburg, Austria; Vulcano, Lipari Is., Italy; Banat, Romania; near Narechen, Rhodope Mts., Bulgaria; Kochbulak deposit, Uzbekistan; Spokoinoe deposit, Transbaikal, Russia; Cirotan, Java. *BM DI:404, R:781, AM 54:579(1969), ABI:295.*

3.4.15.2 Bursaitite $Pb_5Bi_4S_{11}$

Named in 1955 for the locality. Lillianite group. ORTH *Bbmm*. $a = 13.399$, $b = 20.505$, $c = 4.117$, $Z = 2$, $D = 6.56$. $25-431: 3.56_6$ 3.48_{10} 3.40_9 3.13_7 3.00_5 2.92_4 2.90_4 2.05_6 . Small prismatic crystals or radial aggregates. Gray, metallic luster. $H = 2\frac{1}{2}-3\frac{1}{2}$, $VHN = 126-134$. Strongly anisotropic. Organ, Dona Ana Co., NM; Boliden, Sweden; Hurky, Czech Republic; Apuseni Mts., Romania; *Uludag, Bursa Prov., Turkey*; Shumilovsk deposit and Strezhen deposit, Transbaikal, Russia. *BM AM 41:671(1956), 57:328(1972); NJMA 158:293(1988); ABI:73.*

3.4.15.3 Gustavite $PbAgBi_3S_6$

Named in 1970 for Gustav Hageman (1842–1916), Danish chemical engineer. Lillianite group. ORTH *Bbmm*. $a = 13.510$, $b = 20.169$, $c = 4.092$, $Z = 4$, $D = 7.01$. $24-143: 3.98_5$ 3.64_8 3.40_8 3.38_8 3.36_{10} 3.00_{10} 2.90_{10} 2.75_8 . Tabular crystals to 2 mm. Gray, metallic luster. Two distinct cleavages. $H = 3\frac{1}{2}$, $VHN_{100} = 175-218$. $R = 42-46$ (546 nm); distinctly anisotropic. Silver Bell mine, Red Mt., Ouray Co., and Old Lout mine, San Juan Co., CO; South Mt., Owyhee Co., ID; Darwin, Inyo Co., and Randsburg, San Bernardino Co., CA; Tanco pegmatite, Bernic Lake, MB, and Terra mine, Camsell R., NWT, Canada; *Ivigut, Greenland*; Rotgülden, Salzburg, Austria; Monteneme deposit, Galicia, Spain; Kti-Teberda deposit, Caucasus Mts., Russia. *BM CM 10:173(1970), 13:411(1975), ABI:200.*

3.4.15.4 Andorite $PbAgSb_3S_6$

Named in 1894 for Andor von Semsey (1833–1923), Hungarian mineral collector. Lillianite group. ORTH *Pmma*. $a = 12.994$, $b = 19.148$, $c = 4.303$, $Z = 4$, $D = 5.41$. $35-596: 3.76_6$ 3.44_7 3.30_{10} 3.02_6 2.91_9 2.75_7 2.28_6 2.07_5 . Tabular and prismatic crystals to 3 cm, also massive. Dark gray, black streak, metallic luster. No cleavage, smooth conchoidal fracture, brittle. $H = 3-3\frac{1}{2}$. $G = 5.35$. $R = 36.3-40.4$ (540 nm); weakly anisotropic. Keyser mine, Morey district, Nye Co., NV; Bear Basin, King Co., WA; Thompson mine, Darwin, Inyo Co., CA; near Takla Lake, BC, and near Nansen Creek, YT, Canada; Les Farges mine(*), near Ussel, Correze, and Bournac, Montagne Noire, France; Příbram, Czech Republic; *Baia Sprie(*)*, Romania; Llallagua,

Itos(*), and San Jose(*) mines, Oruro, and Tatasi mine, Potosi, Bolivia. *BM DI:457, R:742, P&J:68, ABI:12.*

Quatrandorite and Senandorite

Incompletely characterized minerals occurring in microscopic intergrowths with andorite. *BM NJMM:175(1984), AM 70:219(1985), ZK 180:141(1987).*

3.4.15.5 Uchucchacuaite $Pb_3AgMnSb_5S_{12}$

Named in 1984 for the locality. Lillianite group. ORTH *Pmmm*. $a = 12.67$, $b = 19.32$, $c = 4.38$, $Z = 2$, $D = 5.57$. $38-369$: 3.80_3 3.49_3 3.30_{10} 2.90_8 2.75_3 2.29_1 2.19_1 2.08_3 . Subhedral to anhedral grains. Lead-gray, metallic luster. $H = 3\frac{1}{2}$, $VHN_{100} = 168$. $R = 34.1-43.3$ (540 nm). *Uchuc-Chacua deposit, Cajatambo Prov., Peru.* *BM BM 107:597(1984), AM 70:1332(1985), ABI:547.*

3.4.15.6 Ramdohrite $Pb_6Ag_3Sb_{11}S_{24}$

Named in 1930 for Paul Ramdohr (1890–1985), German mineralogist. Lillianite group. ORTH *Pmma*. $a = 12.99$, $b = 19.21$, $c = 4.29$, $Z = 2$, $D = 5.59$. $25-459$: 3.82_2 3.48_3 3.32_{10} 3.04_3 2.94_6 2.78_5 2.21_5 2.09_2 . Long prismatic crystals to 1 cm, twinned on {010}. Gray-black, gray-black streak, metallic luster. Uneven fracture, brittle. $H = 2$, $VHN_{20} = 206$. $G = 5.43$. $R = 36.0-40.9$ (540 nm); moderately anisotropic. Bear Basin, King Co., WA; Round Valley mine, Bishop Creek, Inyo Co., CA; Alyaskitovoye deposit, Yakutia, Russia; *Colorado vein, Chocaya mine, Potosí, Bolivia.* *BM DI:450, R:742, P&J:164, AM 76:2020(1991), ABI:431.*

3.4.15.7 Roshchinite $Pb_2Ag_5Sb_{13}S_{24}$

Named in 1990 for Yuri V. Roshchin (1934–1979), Russian geologist. Lillianite group. ORTH *Pnma*. $a = 12.946$, $b = 19.048$, $c = 4.236$, $Z = 2$, $D = 5.36$. $42-1422$: 3.24_6 2.85_8 2.70_6 2.10_3 2.05_3 1.99_3 1.87_5 1.77_{10} . Short prismatic crystals to 4 mm. Silver-gray to lead-gray, pale steel-gray streak, metallic luster. Very brittle. $VHN_{15} = 95$. $G = 5.27$. $R = 35.7-39.7$ (560 nm); distinctly anisotropic. *Kvartsitovyye Gorki deposit, Kazakhstan.* *BM DANS 312:197(1990), AM 77:450(1992).*

3.4.15.8 Fizelyite $Pb_{14}Ag_5Sb_{21}S_{48}$

Named in 1926 for Sandor Fizely (1856–1918), Hungarian mining engineer, who discovered the mineral. Lillianite group. ORTH *Pnmm*. $a = 13.167$, $b = 19.246$, $c = 8.700$, $Z = 2$, $D = 5.24$. $23-753$: 3.79_3 3.47_5 3.32_{10} 3.29_6 2.94_6 2.88_3 2.78_3 2.18_3 . Small striated prisms, twinned on {010}. Steel-gray to dark lead-gray, dark gray streak, metallic luster. Cleavage {010}, very brittle. $H = 2$. $G = 5.56$. $R = 38.0-44.9$ (540 nm); distinctly anisotropic. Morey, Nye Co., NV; Les Farges mine, Corrèze, and Bournac, Montagne Noire, France; Příbram, Czech Republic; *Herja and Baita, Romania; Inakuraishi*

mine, Hokkaido, Japan. *BM DI:450, R:742, P&J:164, NJMM:175(1984), ABI:158.*

3.4.16.1 Xilingolite $Pb_3Bi_2S_6$

Named in 1982 for the locality. Dimorphous with lillianite (3.4.15.1). *MON C2/m*. $a = 13.65$, $b = 4.078$, $c = 20.68$, $\beta = 93.0^\circ$, $Z = 4$, $D = 7.07$. *22-651(syn)*: 3.72₃ 3.38₁₀ 3.32₃ 3.08₃ 2.92₄ 2.84₅ 2.17₅ 2.08₄. Prismatic crystals to 8 mm, twinned on {001}. Lead-gray, gray streak, metallic luster. $H = 3$, $VHN = 103$. $G = 7.08$. $R = 41.8-44.5$ (546 nm); distinctly anisotropic. *Chaobuleng district, Xilingola League, Inner Mongolia, China. BM AM 69:409(1984), ABI:581.*

3.4.17.1 Kirkiite $Pb_{10}Bi_3As_3S_{19}$

Named in 1985 for the locality. *HEX P6₃22*. $a = 8.69$, $c = 26.06$, $Z = 2$, $D = 6.88$. *39-339*: 3.65₅ 3.48₆ 3.26₁₀ 3.07₇ 2.85₆ 2.19₅ 2.00₄ 1.82₅. Microscopic euhedral to subhedral crystals. Gray, metallic luster. $H = 3$, $VHN_{100} = 150$. Weakly anisotropic. *Aghios Philippos deposit, near Kirki, Greece. BM BM 108:667(1985), AM 71:1278(1986), ABI:265.*

3.4.18.1 Ernlggliite $Tl_2SnAs_2S_6$

Named in 1992 for Ernst Niggli (b.1917), Swiss mineralogist. *HEX-R P3*. $a = 6.680$, $c = 7.164$, $Z = 1$, $D = 5.24$. *SMPM 72*: 4.51₄ 3.34₁₀ 3.06₅ 3.03₆ 2.68₅ 2.25₄ 1.93₄ 1.87₄. Microscopic hexagonal crystals. Steel-gray to black, red-black streak, metallic luster. Cleavage {0001}, good. $H = 2-3$, $VHN_{10} = 48$. $R = 26.8-27.7$ (543 nm). *Lengenbach, Binn, Switzerland. BM SMPM 72:293(1992).*

3.5.1.1 Neyite $Pb_7(Cu,Ag)_2Bi_6S_{17}$

Named in 1969 for Charles S. Ney (1918-1975), Canadian geologist. *MON C2/m*. $a = 37.5$, $b = 4.07$, $c = 41.6$, $\beta = 96.80^\circ$, $Z = 8$, $D = 7.11$. *23-1156*: 3.72₁₀ 3.51₁₀ 3.39₃ 2.92₁₀ 2.27₅ 2.08₄ 2.04₆ 1.46₄. Prismatic to bladed crystals. Lead-gray, metallic luster. Conchoidal fracture, brittle. $H = 2\frac{1}{2}$. $G = 7.02$. Moderately anisotropic. *Johnny Lyon Hills, near Benson, Cochise Co., AZ; Lame Creek deposit, Kitsault, near Alice Arm, BC, Canada. BM CM 10:90(1969), AM 55:1444(1970), ABI:348.*

3.5.2.1 Boulangerite $Pb_5Sb_4S_{11}$

Named in 1837 for Charles L. Boulanger (1810-1849), French mining engineer. *MON P2₁/a*. $a = 21.56$, $b = 23.51$, $c = 8.09$, $\beta = 100.7^\circ$, $Z = 8$, $D = 6.19$. *18-688*: 3.91₂ 3.73₁₀ 3.67₂ 3.43₂ 3.22₅ 3.03₄ 2.82₄ 2.69₃. Prismatic to needlelike crystals, sometimes forming rings, and as fibrous masses. Lead-gray, brown to brown-gray streak, metallic luster. Cleavage {100}, good; flexible in thin crystals; brittle. $H = 2\frac{1}{2}-3$. $G = 6.0-6.3$. $R = 38.0-40.3$ (540 nm); distinctly anisotropic. Widely distributed in small amounts.

Augusta Mt., Gunnison Co., CO; Iron Mountain mine, Mineral Co., MT; Coeur d'Alene, ID; Echo district, Union Co., NV; Cleveland mine, Stevens Co., WA; Madoc, ON, Canada; Noche Buena, ZAC, Mexico; Sala, Vastmannland, and Boliden, Vasterbotten, Sweden; Wolfsberg, Harz, and Waldsassen, Bavaria, Germany; *Molieres, Gard, France*; Pribram, Czech Republic; Bottino, Tuscany, Italy; Treпча, Serbia; Ciprovici, Bulgaria; Broken Hill, NSW, Australia; Llallagua, Bolivia. *BM DI:420, R:770, P&J:99, ABI:64.*

3.5.2.2 Falkmanite

Probably identical with boulangerite (3.5.2.1). *BM NJMM:498(1989).*

3.5.3.1 Sterryite $\text{Pb}_{10}\text{Ag}_2(\text{Sb,As})_{12}\text{S}_{29}$

Named in 1967 for T. Sterry Hunt (1826–1892), Canadian mineralogist. *ORTH Pbam.* $a = 28.48$, $b = 42.62$, $c = 4.090$, $Z = 4$, $D = 5.91$. $20\text{-}562$: 4.14_5 3.68_9 3.54_6 3.26_{10} 2.97_6 2.84_7 2.35_6 2.05_6 . Fibrous bundles and anhedral grains. Black, black streak, metallic luster. Cleavage parallel to c , perfect. $H = 3\frac{1}{2}$. Strongly pleochroic. *Madoc, ON, Canada.* *BM CM 9:191(1967), MR 13:95(1982), ABI:495.*

3.5.4.1 Diaphorite $\text{Pb}_2\text{Ag}_3\text{Sb}_3\text{S}_8$

Named in 1871 for the Greek for *difference*; resembling but distinct from freieslebenite. *MON C2₁/a.* $a = 15.849$, $b = 32.084$, $c = 5.901$, $\beta = 90.17^\circ$, $Z = 8$, $D = 6.02$. $9\text{-}126$: 3.30_{10} 2.95_4 2.89_2 2.81_8 2.03_4 2.00_2 1.76_3 1.70_3 . Prismatic crystals. Steel-gray, metallic luster. No cleavage, subconchoidal to uneven fracture, brittle. $H = 2\frac{1}{2}\text{-}3$, $\text{VHN}_{100} = 219$. $G = 6.04$. $R = 37.3\text{-}40.7$ (540 nm); strongly anisotropic. Wood River district, Blaine Co., ID; near Morey, Nye Co., NV; Lake Chelan district, Chelan Co., WA; Catorce, SLP, Mexico; Fournial, Cantal, and Pontgibaud, Puy-de-Dome, France; Freiberg, Saxony, Germany; *Pribram* and Kutna Hora, *Czech Republic*; Baia Sprie, Romania; Mangazeika and Bulatsk deposits, Yakutia, Russia; Zancudo, Colombia; Machacamamarca, Bolivia. *BM DI:414, R:745, P&J:146, ABI:132.*

3.5.5.1 Schirmerite $\text{Pb}_{3-6}\text{Ag}_3\text{Bi}_{7-9}\text{S}_{18}$

Named in 1874 for J. H. L. Schirmer, superintendent of the U.S. Mint, Denver, CO. *ORTH Bbmm.* $a = 13.45$, $b = 44.4$, $c = 4.02$, $Z = 8$, $D = 7.58$. $25\text{-}760$: 3.21_9 2.92_9 2.88_7 2.84_7 2.79_7 2.38_7 2.28_7 2.04_{10} . Lath-shaped crystals, also massive, granular. Lead-gray to iron-black, metallic luster. No cleavage, uneven fracture, brittle. $H = 2$, $\text{VHN} = 150\text{-}206$. $G = 6.74$. $R = 42.4\text{-}47.7$ (540 nm); distinctly anisotropic. *Treasury mine, Park Co.*, Old Lout mine, near Ouray, Lake City, Hinsdale Co., and Magnolia district, Boulder Co., CO; Darwin, Inyo Co., CA; Corrie Buie, Perthshire, Scotland; Montanem, Galicia, Spain; Zambaraks deposit, eastern Karamazar, Tajikistan. *BM DI:424, R:746, P&J:338, NJMA 131:56(1977), ABI:464.*

3.5.6.1 Ourayite $Pb_4Ag_3Bi_5S_{13}$

Named in 1977 for the locality. ORTH *Bbmm*. $a = 13.457$, $b = 44.042$, $c = 4.100$, $Z = 4$, $D = 7.11$. *33-1188*: 3.43_{10} 3.33_6 2.96_9 2.85_6 2.09_9 2.04_7 1.79_7 1.32_5 . Microscopic laths. Black, metallic luster. Strongly anisotropic. *Old Lout mine, Ouray, CO*; Pitiquito, SON, Mexico; Ivigtut, Greenland. BM *MJMA 131:56(1977)*, *AM 64:243(1979)*, *CM 22:565(1984)*, *ABI:371*.

3.5.7.1 Madocite $Pb_{17}(Sb,As)_{16}S_{41}$

Named in 1967 for the locality. ORTH *Pba2*. $a = 27.2$, $b = 34.1$, $c = 4.06$, $Z = 2$, $D = 5.98$. *20-567*: 3.87_5 3.67_7 3.40_{10} 3.36_9 3.11_4 3.03_4 2.93_6 2.72_8 . Small elongate grains. Gray-black, gray-black streak, metallic luster. Cleavage {010}, perfect; conchoidal fracture. $H = 3$, $VHN_{50} = 155$. $R = 42.3$ (546 nm); strongly anisotropic. *Madoc, ON, Canada*; Jas Roux, Hautes-Alpes, France; Boliden, Västerbotten, Sweden; Novoye, Khaidarkan, Kirgizstan. BM *CM 9:7(1967)*, *AM 53:1421(1968)*, *MR 13:94(1982)*, *ABI:306*.

3.5.8.1 Wallisite $PbTI(Cu,Ag)As_2S_5$

Named in 1965 for the locality. TRIC *P1*. $a = 7.980$, $b = 8.979$, $c = 7.761$, $\alpha = 106.11^\circ$, $\beta = 114.48^\circ$, $\gamma = 65.48^\circ$, $Z = 2$, $D = 5.71$. *27-279*: 3.72_4 3.62_4 3.50_3 3.33_8 3.31_{10} 2.86_8 2.81_7 2.64_5 . Crystals to 1 mm, usually massive. Lead-gray, metallic luster. Cleavage {001}, good. *Lengenbach, Binn, Canton Wallis, Switzerland*. BM *AM 54:1497(1969)*, *ZK 127:349(1968)*, *ABI:568*.

3.5.8.2 Hatchite $PbTI(Ag,Cu)As_2S_5$

Named in 1912 for Frederick H. Hatch (1864–1932), English geologist. TRIC *P1*. $a = 8.038$, $b = 9.167$, $c = 7.807$, $\alpha = 105.23^\circ$, $\beta = 113.62^\circ$, $\gamma = 64.82^\circ$, $Z = 2$, $D = 5.81$. *25-463*: 4.54_3 4.28_3 3.75_2 3.68_2 3.57_4 3.40_8 3.31_{10} 2.86_9 . Equant crystals to 1 mm. Lead-gray to gray-black, chocolate-brown streak, metallic luster. *Lengenbach, Binn, Switzerland*. BM *DI:487*, *SMPM 45:702(1965)*, *ZK 125:249(1967)*, *ABI:205*.

3.5.9.1 Cosalite $Pb_2Bi_2S_5$

Named in 1868 for the locality. ORTH *Pbnm*. $a = 19.09$, $b = 23.89$, $c = 4.058$, $Z = 8$, $D = 7.13$. *13-502*: 4.45_1 4.10_1 3.96_1 3.44_{10} 3.37_3 2.96_2 2.81_3 1.91_2 . Prismatic crystals, often acicular; usually massive or as fibrous aggregates. Steel-gray to lead-gray, black streak, metallic luster. No cleavage, uneven fracture. $H = 2\frac{1}{2}$ –3. $G = 6.9$ –7.0. $R = 41.5$ –44.5 (540 nm); weakly anisotropic. Widely distributed in small amounts. Red Mountain district, San Juan Co., CO; Magma mine, Superior, and Landsman Camp, Gila Co., AZ; Deer Park, Stevens Co., WA; Darwin, Inyo Co., CA; Boston Creek, McElroy Twp., and Cobalt, ON, Canada; *Nuestra Señora mine, Cosala, SIN, Mexico*; Carrock Fell mine, Cumbria, England; Bjelkes mine, Nordmark, and Boliden, Västerbotten, Sweden; Iilijärvi, Finland; Hurky and Zlata Hory, Czech Republic; Vaskö, Hungary; Baita and Moravicza, Romania; Trepca, Serbia;

Goce-Delav, Bulgaria; Kara Oba(*), Kazakhstan; Ustarasai, Uzbekistan; Strezhen deposit, Altai, Russia; near Oberon, NSW, Australia; Amparin-dravato, Madagascar. *BM DI:445, R:778, P&J:131, ABI:110.*

3.5.9.2 Veenite $Pb_2(Sb,As)_2S_5$

Named in 1967 for R. W. van der Veen (1883–1925), Dutch economic geologist and metallographer. ORTH $P2_1cn$. $a = 4.22$, $b = 26.2$, $c = 7.90$, $Z = 4$, $D = 5.96$. *20-560*: 3.81₁₀ 3.42₈ 3.26₈ 3.23₅ 3.03₉ 2.93₅ 2.83₅ 2.76₇. Flattened prismatic crystals; also massive, granular. Steel-gray, black streak, metallic luster. No cleavage, conchoidal fracture, very brittle. $H = 3\frac{1}{2}$, $VHN_{100} = 155$. $G = 5.92$. Moderately anisotropic. *Madoc, ON, Canada; Huachocolpa, Huancavelica, Peru. BM CM 9:7(1967), AM 53:1422(1968), ABI:556.*

3.5.9.3 Dufrenoyite $Pb_2As_2S_5$

Named in 1845 for Pierre A. Dufrenoy (1792–1857), French mineralogist. MON $P2_1/m$. $a = 8.41$, $b = 25.85$, $c = 7.88$, $\beta = 90.5^\circ$, $Z = 8$, $D = 5.62$. *10-453*: 3.74₁₀ 3.56₅ 3.40₅ 3.21₆ 3.00₉ 2.90₅ 2.70₈ 2.36₆. Tabular crystals to 3 cm. Lead-gray, chocolate-brown streak, metallic luster. No cleavage, parting {010}, conchoidal fracture. $H = 3$, $VHN_{100} = 135-146$. $G = 5.60$. $R = 36.3-39.6$ (540 nm); strongly anisotropic. Silver Star claims, near Fruitland, Stevens Co., WA; Hemlo gold deposit, near Marathon, ON, Canada; *Lengenbach and Reckibach, Binn, Switzerland. BM DI:442, SMPM 45:732(1965), R:752, P&J:151, ABI:140.*

3.5.10.1 Owyheeite $Pb_{10}Ag_3Sb_{11}S_{28}$

Named in 1921 for the locality. ORTH $Pnam$. $a = 22.82$, $b = 27.20$, $c = 8.19$, $Z = 4$, $D = 6.44$. *5-510*: 3.49₇ 3.37₄ 3.25₁₀ 2.90₅ 2.84₆ 2.23₅ 2.13₃ 2.05₆. Small acicular crystals, also massive to coarsely fibrous. Gray to black, red-brown streak, metallic luster. Cleavage {001}, very brittle. $H = 2\frac{1}{2}$, $VHN_{100} = 107$. $G = 6.2-6.5$. $R = 38.0-44.6$ (540 nm); strongly anisotropic. Domingo and Garfield mines, Gunnison Co., CO; *Poorman mine, Silver City district, Owyhee Co., ID; Kaiser Tunnel, Morey, Nye Co., NV; Alma property and Rambler mine, Slovan mining district, BC, Canada; near Yecora, SON, Mexico; Bourneix, Haute-Vienne, France; Kutna Hora, Czech Republic; Rajpura-Dariba, Rajasthan, India; Rivertree, NSW, and Meerschaum mine, near Omeo, VIC, Australia; Roc-Blanc, Morocco; Marmato, Colombia. BM DI:423, AM 34:398(1949), R:745, P&J:285, TMPM 32:271(1984), ABI:372.*

3.5.11.1 Imhofite $Tl_6As_{15}S_{25}$

Named in 1965 for Josef Imhof (1902–1969), Swiss mineral collector. MON $P2_1/n$. $a = 8.755$, $b = 24.425$, $c = 5.739$, $\beta = 108.28^\circ$, $Z = 1$, $D = 4.39$. *30-1343*: 3.94₉ 3.62₇ 3.56₈ 3.25₆ 3.16₇ 2.85₈ 2.68₆ 2.67₁₀. Microscopic plates and aggregates. Copper-red, adamantine luster. $H = 2$. Strongly anisotropic.

Lengensbach, Binn, Switzerland. BM AM 51:531(1966), ZK 144:323(1976), ABI:229.

3.5.12.1 Izoklakeite $\text{Pb}_{26}(\text{Ag}, \text{Cu}, \text{Fe})_2(\text{Sb}, \text{Bi})_{20}\text{S}_{57}$

Named in 1986 for the locality. ORTH *Pnnm*. $a = 33.88$, $b = 38.02$, $c = 4.070$, $Z = 2$, $D = 6.51$. $36\text{-}415$: 3.77_3 3.40_{10} 3.31_4 3.16_3 2.88_4 2.15_6 2.04_4 1.75_4 . Acicular aggregates to 1 mm. Lead-gray, gray-black streak, metallic luster. Cleavage {001}, good; conchoidal fracture; brittle. $H = 4$, $\text{VHN}_{50} = 150\text{-}212$. $G = 6.47$. $R = 40.6\text{-}45.2$ (540 nm); distinctly anisotropic. *Izok Lake, NWT, Canada; Vena mine, Bergslagen, Sweden; Turtschi, Binn, Switzerland. BM CM 24:1(1986), AM 72:821(1987), ABI:245.*

3.5.12.2 Glessenite $\text{Pb}_{26}(\text{Cu}, \text{Ag}, \text{Fe})_2(\text{Bi}, \text{Sb})_{20}\text{S}_{57}$

Named in 1963 for the locality. MON *P2₁/n*. $a = 34.34$, $b = 38.05$, $c = 4.06$, $\beta = 90.33^\circ$, $Z = 2$, $D = 6.93$. $38\text{-}445$: 3.91_6 3.79_6 3.65_6 3.61_6 3.43_{10} 3.40_9 2.03_7 1.75_6 . Microscopic acicular crystals. Gray-black, gray-black streak, metallic luster. $H = 2\frac{1}{2}\text{-}3$, $\text{VHN} = 65$. $R = 34.0$ (549 nm); weakly anisotropic. Bjorkasen deposit, Ofoten, Norway; Vena mine, Bergslagen, Sweden; *Turtschi, Gies-sen, near Binn, Switzerland; Otome mine, Yamanashi Pref., Japan. BM SMPM 43:471(1963), CM 24:19(1986), ABI:184.*

3.5.13.1 Jaskolskiite $\text{Pb}_{2-x}\text{Cu}_x(\text{Sb}, \text{Bi})_{2-x}\text{S}_5$ ($x = 0.2$)

Named in 1984 for Stanislaw Jaskolski (1896–1981), Polish mineralogist. ORTH *Pbnm*. $a = 11.331$, $b = 19.871$, $c = 4.100$, $Z = 4$, $D = 6.50$. $38\text{-}363$: 3.78_4 3.71_{10} 3.60_5 3.33_6 2.97_8 2.76_6 2.75_5 2.05_5 . Small aggregates. Lead-gray, dark gray streak, metallic luster. $H = 4$, $\text{VHN}_{100} = 165\text{-}179$. $R = 36.5\text{-}42.0$ (540 nm); strongly anisotropic. *Vena mine, Bergslagen, Sweden; Izok Lake, NWT, Canada. BM CM 22:481(1984), ZK 171:179(1985), ABI:248.*

3.5.14.1 Zoubekite $\text{Pb}_4\text{AgSb}_4\text{S}_{10}$

Named in 1986 for Vladimir Zoubek (b.1903), Czech geologist. ORTH Space group unknown. $a = 18.698$, $b = 6.492$, $c = 4.577$, $Z = 1$, $D = 5.21$. $39\text{-}342$: 3.67_4 3.25_4 3.07_5 2.39_6 2.22_8 1.96_5 1.80_{10} 1.33_8 . Microscopic laths. Steel-gray, black streak, metallic luster. No cleavage, uneven fracture. $H = 3\frac{1}{2}$, $\text{VHN}_{15} = 154\text{-}170$. $R = 37.6\text{-}43.1$ (540 nm); strongly anisotropic. *Pribram, Czech Republic. BM NJMM:1(1986), AM 72:227(1987), ABI:587.*

3.5.15.1 Watanabeite $\text{Cu}_4(\text{As}, \text{Sb})_2\text{S}_5$

Named in 1993 for Takeo Watanabe (1907–1986), Japanese mineralogist. ORTH Space group unknown. $a = 14.51$, $b = 13.30$, $c = 17.96$, $Z = 16$, $D = 4.66$. $\text{MM}57$: 4.43_1 3.36_1 3.00_{10} 2.59_2 2.24_1 1.98_1 1.83_4 1.56_2 . Microscopic anhedral grains. Silvery lead-gray, lead-gray streak, metallic luster. No cleavage, uneven fracture, brittle. $H = 4\frac{1}{2}$, $\text{VHN}_{100} = 253\text{-}306$. $G = 4.66$.

R = 31.1–32.0 (546 nm); weakly anisotropic. *Teine mine, Sapporo, Hokkaido, Japan*, in a hydrothermal vein. BM *MM* 57:643(1993).

3.6.1.1 Proudite $\text{Pb}_{15}\text{Cu}_2\text{Bi}_{10}(\text{S}, \text{Se})_{44}$

Named in 1976 for J. S. Proud (b.1907), Australian mining director. MON *C2/m*. $a = 31.96$, $b = 4.12$, $c = 36.69$, $\beta = 109.52^\circ$, $Z = 2$, $D = 7.08$. 30-491: 3.90₄ 3.83₅ 3.49₇ 3.45₄ 3.22₅ 2.96₁₀ 2.91₄ 2.07₆. Acicular crystals or irregular laths. Silver-gray, metallic luster. Two good cleavages at 40° . VHN₅₀ = 38–57. Strongly anisotropic. Janos, CHIH, Mexico; *Juno mine, Tennant Creek, NT, Australia*. BM *AM* 61:839(1976), *ABI*:422.

3.6.2.1 Eskimoite $\text{Pb}_{10}\text{Ag}_7\text{Bi}_{15}\text{S}_{36}$

Named in 1977 for the Eskimos, the natives of Greenland. MON *Am*. $a = 30.194$, $b = 4.100$, $c = 13.459$, $\beta = 93.35^\circ$, $Z = 1$, $D = 7.10$. 33-1187: 3.53₃ 3.36₁₀ 2.96₅ 2.87₆ 2.08₄ 2.05₅ 1.75₅ 1.67₄. Small lamellar grains, twinned on {010}. Black, metallic luster. H = 4, VHN₅₀ = 162–223. R = 43.7–46.5 (546 nm); distinctly anisotropic. Flathead mine, Niarada, MT; Manhattan, Nye Co., NV; *Ivigut, Greenland*; Montenem, Galicia, Spain; Rauris Goldberg, Salzburg, Austria; Kochbulak deposit, Uzbekistan. BM *NJMA* 131:56(1977), *AM* 64:243(1979), *ABI*:151.

3.6.3.1 Treasurite $\text{Pb}_6\text{Ag}_7\text{Bi}_{15}\text{S}_{32}$

Named in 1977 for the locality. MON *B2/m*. $a = 26.538$, $b = 4.092$, $c = 13.349$, $\beta = 92.77^\circ$, $Z = 1$, $D = 7.06$. 33-1189: 3.63₅ 3.49₁₀ 3.22₈ 2.93₅ 2.86₅ 2.82₅ 1.99₆ 1.96₆. Small granular aggregates. Black, metallic luster. *Treasury mine, Geneva district, CO*; 10 km SW of Tyrone, Grant Co., NM; Kochbulak deposit, Uzbekistan. BM *NJMA* 131:56(1977), *AM* 64:243(1979), *ABI*:535.

3.6.4.1 Playfairite $\text{Pb}_{16}\text{Sb}_{15}\text{S}_{43}$

Named in 1967 for John Playfair (1748–1819), Scottish scientist. MON *P2₁/m*. $a = 45.12$, $b = 4.139$, $c = 21.45$, $\beta = 92.53^\circ$, $Z = 4$, $D = 5.64$. 20-563: 3.98₄ 3.49₄ 3.39₁₀ 3.32₁₀ 2.97₄ 2.79₇ 2.09₆ 1.77₄. Small tabular crystals. Lead-gray to black, black streak, metallic luster. Cleavage {100}, perfect. H = $3\frac{1}{2}$, VHN₅₀ = 154. R = 35.4–39.2 (589 nm); strongly pleochroic. *Madoc, ON, Canada*; Novoye, Khaidarkan, Kyrgyzstan. BM *CM* 9:191(1967), *AM* 53:1424(1968), *ABI*:412.

3.6.5.1 Cannizzarite $\text{Pb}_4\text{Bi}_6\text{S}_{13}$

Named in 1925 for Stanislao Cannizzaro (1826–1910), Italian chemist. MON *P2₁/m*. $a = 4.13$, $b = 4.09$, $c = 15.48$, $\beta = 98.56^\circ$, $Z = 1$, $D = 6.95$. 9-357: 3.82₁₀ 3.49₃ 3.01₆ 2.87₅ 2.68₆ 2.22₅ 2.03₅ 1.91₄. Thin laths and felted masses. Pale gray, metallic luster. H = 3, VHN₂₀ = 132. G = 6.7. R = 49.2–51.6 (540 nm); strongly anisotropic. Landsman Camp, Graham Co., AZ; Santa Maria, Grisons, and Goppenstein, Valais, Switzerland; *Vulcano, Lipari Is., Italy*; Shu-

milkovsk deposit, Transbaikal, and Vysokogorsk deposit, Far Eastern Region, Russia. BM *DI:472*; *AM 38:536(1953)*, *72:229(1987)*; *ABI:80*.

3.6.5.2 Wittite $Pb_3Bi_4(S, Se)_9$

Named in 1924 for Th. Witt (1847–1908), Swedish mining engineer. MON *P2/m*. $a = 4.19$, $b = 4.08$, $c = 15.56$, $\beta = 101.4^\circ$, $Z = 1$, $D = 6.91$. *25-460*: 3.63₃ 3.38₁₀ 2.99₆ 2.90₉ 2.75₃ 2.13₄ 2.04₈ 1.75₃. Massive. Lead-gray, black streak, metallic luster. One good cleavage. $H = 2-2\frac{1}{2}$, $VHN_{25} = 45-63$. $G = 7.12$. $R = 42.4-44.0$ (540 nm); distinctly anisotropic. Middlemarch Canyon, Cochise Co., AZ; *Falun, Sweden*; Nevskoe deposit, Magadan district, Russia. BM *DI:451*, *P&J:392*, *AM 65:789(1980)*, *ABI:578*, *TMPM 46:137(1992)*.

3.6.6.1 Launayite $Pb_{22}Sb_{26}S_{61}$

Named in 1967 for Louis de Launay (1860–1938), French economic geologist. MON *C2/m*. $a = 42.58$, $b = 4.015$, $c = 32.16$, $\beta = 102.00^\circ$, $Z = 2$, $D = 5.98$. *20-568*: 4.17₈ 3.97₃ 3.45₁₀ 3.40₆ 2.92₈ 2.84₅ 2.75₅ 2.01₇. Microscopic grains. Lead-gray, black streak, metallic luster. Cleavage {100}, {001}, perfect. $H = 3\frac{1}{2}$, $VHN = 179$. $R = 36.9-43.8$ (546 nm); strongly anisotropic. *Madoc, ON, Canada*. BM *CM 9:191(1967)*, *AM 53:1423(1968)*, *ABI:288*.

3.6.7.1 Jamesonite $Pb_4FeSb_6S_{14}$

Named in 1825 for Robert Jameson (1774–1854), Scottish mineralogist. Forms a series with benavidesite. MON *P2₁/a*. $a = 15.65$, $b = 19.03$, $c = 4.03$, $\beta = 91.8^\circ$, $Z = 2$, $D = 5.71$. *13-461*: 4.06₃ 3.82₃ 3.70₄ 3.43₁₀ 3.08₃ 2.81₄ 2.71₄ 1.91₃. Acicular crystals, as radiating and fibrous masses. Lead-gray, lead-gray streak, metallic luster. Cleavage {001}, good; brittle. $H = 2\frac{1}{2}$, $VHN_{100} = 66-86$. $G = 5.5-5.7$. $R = 34.0-39.3$ (540 nm); strongly anisotropic. Widely distributed in small amounts. Slate Creek, Shoshone Co., ID; St. Paul mine, Monashee Mt., BC, Canada; Noche Buena(*) and Noria mine, ZAC, Mexico; *Endellion, Cornwall, England*; Sala, Vastmannland, Sweden; Clausthal, Harz, and Freiberg, Saxony, Germany; Příbram, Czech Republic; Aranyidka and Baia Sprie, Romania; Trepca(*), Serbia; Balkumeisk deposit, Yakutia, Russia; Dachang, Guangxi, China; Chichibu mine, Saitama, Japan; Rivertree, NSW, Australia; Oruro(*), Bolivia. BM *DI:451*, *R:765*, *P&J:217*, *CM 25:667(1987)*, *ABI:247*.

3.6.7.2 Benavidesite $Pb_4(Mn, Fe)Sb_6S_{14}$

Named in 1982 for Alberto Benavides (b.1920), Peruvian mining engineer. Forms a series with jamesonite. MON *P2₁/a*. $a = 15.74$, $b = 19.14$, $c = 4.06$, $\beta = 91.50^\circ$, $Z = 2$, $D = 5.60$. *35-546*: 4.10₃ 3.85₂ 3.45₁₀ 3.17₂ 3.10₂ 2.96₂ 2.83₄ 2.74₃. Microscopic acicular crystals and rounded grains, also massive. Lead-gray, dark gray-brown streak, metallic luster. $H = 2\frac{1}{2}$, $VHN_{15} = 97$. $R = 39.0-42.4$ (540 nm); strongly anisotropic. Sättra mine, near Doverstorp, Södermanland, Sweden; Dachang, Guangxi, China; *Uchucchacua, Cajatambo*

Prov., Peru. BM *BM* 105:166(1982), *AM* 68:280(1983), *CM* 25:667(1987), *ABI*:44.

3.6.8.1 Dadsonite $Pb_{21}Sb_{23}S_{55}Cl$

Named in 1969 for Alexander S. Dadson (1906–1958), Canadian mineralogist. MON Space group unknown. $a = 19.05$, $b = 4.11$, $c = 17.33$, $\beta = 96.33^\circ$, $Z = 0.5$, $D = 5.51$. 21-942: 4.10₄ 3.78₇ 3.62₆ 3.38₁₀ 2.84₇ 2.79₆ 2.22₄ 2.07₄. Minute fibrous crystals. Lead-gray, black streak, metallic luster. $H = 2\frac{1}{2}$, $VHN_{15} = 226-279$. $G = 5.68$. $R = 39.1-43.9$ (540 nm); distinctly anisotropic. Red Bird mine, Pershing Co., NV; Madoc, ON, and *Giant property, Yellowknife, NWT, Canada*; Saint-Pons, Provence, France; Wolfsberg, Germany. BM *MM* 37:437(1969), *CM* 17:601(1979), *ABI*:125.

3.6.9.1 Parajamesonite $Pb_4FeSb_6S_{14}$

Named in 1947 as a dimorph of jamesonite. Probably ORTH Space group unknown. 41-1401: 4.67₄ 4.21₁₀ 3.78₆ 3.29₁ 3.01₁ 2.49₂ 2.23₂ 2.02₂. Columnar crystals to 8 mm. Gray, metallic luster. $G = 5.48$. *Herja, Romania.* BM *SMPM* 27:183(1947), *AM* 34:133(1949), *ABI*:384.

3.6.10.1 Eclarite $Pb_9(Cu, Fe)Bi_{12}S_{28}$

Named in 1984 for Eberhard Clar (b.1904), Austrian mineralogist. ORTH *Pnma*. $a = 54.76$, $b = 4.030$, $c = 22.75$, $Z = 4$, $D = 6.88$. 35-627: 3.49₄ 3.41₁₀ 3.01₆ 2.89₇ 2.74₄ 2.14₅ 2.04₅ 2.01₈. Fan-shaped aggregates of acicular crystals to 1.5 cm, and granular. Tin-white, metallic luster. Cleavage {010}, distinct. $H = 2\frac{1}{2}$, $VHN_{50} = 87-191$. $G = 6.85$. $R = 42.9-47.2$ (546 nm); distinctly anisotropic. *Barenbad, west of Hollersbachtal, Salzburg, Austria.* BM *TMPM* 32:103,259(1984), *AM* 70:215(1985), *ABI*:143.

3.6.11.1 Vikingite $Pb_8Ag_5Bi_{13}S_{30}$

Named in 1977 for the Vikings, who settled Greenland in the tenth century. MON *C2/m*. $a = 13.603$, $b = 25.248$, $c = 4.112$, $\beta = 95.55^\circ$, $Z = 1$, $D = 6.94$. 43-690: 3.62₄ 3.40₁₀ 3.05₄ 2.91₅ 2.10₄ 2.06₈ 1.88₄ 1.75₉. Microscopic lamellar grains. Gray, metallic luster. $H = 3\frac{1}{2}$, $VHN_{50} = 185$. $R = 43.1-43.8$ (546 nm); distinctly anisotropic. Apache Hills, near Hachita, Grant Co., NM; South Mountain, Owyhee Co., ID; Gabbs, Nye Co., NV; *Ivigut, Greenland*; La Roche Balue, France; Kochbulak deposit, Uzbekistan. BM *NJMA* 131:56(1977), *AM* 64:243(1979), *ABI*: 557, *NJMM*:454(1992).

3.6.12.1 Sorbyite $Pb_{19}(Sb, As)_{20}S_{49}$

Named in 1967 for Henry C. Sorby (1826–1908), English chemist and the founder of metallography. MON *C2/m*. $a = 45.15$, $b = 4.146$, $c = 26.53$, $\beta = 113.4^\circ$, $Z = 2$, $D = 5.52$. 20-564: 4.13₆ 4.02₄ 3.64₃ 3.44₁₀ 3.38₉ 3.04₄ 2.96₆ 2.10₅. Microscopic needles and prismatic crystals. Black, black streak, metallic luster. Cleavage {001}, perfect. $H = 3\frac{1}{2}$, $VHN_{50} = 175$. $R = 37-43$

(546 nm); strongly anisotropic. Near Candelaria, Mineral Co., NV; *Madoc, ON, Canada*; Novoye, Khaidarkan, Kyrgyzstan. *BM CM 9:191(1967)*, *MR 13:93(1982)*, *ABI:485*.

3.6.13.1 Baumhauerite $\text{Pb}_3\text{As}_4\text{S}_9$

Named in 1902 for Heinrich A. Baumhauer (1848–1926), German mineralogist. *TRIC P1*. $a = 22.80$, $b = 8.357$, $c = 7.89$, $\alpha = 90.05^\circ$, $\beta = 97.26^\circ$, $\gamma = 89.88^\circ$, $Z = 4$, $D = 5.33$. A monoclinic polytype, baumhauerite-2A, is known. *12-281: 4.15₁₀ 3.59₈ 3.47₈ 3.26₆ 3.02₆ 2.96₉ 2.77₈ 2.72₆*. Short prismatic crystals to 25 mm and granular aggregates. Lead-gray to steel-gray, chocolate-brown streak, metallic luster. Cleavage {100}, good; conchoidal fracture. $H = 3$, $\text{VHN}_{50} = 179$. $G = 5.33$. $R = 35.1\text{--}39.2$ (540 nm); strongly anisotropic. Sterling Hill, NJ; Zuni mine, Silverton, CO; *Madoc, ON, Canada*; *Lengenbach, Binn, Switzerland*; Novoye, Kaidarkan, Kyrgyzstan. *BM DI:460, P&J:85, ABI:42, AM 75:915(1990)*.

3.6.14.1 Sinnerite $\text{Cu}_6\text{As}_4\text{S}_9$

Named in 1964 for Rudolph von Sinner (1890–1961), Swiss scientist. *TRIC P1*. $a = 9.06$, $b = 9.83$, $c = 9.08$, $\alpha = 90.00^\circ$, $\beta = 109.50^\circ$, $\gamma = 107.80^\circ$, $Z = 2$, $D = 4.47$. *25-264: 3.34₂ 3.02₁₀ 2.61₄ 1.85₈ 1.58₇ 1.56₂ 1.31₂ 1.21₃*. Prismatic crystals 1–2 mm. Steel-gray, metallic luster. $\text{VHN} = 357\text{--}390$. $R = 29.5\text{--}31.5$ (546 nm); distinctly anisotropic. *Lengenbach, Binn, Switzerland*. *BM SMPM 44:5(1964)*, *45:691(1965)*, *AM 57:824(1972)*, *ABI:477*.

3.6.15.1 Berryite $\text{Pb}_3(\text{Ag,Cu})_5\text{Bi}_7\text{S}_{16}$

Named in 1966 for Leonard G. Berry (1914–1982), Canadian mineralogist. *MON P2₁/m*. $a = 12.707$, $b = 4.021$, $c = 28.92$, $\beta = 102.6^\circ$, $Z = 2$, $D = 6.87$. *19-703: 3.74₆ 3.51₁₀ 3.50₉ 3.26₆ 3.06₅ 2.91₁₀ 2.88₇ 2.82₇*. Lathlike aggregates to 1 mm; also massive, granular. Blue-gray, metallic luster. $H = 3$, $\text{VHN}_{100} = 131\text{--}152$. $G = 6.7$. $R = 38.6\text{--}47.0$ (546 nm); distinctly anisotropic. *Missouri mine, Park Co.*, and Mike mine, San Juan Co., CO; near Owen Lake, south of Houston, BC, Canada; Ivigtut, Greenland; Nordmark, Värmland, Sweden; Grube Clara, Black Forest, Germany; Kochbulak deposit, Uzbekistan; Adrasman, Kaptar–Hana, and Tary Ekan deposits, Karamazar, Tajikistan. *BM CM 8:407(1966)*, *11:1016(1973)*; *P&J:86; ABI:48*.

3.6.16.1 Robinsonite $\text{Pb}_4(\text{Sb,Bi})_6\text{S}_{13}$

Named in 1952 for Stephen C. Robinson (1911–1981), Canadian mineralogist. *MON I2/m*. $a = 23.698$, $b = 3.980$, $c = 24.466$, $\beta = 93.9^\circ$, $Z = 4$, $D = 5.7$. *35-513: 4.06₅ 3.97₅ 3.81₄ 3.44₉ 3.41₁₀ 3.21₅ 3.04₄ 2.67₅*. Striated prismatic crystals, also massive, fibrous to compact. Bluish lead-gray, metallic luster. Uneven fracture, brittle. $H = 2\frac{1}{2}\text{--}3$. $G = 5.64\text{--}5.75$. Strongly anisotropic. *Red Bird mine, Pershing Co.*, and Silver Coin mine, Humboldt Co., NV; *Madoc, ON*, and Dodger mine, Salmo, BC, Canada; Vall de Ribes, eastern Pyrenees, Spain;

Male Zelezne, Czech Republic. *BM AM 37:438(1952), R:764, CM 20:97(1982), ABI:443.*

3.6.17.1 Liveingite $\text{Pb}_9\text{As}_{13}\text{S}_{28}$

Named in 1901 for George D. Liveing (1827–1924), English chemist. Synonym: Rathite-II. *MON P2₁/m. a = 7.944, b = 70.84, c = 8.335, $\beta = 90.13^\circ$, Z = 4, D = 5.29. 31-678: 4.11₉ 3.70₇ 3.42₉ 2.99₁₀ 2.35₉ 2.09₉ 1.93₈ 1.92₈. Prismatic crystals to 4 cm. Lead-gray to gray-black, chocolate brown streak, dull metallic luster. Cleavage {100}, perfect. H = 3, VHN₁₀₀ = 169–180. G = 5.3. R = 35.6–40.1 (540 nm); distinctly anisotropic. *Lengenbach, Binn, Switzerland. BM DI:462, AM 54:1498(1969), R:751, ABI:298.**

3.6.18.1 Weibullite $\text{Pb}_6\text{Bi}_8(\text{S}, \text{Se})_{18}$

Named in 1910 for Mats Weibull (1856–1923), Swedish mineralogist, who first described it. *ORTH Pnma. a = 53.68, b = 4.11, c = 15.40, Z = 4, D = 6.73. 29-761: 3.85₁₀ 3.64₅ 3.27₈ 3.08₉ 3.02₇ 2.81₇ 2.28₆ 2.14₆. Indistinct prismatic crystals; usually massive, prismatic to fibrous, or foliated. Steel-gray, dark gray streak, metallic luster. One good cleavage, very brittle. H = 2–3, VHN₁₀₀ = 136–156. G = 6.97. R = 40.0–46.6 (540 nm); strongly anisotropic. *Falun, Sweden; Nevskoe deposit, Magadan district, Russia. BM DI:473, R:778, P&J:387, ABI:570, CM 18:1(1980).**

3.6.19.1 Kobellite $\text{Pb}_{22}\text{Cu}_4(\text{Bi}, \text{Sb})_{30}\text{S}_{69}$

Named in 1839 for Franz von Kobell (1803–1882), German mineralogist. Forms a series with tintinaite. *ORTH Pnmm. a = 22.62, b = 34.08, c = 4.02, Z = 1, D = 6.51. 8-122: 3.93₃ 3.51₁₀ 3.38₁₀ 3.11₃ 2.84₅ 2.13₆ 2.03₄ 1.74₄. Massive, fibrous or radiated; also granular. Lead-gray, black streak, metallic luster. Cleavage {010}, good. H = 2½, G = 6.48. R = 41.9–46.4 (540 nm); distinctly anisotropic. Superior quarry, Raleigh, Wake Co., NC; Silver Bell mine, Red Mountain, San Juan Co., and Leadville, Lake Co., CO; Dodger mine, Salmo, BC, and Tintina mines, YT, Canada; *Vena mine, near Askersund, Sweden; Rammelsberg, Harz, Germany; Smolotely, near Pribram, Czech Republic; Ciclova, Romania; Ustarasai deposit, Uzbekistan; Zeehan, TAS, Australia. BM DI:447, R:780, P&J:225, ABI:268.**

3.6.19.2 Tintinaite $\text{Pb}_{22}\text{Cu}_4(\text{Sb}, \text{Bi})_{30}\text{S}_{69}$

Named in 1968 for the locality. Forms a series with kobellite. *ORTH Pnmm. a = 22.234, b = 34.158, c = 4.049, Z = 1, D = 5.52. 20-565: 3.96₄ 3.72₃ 3.52₈ 3.40₁₀ 3.27₄ 2.87₅ 2.83₄ 2.71₇. Blades and small masses to 2 mm. Lead-gray, black streak, metallic luster. Cleavage {010}, good. VHN₅₀ = 151. G = 5.48. *Tintina mines, YT, and Deer Park mine, Rossland, BC, Canada; Boliden, Västerbotten, Sweden. BM CM 9:371(1968), 22:219(1984); AM 54:573(1969), 70:441(1985); ABI:532.**

FÜLÖPPITE GROUP

The fulöppite minerals are a group of monoclinic Pb–Sb sulfosalts with the general formula

where

$$n = 0-3$$

and the space group is $C2/c$. The fulöppite group minerals are rare, and their structures complex (see figure).

FÜLÖPPITE GROUP

Mineral	Formula	Space Group	Space				
			<i>a</i>	<i>b</i>	<i>c</i>	β	
Fulöppite	$\text{Pb}_3\text{Sb}_8\text{S}_{15}$	$C2/c$	13.44	11.73	16.93	94.71	3.6.20.1
Plagionite	$\text{Pb}_5\text{Sb}_8\text{S}_{17}$	$C2/c$	13.47	11.82	19.99	107.33	3.6.20.2
Heteromorphite	$\text{Pb}_7\text{Sb}_8\text{S}_{19}$	$C2/c$	13.63	11.94	21.29	90.92	3.6.20.3
Semseyite	$\text{Pb}_9\text{Sb}_8\text{S}_{21}$	$C2/c$	13.64	11.96	24.46	105.87	3.6.20.4
Rayite	$\text{Pb}_8(\text{Ag, Tl})_2\text{Sb}_8\text{S}_{21}$	$C2/c$	13.60	11.96	24.49	103.94	3.6.20.5

3.6.20.1 Fulöppite $\text{Pb}_3\text{Sb}_8\text{S}_{15}$

Named in 1929 for Bela Fulöpp, Hungarian mineral collector. Fulöppite group. MON $C2/c$. $a = 13.44$, $b = 11.73$, $c = 16.93$, $\beta = 94.71^\circ$, $Z = 4$, $D = 5.19$. $22-648$: 3.89_{10} 3.63_5 3.38_5 3.23_7 3.20_9 2.92_8 2.82_8 2.75_7 . Short prismatic and pyramidal crystals to 2 mm. Gray-black, gray-black streak, metallic luster. $H = 2\frac{1}{2}$, $\text{VHN}_{100} = 140-157$. $G = 5.22$. $R = 31.9-40.1$ (540 nm); distinctly anisotropic. Wet Swine Gill, Caldbeck fells, Cumbria, England; Auliac, Cantal, Bodennec, Finistere, and Bournac, Montagne Noire, France; *Baia Mare, Romania*. BM *DI:463*, *R:762*, *P&J:170*, *ABI:168*.

3.6.20.2 Plagionite $\text{Pb}_5\text{Sb}_8\text{S}_{17}$

Named in 1833 from the Greek for *oblique*, in reference to the obliquity of the crystals. Fulöppite group. MON $C2/c$. $a = 13.47$, $b = 11.82$, $c = 19.99$, $\beta = 107.33^\circ$, $Z = 4$, $D = 5.59$. $22-1129$: 5.87_4 3.87_8 3.77_7 3.61_5 3.26_9 3.21_{10} 2.91_9 2.62_6 . Tabular striated crystals to 1 cm; also massive, granular to compact. Dark lead-gray color and streak, metallic luster. Cleavage $\{112\}$, very good; conchoidal to uneven fracture; brittle. $H = 2\frac{1}{2}$, $\text{VHN}_{100} = 150$. $G = 5.5-5.6$. $R = 34.0-42.5$ (540 nm); distinctly anisotropic. Porter claim, Carbon Hill, Wheaton R. District, YT, Canada; Leyraux, Cantal, Chazelles, Haute-Loire, and Bournac, Montagne Noire, France; *Wolfsberg*(*), *Harz, Germany*; Azatec deposit, Armenia; Balkumeisk deposit, Yakutia, Russia; Kochbulak(*), Uzbekistan; San José mine, Oruro, Bolivia. BM *DI:464*, *R:762*, *P&J:301*, *ZK 139:351(1974)*, *ABI:407*.

PLAGIONITE: $Pb_5Sb_5S_{17}$

Coordination is irregular and for Sb, sometimes asymmetric, typical for sulfosalts.

3.6.20.3 Heteromorphite $Pb_7Sb_8S_{19}$

Named in 1876 from the Greek for *different* and *form*, in allusion to the difference from a proposed dimorphous mineral. Fulopite group. MON $C2/c$. $a = 13.63$, $b = 11.94$, $c = 21.29$, $\beta = 90.92^\circ$, $Z = 4$, $D = 5.82$. 30-693: 3.86₈ 3.82₇ 3.41₉ 3.31₉ 3.30₉ 3.26₈ 3.10₈ 2.89₁₀. Pyramidal crystals and massive. Black, black streak, metallic luster. Cleavage {112}, good; uneven fracture; brittle. $H = 2\frac{1}{2}$ -3. $G = 5.6$ -5.7. Arnsberg, Westphalia, and Wolfsberg, Harz, Germany; Příbram, Czech Republic; Kara Kamar deposit, Tajikstan; Yecora, SON, Mexico. BM *DI*:465, *R*:763, *ZK* 151:193(1980), *ABI*:217.

3.6.20.4 Semseyite $Pb_9Sb_8S_{21}$

Named in 1881 for Andor von Semsey (1833-1923), Hungarian mineral collector. Fulopite group. MON $C2/c$. $a = 13.64$, $b = 11.96$, $c = 24.46$, $\beta = 105.87^\circ$, $Z = 4$, $D = 6.08$. 22-1130: 4.22₄ 3.88₆ 3.81₉ 3.35₇ 3.26₁₀ 2.95₉ 2.86₈ 2.15₅. Tabular and prismatic crystals, sometimes grouped in rosettes. Black, black streak, metallic luster. Cleavage {112}, perfect. $H = 2\frac{1}{2}$. $G = 6.03$. $R = 36.0$ -43.3 (540 nm); strongly anisotropic. Brobdignag prospect, near Silverton, CO; Madoc, ON, Canada; Louisa mine, Eskdale, Dumfriesshire, Scotland; Bwlch mine, near Conway, Wales; Les Anglais mine, Cantal, Montlucan and Bournac, Montagne Noire, France; Wolfsberg, Harz, Germany; Milesov, Krasna Hora, and Bohutin, Czech Republic; Baia Sprie, Herja, and Rodna, Romania; Madan, Bulgaria; Julcani district, Peru; San José mine, Oruro, Bolivia. BM *DI*:466, *R*:764, *P&J*:341, *ABI*:471.

3.6.20.5 Rayite $\text{Pb}_8(\text{Ag,Tl})_2\text{Sb}_8\text{S}_{21}$

Named in 1983 for Santosh K. Ray, Indian scientist. Fülöppite group. *MON C2/c*. $a = 13.60$, $b = 11.96$, $c = 24.49$, $\beta = 103.94^\circ$, $Z = 4$, $D = 6.13$. *35-594*: 3.90_3 3.74_3 3.37_{10} 3.26_9 2.98_5 2.88_2 2.29_2 2.06_3 . Microscopic grains. Lead-gray, lead-gray streak, metallic luster. No cleavage. $R = 37.5\text{--}39.6$ (540 nm); distinctly anisotropic. *Rajpura-Dariba, Udaipur district, Rajasthan, India*. *BM NJMM:296(1983)*, *AM 69:211(1984)*, *ABI:435*.

3.7.1.1 Matildite AgBiS_2

Named in 1883 for the locality. *HEX-R P3m1*. $a = 4.066$, $c = 18.958$, $Z = 3$, $D = 6.99$. *24-1031*: 6.31_3 3.45_2 3.30_8 2.83_{10} 2.03_5 1.97_6 1.71_3 1.25_3 . Prismatic crystals rare; usually massive, granular. Iron-gray to black, pale gray streak, metallic luster. No cleavage, uneven fracture, brittle. $H = 2\frac{1}{2}$, $\text{VHN}_{100} = 72\text{--}85$. $G = 6.9$. $R = 42.8\text{--}48.4$ (540 nm); weakly anisotropic. Leadville, Lake Co., Revell mine, near Silver Cliff, Custer Co., and near Lake City, Hinsdale Co., CO; Bisbee, AZ; Mayflower mine, Boise Basin area, Ada Co., ID; Darwin mine, Inyo Co., CA; Cobalt, ON, Glacier Gulch, BC, and Camsell R., Great Bear Lake, NWT, Canada; Schapbach, Black Forest, Germany; Panasqueira, Portugal; Bustarviejo, near Madrid, Spain; *Matilda mine, near Morococha, Peru*. *BM DI:429*, *R:665*, *P&J:366*, *ABI:315*.

3.7.1.2 Bohdanowiczite AgBiSe_2

Named in 1967 for Karol Bohdanowicz (1864–1947), Polish economic geologist. *HEX-R P3m1*. $a = 4.205$, $c = 19.650$, $Z = 3$, $D = 7.87$. *29-1441*: 3.57_3 3.42_6 2.93_{10} 2.10_8 2.04_8 1.71_5 1.46_5 1.29_4 . Microscopic anhedral grains. Gray, metallic luster. $H = 3$, $\text{VHN} = 63\text{--}96$. $R = 49.8\text{--}51.5$ (546 nm); distinctly anisotropic. Kidd Creek mine, near Timmins, ON, Canada; near Vanos, CHIH, Mexico; Frederik VII mine, near Julianehaab, Greenland; *Kletno, Sudetes Mts., Poland*. *BM MM 43:131(1979)*, *AM 64:1333(1979)*, *CM 18:353(1980)*, *ABI:59*.

3.7.1.3 Volynskite AgBiTe_2

Named in 1965 for I. S. Volynskii (1900–1962), Russian mineralogist. *HEX-R P3m1*. $a = 4.468$, $c = 20.755$, $Z = 3$, $D = 7.943$. *18-1173*: 3.21_8 3.09_{10} 2.33_3 2.21_5 2.15_3 1.82_3 1.61_2 1.55_2 . Microscopic grains. Gray, metallic luster. $H = 2\text{--}2\frac{1}{2}$, $\text{VHN}_{25} = 42\text{--}66$. $R = 53.0\text{--}54.6$ (540 nm); weakly pleochroic and anisotropic. Campbell mine, Bisbee, AZ; Ashley deposit, Bannockburn Twp., ON, Canada; Ivigtut, Greenland; Glava, Värmland, Sweden; Ilomantsi, Finland; *Armenia*, undisclosed locality; Zhana-Tyube Au-Te deposit, Kazakhstan; Kochbulak deposit, Uzbekistan; Champion Reef mine, Kolar, India; Yokozuru mine, Kyushu, Japan; Kambalda, WA, Australia. *BM AM 51:531(1966)*, *R:429*, *CM 21:137(1983)*, *ABI:561*.

3.7.2.1 Trechmannite AgAsS_2

Named in 1905 for Charles O. Trechmann (1851–1917), English mineralogist. Dimorphous with smithite. *HEX-R* $R\bar{3}m$. $a = 13.98$, $c = 9.12$, $Z = 18$, $D = 4.78$. $16-700$: 7.0_6 4.26_6 3.64_6 3.15_8 3.04_6 2.70_{10} 1.94_7 1.89_8 . Small equant crystals. Cinnabar-red color and streak, adamantine luster. Cleavage $\{1011\}$, good; $\{0001\}$, fair; conchoidal fracture; brittle. $H = 1\frac{1}{2}-2$, $VHN_{25} = 97-100$. $R = 23.4-29.9$ (540 nm); moderately anisotropic. Niederbeerbach, Odenwald, Germany; *Lengenbach, Binn, Switzerland*. *BM DI:432, SMPM 45:695(1965), ZK 129:163(1969), ABI:536*.

3.7.3.1 Smithite AgAsS_2

Named in 1905 for G. F. Herbert Smith (1872–1953), English mineralogist. Dimorphous with trechmannite. *MON* $A2/a$. $a = 17.23$, $b = 7.78$, $c = 15.19$, $\beta = 101.2^\circ$, $Z = 24$, $D = 4.93$. $13-136(\text{syn})$: 3.21_8 2.82_{10} 2.72_6 1.98_3 1.95_5 1.70_4 1.66_4 1.61_4 . Platy pseudo-hexagonal and equant crystals to 3 mm. Cinnabar-red color and streak, adamantine luster. Cleavage $\{100\}$, perfect; conchoidal fracture; brittle. $H = 1\frac{1}{2}-2$. $G = 4.88$. $R = 35.0-36.6$ (540 nm). Silver mines, Co. Tipperary, Eire; Jas Roux, Hautes-Alpes, France; Wiesloch, Black Forest, Germany; *Lengenbach, Binn, Switzerland*. *BM DI:430, R:726, P&J:344, ABI:481*.

3.7.3.2 Miargyrite AgSbS_2

Named in 1829 from the Greek for *less* and *silver*, as it contains less silver than other red silver sulfosalts. *MON* $A2/a$. $a = 13.324$, $b = 4.410$, $c = 12.881$, $\beta = 98.48^\circ$, $Z = 8$, $D = 5.25$. $19-1137(\text{syn})$: 3.44_8 3.19_3 3.10_3 2.89_{10} 2.75_7 2.01_4 1.97_3 1.91_2 . Thick tabular crystals to 1 cm, often deeply striated; also massive. Steel-gray to iron-black, cherry-red streak, adamantine to metallic luster. Cleavage $\{010\}$, imperfect; subconchoidal fracture. $H = 2\frac{1}{2}$. $G = 5.2-5.3$. $R = 27.4-40.0$ (540 nm); strongly anisotropic. Widely distributed in small amounts, sometimes an important ore mineral. Silver City and Flint districts, Owyhee Co., ID; Randsburg district(*), San Bernardino Co., CA; Sombrefrete and Veta Grande, ZAC, and Catorce, SLP, Mexico; Andreasberg(*) and Clausthal, Harz, and *Braunsdorf, near Freiberg, Saxony, Germany*; Pribram and Kutna Hora, Czech Republic; Hiendelaencina, Guadalajara Prov., Spain; Strezhen deposit, Altai, Russia; Huancavelica, Peru; Tres Puntas, Atacama, and Huantajaya, Tarapaca, Chile; Colquechaca, Potosi, and Pulcayo, Bolivia. *BM DI:424, R:662, P&J:268, ABI:330*.

3.7.4.1 Aramayoite $\text{Ag}(\text{Sb}, \text{Bi})\text{S}_2$

Named in 1926 for Felix Aramayo (1846–1929), Bolivian mine director. *TRIC* $P\bar{1}$. $a = 7.74$, $b = 8.84$, $c = 8.32$, $\alpha = 100.7^\circ$, $\beta = 90.00^\circ$, $\gamma = 103.9^\circ$, $Z = 6$, $D = 5.65$. $4-696$: 3.44_2 3.22_4 3.16_1 2.82_{10} 2.05_2 1.94_3 1.71_2 1.40_2 . Platy crystals. Iron-black, red-brown to black streak, metallic luster. Cleavage $\{010\}$, perfect; $\{100\}$, fair; $\{001\}$, poor; flexible cleavage flakes; inelastic; sectile. $H = 2\frac{1}{2}$. $G = 5.60$. $R = 39.0-42.2$ (540 nm); strongly anisotropic. Niarada,

Flathead Co., MT; Monts de Blond and Le Bourneix, Hautes-Vienne, and Ste.-Marie-aux-Mines, Haut-Rhin, France; Herminia, Julcani district, and San Genaro mine, Huancavelica, Peru; *Animas mine*, Chocaya, Bolivia; El Indio mine, east of Coquimbo, Chile. BM *DI:427, R:664, P&J:70, ABI:17.*

3.7.5.1 Chalcostibite CuSbS_2

Named in 1847 for the composition. ORTH *Pnam*. $a = 6.016$, $b = 14.505$, $c = 3.800$, $Z = 4$, $D = 5.00$. *24-347*: 3.11₁₀ 3.09₉ 2.99₉ 2.97₉ 2.30₇ 2.11₆ 1.89₆ 1.75₈. Bladed crystals to 4 cm, also massive. Lead-gray to iron-gray, gray streak, metallic luster. Cleavage {010}, perfect; {001}, {100} less so; sub-conchoidal fracture; brittle. $H = 3-4$, $VHN_{50} = 226-279$. $G = 4.95$. $R = 37.5-43.7$ (540 nm); distinctly anisotropic. Mt. Washington mine, Vancouver Is., BC, and Porter property, Carbon Hill, YT, Canada; Nacozari and Moctezuma, SON, Mexico; *Wolfsberg, Harz, Germany*; Milesov and Krasna Hora, Czech Republic; St.-Pons(*), Provence, France; Capileira, Granada Prov., Spain; Tereksai, Kyrgyzstan; Darasun deposit, Yakutia, Russia; Macayan, Philippines; Rar el Anz(*), east of Casablanca, Morocco; Colquechaca, Unica, Oruro, and other localities, Bolivia. BM *DI:433, R:717, P&J:119, ABI:90.*

3.7.5.2 Emplectite CuBiS_2

Named in 1853 from the Greek for *entwined* or *interwoven*, in allusion to its sometimes intimate association with quartz. ORTH *Pnam*. $a = 6.137$, $b = 14.541$, $c = 3.898$, $Z = 4$, $D = 6.43$. *10-474*: 7.38₅ 3.23₉ 3.13₇ 3.05₁₀ 2.17₄ 1.86₃ 1.80₃ 1.66₃. Striated prismatic crystals, flattened on {010}. Tin-white to gray, metallic luster. Cleavage {010}, perfect; {001}, less so; conchoidal to uneven fracture; brittle. $H = 2$, $VHN_{100} = 181$. $G = 6.38$. $R = 35.9-37.0$ (540 nm); strongly anisotropic. Bisbee, AZ; El Cobre mine, Concepcion del Oro, ZAC, Mexico; Corrie Buie, Perthshire, Scotland; Amdal mines, Telemarken, Norway; *Johanngeorgenstadt* and other localities, *Saxony, Germany*; Krupka and Cinvec, Czech Republic; Zidarova, Bulgaria; Ankavan deposit, Armenia; Khayragatsch deposit, Kuramin Mts., Uzbekistan; Akenobe mine, Hyogo Pref., and Hade mine, Okayama Pref., Japan; Cerro Blanco, near Copiapo, Chile. BM *DI:435, R:719, P&J:154, ABI:145.*

3.7.6.1 Lorandite TlAsS_2

Named in 1894 for Eötvös Lorand (1848-1919), Hungarian physicist. MON *P2₁/a*. $a = 12.29$, $b = 11.34$, $c = 6.14$, $\beta = 104.6^\circ$, $Z = 8$, $D = 5.51$. *19-1331*: 3.68₅ 3.59₆ 3.58₁₀ 3.18₂ 3.00₄ 2.88₆ 2.75₃ 2.63₃. Tabular, prismatic, or pyramidal crystals to 2 mm. Red tarnishing to dark gray, cherry-red streak, adamantine to metallic luster. Cleavage {100}, perfect; {201}, very good; {001}, good; flexible cleavage lamellae. $H = 2-2\frac{1}{2}$. $G = 5.53$. $R = 27.0-29.3$ (540 nm); strongly anisotropic. Rambler mine, near Encampment, Albany Co., WY; Carlin gold deposit, Eureka Co., NV; Lenggenbach, Binn, Switzer-

land; *Allchar, Macedonia*; Dzhizhikrut deposit, Tajikistan. BM *DI:437, R:732, P&J:244, ABI:302*.

3.7.7.1 Weissbergite $TlSbS_2$

Named in 1978 for Byron G. Weissberg (b.1930), New Zealand chemist. TRIC $P1$. $a = 11.8$, $b = 6.4$, $c = 6.1$, $\alpha = 109.9^\circ$, $\beta = 81.8^\circ$, $\gamma = 105.4^\circ$, $Z = 4$, $D = 6.22$. *29-1331*(syn); 3.75_1 3.71_1 3.65_1 3.58_1 2.97_{10} 2.84_1 2.35_1 1.49_1 . Microscopic anhedral grains. Steel-gray, dark gray streak, metallic luster. Cleavage: one perfect, two excellent, one good. $H = 1\frac{1}{2}$, $G = 5.79$. $R = 35.0\text{--}36.8$ (546 nm); strongly anisotropic. Lookout Pass, Tooele Co., UT; *Carlin gold mine, Eureka Co., NV*; *Allchar, Macedonia*. BM *AM 63:720(1978), ABI:572, MR 24:446(1993)*.

3.7.8.1 Sartorite $PbAs_2S_4$

Named in 1868 for Sartorius von Waltershausen (1809–1876), German mineralogist. Synonyms: scleroclase, skleroklas. MON $Pbnm$. $a = 19.62$, $b = 7.89$, $c = 4.19$, $\beta = 90^\circ$, $Z = 4$, $D = 5.13$. *11-76*: 9.8_1 4.13_5 3.52_9 3.46_8 2.95_9 2.75_{10} 2.33_7 2.10_4 . Prismatic crystals to 10 cm. Steel-gray, chocolate-brown streak, metallic luster. Cleavage {100}, fair; conchoidal fracture; very brittle. $H = 3$, $VHN = 196$. $G = 5.05$. $R = 34.6\text{--}38.6$ (540 nm); weakly anisotropic. Zuni mine, San Juan Co., CO; *Lengenbach*(*), *Binn, Switzerland*; Pitone quarry, near Seravezza, Tuscany, Italy. BM *DI:478, SMPM 45:714(1965), R:750, P&J:335, ABI:462*.

3.7.8.2 Guettardite $Pb(Sb,As)_2S_4$

Named in 1967 for Jean Guettard (1715–1786), French geologist. MON $P2_1/a$. $a = 20.095$, $b = 7.946$, $c = 8.783$, $\beta = 101.2^\circ$, $Z = 8$, $D = 5.49$. *20-561*: 4.19_5 3.90_5 3.52_{10} 2.80_9 2.67_5 2.65_5 2.33_4 2.14_4 . Minute acicular crystals and anhedral grains. Gray-black, metallic luster. Cleavage {001}, perfect; conchoidal fracture; very brittle. $H = 3\frac{1}{2}$, $VHN_{50} = 180\text{--}197$. $R = 36.1\text{--}41.2$ (546 nm). Brobdignag mine, San Juan Co., CO. *Madoc, ON, Canada*; Jas Roux deposits, Hautes-Alpes, France; Pitone quarry, near Seravezza, Tuscany, Italy; Novoye, Khaidarkan, Kyrgyzstan. BM *CM 9:191(1967), 18:13(1980); ABI:199*.

3.7.8.3 Twinnite $Pb(Sb,As)_2S_4$

Named in 1957 for Robert M. Thompson (1918–1967), Canadian mineralogist; Thompson means *son of Thomas*, which is Aramaic for *twinn*. TRIC $P1$. $a = 19.583$, $b = 7.981$, $c = 8.564$, $\alpha = 89.77^\circ$, $\beta = 89.62^\circ$, $\gamma = 90.27^\circ$, $Z = 8$, $D = 5.32$. *20-559*: 4.18_5 3.91_5 3.51_{10} 2.78_7 2.69_5 2.65_5 2.34_8 2.15_5 . Microscopic grains. Black, black streak, metallic luster. Cleavage {100}, perfect; polysynthetically twinned on {100}. $H = 3\frac{1}{2}$, $VHN_{50} = 147$. $R = 35.0\text{--}42.0$ (540 nm); strongly pleochroic. Hemlo gold deposit, near Marathon, and *Madoc, ON, Canada*; Jas Roux, Hautes-Alpes, France; Rujevac, Yugoslavia;

Novoye, Khaidarkan, Kyrgyzstan. *BM CM* 9:191(1967), *AM* 53:1424(1968), *ABI*:545.

3.7.9.1 Galenobismutite PbBi_2S_4

Named in 1878 for its composition. ORTH *Pnam*. $a = 11.840$, $b = 14.553$, $c = 4.081$, $Z = 4$, $D = 7.12$. $20\text{-}571$: 3.47_{10} 3.41_4 3.36_4 3.02_2 2.90_4 2.20_3 2.05_5 2.04_5 . Acicular and platy crystals, commonly massive, columnar to fibrous, or compact. Tin-white to lead-gray, black streak, metallic luster. Cleavage {110}, good; flexible cleavage plates. $H = 2\frac{1}{2}\text{-}3\frac{1}{2}$, $\text{VHN}_{100} = 142\text{-}194$. $G = 6.9\text{-}7.0$. $R = 45.9\text{-}48.8$ (540 nm); strongly anisotropic. Belzazzar mine, Boise Co., ID; Hatfield mine, Okanogan Co., and Germania mine, Stevens Co., WA; Siscoe mine, Gowganda, ON, Cariboo mine, Barkerville, BC, and Dublin Gulch, YT, Canada; Corrie Buie, Perthshire, Scotland; Gupworthy mine, Somerset, England; *Ko mine*, Nordmark, Gladhammar, and Falun(*), Sweden; Pechtelsgrun, Saxony, Germany; Oberpinzgau, Salzburg, Austria; Karaoba, Kazakhstan; Chatkal Mts., Uzbekistan; Strezhen deposit, Altai, Russia; Chenzhou, Hunan, China; Tae Hwa mine(*), South Korea; Kingsgate, NSW, and Mt. Farrell, TAS, Australia; Spekboom Valley, Transvaal, South Africa; Cerro Bonete, Bolivia. *BM DI*:471, *R*:777, *P&J*:172, *ABI*:171.

3.7.9.2 Sakharovaites $\text{Pb}(\text{Bi}, \text{Sb})_2\text{S}_4$

Named in 1955 for Marina S. Sakharova (b.1917), Russian mineralogist. ORTH Space group unknown. $25\text{-}1398$: 3.41_{10} 3.09_4 2.81_4 2.72_6 2.30_4 2.24_4 2.03_6 1.91_4 . Acicular crystals in radiating aggregates to 1 cm. Lead-gray, metallic luster. One perfect cleavage. Spissko-Gemer deposits, Czech Republic; *Ustarasaisk deposit*, Tian Shan Mts., Kazakhstan. *BM AM* 41:814(1956), 45:1134(1960); *ABI*:458.

3.7.9.3 Berthierite FeSb_2S_4

Named in 1827 for Pierre Berthier (1782-1861), French chemist. ORTH *Pnam*. $a = 11.883$, $b = 14.127$, $c = 3.755$, $Z = 4$, $D = 4.70$. $24\text{-}509(\text{syn})$: 4.35_4 3.66_9 3.63_5 3.18_8 3.00_5 2.86_8 2.62_9 2.60_{10} . Prismatic crystals to 1 cm, also massive, prismatic to fibrous and granular. Dark steel-gray, often with iridescent tarnish, dark brown-gray streak, metallic luster. Prismatic, indistinct cleavage. $H = 2\text{-}3$, $\text{VHN}_{100} = 201$. $G = 4.64$. $R = 30.9\text{-}40.8$ (540 nm); strongly anisotropic. Widely distributed. Boron, Kern Co., CA; San Martin, DGO, and Concepcion del Oro, ZAC, Mexico; Pontgibaud, Puy-de-Dome, Valcros, Provence, *Chazelles*, *Auvergne*, and Charbes, Alsace, France; Braunsdorf, near Freiberg, Saxony, Germany; Pribram and Kutna Hora, Czech Republic; Niccioleta mine, Tuscany, Italy; Herja(*) and Baia Sprie(*), Romania; Ribnova, Rhodope Mts., Bulgaria; Belukha, Transbaikal, Russia; Nakaze mine, Hyugo-ken, Honshu, Japan. *BM DI*:481, *R*:724, *P&J*:87, *ABI*:49.

3.7.9.4 Garavellite FeSbBiS_4

Named in 1979 for Carlo Garavelli (b.1929), Italian mineralogist. ORTH $Pnam$. $a = 11.439$, $b = 14.093$, $c = 3.754$, $Z = 4$, $D = 5.65$. $33\text{-}641$: 14.0_6 7.08_6 3.62_{10} 3.20_{10} 2.98_8 2.89_8 2.63_{10} 2.51_{10} . Microscopic anhedral grains. Gray, metallic luster. $H = 4$, $VHN_{50} = 212\text{-}222$. $R = 32.8\text{-}34.7$ (546 nm); strongly anisotropic. *Valle del Frigido, near Massa, Tuscany, Italy*. BM *MM 43:99(1979)*, *AM 64:1329(1979)*, *ABI:174*.

3.7.10.1 Simonite $\text{TlHgAs}_3\text{S}_6$

Named in 1982 for Simon Engel, son of Peter Engel (b.1942), Swiss crystallographer. MON $P2_1/n$. $a = 5.935$, $b = 11.387$, $c = 15.87$, $\beta = 90.4^\circ$, $Z = 4$, $D = 5.09$. $44\text{-}1460$: 9.30_2 5.37_1 4.38_2 3.63_{10} 3.05_1 2.84_5 2.77_1 2.73_2 . Microscopic crystals. Pale red. *Allchar, Macedonia*. BM *ZK 161:159(1982)*, *AM 69:211(1984)*, *ABI:476*, *MR 24:446(1993)*.

3.7.10.2 Edenharterite $\text{TlPbAs}_3\text{S}_6$

Named in 1992 for Andreas Edenharter (b.1933), Swiss crystal chemist. Contains up to 3% Sb. ORTH $Fdd2$. $a = 15.465$, $b = 47.507$, $c = 5.843$, $Z = 16$, $D = 5.09$. $EM 4$: 3.80_{10} 3.76_2 3.39_2 3.12_2 2.90_2 2.77_4 2.73_4 2.66_2 . Parallel intergrowths of lathlike crystals to 2 mm. Brown-black to black, raspberry-red streak. Cleavage $\{100\}$, distinct; uneven fracture. $H = 2\frac{1}{2}\text{-}3$, $VHN_{10} = 95\text{-}101$. $R = 28.5\text{-}31.5$ (546 nm); very weakly anisotropic. *Lengenbach, Binn, Switzerland*. BM *EJM 4:1265(1992)*.

3.7.11.1 Livingstonite HgSb_4S_8

Named in 1874 for David Livingstone (1813–1873), Scottish missionary and African explorer. MON $A2/a$. $a = 30.25$, $b = 4.00$, $c = 21.48$, $\beta = 104.20^\circ$, $Z = 8$, $D = 4.98$. $25\text{-}555(\text{syn})$: 10.46_3 5.20_{10} 3.81_5 3.75_2 3.47_8 2.85_6 2.59_4 2.27_6 . Prismatic crystals to 12 cm, often in radiating aggregates. Black, red streak, adamantine to metallic luster. Cleavage $\{001\}$, perfect; $\{010\}$, $\{100\}$, poor; flexible. $H = 2$, $VHN_{100} = 96\text{-}125$. $G = 4.8\text{-}5.0$. $R = 30.4\text{-}40.5$ (540 nm); strongly anisotropic. *Huitzuco**, *GRO*, and *Guadalcázar, SLP, Mexico*; *Pedrosa del Rey, Leon, Spain*; *Khaidarkan, Kyrgyzstan*; *Matsuo mine, Iwate Pref., Japan*. BM *DI:485*, *R:733*, *P&J:241*, *ABI:299*.

3.7.12.1 Rathite $\text{Pb}_3\text{As}_5\text{S}_{10}$

Named in 1896 for Gerhard von Rath (1830–1888), German mineralogist. May contain up to 4% Tl. MON $P2_1/n$. $a = 25.16$, $b = 7.94$, $c = 8.47$, $\beta = 100.5^\circ$, $Z = 4$, $D = 5.31$. $9\text{-}426$: 4.19_6 3.60_8 3.39_7 2.97_6 2.87_7 2.75_{10} 2.22_5 2.12_5 . Prismatic crystals, polysynthetically twinned on $\{100\}$. Lead-gray, chocolate-brown streak, metallic luster. Cleavage $\{100\}$, perfect; parting on $\{010\}$; subconchoidal fracture. $H = 3$, $VHN = 161$. $G = 5.37$. $R = 33.8\text{-}39.2$ (540 nm); strongly anisotropic. *Lengenbach, Binn, Switzerland*. BM *DI:455*, *SMPM 45:726(1965)*, *R:752*, *P&J:323*, *ABI:434*.

3.7.13.1 Nordströmite $Pb_3CuBi_7Se_4S_{10}$

Named in 1980 for T. Nordström (1843–1920), Swedish mining engineer. MON $P2_1/m$. $a = 17.97$, $b = 4.11$, $c = 17.62$, $\beta = 94.3^\circ$, $Z = 2$, $D = 7.12$. 35–466: 3.88₃ 3.58₅ 3.48₃ 3.43₃ 3.07₁₀ 3.01₃ 2.90₃ 2.24₇. Microscopic fibrous masses. Lead-gray, metallic luster. One good cleavage. $H = 2-2\frac{1}{2}$, $VHN_{25} = 130-143$. Johnny Lyon Hills, north of Benson, Cochise Co., AZ; *Falun, Sweden*. BM AM 65:789(1980), CM 18:343(1980), ABI:355.

3.7.14.1 Junoite $Pb_3Cu_2Bi_8(S,Se)_{16}$

Named in 1975 for the locality. MON $C2/m$. $a = 26.66$, $b = 4.06$, $c = 17.03$, $\beta = 127.20^\circ$, $Z = 2$, $D = 6.77$. 29-564: 3.90₈ 3.55₁₀ 3.39₄ 3.23₅ 2.97₅ 2.92₇ 2.21₄ 2.07₄. Microscopic tabular crystals and anhedral grains. Lead-gray, metallic luster. One good cleavage. $H = 3-4$, $VHN = 114-213$. $R = 41-49$ (546 nm); strongly anisotropic. Near Potts, Lander Co., NV; Kidd Creek mine, Timmins, ON, Canada; Kochbulak deposit, Uzbekistan; *Juno mine, Tennant Creek, NT, Australia*. BM AM 60:548(1975), CM 18:353(1980), ABI:254.

3.7.15.1 Vrbaite $Hg_3Tl_4Sb_2As_8S_{20}$

Named in 1912 for Karl Vrba (1845–1922), Czech mineralogist. ORTH $C2ca$. $a = 13.399$, $b = 23.389$, $c = 11.287$, $Z = 4$, $D = 5.40$. 20-1264: 5.18₆ 4.31₅ 4.04₁₀ 3.33₈ 3.15₆ 3.08₄ 2.57₈ 2.29₆. Small tabular or pyramidal crystals. Dark gray-black, red-yellow streak, submetallic to metallic luster. Cleavage {010}, good; uneven to conchoidal fracture; brittle. $H = 3\frac{1}{2}$. $G = 5.30$. $R = 29.6-32.5$ (540 nm); distinctly anisotropic. *Allchar, Macedonia*. BM DI:484, R:732, P&J:384, ABI:563.

3.7.16.1 Rohaite Cu_5TlSbS_2

Named in 1978 for John Rose-Hansen (b.1937), Danish mineralogist. ORTH Space group uncertain, probably $Pmmm$. $a = 7.602$, $b = 3.801$, $c = 20.986$, $Z = 4$, $D = 7.752$. 39-412: 3.80₉ 3.08₁₀ 2.62₅ 2.61₅ 2.58₅ 2.39₁₀ 2.16₅ 1.90₉. Microscopic euhedral and subhedral crystals in aggregates to 5 mm. Gray, metallic luster. $H = 3$, $VHN_{25} = 94$. $R = 23.9-35.4$ (540 nm); strongly anisotropic. *Ilimaussaq intrusion, Greenland*. BM AM 65:208(1980), NJMA 138:122(1980), ABI:444.

3.7.17.1 Dervillite Ag_2AsS_2

Named in 1941 for Henri Derville, French paleontologist. MON $P2/a$. $a = 6.833$, $b = 12.932$, $c = 9.638$, $\beta = 99.55^\circ$, $Z = 8$, $D = 5.62$. 35-628: 3.25₃ 3.17₂ 3.08₁₀ 3.02₈ 2.84₅ 2.74₂ 2.66₃ 2.07₂. Microscopic crystals. Gray, metallic luster. $H = 1$, $VHN_{100} = 19.5$. $R = 22.2$ (540 nm); moderately anisotropic. *Ste.-Marie-aux-Mines, Haut-Rhin, France*. BM BM 106:519(1983), AM 68:1041(1983), ABI:130.

3.7.18.1 Watkinsonite $\text{Cu}_2\text{PbBi}_4(\text{Se}, \text{S})_8$

Named in 1987 for David H. Watkinson (b.1937), Canadian mineralogist. MON Space group uncertain, probably *Pm*. $a = 12.921$, $b = 3.997$, $c = 14.989$, $\beta = 109.2^\circ$, $Z = 2$, $D = 7.82$. *42-1375*: 3.57₉ 2.98₁₀ 2.93₁₀ 2.41₇ 2.25₆ 2.14₇ 2.07₇ 1.48₇. Anhedral grains to 3 mm. Black, metallic luster. No cleavage; conchoidal fracture. $H = 3\frac{1}{2}$, $\text{VHN}_{25} = 155\text{--}186$. $R = 48.0\text{--}48.6$ (540 nm); moderately anisotropic. *Otish Mts. uranium deposit, PQ, Canada*. BM *CM 25:625(1987)*, *AM 74:948(1989)*, *ABI:569*.

3.8.1.1 Zinkenite $\text{Pb}_9\text{Sb}_{22}\text{S}_{42}$

Named in 1826 for J. K. L. Zinken (1798–1862), German mineralogist. HEX $P6_3$. $a = 44.15$, $c = 8.62$, $Z = 8$, $D = 5.34$. *7-334*: 3.95₁ 3.45₁₀ 3.02₂ 2.80₄ 2.13₂ 2.06₂ 1.99₃ 1.83₃. Acicular crystals in columnar and radiating fibrous aggregates; also massive. Steel-gray, steel-gray streak, metallic luster. Cleavage {1120}, indistinct. $H = 3\text{--}3\frac{1}{2}$, $\text{VHN}_{100} = 185$. $G = 5.2\text{--}5.3$. $R = 37.9\text{--}42.5$ (540 nm); distinctly anisotropic. Brobdignag prospect, near Silverton, CO; Morey, Nye Co., and Eureka, Eureka Co., NV; Bonanza Creek, Bridge R. district, BC, and Yellowknife Bay area, NWT, Canada; Grainsgill, Carrock Fell, Cumbria, England; Saint-Pons(*), Haute-Provence, and Pontgibaud, Puy-de-Dome, France; *Wolfsberg*(*), Harz, and Aldersbach, Bavaria, Germany; Sacaramb and Baia Mare, Romania; Ziddi deposit, Tajikstan; Magnet mine, Dundas, TAS, Australia; San José, Itos, and other mines, Oruro(*), Bolivia. BM *DI:476*, *R:761*, *P&J:398*, *ABI:586*.

3.8.2.1 Cuprobismutite $\text{Cu}_{10}\text{Bi}_{12}\text{S}_{23}$

Named in 1884 for the composition. MON *C2/m*. $a = 17.628$, $b = 3.911$, $c = 15.190$, $\beta = 101.18^\circ$, $Z = 1$, $D = 6.24$. *29-536(syn)*: 6.27₂ 3.62₅ 3.45₃ 3.22₅ 3.08₁₀ 2.85₃ 2.72₆ 1.95₃. Prismatic crystals and thin blades, also massive. Gray, metallic luster. $\text{VHN}_{100} = 159$. $G = 6.31$. $R = 36.8\text{--}41.3$ (540 nm); distinctly anisotropic. *Missouri mine, Hall's Valley, Park Co.*, and Silver Cliff, Custer Co., CO; Fairfax quarry, Centerville, VA; Marysvale, Piute Co., UT; Baicolliou, Switzerland; Krupka, Czech Republic. BM *DI:437*; *AM 37:447(1952)*, *58:967(1973)*; *R:718*; *P&J:141*; *ABI:119*.

3.8.3.1 Tvalchrelidzeite $\text{Hg}_{12}(\text{Sb}, \text{As})_8\text{S}_{15}$

Named in 1975 for Georgy A. Tvalchrelidze (b.1915), Georgian mineralogist. MON Space group unknown. $a = 11.51$, $b = 4.39$, $c = 15.62$, $\beta = 92.14^\circ$, $Z = 1$, $D = 7.74$. *29-904*: 3.49₁₀ 3.29₇ 3.19₃ 2.92₁₀ 2.89₁₀ 2.08₁₀ 2.03₄ 1.75₃. Granular aggregates. Lead-gray, red-black streak, adamantine luster. One perfect cleavage. $H = 3\frac{1}{2}$, $\text{VHN}_{100} = 172$. $G = 7.38$. $R = 36.7\text{--}39.5$ (540 nm); distinctly anisotropic. Getchell mine, Humboldt Co., NV; Hemlo gold deposit, near Marathon, ON, Canada; *Gomi deposit, Georgia*; Tyute deposit, Altai Mts., Russia. BM *DANS 225:911(1975)*, *AM 62:174(1977)*, *ABI:544*.

3.8.4.1 Hoderushite $\text{Cu}_8\text{Bi}_{12}\text{S}_{22}$

Named in 1970 for the locality. *MON* $A2/m$. $a = 27.205$, $b = 3.927$, $c = 17.575$, $\beta = 92.15^\circ$, $Z = 2$, $D = 6.45$. $25\text{-}267$: 3.62_8 3.48_6 3.22_7 3.10_{10} 2.72_8 2.55_6 1.72_6 1.45_5 . Crystals rare, usually as anhedral grains and fine-grained aggregates. Steel-gray, metallic luster. No distinct cleavage, very brittle. $H = 3\frac{1}{2}$, $VHN = 187\text{-}213$. $G = 6.35$. $R = 37.4\text{-}42.8$ (540 nm); weakly anisotropic. Pioche, Lincoln Co., NV; Bisbee, AZ; *Banska Hoderusa, near Banka Stianvica, Czech Republic*. *BM MM* $37:641(1970)$, *R:723*, *ABI:221*.

3.8.4.2 Paderaitite $\text{Cu}_6\text{Pb}_2\text{AgBi}_{11}\text{S}_{22}$

Named in 1985 for Karel Padera (b.1923), Czech mineralogist. *MON* $P2_1/m$. $a = 28.44$, $b = 3.95$, $c = 17.55$, $\beta = 106.1^\circ$, $Z = 2$, $D = 6.91$. $42\text{-}618$: 6.21_3 3.63_7 3.21_6 3.18_3 3.06_{10} 2.85_4 2.66_4 2.19_3 . Microscopic intergrowths with bis-muthinite. Steel-gray, metallic luster. Moderately anisotropic. *Baita, Romania*. *BM NJMM:557(1985)*, *CM* $24:513(1986)$, *ABI:374*.

3.8.6.1 Hutchinsonite $(\text{Pb}, \text{Tl})_2\text{As}_5\text{S}_9$

Named in 1904 for Arthur Hutchinson (1866–1937), English mineralogist. *ORTH* $Pbca$. $a = 10.80$, $b = 35.35$, $c = 8.16$, $Z = 8$, $D = 4.58$. $8\text{-}124$: 5.40_2 4.44_5 3.78_7 3.05_6 2.74_{10} 2.38_3 2.22_3 1.90_3 . Prismatic and platy crystals to 6 mm. Dark red to black, red streak, adamantine to submetallic luster. Cleavage $\{010\}$, good; conchoidal fracture; brittle. $H = 1\frac{1}{2}\text{-}2$, $VHN_{100} = 170$. $G = 4.6\text{-}4.7$. $R = 30.0\text{-}31.0$ (546 nm); anisotropic. Wiesloch, Black Forest, Germany; *Lengenbach* (*), *Binn, Switzerland*; *Quiruvilca* (*), Peru. *BM DI:468*, *SMPM* $45:707(1965)$, *R:740*, *P&J:205*, *ABI:225*.

3.8.7.1 Pierrotite $\text{Tl}_2\text{Sb}_6\text{As}_4\text{S}_{16}$

Named in 1970 for Roland Pierrot (b.1930), French mineralogist. *ORTH* $Pna2_1$. $a = 38.746$, $b = 8.816$, $c = 7.989$, $Z = 4$, $D = 4.75$. $25\text{-}938$: 3.63_8 3.59_{10} 3.49_9 2.84_8 2.70_9 2.52_6 2.47_6 2.35_8 . Polycrystalline aggregates. Gray-black, metallic luster. $H = 3\frac{1}{2}$. $G = 4.97$. $R = 31.3\text{-}35.0$ (540 nm); distinctly anisotropic. *Jas Roux, Hautes-Alpes, France*. *BM BM* $93:66(1970)$; *AM* $57:1909(1972)$, $70:220(1985)$; *ABI:404*.

3.8.8.1 Gerstleyite $\text{Na}_2(\text{Sb}, \text{As})_8\text{S}_{13} \cdot 2\text{H}_2\text{O}$

Named in 1956 for J. M. Gerstley (b.1907), President, Pacific Coast Borax Company. *MON* Cm . $a = 9.911$, $b = 23.05$, $c = 7.097$, $\beta = 127.85^\circ$, $Z = 2$, $D = 3.53$. $11\text{-}367$: 11.9_{10} 5.64_7 4.03_7 3.56_3 3.05_9 2.81_5 2.74_4 1.93_4 . Platy-fibrous spherules in clay. Cinnabar-red color and streak, weakly adamantine luster. Cleavage $\{010\}$, $\{100\}$, perfect; $\{001\}$, poor. $H = 2\frac{1}{2}$. $G = 3.62$. Biaxial; $N > 2.01$; strongly birefringent; pleochroic. X, salmon-red; Y,Z, deep blood-red. *Baker mine, Boron, Kern Co., CA*. *BM AM* $41:839(1956)$, *ABI:181*.

3.8.9.1 Gillulyite $Tl_2(As,Sb)_8S_{13}$

Named in 1991 for James C. Gilluly (1896–1980), U.S. geologist. *MON* $P2/n$. $a = 9.584$, $b = 5.679$, $c = 21.501$, $\beta = 100.07^\circ$, $Z = 2$, $D = 4.14$. *AM* 76: 4.14₆ 3.87₆ 3.63₉ 3.08₁₀ 2.81₁₀ 2.72₆ 2.50₇ 1.76₇. Microscopic crystals to 1 mm, and cleavable masses to 2 cm. Deep red, brick-red streak, submetallic luster. Cleavage {001}, perfect. $H = 2-2\frac{1}{2}$, $VHN_{15} = 87-132$. $G = 4.02$. $R = 24.1-28.0$ (546 nm); distinctly anisotropic. *Mercur gold deposit, Tooele Co., UT*. *BM AM* 76:653(1991), 78:1099(1993), 80:394(1995).

PAVONITE GROUP

The pavonite group consists of structurally related bismuth sulfosalts with the general formula

where

$A = Ag, Cu, Pb$

and the structure is monoclinic in space group $C2/m$. The pavonite minerals are rare (see figure).

PAVONITE GROUP

Mineral	Formula	Space Group	Space Group				
			a	b	c	β	
Pavonite	$AgBi_3S_5$	$C2/m$	13.35	4.03	16.34	94.5	3.8.10.1
Makovickyite	$Ag_{15}Bi_5S_9$	$C2/m$	13.83	4.04	14.72	97.5	3.8.10.2
Benjaminite	$Ag_3Bi_7S_{12}$	$C2/m$	13.25	4.05	20.25	103.14	3.8.10.3
Mummeite	$Ag_2CuPbBi_6S_{13}$	$C2/m$	13.47	4.06	21.63	92.9	3.8.10.4
Borodaevite	$(Ag, Pb)_6Bi_9S_{17}$	$C2/m$	13.515	4.098	26.00	93.00	3.8.10.5
Cupropavonite	$Cu_2AgPbBi_5S_{10}$	$C2/m$	13.45	4.02	33.06	93.50	3.8.10.6

3.8.10.1 Pavonite $AgBi_3S_5$

Named in 1954 from the Latin *pavo*, peacock, for Martin A. Peacock (1898–1950), Canadian mineralogist. Pavonite group. Contains minor Pb and Cu. *MON* $C2/m$. $a = 13.35$, $b = 4.03$, $c = 16.34$, $\beta = 94.5^\circ$, $Z = 4$, $D = 6.80$. *29-1138*: 5.34₅ 3.59₉ 3.46₁₀ 3.37₇ 3.32₇ 2.96₇ 2.85₁₀ 2.01₇. Tiny bladed crystals and massive. Tin-white to lead-gray, metallic luster. Indistinct cleavage. $H = 2$, $VHN_{50} = 188$. $G_{syn} = 6.8$. $R = 44.0-48.4$ (540 nm); strongly anisotropic. Silver Bell mine, Red Mountain, Ouray Co., and Poughkeepsie Gulch, San Juan Co., CO; Apache Hills mine, near Hachita, Grant Co., NM; Manhattan, Nye Co., and Pioche, Lincoln Co., NV; Keeley mine, South Lorrain Twp., ON, Canada; Panasqueira, Portugal; Banat, Romania; *Porvenir mine, Cerro Bonete, Potosi, Bolivia*. *BM AM* 39:409(1954), *CM* 15:339(1977), *R*:716, *P&J*:291, *ABI*:391.

PAVONITE: AgBi_3S_5

3.8.10.2 Makovickyite $\text{Ag}_{15}\text{Bi}_5\text{S}_9$

Named in 1994 for Emil Makovicky (b.1941), Slovak–Danish mineralogist. Pavonite group. *MON* $C2/m$. $a = 13.83$, $b = 4.04$, $c = 14.72$, $\beta = 97.5^\circ$, $Z = 2$, $D = 6.70$. *NJMA*: 3.63₅ 3.49₅ 3.42₁ 2.97₃ 2.85₁₀ 2.27₄ 2.12₃ 2.01₃. Anhedral grains to 2 mm. Gray, metallic luster. No apparent cleavage. $\text{VHN}_{50} = 210\text{--}221$. $R = 43.2$ (546 nm). *Felbertal, Austria; Baïta Bihorului, Romania*. *BM NJMA* 168:147(1994).

3.8.10.3 Benjaminite $\text{Ag}_3\text{Bi}_7\text{S}_{12}$

Named in 1924 for Marcus Benjamin (1857–1932), editor, U.S. National Museum. Pavonite group. May contain minor Cu and Pb. *MON* $C2/m$. $a = 13.25$, $b = 4.05$, $c = 20.25$, $\beta = 103.14^\circ$, $Z = 2$, $D = 6.68$. *29-577*: 3.54₈ 3.43₈ 3.30₅ 2.94₅ 2.85₁₀ 2.81₆ 2.02₆ 2.01₆. Laths to 6 mm and massive. Lead-gray, lead-gray streak, metallic luster. One fair cleavage. $H = 3\frac{1}{2}$, $\text{VHN}_{50} = 186\text{--}232$. $R = 44.0\text{--}48.6$ (540 nm); strongly anisotropic. Alaska mine, Poughkeepsie Gulch, near Ouray, CO; *Oullaw mine*, 12 miles north of *Manhattan*, and at Round Mt., *Nye Co., NV*; Canadian Keely mine, Cobalt, ON, and Terra Company mine, Camsell R., NWT, Canada; Adrasman deposit, Kuramin Mts., Kyrgyzstan; AW mine, near Tenterfield, NSW, Australia; Porvenir mine, Cerro Bonete, Potosi, Bolivia. *BM DI:441, AM* 38:550(1953), *CM* 13:402(1975), *ABI:45, MR* 22:171(1991).

3.8.10.4 Mummeite $\text{Ag}_2\text{CuPbBi}_5\text{S}_{13}$

Named in 1986 for William G. Mumme (b.1936), Australian mineralogist. Pavonite group. MON $C2/m$. $a = 13.47$, $b = 4.06$, $c = 21.63$, $\beta = 92.9^\circ$, $Z = 1$, $D = 6.64$. NJMM: 5.55₃ 3.53₅ 3.43₅ 3.34₃ 2.86₁₀ 2.02₁₀ 1.65₄ 1.29₄. Short columnar crystals to 1 mm. Gray, metallic luster. No cleavage. VHN₅₀ = 203. $R = 42.8\text{--}47.0$ (540 nm); distinctly anisotropic. *Alaska mine, Poughkeepsie Gulch, Silverton, CO*. BM NJMM:555(1992).

3.8.10.5 Borodaevite $(\text{Ag,Pb})_6\text{Bi}_5\text{S}_{17}$

Named in 1992 for Yuri S. Borodaev (b.1923), Russian mineralogist. Pavonite group. Contains up to 6% Sb. MON $C2/m$ or Cm . $a = 13.515$, $b = 4.098$, $c = 26.00$, $\beta = 93.00^\circ$, $Z = 2$, $D = 6.95$. ZVMO 121: 3.49₈ 3.37₉ 3.24₉ 2.82₁₀ 2.01₇ 1.99₈. Millimeter-size platy crystals and anhedral grains. Gray, black streak, metallic luster. Occurs in an Sn-W deposit at *Alaskitivoje, near Ust-Nera, Yakutia, Russia*. BM ZVMO 121(4):115(1992), MA 45:111(1994).

3.8.10.6 Cupropavonite $\text{Cu}_2\text{AgPbBi}_5\text{S}_{10}$

Named in 1979 for its similarity to pavonite. Pavonite group. MON $C2/m$. $a = 13.45$, $b = 4.02$, $c = 33.06$, $\beta = 93.50^\circ$, $Z = 4$, $D = 7.04$. 42-552: 5.36₇ 3.60₉ 3.47₁₀ 3.00₇ 2.97₇ 2.86₉ 2.84₇ 2.02₇. Lamellar intergrowths with pavonite. Tin-white to lead-gray, metallic luster. $R = 43.0\text{--}48.2$ (540 nm); distinctly anisotropic. *Alaska mine, Poughkeepsie Gulch, San Juan Co.*, and Missouri mine, Hall's Valley, Park Co., CO; Campbell mine, Bisbee, AZ; April Fool mine, Delamar, Lincoln Co., NV. BM BM 102:351(1979), AM 65:206(1980), CM 18:181(1980), ABI:121.

3.8.11.1 Ustarasite $\text{Pb}(\text{Bi,Sb})_6\text{S}_{10}$

Named in 1955 for the locality. Space group unknown. 25-429: 3.89₅ 3.53₁₀ 3.08₇ 2.51₇ 1.92₇ 1.73₇ 1.48₁₀ 1.14₇. Prismatic crystals. Silver-gray to gray, metallic luster. One perfect cleavage. $H = 2\frac{1}{2}$. Strongly anisotropic. Montanem, Galicia, Spain; *Ustarasaisk deposit, western Tian-Shan, Kazakhstan*. BM AM 41:814(1956), ABI:551.

3.8.12.1 Chabourneite $(\text{Tl,Pb})_{21}(\text{Sb,As})_{91}\text{S}_{147}$

Named in 1981 for the locality. TRIC P1. $a = 16.346$, $b = 42.602$, $c = 8.534$, $\alpha = 95.86^\circ$, $\beta = 86.91^\circ$, $\gamma = 96.88^\circ$, $Z = 1$, $D = 5.12$. 35-474: 3.93₇ 3.57₁₀ 3.36₇ 2.85₇ 2.81₈ 2.71₇ 2.35₇ 2.14₉. Microscopic crystals. Black, red-brown streak, greasy to submetallic luster. Conchoidal fracture. $H = 3$, VHN₁₀₀ = 168. $G = 5.10$. $R = 30.8\text{--}36.6$ (540 nm); strongly anisotropic. *Jas Roux deposit, near Chabourneou Glacier, Hautes-Alpes, France*; Toya mine, Abuta, Hokkaido, Japan. BM BM 104:10(1981), AM 67:621(1982), ABI:87.

3.8.13.1 Rebulite $Tl_5Sb_5As_8S_{22}$

Named in 1982, derivation not given. *MON* $P2_1/c$. $a = 17.405$, $b = 7.358$, $c = 31.88$, $\beta = 104.90^\circ$, $Z = 4$, $D = 4.94$. *44-1461*: 4.13_4 3.99_6 3.86_3 3.46_3 3.36_9 3.08_{10} 2.93_7 2.17_7 . Crystals to 3 mm. Dark gray, red-brown streak, submetallic luster. $G = 4.81$. *Allchar, Macedonia*. *BM ZK 160:109(1982)*, *AM 68:644(1983)*, *ABI:437*, *MR 24:446(1993)*.

3.8.13.2 Jankovičite $Tl_5Sb_9(As,Sb)_4S_{22}$

Named in 1995 for Slobodan Janković, Serbian mineralogist. *TRIC* $P1$. $a = 7.393$, $b = 8.707$, $c = 17.584$, $\alpha = 103.81^\circ$, $\beta = 91.79^\circ$, $\gamma = 109.50^\circ$, $Z = 1$, $D = 5.08$. *TMPM 53*: 3.46_{10} 3.39_6 3.18_5 3.08_7 2.80_4 2.58_3 2.29_6 1.74_4 . Microscopic tabular grains. Black, brown-violet streak, metallic luster. Cleavage {100}, subconchoidal fracture, brittle. $H = 2$, $VHN_{50} = 98$. $R = 32.2-35.1$ (540 nm); in reflected light white to blue-white, with dark red internal reflections; distinctly anisotropic. *Allchar, Macedonia*. *BM TMPM 53:125(1995)*, *EJM 6:479(1995)*.

3.8.14.1 Parapierrrotite $Tl(Sb,As)_5S_8$

Named in 1975 for its relation to pierrrotite. *MON* $P2_1/n$. $a = 8.02$, $b = 19.35$, $c = 9.03$, $\beta = 91.97^\circ$, $Z = 4$, $D = 5.04$. *29-1330*: 4.15_9 3.93_6 3.70_9 3.60_7 3.49_{10} 2.91_9 2.83_{10} 2.36_9 . Prismatic crystals to 3 mm. Black, submetallic luster. $H = 2\frac{1}{2}-3$, $VHN = 76$. $G = 5.07$. $R = 29.1-39.7$ (540 nm); distinctly anisotropic. Near Lookout Pass, Tooele Co., UT; Hemlo gold deposit, near Marathon, ON, Canada; Jas Roux, Hautes-Alpes, France; *Allchar, Macedonia*. *BM TMPM 22:200(1975)*, *AM 61:504(1976)*, *P&J:287*, *ABI:385*.

3.8.14.2 Bernardite $Tl(As,Sb)_5S_8$

Named in 1989 for Jan Bernard (b.1928), Czech mineralogist. *MON* $P2_1/c$. $a = 15.647$, $b = 8.038$, $c = 10.750$, $\beta = 91.27^\circ$, $Z = 4$, $D = 4.34$. *MM 53*: 4.46_7 4.28_7 4.09_6 3.78_6 3.72_6 3.07_7 3.06_{10} 2.68_6 . Thick tabular crystals to 4 mm. Black, deep red streak, metallic luster. No cleavage, subconchoidal to uneven fracture. $H = 2$. $G = 4.51$. $R = 25.0-26.7$ (540 nm). Lengenbach, Binn, Switzerland; *Allchar, Macedonia*. *BM MM 53:531(1989)*, *AM 75:1209(1990)*.

3.8.15.1 Vaughanite $TlHgSb_4S_7$

Named in 1989 for David J. Vaughan (b.1946), English mineralogist. *TRIC* Space group uncertain, probably $P1$. $a = 9.012$, $b = 13.223$, $c = 5.906$, $\alpha = 93.27^\circ$, $\beta = 95.05^\circ$, $\gamma = 109.16^\circ$, $Z = 2$, $D = 5.56$. *MM 53*: 12.5_2 8.42_2 4.34_3 4.20_{10} 3.55_2 3.31_6 2.75_4 2.32_3 . Microscopic anhedral grains. Black, black streak, metallic luster. No cleavage, brittle. $H = 3-3\frac{1}{2}$, $VHN_{25} = 100-115$. $R = 32.1-39.4$ (540 nm); moderate to strong anisotropism. *Hemlo gold deposit, near Marathon, ON, Canada*. *BM MM 53:79(1989)*, *AM 75:710(1990)*.

3.9.1.1 Criddleite $\text{TlAg}_2\text{Au}_3\text{Sb}_{10}\text{S}_{10}$

Named in 1988 for Alan J. Criddle (b.1944), English mineralogist. *MON* Space group uncertain, probably $A2/m$. $a = 19.96$, $b = 8.057$, $c = 7.809$, $\beta = 92.08^\circ$, $Z = 2$, $D = 6.57$. *MM* 52(syn): 5.63₉ 5.00₄ 3.91₅ 2.86₇ 2.81₁₀ 2.02₆ 1.96₇ 1.40₄. Microscopic lathlike or anhedral grains. Black, black streak, metallic luster. $H = 3-3\frac{1}{2}$, $\text{VHN}_{25} = 94-129$. $G_{\text{syn}} = 6.86$. $R = 36.7-38.4$ (540 nm); distinctly anisotropic. *Hemlo gold deposit, near Marathon, ON, Canada; Vigès, Creuse, France*. *BM* *MM* 52:691(1988), *AM* 75:706(1990), *ABI*:114, *CM* 28:739(1990).

Simple Oxides

4.1.1.1 Cuprite Cu_2O

Named in 1845 from Latin *cuprum*, copper, in allusion to its composition. ISO $Pn\bar{3}m$. $a = 4.270$, $Z = 2$, $D = 6.100$. NBSC 539(2):23(1953). 5-667(syn): 3.02₁ 2.47₁₀ 2.14₄ 1.51₃ 1.29₂ 1.23₁ 0.980₁ 0.955₁. **Structure:** In the structure of cuprite the oxygens form a body-centered cubic framework. Within each cube of this network there are four copper atoms, which occupy the centers of smaller cubes generated by dividing the primary cube into eight different cubes; only half of these smaller cubes are occupied, distributed alternately in the larger cube and the copper atoms forming the corners of a tetrahedron. AC(A) 46:271(1990). **Habit:** Crystals octahedral or cubic; rarely dodecahedral; sometimes highly modified; also massive or earthy. In the variety *chalcotrichite* crystals are greatly elongated [001] into capillary shapes. **Physical properties:** Dark red to cochineal red, sometimes almost black. Chalcotrichite is bright red. Brownish-red, shining streak; adamantine, submetallic

CUPRITE: Cu_2O

In cuprite each large atom (O) is coordinated to four small atoms (Cu) and each small atom to two large ones.

luster. Cleavage {111}, interrupted; {001}, rare; conchoidal to uneven fracture; brittle. $H = 3\frac{1}{2}$ –4. $G = 6.14$. Fusible with difficulty. Tests: Soluble in hot, concentrated HCl, and the solution when diluted gives a heavy white precipitate of Cu_2Cl . Soluble in NH_4OH and in concentrated solutions of HNO_3 , H_2SO_4 , and NaOH. Optics: Isotropic; $N = 2.849$. Usually exhibits anomalous birefringence and pleochroism. In RL, bluish white with strong internal reflections. $R = 31.1$ (470 nm), 26.0 (546 nm), 24.6 (589 nm), 23.5 (650 nm). *P&J:140*. **Occurrence:** Widespread in the oxidized zone of copper deposits, usually associated with native copper, malachite, azurite, tenorite, chrysocolla, and limonite. **Localities:** In PA at Cornwall, Lebanon Co. Common in several AZ mines, especially at Bisbee(!), where it was found in large transparent crystals; also at Morenci, Ray, and other mines(!). Santa Rita district, NM. Chessy, France(*), in octahedral or dodecahedral crystals, often pseudomorphed by malachite and azurite. Fine crystallized specimens in Cornwall, England(!) at Redruth, Liskeard, Gwennap, St. Just, and especially the Phoenix mine, Linkinhorne, to 30 mm. In the Ural Mts., Russia, at Bogoslovsk and Ekaterinburg. In Namibia at Tsumeb(!) and at the Emke mine, Onganga(!) in transparent crystals up to 8 cm. In fine crystals at the Mashamba West mine, Zaire(!) and at Likasi(!). In Australia at Broken Hill, NSW(!), and at Burra Burra, SA. Corocoro, Bolivia. Andacollo, Chile, in fine crystals(!). Use: An ore of copper. *RG DI:491*.

4.1.2.1 Ice H_2O

From Middle English *is* or *iis*, related to Dutch *ijs* and German *eis*. *HEX* $P6_3/mmc$. $a = 4.523$, $c = 7.367$, $Z = 4$, $D = 0.9167$ at 0° . *16-687*: 3.90_{10} 3.66_{10} 3.40_8 2.67_4 2.25_9 2.07_6 1.92_5 1.52_2 . Data at 90° K. **Habit:** Commonly (as snow) in hexagonal plates, six-rayed stars, and branched stars with dendritic or fern-frond-like arms, all flattened (0001), and in simple and complex combinations of all of these, of great variety and beauty; and in hexagonal prismatic columns and needles elongated [0001], and in combinations of these with the preceding: for example, a prismatic column capped by hexagonal plate or star at both ends, forming a capped column, a tsuzumi type of snow crystal (named after the shape of the Japanese tomtom). Crystal habit is controlled by air temperature and humidity in the clouds at the time the snow crystal grows. Size is generally in the range 0.05 to 7 mm. As frost, in the form of dendritic or feathery aggregates; as skeletal hexagonal prisms with hopper-shaped faces, and as hollow, cup-shaped, or scroll-shaped crystals, the faces being coarsely ribbed and stepped parallel to $\langle 1000 \rangle$ and [0001]. Also as needles $\langle 1000 \rangle$ formed by rapid crystallization on the surface of freezing water. As rounded polycrystalline bodies with concentric structure (as in hailstones and icicles). Often massive. Massive polycrystalline ice such as glacier ice contains crystal grains typically in the size range 1 mm to as much as $\frac{1}{2}$ m, generally increasing in size with age. *LC 8:101*, *L:173*, *CP 23:3(1992)*. A generalized type of twinning has been inferred to explain 12-branched snow crystals and certain crystal-orientation relations observed in

glacier ice. *JXLG* 28:21(1975), *JGL* 21:607(1978). **Structure:** Ice has a structure built of discrete water molecules little altered in size or shape from their configuration in water vapor but linked together in a three-dimensional framework by hydrogen bonds. The oxygen atoms of the water molecules are in a hexagonal arrangement like the Si atoms in β -tridymite. Every oxygen is linked tetrahedrally to four other oxygens at 2.76 Å by hydrogen bonds, in which the H atom lies very near each line connecting adjacent O atoms, nearer to one O (0.96 Å) than the other (1.80 Å). At any moment only two H atoms (protons) are situated close to any one O atom, forming a discrete H_2O molecule with O—H distances 0.96 Å and with a H—O—H angle 104.50° . The protons hop back and forth within each bond and also from bond to bond, forming a proton-disordered but still hydrogen-bonded structure. *PPSL* 45:768(1933), *F* 23:147.

In addition to ordinary ice I, there are at least nine other polymorphs, designated ice II, ice III, and so on. All of these except one are formed under high pressure, are considerably denser than ice I ($D \geq 1.14$) and revert spontaneously to ice I when the high pressure is released. They all have structures in which the water molecules are tetrahedrally hydrogen-bonded to one another. For example, the structure of ice III is analogous to that of keatite (a name given to a synthetic tetragonal polymorph of SiO_2) in the same way that ice I is analogous to β -tridymite. *AC(B)* 41(3)169(1985), *F*:49. **Physical properties:** Colorless; in large transparent masses very pale blue; usually white from included gas bubbles or flaws; white streak, vitreous luster. Cleavage (0001), perfect but difficult to achieve; conchoidal fracture; brittle at low temperatures (less so near the melting point) or on short time scales (like a hammer blow), but when loaded slowly over long periods of time, ice flows in a quasi-viscous manner, as in glacier flow. Single crystals deform readily by dislocation gliding on (0001); deformation of polycrystalline ice (such as glacier ice) is slower and involves several other mechanisms in addition. *F*:185. The hardness of ice is very temperature dependent; at -44° the hardness of ice is about 4 (like fluorite); that is why snow crunches in very cold weather. With a temperature of -78° (dry ice temperature) the hardness becomes ≈ 6 (like feldspar). At such temperatures, which are attained in some arctic or mountainous regions, blowing snow can abrade and significantly erode many rocks. *AJS* 238:61(1939). Static friction between ice and the running surfaces of skis, sled runners, and so on, is low at temperatures above about -10° , but at low temperatures the friction increases and skis do not slide freely. Electrical conductivity is low but appreciable, due to hopping of protons in the ice structure; hence ice has been called a protonic semiconductor. The dielectric constant is very high (≈ 100), for similar reasons. *F*:198. Ice melts to water above 0° , with properties as follows: Color, when pure, similar to that of ice. Density increases 9% on melting, a very unusual property. As a function of temperature, the density reaches a maximum, $G = 0.999973$, at 4° . This property results in water at 4° sinking to the bottom of lakes and rivers, displacing less dense water from below. This, in effect, maintains a reservoir of slightly warmer water at depth, which, in

ICE: H_2O

The positions of the oxygen atoms in hexagonal ice are similar to the positions of silicon atoms in tridymite—basically a hexagonal closest-packed array. The water molecules are linked to each other by hydrogen bonds. Since the space-group symmetry of the oxygen positions is trigonal, the orientation of these bonds must be disordered over the long range to result in this symmetry.

combination with the fact that ice floats, constrains such water bodies to freeze from the top down, slowly, and retards their freezing to the bottom. Water is nearly unique among chemical compounds in this property. The melting point of ice is lowered by the addition of electrolytes, such as NaCl , CaCl_2 , and so on. Compared to other liquids, the specific heat, heat of fusion, heat of vaporization, surface tension, and dielectric constant of water are abnormally high. **Chemistry:** Most water-soluble substances such as salts enter only very sparingly into the ice structure. A water solution of salts, such as seawater, will produce relatively pure ice upon freezing, most of the dissolved salts remaining behind in a residual brine. In the Greenland and Antarctic ice sheets, below a depth of about 1,000 m, the air that had been included as bubbles in the ice at shallower depths reacts with some of the ice to form a transparent solid hydrate $(\text{N}_2, \text{O}_2) \cdot m\text{H}_2\text{O}$ (with $m \approx 6$) of cubic structure ($a = 12.0 \text{ \AA}$) for which the name *craigite* has been proposed. *SCI 165:489(1969)*. (This icelike mineral is also called *clathrate hydrate*.) As a result, the bubbles in the ice at these depths disappear and the mass becomes almost perfectly transparent. The clathrate hydrate structure is analogous to that of *melanophlogite* in the same way that ice I is analogous to β -*tridymite*. *SCI 148:232(1965)*. **Optics:** Uniaxial (+); $N_{\text{O}} = 1.3091$, $N_{\text{E}} = 1.3105$ (Na). **Varieties:** Snow, corn snow (spring snow), firn (*nevé*), glacier ice, graupel, hail, frost, hoar, rime, frazil, anchor ice, grease ice, pancake ice, sea ice, shorefast ice, river ice, lake ice, candle ice, icicle, icing, *aufeis* (*naled*), ground ice

(permafrost), cirrus ice, "diamond dust," ... *L:112,192,242, PLC:2*. **Localities:** Ice is the most abundant single mineral on the surface of the earth, despite being mostly absent at lower latitudes. It forms glaciers in the arctic and antarctic regions and at higher elevations in mountains of the temperate zone and even the tropics. It also occurs as icebergs, in permafrost, and seasonally as snow and as ice covering lakes and streams. Large hoar crystals up to several decimeters in size, formed by subfreezing condensation of water vapor from still air, are found not infrequently in caves, mine tunnels, and snow-bridged crevasses in glaciers at high elevation or high latitude. **Uses and hazards:** Ice (mostly produced artificially) is used in beverages and food (ice cream, sherbet, etc.) and to a declining extent for preserving food by refrigeration. It is also used in several sports (skating, skiing, snowboarding, tobogganing, luge, ice hockey, curling, ice climbing). The expansion in volume as water freezes to ice causes cracking and mechanical disintegration of rock (congelifraction) and frost heaving of soils, contributing to weathering and erosion (nivation). These processes can damage highways and other structures, as can the melting of ground ice (permafrost). *L:213,272,374*. Snow and ice can, of course, be damaging to structures and hazardous to transportation. Glaciers pose rare but locally severe hazards, and travel on glaciers is hazardous because of crevasses, which are tensile fractures in deforming ice. **RG** Reviewed and expanded by Barclay Kamb. *DI:494, LC(1969), L(1990), PLC(1971)*.

PERICLASE GROUP

The periclase structure minerals are anhydrous oxides with the formula

where

A = Mg, Ni, Mn, Cd, Ca, Fe, or Ti

and the structure is the halite structure, face-centered cubic space group *Fm3m*.

PERICLASE GROUP

Mineral	Formula	Space Group	a	D	
Periclase	MgO	<i>Fm3m</i>	4.211	3.581	4.2.1.1
Bunsenite	NiO	<i>Fm3m</i>	4.177	6.806	4.2.1.2
Manganosite	MnO	<i>Fm3m</i>	4.445	5.365	4.2.1.3
Monteponite	CdO	<i>Fm3m</i>	4.695	8.24	4.2.1.4
Lime	CaO	<i>Fm3m</i>	4.8105	3.345	4.2.1.5
Wüstite	FeO	<i>Fm3m</i>	4.307	5.97	4.2.1.6
Hongquuite	TiO	<i>Fm3m</i>	4.293	5.36	4.2.1.7

Notes:

1. See the galena group and the halite group, which are essentially isostructural with the periclase group.
2. Periclase minerals occur in high-temperature metamorphic environments, and their formation depends on the nearly complete absence of water. In the presence of water, they alter readily, chiefly to the hydroxide. Periclase minerals are rare in the near-surface environment.

4.2.1.1 Periclase MgO

Named in 1840 from the Greek for *around* and *fracture*, alluding to the perfect cubic cleavage. Periclase group. iso *Fm3m*. $a = 4.211$, $Z = 4$, $D = 3.581$. *NBSC 539(1):37(1953)*. *4-829(syn)*: 2.43_1 2.11_{10} 1.49_5 1.27_1 1.22_1 1.05_1 0.942_2 0.860_2 . Usually as irregular rounded grains; rarely as octahedrons, cubes, or cubo-octahedrons. Colorless, white, yellow, green, black (due to impurities); white streak; vitreous luster. Cleavage {001}, perfect; {111}, imperfect; parting {011} on glide planes. $H = 5\frac{1}{2}$. $G_{\text{syn}} = 3.56$. Easily soluble in HCl and HNO_3 . Finely powdered periclase gives an alkaline reaction with water [$\text{MgO} + \text{H}_2\text{O} \rightarrow \text{Mg}(\text{OH})_2$]. Most periclase is relatively pure MgO. However, material from Mt. Somma, Italy, has 6% FeO, and that from Nordmark, Sweden, has 9% MnO and 2.5% ZnO, the manganese being due to oriented inclusions of manganosite. Isotropic; $N = 1.732$ (Na). Periclase is usually formed in high-temperature metamorphic deposits derived from dolomitic marble. Found at Crestmore, CA, in part altered to brucite, associated with chondrodite, wilkeite, and spinel. Organ Mts., NM, with forsterite in dolomite xenoliths. Nordmark, Sweden, with hausmannite in dolomitic marble; also at Langban. *Monte Somma, Vesuvius, Italy*, in ejected blocks of limestone and at Teulada, Sardinia. RG *DI:499, AM 61:266(1976)*.

4.2.1.2 Bunsenite NiO

Named in 1868 for Robert Wilhelm Bunsen (1811–1899), German chemist, inventor of spectroscopy, who also gave his name to a type of gas burner. Periclase group. iso *Fm3m*. $a = 4.177$, $D = 6.806$. *NBSC 539(1):47(1953)*. *4-835(syn)*: 2.41_9 2.09_{10} 1.48_6 1.26_2 1.21_1 1.04_8 0.934_2 0.853_2 . Octahedral crystals, sometimes modified by {110} or {011}. Dark pistachio green, brownish black streak, vitreous luster. $H = 5\frac{1}{2}$. $G_{\text{nat}} = 6.90$, $G_{\text{syn}} = 6.7$. Difficultly soluble in acids. Isotropic; $N = 2.37$ (Li). Found in the oxidized portion of a nickel–uranium vein at *Johanngeorgenstadt, Saxony, Germany*, with nickel and cobalt arsenates. RG *DI:500*.

4.2.1.3 Manganosite MnO

Named in 1874 for the composition. Periclase group. iso *Fm3m*. $a = 4.445$, $Z = 4$, $D = 5.365$. *NBSC 539(5):45(1955)*. *7-230(syn)*: 2.57_6 2.22_{10} 1.57_6 1.34_2 1.28_1 1.11_1 1.02_1 0.994_2 . Rarely octahedral, sometimes modified by {001} or {011}; usually in irregular grains or masses, or exsolved laminae in zincite. Emerald green, turning black upon exposure, brown streak, vitreous luster. Cleavage {001}, fair. $H = 5\frac{1}{2}$. $G_{\text{syn}} = 5.0\text{--}5.4$, $G_{\text{nat}} = 5.364$. Dissolves

with difficulty in strong HCl or HNO₃ to a colorless solution. Isotropic; $N = 2.19$. In RL, isotropic gray, with emerald green internal reflections. $R = 14.7$ (470 nm), 13.9 (546 nm), 13.5 (589 nm), 13.6 (650 nm). *P&J:256*. From *Franklin, NJ*, in masses and very rare crystals associated with franklinite, willemite, calcite, and zincite. Långban, Varmland, Sweden, and at Nordmark, with pyrochroite, hausmannite, periclase, and garnet in dolomite. RG *DI:501, BM 92:500(1969)*.

4.2.1.4 Monteponite CdO

Named in 1946 for the locality. Periclase group. Synonym: cadmium oxide. iso *Fm3m*. $a = 4.695$, $Z = 4$, $D = 8.24$. *NBSC 539(2):27(1953)*. 5-640(syn): 2.71₁₀ 2.35₉ 1.66₄ 1.42₃ 1.36₁ 1.08₁ 1.05₁ 0.958₁. Octahedral; as coatings; pulverulent. Gray to black, metallic luster. Cleavage {111}. $H = 3$. $G_{\text{syn}} = 8.1-8.2$. Soluble in dilute acids. Isotropic; $N = 2.49$ (Li). In transmitted light, red to orange-brown. From *Genarutta, near Iglesias, Monte Ponì, Sardinia, Italy*, as a coating over hemimorphite. RG *DI:502, EG 41:761(1946)*.

4.2.1.5 Lime CaO

Named in 1935 from an old English word for the substance, related to Dutch *lijm* and Latin *limus*, mud. Periclase group. iso *Fm3m*. $a = 4.8105$, $Z = 4$, $D = 3.345$. *NBSM 25(14):49(1977)*. 43-1001(syn): 2.78₄ 2.41₁₀ 1.701₅ 1.450₁ 1.389₁ 1.203₁ 1.076₁ 0.982₁. Colorless. Cleavage {011}, perfect; parting {011}. $H = 3\frac{1}{2}$. $G_{\text{syn}} = 3.3$. Isotropic; $N = 1.838$. Hydrolyzes in water to Ca(OH)₂; rapidly alters in air to portlandite and then more slowly to calcite. Found at *Vesuvius, Italy*, as powdery intergranular films in blocks of limestone that were enveloped by lava. RG *DI:503, NBSC 539(1):43(1953)*.

4.2.1.6 Wüstite FeO

Named in 1927 for Ewald Wüst, German geologist. Periclase group. iso *Fm3m*. $a = 4.307$, $Z = 4$, $D = 5.97$. *AC 13:140(1960)*. 6-615: 2.49₈ 2.15₁₀ 1.52₆ 1.30₃ 1.24₂ 1.08₂ 0.988₁ 0.963₂. Minute octahedral crystals. Gray, metallic luster. $G = 5.74$. Strongly magnetic. Found at *Scharnhausen, Württemberg, Germany*; Jharia coal field, Bihar, India, in a natural coke; in the fusion crusts of iron meteorites. RG *DI:504, DANS 168:1390(1960), MM 35:664(1965), NJMM:65(1971)*.

4.2.1.7 Hongquilitite TiO

Named in 1976 for the locality. Periclase group. iso *Fm3m*. $a = 4.293$, $Z = 4$, $D = 5.36$. 29-1361: 2.48₅ 2.14₁₀ 1.53₇ 1.30₅ 1.08₈ 0.985₁ 0.960₂. Perfect cubo-octahedral crystals. Bright white, metallic luster. Brittle. $VHN_{100} = 710$. Nonmagnetic. Isotropic. In reflected light, white with a pinkish tint. Red internal reflections. $R = 28.6$ (466 nm), 27.5 (544 nm), 35.8 (589 nm), 32.6 (656 nm). Found in platinum ores associated with high-temperature rocks of the garnet-hornblende-pyroxenite type in the *Tao district, Hongqui, China*. RG *AM 61:184(1976)*.

4.2.2.1 Zincite (Zn,Mn)O

Named in 1845 for the composition. *HEX C6mc*. $a = 3.249$, $c = 5.205$, $Z = 2$, $D = 5.680$. *NBSC 539(2):25(1953)*. *36-1451(syn)*: 2.81₆ 2.60₄ 2.48₁₀ 1.911₂ 1.625₃ 1.477₃ 1.378₂ 1.358₁. Crystals rare, hemimorphic pyramidal with large negative base {0001}; usually massive, as irregular grains and rounded masses. Red to orange, rarely yellow; subadamantine luster. Cleavage {1010}, perfect but difficult; parting {0001}, sometimes distinct; conchoidal fracture; brittle. $G = 5.64-5.68$. Artificial material fluoresces green to yellow under LWUV; natural material is rarely or only faintly fluorescent, possibly due to quenching by 3-6% manganese impurity. Uniaxial (+); $N_O = 2.013$, $N_E = 2.029$ (Na). Nonpleochroic. In reflected light light rose-brown. $R = 12.5$ (470 nm), 12.0 (546 nm), 11.8 (589 nm), 11.5 (650 nm). *P&J:397*. Found at *Franklin and Sterling Hill, NJ(!)*, where zincite constituted about 1% of the ore, associated with calcite, willemite, franklinite, and other minerals. Crystals only in secondary veins or fractures. Also reported from Olkusz, Kielce, Poland; Bottino, near Saravezza, Tuscany, Italy; Paterna, Almeria, Spain; the Heazlewood mine, TAS, Australia. Many specimens of alleged naturally crystallized zincite are actually smelter products and not natural. *RG DI:504*.

4.2.2.2 Bromellite BeO

Named in 1825 after Magnus von Bromell (1679-1731), Swedish physician and mineralogist. *HEX P6₃mc*. $a = 2.698$, $c = 4.379$, $Z = 2$, $D = 3.009$. *NBSM 25(21):38(1985)*. *43-1000(syn)*: 2.34₉ 2.19₆ 2.061₁₀ 1.598₂ 1.349₃ 1.238₃ 1.149₂ 1.129₁. Structure: *SR 53A:123(1986)*. Prismatic, hemimorphic crystals with dominant {0001} and opposite pyramidal {1011} termination. White, vitreous luster. Cleavage {1010}, perfect; {0001}, good. $H = 9$. $G = 3.017$. Normally not fluorescent, but bromellite from Norway is fluorescent white under SWUV. Uniaxial (+); $N_O = 1.719$, $N_E = 1.733$. Reported in skarn S of Sierra Blanca, Hudspeth Co., TX. *Långban, Värmland, Sweden(!)* in a calcite-hematite skarn associated with swedenborgite, richterite, and manganophyllite; at the Saga I quarry, Tvedalen, Norway; near Ekaterinburg, Ural Mts., Russia, in an emerald mine, associated with phenacite(*). A large polycrystalline mass from this mine weighed 5 kg and was surrounded by a phenacite crust in talc schist. *RG DI:506*.

4.2.3.1 Tenorite CuO

Named in 1841 for Michele Tenore (1781-1861), Italian botanist, University of Naples; melaconite is from the Greek for *black* and *dust*. Synonym: melaconite, for a massive, pitchy variety, often admixed with other minerals. *MON C2/c*. $a = 4.684$, $b = 3.425$, $c = 5.129$, $\beta = 99.47^\circ$, $Z = 4$, $D = 6.51$. *NBSC 539(1):49(1953)*. *41-254(syn)*: 2.531₆ 2.524₁₀ 2.31₁₀ 1.867₃ 1.581₁ 1.506₂ 1.409₁ 1.375₁. Crystals rare and minute; as thin twinned aggregates and laths {100} and elongated {001}; commonly as scales or pulverulent; twinning common on {011} producing featherlike forms and dendritic patterns. Gray-

black, metallic luster. Cleavages in zones [011] and $[0\bar{1}1]$; conchoidal to uneven fracture; brittle. Flexible and elastic thin scales. $H = 3\frac{1}{2}$. $G_{\text{nat}} = 6.4$, $G_{\text{syn}} = 6.45$. Infusible. Easily soluble in dilute HCl or HNO₃. In RL, gray-white with a brownish tint; strongly pleochroic, very strongly anisotropic. $R = 30.7\text{--}20.3$ (470 nm), $30.1\text{--}19.6$ (546 nm), $29.5\text{--}19.5$ (589 nm), $29.0\text{--}19.4$ (650 nm). *P&J:366*. Formerly common in the oxidized portion of copper deposits, but less abundant than cuprite. Often intergrown with chrysocolla. Present to some degree in virtually all oxidized copper deposits. Copper Harbor, Keweenaw Point, MI. In AZ abundant at Bisbee; also at Globe and Morenci. Bingham Canyon, UT; Butte, MT. In Spain at Rio Tinto, Huelva. On lava at *Vesuvius*, Italy. Tsumeb, Namibia. Brittle, lustrous masses at Kakanda and elsewhere in Zaire. Chuquicamata, Chile. An ore of copper. RG *DI:507*.

4.2.4.1 Litharge $\gamma\text{-PbO}$

Named in 1917 from a Greek word given by Dioscorides to a material obtained in the process of separating lead from silver by pyrometallurgy, the material being lead oxide. Dimorph: massicot, $\beta\text{-PbO}$. TET $P4/nmm$. $a = 3.976$, $c = 5.023$, $Z = 2$, $D = 9.355$. *NBSC 539(2):30(1953)*. 5-561(syn): 3.12_{10} 2.81_6 2.51_2 1.99_1 1.87_4 1.68_2 1.56_1 1.54_1 . As alteration crusts on massicot; dense lamellar cleavages. Red, greasy to dull luster. Cleavage {110}. $H = 2$. $G = 9.14$. Easily fusible. Soluble in HCl and HNO₃, slowly soluble in alkalis. Uniaxial (-); $N_O = 2.665$, $N_E = 2.535$ (Li). *Cucamonga Peak, San Bernardino Co.*, and Ft. Tejon, Kern Co., CA. Mineral Hill district, Hailey, Blaine Co., ID, with native lead and leadhillite. Tintic district, UT. Langban, Värmland, Sweden(!). Zashuran River, Kurdistan, Azerbaijan, with massicot, orpiment, realgar, and cerussite. RG *DI:514, NJMA 94:1187(1960)*.

4.2.5.1 Romarchite SnO

Named in 1971 for the initials of the Royal Ontario Museum (ROM), where the mineral was identified, and *archaeology*. TET $P4/nmm$. $a = 3.802$, $c = 4.836$, $Z = 2$, $D = 6.398$. *NBSC 539(4):28(1955)*. 6-395(syn): 2.99_{10} 2.69_4 2.42_1 1.90_1 1.80_3 1.60_3 1.49_1 1.48_1 . Black. Found as small crystals as an oxidation product on tin cooking utensils submerged since 1830 in the Winnipeg River at *Boundary Falls, MB, Canada*, associated with hydromarchite. Abundant in the U.S. Virgin Islands in a vein with cassiterite, native tin, copper, and lead, and various lead-tin oxides and hydroxides. RG *CM 10:916(1971)*.

4.2.6.1 Montroydite HgO

Named in 1903 for Montroyd Sharp, one of the owners of the mine in Texas where the mineral was found. ORTH $Pnma$. $a = 6.608$, $b = 5.518$, $c = 3.519$, $Z = 4$, $D = 11.209$. *NBSC 539(9):39(1960)*. 37-1469(syn): 2.97_{10} 2.84_7 2.76_5 2.41_6 1.82_4 1.63_1 1.50_2 1.44_1 . Crystals long prismatic [001] or equant, often highly modified. As twisted, wormlike aggregates; massive, powdery. Red to reddish brown, yellow-brown streak, vitreous to subadamantine luster.

Cleavage {010}, perfect; crystals glide easily, with T {010}; sectile; very flexible, but not elastic. $H = 2\frac{1}{2}$. $G = 11.3$. In the closed tube volatilizes completely, giving a sublimate of native Hg in the upper part of the tube. Soluble in cold HCl or HNO_3 , and in alkali chloride solutions. Biaxial (+); $XYZ = abc$; $N_x = 2.37$, $N_y = 2.5$, $N_z = 2.65$ (Li); 2V large. From *Terlingua, Brewster Co., TX*, in veins with calcite, terlinguaite, mercury, and eglestonite. Two miles W of Redwood City, San Mateo Co., CA, with eglestonite, calomel, mercury, and cinnabar, and at the Socrates mine, Sonoma Co. Formerly abundant at Huahuaxtla, GRO, Mexico, with a similar mineral suite. Moschellandsberg, Germany, with moschellandsbergite and cinnabar. Guanxi, China(1), in acicular crystals to 10 mm. RG *DI:511, ACHS 10:852(1966)*.

4.2.7.1 Massicot β -PbO

Named in 1841 for a French name for lead oxide, related to the Spanish *mazacote*, of eventual Arabic origin. Dimorph: litharge (γ PbO). ORTH *Pbcm*. $a = 5.891$, $b = 5.489$, $c = 4.755$, $Z = 4$, $D = 9.642$. *NBSC 539(2):32(1953). 38-1477(syn): 3.07₁₀ 2.95₂ 2.75₂ 2.38₂ 1.849₁ 1.796₁ 1.723₂ 1.640₂*. Massive, earthy to scaly. Dull sulfur-yellow, sometimes reddish; lighter yellow streak; greasy to dull luster. Cleavage {100} and {010}, flexible but not elastic. $H = 2$. $G_{syn} = 9.56$. Biaxial (+); probably $Y = a$; $N_x = 2.51$, $N_y = 2.61$, $N_z = 2.71$ (Li), 2V = 90°; strong dispersion. Y, light sulfur-yellow; Z, deep yellow. Massicot is a product of oxidation of galena and found as a sublimation product in fumaroles. It is associated with cerussite and other secondary lead minerals and with limonite and antimony oxides. Found at Austinville, Wythe Co., VA; Leadville and Creede, CO; Redemption mine, Esmeralda Co., NV. Popocatepetl, Ixtacihuatl, and Perote volcanos, Mexico. *Stolberg, near Aachen, Germany*. In Sardinia, Italy, in the Oredde Valley with cerussite, caledonite, and other lead minerals. In the Marico district, Transvaal, South Africa, with minium, vanadinite, and wad. Caracoles, Bolivia. Melrose, NSW, also Dundas, TAS, Australia. RG *DI:516, NJMA 94:1187(1960)*.

CORUNDUM-HEMATITE GROUP

Corundum minerals have the chemical formula

where

$A = Al, Fe^{3+}, Cr,$ or V

and are isostructural in the rhombohedral space group $R\bar{3}c$. The structure consists of an arrangement of oxygen atoms in approximately hexagonal close packing. Between oxygen layers there are sites for cations octahedrally coordinated by six oxygen ions, but only two-thirds of the available positions

CORUNDUM: Al_2O_3

Al atoms occupy two-thirds of the octahedral interstices in a hexagonal-closest-packed array of oxygens. Because the octahedra share faces in pairs, they are considerably distorted.

are filled. Groups of three oxygen ions form a common face to two neighboring octahedra, and thus the groups are linked to a pair of A ions. *DHZ II:536(1992)*, *AC(A)46:271(1990)*.

CORUNDUM-HEMATITE GROUP

Mineral	Formula	Space Group	a	c	D	
Corundum	Al_2O_3	<i>R3c</i>	4.758	12.991	3.987	4.3.1.1
Hematite	Fe_2O_3	<i>R3c</i>	5.036	13.749	5.270	4.3.1.2
Eskolaite	Cr_2O_3	<i>R3c</i>	4.954	13.584	5.245	4.3.1.3
Karelianite	V_2O_3	<i>R3c</i>	4.954	14.008	5.016	4.3.1.4

Notes:

1. See also the ilmenite structures, which are lower-symmetry versions of the corundum structure that accommodate different A and B metals in place of corundum's two A metals.
2. Corundum minerals are typical of high-temperature environments, but hematite also forms extensively in soils.
3. Crystals are all particularly hard.

4.3.1.1 Corundum Al_2O_3

The name *corundum* is probably derived from the Tamil name of the mineral, *kuruntam*, and eventually from the Sanskrit for *ruby*. Corundum-hematite group. *HEX-R R3c*. $a = 4.758$, $c = 12.991$, $Z = 6$, $D = 3.987$. *NBSC 539(2):20(1953)*. *PD 43-1484(syn)*: 3.48_7 2.55_{10} 2.38_4 2.09_{10} 1.740_5 1.602_{10} 1.405_4 1.374_6 . **Habit**: Crystals commonly prismatic, often barrel-shaped, modified by {0001}, {11 $\bar{2}$ 1}, {2241}, {2243}, also {1120}; also tabular {0001}, or rhombohedral with {1011} and {0001}; striae on {0001} parallel to [01 $\bar{1}$ 0].

4.3.11 Corundum

**CORUNDUM: Al_2O_3**

Forms: $c\{0001\}$, $r\{10\bar{1}1\}$, $a\{11\bar{2}0\}$, $n\{22\bar{4}3\}$, $z\{22\bar{4}1\}$, $w\{11\bar{2}1\}$, $e\{33\bar{6}1\}$

Large blocks showing parting on rhombohedron and base, due to exsolution of boehmite, frequently observed. Massive, granular (emery). Twinning common on $\{10\bar{1}1\}$, usually lamellar. Rarely penetration or arrowhead twins; also on $\{0001\}$, less common. **Physical properties:** Corundum can be found in white, gray, blue-gray, several shades of blue (sapphire), blood-red (ruby); also yellow, orange, pink, violet, green, black. For a discussion of the causes of color of corundum gems and other minerals and gems, see *G&G XXIV:81(1988)*. Emery is usually black due to admixed fine magnetite. Uncolored streak, vitreous luster. No cleavage; uneven to conchoidal fracture; brittle, but very tough when compact (emery). $H = 9$; Mohs' scale defines hardness 9 as the hardness of corundum. $G = 4.0$. Rubies are fluorescent and phosphorescent in LWUV, a rich red color. Some sapphires are weakly fluorescent, pink. Insoluble in acids. Infusible. **Chemistry:** Substitution of other elements for Al is low; Fe to a maximum of 1%, and a trace of Ti;

However, trace amounts of Cr, Fe, and Ti are usually present and are important since they are essential to the color of the gem varieties of corundum and influence the optics. **Optics:** Uniaxial (-); $N_O = 1.765-1.776$, $N_E = 1.757-1.767$; absorption $O > E$. Pleochroism in some deeper-colored gems:

Sapphire, Sri Lanka: O, indigo blue; E, light blue

Sapphire, Australia: O, blue; E, emerald- to yellow-green

Ruby, Myanmar: O, deep purple; E, light yellow

Occurrence: Corundum is characteristically found in silica-deficient rocks such as syenites and especially, nepheline syenites and their associated pegmatites; as a product of metamorphism or contact metasomatism in some low-silica schists and gneisses and as a recrystallization product in aluminous xenoliths in igneous rocks; in marbles, especially as in the gem deposits of Myanmar and Afghanistan. **Varieties:** Three subdivisions of corundum can be made based on differences in purity and state of crystallization: (1) sapphire, ruby: gem varieties, characterized by fine colors, transparent to translucent; (2) corundum: includes the kinds with dark or dull colors, not transparent; colors light blue to gray, brown, and black; (3) emery: includes granular corundum, of black or grayish-black color, with intimately mixed magnetite or hematite. It is sometimes associated with an iron spinel, or hercynite. It feels and looks much like a black, fine-grained iron ore, and is very hard and tough. There are all gradations from ordinary emery to distinctly crystalline coarser corundum. **Localities:** In NY at Warwick, Orange Co., bluish and pink with spinel; at Amity, white, blue, and reddish crystals; and near Peekskill, Westchester Co. (emery). In NJ at Franklin and Sparta, Sussex Co. In PA at Corundum Hill near Unionville, Chester Co., in crystals and large masses. Common in a belt from VA through western NC and SC to GA, especially at Franklin, Macon Co., NC(*), and at Laurel Creek, GA. In ONT, Canada, corundum is found in syenites and anorthosites in Hastings Co., at South Burgess in Leeds Co. in red and blue crystals, and many places in Renfrew Co. Arnes, Norway(!) in fine crystals. Bellerberg, Eifel, Germany, in volcanic rock. Ticino, Switzerland, in dolomite. Island of Naxos and nearby islands, Greece (emery), as well as in Asia Minor and Smyrna, Turkey. Zlatoust and Miask, Ilimenskie Mts., southern Ural Mts., Russia(!). Fine red (ruby) crystals are found in gneiss in the Mysore district, India(!). Large opaque crystals come from Steinkopf, Namaqualand, Cape Prov., South Africa, and an important deposit with giant crystals from Zoutpansberg, Transvaal. In Brazil, large corundum crystals come from near Formoso, Goias(*). **Gemmology:** Ruby and sapphire are two of the four stones traditionally considered as precious (as opposed to semiprecious). Corundum can be found in any color and makes fine gems in shades of red, blue, pink, green, yellow, orange, and purple. Only those of a rich red color are called ruby; the pure blue stones are called *sapphire*, and all the other colors can be called *fancy sapphire*, although some go by specialized names for particular shades, such as padparasha sapphire, for an orange-pink color. Star rubies and sapphires owe their asterism to submicroscopic inclu-

sions of rods (crystals) of rutile which have exsolved oriented parallel to the *a* crystallographic axes. The star effect is produced with a source of light, such as the sun, incident along the direction of the *c* axis; such stones are always cut *en cabochon* with the base normal to [0001]. The color of ruby is due to Cr, and of sapphire of various colors mainly to Fe^{3+} and Fe^{2+} . Sapphires and rubies are among the most commonly manufactured stones; several different processes having been developed for doing so (including the star stones). The discrimination of the best synthetics from natural stones may be extremely difficult and depends in part on the study of minute inclusions under a microscope. Also, natural stones of poor or uneven color can be greatly improved by heating and other processes. Gem localities: Near Helena, MT, gem sapphires are found in alluvials along and near the Missouri River, especially at Yogo Gulch. They are derived from a lamprophyre dike that cuts limestone. Alluvial sapphire was studied and described from Espaly, Artois, France, about 1715. Fine blue and fancy sapphires are found in Sri Lanka in the Ratnapura and Rakwana districts, in alluvial deposits, associated with pale rubies, chrysoberyl cat's eye, alexandrite, taaffeite, and other gems. They are formed in schists and other metamorphic rocks. Rubies are found in Afghanistan at Jagdalak, 50 km E of Kabul, in limestone. The best rubies and many sapphires come from the Mogok area in upper Mandalay, Myanmar, in a region encompassing 70 km². The rubies occur *in situ* in limestone and also in the soil of the hillsides and the gem-bearing gravels of the Irrawaddy R., associated with gem spinel and, rarely, peridot. Superb "electric blue" sapphires are found in Kashmir, India, at Soomjam, Padar, at 4,500 m elevation, where metamorphics, including marble beds, are intruded by desilicated pegmatites. Gem rubies and sapphires are found SE of Bangkok, Thailand, and near Battambang, Cambodia. In Madagascar, equant rubies and some sapphires are abundant in decomposed mica schists at Vatondrangy SE of Antsirabe; these are generally opaque, but tabular rubies, including some gems, are found near Ampanihy in the southern part of the country. In Tanzania important deposits of gem sapphires and fancy sapphires in many pastel hues are found in the Umba region near Arusha, and bright red opaque ruby in green chromian zoisite is mined in the Matubitu Mts. In Australia very dark blue, almost black gem sapphires are mined at Anakie, Q, and some fine golden-colored stones have been found there also. **Synthesis:** Synthetic corundum abrasives are manufactured on a large scale by the electric furnace treatment of highly purified $\text{Al}(\text{OH})_3$ from bauxite. **Uses:** The principal use of corundum is as an abrasive, and in this application it is normally called *alumina*. It is used as a gem, and synthetic crystals are used in bearings for watches and fine instruments, and for lasers. RG *DI:520; ZK 117:235(1962), 120:342(1964)*.

4.3.1.2 Hematite Fe_2O_3

Named in antiquity from the Greek *haimatitis*, blood-red, in allusion to the color of the powdered mineral; "concreted blood" (Theophrastus). Corundum-hematite group. Synonyms: specularite, oligiste. HEX-R *R3c. a = 5.036*,

**HEMATITE: Fe₂O₃**Forms: $c\{0001\}$, $r\{10\bar{1}1\}$, $n\{2\bar{2}43\}$, $u\{10\bar{1}4\}$

$c = 13.749$, $D = 5.270$. *NBSM* 25(18):37(1981). *NBSN*(syn): 3.68₃ 2.70₁₀ 2.52₇ 2.21₂ 1.84₄ 1.69₅ 1.49₃ 1.45₃. **Structure:** *AM* 51:123(1966). **Habit:** Thick to thin tabular $\{0001\}$, often as subparallel growths on $\{0001\}$ or as rosettes ("iron roses"). Rhombohedral $\{1011\}$ to produce pseudocubic crystals; rarely prismatic $[0001]$; rarely scalenohedral. Sometimes micaceous to platy. Also compact columnar, or fibrous, frequently radiating. In reniform masses with smooth fracture (kidney ore) and in botryoidal and stalactitic shapes. Commonly earthy, ocherous, or frequently admixed with clay or other impurities. Also granular, friable to compact, concretionary, oolitic. Twinning on $\{0001\}$ as penetration twins, or with $\{1010\}$ as composition plane. On $\{1011\}$, usually lamellar, and showing twin striae on base and rhombohedron.

Physical properties: Steel gray to black crystals; earthy and compact fine-grained material, dull to bright red. In thin splinters or scales deep blood-red by transmitted light or internal reflections. Cherry-red to reddish-brown streak; metallic luster in crystals, earthy when fine grained. No cleavage, subconchoidal to uneven fracture, parting on $\{0001\}$ and $\{10\bar{1}1\}$, brittle in crystals, soft and unctuous in earthy varieties, elastic in thin laminae. $H = 5-6$. $G = 5.26$. Nonmagnetic. Infusible. Soluble in concentrated HCl. Becomes magnetic when heated in reducing flame. **Chemistry:** In the hematite cell there is very little substitution of other elements. Al and Ti may approach 1%; Cr and V much less. Earthy varieties may contain H₂O and/or admixed minerals such as goethite and other hydrous iron oxides. **Optics:** Uniaxial (-); $N_E = 2.94$ (Na); strong dispersion; absorption $O > E$. $R = 31.7-$

28.1 (470 nm), 30.0–26.5 (546 nm), 28.95–25.15 (589 nm), 26.8–23.3 (650 nm). *C&S:157, BM(NH)(1985)*. **Occurrence:** Most large hematite ore bodies are of sedimentary origin, bedded, or are metamorphosed sedimentary deposits like the *itabirites* of Brazil, which are thick sequences over vast areas of alternating thin beds of hematite and silica. In places, most of the silica has been removed by subsequent solution; high-grade hematite ore results. Much of the original deposition is believed to have been caused by bacterial action on dilute iron-bearing lake waters, precipitating hydrated iron oxides which were subsequently dehydrated to hematite. Contact metasomatism by intrusive igneous bodies, mostly granites, has produced high-grade hematite or, often, mainly magnetite. Hematite is also occasionally found as a sublimate on lava as a result of volcanic activity and fumaroles. Hematite is ubiquitous in soils, either derived directly from the decomposing underlying rocks or as a result of alteration of pyrite, magnetite, goethite, siderite, or iron silicates. It accounts for the red color of soils throughout the world, especially in tropical regions, and of many Triassic sedimentary deposits. **Localities:** Major iron deposits, predominantly hematite, are found around the shores of Lake Superior in MN and WI in the Iron Ranges, and in the southern Appalachians, especially AL; in Ukraine, China, and India; in Australia, especially in WA; in Africa, especially Liberia; in Venezuela in the Orinoco region, and in Brazil in the states of MG and PA. Fine crystallized or botryoidal hematite specimens are found in so many places throughout the world that only the most important can be listed.

Hematite crystals are found at several localities in northern NY, especially in St. Lawrence Co.; at Franklin, NJ, in coarse crystalline masses showing rhombohedral parting. In Quartzsite(*), AZ, as brilliant tabular crystals associated with quartz; in the Thomas Range, UT, with topaz in lithophysae in rhyolite. In Mexico in the mines of Concepcion del Oro, ZAC. Beautiful crystals of hematite have long come from the Rio Marina, Elba(!), Italy, and also from Vesuvius, Etna, and Stromboli volcanos. In Switzerland, fine rosettes of crystals are found at Passo di Lucendro, St. Gothard, Ticino(!) and also in plates with rutile at Cavradi, Tavetsch, Grisons, and at Alp Lercheltini, Binntal, Wallis(!). Splendid botryoidal specimens come from Ulverstone(!), Lancashire, England (“kidney ore”). In France, fine crystals are found at Framont, Alsace, and in Puy-de-Dome(!) on Mt. Dor. From Saurüssel, Zillertal, Tyrol, Austria(!) in large roses; in Saxony, Germany, from Altenberg and Johannegeorgenstadt. At Dognaska, Romania(!), in superb twins. In Russia, from the district of Ekaterinburg, Ural Mts.; and at Korshunovskoye, W of Lake Baikal, Siberia(!) magnificent druses of complex crystals. In volcanic rocks, in beautiful crystals, on Ascension Island(*), South Atlantic Ocean. Nador, Morocco, and in South Africa in fine crystals from the Wessels mine, Cape Prov.(*). In Brazil there are many fine localities. In MG at the Miguel Burnier(!) iron mines and at Dom Bosco, Ouro Preto district, large rosettes of thick crystals are found much like the Swiss “iron roses.” In the latter locality the hematite is associated with gem topaz in quartz veins. At the Casa de Pedra iron mine,

Congonhas(!), exceptional well-faceted crystals are found, having sharp faces and brilliant luster, ranging up to 15 cm in size, of a variety of habits from tabular to equant to scalenohedral, and often twinned under a variety of twin laws. At the magnesite deposit of Serra das Eguas(!), Brumado, BA, brilliant crystals and groups are found associated with magnesite. Also in BA in Novo Horizonte(*), crystallized hematite is often associated with epitaxial growths of golden colored rutile, forming stars of great beauty often embedded in clear quartz crystals. Uses: The most important source of iron. Hundreds of millions of tons are mined annually for the iron and steel industries worldwide. Ground hematite is also widely used as a red pigment and as a polishing compound (rouge). Compact black hematite or crystals are sometimes cut and faceted as a semiprecious gemstone. RG *DI:527*, *AM 47:1332(1962)*.

4.3.1.3 Eskolaite Cr_2O_3

Named in 1958 for Pentti Eskola (1883–1964), Finnish geologist, University of Helsinki. Corundum–hematite group. HEX-R *R3c*. $a = 4.954$, $c = 13.584$, $Z = 6$, $D = 5.245$. *NBSC 539(5):22(1955)*. *38-1479(syn): 3.63₇ 2.67₁₀ 2.48₉ 2.18₄ 1.815₄ 1.672₉ 1.465₃ 1.432₄*. Crystals prismatic, less commonly platy, with {0001} and {1010}. Lustrous black, light green streak, vitreous luster. No cleavage. $H = 9$. $G = 5.18$. Nonmagnetic. Infusible. Insoluble in acids or alkalis. Chemical analysis showed 4.5% V_2O_3 and 0.5% Fe_2O_3 in isomorphous substitution in the mineral, giving the formula $(\text{Cr}_{1.90}\text{V}_{0.09}\text{Fe}_{0.01})\text{O}_3$. Pleochroic; O, emerald green; E, olive green. Absorption very strong. In RL, gray, with emerald green internal reflections. $R = 22.0$ (470 nm), 20.8 (546 nm), 20.0 (589 nm), 19.6 (650 nm). *P&J:157*. Found at the *Outokumpu copper mine, Finland*(!), in crystals to 10 mm associated with pyrrhotite, chalcopyrite, pentlandite, uvarovite, chromian spinel, quartz, calcite, and other minerals in a chromian tremolite skarn. As rolled pebbles from the Merume River, Guyana (“merumite”), intergrown with bracewellite, guyanite, mcconnellite, and grimaldiite. As rounded crystals in stream gravels from the Serra das Almas, Parimirim, BA, Brazil, associated with bahianite and cassiterite. RG *AM 43:1098(1958)*, *USGSPP 887:9(1976)*.

4.3.1.4 Karelianite V_2O_3

Named in 1963 for Karelia, the region in Finland where the Outokumpu mine is situated. Corundum–hematite group. HEX-R *R3c*. $a = 4.954$, $c = 14.008$, $Z = 6$, $D = 5.016$. *NBSM 25(20):108(1984)*. *34-187(syn): 3.66₇ 2.71₁₀ 2.48₈ 2.19₄ 1.83₃ 1.70₉ 1.47₂ 1.43₃*. Disseminated grains intergrown with sulfides. Black, black streak. Conchoidal fracture. $H = 8-9$. $G = 4.87$. In polished section, etched by 1:1 HNO_3 ; not affected by other reagents. Analyzed mineral contained about 4% Fe_2O_3 , trace Mn, as isomorphous substitution. In RL, brownish olive-gray. No internal reflections. Weakly pleochroic, strongly anisotropic. $R = 15.0$ (470 nm), 16.9 (546 nm), 17.8 (589 nm), 18.9 (650 nm). *P&J:220*. From the *Outokumpu copper mine, Finland*, in veins in skarn, asso-

ciated with pyrrhotite, chalcopyrite, chrome spinel, and coulsonite. RG *AM* 48:33(1963).

4.3.2.1 Akdalaite $(\text{Al}_2\text{O}_3)_4 \cdot \text{H}_2\text{O}$

Named in 1970 for the Kazakh name for the locality. HEX $P6_1$ or $P6_122$. $a = 12.87$, $c = 14.97$, $Z = 18$, $D = 3.673$. 25-17: 3.24₇ 2.49₉ 2.35₉ 2.32₈ 2.11₁₀ 1.86₇ 1.42₁₀ 1.39₁₀. Accumulations of tabular and elongated tabular crystals showing hexagonal outline. White, vitreous-porcellanous luster. No cleavage, irregular fracture, brittle. $H = 7\frac{1}{4}$. $G = 3.68$. Uniaxial (-); $N_0 = 1.747$, $N_E = 1.741$; extinction parallel to elongation. Found in the *Solvech fluorite deposit, Karaganda region, Kazakhstan*, in veinlets cutting fluorite-magnetite-diopside-vesuvianite-andradite skarn and amesite-fluorite-muscovite rock. RG *AM* 56:635(1971), *ZVMO* 99:333(1970), *IGR* 13:675(1971).

4.3.2.2 Ferrihydrite $\text{Fe}_5\text{O}_6(\text{OH})_3 \cdot 3\text{H}_2\text{O}$; $\text{FeO}(\text{OH})$; (?)

Named in 1973 from the composition. HEX Space group unknown. $a = 5.08$, $c = 9.4$, $Z = 1$. *CCM* 36:111(1988). 29-712: 2.50₁₀ 2.21₈ 1.96₈ 1.72₅ 1.51₇ 1.48₈. *AM* 75:437(1988): 2.52₅ 2.23₄ 1.98₃ 1.72₃ 1.51₅ 1.46₉. (Powder lines are few and broad, probably due to the colloidal particle size and poor structural organization of the mineral.) Yellow brown ochers to dark brown masses, earthy luster. No cleavage. $G_{\text{syn}} = 3.96$. Soft. Highly soluble in ammonium oxalate. Easily synthesized by slow hydrolysis of ferric salts at pH between 3 and 9.5. The presence of iron-fixing bacteria greatly increases the yield. The exact composition is uncertain, being variously given as $\text{FeO}(\text{OH})$; $\text{Fe}_5\text{O}_6(\text{OH})_3 \cdot 3\text{H}_2\text{O}$; $5\text{Fe}_2\text{O}_3 \cdot 9\text{H}_2\text{O}$; $\text{Fe}_2\text{O}_3 \cdot 2\text{FeO}(\text{OH}) \cdot 2.6\text{H}_2\text{O}$, and others, probably due to the loosely held H_2O and hence variability of analytical results on various samples examined. Ferrihydrite, a primary precipitate of iron-fixing bacteria or of the natural hydrolysis of iron salts in solution, is probably a precursor of goethite(limonite); ferroxihite; and many other iron minerals, including some that form large iron deposits. From Kazakhstan; from various localities in Finland; near Hannover, Germany. Widely distributed elsewhere in the world, but seldom recognized or characterized. RG *AM* 65:1044(1980), 60:485(1975); *IGR* 16,1131(1974); *PICCM*:333(1973).

PEROVSKITE GROUP

The perovskite group minerals have the general formula

where

A = Ca, Na, Ce, and rarely Sr

B = Ti or Nb.

PEROVSKITE: CaTiO_3

Space group $Pm\bar{3}m$. This is an idealized structure; perovskite itself has lower symmetry. Ca atoms replace O atoms in a CCP arrangement and Ti atoms are in selected octahedral interstices. Ca–O bonds are not shown.

The ideal perovskite structure is cubic, with a approximately 3.8 Å. The B ions are surrounded by regular octahedra of oxygen that share corners to form a three-dimensional framework. The A ions occupy large holes between the octahedra, and each is surrounded by 12 oxygens. The actual structure is related to the ideal cube by a shear on $\{010\}$, leaving $b \approx 7.64$ Å and a rhombus-shaped a - c face with $\beta = 90.80^\circ$. *DHZ II:556, AC C39:1323(1983)*.

PEROVSKITE GROUP

Mineral	Formula	Space Group	a	b	c	D	
Perovskite	CaTiO_3	$Pnma$	5.441	7.644	5.381	4.036	4.3.3.1
Latrappite	$(\text{Ca}, \text{Na})(\text{Nb}, \text{Ti})\text{O}_3$	$Pcmn$	5.448	7.777	5.553	4.40	4.3.3.2
Loparite-(Ce)	$(\text{Ce}, \text{Na}, \text{Ca})(\text{Ti}, \text{Nb})\text{O}_3$	$Pm\bar{3}m$	3.889			5.25	4.3.3.3
Lueshite	$\beta\text{-NaNbO}_3$	$Pbma$	5.569	15.523	5.505	4.575	4.3.3.4
Tausonite	SrTiO_3	$Pm\bar{3}m$	3.905			4.85	4.3.3.5

4.3.3.1 Perovskite CaTiO_3

Named in 1839 after L. A. Perovski (1792–1856), Russian mineralogist, of St. Petersburg. Perovskite group. ORTH *Pnma*. $a = 5.441$, $b = 7.644$, $c = 5.381$, $Z = 4$, $D = 4.036$. *NBSM 25(9):17(1971)*. *PD NBSM(syn)*: 3.82₁ 2.72₄ 2.70₁₀ 1.91₅ 1.567₁ 1.563₂ 1.557₃ 1.35₁. **Habit**: Crystals cubic, sometimes highly modified, but the faces often irregularly distributed. As cubo-octahedra or octahedra, especially in cerian or niobian varieties. Rarely massive granular, or reniform. Twinning on {111}; also as penetration or lamellar twins. **Physical properties**: Black, brown, yellow, with adamantine luster, or metallic when black; gray to colorless streak. Cleavage {001}, imperfect; subconchoidal to uneven fracture. $H = 5\frac{1}{2}$. $G = 4.01$. Nonfluorescent. Decomposed by hot concentrated H_2SO_4 and by HF. Infusible. **Chemistry**: Wide compositional variation is the rule, as Nb substitutes for Ti up to 44.9 wt % Nb_2O_5 ($\text{Nb}/\text{Ti} = 2:5$); Ce for Ca at least up to $\text{Ce}/\text{Ca} = 4:7$, and Na for Ca to at least $\text{Na}/\text{Ca} = 1:4$. Early analyses showing even higher levels of substitution were not certainly of perovskite but may have been of loparite-(Ce) or latrappite. The unit cell parameters of perovskite increase with Nb content, up to $a = 5.45$, $b = 7.78$, $c = 5.55$ with concomitant X-ray changes. **Optics**: Biaxial (+); $\text{XYZ} = \text{acb}$; $N = 2.34$; $2V = \pm 90^\circ$; $r > v$; absorption $Z > X$. In RL, isotropic gray, with yellow to orange-brown internal reflections. $R = 17.8$ (470 nm), 16.7 (546 nm), 16.3 (589 nm), 16.0 (650 nm). *P&J:296*. **Occurrence**: Perovskite occurs both as an accessory mineral of the magmatic stage and as a late-stage deuteric mineral in basic igneous rocks, especially carbonatites and related rocks. Also in basic pegmatites associated with such rocks and in metamorphosed limestones at the contact with alkalic or basic intrusives. Also found in chlorite or talc schists. Perovskite is thought to be a major constituent of the upper mantle portion of the earth. **Localities**: Niobian perovskite is found in limestone metamorphosed at the contact with alkaline rocks at Magnet Cove, AR(*). Abundant as an accessory in carbonatite at Powderhorn, Gunnison Co., CO. In nepheline syenite pegmatite, Bearpaw Mts., MT. Cerian perovskite is found in alkalic pegmatite at Moose Creek, near Leanchoil, BC, Canada. From the Gardiner complex, Kangerlussuaq Fjord, eastern Greenland, in large black pseudo-octahedral crystals up to 8 cm(!). In Switzerland in crystals and reniform masses in talc schist near the Findelen glacier, Zermatt, Valais(*). In Italy at the Wildkreuzjoch, Pfitschtal, Trentino(!); also in Piedmont at Emarese, Valle d'Aosta, and so on. At Schelingen in the Kaiserstuhl, Baden, Germany, in contact metamorphic limestone, and as an accessory mineral in alkalic–basic intrusives of this district. In chlorite schist, *Zlatoust district, Ural Mts., Russia*(!). In Brazil, in magnetite-rich carbonatite at Catalao, GO, and near Bagagem, MG. *RG DI:730, CM 7:683(1963)*.

4.3.3.2 Latrappite $(\text{Ca}, \text{Na})(\text{Nb}, \text{Ti})\text{O}_3$

Named in 1964 for La Trappe, PQ, Canada, a village close to where the mineral was found. Perovskite group. ORTH *Pcmm*. $a = 5.448$, $b = 7.777$,

$c = 5.553$, $Z = 4$, $D = 4.40$. *CM 8:121(1964)*. $16-694$: 3.89_8 2.77_3 2.74_{10} 1.94_6 1.74_1 1.60_1 1.58_3 1.37_1 . Small black cubes, gray streak, submetallic luster. Cleavage {001}, imperfect; subconchoidal fracture. $H = 5\frac{1}{2}$. $G = 4.40$. Latrapite has $Nb/Ti > 1:1$. Analyzed mineral shows 43.9% Nb_2O_5 , $Nb/Ti = 5:2$. A nearly complete solid solution series exists between perovskite, latrapite, and lueshite. From *Oka, QUE, Canada*, in a pyrochlore-rich carbonatite, in white calcite associated with diopside, biotite, and apatite. Also from Vogtsburg, Kaiserstuhl, Germany, and Yva Prov., Sri Lanka. *RG CM 7:683(1963)*, *AM 49:819(1964)*.

4.3.3.3 Loparite-(Ce) (Ce, Na, Ca)(Ti, Nb)O₃

Named in 1922 after the Russian name for the Lapp inhabitants of the Kola Peninsula. Perovskite group. iso *Pm3m*. $a = 3.889$, $Z = 0.3$, $D = 5.25$. *DANS 140:1090(1961)*. $35-618$: 2.75_{10} 2.24_2 1.94_4 1.59_5 1.37_3 1.23_2 1.04_3 0.917_2 . As cubes. Interpenetration twins on {111}. Loparite is defined as that portion of the solid-solution series in which $REE/Ca > 1:1$. Adequate studies of analyzed materials are lacking. Some weak extra lines in the powder diagram suggest that the true symmetry is other than isometric. The value for Z is unsatisfactory; the indicated cell volume based on $a = 3.89$ Å is almost exactly one-fourth of the cell volume based on an orthorhombic perovskite cell. Needs further study. Black, brownish streak, metallic luster. No cleavage, conchoidal fracture. $H = 5\frac{1}{2}$. $G = 4.86$. Isotropic; $N = 2.33$. Translucent red in fine chips. From Buer, Bjorkedal, Possgrunn, southern Norway; *Khibina Tundra, Kola Peninsula, Russia*; also from an unspecified location in Siberia in albitized and greisenized granites. *RG CMP:84-365(1983)*, *DANS 140:1407(1961)*, *MA 16:455*.

4.3.3.4 Lueshite β -NaNbO₃

Names in 1959 for the locality. Perovskite group. Polymorph: natroniobite. *ORTH Pbma*. $a = 5.569$, $b = 15.523$, $c = 5.505$, $Z = 8$, $D = 4.575$. *NBSM 25(18):64(1981)*. $19-1221$ (syn): 3.9_9 2.76_{10} 1.949_7 1.746_4 1.594_7 1.379_3 1.235_2 1.044_2 . Black pseudocubes with faces lightly striated and gray streak. Cleavage {001}, imperfect, easy. $H = 5\frac{1}{2}$. $G = 4.44$. Biaxial; $N = 2.30$. Powderhorn, CO, in carbonatite. Mt. St.-Hilaire, PQ, Canada. Igdlunguaq, Greenland, in nepheline syenite, associated with neptunite, analcime, and altered eudialyte. Originally found in the Ilimaussaq igneous complex, Greenland, and named igdloite; later found in carbonatite at *Lueshe, 150 km N of Goma, Zaire*, as incrustations on a compact yellow magnesian-calcian mica, at the contact with a cancrinite syenite, and renamed lueshite. *RG AM 44:1327(1959)*, $46:1004(1961)$.

4.3.3.5 Tausonite SrTiO₃

Named in 1984 for L. V. Tauson (1917–1989), Russian geochemist. Perovskite group. iso *Pm3m*. $a = 3.905$, $Z = 1$, $D = 4.85$. $35-734$ (syn): 3.90_1 2.76_{10} 2.25_3 1.95_5 1.59_4 1.38_3 1.24_2 1.04_2 . As cubes and cubo-octahedrons; also irregular

grains. Tausonite has cell contents close to loparite and is probably a member of the perovskite group. A mineral intermediate between loparite and tausonite has been described from Brazil and Paraguay in carbonatites. Red, reddish brown, gray; adamantine luster. Conchoidal fracture, brittle. $H = 6-6\frac{1}{2}$. $G = 4.88$. Insoluble in dilute acids. Isotropic, sometimes slightly anisotropic. From alkalic rocks of the *Murunskii massif, Aldan, Siberia, Russia*. RG *AM 70:218(1985)*, *ZVMO 113:86(1984)*.

4.3.4.1 Natroniobite NaNbO_3

Named in 1960 for the composition. Polymorph: lueshite. MON Space group unknown. *26-1380*: 3.79₄ 3.06₉ 2.97₁₀ 1.89₅ 1.72₆ 1.60₈ 1.59₄ 1.54₄. Irregular grains and fine-grained aggregates. Yellowish, brownish, blackish. $H = 5\frac{1}{2}-6$. $G = 4.40$. Biaxial (+); $X \wedge c = 10-15^\circ$; $N_x = 2.10-2.13$, $N_y = 2.19-2.21$, $N_z = 2.21-2.24$; $2V = 10-30^\circ$; $r < v$. From the *Lesnaya Baraka* and *Sallanlatvi massifs, Kola Peninsula, Russia*, in dolomitic carbonatites with apatite, phlogopite, perovskite, and pyrochlore. RG *AM 47:1483(1962)*, *ZVMO 92:190(1962)*.

ILMENITE GROUP

The ilmenite group is isostructural within itself and nearly isostructural with the corundum group, and conforms to the formula

where

$A = \text{Fe}^{2+}$, Mg, Mn, Zn, Fe^{3+} , and rarely Sb^{5+}

and a structure in space group *R3*. The structure has a rhombohedrally centered lattice, similar to that of the corundum-hematite group but with Ti and another element replacing the A_2 of the corundum structure. Along the three-fold rotoinversion axis of ilmenite pairs of Ti^{4+} ions alternate with pairs of Fe^{2+} ions, forming cation layers perpendicular to that threefold axis. Each cation layer is a mixture of Fe^{2+} and Ti^{4+} .

ILMENITE GROUP

Mineral	Formula	Space Group	D			
			a	c		
Ilmenite	FeTiO_3	<i>R3</i>	5.088	14.093	4.784	4.3.5.1
Geikielite	MgTiO_3	<i>R3</i>	5.054	13.898	3.895	4.3.5.2
Pyrophanite	MnTiO_3	<i>R3</i>	5.140	14.290	4.596	4.3.5.3
Ecandrewsite	$(\text{Zn, Fe, Mn})\text{TiO}_3$	<i>R3</i>	5.090	14.036	4.99	4.3.5.4
Melanostibite	$\text{Mn}(\text{Fe}^{3+}, \text{Sb}^{5+})\text{O}_3$	<i>R3</i>	5.226	14.325	5.63	4.3.5.5

ILMENITE: FeTiO_3

The structure is similar to hematite or corundum, but the pairs of octahedra that share faces are occupied by Fe + Ti.

While the minerals of this group are very similar structurally and in cell parameters to those of the corundum-hematite group, there are important differences. There is nearly complete solid solution between Fe and Mn, and between Fe and Mg, and at least partial solution between Zn and Fe, Mn. In contrast, in the corundum group the minerals are virtually end members with exceedingly small solid solutions of other elements. *DHZ II:543(1992)*, *MJJ 14:179(1989)*.

Note: Ilmenite is an abundant mineral; all the others are rare.

4.3.5.1 Ilmenite FeTiO_3

Named in 1827 after the locality in the Ilmenskie Mts., Russia. Ilmenite group. **HEX-R** $R\bar{3}$. $a = 5.088$, $c = 14.093$, $Z = 6$, $D = 4.784$. *NBSM 25(15):34(1978)*. *29-733(syn)*: 3.74_3 2.75_{10} 2.54_7 2.24_3 1.868_4 1.726_6 1.506_3 1.469_4 . **Habit:** Crystals usually thick tabular {0001}; sometimes thin laminae; also acute rhombohedral. Compact, massive; as disseminated grains, or as a heavy constituent in sand. Twinning on {1011}, lamellar. **Physical properties:** Black, black streak, metallic to submetallic luster. No cleavage, parting {0001} and {1011}, conchoidal fracture. $H = 5-6$. $G = 4.72$. Nonmagnetic or only slightly magnetic, with the latter likely to represent higher Fe_2O_3 content in the structure, or microscopic inclusions of magnetite. **Tests:** Slowly soluble in hot 1:1 HCl. Infusible. **Optics:** Uniaxial (-); birefringence very strong; absorption $E > O$, faint. Transmits only red light. In polished section, grayish white. $\text{VHN}_{100} = 566-698$. Anisotropy strong; bireflectance weak. $R = 19.7-16.9$ (470 nm), $19.2-16.4$ (546 nm), $19.6-17.0$ (589 nm), $20.2-18.0$ (650 nm). *C&S:166*, *BM(NH)(1985)*. **Chemistry:** Extensive solid solution exists between ilmenite and geikielite (to 70 mol % MgTiO_3) and between ilmenite and pyrophanite (to 64 mol % MnTiO_3). But the majority of terrestrial ilmenites contain Fe_2O_3 up to 6% maximum and only minor amounts of MgO and

**ILMENITE: FeTiO_3** Forms: $c\{0001\}$, $r\{10\bar{1}1\}$, $n\{2243\}$.

MnO . Exceptions are the ilmenites in kimberlites and ultrabasic xenoliths, which frequently contain major amounts of MgTiO_3 ; the pyrophanite molecule may become important in carbonatites and certain differentiated acid rocks. Above 6%, Fe_2O_3 is believed to be due to admixed or exsolved magnetite or hematite. **Occurrence:** Ilmenite occurs principally as a common accessory mineral in igneous rocks such as gabbros, diorites, and anorthosites, as veins and disseminated deposits, sometimes of large extent. Massive accumulations may be found as dikes cutting anorthosite. Widespread in granitic rocks, as a minor accessory. In some pegmatites, especially those of intermediate or alkalic composition. Heavy-mineral concentrates derived from beach sands may contain major ilmenite, associated with magnetite, rutile, zircon, and other dense minerals, which are recovered from such deposits in Florida, India, Australia, and Brazil. **Localities:** Crystals are found in pegmatites at Chester and at Quincy, MA. At Sanford Lake, Tahawus, NY, a large deposit is mined associated with magnetite and garnet in anorthosite(*), and at Warwick, Amity, and Monroe in metamorphosed limestone associated with spinel, chondrodite, and rutile. In VA at Roseland in a large dike with apatite and rutile ("nelsonite" rock). Iron Mt., WY, in a large ilmenite-magnetite dike in anorthosite. Summit, OR. In PQ, Canada, at St. Urbain, Charlevoix, as veinlets disseminated in anorthosite. Bancroft, ON, in large crystals(*). In Norway at Kragero, as large crystals in veins in diorite(!). Northern Sweden at Routivare, associated with pyrrhotite in altered gabbro. Crystals are found at Alp Uercheltini, Binnatal, Switzerland, and exquisite ilmenite roses at Maderanertal, Uri(!). In *Russia* in the *Ilmenskie Mts.*, *southern Ural Mts.*(!), in crystals to 20 cm. Large beach sand deposits are found at Travancore, southern India. At the Ambatofotsikely pegmatite, Betafo, Madagascar, in crystals to 20 cm(!). In Australia, at Woodstock, WA (manganoean ilmenite). **Uses:** Ilmenite is a major source of TiO_2 , which is used as a pigment in paints and enamels and as a raw material in the manufacture of titanium. RG *DI:534*, *DHZII 543(1992)*.

4.3.5.2 Geikielite MgTiO_3

Named in 1892 for Archibald Geikie (1835–1924), director of the Geological Survey of Great Britain. Ilmenite group. **HEX-R $R\bar{3}$** . $a = 5.054$, $c = 13.898$,

$Z = 6$, $D = 3.895$. *NBSC 539(5):43(1955)*. *6-494(syn)*: 4.64_3 3.70_5 2.72_{10} 2.53_6 2.22_7 1.85_4 1.71_6 1.46_4 . As irregular grains and as small tabular crystals. Ruby-red to brownish red, inclining to black with increased Fe^{2+} content; metallic to submetallic luster. Cleavage $\{1011\}$, conchoidal to subconchoidal fracture. $H = 5-6$. $G = 3.79$. Uniaxial (-); $N_O = 2.31$ (brownish red), $N_E = 1.95$ (pinkish). In CA at the Jensen quarry, Riverside Co., in disseminated crystals or veinlets in marbles associated with spinel, diopside, fosterite, pyrite, and pyrrhotite, in crystals close to end-member composition; and in magnesian marbles in the Sta. Lucia Mts., Monterrey Co. From *Sri Lanka* as pebbles in gem-bearing gravels. *RG AM 44:879(1959)*, *34:835(1949)*; *DI:535*.

4.3.5.3 Pyrophanite MnTiO_3

Named in 1890 from the Greek for *fire*, and *to appear*, in allusion to its red color. Ilmenite group. *HEX-R R3*. $a = 5.140$, $c = 14.290$, $Z = 6$, $D = 4.596$. *NBSM 25(15):42(1978)*. *29-902(syn)*: 3.78_3 2.79_{10} 2.57_7 2.26_3 1.89_4 1.75_4 1.52_4 1.48_3 . Fine grained, scaly. Deep blood red, metallic to submetallic luster. Cleavage $\{0221\}$, perfect; $\{1012\}$, less so; conchoidal to subconchoidal fracture. $H = 5-6$. $G = 4.54$. Uniaxial (-); $N_O = 2.481$ (yellowish red), $N_E = 2.21$ (Na). In RL, gray. Reddish internal reflections. Weakly pleochroic, moderately anisotropic. $R = 22-18$ (470 nm), $19-16$ (546 nm); $18-14$ (589 nm). From the Sterling Hill mine, Ogdensburg, NJ, associated with pyroxene, gahnite, calcite, and biotite. *Harstig mine, Värmland, Sweden*, associated with ganophyllite, garnet, and manganophyllite, in cavities later filled with calcite. At Queluz, SW of Ouro Preto, MG, Brazil. *RG DI:535*, *CM 23:491(1985)*.

4.3.5.4 EcanAndrewsite $(\text{Zn, Fe, Mn})\text{TiO}_3$

Named in 1988 for E. C. Andrews, pioneering geologist in the Broken Hill region of New South Wales. Ilmenite group. *HEX-R R3*. $a = 5.090$, $c = 14.036$, $Z = 6$, $D = 4.99$. *26-1500(syn)*: 3.72_2 2.73_{10} 2.54_8 2.23_2 1.860_4 1.713_4 1.500_3 1.466_3 . Irregular grains; also euhedral tabular crystals. Although ecanAndrewsite is a member of the ilmenite group, zinc substitution is virtually absent in other members of the group. Dark brown to black, dark brown to black streak, submetallic luster. No cleavage observed. $H = 5\frac{1}{2}$, $\text{VHN}_{100} = 500-600$. In RL, grayish white with a pinkish tinge. Weakly pleochroic, strongly anisotropic. $R = 19.5-17.5$ (470 nm), $19.3-17.4$ (546 nm), $19.2-17.3$ (589 nm), $18.9-17.1$ (650 nm). San Valentin mine, La Union district, Sierra de Cartagena, Spain, in oxidized ore intergrown with zincian ilmenite. From the *Melbourne-Rockwell mine, northern Broken Hill, NSW, Australia*, with almandine-spesartine, ferroan gahnite, and rutile in quartz-rich metasediments. *RG MM 52:237(1988)*, *AM 74:501(1989)*.

4.3.5.5 Melanostibite $\text{Mn}(\text{Fe}^{3+}, \text{Sb}^{5+})\text{O}_3$

Named in 1892 in allusion to its color and antimony content. Ilmenite group. *HEX-R R3*. $a = 5.226$, $c = 14.325$, $Z = 6$, $D = 5.63$. *AM 53:1104(1968)*. *20-699*:

4.78₅ 4.31₄ 3.82₆ 2.81₁₀ 2.61₈ 2.29₄ 1.92₅ 1.77₈. Foliated masses; also tiny striated crystals with prism and pyramid. Twinning on {0001} by rotation. Black, cherry-red streak. Cleavage {0001}, perfect. H = 4. Soluble in 1:1 HCl. Weakly magnetic after ignition. Analytical data show that the Fe/Sb ratio is close to 1:1. Although melanostibite contains no titanium, the Fe³⁺ and Sb⁵⁺ is considered to be the equivalent of Ti⁴⁺. This, combined with the similar unit cell dimensions and resulting formula, puts the mineral within the ilmenite group. Opaque. From the *Sjo mine, Grythytte parish, Orebro, Sweden*, in veinlets in dolomite. RG *DII:1041, AMG 4:449(1967)*.

4.3.5.6 Briziite NaSbO₃

Named in 1994 for G. Brizzi (1936–1992), Italian amateur mineralogist who collected the original specimens. Ilmenite group. HEX *R3*. $a = 5.301$, $c = 15.932$, $Z = 6$, $D = 4.95$. *PD*: 5.30₅ 3.00₅ 2.65₇ 2.37₇ 1.874₁₀ 1.471₇ 1.185₅. Crystals minute, platy to thin tabular, hexagonal in outline, to 0.2 mm. Aggregates of crystals are pale pink to yellow. Cleavage {001}, perfect; flexible. $VHN_{15} = 57$. $G = 4.8$. Nonfluorescent. Uniaxial (-); $N_E = 1.631$, $N_O = 1.84_{\text{calc}}$. Found at the *Cetine antimony mine, Siena, Tuscany, Italy*, encrusting weathered waste material and slag. RG *EJM 6:667(1994)*.

4.3.6.1 Macedonite PbTiO₃

Named in 1971 for the locality, in former Yugoslavia. TET *P4/mmm*. $a = 3.889$, $c = 4.209$, $Z = 1$, $D = 8.09$. *6-452(syn)*: 4.15₃ 3.90₅ 2.84₁₀ 2.76₅ 2.30₄ 1.95₃ 1.66₂ 1.61₄. *AM(nat)*: 3.84₆ 2.84₁₀ 2.73₈ 2.28₇ 1.95₇ 1.60₉ 1.37₅ 1.23₅. Irregular grains and rare stout prismatic crystals with pseudocubic habit. Black, vitreous luster. Cleavage not observed. H = 5½. $G = 7.82$. Soluble in hot HCl, HNO₃, and H₂SO₄. In RL, grayish white. Internal reflections yellow-brown and dark brown. Pleochroism not observed; very weakly anisotropic, almost isotropic. From *Crni Kamen, near Prilep, Macedonia*, in amazonite-rich quartz syenite veins, associated with rutile, zircon, and barite. RG *AM 56:387(1971), LIT 4:101(1971)*.

4.3.7.1 Maghemite $\gamma\text{-Fe}_2\text{67O}_4$

Named in 1927 from the first syllables of *magnetite* and *hematite*, in allusion to the magnetic properties and composition. Synonym: $\gamma\text{-Fe}_2\text{O}_3$. ISO *P4*₁₃₂. $a = 8.351$, $Z = 8$, $D = 4.860$. *24-81(low temp.)(syn)*: 2.95₃ 2.78₂ 2.52₁₀ 2.08₂ 1.70₁ 1.61₃ 1.48₅ 1.09₂. *25-1402(high temp.)(syn)*: 2.95₃ 2.51₁₀ 2.09₂ 1.70₁ 1.60₂ 1.47₄ 1.27₁ 1.09₁. Massive. Brown, brown streak. H = 5. Highly magnetic, about the same as magnetite. The composition is essentially Fe₂O₃, but structural considerations show that the formula should be written Fe₂₆₇O₄. Usually impure, admixed with silica, gibbsite, kaolin, goethite, and other iron oxides and hydroxides. Isotropic; $N > 2.40$. In RL, white to grayish blue, isotropic. Reflectance: > magnetite, < hematite. Formed by slow oxidation at low temperatures of preexisting iron minerals such as siderite, magnetite, or

lepidocrocite. Common in gossans, also in laterites, and very widely distributed throughout the world in rocks of this type, especially in tropic regions. Common in the oxidized outcrops of magnetite deposits. First recognized in a gossan at *Iron Mt., Shasta Co., CA.* Durant, OK, as rounded ocherous masses. Windpass mine, BC, Canada. Katzenbuchel, Baden-Württemberg, Germany. In the Bushveld complex, South Africa. Near Sydney, NSW, Australia, in laterites. RG *DI:708, AM 55:925(1970), PD 3:104(1988), CMP 69:249(1979).*

4.3.7.2 Bixbyite (Mn, Fe)₂O₃

Named in 1897 for Maynard Bixby (1853–1935) of Salt Lake City, UT, miner and mineral collector, discoverer of red beryl in Utah. Synonym (in part): partridgeite (=Mn₂O₃), which was named in 1943 for F. C. Partridge (1903–1939), senior mineralogist, Geological Survey of South Africa. The name *partridgeite*, a virtually Fe-free, orthorhombic variety of bixbyite, has never been submitted to the IMA, CNMMN (International Mineralogical Association, Committee on New Minerals and Mineral Names), as it was found before the IMA came into existence; however, the structure is distinct from that of bixbyite. iso *Ia3*. $a = 9.415$, $Z = 16$, $D = 5.026$. *NBSC 539(9):37(1960). 24-508(syn Mn₂O₃): 3.84₂ 2.719₁₀ 2.35₁ 2.01₁ 1.846₁ 1.664₃ 1.452_{<1} 1.420₁*. Unit cell for Mn₂O₃: ORTH *Pcab*. $a = 9.416$, $b = 9.424$, $c = 9.405$, $Z = 16$, $D = 5.031$. *NBSM 25(11):95(1974)*. As cubes, sometimes modified by {112}; penetration twinning on {111}. Structure: *AC(B)27:821(1971)*. Black, black streak, metallic to submetallic luster. Cleavage {111} in traces, irregular fracture. $H = 6-6\frac{1}{2}$. $G = 4.945$. Difficultly fusible. Slowly soluble in 1:1 HCl, with evolution of Cl₂. In RL, gray, weakly anisotropic. $R = 22.9$ (470 nm), 23.6 (546 nm), 23.1 (589 nm), 22.3 (650 nm). *P&J:94*. The amount of Fe that can enter the bixbyite composition varies with the temperature of formation of the mineral, from about 1 to 60% Fe₂O₃. Bixbyite from the type locality in Utah, a high-temperature environment, contains about 1:1 Fe₂O₃/Mn₂O₃, or usually an excess of Fe₂O₃. From 1 to 60% the structure is isometric and a solid-solution series exists. Below 1% Fe₂O₃ the structure becomes orthorhombic, pseudoisometric. Such material, found only in Postmasburg and Mamatwan, Cape Prov., South Africa, [partridgeite] and exhibits strong anisotropism in polished section. Synthetic Mn₂O₃ also has this structure. *EG 78:1111(1983)*. Most minerals that have been identified as bixbyite have Mn₂O₃ > Fe₂O₃; outside the type locality, hardly any bixbyite is Fe dominant. For those that are Mn dominant and still have the isometric structure, the name *manganbixbyite* would be appropriate, while for the Fe-dominant variety, *bixbyite* would be retained. This question is being submitted to the IMA, CNMMN. From on and near *Topaz Mt., Thomas Range, Juab Co., UT(1)*, in lithophysae in rhyolite, associated with topaz, spessartine, red beryl, and hematite; also with fluorite. Black Range tin district, NM, in rhyolite (manganbixbyite). Barranca del Cobre, Chih., Mexico. Långban, Värmland, Sweden, in metamorphosed manganese ores (manganbixbyite); Ultevis, Sweden (bixbyite); Ribes, Girona, Spain;

Sitapār, Central Provs., India, with braunite and hollandite (manganbixbyite). Postmasburg, Cape Prov., South Africa (manganbixbyite). Valle de las Plumas, Patagonia, Argentina (manganbixbyite). RG *DI:550*, *ZK 129:360(1969)*, *NJMM 1973:426*, *AM 74:1325(1989)*.

4.3.8.1 Avicennite Tl_2O_3

Named in 1958 for Abu Ali Ibn Sina ("Avicenna") (980–1037), Arab physician and scientist, who lived in Bukhara. iso *Ia3*. $a = 10.543$, $Z = 16$, $D = 10.354$. *NBSM 25(16):77(1979)*. *NBSM(syn): 4.30₁ 3.04₁₀ 2.64₄ 2.48₁ 2.07₁ 1.86₃ 1.59₃ 1.55₁*. As small grayish-black cubes, grayish-black streak, metallic luster. Indistinct cleavage, uneven fracture, very brittle. Dissolves with difficulty in concentrated acids. From near *Dzhuzumli*, *Mt. Zirabulaksk*, *Bukhara*, *Uzbekistan*, in a hematite–calcite vein cutting banded, silicified limestones. Vizarron de Marques, Cadereyta, QRO, Mexico, as a coating on quartz and hematite. RG *AM 44:1324(1959)*, *MA 72:3282(1972)*.

4.3.9.1 Arsenolite As_2O_3

Named in 1854 for the composition. Dimorph: claudetite. iso *Fd3m*. $a = 11.074$, $Z = 16$, $D = 3.865$. *NBSC 539(1):51(1953)*. *36-1490(syn): 6.40₄ 3.20₁₀ 2.77₃ 2.54₃ 2.13₁ 1.959₂ 1.670₁ 1.552₁*. Octahedral; also botryoidal or stalactitic; earthy. White, yellowish, reddish; vitreous to silky luster. Cleavage {111}; conchoidal fracture. $H = 1\frac{1}{2}$. $G = 3.87$. In closed-tube sublimes, condensing above in small octahedra. Slightly soluble in hot water. Tastes astringent, sweetish (poisonous). Isotropic; $N = 1.755$ (Na). Formed from the oxidation of arsenic and arsenic sulfides; also formed as a sublimate in mine fires and burning coal seams. In NV from the Ophir mine, as an alteration of native As, and in fine crystals from the White Caps mine, Manhattan(I), from the burning of the shaft. In CA at the Armagosa mine, San Bernardino Co., and as an alteration product of enargite at the Exchequer and Monitor mines, Alpine Co. In Canada at Watson Creek, BC, and near Lake Wanapitei, Sudbury district, ON. *Andreasberg*, *Harz*, *Germany*, as an alteration of smaltite and other arsenides and as an alteration of arsenic at the Lauta mine near Marienberg, Saxony. In France from burning coal dumps at Sorbier, near St. Etienne, Loire, and as a direct oxidation product on native As at Giftgrube vein, Rauenthal, Ste.-Marie-aux-Mines, Haute-Rhin. At Sondalo, Sondrio, and Borgofranco in Torino, Italy. Morocochoa, Peru, with realgar and orpiment. RG *DI:543*.

4.3.9.2 Senarmontite Sb_2O_3

Named in 1851 for Henri de Senarmont (1808–1862), professor of mineralogy at the School of Mines in Paris, who first described the species. Dimorph: valentinite. iso *Fd3m*. $a = 11.152$, $Z = 16$, $D = 5.583$. *NBSC 539(3):31(1954)*. *42-1466(syn): 6.44₂ 3.22₁₀ 2.79₃ 2.56₁ 1.971₃ 1.681₃ 1.610₁ 1.279₁*. Structure: *AC(B) 31:2016(1975)*. Octahedral. Crystals; also granular, massive, and as crusts. Above 460° senarmontite is isometric, but at ordinary temperatures

becomes triclinic, pseudoisometric by twinning. *BM 57:90(1934)*. Colorless, grayish white, resinous to subadamantine luster. Cleavage {111} in traces, uneven fracture, brittle. $H = 2-2\frac{1}{2}$. $G = 5.50$. Isotropic; $N = 2.087$ (Na). Birefringence anomalous, strong, often arranged in zones or segments due to twinning. In Canada with valentinite and kermesite as an alteration of stibnite and antimony at South Ham, Wolfe Co., PQ. At Pernek, Slovakia, with kermesite. Nieddoris, Sardinia, Italy. Anzat-le-Luguet, Puy de Dome, France. Niccioleta, Grosseto, northern Italy. Abundant and well crystallized at *Hami-mat, Constantine, Algeria*(!), with kermesite, valentinite, and other minerals as an alteration of stibnite in veins in a bituminous marly sediment. Also common as an artificial product in old antimony smelters. *RG DI:544*.

4.3.10.1 Claudetite As_2O_3

Named in 1868 for Frederick Claudet, French chemist, who first described the natural mineral. Dimorph: arsenolite. *MON P2₁/n*. $a = 5.339$, $b = 12.984$, $c = 4.541$, $\beta = 94.27^\circ$, $Z = 4$, $D = 4.186$. *NBSM 25(3):9(1964)*. *NBSM(syn)*: 4.92₃ 3.45₅ 3.36₂ 3.33₂ 3.25₁₀ 2.77₄ 2.64₂ 2.26₃. Crystals thin plates on {010}, elongated [001], with {111} and $\{1\bar{1}1\}$ prominent, resembling gypsum. Twinning on {100} as penetration or contact twins. Colorless to white; vitreous luster, pearly on cleavage. Cleavage {010}, perfect; fibrous fracture, parallel to {110}; very flexible. $H = 2\frac{1}{2}$. $G = 4.15$. In closed-tube sublimes, condensing above as small octahedrons of arsenolite. Soluble in hot alkali solutions (**highly poisonous**). Biaxial (+); $X \wedge c = 84^\circ$; $Y = b$; $Z \wedge c = 6^\circ$; $N_x = 1.871$, $N_y = 1.92$, $N_z = 2.01$ (Na); $r < v$. Occurs as a product of oxidation of orpiment, realgar, and other arsenic minerals. Also formed in some mine fires and as a condensate from gases emanating from burning coal seams. Imperial Co., CA, about 50 km N of Yuma, AZ, as an alteration product of realgar, and in Trinity Co. at Island Mt. as crusts in the gossan of a pyrrhotite deposit. *Santo Domingo mine, Portugal*. At Calañas, Andalusia, Spain. With native sulfur and orpiment at the La Salle mine, Decazeville, Aveyron, France. Well crystallized at Smolnik, Slovakia(!), as a sublimation product. *RG DI:545, AM 36:833(1951), SR 41A:213(1975)*.

4.3.10.2 Bismite Bi_2O_3

Named in 1868 for the composition. *MON P2₁c*. $a = 5.850$, $b = 8.170$, $c = 7.512$, $\beta = 112.98^\circ$, $Z = 4$, $D = 9.36$. *WEW(1989)*. 41-1449(syn): 3.31₄ 3.26₁₀ 2.71₅ 2.69₃ 2.56₃ 1.96₅ 1.75₅ 1.51₃. Massive, granular to earthy. Yellow to grayish green, subadamantine to earthy luster. Uneven fracture. $H = 4\frac{1}{2}$. $G = 8.6-9.2$. Biaxial; $N > 2.42$. In pegmatite at Rincon, San Diego Co., CA, as microcrystals associated with bismutite and pucherite. Meymac, Corrèze, France, with bismutite. *Calavi, Potosi, Bolivia*, as an alteration crust on bismuth. Numerous other localities have been reported, such as Petaca, NM; Schneeberg, Germany; Cornwall, England; Mt. McDonald, TAS, Australia, and elsewhere, but the minerals are not certainly of this species. *RG DI:599, AM 28:521(1943), NBSM 25(3):17(1964)*.

4.3.11.1 Valentinite Sb_2O_3

Named in 1845 after Basilius Valentinus, probably a mythical monk and alchemist of the late Middle Ages. Many works published under his name ("a literary forgery") were on the subject of antimony and its compounds. He is alleged to have been born in 1394, but no solid evidence of his life has been found; much of what was attributed to him had been published by others at an earlier date. *PII:183*. Dimorph: senarmontite. ORTH *Pccn*. $a = 4.914$, $b = 12.468$, $c = 5.421$, $Z = 4$, $D = 5.832$. *NBSC 539(10):6(1960)*. 11-689(syn): 4.57₂ 3.49₃ 3.17₂ 3.14₁₀ 3.12₈ 2.65₁ 1.93₁ 1.80₂. Crystals prismatic either [001] or [100]; also tabular {010}. Often in stellate or fan-shaped groups and as aggregates of thin plates. Also massive, lamellar, or granular. Colorless, white, yellowish, reddish; adamantine luster, pearly on cleavage. Cleavage {110}, perfect; {010}, imperfect; brittle. $H = 2\frac{1}{2}$ -3. $G = 5.83$. Easily fusible in closed tube. Soluble in HCl. Colored brown and slowly dissolved by $(\text{NH}_4)_2\text{S}$ solution. Biaxial (-); $XYZ = abc$; $N_x = 2.18$, $N_y = 2.35$, $N_z = 2.35$ (Na); 2V very small; $r < v$, marked. From the Ochoco district, Crook Co., OR(!), in good crystals. Picahotes mine, San Benito Co., CA, with stibnite. In Canada at South Ham, Wolfe Co., PQ, and Prince William, NB. In Mexico at Sombrerete, ZAC, and Arechuybo, CHIH. *Les Chalanches, near Allemont, Isere, France*, as an oxidation product of antimony and allemontite. Braunsdorf, Germany. Příbram, Bohemia, Czech Republic(!), crystals 10 to 15 mm in galena. Le Cetine and Pereta, Tuscany, Italy. Djebel Senza mine, Constantine, Algeria. In crystals to 2 cm at Huanuni and Tatasi(!), Bolivia. Hargreaves, Ouro Preto district, MG, Brazil. *RG DI:547*.

4.3.12.1 Sillénite $\text{Bi}_{12}\text{SiO}_{20}$

Named in 1943 for Lars Gunnar Sillen (1916-1970) of Stockholm, Sweden, who contributed much to the knowledge of the polymorphs of Bi_2O_3 . iso *I23*. $a = 10.110$, $Z = 2$, $D = 9.18$. *MJJ 15(8):343(1991)*. 37-485(syn): 3.57₂ 3.20₁₀ 2.92₂ 2.70₇ 1.73₄ 1.68₂ 1.64₃ 1.49₂. As cubes; massive; earthy. Yellow-green, olive-green, reddish brown; adamantine to dull luster. $\text{VHN}_{50} = 345$ -386. $G = 9.16$. Isotropic; $N > 2.50$. From *Durango, Mexico*, associated with bismutite; also at Navojoa, SON. In cubes up to 5 mm from Fuka, Okayama Pref., Japan(!), on calcite in a gehlenite-spurrite skarn. In pegmatite at Monapo, Mozambique. *RG DI:601, AM 28:525(1943)*.

4.3.13.1 Sphaerobismoite Bi_2O_3

Named in 1995 by Walenta, for the composition and the form of the aggregate. Dimorphous with bismite. TET $P4_22_12$ or $P4_2/n$. $a = 8.08$. $c = 6.46$, $Z = 4$, $D = 7.17$. *AUF 45:245(1995)*. *PD*: 5.73₇ 3.44₅ 3.16₁₀ 3.01₄ 2.82₃ 2.56₄ 2.02₅ 1.90₂₆. Forms spherulitic aggregates of minute tabular crystals. Green, yellowish; white streak, adamantine luster. Translucent. Nonfluorescent. No discernible cleavage, conchoidal fracture, brittle. $H = 4$. Uniaxial (+), $N_O = 2.13$, $N_E = 2.18$ (Na). Nonpleochroic. Upon heating at 600° for 1 hour, converts to delta Bi_2O_3 . Soluble in 1:1 HCl and 1:1 HNO_3 . Found in

the zone of oxidation at *Neubulach and Wittichen, Black Forest, Germany*, associated with bismutite, malachite, mixite, chalcopyrite, and emplectite. RG AUF 213(1979).

RUTILE GROUP

The rutile group comprises nine oxides having the general formula

where

and a tetragonal structure in space group $P4_2/mnm$. The dominant structural feature of the rutile group consists of chains of edge-sharing TiO_6 octahedra that run parallel to c . The octahedra share two opposite edges to form straight chains, which are, in turn, linked by corners to form the framework. The oxygen atoms are coordinated to three titanium atoms in a nearly planar configuration, forming nearly equilateral triangles. CM 17:77(1979).

The formula AO_2 can accommodate several types of structures, with the result that several of these minerals have one or more naturally occurring polymorphs. With the exception of rutile, members of the group show little miscibility, probably due to considerable difference in the ionic radii of the A ions.

RUTILE: TiO_2

Space group $P4_2/mnm$. TiO_6 octahedra share edges to form chains in the c -axis direction, and the chains are also cross-linked in the same way.

RUTILE GROUP

Mineral	Formula	Space Group	Rutile Group			D	
			a	c			
Rutile	TiO ₂	<i>P4₂/mnm</i>	4.593	2.959	4.250	4.4.1.1

4.4.1.1 Rutile TiO₂

Named in 1803 from the Latin *rutilus*, red, in allusion to the usual color. Rutile group. Polymorphs: anatase, brookite. ТЕТ *P4₂/mnm*, $a = 4.593$, $c = 2.959$, $Z = 2$, $D = 4.250$. *NBSM 25(7):83(1969)*. *NBSM(syn): 3.25₁₀ 2.49₅ 2.19₃ 1.69₆ 1.62₂ 1.36₂ 1.35₁ 0.820₁*. **Habit:** Commonly prismatic, often slender to acicular {001}. Prism zone vertically striated. Usually terminated by {101} or {111}. Rarely pyramidal or equant. Also granular, massive, coarse to fine. Twinning on {011} common. Often geniculated, or contact twins of varied habit, sometimes sixlings or eightlings occasionally forming circular groupings, doughnut-shaped. Also reticulated groups ("sagenite"). Epitaxial intergrowths of rutile with hematite, magnetite, ilmenite, brookite, and anatase are common, and oriented microscopic needles of rutile are found in corundum, phlogopite, and quartz, giving rise to asteriated material such as star rubies or star quartz. **Physical properties:** Red, brown, yellow, to black in varieties high in Fe, Nb, or Ta; pale brown to yellow streak; adamantine-metallic luster. Cleavage {110}, distinct; {100}, less so; parting on {092} and {011} due to twin gliding; conchoidal to uneven fracture. $H = 6-6\frac{1}{2}$. $G = 4.23$. Nonfluorescent. **Tests:** Insoluble in acids. Infusible. Decomposed by fusion with alkali or alkali carbonate. **Chemistry:** High amounts of Fe³⁺, Fe²⁺, Nb, and Ta may be present, as well as minor amounts of Sn, Cr, and V. The substitution of Nb⁵⁺ and/or Ta⁵⁺ is coupled with Fe³⁺ and Fe²⁺ in charge compensation; these varieties are black and have densities ranging up to 5.7, depending on content of Nb, Ta, and Fe. High-Nb rutile is called niobian rutile or *ilmenorutile* (4.4.1.2), and high-Ta rutile is tantalian rutile or *struverite* (4.4.1.3). These two mineral names are considered as distinct species names in this book, depending on the content of Nb and Ta, but many consider them to be merely varieties of rutile. *NJMA 101:142(1964)*. **Optics:** Uniaxial (+); $N_O = 2.612$, $N_E = 2.889$ (Na). Dichroism O, distinct, in red;

Prismatic Habit

E, brown, yellow, or green. Absorption $E > O$. Often anomalously biaxial. In RL pale gray, pleochroic, abundant internal reflections of varying shades of red-brown, yellow to colorless, strong anisotropism. $R = 25.3-22.0$ (470 nm), $23.9-20.5$ (546 nm), $23.3-19.9$ (589 nm), $22.7-19.2$ (650 nm). *P&J:331*. **Occurrence:** Rutile is a common accessory mineral in metamorphic rocks, especially gneisses and schists; in granites, syenites, anorthosites, and plutonic rocks rich in hornblende. It is also common in aluminous rocks and in rocks rich in apatite, such as nelsonites; in quartzite with kyanite, pyrophyllite, or lazulite. Also common in pegmatites and in alpine cleft-type veins and fissures. **Localities:** Graves Mt., GA(!), in large, equant crystals and twins up to 10 cm and more, associated with kyanite, pyrophyllite, and lazulite in quartzite; Hiddenite, Alexander Co., NC(!), in fine crystals in pegmatite with muscovite, dolomite, apatite, beryl, and green spodumene (hiddenite); also in NC in Cleveland Co. N of Boiling Springs. Parkersburg, Chester Co., PA(!), in multiple twins, sometimes doughnut-shaped. Roseland, Nelson Co., VA, with ilmenite and apatite ("nelsonite") in anorthosite. Magnet Cove, AR(*), in crystals and twins and in part pseudomorphous after large crystals of brookite. In large sharp crystals in pyrophyllite with andalusite at the Champion

mine, White Mts., Mono Co., CA(!); also at the Jensen quarry, Riverside. In Norway in large amounts in apatite veins in Fogne and in the region of Gjerstadvand and Vegaardsheien; in Sweden at Horrsjöberg, Värmland, with lazulite, pyrophyllite, and kyanite in quartzite. Finely crystallized at many localities in the alpine regions of Switzerland, France, Italy, and Austria, as drusy crystals in crevices and vein deposits mostly in metamorphic rocks, with adularia, albite, hematite, anatase, brookite, titanite, mica, and so on; especially in Switzerland at Alp Lercheltini, Binnatal, Wallis(!); Cavradi, Tavetsch, Grisons, epitaxial with hematite; Lukmanierschlucht, Tavetsch, as sagenite; Pfitsher-Joch, Val di Passa, Tyrol, Italy, large fibrous crystals; Saurüssel, Zillertal, Austria. Near Ambatofinandrahana, Madagascar. In Brazil in fine V-twins in the Ouro Preto district, MG(!), associated with precious topaz in veins. Brumado, BA(!), in fine crystals in a large magnesite deposit. Novo Horizonte, BA(!), as acicular, golden-colored crystals ("Venus hair") embedded in clear quartz crystals ("rutilated quartz"). This rutile sometimes occurs in epitaxial six-rayed stellate groups growing from a hematite crystal nucleus. Uses: Used for making titanium metal and for coating welding rods. RG *DI:554*.

4.4.1.2 Ilmenorutile (Ti, Nb, Ta, Fe³⁺, Fe²⁺)O₂

Named in 1854 for the original locality in the Ilmenskie Mts., Russia, and its similarity to rutile. Rutile group. TET $P4_2mnm$. $a = 4.62$, $c = 2.99$, $Z = 2$, $D = 4.3-5.0$. $16-934$: 3.28_{10} 2.51_9 2.32_3 2.20_5 1.70_{10} 1.64_6 1.47_3 1.37_4 . PD for TiO₂, 59.5%; Nb₂O₅, 28.75%; Ta₂O₅, 1.65% from Vezna, Moravia, Czech Republic. Crystals equant to short prismatic, often twinned on {011}. Black to brownish red, grayish or greenish-black streak, submetallic luster. $H = 6-6.5$. $G = 4.3-5.0$. Slightly magnetic; magnetic susceptibility increases with iron content. Nb, coupled with Ta, Fe²⁺, and/or Fe³⁺ enter the composition of rutile up to a maximum of about 33% Nb₂O₅ or higher amounts of (Nb₂O₅ + Ta₂O₅). Much natural rutile contains at least 1-2% Nb₂O₅. The point at which the Nb₂O₅ content justifies the name of ilmenorutile rather than niobian rutile is arbitrary and not fixed; some feel that with >10% Nb₂O₅, the term *ilmenorutile* can be used. Ilmenorutile also makes a complete series with strüverite (4.4.1.3). Common in pegmatites. Also in some albitites and apogranites. Niobian rutile and/or ilmenorutile are common at Magnet Cove, AR. In pegmatites at Evje, Iceland, and Tvedstrand, southern Norway. Val Vigesso, Piedmont, Italy. In pegmatite near *Miask, Ilmenskie Mts., Russia*. Near Ambatofinandrahana, Madagascar; also at Ampangabe in crystals to 13 cm and at Fefena in rose quartz. Near Mokota, Zimbabwe. Araçuaí, (!) MG, Brazil. RG *DI:558*, *AM 44:620(1959)*, *NJMA 101:142(1964)*.

4.4.1.3 Strüverite (Ti, Ta, Nb, Fe³⁺, Fe²⁺)O₂

Named in 1907 for Giovanni Strüver (1842-1915), professor of mineralogy at the University of Rome. Rutile group. TET $P4_2mnm$. $a = 4.645$, $c = 2.999$, $Z = 2$, $D = 5.0-5.7$. $17-543$: 3.28_{10} 2.52_9 2.32_4 2.21_3 1.71_{10} 1.64_6 1.47_3 1.38_4 .

PD: for TiO_2 , 47.8; Ta_2O_5 , 38.7; Nb_2O_5 , 6.2; FeO , 7.3; Etta mine, SD. Crystals prismatic to blocky; twinning on $\{011\}$. Black, gray-black; black streak; metallic luster. $H = 6-6.5$. $G = 5.0-5.7$. Magnetic susceptibility slight, but increases with content of Fe^{3+} . Traces of Ta are common in rutile and a complete series exists up to about 41% Ta_2O_5 . There is coupled substitution of Ta^{5+} , Fe^{3+} , and/or Fe^{2+} for Ti^{4+} ; the solid-solution composition may be considered to be a mixture of TiO_2 , Fe^{2+} , Ta_2O_6 , and $\text{Fe}^{2+}\text{TaO}_4$; $\text{Fe}^{3+}\text{NbO}_4$ should also be added, since there is a complete solid-solution series between strüverite and ilmenorutile. The Committee of New Minerals and New Mineral Names of the International Mineralogical Association has not yet ruled on the validity of the names *struverite* and *ilmenorutile*, as opposed to *tantalian rutile* and *niobian rutile*; in any event, any line of demarcation drawn between tantalian rutile and strüverite, or their niobian analogs, would be arbitrary and subject to disagreement. The basis of the controversy lies in the fact that even with high percentages of Nb and Ta, there is a higher mol % of TiO_2 in these minerals than Nb or Ta or Nb + Ta; there is no basic structural change, and the powder diffraction patterns differ to only a small degree from pure rutile. A little Mn and Sn also substitute in the composition. From the Etta mine, near Keystone, SD. Also in pegmatite near *Craveggia, Val Vigesso, Piedmont, Italy*(*). Near Fefena and Ampangabe, Madagascar(!). In alluvium near Salak North, Malaysia, where much struverite is recovered by ocean bottom dredging as a tantalum ore. From Madagascar at Tsaramanga, Tongafeno, Ankazobe, Beltsiry, and other localities. In fine crystals at Barra do Cuiete, Conselheira Pena, MG(!), and at Parelhas, RGN(!), Brazil. Used as an important ore of Ta. *RG DI:558, AM 49:792(1964), NJMA 101:142(1964)*.

4.4.1.4 Pyrolusite MnO_2

Named in 1827 from the Greek for *fire* and *to wash*, because it is used to decolorize the brown and green tints of glass. Rutile group. Synonym: polianite. Polymorphs: ramsdellite, akhtenskite. *TET* $P4_2/mnm$. $a = 4.400$, $c = 2.874$, $Z = 2$, $D = 5.189$. *NBSM 25(10):39(1972)*. $24-735(\text{syn})$: 3.11_{10} 2.41_6 2.11_2 1.62_6 1.56_1 1.306_2 1.304_2 1.000_1 . *Habit*: Crystals uncommon, long to short prismatic $[001]$ or equant. In druses of small crystals, and as paracrystals or overgrowths over crystals of manganite. Usually columnar or fibrous, botryoidal, granular massive, earthy. As dendritic growths on fracture surfaces or enclosed in chalcedony (moss agate). The term *polianite* refers to crystallized pyrolusite, which was originally thought to be a distinct mineral. *Structure*: MnO_2 exists in at least three natural polymorphs: pyrolusite, ramsdellite, and akhtenskite. A fourth probable polymorph, β -pyrolusite, is also believed to exist on the basis of powder-diffraction and other data. All of these polymorphs share one dimension of the unit cell near 2.87, and a second dimension near 4.44. Two are orthorhombic (β -pyrolusite and ramsdellite), one tetragonal (pyrolusite) and one hexagonal (akhtenskite). Differentiation of these polymorphs is difficult and usually requires careful

investigation using EM. *AC(B)* 32,2200(1976), *AM* 64,1199(1979). **Physical properties:** Gray or black, black or bluish-black streak, metallic luster. Cleavage {110}, perfect; uneven fracture; brittle. $H = 2$ (earthy), $6\frac{1}{2}$ (crystals), 2–6 (massive). $G = 5.0$. Nonmagnetic. **Tests:** Soluble in concentrated HCl with evolution of Cl_2 . Massive varieties usually yield a little water in the closed tube. **Chemistry:** Most pyrolusite that is not mixed with other Mn phases or impurities is very pure MnO_2 . Small amounts of iron and water are often present, up to about 1%; the presence of other elements such as Ba usually indicates an admixture of other minerals. **Optics:** In RL, cream-white. Very weakly pleochroic, distinctly anisotropic. $R = 31.4\text{--}18.9$ (470 nm), $31.3\text{--}18.7$ (546 nm), $30.6\text{--}18.5$ (589 nm), $29.2\text{--}18.2$ (650 nm). *P&J:313*. **Occurrence:** Pyrolusite is one of the most common manganese minerals. It is apparently always formed under oxidizing conditions and high pH. The chief types of occurrence are as bog, lacustrine, or shallow marine deposits; in the oxidized zone of manganese ore deposits and rocks, and as deposits formed by circulating meteoric waters. Colloidal processes undoubtedly play a major role in the transportation and deposition of pyrolusite. Bacterial action is also important. Associated minerals are other manganese and iron oxides and hydrated oxides, including hausmannite, braunite, manganite, psilomelane, nsutite, marokite, hematite, goethite, and "limonite." Pyrolusite is also deposited as nodules on the deep-sea floor, probably related to bacterial action and/or spreading centers between plates. Vast tonnages of these are known to cover millions of square kilometers of the Pacific and other ocean floors. **Localities:** Pyrolusite is found in small bodies of manganese ores in the Piedmont plateau and with the residual iron ores of the Paleozoic sedimentary rocks, Appalachian region. With the hematite ores of the Lake Superior region, as at Negaunee, MI. It has been mined at Batesville, Independence Co., AR. Was found at Leadville, CO, and at Butte, MT, as a result of oxidation and leaching of manganese carbonate ores. Fine crystals near Bathurst, Gloucester Co., NB, Canada(1). Horni Blatná, Czech Republic(1), in large crystals (polianite). Large deposits are mined in Russia and especially in Kutasi, Georgia. Deposits formed by the weathering of rocks containing manganese silicates are mined extensively in India, and similar deposits are found in Ghana. Also found in large deposits in Brazil in MG and SP. **Uses:** Used as a principal source of manganese in the manufacture of steel; as a decolorizer in the manufacturing of glass; in electric batteries; as an oxidizing agent in the chemical industry, and as a coloring material in bricks, pottery, and so on. *RG DI:562*.

4.4.1.5 Cassiterite SnO_2

Named in 1832 from the Greek *kassiteros*, tin. Rutile group. *TET* $P4_2/mnm$. $a = 4.738$, $c = 3.188$, $Z = 2$, $D = 6.995$. *NBSC* 539(1):54(1953). 14-567(nat): 3.33₈ 2.60₈ 1.75₁₀ 1.42₄ 1.40₄ 1.14₃ 1.082₄ 1.076₄. 21-1250(syn): 3.35₁₀ 2.64₈ 2.37₂ 1.77₆ 1.68₂ 1.50₁ 1.44₂ 1.42₂. **Habit:** Untwinned crystals are the exception, usually short prismatic [001] with {110} and {100} prominent; sometimes

Prismatic and Low Pyramidal Habits

Cornwall Twin

Zinnwald Twins

CASSITERITE: SnO₂Forms: $a\{100\}$, $c\{001\}$, $e\{011\}$, $h\{120\}$, $m\{110\}$, $s\{111\}$, $z\{321\}$

long prismatic with acute terminations due to the development of a steep pyramid (needle tin). Also massive, radial-fibrous botryoidal crusts or concretionary masses (wood tin); granular. Twinning very common on $\{011\}$, both contact and penetration; often repeated, producing complex forms; sometimes stellate fivelings. Twins also reported on $\{031\}$. **Physical properties:** Black, brown, yellow-gray, rarely red, colorless, or white. The color is often in zones parallel to crystal surfaces. White, grayish, brownish streak; adamantine to metallic luster in black varieties, inclining to greasy on fracture surfaces. Cleavage $\{100\}$, imperfect; $\{110\}$, indistinct; subconchoidal to uneven fracture; brittle. $H = 6-7$. $G = 6.99$. Nonfluorescent. Nonmagnetic. **Diagnostic tests:** Slowly attacked by acids; decomposed by fusion with alkalis. Fragments of cassiterite when placed in dilute HCl or H₂SO₄ with metallic zinc become coated with a gray deposit of metallic tin which turns bright on friction. This specific test for cassiterite is used for identifying the mineral when admixed with other black phases, such as in tantalite concentrates. **Chemistry:** Fe³⁺ is usually present in substitution for Sn, to

about Fe/Sn = 1:6, but iron-free cassiterite also occurs; the black color of some cassiterites is related to the iron content. Ta and Nb may also be present in small amounts, in cassiterite derived from pegmatites, and may reach 8% Ta₂O₅. Wood tin may contain unusually high amounts of several elements substituting in the cell, up to (wt %) 10% FeO; 3.5% ZnO; 3.1% SiO₂; 2.4% In₂O₃; 1.5% As₂O₃; and smaller amounts of WO₃, Al₂O₃, and Sb₂O₅, the sum total of such impurities reaching as much as 13% in reported analyses. Optics: Uniaxial (+); N_O = 2.001, N_E = 2.098. Dichroism usually weak or absent, but may be strong. Absorption E > O. In RL, light gray; very weakly pleochroic, strongly anisotropic. R = 12.6–11.4 (470 nm), 12.1–11.0 (546 nm), 12.0–10.9 (589 nm), 12.0–10.7 (650 nm). *P&J:114*. Varieties: *Wood tin* is a type of fine-grained botryoidal cassiterite found in shallow high-temperature deposits. It has concentric structure and is radiated fibrous internally, so that broken pieces with brownish color often have the appearance of wood. The structure of wood tin can accommodate significant amounts of certain other elements, including Sb, As, In, and Ge. Occurrence: Cassiterite is characteristic of deep-seated high-temperature veins, and of association with highly acid igneous rocks such as granites and their derivatives. Important placer deposits are derived from the weathering and erosion of stockworks of cassiterite-bearing veins in granite. Also, large tonnages of cassiterite are found disseminated as small grains in albitites and apogranites, often accompanied by niobium–tantalum minerals, zircon, and xenotime. Cassiterite is also found in some pegmatites, associated with columbite–tantalite, lepidolite, albite, topaz. It is associated with certain rhyolites, although these do not contribute a significant tonnage to total production. Vein-type deposits are important in Cornwall, England; central Europe; and especially Bolivia. Associated minerals are wolframite, tourmaline, topaz, fluorite, and arsenopyrite, and to a lesser extent pyrrhotite, pyrite, chalcopyrite, galena, sphalerite, and several tin-bearing sulfides, such as stannite and teallite. In rhyolites and related extrusive rocks, it is found as wood tin, sometimes associated with rare antimonates and arsenates, such as ordonezite and durangite. Localities: Very little cassiterite has been mined in the United States, and most U.S. occurrences are in pegmatites. In New England at Norway, Hebron, and elsewhere in Oxford Co., ME; also in NH, MA, and CT. Large crystals have been found at the Herbb No. 2 pegmatite, Powhatan Co., VA(1), associated with wadginite and topaz. Harney peak, near Custer, SD. In rhyolite in the Black Range, Sierra and Catron Cos., NM. Veins in the York district, Seward Peninsula, AK, have associated Be mineralization. Fine wood tin is found in rhyolite in several areas in Mexico, especially at Sierra Fria, Rincon de Romos, AGS, but also in GTO, SLP, ZAC, and DGO. In Cornwall, England, veins were mined by Celtic peoples at the time of the Phoenicians; fine crystals were found at St. Agnes, Camborne, St. Just, St. Austell. Panasqueira, Portugal(*) to 3 cm, often twinned, sometimes complex “cross-bit” twins. In Bohemia in veins at Horni Slavoc and Cinovec, often well crystallized(1), and in the neighboring district of Saxony, Germany, at Altenberg and Ehrenfriedersdorf. In Italy at San Piero in Campo, Elba(*), at several of the mines. In crystals to 10 cm

at the Iultin deposit(!), eastern Chukotka, Siberia, Russia, also at Merek(!), far eastern Siberia. Bain Mod, Hentiy district, Outer Mongolia(*), crystals to 6.5 cm. Nuristan, Laghman, Afghanistan(!), sharp crystals and twins to 10 cm. Stak Nala, Gilgit Div., Pakistan(*). Important deposits, mostly alluvial, occur in the Malay Peninsula and on the islands of Billiton and Banka off the coast of Sumatra, Indonesia; also in Thailand, where it is associated with tantalite. Leiyang, Hunan, China. Tae Wha, N of Chungju, Korea(!), with scheelite and wolframite. Fine crystals at Bisesero and Gifurve and other pegmatites in Rwanda(!) and adjacent regions; also disseminated in an enormous pegmatite at Manono, Zaire. Abundant in NSW, Australia over an area of 20,000 km² in the New England range, with fine crystals coming from Emmaville, Glen Innes, and Elsinore(!). Important deposits are found in Bolivia at Llallagua(!), Oruro, and many other places; these are high-temperature vein deposits, many with complex mineralogy. At Viloco (formerly called "Araca")(!) one vein has produced magnificent druses of large, honey-colored twin crystals. In Brazil, fine bipyramidal crystals have been found with topaz and aquamarine in pegmatite in MG at the Fazenda de Funil, Sta. Maria de Itabira(!); Galileia(!), Lavra Toa, Sao José da Safira(!), and other places. Important alluvial deposits are found in RO derived from stockworks of veins in granite, and in Pittinga, AM, a large decomposed apogranite is mined containing cassiterite, columbite, zircon, and xenotime. Use: The principal and practically the only ore of tin. RG *DI:574, NMGS(1986)*.

4.4.1.6 Plattnerite α -PbO₂

Named in 1845 for K. F. Plattner (1800–1858), professor of metallurgy and assaying at Freiburg, Sachsen. Rutile group. Polymorph: scrutinyite. $\text{TRT } P4_2/mmm$. $a = 4.952$, $c = 3.386$, $Z = 2$, $D = 9.563$. *MR 1:75(1970)*. Structure: *AC(B) 36:2394(1980)*. *41-1492*: 3.5₁₀ 2.80₉ 2.48₂ 1.856₅ 1.753₁ 1.567₁ 1.525₁ 1.485₁. Prismatic [001]. Usually in nodular or botryoidal masses, dense to fibrous. Twinning on {011}, as contact or penetration twins. Black; brownish black when massive; chestnut brown streak; metallic, adamantine luster, tarnishing and becoming dull on exposure. No cleavage; fracture of masses, small conchoidal to fibrous; brittle. $H = 5\frac{1}{2}$. $G = 9.56$. Easily fusible. Decomposed to red-lead and oxygen when moderately heated. Soluble in HCl with evolution of Cl₂. Difficultly soluble in HNO₃ or H₂SO₄ with evolution of oxygen. Uniaxial; $N = 2.30 \pm 0.05$. In RL, gray-white with red-brown internal reflections. Pleochroic and anisotropic. $R = 21.1$ – 19.8 (470 nm), 19.4 – 19.9 (546 nm), 18.4 – 18.9 (589 nm), 16.7 – 17.1 (650 nm). *P&J:303*. From the Morning mine, Mullan, Shoshone Co., ID, in large botryoidal masses, in part fibrous; also in the Gilmore district, Lehmi Co. Ojuela mine, Mapimi, DGO, Mexico(*), as druses of small crystals on limonite. *Leadhills, Scotland*,

with cerussite, leadhillite, and pyromorphite. Zandjir mines, Yezd, Iran. Tsu-meb, Namibia, with minium and massicot as coatings. RG *DI:581*.

4.4.1.7 Argutite GeO_2

Named in 1983 for the locality. Rutile group. TET $P4_2/mnm$. $a = 4.396$, $c = 2.863$, $Z = 2$, $D = 6.28$. *AM 69:406(1984)*. 35-729(syn): 3.11₁₀ 2.40₆ 2.20₂ 2.11₁ 1.62₅ 1.55₂ 1.304₂ 1.300₂. As minute prismatic crystals embedded in sphalerite. Colorless; in RL, light gray. Anisotropy distinct. $R = 11.6$ (470 nm), 10.97 (546 nm), 10.93 (589 nm), 10.93 (650 nm). From a zinc deposit at the *Argut Plane, Haute Garonne, Pyrenees, France*, associated with sphalerite, cassiterite, siderite, and rarely briartite. RG *TMPM 31:97(1983)*, *AM 69:406(1984)*.

4.4.1.8 Squawcreekite $(\text{Fe}^{3+}, \text{Sb}^{5+}, \text{Sn}, \text{Ti})\text{O}_2$

Names in 1991 for the locality. Rutile group. TET $P4_2/mnm$, $a = 4.667$, $c = 3.101$, $Z = 2$, $D = 6.02-6.06$. *NJMM: 3.30*₁₀ *2.58*₅ *2.33*₂ *2.26*₁ *2.09*₁ *1.73*₄ *1.65*₁ *1.55*₁. Microscopic prismatic crystals. Yellow-brown, pale yellow-brown streak, adamantine luster. Cleavage {100}, imperfect; conchoidal to subconchoidal fracture. $H = 6-6\frac{1}{2}$. Uniaxial (+); $N_O = 2.18$, $N_E = 2.28$; $r < v$, weak. From the *Squaw Creek tin prospect, Catron Co., NM*. Esperanza tin mine, near Madera, DGO, Mexico. RG *NJMM:363(1991)*.

4.4.1.9 Stishovite SiO_2

Named in 1962 by Chao et al. for Sergei Mikhailovich Stishov (b.1937), Russian crystallographer, who first synthesized the mineral in 1961. Rutile group. Polymorphous with quartz, tridymite, cristobalite, coesite, and lutcite. TET $P4_2/mnm$. $a = 4.1773-4.1791$, $c = 2.6655-2.6659$, $Z = 2$, $D = 4.29$. *PD 45-1374(nat)*: 2.96₁₀ 2.25₂ 1.98₄ 1.87₁ 1.53₄ 1.48₁ 1.33₁ 1.235₁. Isostructural with rutile. Si is in octahedral (sixfold) coordination, compared to the tetrahedral coordination characteristic of all other Si minerals. *JSSC 47:185(1983)*. Raman data indicate that the mineral may be triclinic with lattice vectors three times those of the rutile-type cell. Crystals are elongated on c ; natural crystals are usually submicron in size, but synthetic crystals are as much as 230 microns in length. Colorless to white, vitreous luster. $H = 2080 \text{ kg/mm}^2$ parallel to elongation and 1700 kg/mm^2 perpendicular to elongation. $G = 4.28-4.35$. Insoluble in common acids and only very slowly soluble in HF. Separated from other silica polymorphs by HF treatment. IR: *AM 75:951(1990)*. Raman spectra: *CA 95:135975(1981)*. Essentially pure SiO_2 . Uniaxial (+); syn: $N_O = 1.800$, $N_e = 1.845$; nat: N about 1.77-1.78. Positive elongation; colorless. The mineral is metastable and reverts to quartz after heating at 230° for 3 days; converts to cristobalite when heated in air to 900° . Formed from quartz through high transient shock pressure and high temperature, accompanying the impact of a large meteorite. Occurs with coesite and quartz in sandstone at *Meteor crater, Coconino Co., Arizona* (Canyon Diablo meteorite). Also occurs with coesite in the Ries crater, in granite and

pumiceous tuff, Bavaria, Germany. Popigai impact structure, Siberia, Russia; Lonar crater, Deccan Plateau, India. Vredefort Dome (astrobleme), South Africa, in pseudotachylite veins. RG *JGR* 67:419(1962), *PCM* 13:146(1986), *Am* 75:739(1990), *AC(B)* 47:561(1991).

4.4.2.1 Varlamoffite (Sn, Fe)(O, OH)₂

Named in 1946 for Nicolas Varlamoff (1910–1976), Belgian geologist, who collected the first specimens of the mineral. TET $P4_2/mnm$. $a = 4.667$, $c = 3.096$, $Z = 1$, $D = 3.26$; $D = 5.14$ after heating. *MA* 83:3628. *PD*: 3.30_{7(b)} 2.58_{7(b)} 1.41_{2(b)}. *PD* after heating to 1000°: 3.33₁₀ 2.63₈ 1.76₇ 1.67₄. In the natural state, nearly amorphous, but becomes somewhat crystalline upon heating. Earthy, claylike. Yellow to orange-red, yellow to reddish orange streak, vitreous to greasy luster. $G = 3.21$ – 3.36 . Nonfluorescent. Average $N = 1.81$. Soluble with difficulty in acids. Is not reduced to tin when treated with dilute acid with powdered zinc (as contrasted with cassiterite). Some Fe is invariably present, and lower percentages of other elements, such as Al and Si, may be found. Published analyses show some variation, and the formula is somewhat uncertain. Cligga mine, Cornwall, England. Sungei Lah, Chenderiang, Perak, Malaysia, on cassiterite. From a greisenized Nb–Ta-bearing stock in Guanxi, China, with cassiterite. Sardine mine, near Ewan, Kangaroo Hills district, Q, Australia, in the oxidized portion of a stannite–cassiterite vein. *Kalima, Maniema, Zaire*. RG *AM* 34:618(1949); *MM* 35:622(1965), 37:624(1970); *ZVMO* 99:232(1970).

4.4.3.1 Downeyite SeO₂

Named in 1977 for Wayne F. Downey, Jr. of Harrisburg, PA, who collected and preserved the first specimens. TET $P4_2/mbc$. $a = 8.364$, $c = 5.064$, $Z = 8$, $D = 4.161$. *NBSM* 25(7):60(1969). 22-1314: 4.18₅ 3.74₆ 3.23₅ 3.01₁₀ 2.53₂ 1.93₂ 1.88₁ 1.83₁. Crystals prismatic [001] to acicular, in tufts. Colorless, adamantine luster. Nonfluorescent. Extremely hygroscopic. Crystals of downeyite in air absorb moisture and soon dissolve to a droplet of selenious acid. Stable in air only above 200°, or in a dry atmosphere such as one would obtain in a sealed desiccator. Uniaxial (+); $N > 1.80$. Moderate bireflectance. From near Forestville and near Glen Lyon, Luzerne Co., PA, as a product of burning coal-waste piles, where it deposits as a crystalline condensate close to vents of hot gas. RG *AM* 62:316(1977).

4.4.3.2 Paratellurite TeO₂

Named in 1960 from the Greek *para* and *tellurite*, with which it forms a dimorphous pair. TET $P4_32_1$. $a = 4.810$, $c = 7.613$, $Z = 4$, $D = 6.018$. *NBSC* 539(10):55(1960). 42-1365: 3.40₁₀ 3.10₁ 2.98₁₀ 2.41₂ 1.87₂₅ 1.700₁ 1.661₂ 1.493₁. Usually fine grained, massive. Rare crystals are short prismatic to equant, usually somewhat rounded. Also commonly pseudomorphous after tellurite crystals. Grayish white, honey-colored, black; white streak; resinous to waxy luster. No cleavage. $H = 1$. $G = 5.60$. Nonfluorescent. Uniaxial;

$N > 2.05$. From the *Moctezuma mine, Moctezuma, SON, Mexico*(*), where it forms a black oxidation rind around masses of native tellurium. The black color is due to included finely divided tellurium. Also as waxy, honey-colored coatings on fractures in native Te, and as pseudomorphs after later tellurite crystals at some distance from the tellurium masses. RG *AM* 45:1272(1960), *SPC* 32:354(1987).

4.4.4.1 Anatase TiO_2

Named in 1801 for the Greek for *extension*, in allusion to the greater length of the common pyramidal faces compared to those of other tetragonal minerals. Synonym: octahedrite, named because of the common pseudo-octahedral habit. Polymorphs: rutile, brookite. TET $I4_1/amd$. $a = 3.785$, $c = 9.514$, $Z = 4$, $D = 3.893$. *NBSM* 25(7):82(1969). Structure: *ZK* 136:273(1972). 21-1272(syn): 3.52₁₀ 2.43₁ 2.38₂ 2.33₁ 1.89₃ 1.70₂ 1.67₂ 1.48₁. Commonly acute pyramidal {011}, less commonly tabular or obtuse pyramidal, with {017} or {013}; often highly modified; twinning on {112} rare. Brown, indigo-blue, green, gray, black; colorless to pale yellow streak; adamantine luster, metallic-adamantine in dark varieties. Cleavage {001}, {011}, perfect; subconchoidal fracture; brittle. $H = 5\frac{1}{2}$ -6. $G = 3.90$. Insoluble in acids; infusible; decomposed by fusion with KHSO_4 . Uniaxial (-); $N_O = 2.561$, $N_E = 2.488$. Absorption $E > O$ or $O > E$. Often biaxial with small 2V, especially in deeply colored varieties. Substitution of other elements into the anatase structure is not found to a significant extent as in the case of rutile, although up to 1% or more of Fe, Sn, Nb, and/or Ta are known. Anatase is typically found in veins or crevices of the alpine type ("alpine clefts") in gneiss or schist, where it is derived by leaching from the surrounding rock by hydrothermal solutions. Associated minerals are quartz, brookite, adularia, hematite, chlorite, titanite, and others. From MA with brookite and titanite near diabase dikes at Somers-

ANATASE: TiO_2

Forms: $p\{111\}$, $e\{101\}$, $v\{117\}$

ville and in pockets in pegmatite at Quincy with aegirine, fluorite, and ilmenite. Arvon, Buckingham Co., VA, in joint planes in slate with quartz and pyrite. In fine blue crystals in a diorite dike on Beaver Creek, Gunnison Co., CO(1). With brookite on quartz at Placerville, CA. In many localities in Switzerland, especially superb large complex yellow crystals at Alp Lercheltini, Binntal, Wallis(1) and black octahedra (2 cm) at Crapteig and Crappasusta(1), Thusis. In Italy at Monte Cervandone, Ossola(1). In France at *Maronne, le Bourg d'Oisans, Isere*. In large, brilliant blue-black crystals on quartz crystals from Tysse, Hardangervidda, southern Norway(1). In MG, Brazil, as alluvial rolled pebbles ("favas") at Diamantina, and at Minas Novas(1) in fine crystals on smoky quartz. RG *DI:583*.

4.4.5.1 Brookite TiO_2

Named in 1825 for Henry James Brooke (1771–1857), English crystallographer and mineralogist. Polymorphs: rutile, anatase. ORTH *Pbca*. $a = 9.174$, $b = 5.456$, $c = 5.138$, $Z = 8$, $D = 4.120$. *NBSM 25(3):57(1964)*. Structure: *CM 17:77(1979)*. *29-1360: 3.51₁₀ 3.47₈ 2.90₉ 2.48₃ 2.41₂ 1.89₃ 1.69₂ 1.66₃*. Usually tabular {010} and elongated [001]; also prismatic [001], with {120} prominent; rarely tabular {001}; also pseudo-hexagonal with {120} and {111} equally developed. Various shades of brown, to black with adamantine-metallic luster; uncolored to grayish to yellowish streak. Cleavage {120}, indistinct; subconchoidal fracture; brittle. $H = 5\frac{1}{2}$ –6. $G = 4.14$. Insoluble in acids. Small amounts of Fe^{3+} are usually present, and a niobian variety is known. Biaxial (+); $Z = b$; $N_x = 2.583$, $N_y = 2.584$, $N_z = 2.700$ (Na); 2V small. Weakly pleochroic, in yellowish, reddish, and brownish tints; very strong dispersion. Absorption $Z > Y > X$. Optical properties vary widely with wavelength and temperature. Brookite is found principally in metamorphic rocks in fissures and open cavities in veins of the Alpine cleft type, with anatase, rutile, titanite, albite, chlorite, and so on. Found at the Ellenville lead mine, Ulster Co., NY, on quartz with galena and chalcopyrite. Somerville, MA, in quartz-calcite veinlets in diabase dikes, with anatase, titanite, and rutile. In nepheline syenite pegmatite in the Rocky Boy stock, Bearpaw Mts., MT. In large thick crystals with varied habit, in part altered to rutile, at Magnet Cove, AR(1).

BROOKITE: TiO_2

Forms: $z\{112\}$, $m\{110\}$, $e\{122\}$

Pretege, Tremadog, Gwynedd, Wales(!). Tete Noir(!) and Finhaut, Mt. Blanc massif, Wallis, Switzerland, in crystals >40 mm; also Rieder Tobel(!), Maderanertal, Uri, in tabular crystals. In Austria superb crystals >50 mm at Frossnitzalp(!), Tyrol. In France at *Le Plan du Lac, St. Christophe-en-Oisans, Isere*(!). In volcanic tuff at Biancavilla near Mt. Etna, Italy. In Russia, fine crystals in the Atliansk placers near Miask, Ural Mts.(!), and in the Murunskiy alkalic massif, NE of Lake Baikal, Siberia(!). In the diamond placers of MG and BA, Brazil, as pebbles ("favas"). RG *DI:589, DHZII:554(1992)*.

4.4.6.1 Tellurite TeO_2

Named in 1849 for the composition. Dimorph: paratellurite. ORTH *Pbca*. $a = 5.607$, $b = 12.034$, $c = 5.463$, $Z = 8$, $D = 5.75$. *NBSC 539(9):57(1960)*. 9-433: 3.72₉ 3.28₁₀ 3.01₅ 2.80₃ 2.73₅ 2.30₃ 2.05₂ 1.93₃. Crystals prismatic to acicular [001], usually tapered, and as thin laths {010}. Also grouped in tufts. Structure: *ZK 124:228(1967)*. Yellow, orange, colorless, white; white streak, subadamantine luster. Cleavage {010}, perfect; flexible. $H = 2$. $G = 5.90$. Easily soluble in acids and alkalis. When heated in closed tube fuses to a brown droplet and sublimes. Biaxial (+); XYZ = bac; $N_x = 2.00$, $N_y = 2.18$, $N_z = 2.35$ (Li); $2V$ near 90° ; $r < v$, moderate. Found in the zone of oxidation of mines containing native Te or tellurides. Keystone and other mines, Magnolia district, Boulder Co., CO; also at Cripple Creek with sonorite. Moctezuma(!) and San Miguel mines, Moctezuma, SON, Mexico, in crystals up to 3 cm and groups, in part altered to paratellurite, with tellurium, emmonsite, zemannite, denningite, spiroffite, and other tellurium oxysalts. *Zalathna and Facebaia, Transylvania, Roumania*. Nicolaevsky mine, western Altai, Kazakhstan. With tetradymite and nagyagite at the Rendaizi mine, Idu, Japan. RG *DI:593*.

4.4.6.2 Scrutinyite PbO_2

Named in 1988 to reflect the close scrutiny and sustained examination required to determine the physical properties with a very limited amount of sample material. Polymorph: plattnerite. ORTH *Pbcn*. $a = 4.971$, $b = 5.956$, $c = 5.438$, $Z = 4$, $D = 9.867$. *SR 16:224(1952)*. 45-1416: 3.82₄ 3.12₁₀ 2.72₅ 2.61₃ 2.48₃ 1.840₈ 1.635₄ 1.527₅. Crystals minute, platy {100}. Dark reddish brown, dark brown streak, submetallic luster. Cleavage {100}, perfect; {010}, imperfect. Nonfluorescent. In RL, gray-white, reddish-brown internal reflections. Bireflectance very weak. Pleochroism not seen. Weakly anisotropic, with a bluish color. $R = 17.9\text{--}18.8$ (546 nm), $17.0\text{--}17.9$ (589 nm). From the *Sunshine No.1 mine, Hansonburg district, Bingham, NM*, associated with plattnerite and murdochite on fluorite and quartz. Ojuela mine, Mapimi, DGO, Mexico, with plattnerite. RG *CM 26:905(1988), AM 75:709(1990)*.

4.4.7.1 Ramsdellite $\gamma\text{-MnO}_2$

Named in 1943 for Lewis S. Ramsdell (1895–1975), mineralogist, University of Michigan. Polymorphs: pyrolusite, akhtenskite. ORTH *Pnma*. $a = 9.32$,

$b = 4.46$, $c = 2.850$, $Z = 4$, $D = 4.87$. *SR 15:184(1951)*. *43-1455*: 4.06_{10} 2.55_4 2.43_3 2.34_3 2.14_2 1.903_2 1.655_2 1.616_1 . Crystals stout prismatic [001], usually pseudomorphous after groutite. Gray, black; black streak; metallic to dull luster. Cleavages on three pinacoids and a prism. $H = 2-4$. $G = 4.83$. In RL, yellowish white, pleochroic, strongly anisotropic; high reflectance. From the Monroe-Tener mine, Chisholm, MN. *Lake Valley, Sierra Co., NM*. East River, Pictou Co., NS, Canada. Gavilan mine, BC, Mexico. Bülten-Adenstedt, Niedersachsen, Germany, in crystals to 10 mm. Horni Blatná and Prebuz, Bohemia, Czech Republic. Kodjas Karil mine, Roumelia, Turkey. Dongri Buzurg, India. *RG ACHS 3:163(1949)*; *AM 47:47(1962)*, *64:1199(1979)*.

4.4.8.1 Nsutite $Mn(O,OH)_2$

Named in 1962 for the locality. *HEX* Space group unknown. $a = 9.65$, $c = 4.43$, $Z = 12$, $D = 4.86$. *AC 12:341(1959)*. *17-510*: $4.00_{10}(b)$ 2.42_7 2.33_7 2.13_5 1.64_{10} 1.60_5 $1.48_2(b)$ $1.37_4(b)$. *14-614*(manganooan nsutite): 4.10_{10} 2.66_6 2.45_6 2.36_6 2.16_8 2.13_6 1.67_8 1.39_6 . Massive, earthy. Gray brown; black streak; dull luster. $H = 6.5-8.5$. $G = 4.5$. The formula may be written $Mn_{1-x}^{4+}Mn_x^{2+}O_{2-2x}(OH)_{2x}$ where $x = 0.06-0.07$; for manganooan nsutite $x = 0.16$, and some of the Mn may be in the Mn^{3+} form. Analyzed nsutite from Ghana, for which the strongest X-ray diffraction line is 1.64, gave 90.6% MnO_2 and 2.6% MnO. Another variety, for which the strongest X-ray line is 1.67, gave 74.6% MnO_2 and 11.0% MnO. These varieties are referred to as nsutite and manganooan nsutite, respectively; the observed shift in X-ray diffraction lines is due to an expansion of the unit cell caused by an increased amount of lower-valent (larger) Mn ions. In reflected light, slightly creamy white. Weakly pleochroic, distinctly anisotropic. For nsutite: $VHN_{300} = 1150$; $R = 29.4$ (green), 28.5 (orange), 27.2 (red). For manganooan: $VHN_{300} = 900$; $R = 22.1$ (green), 16.0 (orange), 14.2 (red). Nsutite is a widespread mineral, which has been observed in most of the world's major manganese deposits and probably remains unrecognized in others. Manganooan nsutite typically is derived from the oxidation of manganese carbonate minerals such as rhodochrosite or kutnohorite, and nsutite is formed by the heating or further oxidation of manganooan nsutite. Phillipsburg, MT. Molango, HGO, Mexico. Tartana, Greece. Bülten-Adenstedt, Niedersachsen, Germany. Mysore, India. Busuango Island, Philippines. *Nsula, Ghana*. In Australia at Mossman, Q, and in Barabba, NSW. In Brazil at Conselheiro Lafaiette and in the Quadrilatero Ferrifero, MG. Used as an important ore of manganese. *RG AM 47:246(1962)*, *50:170(1965)*.

4.4.9.1 Vernadite $(Mn^{4+}, Fe, Ca, Na)(O, OH)_2 \cdot nH_2O$

Named in 1944 for Vladimir Ivanovich Vernadskii (1863-1945), Russian naturalist and geochemist. *TET I4/m*. $a = 9.866$, $c = 2.844$, $Z = 4$, $D = 2.95$. *15-604*: 6.81_3 3.11_6 2.39_{10} 2.15_6 1.83_4 1.65_3 1.54_4 1.42_4 . Massive, fine grained; as crusts. The name vernadite is given to poorly crystalline supergene

hydrated Mn^{4+} oxides giving diffraction reflections at 2.4 and 1.4 Å and is distinguished from birnessite by absence of reflections at 7.0–7.2 and 3.5–3.6 Å. It is said to be structurally similar to feroxyhite (Δ -FeOOH). Black, chocolate-brown streak, dull luster, reddish to chocolate brown when dispersed. Vernadite occurs as a weathering product of Mn^{2+} -containing oxides, carbonates, and silicates. It occurs in marine and freshwater iron-manganese crusts and concretions, often in relict bacterial forms. Originally described from an unspecified locality in Russia. Said to be widespread as a superficial oxidation product of manganese oxides. RG *AM* 31:85(1946), 64:1334(1979); *MD* 14:249(1979); *IGR* 22:58(1980).

4.4.10.1 Akhtenskite ϵ - MnO_2

Named in 1979 for the locality. HEX $P6_3/mmc$. $a = 2.80$, $c = 4.45$, $Z = 1$, $D = 4.78$. 30-820(syn): 2.42₇ 2.13₄ 1.64₁₀ 1.40₄ 1.21₁ 1.19₁ 1.07₁ 0.847₁. Small platy particles. Dark gray, black. $G = 4.00$. *Akhtenskii limonite deposit, southern Ural Mts., Russia*, derived from oxidation of Mn-bearing siderite in the absence of Mn-oxidizing microorganisms. It is associated with cryptomelane, nsutite, pyrolusite, and todorokite. Also from the Gumeshevskii deposit, Ural Mts., and from Urbanus, Eisengans, Germany. RG *AM* 68:473(1983).

4.4.11.1 Paramontroseite VO_2

Named in 1955 for the paramorphic relationship with the host phase, montroseite. ORTH $Pnma$. $a = 4.89$, $b = 9.39$, $c = 2.93$, $Z = 4$, $D = 4.18$. 25-1003: 4.35₄ 3.39₁₀ 2.65₅ 2.48₃ 2.21₄ 2.18₃ 1.61₃ 1.43₄. Found as an integral alteration product of crystals of montroseite, which occurs in bladed masses. Physical properties are those of montroseite, with which paramontroseite is invariably intimately intermixed. Black, black streak, submetallic luster. Cleavage {010}, {110}, good. $G = 4.0$. Slightly magnetic. From the *Bitter Creek* and other mines, *Uravan mineral belt, Paradox Valley, Montrose Co., CO*. RG *AM* 40:861(1955).

4.4.12.1 Cerianite-(Ce) CeO_2

Named in 1955 for the composition. ISO $Fm3m$. $a = 5.411$, $Z = 4$, $D = 7.215$. *NBSC* 539(1):56(1953). 43-1002: 3.12₁₀ 2.71₃ 1.913₅ 1.632₃ 1.241₁ 1.210₁ 1.105₁ 1.041₁. Small octahedrons; also, massive, powdery. Isostructural with uraninite and thorianite. Greenish amber, gray-green; subadamantine luster. ThO_2 may substitute for CeO_2 in the cell, as well as other rare earths and minor amounts of Nb_2O_5 , Ta_2O_5 , and ZrO_2 . From mineral claims in *Lackner Twp., Sudbury mining district, ON, Canada*, in carbonatite rock in a nephelized hybrid gneiss. Canon Colorado, Sierra de Bermejillo, DGO, Mexico. Morro de Ferro, Poços de Caldas, MG, Brazil. RG *NBSM* 20:38(1983), *AM* 40:560(1955).

4.4.13.1 Tazheranite (Zr, Ti, Ca)O₂

Named in 1969 for the locality. The cubic modification of ZrO₂. iso *Fm*3*m*, *F*43, or *F*43*c*. $a = 5.108$, $Z = 4$, $D = 4.83$. *AM* 55:318(1970). 22-540: 2.94₁₀ 2.55₆ 1.80₁₀ 1.54₁₀ 1.47₄ 1.17₅ 1.04₅ 0.983₅. Irregular grains, and rounded to thick tabular isometric crystals; yellowish orange, reddish orange, to cherry-red; adamantine to greasy luster. No cleavage; brittle. $H = 7\frac{1}{2}$. $G = 5.01$. Nonfluorescent. Nonmagnetic. Isotropic; $N = 2.35$. From the *Tazheran alkalic massif, W of Lake Baikal, Siberia, Russia*, within bands of periclase-brucite marbles, with calcite, dolomite, spinel, forsterite, pyrrhotite, melilite, clinohumite, ludwigite, magnesioferrite, calzirtite, baddeleyite, geikielite, perovskite, rutile, and zircon. *RG DANS* 186:142, 186:917(1969); *SPC* 14:922(1970).

4.4.13.2 Srilankite (Ti, Zr)O₂

Named in 1983 for the country of origin. *ORTH Pbcn*. $a = 4.706$, $b = 5.553$, $c = 5.024$, $Z = 4$, $D = 4.765$. *ZK* 164:59(1983). 21-1236: 3.5₆ 2.84₁₀ 2.12₆ 1.996₆ 1.697₆ 1.663₁₀ 1.646₁₀ 1.480₆. As rolled pebbles. Black, submetallic to adamantine luster. One indistinct cleavage; conchoidal fracture; brittle. $H = 6.5$. Optically biaxial; $2V = 16^\circ$. Bireflectance high; translucent, blue. $R = 19.4-18.6$ (470 nm), $18.4-16.0$ (546 nm), $18.5-16.4$ (589 nm), $18.7-17.0$ (650 nm). From *Rakwana, Sabaragamuwa, Sri Lanka*, in gem gravels, with zirconolite, baddeleyite, geikielite, spinel, and perovskite, as <1-mm inclusions in these minerals. *RG NJMM* 1983:151, *AM* 69:212(1984).

4.4.14.1 Baddeleyite ZrO₂

Named in 1892 for Joseph Baddeley who brought the original specimens from Sri Lanka. *MON P*2₁/*c*. $a = 5.145$, $b = 5.207$, $c = 5.311$, $\beta = 99.23^\circ$, $Z = 4$, $D = 5.836$. *AC* 18:983(1965). 37-1484: 3.70₁ 3.17₁₀ 2.84₇ 2.62₂ 2.54₁ 1.848₂ 1.819₂ 1.804₁. Crystals short to long prismatic {001}, usually flattened {100}; sometimes radially fibrous or in botryoidal masses. Twinning common, {100}, often polysynthetic; also on {110} and more rarely on {201}. Black, reddish, yellow, green, colorless; vitreous to greasy luster. Cleavage {001}, nearly perfect; subconchoidal to uneven fracture; brittle. $H = 6\frac{1}{2}$. $G = 5.82$. Biaxial; $X \wedge c = 12.8^\circ$; $Y = b$; $N_x = 2.136$, $N_y = 2.236$, $N_z = 2.243$; $r > v$. X , dark brown; Y , brown; Z , light brown. From near Bozeman, MT, in a corundum syenite. Mt. Somma, Italy, in druses in a sanidine rock, with fluorite, nepheline, pyrochlore, and allanite. As rounded crystals in gem gravels at *Rakwana* and *Balangoda, Sri Lanka*, with zircon, tourmaline, spinel, and several rare-earth minerals. In *Phalaborwa, Transvaal, South Africa*, in a large carbonatite, with magnetite, diopside, apatite, and phlogopite, in fine black crystals up to 3×8 cm(!). In *Jacupirangite* at *Jacupiranga, SP, Brazil*, with ilmenite, zirkelite, magnetite, apatite, perovskite, and other minerals, and at *Poços de Caldas, MG*, in botryoidal masses associated with alkalic rocks in a carbonatite(*). As an accessory in some lunar rocks. *RG DI*:608, *AM* 40:275(1955), *AC* 12:507(1959).

4.4.15.1 Tugarinovite MoO_2

Named in 1980 for Aleksei Ivanovich Tugarinov (1917–1977), geochemist, Vernadskii Institute, Moscow, whose wife, V. G. Kruglova, discovered the mineral and named it. MON $P2_1/c$. $a = 5.59$, $b = 4.82$, $c = 5.51$, $\beta = 119.53^\circ$, $Z = 4$, $D = 6.58$. AM 66:438(1981). 32-671(syn): 3.42₁₀ 2.44₃ 2.43₇ 2.40₄ 1.725₃ 1.723₄ 1.711₄ 1.709₄. Crystals 0.5 to 1.5 mm, prismatic or thick tabular. Dark lilac brown, greenish-gray streak, metallic to greasy luster. $H = 4\frac{1}{2}$. Insoluble in hot HCl or H_2SO_4 , slowly soluble in boiling concentrated HNO_3 . Biaxial. Pleochroism pale yellowish to bluish olive-brown. Strong bireflectance. $R = 20.3\text{--}14.7$ (546 nm). From eastern Siberia, Russia, in quartz metasomites, associated with uraninite, molybdenite, zircon, and galena. RG ZVMO 109:465(1980), DANS 264:689(1982).

4.4.16.1 Cervantite Sb_2O_4

Named in 1850 for the locality. ORTH $Pna2_1$. $a = 5.436$, $b = 4.810$, $c = 11.76$, $Z = 4$, $D = 6.641$. NBSC 539(10):8(1960). 11-694: 3.45₃ 3.07₁₀ 2.94₄ 2.65₂ 2.40₂ 1.86₂ 1.78₂ 1.72₂. Fine-grained, earthy; rarely minute acicular. Yellow, reddish white; greasy to earthy luster. $H = 4\text{--}5$. $G = 6.5$. Nonfluorescent. Biaxial; $N_x = 2.0$, $N_z = 2.1$; strong bireflectance; positive elongation. Commonly found as pseudomorphs after stibnite and after various Sb sulfosalts. Emma mine, Salt Lake Co., UT. Wood River district, Blaine Co., ID. San Emidio mine, Kern Co., CA. In Mexico from the Altar district, SON; from Zacualpan, MEX; and from the San Jose mine, (1) Catorce, SLP, in large, sharp pseudomorphs after stibnite. Cervantes, Galicia, Spain. Pereta, Tuscany, Italy. Allemont, Isere, France. Cornwall, England. Siegen region, Nordrhein-Westfalen, Germany. With valentinite at Semsá, Algeria, and at Djebel Tayta, near Guelma. In Australia in the Wiluna district, WA, and the Heazlewood district, TAS. From many localities in Peru and Bolivia. RG DI:595, AM 47:1221(1962), NJMM 1962:93.

4.4.17.1 Lenoblite $\text{V}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$

Named in 1970 for André Lenoble, French mineralogist-geologist. ORTH $P2_12_12_1$. $a = 2.995$, $b = 4.820$, $c = 14.800$. 23-727: 7.46₇ 4.59₁₀ 4.05₄ 3.72₉ 2.80₄ 2.53₈ 2.28₅ 2.20₅. Azure blue, altering to greenish. From the uranium deposit at Mine Oklo, Mounana (near Franceville), Gabon, associated with duttonite. Also from Kyzyl-Kum, Uzbekistan, with other V minerals. RG BM 93:235(1970), AM 56:635(1971), ZVMO 100:488(1971).

4.5.1.1 Molybdate MoO_3

Named in 1963 for the composition. ORTH $Pnma$. $a = 3.962$, $b = 13.858$, $c = 3.697$, $Z = 4$, $D = 4.709$. NBSC 539(3):30(1954). 5-508: 6.93₃ 3.81₈ 3.46₆ 3.26₁₀ 2.70₂ 2.66₄ 2.31₃ 1.85₂. Flat needles or thin plates, forming irregular aggregates, flattened on {010}. Light greenish yellow to nearly colorless, adamantine luster. Cleavage {100}, perfect; {001}, distinct; flexible. Biaxial (+); $XYZ = bac$; $N > 2.0$; 2V large; very high birefringence; parallel

extinction; positive elongation. From *Krupka, northwestern Bohemia, Czech Republic*, associated with molybdenite and betpakdalite, in cavities in topaz-quartz greisen. This mineral is easily confused with ferrimolybdate, which is the normal alteration product of molybdenite and looks almost identical. RG *AM 49:1497(1964)*, *NBSM 20:118(1984)*.

4.5.2.1 Tungstite $\text{WO}_3 \cdot \text{H}_2\text{O}$

Named in 1868 for the composition. ORTH *Pnma*. $a = 5.249$, $b = 10.711$, $c = 5.133$, $Z = 4$, $D = 5.75$. *CM 22:681(1984)*. 43-679: 5.36₈ 3.46₁₀ 2.62₄ 2.56₅ 1.851₄ 1.831₄ 1.731₅ 1.634₄. Massive, pulverulent to earthy; as microscopic platy crystals. Yellow to yellowish green, resinous luster. Cleavage {001}, perfect. $H = 2.5$. $G = 5.52$. Soluble in alkalis but not in acids. Biaxial (-); $X =$ acute bisectrix; $N_x = 1.82$, $N_z = 2.04$; $2V = 27^\circ$; X , colorless; Y, Z , deep yellow; birefringence = 0.22; absorption $Z > Y > X$. Forms as an alteration product of wolframite, ferberite, and scheelite. From *Lane's mine, Monroe, CT*. As an alteration of huebnerite at Osceola, NV. Blue Wing district, Lehmi Co., ID. Kootenay Belle mine, Salmo, BC, Canada. Drakewall mine, Callington, Cornwall, England. Calacalani, Oruro, and at Tazna, Bolivia. RG *DI:605*, *AM 29:194(1944)*.

4.5.3.1 Meymacite $\text{WO}_3 \cdot 2\text{H}_2\text{O}$

Named in 1961 for the locality. Originally called ferritungstite. *PD*: 3.81 (diffuse). Massive, earthy; yellow-brown, resinous-vitreous luster. Conchoidal fracture. $G = 4.0$. Isotropic; $N > 2.0$. From *Meymac, Correze, France*, as an alteration product of scheelite. A highly questionable species. RG *BM 88:613(1965)*, *AM 53:1065(1968)*.

4.5.4.1 Alumotungstite $(\text{W, Al})(\text{O, OH})_3$ (?)

Named in 1971 for the composition. iso Space group unknown. $a = 10.20$, $Z = 8$. Crystals octahedrons, minute; yellow. Isotropic; $N > 1.90$. Originally reported as the aluminian analog of ferritungstite. From the *Kramat Pulai mine, Kinta district, Perak, Malaysia*, associated with yttritungstite-(Y). Gifurve mine, Rwanda, associated with ferritungstite; similarly at the Nyamulilo and the Kirwa mines, Uganda. RG *MR 12:81(1981)*, *MM 38:261(1971)*.

4.5.5.1 Ferritungstite $(\text{K, Ca})_{0.2}(\text{W, Fe})_2(\text{O, OH})_6 \cdot \text{H}_2\text{O}$

Named in 1911 for the composition. iso *Fd3m*. $a = 10.352$, $Z = 1$, $D = 4.75$. *GAC/MAC 13:A37(1988)*. 11-331: 5.94₁₀ 3.10₉ 2.97₁₀ 2.57₆ 1.82₈ 1.55₇ 0.990₆ 0.870₆. As octahedrons, sometimes platy, representing cyclic twins (sixlings); occasionally fibrous. Ocherous yellow, earthy luster. $G = 5.02$. Isotropic; $N = 2.09-2.15$. Usually formed as an alteration product of scheelite. *Germania tungsten mine, Stevens Co., WA*. Nevada scheelite mine, Mineral Co., NV. La Bertrande, Haute Vienne, France. Borralha mine, Minho, Portugal.

Nyakabingu, Rwanda. Namulilo mine, Uganda. RG *DII:1093*, *AM 42:83(1957)*, *MR 12:81(1981)*.

4.5.6.1 Sidwillite $\text{MoO}_3 \cdot 2\text{H}_2\text{O}$

Named in 1985 for Sidney A. Williams (b.1933), American mineralogist, petrologist, and economic geologist. MON $P2_1/c$. $a = 10.618$, $b = 13.825$, $c = 10.482$, $\beta = 91.63^\circ$, $Z = 16$, $D = 3.11$. *BM 108:813(1985)*. $39-363$: 6.94_8 3.79_5 3.68_6 3.46_3 3.32_{10} 3.25_9 2.66_5 2.62_4 . Tabular crystals; bright yellow, resinous luster. Cleavage $\{010\}$, perfect. $H = 2\frac{1}{2}$. $G = 3.12$. Biaxial (-); $X = b$; $Z \wedge a = 47^\circ$; $N_x = 1.70$, $N_y = 2.21$, $N_z = 2.38$; $2V = 48^\circ$. X, colorless; Y, Z, yellow. From *Lake Como, CO*, as an oxidation product of jordisite in a quartz vein, associated with pyrite. RG *AM 71:1546(1986)*.

4.6.1.1 Shcherbinaite V_2O_5

Named in 1972 for Vladimir V. Shcherbina (1907–1978), Russian geochemist. ORTH $Pmmn$. $a = 11.51$, $b = 3.559$, $c = 4.371$, $Z = 2$, $D = 3.372$. *NBSC 539(8):66(1959)*. $41-1426$: 5.77_3 4.38_{10} 4.09_3 3.41_8 2.88_5 2.76_2 2.61_3 1.919_1 . Fibrous aggregates of acicular crystals. Yellow-green; vitreous luster. Brittle. $H = 3-3\frac{1}{2}$. $G = 3.2$. Readily soluble in HCl and HNO_3 . Biaxial; $N \approx 2.42$. From fumaroles in the cupola of the *Bezmyanni volcano, Kamchatka, Siberia, Russia*. RG *DANS 193:135(1970)*, *ZVMO 101:464(1972)*, *AM 58:560(1973)*.

4.6.2.1 Navajoite $\text{V}_2\text{O}_5 \cdot 3\text{H}_2\text{O}$ or $(\text{V}, \text{Fe}^{3+})_{10}\text{O}_{24} \cdot 12\text{H}_2\text{O}$

Named in 1955 for the Navajo Indians, on whose reservation the mineral occurs. MON $C2/m$. $a = 34.92$, $b = 3.597$, $c = 11.79$, $\beta = 97.0^\circ$, $Z = 1$, $D = 2.53$. *AM 75:508(1990)*. $45-1401$: 17.4_1 11.8_{10} 10.5_1 5.79_1 3.41_2 3.18_1 2.90_1 1.992_1 . Fibrous. Dark brown, brown streak, silky to adamantine luster. $H < 2$. $G = 2.56$. Biaxial (-); Z parallel to fiber length; $N_x = 1.905$, $N_y = 2.02$, $N_z = 2.025$; parallel to extinction. X, Y, yellowish brown; Z, dark brown. From the *Monument No.2 Mine, Monument Valley, Apache Co., AZ*, associated with corvusite, tyuyamunite, rauvite, hewettite, steigerite, and limonite. RG *AM 40:207(1955)*, $44:332(1959)$.

4.6.3.1 Ilsemannite $\text{Mo}_3\text{O}_8 \cdot n\text{H}_2\text{O}$ (?)

Named in 1871 for J. C. Ilsemann (1727–1822), mining commissioner at Clausthal, Harz, who had studied molybdenite. $21-574$: 4.23_5 3.36_{10} 3.14_2 2.72_4 2.44_3 2.22_3 1.93_3 1.64_5 . Earthy; as thin crusts and stains. Blue-black, earthy luster. Peptized by water, giving a blue solution or sol. Near Ouray, UT, with halotrichite and molybdenite in sandstone. Gibson, Shasta Co., CA, as an alteration product of molybdenite. *Bleiberg, Carinthia, Austria*, with wulfenite, barite, and gypsum. In sandstone in the Hlatimbe valley, Natal, South Africa. Bamford, Q, Australia, staining molybdenite-bearing quartz. RG *DI:603*, *AM 36:609(1951)*.

4.6.4.1 Paramelaconite $\text{Cu}_2^{2+}\text{Cu}_2^+\text{O}_3$

Named in 1891 for the Greek *para*, near, and *melaconite*, because it is near melaconite in composition. TET $I4_1amd$. $a = 5.837$, $c = 9.932$, $Z = 4$, $D = 5.93$. *AC(B) 34:22(1978)*. *33-480*: 3.17₁₀ 2.92₄ 2.48₁ 1.89₂ 1.88₁ 1.73₂ 1.59₁ 1.54₁. Crystals stout prismatic [001]; {010} striated [100]. Black, brownish-black streak, metallic/adamantine luster. No cleavage, conchoidal fracture. $H = 4\frac{1}{2}$, $G = 5.9$. Readily soluble in cold dilute mineral acids and in dilute NH_4OH and NH_4Cl solutions. In RL, white, with a pinkish-brown tint. Pleochroism weak, anisotropism strong. From the *Copper Queen mine, Bisbee, AZ(!)*, in fine crystals, associated with cuprite, goethite, tenorite, connellite, and malachite. Algomah mine, Ontonagon Co., MI. RG *DI:510, AM 63:180(1978)*.

4.6.5.1 Murdochite $\text{PbCu}_6\text{O}_8-x(\text{Cl,Br})_{2x}$

Named in 1955 for Joseph Murdoch (1890–1973), U.S. mineralogist, University of California, Los Angeles. ISO $Fm\bar{3}m$. $a = 9.224$, $Z = 4$, $D = 6.06$. *AC(C) 39:1143(1983)*. *7-28*: 5.30₁₀ 3.25₈ 2.78₈ 2.66₁₀ 2.30₉ 2.11₉ 1.63₁₀ 1.56₈. As minute cubes, also as octahedra; black, black streak. $H = 4$. $G = 6.47$. Insoluble in cold dilute HNO_3 , but dissolves with effervescence upon warming the acid. *Mammoth-St. Anthony mine, Tiger, AZ*, with wulfenite. Mex-Tex mine, Hansonburg district, NM. RG *AM 69:815(1984), NJMM 1972:104*.

4.6.6.1 Tantite Ta_2O_5

Named in 1983 for the composition. TRIC $P1$. $a = 3.80$, $b = 3.79$, $c = 35.74$, $\alpha = 90.92^\circ$, $\beta = 90.18^\circ$, $\gamma = 90.0^\circ$, $Z = 6$, $D = 8.45$. *MZ 5(3):90(1983)*. *21-1198(syn)*: 3.78₆ 3.77₇ 3.76₅ 3.36₈ 3.35₇ 2.98₁₀ 2.46₇ 2.45₈. As grains and microscopic veinlets; colorless, transparent; adamantine luster. No cleavage. $H = 7$. Nonfluorescent. Weak blue cathodoluminescence. In RL, grayish white; strongly anisotropic. $R = 14.2-17.5$, depending on orientation and wavelength. From granite pegmatites in the *Kola region, Russia*, associated with microlite, stibiotantalite, and holtite. RG *AM 69:1193(1984)*.

4.6.7.1 Nolanite $(\text{V,Fe,Ti})_{10}\text{O}_{14}(\text{OH})_2$

Named in 1957 for Thomas B. Nolan (1901–1992), geologist and director of the U.S. Geological Survey. HEX $P6_3mc$. $a = 5.890$, $c = 9.255$, $Z = 1$, $D = 4.60$. *AC 11:703(1958)*. *19-640*: 4.62₆ 3.41₈ 2.63₁₀ 2.47₁₀ 2.44₈ 2.22₆ 1.96₆ 1.46₈. Thick tabular crystals; black, brownish-black streak. $H = 5-5\frac{1}{2}$. $G = 4.65$. In RL, dark brown and deep blue internal reflections. From the *Eldorado uranium mine, Beaverlodge region, Lake Athabaska, SK, Canada*, in dolomite, with pitchblende, calcite, and sulfides. Kalgoorlie, WA, Australia, with quartz, gold, and various tellurides. RG *AM 52:734(1967), 68:833(1983)*.

Oxides Containing Uranium and Thorium

5.1.1.1 Uraninite UO_2

Named in 1792 for the composition. Uranium was named for the planet Uranus (named for the Greek god), which had been discovered shortly before the element was discovered. Two names, *uraninite* and *pitchblende*, are in common use for this mineral. Uraninite is the correct name for the species, but pitchblende is a rather sharply defined colloform variety of uraninite. It differs from ordinary uraninite in the crystal size, habit, and mode of occurrence. The particle size of pitchblende varies from about 10^{-2} to 10^{-6} mm. iso $Fm\bar{3}m$. $a = 5.468$, $Z = 4$, $D = 10.968$. *NBSC 539(2):33(1953)*. *41-1422: 3.15₁₀ 2.73₅ 1.933₅ 1.647₅ 1.367₁ 1.254₂ 1.222₂ 1.116₂*. *USGSB 1064(syn): 3.14₁₀ 1.93₈ 1.65₉ 1.25₆ 1.22₆ 1.12₆ 1.05₇ 0.924₇*. **Habit:** Octahedral crystals; less commonly cubes, or combinations of these. Twinning on $\{111\}$, rare. Pitchblende is massive, botryoidal, or reniform; banded layers. **Structure:** The crystal structure of uraninite is analogous to that of fluorite, CaF_2 . The U^{4+} ions are each surrounded by eight O^{2-} ions at the corners of a cube, and each O^{2-} ion by four U^{4+} ions at the corners of an octahedron. **Physical properties:** Black, brownish black, dark gray, greenish; streak brownish-black, grayish, olive-green; semimetallic (especially in well-crystallized material) to submetallic luster, pitchy, dull. No cleavage, uneven to conchoidal fracture, brittle. $H = 5-6$. $G = 7.5-9.7$. Nonfluorescent. Highly radioactive. Nonmagnetic. **Tests:** Soluble in HF , HNO_3 , H_2SO_4 , but only very slowly attacked by HCl . Infusible. **Chemistry:** Uraninite, ideally UO_2 , is always partially oxidized, with part of the U^{4+} converted to U^{6+} . Natural material, especially the colloform varieties (pitchblende), approach U_3O_8 for this reason. In crystallized material Th is usually present, and a complete solid-solution series exists between UO_2 and ThO_2 , although in natural material ThO_2 seldom exceeds 14%. Rare earths are also commonly present in small amounts; total REO is normally less than 12%. Pb is also invariably present, from a trace to about 20%; this is believed to be derived mostly from the radioactive decay of the uranium. The unit cell edge of uraninite can vary from 5.37 to 5.55, depending on the state of oxidation; the more highly oxidized it is, the smaller the cell edge. The cell edge also increases linearly

with increasing content of Th. He and possibly Ar are usually present, up to 2.6 wt%. **Optics:** Transparent in thin splinters, usually greenish, yellowish, or deep brown in color. Refractive index is high. In polished section, light gray with a brownish tint. Dark brown internal reflections. Isotropic. $R = 16.7$ (470 nm), 16.0 (546 nm), 15.8 (589 nm), 16.0 (650 nm). *P&J:381*. **Occurrence:** Uraninite is found in pegmatites, usually in crystals, associated with monazite, Nb-Ta minerals, zircon, fluorite, and so on. When in hydrothermal veins, the normal mode of occurrence is as pitchblende; such deposits account for the bulk of uranium production. In high-temperature veins it is associated with cassiterite, arsenopyrite, and Co-Ni-Bi-As minerals; in moderate-temperature hydrothermal veins, with galena and other sulfides; also found as impregnations in sandstone, often associated with V, Cu, and other ores. **Localities:** Topsham, ME(!) in fine cubo-octahedral crystals. Ruggles pegmatite, Grafton, NH, in dendritic masses of crystals associated with curite, uranophane, and so on; fine crystals at Spruce Pine(!) and other localities in western NC, also pegmatitic; in veins in Gilpin Co. and Jefferson Co., CO, with sulfides; at Baringer Hill, Llano Co., TX, in pegmatite with gadolinite and Nb-Ta minerals; in sandstone and conglomerate near Moab, UT, and near Grants, NM. Eldorado mine, Great Bear Lake, NWT, Canada, in veins with native silver and Co and Ni mineralization; also at Lake Athabasca, SK, and in very sharp crystals to 10 cm in Cardiff Twp, ONT. Placeres de Guadalupe, CHIH, Mexico(*), with gold. Cornwall, England(!), botryoidal masses in tin-bearing veins. Fuente-Ovejuna pegmatite, Sierra Albarrana, Cordoba, Spain(!), crystals to 40 kg. Château Lambert, Vosges, France; also at Chameane, Puy de Dôme; Barzot, Saone-et-Loire, and le Retail, Vendée. In *Bohemia, Czech Republic*, at *Jachymov* and *Horní Slavkov* (pitchblende) in veins; Schneeberg and Johanngeorgenstadt, Sachsen, Germany. Ajmer, Rajputana, India, in pegmatite. Kotoge and Masaki, Fukuoka Pref., Japan, in pegmatite. Azgour, Morocco (pitchblende). Shinkolobwe and elsewhere in Shaba, Zaire, as replacement bodies of crystallized uraninite (crystals to 30 mm) with oxidized uranium minerals and copper ores. Morogoro, Tanzania. El Sharana, NT, Australia. **Uses:** The principal ore of uranium. In early times used for coloring glass yellow-green. Now used for generating nuclear power, atomic bombs, and so on. RG *DI:611*, *USGSB 1064:11(1958)*, *EG 56:241(1961)*, *MR 5:79(1974)*.

5.1.1.2 Thorianite ThO_2

Named in 1904 for the composition. iso $Fm\bar{3}m$. $a = 5.600$, $Z = 4$, $D = 9.991$. *NBSC 539(1):57(1953)*. $42-1462$: 3.23_{10} 2.80_4 1.979_5 1.688_5 1.284_2 1.252_1 1.077_2 0.946_2 . Usually as cubes, sometimes modified by {111} or {113}. Penetration twins on {111}, common. Black; dark gray; brownish black, with gray to greenish-gray streak; horny to submetallic luster. Cleavage {001}, poor; uneven to subconchoidal fracture; brittle. $H = 5-6$. $G = 9.7-9.8$. Nonfluorescent. Radioactive. Diamagnetic. Infusible; at high temperatures emits a strong white glow. Thorianite forms a complete solid-solution series with ura-

ninite. It also forms a partial series with cerianite, CeO_2 . Uranium apparently is always present in moderate to large amounts; varieties with $Th/U \approx 1:1$ are called uranothorianite. Pb is also invariably present and is probably of radiogenic origin. The cell edge of thorianite varies from 5.60 to 5.50, decreasing with increasing content of U, Pb, or Ce, and with oxidation of the U^{4+} content to U^{6+} . Isotropic; $N \approx 2.20$ to 2.35. In RL, gray, isotropic, with reddish-brown internal reflections. $R = 16.4$ (470 nm), 15.3 (546 nm), 15.1 (589 nm), 14.8 (650 nm). *P&J:369*. Thorianite is a primary mineral found chiefly in pegmatites or as an accessory mineral in granites. Known occurrences are principally in alluvial deposits derived from these rocks or placers. It is also occasionally found in calcite-fluorite-apatite veins that are transitional to pegmatites. From Easton, PA, in serpentine formed by the alteration of magnesium silicates at the contact of limestone with pegmatite. In black sands in the Missouri River near Helena, MT, and similarly in the Wiseman and Nixon Fork districts, AK. In *Sri Lanka* from the *Balangoda district*, in placers associated with thorite, allanite, baddeleyite, geikielite, and cassiterite. In Madagascar in pyroxenites near Betroka(!), in fine crystals up to 15 cm (uranothorianite) with spinel, phlogopite, diopside; also at Betanimena, Morafeno, and Amboanemba. *RG DI:620, USGSB 1064:47(1958)*.

5.2.1.1 Metaschoepite $UO_3 \cdot < 2H_2O$

5.2.1.2 Paraschoepite $UO_3 \cdot 2H_2O$

5.2.1.3 Schoepite $UO_3 \cdot 2H_2O$

Named in 1923 (schoepite); 1947 (para-); 1960 (meta-); for Alfred Schoep (1881–1966), Belgian mineralogist, who studied the mineralogy of uranium extensively. *Meta*, from the Greek indicating a lower hydrate than schoepite; *para*, from the Greek indicating a close relationship to schoepite. ORTH *Pbna*. $a = 13.99$, $b = 16.72$, $c = 14.73$, $Z = 32$, $D = 4.69$ (metaschoepite). ORTH *Pbca*. $a = 14.12$, $b = 16.83$, $c = 15.22$, $Z = 32$, $D = 4.83$ (paraschoepite). ORTH *Pbca*. $a = 14.33$, $b = 16.79$, $c = 14.73$, $Z = 32$, $D = 4.83$ (schoepite). M: *43-364*: 7.33₁₀ 3.67₃ 3.58₄ 3.49₂ 3.48₁ 3.22₅ 3.16₃ 2.56₂. P: *23-1461*: 7.53₁₀ 3.56₁₀ 3.32₅ 3.22₁₀ 3.17₅ 2.01₃ 1.78₄ 1.73₃. S: *13-407*: 7.28₁₀ 5.08₇ 3.66₁ 3.51₁ 3.44₂ 3.22₁ 2.89₁ 2.54₁. $UO_2(OH)_2$: 5.09₁₀ 3.45₃ 3.39₂ 2.89₁ 2.54₁ 2.48₁ 2.02₁ 1.77₁. Crystals tabular on {001}, elongated [010], with pseudo-hexagonal aspect; also massive, as crusts; twinning not observed. Schoepite, the highest hydrate of the three closely related minerals, dehydrates spontaneously at room temperature to metaschoepite and paraschoepite. Any given sample of schoepite is likely to consist of a mixture of two or even three of these compounds. Crushing or grinding of the crystals also causes dehydration, which may progress as far as $UO_2(OH)_2$, a compound not yet found in nature. The physical properties of these minerals are closely similar, where it has been possible to distinguish between them. Diagnosis of the compounds is best done through powder diffraction data (where it must be kept in mind that any given unknown of the

group is almost certainly a mixture of unknown proportions), or through their optical properties. Amber (schoepite); yellow (meta- and paraschoepite); yellow streak. Cleavage {001}, perfect; {010}, fair; brittle. $H = 2\frac{1}{2}$. $G = 4.8$. Fluorescent pale green under LWUV and SWUV. Biaxial (-); $XYX = cba$; metaschoepite: $N_x = 1.695$, $N_y = 1.730$, $N_z = 1.750$; paraschoepite: $N_x = 1.700$, $N_y = 1.750$, $N_z = 1.770$; schoepite: $N_x = 1.70$, $N_y = 1.720$, $N_z = 1.735$. Schoepite, and by inference, metaschoepite and paraschoepite as its normal alteration products, have been found at Beryl Mt., Acworth, NH, as pseudomorphs after uraninite. Several mines on the Colorado Plateau, including the Monument No. 2 mine, Apache Co., AZ, and the Happy Jack mine, White Canyon, San Juan Co., UT. From Germany at Wölsendorf, Bavaria, with ianthinite and becquerelite, and at Menzenschwand, Black Forest. Margnac II, Haute-Vienne, France, and at Mas d'Alary, Hérault. *Kasolo, Shaba, Zaire*, and also at Musonoi; relatively abundant at Shinkolobwe, Zaire, with other secondary uranium minerals. RG *DI:627, USGSB 1064:72(1958), AM 45:1026(1960), IANS Ser. Geol.:140(1979), JINC 30:1745(1968)*.

5.2.2.1 Masuyite $Pb_3U_8^{6+}O_{27} \cdot 10H_2O$

Named in 1947 for Gustave Masuy (1905–1945), Belgian geologist, shot by the German occupiers at the end of World War II. ORTH *Pban*. $a = 41.93$, $b = 24.22$, $c = 42.61$, $Z = 432$, $D = 5.338$. *AM 45:1026(1960), 13-408: 7.08₁₀ 3.56₃ 3.52₇ 3.48₂ 3.16₁ 3.12₅ 2.01₂ 1.95₂*. Crystals tabular on {001}, with pseudo-hexagonal aspect; invariably twinned, both on {110} and {130}. Reddish orange, brownish orange; adamantine luster. Cleavage {001}, perfect; {010}, fair. $G = 5.08$. Nonfluorescent. Biaxial (-); $XYZ = cba$; $N_y = 1.895$, $N_z = 1.915$ (Na); $2V \approx 50^\circ$. X, Y, golden yellow. Lodive, Hérault, France. *Shinkolobwe, Shaba, Zaire*, minute crystals lining cavities in uraninite, and also at Kamoto. RG *USGSB 1064:78(1958), ZK 113:132(1960)*.

5.3.1.1 Studtite $UO_4 \cdot 4H_2O$

Named in 1947 for Franz Edward Studt, Belgian prospector and geologist, author of the first geological map (1913) of Shaba, Zaire. MON *C2, Cm, or C2/m*. $a = 11.85$, $b = 6.80$, $c = 4.25$, $\beta = 93.85^\circ$, $Z = 2$, $D = 3.64$. *AM 59:166(1974), 16-206(syn): 5.88₁₀ 4.23₁ 3.55₁ 3.49₂ 3.40₂ 3.39₃ 2.94₁ 2.65₁*. Thin crusts composed of minute fibers; as masses of radial-fibrous tufts of acicular crystals on renardite; yellow. No cleavage. $G_{syn} = 3.58$. Soft; non-fluorescent. Biaxial (+); $N_x = 1.537$ (nearly colorless); $N_z = 1.680$; $2V$ small; parallel to elongation. From Menzenschwand, Black Forest, Germany, with billietite, uranophane, and rutherfordine on barite, quartz, and limonite. Davignac, Corrèze, France. Menzenschwand, Black Forest, Germany. In *Zaire* at *Shinkolobwe, Shaba*, with uranophane and rutherfordine, and at Kobokobo, Kivu. RG *BSBG 70:B212(1947), AM 33:384(1948)*.

5.3.1.2 Metastudtite $\text{UO}_4 \cdot 2\text{H}_2\text{O}$

Named in 1983 from Greek *meta* and *studtite*, indicating a lower hydrate than studtite. ORTH *Immm*. $a = 6.51$, $b = 8.78$, $c = 4.21$, $Z = 2$, $D = 4.67$. 35-571: 5.22₁₀ 4.38₅ 3.79₅ 3.54₈ 3.21₅ 2.76₃ 2.67₂ 2.47₂. Silky fibers; radiated nodules. Pale yellow, yellowish streak, silky luster. Nonfluorescent. Soluble in hot HCl without effervescence. Biaxial (+); $Z = c$; $N_x = 1.640$, $N_y = 1.658$, $N_z = 1.760$; $2V = 48^\circ$; no pleochroism. From *Shinkolobwe, Shaba, Zaire*, on dolomite with rutherfordine, becquerelite, masuyite, kasolite, and wolsendorfite; also on massive uraninite. RG *AM 68:456(1983)*.

5.3.2.1 Vandenbrandeite $\text{Cu}(\text{UO}_2)(\text{OH})_4$

Named in 1932 for Pierre van den Brande (1896–1957), Belgian geologist, who discovered the ore deposit at Kalongwe, Zaire. TRIC *P1*. $a = 7.86$, $b = 5.44$, $c = 6.10$, $\alpha = 91.86^\circ$, $\beta = 102.0^\circ$, $\gamma = 89.62^\circ$, $Z = 2$, $D = 5.26$. USGSB 1064:100(1958). 4-340: 5.06₄ 4.29₁₀ 2.92₈ 2.56₄ 2.09₃ 1.85₃ 1.47₃ 1.32₃. 8-325(syn): 5.26₉ 4.44₁₀ 3.85₄ 2.97₈ 2.59₇ 2.20₅ 2.03₆ 1.64₅. Crystals tabular {001}, somewhat elongated; also scalelike. Dark green to blackish green, vitreous luster. Cleavage {110}, perfect. $H = 4$. $G = 5.03$. Nonfluorescent. Biaxial (-); $Z \wedge$ elongation = 40° ; $N_x = 1.765$, $N_y = 1.792$, $N_z = 1.80$; $2V \approx 90^\circ$; strong dispersion. X, blue-green; Z, yellow-green. Rabejac, Lodeve, Herault, France, on pitchblende. In Zaire at *Kalongwe, Shaba*, with kasolite, uranophane, sklodowskite, torbernite, and malachite; also from Luiswishi(!) doubly terminated crystals to 1 cm, and at Musonoi(!), abundant brilliant crystals. RG *DI:632, CSC 6:53(1977)*.

5.4.1.1 Clarkeite $(\text{Na}, \text{Ca}, \text{Pb})_2\text{U}_2(\text{O}, \text{OH})_7$

Named in 1931 for Frank Wigglesworth Clarke (1847–1931), American geochemist, U.S. Geological Survey. 8-315: 5.77₈ 3.34₉ 3.17₁₀ 2.69₅ 1.97₇ 1.86₆ 1.76₅ 1.64₅. Massive, fine grained; brown; dark reddish brown, yellowish-brown streak, waxy luster. Conchoidal to splintery fracture. $H = 4-4\frac{1}{2}$. $G = 6.29$. Nonfluorescent. Readily soluble in acids. Biaxial (-); $N_x = 1.997$, $N_y = 2.098$, $N_z = 2.108$; $2V = 30^\circ-50^\circ$; $r < v$, weak; weakly pleochroic. From the *Deer Park mine, Spruce Pine, Mitchell Co., NC*. Ajmer district, Rajputana, India, associated with uraninite, fourmarierite, and uranophane in pegmatite. RG *DI:624, USGSB 1064:95(1958), AM 41:127(1956)*.

5.4.2.1 Calciouranoite $(\text{Ca}, \text{Ba}, \text{Pb})\text{U}_2\text{O}_7 \cdot 5\text{H}_2\text{O}$

Named in 1974 for the composition. Amorphous. 41-1433: 4.0₅ 3.41₁₀ 3.05₁₀ 2.68₅ 2.00₅ (diffraction diagram made after heating). Brown, orange. $G = 4.62$. From the oxidation zone of a U–Mo deposit, *Russia*, associated with other uranium oxides. RG *ZVMO 103:108(1974), IGR 16:1255(1974), AM 60:161(1975)*.

5.4.2.2 Bauranoite $\text{BaU}_2\text{O}_7 \cdot 4-5\text{H}_2\text{O}$

Named in 1973 for the composition. *ZS-1469*: 3.41₇ 3.09₁₀ 1.98₆ 1.948₆ 1.908₆ 1.723₆ 1.667₆ 1.325₅. Dense, fine-grained aggregates. Reddish brown. $H = 5$. $G = 5.3$. Biaxial (-); $N_x = 1.911-1.916$, $N_z = 1.920-1.932$; $2V = 81^\circ$. From a U-Mo deposit in *Russia*, replacing uraninite, replaced by uranophane. RG *ZVMO 102:75(1973)*, *AM 58:1111(1973)*.

5.4.3.1 Metacalcioranoite $(\text{Ca, Na, Ba})\text{U}_2\text{O}_7 \cdot 2\text{H}_2\text{O}$

Named in 1973 from the Greek *meta* and *calcioranoite*, indicating a lower hydrate. Space group unknown. *ZS-1451*: 3.43₆ 3.09₁₀ 1.99₄ 1.94₄ 1.92₃ 1.73₃ 1.68₇ 1.28₇. Dense, fine-grained aggregates. Orange. $G = 4.90$. Biaxial (-); $N_x = 1.897$, $N_y = 1.911$, $N_z = 1.932$; $2V = 81^\circ$. From the oxidation zone of a U-Mo deposit in *Russia*, replacing pitchblende and being replaced by uranophane. RG *ZVMO 102:75(1973)*, *AM 58:1111(1973)*.

5.4.3.2 Wölsendorfite $(\text{Pb, Ba, Ca})\text{U}_2\text{O}_7 \cdot 2\text{H}_2\text{O}$

Named in 1957 for the locality. ORTH Space group unknown. $a = 11.95$, $b = 13.99$, $c = 7.02$, $Z = 6$, $D = 6.82$. *AM 42:919(1957)*. *ZS-786*: 6.91₄ 3.46₈ 3.09₁₀ 2.44₃ 1.993₃ 1.913₃ 1.725₄ 1.676₄. *MM 46:131(1982)*: 7.03₁₀ 6.03₂ 3.50₈ 3.47₅ 3.13₅ 3.10₆ 2.47₃ 2.01₃. Fine, platy aggregates. Orange-red, adamantine to vitreous luster. Cleavage {001}, good. $H = 5$. $G = 6.8$. Biaxial; $N_x = 2.05$, $N_z = 2.09$. Eldorado mine, Great Bear Lake, NWT, Canada, on pitchblende. *Wolsendorf, Bavaria, Germany*, in fissures in fluorite, and at Menezschwand, Black Forest. In France at Kersegalec-en-Lignol, Vendée, with pitchblende; Margnac II, Haute-Vienne; and La Faye, Grury, Saone et Loire. Shinkolobwe, Shaba, Zaire, with secondary uranium minerals. RG *BM 105:606(1982)*, *ZVMO 103:718(1974)*.

5.5.1.1 Agrinierite $(\text{K}_2, \text{Ca, Sr})\text{U}_3\text{O}_{10} \cdot 4\text{H}_2\text{O}$

Named in 1972 for Henri Agrinier (1928–1971), French engineer, Mineralogy Laboratory, Commission de Energie Atomique. ORTH *Cmmm*. $a = 14.04$, $b = 24.07$, $c = 14.13$, $Z = 16$, $D = 5.62$. *ZS-630*: 7.08₁₀ 6.05₇ 3.52₈ 3.49₉ 3.15₉ 3.13₁₀ 2.79₆ 2.02₈. Crystals tabular {001}, with pseudo-hexagonal section; sector twinning shown. Orange. Cleavage {001}, good. $G = 5.7$. Biaxial (-); $XZ = ab$; $N_y = 2.01$, $N_z = 2.06$ (Na); $2V = 55^\circ$. From the *Margnac uranium deposit, Haute Vienne, Massif Central, France*, with uranophane in small cavities in "gummite" (a massive orange-red alteration product of pitchblende). RG *MM 38:781(1972)*, *AM 58:805(1973)*, *BM 105:606(1982)*.

5.5.2.1 Rameauite $\text{K}_2\text{CaU}_6\text{O}_{20} \cdot 9\text{H}_2\text{O}$

Named in 1972 for Jacques Rameau (1926–1960), French prospector, who discovered the deposit where the mineral occurs. MON *C2/c* or *Cc*. $a = 13.97$, $b = 14.26$, $c = 14.22$, $\beta = 121.02^\circ$, $Z = 4$, $D = 5.55$. *AM 58:805(1973)*. *ZS-631*: 7.12₁₀ 3.57₉ 3.50₁₀ 3.47₉ 3.19₉ 3.14₁₀ 3.12₁₀ 2.50₇. Crystals prismatic, flattened

{010}, elongated [001], with pseudohexagonal section; twinning on {100}. Orange. Cleavage {010}, good. $G = 5.6$. Biaxial; $N_y = 1.95$, $N_z = 1.97$ (Na); $2V = 32^\circ$. *Margnac uranium deposit, Haute Vienne, Massif Central, France*, with calcite and uranophane on pitchblende. RG *MM 38:781(1972)*, *BM 105:606(1982)*.

5.5.3.1 Protasite $Ba(UO_2)_3O_3(OH)_2 \cdot 3H_2O$

Named in 1986 for Jean Protas (b.1931), University of Nancy, France. *MON Pn*. $a = 12.295$, $b = 7.221$, $c = 6.956$, $\beta = 90^\circ 24'$, $Z = 2$, $D = 5.827$. *AM 72:1230(1987)*. *39-349*: 7.06₅ 6.00₂ 3.58₃ 3.14₁₀ 3.11₃ 1.98₂ 1.75₂ 1.60₂. Pseudohexagonal plates, flattened {010}; sector twinning observed. Bright orange, subadamantine luster. Cleavage {010}, good; hackly fracture; brittle. Biaxial (-); $N_y = 1.79-1.83$, $N_z = 1.79-1.83$; high birefringence; $2V = 60-65^\circ$. No pleochroism. From *Shinkolobwe, Shaba, Zaire*, associated with uranophane and uraninite. RG *AM 72:224(1987)*.

5.6.1.1 Ianthinite $U^{4+}U_5^{6+}O_{17} \cdot 10H_2O$

Named in 1926 for the Greek for *violet*, in allusion to its color. *ORTH* Space group unknown. $a = 11.52$, $b = 7.15$, $c = 30.38$, $Z = 4$, $D = 4.99$. *AM 44:1103(1959)*. *12-272*: 7.63₁₀ 3.81₈ 3.59₆ 3.35₆ 3.24₈ 2.61₄ 2.53₄ 2.03₄. Small plates or laths flattened on {001} and elongated along the b axis; also thick tabular {001}. Violet-black, submetallic luster. Cleavage {001}, perfect. $H = 2-3$. $G = 5.16$. Nonfluorescent. Biaxial (-); $XYZ = cba$; $N_x = 1.674$ (colorless); $N_y = 1.90$ (violet); $N_z = 1.92$ (dark violet). $2V$ small. Ianthinite slowly alters in air, first to a violet-brown compound, and finally to a yellow substance ("epi-ianthinite"), which is schoepite probably mixed with other uranium compounds. In Germany at Wolsendorf, Bavaria, and at Menzenschwand, Baden-Württemberg. In France at Bigay, Lachaux, Puy de Dome, and Les Bois-Noirs, St.-Priest-la-Prugne, Loire. From *Shinkolobwe, Shaba, Zaire*. RG *DI:633*, *USGSB 1064:56(1958)*.

5.7.1.1 Compreignacite $K_2U_6O_{19} \cdot 11H_2O$

Named in 1964 for the locality. *ORTH Pnnm*. $a = 7.16$, $b = 12.16$, $c = 14.88$, $Z = 2$, $D = 5.13$. *AM 50:807(1965)*. *17-167*: 7.40₁₀ 3.70₆ 3.58₆ 3.53₈ 3.34₆ 3.19₆ 2.55₆ 2.32₅. *33-1049(syn)*: 7.46₁₀ 3.71₈ 3.58₄ 3.53₆ 3.23₇ 3.20₉ 2.56₄ 2.03₄. Small crystals flattened on {001}; twins on {110}, common. Yellow. Cleavage {001}, perfect. $G = 5.03$. Biaxial (-); $XYZ = cab$; $N_x < 1.790$, $N_y = 1.798$, $N_z = 1.802$; $2V = 10^\circ-15^\circ$; no dispersion. X, colorless; Y, Z, yellow. From the *Margnac mine, Compreignac, Haut Vienne, France*, and in Cornwall, England, at West Wheal Owles, St. Just. RG *BM 87:365(1964)*, *105:606(1982)*.

5.7.1.2 Becquerelite $Ca(UO_2)_6O_4(OH)_6 \cdot 8H_2O$

Named in 1922 for Antoine Henri Becquerel (1852-1908), French physicist, who discovered radioactivity. *ORTH Pn2₁a*. $a = 13.838$, $b = 12.378$, $c = 14.924$, $Z = 4$, $D = 5.119$. *AM 72:1230(1987)*. *13-405*: 7.44₁₀ 4.68₁ 3.73₃ 3.54₂ 3.20₃

2.57₁ 2.04₁ 1.94₁. 29-389(syn): 7.49₁₀ 3.74₄ 3.55₄ 3.45₂ 3.21₈ 3.16₃ 2.57₃ 2.04₃. Usually prismatic, elongated {010}; occasionally tabular on {001}; massive; twinning not observed. Lemon yellow, amber, brownish yellow; yellow streak; adamantine to greasy luster. Cleavage {001}, perfect; also {101}. $H = 2\frac{1}{2}$. $G = 5.2$. Nonfluorescent. Biaxial (-); $XYZ = cab$; $N_x = 1.730$, $N_y = 1.825$, $N_z = 1.830$ (Na); $2V \approx 30^\circ$. X, pale yellow; Y, Z, deep yellow. From the Monument No. 2 mine, Apache Co., AZ, and elsewhere on the Colorado Plateau in small quantities. Eldorado mine, Great Bear Lake, NWT, Canada. In Germany at Wösendorf, Bavaria, with schoepite and uraninite in a fluorite deposit, and at Ellwieler, Pfalz. Margnac II mine, Haute-Vienne, France, and at Bigay-Lachaux, Puy de Dôme. *Kasolo* and *Shinkolobwe, Shaba, Zaire*(1), as an alteration product of uraninite, associated with schoepite, fourmarierite, curite, soddyite, and other secondary uranium minerals. Bemasoandro, Malakialina, Madagascar. RG *DI:625, USGSB 1064:62(1958), AM 45:1026(1960)*.

5.7.1.3 Billietite $Ba(UO_2)_6O_4(OH)_6 \cdot 8H_2O$

Named in 1947 for Valère Billiet (1903–1945), Belgian crystallographer, University of Ghent. ORTH $Pnb2_1$. $a = 12.072$, $b = 30.167$, $c = 7.145$, $Z = 4$, $D = 5.093$. *AM 72:1230(1987)*. 29-208(syn): 7.53₈ 3.76₅ 3.50₇ 3.18₁₀ 2.56₃ 2.05₃ 2.04₅ 1.95₄. Tabular on {001}, with a pseudo-hexagonal aspect; usually twins on {110}. Deep golden yellow; adamantine luster. Cleavage {001}, perfect. $G = 5.28$. Biaxial (-); $XYZ = cab$; $N_x = 1.76$, $N_y = 1.800$, $N_z = 1.805$ (Na); $2V = 37^\circ$. X, pale greenish yellow; Y, greenish yellow; Z, deep yellow. Kruth, and Margnac II, Haute-Vienne, France, common as crusts on gummite. Menzenschwand, Schwarzwald, Germany. In *Shaba, Zaire*, at *Shinkolobwe*, associated with fourmarierite, uranophane, and torbernite, and at Swambo and Luiswishi. RG *USGSB 1064:68(1958), ZK 113:132(1960), BM 105:606(1982)*.

5.8.1.1 Vandendriesscheite $PbU_7O_{22} \cdot 12H_2O$

5.8.1.2 Metavandendriesscheite $PbU_7O_{22} \cdot nH_2O (n < 12)$

Named in 1947 for Adrien Vandendriessche (1914–1940), Belgian mineralogist and geologist. Metav- (1960) indicates a lower state of hydration than V-. ORTH $Pmma$ or $P2_1ma$. $a = 14.07$, $b = 40.85$ (V.), $b = 41.31$ (MV.), $c = 43.33$, $Z = 36$. *AM 45:1026(1960)*. 13-117: 7.25₁₀ 4.53₁ 3.61₁₀ 3.53₃ 3.17₈ 2.52₃ 2.03₂ 1.99₄. Prismatic, elongated [100], {010} striated parallel to [100]; also tabular on {001}, elongated [100], with pseudo-hexagonal aspect; twinning not observed. Yellowish orange, orange; adamantine luster. Cleavage {001}, perfect. $G = 5.45$. Nonfluorescent. Biaxial (-); $XYZ = cba$; $N_x = 1.780$, $N_y = 1.850$, $N_z = 1.860$ (Na); $2V = 60^\circ$. X, colorless; Y, Z, golden yellow. Vandendriesscheite crystals have been shown to have varying proportions of the normal and meta phases, corresponding to varying degrees of partial dehydration which takes place in a normal atmosphere. Differentiating between the

phases, even using X-ray powder diffraction, is not an easy matter. The properties of the two phases are otherwise closely similar. From Newry, ME. Palermo and Ruggles pegmatites, NH. Spruce Pine district, Mitchell Co., NC. Eldorado mine, Great Bear Lake, NWT, Canada, with fourmarierite on altered uraninite. Limouzat quarry, Les Bois-Noirs, Loire, France, common as an orange crust near pitchblende. Kalongwe and *Shinkolobwe, Shaba, Zaire*, in the orange-red oxidic zone of alteration ("gummite" zone) of uraninite. RG *BSBG 70:B212(1947)*, *USGSB 1064:81(1958)*, *AM 45:1059(1960)(Meta-)*.

5.9.1.1 Uranosphaerite $\text{Bi}_2\text{U}_2\text{O}_9 \cdot 3\text{H}_2\text{O}$

Named in 1873 for the composition *uranium* and the Greek for *sphere*, in allusion to its globular forms. Probably ORTH Space group unknown. *8-321*: 5.25₆ 4.37₄ 3.87₇ 3.47₆ 3.16₁₀ 1.97₄ 1.90₅ 1.83₈. In hemispherical forms, radial-fibrous, made up of acutely terminated crystals elongated [001]. Brick-red; orange-yellow, yellow streak, greasy to dull luster. Cleavage {001}. H = 2–3. G = 6.36. Biaxial (+); XYZ = *abc*; $N_x = 1.959$, $N_y = 1.981$, $N_z = 2.060$; $2V = 56^\circ$; $r < v$, strong; no pleochroism. From the *Weisser Hirsch, mine, Neustadt, near Schneeberg, Sachsen, Germany*, with walpurgite, uranospinite, troegerite, zeunerite, erythrite, and cobalt oxides. Kersegalec-en-Lignol, Vendée, France, in red masses. RG *DI:631*, *AM 42:905(1957)*.

5.9.2.1 Fourmarierite $\text{PbU}_4^{6+}\text{O}_{13} \cdot 4\text{H}_2\text{O}$

Named in 1924 for Paul Fourmarier (1877–1970), Belgian geologist. ORTH *Bb2₁m*. $a = 13.986$, $b = 16.400$, $c = 14.293$, $Z = 8$, $D = 5.978$. *AM 72:229(1987)*. *13-116*: 7.20₁₀ 4.36₁ 3.58₅ 3.55₂ 3.18₅ 3.14₁ 2.52₁ 1.98₁. Crystals tabular {001}, elongated [010], with pseudo-hexagonal aspect; also acicular in orange tufts. Reddish orange; brown, subadamantine luster. Cleavage {001}, perfect; {100}, fair. H = 3–4. G = 5.74. Nonfluorescent. Easily soluble in acids to a yellow solution. Biaxial (–); XYZ = *cab*; $N_x = 1.863$, $N_y = 1.885$, $N_z = 1.890$ (Na); $2V = 50^\circ$. Y, pale amber yellow; Z, amber yellow. From the Spruce Pine district, Mitchell Co., NC, as an alteration of uraninite in pegmatites; Palermo mine, near North Groton, NH. Monument No. 2 mine, Apache Co., AZ, in oxidized, mineralized fossil wood. Eldorado mine, Great Bear Lake, NWT, Canada, on altered uraninite. Ajmer district, Rajputana, India. *Shinkolobwe mine, Shaba, Zaire(!)*, with kasolite, torbernite, and other secondary uranium minerals. Mounana, Gabon. RG *DI:628*, *USGSB 1064:87(1958)*, *AM 45:1026(1960)*.

5.9.3.1 Curite $\text{Pb}_2\text{U}_5^{6+}\text{O}_{17} \cdot 4\text{H}_2\text{O}$

Named in 1921 for Pierre Curie (1859–1906), French physicist known for his research on radioactivity. Exact formula uncertain. ORTH *Pnam*. $a = 12.513$, $b = 13.002$, $c = 8.373$, $Z = 1$, $D = 7.435$. *SR 48A:246(1981)*. *14-267*: 6.23₁₀ 3.96₇ 3.52₄ 3.14₈ 3.06₆ 2.53₄ 2.09₄ 1.85₄. Crystals prismatic [001], striated [001]; usually massive, sugary, or earthy. Orange-red, orange streak, adaman-

tine luster. Cleavage {100}; brittle. $H = 4-5$. $G = 7.37$. Nonfluorescent. Easily soluble in dilute acids. Biaxial (-); $XYZ = bac$; $N_x = 2.06$, $N_y = 2.11$, $N_z = 2.15$; $2V$ large; $r > v$, strong. X, pale yellow; Y, light red-orange; Z, dark red-orange. Curite is a secondary mineral formed with other uranium oxysalts during the alteration of uraninite. La Crouzille, Puy de Dome, France, as a component of "gummite." Ellweiler, Pfalz, Germany. *Shinkolobwe mine*, and elsewhere in *Shaba, Zaire*(1), associated with fourmarierite, schoepite, vandendriesscheite, soddyite, kasolite, dewindtite, and torbernite; also in Kivu at Kobokobo. In Madagascar at Bemasoandro. RG *DI:629, USGSB 1064:92(1958), TMPM 26:279(1979)*.

5.9.4.1 Mourite $U^{4+}MO_5^{6+}O_{12}(OH)_{10}$

Named in 1962 for the composition, *molybdenum* and *uranium*. MON *Pc* or *P2/c*. $a = 24.443$, $b = 7.182$, $c = 9.901$, $\beta = 102.22^\circ$, $Z = 4$, $D = 4.22$. *AM 56:163(1971)*. *24-1359*: 5.97₁₀ 3.30₂ 3.23₂ 3.18₂ 3.13₂ 2.98₂ 2.89₄ 2.49₂. Fan-shaped, radiating-fibrous, or vermiform aggregates of plates with rectangular outline, a few microns across; fibers are elongated [010]. Violet, violet-blue streak, adamantine luster. Cleavage {100}, pronounced. $H = 3$. $G = 4.17$. Slowly soluble in hot concentrated HCl; dissolves in concentrated HNO₃ with separation of molybdic acid. Insoluble in H₂SO₄. $N > 1.790$. Pleochroism pale greenish violet to dark blue-violet. $Z \wedge c = 10^\circ$; positive elongation; strong anisotropism; extinction parallel to fiber axis. From the Boso-Hackney prospect, Tordillo hill, 20 km SW of Falls City, Karnes Co., TX. From a U-Mo deposit in *Russia*, associated with iriginite, powellite, sodium-uranospinite, uranophane, tyuyamunite, goethite, jarosite, and kaolinite. RG *ZVMO 91:67(1962), AM 47:1217(1962)*.

5.9.5.1 Richetite $PbU_4O_{13} \cdot 4H_2O$

Named in 1947 for Emile Richet (1884-1938), chief geologist, Union Miniere du Haut Katanga. TRIC *P1* or *P1*. $a = 20.81$, $b = 12.06$, $c = 16.30$, $\alpha = 103.8^\circ$, $\beta = 115.1^\circ$, $\gamma = 90.4^\circ$, $Z = 9$, $D = 6.02$. *AM 70:1335(1985)*. *38-370*: 7.12₈ 3.55₆ 3.47₆ 3.12₁₀ 2.49₄ 2.01₃ 1.96₄ 1.75₃. Pseudo-hexagonal tablets, flattened on {010}; twinning gives hexagonal aspect. Black, adamantine luster. Cleavage {010}, perfect; [010], fair. Biaxial (-); X parallel to *c*; $Y \wedge [110] = 85^\circ$, $Z \wedge [110] = 5^\circ$; $N_x \approx 1.9$, $N_y \approx 2.0$, $N_z \approx 2.0$; $2V$ large. X, pale brown to colorless; Y, Z, dull brown. *Shinkolobwe mine, Shaba, Zaire*, with uranophane. RG *BSBG 70:B212(1947), USGSB 1064:91(1958), BM 107:581(1984)*.

5.9.6.1 Sayrite $Pb_2(UO_2)_5O_6(OH)_2 \cdot 4H_2O$

Named in 1983 for David Sayre (b.1924), American crystallographer. MON *P2₁c*. $a = 10.704$, $b = 6.960$, $c = 14.533$, $\beta = 116.82^\circ$, $Z = 2$, $D = 6.76$. *BM 106:299(1983)*. *35-601*: 7.01₈ 5.67₅ 3.51₉ 3.43₄ 3.11₁₀ 3.05₇ 1.96₅ 1.92₅. Crystals elongated [010], flattened {102}. Yellow-orange, reddish orange. Cleavage

{102}, distinct. Biaxial (-); $X \approx a$, $Y = b$, $Z \approx c$; $N_y \approx 1.94$, $N_z \approx 1.95$; 2V large. Y, pale yellow; Z, amber. From the *Shinkolobwe mine, Shaba, Zaire*, associated with uranophane, becquerelite, masuyite, and richetite. RG *AM* 69:568(1984).

Hydroxides and Oxides Containing Hydroxyl

DIASPORE GROUP

The diaspore group consists of five minerals corresponding to the formula

where

A = Al, Fe, Mn, (V, Fe), or Cr

and the structure is orthorhombic, *Pnma* or *Pnmd*.

The structure of diaspore is based on layers of oxygen atoms, the sequence of which is that of hexagonal close packing. Aluminum ions occupy octahedrally coordinated sites between layers in such a way as to form strips of octahedra, the direction of which defines the *c* parameter of the unit cell. The strips have the width of two octahedra and yield an orthorhombic unit cell in which *a* is twice the distance between oxygen layers. Manganese may substitute for Al and Fe up to about 6% in diaspore and goethite; and Fe for Al and V in diaspore and montroseite to a similar extent. In groutite little Fe substitution is reported; but 5.7% Sb was found replacing manganese in groutite from Franklin, NJ. *DHZ II:574(1952)*, *PCM 5:179(1979)*.

DIASPORE GROUP

Mineral	Formula	Space Group	D				
			<i>a</i>	<i>b</i>	<i>c</i>	D	
Diaspore	AlO(OH)	<i>Pnma</i>	4.396	9.426	2.844	3.380	6.1.1.1
Goethite	FeO(OH)	<i>Pnma</i>	4.62	9.95	3.01	4.26	6.1.1.2
Groutite	α-MnO(OH)	<i>Pnmd</i>	4.560	10.700	2.870	4.171	6.1.1.3
Montroseite	(V, Fe)O(OH)	<i>Pnma</i>	4.54	9.97	3.03	4.11	6.1.1.4
Bracewellite	CrO(OH)	<i>Pnma</i>	4.492	9.860	2.974	4.286	6.1.1.5

6.1.1.1 Diaspore AlO(OH)

Named in 1801 from the Greek *dias*, to scatter, for the unusual decrepitation before the blowpipe. Diaspore group. Dimorph: böhmite. ORTH *Pnma*. *a* = 4.396, *b* = 9.426, *c* = 2.844, *Z* = 4, *D* = 3.380. *NBSC 539(3):41(1954)*. 5-355: 3.99₁₀ 2.56₃ 2.32₆ 2.13₅ 2.08₅ 1.63₄ 1.48₂ 1.38₂. Habit: Crystals

DIASPORE: AlOOH

Like boehmite, diaspore has chains of Al octahedra, but they are linked along their edges to form a framework. The edge-sharing chains are double, unlike those in manganite, MnOOH , which are single. Oxygen atoms are hexagonal closest packed, and H atoms occupy the interstitial positions not occupied by Al.

commonly thin platy {010}, elongated [001]; sometimes prismatic or acicular; rarely tabular {100}. Also massive, foliated, and in thin scales. Disseminated. Twinning on {061} or on {021} to produce pseudo-hexagonal aggregates and fine V-twins. **Physical properties:** White, grayish white, colorless; also greenish gray, hair brown, yellowish, lilac, pink; sometimes violet-blue in one direction, reddish plum in another, and asparagus green in a third; rose-red to dark red in the manganous variety. Vitreous to brilliant luster, pearly on cleavage. Cleavage {010}, perfect; {110}, less so; conchoidal fracture; very brittle. $H = 6\frac{1}{2}$ -7. $G = 3.4$. **Tests:** Not attacked by acids, but soluble in H_2SO_4 after ignition. **Chemistry:** Mn^{3+} substitutes for Al up to about 5% Mn_2O_3 ; also Fe^{3+} substitutes for Al. **Optics:** Biaxial (+); $\text{XYZ} = \text{cba}$; $N_x = 1.702$, $N_y = 1.722$, $N_z = 1.750$; $2V = 84^\circ$; $r < v$, weak; absorption $X < Y < Z$. **Localities:** Chester, MA(!), as large plates and crystals with emery. In cavities in corundum in the Culsagee mine, Franklin, Mason Co., NC(*). Near Laws at White Mountain, CA, with andalusite, corundum, pyrophyllite, and lazulite in quartz-mica schist. Widespread in the bauxites and aluminous clays of AR and MO. Banská Bela, Slovakia. Jordanów, Silesia, Poland. *Mramorskoi*, *Kossoibrod*, *Ural Mountains*, Russia(!), in fine crystals in emery-bearing chlorite schists. Mugla, eastern Anatolia, Turkey(!) (manganiferous diaspore), in fine crystals often of gem quality and from which many stones have been cut. Common in the bauxites of Hungary and France. Shokozan, Bungo, Japan, with alunite, pyrophyllite, and kaolinite in a hydrothermally altered rock. **Use:** An ore of aluminum when it is a constituent of bauxite. **RG DI:675.**

6.1.1.2 Goethite FeO(OH)

Named in 1806 for Johann Wolfgang von Goethe (1749–1832), German poet, philosopher, and naturalist. Diaspore group. Synonym: limonite, from Greek word for *meadow*, in allusion to its occurrence in bogs or swamps. Limonite is a general term for hydrous iron oxides, mostly goethite. Polymorphs: akaganeite, ferrosilite, lepidocrocite. ORTH *Pnma*. $a = 4.62$, $b = 9.95$, $c = 3.01$, $Z = 4$, $D = 4.26$. Structure: *SR 33A:266(1968)*. 29-713: 4.98₁ 4.18₁₀ 2.69₄ 2.58₁ 2.45₅ 2.25₁ 2.19₂ 1.72₂. Habit: Crystals prismatic [001] and striated [001]; also flattened into tablets or scales on {010}; velvety aggregates of capillary crystals. Usually massive as reniform, botryoidal, or stalactitic masses with radial-fibrous structure. Also columnar, compact, ocherous, or earthy and often impure from the presence of clay, sand, and so on. Also oolitic or pisolitic. As thin crusts, as in common rust. Physical properties: Crystals blackish brown; massive varieties yellowish or reddish brown; brownish-yellow or ocher-yellow streak; adamantine to metallic luster, sometimes dull, earthy; also silky. Cleavage {010}, perfect; {100}, less so; uneven fracture; brittle. $G = 4.28$. Tests: In CT gives off water and is converted into hematite. Soluble in HCl. Most varieties test positive for Mn. Nonmagnetic. Optics: Biaxial (-); XYZ = bca, $N_x = 2.260$, $N_y = 2.393$, $N_z = 2.398$ (Na); 2V small to medium; $r > v$, strong; absorption $Z > Y > X$; in polished section gray. Slightly pleochroic, strongly anisotropic. X, clear yellow; Y, brownish yellow; Z, orange-yellow. $R = 16, 18$ (546 nm); 17, 20 (470 nm); 15, 17 (589 nm); 14, 16 (650 nm). Chemistry: Mn is often present substituting for Fe, in amounts up to 5% Mn_2O_3 . Occurrence: Formed under oxidizing conditions as a weathering product of ferrous minerals, especially siderite, pyrite, magnetite, and glauconite. Also as a direct inorganic or biogenic precipitate from marine or meteoric waters and widespread as a deposit in bogs and springs ("bog iron ore"). Forms the weathered capping or gossan of sulfide veins. As a principal component of laterites, which are formed in countries with warm, humid climates where rock decay has progressed without interruption for a long time. Rarely as a low-temperature hydrothermal vein product. Also the principal component of common rust everywhere where iron and steel objects have been subject to corrosion. Localities: Goethite is a very common mineral nearly everywhere, and only a few localities can be mentioned. Formerly common in the Lake Superior hematite deposits, notable specimens having been found in MI at the Jackson mine, Negaunee(!), and the Superior mine near Marquette. Well crystallized in sheaflike groups in pockets in pegmatite in the Pikes Peak granite near Florissant, CO(!) and fine pseudomorphs of "limonite" (goethite) after pyrite from Pelican Point, Great Salt Lake, UT(!). As residual brown iron ores in the Appalachian region, mainly in AL, GA, VA, and TN. Fine, large crystals were found in Cornwall, England, at the Restormel mine, Lostwithiel, and the Botallack mine, St. Just(!). In France as thin acicular crystals to 30 mm at Chaillac, Vienne. In Germany, numerous localities in Nordrhein-Westfalen, Rhine, and Nassau, especially at Siegen, Eisfeld Horhausen, and Oberstein.

Widespread in residual iron ore deposits in Ukraine; and in Russia acicular crystals with amethyst from Lake Onega(*), and at Bakal, southern Ural Mts.(!). As fine large pseudomorphs after pyrite and sometimes siderite crystals from near Diamantina, MG, Brazil(*). Uses: An important ore of iron; also used as pigment in ochers. RG *DI:680*; *AM 32:659(1947)*, *44:254(1959)*; *GSAM 85:187(1962)*.

6.1.1.3 Groutite α -MnO(OH)

Named in 1945 for Frank Fitch Grout (1880–1958), American petrologist, University of Minnesota. Diaspore group. Polymorphs: manganite, feiknechtite. ORTH *Pnmd*. $a = 4.560$, $b = 10.700$, $c = 2.870$, $Z = 4$, $D = 4.171$. *NBSM 25(11):97(1974)*. Structure: *AC(B) 24:1233(1968)*. *12-733(syn)*: 4.20_{10} 2.81_3 2.67_3 2.53_1 2.37_5 2.31_2 1.69_3 1.61_2 . Crystals lens-shaped or wedge-shaped, flattened {100}; also acicular [001], flattened {010}, and elongated [001]. Black, dark brown streak, submetallic/adamantine luster. Cleavage {010}, perfect; {100}, fair; brittle. $H = 3\frac{1}{2}$. $G = 4.144$. Nonfluorescent. In CT gives off water. Biaxial (+); $XYZ = cba$; $N_x = 2.1$ – 2.2 , $N_z = 2.1$ – 2.2 ; 2V medium. X, yellowish brown; Z, dark brown to purplish black. From *Sagamore open pit, Cuyuna Range, MN*, and other mines in the district. Talcville, near Gouverneur, NY, with calcite in vugs in talc. Franklin, Sussex Co., NJ, in franklinite and andradite, an antimonian groutite with 7.6% Sb_2O_5 . From Germany at the Bülten–Adenstedt mine, near Peine, Niedersachsen, in fine radial aggregates making crystallized balls. RG *AM 32:654(1947)*, *52:858(1967)*.

6.1.1.4 Montroseite (V,Fe)O(OH)

Named in 1953 for the locality. Diaspore group. ORTH *Pnma*. $a = 4.54$, $b = 9.97$, $c = 3.03$, $Z = 4$, $D = 4.11$. *AM 40:861(1955)*. *11-152*: 4.31_{10} 3.38_8 2.64_{10} 2.50_8 2.42_6 2.22_8 1.97_6 1.51_8 . Crystals microscopic, bladed, elongated [001]. Black, black streak, submetallic luster. Cleavage {010} and {110}, good; brittle. $G = 4.0$. Weakly magnetic. Opaque. *Bitter Creek mine, Paradox Valley, Montrose Co., CO*, interstitial to sand grains in a sandstone. Also found in other nearby mines: the Matchless mine, Mesa Co.; the Juniper mine, Grand Co., and in UT at Temple Mt., Emery Co. RG *AM 38:1235(1953)*.

6.1.1.5 Bracewellite CrO(OH)

Named in 1967 for Smith Bracewell (1899–1979), director, British Guiana Geological Survey, who first noted the mineral assemblage in which the mineral occurs. Diaspore group. Polymorphs: grimaldiite, guyanaite. ORTH *Pnma*. $a = 4.492$, $b = 9.860$, $c = 2.974$, $Z = 4$, $D = 4.286$. *25-1497*: 4.93_5 4.09_{10} 2.65_8 2.55_7 2.47_5 2.41_7 2.16_7 1.30_6 . As masses and grains intergrown with other Cr oxides. Black, deep red; dark brown streak. $G = 4.47$. From the *Merume River, Mazaruni district, Guyana*, as black alluvial pebbles consisting of one or more of the minerals bracewellite, eskolaite, grimaldiite,

guyanaite, and mcconnellite. The crude pebbles are locally called "merumite." RG *USGSPP 887:13(1976)*, *AM 62:593(1977)*.

6.1.2.1 Boehmite $\text{AlO}(\text{OH})$

Named in 1927 for Johannes Bohm (1857–1938), German geologist and paleontologist, who first recognized the species. Dimorph: diaspore. ORTH *Cmcm*. $a = 2.868$, $b = 12.227$, $c = 3.700$, $Z = 4$, $D = 3.070$. *NBSC 539(3):38(1954)*. *21-1307(syn)*: 6.11_{10} 3.16_6 2.35_5 1.86_3 1.85_2 1.66_1 1.45_2 1.31_2 . Microscopic lenticular crystals tabular {001}. Usually disseminated or as pisolitic aggregates. Structure: *CLM 29:435(1981)*. White to gray. Cleavage {010}. $G = 3.03$. Biaxial (-); $YZ = cb$; $N \approx 1.64$. Widely distributed in bauxite and at times forms the principal constituent of the rock. Also may exsolve from corundum and is responsible for the rhombohedral and basal parting reported in that mineral. Linwood–Barton district, GA. Gant and Baratka, Hungary. Stangenrod, Harz, Germany. Mt. Maggiore, Italy. Ayrshire, Scotland. In France at Recoux, Var, Pereille, and Cardarcet, Ariège. RG *DI:645*, *CCM 27:81(1979)*.

6.1.2.2 Lepidocrocite $\gamma\text{-FeO}(\text{OH})$

Named in 1813 from the Greek for *scale* and *thread* or *fiber*, in allusion to the scaly or feathery habit. Polymorphs: goethite, akaganéite, feroxyhyte. ORTH *Cmc2₁*. $a = 3.08$, $b = 12.50$, $c = 3.07$, $Z = 4$, $D = 3.960$. Structure: The structure of lepidocrocite is similar to that of boehmite and consists of iron-centered oxygen octahedra linked together in chains parallel to X by sharing diagonally opposite edges. The chains make up double sheets of octahedra, the repeat distance of which defines the a parameter of the unit cell. The oxygens within the double octahedral layers are in cubic close-packed relationship. *DHZ II:580,576*, *SR 44A:224(1979)*. *44-1415(syn)*: 6.26_6 3.29_{10} 2.47_8 2.43_3 2.36_4 1.936_7 1.535_3 1.525_3 . Habit: Scales flattened {010}, sometimes aggregated into palmate or plumose groups; loose rosettes; massive, bladed to fibrous, or micaceous. Fibrous varieties elongated [100]. Physical properties: Red, reddish brown; dull-orange streak; submetallic luster. Cleavage {010}, perfect; {100}, less perfect; {001}, good; brittle. $H = 5$. $G = 4.09$. Optics: Biaxial (-); $XYZ = bca$; $N_x = 1.94$, $N_y = 2.20$, $N_z = 2.51$; $2V = 83^\circ$; slight dispersion; absorption $X < Y < Z$. X, yellow; Y, dark red-orange; Z, darker red-orange. In RL, gray-white. Strongly pleochroic, strongly anisotropic. $R = 18.4, 11.9$ (470 nm); $16.8, 10.9$ (546 nm); $15.9, 10.7$ (589 nm); $15.2, 10.4$ (650 nm). *P&J:236*. Occurrence: Lepidocrocite is formed under the same conditions as goethite, and the two minerals are often found together in the same deposit. Localities: From the Lake Superior iron region, MN and MI; Easton, PA; Iron Mt. mine, Shasta Co., CA. Well crystallized at the Eisenzeche mine, Eiserfeld, Siegen, Germany. Rancié en Sem, near Vicdessos, Ariège, France. Near Trosna and other localities, Ukraine. *Zlaté Hory*, Czech Republic. Sometimes found as acicular inclusions in amethystine quartz, in the Alps, Brazil, and so on. (The mineral from Eiserfeld was

originally described and named *goethite*, which then was shown to exist in many other places. Later, it was proved that the Eiserfeld material was actually distinct from the common goethite and was identical to lepidocrocite as described from Zlate Hory. The name *goethite*, however, has been retained for the commoner of the two polymorphs.) RG *DI:642, GSAM 85:185(1962), CLM 14:285(1979)*.

6.1.2.3 Guyanaite CrO(OH)

Named in 1967 for the country of origin. Polymorphs: bracewellite, grimaldiite. ORTH *Pnmm*. $a = 4.857$, $b = 4.295$, $c = 2.958$, $Z = 2$, $D = 4.574$. *AM 62:593(1977)*. *20-312(syn)*: 3.22_{10} 2.53_2 2.43_8 2.15_1 1.72_3 1.64_5 1.61_2 1.42_2 . As discrete grains intergrown with other components of "merumite." Reddish brown, golden brown, dark green. $G = 4.53$. From the *Merume River, Mazaruni District, Guyana*, as a constituent of alluvial pebbles locally called *merumite*, which consist of an intergrowth of eskolaite, bracewellite, guyanaite, grimaldiite, and mcconnellite. RG *USGSPP 887:10(1976)*.

6.1.3.1 Manganite γ -MnO(OH)

Named in 1827 for the composition. Polymorphs: groutite, feitknechtite. MON *P2₁/c*. $a = 8.98$, $b = 5.28$, $c = 5.71$, $\beta = 90^\circ$, $Z = 8$, $D = 4.38$. *ZK 118:303(1963)*. **Structure:** The manganese atoms occupy the centers of O—OH octahedra, and the octahedra share opposite edges and form chains parallel to c . The octahedra are somewhat distorted, the Mn—O distances along b being greater than the Mn—O and Mn—OH distances in the rectangle in the plane of the shared edges. Pairs of OH groups in the a direction form one side of these rectangles, opposite pairs of O atoms forming the other side, thus alternating along the chain. The OH groups of one ribbon bind themselves to the O atoms of the adjacent ribbon to form an (010) sheet corrugated in the direction [001]. The outstanding excellence of the (010) cleavage over the other cleavages in the prismatic zone is thus produced. *ZK 95:163(1936), 118:303(1963)*. *41-1379*: 3.41_{10} 2.64_2 2.52_1 2.417_2 2.414_2 1.782_2 1.672_2 1.670_2 . **Habit:** Crystals pseudo-orthorhombic, short to long prismatic [001], often terminated by {001} alone. Prismatic faces deeply striated [001]. Crystals often grouped in bundles or markedly composite subparallel [001]. Rarely massive, stalactitic. Twins on {011}, both as contact and penetration twins, often repeated; lamellar twinning on {100} invariably present. **Physical properties:** Dark steel gray, black; reddish-brown to black streak, submetallic luster. Cleavage {010}, perfect; {110} and {001}, less so; uneven fracture; brittle. $H = 4$, $G = 4.33$. **Tests:** Infusible. Soluble in HCl with evolution of Cl. **Optics:** Biaxial (+); $XYZ = abc$; $N_x = 2.25$, $N_y = 2.25$, $N_z = 2.53$; $2V$ small; $r > v$, very strong; absorption X and $Y > Z$. X , reddish brown; Z , red brown. In RL, gray-white with a brownish tint. Internal reflections blood red. Weakly pleochroic. $R = 23.9$, 17.9 (470 nm); 22.0 , 16.9 (546 nm); 21.0 , 16.4 (589 nm); 20.2 , 15.9 (650 nm). *P&J:255*. **Occurrence:** Manganite occurs as a low-temperature hydrothermal

vein mineral with barite, calcite, siderite, braunite, and hausmannite. As replacement deposits formed by meteoric waters, with pyrolusite, psilomelane, and goethite. In residual clays. Localities: Jackson mine, Negaunee, MI, and elsewhere in the Lake Superior iron district. Well crystallized at Powell's Fort, near Woodstock, Shenandoah Co., VA(!). Livermore-Tesla district, Alameda Co., CA. Lake Valley district, Sierra Co., NM. Abundant and finely crystallized at *Ilfeld, Harz, Germany*(!!), in veins in porphyrite with barite and calcite; also at Ilmenau, Thuringia, in part pseudomorphous after calcite. In France at Las Cabesses and Rancié, Ariège. Botallack mine, St. Just, Cornwall, and at Egremont, Cumberland, England. Bölet, Sweden. N'Chwaning No. II mine, Kalahari manganese field, Kuruman, Cape, South Africa(!). RG *DI:646, AM 50:1296(1965)*.

6.1.4.1 Heterogenite-2H CoO(OH)

6.1.4.2 Heterogenite-3R CoO(OH)

Named in 1872 (3R) and 1973 (2H) from the Greek for *other* and *kind*, in reference to its difference in composition from other minerals that it otherwise resembles. 3R: HEX $P6_3/mmc$. $a = 2.855$, $c = 8.805$, $Z = 2$, $D = 4.912$. *NJMM:215(1967)*. Heterogenite-3R is isostructural with grimaldiite. 2H: HEX-R $R3m$. $a = 2.855$, $c = 13.156$, $Z = 3$, $D = 4.931$. *MM 39:152(1973)*. *26-1107(2H-nat)*: 4.39₁₀ 2.47₇ 2.38₅ 2.16₈ 1.64₈ 1.43₄ 1.26₅ 1.24₉. *7-169(3R-syn)*: 4.38₁₀ 2.43₁ 2.31₉ 1.98₁ 1.80₈ 1.50₂ 1.43₃ 1.36₃. Botryoidal; reniform or globules; porous aggregates; crystalline masses, with crystals prismatic and {0001} well developed. Twinning common in crystals. The two polytypes of heterogenite have similar physical properties and can be distinguished only through their powder patterns. Crystals lustrous black; other forms black, blackish brown, reddish brown; dark brown streak; metallic to vitreous luster (crystals), to dull luster. Cleavage {0001}, good; conchoidal fracture; somewhat malleable. $H = 4-5$, crystals; $H = 3-4$, massive forms. $G = 4.0-4.72$. A small amount of Ni is usually present, up to about 2%. Copper is also often detected but is believed usually to represent admixed impurities. In RL, white to gray. $N \approx 2.7$. Bireflectance 0.07. Strongly anisotropic. $R = 16.5-23.5$ (589 nm). From *Mindingi, Shaba, Zaire* (heterogenite 2H), where it is abundant and used as an ore of cobalt. *Schneeberg, Saxony, Germany* (heterogenite 3R), as an alteration product of smaltite, with pharmacosiderite and calcite. RG *DI:652*.

6.1.4.3 Feitknechtite β -MnO(OH)

Named in 1965 for Walter Feitknecht (1899-1975), Swiss, professor of chemistry, University of Bern, who first synthesized the compound. Polymorphs: groutite, manganite. Probably HEX Space group unknown. $a = 8.6$, $c = 9.30$. *18-804(syn)*: 4.62₁₀ 2.64₅ 2.36₂ 1.96₁ 1.55₁ 1.50₁. Crystals are thin hexagonal plates. This mineral was indexed on a tetragonal cell; however, this is inconsistent with SEM photographs of synthetically prepared material,

which show clear-cut hexagonal habit. Frondel described "hydrohausmanite" from Franklin, NJ, and Sweden in 1953. This mineral was later shown to be a mixture; one of the components of this mixture, β -MnO(OH), was subsequently named feitknechtite. Black, brownish black; brown streak. $G = 3.80$. Uniaxial (-); $N_O = 2.055$, $N_E = 1.95$. From *Franklin, Sussex Co., NJ*, as an alteration product of pyrochroite and lining solution cavities in a matrix of calcite, sussexite, and zincite. Langban and Pajsberg, Sweden, in altered pyrochroite. RG *AM 38:761(1953)*, *50:1296(1965)*.

6.1.4.4 Feroxyhyte Δ -FeO(OH)

Named in 1976 for the composition. Polymorphs: goethite, lepidocrocite, akaganéite. HEX Space group unknown. $a = 2.93$, $c = 4.60$, $Z = 1$, $D = 4.20$. *AM 62:1057(1977)*. 13-87: 4.61₂ 2.55₁₀ 2.26₁₀ 1.69₁₀ 1.47₁₀ 1.27₂ 1.22₂ 1.10₂. Massive; as nodules and concretions. Δ -FeO(OH) consists of two phases, both hexagonal, one ordered and magnetic, the other, feroxyhyte, disordered or only slightly ordered and nonmagnetic. Alters spontaneously to goethite upon exposure to air. From *Pacific Ocean Fe-Mn nodules*, and from the *Baltic, White, and Kara seas*. RG *IGR 19:873(1977)*, *CCM 28:272(1980)*.

6.1.5.1 Grimaldiite CrO(OH)

Named in 1967 for Frank S. Grimaldi (1915–1985), former chief chemist, U.S. Geological Survey. Polymorphs: bracewellite, guyanaite. HEX-R *R3m*. $a = 2.973$, $c = 13.392$, $Z = 3$, $D = 5.61$. *AM 62:593(1977)*. 9-331: 4.44₁₀ 2.53₁ 2.41₃ 2.23₁ 1.86₃ 1.54₁ 1.49₂ 1.41₁. Tabular rhombohedral crystals; scallop-shaped minute platy aggregates. Structure: *AC 10:423(1957)*. Deep red; pinkish brown (Bolivia). $G = 5.49$. *Merume River, Mazaruni District, Guyana*, as a constituent of black alluvial pebbles locally known as "merumite," consisting of intergrowths of eskolaite, bracewellite, guyanaite, mcconnellite, and grimaldiite. Hiaca mine, Colquechaca, Bolivia, with penroseite in barite. RG *USGSPP 887:17(1976)*, *MM 48:560(1984)*.

6.1.6.1 Akaganéite β -FeO(OH, Cl)

Named in 1961 for the locality. Polymorphs: goethite, lepidocrocite, feroxyhyte. MON *I2/m*. $a = 10.600$, $b = 3.034$, $c = 10.513$, $\beta = 90.23^\circ$, $Z = 8$, $D = 3.6$. *AM 76:272*. 34-1266(syn): 7.47₄ 5.28₃ 3.33₁₀ 2.63₃ 2.55₆ 2.30₄ 1.95₂ 1.64₄. Massive; as crusts; similar to "limonite." The structure consists of double chains of edge-sharing FeO₃(OH)₃ octahedra extending along the c axis. The octahedra comprising the double chains share corners with adjacent chains to form tunnels approximately $5 \times 5 \text{ \AA}$ in size. Each tunnel is composed of adjoining cavities formed by eight OH groups. Infrared studies indicate that at least half of these groups are replaced by Cl-OH in nonstoichiometric proportions. *MM 33:270(1962)*, *32:545(1960)*. Brown to dark brown, brown streak, dull to earthy luster. $G = 3.0$. Other physical properties similar to "limonite" (goethite). From the *Akagane mine, Iwate, Japan*, as an oxidation product of pyrrhotite, associated with goethite. As an important corrosion

crust on some meteorites. A major Fe-oxide component in soils and geothermal brines. A corrosion product of some steels. *RG NJMA 113:29(1970)*, *GCA 41:539(1977)*, *CLM 14:273(1979)*, *AC(A) 35:197(1979)*.

BRUCITE GROUP

The brucite minerals are isostructural simple hydroxides corresponding to the formula

where

$A = \text{Mg}, \text{Fe}^{2+}, \text{Mn}, \text{Ca}, \text{or Ni}$

and which crystallize with rhombohedral symmetry in space group $P\bar{3}m1$.

Brucite has a layered structure in which each layer has two sheets of (OH) parallel to the basal plane, with a sheet of Mg ions between them, each Mg lying between six (OH). The hydroxyl groups are hexagonal close-packed ABABA, with each (OH) linked to three Mg on one side and fitted into three (OH) of the next layer.

This arrangement of the structure leads to polarization of the (OH) group, with the result that the layers of brucite are held together not only by van der Waals forces but also by a type of hydrogen bond. *DHZ 5:89*, *SR 32A:242(1967)*, *ZK Supp. 4:316(1991)*.

BRUCITE: $\text{Mg}(\text{OH})_2$

Two close-packed layers of hydroxyl with Mg in all octahedral interstices. Hydrogen bonds are the only links between sandwiches. Symmetry requires hydrogen atoms to be equidistant from three oxygen atoms to which they might be bonded—in reality, they may be disorderd. See also GIBBSITE.

BRUCITE GROUP

Mineral	Formula	Space Group	a	c	D	
Brucite	Mg(OH) ₂	P3m1	3.147	4.769	2.368	6.2.1.1
Amakinite	(Fe, Mg)(OH) ₂	P3m1	6.918	14.52	2.73	6.2.1.2
Pyrochroite	Mn(OH) ₂	P3m1	3.323	4.738	3.268	6.2.1.3
Portlandite	Ca(OH) ₂	P3m1	3.593	4.909	2.241	6.2.1.4
Theophrastite	Ni(OH) ₂	P3m1	3.131	4.608	3.95	6.2.1.5

Note: See the melonite (2.12.14.1) group for structurally similar sulfides, selenides, and tellurides.

6.2.1.1 Brucite Mg(OH)₂

Named in 1824 for Archibald Bruce (1777–1818), American mineralogist, who first described the species. Brucite group. HEX-R P3m1. $a = 3.147$, $c = 4.769$, $Z = 1$, $D = 2.368$. NBSC 539(6):30(1956). 44-1482(syn): 4.79₅ 2.72₁ 2.37₁₀ 1.796₃ 1.572₃ 1.493₁ 1.374₁ 1.309₁. Crystals tabular {0001}, often subparallel aggregates of plates. Massive, foliated; fibrous; rarely fine granular. White, pale green, gray, blue; manganoan varieties yellow to red; white streak; vitreous to waxy luster, pearly on cleavages. Cleavage {0001}, perfect; flexible foliae; sectile. $H = 2\frac{1}{2}$. $G = 2.39$. Pyroelectric. Infusible; ignited material reacts alkaline. Easily soluble in acids. Uniaxial (+); $N_O = 1.561$, $N_E = 1.581$; manganoan brucite: $N_O = 1.59$, $N_E = 1.60$. Typically formed as a low-temperature hydrothermal vein mineral in serpentine and chloritic or dolomitic schist. Also as an alteration product of periclase in crystalline limestones. Hoboken, Hudson Co., NJ, with hydromagnesite, artinite, and dolomite in serpentine. Well crystallized from the Tilly Foster iron mine, Brewster, Putnam Co., NY. The Wood mine, Texas, Lancaster Co., PA(!), in large fine crystals with chromite in serpentine. Lodi district, NV, in a large deposit with hydromagnesite. Crestmore, Riverside Co., CA, as an alteration of periclase in marble. In Italy in periclase limestone blocks thrown up by Vesuvius. In Sweden as an alteration of periclase in Nordmark, Langban, and elsewhere. Asbest, near Ekaterinburg, Ural Mts., Russia(!), in fine transparent crystals to 5 cm; also in the Kempirsai massif, southern Ural Mts.(!). Phalaborwa, Transvaal, South Africa, in a large carbonatite. RG DI:636, AM 48:86(1963).

6.2.1.2 Amakinite (Fe, Mg)(OH)₂

Named in 1962 for the Amakin expedition, which prospected the diamond pipes of Yakutia. Brucite group. HEX-R P3m1. $a = 6.918$, $c = 14.52$, $Z = 12$, $D = 2.73$. 15-125: 5.49₇ 2.80₈ 2 30₁₀ 1.73₉ 1.55₇ 1.53₈ 1.39₇ 1.27₇. Crystals rhombohedra; also as irregular grains. Pale green to yellow green, when fresh. Rough cleavage observed occasionally. $H = 3\frac{1}{2}$ –4. $G = 2.98$. Weakly magnetic. In CT decrepitates, giving off water, and turns brown to black. Soluble in HCl. Uniaxial (+); $N_O = 1.707$, $N_E = 1.722$. Alters rapidly in air, with formation of brown crusts of hydrous ferric oxide. From the Lucky East-

ern kimberlite pipe, Yakutia, Siberia, Russia. RG *ZVMO* 91:72(1962), *AM* 47:1218(1962).

6.2.1.3 Pyrochroite $\text{Mn}(\text{OH})_2$

Named in 1864 from the Greek *puro*, fire, and *khroma*, color, because of the change in color upon ignition. Brucite group. *HEX-R* $P\bar{3}m1$. $a = 3.323$, $c = 4.738$, $Z = 1$, $D = 3.268$. *MJJ* 3:30(1960). 18-787(syn): 4.72₉ 2.87₄ 2.45₁₀ 1.83₆ 1.66₄ 1.57₃ 1.38₂ 1.37₂. Crystals tabular {0001}; also rhombohedral with {1012} or {1011}; rarely prismatic [0001]. Usually foliated massive and as thin veinlets. Colorless to pale greenish or bluish, but upon exposure soon becomes bronze-brown and then black; pearly luster on cleavages. Cleavage {0001}, perfect; thin flakes flexible. $H = 2\frac{1}{2}$. $G = 3.25$. Easily soluble in dilute HCl. In CT becomes verdigris green, and finally brownish black. Mg substitutes for Mn up to at least Mn/Mg = 5:1. Uniaxial (-); $N_O = 1.723$ (brown), $N_E = 1.681$ (lighter brown); absorption $O > E$. From Franklin and Sterling Hill, Sussex Co., NJ, in secondary hydrothermal veinlets cutting franklinite ore, with rhodochrosite, calcite, willemite, gageite, chlorophoenicite, and hodgkinsonite. From Langban and Persberg, Värmland, Sweden. In crystal druses in limonite near Prijedor, Bosnia. Noda-Tamagawa mine, Japan. Kuruman manganese district, Cape Prov., South Africa. RG *DI:639*, *AM* 50:1296(1965).

6.2.1.4 Portlandite $\text{Ca}(\text{OH})_2$

Named in 1933 because $\text{Ca}(\text{OH})_2$ is a common product of hydration of portland cement. Brucite group. *HEX-R* $P\bar{3}m1$. $a = 3.593$, $c = 4.909$, $Z = 1$, $D = 2.241$. *NBSC* 539(1):58(1953). 44-1481(syn): 4.92₇ 3.11₃ 2.63₁₀ 1.928₃ 1.795₃ 1.69₁ 1.48₁ 1.45₁. Structure: *AC* 14:950(1961). Hexagonal plates {0001}. Colorless, pearly luster on cleavage. Cleavage {0001}, perfect; flexible; sectile. $H = 2$. $G = 2.23$. Soluble in water, giving alkaline solution. Easily soluble in dilute HCl. Uniaxial (-); $N_O = 1.574$, $N_E = 1.547$. From Scawt Hill, Co. Antrim, Northern Ireland, with afwillite and calcite in larnite-spurrite contact rocks. Vesuvius, Italy, in fumaroles. In good crystals in the "mottled" zone complex, Hatrurim region, Israel, with fluorapatite and ettringite. RG *DI:641*, *AM* 48:925(1963).

6.2.1.5 Theophrastite $\text{Ni}(\text{OH})_2$

Named in 1981 for Theophrastos (372-287 B.C.), the first Greek mineralogist. Brucite group. *HEX-R* $P\bar{3}m1$. $a = 3.131$, $c = 4.608$, $Z = 1$, $D = 3.95$. *AM* 66:1021(1981). 14-117: 4.61₁₀ 2.71₅ 2.33₁₀ 1.75₄ 1.56₃ 1.48₂ 1.33₁ 1.30₁. Microacicular crystals forming layers like velvet, aligned perpendicular to the surface of other minerals that are coated by it. Emerald green, pale green streak, vitreous luster. Cleavage {0001}, perfect; conchoidal fracture. $H = 3\frac{1}{2}$. $G = 4.00$. Soluble in acids. Uniaxial (+); $N_O \approx 1.759$, $N_E \approx 1.760$. Birefringence very weak. From Vermion, Macedonia, Greece, in a magnetite-chromite

mine, with vesuvianite, chlorite, andradite, Ni-bearing serpentine minerals, and chlorite. RG *MM* 46:1(1982).

6.2.2.1 Behoite $\text{Be}(\text{OH})_2$

Named in 1970 for the composition, $\text{Be} + \text{HO} (= \text{OH})$. Dimorph: clinobehoite. ORTH $P2_12_12_1$. $a = 4.639$, $b = 7.071$, $c = 4.548$, $Z = 4$, $D = 1.92$. 39-1411(syn): 3.88₉ 3.83₆ 2.95₃ 2.79₃ 2.39₁₀ 2.20₂ 1.983₂ 1.962₂. Crystals equant, showing combinations of {011} with {110}, giving a pseudo-octahedral habit. Colorless; pastel shades of brown, red, or yellow due to impurities; vitreous luster. No cleavage; conchoidal fracture. $H = 4$. $G = 1.92$. Nonfluorescent. Biaxial (-); $XYZ = bac$; $N_x = 1.533$, $N_y = 1.544$, $N_z = 1.548$; $2V = 82^\circ$; $r < v$, strong. From *Rode Ranch pegmatite, Llano Co., TX*, as an alteration product of gadolinite, associated with bastnaesite and tenerite. With bertrandite and fluorite at Sierra Blanca, Hudspeth Co., TX. Mt. St.-Hilaire, QUE, Canada, as radial-fibrous spherules and coating serandite(l). RG *AM* 55:1(1970), *PD* 4:50(1989).

6.2.3.1 Clinobehoite $\text{Be}(\text{OH})_2$

Named in 1989 for the monoclinic symmetry and its chemical identity with behoite. Dimorph: behoite. MON $P2_1$. $a = 11.020$, $b = 4.746$, $c = 8.646$, $\beta = 98.93^\circ$, $Z = 12$, $D = 1.92$. PD 5.43₈ 3.98₆ 3.76₇ 3.61₉ 3.16₇ 2.71₁₀ 2.44₆ 2.31₇. Platy, cuneiform crystals in radial aggregates. Structure: *ZK* 185:612(1988). Colorless, white; vitreous to pearly luster. Cleavage {100}, perfect; {010}, {001}, imperfect; brittle. $H = 2-3$. $G = 1.93$. Soluble in HCl. Biaxial (-); $X \approx c$, $Y = b$; $Z \wedge a \approx 9^\circ$; $N_x = 1.539$, $N_y = 1.544$, $N_z = 1.548$; $2V = 80^\circ$. Dispersion strong. From *Mursinsk, Ural Mts., Russia*, in hydrothermally altered zones of desilicated pegmatites, associated with bavenite, bityite, analcime, phillipsite, and albite. RG *MZ* 11(5):88(1989).

6.2.4.1 Spertiniite $\text{Cu}(\text{OH})_2$

Named in 1981 for Francesco Spertini (b.1937), chief geologist, Jeffrey mine. ORTH $Cmc2$. $a = 2.947$, $b = 10.593$, $c = 5.256$, $Z = 4$, $D = 3.94$. *CM* 19:337(1981). 35-505: 5.29₈ 3.73₉ 2.63₁₀ 2.50₆ 2.36₅ 2.27₇ 1.93₃ 1.72₇. Crystals microscopic, tabular, grouped in botryoidal or radial aggregates. Structure: *AC(C)* 46:2279(1980). Blue, blue-green; vitreous luster. Cleavage not observed. $G = 3.93$. Soft. Nonfluorescent. Soluble in acids, insoluble in cold water. Biaxial; $N_x = 1.720$ (colorless), $N_z > 1.800$ (dark blue); parallel extinction; positive elongation. From the *Jeffrey mine, Shipton Twp., Richmond Co., QUE, Canada*, in a rodingite dike, with diopside, grossular, vesuvianite, chalcocite, and atacamite. RG *AM* 67:860(1982).

6.2.5.1 Calumetite $\text{Cu}(\text{OH}, \text{Cl})_2 \cdot 2\text{H}_2\text{O}$

Named in 1963 for the locality. ORTH 15-669: 7.50₁₀ 3.76₅ 3.42₃ 3.30₃ 3.02₆ 2.48₈ 2.34₃ 1.99₃. Spherules, and sheaves of scaly crystals, with {001} and {110}. Azure blue, powder blue; pearly luster. Cleavage {001}, perfect; brittle.

H = 2. Insoluble in water or NH_4OH ; soluble in cold, dilute acids. Biaxial (-); $\text{XYZ} = \text{cab}$; $N_x = 1.666$, $N_y = 1.690$, $N_z = 1.690$; $2V = 2^\circ$; $Z > Y > X$. X, blue. From the *Centennial mine, Calumet, Houghton Co., MI*, associated with copper, malachite, cuprite, atacamite, paratacamite, buttgenbachite, and other minerals. RG *AM 48:614(1963)*.

6.2.6.1 Anthonyite $\text{Cu}(\text{OH}, \text{Cl})_2 \cdot 3\text{H}_2\text{O}$

Named in 1963 for John W. Anthony (1920–1992), mineralogist, University of Arizona. MON Space group unknown. $\beta = 112.63^\circ$. *15-670*: 5.84₁₀ 5.17₄ 4.14₇ 3.99₆ 3.44₆ 3.18₄ 3.07₄ 2.87₆. Crystals prismatic, elongated [001]. Lavender. Cleavage {100}, perfect; sectile; bends readily on {100} cleavage. H = 2. Insoluble in water; soluble in cold, dilute acids. Dehydrates rather rapidly in air. Biaxial (-); $Y = b$; $Z \wedge c = 13^\circ$; $N_x = 1.526$, $N_y, N_z = 1.602$; absorption $Z = Y > X$. X, lavender; Z, deep smoky blue. From the *Centennial mine, Calumet, Houghton Co., MI*, associated with copper, cuprite, paratacamite, and an unidentified copper chloride. RG *AM 48:614(1963)*.

6.2.7.1 Duttonite $\text{V}^{4+}\text{O}(\text{OH})_2$

Named in 1957 for Clarence E. Dutton (1841–1912), geologist, U.S. Geological Survey, one of the first to work in the Colorado Plateau region. MON *C2/c*. $a = 8.80$, $b = 3.95$, $c = 5.96$, $\beta = 90.67^\circ$, $Z = 4$, $D = 3.24$. Structure: *AC(A)* *11:56(1958)*. *10-377*: 4.40₁₀ 3.61₈ 3.29₁ 2.64₁ 2.48₂ 2.45₂ 1.97₂ 1.84₂. Crusts of six-sided platy crystals, flattened {001}, pseudo-orthorhombic. Pale brown. Cleavage {100}, pronounced. $H = 2\frac{1}{2}$, $G \approx 3.1$. Biaxial (+); $\text{XYZ} = \text{acb}$; $N_x = 1.810$, $N_y = 1.900$, $N_z > 2.01$; $2V \approx 60^\circ$; dispersion $r < v$, moderate. X, pale pinkish brown; Y, pale yellow-brown; Z, pale brown. From the *Peanut mine, Bull canyon mining district, about 24 km W of Naturita, Montrose Co., CO*, with melanovanadite and selenium. RG *AM 42:455(1957)*, *BM 93:235(1970)*.

6.2.8.1 Tivanite $\text{TiVO}_3(\text{OH})$

Named in 1981 for the composition. MON *P2₁c*. $a = 7.494$, $b = 4.552$, $c = 10.005$, $\beta = 129.78^\circ$, $Z = 4$, $D = 4.17$. *35-494*: 3.92₂ 3.88₁₀ 2.80₉ 2.64₇ 2.54₂ 1.69₃ 1.68₃ 1.67₂. Irregular grains. Black, black streak, metallic to submetallic luster. $\text{VHN}_{50} = 650 \text{ kg/mm}^2$. In RL, dark brown–deep blue. No internal reflections. Pleochroism not discernible; weakly to moderately anisotropic. $R = 16.8$ (470 nm), 17.4 (546 nm), 17.7 (589 nm). From *Kalgoorlie, WA, Australia* in the “green leader” mineralized zone, associated with V-bearing sericite, nolanite, and tomichite. RG *AM 66:866(1981)*.

6.2.9.1 Sweetite $\text{Zn}(\text{OH})_2$

Named in 1984 for Jessie M. Sweet (1901–1979), curator, mineral collection, British Museum (Natural History). Polymorphs: wulfingite, ashoverite. TET Space group unknown. $a = 8.222$, $c = 14.34$, $Z = 20$, $D = 3.41$. *AM 70:438(1985)*. *38-356*: 4.53₄ 3.57₆ 2.92₁₀ 2.71₂ 2.26₂ 1.84₁ 1.76₂ 1.56₁. Tetra-

gonal bipyramids, probably {112}, with pseudo-octahedral aspect. White, vitreous luster. $G = 3.33$. Soluble in dilute HCl with slight effervescence. Uniaxial (-); $N_O = 1.636$, $N_E = 1.628$. Northwest of *Milltown, near Ashover, Derbyshire, England*, in fluorite veins in a limestone quarry, on colorless fluorite, associated with barite and ashoverite. RG *MM* 48:267(1984).

6.2.10.1 Wülfingite $Zn(OH)_2$

Named in 1985 for Ernst Anton Wülfing (1860–1930), professor of mineralogy and petrography, Heidelberg University. Polymorphs: sweetite, ashoverite. ORTH $P2_12_12_1$. $a = 8.490$, $b = 5.162$, $c = 4.197$, $Z = 4$, $D = 2.50$. *AM* 73:196(1988). 38-385(syn): 4.41₁₀ 4.25₈ 3.28₁₀ 3.21₈ 2.73₈ 2.46₆ 2.28₈ 2.22₈. As fine grained incrustations; crystals minute, acicular. White to colorless, white streak, waxy luster. No cleavage, conchoidal fracture. $H = 3$. Soluble in dilute acids. Biaxial (-); $N_x = 1.572$, $N_y = 1.578$, $N_z = 1.580$ (Na); $2V = 60^\circ$; $r > v$, extreme. From *Richelsdorfer Hütte, Richelsdorf, Hessen, Germany*, as a weathering product of zinc-bearing slag, associated with simonkolleite, hydrocerussite, diaboelite, zincite, and hydrozincite. Also found at Milltown, Ashover, Derbyshire, England, associated with sweetite and ashoverite on fluorite. RG *NJMM*:145(1985).

6.2.11.1 Ashoverite $Zn(OH)_2$

Named in 1988 for the locality. Polymorphs: sweetite, wülfingite. TET Space group uncertain, probably $I4_1/amd$. $a = 6.83$, $c = 33.35$, $Z = 32$, $D = 3.44$. *MM* 52:699(1988). 41-1359: 3.33₁ 3.03₁ 2.90₁₀ 2.32₁ 1.82₃ 1.70₂ 1.47₁ 1.01₁. Crystals are square plates. Colorless to milky white, white streak, vitreous to dull luster. Cleavage {001}, perfect. $G = 3.3$. Fluoresces bluish white in SWUV. Uniaxial (+); $N_O = 1.629$, $N_E = 1.639$. From *Milltown, near Ashover, Derbyshire, England*, in a vein in a limestone quarry, on fluorite associated with sweetite, wülfingite, and γ - $Zn(OH)_2$. RG *MM* 52:699(1988), *AM* 75:431(1990).

6.2.12.1 Paraotwayite $Ni(OH)_2-x(SO_4, CO_3)_{0.5x}$

Named in 1987 for its close physical and chemical resemblance to otwayite. MON *Pm*. $a = 7.89$, $b = 2.96$, $c = 13.63$, $\beta = 91.1^\circ$, $Z = 6$, $D = 3.520$. *CM* 25:409(1987). 41-1424: 7.95₂ 6.81₁₀ 5.08₈ 3.86₅ 3.39₂ 2.95₄ 2.24₈ 1.97₃. Parallel to subparallel fibers; as cross-fiber veinlets. Emerald green, white streak, silky luster. No cleavage, brittle. $VHN_{20} = 223$ kg/mm². $G = 3.30$. Nonfluorescent. Insoluble in cold HCl or HNO₃. Biaxial; $N_x = 1.655$, $N_z = 1.705$; parallel extinction. Fibers are length-slow. From the *Otway nickel deposit, Nullagine, Pilbara region, WA, Australia*, in veinlets with dolomite and gaspeite, cutting nodules of nickeloan chrysotile with millerite and polydymite. RG *AM* 73:1496(1988).

6.2.13.1 Cianciullite $\text{MnMg}_2\text{Zn}_2(\text{OH})_{10} \cdot 2\text{-}4\text{H}_2\text{O}$

Named in 1991 for John Cianciulli, mineral collector of Sussex, NJ. *MON C2/m*. $a = 15.47$, $b = 6.369$, $c = 5.576$, $\beta = 101.28^\circ$, $Z = 2$, $D = 2.87$. *44-1407*: 7.61₁₀ 5.47₂ 4.17₂ 3.96₅ 3.45₃ 3.00₄ 2.75₆ 2.67₃. Crystals tabular {100}. Dark reddish brown; adamantine to vitreous luster, dull to pearly on {100}. Cleavage {100}, perfect; flexible. $H \approx 2$. Nonfluorescent. In polished section gray; anisotropism weak; bireflectance weak; nonpleochroic; internal reflection orange-red. $R = 8.5$ (470 nm); 8.1 (546 nm), 8.0 (589 nm), 8.0 (650 nm). From the *Franklin mine, Franklin, Sussex Co., NJ*, with willemite and cahnite. *RG AM 76:1789(1991)*.

6.3.1.1 Gibbsite $\gamma\text{-Al}(\text{OH})_3$

Named in 1822 for George Gibbs (1777–1834), original owner of the Gibbs mineral collection acquired by Yale College early in the nineteenth century. Polymorphs: bayerite, doyleite, nordstrandite. *MON P2₁/c*. $a = 8.684$, $b = 5.078$, $c = 9.736$, $\beta = 94.53^\circ$, $Z = 8$, $D = 2.421$. *ZK 139:129(1974)*. *33-18(syn)*: 4.85₁₀ 4.37₇ 4.32₅ 3.31₃ 2.45₄ 2.39₆ 2.05₄ 1.80₃. Habit: Crystals tabular {001}, with a hexagonal aspect. As lamellar-radiate spheroidal concretions. Massive; stalactitic; compact/earthy. Twinning about [130] as twin axis very common; on {001}, common; on {100} and {110}, rare. Usually, the {001} twin law occurs in combination with other laws. **Structure:** The fundamental unit of structure is a layer of Al ions sandwiched between two sheets of close-packed hydroxyl ions. Two out of three of the octahedrally coordinated sites between the oxygen layers are occupied by cations. The layers may be regarded as built of octahedra linked laterally by sharing edges; the network so described may be described as an orthogonal (pseudo-hexagonal) cell. The oxygen layers are in the sequence ABBAABB; thus in the ideal structure of gibbsite, oxygens at the bottom of one layer lie directly above oxygens at the top of the layer below. The structure of gibbsite is in fact somewhat distorted from the ideal; the Al–O octahedra are not regular but have their shared edges longer than the remainder, and the successive layers of octahedra are slightly displaced in the a direction, resulting in a monoclinic cell. *DHZ 5:93, ZK Supp. 4:316(1991)*. **Physical properties:** White, grayish, greenish, reddish white; reddish or yellow when impure; vitreous to pearly luster. Cleavage {001}, perfect; tough. $H = 2\frac{1}{2}$ – $3\frac{1}{2}$. $G = 2.40$. Nonfluorescent. **Tests:** Infusible; in CT yields water. Slowly soluble in concentrated H_2SO_4 ; readily soluble in hot alkali solutions; gives an argillaceous odor when breathed on. **Optics:** Biaxial (+); $X = b$, $Y \wedge c = 69^\circ$, $Z \wedge c = -21^\circ$; $N_x = 1.568$, $N_y = 1.568$, $N_z = 1.587$; $2V = 0^\circ$; variable dispersion, positive or negative elongation. Inclined extinction when fibrous. **Occurrence:** Most gibbsite is a secondary product resulting from the weathering, leaching, and alteration of aluminous minerals. It is an important constituent of many bauxites and may be the chief aluminum mineral present. *Bauxite* is defined as an aluminous lateritic rock in which aluminum hydroxides, amorphous or crystalline, predominate over other lateritic constituents. Gibbsite is also formed as a low-temperature

GIBBSITE: $\text{Al}(\text{OH})_3$

Al atoms occupy two-thirds of the octahedra interstices between two closest-packed hydroxide layers. Sandwiches are held together with hydrogen bonds. Note that some hydrogen bonds are within layers, according to this structure determination. Compare BRUCITE.

hydrothermal mineral in veins or cavities in alkaline or other igneous rocks. **Localities:** From *Richmond, Berkshire Co., MA*, as radial-fibrous crusts in a limonite deposit. Also crystallized near Slatoust in the Schischimsk Mts., Ural Mts., Russia(!), and at Salka, southern Ural Mts.(!); Eikaholm and Lille-Arø, Langesundfjord, Norway(!); Serro, MG, Brazil(*). Important bauxite deposits consisting largely of gibbsite are in AR; Vogelsberg, Hesse, Germany; France; Hungary; in Madras and Maharashtra, India; Ghana; Ouro Preto, MG, Brazil; Suriname; Guyana; Jamaica; Australia; and several other countries throughout the world. **Use:** The principal ore mineral of aluminum. RG *DI:663, AM 55:43(1970), AC(B) 32:1719(1976)*.

6.3.2.1 Bayerite $\alpha\text{-Al}(\text{OH})_3$

Named in 1928 for Karl J. Bayer, German metallurgist. Polymorphs: gibbsite, nordstrandite, doyleite. MON $P2_1/c$. $a = 5.062$, $b = 8.671$, $c = 4.713$, $\beta = 90.45^\circ$, $Z = 4$, $D = 3.06$. Structure: ZK *125:317(1967)*. *20-11(syn)*: 4.71₉, 4.35₇, 3.20₃, 2.22₁₀, 1.72₄, 1.60₁, 1.55₁, 1.46₁. Finely fibrous. Colorless, silky luster. $G = 3.05$. From the *Hatrumim formation, Israel*, with calcite, portlandite, and ettringite. RG *MM 33:723(1963), AM 55:43(1970)*.

6.3.3.1 Nordstrandite $\beta\text{-Al}(\text{OH})_3$

Named in 1958 for R. A. van Nordstrand (b.1917), Sinclair Research Laboratories, who first synthesized the compound. Polymorphs: gibbsite, doyleite, bayerite TRIC $P\bar{1}$. $a = 6.148$, $b = 6.936$, $c = 5.074$, $\alpha = 95.77^\circ$, $\beta = 99.07^\circ$,

$\gamma = 83.30^\circ$, $Z = 4$, $D = 2.454$. *CM 20:77(1982)*. $24\text{-}6(\text{syn})$: 4.79_{10} 4.32_3 4.21_2 2.39_3 2.27_3 2.02_3 1.90_2 1.78_1 . Crystals thick tabular with a rhombic outline. Colorless to coral pink, beige, pale green; vitreous luster, slightly pearly on cleavage. Cleavage $\{110\}$, perfect. $G = 2.43$. Biaxial (+); $Z \wedge c = 32^\circ$; $N_x = 1.580$, $N_y = 1.583$, $N_z = 1.602$; $2V = 24^\circ$; $r < v$, moderate; negative elongation. There are four known types of occurrences for nordstrandite: (1) as a weathering product of bauxitic soils derived from limestones, (2) as a vein- or fissure-filling mineral in dolomitic oil shale, (3) as an alteration product of certain aluminum carbonate minerals, and (4) as a late mineral in pegmatitic pockets in nepheline syenites. Found in oil shale in the Green River formation, northwestern CO. Mt. St.-Hilaire, QUE, Canada, in nepheline syenite pegmatite, and similarly at Narssarssuk, Greenland. As an alteration product of dawsonite and alumohydrocalcite, Berry formation, Sydney Basin, NSW, Australia; *Gunony Kapor, near Bau, Sarawak, Malaysia*, in soil from the edge of a sinkhole in a limestone cliff; *Mt. Alifan-Mt. Lamlan ridge, Guam*, in secondary solution cavities in limestone, near the contact with deeply weathered basalt flows. *RG NJMA 109:185(1968)*; *AM 55:43(1970)*, *60:285(1975)*.

6.3.4.1 Doyleite $\text{Al}(\text{OH})_3$

Named in 1985 for E. J. Doyle (b.1905), Ottawa, Ontario, who collected the first specimens. Polymorphs: gibbsite, bayerite, nordstrandite. $\text{TRIC } P1$ or $P\bar{1}$. $a = 5.002$, $b = 5.175$, $c = 4.980$, $\alpha = 97.5^\circ$, $\beta = 118.6^\circ$, $\gamma = 104.73^\circ$, $Z = 2$, $D = 2.482$. *38-376*: 4.79_{10} 4.30_2 4.18_2 4.09_2 2.36_4 1.97_3 1.86_3 1.84_3 . Rosettes of platy crystals; also finely granular, botryoidal, or smooth porcelainlike crusts. Colorless, also white to bluish white; white streak; vitreous luster, also dull. Cleavage $\{010\}$, perfect; $\{100\}$, poor; crystal plates slightly flexible but not elastic. $H = 2\frac{1}{2}$ -3. $G = 2.48$. Nonfluorescent. Insoluble in cold mineral acids. Biaxial (+); $N_x = 1.545$, $N_y = 1.553$, $N_z = 1.566$ (Na); $2V = 77^\circ$; $r > v$, strong. From *Mt. St.-Hilaire, QUE, Canada*, in vugs in nepheline syenite pegmatite, associated with albite, pyrite, and calcite. Also from the Francon quarry, Montreal, QUE, in vugs in silicocarbonate sills cutting Ordovician limestones, with weloganite, calcite, and quartz. *RG CM 23:21(1985)*.

6.3.5.1 Dzhaldindite $\text{In}(\text{OH})_3$

Named in 1963 for the locality. $\text{iso } Im\bar{3}$. $a = 7.95$, $Z = 8$, $D = 4.34$. *16-161(syn)*: 4.42_4 3.99_{10} 2.82_9 1.78_9 1.63_8 1.40_3 1.20_3 1.07_3 . Yellow-brown grains. Sn, Fe, and Zn may substitute to a limited extent in the formula. In polished section, dark gray. Isotropic; $N = 1.725$. $R = 8.2$ (589 nm). From the Mt. Pleasant sulfide-cassiterite body, SW of Frederickton, NB, Canada, in fractures in sphalerite, with calcite, galena, and quartz. *Dzhaldindin ore deposit, Little Khingan ridge, far eastern Siberia, Russia*, as an oxidation product of indite, in cracks in cassiterite. *RG ZVMO 92:445(1963)*, *AM 49:439(1964)*, *CM 10:781(1971)*.

6.3.5.2 Söhngeite $\text{Ga}(\text{OH})_3$

Named in 1965 for Adolf Paul Gerhard Sohnge (b.1913), South African geologist; chief geologist, Tsumeb Corp., Namibia. iso $Im\bar{3}$. $a = 7.47$, $Z = 8$, $D = 3.847$. *AM* 51:1815(1966). 18-532: 3.74₁₀ 2.63₆ 2.36₃ 2.15₄ 1.87₄ 1.67₇ 1.53₆ 1.24₃. Crystalline aggregates. Light brown. $H = 4-4\frac{1}{2}$. $G = 3.84$. Isotropic; $N = 1.736$. From *Tsumeb, Namibia*, on corroded germanite containing gallite. RG NW 52:493(1965).

6.3.5.3 Bernalite $\text{Fe}(\text{OH})_3 \cdot n\text{H}_2\text{O}$

Named in 1993 for John Desmond Bernal (1901–1971), British crystallographer and historian of science. Hydrated iron hydroxide, with n ranging from 0.0 to <0.25 . ORTH $Immm$. $a = 7.544$, $b = 7.560$, $c = 7.558$ (pseudocubic), $Z = 8$, $D = 3.23$. *AM* 78:827(1993). The structure is not related to that of other iron hydroxides or gibbsite but belongs to the stottite or schoenfliesite groups, consisting of a three-dimensional network of corner-connected $\text{Fe}(\text{OH})_6$ octahedra. 3.78₁₀ 2.68₂ 2.39₂ 2.19₁ 2.02₁ 1.892₁ 1.692₂ 1.545₁. Crystals are pseudo-octahedra, up to 3 mm. Yellow-green to dark bottle green, apple green streak, vitreous to adamantine luster. No cleavage; conchoidal to uneven fracture; brittle. $H = 4$. $G = 3.32$. Biaxial; $N = 1.92-1.94$; other optical properties could not be determined due to micropolysynthetic twinning. Bernalite was found on museum specimens collected long ago from the upper levels of the open pit at the *Proprietary mine, Broken Hill, NSW, Australia*, associated with coronadite and goethite. RG NW 79:509(1992).

WICKMANITE GROUP

The wickmanite minerals are basically tin hexahydroxides, with some substitution, leading to group of minerals of the general formula

where

$A = \text{Mn}, \text{Mg}, \text{Fe}^{2+}, \text{Zn}, \text{Ca}, \text{Na}$

$B =$ usually Sn , but also Ge and Sb^{5+}

and a structure that may be cubic, trigonal, or tetragonal.

In the structure, A and B atoms form a NaCl-like structure, with the (OH) groups octahedrally coordinating the cations, giving an infinite, corner-sharing three-dimensional framework of coordinating octahedra. This normally gives an isometric structure; however, in five members of this group the polyhedra connected along the c axis are alternately rotated slightly along opposite senses of rotation, which lowers the symmetry to tetragonal. The hexagonal–rhombohedral structure of burtite is closely related, but it has not been studied in detail. *AM* 73:657(1988).

WICKMANITE: $\text{MnSn}(\text{OH})_6$

Unlike most other oxides and hydroxides, Mn and Sn octahedra in wickmanite share only corners, not edges. Mn and Sn apparently alternate strictly.

WICKMANITE GROUP

Mineral	Formula	Space Group	a	c	D	
Wickmanite	$\text{MnSn}(\text{OH})_6$	$Pn\bar{3}m$	7.873		3.82	6.3.6.1
Schoenfliesite	$\text{MgSn}(\text{OH})_6$	$Pn\bar{3}$	7.759		3.483	6.3.6.2
Natanite	$\text{FeSn}(\text{OH})_6$	$Pn\bar{3}m$	7.69		4.035	6.3.6.3
Vismirnovite	$\text{ZnSn}(\text{OH})_6$	$Pn\bar{3}m$	7.72		4.073	6.3.6.4
Burtite	$\text{CaSn}(\text{OH})_6$	$R\bar{3}$	11.49	14.08	3.22	6.3.6.5
Mushistonite	$(\text{Cu, Zn, Fe})\text{Sn}(\text{OH})_6$	$Pn\bar{3}m$	7.735		4.08	6.3.6.6
Stottite	$\text{FeGe}(\text{OH})_6$	$P4_2/n$	7.594	7.488	3.545	6.3.7.1
Tetrawickmanite	$\text{MnSn}(\text{OH})_6$	$P4_2/n$	7.787	7.797	3.79	6.3.7.2

Mopungite	$\text{NaSb}(\text{OH})_6$	$P4_2/n$	7.994	7.859	3.264	6.3.7.4

6.3.6.1 Wickmanite $\text{MnSn}(\text{OH})_6$

Named in 1967 for Franz-Erik Wickman (b.1915), Swedish mineralogist, who has studied the mineralogy of Langban extensively. Wickmanite group. Polymorph: tetrawickmanite. iso $Pn\bar{3}m$. $a = 7.873$, $Z = 4$, $D = 3.82$. *AM* 53:1063(1968). Structure: *AC* 13:601(1960). 20-727: 4.55_4 3.93_{10} 2.78_6 2.37_3 1.97_4 1.76_7 1.61_5 1.05_4 . Crystallizes as octahedra. Brownish yellow, greenish yellow, orange. No cleavage. $H = 3-4$. $G = 3.89$. Slowly soluble in common acids. Isotropic; $N = 1.705$. From Whealcock Zawn, Botallack, Cornwall, England, with axinite and grossular. *Langban, Varmland, Sweden. Tvedalen,*

Norway, in a nepheline syenite dyke. Pitkäranta mining district, Lake Ladoga, Karelia, Russia, from the dump of the Toivo shaft, in an altered garnet skarn. Tsumeb mine, Namibia (germanian wickmanite). Llallagua, Bolivia, in cavities in stannite. RG *AMG* 4:395(1967), *MM* 53:388(1989).

6.3.6.2 Schoenfliesite $MgSn(OH)_6$

Named in 1971 for Arthur Moritz Schoenflies (1853–1928), professor of mathematics, University of Frankfurt. Wickmanite group. iso $Pn\bar{3}$. $a = 7.759$, $Z = 4$, $D = 3.483$. *AM* 57:1557(1972). 9-27: 4.48₄ 3.87₁₀ 2.74₄ 2.33₂ 1.94₂ 1.78₂ 1.58₂ 1.49₂. Small grains; prismatic crystals and fibers; minute cubo-octahedral crystals. Colorless. No cleavage. $H = 4$. $G > 3.32$. Soluble in HCl; slowly soluble in NH_4OH . Forms a solid-solution series with wickmanite, $MnSn(OH)_6$. Isotropic; $N = 1.667$. From *Brooks Mountain, Seward Peninsula, AK*, associated with hulsite, goethite, magnetite, fluorite, and hematite. Pitkäranta mining district, Lake Ladoga, Karelia, Russia, in chlorite-serpentine rock, with chondrodite, diopside, fluorite, calcite, dolomite, and magnetite. RG *ZK* 134:116(1971), *CM* 15:437(1977).

6.3.6.3 Natanite $FeSn(OH)_6$

Named in 1981 for Natan Il'ich Ginzburg (1917–1985), Russian mineralogist and geochemist, expert on pegmatites and the mineralogy of Be, Nb, and Ta. Wickmanite group. iso $Pn\bar{3}m$. $a = 7.69$, $Z = 4$, $D = 4.035$. *AM* 67:1077(1982). 33-687: 3.73₉ 2.71₇ 2.22₅ 1.92₃ 1.71₁₀ 1.56₇ 1.28₃ 1.03₄. 31-653(syn): 4.53₂ 3.92₁₀ 2.77₅ 2.26₁ 1.96₂ 1.75₄ 1.60₃ 1.30₁. Greenish brown, vitreous luster. No cleavage. $H = 4\frac{1}{2}$. Soluble in dilute HCl, insoluble in concentrated Na_2CO_3 . Isotropic; $N = 1.755$. From the *Trudov* and *Mushiston deposits, Tadzhikistan*. RG *ZVMO* 110:492(1981).

6.3.6.4 Vismirnovite $ZnSn(OH)_6$

Named in 1981 for Vladimir Ivanovich Smirnov (1910–1988), Russian economic geologist, Moscow State University. Wickmanite group. iso $Pn\bar{3}m$. $a = 7.72$, $Z = 4$, $D = 4.073$. *AM* 67:1077(1982). 33-1376: 3.84₁₀ 2.22₇ 1.73₉ 1.57₈ 1.29₄ 1.16₄ 1.12₅ 1.03₆. Pale yellow, vitreous luster. No cleavage. $H = 3.9$. Soluble in dilute HCl, insoluble in concentrated Na_2CO_3 . Isotropic; $N = 1.735$. From the *Trudov* and *Mushiston deposits, Tadzhikistan*, as an oxidation product of stannite, with varlamoffite, goethite, malachite, azurite, and so on. RG *ZVMO* 110:492(1981).

6.3.6.5 Burtite $CaSn(OH)_6$

Named in 1981 for Donald M. Burt (b.1943), mineralogist and economic geologist; professor, Arizona State University. Wickmanite group. $HEX\bar{R}$ (pseudo-iso) Space group uncertain, probably $R\bar{3}$. $a = 11.49$, $c = 14.08$, $Z = 12$, $D = 3.22$. (Pseudo-iso cell: $Pn\bar{3}$; $a = 8.128$, $Z = 4$.) 9-30(syn): 4.69₅ 4.06₁₀ 2.87₄ 2.57₁ 2.45₁ 2.34₂ 1.81₂ 1.66₂. Crystals are pseudo-octahedrons, superficially altered to varlamoffite. Colorless, vitreous luster. Cleavage

{0001}, good cubic cleavage; very brittle. $H = 3$. $G = 3.28$. Nonfluorescent. Slowly soluble in cold dilute HCl. Uniaxial (+); $N_O = 1.633$, $N_E = 1.633$ (Na). Birefringence < 0.0003 . Nearly isotropic. Optical data demonstrate that the true symmetry is $HEX-R$, pseudo cubic. From a garnetite tin skarn located in the cliffs of the W bank of the *Behit R.* ($33^{\circ}31'26''$ lat., $5^{\circ}49'50''$ W. long.), ≈ 40 km SW of *Meknes, central Morocco*, associated with wickmanite, stoke-site, datolite, and varlamoffite. RG *CM 19:397(1981)*, *AM 67:854(1982)*.

6.3.6.6 Mushistonite (Cu, Zn, Fe)Sn(OH)₆

Named in 1984 for the locality. Wickmanite group. iso $Pn3m$. $a = 7.735$ (Zn > Fe), $a = 7.705$ (Fe > Zn), $Z = 4$, $D = 4.08$. *AM 70:1331(1985)*. *ZVMO* (Zn > Fe): 3.88₁₀ 2.74₅ 2.45₁ 2.33₁ 2.23₂ 1.93₂ 1.73₃ 1.58₂; (Fe > Zn): 3.84₁₀ 2.73₅ 1.72₂. $CuSn(OH)_6$: 20-369(syn): 4.48₅ 4.05₆ 3.79₁₀ 2.77₆ 2.24₆ 1.714₆ 1.694₆ 1.562₆. Fine grained, earthy aggregates. Brownish green. $H = 4-4\frac{1}{2}$. Soluble in dilute HCl. From the *Mushiston tin deposit, Tadzhikistan*, in the oxidation zone, replacing stannite, associated with varlamoffite. RG *ZVMO 113:612(1984)*, *MR 17:383(1986)*.

6.3.7.1 Stottite FeGe(OH)₆

Named in 1958 for Charles E. Stott (1896–1978), U.S. geologist and general director, Tsumeb mine, Namibia. Wickmanite group. TET $P4_2/n$. $a = 7.594$, $c = 7.488$, $Z = 4$, $D = 3.545$. *AM 73:657(1988)*. Structure: *AC 14:205. 11-161*: 3.77₁₀ 2.66₈ 2.17₆ 1.89₆ 1.69₇ 1.67₆ 1.54₆ 1.25₆. Crystals tetragonal bipyramidal, up to 10 mm in size, pseudo-octahedral with {111} dominant. Brown, gray-white streak, greasy luster. Cleavage {100}, {010}, good; {001}, fair. $G = 3.60$. Zinc may replace Fe^{2+} , up to nearly as much mol % Zn as Fe^{2+} . Uniaxial (-); $N_O = 1.7375$, $N_E = 1.728$; $r > v$, weak. Usually anomalously biaxial. From *Tsumeb, Namibia*, in the deep oxidized orebody, formed by the action of circulating waters on renierite and germanite. RG *NJMM 1958:85*, *AM 43:1006(1958)*.

6.3.7.2 Tetrawickmanite MnSn(OH)₆

Named in 1973 for its relationship to wickmanite but with tetragonal symmetry. Wickmanite group. Polymorph: wickmanite. TET $P4_2/n$. $a = 7.787$, $c = 7.797$, $Z = 4$, $D = 3.79$. *MR 4:24(1973)*. 25-553: 4.52₃ 3.94₁₀ 3.88₃ 2.77₉ 2.26₃ 1.76₅ 1.75₃ 1.61₄. Crystals pyramidal {112} with {001} and minor {100}; also pseudocubic (Langban); twinning not observed. Honey yellow, brownish orange. No cleavage. $G = 3.65$. Uniaxial (-); $N_O = 1.724$, $N_E = 1.720$. From the *Foote mine, Kings Mountain, Cleveland Co., NC*, associated with albite, bavenite, siderite, and eakerite. Also from Langban, Varmland, Sweden. RG *AM 58:966(1973)*.

6.3.7.3 Jeanbandyite (Fe, Mn)Sn(OH)₆

Named in 1982 for Jean Arney Bandy (1900–1991), widow of Mark C. Bandy, who collected the original jeanbandyite specimens at Llallagua and whose

superb mineral collection she donated to the Los Angeles County Museum of Natural History. Wickmanite group. TET $P4_2/n$. $a = 7.648$, $c = 7.648$. 35-663: 4.41₂ 3.83₁₀ 2.71₇ 2.21₂ 1.91₂ 1.71₆ 1.56₄ 1.28₂. As crudely pseudo-octahedral crystal aggregates in epitaxial growth upon the vertices of octahedral crystals of wickmanite. Forms observed {111}, {100}, and {001}. Brownish orange, buff streak, vitreous to subadamantine luster. Cleavage {001}, {100}, fair. $H = 3\frac{1}{2}$. $G = 3.81$. Slowly soluble in cold 1:1 HCl. Uniaxial (-); $N_O = 1.837$, $N_E = 1.833$. From *Llallagua, Potosi, Bolivia*, in the Contacto vein and elsewhere in the mine, in vugs in association with fluorapatite, stannite, and other minerals. Santa Eulalia, CHIH, Mexico, also as an epitaxial overgrowth on wickmanite. RG *MR 13:235(1982)*, *AM 68:471(1983)*.

6.3.7.4 Mopungite $\text{NaSb}^{5+}(\text{OH})_6$

Named in 1985 for the locality. Wickmanite group. TET $P4_2/n$. $a = 7.994$, $c = 7.859$, $Z = 4$, $D = 3.264$. *MR 16:73(1985)*. 38-411: 4.58₁₀ 3.99₈ 3.93₄ 1.629₅ 1.325₅ 1.265₅ 1.205₇ 1.192₅. Crystals pseudocubic; as crusts. Colorless, white; vitreous luster. No cleavage. $H = 3$. $G = 3.21$. Nonfluorescent. Soluble in hot but not in cold water. Decomposed by HCl and HNO_3 ; soluble in cold dilute tartaric acid. Uniaxial (-); $N_O = 1.614$, $N_E = 1.605$. From *Mopung Hills, Churchill Co., NV*, associated with stibiconite, senarmontite, romeite, and tripuhyite, all pseudomorphous after stibnite, and with selenium and sulfur. RG *AM 70:1330(1985)*.

6.3.8.1 Jamborite $(\text{Ni}^{2+}, \text{Ni}^{3+}, \text{Fe})(\text{OH})_2(\text{OH}, \text{S}, \text{H}_2\text{O})$

Named in 1973 for John L. Jambor (b.1936), mineralogist, Geological Survey of Canada. HEX Space group unknown. $a = 3.07$, $c = 23.3$, $Z = 3$, $D = 2.69$. 25-1363: 7.78₁₀ 3.89₄ 2.59₆ 2.32₁ 1.98₁ 1.53₅ 1.50₃ 1.32₁. 27-340(syn): 11.0₁₀ 7.68₁₀ 3.79₆ 2.59₆ 2.31₆ 1.95₆ 1.54₆ 1.51₆. Microscopic, fibrous, or lamellar crystals. Green. $G = 2.67$. Uniaxial (-); $N_O = 1.607$, $N_E = 1.602$ (Na). From Hall's Gap, KY, as alteration of millerite. From *Italy at Montescuto Ragazza near Bologna and at Casteluccio di Moscheda near Modena*, in cavities in ophiolitic rock, with calcite, dolomite, and quartz, pseudomorphous after millerite. RG *AM 58:835(1973)*, *MM 44:339(1981)*.

6.3.9.1 Bottinoite $\text{Ni}[\text{Sb}^{5+}(\text{OH})_6]_2 \cdot 6\text{H}_2\text{O}$

Named in 1992 for the locality. HEX-R $P31m$, $P312$, or $P31m$. $a = 16.026$, $c = 9.795$, $Z = 6$, $D = 2.81$. *AM 77:1301(1992)*. 4.88₅ 4.62₁₀ 2.34₈ 2.16₅ 2.09₆ 1.806₇ 1.751₆ 1.648₅. Roselike aggregates of small tabular crystals. Light blue-green, very light blue streak, vitreous luster. Conchoidal fracture; brittle. $H = 3$. $G = 2.83$. Nonfluorescent. Uniaxial (+); $N_O = 1.600$, $N_E = 1.605$. Occurs on fractures in schist with calcite, siderite, quartz, and sulfides, perched on ullmanite crystals, at the *Bottino mine, Alpe Apuani, Italy*. RG

6.4.1.1 Lithiophorite $A_{14}Li_6(OH)_{42}Mn_3^{2+}Mn_{18}^{4+}O_{42}$

Named in 1870 from *lithium* and the Greek for *to bear*, in allusion to the presence of lithium in its composition. HEX $P3_1$. $a = 13.37$, $c = 28.20$, $Z = 3$, $D = 3.376$. $41-1378$: 9.43_7 4.71_{10} 3.14_1 2.37_2 1.880_1 1.453_1 1.447_1 1.436_1 . Structure: *AM 67:817(1982)*. As fine scales; also compact; botryoidal. Black, blue-black; blackish-gray streak; metallic to dull luster. $H = 2-3$. $G = 3.14-3.36$. In RL, white, with very strong pleochroism and anisotropism, no internal reflections. $R = 20.2-9.7$ (546 nm). Although lithium is part of the name of the mineral, Li_2O is highly variable in content, ranging from 0.1 to 3.3%; it is possibly not an essential component. Any of the elements Co, Ni, Cu, Zn, and/or Pb are also usually present in significant amounts up to a maximum of about 5%, but no one of these is essential. Lithiophorite is widespread in soils and in the weathering zones of a variety of ore deposits. It is probably one of the major components of the poorly defined manganese oxide *wad* (*DI:566*), in association with asbolan, vernadite, birnessite, cryptomelane, and so on. In contrast to some of these minerals, lithiophorite is readily identifiable with a crystalline structure that produces excellent X-ray diffraction patterns. From Charlottesville and elsewhere in VA, coating fractures in quartz veins. Lecht mines, Tomintoul, Banffshire, Scotland, with cryptomelane. *Schneeberg, Sachsen, Germany*. In Australia at Groote Eyelandt, Kalgoorlie, and Pilbara, WA, and at Rockhampton and Gympie areas, Q. Itatiaia mine, Conselheira Pena, MG, Brazil, in brilliant botryoidal masses in pegmatite(!). Used as an ore of manganese. RG *DI:569*, *AM 52:1545(1967)*, *MM 37:618(1970)*, *AUM 2:25(1987)*.

6.4.1.2 Quenselite $PbMn^{3+}O_2(OH)$

Named in 1926 for Percy Dudgeon Quensel (1881-1966), Swedish mineralogist and petrologist, University of Stockholm. MON $P2/c$. $a = 5.61$, $b = 5.70$, $c = 9.15$, $\beta = 93.0^\circ$, $Z = 4$, $D = 7.07$. *GSAM 85:200(1962)*. $23-351$: 3.68_7 3.60_7 3.04_{10} 2.95_6 2.72_8 2.44_4 2.08_4 1.99_4 . Crystals tabular {010}, striated on {011} parallel to [100]. Structure: *ZK 134:321*. Pitch black, dark brown to gray streak, metallic to adamantine luster. Cleavage {001}, perfect; micaeous; thin laminae flexible. $H = 2\frac{1}{2}$, $G = 6.84$. Soluble in dilute HCl, with evolution of Cl. Biaxial (+); $X = b$, $Y \approx c$; $N \approx 2.30$; pleochroism deep brown; absorption $Z > X$. From *Langban, Varmland, Sweden*, in the Amerika stope, with calcite and barite in crevices cutting hausmannite-hematite-braunite ore. RG *DI:729*.

6.4.2.1 Hydroromarchite $Sn_3O_2(OH)_2$

Named in 1971 for being a hydrate and for its relationship to romarchite. TET $P4/mnc$ or $P4nc$. $a = 7.98$, $c = 9.17$, $Z = 4$, $D = 4.80$. *AM 58:552(1973)*. $25-1303$: 3.50_{10} 3.26_5 2.96_8 2.77_9 2.48_4 1.92_5 1.90_5 1.77_4 . Crusts of white crystals. Found as a corrosion product on tin cooking utensils found in the remains of a sunken canoe lost 150 years earlier near *Boundary Falls, Winnipeg River, ONT, Canada*. RG *CM 10:916(1971)*.

6.4.3.1 Häggite $V_2O_2(OH)_3$

Named in 1958 for Gunnar Hägg (1903–1986), Swedish chemist, University of Uppsala. *MON C2/m*. $a = 12.17$, $b = 2.99$, $c = 4.83$, $\beta = 98.25^\circ$, $Z = 2$, $D = 3.53$. *AM 45:1144(1960)*. *29-1380*: 4.80_{10} 4.05_5 3.51_1 3.02_3 2.44_3 1.96_2 1.82_1 1.49_1 . Crystals acicular. Black. From *Carlisle, Crook Co., WY*. Also from Kara Tau Range, Kazakhstan. *RG AM 65:210(1980)*, *ZK 116:482(1961)*.

6.4.4.1 Hydrocalumite $Ca_2Al(OH)_6[Cl_{1-x}(OH)_x] \cdot 3H_2O$

Named in 1934 in allusion to the composition. Formula also written $Ca_4Al_2(OH)_{12}(Cl, CO_3, OH, H_2O)_{25} \cdot 4H_2O$. *NJMM 1980:322*. *MON P2/c*. $a = 10.020$, $b = 11.501$, $c = 16.286$, $\beta = 104.22^\circ$, $Z = 2$, $D = 2.15$. *42-553*: 7.9_{10} 3.95_9 3.86_3 3.75_2 2.88_5 2.53_2 2.37_3 2.29_3 . Massive. Colorless, light green; vitreous luster, pearly on cleavage. Cleavage {001}, perfect. $H = 3$. $G = 2.15$. Strongly pyroelectric. Biaxial (-); $X \wedge c = < 3^\circ$; $Y = b$; $N_x = 1.535$, $N_y = 1.553$, $N_z = 1.557$; $2V = 24^\circ$. From *Scawt Hill, County Antrim, Northern Ireland*, in vugs in a larnite rock, with afwillite, portlandite, and ettringite. Boissejour, Puy de Dome, France, with ettringite. Montalto di Castro, Viterbo, Italy. *RG DI:667*, *BM 86:149(1963)*, *AM 74:1403(1989)*.

6.4.5.1 Iowaite $Mg_4Fe^{3+}(OH)_{10}Cl \cdot 3H_2O$

Named in 1967 for the locality. *HEX* Space group unknown. $a = 3.119$, $c = 24.52$, $Z = 0.6$, $D = 2.11$. Structure: *AM 54:296(1969)*. *20-500*: 8.11_{10} 4.05_4 2.64_2 2.36_3 2.02_2 1.56_1 1.53_1 1.45_1 . Crystals platy {0001}. Bluish green to pale green; alters in air to whitish green with a rusty red overtone, due to loss of zeolitic water; white streak; greasy luster. Cleavage {0001}, perfect. $H = 1\frac{1}{2}$. $G = 2.11$. Insoluble in water; readily soluble in mineral acids. The amount of zeolitic water is somewhat variable, depending on atmospheric humidity and other factors; it is all driven off at a temperature of 280° . Uniaxial (-); $N_O = 1.543$, $N_E = 1.533$; crystals length-fast. From *Sioux Co., IA*, in veinlets in serpentinite, encountered in drill core at a depth of 300–450 m, associated with chrysotile, dolomite, brucite, calcite, magnesite, and pyrite. Also from the Komsomolskiy mine, Talnakh, Siberia, Russia(!), in crystals to 2.5 cm, with valeriite, szaibelyite, magnetite, brucite, and serpentine in metamorphosed dolomites associated with porphyry copper deposits. Phalaborwa, Transvaal, South Africa(!), in sharp crystals to 1 cm. *RG AM 52:1261(1967)*, *MA 77:851*.

6.4.6.1 Meixnerite $Mg_6Al_2(OH)_{16} \cdot 4H_2O$

Named in 1975 for Heinrich Herman Meixner (1908–1981), Austrian mineralogist, University of Salzburg. *HEX-R R3m*. $a = 3.046$, $c = 22.93$, $Z = 3/8$, $D = 1.953$. *38-478*: 7.64_6 3.82_7 2.57_6 2.29_7 1.941_{10} 1.523_8 1.494_6 1.268_5 . Crystals tabular. Structurally related to hydrotalcite. Colorless. Cleavage {0001}, perfect. $H = 2$. $G \approx 1.9$. Uniaxial; $N = 1.517$; bireflectance: 0.016. From *Ybbs Persenberg, Austria*, as a secondary mineral with talc and later aragonite in

cracks of a pyrope-serpentine rock. RG *TMPM* 22:79(1975), *AM* 61:176(1976).

6.4.7.1 Janggunite $\text{Mn}_{1-x}^{4+}(\text{Mn}^{2+}, \text{Fe}^{3+})_{1+x}\text{O}_8(\text{OH})_6; X=0.2$

Named in 1977 for the locality. ORTH Space group unknown. $a = 9.324$, $b = 14.05$, $c = 7.956$, $Z = 4$, $D = 3.58$. *AM* 63:794(1978). 29-889: 9.34₁₀ 7.09₁₀ 4.62₈ 4.17₈ 3.55₁₀ 3.10₁₀ 2.47₈ 1.53₈. Radiating groups of flakes; colloform bands, and dendritic masses. Black, brownish-black to dark brown streak, dull luster. Cleavage in one direction; very fragile. $H = 2-3$. $G = 3.59$. In RL, grayish white to gray. No internal reflections; strongly anisotropic, yellowish brown to gray. $R = 13, 15$ (546 nm). From the *Janggun mine, Bonghwa, Korea*, with calcite, nsutite, and todorokite in the zone of supergene manganese oxides. RG *MM* 41:519(1977), *AM* 63:426(1978).

6.4.8.1 Kimrobinsonite $\text{Ta}(\text{OH})_3(\text{O}, \text{CO}_3)$

Named in 1985 for Kim Robinson (b.1951), Australian geologist of Perth, WA, who found the first specimen. ISO Space group unknown. $a = 3.812$, $Z = 1$, $D = 6.87$. *CM* 23:573(1985). 38-461: 3.81₁₀ 2.97₁ 2.70₇ 2.20₂ 1.91₃ 1.70₅ 1.56₄ 1.27₂. Cryptocrystalline, earthy. White; white streak; dull, chalky luster. Friable; soft. Isotropic; $N \gg 2$ (2.23_{calc}). From *Mt. Holland, WA, Australia*, in a deeply weathered pegmatite, intergrown with cesstibitantite, in an apparent pseudomorph after an unknown precursor Ta-Sb mineral, associated with montmorillonite, Li-muscovite, and tourmaline. RG *AM* 72:1025(1987).

6.4.9.1 Asbolane $(\text{Co}, \text{Ni})_{1-y}(\text{Mn}^{4+}\text{O}_2)_{2-x}(\text{OH})_{2-2y+2} \cdot n\text{H}_2\text{O}$

Named in 1847 from the Greek for *to soil like soot*. Synonym: cobaltian wad. HEX Space group unknown. $a = 2.823$, $c = 9.34$. 42-1319: 9.6₁₀ 4.83₁₀ 3.23₁ 2.45₄ 2.38₁ 1.810₁ 1.540₅ 1.420₅. Compact to earthy; massive; sometimes botryoidal. *Wad* is a general term covering soft, impure oxides of manganese. Asbolane is a cobaltian wad with a well-defined structure type; it may also contain significant amounts of Ni, Fe, Cu, V, Ca, and Ba. *AM* 67:417(1982). Black; bluish or brownish black with streak like the color, dull luster. Usually very soft; also hard, to 6 $\frac{1}{2}$. In RL, white to brownish; pleochroism and anisotropism very strong; no internal reflections. $R = 25.5-13.2$ (546 nm). *P&J*:78. From the Blackbird district, Lehmi Co., ID; Mine La Motte, MO (nickelian); Silver Bluff, SC; Schneeberg region, Sachsen, Germany; Markirch, Alsace, France; Capo Calamita, Elba, Italy; Lipov deposit, middle Ural Mts., Russia; and at Nizhni Tagilsk, Siberia; Shaba cobalt district, Zaire; abundant in New Caledonia with garnierite as residual deposits on weathered peridotite containing disseminated Co and Ni minerals. RG *DI*:566,568; *ZVMO* 116:210(1987); *CR* 307:155(1988).

6.4.10.1 Schwertmannite $\text{Fe}_{16}^{3+}\text{O}_{16}(\text{OH})_{12}(\text{SO}_4)_2$

Named in 1994 for Udo Schwertmann (b.1927), German soil scientist, Technical University, Munich. TET $P4/m$. $a = 10.66$, $c = 6.04$, $Z = 1$, $D = 3.77-$

3.99. *MM 58:641(1994)*. *PD* (all lines broad): 4.86₄ 3.39₅ 2.55₁₀ 2.28₂ 1.95₁ 1.66₂ 1.51₂ 1.46₂. Schwertmannite is a common compound but difficult to characterize and study, recognized so far in at least 40 localities worldwide. It is poorly crystalline, very fine grained, the individual crystallites measuring only a few nanometers in size. Its proposed structure is akin to that of akaganite [FeO(OH, Cl)], with sulfate instead of chloride as a stabilizing element in the tunnel cavities. The OH/SO₄ ratio appears to be nonstoichiometric, and the formula might be written Fe³⁺O(OH,SO₄), in which case it could be considered to be a polymorph of goethite, lepidocrocite, feroxyhite, and akaganite. It has a high specific surface area, in the range 100 to 200 m²/g. Most specimens consist of spherical to ellipsoidal particles (aggregates) that are 200 to 500 nm in diameter. Needlelike structures with average widths and thicknesses of 2 to 4 nm and lengths of 60 to 90 nm radiate from the particle surfaces and give the material a pin-cushion morphology. It is very soluble in cold 5 M HCl or in ammonium oxalate at pH 3.0. Upon heating, it converts to hematite with an intermediate phase of Fe₂(SO₄)₃. It was first recognized in the *Pyhasalmi sulfide mine, Oulu Prov., Finland*. The sample was collected as an ochreous, secondary precipitate forming a crust on stones inundated by acidic drainage from a mound of concentrate. It usually forms as a result of rapid oxidation of Fe²⁺ in acid, sulfate-rich effluents, produced from decomposition of primary sulfides, forming what had previously been described as "amorphous" ferric hydroxide. Associated minerals may be jarosite, natrojarosite, goethite, and ferrihydrite. Other recognized occurrences have been noted in Europe, North America, and Australia. Most are related to mining activity or other results of human activity, but one in the Zillertal Alps, Switzerland, at 2600 m elevation, is the purely natural result of the oxidation of a pyritic schist. *RG AM 80:847(1995)*.

Multiple Oxides

7.1.1.1 Delafossite $\text{Cu}^1\text{Fe}^3\text{O}_2$

Named in 1873 for Gabriel Delafosse (1796–1878), French mineralogist. *HEX-R R3m*. $a = 3.035$, $c = 17.166$, $Z = 3$, $D = 5.507$. Structure: *SR 37A:262(1971)*. *39-246*: 2.86₆ 2.51₁₀ 2.24₂ 1.662₂ 1.518₂ 1.437₁ 1.431₁ 1.341₁. Tabular to equant crystals, with {0001} and {1011}; as botryoidal crusts; contact twins on {0001}. Black, black streak, metallic luster. Cleavage {1011}, imperfect; brittle. $H = 5\frac{1}{2}$. $G = 5.41$. Weakly magnetic. Soluble in HCl and H_2SO_4 but insoluble in HNO_3 . Easily fusible. Becomes magnetic on heating. RL, brownish white. Distinctly pleochroic; O, light golden brown; E, darker rose brown; anisotropism strong with characteristic green hues. $R = 22.7\text{--}19.0$ (470 nm), 23.3–19.1 (546 nm), 23.0–19.0 (589 nm), 23.6–20.3 (650 nm). *P&J:145*. From Bisbee, AZ, as crystals and botryoidal crusts with hematite, cuprite, copper, and tenorite. Pope–Shenon copper mine, Salmon, ID. Copreasa mine, Sahuaripa, SON, Mexico. Cartagena mine, Pedroso, Sevilla, Spain. *Ekaterinburg, Ural Mts., Russia*. RG *DI:674*; *AM 31:539(1946)*, *53:1779(1968)*.

7.1.1.2 Mcconnellite CuCrO_2

Named in 1976 for R. B. McConnell (1903–1986), British geologist, former director, British Guiana Geological Survey. *HEX-R R3m*. $a = 2.983$, $c = 17.160$, $Z = 3$, $D = 5.61$. *39-247(syn)*: 2.85₆ 2.55₁ 2.47₁₀ 2.21₃ 1.646₂ 1.488₄ 1.426₂ 1.319₂. Tabular rhombohedral crystals. Dark red. $G = 5.49$. From the *Merume River, Mazaruni district, Guyana*, as alluvial pebbles consisting of mcconnellite intergrown with other chromium oxides: grimaldiite, eskolaite, bracewellite, and/or guyanaite. RG *USGSP 887:17(1976)*, *AM 62:593(1977)*, *JACS 77:896(1955)*.

7.1.2.1 Crednerite CuMnO_2

Named in 1849 for Karl F. H. Credner (1809–1876), German mining geologist and mineralogist. *MON C2/m*. $a = 5.530$, $b = 2.884$, $c = 5.898$, $\beta = 104.6^\circ$, $Z = 2$, $D = 5.49$. *MA 15:261*. *18-448*: 2.85₈ 2.71₁₀ 2.42₁₀ 2.24₆ 1.61₆ 1.56₈ 1.27₅ 1.09₅. Crystallizes as six-sided plates, in radiating, hemispherical, or spherulitic groupings; also earthy coatings. Twinning on {411}, giving a pseudo-hexagonal aspect. Metallic, bright luster. Cleavage {001}, {100},

perfect; {111}, good. H = 4. G = 5.38. Soluble in HCl with evolution of Cl; insoluble in HNO₃. RL creamy white; pleochroism yellowish to gray-brown; strongly anisotropic. Polysynthetic twinning sometimes visible. R = 33.3–25.5 (470 nm), 34.2–23.7 (546 nm), 33.4–23.2 (589 nm), 31.6–22.6 (650 nm). *P&J:134. Friedrichsroda, Thüringen, Germany*, intergrown with psilomelane and hausmannite, associated with malachite, barite, calcite, and wad. Higher Pitts, Mendip Hills, Somerset, England, with hydrocerussite and malachite, and at Merehead quarry, near Shepton Mallet(!), in crystal roses to 20 mm. Tachgalt and Idikel, Morocco. RG *DI:722, AM 51:1819(1966)*.

SPINEL GROUP

The spinel group comprises 22 minerals with the general formula

where

A = Mg, Mn, Fe, Zn, Co, Cu, or Ge

B = Al, Fe³⁺, Cr, or V

SPINEL: MgAl₂O₄

Space group *Fd3m*. This ball-and-stick model has the [111] direction vertical to show the approximately CCP oxygens (horizontal). Mg atoms are in tetrahedral interstices, and Al in octahedral interstices.

and an isometric structure in space group *Fd3m*.

There are 32 oxygen ions and 24 cations in the unit cell. Eight of the cations are in tetrahedral coordination in the A site. The remaining 16 cations are in octahedral coordination in the B site.

Perpendicular to the triad axis, layers of oxygen atoms alternate with layers of cations. The cation layers in which all the cations are in octahedral coordination alternate with other layers in which the cations are distributed among the A and B positions in the proportion A/B=2:1.

Spinel occurs in two structural types, normal and inverse, that differ in their distribution of cations among the A and B positions. Writing the general formula $R_8^{2+}R_{16}^{3+}O_{32}$, the two distributions are:

Normal: $8R^{2+}$ in the A site, $16R^{3+}$ in the B site

Inverse: $8R^{3+}$ in the A site, $8R^{2+}$ plus $8R^{3+}$ in B

Subgroups are defined in terms of the B position.

**Spinel crystals****7.2.1.1 Spinel MgAl_2O_4**

Named in 1546, possibly from the Latin *spinella*, little thorn, in allusion to the spine-shaped octahedral crystals. Spinel group. iso *Fd3m*. $a = 8.083$, $Z = 8$, $D = 3.578$. *NBSM* 25(9):25(1971). *NBSM*(syn): 4.66_4 2.86_4 2.44_{10} 2.02_7 1.56_5 1.43_6 1.052_1 0.825_2 . Structure: *AC(A)* 36:122(1980), (B) 40:96(1984). Habit: Crystals are usually octahedrons, rarely modified by $\{110\}$ or $\{100\}$. Twinning common, on $\{111\}$ (the *spinel law*), with twinned aggregates often flattened parallel to the composition plane, and forming triangular tablets. Physical properties: Green, black, brown, red, blue, and so on; white streak, vitreous luster. No cleavage; parting $\{111\}$, indistinct; conchoidal to uneven fracture. $H = 7\frac{1}{2}$ -8. $G = 3.56$. Nonfluorescent, except for some gem varieties, especially

the red ones. **Nonmagnetic. Optics:** Isotropic; $N = 1.718$. **Chemistry:** Virtually complete solid-solution substitution is possible in this AB_2O_4 mineral, in which in the A position Fe^{2+} , Ni, Co, Mn, and Zn may substitute for Mg, and in the B position Fe^{3+} and Cr may substitute for the Al. Other elements that more rarely enter into this structure are Cu and Ge in the A position and V in the B position. **Occurrence:** Spinel occurs embedded in granular limestone or dolomite as a metamorphic mineral, frequently associated with chondrodite. Spinel (common spinel; also *pleonaste*, *picotite*, and chromite) occurs as an accessory constituent in many basic rocks, especially those of the peridotite group; its formation is the result of the crystallization of a magma very low in silica, high in magnesia, and containing alumina. Since, as in many peridotites, alkalis are absent, feldspars cannot form, and the Al_2O_3 present must form either spinel or corundum. The variety *pleonaste* occurs in rocks of this type that are high in iron content and it is commonly associated with magnetite, the two minerals being the first to crystallize from the magma. Spinel occurs in gneiss, amphibolite, and so on, often as inclusions in garnet and cordierite. It is frequently found in contact zones between eruptive rocks and the carbonate rocks, occurring often in the cavities of the igneous rocks, owing its origin probably to pneumatolytic conditions or to deposits from superheated solutions. **Localities:** Only a few of the many known localities can be mentioned. Abundant in a belt of Precambrian crystalline limestones stretching from Amity, NY, to Andover, NJ, associated with phlogopite, graphite, corundum, tremolite, norbergite, dravite, and so on, especially at Edenville and Warwick, NY, and Sparta and Franklin, NJ. Also in St. Lawrence and adjacent counties in the Grenville marble; with corundum at the Culsagee mine near Franklin, Mason Co., NC. The Parker mine, Notre Dame du Laus, QUE, Canada(!), ferroan spinel. In Greenland at Disko Island associated with native iron. In Sweden at Kaveltorp, Nya-Kopparberg, with chondrodite, diopside, and sulfides in a high-temperature replacement deposit. At Pargas, Finland, with chondrodite in crystalline limestone. In Italy with mica and vesuvianite in ejected blocks on Mt. Somma, and with sillimanite, andalusite, and cordierite in andesite on the Lipari Islands. At Nikolae-Maximilianovskaya, southern Ural Mts., Russia(!), in superb large crystals; also in Aldan, Yakutia, Siberia(!), crystals to 30 cm. Near Betroka, Madagascar(!), large, sharp, complex gray-green crystals, some the size of a human head, with phlogopite and diopside. **Gemology:** Only Mg-Al spinel is of significance as a gemstone. It occurs in a wide range of colors, red, pink, orange, blue, purple, and violet being the most common. Although some fine blue stones are known, especially from Myanmar, it is mostly the red stones that are seen in the jewelry trade; the similarity of these stones to ruby has given rise to names such as *balas ruby* and *ruby spinel*. To add to the confusion, fine red spinels accompany ruby in the gem gravels of Myanmar and elsewhere. Spinel may also exhibit color change, appearing grayish blue in daylight and violet to purple in incandescent light.

The distinction of spinel from ruby is relatively easy, based mostly on the lower refractive index and specific gravity of spinel and its being optically

isotropic. Both stones, of red color, are strongly fluorescent in LWUV. The red color of both stones is due to a trace of Cr.

Spinel is produced, along with ruby, sapphire, peridot, and other gems, from the gem gravels of the Mogok region in Myanmar; from the gem gravels of Thailand; and especially from those of Sri Lanka, where it is accompanied by sapphire of many colors, chrysoberyl (including cat's eye and alexandrite), and several rarer gemstones. It is also found in association with corundum in the alluvial deposits of the Umba River, Tanzania, and fine pink stones come from the Pamir Mountains of Tadzhikistan.

Synthetic spinel has been made by the Verneuil process as boules of various colors. In the blue color, this material is often fluorescent, weak to strong red in LWUV and chalky blue in SWUV, whereas natural blue spinel is not fluorescent. RG *DI:689*, *GSAM 85:191(1962)*, *SPC 13:599(1968)*.

7.2.1.2 Galaxite $MnAl_2O_4$

Named in 1932 from the plant, *galax*, abundant in Alleghany Co., NC, where the mineral was found, and the nearby town of Galax, VA. Spinel group. iso *Fd3m*. $a = 8.258$, $Z = 8$, $D = 4.077$. *NBSC 539(9):35(1960)*. *29-880(syn)*: 2.90_7 2.47_{10} 2.05_3 1.58_5 1.45_4 1.07_1 0.837_2 0.793_2 . Massive or small grains. Black or mahogany red, red-brown streak, vitreous luster. $H = 7\frac{1}{2}$. $G = 4.234$. Isotropic; $N = 1.923$. From the *Bald Knob mine*, *Alleghany Co.*, *NC*, associated with jacobsite, alleghanyite, and calcite. RG *DI:689*, *ZAAC 415:69(1975)*, *AM 68:449(1983)*.

7.2.1.3 Hercynite $FeAl_2O_4$

Named in 1847 for the Latin name for the Bohemian forest *Silva Hercynia*, where the mineral was first found. Spinel group. iso *Fd3m*. $a = 8.153$, $Z = 8$, $D = 4.260$. *NBSM 25(19):48(1982)*. *34-192(syn)*: 2.88_6 2.46_{10} 2.04_2 1.66_2 1.57_4 1.44_4 1.06_1 0.832_1 . Massive; as rounded black grains. Dark gray-green to leek-green streak, vitreous luster. $H = 7\frac{1}{2}$ -8. $G = 3.93$. Isotropic; $N = 1.800 \pm 0.005$. Near Whittles, Pittsylvania Co., VA, with hogbomite in emery. About 5 km NE of Colton, NY, in a pelitic Grenville paragneiss, with sillimanite, ilmenite, and rutile. Sweetwater Wash in the Old Woman Mts., 60 km SW of Needles, CA, with ilmenite, anorthite, staurolite, and corundum. Near Cuauhtemoc, CHIH, Mexico. *Nacetin*, near *Pobezovice*, *Bohemia*, *Czech Republic*. Le Prese, Veltlin, Switzerland, in gabbro with corundum and sillimanite. Near Erode, Coimbatore, Madras, India. In cassiterite placers near Moorina, TAS, Australia. RG *DI:689*, *AM 64:736(1979)*.

7.2.1.4 Gahnite $ZnAl_2O_4$

Named in 1807 for Johann Gottlieb Gahn (1745-1818), Swedish chemist and mineralogist, discoverer of manganese. Spinel group. iso *Fd3m*. $a = 8.085$, $Z = 8$, $D = 4.607$. *NBSC 539(2):38(1953)*. Structure: *ZK 120:476(1974)*. *5-669(syn)*: 2.86_8 2.44_{10} 1.86_1 1.65_2 1.56_4 1.43_4 1.05_1 0.825_1 . As octahedral crystals; also irregular grains, massive. Dark green; yellow; brown, gray streak,

vitreous luster. Conchoidal fracture; brittle. $H = 7\frac{1}{2}$ –8. $G = 4.57$. Isotropic; $N = 1.775$ –1.805. Found in crystalline schists; in granite pegmatites, especially those rich in Li; in contact metamorphosed limestones; in high-temperature replacement ore deposits in schists or marbles or quartzose rocks. From Franklin and Sterling Hill, NJ, in the crystalline limestone wallrock adjacent to the orebody and occasionally in the ore itself, in crystals that may reach 12 cm on edge. In CO as an abundant gangue mineral in the Sedalia copper mine, Salida, and well crystallized at Cotopaxi, Chaffee Co. In granite pegmatites at Topsham, ME; Haddam, CT; Mitchell Co., NC. *Nafversberg and Eric Matts mines, Falun, Sweden*. Träskböle, Pernio parish, Finland, in pegmatite. Greenbushes, WA, Australia, in a large Li-Ta pegmatite. In Brazil in Li-Ta pegmatites at Alto do Giz, Equador, and at the Ermo mine, Carnauba dos Dantas, RGN, and in MG at several Li pegmatites, sometimes in gem-clear nodules. Ambatofotsikely, Madagascar, in pegmatite. *RG DI:689*.

7.2.2.1 Magnesioferrite $MgFe_2^{3+}O_4$

Named in 1859 for the composition. Spinel group. iso *Fd3m*. $a = 8.383$, $Z = 8$, $D = 4.51$. *GSAM 85:192(1962)*. 17-464(syn): 2.96₄ 2.53₁₀ 2.09₃ 1.71₁ 1.61₃ 1.48₄ 1.09₁ 0.855₁. Rarely crystallized as octahedrons. Usually granular, massive. Black, black streak, with metallic to submetallic luster. Octahedral parting; brittle. $H = 6$ –6 $\frac{1}{2}$. $G = 4.6$. Strongly magnetic. Isotropic; $N = 2.38$. Found in metamorphosed dolomites, and in fumaroles, where it appears to have formed by the reaction at high temperature of steam and ferric chloride with magnesian material; also in some high-grade metamorphic environments. Sterling Hill, NJ; Magnet Cove, AR. Langban, Varmland, Sweden, occasionally with associated bromellite. From the fumaroles of 1855, Fosse de Cancherone, Mt. Somma, Vesuvius, Italy; also on Mts. Etna and Stromboli, and on the Lipari Is. In France on Puy de la Tache, Mt. Dore, Puy de Dôme. *RG DI:701, AMG 5:1(1969)*.

7.2.2.2 Jacobsite $MnFe_2^{3+}O_4$

Named in 1869 for the original locality in Jakobsberg, Sweden. Spinel group. Polymorph: iwakiite (7.2.6.2). iso *Fd3m*. $a = 8.499$, $Z = 8$, $D = 4.989$. *NBSC 539(9):36(1960)*. 10-319(syn): 4.91₂ 3.01₃ 2.56₁₀ 2.12₂ 1.73₂ 1.64₃ 1.50₄ 1.11₃. Usually massive. Black, brownish-black streak, metallic-submetallic luster. No cleavage; brittle. $H = 5\frac{1}{2}$ –6. $G = 4.76$. Highly magnetic. Isotropic; $N = \pm 2.3$. In RL, gray, isotropic. $R = 18.3$ (470 nm), 17.7 (546 nm), 17.3 (589 nm), 16.7 (650 nm). *P&J:215*. From the Bald Knob mine, Alleghany Co., NC, with galaxite, alleghanyite, and calcite. *Jakobsberg mine, Varmland, Sweden*, in crystalline limestone with native copper, and at Langban with tephroite and calcite. Debarstica, near Tatar-Pazardzik, Bulgaria. Manganese Hill, 40 km N of Eilat, southern Negev, Israel. *RG DI:698, AM 45:734(1960)*.

7.2.2.3 Magnetite $\text{Fe}^{2+}\text{Fe}_2^{3+}\text{O}_4$

Named in 1845, said to be derived from Magnes, a Greek shepherd, who first discovered the mineral on Mt. Ida by noting that the nails of his shoes and the iron ferrule of his staff clung to a rock. Spinel group. iso $Fd\bar{3}m$. $a = 8.396$, $Z = 8$, $D = 5.197$. *NBSM 25(5):31(1967)*. Structure: *AC(C) 40:1491(1984)*. *19-629(syn)*: 2.97₃ 2.53₁₀ 2.10₂ 1.71₁ 1.62₃ 1.48₄ 1.28₁ 1.09₁. **Habit**: Usually octahedral, sometimes dodecahedral; sometimes complex and highly modified, but {001} form rare. Also granular; massive; as black sands. Twinning on {111} common (spinel twins); sometimes polysynthetic twinning lamellae producing striations on an octahedral face. **Physical properties**: Iron black, black streak, metallic to submetallic luster. Parting octahedral, often highly developed; brittle. $H = 5\frac{1}{2}$ -6. $G = 5.175$. Strongly magnetic; some varieties possessing polarity ("lodestone"). **Tests**: Soluble in HCl; the solution reacts for both ferrous and ferric iron. When heated to 550°, loses its magnetism. **Chemistry**: Ti may be present up to about 6%. Fe^{2+} sometimes partly replaced by Mg and more rarely Ni and/or Mn. Fe^{3+} may be replaced by Al (up to 1.5%), Cr, and V. **Optics**: Isotropic; $N = 2.42$ (Na). In RL, brownish gray. $VHN_{100} = 737$. $R = 20.0$ (470 nm), 19.9 (546 nm), 20.0 (589 nm), 19.95 (650 nm). *C&S:218*. **Occurrence and Paragenesis**: Magnetite is one of the most abundant and widespread of oxides. It is found in diverse geological environments and in some deposits in sufficient abundance to constitute an important iron ore. Following are the principal types of occurrence: (1) as a magmatic segregation deposit, with apatite and pyroxenes; (2) as an accessory mineral in acid igneous rocks, widespread but in minor amounts; (3) in calcic igneous rocks such as gabbros and anorthosites, often associated with ilmenite; (4) in many carbonatites, often associated with apatite; (5) in metasomatic rocks associated with limestones, with garnet, diopside, epidote, hematite, pyrite, and other sulfides; (6) in chlorite schists with pyrite; (7) as an accessory in granite pegmatites; (8) in sulfide vein deposits of relatively high temperature; (9) as a product of fumarolic activity; (10) as a detrital mineral in marine or fluvial deposits, often in large amounts; (11) rarely, as an oxidation product in the zone of weathering. **Alteration**: Magnetite is often pseudomorphously altered to hematite ("martite") or to goethite. **Localities**: Major orebodies of magnetite are found in NY, especially in Warren, Clinton, and Essex Cos. The Tilly Foster mine at Brewster, Putnam Co., NY(!), produced fine crystals, often associated with chondrodite. At the Z.C.A. No. 4 mine, Balmat, St. Lawrence Co.(!), fine bright cubes of magnetite are found with anhydrite, halite, colorless sphalerite, and talc. In PA a major orebody at Cornwall, Lebanon Co.(!), produced fine dodecahedrons, and the French Creek mine, Chester Co.(!), produced brilliant octahedral crystals. In Chester, VT(*), in chlorite schist, well crystallized with pyrite crystals. Magnet Cove, near Hot Springs, AR, both in crystals and as lodestone. In Millard Co., UT(*), well crystallized and as martite. In Mexico at Cerro del Mercado, DGO.(!), in part as martite pseudomorphs. What may be the largest known magnetite orebodies are mined in Sweden at Kiruna and Gällivare. These are

magmatic segregation deposits. Also found at Persberg and Nordmark, Värmland, the latter mine furnishing splendid dodecahedral crystals(!). At Alp Lercheltini, Binntal, Valais, Switzerland(!), in fine lustrous crystals in Alpine clefts. At Traversella, Piedmont, Italy, in a contact of limestones and diorite. In simple and twinned octahedra in the Zillertal, Tyrol, Austria(*). Contact metamorphic deposits have long been mined in the Banat district, Romania; at Moravita(!) large dodecahedral crystals have been found. Magnitogorsk, Ural Mts., Russia, in a large deposit; at Kashnakar, near Zlatoust, southern Ural Mts.(!), in sharp 2.5-cm octahedra modified by dodecahedra; in cubic crystals at Tamvatnei, northeast Siberia(!). Large deposits are found in South Africa, as magmatic segregations in the Bushveld complex and elsewhere. In Brazil at Brumado, BA(!), in fine octahedra in magnesite; and also well crystallized in the Jacupiranga carbonatite, SP(!). The most powerful natural magnets (lodestone) are found in Siberia, Russia; in the Harz Mts., Germany; and on Mt. Elba, Italy. Uses: An important ore of iron. Also, when finely ground and mixed with water, used to make heavy media used in mineral separation processes. RG *DI*:698.

7.2.2.4 Franklinite $ZnFe_2O_4$

Named in 1819 for the locality, and for Benjamin Franklin (1706–1790) after whom the town was named. Spinel group. iso *Fd3m*. $a = 8.441$, $Z = 8$, $D = 5.324$. *NBSM 25(9):60(1971) 22-1012(syn): 2.98₄ 2.54₁₀ 2.11₂ 1.72₁ 1.62₃ 1.49₄ 1.29₁ 1.10₁*. Crystallizes as octahedrons, rarely modified by dodecahedron; crystals usually have rounded edges; also granular, massive. Black, reddish brown to black streak, metallic to submetallic luster. Conchoidal to uneven fracture; parting on {111}; brittle. $H = 5\frac{1}{2}$ – $6\frac{1}{2}$. $G = 5.2$. Slightly magnetic. Infusible. Soluble in HCl, sometimes with evolution of a small amount of Cl_2 . No franklinites with only Zn and Fe^{3+} have been found. Normally, much of the Zn is replaced by Mn^{2+} , and a portion of the Fe^{3+} is replaced by Mn^{3+} . Some of the Zn may also be replaced by Fe^{2+} . Isotropic, $N = 2.36$. In RL, gray-white, isotropic. $R = 19.2$ (470 nm), 18.5 (546 nm), 17.6 (589 nm), 16.7 (650 nm). *P&J:167*. Once abundant at the *Franklin and Sterling Hill mines, Franklin and Ogdensburg, NJ*, where it constituted an important ore of zinc, accompanied by calcite, willemite, zincite, and about 330 other minerals. RG *DI*:698; *GSAM 85:193(1962)*; *AM 50:1672(1965)*, *64:599(1979)*; *LIT 5:69(1972)*.

7.2.2.5 Trevorite $NiFe_2^{+}O_4$

Named in 1921 for Tudor Gruffydd Trevor (1865–1958), Welsh–South African geologist, mining inspector for Pretoria district, Transvaal. Spinel group. iso *Fd3m*. $a = 8.339$, $Z = 8$, $D = 5.368$. *NBSC 539(10):44(1960). 44-1485(syn): 4.81₁ 2.95₃ 2.51₁₀ 2.41₁ 2.09₂ 1.702₁ 1.605₃ 1.474₃*. Usually massive; rarely as octahedral crystals. Black, dusky brown streak, submetallic luster. $H = 6$ – $6\frac{1}{2}$. $G = 5.33$. Strongly magnetic. The composition varies from nearly pure $NiFe_2O_4$ to $\sim(Ni_6Fe_4)Fe_2O_4$, with traces of Co and Mg also substituting

in the Ni position. Isotropic; $N \sim 2.3$. $VHN_{50} = 937 \pm 10 \text{ kg/mm}^2$. $R = 24.1$ (546 nm), 24.0 (589 nm). From 3 km W of the Scotia talc mine, *Bon Accord, Barberton, Transvaal, South Africa*, associated with nickel-olivine, nickel-serpentine, and nickel-chlorite. RG *DI:698; AM 54:1204(1969), 57:1524(1972)*.

7.2.2.6 Cuprospinel $\text{CuFe}_2^+\text{O}_4$

Named in 1973 for the composition and its identity as a member of the spinel group. Spinel group. iso *Fd3m*. $a = 8.369$, $Z = 8$, $D = 5.251$. *25-283: 4.79_3 2.96_5 2.52_{10} 2.10_3 1.61_4 1.48_6 1.27_2 1.09_3*. Irregular black grains, black streak. $H = 6\frac{1}{2}$. $G = 5.40$. In RL, gray, similar to magnetite, but without the pinkish tint. Isotropic. $VHN_{100} = 985 \text{ kg/mm}^2$. $R = 22.7$ (470 nm), 21.7 (546 nm), 21.0 (589 nm), 20.0 (650 nm). From the *Consolidated Rambler mine, near Baie Verte, NFD, Canada*, as a product of a burning ore dump, intergrown with hematite and other spinels. RG *CM 11:1003(1973), AM 59:381(1974)*.

7.2.2.7 Brunogeierite $\text{Ge}^{2+}\text{Fe}_2^{3+}\text{O}_4$

Named in 1972 for Bruno H. Geier (b.1902), chief mineralogist, Tsumeb Corp. Spinel group. iso *Fd3m*. $a = 8.409$, $Z = 8$, $D = 5.51$. *NJMM:263(1972). 25-359: 2.97_5 2.53_{10} 2.10_2 1.716_3 1.618_4 1.486_8 1.095_3 0.858_3*. As thin gray crusts with metallic luster. $H \sim 5-5\frac{1}{2}$. Ferromagnetic. RL isotropic, gray, reflectance lower than that of magnetite. From *Tsumeb, Namibia*, as crusts on tennantite which encloses renierite, and surrounded by stottite. RG *AM 58:348(1973)*.

7.2.3.1 Magnesiochromite MgCr_2O_4

Named in 1868 for the composition and its identity as a member of the spinel group. Spinel group. Synonym: chrompicotite. iso *Fd3m*. $a = 8.333$, $Z = 8$, $D = 4.414$. *NBSC 539(9):34(1960). 10-351(syn): 4.81_6 2.95_1 2.51_{10} 2.41_1 2.08_5 1.60_4 1.47_5 1.41_1*. Massive, granular. Black, brown streak, metallic luster. No cleavage, uneven fracture, brittle. $H = 5\frac{1}{2}$. $G = 4.2$. Sometimes feebly magnetic. Some Fe^{2+} is invariably substituted for Mg, and a complete series exists between MgCr_2O_4 and FeCr_2O_4 . In RL, gray. From *Scottie Creek, Lillooet district, BC, Canada*. In the *Schwarzenberg, near Tampadel, Silesia, Germany*, in serpentine. *Ferdinandovo, Bulgaria*. *Mt. Djetei, Togo* (ferrian). *Dun Mt., New Zealand*, in dunite. RG *DI:709*.

7.2.3.2 Manganochromite $(\text{Mn, Fe}^{2+})(\text{Cr, V})_2\text{O}_4$

Named in 1978 for its composition and identity as a member of the chromite sub-group. Spinel group. iso *Fd3m*. $a = 8.47$, $Z = 8$, $D = 4.88$. *31-630: 4.89_3 2.99_3 2.55_{10} 2.44_3 2.12_1 1.73_3 1.63_{10} 1.50_{10}*. As euhedral to irregular embedded grains. Black. $H = 6\frac{1}{2}$. V_2O_3 substituting for Cr_2O_3 is present up to 27.6%. Similarly, FeO substitutes for MnO up to 10%. A small amount of ZnO also substitutes for MnO. In RL, isotropic, brownish gray. $R = 16.8$ (470 nm), 16.5 (546 nm), 16.5 (589 nm), 16.3 (650 nm). From the *Nairne deposit, Bru-*

kunga, E of Adelaide, SA, Australia, associated with pyrrhotite and diopside, in pyritic beds of the Kanmantoo metasediments. RG *AM* 63:1166(1978).

7.2.3.3 Chromite FeCr_2O_4

Named in 1845 from the composition. Spinel group. Donathite, a supposed tetragonal polymorph of chromite, has been discredited. *AM* 77:1120(1992). iso *Fd3m*. $a = 8.379$, $Z = 8$, $D = 5.055$. *NBSM* 25(19):50(1992). *GSAM* 85:195(1962)(nat): 4.80₄ 2.95₂ 2.51₁₀ 2.08₅ 1.60₆ 1.47₈ 1.08₉ 1.04₄. 34-140(syn): 4.84₁ 2.96₃ 2.53₁₀ 2.09₂ 1.61₄ 1.48₅ 1.09₁ 0.855₁. Crystals usually octahedral, extremely uncommon; usually massive or granular. Black, brown streak, metallic luster. Uneven fracture; brittle. $H = 5\frac{1}{2}$. $G = 4.7$. Sometimes feebly magnetic. Isotropic; $N = 2.08$ – 2.16 . In RL, grayish white, with a brownish tint. Isotropic. $R = 12.7$ (470 nm), 12.0 (546 nm), 11.8 (589 nm), 11.6 (650 nm). *P&J*:120. MgO usually replaces part of the FeO and a complete series exists between chromite and magnesiochromite. Al_2O_3 may replace part of the Cr_2O_3 , as does Fe_2O_3 ; these may result in serious reduction of the Cr_2O_3 content in chromite ore. Chromite deposits are invariably associated with ultramafic ferromagnesian rocks, especially serpentines, peridotites, and dunites. In these chromite may be present as magmatic segregations of large size, or more commonly disseminated as an accessory mineral. Weathering and decomposition of these rocks may give rise to alluvial deposits of chromite. Wood mine, near Texas, Lancaster Co., PA. In the Webster–Addie ultramafic ring, Jackson Co., NC. In CA in Shasta and Siskiyou Cos. and in the Great Serpentine Dike in Eldorado and Placer Cos. In the serpentine areas of QUE, Canada. Abundant in good crystals to 10 mm at Haroldswick and Swinans, Unst Island, Shetlands, Scotland. *Gassin*, Var, France. Ramberget, near Hestmand, Norway. Nizhne–Tagilsk district, Perm, eastern Ural Mts., Russia, associated with platinum. Important deposits are mined in Turkey, at Antioch, Smyrna, and Brussa. In the Zhob valley igneous complex, western Pakistan. In the serpentine of the Great Dike, Zimbabwe. From the Bushveld Complex, South Africa. Tiebaghi, Thio, New Caledonia, in octahedrons >50 mm. Also in the Philippines, Cuba, and elsewhere. The principal, and only, ore of chromium. RG *DI*:709; *AM* 38:1134(1053), 45:579(1960).

7.2.3.4 Nichromite $(\text{Ni}, \text{Co})(\text{Cr}, \text{Fe}^{3+})_2\text{O}_4$

Named in 1978 for the composition. Spinel group. iso *Fd3m*. $a = 8.316$, $Z = 8$, $D = 5.24$. 23-1271(syn): 4.92 2.95₅ 2.51₁₀ 2.08₂ 1.70₂ 1.60₃ 1.47₅ 1.32₁. Minute dark green to black grains, greenish-gray streak, metallic luster. Conchoidal fracture. In RL, isotropic. From the *Bon Accord nickel deposit*, Barberton, Transvaal, South Africa, associated with trevorite, liebenbergite, and bunsenite. RG *BRGMII* 3:225(1978), *AM* 65:811(1980).

7.2.3.5 Cochromite (Co,Ni)(Cr,Al)₂O₄

Named in 1978 for the composition, and its being a member of the chromite subgroup. Spinel group. iso *Fd3m*. $a = 8.292$, $Z = 8$, $D = 5.01$. *AM 65:811(1980)*. *22-1084(syn)*: 4.82_1 2.95_3 2.51_{10} 2.08_2 1.60_3 1.47_4 1.08_1 0.850_1 . As minute grains. Black, greenish-gray streak, metallic luster. Conchoidal fracture. In RL, isotropic, gray. $R = 14.3$ (470 nm), 13.7 (546 nm), 14.0 (589 nm), 13.9 (650 nm). $VHN_{50} = 1218$ kg/mm². From *Bon Accord*, Barber-ton district, Transvaal, South Africa, associated with chromite and trevorite. RG *NBSM 9:21(1971)*.

7.2.3.6 Zincochromite ZnCr₂O₄

Named in 1987 for the composition. Spinel group. iso *Fd3m*. $a = 8.352$, $Z = 8$, $D = 5.434$. *ZVMO 116:367(1987)*. *22-1107*: 2.95_5 2.51_{10} 2.08_2 1.700_1 1.603_4 1.472_4 1.270_1 1.084_1 . Minute octahedral crystals. Brownish black, brown streak, semimetallic luster. No cleavage. $H = 5\frac{1}{2}$. Weakly paramagnetic. In RL, brownish gray with brown internal reflections, isotropic. $R = 12.2$ (470 nm), 11.8 (546 nm), 11.6 (589 nm), 11.6 (650 nm). From the *Onega trough, southern Karelia, Russia*, with quartz and amorphous Cr-V-Fe oxides and hydroxides. RG *AM 73:932(1988)*.

7.2.4.1 Vuorelainenite (Mn,Fe²⁺)(V,Cr)₂O₄

Named in 1982 for Yrjo Vuorelainen (1922-1988), Finnish mineralogist with the Outokumpu Co., who investigated and described many new species from Finland. Spinel group. iso *Fd3m*. $a = 8.48$, $Z = 8$, $D = 4.64$. *35-550*: 4.90_2 2.99_4 2.56_{10} 2.12_3 1.73_2 1.63_8 1.50_3 1.10_2 . As black euhedral grains, submetallic luster. In RL, isotropic, brownish gray. $VHN_{50} = 900$ kg/mm². $R = 15.7$ (470 nm), 15.4 (546 nm), 15.6 (589 nm), 16.2 (650 nm). From the *Stäta (Doverstorp) pyrite deposit, Bergslagen, central Sweden*, associated with pyrrhotite, rutile, pyrophanite, and other minerals. RG *CM 20:281(1982)*, *AM 68:472(1983)*.

7.2.4.2 Coulsonite Fe²⁺V₂O₄

Named in 1937 for Arthur Lennox Coulson (b.1898), geologist, Geological Survey of India. Spinel group. iso *Fd3m*. $a = 8.297$, $Z = 8$, $D = 5.15$. *AM 47:1284(1962)*. *15-122*: 4.79_3 2.93_6 2.50_{10} 2.07_8 1.69_3 1.60_9 1.47_9 1.27_2 . Irregular to subhedral bluish-gray grains, dark brown to black streak, metallic luster. $H = 4\frac{1}{2}$ -5. $G = 5.2$. Slightly magnetic. In RL, isotropic, bluish gray. $R = 23.5$ (green). From the Buena Vista Hills, 32 km SE of Lovelock, NV, in metamorphosed magnetite-rich hornblende andesite. *Singbhum, Bihar, India*, associated with titaniferous magnetite ores. RG *AM 48:948(1963)*.

7.2.4.3 Magnesiocoulsonite MgV₂O₄

Named in 1995 by Reznitsky et al. Spinel group. The magnesium analog of coulsonite. Analogous to chromite-magnesiochromite. Forms a series with

magnesiochromite. iso $Fd\bar{3}m$. $a = 8.385$, $Z = 8$, $D = 4.31$. P.D. 4.84_9 , 2.95_3 , 2.52_{10} , 2.09_8 , 1.612_8 , 1.482_9 , 1.092_7 , 1.048_5 . *ZVMO 124:91(1995)*. Grains are equant and have an octahedral habit. Black, black streak, metallic luster; opaque. Uneven fracture; brittle. $H = 6\frac{1}{2}$. Insoluble in HNO_3 . In RL, light gray; isotropic; no birefractance; nonpleochroic. $R = 14.0$ (470 nm), 13.7 (546 nm), 13.7 (589 nm), 13.7 (650 nm). Found in the Slyuyaanka parametamorphic complex, western Pribaikal. Russia, in quartz–diopside rocks, associated with tremolite, calcite, pyrite, kalininite, florensovite, goldmanite, kammererite, and karelianite. RG

7.2.5.1 Qandilite Mg_2TiO_4

Named in 1985 for the rocks of the Qandil group, where the mineral was found. Spinel group. iso $Fd\bar{3}m$. $a = 8.403$, $Z = 8$, $D = 4.04$. *AM 73:930(1988)*. *25-1157(syn)*: 4.88_5 , 2.99_2 , 2.54_{10} , 2.11_6 , 1.722_1 , 1.624_3 , 1.492_5 , 1.099_1 . Small grains with euhedral outline. Structure inverse spinel type, with Ti^{4+} in octahedral sites and Mg in both tetrahedral and octahedral sites in a ratio of 2:1. *AC(B) 45:542(1989)*. Iron black, black streak, metallic luster. Cleavage {111}, perfect; brittle. $H = 7$. $G = 4.03$. Strongly magnetic, similar to magnetite. Soluble in hot 1:1 HCl. Although the theoretical end-member composition is Mg_2TiO_4 , natural qandilite is a solid solution mixture of 64% Mg_2TiO_4 , 23% $FeFe_2O_4$, and 13% $MgFe_2O_4$. In RL, isotropic, pinkish gray. $VHN_{100} = 998$ kg/mm². $R = 13.4$ (470 nm), 13.1 (546 nm), 13.0 (589 nm), 13.0 (650 nm). From the Kangerdlugssuaq region, East Greenland, in a periclase–forsterite marble in contact with an alkalic ultramafic intrusion. *Quandil rocks, Dupezeh Mt., Hero Town, Qala-Dizeh region, Iraq*, in a forsterite skarn, associated with serpentinized olivine, calcite, perovskite, and spinel. RG *MM 45:135(1982)*.

7.2.5.2 Ulvöspinel $Fe_2^{2+}TiO_4$

Named in 1943 for the locality and its identity as a member of the group. Spinel group. iso $Fd\bar{3}m$. $a = 8.535$, $Z = 8$, $D = 4.777$. *NBSM 25(20):61(1984)*. *34-177(syn)*: 4.92_1 , 3.02_3 , 2.57_{10} , 2.13_2 , 1.74_1 , 1.64_3 , 1.51_4 , 0.871_1 . The structure is that of an inverse spinel, with Ti^{4+} in octahedral sites and Fe^{2+} in both octahedral and tetrahedral sites in a ratio of 1:2. *JAC 11:121(1978)*. As minute grains. Metallic luster. In RL, isotropic, brown. $R = 17.0$ (470 nm), 17.6 (546 nm), 18.4 (589 nm), 19.1 (650 nm). *P&J:378*. 7.2.6.1 Kusachiite $CuBi_2O_4$

Named in 1995 for Isao Kusachi (b.1942), Japanese mineralogist, Okayama University, Fuka, Japan. $TET P4/ncc$. $a = 8.511$, $c = 5.823$, $Z = 4$, $D = 8.64$. *PD*: 4.26_2 , 3.19_{10} , 2.91_2 , 2.70_2 , 2.40_1 , 1.947_2 , 1.728_1 , 1.652_1 . Prismatic crystals to 0.5 mm and as platy grains in globular aggregates. Black, metallic luster.

Cleavage {110}, perfect. $H = 4\frac{1}{2}$, $VHN_{25} = 292-357$. $G = 8.5$. Readily soluble in HCl. Opaque; in RL, gray with deep red to dark brown internal reflections, weak bireflectance; pleochroic brownish gray to gray. $R = 21.1-19.0$ (482 nm), 20.2-18.0 (545 nm), 19.7-17.6 (589 nm), 19.5-17.3 (659 nm). From *Fuka, Okayama Pref., Japan*, on calcite crystals in a cavity in a calcite vein at a gehlenite-spurrite skarn/limestone contact, associated with henmilite, sillenite, bakerite, tenorite, bultfonteinite, apophyllite, cuspidine, and thaumasite. RG *MM 59:545(1995)*, *AM 81:517(1996)*.

7.2.6.2 Iwakiite $Mn^{2+}(Fe^{3+}, Mn^{3+})_2O_4$

Named in 1979 for the locality. Synonym: α -vredenbergite. Dimorphous with jacobsonite. TET $P4_2/nm$. $a = 8.519$, $c = 8.540$, $Z = 8$, $D = 4.88$. *MJJ 9:383(1979)*. Structure: *ZK 185:605(1988)*. *38-430*: 4.93₃ 3.02₄ 2.57₁₀ 2.135₂ 2.13₂ 1.64₃ 1.509₄ 1.506₄. Small grains. Greenish black, black streak, metallic luster. No cleavage. $H = 6-6\frac{1}{2}$, $VHN_{100} = 726$. $G = 4.85$. Strongly magnetic. In RL, olive-gray, moderately anisotropic. $R = 19.9$ (470 nm), 20.8 (546 nm), 20.6 (589 nm), 19.8 (650 nm). From the *Gozaisho mine, Iwaki, Japan*, in manganese ore, associated with rhodonite, quartz, braunite, hematite, rhodochrosite, and spessartine. RG *AM 65:406(1980)*.

7.2.7.1 Hausmannite $Mn^{2+}Mn_2^{3+}O_4$

Named in 1827 for Johann F. L. Hausmann (1782-1859), professor of mineralogy, University of Göttingen. TET $I4_1/amd$. $a = 5.762$, $c = 9.470$, $Z = 4$, $D = 4.834$. *SR 54A:141(1987)*. *24-734*: 4.92₃ 3.09₄ 2.77₉ 2.49₁₀ 2.46₂ 1.80₃ 1.58₃ 1.54₅. Crystals pseudo-octahedral {011}; also stout prismatic; granular, massive. Twin plane {112}, often repeated as fivelings. Brownish black, chestnut-brown streak, submetallic luster. Cleavage {001}, nearly perfect; uneven fracture; brittle. $H = 5\frac{1}{2}$. $G = 4.84$. Slightly paramagnetic. Soluble in hot HCl, with evolution of Cl_2 . Small amounts of Zn and Fe may substitute for the Mn. Uniaxial (-); $N_O = 2.46$, $N_E = 2.15$ (Li); nonpleochroic, deep reddish brown. In RL, grayish white, distinctly anisotropic, red internal reflections. $R = 19.5-16.5$ (470 nm), 18.1-15.5 (546 nm), 17.6-14.9 (589 nm), 17.1-14.4 (650 nm). *P&J:195*. Franklin, NJ, with zinc ore. Batesville district, AR, with pyrolusite and "psilomelane." Prefumo Canyon district, San Luis Obispo Co., CA. Långban, Värmland, Sweden(!), in fine crystals, and at Jacobsberg in granular limestone with garnet, magnetite, hematite, manganophyllite, and jacobsonite. *Ilfeld, Harz*, and at Öhrenstock near Ilmenau, Thuringia(!), *Germany*. Lower Averser valley, Graubunden, Switzerland. Aosta valley, Torino, Italy. Miguel Burnier, MG, Brazil(!), in fine crystals. Kuruman manganese district, Cape Prov., South Africa(!), in fine crystals to 4 cm. RG *DI:712*, *AM 50:1305(1965)*.

7.2.7.2 Hetaerolite $ZnMn_2^{3+}O_4$

Named in 1877 from the Greek *hetaros*, companion, in allusion to the association with chalcophanite in some specimens. TET $I4_1/amd$. $a = 5.720$,

$c = 9.245$, $Z = 4$, $D = 5.252$. *NBSM 25(10):61(19??)*. *24-1133*: 3.05₅ 2.86₂ 2.72₇ 2.47₁₀ 2.02₂ 1.56₃ 1.52₄ 1.43₂. Crystals usually pseudo-octahedral; also massive. Twin plane {112}, as fivelings. Black, dark brown streak; submetallic shining luster. Cleavage {001}, indistinct; uneven fracture; brittle. $H = 6$. $G = 5.18$. In RL, gray, weakly pleochroic; anisotropic, red internal reflections. $R = 20.6\text{--}16.2$ (470 nm), 18.3–14.6 (546 nm), 17.7–14.1 (589 nm), 17.1–13.7 (650 nm). *P&J:200*. *Franklin and Sterling Hill mines, Sussex Co., NJ*, associated with calcite, willemite, manganosite, chalcophanite, gahnite, zincite, and other minerals. *RG DI:715, AM 50:1672(1965), MA 74:3413(1974)*.

7.2.7.3 Hydrohetaerolite $\text{Zn}_2\text{Mn}_4^{3+}\text{O}_8 \cdot \text{H}_2\text{O}$

Named in 1929 because the composition is that of hetaerolite plus water. *TET I4₁/amd*. $a = 5.73$, $c = 9.00$, $Z = 4$, $D = 4.77$. *AM 41:268(1956)*. *9-459*: 3.02₇ 2.87₄ 2.66₈ 2.47₁₀ 1.57₅ 1.51₇ 1.43₄ 1.26₃. Massive; as fibrous crusts with a botryoidal surface. Dark brown to brownish black, dark brown streak, submetallic luster. Cleavage parallel to elongation of fibers. $H = 5\text{--}6$. $G = 4.64$. Soluble in HCl, giving off Cl_2 . Uniaxial (–); $N_O = 2.26$, $N_E = 2.10$. In RL, creamy gray. From the *Wolftone mine, Leadville, Lake Co., CO*, associated with chalcophanite, smithsonite, and hemimorphite in oxidized ore. *Sterling Hill mine, Ogdensburg, NJ*. *RG DI:717, AM 27:48(1942)*.

7.2.8.1 Minium $\text{Pb}^{4+}\text{Pb}_2^{2+}\text{O}_4$

Named in antiquity from the Latin *minium*, derived from the Iberian word for cinnabar, the Romans getting their cinnabar from Spain. Although originally applied to cinnabar, the name is now used for red lead oxide. *TET P4₂/mbc*. $a = 8.815$, $c = 6.565$, $Z = 4$, $D = 8.924$. *NBSC 539(8):32(1959)*. Structure: *SR 41A:212(1975)*. *41-1493(syn)*: 6.23₂ 3.38₁₀ 3.12₂ 2.90₅ 2.79₄ 2.63₃ 1.91₂ 1.76₃. Massive, earthy, or pulverulent; as microscopic scales. Red to brownish red, orange-yellow streak, greasy luster. $H = 2.5$. $G = 9.05$. Soluble in excess 1:1 HCl, with evolution of Cl_2 . Decomposed by HNO_3 , with brown residue of PbO_2 . On heating, color darkens and becomes black, but original color is restored on cooling. Uniaxial; $N \sim 2.42$. Pleochroism: O, deep reddish brown; E, nearly colorless; negative elongation. Abnormal green interference colors. From Austin's mine, Wythe Co., VA. Jay Gould mine, Alturas Co., ID, with native lead and galena. In oxidized ore in several of the mines at Leadville, CO, with galena, cerussite, and iron oxides. Godiva mine, Tintic, UT. In Mexico at the Santa Fe mine, Bolaños, DGO, with massicot and cerussite, and at Zimapán, HGO. Leadhills, Scotland, and at Weardale, Yorkshire, England. Langban, Varmland, Sweden, with native lead. Badenweiler, Baden, and Bleiberg, Baden-Württemberg, Germany. Mine des Molérats, St.-Prix, Saone-et-Loire, France. Sarrabus, Sardinia, Italy. Zmeyewskaja-Gora, Altai Mts., Kazakhstan. Broken Hill, NSW, Australia, as the product of a mine fire. *RG DI:517, NJMA 94:1187(1960)*.

7.2.9.1 Chrysoberyl BeAl_2O_4

Named in 1790 from the Greek for *golden* and *beryl* (a misnomer), in allusion to the common color. ORTH *Pnma*. $a = 9.404$, $b = 5.476$, $c = 4.427$, $Z = 4$, $D = 3.699$. NBSC 539(9):10(1960). **Structure:** Chrysoberyl is isostructural with olivine, $(\text{Mg}, \text{Fe})\text{Si}_2\text{O}_4$, and is the hexagonal close-packed analog of the cubic close-packed spinel structure. The oxygens form a distorted hexagonal close-packed array in which one-eighth of the tetrahedral interstices are occupied by beryllium in tetrahedral coordination, and one-half of the octahedral sites are filled by aluminum in octahedral coordination. The beryllium-oxygen tetrahedra point alternately either way along both the X and Y directions. The Al atoms occupy two sets of nonequivalent lattice positions; half are located at centers of symmetry and half on reflection planes, the former having as nearest neighbors two oxygens from two adjacent tetrahedra, and the latter two oxygens from one adjacent tetrahedron. AM 48:804(1963). 45-1445: 3.23₄ 2.56₇ 2.26₄ 2.09₈ 1.618₁₀ 1.613₉ 1.465₄ 1.361₆. **Habit:** Crystals usually tabular {001}; sometimes stout prismatic [100]. Striated on {001} parallel to [100]. Twinning common, with twin plane {130}. Twinned crystals are generally flattened perpendicular to the composition plane. Simple, somewhat heart-shaped flattened twins are perhaps the most common form of occurrence of two individuals. Also common are contact and penetration twins, often repeated and forming pseudohexagonal crystals as viewed along [001], with or without reentrant angles. Such crystals are called *trillings*. **Physical properties:** Green, yellow, greenish brown; sometimes green or blue in daylight and red or brownish pink in incandescent light (alexandrite); vitreous luster. Cleavage {110}, distinct; {010}, imperfect; uneven to conchoidal fracture; brittle. $H = 8\frac{1}{2}$. $G = 3.75$. Nonfluorescent, except for alexandrite, which is fluorescent weak to moderate red in both LWUV and SWUV. Nonmagnetic. Insoluble in acids. **Chemistry:** Fe^{3+} may substitute for Al up to about 6% Fe_2O_3 . **Optics:** Biaxial (+); XYZ = cba; $N_x = 1.746$, $N_y = 1.748$, $N_z = 1.756$; $2V = 70^\circ$; $r > v$. X, pale pink; Y, pale yellow; Z, pale green. **Occurrence:** Normally found in pegmatites; rarely in some fluorine-rich veins. Alexandrite is usually found in mica schist. **Localities:** At many localities in ME, especially Stoneham, Greenwood, Topsham(*), Haddam, CT(*), with columbite, tourmaline, gahnite, beryl. Drew Hill, Golden Gate Canyon, Jefferson Co., CO(!), in large crystals and twins to 10 cm. Saetersdalen, Norway. Mourne Mts., Northern Ireland. In dolomite with corundum at Campolungo, near St. Gothard, Switzerland. At the Malyshva mine, middle Ural Mts., Russia, in fine nongem alexandrite twins. Hyderabad region, India(*), twins to 5 cm. In schist on the Novello claims, Victoria, Zimbabwe(!) (nongem alexandrite), as pseudohexagonal trillings. In fine flattened crystals and trillings N of Lake Alaotra, Madagascar(!). At numerous places in Brazil, especially in ES in superb trillings to 6 cm at Itaguaçu(!), and at Collatina(!) in magnificent V-twins and single crystals to over 40 cm; in BA fine trillings of nongem alexandrite in schist at Carnaiba(*), associated with emerald; at Itamaraju(!) in large sharp crystals and

twins; Municipio de Prado(!), fine trillings; from Jaqueto, a 24-kg or larger V-twin; Medeiros Neto(!) 5-cm crystals; Teixeira de Freitas, gemmy flat twins and trillings to 5 cm. In MG at Minas Novas in fine small single crystals and twins, and at Americana, Mun. do Teofilo Otoni. Gemology: Chrysoberyl occurs in three distinct gem varieties, two of which, if of fine quality, are among the most expensive, rare, and sought-after gems:

1. Common gem chrysoberyl occurs in shades of light yellow, green, and brown. It is colored by ferric iron. Density is 3.71–3.73; mean index of refraction 1.75, with birefringence 0.009; these values also hold for the other gem varieties of chrysoberyl. The principal sources of gem material are Sri Lanka and Brazil.

2. *Alexandrite*, which at the original locality in Russia is light grass green in daylight and raspberry-red in artificial light. It was named after the czarevitch, later Czar Alexander II of Russia, because it was supposedly first found on the day set apart for celebrating his majority, in 1833. Most alexandrite from Brazil is greenish blue in daylight and deep red in artificial light; some rare stones are deep red in any kind of light and show no color change. From Sri Lanka, alexandrite is slightly yellowish green in daylight and pinkish brown in artificial light. Still other color changes are known, and, in effect, any chrysoberyl that shows any change whatever is often locally called alexandrite, but few of them make attractive gems. The ones that do show a change also vary greatly in the ease with which the change can be demonstrated, depending on the stone and the quality of the light sources used. Larger stones (above 10 ct) that have good quality of change tend to be very dark. The really good, attractive alexandrites are extremely rare and command a high price. Only the Russian stones and a very few from Brazil fit in this category. The colors of alexandrite are caused by a trace of Cr replacing the Al plus variable trace amounts of Fe^{3+} . The most desirable colors have the lowest Fe content. The principal sources are in mica schist with phenacite and emerald near the Takowaja River, 90 km E of Ekaterinburg, Ural Mts., Russia(!); in the gem gravels of Sri Lanka; and near Hematita, MG, Brazil(!).

3. *Cat's eye* is a chrysoberyl that is milky or opalescent in which myriad minute acicular inclusions parallel to the *c* axis of the crystal, in a properly oriented, cabochon-cut stone, reflect a band of light at right angles to the direction of the inclusions, reminiscent of the eye of a cat when a flashlight is directed at it. Good cat's eyes are usually honey yellow or greenish yellow, although alexandrite cat's eyes are known. Fine cat's eyes may reach up to 100 ct and command high prices, comparable to fine sapphires. The best cat's eyes come from Sri Lanka(!); from near Trivandrum, Kerala, India(!); and from Brazil at Padre Paraiso(!) or near Minas Novas, MG.

Synthetics: Synthetic alexandrite has been made by both the Czochralski and the flux-grown methods; their detection requires microscopic examination of minute inclusions usually present. They are also more strongly fluorescent than natural alexandrite. Synthetic corundum with a purplish-blue daylight color and fine red artificial light color has long been available as an alexandrite "look-alike"; it can easily be identified by the difference in refractive index

from true alexandrite. RG *H&K(1991)*, *AM 24:267(1939)*, *DI:718*, *NJMA 134:117(1979)*, *PCM 4:426(1987)*.

7.2.10.1 Marokite $\text{CaMn}_2^3+\text{O}_4$

Named in 1963 for the country of origin. ORTH *Pmab* or *P2₁ab*. $a = 9.71$, $b = 10.03$, $c = 3.162$, $Z = 4$, $D = 4.63$. *BM 86:359(1963)*. Structure: *BM 89:318(1966)*. 16-709: 2.87₆ 2.71₁₀ 2.56₆ 2.29₈ 2.22₁₀ 2.07₈ 1.63₆ 1.58₆. Platy crystals flattened {010}; no twinning. Black, reddish-brown streak, bright shiny luster. Cleavage {100}, perfect; {001}, good. $G = 4.64$. Biaxial (-); $X = c$; $N_x = 2.07$, $N_y \sim 2.42$, $N_z \sim 2.42$; $2V = 20-25^\circ$. X, safflower red; Y, Z, opaque. Plane of optic axes is {100}. In RL, brownish gray with red internal reflections; strongly anisotropic; pleochroic, yellowish gray to gray-brown. $R = 19.7-17.4$ (470 nm), 18.3-16.0 (546 nm), 18.7-16.0 (589 nm), 17.9-15.5 (650 nm). *P&J:258*. From *Tachgagalt, Ouarzazate, Morocco*, associated with calcite, barite, hausmannite, braunite, crednerite, and polianite. Black Rock mine, northwestern Cape Prov., South Africa. RG *AM 49:817(1964)*, *53:495(1968)*.

7.2.11.1 Taaffeite $\text{BeMg}_3\text{Al}_5\text{O}_{16}$

Named in 1951 for Edward Charles Richard Taaffe (1898-1967), Bohemian-Irish gemologist, of Dublin, who discovered the species in a cut stone. HEX *P6₃mc*. $a = 5.687$, $c = 18.34$, $Z = 2$, $D = 3.579$. *NJMM: 393(1983)*. 35-701: 4.58₅ 4.34₄ 2.60₆ 2.42₁₀ 2.38₄ 2.04₆ 1.47₅ 1.42₅. Hexagonal, stout prismatic crystals. Pale mauve; green, vitreous luster. $H = 8$. $G = 3.613$. Fluoresces green under UV radiation. Uniaxial (-); $N_O = 1.723$, $N_E = 1.718$ (Na). From the gem gravels of *Sri Lanka*. Nanling district, Hsianghualing range, Hunan, China, with chrysoberyl and phenakite. Mt. Painter, SA, Australia, with spinel and hōgbomite, in high Mg-Al-bearing schists. Used to a limited extent as a gem. RG *AM 37:360(1952)*, *69:215(1984)*; *MM 43:575(1980)*.

7.2.12.1 Musgravite $(\text{Mg, Fe, Zn})_2\text{BeAl}_6\text{O}_{12}$

Named in 1967 for the locality. HEX-R *R3m*. $a = 5.675$, $c = 41.096$, $Z = 6$, $D = 3.69$. *NJMA 146:15(1983)*. 34-191: 4.57₄ 4.21₃ 2.66₆ 2.41₁₀ 2.27₄ 2.05₇ 1.487₄ 1.419₈. Platy masses, flattened {001}. Blackish green, vitreous luster. $H = 8$. $G = 3.68$. From a pegmatite near zircon point, 2 km S of McIntyre Island, Enderby Land, Antarctica, with sapphirine, surinamite, sillimanite, chrysoberyl, garnet, and rutile. *NNE of Ernabella Mission, Musgrave Range, SA, Australia*. RG *MM 36:305(1967)*, *AM 66:1028(1981)*.

7.2.12.2 Pehrmanite $\text{Be}(\text{Fe, Zn, Mg})_2\text{Al}_6\text{O}_{12}$

Named in 1981 for Gunnar Pehrman (1895-1980), professor emeritus, University of Abo, Turku, Finland. HEX-R *R32* or *R3m*. $a = 5.70$, $c = 41.16$, $Z = 6$, $D = 4.07$. 35-503: 3.15₃ 2.86₈ 2.67₄ 2.53₃ 2.42₁₀ 2.06₄ 1.492₃ 1.426₅. Subhedral hexagonal tabular crystals, and as epitaxial overgrowths on nigerite. Light

gray-green, vitreous luster. No cleavage, very brittle. $H = 8-8\frac{1}{2}$, $VHN_{100} = 1700$. Uniaxial (-); $N_O = 1.79$; parallel extinction; positive elongation. O, pale greenish; E, pale grayish brown. $R = 8.3$ (470 nm), 8.1 (546 nm), 8.0 (589 nm), 7.9 (650 nm). From the wall zone of the *Rosendal pegmatite, Kemijö Island, southwestern Finland*, embedded in albite, with quartz, sillimanite, nigerite, muscovite, spessartine, chlorite, biotite, epidote, allanite, and calcite. RG *CM 19:311(1981)*, *AM 67:859(1982)*, *NJMA 146:15(1983)*.

7.2.13.1 Filipstadite $(Mn, Mg)_2(Sb_{0.5}^{5+}Fe_{0.5}^{3+})O_4$

Named in 1988 for the town of Filipstad, near which Långban is located. ORTH, pseudo-iso Space group unknown. $a = 8.640$ (cubic subcell), $Z = 8$, $D = 4.9$. *AM 73:413(1988)*. PD: 4.97₂ 3.05₃ 2.56₁₀ 2.16₄ 1.66₆ 1.53₇ 1.32₂ 1.13₃. Euhedral equant microcrystals. Black, brown streak, metallic luster. No cleavage, conchoidal fracture, brittle. $VHN_{100} = 831$. In RL, gray, with rare, red internal reflections, weakly anisotropic in shades of dark brownish gray. From *Langban, near Filipstad, Värmland, Sweden*, intergrown with ingersonite and jacobsite. RG

7.2.14.1 Yafsoanite $Ca_3Te_2Zn_3O_{12}$

Named in 1982 for the Russian acronym for Yakut Filial, Siberian Branch, Academy of Sciences, USSR ("Yafsoan" in Russian). iso *Ia3d*. $a = 12.632$, $Z = 8$, $D = 5.54$. *ZVMO 111:118(1982)*, *MP 40:111(1989)*. 35-661: 4.47₃ 3.16₈ 2.82₉ 2.58₁₀ 1.751₃ 1.683₁₀ 1.577₃ 1.024₅. Yafsoanite, rather than being a tellurite or tellurate, has been shown structurally to be a garnet-type oxide with atoms Ca, Te^{6+} , and Zn coordinated to eight, six, and four oxygen atoms, respectively. This accounts for its hardness, nearly 6, far harder than any of the known tellurites or tellurates. Crystals show dodecahedron, cube, and octahedron, also as radiating concentric material. Light to dark brown, also white; vitreous luster. No cleavage. Soluble in acids, unreacted upon by KOH or $FeCl_2$ solution. Isotropic; $N = 1.800$. Found at the Empire mine, Tombstone, AZ, in colorless dodecahedrons on dugganite; originally from the *Kuranakh gold deposit, central Aldan, Yakutia, Siberia, Russia*, associated with dugganite and desclozite. RG *AM 68:282(1983)*, *75:937(1990)*.

7.3.1.1 Welinite $Mn_6(W^{6+}, Mg)_2Si_2(O, OH)_{14}$

Named in 1967 for Eric Welin (b.1923), Swedish mineralogist and geochronologist. HEX P3. $a = 8.155$, $c = 4.785$, $Z = 1$, $D = 4.41$. Structure: *SR 34A:387(1969)*. *AM 53:1064(1968)*. 20-1339: 7.00₅ 4.07₆ 3.95₃ 3.10₈ 2.84₄ 2.33₈ 1.78₁₀ 1.54₆. Fissure fillings and embedded crystal sections. Red-brown to reddish black, resinous luster. Cleavage {0001}, poor; brittle. $H = 4$. $G = 4.47$. Uniaxial (+); $N_O = 1.864$, $N_E = 1.88$. *Langban, Värmland, Sweden*, associated with calcite, barite, sarkinite, and adelite filling fissures in hausmannite ore. RG *AMG 4:459(1968)*, *AM 71:1522(1986)*.

7.3.1.2 Franciscanite $Mn_6V_2Si_2(O,OH)_{14}$

Named in 1986 for the Franciscan complex, the formation in California where it was found. *HEX P3*. $a = 8.148$, $c = 4.804$, $Z = 1$, $D = 3.93$. *AM 71:1522(1986)*. Structure: *NJMM:493(1986)*. *40-487*: 3.97₃ 3.11₉ 2.84₉ 2.67₄ 2.33₁₀ 1.79₇ 1.54₅ 1.37₃. Glassy, irregular grains. Red to brownish red, brownish-red streak, vitreous luster. No cleavage, uneven fracture. $H = 4$. $G = 4.1$. Weakly magnetic, possibly due to microscopic inclusions of a magnetic mineral. Uniaxial (+); $N_O = 1.859$, $N_E = 1.876$; intense absorption; $E \gg O$. O , wine-red; E , dark red to black. From the *Pennsylvania mine, San Antonio Valley, Santa Clara Co., CA*, associated with sonolite, hausmannite, and gageite, in chert. RG

7.3.1.3 Örebroite $Mn_6(Fe,Sb)_2Si_2(O,OH)_{14}$

Named in 1986 for the locality. *HEX P3*. $a = 8.183$, $c = 4.756$, $Z = 1$, $D = 4.77$. *AM 71:1522(1986)*. *40-486*: 4.08₃ 3.94₂ 3.10₁₀ 2.84₅ 2.68₄ 2.33₇ 1.78₉ 1.55₅. Massive, polycrystalline. Dark brown, reddish-brown streak, vitreous luster. No cleavage, irregular fracture. $H = 4$. Slightly magnetic, possibly due to inclusions of a magnetic mineral. Uniaxial (+); $N_O = 1.857$, $N_E = 1.875$. From *Sjögruvan, Grythyttan, Örebro, Sweden*, associated with calcite or with hausmannite and dolomite. RG

7.3.2.1 Grossite $CaAl_4O_7$

Named in 1994 for Shulamit Gross (b.1923), Israeli mineralogist, Geological Survey of Israel, who first found the mineral. *MON C2/c*. $a = 12.94$, $b = 8.910$, $c = 5.446$, $\beta = 107.0^\circ$, $Z = 4$, $D = 2.88$. *EJM 6:591(1994)*. *PD*: 4.46₄ 3.61₁ 3.51₁₀ 2.88₁ 2.60₄ 2.54₁ 2.44₂ 1.764₂. Prismatic, subhedral, microscopic crystals. White to colorless, white streak, vitreous luster, transparent. Biaxial (+); $N_x = 1.618$, $N_y = 1.618$, $N_z = 1.652$; $2V = 12^\circ$. Nonfluorescent. Meteoritic grossite is related to high-temperature processes in the early solar system and has been found in certain meteorites associated with Ca,Al-rich inclusions (*Acfer-182; ALH 85085, etc.*), where it may be a major component, with perovskite, hibonite, melilite, and spinel. Also formed by high-temperature metamorphism of some limestones, associated with brownmillerite and mayenite in the *Hatruhim formation of Israel*. RG *AM 80:630(1995)*.

7.4.1.1 Hibonite $(Ca,Ce)(Al,Ti,Mg)_{12}O_{19}$

Named in 1956 for Paul Hibon, French prospector, who discovered the mineral. *HEX P6₃/mmc*. $a = 5.61$, $c = 22.16$, $Z = 2$, $D = 3.84$. Structure: *NJMA 109:192(1968)*. *38-470(syn)*: 2.78₅ 2.62₉ 2.48₁₀ 2.29₃ 2.11₈ 2.01₆ 1.57₃ 1.534₆. Hexagonal prismatic crystals, flattened {0001}, or with steep pyramids; {0001} face commonly divided into six sectors. Black to brownish black. Cleavage {0001}, easy, parting on {10 $\bar{1}$ 0}, subconchoidal fracture. $H = 7\frac{1}{2}$ -8. $G = 3.84$. Slowly soluble in mixed 1:1 $H_2SO_4 + H_3PO_4$. Uniaxial (-); $N_O = 1.807$, $N_E = 1.79$. O , gray, E , gray. *Mrassu R., Siberia, Russia(1)*. *Esiva, Andranondambo, Madagascar(1)*, in alluvial deposits; also at *Andakato*

and Besakoa, in metamorphosed limestone rich in calcic plagioclase, with corundum, spinel, and thorianite. In the Allende and some other meteorites. RG *AM* 42:119(1957); *GCA* 44:685(1980), 46:575(1982).

7.4.1.2 Yimengite $K(\text{Cr}, \text{Ti}, \text{Fe}, \text{Mg})_{12}\text{O}_{19}$

Named in 1983 for the locality. HEX $P6_3/mmc$. $a = 5.875$, $c = 22.940$, $Z = 2$, $D = 4.35$. *AM* 70:218(1985): 37-480: 2.78₉ 2.63₁₀ 2.45₄ 2.24₅ 2.13₄ 1.67₆ 1.62₉ 1.48₈. Irregular grains, platy to tabular {0001}. Black, brown streak, metallic luster. Cleavage {0001}, perfect; {1011}, fair. $H = 4$. $G = 4.34$. Insoluble in dilute mineral acids. In RL, gray to grayish white, weakly pleochroic. $R = 12.7$, 17.7 (402 nm); 11.3, 18.2 (438 nm); 15.1, 16.0 (498 nm); 15.7, 16.2 (546 nm); 13.0, 16.5 (589 nm); 13.5, 16.7 (624 nm); 12.6, 15.5 (641 nm). *Yimengshan area, Shandong, China*, in kimberlite dikes, with olivine, phlogopite, pyrope, chromite, ilmenite, chrome-diopside, apatite, zircon, moissanite, and perovskite. Guaniamo, Bolivar Prov., Venezuela, in a kimberlite sill. RG *MM* 53:305(1989).

7.4.1.3 Hawthorneite $\text{Ba}(\text{Ti}_3\text{Cr}_4\text{Fe}_2^{2+}\text{Fe}_3^{3+}\text{Mg})\text{O}_{19}$

Named in 1989 for John Barry Hawthorne (b.1934), chief geologist, DeBeers Consolidated Mines, South Africa; an expert on kimberlites and diamonds. HEX $P6_3/mmc$. $a = 5.871$, $c = 23.06$, $Z = 2$, $D = 5.02$. *PD*: 4.65₂ 3.84₂ 2.94₄ 2.77₈ 2.62₁₀ 2.41₅ 2.23₃ 2.12₂. Minute grains. Black, metallic luster. Uniaxial (-); $N_{\text{O calc}} = 2.39$, $N_{\text{E calc}} = 2.33$. In RL, gray with no internal reflections, moderately bireflectant, nonpleochroic. Moderately anisotropic, brown to gray. $R = 18.3$, 17.1 (470 nm); 17.5, 16.4 (546 nm); 17.3, 16.3 (589 nm); 17.05, 16.0 (650 nm). From the *Bultfontein mine, Kimberley, Cape Prov., South Africa*, in a harzburgite xenolith, associated with lindsleyite, chromian spinel, chromian rutile, and magnesian-chromian rutile. RG *AM* 74:668(1989).

7.4.2.1 Magnetoplumbite $\text{Pb}(\text{Fe}^{3+}, \text{Mn}^{3+})_{12}\text{O}_{19}$

Named in 1925 to indicate the magnetic properties and lead content of the mineral. HEX $P6_3/mmc$. $a = 5.873$, $c = 23.007$, $Z = 2$, $D = 5.71$. *AM* 74:1186(1989). 43-666: 3.91₄ 2.97₆ 2.81₁₀ 2.65₉ 2.45₆ 2.26₅ 1.618₆ 1.487₈. Steep pyramidal crystals, doubly terminated. Gray-black, dark brown streak, metallic luster. Cleavage {0001}, perfect. $H = 6$. $G = 5.52$. Strongly magnetic. Slowly soluble in 1:1 HCl, with slight evolution of Cl_2 . In RL, gray with a brown tint; weakly anisotropic. $R = 25.8$ -24.0 (470 nm), 24.5-22.9 (546 nm), 23.7-22.2 (589 nm), 22.7-21.2 (650 nm). *P&J*:251. *Langban, Varmland, Sweden*, associated with manganophyllite and kentrolite. RG *DI*:728, *AM*: 36:512(1951), *NJMM*:141(1980).

7.5.1.1 Braunite I $3\text{Mn}_2^{3+}\text{O}_3 \cdot \text{Mn}^{2+}\text{SiO}_3$

Named in 1831 for Kammerrat Wilhelm Braun (1790-1872) of Gotha, Germany, who was active in mineralogical and geognostical matters. *TET* *I4*₁/*acd*. $a = 9.408$, $c = 18.668$, $Z = 8$, $D = 4.860$. *AM* 61:1226(1976). **Structure:** The

BRAUNITE: Mn_7SiO_{12}

The structure can be described as a three-dimensional framework of intersecting chains of Mn^{3+} octahedra, with Si (4-coordinated) and Mn^{2+} (8-coordinated) occupying channels.

underlying features of the braunite structure are two three-dimensional octahedral arrangements of cations around vacant sites. These cation arrangements must not be confused with the coordination of oxygen atoms around each of these cations. One such arrangement is referred to as the $(Mn^{2+}Mn_4^{3+}Si)$ arrangement, and the other as the (Mn_4^{3+}) arrangement. Certain Mn and Si atoms are surrounded by six each, of the $(Mn^{2+}Mn_4^{3+}Si)$ arrangements, and three other Mn atoms are surrounded by four each of the $(Mn^{2+}Mn_4^{3+}Si)$ and two of the (Mn_4^{3+}) arrangements. One-seventh of the manganese atoms are divalent, and six-sevenths are trivalent. The Mn^{2+} ions have distorted cubic coordination with the surrounding oxygens; the Mn^{3+} atoms have octahedral coordination, and the Si atoms have tetrahedral coordination. *AM 60:1098(1975)*.

41-1367: 3.49₁ 2.71₁₀ 2.36₁ 2.14₁ 1.665₁ 1.659₄ 1.420₂ 1.411₁. **Habit**: Pyramidal crystals, {011}, {131}; striated on {001}, {201} parallel to {010}; also granular, massive; twinning on {112}. **Physical properties**: Brownish black to steel gray, black to gray streak, submetallic luster. Cleavage {112}, perfect; uneven to subconchoidal fracture; brittle. $H = 6-6\frac{1}{2}$. $G = 4.8$. Weakly magnetic. **Tests**: Soluble in HCl with evolution of Cl_2 . Leaves a residue of gelatinous silica. **Chemistry**: Ba is often present, in amounts up to several percent. Some Fe substitutes for Mn. **Optics**: In RL, weakly anisotropic. $R = 22.7-21.3$ (470 nm), 21.1-19.5 (546 nm), 20.5-18.9 (589 nm), 19.7-18.4 (650 nm). *P&J:104*. **Localities**: Spiller manganese mine, NE of Mason Co., TX, as lenses in quartzite. Autlán, JAL, Mexico, in a major manganese deposit. Nombre de Dios, Panama, with pyrolusite and "psilomelane." Lang-

ban, Värmland, and Jakobsberg, Nordmark, Sweden. *Ohrenstock* and *Elgersberg*, near *Ilmenau*, *Thuringia*, *Germany*. St. Marcel, Piedmont, Italy, in fine crystals associated with piemontite. Well crystallized at Kacharwaki, Nagpur, India. Miguel Burnier, Mun. Ouro Preto, MG, Brazil. Use: An important ore of manganese. RG *DI:551*, *AM 52:20(1967)*, *CMP 49:21(1975)*, *EG 78:1111(1983)*.

7.5.1.2 Neltnerite $\text{CaMn}_6^{2+}\text{SiO}_{12}$

Named in 1982 for Louis Neltner, French geologist, a pioneer student of the geology of the High Atlas of Morocco. TET $I4_1/acd$. $a = 9.464$, $c = 18.854$, $Z = 8$, $D = 4.65$. *AM 68:282(1983)*. $35-666$: 2.73_{10} 2.36_3 2.17_3 1.67_8 1.43_6 1.085_5 1.059_4 1.056_4 . As small grains and dipyrnidal crystals. Black, submetallic luster. No cleavage, subconchoidal fracture. $H = 6$. $G = 4.63$. In RL, gray to brownish gray. Weakly anisotropic. $R = 21.3-22.3$ (470 nm), $19.2-20.2$ (546 nm), $18.5-19.5$ (589 nm), $17.7-18.7$ (650 nm). *Tachgagalt*, *Morocco*, with braunite I, braunite II, marokite, and crednerite. RG *BM 105:161(1982)*.

7.5.1.3 Braunite II $7(\text{Mn,Fe})_2\text{O}_3 \cdot \text{CaSiO}_3$

Named in 1967 as in braunite I (7.5.1.1). TET $I4_1/acd$. $a = 9.431$, $c = 37.774$, $Z = 8$, $D = 4.85$. *AM 65:756(1980)*. $41-1368$: 3.68_1 2.72_{10} 2.361_1 2.354_2 2.08_1 1.666_2 1.420_1 1.361_1 . Braunite II is compositionally distinct from braunite I and represents an ordered version of braunite I with an approximately double-size cell. Black, submetallic luster. $H = 6$. $G = 4.75$. Nonmagnetic. In RL, yellow-brown with properties like braunite. From the *Black Rock and Wessels mines*, *Kalahari Manganese district*, *Cape Prov.*, *South Africa*. *Tachgagalt*, *Anti-Atlas*, *Morocco*, with neltnerite, marokite, hausmannite, crednerite, henritermierite, gaufreyite, and calcite. Used as an ore of manganese. RG *EG 78:1111(1983)*, *AM 71:1543(1986)*.

7.5.1.4 Abswurbachite $\text{Cu}^{2+}\text{Mn}_6^{3+}[\text{O}_8/\text{SiO}_4]$

Named in 1991 for Irmgard Abs-Wurbach (b.1938), German crystal chemist, who studied braunite. TET $I4_1/acd$. $a = 9.406$, $c = 18.546$, $Z = 8$, $D = 4.96$. *NJMA 163:117(1991)*. $41-576$: 3.48_1 2.70_{10} 2.35_2 2.13_2 1.663_1 1.651_3 1.416_1 1.402_1 . Minute fibrous to prismatic, also equant, grains. Black, brownish-black streak, metallic luster. Brittle. $\text{VHN}_{25} = 920$. In RL, gray, with weak anisotropy, no internal reflections, nonpleochroic. $R = 20.8-21.2$ (470 nm), $19.6-20.0$ (546 nm), $19.2-19.7$ (589 nm), $18.7-19.2$ (650 nm). *Mount Ochi*, near *Karystos*, *Evvia*, *Greece*, in low-grade, high-pressure metamorphosed quartzites, with tenorite, shattuckite, piemontite, sursassite, ardenite, rutile, and hollandite. RG *AM 77:670(1992)*.

7.5.2.1 Painite $\text{CaZrB}(\text{Al}_9\text{O}_{18})$

Named in 1957 for A. C. D. Pain (d.1971), British gem collector, who first noticed the mineral. HEX $P6_3$. $a = 8.715$, $c = 8.472$, $Z = 2$, $D = 3.996$. *AM*

61:88(1976). 10-405: 7.63₅ 5.76₁₀ 3.70₈ 2.52₁₀ 2.37₈ 2.01₈ 1.73₇ 1.42₇. Hexagonal prismatic crystal, pseudo-orthorhombic. Garnet red, vitreous luster. H = 8. G = 4.01. Insoluble in acids. Uniaxial (-); $N_O = 1.816$, $N_E = 1.787$. O, pale brownish orange; E, ruby red. Near Franklin, NJ, in marble. From *Ohngaing, Mogok district, Sagaing, Myanmar*, where a single crystal was recovered in 1952 from gem concentrates. Additional crystals have subsequently been found there. RG *MM* 31:420(1957), 42:518(1978), 50:267(1986); *AM* 42:580(1957).

7.5.3.1 Birnessite $(\text{Na, Ca, K})_x(\text{Mn}^{4+}, \text{Mn}^{3+})_2\text{O}_4 \cdot 1.5\text{H}_2\text{O}$

Named in 1956 for the locality. *MON* *C2/m*. $a = 5.174$, $b = 2.850$, $c = 7.336$, $\beta = 103.18^\circ$, $Z = 1$, D probably = 3.4. *AM* 75:477(1990). 43-1456(syn): 7.14₁₀ 3.57₃ 2.52₁ 2.43₁ 2.22₁ 2.15₁ 1.823₁ 1.476₁. Massive, earthy, as pseudomorphs. Dark brown to black. H = 1.5. G = 3.0. Uniaxial (-); $N_O \sim 1.73$, $N_E \sim 1.69$. In RL, grayish white, strongly pleochroic and anisotropic. R = 26.1–10.5 (470 nm), 23.1–9.8 (546 nm), 21.9–9.6 (589 nm), 20.8–9.4 (650 nm). *P&J:90*. Found in a wide variety of geological settings. It is a major Mn phase in many soils; an important component in desert varnishes; common in manganese nodules from the ocean floor; and it is also found as an alteration product of Mn-rich ore deposits. Franklin, Sussex Co., NJ, as a weathering product of franklinite. Cummington, MA, as an oxidation product of rhodinite, rhodochrosite, tephroite, spessartine, alleghanyite, and manganoan dolomite. Material abundant at Mt. St.-Hilaire, QUE, Canada, often pseudomorphous after serandite, has erroneously been called birnessite, but is something different as it contains no Na. *Birness, Aberdeenshire, Scotland*, as grains <8 mm cementing gravel in a road cut 30 km N of Aberdeen. RG *MM* 31:283(1956); *AM* 45:871(1960), 69:814(1984); *JGSK* 16:105(1980).

7.5.4.1 Zenzénite $\text{Pb}_3(\text{Fe}^{3+}, \text{Mn}^{3+})_4\text{Mn}_3^{4+}\text{O}_{15}$

Named in 1991 for Nils Zenzen (1883–1959), Swedish mineralogist and historian of science. *HEX* *P6₃/mcm*. $a = 10.008$, $c = 13.672$, $Z = 4$, $D = 6.83$. *CM* 29:350(1991). 45-1345: 3.42₅ 3.18₈ 2.83₇ 2.66₁₀ 2.37₆ 2.10₄ 2.07₃ 1.687₈. Subhedral to euhedral grains, tabular {0001}. Black. Cleavage {0001}, distinct. H = 5½. Weakly paramagnetic. In RL, bright white with no internal reflections, nonpleochroic. Weak bireflectance. R = 31.0–26.1 (470 nm), 29.5–25.0 (546 nm), 28.5–24.4 (589 nm), 27.3–23.5 (650 nm). From *Langban, Varmland, Sweden*, in carbonate-phyllosilicate skarn, associated with magnesioferrite, jacobsonite, hausmannite, and dolomite. RG *CM* 29:347(1991).

7.6.1.1 Cesàrolite $\text{PbH}_2\text{Mn}_3^{4+}\text{O}_8$

Named in 1920 for Giuseppe R. P. Cesàro (1849–1939), professor of mineralogy and crystallography, University of Liège, Belgium. *HEX-R* Space group unknown. $a = 2.811$, $c = 20.386$. *IMA ABST:334(1994)*. 14-489: 3.40₄ 3.21₁ 2.27₁ 2.19₁₀ 2.09₈ 1.76₅ 1.56₅ 1.41₃. Friable masses, botryoidal crusts. Steel gray, submetallic to dull luster. H = 4½. G = 5.29. Soluble in HCl with evolu-

tion of Cl_2 . From *Sidi Amor Ben Salem, Tunisia*, in cavities in galena. RG *DI:744, GSAM 85:206(1962), CE 27:258(1967)*.

7.6.2.1 Bartelkeite $\text{PbFe}^{2+}\text{Ge}_3\text{O}_8$

Named in 1981 for Wolfgang Bartelke, mineral collector and specialist in Tsumeb minerals. MON $P2_1$ or $P2_1/m$. $a = 5.431$, $b = 13.689$, $c = 5.892$, $\beta = 111.48^\circ$, $Z = 2$, $D = 4.97$. *AM 67:413(1982)*. $35\text{--}508$: 5.08_5 4.74_6 4.42_8 3.50_5 2.91_{10} 2.87_8 2.75_7 2.20_7 . Crystals tabular {101} or acicular [101]. Colorless or pale green. Cleavage {101}, distinct. $H = 4$. Soluble in hot HCl. Biaxial (-); $Z = b$; $N_x = 1.885$, $N_y = 1.910$, $N_z = 1.913$; $2V = \sim 35^\circ$; $r < v$. *Tsumeb, Namibia*, in primary ore, in cavities containing germanite, renierite, tennantite, and galena. RG *CE 40:201(1981)*.

7.6.3.1 Kamiokite $\text{Fe}_2^{3+}\text{Mo}_3^{4+}\text{O}_8$

Named in 1985 for the locality. HEX $P6_3mc$. $a = 5.782$, $c = 10.053$, $Z = 2$, $D = 6.02$. *MJJ 12:393(1985)*. Structure: *AC(C) 42:9(1986)*. $36\text{--}526(\text{syn})$: 5.02_{10} 3.54_{10} 2.78_3 2.50_8 2.43_8 2.00_4 1.65_3 1.57_4 . Minute euhedral grains, thick hexagonal crystals. Black, black streak, metallic to submetallic luster. Cleavage {0001}, perfect; even fracture. $H = 4\frac{1}{2}$. $G = 5.96$. In RL, gray, no internal reflections, distinctly pleochroic, strongly anisotropic. $R = 24.0\text{--}17.6$ (470 nm), $22.9\text{--}16.5$ (546 nm), $22.4\text{--}16.0$ (589 nm), $22.3\text{--}15.8$ (650 nm). *P&J:219*. From the Mohawk and Ahmeek mines, MI, as inclusions in domeykite and algonite. *Kamioka mine, Gifu Pref., Japan*, in quartz veinlets containing molybdenite, K-feldspar, fluorite, ilmenite, and scheelite. RG *AM 68:1033(1983), 73:191(1988); TMPM 35:67(1986)*.

7.7.1.1 Pseudobrookite $\text{Fe}_2^{3+}\text{TiO}_5$

Named in 1878 from the Greek *pseudo*, false, and *brookite*, because the mineral at one time was mistakenly thought to be brookite. ORTH $Bbmm$. $a = 9.797$, $b = 9.981$, $c = 3.730$, $Z = 4$, $D = 4.36$. *ZK 73:97(1930)*. Structure: *SR 51A:208(1984)*. $41\text{--}1432(\text{syn})$: 4.90_4 , 3.49_{10} 2.75_8 2.46_2 2.41_2 1.97_2 1.87_2 1.54_2 . Usually tabular {100} and elongated [001], sometimes long prismatic [001] or acicular. Black, dark reddish brown; reddish brown to ochre-yellow streak; metallic to adamantine luster, greasy on fracture surfaces. Cleavage {010}, distinct; uneven to subconchoidal fracture. $H = 6$. $G = 4.39$. Soluble in hot 1:1 HCl or H_2SO_4 , decomposed by HF, infusible. Biaxial (+); $XYZ = bca$; $N_x = 2.38$, $N_y = 2.39$, $N_z = 2.42$ (Li); $2V = 50^\circ$; $r < v$; absorption, in brown, $X < Y < Z$. Usually formed as a pneumatolytic or fumarolic product in volcanic igneous rocks, or as a reaction product of xenoliths in such rocks; usually associated with tridymite, hematite, magnetite, sanidine, apatite, and rutile. At Topax Mt. and elsewhere in the Thomas Range, Juab Co., UT(I), in lithophysae in rhyolite, with topaz, bixbyite, hematite, red beryl, and ilmenite. Red Cone, Crater Lake, OR(I), in cavities in basalt with hypersthene and apatite. In France, in cavities in andesite and trachyte at Riveau Grande, Mt. Doré, Puy de Dôme, with tridymite, hypersthene, and sanidine. Hessen-

brucker Hammer, Hessen, Germany, as a product of fumarolic action on basalt. On lava from the 1872 eruption of Vesuvius, Italy, with hematite, magnetite, and sellaite. In *Uroi*, *Transylvania, Romania*(1), in cavities in andesite, with tridymite, hypersthene, and garnet. As a pneumatolytic product on basalt on the Island of Réunion, Indian Ocean. RG *DI:736, GSAM 85:204(1962), AM 73:1377(1988)*.

7.7.1.2 Armalcolite $\text{FeMgTi}_4\text{O}_{10}$

Named in 1970 for Neil A. Armstrong (b.1930), Edwin E. Aldrin, Jr. (b.1930), and Michael Collins (b.1930), the three astronauts on whose voyage to the moon the samples containing the mineral were collected. ORTH *Bbmm*. $a = 9.770$, $b = 9.983$, $c = 3.739$, $Z = 2$, $D = 4.00$. *AM 62:913(1977)*. $41-1444(\text{syn})$: 4.89_4 3.49_{10} 2.75_7 2.46_2 2.41_2 1.97_2 1.87_3 1.55_2 . Small grains, commonly with rectangular outline. In RL, gray, with no internal reflections, pleochroic, strongly anisotropic, pale gray to dark bluish gray. In armalcolite the middle range of a binary solid-solution series has been named; it is more usual to name the end members. In synthetic material a complete series is known to exist between FeTi_2O_5 (pseudobrookite) and MgTi_2O_5 . From *Tranquillity Base, Moon*, in rocks collected on the *Apollo XI* mission, associated with ilmenite. In lamproites from Smoky Butte, Garfield Co., MT. Kuanamski region, Yakutia, Russia, in picrite porphyrites. Jagersfontein mine, Orange Free State, South Africa, in kimberlite, associated with olivine, perovskite, ilmenite, and mathiasite. 7.7.2.1 Berdesinskiite $\text{V}_2^{3+}\text{TiO}_5$

Named in 1981 for Waldemar Berdesinski (1911–1990), German mineralogist, University of Heidelberg. MON *P2/c* or *Pc*. $a = 10.11$, $b = 5.084$, $c = 7.03$, $\beta = 111.47^\circ$, $Z = 4$, $D = 4.536$. *AM 67:1074(1982)*. $37-463$: 4.72_8 2.90_{10} 2.68_{10} 2.54_8 2.45_{10} 1.73_{10} 1.65_{10} 1.45_{10} . Minute grains. Black, metallic luster. $H = 6-6\frac{1}{2}$. In RL, reddish brown to yellow-brown, weakly pleochroic and anisotropic. $R = 18.1-18.7$ (470 nm), $19.6-20.5$ (546 nm), $20.1-21.2$ (589 nm), $20.6-21.6$ (650 nm). *Lasamba Hill, Kwale district, Voi, Kenya*, in a kornerupine deposit in weathered gneiss, associated with schreyerite, tourmaline, and kornerupine. RG *NJMM:110(1983), AM 68:1038(1983)*.

7.8.1.1 Todorokite $(\text{Na,Ca,K})_x(\text{Mn}^{4+}, \text{Mn}^{3+})_6\text{O}_{12} \cdot 3-4.5\text{H}_2\text{O}$

Named in 1934 for the locality. MON *P2/m*. $a = 9.764$, $b = 2.842$, $c = 9.551$, $\beta = 94.14^\circ$, $Z = 1$, $D = 3.65$. *AM 73:861(1988)*. $38-475$: 9.56_{10} 4.86_2 4.77_2 2.44_2 2.40_4 2.39_3 2.355_2 2.345_2 . **Habit:** Spongy banded and reniform aggregates composed of minute lathlike crystals. **Structure:** Todorokite consists predominantly of triple chains of edge-sharing (Mn^{4+}O_6) octahedra that corner-share to form large roughly square tunnels parallel to b that measure three octahedra on a side. These tunnels accommodate water molecules and cations (Na,

Ca, K, etc.). The octahedra at the edges of the triple chains are larger than those in the middle and therefore likely accommodate the larger cations (i.e., Mg, Mn^{3+} , Cu^{2+} , Co, Ni, etc.). This structure is similar to that of hollandite and romanechite, but with larger tunnels. *AM* 73:861(1988), 68:972(1983). **Physical properties:** Black-brown, metallic luster. Cleavages {100} and {010}, perfect. $H = 1\frac{1}{2}$. $G = 3.67$. **Tests:** Soluble in HCl with evolution of Cl_2 . **Optics:** $Y = b$; $N_s > 1.74$; brown; absorption $Z > X$. In RL, gray-white, very strongly pleochroic and anisotropic. $R = 21.3\text{--}11.4$ (470 nm), $17.7\text{--}9.9$ (546 nm), $16.6\text{--}9.4$ (589 nm), $15.7\text{--}9.0$ (650 nm). *P&J*:371. **Occurrence:** Although todorokite has been demonstrated to be a common product of oxidation and leaching of primary manganese carbonate and silicate minerals, its major occurrence is as the dominant Mn^{4+} phase of deep-sea ferromanganese nodules. **Localities:** Sterling Hill mine, Sussex Co., NJ. Charco Rodondo and many other mines, Oriente Province, Cuba, with pyrolusite, cryptomelane, manganite, and "psilomelane"; Romaneche, France; Farragudo, Portugal; Huttenberg, Carinthia, Austria; *Todoroki mine, Hokkaido, Japan*, as an alteration product of inesite and rhodochrosite; in Australia from the Gladstone area, Q, and the Kalgoorlie and Pilbara areas, WA. N'Chwaning mine and other mines in the Kuruman manganese belt, northern Cape Prov., South Africa. **Uses:** An ore of manganese. As a component of deep-sea manganese nodules, todorokite is not only significant as a potential source of manganese, but also as a source of Cu, Co, and Ni, which are taken up in appreciable

TODOROKITE: $\text{NaMn}_6\text{O}_{12} \cdot 3\text{H}_2\text{O}$ (variable)

Octahedral chains of Mn octahedra are linked sideways to form large channels. Water molecules and Na and other large cations occupy the centers of the channels. The channel atoms are disordered over the positions shown.

amounts up to several percent in some of these nodules. RG *DI:573; AM 45:1167(1960), 64:1333(1979); MM 36:757(1968), 50:336(1986)*.

7.8.1.2 Woodruffite $(\text{Zn}, \text{Mn}^{2+})_2 \text{Mn}_5^{4+} \text{O}_{12} \cdot 4\text{H}_2\text{O}$

Named in 1953 for Samuel Woodruff, late-nineteenth-century miner and mineral collector at Franklin, who collected and preserved many of the finest specimens found at that locality. TET Space group unknown. $a = 8.42$, $c = 9.28$, $Z = 2$, $D = 3.98$. *MM 33:507(1963)*. $16\text{-}338$: 9.34_5 4.66_{10} 4.08_3 2.66_6 2.48_6 1.86_4 1.69_4 1.48_5 . Botryoidal masses, also pulverulent. Iron-black, chocolate brown when pulverulent; brownish streak; dull luster. Smooth conchoidal fracture. $H = 4\frac{1}{2}$. $G = 4.01$. *Sterling Hill mine, Ogdensburg, Sussex Co., NJ*, in oxidized material derived from the orebody outcrop. Sandur mine, Mysore, India, associated with cryptomelane, lithiophorite, pyrolusite, ramsdellite, jacobsonite, manganite, and braunite. RG *AM 38:761(1953)*.

7.8.2.1 Chalcophanite $(\text{Zn}, \text{Fe}^{2+}) \text{Mn}_3^{4+} \text{O}_7 \cdot 3\text{H}_2\text{O}$

Named in 1875 from the Greek for *copper* and *to appear*, in allusion to the change in color on ignition. HEX-R *R3*. $a = 7.533$, $c = 20.794$, $Z = 6$, $D = 3.86$. *AM 73:1401(1988)*. Structure: *AC 8:165(1955)*. $45\text{-}1320$: 6.93_{10} 4.07_3 3.51_2 2.55_2 2.45_2 2.23_4 , 1.897_2 1.590_2 . Crystals tabular {0001}, sometimes with {1011} equally developed giving an equant pseudo-octahedral habit. Commonly as drusy, botryoidal, or stalactitic crusts; massive; granular; or platy; fibrous. Iron black to bluish black, chocolate-brown streak, metallic luster. Cleavage {0001}, perfect; flexible in thin plates. $H = 2\frac{1}{2}$. $G = 4.00$. Uniaxial (-); $N_0 \gg 2.72$, $N_E \sim 2.72$. O, nearly opaque; E, deep red. In RL, white, with deep-red internal reflections, very strongly pleochroic and extremely highly anisotropic. $R = 33.0\text{-}10.2$ (470 nm), $27.7\text{-}9.6$ (546 nm), $26.0\text{-}9.3$ (589 nm), $24.6\text{-}9.1$ (650 nm). *P&J:117*. A common weathering product in many Mn-bearing base metal deposits. *Sterling Hill mine, Ogdensburg, NJ; Bisbee, AZ; Wolfstone mine, Leadville, CO*, with limonite, smithsonite, and hemimorphite. Groot Eyelandt, NT; Buchan, VIC; and Kambalda, WA, Australia. RG *DI:739; GSAM 85:206(1962); MM 44:109(1981), 49:752(1985)*.

7.8.2.2 Aurorite $(\text{Mn}^{2+}, \text{Ag}, \text{Ca}) \text{Mn}_3^{4+} \text{O}_7 \cdot 3\text{H}_2\text{O}$

Named in 1967 for the locality. TRIC *P1*. $a = 7.53$, $b = 7.53$, $c = 8.20$, $\alpha = 90^\circ$, $\beta = 117.20^\circ$, $\gamma = 120^\circ$, $Z = 2$, $D = 3.88$. $19\text{-}88$: 6.94_{10} 4.06_5 3.46_7 2.54_5 2.45_4 2.23_5 1.56_5 1.43_5 . Small irregular masses and platy or scaly grains. $H < 3$. In RL, white to gray, with no internal reflections and strongly pleochroic; strongly anisotropic, cream white to medium gray. *Aurora mine, Treasure Hill, Hamilton, NV*, associated with todorokite, cryptomelane, pyrolusite, quartz, and manganian calcite. RG *EG 62:186(1967), AM 52:1581(1967)*.

7.8.2.3 Jianshuiite $(\text{Mg}, \text{Mn})\text{Mn}_3^{4+}\text{O}_7 \cdot 3\text{H}_2\text{O}$

Named in 1992 for the locality. TRIC *P1*. $a = 7.534$, $b = 7.525$, $c = 8.204$, $\alpha = 89.7^\circ$, $\beta = 7.53^\circ$, $\gamma = 120.0^\circ$, $Z = 2$, $D = 3.598$. *AM* 79:185(1994). *PD*: 6.97₁₀ 5.54₁ 4.09₁ 3.48₁ 2.45₁ 2.23₂. Massive; as soft, porous aggregates of microscopic grains. Brown to brownish black, opaque. Soft. $G = 3.60$. In RL, grayish white, distinctly anisotropic, brown internal reflectance. $R = 23.0$ (470 nm), 19.9 (546 nm), 19.1 (589 nm), 18.6 (650 nm). A hypogene mineral associated with other hydrated manganese oxides in Mn ore near Lu village, Jianshui Co., Yunnan, China. *RG* *AMS* 12:69(1992).

7.8.2.4 Ernie nickelite $\text{NiMn}_2^{4+}\text{O}_7 \cdot 3\text{H}_2\text{O}$

Named in 1994 for Ernest (Ernie) Henry Nickel (b.1925), Canadian–Australian mineralogist, CSIRO (Commonwealth Scientific and Industrial Research Organization) and IMA (International Mineralogical Association). HEX-R *R3* or *R3*. $a = 7.514$, $c = 20.52$, $Z = 6$, $D = 3.83$. *CM* 32:333(1994). *PD*: 6.84₁₀ 4.01₂ 3.44₁ 2.75₁ 2.53₁ 2.22₃ 1.884₂ 1.575₂. Crystallizes in very small, almost circular, thin plates up to 0.5 mm × 0.5 mm × 0.02 mm, and rosettes of plates. Opaque, nearly black, with a red-brown cast; yellow-brown streak; submetallic to vitreous luster. Cleavage {001}, perfect; splintery fracture; brittle. $H = 2$. $G = 3.84$. Uniaxial (-); $N_0 > 2.00$ m, $N_E = 1.97$. Minor Mg and Co substitute for Ni in the formula. Found in cavities in chalcedony in a laterized dunite, associated with goethite, magnesite, nimite, nontronite at the *SM7 open pit N of Siberia, Kalgoorlie district, WA, Australia*. *RG*

7.8.3.1 Lazarenkoite $\text{CaFe}^{3+}\text{As}_3^{3+}\text{O}_7 \cdot 3\text{H}_2\text{O}$

Named in 1981 for Eugeni Konstantinovich Lazarenko (1912–1979), mineralogist; academician, Academy of Science, Ukraine. ORTH Space group unknown. $a = 21.80$, $b = 12.64$, $c = 8.40$, $Z = 10$, $D = 3.59$. 35–669: 11.2₉ 8.40₁₀ 6.55₈ 4.66₉ 3.31₄ 3.20₄ 3.14₄ 3.01₃. Fibrous crystal incrustations. Bright orange, resinous/silky luster. $H = 1$. $G = 3.45$. IR data show negative for $(\text{As}^{5+}\text{O}_4)^{3-}$ or $(\text{As}^{3+}\text{O}_3)^{3-}$. Insoluble in water, readily soluble in acids. Biaxial(-); $N_x = 1.820$, $N_y = 1.920$, $N_z = 1.955$; $2V = 30^\circ$; positive elongation. X, pale yellow; Y, pale brown; Z, rose brown. *Western Siberia, Russia*, as an oxidation product on skutterudite–loellingite ores. *RG* *MZ* 3(3):92(1981), *AM* 67:415(1982), *CA* 100:37241p(1984).

CRYPTOMELANE GROUP

The cryptomelane group of minerals consists of hard black, fine-grained, and visually indistinguishable minerals corresponding to the formula

where

A = Ba, K, Pb, or (Na,K)

B₁ = Mn⁴⁺

B₂ = Mn²⁺

and the structure is that of hollandite, monoclinic but pseudotetragonal. The structure is a distinctive tunnel structure consisting of a framework of octahedrally coordinated metal ions. The octahedra are lined by edge sharing to form double columns parallel to the tunnel axis. The double strings in turn share corners to form a three-dimensional framework containing square tunnels which run through the structure. The tunnels, two octahedra wide, accommodate the K, Na, Ba, and Pb ions and H₂O when present. *AC(B)* 36:1056(1982).

CRYPTOMELANE GROUP

Mineral	Formula	Space Group	Space				
			a	b	c	β	
Hollandite	Ba(Mn ⁴⁺ , Mn ²⁺) ₈ O ₁₆	<i>I2/m</i>	10.026	2.878	9.729	91.03°	7.9.1.1
Cryptomelane	K(Mn ⁴⁺ , Mn ²⁺) ₈ O ₁₆	<i>I2/m</i>	9.956	2.871	9.706	90.95°	7.9.1.2
Manjiroite*	(Na, K)(Mn ⁴⁺ , Mn ²⁺) ₈ O ₁₆	<i>I4/m</i>	9.916		2.864		7.9.1.3
Coronadite	Pb(Mn ⁴⁺ , Mn ²⁺) ₈ O ₁₆	<i>I2/m</i>	9.938	2.868	9.834	90.38°	7.9.1.4

*Cell constants given for the tetragonal cell.

Notes:

1. Space group originally thought to be tetragonal, but detailed examination of powder data indicates a monoclinic cell.
2. The group constitutes a large portion of the material formerly called *psilomelane*.

7.9.1.1 Hollandite Ba(Mn⁴⁺, Mn²⁺)₈O₁₆

Named in 1906 for Thomas H. Holland (1868–1947), British geologist and director, Geological Survey of India. Cryptomelane group. MON (pseudo-TET) *I2/m*. *a* = 10.026, *b* = 2.878, *c* = 9.729, β = 91.03°, *Z* = 1, *D* = 4.83. 38-476: 4.86₂ 3.52₂ 3.46₂ 3.17₄ 3.14₉ 3.10₁₀ 3.07₃ 2.41₄. Short prismatic crystals, terminated by a flat pyramid; also massive, fibrous. Silvery gray to black, black streak, metallic to shining luster. Prismatic, distinct cleavage; brittle. *H* = 6 on crystal faces, less on fracture surfaces. *G* = 4.95. In RL, white, weakly pleochroic, strongly anisotropic. *R* = 36.2–30.1 (440 nm), 32.8–27.6 (546 nm), 31.2–26.5 (589 nm), 29.8–25.7 (650 nm). *P&J*:204. Ultevis, Sweden. *Kajlidongri, Jhabua state, India*, as rough crystals in quartz veins traversing a manganese orebody; also at Sitapar, Chhindwara district, and elsewhere in India. Ambatomiady, Madagascar. Nuba Mt., Kordofan Province, Sudan, intergrown with pyrolusite. *RG DI:743, AM 64:1199(1979), NJMM:30(1986), MJJ 13:119(1986)*.

7.9.1.2 Cryptomelane K(Mn⁴⁺, Mn²⁺)₈O₁₆

Named in 1942 from the Greek for *hidden* and *black*, as the identity of this common black manganese mineral had been lost within the group of such

minerals. Cryptomelane group. MON (pseudo-TET) $I2/m$. $a = 9.956$, $b = 2.871$, $c = 9.706$, $\beta = 90.95^\circ$, $Z = 1$, $D = 4.398$. *AC(B)* 38:1056(1982). 44-1386: 7.01₃ 6.89₃ 4.85₃ 3.12₅ 3.09₅ 2.41₄ 2.40₁₀ 2.39₃. Botryoidal, massive, fine grained to radial fibrous. Gray to black, submetallic to earthy luster. $G = 4.3$. In RL, grayish white. R values close to those for hollandite. Cryptomelane is the commonest of the hard, black, fine-grained manganese oxides formerly called "psilomelane"; a few of many localities are: Mena, AR; Tombstone, Cochise Co., AZ; Deming, NM; Philipsburg, MT; *Chindwara, India*. *RG AM* 27:607(1942), *MM* 32:166(1959), *CMP* 55:191(1976).

CRYPTOMELANE: KMn_8O_{16}

Chains of Mn octahedra link sideways to four square columns, which are linked to each other at their edges. K atoms occupy "tunnels" between the columns.

7.9.1.3 Manjiroite $(Na,K)(Mn^{4+},Mn^{2+})_8O_{16}$

Named in 1967 for Manjiro Watanabe (1891–1980), Japanese mining geologist and professor, Tohoku University. Cryptomelane group. TET $I4/m$. $a = 9.916$, $c = 2.864$, $Z = 1$, $D = 4.41$. *AM* 53:2103(1968). 21-1153: 7.02₁₀ 4.94₈ 3.14₉ 2.41₁₀ 2.16₇ 1.84₅ 1.55₅ 1.43₄. Compact masses. Dark brownish gray, brownish-black streak, dull luster. No cleavage, conchoidal fracture. VHN = 181. $G = 4.29$. In RL, anisotropic, weakly pleochroic. *Kohare mine, Iwate Pref., Japan*, and in several other nearby deposits, with pyrolusite, nsutite, birnessite, cryptomelane, and goethite. *RG*.

7.9.1.4 Coronadite $\text{Pb}(\text{Mn}^{4+}, \text{Mn}^{2+})_8\text{O}_{16}$

Named in 1904 for Francisco Vasquez de Coronado (ca. 1500-1554), Spanish explorer of the American southwest, and for the locality, the Coronado vein. Cryptomelane group. MON (pseudo-TET) ($I2/m$. $a = 9.938$, $b = 2.868$, $c = 9.834$, $\beta = 90.38^\circ$, $Z = 1$, $D = 5.35$. *AM 74:913(1989)*. 41-596: 6.99₁ 3.49₃ 3.12₁₀ 2.40₂ 2.21₂ 2.16₁ 1.837₁ 1.548₁. Massive, radial fibrous. Dark gray to black, brownish-black streak, submetallic to dull luster. $H = 4\frac{1}{2}$ -5. $G = 5.44$. In RL, white, strongly anisotropic. *Horse Shoe Shaft, Coronado vein, Clifton-Morenci district, AZ; Bou Tazoult, Imini, Morocco. Broken Hill, NSW, Australia. RG AM 27:48(1942), DI:742.*

7.9.2.1 Romanechite $(\text{Ba}, \text{H}_2\text{O})(\text{Mn}^{4+}, \text{Mn}^{3+})_5\text{O}_{10}$

Named in 1910 for the locality at Romaneche, Saône-et-Loire, France. Synonym: "psilomelane." *Psilomelane* is from the Greek for *smooth* and *black*, in allusion to its appearance. *Psilomelane* was abandoned as the name of a specific mineral in the 1970s by decision of the IMA Commission on New Minerals and New Mineral Names. The reason was that since the term was introduced in 1827 to refer to a hard black manganese oxide mineral from Schneeberg, Saxony, it was subsequently applied to all such minerals, which by their nature are difficult to distinguish from each other. It is now known that these minerals constitute a group of six or more distinct species. In 1910, Lacroix proposed the name *romanechite* for a mineral identical to the Schneeberg material but from Romaneche, France, and this name has been used in France since that time. It was felt that the name *psilomelane* has been used for so many different minerals that it has ceased to be a well-defined term. Therefore, romanechite will be used in its stead for the mineral $(\text{Ba}, \text{H}_2\text{O})_2\text{Mn}_5\text{O}_{10}$, although the type locality for this mineral continues to be its original source (under a different name) at Schneeberg. *Psilomelane* will probably continue to be used as a convenient term for hard black manganese minerals whose true identity has not been established. MON $C2/m$. $a = 13.929$, $b = 2.846$, $c = 9.678$, $\beta = 92.65^\circ$, $Z = 2$, $D = 4.74$. *AM 73:1155(1988)*. 14-627: 6.96₆ 3.48₆ 2.88₄ 2.41₁₀ 2.37₅ 2.26₄ 2.19₉ 1.824₄. Massive, often botryoidal; also earthy and pulverulent. Iron black to gray; brownish-black to black streak, shining; submetallic to dull luster. $H = 5$ -6. $G = 4.71$. In RL, gray-white, pleochroic, moderately reflective, strongly anisotropic. $R = 35.0$ -28.0 (470 nm), 32.0-26.0 (546 nm), 30.3-25.1 (589 nm), 28.8-24.1 (650 nm). *P&J:328,308*. Mayfield prospect, Chispa, Jeff Davis Co., TX; Hoggett manganese group, Hidalgo Co., NM; Sodaville, NV; Tolbard mine, Paymaster district, Imperial Co., CA. Talamantes mine, Parral, CHIH, Mexico. Restormel mine, Lostwithiel, Cornwall, England; *Romaneche-Thorins*, near *Maçon, Saône-et-Loire, France; Schneeberg, Saxony, Germany; Tekrasni*, Singhbhum district, Central Prov., India; Pilbara district, Australia. *RG DI:668, AM 45:176(1960), MA 87:3126(1987), IANS:68(1983).*

7.9.3.1 Freudenbergitte $\text{Na}_2\text{Fe}_2^{2+}\text{Ti}_6\text{O}_{16}$

Named in 1961 for Wilhelm Freudenberg (b.1881), German geologist, who studied the rocks of Odenwald, Germany, where the mineral was found. MON *C2/m*. $a = 12.267$, $b = 3.823$, $c = 6.483$, $\beta = 107.10^\circ$, $Z = 4$, $D = 3.97$. *AM 46:65(1961)*. *17-531*: 6.32_5 3.63_{10} 3.10_8 3.02_8 2.73_8 2.71_8 2.07_8 2.05_8 . Isostructural with cryptomelane group. *AC(B) 34:255(1978)*. Small grains. Blackish. Cleavage {001}, {010}, good. $G = 4.3$. *Mickelsberg, Katzenbuckel, Odenwald, Germany*, with sanidine, orthopyroxene, apatite, amphibole, and feldspar. Liberia, in garnet-clinopyroxene-plagioclase xenoliths in kimberlite, associated with rutile, ilmenite, perovskite, and titanite. This freudenbergitte is the Fe^{2+} analog, with composition $\text{Na}_2\text{Fe}^{2+}\text{Ti}_7\text{O}_{16}$. RG *NJMM:12(1961)*, *ZK 132:157(1970)*, *MA 85:788(1985)*.

7.9.4.1 Priderite $(\text{K,Ba})(\text{Ti,Fe}^{3+})_8\text{O}_{16}$

Named in 1951 for Rex Tregilgas Prider (b.1910), geologist, University of Western Australia. TET *I4/m*. $a = 10.139$, $c = 2.966$, $Z = 1$, $D = 3.92$. *MM 36:867(1968)*. *6-296*: 7.14_7 5.05_7 3.20_{10} 2.47_6 2.23_4 1.891_6 1.687_4 1.588_5 . Rectangular prismatic crystals. Black; reddish, gray streak, adamantine luster. Cleavage {001}, perfect; {010}, fair. $G = 3.86$. Weakly paramagnetic. Uniaxial (+), $N_0 > 2.10$. O, deep reddish brown; E, deep reddish brown to black. *Walgidee Hills, Fitzroy Basin, Kimberley, WA, Australia*, as a characteristic accessory of all the leucite-bearing rocks in the area. RG *AM 36:793(1951)*, *AUSM 1:298(1985)*.

7.9.4.2 Ankangite $\text{Ba}(\text{Ti,V})_8\text{O}_{16}$

Named in 1989 for the locality. TET *I4/m*. $a = 10.139$, $c = 2.961$, $Z = 1$, $D = 4.389$. *45-1393*: 3.59_3 3.21_{10} 2.48_2 2.27_2 2.23_2 1.891_1 1.690_1 1.589_2 . Prismatic crystals, showing {100} and {110}. Black, grayish-black streak, vitreous to adamantine luster. Uneven fracture, brittle. $\text{VHN}_{50} = 874$. $G = 4.44$. In RL, rosy gray-white, anisotropic, weakly to distinctly birefractant, no internal reflections. $R = 20.1$, 12.8 (589 nm). From *Ankang Co., Shaanxi Prov., China*, in a quartz vein, with barite, barytocalcite, roscoelite, and diopside. RG *AM 76:2020(1991)*.

7.9.5.1 Mannardite $\text{BaTi}_6(\text{V,Cr})_2\text{O}_{16} \cdot \text{H}_2\text{O}$

Named in 1986 for George William Mannard (1932–1982), Canadian mineralogist and president, Kidd Creek Mines Ltd., long interested in the mineral deposits of southern BC. TET *I4₁/a*. $a = 14.356$, $c = 5.911$, $Z = 4$, $D = 4.28$. *CM 24:55(1986)*. *42-615*: 3.20_{10} 2.47_7 2.26_3 2.22_5 1.89_7 1.69_5 1.59_8 1.39_4 . Prismatic, elongated crystals, with {110} and {001}; {110} striated [001]. Jet black; appearance similar to rutile, with white to grayish streak and adamantine luster. Cleavage {001}, prominent; uneven to subconchoidal fracture; very brittle. $H = 7$. $G = 4.12$. Uniaxial (+); $N_0 = 2.26$, $N_E = 2.42$ (calc). In RL, pale reddish brown, no internal reflections; distinctly pleochroic, light to dark brown; strongly anisotropic. $R = 15.7$ – 16.8 (470 nm), 15.2 – 17.5 (546

nm), 15.25–18.05 (589 nm), 15.3–18.55 (650 nm). *Rough claims, Sifton Pass, Kechica River, BC, Canada, in quartz-carbonate veins, with barytocalcite, norsethite, quartz, barite, and sulvanite. Brunswick No. 12 orebody, Bathurst, NB, Canada. RG AM 73:193(1988).*

7.9.5.2 Redledgeite $\text{BaTi}_6\text{Cr}_2^{3+}\text{O}_{16} \cdot \text{H}_2\text{O}$

Named in 1961 for the locality. This mineral was originally described in 1928 with a seriously incorrect analysis and named "chromrutile." *AM 13:69(1928)*. The same material was reexamined by Strunz and, on the basis of new data, renamed *redledgeite*, since it was not a variety of rutile. *NJMM:107(1961)*. TET $I4_1/a$. $a = 14.320$, $c = 5.893$, $Z = 4$, $D = 4.413$. *CM 24:55(1986)*. 39-352: 7.10₂ 3.57₅ 3.20₁₀ 2.83₃ 2.47₆ 2.22₄ 1.89₅ 1.58₆ 1.39₅. Redledgeite is isostructural with mannardite, and the powder patterns are almost identical. The weak line 7.10₂ is, however, diagnostic for redledgeite, as it is absent from the mannardite pattern. Prismatic or equant bipyramidal crystals. Black; another type is pale green; adamantine luster. $H = 6\frac{1}{2}$, $G = 3.72$. *Red Ledge mine, Washington district, Nevada Co., CA, with kammererite and chromite. RG AM 46:1201(1961), NJMM:116(1963).*

7.10.1.1 Ranciéite $(\text{Ca},\text{Mn})\text{Mn}_4^{4+}\text{O}_9 \cdot 3\text{H}_2\text{O}$

Named in 1859 for the locality. HEX Space group unknown. $a = 2.86$, $c = 7.50$. 22-718: 7.49₁₀ 3.74₁ 2.46₁ 2.34₁ 2.06₁ 1.76₁ 1.43₁. Massive; as stalactites with colloform, banded texture. Black; brownish; violet, metallic luster. $G = 3.2$. Oriente Prov., Cuba. *Rancié, near Vicdessos, Ariège, France, in cavities in limonite, as radiated groups of cleavable lamellae; also at the Filhols mine, Pyrénées-Orientales. Monte Gelato, Mazzano, Romano, Italy, in lake deposited tuffs, associated with halloysite. RG DI:572, BM 92:191(1969), AM 54:1741(1969), MM 50:111(1986).*

7.10.1.2 Takanelite $(\text{Mn},\text{Ca})\text{Mn}_4^{4+}\text{O}_9 \cdot \text{H}_2\text{O}$

Named in 1971 for Katsutoshi Takane (1899–1945), professor of mineralogy, Tohoku University, Sendai, Japan. HEX Space group unknown. $a = 8.68$, $c = 9.00$, $Z = 3$, $D = 3.78$. 25-164: 7.57₁₀ 4.43₂ 3.77₃ 2.46₂ 2.35₂ 2.07₂ 1.42₂. Massive; in irregular nodules. Gray; black, brownish-black streak, submetallic to dull luster. No cleavage. $\text{VHN}_{100} = 480$. $G = 3.41$. In RL, yellowish gray, with weak yellowish-white to light yellowish-gray pleochroism, and moderate anisotropy, yellowish gray to light brownish gray. Takanelite is the Mn^{2+} analog of ranciéite. *Nomura mine, Ehime, Japan, in the oxidation zone of a braunite-rhodochrosite-caryopilite deposit, intimately intergrown with braunite, halloysite, goethite, and quartz. RG AM 56:1487 (1971), 69:814 (1984); JGSK 76:105(1980).*

7.10.2.1 Karibibite $\text{Fe}_2^{3+}\text{As}_4^{3+}(\text{O},\text{OH})_9$

Named in 1973 for the locality. ORTH Space group unknown. $a = 27.91$, $b = 6.53$, $c = 7.20$, $Z = 6$, $D = 4.04$. 25-1405: 6.35₄ 5.35₃ 3.50₅ 3.18₈ 3.09₇

2.80₈ 2.67₄ 2.38₁₀. Spindle-shaped bundles of fibers. Brownish yellow. Very soft. $G = 4.07$. Fluoresces yellow in SWUV light. Paramagnetic. Readily soluble in dilute acids or in dilute alkali hydroxide solutions. Biaxial (-); $N_x = 1.96$, $N_z > 2.10$. X, straw yellow; Z, light brownish yellow. *Karibib lithium pegmatite, Namibia*, in vugs in loellingite, associated with eosphorite, scorodite, and quartz. Lavra do Enio (a pegmatite), Galileia, MG, Brazil, after lollingite. RG *LIT 6:265(1973)*, *AM 59:382(1974)*, *NJMA 138:94(1980)*.

7.10.3.1 Otjiseumite $PbGe_4O_9$

Named in 1981 for the Herrero name for the locality, Tsumeb. TRIC. $P1$ or $P1$. $a = 6.945$, $b = 6.958$, $c = 9.279$, $\alpha = 102.56^\circ$, $\beta = 103.03^\circ$, $\gamma = 114.46^\circ$, $Z = 2$, $D = 5.77$. 35-473: 5.87₃ 4.20₄ 3.41₅ 2.95₁₀ 2.41₃ 2.22₃ 1.85₄ 1.78₄. Pseudo-hexagonal crystals, elongated along c axis. White or colorless, subadamantine luster. Cleavage {001} in traces. $H = 3$. Biaxial; $X \wedge c = 3-5^\circ$; $N_x = 1.920$, $N_z = 1.943$; $2V = 20^\circ$. *Tsumeb mine, Namibia*, in small cavities in tennantite-germanite-renierite ore, associated with schaurteite, chalcocite, siderite, and gypsum. RG *NJMM:49(1981)*, *AM 72:1026(1987)*.

7.11.1.1 Muskoxite $Mg_7Fe_4^{3+}O_{13} \cdot 10H_2O$

Named in 1969 for the igneous complex (the Muskox intrusion) in which the mineral occurs. Probably pseudo HEX-R Space group unknown. $a = 3.07$, $c = 4.6$. 22-709: 4.61₈ 4.44₂ 4.12₃ 2.66₃ 2.31₁₀ 1.75₆ 1.54₄ 1.46₂. Aggregates of small crystals, also anhedral grains. Dark reddish brown, light orange-brown streak, vitreous luster. Cleavage {0001}, perfect. $H = 3$. $G = 3.15$. Biaxial (-); $N = 1.80-1.81$; $2V = 10-40^\circ$. *Muskox intrusion, Coppermine River area, NWT, Canada*, in drill core, associated with coalingite, serpentine, and ill-defined mixtures of Mg-Fe-Mn oxides. RG *AM 54:684(1969)*.

7.11.2.1 Brownmillerite $Ca_2(Al,Fe)_2O_5$

Named in 1964 for Lorrin Thomas Brownmiller, chief chemist of the Alpha Portland Cement Co., Easton, PA, who was among the first to prepare and describe the artificial compound, which is found in cement clinker. ORTH *Pcmm*. $a = 5.567$, $b = 14.521$, $c = 5.349$, $Z = 4$, $D = 3.732$. Structure: *AC(B)* 27:2311 (1971). 30-226: 7.25₅ 2.78₃ 2.67₄ 2.64₁₀ 2.58₂ 2.05₄ 1.93₄ 1.81₅. Minute square platelets. Reddish brown. $G = 3.76$. Biaxial (-); $N_x < 2.02$, $N_y, N_z > 2.02$. X and Y are in plane of platelets; diagonal extinction. X, yellowish brown; Y, Z, reddish brown. *Ettringer, Bellerberg, Mayen, Laacher See area, Eifel, Rhineland-Pfalz, Germany*, in metamorphosed marly limestone inclusions in effusive volcanic rocks, associated with wollastonite, gehlenite, larnite, diopside, mayenite, spinel, portlandite, and other minerals. From the "mottled zone" of the Hatrurim formation, Israel-Jordan. RG *NJMM:22(1964)*, *AM 50:2106(1965)*.

7.11.2.2 Srebrodol'skite $\text{Ca}_2\text{Fe}_2^{\text{II}+}\text{O}_5$

Named in 1985 for Boris Ivanovich Srebrodol'ski (b.1927), Ukrainian mineralogist, Lvov State University. ORTH *Pnma*. $a = 5.420$, $b = 14.752$, $c = 5.594$, $Z = 4$, $D = 4.03$. *ZVMO 114:195(1985)*. *38-408: 7.38₁₀ 3.69₁₀ 2.80₆ 2.71₆ 2.68₁₀ 2.08₄ 1.95₇ 1.84₁₀*. Minute grains and crystals, flattened {010}. Black, brownish red; grayish-brown streak; adamantinite-metallic luster. Cleavage {hol}, good. $H = 5.5$. $G = 4.04$. Nonfluorescent. Weakly magnetic. Soluble in HCl. Biaxial (-); X parallel to [010]; $N_x \sim 2.24$, $N_y \sim 2.25$, $N_z \sim 2.27$. *Kopeysk, Chelyabinsk coal basin, Ural Mts., Russia*, in a coal seam in pieces of petrified wood thermally metamorphosed by burning coal, which encloses earthy masses of portlandite, carbonates, and srebrodol'skite. *RG AM 71:1279(1986)*.

7.11.3.1 Mayenite $\text{Ca}_{12}\text{Al}_{14}\text{O}_{33}$

Named in 1964 for the locality. iso *I43d*. $a = 11.982$, $Z = 2$, $D = 2.68$. *NBSC 539(9):20(1960)*. *9-413(syn): 4.89₁₀ 3.00₅ 2.68₁₀ 2.45₅ 2.19₄ 1.95₃ 1.66₃ 1.60₃*. Minute rounded grains. Colorless. $G = 2.85$. Isotropic; $N = 1.643$. *Ettringer, Bellerberg, Mayen, Eifel, Rhineland-Pfalz, Germany*, in thermally metamorphosed inclusions of marly limestone in effusive volcanic rocks, associated with brownmillerite, wollastonite, diopside, portlandite, ettringite, and other minerals. Mayenite is also a common component of portland cement clinker. *RG AM 50:2106(1965)*.

7.11.4.1 Hematophanite $\text{Pb}_4\text{Fe}_3^{\text{II}+}\text{O}_8(\text{OH,Cl})$

Named in 1928 from the Greek *haimato*, blood, and *phaneros*, visible, in allusion to the blood-red color in transmitted light. TET *P4mmm*. $a = 3.910$, $c = 15.287$, $Z = 1$, $D = 8.11$. Structure: *SR 48A:182(1981)*. *27-271: 3.9 3.77₄ 2.76₁₀ 2.71₁₀ 2.24₄ 1.953₄ 1.590₆ 1.566₄*. Thin tablets {001}, in part in lamellar aggregates. Deep red-brown, yellowish-red streak, submetallic luster. Cleavage {001}, very good. $H = 2-3$. $G = 7.70$. Easily soluble in dilute HCl or in HNO_3 . Uniaxial (-). Low birefringence, blood red by transmitted light. *Jakobsberg mine, Värmland, Sweden*, with jacobsite, plumboferrite, andradite, copper, cuprite, and cerussite in calcite. *RG DI:728, AM 56:625(1971)*.

7.11.5.1 Plumboferrite $\text{PbFe}_4^{\text{II}+}\text{O}_7$

Named in 1881 for the composition. HEX-R *P312*. $a = 11.88$, $c = 47.23$, $Z = 42$, $D = 6.55$. *GSAM 85:198(1962)*. *22-656: 3.88₄ 2.96₈ 2.81₉ 2.64₁₀ 1.842₄ 1.680₆ 1.645₆ 1.484₆*. Thick tabular crystals; in cleavable masses. Black, red streak. Cleavage {0001}. $H = 5$. $G = 6.07$. Easily soluble in HCl with evolution of Cl_2 and residue of lead chloride. In RL, gray, with a brownish tint. Weakly anisotropic. $R = 27.2-26.0$ (470 nm), $25.3-24.8$ (546 nm), $24.3-23.9$ (589 nm), $22.8-22.4$ (650 nm). *P&J:305. Jakobsberg mine, Nordmark, Varmland, Sweden*; also from the Sjo mine in Örebro. *RG DI:726*.

7.11.6.1 Carboirite $\text{Fe}^{2+}\text{Al}_2\text{GeO}_5(\text{OH})_2$

Named in 1983 for the locality. TRIC $P\bar{1}$. $a = 9.513$, $b = 5.569$, $c = 9.296$, $\alpha = 96.05^\circ$, $\beta = 101.31^\circ$, $\gamma = 89.27^\circ$, $Z = 4$, $D = 3.95$. 35-586: 4.79₅ 4.53₁₀ 3.02₈ 2.73₉ 2.48₉ 1.85₆ 1.61₇ 1.38₆. Crystallizes in pseudohexagonal plates. Green, vitreous luster. $H = 6$. Biaxial (+); $N_x = 1.731$, $N_y = 1.735$, $N_z = 1.740$; $2V = 7^\circ$. X, bluish green; Y, light blue; Z, colorless to yellow. Carboire, Marimana Dome, Ariège, Pyrenees, France, in a zinc deposit in sphalerite with Ge-bearing quartz. RG *TMPM* 31:97(1983), *AM* 69:406(1984).

7.11.7.1 Högbomite 4H, 5H, 6H, 15H $(\text{Mg,Fe})_{1,4}\text{Ti}_0,3\text{Al}_4\text{O}_8$ **7.11.7.2 Högbomite 8H $(\text{Al,Fe}^{2+},\text{Fe}^{3+},\text{Mg,Ti,Zn})_{11}\text{O}_{15}(\text{OH})$** **7.11.7.3 Högbomite 15R, 18R, 24R $(\text{Mg,Fe})_{1,4}\text{Ti}_0,3\text{Al}_4\text{O}_8$**

Named in 1916 for Arvid Gustaf Hogbom (1857–1940), Swedish geologist, University of Uppsala. The diffraction patterns of all hogbomites studied have been found to exhibit either hexagonal or rhombohedral symmetry. The dimensions of the unit cell are in each instance $a = 5.72$ Å and $c =$ close to some multiple of 4.6 Å. The crystallography of hogbomite can thus be described in terms of a series of polytypes of constant a , to each of which a symbol of the form of $n\text{H}$ or $n\text{R}$ can be assigned, where H and R indicate hexagonal and rhombohedral lattice types and n is given by $c = 4.6 n\text{Å}$. The polytypes arise by variation of the stacking sequence of approximately close-packed oxygen layers, with interstitial cations on fourfold and sixfold sites. The formulas may be represented by $\text{R}_{1.0-1.6}^{2+}\text{Ti}_{0.2-0.4}^{4+}\text{R}_{3.7-4.3}^{3+}(\text{OH})_{0-0.4}$ where $\text{R}^{2+} = \text{Fe, Mg, Zn}$ and $\text{R}^{3+} = \text{Al, Fe}$. The polytypes so far observed are 4H, 5H, 6H, 8H, 15H, 15R, 18R, and 24R. The unit cell constants for each of these polytypes are:

4H: $P6_3mc$; $a = 5.72$, $c = 18.35$, $Z = 4$, $D = 3.72$. *MM* 33:563(1963).

5H: $P62m$; $a = 5.72$, $c = 23.0$, $Z = 5$, $D = 3.73$. *MM* 33:563(1963).

6H: $P6_3mc$; $a = 5.72$, $c = 27.5$, $Z = 6$, $D = 3.75$. *MM* 33:563(1963).

8H: $P6_3mc$; $a = 5.734$, $c = 18.389$, $Z = 1$, $D = 4.04$. *AM* 67:373(1982).

15H: $a = 5.72$, $c = 69.0$, $Z = 15$, $D = 3.73$. *MM* 33:563(1963).

15R: $R32$ or $R3m$; $a = 5.72$, $c = 69.0$, $Z = 15$, $D = 3.73$. *MM* 33:563(1963).

18R: $R32$ or $R3m$; $a = 5.738$, $c = 83.4$, $Z = 18$, $D = 3.68$. *MM* 33:563(1963).

24R: $R32$ or $R3m$; $a = 5.7$, $c = 55.8$, $Z = 24$. *NJMM*:401(1990).

There is no obvious correlation between hogbomite polytypes and composition, optics, or other physical properties, and even powder data are not entirely reliable to differentiate the polytypes. Positive identification can only be made through determination of the unit cell through single-crystal X-ray identification. Several polytypes are often found in a single deposit, and even a single hogbomite crystal may consist of several polytypes. While certain polytypes tend to be concentrated in particular deposits, the location alone is not a reliable means of identification. Insufficient powder diffraction patterns of hogbomite of known polytype have been made to be sure if any

lines or patterns are diagnostic of polytype. Observed differences may well be caused by hōgbomite's substantial variations in chemical composition.

5H—16-336: 4.60₄ 2.86₄ 2.49₆ 2.43₁₀ 2.08₆ 1.978₆ 1.436₆ 1.426₈.

8H—*MM* 41:342(1977): 2.94₂ 2.86₃ 2.60₅ 2.43₁₀ 2.05₂ 1.60₂ 1.47₃ 1.43₅.

18R—16-167: 2.93₄ 2.87₆ 2.69₅ 2.55₅ 2.44₁₀ 2.42₄ 2.08₄ 1.434₆.

Crystals thick to thin tabular {0001}; as minute grains. Twinning on {0001}, sometimes repeated. Black, grey streak, metallic–adamantine luster. Cleavage {0001}, imperfect; conchoidal fracture; brittle. $H = 6\frac{1}{2}$. $G = 3.81$. Weakly magnetic. Uniaxial (-). O, dark golden brown, E, light golden brown. In RL, gray, weakly pleochroic, distinctly anisotropic. Sometimes exhibits lamellar twinning. Localities: (4H), (5H) Perseus claim, Routevaara, near Kvikkjokk, Lapland, Sweden; (6H) near Peekskill, Westchester Co., NY, with emery; (8H) Johannsen's mine, NNE of Alice Springs, Strangeways Range, NT, Australia; (15H) Castor claim, Routevaara, Lapland, Sweden; (15R) Toombeola, Galway Co., Eire; (18R) Dentz farm, Letaba district, Transvaal, South Africa; (24R) Mautia Hill, Morogoro area, Tanzania. Also (unspecified polytypes) near Whittles, Pittsylvania Co., VA, with hercynite, magnetite, and corundum (emery); Bathurst Twp., Lanark Co., ONT, Canada, with corundum pseudomorphs after spinel. RG *DI:723*; *AM* 37:600(1952), 76:1734(1991); *NJMM:373*(1977).

7.11.8.1 Nigerite 6H $(Zn, Mg, Fe^{2+})(Sn, Zn)_2(Al, Fe^{3+})_{12}O_{22}(OH)_2$

7.11.8.2 Nigerite 24R $(Fe^{2+}, Zn)_4Sn_2(Al, Fe^{3+})_{15}O_{30}(OH)_2$

Named in 1947 for Nigeria, the country of origin. Two polytypes of nigerite are known, 6H and 24R. In this respect it is similar to hōgbomite, with which it is structurally related. Nigerite 6H: *HEX* *P3m* or *P3m1*. $a = 5.72$, $c = 13.86$, $Z = 2$, $D = 4.47$. *MM* 28:129(1947). Nigerite 24R: *HEX-R* *R3m*. $a = 5.730$, $c = 55.60$, $Z = 3$, $D = 4.42$. *AM* 64:1255(1979). (6H) 26-1391: 4.65₉ 4.00₉ 2.83₁₀ 2.42₁₀ 1.643₉ 1.544₁₀ 1.426₉ 1.412₉. (24R) 38-436: 4.52₄ 4.20₄ 2.86₅ 2.84₇ 2.435₇ 2.430₁₀ 2.42₅ 1.43₄. Crystals are hexagonal plates, also anhedral grains. Light to dark brown, adamantine luster. Brittle. $H = 8-9$. $G = 4.51$. Weakly magnetic. Insoluble in acids. Uniaxial (+); $N_O = 1.80$, $N_E = 1.81$. Sometimes optically negative. In pegmatites of Seixoso-Macieira, northern Portugal. (6H) *Egbe district, Kabba Prov., Nigeria*, in quartz–sillimanite rocks closely associated with cassiterite-bearing granite pegmatites, associated with sillimanite, andalusite, gahnite, cassiterite, columbite, chrysoberyl, and apatite. The nigerite often forms epitaxial overgrowths on gahnite, {0001} of nigerite on {111} of gahnite. (24R) *Mt. Garnet, Q, Australia*. Jornal area, Amapa, Brazil, in quartz–mica veins with cassiterite, andalusite, tantalite, tourmaline, and chrysoberyl. Venus Creek tantalite placers, Sinnamary R. area, French Guiana. RG *AM* 33:98(1948), 52:864(1967); *MM* 39:837(1974).

7.11.9.1 Pengzhizhongite-6H (Mg,Zn,Fe,Al)₄(Sn,Fe)₂Al₁₀O₂₂(OH)₂**7.11.9.2 Pengzhizhongite-24R (Mg,Zn,Fe,Al)₄(Sn,Fe)₂Al₁₀O₂₂(OH)₂**

Named in 1989 for Peng Zhizhong, late Chinese mineralogist. The Mg analog of nigerite. *HEX*, *HEX-R* Space group unknown. $a = 5.692$, $c = 13.78$, $Z = 1$, $D = 4.16$. *PD*: 2.85₉ 2.42₁₀ 1.639₃ 1.545₄ 1.414₅ 1.050₃. Minute tabular crystals. Light yellowish brown, light yellow, to colorless; white streak; vitreous luster. $H = 8$. $G = 4.22$. From high-temperature metasomatic tungsten ore in the Anhua area, Hunan, China, associated with scheelite, magnetite, rutile, nigerite, cassiterite, zircon, and taaffeite. *RG AMS 9:20(1989)*, *AM 76:1730(1991)*.

7.11.10.1 Kleberite FeTi₆O₁₃ · 4H₂O(?)

Named in 1978 for Will Kleber (1906–1970), Humboldt University, Berlin. Data unsatisfactory; a doubtful species. Probably *HEX* Space group uncertain, probably *P6₃mc*. $a = 4.94$, $c = 4.59$. *PD*: 2.46₃ 2.16₆ 1.67₁₀ 1.42₆. Small grains. Dark brown to black. $H = 4-4\frac{1}{2}$. $G = 3.27$. Uniaxial (–) or biaxial (–); $N \gg 1.80$. Bireflectance = 0.04–0.05. From near *Königshain* and near *Borna*, western *Weissel basin*, Germany, in the heavy-mineral fraction from Tertiary sediments. *RG AM 64:655(1979)*.

7.11.11.1 Mongshanite (Mg,Fe²⁺,Cr)₂(Ti,Zr)₅O₁₂

Named in 1982. Data inadequate; a doubtful species. *HEX* Space group unknown. *AM 73:441(1988)*. *PD*: 3.44₄, 2.89₁₀ 2.26₇ 2.14₇ 1.80₅ 1.60₅ 1.45₇ 0.904₇. As inclusions in ilmenite. Physical properties similar to ilmenite. *Yimengshan area (?)*, *Shandong*, *China*, in kimberlite dikes. *MA 84M:4292(1984)*.

7.11.12.1 Diaoyudaoite NaAl₁₁O₁₇

Named in 1986 for the locality. *HEX P6₃/mmc*. $a = 5.602$, $c = 22.626$, $Z = 2$, $D = 3.21$. *AM 75:240(1990)*. 45-1451: 11.3₁₀ 5.62₄ 2.70₇ 2.26₅ 2.24₆ 2.05₆ 1.430₆ 1.404₈. Minute thin tabular crystals. Colorless to light green, vitreous luster. Well-developed cleavage, conchoidal fracture. $H = 7\frac{1}{2}$. $G = 3.30$. Uniaxial (–); $N_O = 1.688$, $N_E = 1.663$. From seafloor muds near *Diaoyu Dao Island*, *N of Taiwan*, at 1,500 m depth, where it is abundant in the heavy-mineral fraction, associated with hornblende, epidote, dolomite, chlorite, and biotite, and containing inclusions of native Cr (?). *AMS 6(3):224(1986)*.

7.11.13.1 Chiluite Bi₆Te₂⁶⁺Mo₂⁶⁺O₂₁

Named in 1989 for the locality. *HEX P6₃22*, *P6₃m*, or *P6₃*. $a = 8.970$, $c = 12.207$, $Z = 1$, $D = 3.67$. 45-1369: 3.3₁₀ 3.05₉ 2.88₄ 2.51₅ 2.06₅ 1.905₃ 1.790₃ 1.655₅. Plumose replacements, veinlets, irregular to hexagonal grains. Yellow. $H = 3$. $G = 3.65$. Uniaxial (–); $N_O = 2.4$, $N_E = 2.3$; parallel extinction; negative elongation. In *RL*, gray, weakly anisotropic, no bireflectance.

R = 19.5–18.4 (470 nm), 18.3–17.3 (546 nm), 17.8–16.75 (589 nm), 17.3–16.45 (650 nm). *Chilu, Fujian, China*, in a molybdenite deposit, associated with bismuthinite, molybdenite, joseite, koechlinite, and cassiterite. RG *AM 76:666(1991)*.

7.11.14.1 Rilandite $(\text{Cr,Al})_6\text{SiO}_{11} \cdot 5\text{H}_2\text{O}$

Named in 1933 for James L. Riland (1857–1938?), newspaper publisher of Meeker, CO, on whose claim the mineral was found. Symmetry and space group unknown. Not amorphous, but powder diffraction pattern shows broad lines only. Massive, pitchy, with an angular, platy habit. Dark brownish black, grayish-brown streak, dull to brilliant luster. Conchoidal fracture, very brittle. H = 2–3. Needs further study. From carnotite claims 20 km ENE of Meeker, CO, in sandstone, associated with fossil wood. RG *AM 18:195(1933)*.

7.11.15.1 Lindqvistite $\text{Pb}_2(\text{Mn}^{2+}, \text{Mg})\text{Fe}_{16}^{3+}\text{O}_{27}$

Named in 1993 for Bengt Lindqvist (b.1927), Swedish mineralogist and petrologist, and curator, Swedish Natural History Museum. *HEX* $P6_3/mmc$. $a = 5.951$, $c = 33.358$, $Z = 2$, $D = 5.76$. *AM 78:1304(1993)*. *PD*: 4.17₆ 3.33₄ 3.01₆ 2.98₇ 2.80₁₀ 2.78₅ 2.62₁₀ 2.61₉. Found in subhedral tabular crystals (max. 5 mm) flattened on (0001). Black, brownish-black streak, submetallic luster. Cleavage (0001), perfect, brittle. H = 6. Slowly soluble in cold 3:1 HCl, insoluble in HNO₃ or H₂SO₄. In RL, gray with a faint brownish tint, weakly bireflectant, moderately anisotropic, no internal reflections. R = 23.6 (470 nm), 22.8 (546 nm), 22.2 (589 nm), 21.4 (650 nm). Found at the *Jakobsberg mine, Filipstad, Sweden*, associated with hematite, jacobsite, plumboferrite, andradite, and other minerals in skarn. RG

Multiple Oxides Containing Niobium, Tantalum, and Titanium

8.1.1.1 Fergusonite-(Y) $YNbO_4$

Named in 1827 for Robert Ferguson (1767–1840), Scottish advocate, politician, and mineralogist. TET $I4_1/a$. $a = 5.16$, $c = 10.89$, $Z = 4$, $D = 5.38$ (for pure $YNbO_4$). Fergusonite is usually metamict. 9-443(heated): 3.12₁₀ 3.01₂ 2.96₉ 2.74₄ 2.64₂ 2.53₁ 1.90₅ 1.86₃. Crystals prismatic [001] to pyramidal, sometimes with {001} prominent; as irregular masses or grains. Black to brownish black, gray, yellow, brown; brown, yellow-brown, greenish-gray streak; vitreous–submetallic luster. Cleavage {111} in traces, subconchoidal fracture, brittle. $H = 5\frac{1}{2}$ –6 $\frac{1}{2}$. $G = 4.2$ –5.7. Fergusonite takes up water in the process of metamictization; the D and H decrease with hydration. It is essentially an oxide of Y, RE, niobium, and tantalum, with the type formula ABO_4 , where $A = Y, Er, Ce, La, Nd, Di, U, Zr, Th, Ca, Fe^{2+}$. $B = Nb, Ta, Ti, Sn$, and W . A complete series apparently exists between the predominantly niobian fergusonite and the tantalian formanite, although the Ta-rich members are far scarcer. Water is reported in nearly all analyses but is undoubtedly due to alteration. The nearly invariable presence of at least traces of U and Th result in most fergusonites being metamict. Isotropic (when metamict); $N = 2.06$ –2.19, depending on composition. Spruce Pine, Mitchell Co., NC, in pegmatites with allanite; abundant at Barringer Hill, Llano Co., TX, with gadolinite and other rare-earth minerals. Murchison Twp., ONT, Canada, with euxenite. *Qeqertaussaq, Julienhaab district, Greenland*. Iveland district, Norway, in pegmatites with gadolinite, thalenite, and so on, and in Hundholmen with allanite, yttrifluorite, xenotime, and gadolinite; in Russia in the Ilmenskie Mts. at the Blum mine, with samarskite and ilmenorutile. Ytterby, Sweden, in pegmatite with xenotime, cyrtolite, and biotite. In Sri Lanka in gem gravels; Hakatamura and Hagata, Iyo, Japan, in pegmatite; Morogoro, Tanzania. In Madagascar S of Lake Itasy; at Ambatofotsikely; and elsewhere. RG *DI:757; AM 40:805(1955), 46:1516(1961), 52:1536(1967)*.

8.1.1.2 Formanite-Y $YTaO_4$

Named in 1944 for Francis Gloster Forman (1904–1980), government geologist, WA, Australia. TET $I4_1/a$. $a = 7.75$, $c = 11.41$, $Z = 4$, $D = 7.03$ (data from synthetic $YTaO_4$). 26-1478(heated): 3.13₁₀ 2.93₉ 2.72₆ 1.90₇ 1.64₇ 1.57₇ 1.22₆ 1.19₆. As anhedral pebbles, also tabular crystals. Black, pale yel-

low streak, vitreous to submetallic luster. $H = 6$. $G = 6.24$. Isotropic (metamict); $N = 2.14$. Siberia, Russia, in albitized pegmatite with monazite and gadolinite. *Cooglegong, WA, Australia*, in placers with cassiterite, monazite, euxenite, and gadolinite. Used as an ore of tantalum. RG *DI:757, DANS 154:86(1964)*.

8.1.1.3 Fergusonite-(Ce) (Ce,Nd,La)NbO₄ · 0.3H₂O

Named in 1986 for the composition, and as a member of the fergusonite group. TET Space group unknown. $a = 5.17$, $c = 5.30$ (heated material). Irregular poikiloblasts and rare prismatic dipyrarnidal crystals. Dark red to black. $G = 5.48$. Uniaxial (-); $N_O = 2.30$, $N_E = 2.20$. *Novopoltavsk massif, Ukraine*, in carbonatite, associated with magnetite, columbite, allanite, bastnaesite, parisite, apatite, uranpyrochlore, aeschynite, fersmite, and monazite. RG *AM 74:946(1989)*.

8.1.1.4 Fergusonite-(Nd) (Nd,Ce)(Nb,Ti)O₄

Named in 1987 for the composition and as a member of the fergusonite group. Space group unknown. Granular, as equant grains. Dark brown, adamantine luster. From *Bayan Obo, Inner Mongolia, China*, in a rare-earth deposit, in veinlets of aegirine. RG *AM 74:946(1989)*.

8.1.2.1 β -Fergusonite-(Y) YNbO₄

Named in 1961 from the symmetry, and the composition as a Y-dominant member of the fergusonite group. MON $C2/c$. $a = 7.037$, $b = 10.945$, $c = 5.298$, $\beta = 134.07^\circ$, $Z = 4$, $D = 5.57$. *23-1486(syn)*: 3.12_{10} 2.96_9 2.73_5 2.64_5 1.90_7 1.86_6 1.76_4 1.63_4 . Light yellow. $G = 5.65$. *Central-eastern Russia*, in the apical parts of microcline granite stocks. Karasugama mine, Fukushima, Fukushima Pref., Japan. RG *AM 46:1516(1961)*.

8.1.2.2 β -Fergusonite-(Ce) (Ce,La,Nd,Th)NbO₄

Named in 1973 for the symmetry, composition, and its being a member of the fergusonite group. MON $C2/c$. $a = 5.19$, $b = 11.34$, $c = 5.48$, $\beta = 84.95^\circ$, $Z = 4$. *AM 60:485(1975)*. *PD*: 3.21_{10} 3.07_{10} 1.96_8 1.91_7 1.71_6 1.67_6 1.61_6 . *33-332(syn)*: 3.23_{10} 3.06_{10} 2.85_3 2.76_2 2.57_2 1.98_3 1.91_2 1.70_2 . Well-formed crystals, frequently terminated by bipyramids. Red; reddish brown, vitreous to greasy luster. $G = 5.34$. From *northern China*, in a skarn deposit, associated with diopside, phlogopite, and Ce-apatite. RG *AM 62:397(1977)*.

8.1.2.3 β -Fergusonite-(Nd) (Nd,Ce)NbO₄

Named in 1984 for the symmetry, composition, and its being a member of the fergusonite group. MON (heat-treated material) $I2$. $a = 5.07$, $b = 5.62$, $c = 5.41$, $\beta = 93^\circ$, $Z = 2$, $D = 6.45$. *32-680*: 3.21_8 3.04_{10} 2.82_8 2.73_3 2.57_4 1.89_3 1.79_3 1.60_3 . Irregular grains, rarely prismatic crystals. Red, brownish red, yellowish brown; pale brown streak, vitreous to greasy luster. No clea-

vage, subconchoidal fracture. Moderately paramagnetic. Isotropic (metamict); $N = 2.0$. *Bayan Obo, Inner Mongolia, China*, in an Nb-rare earth deposit in proterozoic riebeckite-ferroan dolomite, associated with biotite, magnetite, monazite, bastnaesite, aeschynite-(Nd), ilmenite, and fergusonite-(Ce). RG *AM 69:406(1984)*.

8.1.3.1 Yttrotantalite-(Y) $(Y,U,Fe^{2+})(Ta,Nb)O_4$

Named in 1802 from the composition. Dimorphous with formanite. ORTH Space group unknown. Metamict. Prismatic [001] with {110} and {010}; also tabular {010}. Black; brown, gray streak, submetallic to vitreous/greasy luster. Cleavage {010}, indistinct, conchoidal fracture. $H = 5-5\frac{1}{2}$. $G = 5.7$. Isotropic; $N = 2.15$. Rare metals mine, Aquarius Range, Mojave Co., AZ. In *Sweden* at Finbo and Brodbo, near Falun, with albite, garnet, and topaz; and at *Ytterby* with fergusonite-(Y). Norway near Berg, in Råde, in pegmatite, and at Hattevik E of Dillingo. RG *DI:763*.

8.1.3.2 Yttrocolumbite-(Y) $(Y,U,Fe)(Nb,Ta)O_4$

Named in 1937 from the composition. Inadequately characterized to be certain that the reported material is the Nb-dominant analog of yttrotantalite. Polymorphous with fergusonite-(Y) and β -fergusonite-(Y). ORTH Space group unknown. Metamict. Black, brilliant luster. $H = 6$. $G = 5.49$. From *Mozambique*. RG *MASLI:369(1937)*, *AM 25:155(1940)*.

8.1.4.1 Ishikawaite $(U,Y,Fe)(Nb,Ta)O_4$

Named in 1922 for the locality. More study needed, possibly is uranpyrochlore. Probably ORTH Space group unknown. Metamict. Tabular crystals. Black, dark brown streak, waxy luster. Conchoidal fracture. $H = 5-6$. $G = 6.3$. From the *Ishikawa district, Fukushima, Iwaki Pref., Japan*, in pegmatite, with samarskite. RG *DI:766*.

8.1.5.1 Loranskite-(Y) $(Y,Ce,Ca)(Zr,Ta)_2O_6$ (?)

Named in 1899 for Apollonie Mikhailovich Loranski (1847-1917), inspector and teacher of the Mining Institute, St. Petersburg, Russia. An ill-defined mineral of uncertain formula and identity. Probably ORTH Space group unknown. Metamict. Crystals resemble samarskite. Black, greenish-gray streak, submetallic luster. Conchoidal fracture, brittle. $H = 5$. $G = 4.4$. *Impilaks, Lake Ladoga, Finland*, in pegmatite, with "wiikite" (possibly euxenite). RG *DI:767*.

8.1.6.1 Stibiocolumbite $SbNbO_4$

Named in 1915 for the composition. ORTH $Pc2_1n$. $a = 5.559$, $b = 11.79$, $c = 4.929$, $Z = 4$, $D = 5.728$. *AM 48:1348(1963)*. 16-907(syn): 4.54₁ 3.52₂ 3.13₁₀ 2.95₃ 2.78₁ 2.70₁ 2.46₁ 1.74₂. Crystals prismatic [001]; {010} and

{110} striated parallel to [001]; hemimorphic; twinning common, polysynthetic, twin axis [001], composition plane {010}. Brown, reddish yellow, greenish yellow; pale yellow to yellow-brown streak; resinous to adamantine luster. Cleavage {010}, distinct; {100}, indistinct; subconchoidal to granular fracture; brittle. $H = 5\frac{1}{2}$. $G = 5.98$. Markedly pyroelectric. The Nb-dominant members of the stibiocolumbite-stibiotantalite group are decidedly rare compared to the Ta-rich members, and the nearly pure Nb end member has not been found. Biaxial (+); $XYZ = abc$; $N_x = 2.40$, $N_y = 2.42$, $N_z = 2.46$ (Na); $2V = 73^\circ$. In pegmatite at the *Himalaya mine, Mesa Grande, San Diego Co., CA*, in fine crystals associated with pink beryl, lepidolite, and rubellite. Varutrask, Sweden, in pegmatite. RG *DI:767*.

8.1.6.2 Stibiotantalite $SbTaO_4$

Named in 1893 for the composition. ORTH $Pc2_1n$. $a = 5.535$, $b = 11.814$, $c = 4.911$, $Z = 4$, $D = 7.583$ (syn). *AM 48:1348(1963)*. 16-908: 3.51_4 3.12_{10} 2.95_4 2.692_2 2.687_2 2.456_1 1.888_2 1.735_2 . Isostructural with stibiocolumbite (8.1.6.1). Crystals prismatic, tabular [001]; also equant. Hemimorphic. Polysynthetic twinning common, twin axis [001], composition plane {010}. Brown, reddish yellow, greenish yellow; resinous to adamantine luster. $G = 7.34$. Biaxial (+); $N_x = 2.374$, $N_y = 2.404$, $N_z = 2.457$ (Na). Himalaya mine, Mesa Grande, San Diego Co., CA. Muiane pegmatite, Alta Ligonha, Mozambique, in fine, large crystals up to 10 cm, with rubellite, morganite, and manganotantalite. Benson No. 3 mine, Mtoko, northeastern Zimbabwe, with simpsonite, microlite, and manganotantalite. Abundant at *Greenbushes, WA, Australia*, with other tantalum minerals in a large lithium pegmatite. Used as an ore of tantalum. RG *DI:767*, *AM 42:178(1957)*.

8.1.6.3 Bismutotantalite $Bi(Ta,Nb)O_4$

Named in 1929 from the composition. ORTH $Pcmn$. $a = 5.633$, $b = 11.763$, $c = 4.957$, $Z = 4$, $D = 8.76$. *AM 48:1348(1963)*. Isostructural with bismutocolumbite (8.1.6.4). 16-909(syn): 3.54_2 3.14_{10} 2.94_3 2.48_2 2.03_1 1.90_2 1.73_3 1.53_2 . Crystals stout prismatic [001]. Black to light brown, black to yellowish-brown streak, submetallic to adamantine luster. Cleavages {101} and {010}, good; subconchoidal fracture. $H = 5$. $G = 8.4-8.8$. Not pyroelectric. Insoluble in acids, including HF. Biaxial (+); $N_x = 2.39$, $N_y = 2.40$, $N_z = 2.43$; $2V = 80^\circ$; $r < v$; parallel extinction. *Gamba Hill, Busiro Co., Uganda*, in pegmatite with schorl, muscovite, and cassiterite. In Brazil in pure alluvial pebbles and boulders (some of which exceeded 25 kg) at Saco da Onça, Carnauba dos Dantas, RGN, and at the Alto Manoel Baldoino, Junco, PA, in fine large crystals with bismutomicrolite. RG *DI:769*, *NJMM:241(1955)*, *AM 42:178(1957)*.

8.1.6.4 Bismutocolumbite $Bi(Nb,Ta)O_4$

Named in 1992 for the composition. ORTH $Pcmn$. $a = 5.677$, $b = 11.731$, $c = 4.992$, $Z = 4$, $D_{\text{meas}} = 7.56$, $D_{\text{calc}} = 7.66$. Synthetic $BiNbO_3$ has $a = 4.980$,

$b = 11.709$, $c = 5.675$ (ICDD 16-295). 45-1372: 3.16₁₀ 2.93₉ 2.84₅ 2.50₅ 1.899₄ 1.871₄ 1.769₅ 1.734₈. PD(syn): 3.74₂ 3.15₁₀ 2.92₄ 2.84₃ 2.55₂ 2.04₃ 1.90₃ 1.73₄. Isostructural with bismutotantalite but not with stibiocolumbite–stibiotantalite. Prismatic crystals as much as 2 mm long by 1 mm across (Malkhan) and as much as 4 cm long from the Pala district. Black, yellow streak, submetallic luster, transparent in small (<0.03 mm) fragments. Polysynthetic twinning present. Nonfluorescent. $H = 5\frac{1}{2}$. Cleavage {001}, perfect; conchoidal fracture; brittle. Material from the Malkhan district contains only 0.28% wt% Sb₂O₃ and traces of Sn, Ti, and Pb. Material from Pala, CA, contains major Sb, as well as Bi, Nb, and Ta. Biaxial (+); XYZ = acb; N_x = 2.38, N_y = 2.42, N_z = 2.47; 2V_{z calc} = 85°. In miarolytic cavities within extremely fractionated granitic pegmatites. Associated minerals include elbaite, albite, quartz, and minor rare minerals. *Danburitovaya mine, Malkhan Range, central Transbaikalia, Russia*. Occurs as portions of compositionally zoned crystals (including stibiocolumbite and stibiotantalite) from the Stewart mine, Pala district, CA. RG ZVMO 121:130(1992).

8.1.7.1 Alumotantite AlTaO₄

Named in 1981 for the composition. ORTH *Pbcn*. $a = 4.473$, $b = 11.308$, $c = 4.775$, $Z = 4$, $D = 7.47$. CM 30:653(1992). 36-440: 5.66₅ 3.64₇ 3.13₁₀ 2.89₈ 2.44₅ 1.84₅ 1.65₅ 1.07₅. Colorless, adamantine luster. No cleavage. Strongly luminescent, bright blue in cathode rays. Nonfluorescent in UV. VHN₁₀₀ = 1650–1690. *Kola Penin., Russia*, in albitized areas of granite pegmatites, forming rims around simpsonite and also around natrotantite. Bikita pegmatite, Zimbabwe, replacing and overgrowing simpsonite. Alto do Giz, Equador, RGN, Brazil, replacing simpsonite. RG ZVMO 110:338(1981), AM 67:413(1982), IGR 24:835(1982).

WODGINITE GROUP

The wodginite group includes four isostructural minerals with the general formula

where

and a common structure is found in *C2/c*.

The principal structure element consists of octahedra forming α -PbO₂-like zigzag chains via sharing of polyhedron edges. Oxygen atoms form approximately hexagonal close-packed layers. All of the cations in wodginite are in octahedral coordination. They occupy one-half of the octahedral interstices at each level in the close-packed array of anions. There are three cationic sites, called A, B, and C. A and B lie at the same level, and the C sites lie at a

WODGINITE: $MnSnTa_2O_8$

Like wolframite (huebnerite), wodginite contains hexagonal closest-packed layers of oxygen stacked on (100), with all cations in octahedral interstices. All-Ta layers alternate with Mn-Sn layers. Double chains of Ta-Ta and Mn-Sn edge-sharing octahedra are parallel to the *c* axis.

different level. These layers alternate along *a*. Chains are interconnected by corner sharing of linkages between levels. The A and B polyhedra alternate along the zigzag chains of their level; adjacent levels consist only of chains of C polyhedra. Ideally, the A site contains only Mn, the B site Sn, and the C site Ta, resulting in the ideal formula $MnSnTa_2O_8$.

There is some solid solution among the various members, but all the members of the group except wodginite are very rare, and insufficient analytical data exist to say how extensive this is. Fe, Ti, and Li are usually present to some degree in all wodginites. Vacancies are common in the A site and probably in the B site. *CM 30:597(1992)*.

WODGINITE GROUP

Mineral	Formula	Space Group	Space					D
			<i>a</i>	<i>b</i>	<i>c</i>	β		
Wodginite	$MnSnTa_2O_8$	<i>C2/c</i>	9.489	11.429	5.105	91.1	7.69	8.1.8.1
Ferrowodginite	$Fe^{2+}SnTa_2O_8$	<i>C2/c</i>	9.415	11.442	5.103	91.8	7.02	8.1.8.2
Titanowodginite	$MnTiTa_2O_8$	<i>C2/c</i>	9.466	11.431	5.126	90.32	6.89	8.1.8.3
Lithiowodginite	$LiTa_3O_8$	<i>C2/c</i>	9.441	11.516	5.062	91.07	7.74	8.1.8.4

Note: Partial ordering is common and results in suppression of some lines of the powder pattern, which may be alleviated by heating the sample.

8.1.8.1 Wodginite $MnSnTa_2O_8$

Named in 1963 for the locality. Wodginite group. *MON C2/c*. $a = 9.489$, $b = 11.429$, $c = 5.105$, $\beta = 91.1^\circ$, $Z = 4$, $D = 7.69$. *CM 14:550(1976)*. Structure: *CM 30:597(1992)*. 29-901: 3.67₇ 3.00₁₀ 2.95₇ 2.87₃ 2.55₂ 2.50₃ 1.83₁

1.77₃. Prismatic to blocky crystals, lozenge-shaped, in embedded radiating groups, as discrete grains. Dark brown to reddish brown, light brown streak, resinous luster. $G = 7.36$. Wodginite is rather widely distributed in Ta-bearing pegmatites, and some occurrences hitherto identified as tantalite are actually wodginite. Middletown, CT(*), in pegmatite. Tanco mine, Bernic Lake, MB, Canada(l), with microcline, albite, lepidolite, microlite, tantalite, cassiterite, and tapiolite, where it formed the chief ore mineral in a major tantulum ore-body in a large flat-lying pegmatite. Benson mine, Mtoko, Zimbabwe. *Wodgina*, WA, Australia, in a matrix of albite, quartz, and muscovite; also Greenbushes, WA. In MG, Brazil, at Itinga(!) in very large sharp crystals, and at the Lavra Jabuti, Baixio, Galileia(!), in large, brilliant crystals, sometimes epitaxially intergrown with cassiterite. Used as an important ore of tantalum. RG *CM* 7:390(1963), 30:613(1992); *AM* 59:1040(1974).

8.1.8.2 Ferrowodginite $\text{Fe}^{2+}\text{SnTa}_2\text{O}_8$

Named in 1992 for the composition. Wodginite group. MON $C2/c$. $a = 9.415$, $b = 11.442$, $c = 5.103$, $\beta = 90.8^\circ$, $Z = 4$, $D = 7.02$. *CM* 30:633(1992). *PD*: 4.16₅ 3.64₂ 2.97₁₀ 2.86₂ 2.55₃ 2.49₄ 2.35₂ 1.455₃. Minute irregular grains embedded in cassiterite. Dark brown to black, a dark brown streak, vitreous luster. No cleavage, irregular fracture. $H = 5\frac{1}{2}$. Anisotropic; $N > 2.0$. From a pegmatite near *Sukula*, *Tammela-Somero pegmatite province*, southwestern Finland, with cassiterite, tapiolite, and bismuth. RG

8.1.8.3 Titanowodginite $\text{MnTiTa}_2\text{O}_8$

Named in 1992 for the composition. Wodginite group. MON $C2/c$. $a = 9.466$, $b = 11.431$, $c = 5.126$, $\beta = 90.32^\circ$, $Z = 4$, $D = 6.89$. *CM* 30:637(1992). *PD*: 3.64₅ 2.98₁₀ 2.97₁₀ 2.50₄ 1.77₂ 1.720₂ 1.715₂ 1.455₂. Euhedral bipyramidal crystals. Dark brown to black, dark brown streak, vitreous luster. No cleavage, irregular fracture, brittle. $H = 5\frac{1}{2}$. $G = 6.86$. Nonfluorescent. Biaxial (+); $N > 2.0$. From the *Tanco mine*, *Bernic Lake*, MB, Canada, in the saccharoidal albite unit, with manganocolumbite, microlite, quartz, and beryl. RG

8.1.8.4 Lithiowodginite LiTa_3O_8

Named in 1990 for the composition. Wodginite group. MON $C2/c$. $a = 9.441$, $b = 11.516$, $c = 5.062$, $\beta = 91.07^\circ$, $Z = 4$, $D = 7.74$. *MZ* 12:94(1990). 36-1480(syn): 4.18₃ 3.65₆ 2.98₁₀ 2.94₉ 2.53₄ 2.50₅ 1.779₄ 1.706₄. Forms the central portion of wodginite crystals. Polysynthetically twinned. Dark pink to red, pale pink streak, adamantine luster. No cleavage, uneven fracture. $H = 5-6$. $G = 7.5$. Nonluminescent under UV or cathode rays. Tanco pegmatite, Bernic Lake, MB, Canada, in compact crystalline aggregates to 1 cm, associated with simpsonite. From albitic zones in pegmatite, *Kalba*, eastern Kazakhstan, associated with wodginite, irtyshite, simpsonite, and ixiolite. Greenbushes, WA, Australia. RG *AM* 76:667(1991).

8.1.9.1 Liandratite $U^{6+}(Nb,Ta)_2O_8$

Named in 1978 for Georges Liandrat and his wife, of Samoëns, France, who had prospected extensively in Madagascar. *HEX P31m*. $a = 6.36$, $c = 4.01$, $Z = 1$, $D = 6.87$. *29-1435*(metamict, heated): 4.01_8 3.18_{10} 2.49_4 2.00_1 1.84_3 1.69_2 1.67_1 1.20_2 . As rough crystals, liandratite forming a 1- to 2-mm epitaxial crust on petschekite crystals. Yellow to yellow brown, yellow-white streak, vitreous luster. Conchoidal fracture. $H = 3\frac{1}{2}$. $G = 6.8$. Isotropic; $N = 1.83$. *Antsaoka I pegmatite, Berere region, near Tsaratanana, Madagascar*, associated with petschekite, struverite, monazite, ilmenite, garnet, and tourmaline. Gruta de Generosa, Sabinópolis, MG, Brazil. *RG AM 63:941(1978)*.

8.1.9.2 Petschekite $U^{4+}Fe^{2+}(Nb,Ta)_2O_8$

Named in 1978 for Eckhard Petsch (b.1939), of Idar-Oberstein, Germany, who was a noteworthy prospector in Madagascar. Petschekite progressively alters into partially iron-leached and oxidized forms which are designated "oxypetschekite" and "hydroxypetschekite." Only the altered compounds have been found; the original, source material, petschekite, is hypothesized on theoretical grounds. These compounds have the respective general formulas $U_3^{4+}Fe_2^{3+}(Nb, Ta)_6O_{24}$ and $U^{4+}Fe^{3+}\square_{2/3}(Nb, Ta)_2O_7(OH)$. *HEX P31m*. $a = 6.42$, $c = 4.02$, $Z = 1$, $D = 6.99$ (oxypetschekite). *AM 63:941(1978)*. *29-1426*(heated): 4.02_{10} 3.21_{10} 2.51_8 2.01_2 1.86_2 1.85_3 1.70_4 1.49_2 . Metamict, hydroxypetschekite decomposes on heating and the cell constants are unknown. Tabular crystals, hexagonal shape. Black, brownish-black streak, submetallic luster. $H = 5$. $G = 7$. *Antsaoka I pegmatite, Berere district, Madagascar*, associated with columbite, struverite, ilmenite, monazite, and liandratite, the latter forming a thin epitaxial coating on the petschekite crystals. *RG*

8.1.10.1 Ixiolite $(Ta,Nb,Mn,Sn,Fe^{2+})O_2$

Named in 1857 for Ixion, a mythological character related to Tantalus (ixiolite is mineralogically related to tantalite). *ORTH Pbcn*. $a = 4.785$, $b = 5.758$, $c = 5.160$, $D = 6.93$. *CM 14:540(1976)*. *15-733*: 3.65_3 2.98_{10} 2.57_1 2.51_2 1.77_1 1.75_2 1.72_2 1.46_3 . Rectangular prismatic crystals, with {001}, {010}, {100}, {130}, {112}; also, irregular grains, anhedral masses. The structure of ixiolite can be regarded as a disordered columbite-tantalite structure in which the a axis is one-third the length of the columbite a axis, and the various metal ions are more or less randomly distributed between the layers of oxygen atoms. The unit cell contains M_4O_8 , in which M is Ta, Nb, Mn, Sn, and Fe^{2+} . While Ta and Mn are usually dominant, the other metals can vary over rather wide limits. Blackish gray; dark brown, grayish-brown streak, submetallic luster. Uneven to subconchoidal fracture. $H = 6-6\frac{1}{2}$. $G = 7.1$. In addition to the metals listed in the formula, certain ixiolites may also have significant quantities of Sc^{3+} , Ti, Fe^{3+} , W, U, and/or $Nb > Ta$. Helen Beryl mine, Custer, SD. Tanco mine, Bernic Lake, MAN, Canada, with wodginite, tantalite, microlite, cassiterite, tapiolite, and albite in a large Li/Cs-rich pegmatite. *Skogbole, Kimito, Finland*, in pegmatite with tapiolite. Betanimena, Madagascar (scan-

dian). Muiane, Alto Ligonha, Mozambique (scandian). Araçuaí, MG, Brazil. RG *DI:778*; *AM 48:961(1963)*, *59:1020(1974)*; *IMA Abst.:265(1986)*.

8.1.11.1 Samarskite-(Y) (Y,Fe,U)(Nb,Ta)O₄

Named in 1847 for Vasilií Erafovich Samarski-Bykhovets (1803–1870) of the Russian Corps of Mining Engineers. ORTH *Pbcn*. $a = 5.740$, $b = 4.774$, $c = 5.068$. Always metamict. *39-361*(heated): 3.72_2 3.09_{10} 2.96_9 2.81_2 2.61_3 2.48_2 1.912_3 1.854_2 . Crystals prismatic {001}; also tabular {100} and {010}, usually rough; often massive, and then not easily identified; often found in close association with columbite crystals. Black, sometimes with a brownish tint; externally often brown or yellowish brown due to alteration; dark reddish brown to black streak; vitreous to resinous luster; crystals externally dull. Cleavage {010}, indistinct(?); conchoidal fracture; brittle. $H = 5-6$. $G = 5.69$. Isotropic; $N = 2.20 \pm 0.05$. Found in granite pegmatites, especially those related to orogen-related granites having high Y and RE contents. Wiseman's mica mine, Mitchell Co., NC; also at Spruce Pine, associated with columbite and uranmicrolite. Pelton's quarry, Portland, CT. Topsham, ME, with monazite. Ohio City, CO, in Li-rich pegmatite. Maisonneuve, Berthier Co., QUE, Canada, with beryl and fergusonite. Annerød, near Moss, Norway, with columbite in pegmatite. *Miask, Ural Mts., Russia(!)*, with columbite, aeschynite, monazite, and garnet. Antanamalaza, Madagascar(!), with almandine and magnetite. In Brazil at Divino de Uba(!), MG, and also near Sabinópolis(!), in parallel growth with columbite. RG *DI:797*, *DANS 160:693(1965)*, *AM 70:856(1985)*.

8.1.12.1 Qitianlingite Fe₂³⁺Nb₂W⁶⁺O₁₀

Named in 1985 for the locality. ORTH *Pbcn*. $a = 23.706$, $b = 5.723$, $c = 5.045$, $Z = 4$, $D = 6.42$. *AM 73:1497(1988)*. Qitianlingite is a polysome of wolframite and columbite (i.e., the structure can be described as containing alternate slices of columbite and wolframite structures). Each slice has both the structure and the composition of one of the two parental minerals. Structure: *IMA Abst.:261(1986)*. *41-1415*: 3.65_7 2.96_{10} 2.87_6 2.52_7 2.49_4 1.77_8 1.39_6 1.19_6 . Tabular crystals, flattened {001}. Black, dark brown streak, metallic-semimetallic luster. Cleavage {100}, perfect. $VHN_{50} = 520-580$. Moderately magnetic. Insoluble in dilute HCl. In RL, yellowish white, weakly pleochroic and anisotropic. $R = 12.0-14.0$ (546 nm). *Qitian Ling, Hunan, China*, in a pegmatite with zinnwaldite, cassiterite, wolframite, and "wolframixiolite." RG

PYROCHLORE GROUP

The pyrochlore group consists of 22 isometric minerals with the general formula

where

A = Ca, K, Ba, Y, Ce, Pb, U, Sr, Cs, Na, Sb³⁺, Bi, and/or Th

B = Nb, Ta, Ti, Sn, Fe, W

The pyrochlore structure can be derived from the fluorite structure by removing part of the anions so that half the cubes are changed to flattened octahedra. The A-site cations are arranged in cubes, and the B-site cations are arranged in flattened octahedra.

The cations A and B form a face-centered cubic array (as do the Ca atoms in fluorite) and the anions are located in the tetrahedral interstices of the cationic array. The face-centered A and B cations are ordered in alternate {110} rows in every other {001} plane and in alternate {110} rows in the other {001} planes. This results in three kinds of tetrahedral interstices for anions: 48 *f* positions having 2A and 2B nearest neighbors; 8 *a* positions having four B near neighbors; and 8 *b* positions having four A near neighbors. In the pyrochlore structure the 8 *a* positions are vacant: A₂B₂O₇ versus 4CaF₂. The four B cations that neighbor such an anion vacancy tend to be electrostatically shielded from one another by a displacement *x* of each 48 *f* anion from the center of its tetrahedral interstice toward its two neighbor B cations. *VLA* 2:499(1966), *AC(B)* 35:1450(1979). The pyrochlore group is subdivided into four subgroups. *AC(B)* 35:1450(1979), *JSSC*:123(1978).

PYROCHLORE: CaNaNb₂O₆(OH,F)

NbO₆ octahedra share corners to form an open framework with channels in the <110> directions, which are occupied by the Ca and Na atoms (disordered over a single site) and OH,F.

Notes:

1. Cesplumtantite 8.7.11.1, although tetragonal and having a slightly different formula, has a powder pattern very similar to the pyrochlores and might also be considered a member of the pyrochlore group. Further work on this mineral would be indicated.
2. The stibconite structures are very similar.
3. Because of the complex chemistry of these minerals, there was much confusion in their classification and a large number of mineral names were in use to describe the members, depending upon the perceived chemistry. The present nomenclature and classification follows the 1977 report of the IMA committee formed to consider the matter in *AM 62:403(1977)*.
4. The formulas shown here are simplified; in actuality, many other elements can be found in small amounts in naturally occurring material, among them U and Th. These radioactive elements render many pyrochlore minerals metamict, and the diffraction data and cell constants can be determined only after heating the material under investigation.

8.2.1.1 Pyrochlore $(Na,Ca)_2Nb_2O_6(OH,F) \cdot nH_2O$

Named in 1826 from the Greek for *fire* and *green*, because some specimens of the mineral turn green after ignition. Pyrochlore group. iso *Fd3m*. $a = 10.34-10.43$, $Z = 8$, $D = 4.26$. *CM 6:610(1961)*. $13-254$: 5.98₂ 3.13₂ 3.00₁₀ 2.60₂ 1.84₆ 1.57₅ 1.50₁ 1.19₂. Usually octahedral crystals, sometimes modified by cube faces; as anhedral grains; spinel-law twins common. Brown, black, yellowish brown; light brown to yellowish-brown streak; vitreous to resinous luster. Cleavage {111}, rarely distinct; subconchoidal to uneven fracture; brittle. $H = 5-5\frac{1}{2}$. $G = 4.45$. Nonfluorescent in UV light. Infusible. May turn yellowish green or other color upon ignition. Insoluble in HCl, slowly decomposed by concentrated H_2SO_4 . Isotropic; $N = 1.96$. In RL, isotropic. Strong brown to yellow internal reflections. $R = 11.0$ (470 nm), 10.7 (546 nm), 10.5 (589 nm), 10.4 (650 nm). Pyrochlore is abundant in some carbonatites and is typically found in nepheline syenite rocks and their derivatives. It is also found in pegmatites, particularly those derived from syenitic magmas. St. Peter's Dome area(!), El Paso Co., CO, in pegmatite. In Canada at Oka, QUE, in carbonatite, with latrappite, niocalite, and so on; Verity carbonatite, Blue River, BC(!). In Norway at *Fredricksvarn* and Laurvik in nepheline syenite pegmatites with zircon, polymignite, and cerian apatite. Alnö region, Sweden, in limestone in contact with nepheline syenite intrusive, with perovskite, zircon, apatite, and magnetite. Miask, Ilmen Mts., Russia, in nepheline syenite with aeschynite and zircon. Los archipelago, Conakry, Guinea, in nepheline syenite, with villiaumite, astrophyllite, fluorite, catapleite, and lavenite. The most important ore of niobium. The biggest deposits are in carbonatites, which in some instances may carry up to 4% Nb_2O_5 contained in one of the

pyrochlore group minerals; the particular mineral varies from one carbonatite to another, but bariopyrochlore and pyrochlore are among the most important. RG *DI:748, AM 62:403(1977)*.

8.2.1.2 Kalipyrochlore $(\text{K,Sr})_{2-x}\text{Nb}_2\text{O}_6(\text{O,OH}) \cdot n\text{H}_2\text{O}$

Named in 1978 for the composition, with K (kalium) dominant in the A position. Pyrochlore group. iso *Fd3m*. $a = 10.604$, $Z = 8$, $D = 3.42$. *CM 32:415(1994)*. 30-991: 6.16₈ 3.21₇ 3.07₁₀ 2.05₂ 1.88₄ 1.79₂ 1.60₃ 1.22₁. As octahedral crystals. Greenish; grayish, white streak, vitreous luster. $H = 4-4\frac{1}{2}$. $G = 3.44$. Isotropic; $N = 1.93-1.99$. Formed as a result of leaching pyrochlore by potassium-bearing solutions in the zone of weathering. The crystals are zoned, having a core of normal pyrochlore. *Goma, Lueshe, Kivu, Zaire*, in alluvial deposits and weathered soils derived from the Lueshe carbonatite. RG *AM 63:528(1978)*.

8.2.1.3 Bariopyrochlore $(\text{Ba,Sr})_2(\text{Nb,Ti})_2(\text{O,OH})_7$

Named in 1977 for the composition. Pyrochlore group. Formerly called "pandaite," for the locality in Tanzania. iso *Fd3m*. $a = 10.562$, $Z = 8$, $D = 4.01$. *AM 44:1324(1959)*. 12-285: 6.09₈ 3.18₅ 3.04₁₀ 1.86₇ 1.59₇ 1.21₅ 1.18₅ 1.016₆. Small euhedral crystals, {111} modified by {100}. Yellowish gray, tan, olive-gray. Cleavage {111}, poor; conchoidal fracture. $H = 4\frac{1}{2}-5$. $G = 4.0$. Usually radioactive. Isotropic; $N = 2.07-2.10$. In RL (white light), 13.2%. *Panda Hill, near Mbeya, Tanzania*, in biotite-rich altered carbonatite. *Araxa, MG, and Catalão, GO, Brazil*, in carbonatites. The Araxa deposit is the world's largest and richest niobium deposit. RG *MM 32:10(1959), AM 62:403(1977)*.

8.2.1.4 Ytropyrochlore-(Y) $(\text{Y,Na,Ca,U})_{1-2}(\text{Nb,Ta})_2(\text{O,OH})_7$

Named in 1977 for the composition. Pyrochlore group. Formerly called "obruchevite" for the Russian geologist, V. A. Obruchev (1863-1956). iso *Fd3m*. $a = 10.0-10.34$, $Z = 8$, $D = 4.17$. *AM 43:797(1958)*. 18-765: 5.50₂ 4.43₂ 3.09₃ 3.02₁₀ 2.97₂ 2.95₁₀ 2.80₂ 2.66₂. 25-1015(heated): 3.45₄ 3.15₅ 2.98₁₀ 2.58₃ 2.50₃ 1.70₉ 1.55₅ 1.49₇. Dense masses without crystal form. Chocolate brown, vitreous to adamantine luster. Conchoidal fracture. $H = 4\frac{1}{2}-5$. $G = 3.7$. Isotropic; $N = 1.830-1.835$. *Alakurtti region, Karelia, Russia*, in pegmatites, associated with allanite, garnet, columbite, and fergusonite. RG *AM 62:403(1977)*.

8.2.1.5 Ceriopyrochlore-(Ce) $(\text{Ce,Ca,Y})_2(\text{Nb,Ta})_2\text{O}_6(\text{OH, F})$

Named in 1977 for the composition. Pyrochlore group. Formerly called "marignacite," for the French chemist, G. de Marignac (1817-1894). iso *Fd3m*. $Z = 8$, $D = 4.25$. 41-1385: 3.7₃ 3.3₆ 3.0₁₀ 2.56₃ 2.46₃ 1.82₄ 1.53₃ 1.51₃. Forms octahedral crystals. Light to dark brown, light brown to yellowish-brown streak, resinous luster. Conchoidal fracture, brittle. $H = 5-5\frac{1}{2}$. $G = 4.13$. Isotropic. Sometimes anomalously birefringent. *Wausau, Marathon Co., WI*, an alkalic pegmatite, with acmite, lepidomelane, rutile, fluorite, and various Zr

minerals. Schelingen, Kaiserstuhl, Germany. Nei Monggol, China. RG *DI:755, AM 62:403(1977)*.

8.2.1.6 Plumbopyrochlore $(\text{Pb, Y, U, Ca})_{2-x}\text{Nb}_2(\text{O, OH})_7$

Named in 1966 for the composition. Pyrochlore group. iso *Fd3m*. $a = 10.534$, $Z = 8$, $D = 6.75$. *25-453*: 3.02₁₀ 2.62₆ 1.86₉ 1.58₉ 1.21₇ 1.18₆ 1.08₈ 1.02₈. As grains, and zoned octahedral crystals. Brown, greenish yellow, red. $G = 5.04$. Isotropic; $N = 2.08$. *Ural Mts., Russia*, in metasomatically altered granitic rocks, with microcline, albite, and aegirine; Keivy, Kola Penin.(1), in large crystals. RG *AM 55:1068(1970), 62:403(1977)*.

8.2.1.7 Uranpyrochlore $(\text{U, Ca, Ce})_2(\text{Nb, Ta})_2\text{O}_6(\text{OH})$

Named in 1977 for the composition. Formerly called "hatchettolite," for Charles Hatchett (1765–1847), English chemist, who discovered the element niobium. Pyrochlore group. iso *Fd3m*. $a = 10.333$, $Z = 8$. *MM 53:257(1989)*. *29-1411*: 7.3₄ 3.01₁₀ 2.61₃ 1.84₈ 1.72₁ 1.58₆ 1.20₂ 1.17₂. Octahedrons, modified by {001} and {113}; also massive. Black, red, red-brown; yellowish brown, adamantine to resinous luster. Subconchoidal fracture, brittle. $H = 4$. $G = 4.5-4.9$. Isotropic; $N = 1.98$. From *mica mines, Mitchell Co., NC*, with samarskite. Harding pegmatite, Dixon, NM. Woodcox mine, Hybla, ONT, Canada, in pegmatite with columbite, cyrtolite, titanite, amazonite. Ndale, Ft. Portal area, Uganda, in a calcite-bearing tuff related to a recent carbonate intrusion, associated with pyrochlore, zircon, titanite, monazite, magnetite, biotite, and other minerals. RG *DI:754, AM 62:403(1977)*.

8.2.1.8 Strontipyrochlore $\text{SrNb}_2(\text{O, OH})_7$

Named in 1986 for the composition. Pyrochlore group. iso *Fd3m*. $a = 10.53$, $Z = 8$, $D = 3.99$. *AM 73:930(1988)*. Octahedral crystals. Pale yellow. $VHN = 246$. $G = 3.80$. Isotropic; $N = 2.08$. *Yenisei Ridge, Russia*, in dolomitic carbonatites. RG *DANS 290:1212(1986)*.

8.2.2.1 Microlite $(\text{Na, Ca})_2\text{Ta}_2\text{O}_6(\text{O, OH, F})$

Named in 1835 from the Greek for *small*, in allusion to the minute size of the crystals from the original locality. Pyrochlore group. iso *Fd3m*. $a = 10.40$, $Z = 8$, $D = 6.34$. *3-1139*: 3.00₇ 1.84₈ 1.57₁₀ 1.36₆ 1.19₇ 1.16₆ 1.060₆ 1.000₇. Crystallizes as octahedrons, sometimes modified by {011}, {001}, or {113}; also as anhedral grains. Yellow, brown, green, reddish, black; pale yellowish or brownish streak; resinous to vitreous luster. Cleavage {111}, difficult; subconchoidal to uneven fracture; brittle. $H = 5-5\frac{1}{2}$. $G = 6.42$. Nonfluorescent. Isotropic; $N = 2.023$. Microlite is found typically in pegmatites, especially those rich in albite, or in lepidolite and other lithium minerals. Also disseminated as small grains in some albitites and apogranites. *Chesterfield, Hampshire Co., MA*, in lithium pegmatite with albite, elbaite, spodumene, columbite, and cassiterite. Topsham, ME, with albite, topaz, elbaite, and lepidolite. In CT in pegmatites at Haddam, Middletown, and Portland. Ame-

lia Court House, VA(II), in large crystals in cleavelandite with manganotantalite, columbite, and amazonite. Harding mine, Dixon, NM(*), in considerable amount embedded in pink lithian muscovite, with beryl, albite, and uranpyrochlore. Tanco mine, Bernic Lake, MB, Canada, in albite with wodginite and other tantalum minerals in a very large lithium pegmatite. Also Mattawa, ONT(I), as brown octahedra to 1 cm. Narssarssuk, Greenland. Varutrask, Sweden, with stibiotantalite in pegmatite. Skogbole, Finland, with ixiolite. Echassières, Massif Centrale, France, in kaolinized apogranite. Fine crystals near Shingus, Gilgit, Pakistan. Yi Chun mine, Jiangxi Prov., China, in a lithian albitite. Jooste mine, Karibib, Namibia. Greenbushes and Wodgina, WA, Australia, in pegmatites. In Brazil at many localities, especially São João del Rei, MG(I); Xanda mine, Araçuaí, MG(I); at Alto do Giz, Equador, RGN, with manganotantalite and simpsonite. An important ore of tantalum. RG *DI:748, AM 62:403(1977)*.

8.2.2.2 Bariomicrolite $(\text{Ba,U,Pb})_2(\text{Ta,Nb})_2(\text{O,OH})_7$

Named in 1977 for the composition, being a member of the microlite subgroup. Pyrochlore group. Formerly called "rijkeboerite," for A. Rijkeboer, Dutch chemist. iso *Fd3m*. $a = 10.570$, $Z = 8$, $D = 5.60$. *AM 48:1415(1963)*. 16-616: 6.04₈ 3.18₇ 3.03₁₀ 2.63₆ 1.87₆ 1.78₄ 1.59₅ 1.08₄. Crystallizes in octahedrons. Pink, reddish, or yellowish brown, white or colorless. $H = 4\frac{1}{2}$ -5. $G = 5.7$. $R_{\text{mean}} = 13.2$. From a pegmatite near *Chi Chico, São João del Rei, MG, Brazil*, associated with cassiterite. RG *AM 62:403(1977)*.

8.2.2.3 Plumbomicrolite $(\text{Pb,Na,Ca})_2(\text{Ta,Nb})_2\text{O}_6(\text{O,OH,F})$

Named in 1961 for the composition as a member of the microlite subgroup. Pyrochlore group. iso *Fd3m*. $a = 10.56$, $Z = 8$, $D = 7.2$ (for Ta/Nb = 10:1). *AM 47:1220(1962)*. 44-670: 2.99₁₀ 2.60₆ 1.85₉ 1.58₁₀ 1.209₈ 1.178₈ 1.078₈ 1.017₉. Crystalline masses and rare octahedra. Greenish yellow; orange, greasy luster. $H = 6$. $G = 6.5$ -7.2. Insoluble in acids. Keivy, Kola Penin., Russia(I), as large yellow crystals (often octahedra) frequently in excess of 3 cm. *Kivu, Zaire*, in alluvium derived from nearby spodumene pegmatites. RG *AM 62:403(1977)*.

8.2.2.4 Uranmicrolite $(\text{U,Ca})_2(\text{Ta,Nb})_2\text{O}_6(\text{OH})$

Named in 1957 for the composition, as a member of the microlite subgroup. Pyrochlore group. Formerly called "djalmaite," for Djalma Guimaraes (1895-1973), Brazilian mineralogist and petrologist. iso. *Fd3m*. $a = 10.40$, $Z = 8$, $D = 6.45$. 43-693: 2.95₁₀ 2.55₈ 1.818₁₀ 1.552₁₀ 1.183₈ 1.154₈ 1.054₈ 0.995₈. Crystallizes in octahedra, modified by {113} and {001}. Yellowish brown; greenish brown; brownish black, light yellow streak, greasy luster. No cleavage, irregular fracture. $H = 5\frac{1}{2}$. $G = 5.75$ -5.88. Highly radioactive. Isotropic; $N = 1.97$. In pegmatite from *Fazenda Posse, Brejauba district, Município de Conceição de Serro, MG, Brazil*, with columbite, magnetite, samarskite, garnet, beryl, tourmaline, and bismuth minerals; also Parelhas, RGN, Brazil, in

fine crystals. RG *DI*:805; *AM* 26:347(1941), 62:403(1977); *ABC* 21(4):337(1949).

8.2.2.5 Bismutomicrolite (Bi,Ca)(Ta,Nb)₂O₆(OH)

From the composition and as a member of the microlite subgroup. Pyrochlore group. Formerly called "westgrenite," for Arne Westgren (1889–1975), Swedish chemist and crystallographer, who synthesized BiTa₂O₆F. iso *Fd3m*. $a = 10.485$, $Z = 8$, $D = 6.83$. *AM* 48:215(1963). 26-1042: 5.94₆ 3.14₈ 3.00₁₀ 2.60₆ 2.00₆ 1.84₉ 1.76₆ 1.57₉. Crystallizes as octahedra, also massive, in veinlets. Yellow; pink; brown, resinous to dull luster. Uneven fracture. $H = 5$. $G = 6.5$. Infusible; insoluble in acids. Isotropic; $n = >2.00$. *Wampewo Hill, Busiro Co., Buganda, Uganda*, as veinlets in bismutotantalite. In Brazil at the Alto Manoel Balduino, Junco, PB, in masses with bismutotantalite; Ermo mine, Carnaubá dos Dantas, RGN, in small octahedral crystals, with spessartine, gahnite, euclase, bertrandite, and tantalite. RG *AM* 62:403(1977).

8.2.2.6 Stannomicrolite (Sn²⁺,Fe²⁺,Mn²⁺)₂(Ta,Nb,Sn⁴⁺)₂(O,OH)₇

Named in 1977 from the composition and as a member of the microlite subgroup. Pyrochlore group. Formerly called "sukulaite" for the locality. iso *Fd3m*. $a = 10.57$, $Z = 8$, $D = 7.56$. *AM* 53:2103(1968). 23-1441: 3.05₁₀ 2.64₆ 1.87₈ 1.59₈ 1.52₄ 1.21₄ 1.18₄ 1.02₄. Grains and narrow rims surrounding ferrowodginite. Yellowish brown. In RL, gray with a reddish tint; reddish-brown internal reflections. R value > cassiterite. *Sukula, Tammela, Finland*. RG *BCGF* 229:173(1967), *AM* 62:403(1977), *NJMM*:249(1987).

8.2.2.7 Stibiomicrolite (Sb,Ca,Na)₂(Ta,Nb)₂(O,OH,F)₇

Named in 1938 for the composition and as a member of the microlite subgroup. Pyrochlore group. iso *Fd3m*. $a = 10.455$, $Z = 8$, $D = 5.84$ –6.22. *AM* 73:1499(1988). 40-516: 6.03₈ 3.14₉ 3.01₁₀ 2.61₇ 2.01₅ 1.85₇ 1.58₈ 1.36₄. Microscopic veinlets replacing stibiotantalite. Greenish-white; white, white streak. $H = <$ stibiotantalite. Isotropic; $N = >1.90$; 2.07–2.16 (calc.). In RL, gray, darker than tantalite. *Varuträsk, Sweden*, in pegmatite with albite, lepidolite, lithiophilite, alkali beryl, cassiterite, columbite–tantalite, and allemontite, as veinlets replacing stibiotantalite, associated with native Sb in the veinlets. RG *GFF* 60:216(1938), 109:105(1987); *DI*:757.

8.2.3.1 Betafite (Ca,Na,U)₂(Ti,Nb)₂O₆(OH)

Named in 1912 for the locality. Pyrochlore group. In part, once named "samiresite," a plumboan betafite (Lacroix). iso *Fd3m*. $a = 10.3$, $Z = 8$, $D = 4.63$. Metamict. Physical properties and degree of hydration are variable, due to the variable degree of alteration of betafite from different sources. 13-197: 2.96₁₀ 2.56₂ 1.814₅ 1.546₄ 1.482₂ 1.284₁ 1.179₂ 1.148₂. Known only as crystals, which are octahedral, usually modified by {011}, more rarely {113} and {001}. Greenish brown; yellow; dark brown; black, waxy to vitreous to submetallic luster. Conchoidal to uneven fracture; brittle. $H = 4$ –5½. Strongly

radioactive. Nonfluorescent. Isotropic; $N = 1.92$. Brown Derby pegmatite, Ohio City, Gunnison Co., CO. Silver Crater mine, Bancroft, ONT, Canada(!), in fine crystals. Mina El Muerto, Telixtlahuaca, OAX, Mexico(!). In numerous places in *Madagascar*, in fine crystals up to 15 cm, especially W of *Betafo*(!); *Antanifotsy*(*); *Ambatolampikely*(!); E of *Ampangabe*(!); *Samiresy* ("samiresite"); and at *Tongafeno* with beryl, columbite, and zircon. RG *DI:803*, *CM 6:610(1961)*, *AM 46:1519(1961)*.

8.2.3.2 Yttrobetafite-(Y) $(Y,Ce)_2(Ti,Nb)_2O_6(OH,F)$

Named in 1962 from the composition and as a member of the betafite subgroup. Pyrochlore group. iso *Fd3m*. $Z = 8$, $D = 5.05$. Metamict. *AM 49:440(1964)*. *41-1434*(heated to 900°): 3.26_8 2.99_7 2.50_6 1.76_2 1.69_{10} 1.63_3 1.18_6 1.10_3 . Greenish, greasy to dull luster. $G = 3.65-4.90$. *Alakurtti region*, *northwestern Karelia, Russia*, in quartz-plagioclase-microcline pegmatite. RG *AM 62:403(1977)*.

8.2.3.3 Plumbobetafite $(Pb,U,Ca)(Ti,Nb)_2O_6(OH,F)$

Named in 1969 for the composition and as a member of the betafite subgroup. Pyrochlore group. iso *Fd3m*. $a = 10.33$, $Z = 8$. Metamict. Rounded grains, crude octahedral crystals. Yellowish, adamantine luster. $G = 4.64$. *Burpala massif*, *N of Lake Baikal, Siberia, Russia*, in a microcline-albite-quartz-riebeckite-aegirine dyke cutting nepheline syenite. RG *AM 55:1068(1970)*, *62:403(1977)*.

8.2.3.4 Stibiobetafite $(Sb,Ca)_2(Ti,Nb)_2(O,OH)_7$

Named in 1979 for the composition and as a member of the betafite subgroup. Pyrochlore group. iso *Fd3m*. $a = 10.356$, $Z = 8$, $D = 5.19$. *CM 17:583(1979)*. *37-695*(heated): 5.94_3 2.99_{10} 2.58_4 1.83_6 1.56_5 1.50_3 1.19_3 1.16_3 . Anhedronal veinlets and replacement aggregates, also poorly developed octahedra. Dark brown; brownish black, pale brown streak, vitreous luster. Brittle. $H \sim 5$. $G = 5.30$. Isotropic; $N_{\text{calc}} = >1.78$, 2.2. *Vežná, Moravia, Czech Republic*, as a replacement of columbite-ixiolite, associated with niobian rutile, cassiterite, and metamict zircon, in a sodic pegmatite. RG *AM 66:1278(1980)*.

8.2.3.5 Calciobetafite $(Ca,Na)_2(Ti,Nb)_2(O,OH)_7$

Named in 1983 for its composition and as a member of the betafite subgroup. Pyrochlore group. iso *Fd3m*. $a = 10.298$, $Z = 8$, $D = 4.60$. *AM 68:262(1983)*. *42-2*: 2.97_{10} 2.57_3 1.82_5 1.55_4 1.49_1 1.18_2 1.15_1 1.05_1 . Octahedral crystals. Reddish brown. $G = 4.81$. Isotropic. Oka, QUE, Canada, in carbonatite. *Campi Flegrei, Monte di Procida, Campania, Italy*, in a sanidine, associated with zirconolite 3O and zirconolite 3T. RG

8.2.4.1 Cesstibtantite (Cs,Na)Sb³⁺Ta₄O₁₂

Named in 1982 for the composition. Pyrochlore group. iso *Fd3m*. $a = 10.515$, $Z = 8$, $D = 6.49$. *MP* (1993). 35-672: 3.17₉ 3.04₁₀ 2.02₈ 1.860₁₀ 1.587₁₀ 1.370₉ 1.017₉ 1.012₁₀. Small grains. Colorless; gray; yellow-orange; black, vitreous to adamantine luster. Brittle. $H = 5$. $G = 6.5$. Isotropic; $N > 1.8$. The formula for cesstibtantite from the type locality is $\text{Cs}_{0.31}(\text{Sb,Na,Pb,Bi})_{0.91}(\text{Ta,Nb})_2(\text{O,OH,F})_6(\text{OH,F})_{0.69}$. From the Tanco mine, the formula was $(\text{Cs,K})_{0.23}(\text{Na,Sb,Pb,Ca,Bi})_{1.06}(\text{Ta,Nb})_2(\text{O,OH,F})_6(\text{OH,F})_{0.55}$. Cesstibtantite differs from the normal pyrochlores in that it contains significant amounts of very large cations such as Cs. As these cations are too large for the conventional eight-coordinated A site, they occupy the 18-coordinated ϕ site. The formula can be written $\text{A}_{2-m}\text{B}_2\text{O}_6(\phi, \text{A}')_{1-n}$, where $\text{A} = \text{Na,Sb,Pb,Bi,Ca,Sn}$; $\text{B} = \text{Ta,Nb}$; $\text{O}' = \text{O,OH,F}$; $\phi = \text{OH,F}$; and $\text{A}' = \text{Cs,K}$. It is intermediate between the normal pyrochlore (with only monovalent anions at the ϕ site), and inverse pyrochlore structures (with only large cations at the ϕ site). Tanco mine, Bernic Lake, MB, Canada, with wodginite, simpsonite, and microlite. *Leshaiia, Kola Penin., Russia*, in albitized zones of a pegmatite, as aggregates along simpsonite-stibiotantalite grain boundaries. *RG IGR 24:843(1982)*, *AM 67:413(1982)*, *MP 48:235(1993)*.

8.2.4.2 Natrobistantite (Na,Cs)Bi(Ta,Nb,Sb)₄(O,OH)₁₂

Named in 1983 for the composition. Pyrochlore group. iso *Fd3m*. $a = 10.502$, $Z = 4$, $D = 6.32$. *AM 69:407(1984)*. Possibly isostructural with bismutomicro-lite, or a Cs-bearing variety of that mineral. 35-706: 6.07₆ 3.17₅ 3.03₁₀ 2.63₈ 1.86₉ 1.58₉ 1.21₅ 1.17₅. Octahedral crystals; aggregates and grains. Blue-green, yellow-green, colorless. $G = 6.2$. Colorless grains fluoresce red-orange in UV light; colored grains do not fluoresce. Isotropic. $R = 16.7$ (486 nm), 17.0 (589 nm), 15.7 (656 nm). *Kyokobogor, China*, in granite pegmatite, formed by replacement of bismutotantalite and replaced in turn by microlite; associated with bismuth oxides, pucherite, and clinobisvanite. *RG MZ 5(2):82(1983)*.

8.2.5.1 Zirkelite (Ti,Ca,Zr,Fe³⁺,Ce)O_{2-x}

Named in 1960 for Ferdinand Zirkel (1838–1912), German petrographer, University of Leipzig. Metamict. Probably iso Space group unknown. $a = 5.02$. 38-450: 2.9₁₀ 2.52₄ 1.78₇ 1.52₆ 1.46₂ 1.26₂ 1.16₃ 1.13₂. Irregular segregations and grains. Iron black, light brown streak, adamantine to greasy luster. $H = 6$. $G = 4.37$. Isotropic; $N = 2.5$. Reddish brown in thin section. *Aldan, Arbarastakh massif, Kola Penin., Russia*, in coarse-grained micaceous pyroxenite, in a group of Aldan ultrabasic rocks. *Jacupiranga, SP, Brazil*, in carbonatite with baddeleyite, perovskite, and so on. *RG DI:740, AM 68:262(1983)*, *MM 53:565(1989)*.

8.2.5.2 Zirconolite-3O (Ca,Fe,Y,Th)₂Fe(Ti,Nb)₃Zr₂O₁₄

Named in 1828 for the composition. ORTH *Cmca*. $a = 10.148$, $b = 14.147$, $c = 7.278$, $Z = 4$. Zirconolite-3O is the nonmetamict orthorhombic polytype

(possibly a polymorph) of $\text{CaZrTi}_2\text{O}_7$. Nomenclature of this group was revised in 1989. *MM* 53:565(1989), *AM* 68:272(1983). *PD*: 2.97₁₀ 2.57₃ 1.82₅ 1.55₄ 1.49₁ 1.18₂ 1.15₁ 1.05₁. Prismatic crystals, elongated [100]. Dark red. *G* = 4.8. Anisotropic, parallel extinction, weakly pleochroic. *Fredricksvarn, Norway. Monte di Procida, Campi Flegrei, Campania, Italy*, in sanidinite, associated with calciobetafite and zirconolite-3T. *RG* *DI*:764; *AM* 42:581(1957), 60:341(1975).

8.2.5.3 Zirconolite-2M $\text{CaZrTi}_2\text{O}_7$

Named in 1989 for the composition. Initially described as "zirkelite." See zirkelite (8.2.5.1). Renamed by the IMA. *MM* 53:565(1989). *MON* *C2/c*. *a* = 12.445, *b* = 7.288, *c* = 11.487, β = 100.38°, *Z* = 8, *D* = 4.9. Structure: *AC(B)* 37:306(1981). 34-167: 2.93₁₀ 2.82₄ 2.513₃ 2.507₃ 1.806₁ 1.797₂ 1.754₂ 1.749₂. Brown, black. *G* = 4.2. *Kaiserstuhl, Germany*, in carbonatite. *RG* *AM* 67:615(1982), *T&G*:183-204.

8.2.5.4 Zirconolite-3T $\text{CaZrTi}_2\text{O}_7$

Named in 1989 for the composition. Formerly called "zirkelite" (8.2.5.1). Nomenclature revised by the IMA in 1989. *MM* 53:566(1989). *HEX-R* *P3₁2*. *a* = 7.287, *c* = 16.886, *Z* = 3, *D* = 4.88. *AM* 68:266(1983). 15-12: 2.98₁₀ 2.84₂ 2.53₃ 2.30₁ 1.82₅ 1.75₃ 1.525₁ 1.510₁. Crystals rough, hexagonal, platy {0001}; small grains. Black; brownish black, reddish-brown streak, resinous to sub-metallic luster. Splintery fracture, brittle. *H* = 5½. *G* = 4.72. Uniaxial. *Monte di Procida, Campi Flegrei, Campania, Italy*, with zirconolite-3O and calciobetafite in sanidinite; *Walaweduwa, Bambarabotuwa district, Sabaragamuwa, Sri Lanka*. *RG* *MM* 16:309(1913), *DI*:741.

8.2.5.5 Zirconolite $(\text{Ca,Fe}^{2+},\text{RE,Zr,Th})(\text{Zr,Nb,Ti,Ta,Fe}^{3+})\text{Ti}_2\text{O}_7$

Named in 1989 for the composition. Originally called "polymignite." Metamict. In 1989, the IMA, CNMMN, approved the name *zirconolite* (without suffix) for minerals having the composition ABX_2O_7 (ideally, $\text{CaZrTi}_2\text{O}_7$) which are noncrystalline or of undetermined polytypoid. Metamict "polymignite" is zirconolite. *MM* 53:566(1989). Pseudomorphous crystals, when present, are prismatic [001], striated [001], somewhat flattened {100}; massive; as anhedral grains. Black, dark brown streak, submetallic-metallic luster. Conchoidal fracture. *H* = 6½. *G* = 4.80. Nonfluorescent. Infusible. Decomposed by concentrated H_2SO_4 . Isotropic; *N* ≈ 2.22. In *Norway* at *Fredricksvarn* in pegmatite with magnetite, nepheline, zircon, and pyrochlore; also on the Island of *Svenor* and at *Bommestad, Langesundfjord*. *RG* *DI*:764.

8.2.6.1 Scheteligite $(\text{Ca,Y,Sb})_2(\text{Ti,Ta,Nb,W})_2\text{O}_6(\text{OH})$ (?)

Named in 1937 for Jacob Schetelig (1875-1935), Norwegian mineralogist, director of the Oslo Mineralogical Museum. A questionable mineral. Probably *ORTH* Space group unknown. Metamict. Rough, probably orthorhombic crystals. Black, grayish to pale yellow streak, brilliant luster. Conchoidal fracture.

$H = 5\frac{1}{2}$. $G = 4.74$. *Torvelona, Iveland, Norway*, associated with tourmaline, bismuth, euxenite, thortveitite, monazite, and beryl. RG *AM 23:293(1938)*, *DI:757*.

8.2.7.1 Orthobrannerite $U^{6+}U^{4+}Ti_4O_{12}(OH)_2$

Named in 1978 for the orthorhombic symmetry and similarity to brannerite. Metamict. ORTH (after heating) $P2_122$. $a = 7.37$, $b = 11.67$, $c = 6.33$, $Z = 2$, $D = 5.46$. *33-1434*: 4.87₇ 3.89₈ 3.17₁₀ 2.45₉ 2.29₅ 1.82₄ 1.66₉ 1.20₆. Prismatic crystals, with {001}, {120}, {021}, {140}. Striated [001]. Black, dark brown to black streak, adamantine luster. Conchoidal fracture. $VHN_{100} = 525$. $G = 5.46$. Nonfluorescent. Strongly radioactive. Unattacked by H_2SO_4 or HCl , dissolves in $H_2SO_4 + H_3PO_4$. Isotropic; $N = 2.33$. In RL, grayish white, with reddish-brown internal reflections. *Yunnan, China*, in a biotite pyroxene syenite, and in *Sichuan* in an alkalic lamprophyre. RG *AM 64:656(1979)*.

8.2.8.1 Parabariomicrolite $BaTa_4O_{10}(OH)_2 \cdot 2H_2O$

Named in 1986 for the similarity to bariomicrolite but having a different symmetry. HEX-R $R3m$. $a = 7.429$, $c = 18.505$, $Z = 3$, $D = 5.97$. *CM 24:655(1986)*. *39-401*: 6.18₅ 3.17₆ 3.08₄ 3.04₁₀ 2.64₅ 1.88₄ 1.86₄ 1.59₄. As irregular replacements of microlite. White; pale pink, white streak, vitreous or pearly luster. Cleavage {001}, {101}, good; brittle. $H = 4$. Nonfluorescent. Anisotropic; $N > 2.0$. *Alto do Giz, Equador, RGN, Brazil*, associated with simpsonite, microlite, manganotantalite, tapiolite, natrotantite, alumotantite, stibiotantalite, beryl, spodumene, and petalite. RG *AM 73:194(1988)*.

8.3.1.1 Ferrotapiolite $(Fe,Mn)Ta_2O_6$

Originally called "tapiolite," named in 1863 for *Tapio*, god of the forest in Finnish mythology. Renamed *ferrotapiolite* in 1983 for the composition. Synonym: tapiolite. TET $P4_2/mnm$. $a = 4.762$, $c = 9.272$, $Z = 2$, $D = 8.17$. *23-1124*: 4.22₃ 3.36₁₀ 2.58₉ 2.38₃ 1.746₇ 1.680₃ 1.502₂ 1.407₃. Short prismatic or equant crystals, with {001}, {100}, {110}, and {113} well developed. Twinning on {013}, very common. Twins often show one or more curved faces, which are very characteristic. Tapiolite exists in an ordered and a disordered phase, the ordered phase having a trirutile structure and the disordered one a rutile-type structure. The relationship to rutile is shown by direct correspondence of the a cell dimension, but in ordered tapiolite the c dimension is tripled. Black, cinnamon brown to brownish-black streak, submetallic to subadamantine luster. No cleavage, uneven to subconchoidal fracture. $H = 6-6\frac{1}{2}$. $G = 7.90$. Ferrotapiolite is always Ta-rich, and the solubility of $FeNb_2O_6$ in the structure is limited to about 20%. Ferrotapiolite is also nearly always Fe-rich, although a small amount of Mn is usually present. Only one or two known examples show $Mn > Fe^{2+}$ and then only to a limited degree, so that manganotapiolite is always an intermediate member of the series $FeTa_2O_6-MnTa_2O_6$. Uniaxial (+); $N_O = 2.27$, $N_E = 2.42$ (Li). O, pale reddish brown; E, nearly opaque.

Twin lamellae on {013}. In ME at Topsham, Sagadahoc Co., and Paris, Oxford Co. Old Mike mine, 6 km N of Custer, Custer Co., SD. Tanco mine, Bernic Lake, MB, Canada, with wodginite, tantalite, ixiolite, and microlite. *Kulmala pegmatite, Sukula, Tammela, Finland*, and also at Skogbole, Kimito. Chanteloube, Limoges, France. Muiane mine, Alto Ligonha, Mozambique, in fine crystals up to 8 kg. Greenbushes, and at Strelley, Pilbara, WA, Australia. In Brazil at many localities, especially at the Alto Boqueirão, and at Alto dos Preas, Parelhas, RGN; Alto Marimbondo, Carnauba dos Dantas, RGN; in MG at the Barra do Cuete, Mun. Conselheira Pena, and at the Amuro mine, near São Jose da Safira. RG *DI:775, MM 42:477(1978), BGSF 55:101(1983)*.

8.3.1.2 Manganotapiolite (Mn,Fe)(Ta,Nb)₂O₆

Named in 1983 for the composition. Dimorphous with manganotantalite. TET $P4_2/mnm$. $a = 4.762$, $c = 9.272$, $Z = 2$, $D = 7.72$. $35-626: 4.24_4 3.37_{10} 2.59_9 2.38_6 1.75_9 1.68_6 1.50_4 1.41_4$. Prismatic, minute crystals. Dark brown, dark brown streak. $VHN_{100} = 711$. End-member tetragonal $Mn(Ta,Nb)_2O_6$ has not been found; $Mn > Fe$ members are very rare, the maximum Mn/Fe ratio so far recognized is $Mn_{59}Fe_{32}$. In RL, gray, with strong red-brown internal reflections; weakly pleochroic. $R = 14.7-14.1$ (546 nm). *Vitaniemi, Eräjärvi, Orivesi, Finland*, in a lithium pegmatite, associated with ferrotapiolite. RG *BGSF 55:101(1983), AM 70:217(1985)*.

COLUMBITE GROUP

The columbite group of minerals consists of five isostructural minerals having the general formula

where

A = Fe, Mn, Mg

B = Nb, Ta

and an orthorhombic structure in space group *Pbcn*.

In the structure of the columbite minerals, the oxygen anions are in pseudohexagonal close packing parallel to (100), and the metal cations occupy one-half of the available pseudo-octahedral interstices. In the idealized structure $AB_2O_6 : (Fe,Mn)(Nb,Ta)_2O_6$, the two different cations (Fe,Mn) and (Nb,Ta) are ordered into different octahedral sites in the required ratio of 1:2 so that they also occur in layers parallel to (100) with layers of (Fe,Mn) cations at $x = 0$ and $x = \frac{1}{2}$ and of (Nb,Ta) cations at $x = \frac{1}{6}, \frac{1}{3}, \frac{2}{3}$, and $\frac{5}{6}$. In terms of the linking of cation-oxygen octahedra, the structure can be regarded as chains of staggered octahedra running parallel to z with one chain containing, in the ideal structure, only (Fe,Mn) or (Nb,Ta) cations in the centers of the octahedra, and with one layer of (Fe,Mn) chains followed by two layers of (Nb,Ta)

**COLUMBITE**

chains. In any one chain, one octahedron shares one edge with the octahedron above and one with the octahedron below it along z , and any one chain is linked to its neighboring parallel chains through certain octahedral corners (oxygen). This octahedral linking is such that each oxygen is coordinated by three cations. *CM 14:540(1976)*.

COLUMBITE GROUP

Mineral	Formula	Space Group	D				
			a	b	c	D

*End member not observed in nature.

A nearly complete solid solution series exists between the first four members of the group, the end members of all of them except ferrotantalite having been observed in nature. The end member FeTa_2O_6 has the tetragonal or tapiolite structure. Most tantalites tend to be Mn dominant, and those in which $\text{Fe} > \text{Mn}$ are rare. Most of the Fe, Mn columbites are also intermediate members, with the Fe-dominant members being somewhat more abundant. The Mg-dominant member requires special geological circumstances for its formation and hence is very rare; Mg does not enter into the composition of the other members to a significant degree. Minor quantities of Fe^{3+} , Sc, Ti, Sn, and W are also commonly present.

Note: These minerals are economically important, especially for their tantalum content.

8.3.2.1 Ferrotantalite $(\text{Fe,Mn})(\text{Ta,Nb})_2\text{O}_6$

Named in allusion to the chemistry as a member of the columbite–tantalite group. ORTH *Pbcn*. Black. $G = 7.95$. Many localities have been found for Fe slightly exceeding Mn in mol %; older analyses showing very high Fe/Mn ratios have proven to be ferrotantalite–ferrotapiolite intergrowths. Analyzed ferrotantalite (usually in association with ferrotapiolite) has been found in Upper Bear Gulch, SD; Yellowknife, NWT, Canada; Spittal a. d. Drau, Carinthia, Austria; Nyanga, Uganda; and Muhembe, Rwanda. RG *NJMM:109(1989)*, *MP 41:53(1989)*, *CM 30:587(1992)*.

8.3.2.2 Ferrocolumbite $(\text{Fe,Mn})(\text{Nb,Ta})_2\text{O}_6$

Named in 1802 for the composition and for Columbia, a name for America, where the original specimen was obtained and in which specimen the element columbium (now called niobium) was first recognized by Hatchett. Columbite group. ORTH *Pbcn*. $a = 14.269$, $b = 5.735$, $c = 5.050$, $Z = 4$, $D = 5.427$. *NBSM 25(20):56(1984)*. *33-659*: 3.68₄ 2.98₁₀ 2.87₁ 2.54₁ 2.50₁ 2.39₁ 1.738₁ 1.726₂. **Habit**: Prismatic crystals, often flattened {010} or thick tabular {100}; sometimes nearly equant; massive. Twin plane {201}, common. Usually contact twins, flattened, heart-shaped. **Physical properties**: Black, brownish-black streak, submetallic luster. Cleavage {010}, distinct; {100}, less so; subconchoidal to uneven fracture; brittle. $H = 6$. $G = 5.20$ – 6.76 (depending on Nb/Ta ratio). Paramagnetic. **Tests**: Soluble in HF, partially soluble in hot concentrated H_2SO_4 , insoluble in HCl or HNO_3 . In distinguishing between columbites and tantalites, density is the most useful determinant. Between 5.20 and 6.76, $\text{Nb} > \text{Ta}$ (mol %) and the mineral is in the columbite group. Between 6.76 and 7.95, $\text{Ta} > \text{Nb}$ and it is a tantalite. For $(\text{Fe,Mn})(\text{Nb,Ta})_2\text{O}_6$, where $\text{Fe/Mn} = 3:1$ and $\text{Nb/Ta} = 1:1$, the mineral would contain 31.3% Nb_2O_5 and 51.9% Ta_2O_5 . Above 31.3%, Nb_2O_5 is therefore in the columbite range, and above 51.9%, Ta_2O_5 is in the tantalite range. Proportions of Fe/Mn other than 3:1 would make only a small difference in these numbers. **Optics**: Biaxial (–); $N \approx 2.40$; $Z > X$; strong absorption; weakly anisotropic. **Occurrence**: Ferrocolumbite and manganocolumbite are typical of granitic pegmatites and other environments where $\text{Nb} > \text{Ta}$. They may also rarely be found in alkalic pegmatites; as an alteration product of pyrochlore and other Nb minerals; and as disseminations in albitites and apogranites, associated with zircon, xenotime, cassiterite, and ilmenorutile. Ferrocolumbite is the commonest member of the columbite–tantalite group. **Localities**: Near *New London, CT*, and elsewhere in CT, as at Haddam, Portland, and Branchville. Numerous localities in ME, NH, and MA. Amelia Courthouse, VA; in SD at the Etta, Ingersoll, Peerless, Old Mike, and other mines. Ivigtut, Greenland, in the cryolite mine, nearly pure FeNb_2O_6 . Many localities in Europe, especially in Norway, Sweden, Finland, Germany, Italy, and France. Important alluvial deposits with associated cassiterite are found near Jos, Nigeria. In Madagascar in very large crystals at Ambatofotsikely, and at Ampangabe, Morafeno, Samiresy, and Befanamo. Also common in the

pegmatite regions of Zimbabwe, Zaire, Uganda, and South Africa. Many localities in Brazil: fine large crystals are found in MG at the Golconda district and at São Jose da Safira; and in AM in the large Pittinga alluvial deposit derived from a weathered apogranite. Use: An important ore of tantalum and niobium. RG *DI:780, NJMA 106:1(1966), NJMM:372(1985)*.

8.3.2.3 Manganotantalite (Mn,Fe)(Ta,Nb)₂O₆

Named in 1887 for the mythical Tantalus, in allusion to the tantalizing difficulties encountered in making a solution of the mineral in acids, preparatory to analysis. *Mangano* for the Mn-dominant chemistry. Dimorphous with manganotapiolite. Columbite group. ORTH *Pbcn*. $a = 14.440$, $b = 5.766$, $c = 5.093$, $Z = 4$, $D = 7.95$. *NJMM:372(1985)*. *DANS 148:97(1963)*. *PD(nat): 3.62₉ 2.93₁₀ 1.89₇ 1.71₈ 1.52₈ 1.46₈ 1.44₈ 0.988₈*. *33-909(syn): 7.22₃ 3.70₅ 3.62₁ 2.99₁₀ 2.55₁ 2.51₂ 2.41₁ 1.74₂*. Habit: Crystals prismatic [001], usually flattened {010} or {100}; also equant. Twin plane {201}, common. Usually heart-shaped contact twins. Physical properties: Black, brownish black, orange-red; brownish-black to orange streak; semimetallic luster. Cleavage {010}, distinct; {100}, less so; subconchoidal to uneven fracture; brittle. $H = 6-6\frac{1}{2}$. $G = 6.76-7.95$. Nonfluorescent. Paramagnetic. Tests: Partially decomposed by hot H₂SO₄, insoluble in HCl or HNO₃, soluble in HF. Chemistry: Most tantalites have Mn > Fe, and pure end member MnTa₂O₆ is known from a number of localities. When Fe²⁺ is very low, less than 1%, the mineral is orange-red in color, sometimes transparent. Nb is present in all proportions up to Ta/Nb = 1:1, but the high-Nb members tend to be Mn poor. Optics: Biaxial (+); $N \approx 2.12$; $2V = 34^\circ$; $r < v$, moderate; strong absorption. In RL, red-brown internal reflections. Localities: Manganotantalite is the most abundant mineral that is Ta-dominant. Mt. Apatite and Paris, ME; Portland, CT; Amelia Courthouse, VA(!), with microlite in albite; Etta mine, Keystone, and Helen Beryl mine, Custer, SD. Pala, San Diego Co., CA. Tanco mine, Bernic Lake, MB, Canada(!), with wodginite and microlite. *Uto, Sweden*. In the tin placers of Malaysia and Thailand. Kokoto Hai mine, Xinjiang, China(!). Shingus, Gilgit, Pakistan(!). Bikita and Benson mines, Zimbabwe. Alto Ligonha, Mozambique, at the Morrua(!), Muiane(!), and Marropino mines, sometimes in large crystals and in transparent sharp red twins. In Brazil in RGN, at the Alto do Giz, Equador(!), and at various mines in Parelhas and Carnauba dos Dantas. Greenbushes, WA, Australia; also at Wodgina and Cooglegong. Use: The principal ore of tantalum. RG *DI:783, NJMA 106:1(1966), NJMM:372(1985)*.

8.3.2.4 Manganocolumbite (Mn,Fe)(Nb,Ta)₂O₆

Named in 1892 for the composition. Columbite group. ORTH *Pbcn*. $a = 14.433$, $b = 5.764$, $c = 5.083$, $Z = 4$, $D = 5.28$. *NJMM: 372(1985)*. *33-899(syn): 7.21₁ 3.70₃ 2.99₁₀ 2.88₁ 2.54₁ 2.51₁ 1.75₁ 1.74₁*. *45-1360: 3.65₈ 2.97₁₀ 2.86₃ 2.50₂ 1.771₁ 1.737₂ 1.721₂ 1.454₃*. Habit as with ferrocolumbite. Black, brownish black. Synthetic end member MnNb₂O₆ is red, just like natural end member manganotantalite. $G = 5.20-6.76$. Other properties as with ferrocolumbite.

Manganocolumbite is nearly as common as ferrocolumbite, but very few occurrences approach the MnNb_2O_6 end member. Manganocolumbite can be distinguished from ferrocolumbite only by chemical analysis. Most samples in collections have never been analyzed for the Mn/Fe ratio and are merely labeled "columbite." No natural MnNb_2O_6 end members have been observed iron-free enough to be red, but synthetic MnTa_2O_6 is red. Old Mike mine, Custer Co., and Elk Creek, Pennington Co., SD. San Diego mine, San Diego Co., CA. Londonderry mine, Coolgardie, WA, Australia. RG *DI:780, AM 63:1166(1978)*.

8.3.2.5 Magnocolumbite $(\text{Mg,Fe,Mn})(\text{Nb,Ta})_2\text{O}_6$

Named in 1963 from the composition. Columbite group. ORTH *Pbcn*. $a = 14.193$, $b = 5.700$, $c = 5.032$, $Z = 4$, $D = 5.23$. *33-875(syn)*: 7.11_3 3.64_6 3.55_2 2.95_{10} 2.85_1 1.724_1 1.712_2 1.446_1 . Small prismatic crystals. Black to brownish black, dark brown streak, semimetallic luster. Cleavage {010} and {100}; uneven fracture. $H = 6\frac{1}{2}$. $G = 5.25$. Biaxial (-); $XY = cb$; $N_x = 2.33$ (brownish yellow), $N_z = 2.40$ (brownish red); $2V \approx 80^\circ$. Magnocolumbite forms under the very unusual conditions in pegmatite genesis of Mg saturation and virtual absence of Fe. *Kukh-i-la, southwestern Pamir Mts., Tadzhikistan*, in pegmatite cutting dolomitic marbles, which have been partially assimilated forming cordierite, dravite, spinel, andalusite, and kyanite. It is commonly intergrown with ilmenorutile. Also from eastern Siberia in a similar environment. RG *AM 48:1182(1963), ZVMO 96:720(1967), MA 69:582(1969)*.

8.3.3.1 Fersmite $(\text{Ca,Ce,Na})(\text{Nb,Ti})_2(\text{O,OH,F})_6$

Named in 1946 for Alexandr Evgenievich Fersman (1883–1945), Russian mineralogist and geochemist. Usually metamict. ORTH *Pbcn*. $a = 14.926$, $b = 5.752$, $c = 5.204$, $Z = 4$, $D = 4.78$. Structure: *AM 55:90(1970)*. Fersmite is essentially a distorted Ca analog of columbite. *39-1392*: 3.77_2 3.74_2 3.06_{10} 2.69_2 1.886_1 1.805_3 1.773_2 1.529_2 . Short prismatic crystals [001]. Massive, as irregular grains. Brown; black, grayish-brown streak, resinous luster. No cleavage, conchoidal to uneven fracture, brittle. $H = 4\frac{1}{2}$. $G = 4.79$. Biaxial (+); $N_x = 2.07$, $N_y = 2.08$, $N_z = 2.19$ (Li); $2V = 20-25^\circ$. X, pale greenish; Y, yellow to colorless; Z, dark greenish yellow to olive yellow. From the Dark Star claim, Ravalli Co., MT, in marble, intergrown with ferrocolumbite, associated with monazite, ancylite, barite, quartz, and apatite. In BC, Canada, disseminated in large amounts in the Aley carbonatite E of Williston Lake, probably pseudomorphous after pyrochlore. *Vishnevye Mts., Russia*, as an alteration product of pyrochlore, intergrown with ferrocolumbite. Madagascar, at Anjanabonoina in large (> 2 kg) complex lustrous crystals. RG *AM 32:373(1947)*.

8.3.4.1 Brannerite $(\text{U,Ca,Ce})(\text{Ti,Fe})_2\text{O}_6$

Named in 1920 for John Casper Branner (1850–1922), American geologist. Metamict. MON *C2/m*. $a = 9.812$, $b = 3.770$, $c = 6.925$, $\beta = 118.97^\circ$, $Z = 2$, $D = 6.37$. Structure: *AC 21:974(1966), 12-477(syn)*: 6.04_4 4.74_{10} 3.44_{10}

3.35₁₀ 3.02₄ 2.90₄ 2.77₃ 2.04₄. Indistinct prismatic crystals, usually as rounded or irregular grains. Black, altered material brownish olive-green, yellow brown, yellow; dark greenish-brown to yellowish-brown streak; vitreous luster when fresh, resinous when altered. Conchoidal fracture. $H = 4\frac{1}{2}$ – $5\frac{1}{2}$. $G = 4.2$ – 5.4 . Nonfluorescent. Strongly radioactive. Decomposed by hot concentrated H_2SO_4 . Isotropic; $N = 2.26$ (Na). *Kelly Gulch, Custer Co., ID*, as alluvial grains. California vein, Mt. Antero, Chaffec Co, CO(!) in crystals to 1.5 cm. Dean's mine, Coleville, Mono Co., CA. In a quartz pebble conglomerate at the Pronto mine, Blind River district, ONT, Canada, on the northern shore of Lake Huron. In pegmatite at Fuenteovejuna, Cordoba, Spain(!), crystals to 30 cm. In Switzerland abundant at Lodrino (Iragna), Tessin. In Australia at Crocker's Well, Manna Hill, SA, in quartz veins with rutile, xenotime, apatite, and zircon; and with uraninite in calcite veins in the Nichols Nob copper mine, Flinders Range, SA. RG *DI:774*; *CM 6:483(1960)*, *20:271(1982)*; *NJMA 106:1(1966)*; *IANS:63(1982)*.

8.3.4.2 Thorutite (Th,U,Ca)Ti₂(O,OH)₆

Named in 1958 for the composition. Metamict. *MON C2/m*. $a = 9.822$, $b = 3.824$, $c = 7.036$, $\beta = 118.83^\circ$, $Z = 2$, $D = 6.08$. *19-1351(syn)*: 6.16₅ 4.77₁₀ 4.30₅ 3.49₁₀ 3.40₈ 2.93₅ 2.57₅ 2.49₅. Short prismatic crystals. Black, pale brown streak, resinous luster. Conchoidal fracture. $G = 6.0$. Radioactive. Turns golden when heated in CT and gives off water. Isotropic; $N > 2.1$. From an unspecified locality in *Russia* (?) in a syenite massif in veins of microcline and sericitized nepheline, associated with thorite, zircon, and calcite. RG *ZVMO 87:201(1958)*; *AM 43:1007(1958)*, *48:1419(1963)*.

8.3.5.1 Lucasite-(Ce) CeTi₂(O,OH)₆

Named in 1987 for Hans Lucas, Australian geologist, who discovered the mineral. *MON C2/c*. $a = 5.178$, $b = 8.756$, $c = 9.768$, $\beta = 93.52^\circ$, $Z = 4$, $D = 5.00$. *AM 72:1006(1987)*. *40-1455*: 3.38₁₀ 3.26₆ 3.20₈ 2.58₇ 2.54₄ 2.23₅ 2.03₄ 1.83₆. Crystal grains striated [010], and aggregates. Light to dark brown; gray, white streak, resinous luster. Cleavage {001}, prominent; conchoidal fracture; brittle. $VHN_{10} = 824$. Biaxial; $N_{calc} = 2.32$; 2V large; extreme birefringence. In RL, gray, with brown internal reflections. $R = 16.6$ (470 nm), 15.6 (546 nm), 15.3 (589 nm), 15.0 (650 nm). From the *Argyle AK1 mine, Kimberley, WA, Australia*, in a diamondiferous olivine lamproite tuff, associated with anatase, almandine, chromian pyrope, ilmenite, barite, chromite, and chromian diopside. RG

8.3.6.1 Aeschynite-(Ce) (Ce,Ca,Fe)(Ti,Nb)₂(O,OH)₆

Named in 1828 from the Greek for *shame*, in allusion to the inability of chemical science, at the time of its discovery, to separate some of its constituents. Synonym: eschynite. Metamict. *ORTH Pmnb*. $a = 7.538$, $b = 10.958$, $c = 5.396$, $Z = 4$. *NBSM 25(3):24(1964)*. Structure: *SR 27:535(1962)*. *15-864(syn)*: 5.48₃ 4.43₃ 3.11₄ 3.02₈ 2.98₁₀ 2.70₃ 2.04₃ 1.96₃. Rough prismatic crystals, massive.

Dark brown, brown to nearly black streak, submetallic to resinous luster. $H = 5-6$. $G = 4.20-5.34$. Biaxial (-); $N > 2.0$; $2V$ moderate. Bireflectance = 0.10-0.15. Dark Star claim, Ravalli Co., MT, in carbonatitic rocks, associated with allanite, apatite, monazite, fersmite, magnetite, pyrite, and columbite. *Miask, Ilmen Mts., Russia*, in nepheline syenite. Hytterø, Norway. RG *DI:793, AM 46:1436(1961), DANS 142:181(1962)*.

8.3.6.2 Niobo-aeschnyrite-(Ce) $(Ce,Ca,Th)(Nb,Ti)_2(O,OH)_6$

Named in 1960 for the composition. ORTH *Pbnm*. $a = 5.396$, $b = 11.085$, $c = 7.585$, $Z = 4$. *AM 60:309(1975)*. *29-311: 5.54₂ 3.45₂ 3.13₄ 3.05₇ 2.98₁₀ 2.83₂ 2.70₂ 2.04₂*. Small water-worn grains, some with prismatic habit. Red-brown, dark brown, black; orange-brown to light reddish-brown streak; resinous luster. Conchoidal fracture. $H = 4-5$, $5\frac{1}{2}$. $G = 5.04$. Paramagnetic. Biaxial (-); $XYZ = bca$; $N_x = 2.27$, $N_y = 2.32$, $N_z = 2.34$; $2V = 85^\circ$. X, Y, Z , reddish brown. In placer concentrates from the Tofty tin belt, Hot Springs district, central AK. *Vishnevye Gory, Ural Mts., Russia*, in quartz-arfvedsonite veinlets cutting fenites. RG *AM 47:417(1962)*.

8.3.6.3 Aeschnyrite-(Y) $(Y,Ca,Fe)(Ti,Nb)_2(O,OH)_6$

Named in 1966 for the composition. See aeschnyrite-Ce (8.3.6.1). ORTH *Pbnm*. $a = 5.18$, $b = 10.92$, $c = 7.50$, $Z = 4$, $D = 5.13$. *20-1401: 3.07₃ 2.99₇ 2.91₁₀ 2.77₂ 2.59₂ 1.85₂ 1.57₃ 1.51₃*. Black; brown; yellow, white to pale yellow streak, submetallic-resinous-pearly luster. Cleavage {100}, {010}, {001}, perfect; uneven fracture; brittle. $H = 4\frac{1}{2}$. $G = 4.95$. Moderately paramagnetic. Insoluble in HCl, soluble in HF or in a fusion with $KHSO_4$. Biaxial (+); $N_x = 2.19$, $N_y = 2.21$, $N_z = 2.24$; $2V = 70^\circ$; nonpleochroic. In *Norway* at *Urstad*, Hitterø, and abundantly at Kabuland, Iveland Parish. Nonmetamict aeschnyrite is fairly common as small crystals in Alpine cleft environment, as for example at Wann-Gletscher, Binntal, Wallis, Switzerland; at Lohningerbruch, Rauris, Austria; and Val d'Ossola, Italy. *Miask, Ilmen Mts., Russia*. In southern China in a Y,Re-rich muscovite granite, with xenotime, monazite, zircon, fergusonite, thorite, gadolinite, chernovite, and columbite. In Madagascar at Tongafeno, Ambohitromby, and elsewhere. RG *DI:793; AM 51:152(1966), 61:178(1976)*

8.3.6.4 Tantaloeschnyrite-(Y) $(Y,Ce,Ca)(Ta,Ti)_2O_6$

Named in 1974 for the composition. Metamict. ORTH *Pbnm*. $a = 5.34$, $b = 10.97$, $c = 7.38$, $Z = 4$, $D = 6.39$. *MM 39:571(1974)*. *26-1(heated): 3.71₃ 3.00₁₀ 2.94₁₀ 2.65₅ 2.21₃ 1.86₄ 1.70₅ 1.58₇*. Prismatic, equant crystals, with {010}, {001}, {110}, and {130}. Brownish black; black, light yellowish-brown streak, resinous luster. No cleavage, conchoidal fracture, brittle. $VHN_{100} = 665$, $H = 5\frac{1}{2}-6$. $G = 5.7-6.1$. Isotropic; yellow to orange pleochroism. In RL, dark gray, abundant white to dark red internal reflections. $R = 14.5$ (470 nm), 14.2 (546 nm), 14.0 (589 nm), 14.0 (650 nm). *Raposa pegmatite*,

São Jose do Sabugí, PB, Brazil, with biotite, ferrocolumbite, and beryl. Phyllo-lord alluvial deposit, Thailand. RG *AM 59:1331(1974)*.

8.3.6.5 Aeschynite-(Nd) (Nd,Ce)(Ti,Nb)₂(O,OH)₆

Named in 1982 for the composition. Metamict. Space group unknown. *34-480* (heated): 545₅ 3.00₉ 2.93₁₀ 2.64₅ 2.26₅ 1.95₆ 1.57₇ 1.53₆. Tabular and prismatic crystals, equigranular clusters. Dark to light brown, light brown streak, adamantine luster. Conchoidal fracture, brittle. H = 5–6. G = 4.8. Nonmagnetic, radioactive. Readily soluble in warm HCl, H₂SO₄, and H₃PO₄; with difficulty in HNO₃. Biaxial; N = 2.2–2.4; 2V = 80°. *Bayan Obo, Inner Mongolia, China*, in veins in slate and metamorphosed dolomite, associated with aegirine, riebeckite, barite, fluorite, and phlogopite. RG *AM 69:565(1984)*.

8.3.7.1 Vigezzite (Ca,Ce)(Nb,Ta,Ti)₂O₆

Named in 1979 for the locality. ORTH *Pmnb*. *a* = 7.559, *b* = 11.025, *c* = 5.360, Z = 4, D = 5.54. *MM 43:459(1979)*. *34-1316*: 4.82₉ 3.78₈ 3.04₁₀ 2.97₁₀ 2.68₄ 2.37₄ 1.71₆ 1.60₇. Crystals flat prismatic, {001} striated [001]. Orange-yellow. Cleavage {001}, perfect; brittle. H = 4½–5. Nonfluorescent. Biaxial; N_x = 2.14, N_z = 2.315 (Na); strong birefringence; extreme dispersion; positive elongation. *Alpe Rosso, and Pizzo Marcio, near Orcesco, Valle Vigezzo, Novara, Piemonte, Italy*, in albitic rock, with pyrochlore, columbite, fersmite, bavenite, and emerald. RG *AM 65:812(1980)*.

8.3.7.2 Rynersonite Ca(Ta,Nb)₂O₆

Named in 1978 for the Rynerson family, San Diego Co., CA. Members of the family have operated mines in the Himalaya pegmatite–aplite dike system since 1900. ORTH *Pmnb*. *a* = 7.505, *b* = 11.063, *c* = 5.370, Z = 4, D = 6.394. *AM 63:709(1978)*. *39-1430(syn)*: 4.84₁₀ 3.75₈ 3.04₁₀ 2.69₄ 2.36₅ 1.714₃ 1.596₃. Masses of lath-like crystals. Reddish pink, white streak, earthy luster. Uneven fracture. G = 6.40. Nonfluorescent. Biaxial (+); XYZ = *cba*; N > 2.05 (straw yellow); birefringence 0.14. *Himalaya mine, Mesa Grande district, San Diego Co., CA*, as an alteration product of stibiocolumbite–stibiotantalite crystals, associated with fersmite and antimonian microlite. Wampewo pegmatite, Mengo district, Uganda, with microlite in pseudomorphs after bismutotantalite. RG *SMPM 59:15(1979)*.

8.3.8.1 Polycrase-(Y) (Y,Ca,Ce,U,Th)(Ti,Nb,Ta)₂O₆

Named in 1870 from the Greek for *many* and *mixture*, in allusion to the many rare elements it contains. Metamict. ORTH *Pbcn*. *a* = 14.62, *b* = 5.55, *c* = 5.19, Z = 4, D = 4.30–5.87. *VLA:479*(heated to 800°): 2.98₇ 2.90₁₀ 1.85₆ 1.67₅ 1.57₆ 1.50₅ 1.19₅ 1.07₆. Crystals stoutly prismatic [001], sometimes flattened {010}; also massive. Twinning common on {201}, flattened {010} and striated [001]. Black; yellowish, grayish, or reddish-brown streak; submetallic luster. Subconchoidal to conchoidal fracture. H = 5½–6½. G = 5.0–5.9. The G decreases with alteration and increases after ignition. It also varies significantly with

increase or decrease of the Nb/Ta ratio. Radioactive. Crystal chemical relationships in the polycrase-euxenite group and the identification of its members are complicated by most of them being metamict and by different degrees of hypogene alteration and weathering effects. Deficiencies in the A site are common, coupled with the introduction and removal of various cations. Consequently, heating experiments often fail to restore the original structure of the euxenite-type minerals because of these secondary deviations from the original stoichiometry. Isotropic; $N \approx 2.25$. Polycrase-euxenite are commonly found in K-rich, granite pegmatites, associated with monazite, beryl, columbite, magnetite, biotite, ilmenite, xenotime, gadolinite, allanite, and garnet. They are less common in albite-O-rich pegmatites or Li-rich pegmatites. Davis farm, near Zirconia, Henderson Co., NC. Baringer Hill, Llano Co., TX. In placers near Pioneerville, Boise Co., ID. *Rasvåg, Hitterø, Norway*, and scores of other localities in Norway. Lon Jonköping, Sweden. In Madagascar well crystallized from numerous localities, in potash-rich pegmatites with beryl, columbite, monazite betafite, as at Ankazobe; Ranomafana; Ampangabe; Samiresy. In Brazil in MG at Gruta de Generosa, Sabinopolis; Pomba; Fazenda Santa Clara, and so on. RG *DI:787*.

8.3.8.2 Euxenite-(Y) $(Y,Ca,Ce)(Nb,Ta,Ti)_2O_6$

Named in 1870 from the Greek for *friendly to strangers, hospitable*, in allusion to the rare elements that it contains. Metamict. See also Polycrase-(Y) (8.3.8.1). ORTH *Pbcn*. $a = 14.643$, $b = 5.553$, $c = 5.195$, $Z = 4$. *ZK 152:69(1980)*. 5-603(heated): 3.66_3 2.98_{10} 2.43_3 1.82_4 1.77_3 1.72_4 1.64_3 1.49_4 . Physical properties and localities for euxenite are listed together with those for polycrase, with the understanding that positive identification of the species is not possible in most cases without chemical analysis. These minerals are common worldwide and only a few of the known occurrences can be mentioned. Morton, Delaware Co., PA; Trout Creek Pass, Chaffee Co., CO; in ONT, Canada, at the J. G. Gole quarry, Murchison Twp. in lustrous euhedral crystals to 4 cm, associated with fergusonite-(Y); also in Sabine and Mattawan Twps., Nipissing district. Pegmatite del Bosco, Arvogno, Val di Crana, Val Vigezzo (Novara), Italy. *Jolster, Sondfjord, Norway*, as well as on Hittero and Kragerø Is. Hunttila, Pitkäranta, Finland. Fine crystals from Madagascar at numerous localities, especially Ambatofotsikely and on Mt. Vohambohitra. RG *DI:787*; *AM 35:386(1950)*, *50:2084(1965)*; *NJMA 103:1(1965)*; *CM 15:92(1977)*.

8.3.8.3 Tanteuxenite-(Y) $(Y,Ca,Ce)(Ta,Nb,Ti)_2(O,OH)_6$

Named in 1928 for the composition. Metamict. ORTH *Pcan*. $a = 5.18$, $b = 14.57$, $c = 5.52$, $Z = 4$. 31-1434(heated): 3.12_{10} 2.87_7 2.67_3 2.52_3 2.28_1 2.15_1 . Indistinct tabular crystals. Brownish black, resinous luster. Subconchoidal fracture. $H = 5-6$. $G = 5.4-5.9$. Isotropic. Mattawa, ONT, Canada, as euhedral crystals to 5 mm. Piano de Lavonchio, Craveggia, Val Vigezzo,

Piedmont, Italy. *Cooglegong, Pilbara, WA, Australia*, in tin placers. Liha, Kivu, Zaire. RG *DI:791, USGSB 1036:111(1958), MM 32:308(1959)*.

8.3.8.4 Yttrocrasite-(Y) (Y,Th,U)Ti₂(O,OH)₆

Named in 1906 from the Greek for *mixture*, because it is a mixture of yttrium with many other elements. Metamict. Probably ORTH Space group unknown. A doubtful species. May be identical to polycrase. As rough crystals. Black, resinous to pitchy luster. Conchoidal fracture. $H = 5\frac{1}{2}$ -6. $G = 4.80$. Radioactive. Isotropic; $N \approx 2.12$ -2.15. From *Burnet Co., TX*, 5 km E of the Baringer Hill pegmatite in Llano Co., TX. RG *DI:793, AM 67:156(1982)*.

8.3.8.5 Uranopolycrase (U,Y)(Ti,Nb,Ta)₂O₆

Named for the composition, the uranium-dominant analog of polycrase-Y. ORTH *Pbcn*. $a = 14.51$, $b = 5.558$, $c = 5.173$, $Z = 4$. *EJM 5:1161(1993)*. *PD(heated)*: 3.21₁ 2.99₁₀ 2.78₃ 2.51₁ 1.90₅ 1.86₁ 1.77₄ 1.48₄. Crystals prismatic, tabular {100}. Brown-red, opaque, brownish streak, adamantine luster. Cleavage {100}, good. In RL, pale gray with bluish tones; anisotropism and birefractance not observed. Weak internal reflections. $VHN_{20} = 659$. Found in pegmatite at the *Fonte del Prete quarry, southern Piero in Campo, Elba, Italy*, as inclusions in beryl crystals with stilbite. Associated minerals are quartz, orthoclase, albite, lepidolite, and elbaite. RG

8.3.9.1 Kassite CaTi₂O₄(OH)₂

Named in 1965 for Kicolai Grigorevich Kassin (1885-1949), Russian geologist and academician, discoverer of the Afrikanda massif on the Kola Peninsula. ORTH Space group uncertain, probably *Ammm*. $a = 8.99$, $b = 9.55$, $c = 5.26$, $Z = 2$, $D = 3.28$. *AM 52:559(1967)*. *39-357*: 7.85₁₀ 3.59₃ 3.26₇ 2.99₄ 2.79₃ 2.57₇ 1.910₈ 1.898₆. Crystals flattened on {010}, forming six-sided plates. As rosettes of plates and as spherules. Twinning on {101} and {181}, very common. Pale yellow, adamantine luster. Cleavage {010}, perfect; {101}, distinct; very brittle. $H = 5$. $G = 3.28$. Insoluble in acids. Biaxial (-); $XZ = ab$; $N_x = 1.95$, $N_y = 2.13$, $N_z = 2.21$; $2V = 58^\circ$; $r > v$, very strong. Josephine Creek, OR. Possibly from the Diamond Jo quarry, Magnet Cove alkaline complex, Hot Springs Co., AR, in a nepheline syenite pegmatite. *Afrikanda massif, Kola Penin., Russia*, in miarolytic cavities of alkaline pegmatites. associated with cafetite and titanite, and replacing ilmenite. Henan Prov., China. RG *ZVMO 106:114(1977); AM 71:1045(1986), 76:283(1991)*.

8.3.10.1 Thoreaulite Sn²⁺(Ta,Nb)₂O₆

Named in 1933 for Jacques Thoreau (1886-1971), University of Louvain, Belgium. MON *C2/c*. $a = 17.140$, $b = 4.865$, $c = 5.548$, $\beta = 91.0^\circ$, $Z = 4$, $D = 8.27$. *AM 55:367(1970)*. *44-1411*: 8.59₂ 3.57₁ 3.10₄ 3.07₄ 2.86₁₀ 1.853₂ 1.697₂ 1.683₃. Crystals prismatic [001]. Brown, yellow streak with brownish tint, resinous to adamantine luster. Cleavage {100}, perfect; {011}, imperfect. $H = 6$. $G = 7.6$ -7.9. Biaxial (+); $Y = b$; $Z \wedge c = 27^\circ$; $N \approx 2.38$; $2V = 25^\circ$; bire-

fringence = 0.039. Ungursai, eastern Kazakhstan. From *Zaire* at *Manono*, *Shaba*, with cassiterite in pegmatite; also at *Maniema* and at *Kubitaka*, *Punia*. *Lavra Urubu*, *Itinga*, MG, Brazil, in a lithium pegmatite with lepidolite, rubellite, and petalite. RG *DI:802*, *AM 59:1026(1974)*, *SPD 20:528(1975)*, *CM 26:889(1988)*.

8.3.10.2 Foordite $(\text{Sn}^{2+}, \text{Pb})(\text{Nb}, \text{Ta})_2\text{O}_6$

Named in 1988 for Eugene E. Foord (b.1946), mineralogist and geologist, U.S. Geological Survey, specialist in Nb and Ta minerals. Isostructural with thoreaulite, 8.3.10.1. MON *C2/c*. $a = 17.093$, $b = 4.877$, $c = 5.558$, $\beta = 90.85^\circ$, $Z = 4$, $D = 6.66$. Structure: *CM 26:889(1988)*. *45-1350*: 3.59_4 3.10_5 3.07_5 2.85_{10} 2.78_2 1.853_3 1.694_5 1.681_5 . Found as alluvial pebbles. Brownish yellow, greenish tint, yellowish-white streak, vitreous to adamantine luster. Cleavage $\{100\}$, perfect; $\{011\}$, poor. $H = 6$. $G = 6.73$. Biaxial (+); $N_{\text{calc}} = 2.294$; $2V$ moderate. Birefringence > 0.10 . From *Lutsiro*, *Sebeya River*, *Rwanda*, and *Punia*, *Zaire*. RG.

8.3.11.1 Changbaiite PbNb_2O_6

Named in 1978 for the locality. HEX-R *R3m*. $a = 10.499$, $c = 11.553$, $Z = 9$, $D = 6.51$. *AM 64:242(1979)*. *29-780(syn)*: 5.25_2 3.11_8 3.03_{10} 2.17_3 1.926_1 1.764_4 1.625_2 . Small tabular crystals, and as spherules. Principal forms $\{0001\}$, $\{0111\}$; $\{101\bar{1}\}$, $\{1120\}$. Colorless, white, pale brown, pale yellow-green; white streak; adamantine to pearly luster. Cleavage $\{0001\}$, perfect; $\{1011\}$, distinct; hackly to conchoidal fracture; brittle. $H = 5\frac{1}{2}$. $G = 6.48$. Nonfluorescent. Nonmagnetic. Insoluble in HCl, HNO_3 , and H_2SO_4 ; slightly soluble in warm H_3PO_4 . Uniaxial (-); $N_{\text{O}} = 2.485$, $N_{\text{E}} = 2.476$; $r > v$. $R = 15.9$ (546 nm). *Changbai Mt.*, *Tonghua*, *Jilin*, *China*, in kaolin veinlets and kaolin-filled cavities. RG

8.3.12.1 Kobeite-(Y) $(\text{Y}, \text{U})(\text{Ti}, \text{Nb})_2(\text{O}, \text{OH})_6$

Named in 1950 for the locality. May be identical with polycrase. Needs further study. Metamict. ORTH Space group unknown. $a = 14.758$, $b = 5.753$, $c = 4.985$, $Z = 4$. *AM 42:742(1957)*. *PD(heated)*: 2.92_{10} 2.78_3 2.50_4 2.29_2 1.81_7 1.74_3 1.54_2 1.52_3 . *44-1449*: 5.42_2 4.39_1 3.96_1 3.11_1 2.94_{10} 2.75_3 1.987_2 1.916_2 . Irregular grains. Dark brown, black, resinous to vitreous luster. Brittle. $G = 5.0$. Strongly radioactive. Isotropic; $N = 2.205$. *Shiraishi*, *Kobe-Mura*, *Kyoto Pref.*, *Japan*, in a pegmatite, associated with parisite, zircon, monazite, tscheffkinite, xenotime, and biotite. Also from a cobble found in the *Paringa R.*, *South Westland*, *New Zealand*. RG *AM 36:925(1951)*, *MJJ 3:139(1961)*.

8.4.1.1 Schreyerite $\text{V}_2\text{Ti}_3\text{O}_9$

Named in 1976 for Werner Schreyer (b.1930), Ruhr University, Bochum, Germany. Polymorph: kyzylkumite. MON Space group unknown. $a = 7.06$, $b = 5.01$, $c = 18.74$, $\beta = 119.4^\circ$, $Z = 4$, $D = 4.480$. *30-1429*: 4.08_5 3.38_6 2.87_8 2.74_{10} 2.43_2 . Minute grains embedded in rutile; lamellar twinning prevalent.

Black. VHN = 1150. Insoluble in acids. In RL, reddish brown, moderately anisotropic, yellow-brown to reddish-brown pleochroism. $N \approx 2.7$. *Kwale District, S of Voi, Kenya*, in vanadium-enriched gneiss, associated with kyanite, sillimanite, rutile, kornerupine, biotite, tourmaline, diopside, and epidote. RG *NW 63:293(1976)*; *AM 62:395(1977)*, *63:1182(1978)*; *NJMM:110(1983)*.

8.4.1.2 Olkhonskite $(\text{Cr},\text{V})_2\text{Ti}_3\text{O}_9$

Named in 1994 for the locality. See schreyerite (8.4.1.1). MON Space group unknown. $a = 7.03$, $b = 5.02$, $c = 18.83$, $\beta = 119.6^\circ$, $Z = 4$, $D = 4.48$. *PD: 2.88₇ 2.75₁₀ 2.43₇ 1.426₇ 1.386₁₀*. Forms platy inclusions 1–20 mm wide and 50–150 mm long in rutile. Black, metallic luster. Knoop hardness = 1412 Kp/mm². In RL, light gray, noticeably bireflectant, weakly pleochroic, weakly anisotropic. $R = 21.1\text{--}18.1$ (470 μm), 19.9–18.5 (546 μm), 19.8–18.4 (589 μm), 20.0–18.6 (650 μm). Found in rutile in quartzite schists of the Olkhon series on the western shore of *Lake Baikal, Russia, near Olkhon Is.*, associated with schreyerite, eskolaite, karelianite, and other Cr–V–Ti oxides. RG *ZVMO 123(4):98(1994)*, *AM 81:251*.

8.4.1.3 Kyzylkumite $\text{V}_2^{3+}\text{Ti}_3\text{O}_9$

Named in 1981 for the locality. Polymorph: schreyerite. MON Space group unknown. $a = 33.80$, $b = 4.578$, $c = 19.99$, $\beta = 93.4^\circ$, $Z = 18$, $D = 3.77$. *AM 67:855(1982)*. *35-486: 3.70₈ 2.92₁₀ 2.60₅ 2.20₄ 2.19₅ 1.69₅ 1.68₆ 1.65₅*. Prismatic crystals and grains. Black, vitreous to resinous luster. $G = 3.75$. Insoluble in acids. *Kyzyl-Kum, Uzbekistan*, in siliceous schists, associated with chlorite, pyrite, and rutile. RG *ZVMO 110:607(1981)*, *IGR 24:740(1982)*.

8.4.2.1 Pseudorutile $\text{Fe}_2^{2+}\text{Ti}_3\text{O}_8\text{33}(\text{OH})_{1\text{33}} \cdot n\text{H}_2\text{O}$

Named in 1966 for the composition, as an intermediate product between ilmenite and rutile. HEX *P6₃22*. $a = 14.375$, $c = 4.615$, $Z = 6$, $D = 4.817$. Structure: *AM 60:898(1975)*. *29-1494: 3.67₄ 3.50₁₀ 3.23₃ 2.66₉ 2.51₈ 1.69₇ 1.66₃ 1.48₃*. Microscopic grains and inclusions averaging <20 nm. $G = 4.20$. Paramagnetic. Pseudorutile is a very common and widespread alteration product of ilmenite and is present in ilmenite placers and beach sands throughout the world. Near Hackberry, AZ; FL; NJ; India; Brazil; Singkep Is., Sumatra, Indonesia; South Neptune Is., SA, Australia; as a submicroscopic intergrowth with ilmenite and rutile in all alluvial ilmenites. RG *AM 35:117(1950)*, *52:299(1967)*, *68:985(1983)*; *NAT 211:179(1966)*; *MM 43:659(1980)*.

CRICHTONITE GROUP

The chrichtonite group minerals have the general formula

where

A = a large cation = Sr, Na, Pb, Ca, Ba, K, and U + REE

B = a small cation, dominantly Ti, Cr, Fe, Mg, Zn, and Nb

The atomic arrangement of the crichtonite group is based on a close-packed anion framework with a nine-layer stacking sequence, in which the A atoms occupy one of the anion sites in the cubic layers. The other metal atoms are ordered into both tetrahedral and octahedral interstices between the anion layers. Two types of metal-atom polyhedral arrangements occur, between pairs of hexagonally stacked anion layers, and between hexagonal and cubic anion layers, h-M-h and h-M-c, respectively. Between hexagonally stacked anion layers, two types of metal atoms, M(1) and M(3), occupy octahedral sites only. The M(3)O₆ octahedra, articulate by edge sharing to form interconnected 12-member hexagonal rings, with an isolated M(1)O₆ octahedron at the center of each ring. The h-M-c metal-atom layers, two per unit cell, contain metals in both octahedral and tetrahedral sites. The octahedrally connected atoms, M(4) and M(5), join by edge sharing into six-membered

LINDSLEYITE: $Ba(Ti,Mn)_{21}O_{38}$

This structure is related to perovskite in that it is based on cubic-closest-packed oxygens, with large cations, Ba in this case, replacing some oxygens, and smaller cations, mostly Ti, in octahedral interstices. However, there are also some small cations, Mn in this case, in tetrahedral coordination, and the proportion of large cations is much smaller than in perovskite.

hexagonal rings that are interlinked via corner sharing with basal oxygens of the $M(2)O_4$ tetrahedra. The cubic-stacked anion layers have A cations ordered into one of the available 13 anion sites per unit cell. *AM* 61:1203(1976).

CRICHTONITE GROUP

Mineral	Formula	Space Group	D			
			a	c

8.5.1.1 Landauite $NaMnZn_2(Ti,Fe)_6Ti_{12}O_{38}$

Named in 1966 for Lev D. Landau (1908–1968), Russian physicist, and academician, Moscow University. Crichtonite group. *HEX-R* R3. $a = 10.366$, $c = 20.77$, $Z = 3$, $D = 4.46$. *CM* 16:63(1978). 18-672: 3.36₆ 3.02₆ 2.83₁₀ 2.21₇ 2.11₉ 1.78₈ 1.58₈ 1.43₈. Fine-grained aggregates of irregular grains. Black, gray streak, semimetallic luster. No cleavage, conchoidal fracture. $H = 7\frac{1}{2}$. $G = 4.42$. Dissolves with difficulty in a mixture of HNO_3 and H_2SO_4 . Biaxial (-); $N_x = 2.373$, $N_z = 2.388$; $2V = 60^\circ$; $r > v$, weak; absorption $Z > Y > X$. *Burpala alkalic complex, northern Baikal region, Siberia, Russia*, in albite veinlets in quartz syenite and in syenitic pegmatites, associated with albite, polyolithionite, brookite, strontian chabazite, monazite, and bastnaesite. *RG* *DANS* 166:1420(1966), 261:741(1981); *AM* 51:1546(1966).

8.5.1.2 Loveringite $(Ca,Ce,La)(Ti,Fe,Cr)_{21}O_{38}$

Named for John Francis Lovering (b.1930), Australian geochemist, University of Melbourne. Crichtonite group. *HEX-R* R3. $a = 10.337$, $c = 20.676$, $Z = 3$, $D = 4.415$. *NBSM* 25(16):106(1979). Structure: *AM* 63:28(1978). 30-263: 3.38₈ 3.04₇ 2.87₁₀ 2.83₇ 2.47₅ 2.24₆ 2.13₆ 1.59₆. Irregular grains, acicular crystals. Black, iron-gray streak, metallic-submetallic luster. In RL, white. $VHN_{10} = 440$. *Jimberlana intrusion, near Norseman, WA, Australia*, associated with quartz-K feldspar intergrowths and phlogopite. *RG* *MM* 42:187(1978), *CM* 17:635(1979), *AM* 68:474(1983).

8.5.1.3 Crichtonite (Sr,La,Ce)(Ti,Fe³⁺,Fe²⁺,Mn)₂₁O₃₈

Named in 1813 for Alexander Crichton (1763–1856), Scottish physician and mineral collector. Crichtonite group. Crichtonite was long thought to be identical with ilmenite, but in 1953 was shown to have distinct chemistry and unit cell. **HEX-R R3.** $a = 10.374$, $c = 20.746$, $Z = 3$, $D = 4.54$. $22-1121$: 3.39_{10} 2.88_{10} 2.84_8 2.24_8 2.13_{10} 1.796_8 1.596_{10} 1.440_{10} . Rare crystals are steep rhombohedra terminated by {0001}, more commonly in rose type groups. Black, metallic, brilliant luster. Cleavage {0001}, perfect; conchoidal fracture; brittle. $H = 4.5$. $G = 4.46$. *Plan du Lac, St. Christophe en d'Oisans, Isere, France*, associated with anatase, quartz, chlorite, hematite, and feldspar. Selva, Tavetsch, Switzerland, in crystals to 25 mm; also Waniggletscher, Binntal, Wallis. In Italy from Pizzo Cervandone, Ossola, crystals to 10 mm. **RG DI:537; AM 38:734(1953), 55:534(1970); MM 37:349(1969).**

8.5.1.4 Senaite Pb(Ti,Fe,Mn)₂₁O₃₈

Named in 1898 for Joaquim da Costa Sena, Esola de Minas, Ouro Preto, Brazil. Crichtonite group. **HEX-R R3.** $a = 10.393$, $c = 20.811$, $Z = 3$, $D = 4.59$. $45-1388$: 3.40_{10} 3.06_5 2.99_5 2.89_{10} 2.85_5 2.47_5 2.25_5 1.602_5 . Rhombohedral, tabular, crystals with {0001}, {1011}, {2021}, {4041}. Black, brownish-black streak, submetallic luster, conchoidal fracture. $H = 6+$. $G = 5.30$. Uniaxial (-); $N \approx 2.50$ (Li); low to moderate bireflectance. From *Dattos, Curralinho*, and other localities near *Diamantina, MG, Brazil*, in diamond-bearing stream placers, and at the *Fazenda Guariba(I)* in the same district as crystals in fractures in quartzite. **RG DI:541; AM 53:869(1968), 61:1203(1976).**

8.5.1.5 Davidite-(La) (La,Ce,Ca)(Y,U)(Ti,Fe)₂₀O₃₈

Named in 1906 for Tenatt William Edgeworth David (1858–1934), Australian geologist. Crichtonite group. Metamict. The original davidite. **HEX-R R3.** $a = 10.376$, $c = 20.910$, $Z = 3$, $D = 4.72$. $13-505$: 3.42_7 3.07_5 3.00_4 2.90_{10} 2.85_6 2.48_4 2.25_5 2.14_4 . Massive, as anhedral grains. Black, vitreous luster. $G = 4.42$. Strongly radioactive. Davidite is a fairly common mineral in uranium-rich granite pegmatites and in syenitic rocks; also in pegmatite-like phases of calcite–apatite–diopside–titanite rocks of the Grenville type. Pandora prospect, Quijotos Mts., Pima Co., AZ. McLean Point, NS, Canada, in sandstone with other uranium minerals. Nuevo Continente mine, Mun. Nacozari, SON, Mexico, with autunite. Tete district, Mozambique, in large crystals in a scapolite–calcite–dolomite rock, and in epidiorite with rutile, titanite, magnetite, ilmenite, apatite, tourmaline, and molybdenite. *Radium Hill mine, Olary Prov., SA, Australia*, associated with rutile, ilmenite, and carnotite; also at Billeroo and Crocker's Well, SA. **RG DI:542, AM 46:700(1961), CM 23:495(1986).**

8.5.1.6 Davidite-(Ce) (Ce,La)(Y,U)(Ti,Fe)₂₀O₃₈

Named in 1960 for the composition. Crichtonite group. Metamict. **HEX-R R3.** $a = 10.376$, $c = 20.910$, $Z = 3$, $D = 4.72$. $8-291$: 3.37_7 3.21_7 2.86_8 2.23_8 1.70_{10}

1.69₁₀ 1.59₈ 1.435₉. Crystals tabular {0001}, or pyramidal with ditrigonal pyramids dominant; also cuboidal; commonly massive. Black; dark brown; reddish, grayish-black to dark brown streak, vitreous to submetallic, shiny, luster. Conchoidal to uneven fracture, brittle. H = 6. G = 4.4–4.9. Strongly radioactive. Slowly attacked by HF and strong H₂SO₄ or HNO₃. Isotropic; N ≈ 2.3. In RL, light gray. Faraday mine, Bancroft, ONT, Canada, and at the Baska mine, Kotelmach Lake, Foster Lakes area, SK. *Tuftane, Iveland, Norway*, in pegmatite with thortveitite, gadolinite, and euxenite. RG *DI:542, USGSB 1064:337(1958), NGT 40:277(1960), AM 51:152(1966)*.

8.5.1.7 Mathiasite (K,Ca,Sr)(Ti,Cr,Fe,Mg)₂₁O₃₈

Named in 1983 for Frances Celia Morna Mathias (b.1913), British–South African geochemist, University of Capetown, South Africa. Crichtonite group. HEX-R *R3*. $a = 10.36$, $c = 20.65$, $Z = 3$, $D = 4.39$. *37-420*: 4.14₅ 3.39₆ 2.99₈ 2.88₈ 2.25₉ 2.14₁₀ 1.79₇ 1.44₁₀. Black, metallic luster. Conchoidal fracture. VHN₁₀₀ = 1505. In RL, tan, weakly pleochroic, weakly to moderately anisotropic. *Jagersfontein mine, Orange Free State, South Africa*, in kimberlite, associated with olivine, diopside, phlogopite, chromian ilmenorutile, Mg–Cr spinel, ilmenite, perovskite, and titanite. Also from the Bultfontein mine, and at Kolonkwanen in the MacKenzie's Post district, near the border with Botswana, Cape Prov. RG *AM 68:494(1983)*.

8.5.1.8 Lindsleyite (Ba,Sr)(Ti,Cr,Fe,Mg)₂₁O₃₈

Named in 1983 for Donald H. Lindsley (b.1934), mineralogist, Department of Earth Sciences, State University of New York at Stony Brook. Crichtonite group. HEX-R *R3*. $a = 10.37$, $c = 20.52$, $Z = 3$, $D = 4.63$. *37-421*: 3.04₄ 2.87₇ 2.83₇ 2.13₁₀ 1.80₁₀ 1.59₁₀ 1.50₅ 1.44₁₀. Small grains and aggregates. Black, metallic luster. Conchoidal fracture. VHN₁₀₀ = 1505. In RL, tan with no internal reflections, and weakly pleochroic, pale tan to brown; weakly to moderately anisotropic. *DeBeers mine, Kimberley, Cape Prov., South Africa*, in kimberlite, in peridotite nodules, associated with phlogopite, K-richterite, Cr-spinel, ilmenite, and Cr-diopside. Also found at the Bultfontein mine. RG *AM 68:494(1983)*.

8.6.1.1 Franconite Na₂Nb₄O₁₁·9H₂O

Named in 1984 for the locality. MON Space group unknown. $a = 22.22$, $b = 12.86$, $c = 6.36$, $\beta = 92.23^\circ$, $Z = 4$, $D = 2.71$. *CM 22:239(1984)*. *38-357*: 11.0₁₀ 6.06₄ 5.55₇ 4.73₆ 4.21₅ 3.21₅ 3.18₆ 2.63₅. Aggregates of small globules consisting of radiating, bladed crystals. White, white streak, vitreous to silky luster. No cleavage, basal parting. G = 2.72. Nonfluorescent. Difficultly soluble in HCl. Biaxial (–); N_x = 1.72, N_y = 1.78, N_z = 1.79; 2V ≈ 35°; Y perpendicular to elongation; Z parallel to elongation. *Francon Quarry, Montreal Is., QUE, Canada*, in a dawsonite-bearing still in vugs associated with weloganite, calcite, and quartz. RG *AM 70:436(1985), DANS 305:700(1989)*.

8.6.1.2 Hochelagaite (Ca,Na,Sr)Nb₄O₁₁ · 8H₂O

Named in 1986 for Hochelaga, the original (Native American) name for Montreal, where the mineral was found. *MON* Space group unknown. $a = 19.98$, $b = 12.88$, $c = 6.446$, $\beta = 93.42^\circ$, $Z = 4$, $D = 2.85$. *CM* 24:449(1986). 36-418: 10.0₁₀ 6.18₂ 5.39₅ 4.96₅ 3.21₇ 3.12₈ 2.80₄ 1.98₃. Polycrystalline globules consisting of microscopic radiating blades. White, white streak, vitreous luster. No cleavage, brittle. $H = 4$. $G = 2.9$. Nonfluorescent. Hochelagaite is similar in structure to franconite, and the chemical composition differs only in the presence of Ca instead of Na, and a small difference in the H₂O content. Despite being closely related, however, it is doubtful that they have identical structures or that a complete solid-solution series exists between them. Biaxial (-); $N_x = 1.72$, $N_y = 1.81$, $N_z = 1.82$; $2V \approx 35^\circ$; Y perpendicular to blades; Z parallel to elongation. *Francon quarry, St. Michel district, Montreal Is., QUE, Canada*, in vugs in a dawsonite-bearing still, associated with franconite, welo-ganite, calcite, and quartz. Also from Mt. St.-Hilaire, QUE. *RG AM* 72:1024(1987).

8.6.2.1 Calciotantite Ca(Ta,Nb)₄O₁₁

Named in 1982 for the composition. *HEX-R* *P*6₃22. $a = 6.245$, $c = 12.323$, $Z = 2$, $D = 7.46$. 15-679(syn): 6.15₆ 5.37₆ 3.06₈ 3.00₁₀ 2.77₁₀ 2.47₈ 1.92₆ 1.55₈. *MZ* 4(3):75(1982). 6.11₅ 3.12₇ 3.02₁₀ 2.78₉ 2.47₆ 1.80₇ 1.55₇ 1.51₁₀. Square to rectangular to hexagonal crystals as inclusions in microlite. Colorless, adamantine luster. No cleavage. $VHN_{40} = 970$. Nonfluorescent in UV light, luminesces blue in cathode rays. $R = 16.9\text{--}16.3$ (486 nm), 17.0–16.6 (551 nm), 17.1–16.7 (589 nm), 18.2–18.0 (656 nm). *Kola Penin., Russia*, in granite pegmatites, with albite, spodumene, scheelite, apatite, wodginite, and microlite. *RG AM* 68:471(1983), *SPC* 33:498(1988).

8.6.2.2 Natrotantite Na₂Ta₄O₁₁

Named in 1981 for the composition. *HEX-R* *R*3c. $a = 6.209$, $c = 36.609$, $Z = 6$, $D = 7.706$. Structure: *BM* 108:541(1985). 38-463: 5.15₃ 3.05₅ 3.01₁₀ 2.77₈ 2.47₃ 1.792₅ 1.701₄ 1.547₅. Colorless; yellowish, adamantine luster. No cleavage, uneven fracture. $VHN_{40} = 1270$. Nonfluorescent in UV light, strongly luminescent yellow-green in cathode rays. In RL, strongly pleochroic and strongly anisotropic. $R = 15.0\text{--}13.6$ (470 nm), 12.4–11.9 (589 nm), 12.0–12.0 (650 nm). *Kola Penin., Russia*, in albitized areas of granite pegmatites, intergrown with microlite and rimming simpsonite. Alto do Giz, Equador, RGN, Brazil, as inclusions in simpsonite, with microlite and manganotantalite. *RG ZVMO* 110:338(1981), *AM* 67:413(1982), *IGR* 24:835(1982).

8.6.2.3 Irtyshte Na₂(Ta,Nb)₄O₁₁

Named in 1985 for the locality. *HEX* *P*6₃/m. $a = 6.231$, $c = 36.77$, $Z = 6$, $D = 7.03$. 38-391: 6.13₇ 5.18₆ 3.08₉ 3.03₁₀ 2.78₉ 2.48₆ 1.93₄ 1.80₄. Microscopic veinlets and irregular grains. Colorless, adamantine luster. No cleavage, uneven fracture, brittle. In RL, bireflectant, nonpleochroic. *Irtysk River*

area, eastern Kazakhstan, from granite pegmatites, in altered thoreaulite, lithiotantite, and ixiolite. RG *AM* 71:1545(1986).

8.7.1.1 Murataite $(Y,Na)_6(Zn,Fe)_5(Ti,Nb)_{12}O_{29}(O,F)_{10}F_4$

Named in 1974 for Kiguma Jack Murata (b.1909), geochemist, U.S. Geological Survey. ISO *F*43m. $a = 14.863$, $Z = 4$, $D = 4.64$. *CM* (1995). 26-1383: 8.51₃ 2.86₁₀ 2.47₆ 2.14₂ 1.75₈ 1.49₈ 1.43₅ 1.14₅. Embedded grains with cubic outline. Black, submetallic luster. No cleavage, conchoidal fracture. $H = 6-6\frac{1}{2}$, $VHN_{100} = 827$. $G = 4.69$. Isotropic; $N \approx 2.13$. In RL, gray, with orange internal reflections, slightly pleochroic. $R = 13.6$ (546 nm). *St. Peter's Dome, El Paso Co., CO*, in a pegmatite associated with riebeckite, quartz, astrophyllite, aegirine, and zircon. Burpala massif, northern Baikal region, Siberia, Russia, in rare-metal alkali syenite pegmatites, associated with landauite and brookite. RG *AM* 59:172(1974), *MA* 34:722(1983), *CM* 33:1223(1995).

8.7.2.1 Uhligite $Ca_3(Ti,Al,Zr)_9O_{20}$

Named in 1909 for Alfred Louis Johannes Uhlig (1883–1919), German geologist, leader of the African expedition in which the material was first collected. May possibly be perovskite. Needs further investigation. ISO or pseudo-ISO Space group unknown. $a = 7.654$. Black, gray to brownish-gray streak, metallic luster. Cleavage {001}, imperfect; conchoidal fracture. $H = 5\frac{1}{2}$. $G = 4.15$. Exhibits an internal structure of biaxial lamellae, similar to those in perovskite. *Lake Magadi, Rift Valley, Kenya*, in nepheline syenite. RG *DI*:735.

8.7.3.1 Cafetite $Ca(Fe^{3+},Al)_2Ti_4O_{12} \cdot 4H_2O$

Named in 1959 for the composition. Probably ORTH Space group unknown. $a = 31.34$, $b = 12.12$, $c = 4.96$, $Z = 6$, $D = 3.19$. *AM* 45:476(1960). 20-243: 7.2₃ 5.2₃ 4.78₅ 3.64₄ 3.31₁₀ 2.29₄ 1.764₁₀ 1.504₄. Radial-fibrous or tangled aggregates of acicular crystals. Pale yellow; colorless, adamantine luster. Flexible fibers, brittle. $H = 4-5$. $G = 3.28$. Biaxial (-); $Z \wedge c = 2-4^\circ$; $N_x = 1.95$, $N_y = 2.08$, $N_z = 2.11$; the optics are inconsistent with ORTH symmetry; cafetite may be monoclinic. *Afrikanda massif, Kola Penin., Russia*, in miarolitic cavities in pegmatites cutting pyroxenite, associated with kassite. RG *ZVMO* 88:444(1959); *AM* 71:1045(1986), 76:283(1991).

8.7.4.1 Calzirtite $CaZr_3TiO_9$

Named in 1961 for the composition. TET *I*4₁/acd. $a = 15.094$, $c = 10.043$, $Z = 8$, $D = 4.94$. Structure: *AM* 71:815(1986). 15-121: 2.95₁₀ 2.55₆ 1.80₁₀ 1.54₉ 1.17₇ 1.14₅ 0.981₆ 0.860₆. Tetragonal prismatic, bipyramidal crystals. Light to dark brown, brownish green, nearly black, wine-red, yellow-green; brown streak; semimetallic to adamantine luster, greasy on fracture surfaces. No cleavage, conchoidal fracture, brittle. $H = 6-7$. $G = 5.01$. Nonfluorescent in UV light, luminesces red in cathode rays. Uniaxial (+); $N_O = 2.22$, $N_E = 2.26$. In RL, light gray, with strong reddish brown internal reflections. $R = 15.0-16.4$ (546 nm). *Meimecha Kotui, eastern Siberia, Russia*, in metaso-

matic calcite–forsterite–magnetite rocks of an alkalic ultrabasic massif; also from the Guly massif; from carbonatites in the Kola Penin., and elsewhere. In Uganda in residual soils from the Bukusu carbonatite complex, with perovskite, ilmenite, zircon, and baddeleyite. In Brazil from the Tapira carbonatite, Sacramento, MG, and from the Jacupiranga carbonatite, SP. *RG AM* 46:1515(1961), 52:1880(1967); *MM* 35:544(1965), 36:778(1968).

8.7.5.1 Simpsonite $\text{Al}_4(\text{Ta,Nb})_3\text{O}_{13}(\text{OH})$

Named in 1938 for Edward Sidney Simpson (1875–1939), government mineralogist of Western Australia. *HEX P3*. $a = 7.38$, $c = 4.51$, $Z = 1$, $D = 6.83$. Structure: *SR* 27:540(1962). 15-705(syn): 2.84₉, 2.12₇, 1.64₁₀, 1.39₁₀, 1.28₆, 1.22₅, 1.05₅, 1.02₉. Hexagonal, tabular, or equant crystals; rarely prismatic; prism zone striated [0001]. White, colorless, dark yellow, yellow-brown; adamantine to greasy luster. No cleavage, conchoidal fracture. $H = 7\frac{1}{2}$. $G = 6.81$. Strongly fluorescent bluish white in SWUV. Insoluble in acids. Uniaxial (–); $N_{\text{O}} = 2.045$, $N_{\text{E}} = 2.005$. Tanco mine, Bernic Lake, MB, Canada, with microlite, wadginitite, cesstibtantite, and tapiolite. Northern Kola Penin., Russia, with cleavelandite, cesium beryl, spodumene, montebrasite, pollucite, petalite, eucryptite, elbaite, manganotantalite, microlite, and stibiotantalite. In Zimbabwe at the Benson No. 3 pegmatite, Mtoko, with stibiotantalite, and in the Bikita pegmatite. *Tabba Tabba, WA, Australia*, in pegmatite. In Brazil from the Alto do Giz, Equador, RGN, in fine crystals up to 3 cm, associated with manganotantalite, microlite, and gahnite; also at the nearby Onça mine with tapiolite and microlite. *RG AM* 25:313(1940), *DI*:771, *MM* 33:458(1963).

8.7.6.1 Rankamaite $(\text{Na,K})_{1-x}(\text{Ta,Nb,Al})_4(\text{O,OH})_{11}$

Named in 1969 for Kalervo Rankama (b.1913), Finnish geochemist, University of Helsinki. *ORTH Pban*. $a = 17.184$, $b = 17.689$, $c = 3.942$, $Z = 6$, $D = 5.84$. T. S. Ercit, Ph.D. thesis, University of Manitoba (1986). 25-9: 4.11₃, 3.94₄, 3.47₅, 3.38₆, 3.01₈, 2.97₁₀, 2.79₃, 1.74₂. Massive, felted acicular crystals. White to creamy white, white streak, dull, chalky luster. $H = 3-4$. $G = 5.5$. Nonfluorescent. Biaxial; $N > 2.1$; $Z = c$; positive elongation. Tanco mine, Bernic Lake, MB, Canada, a mineral intermediate between rankamaite and sosedkoite. Near *Mumba, Kivu, Zaire*, in alluvial concentrates, with simpsonite, cassiterite, manganotantalite, and muscovite, probably derived from the alteration of simpsonite in a lithium pegmatite. *RG AM* 55:1814(1970), *BGSF* 41:47(1979), *DANS* 264:442(1982).

8.7.6.2 Sosedkoite $(\text{K,Na})_{1-x}(\text{Ta,Nb,Al})_4(\text{O,OH})_{11}$

Named in 1982 for A. F. Sosedko (1901–1957), Russian mineralogist. *ORTH Pban*. $a = 17.25$, $b = 17.73$, $c = 3.95$, $Z = 6$, $D = 6.90$. T. S. Ercit, Ph.D. thesis, University of Manitoba (1986). 35-687: 6.1₅, 3.95₁₀, 3.47₅, 3.03₉, 2.79₅, 2.38₅, 2.28₄, 1.97₆. Acicular crystals. Colorless, adamantine luster. No cleavage. $\text{VHN}_{20} = 830$. Nonfluorescent, luminesces weak blue under cathode rays. Tanco mine, Bernic Lake, MB, Canada, a mineral intermediate between

soosedkoite and rankamaite. *Kola Penin., Russia*, in granite pegmatites, in microlite and cesstibtantite, and along grain boundaries of these minerals with simpsonite and stibiotantalite. RG *DANS 264:133;442(1982)*, *AM 68:644(1983)*.

8.7.7.1 Lithiotantite $\text{Li}(\text{Ta},\text{Nb})_3\text{O}_8$

Named in 1983 for the composition. MON $P2_1/c$. $a = 7.444$, $b = 5.044$, $c = 15.255$, $\beta = 107.18^\circ$, $Z = 4$, $D = 7.08$. $35\text{-}718$: 6.03_7 4.13_5 2.96_{10} 2.49_5 1.90_5 1.77_6 1.72_8 1.45_8 . Equant crystals, poorly formed. Colorless, stained pink by cassiterite inclusions; adamantine luster. No cleavage, conchoidal to uneven fracture, brittle. $H = 6\text{-}6\frac{1}{2}$. $G = 7.0$. Nonfluorescent, luminesces weak yellow-green in cathode rays. $N > 1.9$; very strong dispersion. In RL, grayish white, nonpleochroic, weakly anisotropic. *Eastern Kazakhstan*, in edge zones of microcline-albite pegmatites, with cassiterite, rankamaite, and thoreaulite. RG *MZ 5(1):91(1983)*, *AM 69:1191(1984)*.

8.7.8.1 Belyankinite $\text{Ca}_{1-2}(\text{Ti},\text{Zr},\text{Nb})_5\text{O}_{12} \cdot 9\text{H}_2\text{O} (?)$

Named in 1950 for Dmitri Stepanovich Belyankin (1876–1953), Russian mineralogist and petrographer. ORTH or MON Space group unknown. Amorphous to X-rays. $38\text{-}455(\text{heated})$: 3.21_8 2.90_3 2.48_6 2.18_3 1.69_{10} 1.63_2 1.36_5 1.26_2 . Massive. Light yellow, brownish yellow; vitreous to oily luster, pearly on cleavage. Cleavage perfect in one direction; uneven fracture. $H = 2\text{-}3$. $G = 2.4$. Completely soluble in hot HCl, infusible. Biaxial (-); $N_x = 1.740$, $N_y, N_z = 1.775\text{-}1.780$. X, brown; Y,Z, light brown to yellow-brown. *Kola Penin., Russia*, in nepheline syenite pegmatite, with microcline, nepheline, aegirine, and zeolites. RG *DANS 71:925(1950)*, *AM 37:882(1952)*.

8.7.8.2 Manganbelyankinite $(\text{Mn},\text{Ca})_2(\text{Ti},\text{Nb})_5\text{O}_{12} \cdot 9\text{H}_2\text{O}$

Named in 1957 for the composition and relation to belyankinite. Amorphous. $38\text{-}454(\text{heated})$: 3.21_5 2.89_5 2.48_8 2.17_3 1.88_3 1.69_{10} . Brownish black, resinous luster. Biaxial (-); $2V = 29^\circ$. *Mt. Kedykverpakh, Lovozero massif, Kola Penin., Russia*, in pegmatite. RG

8.7.8.3 Gerasimovskite $(\text{Mn},\text{Ca})(\text{Nb},\text{Ti})_5\text{O}_{12} \cdot 9\text{H}_2\text{O}$

Named in 1957 for Vasili Ivanovich Gerasimovskii (1907–1979), Russian mineralogist and geochemist; discoverer of 10 new minerals, and of the industrial loparite deposit on the Lovozero massif. AMOR *AM 43:1221(1958)*. $38\text{-}456$: 3.7_8 3.18_6 2.10_4 1.89_{10} 1.64_2 . Platy masses. Brown, gray; pearly luster. Perfect cleavage in one direction. $H = 2$. $G = 2.55$. Biaxial (-); $N_x \approx 1.74$, $N_y \approx 1.81$, $N_z \approx 1.81$; $2V = 18^\circ$; parallel extinction; positive elongation. *Lovozero massif, Kola Penin., Russia*, on Mt. Punkuruaiiv, Mt. Nepkha, and Mt. Alluiv in alkaline ussingite-bearing pegmatites. RG

8.7.9.1 Jeppeite (K,Ba)₂(Ti,Fe)₆O₁₃

Named in 1984 for John Frederick Biccard Jeppe (b.1920), Australian geologist of Nedlands, WA, who discovered the mineral. MON *C2/m*. $a = 15.543$, $b = 3.837$, $c = 9.123$, $\beta = 99.25^\circ$, $Z = 2$, $D = 3.98$. *MM* 48:263(1984). 37-426: 4.50₄ 3.07₁₀ 2.99₁₀ 2.81₁₀ 2.09₆ 2.07₆ 1.92₈ 1.41₅. Finely prismatic to acicular aggregates. Black; brown, pale brown streak, submetallic luster. Cleavage {100}, {201}, perfect; brittle. $H = 5-6$, $G = 3.94$. Biaxial (+); $YZ = bc$; $X \wedge a = 10^\circ$; $N_x = 2.13$, $N_y = 2.21$, $N_z = 2.35$. X, blue; Y, dark greenish brown; Z, brown. In RL, weak bireflectance. *Walgidee Hills, Fitzroy basin, Kimberley, WA, Australia*, in lamproite, associated with priderite, richterite, scherbakovite, wadeite, perovskite, and apatite, in a celadonite-chlorite matrix. *RG AM* 70:872(1985).

8.7.10.1 Zimbabweite Na(Pb,Na,K)₂(Ta,Nb,Ti)₄As₄O₁₈

Named in 1986 for the country of origin. ORTH *Ccmb*. $a = 12.245$, $b = 15.287$, $c = 8.684$, $Z = 4$, $D = 5.97$. Structure: *AM* 73:1186(1988). 39-356: 3.82₆ 3.24₅ 3.20₁₀ 3.03₆ 2.99₇ 2.88₇ 2.55₅ 1.913₅. Crystals are euhedral square tablets showing {010}, {201}, {100}, and {111}. Yellow-brown, white streak, adamantine luster. Cleavage {010}, perfect; brittle. $H = 5$. $G = 6.20$. Nonfluorescent. Nonmagnetic. Insoluble in common acids or bases. Biaxial (+); $XYZ = cba$; $N > 2.10$; $2V = 80^\circ$; $r < v$, strong. X, pale yellow brown, Y, light reddish brown, Z, reddish brown. *St. Ann's mine, Karoi district, SE of Miami, Zimbabwe*, in kaolinized pegmatite. *RG BM* 109:331(1986).

8.7.11.1 Cesplumtantite (Cs,Na,Ca)₂(Pb,Sb,Sn)₃Ta₆O₂₄

Named in 1986 for the composition. Pyrochlore group. TET Space group unknown. $a = 13.552$, $c = 6.445$, $Z = 2$, $D = 6.87$. *MZ* 8(5):92(1986). 40-488: 6.11₅ 3.19₅ 3.05₁₀ 2.65₅ 2.04₅ 1.87₇ 1.59₇ 1.18₅. Microscopic veinlets, showing complex polysynthetic twinning. Colorless, white streak, adamantine luster. No cleavage. $VHN_{40} = 1240$. In RL, light gray, with no internal reflections, weakly bireflectant, strongly anisotropic. *Manono, Shaba, Zaire*, as veinlets in thoreaulite, associated with lithiotantite, cassiterite, calciotantite, and microlite. *RG AM* 74:501(1989).

8.7.12.1 Koragoite (Mn²⁺,Mn³⁺)₃(Nb,Ta)₃(Nb,Mn²⁺)₂W₂O₂₀

Named in 1995. MON *P2₁*. $a = 24.73$, $b = 5.056$, $c = 5.760$, $\beta = 103.5^\circ$, $Z = 2$, $D = 6.11$. *PD*: 6.0₅ 3.74₈ 3.69₈ 2.98₁₀ 1.783₅ 1.744₆ 1.732₇ 1.456₅. Platy crystals. Found in pegmatite in *Pamir, Tadzhikistan*. An inadequately described mineral. *RG K* 40(3):469(1995), *AM* 81:250(1996).

Anhydrous and Hydrated Halides

HALITE GROUP

The halite group minerals are isostructural and have general formula

where

A = Na, K, or Li

X = Cl, F

and the structure is in the cubic space group *Fm3m*.

The structure of halite was the first structure established through the use of X-rays, by W. L. Bragg in 1914. If ions of one type are taken as the corners and face centers of the cell, those of opposite sign lie at the midpoints of cell edges and at the cube center. Each Na atom is thus surrounded by six Cl atoms, and each Cl atom by six Na atoms. The Na and Cl atoms are thus arranged alternately in rows parallel to the edges of the cell. *DHZ 5:367*.

HALITE GROUP

Mineral	Formula	Space Group	<i>a</i>	D	
Halite	NaCl	<i>Fm3m</i>	5.640	2.164	9.1.1.1
Sylvite	KCl	<i>Fm3m</i>	6.93	1.987	9.1.1.2
Villiaumite	NaF	<i>Fm3m</i>	4.634	2.799	9.1.1.3
Carobbiite	KF	<i>Fm3m</i>	5.347	2.524	9.1.1.4
Griceite	LiF	<i>Fm3m</i>	4.027	2.638	9.1.1.5

Notes:

1. The galena and the periclase groups are both isostructural with halite.
2. Osbornite (1.1.19.1), khamrabaevite (1.1.19.2), and carlsbergite (1.1.20.1) are all isostructural with the halite group.

9.1.1.1 Halite NaCl

Named in antiquity from the Greek *hals*, salt. Halite group. Synonyms: salt, rock salt. iso *Fm3m*. *a* = 5.640, *Z* = 4, *D* = 2.164. *NBSC 539(2):41(1953)*. 5-628(syn): 3.26₁ 2.82₁₀ 1.99₆ 1.63₂ 1.41₁ 1.26₁ 1.15₁ 0.892₁. Habit: Usually cubes, rarely with {111}. Sometimes forms hopper-shaped crystals. Massive,

HALITE: NaCl

Space group $Fm\bar{3}m$. Each atom is coordinated by six of the other kind.

bedded. Twinning on $\{111\}$, rare. **Physical properties:** Colorless, white, reddish, blue, purple. The red color may be due to occluded hematite; the bluish and purple colors are due to defects in the structure and disappear if the mineral is dissolved and recrystallized. White streak, vitreous luster. Cleavage $\{001\}$, perfect, easy; conchoidal fracture; brittle. $H = 2$. $G = 2.168$. Nonfluorescent under UV radiation, but occasionally foreign material included in the crystal will fluoresce, giving the impression that the halite is fluorescent. **Tests:** Soluble in water. With concentrated H_2SO_4 gives HCl . Tastes salty. Fuses at 804° , often with decrepitation. **Optics:** Isotropic; $N = 1.544$. **Occurrence:** Halite occurs in deposits of several types. Quantitatively most important are the evaporites, in which halite forms bedded deposits reaching thicknesses of 1000 m and more. Also found in salt domes, which have been derived from deep beds of rock salt that have been plastically deformed. It is a common constituent of salt lakes and playas and may be found crystallizing in these waters near the shore. It crystallizes from seawater in lagoons; halite derived from the evaporation of sea spray is carried into the upper atmosphere in minute crystals, where it assists in nucleating clouds and fog. Often found in volcanic fumaroles; also found as crystals in the fluid inclusions in many minerals. **Localities:** Halite is widely distributed throughout the world in sedimentary deposits of all ages. Important deposits have been mined for many years in upper Silurian sediments in central and western NY. The world's largest rock salt mine is near Retsof, NY. Some is mined by underground methods, but much is also recovered through brine wells. Louann salt formation, AL. In LA, TX, and elsewhere along the Gulf coast important deposits are known, many of them in salt domes; also in AZ in the Verde Valley, Yavapai Co., in fine clear masses. In CA it is associated with borate deposits in San Bernardino Co. In UT, salt is obtained from the waters of Great Salt Lake. In Canada in ONT in Bruce, Huron, and Lambton Cos.; in SK in

extensive beds, and in NF. Famous deposits are found in Germany at Stassfurt, Saxony, and in Leopoldshall; also at Heringen-Werra (Hessen) fine transparent deep blue cleavages are found. Rhythmically banded clear, lilac, pale blue fibrous halite comes from Wittolsheim, Alsace, France; also in Landes and in Lorraine. Large deposits are known in Galicia, Poland, at Kalusz, Bochnia, and Wieliczka; at the latter mine wonderful cubic crystals up to 50 cm on edge were found, the finest in the world. Salzburg, Austria, at Hallein, and in the Tyrol near Innsbruck. Crystallized halite is found in Sicily, Italy, at Girgenti and other localities, and vast beds of it are known to underlie much of the Mediterranean Sea. In Spain near Barcelona; in Cheshire in England. Deposits are known at numerous places in Russia and in China. In Pakistan in the Salt Range. In Africa, in Algeria and Ethiopia. Salar de Uyuni, Bolivia, crystal groups beneath the crust of an enormous salt flat. Uses: The principal uses for salt are for culinary purposes and for food preservation; as a basis for the manufacture of hydrochloric acid and most other chlorine compounds; for the manufacture of sodium, sodium compounds, and glass; and for melting ice and snow on highways, and so on. RG *DII:4*.

9.1.1.2 Sylvite KCl

Named in 1832 for the old chemical name for the substance *sal digestivus Sylvii*, or digestive salt, of Francis Sylvius de le Boë (1614–1672), Dutch physician and chemist of Leyden. Halite group. iso *Fm3m*. $a = 6.93$, $Z = 4$, $D = 1.987$. *NBSC 539(1):65(1953)*. 41-1476: 3.15₁₀ 2.23₄ 1.817₁ 1.573₁ 1.407₁ 1.284₁ 1.049₁ 0.995₁. Commonly in cubes or in cubes modified by octahedrons; also granular crystalline masses intermixed with halite and other salts; compact. Colorless to white, translucent to transparent; other colors due to impurities; vitreous luster. Cleavage {100}, perfect; uneven fracture. $H = 2$. $G = 1.97$ – 1.99 . Soluble in water. Tastes somewhat salty. Isotropic; $N = 1.490$. Sylvite is formed like halite from the fractional crystallization of seawater. It forms sylvite-rich layers in many salt deposits but is much less abundant than halite. Louann salt formation, Alabama. Important deposits occur in the Permian basin of NM and TX, particularly in the region of Carlsbad, NM. In Canada vast deposits are being mined in SK. At Stassfurt and Leopoldshall, northern Germany, and in the southern Harz region; associated with sylvite and halite are many other chlorides and sulfates. Kalusz, Galicia, Poland. *Vesuvius, Italy*, in fumaroles, and at Mt. Etna, Sicily. From the nitrate beds in the desert of Tarapaca, Chile, and adjacent regions of Peru. Used as a raw material in the manufacture of potassium and potassium compounds; an essential ingredient in fertilizers, for which use millions of tons are mined annually. RG *DII:7*, *MM 29:669(1951)*.

9.1.1.3 Villiaumite NaF

Named in 1908 for Mr. Villiaume, French explorer, in whose collection of rocks from Guinea the mineral was first found. Halite group. iso *Fm3m*. $a = 4.634$, $Z = 4$, $D = 2.799$. *NBSC 539(1):63(1953)*. 36-1455: 2.68₁ 2.32₁₀ 1.64₄ 1.40₁

1.34₁ 1.16₁ 1.04₁ 0.946₁. Crystals rare, as cubes sometimes modified by octahedron; as cleavable masses; granular. Carmine red, artificial NaF is colorless, white streak, vitreous luster. Cleavage {001}, perfect. $H = 2-2\frac{1}{2}$, $G = 2.79$. Soluble in water to form a colorless solution; upon recrystallization, the crystals are colorless. Very poisonous. When heated to 300°, becomes colorless. Isotropic; $N = 1.326$. Natural material is anomalously uniaxial (-); weakly birefringent, strongly dichroic. O, pink to carmine; E, yellow. Villiaumite is formed in alkalic rocks such as nepheline syenites, usually in pegmatitic phases. Point of Rocks, Colfax Co., NM. Mt. St.-Hilaire, QUE, Canada, as cleavable masses and small crystals. Ilimaussaq intrusion, Julienhaab district, southwestern Greenland; Kola Penin., Russia; *Rouma Island, Los Archipelago, Guinea*. Poços de Caldas, MG, Brazil, in small crystals. RG *DII:10, NJMM:111(1981)*.

9.1.1.4 Carobbiite KF

Named in 1956 for Guido Carobbi (1900–1983), professor of mineralogy at the University of Florence. Halite group. iso $Fm\bar{3}m$. $a = 5.347$, $Z = 4$, $D = 2.54$. *NBSC 539(1):64(1953)*. *36-1458(syn): 3.09₂ 2.67₁₀ 1.89₅ 1.61₁ 1.54₁ 1.34₁ 1.20₁ 1.09₁*. Crystallizes as small cubes. Colorless, vitreous luster. Cleavage {001}, perfect. $G = 2.52$. Isotropic; $N = 1.362$. From *Vesuvius, Italy*, in cavities in lava. RG *AM 42:117(1957)*.

9.1.1.5 Griceite LiF

Named in 1989 for Joel D. Grice (b.1946), curator of minerals, Canadian Museum of Nature, Ottawa, Canada. Halite group. iso $Fm\bar{3}m$. $a = 4.027$, $Z = 4$, $D = 2.638$. Structure: *CM 27:125(1989)*. *45-1460(syn): 2.32₉ 2.01₁₀ 1.424₅ 1.213₁ 1.163₁ 0.924₁ 0.900₁ 0.822₁*. As millimeter-size aggregates; powdery coatings; translucent irregular grains in villiaumite. White, dull to vitreous luster. Cleavage {001}, good; uneven to conchoidal fracture. $H = 4\frac{1}{2}$, $G = 2.62$. Some specimens fluoresce light yellow in SWUV. Insoluble in H₂O. Not attacked by 30% HCl. Isotropic; $N = 1.392$. *Poudrette quarry, Mt. St.-Hilaire, QUE, Canada*, in a sodalite inclusion in nepheline syenite, associated with ussingite, eudyalite, sphalerite, serandite, and lovozerite; also as inclusions in villiaumite or pseudomorphs of it. RG

9.1.2.1 Hydrohalite NaCl · 2H₂O

Named in 1847 for the water content and similarity to halite in composition. *MON P2₁/c*. $a = 6.331$, $b = 10.118$, $c = 6.503$, $\beta = 114.4^\circ$, $Z = 4$, $D = 1.654$. *NJMM:325(1972)*. Structure: *AC(B) 30:2363(1974)*. *29-1197: 3.87₈ 3.82₉ 3.63₅ 2.98₁₀ 2.88₆ 2.67₁₀ 2.52₁₀ 2.24₉*. Stable only in very cold concentrated NaCl solutions at temperatures below -5°. Colorless. $G = 1.63$. First observed during the winter at a salt works in *Salzburg, Germany*. Said to have been found just below the surface, encrusting rocks in a fjord on the coast of Greenland. From Lake Bonney, Taylor Valley, Victoria Land, Antarctica. RG *DII:15, AJUS 10:179(1975)*.

9.1.3.1 Sal Ammoniac NH_4Cl

Named in 1546 from the medieval Latin for salt of Ammon, used by early writers for common rock salt from near the Oracle of Ammon in Egypt. Later, the name was applied to the present compound, which was manufactured in Egypt. iso $Pm\bar{3}m$. $a = 3.876$, $Z = 1$, $D = 1.527$. *NBSC 539(1):59(1953)*. 7-7(syn): 3.87_3 2.74_{10} 2.24_1 1.94_1 1.73_1 1.58_3 1.37_1 1.23_1 . Crystals usually trapezohedral {112}. May be modified by {113}; rarely shows gyroidal forms. Frequently, skeletal and in parallel growth. Twinning on {111}. Colorless to white, yellowish brown when mixed with FeCl_3 , vitreous luster. Cleavage {111}, imperfect; conchoidal fracture; somewhat plastic, not easily powdered. $G = 1.532$. Isotropic; $N = 1.639$. Weakly birefringent after deformation. Found chiefly at volcanic fumaroles, especially where lava has flowed over soil or vegetation. Also produced by condensation of gases from burning coal seams and in guano deposits. Fissure Springs, Death Valley, and at Mud Volcanos, Niland, CA. The volcanos of Kilauea, Pelée, Vesuvius, Etna, Stromboli, and Vulcano are noteworthy sources. In large crystal groups from burning coal dumps at St. Etienne, Loire, France. In coal seams at Newcastle, England, and elsewhere. Ravat, Tadzhikistan, nice crystals to 50 mm. From the guano deposits of Chile and Peru. *RG DII:15*.

9.1.4.1 Chlorargyrite AgCl

Named in 1875 for the composition: chlorine and silver (argyros). Synonyms: cerargyrite, horn silver. iso $Fm\bar{3}m$. $a = 5.549$, $Z = 4$, $D = 5.571$. *NBSC 539(4):44(1955)*. 31-1238(syn): 3.20_5 2.77_{10} 1.96_5 1.67_2 1.60_2 1.39_1 1.24_1 1.13_1 . Crystals usually cubes, often modified by {111} and {011}. Crystal faces usually curved and poorly formed. As crusts and waxy coatings, hornlike masses, dendritic, columnar, or stalactitic. Twinning on {111}. Colorless when fresh (AgCl) to yellowish or green with increasing ratio of AgBr . Becomes violet brown to gray on exposure to light, the Br-rich varieties showing less tendency to change. Resinous to adamantine luster. Uneven fracture, sectile, plastic, tough. $H = 2\frac{1}{2}$. $G = 5.55-6.00$. Insoluble in water and in dilute HCl but soluble in NH_4OH , KCN , and $\text{Na}_2\text{S}_2\text{O}_3$ solutions. A fragment of chlorargyrite placed on a strip of zinc and moistened with a drop of water swells up, turns black, and is partly reduced to metallic silver, which shows its metallic luster upon being pressed with the point of a knife. Fuses in the flame of a candle. "Horn silver" minerals can be distinguished by their waxy luster and plasticity. Isotropic; $N = 2.07-2.16$. A complete solid-solution series exists between chlorargyrite and bromargyrite; the intermediate compositions, with AgCl/AgBr close to 1:1, is known as *embolite*. Limited solid solution also exists between $\text{Ag}(\text{Cl},\text{Br})$ and AgI , especially toward the Br-rich portion of the series, the maximum, observed ratio in natural material being about 3.5:1. I-rich varieties, which are known as *iodobromite*, are yellowish to orange. Formed in the oxidized zone of silver-bearing deposits, especially in arid regions, associated with native silver, cerussite, malachite, limonite, and so on. Chlorargyrite was formerly abundant in many of the Western silver

campes, especially Leadville, CO; Tombstone, AZ; Rand district, CA; Rochester, Bullfrog, and Chloride districts, NV; Frisco, UT; Lake Valley, NM; Poorman's Lode, ID. Once common in the silver mines of Germany, at Johanngeorgenstadt, Freiberg, and Schneeberg in Saxony, and Andreasberg, Harz. Jachymov, Bohemia, Czech Republic. Altai Mts., Kazakhstan. Also formerly in large amounts at Chañarcillo in Atacama, and in Antofagasta and Tarapaca, in Chile. Potosi, Bolivia. Very abundant in the early days of mining at Broken Hill, NSW, Australia(1). Formerly an important ore of silver. RG *DII:11*.

9.1.4.2 Bromargyrite $\text{Ag}(\text{Br},\text{Cl})$

Named in 1841 for the composition. iso $Fm\bar{3}m$. $a = 5.775$, $Z = 4$, $D = 6.48$. *NBSC 539(4):46(1955)*. 6-438(syn): 3.33₁ 2.89₁₀ 2.04₆ 1.67₂ 1.44₁ 1.33₁ 1.29₁ 1.18₁. Crystallizes as cubes, sometimes with {111}; crystal faces usually rounded; also massive, hornlike. Yellowish green to green, shining streak, waxy to adamantine luster. Very plastic. $H = 2\frac{1}{2}$. $G = 6.00-6.47$. Isotropic; $N = 2.16-2.25$. For chemistry, tests, and occurrence, see chlorargyrite (19.1.4.1). In AZ at Tombstone and at Bisbee. Many other occurrences of bromargyrite have been reported for the western United States, but the exact identity of the material is uncertain. In Mexico in the San Onofre and Plateros districts, ZAC, and at Parilla, DGO. Dernbach, Nassau, Germany; Huelgoat, Finistere, France. Donetsk basin, Ukraine. Chkalov, Russia. Formerly abundant at Chañarcillo, Chile(1), with silver and iodargyrite; also once abundant at Broken Hill, NSW(1), Australia. RG *DII:11*, *AM 47:982(1962)*.

9.1.5.1 Iodargyrite AgI

Named in 1854 for the composition. $\text{HEX } P6_3mc$. $a = 4.592$, $c = 7.510$, $Z = 2$, $D = 5.683$. *NBSC 539(8):51(1959)*. 9-374(syn): 3.98₆ 3.75₁₀ 3.51₄ 2.73₂ 2.30₉ 2.12₃ 1.96₅ 1.33₁. Crystals prismatic [0001] or tabular {0001}, usually showing hemimorphic character; also in rosettes, massive, or scaly. May form paramorphs after miersite, on {3034}. Colorless, changing to pale yellow on exposure to light; also dark yellow, greenish yellow, brownish; yellow, shining streak; resinous to adamantine luster; pearly on cleavage. Cleavage {0001}, perfect; conchoidal fracture; sectile; flexible. $H = 1\frac{1}{2}$. $G = 5.69$. Uniaxial (+); $N_O = 2.21$, $N_E = 2.22$; strong dispersion; abnormal green interference colors. From the oxidized zone of silver deposits in arid regions. Tonopah, NV, in fine crystals; also at Majuba Hill. Commonwealth mine, Pearce Hills, Cochise Co., AZ. *Albarradon, near Mazapil, ZAC, Mexico*. Chañarcillo, Atacama, Chile. Broken Hill, NSW, Australia, in fine specimens. RG *DII:22*.

9.1.6.1 Tocornalite Silver mercury iodide: exact formula uncertain

Named in 1867 for S. F. Tocornal, rector of the University of Santiago, Chile. A questionable species. Space group unknown. *PD: 6.37₇ 3.76₉ 3.61₉ 2.64₁₀ 2.25₇ 2.04₅*. *AM 58:348(1973)*. Massive, granular. Light to bright yellow; on

exposure to light turns green, then black; dull luster. Soft. *Chañarcillo, Atacama, Chile*, with other halides of silver and mercury. Proprietary mine, Broken Hill, NSW, Australia, with embolite; also with iodargyrite and cinnabar. RG *DII:25*.

9.1.7.1 Nantokite CuCl

Named in 1867 for the locality. iso $Fd\bar{3}m$. $a = 5.416$, $Z = 4$, $D = 4.138$. *NBSC 539(4):35(1955)*. $6-344(\text{syn})$: 3.13_{10} 2.71_1 1.92_6 1.63_3 1.35_1 1.24_1 1.11_1 1.04_1 . Massive, granular. Colorless or white, altering to greenish or grayish; white streak; adamantine luster. Cleavage {001}, conchoidal fracture. $H = 2\frac{1}{2}$. $G = 4.14$. Easily soluble in acids and NH_4OH . Easily fusible. Isotropic; $N = 1.93$. Parrsboro area, NS, Canada, as seawater corrosion on copper in basalt joints exposed on beaches. Mapimi, DGO, Mexico(!), in fine blades to 20 mm. *Nantoko, Copiapo, Chile*, with oxidized copper minerals. Broken Hill, NSW, Australia. RG *DII:18*.

9.1.7.2 Miersite (Ag,Cu)I

Named in 1898 for Henry Alexander Miers (1848–1942), English mineralogist, Oxford University. iso $F\bar{4}3m$. $a = 6.495$, $Z = 4$, $D = 5.686$. *NBSC 539(9):48(1960)*. $2-499$: 3.72_6 3.23_{10} 2.28_8 1.95_8 1.49_2 1.32_2 1.29_2 . Tetrahedral crystals; as crusts; twinning on {111}. Canary yellow, yellow streak, adamantine luster. Cleavage {011}, perfect. $G = 5.65$. Insoluble in dilute HNO_3 , with dilute H_2SO_4 and zinc decomposes to metallic Ag plus Cu. Fuses easily to a red liquid. Isotropic; $N = 2.20$. Cu may replace Ag up to 20 mol %. Forms a partial series with marshite. Mildren and Steppe Claim, Pima Co., AZ, as overgrowths on iodargyrite. *Broken Hill, NSW, Australia*. RG *DII:19*, *AM 20:585(1935)*.

9.1.7.3 Marshite CuI

Named in 1892 for C. W. Marsh, Australian mineral collector, who first described the mineral. iso $F43m$. $a = 6.051$, $Z = 4$, $D = 5.710$. *NBSC 539(4):38(1955)*. $6-246(\text{syn})$: 3.49_{10} 3.03_1 2.14_6 1.82_3 1.51_1 1.39_1 1.24_1 1.16_1 . Crystals tetrahedral, also as crusts. Twinning on {111}, sometimes multiple. Colorless to pale yellow, becoming brownish red on exposure to light; yellow streak; adamantine luster. Cleavage {011}, perfect; conchoidal fracture; brittle. $H = 2\frac{1}{2}$. $G = 5.68$. Turns black in dilute HNO_3 . Isotropic; $N = 2.35$. *Broken Hill, NSW, Australia*, with oxidized copper minerals. Chuquicamata, Chile. RG *DII:20*.

9.1.8.1 Calomel HgCl

Named in 1776 for the Greek for *beautiful* and *honey*, in allusion to the sweet taste; or for *beautiful* and *black*, in reference to black mercury sulfide, to which the name was first applied. *TET I4mm*. $a = 4.480$, $c = 10.906$, $Z = 2$, $D = 7.162$. *NBSM 25(13):30(1976)*. Structure: *ZK 187:305(1989)*. $26-312$: 4.15_8 3.17_{10} 2.73_3 2.24_2 2.07_4 1.970_2 1.962_3 1.732_1 . Variable habit; often tab-

ular {001}; prismatic [001]; pyramidal; equant, especially in complex twins. As drusy crusts, massive, earthy. Twinning on {112}, contact or penetration. Colorless, white, grayish, yellowish, brown; color deepens on exposure to light; adamantine luster. Cleavage {110}, good; {011}, imperfect; conchoidal fracture; plastic; sectile. $H = 1\frac{1}{2}$. $G = 7.15$. Fluoresces brick red in SWUV. Insoluble in water, soluble in aqua regia. Blackens when treated with alkalis. Tastes sweet. In CT sublimes, condensing in upper part of tube. Uniaxial (+); $N_0 = 1.973$, $N_E = 2.656$; occasionally, weakly pleochroic. A secondary mineral, found in the oxidized zone of mercury-bearing deposits, usually associated with native Hg and cinnabar. Terlingua, TX(1), in complex crystals. Howard Co., AR. Sunflower district, Maricopa, Co., AZ. In Mexico at Huahuaxtla, GRO, and at El Doctor, QRO, as an alteration of selenian metacinnabar. *Moschellandsberg, Bavaria, Germany*. Idria, Italy. Almaden, Spain. Avala, Serbia(1), fine crystals to 10 mm. Used as an ore of mercury. RG *DII:25*.

9.1.8.2 Kuzminite $Hg_2(Br,Cl)_2$

Named for Alexei Michailovich Kuzmin (1891–1980), Russian mineralogist, Tomsk Polytechnical Institute, western Siberia. TET $I4/mmm$. $a = 4.597$, $c = 11.034$, $Z = 2$, $D = 7.64$. *AM 73:192(1988)*. 40-514: 4.26₂ 3.25₄ 2.76₂ 2.30₁ 2.10₂ 1.989₁ 1.768₁ 1.453₁₀. Irregular grains and powdery masses. Colorless, bluish gray, or dull white, sometimes with brown tint; white to yellowish streak. Cleavage {100}, good; uneven fracture. $H = 2$. Soluble in warm HCl and aqua regia. Darkens in KOH solution. Uniaxial (+); $N > 2.00$. Slightly pleochroic, strongly birefringent. From the *Kadyrel mercury mine, Tuva, Siberia, Russia*, in calcite veins, with calomel, eglestonite, lavrentievite, corderoite, and mercury. RG *ZVMO 115:595(1986)*.

9.1.8.3 Moschelite Hg_2I_2

Named in 1989 for the locality. TET $I4/mmm$. $a = 4.920$, $c = 11.600$, $Z = 2$, $D = 7.75$. *NJMM:524(1989)*. 6-245: 4.54₃ 3.49₁₀ 2.91₃ 2.47₃ 2.23₅ 2.10₂ 1.881₂ 1600₁. Fine crystalline crusts and small irregular plates. Lemon yellow, which changes to dark olive-green upon exposure to light; brown streak; adamantine luster. Imperfect cleavage, conchoidal fracture, sectile. $H = 1-2$. From the dump at the *Backofen mine, Moschel landsberg district, Obermoschel, Rhineland Pfalz, Germany*, associated with cinnabar, mercury, calomel, and terlinguaite. RG

9.2.1.1 Fluorite CaF_2

Named in antiquity from the Latin *to flow*, since it melts more easily than other minerals with which it was confused. Synonym: fluorspar. iso $Fm\bar{3}m$. $a = 5.463$, $Z = 4$, $D = 3.181$. *NBSC 539(1):69(1953)*. 35-816(syn): 3.16₉ 1.932₁₀ 1.647₃ 1.366₁ 1.253₁ 1.115₂ 1.051₁ 0.864₁. **Habit:** Crystals common, usually cubes {001}; less often octahedrons {111}; rarely {011}; combinations of the above forms are fairly common, with small modifying faces {0kl} very common, especially {013} and {012}. Cube corners often modified by {113}

and {124}. {001} may be partly or wholly replaced by a vicinal form {0kl}. Faces {001} and {0kl} are usually smooth and lustrous; {111} is rough, dull, and may be made up of many tiny pits and growths with flat sides parallel to {001}. Large crystals are commonly composite, showing coarse textured mosaic structure. Frequently massive, coarse to fine granular; occasionally earthy; rarely columnar, fibrous, or globular. Twins on {111}, usually as interpenetrating cubes. Overgrowths of fluorite on the corners, or surrounding an earlier-formed crystal of different color, habit, and so on, are well known. **Structure:** The structure of fluorite was one of the earliest (1914) to be investigated by X-rays and serves as a type for several fluorides, chlorides, oxides, and intermetallic compounds. Ca ions are arranged on a cubic face-centered lattice, while each fluorine ion is at the center of one of the smaller cubes obtained by dividing the unit cube into eight parts. Each calcium is therefore coordinated by eight fluorine ions, while each fluorine ion is surrounded by four calcium ions arranged at the corners of a regular tetrahedron. Other minerals with the fluorite structure include uraninite, cerianite, and thorianite. Some oxides, selenides, and tellurides of formula A_2X have the "anti-fluorite" structure in which the metals occupy the positions of F in fluorite, and the nonmetals the positions of Ca. *DHZII 5:347*. **Physical properties:** Commonly colorless, white, and shades of purple, green, blue, and yellow. Pink and red are rare. Colorless and perfectly transparent when pure (used in optics). Some crystals are green by transmitted light but appear blue by reflected light, due to fluorescence. Crystals may show more or less sharp zones of coloration, either forming phantom crystals inside or following the loci of certain faces or edges as they develop in the growth of the crystal. Color may be lightened or lost in many cases by heating. Proximity of uraninite or other radioactive minerals to fluorite in the deposit may result in a deep purple to nearly black color. For a discussion of the causes of color in fluorite and other minerals and gems, reference is made to *G&G XXIV:81(1988)*. White streak, vitreous luster; may be dull in massive varieties. Cleavage {111}, perfect and very easy; flat conchoidal, splintery, or uneven fracture; brittle. $H = 4$ (Mohs' scale defines hardness 4 as the hardness of fluorite). $G = 3.18$; G may increase to as much as 3.6 in yttrian or cerian fluorite. Heating may cause thermoluminescence; a variety producing green thermoluminescence is called *cholorophane*. Occasionally, triboluminescent. Some varieties are strikingly fluorescent blue under LWUV, an effect related to the presence of trace amounts of erbium. Other colors may be caused by other activators. The term *fluorescence* was derived from the observed glow of certain English fluorites when exposed to daylight containing UV light. Electrically nonconductive. Diamagnetic. **Tests:** Decomposed by H_2SO_4 with evolution of HF (poison!) and with difficulty in hot HCl. In closed tube (CT) decrepitates and usually luminesces. **Chemistry:** Y and/or Ce may substitute for Ca to the extent of $Y + Ce/Ca = 1:5$; other rare earths are common in spectrographic amounts. Radiation such as gamma rays from included or nearby radioactive atoms releases atoms of Ca and F in fluorite, causing the very dark violet color. Such material smells of HF or F_2 while being powdered

FLUORITE: CaF_2

Space group $Fm\bar{3}m$. Ca atoms are coordinated by eight F atoms, and F atoms are coordinated by four Ca atoms.

(*antozonite*, also “stink floss”), and turns white and transparent when heated. **Optics:** Isotropic; $N = 1.4338$ (Na). For yttrian varieties, N is up to 1.457. Birefringence absent or weak; common in cleaved, cut, pressed, or otherwise deformed grains. **Occurrence:** A common mineral, fluorite occurs (1) as a vein mineral, either as the chief constituent or with metal ores, especially of Pb and Ag, and usually with quartz, barite, calcite, dolomite; (2) in cavities in secondary carbonate rocks; (3) in replacement deposits associated with igneous contacts; in tactites; (4) in high-temperature pneumatolytic deposits, such as pegmatites and occasionally in cassiterite veins; (5) uncommon as a late hydrothermal product in cavities and joints in granite and its alkalic relatives, sometimes in very fine crystals in alpine-type veins; (6) in veinlike bodies cutting syenite, with calcite, apatite, uraninite, hornblende, biotite; (7) as a hot spring deposit. **Alteration:** Pseudomorphs by substitution of quartz and several other minerals after fluorite are common. Fluorite also forms pseudomorphs after calcite, barite, and galena. **Localities:** Only a few of the many known deposits can be listed. Westmoreland, NH(!) in large transparent green octahedral crystals; Trumbull, CT (chlorophane); Clay Center(*) and Tiffin, OH, with celestite; fine, large (up to 20 cm) multicolored crystals from Rosiclare, IL(!) and adjacent regions of IL and KY; Ft. Wayne, IN(*), in a limestone quarry; Elmwood mine, near Carthage, TN(!) superb cubic crystals reaching over 50 cm, with barite, sphalerite, calcite, and so on; Mt. Antero and Wagon Wheel Gap, CO(*); Hansonburg District, Socorro Co.(*), and fine purple octahedrons from Pine Canyon, Grant Co.(!), NM. In Canada at Madoc, ON in fine crystals(!), and at Wilberforce and elsewhere a dark purple variety associated with U mineralization; at the Rock Candy mine near Grand Forks, BC(!). In Mexico at Naica, CHIH(!) in fine green, colorless, and pale

violet complex crystals; Ivigtut, Greenland. Several localities in England are famous for magnificent crystal groups, as Alston Moor and Cleator Moor, Cumberland(!); Weardale and Durham, Yorkshire(!); Castleton, Derbyshire(!), where a beautiful blue-purple banded massive variety called "blue john" is fashioned into jewelry and objects d'art; from Cu and Sn veins in Cornwall(!) and in Tavistock, Devon. At Kongsberg, Norway(!), colorless, green, violet, and blue cubes and octahedrons, sometimes associated with native silver. In Germany, widespread in Saxony and at several places in the Harz Mts. and in Baden; Wolsendorf, Bavaria, is especially known for the deep purple, nearly opaque variety antozonite. Cínovec, Bohemia, Czech Republic. Alpine-type veins in Goschener Alp, Aar massif, Switzerland(!) and Argentières, Mt. Blanc massif, France(!), in beautiful pink octahedrons. Fine blue cubes come from Le Beix, Puy de Dome, France(!). Sarnthal, Tyrol, Austria(*). In Spain in fine purple modified cubes at La Collada and Berbes, Asturias(!). At Dal'negorsk, Primorskiy Krai, Siberia, Russia(!), magnificent large completely colorless to light green or blue cubic crystals associated with calcite, danburite, sulfides, and so on; in Kazakhstan at Kara Oba, superb cubes and octahedrons, mostly green or purple, with wolframite, pyrite, quartz, cosalite, bertrandite, and at Akchatau(!), purple octahedrons with bertrandite and apatite. In Pakistan in the Tormiq area(!) large pink and greenish cubo-octahedrons formed in alpine-type deposits, and at Nagar, near Aliabad, Hunza Valley(!), superb large cubes and octahedrons, some of exceptional deep pink color associated with gemmy blue beryl crystals and muscovite. Chiang Mai province, Thailand(!), small colorless to light violet transparent cubes coating large stibnite crystals. Obira mine, Kyushu, Japan(!), superb pink octahedrons and greenish cubes with quartz, arsenopyrite, and so on. Zeerust district, Transvaal, South Africa. Okarusu, Orongo Mts., Namibia(*). Mt. Bischof, TAS; and Goulburn Co. and near Deepwater, NSW, Australia. At Huanzala, Peru(!), superb, exceptionally sharp rich pink octahedrons, some with a greenish central core, usually associated with pyrite and sphalerite. Yttrian fluorite occurs in the Franklin marble, Sussex Co., NJ; in Orange Co., NY; Lake George and elsewhere, CO; Hundholmen, Norway; Falun (also cerian), Sweden. Uses: Fluorite is the primary source of all fluorine chemicals, including Freon and other fluorocarbons. It is an essential ingredient in the manufacture of steel, about 7 kg being required per ton. It is also used in the ceramic industry as an ingredient in glazes. Annual production amounts to several million tons. A major part of world output is exported from several localities in China, including some beautiful banded material for decor applications. Other major production comes from mines in NL, SLP, COAH, and GTO in Mexico. *RG DII:29; AM 37:916(1952), 45:855(1960), 52:1003(1967); USGSPP 650:D69.*

9.2.1.2 Frankdicksonite BaF_2

Named in 1974 for Frank W. Dickson (b.1922), American geochemist, Stanford University. *iso Fm3m. a = 6.200, Z = 4, D = 4.886. NBSC 539(1):70(1953). 4-452(syn): 3.58₁₀ 3.10₈ 2.19₈ 1.87₅ 1.55₁ 1.42₁ 1.39₁ 1.27₁.*

Minute cubes. Colorless, vitreous luster. Cleavage {111}, perfect. $H = 2\frac{1}{2}$. Somewhat soluble in water. Istropic; $N = 1.472$. Said to have been found at the *Carlin gold mine, Eureka Co., NV*, embedded in quartz veinlets along a contact between latite and silicified limestone; no matrix specimens are known. RG *AM 59:885(1974)*.

9.2.1.3 Tveitite-(Y) $\text{Ca}_{1-x}(\text{Y,RE})_x\text{F}_{2-x}$ ($x \approx 0.3$)

Named in 1977 for John Peder Tveit (1909–1978), Norwegian miner, who found it in his quarry. MON Space group unknown. $a = 3.924$, $b = 3.893$, $c = 5.525$, $\beta = 90.27^\circ$. *AM 62:1060(1977)*. 29-364: 3.22₄ 3.18₁₀ 2.76₅ 1.963₅ 1.949₇ 1.676₄ 1.664₆ 1.265₈. White to pale yellow, greasy luster, fluorescent faint yellow-orange in SWUV. Biaxial (-); $N_x = 1.476$, $N_y = 1.479$, $N_z = 1.481$; $2V = 34^\circ$. Shows complex polysynthetic twinning. Barringer Hill, TX. In pegmatite at *Hoydalen, Telemark, Norway*, with amazonite, beryl, gadolinite, and monazite. RG *LIT 10:81(1977)*.

9.2.2.1 Sellaite MgF_2

Named in 1868 for Quintino Sella (1827–1884), Italian mining engineer and mineralogist. TET $P4_2mnm$. $a = 4.623$, $c = 3.052$, $Z = 2$, $D = 3.172$. *NBSC 539(4):33(1955)*. 41-1443: 3.27₁₀ 2.55₂ 2.23₈ 2.07₂ 1.711₆ 1.634₂ 1.526₁ 1.375₂. Crystals acicular to stout prismatic or nearly equant, fibrous aggregates. Colorless to white, buff, rarely black; vitreous luster. Cleavage {010} and {110}; conchoidal fracture. $H = 5$. $G = 3.15$. Nonfluorescent, except sellaite from Brazil, which fluoresces blue in SWUV. Slightly soluble in water; decomposed by concentrated H_2SO_4 . Uniaxial (+); $N_O = 1.378$, $N_E = 1.390$ (Na). *Moutiers, Savoie, France*, in bituminous dolomite/anhydrite rock in a glacial moraine. Bleichrode, Harz, Germany. In Italy at Carrara in cavities in marble; also at Vesuvius and at Etna, Sicily. Brock's Creek, NT, Australia. In Brazil in a magnesite mine at Brumado, BA(!), in transparent crystals of great perfection up to 10×3 cm, in vugs, sometimes twinned (V-twins), associated with magnesite and quartz. RG *DII:37, NJMA 136:10(1979)*.

9.2.3.1 Lawrencite FeCl_2

Named in 1877 for John Lawrence Smith (1818–1883), American chemist, mineralogist, and student of meteorites. HEX-R $R3m$. $a = 3.59$, $c = 17.56$, $Z = 3$, $D = 3.22$. 1-1106(syn): 5.90₆ 3.07₃ 2.54₁₀ 1.95₁ 1.80₆ 1.72₁ 1.47₂ 1.14₂. Massive, in veinlets. White, altering in air to green, brown; vitreous luster. Cleavage {0001}, perfect. $G = 3.16$. Soft. Uniaxial (-); $N = 1.567$; weak birefringence. Found in fissures in iron meteorites and in native iron from Oviak, Greenland. Reported as a sublimation product on Vesuvius, Italy. RG *DII:40*.

9.2.3.2 Scacchite MnCl_2

Named in 1869 for Arcangelo Scacchi (1810–1894), Italian mineralogist, University of Naples. HEX-R $R3m$. $a = 3.706$, $c = 17.569$, $Z = 3$, $D = 3.000$. *NBSM 25(8):43(1970)*. 22-720: 5.85₁₀ 3.16₃ 2.59₈ 1.98₁ 1.85₃ 1.81₃ 1.71₁

1.51₁. Crusts and efflorescences. Colorless when fresh, becoming rose-red and dirty red-brown upon exposure. Cleavage {0001}, perfect. Soft. $G = 2.98$. Soluble in water, deliquescent, easily fusible. Uniaxial (-); $N_O = 1.708$; $N_E = 1.622$. *Vesuvius, Italy*, as a deliquescent salt in fumaroles, associated with halite, sylvite, lawrencite, and other salts. RG *DII:40*.

9.2.3.3 Chloromagnesite $MgCl_2$

Named in 1873 for the composition. The existence of the mineral chloromagnesite is questioned by some because its deliquescent character would make its existence as a solid in nature improbable, as well as making its recovery and study difficult. The material studied was prepared synthetically and examined in a special dry atmosphere. HEX-R *R3m*. $a = 3.632$, $c = 17.795$, $Z = 3$, $D = 2.339$. *NBSM 25(11):94(1974)*. *37-774(syn)*: 5.89₁₀ 2.94₅ 2.57₁ 1.809₁ 1.485₁ 1.474₁ 1.178₁ 1.145₁. Colorless. $G = 2.325$. Deliquescent, very soluble in water. Uniaxial (-); $N_O = 1.675$, $N_E = 1.59$. *Vesuvius, Campania, Italy*, as a sublimate in fumaroles, associated with halite and sylvite. RG *DII:41*, *JAC 17:483(1984)*.

9.2.4.1 Rokühnite $(Fe,Mg)Cl_2 \cdot 2H_2O$

Named in 1980 for Robert A. Kühn (b.1911), professor of mineralogy, Kalifornisches Institut, Hannover, Germany. MON *C2/m*. $a = 7.352$, $b = 8.561$, $c = 3.637$, $\beta = 98.06^\circ$, $Z = 2$, $D = 2.385$. *AM 66:219(1981)*. *25-1040(syn)*: 5.55₁₀ 4.28₈ 2.88₅ 2.77₅ 2.76₉ 2.40₅ 2.14₄ 2.09₅. Microscopic crystals, tabular {110} or as short flexible fibers. Colorless. Cleavage {110}, very good; {010}, good. $G = 2.35$. Soluble in water. Rapidly hydrates in air to $FeCl_2 \cdot 4H_2O$. Biaxial (+); $X = b$; $Z \wedge c = -49^\circ$; $N_x = 1.605$, $N_y = 1.633$, $N_z = 1.703$; $2V = 64^\circ$; $r \leq v$. Found in intergrowths of carnallite, rinneite, and halite at the *Salzdetfurth* and *Sigfried-Geisen mines* in the *Zechstein Basin, Germany*. RG *NJMM 1980:125*.

9.2.5.1 Sinjarite $CaCl_2 \cdot 2H_2O$

Named in 1980 for the locality. TET Space group unknown. $a = 7.21$, $c = 5.86$, $Z = 2$, $D = 1.96$. *AM 65:1069(1980)*. *1-989*: 6.10₄ 4.35₅ 3.06₇ 2.83₁₀ 2.52₂ 2.35₂ 2.16₂ 2.12₆. Massive, granular. Prismatic crystals, [001]. Pale pink, white streak, vitreous to resinous luster. Prismatic cleavage, well developed. $H = 1\frac{1}{2}$. $G = 1.66$. Soluble in water; very deliquescent. Melts at 172° in its water of crystallization. Uniaxial; $N = 1.54$; elongated crystals give parallel extinction. Found in detritus in a wadi (intermittent stream) cutting across the Sinjar anticline, *Sinjar, W of Mosul, Iraq*. RG *MM 43:643(1980)*.

9.2.6.1 Antarcticite $CaCl_2 \cdot 6H_2O$

Named in 1965 for the locality. HEX *P321*. $a = 7.876$, $c = 3.955$, $Z = 1$, $D = 1.712$. *NBSM 25(12):16(1975)*. *26-1053*: 6.80₄ 3.93₉ 3.42₇ 2.79₈ 2.58₆ 2.27₆ 2.16₁₀ 1.71₃. Acicular to columnar crystals. Colorless or white. Cleavage {0001}, perfect; {1010}, nearly perfect; brittle. $H = 2-3$. $G = 1.71$. Soluble in

water; deliquescent; temperature sensitive, and melts easily in its own water of crystallization. Uniaxial (-); $N_O = 1.550$, $N_E = 1.492$. Bristol dry lakes, San Bernardino Co., CA. *Don Juan pond*, a saline pool in *Victoria Land*, Antarctica. RG *SCI* 149:975(1965), *AM* 54:1018(1969).

9.2.7.1 Cotunnite $PbCl_2$

Named in 1825 for Domenico Cotugno (Cotunnus) (1736–1822), Italian physician and anatomist, University of Naples. ORTH *Pnam*. $a = 7.622$, $b = 9.045$, $c = 4.535$, $Z = 4$, $D = 5.908$. *NBSM* 25(12):23(1975). Structure: *SPC* 21:38(1976). 26-1150(syn): 4.06₄ 3.89₈ 3.81₄ 3.58₁₀ 2.78₆ 2.51₅ 2.15₄ 2.10₄. Crystals flattened {010} and elongated [001]; also massive, granular. Colorless to white; yellowish; greenish, adamantine to silky or pearly luster. Cleavage {010}, perfect; subconchoidal fracture; sectile. $H = 2\frac{1}{2}$. $G = 5.80$. Slightly soluble in water; more so in sodium acetate solution. Easily fusible. Biaxial (+); $XYZ = bac$; $N_x = 2.199$, $N_y = 2.217$, $N_z = 2.260$ (Na); $2V = 67^\circ$. Usually forms as an alteration of galena under arid, saline conditions. Bentley district, Mojave Co., AZ. *Vesuvius*, Italy, in fumaroles. From several localities in northern Chile and southern Peru. RG *DII*:42, *MA* 69:1075(1969).

9.2.7.2 Hydrophilite $CaCl_2$

Named in 1813 from the Greek for *water* and *friend*, in allusion to its extreme hygroscopic properties. A questionable species, for the same reasons as stated under chloromagnesite, $MgCl_2$. *MM* 43:682(1980). ORTH *Pnmm*. $a = 6.261$, $b = 6.429$, $c = 4.167$, $Z = 2$, $D = 2.175$. *NBSM* 25(11):18(1974). 24-223(syn): 4.48₉ 3.05₁₀ 2.86₄ 2.36₃ 2.33₅ 2.24₃ 2.08₂ 1.91₃. Massive, as crusts. Twinning polysynthetic, complex. Colorless. Prismatic cleavage, perfect. Biaxial (+); $N_x = 1.600$, $N_y = 1.605$, $N_z = 1.613$; $2V$ moderate. *Lüneberg*, Hannover, Germany, with anhydrite, gypsum, and halite. Mt. Etna, Sicily, Italy, from fumaroles. RG *DII*:41.

9.2.8.1 Eriochalcite $CuCl_2 \cdot 2H_2O$

Named in 1884 for the Greek for *wool* and *copper*, because it is a fibrous copper mineral. ORTH *Pbmn*. $a = 7.416$, $b = 8.093$, $c = 3.749$, $Z = 2$, $D = 2.516$. *NBSM* 25(18):33(1981). Structure: *ZK* 189:13(1989). 33-451(syn): 5.47₁₀ 4.05₆ 3.35₂ 3.09₄ 2.64₈ 2.21₃ 2.02₂ 1.60₂. Lichenlike aggregates of crystals elongated [001]; also wool-like. Twinning on {021}. Bluish green to greenish blue, vitreous luster. Cleavage {110}, perfect; {001}, good; conchoidal fracture. $H = 2\frac{1}{2}$. $G = 2.47$. Easily soluble in water; easily fusible, yielding water. Biaxial (+); $XYZ = bca$; $N_x = 1.646$, $N_y = 1.685$, $N_z = 1.745$ (Na); $2V = 75^\circ$; $r < v$, strong. X, pale green; Y, pale olive-green; Z, pale blue. Found in fumaroles during the 1869 eruption of *Vesuvius*, Italy. In Chile at the Quetena mine, Antofagasta, with atacamite and bandylite. RG *DII*:44.

9.2.8.2 Tolbachite CuCl_2

Named in 1983 for the locality. MON $C2/m$. $a = 6.89$, $b = 3.31$, $c = 6.82$, $\beta = 122.3^\circ$, $Z = 2$, $D = 3.42$. AM 69:408(1984). 34-198(syn): 5.78₁₀ 3.45₂ 2.92₁ 2.89₁ 2.37₁ 1.87₁ 1.81₁ 1.65₁. Fibrous, mosslike. Brown to golden brown. Cleavage {001}, perfect. Readily soluble in water. In air alters quickly to eriochalcite, $\text{CuCl}_2 \cdot 2\text{H}_2\text{O}$. Biaxial, pleochroism pale greenish to dark brown; high birefringence; positive elongation. Index of refraction could not be measured because the mineral reacts with immersion media. *Tolbachik volcano, Kamchatka, Russia*, in fumaroles associated with melanothallite, dolerophanite, tenorite, and euchlorine. RG DANS 270:415(1983).

9.2.9.1 Bischofite $\text{MgCl}_2 \cdot 6\text{H}_2\text{O}$

Named in 1877 for Gustav Bischof (1792–1870), German mineral chemist and geologist. MON $C2/m$. $a = 9.871$, $b = 7.113$, $c = 6.079$, $\beta = 93.73^\circ$, $Z = 2$, $D = 1.585$. NBSM 25(11):37(1974). 25-515(syn): 4.10₁₀ 3.96₃ 2.98₄ 2.88₇ 2.74₄ 2.73₆ 2.64₉ 1.85₄. Crystals short prismatic [001]; granular, foliated, sometimes fibrous. Twinning polysynthetic, due to pressure. Colorless to white, vitreous luster. Conchoidal to uneven fracture. $H = 1-2$. $G = 1.604$. Soluble in water, very deliquescent, easily fusible. Tastes bitter, stinging. Biaxial (+); $X = b$; $Y \wedge c = 9.5^\circ$; $N_x = 1.498$, $N_y = 1.505$, $N_z = 1.525$ (Na); $2V = 79^\circ$; $r > v$. Found in saline deposits at *Stassfurt and Leopoldshall, Germany*, associated with carnallite and kieserite. RG DII:46.

9.2.9.2 Nickelbischofite $\text{NiCl}_2 \cdot 6\text{H}_2\text{O}$

Named in 1979 as the nickel analog of bischofite. MON $I2/m$. $a = 8.786$, $b = 7.076$, $c = 6.625$, $\beta = 97.22^\circ$, $Z = 2$, $D = 1.932$. NBSM 25(11):42(1974). 25-1044(syn): 5.59₁₀ 5.50₄ 4.82₄ 2.93₄ 2.75₃ 2.69₂ 2.41₂ 2.18₂. Prismatic crystals, with {110}, {001}, and {100}; as powdery coatings; crusts. Emerald green, very pale green to white streak, vitreous luster. Cleavage {001}, perfect; subconchoidal fracture; brittle. $H = 1\frac{1}{2}$. $G = 1.929$. Deliquescent, readily soluble in water. Biaxial (+); $X \wedge c = 8^\circ$; $Y = b$; $N_x = 1.589$, $N_y = 1.617$, $N_z = 1.644$; $2V = 87^\circ$; absorption $c > a$. X, greenish yellow; Y, pale green; Z, green. Material from Oxford, TX, has been presumed artificial. Found in drill core from the *Dumont ultramafic body, near Amos, QUE, Canada*. In sublimates from fumaroles on Mt. Shirane, Gumma Pref., Japan. RG CM 17:107(1979), AM 67:156(1982).

9.2.10.1 Laurelite $\text{Pb}(\text{F,Cl,OH})_2$

Named in 1989 for the locality. HEX $P6$, $\overline{P6}$, or $P6/m$. $a = 10.252$, $c = 3.973$, $Z = 6$, $D = 6.52$. AM 74:927(1989). 45-1457: 3.33₁₀ 3.13₄ 2.95₄ 2.09₄ 1.934₆ 1.812₄ 1.709₄ 1.282₄. Acicular crystals, twinned by rotation on {0001}. Colorless, white streak, silky luster. Cleavage {001}, imperfect; conchoidal fracture; brittle. $H = 2$. $G = 6.2$. Nonfluorescent. Slowly soluble in water, rapidly so in 1:1 HCl. Uniaxial (+); $N_O = 1.903$, $N_E = 1.946$. *Grand Reef mine, Laurel*

Canyon, Graham Co., AZ, in a vug surrounded by galena and fluorite and associated with grandreefite, pseudograndreefite, and aravaipaite. RG

9.2.11.1 Matlockite PbFCI

Named in 1852 for the locality. $\text{TET } P4/nmm$. $a = 4.110$, $c = 7.233$, $Z = 2$, $D = 7.111$. *NBSM 25(13):25(1976)*. *26-311(syn)*: 3.62_4 3.57_{10} 2.91_5 2.72_4 2.27_4 2.06_2 1.79_2 1.78_3 . Crystals usually tabular {001}, also short pyramidal; as hemispherical rosettes; massive; lamellar. Colorless to yellow or pale amber, greenish; adamantine luster, pearly on {001}. Cleavage {001}, perfect; subconchoidal fracture. $H = 2\frac{1}{2}$ -3. $G = 7.12$. Soluble in HNO_3 , easily fusible. Uniaxial (-); $N_O = 2.145$, $N_E = 2.006$ (Na). Mammoth mine, Tiger, Pinal Co., AZ, in cleavages to 8 cm across. *Bage mine, Bole Hill, Cromford, near Matlock, Derbyshire, England(1)*, associated with phosgenite. Sainte Lucie, Lozère, France, on galena. Laurium, Greece, in altered slag. Challocolla, Tarapacá, Chile, with pseudoboleite. *RG DII:59*.

9.2.11.2 Rorisite CaFCI

Named in 1990 from the Latin *roris*, dew, alluding to the transparent droplets that cover the mineral in moist air. $\text{TET } P4/nmm$. $a = 3.890$, $c = 6.810$, $Z = 2$, $D = 2.94$. *AM 76:1731(1991)*. *24-185(syn)*: 2.75_5 2.56_{10} 2.14_5 1.963_2 1.945_4 1.562_2 1.550_3 1.376_1 . Small tabular crystals flattened {001}. Colorless, white streak, vitreous luster. Cleavages {001}, {110}, perfect; conchoidal fracture; brittle. $H = 2$. $G = 2.78$. Soluble in water; in moist air the colorless plates become turbid and coated with drops of CaCl_2 ; the turbid plates consist of fine grained fluorite. Uniaxial (-); $N_O = 1.668$, $N_E = 1.635$. Fluoresces weak violet in SWUV. *Kopeysk, Chelyabinsk coal basin, Ural Mts., Russia*, in carbonatized wood fragments in old burnt dumps, associated with fluorite, periclase, and troilite. *RG ZVMO 119(3):73(1990)*.

9.3.1.1 Molysite FeCl_3

Named in 1868 from the Greek for *stain*, in allusion to its staining of lavas on which it occurs. $\text{HEX-R } R3$. $a = 6.065$, $c = 17.42$, $Z = 6$, $D = 2.912$. *JAC 22:173(1989)*. *1-1059(syn)*: 5.90_3 4.79_1 2.68_{10} 2.08_4 1.75_3 1.67_1 1.63_2 1.46_1 . Crystals tabular {0001}, massive, as coatings. Yellow to brownish red, purple-red. Crystals are green by reflected light. Cleavage {0001}, perfect. $G = 2.90$. Soft. Very deliquescent, hydrolyzed by water to give a ferric hydrate, fuses at 282° . Uniaxial (-); very strongly birefringent. *Vesuvius, Italy*, as a sublimate in fumaroles; also on Etna and Vulcano. From a fumarole in Iceland. *RG DII:47*.

9.3.2.1 Hydromolysite $\text{FeCl}_3 \cdot 6\text{H}_2\text{O}$

Named in 1965 for the composition, the hydrated analog of molysite. $\text{MON } C2/m$. $a = 11.834$, $b = 7.029$, $c = 5.952$, $\beta = 100.47^\circ$, $Z = 2$, $D = 1.844$. *NBSM 25(17):40(1980)*. *33-645(syn)*: 6.03_1 5.87_8 5.82_{10} 4.41_1 3.16_2 2.91_1 2.75_1 2.44_1 . As small crystals. Orange-red. Somewhat deliquescent. Biaxial;

$N \approx 1.78$. *Rio Marina, Elba, Italy*, in a pyrite mine, where seawater has reacted with oxidizing pyrite, giving rise to incrustations containing gypsum, copiapite, halite, and hydromolysite. RG *AM 44:908(1959)*, *51:1551(1966)*; *ZVMO 94:189(1965)*.

9.3.3.1 Chloraluminite $\text{AlCl}_3 \cdot 6\text{H}_2\text{O}$

Named in 1874 for the composition. HEX Space group unknown. $a = 11.831$, $c = 11.910$, $Z = 6$, $D = 1.666$. *NBSC 539(7):3(1957)*. *8-453(syn): 5.95₃ 5.14₃ 3.89₄ 3.68₄ 3.30₁₀ 3.25₆ 2.76₄ 2.31₅*. Crystalline crusts and stalactites, also small rhombohedral crystals. Colorless to white or yellowish. Uniaxial (-); $N_O = 1.560$, $N_E = 1.507$. Found in fumaroles on *Vesuvius, Italy*, during the 1872 and 1906 eruptions. RG *DII:50*, *AC(B) 27:1069(1971)*.

9.3.4.1 Fluocerite-(Ce) (Ce,La)F₃

Named in 1845 for the composition. Synonym: tysonite. Originally called fluocerite. HEX $P6_3/mcm$. $a = 7.130$, $c = 7.298$, $Z = 6$, $D = 6.12$. *MM 47:41(1983)*. Structure: *SPC 33:105(1988)*. *38-452: 3.64₈ 3.57₈ 3.20₈ 2.06₉ 2.01₉ 1.79₂ 1.731₈ 1.325₇*. Prismatic crystals, rolled alluvial pebbles, irregular nodules. Pale yellow to straw yellow, vitreous to resinous luster. Cleavage {0001}, distinct; {1120}, indistinct; subconchoidal to uneven fracture; splintery; brittle. $H = 4-5$. $G = 5.90$. Soluble in H_2SO_4 , insoluble in HCl or HNO_3 . Uniaxial (-); $N_O = 1.613$, $N_E = 1.609$. Bethlehem, NH. Little Patsy quarry, South Platte district, Jefferson Co., CO. Snowbird mine, MT. In pegmatite at *Finbo and Brodbo, Dalarne, Sweden*. Hammarøj, Nordland, Norway. From albite pegmatites near Odegi, Afu Hills, Nigeria. RG *DII:48*, *MR 21:429(1990)*.

9.3.4.2 Fluocerite-(La) (La,Ce)F₃

Named in 1969 for the composition. Formerly called fluocerite. HEX Space group unknown. $a = 4.135$, $c = 7.295$, $Z = 6$, $D = 5.94$. *AM 69:566(1984)*. *32-483: 3.68₅ 3.60₄ 3.23₁₀ 2.07₆ 2.02₇ 1.807₄ 1.745₃ 1.336₂*. Platy to tabular crystals. Pale greenish yellow, vitreous luster. Pyramidal, imperfect cleavage; conchoidal fracture. $\text{VHN} = 390 \text{ kg/mm}^2$. $G = 5.93$. Uniaxial (-); $N_O = 1.609$, $N_E = 1.603$. *Central Kazakhstan*, in hydrothermal quartz veins in granite. RG

9.3.5.1 Gananite $\alpha\text{-BiF}_3$

Named in 1984 for the locality. iso $P43m$. $a = 5.825$, $Z = 4$, $D = 8.928$. *AM 73:1494(1988)*. *11-10(syn): 3.38₁₀ 2.93₈ 2.07₁₀ 1.76₉ 1.34₇ 1.31₆ 1.20₇ 0.99₇*. Irregular aggregates of grains. Brown to black; greenish black, dark gray streak, resinous to semimetallic luster. No cleavage, uneven fracture, brittle. $H = 3-3\frac{1}{2}$. Soluble in HCl and HNO_3 . In RL, isotropic, gray. $R = 12.3-10.1$ (435 nm), 12.7-11.1 (546 nm), 12.9-12.6 (589 nm), 13.3-11.7 (650 nm). *Lai-keng mining district, Ganan area, Jiangxi, China*, with bismuth, bismuthinite, pyrite, and chalcopyrite in wolframite-bearing quartz veins. RG

9.3.6.1 Rosenbergite $\text{AlF}[\text{F}_{0.5}(\text{H}_2\text{O})_{0.5}]_4 \cdot \text{H}_2\text{O}$ or $\text{AlF}_3 \cdot 3\text{H}_2\text{O}$

Named in 1993 for Philip E. Rosenberg (b.1931), U.S. geochemist, Washington State University. TET $P4/n$. $a = 7.715$, $c = 3.648$, $Z = 2$, $D = 2.111$. *EJM* 5:1167(1993). *PD*(Cetine mine): 5.47₁₀ 2.44₇ 2.03₇ 1.775₈ 1.725₉ 1.388₇ 1.306₇ 1.127₇. 9-108(syn): 5.45₁₀ 3.86₆ 3.33₂ 2.73₃ 2.44₆ 2.03₁ 1.728₄. Tetragonal prisms, ≤ 0.25 mm, in small aggregates. Colorless, transparent, vitreous luster. Cleavage {001}, good. $\text{VHN}_{15} = 103$. $G = 2.10$. Nonfluorescent. Uniaxial (-), $N_O = 1.427$, $N_E = 1.403$. Found at the *Cetine mine, Tuscany, Italy*, in cavities in highly silicified limestone, associated with gypsum, fluorite, elpasolite, ralstonite, and onoratoite, and as a sublimate from fumaroles in the crater of *Mt. Erebus, Ross Island, Antarctica*, associated with gypsum and other phases that were unidentified. *RG AM* 73:855(1988), 79:765(1994).

Oxyhalides and Hydroxyhalides

10.1.1.1 Atacamite $\text{Cu}_2(\text{OH})_3\text{Cl}$

Named in 1801 for the locality. Polymorphs: paratacamite, botallackite. ORTH *Pnam*. $a = 6.030$, $b = 6.865$, $c = 9.120$, $Z = 4$, $D = 3.756$. *USGSPP 800B:119(1972)*. Structure: *AC(C) 42:1277(1986)*. 25-269: 5.48₁₀ 5.03₇ 2.84₅ 2.78₅ 2.76₆ 2.28₇ 2.27₅ 1.61₆. Crystals slender prismatic [001]; also, tabular {010}; rarely pseudo-octahedral. In crystalline aggregates, massive, granular, or fibrous. Twinning on {110}, forming doublets or triplets; also several other twin laws. Bright green, dark emerald green; blackish green, apple green streak, adamantine to vitreous luster. Cleavage {010}, perfect; {101}, fair; conchoidal fracture; brittle. $H = 3-3\frac{1}{2}$. $G = 3.77$. Easily soluble in acids, easily fusible, in CT gives off water and forms a gray sublimate. Biaxial (-); $XYZ = bac$; $N_x = 1.831$, $N_y = 1.861$, $N_z = 1.880$; $2V = 74^\circ$; $r < v$, strong. X, pale green; Y, yellow green; Z, grass green. Atacamite is a secondary mineral found in the oxidized zone of copper deposits, chiefly in arid regions. It often alters pseudomorphously to malachite. Sparingly at Bisbee and at Jerome, AZ. Tintic, UT. Majuba Hill, NV. Boleo, BCS, Mexico. Vesuvius, Italy, in fumaroles. In Australia superb crystals to 80 mm at the New Cornwall mine, near Kedina, NSW(1). *Atacama desert*, northern *Chile*(1), where it has been noted in several mines, in fine crystal groups and rosettes of blades to 25 mm, and at Chuquicamata, Antofagasta, where it was an important ore mineral. Formed as an alteration product on ancient and modern bronzes and copper objects. One of the corrosion products common on the Statue of Liberty. *RG DII.69*.

10.1.1.2 Hibbingite $\gamma\text{-Fe}_2^+(\text{OH})_3\text{Cl}$

Named in 1994 for the city of Hibbing, Minnesota. Isostructural with atacamite. ORTH *Pnam*. $a = 6.31$, $b = 9.20$, $c = 7.10$, $Z = 4$, $D = 3.04$. *AM 79:555(1994)*. *PD*: 5.62₄ 5.16₂ 2.86₆ 2.33₁₀ 2.12₅ 1.87₂ 1.745₂ 1.652₅. As microveinlets in serpentinite. Colorless to pale green, turning yellowish with oxidation. Soft. Soluble in water and ethanol. Upon protracted exposure to air, alters to akaganeite. Biaxial; $N = 1.6-1.7$; moderately birefringent, fast length. Found in drill core of partially serpentinitized troctolitic or peridotitic rocks near the base of the *Duluth complex*, MN, associated with magnetite and serpentine, and in the deep copper zone in the footwall of the *Strathcona mine*,

Sudbury district, ON, Canada, as fracture fillings in chalcopyrite, pentlandite, and cubanite. RG *CM 27:311(1989)*.

10.1.2.1 Paratacamite $\text{Cu}_2(\text{OH})_3\text{Cl}$

Named in 1873 in allusion to the dimorphous relationship to atacamite. Polymorphs: atacamite, botallackite. HEX-R *R3*. $a = 13.654$, $c = 14.041$, $Z = 24$, $D = 3.754$. *JAC 4:530(1971)*. Structure: *AC(B) 31:183(1975)*. *25-1427: 5.507 5.44₁₀ 2.90₃ 2.78₅ 2.76₆ 2.74₆ 2.27₈ 1.71₅*. Rhombohedral crystals; also granular, massive, and in fibrous or spherulitic crusts. Twinning on {1011}, sometimes polysynthetic. Green to greenish black, green streak, vitreous luster. Cleavage {1011}, good; conchoidal to uneven fracture. $G = 3.74$. Tests same as for atacamite. Uniaxial (+); $N_O = 1.843$, $N_E = 1.848$; nonpleochroic; sometimes anomalously biaxial. Common through alteration of copper minerals by seawater under cold conditions. Bisbee, AZ. Levant and Cligga Head mines, St. Just, Cornwall, England. *Generosa* and *Herminia mines, Sierra Gorda, Chile*. Broken Hill, NSW, and in fine crystals at the Nangaroo mine, Murrin Murrin, WA, Australia. RG *DII:74, NJMM:335(1972)*.

10.1.3.1 Botallackite $\text{Cu}_2(\text{OH})_3\text{Cl}$

Named in 1865 for the locality. Polymorphs: atacamite, paratacamite. MON *P2₁/m*. $a = 5.717$, $b = 6.126$, $c = 5.636$, $\beta = 93.07^\circ$, $Z = 1$, $D = 3.598$. Structure: *MM 49:87(1985)*. *8-88: 5.66₁₀ 2.84₄ 2.68₃ 2.57₇ 2.40₈ 1.93₃ 1.53₄ 1.25₃*. Crusts of tiny bladed crystals. Pale bluish green. Cleavage in one direction. $G \approx 3.6$. Tests same as for atacamite. Biaxial (+); X perpendicular to cleavage; $N_x = 1.775$, $N_y = 1.800$, $N_z = 1.846$; $2V = 78^\circ$; $r > v$, strong. *Botallack mine, St. Just, Cornwall, England(1)*, and the nearby Levant mine; also at the Cligga Head mine. Identified as an alteration of ancient bronze objects. RG *DII:76, MM 29:34(1958)*.

10.1.4.1 Kempite $\text{Mn}^{2+}(\text{OH})_3\text{Cl}$

Named in 1924 for James Furman Kemp (1859–1926), American mining geologist and professor at Columbia University. ORTH *Pnam*. $a = 6.49$, $b = 9.52$, $c = 7.12$, $Z = 4$, $D = 2.96$. *25-1158: 5.70₈ 5.36₇ 2.97₇ 2.90₂ 2.84₂ 2.39₁₀ 2.12₂ 1.69₄*. Crystals prismatic [001]. Emerald green. $H = 3\frac{1}{2}$. $G = 2.94$. Soluble in dilute acids. In CT turns black and gives off acid water. Biaxial (-); $XYZ = cba$; $N_x = 1.684$, $N_y = 1.695$, $N_z = 1.698$; $2V = 55^\circ$. *Alum Rock Park, E of San Jose, Santa Clara Co., CA*, in a boulder of manganese minerals, which has since been completely collected and carried away, associated with pyrochroite, hausmannite, and rhodochrosite. RG *DII:73, AJS 8:145(1924)*.

10.1.5.1 Korshunovskite $\text{Mg}_2\text{C}(\text{OH})_3 \cdot 4\text{H}_2\text{O}$

Named in 1982 for the locality. TRIC *P1* or *P1*. $a = 8.64$, $b = 6.25$, $c = 7.42$, $\alpha = 101.40^\circ$, $\beta = 103.90^\circ$, $\gamma = 72.70^\circ$, $Z = 2$, $D = 1.798$. *AM 68:643(1983)*. *36-388: 8.04₁₀ 4.03₇ 3.84₈ 2.87₆ 2.70₆ 2.44₉ 2.19₅ 1.857₇*. Elongated prismatic grains. Colorless. $H = 2$. $G = 1.787$. Slowly soluble in water, rapidly so in

weak acids. Biaxial (-); $N_x = 1.516$, $N_y = 1.538$, $N_z = 1.547$; $2V = 62^\circ$; negative elongation; extinction $6-8^\circ$ to the elongation. *Korshunov iron ore deposit, Irkutsk, Siberia, Russia*, in drill core at a depth of 770 m, as veinlets 1-2 mm wide in dolomitic marble, associated with ekaterinite and shabynite. RG *ZVMO* 111:324(1982).

10.2.1.1 Zavaritskite BiOF

Named in 1962 for Aleksandr Nicolaevich Zavaritskii (1884-1952), Russian petrographer. TET $P4/nmm$. $a = 3.75$, $c = 6.23$, $Z = 2$, $D = 9.21$. AM 48:210(1963). 22-114: 3.11₄ 2.65₁₀ 2.39₄ 2.02₆ 1.873₁₀ 1.793₄ 1.618₁₀ 1.325₆. Gray, translucent in thin edges, semimetallic to greasy luster. $G = 9.0$. Uniaxial; $N_0 = 2.213$; weakly birefringent. *Sherlovoy Gory deposits, eastern Transbaikal, Siberia, Russia*, pseudomorphous after bismuthinite. Egbushu mine, Hirugawa Mura, Ena Gun, Gifu, Japan. RG *DANS* 146:680(1962).

10.2.1.2 Bismoclite BiOCl

Named in 1935 for the composition. TET $P4/nmm$. $a = 3.891$, $c = 7.369$, $Z = 2$, $D = 7.752$. NBSC 539(4):54(1955). 6-249(syn): 7.38₄ 3.44₁₀ 2.75₈ 2.68₁₀ 2.21₃ 1.95₄ 1.83₃ 1.57₃. Minute scaly crystals, massive, earthy, columnar. Creamy white, grayish, yellowish, brown; greasy to silky luster; also dull, earthy. Cleavage {001}, perfect; plastic. $H = 2-2\frac{1}{2}$. $G = 7.72$. Soluble in acids, but BiOCl reprecipitates upon considerable dilution. Melts at red heat and on cooling solidifies to a yellow mass. In CT yields some water, then sublimes to yellow droplets. Substitution of (OH) for Cl is apparently only partial, and does not extend to BiO(OH). Uniaxial (-); $N_0 = 2.15$. Strongly birefringent. Formed by the oxidation of bismuth or bismuthinite, usually under arid conditions. Eagle and Blue Bell mines, Tintic district, UT. Grizzly Bear mine, Goldfield, NV. *Jackal's Water, NNE of Steinkopf, Namaqualand, Cape Prov., South Africa*; Bygoo, NSW, Australia; Manoel Baldoino mine, Junco, PB, Brazil. RG *DII*:60, *CM* 8:390(1965).

10.2.1.3 Daubr eite BiO(OH,Cl)

Named in 1876 for Gabriel Auguste Daubr e (1814-1896), French mineralogist and geologist. TET $P4/nmm$. $a = 3.86$, $c = 7.41$, $Z = 2$, $D = 7.56$ for OH/Cl = 1:1. 43-674: 7.35₅ 3.70₁ 2.72₈ 2.66₁₀ 2.46₁ 1.673₁₀ 1.563₈ 1.259₅. Found only massive, compact, earthy, columnar to platy, fibrous. Creamy white, grayish, yellowish brown; greasy to silky luster, dull, pearly on cleavage surfaces. Cleavage {001}, perfect; very plastic. $H = 2-2\frac{1}{2}$. $G = 6.5$. In the series BiO(OH)-BiOCl there is only partial substitution of (OH) for Cl, and BiO(OH) is not known. Daubr eite refers to material with OH/Cl > 1:1. Uniaxial (-); $N_0 = 1.91$; weakly birefringent. *Constancia mine, Tazna, Bolivia*, mixed with clay. RG *DII*:60, *MM* 24:49(1935), *ST*:168.

10.2.2.1 Laurionite $\text{PbCl}(\text{OH})$

Named in 1887 for the locality. Dimorphous with paralaurionite. ORTH *Pnma*. $a = 9.699$, $b = 4.020$, $c = 7.111$, $Z = 4$, $D = 6.212$. Structure: *ZK 141:246(1975)*. *31-680(syn)*: 5.70_3 4.01_{10} 3.56_4 3.33_3 3.30_6 2.87_3 2.51_3 2.30_5 . Crystals elongated {010} or tabular {100}. Colorless to white; adamantine luster, pearly on {100}. Cleavage {101}, distinct; not brittle. $H = 3-3\frac{1}{2}$. $G = 6.24$. Biaxial (-); $XYZ = cab$, $N_x = 2.077$, $N_y = 2.116$, $N_z = 2.158$ (Na); $2V = 88^\circ$. *Laurium (Laurion), Greece*, in ancient lead slags exposed to the action of seawater, associated with phosgenite, paralaurionite, fiedlerite, and other secondary lead minerals. Wheal Rose, near Sithney, Cornwall, England. RG *DII:62*.

10.2.3.1 Paralaurionite $\text{PbCl}(\text{OH})$

Named in 1899 from the Greek *para* and *laurionite*, a dimorphous pair. MON *C2/m*. $a = 10.79$, $b = 3.98$, $c = 7.19$, $\beta = 117.22^\circ$, $Z = 4$, $D = 6.28$. *MM 29:341(1950)*. *16-158*: 5.14_{10} 3.49_6 3.21_{10} 2.98_7 2.51_9 2.44_6 2.01_6 1.70_6 . Crystals thin tabular {100}, or lathlike by elongation [001]. Twinning on {100} common, simulating orthorhombic symmetry. Colorless to white, also sulfur-yellow, pale greenish, or violet; subadamantine luster. Cleavage {001}, perfect; crystals bend readily about [010] due to translation gliding; not brittle. $G = 6.15$. Soft. Soluble in HNO_3 , easily fusible. Biaxial (-); $Y - b$; $Z \wedge c = 25^\circ$; $N_x = 2.05$, $N_y = 2.15$, $N_z = 2.20$; $2V = 68^\circ$; $r < v$, strong. Mammoth mine, Tiger, AZ; Wheal Rose, near Sithney, Cornwall; and common in large cleavage masses in hydrocerussite at Shepton Mallet, Mendip Hills, Somerset, England; *Laurium, Greece*, in ancient lead slags altered by seawater. In large bladed gray crystals with leadhillite in Toussit, Oujda, northern Morocco(1); San Rafael mine, Cerro Gordo, Chile. RG *DII:64*, *GSC 60(4):58(1960)*.

10.2.4.1 Blixite $\text{Pb}_2\text{Cl}(\text{O},\text{OH})_2$

Named in 1958 for Ragner Blix (b.1898), chemist, Swedish Museum of Natural History. ORTH Space group unknown. $a = 5.832$, $b = 5.694$, $c = 25.47$, $Z = 8$. *AM 45:908(1960)*. *12-542*: 3.88_8 3.18_5 2.93_{10} 2.83_6 2.15_5 2.12_6 2.04_6 1.66_8 . Thin crystalline coatings. Dirty yellow to yellowish green, pale yellow streak, vitreous luster. Distinct cleavage in one direction. $H = 3$. $G = 7.35$. Biaxial (+); $N_x = 2.05$, $N_z = 2.20$; $2V = 80^\circ$. *Långban, Varmland, Sweden*, in the *Amerika stope*, in fissures in dolomite; also in fractures in braunite-hausmannite ore. RG *AMG 2:411(1958)*.

10.2.5.1 Perite PbBiO_2Cl

Named in 1960 for Per Adolf Geijer (1886-1976), Swedish geologist. ORTH *Bmmb*. $a = 5.627$, $b = 5.575$, $c = 12.425$, $Z = 4$, $D = 8.24$. *AM 46:765(1961)*. *13-352*: 3.77_8 2.86_{10} 2.78_7 2.07_7 1.97_7 1.66_7 1.62_9 1.25_8 . Crystals tabular {010}. Sulfur yellow, adamantine luster. Cleavage {010}, distinct. $H = 3$. $G = 8.16$. Easily soluble in dilute acids. Biaxial; $N > 2.4$. Blue Bell claims, Baker, CA.

Langban, Varmland, Sweden, associated with hausmannite and calcite; also from *Glen Florrie, WA, Australia*. RG *AMG 2:565(1960)*.

10.2.5.2 Nadorite PbSbO_2Cl

Named in 1870 for the locality. ORTH $P4nc$. $a = 5.60$, $b = 5.44$, $c = 12.22$, $Z = 4$, $D = 7.05$. $17-469$: 3.71_3 2.80_{10} 2.70_3 2.06_3 2.03_3 1.95_3 1.62_3 1.59_3 . Crystals thin tabular {010} or prismatic [100]; in subparallel groups. Twins on {101}. Yellow to smoky brown, white to yellowish streak, resinous to adamantine luster. Cleavage {010}, perfect. $H = 3\frac{1}{2}-4$. $G = 7.02$. Biaxial (+); $XYZ = bca$; $N_x = 2.30$, $N_y = 2.35$, $N_z = 2.40$ (Li); $2V = 85^\circ$; $r > v$, strong. Commonly partially altered to bindheimite. *Langban, Varmland, Sweden*; the *Bodannan mine, St. Endellion, Cornwall, England*, as an alteration of jamesonite. *Djebel Nador, Constantine, Algeria*; *Touissit, Oujda, northern Morocco*, with anglesite(l). RG *DII:1039, PM 52:335(1973)*.

10.2.6.1 Thorikosite $\text{Pb}_3(\text{Sb,As})\text{O}_3(\text{OH})\text{Cl}_2$

Named in 1985 after the ancient town of Thorikos, near which the Laurium mines are located. TET $I4/mmm$. $a = 3.919$, $c = 12.854$, $Z = 1$, $D = 7.24$. *AM 70:845(1985)*. $38-403$: 6.39_3 3.75_7 3.20_3 2.89_{10} 2.78_5 2.10_3 1.96_2 1.62_3 . Crystals prismatic, flattened {001}. Light yellow, vitreous luster. Cleavage {001}, perfect; very brittle. Found in vugs in ancient lead slags at *Laurium, Greece*, associated with paralaurionite, hydrocerussite, sphalerite, and calcite. RG

10.2.7.1 Asisite $\text{Pb}_7\text{SiO}_6\text{Cl}_2$

Named in 1988 for the Asis farm, where the Kombat mine (source of the mineral) is located. TET $I4/mmm$. $a = 3.897$, $c = 22.81$, $Z = 1$, $D = 8.041$. *AM 73:643(1988)*. $45-1429$: 3.83_3 3.46_4 2.96_{10} 2.75_6 1.984_4 1.757_4 1.627_6 1.602_5 . Platy crystals to 0.5 mm. Yellow to yellow-green, adamantine luster. Cleavage {001}, perfect. $H = 3\frac{1}{2}$. Uniaxial (-); $N_O = 2.39$ $N_E = 2.32$ (Na) (calc); $r < v$. In RL, gray, with distinct internal reflections; nonpleochroic; weakly anisotropic; $R = 18.4$, 6.0 (470 nm); 17.2 , 5.3 (546 nm); 16.8 , 5.1 (589 nm); 16.3 , 4.9 (650 nm). *Kombat mine, Namibia*, with barite in interstices of coarsely crystalline hematophanite. RG

10.2.8.1 Zharchikhite $\text{AlF}(\text{OH})_2$

Named in 1988 for the locality. MON $P2_1/a$. $a = 5.164$, $b = 7.843$, $c = 5.179$, $\beta = 116.25^\circ$, $Z = 4$, $D = 2.82$. *AM 74:504(1989)*. $45-1430$: 3.98_{10} 2.92_8 2.31_7 1.926_5 1.833_9 1.788_5 1.737_7 1.289_7 . Prismatic crystals to 2.5 mm, elongated [001]; drusy aggregates; massive, fine-grained. Colorless to white, vitreous luster. Cleavage {010}, perfect; very brittle. $H = 4.5$. $G = 2.81$. Insoluble in acids, slowly soluble in NaOH solution. Biaxial (-); $Y = b$; $Z \wedge c = 43^\circ$. $N_x = 1.532$, $N_y = 1.552$, $N_z = 1.567$ (Na); $2V = 80^\circ$; inclined dispersion, $r > v$. *Zharchinskoye molybdenum deposit, Zabaykalye, Transbaikal, Russia*, in a fault breccia, associated with propopite, ralstonite, gearskutite, barite, and siderite. RG *ZVMO 117:79(1988)*.

10.2.9.1 Pinalite $Pb_3(WO_4)OCl_2$

Named in 1989 for the county of origin. ORTH *A2aa* or *Amaa*. $a = 11.073$, $b = 13.086$, $c = 5.624$, $Z = 4$, $D = 7.78$. AM 74:934(1989). 6.52₃ 3.78₉ 3.28₄ 2.93₁₀ 2.81₄ 2.77₃ 2.12₃ 1.642₅. Acicular bladed crystals elongated [001], flattened {010}. Bright yellow, adamantine luster. No cleavage, brittle. Nonfluorescent. Biaxial (+); XYZ = *bca*; $N_x = 2.490$, $N_y = 2.495$, $N_z = 2.505$ (calc); nonpleochroic; $2V = 70^\circ$; $r > v$, moderate. From the *Mammoth mine*, *Pinal Co.*, *AZ*, in solution cavities in quartz, with leadhillite, cerussite, matlockite, and so on. RG

10.3.1.1 Mendipite $Pb_3Cl_2O_2$

Named in 1839 for the locality. ORTH *Pnma*. $a = 11.87$, $b = 5.806$, $c = 9.48$, $Z = 4$, $D = 7.30$. Structure: BM 94:323(1971). 23-332: 7.40₆ 3.78₆ 3.51₇ 3.08₆ 3.04₈ 2.90₆ 2.78₁₀ 2.64₉. 25-448(syn): 3.52₆ 3.05₁₀ 2.79₁₀ 2.64₉ 2.10₆ 1.65₆ 1.64₆ 1.63₆. Fibrous or columnar masses, often radiated. Colorless to white or gray, often tinged with pink or other colors; pearly to silky luster on cleavages, resinous to adamantine across fractures. Cleavage {110}, perfect; {100}, {010}, fair; conchoidal to uneven fracture. $H = 2\frac{1}{2}$, $G = 7.24$. Soluble in dilute HNO_3 ; in CT becomes yellow and decrepitates. $PbCl_2$ then sublimes, and the residue melts to a yellow liquid (PbO). Biaxial (+); XYZ = *abc*; $N_x = 2.24$, $N_y = 2.27$, $N_z = 2.31$; $2V_{calc} = 83^\circ$; $r < v$, very strong. Near *Churchill* and at *Higher Pitts*, *Mendip Hills*, *Somerset*, *England*, and in some quantity at the *Foster Yeoman* quarry, *Shepton Mallet*. Also at the *Kunibert* mine, *Brilon*, *Westphalia*, *Germany*. RG DII:56, BM 94:108(1971).

10.3.2.1 Fiedlerite $Pb_3(OH)_2Cl_4$

Named in 1887 for Carl Gustav Fiedler (1791–1853), Saxon commissioner of mines, who directed an exploratory expedition to Laurium, Greece, where the mineral was found. MON *P2₁/a*. $a = 16.62$, $b = 8.02$, $c = 7.20$, $\beta = 102.20^\circ$, $Z = 4$, $D = 5.64$. BM 87:125(1964). 15-59: 3.89₁₀ 3.54₅ 3.33₅ 3.22₅ 2.81₈ 2.55₁₀ 2.01₆ 1.63₃. Lathlike crystals, tabular {100} and elongated [010]. Twinning on {100}. Colorless to white, adamantine luster. Cleavage {100}, good. $H = 3\frac{1}{2}$, $G = 5.88$. Slowly soluble in HNO_3 ; in CT decrepitates, loses water, and fuses, leaving a sublimate of $PbCl_2$. Biaxial (-); $Z = b$; $Y \wedge c = -34^\circ$; $N_x = 1.98$, $N_y = 2.04$, $N_z = 2.10$; $2V = 85^\circ$; $r < v$, perceptible. *Laurium*, *Greece*, formed by action of seawater on ancient lead slags. RG DII:67.

10.3.3.1 Corderoite $Hg_3S_2Cl_2$

Named in 1974 for the locality. Dimorphous with lavrentievite. iso *I2₁3*. $a = 8.949$, $Z = 4$, $D = 6.827$. AM 59:652(1974). Structure: AC(B) 24:156(1968). 39-1386: 6.3₄ 3.66₁₀ 2.83₆ 2.58₇ 2.39₃ 2.24₃ 2.11₃ 1.757₆. Clay-like, as small masses or replacements. Grain size submicroscopic ($< 2 \mu m$). Light orange-pink, but becomes light gray to black upon exposure to sunlight or artificial light; dull luster. $H = 2$, $G = 6.895$. Isotropic; $N > 2.50$. *Cordero mine*, *W of McDermitt*, *Humboldt Co.*, *NV*, in late Miocene playa sediments,

with cinnabar, montmorillonite, quartz, and cristobalite. Kadyrel mercury mine, Tuva, Siberia, Russia. The corderoite replaces cinnabar in all cases. RG *JCG* 1:271(1967).

10.3.4.1 Lavrentievite $\text{Hg}_3\text{S}_2(\text{Cl},\text{Br})_2$

10.3.4.2 Arzakite $\text{Hg}_3\text{S}_2(\text{Br},\text{Cl})_2$

Named in 1984 for Michail Alexeevich Lavrentiev (1900–1980), Russian mathematician and academician, founder of the Siberian Academy of Science. Arzakite named in 1984 for the locality. Lavrentievite is dimorphous with corderoite (10.3.3.1). MON or TRIC $P2/m$, $P2$, or Pm . Lavrentievite: $a = 8.94$, $b = 5.194$, $c = 18.33$, $\beta = 92.73^\circ$, $Z = 5$, $D = 7.26\text{--}7.50$. Arzakite: $a = 8.99$, $b = 5.24$, $c = 18.45$, $\beta = 92.46^\circ$, $Z = 5$, $D = 7.64$. *AM* 70:873(1985). 41-606 (lavrentievite): 5.00₃ 3.96₄ 3.38₅ 3.01₆ 2.61₁₀ 2.29₄ 2.20₄ 1.587₅. 28-658(arzakite)(syn): 5.10₃ 4.06₃ 3.43₃ 3.07₆ 3.06₆ 2.65₁₀ 2.32₅ 1.618₃. Small grains. $H = 2\text{--}2\frac{1}{2}$. $G = 7.4$. Both are found at the Kadyrel and Arzak mercury deposits, Tuva, Siberia, Russia, with cinnabar and corderoite. Lavrentievite is also found at the Kadyrelski ore showing, with calomel, eglestonite, and mercury. RG *DANS* 290:177(1986).

10.3.5.1 Grechishchevite $\text{Hg}_3\text{S}_2(\text{Br},\text{Cl},\text{I})_2$

Named in 1990 for Oleg Konstantinovich Grechishchev, Russian engineering geologist, long-time student of mercury ores from Tuva, Siberia. TRF $P4_2m$, $P4m2$, $P4mm$ or $P4mmm$. $a = 13.225$, $c = 8.685$, $Z = 8$, $D = 7.23$ (for $\text{Hg}_3\text{S}_2(\text{Br}_{10}\text{Cl}_{05}\text{I}_{05})$). *AM* 76:1729(1991). 45-1418: 4, 18₃ 3.95₆ 3.12₂ 3.02₇ 2.65₁₀ 2.60₄ 2.34₃ 1.682₄. Minute intergrown crystals and grains. Bright to dark orange; reddish orange, deep yellow streak, vitreous-adamantine luster. One cleavage, prismatic; brittle. $H = 2\frac{1}{2}$. Unaltered in dilute acids. Blackens slowly upon immersion in 40% KOH solution. Unaxial (+); $N > 2$. In RL, grayish white with strong orange internal reflections; distinctly pleochroic. $R = 17.3$, 19.8 (546 nm). Arzak and Kadyrel mercury deposits, Tuva, Siberia, Russia, in the oxidized zone on fractures, associated with bromian calomel, eglestonite, lavrentievite, arzakite, corderoite, and mercury. RG

10.3.6.1 Radtkeite $\text{Hg}_3\text{S}_2\text{I}$

Named in 1991 for Arthur S. Radtke (b.1936), geologist, U.S. Geological Survey. ORTH $Fmmm$, $F222$, or $Fmm2$. $a = 16.85$, $b = 20.27$, $c = 9.133$, $Z = 16$, $D = 7.05$. *Am* 76:1715(1991). 44-1408(syn): 3.89₅ 3.73₂ 3.38₂ 2.71₄ 2.65₉ 2.54₁₀ 1.827₂ 1.697₂. Submicroscopic grains and minute prismatic crystals. Bright yellow-orange to orange, yellow-orange streak, adamantine luster. Cleavage {010}, perfect; {001}, {100}, very good; hackly to conchoidal fracture. $H = 2\text{--}3$. Biaxial (+); $N > 2.0$; $2V \approx 35^\circ$. McDermitt mercury mine, Humboldt Co., NV, associated with quartz, cinnabar, and corderoite. RG

10.4.1.1 Penfieldite $\text{Pb}_2\text{Cl}_3(\text{OH})$

Named in 1892 for Samuel L. Penfield (1856–1905), American mineralogist and mineral chemist. *HEX* $P6/m$. $a = 11.28$, $c = 48.65$, $Z = 36$, $D = 6.00$. *BM* 91:407(1968). 22-384: 5.70₄ 3.73₁₀ 3.31₆ 3.14₈ 2.74₆ 2.56₆ 2.27₆ 2.15₄. Crystals prismatic {0001}, with {10 $\bar{1}$ 1} or steep pyramids; also tabular {0001}; twins common. Colorless to white, adamantine to greasy luster. Cleavage {0001}, distinct; not brittle. $G = 5.82$ – 5.86 . Decomposed by water, soluble in dilute HNO_3 . Uniaxial (+); $N_0 = 2.13$, $N_E = 2.21$. *Laurium, Greece*, in ancient lead slags exposed to the action of seawater. Sierra Gorda, Antofagasta, Chile, with pseudoboleite. *RG DII:66*.

10.4.2.1 Terlinguaite $\text{Hg}^{1+}\text{Hg}^{2+}\text{ClO}$

Named in 1900 for the locality. *MON* $C2/c$. $a = 19.53$, $b = 5.92$, $c = 9.48$, $\beta = 143.80^\circ$, $Z = 8$, $D = 9.31$. Structure: *AC* 9:956(1956). 25-559(syn): 5.76₈ 4.34₆ 4.17₈ 3.68₆ 3.28₈ 2.96₈ 2.82₈ 2.51₁₀. Complex crystals, usually prismatic {010}, flattened {001}, or equidimensional; usually rounded and sometimes in parallel growth; frequently powdery, or as aggregates. Sulfur-yellow to brown, becoming olive-green on exposure to light; yellow streak; brilliant, adamantine luster. Cleavage {101}, perfect. $H = 2\frac{1}{2}$. $G = 8.725$. Biaxial (-); $Y \wedge c = 83^\circ$; $N_x = 2.35$, $N_y = 2.64$, $N_z = 2.66$; $2V = 20^\circ$; $r < v$, extreme. *Terlingua, Brewster Co., TX*, with calomel, eglestonite, kleinite, montroydite, mercury, and cinnabar. Cahill mine, Humboldt Co., NV. *RG DII:52*.

10.4.3.1 Kleinite $\text{Hg}_2\text{N}(\text{Cl},\text{SO}_4) \cdot n\text{H}_2\text{O}$

Named in 1905 for Carl Klein (1842–1907), German mineralogist, University of Berlin. *HEX* $P6_3/mmc$. $a = 13.56$, $c = 11.13$, $Z = 18$. Structure: *SR* 12:219(1949). Kleinite has hexagonal symmetry above 130° ; below that the symmetry is possibly triclinic. 39-389: 5.19₃ 4.04₂ 2.93₁₀ 2.89₇ 2.79₉ 2.59₁₀ 2.02₂ 1.690₃. Crystals prismatic {0001} with light vertical striations on prism; also equant. Yellow to orange, yellow streak, adamantine to greasy luster. Cleavage {0001}, easy; {10 $\bar{1}$ 1}, imperfect. $H = 3\frac{1}{2}$ –4. $G = 8.0$. Soluble in warm HCl or HNO_3 without deposition of calomel. Since the Cl^- , SO_4^{2-} , and H_2O are somewhat variable, it is probable that these anions and water occupy open channelways as in mosesite. Biaxial (-); $N_x = 2.16$, $N_y = 2.18$; $2V$ small; $r < v$, very strong. *Terlingua, Brewster Co., TX*, with terlinguaite, montroydite, and other mercury oxysalts. *RG DII:87, AM 17:541(1932)*.

10.4.4.1 Melanothallite Cu_2OCl_2

Named in 1870 from the Greek for *black* and *green* (the color of a young twig), alluding to the black color changing to green upon oxidation. *ORTH* *Fddd*. $a = 9.595$, $b = 9.693$, $c = 7.461$, $Z = 8$, $D = 4.08$. *AM* 68:852(1933). 35-679: 5.04₁₀ 2.95₅ 2.82₂ 2.52₈ 2.42₂ 2.18₂ 1.93₂ 1.47₂. Crystals are thin plates. Black to bluish black, deep brown in fine fragments, vitreous luster. Prismatic cleavage, perfect; brittle. Alters rapidly in air to a green material. Partly dissolved by water, completely so by warm acids. Originally found among

sublimates on *Vesuvius, Italy*, associated with eriochalcite, chalcocyanite, euchlorine, and dolerophanite. Later found as a result of the fissure eruption of Tolbachin volcano, Kamchatka Penin., Siberia, Russia, in 1975–1976, with the same associated minerals. RG *DII:44, ZVMO 111:562(1982)*.

10.5.1.1 Cadwaladerite $\text{Al}(\text{OH})_2\text{Cl} \cdot 4\text{H}_2\text{O}$

Named in 1941 for Charles Meigs Biddle Cadwalader (1885–1959), American museum administrator, Academy of Natural Sciences, Philadelphia. An inadequately characterized mineral. Amorphous. Small masses and grains. Lemon yellow, transparent, vitreous luster. Conchoidal fracture. $G = 1.66$. Isotropic; $N \approx 1.513$. *Cerro Pintado, Tarapaca, Chile*, in a sulfate deposit. RG *DII:77*.

10.5.2.1 Poyarkovite Hg_3ClO

Named in 1981 for Vladimir Erastovich Poyarkov, Russian geologist, well-known investigator of mercury and antimony deposits. MON Space group uncertain, probably $C2/m$. $a = 18.82$, $b = 9.02$, $c = 16.79$, $\beta = 112.40^\circ$, $Z = 24$, $D = 9.88$. *AM 67:860(1982)*. $33\text{-}920$: 4.20_4 3.09_5 2.96_4 2.83_{10} 2.74_8 2.60_6 1.88_4 1.80_7 . Irregular grains and aggregates. Deep raspberry- to cherry-red, turning darker and finally black on exposure; red streak; vitreous to adamantine luster. Irregular to conchoidal fracture, very brittle. $H = 2\text{-}2\frac{1}{2}$. $G = 9.50$. Instantly blackened by KOH solution. Decomposed by HNO_3 , insoluble in HCl. Biaxial; $N > 2.0$. Pleochroism deep red to brownish red. In RL, strongly anisotropic; colors may vary with orientation, but always include azure to blue. Janos, CHIH, Mexico. *Khaidarkan deposit, Siberia, Russia*, in close contact with eglestonite and calomel. RG *ZVMO 110:501(1981)*.

10.5.3.1 Pinchite $\text{Hg}_5\text{O}_4\text{Cl}_2$

Named in 1974 for William W. Pinch (b.1940), American mineral collector, who first recognized the species. ORTH *Ibam*. $a = 11.54$, $b = 6.08$, $c = 11.64$, $Z = 4$, $D = 9.26$. *CM 12:417(1974)*. $26\text{-}1267$: 3.94_6 3.26_4 2.92_5 2.84_{10} 2.70_8 2.17_2 1.79_2 1.64_2 . Euhedral crystals up to 1 mm, with tabular {001} habit. Dark brown to black, reddish-brown streak, adamantine luster. No cleavage. Soft. $G = 9.5$. Biaxial; $N > 2.20$; pleochroic, red to almost opaque; strongly birefringent. *Terlingua, Brewster Co., TX*, with terlinguaite and montroydite. RG

10.5.4.1 Eglestonite $\text{Hg}_6^{+}\text{Cl}_3\text{O}(\text{OH})$

Named in 1903 for Thomas Egleston (1832–1900), American mineralogist and metallurgist, Columbia University. ISO *Ia3d*. $a = 16.036$, $Z = 16$, $D = 8.65$. *AM 62:396(1977)*. Structure: *AM 77:839(1992)*. $29\text{-}909$: 4.01_4 3.27_{10} 2.60_1 2.54_5 2.32_1 1.89_6 1.709_1 1.336_1 . Crystals dodecahedral, commonly modified by cube, usually rounded; also as a thin earthy film coating cinnabar. Yellow to brown, becoming darker and finally black on exposure to light; adamantine to resinous luster. Uneven to conchoidal fracture; brittle. $H = 2\frac{1}{2}$. $G = 8.45$. In

NH_4OH turns black immediately. Decomposed by acids with separation of calomel. Isotropic; $N = 2.49$. *Terlingua, Brewster Co., TX*; *McDermitt, NV*; in *CA* at *Kings mine, King's Co.*; *Socrates mine, Sonoma Co.*, and *New Idria mine, San Benito Co.* Also *Pike Co.* and elsewhere in *AR*; *Almaden, Ciudad Real, Spain*; *Arzak and Kadyrel mercury deposits, Tuva, Siberia, Russia*; *Monarch mercury mine, Transvaal, South Africa*. RG *DII:51*

10.5.4.2 Kadyrelite $\text{Hg}_4^{1+}(\text{Br,Cl})_2\text{O}$

Named in 1987 for the locality. iso *Ia3d*. $a = 16.22$, $Z = 24$, $D = 8.79$. *AM 74:503(1989)*. $42-1371$: 4.06_3 2.63_2 2.57_8 2.34_2 1.912_{10} 1.731_2 1.350_2 1.102_2 . Small grains and powdery coatings. Bright to dull orange, orange-yellow streak, vitreous to adamantine luster. No cleavage, conchoidal to uneven fracture; brittle. $H = 2\frac{1}{2}-3$. Turns black in 40% KOH solution; in HCl slowly becomes dark gray; readily soluble in 1:1 HNO_3 , leaving a cottonlike white residue. Isotropic; $N > 2.0$. In *RL*, grayish white; intense orange internal reflections; no birefractance. Found in cavities in carbonate veins, associated with calomel, eglestonite, corderoite, and other mercury minerals at the *Kadyrelski mercury deposit, Tuvinskaya, Armenia*. RG *ZVMO 116:733(1987)*, *AM 77:839(1992)*.

10.5.5.1 Comancheite $\text{Hg}_{13}^{2+}(\text{Cl,Br})_8\text{O}_9$

Named in 1981 for the Comanche Indians, who were the first miners in the *Terlingua* district, using cinnabar for war paint. ORTH *Pnmm* or *Pnn2*. $a = 18.407$, $b = 21.641$, $c = 6.677$, $Z = 4$, $D = 8.0$. *35-510*: 5.68_7 5.42_6 3.82_3 3.10_4 2.88_8 2.71_5 2.67_{10} 2.45_5 . Tiny crystalline masses or stellate acicular crystals. Often mistaken for montroydite. Red; crystals, orange-yellow to yellow resinous luster, vitreous crystals. Cleavage $\{001\}$, $\{110\}$, fair; brittle. $H = 2$. $G = 7.7$. Unaffected by cold concentrated acids; in 40% KOH solution turns dull orange-brown. Biaxial; $N_x = 1.78$, $N_z = 1.79$; strong absorption; parallel extinction; length-fast. Indices lower than predicted by the Gladstone–Dale law. From the *Mariposa mine, Terlingua district, Brewster Co., TX*, encrusting calcite. RG *CM 19:393(1981)*, *AM 67:622(1982)*.

10.5.6.1 Claringbullite $\text{Cu}_4\text{Cl}(\text{OH})_7 \cdot n\text{H}_2\text{O}$

Named in 1977 for Frank Claringbull (1911–1990), British X-ray crystallographer, keeper of minerals and director of the British Museum (Natural History). HEX Space group uncertain, probably *P6_3*. $a = 6.671$, $c = 9.183$, $Z = 2$, $D = 3.99$. *29-539*: 5.75_{10} 4.89_8 4.58_8 2.89_7 2.70_{10} 2.45_9 1.80_7 1.67_7 . Crystals platy $\{0001\}$. Blue to blue-green. Cleavage $\{0001\}$, perfect; $\{1011\}$, $\{1120\}$, distinct. Soft. $G = 3.9$. Uniaxial (–); $N_O = 1.782$, $N_E = 1.780$. *Bisbee, AZ, Nchanga open-pit mine, Zambia*, with cuprite. *M'sesa mine, Kambowe, Shaba, Zaire*. RG *MM 41:433(1977)*, *AM 63:793(1978)*.

10.5.7.1 Onoratoite $\text{Sb}_8\text{O}_{11}\text{Cl}_2$

Named in 1968 for Ettore Onorato (1899–1971), Italian mineralogist, University of Rome. MON $C2/m$. $a = 19.047$, $b = 4.053$, $c = 10.318$, $\beta = 110.25^\circ$, $Z = 2$, $D = 5.425$. Structure: $AC(C) 40:1506(1984)$. $21-52$: 4.39_7 3.19_{10} 3.04_5 2.82_5 2.68_6 2.60_3 2.54_3 1.81_3 . Acicular to bladed crystals, elongated [010], flattened {001}; fibrous [010]. White. $G = 5.3$. Soluble in cold concentrated HCl, and NaOH solution. In CT sublimes, giving oily droplets of SbCl_3 and minute octahedrons of Sb_2O_3 . Biaxial (-); $X \wedge c = 12^\circ$, $Y \wedge a = 8^\circ$, $Z \wedge b = 0-14^\circ$; $N_y = 2.18-2.23$, $N_z = 2.23-2.26$. Bireflectance = 0.24. *Cetine di Cotoriano, Rosia, Siena, Italy*, as an alteration product of stibnite. RG *MM 36:1037(1968)*, *MR 8:285(1977)*, *AM 70:440(1985)*.

10.5.8.1 Simonkollite $\text{Zn}_5(\text{OH})_6\text{Cl}_2 \cdot \text{H}_2\text{O}$

Named in 1985 for Werner Simon (b.1939) and Kurt Kolle (b.1949), mineral collectors from Cornberg, Germany, who submitted the first samples for investigation. HEX-R $R\bar{3}m$. $a = 6.334$, $c = 23.58$, $Z = 3$, $D = 3.35$. *NJMM:145(1985)*. $7-155$: 7.87_{10} 3.58_3 3.17_4 2.94_3 2.73_6 2.67_7 2.37_4 1.59_4 . Tabular to lamellar hexagonal crystals to 1 mm. Colorless, white streak, vitreous luster. Cleavage {0001}, perfect. $H = 1\frac{1}{2}$. $G = 3.20$. Soluble in dilute acids. Uniaxial (+); $N_O = 1.657$, $N_E = 1.700$. Found as a weathering product of Zn-bearing slags at the *Richelsdorf foundry, Hesse, Germany*. RG *AM 73:194(1988)*.

10.5.9.1 Abhurite $\text{Sn}_3\text{O}(\text{OH})_2\text{Cl}_2$

Named in 1985 for the locality. HEX-R $R\bar{3}m$, $R3m$, or $R32$. $a = 10.017$, $c = 44.014$, $Z = 21$, $D = 4.34$. $39-314$: 4.14_5 3.63_4 3.40_5 3.27_4 3.24_4 2.89_7 2.82_5 2.53_{10} . Platy crystals, occasionally twinned {0001}. White to tan, colorless in crystals. Very fragile. $G = 4.29$. Dissolves rapidly in HNO_3 and slowly in HCl. Uniaxial (+); $N \approx 2.06$. Negligible birefringence. Found on corroded tin ingots recovered from an ancient wreck in the *Sharm Abhur*, a cove in the *Red Sea, about 30 km N of Jiddah, Saudi Arabia*. RG *CM 23:233(1985)*.

10.5.10.1 Damaraitite $\text{Pb}_4\text{O}_3\text{Cl}_2$

Named in 1990 for the Damara sequence, the dolostones that host the deposit at the type locality. ORTH $Pma2$, $Pmam$, or $P2_1am$. $a = 15.104$, $b = 6.891$, $c = 5.806$, $Z = 3$, $D = 7.84$. *MM 54:593(1990)*. $6-405(\text{syn})$: 6.5_6 3.75_8 2.92_{10} 2.77_7 2.12_7 1.965_7 1.686_7 1.629_7 . Subhedral grains <0.2 mm. Colorless, adamantine luster. Cleavage {010}, good; subconchoidal to irregular fracture. $H = 3$, $\text{VHN}_{50} = 150$. In RL, gray to bluish gray, faintly pleochroic, weakly anisotropic. From the *Kombat mine, 49 km S of Tsumeb, Namibia*, in veins of barite–calcite–jacobsite–hematite, associated with hausmannite, hematophanite, and copper. RG *AM 77:670(1992)*.

10.5.11.1 Parkinsonite (Pb,Mo,□)₈O₈Cl₂

Named in 1994 for Reginald F. D. Parkinson, English mineral collector from Somerset, U.K. TET *I4/mmm*. $a = 3.992$, $c = 22.514$, $Z = 1$, $D = 7.39$. *MM* 58:59(1994). *PD*: 5.63₉ 3.75₂ 3.53₁ 2.99₃ 2.818₁₀ 2.25₃ 1.994₁ 1.876₁. Small cleavage plates and crystalline patches. Bright red to purplish red, translucent, scarlet streak, adamantine luster. Cleavage {001}, perfect; sectile. $H = 2-2\frac{1}{2}$. $G_{\text{syn}} = 7.32$. Nonfluorescent. In RL, gray, moderately bireflectant, weakly pleochroic, strong red internal reflections. $R = 22.0$ (470 nm), 20.5 (546 nm), 19.6 (589 nm), 18.8 (650 nm). Found at *Merehead Quarry, Cranmore, Somerset, England*, in fractures and cavities in carbonate vugs in veins of manganese and iron oxides, associated with mendipite, diableite, cerussite, and chloroxiphite. RG

10.5.12.1 Lorettoite α -Pb₇O₆Cl₂

Named in 1916 for the original locality. ORTH (pseudo-TET). $a = 5.49$, $b = 22.9$, $c = 5.50$, $Z = 2$, $D = 7.77$. 6-393: 3.86₆ 3.49₆ 2.98₁₀ 2.77₈ 2.31₆ 2.25₆ 1.993₇ 1.642₇. Composite bladelike microcrystals forming wartlike aggregates. Light yellow to reddish yellow, yellow streak, adamantine luster. Cleavage parallel to blades, perfect. $H = 2\frac{1}{2}-3$. $G = 7.39$. Uniaxial (-); $N_O = 2.40$, $N_E = 2.37$ (Li). Originally described from Loretto, TN, but this material was later shown to be an artifact. *AM* 64:1303(1979). More recently the same compound was found in conjunction with the ancient lead slags at *Laurium, Greece*, with hydrocerussite. Since the various laurium compounds have long been accepted as valid minerals despite their having resulted from human activity, lorettoite may eventually also be considered as valid, although the IMA Commission on New Minerals and New Mineral Names has not ruled on the matter. RG *LAP* 11:25(1986), 13:11(1988); *MM* 56:53(1992).

10.5.13.1 Hanawaltite Hg₆⁺Hg₂²⁺O₃Cl₂

Named in 1996 by Roberts et al. in honor of J. D. (Don) Hanawalt (1903–1987), who was a pioneer in the field of X-ray powder diffraction. ORTH *Pbma*. $a = 11.790$, $b = 13.881$, $c = 6.450$, $Z = 4$, $D = 9.51$. *CM*:34(1996). *PD*: 5.25₈ 4.35₄ 3.16₆ 3.05₁₀ 2.95₇ 2.68₅ 2.41₅ 1.747₄. Crystals are subhedral to anhedral, platy to somewhat bladed, max. 0.3 mm × 0.3 mm. Black to very dark brown, black to dark red-brown streak, metallic luster, nonfluorescent. Cleavage {001}, good; uneven fracture, brittle. $H < 5$. In polished section white with dark red internal reflections; pleochroic, white to blue-white; strongly bireflectant. $R = 22.8$, 29.6 (470 nm); 20.7, 25.7 (546 nm); 20.15, 24.35 (589 nm); 20.2, 22.9 (650 nm). Found in a prospect pit near the abandoned *Clear Creek mercury mine, New Idria district, San Benito Co., CA*, associated with calomel, mercury, cinnabar, montroydite, and quartz. RG *PD* 11:45(1996).

10.6.1.1 Diableite Pb₂CuCl₂(OH)₄

Named in 1923 from the Greek for *apart* or *distinct from* and the mineral boleite. TET *P4mm*. $a = 5.870$, $c = 5.494$, $Z = 1$, $D = 5.410$. Structure: ZK

134:69(1971). 21-468: 5.50₁₀ 3.28₉ 2.95₈ 2.57₉ 2.28₁₀ 2.06₈ 1.75₉ 1.53₉. Crystals tabular {001}; also subparallel aggregates of thin plates. Deep blue, pale blue streak. Cleavage {001}, perfect; conchoidal fracture. $H = 2\frac{1}{2}$. $G = 5.42$. Tests similar to chloroxiphite (10.6.4.1). Uniaxial (-); $N_O = 1.98$, $N_E = 1.85$; absorption $O > E$. Distinct crystals(!) at the *Mammoth mine, Tiger, AZ*, in the Collins veins. Mendip Hills, England, in mendipite, with chloroxiphite, and hydrocerussite, in oxidized iron and manganese ores. RG *DII:82, MM 36:933(1968), NJMM:116(1970)*.

10.6.2.1 Koenenite $\text{Na}_4\text{Mg}_4\text{Cl}_{12} \cdot \text{Mg}_5\text{Al}_4(\text{OH})_{22}$

Named in 1902 for Adolf von Koenen (1837–1915), German geologist of Göttingen, who first found the mineral. HEX-R *R3m*. $a = 34.72$, $c = 32.64$, $Z = 3$, $D = 2.162$. Structure: *ZK 126:7(1968)*. 43-1490, 43-684: 10.8₃ 5.43₁₀ 2.82₃ 2.57₄ 2.33₃ 2.28₃ 2.04₅ 1.99₄. Crystals acute scalenohedra or rhombohedra; as crusts. Colorless to yellow, or deep red due to included scales of hematite; pearly luster on cleavage. Cleavage {0001}, perfect; flexible. $H = 1\frac{1}{2}$. $G = 1.98$. Uniaxial (+); $N_O = 1.52$, $N_E = 1.55$. O, red brown; E, colorless. From the potash mine *Justus I near Volpriehausen*, and elsewhere in *Hannover, Germany*. RG *DII:86, NJMM:161(1966)*.

10.6.3.1 Yedlinite $\text{Pb}_5\text{CrCl}_6(\text{OH},\text{O})_8$

Named in 1974 for Neal Yedlin (1908–1977), American amateur mineralogist and micromounter, who first observed the species. HEX-R *R3*. $a = 12.868$, $c = 9.821$, $Z = 3$, $D = 5.80$. Structure: *AM 59:1160(1974)*. 27-269: 6.44₃ 4.51₇ 3.88₃ 2.95₁₀ 2.62₇ 2.47₃ 2.30₂ 1.79₂. Prismatic crystals with {1120}, {1101}, {0001}, and other forms. Red-violet, white streak, vitreous luster. Cleavage {1120}, distinct; somewhat sectile. $H = 2\frac{1}{2}$. $G = 5.85$. Uniaxial (-); $N_O = 2.125$, $N_E = 2.059$. O, pale cobalt blue; E, lavender. *Mammoth mine, Tiger, AZ*, associated with diablete, wulfenite, diopside, phosgenite, and wherryite. RG *AM 59:1157(1974)*.

10.6.4.1 Chloroxiphite $\text{Pb}_3\text{CuCl}_2(\text{OH})_2\text{O}_2$

Named in 1923 from the Greek for *green* and *blade* or *straight sword*, in allusion to the color and habit of the crystals. MON *P2₁/m*. $a = 10.458$, $b = 5.750$, $c = 6.693$, $\beta = 97.78^\circ$, $Z = 2$, $D = 6.84$. Structure: *MM 41:357(1977)*. 33-467: 10.4₇ 5.96₃ 3.89₅ 3.85₅ 2.91₄ 2.87₁₀ 2.83₈ 2.69₄. Bladed crystals, rarely terminated, elongated [010] and flattened {101}, in subparallel groupings. Dull olive-green, similar to epidote; pale greenish-yellow streak; resinous to adamantine luster. Cleavage {101}, perfect; {100}, distinct; very brittle. $H = 2\frac{1}{2}$. $G = 6.76\text{--}6.93$. Soluble in HNO_3 . In CT breaks into cleavage fragments, evolves water followed by vaporization of PbCl_2 . The residue melts to a brown liquid, which on cooling becomes a bright green glass. Biaxial (-); $Z = b$; X perpendicular to {101}; $N_x = 2.16$, $N_y = 2.24$, $N_z = 2.25$; $r > v$, medium to strong. X, Y, brown; Z, green. *Higher Pitts, Mendip Hills, Somerset, England*, embedded in mendipite. RG *DII:84, MM 43:901(1980)*.

10.6.5.1 Zirklerite $(\text{Fe,Mg})_9\text{Al}_4\text{Cl}_{18}(\text{OH})_{12} \cdot 14\text{H}_2\text{O} (?)$

Named in 1928 after Zirkler, director of the Aschersleben potash works, Germany. An inadequately characterized mineral. **HEX-R** Space group unknown. Light gray. Rhombohedral cleavage. $H = 3\frac{1}{2}$. $G = 2.6$. Soluble in water with separation of iron and aluminum hydroxides. Uniaxial (+); $N \approx 1.552$. *Adolfs-glück mine, Hope, Hannover, Germany*, as the chief constituent of a rock containing halite, clay, anhydrite, quartz, and minor rinneite. **RG DII:87**.

10.6.6.1 Boleite $\text{Cu}_{24}\text{Pb}_{26}\text{Ag}_9\text{Cl}_{62}(\text{OH})_{48}$

Named in 1891 for the locality. **iso Pm3m**. $a = 15.29$, $Z = 1$. Structure: *SR 39A:195(1973)*. *27-1206*: 5.09₃ 4.41₁₀ 3.82₈ 3.51₄ 2.70₆ 2.55₄ 2.33₄ 1.99₄. Crystals are cubes, cubo-octahedrons, or rarely dodecahedral. Deep prussian blue; blue streak with a greenish tint; vitreous luster, pearly on cleavages. Cleavage {001}, perfect; {101}, good. $H = 3-3\frac{1}{2}$. $G = 5.05$. Soluble in HNO_3 ; in CT, loses water and fuses. Isotropic; $N = 2.05$. Mammoth–St. Anthony mine, Tiger, AZ; near Phillipsburg, MT, in the foundations of an old silver mill, the result of chemical spills in the mill; *Boleo, near Santa Rosalia, BCS, Mexico*, with and on anglesite, paratacamite, pseudoboleite, and cumengite in white clay; at the South mine, Broken Hill, NSW, Australia; Chalcolloco, Cerro Gordo, Tarapacá, Chile. Used as an ore of silver. **RG DII:78, JSSC 6:86(1973), MR 5:280(1974)**.

10.6.7.1 Cumengite $\text{Cu}_{20}\text{Pb}_{21}\text{Cl}_{42}(\text{OH})_{40}$

Named in 1893 for Edouard Cumenge (1828–1902), French mining engineer. Synonym: cumengite. **TET I4/mmm**. $a = 15.065$, $c = 24.436$, $Z = 2$, $D = 4.66$. Structure: *MM 50:157(1986)*. *27-174*: 12.3₇ 4.83₉ 3.98₇ 3.74₇ 3.22₇ 2.66₈ 2.37₁₀ 2.01₈. Octahedral or cubo-octahedral crystals, with nearly equal development of forms; also found as parallel overgrowths on crystals of boleite, as in the case of pseudoboleite. Indigo blue, sky-blue streak, vitreous luster (not pearly on cleavages). Cleavage {101}, good; {110}, distinct; {001}, poor. $H = 2\frac{1}{2}$. $G = 4.67$. Soluble in HNO_3 . Uniaxial (-); $N_O = 2.026$, $N_E = 1.965$. O, dark blue; E, pure blue. From *Boleo, near Santa Rosalia, BCS, Mexico*. Gunver Head, Padstow, Cornwall, England; also at Newport Beach, Falmouth. Christian Levin coal mine, Essen, Ruhr, Germany. Also found in the Laurium slags, Greece. **RG DII:79, NJMM:116(1970), MR 5:280(1974)**.

10.6.8.1 Pseudoboleite $\text{Pb}_{31}\text{Cu}_{24}\text{Cl}_{62}(\text{OH})_{48}$

Named in 1895 from the Greek *pseudo*, false, and *boleite*, a mineral it resembles. **TET I4/mmm**. $a = 15.24$, $c = 30.74$, $Z = 2$, $D = 5.07$. *NJMM:113(1992)*. *22-470*: 4.43₁₀ 3.83₁₀ 3.51₄ 2.71₁₀ 2.55₆ 2.39₆ 2.33₇ 1.99₆. Observed only in epitaxial overgrowths on boleite, with the {001} faces of the two minerals in common. Euhedral crystals, due to reentrant angles along the cube edges of boleite, resemble twins. Indigo blue; vitreous luster, pearly on cleavages. Cleavage {001}, perfect; {101}, nearly so. $H = 2\frac{1}{2}$. $G = 4.85$. Uniaxial (-); $N_O = 2.03$, $N_E = 2.00$. Mammoth–St. Anthony mine, Tiger, Pinal

PSEUDOBOLEITE: $\text{Pb}_{31}\text{Cu}_{24}\text{Cl}_{62}(\text{OH})_{48}$

Forms: $c\{001\}$, $a\{010\}$, $m\{110\}$, $e\{011\}$, $o\{112\}$

Co., and Daisy shaft, Banner mine, Pima Co., AZ, with connellite, gerhardtite, and atacamite. *Boleo*, near Santa Rosalía, BCS, Mexico(1), with boleite and cumengeite. RG *DII*:80, *MR* 5:280(1974).

10.6.9.1 Bideauxite $\text{Pb}_2\text{AgCl}_3(\text{F},\text{OH})_2$

Named in 1970 for Richard A. Bideaux (b.1935), American mineralogist, who first noted the mineral. iso $Fd\bar{3}m$. $a = 14.132$, $Z = 16$, $D = 6.256$. $25\text{-}461$: 4.26₇ 4.08₇ 3.53₉ 3.24₇ 2.72₁₀ 2.50₉ 1.98₅ 1.84₆. Forms small crystals and masses. Colorless, turning pale lavender on exposure to light; adamantine luster. No cleavage, conchoidal fracture, brittle to sectile. $H = 3$. $G = 6.27$. Isotropic; $N = 2.18\text{--}2.19$. *Mammoth-St. Anthony mine*, *Tiger*, AZ, where it envelops and replaces boleite, associated with leadhillite, anglesite, matlockite, and cerussite. RG *MM* 37:637(1970), *AM* 57:1003(1972).

10.6.10.1 Chlormagaluminite $(\text{Mg},\text{Fe}^{2+})_4\text{Al}_2(\text{OH})_{12}(\text{Cl}_2,\text{CO}_3)\cdot 2\text{H}_2\text{O}$

Named in 1982 for the composition. Originally called "chlor-manasseite." $\text{HEX } P6/mcm$, $P6cm$, or $P6c2$. $a = 5.29$, $c = 15.46$, $Z = 1$, $D = 2.06$. *AM* 68:849(1983). $38\text{-}446$: 7.67₁₀ 3.86₈ 2.60₈ 2.34₉ 2.17₉ 1.839₁₀ 1.555₈ 1.526₉. Aggregates of hexagonal dipyrramids. Colorless to yellow-brown. Cleavage $\{0001\}$, perfect. $G = 2.0$. Uniaxial (+); $N_O = 1.540$, $N_E = 1.560$. Found in skarns from the *Kapaev explosion pipe*, *Angara R.*, southern Siberian Platform, *Russia*, associated with magnetite and chlorite. RG *ZVMO* 111:121(1982).

10.6.11.1 Kelyanite $\text{Hg}_{16}^+ \text{Hg}_{20}^{2+} \text{Sb}_3(\text{Cl},\text{Br})_9\text{O}_{28}$

Named in 1982 for the locality. MON Space group uncertain, probably $C2/m$. $a = 23.50$, $b = 13.62$, $c = 10.31$, $\beta = 97^\circ$, $Z = 2$, $D = 8.51$. *AM* 68:1248(1983). $35\text{-}714$: 3.78₆ 3.30₁₀ 3.24₅ 2.72₆ 2.53₆ 2.36₅ 1.95₅ 1.66₅. Irregular grains. Reddish brown. No cleavage. $G = 8.57$. In RL, grayish white, with red internal reflections, weakly birefractant, anisotropic. $R = 20.5\text{--}19.9$ (460 nm), 18.9–18.1 (546 nm), 17.8–17.1 (620 nm). From the oxidation zone of the stibnite-cinnabar ores of the *Kelyan deposit*, *Buryatia*, *Ural Mts.*, *Russia*, associated with calomel, eglestonite, Sb oxides, Hg, and shakovite. RG *ZVMO* 111:330(1982).

10.6.12.1 Ponomarevite $K_4Cu_4OCl_{10}$

Named in 1988 for Vasili V. Ponomarev (1940–1976), Russian chemist and volcanologist, investigator of the products of fumarolic activity at Tolbachik. MON *C2/c*. $a = 14.73$, $b = 14.86$, $c = 8.93$, $\beta = 104.9^\circ$, $Z = 4$, $D = 2.72$. *AM 75:709(1990)*. *45-1417*: 7.31_8 6.07_7 3.65_6 3.05_6 2.80_{10} 2.79_8 2.47_7 2.31_6 . Fine grained to glassy crusts. Red, orange-red streak, vitreous to resinous luster. Cleavage {001}, imperfect; also {110}; brittle. $H = 2\frac{1}{2}$. $G = 2.78$. Soluble in cold water; unstable in air, altering slowly to mitscherlichite. Biaxial (-); $N_x = 1.686$, $N_y = 1.718$, $N_z = 1.720$. Found as a product of fumarolic activity of the Tolbachik main fracture eruption, Kamchatka, Siberia, Russia, with halite, sylvite, tenorite, tolbachite, dolerophanite, and piypite. *RG DANS 300:1197(1988)*.

Halide Complexes; Alumino-Fluorides

11.1.1.1 Neighborite NaMgF_3

Named in 1961 for Frank Neighbor (b.1906), American petroleum geologist, Sun Oil Co., who observed and preserved the first specimens. ORTH *Pnma*. $a = 5.363$, $b = 7.676$, $c = 5.503$, $Z = 4$, $D = 3.06$. *AM* 46:379(1961). 13-303: 3.83₄ 2.71₅ 2.30₃ 2.23₂ 2.20₁ 1.92₁₀ 1.58₁ 1.56₃. Octahedral crystals, showing polysynthetic twinning; also as rounded grains. Colorless to pink; also brown when in alkalic syenitic rocks; vitreous luster. Uneven fracture. $H = 4\frac{1}{2}$. $G = 3.03$. Insoluble in water, soluble in acids. Nearly isotropic; $N = 1.364$. Birefringence 0.003. *South Ouray, Uintah Co., UT*, from drill cores penetrating the Green River Formation, associated with burbankite, nahcolite, barytoalcite, garrelsite, wurtzite, quartz, and dolomite. Mt. St.-Hilaire, QUE, Canada. Gjerdingen, Nordmark, Norway. *RG AM* 56:1519(1971), *DANS* 210:666(1973).

11.1.2.1 Carnallite $\text{KMgCl}_3 \cdot 6\text{H}_2\text{O}$

Named in 1856 for Rudolph von Carnall (1804-1874), Prussian mining engineer. ORTH *Pnna*. $a = 16.154$, $b = 22.508$, $c = 9.575$, $Z = 12$, $D = 1.590$. *NBSM* 25(8):50(1970). The structural framework of carnallite is made up of KCl_6 octahedra in a very open network with interstitial $\text{Mg}(\text{H}_2\text{O})_6$ octahedra. There are two nonequivalent KCl_6 octahedra, both distorted, one more than the other. Two-thirds of these octahedra share faces (have three common corners), and the other one-third share corners with these and with each other. The large openings in this resulting framework accommodate the unusual Mg octahedrally coordinated with neutral water molecules. These isolated chargeless ions are not bonded to each other or to the rest of the structure, but occupy fixed positions in the framework. The cation and water coordination around Cl is octahedral. There are five different chlorine anions, and each is coordinated to two potassium cations and to four water molecules (transmitting the charge of magnesium cations). *AM* 70:1309(1985). 24-869(syn): 4.69₄ 3.75₅ 3.60₇ 3.56₆ 3.32₁₀ 3.04₇ 2.93₁₀ 2.35₅. Crystals thick tabular {001}, pseudo-hexagonal, pyramidal; usually massive, granular. Colorless to white, often reddish due to enclosed oriented scales of hematite; rarely yellow or blue; greasy luster, dull to shining. No cleavage, conchoidal fracture. $H = 2\frac{1}{2}$. $G = 1.602$. Soluble in water. Tastes bitter. Deliquescent. In the closed

tube, fuses easily. Biaxial (+); XYZ = *cba*; $N_x = 1.468$, $N_y = 1.47$, $N_z = 1.495$; $2V_{\text{calc}} = 66^\circ$; $r < v$. Carnallite typically forms in marine evaporite salt beds, in part by reaction of preexisting saline minerals with liquor rich in potash. From the Permian salt basin of TX and NM, especially in the mines at Carlsbad, NM. *Stassfurt district, Germany*. Besenrode, upper Silesia, and Kalusz, Galicia, Poland. Barcelona and Lerida Provs., Spain. Ozinski, Saratov, Russia, with other potash salts. Ethiopia, on the plains of Danakil. Carnallite is an important source of potash for fertilizers and other purposes. RG *DII:92*, *MM 29:667(1951)*, *NJMM:100(1973)*.

11.1.3.1 Chlorocalcite KCaCl_3

Named in 1872 for the composition, which was originally thought to be chloride of calcium alone. Although chlorocalcite is highly deliquescent, rendering its recovery and study difficult, it has been observed in enough places that there is little doubt about its existence. ORTH Space group unknown. $a = 7.551$, $b = 10.42$, $c = 7.251$, $Z = 4$, $D = 2.155$. *NBSM 25(7):36(1969)*. *21-1170(syn)*: 5.23_3 3.70_3 3.14_4 3.12_3 3.06_2 2.61_{10} 2.38_2 2.11_3 . Forms cubelike crystals, sometimes with octahedral- or dodecahedral-like truncations; also prismatic or tabular. White, sometimes stained violet. Cubelike cleavage, with one direction better than the other two. $H = 2\frac{1}{2}$ -3. Biaxial (-); $N = 1.568$; very low birefringence; shows polysynthetic twinning. Strongly hygroscopic. Tastes bitter. *Mt. Vesuvius, Campania, Italy*, as a volcanic sublimate, associated with halite, sylvite, and hematite. Desdemona potash mine, Leinetal, Prussia, Germany. RG *DII:91*.

11.2.1.1 Pseudocotunnite K_2PbCl_4 (?)

Named in 1873 from the Greek *pseudo*, false, and *cotunnite*, a mineral it resembles in some respects. ORTH *Pnma*. $a = 11.80$, $b = 5.77$, $c = 9.82$, $Z = 4$, $D = 4.25$. Platy crystals, or acicular [001]; as warty aggregates of crusts. Colorless to white, yellow, or greenish yellow; dull luster. Biaxial; $N \approx 2.0$; strongly birefringent. Soluble in warm water, easily fusible. *Vesuvius, Italy*, in fumaroles, associated with cotunnite. RG *DII:96*, *ST:168*.

11.2.2.1 Avogadrite $(\text{K,Cs})\text{BF}_4$

Named in 1926 for Amadeo Avogadro (1776-1856), Italian physicist, University of Turin. Barite group [see barite (28.3.1.1)]. ORTH *Pnma*. $a = 8.659$, $b = 5.480$, $c = 7.030$, $Z = 4$, $D = 2.507$ -3.0, depending on Cs content. Structure: *AC(B) 25:2161(1969)*. *16-378(syn)*: 3.51_5 3.41_{10} 3.26_8 3.06_8 2.80_4 2.23_3 2.09_4 2.07_6 . Minute crystals, tabular {001} or elongated [010] or [100]; as dense crusts. Colorless to white. $G = 2.6$. Biaxial (-); $N_x = 1.324$, $N_y = 1.3245$, $N_z = 1.325$; $2V$ large, 90° (calc). Soluble in water, easily fusible. Tastes bitter. *Vesuvius, Italy*, in fumaroles. RG *DII:97*, *MA 11:535(1952)*.

11.2.3.1 Ferruccite NaBF_4

Named in 1933 for Ferruccio Zambonini (1880–1932), Italian mineralogist. ORTH *Cmcm*. $a = 6.837$, $b = 6.262$, $c = 6.792$, $Z = 4$, $D = 2.507$. Structure: *AC(B) 24:1703(1968)*. *11-671(syn)*: 3.82_2 3.41_9 3.39_{10} 2.84_3 2.31_4 2.14_2 2.03_2 2.00_2 . Minute crystals, tabular {001} or {010}. Colorless to white. Cleavage {100}, {010}, and {001}. $H = 3$. $G = 2.49$. Biaxial (+); $XYZ = cba$; $N_x = 1.301$, $N_y = 1.301$, $N_z = 1.307$; $2V = 11^\circ$. Soluble in water, giving a bitter, acid taste; easily fusible. *Vesuvius, Italy*, in fumaroles. RG *DII:98*.

11.2.4.1 Barberiite NH_4BF_4

Named in 1994 for Franco Barberi, Italian volcanologist, University of Pisa. ORTH *Pnma*. $a = 9.062$, $b = 5.673$, $c = 7.267$, $Z = 4$, $D = 1.90$. *AM 79:381(1994)*. *15-745(syn)*: 4.53_6 4.48_{10} 3.84_5 3.64_5 3.54_9 3.19_9 2.90_6 2.54_5 . Minute crystals, tabular to platy on {001}, forming globular aggregates. Colorless, transparent to translucent, white streak, vitreous luster. Cleavage {100}, perfect; {010}, {001}, good. $VHN_{25} = 14.2$ mg/mm². $G = 1.89$. Very unstable in air. Biaxial; $N_{\text{mean calc}} = 1.308$; $2V = \pm 90^\circ$. Found in fumaroles at the *Fossa crater on Vulcano, Aeolian Islands, Italy*, where it formed at a temperature of $< 600^\circ$, associated with sulfur, salammoniac, sassolite, mallardite, realgar, and various rare sulfides. RG

11.3.1.1 Douglasite $\text{K}_2\text{Fe}^{2+}\text{Cl}_4 \cdot 2\text{H}_2\text{O}$

Named in 1879 for the locality at Douglashall, Germany. MON Space group unknown. $\beta = 104.76^\circ$. *41-1358*: 5.07_5 4.16_6 4.03_6 3.67_8 3.08_{10} 2.97_5 2.37_4 1.822_4 . Coarsely granular. Light green, altering to brownish red; vitreous luster. Uniaxial (+); $N_O = 1.488$, $N_E = 1.500$. *Douglashall, NW of Stassfurt, Saxony, Germany*, associated with carnallite, sylvite, and halite. RG *DII:100*.

11.3.2.1 Mitscherlichite $\text{K}_2\text{CuCl}_4 \cdot 2\text{H}_2\text{O}$

Named in 1925 for Eilhard Mitscherlich (1794–1863), German crystallographer and chemist, who first prepared the compound. He also was the discoverer of isomorphism, in 1819. TER *P4₂/mnm*. $a = 7.454$, $c = 7.909$, $Z = 2$, $D = 2.416$. *NBSM 25(9):34(1971)*. *23-478(syn)*: 5.42_7 3.96_2 3.16_5 3.07_3 2.71_{10} 2.64_{10} 1.98_3 1.58_3 . Crystals pyramidal {011} or short prismatic {001}, twinning on {011}. Greenish blue, vitreous luster. $H = 2\frac{1}{2}$. $G = 2.42$. Uniaxial (-); $N_O = 1.638$, $N_E = 1.613$. O, sky blue; E, grass green. Soluble in water. *Vesuvius, Italy*, as stalactites on the floor of the crater. RG *DII:100*.

11.4.1.1 Erythrosiderite $\text{K}_2\text{Fe}^{3+}\text{Cl}_5 \cdot \text{H}_2\text{O}$

Named in 1872 for the Greek for *red* and *iron*. ORTH *Pnma*. $a = 13.585$, $b = 9.706$, $c = 7.018$, $Z = 4$, $D = 2.364$. *NBSM 25(14):27(1977)*. *29-1004(syn)*: 5.68_4 5.57_4 4.88_1 2.99_2 2.84_2 2.78_{10} 2.44_3 2.43_4 . Tabular or pseudo-octahedral crystals. Ruby-red to brownish red, vitreous luster. Cleavage {210} and {011}, perfect. $G = 2.37$. Slightly deliquescent. Biaxial (+);

XYZ = *abc*; $N_x = 1.715$, $N_y = 1.75$, $N_z = 1.80$; $2V = 62^\circ$; $r > v$, strong. *Vesuvius, Italy*, in fumaroles, associated with hematite. Stassfurt, Germany, as an efflorescence on rinneite. RG *DII:101*.

11.4.1.2 Kremersite $(\text{NH}_4, \text{K})_2\text{Fe}^{3+}\text{Cl}_5 \cdot \text{H}_2\text{O}$

Named in 1853 for Peter Kremers (b.1827), German chemist. ORTH *Pnma*. $a = 13.657$, $b = 9.808$, $c = 7.028$, $Z = 4$, $D = 2.175$. *NBSM 25(14):8(1977)*. *28-734(syn)*: 5.72₈ 5.61₆ 4.90₄ 2.86₃ 2.80₁₀ 2.79₆ 2.78₆ 2.45₇. Pseudo-octahedral crystals with {011} and {210} in equal development. Ruby-red to brownish red, vitreous luster. Cleavage {210} and {011}, perfect. $G = 2.00$. Biaxial (+). Soluble in water, very deliquescent. In natural kremersite the NH_4 has replaced only a little over half of the K, and the name refers to compounds where $\text{NH}_4/\text{K} > 1$. Al can substitute for some of the Fe. *Vesuvius, Italy*, in fumaroles. RG *DII:101*.

11.5.1.1 Hieratite K_2SiF_6

Named in 1882 for the locality in the crater of Vulcano (Greek name, Hiera). iso *Fm3m*. $a = 8.133$, $Z = 4$, $D = 2.719$. *NBSC 539(5):50(1955)*. *7-217(syn)*: 4.70₁₀ 2.88₇ 2.35₇ 2.03₅ 1.66₁ 1.56₁ 1.44₂ 1.29₁. Octahedral or cubo-octahedral crystals; as stalactitic concretions. Colorless to white or gray, vitreous luster. Cleavage {111}, perfect. $H = 2\frac{1}{2}$. $G = 2.668$. Isotropic; $N = 1.340$ (Na). Soluble in water; in CT sublimes without residue. *Vulcano, Lipari Is., Sicily, Italy*, in fumaroles; also on Vesuvius. RG *DII:103*.

11.5.1.2 Cryptohalite $(\text{NH}_4)_2\text{SiF}_6$

Named in 1873 from the Greek for *concealed* and *salt*, in allusion to its intimate mixture with other salts at the original locality. Dimorphous with bararite (11.5.2.2). iso *Fm3m*. $a = 8.395$, $Z = 4$, $D = 2.000$. *NBSC 539(5):5(1955)*. *44-1484(syn)*: 4.84₁₀ 4.20₁ 2.97₁ 2.53₁ 2.42₂ 2.10₁ 1.615₁ 1.484₁. Massive or arborescent; mammillary. Colorless to white or gray, vitreous luster. Cleavage {111}, perfect. $H = 2\frac{1}{2}$. $G = 2.00$. Isotropic; $N = 1.369$ (Na). Soluble in water, in CT sublimes without residue. *Vesuvius, Italy*, in fumaroles. Kladno, Bohemia, Czech Republic, in burning coal-waste heaps. Barari, Jharia coal field, India, in crevices as a sublimate over a burning coal seam. RG *DII:104*.

11.5.2.1 Malladrite Na_2SiF_6

Named in 1926 for Alessandro Malladra (1868–1945), Italian volcanologist, director of the Vesuvius Observatory. HEX-R *P321*. $a = 8.866$, $c = 5.043$, $Z = 3$, $D = 2.729$. *NBSM 25(16):68(1979)*. Structure: *AC 17:1408(1964)*. *33-1280(syn)*: 4 43₁₀ 4.21₉ 3.33₉ 3.06₅ 2.28₉ 1.80₅ 1.66₂ 1.59₂. Crystals prismatic [001]; as crusts. Pale rose to colorless. $G = 2.755$. Uniaxial (-); $N_O = 1.313$, $N_E = 1.309$. Slightly soluble in water, more so in hot water. *Vesuvius, Italy*, in fumaroles. RG *DII:105*.

11.5.2.2 Bararite (NH₄)₂SiF₆

Named in 1951 for the locality. Dimorphous with cryptohalite (11.5.1.2). HEX-R $P3m1$. $a = 5.77$, $c = 4.78$, $Z = 1$, $D = 2.144$. $44-1424$: 4.99_{10} 4.77_2 3.45_3 2.39_{10} 2.21_4 1.753_1 1.724_1 1.479_1 . Crystals tabular {0001}; also arborescent, mammillary. White to colorless, vitreous luster. Cleavage {0001}; perfect. $H = 2\frac{1}{2}$. $G = 2.15$. Uniaxial (-); $N_O = 1.406$, $N_E = 1.391$ (Na). Soluble in water; in the closed tube sublimes without residue. Vesuvius, Italy, in fumaroles. *Barari, Jharlia coalfield, Bengal, India*, as a crusted sublimate above a burning coal seam. RG *DII:106, AM 37:361(1952)*.

11.5.3.1 Rinneite K₃NaFe²⁺Cl₆

Named in 1909 for Freidrich Wilhelm Berthold Rinne (1863–1933), German crystallographer and petrographer. HEX-R $R3c$. $a = 12.024$, $c = 13.852$, $Z = 6$, $D = 2.348$. Structure: *SR 49A:115(1982)*. $20-925$: 6.00_6 5.75_4 3.65_2 3.46_3 2.81_4 2.65_4 2.59_5 2.51_{10} . Massive, granular. Colorless when pure and fresh; usually rose, violet, or yellow, becoming brown on exposure; brilliant luster, sometimes silky. Cleavage {1120}, good; splintery, conchoidal fracture. $H = 3$. $G = 2.35$. Uniaxial (+); $N_O = 1.589$, $N_E = 1.589$ (Na); birefringence 0.0008. Soluble in water, tastes astringent, in CT easily fusible. Formed as a secondary product in marine evaporite salt deposits. *Wolkramshausen, near Nordhausen, Saxony, Germany*, and at several localities in Hannover. RG *DII:107*.

11.5.4.1 Chlormanganokalite K₄MnCl₆

Named in 1906 for the composition. HEX-R $R3c$. $a = 11.94$, $c = 14.81$, $Z = 6$, $D = 2.310$. 3.856 (syn): 5.90_5 4.90_2 3.55_5 3.45_2 2.82_3 2.69_8 2.55_{10} 2.50_2 . Crystals rhombohedrons, sometimes arranged in parallel groups. Pale yellow to canary yellow, vitreous luster. Conchoidal fracture, brittle. $H = 2.5$. $G = 2.31$. Uniaxial (+); $N \approx 1.59$; low birefringence. *Vesuvius, Italy*, with halite, sylvite, and hematite crystals, lining cavities in blocks of scoria. RG *DII:109, ST:163*.

11.5.5.1 Tachyhydrite Mg₂CaCl₆ · 12H₂O

Named in 1856 from the Greek for *quick water*, in allusion to its ready deliquescence. HEX-R $R3$. $a = 10.136$, $c = 17.318$, $Z = 3$, $D = 1.673$. Structure: *AC(B) 36:2736(1980)*. $34-788$: 5.77_4 5.07_1 3.81_1 3.10_1 2.88_{10} 2.61_3 1.983_2 1.443_3 . Massive. Colorless to yellow, vitreous luster. Cleavage {1011}, perfect. $H = 2$. $G = 1.667$. Uniaxial (-); $N_O = 1.520$, $N_E = 1.512$ (Na). Very deliquescent, tastes sharp and bitter. *Stassfurt* and elsewhere in *Saxony, Germany*, a rare constituent of marine evaporites. RG *DII:95*.

11.5.6.1 Gagarinite-(Y) NaCaY(F,Cl)₆

Named in 1961 for Yuri Alekseevich Gagarin (1934–1968), Russian cosmonaut, first person to travel in space. HEX-R $P3$. $a = 5.99$, $c = 3.53$, $Z = 1$, $D = 4.02$. *DANS 149:672(1963)*. $15-69$: 5.24_3 3.00_5 2.92_5 2.28_2 2.09_9 1.96_2 1.72_{10} 1.13_3 . Cryptocrystalline, massive. Creamy to yellowish or rosy, white

streak, dull to vitreous luster. Cleavage $\{0001\}$, fair; brittle. $H = 4\frac{1}{2}$. $G = 4.21$. Slightly magnetic, similar to glaucophane. Uniaxial (+); $N_O = 1.472$, $N_E = 1.492$; sometimes anomalously biaxial, with $2V$ to 20° . Soluble in acids, partially decomposed by H_2O . Found in alkaline rocks. Washington Pass, WA. Langesundfjord, Norway. *Kazakhstan*. RG *DANS 141:954(1961)*, *AM 47:805(1962)*.

11.5.7.1 Zajacite-(Ce) $Na(Ce,REE,Ca)_2F_6$

Named in 1995 for Ihor Stephan Zajac (b.1935), Canadian geologist, who led the exploration group that discovered the Strange Lake, Canada, deposit. *HEX-R P3*. $a = 6.099$, $c = 11.064$, $Z = 3$, $D = 4.55$. *PD*: 5.29₇ 3.04₁₀ 2.35₃ 2.15₇ 1.75₈ 1.361₃ 1.152₄ 0.919₄. Forms anhedral grains to 2 mm. Colorless to pale pink, white streak, vitreous luster, nonfluorescent. No cleavage, conchoidal fracture. $H = 3\frac{1}{2}$. $G = 4.44$. Uniaxial (+); $N_E = 1.483$, $N_O = 1.503$ (Na). From the peralkaline granite intrusive complex at *Strange Lake, near Schefferville, QUE/NF border, Canada*, associated with bastnaesite-(Ce) and vlasovite. RG *CM 34:(1996)*.

11.6.1.1 Cryolite Na_3AlF_6

Named in 1799 from the Greek for *ice* and *stone*, in allusion to the icelike appearance of the mineral. *MON P2₁/n*. $a = 5.402$, $b = 5.596$, $c = 7.756$, $\beta = 90.28^\circ$, $Z = 2$, $D = 2.963$. Structure: *CM 13:37(1975)*. *22-772(syn)*: 4.54₆ 4.44₄ 3.89₇ 2.80₃ 2.75₁₀ 2.34₃ 1.94₁₀ 1.57₄. Rare, equant, pseudocubic crystals; usually massive, coarsely granular; twinning common, by several different laws, often repeated or polysynthetic. Colorless to white; also brownish, reddish, brick-red, rarely black; white streak; vitreous to greasy luster. No cleavage; uneven fracture; parting on $\{100\}$ and $\{110\}$, producing cuboidal forms; brittle. $H = 2\frac{1}{2}$. $G = 2.97$. Weakly thermoluminescent. Biaxial (+); $Y = b$; $Z \wedge c = -44^\circ$; $N_x = 1.3376$, $N_y = 1.3377$, $N_z = 1.3387$ (Na); $2V = 43^\circ$; $r < v$, horizontal. Small clear fragments, when placed in water, become nearly invisible. Easily soluble in $AlCl_3$ solution, soluble in H_2SO_4 with evolution of HF (poison!). Fusible in small fragments in a candle flame. Alters by weathering to a series of secondary fluorides, including pachnolite, thomsenolite, gearksutite, prosopite, cryolithionite, weberite, jarlite, and others. St. Peter's Dome, Pikes Peak area, CO; Morefield mine, Amelia, VA; Francon quarry, Montreal, QUE, Canada, in small yellow crystals; also Mt. St.-Hilaire. Cryolite was the principal mineral in an extraordinary large pegmatite mass at *Ivigtut, Greenland*. This body, which was mined more or less continuously for over 100 years, also contained siderite, microcline, quartz, fluorite, chiolite, topaz, and minor sulfides and oxides, in addition to other rare and unusual fluorides, many formed by alteration. Miask, Ural Mts., Russia. Molten cryolite is used as a solvent for bauxite in the electrolysis of aluminum oxide to form aluminum. Since the depletion of the Ivigtut deposit, all cryolite used today is synthetic. RG *DII:110*, *AM 35:149(1950)*, *MA 78:877(1978)*, *MR 24:31(1993)*.

11.6.2.1 Elpasolite K_2NaAlF_6

Named in 1883 for the locality in El Paso Co., CO. iso $Fm\bar{3}m$. $a = 8.122$, $Z = 4$, $D = 3.002$. *NBSM 25(9):43(1971)*. Structure: *NJMM:481(1987)*. *22-1235(syn)*: 4.69_2 2.87_{10} 2.35_8 2.03_9 1.66_3 1.44_4 1.28_1 1.09_1 . Massive, as indistinct cubo-octahedral crystals. Colorless to white, vitreous to greasy luster; also purple. No cleavage, uneven fracture. $H = 2\frac{1}{2}$. $G = 2.99$. Isotropic; $N = 1.376$. Morefield pegmatite, Amelia, VA, in purple masses, with chiolite, cryolite, and prosopite. *St. Peter's Dome, Pikes Peak region, El Paso Co., CO*, lining cavities in massive pachnolite in a cryolite pegmatite. *RG DII:114*.

11.6.3.1 Colquiriite $LiCaAlF_6$

Named in 1980 for the locality. $HEX-R$ $P\bar{3}1c$. $a = 5.02$, $c = 9.67$, $Z = 2$, $D = 2.95$. *43-1481*: 3.96_6 3.22_{10} 2.22_9 2.11_3 1.976_4 1.735_8 1.551_4 1.445_4 . Anhedronal grains to 1 cm. White. No cleavage, conchoidal fracture. $H = 4$. $G = 2.94$. Nonfluorescent. Uniaxial (-); $N_O = 1.388$, $N_E = 1.385$. *Colquiri cassiterite deposit, Bolivia*, intergrown with ralstonite and gearsutite. *RG TMPM 27:275(1980)*, *AM 66:879(1981)*.

11.6.4.1 Cryolithionite $Na_3Li_3Al_2F_{12}$

Named in 1904 for the mineral cryolite, which it resembles, plus the additional lithium content. iso $Ia\bar{3}d$. $a = 12.125$, $Z = 8$, $D = 2.770$. *NBSM 25(9):23(1971)*. *22-416*: 4.28_{10} 3.03_6 2.71_4 2.38_4 2.21_5 1.97_6 1.92_2 1.62_3 . Dodecahedral crystals, massive, as irregular grains. Colorless to white, vitreous luster. Cleavage {011}, distinct; uneven fracture. $H = 2\frac{1}{2}$. $G = 2.77$. Isotropic; $N = 1.3395$ (Na). *Ivigut, Greenland*, intimately associated with cryolite. Also with cryolite at Miask, Ural Mts., Russia. *RG DII:99, AM 56:18(1971)*, *MR 24:33(1993)*.

11.6.5.1 Pachnolite $NaCaAlF_6 \cdot H_2O$

Named in 1863 from the Greek for *frost* and *stone*, in allusion to its appearance. Dimorphous with thomsenolite (11.6.6.1). MON $F2/d$. $a = 12.117$, $b = 10.414$, $c = 15.680$, $\beta = 90.36^\circ$, $Z = 16$, $D = 2.983$. Structure: *CM 21:561(1983)*. *5-356*: 3.95_{10} 3.26_1 3.02_2 2.92_1 2.79_7 2.40_1 2.16_5 1.97_9 . Prismatic crystals, bounded by {110} and {111}, always twinned [001]. White, vitreous luster. Cleavage {001}, indistinct; uneven fracture. $H = 3$. $G = 2.98$. Biaxial (+); $X = b$; $Z \wedge c = 69^\circ$; $N_x = 1.411$, $N_y = 1.413$, $N_z = 1.420$; $2V = 76^\circ$; $r < v$, weak; strong horizontal dispersion. Soluble in H_2SO_4 , easily fusible; in CT decrepitates, yields acid water, etches the glass, and leaves a white coating of silica. Morefield mine, Amelia, VA. *St. Peter's Dome, El Paso Co., CO*, with thomsenolite, elpasolite, and other fluorides. *Ivigut, Greenland*, as an alteration product of cryolite. Gjerdingen, Norway. Hagendorf Süd, Germany. *RG DII:114, MR 24:34(1993)*.

11.6.6.1 Thomsenolite $\text{NaCaAlF}_6 \cdot \text{H}_2\text{O}$

Named in 1868 for Hans Peter Jorgen Julius Thomsen (1826–1909), Danish physical chemist and founder of the Greenland cryolite industry. Dimorphous with pachnolite (11.6.5.1). MON $P2_1/c$. $a = 5.583$, $b = 5.508$, $c = 16.127$, $\beta = 96.43^\circ$, $Z = 4$, $D = 2.974$. NBSM 25(8):132(1970). Structure: AC 23:162(1967). 5-343: 4.02₁₀ 3.43₁ 2.92₅ 2.16₂ 2.00₈ 1.96₉ 1.76₃ 1.64₂. Crystals long prismatic {110} and {001}; occasionally, pseudocubic; also massive. White to colorless or pale pink, sometimes stained with iron oxides; vitreous luster, pearly on {001}. Cleavage {001}, perfect; {110}, distinct; uneven fracture; brittle. $H = 2$. $G = 2.98$. Biaxial (-); $Z = b$; $X \wedge c = -52^\circ$; $N_x = 1.407$, $N_y = 1.414$, $N_z = 1.415$; $2V = 50^\circ$; $r < v$, weak. Easily soluble in H_2SO_4 ; in CT decrepitates, yields acid water, and etches the glass. St. Peter's Dome, Pikes Peak region, El Paso Co., CO. In rhyolite at the Spider claim, Juab Co., UT, associated with drusy tridymite and sodium boltwoodite. Ivigtut, Greenland, with pachnolite, ralstonite, and fluorite. Miask, Ural Mts., Russia. RG DII:116, MR 24:34(1993).

11.6.7.1 Carlhintzeite $\text{Ca}_2\text{AlF}_7 \cdot \text{H}_2\text{O}$

Named in 1979 for Carl Hintze (1851–1916), German mineralogist, professor of mineralogy at the University of Breslau and compiler of the *Handbuch der Mineralogie*. TRIC (pseudo-MON $C1$ or $C1$). $a = 9.48$, $b = 6.98$, $c = 9.30$, $\alpha = 91.13^\circ$, $\beta = 104.85^\circ$, $\gamma = 90.00^\circ$, $Z = 4$, $D = 2.89$. CM 17:103(1979). 33-249: 4.56₇ 3.69₆ 3.48₁₀ 2.85₄ 2.28₃ 2.24₃ 2.08₃ 1.46₄. Crystals prismatic [010], always twinned about [010], with forms {100}, {001}, and {110}; sometimes in radiating druses resembling pectolite. White to colorless, vitreous luster. $G = 2.86$. Biaxial (+); $X = b$; $Z \wedge c = 10^\circ$; $N_x = 1.411$, $N_y = 1.416$, $N_z = 1.422$; $2V = 77^\circ$. Hagendorf, Germany, in pegmatite, associated with rockbridgeite, pyrite, strengite, and apatite, formed from the hydrothermal alteration of primary triphylite. RG AM 65:205(1980).

11.6.8.1 Gearsutite $\text{CaAl}(\text{F},\text{OH})_5 \cdot \text{H}_2\text{O}$

Named in 1868 from the Greek *Ge*, Earth, because it is usually earthy, and *arksutite*, from the locality near Arksut fjord. Pseudo-TET (possibly MON) Space group unknown. 5-283: 4.55₁₀ 3.34₇ 3.15₈ 2.28₈ 2.15₆ 2.07₄ 1.93₈ 1.74₆. Massive or earthy, chalky, consisting of minute needles. White, dull luster. $H = 2$. $G = 2.77$. Biaxial (-); $X = b$; $Z \wedge$ elongation; $N_x = 1.448$, $N_y = 1.454$, $N_z = 1.456$; $2V_{\text{calc}} = 60^\circ$. In CO at St. Peter's Dome, Pikes Peak area, in a cryolite pegmatite, and Wagon Wheel Gap, in wall-rock alteration of a fluorite–barite vein in rhyolite. Grand Reef mine, Graham Co., AZ. Sierra Blanca Peaks, Hudspeth Co., TX. Ivigtut, Greenland, as an alteration product of cryolite. Miask, Ural Mts., Russia. RG DII:119, AM 34:383(1949).

11.6.9.1 Prosopite $\text{CaAl}_2(\text{F},\text{OH})_8$

Named in 1853 from the Greek for *mask*, in allusion to the deceptive character of the mineral. MON $C2/c$. $a = 6.705$, $b = 11.158$, $c = 7.364$, $\beta = 95^\circ$, $Z = 4$,

$D = 2.898$. *NJMM:329(1986)*. $5-307: 4.35_{10} 3.24_4 3.07_5 2.31_4 2.13_6 1.91_5 1.84_6 1.81_6$. Crystals tabular {010}; also massive, granular to powdery. Colorless to white or grayish, also lavender; vitreous to greasy luster. Cleavage {111}, perfect; uneven to conchoidal fracture. $H = 4\frac{1}{2}$. $G = 2.89$. Biaxial (+); $Y = b$; $Z \wedge c = -35^\circ$; $N_x = 1.501$, $N_y = 1.503$, $N_z = 1.510$ (Na); $2V = 63^\circ$; $r > v$, strong. Soluble in H_2SO_4 , infusible. Morefield mine, Amelia, VA, in fine-grained lavender to gray masses, associated with topaz, fluorite, albite, and kaolinite. St. Peter's Dome, El Paso Co., CO. Ivigtut, Greenland. *Altenberg, Sachsen, Germany*, in greisen, partly altered to kaolin and fluorite. In the tin veins of Schlaggenwald, Bohemia, Czech Republic. Mt. Bischoff, TAS, Australia. *RG DII:121, AM 34:383(1949), DANS 190:665(1970)*.

11.6.10.1 Jarlite $NaSr_3Al_3(F,OH)_{16}$

Named in 1933 for Carl Frederick Jarl (1872–1951), Danish chemist, owner of the Danish cryolite industry, 1912–1943. *MON C2/m*. $a = 15.942$, $b = 10.821$, $c = 7.241$, $\beta = 101.82^\circ$, $Z = 4$, $D = 4.06$. Structure: *CM 21:553(1983)*. $5-594: 3.63_4 3.45_4 3.19_9 3.11_6 2.98_{10} 2.15_7 2.00_4 1.82_6$. Minute crystals, tabular {100}; often in sheaflike aggregates; also massive. Colorless to white; gray; greenish gray, vitreous luster. $H = 4-4\frac{1}{2}$. $G = 3.78-3.93$. Biaxial (\pm); $Y = b$; $X \wedge c = -6^\circ$; $Z \wedge c = 84^\circ$; $2V \approx 90^\circ$. Some Ca, Mg, and Ba can substitute for Sr. Soluble in $AlCl_3$ solution; easily fusible, with effervescence. *Ivigtut, Greenland*, with cryolite, thomsenolite, and chiolite. *RG DII:118, AM 34:383(1949), NJMM:543(1985), MR 24:35(1993)*.

11.6.10.2 Calcjarlite $Na(Ca,Sr)_3Al_3(F,OH)_{16}$

Named in 1973 for the composition, calcium-dominant jarlite. *MON C2/m*. $a = 16.19$, $b = 9.868$, $c = 7.157$, $\beta = 99.2^\circ$, $Z = 4$, $D = 3.32$. $29-1195: 3.51_5 3.44_3 3.16_6 3.04_7 2.96_{10} 2.68_8 2.23_4 2.15_4$. Massive. White, vitreous luster. No cleavage, uneven fracture. $H = 4$. $G = 3.51$. Biaxial (+); $Z \wedge c = 10-15^\circ$; $N_x = 1.425$, $N_y = 1.428$, $N_z = 1.432$; $2V = 72^\circ$. *Yenisei region, Siberia, Russia*, with fluorite and usovite. *RG ZVMO 99:458(1970), AM 59:873(1974)*.

11.6.11.1 Chiolite $Na_5Al_3F_{14}$

Named in 1846 from the Greek for *snow*, in allusion to its appearance. *TET P4/mnc*. $a = 7.014$, $c = 10.400$, $Z = 2$, $D = 2.998$. *NBSM 25(16):63(1979)*. $30-1144(\text{syn}): 5.81_2 5.20_3 2.91_{10} 2.33_5 2.00_3 1.79_3 1.75_2 1.55_3$. Crystals rare, dipyrmidal {011}; usually massive, granular; twinning on {011}, sometimes distorted into prismatic shapes. Colorless to white; vitreous luster, pearly on cleavage. Cleavage {001}, perfect; {011}, distinct. $H = 3\frac{1}{2}-4$. $G = 3.00$. Soluble in H_2SO_4 and in $AlCl_3$ solution, easily fusible. Uniaxial (-); $N_O = 1.343$, $N_E = 1.350$. In crystals at the Morefield mine, Amelia, VA, associated with elpasolite, cryolite, and prosopite. Ivigtut, Greenland, in small masses. *Miask, Ilmen Mts., Ural Mts., Russia*, in a cryolite pegmatite, with topaz, phenacite, fluorite, and other fluorides. *RG DII:123, BGS D 26:95(1977)*.

11.6.12.1 Ralstonite $\text{Na}_x\text{Mg}_x\text{Al}_{2-x}(\text{F},\text{OH})_6 \cdot \text{H}_2\text{O}$

Named in 1871 for J. Grier Ralston of Norristown, PA (1815–1880), minister, educator, and amateur scientist, who first observed the mineral. ISO *Fd3m*. $a = 9.91$, $Z = 8$, $D = 2.78$. Structure: *NJMM:97(1984)*. 45-1331: 5.74₁₀ 2.99₆ 2.86₅ 2.28₁ 2.03₁ 1.903₂ 1.755₃ 1.497₁. Crystallizes as octahedra; more rarely as cubes, or the two in combination. Colorless to white, vitreous luster. Cleavage {111}, imperfect; uneven fracture. $H = 4\frac{1}{2}$. $G = 2.50$ –2.68. Isotropic; $N = 1.37$ –1.43. Decomposed by H_2SO_4 with evolution of HF (poison!); in closed tube whitens, yields acid water, then a copious white sublimate that etches the tube. The composition varies rather widely, even in a single crystal, from near $\text{NaMgAl}(\text{F},\text{OH})_6 \cdot \text{H}_2\text{O}$ to $\text{Na}_{0.5}\text{Mg}_{0.5}\text{Al}_{1.5}(\text{F},\text{OH})_6 \cdot \text{H}_2\text{O}$ and F/OH from 2:1 to 11:1. The hypothetical Al-rich end member is basic aluminum fluoride, $\text{Al}_2(\text{F},\text{OH})_6 \cdot \text{H}_2\text{O}$, but natural material with this composition has not been found. St Peter's Dome, El Paso Co., CO; *Ivigut, Greenland*; also in Kazakhstan, and in Kamchatka, Siberia, Russia. RG *DII:126, AM 50:1851(1965), MM 54:599(1990)*.

11.6.13.1 Weberite $\text{Na}_2\text{MgAlF}_7$

Named in 1938 for Theobald C. F. Weber (1823–1886), one of the founders of the cryolite industry in Denmark. ORTH *Imma*. $a = 7.060$, $b = 10.000$, $c = 7.303$, $Z = 4$, $D = 2.948$. Structure: *TMPM 25:57(1978)*. 5-733: 5.90₅ 5.06₆ 2.96₉ 2.90₉ 2.30₅ 1.78₁₀ 1.55₅ 0.882₆. Irregular grains and masses. Light gray, white streak, vitreous luster. Cleavage {101}, poor; {010}, indistinct; uneven fracture. $H = 3\frac{1}{2}$. $G = 2.96$. Biaxial (+); $\text{XYZ} = abc$; $N_x = 1.346$, $N_y = 1.348$, $N_z = 1.350$; $2V = 83^\circ$. Soluble in AlCl_3 solution; in closed tube gives acid vapors. St. Peter's Dome, El Paso Co., CO. *Ivigut, Greenland*, with cryolite and other fluorides. RG *DII:127, AM 34:383(1949)*.

11.6.14.1 Usovite $\text{Ba}_2\text{CaMgAl}_2\text{F}_{14}$

Named in 1967 for Mikhail Antonovich Usov (1883–1939), Russian geologist. MON *C2/c* or *Cc*. $a = 13.565$, $b = 5.200$, $c = 14.557$, $\beta = 91.35^\circ$, $Z = 4$, $D = 4.26$. 19-1391: 3.41₁₀ 2.04₇ 1.205₉ 1.132₈ 1.093₈ 1.025₈ 1.012₈ 1.005₈. Irregular grains, or indistinct elongated platy forms. Brown, white streak, vitreous to greasy luster. Cleavage in one direction, perfect; irregular fracture. $H = 3\frac{1}{2}$. $G = 4.18$. Biaxial (+); Y parallel to cleavage; $N_x = 1.441$, $N_y = 1.442$, $N_z = 1.444$; $2V = 70^\circ$; absorption $X = Y > Z$. X, Y, brownish yellow; Z, pale yellow. *Upper Noiby River area, Yenisei region, Siberia, Russia*, in a fluorite vein. RG *AM 52:1582(1967), 60:739(1975)*.

11.6.15.1 Yaroslavite $\text{Ca}_3\text{Al}_2\text{F}_{10}(\text{OH})_2 \cdot \text{H}_2\text{O}$

Named in 1966 for the locality. ORTH Space group unknown. $a = 8.76$, $b = 5.54$, $c = 4.52$, $Z = 4$, $D = 3.15$. 18-272: 4.51₆ 3.66₇ 3.45₁₀ 2.83₅ 2.26₅ 2.23₈ 1.839₆ 1.47₆. Radial-fibrous or spherical growths. White, vitreous luster. Pinacoidal cleavage, irregular fracture. $H = 4$. $G = 3.09$. Slightly fluorescent pale violet in SWUV. Biaxial (+); $N_x = 1.413$, $N_z = 1.423$; $2V = 74^\circ$; negative

elongation. *Yaroslav, Siberia, Russia*, in cavities in sellaite in banded fluorite–sellaite–tourmaline ores. RG *ZVMO* 95:39(1966), *AM* 51:1546(1966).

11.6.16.1 Tikhonenkovite $\text{SrAl}(\text{OH})\text{F}_4 \cdot \text{H}_2\text{O}$

Named in 1964 for Igor Petrovich Tikhonenkov (1927–1961), Russian student of alkaline rocks and minerals. Dimorphous with acuminite (11.6.17.1). MON Space group unknown. $a = 8.73$, $b = 10.62$, $c = 5.02$, $\beta = 102.43^\circ$, $Z = 4$, $D = 3.30$. 17-501: 4.89₁₀ 4.44₅ 3.64₉ 3.33₅ 3.27₈ 3.14₅ 2.30₆ 2.10₇. Prismatic crystals. Colorless to slightly pink, vitreous luster. Cleavage {001}, perfect; conchoidal to uneven fracture. $H = 3\frac{1}{2}$. $G = 3.26$. Biaxial (-); $N_x = 1.452$, $N_y = 1.456$, $N_z = 1.458$; $2V = 70^\circ$. *Karasug, Tannu-Ola range, Tuva, Russia*, in fissures and druses in iron ores, with gearksutite, fluorite, celestite, strontianite, and barite. RG *DANS* 156:104,345(1964), 174:193(1967); *AM* 49:1774(1964).

11.6.17.1 Acuminite $\text{SrAlF}_4(\text{OH}) \cdot \text{H}_2\text{O}$

Named in 1987 from the Latin for *spearhead*, in allusion to the crystal shape. Dimorphous with tikhonenkovite (11.6.16.1). MON $C2/c$. $a = 13.223$, $b = 5.175$, $c = 14.251$, $\beta = 111.6^\circ$, $Z = 8$, $D = 3.305$. Structure: *ZK* 194:221(1991). *PD*: 4.77₁₀ 4.71₁₀ 3.50₁₀ 3.35₁₀ 3.31₈ 3.29₈ 2.07₉ 2.03₈. Aggregates of crystals shaped like spear points and about 1 mm long, with {110} and {111}; twins on {100}. Colorless, vitreous luster. Cleavage {001}, perfect. $H = 3\frac{1}{2}$. $G = 3.295$. Nonfluorescent. Biaxial (+); $X = b$; $Y \wedge c = 15^\circ$; $N_x = 1.451$, $N_y = 1.453$, $N_z = 1.463$; $2V = 46\text{--}57^\circ$; $r > v$, very strong. *Iviglut, Greenland*, with celestite, fluorite, jarlite, thomsenolite, and other fluorides. RG *NJMM* 1987:502, *AM* 73:1492(1988), *MR* 24:36(1993).

11.6.18.1 Artroeite $\text{PbAlF}_3(\text{OH})_2$

Named in 1995 for Arthur (Art) Roe (1912–1993), U.S. chemist, professor, University of North Carolina, micromounter, and mineralogist. TRIC $P1$. $a = 6.259$, $b = 6.791$, $c = 5.053$, $\alpha = 90.92^\circ$, $\beta = 107.45^\circ$, $\gamma = 104.45^\circ$, $Z = 2$, $D = 5.47$. *AM* 80:179(1995). *PD*: 4.42₀ 4.05₄ 3.27₄ 3.22₄ 2.60₇ 2.19₇ 2.03₅ 2.015₄. Minute crystals, bladed, flattened on {10 $\bar{1}$ }, usually twinned on [010]. Colorless, white streak, vitreous luster. Cleavage {100}, perfect; {010}, good; conchoidal fracture; brittle. $H = 2\frac{1}{2}$. $G = 5.36$. Biaxial (-); $N_x = 1.629$, $N_y = 1.682$, $N_z = 1.691$; $r > v$, strong. Found in a single 15 mm \times 5 mm vug surrounded by galena and fluorite, at the *Grand Reef mine, near Klondyke, Graham Co., AZ*. RG

11.6.19.1 Aravaipaite $\text{Pb}_3\text{AlF}_9 \cdot \text{H}_2\text{O}$

Named in 1989 for the locality in the Aravaipa mining district, AZ. TRIC $P1$ or $P\bar{1}$. $a = 5.842$, $b = 25.20$, $c = 5.652$, $\alpha = 93.83^\circ$, $\beta = 90.13^\circ$, $\gamma = 85.28^\circ$, $Z = 4$, $D = 6.37$. 45-1458: 12.5₈ 3.65₇ 3.50₆ 3.33₆ 3.13₁₀ 2.92₄ 2.82₄ 2.03₄. Crystals platy {010}, polysynthetically twinned. Colorless, white streak, vitreous to pearly luster. Cleavage {010}, perfect; {100}, {001}, {101}, {101}, good; irre-

gular fracture; flexible. $H = 2$. No fluorescence. Biaxial (-); $X \wedge \phi = 67^\circ$; $Z \wedge \theta = 76^\circ$; $N_x = 1.678$, $N_y = 1.690$, $N_z = 1.694$; $2V = 70^\circ$; $r < v$, strong. Formed by the reaction of supergene solutions on galena and fluorite. *Grand Reef mine, Laurel Canyon, Graham Co., AZ*, in a vug surrounded by layers of quartz, fluorite, and galena. RG AM 74:927(1989).

11.6.20.1 Bøgvadite $\text{Na}_2\text{SrBa}_2\text{Al}_4\text{F}_{20}$

Named in 1988 for Richard Bøgvad (d.1952), Danish, former chief geologist for the cryolite mining company. ORTH $Pn\bar{m}n$ or $Pn2n$. $a = 7.110$, $b = 19.907$, $c = 5.347$, $Z = 2$, $D = 3.898$. BGSD 37:21(1988). 45-1419: 9.97₄ 6.69₄ 3.24₁₀ 3.19₅ 2.92₅ 2.67₄ 2.38₄ 2.12₅. Blocky crystals, showing {110}, {010}, and {012}. Colorless, white streak, vitreous luster. Uneven fracture. $VHN_{25} = 300$. $G = 3.85$. Nonfluorescent. Biaxial (-); $XYZ = cab$; $OAP = \{010\}$; $N_x = 1.433$, $N_y = 1.436$, $N_z = 1.439$ (Na); $2V = 87^\circ$. *Ivigut, Greenland*, with jarlite, ralstonite, barite, muscovite, and quartz. RG AM 76:1728(1991), MR 24:36(1993).

11.6.21.1 Karasugite $\text{SrCaAl}[\text{F},(\text{OH})]_7$

Named in 1994 for the locality. MON $P2_1/c$. $a = 8.215$, $b = 11.989$, $c = 6.076$, $\beta = 96.22^\circ$, $Z = 2$, $D = 3.206$. NJMM:209(1994). PD: 6.76₇ 4.25₁₀ 3.64₈ 3.15₇ 3.06₈ 3.03₇ 2.84₇ 2.13₈. Rosettes and fan-shaped aggregates of microcrystals, bladed on {100}, elongated [001], twinned with (100) as both twin and composition plane. Colorless, transparent, white streak, vitreous luster. Cleavage {100}, perfect; splintery fracture; brittle. Nonfluorescent. Biaxial (+); $Y = b$, $X \wedge c = 7^\circ$; $N_x = 1.424$, $N_y = 1.432$, $N_z = 1.442$; $2V_{\text{meas}} = 94.5^\circ$. From the *Karasug Fe-REE-barite-fluorite deposit, in the western part of the Tannu-Ola range, N of Karasug in southern Siberia, Russia*, in fissures cutting limonite-hematite ores, with "limonite," tikhonenkovite, and gearksutite. RG AM 80:185(1995).

Compound Halides

12.1.1.1 Stenonite $(\text{Sr}, \text{Ba}, \text{Na})_2\text{Al}(\text{CO}_3)\text{F}_5$

Named in 1962 for Nicholas Stenonis (Niels Steensen) (1638–1686), Danish anatomist, discoverer of the law of constancy of interfacial angles. *MON P2₁m*. $a = 5.450$, $b = 8.704$, $c = 13.150$, $\beta = 98.20^\circ$, $Z = 4$, $D = 3.847$. Structure: *CM 22:245(1984)*. 15-366: 3.39₁₀ 2.24₆ 2.21₆ 2.17₁₀ 2.14₆ 1.93₈ 1.87₆ 1.79₆. Small masses and grains. Colorless to white, vitreous luster. Cleavage {001}, {120}, and {120}, good. $H = 3\frac{1}{2}$. $G = 3.86$. Biaxial (-); $X = b$; $Z \wedge c = 32^\circ$; $N_x = 1.452$, $N_y = 1.527$, $N_z = 1.538$; $2V = 43^\circ$. *Ivigut, Greenland*, associated with jarlite, cryolite, fluorite, and other fluorides. *RG AM 48:1178(1963)*.

12.1.2.1 Grandreefite $\text{Pb}_2\text{SO}_4\text{F}_2$

Named in 1989 for the locality. *MON A2/a*. $a = 8.667$, $b = 4.442$, $c = 14.242$, $\beta = 107.41^\circ$, $Z = 4$, $D = 6.96$. Structure: *AM 76:278(1991)*. 45-1455: 3.16₁₀ 3.12₉ 3.08₈ 2.28₅ 1.824₅ 1.806₆ 1.780₄ 1.370₅. Crystals prismatic {001}, with {120}, {130}, {293}, and {101}. Colorless, white streak, subadamantine luster. No cleavage, conchoidal fracture, brittle. $H = 2\frac{1}{2}$. $G = 7.0$. Nonfluorescent. Biaxial (+); $N_x = 1.872$, $N_y = 1.873$, $N_z = 1.897$. $2V$ small; $2V_{\text{calc}} = 23^\circ$; $r < v$, weak. Coarse polysynthetic twinning observed in polarized light. Decomposed by cold water, slowly soluble in high-index immersion fluids. *Grand Reef mine, Graham Co., AZ*, in a vug surrounded by fluorite and galena, believed to have been formed by reaction of supergene fluids with these minerals. *RG AM 74:927(1989)*.

12.1.3.1 Pseudograndreefite $\text{Pb}_6\text{SO}_4\text{F}_{10}$

Named in 1989 for its close similarity to grandreefite in its composition, physical properties, and structure. *ORTH F222*. $a = 8.518$, $b = 19.574$, $c = 8.493$, $Z = 4$, $D = 7.08$. 45-1456: 3.89₂ 3.20₁₀ 3.00₃ 2.21₃ 2.12₂ 1.900₂ 1.779₇ 1.364₃. Square crystals (pseudotetragonal), tabular on {010}. Colorless, white streak, subadamantine luster. No cleavage, conchoidal fracture, brittle. $H = 2\frac{1}{2}$. $G = 7.0$. Nonfluorescent. Biaxial (+); $XYZ = cab$; $N_x = 1.864$, $N_y = 1.865$, $N_z = 1.873$; $2V = 30^\circ$; $r > v$, strong. Decomposed in cold water, slowly attacked by high-index optical immersion fluids. *Grand Reef mine, Graham Co., AZ*, associated with grandreefite, laurelite, aravaipaite, galena, and fluorite. *RG AM 74:927(1989)*.

12.1.4.1 Creedite $\text{Ca}_3\text{Al}_2\text{SO}_4(\text{OH})_2\text{F}_8 \cdot 2\text{H}_2\text{O}$

Named in 1916 for the locality. MON *C2/c*. $a = 13.936$, $b = 8.606$, $c = 9.985$, $\beta = 94.4^\circ$, $Z = 4$, $D = 2.738$. Structure: *NJMM:69(1983)*. 8-72: 7.30₉ 6.90₉ 5.79₈ 3.92₉ 3.67₇ 3.48₁₀ 3.07₈ 2.16₉. Crystals short prismatic to acicular [001], with {111}, {110}, and/or {111} dominant; also {001}; commonly in radiating aggregates or drusy masses. Colorless to white; rarely purple; vitreous luster. Cleavage {100}, perfect; conchoidal fracture; brittle. $H = 4$. $G = 2.71\text{--}2.73$. Biaxial (-); $Y = b$; $Z \wedge c = 42^\circ$; $N_x = 1.463$, $N_y = 1.476$, $N_z = 1.484$ (Na); $2V = 64^\circ$; $r > v$, strong. Slowly soluble in acids. *Wagon Wheel Gap, Creede quadrangle, Mineral Co., CO(*)*, in a fluorite-barite vein. Grand Reef mine, Graham Co., AZ. Granite, Nye Co., NV. Santa Eulalia, CHIH, Mexico(!), in fine purple crystals and groups. Aktschatau, central Kazakhstan(!), in large well-crystallized violet groups. Crystals to 2.5 cm at the Colquiri mine, La Paz Dept., Bolivia. RG *DII:129, AM 37:787(1952)*.

12.1.5.1 Chukhrovite-(Y) $\text{Ca}_3(\text{Y,Ce})\text{Al}_2(\text{SO}_4)\text{F}_{13} \cdot 10\text{H}_2\text{O}$ **12.1.5.2 Chukhrovite-(Ce)** $\text{Ca}_3(\text{Ce,Nd})\text{Al}_2(\text{SO}_4)\text{F}_{13} \cdot 10\text{H}_2\text{O}$

Named in 1960 for Fedor Vasilevich Chukhrov (1908–1988), Russian mineralogist, academician, and director, Institute of Geology of Ore Deposits, Moscow. Chukhrovite-(Y): iso *Fd3*. $a = 16.710$, $Z = 8$, $D = 2.274$ ($\text{Y/Ce} = 1:1$), $D = 2.35$ (Y). Chukhrovite-(Ce): iso *FD#*. $a = 16.80$, $Z = 8$. Structure: *AM 66:392(1981)*. 14-61(chukhrovite-Y): 3.26₉ 2.84₈ 2.57₉ 2.25₉ 2.19₁₀ 1.83₁₀ 1.68₈ 1.51₈. 43-667(chukhrovite-Ce): 9.75₁₀ 5.93₈ 4.20₅ 3.22₇ 2.56₆ 2.24₅ 2.17₆ 1.824₅. Crystallizes as cubo-octahedrons. White to colorless, vitreous to pearly luster. Cleavage {111}, indistinct; irregular fracture; brittle. $H = 3$. $G = 2.27\text{--}2.40$. Isotropic; $N = 1.440\text{--}1.483$. Chukhrovite-(Y) was found in the oxidized zone of the *Kara Oba molybdenum-tungsten deposit, central Kazakhstan*, associated with creedite, gearksutite, halloysite, fluorite, and other minerals. Chukhrovite-(Ce) was found at the *Clara mine, Oberwolfach, middle Black Forest, Germany*. RG *CE 38:331(1979)*; *AM 65:1065(1980)*, *45:1132(1960)*; *ZVMO 102:201(1973)*.

12.1.6.1 Boggildite $\text{Na}_2\text{Sr}_2\text{Al}_2(\text{PO}_4)\text{F}_9$

Named in 1954 for Ove Balthasar Boggild (1872–1956), Danish geologist and mineralogist, University of Copenhagen; author of *Mineralogia Groenlandia* (1905) and *The Mineralogy of Greenland* (1953). MON, pseudo-ORTH *P2₁/c*. $a = 5.251$, $b = 10.464$, $c = 18.577$, $\beta = 107.32^\circ$, $Z = 4$, $D = 3.692$. Structure: *CM 20:263(1982)*. 14-417: 3.96₇ 3.89₈ 3.16₁₀ 3.13₇ 2.88₅ 2.87₅ 2.75₅ 2.63₇. Massive, with twinning lamellae. Flesh-red. $H = 4\text{--}5$. $G = 3.66$. $Z = b$; $X \wedge a = 36^\circ$; $N_x = 1.462$, $N_y = 1.466$, $N_z = 1.469$; $2V = 80^\circ$. *Iviglut, Greenland*, with black cryolite, siderite, sphalerite, and fluorite near a greisen contact with the cryolite orebody. RG *AM 39:848(1954)*, *41:959(1956)*.

12.1.7.1 Barstowite $\text{Pb}_4(\text{CO}_3)\text{Cl}_6 \cdot \text{H}_2\text{O}$

Named in 1991 for Richard William Barstow (1947–1982), Cornish mineral dealer. MON $P2_1$ or $P2_1/m$. $a = 4.218$, $b = 9.180$, $c = 16.673$, $\beta = 91.48^\circ$, $Z = 2$, $D = 5.77$. PD : 4.16₅ 4.02₁₀ 3.79₃ 3.05₃ 2.48₃ 2.38₆ 2.30₈ 2.11₄. Prismatic crystals (microscopic) with rectangular outline. Colorless to white, adamantine luster. Prismatic, imperfect cleavage; uneven fracture; brittle. $H = 3$. $G = 5.71$. In polished section gray to dark gray; moderately anisotropic; colorless internal reflections. $R = (\text{air})$: 13.5, 14.0 (470 nm); 12.9, 13.4 (546 nm); 12.7, 13.1 (589 nm); 12.4, 12.8 (650 nm). *Bounds Cliff, St. Endellion, Cornwall, England*, in a quartz–dolomite vein containing Pb, Sb, and Cu, just above sea level, with barstowite, phosgenite, and other minerals, formed by the action of seawater on the exposed ore. RG *MM* 55:121(1991), *AM* 77:670(1992).

12.1.8.1 Arzrunite $\text{Cu}_4\text{Pb}_2\text{SO}_4(\text{OH})_4\text{Cl}_6 \cdot 2\text{H}_2\text{O}$

Named in 1899 after Andreas Arzruni (1847–1898), German mineralogist, University of Aachen, who first recognized the mineral. Probably ORTH Space group unknown. Prismatic crystals, with {110}, {010}, and {001}. Blue to bluish green. Biaxial, parallel extinction, optic axis perpendicular to {110}. Strongly pleochroic, blue to nearly colorless. *Buena Esperanza mine, Challacolla, Tarapaca, Chile*, with lanarkite. RG *DII*:130.

Acid Carbonates

13.1.1.1 Nahcolite NaHCO_3

Named in 1929 after the chemical formula. Synonym: sodium bicarbonate. MON $P2_1/n$. $a = 7.475$, $b = 9.686$, $c = 3.481$, $\beta = 93.38^\circ$, $Z = 4$, $D = 2.16$. JCP 1:634(1933). Structure consists of infinite chains of cross-linked HCO_3^- ions associated with Na, forming layers of HCO_3^- and Na, nearly parallel to $c(101)$. 15-700(syn): 3.48₃ 3.06₄ 2.96₇ 2.94₁₀ 2.60₁₀ 2.68₃ 2.21₄ 2.04₃. Crystals prismatic [001], with {110}, {010} dominant, terminated by {101}; often as aggregates or friable porous masses. Colorless, white to gray, or buff; colorless streak; transparent; vitreous to pearly luster. Cleavage {101}, perfect; {111}, good; {100}, distinct; brittle; contact and penetration twins common. $H = 2.5$. $G = 2.21$. IR. MSLM 4:261(1974). Biaxial (-); $Y = b$; $X \wedge c = 27^\circ$; $N_x = 1.377$, $N_y = 1.503$, $N_z = 1.583$; $2V = 75^\circ$; $r < v$, weak. AM 25:769(1940). Natural material contains <0.5% Ca, Fe, Al. Easily soluble in H_2O , forming alkaline solution which on heating gives off CO_2 ; also soluble in glycerine. Lacustrine evaporite mineral. Large deposits are found in central Searles Lake, San Bernardino, CA, in thin beds associated with gaylussite, thenardite, burkeite, northupite, borax, and halite. Concretions up to 1.5 m diameter in oil shales of Green River formation (Eocene), Anvil Pts., Rifle, CO. Admixed with trona, thermonatrite as efflorescence in old Roman conduit at hot springs, Naples, Italy. In dry Little Lake Mogadi, 40 km south of Lake Mogadi, Kenya, as fibrous pseudomorphs after gaylussite, and as alteration

Searles Lake Prismatic Habit
Forms: $a\{100\}$, $b\{010\}$, $m\{110\}$, $o\{111\}$, $r\{101\}$

Searles Lake Twin on {101}

Nahcolite

rims around thermonatrite. Medical use: to attain alkalinity; a major source of sodium carbonate in the manufacture of soaps. *HCWS DII:134*.

13.1.2.1 Kalicinite KHCO_3

Named in 1898 after the composition, potassium = kalium. *MON P2₁/a*. $a = 15.173$, $b = 5.628$, $c = 3.711$, $\beta = 104.63^\circ$, $Z = 4$ $D = 2.15$. *AC(B) 30:1155(1974)*. $12-292(\text{syn})$: 7.34_2 3.67_{10} 2.97_4 2.86_9 2.82_8 2.63_9 2.38_4 1.832_3 . Fine-crystalline aggregates; synthetic material short prismatic crystals. Colorless to white-yellow, transparent. Cleavage $\{100\}$, $\{001\}$, $\{101\}$. Soft. $G_{\text{syn}} = 2.17$. Biaxial (-); $X \wedge c = 30^\circ$; $N_x = 1.380$, $N_y = 1.482$, $N_z = 1.578$. $2V = 81.5^\circ$. Soluble in H_2O . Found as a result of decomposition under a dead tree, *Chypis, Canton Wallis, Switzerland*, possibly in association with trona in Hungary. *HCWS DII:136*.

13.1.3.1 Teschemacherite $(\text{NH}_4)\text{HCO}_3$

Named in 1868 by English chemist Frederick Edward Teschemacher (1791–1863), who described the species. *ORTH Pccn*. $a = 7.225$, $b = 10.709$, $c = 8.746$, $Z = 8$, $D = 1.51$. *TMPM 29:67(1981)*. $9-415(\text{syn})$: 5.34_6 4.05_4 3.62_5 3.20_2 3.07_3 3.01_4 3.00_{10} 2.16_3 . See also *44-1483*. Compact crystalline masses; synthetic crystals short prisms $\{001\}$. Colorless, or white-yellow, transparent. Cleavage $\{110\}$, perfect; brittle. $H = 1\frac{1}{2}$. $G = 1.57$. Biaxial (-); $N_x = 1.4227$, $N_y = 1.5358$, $N_z = 1.5545$; $2V = 24^\circ$; $r < v$, weak. *AJS 269:97(1971)*. Decomposes in moist air, soluble in H_2O , effervesces with dilute acids. Synthesized. In guano deposits: Saldanha Bay, Cape Prov., South Africa; on Chicha and Guanape Is., Peru. Deposited at the capped wellhead for geothermal waters at Broadlands, New Zealand. *HCWS DII:137, AM 57:1304(1972)*.

13.1.4.1 Trona $\text{Na}_3\text{CO}_3(\text{HCO}_3) \cdot 2\text{H}_2\text{O}$

Named in 1773 for the reduced form of the word for native salt in Arabic, *natrun*. *MON C2/c(syn)*. $a = 20.362$, $b = 3.481$, $c = 10.291$, $\beta = 106.48^\circ$, $Z = 4$, $D = 2.147$. Structure: *AC(B) 38:2874(1982)*. Planar $(\text{CO}_3)^{2-}$ groups, somewhat distorted, are linked by H^+ and coordinated octahedrally with Na. $29-1447$: 9.77_5 4.89_6 3.20_2 3.07_8 2.65_{10} 2.44_3 2.25_3 2.03_3 . Rare crystals elongated $\{010\}$, flattened $\{001\}$; $\{h0l\}$ faces striated parallel to $\{010\}$; often fibrous. Colorless to gray or yellow-white, translucent, usually columnar or massive, vitreous luster. Cleavage $\{100\}$, perfect, uneven columnar fracture. $H = 2\frac{1}{2}$. $G = 2.11$. IR. *MSLM 4:263(1974)*. Biaxial (-); $Y \wedge c = -7^\circ$; $N_x = 1.418$, $N_y = 1.492$, $N_z = 1.543$; $2V = 75.8^\circ$. Not altered by exposure to dry air. Alkaline taste. Crystals of trona may be obtained by reacting NaHCO_3 with $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$ in sodium chloride solution at temperatures up to 195° . Lacustrine evaporitic mineral; also as efflorescence on soils in arid regions. Commonly associated minerals are natron, thermonatrite, nahcolite, halite, glauberite, thenardite, mirabilite, and gypsum. Trona has wide occurrence in the western United States, especially in soda lakes near Laramie, and with shortite, northupite, bradleyite, and pirssonite in Green River oil shales of

Sweetwater Co., WY; present in large quantities in NV at Double Springs Marsh near Fallon. Trona occurs with borax, hanksite, thenardite, and other salts at Searles Lake, San Bernardino Co., at Borax Lake, Lake Co., and as layers along the shores of Owens Lake, Inyo Co., CA.; at shallow depths in Lake Goodenough, BC, Canada; in the subsurface residual brines from former alkaline lakes, Lake Texcoco, Mexico. The oldest known deposits of trona are in the Nile Valley near Memphis, Egypt. It has been found at the eastern Sahara Oasis of Bilma, Libya; also found in the alkali deserts of Hungary, Mongolia, and Tibet; as efflorescences near Lake Chad, Chad; at Lake Magadi, Kenya; and at Lake Nyasa, Tanzania. *HCWS DII:138.*

13.1.5.1 Nesquehonite $Mg(HCO_3)(OH) \cdot 2H_2O$

Named in 1890 after the locality. *MON P2₁/n.* $a = 7.705$, $b = 5.367$, $c = 12.121$, $\beta = 90.6^\circ$, $Z = 4$, $D = 1.856$. Structure: *AC(B) 28:1031(1972). 20-669(syn):* 6.48₁₀ 4.91₁ 3.85₈ 3.23₂ 3.03₃ 2.62₆ 2.34₂ 1.925₂. Radiating tufts of acicular crystals, also botryoidal. Colorless to white, transparent to translucent, vitreous luster. Some felted aggregates are pseudomorphs after lansfordite. Cleavage {110}, perfect; {001}, less so; splintery to fibrous fracture. $H = 2\frac{1}{2}$. $G = 1.852$. Biaxial (-); N_x calc = 1.417, $N_y = 1.503$, $N_z = 1.527$; $2V = 53^\circ$; $r < v$. Easily soluble in dilute acids with effervescence; soluble in H₂O, especially in the presence of CO₂. Like lansfordite, appears to be a recent product formed under atmospheric conditions. Found in a coal mine at *Nesquehoning, near Lansford, Carbon Co., PA*, where it formed the base of stalactites and was associated with lansfordite; also lining crevices in serpentinites, especially noted at *Francia asbestos mine, Val Lanterna, Lombardy, Italy*. Described from a mineral springs deposit *Rohitsch-Sauerbrunn, Austria*. *HCWS DII:225.*

13.1.6.1 Wegscheiderite $Na_5CO_3(HCO_3)_3$

Named in 1962 after R. Wegscheider (b.1913), who synthesized the compound. *TRIC P1.* $a = 10.04$, $b = 15.56$, $c = 3.466$, $\alpha = 91.92^\circ$, $\beta = 95.82^\circ$, $\gamma = 108.67^\circ$, $Z = 2$, $D = 2.334$. *15-653:* 3.68₆ 2.95₁₀ 2.91₃ 2.83₄ 2.80₅ 2.66₄ 2.64₆ 2.21₆. Crystals acicular to bladed and fibrous up to 5 cm in length with no well-developed faces. Colorless when pure, red-brown with 4% organic inclusions, vitreous luster. Prismatic cleavage, subconchoidal fracture. Non-piezoelectric. $H = 2\frac{1}{2}$ -3. $G = 2.34$. Biaxial (-); $N_x = 1.433$, $N_y = 1.519$, $N_z = 1.528$; $2V = 32.4^\circ$; strongly birefringent. Soluble in cold H₂O, decomposes rapidly in common acids releasing CO₂. A lacustrine mineral deposited in strata up to depths of 645 m in *Perkins Well No. 1, in the Wilkins Peak member of Green River Shales, northeastern Sweetwater Co., WY*. Trona is replaced by wegscheiderite, which is replaced by halite. *HCWS AM 48:400(1963).*

13.1.7.1 Sergeevite $Ca_2Mg_{11}(CO_3)_9(HCO_3)_4(OH)_4 \cdot 6H_2O$

Named in 1980 for Evengi M. Sergeev (b.1914), engineering geologist, Moscow University. Compare with huntite (14.4.3.1). *HEX-R R32.* $a = 19.01$,

$c = 7.82$, $Z = 3$, $D = 2.64$. *AM 66:1100(1981)*. *41-1403*: 7.14₃ 3.58₃ 3.37₂ 2.87₃ 2.82₁₀ 2.68₁ 1.965₃ 1.755₂. IR shows CO_3^{2-} , $(\text{HCO}_3)^-$, OH and H_2O . White, very fine-grained, dull aggregates with uneven to conchoidal fracture. $H = 3\frac{1}{2}$. $G = 2.2-2.35$. $N_{\text{av}} = 1.581$, birefringence ≈ 0.010 . Decomposed by cold 1:10 HCl. Weathering product of pyroxene, garnet skarn, Tyrnyauz, Caucasus, Russia. *HCWS ZVMO 109:217(1980)*.

13.1.8.1 Barentsite $\text{Na}_7\text{Al}(\text{CO}_3)_2(\text{HCO}_3)_2\text{F}_4$

Named in 1983 to honor Dutch sailor Willem Barents and the sea that washes the Kola Peninsula. *TRIC P1 or P1*. $a = 6.472$, $b = 6.735$, $c = 3.806$, $\alpha = 92.5^\circ$, $\beta = 97.33^\circ$, $\gamma = 119.32^\circ$, $Z = 1$, $D = 2.55$. *AM 69:565(1984)*. *35-693*: 2.89₉ 2.78₁₀ 2.66₁₀ 2.54₃ 2.32₅ 2.17₇ 1.870₄ 1.670₃. Crystals up to 3–5 mm. Colorless, water-clear, vitreous luster, but pearly on faces. Cleavage {001}, {100}, perfect; brittle. $H = 3$. $G = 2.56$. IR, DTA. Biaxial (-); X near (001); $X \wedge a \approx 45^\circ$; $N_x = 1.358$, $N_y = 1.479$, $N_z = 1.530$; $2V = 62^\circ$; $r < v$, weak. In air becomes covered with white dull powder, effervesces in HCl. Described from drill core 600 m deep in *Mt. Restinyon, Kola Penin., Russia*, where it occurs with trona and natrite in the interstices of hydrothermal veinlets composed of shortite, albite, and natrolite that cut pegmatitic rock. *HCWS ZVMO 112:474(1983)*.

Anhydrous Carbonates

The anhydrous carbonates fall into two divisions based on their crystallization character. One division consists of minerals with hexagonal/rhombohedral form and structure, similar to calcite, the most common carbonate mineral species. The other division includes minerals which are often pseudo-hexagonal, such as those of the aragonite group. A subset under each of these divisions are the double carbonates such as dolomite, $\text{CaMg}(\text{CO}_3)_2$, and alstonite, $\text{BaCa}(\text{CO}_3)_2$.

The structures of all these minerals are dominated by the trigonal carbonate $(\text{CO}_3)^{2-}$ group whose C-O distances, $1.28\text{Å} \pm 0.02\text{Å}$, and O-C-O angles, $120^\circ \pm 2^\circ$, are effectively constant for all carbonates whose structures have been determined *FM 58:95 (1981)*. The group, planar in the hexagonal/rhombohedral anhydrous carbonates becomes slightly puckered in the orthorhombic/monoclinic forms.

CALCITE GROUP

The calcite group minerals are carbonates conforming to the formula

where

A = Ca, Mg, Mn, Fe, Co, Ni, Zn, or Cd

and the minerals crystallize in the hexagonal-rhombohedral space group $R3c$.

The eight known endmembers (Table) typically show at least some solid solution (substitution) of several different cations. For example, there is complete miscibility for the cation pairs Ca-Cd, Mg-Co, Mg-Mn, Fe-Mg, and Fe-Mn, and limited miscibility for Ca-Mg, Ca-Fe, Ca-Mn, Ca-Co, Ca-Ni, and Ni-Mg. *MSASC 11:11(1983)*, *AM 51:677(1966)*, *DII:151-178*.

The carbonate group, effectively an oxygen-bounded equilateral triangle with carbon at the center, are planar, have trigonal symmetry, and form layers alternating with layers of the divalent metal ions in octahedral coordination with six oxygens from six carbonate groups. All layers are perpendicular to the c axis, with carbonate triangles of successive layers pointing in opposite directions.

CALCITE: CaCO₃

Projection down the unique *c* axis of calcite shows the basic hexagonal features of this structure dominated by planar (CO₃)²⁻ groups. However, the appearance belies the fact that the CO₃ groups are actually rhombohedral, and form layers alternating with layers of divalent metal ions perpendicular to *c*. Every other layer of CO₃ groups in the sequence Ca-CO₃-Ca-CO₃ point in opposite directions. The divalent cations in the calcite group minerals have octahedral coordination with six oxygens from six different CO₃ groups. Compare with aragonite (14.1.3.1), and the ordered double carbonate dolomite (14.2.1.1).

CALCITE GROUP

Mineral	Formula	Space Group	<i>a</i>	<i>c</i>	<i>D</i>	
Calcite	CaCO ₃	<i>R3c</i>	4.9896	17.061	2.71	14.1.1.1
Magnesite	MgCO ₃	<i>R3c</i>	4.63328	15.0129	3.00	14.1.1.2
Siderite	FeCO ₃	<i>R3c</i>	4.6916	15.3796	3.936	14.1.1.3
Rhodochrosite	MnCO ₃	<i>R3c</i>	4.7682	15.6354	3.72	14.1.1.4
Sphaerocobaltite	CoCO ₃	<i>R3c</i>	4.6581	14.958	4.208	14.1.1.5
Smithsonite	ZnCO ₃	<i>R3c</i>	4.656	15.027	4.43	14.1.1.6
Otavite	CdCO ₃	<i>R3c</i>	4.923	16.287	5.03	14.1.1.7
Gaspeite	NiCO ₃	<i>R3c</i>	4.621	14.93	4.35	14.1.1.8

MSASC 11:11(1983), AM51:677(1966), DII 151-178, ASTR(1992)

Notes:

1. There is virtually no substitution for the carbonate group in the calcite group structures.
2. Carbonate groups are largely responsible for the characteristically large birefringence of the group *MSASC 11:49(1983)*.
3. See aragonite (14.1.3.1), the orthorhombic polymorph of calcium carbonate, and the dolomite (14.2.1.1) group, ordered double carbonates.
4. The aragonite group minerals crystallize with larger A cations in a different structure.
5. See vaterite (14.1.2.1) a hexagonal polymorph of calcium carbonate.
6. See the dolomite group minerals crystallize in space group *R3*.

14.1.1.1 Calcite CaCO_3

Named by Haidinger in 1845 after a Greek root meaning *to reduce to a powder by heat* (also Latin *calx*, burnt lime). Calcite group. The most common carbonate mineral species, calcite has been known and used as a source of lime since antiquity. The occurrence of many beautiful, perfect, clear crystals with a variety of forms and faces fascinated seventeenth-century scientists, with the result that the mineral was instrumental in advancing not only mineralogy but also physics and materials science. For example, cleavage fragments of calcite were used in the discovery of double refraction described by Bartholinus (1669) and Huygens (1678), and the polarization of light by Malus (1808). The faces and forms on calcite crystals measured by a new method, contact goniometry, reported by de Lisle (1783), were the observations that became part of the basis of Hauy's theory of crystal structure and the foundation of geometric crystallography. Mineralogical concepts aided by studies on calcite include pressure twinning and twin gliding (Brewster, 1815), polymorphism (Mitscherlich, 1821), and the relationship of X-ray diffraction and optical character to morphology (Bragg, 1914). The chemical composition of calcite, determined in 1804 by Bucholz, was followed by studies of chemical variations in other carbonate minerals. The demonstration that the interfacial angle of the crystal forms varied with composition for isostructural compounds, such as those in the calcite group, established the concept of an isostructural series of minerals forms are isomorphic. The polymorphic relationship of calcite to aragonite was recognized by Hauy and Mitscherlich (1821), who postulated the structural relationship, but it was Bragg (1924) using X-ray diffraction who confirmed the actual structural differences. Calcite could be called a "mineralogists' mineral."

Calcite, the dominant member of the calcite group (see group description), has had numerous names over its long history, such as *calcspar*, *kalkspar*, *kalkstein*, *doppelstein*, *Iceland spar*, *lublinite*, and many other varietal names: *satın spar*, *slate spar*, *cave pearls*, *stinkcalc*, *sand calcite*, depending on the habit, inclusions, or environment of formation. **Physical properties:** HEX-R $R3c$. $a = 4.9896$, $c = 17.061$, $Z = 6$, $D = 2.71$ *ZK 156:233(1981)*. *5-586(syn)*: 3.86_1 3.035_{10} 2.495_1 2.285_2 1.913_2 1.875_2 1.604_1 . *24-27(calc)*: 3.852_3 3.030_{10} 2.284_2 2.094_3 1.9071_2 1.8726_3 1.6040_2 . See also *43-697*, magnesian calcite. **Structure:** Calcite (Fig. 14.1.1.1A) is the thermodynamically stable form of CaCO_3 at the surface of the earth. Figure 14.1.1.1B illustrates the relationship between the true unit cell of calcite, the commonly observed cleavage rhomb, and the hexagonal prism. There are two low-temperature polymorphs of CaCO_3 : aragonite (14.1.3.1) and vaterite (14.1.2.1). A slightly different structure, calcite II, forms via displacive transition at 15 kb and room temperature [*AC(B) 31:343(1975)*], and another, calcite III, forms above 20 kb [*AM 75:801(1990)*]. Calcite IV and V, higher-temperature forms, probably with rotational anion disorder, have not yet been fully described. *MSASC 11:191(1983)*. **Habit:** Hundreds of different crystal faces and forms have been described for calcite, and a few of the common habits are illustrated in

14.1.1.1 Calcite

Figures 14.1.1.1a and 14.1.1.1b

Calcite Rhomb and Unit Cell Relationships (a) The arrangement of Ca^{2+} and CO_3^{2-} groups relative to the cleavage rhomb of calcite. (b) The relationship between the steep, true rhombohedral unit cell ($\alpha = 46.11^\circ$) of calcite to the cleavage rhomb ($\alpha = 101.91^\circ$) and the hexagonal cell in which $c/a = 3.42$ (AJS 254:65 (1956) MSASC 11:1 (1983) DM 20:329 Fig.10.2).

Fig. 14.1.1.1C. Note that the forms have been given individual letters (see *DII:143* for a complete list). Miller indices, which identify the forms, may refer to the cleavage rhomb or to the hexagonal cell with $c/a = 0.854$. The typical rhomb, and the scalenohedral forms, may be modified by an amazing variety of faces (e.g., the Lake Superior crystal on which $\{18.0\bar{1}8.1\}$ has been described). Commonly observed calcite crystal forms: obtuse to acute rhombohedrons $\{0221\}$, $\{4041\}$, $\{0554\}$, $\{0332\}$ alone or in combination; scaleno-

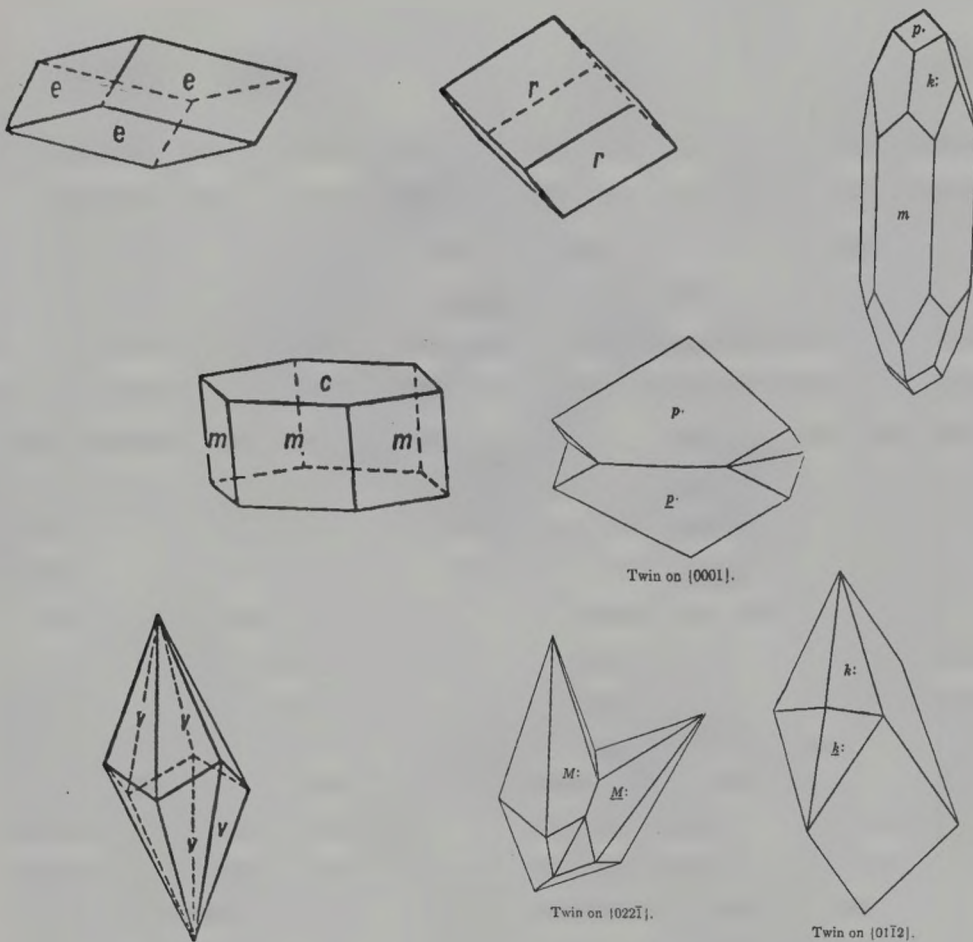

Figure 14.1.1.1c

THE MANY CRYSTALLINE FORMS OF CALCITE

The crystal morphologies depicted show the following common crystal faces: $c = 0001$ $e = 01\bar{1}2$ $k := 21\bar{3}1$ $m = 10\bar{1}0$ $M := 74\bar{1}13$ $p = 10\bar{1}1$. Underlined symbols refer to the second or twin crystal face in the pair. These forms were selected from DF:512 and Dll:146, 147, 161. There are many additional morphologies and faces presented in these references.

hedrons with $\{2131\}$ dominant; prismatic $[0001]$ crystals with $\{1010\}$, $\{1120\}$; thin-to-thick tabular on $\{0001\}$, bounded by rhombohedral faces, and a variety of shapes created by twinning. At least four twin laws have been determined. The most common is when the twin plane and the composition plane are $\{0112\}$. A repeated effect, produced by pressure, this twinning law is especially encountered in marble. Also common is twinning on $\{0001\}$ with $\{0001\}$ as the composition surface, which produces reentrant angles (see Fig. 14.1.1.1C). Twins with $\{1011\}$ or $\{0221\}$ as twin plane and composition surface are uncommon but may result in heart-shaped crystals ("butterfly twins") or distorted forms in some localities. Calcite also is found as fibers, both coarse and fine, sometimes lamellar, and may be granular and compact, forming multiple aggregates or earthy (chalk). Nodular (oolitic) and stalactitic forms are often observed.

Colorless and transparent to white when pure, natural samples are usually white but do occur in virtually every color, including blue and black, reflecting, at least in part, the isomorphous substitution of other, mostly divalent, elements defect color centers within the crystals, or admixtures of other minerals. Streak, usually white, will be influenced by admixtures. Luster

vitreous, sometimes pearly to iridescent on cleavage surfaces. Cleavage {1011}, perfect; ready parting along twin lamellae {0112}, {0001}; brittle. $H = 3$, variable on different faces or planes and directions within the faces or planes. Mohs' hardness $H = 3$ is defined as the hardness of calcite. $G \approx 2.96$. Natural and artificial etch figures conform with $HEX-R$ symmetry $32/m$. Specimens may be fluorescent, or phosphorescent, on excitation by UV, X-ray, cathode radiation, or sunlight; occasionally, thermoluminescent *JP(C) 17:2027(1984)*. Reddish-yellow fluorescent Mn-containing (up to 3.5% $MnCO_3$) calcites are common at Franklin and Sterling Hill, NJ, and Långban, Sweden. IR (*SWV:54*) and Raman spectra have been measured for all members of the calcite group [*AM 62:36(1976)*] as well as on calcite II [*AM 75:801(1990)*] and the Mg-containing biogenic forms [*AM 76:641(1991)*]. **Optics:** Uniaxial (-); $N_O = 1.658$, $N_E = 1.486$. In transmitted light calcite is colorless, occasionally abnormally biaxial ($2V$ up to 30°) as a result of mechanically induced strain. Variations in N value with temperature, composition, and wavelength have been summarized. *DII:151*. **Chemistry:** The most common, and perhaps the most important, solid substitution in nature considering the widespread occurrence of limestones, marls, dolomitic limestones, and marbles is that of Mg in calcite. The chemical variations have been used to interpret the environments that existed during the formation of these sedimentary and metamorphic rocks. Phase relations determined for the binary system $CaCO_3$ - $MgCO_3$ show two solid-solution series separated by the double carbonate ordered phase dolomite $CaMg(CO_3)_2$ (14.2.1.1): calcite-dolomite, and dolomite-magnesite (14.1.1.2). Biologically mediated metastable formation and the geological persistence of magnesian calcites (Mg content may be up to 20% $MgCO_3$) is widespread and well documented. Calcite is easily produced via precipitation from solution below 30° unless sulfates or salts containing Mg, Pb, Sr, or other large cations are present. Single crystals may be grown via slow diffusion of a soluble carbonate solution into a Ca-containing gel with the crystal habit dependent on associated other ions or molecules. The kinetics of precipitation and dissolution have been reviewed *MSASC 11:227(1983)*. Calcite is usually detected, and discriminated from dolomite or magnesite, by fizzing on contact with cold dilute (1:10) HCl. **Occurrence:** Perhaps the most common occurrences of calcite are the massive and thick sedimentary rocks in which calcite is usually predominant: limestone, chalk, marl, oolitic limestone, tufa, travertine, calc-sinter. The grain size of calcite in these rocks ranges from sub-microscopic to coarse, depending on the depositional environment and subsequent metamorphism, or diagenesis. Other low-temperature environments in which calcite forms include earthy crusts and efflorescences on soils, the intricate formations (stalactites) in calcareous springs or streams in caves, as cementing material in sedimentary rocks, and as veins deposited from lime-bearing carbonated surface waters which are found in all types of rock. Calcite is a common gangue mineral and is a minor but widespread constituent in all types of rock alteration. The unusually large accumulations of sedimentary strata representing quiet-water calcite deposits are

often lamellar, porous, concretionary, and fossiliferous and may have been deposited in the sea or by lakes and springs. Freshwater calcite deposits occur on all continents. Coralline and shelly deposits characteristic of invertebrate organisms that inhabit the seas are usually calcitic, but may be aragonitic, indicating a specific invertebrate species or distinctive temperature of deposition. The crystalline habit of calcite in hydrothermal deposits has also been used to indicate temperature or other conditions of deposition. Often the petrifying substance of fossil organic materials (i.e., wood), calcite is usually the replacement for the initial depositional biomineral aragonite. It is also replaced by, or replaces, other mineral species (i.e., there are pseudomorphs of quartz, chalcedony, or iron oxides after calcite, and calcite pseudomorphous after gypsum, barite, and fluorite). In all low-temperature deposits calcite is normally finely crystalline. Aggregates of calcite crystals are common, as are clusters that reflect oriented overgrowth of secondary calcite (epitaxy). Platy aggregates, lamellar aggregates and soft, scaly, often powdery forms, as well as fibrous calcite with a silky luster, have been described. The mineral may exhibit a range of minor and trace elements which, together with C and O isotopic data, have been used to determine the conditions and time of formation of these deposits. **Localities.** There is an almost endless number of localities for crystallized calcite worldwide, the following are some of the most noteworthy: 1. *Euhedral or single-crystal localities.* The greatest source of optical calcite (one crystal measured 7 m × 2.5 m) was the cavernous basalt at Helgustader, Eskifjord, Iceland (ice-land spar). From NY as fine crystals to 5 cm from Rossie, in large pink twinned crystals, suitable for faceting flawless rainbow-hued gemstones to several thousand carats, from Balmat, St. Lawrence Co. In NJ in basalt quarries associated with zeolites from Great Notch; at Upper New Street and Prospect Park quarries, West Paterson, with prehnite and zeolites; red-fluorescent calcite with green-fluorescent willemite and yellow-fluorescent esperite and about 250 other minerals from Franklin and Sterling Hill, Sussex Co. Baseball-sized crystals with pyrite inclusions forming a three-rayed star from Staunton, VA. The Elmwood and Gordonsville mines near Carthage, TN, in magnificent transparent amber, large twinned (0001) crystals with sphalerite, fluorite, and barite. In IN, from North Vernon, Jennings Co., fine pale-brown crystals of low prismatic hexagonal form terminated by low rhombohedrons, with a nearly spherical shape. In OH at White Rock quarry in Clay Center, as yellow rhombs of calcite on white blades of celestite. Splendid white to clear crystals up to 15 cm enclosing brilliant native copper in mines on the Keweenaw Peninsula, MI, notably from the Calumet, Quincy, and other mines. The Sweetwater and Buick mines, Reynolds Co., MO, produce crystals over 60 cm associated with large galena crystals; also giant "dogtooth" yellow crystals, sometimes with a lavender core, and "fishtail" twins from Joplin and nearby Treece, KS, and Picher, OK, in the Tri-State zinc mining district, associated with sphalerite, galena, dolomite, and chalcopyrite. Sand calcite crystals with 70% sand included from Rattlesnake Butte in the badlands of Washington Co., SD. Near Ter-

lingua, TX, calcite that fluoresces brilliant red or yellow and phosphoresces bright blue, depending on the material and the UV wavelength used. At the Iceberg claim near the Harding mine, Taos Co., NM, fine optical calcite in flawless rhombs to 20 cm. In AZ at Ray with cuprite inclusions; at Bisbee with malachite inclusions; and at the Cyprus mine near Baghdad clear twins of many kinds, resembling English material. In Canada at Chibogamou, QUE, gray scalenohedra with cubanite phantoms; from St. Clothilde as yellow modified rhombs on dolomite. In Mexico many localities: in CHIH the Buena Tierra mine with red phantoms; the Potosi mine with clear to red crystals on stalactites; at Areponapuchic as large V-twins, some over 11 kg; N of Chihuahua city the "cocoanut" geodes with many types of calcite associated with crystallized quartz, including smoky and amethyst types. In DGO large boxwork clusters of thin snow-white plates to over 1 m across ("angel wing") from La Amparo mine, San Antonio; this area has produced much optical iceland spar. In SLP the San Sebastian mine at Charcas has tabular crystals to 18 cm across in red-fluorescent groups to several meters across, associated with danburite, datolite, and stilbite. In Guanajuato, GTO, the Valenciana, San Juan de Rayas, and Peregrina mines in crystals to 40 cm associated with amethyst and dolomite with complex, light purple, interpenetrating twins. In ZAC the El Cobre mine has green crystals with malachite and azurite. In Norway as white rhombs with silver at Kongsberg. In Sweden the Malmberget mine, Lappland, as clear orange V-twins; also from Langban. Beautiful brilliant crystals of many forms, often twinned, occur in England from the following classic localities: Alston Moor, Egremont; Frizington, Cumbria; Weardale, Durham; the Stank mine near Furness in Lancashire; Wheal Ray and elsewhere in Cornwall. In Germany from Andreasburg, and as heart-shaped twins from the Elbingerode, Harz; at Freiburg and Schneeberg, Saxony. At Příbram, Czech Republic, in thin, flowerlike formations. Felsobanya, Romania, has rhombs, balls, and stalactites; at Trepeca, Serbia, as white rhombs with sulfides. In France from Pau, Bearn as clear brilliant crystals in geodes, and from the famous Fontainebleu deposit near Paris rhombs and large rounded flowing shapes of sand calcite of great beauty and complexity. In Spain at La Collada and La Viesca, large white scalenohedra on blue fluorite, and yellow crystals on dolomite from the zinc mines at Reocin. In Kazakhstan as beautiful clear yellow (faceting quality) twins over 5 cm from Sarbay-Sokolov, and from Dzezkazgan associated with chalcocite, bornite, and silver. One of the world's outstanding localities is Dal'negorsk, Primorski Krai, far eastern Russia, with many associations and habits. Hunan, China, has provided many large white to clear yellow and gray phantom crystals with realgar and orpiment. In India from vugs in the Deccan traps, clear crystals with okenite, prehnite, apophyllite, and zeolites from Bombay Island; also from Nasik, Maharashtra, with stilbite and powellite. Mashamba West, Shaba, Zaire, has fine clear and pink cobaltian calcite associated with malachite. One of the finest calcite localities is Tsumeb, Namibia, where crystals are associated with diopside, malachite, and other minerals; also at Onganja, rhombs and dogtooth crys-

tals with cuprite. In Australia large crystals and iceland spar were found at the Garibaldi mine, Lionville, NSW. In Peru white manganoan calcite crystals, sometimes with sulfides, from Huanzala and Pachapqui, Huanaco; also at Casapalca, Junin. At Irai, RGS, Brazil, and neighboring Artigas, Uruguay, white crystals of many forms occur inside amethyst geodes in basalt.

2. *Massive varieties.* Chalks, such as the White Cliffs of Dover, England, and limestone strata in the rock sequences on every continent, though predominantly calcitic, often contain other carbonate species, clays, and quartz. Marbles, equally globally distributed, modulate calcite dominance with the metamorphic formation of dolomite from hydrothermal activity. Vein calcites are usually described from mining localities, where the associations may be with massive sulfides or native metals such as copper and silver. Colored calcites, indicating some solid solution of Mn, Fe, Zn, Co, Pb, Sr, Mg, or Ba, are often described as one of the gangue minerals in well-known mines, such as Langban, Sweden. Calcite hot springs have been described at Hammam Meskoutine, Algeria, and at the Kennardt district, Cape Prov., South Africa. Tufa deposits are prominent in northwestern NV at the shores of former Lake Lahontan, and in Mono Lake, CA. The tufa contains particularly interesting pseudomorphs that have occasionally been given separate names, such as *barleycorn* described originally from Obersdorf near Sangerhausen, Thuringia, Germany; *jarrowite*, prismatic pyramidal and laterally grooved or rough, brown/red-brown crystals, originally described from the river clays of Jarrow on Tyne, Durham, England; or *glendonites*, widely distributed in the Permo-Carboniferous mudstones of NSW and Q, Australia (perhaps after glauberite). Travertine outcrops found near Rome, Italy, have been used as building materials for millennia. Stalactites and stalagmites, many still growing in numerous caverns, are well-known tourist attractions, such as in Mammoth Cave, KY and Guilin, China. Fine-grained but well-crystallized calcite is the hallmark of invertebrate species from modern to ancient forms. However, calcitic species may be replaced by other minerals, such as pyrite, in black shales. *ncws DF 511, DII:141, MSASC:11(1983).*

14.1.1.2 Magnesite $Mg(CO_3)$

Named in 1807 for the composition. Calcite group. See also the Ca and Mg double carbonates dolomite, $CaMg(CO_3)_2$ (14.2.1.1), and huntite, $(Mg_3Ca)(CO_3)_4$ (14.4.3.1). *HEX-R R3c. a = 4.633, c = 15.013, Z = 6, D = 3.00. ZK 156:233(1981). 8-479(syn): 2.74₁₀ 2.50₂ 2.10₅ 1.939₁ 1.700₄ 1.354₁ 1.338₁ 0.9134₁.* Distinct colorless and transparent crystals of magnesite, either rhombohedral or prismatic, are rare; usually massive, coarse to fine-grained, or compact and porcelaneous, chalky, lamellar, or fibrous. Normally white or light gray, with coloration influenced by the amount of cation solid solution (e.g., the ferroan forms of magnesite are often yellow or brownish, becoming brown on exposure, and the manganoan forms grade into pink). White streak. Cleavage {1011}, perfect; conchoidal fracture. $H = 3\frac{1}{2}$ – $4\frac{1}{2}$. $G = 3.0$, variable with level of cation substitution. *IR. MSLM 4:239(1974).*

Magnesite is normally nonfluorescent, but some fine-grained varieties fluoresce greenish to bluish white under LWUV; may also be phosphorescent in UV or triboluminescent. Uniaxial (-); $N_O = 1.700$, $N_E = 1.509$ (pure $MgCO_3$). Slightly soluble in cold HCl, soluble with effervescence in warm acids. Virtually no Ca is found in natural or synthetically produced magnesite, but the biologically mediated formation of magnesian calcites is well documented. *MSASC 11:97(1983)*. Cryptocrystalline magnesite deposits, often with admixed opaline silica, appear to be the result of the alteration of magnesian-rich rocks such as serpentinites, peridotites, or dunites by carbonate-containing waters. Magnesite, usually in association with dolomite, occurs as the result of the replacement of calcitic rocks, but primary sedimentary magnesite has been described. Magnesite has been discovered in cavities in volcanoes, oceanic salt deposits, igneous rocks, and meteorites. Magnesite is associated with serpentinites and with dolomites in deposits on the east and west coasts of the United States and from similar localities in Canada (e.g., Grenville, Argenteuill Co., QUE). Large bodies of sedimentary magnesite occur in the Muddy Valley district, Clark Co., NV; hydrothermal magnesite in dolomite was described from the Paradise Range, NV. Magnesite is found in chlorite schists in the Pfitschtal and at Greiner in Zillertal, as well as in rock salt at Hall, Tyrol, Austria, which may be a sedimentary precipitate. Notable deposits of magnesite are recorded from Radenthein, Carinthia, Austria; from Snarum in Buskerud, Norway; on the island of Euboea, Greece; near Salem, Madras, India; as veinlets in gabbro-amphibolites, Saryku-Boldy, Kazakhstan; as coarse crystals stratified with dolomite and marble in Shenking Prov. and on the Liaodong Peninsula, Liaoning, near Mukden, northeastern China. Magnesite has been described as precipitating from brackish lagoons along with magnesian calcite, hydromagnesite, and dolomite in the Coorong, southeastern SA, Australia. Large clear magnesite crystals and twins are obtained from a major magnesite deposit at Brumado, BA, Brazil(!), associated with dolomite, hematite, uvite, talc, sellaite, and many other minerals. Magnesite is one of the sources of the magnesia in the manufacture of chemical compounds such as epsom salts. *HCWS DII:162, MSASC:11(1983)*.

14.1.1.3 Siderite $FeCO_3$

Named in 1845 after the Greek for *iron*. Calcite group. *Chalybite* has been used in England. **HEX-R** *R3c*. $a = 4.6916$, $c = 15.3796$, $Z = 6$, $D = 3.936$. *ZK 156:233(1981)*. *29-696*: 3.59₃ 2.80₁₀ 2.35₂ 2.13₂ 1.965₂ 1.738₃ 1.732₄ 1.506₁. Rhombohedral crystals with {1011} or {0112} often curved or composite; also tabular or prismatic or scalenohedral. Often massive, coarse to fine granular, botryoidal, and globular with fibrous structure. Twinning uncommon. Translation gliding {0001}, {1011}. Yellowish-grayish brown to red brown, dark brown color usually due to oxidation, also shades of gray to pale green, occasionally white; white streak, vitreous or silky luster; translucent. $H = 4$. $G = 3.96$; decreases with substitution of Mn, Mg, and Ca for Fe. IR *MSLM*

4:239(1974), Mossbauer *NJMM:101(1975)*. Uniaxial (-); colorless to yellow/yellow-brown; $N_O = 1.875$, $N_E = 1.633$ (pure).

Studies in the ternary system $\text{CaCO}_3\text{-MgCO}_3\text{-FeCO}_3$ confirm a limited solution of Ca in siderite, a somewhat larger amount of Fe in solution in calcite, and a complete solid solution Fe-Mg between magnesite and siderite, but an Fe analog of dolomite, $\text{CaFe}(\text{CO}_3)_2$, has not been synthesized, nor does it exist in nature *MSASC 11:66(1983)*. The phase ankerite, or ferroan dolomite, is discussed in 14.2.1.2. A complete Fe-Mn solid solution from siderite to rhodochrosite also exists.

Siderite occurs primarily in bedded biosedimentary deposits with shale, clay, and organics (coal), where it is often massive and fine grained, or concretionary. These morphologies indicate that siderite was probably biogenically generated under low-oxygen, low-Eh conditions. Also found in metamorphosed sedimentary deposits with larger grain size, in pegmatites, as a gangue mineral in hydrothermal vein deposits, and in nepheline syenite pegmatites. A large vein deposit of siderite mined by the original colonists is still accessible at Mine Hill, Roxbury, CT(*); formerly mined with limonite, "black-band" ore, clay stone, and coal measures in eastern PA, IL, ID, OH, KY, and WV; in cretaceous clays of coastal plain, MD. Prominent in the iron ranges of Northern Peninsula, MI, and as an important gangue mineral in lead silver mines of Coeur d'Alene and other districts in ID, and in Bisbee district, AZ. Globular fibrous siderite is found in diabase in Weehawken, NJ, and Spokane, WA. Canadian occurrences: Slocan district, BC; Keno City, YT; and at the Acadia mines, Londonderry, NS; fine crystals to 15 cm at Mt. St.-Hilaire(!), QUE, Canada. Siderite is associated with cryolite at Ivigtut(*), Greenland. Well-crystallized siderite was found in the tin veins of Cornwall, especially at Camborne, Redruth, St. Austell, and at Tavistock, Devonshire; mined with the black-band ores in Somerset, Durham, Northumberland, and Yorkshire, England. Important replacement and metamorphic deposits are found in Erzberg near Eisenerz, Styria, and at Hüttenberg-Lölling, Carinthia, Austria; in the silver veins at Freiberg, in the Harz Mts., in the Siegen region of Westphalia, and in Kamsdorf, Thuringia, Germany; finely crystalline siderite in the Piedmont, Italy; at Isere, France; in Val Tavetsch, Switzerland. Siderite was also a common constituent of the clay iron ores near Radom, central Poland, and of the black-band ores in the Kertsch and Taman peninsulas, Russia. At Tatasi, Bolivia; also at the Morro Velho gold mine(!), Nova Lima, and in large perfect crystals up to 15 cm in alpine cleft-type vugs in gneiss on Ibituruna Mt.(!), Governador Valadares, MG, Brazil. hcws *DII:166, MSASC:11(1983)*.

14.1.1.4 Rhodochrosite MnCO_3

Named in 1800 after the (rose) color. Calcite group. $\text{HEX-R } R\bar{3}c$. $a = 4.7682$, $c = 15.6354$, $Z = 6$, $D = 3.72$ *MSASC 11:11(1983)*. $44\text{-}1472(\text{syn})$: 3.67_3 2.85_{10} 2.40_2 2.178_2 2.005_2 1.773_2 1.766_3 1.538_1 . Distinct crystals infrequent but rhombohedral forms often rounded, rarely scalenohedral, thick tabular, pris-

matic. Usually massive, coarsely granular, incrusting, botryoidal and globular aggregates that are concentrically banded and radially fibrous to columnar. In parallel growth with dolomite, and with $\text{Li}(\text{NO}_3)_{\text{syn}}$. {0112} twinning rare. Various shades of pink to red, also yellow-gray, beige to brown; white streak; vitreous to pearly luster, subtransparent to translucent. Cleavage {1011}, perfect; sometimes {0112} parting; translation gliding $T\{0001\}$, $t\{1010\}$. $H = 3\frac{1}{2}$ –4. $G = 3.70$ (pure). IR. *MSLM* 4:239(1974). Uniaxial (–); colorless to pale rose; $N_O = 1.816$, $N_E = 1.597$; variations with Ca, Fe, and Mg substitution. Deep-red varieties may be faintly dichroic, $O > E$. The CaCO_3 – MnCO_3 system resembles the CaCO_3 – MgCO_3 system with the double carbonate phase kutnahorite, $\text{CaMn}(\text{CO}_3)_2$ (14.2.1.3), separating two solid solution series. *MSASC* 11:60(1983). Rhodochrosite is a common primary gangue mineral in moderate- to low-temperature hydrothermal veins with Ag, Pb, Zn, Cu ores containing manganite, alabandite, tetrahedrite, and sphalerite, along with calcite, siderite, dolomite, fluorite, barite, and quartz; also high-temperature metasomatic deposits with rhodonite, friedelite, garnet, braunite, alabandite, hausmannite, and tephroite; and in pegmatites, especially with lithiophilite, also as a secondary mineral in deposits of iron and manganese oxyhydroxides and oxides. Occurrences found in the pegmatites of Poland, ME; at Franklin, Sussex Co., NJ; in veins in Batesville, AR; in CO as rose-red crystals in John Reed mine(*), Alicante, the Climax mine(!), and the Matchless mine(!), near Leadville, Lake Co.; at the Moose mine(*), Central City, Gilpin Co.; at the Sweet Home mine(!), near Alma, Park Co., in clear simple rhombs to 10 cm on quartz druses with fluorite; at the American Tunnel mine(!), Gladstone, San Juan Co., in rhombs to 5 cm on white quartz. Rhodochrosite is abundant at Butte and at Phillipsburg, MT; at the silver mines near Austin, Tonopah, and other districts in NV; at Park City, Marysvale, and Bingham, UT; and in the Tesla district, Alameda Co., with bementite in southern Trinity Co., CA. In Canada at Mt. St.-Hilaire(!), QUE, in color-zoned (orange-red with a red-brown exterior) rhombs to 10 cm, usually twinned, associated with aegirine, albite, leucophanite, microcline, polyolithionite, and sphalerite; brownish to pinkish rhombs. In Mexico at the Potosi mine(!), Sta. Eulalia, CHI, in rhombs and scalenohedra to 5 cm and botryoids of pink to blood-red color, often gem quality, associated with fluorite, hubnerite, helvite, kutnahorite, and so on. Rhodochrosite is found in western Merionethshire, England; with rhodonite, friedelite at Vielle Aure, Hautes-Pyrenees, in France; in the Ardennes, Belgium; at Waldalgesheim, Germany, in spheres to 8 mm and fine microcrystals at Grube Wolf, Herdorf, Siegerland. A well-known European locality is Kapnik, Romania; also Ljubija, Slovenia; bladed rhodochrosites are found on sphalerite crystals from Treпча(!), Serbia; in the Polunchony district, northern Ural Mts., and Krasnoyarsk, Siberia, Russia. In Japan there are beautiful banded and botryoidal formations that contain rhombohedral crystals in a druse of rhodochrosite associated with pyrite, sphalerite at the Inakuraishi(*) and Yakuno(*) mines, Hokkaido, where the ore consists of rhodochrosite, alabandite, sphalerite, galena, pyrite, marcasite, pyrrotite, tetrahedrite–tennantite, pyrrhotite,

gyrite, also at the Oppu mine, Aomori Pref. At Mounana, Gabon; as clear red scalenohedral crystals at N'Chwaning mine(1), Kurumen Mt. district, and in banded stalactitic deposits at Hotazel(1), Kalahari manganese field in the Cape Prov., South Africa; at Burra, SA, and at Broken Hill, NSW, Australia. Exceptional large red rhombs to 15 cm have been found at Huallapon mine(1), Pasto Bueno, Ancash Prov., Peru; at la Rioja, Capillitas bed(1), in Andalgala Co., Catamarca, Argentina, rhodochrosite is found in caverns as large, deep-pink, banded stalactites from which polished decorative objects are made. HCWS *DII:174*, *MSASC 11(1983)*.

14.1.1.5 Sphaerocobaltite CoCO_3

Named in 1877 for composition and form. Calcite group. Also called cobaltocalcite. HEX-R *R3c*. $a = 4.6581$, $c = 14.958$, $Z = 6$, $D = 4.208$. *AM 46:1283(1961)*. *11-692(syn)*: 3.55_4 2.74_{10} 2.33_2 2.11_2 1.948_2 1.702_3 1.697_3 1.495_1 . Crystals are rare; usually as small spherical masses or crusts with concentric and radiating structure. Rose-red, altering to gray, brown, or velvet black; peach-blossom pink streak; translucent. Cleavage {1011}. $H = 4$. $G = 4.13$. IR. *MSLM 4:239(1974)*. Uniaxial (-); $N_O = 1.855$, $N_E = 1.60$; dichroic, violet-red to rose-red. Small amounts of Ni, Fe, and Ca substitute for Co. Found at Boleo, BCS, Mexico; *Schneeberg, Saxony, Germany*, with erythrite and annabergite in Co-Ni veins; in dolomite at Etoile du Congo mine(1), Shaba, Zaire; Jervois Range, NT, Australia. HCWS *DII:175*.

14.1.1.6 Smithsonite ZnCO_3

Named in 1832 after James Smithson (1754-1829), whose generous bequest facilitated the founding of the Smithsonian Institution in Washington, DC. Calcite group. HEX-R *R3c*. $a = 4.653$, $c = 15.026$, $Z = 6$, $D = 4.43$. *MSASC 11:11(1983)*. *8-449*: 3.55_5 2.75_{10} 2.33_3 2.11_2 1.946_3 1.776_1 1.703_5 1.515_1 . Rarely well crystallized; rhombohedral faces generally curved, rough, and composite; ordinarily botryoidal, reniform, stalactitic; encrusting; coarsely granular to compact; massive, earthy, and friable. As porous to cellular or cavernous masses with drusy surfaces. Grayish white to dark gray, greenish or brownish white, also green to apple-green, blue, green-blue, yellow, pink, brown, or white; rarely colorless and transparent; translucent; white streak. Cleavage {1011}, not perfect; translation gliding $T\{0001\}$, $t\{1011\}$; uneven to conchoidal fracture; brittle. $H = 4-4\frac{1}{2}$. $G = 4.2$ (pure). IR. *MSLM 4:239(1974)*. May fluoresce greenish or bluish white in UV. Uniaxial (-); $N_O = 1.848$, $N_E = 1.621$ (Na). Synthetic studies ($> 600^\circ\text{C}$) showed no evidence of a double carbonate, but see minrecordite, $\text{CaZn}(\text{CO}_3)_2$ (14.2.1.4). Limited amounts of Fe, Co, Cu, Mn, Cd, Mg, and Pb are often found in natural smithsonite. Soluble in acids with effervescence. Varieties with a range of colors (e.g., ferroan, manganoan) are well known. A common mineral but not yet described as a primary hydrothermal phase, smithsonite is normally found in the oxidized zone of ore deposits or as a replacement of adjacent calcareous

rocks, where it probably derived from the alteration of sphalerite. Often found in association with hemimorphite, cerussite, malachite, azurite, anglesite, pyromorphite, mimetite, aurichalcite, willemite, and hydrozincite. Smithsonite is found at Friedensville, Lehigh Co., PA; Mineral Point, Iowa Co., WI; Joplin and Granby districts, MO; in large deposits at Monarch and Leadville, CO; Tintic and Ophir districts, UT; Elkhorn district, MT; as fine green to blue botryoidal masses at Kelly mine(1), Magdalena Co., NM; Wood River district, ID; in the 79 mine(*), Gila Co., the Mammoth St. Anthony mine(*), Tiger, Pinal Co., micromount samples were obtained at the Old Yuma mine, Pima Co., AZ; at Bisbee, Cochise Co.; and in the Cerro Gordo district, Inyo Co., CA. In Mexico as pink, botryoidal masses with balls to 5 cm at Choix, SIN, and at the San Antonio mine, CHIH, as stalactites and botryoidal masses to 25 cm in gray, green, yellow, and bright orange (Cd). Abundant in the lead-zinc deposits of the Iglesias district in Sardinia, Italy; in the Aachen district, Rhineland, Germany; at Tarnowskie and Bytom, Silesia, Poland; a cobaltiferous variety at Stoima Planina, Bulgaria: in a variety of colors at Laurium mines(*), Attica, Greece; at Broken Hill Mine, Zambia, both botryoidal and as crystals; fine rhombohedral and scalenohedral colorless, white, pink, bright green, blue, yellow, and in-between-shade crystals up to several centimeters were found at Tsumeb(1), Namibia, associated with cerussite, mimetite, duftite, willemite, and rosasite; at Proprietary mine(1), Broken Hill, NSW, Australia, in botryoidal and mammillary forms as well as crystals. HCWS *DII:176*, *MSASC:11(1983)*.

14.1.1.7 Otavite CdCO_3

Named in 1906 for the Otavi district, Namibia, where Tsumeb is located. Calcite group. HEX-R *R3c*. $a = 4.923$, $c = 16.287$, $Z = 6$, $D = 5.03$. *MSASC 11:11(1983)*. Structure: *DANS 245:1099(1979)*. *42-1342(syn)*: 3.78_7 2.95_{10} 2.46_3 2.07_2 1.891_1 1.839_2 1.826_3 1.583_2 . See also *8-456(syn)*. Minute rhombohedral crystals {1011}. Crusts of white to yellow-brown or reddish, adamantine luster. Not brittle. $H = 4$. $G = 4.96$. Uniaxial (-); $N_O = 1.851$, $N_E = 1.612$. A secondary mineral associated with smithsonite, cerussite, olivenite, pyromorphite, azurite, and malachite from *Tsumeb, Namibia*. HCWS *DII:181*.

14.1.1.8 Gaspeite NiCO_3

Named in 1966 for the locality, Gaspé Peninsula, QUE, Canada. Calcite group. HEX-R *R3c*. $a = 4.621$, $c = 14.93$, $Z = 6$, $D = 4.35$ ($\approx 10\%$ Mg gaspeite). *12-771(syn)*: 3.51_5 2.71_{10} 2.30_3 2.09_4 1.926_3 1.755_2 1.681_5 1.673_4 . See also *23-437*, (Ni, Mg) CO_3 . Rhombohedral crystals up to 0.5 mm length. Light green, yellow-green streak, vitreous to dull luster. Good rhombohedral cleavage (1011), uneven fracture. $H = 4\frac{1}{2}$ -5. $G = 3.71$. IR, DTA magnesian gaspeite. Uniaxial (-); light green; $N_O = 1.83$, $N_E = 1.61$ for magnesian-gaspeite. Gaspeite occurs as a 60-cm wide light green vein, essentially pure (minor serpentine and chrome spinel), in varicolored siliceous dolomite in *Lemieux*

Twsp., Gaspé Nord Co., QUE, Canada, in association with crystalline millerite, niccolite, annabergite, gersdorffite, and magnesite; at Kambalda, WA, Australia. HCWS *AM 51:677(1966)*.

14.1.2.1 Vaterite CaCO_3

Named in 1911 after Heinrich Vater (1859–1930), mineralogist and chemist of Tharandt, Saxony, Germany. Polymorphs: calcite (14.1.1.1) and aragonite (14.1.3.1). *HEX* $P6_3/mmc$. $a = 7.135$, $c = 16.98$, $Z = 12$, $D = 2.645$. *MM 32:535(1960)*. *33-268*: 4.22_3 3.57_6 3.29_{10} 2.73_9 2.11_2 2.06_5 1.854_3 1.820_7 . See also *13-192(syn)*. Often spherulitic, radially fibrous, admixed with aragonite or calcite. Hexagonal plates or lens-shaped skeletal crystals resembling snowflakes were grown artificially. White, or colorless, transparent. $G = 2.645$. IR, Raman. *MSLM 4:247(1974)*. Uniaxial (+); $N_O = 1.550$, $N_E = 1.650$. Synthesized from hydrogels containing KCO_3 at 5° . Inverts to aragonite or calcite in boiling water, and to calcite if water contains NaCl. Dry crystals are stable in air but change to calcite at 440° . Vaterite has been found as rims around amorphous Ca_3SiO_5 in boreholes of Arco No. 1, Susi, Ulster Co., NY; as pseudomorphs after larnite in *Ballycraigy, Larne, Northern Ireland*; in the Hatrurim formation, Israel; in the nacre of mollusks. HCWS *DII:181, ZK 128:183(1969)*.

14.1.2.2 Gregoryite $(\text{Na}_2, \text{K}_2, \text{Ca}, \square)\text{CO}_3$

Named in 1981 for J. W. Gregory (1864–1932), English geologist. *HEX* $P6_3mc$. $a = 5.215$, $c = 6.584$, $Z = 2$, $D = 2.269$. Phase stable $> 490^\circ$; X-ray data at 565° . *25-815(syn)*: 3.72_3 3.29_4 2.66_{10} 2.61_8 2.14_4 1.863_3 1.707_1 1.506_1 . Pattern probably also contains nyerereite (14.3.4.1). Equigranular, rounded, brownish, in a matrix containing bladed crystals of nyerereite and opaque grains of alabandite, MnS. Phase plots close to the solubility limit of CaCO_3 in $(\text{NaK})_2(\text{CO}_3)$. Intimately associated with nyerereite in the *carbonate lavas* that emanated from *Oldoinyo Lengai volcano, Tanzania*. HCWS *AM 66:879(1981)*, *LIT 13:23(1980)*.

ARAGONITE GROUP

The aragonite mineral group is similar to the calcite mineral group, both having the chemical formula

but in aragonite

$A = \text{Ca}, \text{Sr}, \text{Ba}, \text{Pb}$

and these species crystallize in the orthorhombic system, space group *Pmcn*.

The structure [*AM 56:758(1956)*] consists of alternating layers of cations and trigonal carbonate groups perpendicular to the c axis, with the triangles pointing in opposite directions in alternate layers, similar to the minerals of the calcite group. The larger size and coordination number of the cations in arago-

nites group leads to an orthorhombic structure type. The carbon of the aragonite CO_3^{2-} is slightly out of the plane (0.026 Å in aragonite, less in strontianite and witherite) slightly displaced along the b axis (0.20 Å in aragonite) from one carbonate layer to the next along c , and the plane defined by the three oxygens is tilted about 2.5° from (001). Further, the divalent cations are not strictly planar. Alternate atoms vary, each being ± 0.05 Å out of the plane and coordinated with a total of nine oxygens: six bonds are made with two (edge) oxygens on three separate carbonate groups, and three bonds with single (corner) oxygens of three other carbonate groups. The result is a distorted polygon in which the distances to corner oxygens are shorter than those with the six edge oxygens (2.41–2.45 Å versus 2.52–2.66 Å for aragonite). Because the cations are pseudohexagonally arranged within (001), the disposition of the slightly puckered atoms produces an ABAB layered sequence along c , and the stacking order of the alternating cation and anion planes along c becomes $\text{AC}_1\text{BC}_2\text{AC}_1\text{BC}_2$. The result is an orthorhombic rather than hexagonal–rhombohedral space group. *MSASC 11:146(1983)*.

ARAGONITE: CaCO_3

The aragonite structure is similar to calcite (14.1.1.1) with alternating layers of CO_3 pointing in opposite directions but larger size cations take on nine-fold coordination with the oxygens of the CO_3 groups. This c axis projection illustrates the different polygonal arrangement for calcium. Minerals in the group normally have a prismatic habit and orthorhombic, pseudo-hexagonal symmetry. Aragonite, for example, has a prism angle of $62\text{--}63^\circ$ and repeated twinning on $\{110\}$ results in pseudo-hexagonal aggregates. Compare with ancylite (16b.1.1.1).

ARAGONITE GROUP*

Mineral	Formula	Space Group	Space Group				D
			a	b	c	D	
Aragonite	CaCO ₃	<i>Pmcn</i>	4.9598	7.9641	5.7379	2.944	14.1.3.1
Witherite	BaCO ₃	<i>Pmcn</i>	5.3126	8.8958	6.4284	4.29	14.1.3.2
Strontianite	SrCO ₃	<i>Pmcn</i>	5.090	8.358	5.997	3.785	14.1.3.3
Cerussite	PbCO ₃	<i>Pmcn</i>	5.1800	8.492	6.134	6.582	14.1.3.4

*For data from synthetic samples, see *MSASC 11:146(1993) table 1a*).

There is limited isomorphous substitution detected between members of the group. *MSASC 11:159(1983)*.

MAXIMUM MISCIBILITY IN THE ARAGONITE GROUP (MOL %)

	Ca	Sr	Ba	Pb
Aragonite	—	14%	0	2%
Strontianite	27%	—	3%	0
Witherite	0.5%	8%	—	trace
Cerussite	3%	3%	0	—

At elevated temperatures and pressures there is complete miscibility for the end members except for the pairs Ca–Ba and Ca–Pb.

Notes:

1. The orthorhombic space group of the Aragonite Group minerals is usually given as *Pmcn* to conform with the order of increasing length for the unit cell parameters: $a < c < b$, which facilitates comparison of morphology and physical properties.
2. Synthetics rare-earth carbonates (Yb, Eu, Sm) and radium confirm the preference of large cations for the aragonite structure *MSASC 11:145(1983)*.
3. Three double carbonates have been described. All are polymorphs of BaCa(CO₃)₂.
4. See also the ancylite group (16b.1.1.1).

14.1.3.1 Aragonite CaCO₃

Named in 1790 by Abraham Gottlob Werner (1749–1817), after the original locality in Aragon, Spain. Aragonite group. Polymorphs: calcite (14.1.1.1) and vaterite (14.1.2.1). ORTH *Pmcn*. $a = 4.9598$, $b = 7.9641$, $c = 5.7379$, $Z = 4$, $D = 2.944$. *MSASC 11:146(1983)*. $41-1475$: 3.40_{10} 3.27_5 2.70_6 2.48_4 2.37_5 2.34_3 2.33_3 1.977_6 . See also *5-453*. **Physical properties:** Crystals short to long prismatic [001], sometimes flattened {010}; or acicular, often with steep domes or pyramids; or tabular {001}. Most seemingly single crystals are twinned. Polysynthetic twins produce lamellae or fine striations parallel to [001] which become obvious on optical exam or with etching. If {110} is the twin plane and the composition plane, the result is the formation of pseudo-hexagonal aggregates of contact and penetration types (Fig. 14.1.3.1A). Aragonite is also found as stalactites; as columnar, radiating, or stellate aggregates; as lamellar crusts composed of fibers; as acicular crystals. Colorless to white, gray, pale to deep blue, green, rose-red or violet; uncolored streak; transparent to translucent; vitreous to resinous luster. Cleavage {010}, distinct; subconchoidal fracture; translation gliding T{010}, t[100],

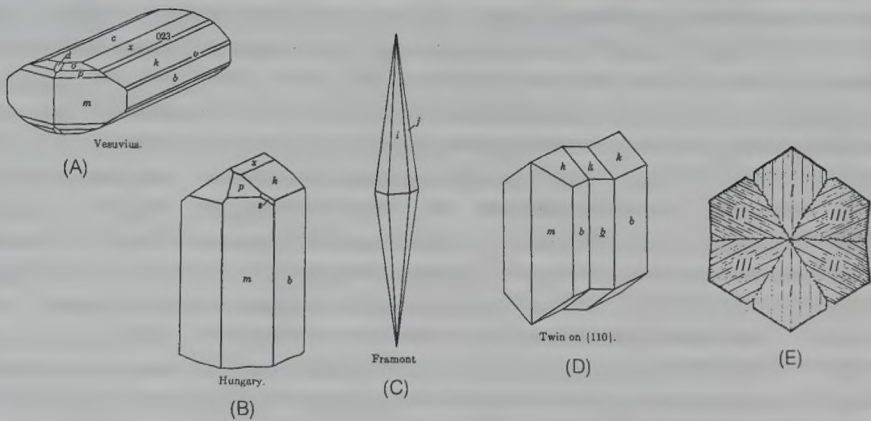

Figure 14.1.3.1a

CRYSTAL FORMS OF ARAGONITE

(A) Prismatic [001], (B) Prismatic {110}, {010}, (C) Acicular with steep pyramids, (D) twin on {110}, (E) Pseudohexagonal aggregate of contact and penetration twins. $b = (010)$, $c = (001)$, $d = (102)$, $i = (021)$, $j = (0, 10, 1)$, $k = (011)$, $m = (110)$, $p = (111)$, $s = (121)$, $v = (031)$, $x = (012)$.

and twin gliding; brittle. $H = 3\frac{1}{2}$ –4. $G = 2.947$. IR, Raman *MSLM 4:242(1974)*, *SWVD:36(1991)*. Fluorescent under electron, X-ray, UV, usually pale rose, yellow, bluish, with greenish phosphorescence in LWUV, yellowish in SWUV. Biaxial (-); $N_x = 1.531$, $N_y = 1.681$, $N_z = 1.685$; $2V_{\text{calc}} = 18.25^\circ$; $r < v$; optics variable with cationic substitution. **Chemistry:** Some minor substitution of Sr, Pb, and Zn are usual with the varieties exhibiting zoning. Limited F substitution detected in inorganic marine aragonites and Sr, Na, and Mg in aragonitic shell materials. Soluble with dilute acids, with effervescence. Easily synthesized from concentrated solutions of calcium salts, especially in the presence of the larger atoms named above, at relatively higher temperature than calcite, or with more rapid precipitation from highly concentrated reactants. **Occurrence:** Aragonite, the most common orthorhombic anhydrous carbonate and one of the three polymorphs of CaCO_3 , is unstable relative to calcite at surficial temperature and pressure; paramorphs of calcite after aragonite are common. However, the mineral is often found in stalactites and stalagmites; as pisolites, sinters, and massive lamellar deposits at geysers and hot springs along with sulfates; as sea-bottom oolites; with siderite in iron deposits, with calcite and dolomite and other magnesian minerals in altered serpentines, or as the replacement mineral in sedimentary, metamorphic, and basic igneous rocks; in ore deposits, where it forms from low-temperature and pressure aqueous solutions; as the carbonate phase in invertebrate skeletons and the sediments derived from them. Aragonite may be a primary phase in high-pressure metamorphic rocks. **Localities:** Good crystals come from many localities, but North American specimens are uncommon. Fine crystals are found in numerous caves along the Appalachian mountain chain, and with calcite, from the Magdalena district, Socorro Co., NM. A

zincian variety occurs with secondary zinc ores from Leadville, CO; in the Tintic district, UT; as coralloidal masses, sometimes copper-stained, from Bisbee, Cochise Co., AZ; also as large twinned crystals replaced by calcite from clay beds around Las Animas, Bent Co., CO. Very nice cave growths from numerous localities in Mexico, especially at the Francisco Portillo mine, Santa Eulalia, CHIH. As pseudo-hexagonal prisms up to 20 cm from Frizington, Cleator Moor, and other places in Cumbria, England, and in the Leadhills, Scotland. From Spain as coralloidal (flos-ferri or iron flowers) intertwined slender snow-white branches and stalagmites from the Florida mine, Santander province, and in fine yellow crystals to 8 cm from a magnetite quarry at Eugui, Navarra Prov., and at the original site of Molina, Aragon Prov., and near the Caracol salt mine near Minglanilla, Cuenca Prov., as twinned pseudo-hexagonal prisms up to 15 cm and tablets in a red-brown and blue-gray gypsum-bearing clay. In France similar deposits are found in the region of Dax, Pouillon, and Bastennes; also occurring in volcanic rocks of the Auvergne, Puy de Dome. From Germany in basaltic rock at Kaiserstuhl, Baden, and as pseudomorphs after gypsum (schaumkalk) at Wiederstadt in the Harz. A plumbian variety (tarnowitzite) occurs in dolomitic lead ore from Tarnowitz, Silesia, Poland. From Austria as flos-ferri at Erzberg near Eizsennerz and Huttenberg, Lolling, also as crystals from Werfen and Leogang, Salzburg. Beautiful orthorhombic clear yellow crystals (suitable for faceting) to over 10 cm from veins traversing basalt near Horschenz (Bilin), Czech Republic, and as pseudo-hexagonal twins from Herrengrund, and as the finest white elongated prisms reaching 30 cm from Podrechany, Hungary. Numerous localities from the sulfur mines of Sicily, Italy, particularly from Racaulto, Cianciana, and Agrigento as fine pseudo-hexagonal prisms to 10 cm. Fine flos-ferri from the old iron, lead, and silver mines around Laurion, in southern Greece. Also found with the geyser deposits and sulfurous hot pools at Osorezan; Tottoku dist.; at Kuriyama Yuzawa, Shimotsuke Pr., at the Takasecawa R., Shinano Pr.; as nodular aggregates in clay and gypsum at Matsushiro, Iwami Pr., Japan. From Morocco in bursts of crystals similar to the Spanish pseudo-hexagonal twins from Tezouta, near Sefrou and as blue-green and olive green botryoidal crusts on galena, and as plumbian variety white pseudo-hexagonal prisms to 7 cm from Touissit mine, south of Oujda; as clear, white, and blue needlelike and white elongated pseudo-hexagonal prisms of plumbian variety crystals from Tsumeb, Namibia. Pseudomorphs of copper after aragonite are found at Corocoro, Bolivia. *ncws DII:191, MSASC 11:195(1983)*.

14.1.3.2 Witherite $BaCO_3$

Named in 1790 after William Withering (1741–1799), English physician and mineralogist, who called attention to the mineral. Aragonite group. See alstonite (14.2.5.1), paralstonite (14.2.2.2), and barytocalcite (14.2.6.1), all polymorphs of the double carbonate $BaCa(CO_3)_2$. ORTH *Pmcn*. $a = 5.3126$, $b = 8.8958$, $c = 6.4284$, $Z = 4$, $D = 4.29$. *MSASC 11:146(1983)*. 45-1471:

3.72₁₀ 3.66₅ 3.22₂ 2.63₃ 2.59₄ 2.15₅ 2.02₄ 1.94₃. See also 44-1487(syn). Crystals always repetitively twinned on {110}, resulting in pseudo-hexagonal dipyr-amids, also short prismatic [001], tabular to lenticular. Morphology often complex, faces rough, horizontally striated; also globular, botryoidal, granular, coarse fibrous. Colorless to milky white-gray, also tinted yellow, brown, or green; white streak; transparent to translucent. Cleavage {010}, distinct; {110}, imperfect; uneven fracture. $H = 3-3\frac{1}{2}$. $G = 4.291$. IR, Raman. *MSLM* 4:242(1974). Fluorescent and phosphorescent in X-ray, electron beams, UV. Thermoluminescent. Biaxial (-); XYZ = *cba*; $N_x = 1.529$, $N_y = 1.676$, $N_z = 1.677$ (Na); $2V = 16^\circ$; $r > v$, weak. Minor amounts of Sr and Ca detected in analyses. Soluble in dilute HCl. Witherite is the most common barium mineral after barite, although a rare mineral. It occurs in low-temperature hydrothermal veins with barite, alstonite, calcite, galena, and other sulfides. Fine crystals at Minerva mine, Cave in Rock, Hondin Co., IL(1); at El Potal, Mariposa Co., CA. Important commercial vein deposits with barite occur in northern England, particularly *Alston Moor, Cumberland*; in Lamothe coal measures and at Brioude, Haute-Loire, France; in barite veins in Arkhyz and Djalankol deposits, North Caucasus, Kopets Mts., Karakala region, Turkmenistan; as radial aggregates at Tsuaki silver mine Ugo Pref., Japan. *HCWS DII:196, MSASC 11:145(1983)*.

14.1.3.3 Strontianite $SrCO_3$

Named in 1791 after the town in Scotland where the mineral was found. Aragonite group. The element Sr was discovered in this material (1790). ORTH *Pmcn*. $a = 5.090$, $b = 8.358$, $c = 5.997$, $Z = 4$, $D = 3.785$. *MSASC 11:146(1983)*. 5-418(syn): 3.54₁₀ 3.45₇ 2.48₃ 2.46₄ 2.45₃ 2.05₅ 1.986₃ 1.905₄. See also 44-1421, calcian strontianite. Crystals short prismatic [001], often acicular, or acute spear-shaped. High calcian varieties often show steep pyramidal forms; often pseudo-hexagonal. {110} and {010} striated horizontally, {*hhl*} and {*0kl*} sometimes rounded; massive, columnar to fibrous; granular; rounded masses. Twinning common, twin plane {110}, usually contact rarely penetration twins; repeated twinning gives trillings; polysynthetic twinning results in obvious twin lamellae. Colorless to gray, yellowish, greenish, yellow-brown to reddish; transparent to translucent. Cleavage {110}, nearly perfect; uneven to subconchoidal fracture; brittle. $H = 3\frac{1}{2}$. $G = 3.76$ (pure). IR, Raman. *MSLM* 4:242(1974). Fluorescent and phosphorescent in X-ray, electron beams, and UV, sometimes thermoluminescent. Biaxial (-); XYZ = *cba*; $N_x = 1.520$, $N_y = 1.667$, $N_z = 1.669$ (Na); $2V_{calc} = 7.1^\circ$; $r < v$, weak. Solid solutions of Ca in strontianite up to 27 mol %, Ba up to 3.3%. Soluble in dilute HCl. Strontianite is a low-temperature hydrothermal mineral associated with barite, celestite, and calcite, often as veins in limestone or marble; occasionally, part of the gangue with sulfide minerals; also forms geodes, concretionary forms in clays. Geodes and veins with celestite and calcite in limestones of Schoharie Co., NY; with aragonite in limestones in Mifflin Co., PA; also with celestite in calcite cap rock of salt domes, Gulf coast LA and

TX; large deposits in Strontium Hills, N of Barstow, San Bernardino Co., CA. In Canada vein deposits in limestones at Nepean, Carleton Co., ONT, and in Cariboo district, BC. Commercially important deposits in marls of Westphalia, Germany, principally near Hamm and Munster, also with metal veins in the Harz and near Freiberg, Saxony; also with zeolites at Oberschaffhausen in the Kaiserstuhl, Baden. Original description from veins in a gneiss at *Strontian, Argyllshire, Scotland*. With celestite in a lead-silver deposit in Sierra Mojada district, COAH, Mexico; with celestite, gypsum, and phosphatic nodules in clay at Trichy, India. *ncws DII:196, MSASC 11:158(1983)*.

14.1.3.4 Cerussite PbCO_3

Artificial lead carbonate was written about as early as 400 B.C. by the Greeks, named after *cerussa* (Latin, *white lead*). Aragonite group. ORTH *Pmcn*. $a = 5.1800$, $b = 8.492$, $c = 6.134$, $Z = 4$, $D = 6.582$. *MSASC 11:146(1983)*. 5-417(syn): 3.59_{10} 3.50_4 3.07_2 2.52_2 2.49_3 2.08_3 1.933_2 1.859_2 . **Physical and chemical properties:** Extremely varied crystal forms, including tabular {010}, elongated [001] or [100], equant, dipyrmidal, pseudo-hexagonal, rarely acicular, thin tabular {001}. {010} and {0kl} striated on [100]; commonly groups in clusters due to almost universal twinning on {110}, {130}. Colorless to white, gray, smoky, sometimes dark gray to black, due to included particles of sulfides, manganese oxides, or carbonaceous materials; also blue to green with copper impurity; colorless to white streak; adamantine to vitreous, resinous, and pearly luster, sometimes submetallic if dark due to surface films; transparent to translucent. Cleavage {110}, {201}, distinct; conchoidal fracture; brittle. $H = 3-3\frac{1}{2}$. $G = 6.55$. IR, Raman. *MSLM 4:242(1974)*. Fluorescent yellow with X-rays, LWUV. Biaxial (-); $N_x = 1.804$, $N_y = 2.077$, $N_z = 2.079$ (Na); $2V_{\text{calc}} = 9^\circ$; $r > v$, strong. Soluble with effervescence in 1:10 HNO_3 . Natural cerussite shows little cation substitution. **Occurrence:** Cerussite is a secondary Pb mineral, an alteration product of galena, PbS, and anglesite, PbSO_4 . It is the corrosion product of metallic lead or lead alloys and has been known since Roman times. A common lead mineral, cerussite is found in the upper oxidized portions of ore deposits with iron oxides, anglesite, pyromorphite, malachite, azurite, smithsonite, and other lead, zinc, or copper secondary minerals. **Localities:** Fine specimens were found at Wheatley Mines, Phoenixville, PA(!); Austinville, VA; Joplin, MO; Mineral Point in southern WI; abundant at Leadville, CO(*); Elkhorn and Wickes districts, Jefferson Co., MT; an important ore mineral in silver-lead districts of Shoshone and Coeur d'Alene, ID. Twinned crystals from Stevenson-Bennet mine(!), Organ district, Dona Ana Co., NM, and in the Magdalena district(!) and other places; fine twin specimens and reticulated masses with wulfenite and other minerals at the Mammoth-St. Anthony mine(!), Tiger, Pinal Co.; in the Warren district(*); the Hilltop mine(!), Cochise Co.; the 79 mine(!), Gila Co.; Flux mine(!), Santa Cruz Co.; Red Cloud mine(!), Yuma Co., AZ; also occurs in the Eureka and Goodsprings districts, NV; at the Modoc mine(!), Monster mine(!), and the Cerro Gordo mine, Inyo Co., as well as others in

southern CA. In Mexico at the Bilbao mine(*), ZAC, and in CHIH at Santa Eulalia, and as pseudomorphs after anglesite at Mina Erupcion(!), Los Lamentos. In Canada at Salmo, BC, in the Moyie and H.B. mines. Abundant in Spain in Sierra de Cartagena, Murcia, and in Linares regions of Andalusia; fine crystals were found with leadhillite, caledonite, and linarite at Leadhills(!), Scotland; at Mies, Bohemia, Czech Republic; at Rēzbānya, Comitat Bihar, Hungary; with anglesite and phosgenite in lead mines of Monteponi(!) and Montevecchio(!), Sardinia, Italy; V-shaped twins occur at the Touissit Mine(!), Oujda district, and crystals associated with barite are found at Mibladen, Sefron region, Morocco; exceptional large transparent twin crystals at the Kombat mine(!), Klein Otavi, and crystals, reticulated twins, of exceptional size, variety, and perfection are associated with azurite, malachite, smithsonite, and other minerals at the Tsumeb mine(!), Namibia; at the Broken Hill mine, Zambia; occurs with zinc phosphates at Mindouli, Zaire. At the Proprietary mine(!), Broken Hill, NSW, Australia, the major portion of the oxidized zone was pure cerussite, and magnificent crystals and reticulated groups of large size were obtained, and also in TAS, the Mt. Bischoff(!) and Magnet(!) mines near Waratah produced bright yellow crystals of chromian cerussite and the Comet mine(!) near Dundas gave spectacular specimens; in New Zealand the Tui mine(!) on Mt. Te-Aroha; at the San Jose mine(*), Oruro Prov., Bolivia. Cyclic twinned crystals and flat crystals up to 5 cm length were found at the Boquira mine(!), BA, Brazil, and the Santana Nova prospect(*) near Lagerado, SP, gave crystals and twins to 10 cm. HCWS *DII:200*, *MSASC 11:174(1983)*.

14.1.4.1 Rutherfordine $(\text{UO}_2)\text{CO}_3$

Named in 1906 for New Zealand-born, British atomic physicist and Nobel laureate Ernest Rutherford (1871–1937). ORTH *Pmmn*. $a = 4.845$, $b = 9.205$, $c = 4.296$, $Z = 2$, $D = 5.72$. *SCI 121:472(1955)*. $11-263$: 4.61₁₀ 4.30₇ 3.92₃ 3.23₄ 2.64₃ 2.31₂ 2.06₂ 1.926₂. Lathlike crystals up to 3 mm length with [001] elongation, large (100), (010); striated on (100) parallel to [001]. Pale yellow to amber. Cleavage parallel to (010), perfect; (001) fair. Biaxial (+); XYZ = *bca* (*c* elongation); $N_x = 1.715$, $N_y = 1.730$, $N_z = 1.795$; $2V_{\text{calc}} = 53^\circ$. *AM 41:844(1957)*. The positive sign, which distinguishes this carbonate mineral, is probably due to the disposition of linear $(\text{O}-\text{U}-\text{O})^{+2}$ ions perpendicular to the layers of $(\text{CO}_3)^{2-}$ groups which parallel (010) in the structure. Soluble in acids. Found as pseudomorphs after uraninite in pegmatites in *Uruguru Mts., Morogoro district, Tanzania*; as radiating strawlike clusters on uraninite with masuyite from Shinkolobwe, Shaba, Zaire; El Sharana, NT, Australia. HCWS *DII:247*.

14.1.5.1 Widenmannite $\text{Pb}_2(\text{UO}_2)(\text{CO}_3)_3$

Named in 1961 after Bergrat J. F. Widenmann (1764–1798), who first discovered uranium containing micas in the Schwarzwald. ORTH *Pnnm*, *Pnm2₁*, or *P22₁2₁*. $a = 8.99$, $b = 9.36$, $c = 4.95$, $Z = 2$, $D = 6.89$. *SMPM 56:167(1976)*.

27-281: 4.16₁₀ 3.34₇ 3.19₈ 2.57₄ 2.34₁₀ 1.911₅ 1.869₅ 1.473₅. Fragile, tabular (100), yellow crystals. Pearly to silky luster. Cleavage {100}, perfect. Not fluorescent in UV. Biaxial (-); XYZ = *bac*; $N_x = 1.803$, $N_y = 1.905$, $N_z = 1.945$; $2V = 63^\circ$. Soluble in 1:10 HNO₃. Occurs as tufts or radiating bundles of lathlike crystals in cavities associated with compact quartz, cerussite, hügelite, hallimondite, and altered galena in the *Michael mine, Weiler bei Lehr, Schwarzwald, Germany*. HCWS AM 47:415(1961).

14.1.6.1 Natrite Na₂CO₃

Named in 1983 for the composition. Zabuyelite (14.1.6.2) is the Li analog; see also thermonatrite (15.1.1.1). MON C2 or C_m. $a = 8.906$, $b = 5.238$, $c = 6.045$, $\beta = 101^\circ$, $Z = 4$, $D = 2.55$. ZVMO 111:220(1983). 37-451: 2.96₁₀ 2.62₃ 2.60₄ 2.55₆ 2.37₇ 2.25₄ 2.19₂ 2.18₄. Massive, pseudo-hexagonal. Gray-white to colorless, dull luster. Cleavage {001}, perfect; (100) (110), less perfect. $H = 3\frac{1}{2}$, $G = 2.54$. Soluble in water. DTA, DGA data. IR confirms absence of water in compound. Biaxial (-); $Y = b$; $N_x = 1.410$, $N_y = 1.535$, $N_z = 1.543$; OAP (010); $2V = 28^\circ$. Occurs in deep workings and drill cores in mines of Kola Penin., Khibina massif, and with foyaite(?) on mine dumps on *Mt. Karnasurt, Lovozero massif, Kola Penin., Russia*. HCWS MA:755(1983).

14.1.6.2 Zabuyelite Li₂CO₃

Named in 1978 for the locality. MON C2/c. $a = 8.356$, $b = 4.964$, $c = 6.185$, $\beta = 114.6^\circ$, $Z = 4$, $D = 2.10$. AM 75:243(1990). 22-1141(syn): 4.16₉ 3.80₂ 3.03₃ 2.92₈ 2.81₁₀ 2.63₃ 2.49₂ 2.43₄. Prismatic crystals 1.5–7 μm long embedded in rock salt layers with gaylussite and northupite, or as doubly terminated (pyramids) prisms up to 1.2 mm long from periphery of Li-rich salt lake. Colorless, transparent, vitreous luster. Cleavage {100}, perfect; {011}, moderate; brittle; twinned (100). Not fluorescent. $G = 2.09$. Biaxial (-); $Y = b$; $Z \wedge c = 10^\circ$; $N_x = 1.429$, $N_y = 1.567$, $N_z = 1.574$; $2V = 25^\circ$. Slightly soluble in water, effervesces in 1:10 HCl. Found at *Zabuye Salt Lake, Nagri, Tibet, China*. CS MM 54:671(1990).

DOLOMITE GROUP

The dolomite group, four double carbonates of divalent cations, has the general formula

where

A = Ca

B = Mg, (Fe²⁺, Mg), Mn²⁺, Zn

and where the space group is *R*3.

The dolomite group minerals show similarities with the calcite group. (CO₃)²⁻ groups in planar layers are perpendicular to the *c* axis and alternate

with layers of cations. The two types of cations are segregated into self-contained layers giving rise to the ordered sequence A-(CO₃)-B-CO₃-A-(CO₃)-B(CO₃)... along *c*. The ordering influences the cation-oxygen bond lengths, and results in a lowering of the space group symmetry from R3c in calcite to R3 in dolomite.

DOLOMITE GROUP

Mineral	Formula	Space Group	<i>a</i>	<i>c</i>	<i>D</i>	
Dolomite	CaMg(CO ₃) ₂	R3	4.8069	16.0034	2.85	14.2.1.1
Ankerite	Ca(Fe ²⁺ , Mg, Mn ²⁺)(CO ₃) ₂	R3	4.830	16.167	3.00-3.10	14.2.1.2
Kutnohorite	Ca(Mn ²⁺ , Mg, Fe ²⁺)(CO ₃) ₂	R3	4.915	16.639	3.12	14.2.1.3
Minrecordite	CaZn(CO ₃) ₂	R3	4.8183	16.0295	3.44	14.2.1.4

Notes:

1. CaFe(CO₃)₂, is not known experimentally nor in nature.
2. Substitution and disordering between the A and B cation positions is common with a concomitant reduction of stability of the ordered structure relative to single cation rhombohedral end members. This is especially true for Fe-containing systems.
3. Microscale compositional (and structural) variations are evidenced in the saddle-shaped habit of some dolomite group minerals (R. Faux, pers. com., 1996).

DOLOMITE: CaMg(CO₃)₂

This projection down *a*^{*} of dolomite, a rhombohedral double carbonate, is virtually identical to adleite, but with two ordered and distinct cation layers representing the 50:50 mole proportions of A and B cations. The space group changes to R3.

14.2.1.1 Dolomite $\text{CaMg}(\text{CO}_3)_2$

Named in 1791 after Deodat Guy Silvain Tancrede Gratet de Dolomieu (1750–1801), French engineer and mineralogist. Dolomite group. **HEX-R** $R\bar{3}$. $a = 4.8069$, $c = 16.0034$, $Z = 3$, $D = 2.85$. *MSACS 11:22(1983)*. *36-426*: 3.70₁ 2.89₁₀ 2.67₁ 2.40₁ 2.19₂ 2.02₁ 1.805₁ 1.787₁. See also 11-78. **Physical properties**: Commonly rhombohedral $\{10\bar{1}1\}$, or $\{4041\}$ dominant; prismatic $\{1120\}$ terminated by rhombohedrons; tabular $\{0001\}$ with $\{11\bar{2}0\}$. $\{10\bar{1}1\}$ often striated horizontally or curved, the “saddle” forms. Twinning with $\{0001\}$, $\{1010\}$, or $\{1120\}$ twin planes common. Also massive, coarse to fine granular; fibrous or pisolitic. Colorless to white, grayish, greenish, becoming more brown with increase of Fe^{2+} , or reddish with Mn^{2+} ; streak same colors; vitreous to pearly luster, sometimes porcelaneous or opaline; subtranslucent. Cleavage $\{1011\}$, perfect; conchoidal fracture; brittle; twin gliding $\{0221\}$; translation gliding $T\{0001\}$, $t[1010]$. $H = 3\frac{1}{2}$ –4. $G = 2.85$, values increase when Fe or Mn substitutes for Mg. Uniaxial (-); $N_O = 1.679$, $N_E = 1.500$ (pure). IR, Raman. *MSLM 4:254(1974)*, *ISM:82,84,86(1991)*. Some varieties fluoresce in UV; triboluminescent. **Chemistry**: Limited substitution in the cation positions; ferroan, cobaltian, plumbian, and manganian dolomite with distinct coloration have been described. The maximum Ca detected in dolomite can be expressed as $\text{Ca}_{57}\text{Mg}_{43}$. Differences in the unit cell parameters between low- and high-temperature dolomite add to the complexity of interpretation of cation ordering. *MSASC 11:37(1983)*. Synthesis of dolomite at ordinary temperatures and pressures has not been demonstrated except at elevated CO_2 pressures, but “protodolomite” precipitates in lagoons. *AJS 261:449(1963)*. **Occurrence**: Dolomite is a common and important sedimentary and metamorphic carbonate mineral. It may be found in massive amounts in marbles, rocks that reflect metamorphism, especially the chemical alteration, of calcitic limestones. In addition to calcite and dolomite, these rocks often contain a variety of silicate minerals. Dolomite is also found as a hydrothermal mineral with barite, fluorite, calcite, siderite, quartz, and sulfides; forming crystals in cavities in limestones or marbles; in serpentinites and soapstone-talc rock. See also discussion of dedolomitization. *AAPG(B) 12:762–764*. **Localities**: Rhombohedral crystals of dolomite are found in talc at Roxbury, VT, and with magnesite, pyrite, and talc in chloritic rocks; with gypsum and celestite in cavities at Rochester and Niagara Falls, and at the Tilly Foster mine, Putnam Co., NY, with magnetite and serpentine; at Franklin, Sussex Co., NJ, in the Buckwheat open pit; in pegmatite veins with rutile and muscovite at Stony Point, Alexander Co., NC; in quartz geodes from Keokuk, Lee Co., IA; in the Mascot-Jefferson City district, Knox and Jefferson Cos., TN. Dolomite is abundant as gangue mineral in the Tri-State Zn–Pb mining district, MO–KS–OK; in the Marquette iron district, MI; in many western U.S./Canadian mining districts as a gangue mineral (i.e., at Climax mine, Lake Co., and Camp Bird mine, Ouray Co., CO); ferroan dolomite is found at the Vekol mine, Casa Grande, AZ; at Guanajuato silver mines, GTO, Mexico, and at Santa Eulalia(*), CHIH, in crystals to 5 cm. Sharp, clear,

transparent individuals to 10 cm and crystalline groups were found in a quarry at Eugui, Navarre, Spain(!); in England in the metallic veins of Cornwall; in France at Markirch, Alsace; in the German mines of Freiberg, Saxony. Fine crystals are found in Brosso(!), Traversella in the Piedmont, and at Pfitschtal in Trentino, Tuscany, while massive dolomite strata gave the name to the Dolomites, a mountain chain in northern Italy; notable crystals occur in dolomite rock at Lengenbach quarry(!), Binnenthal, Valais, and in rock salt at Bex, Switzerland; clear crystals are found near Djelfa(*), Algeria; and Co, Mn, Pb, and Zn varieties are found at the Tsumeb mine(!), Tsumeb, Namibia. A relatively homogeneous gray dolostone comprised almost entirely of interlocking rhombohedral dolomite crystals is found in Minowa, Kuzuu, Ashio Mts., Tochigi, Japan; dolomite is also found in the Ibi district, Gifu Pref.; at the Proprietary mine, Broken Hill, NSW, and in the modern sediments of the Coorong, southeastern SA, Australia; in Brazil at the Pedra Preta mine(!), Brumado district, BA, in sharp yellowish crystals and twins to 20 cm associated with crystalline magnesite and other minerals; ferroan dolomite at the Morro Velho gold mine(!), Nova Lima, MG, Brazil. Dolomite has been reported in carbonaceous chondrites. *HCWS DII:208*.

14.2.1.2 Ankerite $\text{Ca}(\text{Fe}^{2+}, \text{Mg}, \text{Mn}^{2+})(\text{CO}_3)_2$

Named in 1825 after Mathias Joseph Anker (1771–1843), Styrian (Austria) mineralogist. Dolomite group. The pure iron analog of dolomite does not exist naturally or synthetically; up to 70 mol % $\text{CaFe}(\text{CO}_3)_2$ is soluble in the dolomite structure with high Fe (>17.5 mol % Fe) containing specimens called ankerite, the others ferroan dolomite. Data that follow are for $\text{Ca}[\text{Mg}_{0.27}\text{Fe}_{0.63}\text{Ca}_{0.05}\text{Mn}_{0.05}](\text{CO}_3)_2$. *HEX-R R3*. $a = 4.830$, $c = 16.167$, $Z = 3$, $D = 3.00\text{--}3.10$. *MSASC 11:24(1983)*. d_{41-586} : 3.71_1 2.91_{10} 2.41_1 2.20_1 2.02_1 1.818_1 1.797_3 1.795_3 . See also *33-282*. Similar to dolomite with rhombic crystalline forms, also massive fine to coarse granular; twinning on {0001}, {1010}, {1120}. Colorless, white to grays, browns, darker on weathering; translucent, vitreous to pearly luster. Cleavage {1011}, perfect; subconchoidal fracture. $H = 3\frac{1}{2}\text{--}4$. $G = 2.87$. *IR. AM 45:311(1960)*. Fluorescent in UV, triboluminescent. Uniaxial (-); $N_O = 1.764$, $N_E \approx 1.52$. *DII:211*. Fe and Mg contents are highly correlated, while few ankerites show Ca deficiencies. Ferroan dolomite is commonly found in similar occurrences as dolomite. High-Fe-containing species do not occur on a rock-forming scale but are associated with iron ores, such as with hematite at Antwerp Jefferson Co., NY; at Jeffrey quarry, Little Rock, AR; Snowbird mine, Mineral Co., MO; at Coeur d'Alene region in sulfide veins, Shoshone Co., ID; King Co., Spruce Peak, WA; in Nova Scotia in ores at Londonderry, Colchester Co., NB; also at Erzberg near Eisenerz, Austria, and with siderite at Csetnek, Com G6m6r, and at Pribam, Bohemia, Czech Republic; at Tsumeb mine, Namibia; at the Mamatwan and Boltsburn mines, Durham, Cape Prov., South Africa; in Oगतatown, Oita Pref., Japan; at the Muzo emerald mine, Boyaca, Colombia. *HCWS DII:216, MSASC 11:28(1983)*.

14.2.1.3 Kutnohorite $\text{Ca}(\text{Mn}^{2+}, \text{Mg}, \text{Fe}^{2+})(\text{CO}_3)_2$

Named in 1901 after the locality. Dolomite group. HEX-R R3. $a = 4.915$, $c = 16.639$, $Z = 3$, $D = 3.12$. *JPD* 3:172(1988). 11-345: 3.75₂ 2.94₁₀ 2.44₁ 2.23₂ 2.04₂ 1.876₁ 1.837₃ 1.814₃. Sample from Franklin, NJ, which contains Mn, minor Mg and <0.5% Fe. See also 19-234, calcian kutnohorite, and 43-695, magnesian kutnohorite. Granular, massive. White to pale rose, translucent. Cleavage {1011}, perfect; subconchoidal fracture; brittle. $H = 3\frac{1}{2}$ -4. $G = 3.12$. IR. *MSLM* 4:253(1974). Uniaxial (-); $N_O = 1.727$, $N_E = 1.535$ (Franklin, NJ). Ca deficiencies of up to 10% CaCO_3 as well as excess Ca have been reported. Mn content varies from 38 to 84 at %. Typical sample gives diffuse diffraction patterns, which suggest microscale composition and structure inhomogeneities. Occurs at Franklin and Sterling Hill mines, Ogdensburg, NJ; Camp Bird mine, Ouray, CO; at Providencia, Mexico; at *Kutna Hora, central Bohemia, Czech Republic*; at Ryujima mine, Nagano Pref., and Hoei mine, Oita Pref., Japan; at Broken Hill, NSW, Australia. *HCWS DII:217*; *AM* 40:748(1953), 52:1751(1967); *AMG* 4:187(1966); *MSASC* 11:31(1983).

14.2.1.4 Minrecordite $\text{CaZn}(\text{CO}_3)_2$

Named in 1982 after the journal *Mineralogical Record*. Dolomite group. HEX-R R3. $a = 4.8183$, $c = 16.0295$, $Z = 3$, $D = 3.44$. 35-667: 4.04₁ 3.70₂ 2.89₁₀ 2.41₃ 2.20₂ 2.02₂ 1.806₄ 1.789₄. Rhombs {1014}, up to 0.5 mm. Milky white, pearly luster. Often saddle-shaped, with {1014} cleavage. $H = 3\frac{1}{2}$. $G = 3.45$. Uniaxial (-); $N_O = 1.750$, $N_E = 1.550$. No fluorescence with UV. Found on diopside, and with zincian dolomite, duftite, and malachite needles in the oxidation zone of *Tsumeb mine, Tsumeb, Namibia*. Mg-rich minrecordite (larger unit cell, lower indices) is also found at this locality. These colorless, glassy, transparent crystals contain ochre inclusions and are associated with cerussite and calcite. *HCWS MR* 13:131(1982).

14.2.2.1 Norsethite $\text{BaMg}(\text{CO}_3)_2$

Named in 1960 for Keith Norseth (1927-1991), U.S. engineering geologist at Westvaco mine, west of Green River, WY. HEX-R R32. $a = 5.02$, $c = 16.75$, $Z = 3$, $D = 3.84$. *AM* 46:420(1961). 12-530: 4.21₃ 3.86₄ 3.02₁₀ 2.66₄ 2.51₄ 2.10₄ 1.931₄ 1.864₄. Structurally similar to dolomite group. Platy {0001} rhombs which may show {1120}, {1010}, and {1011}. Clear to milky white, vitreous to pearly luster. Good rhombohedral cleavage, hackly fracture. $H = 3\frac{1}{2}$. $G = 3.84$. Uniaxial (-); $N_O = 1.694$, $N_E = 1.519$. Found as rhombohedral crystals below the main trona bed in black dolomitic oil shale at Westvaco mine, Sweetwater Co., WY, associated with shortite, labuntsovite, searsite, loughlinite, and pyrite, also with northupite in gray shale. *HCWS MA* 14:343(1960).

14.2.2.2 Paralstonite $\text{BaCa}(\text{CO}_3)_2$

Named in 1979 after alstonite. A trimorph of $\text{BaCa}(\text{CO}_3)_2$. See alstonite (14.2.5.1), barytocalcite (14.2.6.1); olekminskite (14.2.2.3), $\text{SrSr}(\text{CO}_3)_2$, forms a solid-solution series with paralstonite. HEX-R P321. $a = 8.692$, $c = 6.148$, $Z = 3$, $D = 3.62$. *AM 64:1332(1979)*. 33-178: 6.15₂ 4.35₁ 3.55₁₀ 2.85₁ 2.51₇ 2.05₂ 1.943₂ 1.853₂. Structure similar to other double carbonates. *MSASC 11:156(1983)*. Pyramidal crystals up to 1 mm. Colorless to smoky white and gray masses, vitreous luster. $H = 4-4\frac{1}{2}$. $G = 3.75$ (high, due to barite impurity). Uniaxial (-); $N_O = 1.672$, $N_E = 1.527$. Dissolves with effervescence in dilute HCl. Occurs as coatings on barite at Cave-in-Rock district, IL, with yellow calcite, gray alstonite, purple fluorite, and dark brown sphalerite. *HCWS GSCP 79-1c:99(1979)*.

14.2.2.3 Olekminskite $\text{Sr}(\text{Sr,Ca,Ba})(\text{CO}_3)_2$

Named in 1991 for the city Olekminsk, administration center of the Murunskij alkaline complex, Aldan Shield, Siberia. Forms a series with paralstonite (14.2.2.2). HEX-R P321. $a = 8.66$, $c = 6.08$, $Z = 3$, $D = 3.65$. *AM 78:451(1993)*. 44-1422: 3.50₁₀ 2.49₃ 2.03₉ 1.928₆ 1.837₆ 1.581₆ 1.443₆ 1.305₇. Needlelike crystals up to 0.010 mm thick, round or hexagonal in cross section, form spherulitic aggregates 0.20–0.30 mm in diameter. Crystal centers are enriched in Ca and Ba, while the rims have high Sr. Transparent, vitreous luster. Brittle. $H = 3$. $G = 3.70$. Uniaxial (-); $N_O = 1.670$, $N_E = 1.527$; negative elongation. Analyses show virtually the complete range between SrSrCO_3 and paralstonite, $\text{CaBa}(\text{CO}_3)_2$; La and Ce in minor or trace amounts. Found in barytocalcite–quartz veins 5–10 cm wide that cut intrusive breccias accompanying the alkaline Kedrovij massif, close to the Murunskij alkaline complex, *Aldan Shield, Siberia*. *HCWS ZVMO 120:89(1991)*.

14.2.3.1 Benstonite $\text{Ba}_6\text{Ca}_6\text{Mg}(\text{CO}_3)_{13}$

Named in 1961 for Orlando J. Benston (1901–1966), metallurgist at National Lead Co., Malvern, AR, who developed the method of flotation for barite. HEX-R R3. $a = 18.28$, $c = 8.67$, $Z = 3$, $D = 3.648$. *AM 47:585(1962)*. 14-637: 4.19₂ 3.92₄ 3.60₁ 3.35₁ 3.09₁₀ 2.54₃ 2.13₃ 1.905₂. Massive. White to ivory, white streak. Good rhombohedral cleavage {3142}. $H = 3-4$. $G = 3.596$. Uniaxial (-); $N_O = 1.690$, $N_E = 1.527$. Fluoresces red under LWUV or SWUV. Soluble in HCl. Found at the barite mine in Hot Spring Co., AR, associated with milky quartz, barite, and calcite. *HCWS NW 48:550(1961)*.

14.2.4.1 Ewaldite $\text{Ba}(\text{Ca,Y,Na,K})(\text{CO}_3)_2$

Named in 1971 for Paul P. Ewald (1888–1985), German crystallographer, founder of *Zeitschrift für Kristallographie* and *Acta Crystallographica*, professor at Brooklyn Polytechnical Institute, NY. HEX P6₃mc. $a = 5.318$, $c = 12.837$, $Z = 2$, $D = 3.37$. *ZVMO 121:56(1992)*. Structure: *TMPM 15:201(1971)*. 43-678: 6.39₁₀ 4.58₂ 4.31₆ 3.72₄ 3.20₁ 2.62₁ 2.44₁ 1.714₁. Tiny, < 1 μm , untwinned flattened hexagonal dipyramids or prisms with {0001} terminations. Blue-

green. $G = 3.25$. Uniaxial (-); $N_O = 1.646$, $N_E \approx 1.572$. O, dark blue-green; E, pale yellow-green. From *Green River formation, Sweetwater Co., WY*, trona mine and exploratory drill holes, crystals intimately intergrown with black mckelveyite (15.3.4.2), and associated with trona, labuntsovite, leuospherite, searlsite, and other minerals; Y-rich variety in carbonatites of Vuorijarvi ultrabasic massif, and (Ce + Nd)-rich varieties in hydrothermal sites in the Khibiny alkaline massif, Russia. *HCWS AM 56:2156(1971)*, *TMPM 15:185(1971)*.

14.2.5.1 Alstonite $BaCa(CO_3)_2$

Named in 1841 after locality. Trimorph. See paralstonite (14.2.2.2) and barytocalcite (14.2.6.1). TRIC $P1$ or $P1$. $a = 17.38$, $b = 14.40$, $c = 6.123$, $\alpha = 90.35^\circ$, $\beta = 90.12^\circ$, $\gamma = 120.08^\circ$, $Z = 12$, $D = 3.605$. Alstonite appears to have a superstructure based on paralstonite without long-range order of the metal cations or the CO_3 groups. *MSASC 11:156(1983)*. 27-32: 5.65₁ 3.55₁₀ 2.84₁ 2.51₅ 2.18₁ 2.05₃ 1.94₃ 1.846₂. Crystals steep pseudodihexagonal pyramids, faces striated horizontally, twinned. White, gray, creamy to reddish (bleached on exposure); white streak; vitreous luster. Cleavage $\{110\}$, imperfect; uneven fracture. $H = 4-4\frac{1}{2}$. $G = 3.70$. IR. *MSLM 4:258(1974)*. Biaxial (-); $XYZ = cab$; $N_x = 1.526$, $N_y = 1.671$, $N_z = 1.672$; $2V = 6^\circ$; $r > v$, weak. Weakly fluorescent yellow in LWUV. Sr (and Mn) solid solution noted in studies of $CaCO_3$ - $SrCO_3$ - $BaCO_3$ - $PbCO_3$ system. *MSASC 11:145(1983)*. Found at Minerva mine, Cave-in-Rock, IL; in low-temperature hydrothermal deposits at *Brownley Hill lead mine, Alston, Cumberland*, associated with calcite, barite, and witherite, also at the *Fallowfield lead mine near Hexham, Northumberland*, and in veins at New Brancepeth near Durham, England. *HCWS DII:218*.

14.2.6.1 Barytocalcite $BaCa(CO_3)_2$

Named in 1824 in allusion to the composition. MON $P2_1/m$. $a = 8.092$, $b = 5.2344$, $c = 6.544$, $\beta = 106.05^\circ$, $Z = 2$, $D = 3.65$. *NBSR 75A:197(1971)*. Trimorph with alstonite (14.2.5.1) and paralstonite (14.2.2.2). 15-285: 4.34₃ 4.02₄ 3.14₉ 3.13₁₀ 2.51₂ 2.38₂ 2.16₃ 2.01₂. Structure similar to dolomite but with two crystallographically distinct CO_3 groups. *MSASC 11:156(1983)*. Short to long prismatic $[101]$, $[001]$ or equant; $\{100\}$ striated $[001]$, other faces striated $[101]$; massive. Often oriented growths on barite, or calcite on barytocalcite. Colorless to white, grayish, greenish, yellowish; white streak; vitreous to resinous luster; transparent to translucent. Cleavage $\{210\}$, perfect; $\{001\}$, imperfect; uneven fracture; brittle. $H = 4$. $G = 3.66$. IR. *MSLM 4:258(1974)*. Weakly fluorescent in UV. Biaxial (-); $Z = b$; $X \wedge c = 64^\circ$; $Y \wedge c = 26^\circ$; $N_x = 1.525$, $N_y = 1.684$, $N_z = 1.686$; $2V = 15^\circ$; $r > v$, slight. Found as crystals up to 5 cm long, and also massive, in veins in limestones at *Blagill mine(!), Alston Moor, Cumberland, England*; at *Långban, Värmland, Sweden*, with hedyphane and hausmannite; in barite ore of *Tolecheinski deposit, Krasnoyark region, Siberia, Russia*. *HCWS DII:220*.

14.3.1.1 Bütschliite $K_2Ca(CO_3)_2$

Named in 1947 for Johann Adam Otto Bütschli (1848–1920), professor of zoology, Heidelberg, Germany, who studied the double carbonates of K and Ca. Dimorph with fairchildite (14.3.3.1). *HEX-R* $R\bar{3}m$. $a = 5.38$, $c = 18.12$, $Z = 3$, $D = 2.61$. *AM* 59:353(1974). Structure similar to eitelite (14.3.2.1). *AM* 58:211(1973). 25-626(syn): 3.02₃ 2.86₁₀ 2.69₁ 2.07₁ 1.690₂ 1.641₂ 1.044₂ 0.933₂. Microscopic, barrel-shaped crystals showing {10 $\bar{1}1$ }, {0112}, {0001}, {1120}, {1122}; cleavage {0001}. IR. *MSLM* 4:256(1974). Attacked by moisture, producing a $CaCO_3$ coating that protects butschliite stability. Fairchildite is the high-temperature ($> 500^\circ$) modification. Occurs in the clinkers of melted wood ash found in partly burned trees, mainly hemlock and fir, in the forests of the western United States. *HCWS DII:231*, *AM* 32:607(1947).

14.3.2.1 Eitelite $Na_2Mg(CO_3)_2$

Named in 1955 after Wilhelm Hermann Julius Eitel (1891–1979), chemist, and founder and director of the Institute for Silicate Research, University of Toledo, Ohio. *HEX-R* $R\bar{3}$. $a = 4.942$, $c = 16.406$, $Z = 3$, $D = 2.74$. *AM* 58:211(1973). 24-1227(syn): 3.79₂ 2.73₃ 2.60₁₀ 2.47₃ 2.25₂ 2.07₂ 1.898₂ 1.531₁. Colorless rhombohedral crystals a few millimeters in diameter with rounded edges; synthetics show {0001}, {10 $\bar{1}1$ }, {0112}; good cleavage parallel to {0001}. $H = 3\frac{1}{2}$. $G = 3.737$. IR. *MSLM* 4:256(1974). Uniaxial (-); $N_O = 1.605$, $N_E = 1.450$. Found in drill-hole samples from the Green River formation, Uinta basin, UT, associated with reedmergnerite, leucosphenite, shortite, searlesite, and crocidolite; abundant in core from *Mapco Shrine Hospital No. 1 well, Duchesne Co., UT*, into brown marlstone, associated with trona, nahcolite, shortite, and northupite; at Malha Crater lake, Sudan. *HCWS AM* 40:356(1955).

14.3.3.1 Fairchildite $K_2Ca(CO_3)_2$

Named in 1949 after John Gifford Fairchild (1882–1965), analytical chemist at the U.S. Geological Survey. Dimorph with bütschliite (14.3.1.1). *AM* 59:353(1974). See also natrofairchildite (14.3.5.1). *HEX* $P6_3/mmc$. $a = 5.272$, $c = 13.280$, $Z = 2$, $D = 2.441$. 21-1287(syn): 6.67₁ 3.19₁₀ 2.70₃ 2.65₇ 2.23₂ 2.17₂ 2.04₁ 1.891₁. Microscopic clear, colorless hexagonal blades parallel to {0001} with good {0001} cleavage. IR. *MSLM* 4:256(1974). Uniaxial (-); $N_O = 1.533$, $N_E = 1.498$. Soluble in H_2O , decomposes. P, Al, Fe, and Mn are minor contaminants. Higher temperature form than bütschliite. Fairchildite blades are enclosed in dense, light gray bluish, or gray, friable matrix with a white porcelaneous crust that also contains bütschliite and calcite. The samples are fused wood-ash clinkers that occur in partly burned fir and hemlock trees in many national parks and forests in the western United States. *HCWS DII:222*, *BGSA* 57:1218(1947).

14.3.3.2 Zemkorite $\text{Na}_2\text{Ca}(\text{CO}_3)_2$

Named in 1988 for the Institute of the Earth's Crust (Russian, *zemnoy kory* = earths crust), Russian Academy of Science, Siberian Branch, where the mineral was studied. Trimorph with nyerereite (14.3.4.1), natrofairchildite (14.3.5.1). **HEX** $P6_3/mmc$. $a = 10.06$, $c = 12.72$, $Z = 8$, $D = 2.47$. *41-1440*: 6.36_9 4.36_{10} 3.18_6 3.04_{10} 2.52_{10} 2.18_7 2.06_{10} 1.797_8 . Tabular grains, 0.1–0.5 mm across, show no faces; also as fan-shaped aggregates 3–4 mm across. Colorless, transparent, vitreous to pearly luster. Perfect cleavage parallel to tabular direction, no twinning, brittle. $H = 2$. $G = 2.46$. Uniaxial (–); $N_O = 1.535$, $N_E = 1.513$. Analyses also showed K and trace of Al. Found in drill cores at 400–450 m depth into the eastern body of the *Udachnaya pipe, Daldyn kimberlite field, Yakutiya, Russia*. The mineral occurs as fracture fillings in unaltered kimberlite, along contacts between groundmass and olivine xenoliths and xenocrysts, or in the interstices. Associated with shortite and rarely halite. **HCWS** *AM 75:933(1990)*.

14.3.4.1 Nyerereite $\text{Na}_2\text{Ca}(\text{CO}_3)_2$

Named in 1963 after the president of Tanzania, Julius K. Nyerere (b.1922). Dimorph of zemkorite (14.3.3.2), possibly also of natrofairchildite (14.3.5.1). **ORTH** $Cmc2$. $a = 5.044$, $b = 8.809$, $c = 12.743$, $Z = 4$, $D = 2.417$. *AM 63:600(1978)*. *33-1221*: 6.38_9 4.39_9 3.05_{10} 2.58_8 2.54_9 2.20_8 2.16_9 2.07_9 . Colorless pseudo-hexagonal platy crystals up to 0.5 mm across, invariably twinned. $G = 2.54$. Biaxial (–); $XYZ = cab$; $N_x = 1.511$, $N_y = 1.533$, $N_z = 1.534$; $2V = 29^\circ$. Analyses also show Sr, Ba, K, SO_3 , Cl, and F. Inverts to hexagonal cell at 292° ; synthetic material has $a = 20.3$, $c = 12.4$. A major constituent of the 1960–1965 “carbonate” lavas from *Mt. Oldoinyo Lengai, Tanzania*. **HCWS** *AM 60:487(1975)*.

14.3.5.1 Natrofairchildite $\text{Na}_2\text{Ca}(\text{CO}_3)_2$

Named in 1971 as the Na analog of fairchildite (14.3.3.1). Possibly trimorphous with nyerereite (14.3.4.1) and zemkorite (14.3.3.2). **HEX** $P6_3/mmc$. $a = 5.291$, $c = 13.218$, $Z = 2$, $D = 2.14$. *25-804*: 6.71_6 4.50_3 3.18_{10} 2.67_4 2.64_9 2.20_6 2.10_5 1.891_6 . Single platy crystals 1–2 mm without faces, or fan-shaped aggregates. White, vitreous luster. One (probably basal) cleavage, polysynthetic twinning parallel to cleavage. $H = 2\frac{1}{2}$. Uniaxial (–); $N_O = 1.459$, $N_E = 1.525$. Slightly luminescent orange in UV. Analyses show only 1.4% K, lower amounts of Sr and Ba, traces of Mg, Fe, Mn, La, and Y; decomposes in air. Found in burbankite–calcite veins at depths greater than 70 m, *Vuori-Jarvi massif, Kola Penin., Russia*. **HCWS** *AM 60:488(1975)*.

14.4.1.1 Shortite $\text{Na}_2\text{Ca}_2(\text{CO}_3)_3$

Named in 1940 after Maxwell Naylor Short (1889–1952), professor of mineralogy, University of Arizona. **ORTH** $C2mm$. $a = 4.961$, $b = 11.03$, $c = 7.12$, $Z = 2$, $D = 2.621$. Structure: *AMG 1:95(1949)*. *21-1348*: 5.99_5 5.52_7 4.96_7 3.83_5 2.56_{10} 2.48_5 2.18_7 1.996_6 . Wedge-shaped crystals, tabular parallel to $\{100\}$, equant or short prismatic $\{100\}$; $\{011\}$ often striated $[100]$ in combina-

tion with $\{001\}$. Colorless to pale yellow, transparent. Distinct cleavage parallel to $\{010\}$, conchoidal fracture. $H = 3$. $G = 2.6$ (probably impure). IR. *MSLM* 4:256. Fluoresces amber color in UV. Biaxial (-); $XYZ = cab$; $N_x = 1.531$, $N_y = 1.555$, $N_z = 1.570$; $2V = 75^\circ$; $r < v$, moderate. Decomposes in H_2O giving $CaCO_3$ ppt. Occurs with calcite and pyrite as single crystals in inch-wide bands in the montmorillonite clay associated with trona in *Green River formation*, WY, and UT; in oil-well cores, Sweetwater and Uintah Cos., UT; in kimberlite at Upper Canada gold mine, Ontario, Canada; minute inclusions in apatite from Tororo carbonatite complex, eastern Uganda. *HCWS AM* 24:514(1939), *DII*:222, *USGSPP*:B1(1969).

14.4.2.1 Sahamalite-(Ce) $MgCe_2(CO_3)_4$

Named in 1953 after Thure Georg Sahama (1910–1983), petrologist, University of Helsinki, Finland. *MON. P2₁/a*. $a = 1.679$, $b = 16.21$, $c = 4.63$, $\beta = 106.7^\circ$, $Z = 2$, $D = 4.30$. *AM* 38:941(1953). 6-189: 5.33₇ 4.26₇ 3.90₁₀ 3.65₁₀ 3.03₇ 2.87₁₀ 2.12₇ 2.10₇. Crystals up to 0.2 mm tabular parallel to $\{201\}$, other forms $\{131\}$, $\{120\}$, $\{110\}$, $\{010\}$, $\{011\}$. Colorless. Poor cleavage parallel to $\{010\}$. $G = 4.30$. Biaxial (-); Y parallel to b ; $Z \wedge c = 29^\circ$; $N_x = 1.679$, $N_y = 1.776$, $N_z = 1.807$; $2V = 57^\circ$; $r < v$. Minor amounts of Fe^{2+} substitute for Mg, and La and Nd for Ce. Insoluble in boiling HCl, soluble boiling 3N HNO_3 . Occurs in barite-dolomite rock at *Mountain Pass*, *San Bernardino Co.*, CA, associated with parisite and altered bastnasite. *HCWS AM* 38:941(1953).

14.4.3.1 Huntite $Mg_3Ca(CO_3)_4$

Named in 1955 after Walter Frederick Hunt (1882–1975), professor of mineralogy, University of Michigan. *HEX-R. R32*. $a = 9.505$, $c = 7.821$, $Z = 3$, $D = 2.87$. *AM* 46:1304(1961). Structure: *AC* 15:238(1962). 14-409: 2.89₂ 2.83₁₀ 2.60₁ 2.43₁ 1.991₁ 1.972₃ 1.765₂ 1.757₂. Compact, chalklike with submicroscopic ($< 1 \mu m$) platelets or fibers. White, earthy; subconchoidal fracture of mass. Soft. $G = 2.696$. DTA, IR. *MSLM* 4:255(1974). $N_{av} = 1.617$. Effervesces in 1:1 HCl, HNO_3 , H_2SO_4 . Occurs in caves where rocks are magnesium-rich and as a near-surface weathering product of rocks containing brucite, dolomite, magnesite, and serpentines; as a diagenetic product in recent sediments. Found at *Gabbs*, NM; Carlsbad Caverns, NM; Crestmore, CA; Grotte de la Clamouse, Hérault region, France; Dorog, Hungary; Kurgashinkin, Uzbekistan; aggregates of several kilograms in serpentinites, Yazd, Iran; Tea Tree Gully, SA, Australia. *HCWS AM* 38:4(1953).

BURBANKITE GROUP

The burbankite group of REE-containing anhydrous carbonate minerals conform to the general formula

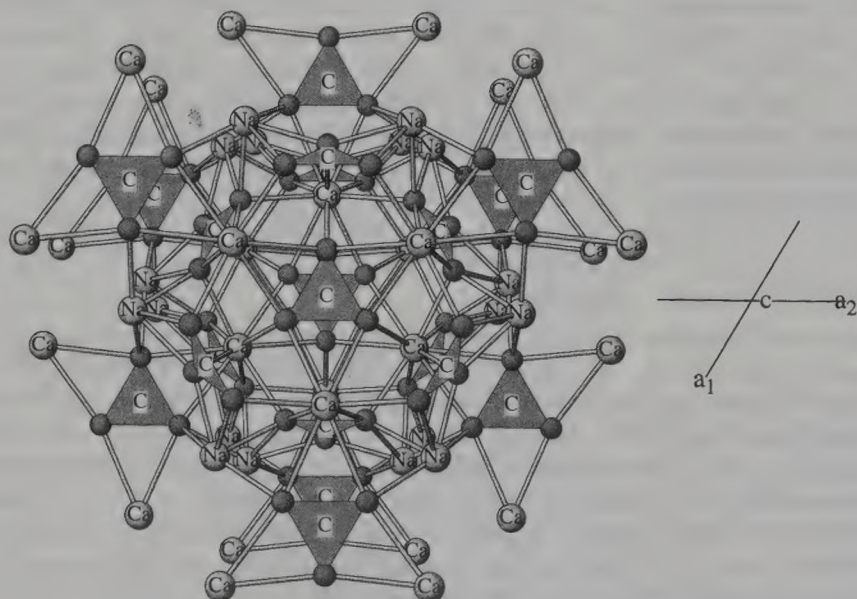

where

A = Na, Ca, □

B = Ca, Sr, Ba or rare-earth elements

and crystallized in layered structure with hexagonal or monoclinic pseudo-hexagonal symmetry.

The five minerals so far determined as belonging in the group show Na as essential with series between the remaining cationic species. As described for other layered carbonates, there is evidence of supercells.

BURBANKITE: $Na_3Ca_3(CO_3)_5$

In this *c* axis projection of burbankite [simplified to $Na_3Ce_3(CO_3)_5$] three distinct crystallographic sites for CO_3 groups are visible: one group at the center of the projection is on a mirror plane perpendicular to '*c*' with the C_1 atom having 6_3 or rhombohedral symmetry; the second group, almost parallel to '*c*' can only be seen end-on, while the third CO_3 group (also perpendicular to the *c* axis) appears as an outer ring. All three CO_3 groups are effectively planar. The A site cations (usually occupied by Na or Ca with a vacancy to balance any charge requirements) have eight-fold coordination. The B site cations (REE, Ba) have ten-fold coordination. Petersenite has tenfold cation coordination for both A and B sites *NJMM:161 (1985)*, *SPC 13:192 (1968)*.

BURBANKITE GROUP

Mineral	Formula	Space Group	a	b	c	β	D
Burbankite	(Na,Ca, \square) ₃ (REE, Ba, Sr) ₃ (CO ₃) ₅	<i>P6₃mc</i>	10.514		6.520		3.5
Khanneshite	(Na,Ca, \square) ₃ (Ba, REE, Sr) ₃ (CO ₃) ₅	<i>P6₃mc</i>	10.65		6.58		3.94
Calcioburbankite	Na ₃ (Ca,REE,Sr) ₃ (CO ₃) ₅	<i>P6₃mc</i> , <i>P6₃mmc</i> , or <i>P62c</i>	10.447		6.318		3.46
Remondite-(Ce)	Na ₃ (Ce,La,Ca,Na, Sr) ₃ (CO ₃) ₅	<i>P2₁</i>	10.444	6.313	10.445	119.86	3.46
Petersenite-(Ce)	Na ₄ (REE) ₂ (CO ₃) ₅	<i>P2₁</i>	20.872	6.367	10.601	120.50	3.67

14.4.4.1 Burbankite (Na,Ca, \square)₃(Sr,Ba,Ce)₃(CO₃)₅

Named in 1955 after Wilbur Swett Burbank (1898–1975) of the U.S. Geological Survey. Burbankite group. *HEX P6₃mc*. $a = 10.514$, $c = 6.520$, $Z = 2$, $D = 3.5$. *CM 12:342(1974)*. Structure: *NJMM:161(1985)*, *AC(C) 45:185(1989)*. *26-1374(syn)*: 5.24₅ 3.71₆ 3.03₈ 2.74₄ 2.63₁₀ 2.62₁₀ 2.14₆ 1.982₄. Slender hexagonal prisms terminated by {0001}; as radiating aggregates or cleavable masses up to 3 cm across; microbotryoidal crusts. Colorless, pale yellow to pinkish. Cleavage {1000}, distinct to imperfect. $H \approx 3\frac{1}{2}$, $G = 3.5$. Uniaxial (-); $N_O = 1.616$, $N_E = 1.597$. May have up to 13 wt % Ba or up to 15 wt % RE (Ce, Y, La, Pr, Nd, Sm, Dy, Yb). Soluble in dilute HCl with effervescence. Found as yellow crystals intimately intergrown with ancyllite and other rare-earth carbonates in veins in shonkinites(!), *Big Sandy Creek, Hill Co., Bearpaw Mts., MT*; as crusts or in veins containing much organic material and RE = 22%; associated with mckelveyite–ewaldite in the Wilkins Peak member of the Green River formation, Sweetwater Co., WY; as dihexagonal prismatic crystals embedded in analcime in pegmatite dikes(!) in Mt. St.-Hilaire, QUE, Canada, associated with microcline, aegirine, calcite, siderite, and ancyllite; with kamerinite in the Nlende deposit, Kribi, Cameroon. *HCWS AM 38:1169(1953)*, *62:158(1977)*.

14.4.4.2 Khanneshite (Na,Ca)₃(Ba,Sr,Ce)₃(CO₃)₅

Named in 1982 for the locality. Burbankite group. Possibly forms a series with burbankite (14.4.4.1) and remondite-(Ce) (14.4.5.1). *HEX P6₃mc*. $a = 10.65$, $c = 6.58$, $Z = 2$, $D = 3.94$. *AM 68:1249(1983)*. *35-700*: 9.25₃ 5.34₃ 3.78₅ 3.29₃ 3.08₆ 2.66₁₀ 2.19₆ 2.09₄. Prismatic crystals 5–10 mm long, 2–3 mm wide. Pale yellow. Indistinct cleavage parallel elongation, rough transverse parting, brittle. Soft. $G = 3.8$ – 3.9 . DTA. Uniaxial (-); $N_O = 1.623$ – 1.620 , $N_E = 1.610$ – 1.609 . Chemical analyses show total REE oxides >8 wt %: La, Ce, Pr, Nd, Sm, Eu, Gd, Dy, Ho, Er, Tm, Yb, Y detected. Readily dissolved by HCl. Commonly altered and replaced by barite. Disseminated in fine-grained car-

bonatite associated with dolomite, calcinsite, carbocernaite, barite, and chlorite at *Khanneshin, Afghanistan*. HCWS *ZVMO* 111:321(1982).

14.4.4.3 Calcioburbankite $\text{Na}_3(\text{Ca,REE,Sr})_3(\text{CO}_3)_5$

Named in 1995 for the resemblance to burbankite (14.4.1.1). Burbankite group. HEX $P6_3mc$, $P6_3mmc$, or $P62c$. $a = 10.447$, $c = 6.318$, $Z = 2$, $D = 3.46$. *CM* 33:1231(1995). *PD*: 5.20₅ 3.68₅ 2.601₁₀ 2.63₅ 2.180₅ 2.130₅ 2.050₅. Crystals elongate parallel to [001] to 2 cm in length with deep orange interior color, also equant to 0.5 mm showing {100}, {001}, and silky white exterior with light pink interior; vitreous luster. Cleavage {100}, indistinct. $H = 3-4$. $G = 3.45$. Uniaxial (-); $N_0 = 1.636$, $N_E = 1.631$; nonpleochroic. Microprobe analysis (wt %): Na_2O , 15.17; CaO , 11.8; BaO , 0.46; SrO , 7.65; La_2O_3 , 9.30; Ce_2O_3 , 14.38; Pr_2O_3 , 1.26; Nd_2O_3 , 3.76; Sm_2O_3 , 0.04; CO_2 (calc), 35.13. Dissolves readily in 1:10 HCl. There are two different associations for this mineral at *Mt. St.-Hilaire, QUE, Canada*: (1) with ancylite-(Ce), calcite, chlorite-group minerals, donnayite-Y, fluorapatite, natrolite, pyrite, rhodochrosite, and rutile perhaps formed in an associated vent [*MR* 21:310,368(1990)], and (2) as subhedral crystals in a fragment of a marble xenolith where shortite is the predominant mineral phase along with aegirine, calcite, fluorite, galena, leucophanite, mangan-neptunite, microcline, molybdenite-2H and 3R, narsarsukite, pictolite, schairerite, sodalite, sphalerite, thermonatite, and titanite. HCWS

14.4.5.1 Remondite-(Ce) $\text{Na}_3(\text{Ce,L a,C a,N a,S r})_3(\text{CO}_3)_5$

Named in 1988 for Guy Remond (b.1935), physicist and research mineralogist at Bureau de Recherches Geologiques et Minières, Orleans, France. Burbankite group. MON $P2_1$. $a = 10.444$, $b = 6.313$, $c = 10.445$, $\beta = 119.86^\circ$, $Z = 2$, $D = 3.46$. *CR* 307:915(1988), *AC(C)* 45:185(1989). *PD*: 5.17₄ 3.01₄ 3.006₇ 2.62₅ 2.61₇ 2.59₁₀ 2.13₇ 2.127₅. *AM* 75:433(1990). Massive, pseudo-hexagonal. Red-orange, vitreous luster, transparent. Imperfect cleavage, conchoidal fracture. $H = 3-3\frac{1}{2}$. $G = 3.43$. TGA. Biaxial (+); $N_x = 1.632$, $N_y = 1.633$, $N_z = 1.638$; $2V = 40^\circ$. REE dominate, in addition to Ce minor amounts of La, Nd, Y, and trace Pr, Sm, Eu, Gd, Dy, Ho, Er, Yb, and Lu. Soluble in HCl, HNO_3 with effervescence. Found as massive fillings in veinlets in nepheline syenite orthogneiss at *Ebounja, near Kribi, Cameroon*, associated with nepheline, monazite, pyrochlore, betafite, bastnaesite, cancrinite, sodalite, and calcite. HCWS *MA* 89:3585(1989).

14.4.5.2 Petersenite-(Ce) $\text{Na}_4(\text{REE})_2(\text{CO}_3)_5$

Named in 1994 for Ole Valdemar Petersen (b.1939), mineralogist and curator at the Paterson Mineral Museum in Copenhagen, Denmark, for his contributions to the mineralogy and genesis of alkaline rocks. Burbankite group. MON $P2_1$. $a = 20.872$, $b = 6.367$, $c = 10.601$, $\beta = 120.5^\circ$, $Z = 4$, $D = 3.67$. Structure: *CM* 32:405(1994). Layered structure similar to burbankite but with a supercell that illustrates changes to 10- rather than eightfold coordinated cations.

PD: 9.13₃ 5.22₅ 4.13₃ 3.70₄ 2.61₁₀ 2.15₃ 1.921₃. Diffraction maxima that distinguish petersenite from other members of the group are at 6.84, 5.47, 4.13, and 3.18 Å. Acicular crystals up to 7 mm long, some showing striated prisms. Gray with pink, mauve, or yellow tinge; vitreous luster; translucent to transparent. Conchoidal fracture, brittle. $H \approx 3$. $G = 3.69$. Biaxial; $XZ = ba$, $Y \wedge c = 30^\circ$; $N_x = 1.623$, $N_y = 1.636$, $N_z = 1.649$; $2V = 89.7^\circ$; no dispersion, no absorption. EPMA (wt %): Ce₂O₃, 23.7; NaO, 17.4; La₂O₃, 14.49; Nd₂O₃, 5.8; Pr₂O₃, 2.0; SrO, 1.7; CaO, 1.3; Sm₂O₃, 0.6; BaO, 0.3; CO₂ (calc), 32.9. Occurs at several sites within the *Poudrette quarry, Mt. St.-Hilaire, QUE, Canada*, at the contact with the hornfels pegmatite phase of the nepheline-sodalite syenite intrusive complex: yellow-tinged crystals are found embedded in trona, and light mauve crystals in a soda-rich inclusion associated with microcline, albite, aegirine, and schomyokite-(Y). HCWS

14.4.6.1 Carbocernaite (Ca,Na)(Sr,Ce)(CO₃)₂

Named in 1961 for the composition carbon-cerium-sodium. See remondite-(Ce) (14.4.5.1) and burbankite (14.4.4.1). ORTH *Pmc*2. $a = 5.214$, $b = 6.430$, $c = 7.301$, $Z = 2$, $D = 3.60$. *AM* 68:1251(1983). 25-175: 6.39₃ 5.19₄ 4.81₅ 4.05₅ 3.53₄ 2.99₁₀ 2.93₃ 2.01₅. Platy on {100}; crystals also show {010}, {001}, {021}, {540}, and {210}. Colorless, white, turns yellowish, brownish, rose when altered; vitreous luster on crystal faces, greasy on fracture surfaces. Cleavage {100}, {021}, {010}, poor; brittle. $H = 3$. $G = 3.53$. Biaxial (-); $XYZ = bac$; $N_x = 1.569$, $N_y = 1.679$, $N_z = 1.708$; $2V = 52^\circ$; $r > v$, marked. Mineral contains high amounts of REE (wt %): 15% CaO, 5% Na₂O, 12% SrO, 3% BaO, 26% REE oxides (La, Ce, Nd, Sm, Y). Canadian sample contains F, no Na or Ba, more Sr. Soluble in dilute HCl. Found at Sturgeon Narrows, Thunder Bay, ONT, Canada, in dolomite-calcite-carbonatite veins in pyroxenites and ijolites of the *Vuoriyärvi massif, Kola Penin., Russia*, with chlorite, ankerite, and other minerals, and in cavities associated with alstonite, anatase, quartz, and zeolites; also at Phan Si Pan Reso, North Vietnam. HCWS *AM* 46:1202(1961), *CM* 11:812(1972).

Hydrated Carbonates

15.1.1.1 Thermonatrite $\text{Na}_2\text{CO}_3 \cdot \text{H}_2\text{O}$

Named in 1845 because it results from drying out of natron. ORTH $P2_1ab$. $a = 10.72$, $b = 5.249$, $c = 6.469$, $Z = 4$, $D_{\text{syn}} = 2.259$. Structure: $AC(B)$ 31:890(1975). 8-448(syn): 5.35₂ 5.24₂ 2.77₁₀ 2.75₆ 2.68₆ 2.48₃ 2.37₆ 2.01₃. Crystals rare, thin tabular parallel to {001} or {010} prismatic parallel to a ; usually encrusting, an efflorescence. Colorless, white, grayish, yellowish; transparent; vitreous luster. Cleavage parallel to {100}, difficult. $H = 1$. $G = 2.26$. IR. MSLM 4:262(1974). Biaxial (-); XYZ = bca ; $N_x = 1.420$, $N_y = 1.506$, $N_z = 1.524$; $2V = 48^\circ$; $r < v$, weak. Loses H_2O easily with small amount of heat but does not dissolve in solutions containing other salts (K_2CO_3 , NaHCO_3 , NaCl) until 112° ; soluble in hot water giving alkaline solution. As an efflorescence on soils in arid regions; deposits from saline lakes, usually with trona and natron. Found in Death Valley, Inyo Co., and San Joaquin Valley; with sborgite at Twenty Mule Team Canyon, and with halite at Borax Lake, Lake Co.; probably also at Owens, Searles, and other saline lakes, CA; identified from the fumaroles, Mt. Vesuvius, Italy; bedded deposit in Gorodki oil field, Kama region, Russia; deserts in other parts of the world, such as Sudan and Egypt. *HCWS DII:224*.

15.1.2.1 Natron $\text{Na}_2\text{CO}_3 \cdot 10\text{H}_2\text{O}$

Named in antiquity after *neter*, Hebraic for *alkaline salts of all varieties*; in the seventeenth century, *natron* (as distinct from *nitre*=saltpeter or potassium carbonates) was applied only to sodium carbonates. Easily confused with trona (13.1.4.1) or thermonatrite (15.1.1.1). MON Cc . $a = 12.83$, $b = 9.026$, $c = 13.44$, $\beta = 123.0^\circ$, $Z = 4$, $D = 1.46$. Structure: $AC(B)$ 25:2656(1969). Basically a distorted NaCl structure in which two Na in octahedral coordination form $[\text{Na}_2(\text{H}_2\text{O})_{10}]^{2+}$ units by sharing an edge. The units form a three-dimensional framework with spaces in which disordered but effectively planar $(\text{CO}_3)^{2-}$ groups fit. The CO_3 groups are H-bonded to the surrounding H_2O molecules. 15-800(syn): 5.37₅ 4.50₂ 3.94₃ 3.45₃ 3.04₁₀ 3.02₇ 2.89₆ 2.38₂. Fine-grained,

granular, or columnar crusts or friable coatings. Synthetic crystals may show {001}, {010}, {100}, {110}, {011}, {101}, {112} with tendency to tabular parallel to {010}; twins on {001}. Colorless, white, gray, or yellow, if impure; vitreous luster. Distinct cleavage parallel to {001}, imperfect parallel to {010}; conchoidal fracture; brittle. $H = 1$. $G = 1.478$. IR. *MSLM* 4:262(1974). Biaxial (-); X parallel to b ; $Z \wedge c \approx 41^\circ$; $N_x = 1.405$, $N_y = 1.425$, $N_z = 1.440$; $2V_{\text{calc}} = 82^\circ$; $r > v$. Decomposes with slight heating to thermonatrite (15.1.1.1) and H_2O , soluble in H_2O (0.40 g/g at 30°) forming alkaline solution, effervesces with acids. Forms from H_2O solution below 32° , but when other salts are present the temperature limit may be lower. Occurs in soda lakes at Ragtown, NV; Clinton, Lilloet district, BC; Debreczin and Szegedin regions, Hungary; in salt lakes of eastern Gobi desert, Mongolia, China, usually associated with thermonatrite, trona, gaylussite, and calcite. *HCWS DII:230:304*.

15.1.3.1 Monohydrocalcite $CaCO_3 \cdot H_2O$

Named in 1964 from the composition. *HEX* $P3_112$. $a = 10.566$, $c = 7.573$, $Z = 9$, $D = 2.38$. *AM* 60:669(1975). 29-306: 5.28₄ 4.33₁₀ 3.08₈ 2.83₅ 2.38₄ 2.17₆ 1.945₃ 1.931₆. Cryptocrystalline, earthy. White to gray. Uniaxial (-); $N_O = 1.590$, $N_E = 1.543$. *NW* 46:553(1959). Synthesized at $pH > 8$ and in the presence of Mg; there appears to be a relationship with algal or bacterial matter in the natural occurrences. Found in a polymetallic vein of the Vranice deposit near Příbram, Czech Republic; in the bottom sediments of *Lake Issyk-Kul, Kirgizia, Russia*; in the beach rocks surrounding Lake Fellmongery, Robe, SA, Australia; as a precipitate in the air scrubbers of air-conditioning plants; also in otoliths and bladderstones. *HCWS AM* 49:1151(1964), 62:273(1977).

15.1.4.1 Ikaite $CaCO_3 \cdot 6H_2O$

Named in 1963 for the locality. *MON* $C2/c$ or Cc . $a = 8.87$, $b = 8.23$, $c = 11.02$, $\beta = 110.2^\circ$, $Z = 4$, $D = 1.8$. *AM* 49:439(1964). 37-416(syn): 5.85₃ 5.17₁₀ 4.16₃ 2.80₅ 2.64₉ 2.63₇ 2.61₃ 2.46₃. Stout prismatic to tabular {001} crystals. Chalky white. $G = 1.77$. IR. *MSLM* 4:264(1974). Biaxial (-); $N_x = 1.455$, $N_y = 1.538$, $N_z = 1.545$; $2V = 45^\circ$; distinct dispersion. Dehydrates spontaneously above 8° to calcite. Natural material very close to synthetic. *AJS* 41:473(1916). Found below the water surface at the inner portion of *Ika Fjord, Ivigtut, Greenland*, in stalagmite-like aggregates. *HCWS DII:228*.

15.1.5.1 Barringtonite $MgCO_3 \cdot 2H_2O$

Named in 1965 for the locality. *TRIC* $P1$ or $P1$. $a = 9.156$, $b = 6.202$, $c = 6.092$, $\alpha = 94.0^\circ$, $\beta = 95.5^\circ$, $\gamma = 108.7^\circ$, $Z = 4$, $D = 2.83$. *AM* 50:2103(1965). 18-768: 8.68₁₀ 6.09₈ 5.82₈ 3.09₁₀ 3.02₆ 2.94₁₀ 2.50₈ 2.31₈. Nodules of radiating fibers averaging 0.01 mm \times 0.03 mm in size. Colorless. Cleavage {001}, {100}, {010}, distinct. Biaxial (+); $N_x = 1.458$, $N_y = 1.473$, $N_z = 1.501$; $2V_{\text{calc}} = 73.7^\circ$; length slow. Found with nesquehonite on the surfaces of olivine

basalt under Rainbow Falls, Sempill Creek, *Barrington Tops, NSW, Australia*. HCWS *MM 34:370(1965)*.

15.1.6.1 Lansfordite $\text{MgCO}_3 \cdot 5\text{H}_2\text{O}$

Named in 1888 for the locality. *MON* $P2_1/m$. $a = 12.48$, $b = 7.55$, $c = 7.34$, $\beta = 101.7^\circ$, $Z = 4$, $D = 1.693$. *MM 46:453(1982)*. 35-680(syn): 7.18₃ 5.24₃ 5.11₃ 4.58₁₀ 3.24₆ 3.01₃ 2.84₁₀ 1.710₄. Stalactitic, short prismatic crystals [001]. Colorless to white; translucent; vitreous luster resembling paraffin when fresh, but rapidly alters, becoming dull and opaque. Cleavage {001}, perfect; {100}, distinct. $H = 2\frac{1}{2}$. $G = 1.70$. IR. *MSLM 4:264(1974)*. Biaxial (+); $XZ = bc$; Y perpendicular to {100}; $N_x = 1.456$, $N_y = 1.469$, $N_z = 1.508$; $2V = 59.5^\circ$ (Italy). Alters to nesquehonite; soluble, effervescent in 1:10 acids. Loses all H_2O at 110° . Precipitated with nesquehonite when alkaline carbonates added to magnesian chloride solution in the cold. Found as small stalactites attached to the roof of an anthracite mine in *Nesquehoning, Lansford, Carbon Co., PA*, associated with nesquehonite; also as small crystals in hydro-magnesite deposit at Atlin, BC, Canada; with nesquehonite in serpentinous rock, Cogne, Val d'Aosta, Piedmont, Italy. HCWS *DII:228*.

15.1.7.1 Hellyerite $\text{NiCO}_3 \cdot 6\text{H}_2\text{O}$

Named in 1958 after Henry Hellyer (b.1826), first surveyor general of Van Diemen's Land, TAS, Australia. *MON* $C2/c$. $a = 10.77$, $b = 7.30$, $c = 18.68$, $\beta = 94.0^\circ$, $Z = 8$, $D = 2.06$. 12-276: 9.4₁₀ 6.06₁₀ 3.65₇ 3.40₆ 3.11₄ 2.78₄ 2.38₅ 2.31₄. See also 24-523(calc). Fine-grained coatings [in part on zaratite (16.1.2.1)], in shear planes in serpentinites. Pale blue, vitreous luster. Lamellar twinning parallel to perfect cleavage, two less perfect cleavages nearly 90° from first make angle of 112° . $H = 2\frac{1}{2}$. $G = 1.97$. Biaxial (-); $X = Y < Z$; $N_x = 1.455$, $N_y = 1.503$, $N_z = 1.549$; $2V = 85^\circ$. Y , pale greenish blue, is normal to perfect cleavages, OAD nearly normal to cleavages. Readily decomposes to basic carbonate without much change in X-ray pattern. Found associated with zaratite at *Old Lord Brassey nickel mine, Heazlewood, TAS, Australia*. HCWS *AM 44:533(1959)*.

15.1.8.1 Joliotite $(\text{UO}_2)\text{CO}_3 \cdot n\text{H}_2\text{O}$ ($n \approx 2$)

Named in 1976 for J. Frederic Joliot (1900-1958), French physicist, and I. Joliot-Curie. *ORTH* $P222$, $Pmm2$, or $Pmmm$. $a = 8.16$, $b = 10.35$, $c = 6.32$, $Z = 4$, $D = 4.55$. *MA 28:208(1977)*. 29-1378: 8.09₁₀ 4.48₂ 4.10₅ 3.42₉ 3.18₈ 2.11₃ 2.04₂ 1.882₄. Spherulites of scaly crystals {100}, {010}, {011}. Lemon yellow, yellow streak, translucent. Cleavage parallel to (100). $H = 1-2$. $G = 4.04$. Weakly fluorescent. Biaxial (-); $N_x = 1.600$, $N_y = 1.644$, $N_z = 1.644$, $2V$ small. Z , yellow. Dehydration leads to contraction of a axis in unit cell. Occurs as crusts on "limonite" and barite at uranium deposit, *Menzenschwald, Schwarzwald, Germany*, associated with rutherfordine, studtite, and billietite. HCWS *SMPM 56:167(1976)*.

15.2.1.1 Pirssonite $\text{Na}_2\text{Ca}(\text{CO}_3)_2 \cdot 2\text{H}_2\text{O}$

Named in 1896 after Louis Valentine Pirsson (1860–1919), petrographer, Yale University. Suolunite is the Si analog. ORTH. *Fdd2*. $a = 11.32$, $b = 20.06$, $c = 6.00$, $Z = 8$, $D = 2.367$. *USGSPP 405:1(1962)*, Structure: *AC 23:763(1967)*. *22-476*: 5.13₇ 4.93₆ 3.15₅ 2.89₅ 2.65₉ 2.57₈ 2.51₁₀ 2.02₅. See also *24-1065(syn)*. Short prismatic [001] with variable upper terminations, also tabular {010}, or pyramidal; crystals notably hemimorphic with only {111} on one end, {131} more obvious than {111} on other end, also {010}, {110} occasionally {311}. Colorless to white, grayish due to inclusions; vitreous luster; transparent. Conchoidal fracture, brittle. $H = 3-3\frac{1}{2}$. $G = 2.352$. IR. *MSLM 4:270(1974)*. Pyroelectric parallel to [001]. Biaxial (+); $N_x = 1.504$, $N_y = 1.510$, $N_z = 1.575$ (Na); $2V = 31.3^\circ$, increases with T; $r < v$. Soluble, effervescent in cold 1:10 acids. From drill cores with shortite, bradleyite, northupite, gaylussite, and trona near *Green River, Sweetwater Co., WY*; as euhedral crystals in mud layers and consolidated strata *Searles Lake, San Bernardino Co.(!), CA*, and with northupite, tychite, gaylussite, and other minerals in salt lakes such as Borax Lake; in the Khibina alkaline massif, Kola Penin., Russia; with trona and thenardite at Otjiwalundo Salt Pan, Namibia. *HCWS DII:233*.

15.2.2.1 Gaylussite $\text{Na}_2\text{Ca}(\text{CO}_3)_2 \cdot 5\text{H}_2\text{O}$

Named in 1826 after Joseph Louis Gay-Lussac (1778–1850), French chemist and physicist. MON *C2/c* or *Cc*. $a = 11.589$, $b = 7.779$, $c = 11.207$, $\beta = 102.0^\circ$, $D = 1.989$. *AM 52:1570(1967)*. *21-343*: 6.41₁₀ 4.50₅ 4.43₄ 3.21₆ 2.73₉ 2.70₅ 2.64₁₀ 2.51₅. Crystals elongated parallel to a , flattened or wedgelike with {110}/{001} dominant, faces usually rough, {011} striated parallel to [111]; {110}, {011}, {001}, {112} common. Colorless to white with yellow or gray tinge; streak uncolored; vitreous luster; transparent to translucent. Perfect cleavage parallel to {110}, difficult parallel to {001}, conchoidal fracture, brittle. $H = 3-3\frac{1}{2}$. $G = 2.367$. IR. *MSLM 4:270(1974)*. Biaxial (-); $N_x = 1.443$, $N_y = 1.516$, $N_z = 1.523$; $2V = 34^\circ$ (Na); $r < v$, strong, crossed. Effloresces slowly in dry air. Soluble, effervescent in acids; slightly soluble in H_2O , giving CaCO_3 ppt., readily alters to calcite. Usually found in soda lakes with natron, thermonatrite, trona, pirssonite, calcite, and borax. Calcite pseudomorphs after gaylussite have been described. Found at sinks in Carson desert near Ragtown, NV; with northupite and pirssonite in trona at Borax Lake, Lake Co.; Mono Lake, Mono Co., Searles Lake, San Bernardino Co., CA. Crystals formed in a clay bed adjacent an alkali lake at *Lagunillas, Merida, Venezuela*; also in the Taboos-nor (salt lake) in eastern Gobi desert, Mongolia, China. *HCWS DII:235*.

15.2.3.1 Chalconatronite $\text{Na}_2\text{Cu}(\text{CO}_3)_2 \cdot 3\text{H}_2\text{O}$

Named in 1955 after the composition: copper and natron (soda). MON *P2₁/n*. $a = 13.72$, $b = 6.12$, $c = 9.70$, $\beta = 91.3^\circ$, $Z = 4$, $D = 2.31$. *SCI 122:75(1955)*. *22-1458(syn)*: 7.82₅ 6.90₁₀ 5.18₇ 4.18₈ 3.68₉ 2.89₆ 2.85₇ 2.53₆. Fine-grained

incrustation on Egyptian bronze objects, presumably buried for centuries with owners' bodies. Greenish-blue crystals are platy or lath shaped, pseudohexagonal. Soft. $G = 2.27$. Biaxial (+); Y parallel to elongation; $N_x = 1.483$, $N_y = 1.530$, $N_z = 1.576$; 2V large. X, colorless; Y, pale blue; Z, blue. Decomposes in water, soluble with effervescence in cold acids. At the time this mineral was described there was a debate whether such occurrences should be given "mineral" designation. It has since been found at Grube Glückrad, near Oberschulenberg, Hartz Mts. Germany; and at Carr Boyd nickel mine 50 km north of Kalgoorlie, WA, Australia. hcws

15.2.4.1 Baylissite $K_2Mg(CO_3)_2 \cdot 4H_2O$

Named in 1976 after Noel Stanley Bayliss, chemist, University of Western Australia, Nedlands, WA, Australia. *MON P2₁/a*. $a = 12.37$, $b = 6.24$, $c = 6.86$, $\beta = 114.5^\circ$, $Z = 2$, $D = 2.03$. *SMPM 567:187(1976)*. *29-1017(syn)*: 6.31₈ 4.19₇ 3.13₈ 3.01₁₀ 2.98₉ 2.56₈ 2.46₈ 2.06₈. Colorless fine-grained anhedral aggregates and crusts. No cleavage, conchoidal fracture. $H = 2-3$. $G = 2.01$. Biaxial (-); $N_x = 1.465$, $N_y = 1.485$, $N_z = 1.535$; 2V = 64°. Synthetic compound known. Decomposes in H₂O and at high humidity. Found in the cable tunnel of Gersternegg/Sommerlock, in the *Grimsel Area, Canton Bern, Switzerland*, where mineralized fissures intersect Grimsel granodiorite or aplite granite; associated with quartz, feldspar, grimselite, calcite, monohydrocalcite, and schrockingerite. hcws

15.2.5.1 Andersonite $Na_2Ca(UO_2)(CO_3)_3 \cdot 6H_2O$

Named in 1948 for Charles Alfred Anderson (1902-1990), U.S. Geological Survey. *HEX-R R3*. $a = 18.009$, $c = 23.838$, $Z = 18$, $D = 2.875$. *NJMM:488(1987)*. *20-1092*: 13.0₁₀ 7.93₁₀ 5.67₁₀ 5.23₈ 5.14₈ 4.31₆ 3.68₁₀ 3.13₆. Structure: *AC(B) 37:1946(1981)*. Rhombohedral crystals up to 1 cm, also tiny pseudocubic crystals; thick crusts and veinlets. Bright yellow-green, transparent to translucent, vitreous to pearly luster. $H = 2\frac{1}{2}$. $G = 2.8$. IR. *MSLM 4:273(1974)*. Fluoresces bright yellow green in UV. Uniaxial (+); $N_O = 1.520$, $N_E = 1.540$. *DII:239*. Soluble in water; crystals can be obtained by evaporating a solution of K₂CO₃ and the nitrates of Na, Ca, and uranium. A secondary mineral found as efflorescences on mine walls or in veins associated with U deposits. Occurs with liebigite and carnotite in Jim Thorpe, PA; at Atomic King No. 2 mine(!) in thick crusts, crystals up to $\frac{1}{2}$ in., and at Cane Creek Wash(!) near Moab, San Juan Co., Skinny No. 1 mine, southeast of Thompsons, Grand Co., UT; large crystals encrusting sandstone in Ambrosia Lakes district, McKinley Co., NM; with bayleyite, swartzite, schrockingerite, and gypsum at *Hillside mine, Bagdad, Yavapai Co., AZ*; on tunnel walls, Geevor mine, Cornwall, England. hcws *AM 34:274(1949)*, *USGSB 1064:115(1958)*.

15.2.6.1 Grimselite $K_3Na(UO_2)(CO_3)_3 \cdot H_2O$

Named in 1972 for the locality. *HEX* $P62c$. $a = 9.30$, $c = 8.26$, $Z = 2$, $D = 3.27$. *SMPM* 52:93(1972). 25-679: 8.06₈ 5.78₁₀ 4.66₇ 4.14₆ 3.63₈ 3.08₈ 2.67₇ 2.01₇. Crusts of fine-grained aggregates, mostly anhedral; crystals showing {1010}, {10 $\bar{1}$ 1}, and {0001}. Yellow, pale yellow streak. No distinct cleavage, conchoidal fracture, brittle. $H = 2-2\frac{1}{2}$. $G = 3.30$. Nonfluorescent. Uniaxial (-); $N_O = 1.601$, $N_E = 1.480$. O-yellow; E-colorless. Analysis shows small amounts of Al, Ca, and Mg, traces of Cu, Fe, Si, and Mn. Has been synthesized from solutions of K_2CO_3 , Na_2CO_3 , and uranyl acetate; H_2O determined by loss on heating, DTA. Found as crusts in cable tunnel between Gerstemegg and Sommerloch, *Grimsel area, Aar massif, Oberhasli, Switzerland*; also on fissures and veins in aplite granite, associated with schrockingerite, monohydrocalcite, and other carbonates. *HCWS AM* 58:139(1973).

15.3.1.1 Zellerite $Ca(UO_2)(CO_3)_2 \cdot 5H_2O$

Named in 1963 for Howard D. Zeller (b.1922), U.S. Geological Survey, who found the mineral. See metazellerite (15.3.1.2). *ORTH* $Pmmm$ or $Pmn2_1$. $a = 11.220$, $b = 19.252$, $c = 4.933$, $Z = 4$, $D = 3.24$. *AM* 51:1567(1966). 19-257: 9.66₁₀ 7.33₂ 5.59₄ 4.85₅ 4.41₃ 3.65₄ 2.95₁ 2.69₁. Hairlike, pin-cushion clumps of needlelike crystals, individual crystal faces not discernible. Light yellow. No cleavage observed. $H \approx 2$. $G = 3.25$. Weak patchy fluorescence in UV. Biaxial (-); $Z = c$; $N_x = 1.536$, $N_y = 1.559$, $N_z = 1.697$; $2V = 30-45^\circ$, dependent on hydration; $r < v$. X, Y, colorless; Z, light yellow. Zellerite is metastable relative to metazellerite at higher temperatures or lower humidities. Minor amounts of REE, K, Na, and Si in analysis. A secondary mineral that forms as clumps or small veins in oxidized uranium ores usually under relatively high CO_2 and $pH > 7$. Found along with liebigite and gypsum, "limonite," and partially altered iron sulfides, on fine-grained mixture of uraninite, coffinite, and iron sulfides in intergranular areas in arkose at *Lucky Mc mine, Fremont Co.*, and Pat No. 8 mine, Powder River Basin, WY. *HCWS*

15.3.1.2 Metazellerite $Ca(UO_2)(CO_3)_2 \cdot 3H_2O$

Named in 1966 for the relationship to zellerite. *ORTH* $Pbn2_1$ or $Pbnm$. $a = 9.718$, $b = 18.226$, $c = 4.965$, $Z = 4$, $D = 3.41$. *AM* 51:1567(1966). 19-258(syn): 9.1₁₀ 4.70₄ 4.55₂ 4.41₂ 4.30₄ 3.98₂ 3.79₅ 3.17₂. Intimately associated with zellerite (15.3.1.1), this mineral is the trihydrate, or more dehydrated version, and is similar in physical and chemical properties to zellerite with chalky yellow color and dull luster. $Biaxial_{mean} = 1.626$. Formation sensitive to pCO_2 , H_2O . Occurs with zellerite in oxidized zones at *Lucky Mc mine, Gas Hills, WY*, associated with liebigite, gypsum, "limonite," partially altered iron sulfides, and fine-grained mixture of uraninite and coffinite in intergranular areas of arkose. *HCWS*

15.3.2.1 Liebigite $\text{Ca}_2(\text{UO})_2(\text{CO}_3)_3 \cdot 11\text{H}_2\text{O}$

Named in 1848 after German chemist Justus van Liebig (1803–1873). ORTH *Pba*2. $a = 16.703$, $b = 17.513$, $c = 13.741$, $Z = 8$, $D = 2.43$. USGSB 1064:108(1958). 11-296: 8.68₉ 6.81₁₀ 4.55₆ 3.33₅ 3.31₅ 3.10₆ 2.15₄ 1.998₅. Crystals short prismatic [001], or equant, usually indistinct with rounded edges and convex or vicinal faces; commonly granular or scaly aggregates, thin crusts, botryoidal. Green to yellow-green, vitreous luster, pearly on cleavage; transparent to translucent. Cleavage {100}. $H = 2\frac{1}{2}$, $G = 2.41$. Fluorescent green in UV. Biaxial (+); $N_x = 1.497$, $N_y = 1.502$, $N_z = 1.539$; $2V = 40^\circ$; $r > v$, moderate. X, colorless; Y, Z, pale yellow green. Soluble with effervescence in H_2SO_4 leaving a white deposit, solution is green. A secondary mineral in the oxidized portions of uranium deposits associated with other uranium-containing carbonate and hydrated carbonate minerals and β -uranophane. Found at Jim Thorpe mine, PA; Schwartzwalder mine, Jefferson Co., CO; Lucky Mc mine, Fremont Co., Silver Cliff mine at Lusk, and Pumpkin Buttes, WY; Mi Vida mine, Moab in San Juan Co., Black Apes mine in Grand Co., UT; Midnite mine, Stevens Co., WA; Nicholson mine, Goldfields, SAS, Canada; at Wheal Basset, Cornwall, England; as efflorescence on mine walls Joachimov, Bohemia, Czech Republic; at Schmiedeberg, Eisleben, and Schneeberg, Germany; at Stripa, Sweden; at *Edirne, near Adrianople, Turkey*. hcws DII:241.

15.3.3.1 Bayleyite $\text{Mg}_2(\text{UO}_2)(\text{CO}_3)_3 \cdot 18\text{H}_2\text{O}$

Named in 1948 after William Shirley Bayley (1861–1943), mineralogist and economic geologist, University of Illinois, Urbana, IL. MON $P2_1/c$. $a = 26.65$, $b = 15.3$, $c = 6.53$, $\beta = 93.1^\circ$, $Z = 4$, $D = 2.06$. AM 36:1(1951). Syn: $P2_1/a$. $a = 26.560$, $b = 15.25$, $c = 6.505$, $\beta = 92.9^\circ$. Structure: *TMPM 35:133(1986)*. H-bonded pseudohexagonal framework composed of two types of Mg—O octahedra: $\text{Mg}_1(\text{H}_2\text{O})_6$ and two $\text{Mg}_3(\text{H}_2\text{O})_6$, and two $\text{UO}_2(\text{CO}_3)_3$ groups, that have channels parallel to c occupied by another Mg—O octahedral group: $\text{Mg}_2(\text{H}_2\text{O})_6$ and 12 H_2O molecules. 4-130: 13.1₉ 7.66₁₀ 6.53₄ 5.85₄ 5.08₄ 3.83₆ 2.69₅ 2.21₅. Short prisms [001] to acicular, bladed crystals in crusts and radiating groups. Synthetic material has beautiful prism [001] crystals, showing {100}, {110}, {210}, {001}, {401}, {021}, {211}, {111}, {311}. Light yellow, vitreous luster, transparent, becoming dull on dehydration. Conchoidal fracture. $G = 2.05$. DTA (syn). Feebly fluorescent in UV. Biaxial (–); $N_x = 1.455$, $N_y = 1.490$, $N_z = 1.500$; $2V_{\text{calc}} = 30^\circ$; inclined extinction. Syn: $Y = b$; $X \wedge c = 11^\circ$; $N_x = 1.453$, $N_y = 1.498$, $N_z = 1.499$; $V = 16^\circ$. On exposure to air rapidly dehydrates to phase with $N_x = 1.502$, $N_z = 1.551$ and strong green fluorescence. Soluble in H_2O . Widespread in Colorado Plateau region, bayleyite is found in crusts on sandstone in the Ambrosia Lakes district, McKinley Co., NM; Pumpkin Buttes area of Powder River Basin, WY; at Southwest mine, Bisbee, Cochise Co., and with schrockingerite, anderssonite, swartzite, and gypsum as coatings on mine walls, *Hillside mine, Yavapai Co., AZ*; as an efflorescence with epsomite and gypsum in a tunnel at Azegour,

Morocco. HCWS *DII:237*, *USGSB 1064:112(1958)*, *USGSPP 400-B:B440(1966)*.

15.3.3.2 Swartzite $\text{CaMg}(\text{UO}_2)(\text{CO}_3)_3 \cdot 12\text{H}_2\text{O}$

Named in 1951 after Charles K. Swartz (1861–1949), geologist and mineralogist, Johns Hopkins University. *MON P2₁/m*. $a = 11.12$, $b = 14.72$, $c = 6.47$, $\beta = 99.5^\circ$, $Z = 2$, $D = 2.32$. *USGSB 1064:117(1958)*. *4-111*: 8.76₁₀ 7.31₉ 5.50₁₀ 4.82₈ 3.66₇ 2.91₈ 2.06₈ 1.71₈. Tiny green prismatic [010] crystals in clusters or in crusts that turn dull yellowish white on dehydration. $G = 2.3$. Fluoresces bright green in UV. Biaxial (–); $N_x = 1.465$, $N_y = 1.51$, $N_z = 1.540$; $2V_{\text{calc}} = 40^\circ$. X, colorless; Y,Z, yellow. Soluble in H_2O . Found as efflorescence on mine walls at the *Hillside mine*, *Yavapai Co.*, *AZ*, associated with gypsum, bayleyite, andersonite, and schrockingerite; at Coral claim, Elk Ridge, San Juan Co., *UT*. HCWS *DII:238*.

15.3.4.1 Donnayite-(Y) $\text{NaCaSr}_3\text{Y}(\text{CO}_3)_6 \cdot 3\text{H}_2\text{O}$

Named in 1978 after Joseph Desiré Hubert Donnay (1902–1994), Belgian–American–Canadian crystallographer and mineralogist, and Gabrielle (Hamburger) Donnay (1920–1987), American–Canadian mineralogist, McGill University. Related to weloganite (15.3.4.3) and mckelveyite (15.3.4.2); see also ewaldite (14.2.4.1). *TRIC P1*. $a = 9.000$, $b = 8.999$, $c = 6.793$, $\alpha = 102.77^\circ$, $\beta = 116.28^\circ$, $\gamma = 59.99^\circ$, $Z = 1$, $D = 3.266$. *CM 16:335(1978)*. *29-1445*: 6.10₄ 4.37₇ 3.21₃ 2.84₁₀ 2.60₄ 2.04₃ 2.02₃ 1.978₃. Crystals all less than 2 mm in size may be platy, tabular, saucer- or barrel-shaped, and columnar; some are hemimorphic; terminations “capped” by ewaldite or mckelveyite. Colorless, white, yellow, gray; white streak; vitreous luster. $H = 3$. $G = 3.30$. Biaxial (–); $N_x = 1.551$ – 1.561 , $N_y = 1.646$, $N_z = 1.652$; $2V = 0$ – 20° . Found in nepheline syenite at *Mt. St.-Hilaire*, *QUE*, *Canada*, associated with microcline, analcime, natrolite, aegirine, arfvedsonite, siderite, rhodochorsite, ancylite, and others. HCWS

15.3.4.2 Mckelveyite-(Y) $(\text{Ba,Sr})(\text{Na,Ca,Y,REE})(\text{CO}_3)_2 \cdot 3\text{--}5\text{H}_2\text{O}$

Named in 1965 after Vincent E. McKelvey (1916–1985), director of the U.S. Geological Survey. See donnayite (15.3.4.1) and weloganite (15.3.4.3). *TRIC P1*. $a = 9.142$, $b = 9.141$, $c = 7.000$, $\alpha = 102.51^\circ$, $\beta = 115.67^\circ$, $\gamma = 59.99^\circ$, $Z = 1$. *ZVMO 119:76(1990)*. *PD*: 6.36₅ 4.46₉ 4.12₅ 3.29₅ 2.92₁₀ 2.64₈ 2.26₆ 2.02₇. See also *18-901*. Hemimorphic crystals and aggregates of plates < 0.5 mm (Green River); barrel-shaped pseudohexagonal crystals to 3 cm with sector zoning (Khibiny), disk-shaped pseudorhombohedral crystals to 3 mm across (Khibiny), platy aggregates (Sallanlatvi, Vuoriyarvi). Greenish or yellowish gray, white, reddish brown, brown, lime green, or black with amorphous carbonaceous inclusions (Green R.); translucent to opaque, colorless in thin section. No cleavage, uneven fracture. $H = 3.5$ – 4 . $G = 3.47$. IR, DTA (Russian samples). All Russian samples appear uniaxial (–); $N_O = 1.649$, $N_E = 1.550$ (Sallanlatvi); $N_O = 1.652$ – 1.658 ; $N_E = 1.553$ – 1.554 (Khibiny).

Microprobe analyses on Russian samples show Y, La, Ce, Sm, Eu, Gd, Tb, Ho, Er, and Yb; CO₂ and H₂O for formula calculated. Found in drill core from four subsurface localities in the *Green River formation, Sweetwater Co., WY*, where it forms syntactic intergrowths with ewaldite associated with labuntsovite, ewaldite, leucospheinite, searlesite, and other minerals. In Khibiny massif mckelveyite is occasionally zoned with Sr enrichment outward [toward donnayite-(Y)] and occurs in aegirine-feldspar-natrolite-calcite veins in the syenite, in siderite-ankerite-natrolite veins in carbonatized foyaite, and in the cataclastic albitite at the contact zone. In the Sallanlatvi and Vuoriyarvi massifs mckelveyite is found in solution cavities in carbonatite. Associated minerals are sphalerite, galena, pyrite, barite, strontionite, fluorite, ancyllite, ewaldite, cordylite, donnayite, vinogradovite, catapleiite, epididymite, zhonghuacerite, orthoclase, zircon, and burbankite. HCWS *AM 78:236(1993)*, *50:593(1965)*, *52:860(1967)*; *TMPM 15:185(1971)*.

15.3.4.3 Mckelveyite-(Nd) (Ba,Sr)(Ca,Na,Nd,REE)(CO₃)₂·3–10 H₂O

Named in 1993 for its composition and relationship to Mckelveyite-(Y). The Nd endmember in series with mckelveyite-(Y) (15.3.4.2). TRIC. $a = 9.183$, $b = 9.182$, $c = 7.042$, $\alpha = 102.52^\circ$, $\beta = 115.66^\circ$, $\gamma = 59.99^\circ$, $Z = 1$ *ZVMO 119:76(1993)*. PD 6.39₅ 4.49₉ 4.15₅ 2.93₁₀ 2.66₈ 2.28₆ 2.03₇ 1.964₆. Single disk-shaped pseudorhomboidal crystals to 1 mm or in parallel growth with mckelveyite-Y, platy aggregates. No cleavage, uneven fracture. H = 3–3½. Two varieties: 1) pale green, transparent, colorless in thin section, Biaxial (-); N_x1.556, N_y1.650, N_z1.653, 2V = 10–13°, 2) yellow-brown, opaque, colorless in thin section, Uniaxial (-); N_o1.651, N_e1.556. The latter variety shows a higher amount of Ba, and Sr, and an absence of Na not compensated by Ca. Microprobe analyses: Sr, Ba, Na or ■, Ca, Y, La, Ce, Pr, Nd, Sm, Eu, Gd, Dy. CO₂ and H₂O calculated. Both varieties are described from the solution cavities in the carbonatites at the *Vuoriyarvi massif, Kola Penin., Russia* associated with chalcopyrite, sphalerite, galena, pyrite, barite, strontionite, chlorite, ancyllite, ewaldite, cordylite, carbonate spatite, alstonite, carbocernaite. HCWS

15.3.4.4 Weloganite Na₂Sr₃Zr(CO₃)₆·3H₂O

Named in 1968 after William E. Logan (1798–1875), first director of the Canadian Geologic Survey (1842–1870). See also donnayite (15.3.4.1) and mckelveyite-(Y) (15.3.4.2). TRIC P1. $a = 8.988$, $b = 8.988$, $c = 6.730$, $\alpha = 102.84^\circ$, $\beta = 116.42^\circ$, $\gamma = 59.99^\circ$, $Z = 1$, $D = 3.21$. *CM 13:22(1975)*. *27-790*: 6.02₅ 4.36₈ 2.82₁₀ 2.59₇ 2.38₆ 2.23₇ 2.01₇ 1.966₇. Crystals 2 mm to 3 cm, elongated parallel to *c*, pseudo-hexagonal in outline, pyramidal terminations with pedion, prism faces heavily striated and grooved parallel to the base, indicating parallel growth; crystals often vary in cross section, giving a hemimorphic aspect, and hourglass or other odd shapes; also massive. White, lemon-yellow, amber, thin fragments colorless and transparent, larger crystals may be zoned shades of yellow on basal sections; white streak; vitreous luster. Perfect basal clea-

vage, conchoidal fracture. $H = 3\frac{1}{2}$. $G = 3.22$. Biaxial (-); $N_x = 1.558$, $N_y = 1.646$, $N_z = 1.648$; $2V \approx 15^\circ$. Soluble with effervescence in dilute HCl. From the *St. Michel quarry, Montreal Is., QUE, Canada*, where an alkalic sill intrudes an Ordovician limestone, associated with calcite, quartz, dawsonite, dresserite, and other minerals. *HCWS CM 9:468(1968)*.

15.3.5.1 Voglite $\text{Ca}_2\text{Cu}(\text{UO}_2)(\text{CO}_3)_4 \cdot 6\text{H}_2\text{O}$

Named in 1853 after Josef Florian Vogl, Austrian mining official and mineralogist, who described the compound and published on uranium mines and minerals of Jachymov, Czech Republic. *MON P2₁*. $a = 25.97$, $b = 24.50$, $c = 10.70$, $\beta = 104^\circ$, $Z = 16$, $D = 3.06$. *33-274*: 12.6₁₀ 9.65₈ 8.70₁₀ 7.10₆ 6.13₄ 4.65₃ 4.32₅ 3.94₃. Rhomboidal scales flattened on {010} or coatings with plane angles of 78° and 102° striated on flat surface parallel to an edge. Emerald to grass-green, pale green streak, pearly luster on cleavages. Cleavage {010}, perfect; lamellar twinning on {100}. Biaxial (+); $N_x = 1.541$, $N_y = 1.547$, $N_z = 1.564$; $2V = 60^\circ$; $r < v$, strong. X, blue-green; Y,Z, pale yellow. Soluble with effervescence in acids. A secondary mineral found encrusting sandstone at Frey Point, and at White Canyon No. 1 mine, San Juan Co., UT; Red Mesa Trading Post, Navajo Co., AZ; with liebigite as an alteration product of uraninite at *Elias mine, Jachymov, Bohemia, Czech Republic*. *HCWS DII:237, USGSB 1064:126(1958)*.

15.3.6.1 Fontanite $\text{Ca}(\text{UO}_2)_3(\text{CO}_3)_4 \cdot 3\text{H}_2\text{O}$

Named in 1992 for François Fontan, mineralogist, University of Paul-Sabater, Toulouse, France. *ORTH Pmm, Pmn2₁, P2₁nm*. $a = 15.337$, $b = 17.051$, $c = 6.931$, $Z = 4$, $D = 4.19$. *EJM 4:1271(1992)*. *PD*: 8.55₁₀ 6.94₅ 4.11₆ 3.72₆ 3.46₅ 3.21₄ 2.77₇ 2.52₂. Radiating aggregates to 4 mm diameter of rectangular laths up to 1.2 mm \times 0.15 mm \times 0.05 mm, elongate [001], platy (010) showing {100}, {010}. Bright yellow, white streak, transparent, vitreous luster. Cleavage {010}, {001}, {100}. $H = 3$. $G = >4.10$. Fluoresces light green in LWUV. Biaxial (-); $XYZ = bac$; $N_{x \text{ calc}} = 1.603$, $N_y = 1.690$, $N_z = 1.710$; $2V = 49^\circ$; $r > v$, weak; nonpleochroic. Occurs in the alteration zone of the *Rabejec deposit* (7 km SSE of Lodeve), *Herault, France*, with billietite and uranophane, where the primary minerals are pitchblende, uraniferous carbon, and coffinite. *HCWS*

15.4.1.1 Calkinsite-(Ce) $\text{Ce}_2(\text{CO}_3)_3 \cdot 4\text{H}_2\text{O}$

Named in 1953 after Frank Cathcart Calkins (1878–1974) of the U.S. Geological Survey. *ORTH P2₁22₁*. $a = 9.57$, $b = 12.65$, $c = 8.94$, $Z = 4$, $D = 3.27$. *AM 38:1169(1953)*. *6-76*: 6.54₁₀ 4.78₄ 4.49₄ 3.27₅ 2.93₃ 2.13₃ 2.12₃ 2.07₃. Thin tabular crystals parallel to {010} with {010} dominant and also {122}, {132}, {100}, {001}, {102} with maximum length 1 mm; twins {101}. Pale yellow. Perfect cleavage parallel to {010}, distinct parallel to {101}, sometimes parallel to {001}. $H \approx 2\frac{1}{2}$. $G = 3.28$. Biaxial (-); $N_x = 1.569$, $N_y = 1.657$, $N_z = 1.686$; $2V = 54^\circ$; $r < v$. X = b, yellow; Y = c, colorless;

$Z = a$. Occurs with barite in vugs of weathered burbankite and ancylite veins, also showing lanthanite and goethite, at head of *Big Sandy Creek, SE Hill Co., MT*; at Khanneshin, Afghanistan. HCWS

15.4.2.1 Lanthanite-(La) $\text{La}_2(\text{CO}_3)_3 \cdot 8\text{H}_2\text{O}$

Named in 1845 for the composition. See other end members of the solid-solution series lanthanite-(Ce) (15.4.2.3), lanthanite-(Nd) (15.4.2.2), and possibly calcinsite (15.4.1.1). ORTH. *Pbnb*. $a = 9.504$, $b = 16.943$, $c = 8.937$, $Z = 4$, $D = 2.78$ for $\text{LaCe}(\text{CO}_3)_3 \cdot 8\text{H}_2\text{O}$. Structure: *AM 62:142(1977)*. Two types of REE—O polyhedra in which the cations are in 10-fold coordination: REE_1 —O bonds with six O from CO_3 groups and four O from H_2O , while REE_2 —O bonds with eight O from CO_3 groups and two O from H_2O , form layers parallel to the *ac* plane. The layers are connected only by H bonds. Lathlike, platy to thick tabular crystals show twinning on {101}, also scaly, granular to earthy. Colorless, white, yellowish, pinkish; pearly luster; transparent. Micaceous cleavage on {010}, not brittle. $H = 2\frac{1}{2}$ –3. $G = 2.69$ –2.73. Biaxial (-); $N_x = 1.52$, $N_y = 1.587$, $N_z = 1.613$; $2V \approx 63^\circ$ (Na); $r < v$, weak. Other rare earths are present. Soluble in acids, decomposed into white powder by boiling H_2O . Alteration product in magnetite deposit, Sanford mine, Moriah, Essex Co., NY; rare mineral in oxidized zinc ores, Bethlehem, Lehigh Co., PA; with allanite in pegmatite at Baringer Hill, Llano Co., TX; coats cerite at *Bastnaes mine, near Riddarhyttan, Västmanland, Sweden*; found at Grimsel Pass, Switzerland, and at Curitiba, Paraná, Brazil. HCWS *DII:241*.

15.4.2.2 Lanthanite-(Nd) $\text{Nd}_2(\text{CO}_3)_3 \cdot 8\text{H}_2\text{O}$

Named in 1980 for the composition. Nd end member of the series. ORTH *Pbnb*. $a = 9.476$, $b = 16.940$, $c = 8.942$, $Z = 4$, $D = 2.82$. *BM 102:342(1979)*. *42-593: 8.50*₁₀ *4.74*₅ *4.47*₆ *4.14*₃ *3.95*₃ *3.25*₆ *3.04*₆ *2.58*₃. Orthorhombic crystals < 2 mm long flattened on [010] show many other faces with striations often seen on (010). Bright pink, vitreous luster. Cleavage {010}, perfect; {101}, good; twinned on {101}. $H = 2\frac{1}{2}$ –3. Nonfluorescent. Biaxial (-); $XYZ = bca$; $N_x = 1.532$, $N_y = 1.590$, $N_z = 1.614$; $2V = -61^\circ$. Decomposes with effervescence in dilute HCl. Analysis shows slightly higher amounts of Nd over La plus > 4 wt % Pr_2O_3 , Sm_2O_3 , and minor amounts of Gd, Eu, Dy, Y, Ce, and Th. Occurs in recent silty, arenaceous clays and carbonate sediments near Curitiba, Paraná, Brazil. HCWS *GSCP 80-1C:141(1980)*.

15.4.2.3 Lanthanite-(Ce) $\text{Ce}_2(\text{CO}_3)_3 \cdot 8\text{H}_2\text{O}$

Named in 1985 for the composition. Ce end member of the series. ORTH *Pbnb*. $a = 9.482$, $b = 16.938$, $c = 8.965$, $Z = 4$, $D = 2.79$. *AM 70:411(1985)*. *38-377: 8.47*₁₀ *4.75*₇ *4.46*₆ *4.21*₄ *4.13*₄ *3.94*₄ *3.26*₇ *3.03*₇. Colorless transparent plates {010} with ragged edges are sectile; white streak; vitreous luster. Cleavage {010}. $H = 2\frac{1}{2}$. $G = 2.76$. Nonfluorescent. Biaxial (-); $XYZ = bca$; $N_x = 1.532$, $N_y = 1.594$, $N_z = 1.616$; $2V = 60^\circ$. Ce-dominant element followed by La, Nd with less than 2.5 wt % Sm, Gd, and Y. Dissolves in dilute acids with effer-

vescence, yielding a gel-like ppt. of La hydroxides. A secondary mineral occurring in oxidized copper ore at *Britannia mine, Snowdonia, northern Wales*, in plates covered by radiating tufts of malachite, associated with brochantite, posnjakite, and chalcoalumite. HCWS

15.4.3.1 Tengerite-(Y) $Y_2(CO_3)_3 \cdot 2-3H_2O$

Named in 1838 after C. Tenger, Swedish geologist. See lokkaite (15.4.4.1) and kimuraite (15.4.5.1). ORTH $Pb2_1m$. $a = 6.078$, $b = 9.157$, $c = 15.114$, $Z = 4$, $D = 3.11$. Structure: *AM 78:425(1993)*. Corrugated sheets of Y—O in ninefold coordination and trigonal planar CO_3 groups are connected by other CO_3 groups to form a three-dimensional framework. *27-91: 7.54₆ 5.60₆ 4.55₇ 3.87₁₀ 3.55₆ 2.95₇ 2.53₅ 1.970₅*. See also *24-1419*. Pulverulent or fibrous, white, coatings (originally on gadolinite). Most specimens are intimate mixture of at least five different rare-earth carbonate minerals: lanthanite, lokkaite-(Y), kimuraite-(Y), bastnasite-(Ce), and tengerite-(Y). IR. Biaxial; $N_x = 1.587$, $N_z = 1.616$. In addition to Y, natural samples contain La, Ce, Pr, Nd, Sm, Gd, Tb, Dy, Er, Ho, Tm, Yb, Lu, No, and Ca. Found at Luster pegmatite, southern Platte district, Jefferson Co., CO; at Clear Creek pegmatite, Burnet and Llano Cos., TX; Evans-Lou mine QUE. Canada; Ytterby, Sweden; Rosas, Norway; Pyörönmaa, Finland; and Iisaka, Japan. HCWS *DII:275*.

15.4.4.1 Lokkaite-(Y) $CaY_4(CO_3)_7 \cdot OH_2O$

Named in 1970 for Lauri Lokka (1885–1966), mineralogist and chief chemist, Geological Survey of Finland. See tengerite (15.4.3.1). ORTH $Pb2m$. $a = 39.35$, $b = 6.104$, $c = 9.26$, $Z = 4$, $D = 2.92$. Supercell detected in structure refinement of this mineral. *AM 71:1028(1986)*. See kimuraite (15.4.5.1). *PD(calc): 19.67₃ 9.84₅ 6.56₇ 5.83₅ 4.63₆ 3.93₅ 3.83₁₀ 2.95₄. 25-170: 19.60₄ 9.77₅ 6.51₆ 5.79₅ 4.59₈ 3.90₆ 3.81₁₀ 2.93₄* (Finland). Isolated disklike radial aggregates, 0.5 to 1 mm in diameter, composed of white fibers. Brittle. IR, DTA. Biaxial (-); $Z = c$; $N_x = 1.569$, $N_y = 1.592$, $N_z = 1.620$. Alteration product of rare-earth minerals. Found at Evans-Lou mine, QUE, Canada; in fissures of albite in *Pyoronmaa pegmatite, Kangasala, Finland*; in fissures of alkali olivine basalt, Kirigo, Saga Pref., Japan. HCWS *AM 56:1838(1971)*.

15.4.5.1 Kimuraite-(Y) $CaY_2(CO_3)_4 \cdot 6H_2O$

Named in 1986 for Kenjiro Kimura (b.1896), geochemist, University of Tokyo, Japan. ORTH $Imm2$, $Immm$, $I222$, or $I2_12_12_1$. $a = 9.25$, $b = 23.98$, $c = 6.04$, $Z = 4$, $D = 2.98$. *AM 71:1028(1986)*. *40-473: 12.06₁₀ 6.02₄ 5.93₂ 4.87₁ 4.64₂ 4.01₂ 3.76₃ 2.93₁*. Spherulitic aggregates of scales 4 cm long \times 2 cm wide, individual crystals are tabular. Light purple to pinkish white, vitreous to silky on perfect cleavage planes $\{010\}$. $H = 2\frac{1}{2}$. $G = 2.6$ (porous nature accounts for the discrepancy with D). IR. Reddish-purple and purple strong fluorescence in UV. Biaxial (-); $XYZ = abc$; $N_x = 1.548$, $N_y = 1.612$, $N_z = 1.626$; $2V = 70^\circ$; $r < v$, weak. Microprobe analysis shows Y is 75% of

REE, dominant others Nd, Gd, Dy, Er, Sm, less of La, Ce, Eu, Tb, Ho, Tm, Yb, and Lu. Soluble with effervescence in 1:1 HCl. A secondary mineral found in fissures up to 10 cm wide that parallel the flow structures in an alkali olivine basalt, *Kirigo, Hizen, Higashi Matsuura, Saga Pref., Japan.* HCWS

15.4.6.1 Tuliokite $\text{Na}_6\text{BaTh}(\text{CO}_3)_6 \cdot 6\text{H}_2\text{O}$

Named in 1990 for the locality. HEX-R R3. $a = 14.175$, $c = 8.605$, $Z = 3$, $D = 3.25$. AM 76:668(1991). 42-1395: 7.03₉ 4.07₆ 3.51₅ 3.15₈ 2.67₉ 2.35₁₀ 2.04₆ 1.959₇. Prismatic crystals up to 4 mm, and also rhombohedral crystals. Light or dark gray, color dependent on amount of included organic material; vitreous luster. No cleavage, brittle. $H = 3-4$. $G = 3.15$. Nonfluorescent. IR. AM 77:209(1992). Uniaxial (-); $N_O = 1.574$, $N_E = 1.587$ (598 nm). Easily soluble in 1:10 HCl with evolution of CO_2 . The H_2O content of the mineral is in some doubt, as single-crystal analyses gave the ideal formula with six H_2O , while microprobe/penfield H_2O analyses suggest eight. Occurs overgrowing sidorenkite, vinogradovite, and villiaumite in cavities between altered microcline crystals in 2- to 10-cm-thick pegmatite vein, or as rhombohedral crystals on pirssonite and shortite in 5- to 7-cm-thick natrolite-aegirine-microcline veinlets with trona, thermonatrite, natron, and villiaumite filling the interstices. Both occurrences in the nepheline syenites of *Mt. Kukisvumchorr, at Tuliok R., Khibiny massif, Kola Penin., Russia.* HCWS

15.4.7.1 Shomiokite-(Y) $\text{Na}_3(\text{Y,Dy})(\text{CO}_3)_3 \cdot 3\text{H}_2\text{O}$

Named in 1992 for the river close to the discovery site. ORTH P. $a = 10.136$, $b = 17.348$, $c = 5.970$, $Z = 4$, $D = 2.59$. ZVMO 121:129(1992). PD: 6.53₆ 5.05₅ 4.85₇ 2.86₇ 2.23₅ 2.08₁₀. Irregular grains and short prismatic pseudo-hexagonal crystals up to 1-2 mm in diameter, rosettelike aggregates up to 3 mm. Faces {010}, {110}, {011}, dull and uneven. Colorless, waxy to silky luster, translucent to transparent in thin pieces. Cleavage {110}, perfect; parting {001} forming needles parallel to c . $H = 2-3$. $G = 2.52$. IR. Biaxial (+); $XYZ = bca$; $N_x = 1.528$, $N_y = 1.529$, $N_z = 1.531$; $2V = 49^\circ$. Soluble with effervescence in 1:10 acids; becomes turbid and dehydrates on heating. Microprobe analysis: 21.93% Na_2O , 21.52% Y_2O_3 , 5.03% Dy_2O_3 , 1.80% Gd_2O_3 , 1.24% Er_2O_3 , 0.46% Tb_2O_3 , 0.63% H_2O_3 , 0.09% Ce_2O_3 , 0.01% CaO . Occurs among the interstices of potassium feldspar crystals in pegmatites of the *Alluain Mt., Lovozero massif, Kola Penin., Russia*, associated with albite, cancrinite, kogarite, villiaumite, neighborite, and sidorenkite. HCWS AM 79:765(1994).

Carbonates Containing Hydroxyl or Halogen

BASTNÄSITE/SYNCHYSITE/PARASITE GROUPS

Several rare-earth-element carbonate minerals conform to the general formula

where

REE = Ce, La, Nd, Y mainly, but Pr, Sm, Gd, etc. are also usually detected.

The minerals form layered structures and several subsets based on the ratios of the three formula components have been determined. These subsets can be described:

1:1:0 = bastnäsites

1:1:1 = synchysites

2:2:1 = parisites

3:3:2 = röntgenite-(Ce)

The minerals crystallize in hexagonal, rhombohedral, or with pseudo-hexagonal space groups in the orthorhombic and monoclinic systems.

Note that none contain molecular water, and thorbastnäsite, in which molecular water has been detected is, in spite of the name, placed in the ancylite group (16b.1.1.1).

The synchysites, parisites and röntgenite-(Ce) have additional cation-CO₃ layers. The stacked layering in the synchysites, for example, is slightly oblique to *c* resulting in monoclinic symmetry (see Figure). All these minerals show pronounced subcells due to the layering, and with different layer repeats and cation substitutions there are often supercells, or polytypes (see parisite-(Ce) 16a.1.5.1). Cation segregation during crystallization results in syntactic intergrowths which may interfere with definitive identification. However, it is important to note that there is not a continuous series between the one and two cation subsets of the REE-CO₃-F(OH) minerals i.e. between bastnäsites and synchysites. Further, all these minerals show large positive birefringence. Compare Ba-containing REE-CO₃-F species that show negative birefringence: cordylite (16a.1.6.1), huanghoite (16a.1.7.1), zhonghuacernite (16a.1.8.1) and cebaite (16a.1.91).

16a.1.1.1 Bastnasite-(Ce) Ce(CO₃)F

Named in 1841 after the locality. Bastnasite group. HEX P62c. $a = 7.16$, $c = 9.79$, $Z = 6$, $D = 5.02$. AM 38:932(1953). 11-340: 4.88₄ 3.56₇ 2.88₁₀ 2.06₄ 2.02₄ 1.898₄ 1.674₂ 1.573₄. Stacked thin plates, anhedral masses or granular. Crystals tabular {0001}, usually with {1010} alone, also deeply grooved horizontally due to oscillatory combination of {1011} and {1010}. Often intergrown with parisite, röntgenite, and/or synchysite; epitaxial or alteration pseudomorphs after fluocerite. Waxy yellow to reddish brown;

BASTNÄSITE: Ce(CO³)F

The projection down a_2^* , perpendicular to (010) of the bastnäsite structure shows alternating layers along the c axis of planar CO_3 groups that have one edge parallel to c , and layers of REE-F groups. The REE in the bastnäsites are in 9 fold coordination with 6 oxygens and 3 F *AM 78.415 (1993)*. In the hydroxy-bastnäsites Oh replaces F.

vitreous to greasy luster, pearly on parting surfaces; transparent to translucent. Cleavage {1010}, indistinct; distinct to perfect parting on {0001}; uneven fracture; brittle. $H = 4-4\frac{1}{2}$. $G = 4.9-5.2$. IR shows no OH or H_2O . *GI 3:444(1966)*. Uniaxial (+); $N_O = 1.722$, $N_E = 1.823$; faintly pleochroic; $E > O$. Strongly piezoelectric. Soluble in strong hot acids. Found in contact or alteration zones in alkalic rocks, especially alkalic pegmatites, and in hydrothermal deposits related to alkali syenites. Occurs at a contact zone at Jamestown, Boulder Co., with cerite, fluorite, allanite, and tobernite; and with fluorocerite in pegmatites in the Pikes Peak granite at Cheyenne Mt., El Paso Co., CO; in great abundance associated with other rare-earth minerals and barite in dolomite breccias associated with syenitic intrusions at Mountain Pass, San Bernardino Co., CA. Originally described from *Bastnas, Riddarhyttan district, Vastermanland, Sweden*, associated with allanite, cerite, and fluorocerite in narrow bands in a contact-metamorphic amphibole skarn; also as an alteration of fluorocerite at Finbo near Fahlun, Sweden; in the Kychtym district in the Ural Mts., with allanite, cerite, britholite, and tobernite, and as pebbles in the gold placers of the Motchaline-log tributary of the Borzovka R., Russia; in the contact zone of an alkali granite-pegmatite with glauconite and tscheffkinite in Toren-drika-Ifasina, Madagascar; in millions of tons at Bayan Obo, Inner Mongolia, China; also from the Potgietersrust tin field, Transvaal, South Africa. *HCWS DII:289*.

16a.1.1.2 Bastnasite-(La) La(CO₃)F

Named in 1966 as the La-rich end member of bastnasite group; see also hydroxylbastnasite-(La) (16a.1.2.2). No end member data exist presently, but single-crystal data on optical-quality material from the brecciated contact line, Gallinas Mts., NM, of composition (La_{2.22} Ce_{2.88} Pr_{0.22} Nd_{0.58} Sm_{0.04} Eu_{0.01} Gd_{0.02} Y_{0.03})₆ (CO₃)₆ F₆ gave *P62c*; $a = 7.118$, $c = 9.762$, $Z = 6$, $D = 4.89$. *AM 78:415(1993)*; *CM 16:361(1978)*. Sample from Siberia with REE content: 32.7% La₂O₃, 28.6% Ce₂O₃, 7.5% Nd₂O₃, 2.2% Pr₂O₃, 1.7% Y₂O₃, 0.9% Sm₂O₃, 0.9% Gd₂O₃, 0.09% ThO₂, gives the following data: 41-595: 3.55₈ 2.87₁₀ 1.900₉ 1.301₁₀ 1.156₉ 1.068₉ 1.039₉ 1.006₉ (Siberia). *HCWS G 6:596(1960)*.

16a.1.1.3 Bastnasite-(Y) Y(CO₃)F

Named in 1970 as Y end member of the bastnasite series, bastnasite group. *HEX P62c*. $a = 6.57$, $c = 9.48$, $Z = 6$. *ZVMO 99:328(1970)*, *AM 57:594(1972)*. 25-1009: 3.43₈ 2.78₁₀ 1.976₈ 1.948₁₀ 1.822₈ 1.608₁₀ 1.521₄ 1.260₅. Massive, fine grained. Brick-red, brown in thin section. $H = 4-4\frac{1}{2}$. $G = 3.9-4.0$. DTA. Biaxial (+); highly birefringent. Analysis shows Y is 40% of total rare-earth content; Dy, 11%; Er, 6.8%; Ce, 7.0%; Na, 6.2%. Occurs as pseudomorphs up to 8 cm in length after gagarinite in microcline pegmatite, *Kazakhstan*. *HCWS CM 16:361(1978)*.

16a.1.2.1 Hydroxylbastnasite-(Ce) Ce(CO₃)(OH)

Named in 1964 as the hydroxyl analog of bastnasite-(Ce). Bastnasite group. *HEX P62c*. $a = 7.23$, $c = 9.98$, $Z = 6$, $D = 4.79$. *AM 50:805(1965)*. 17-503: 3.59₉ 2.92₁₀ 2.09₉ 2.05₈ 1.923₉ 1.698₇ 1.460₅ 1.319₇. 32-189(syn): 4.99₇ 3.62₉ 2.93₁₀ 2.49₂ 2.09₃ 2.05₅ 1.926₃ 1.700₂. Reniform aggregates in cavities. Waxy yellow to dark brown or colorless, vitreous to greasy luster. Cleavage {1120}, imperfect. $H \approx 4$. $G = 4.475$. IR shows OH takes the place of F in the structure. *GI 3:444(1966)*. Uniaxial (+); $N_0 = 1.760$, $N_E = 1.870$. Analysis: 27% La₂O₃, 37.5% Ce₂O₃, 4% H₂O, 1.1% F. Dissolves in cold HCl or H₂SO₄. Occurs at an unspecified Russian locality where alkali-ultrabasic rocks have late carbonatite veins, associated with barite, strontianite, monazite, ancylite, altered burbankite, pyrite, and other sulfides. *cs*

16a.1.2.2 Hydroxylbastnasite-(La) La(CO₃)(OH)

Named in 1983 to conform with bastnasite group designations. Bastnasite group. *ORTH C222₁*. $a = 21.891$, $b = 12.639$, $c = 10.047$, $Z = 36$, $D = 4.64$. *JSSC 12:115(1975)*. 29-744(syn): 5.02₈ 3.65₈ 2.95₁₀ 2.51₆ 2.11₆ 2.07₈ 1.943₈ 1.824₆ (end member with ideal composition). La/Nd appears to be a useful indicator of paragenetic type [*GCA 33:725(1969)* 29:755(1965)]. Described as fine-grained fracture fillings from lower portions of karstic bauxites in Hungary and Yugoslavia associated with bastnasite-(Ce), bastnasite-(La), hydroxylbastnasite-(Nd), synchysite-(Nd), monazite-(Nd), and neodymian goyazite. *HCWS DANS 159:93(1983)*; *AM 71:1277(1986)*.

16a.1.2.3 Hydroxylbastnasite-(Nd) Nd(CO₃)(OH)

Named in 1985 as the Nd end member in the hydroxylbastnasite series in the bastnasite group. *HEX P62c*. $a = 7.191$, $c = 9.921$, $Z = 6$, $D = 4.89$. *MM 49:717(1985)*. *38-400*: 4.95₉ 3.60₈ 2.91₁₀ 2.48₂ 2.08₃ 2.04₅ 1.914₃ 1.690₂. Irregular aggregates of plates 100–200 μm in diameter. Whitish, white streak, dull. Probably parting on {001}. $H = 1-2$. Nonfluorescent. TG/DTG, IR. *GI 3:444(1966)*. Uniaxial (+); $N_O = 1.715$, $N_E = 1.81$. 27% La₂O₃, 31.5% Nd₂O₃, 4.4% Sm₂O₃. Calculation brings H₂O% > F. Occurs in the red karstic bauxites of Niksic, Montenegro, Yugoslavia. *HCWS AM 38:932(1953)*, *51:152(1966)*, *NJMM 289(1985)*.

16a.1.3.1 Synchronite-(Ce) CaCe(CO₃)₂F

Named in 1901 for "confounding," having been mistaken for parisite (16a.1.5.1). Synchronite group. *MON C2/c*. $a = 12.329$, $b = 7.110$, $c = 18.741$, $\beta = 102.68^\circ$, $Z = 12$, $D = 3.99$. *CM 32:865(1994)*. Pronounced pseudocell $a' = 7.11$, $c' = 18.285$. *18-284*: 9.1₆ 4.53₅ 3.55₁₀ 3.32₄ 2.80₁₀ 2.06₅ 1.934₅ 1.873₄. See also *44-1431*. Pseudorhombohedral with acute rhombs and small {0001}, or thick tabular {0001}, occasionally hemimorphic. Crystals of the two habits intergrown and may be separate species. {0001} smooth and brilliant, lateral faces striated horizontally. Waxy yellow to brown, vitreous to greasy luster, translucent. Twinning {0001} common, also lamellar. Cleavage or parting on {0001}, subconchoidal to splintery fracture, brittle. $H = 4\frac{1}{2}$, $G = 3.90$. Uniaxial (+); $N_O = 1.674$, $N_E = 1.770$ (Na). Crystals alter, becoming grayish white with reduced hardness and loss of transparency and luster, probably forming bastnasite or calcite. Altered core in some crystals may have dark transparent terminations (possibly a parisite) that are anhydrous. Readily soluble in acids. Found with parisite in Quincy, MA; at the Scrub Oaks mine, Dover, NJ, intimately intergrown with quartz, xenotime, bastnasite, leucoxene, and hematite; also from Henry pegmatite, Cotopaxi, CO, associated with cenosite; with gadolinite, aadularia, and xenotime in alpine vein, Piz Blas, Val Naps, Graudunden, Switzerland; in pegmatitic segregations in syenite at *Narssarssuk, Julianehaab district, Greenland*. *HCWS DII:287, AM 38:392(1953)*.

16a.1.3.2 Synchronite-(Y) CaY(CO₃)₂F

Named in 1966 for the composition. Synchronite group. Synonym: doverite. *AM 47:332(1962)*. *MON C2/c*. $a = 12.039$, $b = 6.960$, $c = 18.436$, $\beta = 102.45^\circ$, $Z = 12$, $D = 3.9$. *CM 32:865(1994)*. *44-1431*: 8.99₁₀ 4.50₅ 3.48₄ 2.75₁₀ 2.01₅ 1.831₅ 1.623₄ 1.376₃ (Dover). See also *14-570*. Massive, fine-grained compact. Reddish-brown, brownish streak, dull luster. $H = 4\frac{1}{2}-6\frac{1}{2}$. $G = 3.89-4.11$. *AM 45:94(1960)*. Biaxial; $N = 1.643-1.73$. Analysis: 35% Y, 12% Ce, 24% Ca, 5% F, on material that contained some xenotime impurities. Found at *Scrub Oaks mine, Dover, Morris Co., NJ*; Henry pegmatite, Cotopaxi, CO. *cs AM 51:152(1966)*.

16a.1.3.3 Synchronsite-(Nd) $\text{CaNd}(\text{CO}_3)_2\text{F}$

Named in 1978 as the Nd end member of the series with ORTH Space group unknown. $a = 4.039$, $b = 6.984$, $c = 9.045$, $Z = 2$, $D = 4.14$. *AM 64:658(1979)*, however, a supercell HEX $P3_1$ with $c = 54 \text{ \AA}$ was described *NJMM 201(1983)* and most recently a high resolution single crystal analysis of synchronsite-(Ce) has shown the spacegroup to be $C2/c$ monoclinic, pseudo-hexagonal (see 16a.1.3.1) *CM 33:865(1994)*. A reanalysis for this Nd end member is needed. $35-589$: 9.04_6 4.52_{10} 3.50_2 3.25_2 3.02_1 2.77_4 2.26_2 1.898_4 . Fine aggregates up to 100μ in diameter, light grey-blue, streak white, dull. No cleavage. $H = 1$. Frequent inclusions and intergrown. Nonfluorescent. Biaxial (+); $N_x = 1.61$, $N_y = 1.66$, $N_z = 1.74$, negative elongation; parallel to extinction; pleochroic light violet to colorless. Electron microprobe data on three samples gave the following (average) formula: $\text{Ca}_{1.10}(\text{Nd}_{0.34}\text{La}_{0.27}\text{Y}_{0.12}\text{Pr}_{0.10}\text{Sm}_{0.06}\text{Gd}_{0.05}\text{Ce}_{0.04}\text{Dy}_{0.02})(\text{CO}_3)_{1.90}\text{F}_{0.90}$. Occurs as microcavity fillings in sandstone-type uranium deposits at *Straz block, Holicky deposit, Česká Lepa, Bohemia, Czech Republic*, associated with florencite-(La), sphalerite, manganian siderite, pyrite, quartz (chalcedony), and kaolinite; at *Pyrönmaa pegmatite, Kangasela, southwestern Finland*; in limestones at the base of the *Gerbnik bauxite deposit, Yugoslavia*. *HCWS AM 47:337(1962)*, *ZVMO 111:233(1978)*.

16a.1.4.1 Huanghoite-(Ce) $\text{BaCe}(\text{CO}_3)_2\text{F}$

Named in 1961 for the locality near the Yellow River (Huang Ho), China. Synchronsite group. HEX-R $R3m$. $a = 5.072$, $c = 38.46$, $Z = 6$, $D = 4.84$. Structure: *NJMM:163(1993)*. $15-286$: 3.91_7 3.21_{10} 2.50_7 2.01_9 1.937_{10} 1.616_7 1.557_7 1.325_7 . Plates up to $10 \text{ cm} \times 5 \text{ cm}$. Honey yellow to yellowish green, greasy luster, translucent. Cleavage $\{0001\}$, distinct; irregular fracture. $H \approx 4.7$. $G = 4.51-4.67$. Uniaxial (-); $N_O = 1.768$, $N_E = 1.603$; weakly pleochroic, green-yellow. Vigorously dissolved by HCl. Occurs in the calcite veins distributed in hydrothermal deposits, especially those in granite-syenites, or in hydrothermally altered dolomites, associated with aegirine, fluorite, magnetite, monazite, hematite, bastnäsite, parisite, and aeschynite at *Bayan Obo, 150 km north of the Yellow River, Inner Mongolia, China*. *HCWS SS 10:1007(1961)*, *ZVMO 92:199(1963)*, *AM 48:1179(1963)*.

16a.1.5.1 Parisite-(Ce) $\text{Ca}(\text{Ce},\text{La})_2(\text{CO}_3)_3\text{F}_2$

Named in 1835 for J. J. Paris, mine proprietor at Muzo, north of Bogota, Colombia. HEX-R $R3$. $a = 7.125$, $c = 14.018$, $Z = 3$, $D = 4.38$. *AM 38:932(1953)*. Several supercell polytypes have been described: (3H): $a = 7.110$, $c = 83.83$ [*NJMM:192(1992)*]; (4H): $a = 7.12$, $c = 56.4$ [*SGS 20(1993)*]; (6R, 42R): $c = 59.346$; (48R): $c = 67.824$; (16H): $c = 22.608$ *AMS 13:331(1993)*. The different lattices all show a subcell with $a' = 4.11$, $c' = 4.70$. $42-1332$: 14.03_4 4.68_4 3.57_{10} 2.84_{10} 2.06_8 1.938_6 1.882_5 1.658_5 . Rhombs or prismatic crystals to 4 cm with acute double hexagonal pyramids, lateral faces striated or deeply grooved. $\{0001\}$ common. Some crystals show zones or cores of different color or optical properties representing intergrowths

with synchysite or other members of this group of minerals. Brown, yellow to wax-yellow; vitreous to resinous luster, {0001} parting pearly; transparent to translucent. Cleavage {0001}, distinct; subconchoidal to splintery fracture; brittle. $H = 4\frac{1}{2}$. $G = 4.36$. IR data: *MSLM* 4:272(1974). Uniaxial (+); $N_O = 1.676$, $N_E = 1.757$ (Na). O, light yellow; E, golden yellow. Soluble in hot, strong acids. May alter by hydration. Occurs at Ballou and Fallon Bros. quarries, Quincy, MA, with aegirine, microcline, riebeckite, fluorite, ilmenite, and anatase in pegmatite pipes in granite; with pyrite in an altered trachyte near Pyrites, Ravalli Co., MT; at Lassur, France; with eudidymite from an alkali pegmatite in nepheline syenite on Övre-Arø Is., Langesund Fjord, Norway; in riebeckite-granite veinlets Montorfano, Lombardy, Italy; with bastnasite and tscheffkinite from Ifasina, Torendrika, Madagascar; at the emerald deposits at *Muzo*, *Boyacá*(1), 100 km N of *Bogota*, *Colombia*, with pyrite, marcasite, cerian dolomite, albite, calcite, quartz, gypsum, and beryl (emerald) in pockets and veins in intensely folded carbonaceous shale beds. *HCWS DII:283(1952)*, *AM 38:932(1953)*.

16a.1.5.2 Parisite-(Nd) $\text{CaNd}_2(\text{CO}_3)_3\text{F}_2$

Named in 1986 as the Nd-rich end member of the parisite series. Synchysite group. *HEX-R R3*. No unit cell data but assumed similar in all respects with parisite-Ce, as "both have the same diffraction pattern." *AM 73:1496(1988)*. Large yellowish-brown grains in a quartz matrix, vitreous luster. Conchoidal fracture. $H = 4-5$. $G = 4.2-4.5$. Uniaxial (+); $N_O = 1.679$, $N_E = 1.754$. REE (average of two determinations): 9.3% La, 35.9% Ce, 7.7% Pr, 40.7% Nd, 4.5% Sm, 0.4% Eu, 0.95% Gd, 0.25% Dy, 0.1% Yb, 0.25% Y. Occurs in a quartz matrix with hematite, or calcite, barite, sodic pyroxene, and sodic amphibole in the *Bayan Obo iron-rare earth deposit*, *Inner Mongolia, China*. *HCWS*

16a.1.6.1 Röntgenite-(Ce) $\text{Ca}_2\text{Ce}_3(\text{CO}_3)_5\text{F}_3$

Named in 1953 after William Conrad von Rontgen (1845–1923), German physicist and discoverer of X-rays. Synchysite group. *HEX-R R3*. $a = 7.13$, $c = 69.4$, $Z = 9$, $D = 4.19$. *AM 38:868,932(1953)*. Pronounced supercell similar to other Ce-F-containing carbonates; see synchysite-(Ce) (16a.1.3.1). *35-579*: 23.1₁₀ 11.6₇ 7.7₁ 4.63₄ 3.57₅ 2.82₅ 2.06₂ 1.940₂. Polycrystalline, similar to parisite, bastnasite, and synchysite. Crystals show single terminations {1011}, {0112}, striated horizontally, truncated with {0001}; twinning uncommon. Waxy yellow to brown, transparent to translucent. No cleavage observed. $H \approx 4\frac{1}{2}$. Occurs as minute crystals intergrown with bastnasite minerals at *Narssarssuk, Greenland*. *HCWS*

16a.1.7.1 Cordylite-(Ce) $\text{BaCe}_2(\text{CO}_3)_3\text{F}_2$

Named in 1898 for the Greek for *club*, in allusion to the shape of the crystals. Synchysite group. *HEX P6₃/mmc*. $a = 5.098$, $c = 23.050$, $Z = 2$, $D = 3.97$. *CM 13:93(1975)*. *27-34*: 4.34₈ 4.13₆ 3.84₈ 3.51₉ 3.19₁₀ 2.55₈ 2.12₇ 2.04₈. Tiny, hex-

agonal prisms parallel to c , often with enlarged pyramidal terminations that give a scepter-like appearance due to the interaction of several different pyramidal forms. Colorless, waxy yellow to ochreous yellow; greasy to adamantine luster, pearly on {0001}, dull with surface alterations. Basal sections may show concentric hexagonal zones varying from colorless to yellow, clear to cloudy, also radial striations. Distinct cleavage parallel to {0001}, conchoidal fracture, brittle. $H = 4\frac{1}{2}$. $G = 4.10$. Uniaxial (-); $N_O = 1.764$, $N_E = 1.577$. O, green-yellow; E, brown-yellow. Easily soluble in acids. Found in pegmatite veins in nepheline-syenite *Narssarssuk, Julianehaab district, Greenland*, associated with aegirite, ancylite, synchysite, and neptunite; at Bayan Obo, Inner Mongolia, China. *HCWS DII:285*.

16a.1.8.1 Zhonghuacerite-(Ce) $Ba_2Ce(CO_3)_3F$

Named in 1981 to honor the source and composition; the name means *a cerium mineral from China*. *HEX-R* Space group unknown. $a = 5.07$, $c = 9.82$, $Z = 1$, $D = 4.66$. *AM 67:1078(1982)*. 39-396: 3.92₈ 3.42₄ 3.22₁₀ 2.51₆ 2.12₃ 2.10₁₀ 1.979₁₀ 1.638₃ 1.572₃. Powder pattern close to huanghoite (16a.1.4.1), relationship to cebaite (16a.1.9.1) not clear. Aggregates of small yellow grains, vitreous to resinous luster, transparent. Uniaxial (-); $N_O = 1.745$, $N_E = 1.565$. Contains 45% BaO, 10.5% Ce₂O₃, 12% (La, Nd)₂O₃, with some Sr, Fe, Mg, Al, and Th. Dissolves readily in acids. Found in a metamorphosed dolomite at *Bayan Obo, Inner Mongolia, China*, associated with cebaite, ferrodolomite, phlogopite, riebeckite, magnetite, and quartz. *HCWS*

16a.1.9.1 Cebaite-(Ce) $Ba_3Ce_2(CO_3)_5F_2$

Discovered in 1973, later named for the composition. *MON C2/m* or *C2*. $a = 21.426$, $b = 5.035$, $c = 13.240$, $\beta = 94.6^\circ$, $Z = 4$, $D = 4.81$. *AM 60:738(1975)*, *70:214(1985)*. Pronounced rhombohedral subcell $a' = 5.11$, $c' = 9.8$, similar to huanghoite-(Ce) (16a.1.4.1). 43-691: 3.96₆ 3.35₁ 3.22₁₀ 2.53₃ 2.13₄ 1.995₅ 1.355₂ 1.260₂. Granular aggregates and tabular grains. Orange-yellow to waxy yellow; orange-yellow to gray-white streak; vitreous, waxy luster. Probably cleavage on {301}, uneven fracture. $H = 4\frac{1}{2}$ -5. $G = 4.66$ -4.31. IR, DTA. Biaxial (-); $N_x = 1.598$ -1.604, $N_y = 1.735$, $N_z = 1.740$ -1.748; $2V \approx 5^\circ$. A Nd-rich form has been reported. *AM 73:1493(1988)*. Occurs in Fe-Nb rare-earth deposit at *East mine, Bayan Obo, Inner Mongolia, China*, associated with acmite, fluorite, barite, cordylite, huanghoite, and baiyuneboite-(Ce). *HCWS*

16a.2.1.1 Azurite $Cu_3(CO_3)_2(OH)_2$

Named in antiquity after the Persian *lazhward*, blue color. *MON C2₁/c*. $a = 5.00$, $b = 5.85$, $c = 10.35$, $\beta = 92.33^\circ$, $Z = 2$, $D = 3.834$. *AC 11:866(1958)*. Figure 16a.2.1.1 and Table 16a.2.1.1 compare structural elements of azurite ($Cu/CO_3 = 3:2$) with malachite (2:1). 11-682: 5.15₆ 5.08₃ 3.67₅ 3.52₁₀ 2.54₃ 2.51₄ 2.29₄ 2.22₇. **Physical properties:** Crystals with varied forms (over 45 well-established, and over 100 rare or vicinal, faces have been described) are com-

mon; often tabular {001}, less common {102} or {102}; or prismatic [001] or [010]; sometimes equant or rhombohedral, often composite. Faces commonly wavy with striations on {001} parallel to *a*, on {100} parallel to *b*. Twins are rare across {101}, {102}, or {001}. May also be massive, stalactitic, or botryoidal. Azure blue to very dark blue; blue streak; vitreous to dull and earthy luster, earthy types light blue; transparent to translucent. Cleavage {011}, perfect; {100}, fair; conchoidal fracture; brittle. $H = 3\frac{1}{2}$ -4. $G = 3.77$. IR. *MSLM* 4:268(1974). Biaxial (+); $Z \wedge c = 12.6^\circ$, *X* parallel to *b*; $N_x = 1.730$, $N_y = 1.758$, $N_z = 1.838$; $2V = 67^\circ$; $r > v$, strong; pleochroic, blue with absorption $Z > Y > X$. **Chemical properties:** Soluble, effervescent in dilute acids, decomposes in boiling H_2O . Most specimens quite pure; National Museum specimen No. R8545 contains less than 0.1% Zn, 0.01% Si, Al, and Fe. **Occurrence:** A secondary mineral found in the oxidized portions of copper deposits, azurite is formed by the action of carbonated waters on copper-containing minerals or by Cu-containing solutions ($CuSO_4$, $CuCl_2$) with limestones. Usually in close association with, but less common than, malachite (16a.3.2.1), azurite often alters to malachite, giving fibrous pseudomorphs (Chessy, Tsumeb). Also associated with "limonite," wad, cuprite, tenorite, chrysocolla, chalcocite, calcite, native Cu, and other Cu-bearing minerals. Pseudomorphs after cuprite, cerussite, and tetrahedrite. **Localities:** Hundreds of localities have been reported. A selected list for fine crystals follows: hollow paramorphs of azurite after gypsum to 25 cm(!) are found at Apex Mine, St. George, Washington Co., UT; in AZ crystals to 8 cm completely or partially pseudomorphed by malachite were common at the Copper Queen mine(!), Warren Mining district, Cochise Co., Bisbee(!) [see *MR* 12(3):259(1981)]; and in Gila Co., the Payson district; and in Tiger, Pinal Co., at the Mammoth St. Anthony mine(!) and at the Silver King mine(*), Pioneer district; and at the New Cornelia mine(*), Ajo, Pima Co.; and at the Copper Mt. prospect, Anaconda district. In NM at the Georgetown District(*), Grant Co.; at the Kelly mine and elsewhere in the Magdalena District(*), Socorro Co. In Mexico at the San Eligio mine, Aranzazu, the El Cobre mine, Concepcion del Oro, and the San Carlos mine(!), Mazapil, all in ZAC; in CHIH at Santa Eulalia(!), and Sierra Rica. In Cornwall, England, at Wheal Phoenix mine, near Liskeard; at Chessy(!) near Lyon, Rhone, France, where finely crystallized material is known as "Chessylite"; in Poland at Montes Chauves, near Kielce; at Rosas(*), and near Alghero, Sardinia, Italy; in Romania at Kisbanya and at Moldava, Banat district; from the Laurium mine, Greece; at Beresov(!), Tomsk and Solutuschinsk(*) in the Altai Mts., Siberia, Russia; large spherical aggregates to 8 cm were found at Shilu(!), Guangdong Prov., China; at Bou Beker, Bou Skour(!), Kerouchen, and at the Touissit mine(!) Oujda, Morocco, where azurite-malachite crystals up to several inches were found. The Tsumeb mine, Namibia, was the world's premier source for fine azurite, both in quantity, variety of crystal form, perfection, and beauty; lustrous single azurite crystals up to 25 cm long as well as magnificent groups of large crystals(!) were associated with olivenite, mimetite, mottramite, anglesite, and cerussite; also many partly or wholly

converted pseudomorphs to fibrous malachite. In Australia at the Proprietary mine(1), Broken Hill, the Gladstone mine(*), Cobar district, NSW; and at the Girofla(*) and Muldiva(*) mines, Chillagoe district, Q; and in SA at Moonta(*), near Walleroo, and at the Burra mine(1), near Burra Burra, in the St. Dominick mine, Arkaroola, where spherical aggregates and rosettes as

AZURITE: $\text{Cu}_3(\text{CO}_3)_2(\text{OH})_2$

A hydrated carbonate structure this c axis projection shows trigonal planar CO_3 groups almost edge on with some, but not obvious layering, and two distinct copper atom sites. Each metal ion is coordinated with two (OH) and two (CO_3) oxygen atoms approximating a square configuration, with two longer Cu-O bonds. Compare with malachite, 16a.3.2.1.

Azurite, $\text{Cu}_3(\text{CO}_3)_2(\text{OH})_2$, Cu: CO_3 3:2, a blue copper carbonate often occurs in close association with green malachite (16a.3.2.1), $\text{Cu}_2(\text{CO}_3)(\text{OH})_2$, with Cu: CO_3 2:1. Both copper carbonates crystalize with similar monoclinic space groups, but malachite has a more open structure. (See malachite 16.3.2.1)

TABLE 16.2.1.1 COMPARISON OF AZURITE AND MALACHITE

	Azurite	Malachite
Space group	$P2_1/c$	$P2_1/a$
Bond distances (in Å)		
Cu ₁ -2(O)	1.88	1.95 -
Cu ₁ -2(OH)	1.98	- 2.00
Cu ₁ -2(O, OH)	2.38	2.71
Cu ₂ -2(O)	1.92 -	1.91 -
Cu ₂ -2(OH)	- 2.04	- 2.07
Cu ₂ -2(O, OH)	2.38	≈ 2.41
C - O	1.24 -	
	- 1.30	

References: Azurite AC 11:866 (1958), NATW 45:208 (1958), Malachite AC 4:200 (1951)

MALACHITE: $\text{CO}_2(\text{CO}_3)(\text{OH})_4$

Also a c axis projection the layering of the trigonal, virtually planar, CO_3 groups in malachite shows them perpendicular to the c axis, parallel to {001}. The two Cu ions positions in malachite have relatively longer Cu-O and Cu-(OH) bonds (TABLE 16.2.1.1) resulting in a different space group and larger size unit cell than azurite (16.2.1.1).

well as single crystals were found; in Chile at Coquimbo. See *R&M* 66:24(1991) for worldwide azurite localities. An ore of copper, azurite was also used as the blue pigment in ancient art and in Europe from the fifteenth to seventeenth centuries. In some instances it has altered to green malachite. *HCWS AM* 35:985(1950), *DII*:264.

16a.2.2.1 Hydrocerussite $\text{Pb}_3(\text{CO}_3)_2(\text{OH})_2$

Named in 1877 in allusion to the composition. **HEX** Space group unknown. $a = 5.24$, $c = 23.74$, $Z = 3$, $D = 6.84$. *TMPM* 3:298(1953). 13-131(syn): 4.47₆ 4.25₆ 3.61₉ 3.29₉ 2.62₁₀ 2.49₃ 2.23₅ 1.696₄. Crystals thin scales with hexagonal outline and flattened {0001}, also thick tabular {0001}, or steep pyramidal {h0hl}. Colorless to white, sometimes faintly greenish; adamantine luster, pearly on {0001}; transparent to translucent. Cleavage {0001}, perfect; brittle. $H = 3\frac{1}{2}$, $G = 6.8$. IR. *MSLM* 4:268(1974). Uniaxial (-); $N_O = 2.09$, $N_E = 1.94$. Small amounts of Cl substitute for (OH). A secondary mineral found with other lead-bearing minerals: leadhillite, matlockite, cerussite, mendipite, and paralaurionite. Large crystals were described from the Mammoth Mine, Tiger, AZ; in Scotland in cavities in galena at Wanlockhead, Dumfries, and from Leadhills, Lanark; abundant at Mendip Hills, Somerset, England; at *Långban, Sweden*, as an alteration product of native lead; an alteration product of ancient lead slags, Laurium, Greece; at Rederovski mine, Altai Mts.,

Russia. Hydrocerussite is one of the chief components of commercial white lead, synthesized by heating PbCl_2 and urea solution at 180° in air. *HCWS DII:271*.

16a.2.3.1 Beyerite $(\text{Ca,Pb})\text{Bi}_2(\text{CO}_3)_2\text{O}_2$

Named in 1943 after Adolf Beyer (1743–1805), a mining engineer in Schneeberg, Saxony, who had recognized the occurrence of bismuth carbonate [bismutite (16a.3.5.1)] in nature. Composition not fully determined. TET $I4/mmm$. $a = 3.784$, $c = 21.76$, $Z = 2$, $D = 6.58$. *AM 54:1720(1969)*. *22-1067*: 10.9₉ 3.35₈ 2.85₁₀ 2.67₇ 2.15₇ 1.907₅ 1.689₆ 1.578₇. Thin rectangular plates flattened {001}, also compact earthy masses. Bright yellow to lemon-yellow, vitreous luster; when massive material is yellowish white to gray. Conchoidal fracture. $H = 2-3$. $G = 6.56$, lower in earthy porous material. Uniaxial (-); $N_O = 2.13$, $N_E = 1.99$; pale, yellow to colorless; some crystals anomalously biaxial with small $2V$. Easily soluble with effervescence in acids. A secondary mineral associated with bismuth-containing minerals. Found massive with bismutite as alteration of primary bismuth minerals in Mica Lode and School Section pegmatites in Eight Mile Park district, near Carson City, Fremont Co., and Meyers Ranch pegmatite, Park Co., CO; as compact gray masses in Stewart Mine, San Diego Co., Pala, CA, yellow platy crystals over bismutite and chalcedonic quartz *Schneeberg, Saxony, Germany*; crystals at Bisundi, Rajasthan, India, with massicot, litharge, calcite, and bismutite. *HCWS DII:282*.

ROSASITE GROUP

The rosasite group minerals are copper-containing carbonates corresponding to

where

A = Cu

B = Zn, Ni, Co, Mg

Z = (OH)

The structure of these minerals [*CM 19:315(1981)*] appears to be similar to malachite (16a.3.2.1), but because of the difficulty in obtaining good (untwinned) samples, there is the possibility that the minerals may actually be triclinic with small angular deviations from monoclinicity as determined for kolwezite. Glaukospherite is pseudo-orthorhombic.

ROSASITE GROUP

Mineral	Formula	Space								
		Group	a	b	c	α	β	γ	D	
Rosasite	(CuZn)(CO ₃) (OH) ₂	<i>P</i> 2 ₁ / <i>m</i> or <i>P</i> 2/ <i>a</i>	9.366	12.116	3.127		90.06		3.8	16a.3.1.1
Glaukospherite	(Cu,Ni) ₂ (CO ₃) (OH) ₂	<i>P</i> 2 ₁ / <i>a</i>	9.35	11.97	3.13		96		4.217	16a.3.1.2
Kolwezite	(Cu,Co) ₂ (CO ₃) (OH) ₂	<i>P</i> 1 or <i>P</i> 1	9.50	12.15	3.189	93.32	90.74	91.47	3.94	16a.3.1.3
Zincrosasite	(Zn,Cu) ₂ (CO ₃) (OH) ₂									16a.3.1.4
Mcguinnessite	(Mg,Cu) ₂ (CO ₃) (OH) ₂	<i>P</i> */ <i>a</i>	9.398	12.011	3.379		93.28		3.076	16a.3.1.5

16a.3.1.1 Rosasite CuZn(CO₃)(OH)₂

Named in 1908 after the locality, a mine in Sardinia. Rosasite group. MON *P*2₁/*m* or *P*2₁. $a = 9.366$, $b = 12.116$, $c = 3.127$, $\beta = 90.06^\circ$, $Z = 4$, $D = 3.8$. *CM 19:315(1981)*. MON *P*2₁/*a*. $a = 12.88$, $b = 9.36$, $c = 3.164$, $\beta = 110.42^\circ$, $Z = 4$, $D = 4.15$. *PD 1:56(1986)*. *36-1475*: 6.05₉ 5.07₉ 3.69₉ 2.96₇ 2.60₁₀ 2.53₅ 2.50₄ 2.34₄. Mammillary, spherulitic or botryoidal crusts of rectangular platy or lathlike fibers (to 0.5 mm), elongated on c and invariably twinned with rotation about a^* . Green to bluish green and sky blue. Cleavage in two directions at right angles, brittle. $H \approx 4\frac{1}{2}$. $G = 4.0-4.2$. Biaxial (-); $XYZ = ca^*b$; $N_x = 1.673$, $N_y = 1.796$, $N_z = 1.811$; $2V = 33^\circ$; strong absorption light to dark emerald green; no dispersion. Analysis: Cu/Zn = 32.8:23.7 but variable even along the length of fibers. Found at Jack Pot Claim near Wellington, Majuba Hill, NV; Tombstone district, Cochise Co., AZ; with aurichalcite at Kelly, NM; with smithsonite and hemimorphite at Cerro Gordo, Inyo Co., CA; described from *Rosas mine, Sulcis, Sardinia*, where it is associated with brochantite, malachite, aurichalcite, greenockite, and siderite; at Bakara, Bulgaria; also from Tsumeb, Namibia, with malachite, smithsonite, and hydrozincite. HCWS *DII:251*.

16a.3.1.2 Glaukospherite (Cu,Ni)₂(CO₃)(OH)₂

Named in 1974 for the color and the habit from the Greek for *blue* and *sphere*. Rosasite group. MON Pseudo-orthorhombic. *P*2₁/*a*. $a = 9.35$, $b = 11.97$, $c = 3.13$, $\beta = 96^\circ$, $Z = 4$, $D = 4.217$ (Zaire). *CM 19:315(1981)*. *27-178*: 5.96₂ 5.04₃ 3.68₇ 3.02₂ 2.95₂ 2.59₁₀ 2.52₄ 2.12₃. Fibrous green spherulites, fibers elongated parallel to c , dull to subvitreous and silky luster. Good cleavage parallel to fiber elongation. $H = 3-4$. $G = 3.78$. Biaxial (-); $N_x = 1.69$, $N_y = 1.83$, $N_z = 1.83$. Microprobe analysis shows 41.57% CuO, 25.22% NiO, 1.23% MgO, trace Ca and Zn. Found at Kambalda, Windarra, Scotia, *Carr Boyd Rocks, Widgiemooltha, and St. Ives, WA, Australia*, associated with goethite, quartz, paratacamite, gypsum, nickeloan malachite, and nickeloan magnesite; Kasompi, Zaire. HCWS *MM 39:737(1974)*.

16a.3.1.3 Kolwezite $(\text{Cu,Co})_2(\text{CO}_3)(\text{OH})_2$

Named in 1980 for the mine locality. Rosasite group. TRIC. $P1$ or $P1$. $a = 9.50$, $b = 12.15$, $c = 3.189$, $\alpha = 93.32^\circ$, $\beta = 90.74^\circ$, $\gamma = 91.47^\circ$, $Z = 4$, $D = 3.94$. *CM* 19:315(1981). 29-1416: 6.04₈ 5.08₈ 3.70₁₀ 3.02₄ 2.96₅ 2.59₈ 2.54₅ 2.34₄. Nodules (1–10 mm) or crystalline crusts. Black to beige. $H \approx 4$. $G = 3.97$. DTA and IR show similarity with rosasite and glaukospherite. *BM* 103:179(1980). $N_x = 1.688$, $N_z = 1.90$. Analysis showed $\text{Cu/Co} = 2:1$. Found as nodules (1–10 mm) and thin microcrystalline crusts in the oxidized zone of a Cu–Co deposit, *Kolwezi–Kamoto–Musonoi, southern Shaba, Zaire*. HCWS *AM* 65:1067(1980).

16a.3.1.4 Zincrosasite $(\text{Zn,Cu})_2(\text{CO}_3)(\text{OH})_2$

Named in 1959 for the composition and as a possible member of the rosasite group with $\text{Zn} > \text{Cu}$. Botryoidal and mammillary crusts with radial-fibrous structure, light blue to whitish with cleavage in two directions. $H \approx 3$. Described from *Tsumeb, Namibia*. HCWS *FM* 37:87(1959), *AM* 44:1323(1959).

16a.3.1.5 Mcguinnessite $(\text{Mg,Cu})_2(\text{CO}_3)(\text{OH})_2$

Named in 1981 for Albert L. McGuinness (1926–1990), mineral dealer, San Mateo, CA. Rosasite group. See also pokrovskite (16a.3.2.3). *MON* $P2/a$ or $P2_1/a$. $a = 9.398$; $b = 12.011$; $c = 3.379$; $\beta = 93.28^\circ$; $D = 3.076$ (Mg-rich), 3.234 (Cu-rich). *MR* 12:143(1981). Structure very similar to malachite but with only one octahedral cation group: sheets parallel to (102) are made up of edge sharing $\text{Mg}(\text{OH})_5(\text{CO}_3)$ octahedra. 35-481: 7.40₁ 6.02₁₀ 5.05₂ 3.69₇ 3.00₁ 2.53₃ 2.33₂ 2.14₃. Spherules 0.1–2 mm in diameter composed of light blue-green fibers with Cu-rich cores darker blue, and Mg-rich rims pale blue-green to nearly white; vitreous to silky luster. Brittle, inelastic. $H = 2\frac{1}{2}$. $G = 3.02$ (Mg-rich), 3.22 (Cu-rich). DTA data. Biaxial (–); $X \wedge c = 11^\circ$; $N_x = 1.602$, $N_y = 1.730$, $N_z = 1.732$ (Na); negative elongation; maximum extinction; weakly pleochroic. X, very pale green; Y,Z, light blue-green. Occurs in serpentinized peridotite at *Red Mt., Mendocino Co., CA*, associated with vuagnatite, goethite, malachite, azurite, and chrysocolla; at *Gabbs, NV*; in Mexico at *El Calvario, Municipio de Malege, BCS*; and at *Carr Boyd Rocks mine, WA, Australia*. HCWS *AM* 66:1276(1981).

16a.3.2.1 Malachite $\text{Cu}_2(\text{CO}_3)(\text{OH})_2$

Named in antiquity after the Greek *mallows*, in allusion to the color. *MON* $P2_1/a$. $a = 9.48$, $b = 12.03$, $c = 3.21$, $\beta = 98^\circ$, $Z = 4$, $D = 4.00$. *AC* 4:200(1951). 10-399(syn): 5.99₆ 5.06₈ 3.69₉ 2.86₁₀ 2.82₄ 2.78₅ 2.52₆ 2.46₄. 41-1390(syn): 5.97₈ 5.04₁₀ 3.69₁₀ 2.99₂ 2.86₇ 2.78₃ 2.52₆ 2.13₂. **Structure:** see azurite (16a.2.1.1) **Physical properties:** Crystals are rare, usually short or long prismatic [001], or needles, and are often grouped in tufts and rosettes. Untwinned crystals virtually unknown, twin plane {100} sometimes penetration or polysynthetic twinning, axis [201]. Commonly massive, incrusting with the surface mammillary, botryoidal; internally fibrous, usually radial on

coarse to fine scale, showing color banding. Delicate fibrous aggregates, sheaf-like or compact; concentrically banded stalactites, sometimes alternating with azurite. Bright green with crystals deeper shades even blackish; pale green streak; adamantine luster in crystals, fibrous varieties silky or velvety, often dull and earthy; translucent to opaque. Cleavage {201}, perfect; {010}, fair; subconchoidal fracture of compact masses. $H = 3\frac{1}{2}$ -4. $G = 4.05$ (crystals), to 3.6 in massive fibrous material. IR. *MSLM* 4:268(1974), *GI* 3:444(1966). Biaxial (-); $X \wedge c = 23.5^\circ$; $N_x = 1.655$, $N_y = 1.875$, $N_z = 1.909$; $2V = 43^\circ$; $r < v$, strong. X, nearly colorless; Y, yellowish green; Z, deep green. **Chemical properties:** Some analyses contain traces of Zn, but higher contents probably mean that the sample is one of the rosasite group. Water and CO_2 lost at $\approx 315^\circ$, a lower temperature than azurite, leaving tenorite. Easily soluble in dilute acids. **Occurrence:** Malachite is the most common secondary mineral of copper and virtually every oxidized zone of Cu ore deposits will show some of this mineral. Typically found with azurite, and more abundant than that species, it is also associated with goethite-hematite, cuprite, tenorite, *wad*, calcite, chalcedony, chrysocolla, and other secondary minerals. **Localities:** Only the most important localities for specimens will be mentioned. Malachite was found in the copper mines of Ducktown, TN, and Copper Co., MI, and is widespread in NM at the Fiero-Hanover district(*) and the Santa Rita district, Grant Co.; also in the Magdalena district(*), Socorro Co. In NV in the Good Springs district. Acicular crystals were found in AZ at the Copper Queen mine(!) and other mines in Bisbee district(!), Cochise Co., where it is often alternatively banded with azurite or pseudomorphous after azurite crystals; in Gila Co., the Inspiration mine(!) has fine banded masses of alternating malachite, chrysocolla, and chalcedony; in Pima Co. at the New Cornelia open pit(*) concentric structures with azurite and quartz; in Yavapi Co., at the Yeager mine, Black Hills district, AZ. In Mexico at the El Cobre mine(!), Concepcion del Oro, ZAC, malachite pseudomorphous after azurite crystals to 12 cm. In France at Chessy(!) near Lyon, often pseudomorphous after cuprite, and with secondary arsenates and phosphates in crevices in Keuper sandstone at Cap Garonne, near Hyere, Maures; in the Rhineland, Germany, at Betzdorf; at Rudabaya and Moldawa, Banat region, Romania; in Russia at Ekaterinburg(!), in the Ural Mts., and large amounts of beautifully banded malachite came from the Demidoff mine(!) at Nizhni-Tagil(!), where one banded mass contained over 1 million kilograms of the pure mineral was mined in the early part of the nineteenth century. Cut into slabs, these pieces were made into tabletops, pillars, vases, and other decorative pieces and may be seen in many world-famous museums (e.g., Uffizi, and St. Peters, Italy); in China in the Hubei and Hunan provinces and at Shilu(*), Guandong. Malachite was called "Shilu" in ancient China, where it was highly prized. In Morocco at the Aouli mine, Aouli, at Bou Skour and at the Touissit mine(!), Oujda; cobaltian varieties and stalactites to 90 cm form at Kolwesi(!), Shaba, Zaire, while fine crystals to 10 mm are found at Kambove(*); in Zambia at Bwana Mkubwa; at Tsumeb(!), Namibia, where it is the most abundant secondary Cu mineral. Malachite forms small needles and crusts with native Cu and cuprite, thick banded masses, stalactites, and pseu-

domorphs after azurite. *MR 8(3)(1977)*. In Australia in NT at Rum Jungle; in SA at Arkaroola, at Wallaroo, and in the Burra district, especially at the Burra mine(!), where large masses of interbanded azurite-malachite similar to the Russian material at Demidoff were found; also at Broken Hill(!) (plumbian and zincian varieties) and at Coba, NSW, Australia; in Brazil at Morro do Bule, Ouro Preto district, fine pseudocubic crystals to 6 mm are found in a limestone quarry. As a secondary ore of Cu, malachite was mined at Bisbee, Tsumeb, and elsewhere, but probably the most prominent use, especially where banding was beautifully displayed, was for decorative pieces. Large ornamental objects and elegant jewelry continue to bring high prices. *HCWS DII:255*.

16a.3.2.2 Nullaginite $\text{Ni}_2(\text{CO}_3)(\text{OH})_2$

Named in 1981 for the locality. *MON P2₁* or *P2₁/m*. $a = 9.23$, $b = 12.001$, $c = 3.091$, $\beta = 90.48^\circ$, $Z = 4$, $D = 4.07$. *CM 19:315(1981)*. Structurally similar to malachite. *35-501*: 7.30₃ 5.04₃ 4.62₄ 3.66₄ 2.58₁₀ 2.56₉ 1.545₃ 1.541₃. Nodular bright green grains up to 2 mm or cross-fiber veinlets in matrix of chlorite and Ni-rich serpentine (pecoraite). $G = 3.56$. Biaxial; $X \wedge c = 6^\circ$; $N = 1.67-1.78$; slightly pleochroic; maximum absorption parallel to c . Found as a secondary mineral in the serpentinized peridotites of the Otway Belt, *Nullagine district, WA, Australia*, in association with millerite, polydymite, pecoraite, gaspeite, otwayite, parkerite, shandite, and breithauptite. *HCWS*

16a.3.2.3 Pokrovskite $\text{Mg}_2(\text{CO}_3)(\text{OH})_2 \cdot 0.5\text{H}_2\text{O}$

Named in 1984 for Pavel Vladimirovich Pokrovskii (1912-1979), mineralogist from the Ural Mts., Russia. *MON P2₁/a*. $a = 9.43$, $b = 12.27$, $c = 3.395$, $\beta = 96.6^\circ$, $Z = 4$, $D = 2.58$. *AM 70:217(1985)*. Probably isostructural with malachite (16a.3.2.1); see also the rosasite group. *37-454*: 6.10₇ 5.20₄ 4.70₇ 3.73₇ 2.60₁₀ 2.17₉ 1.561₇ 1.385₅. Prismatic to acicular crystals in spherulitic aggregates. White with a flesh tint, white streak, dull luster, opaque because of microinclusions. $H \approx 3$. $G = 2.51$, crystals; 2.27, aggregates. DTA, IR. Biaxial (-); $X \wedge c = 8^\circ$; $N_x = 1.537$, $N_{y \text{ calc}} = 1.611$, $N_z = 1.619$; negative elongation. Insoluble in H_2O , dissolves in 1:10 HCl, turns brown when heated. Original reports of CaO in the mineral probably due to admixed dolomite. IR shows both (OH) and H_2O present. Vein mineral in ultramafic rocks. Occurs in the *Zlatogorsk intrusive, central Kazakhstan*, within dunite and associated with dolomite, magnesite, and a sjögrenite-like mineral. *HCWS*

16a.3.3.1 Georgeite $\text{Cu}_2\text{CO}_3(\text{OH})_2$

Named in 1979 for George Herbert Payne (1912-1989), past chief of the mineral division, Western Australian Government Chemical Laboratories. Amorphous analog of malachite (16a.3.2.1). *AM 77:212(1992)*. Light blue, pale blue streak, vitreous to earthy luster, transparent to subopaque aggregates. Soft. $G = 2.55$. Isotropic; $N_{av} = 1.593$ (Na). Forms thin coatings associated with malachite and chalconatronite on partly weathered tremolitic rock that contains disseminated copper and iron sulfides. Analysis of synthetic

material compared to georgeite from *Carr Boyd mine, 100 km N of Kalgoorlie, WA, Australia*, and *Britannia mine, Wales*, showed them to be identical. *ncws*

16a.3.4.1 Phosgenite $\text{Pb}_2(\text{CO}_3)\text{Cl}_2$

Named in 1841 for the composition *phosgen*, a name for carbonyl chloride, COCl_2 , as the mineral contains these elements. TET $P4/mbm$. $a = 8.112$, $c = 8.814$, $Z = 4$, $D = 6.136$. *MM 31:883(1958)*. $12-218$: 4.40₆ 4.04₅ 3.61₈ 2.79₁₀ 2.56₈ 2.21₄ 1.800₄ 1.426₄. Short prismatic {001}; rarely thick tabular {001}, usually terminated with large {001}, sometimes {111} dominant; also massive, granular. Yellowish white to yellowish brown, smoky brown, also colorless, white, rose, grayish, and greenish; white streak; adamantine luster; transparent to translucent. Cleavage {001}, {110}, distinct; {010}, less distinct; conchoidal fracture; sectile. Translation gliding $T\{110\}$, $t\{001\}$ crystals easily flexed about directions perpendicular [001]. Percussion figure on {001} with rays parallel to [110]. $H = 2-3$ varying with direction. $G = 6.133$. IR. *MSLM 4:272(1974)*. Weakly fluorescent yellow in LWUV, X-rays. Uniaxial (+); $N_O = 2.118$, $N_E = 2.144$ (Na). O, reddish; E, greenish in thick sections. Sometimes weakly biaxial especially after mechanical deformation. Soluble with effervescence in dilute HNO_3 . A secondary mineral formed under surface conditions from primary lead minerals such as galena; commonly associated with cerussite, forms epitaxial growths, and alters providing many pseudomorphs of cerussite after phosgenite. Found in Southampton lead mine, Hampshire Co., MA; abundant large masses in part altered to cerussite at Terrible mine, Isle, Custer Co., CO; with diaboileite at Mammoth mine, Pinal Co., AZ; in Organ district, Dona Ana Co., NM; Silver Sprout mine, Inyo Co., CA; with matlockite at Matlock and in Cromford, Derbyshire, England; crystals up to 5 in. were found at Monteponi and Montevecchio(!) near Iglesias and at Gibbas(!) near Cagliari, Sardinia, Italy; at Laurium, with laurionite and other lead minerals from the reaction of seawater on old lead slags, Greece; in fine crystals at Tsumeb(!), Namibia; at the Comet mine, Dundas, TAS, and Broken Hill, NSW, Australia. *ncws DII:258*.

16a.3.5.1 Bismutite $\text{Bi}_2(\text{CO}_3)\text{O}_2$

Named in 1841 in allusion to the composition. TET $I4/mmm$. $a = 3.870$, $c = 13.697$, $Z = 2$, $D = 8.28$. *BGSF 40:145(1960)*. $41-1488(\text{syn})$: 6.84₃ 3.72₄ 2.95₁₀ 2.73₄ 2.14₃ 1.933₂ 1.750₃ 1.617₄. Dense earthy masses, opaline crusts, and radial-fibrous crusts or spheroidal aggregates, rarely scaly to lamellar aggregates, may appear prismatic or take on other pseudomorphous habits. Straw-yellow to brown-yellow, greenish gray, green, brown to black, especially if pseudomorph after bismuthinite; gray streak; vitreous to pearly luster in fibrous or scaly forms, dull to earthy; transparent in small grains. Cleavage {001}. $H = 2\frac{1}{2}-3\frac{1}{2}$, variable with state of aggregation. $G = 6.7-7.4$. $N_{av} = 2.12-2.30$ on cryptocrystalline material; moderately birefringent; fibers show parallel to extinction; positive elongation. Cu, Fe, and Ca reported in

analyses may be admixture. Effervesces in acids. A secondary mineral usually an alteration of bismuthinite, or other primary Bi-containing species, in veins of Co-Ni-Ag-Bi-containing minerals, or in pegmatites with Bi minerals. Found in pegmatites at Portland, CT; Casher's Valley, Jackson Co., NC; at Leadville, Salida, Chaffee Co., and at Telluride, San Miguel Co., CO; in the Petaca district, Rio Arriba Co., and San Andreas Mts., Otero Co., and the Organ district, Hidalgo Co., and at Harding pegmatite, Dixon, NM; in the Tintic district, UT, with bismuth arsenates and bismocelite; at Bagdad copper mine W of Hillside Tavapai Co., also Hualpai Mts. E of Yucca, Mohave Co., NV; at Pala, San Diego Co., CA; at Durango in the El Carmen mine and at Guanajuato, GTO, Mexico; in Cornwall, England; Meymac, Correze, France; *Ullersreuth, Voigtland, Germany*; as an alteration of aikinite in Berezov, Ural Mts., Russia; also in pegmatites in Ampangabe, Madagascar; and at Bokspit, in Gordonia, Cape Prov., South Africa; in the Sn-sulfide veins, Tazna district, Bolivia; at São Jose de Bryamba, MG, Brazil; and in the pegmatite pipes at Kingsgate, NSW, Australia. *HCWS DII:259*.

16a.3.6.1 Brenkite $\text{Ca}_2(\text{CO}_3)\text{F}_2$

Named in 1978 for the locality in Germany. *ORTH. Pbcn.* $a = 7.650$, $b = 7.550$, $c = 6.548$, $Z = 4$, $D = 3.126$. *NJMM:325(1978)*. *29-322: 3.28₆ 3.03₈ 2.79₁₀ 2.49₄ 2.27₆ 1.888₅ 1.835₈ 1.790₆*. Radiating aggregates of lathlike crystals up to 1 mm with {010}, {102}, {021}. Colorless, white streak. No distinct cleavage. $H = 5$. $G = 3.10$. IR. Biaxial (-); $XY = ca$; $N_x = 1.525$, $N_y = 1.590$, $N_z = 1.593$; $2V = 26-28^\circ$. Dissolves with effervescence in 1:10 HCl. Found at *Brenk, Eifel, Germany*. *HCWS AM 64:241(1979)*.

16a.3.7.1 Kettnerite $\text{CaBi}(\text{CO}_3)\text{OF}$

Named in 1956 after Radim Kettner (1891-1968), professor of geology, Charles University, Prague, Czech Republic. *TET P4/nmm.* $a = 3.79$, $c = 13.59$, $Z = 2$, $D = 5.85$. *AM 43:385(1958)*. *38-462: 13.5₁₀ 6.78₃ 3.66₄ 3.31₄ 2.91₉ 2.10₅ 1.725₆ 1.588₄*. See also *25-126*. Small (0.2-0.3 mm) plates, {001} dominant, also {111}. Brown, brownish yellow to lemon yellow. $G = 5.80$. Biaxial (-); $N > 2.05$. In cavities on quartz-fluorite in quartz veins cutting pegmatites that contain plagioclase. Occurs near *Krupke (Graupen), northwestern Bohemia, Czech Republic*, associated with fluorite, bismuth, bismuthinite, hematite, and altered topaz. *cs CMG 1:195(1956)*.

16a.3.8.1 Dawsonite $\text{NaAl}(\text{CO}_3)(\text{OH})_2$

Named in 1874 after John William Dawson (1820-1899), Canadian geologist, principal of McGill University. *ORTH. Imam.* $a = 6.71$, $b = 10.411$, $c = 5.58$, $Z = 4$, $D = 2.434$. Structure: *CM 9:51(1967)*. *45-1359: 5.67₁₀ 3.38₁ 2.79₅ 2.61₂ 2.51₁ 2.15₁ 1.993₁ 1.730₁*. Thin encrustations or rosettes of bladed to acicular crystals, and as tufts of fine needles. Colorless to white, colorless streak, vitreous to silky luster in fine aggregates, transparent. Cleavage {110}, perfect. $H = 3$. $G = 2.44$. IR. *MSLM 4:270(1974)*. Biaxial (-); $XY = ac$; $N_x = 1.462$,

$N_y = 1.537$, $N_z = 1.589$ (Na); $2V = 76.75^\circ$; $r < v$. A low-temperature hydrothermal mineral from decomposing aluminous silicates. Found as coatings on joint surfaces of felspathic dike in *Trenton Limestone, McGill University environs, Montreal, QUE, Canada*, associated with calcite, dolomite, pyrite, galena, and *wad*. In veins associated with late Tertiary basalts in Sollingen, Germany; also at Pian Castagnaio and Santa Fiora near Mte. Amiata, Siena, Tuscany, Italy, associated with calcite, dolomite, pyrite, fluorite, and cinnabar; in Komana, Drin Valley, northern Albania; with barite east of Tenès, Alger, Algeria. HCWS *DII:278, RZ 9:B196(1985)*.

16a.3.9.1 Northupite $\text{Na}_3\text{Mg}(\text{CO}_3)_2\text{Cl}$

Named in 1895 after C. H. Northup (b.1861), grocer, of San Jose, CA, who found the first specimen. iso *Fd3* or *Fd3m*. $a = 13.98$, $Z = 16$, $D = 2.40$. *CR 193:1421(1931)*. *19-1213*: 8.08₅ 4.96₃ 3.21₄ 2.86₃ 2.70₈ 2.47₁₀ 2.37₃ 2.11₆. Octahedral crystals {111} which sometimes contain symmetrical inclusions of clay. Colorless to pale yellow, gray, or brown due to included clay and organic matter; vitreous luster; transparent. Conchoidal fracture, brittle. $H = 3\frac{1}{2}$. $G = 2.38$. IR. *MSLM 4:272(1974)*. Isotropic, $N = 1.5144$ (Na); anomalous birefractance in sectors. Crystals embedded in clay sediments, *Searles Lake, San Bernardino Co., CA*, associated with tychite and pirssonite; with shortite, bradleyite, trona, pirssonite, and gaylussite in drill cores in the oil shales, Green R., Sweetwater Co., WY. cs *DII:278*.

16a.4.1.1 Hydrozincite $\text{Zn}_5(\text{CO}_3)_2(\text{OH})_6$

Named in 1853 after the composition. *MON C2/m*. $a = 13.58$, $b = 6.28$, $c = 5.41$, $\beta = 95.51^\circ$, $Z = 2$, $D = 3.97$. *CM 8:385(1965)*. Structure: *AC 17:1051(1964)*. *19-1458*: 6.77₁₀ 3.66₄ 3.14₅ 2.85₃ 2.72₆ 2.48₇ 1.915₃ 1.688₄. Massive, earthy, porous to compact, and as encrustations sometimes concentrically banded with fine, fibrous, radial structure; dense agatelike masses; stalactitic, reniform, or pisolitic. Lath or bladed crystals flattened {100} and elongated [001] often tapering to sharp point, and projecting from massive aggregates. Intimate twinning observed on single-crystal examination for structure determinations. Pure white to gray, yellowish, brownish pinkish, pale lavender; dull to shining streak; dull to earthy luster; pearly on crystals. Cleavage {100}, perfect; brittle. $H = 2-2\frac{1}{2}$. $G = 4.0$, 3.5–3.8 in massive material. IR. *MSLM 4:268*. Fluoresces pale blue to lilac in UV. Biaxial (-); $X = b$; $Z \wedge c \approx 40^\circ$; $N_x = 1.640$, $N_y = 1.736$, $N_z = 1.750$; $2V = 40^\circ$; $r < v$, strong. Although compositionally similar, hydrozincite does not contain Cu in significant amounts compared with aurichalcite (16a.4.2.1). A secondary mineral in the oxidized zone of ore deposits containing Zn minerals such as sphalerite. Easily soluble in acids. Found at Friedensville, Lehigh Co., PA; Linden, Iowa Co., WI; as concentric, contorted laminae and botryoidal crusts in Marion Co., AR; in Joplin, MO; with hemimorphite and smithsonite at Galena district, Cherokee Co., KS; in Magdalena district, Socorro Co., NM; Tintic district, Juab Co., UT; abundant at Goodsprings, NV; with hemimorphite and willemite in the Cerro Gordo

mine, Inyo Co., CA; large quantities in Dolores mine, Udias V. Santander Prov., Spain; at Bleiberg, Carinthia, Austria; Raibl, Yugoslavia; Auronzo in Venetia and Mt. Malfidano, Iglesias, Sardinia, Italy; at Yaaz, Iran; at Bou Thaleb, Algeria; with cerussite, "limonite," and sphalerite at Narlarla, western Kimberley district, WA, Australia. *ncws DII:248*.

16a.4.2.1 Aurichalcite $(\text{Zn,Cu})_5(\text{CO}_3)_2(\text{OH})_6$

Named in eighteenth century after the Greek for *mountain brass*. ORTH $P2_1/m$. $a = 13.82$, $b = 6.419$, $c = 5.29$, $\beta = 101.04^\circ$, $Z = 2$, $D = 3.93$. *AC(B) 50:673(1994)*. $17\text{-}743$: 6.78_{10} 3.68_7 3.25_3 2.89_4 2.81_3 2.72_4 2.61_8 1.656_4 . Crystals elongated [001], forming tufted, feathery druses like velvet, rarely columnar, laminated, or granular. {100} zone striations parallel to (001), (010), producing a gridlike appearance corresponding to cleavage or twin directions. Pale green to green-blue and sky blue, silky to pearly luster, transparent. Cleavage {010}, perfect; fragile. $H = 1\text{-}2$. $G = 3.64$. IR. *MSLM 4:268(1974)*. Aurichalcite crystals from Mapimi, DGO, Mexico, show $\text{Zn}/\text{Cu} = 2.4$, compared to the virtually absent Cu in hydrozincite. Soluble in acids and in ammonia. A secondary mineral in oxidized copper and zinc ore deposits. Forms encrustations with malachite, azurite, cuprite, smithsonite, hemimorphite, hydrozincite, and rosasite, in mine areas at Bisbee, Cochise Co., AZ; Cottonwood Canyon, Salt Lake Co., and in Tintic district, Juab Co., UT; Magdalena district, Socorro Co., NM; Goodsprings, NV; Cerro Gordo and Defiance mines, Darwin district, Inyo Co., CA; Cigarrero mine, Almdoya, CHIH, and Mina Ojuela, Mapimi, DGO, Mexico; Cumberland, England; Leadhills, Lanark, Scotland; Chessy, near Lyon, Rhone, France; Campiglia, Tuscany, Italy; Monteponi near Iglesias, Sardinia, Italy; Laurium, Greece; Moravicza and Rezbanya, Romania; near Loktevsk on the Alei R. in the Altai district, Tomsk, Russia; in Pref. Nagato, Japan; at Mindouli, Zaire; at Tsumeb, Namibia; at Broken Hill, NSW, Australia. *ncws DII:250*, *DS:298(1892)*, *CM 8:385(1965)*.

16a.5.1.1 Plumbonacrite $\text{Pb}_{10}(\text{CO}_3)_6\text{O}(\text{OH})_6$ III

Name proposed in 1889 for a mineral from Wanlockhead, Scotland *MM 8:200(1988)* but incompletely characterized. See hydrocerussite 16a.2.2.1 *HEX* $a = 9.076$, $c = 24.96$ *JINCh 28:2507(1966)* *PD*: 4.26_8 3.357_7 2.953_4 2.619_{10} 2.235_4 1.699_5 . This is a second lead carbonate which may be intimately mixed with hydrocerussite in synthetic materials. Whether or not it occurs naturally has not yet been determined *AM 52:563(1967)*.

16a.5.2.1 Tunisite $\text{NaCa}_2\text{Al}_4(\text{CO}_3)_4(\text{OH})_6\text{Cl}$

Named in 1969 for the country of origin. *TET P4nmm*. $a = 11.22$, $c = 6.582$, $Z = 2$, $D = 2.48$. *AM 54:1(1969)*. $27\text{-}1001$: 5.62_{10} 5.07_6 3.55_8 3.29_7 3.13_6 2.75_7 2.59_9 2.56_7 . Crystalline aggregates, usually < 0.2 mm, tabular on (001), with occasional crystals up to 8 mm that display (110), (100), (101). Colorless. Cleavage {001}, {110}, perfect. $H = 4\frac{1}{2}$. $G = 2.51$. IR DTA. Uniaxial (+);

$N_O = 1.573$, $N_E = 1.599$. Easily soluble in HCl. Late hydrothermal mineral filling cavities created in veins composed mainly of white calcite; may cover portions of the calcite. Found on the dumps of the Pb-Zn ore deposit of *Sakiet Sidi Yousseff, Tunisia*. The calcite veins that contain the mineral reach a thickness of 2 m in the area of the ore consisting of galena, sphalerite, marcasite, and pyrite. HCWS *AM 69:2389(1969)*.

16a.5.3.1 Loseyite $Mn_4Zn_3(CO_3)_2(OH)_{10}$

Named in 1929 after Samuel R. Losey (b.1833) of Franklin, NJ, a mineral collector. MON *A2/a*. $a = 16.23$, $b = 5.51$, $c = 14.95$, $\beta = 95.37^\circ$, $Z = 4$, $D = 3.37$. Structure: *AC(B) 37:1323(1981)*. *17-206*: 7.49₈ 3.80₉ 3.68₁₀ 3.54₆ 2.79₈ 2.77₆ 2.63₁₀ 2.54₇. Subparallel aggregates and radiating bundles of lath-like crystals elongated [010]. Bluish white, brownish, transparent. Cleavage not observed. $H \approx 3$. $G = 3.27$. Biaxial (+); $Y = b$; $N_x = 1.637$, $N_y = 1.648$, $N_z = 1.676$; $2V = 64^\circ$; $r > v$, weak. Small amounts of Mg in isomorphous substitution. In small veinlets in massive ore at *Franklin, Sussex Co., NJ*, with altered pyrochroite, sussexite, chlorophoenicite, and calcite. HCWS *DII:245*.

16a.5.3.2 Sclarite $(Zn,Mg,Mn^{2+})_4Zn_3(CO_3)_2(OH)_{10}$

Named in 1989 for Charles B. Sclar (b. 1925), professor of mineralogy, Lehigh University, PA. MON *A2/a*. $a = 16.110$, $b = 5.432$, $c = 15.041$, $\beta = 95.49^\circ$, $Z = 4$, $D = 3.547$. Isostructural with loseyite (16a.5.3.1). Zn in both octahedral and tetrahedral coordination. *PD*: 7.50₁₀ 5.23₂ 4.82₂ 3.75₄ 3.63₅ 3.53₄ 2.62₅ 2.50₄. Clusters of 0.2-mm crystals form 1.5-mm coarse-surfaced spherules; platy on {001}, elongate parallel to [010], minor {100}. Clear, colorless, transparent crystals appear grayish white in aggregates; white streak; vitreous luster. No cleavage or parting observed, brittle. $H = 3-4$. $G = 3.51$. No fluorescence in LWUV or SWUV. Biaxial (+); $Y = b$; $X \wedge c = +49^\circ$; $N_x = 1.648$, $N_y = 1.664$, $N_z = 1.702$; $2V = 63.4^\circ$; $r > v$, strong. Analyses showed Mg, Mn, and trace Fe in addition to Zn. A secondary mineral found in an intensely altered specimen from *Franklin mine, Franklin, Sussex Co., NJ*, associated with willemite, secondary zincite, another zinc-carbonate mineral (unnamed), rhodocrosite, gageite, chlorophoenicite, and leucophoenicite. HCWS *AM 74:1355(1989)*.

16a.5.4.1 Sabinaitite $(Na,Ca)_4Zr_2Ti(CO_3)_4O_4$

Named in 1980 for Ann Phyllis Sabina Stenson (b. 1930), mineralogist, Geological Survey of Canada. MON. *C2/c*. $a = 10.171$, $b = 6.623$, $c = 17.976$, $\beta = 94.32^\circ$, $Z = 4$, $D = 3.48$. *AM 71:231(1986)*. *36-414*: 8.96₁₀ 4.48₃ 3.25₅ 2.99₅ 2.73₃ 2.29₄ 2.02₅ 1.795₄. Fine-grained white, powdery coatings and chalky aggregates; max. dimensions 0.01 mm \times 0.001 mm. St. Hilaire crystals tabular on (001) and elongated on a ; forms {001}, {010}, {100}, and {110}. Cleavages {001}, perfect; {010}, distinct. DTA. Biaxial (+); $Y = b$. $X \wedge c = 13^\circ$ in obtuse β ; $N_x = 1.720$, $N_y = 1.79$, $N_z = 1.90$; $2V = 82^\circ$ (Na); $r > v$. Found in a dawsonite-rich sill associated with calcite, quartz, weloga-

nite, and cryolite on *St. Michel, Montreal Is.*, and at *Mt. St.-Hilaire, QUE, Canada*. *HCWS AM 66:1277(1981)*, *CM 23:17(1985)*.

16a.5.5.1 Rouvilleite $\text{Na}_3\text{Ca}_2(\text{CO}_3)_3\text{F}$

Named in 1991 for the locality. *MON Cc* or *C2/c*. $a = 8.043$, $b = 15.812$, $c = 7.030$, $\beta = 101.16^\circ$, $Z = 4$, $D = 2.69$. *44-1471*: 7.0_2 3.52_5 2.92_3 2.90_3 2.86_{10} 2.78_1 2.69_1 1.737_2 ; also *CM 29:107(1991)*: 7.08_8 2.94_7 2.90_{10} 2.71_9 2.637_6 2.04_7 1.87_8 1.75_6 . Irregular crystalline masses up to 3 mm across in cavities; rare euhedral crystals show {010}, {110}, {100}, {001}, but other forms displayed are inconsistent with space group determination. Tan to colorless, white streak, vitreous to slightly waxy luster, transparent. Cleavage {001}, good; {010}, imperfect; uneven fracture; brittle. $H = 3$. $G = 2.67$. IR. Not fluorescent. Biaxial (-); $Y = b$; $X \wedge c = 6^\circ$ in acute angle β ; $N_x = 1.472$, $N_y = 1.562$, $N_z = 1.569$ (Na); $2V = 25-30^\circ$; nonpleochroic. Strongly effervescent in cold 1:1 HCl, insoluble in H_2O . As described contains > 6.8% MnO. Mn-bearing and Mn-free rouvilleite have been synthesized. A secondary mineral in cavities in sodalite syenite inclusion in nepheline syenite at the *Poudrette quarry, Rouville Co., Mt. St.-Hilaire, QUE, Canada*. Mineral occurs with villiaumite and kupletskite. *HCWS AM 76:2023(1991)*.

ANCYLITE GROUP

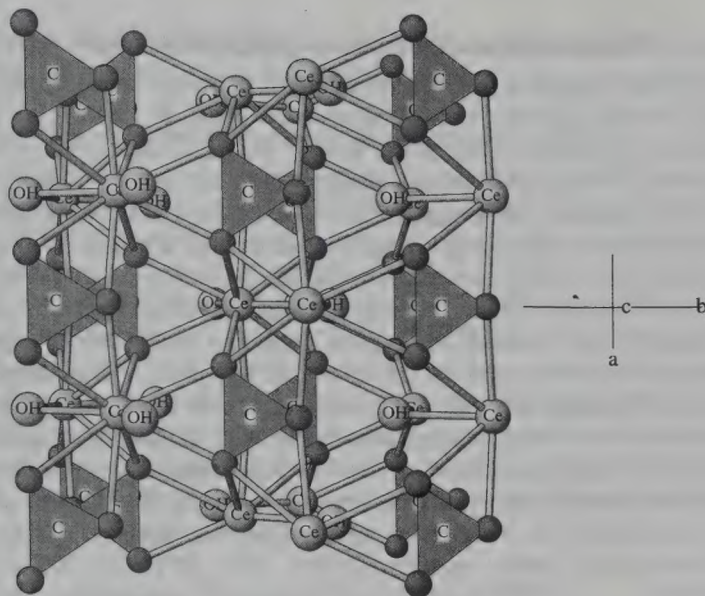

The four end members of the ancylite group, rare-earth-element-containing hydrated hydroxycarbonates, have the general formula

and crystallize with orthorhombic or monoclinic symmetry. The structure [*AM 60:280(1975)*] resembles that of aragonite (14.1.3.1). In spite of the introduction of (OH), H_2O and large REE cations *AM60:280(1975)*. There are relative shifts and an increase in the angle of tilt of the carbonate ions in the carbonate layers. Compare also with the bastnäsite/synchysite group.

ANCYLITE GROUP

ANCYLITE: $\text{La}_2(\text{CO}_3)_2(\text{OH})_2$

This c axis projection of ancylite [(simplified to $\text{Ce}(\text{CO}_3)_2(\text{OH})\cdot\text{H}_2\text{O}$)] shows direct similarities to the aragonite (14.1.3.1) structure. The large REE and Sr ions are in tenfold coordination with OH and O of the (CO_3) groups. Note only OH is depicted in this diagram as the structure analysis did not discriminate between (OH) and H_2O in the calculation of bonding to O AM 60:280 (1975).

16b.1.1.1 Ancylite-(Ce) $\text{SrCe}(\text{CO}_3)_2(\text{OH})\cdot\text{H}_2\text{O}$

Named in 1899 for Greek for *curved* in allusion to the rounded and distorted character of the crystals. Ancylite group. ORTH $Pm\bar{c}n$. $a = 5.062$, $b = 8.586$, $c = 7.303$, $Z = 2$, $D = 3.939$. Structure: AM 60:280(1975). 29-384: 5.57₅ 4.34₁₀ 3.71₁₀ 2.96₁₀ 2.35₈ 2.09₇ 2.02₇ 1.953₅. Pseudo-octahedral crystals with faces curved and often dull, also short prismatic [001], and as groups and clusters of small rounded crystals. Pale yellow with tinge of orange, yellow-brown to brown, gray; white streak; vitreous luster on faces, greasy on fracture surfaces; translucent to subtranslucent. No cleavage, splintery fracture, tough, brittle. $H = 4-4\frac{1}{2}$. $G = 3.95$. Biaxial (-); $XYZ = abc$; $N_x = 1.625$, $N_y = 1.700$, $N_z = 1.735$; 2V medium large; colorless, sometimes cloudy with inclusions (Narssarssuk). Occurs in hydrothermal veins associated with felsic alkaline rocks, or in pegmatites in alkaline rocks and in carbonatites. Found in veins in the Bearpaw Mts. as fine grains intimately intergrown with calcite, quartz, and barite, also in masses several feet across in Sheep Creek vein, Ravalli Co., MT; in the carbonatite, Mt. St.-Hilaire, QUE, Canada; in druses in pegmatite veinlets in nepheline-syenite at Narssarssuk in the *Julianejaab district, Greenland*, associated with aegirite, albite, microcline, zircon, synchisite, cordylite, and eudidymite; in Langesundfjord district, Norway; in the Khibina tundra, Kola Penin., Russia. *HCWS DII:291*.

16b.1.1.2 Calcioancylite-(Ce) $\text{CaCe}(\text{CO}_3)_2(\text{OH}) \cdot \text{H}_2\text{O}$

Named in 1922 to reflect the relationship to ancylite for compositions with $\text{Ca} > \text{Sr}$. Ancylite group. ORTH *Pmmm*. $a = 7.24$, $b = 8.49$, $c = 5.02$. *CM* 8:398(1968). *PD*: 2.95₅ 2.65₅ 2.53₅ 2.35₁₀ 2.09₁₀ 2.02₁₀ 1.95₉ 1.85₆. *AM* 46:1424(1961). Blocky pseudo-octahedral crystals up to 2 mm (Cornog, PA), partially coated with drusy pyrite show {120}, {111}. Pink under ordinary light, change to blue-gray under fluorescent as a result of Nd content; frosty luster. $H = 4-4\frac{1}{2}$. $G = 4.30$. Biaxial (-); $N_x = 1.654$, $N_y = 1.733$, $N_z = 1.772$; $2V = 60-70^\circ$; $r < v$, small. Calcioancylites contain higher Ca than Sr, usually much higher than other members of the ancylite group. La, as well as Nd, Pr, Sm, and so on, are also present. A secondary mineral associated with carbonates and alkalic igneous rocks such as syenitic pegmatites. Occurs in the Li-pegmatites associated with monazite in pegmatite at *Foote mine, Cleveland Co., NC*; in calcite-lined cavities in an amphibole gneiss-migmatite (similar to alpine cleft minerals of hydrothermal origin) at Cornog, Chester Co., PA; at Mt. St.-Hilaire, QUE, Canada; reported from a granitic boulder in the Kola Penin., western Russia. *HCWS DII:291*; *MR* 2:18(1971), 18:203(1987).

16b.1.1.3 Calcioancylite-(Nd) $\text{CaNd}(\text{CO}_3)_2(\text{OH}) \cdot \text{H}_2\text{O}$

Named in 1991 to show the association to calcioancylite-(Ce) and the dominant element, Nd. Ancylite group. MON *Pm*. Note that the space group is different from ancylite-(ce). $a = 7.212$, $b = 4.976$, $c = 8.468$, $\beta = 90.04^\circ$, $Z = 1$, $D = 4.08$. Structure: *EJM* 2:413(1990). 42-1424: 5.49₆ 4.26₁₀ 3.67₇ 2.91₉ 2.63₄ 2.32₇ 2.05₈ 1.979₇. Pine cone aggregates up to 1 mm long composed of individual dipyramidal pseudoorthorhombic crystals. Pale pink, white streak, vitreous luster. Irregular fracture, brittle. $H = 4-4\frac{1}{2}$. $G = 4.02$. Non-fluorescent. Biaxial (-); $Z = c$; $N_x = 1.660$, $N_y = 1.725$, $N_z = 1.761$; $2V = 70^\circ$; $r < v$, weak; nonpleochroic. Dominant Nd, with Ce, Sm, Gd, Y, Pr, La, Dy, Tm also detected on analysis. Found on a pink orthoclase in a miarolitic cavity in granite in a quarry near *Baveno, Piedmont, Italy*. *HCWS AM* 76:1729(1991).

16b.1.1.4 Gysinite-(Nd) $\text{PbNd}(\text{CO}_3)_2(\text{OH}) \cdot \text{H}_2\text{O}$

Named in 1985 after Marcel Gysin (1891-1974), mineralogist, University of Geneva, Switzerland. Ancylite group. ORTH *Pmcn*. $a = 5.04$, $b = 8.50$, $c = 7.25$, $Z = 2$, $D = 4.82$. 39-364: 5.54₅ 4.33₁₀ 3.68₁₀ 3.34₄ 2.95₅ 2.34₅ 2.07₆ 2.02₅. Isolated pseudo-octahedral crystals with {111} and {110} up to 1 mm in length elongated on b ; aggregates and penetration twins with twin plane (100). Light pink to reddish pink, white-light pink streak, vitreous to greasy luster, translucent. No cleavage, brittle. No fluorescence with LWUV or SWUV. Biaxial (-); $XYZ = cab$; $N_x = 1.745$, $N_y = 1.805$, $N_z = 1.840$; $2V = 70^\circ$; $r < v$. Probe analysis showed Pb, La, Nd, and no other rare-earth elements. H_2O confirmed by TGA. Soluble with effervescence in cold 1:10 HCl. Occurs in the uraninite-containing ore deposits at *Shinkolobwe, Shaba, Zaire*, associated with

schuilingite, malachite, cerussite, talc-chlorite, bornite, wulfenite, kasolite, native gold, and garnet. HCWS *AM* 70:1314(1985).

16b.1.2.1 Thorbastnäsite $\text{Th}(\text{Ca,Ce})(\text{CO}_3)_2\text{F}_2 \cdot 3\text{H}_2\text{O}$

Named in 1965 for the compositional and crystal structural resemblance to the bastnäsite group (16a.1.2.1). HEX $P62c$. $a = 6.99$, $c = 9.71$, $D = 5.70$. *AM* 50:1505(1965). 18-1362: 3.54₈ 2.85₁₀ 2.03₁₀ 1.870₇ 1.656₅ 1.279₆ 1.165₅ 1.134₅. Cryptocrystalline, locally subparallel aggregates, brown. $G = 4.04$ (discrepancy ascribed to "molecular water"). DTA and IR data similar to parisite and bastnäsite, but there is molecular water. Uniaxial (+); $N = 1.670-1.678$. Pb also present; Fe, Al, and Si in analyses are admixtures of other minerals. An accessory mineral in iron-rich saccaroidal albitites, may be a pseudomorph after thorite, associated with hydrous iron oxides, quartz, and albite. Found in "exocontact alkaline metasomatic rocks" of an unnamed nepheline syenite intrusion, eastern Siberia, Russia, replacing ferrian thorite. HCWS *ZVMO* 94:105(1965), *MA* 17:398(1965).

16b.1.3.1 Indigirite $\text{Mg}_2\text{Al}_2(\text{CO}_3)_4(\text{OH})_2 \cdot 15\text{H}_2\text{O}$

Named in 1971 after the locality. Space group unknown. Cell data (partially dehydrated under EM) = 6.23, parallel to elongation; 3.16, perpendicular to elongation. *ZVMO* 100:178(1971). 25-510: 7.62₉ 5.80₁₀ 5.24₉ 4.56₈ 3.65₄ 2.70₉ 2.60₉ 1.625₅. Radiating aggregates (rosettes) of very fine flexible fibers, needles, or plates up to 1 mm in length, flexible. Snow white, vitreous to silky luster. $H \approx 2$. $G = 1.6$. IR, DTA. Uniaxial; $N_0 = 1.472$, $N_E = 1.502$; positive elongation parallel to extinction. Insoluble in H_2O , alcohol, and ammonia; dissolved by acids, KOH solution. Found in the oxidation zone of the Sarylakh Au-Sb deposit, Indigirka R., northeastern Yakutia, Russia, associated with gypsum, amorphous Fe-oxides, quartz, and gibbsite. HCWS *AM* 57:326(1972).

16b.1.4.1 Schuilingite-(Nd) $\text{PbCuNd}(\text{CO}_3)_3(\text{OH}) \cdot 1.5\text{H}_2\text{O}$

Named in 1947 after H. J. Schuiling, Belgian geologist to Union Minière du Haut-Katanga, Zaire. ORTH $Pm\bar{c}n$. $a = 7.43$, $b = 18.89$, $c = 6.40$, $Z = 2$, $D = 4.59$ (Schinkolobwe). *SMPM* 63:1(1983). 41-583: 9.46₁₀ 6.06₉ 4.80₅ 4.72₆ 4.49₉ 3.85₁₀ 2.93₅ 2.64₄. See also 35-545. Crusts of minute acicular crystals elongated [001] with prism and terminal domes. Azure blue, turquoise; adamantine luster; translucent. Cleavage {110}, perfect; {100}, poor. $H = 3\frac{1}{2}$. $G = 4.50$. Biaxial (-); $XYZ = acb$; $N_x = 1.730$, $N_y = 1.770$, $N_z = 1.795$; $2V = 75^\circ$; weakly pleochroic (Schinkolobwe). Found at Kalompe, and Schinkolobwe, Shaba, Zaire, associated with cerussite, calcite, pyrite, and so on. HCWS *DII*:252, *BM* 105:225(1982), *AM* 69:1196(1984).

16b.1.5.1 Shabaite-(Nd) $\text{CaNd}_2(\text{UO}_2)(\text{CO}_3)_4(\text{OH})_2 \cdot 6\text{H}_2\text{O}$

Named in 1989 for the locality. MON. $P2_1Pm$, or $P2/m$. $a = 9.208$, $b = 32.09$, $c = 8.335$, $\beta = 90.3^\circ$, $Z = 5$, $D = 3.23$. *EJM* 1:85(1989). *PD*: 15.9₁₀ 7.31₇ 4.58₆ 4.17₇ 4.13₇ 4.01₃ 3.79₃ 3.09₆. Micaceous flakes and rosettes up to 5 mm in

diameter, tabular on {010}, elongate [100], twinned {001}; pale greenish yellow, translucent to opaque, pearly. $H = 2\frac{1}{2}$. $G = 3.13$. Biaxial (-); $Y = b$; $Z \wedge a = 3-4^\circ$; $N_x = 1.534$, $N_y = 1.590$, $N_z = 1.600$; $2V = 44^\circ$; nonpleochroic. Electron microprobe analyses showed 0.38% Nd, 0.15% Sm, 0.21% Y, 0.07% Dy, 0.07% Pr, 0.04% La, 0.02% Ce. Soluble in HCl. Occurs with uraninite, kamotoite-(Y), schuilingite-(Nd), and uranophane in Cu-Co deposit, *Kamoto East, 5 km W of Kolwèzi, Shaba, Zaire*. HCWS AM 75:433(1990).

16b.1.6.1 Astrocyanite-(Ce) $\text{Cu}_2\text{Ce}_2(\text{UO}_2)(\text{CO}_3)_5(\text{OH})_2 \cdot 1.5\text{H}_2\text{O}$

Named in 1990 for its starlike morphology and the Greek *cyan*, blue. HEX $P6/mmm$. $a = 14.96$, $c = 26.86$, $Z = 12$, $D = 3.95$. *EJM* 2:407(1990). 42-1396: 13.3₄ 6.73₁₀ 4.30₅ 4.16₆ 3.72₉ 2.49₄ 2.15₄ 2.07₄. Isolated tablets {001}, or aggregates to millimeter size, rosettes. Pale blue, bright blue, and blue-green; individuals show vitreous luster, but earthy luster in rosettes; translucent to opaque. Cleavage {001}. $H = 2-3$. $G = 3.80$. Uniaxial (-); $N_O = 1.638$, $N_E = 1.688$; N_E normal to {001}; pleochroic, bright blue to almost colorless. Microprobe analyses show $\text{Cu}/\text{U} = 2$, Ce and Nd predominant REE, La, Pr, Sm, and Y also present. Effervescent in HCl 1:10. Oxidation product of uraninite. Found in *East Kamoto Cu-Co deposit, southern Shaba, Zaire*, associated with uranophane, kamotoite-(Y), francoisite-(Nd), shabaite-(Nd), schuilingite, and masuyite. HCWS AM 76:665(1991).

16b.1.7.1 Kamphaugite-(Y) $\text{Ca}_2(\text{Y,REE})_2(\text{CO}_3)_4(\text{OH})_2 \cdot 3\text{H}_2\text{O}$

Named in 1993 after Erling Kamphaug (b. 1931), Norwegian mineral collector who provided a specimen for study. Related to tenerite (15.4.3.1), lokkaite (15.4.4.1), kimuraite (15.4.5.1). TET $P4_12_12_1$. $a = 7.434$, $c = 21.793$, $Z = 4$, $D = 3.24$. Structure: *EJM* 5:679(1993), 5:685(1993). *PD*: 6.14₁₀ 4.38₈ 3.52₆ 2.83₅ 2.72₂ 2.63₉ 2.45₂ 1.891₃. Crystals roughly square in outline up to 1 mm across, platy on {001}; as divergent, rosellike spherules and aggregates; each platelet is a subparallel group. White to colorless, some spherules pale yellow or pale brown; white streak; vitreous luster; transparent. No cleavage, uneven fracture. $H = 2-3$. $G = 3.19$. Nonfluorescent. Uniaxial (+); $N_O = 1.627$, $N_E = 1.663$; $2V \approx 15^\circ$; anomalously biaxial. Effervesces in 1:10 acids. Norwegian samples contain appreciable REE especially Dy. Low-temperature late-stage secondary mineral. Occurs as white crusts at Evans Lou pegmatite, QUE, Canada; at Tordal, Telemark, and at the Tangen granite pegmatite quarry, near Kragerys, as rosettes along cracks in feldspar and quartz; an alteration product of kuliokite-(Y), and in a magnetite and helvite contact skarn at *Hortekollen, Hoydalen, Oslo region, Norway*; replaces gagarinite, Kazakhstan; as white spheroids on opal from a quartz and barite vein, Transvaal, South Africa. HCWS AM 79:387(1993).

16b.2.1.1 Dundasite $\text{PbAl}_2(\text{CO}_3)_2(\text{OH})_4 \cdot \text{H}_2\text{O}$

Named in 1893 for the locality in TAS, Australia. ORTH. *Pbmm*. $a = 9.08$, $b = 16.37$, $c = 5.62$, $Z = 4$, $D = 3.573$. Structure: *MM 33:565(1972)*. 21-936: 7.91₁₀ 4.63₅ 3.60₈ 3.23₅ 3.09₆ 2.97₄ 2.67₅ 2.64₄. See also 33-731 (calc). Spheroidal aggregates with radiating needles parallel to c and as matted or felty crusts. White, vitreous or silky luster, transparent. Cleavage {010}, perfect. $H = 2$. $G = 3.25$. DTA, IR. *AM 35:985(1950)*. Biaxial (-); $XYZ = abc$; $N_x = 1.603$, $N_y = 1.716$, $N_z = 1.742$; $2V \approx -50^\circ$. Effervescent in acids. Secondary mineral in the oxidation zone of lead deposits. Found with cerussite and allophane at mines near Trefriw, Carnarvonshire, Wales; at Clements lead mine near Maam, County Galway, Ireland; with cerussite, hemimorphite, and greenockite at the Mill Close mine, Wensley, Derbyshire, Wheal Rose, Sithney, and with allophane at Port Quin antimony mine, Cornwall, England; with crocoite and pyromorphite and iron oxyhydroxides in gossan in the *Adelaide Prop. mine, Dundas*, with cerussite and gibbsite at *Hercules mine, Mt. Read, TAS, Australia*. HCWS *DII:279, BSFM:83(1960)*.

16b.2.1.2 Dresserite $\text{Ba}_2\text{Al}_4(\text{CO}_3)_4(\text{OH})_8 \cdot 3\text{H}_2\text{O}$

Named in 1970 for John Alexander Dresser (1866–1954), Canadian geologist, an authority on asbestos deposits and for his contributions to the geology of the Monteregian Hills. Ba analog of dundasite (16b.2.1.1). ORTH *Pbmn*. $a = 9.27$, $b = 16.83$, $c = 5.63$, $Z = 2$, $D = 3.06$. *CM 10:84(1970)*. 20-617: 8.09₁₀ 6.23₆ 4.68₃ 4.63₂ 3.66₅ 3.17₃ 2.73₄ 2.67₃. Spherulitic up to 3 mm in diameter; radiating blades elongated [001], flattened parallel to {010}. White, white streak, vitreous to silky luster. Biaxial (-); $N_x = 1.518$, $N_z = 1.601$; $2V = 30-40^\circ$; parallel extinction; length-slow. Dissolves in HCl with effervescence. From *St. Michel, Montreal Island, QUE, Canada*, in cavities of an alkali sill intruding Ordovician limestones associated with welogamite, plagioclase, quartz, dawsonite, and others. HCWS

16b.2.1.3 Strontiodresserite $\text{SrAl}_2(\text{CO}_3)_2(\text{OH})_4 \cdot \text{H}_2\text{O}$

Named in 1977 from the composition and analogy with dresserite. Sr analog of dresserite (16b.2.1.2). ORTH *Pbnm*. $a = 9.168$, $b = 16.037$, $c = 5.598$, $Z = 4$, $D = 2.73$. *GSCP 78:180(1978)*. 29-1295: 7.93₁₀ 5.99₆ 3.55₄ 4.39₈ 3.00₇ 2.64₆ 2.05₄ 1.732₅. "Atoll-like" coatings of lathlike 0.1 mm \times 0.01 mm \times 0.001 mm crystals. White, silky luster. $G = 2.71$. Biaxial (-); $N_x = 1.510$, $N_y = 1.583$, $N_z = 1.595$; $2V = 42.5^\circ$. Complete solid solution between strontiodresserite and dundasite. Occurs as secondary mineral in silicocarbonatite sill at *Francon Quarry, St. Michel, Montreal Is., QUE, Canada*. HCWS *CM 15:405(1977)*.

16b.2.2.1 Hydrodresserite $\text{BaAl}_2(\text{CO}_3)_2(\text{OH})_4 \cdot 3\text{H}_2\text{O}$

Named in 1977 for its relation to dresserite as it gradually dehydrates to that phase. Ba analog of alumohydrocalcite (16b.2.3.1), structurally distinct. TRIC $P1$ or $P\bar{1}$. $a = 9.79$, $b = 10.42$, $c = 5.62$, $\alpha = 96.05^\circ$, $\beta = 92.20^\circ$, $\gamma = 115.71^\circ$,

$Z = 2$, $D = 2.81$. *AM 64:654(1979)*. 29-145: 9.30₃ 8.75₄ 8.52₁₀ 5.32₃ 4.26₅ 3.62₃ 3.42₇ 3.10₆. Spheres and hemispheres up to 2 mm in diameter of radiating fibrous crystals elongated on {001} exhibiting {010}, {210}, {102}. Colorless, white; white streak; vitreous luster. $H = 3-4$. $G = 2.80$. DTA. Biaxial (-); $N_x = 1.502$, $N_y = 1.594$, $N_z = 1.595$; $2V = 17^\circ$. Loses H_2O readily even at room temperature, breaking down to dresserite or another carbonate. Found in an alkalic sill *Francon quarry Montreal Is., QUE, Canada*. HCWS *CM 15:399(1977)*.

16b.2.3.1 Alumohydrocalcite $CaAl_2(CO_3)_2(OH)_4 \cdot 3H_2O$

Named in 1926 for the composition. TRIC $P\bar{1}$. $a = 6.498$, $b = 14.457$, $c = 5.678$, $\alpha = 95.83^\circ$, $\beta = 93.23^\circ$, $\gamma = 82.24^\circ$, $Z = 2$, $D = 2.21$. *NJMM:630(1969)*. 42-592: 7.15₈ 6.44₈ 6.18₁₀ 5.12₄ 3.23₃ 3.22₅ 2.85₄ 2.54₃. See also 22-138. Chalky masses of fibrous crystals. White, pale blue, violet, gray. Cleavage {100}, perfect; {110}, imperfect; brittle. $H = 2\frac{1}{2}$. $G = 2.23$. Biaxial (-); $Z \wedge c = 6^\circ$; $N_x = 1.502$, $N_y = 1.562$, $N_z = 1.585$; $2V = 64^\circ$; extinction (Pakistan). *AM 63:795(1978)*. Found at Mount Hamilton, Santa Clara Co., CA; in a dolomite quarry near Bergisch-Gladbach, Germany; Vise, Belgium; Cr-bearing form at Nowej Rudy, Silesia, Germany; originally described as an alteration product of allophane in the *Khakassy district, Siberia, Russia*, in association with volbothite, malachite, and so on; at Chitral, Northwest Frontier Prov., Pakistan, associated with aragonite, quartz, and dickite; in Osaka Pref., Japan. HCWS *DII:280*.

16b.2.3.2 Para-alumohydrocalcite $CaAl_2(CO_3)_2(OH)_4 \cdot 6H_2O$

Named in 1977 for its relation to alumohydrocalcite, differing in H_2O content. *ZVMO 106:336(1977)*. See alumohydrocalcite (16b.2.3.1). 30-222: 7.90₁₀ 6.20₃ 4.04₂ 3.90₃ 3.32₃ 3.03₂ 2.68₃ 2.64₃. Radiating aggregates of fibrous crystals, white but colorless in thin section with extinction 10° from the fiber length. $H = 1\frac{1}{2}-2$. $G = 2.0$. DTA. Biaxial (-); $N_x = 1.473$, $N_z = 1.502$; $2V = 69^\circ$; positive elongation. HCl only slightly effective in dissolution. Found with gypsum and calcite in the oxidized zone of the sulfur deposits of *Vodinsk, Ukraine*, and *Gaurdok, Turkmenistan*. HCWS *AM 63:795(1978)*.

16b.2.4.1 Bijvoetite-(Y) $(Y,Dy)_2(UO_2)_4(CO_3)_4(OH)_6 \cdot 11H_2O$

Named in 1982 to honor Dutch crystallographer Johannes Martin Bijvoet (1892-1980). ORTH $C2ma$ or $Cmma$. $a = 21.22$, $b = 45.30$, $c = 13.38$, $Z = 16$, $D = 3.907$. *CM 20:231(1982)*. 35-551: 8.61₈ 6.70₁₀ 4.16₆ 3.52₅ 3.36₅ 3.00₆ 2.14₄ 1.763₄. Minute tabular {001} crystals elongated along [110]; forms {001}, {110}, {130}, {010}. Cleavage {001}, perfect. Sulfur yellow, vitreous luster, transparent. $G = 3.95$. Nonfluorescent under SWUV or LWUV. Biaxial (+); $XYZ = cab$; $N_x = 1.600$, $N_y = 1.650$, $N_z = 1.722$; $2V = 84^\circ$. X, colorless; Y, pale yellow; Z, dark yellow. Microprobe analysis also showed Gd and Tb. Occurs with lepersonite and hydrated uranium oxides near primary ura-

ninite in lower portion of oxidation zone in *Shinkolobwe, Zaire*. HCWS AM 68:11248(1983).

16b.3.1.1 Artinite $Mg_2(CO_3)(OH)_2 \cdot 3H_2O$

Named in 1902 after Ettore Artini (1866–1928), mineralogist at the University of Milan. MON $C2$ or $C2/m$. $a = 16.56$, $b = 3.15$, $c = 6.22$, $\beta = 99.16^\circ$, $Z = 2$, $D = 2.02$. Structure: AC 5:286(1952). 6-484: 8.18₃ 5.37₈ 3.69₅ 2.74₁₀ 2.67₂ 2.27₂ 2.21₄ 1.918₂. Crusts of acicular crystals elongated [010]; botryoidal masses of silky fibers; spherical aggregates of radiating fibers and cross-fiber veinlets. White; white streak; single crystals, vitreous fibers silky; transparent. Cleavage {100}, perfect; {001}, good; brittle. $H = 2\frac{1}{2}$, $G = 2.02$. Biaxial (-); Y parallel to b ; $Z \wedge c = 30^\circ$; $N_x = 1.488$, $N_y = 1.534$, $N_z = 1.556$; $2V = 70^\circ$; optic axis perpendicular to {100}. Easily soluble with effervescence in cold acids. DTA. Low-temperature hydrothermal mineral in veins and crusts in serpentinized ultrabasic rocks associated with hydromagnesite, brucite, aragonite, calcite, dolomite, magnesite, pyroaurite, and crysotile. Found in asbestos deposits at Hoboken, NJ, and on Staten Island, NY, with brucite and hydromagnesite; at Luning, NV, as cross fibers veinlets with hydromagnesite in massive brucite; with pyroaurite along joint planes in serpentinite, Eden Mills, VT; in asbestos deposits *Val Brutta*, and *Francia in the Val Lanterna, Lombardy, Italy*, and in the Val di Lanzo, Val d'Aosta, and near Torre Santa Maria, Val Malenco; with hydromagnesite at Kraubat Styria, Austria; at Lojane, southern Serbia; Yavoritsy, Bulgaria. HCWS DII:263.

16b.3.2.1 Otwayite $Ni_2(CO_3)(OH)_2 \cdot H_2O$

Named in 1977 after Charles Albert Otway (b.1922), miner and prospector of Gosnells, WA, Australia. ORTH Space group unknown. $a = 10.18$, $b = 27.4$, $c = 3.22$, $Z = 8$, $D = 3.346$. 29-868: 6.84₁₀ 5.67₈ 3.02₅ 2.74₆ 2.53₅ 2.37₄ 2.24₅ 1.732₄. Structure probably related to aurichalcite (16a.4.2.1). Fibrous, with individuals $\approx 0.05 \mu\text{m}$ in diameter and several $100 \mu\text{m}$ in length, form rosette aggregates. Bright green, silky luster. VHN = 247 (5 g load). $G = 3.41$. Biaxial; $N_{\text{parallel to } c} = 1.65$, $N_{\text{perpendicular to } c} = 1.72$; pleochroic, pale green to darker green perpendicular to length; parallel to extinction; length fast. Dissolves slowly in cold 1:1 HCl at room temperature, with effervescence at 100° . Found within narrow (1-mm-wide) veinlets, probably late-stage fracture fillings, in nickeloan serpentinites that contain millerite, polydymite, and apatite in the *Nullagine region of WA, Australia*. The fibers, oriented normal to the veinlet walls, are associated with magnesite, gaspeite, and pecoraite. HCWS AM 62:999(1977).

16b.3.3.1 Kamotoite-(Y) $Y_2(UO_2)_4(CO_3)_3(OH)_6 \cdot 10-11H_2O$

Named in 1986 for the locality. MON $P2_1/m$. $a = 21.22$, $b = 12.93$, $c = 12.39$, $\beta = 115.3^\circ$, $Z = 4$, $D = 3.94$. BM 109:643(1986). 40-482: 8.49₈ 6.48₁₀ 3.93₄ 3.49₄ 3.05₆ 2.76₄ 2.13₄ 1.749₄. Crusts of elongate [100] blades up to 5 mm with sharp pointed ends; crystals show {001}, {100}, {101}. Bright yellow,

vitreous luster, transparent to translucent. Twinned on (001). Cleavages {010}, possible; {001}, easy. $G = 3.93$. Nonfluorescent LWUV or SWUV. Biaxial (-); $N_x = 1.604$, $N_y = 1.667$, $N_z = 1.731$; $2V = 87^\circ$; positive elongation; absorb $Z > Y > X$; no dispersion. $X = b$, colorless; $Y \wedge c = 25^\circ$, pale yellow-green; $Z = a$, bright yellow. Microprobe analyses showed also Nd, Sm, Gd, and Dy. Occurs on uraninite in *Kamoto, southern Shaba, Zaire*. HCWS *AM 73:191(1988)*.

16b.4.1.1 Zaratite $Ni_3(CO_3)(OH)_4 \cdot 4H_2O$

Named in 1851 for Antonio Gil y Zarate (1793–1861), Spanish dramatist, general director of public education, and counselor of state. A mixture of amorphous and fibrous particles rather than a discrete mineral species. *MM 33:663(1963)*. 16-164: 8.93₇ 5.07₁₀ 2.73₅ 2.45₇ 2.00₄ 1.91₂ 1.74₁ 1.55₂. Crusts, small stalactitic or minute mammillary, microcrystalline, also massive, compact, and as thin films on millerite. Emerald-green, paler streak, vitreous to greasy luster, translucent to transparent. Conchoidal fracture of aggregates, brittle. $H = 3\frac{1}{2}$. $G = 2.57$. IR. *MSLM 4:268(1974)*. $N = 1.56$ – 1.61 ; fibers parallel to extinction; positive elongation; pleochroic. Length, emerald-green; perpendicular, yellow-green. Soluble with effervescence in 1:10 HCl. Synthesized by action of NiCl on nesquehonite. Associated with dolomite, aragonite, calcite, hydromagnesite, brucite, chromite, pentlandite, and pyrrhotite. Alteration product of millerite and meteoritic iron. Found with chromite at Low's mine and Wood's mine, Lancaster Co., and at West Nottingham, Chester Co., PA; in serpentinites in Swinanes, Unst, Shetland Is., England; as an incrustation on magnetite with NiS at *Cape Ortegal, Galicia, Spain*; with millerite and chromite near Kraubat, Styria, Austria; as the alteration of millerite in geodes and sideritic septaria at Rapice, Dubi, Bohemia, Czech Republic; at Lilaz, Cogne, Piedmont, Italy, in serpentinites with aragonite and nesquehonite; in the ultrabasic rocks containing Ni deposits of Khalilova massif near Orsk in the southern Ural Mts., Russia; in Broken Hill, NSW, and as an alteration product of heazlewoodite (Ni_3S_2), TAS, Australia; at Dun Mountain, Nelson, New Zealand. HCWS *DII:245*.

16b.4.2.1 Defernite $Ca_6(CO_3)_2(OH)_7Cl \cdot nH_2O$

Named in 1980 after Jacques Deferne (b.1934), Curator of Mineralogy, Museum d'Histoire Naturelle, Geneva, Switzerland. ORTH $Pna2_1$ or $Pnam$. $a = 17.860$, $b = 22.775$, $c = 3.658$, $Z = 8$, $D = 2.42$. *BM 103:185(1980)*. 42-1324: 11.38₁₀ 8.32₉ 5.68₃ 3.07₄ 2.99₄ 2.89₄ 1.889₃ 1.814₃. See also 35-488. Fan-shaped aggregates 100–200 μm in size, crystals showing {001}, {100}, {010}, {101}, {201}. Colorless, vitreous luster. Cleavage {010}, perfect; {100}, distinct. $G = 2.5$. Biaxial (-); $XYZ = cba$; $N_x = 1.546$, $N_y = 1.572$, $N_z = 1.576$; $2V = 42^\circ$; $r < v$. Dissolves in cold HCl with effervescence. Occurs as secondary mineral in skarn contact of granite with Cretaceous limestone near *Güneyce-Ikizere, Trabson region, Turkey*, associated with vesuvianite,

wollastonite, andradite, diopside, calcite, rustumite, spurrite, and hillebrandite. HCWS *AM* 65:1066(1980).

16b.4.2.2 Holdawayite $\text{Mn}_6(\text{CO}_3)_2(\text{OH})_7(\text{Cl},\text{OH})$

Named in 1988 after Michael J. Holdaway (b.1936), petrologist, Southern Methodist University, Dallas, TX. *MON* *C2/m*. $a = 23.437$, $b = 3.314$, $c = 16.618$, $\beta = 111.15^\circ$, $Z = 4$, $D = 3.24$. *AM* 73:632(1988). *PD*: 10.93₁₀ 7.77₄ 5.46₈ 3.88₇ 2.93₄ 2.69₆ 2.59₅ 1.789₇. Subhedral grains up to 2 cm in diameter or fibrous aggregates. Pink, light pink streak, silky to vitreous luster, translucent, may be covered with black sooty coating. Cleavage {100}, perfect; irregular fracture, brittle. $H \approx 3$. $G = 3.19$. Nonfluorescent. Effervesces weakly in 1:10 HCl. Biaxial (-); $X = b$; $Z \wedge c = 45^\circ$ in obtuse β ; $N_x = 1.644$, $N_y = 1.719$, $N_z = 1.721$; $2V = 12^\circ$ (Na); $r < v$. Occurs as coarse veins cutting silicate-facies Mn-bearing rocks. Found at *Kombat mine, 37 km E of Otavi and 49 km S of Tsumeb, Namibia*, as an anastomosing mesh of veinlets 1–8 mm thick in a hematite–carbonate matrix, and also as patches and blebs 1–4 cm in diameter. The mineral was restricted to the footwall zone of a complexly deformed body of intercalated manganese and iron ores, and occasionally formed up to 40% of the ore. HCWS

16b.4.3.1 Claraite $(\text{Cu},\text{Zn})_3(\text{CO}_3)(\text{OH})_4 \cdot 4\text{H}_2\text{O}$

Named in 1982 for the locality. An inadequately characterized mineral. *TRIC* (pseudo-*HEX*) *P1* or *P1*. $a = 26.22$, $c = 21.56$, $Z = 66$, $D = 3.34$. *CE* 41:97(1982). 35–549: 13.47₁₀ 7.84₉ 5.69₈ 5.17₆ 3.65₈ 3.24₅ 2.96₆ 2.72₄. Radiating fibrous spherulitic aggregates up to 0.2 mm [on barite, *AM* 62:175(1977)]; blue-green with perfect {1010} cleavage. $H \approx 2$. $G = 3.35$. Biaxial (-); $Z \wedge c = 30^\circ$; $N_O = 1.645$, $N_E = 1.751$; $r > v$, strong. *X*, colorless; *Z*, pale green to bluish green. Dissolves in 1:10 HNO_3 with effervescence. Associated with malachite, azurite, and olivenite at *Clara Mine, Black Forest, Germany*. HCWS *AM* 68:471(1983).

16b.4.4.1 Peterbaylissite $\text{Hg}_2(\text{CO}_3)(\text{OH}) \cdot 2\text{H}_2\text{O}$

Named in 1995 for Peter Bayliss, University of Calgary, Alberta, Canada, for his contributions to structural and experimental mineralogy. *ORTH* *Pcab*. $a = 11.130$, $b = 11.139$, $c = 10.725$, $Z = 8$, $D = 7.14$. Structure: *CM* 33:47(1995). Pseudotetragonal. A unique mineral occurrence of Hg^+ ion. There are four cation sites, three occupied by Hg, the fourth C as (CO_3) . Puckered hexagonal sheets with Hg along the edges of the hexagons and CO_3 and H_2O reinforcing bonding between sheets. *PD*: 6.35₄ 4.95₄ 4.84₅ 2.969₇ 2.786₇ 2.648₁₀ 2.419₆ 1.580₂. Clusters and isolated wedge-shaped crystals elongate [001], also platy. Black to dark red-brown, dark brown to black streak, submetallic to adamantine luster, opaque. Resembles specular hematite and magnesiochromite, which also occur at New Idria. Brittle, irregular fracture. $H < 5$. Nonfluorescent. IR confirmed presence of H_2O , (OH), and CO_3 . $N_{\text{av calc}} = 2.10$ (589 nm); in reflected light, gray with blue tinge, nonpleochroic, weakly to moder-

ately bireflectant, internal reflections from yellow-white to orange, weakly anisotropic, dull dark gray and brown. R_1 % (air), R_2 % (oil): 11.4, 12.15; 2.02, 2.35 (470 nm); 10.95, 11.6; 1.88, 2.15 (546); 10.9, 11.5; 1.85, 2.11 (589); 10.7, 11.2; 1.82, 2.04 (650). Becomes transparent without effervescence in 1:1 HCl. Electron microprobe analysis is consistent with composition. Crystals up to 0.2 mm long occur on ferroan magnesite and quartz on a single specimen from the former *Clear Creek mercury mine, New Idria district, San Benito Co., CA.* HCWS

16b.5.1.1 Callaghanite $\text{Cu}_2\text{Mg}_2(\text{CO}_3)(\text{OH})_6 \cdot 2\text{H}_2\text{O}$

Named in 1954 after Eugene Callaghan (1904–1990), director of the New Mexico Bureau of Mines. MON $C2/c$. $a = 10.006$, $b = 11.752$, $c = 8.213$, $\beta = 107.4^\circ$, $Z = 4$, $D = 2.65$. *AM 58:551(1973)*. 11-332: 7.45₁₀ 6.17₁₀ 4.80₆ 3.87₉ 3.72₆ 3.18₉ 2.67₆ 2.30₇. Encrustations, tiny disseminated monoclinic crystals showing {111}, $\{\bar{1}\bar{1}\bar{1}\}$, {221}, $\{\bar{2}\bar{2}\bar{1}\}$, and veinlets. Blue, white streak, vitreous luster, transparent. Cleavage {111}, $\{\bar{1}\bar{1}\bar{1}\}$, perfect; irregular fracture; brittle. $H = 3\text{--}3\frac{1}{2}$. $G = 2.71$. Biaxial (-); $N_x = 1.559$, $N_y = 1.653$, $N_z = 1.680$; $2V = 55^\circ$. Occurs in magnesite and dolomite rock in Gabbs Refractory, Inc. mine near *Gabbs, Nye Co., NV.* HCWS *AM 39:316,630(1954)*.

16b.5.2.1 Urancalcarite $\text{Ca}(\text{UO}_2)_3(\text{CO}_3)(\text{OH})_6 \cdot 3\text{H}_2\text{O}$

Named in 1984 for the composition. ORTH $Pbnm$ or $Pbn2_1$. $a = 15.42$, $b = 16.08$, $c = 6.970$, $Z = 4$, $D = 4.10$. *BM 107:21(1984)*. 38-350: 8.06₁₀ 7.00₃ 4.02₈ 3.49₇ 3.28₃ 3.19₅ 2.83₄ 2.10₅. Acicular crystals in radiating aggregates to 4 mm in diameter. Bright yellow. Crystals, elongated on [001], flattened on (100), show {100}, {010}, and {001}. No cleavage. $H \approx 2\text{--}3$. $G = 4.03$. Biaxial (-); $XYZ = abc$; $N_x = 1.660$, $N_y = 1.712$, $N_z = 1.736$; $2V = 67^\circ$. Found on uraninite associated with uranophane, masuyite, and wyartite in *Shinkolobwe, Shaba, Zaire.* HCWS *AM 70:438(1985)*.

16b.5.3.1 Montroyalite $\text{Sr}_4\text{Al}_8(\text{CO}_3)_3(\text{OH},\text{F})_{26} \cdot 10\text{--}11\text{H}_2\text{O}$

Named in 1986 after Monterregian Hill (Mont Royal), a landmark in Montreal, QUE, Canada. Probably TRIC $a' = 7.14$, $c' = 6.55$. *CM 24:455(1986)*. Resembles aluminohydrocalcite. 40-470: 6.57₁₀ 4.00₅ 3.28₆ 3.19₅ 2.86₄ 2.55₄ 2.48₄ 2.36₅. Fibers, lath-shaped 20 μm long, 5 μm wide, radiate from millimeter-size white translucent hemispheres. White, white streak, waxy luster. Polysynthetic twinning noted with EM. No visible cleavage, uneven to splintery fracture, brittle. $H = 3\frac{1}{2}$. $G = 2.667$. TGA/EGA. Biaxial (-); $N_x = 1.51$, $N_y = 1.530$, $N_z = 1.545$; $2V = 80^\circ$; Y parallel to length; X,Z approximately 45° to plane of lath. Found in cavities in a silicocarbonatite sill exposed at *Francon quarry, Montreal, QUE, Canada*, associated with albite, quartz, strontiodresserite, calcite, dawsonite, ankerite, and fluorite. HCWS

SJÖGRENITE: $Mg_6Al_2(CO_3)(OH)_{16} \cdot 4H_2O$

An a^* projection of the structure (simplified) showing two brucite-like layers and an intercalated layer of CO_3 groups. Note neither the differently charged cations in the brucite-like layer, nor the disorder in the CO_3 layer that also includes H_2O are depicted.

SJÖGRENITE-HYDROTALCITE GROUP

The sjögrenite-hydrotalcite minerals conform to the formula

where

A = Mg, Ni

B = Al, Cr^{3+} , Fe^{3+} , Mn^{3+} , Co^{3+}

and crystallize with hexagonal or hexagonal-rhombohedral space groups. The general structure [CCM 35:401(1982)] is composed of two types of layers; a positively charged brucite-type layer $[(A_{1-x}^{2+}B_x^{3+})(OH)_2]$ that is intercalated 1:1 with a negatively charged layer that contains $(CO_3)^{2-}$ groups and molecular water. The trigonal planar $(CO_3)^{2-}$ groups are usually highly disordered, possibly missing, or may be replaced by other anion groups. The H_2O-CO_3 interlayer contributes only to the 00l and 10l diffraction maxima. Subgroups result from the different stacking of the layers.

SJÖGRENITE SUBGROUP: HEXAGONAL

Mineral	Formula	Space Group	a	c	D	
Manasseite	$Mg_6Al_2(CO_3)(OH)_{16} \cdot 4H_2O$	$P6_3/mmc$	6.12	15.324	2.02	16b.6.1.1
Barbertonite	$Mg_6Cr_2^{3+}(CO_3)(OH)_{16} \cdot 4H_2O$	$P6_3/mmc$	6.20	15.6	2.11	16b.6.1.2
Sjögrenite	$Mg_6Fe_2^{3+}(CO_3)(OH)_{16} \cdot 4H_2O$	$P6_3/mmc$	6.22	15.61	2.097	16b.6.1.3

HYDROTALCITE SUBGROUP: RHOMBOHEDRAL

Mineral	Formula	Space Group	a	c	D	
Hydrotalcite	$Mg_6Al_2(CO_3)(OH)_{16} \cdot 4H_2O$	<i>R3m</i> or <i>R3m</i>	6.15	46.5	1.929	16b.6.2.1
Stichtite	$Mg_6Cr_2^{3+}(CO_3)(OH)_{16} \cdot 4H_2O$	<i>R3m</i> or <i>R3m</i>	6.19	46.47	2.11	16b.6.2.2
Pyroaurite	$Mg_6Fe_2^{2+}(CO_3)(OH)_{16} \cdot 4H_2O$	<i>R3m</i> or <i>R3m</i>	6.219	46.83	2.10	16b.6.2.3

HYDROTALCITE SUBGROUP: RHOMBOHEDRAL (cont'd)

Mineral	Formula	Space Group	a	c	D	
Desautelsite	$Mg_6Mn_2^{3+}(CO_3)(OH)_{16} \cdot 4H_2O$	<i>R3m</i> or <i>R3m</i>	6.23	46.78	2.10	16b.6.2.4
Reevesite	$Ni_6Fe_2^{3+}(CO_3)(OH)_{16} \cdot 4H_2O$	<i>R3m</i> or <i>R3m</i>	6.164	45.54	2.89	16b.6.3.1

Comblainite	$Ni_6^{2+}Co_2^{3+}(CO_3)(OH)_{16} \cdot 4H_2O$	<i>R3m</i> or <i>R3m</i>	6.08	45.58	3.16	16b.6.3.3

Note: See honessite and hydrohonessite for SO_4 analogs of reevesite.

Some end-member compositions have both hexagonal and rhombohedral polytypes; that is, they are polymorphs. For example, pyroaurite (hydrotalcite group) is the rhombohedral variation of sjögrenite. Both minerals are composed of $[Mg_6Al_2(OH)_{16}]^{2+}$ layers alternating with $[CO_3 \cdot 4H_2O]^{2-}$ interlayers. Pyroaurite has a different stacking order than sjögrenite but the two layers are identical.

There are many layered structures with similar compositions. Variations include: (1) cationic substitution within the brucitelike layers, (2) anionic substitution in the interlayers, (3) variations in the periodicity of layers, and (4) combinations of the several types of layers leading to mixed-layer minerals. *CCM 35:401(1987)*.

Mineral species with predominantly R^{3+B} (*i.e.*, $Al(OH)_3$ instead of mg plus Al, or $(SO_4)^{2-}$ and Cl^- in addition to $(CO_3)^{2-}$ in the interlayer, or mixed layers and multiple periodicities are reported in classes 16b.7 or class 17). More are anticipated.

16b.6.1.1 Manasseite $Mg_6Al_2(CO_3)(OH)_{16} \cdot 4H_2O$

Named in 1941 after Ernesto Manasse (1875–1922), mineralogist of Florence, Italy. Sjögrenite group, aluminum end member. Dimorphous with hydrotalcite (16b.6.2.1). *HEX* $P6_3/mmc$. $a = 6.12$, $c = 15.324$, $Z = 1$, $D = 2.02$.

NJMM:161(1966). 14-525: 7.67₁₀ 2.60₅ 2.49₃ 2.34₄ 2.17₄ 2.00₄ 1.84₆ 1.52₃. Massive with a foliated or contorted structure, lamellar on {0001}; pyramidal prismatic crystals with triangular cross section, faces striated parallel to cleavage. White, bluish, grayish, or brownish white; transparent luster; greasy feel. Cleavage {0001}, perfect; laminae flexible but not elastic; crushes to talclike powder. $H = 2$. $G = 2.05$. Uniaxial(-); $N_O = 1.524$, $N_E = 1.510$. Occurs in association with hydrotalcite, dolomite, and serpentine minerals in the serpentinites at Amity, Orange Co., NY; at Mt. St.-Hilaire, QUE, Canada; at Nordmark, Snarum, and *Kongsberg, Norway*; in iron ore skarns of Kapaev explosive pipe, southern Siberian platform, Russia. *HCWS DI:658*, *ZVMO 113:47(1984)*, *CCM 35:401(1987)*.

16b.6.1.2 Barbertonite $Mg_6Cr^{3+}(CO_3)(OH)_{16} \cdot 4H_2O$

Named in 1940 for the locality. Sjögrenite group. Dimorphous with stichtite (16b.6.2.2). *HEX* $P6_3/mmc$. $a = 6.20$, $c = 15.6$, $Z = 1$, $D = 2.11$. *CCM 35:401(1987)*. Contorted lamellar-fibrous masses and cross-fiber veinlets. Microcrystals stacked about [0001]. Rose-pink to violet. Cleavage {0001}, perfect. $H = 1\frac{1}{2}$ -2. $G = 2.10$. Uniaxial (-); $N_O = 1.557$, $N_E = 1.529$. Found at Cunningsburgh, Scotland, at *Barberton, Transvaal, South Africa*, and at Dundas, TAS, Australia, in association with stichtite. *HCWS AM 26:196,295(1941)*, *MM 39:377(1973)*.

16b.6.1.3 Sjögrenite $Mg_6Fe^{3+}(CO_3)(OH)_{16} \cdot 4H_2O$

Named in 1940 after Sten Naders Hjalmar Sjögren (1856-1922), mineralogist, National Museum, Stockholm, Sweden. Sjögrenite group, iron end member. Dimorphous with pyroaurite (16b.6.2.3). *HEX* $P6_3/mmc$. $a = 6.22$, $c = 15.61$, $Z = 1$, $D = 2.097$. *NJMM 161(1966)*. 24-1091: 7.8₁₀ 3.9₃ 2.66₁ 2.55₁ 2.39₁ 2.22₁ 1.87₁ 1.58₁. Thin plates {0001}, hexagonal outline, with striated and indistinct faces; plates flexible but not elastic. Yellowish or brownish; waxy to vitreous luster, pearly on cleavages; transparent. $H = 2\frac{1}{2}$. $G = 2.11$. *IR. MSLM 4:271(1974)*. Uniaxial (-); $N_O = 1.573$, $N_E = 1.559$. Pale yellow to colorless. Soluble with effervescence in 1:10 acids. Epitactic overgrowths on pyroaurite crystals from Sterling Hill mine, Ogdensburg, Sussex Co., NJ; with calcite and pyroaurite as hydrothermal product at *Langban, Sweden*; at Yoshikawa, Aichi Pref., Japan. *HCWS AM 26:196,295(1941)*, *DI:659*.

16b.6.2.1 Hydrotalcite $Mg_6Al_2(CO_3)(OH)_{16} \cdot 4H_2O$

Named for the resemblance to talc in its physical properties and its water content. Sjögrenite group, aluminum end member of the hydrotalcite subgroup. Dimorphous with manasseite (16b.6.1.1). *HEX-R* $R3m$ or $R3m$. $a = 6.15$, $c = 46.5$, $Z = 3$, $D = 1.929$. Structure: *NJMM 544(1969)*, *CCM 35:401(1987)*. 41-1428: 16.12₆ 7.84₁ 4.34₁₀ 3.91₈ 2.61₃ 2.52₁ 2.20₁ 1.862₂. 22-700(syn): 7.84₁₀ 3.90₆ 2.60₄ 2.33₃ 1.990₃ 1.541₄ 1.498₃ 1.265₁. Massive with a foliated or contorted lamellar structure on {0001}, lamellar-fibrous or in indistinct plates {0001}. White, sometimes with a brownish tint; white streak;

pearly to waxy luster; transparent. Cleavage {0001}, perfect; laminae flexible but not elastic; crushes to talc-like powder. $H = 2$. $G = 2.06$. Uniaxial (-); $N_O = 1.511$, $N_E = 1.495$; occasionally biaxial due to strain; nonpleochroic. Soluble with effervescence in 1:10 HCl. IR. *MSLM* 4:271(1974). An alteration product of spinel at Somerville, St. Lawrence Co., and at Amity, Orange Co., also in close association with manasseite at Rossie, St. Lawrence Co., and at Antwerp and Oxbow, Jefferson Co., NY; at Vernon, Sussex Co., NJ; at Nordmark, and at *Snarum, Norway*, in an intimate mixture with manasseite as foliated masses in serpentinites; with brucite, pyroaurite, antigorite, and calcite in an asbestos mine, Bashenowo, Ural Mts., Russia; Jianshibao asbestos mine, Sichuan, China. *HCWS* *DI:653*, *AM* 53:1057(1968).

16b.6.2.2 Stichtite $Mg_6Cr_2(CO_3)(OH)_{16} \cdot 4H_2O$

Named in 1910 after Robert Sticht (1856–1922), general manager of Mount Lyell Mining and Railway Co., TAS, Australia. Sjögrenite group, chromium end member in the hydrotalcite subgroup. Dimorphous with barbertonite (16b.6.1.2). *HEX-R* $R3m$ or $R3m$. $a = 6.19$, $c = 46.47$, $Z = 3$, $D = 2.11$. *MM* 39:377(1973). *14-330*: 7.8₁₀ 4.30₁ 3.91₉ 2.60₄ 2.32₃ 1.97₃ 1.540₂ 1.510₂. Massive, in matted and contorted aggregates of plates or fibers and as cross-fiber veinlets; in micaceous scales. Intense lilac to rose-pink; pale to white streak; waxy to greasy, faintly pearly luster; greasy feel; transparent. Cleavage {0001}, perfect; laminae flexible but not elastic. $H = 1\frac{1}{2}$. $G = 2.16$. IR. *MSLM* 4:271(1974). Uniaxial (-); $N_O = 1.545$, $N_E = 1.518$; sometimes biaxial; pleochroic, dark rose pink to lilac, light rose-pink to lilac; positive elongation. Found as blebs or veinlets in serpentinites at Megantic mine, Black Lake, QUE, Canada; at Kaapsche Hoop, Barberton district, Transvaal, South Africa; closely associated with chromite, barbertonite, and antigorite at *Dundas, TAS, Australia*. *HCWS* *DI:655*.

16b.6.2.3 Pyroaurite $Mg_6Fe_2^{3+}(CO_3)(OH)_{16} \cdot 4H_2O$

Named in 1865 in allusion to the golden yellow color that appears on heating to relatively low temperatures. Sjögrenite group, hydrotalcite subgroup. Dimorphous with sjögrenite (16b.6.1.3). *HEX-R* $R3m$ or $R3m$. $a = 6.219$, $c = 46.83$, $Z = 3$, $D = 2.10$. Structure: *AC(B)* 24:972(1968) and also *CCM* 35:401(1987). *25-521*: 7.77₁₀ 3.89₈ 2.62₅ 2.33₅ 1.97₅ 1.76₁ 1.55₂ 1.52₂. Tabular {0001} with lateral faces striated and indistinct, crushes to talc-like powder, also thick tabular {0001} with {0115} alone or with {2025}. Yellowish to brownish white, also green, colorless; white streak; waxy to vitreous, pearly luster; transparent. $H = 2\frac{1}{2}$. $G = 2.12$. Uniaxial (-); $N_O = 1.564$, $N_E = 1.543$; pale yellow, brownish, reddish to colorless; occasionally biaxial with small 2V. A secondary mineral in low-temperature hydrothermal veins and serpentinites. Found at Sterling Hill, Sussex Co., NJ; at Cornwall, Lebanon Co., and Wood's chrome mine, Lancaster Co., PA; at Blue Mont, MD, as a coating on serpentine; in dolomitic rock at Rutherglen, ONT, Canada; in *Långban, Sweden*, as a parallel mixture of sjögrenite and pyroaurite intergrown with

calcite in veins; at Kraubat, Styria, Austria, associated with brucite, aragonite, calcite, hydromagnesite, artinite, and magnesite in serpentine; and at Val Malenco, Lombardy, and Val Ramazzo, Liguria, Italy. HCWS *DI:656*.

16b.6.2.4 Desautelsite $\text{Mg}_6\text{Mn}_2^{3+}(\text{CO}_3)(\text{OH})_{16} \cdot 4\text{H}_2\text{O}$

Named in 1979 after Paul Desautels (1920–1991), curator of minerals and gems, National Museum of Natural History, Smithsonian Institution, Washington, DC. Sjögrenite group, hydrotalcite subgroup. HEX-R *R3m* or *R3m*. $a = 6.23$, $c = 46.78$, $Z = 3$, $D = 2.10$. *AM 64:127(1979)*. 33-869: 7.76₁₀ 3.88₆ 2.62₅ 2.33₆ 1.981₆ 1.768₂ 1.670₂ 1.527₃. See also 44-1446(syn). Euhedral, simple, hexagonal crystals tabular on [0001] with only {0001} and {1010}; usually less than 0.2 mm in diameter. Bright orange, light orange streak. Cleavage {0001}, perfect. $H \approx 2$. $G = 2.13$. Does not fluoresce in UV. Uniaxial (-); $N_O = 1.569$, $N_E = 1.547$, strongly pleochroic. O, deep orange; E, light orange. Readily soluble in fumes of HCl which distinguishes it from pyroaurite, which requires liquid dissolution. Desautelsite solution is deep brown in 1:1 HCl, while pyroaurite is light greenish yellow. Occurs embedded in colorless brucite at *Cedar Hill quarry, Lancaster Co., PA*; abundant in two localities near New Idria, San Benito Co., CA, associated with the highly sheared serpentinized masses that contain talc, antigorite, and chrysotile, where desautelsite forms an orange crust on serpentine fragments and in veins with artinite (Aker's claim). HCWS

16b.6.3.1 Reevesite $\text{Ni}_6\text{Fe}_2^{3+}(\text{CO}_3)(\text{OH})_{16} \cdot 4\text{H}_2\text{O}$

Named in 1967 for Frank Reeves (1896–1986), U.S. geologist, who discovered the Wolf Creek meteorite crater, WA, Australia. Sjögrenite group, hydrotalcite subgroup; see honessite and hydrohonessite, SO_4 equivalents of reevesite. HEX-R *R3m* or *R3m*. $a = 6.164$, $c = 45.54$, $Z = 3$, $D = 2.89$. *AM 56:1077(1973)*. 26-1286: 7.6₁₀ 3.8₅ 2.60₅ 2.30₄ 1.947₄ 1.735₂ 1.541₃ 1.510₃. Hexagonal platelets up to 100 μm in diameter. Greenish or canary yellow. No cleavage. $G = 2.87$. IR. Uniaxial (-); $N_O = 1.735$, $N_E = 1.65$ (Wolf Creek samples); $N_O = 1.72$, $N_E = 1.63$ (Barberton samples). Occurs as hexagonal plates in druses with violarite and millerite in the Ni ore of the Bon Accord area, Barberton Mt. Land, South Africa, associated with minute quartz crystals, thin films of opaline silica, and goethite stains; also as alteration product in cracks and crevices of weathered *Wolf Creek meteorite, WA, Australia*, and in many weathered meteorites. HCWS *AM 52:1190(1967)*.

16b.6.3.2 Takovite $\text{Ni}_6\text{Al}_2(\text{CO}_3)(\text{OH})_{16} \cdot 4\text{H}_2\text{O}$

Named in 1957 for the locality. Sjögrenite group, hydrotalcite subgroup. HEX-R *R3m* or *R3m*. $a = 6.04$, $c = 45.16$, $Z = 3$, $D = 2.79$. *AM 62:458(1977)*. 15-87: 7.57₁₀ 3.77₉ 2.60₄ 2.55₉ 2.38₅ 2.26₈ 1.917₉ 1.708₇. Poorly crystalline massive, plates about 1 μm . Bluish green. Uniaxial; $N_O = 1.605$, $N_E = 1.598$; parallel extinction; positive elongation. DTA, IR. Secondary crust, or fracture filling; most data derived from synthetic preparations and by analogy with Mg, Al

hydroxycarbonates as impure material analyses give variable Ni : Al, CO₃, and H₂O. Zincian variety: "eardleyite." *AM* 62:449(1977). Occurs intimately mixed with other minerals, especially silicates; for example, at Var, France, takovite is associated with boehmite and kaolinite or as a thin green coating on bauxite; with gibbsite, allophane at the contact of limestone and metamorphosed serpentinite at *Takovo, Serbia*; from the Perseverance Mine, Agnew, WA, Australia. *HCWS MA* 13:624(1958), *AM* 57:1559(1972).

16b.6.3.3 Comblainite $\text{Ni}_6^{2+}\text{Co}_2^{3+}(\text{CO}_3)(\text{OH})_{16} \cdot 4\text{H}_2\text{O}$

Named in 1980 for Gordon Comblain (b.1920) of the Musée Royal de l'Afrique Centrale, Tervuren, Belgium, who discovered the mineral. Sjögrenite group, hydrotalcite subgroup. *HEX-R* $R\bar{3}m$ or $R3m$. $a = 6.08$, $c = 45.58$, $Z = 3$, $D = 3.16$. *BM* 103:113(1980). *33-429*: 7.64₁₀ 3.81₅ 2.61₁ 2.57₇ 2.28₅ 1.934₄ 1.519₂ 1.489₃. Cryptocrystalline crusts, turquoise-blue, on altered uraninite. TGA, IR, ESCA used to determine Ni and Co valences. Uniaxial (-); $N_O = 1.690$, $N_E = 1.684$; nonpleochroic, yellow-green. Found in the uranium deposits at *Shinkolobwe, Zaire*, associated with becquerelite, curite, rutherfordine, and heterogenite. *HCWS AM* 65:1065(1980).

16b.6.4.1 Quintinite-2H $\text{Mg}_4\text{Al}_2(\text{OH})_{12}\text{CO}_3 \cdot 3\text{H}_2\text{O}$

Named in 1995 for Quintin Wight (b.1935), Scottish-Canadian amateur mineralogist, micromounter, and author, for his contributions to the study of the minerals of Mt. St.-Hilaire. *HEX* $P6_322$. $a = 10.571$, $c = 15.139$, $Z = 4$, $D = 2.14$. *PD*: 7.57₁₀ 3.78₁₀ 2.60₂ 2.50₂ 2.34₂ 2.17₂ 1.991₂ 1.825₂. Crystals equant to 5 mm or prismatic to 3 mm, hexagonal, trapezohedral. Orange-brown, pale brown; white streak; vitreous luster, transparent. Cleavage {0001}, perfect; brittle. $H = 2$. $G = 2.14$. Uniaxial (+); $N_O = 1.533$, $N_E = 1.533$. O, yellow; E, lighter yellow. From the *Jacupiranga carbonatite, Jacupiranga, SP, Brazil*, in beautiful sharp crystals and groups, which were at first mistakenly believed to be manasseite, associated with dolomite, magnetite, fluorapatite, phlogopite, and pyrrhotite. *HCWS CM*:34(1996).

16b.6.4.2 Quintinite-3T $\text{Mg}_4\text{Al}_2(\text{OH})_{12}(\text{CO}_3) \cdot 3\text{H}_2\text{O}$

Named as for quintinite-2H. *HEX-R* $P3_112$ or $P3_212$. $a = 10.571$, $c = 22.71$, $Z = 6$, $D = 2.14$. *PD*: 7.57₁₀ 3.78₉ 2.57₄ 2.28₄ 1.932₄ 1.524₂ 1.493₂. Crystals hexagonal, tabular, to 1 mm, sometimes so thin as to appear micaceous; also as rosettes. Yellow to pale yellow or colorless, white streak, vitreous luster, transparent. Cleavage {0001}, perfect; brittle. $H \approx 2$. $G = 2.14$. Uniaxial (\pm); $N_O = 1.533$, $N_E = 1.533$. From *Mt. St.-Hilaire, QUE, Canada*, in nepheline syenite, mainly in silicate and carbonate cavities and pegmatites, with microcline, analcime, albite, tetranatrolite, aegirine, siderite, donnayite, kupletskite, ancylite-Ce, and so on. *HCWS CM (in press)*(1996).

16b.6.4.3 Caresite $\text{Fe}_4^{2+}\text{Al}_2(\text{CO}_3)(\text{OH})_{12} \cdot 3\text{H}_2\text{O}$

Named for Steve Cares (b.1909), machinist, and Janet Cares (b.1921), chemist, amateur mineralogists of Sudbury, MA, who found the mineral. **HEX** $P3_112$ or $P3_212$. $a = 10.805$, $c = 22.48$, $Z = 6$, $D = 2.59$. *PD*: 7.49₁₀ 3.75₅ 2.63₄ 2.31₅ 1.948₄ 1.558₂ 1.526₂. Tabular to prismatic crystals, barrel-shaped, to 0.5 mm. Green-brown with black coating of smectite or chamosite, white streak, vitreous luster, transparent. Cleavage {001}, perfect; brittle. $H \approx 2$. $G = 2.59$. Uniaxial (-); $N_O = 1.599$, $N_E = 1.570$. O, pale green; E, green. Mt. St.-Hilaire, QUE, Canada, mainly in silicate and carbonate cavities and nepheline syenite pegmatites, with microcline, analcime, analcite, smectite, and aegirine. *HCWS CM (in press)(1996)*.

16b.6.4.4 Charmarite-2H $\text{Mn}_4^{2+}\text{Al}_2(\text{CO}_3)(\text{OH})_{12} \cdot 3\text{H}_2\text{O}$ **16b.6.4.5 Charmarite-3T** $\text{Mn}_4^{2+}\text{Al}_2(\text{CO}_3)(\text{OH})_{12} \cdot 3\text{H}_2\text{O}$

Named in 1995 for Charles (b.1917) and Marcel (b.1918) Weber, amateur mineralogists of Guilford, CT, who contributed extensively to the knowledge of Mt. St.-Hilaire and also found the mineral. Charmarite-2H: **HEX** $P6_322$. $a = 10.985$, $c = 15.10$, $Z = 4$, $D = 2.50$. *PD*: 7.53₁₀ 3.77₆ 2.58₅ 2.22₄ 1.856₄ 1.586₂ 1.552₄. Hexagonal, tabular crystals, to 0.5 mm. Orange-brown, pale brown, pale blue, colorless, transparent. $H = 2$. $G = 2.47$. Uniaxial (-); $N_O = 1.587$, $N_E = 1.547$. Charmarite-3T: **HEX-R** $P3_112$ or $P3_212$. $a = 10.985$, $c = 22.63$, $Z = 6$, $D = 2.50$. *PD*: 7.55₁₀ 3.77₉ 2.67₇ 2.35₇ 1.973₆ 1.586₃ 1.662₃. Hexagonal prisms, may be fluted with star-shaped cross sections. May be tipped by places of C-2H. Orange brown, pale brown, vitreous, transparent. Uniaxial (-); $N_O = 1.587$. Both polytypes from Mt. St.-Hilaire, QUE, Canada, in silicate and carbonate cavities and in pegmatites in nepheline syenite with microcline, analcime, albite, aegirine, astrophyllite, siderite, rhodochrosite, calcite, and others. *HCWS CM (in press)(1996)*.

16b.7.1.1 Hydromagnesite $\text{Mg}_5(\text{CO}_3)_4(\text{OH})_2 \cdot 4\text{H}_2\text{O}$

Named in 1835 for the composition. **MON** $P2_1/c$. $a = 10.11$, $b = 8.94$, $c = 8.38$, $\beta = 114.5^\circ$, $Z = 2$, $D = 2.25$. *MR 4:18(1973)*. Pseudo-ORTH. Structure: *AC(B) 33:1273(1968)*. 25-513: 9.20₄ 6.40₄ 5.79₁₀ 4.19₃ 3.32₃ 3.14₂ 2.90₈ 2.69₃. Tufted acicular crystals parallel to c flattened parallel to {100}, also massive and loose-granular to chalky; usually multiply twinned across {100}. Colorless or white; vitreous luster in larger grains, also earthy, silky, pearly. Perfect cleavage parallel to {010}; parting parallel to {100}; brittle. $H = 3.5$. $G = 2.24$. Biaxial (+); Z parallel to b ; $X \wedge c = 47^\circ$; $N_x = 1.523$, $N_y = 1.527$, $N_z = 1.545$; 2V moderate. Effervesces in acids. Found in veinlets in serpentines and altered magnesium-rich rocks with opal, calcite, dolomite, magnesite, artinite, deweylite, and pyroaurite. Occurs in old chrome mines, such as Wood's mine, near the town of Texas, and Cedar Hill quarry, State Line district, southern Lancaster Co., PA; in serpentine rock at Sulfur Creek area, Colusa Co., and at New Idria district, CA; with magnesite in valley

bottoms in the Caribou, Atlin, and Kamloops districts, BC, Canada; as an alteration product of brucite in marble-serpentinites, Kraubat, Styria, Austria; in chromite mines in Serbia; as the alteration product in the periclase marbles at Predazzo, southern Tyrol, and at Viu, Lombardy, Italy; at Shabani, Belingwe district, Zimbabwe; at São Felix do Minato mine, BA, Brazil. HCWS *DII:271, AM 39:24(1954)*.

16b.7.1.2 Widgiemoolthaite $(\text{Ni,Mg})_5(\text{CO}_3)_4(\text{OH})_2 \cdot 4-5\text{H}_2\text{O}$

Named in 1993 for the locality. Ni analog of hydromagnesite (16b.7.1.1). MON Space group unknown. $a = 10.06$, $b = 8.75$, $c = 8.32$, $\beta = 114.3^\circ$, $Z = 2$, $D = 3.24$. *AM 78:819(1993)*. Pattern diffuse; fiber bundle analysis shows b axis $\approx 8.8 \text{ \AA}$ and superlattice 62 \AA , approximately seven hydromagnesite layers. Pseudo-orthorhombic, may be twinned. *PD: 9.7₁ 6.30₅ 5.75₁₀ 4.36₄ 4.14₃ 2.87₄ 2.45₂ 2.12₃*. Isolated spheroids to 2 mm in diameter of radiating fibers and up to 1 μm long. Grassy green when massive to blue green; pale blue-green streak; silky luster. Fibrous cleavage, brittle. $G = 3.13$. Biaxial (+); $N_{\text{min}} = 1.630$ parallel to length, fast ($= b$); $N_{\text{max}} = 1.640$ perpendicular to length; 2V high. Reacts weakly with 1:1 HCl, not at all with 1:10 HCl, 1:1 H_2SO_4 . Found along with several other unnamed Ni minerals and gaspēite, carboydite, pecoraite, glaukosphaerite, hydrohonessite, nepouite, kambaldite, nullaginite, otwayite, reevesite, retgersite, takovite, anabergite, and nickeloan paratacamite, in a weathered stockpile at the *132 North nickel mine, 4 km SW of Wudgiemooltha, 80 km S of Kalgoorlie, WA, Australia*. HCWS

16b.7.2.1 Dypingite $\text{Mg}_5(\text{CO}_3)_4(\text{OH})_2 \cdot 5\text{H}_2\text{O}$

Named in 1970 for the locality. Mineral is part of a series of hydrates; see giorgiosite (16b.7.2.2), a higher hydrate, and hydromagnesite (16b.7.1.1), the lower and most stable hydrate. MON $a = 32.6$, $b = 23.8$, $c = 9.45$, $Z = 8$, $D = 2.15$. *23-1218* (Dypingdal, $5\text{H}_2\text{O}$): *15.2₃ 10.6₁₀ 6.34₆ 5.86₉ 4.20₃ 3.16₄ 3.07₄ 2.93₄*. *29-857* (Japan, $8\text{H}_2\text{O}$): *33.2₆ 16.4₄ 10.80₆ 7.35₃ 6.45₆ 5.89₁₀ 4.21₄ 2.93₆*. Globular aggregates with radiating structure, fibrous parallel to c . White to colorless, pearly luster. Fluorescent, light blue; phosphorescent, yellow-green. IR, DTA. Biaxial (+); $N_x = 1.508$, $N_y = 1.510$, $N_z = 1.516$; elongation parallel to Y . Effervescent in cold 1:10 HCl. Dehydrates to hydromagnesite on heating to 150° . Synthesized during production of high-purity magnesia from magnesite; supercell obvious in synthetic preparation. *MM 48:437(1984)*. Found at Sterling Hill mine, Ogdensburg, Sussex Co., NJ; at New Idria district and San Raphael district, Emery Co., CA; in *Dypingdal serpentine-magnesite deposit, Snarum, Norway*, as coatings on fracture surfaces on serpentines or hydrotalcite; at Yoshikawa, Aichi Pref., Japan. HCWS *AM 55:1457(1970)*.

16b.7.2.2 Giorgiosite $\text{Mg}_5(\text{CO}_3)_4(\text{OH})_2 \cdot 6\text{H}_2\text{O}$

Named in 1905 for one of the cones, Giorgios, created during the eruption at Santorin islands in 1866. See also dypingite (16b.7.2.1). *29-858(syn)*: *11.8₁₀ 5.85₄ 4.44₆ 3.38₇ 3.28₇ 2.92₆ 2.62₄ 1.439₇*. Fibrous spherulitic crusts of fine

needles or globular aggregates. White. $G = 2.155\text{--}2.185$. DTA. Biaxial; $N_x = 1.498\text{--}1.501$, $N_z = 1.508\text{--}1.513$; parallel extinction, positive elongation. Synthesized in aqueous environment, temperature $\approx 60^\circ$; phase is a metastable form between nesquehonite and hydromagnesite and more hydrated than dypingite. Occurs on the lava at *Alphroessa, Santorin, Greece*. HCWS *DII:274*, *AM 55:1457(1970)*, *NJMM:196(1975)*.

16b.7.3.1 Rabbittite $\text{Ca}_3\text{Mg}_3(\text{UO}_2)_2(\text{CO}_3)_6(\text{OH})_4 \cdot 18\text{H}_2\text{O}$

Named in 1955 for John Charles Rabbitt (1907–1957), geologist with the U.S. Geological Survey. MON $a = 32.6$, $b = 23.8$, $c = 9.45$, $\beta = 90^\circ$, $Z = 8$, $D = 2.69$. *AM 40:201(1955)*. 7-365: 11.3₅ 8.24₁₀ 7.79₈ 5.83₅ 5.72₅ 4.81₅ 4.71₇ 4.37₈. Fibrous, acicular parallel to c , silky masses. Pale green. Two perfect cleavages parallel to fiber length, also perpendicular (probably {001}), possibly twin gliding as crystals easily deformed on grinding. $H = 2+$. $G \approx 2.6$. Biaxial (+); Y parallel to b ; $Z \wedge c \approx 15^\circ$; $N_x = 1.502$, $N_y = 1.508$, $N_z = 1.525$; $2V \approx 20^\circ$. Soluble in HCl, slowly in H_2O . Found as efflorescence on walls of *Lucky Strike No. 2 mine, Emery Co., UT*. HCWS

16b.7.4.1 Wyartite $\text{Ca}_3\text{U}^{4+}(\text{UO}_2)_6(\text{CO}_3)_2(\text{OH})_{18} \cdot 3\text{--}5\text{H}_2\text{O}$

Named in 1958 after Jean Wyart (1902–1992), mineralogist at the Sorbonne, Paris. ORTH $P2_12_12_1$. $a = 11.25$, $b = 7.08$, $c = 20.98$, $Z = 2$, $D = 4.81$. *AM 45:200(1960)*. 12-635: 10.3₁₀ 5.19₃ 4.26₁ 3.55₁ 3.47₁ 3.36₁ 3.28₁ 3.01₁. Platy {001} small crystals elongated on [010] with {110}. The {001} forms strongly striated parallel to [010]. Black to violet-black, alters greenish; brownish-violet streak; dull, vitreous luster on cleavages, opaque to translucent. Cleavage {001}, perfect; also {010}. $H = 3\text{--}4$. $G = 4.69$. DTA. Biaxial (-); $XYZ = cba$; $N_x = 1.89$, $N_z = 1.91$; $2V = 48^\circ$; negative elongation; strongly pleochroic. X , gray; Y , violet; Z , lavender-blue. Sample alters on standing or in X-ray beam (see 12-636). A product of the alteration of red rims surrounding uraninite at *Shinkolobwe, Shaba, Zaire*. HCWS *AM 44:908(1959)*, *BM 82:80(1959)*.

16b.7.5.1 Brugnatellite $\text{Mg}_6\text{Fe}^{3+}(\text{CO}_3)(\text{OH})_{13} \cdot 4\text{H}_2\text{O}$

Named in 1909 after Luigi Brugnatelli (1859–1928), mineralogist, University of Pavia, Italy. HEX-R $P6_3/mmc$. $a = 5.48$, $c = 16.00$, $Z = 1$, $D = 2.21$. 14-365: 7.93₁₀ 3.96₉ 2.63₅ 2.35₆ 2.00₇ 1.56₄ 1.53₄ 1.30₂. Massive in lamellar or foliated masses of small flakes flattened on {0001}; flakes may have three- or six-sided outline with striations intersecting at 60° . Flesh-pink to yellowish or brownish white, white streak, pearly luster, transparent. Cleavage {0001}, perfect; crushes to talc-like powder. $H \approx 2$. $G = 2.14$. Uniaxial (-); $N_0 = 1.533$, $N_E = 1.510$; pleochroic. O , yellowish red; E , colorless. Found at York R., Bancroft, ONT, Canada; as crusts and coatings along cracks in serpentinites associated with artinite, hydromagnesite, pyroaurite, magnesite, chrysotile, aragonite, and brucite at *Ciappanico in Torre Sita Maria, and Sandrio, Val Malenco, Italy*, and other localities close by, such as at Viu, Val di Lanzo, and

at Cogne, Val d'Aosta, Piedmont, and as an alteration product of brucite at Monte Ramazzo, Liguria. HCWS *DI:660, AM 14:42(1929)*.

16b.7.6.1 Coalingite $\text{Mg}_{10}\text{Fe}_2^{2+}(\text{CO}_3)(\text{OH})_{24} \cdot 2\text{H}_2\text{O}$

Named in 1965 after the locality. HEX-R *R3m*. $a = 6.24$, $c = 74.8$, $Z = 4$, $D = 2.26$. *AM 50:1893(1965)*. see Pyroaurite (16b.6.2.3) Structure: *MM 38:286(1971)*. Layered structure composed of two brucite-like layers and one disordered CO_3 and H_2O layer repeated along c . Mg and Fe have random distributions in the brucitelike layers. Different multiples of the brucitelike layer and other stacking disorders are very probable; resembles sjogrenite structure. *26-1217*: 13.4₄ 6.05₅ 4.20₈ 2.67₃ 2.34₁₀ 1.884₃ 1.712₃ 1.558₅. *34-182(calc)*: 12.4₁₀ 6.23₁ 4.16₅ 3.12₁ 2.67₁ 2.54₁ 2.12₁ 1.899₁. Platy (0001), also equant grains, 0.1 to 0.2 mm; reddish brown, resinous. $H = 1-2$. $G = 2.32$. DTA, TGA, IR. Uniaxial (-); $N_O = 1.588-1.594$, $N_E = 1.560-1.564$; nonpleochroic; some strained plates show undulant extinction, anomalous biaxial (to 20°). Elongate grains oriented normal to plates are length-slow, striated parallel to length, and markedly pleochroic, from deep golden brown to colorless, absorption $O > E$, strong birefringence. Variations may be due to differences in stacking of plates or hydration level. Formed by the weathering of Fe-rich brucite in serpentinites. From the *New Idria serpentinite, Coalinga, Fresno and San Benito Cos., CA*, intimately intermixed with chrysotile or pyroaurite and associated with artinite and hydromagnesite; at Muskox intrusion, Canada. HCWS

16b.7.7.1 Carbonate-Cyanotrichite $\text{Cu}_4\text{Al}_2(\text{CO}_3, \text{SO}_4)(\text{OH})_{12} \cdot 2\text{H}_2\text{O}$

Named in 1963 after the composition and structural similarity to cyanotrichite. ORTH Space group unknown. *16-365*: 10.1₁₀ 5.63₅ 5.03₆ 4.21₁₀ 3.33₆ 2.77₅ 2.51₅ 2.01₆. Fibrous aggregates, plates up to 5 mm long. Pale blue to azure, silky luster. $G = 2.66$. Biaxial (+); $N_x = 1.616$, $N_z = 1.677$; $2V = 55-60^\circ$; $r > v$, strong; negative elongation; parallel extinction; strongly pleochroic. X, colorless; Z, bright blue. Soluble in acids with effervescence. From Chester, Hampton Co., MA; Cole shaft and Lavender pit, Bisbee, Cochise Co., AZ; at *Balasauskandyk, in NW Kara-Tau area, Kazakhstan*, in cleavage surfaces and cavities of weathered vaniferous (Middle Cambrian) shales with gypsum, variscite, volborthite, malachite, aurichalcite, and azurite. HCWS *ZVMO 92:458(1963), AM 49:441(1964)*.

16b.7.8.1 Scarbroite $\text{Al}_5(\text{CO}_3)(\text{OH})_{13} \cdot 5\text{H}_2\text{O}$

Named in 1960 after the locality. See hydroscarbroite (16b.7.9.1) and sjogrenite-hydroतालcite group (16b.6.1.1). TRIC *P1* or *P1*. $a = 9.94$, $b = 14.88$, $c = 26.47$, $\alpha = 98.7^\circ$, $\beta = 96.5^\circ$, $\gamma = 89.0^\circ$, $Z = 4$, $D = 2.03$. Structure: *MM 32:363(1960), 43:615(1980)*. Layers: two gibbsite, $\text{Al}(\text{OH})_3$, and one layer containing $\text{H}_2\text{O}-(\text{CO}_3)$ are stacked along c . *12-627*: 8.66₁₀ 8.34₄ 5.99₅ 5.63₄ 4.91₄ 4.46₄ 4.33₅ 3.72₆. See also *31-18*. Compact thin rhombic plates about 1 μm in size. White. $H = 1-2$. $G = 1.85-2.05$. $N_{av} = 1.509$. Transforms at 130°

to metascarbroite, hydrates to hydroscarbroite on immersion in H_2O . Found at *South Bay, Scarborough, England*, in vertical fissures in sandstone, and probably in the bauxite deposits at Carev Most near Niksic, Montenegro, Yugoslavia. *HCWS AM 43:384(1958), 50:1504(1965); MM 32:353(1960)*.

16b.7.9.1 Hydroscarbroite $\text{Al}_{14}(\text{CO}_3)_3(\text{OH})_{36} \cdot n\text{H}_2\text{O}$

Named in 1960 for the relationship to scarbroite. An inadequately characterized mineral. *42-588(Scarborough): 9.0₁₀ 6.77₃ 6.69₃ 5.72₃ 4.71₅ 4.39₅ 4.07₂ 1.167₅*. Produced when scarbroite stands in humid air (never completely hydrated). Dehydrates to scarbroite in air at 40° or above. Found with scarbroite at *South Bay, Scarborough, Yorkshire, England*. *HCWS MM 32:353(1960)*.

16b.7.10.1 Sharpite $\text{Ca}_2(\text{UO}_2)_6(\text{CO}_3)_5(\text{OH})_4 \cdot 6\text{H}_2\text{O}$

Named in 1938 after R. R. Sharp (1881–1956), English engineer, prospector, and soldier, who discovered the Shinkolobwe uranium deposit in 1915. *ORTH. $a = 21.99$, $b = 15.63$, $c = 4.487$, $Z = 2$, $D = 4.61$. *NJMM:109(1984). 12-164: 11.0₄ 5.34₄ 4.49₁₀ 4.30₄ 3.93₆ 3.18₄ 2.99₆ 2.45₆*. Crusts and aggregates of fine radiating fibers. Light yellowish green to gray-white. $H = 2\frac{1}{2}$. $G > 4.45$. IR, TGA. Biaxial (+); $N_x = 1.633$, $N_z \approx 1.72$; needles parallel extinction; $Z =$ elongation; nonpleochroic; aggregates show pleochroic. X, brownish; Z, greenish yellow. Found with uranophane, curite, vandenbrandite, and becquerelite at *Shinkolobwe, Shaba, Zaire*. *HCWS DII:275, AM 70:220(1985)*.*

16b.7.11.1 Albrechtschraufite $\text{MgCa}_4[(\text{UO}_2)(\text{CO}_3)_3]_2\text{F}_2 \cdot 17\text{H}_2\text{O}$

Named in 1984. *TRIC P1. $a = 13.562$, $b = 13.406$, $c = 11.636$, $\alpha = 115.72^\circ$, $\beta = 107.66^\circ$, $\gamma = 92.86^\circ$, $Z = 2$. *AC(A) 40:C-247(1984)*. A layered structure of $\text{MgCaF}_2[(\text{UO}_2)(\text{CO}_3)_3] \cdot 8\text{H}_2\text{O}$ interconnected into a framework by $[(\text{UO}_2)(\text{CO}_3)_3]$ units, one Ca, five Ca-bonded water molecules, and four lattice water molecules. Found on a specimen of schroëckingerite from *Joachimov, Bohemia, Czech Republic*. *HCWS**

16b.7.12.1 Kambaldaite $\text{Na}_2\text{Ni}_6(\text{CO}_3)_6(\text{OH})_6 \cdot 6\text{H}_2\text{O}$

Named in 1985 for the locality. *HEX P6₃. $a = 10.340$, $c = 6.097$, $Z = 1$, $D = 3.193$. Structure: *AM 70:419(1985). 39-316: 9.03₁₀ 4.49₉ 3.61₄ 2.68₄ 2.58₄ 2.52₄ 2.26₄ 1.970₃*. Needles and prismatic crystals elongated in the c direction and as cryptocrystalline masses in veins, layers, and concretions up to 2 mm. Hexagonal prisms terminated {0001}, occasional pyramids; zoned with clear core, transparent margins giving a "fish-eye" appearance. Emerald green; pale green streak; silky luster on fracture, chalky when massive. $G = 3.18$. Uniaxial (+); $N_0 = 1.65$, $N_E = 1.69$. O, light green; E, emerald green. Found together with gaspeite and aragonite on fracture surfaces in altered primary Ni-sulfide ores now goethitic in the *Otter shoot, Kambalda, WA, Australia*, associated with reevesite, pyrite, pentlandite, pyrrhotite, and millerite. *HCWS**

16b.7.13.1 Roubaultite $\text{Cu}_2(\text{UO}_2)_3(\text{CO}_3)_2\text{O}_2(\text{OH})_2 \cdot 4\text{H}_2\text{O}$

Named in 1970 after Marcel Roubault (b.1905), geologist, University of Nancy, France. TRIC $P\bar{1}$. $a = 7.767$, $b = 6.924$, $c = 7.850$, $\alpha = 92.16^\circ$, $\beta = 90.89^\circ$, $\gamma = 93.48^\circ$, $Z = 1$, $D = 4.71$. *AC(C)* 41:654(1985). 25-318: 7.74₉ 6.88₈ 5.55₁₀ 4.42₅ 3.50₇ 3.45₈ 3.23₈ 3.18₈. Platy (100) crystals in rosettes to 3 mm in diameter. Grass- to apple-green, brilliant to slightly greasy luster. $H \approx 3$. DTA. Biaxial (+); $N_x = 1.700$, $N_y = 1.800$, $N_z = 1.82\text{--}1.84$; $2V_{\text{calc}} = 55^\circ$; pleochroic. X, Y, colorless; Z, yellow green. From the oxidation zone of the U deposit, *Shinkolobwe, Shaba, Zaire*, on pitchblende associated with becquerelite, vandenbrandite, soddyite, and cuprosklodowskite. cs *BM* 93:550(1970), *AM* 57:1912(1972).

16b.7.14.1 Znucalite $\text{Zn}_{12}(\text{UO}_2)\text{Ca}(\text{CO}_3)_3(\text{OH})_{22} \cdot 4\text{H}_2\text{O}$

Named in 1990 for the composition: Zn, U, Ca. TRIC $P\bar{1}$ or $P1$. $a = 12.692$, $b = 25.096$, $c = 11.685$, $\alpha = 89.08^\circ$, $\beta = 91.79^\circ$, $\gamma = 90.37^\circ$, $Z = 4$, $D = 3.09$. *NJMM:393(1990)*. *PD*: 25.10₆ 6.14₈ 3.16₇ 2.73₉ 2.71₁₀ 2.68₆ 1.582₈ 1.556₇. Porous coatings of saucer-shaped aggregates up to 10 cm², sometimes consisting of plates 15 $\mu\text{m} \times 8 \mu\text{m} \times 0.4 \mu\text{m}$. White, light yellow, grayish yellow; silky luster; translucent. Cleavage {010}, perfect. $G = 3.01$. Fluoresces yellow green in UV. IR, TGA. Biaxial (-); $N_x = 1.563$, $N_y = 1.621$, $N_z = 1.621$; $2V_{\text{calc}} \approx 0^\circ$; negative elongation; extinction $\approx 9^\circ$. Soluble in acids with effervescence. An oxidation product of the U dump material at the *Lill mine*, which operated in the second half of the nineteenth century at *Přibram, central Bohemia, Czech Republic*; occurs with gypsum, hydrozincite, aragonite, sphalerite, galena, and pyrite. hcws *AM* 76:1732(1991).

16b.7.15.1 Szymanskiite $\text{Hg}_{16}\text{Ni}_6(\text{CO}_3)_{12}(\text{OH})_{12}(\text{H}_3\text{O})_8 \cdot 3\text{H}_2\text{O}$

Named in 1990 after Jan T. Szymanski (b.1938), crystallographer, CANMET, Ottawa, Canada, who solved the crystal structure. HEX $P6_3$. $a = 17.415$, $c = 6.011$, $Z = 1$, $D = 4.86$. Structure: *CM* 28:703(1990), 28:709(1990). 44-1395: 14.9₁₀ 5.60₁₀ 3.30₈ 3.21₅ 2.70₆ 2.67₆ 2.48₅ 1.751₅. Acicular or prismatic crystals with HEX cross section, up to 0.4 mm long, elongate [0001], major {1010}, minor {0001}, striations parallel to [0001] on {1010}. Light blue-gray, pale blue streak, vitreous luster, transparent. Cleavage {1010}, poor; irregular to conchoidal fracture, brittle. Light sensitive, non-fluorescent. IR. Uniaxial (-); $N_O = 1.795$, $N_E = 1.786$; pleochroic. O, yellowish green; E, bluish green. Whitens but no effervescence in 1:10 HCl. Mineral includes structural water (OH), and H₂O. Crystal sprays of millimeter size in vugs and cavities, also as disseminated crystals within massive quartz matrix that also includes chalcedony, opal, ferroan magnesite, goethite, chromite, and minor chlorite and dolomite. Associated with cinnebar, montroydite, native mercury, edgarbaileyite, and millerite at *Clear Creek HG mine, New Idria district, San Benito Co., CA*. hcws *AM* 76:1731(1991).

Compound Carbonates

17.1.1.1 Tychite $\text{Na}_6\text{Mg}_2(\text{CO}_3)_4(\text{SO}_4)$

Named in 1905 for the Greek for *luck or chance* in allusion to the fact that of about 5000 northupite crystals, the first and one of the last 10 turned out to be tychite. iso *Fd3*. $a = 13.90$, $Z = 8$, $D = 2.59$. Structure: *AC(B) 36:1332(1980)*. 22-479: 4.19₈ 3.19₃ 2.67₁₀ 2.46₄ 2.35₂ 2.01₂ 1.736₂ 1.605₃. Octahedral crystals. White, vitreous luster, transparent. Conchoidal fracture. $H = 4$. $G = 2.456$. Isotropic; $N = 1.508$ (Na), colorless. A chromate analog has been prepared. Occurs with northupite, as, for example, in cuttings from a borehole in a clay bed, *Borax Lake, CA*, also associated with gaylussite, thenardite, pirssonite, and schairerite; in Green River formation, WY, CO, UT; at Lake Kahve, Uganda. HCWS *DII:294*.

17.1.1.2 Ferrotychite $\text{Na}_6\text{Fe}_2(\text{CO}_3)_4(\text{SO}_4)$

Named in 1981 for the composition and analogy to tychite. iso *Fd3*. $a = 13.962$, $Z = 8$, $D = 2.794$. *ZVMO 110:600(1981)*. 35-707: 4.18₉ 2.68₁₀ 2.47₈ 2.36₄ 2.10₃ 1.958₄ 1.614₆ 1.351₄. Small grains (0.5–1 mm) with golden-brown surface film alteration product. Fresh surfaces colorless to light yellow, vitreous luster. Conchoidal fracture. $H = 4$. Strongly magnetic. Isotropic; $N = 1.550$. Found in a drill core at 539 m in southeastern part of *Khibina alkalic massif, Kola Penin., Russia*. HCWS *AM 67:622(1982)*.

17.1.1.3 Manganotychite $\text{Na}_6(\text{Mn,Fe,Mg})_2(\text{CO}_3)_4(\text{SO}_4)$

Named in 1990 for the composition and resemblance to tychite (17.1.1.1) and ferrotychite (17.1.1.2). iso *Fd3*. $a = 13.995$, $Z = 8$, $D = 2.79$. *ZVMO 119:46(1990)*. 43-1482: 4.22₈ 2.70₁₀ 2.47₇ 2.37₃ 2.11₂ 1.959₃ 1.616₃ 1.605₃. Irregular grains up to 1 cm across and massive aggregates to 5 cm. Pale pink, dull vitreous luster. Conchoidal fracture. $H = 4$. $G = 2.70$. Weakly magnetic. IR, DTA. $N = 1.544$. Dissolves slightly in cold H_2O , developing a brown coating, effervesces in 1:10 acids. Found intimately mixed with shortite in the core of hyperalkalic pegmatite veins at *Alluaiv Mt., Lovozero massif, Kola Penin., Russia*, associated with potassium feldspar, cancrinite, aegirine,

villiaumite, cryolite, kogarkoite, trona, sidorenkite, and other minerals. HCWS *AM* 77:448(1992).

17.1.2.1 Leadhillite $Pb_4(CO_3)_2(SO_4)(OH)_2$

Named in 1832 after the locality. Polymorphous with susannite (17.1.3.1) and macphersonite (17.1.4.1). MON $P2_1/a$. $a = 9.09$, $b = 11.57$, $c = 20.74$, $\beta = 90.5^\circ$, $Z = 8$, $D = 6.58$. *AM* 35:985(1950). 35-617: 11.6₆ 6.78₃* 3.57₁₀ 2.94₇ 2.89₆ 2.62₆ 2.11₆ 2.06₆ 1.554₆ *Note*: * line distinguishes leadhillite from susannite. Crystals usually pseudo-hexagonal thin to thick tabular {001} with hexagonal outline, several rhombohedral and pyramidal forms common, also prismatic [001] or equant, massive, granular. [101] when developed shows striations or may be curved. Crystals commonly twinned, twin plane {140}, also contact twins of aragonite type, penetration twins, lamellar twins with composition plane parallel to {142} or {340}. Other twin laws give rise to pseudo-hexagonal groupings. Colorless to white, gray, pale green, pale bluish green, pale blue or yellowish; resinous to adamantine luster, pearly on {001}; transparent to translucent. Cleavage {001}, perfect, easy. Translation gliding on {001}, also twin gliding. Yellowish fluorescence in UV. DTA, IR. *MSLM* 4:273,427(1974). Biaxial (-); $Z = b$; $X \wedge c = -5\frac{1}{2}^\circ$; $N_x = 1.87$, $N_y = 2.00$, $N_z = 2.01$; $r < v$, strong. Soluble with effervescence in HNO_3 , leaving lead sulfate. Exfoliates in hot H_2O . A secondary mineral found in the oxidized zone of lead deposits associated with cerussite, anglesite, lanarkite, caledonite, linarite, and pyromorphite. Pseudomorphs after galena, calcite; calcite and cerussite may form pseudomorphs after leadhillite. Occurs at Loudsville mine, Hampshire Co., MA; found at Joplin, MO; at Lookout and Caledonia mines, Shoshone Co., ID; with lanarkite at Leadville, CO; at Campbell and Cole shafts(!), Bisbee, Cochise Co., Grand Reef mine, Graham Co., Mammoth-St. Anthony mine(!), Tiger, Pinal Co., AZ; in the Tintic district(!), UT; Blue Bell mine, Baker, CA; from the Wanlockhead district and especially from *Susanna mine*(!), *Leadhills, Lanarkshire, Scotland*; at Red Gill, Cumberland, and Matlock, Derbyshire, England; at Nantycagal (Eaglebrook), Pyfed, Wales; at Mala-Calzetta lead mine near Iglesias and Tiny mine in Oriddo V., Sardinia, Italy; at Nertchinsk and Beresovak, Ural Mts., Russia; from the Toroku mine, Miyazaki Pref., Japan; at Djebel Ressay, Tunisia; at Tsumeb mine(!), Namibia; at Dundas and Victoria Magnet mine, Whyte R., TAS, Australia. HCWS *DII*:295.

17.1.3.1 Susannite $Pb_4(CO_3)_2(SO_4)(OH)_2$

Named in 1845 after the locality. Polymorphous with leadhillite (17.1.2.1) and macphersonite (17.1.4.1). HEX-R $R3$. $a = 9.072$, $c = 11.539$, $Z = 3$, $D = 6.534$. *MM* 49:759(1985). 39-372: 11.5₂ 6.52₁* 4.54₇ 3.57₁₀ 2.94₈ 2.62₈ 2.32₅ 2.11₇ 2.07₅. *Note*: * line distinguishes susannite from leadhillite. Acute rhombohedral crystals with {0001}, hexagonal prisms. Colorless to greenish or yellowish. IR. Uniaxial; see leadhillite (17.1.2.1). Found at Mammoth-St. Anthony mine, Tiger, Pinal Co., AZ; at Tintic district, UT; at *Susanna mine, Leadhills*,

Scotland; at Moldawa, Hungary; at Nertschinsk, Siberia, Russia. *HCWS DII:298, CM 10:141(1972), MM 48:295(1984)*.

17.1.4.1 Macphersonite $\text{Pb}_4(\text{CO}_3)_2(\text{SO}_4)(\text{OH})_2$

Named in 1985 for Harry Gordon Macpherson (b.1925), mineralogist at Royal Scottish Museum, Edinburgh, Scotland. Polymorph of leadhillite (17.1.2.1) and susannite (17.1.3.1). *ORTH Pcab*. $a = 10.37$, $b = 23.10$, $c = 9.35$, $Z = 8$, $D = 6.6$. *MM 48:277(1984)*. $38-354$: 4.53_3 3.27_5 3.23_{10} 2.65_9 2.60_3 2.31_3 2.18_3 2.03_3 . Tabular on b , and dumbbell-shaped composite crystals, occasionally pseudo-hexagonal. White, pale amber, colorless in thin flakes; resinous to adamantine luster. Polysynthetic and contact twins. Cleavage $\{010\}$, perfect; uneven fracture. $H = 2\frac{1}{2}-3$. $G = 6.5$. Strong yellow fluorescence in UV (Scottish samples). IR. Biaxial (-); $XYZ = bca$; $N_x = 1.87$, $N_y = 2.00$, $N_z = 2.01$; $2V = 35^\circ$; $r > v$. Effervesces in acids with precipitant PbSO_4 . Occurs at *Leadhills, Lanarkshire, Scotland*, and at *Argentolle mine St.-Prix, Saône-et-Loire, France*, associated with leadhillite, susannite, cerussite, caledonite, pyromorphite, and scotlandite. *HCWS MM 48:295(1984)*.

17.1.5.1 Schröckingerite $\text{NaCa}_3(\text{UO}_2)(\text{CO}_3)_3(\text{SO}_4)\text{F} \cdot 10\text{H}_2\text{O}$

Named in 1783 after Julius Freiherr Schröckinger von Neudenberg (1814–1882), who found and described the U occurrence at Jachymov, Bohemia, Czech Republic. *TRIC P1*. $a = 9.634$, $b = 9.635$, $c = 14.391$, $\alpha = 91.4^\circ$, $\beta = 92.3^\circ$, $\gamma = 120.3^\circ$, $Z = 2$, $D = 2.56$. Structure: *TMPM 35:1(1986)*. $8-397(\text{syn})$: 14.3_3 8.48_7 7.26_{10} 5.42_2 4.80_8 3.36_2 2.88_7 2.39_2 . Clusters or globular aggregates of flexible, pseudo-hexagonal scales up to $1 \text{ mm} \times 0.02 \text{ mm}$, flattened $\{001\}$; crusts, pisolitic; subparallel intergrowths, (001) twinning. Greenish yellow; vitreous luster, pearly on $\{001\}$, transparent. Cleavage $\{001\}$, perfect. $H = 2\frac{1}{2}$. $G = 2.51$. Strongly fluorescent yellow green in UV. DTA. Biaxial (-); $XYZ = cba$; $N_x = 1.489$, $N_y = 1.539$, $N_z = 1.541$; $2V = 25^\circ$; $r < v$; pleochroic. X, colorless; Y, pale yellow; Z, pale green. Extinctions are not parallel to faces, about $1-2^\circ$ off. Loses six H_2O by 75° . Dehydration in stages does not interrupt basic structure. Found as small concretions in gypsumiferous clay and in arkose near Wamsutter, Sweetwater Co., WY; at Shinarump No. 3 mine(!), Seven Mile Canyon, Moab, UT; as efflorescence on walls of Hillside mine, Yavapai Co., AZ, associated with bayleytite, swartzite, andersonite, and gypsum; as an alteration product of uraninite at *Jachymov, Bohemia, Czech Republic*; at *Johanngeorgenstadt, Saxony, Germany*; at *Radhausberg, Bad Gastein, Austria*; at *La Soberania mine, San Isidro, Mendoza Prov., Argentina*. *HCWS DII:236, USGSB 1064:121(1958), AM 44:1020(1959)*.

17.1.6.1 Nasledovite $\text{PbMn}_3\text{Al}_4(\text{CO}_3)_4(\text{SO}_4)\text{O}_5 \cdot 5\text{H}_2\text{O}$

Named in 1975 after B. N. Nasledov (1891–1942) of Russia. $25-438$: 3.26_{10} 2.98_4 2.85_5 2.03_6 2.02_6 1.749_4 1.592_3 1.462_6 . Oolitic up to 3 mm, made of radiating fibers. Snow-white on fresh surfaces but usually covered with dark red/brown film, silky luster. $H = 2$. $G = 3.07$. $N_{av} = 1.591$, fibers give wavy

extinction. Found as fissure fillings along with cerussite in sooty pyrolusite and Fe oxides in polymetallic ore zone in granodiorite at *Sardab, E of Altyn-Topkansk ore field, Kuraminsk Mts., Kazakhstan*. HCWS *DAN-U 45:13(1958)*, *AM 44:1325(1959)*.

17.1.7.1 Motukoreaite $\text{Na}_2\text{Mg}_{38}\text{Al}_{24}(\text{CO}_3)_{13}(\text{SO}_4)_8(\text{OH})_{108} \cdot 56\text{H}_2\text{O}$

Named in 1977 for the Maori name of the locality: Motukorea, meaning "island of the cormorants." *HEX-R R3m*. $a = 9.172$, $c = 33.51$, $Z = 1$, $D = 1.90$ *AM 74:1054(1989)*. Structure: *NJMM: 263(1986)*. Similar to pyroaurite and sjogrenite with two layers: one brucite-like, the other containing Na, SO_4 , CO_3 , and H_2O connected by OH—O hydrogen bonds. *41-1380: 11.3₁₀ 5.59₄ 4.58₃ 3.72₇ 2.58₄ 2.39₃ 2.16₂ 1.924₃*. Fibrous radiating aggregates of hexagonal plates. White. $H = 1-1\frac{1}{2}$. $G = 1.48-1.53$. Nearly isotropic; $N_{\text{av}} = 1.51$. Samples show variable H_2O , as well as CO_3 and SO_4 . It is suggested that the composition of the basaltic glass (lava) and seawater influence the final composition and formation of the mineral. Found as an alteration product in vesicles and filling veinlets as claylike cement in beach rock and basaltic volcanic tuffs on flanks of small extinct basaltic cone at *Brown's Island, (Motukorea) within Waitemata Harbor, New Zealand*; as the rim cement in volcanic breccias in weathered submarine environments. HCWS *AM 63:598(1978)*, *MM 41:389(1977)*, *43:337(1979)*.

17.1.8.1 Canavesite $\text{Mg}_2(\text{CO}_3)(\text{HBO}_3) \cdot 5\text{H}_2\text{O}$

Named in 1978 for the locality. *MON P2/m*. $a = 23.49$, $b = 6.164$, $c = 21.91$, $\beta = 114.91^\circ$, $Z = 12$, $D = 1.79$. *CM 16:69(1978)*. *29-1431: 9.54₁₀ 8.12₄ 7.80₂ 7.53₂ 4.56₂ 3.69₁ 3.33₁ 3.11₂*. Fibers in aggregates, rosettes; fibers elongated in the direction [010]; with several {*h0l*} cleavages. White, vitreous luster. $G = 1.80$. IR, DTA, TG. Biaxial (+); $Z = b$; $N_x = 1.485$, $N_y = 1.494$, $N_z = 1.505$; 2V large. Occurs in fractures in ludwigite and magnetite skarns at the *Vola Gera tunnel, Brosso iron mine, Canavese district, Piedmont, Italy*. HCWS

17.1.9.1 Harkerite $\text{Ca}_{24}\text{Mg}_8[\text{AlSi}_4(\text{O},\text{OH})_{16}]_2(\text{BO}_3)_8(\text{CO}_3)_8(\text{H}_2\text{O},\text{Cl})$

Named in 1948 after Alfred Harker (1859–1939), petrologist, Cambridge University, England. Compare with sakhaite, a borate mineral. Both minerals show marked pseudosymmetry in cubic space group *Fd3m*. *DANS 236:1203(1977)*. *HEX-R R3m*. $a = 18.131$, $\alpha = 33.46^\circ$, $Z = 2$, $D = 3.00$ (rhombohedral cell). Structure: *AM 62:263(1977)*. Ca (in 8- or 10-fold coordination) is in incomplete cubic closest packing with O atoms, Mg octahedral coordination; structural disorder results from mutual replacement of (Si, Al) $\text{O}_4\text{—CO}_3\text{—BO}_3\text{—H}_2\text{O—OH}$ groups. *10-465: 5.22₇ 3.39₆ 3.01₆ 2.84₆ 2.61₁₀ 2.13₈ 1.84₉ 1.51₇*. Simple octahedral crystals. Colorless, vitreous luster. No cleavage. $G = 2.959$. IR. Frequently anomalously biaxial; $N_{\text{av}} = 1.653$. Readily alters to calcite; dissolves with effervescence in acids. Some substitution or disorder of the aluminosilicate, borate, and carbonate groups, OH and H_2O , will influence

the crystalline modification. Occurs at contacts (scarns) of dolomitic limestones with granites; found in association with monticellite, calcite, bornite, chalcocite, magnetite, and diopside in *Camas Malag, Bradford area, Isle of Skye, Scotland*; Alban Hills, Italy; Balkash region, Kazakhstan, Russia; Dadang tin-iron ore deposit, China. *HCWS MM 29:621(1951), AM 51:1820(1966)*.

17.1.10.1 Daqingshanite-(Ce)

Named in 1983 for a mountain, Daqingshan, near the Bayan Obo iron ore deposit, China. *HEX-R R3m, R3m, or R32. a = 10.058, c = 9.225, Z = 3, D = 3.71. G(C) 2:180(1983). 37-455: 3.95₆ 3.16₁₀ 2.52₇ 2.11₅ 2.04₆ 1.941₆ 1.895₄ 1.620₄*. Rhombohedral crystals (0.05 mm) with rounded edges. Pale yellow, white streak, greasy-glassy luster. Cleavage {1011}, perfect; conchoidal fracture. *VHN₂₀ = 335. G = 3.81. Nonfluorescent. IR. Uniaxial (-); N_O = 1.708, N_E = 1.609; colorless. Soluble in 1:10 HCl. Found as monomineralic aggregates in veins cutting dolomite in footwall of Bayan Obo Fe-Nb-REE deposits, Inner Mongolia, China, with benstonite, huntite, strontianite, pyrite, phlogopite, and monazite. HCWS AM 69:811(1984)*.

17.1.11.1 Tundrite-(Ce) Na₃Ce₄(Ti,Nb)₂(CO₃)₃(SiO₄)₂O₄(OH) · 2H₂O

Named in 1963 after the locality, the Lovozero tundra. Solid-solution series with tundrite-(Nd) (17.1.11.2). *TRIC P1. a = 7.57, b = 13.98, c = 5.03, α = 101.5°, β = 70.4°, γ = 101.5°, Z = 2, D = 3.96. SPD 14:304(1969). 25-1188: 13.56₁₀ 6.78₅ 4.52₁ 4.15₁ 3.69₁ 3.62₁ 3.54₁ 3.46₂*. Fine acicular crystals up to 5 mm long with (210) (001) (100) (010); spherules to 15 mm in diameter; radial aggregates to 0.5 cm of flattened prismatic crystals (Khibiny). Brownish yellow, golden green; silky or vitreous luster. Cleavage parallel to (010), distinct; other cleavage perpendicular to *c* and 86° to (010); brittle. *H ≈ 3. G = 3.70. DTA, TGA, IR. Biaxial (+); Z ∩ c = 4°; N_x = 1.743, N_y = 1.80, N_z = 1.88; 2V = 76°; pleochroic. X, pale yellow; Z, greenish yellow. Khibiny sample which contains 10% CO₂, 3.75% H₂O, no SO₄ shows N_x = 1.761, N_z = 1.880, 2V ≈ 90°, Z parallel to elongation. REE variations. Alters to rhabdophane. Occurs in nepheline syenite pegmatites at *Mt. Nepkha, Lovozero tundra, Kola Penin., Russia*, associated with aegirine, lamprophyllite, and ramsayite; in Khibiny massif in a greenstone contact with nepheline syenite associated with aegirine, rinkite, apatite, and fluorite; in the Ilimaussaq alkaline intrusive, southern Greenland. *HCWS AM 50:2097(1965), 59:633(1971); SPC 21:399(1976); DANS 211:128(1973)* (Engl. transl.).*

17.1.11.2 Tundrite-(Nd) Na₃Nd₄(Ti,Nb)₂(CO₃)₃(SiO₄)₂O₄(OH) · 2H₂O

Named in 1968 for the composition and similarity to tundrite-(Ce); end member of the Nd-Ce series. *TRIC P1* by analogy. No data available specifically on high-Nd-containing mineral. Found at the *Ilimaussaq intrusive, Greenland*;

Khibiny massif, Russia. *HCWS AM 53:1780(1968)*, *59:633(1974)*; *DANS 211:128(1973)* (Engl. transl.).

17.1.12.1 Lepersonnite-(Gd)

Named in 1982 for Jacques Lepersonne (b.1909), honorary head of the Department of Geology and Mineralogy, Musée Royale de l'Afrique Centrale, Brussels, Belgium. *ORTH Pnnn* or *Pnn2*. $a = 16.23$, $b = 38.74$, $c = 11.73$, $Z = 2$, $D = 4.01$. *CM 20:231(1982)*. *35-552*: 11.1₁ 8.15₁₀ 6.46₁ 4.06₂ 3.65₇ 3.21₅ 3.00₁ 2.86₄. Crusts and spherules (to 5 mm) of radiating acicular crystals. Bright yellow, transparent, translucent. Nonfluorescent. $G = 3.97$. Biaxial (-); $Y = c$; $N_x = 1.638$, $N_y = 1.666$, $N_z = 1.682$; $2V_{\text{calc}} = 73^\circ$; pleochroic. X, pale yellow; Y, Z, bright yellow. Microprobe analysis: 22.79% SiO₂, 76.14% UO₃, 2.09% Gd₂O₃, 1.07% Dy₂O₃, 0.41% Y₂O₃, 0.09% Tb₂O₃, 0.45% CaO, 4.02% CO₂ (by chromatography), 12.12% H₂O (TGA). Found in a black crust in the lower portion of the oxidation zone at *Shinkolobwe, Shaba, Zaire*, with bijvoetite, sklodowskite, uranophane, becquerelite, rutherfordine, and uraninite. *HCWS AM 68:1248(1983)*.

17.1.13.1 Qilianshanite NaHCO₃ · H₃BO₃ · 2H₂O

Named in 1993 for the locality composition approximate. *MON C2*. $a = 16.119$, $b = 6.928$, $c = 6.730$, $\beta = 100.46^\circ$, $Z = 4$, $D = 1.639$. *AMS 13:97(1993)*. *PD*: 6.36₃ 4.20₁ 3.46₁₀ 3.17₆ 2.61₁ 1.731₂. Aggregates to 4 mm, tabular or prismatic crystals to 2 mm; colorless, white streak, vitreous luster, transparent. Cleavages {100}, {010}, perfect. $H = 2$. $G = 1.706$. Polysynthetically twinned. DTA. Biaxial (-); $X = b$; $Z \wedge c = 9^\circ$; $N_{x \text{ calc}} = 1.351$, $N_y = 1.459$, $N_z = 1.486$; $2V = 50^\circ$. Soluble in H₂O, with effervescence in 1:10 HCl. Occurs at the *Juhongtu boron deposit, SW Qilian Mt. system, Qinghai Prov., China*, associated with quartz, calcite, tinalconite, and nahcolite. *HCWS AM 79:765(1994)*.

17.1.14.1 Mineevite-(Y)

Named in 1992 for D. A. Mineev (1935–1992), Russian mineralogist. Chemical formula not consistent with analysis. *HEX P6₃/M*. $a = 8.811$, $c = 37.03$, $Z = 2$, $D = 2.84$. *ZVMO 121:138(1992)*. *PD*: 2.83₁₀ 2.66₅ 2.53₇ 2.27₉ 1.660₅. Irregular grains 0.5–1.0 cm in diameter. Colorless to pale green or yellow green, vitreous to pearly luster (on cleavage), transparent. Cleavage {0001}, perfect; steplike fracture, brittle. $H = 4$. $G = 2.85$. Fluoresces weakly yellow green in UV. IR, DTA. Uniaxial (-); $N_0 = 1.536$, $N_E = 1.510$. Stable in water, readily decomposed in 1:10 acids with effervescence. Microprobe analysis: 36.9% Na₂O, 7.3% BaO, 5.9% Y₂O₃, 2.3% Gd₂O₃, 1.80% Dy₂O₃, 7.6% SO₃, 1.7% Cl, 1.8% F, 0.95% Sm₂O₃; remainder less than 0.6%: Ce, Nd, Tb, Ho, Er, Yb, CO₂ 30.8; 1.66% H₂O (by difference and not accounted for in formula). Occurs in the interstices of potassium feldspar crystals in the peg-

matites of the Alluaiv Mts., Lovozero massif, Kola Penin., Russia, in association with nahcolite, trona, thermonatrite, sidorenkite, neighborite, aegirine, albite, sphalerite, manganotychite, and others. hcws

17.1.15 Brianyoungite $Zn_{12}(CO_3,SO_4)(OH)_4$

Named in 1993 for Brian Young (b.1947), field geologist with the British Geological Survey, who collected the specimen. ORTH/MON Space group unknown. $a = 15.724$, $b = 6.256$, $c = 5.427$, $\beta \approx 90^\circ$, $Z = 4$, $D = 4.11$. *MM* 57:665(1993). Structurally similar to hydrozincite. *PD*: 15.4₁₀ 7.88₁₀ 5.25₂ 2.71₄ 2.58₂ 2.40₂ 1.565₃. Rosettes of <100 μm composed of thin blades ($\approx 1\text{--}2 \mu\text{m}$) elongate [010] that taper to a sharp point. White, vitreous luster, transparent. Cleavage {100}, perfect; {001}, possible. $G = 3.93\text{--}4.09$. Non-fluorescent. TGA, IR. Biaxial (-); $N_O = 1.635$, $N_E = 1.650$; straight extinction. Readily soluble with effervescence in 1:10 acids. Analysis: 9.90% CO_2 , 6.62% SO_3 . IR: (OH) not H_2O . Occurs with gypsum on rubbly limestone in oxidized zone of *Brownley Hill mine, Nenthead, Cumbria, England*, and on specimens from *Smallcleugh mine, Nenthead*; at the *Bastenberg mine, Ramsbeck, Germany*; at *Vieille, Montagne, Hollogne, Belgium*. hcws *AM* 79:1009(1994).

Nitrates

18.1.1.1 Nitratine NaNO_3

Synonym: soda-niter. Named in 1845 for the composition. *HEX-R R3c*. $a = 5.070$, $c = 16.829$, $Z = 6$, $D = 2.26$. Calcite structure. 7-271(syn): 3.89₁ 3.03₁₀ 2.81₂ 2.53₁ 2.31₃ 2.13₁ 1.90₂ 1.88₁. Rhombohedral crystals; usually massive, granular. Colorless or white, except when tinted by impurities; white streak; vitreous luster. Cleavage {0112}, perfect; conchoidal fracture; rather sectile. $H = 1\frac{1}{2}$ -2. $G = 2.24$ -2.29. Soluble in H_2O . Cooling taste. Uniaxial (-); $N_0 = 1.587$, $N_E = 1.336$. This water-soluble salt commonly occurs as a surface impregnation or efflorescence in arid areas. It is typically associated with gypsum, halite, and other nitrates and sulfates. The only significant deposits occur in a narrow belt about 450 miles long in the deserts of northern Chile, along the virtually rainless eastern slopes of the coast ranges. These deposits, which consist of a near-surface layer from a few inches to a few feet in thickness, and which contain numerous other salts, have supplied important amounts of nitrate for the world's demands. The nitrate rock (known as caliche) also contains iodates, which are the only mineral source of iodine; the iodine is a valuable by-product of nitrate production. In 1988 Chile produced some 750,000 tons of nitrates and 4,000 tons of iodine. Aqua Fria Mt., Brewster Co., TX, veinlets in trachyte; Hidalgo Co., NM; near Homedale, Owyhee Co., UT, in veinlets in rhyolite; Niter Buttes, SE of Lovelock, NV; Armagosa R. and Death Valley, Inyo and San Bernardino Cos., and near Tulare, Tulare Co., CA. Small deposits of nitratine similar to those in Chile occur in the deserts of Bolivia, Peru, North Africa, Egypt, Russia, Kazakhstan, and India. *BM DII:300, AM 55:1500(1970), CG 67:85(1988)*.

18.1.2.1 Niter KNO_3

Name derived from Hebraic *neter*, used in ancient times for alkaline salts extracted by water from vegetable ashes. Synonym: saltpeter. *ORTH Pmcn*. $a = 5.414$, $b = 9.164$, $c = 6.431$, $Z = 4$, $D = 2.11$. Aragonite structure. 5-377(syn): 4.66₂ 3.78₁₀ 3.73₆ 3.03₆ 2.76₃ 2.71₂ 2.66₄ 2.65₆. Thin crusts, or massive, granular, or columnar. Colorless to white or gray, white streak, vitreous

luster. Cleavage {001}, nearly perfect; {010}, good. $H = 2$. $G = 2.10$. Soluble in water. Tastes saline and cooling. Biaxial (-); $N_x = 1.332$, $N_y = 1.504$, $N_z = 1.504$; $2V = 7^\circ$; $r < v$, weak. Niter is a minor constituent in most deposits of nitratine. It is also found in some limestone caves, as in VA, TN, KY, AL, and OH, from which it was mined for the manufacture of gunpowder in the War of 1812 and the Civil War. A massive granular deposit of more than 125 tons was mined from a cave near Lava Station, Socorro Co., NM; North Table Butte, Leucite Hills, WY; Death Valley, CA. *BM DII:303, CG 67:85(1988)*.

18.2.1.1 Nitrobarite $Ba(NO_3)_2$

Named in 1882 for the composition. iso $P2_13$. $a = 8.118$, $Z = 4$, $D = 3.24$. $24-53(\text{syn})$: 4.69₁₀ 4.06₄ 3.32₁ 2.87₃ 2.45₈ 2.34₅ 1.86₂ 1.82₂. Octahedral crystals, twinned on {111} (spinel law). Colorless, white streak, vitreous luster. No cleavage. $H = 3$. $G = 3.25$. Isotropic; $N = 1.571$. Easily soluble in water. Known from one specimen from Chile, presumably from the nitrate deposits. *BM DII:305*.

18.2.2.1 Nitrocalcite $Ca(NO_3)_2 \cdot 4H_2O$

Named in 1835 for the composition. *MON* $P2_1/n$. $a = 14.48$, $b = 9.160$, $c = 6.285$, $\beta = 98.4^\circ$, $Z = 4$, $D = 1.90$. $26-1406(\text{syn})$: 7.72₇ 5.42₇ 5.14₁₀ 4.36₆ 3.58₇ 3.12₆ 2.81₆ 2.31₄. Efflorescent silken tufts and massive. Colorless or white, white streak, vitreous luster. Soft. $G = 1.90$. Biaxial (-); $N_x = 1.465$, $N_y = 1.498$, $N_z = 1.504$; $2V = 50^\circ$. Soluble in water. Tastes sharp and bitter. Occurs as an efflorescence in limestone caves or on calcareous rocks and soils. Mammoth Cave and other caves, KY, Wyandotte Cave, IN, Death Valley, CA; Kuramin Mts., Kyrgyzstan. *BM DII:306, ZVMO 86:403(1957), AC(B) 33:1861(1977)*.

18.2.3.1 Nitromagnesite $Mg(NO_3)_2 \cdot 6H_2O$

Named in 1835 for the composition. *MON* $P2_1/c$. $a = 6.194$, $b = 12.71$, $c = 6.600$, $\beta = 93.0^\circ$, $Z = 2$, $D = 1.64$. $14-101(\text{syn})$: 5.84₅ 4.43₆ 4.15₄ 3.30₁₀ 3.19₄ 2.93₈ 2.69₄ 2.08₃. Efflorescences. Colorless or white, white streak, vitreous luster. Cleavage {110}, perfect. $G = 1.58$. Biaxial (-); $N_x = 1.34$, $N_y = 1.506$, $N_z = 1.504$; $2V = 5^\circ$; $r < v$. Soluble in water. Bitter taste. Associated with nitrocalcite in limestone caves, but definitely identified only from Madison Co., KY. *BM DII:307, AC 14:1296(1961)*.

Nitrates Containing Hydroxyl or Halogen

19.1.1.1 Gerhardtite $\text{Cu}_2(\text{NO}_3)(\text{OH})_3$

Named in 1885 for Charles F. Gerhardt (1816–1856), who first prepared the artificial compound. ORTH $P2_12_12_1$. $a = 5.592$, $b = 6.075$, $c = 13.812$, $Z = 4$, $D = 3.40$. 14-687: 6.91₁₀ 3.45₆ 2.80₆ 2.67₆ 2.62₈ 2.60₇ 2.31₈ 1.92₆. Thick tabular crystals. Emerald green to dark green, light green streak. Cleavage {001}, perfect; {100}, good. $H = 2$. $G = 3.40$ – 3.43 . Biaxial (+); $N_x = 1.703$, $N_y = 1.713$, $N_z = 1.722$; 2V large; $r < v$, very strong; pleochroic. X, Y, green; Z, blue. Insoluble in water, soluble in dilute acid. *United Verde mine, Jerome, AZ*, in cavities in cuprite; Great Australia Mine, Cloncurry, Q, Australia; Likasi, Shaba, Zaire. BM *DII:308, ZK 116:210(1961)*.

19.1.2.1 Buttgenbachite $\text{Cu}_{19}\text{Cl}_4(\text{NO}_3)_2(\text{OH})_{32} \cdot 2\text{H}_2\text{O}$

Named in 1925 for Henri J. Buttgenbach (1874–1964), Belgian mineralogist. HEX $P6_3/mmc$. $a = 15.82$, $c = 9.14$, $Z = 2$, $D = 3.44$. 8-136: 13.7₁₀ 7.95₁₀ 3.27₈ 2.75₉ 2.61₆ 2.51₈ 2.30₁₀ 1.62₉. Minute flat needles. Azure-blue, blue streak, vitreous luster. $H = 3$. $G = 3.42$. Uniaxial (+); $N_0 = 1.738$, $N_E = 1.752$; non-pleochroic, blue. Mildren and Steppe claims, Pima Co., AZ; Great Australia mine, Cloncurry, Q, Australia; Likasi, Shaba, Zaire, in cavity in cuprite. BM *DII:572, MM 39:264(1973)*.

19.1.3.1 Sveite $\text{KAl}_7(\text{NO}_3)_4\text{Cl}_2(\text{OH})_{16} \cdot 8\text{H}_2\text{O}$

Named in 1980 for Sociedad Venezolana de Espeleologia. MON Space group unknown. $a = 10.89$, $b = 13.04$, $c = 30.71$, $\beta = 92.1^\circ$, $Z = 6$, $D = 2.20$. 33-986: 10.2₁₀ 6.17₂ 6.00₄ 4.21₂ 3.69₄ 3.27₂ 2.75₂ 2.44₆. Flaky aggregates. White. Cleavage {001}, perfect. Soft. $G = 2.0$. Biaxial (+); $N_x = 1.501$, $N_y = 1.503$, $N_z = 1.535$; 2V small. *Autana Cave, Amazonas Terr., Venezuela*, as crusts and efflorescences on the walls. BM *AM 67:1076(1982)*.

19.1.4.1 Mbobomkulite $(\text{Ni,Cu})\text{Al}_4(\text{NO}_3\text{SO}_4)_2(\text{OH})_{12} \cdot 3\text{H}_2\text{O}$

Named in 1980 for the locality. MON $P2_1$. $a = 10.171$, $b = 8.865$, $c = 17.145$, $\beta = 95.37^\circ$, $Z = 4$, $D = 2.34$. 35-696: 8.55₁₀ 7.87₂ 4.55₂ 4.27₄ 3.18₂ 3.05₂ 2.51₂ 2.00₂. Powdery nodules. Sky blue. $G = 2.30$. Cleavage {001}, perfect. $N_x = 1.515$, $N_z = 1.585$. *Mbobo Mkulu cave, Nelspruit district, South Africa*, as friable nodules in allophane. BM *AM 67:415(1982)*.

19.1.4.2 Hydrombobomkulite $(\text{Ni,Cu})\text{Al}_4(\text{NO}_3\text{SO}_4)_2(\text{OH})_{12} \cdot 14\text{H}_2\text{O}$

MON Space group unknown. $a = 10.145$, $b = 17.155$, $c = 20.870$, $\beta = 90.55^\circ$, $Z = 8$. 35-697: 10.45₁₀ 6.23₁ 5.23₅ 4.90₁ 3.49₃ 3.13₁ 2.79₁ 2.49₂. Blue nodules. Dehydrates in the atmosphere in a few hours to mbobomkulite. BM AM 67:415(1982).

19.1.5.1 Likasite $\text{CuNO}_3(\text{OH})_6 \cdot 2\text{H}_2\text{O}$

Named in 1955 for the locality. ORTH *Pcmn*. $a = 5.830$, $b = 6.775$, $c = 21.711$, $Z = 4$, $D = 2.89$. 30-497: 10.8₈ 5.75₁₀ 3.23₆ 3.18₆ 2.72₇ 2.66₆ 2.52₇ 2.17₇. Tabular crystals and massive. Blue. Cleavage {001}, perfect. $G = 2.97$. Biaxial (-); $N_x = 1.615$, $N_z = 1.685$; pleochroic. X, green-blue; Z, pale blue. *Likasi mine, Shaba, Zaire*. BM BM78:84(1955), NJMM: 101(1986).

Compound Nitrates

20.1.1.1 Darapskite $\text{Na}_3(\text{NO}_3)(\text{SO}_4) \cdot \text{H}_2\text{O}$

Named in 1891 for Ludwig Darapsky (b.1857), Chilean chemist and mineralogist. MON $P2_1/m$. $a = 10.571$, $b = 6.917$, $c = 5.189$, $Z = 2$, $D = 2.20$. $23-1408(\text{syn})$: 10.3_{10} 4.13_2 3.53_2 3.46_4 3.27_2 2.87_3 2.86_3 2.59_3 . Tabular crystals, platy masses, and granular; crystals twinned on $\{100\}$, frequently polysynthetic. Colorless, white streak, vitreous luster. Cleavage $\{100\}$, perfect; $\{010\}$, good; uneven fracture; brittle. $H = 2\frac{1}{2}$. $G = 2.20$. Biaxial (-); $N_x = 1.388$, $N_y = 1.479$, $N_z = 1.486$; $2V$ small; $r > v$, strong. A widespread mineral in the Chilean nitrate deposits; also Chuquicamata Cu deposit, Chile, in veins; Flower Cave, Big Bend National Park, TX, and Death Valley, CA, associated with nitratine and niter; Roberts Massif, Shackleton Glacier, Antarctica, in saline arid soil. BM *DII:309*, *AM 55:1500(1970)*, *MM 41:548(1977)*, *CG 67:85(1988)*.

Anhydrous and Hydrated Iodates

21.1.1.1 Lautarite $\text{Ca}(\text{IO}_3)_2$

Named in 1891 for the locality. MON $P2_1/n$ or $P2_1/c$. $a = 7.148$, $b = 11.304$, $c = 7.280$, $\beta = 106.36^\circ$, $Z = 4$, $D = 4.588$. Structure: *AC(B) 34:84(1978)*. 28-221(syn): 4.36₅ 3.49₆ 3.43₈ 3.34₄ 3.32₃ 3.16₁₀ 2.84₃ 2.01₃. Crystals short prismatic {001}; in radial or stellate aggregates. Colorless or yellowish. Cleavage {011}, good. $H = 3\frac{1}{2}$ -4. $G = 4.50$. Slightly soluble in water, soluble in HCl with evolution of Cl_2 . Biaxial (+); $Y = b$; $X \wedge c = 25^\circ$; $N_x = 1.792$, $N_y = 1.840$, $N_z = 1.888$; $2V \approx 90^\circ$; $r > v$, moderate. *Pampa del Pique III, Oficina Lautaro, Atacama desert, Antofagasta, Chile*, as crystals coating fractures, or embedded in gypsum bands in the nitrate deposits. RG *DII:312*.

21.1.2.1 Brüggerite $\text{Ca}(\text{IO}_3)_2 \cdot \text{H}_2\text{O}$

Named in 1971 for Juan Brügger M. (1887–1953), Chilean geologist. MON $P2_1/c$. $a = 8.505$, $b = 10.00$, $c = 7.498$, $\beta = 95.25^\circ$, $Z = 4$, $D = 4.267$. *AM 57:1911(1972)*. 26-1405: 4.24₈ 3.74₆ 3.50₈ 3.24₉ 3.05₁₀ 2.52₆ 1.777₆ 1.748₆. Anhedronal columnar crystals. Colorless to bright yellow, vitreous luster. Conchoidal fracture, brittle, $H = 3\frac{1}{2}$. $G = 4.24$. Biaxial (-); $Z = b$; $X \wedge a = 9^\circ$; $N_x = 1.773$, $N_y = 1.797$, $N_z = 1.814$; $2V = 88^\circ$; $r > v$, moderate to strong; negative elongation. *Pampa del Pique III, Oficina Lautaro, Antofagasta, Chile*, in columnar crystals intergrown with nitratine. RG

21.1.3.1 Bellingerite $\text{Cu}_3(\text{IO}_3)_6 \cdot 2\text{H}_2\text{O}$

Named in 1940 for Herman C. Bellinger (1867–1940), American metallurgist, manager of the copper mine at Chuquicamata. TRIC $P1$. $a = 7.256$, $b = 7.950$, $c = 7.856$, $\alpha = 105.01^\circ$, $\beta = 92.95^\circ$, $\gamma = 96.95^\circ$, $Z = 1$, $D = 4.932$. Structure: *AC(B) 30:965(1974)*. 19-393: 3.82₇ 3.72₁₀ 3.57₅ 3.35₉ 3.25₅ 3.17₉ 3.13₅ 3.07₆. Crystals prismatic {001}, somewhat tabular {100}; twinning on {101}, with or without reentrant angles. Light green. Subconchoidal fracture, brittle. $H = 4$. $G = 4.89$. Slightly soluble in hot water, easily so in HCl. In CT gives water with purple fumes of iodine which crystallizes on walls of tube. Biaxial (+); $N_x = 1.890$, $N_y = 1.90$, $N_z = 1.99$; $2V$ medium; $r > v$, strong; absorption $Z > X, Y$. XY, light bluish green; Z, blue-green. *Chuquicamata, Antofagasta, Chile*, as isolated crystals associated with leightonite and gypsum. RG *DII:313*.

Iodates Containing Hydroxyl or Halogen

22.1.1.1 Salesite $\text{Cu}(\text{IO}_3)(\text{OH})$

Named in 1939 for Reno H. Sales (1876–1969), chief geologist, Anaconda Copper Mining Co. ORTH *Pnma*. $a = 10.794$, $b = 6.708$, $c = 4.781$, $Z = 4$, $D = 4.900$. *AM* 63:172(1978). 22-236: 5.38₄ 4.37₁₀ 3.66₇ 2.70₅ 2.65₃ 2.39₆ 1.89₃ 1.79₆. Crystals stout prismatic {001} with pyramidal terminations. Bluish green, vitreous luster. Cleavage {110}, perfect. $H = 3$. $G = 4.77$. Insoluble in H_2O , easily soluble in HNO_3 ; in CT, gives water and copious purple fumes of iodine, which crystallizes on the walls of the tube. Biaxial (-); $\text{XYZ} = acb$; $N_x = 1.786$, $N_y = 2.070$, $N_z = 2.075$; $2V = 0-5^\circ$; $r > v$, extreme. X, colorless; Y, light bluish green; Z, bluish green. *Chuquicamata, Antofagasta, Chile*, in oxidized copper ore. *RG AM* 24:388(1939), *DII*:315, *AC* 15:1105(1962).

22.1.2.1 Seeligerite $\text{Pb}_3(\text{IO}_3)\text{OCl}_3$

Named in 1971 for Erich Seeliger, German mineralogist, Technical University, Berlin. ORTH (pseudo-TET) *C222*₁. $a = 7.964$, $b = 7.964$, $c = 27.288$, $Z = 8$, $D = 7.052$. *AM* 57:327(1972). 25-450: 3.65₈ 3.21₁₀ 2.81₆ 2.78₈ 1.99₈ 1.75₈ 1.69₈ 1.62₉. Crystallizes in thin plates. Bright yellow. Cleavage {001}, perfect; {110}, good. $G_{\text{syn}} = 6.83$. Biaxial (-); $N_x = 2.12$, $N_y = 2.32$, $N_z = 2.32$; $2V = 4^\circ$. *Santa Ana mine, Caracoles, Sierra Gorda, Chile*, associated with schwartzembergite, paralaurionite, and boleite. *RG NJMM*:210(1971).

22.1.3.1 Schwartzembergite $\text{Pb}_6(\text{IO}_3)_2\text{O}_3\text{Cl}_4$

Named in 1864 for Schwartzemberg, assayer, Copiapó, Chile. ORTH (pseudo-TET) *P4*₂/*nmm*. $Z = 1$, $D = 7.09$. *AM* 55:1814(1970). 24-572: 3.78₆ 2.88₁₀ 2.81₈ 2.09₇ 1.986₆ 1.758₅ 1.677₅ 1.633₉. Rounded, flat-pyramidal crystals, earthy crusts and masses. Yellow, reddish brown; straw-yellow streak; adamantine luster. Cleavage {001}, distinct. $H = 2-2\frac{1}{2}$. $G = 7.39$. Soluble in HCl with evolution of Cl_2 , easily fusible. Biaxial (-); $N_x = 2.25$, $N_y = 2.35$, $N_z = 2.36$ (Li); $2V$ small; dispersion not noticeable. *Cachinal, Atacama desert, Chile*, with cerussite and anglesite on galena. Also from the San Rafael mine, Sierra Gorda, Caracoles district, with paralaurionite, and elsewhere in northern Chile. *RG DII*:317, *NJMM*:467(1970).

Compound Iodates

23.1.1.1 Dietzeite $\text{Ca}_2\text{H}_2\text{O}(\text{IO}_3)_2(\text{CrO}_4)$

Named in 1894 for August Dietze (d. 1893), German chemist, who first described the mineral. MON $P2_1/c$. $a = 10.118$, $b = 7.238$, $c = 13.965$, $\beta = 106.37^\circ$, $Z = 4$, $D = 3.822$. Structure: *CM 31:313(1993)*. *25-132*: 3.61₉ 3.48₁₀ 3.13₁₀ 2.98₆ 2.88₆ 1.870₆ 1.741₅ 1.711₅. Crystals tabular, {100}; elongated, [001]; fibrous crusts; columnar. Deep golden yellow. Cleavage {100}, poor; conchoidal fracture. $H = 3\frac{1}{2}$. $G = 3.62$. Soluble in hot water; solution deposits $\text{Ca}(\text{IO}_3)_2 \cdot 6\text{H}_2\text{O}$ upon cooling. Biaxial (-); $Y = b$; $Z \wedge c = 6^\circ$; $N_x = 1.825$, $N_y = 1.842$, $N_z = 1.857$; $2V = 86^\circ$; $r < v$, very strong, inclined. *Atacama desert, Antofagasta*, and in the *Oficina Maria Elena*, near *Tocopilla, Chile*, with lopezite, tarapacaite, and ulexite in nitrate rock. *RG DII:318*.

23.1.2.1 Fuenzalidaite $\text{K}_6(\text{Na,K})_4\text{Na}_6\text{Mg}_{10}(\text{SO}_4)_{12}(\text{IO}_3)_{12} \cdot 12\text{H}_2\text{O}$

Named in 1994 for Humberto Fuenzalida (1904–1966), Chilean geologist, who planned and directed the first school of geology in Chile at the University of Chile. *HEX-R P3c1*. $a = 9.464$, $c = 27.336$, $Z = 1$, $D = 3.284$. *AM 79:1003(1994)*. *PD*: 13.67₅ 7.05₄ 3.93₁₀ 3.52₂ 3.10₂ 3.02₄ 2.68₃ 2.33₂. Crystals are thin hexagonal plates on (0001), < 0.2 mm. Pale yellow, vitreous luster, transparent. Brittle. $H \approx 2-3$. Slowly soluble in water. Uniaxial (-); $N_O = 1.622$, $N_E = 1.615$. In analyzed material the cation "M" (Na,K) ratio is $(\text{Na}_{2.8}\text{K}_{1.2})$ and in the anions $(\text{S}_{0.95}\text{Se}_{0.05})$. Found in the *Chilean nitrate fields* in veins and veinlets of *caliche blanco* (white nitrate ore) about 1 km S of the former plant site of *Oficina Santa Luisa*. *RG*

23.1.2.2 Carlosruizite $\text{K}_6(\text{Na,K})_4\text{Na}_6\text{Mg}_{10}(\text{SeO}_4)_{12}(\text{IO}_3)_{12} \cdot 12\text{H}_2\text{O}$

Named in 1994 for Carlos Ruiz F. (b.1916), Chilean geologist, Instituto de Investigaciones Geológicas. *HEX-R P3c1*. $a = 9.590$, $c = 27.56$, $Z = 1$, $D = 3.400$. *AM 79:1003(1994)*. *PD*: 13.75₃ 7.10₂ 3.97₂ 3.56₁₀ 3.08₃ 3.06₄ 2.72₄ 2.36₁. Crystals hexagonal, thin plates on (0001), diameter < 0.2 mm. Pale yellow, vitreous luster, transparent. Brittle. $H \approx 2-3$. Slowly soluble in water. Uniaxial (-); $N_O = 1.655$, $N_E = 1.642$. In analyzed material the (Na,K) ratio is $(\text{Na}_{2.6}\text{K}_{1.4})$ and in the anions, $(\text{Se}_{0.54}\text{S}_{0.36}\text{Cr}_{0.10})$. Found in the *Chilean nitrate fields* in material collected long ago, from an unknown locality but probably near *Zapiga*, in samples of iquiqueite obtained by leaching *caliche amarillo* (yellow nitrate ore). *RG*

Anhydrous Borates

24.1.1.1 Sinhalite $MgAlBO_4$

Named in 1952 for *Sinhala*, the Sanskrit name for Sri Lanka. Contains up to 2% Fe_2O_3 . ORTH *Pbnm*. $a = 4.332$, $b = 9.882$, $c = 5.681$, $Z = 4$, $D = 3.45$. Olivine structure. *34-157*: 4.94_4 3.96_3 3.25_7 2.62_6 2.38_4 2.31_5 2.14_{10} 1.62_9 . Water-worn pebbles to 2 cm and massive. Colorless, yellow, pink, brown; white streak; vitreous luster. No cleavage, conchoidal fracture. $H = 7$. $G = 3.49$. Biaxial (-); $N_x = 1.669$, $N_y = 1.698$, $N_z = 1.706$; $2V = 55^\circ$; iron-rich varieties pleochroic in brown. Bodnar quarry, near Hamburg, Sussex Co., NJ; Johnsbury, Warren Co., NY; Bancroft area, ONT, Canada; southern Yakutia, Russia; *Ratnapura area, Sri Lanka*, in gem gravels; Mogok, Burma; Tanzania. *BM MM 29:841(1952)*, *35:196(1965)*; *MR 13:226(1982)*; *EJM 6:313(1994)*.

24.1.2.1 Behierite $(Ta,Nb)BO_4$

Named in 1962 for Jean Behier (1903-1965), French mineralogist. TET *I4₁/amd*. $a = 6.206$, $c = 5.472$, $Z = 4$, $D = 8.02$. Zircon structure. *7-131*: 4.1_6 3.1_8 2.48_5 2.33_6 1.94_6 1.75_4 1.64_6 1.59_{10} . Octahedral crystals to 7 mm. Pink-gray, white streak, adamantine luster. Cleavage $\{110\}$, $\{010\}$, distinct; subconchoidal fracture. $H = 7-7\frac{1}{2}$. $G = 7.86$. Uniaxial (+); $N > 2.0$; strongly birefringent. *Manjaka, Madagascar*, in pegmatite. *BM AM 47:414(1962)*.

LUDWIGITE GROUP

The ludwigite minerals are borates with the general formula

where

$A = Mg, Fe^{2+}, Ni$

$X = Fe^{3+}, Al, Ti, Mg, Mn^{3+}, Sb^{5+}$

and a structure in space group *Pbam*. The structure of these rare minerals is complex and cannot be described adequately in a brief paragraph.

LUDWIGITE: $Mg_2AlO_2(BO_3)$

Layers of Al and BO_3 triangles alternate with layers containing Mg and O. Al and Mg are both octahedral. The packing is efficient and the density is high.

LUDWIGITE GROUP

Mineral	Formula	Space Group	a	b	c	D	
Ludwigite	$(Mg,Fe)_2(Fe,Al)O_2(BO_3)$	<i>Pbam</i>	9.26	12.26	3.05	3.75	24.2.1.1
Vonsenite	$(Fe,Mg)_2(Fe,Al)O_2(BO_3)$	<i>Pbam</i>	9.463	12.305	3.073	4.81	24.2.1.2
Azoproite	$(Mg,Fe)_2(Fe,Ti,Mg)O_2(BO_3)$	<i>Pbam</i>	9.279	12.232	3.001	3.62	24.2.1.3
Bonaccordite	$Ni_2FeO_2(BO_3)$	<i>Pbam</i>	9.213	12.229	3.001	5.19	24.2.1.4
Chestermanite	$Mg_2(Fe,Mg,Al,Sb)O_2(BO_3)$	<i>Pbam</i>	18.525	12.272	3.022	3.65	24.2.1.5
Fredrikssonite	$Mg_2MnO_2(BO_3)$	<i>Pbam</i>	9.18	12.555	2.954	3.80	24.2.1.6

24.2.1.1 Ludwigite $(Mg,Fe)_2(Fe,Al)O_2(BO_3)$

Named in 1874 for Ernst Ludwig (1842–1915), Austrian chemist. Ludwigite group. Forms a series with vonsenite. ORTH *Pbam*. $a = 9.26$, $b = 12.26$, $c = 3.05$, $Z = 4$, $D = 3.75$. 15-797: 5.12₁₀ 2.99₃ 2.55₇ 2.52₇ 2.17₄ 2.12₂ 2.03₅ 1.90₃. Prismatic crystals, radiating plates, and massive, fibrous or granular.

Dark green to brown and black; green-black to black streak; submetallic luster, silky in fibrous material. No cleavage. $H = 5$. $G = 3.82\text{--}4.32$, increasing with Fe content. Biaxial (+); $N_x = 1.805\text{--}1.850$, $N_y = 1.805\text{--}1.865$, $N_z = 1.915\text{--}1.985$; 2V small; $r > v$, extreme; strongly pleochroic, green to brown. Occurs in contact-metamorphic deposits and skarns. Near Philipsburg, Granite Co., MT; Big and Little Cottonwood districts, Salt Lake Co., UT; Texas district, Lemhi Co., ID; Pioche, Lincoln Co., NV; Crestmore, Riverside Co., and Twin Lakes, Fresno Co., CA; near Bancroft, ONT, Canada; Kilbride, Skye, Scotland; Norberg, Sweden; Brosso, Italy; *Moraviczka, Banat, Romania*; many localities in Russia: Ural Mts., Yakutia, Transbaikal, Sayan Mts.; Hol Kol mine, Suan, Korea; Liaoning, northeastern China; Haneyama mine, Fukushima Pref., Japan; Toro Mocho, Morococho, Peru. *BM DII:321; NJMM:95(1974), 69(1989)*.

24.2.1.2 Vonsenite $(\text{Fe,Mg})_2(\text{Fe,Al})\text{O}_2(\text{BO}_3)$

Named in 1920 for Marcus Vonsen (1879–1954), U.S. mineral collector. Ludwigite group. Forms a series with ludwigite. ORTH *Pbam*. $a = 9.463$, $b = 12.305$, $c = 3.073$, $Z = 4$, $D = 4.81$. $25\text{--}395$: 5.15_3 4.73_1 2.84_1 2.58_{10} 1.94_1 1.60_1 1.54_2 1.40_2 . Short prisms and massive, granular. Black, brown-black streak, metallic luster. No cleavage. $H = 5$. $G = 4.3\text{--}4.8$. Jayville, St. Lawrence Co., NY; *North Hill quarry, Riverside, CA*; Brooks Mt., Seward Peninsula, AK (*pageite*); Christophe mine, Breitenbrunn, Saxony, Germany; Badajoz, Spain; Capo di Bove (*breislakite*) and Mt. Vesuvius, Italy; Kamaishi mine, Iwate Pref., Japan. *BM DII:322; AM 46:786(1961); NJMM:95(1974), 69(1989)*.

24.2.1.3 Azoproite $(\text{Mg,Fe})_2(\text{Fe,Ti,Mg})\text{O}_2(\text{BO}_3)$

Named in 1970 for AZOPRO, acronym for International Geological Association for Study of Deep Zones of the Earth's Crust. Ludwigite group. ORTH *Pbam*. $a = 9.279$, $b = 12.232$, $c = 3.001$, $Z = 4$, $D = 3.62$. $25\text{--}523$: 5.07_8 2.99_4 2.52_{10} 2.32_3 2.16_6 2.11_5 2.02_6 1.90_5 . Prismatic crystals to 2 cm. Black, green-black streak, adamantine luster. Cleavage (possibly parting) $\{010\}$, good; $\{001\}$, less good; conchoidal fracture; brittle. $H = 5\frac{1}{2}$. $G = 3.63$. Biaxial (+); $N_x = 1.799$, $N_y = 1.822$, $N_z = 1.855$; $2V = 80^\circ$; strongly pleochroic. X, pale green; Y, dark green; Z, red-brown. *Tazheranskii massif, Baikal, Russia*, in skarn. *BM ZVMO 99:225(1970), AM 56:360(1971)*.

24.2.1.4 Bonaccordite $\text{Ni}_2\text{FeO}_2(\text{BO}_3)$

Named in 1974 for the locality. Ludwigite group. ORTH *Pbam*. $a = 9.213$, $b = 12.229$, $c = 3.001$, $Z = 4$, $D = 5.19$. $29\text{--}330$: 5.1_5 4.61_4 2.55_{10} 2.51_{10} 2.33_4 2.11_3 2.03_4 1.90_5 . Microscopic prisms and radiating rosettes. Red-brown. $H = 7$. Biaxial; $N_{\text{calc mean}} \sim 2.2$. *Bon Accord area, Barberton, Transvaal, South Africa*. *BM AM 61:502(1976)*.

24.2.1.5 Chestermanite $Mg_2(Fe,Mg,Al,Sb)O_2(BO_3)$

Named in 1988 for Charles W. Chesterman (1913–1991), U.S. geologist, who discovered the mineral. Ludwigite group. ORTH *Pbam*. $a = 18.525$, $b = 12.272$, $c = 3.022$, $Z = 8$, $D = 3.65$. *CM* 26: 5.11₁₀ 3.07₂ 2.75₃ 2.56₉ 2.48₂ 2.17₆ 2.00₃ 1.71₂. Rare prismatic crystals to 2 mm, usually fibrous or asbestiform. Gray-green to black, gray-green streak, vitreous to silky luster. No cleavage, conchoidal to uneven fracture. $H = 6$. $G = 3.72$. Biaxial (+); $N_x = 1.753$, $N_y = 1.763$, $N_z = 1.791$; $2V = 63^\circ$; pleochroic. X, dark blue-green; Y, green; Z, pale yellow-brown. *Twin Lakes region, Fresno Co., CA*. BM *CM* 26:911(1988).

24.2.1.6 Fredrikssonite $Mg_2MnO_2(BO_3)$

Named in 1983 for Kurt A. Fredriksson (b.1926), Swedish–U.S. geochemist. Ludwigite group. Polymorphous with pinakiolite, orthopinakiolite, and takēuchiite. ORTH *Pbam*. $a = 9.18$, $b = 12.555$, $c = 2.954$, $Z = 4$, $D = 3.80$. *38-412*: 5.16₈ 2.59₁₀ 2.49₉ 2.20₃ 2.01₅ 1.90₂ 1.57₃ 1.51₄. Small prismatic crystals. Red-brown, yellow to brown streak, vitreous luster. Poor cleavage. $H = 6$. $G = 3.84$. Biaxial (+); $N_x = 1.82$, $N_y = 1.86$, $N_z = 1.99$; $2V = 51^\circ$; strongly pleochroic. X, golden brown; Z, dark red-brown to black. *Langban, Varmland, Sweden*, in dolomite. BM *AM* 71:227(1986), *CM* 32:397(1994).

24.2.2.1 Warwickite $(Mg,Fe)_3TiO_2(BO_3)_2$

Named in 1838 for the locality. May contain up to 13% Cr_2O_3 and 2% Al_2O_3 . ORTH *Pnam*. $a = 9.236$, $b = 9.444$, $c = 3.001$, $Z = 2$, $D = 3.40$. *12-171*: 6.68₄ 4.25₄ 2.99₄ 2.58₁₀ 2.10₄ 1.60₅ 1.55₄ 1.50₅. Prismatic crystals to 3 cm. Dark brown to black, blue-black streak, pearly to adamantine luster. Cleavage {100}, perfect; uneven fracture; brittle. $H = 3\frac{1}{2}$ –4. $G = 3.35$. Biaxial (+); $N_x = 1.772$ –1.808, $N_y = 1.773$ –1.813, $N_z = 1.792$ –1.827; $2V$ small and variable; pleochroic in shades of brown. Near *Warwick, Orange Co., NY*, in marble; *Twin Lakes area, Fresno Co., CA*; *Bancroft area, ONT, Canada*; *Jumilla, Murcia Prov., Spain*; *Taiga deposit, southern Yakutia, Russia*; *Hol Kol mine, Korea*. BM *DII*:326; *AM* 59:985(1974), 76:1380(1991).

24.2.2.2 Yuanfulite $(Fe,Mg,Al,Ti)_4O_2(BO_3)_2$

Named in 1994 for Yuan Fuli (1893–1987), Chinese geologist. ORTH *Pnam*. $a = 9.258$, $b = 9.351$, $c = 3.081$, $Z = 2$, $D = 3.80$. *AM* 81: 6.56₂ 4.18₄ 2.96₃ 2.57₁₀ 2.09₂ 1.59₂ 1.55₂. Prismatic crystals to 1 mm. Black, brown-black streak, adamantine to submetallic luster. Cleavage {100}, perfect. $H = 5$ –6, $VHN_{50} = 843$. In RL, pale gray with red-brown internal reflections, weakly anisotropic; $R = 9.7$ (540 nm). In metamorphosed marble in the *Zhuanmiao deposit, Liaoning Prov., China*. BM *APM* 13:328(1994), *AM* 81:252(1996), *MR* 27:204(1996).

24.2.3.1 Hulsite (Fe,Mg)₂(Fe,Sn)O₂(BO₃)

Named in 1908 for Alfred Hulse Brooks (1871–1924), U.S. geologist. MON *P2/m*. $a = 10.695$, $b = 3.102$, $c = 5.431$, $\beta = 94.21^\circ$, $Z = 2$, $D = 4.54$. 17-511: 5.35₇ 4.99₄ 2.66₁₀ 2.59₇ 2.49₄ 2.37₂ 2.35₂ 2.04₅. Small rectangular crystals and tabular masses. Black, black streak, vitreous to submetallic luster. Cleavage {110}, good. H = 6. G = 4.57. *Brooks Mt., Seward Peninsula, AK*. BM *DII:326, NJMM:95(1974), AM 61:116(1976)*.

24.2.3.2 Magnesiohulsite (Mg,Fe)₂(Mg,Fe,Sn)O₂(BO₃)

Named in 1985 for the composition. MON *P2/m*. $a = 10.70$, $b = 3.06$, $c = 5.45$, $\beta = 94.6^\circ$, $Z = 2$, $D = 4.15$. 41-1374: 5.32₇ 2.67₁₀ 2.56₉ 2.47₈ 2.35₅ 2.13₆ 2.02₈ 1.97₆. Aggregates of microscopic needles. Black, dark brown streak, submetallic luster. H = 6. G = 4.18. Biaxial; $N_x = 1.88$, $N_z = 1.95$; strongly pleochroic. X, dark green; Z, dark brown. *Qiliping, Changning Co., Hunan, China*, in skarn. BM *AM 73:929(1988)*.

24.2.4.1 Pinakolite Mg₂MnO₂(BO₃)

Named in 1890 from the Greek for *small tablet*, in allusion to the morphology. MON *C2/m*. $a = 21.79$, $b = 5.977$, $c = 5.341$, $\beta = 95.63^\circ$, $Z = 8$, $D = 4.09$. 36-413: 5.42₈ 2.70₉ 2.51₁₀ 2.16₄ 1.99₆ 1.62₄ 1.52₅ 1.50₄. Thin rectangular tablets. Black, gray-brown streak, metallic luster. Cleavage {010}, good; very brittle. H = 6. G = 3.88. Biaxial (-); $N_x = 1.908$, $N_y = 2.05$, $N_z = 2.065$; $2V = 32^\circ$; $r < v$; pleochroic. X, red-brown; Y, nearly opaque; Z, yellow-red. *Långban, Värmland, Sweden*, in dolomite. BM *DII:324, AM 59:985(1974)*.

24.2.5.1 Orthopinakolite Mg₂MnO₂(BO₃)

Named in 1960 as a dimorph of pinakolite (24.2.4.1). ORTH *Pnnm*. $a = 18.357$, $b = 12.591$, $c = 6.068$, $Z = 16$, $D = 4.06$. 33-656: 5.96₂ 5.19₇ 3.03₃ 2.80₃ 2.60₁₀ 2.53₉ 2.38₂ 2.21₃. Acicular crystals. Black, gray-brown streak, metallic luster. H = 6. G = 4.03. *Långban, Värmland, Sweden*, in dolomite. BM *AKMG 2:551(1960), AM 46:768(1961), CM 16:475(1978)*.

24.2.6.1 Takeuchiite Mg₂MnO₂(BO₃)

Named in 1980 for Yoshio Takeuchi (b.1924), Japanese mineralogist. ORTH *Pnnm*. $a = 27.585$, $b = 12.561$, $c = 6.027$, $Z = 24$, $D = 3.93$. 33-864: 5.20₉ 3.02₇ 2.73₇ 2.60₉ 2.53₆ 2.21₇ 2.04₈ 1.51₁₀. Acicular crystals to 8 mm. Black, brown streak, metallic luster. Uneven fracture. H = 6. *Långban, Värmland, Sweden*, in dolomite. BM *AM 65:1130(1980), ZK 181:135(1987)*.

24.2.7.1 Blatterite (Mn,Mg)₂(Mn,Sb)O₂(BO₃)

Named in 1988 for Fritz Blatter (b.1943), German mineral collector, who discovered the mineral. ORTH *Pnnm* or *Pnn2*. $a = 37.693$, $b = 12.620$, $c = 6.254$, $Z = 32$, $D = 4.35$. *NJMM: 5.24₅ 2.72₄ 2.63₃ 2.60₁₀ 2.52₃ 2.09₄ 1.56₃ 1.54₃*. Prismatic crystals to 5 mm. Black, brown streak, submetallic to

metallic luster. Cleavage {001}, perfect. $H = 6$. $G = 4.7$. Biaxial (-); $N_x = 1.91$, $N_y = 1.97$, $N_z = 2.00$. *Kittel mine, Varmland, Sweden*. BM *NJMM:121(1988)*, *AM 74:1399(1989)*.

24.3.1.1 Sassolite H_3BO_3

Named in 1800 for the locality. TRIC *P1*. $a = 7.039$, $b = 7.053$, $c = 6.578$, $\alpha = 92.58^\circ$, $\beta = 101.17^\circ$, $\gamma = 119.83^\circ$, $Z = 4$, $D = 1.50$. 25-97: 6.06₅ 6.03₅ 5.91₁₀ 2.96₅ 2.92₅ 2.84₇ 2.26₆ 2.23₅. Tabular pseudo-hexagonal crystals. White to gray, white streak, pearly luster. Cleavage {001}, perfect. Acid taste, slightly saline and bitter. $H = 1$. $G = 1.48$. Biaxial (-); $N_x = 1.340$, $N_y = 1.456$, $N_z = 1.459$; $2V = 17^\circ$. Wichita Mts., Comanche Co., OK; in borate deposits at Boron and Death Valley, and at Sulphur Bank and the Geysers, Lake Co., CA; *Sasso, Tuscany*, deposited by hot-spring vapors, and in fumaroles at Vulcano, Vesuvius, and Solfatara, *Italy*; Bezymyanni volcano, Kamchatka, Russia; Iwo-dake volcano and other localities in Japan. BM *DI:662*, *AM 42:56(1957)*.

24.3.2.1 Kotoite $Mg_3(BO_3)_2$

Named in 1939 for Bundjiro Koto (1856–1935), Japanese geologist. ORTH *Pnmm*. $a = 5.401$, $b = 8.422$, $c = 4.507$, $Z = 2$, $D = 3.09$. 38-1475(syn): 3.46₂ 2.67₁₀ 2.32₃ 2.23₇ 2.18₈ 1.73₅ 1.67₅ 1.52₃. Massive, granular. Colorless or white, white streak, vitreous luster. Cleavage {110}, perfect; parting {101}. $H = 6\frac{1}{2}$. $G = 3.10$. Biaxial (+); $N_x = 1.652$, $N_y = 1.653$, $N_z = 1.673$; $2V = 21^\circ$; $r > v$. Big Cottonwood mine, Brighton, UT; Jumbo Mt., Snohomish Co., WA; Baita Bihor, Romania; Korotov deposit, Transbaikal, Russia; *Hol Kol mine, Suan, Korea*, in contact-metamorphosed dolomite; Neichi mine, Iwate Pref., Japan. BM *DII:328*.

24.3.2.2 Jimboite $Mn_3(BO_3)_2$

Named in 1963 for Kotora Jimbo (1867–1924), founder of the Mineralogical Institute, University of Tokyo. ORTH *Pnmm*. $a = 5.663$, $b = 8.714$, $c = 4.651$, $Z = 2$, $D = 4.09$. 19-781: 4.1₂ 2.78₁₀ 2.59₅ 2.46₂ 2.33₄ 1.80₃ 1.73₄ 1.53₂. Probably massive. Pale purple-brown, white streak, vitreous luster. Cleavage {110}, perfect; parting {101}. $H = 5\frac{1}{2}$. $G = 3.98$. Biaxial (+); $XY = ab$; $N_x = 1.792$, $N_y = 1.794$, $N_z = 1.821$; $2V = 35^\circ$; $r > v$. *Kaso mine, Tochigi Pref., Japan*. BM *AM:1416(1963)*.

24.3.3.1 Nordenskiöldine $CaSn(BO_3)_2$

Named for Nils A. E. Nordenskiöld (1832–1901), Swedish mineralogist and Arctic explorer. HEX R *R3*. $a = 4.857$, $c = 16.066$, $Z = 3$, $D = 4.22$. Isostructural with dolomite. 36-394: 5.36₈ 4.07₇ 3.73₈ 2.91₁₀ 2.43₆ 2.21₅ 2.04₆ 1.80₆. Tabular crystals and subparallel growths. Colorless or yellow, white streak, vitreous luster. Cleavage {0001}, perfect; {1011}, indistinct; conchoidal fracture; brittle. $H = 5\frac{1}{2}$ -6. $G = 4.20$. Uniaxial (-); $N_O = 1.778$, $N_E = 1.660$. Brooks Mt., AK; Seagull batholith, YT, Canada; *Arö, Langesundsfjord, Nor-*

way, in syenite pegmatite; Uchkosilkon tin deposit, eastern Kirgizia; Geiju tin deposit, Yunnan, China; Arandis tin deposit, Namibia. BM *DII:332*, *NJMM:111(1986)*, *CM 32:81(1994)*.

24.3.3.2 Tusionite $\text{MnSn}(\text{BO}_3)_2$

Named in 1983 for the locality. HEX-R *R3*. $a = 4.787$, $c = 15.30$, $Z = 3$, $D = 4.78$. Dolomite structure. *35-727*: 5.12_4 4.02_4 3.65_9 2.82_{10} 2.39_6 2.17_4 2.00_6 1.74_8 . Small tabular crystals, and lamellar intergrowths to 1.5 cm. Colorless to yellow-brown, white streak, vitreous luster. Cleavage {0001}, perfect. $H = 6$. $G = 4.73$. Uniaxial (-); $N_O = 1.854$, $N_E = 1.757$. Thomas Mt., Riverside Co., CA; Recice, Czech Republic; *Tusion R.*, *Pamir Mts.*, *Tajikistan*, in granite pegmatite. BM *DANS 272:1449(1983)*, *AM 69:1193(1984)*, *CM 32:903(1994)*.

24.3.4.1 Peprossiite-(Ce) $(\text{Ce,L a})\text{Al}_2(\text{BO}_3)_3$

Named in 1993 for Giuseppe Rossi (1938–1989), Italian mineralogist. HEX *P62m*. $a = 4.610$, $c = 9.358$, $Z = 1$, $D = 3.47$. *EM 5*: 3.67_{10} 3.04_{10} 2.46_8 2.31_5 2.02_5 1.95_5 1.86_5 1.84_5 . Hexagonal plates to 2 mm. Pale yellow, white streak, vitreous luster. Cleavage {0001}, perfect; {1120}, distinct. $H = 2$. $G = 3.45$. Uniaxial (+); $N_O = 1.703$, $N_E = 1.711$. *Sacrofano volcanic center*, *Campagnano*, *Latium*, *Italy*, in pyroclastics. BM *EM 5:53(1993)*.

24.3.5.1 Takedaite $\text{Ca}_3(\text{BO}_3)_2$

Named in 1995 for Hiroshi Takeda (b.1934), Japanese mineralogist. HEX-R *R3c*. $a = 8.638$, $c = 11.850$, $Z = 6$, $D = 3.11$. *MM 59*: 4.65_1 2.92_{10} 2.76_6 2.49_4 2.16_2 2.04_2 1.98_2 1.90_8 . Microscopic granular crystals. White or pale gray, vitreous luster. $H = 4\frac{1}{2}$. $G = 3.10$. Uniaxial (-); $N_O = 1.726$, $N_E = 1.630$. Occurs in limestone skarn at *Fuka*, *Okayama Pref.*, *Japan*. BM *MM 59:549(1995)*.

24.4.1.1 Suanite $\text{Mg}_2\text{B}_2\text{O}_5$

Named in 1953 for the locality. MON *P2₁/a*. $a = 12.31$, $b = 3.120$, $c = 9.205$, $\beta = 104.3^\circ$, $Z = 4$, $D = 2.91$. *16-168*: 4.47_3 2.98_2 2.82_5 2.64_2 2.56_{10} 2.01_6 1.92_3 1.56_2 . Possibly massive. White, white streak, pearly to silky luster. $H = 5\frac{1}{2}$. $G = 2.91$. Biaxial (-); $X = b$; $N_x = 1.596$, $N_y = 1.639$, $N_z = 1.670$; $2V = 70^\circ$; $r > v$, weak. *Hol Kol mine*, *Suan Co.*, *Korea*; *Aldan*, *Yakutia*, *Russia*; *Liaoning*, northeastern China; *Miyako*, *Japan*. BM *MJJ 1:54(1953)*, *AM 40:941(1995)*.

24.4.2.1 Kurchatovite $\text{Ca}(\text{Mg,Mn,Fe})\text{B}_2\text{O}_5$

Named in 1966 for Igor V. Kurchatov (1903–1960), Russian physicist. Dimorphous with clinokurchatovite. ORTH *P2₁2₁2₁*. $a = 11.15$, $b = 36.4$, $c = 5.55$, $Z = 24$, $D = 3.03$. *19-648*: 2.89_4 2.78_{10} 2.67_8 2.26_7 2.01_7 1.92_9 1.63_6 1.23_8 . Massive. Pale gray, white streak, vitreous luster. One perfect cleavage. $H = 4\frac{1}{2}$.

$G = 3.02$. Biaxial (-); $XZ = bc$; $N_x = 1.635$, $N_y = 1.681$, $N_z = 1.698$; $2V = 66^\circ$; $r > v$. Luminesces bright violet in LWUV. *Solongo, Transbaikalia, Russia*, in skarn. BM *ZVMO* 95:203(1966), *AM* 51:1817(1996).

24.4.3.1 Clinokurchatovite $\text{Ca}(\text{Mg}, \text{Mn}, \text{Fe})\text{B}_2\text{O}_5$

Named in 1983 as the dimorph of kurchatovite. MON $P2_1/b$. $a = 12.19$, $b = 10.95$, $c = 5.59$, $\beta = 102.0^\circ$, $Z = 8$, $D = 3.27$. 36-389: 3.09₈ 2.80₁₀ 2.59₅ 2.03₅ 1.99₄ 1.72₄ 1.57₄ 1.24₅. Polysynthetically twinned crystals to 2 mm. White, white streak, vitreous luster. $H = 4\frac{1}{2}$. $G = 3.08$. Biaxial (-); $N_x = 1.644$, $N_y = 1.675$, $N_z = 1.704$; $2V = 82-88^\circ$. *Sayak-IV* and other deposits, *Ural Mts., Russia*, in skarn. BM *ZVMO* 112:483(1983), *AM* 69:810(1984).

24.5.1.1 Metaborite HBO_2

Named in 1964 for the composition. ISO $P43n$. $a = 8.885$, $Z = 24$, $D = 2.49$. 15-868 (syn): 6.28₄ 4.44₁₀ 3.97₄ 3.63₅ 2.81₄ 2.37₃ 2.09₃ 1.94₉. Crystal aggregates showing tetrahedron faces. Colorless to brown, white streak, vitreous luster. $H = 5$. $G = 2.47$. Isotropic; $N = 1.618$. Slowly soluble in water. In a salt deposit, probably in Kazakhstan. BM *ZVMO* 93:329(1964), *AM* 50:261(1965).

24.5.2.1 Calciborite CaB_2O_4

Named in 1956 for the composition. ORTH $Pccn$. $a = 8.38$, $b = 13.81$, $c = 5.00$, $Z = 8$, $D = 2.89$. 27-67: 7.1₆ 3.81₆ 3.57₈ 3.44₁₀ 2.66₆ 2.31₆ 1.98₇ 1.87₇. Radial aggregates. White, white streak, vitreous luster. No cleavage, conchoidal to uneven fracture. $H = 3\frac{1}{2}$. $G = 2.88$. Biaxial (-); $N_x = 1.595$, $N_y = 1.654$, $N_z = 1.670$; $2V = 54^\circ$. Insoluble in water, readily soluble in acids. *Novofrolorsk deposit, Ural Mts., Russia*, in contact-metamorphosed limestone. BM *ZVMO* 85:76(1956), *AM* 41:815(1956).

24.5.3.1 Johachidolite CaAlB_3O_7

Named in 1942 for the locality. ORTH $Cmma$. $a = 7.968$, $b = 11.724$, $c = 4.374$, $Z = 4$, $D = 3.44$. 29-280: 3.99₂ 3.51₂ 2.63₁₀ 2.43₃ 2.00₃ 1.96₅ 1.82₃ 1.75₂. Equant anhedral grains to 1 mm. Colorless, white streak, vitreous luster. No cleavage, subconchoidal fracture. $H = 7\frac{1}{2}$. $G = 3.37$. Biaxial (+); $XYZ = acb$; $N_x = 1.712$, $N_y = 1.717$, $N_z = 1.726$; $2V = 70^\circ$; $r > v$, strong. Fluoresces pale blue in SWUV. *Johachido, Kisshu Co., North Korea*. BM *DII*:384, *AM* 62:327(1977).

24.5.4.1 Diomignite $\text{Li}_2\text{B}_4\text{O}_7$

Named in 1987 from the Greek for *divine mix*. TET $I4_1cd$. $a = 9.470$, $c = 10.279$, $Z = 8$, $D = 2.437$. 18-717(syn): 4.07₁₀ 3.91₂ 3.50₅ 2.66₆ 2.59₄ 2.24₂ 2.09₂ 2.05₄. Microscopic euhedral to anhedral crystals in fluid inclusions in spodumene. Uniaxial (-); $N_O = 1.605$, $N_{E \text{ syn}} = 1.560$. *Tanco pegmatite, Bernic Lake, MB, Canada*. BM *CM* 25:173(1987).

Anhydrous Borates Containing Hydroxyl or Halogen

25.1.1.1 Hambergite $\text{Be}_2(\text{BO}_3)(\text{OH},\text{F})$

Named in 1890 for Axel Hamberg (1863–1933), Swedish mineralogist. A complete series exists between OH and F end members. ORTH *Pbca*. $a = 9.78$, $b = 12.23$, $c = 4.43$, $Z = 8$, $D = 2.37$. 17-475: 4.52₄ 3.81₁₀ 3.16₅ 3.13₉ 2.40₄ 2.21₄ 2.13₄ 2.09₄. Prismatic crystals to 3.5 cm, showing reticulated twinning on {110}. Colorless or white, white streak, vitreous luster. Cleavage {010}, perfect; {100}, good; brittle. $H = 7\frac{1}{2}$. $G = 2.35\text{--}2.37$. Biaxial (+); $XY = ab$; $N_x = 1.543\text{--}1.560$, $N_y = 1.580\text{--}1.591$, $N_z = 1.617\text{--}1.631$; $2V = 84\text{--}90^\circ$; $r > v$, weak. Occurs in granite and syenite pegmatites. Little Three and Himalaya mines, San Diego Co., CA; *Helgaråen, Langesundsfjord, Norway*; Elba, Italy; Susice, Bohemia, and Ctidruzice, Moravia, Czech Republic; Burpala pluton, north Baikal, Russia; Turakuloma Range(*), East Pamirs, Tadjikistan; Drot(*), Gilgit, Pakistan; Betafo(*) and Mt. Bity(*), Madagascar. BM *DII:370, AM 50:85(1965)*.

25.1.2.1 Fluoborite $\text{Mg}_3(\text{BO}_3)(\text{F},\text{OH})_3$

Named in 1926 for the composition. HEX *P6₃/m*. $a = 8.827$, $c = 3.085$, $Z = 2$, $D = 3.01$. 15-667: 7.72₆ 4.46₈ 2.58₆ 2.42₁₀ 2.14₈ 2.13₈ 1.82₆ 1.48₆. Hexagonal prisms to 2 cm, also fibrous, radiating. Colorless or white, white streak, vitreous luster. Cleavage {0001}, good. $H = 3\frac{1}{2}$. $G = 2.85\text{--}2.99$, increasing with F content. Uniaxial (-); $N_O = 1.525\text{--}1.570$, $N_E = 1.504\text{--}1.534$, increasing with OH content. Fluoresces cream in SWUV. Sparta, Hamberg, and Sterling Hill, NJ; Crestmore, Riverside Co., Amboy, San Bernardino Co., and Twin Lakes area, Fresno Co., CA; Bancroft, ONT, Canada; Broadford, Skye, Scotland; Querigut, France; *Tallgruvan, Norberg, Sweden*; Nocera, Italy; Pitkäranta, Karelia, and other localities in Russia; Hol Kol mine, Suan, South Korea; Seilibin, Malaya. Usually in skarn deposits. BM *DII:369, AM 48:678(1963)*, *TMPM 21:94(1974)*, *MR 13:223(1982)*.

25.1.3.1 Frolovite $\text{Ca}[\text{B}(\text{OH})_4]_2$

Named in 1957 for the locality. TRIC *P1*. $a = 7.774$, $b = 5.680$, $c = 8.136$, $\alpha = 113.15^\circ$, $\beta = 101.67^\circ$, $\gamma = 107.87^\circ$, $Z = 2$, $D = 2.17$. 13-453: 6.08₁₀ 3.86₉ 3.47₈ 2.65₆ 2.52₇ 2.36₈ 2.33₇ 2.04₆. Veinlets and irregular masses, replacing calciborite. Gray-white, white streak, dull luster. Brittle. $H = 3\frac{1}{2}$. $G = 2.14$.

Biaxial (+); $N_x = 1.563$, $N_y = 1.572$, $N_z = 1.586$; $2V = 70^\circ$. *Novo-Frolovsk, Turinsk region, Ural Mts., Russia*, in a skarn deposit. BM *ZVMO* 86:622(1957), *AM* 43:385(1958), *DANS* 202:78(1972).

25.1.4.1 Teepleite $\text{Na}_2\text{B}(\text{OH})_4\text{Cl}$

Named in 1939 for John E. Teeple (1874–1931), U.S. chemist, who studied the Searles Lake deposit. TET $P4/nmm$. $a = 7.26$, $c = 4.85$, $Z = 2$, $D = 2.08$. 11-12: 2.90₈ 2.70₁₀ 2.26₇ 2.02₉ 1.82₇ 1.66₈ 1.54₇ 1.40₇. Tabular euhedral crystals to 5 cm. Colorless or white, white streak, vitreous to greasy luster. Alters rapidly to tinalconite on exposure. Irregular to subconchoidal fracture, very brittle. $H = 3-3\frac{1}{2}$. $G = 2.076$. Uniaxial (-); $N_O = 1.519$, $N_E = 1.503$. *Borax Lake, Lake Co., and Searles Lake, San Bernardino Co., CA*. BM *DII:372*, *MR* 6:80(1975), *AC(B)* 38:82(1982).

25.1.4.2 Bandyite $\text{CuB}(\text{OH})_4\text{Cl}$

Named in 1938 for Mark C. Bandy (1900–1963), U.S. mineralogist, who discovered the mineral. TET $P4/n$. $a = 6.14$, $c = 5.58$, $Z = 2$, $D = 2.81$. 12-631: 5.59₁₀ 4.35₆ 4.13₅ 3.08₈ 2.54₈ 1.95₇ 1.66₆ 1.46₅. Thick tabular or equant crystals. Blue, pale blue streak, vitreous luster. Cleavage {001}, perfect. $H = 2\frac{1}{2}$. $G = 2.81$. Uniaxial (-); $N_O = 1.691$, $N_E = 1.641$; pleochroic. O, deep blue; E, pale yellow-green. *Mina Quetena, near Calama, Antofagasta, Chile*. BM *DII:373*, *AM* 44:875(1959).

25.1.5.1 Vimsite $\text{Ca}[\text{BO}(\text{OH})_2]_2$

Named in 1968 for Vsesuosny Institut Mineralogo, Moscow. MON $B2/b$. $a = 10.026$, $b = 4.440$, $c = 9.558$, $\beta = 91.31^\circ$, $Z = 4$, $D = 2.56$. 21-134: 6.87₆ 3.72₇ 3.48₁₀ 3.04₆ 2.61₇ 2.55₆ 2.50₆ 2.22₈. Elongated crystals to 2 mm. Colorless, white streak, vitreous luster. Cleavage perfect along elongation. $H = 4$. $G = 2.54$. Biaxial (-); $N_x = 1.585$, $N_y = 1.614$, $N_z = 1.614$; $2V = 28^\circ$. *Solongo, Transbaikalia, Russia*, in skarn. BM *DANS* 182:821,1402(1968), *AM* 54:1219(1969).

25.1.6.1 Olshanskyite $\text{Ca}_3(\text{OH})_2[\text{B}(\text{OH})_4]_4$

Named in 1969 for Yakov I. Olshansky (1912–1958), Russian geochemist. TRIC $P1$ or $P1$. $a = 9.991$, $b = 14.740$, $c = 7.975$, $\alpha = 94.53^\circ$, $\beta = 69.08^\circ$, $\gamma = 112.44^\circ$, $Z = 3$, $D = 2.31$. 22-144: 7.61₅ 6.78₅ 4.50₃ 3.35₅ 3.05₈ 2.81₁₀ 2.57₄ 2.02₄. Fibrous aggregates of microscopic twinned crystals. Colorless, white streak, vitreous luster. $H = 4$. $G = 2.23$. Biaxial (-); $N_x = 1.557$, $N_y = 1.568$, $N_z = 1.570$; $2V = 54^\circ$; $r > v$, weak. *Eastern Siberia, Russia*, in skarn; Fuka, Okayama Pref., Japan. BM *DANS* 184:1398(1969), *AM* 54:1737(1969), *MM* 58:279(1994).

25.2.1.1 Sussexite (Mn,Mg)BO₂(OH)

Named in 1868 for the locality. Forms a series with szaibelyite (25.2.1.2). MON $P2_1/a$. $a = 12.832$, $b = 10.700$, $c = 3.283$, $\beta = 94.67^\circ$, $Z = 8$, $D = 3.30$ (Mn end member). 13-599: 6.32₁₀ 3.43₄ 3.32₄ 3.11₄ 2.74₈ 2.48₈ 2.26₄ 1.79₆. Felted fibrous masses. White to pink, white streak, silky luster. $H = 3-3\frac{1}{2}$. $G = 3.0-3.3$, decreasing with Mg content. Biaxial (-); $N_x = 1.63-1.67$, $N_y = 1.69-1.73$, $N_z = 1.69-1.73$; $2V \sim 25^\circ$; $r > v$, moderate; weakly pleochroic, colorless to pink. *Franklin* and *Sterling Hill, Sussex Co., NJ*; *Chicagon mine, Iron Co., MI*; *Gonzen, Switzerland*; *Val Graveglia, Italy*; *Matsuo mine, Kochi Pref., Japan*; *Hotazel, Cape Prov., South Africa*. Occurs in metamorphosed Mn deposits. BM *DII:375*.

25.2.1.2 Szaibelyite (Mg,Mn)BO₂(OH)

Named in 1861 for Stephan Szaibely (1777-1855), Hungarian mine surveyor, who first collected the mineral. Forms a series with sussexite. MON (an ORTH dimorph is known) $P2_1/a$. $a = 12.577$, $b = 10.393$, $c = 3.139$, $\beta = 95.88^\circ$, $Z = 8$, $D = 2.65$ (Mg end member). 29-864: 6.2₁₀ 5.17₅ 3.24₄ 3.02₄ 2.66₈ 2.42₈ 2.20₈ 2.08₆. Powdery or fibrous. White, white streak, silky luster in fibrous varieties. $H = 3-3\frac{1}{2}$. $G = 2.6-2.9$, increasing with Mn content. Biaxial (-); $N_x = 1.57-1.62$, $N_y = 1.65-1.69$, $N_z = 1.65-1.69$; $2V \sim 25^\circ$; $r > v$. Widely distributed: in metamorphosed limestone and dolomite, in skarns, on serpentinite, and in salt deposits. *Clarke Co., AL*, in salt cores; near *Pioche, Lincoln Co., NV*; *Stinson Beach, Marin Co., CA*; *Penobsquis and Salt Springs, NB*, and *Douglas Lake, BC, Canada*; *Kilchrist and Kilbride, Skye, Scotland*; *Snarum, Norway*; *Tallgruvan, Norberg, Sweden*; *Aschersleben, Saxony, Germany*; *Brosso, Ivrea, Italy*; *Klodowa, Poland*; *Baita Bihor, Romania*; *Inder, Kazakhstan*; *Ural Mts. and eastern Siberia, Russia*; *Hol Kol mine, Suan, South Korea*; *Fengchen, Liaoning Prov., China* (mined as a source of boron compounds); *Bou Azzer, Morocco*. BM *DII:375*, *AM 60:273(1975)*, *CM 19:291(1981)*.

25.2.2.1 Sibirskite CaHBO₃

Named in 1962 for the locality. MON Space group unknown. $a = 3.67$, $b = 4.89$, $c = 19.30$. 15-282: 3.74₄ 3.29₆ 2.93₁₀ 2.58₁₀ 2.20₄ 2.05₄ 1.93₄ 1.88₆. Anhedra grains and powdery aggregates. Gray, white streak, vitreous luster. Biaxial (-); $N_x = 1.555$, $N_y = 1.643$, $N_z = 1.658$; $2V = 43^\circ$. *Solongo, Transbaikalia, Russia*, in skarn. BM *ZVMO 91:455(1962)*, *AM 48:433(1963)*, *DANS 216:166(1974)*.

25.2.3.1 Pinnolite MgB₂O(OH)₆

Named in 1884 for chief councillor of Mines Pinno, of Halle, Germany. TET $P4_2$. $a = 7.62$, $c = 8.19$, $Z = 4$, $D = 2.29$. 25-1119: 5.39₁₀ 3.61₄ 3.14₄ 2.31₇ 2.25₃ 2.05₅ 1.91₃ 1.57₂. Radiating nodules or granular. Yellow to green, pale yellow streak, vitreous luster. Uneven fracture. $H = 3\frac{1}{2}$. $G = 2.27$. Uniaxial (-); $N_O = 1.565$, $N_E = 1.575$. *Eagle Borax works, Death Valley, CA*; *Stassfurt*

and Aschersleben, *Saxony, Germany*, in salt deposits; Inder, Kazakhstan; Qinghai-Xizai Plateau, China, in saline lakes. *BM DII:334*.

25.3.1.1 Ameghinite $\text{NaB}_3\text{O}_3(\text{OH})_4$

Named in 1967 for Florentino (1854–1911) and Carlos (1865–1936) Ameghino, pioneer Argentine geologists. *MON C2/c*. $a = 18.428$, $b = 9.882$, $c = 6.326$, $\beta = 104.3^\circ$, $Z = 8$, $D = 2.04$. *20-1081*: 4.95₁ 3.35₂ 3.15₈ 3.06₁₀ 2.91₂ 2.70₁ 2.66₁ 2.55₃. Nodular masses in borax. Colorless, white streak, vitreous luster. Cleavage {100}, very good; {001}, {010} poor. Conchoidal fracture, very brittle. $H = 2\frac{1}{2}$. $G = 2.03$. Biaxial (-); $Z = b$; $X \wedge c = 9^\circ$; $N_x = 1.429$, $N_y = 1.528$, $N_z = 1.538$; $2V = 33^\circ$; $r < v$, weak. Fluoresces pale blue in UV. *Tincalayu borax deposit, Salta, Argentina*. *BM AM 52:935(1967)*, *60:879(1975)*.

25.3.2.1 Solongoite $\text{Ca}_2\text{B}_3\text{O}_4(\text{OH})_4\text{Cl}$

Named in 1974 for the locality. *MON P2₁/c*. $a = 7.93$, $b = 7.26$, $c = 12.54$, $\beta = 94.00^\circ$, $Z = 4$, $D = 2.53$. *26-1051*: 7.84₉ 3.40₆ 2.74₇ 2.61₈ 2.54₈ 2.20₁₀ 1.91₈ 1.73₉. Microscopic prismatic crystals. Colorless, white streak, vitreous luster. $H = 3\frac{1}{2}$. $G = 2.51$. Biaxial (+); $Z \wedge c = 25^\circ$; $N_x = 1.510$, $N_y = 1.510$, $N_z = 1.545$; $2V$ very small; $r > v$, very weak. *Solongo, Transbaikalia, Russia*. *BM ZVMO 93:117(1974)*, *AM 60:162(1975)*.

25.3.3.1 Fabianite $\text{CaB}_3\text{O}_5(\text{OH})$

Named in 1962 for Hans-Joachim Fabian, German geologist. *MON P2₁/a*. $a = 6.593$, $b = 10.488$, $c = 6.365$, $\beta = 113.38^\circ$, $Z = 4$, $D = 2.79$. *15-631*: 3.96₆ 3.27₁₀ 3.03₉ 2.92₉ 2.62₅ 2.24₄ 2.07₆ 2.03₆. Prismatic crystals to 25 mm. Colorless, white streak, vitreous luster. Cleavage {011}. $H = 6$. $G = 2.796$. Biaxial (-); $XZ = ba$; $X \wedge c = 23^\circ$; $N_x = 1.608$, $N_y = 1.637$, $N_z = 1.650$; $2V = 65^\circ$; $r < v$, weak. Fluoresces yellow-brown. *Rehden, near Diepholz, Germany*, in drill core from salt deposit. *BM NW 49:230(1962)*, *AM 48:212(1963)*, *CM 10:108(1969)*, *ZK 132:241(1970)*.

25.3.4.1 Uralborite $\text{CaB}_2\text{O}_2(\text{OH})_4$

Named in 1961 for the composition and locality. *MON P2₁/n*. $a = 6.881$, $b = 12.305$, $c = 9.791$, $\beta = 97.46^\circ$, $Z = 8$, $D = 2.61$. *14-272*: 7.61₁₀ 6.18₆ 4.81₅ 3.42₆ 2.97₉ 2.13₁₀ 1.83₅ 1.41₈. Prismatic crystals to 7 mm. Colorless, white streak, vitreous luster. Distinct cleavage, parallel to elongation. $H = 4$. $G = 2.60$. Biaxial (+); $N_x = 1.604$, $N_y = 1.609$, $N_z = 1.615$; $2V = 85^\circ$; $r > v$, strong. Fluoresces violet in LWUV. *Solongo, Transbaikalia, Russia*, in skarn. *BM ZVMO 90:673(1961)*, *AM 47:1482(1962)*, *DANS 189:532(1969)*.

25.3.5.1 Howlite $\text{Ca}_2\text{SiB}_5\text{O}_9(\text{OH})_5$

Named in 1868 for Henry How (1828–1879), Canadian chemist, who discovered the mineral. *MON P2₁/c*. $a = 12.820$, $b = 9.351$, $c = 8.608$, $\beta = 104.84^\circ$, $Z = 4$, $D = 2.61$. *26-1404*: 12.4₃ 6.21₁₀ 4.12₂ 3.89₉ 3.09₇ 3.01₄ 2.93₃ 2.89₃. Tab-

ular crystals rare, usually as nodular masses. White, white streak, subvitreous luster. $H = 3\frac{1}{2}$. $G = 2.58$. Biaxial (-); $X = b$; $Z \wedge a = 55^\circ$; $N_x = 1.582$, $N_y = 1.595$, $N_z = 1.607$; $2V = 70-80^\circ$. Lang, Los Angeles Co., Furnace Creek, Inyo Co., Boron, Kern Co., and Calico Mts., San Bernardino Co., CA; Flat Bay, NF, near *Windsor*, Iona(*), and other localities in *NS, Canada*; Magdalena, SON, Mexico; Rehden borehole, Emsland, Germany; Jarando, Yugoslavia; Susurluk, Turkey; southern Ural Mts., Russia. *BM DII:362*; *AM 55:716(1970)*, *73:1138(1988)*.

25.4.1.1 Roweite $\text{Ca}_2\text{Mn}_2\text{B}_4\text{O}_7(\text{OH})_6$

Named in 1937 for George Rowe (1868–1947), mine captain at Franklin. *ORTH Pbam*. $a = 9.057$, $b = 13.357$, $c = 8.289$, $Z = 4$, $D = 2.933$. *26-1065*: 3.97₁₀ 3.06₃ 2.60₇ 2.26₃ 2.18₅ 2.13₄ 1.71₃ 1.64₃. Subhedral platy crystals to 5 mm. Amber to brown, white streak, vitreous luster. Cleavage {100}, fair. $H = 4\frac{1}{2}$. $G = 2.935$. Biaxial (-); $N_x = 1.646$, $N_y = 1.658$, $N_z = 1.660$; $2V = 28^\circ$; $r < v$, strong; moderately pleochroic, colorless to yellow-brown. *Franklin, Sussex Co., NJ*; Solongo, Transbaikalia, Russia. *BM DII:377*, *AM 59:60,66(1974)*.

25.4.1.2 Federovskite $\text{Ca}_2(\text{Mg},\text{Mn})_2\text{B}_4\text{O}_7(\text{OH})_6$

Named in 1976 for Nikolai M. Federov (1886–1956), Russian mineralogist. Forms a series with roweite (25.4.1.1). *ORTH Pbam*. $a = 8.96$, $b = 13.15$, $c = 8.15$, $Z = 4$, $D = 2.82$. *29-347*: 3.92₁₀ 3.02₇ 2.59₁₀ 2.28₆ 2.16₆ 2.12₇ 1.91₆ 1.69₇. Fibrous veinlets. Brown, pale streak, vitreous luster. Cleavage {100}, perfect. $H = 4\frac{1}{2}$. $G = 2.65-2.90$, increasing with Mn content. Biaxial (-); $XZ = ca$; $N_x = 1.619-1.643$, $N_y = 1.627-1.653$, $N_z = 1.629-1.654$; $2V = 40^\circ$; $r < v$, very strong; pleochroic, colorless to bright yellow. *Solongo, Transbaikalia, Russia*, in skarn. *BM ZVMO 105:71(1976)*, *AM 62:173(1977)*.

25.5.1.1 Priceite $\text{Ca}_4\text{B}_{10}\text{O}_{19} \cdot 7\text{H}_2\text{O}$

Named in 1873 for Thomas Price (b.1837), San Francisco metallurgist, who first analyzed the mineral. *TRIC* Space group unknown. *9-147*: 10.9₁₀ 5.99₂ 5.46₈ 4.29₄ 3.63₁₀ 3.49₇ 2.72₆ 2.18₅. Nodular chalky masses. White, white streak, dull luster. $H = 3-3\frac{1}{2}$. $G = 2.42$. Biaxial (-); $N_x = 1.573$, $N_y = 1.594$, $N_z = 1.597$; $2V = 32-42^\circ$; $r < v$, strong. Near *Chetco, Curry Co., OR*; Furnace Creek, Inyo Co., CA; Wentworth and Hillsborough, NB, Canada; Meldon, Devon, England; Pohla, Erzgebirge, Germany; Radotin, Czech Republic; Kirka, Turkey; Inder, Kazakhstan. *BM DII:341*, *AM 41:689(1956)*, *CM 19:291(1981)*.

BORACITE GROUP

The boracite minerals are borates with the general formula

where

and the structure is either an orthorhombic, pseudocubic structure or a rhombohedral structure.

BORACITE: $Mg_3B_7O_{13}$

The high-temperature cubic form of boracite has an open three-dimensional framework of BO_4 tetrahedra—this includes some linkages of three tetrahedra to a single oxygen, which is not seen in silicates. Mg and Cl occupy large interstices. In the pictured low-temperature orthorhombic form (a displacive transition) some B—O linkages are shifted, resulting in a complex sheet structure.

BORACITE GROUP

Mineral	Formula	Space Group	Space				D
			a	b	c		
Boracite	$(Mg, Fe)_3B_7O_{13}Cl$	$Pca2_1$	8.550	8.550	12.091	2.945	25.6.1.1
Ericaite	$(Fe, Mg)_3B_7O_{13}Cl$	$Pca2_1$	8.58	8.69	12.17	3.44	25.6.1.2
Chambersite	$Mn_3B_7O_{13}Cl$	$Pca2_1$	8.68	8.68	12.26	3.48	25.6.1.3
Congolite	$Fe_3B_7O_{13}Cl$	$R3c$	8.612		21.065	3.44	25.6.2.1
Trembathite	$(Mg, Fe)_3B_7O_{13}Cl$	$R3c$	8.574		20.99	3.14	25.6.2.2

25.6.1.1 Boracite (Mg,Fe)₃B₇O₁₃Cl

Named in 1789 for the composition. Boracite group. Forms a series with ericaite. ORTH (ISO above 265°) *Pca*2₁. $a = b = 8.550$, $c = 12.091$, $Z = 4$, $D = 2.945$. 5-710: 3.04₇ 2.72₅ 2.14₄ 2.06₁₀ 1.83₃ 1.76₅ 1.36₄ 1.24₅. Pseudocubic crystals. White to gray, green in ferroan varieties; white streak; vitreous luster. No cleavage, conchoidal to uneven fracture. $H = 7-7\frac{1}{2}$. $G = 2.95-3.10$, increasing with Fe content. Strongly piezoelectric and pyroelectric. Biaxial (+); $XY = ca$; $N_x = 1.658$, $N_y = 1.662$, $N_z = 1.668$; $2V = 82^\circ$. A common accessory in salt deposits. Choctaw salt dome, Iberville Parish, LA; Clarke Co., AL; Wayne Co., MS; Wichita Mts., OK; Penobsquis and Salt Springs, NB, Canada; Aislaby(*), Yorkshire, England; Luneville, France; Lüneberg(*), Hannover, and Stassfurt and other salt deposits, Saxony, Germany; Inowroclow salt dome, Poland; Inder, Kazakhstan; Khorat Plateau, Thailand; Alto Chapare(*), Cochabamba, Bolivia. BM *DII:378*, *AM 58:691(1973)*, *ZK 138(1973)*, *CM 19:291(1981)*.

25.6.1.2 Ericaite (Fe,Mg)₃B₇O₁₃Cl

Named in 1950 for the purple color (*Erica* is the heather genus). Boracite group. Forms a series with boracite. ORTH *Pca*2₁. $a = 8.58$, $b = 8.69$, $c = 12.17$, $Z = 4$, $D = 3.44$. 29-697: 3.51₄ 3.04₁₀ 2.72₆ 2.15₅ 2.06₇ 1.83₄ 1.47₂ 1.24₃. Pseudocubic crystals to 4 mm. Green, red, purple, brown, black. $G = 3.17-3.27$. Biaxial (-); $N_x = 1.731$, $N_y = N_z = 1.755$, $2V$ small. Wayne Co., MS; Clarke Co., AL; Boulby, Cleveland, England; Wathlingen-Hanigsen, Hannover, Germany. BM *AM 41:372(1956)*, *MM 41:404(1977)*.

25.6.1.3 Chambersite Mn₃B₇O₁₃Cl

Named in 1962 for the locality. Boracite group. Contains up to 2% FeO. ORTH *Pca*2₁. $a = b = 8.68$, $c = 12.26$, $Z = 4$, $D = 3.48$. 14-638: 3.54₅ 3.07₁₀ 2.74₆ 2.50₃ 2.17₅ 2.08₆ 1.85₅ 1.77₃. Tetrahedral crystals to 2 cm. Colorless to deep purple, white streak, vitreous luster. No cleavage, subconchoidal to uneven fracture. $H = 7$. $G = 3.49$. Biaxial (+); $N_x = 1.732$, $N_y = 1.737$, $N_z = 1.744$; $2V = 83^\circ$. Venice salt dome, Plaquemines Co., LA; Barber's Hill salt dome, Chambers Co., TX; Pomyarka, Carpathian Mts., Ukraine; Hebei Prov., China. BM *AM 47:665(1962)*, *NJMM:69(1982)*.

25.6.2.1 Congolite Fe₃B₇O₁₃Cl

Named in 1972 for the country of origin. Boracite group. Dimorphous with ericaite (25.6.1.2). HEX-R *R3c*. $a = 8.612$, $c = 21.065$, $Z = 6$, $D = 3.44$. 25-2: 3.05₈ 2.73₁₀ 2.16₆ 2.15₆ 2.06₈ 1.84₇ 1.83₇ 1.76₆. Fine-grained. Pale red, white streak, vitreous luster. Uniaxial (-); $N_O = 1.755$, $N_E = 1.731$. Bischofferode, Hannover, Germany; Brazzaville, Congo, insoluble residue from drill core. BM *AM 57:1315(1972)*, *ZK 138:64(1973)*.

25.6.2.2 Trembathite (Mg,Fe)₃B₇O₁₃Cl

Named in 1992 for Lowell T. Trembath (1936–1993), Canadian mineralogist. Boracite group. Dimorphous with boracite. *HEX-R R3c*. $a = 8.574$, $c = 20.99$, $Z = 6$, $D = 3.14$. *CM 30*: 3.50₃ 3.03₁₀ 2.71₇ 2.48₂ 2.14₄ 2.05₇ 1.83₃ 1.75₂. Rhombohedra to 2 mm. Colorless to pale blue, white streak, vitreous luster. No cleavage, conchoidal fracture. $H = 6-8$. $G = 2.84-3.34$. Uniaxial (-); $N_O = 1.684$, $N_E = 1.668$. *Salt Springs potash deposit, Sussex, NB, Canada*. *BM CM 30:445(1992)*.

25.6.3.1 Strontioborite SrB₆O₁₁(OH)₄

Named in 1960 for the composition. *MON P2₁*. $a = 9.909$, $b = 8.130$, $c = 7.623$, $\beta = 108.4^\circ$, $Z = 2$, $D = 2.38$. *18-1285*: 7.2₁₀ 5.4₇ 4.09₉ 3.52₇ 3.29₈ 3.07₇ 2.61₇ 2.33₆. Platy crystals to 2 mm. Colorless, white streak, vitreous luster. $G = 2.40$. Biaxial (+); $N_x = 1.470$, $N_y = 1.510$, $N_z = 1.579$; $2V$ near 90° . *Caspian region, Russia, in rock salt*. *BM DANS 135:173(1960)*, *AM 46:768(1961)*.

25.7.1.1 Preobrazhenskite Mg₃B₁₁O₁₅(OH)₉

Named in 1956 for Pavla I. Preobrazhensk (1874–1944), Russian geologist. *ORTH Pbcn*. $a = 16.33$, $b = 9.16$, $c = 10.59$, $Z = 4$, $D = 2.45$. *31-788*: 5.28₁₀ 3.79₁₀ 3.23₉ 3.19₉ 2.82₉ 2.77₉ 2.64₉ 2.13₁₀. Tabular crystals. Colorless to lemon yellow or gray, white streak, vitreous luster. Very friable. $H = 4\frac{1}{2}-5$. Biaxial (+); $N_x = N_y = 1.570$, $N_z = 1.595$; $2V$ very small. *Inder(*)*, *Kazakhstan, in salt deposits*. *BM DANS 11:1087(1956)*, *AM 42:704(1957)*, *CM 32:387(1994)*.

25.8.1.1 Jeremejevite Al₆(BO₃)₅F₃

Named in 1883 for Pavel V. Jeremejev (1830–1899), Russian mineralogist. *HEX P6₃/m*. $a = 8.558$, $c = 8.183$, $Z = 2$, $D = 3.28$. *35-504*: 4.28₁₀ 3.79₆ 2.80₃ 2.47₃ 2.20₄ 2.06₅ 1.68₃ 1.39₃. Hexagonal prisms to several centimeters. Colorless to pale yellow-brown or blue, white streak, vitreous luster. No cleavage, conchoidal fracture. $H = 7\frac{1}{2}$. $G = 3.29$. Uniaxial (-), in part anomalously biaxial; $N_O = 1.647$, $N_E = 1.637$. *Mt. Soktuj, S of Nerchinsk, Transbaikal, Russia*; *Emmelberg, near Udersdorf, Eifel, Germany*, *Usakos and Cape Cross, Namibia*. *BM DII:330, CM 19:303(1981), ZK 165:255(1983)*.

25.8.2.1 Rhodizite (K,Cs)Al₄Be₄(B,Be)₁₂O₂₈

Named in 1834 for the Greek for *rose-colored*, because it tinges the blowpipe flame red. *iso P43m*. $a = 7.317$, $Z = 1$, $D = 3.345$. *18-327*: 7.31₂ 3.27₅ 2.98₁₀ 2.44₅ 2.21₂ 2.11₄ 1.96₂ 1.78₃. Dodecahedral or tetrahedral crystals. Colorless to white or yellow, white streak, vitreous to adamantine luster. Cleavage {111}, {111}, difficult; conchoidal fracture. $H = 8\frac{1}{2}$. $G = 3.36$. Isotropic;

N = 1.693. Pyroelectric and piezoelectric. *Sarapulsk and Schaitansk, near Mursinsk, Ural Mts., Russia; Ambatofinandrahana, Manjaka, and Antandrokomby, Madagascar. BM DII:329, TPM 10:409(1965), ZK 125:423(1967), MM 50:163(1986).*

Hydrated Borates Containing Hydroxyl or Halogen

26.1.1.1 Berborite $\text{Be}_2(\text{BO}_3)(\text{OH}) \cdot \text{H}_2\text{O}$

Named in 1967 for the composition. *HEX-R P3* (1T polytype; 2T and 2H polytypes are known). $a = 4.434$, $c = 5.334$, $Z = 1$, $D = 2.05$. *22-107*: 5.34_{10} 3.84_1 3.12_{10} 2.67_6 2.22_2 2.05_3 1.39_2 1.28_1 . Crystals to 5 mm. Colorless, white streak, vitreous luster. Cleavage {0001}, perfect. $H = 3$. $G = 2.03-2.06$. Uniaxial (-); $N_O = 1.580$, $N_E = 1.485$. Tvedalen district, Langesundsfjord, Norway, in nepheline syenite pegmatites; *Pitkaranta, Karelia, Russia*, in skarn. *BM DANS 174:189(1967)*, *AM 53:348(1968)*, *NJMA 162:101(1990)*.

26.1.2.1 Wightmanite $\text{Mg}_5(\text{BO}_3)\text{O}(\text{OH})_5 \cdot 2\text{H}_2\text{O}$

Named in 1962 for R. H. Wightman (1902-1969), Director of Exploration, Riverside Cement Co. *MON I2/m*. $a = 13.46$, $b = 3.102$, $c = 18.17$, $\beta = 91.60^\circ$, $Z = 2$, $D = 2.58$. *14-640*: 10.7_{10} 9.07_{10} 4.74_2 3.03_3 2.67_3 2.45_2 2.35_2 2.12_2 . Pseudohexagonal prisms. Colorless, white streak, vitreous luster. Cleavage {101}, perfect. $H = 5\frac{1}{2}$. $G = 2.59$. Biaxial (-); $N_x = 1.585$, $N_y = 1.601$, $N_z = 1.602$; $2V = 29^\circ$; $r < v$, strong. *Crestmore, Riverside Co.*, and *Twin Lakes area, Fresno Co., CA*. *BM AM 47:718(1962)*, *59:985(1974)*.

26.1.3.1 Shabynite $\text{Mg}_5(\text{BO}_3)\text{Cl}_2(\text{OH})_5 \cdot 4\text{H}_2\text{O}$

Named in 1980 for Leonid I. Shabynin (b.1909), Russian geologist. Possibly *MON Space* group unknown. *41-1405*: 9.27_{10} 5.47_6 4.70_4 4.21_5 3.69_7 2.44_8 2.36_8 1.80_5 . Finely fibrous. White, white streak, silky luster. $H = 3$. $G = 2.32$. Biaxial (-); $N_x = 1.543$, $N_y = 1.571$, $N_z = 1.577$; $2V = 49^\circ$; straight extinction. *Korshunov skarn-magnetite deposit, Baikalia, Russia*. *BM ZVMO 109:569(1980)*, *AM 66:1101(1981)*.

26.1.4.1 Hexahydroborite $\text{Ca}[\text{B}(\text{OH})_4]_2 \cdot 2\text{H}_2\text{O}$

Named in 1976 for the composition. *MON P2/a*. $a = 8.006$, $b = 8.012$, $c = 6.649$, $\beta = 104.21^\circ$, $Z = 2$, $D = 1.88$. *30-236*: 7.76_{10} 6.64_4 3.95_2 3.35_8 2.52_4 2.47_3 2.30_2 1.97_2 . Microscopic prismatic crystals. Colorless, white streak, vitreous luster. $H = 2\frac{1}{2}$. $G = 1.87$. Biaxial (+); $X \wedge c = 14^\circ$; $N_x = 1.498$, $N_y = 1.503$, $N_z = 1.510$; $2V = 83^\circ$; $r > v$, strong. *Solongo, Transbaikalia, Russia*. *BM DANS 228:1337(1976)*, *AM 62:1259(1977)*.

26.1.5.1 Henmilite $\text{Ca}_2\text{Cu}[\text{B}(\text{OH})_4]_2(\text{OH})_4$

Named in 1986 for Kitinosuke Henmi (b.1919), Japanese mineralogist. TRIC P1. $a = 5.762$, $b = 7.977$, $c = 5.649$, $\alpha = 109.61^\circ$, $\beta = 91.47^\circ$, $\gamma = 83.69^\circ$, $Z = 1$, $D = 2.52$. 40-481: 5.25₁₀ 4.35₈ 3.93₅ 3.71₈ 3.30₈ 2.49₈ 2.43₈ 2.35₈. Microscopic crystals and anhedral masses. Blue-violet, pale violet streak, vitreous luster. $H = 2$. Biaxial (-); $N_x = 1.585$, $N_y = 1.608$, $N_z = 1.615$; $2V = 58^\circ$; strongly pleochroic. X, pale pink; Y, pale purple; Z, pale blue. *Fuka mine, Okayama Pref., Japan*, in borate veins cutting marble. BM AM 71:1234(1986).

26.2.1.1 Pentahydroborite $\text{CaB}_2\text{O}(\text{OH})_6 \cdot 2\text{H}_2\text{O}$

Named in 1961 for the composition. TRIC P1. $a = 7.845$, $b = 6.525$, $c = 8.124$, $\alpha = 111.62^\circ$, $\beta = 11.19^\circ$, $\gamma = 73.44^\circ$, $Z = 2$, $D = 2.14$. 14-339: 7.04₁₀ 5.86₄ 3.54₈ 3.20₅ 2.99₉ 2.88₆ 2.49₅ 1.94₈. Small grains. Colorless, white streak, vitreous luster. No cleavage. $H = 2\frac{1}{2}$. $G = 2.03$. Biaxial (+); $N_x = 1.531$, $N_y = 1.536$, $N_z = 1.544$; $2V = 73^\circ$. *Solongo, Transbaikalia, Russia*, in skarn; *Fuka mine, Okayama Pref., Japan*. BM ZVMO 90:673(1961); AM 47:1482(1962), 71:1234(1986).

26.3.1.1 Inyoite $\text{CaB}_3\text{O}_3(\text{OH})_5 \cdot 4\text{H}_2\text{O}$

Named in 1916 for the locality. MON P2₁/a. $a = 10.621$, $b = 12.066$, $c = 8.408$, $\beta = 114.02^\circ$, $Z = 4$, $D = 1.87$. 37-1459: 7.67₁₀ 7.57₂ 3.84₂ 3.45₂ 3.37₂ 2.80₂ 2.78₂ 2.55₂. Short prismatic or tabular crystals, coarse spherulitic aggregates, and massive. Colorless or white, white streak, vitreous luster. Cleavage {001}, good; irregular fracture. $H = 2$. $G = 1.875$. Biaxial (-); $Y = b$; $X \wedge c = 36^\circ$; $N_x = 1.490$, $N_y = 1.505$, $N_z = 1.516$; $2V = 86^\circ$; $r < v$, weak. Soluble in hot water and dilute acids. *Monte Blanco, Inyo Co.*, and *Boron, Kern Co., CA*; *Wentworth and Hillsborough, NB, Canada*; *Donets basin, Ukraine*; *Kirka, Turkey*; *Inder(*)*, *Kazakhstan*; *Qinghai-Xizaig Plateau, China*; *Laguna Salinas, Peru*; *Monte Azul mine, Sijes, and Tincalayu, Salta Prov., Argentina*. Occurs in sedimentary borate deposits. BM DII:358, AM 38:912(1953), CM 19:291(1981), SR 49A:239(1982).

26.3.1.2 Inderborite $\text{CaMg}[\text{B}_3\text{O}_3(\text{OH})_5]_2 \cdot 6\text{H}_2\text{O}$

Named in 1941 for the locality and composition. MON C2/c. $a = 12.137$, $b = 7.433$, $c = 19.234$, $\beta = 90.29^\circ$, $Z = 4$, $D = 1.919$. 12-70: 9.58₂ 6.34₄ 6.07₁₀ 4.51₂ 3.28₃ 3.20₃ 3.03₂ 3.01₂. Crystals to 2 cm and massive. Colorless or white, white streak, vitreous luster. Cleavage {100}, good; conchoidal fracture. $H = 3\frac{1}{2}$. $G = 2.00$. Biaxial (-); $Z = b$; $X \wedge c = 2^\circ$; $N_x = 1.483$, $N_y = 1.512$, $N_z = 1.530$; $2V = 77^\circ$. Slowly soluble in water. *Furnace Creek, Inyo Co., CA*; *Sarikaya, Kirka Co., Turkey*; *Inder, Kazakhstan*; *Sijes, Salta Prov., Argentina*. BM DII:355, AC 21:A61(1966), CM 32:533(1994).

26.3.1.3 Inderite $MgB_3O_3(OH)_5 \cdot 5H_2O$

Named in 1937 for the locality. *MON P2₁/a*. $a = 12.026$, $b = 13.116$, $c = 6.821$, $\beta = 104.49^\circ$, $Z = 4$, $D = 1.784$. *36-423*: 6.61_4 5.84_4 5.72_6 5.05_{10} 3.36_7 3.28_4 2.66_4 2.56_4 . Tabular or acicular crystals, and nodular aggregates. Colorless or white, white streak, vitreous to pearly luster. Cleavage {010}, perfect; {110}, good. $H = 2\frac{1}{2}$. $G = 1.80$. Biaxial (+); $Z \wedge c = 9^\circ$; $N_x = 1.488$, $N_y = 1.491$, $N_z = 1.505$; $2V = 37^\circ$; $r > v$, weak. Boron(*), Kern Co., and Furnace Creek, Inyo Co., CA; Kirka, Turkey; *Inder*(*), *Kazakhstan*; Qinghai-Xizaig Plateau, China. *BM DII:360*, *AM 45:732(1960)*, *AC(B) 32:1329(1976)*.

26.3.2.1 Meyerhofferite $CaB_3O_3(OH)_5 \cdot H_2O$

Named in 1914 for Wilhelm Meyerhoffer (1864-1906), German chemist, who synthesized the mineral. *TRIC P1*. $a = 6.63$, $b = 8.35$, $c = 6.46$, $\alpha = 90.55^\circ$, $\beta = 102.28^\circ$, $\gamma = 87.2^\circ$, $Z = 2$, $D = 2.13$. *12-411*: 8.31_{10} 6.47_{10} 4.97_3 4.15_2 3.29_1 3.15_2 3.07_2 2.50_2 . Radiating prismatic crystals, and as pseudomorphs after inyoite. Colorless or white, white streak, vitreous to silky luster. Cleavage {010}, perfect. $H = 2$. $G = 2.12$. Biaxial (-); $N_x = 1.500$, $N_y = 1.535$, $N_z = 1.560$; $2V = 78^\circ$; $r > v$. *Monte Blanco*(*) and Gower Gulch, Furnace Creek, Inyo Co., and Boron, Kern Co., CA; Kirka, Turkey; *Inder*, *Kazakhstan*; Sijes, Salta Prov., Argentina. *BM DII:356*, *ZK 114:321(1960)*.

26.3.3.1 Kurnakovite $MgB_3O_3(OH)_5 \cdot 5H_2O$

Named in 1940 for Nikolai S. Kurnakov (1860-1941), Russian mineralogist. *TRIC P1*. $a = 8.344$, $b = 10.59$, $c = 6.443$, $\alpha = 99.0^\circ$, $\beta = 108.9^\circ$, $\gamma = 105.5^\circ$, $Z = 2$, $D = 1.855$. *29-856*: 7.22_{10} 5.01_8 4.90_9 4.21_8 3.48_7 2.68_8 2.53_7 2.48_7 . Crystals to 30 cm, and granular aggregates. Colorless or white, white streak, vitreous luster. Cleavage {010}, perfect. $H = 3$. $G = 1.847$. Biaxial (-); $Z \wedge c = 22^\circ$; $N_x = 1.489$, $N_y = 1.510$, $N_z = 1.525$; $2V = 80^\circ$; $r > v$. Boron(*), Kern Co., and Furnace Creek area, Inyo Co., CA; Kirka, Turkey; *Inder*, *Kazakhstan*; Qinghai-Xizaig Plateau, China; Tincalayu(*), Salta Prov., Argentina. *BM DII:360*, *AC(B) 30:2194(1974)*.

26.3.4.1 Hydrochlorborite $Ca_2B_4O_4(OH)_7Cl \cdot 7H_2O$

Named in 1965 for the composition. *MON I2/a*. $a = 22.783$, $b = 8.745$, $c = 17.066$, $\beta = 96.71^\circ$, $Z = 8$, $D = 1.841$. *29-312*: 8.48_{10} 8.18_1 6.01_3 4.14_1 3.82_1 3.70_1 3.60_1 2.80_1 . Platy crystals or dense masses. Colorless or white, white streak, vitreous luster. Cleavage {001}, good. Brittle. $H = 2\frac{1}{2}$. $G = 1.825$. Biaxial (+); $Y = b$; $X \wedge c = 25^\circ$; $N_x = 1.499$, $N_y = 1.502$, $N_z = 1.521$; $2V = 45^\circ$; $r < v$. *China*; Salar Carcote, Antofagasta, Chile. *BM SS 14:943(1965)*; *AM 62:147(1977)*, *63:814(1978)*.

26.3.5.1 Colemanite $CaB_3O_4(OH)_3 \cdot H_2O$

Named in 1884 for William T. Coleman (1824-1893), founder of the California borate industry. *MON P2₁/a*. $a = 8.726$, $b = 11.253$, $c = 6.098$, $\beta = 110.12^\circ$,

$Z = 4$, $D = 2.43$. 33-267: 5.63₇ 4.01₆ 3.85₈ 3.29₈ 3.14₁₀ 2.89₆ 2.14₆ 2.01₈. Complex crystals to several cm, also massive, granular to compact, and as pseudomorphs after inyoite. Colorless to white or gray, white streak, vitreous to adamantine luster. Cleavage {010}, perfect; {001}, distinct; uneven to subconchoidal fracture. $H = 4\frac{1}{2}$. $G = 2.42$. Biaxial (+); $X = b$; $Y \wedge c = 6^\circ$; $N_x = 1.586$, $N_y = 1.592$, $N_z = 1.614$; $2V = 55^\circ$; $r > v$, weak. Pyroelectric and ferroelectric below -6° . Soluble in hot HCl. Muddy Mts., Clark Co., NV; Lila B(*), Bidy McCarthy(*), and other mines in the *Furnace Creek area*, Inyo Co., Boron, Kern Co., Borate, San Bernardino Co., Tick Canyon, Los Angeles Co., and other localities in CA; Penobsquis and Salt Springs, NB, Canada; Kirka, Turkey; Inder(*), Kazakhstan; Sijes, Salta Prov., Argentina. An important ore of boron. *BM DII:349*, *AM 38:411(1953)*, *AC 11:761(1958)*.

26.3.6.1 Hydroboracite $\text{CaMg}[\text{B}_3\text{O}_4(\text{OH})_3]_2 \cdot 3\text{H}_2\text{O}$

Named in 1834 for the composition. *MON P2/c*. $a = 11.769$, $b = 6.684$, $c = 8.235$, $\beta = 102.59^\circ$, $Z = 2$, $D = 2.17$. 35-646: 6.69₉ 5.78₁₀ 4.47₁ 4.36₁ 3.32₇ 2.44₁ 2.23₁ 1.91₂. Radiating aggregates of prismatic to acicular crystals, also fibrous to compact. Colorless or white, white streak, vitreous or silky luster. Cleavage {010}, perfect. $H = 5-6$. $G = 2.15$. Biaxial (+); $Y = b$; $X \wedge c = 33^\circ$; $N_x = 1.520$, $N_y = 1.534$, $N_z = 1.569$; $2V = 60-66^\circ$; $r < v$. Thompson mine(*) and other localities in the *Furnace Creek area*, Inyo Co., and Boron(*), Kern Co. (a single mass weighing more than a ton and as good crystals in vugs), CA; Penobsquis and Salt Springs, NB, Canada; Woffleben, Germany; Kirka, Turkey; *Caucasus Mts.*, *Russia*; Inder(*), Kazakhstan; Qinghai-Xizaig Plateau, China; in nitrate deposits, northern Chile; Pastos Grandes and Sijes, Salta Prov., Argentina. *BM DII:353*; *MR 4:21(1973)*, *9:379(1978)*; *CM 16:75(1978)*.

26.3.7.1 Nifontovite $\text{Ca}_3[\text{B}_3\text{O}_3(\text{OH})_6]_2 \cdot 2\text{H}_2\text{O}$

Named in 1961 for Roman V. Nifontov (1901-1960), Russian geologist. *MON C2/c*. $a = 13.089$, $b = 9.498$, $c = 13.566$, $\beta = 119.58^\circ$, $Z = 4$, $D = 2.36$. 27-68: 7.28₁₀ 5.52₆ 3.84₈ 2.95₆ 2.75₇ 2.24₈ 2.21₇ 2.06₈. Colorless, white streak, vitreous luster. Cleavage poor parallel to elongation. $H = 3\frac{1}{2}$. $G = 2.36$. Biaxial (+); $N_x = 1.575$, $N_y = 1.578$, $N_z = 1.584$; $2V = 76^\circ$; $r > v$, strong. Fluoresces violet in LWUV. *Novofrolovo mine*, *Ural Mts.*, *Russia*, in skarn; Fuka, Okayama Pref., Japan. *BM DANS 139:188(1961)*, *AM 47:172(1962)*, *MM 58:279(1994)*.

26.4.1.1 Borax $\text{Na}_2\text{B}_4\text{O}_5(\text{OH})_4 \cdot 8\text{H}_2\text{O}$

Named in 1753 from the Arabic for white. *MON A2/a*. $a = 12.219$, $b = 10.665$, $c = 11.884$, $\beta = 106.64^\circ$, $Z = 4$, $D = 1.71$. Contains anionic complex groups $\text{B}_4\text{O}_5(\text{OH})_4^{2-}$ made up of two triangle and two tetrahedral groups, one corner of each tetrahedron and each triangle is occupied by (OH). All the oxygen atoms are shared by two tetrahedrons or by a tetrahedron and a triangle. *AC(B) 34:3502(1978)*. 33-1215: 5.84₄ 5.69₅ 4.86₈ 3.94₅ 2.87₇ 2.83₆ 2.58₁₀ 2.57₉. Short prismatic crystals {001} and often somewhat tabular {100}; pro-

minent zones [001] and [110]. Colorless; in dry air dehydrates to the trihydrate, tincalconite, and becomes chalky; white streak; vitreous to resinous luster. Cleavage {100}, perfect; {110}, less so; conchoidal fracture; brittle. $H = 2-2\frac{1}{2}$. $G = 1.715$. Soluble in water. Tastes sweetish alkaline. Fuses easily to a colorless glass. Biaxial (-); $X = b$; $Z \wedge c = 55^\circ$; $N_x = 1.447$, $N_y = 1.469$, $N_z = 1.472$; $2V = 40^\circ$; $r > v$, strong. Borax is an evaporite mineral associated with halite, sulfates, carbonates, and other borates in alkaline lakes and playas. Originally brought to Europe from salt lakes in Kashmir and Tibet. Borax Lake(*), Esmeralda Co., NV; Furnace Creek district, Inyo Co., Borax Lake, Lake Co., Searles Lake(*), San Bernardino Co., Boron(*), Kern Co., CA; Kirka, Turkey; Inder, Kazakhstan; Lake Ma-Pin-Montalei, Tibet; Ladakh, Kashmir; Salar Cauchari(*), Jujuy Prov., Argentina. An important source of boron compounds. *BM DII:339, MR 6:74,84(1975)*.

26.4.2.1 Tincalconite $\text{Na}_2\text{B}_4\text{O}_5(\text{OH})_4 \cdot 3\text{H}_2\text{O}$

Named in 1878 from tincal, the Sanskrit for borax. *HEX-R R32*. $a = 11.12$, $c = 21.20$, $Z = 9$, $D = 1.91$. *7-277*: 8.75₆ 4.71₃ 4.38₉ 3.44₆ 2.92₁₀ 2.59₃ 2.26₃ 2.19₄. Pseudo-octahedral crystals rare; usually as a powder or pseudomorphs, the dehydration product of borax. White, white streak, earthy or vitreous luster. $G = 1.88$. Uniaxial (-); $N_O = 1.461$, $N_E = 1.474$. Localities as for borax; crystals from Searles Lake, San Bernardino Co., and Boron(*), Kern Co., CA; Larderello(*), Italy; Kirka, Turkey. *BM DII:337; AM 33:472(1948), 58:523(1973); PM 43:583(1973)*.

26.4.3.1 Hungchaoite $\text{MgB}_4\text{O}_5(\text{OH})_4 \cdot 7\text{H}_2\text{O}$

Named in 1964 for Chang Hung-Chao (1877-1951), Chinese mineralogist. *TRIC P1*. $a = 8.811$, $b = 10.644$, $c = 7.888$, $\alpha = 103.38^\circ$, $\beta = 108.58^\circ$, $\gamma = 97.15^\circ$, $Z = 2$, $D = 1.705$. *34-1288*: 7.14₆ 6.71₁₀ 5.85₆ 5.36₉ 4.09₈ 4.08₇ 3.36₉ 2.91₈. Tabular or equant crystals to 0.5 mm, and as nodules and crusts. Colorless or white, white streak, vitreous luster. Cleavage {111}, { $\bar{1}\bar{1}\bar{1}$ }, good; {010}, imperfect. $H = 2\frac{1}{2}$. $G = 1.706$. Biaxial (-); $X \wedge a = 28^\circ$; $Z \wedge b = 37^\circ$; $N_x = 1.445$, $N_y = 1.485$, $N_z = 1.490$; $2V = 15^\circ$; $r < v$, distinct. Furnace Creek district, Inyo Co., CA; *Qinghai-Xizaiig Plateau, China*, in saline lakes. *BM SS 13:525(1964); AM 50:262(1965), 62:1135(1977), 64:369(1979)*.

26.4.4.1 Halurgite $\text{Mg}_2[\text{B}_4\text{O}_5(\text{OH})_4]_2 \cdot \text{H}_2\text{O}$

Named in 1962 for the Institute of Halurgy, Moscow. *MON* Space group uncertain, probably *P2/c*. $a = 13.25$, $b = 7.60$, $c = 13.20$, $\beta = 92.2^\circ$, $Z = 4$, $D = 2.25$. *15-180*: 6.76₅ 4.81₉ 3.87₁₀ 3.69₅ 3.57₆ 3.29₁₀ 2.64₇ 2.16₉. Microscopic platy crystals or fine-grained masses. White, white streak, vitreous luster. $H = 2\frac{1}{2}-3$. $G = 2.19$. Biaxial (+); $X = b$; $N_x = 1.532$, $N_y = 1.545$, $N_z = 1.572$; $2V = 70^\circ$. *Kungur salt deposits, Ural Mts., Russia*. *BM DANS 143:693(1962), AM 47:1217(1962)*.

26.4.5.1 Kernite $\text{Na}_2\text{B}_4\text{O}_6(\text{OH})_2 \cdot 3\text{H}_2\text{O}$

Named in 1927 for the locality. MON $P2_1/c$. $a = 7.016$, $b = 9.152$, $c = 15.678$, $\beta = 108.86^\circ$, $Z = 4$, $D = 1.905$. 25-1322: 7.40₁₀ 6.64₉ 3.90₂ 3.71₂ 3.25₃ 3.13₃ 2.88₃ 2.47₃. Large equant crystals and cleavage masses several meters thick. Colorless, surface usually white from a coating of tinalconite; white streak; vitreous luster. Cleavage {100}, {001}, perfect; {102}, fair. $H = 2\frac{1}{2}$. $G = 1.906$. Biaxial (-); $Z = b$; $X \wedge c = 71^\circ$; $N_x = 1.454$, $N_y = 1.473$, $N_z = 1.488$; $2V = 80^\circ$; $r > v$, weak. Boron(*), Kern Co., CA, in clay-shales, apparently a somewhat altered buried lake deposit. A large proportion of boron production in the United States is obtained from this deposit; Furnace Creek district, Inyo Co., CA; Kirka, Turkey; Tincalayu, Salta Prov., Argentina. BM *DII:335*, *AM 58:21,308(1973)*.

26.5.1.1 Sborgite $\text{NaB}_5\text{O}_6(\text{OH})_4 \cdot 3\text{H}_2\text{O}$

Named in 1957 for Umberto Sborgi (1883-1955), Italian mineralogist. MON $P2/c$. $a = 11.119$, $b = 16.474$, $c = 13.576$, $\beta = 112.83^\circ$, $Z = 8$, $D = 1.72$. 24-1056: 6.86₄ 4.60₁₀ 4.30₃ 3.56₄ 3.52₄ 3.30₈ 3.20₈ 2.57₄. White, white streak, earthy luster. $H = 3\frac{1}{2}$. $G = 1.713$. Biaxial (+); $N_x = 1.431$, $N_y = 1.438$, $N_z = 1.507$; $2V = 35^\circ$; $r > v$, weak. Furnace Creek area, Inyo Co., CA, as an alteration product of colemanite and priceite; Larderello, Tuscany, Italy, as incrustations around hot springs. BM *AM 43:378(1958)*, *AC(B) 28:3559(1972)*.

26.5.2.1 Santite $\text{KB}_5\text{O}_6(\text{OH})_4 \cdot 2\text{H}_2\text{O}$

Named in 1970 for Giorgi Santi (1746-1823), Tuscan naturalist. ORTH $Aba2$. $a = 11.065$, $b = 11.171$, $c = 9.054$, $Z = 4$, $D = 1.74$. 25-624 (syn): 5.93₂ 5.60₇ 3.52₉ 3.36₁₀ 3.28₂ 2.77₅ 2.52₁ 2.18₂. Microscopic anhedral grains. Colorless, white streak, vitreous luster. Cleavage {010}, perfect; {100}, distinct. $H = 2\frac{1}{2}$. $G = 1.74$. Biaxial (+); $XY = cb$; $N_x = 1.422$, $N_y = 1.435$, $N_z = 1.480$; $2V = 70^\circ$. Larderello, Tuscany, Italy. BM *CMP 27:159(1970)*, *AM 56:636(1971)*.

26.5.3.1 Ammonioborite $(\text{NH}_4)_3\text{B}_{15}\text{O}_{20}(\text{OH})_8 \cdot 4\text{H}_2\text{O}$

Named in 1931 for the composition. MON $C2/c$. $a = 25.27$, $b = 9.65$, $c = 11.56$, $\beta = 94.29^\circ$, $Z = 4$, $D = 1.80$. 12-637: 8.98₄ 5.70₆ 5.44₃ 4.82₂ 3.16₁₀ 3.09₁₀ 3.01₅ 2.88₆. Minute platy crystals or fine-grained granular masses. White, white streak, dull luster. $G = 1.76$. Biaxial (+); $Y = b$; $Z \wedge c = 7^\circ$; $N_x = 1.470$, $N_y = 1.487$, $N_z = 1.540$; $2V = 59^\circ$; $r < v$, weak. Larderello, Tuscany, Italy. BM *DII:366*, *AM 44:1150(1959)*, *SCI 171:377(1971)*.

26.5.4.1 Larderellite $\text{NH}_4\text{B}_5\text{O}_7(\text{OH})_2 \cdot \text{H}_2\text{O}$

Named in 1854 for Francesco de Larderell (1848-1925), a proprietor of the Tuscan borate industry. MON $P2_1/a$. $a = 11.63$, $b = 7.615$, $c = 9.447$, $\beta = 96.75^\circ$, $Z = 4$, $D = 1.89$. 12-633: 9.45₅ 5.44₇ 5.12₅ 4.70₁₀ 3.14₄ 2.96₇ 2.92₁₀ 2.89₁₀. Microscopic plates. White, white streak, dull luster. Cleavage

{001}, {010}, perfect. Biaxial (+); $X = b$; $Z \wedge c = 30^\circ$; $N_x = 1.493$, $N_y = 1.509$, $N_z = 1.561$; $2V = 58^\circ$; $r < v$. *Larderello, Tuscany, Italy*. BM *DII:365, AM 45:1087(1960), AC(B) 25:2264(1969)*.

26.5.5.1 Ezcurrite $\text{Na}_2\text{B}_5\text{O}_7(\text{OH})_3 \cdot 2\text{H}_2\text{O}$

Named in 1957 for Juan M. de Ezcurra (1900–1970), manager of the Tinca-layu borate company. TRIC *P1*. $a = 8.598$, $b = 9.570$, $c = 6.576$, $\alpha = 102.75^\circ$, $\beta = 107.50^\circ$, $\gamma = 71.50^\circ$, $Z = 2$, $D = 2.05$. *26-1370*: 8.99₂ 6.93₁₀ 4.49₁ 4.20₁ 3.30₁ 3.13₃ 3.09₄ 3.08₄. Cleavable masses with bladed fibrous structure up to 7 cm. Colorless, white streak, vitreous to silky luster. Cleavage {110}, perfect; {010}, good; {100}, fair. $H = 3-3\frac{1}{2}$. $G = 2.05$. Biaxial (-); $N_x = 1.468$, $N_y = 1.507$, $N_z = 1.529$; $2V = 74^\circ$; $r > v$. *Tinca-layu borate mine, Salta Prov., Argentina*. BM *EG 42:426(1957); AM 52:1048(1967), 58:110(1973)*.

26.5.6.1 Nasinite $\text{Na}_2\text{B}_5\text{O}_8(\text{OH}) \cdot 2\text{H}_2\text{O}$

Named in 1961 for Raffaello Nasini (1854–1931), Italian chemist. ORTH *Pna2₁*. $a = 12.015$, $b = 6.518$, $c = 11.173$, $Z = 4$, $D = 2.13$. *29-1180*: 5.99₉ 5.59₆ 5.27₁₀ 4.09₃ 3.03₅ 3.00₆ 2.82₃ 2.79₃. Earthy masses. Orange-yellow to pale gray, white streak. $G = 2.12$. Biaxial (-); $Y = b$; $Z \wedge a = 7^\circ$; $N_x = 1.494$, $N_y = 1.512$, $N_z = 1.524$; $2V = 67^\circ$. *Larderello, Tuscany, Italy*. BM *AM 48:709(1963), AC(B) 31:2405(1975)*.

26.5.7.1 Biringuccite $\text{Na}_2\text{B}_5\text{O}_8(\text{OH}) \cdot \text{H}_2\text{O}$

Named in 1961 for Vannoccio Biringuccio (1480–1537), Italian alchemist. MON *P2₁/c*. $a = 11.196$, $b = 6.561$, $c = 20.757$, $\beta = 93.89^\circ$, $Z = 8$, $D = 2.32$. *35-421*: 10.3₈ 5.18₄ 3.45₁₀ 3.05₆ 3.03₆ 2.85₄ 2.68₃ 2.59₅. Microscopic pseudo-hexagonal plates or needles. Colorless or white, white streak. Cleavage {001}, {100}, good. $G = 2.30$. Biaxial (-); $Y = b$; $Z \wedge a = 5^\circ$; $N_x = 1.496$, $N_y = 1.539$, $N_z = 1.557$; $2V = 63^\circ$. *Larderello, Tuscany, Italy*. BM *AM 48:709(1963), 59:1005(1974)*.

26.5.8.1 Gowerite $\text{CaB}_6\text{O}_8(\text{OH})_4 \cdot 3\text{H}_2\text{O}$

Named in 1959 for Harrison P. Gower (1890–1967), U.S. Borax & Chemical Corp. MON *P2₁/a*. $a = 12.882$, $b = 16.630$, $c = 6.558$, $\beta = 121.62^\circ$, $Z = 4$, $D = 2.003$. *12-528*: 9.2₃ 8.2₁₀ 4.09₂ 3.94₁ 3.84₁ 3.19₅ 2.96₁ 1.90₂. Globular clusters of long prismatic needles. Colorless or white, white streak, vitreous luster. Cleavage {001}, distinct. $H = 3$. $G = 2.00$. Biaxial (+); $Y = b$; $Z \wedge c = 26^\circ$; $N_x = 1.485$, $N_y = 1.502$, $N_z = 1.550$; $2V = 61^\circ$; $r > v$, weak. *Furnace Creek district, Inyo Co., CA*, from the weathering of colemanite and priceite; N'Chwaning II mine, Kalahari manganese field, South Africa; Surire Salar, Arica Prov., Chile; Sijes, Salta Prov., Argentina. BM *AM 44:911(1959), 57:381(1972); MR 22:285(1991)*.

26.5.9.1 Veatchite $\text{Sr}_2[\text{B}_5\text{O}_8(\text{OH})]_2 \cdot \text{B}(\text{OH})_3 \cdot \text{H}_2\text{O}$

Named in 1938 for John A. Veatch (1808–1870), U.S. physician and geologist, who first detected borates in mineral waters of California. MON Aa (a $P2_1$ polytype is also known). $a = 20.060$, $b = 11.738$, $c = 6.652$, $\beta = 92.10^\circ$, $Z = 4$, $D = 2.664$. $12\text{-}712$: 10.5₁₀ 5.64₁ 5.12₁ 3.47₂ 3.32₄ 2.87₁ 2.60₃ 2.40₁. Platy crystals and as cross-fiber veins. Colorless or white, white streak, vitreous to pearly luster. Cleavage {010}, perfect. $H = 2$. $G = 2.66$. Biaxial (+); $Z = b$; $X \wedge c = 52^\circ$; $N_x = 1.551$, $N_y = 1.553$, $N_z = 1.621$; $2V = 37^\circ$; $r > v$, weak. *Sterling borax mine, Tick Canyon, Los Angeles Co.*, and *Billy mine, Death Valley, Inyo Co., CA*; *Penobsquis, NB, Canada*; *Aislaby, Yorkshire, England*; *Reyershausen, near Gottingen, Germany*; *Nepa salt deposit, Baikalia, Russia*; *Inder, Kazakhstan*. BM *DII:348*, *AM 56:1934(1971)*.

26.5.10.1 Veatchite-A $\text{Sr}_2[\text{B}_5\text{O}_8(\text{OH})]_2 \cdot \text{B}(\text{OH})_3 \cdot \text{H}_2\text{O}$

Named in 1979 as a dimorph of veatchite. TRIC $A1$ or $A1$. $a = 20.80$, $b = 11.72$, $c = 6.63$, $\alpha = 90^\circ$, $\beta = 90.80^\circ$, $\gamma = 91.95^\circ$, $Z = 4$, $D = 2.77$. $30\text{-}1284$: 10.4₁₀ 4.09₆ 3.45₈ 3.32₁₀ 2.84₈ 2.59₁₀ 1.79₈ 1.75₈. Nodules with euhedral crystals on the surface. Colorless or white, white streak, vitreous luster. Cleavage {100}, perfect; {011}, {011}, good. $H = 2$. $G = 2.73$. Biaxial (+); $XZ = cb$; $N_x = 1.549$, $N_y = 1.551$, $N_z = 1.621$; $2V = 25^\circ$; $r < v$, strong. *Emet borate deposit, Kutahya, Turkey*. BM *AM 64:362(1979)*, *MD 19:217(1984)*.

26.5.11.1 Ulexite $\text{NaCaB}_5\text{O}_8(\text{OH})_6 \cdot 5\text{H}_2\text{O}$

Named in 1850 for George L. Ulex (d.1883), German chemist, who determined its composition. TRIC $P\bar{1}$. $a = 8.816$, $b = 12.870$, $c = 6.678$, $\alpha = 90.36^\circ$, $\beta = 109.05^\circ$, $\gamma = 104.98^\circ$, $Z = 2$, $D = 1.955$. $12\text{-}419$: 12.2₁₀ 8.03₂ 7.75₈ 6.00₃ 4.33₂ 4.16₃ 3.10₂ 3.01₂. Nodules, sometimes loose-textured (cotton-balls), fibrous veins, rarely as needlelike crystals. Colorless or white, white streak, vitreous or silky luster. Cleavage {120}, perfect; {110}, good. $H = 2\frac{1}{2}$. $G = 1.955$. Biaxial (+); $X = b$; $Y \wedge c = 20^\circ$; $N_x = 1.493$, $N_y = 1.505$, $N_z = 1.526$; $2V = 75^\circ$. Decomposed by hot water. Occurs in salt playas and in sedimentary borate deposits. *Columbus, Rhodes, and Teels Marshes, NV*; *Furnace Creek district, Inyo Co., Boron, Kern Co., Sterling borax mine, Los Angeles Co., Calico Mts., San Bernardino Co., CA*; *Fischell's Brook and Flat Bay, NFD, and Wentworth, Hillsborough and other localities in NB, Canada*; *Niederellenbach, Hesse, Germany*; *Donets Basin, Ukraine*; *Kirka, Turkey*; *Inder, Kazakhstan*; *Arequipa, Peru*; *Iquique, Tarapaca, Chile*; *salars in Salta and Jujuy Prov., Argentina*. BM *DII:345*; *AM 44:712(1959)*, *63:160(1978)*; *CM 19:291(1981)*.

26.5.12.1 Probertite $\text{NaCaB}_5\text{O}_7(\text{OH})_4 \cdot 3\text{H}_2\text{O}$

Named in 1929 for Frank H. Probert (1876–1940), University of California, who discovered the mineral. MON $P2_1/a$. $a = 13.43$, $b = 12.57$, $c = 6.59$, $\beta = 100.25^\circ$, $Z = 4$, $D = 2.13$. $12\text{-}420$: 9.12₁₀ 6.62₂ 3.52₂ 2.94₂ 2.88₂ 2.81₄ 2.17₂ 1.99₂. Acicular or platy crystals in rosettes or radial groups, also mas-

sive. Colorless or white, white streak, vitreous luster. Cleavage {110}, perfect. $H = 3\frac{1}{2}$. $G = 2.14$. Biaxial (+); $Y = b$; $Z \wedge c = 12^\circ$; $N_x = 1.515$, $N_y = 1.525$, $N_z = 1.544$; $2V = 73^\circ$; $r > v$. Partly decomposed by hot water. Southard, Blaine Co., OK; *Boron, Kern Co.*, Furnace Creek district, Inyo Co., Sterling borax mine, Los Angeles Co., Calico Mts., San Bernardino Co., CA; Bakhmut Basin, Ukraine; Tincalayu, Salta Prov., Argentina. BM *DII:343*, *AM 44:712(1959)*, *AC(B) 38:3072(1982)*.

26.5.12.2 Tuzlaite $\text{NaCaB}_5\text{O}_8(\text{OH})_2 \cdot 3\text{H}_2\text{O}$

Named in 1994 for the locality. MON *P2*₁/*c*. $a = 6.506$, $b = 13.280$, $c = 11.462$, $\beta = 92.97^\circ$, $Z = 4$, $D = 2.23$. *AM 79: 8.64*₁₀ *6.62*₃ *5.71*₁ *5.23*₁ *4.18*₂ *2.87*₃ *2.59*₂ *2.41*₁. Prismatic crystals to 0.5 mm, and veinlets. Colorless or white, white streak, silky to pearly luster. Cleavage {001}, perfect. $H = 2-3$. $G = 2.21$. Biaxial (+); $Y = b$; $Z \wedge a = 14^\circ$; $N_x = 1.532$, $N_y = 1.544$, $N_z = 1.561$; $2V = 82^\circ$. In dolomitic marl at the *Tuzla salt mine, Bosnia*. BM *AM 79:562(1994)*.

26.5.13.1 Kaliborite $\text{HKMg}_2\text{B}_{12}\text{O}_{16}(\text{OH})_{10} \cdot 4\text{H}_2\text{O}$

Named in 1889 for the composition. MON *C2*/*c*. $a = 18.93$, $b = 8.62$, $c = 14.97$, $\beta = 99.9^\circ$, $Z = 4$, $D = 2.110$. *18-669: 7.22*₁₀ *3.84*₅ *3.77*₅ *3.36*₅ *3.10*₇ *2.49*₇ *2.35*₅ *2.07*₅. Small crystals, also massive granular. Colorless or white, white streak, vitreous luster. Cleavage {001}, {101}, perfect; {100}, good. $H = 4$. $G = 2.116$. Biaxial (+); $Y = b$; $Z \wedge c = 65^\circ$; $N_x = 1.508$, $N_y = 1.526$, $N_z = 1.550$; $2V = 81^\circ$. Eagle Borax works, Furnace Creek, Inyo Co., CA; *Schmidtmannshall* and *Leopoldshall, Saxony, Germany*; Sallent, Spain; Monte Sambuco, Sicily; Inder(*), Kazakhstan. BM *DII:367*, *AM 50:1079(1965)*, *SR 31A:172(1966)*.

26.5.14.1 Hilgardite $\text{Ca}_2\text{B}_5\text{O}_9\text{Cl} \cdot \text{H}_2\text{O}$

Named for Eugene W. Hilgard (1833–1916), German–U.S. geologist, one of the first to describe the Louisiana salt deposits. Hilgardite occurs in three polytypes, designated 4M, 1A, 3A (M, MON; A, TRIC; 1, 3, 4 are the number of formula units in the unit cell). Data are for the 4M polytype. The 3A polytype has been known as *parahilgardite*. MON *Aa*. $a = 11.438$, $b = 11.318$, $c = 6.318$, $\beta = 90.06^\circ$, $Z = 4$, $D = 2.69$. *11-404: 5.72*₄ *5.67*₄ *2.86*₁₀ *2.84*₁₀ *2.76*₆ *2.55*₆ *2.11*₈ *1.99*₈. Tabular hemimorphic crystals to 2 cm. Colorless or white, white streak, vitreous luster. Cleavage {010}, {100}, perfect. $H = 5$. $G = 2.71$. Biaxial (+); $Y = b$; $Z \wedge c = 2^\circ$; $N_x = 1.630$, $N_y = 1.636$, $N_z = 1.664$; $2V = 35^\circ$. *Choctaw salt dome, Iberville Parish, LA*, in insoluble residues of rock salt; Esmeralda Co., NV; Penobsquis, Sussex, and Salt Springs, NB, Canada; Boulby salt mine, Yorkshire, England; Reyershausen, Germany; Angara, Irkutsk region, Russia; Inder, Kazakhstan. BM *DII:382*; *AM 64:187(1979)*, *68:604(1983)*, *70:636(1985)*.

26.5.15.1 Tyretskite $\text{Ca}_2\text{B}_5\text{O}_9(\text{OH}) \cdot \text{H}_2\text{O}$

Named in 1964 for the locality. TRIC $P1$. $a = 6.44$, $b = 6.45$, $c = 6.41$, $\alpha = 118.23^\circ$, $\beta = 119.75^\circ$, $\gamma = 73.50^\circ$, $Z = 1$, $D = 2.59$. $26\text{-}2$: 5.82_3 3.23_6 2.93_{10} 2.86_{10} 2.80_7 2.14_9 2.06_8 1.85_9 . Small platy crystals and radiating fibrous aggregates. White to brown, white streak, vitreous luster. $G = 2.189$. Biaxial (+); $N_x = 1.637$, $N_y = 1.642$, $N_z = 1.670$; $2V = 46^\circ$. *Tyret, eastern Siberia, Russia*, in drill core from salt deposit; Inder, Kazakhstan. BM *MA 17:500(1966)*; *AM 53:2084(1968)*, *70:636(1985)*.

26.5.16.1 Volkovskite $\text{KCa}_4\text{B}_{22}\text{O}_{32}(\text{OH})_{10}\text{Cl} \cdot 4\text{H}_2\text{O}$

Named in 1966 for A. I. Volkovskaya, Russian mineralogist, who found the mineral. TRIC $P1$. $a = 6.575$, $b = 23.921$, $c = 6.522$, $\alpha = 90.58^\circ$, $\beta = 119.10^\circ$, $\gamma = 95.56^\circ$, $Z = 1$, $D = 2.28$. $18\text{-}1460$: 8.1_{10} 6.03_6 5.42_6 3.28_9 2.81_7 2.63_8 2.15_7 1.98_7 . Thin plates to 1.5 mm. Colorless to pink, white streak, vitreous luster. Cleavage $\{010\}$, perfect; $\{001\}$, good. Brittle. $H = 2\frac{1}{2}$, $G = 2.27$. Biaxial (+); $Y = b$; $Z \wedge a = 31^\circ$; $N_x = 1.536$, $N_y = 1.539$, $N_z = 1.603$; $2V = 24^\circ$. Clarke Co., AL; Sussex, NB, Canada; *Nepa deposit, eastern Siberia, Russia*. BM *ZVMO 95:45(1966)*, *AM 51:1550(1966)*, *CM 28:351(1990)*.

26.5.17.1 Pringleite $\text{Ca}_9\text{B}_{26}\text{O}_{34}(\text{OH})_{24}\text{Cl}_4 \cdot 13\text{H}_2\text{O}$

Named in 1993 for Gordon J. Pringle, Canadian mineralogist. Dimorphous with ruitenbergitte. TRIC $P1$. $a = 12.759$, $b = 13.060$, $c = 9.733$, $\alpha = 102.14^\circ$, $\beta = 102.03^\circ$, $\gamma = 85.68^\circ$, $Z = 1$, $D = 2.11$. *CM 31*: 9.21_7 7.69_{10} 5.74_6 4.63_4 3.85_4 2.80_3 2.20_3 2.06_3 . Subhedral platy or prismatic crystals to 2 mm. Colorless or very pale yellow, white streak, vitreous luster. Cleavage $\{110\}$, good. Brittle. $H = 3\text{-}4$. $G = 2.22$. Biaxial (+); $X = c$; $Y \wedge a = 40^\circ$; $N_x = 1.537$, $N_y = 1.548$, $N_z = 1.570$; $2V = 77^\circ$; $r < v$, strong. *Sussex, NB, Canada*, in salt deposit. BM *CM 31:795(1993)*, *32:1(1994)*.

26.5.17.2 Ruitenbergitte $\text{Ca}_9\text{B}_{26}\text{O}_{34}(\text{OH})_{24}\text{Cl}_4 \cdot 13\text{H}_2\text{O}$

Named in 1993 for Arie A. Ruitenbergt, Canadian geologist. Dimorphous with pringleite (26.5.17.1). MON $P2_1$. $a = 19.88$, $b = 9.715$, $c = 17.551$, $\beta = 114.85^\circ$, $Z = 2$, $D = 2.13$. *CM 31*: 9.03_6 8.56_{10} 6.62_7 6.14_3 5.12_3 3.79_3 3.49_3 2.89_3 . Anhedra 7 mm \times 4 mm grain. Colorless, white streak, vitreous luster. Cleavage $\{100\}$, good. $H = 3\text{-}4$. Biaxial (+); $X = b$; $Y \wedge a = 25^\circ$; $N_x = 1.542$, $N_y = 1.545$, $N_z = 1.565$; $2V = 47^\circ$. *Sussex, NB, Canada*, in salt deposit. BM *CM 31:795(1993)*, *32:1(1994)*.

26.6.1.1 Rivadavite $\text{Na}_6\text{Mg}[\text{B}_6\text{O}_7(\text{OH})_6]_4 \cdot 10\text{H}_2\text{O}$

Named in 1967 for Bernardino Rivadavia (1780–1845), first president of Argentina. MON $P2_1/c$. $a = 15.870$, $b = 8.010$, $c = 22.256$, $\beta = 116.43^\circ$, $Z = 2$, $D = 1.910$. $19\text{-}1211$: 14.2_{10} 7.59_{10} 6.23_5 5.34_5 3.25_7 2.95_7 2.85_5 2.45_3 . Nodular masses, aggregates of platy crystals to 3 mm. Colorless or white, white streak, vitreous luster. Cleavage $\{100\}$, $\{101\}$, perfect; $\{010\}$, poor. $H = 3\frac{1}{2}$.

$G = 1.905$. Biaxial (+); $Y = b$; $Z \wedge a = 32^\circ$; $N_x = 1.470$, $N_y = 1.481$, $N_z = 1.497$; $2V = 80^\circ$. Furnace Creek district, Inyo Co., CA; *Tincalayu borate deposit, Salta Prov., Argentina*. BM AM 52:326(1967), NW 60:350(1973).

26.6.2.1 McAllisterite $Mg_2[B_6O_7(OH)_6]_2 \cdot 9H_2O$

Named in 1965 for James F. McAllister (b.1911), U.S. geologist, who discovered the mineral. Dimorphous with admontite (26.6.3.1). HEX-R $R3c$. $a = 11.546$, $c = 35.562$, $Z = 6$, $D = 1.864$. 18-767: 8.72₁₀ 6.65₃ 5.77₅ 4.36₄ 4.06₅ 3.35₅ 3.26₅ 2.81₅. Equant rhombohedral crystals to 1 mm, and efflorescences. White to amber, white streak, vitreous luster. Cleavage {0001}, {0112}, good. $H = 2\frac{1}{2}$. $G = 1.868$. Uniaxial (-); $N_O = 1.507$, $N_E = 1.465$. Sterling Hill, NJ; *Furnace Creek district, Inyo Co., CA*; Qinghai-Xizai Plateau, China; *Tincalayu borate deposit, Salta Prov., Argentina*. BM AM 50:629(1965), 52:1776(1967); SR 41A:421(1975).

26.6.3.1 Admontite $Mg_2[B_6O_7(OH)_6]_2 \cdot 9H_2O$

Named in 1979 for the locality. Dimorphous with mcallisterite (26.6.2.1). MON $P2_1/c$. $a = 12.68$, $b = 10.07$, $c = 11.32$, $\beta = 109.68^\circ$, $Z = 2$, $D = 1.875$. 34-1438: 12.1₉ 7.60₁₀ 5.72₄ 5.29₇ 3.93₈ 3.09₆ 2.68₉ 2.00₂. Microscopic platy crystals. Colorless, white streak, vitreous luster. No cleavage, conchoidal fracture. $H = 2-3$. $G = 1.82$. Biaxial (-); $X \wedge c = 45^\circ$; $N_x = 1.442$, $N_y = 1.500$, $N_z = 1.504$; $2V = 30^\circ$; $r < v$. Near Admont, Styria, Austria, in a gypsum deposit. BM *TMPM* 26:69(1979), AM 65:205(1980).

26.6.4.1 Aksaitite $MgB_6O_7(OH)_6 \cdot 2H_2O$

Named in 1962 for the locality. ORTH $Pbca$. $a = 12.540$, $b = 24.327$, $c = 7.480$, $Z = 8$, $D = 1.975$. 15-654: 6.4₁₀ 6.3₄ 6.1₅ 4.72₅ 4.37₃ 3.59₄ 3.19₅ 3.11₅. Elongated crystals to 7 mm. Colorless to pale gray, white streak, vitreous luster. Cleavage {100}, {010}. $H = 2\frac{1}{2}$. $G = 1.99$. Biaxial (-); $XZ = cb$; $N_x = 1.472$, $N_y = 1.503$, $N_z = 1.526$; $2V = 80^\circ$. Ak-Sai, Kazakhstan, in salt deposit. BM *ZVMO* 91:447(1962); AM 48:209,930(1963), 56:1553(1971).

26.6.5.1 Aristarainite $Na_2Mg[B_6O_8(OH)_4]_2 \cdot 4H_2O$

Named in 1974 for Lorenzo F. Aristarain (b.1926), Argentine mineralogist. MON $P2_1/a$. $a = 18.886$, $b = 7.521$, $c = 7.815$, $\beta = 97.72^\circ$, $Z = 2$, $D = 2.102$. 26-1379: 7.74₁₀ 5.40₁ 3.87₁ 3.78₁ 3.12₁ 3.04₁ 2.58₂ 2.40₁. Platy crystals to 1 mm. Colorless, white streak, vitreous luster. Cleavage {001}, {100}, perfect; {110}, fair. $H = 3\frac{1}{2}$. $G = 2.027$. Biaxial (-); $Y \wedge c = 38^\circ$, $Z \wedge a = 46^\circ$; $N_x = 1.484$, $N_y = 1.498$, $N_z = 1.523$; $2V = 70^\circ$; $r > v$, weak. Fluoresces cream-white in SWUV. *Tincalayu borate deposit, Salta Prov., Argentina*. BM AM 59:647(1974), 62:979(1977).

26.6.6.1 Nobleite $\text{CaB}_6\text{O}_9(\text{OH})_2 \cdot 3\text{H}_2\text{O}$

Named in 1961 for Levi F. Noble (1882–1965), U.S. geologist. MON $P2_1/a$. $a = 14.56$, $b = 8.016$, $c = 9.838$, $\beta = 111.75^\circ$, $Z = 4$, $D = 2.098$. $13-243$: 6.79₁₀ 5.18₁ 3.94₁ 3.39₃ 3.12₁ 2.57₁ 2.31₁ 2.10₁. Platy crystals to 3 mm and fine-grained aggregates. Colorless or white, white streak, vitreous luster. Cleavage {100}, perfect; {001}, indistinct; sectile and flexible crystals; inelastic. $H = 3$. $G = 2.09$. Biaxial (+); $Y = b$; $Z \wedge c = 7^\circ$; $N_x = 1.500$, $N_y = 1.520$, $N_z = 1.554$; $2V = 76^\circ$; $r > v$, weak. *Furnace Creek district, Inyo Co., CA*; *Sijes, Salta Prov., Argentina*. BM *AM 46:560(1961)*.

26.6.6.2 Tunellite $\text{SrB}_6\text{O}_9(\text{OH})_2 \cdot 3\text{H}_2\text{O}$

Named in 1961 for George Tunell (1900–1996), U.S. mineralogist. Contains up to 15% BaO. MON $P2_1/a$. $a = 14.390$, $b = 8.213$, $c = 9.934$, $\beta = 114.03^\circ$, $Z = 4$, $D = 2.381$. $14-616$: 6.97₃ 6.57₁₀ 6.21₂ 5.14₃ 4.53₂ 3.87₂ 3.52₂ 3.05₂. Prismatic and tabular crystals to 9 cm and nodules of radiating prisms. Colorless, white streak, subvitreous to pearly luster. Cleavage {100}, perfect; {001}, distinct. $H = 2\frac{1}{2}$. $G = 2.40-2.46$, increasing with Ba content. Biaxial (+); $Y = b$; $Z \wedge c = 5^\circ$; $N_x = 1.519$, $N_y = 1.534$, $N_z = 1.569$; $2V = 68^\circ$; $r > v$, weak. *Furnace Creek district, Inyo Co., Boron(*), Kern Co., CA*; *Kirka, Turkey*. BM *AM 47:416(1962)*, *49:1549(1964)*.

26.6.7.1 Ginorite $\text{Ca}_2\text{B}_{14}\text{O}_{20}(\text{OH})_6 \cdot 5\text{H}_2\text{O}$

Named in 1934 for Piero Ginori Conti (1865–1939), a leader in the development of the Tuscan borax industry. MON $P2_1/c$. $a = 13.375$, $b = 14.368$, $c = 12.261$, $\beta = 101.2^\circ$, $Z = 4$, $D = 2.14$. $8-116$: 7.18₁₀ 5.36₈ 4.68₄ 3.90₅ 3.57₆ 3.28₆ 3.12₅ 2.09₈. Platy crystals and dense masses. Colorless or white, white streak, vitreous luster. Cleavage {010}, good. $H = 3\frac{1}{2}$. $G = 2.09$. Biaxial (+); $Y = b$; $Z \wedge c = 39^\circ$; $N_x = 1.517$, $N_y = 1.525$, $N_z = 1.579$; $2V = 42^\circ$. *Furnace Creek district, Inyo Co., CA*; *Windsor, NS, Canada*; *Sasso Pisano, Tuscany, Italy*; *Caspian Sea region, Russia*. BM *DII:364*, *MM 29:955(1952)*, *CM 19:291(1981)*.

26.6.7.2 Strontioginorite $\text{SrCaB}_{14}\text{O}_{20}(\text{OH})_6 \cdot 5\text{H}_2\text{O}$

Named in 1959 for the composition and relationship to ginorite. MON $P2_1/a$. $a = 12.850$, $b = 14.48$, $c = 12.845$, $\beta = 101.6^\circ$, $Z = 4$, $D = 2.265$. $13-137$: 7.25₁₀ 5.40₆ 4.75₄ 3.92₆ 3.34₆ 3.15₄ 2.10₈ 1.19₆. Tabular crystals to 3 mm. Colorless, white streak, silky luster. Cleavage {010}, perfect; {001}, good. $H = 3$. $G = 2.25$. Biaxial (+); $Y = b$; $Z \wedge c = 40^\circ$; $N_x = 1.512$, $N_y = 1.524$, $N_z = 1.577$; $2V = 52^\circ$. *Furnace Creek district, Inyo Co., CA*; *Reyershausen, near Gottingen, Germany*; *Inder, Kazakhstan*. BM *CMP 6:366(1959)*; *AM 45:478(1960)*, *55:1911(1970)*; *USGSJR 2:699(1974)*.

26.7.1.1 Korzhinskite $\text{CaB}_2\text{O}_4 \cdot \text{H}_2\text{O}$

Named in 1963 for Dimitri S. Korzhinsky (1899–1985), Russian geochemist. Probably ORTH Space group unknown. 16-366: 3.11₇ 2.81₇ 2.21₃ 2.02₁₀ 1.93₃ 1.91₅ 1.76₄ 1.37₂. Lamellar aggregates of prismatic crystals. Colorless, white streak. Cleavage in direction of elongation. Biaxial (+); $N_x = 1.642$, $N_y = 1.647$, $N_z = 1.672$; $2V = 44^\circ$; straight extinction. *Novofrolovo mine, Tur-linsk deposit, Ural Mts., Russia*, in skarn. BM ZVMO 92:555(1963), AM 49:441(1964).

26.7.2.1 Chelkarite $\text{CaMgB}_2\text{O}_4\text{Cl}_2 \cdot 7\text{H}_2\text{O}$

Named in 1968 for the locality. ORTH *Pbca*. $a = 13.69$, $b = 20.84$, $c = 8.26$, $Z = 10$, $D = 2.44$. 27-72: 10.4₉ 6.68₅ 4.96₇ 3.53₁₀ 2.75₄ 2.58₄ 2.21₈ 2.03₇. Prismatic crystals to 1.5 cm. Colorless to pale pink, white streak, vitreous luster. $G = 2.21$. Biaxial (+); $N_x = 1.520$, $N_z = 1.558$. *Chelkar, Kazakhstan*, in salt deposit. BM AM 56:1122(1971).

26.7.3.1 Ekaterinite $\text{Ca}_2\text{B}_4\text{O}_7(\text{Cl},\text{OH})_2 \cdot 2\text{H}_2\text{O}$

Named in 1980 for Ekaterina V. Rozhkova (1898–1979), Russian mineralogist. HEX *P6*. $a = 11.86$, $c = 23.88$, $D = 2.23$. 33-270: 11.9₇ 2.51₉ 2.31₁₀ 2.09₁₀ 2.05₁₀ 1.92₁₀ 1.83₈ 1.28₉. Foliated aggregates of hexagonal crystals. White, white streak, pearly luster. $H = 1$. $G = 2.44$. Biaxial (-); $N_x = 1.574$, $N_y = N_z = 1.577$; $2V$ very small. *Korshunov skarn iron-ore deposit, Lower Ilim region, Irkutsk district, Russia*. BM ZVMO 109:469(1980), AM 66:437(1981).

26.7.4.1 Satimolite $\text{KNa}_2\text{Al}_4(\text{B}_2\text{O}_5)_3\text{Cl}_3 \cdot 13\text{H}_2\text{O}$

Named in 1969, origin not given. ORTH Space group unknown. $a = 12.62$, $b = 18.64$, $c = 6.97$, $Z = 2$, $D = 1.70$. 25-1350: 9.5₉ 6.3₉ 4.01₉ 3.51₈ 3.20₁₀ 2.44₈ 1.97₈ 1.94₇. Rounded nodules. White, white streak. $G = 2.1$. Biaxial (-); $N_x = 1.535$, $N_y = 1.552$, $N_z = 1.553$; $2V$ very small. *Chelkar, Kazakhstan*, in salt deposit. BM AM 55:1069(1970).

26.7.5.1 Tertschite $\text{Ca}_4\text{B}_{10}\text{O}_{19} \cdot 20\text{H}_2\text{O}$

Named in 1953 for Hermann Tertsch (1880–1962), Austrian mineralogist. Probably MON Space group unknown. AM-39: 3.12 2.83 2.35 2.16 2.02 1.93 (strongest diffraction lines). Fibrous masses. White, white streak, silky luster. Biaxial; $Z \wedge c = 30^\circ$; $N_x = 1.502$, $N_z = 1.517$. Fluoresces blue-violet in UV. *Kurtpinari mine, Faras, Turkey*. BM CMP 3:443(1953), AM 39:849(1954).

26.7.6.1 Braitschite-(Ce) $(\text{Ca},\text{Na}_2)_7(\text{Ce},\text{La})_2\text{B}_{22}\text{O}_{43} \cdot 7\text{H}_2\text{O}$

Named in 1968 for Otto Braitsch (1921–1966), German mineralogist. HEX Space group unknown. $a = 12.156$, $c = 7.377$, $Z = 1$, $D = 2.84$. 21-158: 10.5₆ 4.28₁₀ 3.17₅ 3.16₄ 3.02₉ 2.81₆ 2.14₃ 1.91₄. Microscopic hexagonal plates and as nodules. Colorless, white, and pink, white streak, vitreous luster. $G = 2.903$.

Uniaxial (+); $N_O = 1.646$, $N_E = 1.647$. *Cane Creek potash mine, near Moab, Grand Co., UT. BM AM 53:1081(1968)*.

26.7.7.1 Wardsmithite $\text{Ca}_5\text{Mg}(\text{B}_4\text{O}_7)_6 \cdot 30\text{H}_2\text{O}$

Named in 1970 for Ward C. Smith (b.1906), U.S. geologist. Probably HEX Space group unknown. *23-120*: 13.5₁₀ 12.3₆ 7.43₂ 6.73₂ 6.12₆ 4.72₄ 3.36₅ 2.74₃. Microscopic hexagonal plates and fine-grained nodules. Colorless or white, white streak, vitreous luster. Cleavage {0001}, good. $H = 2\frac{1}{2}$. $G = 1.88$. Uniaxial (-); $N_O = 1.490$, $N_E = 1.476$. *Furnace Creek district, Inyo Co., and Boron, Kern Co., CA. BM AM 53:349(1970)*.

26.7.8.1 Studenitsite $\text{NaCa}_2\text{B}_9\text{O}_{14}(\text{OH})_4 \cdot 2\text{H}_2\text{O}$

Named in 1995 for the Studenitsa monastery, near the type locality. MON $P2_1/c$. $a = 11.499$, $b = 12.588$, $c = 10.530$, $\beta = 99.42^\circ$, $Z = 4$, $D = 2.34$. *ZVMO 124*: 5.41₇ 5.20₆ 4.20₆ 3.35₉ 3.27₆ 3.04₁₀ 2.21₆ 1.96₄. Wedge-shaped crystals to 5 mm. Colorless to pale yellow, white streak, vitreous luster. No cleavage. $H = 5\frac{1}{2}$. $G = 2.29$. Biaxial (+); $ZX = ab$; $Y \wedge c = 10^\circ$; $N_x = 1.532$, $N_y = 1.538$, $N_z = 1.564$; $2V = 54^\circ$; $r > v$. Insoluble in water, soluble in dilute HCl. Occurs in a borate lens in sedimentary clays in *Pobrdzhsk Potok and Piskan deposits on the Ibar R., southern Serbia. BM ZVMO 124(3):57(1995)*.

Compound Borates

27.1.1.1 Carboborite $\text{Ca}_2\text{Mg}[\text{B}(\text{OH})_4]_2(\text{CO}_3)_2 \cdot 4\text{H}_2\text{O}$

Named in 1964 for the composition. MON $P2_1/n$. $a = 11.011$, $b = 6.674$, $c = 10.692$, $\beta = 116.64^\circ$, $Z = 2$, $D = 2.15$. 17-529: 5.63₁₀ 4.86₅ 4.32₁₀ 3.20₅ 3.14₈ 2.73₇ 2.44₆ 2.16₈. Crystals resembling steep rhombohedrons to 3 mm. Colorless, white streak, vitreous luster. Cleavage {100}, perfect; {111}, distinct. $H = 2$. $G = 2.12$. Biaxial (-); $Y = b$; $Z \wedge c = 12^\circ$; $N_x = 1.507$, $N_y = 1.546$, $N_z = 1.569$; $2V = 75^\circ$. Fluoresces white in UV. Furnace Creek area, Inyo Co., CA; Qinghai-Xizaig Plateau, China, in saline lakes. BM SS 13:813(1964), AM 50:262(1965), BM 104:578(1981).

27.1.2.1 Gaudefroyite $\text{Ca}_4\text{Mn}_3(\text{BO}_3)_3(\text{CO}_3)\text{O}_3$

Named in 1964 for Christophe Gaudefroy (b.1878), French mineralogist. HEX $P6_3$. $a = 10.61$, $c = 5.879$, $Z = 2$, $D = 3.44$. 17-154: 9.1₈ 4.89₆ 4.54₈ 2.95₁₀ 2.69₈ 2.62₁₀ 2.46₁₀ 2.31₆. Hexagonal prisms to 5 cm. Black, brown streak, submetallic luster. Conchoidal fracture. $H = 6$. $G = 3.44$. Uniaxial (+); $N_O = 1.81$, $N_E = 2.02$. Tachgagalt manganese mine, near Ouarzazarte, Morocco; Wesels and N'Chwaning mines, Cape Prov., South Africa. BM BM 87:216(1964), AM 50:806(1965), MR 22:285(1991), NJMM:385(1993).

27.1.3.1 Borcarite $\text{Ca}_4\text{Mg}[\text{B}_4\text{O}_6(\text{OH})_6](\text{CO}_3)_2$

Named in 1965 for the composition. MON $C2/m$. $a = 17.840$, $b = 8.380$, $c = 4.445$, $\beta = 102.04^\circ$, $Z = 2$, $D = 2.790$. 22-532: 2.90₈ 2.72₇ 2.66₁₀ 2.38₅ 2.26₆ 2.21₆ 1.88₉ 1.70₆. Massive. Blue to green, white streak, vitreous to pearly luster. Cleavage {100}, {110}, perfect. $H = 4$. $G = 2.77$. Biaxial (-); $Z = b$; $Y \wedge c = 28^\circ$; $N_x = 1.590$, $N_y = 1.651$, $N_z = 1.657$; $2V = 30^\circ$; $r < v$. Solongo, Transbaikalia, Russia, in skarn. BM ZVMO 94:180(1965), AM 50:2097(1965), DANS 225:823(1976), MM 59:297(1995).

27.1.4.1 Sakhaite $\text{Ca}_3\text{Mg}(\text{BO}_3)_2(\text{CO}_3) \cdot 0.36\text{H}_2\text{O}$

Named in 1966 for the locality, Sakha being the name for Siberia in the Yakut language. iso $F4_132$. $a = 14.685$, $Z = 16$, $D = 2.79$. 19-1112: 8.4₁ 5.16₂ 3.35₁ 2.81₁ 2.58₁₀ 2.11₆ 1.83₂ 1.49₁. Octahedral crystals to 8 mm and massive. White to gray, white streak, vitreous luster. No cleavage. $H = 5$. $G = 2.78-2.88$. Isotropic; $N = 1.638-1.642$. Solongo, Transbaikalia, Russia, in skarn; Kombat

mine, near Tsumeb, Namibia. BM *ZVMO* 95:193(1966), *AM* 51:1817(1966), *DANS* 239:1103(1978), *MM* 54:105(1990).

27.1.5.1 Sulfoborite $Mg_3[B(OH)_4]_2(SO_4)(OH,F)_2$

Named in 1893 for the composition. ORTH *Pnma*. $a = 10.132$, $b = 12.537$, $c = 7.775$, $Z = 4$, $D = 2.37$. 14-639: 5.55₄ 3.47₁₀ 3.13₈ 3.09₁₀ 2.97₇ 2.43₅ 2.05₁₀ 1.90₉. Prismatic crystals. Colorless, white streak, vitreous luster. Cleavage {110}, good; {001}, fair. $H = 4-4\frac{1}{2}$. $G = 2.38-2.45$. Biaxial (-); $XY = ab$; $N_x = 1.522$, $N_y = 1.540$, $N_z = 1.552$; $2V = 70-88^\circ$. Occurs in salt deposits. Yorkshire, England; Wittmar, Brunswick, and *Westeregeln, Saxony, Germany*; Inder(*), Kazakhstan. BM *DII*:387, *MM* 34:460(1965), *DANS* 228:1076(1976), *AM* 68:255(1983).

27.1.6.1 Teruggite $Ca_4Mg[AsB_6O_{11}(OH)_6]_2 \cdot 14H_2O$

Named in 1968 for Mario E. Teruggi (b.1919), Argentine geologist. MON *P2₁/a*. $a = 15.675$, $b = 19.920$, $c = 6.255$, $\beta = 99.33^\circ$, $Z = 2$, $D = 2.19$. 21-150: 12.1₁₀ 9.98₂ 8.37₂ 4.65₂ 3.85₂ 3.58₂ 2.79₃. Rounded nodules of microscopic acicular crystals. Colorless or white, white streak, vitreous luster. Cleavage {001}, good; {110}, fair. $H = 2\frac{1}{2}$. $G = 2.20$. Biaxial (+); $Z = b$; $X \wedge c = 26^\circ$; $N_x = 1.526$, $N_y = 1.528$, $N_z = 1.551$; $2V = 33^\circ$; $r > v$, weak. Emet mine, Kütahya, Turkey, *Loma Blanca deposit, Jujuy Prov., Argentina*. BM *AM* 53:1815(1968), 58:1034(1973).

27.1.7.1 Garrelsite $Ba_3NaSi_2B_7O_{16}(OH)_4$

Named in 1955 for Robert M. Garrels (1916-1988), U.S. geochemist. MON *C2/c*. $a = 14.639$, $b = 8.466$, $c = 14.438$, $\beta = 114.21^\circ$, $Z = 4$, $D = 3.88$. 26-1369: 6.13₃ 4.23₃ 3.94₃ 3.64₈ 3.05₁₀ 2.87₅ 2.76₅ 2.03₆. Bipyramidal crystals to 3 mm. Colorless, white streak, vitreous luster. $H \sim 6$. $G = 3.68$. Biaxial (-); $Z = b$; $N_x = 1.620$, $N_y = 1.633$, $N_z = 1.640$; $2V = 55^\circ$. *South Ouray No. 1 well, Uintah Co., UT*, in bore core from dolomitic shale; Boron, Kern Co., and Searles Lake, San Bernardino Co., CA. BM *BGSA* 66:1597(1955), *NW* 60:349(1973), *USGSJR* 2:213(1974).

27.1.8.1 Iquiqueite $Na_4K_3Mg(CrO_4)B_{24}O_{39}(OH) \cdot 12H_2O$

Named in 1986 for the locality. HEX *P31c*. $a = 11.637$, $c = 30.158$, $Z = 3$, $D = 2.07$. 39-358: 10.1₉ 6.04₉ 3.28₉ 3.22₉ 3.02₁₀ 2.91₈ 2.89₈ 2.86₁₀. Microscopic hexagonal plates and crystal aggregates. Yellow, yellow streak, vitreous luster. Cleavage {0001}, perfect; {1010}, imperfect. $H = 2$. $G = 2.05$. Uniaxial (-); $N_O = 1.502$, $N_E = 1.447$. *Iquique, Tarapaca Prov., Chile*, disseminated in nitrate ore. BM *AM* 71:830(1986).

27.1.9.1 Moydite-(Y) $YB(OH)_4CO_3$

Named in 1986 for Louis Moyd (b.1916), Canadian mineralogist. ORTH *Pbca*. $a = 9.080$, $b = 12.222$, $c = 8.911$, $Z = 8$, $D = 3.01$. 40-508: 6.11₁₀ 4.50₉ 3.18₇

3.05₃ 2.82₅ 2.75₃ 2.53₄ 1.86₆. Platy crystals to 1 mm. Yellow, white streak, vitreous luster. Cleavage {010}, good; {101}, poor. Soft. $G = 3.13$. Biaxial (-); $XY = ab$; $N_x = 1.588$, $N_y = 1.681$, $N_z = 1.690$; $2V = 32^\circ$; $r > v$. *Evans-Lou granite pegmatite, near Wakefield, QUE, Canada. BM CM 24:665(1986).*

27.1.10.1 Wiserite $(Mn,Mg)_{14}(B_2O_5)_4(SiO_4)(OH,Cl)_8$

Named in 1845 for David F. Wiser (1802–1878), Swiss mineralogist. TET $P4/n$. $a = 20.192$, $c = 3.281$, $Z = 2$, $D = 3.57$. 13-598: 14.2₁₀ 6.40₆ 5.08₄ 4.78₄ 3.36₆ 2.87₆ 2.53₈ 2.35₆. Prismatic crystals to 1 cm or fibrous. White to pink or brown, white streak, vitreous or silky luster. $H = 2\frac{1}{2}$. $G = 3.54$. Uniaxial (-); $N_O = 1.751$, $N_E = 1.700$; weakly pleochroic, colorless to brown. *Gonzen, Switzerland; Japan (17 localities); Kombat mine, near Tsumeb, Namibia. BM DII:245, SMPM 39:85(1959), AM 74:1351,1374(1989).*

Anhydrous Acid and Sulfates

28.1.1.1 Mercallite KHSO_4

Named in 1935 for Giuseppe Mercalli (1850–1914), Italian geologist, director of the Vesuvius Observatory. ORTH *Pbca*. $a = 8.412$, $b = 9.800$, $c = 19.957$, $Z = 16$. Structure: *AC(B)* 31:302(1977). 11-649(syn): 3.87₇ 3.84₁₀ 3.52₉ 3.41₉ 3.26₉ 3.03₇ 2.74₃ 2.37₃. Stalactites composed of minute tabular crystals. Colorless, also sky blue due to admixed copper salt; vitreous luster. No cleavage. $G = 2.33$. Biaxial (+); $XYZ = bca$; $N_x = 1.445$, $N_y = 1.460$, $N_z = 1.491$; $2V = 56^\circ$. Found as stalactites in fumaroles in the crater of *Vesuvius, Italy*, admixed with misenite, hieratite, and carobbiite. RG *DII:395*.

28.1.2.1 Misenite $\text{K}_2\text{H}_6(\text{SO}_4)_7$ (?)

Named in 1849 for the locality. MON Space group unknown. $a = 23.00$, $b = 7.104$, $c = 8.710$, $\beta = 102.66^\circ$. 41-1363: 4.92₄ 4.83₄ 4.35₂ 4.24₁₀ 3.95₃ 3.65₆ 3.49₃ 2.89₃. Fibrous masses and aggregates of needle- or lathlike crystals, elongated [100] and flattened {001}. Colorless to grayish white, pearly or silky luster. Cleavage {010}, distinct. $G = 2.32$. Biaxial (+); $Z = b$; $X \wedge c = 29^\circ$; $N_x = 1.475$, $N_y = 1.480$, $N_z = 1.487$; $2V = 81^\circ$. Found with potassium alum, alunogen, and possibly arcanite as a transient efflorescence in a fumarole on *Cape Miseno, near Naples, Italy*. RG *DII:396*.

28.1.3.1 Letovicite $(\text{NH}_4)_3\text{H}(\text{SO}_4)_2$

Named in 1932 for the locality. TRIC *P1* or *P1*. $a = 5.87$, $b = 10.17$, $c = 8.27$, $\alpha = 101.10^\circ$, $\beta = 111.10^\circ$, $\gamma = 89.90^\circ$, $Z = 2$, $D = 1.82$. 35-1500: 4.98₈ 4.95₈ 4.65₄ 3.81₃ 3.77₆ 3.39₁₀ 3.36₄ 2.93₈. Minute pseudohexagonal plates on {001}; granular masses; lamellar twinning common. Colorless. Cleavage {001}, distinct; uneven fracture. $G = 1.83$. Biaxial (-); $Z = b$; $X \wedge c = -12^\circ$; $N_x = 1.501$, $N_y = 1.516$, $N_z = 1.525$ (Na); $2V = 75^\circ$. Formed during the burning of waste coal heaps at *Letovice, Moravia, Czech Republic*, and at *Kladno, Bohemia, Czech Republic* of similar origin. RG *DII:397*, *MA 73:4375*.

28.2.1.1 Mascagnite $(\text{NH}_4)_2\text{SO}_4$

Named in 1779 for Paolo Mascagni (1752–1815), Italian anatomist, University of Siena, who first described the natural salt. ORTH *Pnma*. $a = 7.78$, $b = 10.36$, $c = 5.99$, $Z = 4$, $D = 1.765$. 10-343: 5.22₃ 4.39₇ 4.33₁₀ 3.89₄ 3.14₃

3.12₃ 3.06₆ 3.00₃. Crystals equant to short prismatic [100]; usually as stalactites or crusts; twinning on {011}. Colorless to gray or yellow, vitreous to dull luster. Cleavage {100}, good; uneven fracture; slightly sectile. $H = 2-2\frac{1}{2}$. $G = 1.768$. Biaxial (+); $XYZ = cba$; $N_x = 1.521$, $N_y = 1.532$, $N_z = 1.539$ (Na); $2V = 52^\circ$; $r > v$, weak. A complete solid-solution series exists between mascagnite and arcanite, K_2SO_4 . A compound in this series containing about 16 mol % $(NH_4)_2SO_4$ has been named taylorite, and was formed as a leachate of guano; see arcanite (28.2.1.2). Soluble in water; tastes sharp and bitter; readily fusible. Occurs as a sublimation product in fumaroles and from burning coal seams. The Geysers, Sonoma Co., CA, with boussingaultite and ammonioalunite. Commeny, France, from burning coal seams; *Vesuvius*, and Etna, *Italy*, in fumaroles; also from the solfatara of Tuscany; Nyamlagira volcano, Zaire. RG *DII:398*, *AM 36:591(1951)*, *PM 54:32(1985)*.

28.2.1.2 Arcanite K_2SO_4

Named in antiquity from the mediaeval Latin alchemical name for the compound *arcantum duplicatum*, double secret. Synonym: taylorite, ammonian arcanite, named in 1892 for W. J. Taylor (1833-1864), Philadelphia mineral chemist. ORTH *Pnma*. $a = 7.476$, $b = 10.071$, $c = 5.763$, $Z = 4$, $D = 2.70$. *AC(B) 28:2845(1972)*. *24-703*: 4.16₄ 3.74₂ 3.00₉ 2.90₁₀ 2.89₈ 2.42₃ 2.23₂ 2.08₃. Crystals are thin tablets which are cyclic twins of six individuals bounded by {100}, {110}, and {211}; as crusts, lumps, or concentric with crystalline structure. Colorless to white. Cleavage {010} and {100}, good. $G = 2.66$. Biaxial (+); $XYZ = cab$; $N_x = 1.494$, $N_y = 1.495$, $N_z = 1.497$ (Na); $2V = 67^\circ$; $r > v$, moderate. A complete solid-solution series exists between arcanite and mascagnite; taylorite contains only about 16 mol % $(NH_4)_2SO_4$, and the name should be dropped. Found in a pine railroad tie in the *Santa Ana mine, Trabuco Canyon, Orange Co., CA*. Taylorite was described from the guano beds of the Chincha Is., Peru. RG *DII:399*, *AM 36:592(1951)*, *NJMM:75(1973)*.

28.2.2.1 Aphthitalite $(K,Na)_3Na(SO_4)_2$

Named "aphthalose" in 1813 from the Greek for *unalterable* and *salt*, in allusion to its stability in air. Synonym: *glaserite*, after Christoph Glaser, seventeenth-century German chemist. HEX-R *P3m1*. $a = 5.680$, $c = 7.309$, $Z = 1$, $D = 2.697$. *AC(B) 36:919(1980)*. *20-928*: 4.09₃ 3.67₂ 2.94₈ 2.84₁₀ 2.44₂ 2.33₁ 2.04₅ 1.66₁. Crystals tabular {0001}; as bladed aggregates, crusts, or massive; twins on {0001} or {1120}. Colorless to white; rarely pale shades of gray, blue, green, red due to impurities; white streak; vitreous to resinous luster. Cleavage {1011}, fair; {0001}, poor; conchoidal fracture. $G = 2.66-2.71$. Uniaxial (+); $N_O = 1.490$, $N_E = 1.496$ (for 68 mol % K_2SO_4). K_2SO_4 can vary in the range 44 to 75%. Soluble in water, with a saline, bitter taste. Formed in volcanoes as incrustations in fumaroles, and in lacustrine salt deposits. Carlsbad potash district, NM; Searles lake, San Bernardino Co., CA; Kilauea, HI. *Vesuvius*, and Etna, *Italy*. Stassfurt salt deposits, Germany, especially at

Douglashall, Kalusz, Galicia, Ukraine, as crystals embedded in picromerite. RG *DII:400*, *NJMM:75(1973)*, *PM 54:34(1985)*.

28.2.3.1 Thenardite Na_2SO_4

Named in 1826 for Louis Jacques Thenard (1777–1857), French chemist, University of Paris. Five different polymorphs of Na_2SO_4 are known, but thenardite is the only naturally occurring one. ORTH *Fddd*. $a = 9.829$, $b = 12.302$, $c = 5.868$, $Z = 8$, $D = 2.659$. *CM 13:186(1975)*. *37-1465*: 4.66₇ 3.84₂ 3.18₅ 3.08₆ 2.78₁₀ 2.65₅ 2.33₃ 1.87₄. Crystals dipyrmidal {111}; also tabular {010}. Common forms {010}, {011}, {101}, {111}, {311}. Large crystals common. Also as crusts and efflorescences. Twins on {110} and {011}. Colorless to white; also light shades of gray, yellow, brown, red; vitreous to resinous luster. Cleavage {010}, perfect; {101}, fair; uneven to hackly fracture. $H = 2\frac{1}{2}$ –3. $G = 2.664$. Thenardite from Sodaville, Mineral Co., NV, fluoresces bright white under LWUV or SWUV, after which it shows greenish-white phosphorescence. Biaxial (+); XYZ = *cba*; $N_x = 1.464$, $N_y = 1.474$, $N_z = 1.485$ (Na); $2V = 82.5^\circ$. Analyses conform closely to the formula. Traces of K, Mg, Ca, and Cl are probably due to admixture. Soluble in water. Tastes salty. Salt lakes and playas containing Na_2SO_4 are found in arid parts of most continents. Thenardite, along with other sulfates, carbonates, and halides, is deposited from these waters. Also found as an efflorescence in soils in alkali regions, especially in caliche, and as an incrustation on lavas and around fumaroles. In CA at Searles Lake, Death Valley, Inyo Co., and at Salton Sinks, Imperial Co. In AZ as extensive beds near Camp Verde, Yavapai Co., Esmeralda Co., NV. In the sodium sulfate lakes of western Canada. First reported from *Lago Espartinus*, near *Aranjuez*, *Madrid Province*, *Spain*, where extensive bedded deposits are found. Vesuvius and Etna, Italy. In Russia in the Volga region and in Central Asia. At the Natron Lakes NW of Cairo, Egypt, and in the Sudan. At several places in Chile and in the arid regions of the west coast of South America. Ross Island, Antarctica. RG *DII:404*, *BM 95:529(1972)*, *NJMM:408(1978)*.

28.2.4.1 Gianellaite $\text{Hg}_4(\text{SO}_4)\text{N}_2$

Named in 1977 for Vincent Paul Gianella (1886–1983), Mackay School of Mines, University of Nevada. iso *F43m*. $a = 9.521$, $Z = 4$, $D = 7.13$. *NJMM:119(1977)*. *29-907*: 5.51₈ 2.87₁₀ 2.74₁₀ 2.37₇ 2.18₆ 1.83₆ 1.68₇ 1.43₇. Rosettes of flattened subhedral crystals, rarely as euhedral distorted octahedra. Straw yellow. $H = 3$. $G = 7.19$. Isotropic; $N = 2.085$. Not attacked by H_2SO_4 or concentrated HNO_3 , decomposed by concentrated HCl at room temperature. Darkens when heated above 130° , and when exposed to light for several weeks. Turns white and volatilizes above 400° . *Mariposa mine*, *Terlingua*, *Brewster Co.*, *TX*, associated with terlinguaite, calomel, montroydite, mercury, and cinnabar on fracture surfaces in limestone. RG *AM 62:1057(1977)*.

BARITE GROUP

The barite group consists of seven isostructural minerals that contain a tetrahedral group, usually sulfate, and a variety of other elements including most often barium or lead. The formula is

or a multiple thereof where

A = Pb, Ba, Sr, K, Cs

TO₄ = a tetrahedral group = SO₄, CrO₄, SeO₄, BF₄, [GeO₂(OH)₂]

In BaSO₄, for example, the sulfate ions are regular tetrahedra arranged with the sulfur and two oxygen atoms lying on a mirror plane of the structure. The other two oxygen atoms are equidistant above and below the plane. The Ba ions also lie on this same mirror plane and are in 12-fold coordination with oxygens belonging to seven different sulfate groups.

Strontium may substitute for Ba, and a complete solid-solution series may exist between barite and celestine. However, varieties of barite containing more than a few percent Sr are rare. Ca may also substitute for Ba up to a maximum ratio Ca/Ba = 1:12. Pb rarely substitutes for Ba but may reach a Pb/Ba ratio of 1:4. A complete series barite-anglesite has not been found in nature. Rarely (Musonoi, Zaire) Se may substitute for some of the S.

BARITE: BaSO₄

Perspective view down c axis.

Note: Anhydrite, CaSO₄ is structurally distinct from barite.

28.3.1.1 Barite BaSO₄

Named in 1640 from the Greek for *weight*. Barite group. Synonym: barytes, from the Greek for *heavy*. ORTH *Pnma*. $a = 8.884$, $b = 5.456$, $c = 7.157$, $Z = 4$, $D = 4.50$. *CM 15:522(1977)*. *24-1035*: 3.90_5 3.45_{10} 3.32_7 3.10_{10} 2.84_5 2.73_5 2.12_8 2.11_8 . **Habit**: Often well crystallized, usually thin to thick tabular {001}, bounded by {210} alone or in combination with {101}, {011}, or other forms. Also flattened {001}, and elongated to prismatic [010] or [100]. Rarely prismatic [001]; equant. Other common forms are {211}, {010}, {100}, {201}, and {102}. Often forms aggregates of tabular crystals whose edges project into crestlike forms, or as rosettes of crystals ("desert roses"). Also massive, compact, laminated, concretionary, fibrous, stalactitic, or earthy. Forms epitaxial growths with anglesite, celestite, witherite, and calcite. **Physical properties**: Colorless or white; also yellow, brown, gray, reddish or blue; white streak; vitreous to pearly luster. Cleavage {001}, perfect; {210}, less so; {010}, imperfect; uneven fracture. $H = 2\frac{1}{2}$ - $3\frac{1}{2}$. $G = 4.50$. Often fluorescent in LWUV, usually in shades of yellow but occasionally orange or pink; SWUV also may excite fluorescence. Barite from the badlands of SD, under SWUV, fluoresces yellow, after which it phosphoresces strongly greenish white. **Tests**: Insoluble in water or acids, infusible in CT, occasionally fetid when rubbed. **Optics**: Biaxial (+); $XYZ = cba$; $N_x = 1.636$, $N_y = 1.637$, $N_z = 1.648$ (Na); $2V = 37^\circ$; $r < v$, weak. Colored varieties are weakly pleochroic. **Occurrence**: Barite is the most abundant mineral of barium and is common as a gangue mineral in metalliferous veins of epithermal or mesothermal origin, associated with fluorite, calcite, dolomite, quartz, galena, and so on. Also widely distributed in sedimentary rocks as veins and lenses or replacement deposits, both of hypogene and supergene origin. Also found in important amounts in residual deposits resulting from the weathering of limestones or dolomites. Occasionally, an important constituent of carbonatites. **Localities**: An early location of large crystals was in Cheshire, CT, while polished slabs were made from massive deposits in Jefferson Co., NY. Noteworthy residual deposits are found in southern Appalachia, especially GA, and in MO and AR. Beautiful yellow-brown crystals(!) line cavities in septaria near Elk Creek in the badlands of

Barite

Forms: $m\{110\}$, $c\{001\}$, $d\{102\}$, $o\{011\}$, $z\{111\}$

SD. "Desert roses" and concretionary crystals containing much included sand occur at Norman in central OK. In Co as fine blue crystals(!) with calcite in veins in shale at Stoneham in Logan Co. and as brilliant, clear colorless or pale violet crystals from concretions in the Book Cliffs, Mesa Co.(!). Important commercial deposits are found near Battle Mt., Lander Co., NV, and in southeastern Tulare Co., CA. Fine crystals are found with copper ore in deep levels of the Magma mine, Superior, AZ(*). In Canada, barite is mined in NS, and good crystals are found in ONT at Galetta, and in QUE. Fine crystals(*) are found with fluorite at the Rock Candy mine near Grand Forks, BC. In Mexico large deposits are mined, especially in the states of MICH, PUE, COAH, and NL. Many localities for fine crystals are in England, especially at Alston Moor(!); Frizington(!); at the Pallafat, Mowbray, and Dalmellington mines, Frizington, Cumbria(!), in superb blue, yellow, or amber elongated and flat large crystals and groups; and in the veins of Cornwall(*). Found at many places in Germany, often in fine crystallized specimens, as at Beihilfe mine, Halsbrücke, Saxony, and at Pöhla mine, Crottendorf. In France at La Cö-d'Abo, Puy de Dôme, in very large flawless amber prismatic crystals, and at Le Maine mine, near Autun, Saône et Loire. Moscona mine, Villabona, Oviedo, Asturias, Spain, in blue prismatic crystals, and large deposits are known in Castile and Andalusia. Silius, Cagliari, Sardinia, in large yellow and brown crystals. Baia Sprie and Cavnik, Maramures, Romania(!), associated with stibnite veins in nice, flawless, blue or red (inclusions of realgar) flat crystals. Plumbian varieties are found on Taiwan and at Shibukuro, Japan. In India from Madras in large, clear, colorless cleavages. Morocco at Taouz, Sahara, in extremely large (> 1.0 m) white elongated crystals and at M'Rit, Midelt, in colorless tabular crystals. Mashamba West, Zaire, in flat gemmy orange crystals. From Brazil in carbonatite at Araxa, MG, in beautiful green crystal groups(*); also near Joao Pessoa, PB, in roseate groups in limestone fissures. Uses: The principal use, accounting for hundreds of thousands of tons annually, is for making high-density muds for oil well drilling; also used for pigments. RG *DII*:408; *AM* 52:1877(1967), 63:506(1978); *NBSM* 25(10):12(1974).

28.3.1.2 Celestine SrSO_4

Named in 1791 from the Latin *coelestis*, heavenly, in allusion to the faint blue color of the first specimens described. Barite group. Synonym: celestite. ORTH *Pnma*. $a = 8.371$, $b = 5.355$, $c = 6.870$, $Z = 4$, $D = 3.982$. *AM 63:506(1978)*. Structure: *CM 13:181(1975)*. 5-593(syn): 3.30_{10} 3.18_6 2.97_{10} 2.73_6 2.67_5 2.05_6 2.04_6 2.00_5 . Habit: Crystals tabular {001}, commonly with large {210}, or lathlike elongated [100], or with equant cross section. Common forms {001}, {100}, {210}, {011}, {102}, {101}, {111}, {211}. Also massive; as fibrous veinlets or nodules, granular, earthy. **Physical properties:** Pale blue or colorless; also white, light red, green, or brown, vitreous luster, pearly on cleavage. Cleavage {001}, perfect; {210}, good; uneven fracture. $H = 3-3\frac{1}{2}$. $G = 3.97$. Some celestines fluoresce white under LWUV, and to a lesser extent under SWUV. **Optics:** Biaxial (+); XYZ = *cba*; $N_x = 1.622$, $N_y = 1.624$, $N_z = 1.631$ (Na); $2V = 50^\circ$; $r < v$; pleochroic if colored. **Chemistry:** Ba substitutes for Sr and a probable complete series extends to barite. Some Ca may replace Sr, with a maximum Ca/Sr ratio about 1:11. Normally, Ba and Ca are present only up to few mol %. Very slightly soluble in water. Slowly soluble in concentrated acids or alkali carbonate solutions. Difficulty fusible. **Occurrence:** Celestine may be directly deposited from seawater or precipitated from percolating surface waters in veins and fissures, presumably leached from nearby sedimentary rocks. It also forms occasionally in hydrothermal deposits. It is common as a minor constituent of evaporites, and disseminated in shales, limestone, dolomite, and sandstone. **Localities:** At the lead mine at Rossie, NY; in PA at *Bellwood, Blair Co.*, in blue fibrous layers. In OH at Clay Center(*) and at Put-in-Bay on South Bass Is., Lake Erie, in a large vug in dolomite(!). In CA in fine clear crystals(*) with colemanite at Death Valley, Inyo Co., and in massive beds 3-6 m thick near Ludlow. Dundas, ONT, Canada, in pale blue crystals. In Mexico in large blue crystals to 40 cm(*) near Matehuala, SLP, and elsewhere in the region in commercial deposits. In England near Bristol, Gloucester, in good crystals(*). Found at numerous places in Germany, Austria, and the Slovakia. In the amygdules of a volcanic rock at Montecchio Maggiore, Italy, and in splendid groups of crystals at Girgenti with sulfur, aragonite, and gypsum and at the Floristella mine, Caltanissetta, Sicily(!), blue crystals > 100 mm on corroded sulfur. Near Sakoany, SW of Majunga, Madagascar, as large, brilliant, often clear blue crystals(!) in

Celestine

Forms: $m\{110\}$, $c\{001\}$, $k\{104\}$, $d\{102\}$, $o\{011\}$

large geodes in early Tertiary marls. RG *DII:415*, *AM 46:189(1961)*, *ZK 121:204(1965)*.

28.3.1.3 Anglesite PbSO_4

Named in 1832 for the locality. Barite group. ORTH *Pnma*. $a = 8.482$, $b = 5.398$, $c = 6.959$, $Z = 4$, $D = 6.36$. Structure: *AM 63:506(1978)*. 36-1461(syn): 4.27₅ 4.24₅ 3.33₇ 3.22₅ 3.01₉ 2.07₁₀ 2.032₆ 2.027₅. Variable habit; thin to thick tabular {001}, often with {210}, {101}, and rhomboidal outline; also prismatic [001], [100], or [010] in combination with {210}, {011}, {102}; equant or pyramidal {111} or {211}. {100} and {210} often striated [001]. Usually massive, granular to compact, often with concentric banding and enclosing an unaltered core of galena. May form epitaxial overgrowths on galena or barite. Colorless to white, often tinged with gray, yellow, green, or blue; colorless streak; adamantine to resinous luster, or vitreous. Cleavage {001}, good; {210}, distinct; {001} in traces; conchoidal fracture; brittle. $H = 2\frac{1}{2}$ -3. $G = 6.38$. Often fluoresces yellow under LWUV radiation. Biaxial (+); $XYZ = cba$; $N_x = 1.877$, $N_y = 1.883$, $N_z = 1.894$ (Na); $2V = 75^\circ$. A small amount of substitution of Ba for Pb has been reported. Slowly soluble in HNO_3 , easily so in ammonium acetate solution. Fragments placed in $(\text{NH}_4)_2\text{CO}_3$ solution are coated with white PbCO_3 , and in $(\text{NH}_4)_2\text{S}$ solution turn black and lustrous. Easily fusible. Anglesite is normally formed from the oxidation of galena and is common in the upper portion of lead deposits. Cavities in altering galena are often lined with fine crystals of anglesite, sometimes accompanied by sulfur crystals. Anglesite forms pseudomorphs after galena, and in turn readily alters to cerussite, which may vein massive anglesite or form crusts on it. Formerly found well crystallized(*) at the Wheatley mine, Chester Co., PA. In UT in the Tintic district, Juab Co. Fine specimens come from the Coeur d'Alene district(*), ID; also noted in AZ, NV, CO, and CA. In Mexico abundant in massive form at Sierra Mojada, COAH, associated with boleite at Boleo, BCS, and elsewhere in the country. In *Wales* at *Pary's mine* on the *Island of Anglesey*. In England at Matlock and Cromford, Derbyshire(*); in Scotland at Leadhills, Lanark. Found in Germany in the lead mines near Siegen, Westphalia; at Bleiberg, Carinthia, Austria; in France at Huelgoat, Brittany. In Italy on the island of Sardinia at Monte-

Anglesite

Forms: $m\{110\}$, $c\{001\}$, $l\{104\}$, $d\{102\}$, $o\{011\}$

vecchio and finely crystallized at Monteponi(1). In Africa crystals of exceptional size (to 80 cm), beauty, and transparency at Touissit, Morocco(1), with cerussite and phosgenite; at Sidi-Amor-Ben-Salem, Tunisia, and at Tsumeb, Namibia(1). In Australia at Broken Hill, NSW, and at Dundas, TAS. *RG DII:420*.

28.3.2.1 Anhydrite CaSO_4

Named in 1795 for the Greek term for *without water*, in allusion to its composition. ORTH *Cmcm*. $a = 6.993$, $b = 6.995$, $c = 6.245$, $Z = 4$, $D = 2.96$. *CM 13:289(1975)*. *37-1496(syn): 3.50₁₀ 2.85₃ 2.33₂ 2.21₃ 2.09₁ 1.87₂ 1.75₁ 1.65₁*. **Structure:** The unit cell has two edges approximately equal but the structure is not pseudotetragonal. It is very different from that of barite but more reminiscent of zircon. S atoms, which are at the centers of regular tetrahedra of O's, and Ca atoms, lie on the lines of intersection of two sets of mirror planes. Planes containing evenly spaced Ca and SO_4 ions lie parallel to $\{100\}$ and $\{010\}$, whereas layering is not so well defined parallel to $\{001\}$. This is in accord with the better cleavage on $\{100\}$ and $\{010\}$ than on $\{001\}$. The succession of Ca and SO_4 ions in the Z direction can be regarded as a chainlike feature, which also occurs in the structure of gypsum. *DHZ 2nd ed.: 617(1992)*, *AC(B) 31:2164(1965)*. **Habit:** Crystals uncommon, usually equant or thick tabular on $\{010\}$. Usually massive, coarsely crystalline, showing pseudocubic cleavage; granular, or fibrous. Twinning on $\{011\}$ or $\{120\}$. **Physical properties:** Colorless to white; also pale shades of blue or violet; rose, mauve, brownish, reddish, gray; white streak; vitreous to pearly luster. Cleavage $\{010\}$, perfect; $\{100\}$, nearly so; $\{001\}$, good to imperfect; uneven to splintery fracture. $H = 3\frac{1}{2}$. $G = 2.98$. Nonfluorescent. **Optics:** Biaxial (+); $XYZ = bac$; $N_x = 1.570$, $N_y = 1.575$, $N_z = 1.614$ (Na); $2V = 43.7^\circ$; absorption $Z > Y > X$. **Chemistry:** The composition of anhydrite apparently varies only slightly from the theoretical formula through isomorphous substitution for Ca. Sr and Ba have been reported in amounts less than 1%. **Test:** Soluble in acids. **Occurrence:** Anhydrite is one of the most important minerals of the marine evaporites, forming beds that may reach a thickness of hundreds of meters. It precipitates from concentrated saline solutions at temperatures above 42° . It is often associated with gypsum, at the expense of which it can be formed. Occasionally found as a gangue mineral in hydrothermal veins; also as a sublimation product in fumaroles. **Alteration:** Anhydrite alters readily by hydration to gypsum, accompanied by an increase in volume, with resulting mechanical deformation of the rock. Pseudomorphs after anhydrite, mostly by incrustation, are found in many places. Hollow rectangular molds after anhydrite crystals are very common in the zeolite-containing cavities in diabasic igneous rocks. **Localities:** Found in druses in the Lockport dolomite, NY; as crystalline masses or hollow casts after anhydrite crystals in quartz, prehnite, and zeolites in the Triassic diabase of Paterson and elsewhere in NJ. From the Carlsbad salt beds of the Permian basin, TX-NM, and in the cap rock of salt domes in TX and LA. In Canada in bedded deposits in NS and on

ANHYDRITE: CaSO_4

Ca atoms and SO_4 tetrahedra alternate in all three directions, as in halite, but the sulfate groups are considerably flattened in the *a* directions and are off center. The structure is basically the same as that of zircon and xenotime.

Calumet Island, QUE. In Mexico in orebodies at Nacozari, SON, and at Naica, CHIH, in fine blue crystals(!). Important deposits in the Stassfurt region, Germany. *Hall*, near Innsbruck, Tyrol, Austria. In Switzerland at the Simplon tunnel, Valois (km 7.25 and 9.4–9.6 from northern Portal) in fine transparent lavender crystals(!); also at many places in Swiss Triassic deposits, superb crystals to 10 cm, and nice flat twins in the clefts. In France at numerous places in the rock salt and gypsum deposits of the Pyrenees; from fumaroles at Vesuvius, Italy; from the salt beds of Krakow, Poland. In the ore at the Hanaoka and Kano mines, Ugo, Japan. With calcite, apatite, titanite, and diopside in Grenville-type deposits near Betroka, Madagascar. RG *DII:424*, *AC 16:767(1969)*, *NBSC 539(4):65(1955)*.

28.3.3.1 Chalcocyanite CuSO_4

Named in 1873 from the Greek for *copper* and *azure blue*, in allusion to the composition, and color change when hydrated. Synonym: chalcocyanite. Originally called "hydrocyanite." ORTH *Pmna*. $a = 8.409$, $b = 6.709$, $c = 4.833$, $Z = 4$, $D = 3.89$. *MPA 39:201(1988)*. *15-775(syn)*: 4.19_8 3.55_{10} 2.61_{10} 2.42_5 1.96_2 1.77_3 1.433_2 1.429_2 . Crystals tabular {100}. Colorless when pure; normally pale green, brownish, or yellowish; also sky blue, due to partial hydra-

tion. No cleavage. $H = 3\frac{1}{2}$. $G = 3.65$. Biaxial (-); $XYZ = abc$; $N_x = 1.724$, $N_y = 1.733$, $N_z = 1.739$ (\bar{N}_a); $2V = 80^\circ$; $r > v$, extreme. Soluble in water; very hygroscopic. Found in fumaroles on *Vesuvius, Italy*. RG *DII:429, AM 46:758(1961)*.

28.3.4.1 Yavapaiite $KFe(SO_4)_2$

Named in 1959 for the Yavapai Indian tribe that inhabited the area of Arizona where the mineral was found. MON $C2/m$. $a = 8.152$, $b = 5.153$, $c = 7.877$, $\beta = 94.90^\circ$, $Z = 2$, $D = 2.891$. *AM 56:1917(1971)*. *29-1438(syn)*: 7.87_7 4.07_5 3.89_7 3.74_7 3.49_6 2.99_{10} 2.85_5 2.40_6 . Crystals minute, elongated [010]. Pale pink, with adamantine to vitreous luster. Cleavage {100} and {001}, perfect; {110}, distinct. Fracture conchoidal. $H = 2\frac{1}{2}$ -3. $G = 2.88$. Biaxial (-); $XZ = ab$; $X \wedge c = 6^\circ$; $N_x = 1.593$, $N_y = 1.684$, $N_z = 1.698$; $2V = 30^\circ$; $r > v$, strong. From the *United Verde Extension mine, Jerome, AZ*, as crystal aggregates coating rubble, associated with voltaite, jarosite, and sulfur. RG *AM 44:1105(1959)*.

28.3.5.1 Sabieite $NH_4Fe(SO_4)_2$

Named in 1983 for the locality. HEX-R $P321$. $a = 4.82$, $c = 8.17$, $Z = 1$, $D = 2.361$. *AM 71:229(1986)*. *24-44*: 8.3_7 3.74_{10} 2.95_5 2.42_3 2.31_1 1.871_1 1.861_1 1.397_1 . Microscopic thin platelets, powdery. White. Parallel extinction. Derived from the dehydration of loncreekite. From the *Lone Creek cavern, near Sabie, Transvaal, South Africa*. RG *AGSSA 17:29(1983)*.

28.3.5.2 Godovikovite $NH_4(Al,Fe)(SO_4)_2$

Named in 1988 for Alexandr A. Godovikov (1927–1995), Russian mineralogist, director of the Fersman Museum, Moscow. HEX-R $P321$. $a = 4.75$, $c = 8.30$, $Z = 1$, $D = 2.52$. *ZVMO 117:208(1988)*. *23-1*: 8.28_6 3.68_{10} 2.92_3 2.76_1 2.37_2 1.849_1 1.839_1 1.525_1 . Compact or porous chalky aggregates of fine hairs. White, dull luster. Uneven fracture. $H = 2$. $G = 2.53$. Uniaxial (+); $N_O = 1.572$, $N_E = 1.581$. From burning dumps of coal mines near *Kopeysk, Chelyabinsk coal basin, southern Ural Mts., Russia*. RG *AM 75:241(1990)*.

28.4.1.1 Vanthoffite $Na_6Mg(SO_4)_4$

Named in 1902 for Jacobus Hendricus van't Hoff (1852–1911), Dutch physical chemist. MON $P2_1/c$. $a = 9.797$, $b = 9.217$, $c = 8.199$, $\beta = 113.30^\circ$, $Z = 2$, $D = 2.67$. *AC 17:1613(1964)*. *29-1240(syn)*: 4.03_{10} 3.92_7 3.43_{10} 3.11_8 3.06_5 2.91_7 2.85_6 2.83_6 . Massive, bedded. Colorless, vitreous to pearly luster. Uneven to flat conchoidal fracture; friable. $H = 3\frac{1}{2}$. $G = 2.694$. Biaxial (-); $N_x = 1.485$, $N_y = 1.488$, $N_z = 1.489$; $2V = 84^\circ$; $r < v$, weak. Formed in marine evaporites. *Wilhelmshall, Stassfurt region, Germany*; Hall, Tyrol, Austria. RG *DII:430*.

28.4.2.1 Glauberite $\text{Na}_2\text{Ca}(\text{SO}_4)_2$

Named in 1808 in allusion to its similarity in composition to Glauber's salt ($\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$), which was named for Johann Rudolph Glauber (1603–1668), German alchemist. *MON* $C2/c$. $a = 10.129$, $b = 8.306$, $c = 8.533$, $\beta = 112.20^\circ$, $Z = 4$, $D = 2.78$. *AM* 52:1272(1967). **Structure:** Ca atoms bind eight O's lying at the corners of a distorted square antiprism, its bases being nearly parallel to (100). Na atoms bind seven O's arranged at the corners of a polyhedron having one face centered. Each Na polyhedron shares three edges with the surrounding Na polyhedra, forming three types of zigzag chains: one along the c axial direction, another along the ab diagonal direction, and the third along the ac diagonal. The Ca polyhedra, connected to each other by one edge, are placed along the voids of the Na–O framework, parallel to the c axis. Structurally weak points are localized along layers formed by the Na atoms; these layers are parallel to (001), and along them the mineral shows the main cleavage {001}. As could be surmised from its high density, the structure of glauberite is very compact. *ZK* 122:175(1965). 19-1187(syn): 4.38₅ 3.18₈ 3.13₁₀ 3.11₈ 2.86₅ 2.81₇ 2.68₆ 1.98₆. **Habit:** Variable crystal habit: prismatic [001]; tabular {001}; dipyramidal through combination of {111} and {110}. **Common forms** {001}, {100}, {110}, and {111}. **Physical properties:** Usually

**GLAUBERITE: $\text{Na}_2\text{Ca}(\text{SO}_4)_2$**

Ca atoms are roughly in planes (parallel to (100); Na atoms in planes parallel to (001). Cleavage breaks weak Na–O bonds on (001).

gray or yellowish, sometimes colorless or reddish; white streak; vitreous to waxy luster, pearly on {001} cleavage. Cleavage {001}, perfect; {110}, indistinct; conchoidal fracture. $H = 2\frac{1}{2}$ –3. $G = 2.75$ –2.85. Tests: Whitens in water due to leaching of Na_2SO_4 and deposition of gypsum. Soluble in HCl. Tastes slightly saline. Fusible to a white enamel. **Chemistry:** Analyses of natural glauberites deviate hardly at all from the stoichiometric quantities of Na, Ca, SO_4 , and H_2O . **Optics:** Biaxial (-); $Z = b$; $Y \wedge c = 12^\circ$; $N_x = 1.515$, $N_y = 1.535$, $N_z = 1.536$; $2V = 7^\circ$; $r > v$, strong, horizontal. **Occurrence:** Glauberite is formed under a variety of conditions: as a constituent of both marine and lacustrine evaporites, in cavities in basaltic extrusive rocks, in fumaroles, and with nitrate or borate deposits under extremely arid conditions. **Localities:** Abundant as molds and casts of prehnite and quartz after glauberite in cavities in basalt at Paterson and elsewhere in NJ. From the Verde Valley salt beds, Yavapai Co., AZ. In CA at Searles Lake and in the Saline Valley clays, Inyo Co. In the upper Silurian beds at Gypsumville, MB, Canada. First recognized as crystals in halite at *Villarubia, Toledo, Spain*. From the Triassic salt deposits of Lorraine, France. In Germany in the Stassfurt potash region, often in fine crystals(1). In fumarole deposits at Vulcano in the Lipari Islands, Italy. From the Permian salt deposits at Kairovka and elsewhere in southern Russia. The Mayo mine, Salt Range, Pakistan. In the Atacama desert, Chile. RG *DII:431*.

28.4.3.1 Palmierite $\text{K}_2\text{Pb}(\text{SO}_4)_2$

Named in 1907 for Luigi Palmieri (1807–1896), Italian scientist and director of the observatory on Vesuvius. **HEX-R $R\bar{3}m$.** $a = 5.584$, $c = 20.677$, $Z = 3$, $D = 4.35$. *29-1015*(syn): 6.95₄ 4.64₃ 4.33₅ 3.14₁₀ 2.75₇ 2.56₄ 2.16₃ 2.07₄. Microscopic micaceous plates with a hexagonal outline. Colorless to white; vitreous luster, pearly on base. $G = 4.33$. Uniaxial (-); $N \approx 1.712$. Found in fumarole deposits on *Vesuvius, Italy*, after the eruptions of 1906 and 1919, associated with apthitalite. RG *DII:403, PM 54:34(1985)*.

28.4.3.2 Kalistrontite $\text{K}_2\text{Sr}(\text{SO}_4)_2$

Named in 1962 for the composition. **HEX-R $R\bar{3}m$.** $a = 5.463$, $c = 20.843$, $Z = 3$, $D = 3.32$. *ZVMO 91:712(1962)*. *29-1049*(syn): 6.94₂ 4.31₂ 3.13₁₀ 2.73₇ 2.15₂ 2.06₃ 1.91₂. Prismatic crystals and hexagonal plates. Colorless, vitreous luster. Cleavage {0001}, perfect; brittle. $H = 2$. $G = 3.20$. Uniaxial (-); $N_O = 1.569$, $N_E = 1.549$. Found near *Alshtan, Bachkir region, southern Russia*, in drill core with anhydrite, dolomite, and sylvite. RG *AM 48:708(1963)*.

28.4.3.3 Mereiterite $\text{K}_2\text{Fe}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1995 for Kurt Helmut Mereiter (b.1945), Austrian mineralogist, University of Vienna. Compare leonite (29.3.3.3). **MON $C2/m$.** $a = 11.844$, $b = 9.556$, $c = 9.947$, $Z = 4$, $D = 2.358$. *PD: 4.78₃ 3.51₅ 3.44₁₀ 3.33₅ 3.05₃ 2.41₃ 2.39₅*. Subhedral crystals up to 10 mm × 8 mm × 6 mm, embedded in gypsum. Pale yellow, vitreous to greasy luster, transparent. No cleavage,

conchoidal fracture, brittle. $H = 2\frac{1}{2}$ -3. $G = 2.36$. Nonfluorescent. Readily soluble in water. Biaxial (+); $X = [010]$; $Z \wedge c \approx 20^\circ$; $N_x = 1.497$, $N_y = 1.501$, $N_z = 1.509$; $2V = 71^\circ$; nonpleochroic; $r > v$, weak. From the *Hilarion adit, Agios Konstandinos, Laurium mining district, Greece*, formed by the oxidation of primary sulfides. RG *EJM* 7:559(1995), *AM* 81:251(1996).

28.4.4.1 Langbeinite $K_2Mg_2(SO_4)_3$

Named in 1891 for A. Langbein, German chemist, Leopoldshall. iso $P2_13$. $a = 9.920$, $Z = 4$, $D = 2.824$. *NJMM*:182(1979). 19-97 $\frac{1}{4}$ (syn): 4.05 $\frac{3}{4}$ 3.14 $\frac{10}{10}$ 2.99 $\frac{2}{2}$ 2.75 $\frac{2}{2}$ 2.65 $\frac{4}{4}$ 2.41 $\frac{1}{1}$ 1.95 $\frac{1}{1}$ 1.61 $\frac{1}{1}$. Rarely in crystals; as nodules or grains. Colorless or pale colors, vitreous luster. No cleavage, conchoidal fracture. $H = 3\frac{1}{2}$ -4. $G = 2.83$. Reported to be Piezoelectric. (*Bond, Bell Syst. Tech. J.* 22:145(1943)). Isotropic; $N = 1.533$ -1.535. Slightly soluble in water, easily fusible, turns white on slight heating. Found in marine evaporites. May be pseudomorphously replaced by kainite. Abundant in salt beds 24 km E of Carlsbad, NM, where some beds up to 2 m thick contain up to 90% langbeinite, associated with halite and sylvite. Partly in crystals up to 2 cm. At *Wilhelmshall, Stassfurt region, northern Germany*, also in Solvayhall and elsewhere. At Hall, Tyrol, Austria. Stebnik, Galicia, Poland. Mayo mine, Salt Range, Pakistan. Mined on a large scale as a source of potash. RG *DII*:434, *PM* 54:1(1985).

28.4.4.2 Manganolangbeinite $K_2Mn_2(SO_4)_3$

Named in 1924 for its composition and relationship to langbeinite. iso $P2_13$. $a = 10.114$, $Z = 4$, $D = 3.02$. *NBSM* 6:43(1968). 20-909(syn): 5.84 $\frac{1}{1}$ 4.13 $\frac{1}{1}$ 3.20 $\frac{10}{10}$ 3.05 $\frac{2}{2}$ 2.70 $\frac{5}{5}$ 2.06 $\frac{1}{1}$ 1.98 $\frac{1}{1}$ 1.64 $\frac{2}{2}$. Crystallizes as small tetrahedra. Rose-red, vitreous luster. No cleavage. $H = 3\frac{1}{2}$ -4. $G = 3.02$. Piezoelectric. Isotropic; $N = 1.572$. Found in a lava cavern at *Vesuvius, Italy*. RG *DII*:435.

28.4.4.3 Efremovite $(NH_4)_2Mg_2(SO_4)_3$

Named in 1989 for Ivan Antonovich Yefremov (1907-1972), Russian geologist and science fiction writer. iso $P2_13$. $a = 9.99$, $Z = 4$, $D = 2.52$. 42-1432: 5.76 $\frac{2}{2}$ 4.08 $\frac{7}{7}$ 3.53 $\frac{1}{1}$ 3.15 $\frac{10}{10}$ 3.01 $\frac{3}{3}$ 2.77 $\frac{1}{1}$ 2.67 $\frac{3}{3}$ 1.737 $\frac{1}{1}$. Aggregates of equant grains. Colorless to gray, vitreous to dull luster. No cleavage, uneven fracture. $H = 2$. Isotropic; $N = 1.550$. Soluble in water; in CT, evolves ammonia. Spontaneously hydrates to boussingaultite in air over several days. From burning coal dumps in the Chelyabinsk coal basin, southern Ural Mts., Russia. RG *AM* 76:299(1991).

28.4.5.1 Millosevichite $(Al,Fe)_2(SO_4)_3$

Named in 1913 after F. Millosevich (1875-1942), Italian mineralogist, University of Rome. *HEX-R R3*. $a = 8.055$, $c = 21.191$, $Z = 6$, $D = 2.86$. *NBSM* 15:8(1978). 42-1410(syn): 5.82 $\frac{4}{4}$ 4.22 $\frac{2}{2}$ 4.03 $\frac{1}{1}$ 3.53 $\frac{4}{4}$ 3.50 $\frac{10}{10}$ 2.92 $\frac{2}{2}$ 2.66 $\frac{2}{2}$ 2.62 $\frac{1}{1}$. Granular masses which show small clear crystals on their surfaces. Clear red to brick red, also violet-blue; vitreous luster. $H = 1\frac{1}{2}$. Nearly isotropic;

$N \approx 1.573$. From *Vulcano, Lipari Islands, Italy*, in the Alum Grotto. In the Lvovsko-Volynskii Bolynskir coal basin, Ukraine, Russia, in fractures in rocks from which H_2S and SO_2 are escaping. RG *DII:539*.

28.4.5.2 Mikasaite $(Fe^{3+}, Al)_2(SO_4)_3$

Named in 1994 for the locality. The Fe^{3+} analog of millosevichite (28.4.5.1). **HEX-R** *R3*. $a = 8.14$, $c = 21.99$, $Z = 6$. *PD*: 5.99₃ 4.35₂ 3.56₁₀ 2.97₂ 2.72₂ 2.64₁ 2.35₁ 2.24₁, in good agreement with *JCPDS 33-679* [synthetic $Fe_2(SO_4)_3$]. Forms aggregates of porous material made up of hollow spherical crystallites to 100 μm in diameter. White to light brown with a similar streak. Soft. Highly deliquescent. Uniaxial (+); $N_x = 1.504$, $N_y = 1.518$. Found as a sublimate in fissures with escaping high-temperature gas over a burning coal seam in *Ikushunbetsu, Mikasa City, Hokkaido, Japan*. RG *MM 58:649(1994)*, *AM 80:846(1995)*.

28.4.6.1 Klyuchevskite $K_3Cu_3(Fe^{3+}, Al)O_2(SO_4)$

Named in 1989 for the locality, the Klyuchevsk group of volcanoes. **MON 12** $a = 18.412$, $b = 4.944$, $c = 18.640$, $\beta = 101.5^\circ$, $Z = 4$, $D = 2.98$. *41-1463* 9.17₉ 9.03₁₀ 7.20₄ 4.50₃ 3.76₆ 3.68₂ 3.45₂ 3.41₃. Crystals acicular, elongate [010], to 0.1mm, as unoriented aggregates, dark green to olive green, light green streak, semimetallic luster, cleavage perfect {h01}, $H = 2\frac{1}{2}$, $G = 3.00-3.15$. Soluble in cold water and in weak acids, hydrates slowly in air to a white powder. Biaxial +, $N_\alpha 1.549$ (olive), $N_\beta 1.550$ (green), $N_\gamma 1.680$ (dark olive), $2V_{calc} 11^\circ$, $Y = b$. Found in cavities and fissures in massive sublimate at the *Great Tolbachik Fissure Eruption, Kamchatka, Russia*, associated with kamchatkite, pononarevite, and hematite. *ZVMO 118(1):65(1989)* *AM 75:1210(1990)* *MM 56:411(1992)* *AM 78:454(1993)*.

28.4.6.2 Alumoklyuchevskite $K_3Cu_3(Al, Fe^{3+})O_2(SO_4)_4$

Named in 1995 as the Al-dominant analog of klyuchevskite. **MON 12**. $a = 18.423$, $b = 5.139$, $c = 18.690$, $Z = 4$, $D = 2.95$. *PD*: 9.15₈ 9.04₁₀ 7.20₅ 4.51₂ 3.78₄ 3.76₃ 3.42₂ 2.79₂. Acicular, prismatic crystals, to 1 mm, in aggregates. Transparent, dark green. Cleavage (h0l), perfect. $H = 2$. $G = 3.1$. Biaxial (+); $N_x = 1.542$, $N_y = 1.548$, $N_z = 1.641$; $2V = 30^\circ$. X, light green; Y, grayish green; Z, dark green. Soluble in water, hydrates slowly in air to a white powder. Found in fumaroles in the *Main Tolbachik fracture eruption, Kamchatka, Russia*, associated with fedotovite, tenorite, langbeinite, and lammerite. RG *ZVMO 124(1):95(1995)*.

Hydrated Acid and Sulfates

29.1.1.1 Rhomboclase $\text{HFe}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1891 in allusion to the basal cleavage and crystal shape. ORTH *Pnma*. $a = 9.724$, $b = 18.333$, $c = 5.421$, $Z = 4$, $D = 2.206$. *TMPM* 21:216(1974). 27-245: 9.15₄ 4.74₄ 4.29₄ 4.21₄ 4.05₅ 3.55₄ 3.33₅ 3.11₁₀. Crystals thin tabular {001}, also as stalactites with radiating bladed structure. Colorless to white, gray, or pale yellow, or tinted blue or green; vitreous to pearly luster. Cleavage {001}, perfect; {110}, good; conchoidal to fibrous fracture; cleavage folia are flexible. $H = 2$. $G = 2.23$. Biaxial (+); $XYZ = cab$; $N_x = 1.534$, $N_y = 1.553$, $N_z = 1.638$ (Na); $2V = 27^\circ$. Slowly soluble in water, easily in acids. From *Smolnik, Slovakia*, associated with other sulfates in altering pyritic ores. Esperanza mine, Cerro de Pasco, Peru, as incrustations in abandoned workings. Alcaparrosa, near Cerritos Bayos, Chile, with szomolnokite and roemerite. Thin platy crystals to 2 cm(!) with melanterite and copiapite, Socavon mine, Oruro, Bolivia. RG *DII:436, TMPM 16:155(1970)*.

29.1.2.1 Matteuccite $\text{NaHSO}_4 \cdot \text{H}_2\text{O}$

Named in 1952 for Vittorio Matteucci (1862–1909), Italian vulcanologist. MON *Cc*. $a = 7.81$, $b = 7.82$, $c = 8.03$, $\beta = 117.48^\circ$, $Z = 4$, $D = 2.108$. 22-1379(syn): 5.18₂ 5.11₄ 3.63₃ 3.56₁₀ 3.46₇ 3.42₆ 3.38₂ 2.76₂. Mixed with other salts in fine-grained stalactites. Colorless, vitreous luster. Biaxial (+); $2V = 86^\circ$. Found as a third component in stalactites in fumaroles in the 1933 eruption of *Vesuvius, Italy*, mixed with mercallite and ralstonite. The identity of this component with synthetic $\text{NaHSO}_4 \cdot \text{H}_2\text{O}$ is probable but not positive. RG *AM 39:848(1954), AST 109:532(1975)*.

29.1.3.1 Monsmeditite $\text{H}_3\text{K}_2\text{Ti}_2(\text{SO}_4)_8 \cdot 11\text{H}_2\text{O}$

Named in 1968 for the Latin *Mons Medius*, for Baia Sprie, Romania, the locality for the mineral. ORTH Space group unknown. 41-1448: 5.49₁ 3.56₄ 3.40₁₀ 3.06₁ 2.86₄ 2.32₄ 2.08₄ 1.57₄. Cubelike crystals, with {111} and {110}. Dark green to black, nearly opaque in large crystals, pitchy luster. Prismatic and pyramidal cleavage. $H > 2$. $G = 3.0$. Biaxial (-); $N \approx 1.608$; birefringence = 0.011; $r > v$. Found in geodes with marcasite and barite on kaolinite and limonite at *Baia Sprie, Baia Mare region, Romania*, in the oxidation zone of a silver-bearing lead-zinc deposit. RG *AM 53:2104(1968), 54:1496(1969)*.

29.2.1.1 Lecontite $\text{NH}_4\text{Na}(\text{SO}_4) \cdot 2\text{H}_2\text{O}$

Named in 1858 for John L. LeConte (1825–1883), American entomologist, who discovered the mineral. ORTH $P2_12_12_1$. $a = 8.216$, $b = 12.854$, $c = 6.232$, $Z = 4$, $D = 1.747$. Structure: *AC 22:683(1967)*. *15-283(syn)*: 5.07_{10} 4.65_6 3.94_5 3.80_{10} 3.45_6 3.32_7 3.03_9 2.69_8 . *15.370(nat)*: 5.06_8 4.98_5 4.64_{10} 3.91_5 3.80_5 3.32_5 3.04_9 , 1.997. Prismatic or lathlike crystals. Colorless, vitreous luster. Biaxial (-); $\text{XYZ} = acb$; $N_x = 1.440$, $N_y = 1.452$, $N_z = 1.453$; $r < v$, strong. Soluble in water. Tastes saline, bitter. Found embedded in bat guano in *Las Peidras cave, near Camayagua, Honduras*. RG *DII:438*; *AM 36:596(1951)*, *48:180(1963)*.

29.2.2.1 Mirabilite $\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$

Named in 1845 from the Latin *sal mirabile*, wonderful salt, suggested by J. R. Glauber (1603–1668), who was surprised at its formation during an experiment. Synonym: Glauber's salt. MON $P2_1/c$. $a = 11.51$, $b = 10.37$, $c = 12.85$, $\beta = 107.80^\circ$, $Z = 4$, $D = 1.465$. Structure: *AC(B) 34:3502(1978)*. *11-647*: 5.49_{10} 4.77_5 3.83_4 3.26_6 3.21_8 3.11_6 2.80_8 2.52_4 . Crystals short prismatic to acicular [001] or [010]; also tabular or lathlike; commonly massive, as crusts, or stalactitic. Twins by interpenetration on {001}; also on {100}. Colorless to white, white streak, vitreous luster. Conchoidal fracture. $H = 1\frac{1}{2}$ –2. $G = 1.490$. Biaxial (-); $X = b$, $Z \wedge c = 31^\circ$; $N_x = 1.396$, $N_y = 1.410$, $N_z = 1.419$ (Na); $2V = 76^\circ$; $r < v$, strong, crossed. Soluble in water. Tastes cool, slightly saline, and bitter. In CT, loses water and melts. Loses its water in dry air and falls to a loose powder. Formed in saline lakes, playas, and springs, and as an efflorescence on alkali soils. In CA at several places, especially at Mono Lake, Searles Lake, and Soda Lake, San Luis Obispo Co. In UT along the southern shore of Great Salt Lake, where it crystallizes during winter due to decreased solubility at low temperatures. In Canada in alkaline lakes in SK. Ischl, Hallstatt, and elsewhere in Austria; Ebro, Spain; Montedoro, Girgenti, Sicily, Italy. Salar de Pintados, Tarapaca, Chile, as ice-clear anhedral crystals. RG *DII:439*, *MR 1:12(1970)*.

29.3.1.1 Syngenite $\text{K}_2\text{Ca}(\text{SO}_4)_2 \cdot \text{H}_2\text{O}$

Named in 1872 from the Greek meaning *related*, because of its chemical resemblance to polyhalite. MON $P2_1/m$. $a = 9.777$, $b = 7.147$, $c = 6.250$, $\beta = 104.02^\circ$, $Z = 2$, $D = 2.574$. *NBSM 25:14(1977)*. Structure: *SPC 23:271(1978)*. *28-739*: 9.49_4 5.71_6 4.62_4 3.35_4 3.17_8 2.86_{10} 2.83_5 2.74_6 . In crystalline crusts and lamellar aggregates; crystals tabular {100} to prismatic [001], often rich in forms. Contact twins on {100}. Colorless, white, or faintly yellow; vitreous luster. Cleavage {110} and {100}, perfect; {010} distinct; conchoidal fracture. $H = 2\frac{1}{2}$. $G = 2.58$ –2.60. Biaxial (-); $Z = b$; $X \wedge c = -2^\circ$; $N_x = 1.501$, $N_y = 1.517$, $N_z = 1.518$ (Na); $2V = 28^\circ$; $r < v$, strong. Does not alter in dry air. Partially dissolves in water with separation of gypsum. Easily fusible. Formed in marine salt deposits or in fumaroles. In the crater of Haleakala,

Maui, Hawaii. *Kalusz, Galicia, Poland*. Glück Auf, Germany. In lava at Vesuvius, Italy. RG *DII:442*, *ZK 124:398(1967)*, *SPC 20:773(1975)*.

29.3.1.2 Koktaite $(\text{NH}_4)_2\text{Ca}(\text{SO}_4)_2 \cdot \text{H}_2\text{O}$

Named in 1948 for Jaroslav Kokta (1904–1970), Czech chemist, who analyzed the artificial compound. MON $P2_1/m$. $a = 6.324$, $b = 7.129$, $c = 10.098$, $\beta = 102.58^\circ$. $Z = 2$, $D = 2.140$. $11\text{-}475$: 9.83_{10} 5.83_2 4.96_4 4.08_1 3.56_2 3.30_7 3.00_2 2.89_2 . Acicular or fibrous crystals, with $\{100\}$, $\{110\}$, $\{001\}$, $\{011\}$, $\{101\}$; twins on $\{100\}$ frequent. Colorless to white. No cleavage. $G = 2.09$. Soluble in water with separation of gypsum, easily fusible. Biaxial (-); $Y = b$; $Z \wedge c = 2^\circ$; $N_x = 1.524$, $N_y = 1.532$, $N_z = 1.536$; $2V = 72^\circ$. Found as pseudomorphs after gypsum with mascagnite and ammonia alum on the waste heaps of a lignite mine at *Zeravice, near Kyjov in southeastern Moravia, Czech Republic*. RG *DII:444*, *AM 34:618(1949)*, *PM 54:29(1985)*.

29.3.2.1 Kröhnkite $\text{Na}_2\text{Cu}(\text{SO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1876 for B. Kröhnke, who first analyzed the mineral. MON $P2_1/c$. $a = 5.807$, $b = 12.656$, $c = 5.517$, $\beta = 108.19^\circ$, $Z = 2$, $D = 2.913$. $25\text{-}826$: 6.32_{10} 4.15_3 3.71_4 3.35_3 3.28_8 3.10_4 2.93_7 2.76_5 . Structure: *AC(B) 31:1753(1975)*. Short prismatic crystals; also pseudo-octahedral; commonly as crusts or cross-fiber veinlets; massive; granular. Twins on $\{101\}$, sometimes heart-shaped. Sky blue to greenish blue, vitreous luster. Cleavage $\{010\}$, perfect; $\{101\}$, poor; conchoidal fracture. $H = 2\frac{1}{2}\text{-}3$. $G = 2.90$. Soluble in water, easily fusible, in CT gives water. Biaxial (-); $Y = b$; $X \wedge c = 48^\circ$; $N_x = 1.544$, $N_y = 1.578$, $N_z = 1.601$ (Na); $2V = 79^\circ$; $r < v$, weak, inclined. Formerly an abundant ore mineral at *Chuquicamata, Antofagasta, Chile*, where it was associated with chalcantite, natrochalcite, antlerite, and other soluble copper salts. Also at the Salvador mine, Quetana, and elsewhere in the Atacama desert region. RG *DII:444*, *PM 23:223(1954)*.

29.3.3.1 Blödite $\text{Na}_2\text{Mg}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1821 for Carl August Bloede (1773–1820), German chemist. Synonym: bloedite. MON $P2_1/a$. $a = 11.128$, $b = 8.246$, $c = 5.543$, $\beta = 100.87^\circ$, $Z = 2$, $D = 2.218$. *NBSM 25(6):43(1968)*. Structure: *CM 23:669(1985)*. $19\text{-}1215$: 4.56_{10} 3.29_{10} 3.25_{10} 2.97_4 2.73_4 2.72_4 2.65_4 2.64_4 . Crystals short prismatic $\{001\}$, often highly modified; also massive, granular to compact. Colorless; sometimes greenish, reddish, gray due to inclusions; vitreous luster. No cleavage, conchoidal fracture, brittle. $H = 2\frac{1}{2}\text{-}3$. $G = 2.25$. Soluble in water. Tastes saline, bitter. Biaxial (-); $Y = b$; $X \wedge c = 37^\circ$; $N_x = 1.483$, $N_y = 1.486$, $N_z = 1.487$; $2V = 71^\circ$. Formed in both marine and lacustrine salt deposits, and with nitrates in extremely arid regions. Soda Lake, San Luis Obispo Co., CA. Stassfurt region, Germany, and at the *Ischl deposit* and *Hallstatt deposit* in *Austria*. *Kalusz, Galicia, Poland*. In salt lakes near *Korduansk, Russia*. *Chuquicamata, Chile*, and elsewhere in the Atacama desert. RG *DII:447*.

29.3.3.2 Nickelblödite $\text{Na}_2(\text{Ni}, \text{Mg})(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1977 from the composition and relationship to blödite. MON $P2_1/c$. $a = 10.87$, $b = 8.07$, $c = 5.46$, $\beta = 100.72^\circ$, $Z = 2$, $D = 2.455$. *MM* 41:37(1977). 29-1253: 4.47₉ 4.19₇ 3.72₆ 3.22₁₀ 3.19₈ 2.90₅ 2.59₆ 2.24₅. Efflorescences; also minute tabular crystallites. Light green. $\text{VHN}_5 = 104\text{--}139$. $G = 2.43$. Biaxial (-); $N_x = 1.513$, $N_y = 1.518$, $N_z = 1.520$; $2V = 60\text{--}70^\circ$. Found as efflorescences encrusting ores containing violarite and pyrite at *Durkin nickel mine, Kambalda, WA, Australia*, and at *Carr Boyd Rocks, WA*. *RG AM* 62:1059(1977).

29.3.3.3 Leonite $\text{K}_2\text{Mg}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1896 for Leon Strippelmann, director of the salt works at Westerregeln, Germany. See mereiterite (29.3.3.4). MON $C2/m$. $a = 11.769$, $b = 9.539$, $c = 9.889$, $\beta = 95.30^\circ$, $Z = 4$, $D = 2.203$. Structure: *ZK* 173:75(1985). 21-995: 5.88₂ 3.49₄ 3.42₁₀ 3.31₄ 3.04₅ 2.88₃ 2.38₅ 2.17₂. Crystals tabular {100} and elongated [001], usually anhedral, intergrown with other minerals; colorless to yellowish, waxy to vitreous luster. Conchoidal fracture. $H = 2\frac{1}{2}\text{--}3$. $G = 2.201$. Easily soluble in water. In CT, loses water and fuses. In air alters and becomes coated with a white crust of picromerite. Tastes bitter. Biaxial (+); $Y = b$; $Z \wedge a = \text{small}$; $N_x = 1.479$, $N_y = 1.482$, $N_z = 1.487$; $2V \approx 90^\circ$. Formed in marine salt deposits. Found in drill cores from wells in Eddy and Lea Cos., MN. *Westerregeln, Leopoldshall*, and elsewhere in the *German potash districts*. *RG DII:450, USGSPP* 550B:125(1966), *MA* 74:3459.

29.3.4.1 Wattevillite $\text{Na}_2\text{Ca}(\text{SO}_4)_2 \cdot 4\text{H}_2\text{O}$ (?)

Named in 1879 for Oscar de Watteville of Paris, France. A questionable mineral species. ORTH or MON Space group unknown. 41-1360: 5.44₅ 5.10₄ 4.39₁₀ 4.20₆ 4.03₄ 2.95₅ 2.89₅ 2.67₄. Aggregates of minute acicular crystals, in part twinned. Snow-white, silky luster. $G = 1.81$. Biaxial (-); $N_x = 1.435$, $N_y = 1.455$, $N_z = 1.459$; $2V = 48^\circ$; no perceptible dispersion. *Einigkeit mine, Bauersberg, near Bischofsheim, Bavaria, Germany*, associated with other sulfates in pyritic lignite. *RG DII:452*.

29.3.5.1 Konyaite $\text{Na}_2\text{Mg}(\text{SO}_4)_2 \cdot 5\text{H}_2\text{O}$

Named in 1982 for the locality. MON $P2_1/c$. $a = 5.784$, $b = 24.026$, $c = 8.066$, $\beta = 95.37^\circ$, $D = 2.097$. *AM* 67:1035(1982). 35-649(syn): 12.0₁₀ 4.55₆ 4.20₂ 4.18₂ 4.00₇ 3.96₁ 2.81₁ 2.73₁. Efflorescences consisting of aggregates of minute crystals; colorless to white. $H = 2\frac{1}{2}$. $G = 2.09$. Soluble in water. Biaxial (-); $X = b$; $Z \wedge c = 70^\circ$; $N_x = 1.464$, $N_y = 11.468$, $N_z = 1.474$; $2V = 74^\circ$. *Great Konya Basin, Central Anatolia, Turkey*, as salt efflorescences on saline soils, associated with gypsum, hexahydrate, loeweite; halite, and blödite. *RG AM* 74:1382(1989).

PICROMERITE GROUP

The picromerite group consists of five isostructural sulfate hexahydrates of general formula

where

A = K, NH₄

B = Mg, Cu, Fe, or Ni

and the space group is monoclinic. *CSMQ 1:1(1972)*, *AC 17:1478(1964)*.

MOHRITE: (NH₄)₂Fe(SO₄)₂ · 6H₂O (picromerite group)

NH₄(K) and sulfate are mutually eight-coordinated and form a loose framework. Fe(H₂O)₆ octahedra are in interstices. Structural formula could be NH₄)₂(SO₄)₂ · Fe(H₂O)₆.

PICROMERITE GROUP

Mineral	Formula	Space Group	Dimensions					D
			a	b	c	β	D	
Picromerite	K ₂ Mg(SO ₄) ₂ ·6H ₂ O	P2 ₁ /a	9.096	12.254	6.128	104.78°	2.025	29.3.6.1

29.3.6.1 Picromerite $K_2Mg(SO_4)_2 \cdot 6H_2O$

Named in 1855 for the Greek for *bitter* and *part*, in allusion to the magnesium content, salts of which are usually bitter. Picromerite group. MON $P2_1/a$. $a = 9.096$, $b = 12.254$, $c = 6.128$, $\beta = 104.78^\circ$, $Z = 2$, $D = 2.025$. NBSM 25(8):54(1970). 21-1400(syn): 4.16₉ 4.06₁₀ 3.71₁₀ 3.16₄ 3.06₇ 2.96₆ 2.81₄ 2.39₅. Short prismatic crystals, as crusts, massive. Colorless to white; also yellowish, reddish, gray, due to admixture; vitreous luster. Cleavage {201}, perfect. $H = 2\frac{1}{2}$. $G = 2.028$. Soluble in water, easily fusible. Biaxial (+); $Y = b$; $X \wedge a = -1^\circ$; $N_x = 1.460$, $N_y = 1.462$, $N_z = 1.472$ (Na); $2V = 48^\circ$; $r > v$, weak. From fumarole deposits on *Vesuvius*, *Italy*. Stassfurt salt deposits, Germany; Kalusz, Galicia, Poland. RG DII:453, NW 44:350(1957), CE 24:94(1965)

29.3.6.2 Cyanochroite $K_2Cu(SO_4)_2 \cdot 6H_2O$

Named in 1855 from the Greek for *blue* and *color*, in allusion to the color of the mineral. Picromerite group. MON $P2_1/a$. $a = 9.080$, $b = 12.123$, $c = 6.164$, $\beta = 104.43^\circ$, $Z = 2$, $D = 2.234$. NBSM 25(21):99(1985). PD(syn): 4.25₃ 4.18₉ 4.06₈ 3.67₁₀ 2.99₄ 2.97₇ 2.82₄ 2.38₅. Crystalline crusts, artificial crystals tabular {001}. Greenish blue, vitreous luster. Cleavage {201}, perfect. $G_{syn} = 2.224$. Soluble in water. Biaxial (+); $Y = b$; $X \wedge c = 18^\circ$; $N_x = 1.484$, $N_y = 1.486$, $N_z = 1.502$ (Na); $2V = 46.30^\circ$; $r < v$, strong. *Vesuvius*, *Italy*, in fumaroles. RG DII:454, PM 54:1(1985).

29.3.7.1 Mohrite $(NH_4)_2Fe(SO_4)_2 \cdot 6H_2O$

Named in 1964 for Karl Friedrich Mohr (1806–1879), German analytical chemist. Picromerite group. Artificial material is known as "Mohr's salt." MON $P2_1/a$. $a = 9.292$, $b = 12.601$, $c = 6.249$, $\beta = 106.80^\circ$, $Z = 2$, $D = 1.859$. NSBM 25(21):10(1985). 35-764(syn): 5.41₄ 4.27₄ 4.20₁₀ 4.16₄ 3.80₃ 3.03₅ 2.83₃ 2.46₃. Irregular laminae and minute quasisubhedral crystals. Pale green, vitreous luster. Cleavage {102}, perfect; {010}, distinct. $G = 1.862$. Biaxial (+); $N_x = 1.486$, $N_z = 1.497$; $2V = 75^\circ$. Found as pale green incrustations from the boriferous soffoni of *Travale*, *Val di Cecina*, *Tuscany*, *Italy*. RG AM 50:805(1965).

29.3.7.2 Boussingaultite $(NH_4)_2Mg(SO_4)_2 \cdot 6H_2O$

Named in 1864 after the French chemist Jean-Baptiste Boussingault (1802–1887). Picromerite group. MON $P2_1/a$. $a = 9.325$, $b = 12.605$, $c = 6.208$, $\beta = 107.10^\circ$, $Z = 2$, $D = 1.717$. NBSM 25(21):14(1985). Structure: ZK 117:344(1962). 35-771(syn): 5.38₆ 4.26₆ 4.21₁₀ 4.14₃ 3.80₉ 3.15₅ 3.01₃ 2.78₃. Usually massive, as crusts or stalactites; crystals short prismatic {001}. Colorless to yellowish pink. Cleavage {201}, perfect. $H = 2$. $G_{syn} = 1.722$. Soluble in water. Biaxial (+); $Y = b$; $Z \wedge c = 12^\circ$; $N_x = 1.470$, $N_y = 1.472$, $N_z = 1.479$ (Na); $2V = 51.17^\circ$; $r > v$, perceptible. Near Mahanoy City, Schuylkill Co., PA, as small crystals in cavities in a waste coal heap; the Geysers, Sonoma

Co., CA, and in sandstone at South Mountain, Ventura Co. From the boric acid fumaroles of *Travale, Tuscany, Italy*. RG *DII:455*.

29.3.7.3 Nickel-Boussingaultite $(\text{NH}_4)_2\text{Ni}(\text{SO}_4)_2 \cdot 6\text{H}_2\text{O}$

Named in 1976 after the composition, the nickel analog of boussingaultite. Picromerite group. MON $P2_1/c$. $a = 9.241$, $b = 12.544$, $c = 6.243$, $\beta = 106.97^\circ$, $Z = 2$, $D = 1.85$. *AC 17:1478(1964)*. *31-62: 6.24₃ 5.39₄ 4.24₄ 4.17₁₀ 4.15₇ 3.76₉ 3.04₃ 3.03₄*. Thin films and crusts composed of tiny prismatic grains. Greenish blue. Imperfect cleavage. $H = 2\frac{1}{2}$. Soluble in water. Biaxial (+); $X \wedge c = 0-4^\circ$; $N_x = 1.490$ (bluish), $N_y = 1.494$, $N_z = 1.501$ (yellow). From the *Noril'skiye nickel deposit, Siberia, Russia*, in the oxidation zone in old workings near or on old timbers, resembling coatings of chrysocolla. RG *ZVMO 105:710(1976)*, *AM 71:1545(1976)*, *AC(B) 35:155(1979)*.

29.3.8.1 Mosesite $\text{Hg}_2\text{N}(\text{Cl}, \text{SO}_4, \text{MoO}_4) \cdot \text{H}_2\text{O}$

Named in 1910 for Alfred J. Moses (1859–1920), professor of mineralogy, Columbia University, who first described several of the mercury minerals from Terlingua. ISO *F43m*. $a = 9.524$, $Z = 8$, $D = 7.53$. *AM 38:1225(1953)*. *39-388: 5.51₈ 2.88₉ 2.76₁₀ 2.38₄ 2.19₄ 1.834₃ 1.685₄ 1.436₃*. The structure of mosesite consists of a cubic cristobalite-like configuration of Hg_2N^+ groups. This structure has open spaces occupied by H_2O and exchangeable ions such as SO_4^{2-} , Cl^- , ASO_4^{2-} , and CO_3^{2-} . Mosesite is isostructural with and essentially identical to $\text{Hg}_2\text{NOH} \cdot \text{H}_2\text{O}$, "Millon's base," and the presence of Cl^- and other ions is dependent entirely on ion exchange with whatever is present in the ore-forming solutions. Crystals are octahedrons or cubes, or a combination of both. Twinning on {111}. Yellow, becoming light olive-green on long exposure to light, very pale yellow streak, adamantine luster. Cleavage {111}, imperfect; uneven fracture; brittle. $H = 3\frac{1}{2}$. $G = 7.72$. In CT turns dark brown to black and partially volatilizes, depositing mercury and calomel on the walls of the tube. Partially soluble in cold HCl. Isotropic; $N = 2.065$. *Terlingua, Brewster Co., TX*, associated with montroydite. Clack quicksilver mine, Fitting district, Pershing Co., NV. Huahuaxtla, GRO, Mexico, with terlinguaite, montroydite, eglestonite, and calomel. Several localities in Russia. RG *DII:89*.

29.4.1.1 Hydroglauberite $\text{Na}_{10}\text{Ca}_3(\text{SO}_4)_8 \cdot 6\text{H}_2\text{O}$

Named in 1969 for the composition, rather similar to glauberite, but hydrated. Probably ORTH Space group unknown. *24-1071: 9.20₉ 4.60₈ 4.20₆ 3.52₆ 3.08₁₀ 2.90₇ 2.78₉ 2.25₆*. Dense masses consisting of microscopic fibers. Snow white, silky luster. Cleavages: one good, one distinct, one poor. Soluble in water, with separation of gypsum. Tastes salty, slightly bitter. Biaxial (-); $N_x = 1.488$, $N_z = 1.500$; parallel extinction, positive elongation. Kara-Kalpakii, Uzbekistan, as an alteration product of glauberite, associated with halite, astrakhanite, mirabilite, and polyhalite. RG *ZVMO 98:58(1969)*, *AM 55:321(1970)*.

29.4.2.1 Eugsterite $\text{Na}_4\text{Ca}(\text{SO}_4)_3 \cdot 2\text{H}_2\text{O}$

Named in 1981 for Hans P. Eugster (1925–1987), Swiss–American mineralogist, Johns Hopkins University, awarded the Roebling Medal, 1983. MON Space group unknown. $\beta = 116^\circ$. $35\text{-}487(\text{syn})$: 9.20₄ 5.50₆ 4.50₃ 3.45₃ 3.43₁₀ 2.94₂ 2.76₃ 2.75₅. Clusters of thin fibers, as efflorescences. Colorless. Very soft. $G \approx 2.50$. Soluble in water. Biaxial; $Y \wedge c = 27^\circ$; $N_x = 1.492$, $N_z = 1.496$. Found as surface efflorescences on soils at *Sindo and Luanda, near Lake Victoria, Kenya*, and in the *Konya Basin, Central Anatolian Plateau, Turkey*. RG *AM 66:632(1981)*.

29.4.3.1 Löweite $\text{Na}_{12}\text{Mg}_7(\text{SO}_4)_{13} \cdot 15\text{H}_2\text{O}$

Named in 1847 for Alexander Loewe (1808–1895), Austrian chemist. Synonym: loeweite. HEX-R *R3*. $a = 18.866$, $c = 13.434$, $Z = 3$, $D = 2.364$. *NBSM 25(14):35(1977)*. $29\text{-}1241(\text{syn})$: 10.4₁₀ 5.45₃ 4.29₇ 4.05₆ 3.46₅ 3.28₅ 3.18₄ 2.70₅. Anhydral grains embedded in other sulfates. Colorless, also reddish yellow due to included material; vitreous luster. Conchoidal fracture. $H = 2\frac{1}{2}\text{-}3$. $G = 2.36$. Soluble in water. Tastes slightly bitter. Uniaxial (-); $N_0 = 1.490$, $N_E = 1.471$. Formed only in marine evaporites. With anhydrite at *Ischl and Hallstatt, Austria*; also at Hall, Tyrol, and in the Stassfurt area, Germany. RG *DI:446, CMP 6:201(1959), AM 55:378(1970)*.

29.4.4.1 Ferrinatriite $\text{Na}_3\text{Fe}^{3+}(\text{SO}_4)_3 \cdot 3\text{H}_2\text{O}$

Named in 1889 for the composition. HEX-R *P3*. $a = 15.566$, $c = 8.69$, $Z = 6$, $D = 2.55$. *MM 41:375(1977)*. $41\text{-}609$: 7.78₁₀ 4.39₅ 3.89₂ 3.43₇ 3.30₅ 2.94₆ 2.91₉ 2.83₆. Crystals short prismatic [0001], also cleavable masses or fibrous aggregates, cryptocrystalline. Colorless, white, greenish, bluish green, pale amethystine; vitreous luster. Cleavage {1010}, perfect; (1120), fair; splintery fracture; brittle. $H = 2\frac{1}{2}$. $G = 2.55\text{-}2.61$. Uniaxial (+); $N_0 = 1.558$, $N_E = 1.613$ (Na). Alters to sideronatriite on standing in moist air. Vesuvius, Italy, in fumaroles, with apthitalite and alum. *Mina La Compania, S of Sierra Gorda, Atacama desert, Chile*; also at Alcaparossa, Cerritos Bayos, and at Chuquicamata. RG *DII:456, TMPM 23:317(1976)*.

29.4.5.1 Polyhalite $\text{K}_2\text{MgCa}_2(\text{SO}_4)_4 \cdot 2\text{H}_2\text{O}$

Named in 1818 from the Greek for *many* and *salt*, in allusion to the several component salts present. TRIC *P1* or *P1*. $a = 11.69$, $b = 16.33$, $c = 7.60$, $\alpha = 91.60^\circ$, $\beta = 90^\circ$, $\gamma = 91.90^\circ$, $Z = 4$, $D = 2.76$. *TMPM 14:75(1970)*. $21\text{-}982$: 6.00₁ 5.93₁ 3.18₁₀ 2.95₂ 2.91₃ 2.90₁ 2.89₃ 2.85₃. Crystals rare, tabular {010} or elongated [001]; usually massive or fibrous; twins on {010} and {100}, often polysynthetic. Colorless or white, occasionally colored by included matter; vitreous to resinous luster. Cleavage {101}, perfect; parting {010}. $H = 3\frac{1}{2}$. $G = 2.78$. Decomposed by water with separation of gypsum. Biaxial (-); $N_x = 1.547$, $N_y = 1.560$, $N_z = 1.567$; $2V = 62^\circ$. Widely formed as a constituent of marine evaporites, associated with halite and anhydrite. Found in the TX–NM salt deposits and in Grand Co., UT. *Ischl, upper Aus-*

tria; also at Hallstatt and Hall. Abundant disseminated in halite in the Stassfurt district, Germany. Also from France, Poland, and England; very abundant in Kazakhstan. RG *DII*:458, *MM* 29:667(1951).

29.4.5.2 Leightonite $K_2CuCa_2(SO_4)_4 \cdot 2H_2O$

Named in 1938 for Tomas Leighton Donoso (1896–1967), Chilean mining engineer and mineralogist, University of Santiago. ORTH *Fmmm*. $a = 11.67$, $b = 16.52$, $c = 7.492$, $Z = 4$, $D = 2.953$. *CM* 7:272(1962). 15-128: 3.18₆ 2.90₁₀ 2.51₁ 2.40₁ 2.22₂ 1.78₃ 1.46₁ 1.047₁. Crystallizes as blades or laths elongated [001] and flattened {100}, rarely equant, also as cross-fiber veinlets. Pale watery blue to greenish blue, vitreous luster. No cleavage. $H = 3$. $G = 2.95$. Biaxial (-); $XYZ = bca$; $N_x = 1.578$, $N_y = 1.587$, $N_z = 1.595$ (Na); $2V = 86^\circ$; $r > v$, fairly strong. *Chuquicamata, Chile*, in open crevices, associated with atacamite and krohnkite. RG *DII*:461.

29.4.6.1 Metavoltine $K_4Na_4(Fe^{2+},Zn)Fe_6^{3+}(SO_4)_{12}O_2 \cdot 20H_2O$

Named in 1883 from the Greek for *with* and *voltine*, because it was found associated with voltaite at the original locality. HEX-R *P3*. $a = 9.545$, $c = 18.09$, $Z = 1$, $D = 2.435$. *IMA ABST*:80(1994). 29-1043: 18.2₈ 9.1₁₀ 3.76₂ 3.29₃ 3.07₂ 2.90₂ 2.60₂ 2.02₄. Minute crystals tabular {0001} with prominent {1011}; fine granular, scaly, incrusting. Orange brown and yellowish brown to greenish brown, resinous luster. Cleavage {0001}, perfect. $H = 2\frac{1}{2}$. $G = 2.5$. Partially soluble in water, decomposed by dilute acids. Uniaxial (-); $N_0 = 1.588$ –1.595, $N_E = 1.573$ –1.581. O, dark yellowish brown; E, light yellow to pale greenish yellow. Near Borate, Calico Hills, San Bernardino Co., CA. In fumaroles on Vesuvius, Italy, and at the solfatara of Pozzuoli, near Naples. Near *Madeni Zakh, Iran*, as an alteration of pyritic trachyte. At several localities in Chile, with copiapite, alunogen, and other sulfates at Chuquicamata, Sierra Gorda, Quetena, Alcaparrosa, and La Compania. RG *DII*:619, *TMPM* 23:155(1976).

29.4.7.1 Gorgeyite $K_2Ca_5(SO_4)_6 \cdot H_2O$

Named in 1953 for Rolf von Gorgey (1886–1915), Austrian mineralogist, student of the petrography of Austrian salt deposits. MON *C2/c*. $a = 17.47$, $b = 6.83$, $c = 18.22$, $\beta = 113.30^\circ$, $Z = 4$, $D = 2.887$. *NJMM*:126(1965). 18-997: 5.60₁ 3.16₇ 3.03₂ 3.01₁₀ 2.82₄ 2.76₃ 1.90₂ 1.84₃. Crystals thin tabular {100}. Colorless to yellowish, vitreous luster. Cleavage {100}, distinct; splintery fracture. $H = 3\frac{1}{2}$. $G = 2.75$. Insoluble in hot water. Biaxial (+); $N_x = 1.560$, $N_y = 1.569$, $N_z = 1.584$; $2V = 79^\circ$. From the *Leopold horizon, Ischl salt deposit, Austria*, with glauberite, halite, and polyhalite. RG *AM* 39:403(1954), *NJMM*:26(1965), *ZK* 151:49(1980).

29.5.1.1 Krausite $KFe^{3+}(SO_4)_2 \cdot H_2O$

Named in 1931 for Edward Henry Kraus (1875–1973), American mineralogist, University of Michigan. MON *P2₁/m*. $a = 7.91$, $b = 5.15$, $c = 8.99$,

$\beta = 102.75^\circ$, $Z = 2$, $D = 2.839$. *AM 50:1929(1965)*. 18-1028: 6.59₇ 4.40₈ 4.26₅ 3.69₇ 3.09₁₀ 2.77₄ 2.58₄ 2.55₄. Crystals short prismatic {001}, also equant to tabular {001}. Pale lemon yellow, white streak, vitreous luster. Cleavage {001}, perfect; {100}, good. $H = 2\frac{1}{2}$. $G = 2.84$. Slowly decomposed by water, soluble in HCl, in CT yields acid water. Biaxial (+); $Z = b$; $Y \wedge c = -35^\circ$; $N_x = 1.588$, $N_y = 1.650$, $N_z = 1.722$; 2V large. X, colorless; Y, Z, pale yellow. *Borate, Calico Hills, San Bernardino Co., CA*. Santa Maria mine, Velardeña, DGO, Mexico, in drusy crusts in limestone. *RG DII:462, AM 50:504(1965)*.

29.5.2.1 Goldichite $KFe^{3+}(SO_4)_2 \cdot 4H_2O$

Named in 1955 for Samuel Stephen Goldich (b.1909), American mineralogist and petrologist, University of Minnesota. *MON P2₁/c*. $a = 10.387$, $b = 10.486$, $c = 9.086$, $\beta = 101.68^\circ$, $Z = 4$, $D = 2.461$. *AM 56:1919(1971)*. 11-428: 10.3₈ 7.35₉ 6.85₇ 4.00₆ 3.40₆ 3.25₅ 3.07₁₀ 2.66₆. Crystals short prismatic {001}, as radiating clusters, fine grained incrustations. Pale yellow-green, lavender in artificial light; vitreous luster. Cleavage {100}, perfect. $H = 2\frac{1}{2}$. $G = 2.43$. Slightly soluble in cold water, easily in hot; soluble in dilute acids. Biaxial (+); $X = b$; $Z \wedge c = 11^\circ$; $N_x = 1.582$, $N_y = 1.602$, $N_z = 1.629$; 2V = 82°. *Dexter No. 7 mine, Calf Mesa, San Rafael Swell, UT*, associated with other sulfates in a pyritic uranium mine. Gansu Prov., China, in crystals to several centimeters. Santa Barbara mine, Jujuy, Argentina. *RG AM 40:469(1955), 50:505(1965)*.

29.5.3.1 Tamarugite $NaAl(SO_4)_2 \cdot 6H_2O$

Named in 1889 for the locality. *MON P2₁/a*. $a = 7.353$, $b = 25.225$, $c = 6.10$, $\beta = 95.20^\circ$, $Z = 4$, $D = 2.066$. *AM 54:19(1969)*. 19-1186: 12.5₂ 4.22₁₀ 4.21₈ 4.16₁ 3.96₃ 3.65₆ 3.15₂ 2.90₃. Crystals tabular {010}, also short prismatic {001}, as fibrous or granular masses. Colorless, vitreous luster. Cleavage {010}, perfect. $H = 3$. $G = 2.06$. Soluble in water. Tastes sweetish, astringent. Biaxial (+); $Y = b$; $X \wedge c = 4^\circ$; $N_x = 1.484$, $N_y = 1.486$, $N_z = 1.497$ (Na); 2V = 60°. In MO near Eureka, St. Louis Co., and at Fulton, Calloway Co., altering from mendozite. St. Bartholomew Is., West Indies. At the Skouriotissa mine, Cyprus. Miseno near Naples, Italy. *Tamarugal Pampa, Cerro Pintado, Tarapaca, Chile*. Anglesea, VIC, Australia. *RG DII:466, AM 51:1805(1966), MM 40:642(1976), NJMM:171(1987)*.

29.5.3.2 Amarillite $NaFe^{3+}(SO_4)_2 \cdot 6H_2O$

Named in 1933 for the locality. *MON C2/c*. $a = 8.419$, $b = 10.841$, $c = 12.472$, $\beta = 95.48^\circ$, $D = 2.222$. *AM 77:212(1992)*. Crystals equant, thick tabular {001}; rarely prismatic {001}. Pale yellow with a greenish tint; vitreous, brilliant luster. Cleavage {110}, good; conchoidal fracture. $H = 2\frac{1}{2}$ -3. $G = 2.19$. Soluble in water, tastes astringent. Biaxial (+); $Y = b$; $X \wedge c = -39^\circ$; $Z \wedge c = 51^\circ$; $N_x = 1.532$, $N_y = 1.555$, $N_z = 1.591$; 2V large; $r < v$. *Tierra Amarilla, near Copiapó, Chile*, as veinlets in massive coquimbite. *RG DII:468*.

29.5.4.1 Mendozite $\text{NaAl}(\text{SO}_4)_2 \cdot 11\text{H}_2\text{O}$

Named in 1868 for the locality. *MON C2/c*. $a = 21.75$, $b = 9.11$, $c = 8.30$, $\beta = 92.47^\circ$, $Z = 4$, $D = 1.781$. *AM 57:1081(1972)*. *22-475(syn)*: 10.9_3 4.76_9 4.61_3 4.58_7 4.15_5 3.60_4 3.50_{10} 2.64_4 . Fibrous masses. Colorless to white. Cleavage {100}, good. $H = 3$. $G = 1.730\text{--}1.765$. Biaxial (-); $X = b$; $Y \wedge c = 30^\circ$; $N_x = 1.449$, $N_y = 1.461$, $N_z = 1.463$; $2V = 56^\circ$; distinct, crossed dispersion. Alters to tamarugite upon exposure to air. Shimare, Idzumo, Japan. *San Juan, Mendoza, Argentina*. Many other occurrences of hydrated sodium aluminum sulfates are known which are suspected to contain mendozite, without definite proof that this phase is present. These include places in MO, CA, and UT. *RG DII:469*.

29.5.4.2 Kalinite $\text{KAl}(\text{SO}_4)_2 \cdot 11\text{H}_2\text{O}$

Named in 1868 for the composition: contains potassium (kalium). *MON C2/c*. $a = 19.92$, $b = 9.27$, $c = 8.304$, $\beta = 98.79^\circ$, $Z = 4$, $D = 2.00$. *ICDD Grant-in-Aid (1988)*. *41-1362*: 4.94_6 4.80_{10} 4.60_5 4.31_9 4.12_7 3.49_8 2.68_3 1.873_3 . A fibrous, birefringent type of alum distinct from isometric potassium alum. Fibrous. Biaxial (-), or uniaxial; $Y \wedge c = 13^\circ$; $N_x = 1.430$, $N_y = 1.452$, $N_z = 1.458$; $2V = 52^\circ$. San Bernardino Co., CA (uniaxial); Mt. Wingen, Australia; with jarosite from Quetena, Chile. *RG DII:471*.

29.5.5.1 Potassium alum $\text{KAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$

Named in 1875 for the composition. Synonym: potash alum. *iso Pa3*. $a = 12.157$, $Z = 4$, $D = 1.753$. *NBSC 539(6):36(1956)*. Structure: *AC 22:793(1967)*. *7-17(syn)*: 5.44_4 4.96_2 4.30_{10} 4.05_5 3.25_6 3.04_3 2.95_2 2.79_4 . Octahedral crystals; as cubes when crystallized from alkaline solutions; also massive, granular, stalactitic, as coatings. Twins on {111}, rare. Colorless; vitreous luster. Cleavage {111}, poor; conchoidal fracture. $H = 2\text{--}2\frac{1}{2}$. $G = 1.757$. Soluble in water; in CT, dissolves in its own water of crystallization. Tastes sweetish and astringent. Isotropic; $N = 1.456$; anomalous birefringence, frequent. Alum Cave, Sevier Co., TN. Near Silver Peak, Esmeralda Co., NV. The Geysers, Sonoma Co., and at the Sulphur Bank mercury mine, Lake Co., CA. Numerous places in Germany and France in brown coal deposits. Similarly in Spain and England. Chuquicamata, Chile. *RG DII:472*.

29.5.5.2 Sodium alum $\text{NaAl}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$

Named for the composition. Synonym: soda alum. *iso Pa3*. $a = 12.214$, $Z = 4$, $D = 1.670$. *NBSM 25(15):68(1978)*. *29-1167(syn)*: 7.05_1 4.31_{10} 3.53_1 3.26_1 2.96_4 2.49_1 1.908_1 1.632_1 . Structure: *AC 22:182(1967)*. Artificial crystals are octahedral. Colorless, vitreous luster. Conchoidal fracture. $H = 3$. $G = 1.67$. Soluble in water, fuses in its water of crystallization at about 63° . Isotropic; $N = 1.439$. K does not substitute for Na to any significant extent in natural material. A number of occurrences of sodium alum in nature have been reported, but none can be referred with certainty to this species. See mendozite (29.5.4.1). *RG DII:474*.

29.5.5.3 Tschermigite $\text{NH}_4\text{Al}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$

Named in 1853 for the locality. Synonym: ammonia alum. iso $Pa3$. $a = 12.240$, $Z = 4$, $D = 1.642$. *NBSC 539(6):3(1956)*. Structure: *ZK 157:147(1982)*. 7-22(syn): 7.07₆ 5.48₅ 5.00₄ 4.33₁₀ 4.08₈ 3.69₄ 3.27₈ 2.81₄. Fibrous and columnar masses, efflorescences; artificial crystals are octahedral. Colorless to white, vitreous or silky luster. Conchoidal fracture. $H = 1\frac{1}{2}$. $G = 1.645$. Melts at 93° in its water of crystallization. Tastes sweetish, astringent. Isotropic; $N = 1.459$ (Na). Natural material conforms closely to the formula. In artificial material K can substitute for (NH_4) and a complete solid-solution series can be prepared. Formed chiefly in lignite or brown coal beds; in burning coal seams or coal waste heaps; in fumaroles. The Geysers, Sonoma Co., CA, with boussingaultite, mascagnite, and voltaite. Wamsutter, WY, with gypsum and ammoniojarosite in bituminous shale. *Tschermig, Bohemia, Czech Republic*, in brown coal. In the solfatara of Pozzuoli at Naples and in the crater of Etna, Italy. With sulfur and mascagnite at Nyamlagira volcano, Zaire. *RG DII:475, NJMM:171(1987)*.

29.5.5.4 Loncreekite $\text{NH}_4\text{Fe}^{3+}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$

Named in 1983 for the locality. iso $Pa3$, $a = 12.302$, $Z = 4$, $D = 1.691$. *AM 71:229(1986)*. 7-5: 7.1₆ 5.51₃ 4.34₁₀ 4.10₆ 3.71₅ 3.29₇ 3.08₄ 2.08₃. Colorless, vitreous luster. $G = 1.693$. Isotropic; $N = 1.483$. Dehydrates to sabieite. *Lone Creek Fall cave, near Sabie, eastern Transvaal, South Africa*, where oxidizing pyrite reacts with ammonia produced by the decay of organic matter. *RG AGSSA 17:29(1985), AM 71:229(1986)*.

29.6.1.1 Bassanite $2\text{CaSO}_4 \cdot \text{H}_2\text{O}$

Named in 1910 for Francesco Bassani (1853–1916), Italian paleontologist, University of Naples. Synonym: plaster of Paris. ORTH Space group unknown. $a = 12.031$, $b = 12.695$, $c = 6.934$, $Z = 6$, $D = 2.731$. *NBSM 25(18):22(1981)*. 41-224(syn): 6.01₈ 3.47₅ 3.01₁₀ 2.80₉ 1.849₂ 1.845₃ 1.693₂ 1.665₂. Chalky, as microscopic needles in parallel arrangement, sometimes pseudomorphous after gypsum. Snow white. $G = 2.69$ – 2.76 . Dehydrates at about 130°, somewhat unstable, rehydrates gradually to gypsum in a normal slightly humid atmosphere. Uniaxial or biaxial (+); $N_x = 1.550$, $N_z = 1.577$ (Na); 2V small; positive elongation. Found in drill core at Darby dry lake and at a dry lake near Ballarat, southeastern CA, associated with gypsum, celestite, and clay. *Vesuvius, Italy*, in cavities in leucite–tephrite blocks, 1906 eruption, and with gibbsite in fumaroles, 1911 eruption. *RG DII:476; AM 38:1266(1953), 69:910(1984); MM 35:354(1965)*.

KIESERITE GROUP

The kieserite group consists of six isostructural sulfate monohydrates of the general formula

where

$A = Mg, Fe, Mn, Cu, Zn, Ni$

and the structure is monoclinic, isostructural with kieserite. The structure of these very rare minerals is described in *NJMA 157:121(1987)*.

KIESERITE: $Mg(SO_4) \cdot H_2O$

Mg and SO_4/H_2O alternate in a layer structure on (001). Mg is octahedrally coordinated, to four sulfate oxygens and two H_2O .

KIESERITE GROUP

Mineral	Formula	Space Group	a			b			c		
			a	b	c	β	D				
Kieserite	$MgSO_4 \cdot H_2O$	$A2/a$	7.511	7.611	6.921	116.17°	2.589	29.6.2.1

29.6.2.1 Kieserite $\text{MgSO}_4 \cdot \text{H}_2\text{O}$

Named in 1860 for D. G. Kieser (1779–1862), German, president of the Jena Academy. Kieserite group. MON *A2/a*. $a = 7.511$, $b = 7.611$, $c = 6.921$, $\beta = 116.17^\circ$, $Z = 4$, $D = 2.589$. *NBSM 25(16):46(1979)*. *33-882(syn): 4.82₈ 3.41₁₀ 3.35₇ 3.31₇ 3.05₄ 2.56₄ 2.52₃ 2.05₂*. Massive granular, intergrown with other salts; crystals rare, bipyramidal {111} and {110}. Twinning polysynthetic; also contact on {001}. Colorless, grayish white, or yellowish; vitreous luster. Cleavage {110} and {111}, perfect; friable to firm. $H = 3\frac{1}{2}$. $G = 2.571$. Dissolves slowly in water, easily fusible. Biaxial (+); $Y = b$; $Z \wedge c = -76.5^\circ$; $N_x = 1.520$, $N_y = 1.533$, $N_z = 1.584$ (N_a); $2V = 55^\circ$; $r > v$, moderate. Formed principally in marine evaporites. Common in the Permian salt deposits of west TX and NM, with polyhalite, anhydrite, and halite. *Stassfurt* and other places in the potash deposits of *Germany*. Good crystals were found at Hildesheim, Wathlingen, and Westerregeln; also at Hallstatt, upper Austria. Kalusz, Galicia, Poland. Kieserite constitutes up to 99% of salt deposits penetrated by borings SW of Saratov, Russia. From the Mayo mine, Punjab Salt Range, India. *RG DII:477*, *MM 29:667(1951)*.

29.6.2.2 Szomolnokite $\text{FeSO}_4 \cdot \text{H}_2\text{O}$

Named in 1877 for the locality. Kieserite group. MON *C2/c*. $a = 7.62$, $b = 7.47$, $c = 7.12$, $\beta = 115.85^\circ$; $Z = 4$, $D = 3.08$. *45-1365: 4.86₂ 3.45₁₀ 3.30₃ 3.11₅ 2.53₄ 1.998₃ 1.622₃ 1.600₄*. Crystals bipyramidal {111} and {110}, or tabular {111}; globular to stalactitic; twinning common. Sulfur-yellow to reddish brown; blue or colorless, vitreous luster. Conchoidal to uneven fracture, brittle. $H = 2\frac{1}{2}$. $G = 3.03$ – 3.07 . Dissolves in water very slowly, yielding a brown solution; in CT, gives off acid water and leaves a black residue. Biaxial (+); $Y = b$; $X \wedge c = -26^\circ$; $N_x = 1.591$, $N_y = 1.623$, $N_z = 1.663$; $2V = 80^\circ$; $r > v$, strong. Commonly associated with oxidizing pyrite. At the Tintic Standard mine, Dividend, UT. *Szomolnok*, *Slovakia*, where it was found with rhomboclase; also near Skrivan, Bohemia, Czech Republic. Alcaparrosa, Chile, with roemerite and rhomboclase. With copiapite at the Sta. Elena mine, La Alcaparrosa, San Juan, Argentina. *RG DII:479*, *CM 11:958(1973)*, *PM 54:32(1985)*.

29.6.2.3 Szmikite $\text{MnSO}_4 \cdot \text{H}_2\text{O}$

Named in 1877 for Ignaz Szmik (1815–1881), Hungarian mining official at Felsobanya. Kieserite group. MON *A2/a*. $a = 7.766$, $b = 7.666$, $c = 7.120$, $\beta = 115.85^\circ$, $Z = 4$, $D = 2.943$. *NBSM 25(16):49(1979)*. *33-906(syn): 4.92₅ 4.86₃ 3.51₁₀ 3.45₂ 3.36₃ 3.14₄ 2.61₂ 2.58₃*. Stalactitic masses with a botryoidal surface. Dirty white to reddish, rose-red. Splintery to earthy fracture. $H = 1\frac{1}{2}$. $G = 3.15$. Biaxial (+); $Z = b$; $N_x = 1.562$, $N_y = 1.595$, $N_z = 1.632$; $2V \approx 90^\circ$. *Baia Sprie* (formerly *Felsobanya*), *Romania*, as an efflorescence. *RG DII:481*, *PM 54:32(1985)*.

29.6.2.4 Poitevinite (Cu,Fe,Zn)SO₄ · H₂O

Named in 1964 for Theophile Eugene Poitevin (1888–1978), Canadian mineralogist, Geological Survey of Canada. Kieserite group. *MON C2/c*. $a = 7.48$, $b = 7.42$, $c = 7.05$, $\beta = 114.67^\circ$, $Z = 4$, $D = 3.30$. *CM 8:109(1965)*. 15-120: 4.85₄ 4.72₅ 3.46₁₀ 3.34₂ 3.26₂ 3.08₈ 2.51₄ 1.67₃. Powdery to vermiform, very fine grained. Salmon colored. $H = 3-3\frac{1}{2}$. $G = 3.30$. Biaxial: $N_x = 1.610$, $N_z = 1.636$; 2V large. The natural material from Lillooet, BC, has a Cu/Fe/Zn ratio of 100:92:16. *Hat Creek, Bonaparte River, Lillooet, BC, Canada*, associated with bonattite. *RG AM 50:263(1965)*.

29.6.2.5 Gunningite (Zn,Mn)SO₄ · H₂O

Named in 1962 for Henry Cecil Gunning (1901–1991), geologist, Geological Survey of Canada. Kieserite group. *MON A2/a*. $a = 7.508$, $b = 7.587$, $c = 6.936$, $\beta = 116.25^\circ$, $Z = 4$, $D = 3.364$. *NBSM 25(19):86(1982)*. Structure: *CM 7:209(1962)*. 33-1476: 4.81₄ 4.76₄ 3.40₁₀ 3.35₂ 3.31₃ 3.06₅ 2.52₅ 2.19₂. Fine-grained efflorescences. White, vitreous luster. $H = 2\frac{1}{2}$. $G_{\text{syn}} = 3.321$. Easily soluble in cold water. Biaxial; $N_x = 1.577$, $N_z = 1.630$; birefringence = 0.06. *Comstock-Keno mine, Keno Hill, YT, Canada*, and at several other mines in the district, in association with oxidizing sphalerite, arsenopyrite, pharmacosiderite, jarosite, and gypsum. *RG AM 47:1218(1962)*.

29.6.2.6 Dwornikite (Ni,Fe)SO₄ · H₂O

Named in 1982 for Edward J. Dwornik, geologist, U.S. Geological Survey. Kieserite group. *MON P2/c*. $a = 6.839$, $b = 7.582$, $c = 7.474$, $\beta = 117.85^\circ$, $Z = 4$, $D = 3.346$. *AM 68:642(1983)*. 21-974: 4.74₅ 4.73₇ 3.33₁₀ 3.31₃ 3.29₄ 3.02₅ 2.49₄ 2.33₂. Aggregates of very fine-grained particles. Snow white with a faint greenish tinge. Other physical properties not measurable; probably close to those of szomolnokite. Biaxial; $N_{\text{mean}} = 1.63$. *Minasragra, Peru*, with patronite, various sulfates, and bitumen. *RG MM 46:351(1982)*.

GYPSUM GROUP

The gypsum group is comprised of five isostructural minerals, including a variety of anions. The general formula is

where

$A = \text{Ca, Nd, (Y,Er)}$

$XO_4 = \text{SO}_4, \text{HPO}_4, \text{HAsO}_4, \text{PO}_4$

and the structure is a layered monoclinic structure in space group *C2/c* or *Cc*. In the gypsum structure, there are two sheets consisting of $(\text{SO}_4)^{2-}$ ions bound to one another by Ca ions. The two sheets are separated by layers of water molecules. Each Ca is coordinated by six O's of SO_4 groups and by two water

molecules. The water molecules lie near the centers of triangles formed by two oxygens (of sulfate groups) to which they are hydrogen bonded and by a Ca ion. Each water molecule links a Ca both to an oxygen in the same double sheet and one in a neighboring sheet. *AC(B) 38:1056(1982)*.

GYP SUM: $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$

The (010) cleavage passes through the double layer of water molecules, where the structure is held together with hydrogen bonds at most.

GYP SUM GROUP

Mineral	Formula	Space Group	Space			β	D	
			a	b	c			
Gypsum	$\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$	<i>C2/c</i>	5.678	15.20	6.52	118.43°	2.308	29.6.3.1
Brushite	$\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$	<i>C2/c</i>	6.361	15.191	5.814	118.40°	2.318	39.1.1.1
Pharmacolite	$\text{CaHAsO}_4 \cdot 2\text{H}_2\text{O}$	<i>P2/m</i>	5.975	15.434	6.280	114.80°	2.731	39.1.1.2
Churchite-(Nd)	$\text{NdPO}_4 \cdot 2\text{H}_2\text{O}$	<i>C2/c</i>	6.19	15.14	5.61	115.10°	3.84	40.0.7.1
Churchite-(Y)	$(\text{Y,Er})\text{PO}_4 \cdot 2\text{H}_2\text{O}$	<i>C2/c</i>	5.61	15.14	6.19	115.30°	3.07	40.4.6.1

Note: Perfect (010) cleavage is due to cleavage along the sheets of water molecules in the structure.

29.6.3.1 Gypsum $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$

Named in antiquity from the Greek *gypsos*, plaster, which was applied equally to gypsum, dehydrated gypsum, lime, and similar materials. Gypsum group. Synonyms: gips, selenite. MON *C2/c*. $a = 5.678$, $b = 15.20$, $c = 6.52$,

9.6.3.1 Gypsum

Prismatic Habits

Swallow-tail Twins on {100}

GYPSUM $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ Forms: $b\{010\}$, $l\{111\}$, $m\{110\}$, $e\{\bar{1}03\}$

$\beta = 118.43^\circ$, $Z = 4$, $D = 2.308$. $AC(B)$ 38:1074(1982). 33-311(syn): 7.63₁₀ 4.28₁₀ 3.80₂ 3.07₈ 2.87₅ 2.69₄ 2.22₂ 2.09₃. **Habit:** Crystals tabular {010} with $\{\bar{1}11\}$ and {120}. Also prismatic [001], stout to acicular, the prism zone often striated [001]. Sometimes lenticular by rounding of {111} and {103}. Crystals often have warped or curved surfaces, bent, or twisted. Rosettelike aggregates of lenticular crystals common. Also granular; massive, bedded, fibrous veinlets, or concretions. Twins common on {100} ("swallowtail twins"); on {101} as contact twins, butterfly- or heart-shaped. **Physical properties:** Colorless to white; yellowish, brownish due to impurities; white streak; subvitreous luster, pearly on cleavages. Cleavage {010}, perfect and easy, almost micaceous; {100} and {011}, distinct; cleavage fragments have rhombic form with angles of 66° and 114° ; flexible, but not elastic. $H = 2$ (Mohs' scale defines hardness 2 as the hardness of gypsum). $G = 2.317$. Rarely fluorescent, or when caused by included fluorescent matter. **Tests:** Very slightly soluble in water, soluble in HCl, in CT loses water and becomes opaque, white. **Chemistry:** Only trace amounts of Ba, Sr, and occasionally Mg can substitute for the Ca, and gypsum adheres very closely to its theoretical formula. When heated above 70° , it slowly converts to the hemihydrate (bassanite); rapidly above 90° . At temperatures above 250° gypsum converts to anhydrite. **Optics:** Biaxial (+); $Y = b$; $Z \wedge c = 51.87^\circ$; $N_x = 1.521$, $N_y = 1.523$, $N_z = 1.530$ (Na); $2V = 58^\circ$; $r > v$, strongly inclined. **Varieties:** (1) crystallized, or *selenite*—distinct crystals or broad folia, transparent; (2) fibrous, or *satin spar*—aggregates with a parallel fibrous structure, often translucent with the pearly opalescence of

moonstone; (3) massive, fine-grained, often banded, or *alabaster*. **Occurrence:** Gypsum is the commonest of the sulfate minerals and is of extremely widespread occurrence, especially in marine evaporites; around solfatara and fumaroles; and to some extent in the oxidized zone of sulfide deposits. In the evaporation of seawater, gypsum crystallizes out before other sulfates or halides, followed by anhydrite and then halite. This has given rise to large sedimentary beds of gypsum, often augmented by subsequent hydration of associated anhydrite. Gypsum also forms crystals and nodules in certain clays and marls and in some limestone caves. **Localities:** In the United States, fine crystals are found in drusy cavities of the Lockport dolomite in Niagara Co., NY(*), and at Balmat, St. Lawrence Co. In Prince Georges Co., MD, in a road cut near the Potomac R. near Ft. Foote, crystals to 15 cm. At the Camp Bird mine, Ouray, CO(!), fine water-clear crystals to 6.5 cm. Large curved crystals are found near the edge of Great Salt Lake, UT; also at Hanksville, Wayne Co. (*), crystals to 1.0 m and 70 lb weight, and at the Apex mine(!) near St. George, Washington Co., azurite has encrusted gypsum crystals to 20 cm; the gypsum has subsequently been dissolved leaving hollow tubes of azurite. In OK, fine crystals are formed in a mud flat on the southwestern edge of the Salt Plains National Wildlife Refuge(*). Crystals form at shallow depth by precipitation from saline groundwater in response to weather conditions; most have zoned reddish inclusions in the form of an hourglass. In NM the sand in the White Sands National Monument is composed of gypsum; the dunes, covering about 560 km², constitute one of the world's greatest deposits. In AZ at the San Xavier mine, Pima Co.; in the Warren district, Cochise Co., excellent examples of the curved "ram's horn" variety. Commercial deposits of gypsum are exploited in many states and provinces of Canada. Near Winnipeg, MB, fine radiating aggregates of crystals forming balls up to 10 cm are found along the Red River floodway(!); also at Hines Creek, AB; Swift Current, SK, and at Endicott Pit No. 2, Endicott, NB. In Mexico, in a lead-zinc mine at Naica, CHIH, crystals are formed in clefs in limestone, attaining 2.0 m in length and are sharp and transparent (the "Cave of the Swords")(!). Similar large crystals are also found at the San Antonio mine, Santa Eulalia, CHIH(!). At the Bex mine, Vaud, Switzerland(!), in saline clays. Fine crystals are found at the sulfur mines of the Caltanissetta district, Sicily, Italy(!), associated with celestite and aragonite; the variety alabaster is mined extensively in Tuscany, and superb crystals are found in the pyrite mines there; also in Tuscany at the Carrara marble quarries, fine limpid crystals to 10 cm. Common in the clays at Cormeilles-en-Parisis near Paris, France(*) (hence "plaster of paris") and at Caresse, Pyrenees-Atlantique. In the salt mines of Stassfurt, Germany, and of Austria. The Machow sulfur mine, Tarnobrzeg, Poland, contains embedded gypsum crystals to 4.0 m. In Spain crystals of exceptional perfection, transparency, and brilliance to 10 cm are found in alabaster quarries near Fuentes de Ebro, SE of Zaragoza(!), and at El Gorguel, La Union, Murcia. In Ukraine at the Optimisticheskaya and Kristalnaya Caves, Tarnopol region. Gaurdak, Turkmenistan(!), fine transparent crystals. At Juayma, Ras Tanura, Saudi Arabia. In Africa pink sand

“roses” are found in the Sahara desert; at the N’Chwaning mine(*), Kuruman district, South Africa. In Australia at the Broken Hill mine, NSW, and at Swan Hill, VIC. In Chile at the Teniente mine, enormous fine crystals (up to 4.0 m × 0.6 m in diameter) were found in 1974 in an open cavity of 300 m³, as well as in similar smaller cavities; these were formed in the last phase of the primary mineralization. In Australia, at the Mt. Elliott mine, Q(1), large clear crystals to 1.0 m, some containing beautiful arborescent crystals of native Cu; from the Walaroo mine, York Peninsula, SA(1), fine crystals to 25 cm, some enclosing dolomite and chalcopyrite; also, in mud at the bottom of Lake Gilles, 30 km NW of Iron Knob, SA(1), fine transparent crystals and twins of a variety of habits; and at Broken Hill, NSW, and Swan Hill, VIC. In Brazil around the hills W of Iraí, RGS(*), large crystals (up to 20 kg) are found in amygdaloidal cavities associated with quartz and amethyst. Uses: Gypsum, upon moderate heating, alters to the hemihydrate (bassanite) normally known as plaster of paris. This material is used in huge amounts in home construction, the manufacture of wallboard, and similar products. Alabaster is widely used like marble for architectural purposes; the great pyramid of Cheops in Egypt was originally faced entirely with alabaster, which during the Middle Ages was all removed (stolen) for home construction. RG *DII*:482, *JSSC* 85:23(1990).

29.6.4.1 Sanderite $\text{MnSO}_4 \cdot 2\text{H}_2\text{O}$

Named for Bruno Sander (1884–1979), Austrian geologist, Alte Universitat, Innsbruck. An inadequately characterized mineral. 20-689(syn): 5.51₃ 4.42₈ 4.25₉ 3.92₄ 3.74₄ 3.25₃ 3.10₁₀ 2.73₅. Found as efflorescences on kieserite at the *Hansa I shaft, Empelde*, and the *Niedersachsen shaft, near Wathlingen, Austria*. RG *NJMM*:28(1952), *AM* 37:1072(1952).

29.6.5.1 Bonattite $\text{CuSO}_4 \cdot 3\text{H}_2\text{O}$

Named in 1957 for Stefano Bonatti (1902–1968), Italian petrologist, Pisa. MON *Cc.* $a = 5.592$, $b = 13.029$, $c = 7.341$, $\beta = 97.03^\circ$, $z = 4$, $d = 2.68$. *AC(B)* 24:508(1968). 22-249: 5.11₇ 4.42₁₀ 3.65₆ 3.42₅ 3.25₆ 3.19₄ 3.01₆ 2.50₅. Concretions composed of minute individual crystals; vermiform masses. Pale blue. $G = 2.663$. Biaxial (+); $N_x = 1.554$, $N_y = 1.577$, $N_{z \text{ syn}} = 1.618$. Avoca claim, Bonaparte R., near Lillooet, BC, Canada. *Cape Calamita, Elba, Italy*, as a secondary mineral in pyrite deposits. RG *RSIMP* 13:268(1957); *AM* 43:180(1958), 47:1223(1962); *CM* 7:245(1962).

ROZENITE GROUP

The rozenite group consists of five minerals that are isostructural and that conform to

where

A = Fe, Mg, Mn, Co, or Zn

and the structure is monoclinic, space group $P2_1/c$. The structure of these very rare minerals is described in *AC 15:815(1962)*.

ROZENITE: $FeSO_4 \cdot 4H_2O$

This structure is composed of molecules containing two Fe octahedra and two sulfate tetrahedra, sharing corners.

ROZENITE GROUP

Mineral	Formula	Space Group	Dimensions (Å)			β	D	Z
			a	b	c			
Rosenite	$FeSO_4 \cdot 4H_2O$	$P2_1/c$	5.80	13.65	7.98	90.43°	2.28	29.6.6.1
Starkeyite	$MgSO_4 \cdot 4H_2O$	$P2_1/c$	5.92	13.60	7.91	90.85°	2.007	29.6.6.2
Ilesite	$MnSO_4 \cdot 4H_2O$	$P2_1/c$	5.94	13.76	8.01	90.80°	2.26	29.6.6.3
Apowite	$(Co,Mn,Ni)SO_4 \cdot 4H_2O$	$P2_1/c$	5.94	13.56	7.90	90.50°	2.36	29.6.6.4
Boyleite	$ZnSO_4 \cdot 4H_2O$	$P2_1/c$	5.95	13.60	7.96	90.30°	2.34	29.6.6.5

29.6.6.1 Rozenite $\text{FeSO}_4 \cdot 4\text{H}_2\text{O}$

Named in 1960 for Zygmunt Rozen (1874–1936), Polish mineralogist, Mining Academy, Krakov. Rozenite group. MON $P2_1/c$. $a = 5.80$, $b = 13.65$, $c = 7.98$, $\beta = 90.43^\circ$, $Z = 4$, $D = 2.28$. AC 15:815(1962). 19-632(syn): 6.88₃ 5.48₈ 4.49₁₀ 3.99₇ 3.40₄ 3.23₃ 2.98₄ 2.96₃. Efflorescences and coatings, mixed with other sulfates, fine grained, crystalline. White or colorless. $G = 2.195$. Soluble in water. Biaxial (-); $N_x = 1.527$, $N_z = 1.543$; $2V_{\text{calc}} = 82^\circ$. Dolliver State Park, near Ft. Dodge, IA, on outcrops of the "copperas beds," with halotrichite and szomolnokite. *Stazic pyrite mine, Rudki*, and on pyritic gneiss on the slopes of *Ornak, western High Tatra, Poland*. RG AM 46:242(1961); CM 7:751(1963), 11:958(1973); MM 51:176(1987).

29.6.6.2 Starkeyite $\text{MgSO}_4 \cdot 4\text{H}_2\text{O}$

Named in 1956 for the locality. Rozenite group. MON $P2_1/c$. $a = 5.92$, $b = 13.60$, $c = 7.91$, $\beta = 90.85^\circ$, $Z = 4$, $D = 2.007$. 24-720: 6.83₅ 5.43₈ 4.70₄ 4.46₁₀ 3.95₇ 3.40₅ 3.22₄ 2.95₆. Powdery efflorescences. White to yellowish; greenish. Soluble in water. Biaxial (-); $N \approx 1.496$; $2V$ large; $r > v$. Probably a complete solid-solution series exists between starkeyite and rozenite; the California material is ferroan starkeyite. *Starkey mine, Madison Co., MO*, on altered pyrite and marcasite in a dolomite rock. *Alta troilite mine, Del Norte Co., CA*. *Hansa shaft, Empelde, Germany*. RG AM 41:662(1956), AC 17:863(1963), CM 12:229(1973), MR 6:144(1975).

29.6.6.3 Ilesite $\text{MnSO}_4 \cdot 4\text{H}_2\text{O}$

Named in 1881 for Malvern W. Iles (1853–1890), American metallurgist, Denver, CO. Rozenite group. MON $P2_1/c$. $a = 5.94$, $b = 13.76$, $c = 8.01$, $\beta = 90.80^\circ$, $Z = 4$, $D = 2.26$. 32-651: 5.50₉ 4.55₁₀ 4.01₉ 3.46₈ 3.28₈ 3.01₇ 2.99₉ 2.58₇. Loosely adherent crystalline aggregates, prismatic. Clear green, becoming white on partial dehydration. $G_{\text{syn}} = 2.25$. Soluble in water. Biaxial (-); $N_x = 1.511$, $N_y = 1.519$, $N_z = 1.521$; $2V_{\text{calc}} = 53^\circ$. The original material contained Mn/Zn/Fe = 5.4:1.3:1. From several sulfide veins at the head of *Hall valley, Park Co., CO*. RG DII:486.

29.6.6.4 Aplowite $(\text{Co,Mn,Ni})\text{SO}_4 \cdot 4\text{H}_2\text{O}$

Named in 1965 for Albert Peter Low (1861–1942), Canadian geologist, former director of the Geological Survey of Canada. Rozenite group. MON $P2_1/c$. $a = 5.94$, $b = 13.56$, $c = 7.90$, $\beta = 90.50^\circ$, $Z = 4$, $D = 2.36$. CM 8:166(1965). 16-488: 6.82₄ 5.44₉ 4.46₁₀ 3.94₅ 3.39₄ 3.21₃ 2.94₃ 2.56₂. Efflorescences and coatings, overlain by moorhouseite. Bright pink, white streak, vitreous luster. $H = 3$. $G = 2.33$. Biaxial (-); $N_x = 1.528$, $N_z = 1.536$; $2V$ medium. Natural aplowite gave the ratio Co/Mn/Ni/Cu/Fe/Zn = 100:50:45:3:2:2. *Magnet Cove Barium Corp. mine, Walton, NS, Canada*, as an oxidation product on specimens of barite–siderite containing various sulfides, including cobaltian pyrite. RG AM 50:809(1965).

29.6.6.5 Boyleite $ZnSO_4 \cdot 4H_2O$

Named in 1978 for Robert William Boyle (b.1920), geochemist, Geological Survey of Canada. Rozenite group. *MON* $P2_1/c$. $a = 5.95$, $b = 13.60$, $c = 7.96$, $\beta = 90.30^\circ$, $Z = 4$, $D = 2.34$. *CE* 37:73(1978). 31-818: 6.85₈ 5.46₁₀ 4.47₁₀ 3.96₈ 3.39₇ 3.20₅ 2.95₇ 2.55₅. Earthy crusts, reniform masses. White. No cleavage, uneven fracture. $H \approx 2$. Soluble in water. Biaxial (-); $N_x = 1.522$, $N_z = 1.536$; $2V \approx 70^\circ$. Analyzed material contained $(Zn_{0.84}, Mg_{0.16})SO_4 \cdot 4H_2O$. In dry air dehydrates to gunningite. Keno Hill, Yukon, Canada. *Kropbach quarry, southern Black Forest, Germany*, formed from the decomposition of sphalerite, associated with gypsum. *RG AM* 64:241,464(1979).

CHALCANTHITE GROUP

The chalcantHITE group consists of four isostructural minerals, sulfate pentahydrates, with the general formula

where

A = Cu, (Fe, Cu), Mg, Mn

and the structure is in the triclinic space group $P\bar{1}$. The structure of these rare minerals is described in *AC(B)* 28:1448(1972). Some solid solution exists between the various members, especially between chalcantHITE, siderotil, and pentahydrite. However, it is doubtful whether end-member $FeSO_4 \cdot 5H_2O$ exists, and the usual dehydration product of the higher hydrates is rozenite, $FeSO_4 \cdot 4H_2O$.

CHALCANTHITE GROUP

Mineral	Formula	Space Group	Space							D
			a	b	c	α	β	γ		
ChalcantHITE	$CuSO_4 \cdot 5H_2O$	$P\bar{1}$	6.110	10.673	5.95	97.6	107.2	77.55	2.282	29.6.7.1
Siderotil	$(Fe,Cu)SO_4 \cdot 5H_2O$	$P\bar{1}$	6.26	10.63	6.06	92.1	110.2	77.1	2.212	29.6.7.2
Pentahydrite	$MgSO_4 \cdot 5H_2O$	$P\bar{1}$	6.31	10.57	6.03	81.1	109.8	105.1	1.93	29.6.7.3
Jokokuite	$MnSO_4 \cdot 5H_2O$	$P\bar{1}$	6.37	10.77	6.13	98.8	110.0	77.8	2.094	29.6.7.4

Note: The chalcantHITE group minerals are all water soluble.

CHALCANTHITE: $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$

Each Cu octahedron has two sulfate oxygens and four H_2O . The octahedra and sulfate tetrahedra from corner-sharing chains parallel to (110)

29.6.7.1 Chalcantinite $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$

Named in antiquity from "chalcanthum," its old name, meaning *flowers of copper*. Chalcantinite group. TRIC P1. $a = 6.110$, $b = 10.673$, $c = 5.95$, $\alpha = 97.58^\circ$, $\beta = 107.17^\circ$, $\gamma = 77.55^\circ$, $Z = 2$, $D = 2.282$. 11-646(syn): 5.48₆ 4.73₁₀ 3.99₈ 3.71₉ 3.30₆ 2.82₄ 2.75₅ 2.66₄. Crystals short prismatic [001], less commonly thick tabular {111}. Natural crystals very rare, artificial crystals very easily made. Commonly stalactitic; as veinlets, massive, granular. Cruciform twins rare, with {010} in common. Sky blue of different shades, sometimes a little greenish; colorless streak; vitreous luster. Cleavage {110}, imperfect; conchoidal fracture. $H = 2\frac{1}{2}$. $G = 2.286$. Soluble in water. Tastes metallic and nauseous. In CT, loses water and turns whitish but does not fuse. Biaxial (-); $X \wedge \phi = 169^\circ$, $X \wedge \sigma = 76^\circ$; $Y \wedge \phi = 76^\circ$, $Y \wedge \sigma = 78^\circ$; $Z \wedge \phi = -57^\circ$, $Z \wedge \sigma = 18^\circ$; $N_x = 1.514$, $N_y = 1.537$, $N_z = 1.543$ (Na); $2V = 56^\circ$; $r < v$. Mg, Mn, Zn, and Fe can all substitute for Cu in the cell to a minor degree, but in nature only Fe substitution is found to any extent, up to about 2%. Chalcantinite is a common mineral in the oxide zone of copper deposits and in arid regions may constitute an important ore mineral. Copper sulfate is common dissolved in mine waters, from which it may crystallize, forming crusts and stalactites on the timbers and walls of mines. Bluestone mine,

Yerington district, NV; widespread in AZ, especially at the United Verde mine, Yavapai Co., and in the Clifton–Morenci district. Formerly abundant at Butte, MT. Known since early times in the copper mines of Cyprus; at Rio Tinto, Spain; Rammelsberg and Goslar in the Harz, Germany; well crystallized at Zajecar, Serbia. In fumaroles at Vesuvius, Italy. Abundant at several copper mines along the Pacific coast of South America, especially at Chuquicamata, Quetena, and Copaque, Chile. Used as an ore of copper. RG *DII:488*, *AM 37:95(1952)*.

29.6.7.2 Siderotil (Fe,Cu)SO₄ · 5H₂O

Named in 1891 from the Greek for *iron* and *fiber*, in allusion to its composition and structure. Chalcantite group. TRIC $P\bar{1}$. $a = 6.26$, $b = 10.63$, $c = 6.06$, $\alpha = 92.13^\circ$, $\beta = 110.17^\circ$, $\gamma = 77.08^\circ$, $Z = 2$, $D = 2.212$. *CM 7:751(1963)*. *22-357*: 5.73₅ 5.57₆ 4.89₁₀ 3.90₃ 3.73₈ 3.21₄ 2.92₄ 2.68₄. Fibrous crusts and divergent groups of needle-like crystals. White to yellowish, greenish white. Soluble in water. Biaxial (-); $N_x = 1.515$, $N_y = 1.525$, $N_z = 1.535$; $2V = 50-60^\circ$. All data are for (Fe,Cu)SO₄ · 5H₂O, with Fe/Cu = 0.55:0.45. It is not at all certain that pure FeSO₄ · 5H₂O exists in nature or can be prepared artificially, or what the limits are in the Fe/Cu ratio, except that a complete solid-solution series exists for high-Cu members. Ducktown, TN; Yerington, NV; Bingham Canyon, UT; Mt. Diablo mine, Contra Costa Co., CA; *Idria, Gorizia, Italy*, with melanterite. Because of the fine-grained nature of most of the suspected occurrences and difficulties of analysis, the exact nature of some of the occurrences cited is uncertain. RG *DII:491*.

29.6.7.3 Pentahydrate MgSO₄ · 5H₂O

Named in 1951 for the composition (five waters of crystallization). Chalcantite group. TRIC $P1$. $a = 6.31$, $b = 10.57$, $c = 6.03$, $\alpha = 81.12^\circ$, $\beta = 109.82^\circ$, $\gamma = 105.08^\circ$, $Z = 2$, $D = 1.93$. *25-532(syn)*: 5.15₃ 4.93₁₀ 3.65₃ 3.26₄ 2.95₃ 2.79₃ 2.68₃ 2.00₄. Granular crusts, massive; artificial crystals elongated [001]. Colorless to white. No cleavage. $G = 1.718$. Soluble in water. Biaxial (-); $N_x = 1.495$, $N_y = 1.512$, $N_z = 1.518$; $2V = 55^\circ$; $r < v$. Reported from several localities, but usually as a very impure salt with other metals replacing part of the Mg. *The Geysers, Sonoma Co., CA*, as a pseudomorphous dehydration product of epsomite. Comstock Lode, NV. Copaque, Tarapaca, Chile. RG *DII:492*, *AM 36:641(1951)*.

29.6.7.4 Jokokuite MnSO₄ · 5H₂O

Named in 1978 for the locality. Chalcantite group. TRIC $P\bar{1}$. $a = 6.37$, $b = 10.77$, $c = 6.13$, $\alpha = 98.77^\circ$, $\beta = 109.97^\circ$, $\gamma = 77.83^\circ$, $Z = 2$, $D = 2.094$. *AM 64:655(1979)*. *31-836*: 5.84₁₀ 5.66₆ 4.98₆ 4.39₃ 3.28₃ 2.73₇ 2.29₃ 1.62₃. As stalactites. Pale pink, vitreous luster. No cleavage. $H = 2\frac{1}{2}$. $G = 2.03$. Soluble in water. Biaxial (-); $N_x = 1.498$, $N_y = 1.510$, $N_z = 1.517$; $2V = 70-80^\circ$; weak dispersion. *Jokoku manganese mine, southwestern Hokkaido, Japan*,

with gypsum, szmikite, ilesite, rozenite, siderotil, ferrohexahydrate, mallardite, melanterite, and goslarite. RG *MJJ* 9:28(1978).

HEXAHYDRITE GROUP

The hexahydrate group minerals are isostructural hexahydrates of sulfates corresponding to

where

A = Mg, Zn, Fe, Co, Ni, or Mn

and the minerals crystallize with monoclinic symmetry in space group $C2/c$. The structure of these rare minerals is described in *AC* 17:235(1964).

HEXAHYDRITE: $MgSO_4 \cdot 6H_2O$

Independent $Mg(H_2O)_6$ octahedra and sulfate groups, in layers on (001). The structural formula could be $Mg(H_2O)_6(SO_4)$.

HEXAHYDRITE STRUCTURE

Mineral	Formula	Space						
		Group	a	b	c	β	D

29.6.8.1 Hexahydrate $\text{MgSO}_4 \cdot 6\text{H}_2\text{O}$

Named in 1911 for the composition: six waters of crystallization. Hexahydrate group. MON *C2/c*. $a = 10.11$, $b = 7.21$, $c = 24.41$, $\beta = 98.30^\circ$, $Z = 8$, $D = 1.745$. *24-719*: 5.45₅ 5.10₅ 4.88₃ 4.39₁₀ 4.16₄ 4.04₅ 2.94₃ 2.90₃. Coarse columnar to delicately fibrous; crystals rare, thick tabular {001}. Colorless to white, pearly to vitreous luster. Cleavage {100}, perfect. $G = 1.757$. Soluble in water. Tastes bitter, salty. Biaxial (-); $Y = b$; $X \wedge c = -25^\circ$; $N_x = 1.426$, $N_y = 1.453$, $N_z = 1.456$; $2V = 38^\circ$. Formed as a dehydration product of epsomite. Oroville, WA, as efflorescence on epsomite. *Bonaparte River, BC, Canada*. Pseudomorphous after epsomite at Kelcany, Moravia, and at Kladno, Bohemia, Czech Republic. From the Kujawy salt deposits, Poland, with syngenite and other sulfates: Saki salt lakes, Crimea, Russia. RG *DII:494, MA 74:3459*.

29.6.8.2 Bianchite $\text{ZnSO}_4 \cdot 6\text{H}_2\text{O}$

Named in 1930 for Angelo Bianchi (1892-1970), Italian mineralogist, University of Padova. Hexahydrate group. MON *C2/c*. $a = 10.10$, $b = 7.20$, $c = 24.49$, $\beta = 98.27^\circ$, $Z = 8$, $D = 2.031$. *12-16*: 5.85₅ 5.47₇ 4.42₁₀ 4.03₉ 3.61₆ 2.97₈ 2.91₈ 2.27₆. Crusts of indistinct crystals; artificial crystals are tabular {001}, with {110} and {112}. Twinning common on {001} in artificial material. White, becoming yellow on oxidation if much Fe is present in the molecule; vitreous luster. $H = 2\frac{1}{2}$. $G = 2.07$. Biaxial (-); $Y = b$; $X \wedge c = -26^\circ$; $N_x = 1.465$, $N_y = 1.494$, $N_z = 1.495$; $2V = 10^\circ$. Data are for Zn/Fe = 2:1. Fe and Cu may substitute for some of the Zn, up to at least Zn/Fe = 2:1. From the walls of mines at *Raibl, Predil, Julian Alps, Italy*. Borieva mine, Madan region, Bulgaria. RG *DII:495, MA 75:1368, PM 54:9(1985)*.

29.6.8.3 Ferrohexahydrate $\text{FeSO}_4 \cdot 6\text{H}_2\text{O}$

Named in 1962 for the composition. Hexahydrate group. MON *C2/c*. $a = 10.08$, $b = 7.28$, $c = 24.59$, $\beta = 98.37^\circ$, $Z = 8$, $D = 1.934$. *ZVMO 91:490(1962)*. *15-393*: 4.89₆ 4.43₁₀ 2.97₇ 2.93₇ 2.80₅ 2.03₆ 1.88₆ 1.86₆. Capillary or fibrous crystals. Colorless. Biaxial; $N_x = 1.468$, $N_z = 1.498$. *Northeastern Tataria, Russia*, in a core from lower Carboniferous deposits, possibly resulting from alteration of melanterite. RG *AM 48:433(1963)*.

29.6.8.4 Nickel-Hexahydrate NiSO₄ · 6H₂O

Named in 1965 for the composition. Hexahydrate group. Dimorphous with retgersite (29.6.9.1). MON *C2/c*. $a = 9.895$, $b = 7.241$, $c = 24.188$, $\beta = 98.42^\circ$, $Z = 8$, $D = 2.037$. *MM 39:246(1973)*. 33-955: 5.42₂ 4.90₅ 4.78₂ 4.37₁₀ 4.10₂ 4.00₆ 2.92₃ 2.89₄. Fine-grained crusts. Bluish green, vitreous luster. Cleavage {010}, perfect; {100}, fair. Biaxial (-); $Z \wedge c = 45^\circ$; $N_x = 1.469$, $N_z = 1.494$. Considerable Mg and Fe may substitute for Ni in the structure. *Severnaya mine, Norilsk, Siberia, Russia*. Noddy's Creek, TAS, Australia. RG *ZVMO 94:534(1965)*, *AM 51:529(1966)*, *AC 12:72(1965)*.

29.6.8.5 Moorhouseite (Co,Ni,Mn)SO₄ · 6H₂O

Named in 1965 for Walter Wilson Moorhouse (1913-1969), Canadian geologist, University of Toronto. Hexahydrate group. MON *C2/c*. $a = 10.03$, $b = 7.23$, $c = 24.26$, $\beta = 98.37^\circ$, $Z = 8$, $D = 2.01$. *CM 8:166(1965)*. Structure: *AC(C) 44:599(1988)*. 16-304: 5.85₃ 5.45₃ 4.38₁₀ 4.14₂ 4.02₆ 3.58₂ 2.92₂ 2.90₂. Crusts and efflorescences. Light pink, vitreous luster. Conchoidal fracture. $H = 2\frac{1}{2}$. $G = 1.97$. Soluble in water. Biaxial (-); $Y = b$; $N_x = 1.470$, $N_z = 1.496$; $2V \approx 20^\circ$; $X \gg Z$. Natural moorhouseite had Co/Ni/Mn/Cu/Fe/Zn = 100:45:21:9:6:1. *Magnet Cove Barium Corp. mine, Walton, NS, Canada*, encrusting sulfide-bearing barite-siderite rock. RG *AM 50:808(1965)*.

29.6.8.6 Chvaleticeite (Mn,Mg)SO₄ · 6H₂O

Named in 1986 for the locality. Hexahydrate group. MON *C2/c*. $a = 10.05$, $b = 7.24$, $c = 24.3$, $\beta = 98.00^\circ$, $Z = 8$, $D = 1.84$. *NJMM:121(1986)*. 42-614: 5.45₈ 4.91₁₀ 4.47₈ 3.98₈ 3.69₅ 3.42₇ 3.25₈ 2.97₇. Tough, fine-grained aggregates; loose coatings. White; also pinkish, yellowish. $H = 1\frac{1}{2}$. $G = 1.84$. Soluble in water. $N_x = 1.457$, $N_z = 1.506$. *Chvaletice, Bohemia, Czech Republic*, on pyrite-manganese ores, associated with melanterite, epsomite, and other sulfates. RG *AM 72:1023(1987)*.

29.6.9.1 Retgersite NiSO₄ · 6H₂O

Named in 1949 for Jan Willem Retgers (1856-1896), Dutch chemical crystallographer. Dimorphous with nickel-hexahydrate (29.6.8.4). TET *P4₁2₁2*. $a = 6.782$, $c = 18.28$, $Z = 4$, $D = 2.075$. *NBSC 539(7):36(1957)*. 8-470(syn): 4.64₂ 4.57₄ 4.25₁₀ 3.39₁ 2.96₂ 2.72₂ 2.57₁ 2.33₁. Fibrous crusts and veinlets, elongated [001]. Crystals rare, thick tabular {001}, grading to short prismatic. Deep emerald green with a tinge of blue, greenish white streak, vitreous luster. Cleavage {001}, perfect; {110}, poor. Subconchoidal to uneven fracture; brittle. $H = 2\frac{1}{2}$. $G = 2.04$. Soluble in water. Tastes slightly bitter and metallic. Uniaxial (-); $N_0 = 1.511$, $N_E = 1.487$. Gap nickel mine, Lancaster Co., PA. Cottonwood Canyon, Churchill Co., NV, as an alteration of nickeline. Lichtenberg, Bavaria, and Lobenstein, Thuringia, Germany. Allarechensk deposit, Kola Penin., Russia, on oxidized ores or as veinlets in cracks in ore. *Minasragra, Peru*, in crystals with morenosite and minasragrite. RG *DII:497, MA 19:143(1968)*.

MELANTERITE GROUP

The melanterite group minerals are sulfate heptahydrates with the general formula

with

A = Fe, Cu, Zn, Co, Mn

and a monoclinic structure in space group $P2_1/c$. The melanterite group minerals are believed to be isostructural, although in two cases cell data are incomplete. *AC 17:1167(1964)*.

MELANTERITE: $FeSO_4 \cdot 7H_2O$

Completely independent (except for H bonds), $(Fe)(H_2O)_6$ octahedra and sulfate groups alternate in layers on (100). There is one free H_2O .

MELANTERITE GROUP

Mineral	Formula	Space Group	Space			β	D	
			a	b	c			
Melanterite	$FeSO_4 \cdot 7H_2O$	$P2_1/c$	14.077	6.509	11.054	105.60°	1.893	29.6.10.1
Boothite	$CuSO_4 \cdot 7H_2O$							29.6.10.2
Zinc-melanterite	$(Zn,Cu)SO_4 \cdot 7H_2O$							29.6.10.3
Bieberite	$CoSO_4 \cdot 7H_2O$	$P2_1/c$	14.13	6.55	11.00	105.40°	1.842	29.6.10.4
Mallardite	$MnSO_4 \cdot 7H_2O$	$P2_1/c$	14.15	6.50	11.06	105.60°	1.838	29.6.10.5

29.6.10.1 Melanterite $\text{FeSO}_4 \cdot 7\text{H}_2\text{O}$

Named in 1850 from the Greek word for *copperas*, ferrous sulfate. Melanterite group. MON $P2_1/c$. $a = 14.077$, $b = 6.509$, $c = 11.054$, $\beta = 105.60^\circ$, $Z = 4$, $D = 1.893$. NBSM 25(8):38(1970). 22-633: 5.49₁ 4.90₁₀ 4.87₅ 4.03₁ 3.78₆ 3.73₂ 3.29₂ 3.21₁. Usually in stalactitic or concretionary forms; as fibrous or capillary aggregates, massive, pulverulent. Crystals rare, equant to short prismatic {001}; also pseudo-octahedral. Colorless to white or green; also greenish blue or blue with increasing substitution of Cu for Fe; upon exposure to dry air becomes yellowish white and opaque; vitreous luster. Cleavage {001}, perfect; {110}, distinct; conchoidal fracture; brittle. $H = 2$. $G = 1.89$. Soluble in water; in CT, yields water and on strong heating, SO_2 and SO_3 . Tastes sweetish, astringent, and metallic. Biaxial (\pm); $Y = b$; $Z \wedge c = 61^\circ$; $N_x = 1.471$, $N_y = 1.478$, $N_z = 1.484$ (Na); 2V large; $r > v$ weak, inclined. A number of divalent metals, especially Cu, Mg, Zn, Co, Ni, and Mn, may substitute in part for the Fe, giving a partial solid-solution series to the respective end-member heptahydrates, especially Cu. The name *pisanite* is applied to members containing $(\text{Mg} + \text{Fe})/\text{Cu} < 5:1$ and $>2:1$, the maximum observed in nature. *Kirovite* is a Mg-rich member having $\text{Mg}/(\text{Fe} + \text{Cu}) > 1:5$ and $< 1:1$. Melanterite and its varieties are secondary products formed by the oxidation of pyrite, marcasite, and other iron sulfides. They occur typically as beardlike efflorescences on the walls and timbers of mine workings; in the oxide zone of pyritic deposits, especially in arid regions; and in sheltered crevices in pyritic sedimentary and metamorphic rocks; also in coal and lignite deposits, where usually derived from marcasite. Associated minerals may include epsomite, chalcantite, pickeringite, halotrichite, alunogen, alums, and gypsum. Melanterite alters in air by dehydration to siderotil or any of the other iron sulfate hydrates, depending on temperature and humidity conditions. Found at many U.S. mines; the copper deposits of Ducktown, TN; Butte, MT; Bingham Canyon, UT; Comstock Lode, NV; and the Cu deposits of Shasta and Trinity Cos., CA. Pisanite at Rammelsberg, Harz, Germany; Rio Tinto, Spain; Falun, Sweden; Quetena mine, Calama, Chile. Kirovite at the Kalata mine, Kirovgrad, Ural Mts., Russia; Idria, Italy; and Szomolnok, Czech Republic. Melanterite is used in the manufacture of fertilizers and inks and in water purification. RG DII:499.

29.6.10.2 Boothite $\text{CuSO}_4 \cdot 7\text{H}_2\text{O}$

Named in 1903 for Edward Booth (1857–1917), American chemist, University of California. Melanterite group. MON Space group unknown. Usually massive with a crystalline structure, or fibrous. Crystals rare. Blue, paler than chalcantite; vitreous to silky or pearly luster. Cleavage {001}, imperfect. $H = 2 - 2\frac{1}{2}$. $G \approx 2.1$. Biaxial; X near c ; $Y = b$; $N_x = 1.47$, $N_y = 1.48$, $N_z = 1.49$; 2V large. Boothite is apparently separated by a gap in the solid-solution series from cuprian melanterite. *Alma pyrite mine, near Leona Heights, Alameda Co., CA*, with chalcantite and melanterite. Also from Sain-Bel, near Lyon, Rhone, France. RG DII:504.

29.6.10.3 Zinc-melanterite (Zn,Cu)SO₄ · 7H₂O

Named in 1920 from the composition and relationship to melanterite. Melanterite group. MON Space group unknown. Massive, columnar, consisting of microscopic rodlike crystals. Pale greenish blue, vitreous luster. $H \approx 2$. $G = 2.02$. Biaxial (+); $Y \wedge$ elongation = 34° ; $N_x = 1.479$, $N_y = 1.483$, $N_z = 1.488$; $2V \approx 90^\circ$; slight dispersion. The pure end member, $ZnSO_4 \cdot 7H_2O$, is not stable in artificial systems. The name zinc-melanterite is applied to compositions where $Zn > (Cu, Fe, \text{etc.})$. Found in considerable amounts as an oxidation product of pyrite-chalcopyrite-sphalerite ore at the *Good Hope and Vulcan mines, Gunnison Co., CO.* RG *DII:508*.

29.6.10.4 Bieberite CoSO₄ · 7H₂O

Named in 1845 for the locality. Melanterite group. MON $P2_1/c$. $a = 14.13$, $b = 6.55$, $c = 11.00$, $\beta = 105.40^\circ$, $Z = 4$, $D = 1.842$. *16-487*: 5.41₁ 4.87₁₀ 4.82₆ 4.02₁ 3.76₈ 3.71₂ 3.25₁ 2.73₃. Crusts and stalactites. Artificial crystals similar to melanterite. Rose-red or flesh-red, vitreous luster. Cleavage {001}, perfect; {110}, fair. $H \approx 2$. $G = 1.96$. Soluble in water, in CT gives off water. Biaxial (+); $Y = b$; $Z \wedge c = 29^\circ$; $N_x = 1.475$, $N_y = 1.482$, $N_z = 1.489$ (Na); $2V_{\text{artif}} = 88^\circ$. In natural material Mg may substitute for some of the Co, up to $Mg/Co = 1:2.8$. In artificial material a complete series exists between the Co and Fe analogs; Cu substitutes for Co in part. Formed from the oxidation of sulfide-bearing ores containing cobalt. Island Mt., Trinity Co., CA. *Bieber, Hesse, Germany*, and at Siegen, Westphalia, in the cobalt veins. Chalanches, Isère, France. Tres Puntos, near Copiapó, Chile. Lomagundi, Zimbabwe. RG *DII:505*, *PM 54:1(1985)*.

29.6.10.5 Mallardite MnSO₄ · 7H₂O

Named in 1879 for Ernest Mallard (1833-1894), French crystallographer. Melanterite group. MON $P2_1/c$. $a = 14.15$, $b = 6.50$, $c = 11.06$, $\beta = 105.60^\circ$, $Z = 4$, $D = 1.838$. *MA 33:82-4639(1982)*. *33-905*: 5.49₇ 4.92₁₀ 4.88₆ 4.04₃ 3.79₄ 3.26₄ 3.13₃ 2.76₄. Fibrous masses and crusts, artificial crystals are tabular. Pale rose to colorless, vitreous luster. Cleavage {001}, good. $H \approx 2$. $G = 1.846_{\text{artif}}$. Soluble in water; in CT loses water, and on strong heating affords SO_3 and leaves a brown residue. Biaxial (+); $Y = b$; $Z \wedge c = 43^\circ$; $N_x = 1.462$, $N_y = 1.465$, $N_z = 1.474$; $2V$ large. *Lucky Boy mine, Butterfield Canyon, Salt Lake Co., UT*. Bayard area, Central district, Grant Co., NM (cuprian and zincian mallardite). Jokoku mine, Hokkaido, Japan. RG *DII:507*, *BM 2:117(1879)*.

29.6.11.1 Epsomite MgSO₄ · 7H₂O

Named in 1824 for the locality. Synonym: Epsom salt. ORTH $P2_12_12_1$. $a = 11.86$, $b = 11.99$, $c = 6.858$, $Z = 4$, $D = 1.678$. *NBSC 539(7):30(1957)*. Structure: *AC 17:1361(1964)*. *36-419*: 5.98₃ 5.34₃ 5.31₂ 4.22₁₀ 4.20₈ 2.88₂ 2.67₂ 2.66₃. Crystals rare. Usually fibrous to acicular crusts, elongated [001]; botryoidal masses, stalactitic. Colorless or white, also pink (with Co) or green

(with Ni); vitreous luster, also silky or earthy. Cleavage {010}, perfect; {101}, distinct; conchoidal fracture. $H = 2-2\frac{1}{2}$. $G = 1.677$. Soluble in water. Tastes bitter. Biaxial (-); $XYZ = acb$; $N_x = 1.432$, $N_y = 1.455$, $N_z = 1.461$; $2V = 52^\circ$; $r < v$, weak. Epsomite forms complete series with morenosite and goslarite. Fe, Mn, Cu, and Co can also substitute to a limited extent, up to $Fe/Mg = 1:5$ and $Mn/Mg = 1:10$. The name *epsomite* refers to Mg-dominant compounds. Epsomite commonly forms as crusts or delicate fibrous efflorescences on the walls of mine workings in coal or metal deposits, on the walls or floors of limestone caves, and as efflorescences in sheltered places on outcrops of dolomitic or calcareous sedimentary rocks. Also found in salt lakes and oceanic salt deposits. It dehydrates partially at room temperature in dry air, losing one H_2O . The change is reversible. Found in limestone caves in KY, TN, and IN. In salt lakes in Albany, Catron, and Natron Cos., WY. Carlsbad potash deposit, NM. Widespread in playas in NV; near Oroville, WA, in salt lakes with mirabilite. Near Ashcroft, BC, Canada, in lake deposits. *Epsom, Surrey, England*, in mineral waters and as deposits therefrom. Idria, Italy, in silky fibers at the mercury deposits. From mineral springs at Saldschitz and Sedlitz, Bohemia, Czech Republic, and in burning coal heaps near Kladno. Stassfurt, Germany, massive in thin layers with carnallite in the salt deposits. Used as a source of magnesium in industry; also used in medicine. RG *DII:509, JCS:816(1973)*.

29.6.11.2 Goslarite $ZnSO_4 \cdot 7H_2O$

Named in 1847 for the locality. ORTH $P2_12_12_1$. $a = 11.799$, $b = 12.050$, $c = 6.822$, $Z = 4$, $D = 1.972$. *NBSC 539(8):71(1958)*. $9-395: 5.36_8 5.29_4 4.46_3 4.21_{10} 4.18_5 3.46_3 2.87_4 2.65_3$. Efflorescent crusts; stalactites; massive, granular, or fibrous. Colorless to white, inclining to brownish, pinkish, or greenish in material containing Fe, Mn, or Cu; vitreous luster, silky if fibrous. Cleavage {010}, perfect. $H = 2-2\frac{1}{2}$. $G = 1.978$. Soluble in water; in CT, yields water. Biaxial (-); $XYZ = bca$; $N_x = 1.457$, $N_y = 1.480$, $N_z = 1.484$ (Na); $2V = 46^\circ$; $r < v$, weak. Formed from the oxidation of sphalerite in sulfide orebodies, occurring as an efflorescence on timbers and on the walls of mine passages. Webb City, MO (ferroan goslarite); Galena, KS (cuprian goslarite); Gagnon mine, Butte, MT; Bingham Canyon, UT; Comstock Lode, NV. *Rammelsberg mine, near Goslar, Harz, Germany*; also Freiberg, Saxony. Falun, Kopparberg, Sweden. Ceilmes, Herault, France, green incrustations on gossan. Almagrera mine, Huelva, Spain. Cerro de Pasco, Peru. La Alcaparrosa, San Juan, Argentina. RG *DII:513*.

29.6.11.3 Morenosite $NiSO_4 \cdot 7H_2O$

Named in 1851 for Antonio Moreno Ruiz (1796-1852), Spanish pharmacist and chemist, Academia de Ciencias Naturales, Madrid. ORTH $P2_12_12_1$. $a = 11.86$, $b = 12.08$, $c = 6.81$, $Z = 4$, $D = 1.93$. $1-403(\text{syn}): 5.30_6 4.45_1$

4.20₁₀ 3.75₂ 3.45₂ 2.85₃ 2.65₂ 2.19₁. Efflorescent crusts of indistinct crystals and fibers; stalactitic. Apple green to greenish white, vitreous luster. Cleavage {010}, distinct; conchoidal fracture. $H = 2-2\frac{1}{2}$. $G = 1.953$. Soluble in water; in CT, loses water, swells, and finally turns yellow. Tastes astringent. Biaxial (-); $XYZ = acb$; $N_x = 1.469$, $N_y = 1.489$, $N_z = 1.492$; $2V = 42^\circ$; $r > v$, weak. Forms a complete solid-solution series with epsomite. Fe may substitute for some Ni forms by oxidation of nickel-bearing sulfides under atmospheric conditions. Dehydrates easily to retgersite. Gap nickel mine, Lancaster Co., PA. Abundant in the Sudbury nickel district, ONT, Canada, and at the Marbridge mine, LaMotte Twp., QUE, coating millerite. *Cap Hortegal, Galicia, Spain*. St. Patrick's copper mine, Avoca, Co. Wicklow, Eire. Jachymov, Bohemia, Czech Republic. Val Malenco, Lombardy, Italy. Minasragra, Peru, with retgersite. RG *DII:516, MM 33:1110(1964)*.

29.6.12.1 Minasragrite ($V^{4+}O$)SO₄ · 5H₂O

Named in 1915 for the locality. MON $P2_1/a$. $a = 12.947$, $b = 9.748$, $c = 7.005$, $\beta = 110.93^\circ$, $Z = 4$, $D = 2.036$. *AM 58:531(1973)*. *26-1393*: 6.05₂ 5.43₆ 5.14₁₀ 3.91₇ 3.83₄ 3.73₂ 3.66₃ 3.51₂. Delicate efflorescences composed of minute crystals; granular, mammillary, or spherulitic. Blue, vitreous luster. No cleavage, conchoidal fracture. $H = 1\frac{1}{2}-2$. $G = 2.03$. Easily soluble in cold water, in CT melts. Biaxial (-); $X = b$; $Z \wedge c$ small; $N_x = 1.513$, $N_y = 1.536$, $N_z = 1.545$; absorption $X > Y > Z$. *Minasragra, Peru*, encrusting patronite. RG *DII:437*.

29.6.13.1 Stanleyite ($V^{4+}O$)SO₄ · 6H₂O

Named in 1982 for Henry Morton Stanley (1841-1904), British journalist and explorer. ORTH Space group unknown. $a = 12.12$, $b = 9.71$, $c = 14.92$, $Z = 8$, $D = 2.01$. *MM 45:163(1982)*. *35-557*: 4.98₉ 4.69₈ 4.41₆ 4.20₁₀ 3.81₆ 3.73₆ 3.09₂ 2.74₂. Fine-grained efflorescences consisting of minute crystallites. Aquamarine blue to cobalt blue, white streak. No cleavage. $H = 1-1\frac{1}{2}$. $G = 1.95$. Non-fluorescent. Very soluble in cold water, slowly soluble in alcohol. Biaxial (+); $N_x = 1.505$, $N_y = 1.519$, $N_z = 1.533$; $2V$ large; absorption $X = Y > Z$. *Minasragra, Peru*, associated with patronite and pyrite. RG *AM 68:644(1983)*.

29.7.1.1 Ransomite $CuFe_2^{3+}(SO_4)_4 \cdot 6H_2O$

Named in 1928 for Frederick Leslie Ransome (1868-1935), U.S. mining geologist. MON $P2_1/c$. $a = 4.811$, $b = 16.217$, $c = 10.403$, $\beta = 93.02^\circ$, $Z = 2$, $D = 2.735$. *AM 55:729(1970)*. Crusts and radiating tufts of needlelike crystals elongated [001]. Bright sky blue; vitreous luster, pearly on cleavage. Cleavage {001}, perfect. $H = 2\frac{1}{2}$. $G = 2.632$. Biaxial (+); $N_x = 1.631$, $N_y = 1.643$, $N_z = 1.695$; $2V = 53^\circ$. Al substitutes for Fe^{3+} up to $Al/Fe = 1:10$. Found with other hydrated sulfates as the result of a fire in the *United Verde mine, Jerome, AZ*. RG *DII:519*.

29.7.2.1 Römerite $\text{Fe}^{2+}\text{Fe}_2^{3+}(\text{SO}_4)_4 \cdot 14\text{H}_2\text{O}$

Named in 1858 for Friedrich Adolph Romer (1809–1869), German geologist. TRIC $P\bar{1}$. $a = 6.48$, $b = 15.26$, $c = 6.27$, $\alpha = 90.07^\circ$, $\beta = 100.80^\circ$, $\gamma = 85.47^\circ$, $Z = 1$, $D = 2.199$. *CM* 6:348(1959). 34-144: 5.06₄ 4.81₁₀ 4.25₂ 4.12₂ 4.05₇ 3.98₃ 3.17₂ 3.05₂. Crystals cuboidal, thick tabular {010} with large {001} and prominent [001] zone. Crystal aggregates; stalactitic; granular. Rust-brown to yellow, also violet-brown; oily to vitreous luster. Cleavage {010}, perfect; {001}, good; uneven fracture. $H = 3-3\frac{1}{2}$. $G = 2.174$. Biaxial (-); $N_x = 1.519-1.524$, $N_y = 1.570-1.571$, $N_z = 1.580-1.583$; $2V = 51-45^\circ$; $r > v$, very strong, crossed. X, reddish yellow; Y, pale yellow; Z, yellow-brown. Island Mt., Trinity Co., CA. Copper Queen mine, Bisbee, AZ. *Rammelsberg, Harz, Germany*, associated with copiapite. Blyava sulfate deposits, southern Ural Mts., Russia. Madeni Zakh, Iran, with voltaite. Tierra Amarilla, Alcaparrosa, Chile. *RG DII:520, AM 55:78(1970)*.

29.7.2.2 Lishizhenite $\text{ZnFe}_2^{3+}(\text{SO}_4)_4 \cdot 14\text{H}_2\text{O}$

Named in 1990 for Li Shizhen (1518–1593), a famous Chinese pharmacologist. TRIC $P\bar{1}$. $a = 6.477$, $b = 15.298$, $c = 6.309$, $\alpha = 90.12^\circ$, $\beta = 101.07^\circ$, $\gamma = 93.58^\circ$, $Z = 1$, $D = 2.201$. Structure: *AM* 76:670(1991). 45-1394: 5.07₇ 4.79₁₀ 4.11₃ 4.06₇ 3.98₄ 3.51₈ 3.05₂ 2.86₄. Crystal aggregates and clusters; veinlets; massive. Crystals elongated [100], tabular prismatic and showing {010}, {100}, and {001}. Light violet, deeper in clusters; vitreous luster. Cleavage {010}, nearly perfect; {001}, poor. $H = 3\frac{1}{2}$. $G = 2.206$. Biaxial (-); Optic Axis Plane \wedge {010} = 86° ; $N_x = 1.522$, $N_y = 1.568$, $N_z = 1.578$; $2V = 47^\circ$. $r > v$, strong. *Xitieshan, Qinghai, China*, in the oxidation zone of a Pb-Zn deposit in cavities in anhydrite, associated with roemerite, copiapite, sulfur, gypsum, pyrite, and quartz. *RG AM 76:2022(1991)*.

HALOTRICHITE GROUP

The halotrichite group consists of isostructural hydrated sulfates corresponding to

where

A = Mg, Fe^{2+} , Mn^{2+} , or Zn

B = Al, Fe^{3+} , or Cr

and the structure is monoclinic in $P2_1/c$, $P2/m$, or $P2$. The structure of these rare minerals is described in *MM 40:599(1976)*.

APJOHNITE: $MnAl_2(SO_4)_4 \cdot 22H_2O$ (halotrichite group)

This structure consists largely of independent radicals—there is only one bond from Mn to one of the four sulfate groups. Mn and Al are octahedrally coordinated by H_2O except for the one sulfate oxygen on Mn. The structural formula could be written $2[Al(H_2O)_6] \cdot Mn(H_2O)_5(SO_4)_4 \cdot 3(SO_4) \cdot 9H_2O$.

HALOTRICHITE GROUP

Mineral	Formula	Space Group	Space			β	D	
			a	b	c			
Pickeringite	$MgAl_2(SO_4)_4 \cdot 22H_2O$	$P2/m$	20.8	24.2	6.17	95°	1.84	29.7.3.1
Halotrichite	$Fe^{2+}Al_2(SO_4)_4 \cdot 22H_2O$	$P2/m$	20.51	24.29	6.179	101°	1.95	29.7.3.2
Apjohnite	$Mn^{2+}Al_2(SO_4)_4 \cdot 22H_2O$	$P2_1/c$	6.198	24.347	21.266	100.47°	1.87	29.7.3.3
Dietrichite	$ZnAl_2(SO_4)_4 \cdot 22H_2O$	$P2_1/c$	6.240	24.434	21.379	100.60°	1.86	29.7.3.4
Bilinite	$Fe^{2+}Fe_2^{3+}(SO_4)_4 \cdot 22H_2O$	$P2_1c$	6.208	24.333	21.255	100.18°	1.993	29.7.3.5
Redingtonite	$(Fe^{2+}, Mg)(Cr, Al)_2(SO_4)_4 \cdot 22H_2O$							29.7.3.6
Wupatkiite	$(Co, Mg)Al_2(SO_4)_4 \cdot 22H_2O$	$P2_1c$	6.189	24.234	21.204	100.33°	1.87	29.7.3.7

Note: A complete solid-solution series exists between pickeringite and halotrichite, and it is probable that this series extends to apjohnite.

29.7.3.1 Pickeringite $MgAl_2(SO_4)_4 \cdot 22H_2O$

Named in 1844 for John Pickering (1777–1846), president, American Academy of Sciences. Halotrichite group. MON $P2/m$. $a = 20.8$, $b = 24.2$, $c = 6.17$, $\beta = 95^\circ$, $Z = 4$, $D = 1.84$. 12-299: 6.08₂ 4.97₂ 4.82₁₀ 4.32₃ 4.18₂ 4.12₃ 3.79₃ 3.51₉. Crystals acicular [001]; matted aggregates; tufted, spheroidal; as incrustations. Colorless to white, also yellowish, reddish; vitreous luster. Cleavage {010}, poor; conchoidal fracture; brittle. $H = 1\frac{1}{2}$. $G = 1.76$. Soluble in water; in CT, fuses easily in its water of crystallization. Tastes astringent. Biaxial (-); $Y = b$; $Z \wedge c = 36^\circ$; $N_x = 1.475$, $N_y = 1.480$, $N_z = 1.483$; $2V = 60^\circ$. The

Geysers, Sonoma Co., CA. Near Tucumcari, Quay Co., NM. Fallon, Churchill Co., NV. Alum Point, Salt Lake Co., UT (manganous). Elba, Italy, in the iron mines. Wetzstein near Saalfeld, Germany. Terlano, Tyrol (manganous), and Dienten, Salzburg (ferrous), Austria. Abundant in the deserts of the west coast of South America: *Cerros Pintados, near Iquique, Tarapacá, Chile*, and at Chuquicamata and Quetena. RG *DII:523, BGSA 74:709(1963)*.

29.7.3.2 Halotrichite $\text{Fe}^{2+}\text{Al}_2(\text{SO}_4)_4 \cdot 22\text{H}_2\text{O}$

Named in 1839 from the Latin *halotrichum*, which in turn is for the older German name *haarsalz*, hair salts, in allusion to its crystal habit. Halotrichite group. MON $P2/m$. $a = 20.51$, $b = 24.29$, $c = 6.179$, $\beta = 101^\circ$, $Z = 4$, $D = 1.95$. *39-1387*: 15.8₂ 6.02₄ 4.93₂ 4.78₁₀ 4.29₃ 3.95₂ 3.75₃ 3.48₈. Crystals acicular [001], similar to pickeringite. Colorless to white, yellowish, greenish; vitreous luster. Cleavage {010}, poor; conchoidal fracture; brittle. $H = 1\frac{1}{2}$. $G = 1.89$. Soluble in water giving an acid solution; in CT, melts in its water of crystallization. Biaxial (-); $Y = b$; $Z \wedge c = 38^\circ$; $N_x = 1.480$, $N_y = 1.486$, $N_z = 1.490$ (Na); $2V = 35^\circ$. Probably forms a complete solid-solution series with pickeringite. However, most analyses of natural material are near the respective end members. Halotrichite and pickeringite are formed as a result of weathering of pyritic aluminous rocks and accumulate as efflorescences in sheltered places. Also observed as hairlike efflorescences in mine workings, especially coal mines. From outcrops of the "copperas" beds, Dolliver State Park, Webster Co., IA. Alum Mt. district, Grant Co., NM. In CA in the sulfate deposit near Calico Hills, San Bernardino Co., and near hot springs on Lassen Peak, Shasta Co. Glace Bay coal mines, NS, Canada. On brown coal at the Wohlforth mine, Hesse-Nassau, Germany. Idria mines, Italy, and at the solfatara of Pozzuoli near Naples. Fahlun, Sweden. The solfatara of Krisuvig, Iceland. Urumiya, Iran. Common in the Chilean desert regions. RG *DII:523, CM 10:958(1973)*.

29.7.3.3 Apjohnite $\text{Mn}^{2+}\text{Al}_2(\text{SO}_4)_4 \cdot 22\text{H}_2\text{O}$

Named in 1838 for James Apjohn (1796-1886), professor of chemistry and mineralogy, Trinity College, Dublin. Halotrichite group. MON $P2_1/c$. $a = 6.198$, $b = 24.347$, $c = 21.266$, $\beta = 100.47^\circ$, $D = 1.87$. *MM 40:599(1976)*. *29-886*: 6.07₂ 4.82₉ 4.34₃ 4.32₃ 4.13₂ 3.97₃ 3.79₄ 3.52₁₀. Masses and crusts composed of fibrous or acicular crystals; also asbestiform. Colorless to white; also tinted rose, pale green, or yellow; silky luster. $H = 1\frac{1}{2}$. $G = 1.78$. Soluble in water. Probably a complete series exists to pickeringite. Large amounts were found at Alum Cave, Sevier Co., TN, under an overhanging cliff at the headwaters of Little Pigeon creek. Szomolnok, Czech Republic. *Delagoa Bay, Mozambique*. RG *DII:527*.

29.7.3.4 Dietrichite $\text{ZnAl}_2(\text{SO}_4)_4 \cdot 22\text{H}_2\text{O}$

Named in 1878 for Gustav Heinrich Dietrich, Bohemian analytical chemist, Příbram, Czech Republic, who analyzed the mineral. He was said to have been among the first to be able to distinguish Fe^{2+} from Fe^{3+} in analysis. Halo-

trichite group. MON $P2_1/c$. $a = 6.240$, $b = 24.434$, $c = 21.379$, $\beta = 100.10^\circ$, $Z = 4$, $D = 1.86$. $25-1173$: 4.99_3 4.84_4 4.33_{10} 4.20_2 4.15_3 3.52_{10} 2.74_2 1.88_3 . Fibrous tufted aggregates; efflorescences and incrustations. Dirty white to brownish yellow, silky luster. $H = 2$. Biaxial (+); $X = b$, $Z \wedge c = 29^\circ$; $N_x = 1.475$, $N_y = 1.480$, $N_z = 1.488$; 2V large. Analyzed material contains substantial Fe and Mn substituting for the Zn. *Felsobanya, Hungary*, as a recent efflorescence in mine workings. RG *DII:528*.

29.7.3.5 Bilinite $\text{Fe}^{2+}\text{Fe}^{3+}(\text{SO}_4)_4 \cdot 22\text{H}_2\text{O}$

Named in 1913 for the locality. Halotrichite group. MON $P2_1/c$. $a = 6.208$, $b = 24.333$, $c = 21.255$, $\beta = 100.30^\circ$, $Z = 4$, $D = 1.993$. $25-1153$: 5.48_3 4.96_3 4.84_5 4.31_{10} 4.10_4 3.51_{10} 3.29_3 2.89_3 . Radial-fibrous aggregates. White to yellowish. $H = 2$. $G = 1.875$. $N \approx 1.500$; inclined extinction, about 37° . *Schwarz, near Bilina, Bohemia, Czech Republic*. RG *DII:529*.

29.7.3.6 Redingtonite $(\text{Fe}^{2+},\text{Mg})(\text{Cr},\text{Al})_2(\text{SO}_4)_4 \cdot 22\text{H}_2\text{O}$

An inadequately characterized mineral. Halotrichite group. Named in 1888 for the locality. MON Space group unknown. Massive, with fine parallel-fibrous structure. White; purple on fractures across fiber length; silky luster. $G = 1.761$. Inclined extinction, feeble birefringence. *Redington mercury mine, Knoxville, Napa Co., CA*. RG *DII:529*, *MR 2:152(1971)*.

29.7.3.7 Wupatkiite $(\text{Co},\text{Mg})\text{Al}_2(\text{SO}_4)_4 \cdot 22\text{H}_2\text{O}$

Named in 1995 for the prehistoric native American dwelling, Wupatki, near the discovery site of the mineral. Halotrichite group. MON $P2_1/c$. $a = 6.189$, $b = 24.234$, $c = 21.204$, $\beta = 100.33^\circ$, $Z = 4$, $D = 1.87$. *PD*: 6.03_2 4.79_{10} 4.30_3 4.16_2 4.11_2 3.95_3 3.77_3 3.49_9 . Forms cross-fiber veinlets with fibers 5–10 μm in diameter but 8 mm long. Empire rose colored, white streak, silky luster. Cleavage oblique to length of fibers. $H = 1\frac{1}{2}$. $G = 1.92$. Biaxial (-); $Z \wedge$ fiber length, to 12° ; $N_x = 1.484$, $N_y = 1.477$. Found 12 km ESE of Gray Mountain, Cameron uranium district, Coconino Co., AZ, as a postmine oxidation product at a U-Co-Ni-Mo prospect in the Chinle formation, associated with pickeringite and moorhouseite. RG *MM 59:553(1995)*, *AM 81:518(1996)*.

29.8.1.1 Lausenite $\text{Fe}_2^+(\text{SO}_4)_3 \cdot 6\text{H}_2\text{O}$

Named in 1928 for Carl Lausen, U.S. mining engineer, who first described the species. MON Space group unknown. *DANS 219:125(1974)*. *PD*: 5.55_4 3.52_{10} 3.38_{10} 3.03_5 2.85_5 2.52_4 2.28_4 2.07_6 . Lumpy aggregates of minute fibers. White, silky luster. Biaxial (-); $X \wedge c = 27^\circ$; $N_x = 1.598$, $N_y = 1.628$, $N_z = 1.654$; 2V large. *United Verde mine, Jerome, AZ*, with copiapite and other sulfates, formed as a result of a mine fire. RG *DII:530*.

29.8.2.1 Kornelite $\text{Fe}_2^{3+}(\text{SO}_4)_3 \cdot 7\text{H}_2\text{O}$

Named in 1888 after Kornel Hlavacsek (1835–1914), Hungarian mining engineer at the Szomolnok copper mine, where the mineral was found. *MON P2₁/c*. $a = 14.30$, $b = 20.12$, $c = 5.425$, $\beta = 96.80^\circ$, $D = 2.254$. *AM 58:535(1973)*. *44-1426*: 10.1₄ 7.11₆ 6.70₁₀ 3.55₈ 3.50₅ 3.36₅ 3.20₅ 2.67₅. Crystals lathlike {010} or acicular [001]; as crusts, tufted aggregates, or globular masses with radial-fibrous structure. Pale rose-pink to violet, silky luster. Cleavage {010}. $G = 2.306$. Soluble in water. Biaxial (+); $Z = b$; $X \wedge c = 20^\circ$; $N_x = 1.572$, $N_y = 1.586$, $N_z = 1.640$; $2V = 49-62^\circ$; $r > v$, perceptible. Tintic Standard mine, Dividend, UT; Copper Queen mine, Bisbee, AZ, with coquimbite, roemerite, voltaite, and rhomboclase. Smolník (Szomolnok), Slovakia (formerly Hungary), with voltaite and coquimbite. *RG DII:530, BM 87:125(1964)*.

29.8.3.1 Coquimbite $\text{Fe}_2^{3+}(\text{SO}_4)_3 \cdot 9\text{H}_2\text{O}$

Named in 1841 for the locality. Dimorphous with paracoquimbite. *HEX-R P31m*. $a = 10.922$, $c = 17.084$, $Z = 4$, $D = 2.137$. *AM 55:1534(1970)*. *44-1425*: 8.28₈ 5.47₆ 4.60₆ 3.64₆ 3.50₅ 3.36₁₀ 2.77₅ 2.76₈. Crystals short prismatic [0001] with {1011} and {1120}; pyramidal {1011}; also massive, granular. Pale violet to deep amethystine, also yellowish or greenish; vitreous luster. Cleavage {1011}, imperfect; {1010}, difficult. $H = 2\frac{1}{2}$. $G = 2.11$. Soluble in cold water and in acids. If a water solution is heated, hydrous ferric oxide precipitates. Tastes astringent. Uniaxial (+); $N_O = 1.539$, $N_E = 1.548$. Al substitutes for Fe^{3+} up to at least $\text{Al/Fe} = 1:1.49$. San Rafael Swell, Emery Co., UT, in uranium mines. United Verde mine, Jerome, AZ, in the fire zone. Near Borate, San Bernardino Co., CA, in the sulfate deposit. Concepcion mine, Huelva, Spain. Skouriotissa, Cyprus. Abundant in Chile, especially in Coquimbo Prov. and at Tierra Amarilla, Quetena, Chuquicamata, and Alcaparrosa. *RG DII:532, NJMM:89(1974)*.

29.8.4.1 Paracoquimbite $\text{Fe}_2^{3+}(\text{SO}_4)_3 \cdot 9\text{H}_2\text{O}$

Dimorphous with coquimbite. Named in 1935 from the Greek *para* and coquimbite; the minerals are polytypic. *HEX-R R3*. $a = 10.93$, $c = 51.30$, $Z = 12$, $D = 2.115$. *AM 56:1567(1971)*. *27-254*: 8.88₁₀ 8.55₂ 7.62₄ 5.47₃ 4.71₂ 4.61₃ 3.37₃ 2.76₁. Rhombohedral crystals, with large {0112}; also equant pseudocubic with {0001} and {0112}; or prismatic; massive, granular. Pale violet, vitreous luster. Cleavage {0112} and {1014}, imperfect. $H = 2\frac{1}{2}$. $G = 2.11$. Soluble in water. Tastes astringent. Tierra Amarilla, Alcaparrosa, and Quetena, Chile, with coquimbite and other sulfates. *RG DII:534, NJMM:89(1974)*.

29.8.5.1 Quenstedtite $\text{Fe}_2^{3+}(\text{SO}_4)_3 \cdot 11\text{H}_2\text{O}$

Named in 1889 for Friedrich August Quenstedt (1809–1889), German mineralogist. *TRIC P1*. $a = 6.184$, $b = 23.60$, $c = 6.539$, $\alpha = 94.18^\circ$, $\beta = 101.73^\circ$, $\gamma = 96.27^\circ$, $Z = 2$, $D = 2.145$. *AM 59:582(1974)*. *28-496*: 5.84₇ 5.64₅ 5.38₃ 5.08₅ 4.48₃ 4.22₉ 4.11₁₀ 3.82₅. Crystals tabular {010} or short

prismatic [100]; aggregates of minute crystals. Pale violet to reddish violet. Cleavage {010}, perfect; {100}, good. $H = 2\frac{1}{2}$. $G = 2.147$. Readily soluble in water. Biaxial (+); $X \wedge \phi = -43^\circ$, $X \wedge \sigma = 45^\circ$, $Y \wedge \phi = 128^\circ$, $Y \wedge \sigma = 43^\circ$, $Z \wedge \phi = -138^\circ$, $Z \wedge \sigma = 88^\circ$; $N_x = 1.547$, $N_y = 1.566$, $N_z = 1.594$ (Na); $2V = 70^\circ$; $r < v$, strong. *Tierra Amarilla, near Copiapo, Chile*, and at Alcaparrosa near Calama. RG *DII:535*.

29.8.6.1 Alunogen $Al_2(SO_4)_3 \cdot 17H_2O$

Named in 1832 from the Greek to *make alum*. TRIC P1. $a = 7.420$, $b = 26.97$, $c = 6.062$, $\alpha = 89.95^\circ$, $\beta = 97.57^\circ$, $\gamma = 91.88^\circ$, $Z = 2$, $D = 1.791$. *AM 61:311(1976)*. $26-1010$: 13.5_6 4.49_{10} 4.39_8 4.33_8 3.97_8 3.90_5 3.68_5 3.02_4 . Delicate fibrous masses or crusts; efflorescences. Crystals small and rare, prismatic [001], or {010} with a six-sided outline; twinning on {010}. Colorless to white, or tinged by impurities; vitreous to silky luster. Cleavage {010}, perfect; also {100}, {313}. $H = 1\frac{1}{2}-2$. $G = 1.77$. Easily soluble in water; in CT, gives water, and at a higher temperature, sulfuric acid; melts at about 114° . Tastes acid and sharp, like alum. Biaxial (+); $X \approx b$; $Z \wedge c = 42^\circ$; $N_x = 1.459$, $N_y = 1.463$, $N_z = 1.473$; $2V = 31^\circ$. Formed as an efflorescence in coal formations, and especially in arid regions, as a result of oxidation of pyrite or other sulfides in orebodies, giving rise to sulfuric acid, which reacts with aluminous minerals in wall rock. Also formed in fumaroles and solfatara. Abundant at Smoky Mt., Jackson Co., NC. In NM extensive deposits in the Alum Mt. district, Grant Co., as crusts 1.0 m or more thick on cliffs; also in Sandoval Co. as a thick bed. In CA around the Mt. Lassen hot springs, Shasta Co., and at the Geysers, Sonoma Co. In BC, Canada, near Vernon with epsomite in veins. Kolosoruk, Bohemia, Czech Republic, in brown coal, and in the opal mines of Cervenera (Opalbanya), Slovakia. In fumaroles on Mt. Vesuvius, Italy; in the solfatara of Pozzuoli; at Miseno in the sulfur caves; and at Libiola, Sestri Levante, Genova(*). At numerous places in Chile and Peru, as in the Cerro Pintado near Iquique and at Francisco de Vergara, Antofagasta Prov. RG *DII:537*, *AM 49:1763(1964)*, *BM 96:385(1973)*, *TMPM 21:164(1974)*.

29.8.7.1 Meta-alunogen $Al_2(SO_4)_3 \cdot 14H_2O$

Named in 1942 from the Greek *meta* and alunogen, indicating a lower hydrate than alunogen. An inadequately characterized mineral. ORTH Space group unknown. $a = 12.25$, $b = 13.95$, $c = 15.95$. $22-23$ (syn): 12.2_3 6.11_1 4.21_1 4.07_{10} 3.99_1 3.86_1 3.02_1 . White, waxy or pearly luster. Biaxial (+); $N_x = 1.469$, $N_y = 1.473$, $N_z = 1.491$; $2V$ large. *Francisco de Vergara, Antofagasta, Chile*, as a dehydration product of alunogen. RG *DII:539*, *AM 28:61(1943)*.

29.9.1.1 Voltaite $K_2Fe_5^{2+}Fe_4^{3+}(SO_4)_{12} \cdot 18H_2O$

Named in 1841 for Alessandro Volta (1745–1827), Italian physicist. iso *Fd3c*. $a = 27.254$, $Z = 16$, $D = 2.662$. $20-1388$: 9.63_4 6.80_3 5.55_6 3.54_8 3.40_{10} 3.03_5 2.85_4 2.08_3 . Crystals form cubes, octahedrons, and combinations of these;

rarely dodecahedral; also massive, granular. Greenish black to black; dark oil-green, grayish-green streak, resinous luster. No cleavage, conchoidal fracture. $H = 3$. $G = 2.7$. Isotropic; $N = 1.593\text{--}1.608$. Weak anomalous birefringence common. Al and Mg may replace a portion of the Fe^{3+} and Fe^{2+} , resulting in lower refractive indices. United Verde mine, Jerome, AZ, in the fire zone; also at Bisbee at the Copper Queen mine. At the sulfate deposit near Borate, San Bernardino Co., CA. The solfatara of *Pozzuoli near Naples, Italy*, as well as in fumaroles on Vesuvius and in the sulfur cave of Miseno. The Rammelsberg mine, near Goslar, Harz, Germany. In the pyrite mines of Huelva, Spain. With metavoltine and roemerite at Madeni Zakh, Iran. Quetena, Chuquicamata, and Alcaparrosa, Chile. RG *DII:464, NW:670(1970), TMPM 18:185(1972)*.

29.9.1.2 Zincovoltaitite $K_2Zn_5Fe_4^{3+}(SO_4)_{12} \cdot 18H_2O$

Named in 1987 as the zincian analog of voltaite. iso *Fd3c*. $a = 27.18$, $Z = 16$, $D = 2.767$. *AM 75:244(1990)*. *PD*: 5.53₄ 4.24₃ 3.54₇ 3.39₁₀ 3.13₄ 3.03₃ 2.84₃. Single grains and granular aggregates; also veinlets cutting pyrite. Crystals isometric with {111} and {100}; also {110} and {211}. Greenish black to oil green, with gray-green streak and pitchy to resinous luster, vitreous on crystal faces. No cleavage, conchoidal fracture, brittle. $H = 3$. $G = 2.756$. Isotropic; $N = 1.605$ (N_a); sometimes anomalously uniaxial. From a lead-zinc mine at Xitianshan, Qinghai, China, associated with roemerite, melanterite, and gypsum. RG

29.9.2.1 Zircosulfate $(Zr,Ti)(SO_4)_2 \cdot 4H_2O$

Named in 1965 for the composition. ORTH *Fddd*. $a = 25.92$, $b = 11.62$, $c = 5.532$, $Z = 8$, $D = 2.833$. *AM 51:529(1966)*. 8-495(syn): 6.49₅ 4.90₃ 4.32₁₀ 3.47₄ 2.98₉ 2.90₂ 2.33₃ 2.13₂. Compact, powdery masses. Colorless to white, dull luster. $H = 2\frac{1}{2}\text{--}3$. $G = 2.85$. Easily soluble in cold water. Biaxial (+); $N_x = 1.620$, $N_y = 1.644$, $N_z = 1.674$; $2V = 75^\circ$. Found in a cavity in nepheline syenite pegmatite in the Korgeredabin alkalic massif, southeastern Tuva, Russia, and probably resulted from the dissolution of preexisting eudialyte by sulfuric acid solutions. RG *ZVMO 94:530(1965)*.

29.9.3.1 Bazhenovite $CaS_5 \cdot CaS_2O_3 \cdot 6Ca(OH)_2 \cdot 20H_2O$

Named in 1987 for A. G. Bazhenov (petrographer) and L. F. Bazhenova (analytical chemist), Russian scientists. A questionable "mineral." Chemical classification uncertain. MON *P2₁/c*. $a = 8.45$, $b = 17.47$, $c = 8.24$, $\beta = 119.50^\circ$, $Z = 1$, $D = 1.845$. *AM 74:500(1989)*. Crystal structure is layered, with $Ca(OH)_2$, polysulfide, and water-bearing layers parallel to {010}. 42-1361: 8.76₁₀ 4.39₁₀ 2.91₆ 2.81₅ 2.62₅ 2.28₅ 1.996₇. Granular aggregates of blades flattened {010} and elongated [001]. Orange-yellow, light yellow streak, vitreous to pearly luster. Cleavage {010}, very good; brittle, but elastic in thin

leaves. $H = 2$. $G = 1.83$. Biaxial (+); $XY = ba$; $Z \wedge c = 30^\circ$; $N_x = 1.595$, $N_y = 1.619$, $N_z = 1.697$; $2V = 60^\circ$; absorption $X > Z > Y$. X, deep yellow-green; Y, greenish yellow; Z, pale greenish yellow. *Chelyabinsk coal basin, southern Ural Mts., Russia*, from old burning coal dumps, associated with native (?) iron, sulfur, oldhamite, troilite, pyrrhotite, fluorite, and periclase in altered pyritized siderite fragments. RG *ZVMO* 116:737(1987).

Anhydrous Sulfates Containing Hydroxyl or Halogen

30.1.1.1 Sundiusite $\text{Pb}_{10}(\text{SO}_4)(\text{Cl}_2)_8$

Named in 1980 for Nils Sundius (1886–1976), Swedish mineralogist. *MON* $C2$, Cm , or $C2/m$. $a = 24.67$, $b = 3.781$, $c = 11.881$, $\beta = 100.07^\circ$, $Z = 2$, $D = 7.20$. *AM* 65:506(1980). 33-761: 6.10₃ 3.91₂ 3.74₃ 3.43₂ 3.10₆ 3.04₆ 2.98₁₀ 2.74₈. Plumose aggregates of crystals. White to colorless, adamantine luster. Cleavage {100}, perfect; brittle. $H = 3$. $G = 7.0$. Not fluorescent. Biaxial (+); $N > 2.10$; maximum birefringence = 0.07; cleavage laths length-slow. *Amerika stope, Långban, Värmland, Sweden*. RG

30.1.2.1 Elyite $\text{Pb}_4\text{Cu}(\text{SO}_4)(\text{OH})_8$

Named in 1972 for John Ely, an important figure in the early mining history of eastern Nevada. *MON* $P2_1/a$. $a = 14.248$, $b = 5.768$, $c = 7.309$, $\beta = 100.43^\circ$, $Z = 2$, $D = 6.32$. *AM* 57:364(1972). 25-293: 7.19₁₀ 3.34₃ 3.14₃ 3.08₃ 3.05₃ 3.00₈ 2.88₄. Prismatic to fibrous crystals in radiating sprays and tufts; crystals elongate [010], tabular {001}; twinning common, on {001}. Violet, pale violet to white streak, silky luster. Cleavage {001}, good; sectile. $H = 2$. $G \approx 6.0$. Nonfluorescent. Insoluble in water, turns white in dilute HNO_3 or HCl . Biaxial (-); $Y = b$; $X \wedge c = 45^\circ$; $N_x = 1.990$, $N_y = 1.993$, $N_z = 1.994$ (Na); $2V = 68^\circ$; noticeable dispersion; absorption $Z > Y > X$. *Silver King Mine, Ward, NV*, in voids in oxidizing Pb–Cu–Zn sulfide ore, associated with earthy secondary galena. Tsumeb, Namibia. Common as a smelter product in slags. RG

30.1.3.1 Brochantite $\text{Cu}_4(\text{SO}_4)(\text{OH})_6$

Named in 1824 for A. J. M. Brochant de Villiers (1772–1840), French geologist and mineralogist. *MON* $P2_1/a$. $a = 13.08$, $b = 9.85$, $c = 6.02$, $\beta = 103.37^\circ$, $Z = 4$, $D = 3.98$. Structure: *SR* 23:451(1959). 43-1458: 6.38₈ 5.35₇ 3.90₁₀ 3.19₅ 2.92₂ 2.68₅ 2.52₈ 1.740₂. Crystals stout prismatic to acicular [001]; also elongated [010] or tabular {001}; massive, granular. Twinning common on {100}, giving a pseudo-orthorhombic appearance. Emerald green to blackish green, pale green streak, vitreous luster, pearly on cleavage. Cleavage {100}, perfect; uneven to conchoidal fracture. $H = 3\frac{1}{2}$ –4. $G = 3.97$. Soluble in acids; in CT, yields water. Biaxial (-); $X \approx a$; $Y = b$; $Z \approx c$; $N_x = 1.728$, $N_y = 1.771$, $N_z = 1.800$ (Na); $2V = 77^\circ$; $r < v$, medium. X, bluish; Y, green. Formed in

the oxide zone of copper deposits under conditions of low acidity. Tintic district, Juab Co., UT, and also at the Apex mine, Washington Co. Organ district, Dona Ana Co., NM. In AZ at the Mammoth-St. Anthony mine, Pinal Co.(*), with linarite; in Cochise Co. at the Shattuck mine(!) in centrimetric square prisms with malachite, and at Bisbee(!). In England at Roughten Gill, Cumberland. Nassau, Hesse-Nassau, Germany. Rosas, Sardinia, Italy. Rio Tinto, Huelva, Spain. *Gumeshevsk, near Ekaterinburg, Ural Mts., Russia*. Brilliant crystals at Aïn Barbar, Constantine, Algeria(*), and in the mines at Bou Beker on the Algerian border near Oujda, Morocco. Shaba, Zaire. Spectacular specimens from Tsumeb, Namibia(!). Chuquicamata, and in the Atacama desert region, Chile. Broken Hill, NSW, Australia. Used as an ore of copper. RG *DII:541*.

30.1.5.1 Klebelsbergite $\text{Sb}_4\text{O}_4(\text{SO}_4)(\text{OH})_2$

Named in 1929 for Kuno Klebelsberg (1875–1932), Hungarian educator. ORTH *Pca2*. $a = 5.766$, $b = 11.274$, $c = 14.887$, $Z = 4$, $D = 4.69$. *AM 65:931(1980)*. *35-464*: 6.22₈ 3.89₈ 3.55₈ 3.15₈ 3.13₁₀ 2.83₈ 2.44₈ 1.81₈. Tufts of minute acicular crystals elongated [001] and flattened {010}. Pale yellow to orange-yellow, yellow streak, vitreous luster. No cleavage. $\text{VHN}_{10} = 200$. $G = 4.62$. Nonfluorescent. Slowly soluble in cold concentrated HCl. In CT, fuses and gives acid water. Biaxial (-); $N \approx 1.95$; $2V \approx 70^\circ$; nonpleochroic. *Baia Sprie* (formerly *Felsőbánya*), *Maramures, Romania*, on stibnite. Pereta mine, Tuscany, Italy(!), in crystals to 2 cm; also at La Cetine. RG *DII:583*, *AM 65:499(1980)*, *NJMM:223(1980)*.

30.1.6.1 Kogarkoite $\text{Na}_3(\text{SO}_4)\text{F}$

Named in 1973 for Lia Nikolaevna Kogarko (b.1936), Russian geochemist, who first noticed the mineral in Russia. MON (pseudorhombohedral) Space group unknown. $a = 18.074$, $b = 6.958$, $c = 11.443$, $\beta = 107.71^\circ$, $Z = 12$, $D = 2.679$. *MM 43:753(1980)*. *25-827*: 4.29₅ 3.80₇ 3.48₁₀ 2.99₉ 2.72₉ 2.71₉ 2.56₇ 2.14₉. Pseudo-hexagonal crystals; also as chalky incrustations; twinning on {0001}. Pale blue, also white or colorless; vitreous luster. $H = 3\frac{1}{2}$. $G = 2.676$. Biaxial (+); pseudouniaxial (+); $N_x = 1.439$, $N_y = 1.439$, $N_z = 1.442$; $2V$ near 0° . *Hortense Hot Springs, Chalk Creek, Chaffee Co., CO*, as a sublimate from steam issuing from the springs. Lovozero Massif, Kola Penin., Russia, in crystals up to 2 cm in nepheline syenite pegmatite, associated with villiaumite, nepheline, aegirine, ramsayite, and apatite. RG *AM 58:116(1973)*.

30.1.7.1 Sulphohalite $\text{Na}_6(\text{SO}_4)_2\text{FCl}$

Named in 1888 for the composition. iso *Fm3m*. $a = 10.068$, $Z = 4$, $D = 2.503$. *AM 56:177(1971)*. *15-668*: 5.81₂ 3.56₁₀ 3.03₄ 2.91₈ 2.51₆ 2.25₃ 1.94₅ 1.78₇. Usually dodecahedral; also octahedral, or combinations of {100}, {111}, and {110}. Colorless to pale greenish yellow, or gray, vitreous to greasy luster. Conchoidal fracture. $H = 3\frac{1}{2}$. $G = 2.505$. Slowly soluble in cold water, easily

fusible. Tastes weakly saline. Isotropic; $N = 1.455$. From the saline beds of *Searles Lake, San Bernardino Co., CA*, with hanksite. Crystals attain 3 cm. Abundant at Otjivalundo salt pan, 250 km N of Otavi, Namibia, with trona, thenardite, and pirssonite. RG *DII:548, MM 40:131(1975)*

30.1.8.1 Galeite $\text{Na}_{15}(\text{SO}_4)_5\text{F}_4\text{Cl}$

Named in 1955 for William Alexander Gale (b.1898), American physical chemist, American Potash and Chemical Corp. *HEX-R P31m*. $a = 12.97$, $c = 13.955$, $Z = 3$, $D = 2.610$. *MM 40:357(1975)*. 15-651: 3.68₇ 3.52₈ 3.04₄ 2.97₆ 2.79₁₀ 2.55₇ 1.85₄ 1.76₆. Crystals hexagonal, barrel-shaped or tabular. Common forms are $\{1120\}$, $\{1121\}$, $\{21\bar{1}1\}$, and $\{0001\}$. Colorless. $G = 2.605$. Uniaxial (+); $N_O = 1.447$, $N_E = 1.449$. *Searles Lake, San Bernardino Co., CA*, found in a drill core that penetrated a lower salt bed, associated with gaylussite and northupite. RG *AM 41:672(1956), 48:485(1963), 56:174(1971)*.

30.1.9.1 Schairerite $\text{Na}_{21}(\text{SO}_4)_7\text{F}_6\text{Cl}$

Named in 1931 for John Frank Schairer (1904–1970), American physical chemist, Geophysical Laboratory, Washington, DC. *HEX-R P31m*. $a = 12.197$, $c = 19.259$, $Z = 3$, $D = 2.627$. *MM 40:131(1975)*. 16-165: 4.44₂ 3.79₇ 3.52₈ 3.01₆ 2.76₁₀ 2.58₆ 2.41₂ 1.76₇. Rhombohedral crystals with $\{0332\}$ and $\{1011\}$ prominent; artificial crystals are tabular $\{0001\}$; twinning $\{0001\}$, common. Colorless, vitreous luster. Conchoidal fracture, brittle. $H = 3\frac{1}{2}$. $G = 2.616$. Slowly soluble in water, easily fusible. Uniaxial (+); $N_O = 1.440$, $N_E = 1.445$. Found in a drill core in a lower salt bed at *Searles Lake, San Bernardino Co., CA*, with gaylussite, tychite, pirssonite, hanksite, and other salts. RG *DII:547, AM 56:174(1971)*.

30.1.10.1 D'Ansite $\text{Na}_{21}\text{Mg}(\text{SO}_4)_{10}\text{Cl}_3$

Named in 1958 for Jean D'Ans (1881–1969), German chemist, Technical University, Berlin. *ISO I43m*. $a = 15.913$, $Z = 4$, $D = 2.66$. 41-1473(syn): 4.26₃ 3.98₃ 3.40₁₀ 3.12₆ 2.82₁₀ 2.58₄ 2.52₃ 1.717₃. Synthetic crystals tetrahedral with $\{211\}$ dominant; also $\{211\}$ and $\{110\}$. Colorless. $G = 2.655$. Easily fusible. Isotropic; $N = 1.489$ (Na). *Hall, near Innsbruck, Tyrol, Austria*, enclosed in bloedite, associated with vanthoffite. RG *NW 45:362(1958), AM 43:1221(1958), NJMM:152(1958), ZK 152:83(1980)*.

30.1.11.1 Chlorothionite $\text{K}_2\text{Cu}(\text{SO}_4)\text{Cl}_2$

Named in 1872 for the composition: chlorine and sulfur (Greek *theion*). *ORTH Pnma*. $a = 7.732$, $b = 6.078$, $c = 16.292$, $Z = 4$, $D = 2.678$. 29-998: 5.69₃ 3.26₃ 3.15₂ 3.04₁₀ 2.85₄ 2.49₂ 2.19₇ 1.99₂. Crystalline incrustations. Bright blue. $H = 2\frac{1}{2}$. $G_{\text{syn}} = 2.67$. Soluble in water. Biaxial (+); 2V large; $r > v$. Found in fumaroles during the 1872 eruption of *Vesuvius, Italy*. RG *DII:547, ZK 144:226(1976)*.

30.1.12.1 Antlerite $\text{Cu}_3(\text{SO}_4)(\text{OH})_4$

Named in 1889 for the locality. ORTH *Pnam*. $a = 8.244$, $b = 11.987$, $c = 6.043$, $Z = 4$, $D = 3.93$. *CM 27:205(1989)*. 7-407(syn): 6.01₃ 5.40₃ 4.86₁₀ 3.60₈ 2.68₈ 2.57₉ 2.50₃ 2.13₂. Crystals thick tabular {001}, also equant or short prismatic [001], as cross-fiber veinlets, aggregates of acicular crystals, granular. Emerald green to blackish green, also light green; very similar to brochantite; pale green streak; vitreous luster. Cleavage {010}, perfect; {100}, poor; brittle. $H = 3\frac{1}{2}$. $G = 3.88$. Soluble in dilute H_2SO_4 , fusible. Biaxial (+); XYZ = bac; $N_x = 1.726$, $N_y = 1.738$, $N_z = 1.789$; $2V = 53^\circ$. X, yellow-green; Y, blue-green; Z, green. Antlerite is a secondary mineral found in the oxidized zone of copper deposits in arid regions, associated with atacamite and other copper sulfates. *Antler mine, Hualpai Mts., Mojave Co., AZ*; also from Bisbee, Cochise Co. Northern light mine, Black Mt., NV. In the Sierra Mojada, COAH, Mexico. Torre Capdulla, Lerida, Italy. Abundant at the great Chuquicamata copper deposit, Antofagasta, Chile, where for many years it was the principal ore mineral in the oxidized zone, associated with kröhnkite, natrochalcite, atacamite, and brochantite. *RG DII:544, MJJ 3:223(1961), NAT 197:70(1963)*.

30.1.13.1 Schuetteite $\text{Hg}_3\text{SO}_4\text{O}_2$

Named in 1959 for Curt Nicolaus Schuette (1895–1975), American mining engineer and geologist, specialist in mercury deposits. *HEX-R P3₁21*. $a = 7.07$, $c = 10.05$, $Z = 3$, $D = 8.36$. *AM 44:1026(1959)*. 12-724(syn): 5.19₂ 3.34₇ 2.91₁₀ 2.60₆ 2.30₂ 1.93₃ 1.76₂ 1.56₂. Thin crusts and films. Bright canary yellow, yellow streak. Friable. $H \approx 3$. $G_{\text{syn}} = 8.18$. The color does not darken on exposure to sunlight, which distinguishes schuetteite from the yellow mercury oxychlorides. Uniaxial (-); $N > 2.10$; pleochroic, greenish yellow to orange-yellow; moderately to highly birefringent. Formed either by the oxidation of cinnabar ore exposed to sunlight, or in the bricks and remains of old mercury furnaces and condensers. It is not known to form underground under natural circumstances. *Silver Cloud mine, Ivanho district, N of Battle Mountain, NV*, and at at least five other NV mercury mines; the Opalite mine, southeastern Oregon; the Idaho Almaden mine, E of Weiser, ID; the Sulphur Bank mine, Lake Co., and elsewhere in CA; at the dismantled Chisos mine furnace, Brewster Co., TX. *RG*

30.1.14.1 Mammothite $\text{Cu}_4\text{Pb}_6\text{AlSb}^{5+}\text{O}_2(\text{SO}_4)_2(\text{OH})_{16}\text{Cl}_4$

Named in 1985 for the locality. *MON C2/m*. $a = 18.933$, $b = 7.331$, $c = 11.532$, $\beta = 112.43^\circ$, $Z = 2$, $D = 5.25$. 38-389: 10.4₆ 6.67₉ 6.08₆ 5.24₃ 4.72₈ 3.59₃ 3.05₉ 2.90₁₀. Microscopic crystals, tabular to prismatic; also acicular. Bright blue to greenish blue, pale blue, vitreous luster. Cleavage {010}, distinct; very brittle. $H = 3$. $G = > 4.2$. Nonfluorescent. Biaxial (+); $N_x = 1.868$, $N_y = 1.892$, $N_z = 1.928$; $2V = 80^\circ$; moderately pleochroic; absorption $Z < Y \leq X$. *Mammoth vein, Tiger, AZ*, associated with anglesite and phosgenite, and from

Laurium, Attika, Greece, with cerussite and phosgenite. RG *MR* 16:117(1985), *TMPM* 34:279(1985), *AM* 71:1548(1986).

30.1.15.1 Ye'elimite $\text{Ca}_4\text{Al}_6(\text{SO}_4)\text{O}_{12}$

Named in 1983 for the locality. ISO *I4*₁32. $a = 18.392$, $D = 2.61$. 33-256(syn): 4.92₁ 3.76₁₀ 3.25₁ 2.91₁ 2.65₃ 2.46₁ 2.17₂ 1.62₁. Colorless. $G = 2.61$. Isotropic; $N = 1.568$. Formed as a result of high-temperature metamorphism of calcareous rocks. *Hatnurim basin, W of the Dead Sea, Israel, near Har Ye'elim and Nahal Ye'elim*, a hill and a wadi. From the Hatnurim formation in cobbles in a pseudoconglomerate, with larnite, brownmillerite, and ellestadite. RG *JACH* 12:413(1962), *GSICR*:1(1983), *AM* 72:226(1987).

30.1.16.1 Chenite $\text{Pb}_4\text{Cu}(\text{SO}_4)_2(\text{OH})_6$

Named in 1986 for Tsong T. Chen (b.1942), Canadian mineralogist. TRIC *P1*. $a = 5.791$, $b = 7.940$, $c = 7.976$, $\alpha = 112.01^\circ$, $\beta = 97.73^\circ$, $\gamma = 100.45^\circ$, $Z = 1$, $D = 6.044$. 45-1379: 5.57₅ 4.32₇ 3.61₁₀ 3.57₈ 3.43₇ 3.39₇ 3.30₅ 3.01₅. Minute crystals, prismatic to equant; twinning rare. Sky blue, pale blue streak, vitreous to resinous luster. Cleavage {100}, good. $H = 2\frac{1}{2}$. $G = 5.98$. Nonfluorescent. Biaxial; $N_x = 1.871$, $N_y = 1.909$, $N_z = 1.927$ (N_a); $2V = 67^\circ$; $r > v$, very strong; weakly pleochroic. *Susanna mine, Leadhills, Scotland*, on partially oxidized galena and chalcopyrite, associated with caledonite, linarite, and leadhillite. Also in cavities in slag from the old Glengaber smelter at Wanlockhead, Scotland. RG *MM* 50:129(1986), *AM* 72:222(1987), *NJMM*:259(1988).

30.1.17.1 Nabokoite $\text{KCu}_7\text{Te}^{4+}\text{O}_4(\text{SO}_4)_5\text{Cl}$

Named in 1987 for Sof'ya I. Naboko (b.1909), Russian vulcanologist. Needs further study and substantiation. TET *P4/ncc*. $a = 9.833$, $c = 20.591$, $Z = 4$, $D = 3.974$. *ZVMO* 116:358(1987). 42-1337: 10.4₁₀ 4.57₄ 3.56₄ 3.42₆ 2.88₅ 2.44₇ 1.972₄ 1.775₄. Zoned crystals, thin tabular {001}. Light yellow-brown to honey-brown zones alternating with dark brown zones (atlasovite), vitreous luster. Cleavage {001}, perfect. $H = 2-2\frac{1}{2}$. $G = 4.18$. Insoluble in water, soluble in HCl or HNO₃, reacts with KOH. Uniaxial (-); $N_0 = 1.778$, $N_E = 1.773$. Found as a sublimate on porous basalt near a fumarole formed during the *Great Clefted Tolbachik eruption, Kamchatka, Russia*, associated with anglesite, chalcocyanite, and dolerophanite. RG *AM* 73:929(1988), *TMPM* 38:291(1988).

30.1.17.2 Atlasovite $\text{Cu}_6\text{Fe}^{3+}\text{BiO}_4(\text{SO}_4)_5 \cdot \text{KCl}$

Named in 1987 for Vladimir V. Atlasov (1661-1711), Russian explorer. Because of wide variations in the analytical data given, the formula and unit cell are open to question and reinterpretation. TET *P4/ncc*. $a = 9.86$, $c = 20.58$, $Z = 4$, $D = 4.12$. *ZVMO* 116:358(1987). The unit cell was derived from the powder data by analogy with nabokoite. 42-1338: 10.8₉ 10.4₁₀ 4.57₅ 3.57₄ 3.43₇ 2.89₇ 2.64₄ 2.45₈. Crystals tabular {001}, zoned. Dark brown, light brown streak, vitreous luster. Cleavage {001}, perfect. $H = 2-2\frac{1}{2}$. $G = 4.20$.

Tests same as with nabokoite. Uniaxial (-); $N_O = 1.783$, $N_E = 1.776$. O, red-brown; E, yellowish. Atlasovite and nabokoite form separate zones in tabular tetragonal crystals, in which Fe^{3+} and Bi^{3+} substitute for Te and Cu in an incompletely understood manner. Found as zones in crystals that were a sublimate from the *Great Clefited Tolbachik volcanic eruption, Kamchatka, Russia*. RG AM 73:927(1988).

30.1.18.1 Coquandite $Sb_6O_8(SO_4) \cdot H_2O$

Named in 1992 for Henri Coquand (1811–1881), French scientist, who studied the Sb deposits of Tuscany. TRIC *P1*. $a = 11.434$, $b = 29.77$, $c = 11.314$, $\alpha = 91.07^\circ$, $\beta = 119.24^\circ$, $\gamma = 92.82^\circ$, $Z = 12$, $D = 5.78$. *MM 56:599(1992)*. *PD*: 14.84₅ 9.27₄ 8.01₃ 6.81₇ 3.30₉ 3.20₄ 3.09₁₀ 2.84₃. White powdery masses and thin crusts, spheroidal knobs of feathery aggregates of silky fibers, flexible lamellar crystals, minute tabular crystals, elongate [001], flattened (010). White to colorless, white streak, adamantine luster, transparent. Flexible, no cleavage. Biaxial (+); $N_{mean} = 2.08$; $2V = >> 60^\circ$; length-slow; nonpleochroic; parallel extinction on {010}; axial plane parallel to [001]; polysynthetically twinned on (010), nonfluorescent. Found at the Lucky Knock mine, Tonasket, Okanogan Co., WA; at the *Pereta stibnite mine, Tuscany, Italy*, where a stibnite vein with quartzite gangue fills a fracture in limestone. The coquandite is embedded between the needles of columnar stibnite, where it is associated with peretaite and klebelsbergite. Also at the Cetine mine, Tuscany. RG AM 78:845(1993).

30.2.1.1 Lanarkite $Pb_2(SO_4)O$

Named in 1832 for the locality. MON *C2/m*. $a = 13.769$, $b = 5.698$, $c = 7.079$, $Z = 4$, $D = 7.00$. *37-516(syn)(calc)*: 6.37₂ 4.43₂ 3.34₁₀ 2.96₃ 2.95₈ 2.87₂ 2.85₄ 2.05₂. Crystals elongated [010], twinning rare, polysynthetic. Gray to greenish white, pale yellow; adamantine to resinous luster, pearly on cleavages. Cleavage {201}, perfect; {401}, {201}, imperfect. Thin flexible laminae. $H = 2-2\frac{1}{2}$. $G = 6.92$. Fluoresces yellow in LWUV and in X-rays. Soluble in KOH and in warm HNO_3 . Biaxial (-); $Y = b$; $Z \wedge c = 30^\circ$; $N_x = 1.928$, $N_y = 2.007$, $N_z = 2.036$; $2V = 60^\circ$; $r > v$, strong, inclined. *Susanna mine, Leadhills, Lanarkshire, Scotland*, with leadhillite, cerussite, and caledonite. Tanne, Harz Mts., Germany. Laquorre mine near Aulus, Ariège, France. Challocolla, Atacama, Chile. RG *DII:550, AC 4:471(1951), ZK 132:99(1970)*.

30.2.2.1 Dolerophanite $Cu_2(SO_4)O$

Named in 1873 from the Greek for *fallacious appearance*, because its appearance does not suggest its composition. MON *C2/m*. $a = 9.370$, $b = 6.319$, $c = 7.639$, $\beta = 122.33^\circ$, $Z = 4$, $D = 4.16$. Structure: *AC 16:1009(1963)*. *13-189*: 6.44₅ 4.76₁ 3.62₁₀ 2.78₂ 2.62₄ 2.55₂ 2.26₃ 2.03₁. Tabular crystals, elongated [010]; prism faces usually striated [010], other faces smooth and lustrous. Chestnut brown to dark brown and nearly black, yellowish to brown streak. Cleavage {101}, perfect. $H = 3$. $G = 4.17$. Easily soluble in HNO_3 , decom-

posed by water, giving a blue solution. Biaxial (+); $Y = b$; $Z \wedge c = -10^\circ$; $N_x = 1.715$, $N_y = 1.820$, $N_z = 1.880$; $2V = 85^\circ$; $r > v$, very strong, crossed. X, deep brown; Y, brownish yellow; Z, lemon yellow. Found as a sublimate formed during the eruption of *Vesuvius, Italy*, in 1868, associated with chalcocyanite, euchlorine, and eriochalcite. RG *DII:551, AM 46:147(1961)*

30.2.3.1 Linarite $PbCu(SO_4)(OH)_2$

Named in 1839 for the locality. MON $P2_1/m$. $a = 9.691$, $b = 5.650$, $c = 4.687$, $\beta = 102.65^\circ$, $Z = 2$, $D = 5.315$. NBSM *25(16):34(1979)*. Structure: AC *14:747(1961)*. *30-493*: 4.85₄ 4.52₆ 3.63₃ 3.56₆ 3.15₁₀ 3.11₄ 2.71₃ 2.59₃. Crystals elongated [010], or tabular $\{101\}$ and $\{001\}$; as crusts or aggregates; twinning on $\{100\}$, fairly common. Deep azure blue, similar to azurite; pale blue streak, vitreous to subadamantine luster. Conchoidal fracture, brittle. $H = 2\frac{1}{2}$. $G = 5.35$. Soluble in HNO_3 with separation of $PbSO_4$; easily fusible; in CT decrepitates, darkens, and loses water. Biaxial (-); $Z = b$; $X \wedge c = -24^\circ$; $N_x = 1.809$, $N_y = 1.838$, $N_z = 1.859$ (Na); $2V = 80^\circ$; $r < v$, strong. X, pale blue; Y, clear blue; Z, prussian blue. Mammoth mine(!), Tiger, AZ, and in superb crystals at the Grand Reef mine(!) in Laurel Canyon, Graham Co. Tintic and Eureka districts, UT. Cerro Gordo mine, Inyo Co., CA. At the Blanchard mine(*), Bingham, NM, with galena and fluorite. Beaver Mt., Slocan District, BC, Canada. *Linares, Jaen, Spain*. San Giovanni and Arenas, Sardinia, Italy. Leadhills, Lanarkshire, Scotland, and at Red Gill and other mines in Cumberland, England(!), sometimes in fine crystals. In Germany at Badenweiler and elsewhere; in Russia at Nerchinsk, and near Beresovsk, Ural Mts. Abundant at Tsumeb, Namibia(*). Broken Hill, NSW, Australia. At the Ortiz mine, Catamarca, Argentina, and at several places in Chile and Peru. RG *DII:553, MJJ 3:282(1961), MA 87:3984(1987)*.

ALUNITE GROUP

The alunite minerals are isostructural and conform to the formula

where

A = K, Na, Tl, H_3O , NH_4 , Ag, Pb, Ca, Ba

B = Al, Fe^{3+} , or Cu

T = S (and also minor P, As, V, Si)

and crystallize in the rhombohedral system, space group $R\bar{3}m$.

In this structure, Al^{3+} ions are at the maximum separation from each other permitted by the crystal symmetry, and are near the maximum possible distance from the S^{6+} that still permits an Al-(SO_4) distance of 1.936 Å. The Al is in octahedral coordination surrounded by a nearly regular octahedron made up of four $(OH)^-$ groups and two O's of two different (SO_4) ions. The sulfur

atoms lie on the trigonal axis and are surrounded by three oxygen atoms which form the base of a tetrahedron and one apical oxygen at a shorter bond length which also lies on the threefold axis. The coordination number of K is six, with six O's from six separate (SO_4) groups at 2.82 Å forming flattened octahedra. The basal oxygen atoms of the (SO_4) tetrahedra are surrounded by the three (OH) groups. Large variations of the ionic radii of the ion in the A position are allowed by the structure, ranging from $r = 0.95$ Å for Na to $r = 1.33$ Å for K, which is considerably greater than usually found in an isomorphous series. On the other hand, the $(\text{SO}_4)^{2-}$, $(\text{PO}_4)^{3-}$, and $(\text{AsO}_4)^{3-}$ differ but slightly in dimensions, making possible the phosphate-phosphate, sulfate-phosphate, or sulfate-arsenates of the related beudantite group and crandallite that are isostructural with the alunites. *AC 18:249(1965)*.

JAROSITE: $\text{KFe}_3(\text{SO}_4)_2(\text{OH})_6$

Jarosite, which is isostructural with alunite, in a sense consists of alternating layers of potassium sulfate and layers of iron (aluminum) hydroxide. However, hydroxide atoms form only four of the six corners of the $\text{Fe}(\text{Al})\text{-O}$ octahedra and the other two are sulfate oxygens. Layers are also tied together with K-OH bonds. See also *TURQUOISE* under *Phosphates, Arsenates, and Vanadates*.

*Half the available A positions are occupied by Pb ions, and the others remain vacant to provide valence compensation.

Note: The alunite groups are isostructural with crandallite and with the beudantite group.

30.2.4.1 Alunite KAl₃(SO₄)₂(OH)₆**30.2.4.2 Natroalunite NaAl₃(SO₄)₂(OH)₆**

Named in 1824 (alunite) and 1911 (natroalunite) for the composition. *Alunite* is a contraction of an earlier term, "aluminilite." Alunite group. *HEX-R R3m*. *a* = 6.970 (alunite), 6.990 (natroalunite); *c* = 17.27 (alunite), 16.905 (natroalunite); *Z* = 3; *D* = 2.839 (alunite), 2.819 (natroalunite). *14-136*(alunite): 5.77₃ 4.96₆ 2.99₁₀ 2.89₁₀ 2.29₈ 1.93₇ 1.90₃ 1.50₄. *41-1467*(natroalunite): 4.90₇ 3.49₃ 2.98₇ 2.96₁₀ 2.93₂ 2.22₄ 1.895₄ 1.745₃. **Habit:** Massive, granular to dense; as rocky masses admixed with quartz, kaolin, or other minerals. Rare crystals usually minute pseudocubic rhombohedrons {0112}; fibrous or columnar. **Physical properties:** White; also grayish, yellowish, reddish, reddish brown; dull to vitreous luster, pearly on {0001}. Cleavage {0001}, distinct; {0112}, poor; conchoidal to splintery fracture; brittle. *H* = 3½–4. *G* = 2.6–2.9. Not fluorescent, strongly pyroelectric. **Tests:** Slowly soluble in dilute H₂SO₄, nearly insoluble in HCl and HNO₃, infusible. **Optics:** Uniaxial (+); *N*₀ = 1.572, *N*_E = 1.592 (Na)(alunite); *N*₀ = 1.568, *N*_E = 1.58 (Na)(natroalunite). **Chemistry:** Na can substitute for K in alunite up to at least Na/K = 9:2, but the

pure Na end member is not known in nature. Na-bearing alunites beyond trace amounts are relatively uncommon. The name *natroalunite* is given to that part of the series with $\text{Na} > \text{K}$. **Occurrence:** Alunite and natroalunite are widespread in rocks that have been altered by solfataric action, or "alunized." In some places they result from the action of sulfuric acid derived from the oxidation of pyrite or other sulfides on nearby rocks. Alunization may be accompanied by kaolinization and silicification. **Localities:** Many deposits are found in the western United States, as at Red Mt., Hinsdale Co., and at the head of South River, Mineral Co., CO; in altered volcanic rocks of the Goldfield district, NV. Ubiquitous around the hot springs of Lassen Volcanic National Park, CA. Commercially important deposits occur near Marysvale, Piute Co., UT. From the solfataric deposits of *Tolfa, Civita Vecchia, Italy*, which have been the basis of an alum industry since the fifteenth century. Near Almeria, Spain; Beregovo, Ukraine; Fanshan, southwestern China; near Bulla Delah, NSW, Australia. Natroalunite is much less common than alunite. At the *National Belle mine, Red Mt., Silverton, CO*. Sugarloaf Butte, near Quartzite, AZ; Funeral Range, Death Valley, CA; Kalgoorlie, WA, Australia; Salamanca, Chile; Ukusu, Izu Prov., Japan. **Uses:** Alunite is mined extensively, and is used for the manufacture of alum, potash, and alumina. RG *DII:556; AM 47:127(1962), 65:953(1980), 77:1092(1992); GSPP 1076A:2(1978); NJMM:534(1982)*.

30.2.4.3 Schlossmacherite $(\text{H}_3\text{O,Ca})\text{Al}_3(\text{SO}_4,\text{AsO}_4)_2(\text{OH})_6$

Named in 1980 for Karl Schlossmacher (b.1887), mineralogist and honorary president of the German Gemological Society. Alunite group. $R\bar{3}m$. $a = 6.998$, $c = 16.67$, $D = 3.00$. *NJMM:215(1980)*. $33-973$: 4.92_7 3.51_4 2.98_5 2.96_{10} 2.22_3 1.90_4 1.75_3 1.46_2 . The composition of analyzed material places this mineral intermediate between the alunite and beudantite groups. Since the ratio of $(\text{SO}_4)^{2-}$ to $(\text{AsO}_4)^{3-}$ is nearly 2:1, it is considered to be part of the alunite group, but some authorities differ on this. *Emma Luisa mine, Guanaco, Chile*, associated with ceruleite and chenevixite. RG *AM 65:1069(1980)*.

30.2.4.4 Osarizawaite $\text{PbCuAl}_2(\text{SO}_4)_2(\text{OH})_6$

Named in 1961 for the locality. Alunite group. $R\bar{3}m$. $a = 7.075$, $c = 17.248$, $D = 4.20$. *AM 47:1216(1962)*. $15-178$: 5.75_8 3.52_6 3.00_{10} 2.87_5 2.28_5 2.23_4 1.92_5 1.50_5 . Fine grained, earthy; as powdery crusts; rarely as microscopic ring crystals. Greenish yellow, dull luster. $G = 3.89-4.02$. Insoluble in water and HNO_3 , decomposed by boiling concentrated HCl or H_2SO_4 . Uniaxial (+); $N_O = 1.714$, $N_E = 1.731$; sometimes anomalously biaxial (+). Osarizawaite is the aluminian analog of beaverite. From the *Osarizawa mine, Akita Pref., Japan*. Mt. Edgar Pastoral Station, ESE of Marble Bar, Pilbara district, and from Whim Creek, WA, Australia. RG *MJJ 3:181(1961); NJMM:39(1977), 401(1980); AM 65:1287(1980)*.

30.2.4.5 Minamiite $(\text{Na,K,Ca},\square)\text{Al}_3(\text{SO}_4)_2(\text{OH})_6$

Named in 1982 for A. E. Minami (1899-1977), Japanese geochemist. Alunite group. *R3m*. $a = 6.98$, $c = 33.490$, $D = 2.81$. *AM 67:114(1982)*. *34-143*: 4.90₉ 3.49₃ 2.98₅ 2.96₁₀ 2.22₄ 1.90₄ 1.75₃ 1.46₂. Crystals are hexagonal tablets up to 0.2 mm maximum. White to nearly colorless; vitreous luster, pearly on cleavage. Cleavage {0001}, perfect. $H = 3.5$. $G = 2.8$. Nonfluorescent. Uniaxial (+); $N_O = 1.580$, $N_E = 1.604$. Found in hydrothermally altered andesite at *Okumanza, Mt. Shirane, Gumma Pref., Japan*, intimately mixed with quartz and alunite. RG

30.2.4.6 Ammonioalunite $(\text{NH}_4)\text{Al}_3(\text{SO}_4)_2(\text{OH})_6$

Named in 1988 for the composition. Alunite group. *R3m*. $a = 7.013$, $c = 17.855$, $D = 2.58$. *AM 73:145(1988)*. *42-1334*: 5.02₃ 3.51₂ 3.02₁₀ 2.99₃ 1.977₂ 1.915₄ 1.752₂ 1.536₂. Massive, fine grained; microcrystals (<20 μm) euhedral with characteristic rhombohedral morphology. Grayish white, white streak, vitreous luster. $H = 2-3$. $G \approx 2.4$. Nonfluorescent. Nearly insoluble in cold dilute HCl, slowly soluble in cold dilute H_2SO_4 , decomposes in 1.0 N KOH. Uniaxial (+); $N_O = 1.590$, $N_E = 1.602$. "Ammonioalunite" refers to alunites $\text{NH}_4^+ > \text{Na}^+$ or K^+ . A complete solid-solution series exists between these three elements, but NH_4^+ -rich members are rare. The maximum observed NH_4^+ content was 0.92 mol %. Found in alteration zones, usually near acidic hot springs, with temperatures below 100°, and with abundant NH_4^+ and SO_4^{2-} but few K^+ ions. *The Geysers, Sonoma Co., CA*, with opal and quartz. Also from the Ivanhoe deposit, a fossil hot spring associated with Au-Hg mineralization, *Elko Co., NV*. RG

30.2.4.7 Walthierite $\text{Ba}_{0.5}\square_{0.5}\text{Al}_3(\text{SO}_4)_2(\text{OH})_6$

Named for Thomas Nash Walthier (1923-1990), U.S. economic geologist, St. Joseph Minerals Co., who played a significant role in exploration of El Indio deposit and the Tambo district. Alunite group. *HEX-R R3m*. $a = 6.992$, $c = 34.443$, $Z = 6$, $D = 3.02$. *AM 77:1275(1992)*. *PD*: 5.73₅ 4.97₅ 3.49₆ 2.98₁₀ 2.28₈ 1.909₇ 1.747₆ 1.503₄. Subhedral to anhedral crystals, 5 to 100 μm in length in individual grains and as aggregates. White to yellowish, white streak, vitreous luster. Cleavage {001}, perfect. Uniaxial (+); $N_O = 1.588$, $N_E = 1.604$; negative elongation, nonpleochroic. Found in the *Tambo mining district, Chile, in the Reina vein about 7 km SE of the El Indio gold mine*, where walthierite is intimately associated with alunite, barite, quartz, pyrite, and jarosite. RG

30.2.4.8 Huangite $\text{Ca}_{0.5}\square_{0.5}\text{Al}_3(\text{SO}_4)_2(\text{OH})_6$

Named in 1992 for Yunhui Huang (b.1926), Chinese mineralogist, who studied the minerals of the Hsianghualing Range, Hunan. Alunite group. *HEX-R R3m*. $a = 6.983$, $c = 33.517$, $Z = 6$, $D = 2.80$. *AM 77:1275(1992)*. *PD*: 4.91₈ 3.49₃ 2.97₁₀ 2.46₄ 2.23₅ 1.899₄ 1.745₄ 1.375₄. Huangite forms anhedral to subhedral crystals typically 3-10 μm in diameter. White to yellowish, white

streak, vitreous luster. Cleavage {001}, perfect. Uniaxial (+), negative elongation, nonpleochroic. Because of small grain size, N values could not be measured. Found at the *El Indio* Au–Ag–Cu deposit in the *Campana B vein*, *Coquimbo region*, *Chile*, associated with kaolinite and pyrite. Other associated minerals are enargite, minamiite, and woodhouseite. RG

30.2.5.1 Jarosite $KFe_3^{3+}(SO_4)_2(OH)_6$

30.2.5.2 Natrojarosite $NaFe_3^{3+}(SO_4)_2(OH)_6$

30.2.5.3 Hydronium jarosite $(H_3O)Fe_3^{3+}(SO_4)_2(OH)_6$

Jarosite named in 1852 for the locality, natrojarosite named in 1902 for the composition, hydronium jarosite named in 1960 for the composition. Alunite group. Synonym: hydronium jarosite was formerly called carphosiderite. **HEX-R** *R3m*. *a* = 7.304 (jarosite), 7.327 (natrojarosite), 7.17 (hydronium jarosite); *c* = 17.268 (jarosite), 16.634 (natrojarosite), 16.6 (hydronium jarosite); *Z* = 3; *D* = 3.25 (jarosite), 3.29 (natrojarosite), 3.01 (hydronium jarosite). *AM* 50:1595(1965). 22-827(syn)(jarosite): 5.93₅ 5.09₇ 3.65₄ 3.11₈ 3.08₁₀ 2.29₄ 1.98₅ 1.83₅. 36-425(syn)(natrojarosite): 5.95₂ 5.59₃ 5.06₈ 3.12₉ 3.07₁₀ 2.24₃ 1.98₃ 1.83₃. 36-427(syn)(hydronium jarosite): 5.93₂ 5.08₆ 3.66₂ 3.12₇ 3.08₁₀ 2.27₂ 1.98₁ 1.83₁. **Habit**: Minute crystals, usually pseudocubic {0113} or tabular {0001}. **Granular massive**; as crusts or coatings; fibrous, nodular, concretionary, pulverulent, or earthy. **Physical properties**: Ocherous, amber-yellow, or dark brown; pale yellow streak; sometimes glistening; subadamantine to vitreous luster, resinous on fractures. Cleavage {0001}, distinct; uneven to conchoidal fracture; brittle. $H = 2\frac{1}{2}$ – $3\frac{1}{2}$. $G = 2.9$ – 3.26 . Strongly pyroelectric. **Tests**: In CT affords acid water, insoluble in water, soluble in HCl. **Optics**: Uniaxial (–); jarosite: $N_O = 1.820$ (reddish brown), $N_E = 1.715$ (colorless); natrojarosite: $N_O = 1.832$ (pale yellow), $N_E = 1.750$ (colorless); hydronium jarosite: $N_O = 1.816$ (deep yellow), $N_E = 1.728$ (pale yellow). Usually anomalously biaxial with very small 2V. **Chemistry**: Al may substitute for Fe and a complete solid-solution series between alunite and jarosite probably exists, but intermediate members are rare. Na substitutes for K to at least Na/K = 1:2.4, but it is doubtful if a complete series exists between jarosite and natrojarosite. Similarly, there is at least partial substitution of K for Na in natrojarosite. Al also substitutes for Fe, and the material from Kopec, Czech Republic, has about equal Fe and Al, but the amount of Al entering jarosite is normally small. **Occurrence**: Jarosite is widespread as crusts and coatings in the oxidized zone of sulfide deposits and in cracks in the adjoining rocks. It is formed by reaction of H_2SO_4 derived from the oxidation of pyrite with the gangue and wall rock. It is usually accompanied by goethite (limonite), from which it may be difficult to distinguish. **Localities**: Jarosite is abundant in association with mineral deposits of the western United States and is probably present in nearly every major copper, lead, zinc, silver, gold, and iron mine, but is seldom seen in material that is noteworthy in any way. From the *Barranco Jaroso*, *Sierra Almagrera*, *Spain*; in Germany, France, Italy, Great Britain, and so on; in Chile at Chuquicamata

and elsewhere; abundant in Australia, and throughout the world. Natrojarosite is less abundant than jarosite but it is also widespread. At many places in the United States, including the eastern side of *Soda Springs Valley, Esmeralda Co., NV*; at Santa Eulalia, CHIH, Mexico; from Bohemia, Czech Republic, as an alteration of pyritic shales; in cracks in Eocene clay in Denmark. Hydronium jarosite was found at the *Upernivik district, Langø, Greenland* (carphosiderite); also at the *Staszic mine, Góry Świętokrzyskie (Holy Cross Mt.), Poland*. Probably many low-alkali jarosite minerals which have been investigated would prove to be hydronium jarosite if reanalyzed in the light of present knowledge. RG Jarosite: *DII:560, NJMM:406(1976), MJJ 8:419 (1977), AM 72:178(1987)*; natrojarosite: *DII:563, NJMM:406(1976)*; hydronium jarosite: *DII:566, AM 46:243(1961)*.

30.2.5.4 Ammoniojarosite $(\text{NH}_4)\text{Fe}_3^{3+}(\text{SO}_4)_2(\text{OH})_6$

Named in 1927 for the composition. Alunite group. *R3m. a = 7.327, c = 17.500, D = 3.112. JAC 6:490(1973). 26-1014(syn): 5.81₁ 5.12₆ 3.11₁₀ 2.91₁ 2.57₁ 2.32₂ 1.99₃ 1.83₃*. Small lumps and nodules composed of microscopic tabular grains. Pale ochreous yellow; dull, waxy to earthy luster. Uniaxial (-); $N_O = 1.800$, $N_E = 1.750$. Found with tschermigite, epsomite, and jarosite in a lignitic shale on the *western side of the Kaibab fault, UT*. In a similar environment in the Wasatch formation, Buffalo, WY. With budding-tonite at the Sulfur Bank mercury mine, Lake Co., CA. RG *DII:562, CM 20:91(1982)*.

30.2.5.5 Argentojarosite $\text{AgFe}_3^{3+}(\text{SO}_4)_2(\text{OH})_6$

Named in 1923 for the composition. Alunite group. *R3m. a = 7.347, c = 16.580, D = 3.66. AM 58:936(1973). 41-1398(syn): 5.96₅ 3.68₂ 3.06₁₀ 2.77₄ 2.53₃ 2.22₆ 1.838₃ 1.471₃*. Fine-grained masses and coatings consisting of microscopic platy hexagonal crystals. Yellow to brown, yellow streak, brilliant luster. Cleavage {0001}. $G = 3.62$. Uniaxial (-); $N_O = 1.889-1.890$ (yellow), $N_E = 1.789-1.790$ (pale yellow). *Tintic Standard mine, Tintic, UT*, with anglesite, barite, and quartz. RG *DII:565*

30.2.5.6 Plumbojarosite $\text{Pb}[\text{Fe}_3^{3+}(\text{SO}_4)_2(\text{OH})_6]_2$

Named in 1902 for the composition. Alunite group. *R3m. a = 7.305, c = 33.675, D = 3.71. CM 23:659(1985)*. The presence of the divalent cation Pb^{2+} results in a doubling of the *c* axis of the hexagonal cell when compared with jarosite, with half of the Pb^{2+} sites being vacant in an ordered arrangement. This also results in other minor compensating differences from the conventional jarosite structure. *39-1353: 3.06₁₀ 2.81₅ 2.53₃ 2.25₈ 1.975₃ 1.827₃ 1.532₃ 1.487₄*. Crusts or masses consisting of microscopic hexagonal plates; also pulverulent, earthy, or ochreous. Golden brown to dark brown, dull to glistening or silky luster. Cleavage {1014}, fair. Soft. $G = 3.665$. Uniaxial (-); $N_O = 1.875$, $N_E = 1.786$. O, yellow-brown; E, nearly colorless. Common in the oxidized zone of lead mines in arid regions. *Cook's Peak district,*

Luna Co., NM; Tintic district, UT; Tombstone, AZ; Boss mine, Clark Co., NV. Bolkardag, Anatolia, Turkey. Carguaicollo tin deposits, Potosi, Bolivia. RG DII:568, AM 51:443(1966), CM 23:47(1985).

30.2.5.7 Beaverite $\text{PbCu}(\text{Fe}^{3+},\text{Al})_2(\text{SO}_4)_2(\text{OH})_6$

Named in 1911 for the locality. Alunite group. $R\bar{3}m$. $a = 7.256$, $c = 34.30$, $D = 4.31$. *CM 23:49(1985)*. Structural considerations show that Pb^{2+} occupies the position of the alkali ion in the jarosite structure, whereas Cu^{2+} substitutes for one of the Fe^{3+} in the sheet units. The c dimension of the lattice is doubled as in plumbojarosite. *17-476: 5.85₁₀ 3.60₄ 3.31₄ 3.03₁₀ 2.52₃ 2.28₅ 1.95₃ 1.80₃*. Earthy and friable masses consisting of microscopic hexagonal plates. Canary yellow, dull luster. $G = 4.36$. Soluble in hot HCl, insoluble in water. Uniaxial (-); $N \approx 1.85$; strongly birefringent. Al may substitute for some of the Fe^{3+} , but pure ferrian beaverite has been found in Zaire. Occurs in the oxidized portion of Pb-Cu deposits in arid regions. *Horn Silver mine, Frisco, Beaver Co., UT. Kipushi, Shaba, Zaire. RG DII:568, AM 47:1085(1962)*.

30.2.5.8 Dorallcharite $\text{Tl}_6\text{K}_2\text{Fe}_3^{3+}(\text{SO}_4)_2(\text{OH})_6$

Named in 1994 for the locality and the golden yellow color (*doré* in French). Alunite group. $\text{HEX-R } R\bar{3}m$. $a = 7.330$, $c = 17.663$, $Z = 3$, $D = 3.85$. *EJM 6:255(1984)*. *PD: 5.95₉ 3.67₃ 3.11₁₀ 2.99₂ 2.58₂ 1.991₃ 1.833₂*. Fine-grained, earthy masses consisting of microscopic pseudocubic to pseudo-octahedral crystals (< 0.01 mm) which are probably rhombohedra. Golden yellow, yellow streak. Cleavage $\{0001\}$, distinct. Colorless in transmitted light. Uniaxial (-); $N_0 = 1.822$, $N_E = 1.768$; nonpleochroic. Found as an oxidation product at *Allchar, Macedonia*, a deposit known for its As-Tl mineralization and profusion of rare sulfosalts. *RG AM 80:184(1995)*.

30.2.6.1 Itoite $\text{Pb}_3[\text{GeO}_2(\text{OH})_2](\text{SO}_4)_2$

Named in 1960 for Tei-Ichi Ito (1898-1980), mineralogist and crystallographer, University of Tokyo, Japan. Barite group; see barite (28.3.1.1). $\text{ORTH } Pnma$. $a = 8.47$, $b = 5.38$, $c = 6.94$, $Z = 4$, $D = 6.67$. *12-641: 4.24₈ 3.79₆ 3.60₆ 3.33₉ 3.21₇ 3.00₉ 2.07₁₀ 2.03₈*. Silky fibers. White, silky luster. Soft. $N_{\text{Smean}} = 1.84-1.85$. *Tsumeb, Namibia*, as an alteration product of anglesite, associated with fleischerite, cerussite, and mimetite. *RG NJMM:132(1960), AM 45:1313(1960)*.

30.2.7.1 Piypite $\text{K}_2\text{Cu}_2(\text{SO}_4)_2\text{O} \cdot (\text{Na,Cu})\text{Cl}$

Named in 1984 for Boris I. Piyp (1906-1966), Russian geologist and director, Institute of Volcanology, Petropavlovsk-Kamchatskii. $\text{TET } I4mmm$. $a = 13.60$, $c = 4.98$, $Z = 2$, $D = 3.0$. *AM 75:1215(1990)*. *37-464: 9.63₁₀ 6.79₄ 4.31₂ 3.21₁ 3.04₇ 3.01₃ 2.67₂ 1.92₂*. Mosslike aggregates of acicular or columnar crystals. Emerald-green, dark green to black; yellowish-green streak; vitreous luster. Perfect cleavage parallel to elongation. $H = 2\frac{1}{2}$. $G = 3.10$. Unstable in

air, decomposed by water, soluble in acids. Uniaxial (+); $N_O = 1.583$, $N_E = 1.695$. O, pale green; E, deep green. Found in 500° fumarole incrustations of *Great Tolbachik fissure extrusion, Kamchatka, Russia*, associated with apthitalite, dolerophanite, euchlorine, chalcocyanite, and tenorite. RG *DANS 275:714(1984)*, *AM 70:437(1985)*.

30.2.8.1 Kamchatkite $KCu_3(SO_4)_2OCl$

Named in 1988 for the locality. ORTH $Pna2_1$. $a = 9.741$, $b = 12.858$, $c = 7.001$, $Z = 4$, $D = 3.58$. *41-1394*: 7.76₁₀ 3.50₇ 3.22₃ 2.90₂ 2.68₃ 2.59₄ 2.28₂ 2.27₂. Prismatic crystals, elongate [001] with rhombic cross section. Greenish to yellowish brown, yellow streak, vitreous luster. Cleavage {011}, {100}, perfect. $H = 3\frac{1}{2}$. $G = 3.48$. Soluble in water and in weak acid solutions, hygroscopic. Biaxial (+); $XYZ = cab$; $N_x = 1.695$, $N_y = 1.718$, $N_z = 1.759$; $2V = 75^\circ$; nonpleochroic; no dispersion; negative elongation. Found as a fumarolic product of the *Great Tolbachik fissure eruption, Kamchatka, Russia*, with ponomarevite, hematite, and klyuchevskite. RG *ZVMO 117:459(1988)*, *AM 75:1210(1990)*.

30.2.9.1 Cannonite $Bi_2O(OH)_2(SO_4)$

Named in 1992 for Benjamin Bartlett Cannon V (b.1950), U.S. amateur mineralogist, who first recognized the mineral and donated specimens for investigation. MON $P2_1/c$. $a = 7.700$, $b = 13.839$, $c = 5.686$, $\beta = 109.11^\circ$, $Z = 4$, $D = 6.515$. *MM 56:505(1992)*. *45-1439*: 3.64₆ 3.51₄ 3.47₆ 3.21₁₀ 2.92₇ 2.78₅ 1.984₉ 1.561₄. Intergrown crystalline aggregates of euhedral equant to prismatic (< 0.2 mm) crystals. Colorless, white streak, adamantine luster, transparent. No apparent cleavage, uneven to conchoidal fracture, brittle. $H = 4$. Nonfluorescent, biaxial. In RL, weakly bireflectant gray to darker gray, weakly anisotropic. Nonpleochroic, strong internal reflections. $N_{calc} = 1.91-1.99$ (589 nm). From the *Tunnel Extension mine, Ohio mining district, Marysvale, UT*, in cavities in quartz gangue, associated with cuprobismutite, bismuthinite, and covelline. RG *AM 78:845(1993)*.

30.3.1.1 Euchlorine $NaKCu_3O(SO_4)_3$

Named in 1869 from the Greek for *pale green*, in allusion to its color. MON $C2/c$. $a = 18.41$, $b = 9.43$, $c = 14.21$, $\beta = 113.7^\circ$, $Z = 8$, $D = 3.27$. *NJMM:541(1989)*. *45-1332*: 8.44₁₀ 6.61₂ 3.48₃ 3.24₃ 2.85₄ 2.84₄ 2.82₅ 2.54₅. Rectangular crystal tablets, also incrustations. Emerald-green. Cleavage in two directions. $G = 3.10-3.27$. Partly soluble in water. Biaxial (+); $N_x = 1.580$, $N_y = 1.605$, $N_z = 1.644$; $2V$ large. X, pale grass-green; Y, grass-green; Z, bright yellow-green. A fumarolic product from the 1868 eruption of *Vesuvius, Italy*, associated with dolerophanite, eriochalcite, and chalcocyanite. RG *DII:570*, *AM 75:1214(1990)*, *NJMA 161:241(1990)*.

30.3.2.1 Caracolite $\text{Na}_3\text{Pb}_2(\text{SO}_4)_3\text{Cl}$

Named in 1886 for the locality. HEX $P6_3/m$. $a = 9.81$, $c = 7.14$, $Z = 2$, $D = 4.50$. *NJMM:284(1967)*. 25-706: 8.45₃ 4.03₃ 3.55₆ 2.93₁₀ 2.88₅ 2.13₄ 1.91₆ 1.87₂. Incrustations and imperfect crystals; twinning polysynthetic, complex. Colorless, also grayish, or stained green; vitreous luster. No cleavage. $H = 4\frac{1}{2}$. $G \approx 5.1$. Partially decomposed in water, soluble in ammonium acetate solution or hot KOH solution. Biaxial (-); $N_x = 1.743$, $N_y = 1.754$, $N_z = 1.764$; 2V very large; $r > v$, strong. *Mina Beatriz, near Caracoles, Sierra Gorda, Atacama, Chile*, with bindheimite, anglesite, and galena. *RG DII:546, PM 54:34(1985)*.

30.3.3.1 Cesanite $\text{Ca}_{1+x}\text{Na}_{4-x}(\text{SO}_4)_3(\text{OH})_x$

Named in 1981 for the locality. Isotypic with apatite. HEX $P6_3/m$. $a = 9.446$, $c = 6.895$, $Z = 2$, $D = 2.831$. *MM 47:59(1983)*. 35-506: 4.72₅ 3.90₇ 3.45₉ 2.82₆ 2.73₁₀ 2.64₅ 2.27₅ 1.84₇. Medium to coarse granular; subhedral crystals prismatic, somewhat elongated parallel to c ; occasionally twinned. Colorless to white, greasy to silky luster. Cleavage {0001}, pronounced. $H = 2-3$. $G = 2.786$. Nearly insoluble in water, slightly soluble in hot or cold acids, completely soluble in aqua regia. Uniaxial (-); $N_O = 1.570$, $N_E = 1.564$. From the *Cesano I geothermal well*, on the edge of *Baccano Caldera, Cesano, Italy*, with gypsum, anhydrite, apthitalite, gorgeyite, and kalistrontite, in veins and cavity fillings. *RG MM 44:269(1981), AM 67:621(1982)*.

30.3.4.1 Fedotovite $\text{K}_2\text{Cu}_3(\text{SO}_4)_3\text{O}$

Named in 1988 for S. A. Fedotov (b.1931), Russian geologist. MON $P2_1/c$. $a = 19.06$, $b = 9.47$, $c = 14.18$, $\beta = 112.37^\circ$, $Z = 8$, $D = 3.17$. *AM 75:240(1990)*. 45-1405: 8.83₁₀ 6.59₁ 6.54₁ 4.54₁ 4.41₁ 4.21₁ 2.94₂ 2.84₁. Crystals flattened {100}, somewhat irregular; micaceous; as crusts. Emerald- to grass-green, light grass-green streak, silky to vitreous luster. Cleavage {100}, perfect. $H = 2\frac{1}{2}$. $G = 3.205$. Biaxial (+); $Z = b$; $Y \wedge c \approx 0^\circ$; $N_x = 1.577$, $N_y = 1.594$, $N_z = 1.633$; 2V = 68° ; absorption $Z > Y$. X, greenish blue; Y, Z, yellow-green. From *Great Tolbachik fissure eruption, Kamchatka, Russia*, with dolerophanite, tolbachite, chalcocyanite, piypite, melanothallite, and tenorite. *RG DANS 299:961(1988), MM 52:724(1988)*.

30.4.1.1 Klyuchevskite $\text{K}_3\text{Cu}_3\text{Fe}^{3+}\text{O}_2(\text{SO}_4)_4$

Named in 1989 for the locality. MON $I2/m$, Im , or $I2$. $a = 18.41$, $b = 4.94$, $c = 18.64$, $\beta = 101.50^\circ$, $Z = 4$, $D = 3.02$. *ZVMO 118:65(1989)*. 41-1463: 9.17₉ 9.03₁₀ 7.20₄ 4.50₃ 3.76₆ 3.68₂ 3.45₂ 3.41₃. Unoriented aggregates of acicular crystals, elongated [010]. Dark green to olive-green, light green streak, semi-metallic luster. Cleavage { $h0l$ }, perfect. $G = 3.00-3.15$. Soluble in water and weak acids. Biaxial (+); $Y = b$; $N_x = 1.549$, $N_y = 1.550$, $N_z = 1.680$; 2V = 11° . X, olive-green; Y, green; Z, dark olive-green. From fumaroles at the *Great Tolbachik fissure eruption, Kamchatka, Russia*, with kamchatkite, ponomarevite, and hematite. *RG AM 75:1210(1990)*.

Hydrated Sulfates Containing Hydroxyl or Halogen

31.1.1.1 Connellite $\text{Cu}_{19}\text{Cl}_4(\text{SO}_4)(\text{OH})_{32} \cdot 3\text{H}_2\text{O}$

Named in 1850 for Arthur Connell (1794–1863), Scottish chemist. *HEX P62c*. $a = 15.78$, $c = 9.10$, $Z = 2$, $D = 3.46$. Structure: *AM 57:426(1972)*. 35-538: 13.7₈ 7.89₁₀ 5.46₂ 5.17₃ 3.22₂ 2.73₄ 2.49₃ 2.28₄. Crystals acicular [0001], striated [0001], in radiating groups. Azure blue, pale greenish-blue streak, vitreous luster. $H = 3$. $G = 3.36$. Insoluble in water; soluble in acids and in NH_4OH ; easily fusible; in CT, affords acid water. Uniaxial (+); $N_O = 1.724$ – 1.738 , $N_E = 1.746$ – 1.758 ; nonpleochroic. (NO_3) may substitute for up to 20% of the $(\text{SO}_4)^{2-}$ in the structure. Connellite is isostructural with buttgembachite $\text{Cu}_{19}\text{Cl}_4(\text{NO}_3)(\text{OH})_{32} \cdot 2\text{H}_2\text{O}$. *MM 39:266(1973)*. Bisbee, AZ, at Copper Queen(!) and several other mines, associated with cuprite, malachite, azurite, and spangolite. Grand Central mine, Tintic, UT. *Wheal Gorland, Gwennap, Cornwall, England*(!), in blue masses of felted crystals; Arenas, Sardinia, Italy; Mouzaïa, Algeria; Likasi, Shaba, Zaire(!). *RG DII:572; MM 29:280(1950), 54:425(1990)*.

31.1.2.1 Shigaite $\text{Mn}_7\text{Al}_4(\text{SO}_4)_2(\text{OH})_{22} \cdot 8\text{H}_2\text{O}$

Named in 1985 for the locality. *HEX-R R3* or *R3*. $a = 9.51$, $c = 32.83$, $Z = 3$, $D = 2.35$. *AM 71:1546(1986)*. Structurally related to mooreite, lawsonbauerite, and torreyite. 38-428: 10.9₁₀ 5.47₉ 4.36₄ 3.66₈ 2.66₄ 2.46₉ 2.20₆ 1.94₆. Small tabular hexagonal crystals. Light yellow, very light yellow to white streak. Cleavage {0001}, perfect; moderately flexible. $H = 2$. $G = 2.32$. Nonfluorescent. Uniaxial (-); $N_O = 1.546$; absorption $O > E$. O , medium yellow; E , very light yellow. *Loi mine, Shiga Pref., Japan*, in manganosite–rhodochrosite–sonolite ore, in veinlets with pyrochroite, jacobsite, hausmannite, and galaxite. *RG NJMM:453(1985)*.

31.1.3.1 Mooreite $(\text{Mg,Zn,Mn})_{15}(\text{SO}_4)_2(\text{OH})_{26} \cdot 8\text{H}_2\text{O}$

Named in 1929 for Gideon E. Moore (1842–1895), U.S. chemist, an early investigator of the ores of Franklin and Sterling Hill, NJ. *MON P2₁/a*. $a = 11.147$, $b = 20.350$, $c = 8.202$, $\beta = 92.7^\circ$, $Z = 2$, $D = 2.54$. Structure: *AC(B) 36:1304(1980)*. Structurally related to shigaite, lawsonbauerite, and torreyite. 43-696: 10.1₈ 5.08₁₀ 3.45₅ 2.67₄ 2.38₈ 1.732₅ 1.619₆ 1.546₃. Crystals tabular to platy {010}. Colorless, vitreous luster. Cleavage {010}, perfect.

H = 3. G = 2.47. Biaxial (-); X = b; Z \wedge c = 44°; N_x = 1.533, N_y = 1.545, N_z = 1.547; 2V = 50°; r > v, perceptible. *Sterling Hill mine, Ogdensburg, NJ*, with rhodochrosite, torreyite, zincite, fluorborite, and pyrochroite in veinlets cutting zinc ore. RG *DII:574; AM 54:973(1969), 68:474(1983)*.

31.1.4.1 Torreyite (Mg,Mn)₉Zn₄(SO₄)₂(OH)₂₂ · 8H₂O

Named in 1949 from John Torrey (1796–1873), American naturalist, who early studied the Franklin minerals. MON *P2₁/c*. a = 16.486, b = 9.292, c = 10.619, β = 95.42°, Z = 2, D = 2.65. *AM 64:949(1979), 33-874: 10.2₁₀ 6.10₃ 5.16₅ 4.52₂ 3.84₄ 3.47₂ 2.73₄ 1.57₅*. Massive, granular. White to colorless, dull to vitreous luster. Cleavage {010}, good; not brittle. H = 3. G = 2.665. Soluble in acids. Biaxial (-); N_x = 1.570, N_y = 1.584, N_z = 1.585; 2V = 40°. *Sterling Hill mine, Ogdensburg, NJ*, with altered pyrochroite, mooreite, and fluorborite, in veinlets cutting willemite–franklinite ore. RG *DII:575; AM 34:589(1949), 67:1029(1982)*.

31.1.4.2 Lawsonbauerite (Mg,Mn)₅Zn₄(SO₄)₂(OH)₂₂ · 8H₂O

Named in 1979 for Lawson H. Bauer (1889–1954), American mineral chemist at Franklin, NJ. MON *P2₁/c*. a = 10.50, b = 9.64, c = 16.41, β = 95.22°, Z = 2, D = 2.92. *AM 67:1029(1982), 33-873: 10.5₁₀ 6.24₃ 5.24₆ 4.77₂ 3.90₅ 3.33₃ 2.77₄ 1.587₅*. Crystals minute, prismatic, bladed, flattened {001}, and elongate [010]. Colorless to white, dull luster. No cleavage, even fracture, brittle. H = 4½. G = 2.87. Nonfluorescent. Biaxial (-); Y parallel to b; Z \wedge c = 7°; N_x = 1.590, N_y = 1.608, N_z = 1.611; 2V = 42°; r > v, strong. *Sterling Hill mine, Ogdensburg, NJ*, intimately associated with sussexite and calcite, also with zincite and franklinite. RG *AM 64:949(1979), 67:1029(1982)*.

31.1.5.1 Spangolite Cu₆Al(SO₄)Cl(OH)₁₂ · 3H₂O

Named in 1890 for Norman Spang (1842–1922), U.S. mineral collector, who supplied the original specimens for study. HEX-R *C3c*. a = 8.245, c = 14.34, Z = 2, D = 3.14. *AM 34:181(1949)*. Structure: *NJMM: 349(1992), 5-142: 7.10₁₀ 3.59₈ 2.66₄ 2.54₇ 2.36₅ 2.17₄ 1.98₆ 1.80₇*. Hemimorphic crystals; however, often holohedral in aspect; commonly tabular {0001}, less often short prismatic. Twinning rare, on {0001}, the acute antilogous poles of two individuals joined together. Dark green, bluish green, emerald-green; pale green streak; vitreous luster. Cleavage {0001}, perfect; also on {1011}, distinct; conchoidal fracture; brittle. H = 2 on {0001}, H = 3 on inclined faces. G = 3.14. Pyroelectric. Uniaxial (-); N_O = 1.681–1.686, N_E = 1.627–1.638. O, weak, green; E, bluish green. In *AZ* at *Tombstone*, also at the Copper Queen mine, Bisbee(I), in crystals up to 3 cm, and at the Metcalf mine, Clifton–Morenci. Majuba Hill, NV; Grand Central mine, Tintic, UT; Mex–Tex mine, Bingham, NM(*). Wheal Gorland, Gwennap, Cornwall, England(I). Arenas, Sardinia, Italy. St. Rome-de-Tarn, Aveyron, and Vezzani, Corsica, France. RG *DII:576*.

31.1.6.1 Schulenbergite $(\text{Cu,Zn})_7(\text{SO}_4,\text{CO}_3)_2(\text{OH})_{10} \cdot 3\text{H}_2\text{O}$

Named in 1984 for the locality. *HEX-R* $P3$ or $P\bar{3}$. $a = 8.249$, $c = 7.183$, $Z = 1$, $D = 3.38$. $38-349$: 7.19_{10} 3.58_4 3.21_3 2.70_8 2.53_8 2.16_3 1.791_3 1.559_3 . Crystals thin tabular $\{0001\}$, microscopic, often in rosettes. Light blue-green, pale blue-green streak, pearly luster. $H = 2$. $G = 3.28$. Nonfluorescent. Uniaxial (-); $N_O = 1.640$, $N_E = 1.623$; faintly dichroic. From the dumps of the *Glücksrad mine*, near *Oberschulenberg*, *Harz*, *Germany*. *RG NJMM:17(1984)*, *AM 70:438(1985)*.

31.2.1.1 Cyanotrichite $\text{Cu}_4\text{Al}_2\text{SO}_4(\text{OH})_{12} \cdot 2\text{H}_2\text{O}$

Named in 1839 from the Greek for *blue* and *hair*. *ORTH* Space group unknown. $a = 10.16$, $b = 12.61$, $c = 2.90$, $Z = 1$, $D = 2.88$. $11-131$: 10.2_{10} 5.47_5 5.26_8 3.88_9 3.38_4 3.04_4 2.39_4 2.03_4 . Plushlike coatings of minute, acicular, radial-fibrous crystals. Bright azure blue, pale blue streak, silky luster. $G = 2.74-2.95$. Soluble in acids. Biaxial (+); X perpendicular to laths; Z parallel to elongation; $N_x = 1.588$ (nearly colorless), $N_y = 1.617$, $N_z = 1.655$; $2V = 82^\circ$; $r < v$, strong. Y , pale blue; Z , bright blue. *Grandview mine*, *Grand Canyon*, *Cococino Co.*, *AZ*; *American Eagle mine*, *Tintic district*, *UT*; *Cap Garonne*, *Var*, *France*, with *chalcophyllite* and *parnauite*; *Leadhills*, *Scotland*; *Laurium*, *Greece*; *Moldova*, *Banat*, *Romania*. *Mednorudyansk*, near *Nizhnii Tagil*, *Russia*. *RG DII:578*.

31.2.2.1 Woodwardite $\text{Cu}_4\text{Al}_2(\text{SO}_4)(\text{OH})_{12} \cdot z-4\text{H}_2\text{O}$

Named in 1866 for *Samuel P. Woodward* (1821-1865), English naturalist and geologist. An inadequately characterized mineral. *HEX-R* Space group unknown. $a = 3.00$, $c = 27.3$. $39-726$: 10.9_{10} 5.46_6 3.66_5 2.61_4 2.45_2 1.535_1 . Minute botryoidal concretions with a fibrous structure. Greenish blue to turquoise-blue. $G = 2.38$. Biaxial (+); $N_x = 1.552$, $N_y = 1.555$, $N_z = 1.565$. *Cornwall*, *England*. *Klausen*, *Trentino*, *Italy*. *Mine du Chateau*, *Urbeis*, *Bas Rhin*, *France*, as a postmine product. *RG DII:580*, *MM 40:644(1976)*, *AM 62:599(1977)*.

31.2.3.1 Zincaluminite $\text{Zn}_6\text{Al}_6(\text{SO}_4)_2(\text{OH})_{26} \cdot 5\text{H}_2\text{O} (?)$

Named in 1881 for the composition. A questionable, inadequately characterized mineral. *ORTH* or *HEX* Space group unknown. $41-1361$: 11.1_5 7.07_4 4.83_{10} 4.35_3 3.55_2 2.71_2 2.45_3 2.40_3 . Crusts of minute crystals with a hexagonal outline. White to pale blue. $H = 2\frac{1}{2}-3$. $G = 2.26$. Soluble in acids and alkalis; in *CT*, affords slightly alkaline water. Uniaxial (-); $N_O = 1.534$, $N_E = 1.514$. *Laurium*, *Greece*, with *smithsonite*, *serpierite*, and other secondary minerals. *RG DII:579*.

31.2.4.1 Guarinoite $(\text{Zn,Co,Ni})_6(\text{SO}_4)(\text{OH,Cl})_{10} \cdot 5\text{H}_2\text{O}$

Named in 1993 for *Andre Guarino*, French mineral collector. *HEX* $P6_3$, $P6_3/m$, or $P6_322$. $a = 8.344$, $c = 21.59$, $Z = 3$, $D = 2.77$. *AS 46:37(1993)*. *PD: 10.8_{10}*

3.30₉ 2.73₆ 2.56₅ 2.35₄ 1.575₃. Rounded aggregates of thin hexagonal crystals to 0.04 mm × 0.2 mm. Bright to deep pink, light pink streak, vitreous to pearly luster, transparent. Cleavage {001}, perfect; irregular fracture. Soft. Soluble in HCl. Uniaxial (-); $N_O = 1.584$, $N_E = 1.544$; strongly pleochroic. Non-fluorescent. O, pink; E, light pink. From the *Cap Garonne mine, Var, France*, as a secondary mineral in the zone of oxidation, with anglesite, antlerite, cerussite, and so on. RG *AM 78:1314(1993)*.

31.2.5.1 Therese magnanite $(Co,Zn,Ni)_6(SO_4)(OH)_{10} \cdot 8H_2O$

Named in 1993 for Therese Magnan for her contributions to knowledge about the Cap Garonne mine. HEX $P6_3$. $a = 8.363$, $c = 26.18$, $Z = 3$, $D = 2.48$. *AS46:37(1993)*. PD: 13.1₁₀ 3.52₃ 2.99₃ 2.68₄ 2.53₉. Thin platy crystals, tabular {0001}, making up radiating spherules to 0.2 mm. Pink to light pink, streak light pink, pearly luster, transparent. Cleavage {0001}, perfect; irregular fracture. Soft. $G = 2.52$. Soluble in HCl. Nonfluorescent. Uniaxial (-); $N_O = 1.568$, $N_E = 1.542$. From the *Cap Garonne mine, Var, France*, as secondary, alteration minerals on quartz, associated with anglesite, antlerite, ktenasite, cerussite, brochantite, covellite, tennantite, and gersdorffite. RG *AM 78:1314(1993)*.

31.2.6.1 Uranopilite $(UO_2)_6(SO_4)(OH)_{10} \cdot 12H_2O$

Named in 1882 for uranium and the Greek for *felt*, alluding to the composition and habit. Probably MON Space group unknown. $c = 8.91$. *8-443*: 9.18₈ 7.12₁₀ 5.51₄ 4.28₈ 3.65₅ 3.31₄ 2.99₃ 2.90₃. Microscopic needles and laths forming velvety incrustations and globular or reniform masses. Lemon to golden yellow, silky luster. Cleavage {010}, perfect. $G = 3.7-4.0$. Fluoresces bright greenish yellow in LWUV or SWUV. Insoluble in water, soluble in dilute acids. Biaxial (+); $X = b$, $Y \wedge c = 18^\circ$; $N_x = 1.623$, $N_y = 1.625$, $N_z = 1.634$ (Na); 2V large; $r < v$, extreme; also, $r > v$. A secondary mineral found on altering uraninite. Goldfields, SK, Canada; also Eldorado mine, Great Bear Lake, and Hottah Lake, NWT, Johannegeorgenstadt, Saxony, Germany. *Jachymov, Bohemia, Czech Republic*; *Urgeriça, Portugal*; *Shinkolobwe, Shaba, Zaire*. RG *AM 37:394(1952)*, *37:950(1952)*; *USGSB 1064:135(1958)*.

31.2.7.1 Meta-Uranopilite $(UO_2)_6(SO_4)(OH)_{10} \cdot 5H_2O$

Named in 1952 as a lower hydrate than uranopilite. Probably ORTH Space group unknown. *18-309*: 8.65₁₀ 5.53₈ 5.08₄ 4.36₄ 3.67₄ 3.57₁₀ 3.31₉ 3.00₅. Minute needles and laths. Yellow, grayish, brown, or green; fluoresces yellow-green. Biaxial (-); $XYZ = bca$; $N_x = 1.72$, $N_y = 1.76$, $N_z = 1.76$. *Jachymov, Bohemia, Czech Republic*, and probably at other localities where uranopilite has been found. RG *DII:582*, *AM 37:950(1952)*, *USGSB 1064:140(1958)*.

31.3.1.1 Chalcoalumite $CuAl_4(SO_4)(OH)_{12} \cdot 3H_2O$

Named in 1925 in allusion to the composition. MON $P2_1$. $a = 17.090$, $b = 8.915$, $c = 10.221$, $\beta = 95.88^\circ$, $Z = 4$, $D = 2.25$. *MR 2:126(1971)*. *25-1430*: 8.50₁₀

7.90₂ 6.71₁ 5.10₁ 4.79₂ 4.25₉ 4.18₃ 2.52₁. Botryoidal crusts of matted fibers or laths; also microcrystals flattened {100}; as small spherules. Twinning common, on {100} and {010}. Turquoise green to pale blue, white streak, dull to vitreous luster. Cleavage {100}, perfect; somewhat sectile. $H = 2\frac{1}{2}$. $G = 2.29$. Slowly soluble in dilute acids, difficultly fusible. Biaxial (+); $N_x = 1.523$, $N_y = 1.525$, $N_z = 1.532$; 2V small; $r > v$, strong. Alters to cuprian gibbsite. *Holbrook shaft, Copper Queen mine, Bisbee, AZ(1)*, as thin crusts and as platy crystals in vugs, associated with goethite, cuprite, azurite, and malachite; also in the Lavender Pit(1). RG *DII:580*.

31.3.1.2 Nickelalumite $(\text{Ni,Cu})\text{Al}_4[(\text{SO}_4)(\text{NO}_3)](\text{OH})_{12} \cdot 3\text{H}_2\text{O}$

Named in 1980 in allusion to the composition. MON *P2*₁. $a = 10.175$, $b = 8.860$, $c = 17.174$, $\beta = 95.95^\circ$, $Z = 4$, $D = 2.28$. *AM 67:416(1982)*. 35-698: 8.54₁₀ 7.88₂ 4.78₁ 4.58₁ 4.27₆ 2.51₂ 2.29₂ 2.00₂. Coatings and crusts, also nodules. Pale blue. $G = 2.24$. Biaxial; $X \wedge c = 30^\circ$; $N_x = 1.532$, $N_z = 1.543$. *Mbobo Mkulu cave, eastern Transvaal, South Africa*, as crusts on gypsum crystals. RG

31.3.2.1 Wermlandite $\text{CaMg}_7(\text{Al,Fe})_2(\text{SO}_4)_2(\text{OH})_{18} \cdot 12\text{H}_2\text{O}$

Named in 1971 for the locality. HEX-R *Pc*1. $a = 9.303$, $c = 22.57$, $Z = 2$, $D = 1.96$. *ZK 168:133(1984)*. 25-153: 11.2₇ 7.98₁₀ 5.62₄ 4.63₅ 3.89₄ 2.61₄ 1.54₄ 1.51₃. Thin hexagonal plates {0001}. Pale greenish gray. Cleavage {0001}, perfect; folia are flexible as in mica, but inelastic. $H = 1\frac{1}{2}$. $G = 1.932$. Uniaxial (-); $N_O = 1.493$, $N_E = 1.482$; sometimes anomalously biaxial with small 2V. *Långban, Värmland, Sweden*, associated with calcite and magnetite. RG *LIT 4:213(1971)*, *AM 57:327(1972)*.

31.4.1.1 Posnjakite $\text{Cu}_4(\text{SO}_4)(\text{OH})_6 \cdot 2\text{H}_2\text{O}$

Named in 1967 for E. W. Posnjak (1888–1949), U.S. geochemist, investigator of the system $\text{CuO} \cdot \text{SO}_3 \cdot \text{H}_2\text{O}$. MON *Pc*. $a = 10.578$, $b = 6.345$, $c = 7.863$, $\beta = 117.98^\circ$, $Z = 2$, $D = 3.351$. *ZK 149:249(1979)*. 43-670: 7.00₁₀ 3.50₇ 3.35₅ 2.70₈ 2.43₉ 2.34₆ 1.873₆ 1.550₈. Grains, small tabular crystals, and fissure fillings. Blue to dark blue, bluish streak, vitreous luster. $H = 2-3$. $G = 3.32$. Insoluble in NH_4OH , in CT gives off water and melts to a dark enamel. Biaxial (-); $N_x = 1.625$, $N_y = 1.680$, $N_z = 1.706$; 2V = 57°; absorption $Y \gg Z > X$. X, bluish to colorless; Y, blue to dark blue; Z, greenish blue. Murray mine, Georgetown, and the Yellow Pine mine, Crisman, CO. Drake-walls mine, Gunnislake, Cornwall, England, in rich blue incrustations; also the Fowley Consols mine. La Petite Verriere, Les Ardillats, Rhone, France. From quartz-tungsten veins of the *Nura-Tadinsk, central Kazakhstan*, with aurichalcite and other minerals associated with oxidizing chalcopyrite. Piesky, near Banská Bystrica, Slovakia. RG *AM 52:1582(1967)*, *68:1251(1983)*; *NJMM: 16(1982)*.

31.4.2.1 Wroewolfeite $\text{Cu}_4(\text{SO}_4)(\text{OH})_6 \cdot 2\text{H}_2\text{O}$

Named in 1975 for Caleb Wroe Wolfe (1908–1980), U.S. crystallographer, Boston University. Dimorphous with langite (31.4.3.1). *MON Pc*. $a = 6.045$, $b = 5.646$, $c = 14.337$, $\beta = 93.38^\circ$, $Z = 2$, $D = 3.32$. *AM 70:1050(1985)*. $27\text{-}1133$: 7.15_{10} 3.58_7 2.77_2 2.63_4 2.43_2 2.38_2 2.28_2 2.00_3 . Crusts of small crystals, twinning on {001}. Deep greenish blue, light blue streak, vitreous luster. Cleavage {010}, {100}, {001}, perfect. $H = 2\frac{1}{2}$. $G = 3.27$. Biaxial (-); $N_x = 1.637$, $N_y = 1.682$, $N_z = 1.694$; $2V = 53^\circ$; absorption $Y > Z > X$. X, light blue; Y, deep greenish blue; Z, greenish blue. From the oxidation zone of the old lead mine, *Loudville, MA*, with chalcocite, covellite, and langite. Ladywell mine, Shelve, Shropshire, England; Nant-y-Cagal mine, Ceulany-waesmawr, Cardigan, Wales; West Blackcraig mine, Kirkcudbright, Scotland. *RG MM 40:1(1975)*, *AM 61:179(1976)*.

31.4.3.1 Langite $\text{Cu}_4(\text{SO}_4)(\text{OH})_6 \cdot 2\text{H}_2\text{O}$

Named in 1864 for Victor von Lang (1838–1921), Austrian physical crystallographer, University of Vienna. Dimorphous with wroewolfeite (31.4.2.1). *MON Pc*. $a = 7.118$, $b = 6.034$, $c = 11.209$, $\beta = 90.01^\circ$, $Z = 2$, $D = 3.37$. *BM 107:641(1984)*. Structure: *AC(C) 40:1309(1984)*. $43\text{-}671$: 7.07_{10} 3.57_9 2.65_7 2.62_7 2.50_8 2.21_6 2.13_9 1.773_7 . Crystals small equant or elongated [100]; as scales, crusts; also earthy. Twinning common on {110}, at times multiple, resembling aragonite. Fine blue to greenish blue, vitreous to silky luster. Cleavage {001} and {010}. $H = 2\frac{1}{2}\text{-}3$. $G = 3.28$. Insoluble in water, easily soluble in dilute acids or NH_4OH . Biaxial (-); $XYZ = cba$; $N_x = 1.641$, $N_y = 1.690$, $N_z = 1.712$; $2V = 66^\circ$. X, light yellowish green; Y, blue-green; Z, sky blue. Caroline tunnel of the Ward mine, Ely, NV. Eschach, Styria, Austria. Viel Salm, Belgium. *St. Blazey and St. Just, Cornwall*; also Copper Hill mine, Redruth, and East Pool and Dolcoath, Camborne, Cornwall, *England*. Nice rippled crusts at the Allegmenes mine, Castlehawn, Beachhaven Co., Cork Ireland(*). *St.-Rome-de-Tarn, Aveyron, France*(*), crystals to 5 mm on barite. Mollau, Haut Rhin, France. *RG DII:583*, *AM 49:1143(1964)*, *NJMM:16(1982)*, *BM 81:257(1975)*.

31.4.4.1 Felsöbanyaite $\text{Al}_4(\text{SO}_4)(\text{OH})_{10} \cdot 5\text{H}_2\text{O}$

Named in 1853 for the locality. *HEX* Space group unknown. $a = 22.556$, $c = 19.032$, $Z = 24$, $D = 2.21$. $25\text{-}1491$: 5.96_3 4.79_{10} 4.64_{10} 3.67_4 2.71_4 2.45_4 2.27_5 2.19_3 . Globular, radial aggregates of lamellar crystals. Colorless, vitreous luster. Cleavage {001}, perfect; also {100}, {010}. $H = 1\frac{1}{2}$. $G = 2.33$. Uniaxial (+); $N_O = 1.516$, $N_E = 1.533$. *Baia Sprie, Maramures, Romania* (formerly known as *Felsobanya*, in *Hungary*). *RG DII:585*, *MM 29:8(1950)*, *AM 50:812(1965)*.

31.4.5.1 Basaluminite $\text{Al}_4(\text{SO}_4)(\text{OH})_{10} \cdot 4\text{H}_2\text{O}$

Named in 1948 from the composition (a basic sulfate of aluminum). *MON* Space group unknown. $a = 14.857$, $b = 10.011$, $c = 11.086$, $\beta = 122.28^\circ$,

$Z = 4$, $D = 2.211$. *MM* 43:931(1980). 42-556: 9.39₁₀ 4.73₆ 3.69₅ 2.46₄ 2.28₄ 2.20₄ 1.887₄ 1.438₆. Compact masses. White, dull luster. Conchoidal fracture, not plastic. $G = 2.10$. In CT yields water. $N \approx 1.520$; $N_{\text{calc}} = 1.539$ (Na); negative elongation. Basaluminite is probably always formed by the dehydration of hydrobasaluminite under weathering conditions. Above the Fleming coal in the Cabaniss formation, Crawford Co., KS; also from IN and TN. *Irchester, Northamptonshire, and Clifton Hill, Brighton, Sussex, England*; also in the Oxford clay, Chickerell, Dorset. Epernay, Marne, France. *RG DII:586, AM 53:722(1968), CM 9:644(1969), MM 37:29(1969)*.

31.4.6.1 Hydrobasaluminite $\text{Al}_4(\text{SO}_4)(\text{OH})_{10} \cdot 15\text{H}_2\text{O}$

Named in 1948 for the composition and relation to basaluminite. Probably the same as "winebergite" (discredited). *MON* Space group unknown. $a = 14.911$, $b = 9.993$, $c = 13.640$, $\beta = 112.24^\circ$, $Z = 4$, $D = 2.277$. 8-76: 12.6₁₀ 6.18₇ 5.29₇ 4.70₇ 4.23₆ 4.00₆ 3.73₇ 3.07₇. Claylike. White to light yellowish brown, dull luster. Plastic. Dehydrates rapidly in air to form basaluminite. Since hydrobasaluminite is apparently always the precursor of basaluminite, the localities for hydrobasaluminite are the same as those given for basaluminite. It is a widespread mineral but difficult to recognize because of its claylike properties. KS, IN, TN; *Irchester*, and elsewhere in *England*. *RG AM 33:747(1948), 53:773(1968), 54:1363(1969); MM 43:931(1980)*.

31.4.7.1 Namuwite $(\text{Zn,Cu})_4(\text{SO}_4)(\text{OH})_6 \cdot 4\text{H}_2\text{O}$

Named in 1982 for the country of origin, and the National Museum of Wales. *HEX* Space group unknown. $a = 8.29$, $c = 10.50$, $Z = 2$, $D = 2.81$. 35-528: 10.6₁₀ 5.31₂ 4.15₃ 2.71₄ 2.63₄ 2.41₂ 1.57₃ 1.55₂. Fine grained encrustations consisting of minute hexagonal plates. Pale sea-green, pale green streak, pearly luster. Cleavage {0001}, perfect. $H = 2$. $G = 2.77$. Uniaxial; $N = 1.577$; extremely low birefringence. *Averlyn lead mine, Llanrwst mining district, northern Wales*, encrusting hydrozincite. *RG MM 46:51(1982), AM 68:281(1983)*.

31.4.8.1 Glaucocerinite $(\text{Zn,Cu})_5\text{Al}_3(\text{SO}_4)_1\text{S}(\text{OH})_{16} \cdot 9\text{H}_2\text{O}$

Named in 1932 from the Greek for *blue* and *waxlike*. *HEX-R* Space group unknown. $a = 3.057$, $c = 32.52$ (pseudocell), $D = 2.33$. *MM 49:583(1985)*. 39-338: 10.9₁₀ 5.45₉ 3.63₈ 2.62₆ 2.46₆ 2.23₅ 1.98₅ 1.54₄. Warty masses with radial-fibrous structure. Sky blue to turquoise-blue, waxy luster. $H = 1$. $G = 2.40$. Uniaxial; $N_{\text{mean}} = 1.542$; sometimes anomalously biaxial; $N_x = 1.540$, $N_y = 1.554$, $N_z = 1.562$; $2V = 60^\circ$; positive elongation; parallel to extinction. *Laurium, Greece*, with smithsonite, adamite, gypsum, and malachite. *RG DII:574, AM 72:1028(1987)*.

31.4.9.1 Ramsbeckite $(\text{Cu,Zn})_{15}(\text{SO}_4)_4(\text{OH})_{22} \cdot 6\text{H}_2\text{O}$

Named in 1985 for the locality. *MON* $P2_1/c$. $a = 16.088$, $b = 15.576$, $c = 7.102$, $\beta = 90.22^\circ$, $Z = 2$, $D = 3.41$. *NJMM:38(1988)*. 39-365: 7.09₁₀ 3.55₃ 2.69₃ 2.68₂ 2.52₈ 2.51₂ 2.15₂ 1.776₂. Equant to tabular, rhomb-shaped crystals. Green,

light green streak, vitreous luster. Cleavage {001}, perfect; conchoidal fracture. $H = 3.5$. $G = 3.39$. Nonfluorescent. Soluble in dilute acids. Biaxial (-); $Y = b$; $X \wedge c = 5^\circ$, $Z \wedge a = 5^\circ$; $N_x = 1.635$, $N_y = 1.675$, $N_z = 1.680$; $2V = 37^\circ$; $r > v$. X, Y, Z, bright blue. Ecton mine, near Audubon, Montgomery Co., PA, associated with anglesite, linarite, and posnjakite. *Bastenberg mine, near Ramsbeck, Germany*, and elsewhere in old German mine dumps. RG *NJMM:550(1985)*, *AM 72:225(1987)*, *MR 18:131(1987)*.

31.5.1.1 Vonbezingite $\text{Ca}_6\text{Cu}_3(\text{SO}_4)_3(\text{OH})_{12} \cdot 2\text{H}_2\text{O}$

Named for Karl Ludwig ("Ludi") von Bezing (b.1945), Austrian-South African radiologist and amateur mineralogist. MON $P2_1/c$. $a = 15.122$, $b = 14.358$, $c = 22.063$, $\beta = 108.68^\circ$, $Z = 8$, $D = 2.81$. *AM 77:1292(1992)*. PD: 3.39_{10} 3.37_6 3.20_5 3.19_7 3.12_9 3.10_6 2.769_4 2.763_4 . Euhedral crystals, elongated [001] with maximum length 10 mm. Dark blue, similar to azurite; light blue streak; vitreous luster on fracture surfaces, subvitreous on crystal faces. Macroscopically the mineral is almost indistinguishable from azurite, from which it could be distinguished mainly by the dull, earthy luster of its crystal faces. No cleavage, subconchoidal fracture, brittle. $H = 4$. $G = 2.82$. Nonfluorescent. Biaxial (-); $X = b$; $Y \wedge a = 30.2^\circ$, $Z \wedge c = 11.5^\circ$. $N_x = 1.590$, $N_y = 1.610$, $N_z = 1.619$; $2V = 65^\circ$; $r > v$, moderate, dispersion strong. X, dark blue; Y, gray blue; Z, light blue. The mineral was found in a single solution cavity at the *Wessels mine, Kalahari manganese field, northwestern Cape Prov., South Africa*, associated with yellowish sturmanite crystals, bultfonteinite, gypsum, calcite, barite, azurite, and others. RG *MR 22:279(1991)*.

31.6.1.1 Devilline $\text{CaCu}_4(\text{SO}_4)_2(\text{OH})_6 \cdot 3\text{H}_2\text{O}$

Named in 1864 for H. E. Sainte-Claire Deville (1818-1881), French chemist. MON $P2_1/c$. $a = 20.870$, $b = 6.135$, $c = 22.191$, $\beta = 102.73^\circ$, $Z = 8$, $D = 3.06$. Structure: *AC(B) 28:1182(1972)*. *35-561*: 10.2_{10} 5.10_{10} 3.75_4 3.39_7 3.21_4 3.19_4 2.52_2 2.10_4 . Thin six-sided plates, flattened {001} and striated {010}; crusts or rosettes of crystals; twinning on {010}. Dark emerald green to bluish green, light green streak, vitreous luster, pearly on {001}. Cleavage {001}, perfect; {110}, {101}, {101}, distinct; not very brittle. $H = 2\frac{1}{2}$. $G = 3.13$. Insoluble in water and concentrated H_2SO_4 , soluble in HNO_3 , in CT affords water. Biaxial (-); $X \approx c$, $Z = b$; $N_x = 1.585$, $N_y = 1.649$, $N_z = 1.660$; $2V = 39^\circ \pm 2^\circ$; $r < v$, marked. X, very pale green; Y, green; Z, turquoise-green. Ecton copper mine, Montgomery Co., PA. *Cornwall, England*. Vezzani, Corsica, France, in stalactites with spangolite. Spania Dolina, N of Banská Bystrica, Slovakia(1), in platy rosettes to 4 cm with gypsum, azurite and malachite. RG *DII:590, AM 54:329(1969)*, *NJMM:79(1983)*.

31.6.1.2 Lautenthalite $\text{PbCu}_4[(\text{OH})_6](\text{SO}_4)_2 \cdot 3\text{H}_2\text{O}$

Named in 1993 for the locality. The Pb analog of devilline. MON $P2_1/c$. $a = 21.642$, $b = 6.040$, $c = 22.544$, $\beta = 108.2^\circ$, $Z = 8$, $D = 3.84$. *NJMM:401(1993)*. PD: 5.14_{10} 4.53_6 3.40_8 2.63_5 2.53_4 2.21_4 . Crystals tabular

(100) and elongate [010] to 0.5 mm, and as sheaflike aggregates, usually twinned on (100). Bright blue, white streak, vitreous luster, transparent. Cleavages {010} and {100}. Soluble in HCl, leaving a residue of PbSO₄. Biaxial (-); $Z = b$; $Y \wedge c = 4^\circ$; $N_x = 1.659$, $N_y = 1.703$, $N_z = 1.732$; $2V = 79^\circ$; $r > v$, distinct; faintly pleochroic. Found in a Ag-rich galena specimen from *Lautenthal, Harz, Germany*, on anglesite, accompanied by serpierite and devil-line. Also from Öblarn, Steiermark, Austria. RG *AM 79:571(1994)*.

31.6.2.1 Serpierite $\text{Ca}(\text{Cu,Zn})_4(\text{SO}_4)_2(\text{OH})_6 \cdot 3\text{H}_2\text{O}$

Named for Giovanni Battista Serpieri (1832–1897), Italian mining entrepreneur, founder of the Montecatini Company, and developer of the Laurium mines, Greece. Dimorphous with orthoserpierite. MON *C2/c*. $a = 22.186$, $b = 6.250$, $c = 21.853$, $\beta = 113.37^\circ$, $Z = 8$, $D = 3.08$. Structure: *AC(B)* *24:1214(1968)*. *22-148*: 10.2₁₀ 5.09₈ 3.39₈ 2.71₆ 2.65₆ 2.44₆ 2.17₆ 1.57₆. Crusts and tufted aggregates of tiny lathlike crystals, elongated [100] and flattened {001}; botryoidal. Sky blue; vitreous luster, pearly on cleavage. Cleavage {001}, perfect. $G = 3.07$. Soluble in acids. Biaxial (-); $YZ = bc$; $X \wedge a = 24^\circ$; $N_x = 1.584$, $N_y = 1.642$, $N_z = 1.647$; $2V = 35^\circ \pm 2^\circ$; $r > v$, strong. X, pale green; Y,Z, bluish green. Otoño mine, Altar district, SON, Mexico. *Laurium, Greece*, with smithsonite. Ross Island, Killarney, Eire. Akchagyl, Kazakhstan, with linarite and cyanotrichite. RG *DII:592, AM 54:328(1969)*.

31.6.3.1 Ktenasite $\text{ZnCu}_4(\text{SO}_4)_2(\text{OH})_6 \cdot 6\text{H}_2\text{O}$

Named in 1950 for Constantine A. Ktenas (d.1935), Greek mineralogist. MON *P2₁/c*. $a = 5.589$, $b = 6.166$, $c = 23.751$, $\beta = 95.55^\circ$, $Z = 2$, $D = 2.93$. *29-591*: 11.8₁₀ 5.93₉ 4.85₉ 2.96₅ 2.79₆ 2.69₆ 2.66₅ 2.58₇. Tabular crystals to 1.01 mm. Blue-green, vitreous luster. $H = 2-2.5$. $G = 2.98$. Soluble in dilute acids and ammonia. Biaxial (-); $Z = b$; $N_x = 1.511$, $N_y = 1.613$, $N_z = 1.623$; $2V = 51^\circ$. *Laurium, Greece*, with glaucokerinite and serpierite in smithsonite. RG *AM 36:381(1951), ZK 147:129(1978)*.

31.6.4.1 Peretaite $\text{CaSb}_4^{3+}\text{O}_4(\text{SO}_4)_2(\text{OH})_2 \cdot 2\text{H}_2\text{O}$

Named in 1980 for the locality. MON *C2/c*. $a = 24.665$, $b = 5.601$, $c = 10.185$, $\beta = 95.98^\circ$, $Z = 4$, $D = 4.06$. *AM 65:940(1980)*. *33-264*: 12.2₁₀ 6.12₂ 5.45₂ 3.10₃ 3.06₇ 2.53₂ 2.45₃ 2.07₂. Crystals tabular {100}, elongated [001], always twinned on {100}. Colorless, vitreous luster. Cleavage {100}, perfect. $H = 3\frac{1}{2}$. $G = 4.0$. Biaxial (+); $Y \wedge b = 28^\circ$; Z parallel to c ; $N_y = 1.841$, $N_z = 1.935$; $2V$ very large. *Pereta, Tuscany, Italy*, in an antimony-bearing vein in silicified limestone, in vugs, associated with klebelsbergite, valentinite, kermesite, sulfur, and stibnite. Also La Cetine mine. RG.

31.6.6.1 Campigliaite $\text{Mn}^{2+}\text{Cu}_4(\text{SO}_4)_2(\text{OH})_6 \cdot 4\text{H}_2\text{O}$

Named in 1982 for the locality. MON *C2*. $a = 21.707$, $b = 6.098$, $c = 11.245$, $\beta = 100.3^\circ$, $Z = 4$, $D = 3.06$. *AM 67:388(1982)*. *35-529*: 10.7₁₀ 5.34₆ 3.56₅ 2.77₁ 2.67₁ 2.57₁ 1.78₁ 1.52₁. Bladelike crystals, flattened {100} and elongated

[010]. Light blue, vitreous luster. Cleavage {100}, perfect. $G = 3.00$. Slowly soluble in acetic acid. Biaxial (-); $X \approx a$, $Y \approx c$, $Z = b$; $N_x = 1.589$, $N_y = 1.645$, $N_z = 1.659$; nonpleochroic; $2V = 52^\circ$; $r < v$, weak. *Temperino mine, Campiglia Marittima, Tuscany, Italy*, in vugs in an ilvaite-rich skarn, associated with gypsum, brochantite, and antlerite. RG

31.6.7.1 Orthoserpierite $\text{Ca}(\text{Cu,Zn})_4(\text{SO}_4)_2(\text{OH})_6 \cdot 3\text{H}_2\text{O}$

Named in 1985 from the relationship to serpierite, with which it is dimorphous. ORTH *Pca*2₁. $a = 22.10$, $b = 6.20$, $c = 20.39$, $Z = 8$, $D = 3.07$. 39-346: 10.2₁₀ 5.10₉ 3.40₉ 3.18₅ 2.61₅ 2.56₅ 2.51₄ 2.38₆. Masses and fibrous crusts; crystals flattened {001} and elongated [010]. Sky blue, light green streak; vitreous luster. Splintery fracture. $G = 3.00$. Fluorescent mauve in LWUV and SWUV. Biaxial (-); XYZ = *cab*; $N_x = 1.586$, $N_y = 1.645$, $N_z = 1.650$; $2V = 32^\circ$; $r > v$, distinct. X, nearly colorless, Y,Z, pale green. *Chessy copper mine, near Lyon, France*, with gypsum, devilline, and calcite in brecciated argillite, as a postdump product. RG *SMPM 65:1(1985)*, *AM 72:1026(1987)*.

31.6.8.1 Rabejacite $\text{Ca}(\text{UO}_2)_4(\text{SO}_4)_2(\text{OH})_6 \cdot 6\text{H}_2\text{O}$

Named in 1993 for the locality. ORTH Space group unknown. $a = 8.73$, $b = 17.09$, $c = 15.72$, $Z = 4$, $D = 4.31$. *EJM 5:873(1993)*. PD: 7.90₁₀ 3.98₄ 3.49₃ 3.38₇. Acicular crystals, flattened tablets on {001}; or rounded nodules. Amber yellow, vitreous luster, transparent to translucent. No cleavage. $H = 3$. $G = 4.1$. Fluorescent light yellow under SWUV and LWUV. Biaxial (-); $X = c$; Y and Z in the plane of the tablets; $N_{x \text{ calc}} = 1.617$, $N_y = 1.710$, $N_z = 1.758$; $2V = 68^\circ$; $r > v$, weak; strongly pleochroic from pale yellow (Y) to sulfur-yellow (Z). Found at *Rabejac and Mas d'Alary village a few kilometers from Lodeve, France*, accompanied by gypsum and other secondary U minerals as an alteration product of pitchblende. RG *AM 79:572(1994)*.

31.7.1.1 Kainite $\text{K}_4\text{Mg}_4(\text{SO}_4)_4\text{Cl}_4 \cdot 11\text{H}_2\text{O}$

Named in 1865 from the Greek for *recent*, in allusion to its recent (secondary) formation. MON *C2/m*. $a = 19.72$, $b = 16.23$, $c = 9.53$, $\beta = 94.92^\circ$, $Z = 4$, $D = 2.176$. *AM 57:1325(1972)*. 25-1237: 8.12₇ 7.77₈ 7.37₁₀ 4.62₄ 3.08₉ 3.05₄ 3.03₇ 2.95₃. Massive, granular; as thick tabular crystals flattened {100}, often rich in forms. Colorless, also other colors due to included foreign matter; vitreous luster. Cleavage {001}, perfect; smooth to splintery fracture; brittle. $H = 2\frac{1}{2}$ -3. $G = 2.15$. Tastes salty and bitter. Biaxial (-); $Y = b$; $Z \wedge c = 13^\circ$; $N_x = 1.494$, $N_y = 1.505$, $N_z = 1.516$; $2V = 90^\circ$; $r > v$, very weak. Formed only in marine evaporite potash deposits, often as a result of subsequent metamorphism. Eddy Co., NM, in the Permian potash deposits, associated with sylvite and langbeinite. *Stassfurt* and many other *northern German potash deposits*, associated with sylvite, halite, carnallite, kieserite, and other salt minerals. Kalusz, Galicia, Poland. Used as an ore of potash and magnesium. RG *DII:594*.

31.7.2.1 Uklonskovite $\text{NaMg}(\text{SO}_4)\text{F} \cdot 2\text{H}_2\text{O}$

Named in 1964 for A. S. Uklonskii (1888–1972), mineralogist, Uzbekistan. MON $P2_1/m$. $a = 7.202$, $b = 7.214$, $c = 5.734$, $\beta = 113.14^\circ$, $Z = 2$, $D = 2.414$. AM 71:1282(1986). 39-320(syn): 6.61₈ 5.27₆ 4.88₃ 3.51₁₀ 3.31₅ 3.15₆ 3.01₅ 2.97₅ 1.70₆. Minute, prismatic crystals, flattened {010}, elongated [010]. Colorless, vitreous luster. $G = 2.42$. Insoluble in water, soluble in cold dilute HCl. Biaxial (+); $N_x = 1.476$, $N_z = 1.500$. From cavities in clays covering a saline layer in Neogene rocks of *Kara-Kalpakii*, lower *Amu-Darya* river, *Kara Tau*, *Kazakhstan*, associated with glaserite and polyhalite. Also from the Cetine mine, Tuscany, Italy. RG *DANS* 158:116(1964), *AM* 50:520(1965), *BM* 108:133(1985).

31.7.3.1 Clinoungemachite $\text{Na}_2\text{K}_3\text{Fe}^{3+}(\text{SO}_4)_6(\text{OH})_3 \cdot 9\text{H}_2\text{O}$ (?)

Named in 1938 for its similarity to ungemachite except for its crystal system. Physical and chemical properties presumed to be similar to ungemachite. Needs confirmation. MON (pseudo-*HEX-R*) Space group unknown. $\beta = 110.67^\circ$. Crystals thick tabular {001}. Indistinguishable in appearance from ungemachite except through measurement of individual crystals. Colorless to yellowish. Soluble in weak HCl. *Chuquicamata*, *Chile*, with sideronatriite in massive altered iron sulfates. RG *DII*:597.

31.7.4.1 Aluminite $\text{Al}_2(\text{SO}_4)(\text{OH})_4 \cdot 7\text{H}_2\text{O}$

Named in 1807 for the composition. MON $P2_1/c$. $a = 7.440$, $b = 15.583$, $c = 11.700$, $\beta = 110.18^\circ$, $Z = 4$, $D = 1.794$. Structure: *AC(B)* 34:2407(1978). 30-44: 8.98₁₀ 7.79₉ 6.37₄ 5.49₃ 5.01₄ 4.70₅ 3.74₄ 3.71₃. Reniform or nodular masses consisting of minute fibers. White, dull luster. Earthy fracture, friable. $H = 1-2$. $G = 1.7$. Soluble in acids, in CT affords much water. Biaxial (+); $X = \text{elongation}$; $N_x = 1.459$, $N_y = 1.464$, $N_z = 1.470$; $2V \approx 90^\circ$. Formed in recent or Tertiary clays, marls, and lignites by the action of sulfate solutions derived from the alteration of pyrite or marcasite, on aluminous silicates. Joplin, MO, coating limestone. At the railroad crossing of the Green River, UT; *Halle*, *Saxony*, *Germany*. Epernay, Marne, France, and at Auteuil near Paris. Vesuvius, Italy, with halite and sylvite. In chalk at New Haven, Sussex, England. Salt Range, Punjab, Pakistan. RG *DII*:600, *ZK* 151:141(1980).

31.7.5.1 Meta-Aluminite $\text{Al}_2(\text{SO}_4)(\text{OH})_4 \cdot 5\text{H}_2\text{O}$

Named in 1968 for the similarity to aluminite, but a lower hydrate. MON Space group unknown. $a = 7.930$, $b = 16.879$, $c = 7.353$, $\beta = 106.73^\circ$, $Z = 4$, $D = 2.17$. *ZK* 151:141(1980). 32-27(syn): 8.46₆ 4.52₁₀ 4.39₉ 3.74₄ 3.62₅ 3.54₆ 2.71₄ 2.27₄. Nodular microcrystalline aggregates and concretions. Snow white, silky luster. Soft. $G = 2.18$. Biaxial (-); $Z = b$; $N_x = 1.497$, $N_y = 1.512$, $N_z = 1.513$; $2V$ small. Upon heating to 55° loses some water and alters to aluminite. Otherwise stable under normal conditions. *Fumerole uranium mine*, *Temple Mt.*, *San Rafael Swell*, *Emery Co.*, *UT*. RG *AM* 53:717(1968).

31.7.6.1 Despujolsite $\text{Ca}_3\text{Mn}^{4+}(\text{SO}_4)_2(\text{OH})_6 \cdot 3\text{H}_2\text{O}$

Named for Pierre Despujols, founder of the Service Geologique, Morocco. *HEX P62c*. $a = 8.56$, $c = 10.76$, $Z = 2$, $D = 2.54$. *BM 91:43(1968)*. 20-226: 7.40₆ 4.26₈ 3.49₄ 3.34₁₀ 2.57₆ 2.24₄ 2.13₈ 2.03₆. Hexagonal prismatic crystals, in aggregates. Lemon yellow, vitreous luster. Conchoidal fracture, brittle. $H = 2\frac{1}{2}$. $G = 2.46$. Dissolves in HCl with release of chlorine; turns brown, then black, with dilute HNO_3 ; insoluble in cold acetic acid. Uniaxial (+); $N_O = 1.656$, $N_E = 1.682$. O, paler yellow; E, pale yellow. *Tachgagalt, Morocco*, associated with gaufreyite. *RG AM 54:326(1969)*.

31.7.6.2 Schaurteite $\text{Ca}_3\text{Ge}^{4+}(\text{SO}_4)_2(\text{OH})_6 \cdot 3\text{H}_2\text{O}$

Named in 1965 for Werner T. Schaurte (1893–1978), South African scientist. *HEX P62c*. $a = 8.525$, $c = 10.803$, $Z = 2$, $D = 2.64$. *AM 53:507(1968)*. 19-225: 7.40₅ 4.26₇ 3.49₅ 3.34₁₀ 2.58₅ 2.24₅ 2.21₅ 2.13₆. Minute acicular to fibrous crystals. White, silky luster. $G = 2.65$. Uniaxial (+); $N_O = 1.569$, $N_E = 1.581$. *Tsumeb, Namibia*, as an alteration product of Ge-bearing ores. *RG NJMA 123:160(1975)*.

31.7.6.3 Fleischerite $\text{Pb}_3\text{Ge}^{4+}(\text{SO}_4)_2(\text{OH})_6 \cdot 3\text{H}_2\text{O}$

Named in 1960 for Michael Fleischer (b.1908), American geochemist, U.S. Geological Survey. *HEX P62c*. $a = 8.867$, $c = 10.875$, $Z = 2$, $D = 4.674$. *SR 41A:345(1975)*. 29-771: 7.70₅ 6.27₇ 3.62₁₀ 3.44₈ 2.64₉ 1.89₉ 1.72₆ 1.68₆. Aggregates of fibrous crystals. White to pale rose, silky luster. Soft. $G = 4.55$. Non-fluorescent. Becomes rose-violet when irradiated with X-rays. Uniaxial (+); $N_O = 1.747$, $N_E = 1.776$. *Tsumeb mine, Namibia*, associated with cerussite, mimetite, and altered tennantite, in the upper oxidation zone. *RG AM 45:1313(1960)*, *NJMM:132(1960)*, *NJMA 123:160(1975)*.

31.8.1.1 Natrochalcite $\text{NaCu}_2(\text{SO}_4)_2(\text{OH}) \cdot \text{H}_2\text{O}$

Named in 1908 for the composition. *MON* Space group unknown. $a = 8.812$, $b = 6.188$, $c = 7.510$, $\beta = 118.7^\circ$, $Z = 2$, $D = 3.487$. Structure: *ZK 187:239(1989)*. 45-1364: 6.57₈ 4.82₂ 3.46₈ 3.20₈ 2.80₁₀ 2.53₇ 2.31₄ 1.682₂. Crystals pyramidal {111}, with {110} well developed; cross-fiber veinlets. Bright emerald green, greenish-white streak, vitreous luster. Cleavage {001}, perfect. $H = 4\frac{1}{2}$. $G = 3.49$. Slowly soluble in water, easily so in acids; in CT, affords acid water and fuses to a dark enamel. Biaxial (+); $Y = b$; $X \wedge c = -12^\circ$; $N_x = 1.649$, $N_y = 1.655$, $N_z = 1.714$ (Na); $2V = 37^\circ$; $r < v$, strong. *Chuquicamata, Antofagasta, Chile*, associated with kroehnkite, antlerite, bloedite, atacamite, and other sulfates. Used as an ore of copper at Chuquicamata. *RG DII:602*, *DANS 123:78(1958)*, *BGSA 74:709(1963)*.

31.8.2.1 Johannite $\text{Cu}(\text{UO}_2)_2(\text{SO}_4)_2(\text{OH})_2 \cdot 8\text{H}_2\text{O}$

Named in 1830 after Archduke Johann (1782–1859) of Austria, founder of the Styrian Landesmuseum in Graz. *TRIC P1* or *P1*. $a = 8.903$, $b = 9.499$,

$c = 6.812$, $\alpha = 109.87^\circ$, $\beta = 112.01^\circ$, $\gamma = 100.4^\circ$, $Z = 1$, $D = 3.44$. *TMPM* 30:47(1982). 17-530: 7.73₁₀ 6.16₉ 5.59₄ 4.38₆ 3.87₇ 3.41₈ 3.13₇ 3.04₇. Crystals prismatic {001} and thick tabular {100}; as spheroidal aggregates and coatings. Emerald-green to apple-green, pale green streak, vitreous luster. Cleavage {100}, good; not brittle. $H = 2\frac{1}{2}$. $G = 3.32$. Decomposed by water, soluble in acids. Tastes bitter. Biaxial (\pm); $X \wedge \phi = -101^\circ$, $X \wedge \sigma = 85^\circ$; $Y \wedge \phi = 37^\circ =$, $Y \wedge \sigma = 8^\circ$; $Z \wedge \phi = 169^\circ$, $Z \wedge \sigma = 85^\circ$; $N_x = 1.572$, $N_y = 1.595$, $N_z = 1.614$; $2V \approx 90^\circ$; $r > v$, strong (Joach.); $r < v$, strong (CO). Formed by the oxidation of uraninite usually in the presence of gypsum. Central City District, Gilpin Co., CO. *Jáchymov, Bohemia, Czech Republic*. Johannegeorgenstadt, Saxony, Germany, Mine du Limouzat, St.-Priest-la-Prugne, Loire, France. Cornwall, England. RG *DII:606, USGSB 1064:130(1958), AM 68:851(1983), NJMA 159:297(1988)*.

31.8.3.1 Sideronatrite $\text{Na}_2\text{Fe}^{3+}(\text{SO}_4)_2(\text{OH}) \cdot 3\text{H}_2\text{O}$

Named in 1878 for the composition. ORTH *Pnn2* or *Pnnm*. $a = 7.27$, $b = 20.50$, $c = 7.15$, $Z = 4$, $D = 2.276$. 17-156: 10.2₁₀ 6.78₄ 5.86₃ 3.58₄ 3.38₆ 3.01₈ 2.68₆ 1.754₃. Minute needles elongated [001], nodular masses, fibrous crusts, earthy. Yellow to pale yellow, orange, yellow-brown; pale yellow streak. Cleavage {100}, perfect. $H = 1\frac{1}{2}$ - $2\frac{1}{2}$. $G = 2.28$. Insoluble in cold water, decomposed in boiling water, with separation of ferric oxide. Biaxial (+); $XYZ = abc$; $N_x = 1.508$, $N_y = 1.525$, $N_z = 1.586$; $2V = 58^\circ \pm 5^\circ$; $r > v$, strong. X, nearly colorless; Y, pale amber-yellow; Z, pale yellow. With melanterite on the Urus plateau, Cheleken Is., Caspian Sea, Turkmenistan. *San Simon mine, Huantajaya, Tarapacá, Chile*, and elsewhere in the arid regions of Chile. With voltaite at Potosi, Bolivia. RG *DII:604, TMPM 28:315(1981), PM 54:15(1985)*.

31.8.4.1 Metasideronatrite $\text{Na}_2\text{Fe}^{3+}(\text{SO}_4)_2(\text{OH}) \cdot \text{H}_2\text{O}$

Named in 1938 for the similarity to sideronatrite but being a lower hydrate. ORTH *Pbnm* or *Pbn2*₁. $a = 7.36$, $b = 64.08$, $c = 7.08$, $Z = 16$, $D = 2.76$. *AM 58:1080(1973)*. 29-1219: 8.05₉ 6.68₇ 3.99₃ 3.68₁₀ 3.49₄ 3.15₃ 2.75₅ 2.67₅. Crystals rare, prismatic [001]; usually as coarse to fine crystal aggregates. Golden yellow to straw yellow, silky luster. Cleavage {100}, {010}, perfect; {001}, good; fibrous fracture. $H = 2\frac{1}{2}$. $G = 2.68$. Insoluble in cold water, decomposes in boiling water, soluble in acids, in CT yields abundant water. Biaxial (+); $XYZ = abc$; $N_x = 1.543$, $N_y = 1.575$, $N_z = 1.634$; $2V = 60^\circ$; $r > v$, strong. X, colorless; Y, light yellow; Z, brownish yellow. *Chuquicamata, Antofagasta, Chile*, with metavoltine and other secondary sulfates. RG *DII:603, NJMM 1982:248*.

31.9.1.1 Butlerite $\text{Fe}^{3+}(\text{SO}_4)(\text{OH}) \cdot 2\text{H}_2\text{O}$

Named in 1928 for Gurdon Montague Butler (1881-1961), American mining geologist, University of Arizona. Dimorphous with parabutlerite (31.9.2.1). MON *P2*₁/*m*. $a = 6.50$, $b = 7.37$, $c = 5.84$, $\beta = 108.38^\circ$, $Z = 2$, $D = 2.564$. *NBSM 25(10):95(1972)*. 25-409: 4.99₁₀ 4.74₁ 3.60₁ 3.24₁ 3.17₅ 3.08₁ 2.50₁

1.844₁. Crystals usually tabular {001} or {100} with a tendency for elongation [010]; also pseudo-octahedral. Twinning on {105}, very common. Deep orange, pale yellow streak, vitreous luster. Cleavage {100}, perfect. $H = 2\frac{1}{2}$. $G = 2.55$. Biaxial (\pm); $Z = b$; $X \wedge c = -18^\circ$; $N_x = 1.593-1.604$, $N_y = 1.665-1.674$, $N_z = 1.741-1.731$; $2V$ large. X, colorless; Y, faint yellow; Z, light yellow. With copiapite and other sulfates at the *United Verde mine, Jerome, AZ*, formed under fumarolic conditions after a mine fire. Dexter No. 7 mine, Calf Mesa, San Rafael Swell, Emery Co., UT. Santa Elena mine, La Alcaparrosa, Argentina. Chuquicamata, Chile. RG *DII:608, AM 40:477(1955)*.

31.9.2.1 Parabutlerite $\text{Fe}^{3+}(\text{SO}_4)(\text{OH}) \cdot 2\text{H}_2\text{O}$

Named in 1938 from the Greek *para* and butlerite, a dimorphous pair. ORTH *Pmnb* or *Pmma*. $a = 20.13$, $b = 7.38$, $c = 7.22$, $Z = 8$, $D = 2.47$. *BM 93:185(1970)*. *16-939*: 5.85_6 4.99_{10} 4.07_2 3.60_4 3.11_{10} 2.91_2 2.50_4 1.84_3 . Crystals prismatic [001], striated [001]; twinning on {142}, rare. Light orange to light orange-brown, vitreous luster. Cleavage {110}, poor; conchoidal fracture; brittle. $H = 2\frac{1}{2}$. $G = 2.55$. Insoluble in water; soluble in acids; in CT, yields acid water. Biaxial (+); $XYZ = bca$; $N_x = 1.589-1.598$, $N_y = 1.660-1.663$, $N_z = 1.750-1.737$ (Na); $2V = 87^\circ$; $r > v$, moderate. X, colorless; Y, faint yellow; Z, light yellow. *Alcaparrosa, near Cerritos Bayos, Antofagasta, Chile*, in a bed as an alteration product of copiapite. Santa Elena mine, La Alcaparrosa, San Juan, Argentina, with butlerite, fibroferrite, and other sulfates. RG *DII:610*.

31.9.3.1 Amaranthite $\text{Fe}_2^{3+}(\text{SO}_4)_2\text{O} \cdot 7\text{H}_2\text{O}$

Named in 1888 from the Greek *amaranthos*, in allusion to its red color. TRIC *P1*. $a = 8.976$, $b = 11.678$, $c = 6.698$, $\alpha = 95.65^\circ$, $\beta = 90.37^\circ$, $\gamma = 97.2^\circ$, $Z = 2$, $D = 2.14$. *ZK 127:261(1968)*. *17-158*: 11.3_{10} 8.69_{10} 5.16_4 4.98_4 3.57_8 3.41_4 3.11_6 3.05_8 . Crystals elongated [001] or flattened {100}; striated [001]; aggregates of acicular crystals, radiating, columnar, or bladed. Amaranth-red; orange-red, lemon yellow streak, vitreous luster. Cleavage {010}, {100}, perfect; brittle. $H = 2\frac{1}{2}$. $G = 2.2$. Decomposed by water, soluble in HCl. Biaxial (-); $X \wedge \phi = 82^\circ$, $X \wedge \sigma = 72^\circ$; $Y \wedge \phi = 178^\circ$, $Y \wedge \sigma = 68^\circ$; $Z \wedge \phi = -44^\circ$, $Z \wedge \sigma = 29^\circ$; $N_x = 1.516$, $N_y = 1.598$, $N_z = 1.621$ (Na); $2V = 30^\circ$; $r < v$, horizontal. X, colorless; Y, pale yellow; Z, reddish brown. Santa Maria Mts., Riverside Co., CA. *Caracoles, Sierra Gorda, Chile*; also from Copiapo, Quetena, Alcaparrosa, and Chuquicamata. RG *DII:611, MM 42:144(1978)*.

31.9.4.1 Hohmannite $\text{Fe}_2^{3+}(\text{SO}_4)_2\text{O} \cdot 8\text{H}_2\text{O}$

Named in 1888 for Thomas Hohmann, Chilean mining engineer, who discovered the mineral. TRIC *P1* or *P1*. $a = 9.148$, $b = 10.922$, $c = 7.183$, $\alpha = 90.28^\circ$, $\beta = 90.78^\circ$, $\gamma = 107.37^\circ$, $Z = 2$, $D = 2.250$. *MM 42:144(1978)*. *17-155*: 10.4_6 8.69_8 7.92_{10} 5.31_4 3.95_3 3.46_6 3.26_3 3.12_4 . Crystals short prismatic [001]; as granular aggregates. Chestnut-brown to orange and reddish, orange-yellow streak, vitreous, brilliant luster. Cleavage {010}, perfect; {110} and {110},

fair. $H = 3$. $G = 2.255$. Insoluble in cold water, decomposed by hot water; soluble in HCl; in CT affords acid water. Biaxial (-); $N_x = 1.559$ (pale yellow), $N_y = 1.643$ (pale greenish yellow), $N_z = 1.655$ (dark greenish yellow) (Na); $2V = 40^\circ$; $r > v$, extreme. Upon exposure rapidly dehydrates and crumbles to metahohmannite. Redington mine, Knoxville, Napa Co., CA, with sulfur and cinnabar. *Sierra Gorda, near Copiapó, Chile*; also at Quetena and Chuquicamata. *DII:613*.

31.9.5.1 Metahohmannite $\text{Fe}_2^{3+}(\text{SO}_4)_2(\text{OH})_2 \cdot 3\text{H}_2\text{O}$ (?)

Named in 1938 for the similarity to hohmannite, with a lower state of hydration. Probably TRIC P1 or P1. *39-379*: 9.7₆ 7.18₁₀ 7.04₆ 4.27₇ 3.28₇ 2.96₇ 2.70₇ 2.49₇. Pulverulent masses. Orange. Biaxial (+); $N_x = 1.709$, $N_y = 1.718$, $N_z = 1.734$. X, pale yellow; Y, reddish yellow; Z, reddish brown. Formed rapidly from the dehydration of hohmannite. *Chuquicamata, Quetena, and Alcaparrosa, Chile*. RG *DII:608, MM 42:M11(1978)*.

31.9.6.1 Botryogen $\text{Fe}^{3+}\text{Mg}(\text{SO}_4)_2(\text{OH}) \cdot 7\text{H}_2\text{O}$

Name derived in 1828 from the Greek for *bear* and *a bunch of grapes*, in allusion to the botryoidal masses originally found at Falun. MON $P2_1/n$ or $P2_1/c$. $a = 10.526$, $b = 18.872$, $c = 7.136$, $\beta = 100.13^\circ$, $Z = 4$, $D = 2.23$. Structure: *AC(B) 24:760(1968)*. *17-157*: 8.87₁₀ 6.29₆ 5.34₄ 5.11₆ 4.07₄ 3.74₄ 3.50₄ 3.00₈. Crystals prismatic [001], striated [001], with {101} large; mostly botryoidal, reniform, or radiating globular aggregates. Light to dark orange-red, ocher-yellow streak, vitreous luster. Cleavage {010}, perfect; {110}, good; conchoidal fracture; brittle. $H = 2-2\frac{1}{2}$. $G = 2.19$. Partly soluble in boiling water, leaving an ocherous residue; soluble in HCl. Biaxial (+); $X = b$; $Z \wedge c = 12^\circ$; $N_x = 1.523$, $N_y = 1.530$, $N_z = 1.582$; $2V = 42^\circ$; $r > v$, strong. X, colorless to pale brown; Y, cinnamon-brown; Z, golden yellow. Cornwall, Lebanon Co., PA. Redington mine, Knoxville, Napa Co., CA. The copper mine at *Falun, Sweden*. Rammelsberg, Harz, Germany. Miniera di Terranera, Rio Marina, Elba, Italy(*), with pickeringite and copapite. Madeni Zakh, Iran. Abundant at Chuquicamata, Quetena, and Alcaparrosa, Chile. Santa Elena mine, La Alcaparrosa, Argentina. RG *DII:617*.

31.9.6.2 Zincobotryogen $\text{Fe}^{3+}\text{Zn}(\text{SO}_4)_2(\text{OH}) \cdot 7\text{H}_2\text{O}$

Named in 1964 as the zincian analog of botryogen. MON $P2_1/n$. $a = 10.523$, $b = 17.841$, $c = 7.137$, $\beta = 100.12^\circ$, $Z = 4$, $D = 2.237$. *NBSM 25(20):67(1984)*. *34-186*: 8.96₁₀ 6.35₆ 5.16₈ 4.34₄ 4.10₅ 3.22₅ 3.03₆ 2.76₅. Prismatic crystals and radiating crystalline aggregates. Bright orange-red, vitreous to greasy luster. $H = 2\frac{1}{2}$. $G = 2.201$. Biaxial (+); $N_x = 1.542$, $N_y = 1.551$, $N_z = 1.587$; $2V = 54^\circ$; $r > v$; strongly pleochroic; negative elongation. Rammelsberg, Harz, Germany. *Xitieshan*, in the arid *Qaidam (Chaidamu) basin, Qinghai, China*, associated with pickeringite. RG *AM 46:1517(1955), 49:1776(1964)*; *IGR 10:917(1968)*.

31.9.6.3 Xitieshanite $\text{Fe}^{3+}(\text{SO}_4)\text{Cl} \cdot 6\text{H}_2\text{O}$

Named in 1983 for the locality. MON $P2_1/c$. $a = 14.102$, $b = 6.908$, $c = 10.673$, $\beta = 111.27^\circ$, $Z = 4$, $D = 2.025$. AM 74:1404(1989). 35-719: 6.67₆ 6.09₅ 5.69₅ 4.96₁₀ 4.81₁₀ 4.21₅ 3.90₉ 3.25₄. Rhombic, rectangular crystals, or as massive aggregates. Bright yellowish green, yellow streak. Imperfect cleavage, uneven to conchoidal fracture. $H = 2\frac{1}{2}$, $G = 1.99$. Soluble in cold water and in dilute acids. Biaxial (-); $N_x = 1.536$, $N_y = 1.570$, $N_z = 1.628$; $2V = 77^\circ$; $r > v$. X, colorless to pale yellow; Y, pale yellow; Z, light greenish yellow. From the oxidation zone of the Xitieshan lead-zinc mine, Qaidam basin, Qinghai, China, with copiapite, roemerite, and other sulfates. RG AM 69:1194(1984), KT 33:502(1988), SS(Geol):106(1989).

31.9.7.1 Guildite $\text{CuFe}^{3+}(\text{SO}_4)_2(\text{OH}) \cdot 4\text{H}_2\text{O}$

Named in 1928 for Frank Nelson Guild (1870-1939), geologist, professor of mineralogy, University of Arizona. MON $P2_1/m$. $a = 9.786$, $b = 7.134$, $c = 7.263$, $\beta = 105.28^\circ$, $Z = 2$, $D = 2.717$. AM 63:478(1978). 23-217: 9.46₄ 6.50₁ 5.00₃ 3.61₂ 3.14₁₀ 2.91₁ 2.36₁ 2.08₁. Short prismatic, pseudocubic crystals. Brown, pale canary yellow streak, vitreous luster. Cleavage {001}, {100}, perfect; conchoidal fracture; brittle. $H = 2\frac{1}{2}$, $G = 2.695$. Biaxial (+); $N_x = 1.623$, $N_y = 1.630$, $N_z = 1.684$; $2V$ small. X, Y, pale yellow; Z, greenish yellow. Formed with coquimbite and other sulfates as a result of the mine fire at the United Verde mine, Jerome, AZ. RG DII.619, AM 55:502(1970).

31.9.7.2 Chaidamuite $\text{ZnFe}^{3+}(\text{SO}_4)_2(\text{OH}) \cdot 4\text{H}_2\text{O}$

Named in 1986 for the locality. MON $P2_1/m$. $a = 9.759$, $b = 7.134$, $c = 7.335$, $\beta = 106.20^\circ$, $Z = 2$, $D = 2.72$. AM 73:1493(1988). 41-1375: 9.40₈ 5.03₇ 5.00₈ 3.64₇ 3.57₄ 3.12₁₀ 3.09₁₀ 2.05₄. Crystals thick tabular {001} or short prismatic [001], usually as disseminated grains and granular aggregates. Brown to yellowish brown, pale yellow streak, vitreous luster. Cleavage {001}, {100}, perfect; conchoidal fracture. $H = 2\frac{1}{2}$ -3. $G = 2.722$. Nonfluorescent. Insoluble in water, slightly soluble in dilute HCl. Biaxial (+); $X = b$; $Y \wedge c = 12^\circ$, $Z \wedge a = 28^\circ$; $N_x = 1.688$, $N_y = 1.640$, $N_z = 1.632$; $2V = 44^\circ$; $r < v$. X, colorless to light yellow; Y, light yellow; Z, brownish yellow. Xitieshan lead-zinc mine, in the arid Chaidamu (Qaidam) basin, Qinghai, China, associated with zincobotryogen, coquimbite, copiapite, butlerite, and other sulfates. RG

31.9.8.1 Aubertite $\text{CuAl}(\text{SO}_4)_2\text{Cl} \cdot 14\text{H}_2\text{O}$

Named in 1978 for J. Aubert (b.1929), French geophysicist, who collected the mineral. TRIC $P1$. $a = 6.288$, $b = 13.239$, $c = 6.284$, $\alpha = 91.87^\circ$, $\beta = 94.67^\circ$, $\gamma = 82.45^\circ$, $Z = 1$, $D = 1.83$. Structure: AC(B) 35:2499(1979). 33-447: 6.25₅ 5.59₄ 4.83₄ 4.50₁₀ 4.25₇ 3.95₆ 3.69₄ 3.13₄. Crusts of corroded grains. Azure blue. Cleavage {010}, perfect. $G = 1.815$. Biaxial (-); $N_x = 1.462$, $N_y = 1.482$, $N_z = 1.495$ (Na); $2V = 71^\circ$; $r > v$, moderate; optic axis nearly perpendicular to {010}. Quetena, Antofagasta, Chile, with copiapite, amaran-

tite, parabutlerite, and hohmannite. RG *BM* 102:348(1979), *AM* 65:205(1980).

31.9.8.2 Svyazhinite $\text{MgAl}(\text{SO}_4)_2\text{F} \cdot 14\text{H}_2\text{O}$

Named for Nikolai Vasilevich Svyazhin (1927–1967), Russian mineralogist. TRIC $P\bar{1}$ or $P1$. $a = 6.217$, $b = 13.306$, $c = 6.255$, $\alpha = 90.05^\circ$, $\beta = 93.30^\circ$, $\gamma = 82.03^\circ$, $Z = 1$, $D = 1.69$. *AM* 70:877(1985). 37-443: 5.68₇ 4.91₁₀ 4.40₅ 4.26₄ 4.15₅ 3.39₄ 2.84₅ 2.82₅. Crystals tabular {014}, with complex morphology. Usually as nodules. Twinning on {014}. Yellowish. Biaxial (-); $N_x = 1.423$, $N_y = 1.439$, $N_z = 1.444$; 2V small; $2V_{\text{calc}} = 57^\circ$. Found in fractures cutting pyroxene-amphibole fenites. *Ilmeniskie Mts.*, *Ural Mts.*, *Russia*, associated with pyrite and fluorite. *ZVMO* 113:347(1984).

31.9.8.3 Magnesioaubertite $(\text{Mg,Cu})\text{Al}(\text{SO}_4)_2\text{Cl} \cdot 14\text{H}_2\text{O}$

Named in 1988 for the composition and relationship to aubertite. TRIC $P1$. $a = 6.31$, $b = 13.20$, $c = 6.29$, $\alpha = 91.70^\circ$, $\beta = 94.50^\circ$, $\gamma = 82.60^\circ$, $Z = 1$, $D = 1.78$. *AM* 75:1433(1990). 45-1403: 6.26₅ 5.61₇ 4.81₅ 4.50₁₀ 4.25₆ 3.97₈ 3.68₆ 3.12₅. Polycrystalline aggregates of grains. Sky blue, white streak, glassy luster. Cleavage {010}, good. $H = 2-3$. $G = 1.80$. Biaxial (-); $X \wedge \{010\} = 17^\circ$; $N_x = 1.466$, $N_y = 1.481$, $N_z = 1.488$; $2V = 112^\circ$; $r > v$. X, colorless; Y, Z, light blue. *Grotta de Faraglione*, *Porte de Levante*, *Vulcano island (Lipari group)*, *N of Sicily, Italy*, in crystal aggregates enclosed in pickeringite on alunogen, with metasideronatrite, sulfur, aluminocopiapite, and metavoltine. RG *AUF* 39:97(1988).

31.9.9.1 Wilcoxite $\text{MgAl}(\text{SO}_4)_2\text{F} \cdot 18\text{H}_2\text{O}$

Named in 1983 for William Wilcox, who discovered the mining district in 1879. He was killed by Apaches in 1880. TRIC $P1$ or $P\bar{1}$. $a = 14.90$, $b = 6.65$, $c = 6.77$, $\alpha = 117.43^\circ$, $\beta = 100.58^\circ$, $\gamma = 89.17^\circ$, $Z = 1$, $D = 1.67$. 35-575: 5.88₄ 5.65₉ 4.91₁₀ 4.37₆ 4.12₄ 3.38₅ 2.98₄ 2.83₄. Distinct triclinic crystals with {010}, {110}, {100}, {110}, and {011}. Colorless to white, vitreous luster. $H = 2$. $G = 1.58$. Soluble in cold water and dilute acids; in CT, dissolves in its water of crystallization. Biaxial (-); $N_x = 1.424$, $N_y = 1.436$, $N_z = 1.438$; $2V = 48^\circ$; imperceptible dispersion. *Lone Pine mine*, *Wilcox district*, *Catron Co.*, *NM*, forming crusts and efflorescences, associated with khademite, gypsum, and lannonite. RG *MM* 47:37(1983), *AM* 69:408(1984).

31.9.10.1 Jurbanite $\text{Al}(\text{SO}_4)(\text{OH}) \cdot 5\text{H}_2\text{O}$

Named in 1976 for Joseph John Urban (b.1915), mineral collector, Tucson, AZ, who first called attention to the species. Dimorphous with rostitite. MON $P2_1/n$ or $P2_1/c$. $a = 8.396$, $b = 12.479$, $c = 8.155$, $\beta = 101.92^\circ$, $Z = 4$, $D = 1.828$. *ZK* 173:33(1985). 17-388: 6.75₁₀ 5.73₁₀ 4.48₁₀ 4.00₁₀ 3.99₁₀ 3.90₁₀ 3.71₁₀ 2.60₁₀. Crystals prismatic [001] to equant, with {011} and {110}. Colorless, vitreous luster. No cleavage, brittle. $H = 2\frac{1}{2}$. $G = 1.786$. Soluble in water. Biaxial (-); $Y = b$; $Z \wedge a = -5^\circ$; $N_x = 1.459$, $N_y = 1.473$, $N_z = 1.483$; $2V = 80^\circ$. *San Manuel mine*, *Pinal Co.*, *AZ*, on the 2075 level, as a postmine

stalactitic assemblage with epsomite, hexahydrate, pickeringite, and other sulfates. La Cetine mine, Tuscany, Italy, with gypsum and halotrichite. RG *AM 61:1(1976)*.

31.9.11.1 Khademite $\text{Al}(\text{SO}_4)\text{F} \cdot 5\text{H}_2\text{O}$

Named in 1973 for N. Khadem (b.1910), director, Geological Survey of Iran. ORTH *Pcab.* $a = 11.181$, $b = 13.048$, $c = 10.885$, $Z = 8$, $D = 1.942$. *AM 66:1102(1981)*. $26-1011$: 4.25_{10} 4.18_7 3.90_5 3.35_2 2.74_2 2.73_6 2.50_1 2.03_2 . Crystals tabular {001}, with {010}, {110}, {111}, and {313}; in crusts. Colorless. No cleavage. $G = 1.925$. Biaxial (-); $YZ = ba$; $N_x = 1.44$, $N_y = 1.460$, $N_z = 1.487$; $2V = 68^\circ$. Lone Pine mine, Catron Co., NM, associated with wilcoxite, lannonite, and gypsum as a postmine efflorescence. *Saghand, Iran*, associated with copiapite, butlerite, parabutlerite, and other sulfates. RG *AM 60:486(1975)*, *BM 104:19(1981)*, *MM 52:133(1988)*.

31.9.11.2 Rostite $\text{AlSO}_4(\text{OH},\text{F}) \cdot 5\text{H}_2\text{O}$

Named in 1979 for Rudolph Rost (b.1912), Czech mineralogist, who originally described the species but thought it to be "lapparentite." It has been redefined as a new species. *NJMM:193(1979)*. Dimorphous with jurbanite. ORTH *Pcab.* $a = 11.175$, $b = 13.043$, $c = 10.878$, $Z = 8$, $D = 1.961$. *NJMM:476(1988)*. $41-1382$: 4.26_{10} 4.19_6 3.91_5 3.35_1 3.27_1 2.73_1 2.50_1 2.03_1 . Chalky masses. White. $G = 1.892$. Biaxial (+); Z perpendicular to flattening; Y bisects acute angle of crystals; $N_x = 1.461$, $N_y = 1.470$, $N_z = 1.484$. From the burning waste heaps of the *Schoeller coal mine, Libušín, Kladno district, Bohemia, Czech Republic*, with copiapite and ammonia alum. RG *DII:601, AM 64:1331(1979)*, *MM 52:133(1988)*.

31.9.12.1 Fibroferrite $\text{Fe}^{3+}(\text{SO}_4)(\text{OH}) \cdot 5\text{H}_2\text{O}$

Named in 1833 for its fibrous nature and composition. HEX-R *R3.* $a = 20.177$, $c = 7.656$, $Z = 18$, $D = 1.996$. *MA 34M:1237(1983)*. $38-481$: 12.1_{10} 6.98_4 4.57_5 4.07_4 3.44_2 3.35_3 2.99_3 2.78_3 . Fine-fibrous crusts and masses; radial fibrous, botryoidal. Fibers elongated [0001]. Pale yellow to nearly white; pale greenish shades, silky to pearly luster. Cleavage {001}, perfect. $H = 2\frac{1}{2}$. $G = 1.95$. Decomposed by water, giving an acid solution and a brown precipitate of ferric hydroxide. Uniaxial (+); $N_O = 1.513$, $N_E = 1.571$. O, colorless; E, pale amber yellow. Commonly formed from the oxidation of bodies of pyrite, pyrrhotite, or marcasite. Dehydrates partially at room temperature so that the exact state of hydration of a given sample may be uncertain. Genette Mt., AZ. From the pyrrhotite deposit, Island Mt., Trinity Co., CA; also in the Calico Hills near Borate, San Bernardino Co., with krausite, coquimbite, and other sulfates. Pallieres mines, Gard, France; Pöham, Salzburg, Austria; Skouriotissa, Cyprus. *Tierra Amarilla, near Copiapó, Chile*; also abundant at Chuquicamata. Santa Elena mine, La Alcaparrosa, Argentina. Yetar Spring, near Chidlows, WA, Australia. RG *DII:614, TPM 28:17(1981)*, *NJMM:171(1987)*.

31.9.13.1 Slavikite $\text{NaMg}_2\text{Fe}_5^{3+}(\text{SO}_4)_7(\text{OH})_6 \cdot 33\text{H}_2\text{O}$

Named in 1926 for František Slavík (1876–1957), Czech mineralogist and professor, Charles University, Prague. *HEX-R R3*. $a = 12.20$, $c = 35.13$, $Z = 3$, $D = 1.90$. *SR 41A:351(1975)*. *20-679*: 11.7₈ 9.04₁₀ 5.83₈ 5.41₈ 4.21₈ 3.47₈ 2.95₈ 2.70₈. Crystals minute, tabular {0001}, with prominent {1011}; granular; scaly; as crusts. Greenish yellow, vitreous luster. $G = 1.89$. Uniaxial (-); $N_O = 1.533$ –1.530, $N_E = 1.497$ –1.506. O, lemon yellow; E, nearly colorless. Formed as a weathering product of pyritic shales at *Valachov Hill, near Skřivany, Bohemia, Czech Republic*, with halotrichite, pickeringite, and gypsum. Poham, Salzburg, Austria. Santa Elena mine, La Alcaparrosa, San Juan, Argentina, with fibroferrite. *RG DII:621; BM 87:622(1964); NJMM:93(1973), 27(1975)*.

31.9.14.1 Lannonite $\text{HCa}_4\text{Mg}_2\text{Al}_4(\text{SO}_4)_8\text{F}_9 \cdot 32\text{H}_2\text{O}$

Named in 1983 for Dan Lannon, who in 1893 staked important claims in the Wilcox district. *TET* Space group unknown. $a = 6.84$, $c = 28.01$, $Z = 1$, $D = 2.322$. *AM 69:407(1984)*. *35-576*: 14.0₁₀ 4.84₇ 4.67₄ 3.98₅ 3.46₇ 3.33₅ 2.91₄ 2.76₄. Nodules consisting of microscopic square plates. Chalky white, dull luster. $H = 2$. $G = 2.22$. Insoluble in water; dissolves in cold, dilute acids; in CT yields water and HF. Uniaxial (+); $N_O = 1.460$, $N_E = 1.478$. *Lone Pine mine, Wilcox district, Catron Co., NM*, with wilcoxite, khademite, and gypsum, as a postmine efflorescence. *RG MM 47:37(1983)*.

31.10.1.1 Carrboydite $(\text{Ni,Cu})_{14}\text{Al}_9(\text{SO}_4,\text{CO}_3)_6(\text{OH})_{43} \cdot 7\text{H}_2\text{O}$

Named in 1976 for the locality. *HEX* Space group unknown. $a = 9.14$, $c = 10.34$, $Z = 4$, $D = 2.692$. *AM 61:366(1976)*. *29-926*: 10.5₁₀ 5.25₈ 3.48₆ 2.62₄ 2.55₇ 2.36₄ 2.07₄ 1.51₆. Platy crystallites forming nodules. Yellowish green to blue-green. $G = 2.50$. Uniaxial (-); $N_O = 1.56$, $N_E = 1.54$. The formula is based on a brucite-type interlayer structure. *MM 44:337(1981)*. Found in surface material at the nickel mine at *Carr Boyd Rocks, WA, Australia*. *RG*

ETTRINGITE GROUP

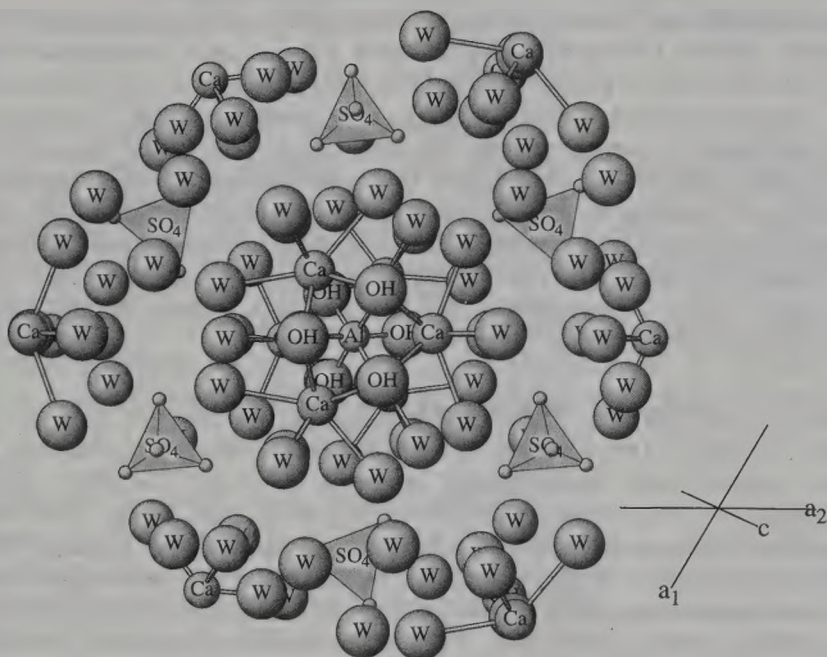

The ettringite group minerals are basically isostructural and conform to chemistry

where

and the structure is hexagonal or rhombohedral. Although there is considerable variation in chemistry, and to a lesser extent in cell parameters, the structures are all very similar. For details of the structure, see *AC(B) 26:386(1970), 27:594(1971), 25:1943(1969)*.

ETTRINGITE: $\text{Ca}_6\text{Al}_2(\text{SO}_4)_3(\text{OH})_{12} \cdot 26\text{H}_2\text{O}$

This structure has columns consisting of octahedral Al alternating with triplets of eight-coordinated Ca. The ligands are (OH) or H_2O . Sulfate ions are independent, lying between columns with some free H_2O .

ETTRINGITE GROUP

Mineral	Formula	Space Group	a	c	D

31.10.2.1 Ettringite $\text{Ca}_6\text{Al}_2(\text{SO}_4)_3(\text{OH})_{12} \cdot 26\text{H}_2\text{O}$

Named in 1874 for the locality. Ettringite group. HEX-R *P31c*. $a = 11.23$, $c = 21.44$, $Z = 2$, $D = 1.754$. *NBSC 539(8):3(1959)*. *41-1451(syn): 9.72₁₀ 5.61₈ 4.69₂ 3.87₃ 3.48₂ 3.24₂ 2.77₃ 2.56₃*. Crystals prismatic [0001], often without terminal faces, or with {1012}. Colorless to white, yellow to light brown. Cleavage {1010}, perfect. $H = 2-2\frac{1}{2}$. $G = 1.77$. Partly decomposed by water, giving an alkaline solution; easily soluble in dilute acids. Uniaxial (-); $N_O = 1.491$, $N_E = 1.470$ (Franklin); $N_O = 1.466$, $N_E = 1.462$ (Scawt Hill). Franklin, Sussex Co., NJ, with andradite, manganophyllite, and other minerals. Lucky Cuss mine, Tombstone, AZ, as an alteration of Ca-Al silicates. *Near Ettringen, between Mayen and the Lacker See, Rhine, Germany*, in cavities in metamorphosed limestone inclusions in leucite-nepheline tephrite. Scawt Hill, Co. Antrim, Eire. Boissèjour, near Clermont-Ferrand, Puy de Dôme, France(*). N'Chwaning mine, Kuruman manganese district, Cape Prov., South Africa(!), in superb crystals and groups to 20 cm. *RG DII:589, AM 45:1137(1960), MM 39:377(1973)*.

31.10.2.2 Bentorite $\text{Ca}_6(\text{Cr,Al})_2(\text{SO}_4)_3(\text{OH})_{12} \cdot 26\text{H}_2\text{O}$

Named in 1980 for Y. K. Bendor, American geologist, University of California, San Diego. Ettringite group. HEX *P6₃/mmc*. $a = 22.35$, $c = 21.41$, $Z = 8$, $D = 2.021$. *AM 66:637(1981)*. *33-248: 9.66₁₀ 5.59₄ 3.89₁ 3.60₁ 3.23₁ 2.77₁ 2.21₁ 1.94₂*. Minute hexagonal prisms with {1011} {1010}, twinning on {1010}. Bright violet, very pale violet streak, vitreous luster. Cleavage {1010}, perfect; {0001}, distinct. $H = 2$. $G = 2.025$. Uniaxial (+); $N_O = 1.478$, $N_E = 1.484$; absorption $E > O$; positive elongation. O, nearly colorless; E, pale violet. *Hatrurim formation, southern Israel*, as a fracture filling cutting calcite-spurrite marble, with brownmillerite, mayenite, and other phases. *RG IJES 29:81(1980)*.

31.10.3.1 Zaherite $\text{Al}_{12}(\text{SO}_4)_5(\text{OH})_{26} \cdot 20\text{H}_2\text{O}$

Named for M. A. Zaher, Geological Survey of Bangladesh, who discovered the mineral. TRIC *P1* or *P1*. $a = 18.475$, $b = 19.454$, $c = 3.771$, $Z = 1$, $D = 2.006$. *MM 49:145(1985)*. *38-379: 18.1₁₀ 9.56₁ 9.08₁ 4.82₁ 4.61₁ 4.56₁ 4.44₁ 3.22₁*. Densely packed aggregates of small grains; in pure veinlets, micro- to microcrystalline. Chalk white to light bluish green, pearly to earthy luster. Well-developed cleavage in one direction. $H = 3\frac{1}{2}$. $G = 2.007-2.011$. Biaxial (+); $N_x = 1.498$, $N_z = 1.499$ (Na); 2V moderate. *Salt Range, Pakistan*, in massive kaolinite-boehmite rock, associated with aluminite. In a sillimanite quarry 65 km W of Pofadder, Bushmanland, Cape Prov., South Africa. *RG AM 62:1125(1977), MM 48:131(1984)*.

ZIPPEITE GROUP

The zippeite group minerals are poorly characterized and probably a structurally heterogeneous group with the general formula

where

A = K, Na (and $x = 4$, $n = 4$), or

A = Mg, Ni, Co, Zn (and $x = 2$, $n = 16$)

CM 14:429(1976).

ZIPPEITE GROUP

Mineral	Class	
Zippeite	Monoclinic	31.10.4.1
Sodium zippeite	Orthorhombic (?)	31.10.4.2
Magnesium zippeite	Orthorhombic (?)	31.10.4.3
Nickel zippeite	Orthorhombic (?)	31.10.4.4
Zinc zippeite	Orthorhombic (?)	31.10.4.5

Note: The minerals are all very fine grained, and single-crystal work on natural material has not been possible.

31.10.4.1 Zippeite $\text{K}_4(\text{UO}_2)_6(\text{SO}_4)_3(\text{OH})_{10} \cdot 4\text{H}_2\text{O}$

Named for Franz Xaver Maxmillian Zippe (1791–1863), Austrian mineralogist. *MON C2/m*. $a = 8.81$, $b = 14.13$, $c = 8.85$, $\beta = 104.25^\circ$, $Z = 2$, $D = 3.68$. *AM 37:394(1952)*. *29-1062*: 7.06_{10} 5.45_3 3.66_3 3.50_9 3.12_8 2.87_4 2.65_4 2.22_4 . Crystals (syn) are flat plates {010} with elongate, doubly terminated, rhombic outline. Twinning on {001}. Naturally, the mineral forms fine-grained pulverulent crusts, and is rather common underground in uranium mines but rare in collections. Orange-yellow. $H = 2$. $G = 3.66$. Fluorescent bright yellow, LWUV or SWUV. Highly radioactive. Fairly soluble in acid waters. Biaxial (-); $X = b$; $Z \wedge a = 3^\circ$; $N_x = 1.655$, $N_y = 1.717$, $N_z = 1.765$. X, colorless; Y, pale yellow; Z, yellow. The cell parameters and optics herein given for zippeite were determined for crystals synthetically grown whose identity as zippeite is not certain, since no analysis was made for K and the formula assumed at that time (1951) was incorrect. Nevertheless, based on powder data and other factors, it is considered probable that this synthetic material was zippeite. Gilpin Co., CO; Eldorado mine, Great Bear Lake, NWT, Canada; La Crouzille, Haute-Vienne, and Ronchamp, Haute-Saone, France. *Jachymov (St. Joachimsthal), Bohemia, Czech Republic*; Cornwall, England. *RG MM 43:539(1979)*.

31.10.4.2 Sodium Zippeite $\text{Na}_4(\text{UO}_2)_6(\text{SO}_4)_3(\text{OH})_{10} \cdot 4\text{H}_2\text{O}$

Named in 1976 from the composition. Probably ORTH Space group unknown. 29-1285(syn): 7.34₁₀ 3.75₁ 3.66₅ 3.49₄ 3.15₄ 2.86₂ 2.12₁ 1.75₁. Velvety crusts of minute crystals; earthy. Yellow, dull luster. Cleavage parallel to flattening of grains, perfect. $G > 3.3$. Fluoresces bright yellow under LWUV or SWUV. Optically, the crystal grains conform to orthorhombic symmetry. Biaxial (-); $N_x = 1.63$; the acute bisectrix X is perpendicular to the plane of flattening and cleavage, {010}, with Z parallel to the elongation or *c* axis; 2V moderate to large; pleochroic. X, colorless to pale yellow; Y, yellow; Z, dark yellow to golden yellow. Twinning is common. Sodium zippeite is the commonest member of the group. From many mines on the Colorado Plateau, including the Happy Jack mine, White Canyon, San Juan Co., UT; Delta mine, San Rafael Swell, Emery Co., UT; Fruita, CO; Jachymov, Bohemia, Czech Republic. RG CM 14:429(1976).

31.10.4.3 Magnesium Zippeite $\text{Mg}_2(\text{UO}_2)_6(\text{SO}_4)_3(\text{OH})_{10} \cdot 16\text{H}_2\text{O}$

Named in 1976 for the composition. Probably ORTH Space group unknown. 29-876: 9.7₁ 7.2₈ 3.58₁₀ 3.48₈ 3.11₆ 2.88₂ 2.74₃ 2.52₂. Orange-yellow. Physical properties like sodium zippeite. $N_x = 1.70$ –1.75; other optics like those of sodium zippeite. A complete solid-solution series probably exists between the Mg, Co, and Ni members. *Lucky Strike No. 2 mine, Emery Co., UT*. RG CM 14:429(1976), MM 43:539(1979).

31.10.4.4 Nickel Zippeite $\text{Ni}_2(\text{UO}_2)_6(\text{SO}_4)_3(\text{OH})_{10} \cdot 16\text{H}_2\text{O}$

Named in 1976 for the composition. Probably ORTH Space group unknown. 29-1434(syn): 7.21₁₀ 3.94₁ 3.59₅ 3.47₂ 3.12₃ 2.65₁ 2.49₁ 1.96₁. Habit similar to sodium zippeite. Dark yellow to tan. Physical properties and optics similar to magnesium zippeite. *Happy Jack mine, White Canyon, San Juan Co., UT*, with sodium zippeite, uranopilite, johannite, and zeunerite. Eldorado mine, Great Bear Lake, NWT, Canada. Jachymov, Bohemia, Czech Republic. RG CM 14:426(1976), MM 43:539(1979).

31.10.4.5 Zinc Zippeite $\text{Zn}_2(\text{UO}_2)_6(\text{SO}_4)_3(\text{OH})_{10} \cdot 16\text{H}_2\text{O}$

Named in 1976 for the composition. Probably ORTH Space group unknown. 29-1395(syn): 9.62₃ 7.08₁₀ 4.84₁ 3.54₅ 3.44₄ 3.10₃ 2.47₂ 1.94₂. Habit, color, and physical properties similar to sodium zippeite. Optics similar to magnesium zippeite. *Hillside mine, Bagdad, Yavapai Co., AZ*, associated with sodium zippeite as yellow, orange, and reddish-brown coatings on quartzose ore containing disseminated sulfides and uraninite. RG CM 14:428(1976), MM 43:539(1979).

31.10.4.6 Cobalt Zippeite $\text{Co}_2(\text{UO}_2)_6(\text{SO}_4)_3(\text{OH})_{10} \cdot 16\text{H}_2\text{O}$

Named in 1976 for the composition. Probably ORTH Space group unknown. 29-520(syn): 7.21₁₀ 3.94₁ 3.59₅ 3.47₂ 3.12₃ 2.65₁ 2.49₁ 1.96₁. Velvety crusts of

minute crystals, botryoidal coatings, earthy. Color, physical properties, and optics similar to those of nickel zippeite. *Happy Jack mine, White Canyon, San Juan Co., UT.* RG *CM 14:429(1976)*, MM *43:539(1979)*.

COPIAITE GROUP

The copiaite minerals have the general formula

where

A = either divalent ions Fe, Mg, Cu, Ca, or Zn, or the trivalent elements Fe³⁺ or Al and the space group is *P1*. The structure of these very rare minerals is described in *AM 58:314(1973)*.

COPIAPITE (magnesio): $MgFe_4^{3+}(SO_4)_6(OH)_2 \cdot 20H_2O$

Layers of $Mg(H_2O)_6$ octahedra alternating with layers containing octahedra Fe^{3+} and sulfate on (010). Layer sequence is ABA ABA . . . , where A is Fe-sulfate and B is $Mg(H_2O)_6$. Only hydrogen bonds join layers.

COPIAPITE GROUP

Mineral	Formula	Space Group	Space							
			a	b	c	α	β	γ	D	
Copiapite	$\text{Fe}^{2+}\text{Fe}_4^{3+}(\text{SO}_4)_6(\text{OH})_2 \cdot 20\text{H}_2\text{O}$	$\bar{P}1$	7.337	18.76	7.379	91.28	102.11°	98.57	2.118	31.10.5.1

31.10.5.1 Copiapite $\text{Fe}^{2+}\text{Fe}_4^{3+}(\text{SO}_4)_6(\text{OH})_2 \cdot 20\text{H}_2\text{O}$

Named in 1833 for the locality. Copiapite group. $\text{TRI } \bar{P}1$. $a = 7.337$, $b = 18.76$, $c = 7.379$, $\alpha = 91.47^\circ$, $\beta = 102.18^\circ$, $\gamma = 98.95^\circ$, $Z = 1$, $D = 2.118$. *NJMM:158(1983)*. 35-583; 18.4₁₀ 9.23₁₀ 6.15₆ 5.57₇ 5.32₃ 4.20₄ 3.58₆ 3.49₆. Crystals tabular {010}, sometimes highly modified; in loose aggregations of scales, granular or incrusting. Sulfur-yellow to orange; when massive, greenish yellow to olive-green; pearly luster on {010}. Cleavage {010}, perfect; {101}, imperfect. $H = 2\frac{1}{2}$ -3. $G = 2.1$. Easily soluble in water, forming a yellow solution which becomes turbid on heating; in CT affords abundant water. Biaxial (+); X perpendicular to {010}; Y = {101}; Z = {101}; $N_x = 1.509$, $N_y = 1.532$, $N_z = 1.577$; $2V = 73^\circ$; $r > v$, strong. X, greenish yellow to yellow; Y, yellow to colorless; Z, sulfur-yellow to yellow-green. In CA at the Redington mine, Knoxville, Napa Co.; at Sulfur Bank hot springs, Lake Co.; at the Island Mt. copper mine, Trinity Co. Comstock Lode, NV. Copper Queen mine, Bisbee, AZ. Goslar, Harz, Germany. Falun, Sweden. Vigneria and Capo Calamita, Elba, Italy. Common in coal mines in France, especially near Commentry, Plateau Central. *Tierra Amarilla, near Copiapo, Chile*, with melanterite, fibroferrite, alunogen, halotrichite, and other sulfates; also at Alcaparrosa, Quetena, and Chuquicamata. *RG DII:623, ZK 135:34(1972), AM 58:314(1973), CM 23:53(1985)*.

31.10.5.2 Magnesiocopiapite $\text{MgFe}_4^{3+}(\text{SO}_4)_6(\text{OH})_2 \cdot 20\text{H}_2\text{O}$

Named in 1938 for the composition and relationship to copiapite. Copiapite group. $\text{TRI } \bar{P}1$. $a = 7.342$, $b = 18.818$, $c = 7.389$, $\alpha = 91.45^\circ$, $\beta = 102.15^\circ$, $\gamma = 98.85^\circ$, $Z = 1$, $D = 2.05$. *ZK 135:34(1972)*. 42-599; 18.6₉ 9.3₁₀ 6.19₅ 5.60₈ 4.21₄ 4.03₃ 3.59₅ 3.51₄. Habit, physical properties, tests as for copiapite. $G = 2.04$. Biaxial (+); $N_x = 1.507$, $N_y = 1.529$, $N_z = 1.576$; $2V = 67^\circ$. With amarantite in the *Santa Maria Mts., near Blythe, Riverside Co., CA*. Laird Post, BC, Canada. Falun, Sweden. *RG DII:623, CM 23:53(1985)*.

31.10.5.3 Cuprocopiapite $\text{CuFe}_4^{3+}(\text{SO}_4)_6(\text{OH})_2 \cdot 20\text{H}_2\text{O}$

Named in 1938 for the composition and relation to copiapite. Copiapite group. TRI P1. $a = 7.31$, $b = 18.15$, $c = 7.25$, $\alpha = 92.5^\circ$, $\beta = 102.3^\circ$, $\gamma = 100.4^\circ$, $Z = 1$, $D = 2.26$. CM 23:55(1985). 19-394: 8.81₈ 6.32₄ 5.82₅ 3.90₃ 3.76₃ 3.56₁₀ 3.29₃ 3.08₄. Small crystals, rounded masses. Yellowish green. $G = 2.154$. Biaxial (+); $N_x = 1.558$, $N_y = 1.575$, $N_z = 1.620$; $2V = 63^\circ$. Chuquicamata, Antofagasta, Chile. RG AM 23:737(1938), DII:623.

31.10.5.4 Ferricopiapite $(\text{Fe}^{3+}, \text{Al})_{2/3}\text{Fe}_4^{3+}(\text{SO}_4)_6(\text{OH})_2 \cdot 20\text{H}_2\text{O}$

Named in 1938 for the composition and relation to copiapite. Copiapite group. TRI P1. $a = 7.390$, $b = 18.213$, $c = 7.290$, $\alpha = 93.7^\circ$, $\beta = 102.2^\circ$, $\gamma = 99.3^\circ$, $Z = 1$, $D = 2.123$. AM 58:314(1973). 29-714: 18.4₇ 9.06₁₀ 6.04₇ 5.58₈ 5.39₅ 4.03₅ 3.58₈ 3.53₇. Yellow. $H = 2\frac{1}{2}$ -3. $G = 2.1$. Biaxial (+); $N_x = 1.531$, $N_y = 1.546$, $N_z = 1.597$; $2V = 52^\circ$. Coso Hot Spring, Inyo Co., CA. Tierra Amarilla, Copiapó, Chile. RG DII:625, CM 23:53(1985).

31.10.5.5 Calcicopiapite $\text{CaFe}_4^{3+}(\text{SO}_4)_6(\text{OH})_2 \cdot 20\text{H}_2\text{O}$

Named in 1960 for the composition and relation to copiapite. Copiapite group. TRI P1. $a = 7.44$, $b = 18.79$, $c = 7.22$, $\alpha = 85.3^\circ$, $\beta = 104.7^\circ$, $\gamma = 102.2^\circ$, $Z = 1$, $D = 2.159$. CM 23:55(1985). 27-77: 3.46₉ 3.11₁₀ 3.03₁₀ 2.81₁₀ 1.86₁₀ 1.30₉ 1.27₉ 1.24₉. The lack of powder lines of high value, normal to other members of the copiapite group, suggests that such lines may have been obscured during the examination of calcicopiapite; further study is needed. Powdery crusts. Grayish to brownish yellow. Dashkesan, middle Caucasus, Azerbaijan, as a supergene product of weathering of magnetite ores containing pyrite and calcite. RG AM 47:807(1962).

31.10.5.6 Zincopiapite $\text{ZnFe}_4^{3+}(\text{SO}_4)_6(\text{OH})_2 \cdot 20\text{H}_2\text{O}$

Named in 1964 for the composition and relation to copiapite. Copiapite group. TRIC P1. $a = 7.33$, $b = 18.72$, $c = 7.35$, $\alpha = 91.5^\circ$, $\beta = 102.1^\circ$, $\gamma = 98.7^\circ$, $Z = 1$, $D = 2.09$. AM 49:1777(1964). 45-1323: 18.2₁₀ 9.06₉ 6.55₃ 6.06₅ 5.71₄ 5.20₃ 4.87₃ 3.57₅. Compact, massive aggregates of crystals. Yellowish green, vitreous luster. $H = 2$. $G = 2.181$. Biaxial (+); $N_x = 1.534$, $N_y = 1.554$, $N_z = 1.586$; $2V = 78^\circ$; $r > v$. Xitianshan lead-zinc mine, Qaidam Basin, Qinghai Prov., China, with copiapite, halotrichite, coquimbite, roemerite, sideronatriite, and melanterite. RG AGS 44:100(1964), IGR 10:917(1968), CM 23:53(1985).

31.10.5.7 Aluminocopiapite $(\text{Al}, \text{Mg})_{2/3}\text{Fe}_4^{3+}(\text{SO}_4)_6(\text{OH})_2 \cdot 20\text{H}_2\text{O}$

Named in 1947 for the composition and relation to copiapite. Copiapite group. TRI P1. $a = 7.30$, $b = 18.80$, $c = 7.31$, $\alpha = 91.5^\circ$, $\beta = 102.3^\circ$, $\gamma = 98.7^\circ$, $Z = 1$, $D = 2.07$. CM 23:55(1985). 20-659: 18.1₈ 9.2₁₀ 6.17₇ 5.58₈ 5.32₃ 4.68₃ 3.58₅ 3.50₅. Minute scales and earthy blooms. Lemon yellow, pearly luster on {010}. Cleavage {010}, perfect; {101}, imperfect. $H = 2\frac{1}{2}$ -3. Soluble in water; in CT,

gives acid water. Biaxial (+); $N_y = 1.535$, $N_z = 1.585$; 2V moderate; $r > v$, strong. Y, colorless; Z, greenish yellow. *Island Mt., Trinity Co., CA*. Northern bank of Mosquito Fork of the Forty Mile R., AK. RG *DII:625, AM 52:1220(1967)*.

31.10.6.1 Honessite $Ni_6Fe_2^{3+}(OH)_{16}(SO_4) \cdot 4H_2O$

Named in 1959 for Arthur P. Honess (1886–1942), Pennsylvania State University. HEX-R *R3m* or *R3m*. $a = 3.083$, $c = 26.71$. *MM 44:340(1981)*. *42-573*: 8.84₁₀ 4.43₄ 2.65₁ 2.62₂ 2.39₁ 2.09₁ 1.54₂ 1.52₂ Fine-grained coatings and masses with a microfibrinous structure. Orange to yellow, reddish, green; dull luster. Soft. Slowly soluble in weak, cold acids; rapidly so in concentrated acids. Uniaxial; $N = 1.615$ – 1.635 . Honessite is derived from the oxidation of millerite and other primary nickel minerals. *Linden, Iowa Co., WI*, as coatings in the oxidized portion of lead deposits containing traces of nickel; also at Dodgeville, Shullsburg, and Galena. Hagdale, Unst, Shetland, Scotland, on nickeliferous chromite, associated with reevesite. RG *AM 44:995(1959)*, *BM 103:170(1980)*.

31.10.7.1 Hydrohonessite $Ni_6Fe_2^{3+}(SO_4)(OH)_{16} \cdot 7H_2O$

Named in 1981 to indicate its relationship to honessite. HEX Space group unknown. $a = 3.09$, $c = 10.80$. *36-382*: 11.0₁₀ 5.56₅ 3.68₄ 2.71₃ 2.60₂ 2.39₂ 2.15₁ 1.91₁. Thin incrustations of tiny hexagonal plates. Bright yellow. Soluble in dilute acids. Uniaxial (-); $N_O = 1.63$, $N_E = 1.59$. *Otter Shoot nickel mine, Kambalda, WA, Australia*; also from the Carr Boyd mine, Kambalda. Unst, Shetland, Scotland. RG *MM 44:333(1981)*, *AM 67:623(1982)*.

31.10.8.1 Clairite $(NH_4)_2Fe_3^{3+}(SO_4)_4(OH)_3 \cdot 3H_2O$

Named in 1983 for Claire Martini, South African, wife of the describer of the species, Jacques Edouard Martini. TRIC *P1* or *P1*. $a = 9.368$, $b = 9.150$, $c = 52.610$, $\alpha = 88.15^\circ$, $\beta = 90^\circ$, $\gamma = 118.37^\circ$, $Z = 8$, $D = 2.32$. *39-1388*: 17.5₁₀ 8.78₁₀ 8.23₂ 7.76₁ 7.31₁ 3.42₂ 3.28₃ 3.04₂. Yellow. Cleavage {001}, perfect. $G = 2.31$. Biaxial; X parallel to c ; $N_x = 1.595$, $N_z = 1.607$. X, pale yellow; Z, dark yellow. Formed by reaction of the oxidation products of pyrite with ammonia produced by the decay of organic matter. *Lone Creek Fall cave, near Sabri, eastern Transvaal, South Africa*. RG *AM 71:229(1986)*.

31.10.9.1 Caminite $MgSO_4 \cdot xMg(OH)_2 \cdot yH_2O$

Named in 1983 from the Latin *caminus*, chimney, in allusion to its mode of occurrence. TET *I4₁/amd*. $a = 5.239$, $c = 12.988$, $Z = 4$, $D = 2.145$. *AM 71:819(1986)*. *39-359*: 3.35₁₀ 3.22₈ 2.06₂ 2.04₂ 1.87₅ 1.85₂ 1.67₂ 1.62₃. Colorless or white. Cleavage {001}, good. $H = 2\frac{1}{2}$. $G = 2.5$. Uniaxial (-); $N_O = 1.534$, $N_E = 1.532$. Caminite is precipitated from seawater as part of the structure of "black smoker" chimneys on the *East Pacific Rise, 21° N latitude, 2600 m depth*. It is associated with anhydrite of similar origin and various sulfides. RG *GCA 47:2053(1983)*.

Compound Sulfates

32.1.1.1 Burkeite $\text{Na}_6(\text{SO}_4)_2\text{CO}_3$

Named in 1921 for William Edmund Burke (1880–1966), chemical engineer, American Potash and Chemical Co., who discovered the artificial salt. ORTH *Pmnm*. $a = 5.167$, $b = 9.215$, $c = 7.055$, $Z = 2$, $D = 2.61$. *NBSM* 25(11):52(1974). 24-1134: 3.85₄ 3.80₈ 3.53₈ 2.80₁₀ 2.78₆ 2.64₈ 2.58₈ 1.93₃. Crystals tabular {100}, reticular aggregates of platy crystals, massive, as nodules; twinning common as X-shaped interpenetration twins, on {110}. White to pale buff or grayish; vitreous to greasy luster, like cryolite. Conchoidal fracture, brittle. $H = 3\frac{1}{2}$. $G = 2.57$. Soluble in cold water, easily fusible. Biaxial (-); $XYZ = cab$; $N_x = 1.448$, $N_y = 1.489$, $N_z = 1.493$; $2V = 34^\circ$; $r > v$, distinct. In artificial material (SO_4) and (CO_3) can substitute mutually over a wide range. *Searles Lake, San Bernardino Co., CA*, in drill cuttings from a clay stratum, associated with gaylussite, trona, sulfohalite, borax, northupite, and other salts. *Konya basin, central Anatolia, Turkey*, with halite and trona. *Eastern shore of Lake Turkmana, northern Kenya*. RG *DII:633, MM* 43:341(1979), *NJMM:203(1988)*.

32.1.2.1 Hectorfloresite $\text{Na}_9(\text{SO}_4)_4(\text{IO}_3)$

Named in 1989 for Hector Flores W. (1906–1984), Chilean geologist and professor, University of Chile. MON Space group unknown. $a = 18.775$, $b = 6.936$, $c = 14.239$, $\beta = 108.92^\circ$, $Z = 4$, $D = 2.90$. *AM* 74:1207(1989). *PD*: 6.17₁ 4.69₂ 3.88₁₀ 2.79₃ 2.70₈ 1.94₂ 1.68₁ 1.56₁. *PD(syn)*: 4.68₃ 3.88₆ 2.79₂ 2.70₁₀ 2.37₁ 2.34₁ 2.16₁ 1.94₁. Minute, prismatic crystals, elongated [010], with multiple twinning to give a pseudo-hexagonal morphology. White. No cleavage, conchoidal fracture, brittle. $H = 2$. $G = 2.80$. Biaxial (-); $N_x = 1.493$, $N_y = 1.521$, $N_z = 1.523$ (Na); $2V = 26^\circ$; $r < v$, faint. *Alianza nitrate mine, Oficina Victoria, Tarapacá, Chile*, associated with darapskite, nitratine, bloedite, halite, and glauberite. RG

32.1.3.1 Olsacherite $\text{Pb}_2(\text{SO}_4)(\text{SeO}_4)$

Named in 1969 for Juan A. Olsacher (1903–1964), Argentine mineralogist, University of Cordoba. Barite group. See barite (28.3.1.1). ORTH *P222*₁. $a = 8.42$, $b = 10.96$, $c = 7.00$, $Z = 4$, $D = 6.55$. *AM* 54:1523(1969). Isostructural with barite. 22-1135: 4.32₄ 3.85₅ 3.34₁₀ 3.23₁₀ 3.02₁₀ 2.79₆ 2.09₇ 2.04₄.

Acicular crystals, terminated by steep pyramids, elongated [010]. Colorless, vitreous luster. Cleavage {101}, good; {010}, fair; very brittle. $H = 3-3\frac{1}{2}$. Biaxial (-); $XYZ = acb$; $N_x = 1.935$, $N_y = 1.966$, $N_z = 1.983$ (N_a); $2V = 80^\circ$; no dispersion. Tests with synthetic lead selenate-sulfates indicate that (SO_4) and (SeO_4) can mutually substitute to a limited but unquantified extent. *Pacajake mine, Hiaco, Bolivia*, associated with cerussite, anglesite, wulfenite, chalcomenite, ahlfeldite, and selenium; also from the El Dragon mine, Potosi. Cachueta, Mendoza, Argentina. RG

32.2.1.1 Rapidcreekite $Ca_2(SO_4)(CO_3) \cdot 4H_2O$

Named in 1986 for the locality. ORTH *Pbcn*. $a = 15.49$, $b = 19.18$, $c = 6.157$, $Z = 8$, $D = 2.239$. *CM 24:51(1986)*. *39-351: 7.78₁₀ 4.31₇ 3.88₇ 3.11₈ 2.92₅ 2.80₆ 2.56₅ 1.90₅*. Acicular crystals, as sprays and crystalline coatings. White, vitreous luster. Cleavage {010}, perfect; {100}, good; splintery fracture; brittle. $H = 2$. $G = 2.21$. Nonfluorescent. Biaxial (+); $XYZ = cab$; $N_x = 1.516$, $N_y = 1.518$, $N_z = 1.531$; $2V = 45^\circ$. *Rapid Creek, Big Fish river area, YT, Canada*, along the valley of a tributary (*Crescent Creek*), with gypsum and aragonite on joint surfaces of siderite iron formation. RG *AM 72:224(1987)*.

32.2.2.1 Humberstonite $Na_7K_3Mg_2(SO_4)_6(NO_3)_2 \cdot 6H_2O$

Named in 1970 for James Thomas Humberstone (1850-1939), who worked on the saline minerals of the Chilean nitrate deposits. HEX-R *R*. $a = 10.900$, $c = 24.410$, $Z = 3$, $D = 2.252$. *AM 55:1518(1970)*. *21-682: 8.80₄ 8.14₆ 7.47₃ 4.53₄ 4.07₃ 3.39₁₀ 2.72₇ 2.58₄*. Minute crystals, platy {0001}, in aggregates. Colorless, vitreous luster. Cleavage {0001}, perfect; irregular fracture; brittle. $H = 2\frac{1}{2}$. $G = 2.252$. Nonfluorescent. Soluble in water, insoluble in acetone or alcohol. Uniaxial (-); $N_O = 1.474$, $N_E = 1.436$. *Talial nitrate district, Atacama desert, Chile*, at several places, associated with bloedite and nitratine. RG *KUS 5:190(1969)*, *AM 55:1072(1970)*.

32.2.3.1 Ungemachite $K_3Na_9Fe^{3+}(SO_4)_6(NO_3)_2 \cdot 6H_2O$

Named in 1936 for Henri-Leon Ungemach (1880-1936), Belgian crystallographer. HEX-R *R*. $a = 10.898$, $c = 24.989$, $Z = 3$, $D = 2.259$. *AM 71:826(1986)*. *20-1326: 8.82₃ 8.33₆ 7.55₃ 3.43₁₀ 2.96₂ 2.72₆ 2.59₄ 1.88₃*. Crystals thick tabular {0001} with numerous rhombohedral forms. Colorless to pale yellow, vitreous luster. Cleavage {0001}, perfect; irregular fracture; brittle. $H = 2\frac{1}{2}$. $G = 2.287$. Easily soluble in dilute HCl. Uniaxial (-); $N_O = 1.502$, $N_E = 1.449$. *Chuquicamata, Antofagasta, Chile*, as vein fillings and in cavities in jarosite and metasideronatriite, associated with metavoltine, fibroferrite, and sodium alum. RG *DII:596*.

32.3.1.1 Hanksite $KNa_{22}(SO_4)_9(CO_3)_2Cl$

Named in 1885 for Henry G. Hanks (1826-1907), a state mineralogist of California. HEX *P6₃/m*. $a = 10.465$, $c = 21.191$, $Z = 2$, $D = 2.585$. *AM 58:799(1973)*. Structure: *AC(B) 28:3614(1972)*. *25-1348: 3.81₁₀ 3.53₈ 3.43₆*

2.93₃ 2.87₂ 2.79₇ 2.62₅ 2.45₂. Hexagonal prismatic crystals {100}, with {102} as quartzoids; also tabular {0001}, often of large size; as interpenetrating groups. Colorless, sometimes slightly yellow or gray due to included clay; vitreous to dull luster. Cleavage {0001}, good; uneven fracture; brittle. $H = 3 - 3\frac{1}{2}$. $G = 2.562$. Weakly fluorescent pale yellow in LWUV. Soluble in water, effervesces weakly in dilute acids, easily fusible. Tastes saline. Uniaxial (-); $N_O = 1.481$, $N_E = 1.461$. Abundant at *Searles Lake, San Bernardino Co., CA*, associated with halite, borax, trona, and apthitalite. Also reported from Death Valley. RG *DII:628*.

32.3.2.1 Caledonite $Cu_2Pb_5(SO_4)_3(CO_3)(OH)_6$

Named in 1932 from *Caledonia* (an ancient name for Scotland), because it was found in Scotland. ORTH $Pmn2_1$. $a = 20.089$, $b = 7.146$, $c = 6.560$, $Z = 2$, $D = 5.689$. Structure: *AC(B) 29:1986(1973)*. *29-565*: 4.69₆ 3.15₄ 3.14₁₀ 3.03₆ 2.75₅ 2.27₃ 2 23₄ 1.86₆. Prismatic crystals, elongated [001]; often striated and with vicinal faces in [001] zone. Deep verdigris green or bluish green, resinous luster. Cleavage {010}, perfect; {100}, {101}, incomplete; uneven fracture; brittle. $H = 2\frac{1}{2} - 3$. $G = 5.76$. Dissolves with effervescence in nitric acid, leaving a residue of lead sulfate; in CT decrepitates and affords water. Biaxial (-); $XYZ = cab$; $N_x = 1.818$, $N_y = 1.866$, $N_z = 1.909$; weakly pleochroic; $2V = 85^\circ$; $r < v$, faint. Found in small amounts in the oxidized zone of copper-lead deposits, with cerussite, anglesite, linarite, leadhillite, malachite, azurite, and other sulfates-carbonates. Mammoth mine(I), Tiger, AZ; Organ District, Dona Ana Co., NM; Cerro Gordo, Inyo Co., CA; Talisman mine, Beaver Creek, UT; *Leadhills(I), Lanarkshire, Scotland*. Red Gill, Cumberland, England. Malacalzetta, Iglesias, and Tiny Arenas, Sardinia, Italy. Preobrazhenskyi mine, Berezovsk, Ural Mts., Russia. Tchah Mille, Anarak, Iran(I), crystals to 1 cm. Chalcollo, Sierra Gorda, Atacama, Chile. RG *DII:630, NW 57:127(1970), MM 40:536(1976)*.

32.3.3.1 Wherryite $CuPb_4O(SO_4)_2(CO_3)(OH,Cl)_2$

Named in 1950 for Edgar T. Wherry (1885-1982), American mineralogist and plant ecologist. MON $P2_1/m$. $a = 20.82$, $b = 5.79$, $c = 9.17$, $\beta = 91.28^\circ$, $Z = 4$, $D = 7.22$. *AM 55:505(1970)*. *23-218*: 4.78₄ 4.57₄ 3.22₂ 3.16₁₀ 3.06₅ 2.90₃ 2.75₅ 1.88₄. Usually massive, fine granular; minute crystals, equant to acicular. Light apple-green to yellowish green, light yellow. $G = 6.45$. Slowly soluble in cold HCl or HNO₃. Biaxial (-); $N_x = 1.942$, $N_y = 2.010$, $N_z = 2.024$ (Na); $2V = 50^\circ$. *Mammoth mine, Tiger, Pinal Co., AZ*, with leadhillite, paralauro-nite, diaboileite, chrysocolla, and cerussite. RG *AM 35:93(1950), DII:632, BM 74:528(1951)*.

32.3.4.1 Hauckite $Fe_3^{2+}(Mg, Mn)_{24}Zn_{18}(SO_4)_4(CO_3)_2(OH)_{11} (?)$

Named in 1980 for Richard Hauck (b.1935), New Jersey mineral collector. HEX $P6/mmm$. $a = 9.17$, $c = 30.21$, $Z = 1$, $D = 3.10$. *33-872*: 7.80₉ 5.02₅ 4.57₆ 3.96₁₀ 3.78₅ 3.02₆ 1.75₃ 1.58₂. Crystals simple hexagonal plates {0001}, with

{010}. Bright orange to light yellow, vitreous to slightly pearly luster. Cleavage {0001}, perfect and easy; brittle. H = 2–3. G = 3.02. Nonfluorescent. Uniaxial (+); $N_O = 1.630$, $N_E = 1.638$. O, golden brown; E, pale yellow. *Sterling Hill mine, Ogdensburg, NJ*, associated with phlogopite and mooreite on a calcite–serpentine matrix. RG *AM 65:192(1980)*.

32.3.5.1 Heidornite $\text{Na}_2\text{Ca}_3(\text{SO}_4)_2[\text{B}_5\text{O}_8(\text{OH})_2]\text{Cl}$

Named in 1956 for F. Heidorn, German geologist, who studied the Zechstein formation. MON *C2/c*. $a = 10.21$, $b = 7.84$, $c = 18.79$, $\beta = 93.5^\circ$, $Z = 4$, $D = 2.698$. *NJMM:157(1967)*. 25–805: 3.77₈ 3.11₁₀ 2.96₇ 2.90₆ 2.81₆ 2.74₈ 2.54₆ 1.98₆. Prismatic, spearlike crystals, with {110}, and {111} and {112}. Colorless, vitreous luster. Cleavage {001}, perfect. H = 4–5. G = 2.753. Biaxial (+); $Y = b$; $Z \wedge a = 23^\circ$; $N_x = 1.579$, $N_y = 1.588$, $N_z = 1.604$ (N_a); $2V = 74^\circ$; $r < v$. Found associated with glauberite in a cavity in drill core from 1,968 m depth in the upper anhydrite of the Zechstein formation, on the German–Dutch border, NE of Nordhorn. RG *AM 42:120(1957)*.

32.4.1.1 Nakauriite $(\text{Mn,Ni,Cu})_8(\text{SO}_4)_4(\text{CO}_3)(\text{OH})_6 \cdot 4\text{H}_2\text{O}$

Named in 1976 for the locality. ORTH Space group unknown. $a = 14.585$, $b = 11.47$, $c = 16.22$, $Z = 2$, $D = 2.35$. *AM 62:594(1977)*. 28–538: 7.31₁₀ 7.08₁ 4.84₁ 3.94₁ 3.65₂ 2.40₁ 2.37₂ 1.91₂. Aggregates of minute acicular to fibrous crystals. Sky blue. G = 2.39. Dissolves with effervescence in dilute acids. Biaxial (–); $N_x = 1.585$, $N_y = 1.604$, $N_z = 1.612$ (N_a); $2V = 65^\circ$; parallel to extinction; positive elongation. X, colorless; Y, light greenish blue; Z, pale sky blue. *Nakauri, Achi Pref., Japan*, as veins cutting massive serpentinite, associated with chrysotile, magnetite, pyroaurite, and artinite. RG *AM 67:156(1982)*.

32.4.2.1 Tatarskite $\text{Ca}_6\text{Mg}_2(\text{SO}_4)_2(\text{CO}_3)_2\text{Cl}_4(\text{OH})_4 \cdot 7\text{H}_2\text{O}$

Named in 1963 for Vitalii Borisovich Tatarskii (b.1907), Russian mineralogist, Leningrad University. Probably ORTH Space group unknown. 15–785: 5.34₈ 2.97₁₀ 2.92₇ 2.63₉ 2.52₆ 2.31₆ 2.00₈ 1.59₇. Coarsely crystalline masses. Colorless; vitreous luster, pearly on cleavage. Two pinacoidal cleavages, fair. H = 2½. G = 2.341. Soluble in boiling water or cold dilute HCl. Biaxial (–); $N_x = 1.567$, $N_y = 1.654$, $N_z = 1.722$; $2V = 83^\circ$; parallel to extinction; positive elongation. From drill core in the *Caspian Depression, Kazakhstan*, at depths of 850–900 m in anhydrite rock, associated with halite, bischofite, magnesite, hilgardite, and strontiohilgardite. RG *ZVMO 92:697(1964)*, *AM 49:1151(1964)*.

32.4.3.1 Mountkeithite

$(\text{Mg,Ni})_{11}(\text{Fe}^{3+},\text{Cr})_3(\text{SO}_4,\text{CO}_3)_{35}(\text{OH})_{24} \cdot 11\text{H}_2\text{O}$

Named in 1981 for the locality. HEX Space group unknown. $a = 10.698$, $c = 22.545$, $Z = 2$, $D = 1.95$. *MM 44:345(1981)*. 41–578: 11.30₁₀ 5.63₈ 4.63₂ 3.76₆ 2.65₄ 2.55₄ 1.55₅ 1.51₃. Flaky grains and crusts; scales; rosettes. Pale

pink to white, pearly luster. $G = 2.12$. Uniaxial (-); $N_O = 1.52$, $N_E = 1.51$. *Mount Keith nickel deposit, 400 km NNW of Kalgoorlie, WA, Australia*, associated with stichtite, hexahydrite, and morenosite on a bleached serpentinite matrix. RG

32.4.4.1 Charlesite $\text{Ca}_6\text{Al}_2(\text{SO}_4)_2[\text{B}(\text{OH})_4](\text{OH},\text{O})_{12} \cdot 26\text{H}_2\text{O}$

Named in 1983 in honor of Charles Palache (1869–1954), professor of mineralogy, Harvard University. Ettringite group. See ettringite (31.10.2.1). HEX-R P31c. $a = 11.16$, $c = 21.21$, $Z = 2$, $D = 1.79$. 35-606: 9.70₁₀ 5.58₈ 4.65₄ 3.85₈ 2.75₇ 2.54₇ 2.19₇ 2.13₅. Crystals are hexagonal bipyramids with {104} only. Colorless to white, vitreous luster. Cleavage {101}, perfect; brittle. $H = 2\frac{1}{2}$. $G = 1.77$. Weakly fluorescent in SWUV, light violet or light green. Uniaxial (-); $N_O = 1.492$, $N_E = 1.475$. *Franklin, Sussex Co., NJ*, on the 800 level close to the Palmer shaft, associated with willemite, rhodonite, ganophyllite, pectolite, and grossular. RG *AM 68:1033(1983)*.

32.4.4.2 Sturmanite $\text{Ca}_6\text{Fe}_2^{3+}(\text{SO}_4)_2\text{Al}_2[\text{B}(\text{OH})_4]_{12}(\text{OH})_{12} \cdot 25\text{H}_2\text{O}$

Named in 1983 for B. Darko Sturman (b.1937), Canadian mineralogist, Royal Ontario Museum, Toronto. Ettringite group. See ettringite (31.10.2.1). HEX-R P31c. $a = 11.16$, $c = 21.79$, $Z = 2$, $D = 1.855$. 35-637: 9.67₁₀ 5.58₇ 4.75₂ 3.89₇ 2.77₅ 2.58₆ 2.22₅ 2.16₄. Crystals are simple hexagonal bipyramids with {104} and traces of {114}. Bright yellow, vitreous luster. Cleavage {100}, perfect; brittle. $H = 2\frac{1}{2}$. $G = 1.847$. Nonfluorescent. Uniaxial (+); $N_O = 1.500$, $N_E = 1.505$. O, pale green; E, pale yellowish green. Some crystals zoned, with cores uniaxial (-); $N_O = 1.499$, $N_E = 1.497$. In the structure of sturmanite there is some substitution of $[\text{B}(\text{OH})_4]^-$ radicals for $(\text{SO}_4)^{2-}$ so that the ratio of (SO_4) to $[\text{B}(\text{OH})_4]$ is not exactly 2:1, thereby preserving charge balance. *Black Rock mine, Kuruman district, Cape Prov., South Africa*, associated with barite and hematite. RG *CM 21:705(1983)*.

32.4.4.3 Jouravskite $\text{Ca}_3(\text{SO}_4)(\text{CO}_3)[\text{Mn}^{4+}(\text{OH})_6] \cdot 12\text{H}_2\text{O}$

Named in 1965 for Georges Jouravsky (1896–1964), chief geologist, Division de la Geologie du Maroc. Ettringite group. See ettringite (31.10.2.1). HEX P6₃. $a = 11.06$, $c = 10.50$, $Z = 2$, $D = 1.93$. The Mn^{4+} is in six-coordination with hydroxyl ions, as in the case of Si^{4+} in thaumasite (32.4.4.4). AC(B) 25:1943(1969). 18-668: 9.60₁₀ 5.53₆ 3.81₆ 3.54₄ 3.42₅ 2.73₅ 2.52₅ 2.17₅. Small groups of grains occurring as spots on other manganese minerals. Greenish yellow to greenish orange. Cleavage {100}, good. $H = 2\frac{1}{2}$. $G = 1.95$. Uniaxial (-); $N_O = 1.556$, $N_E = 1.540$; interference colors abnormal, green and russet. *Tachgagalt No. 2 vein, Anti Atlas, Morocco*, associated with calcite and manganese on a matrix of other manganese minerals. RG *BM 88:254(1965)*, *AM 50:2102(1965)*.

32.4.4.4 Thaumassite $\text{Ca}_3(\text{SO}_4)(\text{CO}_3)[\text{Si}(\text{OH})_6] \cdot 12\text{H}_2\text{O}$

Named in 1878 from the Greek for *astonishment*, in allusion to its remarkable composition, consisting of silicate, carbonate, and sulfate components. Ettringite group. See ettringite (31.10.2.1). *HEX* $P6_3$. $a = 11.030$, $c = 10.396$, $Z = 2$, $D = 1.876$. *NJMM:60(1983)*. The silicon atom is at the center of an octahedron of (OH) radicals. Octahedral coordination of Si by O is rare in minerals formed at ordinary pressures and is ascribed in this instance to the effect of electronegative H atoms attached to the oxygens. This was the first proved example of six-coordination of silicon by hydroxyl. *AC(B) 27:594(1971)*. 25-128: 9.56₁₀ 5.51₄ 3.78₂ 3.41₂ 3.18₂ 2.71₁ 2.57₁ 2.16₁. Massive, rarely as small crystals, fibrous crystalline masses consisting of acicular prismatic crystals. Snow white; dull to earthy, or silky, luster. Cleavage in traces, subconchoidal fracture, brittle. $H = 3\frac{1}{2}$. $G = 1.881$. In CT decrepitates and affords much water. Uniaxial (-); $N_O = 1.507$, $N_E = 1.468$. West Paterson and Great Notch, Passaic Co., NJ, where it is sometimes pseudomorphous after anhydrite. Beaver Co., UT. Crestmore, Riverside Co., CA, with spurrite, ettringite, or monticellite. *Bjelke mine, near Åreskutan*, and Kalls Parish, Jemtland, Sweden, also Långban, Värmland. Sulitelma, Norway. Haslach, Baden, Germany. Halap, Hungary. N'Chwaning mine, Kuruman manganese district, Cape Prov., South Africa(!), in gemmy yellowish crystals to 15 mm. *RG AMG 2(HI-2):137(1957)*, *AM 45:1277(1960)*.

32.4.5.1 Hotsonite $\text{Al}_5(\text{SO}_4)(\text{PO}_4)(\text{OH})_{10} \cdot 8\text{H}_2\text{O}$

Named in 1984 for the locality. Ettringite group, which see *TRIC P1* or $P\bar{1}$. $a = 11.23$, $b = 11.66$, $c = 10.55$, $\alpha = 112.53^\circ$, $\beta = 107.53^\circ$, $\gamma = 64.45^\circ$, $Z = 2$, $D = 2.026$. *AM 69:979(1984)*. 38-366: 10.1₁₀ 8.45₄ 5.20₁ 5.01₁ 4.63₂ 4.43₁ 4.34₁ 3.67₁. Compact masses, chalklike; under high magnification, lathlike crystals. Colorless to white, dull to silky luster. Earthy fracture. $H = 2\frac{1}{2}$. $G = 2.06$. Biaxial; $N_x = 1.519$, $N_z = 1.521$. From the farm *Hotson 42*, about 65 km W of Pofadder, Bushmanland, Cape Prov., South Africa, in a sillimanite quarry, encrusting zaehrite. *RG MM 53:385(1989)*, *ZVMO 119:121(1990)*, *AM 76:1734(1991)*.

32.4.6.1 Chessexite $\text{Na}_4\text{Ca}_2\text{Mg}_3\text{Al}_8(\text{SO}_4)_{10}(\text{SiO}_4)_2(\text{OH})_{10} \cdot 40\text{H}_2\text{O}$

Named in 1982 for Ronald Chessex (b.1929), Swiss petrologist and professor, University of Geneva. Ettringite group, which see *ORTH* Space group unknown. $a = 13.70$, $b = 27.96$, $c = 9.99$, $Z = 2$, $D = 2.21$. *AM 69:406(1984)*. 35-692: 13.9₁₀ 4.85₉ 3.98₆ 3.45₄ 3.42₁₀ 3.32₄ 2.91₃ 2.16₃. Minute crystals, square or rectangular plates. White, silky luster. Biaxial (+); $XYZ = acb$; $N_x = 1.456$, $N_y = 1.460$, $N_z = 1.480$; $2V = 47^\circ$. *Maine mine, Autun, Saône et Loire, France*, coating fluorite. *RG SMPM 62:337(1982)*.

Selenates and Tellurates

33.1.1.1 Schmiederite $\text{Cu}_2\text{Pb}_2(\text{SeO}_3)(\text{SeO}_4)(\text{OH})_4$

Named in 1962 for Oskar Schmieder (b.1891), German geographer, Universidad Nacional at Cordoba, Argentina. Isostructural with linarite. *MON* $P2_1/m$. $a = 9.922$, $b = 5.712$, $c = 9.396$, $\beta = 101.97^\circ$, $Z = 2$, $D = 5.63$. *MP* 36:3(1987). 41-1377: 4.85₄ 4.47₅ 3.53₅ 3.18₁₀ 3.11₈ 2.33₃ 2.11₃ 1.819₃. Fracture fillings and small crystals in vugs, showing prismatic habit; also radial-fibrous tufts of acicular crystals. Light blue, greenish blue. *Condor mine, La Rioja, Argentina*(*). El Dragon mine, Potosi, Bolivia. *RG AM* 49:1498(1964), *SMPM* 67:219(1987).

33.1.2.1 Xocomecatlite $\text{Cu}_3\text{Te}^{6+}\text{O}_4(\text{OH})_4$

Named in 1975 for the Nahuatl for *bunches of grapes*, in allusion to the appearance of the green spherules of the mineral. Probably *ORTH* Space group unknown. $a = 12.140$, $b = 14.318$, $c = 11.662$, $Z = 12$, $D = 4.42$. 29-579: 4.63₁₀ 3.44₄ 3.32₃ 3.10₄ 2.83₃ 2.67₆ 2.63₃ 2.43₄. Minute spherules, to 0.15 mm, of radial-fibrous structures. Emerald-green. Tough. $H = 4$, $G = 4.65$. Nonfluorescent. Biaxial (-); $N_x = 1.775$, $N_y = 1.900$ (rich bluish green), $N_z = 1.920$; $2V = 41^\circ$; low dispersion; absorption $Z > X = Y$. Centennial Eureka mine, Tintic district, Juab Co., UT, as emerald-green crystallized balls. *Bambollita mine, Moctezuma, SON, Mexico*(*), in cracks in altered rhyolite. *RG MM* 40:221(1975), *AM* 61:504(1976).

33.1.3.1 Khinite $\text{Cu}_3\text{PbTe}^{6+}\text{O}_4(\text{OH})_6$

Named in 1978 for Ba Saw Khin (b.1931), Burmese-American geologist and petrographer. Dimorphous with parakhinite. *ORTH* *Fddd*. $a = 5.740$, $b = 9.983$, $c = 23.960$, $Z = 8$, $D = 6.69$. 29-1419: 4.87₈ 3.45₉ 3.00₇ 2.82₆ 2.49₁₀ 2.20₇ 1.92₆ 1.56₆. Minute, bipyramidal crystals. Bottle green. Cleavage {001}, fair; brittle. $H = 3\frac{1}{2}$. $G = 6.5-7.0$. Nonfluorescent. Biaxial (+); $N_x = 2.110$, $N_y = 2.112$, $N_z = 2.165$; $2V = 20^\circ$; strong dispersion; absorption $Z = Y > X$. X, vivid emerald-green; Y,Z, yellowish green. *Tombstone, AZ*, at the *Old Guard mine*; also at the *Empire mine*(!) in green micaceous plates, with parakhinite, gold, hessite, and torbernite. *RG AM* 63:1016(1978).

33.1.4.1 Frankhawthorneite $\text{Cu}_2\text{Te}^{6+}\text{O}_4(\text{OH})_2$

Named in 1995 for Frank C. Hawthorne (b.1946), Canadian mineralogist, University of Manitoba, in recognition of his studies of Cu oxysalts. *MON* $P2_1/n$. $a = 9.095$, $b = 5.206$, $c = 4.604$, $\beta = 98.69^\circ$, $Z = 2$, $D = 5.43$. *PD*: 4.50_4 4.34_6 3.84_5 2.89_7 2.60_{10} 1.834_4 1.713_4 1.500_4 . Minute crystals to 0.1 mm, prismatic to stubby bladed, elongate [001]. Leaf-green, lighter green streak, vitreous luster. Uneven fracture, brittle. $H = 3-4$. Nonfluorescent. Pale gray in reflected light, weakly bireflectant, nonpleochroic, $N_{\text{mean calc}} = 2.00$; $R = 10.5$ (589 nm). From the mine dumps at the *Centennial Eureka mine, Tintic district, Juab Co., UT*, associated with drusy quartz, mecalpineite, hematite, chrysocolla, connellite, enargite, and other Cu oxysalts, including other new Te species. *RG CM 33:641(1995), AM 81:516(1996)*.

33.2.1.1 Kuranakhite $\text{PbMn}^{4+}\text{Te}^{6+}\text{O}_6$

Named in 1975 for the locality. *ORTH* Space group unknown. $a = 5.1$, $b = 8.9$, $c = 5.3$, $Z = 2$, $D = 6.7$. *29-779*: 3.4_{10} 3.04_1 2.56_6 2.32_1 2.05_5 1.851_5 1.668_1 1.596_4 . Small grains, maximum 0.012 mm. Brownish to nearly black, brown streak, vitreous luster. Brittle. $H = 4-5$. Soluble in hot concentrated HCl or aqua regia. $N_x = 1.952$, $N_z = 2.002$. In RL, light gray with a bluish tint; weakly bireflectant, distinctly in oil, with rose tints. No internal reflections; distinctly anisotropic, blue to brown. $R = 24.4$ (470 nm), 24.0 (546 nm), 24.5 (589 nm), 23.0 (650 nm). *Kuranakh gold deposit, southern Yakutia, Russia*, in quartz-limonite ores associated with supergene Au, electrum, and hydrous ferric oxides. Moctezuma mine, Moctezuma, SON, Mexico. *RG ZVMO 104:310(1975), AM 61:339(1976)*.

33.2.2.1 Montanite $\text{Bi}_2\text{Te}^{6+}\text{O}_6 \cdot 2\text{H}_2\text{O}$

Named in 1868 for the locality. An inadequately characterized mineral. *38-417*: 3.54_{10} 3.22_5 2.95_3 2.60_9 2.04_2 1.892_8 1.708_5 1.504_3 . Earthy to compact. Yellowish brown, greenish, white; dull to waxy luster. Soft. $G = 6.2$. Biaxial (-); $N = 2.09$; abnormally pleochroic, green; 2V small; bireflectance = 0.01; $r < v$, extreme. *Highland, MT*, as an alteration of tetradymite. Davidson Co., NC. Norongo, near Captain's Flat, NSW, Australia, with tetradymite. *RG DII:636, SMMB 1:12(1985)*.

33.2.3.1 Cuzticiticite $\text{Fe}^{3+}\text{Te}^{6+}\text{O}_6 \cdot 3\text{H}_2\text{O}$

Named in 1982 from the Nahuatl for *something yellow*, in allusion to its color. *HEX* Space group unknown. $a = 5.045$, $c = 14.63$, $Z = 2$, $D = 4.01$. *35-664*: 4.87_4 3.26_{10} 2.52_7 2.24_3 1.99_2 1.75_2 1.56_3 1.46_3 . Crystallized crusts, scaly, stactalitic. Yellow to brownish yellow, similar to goethite. $H = 3$. $G = 3.9$. Soluble in cold dilute HCl, insoluble in alkalis, in CT affords water. Uniaxial (-); $N_O = 2.06$, $N_E = 2.05$; nondichroic. *Moctezuma mine, Moctezuma, SON, Mexico*. *RG MM 46:257(1982)*.

33.2.4.1 Parakhinite $\text{Cu}_3\text{PbTe}^{6+}\text{O}_4(\text{OH})_6$

Named in 1978 in allusion to its dimorphous relationship to khinite. *HEX* $P6_222$ or $P6_422$. $a = 5.753$, $c = 17.958$, $Z = 3$, $D = 6.69$. *29-1420*: 4.80₈ 3.34₁₀ 2.99₅ 2.91₇ 2.49₁₀ 2.25₆ 2.00₅ 1.56₈. Thin crystalline films and tabular hexagonal euhedra. Bottle green. $H = 3\frac{1}{2}$. $G = 6.5-7$. Uniaxial (-); $N_O = 2.155$, $N_E = 2.120$; strong dispersion. *Tombstone, AZ*, at the *Emerald mine*; also at the *Empire mine*(!) with khinite, dugganite, gold, and hessite, the habit and color resembling those of paratacamite. *RG AM 63:1016(1978)*.

33.2.5.1 Mcalpineite $\text{Cu}_3\text{Te}^{6+}\text{O}_6 \cdot \text{H}_2\text{O}$

Named in 1994 for the locality. *iso* Space group unknown. $a = 9.555$, $Z = 8$, $D = 6.65$. *MM 58:417(1994)*. *PD*: 4.76₃ 4.26₄ 3.91₃ 2.76₁₀ 2.38₇ 1.873₄ 1.689₈ 1.440₆. Found as crusts, coatings, and millimeter-size cryptocrystalline nodules consisting of micron-size sheaves of fibrous or prismatic crystals. Emerald-green, olive-green, to green-black; lighter green streak; adamantine luster. Uneven fracture, brittle. H and G could not be determined due to limitations on size of available specimens. In *RL*, gray, with abundant internal reflections, isotropic. $R = 12.8$ (470 nm), 11.6 (546 nm), 11.2 (589 nm), 11.0 (650 nm). First found on the dumps of the *McAlpine mine, Tuolumne Co., CA*, on drusy quartz with chromian muscovite and several primary sulfides and tellurides; and subsequently on dumps of the *Centennial-Eureka mine, Juab Co., UT*, with xocomecatlite, jensenite, and other hydrated copper tellurates. *RG*

33.2.6.1 Jensenite $\text{Cu}_3\text{Te}^{6+}\text{O}_6 \cdot 2\text{H}_2\text{O}$

Named in 1996 for Martin C. Jensen (b.1959), U.S. mineralogist, scanning electron microprobe specialist, and mineral collector, Reno, NV. Dimorphous with cesbronite. *MON* $P2_1/n$. $a = 9.204$, $b = 9.170$, $c = 7.584$, $Z = 4$, $D = 4.78$. *CM 34:49(1996)*. *PD*: 6.43₁₀ 4.52₃ 3.22₇ 2.60₄ 2.53₅ 2.36₃ 2.14₄ 1.750₄. Subhedral to euhedral crystals, as nearly equant rhombs, some slightly elongate [101], up to 0.4 mm. Emerald green, somewhat lighter streak, adamantine luster. Cleavage {101}, fair; uneven fracture; brittle. $H = 3-4$. Nonfluorescent. In *RL*, gray in air, much darker gray in oil, weakly bireflectant and nonpleochroic, nonanisotropic but strong green internal reflections. $R = 10.7$ (470 nm), 10.4 (546 nm), 9.8 (589 nm), 9.15 (650 nm). Found on the dumps of the *Centennial Eureka mine, Tintic district, Juab Co., UT*, associated with mc Alpineite, xocomecatlite, and other tellurium-bearing minerals. *RG*

33.2.7.1 Cesbronite $\text{Cu}_3\text{Te}^{6+}\text{O}_6 \cdot 2\text{H}_2\text{O}$

Named in 1974 for Fabien Cesbron (b.1938), French mineralogist, Bureau de Recherches Geologiques et Miniere, Orleans. Dimorphous with jensenite. *ORTH* $Cmc2_1$. $a = 2.937$, $b = 11.864$, $c = 8.621$, $Z = 2$, $D = 4.983$. *T.S. Ercit, pers. comm. 27-194*: 5.93₁₀ 4.89₇ 3.49₉ 2.38₄ 2.36₇ 2.16₃ 1.70₃ 1.59₃. Small spherules of radiating crystals, or as minute wedge-shaped crystals elongated on a . Bright emerald green, bright luster. Cleavage {021}, good; {010}, poor;

brittle. $H = 3$. $G = 4.45$. Nonfluorescent. Soluble in dilute HCl and HNO_3 , insoluble in water or in KOH solution. Biaxial (+); $X = a$; $N_x = 1.880$, $N_y = 1.928$, $N_z = 2.029$ (Na); $2V = 72^\circ$; $r > v$; absorption $Z \approx Y > X$. X, pale bluish green; Y, rich yellow-green; Z, deep emerald-green. From the Centennial Eureka mine, Tintic district, Juab Co., UT, with xocomecatlite. *Bambollita* ("La Oriental") mine, Moctezuma, SON, Mexico, on fracture surfaces associated with a pea-green amorphous Cu-Fe-Te mineral, carlfriesite, and teinite. RG *MM* 39:744(1974), *AM* 64:653(1979).

33.3.1.1 Schieffelinite $\text{Pb}(\text{Te, S})\text{O}_4 \cdot \text{H}_2\text{O}$

Named in 1980 for Ed Schieffelin (1847–1897), stagecoach driver and prospector, who about 1880 discovered the Tombstone district. ORTH *Cmcm*. $a = 9.67$, $b = 19.56$, $c = 10.47$, $Z = 16$, $D = 5.15$. 33-771: 9.78₁₀ 3.56₅ 3.43₆ 3.34₅ 3.25₆ 3.03₅ 2.93₅ 2.60₅. Platy or scaly; also as minute, sharp prismatic crystals. Colorless to white, adamantine luster. Cleavage {010}, perfect and easy. $H = 2$. $G = 4.98$. Nonfluorescent. Soluble in cold dilute HCl or HNO_3 , in CT fuses easily and affords water. Biaxial (-); $XYZ = bca$; $N_x = 1.897$, $N_y = 1.940$, $N_z = 1.942$ (Na); $2V = 24^\circ$; $r < v$, marked. *Joe and Grand Central mines, Tombstone, AZ*, associated with girdite, rodalquilarite, bromargyrite, and gold. RG *MM* 43:771(1980), *AM* 66:219(1981).

33.3.2.1 Tlalocite $\text{Cu}_{10}\text{Zn}_6(\text{Te}^{4+}\text{O}_3)(\text{Te}^{6+}\text{O}_4)_2\text{Cl}(\text{OH})_{25} \cdot 27\text{H}_2\text{O}$

Named in 1975 for Tlaloc, the god of rain in the Toltec and Aztec civilizations, in allusion to its high water content. ORTH Space group unknown. $a = 16.780$, $b = 19.985$, $c = 12.069$, $D = 4.58$. 29-590: 16.8₁₀ 8.39₈ 4.20₁₀ 3.36₆ 2.80₃ 2.59₃ 2.47₃ 1.56₄. Velvety crusts and coatings showing fibrous structure. Sky blue (Capri blue). Sectile. $H = 1$. $G = 4.55$. Nonfluorescent. Biaxial (-); Z parallel to crystal length; $N_x = 1.758$, $N_y = 1.796$, $N_z = 1.810$; $2V = 64^\circ$; absorption $Z > Y > X$. X, yellowish green; Y, Z, bluish green. *Bambollita mine, Moctezuma, SON, Mexico*, in fractures, with tenorite, azurite, and malachite. RG *MM* 40:221(1975), *AM* 61:504(1976).

33.3.3.1 Girdite $\text{Pb}_3\text{H}_2(\text{Te}^{4+}\text{O}_3)(\text{Te}^{6+}\text{O}_6)$

Named in 1979 for Richard Gird (1836–1910), mining engineer and assayer, who made the first rich silver assays and helped open up the Tombstone district. MON Space group unknown. $a = 6.241$, $b = 5.686$, $c = 8.719$, $\beta = 91.68^\circ$, $Z = 1$, $D = 5.49$. 34-1428: 3.12₇ 3.05₁₀ 2.99₇ 2.84₈ 2.18₅ 2.10₇ 1.81₃ 1.76₅. Spherules up to 3 mm, also as slender tapered prisms of twinned crystals. White. Tough, brittle. $H = 2$. $G = 5.5$. Nonfluorescent. Readily soluble in cold dilute HCl and HNO_3 . Biaxial (+); $Z = b$; $Y \wedge c = 34^\circ$; $N_x = 2.44$, $N_y = 2.47$, $N_z = 2.48$; $2V = 70^\circ$; $r > v$, strong. *Grand Central mine, Tombstone, AZ*, with chlorargyrite, gold, anglesite, rodalquilarite, and several other tellurites. RG *MM* 43:453(1979), *AM* 65:809(1980).

33.3.5.1 Cheremnykhite $\text{Pb}_3\text{Zn}_3\text{TeO}_6(\text{VO}_4)_2$

Named in 1990 for I. M. Cheremnykh, Russian prospector, one of the discoverers of the Kuranakh deposit. Isostructural with kuksite and dugganite. ORTH $Cmmm$, $C222$, $Cm2m$, or $Cmm2$. $a = 8.58$, $b = 14.86$, $c = 5.18$, $Z = 2$, $D = 6.44$. ZVMO 119:50(1990). PD: 3.30₁₀ 3.00₉ 2.47₄ 1.903₅ 1.607₆. Tabular, elongate crystals, with well developed {100} and {010}. Greenish yellow, adamantine luster, transparent. Perfect cleavage, brittle. VHN₁₀ = 673 kg/cm². Nonfluorescent. Biaxial (-); XYZ = abc; N_x = 1.986; N_z = 1.997; 2V = 20°; positive elongation; r > v; nonpleochroic. Found at the *Kuranakh gold deposit, central Aldan, Siberia, Russia*, as a late-stage interstitial mineral in calcite, with kuksite, dugganite, yafsoanite, and descloizite. RG AM 77:446(1992).

33.3.5.2 Kuksite $\text{Pb}_3\text{Zn}_3\text{TeO}_6(\text{PO}_4)_2$

Named in 1990 for A. I. Kuks, Russian prospector, one of the discoverers of the Kuranakh gold deposit. Isostructural with cheremnykhite and dugganite. ORTH $Cmmm$. $a = 8.50$, $b = 14.72$, $c = 5.19$, $Z = 2$, $D = 6.21$. ZVMO 119:50(1990). PD: 3.29₁₀ 3.00₈ 2.59₄ 1.903₅ 1.606₃. Crystals thin tabular {100}. Gray, white streak, adamantine luster, transparent to turbid. Perfect cleavage, brittle. VHN₁₀ = 325 kg/cm². Weakly fluorescent. Biaxial (-); Z = c; N_x = 1.971, N_z = 1.981; positive elongation; r > v; nonpleochroic. Found at the *Kuranakh gold deposit, central Aldan, southern Yakutia, Siberia, Russia*, associated with cheremnykhite, dugganite, yafsoanite, and descloizite. RG AM 77:446(1992).

33.3.5.3 Dugganite $\text{Pb}_3\text{Zn}_3(\text{TeO}_6)(\text{AsO}_4)(\text{OH})_3$

Named in 1978 for Marjorie Duggan (b.1927), U.S. chemist, who analyzed the mineral. Isostructural with kuksite and cheremnykhite. HEX $P6/mmm$. $a = 8.472$, $c = 5.208$, $Z = 1$, $D = 6.33$. AM 63:1016(1978). 29-1429: 4.23₄ 3.28₁₀ 3.00₈ 2.77₅ 2.45₆ 1.603₆ 1.209₄ 1.177₅. Prismatic, microscopic crystals. Colorless to green, white streak, adamantine luster. Cleavage {1120}, poor; very brittle. H = 3. G = 6.33. Nonfluorescent. Uniaxial (-); N_O = 1.977, N_E = 1.967. From the *Emerald and other mines, Tombstone, AZ*, associated with parakhinite, rodalquilarite, and other tellurites-tellurates. Kuranakh gold deposit, central Aldan, Yakutia, Siberia, Russia, associated with kuksite, cheremnykhite, yafsoanite, and descloizite. RG

Selenites, Tellurites, and Sulfites

34.1.1.1 Molybdomenite PbSeO_3

Named in 1882 for the composition: lead and selenium. It is derived from the Greek *molybdos*, lead, and *mene*, moon. The word selenium is derived from a different Greek word meaning "moon". Hence, by rather tortured reasoning, molybdomenite = lead selenite. *MON* $P2_1$ or $P2_1/m$. $a = 6.86$, $b = 5.48$, $c = 4.50$, $\beta = 112.75^\circ$, $Z = 2$, $D = 7.12$. *CM* 8:149(1964). 15-462(syn): 3.39₇ 3.30₈ 3.14₉ 2.74₁₀ 2.25₄ 2.07₆ 1.52₄ 1.23₅. Flat, bladed crystals. Colorless to white, pearly to adamantine luster. Cleavage {001}, good; {h0l}, fair; brittle. $G_{\text{syn}} = 7.07$. Biaxial (-); $N_x = 2.12$, $N_z = 2.14$; $2V = 80^\circ$; positive elongation. Ranwick uranium mine, Montreal River area, ONT, Canada, as an alteration product of clausthalite. Trogtal, Harz, Germany. *Cerro de Cachueta, Mendoza, Argentina*. In Bolivia at the Pacajake mine near Colquechaca, and at the El Dragon mine, Potosi. *RG* *DII*:640, *AM* 50:812(1965), *TMPM* 17:196(1972).

34.1.1.2 Scotlandite PbSO_3

Named in 1984 for the country of origin. *MON* $P2/m$. $a = 4.505$, $b = 5.333$, $c = 6.405$, $\beta = 106.23^\circ$, $Z = 2$, $D = 6.456$. *MM* 48:283(1984). 38-409: 4.04₁₀ 3.36₇ 3.26₇ 3.08₉ 2.67₄ 2.04₃ 2.01₃ 1.709₂. Minute prismatic chisel-shaped crystals and fan-shaped aggregates. Colorless to yellowish; adamantine luster, pearly on cleavage. Cleavage {100}, perfect; {010}, good. $H = 2$. $G = 6.37$. Confirmed as a sulfite by IR absorption bands: $V_3 = 920.9$, $V_1 = 970$, $V_2 = 620.6$, $V_4 = 488.5$; scotlandite was the first naturally occurring sulfite to be recognized. Biaxial (+); $Y = b$; $N_x = 2.035$, $N_y = 2.040$, $N_z = 2.085$ (Na); $2V = 35.4^\circ$; $r \ll v$, strong. *Leadhills, Scotland*, in cavities in massive barite and anglesite, associated with lanarkite, susannite, and leadhillite. The crystals have a thin coating of anglesite, which probably protected them from further oxidation. Argentolle mine, St. Prix, Saone-et-Loire, France. *RG* *AM* 70:876(1985).

34.1.2.1 Fairbankite PbTeO_3

Named in 1979 for Nathaniel Kellogg Fairbank (1829–1903), an important American entrepreneur in the early development of Tombstone. Dimorphous with plumbotellurite (34.1.4.1). *TRIC* $P1$ or $P\bar{1}$. $a = 7.81$, $b = 7.11$, $c = 6.96$, $\alpha = 117.2^\circ$, $\beta = 93.78^\circ$, $\gamma = 93.4^\circ$, $Z = 4$, $D = 7.45$. *MM* 43:453(1979). 34-

1253: 3.27₁₀ 3.15₆ 3.10₆ 3.02₅ 2.83₆ 2.52₅ 2.08₃ 1.94₃. Small crystals. Colorless, resinous to adamantine luster. No cleavage, brittle. $H = 2$. Slowly soluble in cold dilute HNO_3 or HCl , rapidly soluble in hot acids, easily fusible. Biaxial; $N_x = 2.29$, $N_y = 2.31$, $N_z = 2.33$; $2V = 86^\circ$; negligible dispersion. *Grand Central mine, Tombstone, AZ*, associated with oboyerite, jarosite, and opal. RG *AM* 65:809(1980).

34.1.3.1 Balyakinite CuTeO_3

Named in 1980 for Tatiana Stepanovna Balyakina (1906–1990), Russian teacher of geology, Moscow State University. ORTH *Pnma* or *Pmcn*. $a = 7.60$, $b = 5.83$, $c = 12.69$, $Z = 8$, $D = 5.64$. *AM* 66:436(1981). 22-1092: 4.35₆ 3.43₆ 3.18₆ 3.09₈ 2.93₆ 2.85₁₀ 2.84₉ 2.28₆. Minute, short prismatic crystals. Gray-green to blue-green. No cleavage. $H = 3$. $G = 5.6$. Biaxial (-); $XYZ = abc$; $N_x = 2.11$, $N_y = 2.18$, $N_z = 2.22$; weakly pleochroic; $2V = 80^\circ$. *Pionersk deposit, eastern Sayan*, and the *Aginsk deposit, central Kamchatka, Russia*, with tellurite and lead-copper tellurites in the oxidation zone of these deposits. RG *DANS* 253:1448(1980).

34.1.4.1 Plumbotellurite PbTeO_3

Named in 1982 for the composition. Dimorphous with fairbankite (34.1.2.1). ORTH Space group unknown. $a = 8.423$, $b = 13.739$, $c = 9.199$, $Z = 12$, $D = 7.16$. *AM* 67:1075(1982). 35-644: 3.21₃ 3.17₁₀ 3.10₄ 2.98₃ 2.86₃ 2.73₂ 2.11₁ 2.10₁. Replacement rims and pseudomorphs after altaite. Gray, yellowish gray, to brown. No cleavage. $H = 2$. $G = 7.2$. Biaxial (+); $N_x = 2.19$, $N_y = 2.23$, $N_z = 2.35$; $2V = 50^\circ$. *Moctezuma, SON, Mexico*, as gray-white scales. *Zhana-Tyube deposit, northern Kazakhstan*, associated with altaite. RG *DANS* 262:1231(1982).

34.1.5.1 Moctezumite $\text{Pb}(\text{UO}_2)(\text{TeO}_3)_2$

Named for the locality, which was named after Moctezuma (1466–1520), last king of the Aztecs. MON $P2_1/c$. $a = 7.819$, $b = 7.070$, $c = 13.836$, $\beta = 93.62^\circ$, $Z = 4$, $D = 7.25$. *AM* 50:1158(1965). 18-707: 5.34₃ 3.49₉ 3.39₆ 3.16₁₀ 3.09₇ 3.00₈ 2.01₅ 1.95₄. Prismatic crystals, bladelike, flattened {201}, and elongated [010]. Bright orange, dull luster. Cleavage {100}, perfect. $H = 3$. $G = 5.73$. Readily soluble in dilute HCl and dilute NaOH solution. Biaxial (-); $N > 2.11$; $2V = 5-10^\circ$. Sometimes pseudomorphously alters to schmitterite. *Moctezuma mine, Moctezuma, SON, Mexico*(1) (also known as "La Bombolla"), associated with zemannite, burckhardtite, schmitterite, other tellurites, and pyrite. RG *AM* 78:835(1993).

34.1.6.1 Schmitterite $\text{UO}_2(\text{TeO}_3)$

Named in 1971 for Eduardo Schmitter Villada (1904–1982), professor of mineralogy, Instituto de Geologia, Universidad Nacional Autonoma de Mexico. ORTH *Pca2₁*. $a = 10.161$, $b = 5.363$, $c = 7.862$, $Z = 4$, $D = 6.91$. *AM* 56:411(1971). Structure: *AC(B)* 29:1251(1973). 25-1001: 5.35₉ 4.73₈ 3.68₁₀

3.17₈ 3.10₉ 1.97₇ 1.73₅ 1.55₆. Minute, bladelike crystals, elongated [100], and flattened {001}. Very pale straw yellow, vitreous to pearly luster, glistening. Flexible but not elastic. $H = 1$. $G = 6.88$. Readily soluble in dilute HCl and alkalis. Biaxial (-), $XYZ = cba$; $N_y = 2.05$, $N_z > 2.11$; $2V = 75^\circ$. *Moctezuma mine* ("La Bambolla"), *Moctezuma, SON, Mexico* (!), with emmonsite, moctezumite, and other tellurites; also from the San Miguel mine, Moctezuma. Shinkolobwe, Shaba, Zaire. RG *BM 99:334*(1976).

34.1.7.1 Magnolite Hg_2TeO_3

Named in 1877 for the locality. ORTH *Pma2*. $a = 5.958$, $b = 10.576$, $c = 3.749$, $Z = 2$, $D = 8.12$. *CM 27:133*(1989). 45-1459: 5.25₅ 3.95₇ 3.74₄ 3.04₁₀ 2.59₅ 1.986₄ 1.944₃ 1.757₅. Acicular crystals, sometimes radiating, elongated [001]. Colorless, adamantine luster. Cleavage {010}, perfect; {001}, good; brittle. Soft. Biaxial (+); $XYZ = bac$; $N > 2.0$; $2V = \pm 45^\circ$; no dispersion. *Keystone mine*, and the Mountain Lion mine, *Magnolia District, Boulder Co., CO*, as an alteration product of coloradoite, associated with kestonite, melonite, and tellurium. RG *AJS 27:118*(1877), *AM 75:437*(1990).

34.1.8.1 Smirnite Bi_2TeO_5

Named in 1984 for Vladimir Ivanovich Smirnov (1910-1988), Russian economic geologist and department chairman, University of Moscow. ORTH *Cm2a*. $a = 16.447$, $b = 5.513$, $c = 11.579$, $Z = 8$, $D = 7.72$. *AM 70:876*(1985). 38-420: 3.23₁₀ 2.89₆ 2.75₂ 2.74₂ 1.996₃ 1.992₃ 1.727₃ 1.668₂. Tabular crystals or crusts. Colorless, light gray, or light yellow. Cleavage {001}, perfect; brittle. $H = 3\frac{1}{4}$ -4. $G = 7.78$. Biaxial (+); $XYZ = cba$; $N_x = 2.35$, $N_y = 2.36$, $N_z = 2.46$ (Na); $2V = 35$ -40°; darkens on exposure to sunlight. *Zod deposit, Armenia*; also from the northern Aksu and the Zakharpattia deposits, Kazakhstan, associated with tellurobismuthite, tetradymite, volynskite, and galena. RG *DANS 278:199*(1984).

34.2.1.1 Graemite $CuTeO_3 \cdot H_2O$

Named in 1975 for Richard Graeme (b.1941), American mining geologist. ORTH *Pmma*. $a = 6.805$, $b = 25.613$, $c = 5.780$, $Z = 10$, $D = 4.24$. *MR 6:32*(1975). 26-1118: 12.8₅ 6.40₁₀ 5.64₃ 3.43₈ 2.87₄ 2.80₃ 2.56₅ 2.34₄. Crystals short prismatic [100]. Blue-green, vitreous luster. Brittle. $H = 3$ -3 $\frac{1}{2}$. $G = 4.13$. Nonfluorescent. Insoluble in water, easily soluble in cold dilute acids or 40% KOH. Biaxial (+); $XYZ = bca$; $N_x = 1.920$, $N_y = 1.960$, $N_z = 2.20$ (Na); $2V = 48.5^\circ$; no dispersion; absorption $Y > Z = X$. X, yellowish green; Y, Z, blue-green. *Cole shaft, Bisbee, AZ*, associated with malachite, cuprite, and teineite. Also in AZ from Tombstone, Cochise Co., and from the Dome Rock Mts., Yuma Co. It was formed by the dehydration of teineite. RG *AM 60:486*(1975).

34.2.2.1 Chalcomenite $\text{CuSeO}_3 \cdot 2\text{H}_2\text{O}$

Named in 1881 from the Greek for *copper* and *moon*. See molybdomenite (34.1.1.1). ORTH $P2_12_12_1$. $a = 6.666$, $b = 9.169$, $c = 7.373$, $Z = 4$, $D = 3.346$. *NJMM:551(1989)*. 17-523: 5.39₁₀ 4.94₉ 3.77₇ 3.35₈ 3.04₇ 2.88₆ 2.53₇ 2.16₆. Crystals prismatic [001] acicular to equant. Bright blue, vitreous luster. No cleavage. $H = 2-2\frac{1}{2}$. $G = 3.35$. Soluble in acids, in CT affords water and a sublimate of SeO_2 , easily fusible. $XYZ = acb$; $N_x = 1.712$, $N_y = 1.732$, $N_z = 1.732$ (Na); $r < v$, strong (Bolivia); also $r > v$, strong (Argentina). X, pale blue; Y, Z, darker blue. Eagle shaft, Eldorado mine, Uranium City, SK, Canada. Liauzun-en-Olloix, Puy de Dome, France, in blue incrustations. In Argentina at the Cerro de Cacheuta, Mendoza, and at the Sierra de Umango and the Sierra de Famatina, La Rioja. In Bolivia at Pacajake, near Colquechaca, and at the El Dragon mine, Potosi. In fine crystals at the Musonoi mine, Kolwezi, Zaire(!), with guilleminite, derriksite, and other selenites. RG *DII:638*, *AM 49:1481(1964)*, *AC 11:377(1958)*.

34.2.2.2 Teineite $\text{CuTeO}_3 \cdot 2\text{H}_2\text{O}$

Named in 1939 for the locality. ORTH $P2_12_12_1$. $a = 6.634$, $b = 9.597$, $c = 7.428$, $Z = 4$, $D = 3.864$. *TMPM 24:287(1977)*. 17-733: 5.87₆ 5.45₉ 4.96₆ 3.45₁₀ 3.06₈ 2.94₇ 2.88₇ 2.39₇. Crystals prismatic [001]; sometimes also flattened {010}; as crusts. Deep sky blue. Cleavage {010}, good, {001}, {100}, poor; brittle. $H = 2\frac{1}{2}$. $G = 3.88$. Soluble in HCl and HNO_3 ; in CT, affords water. Biaxial (-); $XYZ = abc$; $N_x = 1.767$, $N_y = 1.782$, $N_z = 1.791$; $2V = 36^\circ$; absorption $Z > Y > X$. X, greenish blue; Y, blue; Z, indigo blue. Cole shaft, Bisbee, AZ, associated with malachite, graemite, and cuprite. Bambollita mine, Mochizuma, SON, Mexico. *Teine mine, Hokkaido, Japan*(!), with tellurite, as an alteration product of tetrahedrite and tellurium. RG *DII:635*, *AM 46:466(1961)*, *AC 15:698,863(1962)*.

34.2.3.1 Clinochalcomenite $\text{CuSeO}_3 \cdot 2\text{H}_2\text{O}$

Named in 1980 for its monoclinic symmetry and dimorphous relationship to chalcomenite. MON $P2_1/c$. $a = 8.177$, $b = 8.611$, $c = 6.290$, $\beta = 97.27^\circ$, $Z = 4$, $D = 3.42$. *AM 66:217(1981)*. 38-479: 5.89₁₀ 4.06₇ 3.66₉ 2.93₈ 2.69₇ 2.57₆ 2.48₇ 1.82₇. Crystals prismatic [001], striated [001]. Bluish green, vitreous luster. Cleavage {110}, perfect; brittle. $H = 2$. $G = 3.28$. Biaxial (-); $Y = b$; $Z \wedge c = 10^\circ$; $N_x = 1.675$, $N_y = 1.723$, $N_z = 1.765$; $2V = 78^\circ$; $r < v$; positive elongation. X, Y, colorless; Z, bluish green. From a *uranium deposit in China*, associated with volborthite, chalcomenite, umangite, and malachite. El Dragon mine, Potosi, Bolivia. RG *KT 25:89(1980)*.

34.2.3.2 Cobaltomenite $\text{CoSeO}_3 \cdot 2\text{H}_2\text{O}$

Named in 1882 for the composition: cobalt and selenium. See molybdomenite (34.1.1.1). MON $P2_1/c$. $a = 7.615$, $b = 8.814$, $c = 6.499$, $\beta = 98.85^\circ$, $Z = 4$, $D = 3.42$. *CM 12:304(1974)*. 25-125(syn): 5.72₁₀ 4.04₄ 3.80₇ 3.46₆ 3.02₁₀ 2.95₄ 2.74₆ 2.51₄. Crystals long prismatic [001], or tabular {101}. Red to

pink, vitreous luster. Cleavage {110}, {103}; brittle. $H = 2-2\frac{1}{2}$. $G = 3.37$. Biaxial (-); $Z \wedge c = -12^\circ$; $N_x = 1.681$, $N_y = 1.728$, $N_z = 1.769$; no dispersion. X, pale pink; Y, pink; Z, red. A complete solid-solution series exists between cobaltomenite and ahlfeldite. Most natural members of the series are in the range Ni/Co 4:1 to 1:2. In Bolivia from the Pacajake mine, Hiaco, near Colquechaca, associated with chalcomenite and ahlfeldite; and from the El Dragon mine near Potosi associated with other selenites. Musonoi mine, Kolwezi, Zaire(I), associated with derriksite, chalcomenite, and other selenites. *Cerro de Cacheuta, Mendoza, Argentina*, with molybdomenite. RG *DII:639, NW 50:333(1963), AM 48:1183(1963)*.

34.2.3.3 Ahlfeldite $NiSeO_3 \cdot 2H_2O$

Named for Federico Ahlfeld (1892–1982), German–Bolivian geologist and mineralogist, who studied the minerals of Bolivia. MON $P2_1/c$. $a = 7.519$, $b = 8.751$, $c = 6.448$, $\beta = 99^\circ$, $Z = 4$, $D = 3.51$. *CM 12:304(1974)*. 25-1233(syn): 5.66₁₀ 3.77₅ 3.42₇ 2.99₇ 2.72₅ 2.35₄ 2.19₅ 1.71₄. Crystals prismatic [001] or flattened {110}. Pale green to brownish green, pinkish; vitreous luster. Cleavage {110}, {103}, fair; brittle. $H = 2-2\frac{1}{2}$. $G = 3.37$. Biaxial; $Z \wedge c = -12^\circ$; $N_x = 1.703$, $N_y = 1.744$, $N_z = 1.786$; $2V = 87^\circ$; $r < v$; absorption $Z > Y > X$. X, very pale green; Y, pale green; Z, green. Forms a complete solid-solution series with cobaltomenite, $CoSeO_3 \cdot 2H_2O$. In *Bolivia* at the *Pacajake mine, Hiaco*, formed as an alteration product of penroseite and other selenides, associated with cerussite, anglesite, chalcomenite, cobaltomenite. Also at the El Dragon mine near Potosi. RG *DII:635, AM 54:449(1969)*.

34.2.4.1 Choloalite $CuPb(TeO_3)_2 \cdot H_2O$

Named in 1981 from the Nahua *choloa*, evasive, in allusion to the fact that the mineral escaped detection in the mine for many years. ISOM Space group unknown. $a = 12.519$, $Z = 12$, $D = 6.41$. *MM 44:55(1981)*. 34-1248: 7.26₅ 4.19₂ 3.63₃ 3.49₄ 3.36₆ 3.05₁₀ 2.96₃ 1.966₂. Crystals are simple octahedra. Forest green, adamantine luster. No cleavage, irregular fracture, brittle. $H = 3$. $G = 6.4$. Soluble in dilute acids. Isotropic; $N = 2.04$; anomalous birefringence, up to 0.011. Tombstone, AZ, near the Joe and Grand Central shafts, associated with emmonsite, rodalquilarite, and cerussite. *Bambollita mine, Moctezuma, SON, Mexico*. RG

34.2.5.1 Hannebachite $CaSO_3 \cdot 0.5H_2O$

Named in 1985 for the locality. ORTH *Pbcn* or *Pbna*. $a = 6.473$, $b = 9.782$, $c = 10.646$, $Z = 8$, $D = 2.52$. *AM 73:928(1988)*. 39-725(syn): 5.56₅ 5.34₂ 3.80₂ 3.16₁₀ 2.82₂ 2.63₆ 1.851₃ 1.807₂. Crystals elongated [010], flattened {001}, bladelike. Colorless, vitreous luster. Cleavage {110}, perfect. $H = 3\frac{1}{2}$. $G = 2.52$. IR spectrum has absorption bands characteristic for $(SO_3)^{2-}$. Biaxial (+); $XYZ = acb$; $N_x = 1.596$, $N_y = 1.600$, $N_z = 1.634$; $2V = 38^\circ$. From the Quaternary volcano at *Hannebacher Ley, Eifel, Germany*, in cavities in meli-

lite-nepheline-leucite lava, with calcite, aragonite, gypsum, barite, celestine, zeolites, and whewellite. RG *NJMM:241(1985)*.

34.2.5.2 Gravegliaite $\text{MnSO}_3 \cdot 3\text{H}_2\text{O}$

Named in 1991 for the locality. ORTH *Pnma*. $a = 9.763$, $b = 5.635$, $c = 9.558$, $Z = 4$, $D = 2.39$. *ZK 197:97(1991)*. 29-899(syn)(calc): 6.81₉ 4.77₃ 4.34₁₀ 4.28₅ 3.43₄ 3.41₅ 2.69₄ 2.40₄. See also 44-1445. Prismatic crystals, elongated [010] and prismatic {h0l} with a pyramidal termination; also as sheaflike or radial aggregates. Colorless, white streak, vitreous luster, transparent. Cleavage [010]. Insoluble in water, soluble in strong acids. Nonfluorescent. Biaxial (+), $N_x = 1.590$, $N_y = 1.596$, $N_z = 1.636$; $2V = 41^\circ$; strong dispersion. Found in cavities along fractures that cut Mn ore at the *Gambatesa mine, Val Graveglia, eastern Liguria, Italy*; associated minerals are chalcocite and rare alabandite. RG *AM 77:672(1972)*.

34.3.1.1 Cliffordite UTe_3O_8

Named in 1969 for Clifford Frondel (b.1907), American mineralogist and professor, Harvard University; connoisseur of uranium minerals. iso *Pa3*. $a = 11.371$, $Z = 8$, $D = 6.76$. *AM 54:697(1969)*. Structure: *AC(B) 27:608(1971)*. 25-999: 4.63₆ 4.02₆ 3.27₁₀ 2.84₈ 2.76₇ 2.01₈ 1.80₆ 1.71₇. Octahedral crystals; as crusts. Bright yellow, adamantine luster. No cleavage. $H = 4$. $G = 6.57$. Nonfluorescent. Soluble in concentrated HCl, insoluble in dilute HCl. Isotropic; $N = 2.25$. *TMPM 29(1):1(1981)*. *San Miguel mine, Moctezuma, SON, Mexico*, associated with barite and mackayite, and in small amounts at the Moctezuma mine. RG *AM 57:597(1972)*.

34.3.2.1 Zemannite $\text{Mg}_5[\text{ZnFe}^{3+}(\text{TeO}_3)_3] \cdot 4.5\text{H}_2\text{O}$

Named in 1969 for Dr. Josef Zemann (b. 1923), Austrian mineralogist, University of Vienna, who has studied the tellurium oxysalts extensively. HEX *P6₃/m*. $a = 9.41$, $c = 7.64$, $Z = 2$, $D = 4.34$. *CM 14:387(1976)*. 31-1310: 8.15₁₀ 4.07₈ 2.96₆ 2.85₆ 2.78₉ 2.35₅ 2.16₅ 1.726₆. Small hexagonal prisms {1010} terminated by a pyramid, {1011}; rarely tabular hexagonal {0001}; occasionally acicular. Dark to light brown; yellowish brown when acicular, with vitreous to adamantine luster. No cleavage, brittle. $H = 2$. Uniaxial (+); $N_O = 1.85$, $N_E = 1.93$; absorption $O > E$. O, reddish brown; E, yellowish brown. *Moctezuma mine ("La Bambolla"), Moctezuma, SON, Mexico(!)*, associated with tellurite, moctezumite, denningite, burckhardtite, spiroffite, and other tellurium oxysalts. RG *TMPM 12:108(1967)*, *AM 55:1448(1970)*, *EJM 7:509(1995)*.

34.3.2.2 Kinichilite $\text{Mg}_5[\text{Mn}^{2+}\text{Fe}^{3+}(\text{TeO}_3)_3] \cdot 4.5\text{H}_2\text{O}$

Named in 1981 for Kin-Ichi Sakurai (b.1912), Japanese amateur mineralogist and collector, coauthor of *Minerals of Japan* (1938). Isostructural with zemannite and keystoneite. HEX *P6₃/m*. $a = 9.419$, $c = 7.666$, $Z = 2$, $D = 3.96$. 33-609: 8.15₉ 4.08₁₀ 3.82₄ 3.47₁ 2.97₃ 2.86₅ 2.79₈ 1.735₂. Hexagonal

crystals with $\{10\bar{1}0\}$ and $\{0001\}$. Dark brown, brown streak, subadamantine luster. No cleavage. Soft. Uniaxial (+); $N_O > 1.80$, $N_E > 1.80$. O, light brown; E, yellowish brown. Kinichilite is the Mn^{2+} -dominant analog of zemannite and keystoneite. Moctezuma mine, Moctezuma, SON, Mexico, with tellurite and other Te oxysalts, *Kawazu mine, Shimada, Izu Penin., Japan*, in a quartz vein. RG *MJJ 10:333(1981)*, *EJM 7:509(1995)*, *AM 67:623(1982)*.

34.3.2.3 Keystoneite $Mg_{0.5}[NiFe^{3+}(TeO_3)_3] \cdot 4.5H_2O$

Named in 1988 for the locality. Isostructural with zemannite and kinichilite. $HEX P6_3/m$ or $P6_3$. $a = 9.358$, $c = 7.608$, $Z = 2$, $D = 4.27$. *CM (in press)(1997)*. *PD*: 8.12₉ 4.05₈ 3.81₄ 2.95₅ 2.84₅ 2.77₁₀ 1.720₆ 1.498₅. Radiating sprays of acicular microcrystals. Golden yellow to orange yellow, adamantine luster, no cleavage, brittle. $G_{calc} = 4.23$ – 4.35 . Uniaxial (+); $N_O = 1.85$, $N_E = 1.99$ (Na). From the *Keystone mine, Magnolia district, Boulder Co., CO*, associated with melonite, tellurium, pyrite, paratellurite, and magnolite. RG *GAC-MAC abstr. A4a(1988)*, *EJM 7:509(1995)*.

34.3.3.1 Emmonsite $Fe_2^{3+}(TeO_3)_3 \cdot 2H_2O$

Named in 1885 for Samuel Franklin Emmons (1841–1911), economic geologist, U.S. Geological Survey. $TRIC P1$. $a = 7.90$, $b = 8.00$, $c = 7.62$, $\alpha = 96.7^\circ$, $\beta = 95^\circ$, $\gamma = 84.5^\circ$, $Z = 2$, $D = 4.719$. Structure: *SR 39A:323(1973)*. *7-404*: 5.81₇ 3.69₈ 3.14₁₀ 2.87₉ 2.67₈ 2.52₉ 2.29₇ 1.80₈. Crystals rare; usually as filiform and vermiform matted crystal aggregates, velvety. Bright yellow-green, grass green, blackish green; vitreous luster. Cleavage $\{010\}$, perfect; $\{100\}$, $\{001\}$, good. $H = 5$. $G = 4.549$. Nonfluorescent. Easily soluble in strong acids; in CT melts easily to a deep red liquid, loses water, and leaves an anhydrous residue. Biaxial (-); $Y = b$; $N_x = 1.962$, $N_y = 2.09$, $N_z = 2.10$; weakly pleochroic; $2V \pm 20^\circ$; $r > v$, strong; absorption $Z > X$. *Tombstone, AZ*, from which mine, unknown. In good crystals at Goldfield, NV(1), with macKayite. Good Hope mine, Vulcan, Gunnison Co., CO, with sonoraite, rickardite, and weissite. Formerly abundant at the Moctezuma mine, Moctezuma, SON, Mexico(1), associated with schmitterite, cuzticite, sonoraite, and other tellurites, where it was a product of the oxidation of a tellurium–pyrite orebody. El Plomo mine, Ojojona district, Tegucigalpa, Honduras (“durdenite”). RG *DII:640*, *MR 3:82(1972)*, *TMPM 18:157(1972)*.

34.3.4.1 Mandarinoite $Fe_2^{3+}(SeO_3)_3 \cdot 6H_2O$

Named in 1978 for Joseph A. Mandarino (b.1929), American–Canadian mineralogist, Royal Ontario Museum, Toronto. $MON P2_1/c$. $a = 16.810$, $b = 7.880$, $c = 10.019$, $\beta = 98.27^\circ$, $Z = 4$, $D = 3.037$. *CM 22:475(1984)*. *29-719*: 8.25₄ 7.10₁₀ 3.55₅ 3.43₄ 2.98₇ 2.80₂ 1.52₂ 1.48₂. Prismatic crystals, with $\{100\}$, $\{110\}$, $\{011\}$, and $\{101\}$; usually twinned on $\{100\}$. Light green, similar to gem peridot; vitreous to greasy luster. No cleavage. $H = 2\frac{1}{2}$, $G = 2.93$. Nonfluorescent. Biaxial (-); X parallel to b ; $Z \wedge c = 2^\circ$; $N_x = 1.715$, $N_y = 1.80$, $N_z = 1.87$; $2V = 85^\circ$; no dispersion. DeLamar silver mine, ID,

with chlorargyrite. El Plomo mine, Ojojona district, Honduras. Skouriotissa mine, Cyprus, on quartz. In *Bolivia* at the *Pacajake mine, near Hiaco, ENE of Colquechaca*, with other selenites on penroseite; also at the El Dragon mine, Potosi, with chalcomenite and kerstenite on krutaite. RG *CM 16:605(1978)*, *AM 70:440(1985)*.

34.4.1.1 Denningite $(\text{Ca,Mn})(\text{Mn,Zn})\text{Te}_4\text{O}_{10}$

Named in 1963 for Reynolds M. Denning (1916–1967), mineralogist, University of Michigan. TET $P4_2/nbc$. $a = 8.82$, $c = 13.04$, $Z = 8$, $D = 5.07$. *CM 7:443(1963)*. 15-129: 6.26₅ 4.42₁₀ 3.38₈ 3.12₇ 2.62₇ 2.03₇ 1.53₆ 1.51₅. See also 45-1368(syn). Crystals tabular to platy {001}; also massive, or scaly. Pale apple green to colorless, brownish, purplish; adamantine luster. Cleavage {001}, perfect; conchoidal fracture. $H = 4$. $G = 5.05$. Nonfluorescent. Soluble in cold HCl, giving a yellow solution; insoluble in HNO₃; slightly soluble in H₂SO₄. Uniaxial (+); $N_O = 1.89$, $N_E = 2.00$. *Moctezuma mine ("La Bombolla")*, *Moctezuma, SON, Mexico*(1), in a quartz vein associated with tellurite, zemannite, spiroffite, and other tellurites. RG *AM 47:1484(1962)*, *TMPM 10:241(1965)*.

34.4.2.1 Rajite CuTe_2O_5

Named in 1979 for the initials of Robert Allen Jenkins (b.1944), mineralogist and geologist, Phelps Dodge Corp., who first recognized the species. MON $P2_1/c$. $a = 6.866$, $b = 9.314$, $c = 7.598$, $\beta = 109.1^\circ$, $Z = 4$, $D = 5.77$. *MM 43:91(1979)*. 33-494: 4.65₈ 3.79₆ 3.35₈ 3.11₇ 3.06₁₀ 2.84₅ 2.80₅ 2.74₇. Minute crystals, bladed or tabular. Bright green, resinous luster. Cleavage {010}, perfect; brittle. $H = 4$. $G = 5.75$. Nonfluorescent. Easily soluble in acids, readily fusible. Biaxial (+); $Y = b$; $Z[100] = 3^\circ$; $N_x = 2.115$, $N_y = 2.135$, $N_z = 2.26$ (Na); weakly pleochroic; $2V = 40^\circ$; absorption $Z > Y > X$. From a small prospect near the *Lone Pine Au-Te deposit, Catron Co., NM*, associated with mackayite on quartz breccia. RG *AM 64:1331(1979)*.

34.5.1.1 Spiroffite $(\text{Mn,Zn})_2\text{Te}_3\text{O}_8$

Named in 1962 for Kiril Spiroff (1901–1981), Bulgarian–American economic geologist, Michigan College of Mining and Technology. MON Cc or $C2/c$. $a = 13.00$, $b = 5.38$, $c = 12.12$, $\beta = 98^\circ$, $Z = 4$, $D = 4.97$. *CM 7:450(1962)*. 24-740: 4.96₈ 4.66₃ 4.04₆ 3.30₁₀ 2.99₁₀ 2.82₅ 2.77₃ 1.620₃. No euhedral crystals, forms coxcomblite druses of crystals, massive. Deep pink to purplish pink, subadamantine luster. Cleavage in two directions, conchoidal fracture. $H = 3\frac{1}{2}$. $G = 5.01$. Nonfluorescent. Readily soluble in HCl, giving a yellow solution, insoluble in hot HNO₃ or H₂SO₄, readily fusible. Biaxial (+); $N_x = 1.85$, $N_y = 1.91$, $N_z > 2.10$ ($N_z \text{ calc} = 2.20$); $2V = 55^\circ$. *Moctezuma mine ("La Bombolla")*, *Moctezuma, SON, Mexico*(1), with tellurite, denningite, zemannite, other tellurites, and tellurium, in quartz matrix. RG *AM 47:196(1962)*, *MSASP 1:305(1963)*, *NW 54:199(1967)*.

34.5.2.1 Winstanleyite TiTe_3O_8

Named in 1979 for Betty Jo Winstanley (b.1934), amateur mineralogist, who found the first specimen. iso $Ia\bar{3}$. $a = 10.963$, $Z = 8$, $D = 5.632$. *MM* 43:453(1979). 34-1485: 4.47₆ 3.17₁₀ 2.93₄ 2.74₇ 2.58₄ 1.94₈ 1.65₈ 1.39₄. Crystallizes in cubes, occasionally modified by {111}. Chinese yellow; also tan or cream-colored, adamantine luster. No cleavage, tough. $H = 4$. $G = 5.57$. Very slowly soluble in 1:1 HNO_3 or 1:1 HCl , in CT readily fusible. Isotropic; $N = 2.34$; sometimes anomalously birefringent up to 0.011. *Grand Central mine, Tombstone, AZ*, in a silicified granodiorite dike, associated with jarosite, chlorargyrite, and rodalquilarite. *RG AM* 65:810(1980).

34.5.3.1 Carlfriesite $\text{CaTe}_2^{4+}\text{Te}^{6+}\text{O}_8$

Named in 1975 for Carl Fries, Jr. (1910–1965), American geologist, U.S. Geological Survey and Instituto de Geologia, UNAM, who devoted his career to studying the geology of Mexico. *MON C2/c*. $a = 12.576$, $b = 5.662$, $c = 9.994$, $\beta = 115.57^\circ$, $Z = 4$, $D = 5.699$. *AM* 63:847(1978). 29-333: 5.06₈ 4.83₃ 4.09₂ 3.37₄ 3.17₁₀ 3.08₉ 2.83₆ 2.70₃. Crystals prismatic to bladelike [001], also as botryoidal crusts. Bright yellow. Cleavage {010}, fair; brittle. $H = 3\frac{1}{2}$. $G = 6.3$. Nonfluorescent. Biaxial (-); Y parallel to b ; $N_x = 1.982$, $N_y = 2.095$, $N_z = 2.19$ (Na); weakly pleochroic; $2V = 80^\circ$; absorption $Z > X = Y$. From the *Bambollita mine* (also known as "La Oriental"), *Moctezuma, SON, Mexico*, on fractures in barite-quartz vein material, associated with an amorphous copper tellurite, dickite, and chlorargyrite. *RG MM* 40:127(1975).

34.5.4.1 Pinguite $\text{Bi}_6\text{Te}_2^{4+}\text{O}_{13}$

Named in 1994 for the locality. *ORTH* Space group unknown. $a = 5.689$, $b = 10.791$, $c = 5.308$, $Z = 1$, $D = 8.64$. *PD*: 3.15₁₀ 2.84₈ 2.69₂ 2.65₉ 1.956₁₀ 1.891₈ 1.695₂ 1.631₁. Rounded granular aggregates of minute crystals (grain size 0.3–0.6 μm). Yellowish green, light yellow-green streak, vitreous to adamantine luster, transparent. $H = 5-6$, $\text{VHN}_{50} = 510 \text{ kg/mm}^2$. $G = 8.44$. Nonfluorescent. Biaxial; $N > 2.0$. $R = 13.25$ (589 nm). From the oxidation zone of a small gold deposit at *Yangjiava, Pinggu Co. (near Beijing), China*, associated with "limonite," malachite, pyromorphite, bismutite, gold, and other minerals. *RG AMS* 14(4):315(1994), *MR* 27:119(1996).

34.6.1.1 Mackayite $\text{Fe}^{3+}\text{Te}_2\text{O}_5(\text{OH})$

Named in 1944 for John William Mackay (1831–1902), mine operator, Comstock Lode, and benefactor of the Mackay School of Mines, University of Nevada. *TET* $I4_1/a$. $a = 11.704$, $c = 14.984$, $Z = 16$, $D = 5.281$. *NJMM*: 145(1977). 29-730: 5.56₄ 4.95₇ 3.76₅ 3.33₁₀ 3.17₉ 2.79₅ 2.73₄ 1.622₅. Short prismatic to equant crystals, bipyramidal, showing {010} and {112}, often pseudo-dodecahedral. Bottle green to brownish green, adamantine to vitreous luster. No cleavage, subconchoidal fracture; brittle. $H = 4\frac{1}{2}$. $G = 4.86$. Nonfluorescent. Soluble in hot dilute HCl , in CT fuses. Uniaxial (+); $N_0 = 2.19$,

$N_E = 2.21$. O, green; E, yellowish green. *Mohawk mine, Goldfield, NV*, associated with emmonsite and sonoraite. Abundant at the San Miguel mine, Moctezuma, SON, Mexico(1), in druses associated with cliffordite, tellurite, and barite. RG *AM 29:211(1944)*, *55:1072(1970)*; *DII:642*; *TMPM 13:213(1969)*.

34.6.2.1 Rodalquilarite $H_3Fe_2(TeO_3)_4Cl$

Named in 1968 for the locality. TRIC $P1$ or $P\bar{1}$. $a = 8.89$, $b = 5.08$, $c = 6.63$, $\alpha = 103.17^\circ$, $\beta = 107.08^\circ$, $\gamma = 77.87^\circ$, $Z = 1$. Structure: *AC(B) 25:1551(1969)*. *20-536*: 4.24₁₀ 3.46₂ 3.31₆ 2.97₄ 2.85₅ 2.62₈ 2.17₆ 1.873₃. Minute stout crystals and crusts. Grass-green to emerald-green, greasy luster. One good cleavage, very brittle. $H = 2-3$. $G = 5.10$. Biaxial (-); N between 2.1 and 2.2; nonpleochroic; $2V = 38^\circ$. Grand Central shaft, Tombstone, AZ, associated with jarosite, chlorargyrite, and winstanleyite. *Rodalquilar gold deposit, Almeria, Spain*, with jarosite, gold, and emmonsite. Wendy pit, El Indio gold mine, 4th Region, Chile(1), associated with gold and jarosite. RG *BM 91:28(1968)*, *AM 53:2104(1968)*.

34.6.3.1 Quetzalcoatlite $Cu_4Zn_8(TeO_3)_3(OH)_{18}$

Named in 1973 for Quetzalcoatl, a god of the Toltecs, who was associated with the sea, in allusion to the beautiful sea-blue color of the mineral. HEX $P6_322$. $a = 10.097$, $c = 4.944$, $Z = 1$, $D = 6.12$. *MM 39:261(1973)*. *26-485*: 8.75₁₀ 5.05₂ 3.53₄ 3.27₃ 2.75₇ 2.52₄ 2.25₂ 1.77₃. Very minute crystals, simple combinations of {0001} and {1010}; as crusts or sprays of needles. Sea-blue. Cleavage {1010}, fair; brittle. $H = 3$. $G = 6.05$. Nonfluorescent. Uniaxial (-); $N_O = 1.802$, $N_E = 1.740$ (Na). O, blue-green; E, almost colorless. Empire mine, Tombstone, AZ. *Bambollita mine, Moctezuma, SON, Mexico*, associated with dickite, barite, azurite, hessite, and galena. RG *AM 59:874(1974)*.

34.6.4.1 Chekhovichite $Bi_2Te_4O_{11}$

Named in 1987 for Sergei K. Chekhovich, Kazakh geologist, Polytechnical Institute of Alma Ata. MON $P2_1$. $a = 19.00$, $b = 7.982$, $c = 6.938$, $\beta = 95.67^\circ$, $Z = 4$, $D = 7.005$. *AM 74:1400(1989)*. *42-1323*: 3.29₁₀ 3.15₉ 3.14₁₀ 2.73₅ 2.002₄ 1.998₅ 1.686₃ 1.683₃. Aggregates of grains; crusts. Gray, with yellowish, whitish, or greenish tints; adamantine luster. Perfect cleavage parallel to elongation of grains, and a second perfect cleavage at 87° to it. $H = 4$. $G = 6.88$. Biaxial (-); $X \wedge c = 21^\circ$, $Z \wedge a = 25^\circ$; $N_x = 2.45$, $N_y = 2.50$, $N_z = 2.65$ (Na); $2V = 65^\circ$; $r < v$. From the mines at *Zod, Armenia*, and at *Zhana Tyube and North Aksu, northern Kazakhstan*, with limonite and as pseudomorphs after tellurobismuthite. RG

34.6.5.1 Sopiite $Zn_2(SeO_3)Cl_2$

Named in 1989 for Sophia Ivanovna Noboko (b.1909), Russian vulcanologist and mineralogist, a leading investigator of the volcanoes of Kamchatka. ORTH *Pccn*. $a = 10.251$, $b = 15.223$, $c = 7.666$, $Z = 8$, $D = 3.64$. *AM 75:1211(1990)*.

45-1463: 7.61₁₀ 3.81₂ 3.24₁ 3.06₁ 2.92₁ 2.73₁ 2.54₁ 2.13₁. Thin platy crystals, pseudo-hexagonal on {010}, sometimes elongated [001]; swallowtail twins on {100}. Colorless, becoming sky blue on long exposure to air; vitreous to greasy or silky luster. Cleavage {010}, perfect; {201}, fair; brittle. H = 2. Biaxial (+); XYZ = bca; N_x = 1.709, N_y = 1.726, N_z = 1.750; 2V = 81°. Found in fumaroles of the *Great Tolbachik Fissure Eruption, Kamchatka, Russia*, with tenorite, cotunnite, gold, ponomarevite, halite, and sylvite. Specimens were collected at 180–230°. RG *ZVMO* 118:65(1989).

34.6.6.1 Francisite $\text{Cu}_3\text{Bi}(\text{SeO}_3)_2\text{O}_2\text{Cl}$

Named in 1990 for Glyn Francis (b.1939), quality control officer at the Iron Monarch iron mine. ORTH *Pmmn*. $a = 6.354$, $b = 9.630$, $c = 7.220$, $Z = 2$, $D = 5.42$. Structure: *AM* 75:1421(1990). *PD*: 5.31₆ 3.39₁₀ 3.18₃ 2.87₈ 2.65₇ 2.49₆ 1.695₃ 1.588₆. Radiating clusters of bladelike crystals, elongated [010]; contact twinning sometimes present. Bright apple-green, adamantine luster. No cleavage, conchoidal fracture. H = 3–4. Biaxial; $N > 1.79$; francisite reacts with high-refractive-index liquids. From the *Iron Monarch iron deposit, Middleback Ranges, SA, Australia, about 400 km NW of Adelaide*, in cavities in a barite lens in the iron deposit, associated with muscovite, chlorargyrite, bismuth, naumannite, djurleite, and other minerals. RG

34.7.1.1 Sonoraite $\text{Fe}^{3+}\text{TeO}_3(\text{OH}) \cdot \text{H}_2\text{O}$

Named in 1968 for the locality. MON *P2₁/c*. $a = 10.984$, $b = 10.268$, $c = 7.917$, $\beta = 108.48^\circ$, $Z = 8$, $D = 4.179$. Structure: *SR* 40A:311(1974). *21-430*: 10.4₁₀ 6.09₄ 5.18₅ 4.66₈ 3.66₆ 3.29₇ 3.11₈ 3.04₅. Crystals platy {100}, striated parallel to c , with {110} and {011}. Yellowish green, vitreous to subadamantine luster. H = 3. G = 3.95. Soluble in dilute acids. Biaxial (-); N_x = 2.018, N_y = 2.023, N_z = 2.025; 2V = 20–25°. Mohawk mine, Goldfield, NV; Cripple Creek, CO; Good Hope mine, Vulcan, Gunnison Co., CO; Joe shaft, Tombstone, AZ(!), with jarosite and rodalquilarite. *Moctezuma mine, Moctezuma, SON, Mexico*(!), with emmonsite, goethite, cuzticitic, and anglesite. RG *AM* 53:1828(1968), *TMPM* 14:27(1970), *MR* 3:82(1972).

34.7.2.1 Cesbronite $\text{Cu}_5(\text{TeO}_3)_2(\text{OH})_6 \cdot 2\text{H}_2\text{O}$

Named in 1974 for Fabien Cesbron (b.1938), French mineralogist, Bureau de Recherches Geologiques et Minière, Orleans. ORTH *Pbcn*. $a = 8.624$, $b = 11.878$, $c = 5.872$, $Z = 2$, $D = 4.455$. *MM* 39:744(1974). *27-194*: 5.93₁₀ 4.89₇ 3.49₉ 2.38₄ 2.36₇ 2.16₃ 1.70₃ 1.59₃. Small spherules of radiating crystals, or as minute wedge-shaped crystals elongated on a . Bright emerald-green, bright luster. Cleavage {021}, good; {010}, poor; brittle. H = 3. G = 4.45. Nonfluorescent. Soluble in dilute HCl and HNO₃, insoluble in water or in KOH solution. Biaxial (+); X = a ; N_x = 1.880, N_y = 1.928, N_z = 2.029 (Na); 2V = 72°; $r > v$; absorption ZY > X. X, pale bluish green; Y, rich yellow-green; Z, deep emerald-green. From the Centennial Eureka mine, Tintic district, Juab Co., UT, with xocomecatlite. *Bambollita ("La Oriental") mine,*

Moctezuma, SON, Mexico, on fracture surfaces associated with a pea-green amorphous Cu-Fe-Te mineral, carlfriesite, and teinite. RG *AM* 64:653(1979).

34.7.3.1 Guilleminite $\text{Ba}(\text{UO}_2)_3(\text{SeO}_3)_2(\text{OH})_4 \cdot 3\text{H}_2\text{O}$

Named in 1965 for Claude Guillemin (1923–1994), French mineralogist and inspector general, Bureau de Recherches Geologiques et Minière. ORTH *Pmna*. $a = 7.25$, $b = 16.84$, $c = 7.08$, $Z = 2$, $D = 5.08$. *AM* 50:2103(1965). 18-582: 8.39₁₀ 7.29₁₀ 6.68₆ 6.51₂ 3.55₈ 3.17₄ 3.04₆ 2.80₆. Bladelike crystals flattened {010}, yellow coatings, silky masses. Light canary-yellow. Cleavage {100}, perfect; {010}, good; fragile and brittle. $G = 4.88$. Biaxial (-); $XYZ = cba$; $N_x = 1.805$, $N_y = 1.798$, $N_z = 1.720$; $2V = 35^\circ$; $r > v$, strong. X, bright yellow; Y, yellow; Z, colorless. In microcrystals at Liauzun en Olloix, Puy de Dôme, France. *Musonoi mine, Kolwezi, Shaba, Zaire*(1), in cavities in selenian digenite, associated with malachite, derriksite, marthozite, and other selenites. RG *BM* 88:132(1965).

34.7.4.1 Marthozite $\text{Cu}(\text{UO}_2)_3(\text{SeO}_3)_3(\text{OH})_2 \cdot 7\text{H}_2\text{O}$

Named in 1969 for Aimé Marthoz (1894–1962), Belgian civil engineer, formerly director general of the Union Minière du Haut-Katanga. ORTH *Pnma* or *Pn2₁a*. $a = 16.40$, $b = 17.20$, $c = 6.98$, $Z = 4$, $D = 4.7$. *AM* 55:533(1970). 25-320: 8.65₇ 8.23₁₀ 4.44₇ 3.50₈ 3.22₉ 3.09₁₀ 3.02₈ 2.90₉. Crystals flattened on {100}; {100} faces striated parallel to [001]. Yellowish green to greenish brown. Cleavage {100}, perfect; {010}, imperfect. $G = 4.4$. Soluble in 1:1 HNO_3 and in dilute HCl . Biaxial (-); $XY = ab$; $N_y = 1.780$ –1.785, $N_z = 1.780$ –1.785 (N_a); $r > v$. X, yellow-brown; Y, greenish yellow. Dehydrates at room temperature to a “meta” phase, with $a = 15.80$, $b = 17.20$, $c = 6.98$. From the zone of oxidation of the *Musonoi mine, Kolwezi, Shaba, Zaire*, with demesmaekerite, guilleminite, malachite, and chalcomenite, in cavities in selenian digenite. RG *BM* 92:278(1969).

34.7.5.1 Derriksite $\text{Cu}_4(\text{UO}_2)(\text{SeO}_3)_2(\text{OH})_6$

Named in 1971 for Joseph Derriks (b.1912), Belgian mining geologist, who studied the Shinkolobwe uranium deposits. ORTH *Pn2₁m*. $a = 5.570$, $b = 19.088$, $c = 5.965$, $Z = 2$, $D = 4.72$. Structure: *AC(C)* 39:1605(1983). 25-319: 5.35₅ 4.78₁₀ 4.35₆ 4.20₅ 4.07₈ 3.75₈ 3.43₅ 3.22₆. Crystals elongated [001], bladelike, flattened on {100}. Green to bottle-green. Cleavage {010}, very good. Biaxial (-); $XYZ = abc$; $N_x = 1.77$, $N_y = 1.85$, $N_z = 1.89$ (520 nm). *Musonoi mine, Kolwezi, Shaba, Zaire*, in cavities in selenian digenite, associated with chalcomenite and demesmaekerite on malachite. RG *BM* 94:534(1971), *AM* 57:1912(1972).

34.7.6.1 Demesmaekerite $\text{Cu}_5\text{Pb}_2(\text{UO}_2)_2(\text{SeO}_3)_6(\text{OH})_6 \cdot 2\text{H}_2\text{O}$

Named in 1965 for Gaston Demesmaeker (b.1911), Belgian mining geologist. TRIC *P1*. $a = 11.955$, $b = 10.039$, $c = 5.639$, $\alpha = 89.78^\circ$, $\beta = 100.37^\circ$, $\gamma = 91.33^\circ$, $Z = 1$, $D = 5.42$. Structure: *AC(C)* 39:824(1983). 18-692: 5.89₆ 5.42₈ 5.14₅

4.72₅ 4.67₅ 4.58₅ 3.34₆ 2.97₁₀. Triclinic crystals, elongated [100] and flattened {100}. Bottle green when fresh, turning somewhat brownish upon dehydration. No cleavage. $H = 3-4$. $G = 5.28$. Biaxial (+); $N_x = 1.835$, $N_z = 1.910$. *Musonoi mine, Kolwezi, Shaba, Zaire*, in the lower part of the oxidation zone, associated with cuprosklodowskite, kasolite, malachite, guilleminite, and chalcocomenite in selenian digenite. RG *BM 88:422(1966)*, *AM 51:1815(1966)*.

34.7.7.1 Haynesite $(\text{UO}_2)_3(\text{OH})_2(\text{SeO}_3)_2 \cdot 5\text{H}_2\text{O}$

Named in 1991 for Patrick Haynes, U.S. geologist who first collected the mineral. ORTH *Pnc2* or *Pncm*. $a = 8.025$, $b = 17.43$, $c = 6.935$, $Z = 2$, $D = 4.07$. *CM 29:561(1991)*. *45-1349*: 8.01₁₀ 5.93₃ 4.01₇ 3.47₆ 3.19₅ 3.12₇ 2.91₈ 2.47₄. Crystallizes as tablets elongate [001], and as acicular prismatic rosettes to 3 mm in diameter. Amber-yellow, vitreous luster, transparent. Cleavage {010}, easy. $H = 1\frac{1}{2}-2$. $G = 4.1$. Fluorescence yellowish green. Biaxial (-); $XYZ = abc$; $N_x = 1.618$, $N_y = 1.738$, $N_z = 1.765$; $2V = 45^\circ$; pleochroic, pale yellow to bright yellow. Found at the *Repete mine near Blanding, San Juan Co., UT*, associated with andersonite, boltwoodite, gypsum, and calcite as crusts on mudstones and sandstones of the Morrison formation. RG *AM 77:447(1992)*.

34.8.1.1 Poughite $\text{Fe}_3(\text{TeO}_3)_2(\text{SO}_4) \cdot 3\text{H}_2\text{O}$

Named in 1968 for Frederick Harvey Pough (b.1906), American mineralogist, curator, and writer. ORTH *Pna2₁*. $a = 9.66$, $b = 14.20$, $c = 7.86$, $Z = 4$, $D = 3.76$. *SR 37A:318(1971)*. *21-435*: 7.10₁₀ 5.74₁₀ 3.56₆ 3.34₆ 3.24₇ 3.05₆ 2.94₅ 2.87₅. Crystals tabular, diamond-shaped, flattened {010}; also as botryoidal crusts. Yellowish to brownish and greenish yellow, vitreous luster. Cleavage {010}, perfect; {101}, good. $H = 2\frac{1}{2}$. $G = 3.75$. Nonfluorescent. Easily soluble in HCl, slowly soluble in hot dilute H_2SO_4 . Biaxial (-); $XYZ = bac$; $N_x = 1.72$, $N_y = 1.985$, $N_z = 1.990$; $2V = 15-20^\circ$. X, colorless; Y, pale greenish yellow; Z, pale yellow. Lone Pine Au-Te deposit, Catron Co., NM, as brown crusts. *Moctezuma mine ("La Bambolla"), Moctezuma, SON, Mexico*, with goethite, emmonsite, jarosite, and pyrite. In small crystals at the *El Plomo mine, Ojojona district, Tegucigalpa, Honduras*. RG *AM 53:1075(1968)*, *TMPM 15:279(1971)*.

34.8.2.1 Tlapallite $\text{H}_6(\text{Ca,Pb})_2\text{Cu}_3(\text{TeO}_3)_4(\text{TeO}_6)(\text{SO}_4)$

Named in 1978 from the Nahua *tlapalli*, paint, in allusion to its paintlike coating of rock surfaces. MON $a = 11.97$, $b = 9.11$, $c = 15.66$, $\beta = 90.04^\circ$, $Z = 4$, $D = 5.05$. *MM42:183(1978)*. *29-319*: 12.0₁₀ 5.95₅ 4.73₄ 3.73₄ 3.54₆ 3.28₄ 2.99₁₀ 2.89₅. Paintlike thin crusts, or somewhat botryoidal when the crusts are thicker. Slightly yellowish green; vitreous luster. No cleavage observed. $G = 4.65$. Nonfluorescent. Pb may substitute for part of the Ca and the Tombstone material is Pb-rich, with $\text{Ca/Pb} = 5:4$, accounting for the higher density, the higher refractive indices, and the slightly larger unit cell of this variety versus that of the Mexican material whose data is given

here. A small amount of zinc substitutes for the copper in both Arizona and Sonora material. Biaxial (-); $N_x = 1.815$, $N_y = 1.960$, $N_z = 1.960$; $2V$ small. At Tombstone, AZ, probably the Lucky Cuss mine, a plumbian tlapallite was found cementing a calc-silicate tactite. At the *Bambollita mine* ("La Oriental"), *Moctezuma, SON, Mexico*, it was found on fracture surfaces adjacent to veins cutting intensely sericitized rhyolites, sometimes associated with carlfriesite. RG *AM 64:465(1979)*.

34.8.3.1 Oboyerite $H_6Pb_6(TeO_3)_3(TeO_6)_2 \cdot 2H_2O$

Named in 1979 for O. (Oliver) Boyer, one of the men who first staked the Grand Central lode claim in the Tombstone district. TRIC *P1* or *P1*. $a = 12.249$, $b = 15.113$, $c = 6.868$, $\alpha = 116.45^\circ$, $\beta = 98.58^\circ$, $\gamma = 85.82^\circ$, $Z = 2$, $D = 6.66$. *AM 66:220(1981)*. $34-1260$: 9.04_3 6.08_3 3.18_7 3.04_{10} 2.98_5 2.93_5 2.86_5 1.80_4 . Minute spherulites with radiating fibrous structure. White. One cleavage, perfect. $H = 1\frac{1}{2}$. $G = \pm 6.4$. Nonfluorescent. Readily soluble in cold dilute HNO_3 , slowly soluble in 1:6 HCl, easily fusible. Biaxial; $N_x = 2.24$, $N_z = 2.26$; no dispersion. *Grand Central mine, Tombstone, AZ*, associated with jarosite, fairbankite, and opal in altered, mineralized shale. RG *MM 43:453(1979)*, *AM 65:809(1980)*.

34.8.4.1 Mroseite $CaTeO_2(CO_3)$

Named for Mary Emma Mrose (b.1910), American mineralogist, U.S. Geological Survey. ORTH *Pbca*. $a = 6.988$, $b = 11.201$, $c = 10.566$, $Z = 8$, $D = 4.171$. Structure: *CM 13:383(1975)*. $29-309$: 5.60_6 5.14_9 4.20_8 3.35_7 3.14_{10} 3.02_7 2.39_7 1.97_8 . Massive, sometimes with radiating structure, crude crystals elongated [001], sometimes platy. Colorless to white, resembling cerussite or barite; adamantine luster. No cleavage. $H = 4$. $G = 4.35$. Nonfluorescent. Soluble with effervescence in cold dilute HCl. Biaxial (-); $XYZ = acb$; $N_x = 1.79$, $N_y = 1.85$, $N_z = 1.89$; $2V = 74^\circ$; $r < v$, strong. *Moctezuma mine, Moctezuma, SON, Mexico*, associated with tellurite and spiroffite. RG *CM 13:286(1975)*, *AM 61:339(1976)*.

34.8.5.1 Eztlite $Fe_6^{3+}Pb_2(Te^{4+}O_3)_3(Te^{6+}O_6)(OH)_{10} \cdot 8H_2O$

Named in 1982 from the Nahua *eztli*, blood, in allusion to the color of the mineral. MON Space group unknown. $a = 6.58$, $b = 9.68$, $c = 20.52$, $\beta = 90.25^\circ$, $Z = 2$, $D = 4.61$. *MM 46:257(1982)*. $35-665$: 10.3_5 5.13_6 4.04_9 3.43_{10} 3.29_{10} 3.24_9 2.61_6 2.45_7 . Thin sparkling crusts of minute crystals. Brilliant red, orange streak. Cleavage {001}, good; very brittle. $H = 3$. $G = 4.5$. Readily soluble in dilute HCl, soluble with difficulty in warm 1:1 HNO_3 . $N_x = 2.14$, $N_z = 2.15$; nonpleochroic. From the oxidation zone of the *Moctezuma mine* ("La Bambolla"), *Moctezuma, SON, Mexico*, associated with cuzticite and kuranakhite. RG *AM 68:471(1983)*.

34.8.6.1 Yecoraite $\text{Bi}_5\text{Fe}_3^{3+}\text{O}_9(\text{Te}^{4+}\text{O}_3)(\text{Te}^{6+}\text{O}_4)_2 \cdot 9\text{H}_2\text{O}$

Named in 1985 for the locality. TET or HEX No material suitable for single-crystal X-ray work was found, and cell constants could not be determined. PD: 5.45₄ 3.72₄ 3.21₇ 2.96₄ 2.74₁₀ 1.94₃ 1.63₃. Cryptocrystalline to glassy masses. Orange to honey colored; pale yellow to brown, resinous to waxy luster. No cleavage, conchoidal fracture, brittle. H = 3. G = 5.59. Nonfluorescent. Readily soluble in cold dilute HCl or HNO₃, fuses easily to a red glass, affords water in CT. Uniaxial (+); N_O = 1.812, N_E = 1.824; microfibers show parallel extinction and are length-slow. *San Martin de Porres mine, W of Yecora, Son., Mexico*, associated with and derived from the oxidation of tetradymite and pyrite. RG *SMMB* 1:10(1985), *AM* 71:1547(1986).

34.8.7.1 Orschallite $\text{Ca}_3(\text{SO}_3)_2(\text{SO}_4) \cdot 12\text{H}_2\text{O}$

Named in 1993 for P. Orschall, German mineralogist, who discovered the mineral. HEX-R *R3c*. $a = 11.350$, $c = 28.321$, $Z = 6$, $D = 1.87$. *MP* 48:168(1993). 45-1484: 8.11₈ 5.73₁₀ 4.87₃ 4.63₃ 3.63₆ 3.28₄ 2.69₈ 2.11₄. Crystals are colorless, transparent pseudocubes to 0.3 mm, vitreous luster. No cleavage, irregular fracture. H ≈ 4. G = 1.90. Uniaxial (+); N_O = 1.494, N_E = 1.496. IR, TGA. Found in cavities in melilite, nepheline, leucitite at *Hannebacher Ley, Eifel, Germany*, with clinopyroxene, phillipsite, and apatite; other cavities contain hannebachite, CaSO₃ · 0.5H₂O. RG *AM* 79:572(1994).

Anhydrous Chromates

35.1.1.1 Tarapacaite K_2CrO_4

Named in 1878 for the locality. ORTH *Pmcn* or *Pnma*. $a = 7.663$, $b = 10.388$, $c = 5.922$, $Z = 4$, $D = 2.736$. Structure: *AC(B)* 28:2845(1972). 15-365(syn): 3.08₁₀ 2.99₈ 2.96₄ 2.60₂ 2.57₂ 2.48₃ 2.29₃ 2.13₂. Crystals thick tabular {001}; pseudo-hexagonal twins on {110}, analogous to aragonite. Bright canary yellow, vitreous luster. Cleavage {010}, {001}, distinct. $G = 2.74$. Easily soluble in water. Biaxial (-); XYZ = *bac*; $N_x = 1.687$, $N_y = 1.722$, $N_z = 1.731$; $2V = 52^\circ$; $r > v$, weak. *Tarapaca province, Chile*, and also in the nitrate deposits of Antofagasta and Atacama provinces. RG *DII:644, ZPC 35:109(1962)*.

35.1.2.1 Phoenicochroite $Pb_2(CrO_4)O$

Named in 1839 from the Greek for *deep red* and *color*, in allusion to the color. MON *C2/m*. $a = 14.001$, $b = 5.675$, $c = 7.137$, $\beta = 115.22^\circ$, $Z = 4$, $D = 7.073$. *AM 55:784(1970)*. 29-768: 6.46₂ 6.34₂ 3.39₁₀ 2.98₈ 2.88₂ 2.84₄ 2.06₂ 1.869₂. Crystals tabular, imperfect; also massive and as thin coatings. Dark red, becomes lemon yellow on exposure; resinous or adamantine luster. Cleavage {201}, perfect. $H = 2\frac{1}{2}$. $G = 7.01$. Soluble in HCl with separation of lead chloride. Biaxial (+); $Y = a$; $Z \wedge b = 2^\circ$; $N_x = 2.34$, $N_y = 2.38$, $N_z = 2.65$ (Li); $2V = 58^\circ$; $r > v$, strong. Potter-Cramer property and Pack Rat claim, S of Wickenburg, Maricopa Co., and elsewhere in AZ, with mimetite, willemite, hemihedrite, and vauquelinite. *Beresov, Ural Mts., Russia*, with angle-site, galena, and crocoite. Anarak, Iran. Sierra Gorda, Antofagasta, Chile. RG *DII:649, BMNHB 2(8)(1974), BM 103:469(1980)*.

35.2.1.1 Lopezite $K_2Cr_2O_7$

Named in 1937 for Emiliano Lopez Saa (1871-1959), Chilean mining engineer and mineral collector from Iquique. Artificial $K_2Cr_2O_7$, besides the triclinic unit cell, also exists in two monoclinic modifications. It has not been established to which of these possibilities Lopezite belongs. TRIC *P1*. $a = 13.419$, $b = 7.391$, $c = 7.468$, $\alpha = 90.87^\circ$, $\beta = 96.23^\circ$, $\gamma = 98.13^\circ$, $Z = 4$, $D = 2.682$. *NBSM 25(15):47(1978)*. 27-380(syn): 4.87₅ 3.66₉ 3.47₉ 3.30₁₀ 3.06₃ 3.03₃ 2.88₃ 2.86₃. Small ball-like aggregates of crystals. Orange-red to red. Cleavage {010}, perfect; {100}, {001}, distinct. $H = 2\frac{1}{2}$. $G = 2.69$. Easily soluble in water to an orange solution. Biaxial (+); $N_x = 1.714-1.720$, $N_y = 1.732-$

1.738, $N_z = 1.805\text{--}1.820$; $2V \approx 51^\circ$; $r > v$, medium. *Huaram, Iquique Pampa, Oficina Rosario, Tarapaca, Chile*, in vugs in massive nitrate rock with tarapaite, dietzeite, and ulexite. RG *DII:645, DANS 172:1068(1967), CJC 46:933(1968)*.

35.3.1.1 Crocoite PbCrO_4

Named in 1832 from the Greek for *saffron*, in allusion to the color. MON $P2_1/n$. $a = 7.127$, $b = 7.438$, $c = 6.799$, $\beta = 102.43^\circ$, $Z = 4$, $D = 6.10$. Structure: AC *19:287(1965)*. 8-209(syn): 4.96_2 4.38_2 3.48_5 3.28_{10} 3.03_6 3.00_3 2.25_2 2.09_2 . Crystals prismatic [001]; also elongated parallel to [101]; sometimes octahedral with {111} and {111}; crystals frequently are cavernous or hollow; massive; granular. Orange, red; yellow, orange streak, adamantine to vitreous luster. Cleavage {110}, distinct; conchoidal to uneven fracture; brittle; sectile. $H = 2\frac{1}{2}$ -3. $G = 6.0$. Fusible; in CT blackens and decrepitates, but recovers its color on cooling. Biaxial (+); $N_x = 2.29$, $N_y = 2.36$, $N_z = 2.66$ (Li); $2V = 57^\circ$. Crocoite is a secondary mineral found in the oxidized zone of lead deposits, especially those associated with ultrabasic rocks. It forms later than anglesite, often replacing it, but usually earlier than cerussite. With wulfenite at the Darwin mines, Inyo Co., CA. In AZ south of Wickenburg, Maricopa Co., at the Potter-Cramer and Phoenix prospects, and the Rat Tail claim. Callenberg, Saxony, Germany(*). Leadhills, Scotland, in microcrystals. Nontron, Dordogne, France. *Beresov, Ekaterinburg, Ural Mts., Russia*(!), with phoenicochroite, anglesite, galena, cerussite, and so on; also from Mursinsk and at Nizhne Tagilsk. Several mines in Zimbabwe, including the Old West and Proprietary mines, Penhalonga; Pet mine, Victoria; Howard's Luck mine, Umtali. In Brazil from Goyabeira, Congonhas do Campo, MG(*), in good crystals. From the Dundas district, TAS, Australia(!), from the Adelaide, West Coast, Dundas Extension, and other mines in magnificent crystals and groups, some individuals reaching 15 cm in length, associated with chromian cerussite, dundasite, massicot, and Mn oxides. RG *DII:646, BMNHB 2:8(1974), ZK 176:75(1986)*.

35.3.2.1 Chromatite CaCrO_4

Named in 1963 for the composition, a chromate. TET $I4_1/amd$. $a = 7.242$, $c = 6.290$, $Z = 4$, $D = 3.142$. NBSC *539(7):13(1957)*. 8-458(syn): 3.62_{10} 2.88_2 2.68_5 2.56_1 2.38_2 1.85_4 1.81_2 1.50_1 . Small grains and coatings. Citron-yellow. No cleavage, conchoidal fracture. Uniaxial (+); $N_O = 1.81\text{--}1.85$, $N_E = 1.84\text{--}1.88$; nonpleochroic. From the *Jerusalem-Jericho highway, Jordan*, in road cuts, from cleft surfaces in upper Cretaceous limestones, associated with gypsum. RG *NW 50:612(1963), AM 49:439(1964)*.

35.3.3.1 Hashemite $\text{Ba}(\text{Cr,S})\text{O}_4$

Named in 1983 for the locality, the Hashemite Kingdom of Jordan. Barite group. See barite (28.3.1.1). ORTH *Prma*. $a = 9.103$, $b = 5.528$, $c = 7.331$, $Z = 4$, $D = 4.52$. Structure: AC(C) *43:1467(1987)*. 35-642: 3.67_6 3.52_{10} 3.40_3

3.17₈ 2.90₃ 2.77₄ 2.18₆ 2.15₄. Prismatic crystals, stubby to tabular. Dark to light brown, adamantine luster. Cleavage {001}, perfect; {010}, {100}, good. $H = 3\frac{1}{2}$. $G = 4.54$. Analyzed material from the type locality varied from $Ba(Cr_{0.93}S_{0.07})O_4$ (dark material) to $Ba(Cr_{0.64}S_{0.36})O_4$ (light material). Probably a complete solid-solution series exists between $BaCrO_4$ and $BaSO_4$. Biaxial (+); $N_x = 1.952$, $N_y = 1.960$, $N_z = 1.977$ (Na); $2V = 56-57^\circ$ (dark brown); $N_x = 1.810$, $N_y = 1.813$, $N_z = 1.824$ (Na); $2V = 35-45^\circ$ (light brown); $r < v$, extreme. *Lisdan-Siwaga fault, Hashem region, 60 km SE of Amman, Jordan*, in specimens from building stone quarries in a phosphatic carbonate rock of Cretaceous age, associated with chrome-bearing ettringite, blue-green apatite, and minor calcite. RG *AM 68:1223(1983), 71:1217(1986)*.

35.4.1.1 Santanaite $9PbO \cdot 2PbO_2 \cdot CrO_3$

Named in 1972 for the locality. HEX $P6_322$. $a = 9.03$, $c = 39.84$, $Z = 6$, $D = 9.155$. *25-435*: 3.54₁₀ 2.95₄ 2.85₄ 2.61₈ 2.24₄ 2.10₄ 2.08₅ 1.70₅. Aggregates of minute platelets. Straw yellow, adamantine luster. Cleavage {0001}, perfect; also {1210}, {1010}. $H = 4$. Uniaxial (-); $N_O = 2.32$, $N_E = 2.12$. *Santa Clara mine, Caracoles, Sierra Gorda, Chile*, in corroded galena, associated with phenicochroite, chromian wulfenite, diaboileite, and quartz. RG *NJMM:455(1972), AM 58:966(1973)*.

35.4.2.1 Wattersite $Hg_4^{1+}Hg^{2+}Cr^{6+}O_6$

Named in 1991 for Lu Watters (1911-1989), California mineral collector, chef, musician, botanist, inventor, and environmentalist. MON $C2/c$. $a = 11.250$, $b = 11.630$, $c = 6.595$, $\beta = 98.17^\circ$, $Z = 4$, $D = 8.91$. *MR 22:269(1991)*. *45-1381*: 8.06₈ 5.58₅ 3.60₅ 3.30₆ 3.26₆ 2.95₅ 2.92₅ 2.66₁₀. Minute crystals on fracture surfaces, or shell-like aggregates in vugs. Dark reddish brown to black, dark brick-red streak, submetallic luster. Cleavage {010}, good; {001}, fair; conchoidal fracture; brittle. $H < 5.0$. Nonfluorescent. Soluble in cold dilute HCl giving a precipitate of calomel; in CT, gives off Hg, which condenses on the side of the tube, leaving a residue of green Cr_2O_3 . In RL, lilac-gray, with deep to bright red internal reflections. Moderately pleochroic, strongly anisotropic. Purple, dark blue, greenish blue, turquoise. $R = 22.4-23.5$ (470 nm), 19.9-26.1 (546 nm), 18.9-23.3 (589 nm), 18.3-21.2 (650 nm). From a prospect pit near the *Clear Creek mercury mine, New Idria district, San Benito Co., CA*, associated with cinnabar and mercury. RG *AM 77:672(1992)*.

35.4.3.1 Deanesmithite $Hg_2^{1+}Hg_3^{2+}Cr^{6+}O_5S_2$

Named in 1993 for Deane K. Smith (b.1930), American mineralogist, Pennsylvania State University, who gave long service to the International Centre for Diffraction Data. TRIC $P\bar{1}$. $a = 8.116$, $b = 9.501$, $c = 6.891$, $\alpha = 100.43^\circ$, $\beta = 10.23^\circ$, $\gamma = 82.8^\circ$, $Z = 2$, $D = 8.14$. *CM 31:787(1993)*. *PD*: 5.72₉ 3.37₆ 3.01₁₀ 2.86₅ 2.77₅ 2.54₅ 2.49₅ 2.43₆. Bladed to acicular radiating crystal clusters, flattened {100}, elongated [001]. Orange-red, adamantine luster. Cleavage {110}, well developed; {001}, fair; irregular to subconchoidal fracture;

brittle to friable. $H < 5$. In RL, dark bluish gray, with bright orange internal reflections, weakly birefringent, weakly pleochroic. $R = 23.4, 23.5$ (470 nm), 20.4, 22.7 (546 nm), 20.0, 21.65 (589 nm), 19.65, 20.95 (650 nm). Found in a quartz–magnesite rock from a prospect pit near *Clear Creek mercury mine, New Idria district, San Benito Co., CA*, with cinnabar, edoylerite, edgarbaileyite, and other Hg minerals. RG *AM 79:1009(1994)*.

35.4.4.1 Edoylerite $\text{Hg}_3^{2+}\text{Cr}^{6+}\text{O}_4\text{S}_2$

Named in 1993 for Edward H. Oyler (b.1915), American mineral collector, who discovered the mineral. MON $P2_1/a$. $a = 7.524$, $b = 14.819$, $c = 7.443$, $\beta = 118.72^\circ$, $Z = 4$, $D = 7.13$. *MR 24:471(1993)*. $45-1452$: 5.94_4 4.88_5 3.21_{10} 3.01_6 2.31_4 2.21_4 2.19_4 1.908_3 . Crystals acicular to prismatic [001], usually in stellate groupings. Canary- to orange-yellow, adamantine luster. Photosensitive, slowly turns olive-green in daylight. Subconchoidal fracture, brittle. Insoluble in common acids, but dissolves slowly in aqua regia. Biaxial; $Z = c$; $N \gg 1.78$; strongly birefringent; weakly pleochroic; absorption $Z > X = Y$. In RL, light gray, weakly birefringent, weakly pleochroic; no internal reflections. $R = 17.6, 19.0$ (470 nm), 16.95, 19.7 (546 nm), 16.4, 19.55 (589 nm), 16.0, 19.15 (650 nm). *Clear Creek claim, New Idria mining district, San Benito Co., CA*, with cinnabar and secondary mercury minerals on a quartz–ferroan magnesite matrix. RG *AM 79:1009(1994)*.

Compound Chromates

36.1.1.1 Iranite $\text{Pb}_{10}\text{Cu}(\text{CrO}_4)_6(\text{SiO}_4)_2(\text{F}, \text{OH})_2$

Named in 1963 for the country of origin. TRIC $P1$ or $P\bar{1}$. $a = 9.543$, $b = 11.403$, $c = 10.740$, $\alpha = 120.43^\circ$, $\beta = 92.5^\circ$, $\gamma = 55.55^\circ$, $Z = 1$, $D = 6.67$. *BM 103:469(1980)*. *15-683*: 4.84₈ 4.42₈ 3.60₁₀ 3.49₁₀ 3.44₈ 3.28₁₀ 3.18₁₀ 3.08₁₀. Minute crystals. Saffron-yellow, vitreous luster. $G = 6.1$. Soluble in warm Na_2CO_3 solution. Biaxial; $N_x = 2.25\text{--}2.30$ (brownish orange, parallel elongation), $N_z = 2.40\text{--}2.50$ (yellow-orange, perpendicular to elongation); $2V$ very large. *Sebarz mine, NE of Anarak, Iran*, associated with diopase and fornacite. *RG BM 86:133(1963)*, *AM 48:1417(1963)*, *NJMM:406(1972)*.

36.1.1.2 Hemihedrite $\text{Pb}_{10}\text{Zn}(\text{CrO}_4)_6(\text{SiO}_4)_2\text{F}_2$

Named in 1967 in allusion to its morphology. TRIC $P1$. $a = 9.497$, $b = 11.443$, $c = 10.841$, $\alpha = 120.5^\circ$, $\beta = 92.1^\circ$, $\gamma = 55.83^\circ$, $Z = 1$, $D = 6.50$. *AM 55:1088(1970)*. Structure: *AM 55:1103(1970)*. *24-1457*: 4.87₉ 4.36₈ 3.30₁₀ 3.16₈ 3.10₈ 2.92₆ 2.85₅ 2.18₅. Triclinic crystals, with hemihedral symmetry; four twin laws observed. Bright orange, brown, nearly black; yellow streak. $H = 3$. $G = 6.42$. Decomposed by 1:1 NH_4OH or 1:1 HCl with formation of white residues, slowly decomposed by 20% KOH . Biaxial (-); $N_x = 2.105$, $N_y = 2.32$, $N_z = 2.65$; $2V = 85^\circ$; strong dispersion, unsymmetric. *Florence mine, Pinal Co., and Pack Rat claim, Wickenburg, Maricopa Co., AZ*, associated with cerussite, phoenicochroite, vauquelinite, willemite, and wulfenite. *RG CM 9:310(1967)*, *NJMM:328(1972)*, *BM 103:469(1980)*.

36.1.2.1 Macquartite $\text{Pb}_3\text{Cu}(\text{CrO}_4)(\text{SiO}_3)(\text{OH})_4 \cdot 2\text{H}_2\text{O}$

Named in 1980 for Louis Charles Henri Macquart (1745–1803), French chemist, who brought to France from Russia the samples of crocoite in which the element chromium was discovered. MON Space group uncertain, probably $C2/m$. $a = 20.81$, $b = 5.84$, $c = 9.26$, $\beta = 91.8^\circ$, $Z = 4$, $D = 5.58$. *AM 66:638(1981)*. *33-466*: 4.82₉ 4.63₉ 3.16₁₀ 3.09₈ 2.93₅ 2.77₅ 2.32₄ 2.24₄. Small euhedral crystals, somewhat resembling mimetite. Orange, pale orange streak. Cleavage $\{100\}$, good. $H = 3\frac{1}{2}$. $G = 5.49$. Decomposed by 40% HClO_4 or concentrated HCl . Biaxial (-); $Y = b$; $X \wedge c = 35^\circ$; $N_x = 2.28$, $N_y = 2.31$, $N_z = 2.34$; $2V = 85^\circ$. *Mammoth mine, Tiger, Pinal Co., AZ*, encrusting diopase, associated with willemite and quartz. *RG BM 103:530(1980)*.

Anhydrous Acid Phosphates, Arsenates, and Vanadates

37.1.1.1 Monetite CaHPO_4

Named by C. U. Shepard in 1882 for the locality. TRIC $P\bar{1}$. $a = 6.910$, $b = 6.627$, $c = 6.998$, $\alpha = 96.34^\circ$, $\beta = 103.82^\circ$, $\gamma = 88.33^\circ$, $Z = 4$, $D = 2.924$. Structure: $AC(B)$ 33:1223(1977). 9-80(syn): 3.37₇ 3.35₈ 3.13₂ 2.96₁₀ 2.94₄ 2.75₂ 2.72₄ 1.850₂. Crystals small with rough faces, usually flattened {010} with rhombohedral outline, interpenetrating groups; massive aggregates of minute crystals, crusts, or stalactites. Pale yellowish white, synthetic pure white; vitreous luster; translucent. Indistinct cleavage in three directions, uneven fracture, brittle. $H = 3\frac{1}{2}$. $G = 2.929$. Biaxial (+); $N_x = 1.587$, $N_y \approx 1.615$, $N_z = 1.640$; 2V large; $r > v$, weak. Finely divided monetite takes up H_2O from atmosphere forming brushite. Loses H_2O , forming $\text{Ca}_2\text{P}_2\text{O}_7$ at elevated temperature and pressure. Occurs in phosphate-rock deposits in limestone underlying bed of bird guano on *Moneta Is.* and *Mona Is.*, 6½ km S of *Mayaguez, PR*, with gypsum. Also with whitlockite on *Los Monges Is.*, off Gulf of Maracaibo, Venezuela; on *Ascension Is.*, South Atlantic Ocean, with apatite and newberyite; cave deposit of phosphates at *Gunong Jerneh, Malaysia*; *Enderbury Is.*, *Phoenix Islands*. HCWS *DII:660, MRB 5:437(1970)*.

37.1.1.2 Weillite CaHAsO_4

Named by Herpin and Pierrot in 1963 for René Weil (b.1901), mineralogist of Strasbourg, France, known for his study of Alsatian minerals. TRIC $P1$. $a = 7.059$, $b = 6.891$, $c = 7.201$, $\alpha = 97.43^\circ$, $\beta = 103.55^\circ$, $\gamma = 87.75^\circ$, $Z = 4$, $D = 3.45$ $AC(B)$ 26:403(1970). 16-710(syn): 4.55₆ 3.48₅ 3.43₁₀ 3.22₅ 3.05₁₀ 2.79₇ 2.60₅ 2.29₆. Powdery incrustations or pseudomorphs after pharmacolite, haidingerite. White, porcelanous, greasy to pearly luster. $G = 3.48$. Biaxial (-); $X \wedge (001) = 20^\circ$, $Y \wedge (001) = 27^\circ$; Z perpendicular to (001)– 34° ; $N_x = 1.688$, $N_z = 1.664$ in (001); 2V = 82° . A secondary mineral in oxidized As-rich veins, usual alteration product of pharmacolite (39.1.1.2) and haidingerite (39.1.5.1), which are hydrated Ca arsenates. Found at *Getchell mine, Humboldt Co., NV*; *St.-Marie-aux-mines, Haut-Rhin, France*, and at *Schneeberg, Saxony, Germany*. HCWS *AM 49:816(1964)*.

37.1.2.1 Schultenite PbHAsO_4

Named in 1926 by L. J. Spencer for Baron August Benjamin de Schulten (1856–1912) of Helsingfors and Paris, who prepared and described artificial crystals of the compound. MON $P2/a$. $a = 5.827$, $b = 6.743$, $c = 4.847$, $\beta = 95.34^\circ$, $Z = 2$, $D = 6.079$ MM 49:65(1985). 29-772(syn): 6.74₃ 4.41₂ 3.38₁₀ 3.15₇ 2.92₂ 2.91₂ 2.56₂ 2.20₂. Crystals tabular parallel to {010}, resembling gypsum in outline with {001} usually, but may show {111}, {130}, {140}, {011}, {121}, { $\bar{3}22$ }. Striations parallel to c on {010} and parallel to a on {001}. White, pale yellow, colorless; white streak; vitreous to adamantine luster; transparent; brilliant. Fishtail twins from North Bend up to 3.5 mm. Cleavage parallel to {010}, good; brittle. $H = 2\frac{1}{2}$. $G = 6.07$. Fluoresces dull yellow in LWUV (North Bend). Biaxial (+); X parallel to b ; $Y \wedge c = -24^\circ$, $Z \wedge c = 66^\circ$; $N_{x \text{ calc}} = 1.890$, $N_y = 1.910$, $N_z = 1.977$ (Na); $2V = 58.2^\circ$; strong dispersion. Found at *Tsumeb, Namibia*, associated with anglesite and bayldonite; alters to anglesite. Also at North Bend, King Co., WA, Australia, in vugs in quartz–arsenopyrite–galena vein with galena and mimetite and associated with cuprian adamite, keyite, and tennantite. The common constituent of the “lead arsenate” of commerce, widely used as an insecticide. hcws *DII:661*, MM 29:287(1950).

37.1.3.1 Phosphammite $(\text{NH}_4)_2\text{HPO}_4$

Named by C. U. Shepard in 1870 for the composition. See biphosphammite (37.1.4.1). MON $P2_1/c$. $a = 8.03$, $b = 6.68$, $c = 11.02$, $\beta = 113.6^\circ$, $Z = 4$, $D = 1.61$. AC 10:709(1957). 29-111(syn): 5.57₇ 5.05₁₀ 4.94₆ 4.13₄ 3.78₅ 3.22₆ 3.14₄ 3.06₄. Colorless crystals, translucent. $G = 1.62$. Found with biphosphammite in the guano deposits at *Guañape Is., Peru*, 640 km NE of Chincha Is.; also with urea, ammonian apthitalite, and weddelite in guano at Toppin Hill ($28^\circ 42' \text{ S}$, $123^\circ 56' \text{ E}$), WA, Australia. hcws *DS 6:807(1892)*, MM 39:346(1973).

37.1.4.1 Biphosphammite $(\text{NH}_4, \text{K})\text{H}_2\text{PO}_4$

Named by C. U. Shepard in 1870 for the composition. See phosphammite (37.1.3.1) and archerite (37.1.4.2). TET $I42d$. $a = 7.4935$, $c = 7.340$, $Z = 4$, $D \approx 1.98$. Structure: AC(B) 29:2721(1973). 37-1479: 5.32₁₀ 3.75₉ 3.08₉ 3.07₉ 2.66₂ 2.65₂ 2.02₄ 2.01₄. Powdery crusts. White to deep brown, white streak, dull, earthy luster. Very soft. $G = 2.04$. Uniaxial (-); $N_0 = 1.525$, $N_E = 1.480$; synthetic identical. Found on phosphammite in guano deposits at *Guañape Is., Peru*; crusts on bat guano, Murra-el-Elevyn cave, Cockle-biddy, WA, Australia. hcws *DS 6:807(1892)*, MM 38:965(1972), AM 58:806(1973).

37.1.4.2 Archerite KH_2PO_4

Named by P. J. Bridge in 1977 for Michael Archer (b.1945), professor of biology, University of NSW, Sydney, Australia, who drew attention to the deposit. TET $I42d$. $a = 7.453$, $c = 6.974$, $Z = 4$, $D = 2.33$. NBS M

25:21:101(1985) Structure: ZK 74:306(1930). 35-807(syn): 5.09₁ 3.72₁₀ 3.01₁ 2.91₈ 2.64₂ 2.34₁ 1.982₁ 1.953₅. Tetragonal crystals up to 2 mm long with second-order prisms and pyramids. White, translucent, no distinct cleavage, relatively soft, water soluble. Uniaxial (-); $N_O = 1.511$, $N_E = 1.43$. Found in stalactites at *Petrogale cave, near Madura Motel (31°54' S, 127° E), WA, Australia*, with biphosphammite, other phosphates, and saline minerals such as apthitalite, syngenite, stercordite, weddelite, whitlockite, newberyite, calcite, and halite. HCWS *MM 41:33(1977), AM 62:1057(1977)*.

37.1.5.1 Nahpoite Na_2HPO_4

Named in 1981 after the composition (mnemonic). MON $P2_1/m$ or $P2_1$. $a = 5.47$, $b = 6.84$, $c = 5.45$, $\beta = 116.33^\circ$, $Z = 2$, $D = 2.58$. *CM 19:373(1981)*. 35-735(syn): 3.98₅ 3.84₆ 3.42₂ 2.88₄ 2.81₁₀ 2.73₅ 2.72₃ 2.66₂. Fine grained, earthy, white, soft. Microscopic grains are elongate to 4 μm with irregular edges. $N_{\text{max}} = 1.505$, $N_{\text{min}} = 1.490$; parallel extinction; length-fast. Found Mt. St.-Hilaire, QUE, Canada; in nodules in phosphatic ironstones in *Big Fish R. in northern Richardson Mts., YT, Canada*, with maricite and satterlyite; also in Khibina and Lovozero massifs, Kola Penin., Russia. HCWS

37.1.6.1 Lotharmeyerite $\text{CaZnMn}^{3+}(\text{AsO}_3\text{OH})_2(\text{OH})_3$

Named by P. Dunn in 1983 for Julius Lothar Meyer (1830-1895), German chemist who developed concepts for the periodic table. Mn^{3+} end member in Mn^{3+} - Fe^{3+} series with ferrilotharmeyerite (37.1.6.2). MON $C2$, Cm , $C2/m$. $a = 9.066$, $b = 6.276$, $c = 7.408$, $\beta = 116.16^\circ$, $Z = 2$, $D = 4.29$. *MR 15:223(1984)*. 35-620: 4.94₈ 3.41₉ 3.18₉ 2.91₉ 2.82₈ 2.71₈ 2.56₁₀ 1.687₈. Equant twinned crystals. Dark reddish orange, orange streak, vitreous luster. $H = 3$. $G = 4.23$. $N_{\text{av}} > 1.80$; strongly pleochroic, dark red-orange to light pink-orange. Occurs as drusy incrustations on adamite and Mn oxides (e.g., cryptomelane). Found at *Ojuela mine, Mapimi, DGO, Mexico*. HCWS *AM 68:849(1983), 68:849(1983); MR 14:35(1983)*.

37.1.6.2 Ferrilotharmeyerite $\text{Ca}(\text{Zn,Cu})(\text{Fe}^{3+},\text{Zn})(\text{AsO}_3\text{OH})_2(\text{OH})_3$

Named in 1992 for its relationship to lotharmeyerite (37.1.6.1). MON $C2$, Cmn , $C2/m$. $a = 8.997$, $b = 6.236$, $c = 7.390$, $\beta = 115.74^\circ$, $Z = 2$, $D = 4.25$. Structure: *CM 30:225(1992)*. *PD*: 4.95₇ 3.40₁₀ 3.18₁₀ 2.94₁₀ 2.82₇ 2.70₇ 2.54₁₀. Aggregates (to 3 mm) of subhedral crystallites (0.2 mm long) and tabular to wedge- or lozenge-shaped (0.6 mm long). Brownish yellow, pale yellow streak, adamantine to greasy luster, transparent to translucent. Cleavage $\{001\}$, good; uneven fracture. $H = 3$. $G = 4.25$. Nonfluorescent. Biaxial (+); $X \approx a$, $Y = b$; $N_x = 1.811$, $N_y = 1.844$, $N_z = 1.88$; $2V = 85^\circ$; strongly pleochroic; olive-green; Y, pale green; Z, colorless inclined dispersion; $r > v$. X. Occurs with tennantite, scorodite, conicalcite, beudantite, and schneiderhönite at the *Tsumeb mine, Tsumeb, Namibia*. HCWS

Anhydrous Normal Phosphates, Arsenates, and Vanadates

38.1.1.1 Triphylite $\text{LiFe}^{2+}\text{PO}_4$

Named by J. Fuchs in 1834 from the Greek for *threefold* and *family*, in allusion to the composition containing three cations. In a series (Mn–Fe) with lithiophilite (38.1.1.2). Isostructural with olivines. *CIWY* 68:290(1970). ORTH *Pbnm*. $a = 4.704$, $b = 10.347$, $c = 6.0189$, $Z = 4$, $D = 3.59$. See also *JPD* 4:26(1989). Structure: AC(B) 32:2761 (1976). 40-1499: 5.18₃ 4.28₈ 3.92₃ 3.49₇ 3.01₁₀ 2.78₃ 2.53₈ 2.46₂. See also 19-721(syn). Euhedral crystals rare, usually coarse with uneven surfaces, stout prismatic [100]. Grains up to 5 mm have been found in pegmatites. Commonly massive, cleavable. Bluish gray or greenish gray, colorless to grayish white streak, vitreous to subresinous luster, transparent to translucent. Cleavage {001}, nearly perfect (distinctive from olivines); {010}, imperfect; {011}, interrupted; uneven to subconchoidal fracture. $H = 4\frac{1}{2}$. $G = 3.565$. Oriented growth with graftonite, or armored by blue tourmaline. Biaxial (–) at highest Fe–Mn contents; $N_x = 1.694$, $N_y = 1.695$, $N_z > 1.71$ (Na); $2V \approx 0^\circ$; nonpleochroic; see *DII:666*. Oxidation, leaching of Li increases N, while Mg reduces N (*AM*28:90(1943)). Altered by meteoric and hydrothermal solutions with ease, forming ferrisicklerite with concomitant leaching of Li. The oxidation products are often found as oriented single-crystal pseudomorphs after original crystals and may ultimately alter completely to iron oxyhydroxides. Alteration is usually accompanied by the formation of secondary Fe-phosphates such as strengite, metastrengite, dufrenite, frondelite, rockbridgeite, and vivianite. Occurs as primary mineral in granite pegmatites. Many localities worldwide were summarized in *MR* 4:103(1973). New England sites prominent in the list are mines and quarries in ME: at Mount Apatite and Pulsifer quarry, near Auburn, at Mt. Mica mine, near Paris, and the Black Mt. and Red Hill mines near Rumford; in NH: at E. E. Smith mine, Newport, Sullivan Co., near Alexandria(II), the Buzzo quarry and Parker Mt. mine near Center Strafford, at mine 4 at Palermo No. 1 and No. 2(I), North Groton, and at the Ruggles mine(I) near Grafton Center. Also found at Cobalt, and *Branchville, CT*; in the pegmatites of the Keystone district in the Black Hills at the Tin Mt. Lode, Big Chief mine, Dan Patch and Bull Moose pegmatite(I), near Custer, SD; at Pala, San Diego Co., CA; and at Pointe du Bois, MB, Canada. European localities: La Vilate, and Hureaux, France; at Hagedorf Süd(I) and Hühnerkobel, Bavaria, Germany, triphylite is embedded in “bull” quartz, and associated with beryl,

tantalite, tourmaline, and minor sulfides-arsenides; at Dolaj Bory, Moravia, Czech Republic; at Norrö and Varuträsk, Sweden; at Sukula and Tammela, Finland; Kalbinsk pegmatite, Russia; at Aracuai, Lavra Velha, and Galileia, Lavra do Enio, and at Sapucaia(l), MG, Brazil. Collectors often find good micromounts of many phosphate minerals at these locations. *HCWS DII:665; SPD 22:347(1978); BM 99:274(1976), 99:271(1976); MR 4:103(1973)*.

38.1.1.2 Lithiophilite $\text{LiMn}^{2+}\text{PO}_4$

Named in 1878 for the composition and from the Greek for *friend*. See triphylite (38.1.1.1). *ORTH Pbnm*. $a = 4.749$, $b = 10.454$, $c = 6.106$, $Z = 4$, $D = 3.44$. Structure: *AC 13:325(1960)*. Isostructural with olivine. *33-803: 5.24₃ 4.31₆ 3.96₃ 3.52₇ 3.05₉ 2.81₃ 2.55₁₀ 2.49₃*. See also *33-804(syn)*. Crystals rare, coarse with uneven surfaces, stout prismatic, commonly massive, cleavable to compact. Clove-brown, yellowish brown to honey-yellow, salmon, exposed surfaces often brown, dark gray to black due to alteration; colorless to grayish white streak; vitreous luster; transparent. Cleavage {001}, nearly perfect; {010}, imperfect; {011}, interrupted; uneven to subconchoidal fracture. $H = 4\frac{1}{2}$. $G = 3.34$. Biaxial (+); $XYZ = acb$; $N_x = 1.669$, $N_y = 1.673$, $N_z = 1.682$; $2V \approx 65^\circ$; $r < v$, strong. Mg substitution markedly lowers N *DII:666*. Small amounts of Na substitute for Li. Soluble in acids. Readily undergoes alteration with meteoric or hydrothermal solutions to other phosphate minerals with Mn predominant, such as the Mn end members sicklerite, triploidite, reddingite, eosphorite, fairfieldite, dickinsonite, fillowite, and rhodochrosite. Further oxidation (Mn^{2+} to Mn^{3+} , associated with Fe^{2+} to Fe^{3+}) yields purpurite-heterosite series minerals. The oxidized forms are often pseudomorphic around unaltered cores of lithiophilite, other Mn^{3+} - Fe^{3+} phosphates, and hydrated phosphate phases, such as hureaulite, may be present. Lithiophilite is a primary mineral in granite pegmatites, commonly associated with the alteration minerals listed above, and spodumene, albite, beryl, amblygonite, and graptone. Found at Tamminen quarry, Greenwood, Oxford Co.; Pulsifer quarry, Auburn, Androscoggin Co. ME; Strickland quarry, Portland, Middlesex Co.; *Fillow quarry(l)*, *Branchville*, *Redding Twp.*, *Fairfield Co., CT*; Foote mine(l), Kings Mt., NC; Animikie Red Ace pegmatite, Florence Co., WI; Custer Mt. pegmatite, Custer, Custer Co., SD; Harding mine, Taos Co., NM; Outpost mine, White Picacho district, AZ; Stewart mine, Pala, San Diego Co., CA; Tanco mine, Bernic Lake, Manitoba, Canada; Mangualde(l), Portugal; Viitaniemi, Eräjärvi, Finland; Sajany, Siberia, Russia; Picuí, Paraíba, Brazil; Karibib, Namibia; Noumas pegmatite, Steinkopf, Namaqualand, South Africa; Wodgina, WA, Australia. *HCWS MR 4:103(1973)*.

38.1.1.3 Natrophilite $\text{NaMn}^{2+}\text{PO}_4$

Named in 1890 from the Latin *natrium*, sodium, and from the Greek for *friend*. *ORTH Pbnm*. $a = 4.985$, $b = 10.517$, $c = 6.314$, $Z = 4$, $D = 3.47$. Olivine structure; Na confined to one cation site. *AM 57:1333(1972)*. *25-846: 4 50₆ 4.05₆ 3.66₅ 3.15₅ 2.86₈ 2.60₁₀ 2.58₁₀ 1.831₇*. Rare, indistinct crystals, resembling triphylite, commonly as cleavable masses or granular. Deep wine-yellow; adaman-
