tine, resinous luster, pearly on cleavage; transparent to translucent. Cleavage {001}, good; {010}, indistinct; {021}, interrupted; conchoidal fracture. $H = 4.7$. $G = 3.41$. Biaxial (+); $XYZ = acb$; $N_x = 1.671$, $N_y = 1.674$, $N_z = 1.684$; $2V = 75^\circ$; $r < v$, strong. Fe^{2+} substitutes for Mn^{2+} with maximum $Fe/Mn \approx 1.13$. Soluble in acids. Alters to fine-fibrous yellow mineral with silky luster. Found sparingly with lithiophilite, triplodite, eosphorite, hureauite, fairfieldite, and dickinsonite in granite pegmatite at *Fillow quarry, Branchville, Fairfield Co., CT*. $HCWS$ *DII:670*.

38.1.2.1 Maricite $NaFe^{2+}PO_4$

Named in 1977 for Luka Maric (b.1899), mineralogist, University of Zagreb, Croatia. ORTH $Pmnb$. $a = 6.861$, $b = 8.987$, $c = 5.045$, $Z = 4$, $D = 3.64$. Structure: *CM 15:518(1977)*. Pseudo-hexagonal; buchwaldite (38.1.2.2) is the Ca analog. *29-1216*: 4.40_2 3.71_4 2.73_9 2.71_8 2.57_{10} 2.53_3 1.881_3 1.853_6 . Nodular, elongate on a . Ludlamite, quartz, and vivianite may be inclusions within the maricite. Colorless, gray, pale brown; white streak; vitreous luster; transparent. No cleavage. Nonfluorescent. $G = 3.66$. Biaxial (-); $XYZ = abc$; $N_x = 1.676$, $N_y = 1.695$, $N_z = 1.698$; $2V = 43^\circ$; $r > v$, weak, nonpleochroic. Found as concretions in shales in sideritic ironstones, occasionally monomineralic, but often with kulanite, baricite, and penikisite. Associated with lazulite, childrenite, and siderite at *Big Fish R., YT, Canada*. $HCWS$ *CM 15:396(1977)*.

38.1.2.2 Buchwaldite $NaCaPO_4$

Named in 1977 for Vagn Buchwald, Department of Metallurgy, Danmarks Tekniske Højskole, Lyngby, Denmark. ORTH $Pmn2_1$. $a = 5.167$, $b = 9.259$, $c = 6.737$, $Z = 4$, $D = 3.21$. *AM 62:362(1977)*. *29-1194*: 3.79_9 2.72_{10} 2.63_6 2.58_5 2.51_4 2.19_4 1.91_8 1.54_3 . Minute inclusions mostly $< 10 \mu m$ across, polycrystalline interlocking masses of fine needles. White, translucent. $H < 3$. Biaxial (-); $N_x = 1.607$; $N_y = 1.610$, $N_z = 1.616$; $2V \approx 65^\circ$; parallel extinction; positive elongation. A meteorite mineral found within troilite nodules of the *Agpalilik fragment, Cape York Meteorite, Greenland*, associated with single crystals of chromite and two other phosphate phases, one Cr-rich, the other Mn-rich. $HCWS$

38.1.3.1 Olgite $Na(Sr, Ba)PO_4$

Named in 1980 for Olga Anisimovne-Vorobiova (1902–1974), Russian mineralogist. HEX-R $P3$. $a = 5.565$, $c = 7.050$, $D = 3.52$. *SPC 29:633(1984)*. *33-1212*: 6.99_3 3.97_4 2.84_{10} 2.76_{10} 2.27_3 1.982_6 1.647_3 1.607_4 . Crystals up to 2 mm in diameter exhibit (1010), (1011) dominant, also (0001), (1120), (1121). Bright blue, bluish green; vitreous luster. $H = 4\frac{1}{2}$. $G = 3.94$. IR. Uniaxial (-); $N_O = 1.623$, $N_E = 1.619$. Insoluble in H_2O , dissolves in cold 1:10 HCl. Occurs in nepheline syenite pegmatite in analcime and natrosilite at *Mt. Karnasurt, Lovozero massif, Kola Penin., Russia*. $HCWS$ *ZVMO:109(1981)*, *AM 66:438(1981)*.

38.1.4.1 Ferrisicklerite $(\square_x, \text{Li}_{1-x})(\text{Fe}_{1-x}^{2+}, \text{Fe}_x^{3+})\text{PO}_4$

Named in 1937 for the Sickler family of Pala, CA. End member of the series $(\text{Fe}^{2+}, \text{Fe}^{3+})\text{-Mn}^{2+}$ with sicklerite (38.1.4.2); intermediate in alteration of triphylite (38.1.1.1). ORTH *Pbnm*. $a = 4.796$, $b = 10.026$, $c = 5.916$, $Z = 4$, $D = 3.53$. Structure: *AC(B) 32:2761(1976)*. Related to olivines. 29-808: 5.01₇ 4.33₄ 3.82₂ 3.49₃ 2.96₁₀ 2.49₃ 2.44₁ 1.479₁. Massive. Yellowish, dark brown; streak and powder light yellow-brown to brown but not purple; subtranslucent to opaque. Cleavage {100}, good. $H = 4$. $G = 3.41$. A secondary mineral formed through alteration of triphylite–lithiophilite, usually as rims around these species in crystallographic continuity. Some (OH) may substitute for O of (PO_4) . Found in pegmatites associated with hureaulite, stewartite, jahnsite, and metastrengite at Center Strafford, Rochester, and North Groton, NH; at Peru and Stoneham, ME, and other pegmatite localities in New England; at Williams prospect, Carson Co., AL; in Keystone and Custer districts, Black Hills, SD; with sicklerite at Pala, CA; in the pegmatite district in Haute-Vienne, Plateau Central, France; at Hühnerkobel and Hagendorf, Bavaria, Germany; Varutrask, Sweden; Tammela, Finland; Telirio mine, MG, Brazil; Euriowie Range, NSW, Australia. *hcws DII:672, MR 4:103(1973), BM 99:271(1976)*.

38.1.4.2 Sicklerite $(\square_x, \text{Li}_{1-x})(\text{Mn}_{1-x}^{2+}, \text{Mn}_x^{3+})\text{PO}_4$

Named in 1912 for the Sickler family of Pala, CA. End member of a series $\text{Mn}^{2+}\text{-}(\text{Fe}^{2+} + \text{Fe}^{3+})$ with ferrisicklerite (38.1.4.1); intermediate in alteration of lithiophilite (38.1.1.2). ORTH *Pbnm*. $a = 4.794$, $b = 10.063$, $c = 5.947$, $D = 3.50$. *BM 99:274(1976)*. 33-802: 5.04₃ 4.33₃ 3.50₄ 2.97₁₀ 2.50₈ 2.45₄ 1.608₃ 1.487₃ (contains Fe). Massive. Yellow, dark brown; streak and powder light yellow-brown to brown, red-brown, but not purple; subtranslucent to opaque. Cleavage {100}, good. $H = 4$. $G = 3.36$. Biaxial (-); $X = a$; $N_x = 1.715$, $N_y = 1.735$, $N_z = 1.745$; 2V medium large; $r > v$, very strong. Alters to purpurite. Alteration product of lithiophilite in pegmatites in New England and in the weathering zone at Naylor–Vanderburg mine, Pala, San Diego Co., CA, associated with hureaulite, stewartite, jahnsite, and metastrengite; at Varutrask, Sweden; at Erajarvi near Orivasi and Tammela, Finland; at Wodgina, WA, Australia. *hcws DII:672, MR 4:103(1973)*.

38.1.5.1 Beryllonite NaBePO_4

Named in 1888 for the composition. See esperite, a silicate analog containing (Pb,Ca,Zn). MON *P2₁/c*. $a = 8.178$, $b = 7.818$, $c = 14.114$, $\beta = 90^\circ$, $Z = 12$, $D = 2.802$. Structure: *TMPM 20:1(1973)*. Puckered PO_4 and BeO_4 in pseudoditrigonal rings that parallel (010). Na in channels. 33-1213(syn): 4.09₂ 3.90₁₀ 3.62₄ 3.60₃ 2.82₆ 2.25₄ 1.954₂ 1.948₄. *PD: 4.41₄ 3.90₇ 3.62₈ 3.61₄ 2.823₁₀ 2.816₆ 2.35₄ 2.25₆*. *JPD 8:47(1993)*. Tabular {010} to short prismatic [010], crystals often complex with multiple faces in the zone [010] near {100}. Faces often dull or rough may be in oscillatory combination in the zones [100] and [010]. Twin plane {101}, contact and penetration twins, repeating, and in pseudohexagonal stellate forms, also polysynthetic. Crystals often show columnar structure due

to presence of hollow canals and fluid-filled cavities parallel to [010]. Colorless to snow white, pale yellowish; vitreous, brilliant luster, pearly on {010}; transparent to translucent. Cleavage {010}, perfect; {100}, good; {101}, indistinct; conchoidal fracture; brittle. $H = 5\frac{1}{2}$ –6. $G = 2.81$. Biaxial (-); $XYZ = bac$; $N_x = 1.552$, $N_y = 1.558$, $N_z = 1.561$ (Na); $2V = 67.95^\circ$; $r < v$, weak. Found at Emmons quarry, Greenwood; with hydroxylherderite and elbaite at Dunton quarry, Newry; with smoky quartz crystals, muscovite, fluorapatite, triplite, beryl, cassiterite, microcline, and albite in a disintegrated *pegmatite at base of Sugarloaf Mt(1)* (erroneously McKean Mt.), Stoneham, Oxford Co., ME; Rio Tinto mine, Ungave, Labrador; Mt. St-Hilaire, QUE, Canada; Viitaniemi, Eräjärvi, Finland; Altai, Russia; Lavra da Ilha(1), Taquaral; Almerindo mine, Linópolis; Lavra do Enio, Galiléia, MG, Brazil; Paroc(1), Kunar, Laghman Prov., Afghanistan. *HCWS DII:677, AM 37:931(1958), MR 4:103(1973)*.

38.1.6.1 Panethite $(Na,Ca,K)_2(Mg,Fe^{2+},Mn^{2+})_2(PO_4)_2$

Named in 1967 for Friedrich Adolph Paneth (1887–1958), director of the Max-Planck Institute for Chemistry, Mainz, Germany, who studied meteorites. *MON P2₁/n*. $a = 10.18$, $b = 14.90$, $c = 25.87$, $\beta = 91.10^\circ$, $Z = 4$, $D = 2.99$. *GCA 31:1711(1967)*. *20-828*: 5.10₆ 4.21₄ 3.95₄ 3.24₅ 3.01₁₀ 2.75₅ 2.71₇ 2.55₄. Grains in meteorite, shows simple twinning. Pale amber, transparent. $G = 2.9$. Biaxial (-); $N_x = 1.567$, $N_y = 1.576$, $N_z = 1.579$ (Na); $2V = 51^\circ$. Microprobe analysis; has been synthesized. A meteorite mineral. Occurs with brianite in the *Dayton meteorite, Montgomery Co., OH*. *HCWS AM 53:509(1968)*.

38.1.7.1 Brianite $Na_2CaMg(PO_4)_2$

Named in 1967 for Brian Mason (b.1917), mineralogist, Smithsonian Institution, Washington, DC. *MON P2₁/a*. $a = 13.36$, $b = 5.23$, $c = 9.13$, $\beta = 91.2^\circ$, $Z = 4$, $D = 3.127$. *AM 60:717(1975)*. Isostructural with merwinite. *29-1192*: 3.73₉ 3.34₇ 3.16₆ 2.72₈ 2.68₉ 2.63₁₀ 2.23₇ 1.875₉. Grains up to 0.2 mm with fine lamellar structure. Colorless, transparent. $H = 4\frac{1}{2}$. $G = 3.10$. Biaxial (-); $N_x = 1.598$, $N_y = 1.605$, $N_z = 1.608$; $2V \approx 65^\circ$; extinct between lamellae $2-3^\circ$. Synthesized, melts between 800 and 100° ; insoluble in H_2O . Occurs in small pockets in the metallic phase in the *Dayton meteorite, Montgomery Co., OH*, associated with whitlockite, panethite, albite, and enstatite. *HCWS GCA 31:1711(1967), AM 53:508(1968)*.

38.1.8.1 Vitusite-Ce $Na_3(Ce,La,Nd)(PO_4)_2$

Named in 1979 for Vitus Bering (1681–1741), explorer of northern seas. *ORTH Pcmb* or *Pc2₁b*. $a = 5.342$, $b = 18.680$, $c = 14.062$, $Z = 8$, $D = 3.86$ (Ilimaussaq). *NJMA 137:42(1979)*. Indications of superlattice with $a = 58.75$. Structure may be related to glaserite and apatite. *MM 56:235(1992)*. *33-1232*: 6.58₉ 4.67₉ 4.63₉ 3.51₉ 2.81₁₀ 2.80₁₀ 2.69₉ 2.67₉. Pale pink (Lovozero), white to pale green (Ilimaussaq, I), pseudohexagonal, twinned after (160), (120); vitreous luster. Cleavages {100}, {010}, {001}. Biaxial (-); $XYZ = abc$; $N_x = 1.604$, $N_y = 1.647$, $N_z = 1.649$; $2V = 28.5^\circ$ (I). Vitusite-Nd has been synthesized. Readily dis-

solves in cold 1:10 HCl or H₂SO₄. Occurs in the natrolite zone of an alkalic pegmatite at Yubileynayn, *Mt. Karnasurt, Kola Penin., Russia*, associated with steenstrupine, belovite, neptunite, leucosphenite, and sazhinite, and at the *Ilimaussaq intrusion, southern Greenland*, a melanocratic nepheline syenite with arfvedsonite, albite, microcline, nepheline, sodalite, steenstrupine, and two other phosphate minerals. HCWS *AM 65:812(1980)*, *MM 56:235(1992)*.

38.2.1.1 Berzeliite (Ca,Na)₃(Mg,Mn)₂(AsO₄)₃

Named in 1840 for Jöns Jacob Berzelius (1779–1848), Swedish chemist. End member of the series with manganberzeliite (38.2.1.2). iso *Ia3d*. *a* = 12.355, *Z* = 8, *D* = 4.088. Structure: *AC(B) 32:1581(1976)*. Isostructural with garnet. 19-165: 5.03₆ 3.30₅ 3.09₆ 2.75₁₀ 2.63₆ 1.780₅ 1.712₇ 1.648₇. Usually massive or as rounded grains, rarely as trapezohedrons with small modifying faces. Yellow or honey-yellow to orange-yellow and yellowish red; red tint increases with Mn content; white to orange-yellow streak; resinous luster; transparent to translucent. No cleavage, subconchoidal to uneven fracture, brittle. *H* = 4 $\frac{1}{2}$ –5. *G* ≈ 4.08. *N* = 1.702 (535 nm); colorless to orange, sometimes anomalous birefringence. Na₂O about 4.5 wt % usual. Na/Ca ≈ 2:5; also Sb/As up to 1:10, usually trace amount. Members of the series have been synthesized. Occurs at *Långban*, and Moss mine, *Värmland*, in limestone skarn associated with hausmannite, manganophyllite, and caryinite, and at Sjö mine, Grythytte parish, Örebro, *Sweden*, in veinlets with rhodonite, tephroite, manganosite, pyrochroite, and barite. HCWS *DII:681*, *AM 53:316(1968)*.

38.2.1.2 Manganberzeliite (Ca,Na)₃(Mn²⁺,Mg)₂(AsO₄)₃

Named in 1894 for the composition and similarity to berzeliite (38.2.1.1). Mn end member of the series. iso *Ia3d*. *a* = 12.52, *Z* = 8, *D* = 4.379. *AM 53:316(1968)*. Isostructural with garnet. 20-1089(syn): 5.10₄ 3.34₃ 3.13₅ 2.80₁₀ 2.67₃ 2.56₉ 1.736₄ 1.673₈. Similar to berzeliite in habit and other physicochemical properties. Reddish tint indicates Mn-rich; synthetic manganberzeliite is brown, dodecahedra, translucent, and optically yellow. *N* = 1.77. Only trace Fe²⁺ in analyses; no Fe analog has been synthesized. Occurs in *Långban, Värmland, Sweden*. HCWS *DII:681*, *AM 48:663(1963)*.

38.2.1.3 Palenzonaite (Ca₂Na)Mn₂(VO₄)₃

Named in 1987 for A. Palenzona, Italian amateur mineralogist, who discovered the mineral. iso *Ia3d*. *a* = 12.534, *Z* = 8, *D* = 3.78. Structure: *NJMM:136(1987)*. Isostructural with garnet; analogous to manganberzeliite (38.2.1.2), an arsenate garnet. 41-608: 5.12₁ 3.13₆ 2.80₁₀ 2.67₂ 2.56₈ 2.46₁ 1.738₂ 1.675₄. Dodecahedral crystals and anhedral grains up to 6 mm in diameter. Wine red, streak brownish red, adamantine luster, transparent. No cleavage, subconchoidal fracture. *H* = 5–5 $\frac{1}{2}$. *G* = 3.63. Nonfluorescent. *N* = 1.965, wine-red in thick section. Soluble in strong acids. Some As and Si substitution with an excess of Ca compared to idealized formula. Occurs in veinlets about 1 mm thick cutting quartz–braunite (Mn) ore and as crystals in a

manganooan calcite vein 2 cm wide in the *Molinello manganese mine, Val Graveglia, eastern Liguria, Italy*. Veinlets also contain saneroite, ganophillite, axinite, or tinaenite. *HCWS AM 73:930(1988)*.

ALLAUDITE-WYLLIEITE GROUPS

The alluaudite-wyllieite minerals have general formula

where

A = Ca, Na, Mn^{2+} , or \square

B = Al, Ca, Cu, Fe^{2+} , Fe^{3+} , H, Mg, Mn^{2+} , Pb, Zn

T = As, P

and crystallize in a monoclinic, pseudoisometric space group.

The basic structure *MM 56:1955(1971)*, is composed of staggered chains of distorted cation-O octahedra stacked parallel to the {101} plane these layers are linked by TO_4 groups into pleated sheets that parallel y . The alluaudite subgroup members have four distinct cation sites called A2, A1, B2 and B1. The wyllieite subgroup minerals have six (called A2, A1a, A1b, B1, B2a and B2b) and show intrachain ordering. Formulae to express crystallographic information are based on 48 oxygens: for the alluaudites: $(A2)_4(A1)_4(B1)_4(B2)_8[(P,As)O_4]_{12}$. For the wyllieites: $(A2)_4(A1a)_2(A1b)_2(B1b)_2(B1a)_2(B2a)_4(B2b)_4(PO_4)_{12}$.

ALLAUDITE SUBGROUP $(A2)_4(A1)_4(B1)_4(B2)_8[(P,As)O_4]_{12}$ Space Group $C2/c$

* Original space group transformed

Notes:

- In the alluaudite subgroup, leaching of alkali ions, or the oxidation of cations (i.e., Fe^{3+} rather than Fe^{2+}) usually results in a site that may be vacant (\square) or partially vacant. Cation site placement and occupancy or vacancy are proposed from cation—O bond lengths calculated from single-crystal structure determinations.
- Assignment of cations (or vacancies) to sites requires not only chemical analyses but single crystal structure determinations. Actual chemical analyses on alluaudite give the formula $\square NaMn^{2+}ZnFe_2^{3+}(PO_4)_3$, or without vacancies $NaMn^{2+}ZnFe_2^{3+}(PO_4)_3$. Similarly the formula for O'Danielite, $\square NaZnZn_2(AsO_4)(AsO_3OH)_2$ may be presented as $NaZn_3H_2(AsO_4)_3$.

ALLUAUDITE: $\square\text{NaMn}^{2+}\text{Fe}_2^{3+}(\text{PO}_4)_3$

In this a axis projection of alluaudite [presentation depicts Na, and Fe^{3+} ions, and PO_4 groups, a simplified version of $\square\text{Na}_4\text{Mn}_4\text{Fe}_8(\text{PO}_4)_{12}$] the staggered chains of distorted (Mn,Fe) octahedra show as layers parallel to (101) linked through the oxygens of PO_4 groups. The result is pleated sheets with Na (or other A ions, or \square) in the interstices *MM* 56:1955 (1971) *KB*:128 (1989).

WYLLIEITE SUBGROUP

Space Group $P2_1/n$, a subgroup of $C2/c$

Mineral	A2	A1a	A1b	B1	B2a	B2b	a	b	c	β	
Ferrowyllieite	(Na, \square)	Na	(Fe^{2+} , Ca)	(Fe^{2+} , Mg)	(Fe^{2+} , Mn)	Al^{3+}	11.834	12.298	6.323	114.20	38.2.4.1
Wyllieite	(Na, \square)	(Na, \square)	(Mn^{2+} , Ca)	(Mn^{2+} , Fe^{2+})	(Fe^{2+} , Mg)	(Al^{3+} , Fe^{3+})	11.868	12.382	6.354	114.52	38.2.4.2
Rosemaryite	\square	Na	(Mn^{2+} , Fe^{2+})	(Mn^{2+} , Fe^{2+})	Fe^{3+}	Al	11.977	12.388	6.320	114.45	38.2.4.3

Bobfergusonite*	Na	Na	Mn^{2+}	Mn^{2+}	Fe^{3+}	Al	12.045	12.486	12.773	114.35	38.2.4.5

* *Bobfergusonite* original space group $P2_1/n$ transformed to $C2/c$ to show coincidence with other minerals.

Notes:

1. Al^{3+} is an essential component in the wyllieite subgroup and changes the association of the chains and the space group. Wyllieite has three ordered sites, ferrowyllieite has two ordered sites, and Bobfergusonite is probably the most ordered structure in the subgroup.

38.2.2.1 Caryinite $(\text{Na,Pb})\text{Ca}(\text{Mn}^{2+},\text{Ca})(\text{Mn}^{2+},\text{Mg})_2(\text{AsO}_4)_3$

Named in 1874 for *in error*, not for the color *nut brown* in Greek. Dana (1892) changed "K" to "c." Alluaudite group and subgroup. See also arsenioleite (38.2.2.2). MON $P2_1/c$. $a = 11.48$, $b = 13.17$, $c = 6.67$, $\beta = 99^\circ$; or by analogy to alluaudites $C2/c$. $a = 12.42$, $b = 13.17$, $c = 6.87$, $\beta = 114.1^\circ$, $Z = 4$, $D = 4.486$. AMG 2:333(1957) MM 57:721(1993). 12-295: 3.29₂ 3.14₂ 3.03₃ 2.90₂ 2.87₁₀ 2.85₁₀ 2.79₂ 2.73₂. Fine-granular and as cleavable masses. Brown, yellowish brown; greasy luster; subtranslucent. Cleavage {110}, {010}, distinct. $(010) \wedge (110) \approx 49^\circ$. $H = 4$. $G = 4.29$. Biaxial (+); XYZ = *cab*; $N_x = 1.776$, $N_y = 1.780$, $N_z = 1.805$; $2V = 41^\circ$; $r > v$, slight; nonpleochroic. Analysis: 18.66% MnO, 12.12% CaO, 9.21% PbO, 5.16% Na₂O, 3.09% MgO, 1.03% BaO, 49.8% As₂O₅. Soluble in HNO₃. Alters to berzeliite. Found at Langban, Varmland, Sweden, associated with berzeliite, calcite, hedyphane, and hausmannite in veinlets in skarn containing rhodonite and manganian aegirine. HCWS DII:683; AM 47:163(1962), 56:1955(1971); MM 51:281(1987).

38.2.2.2 Arsenioleite $\text{NaCa}(\text{Mn}^{2+})_3(\text{PO}_4)_3$

Named in 1888 from the Latin for the element As, and Greek for *more* because it adds to the number of related minerals already described. Alluaudite group and subgroup. Mn-rich member of solid-solution series with caryinite (38.2.2.1). MON $P2_1/c$. $a = 11.31$, $b = 13.06$, $c = 6.86$, $\beta = 99^\circ$, recalculated to $C2/c$, $a = 12.36$, $b = 13.06$, $c = 6.68$, $\beta = 114.0^\circ$, $Z = 4$. $D = 4.29$ (Chanteloube). AMG 4:425(1966). 20-224: 6.52₄ 4.13₄ 3.27₄ 2.99₅ 2.83₁₀ 2.79₄ 2.68₆ 1.693₅. Massive, granular. Deep brownish red, cherry-red, to apricot; yellowish-brown streak, opaque. Pseudorhombhedral cleavage, conchoidal fracture. $H = 3\frac{1}{2}$, $G = 4.22$. Easily soluble in 1:10 HCl, HNO₃. Some Fe³⁺ detected in analyses. Found at Canteloube, France; as irregular seams or fracture fillings of orange crystals with calcite and berzeliite at Langban mine, Filipstad, Varmland, and as fissure material in thin veins and as nodules in marble with rhodonite, tephroite, and hedyphane at Sjö mine, Grythyttle Parish, Örebro, Sweden. HCWS DII:844; AMG 2:333(1957), AM 56:1955(1971), 73:666(1988); MM 57:721(1993).

38.2.3.1 Ferrohagendorfite $\text{Na}(\text{Ca,Na})(\text{Fe}^{2+},\text{Fe}^{3+})_3(\text{PO}_4)_3$

Named in 1979 as the iron end member in the series with hagendorfite. Alluaudite group and subgroup. See hagendorfite (38.2.3.2). HCWS MM 43:227(1979).

38.2.3.2 Hagendorfite $\text{Na}(\text{Ca,Na})\text{Mn}^{2+}(\text{Fe}^{2+},\text{Fe}^{3+})_2(\text{PO}_4)_3$

Named in 1954 for the locality. Alluaudite group and subgroup. The Mn²⁺-containing end member in a series with ferrohagendorfite (38.2.3.1). MON $C2/c$. $a = 11.92$, $b = 12.59$, $c = 6.52$, $\beta = 114.7^\circ$, $Z = 4$, $D = 3.84$. BGSA 67:1694(1956). 29-1191: 6.11₅ 3.42₇ 3.08₅ 2.85₅ 2.69₁₀ 2.59₈ 2.12₅ 2.09₅. Massive. Greenish black. Three cleavages with one good, others indistinct. $H = 3\frac{1}{2}$. $G = 3.71$. Biaxial (-); $N_x = 1.739$, $N_y = 1.742$, $N_z = 1.745$; $2V = 70^\circ$; pleochroic. X=yellowbrown Y=green Z=bluegreen. Found in the

Hagendorf-Süd pegmatite, Waidhaus, Oberpfalz, Bavaria, Germany, associated with triphylite, wolfeite, and hematite; at Norrö, Sweden. HCWS NJMM:252(1954), MM 43:227(1979) AM 40:1100(1956).

38.2.3.3 Varulite $\text{NaCaMn}^{2+}(\text{Mn}^{2+}, \text{Fe}^{2+}, \text{Fe}^{3+})_2(\text{PO}_4)_3$

Named in 1937 for the locality. Alluaudite group and subgroup. The Mn-rich member in series with ferrohagendorfite (38.2.3.1) and with hagendorfite (38.2.3.2). MON C2/c. $a = 11.91$, $b = 12.54$, $c = 6.46$, $\beta = 114.98^\circ$, $D = 3.89$. AMG 2:9(1956). 6-487: 6.35₃ 5.46₃ 3.50₄ 3.12₃ 2.91₃ 2.79₂ 2.74₁₀ 2.56₄. Massive, granular. Dull olive-green, becomes yellowish or brownish on alteration; vitreous luster. Cleavage {100}, good; {010}, distinct. $H = 5$. $G = 3.5$. Biaxial (+); $N_x = 1.708$, $N_z = 1.722$; 2V large; $r > v$; pleochroic. X, yellow-green; Z, grass green. Analysis: 21.06% MnO, 12.01% FeO, 6.44% Fe₂O₃, 9.72% Na₂O, 3.60% CaO, 1.66% H₂O. Occurs at *Varuträsk pegmatite, Boliden mine, Skellefteå, Västerbotteå, Sweden. HCWS DII:669, AM 35:59(1950), MM 43:227(1979).*

38.2.3.4 Maghagendorfite $\text{NaMn}^{2+}(\text{Mg}, \text{Fe}^{3+}, \text{Fe}^{2+})_2(\text{PO}_4)_3$

Named in 1979 as the Mg-containing member of the series with hagendorfite (38.2.3.2). Alluaudite group and subgroup. Analysis: 20.42% MnO, 9.89% Fe₂O₃, 8.75% FeO, 6.12% Na₂O, 5.06% MgO. Found in the *Dyke lode, Custer, SD. cs MM 43:227(1979), AM 65:810(1980).*

38.2.3.5 Ferroalluaudite $\square\text{NaFe}^{2+}(\text{Fe}^{3+}, \text{Fe}^{2+})_2(\text{PO}_4)_3$

Named in 1979 as the Fe-rich partially oxidized end member of the series with alluaudite. Alluaudite group and subgroup. Synonym: ferri-alluaudite. MON $I2_1/a$, $a = 11.002$, $b = 12.527$, $c = 6.41$ AM50: 713(1965) or transformed to C2/c. $a = 11.87$, $b = 12.54$, $c = 6.46$, $\beta = 114.6^\circ$, $Z = 4$, $D = 3.61$. 39-337 6.28₇ 5.45₂ 4.11₂ 3.49₃ 3.08₅ 2.72₁₀ 2.53₃ 2.09₂. Single and grouped prismatic crystals up to 3 mm across, elongated on {010}, {001} with well-developed prism faces; granular, cleavable masses up to 10 cm across. Greenish black, vitreous luster. $H = 5$. $G = 3.5$. Biaxial (+); $N_x = 1.727$, $N_z = 1.738$; emerald green. X, tan; Z, blue-green. Analysis: 28.2% Fe₂O₃, 9.1% FeO, 7.3% MnO, 2.0% MgO, 1.6% CaO, 6.9% Na₂O, 43.1% P₂O₅. Crystals more or less replaced by ludlamite are found along one side of pod associated with arrojadite embedded in siderite, ludlamite, and vivianite masses which are within quartz-mica-perthite at the core of Palermo No. 1 pegmatite(!), North Grotton, NH; at *Pleasant Valley pegmatite, Chester, Custer Co., SD*; at *Hühnerkobel, Bavaria, Germany, and Norrö, Ranö, Sweden. HCWS AM 56:1955(1971), MM 43:227(1979).*

38.2.3.6 Alluaudite $\square\text{NaMn}^{2+}\text{Fe}^{3+}_2(\text{PO}_4)_3$

Named in 1848 for François Alluaud of Limoges, France, who discovered the Chanteloube material. Alluaudite group and subgroup. The Mn-containing member of a series with ferroalluaudite (38.2.3.5). Synonym: hühnerkobelite. MON C2/c. $a = 12.004$, $b = 12.533$, $c = 6.404$, $\beta = 114.4^\circ$,

$Z = 4$, $D = 3.62$. (Buranga) *AM* 56:1995(1971). 42-581: 6.27₈ 5.47₄ 3.50₄ 3.07₅ 2.87₃ 2.73₅ 2.72₁₀ 2.52₄. Massive, compact granular, radiating fibrous or globular aggregates. Dirty yellow to brownish yellow, greenish black, outwardly brownish black or black due to alteration; dirty yellow streak and powder; subtransparent to opaque. Cleavage {100}, {010}, good. $H = 5.2$. $G = 3.45$. Biaxial (+), $N_x = 1.782$, $N_y = 1.802$, $N_z = 1.835$ (Pringle Fe/Mn = 2.29), $X =$ straw yellow, $Y, Z =$ light yellow, $2V = 79^\circ$ (Na), $r > v$. Soluble in acids. Alters to heterosite, purpurite with leaching of Na and oxidation of Fe, and Mn. Found as a secondary mineral in pegmatites in the many mines in NH and SD listed under triphylite (38.1.1.1); also at Mangualde, Portugal; *La Vilate quarry, Chanteloube, Haute-Vienne, France*; Hagendorf Süd, Bavaria, Germany; Dolni Bory, western Moravia, Czech Republic; Norro, Strumpe-torp, and Varutrask, Sweden; Sukula, Finland; Sidi-Bou-Othmane, Morocco; Buranga, Rwanda; Lavra do Enio, Galileia, MG, Brazil. *ncws DII:674, AM 40:1100(1956), MR 4:103(1973), MM 43:227(1979)*.

38.2.3.7 O'Danielite $\square\text{NaZn}_3\text{H}_2(\text{AsO}_4)(\text{AsO}_3\text{OH})_2$

Named in 1980 for Herbert O'Daniel (1903-1977), professor of mineralogy, University of Munich, Germany. Alluaudite group and subgroup. *MON C2/c*. $a = 12.113$, $b = 12.445$, $c = 6.793$, $\beta = 112.87^\circ$, $Z = 4$, $D = 4.49$. Structure: *NJMM 4:155(1981)*. 35-482: 6.22₁₀ 5.59₅ 3.56₇ 3.26₁₀ 2.78₈ 2.72₈ 1.687₇ 1.664₆. Pale violet, vitreous luster. Cleavage {010}, {100}, perfect; also {001}. $G = 4.24$. Biaxial (+); $Z = b$; $Y \wedge c = 18^\circ$; $N_x = 1.745$, $N_y = 1.753$, $N_z = 1.778$; $2V = 60^\circ$; no dispersion observed. Analysis: 54.4% As_2O_5 33.8% ZnO, 4.7% Na_2O , 2.9% MgO, minor CaO, FeO. Found with cuprian adamite, koritnigite, or prosperite at *Tsumeb mine, Tsumeb, Namibia*. *ncws FM 58:68(1980), AM 66:1276(1981)*.

38.2.3.8 Johillerite $\square\text{Na}(\text{Mg},\text{Zn})_3\text{Cu}(\text{AsO}_4)_3$

Named in 1982 for Johannes Eric Hiller (1911-1972), professor of mineralogy, Stuttgart, Germany. Alluaudite group and subgroup. *MON C2/c*. $a = 11.870$, $b = 12.755$, $c = 6.770$, $\beta = 113.42^\circ$, $Z = 4$, $D = 4.21$. *TMPM 29:169(1982)*. 35-522: 4.06₅ 3.50₄ 3.25₈ 2.75₁₀ 2.64₅ 1.952₄ 1.682₄ 1.660₅. Radial aggregates of thin platelets (010), elongation parallel to c , size 1 mm \times 0.3 mm \times 0.1 mm. Violet, transparent. Cleavage {010}, perfect; {001}, good. $H = 3$. $G = 4.15$. Analysis: 5.4% Na_2O , 18.3% MgO, 5.4% ZnO, 15.8% CuO, 55.8% As_2O_5 . Found in cavities with conchalcite and cuprian adamite on specimen of altered tennantite with chalcocite from *Tsumeb, Namibia*. *ncws AM 67:1075(1982)*.

38.2.3.9 Nickenichite $(\text{Na},\square)(\text{Ca},\square)(\text{Cu},\square)(\text{Mg},\text{Fe}^{3+},\text{Al})_3(\text{AsO}_4)_3$

Named in 1993 for the locality. Alluaudite group and subgroup. *MON C2/c*. $a = 11.882$, $b = 12.760$, $c = 6.647$, $\beta = 112.81^\circ$, $Z = 4$. Structure: *TMPM 48:153(1993)*. Two distorted octahedral (Mg, Fe^{3+} , Al)- O_6 groups share edges forming zigzag chains in [101] which are connected by tetrahedral (AsO_4) groups into a three-dimensional framework. Two types of channels parallel to [001]

result: one for monovalent, the other for divalent, cations. Multiple opportunities for vacancies: Na site ≈ 0.8 , Ca site ≈ 0.4 , Cu site ≈ 0.9 occupancy. *PD*: 4.35₄ 4.06₅ 3.56₄ 3.53₄ 3.20₆ 3.07₄ 2.74₁₀ 2.61₄. Acicular crystals < 20 mm long. Bright blue, vitreous luster. Cleavage {010}, perfect; {100}, {101}, good. *H* ≈ 3 . Analysis: 9.6% Na₂O, 2.8% CaO, 17.9% MgO, 4.7% CuO, 5.5% Fe₂O₃, 1.1% Al₂O₃, 64.3% As₂O₅. Biaxial (+); $\gamma \wedge c \approx 28^\circ$ on (010); *Y* parallel to *b*; *N_x* = 1.714, *N_y* = 1.744, *N_z* = 1.783 (598 nm); 2*V* = 60°; 2*V*_{calc} = 84°; weak dispersion. Found in a cavity covered by vanadinite in pyroclastic rocks near the village of *Nickenich, in the Eifel, Germany*. *HCWS AM 79:571(1994)*.

38.2.4.1 Ferrowyllieite Na₂(Fe²⁺,Mn²⁺)₂Al(PO₄)₆

Named in 1979 for Peter John Wyllie (b.1930), mineralogist and petrologist, California Institute of Technology, Pasadena, as the Fe²⁺-rich end member of a series with wyllieite. Alluaudite group. Wyllieite subgroup. *MON P2₁/c*. *a* = 11.834, *b* = 12.293, *c* = 6.323, $\beta = 114.20^\circ$, *Z* = 4, *D* = 3.68. Structure: *AM 59:280(1974)*. 39-409: 6.14₂ 3.45₂ 3.03₂ 2.83₃ 2.71₁₀ 2.70₆ 2.48₃. Crystals rare, usually as masses. Bluish green, grayish green, green; submetallic luster. Cleavage {010}, perfect; {101}, poor to good; brittle. *H* = 4-4.5. *G* = 3.60. Biaxial (+); *N_x* = 1.688, *N_y* = 1.691, *N_z* = 1.696; 2*V* $\approx 50^\circ$; *r* < *v*, strong; pleochroic. *X*, smoky blue-gray; *Y*, smoky blue-green; *Z*, green. DTA. Analysis: 43.8% P₂O₅, 29.2% FeO, 8.0% NaO, 7.9% Al₂O₃, 4.3% MnO, 2.5% CaO, 1.97% MgO. Larger alkali sites in the structure are extensively occupied by Fe²⁺ and Mn²⁺. Found at *Victor mine, Custer, Custer Co., SD*. *HCWS MM 43:227(1979)*, *AM 65:810(1980)*.

38.2.4.2 Wyllieite Na₂(Mn²⁺)₂(Al,Fe³⁺)₂(PO₄)₆

Named in 1973 for Peter John Wyllie (b.1930), mineralogist and petrologist, California Institute of Technology, Pasadena. Alluaudite group. Wyllieite subgroup. Redefined as the Mn end member of the series with ferrowyllieite (38.2.4.1). *MON P2₁/n*. *a* = 11.868, *b* = 12.382, *c* = 6.354, $\beta = 114.52^\circ$, *Z* = 4, *D* = 3.68. Structure: *AM 59:280(1974)*. 26-1378: 8.12₄ 6.15₆ 3.34₅ 3.05₄ 2.85₄ 2.69₁₀ 2.67₁₀ 2.50₅. Euhedral crystals up to 2 cm × 10 cm. Bluish green, grayish green, greenish black; dirty olive-green streak and powder; vitreous to submetallic luster. Cleavage {010}, perfect; {101}, distinct; brittle. *G* = 3.601. Analysis: 45.4% P₂O₅, 14.7% FeO, 11.2% MnO, 10.6% Fe₂O₃, 6.5% Al₂O₃, 3.9% NaO, 3.1% CaO, 1.7% MgO. Al is an essential element in this subgroup. Wyllieite has lower Fe²⁺ and higher Fe³⁺ and Mn²⁺ than ferrowyllieite. Found at *Old Mike mine, Custer, Custer Co., SD*, with quartz, muscovite, plagioclase, graftonite, and sarcopide, also arsenopyrite, scorzalite, ludlamite, vivianite, and garnet and at the *Kestone Nickel Plate pegmatite mine*; at *Corrego Frio mine, MG, Brazil*. *HCWS MR 4:131(1973)*, *MM 43:227(1979)*.

38.2.4.3 Rosemaryite □Na(Mn²⁺,Fe²⁺)Fe³⁺Al(PO₄)₃

Named in 1979 for F. Rosemary Wyllie, wife of Peter J. Wyllie, to designate a member in the series with prominent Fe³⁺. Alluaudite group. Wyllieite

subgroup. MON $P2_1/n$. $a = 11.977$, $b = 12.388$, $c = 6.320$, $\beta = 114.45^\circ$. *EJM* 7:567(1995). PD: 6.19₅ 5.45₅ 3.49₇ 3.02₁₀ 2.84₆ 2.73₉ 2.69₁₀ 2.06₆. Bottle green, dark brown to reddish brown; resinous luster. Cleavage observed. Biaxial (-); $N_x = 1.723$, $N_y = 1.742$, $N_z = 1.758$; $2V = 80^\circ$; pleochroic. X, brownish yellow; Z, greenish yellow. Analysis: 43.8% P_2O_5 , 14.6% Fe_2O_3 , 13.6% MnO , 11.6% FeO , 6.9% Al_2O_3 , 3.4% Na_2O , 1.8% CuO . Found as an alteration of triphylite at *Rock Ridge pegmatite, Custer, Custer Co., SD*; with trolleite and scorzalite or with montebbrasite and alluaudite-Na□ at Buranga pegmatite (also Na-rich), Gatumba, Gisenyi Prov., Rwanda. HCWS *MM* 43:227(1979), *AM* 65:810(1980).

38.2.4.4 Qingheite $Na_2(Mn^{2+}, Mg, Fe^{2+})_2(Al, Fe^{3+})(PO_4)_3$

Named in 1983 for the locality. Alluaudite group, Wyllieite subgroup. MON $P2_1/n$. $a = 11.856$, $b = 12.411$, $c = 6.421$, $\beta = 114.27^\circ$, $Z = 2$, $D = 3.61$. Structure: *SS* 26B:876(1983). 41-588: 8.14₂ 6.21₄ 3.46₃ 3.07₂ 2.86₃ 2.83₂ 2.69₁₀ 2.52₃. Irregular, short prismatic grains, tabular up to 4 mm. Jade-green, glassy luster. Cleavage {010}, imperfect; conchoidal fracture; brittle. $H = 5\frac{1}{2}$. $G = 3.718$. Biaxial (+); $N_x = 1.678$, $N_y = 1.684$, $N_z = 1.691$; $2V = 79.6^\circ$; strongly pleochroic. X, light yellow-green; Y, jade-green; Z, dark bluish green; $r \gg v$, strong. Analysis: 23.7% MnO , 9.8% MgO , 8.7% Na_2O , 4.5% Al_2O_3 , 3.9% FeO , 2.2% Fe_2O_3 . Found in muscovite pegmatite at *Qinghe Co., Altay Pref., Uygur Autonomous Region of Xinjiang, China*, associated with muscovite, quartz, perthite, microcline, braunite, and pyrolusite. HCWS *AMS* 3:161(1983), *AM* 69:567(1984).

38.2.4.5 Bobfergusonite $Na_2Mn_5Fe^{3+}Al(PO_4)_6$

Named in 1986 for Robert Bury Ferguson (b.1920), Canadian feldspar mineralogist interested in pegmatites. Alluaudite group, Wyllieite subgroup. MON $P2_1/n$, $a = 12.776$, $b = 12.488$, $c = 11.035$, $\beta = 97.21^\circ$ recalculated as $C2/c$. $a = 12.045$, $b = 12.486$, $c = 12.773$, $\beta = 114.35^\circ$, $Z = 4$, $D = 3.57$. Structure: *CM* 24:605(1986). 40-509: 3.05₁₀ 2.90₄ 2.87₇ 2.82₄ 2.74₄ 2.71₅ 2.51₅ 2.08₇. Anhedral grains. Red to green brown, medium brown; resinous luster. Cleavage {101} perfect, {100} prominent. Biaxial (+); Y parallel to b ; $X \wedge a = +10^\circ$; $N_x = 1.694$, $N_y = 1.698$, $N_z = 1.715$. X, Y, yellow-orange; Z, orange. Analysis: 45.1% P_2O_5 31.7% MnO , 7.5% Al_2O_3 , 6.9% Fe_2O_3 , 6.8% Na_2O , 1.2% CaO . Found on an island 5 km NNW of *Cross Lake, MB, Canada*. HCWS.

38.2.5.1 Fillowite $\square_2Na_2Ca(Mn^{2+}, Fe^{2+})_7(PO_4)_6$

Named in 1879 for Abijan N. Fillow, the original owner and operator of the Branchville pegmatite mine, CT, who first collected the manganese phosphates for which the locality is known. See also johnsomervilleite (38.2.5.2). HEX-R $R3$. $a = 15.282$, $c = 43.507$, $Z = 18$, $D = 3.54$. Structure: *AM* 74:918(1989). Very complicated structure with nine distinct cation $-O_6$ octahedra, six additional cation polyhedra with five-, seven-, and eight-coordination, and six distinct PO_4 sites. 18-516: 11.44₃ 8.49₂ 3.79₄ 3.02₇ 2.81₁₀ 2.55₆

2.16₂ 1.888₄. Granular crystalline masses. Waxy yellow, orange to reddish brown, colorless; white streak; subresinous to greasy luster; transparent to translucent. Cleavage {0001}, nearly perfect; uneven fracture; brittle. $H = 4\frac{1}{2}$. $G = 3.43$. Uniaxial (+); $N_O = 1.672$, $N_E = 1.676$; 2V small; $r < v$; strong. Colorless to yellow. Soluble in acids. In pegmatite at *Branchville, CT*, associated with triploidite, fairfieldite, and reddingite; Kabira, Uganda. *HCWS DII:719; AM 50:1643(1965)*.

38.2.5.2 Johnsomervilleite $\square_2\text{Na}_2\text{Ca}(\text{Mg},\text{Fe}^{2+},\text{Mn}^{2+})_7(\text{PO}_4)_6$

Named in 1980 for John M. Somerville, who presented the specimen to the Royal Scottish Museum, Edinburgh, Scotland. Mg-Fe analog of fillowite (38.2.5.1). *HEX-R*. $a = 15.00$, $c = 42.75$, $Z = 18$, $D = 3.41$. *MM 43:833(1980)*. *33-1224*: 11.20₅ 4.48₁ 3.70₇ 3.55₇ 2.97₇ 2.76₁₀ 2.50₄ 1.852₂. Anedral crystals up to 1.5 mm. Dark brown, light brown streak, glassy luster. Cleavage {0001}, perfect; subconchoidal fracture; brittle. $H = 4\frac{1}{2}$. $G = 3.35$. Nonfluorescent. Anomalously biaxial; $N_{av} = 1.655$; low birefringence; nonpleochroic. Found in metamorphic terrane in segregation pods 15–30 cm long in kyanite–silimanite gneiss at *Glenn Cosaidh, Loch Quoich, Scotland*, but not in the pegmatite. Associated with apatite, graftonite, and secondary phosphates such as jahnite, phosphosiderite, rockbridgite, mitridatite, and vivianite; at Sapucaia pegmatite, MG, Brazil. *HCWS AM 66:437(1981)*.

38.2.5.3 Chladniite $(\text{Na},\square)_2\text{CaMg}_7(\text{PO}_4)_6$

Named in 1994 for Ernst Florens Friedrich Chladni (1756–1827), the “Father of Meteoritics.” Mg end member in series with fillowite (38.2.5.1) and johnsomervilleite (38.2.5.2). *HEX-R R3*. $a = 14.967$, $c = 42.595$. Structure: *M 28:394(1993)*. Synthetic and natural material have Na(1) site partially vacant. Polished section shows grain as dark gray, weakly anisotropic. Found in the *Carlton (IIICD) meteorite* as a single large (975 $\mu\text{m} \times 175 \mu\text{m}$) grain within a silicate-bearing inclusion that is mostly chlorapatite; associated with olivine, pyroxene, plagioclase, schreibersite, troilite, and cross cut by FeOOH of terrestrial origin. *HCWS LPS XXV:1337(1994)*.

38.3.1.1 Sarcopside $\text{Fe}_3^{2+}(\text{PO}_4)_2$

Named in 1868 from the Greek for *flesh* and *view* in allusion to its color. *MON P2₁/a*. $a = 10.437$, $b = 4.768$, $c = 6.026$, $\beta = 90.0^\circ$, $Z = 2$, $D = 3.94$. Structure: *JMC 2:191(1991)*. Isostructural with olivine. *39-341*: 3.91₅ 3.52₁₀ 3.01₆ 2.82₇ 2.49₇ 2.47₄ 1.769₄ 1.758₅. Irregular masses with fibrous structure, sometimes distorted hexagonal plates. Flesh-red, to reddish brown, changing on exposure to dark brown, blue, lavender, or green; silky and glistening luster; translucent. Cleavage distinct perpendicular to fibers, another less distinct parallel to fibers. Splintery fracture, fibrous. $H = 4$. $G = 3.73$ (Silesia), 3.64 (NH). Biaxial (-); $Z = b$; $X \wedge c = 45^\circ$; $N_x = 1.675$, $N_y = 1.728$, $N_z = 1.730$; 2V small; $r > v$. Flesh-red in transmitted light. Occurs in pegmatite lens in gneiss on Gingrass farm near Deering, and at Demott mine, East Alstead, G.E. Smith

mine, Newport, NH; at the Victory and Bull Moose mines, Custer, SD; in pegmatite *Gory Sowie, near Michelsdorf, Eulengebirge, Silesia, Germany*, intergrown with graffonite, and with hureaulite and vivianite later alteration products; Dolni Bory, Moravia, Czech Republic; Lavra do Enio, Galileia, MG, Brazil. *HCWS DII:858; AM 50:1698(1965), 57:24(1972)*.

38.3.1.2 Farringtonite $\text{Mg}_3(\text{PO}_4)_2$

Named in 1961 for O. C. Farrington (1864–1935), expert on meteorites, curator of geology, Field Museum, Chicago. See sarcopsite (38.3.1.1). *MON P2₁/n*. $a = 7.599$, $b = 8.235$, $c = 5.076$, $\beta = 94.06^\circ$, $Z = 2$, $D = 2.76$. Structure: *ACHS 22:1466(1968)*. *33-876(syn)*: 4.36_3 4.31_2 4.12_3 4.08_3 3.85_9 3.66_3 3.44_{10} 2.41_3 . $G = 2.74$. Biaxial (+); $Z \wedge c = 16^\circ$; $N_x = 1.540$, $N_y = 1.544$, $N_z = 1.559$; $2V = 54^\circ$. A meteorite mineral. Some Fe^{2+} in solid solution, but < 500 ppm Si. Found in the Krasnojarsk and *Sringwater pallasite (meteorites)*, where it coexists with olivine, iron metal, and schreibersite and shows alteration to a straw-yellow powder, a hydrous magnesian phosphate. *HCWS GCA 24:198(1961); AM 46:1513(1961), 58:949(1973)*.

38.3.2.1 Xanthiosite $\text{Ni}_3(\text{AsO}_4)_2$

Named in 1869 by G. J. Adam from the Greek for *yellow and sulfur*. *MON P2₁/a*. $a = 10.174$, $b = 9.548$, $c = 5.766$, $\beta = 92.98^\circ$, $Z = 2$, $D = 5.388$. *MM 35:72(1965)*. *18-874*: 4.32_6 3.90_5 3.67_5 3.46_8 2.75_8 2.69_8 2.62_6 2.53_{10} . Massive. Golden yellow, translucent. $H = 4$. $G = 5.37$. Synthetic investigations show a high-temperature polymorph. Secondary mineral occurring with aerugite in comby quartz vein material in the deeper workings of the *South Terras mine, St. Stephen-in-Brannel, Cornwall, England*, associated with Ni–Co–As ores and decomposing pitchblende; at Johanngeorgenstadt, Saxony, Germany. *HCWS AM 50:2108(1965)*.

38.3.3.1 Graffonite $(\text{Fe}^{2+}, \text{Mn}^{2+}, \text{Ca})_3(\text{PO}_4)_2$

Named in 1900 for the locality. See also beusite (38.3.3.2), with which it forms an isomorphous Fe–Mn solid solution. *MON P2₁/c*. $a = 8.882$, $b = 11.171$, $c = 6.143$, $\beta = 99.31^\circ$, $Z = 4$, $D = 3.95$. Structure: *AM 67:826(1982)*. Mossbauer, neutron diffraction established occupancies of three distinct cation sites. *27-250*: 3.42_{10} 3.02_5 2.92_5 2.91_4 2.84_8 2.83_7 2.79_3 2.73_6 . Stout prismatic and rough composite crystals; massive, cleavable. Often intergrown in laminations with triphylite such that graffonite {010}, [110] is parallel to triphylite {102}, [010]. Salmon pink to reddish brown, dark brown on alteration; white to faintly pink streak; vitreous to slightly resinous luster. Cleavage {010}, good; {100}, fair, but not easily observed; conchoidal fracture. $H = 5$. $G = 3.67$ – 3.79 varying with Fe/Mn/Ca. Biaxial (+); $X = b$; $Z \wedge c = 36^\circ$; $N_x = 1.70$, $N_y = 1.705$, $N_z = 1.724$; $2V$ small, faintly pleochroic. $r > v$. X, Y, colorless; Z, pink. Analysis (Graffon, NH): 9.2% CaO, 30.6% FeO, 17.6% MnO. Nickel Plate mine sample with higher Mn, but not $> \text{Fe}$, 6.0% CaO has $N_x = 1.709$, $N_y = 1.7140$, $N_z = 1.736$; $2V = 60^\circ$; $r < v$, strong.

Easily soluble in acids. A primary mineral in complex granite pegmatites often with triphylite in intergrowths in which triphylite may be altered to ferrisicklerite or heterosite. Found on *Melvin Mt., Grafton, Grafton Co., NH*, also at Palermo and Rice mines, N. Groton, Grafton Co., and Center Strafford, NH; with arrojadite in Nickel Plate mine, Pennington Co., SD; at Olgiasca, Lake Como, Italy; Brissago, Tessin, Switzerland; in pegmatites of Kaondakovo district, eastern Siberia, and Altyntau granite, Uzbekistan. *HCWS DII:686, AM 53:72(1968), RZ 6B 58(1985)*.

38.3.3.2 Beusite $(\text{Mn}^{2+}, \text{Fe}^{2+}, \text{Ca})_3(\text{PO}_4)_2$

Named in 1968 for Alexei A. Beus, Russian mineralogist and geochemist, Moscow Polytechnical Institute. The Mn-rich end member in series with graftonite (38.3.3.1). *MON P2₁/c*. $a = 9.797$, $b = 11.758$, $c = 6.170$, $\beta = 99.31^\circ$, $Z = 4$, $D = 3.715$. Structure: *CM 28:141(1990)*. *36-401*: 3.52₁₀ 2.65₄ 2.95₂ 2.93₃ 2.88₆ 2.86₆ 2.74₂ 2.71₆. Rough prismatic crystals up to 30 cm long interlaminated with lithiophyllite. Red-brown, pale pink streak, vitreous luster. Cleavage {010}, good; {100}, fair. $H = 5$. $G = 3.702$. DTA. Biaxial (+); $X = b$; $Z \wedge c = 37^\circ$; $N_x = 1.702$, $N_y = 1.703$, $N_z = 1.722$; $2V = 25^\circ$; $r > v$, strong. Chemical analysis is necessary to distinguish between graftonite and beusite (i.e., Fe/Mn ratio). A Ca-free form has been described from a meteorite, other elements in analyses: Mg, Zn, Ni, Co, Cd. A primary phase in granite pegmatites. Found at a small pegmatite at *Los Aleros(!), San Luis Prov., Argentina*, also at San Salvador, Amanda, Cacique Cachueta, Ranquel mine in San Luis Prov.; in euhedral crystals within troilite nodules surrounded by Fe-Ni metal in El Sampal (IIIA) iron meteorite(!) found in 1973 near Nueva Lubuka, Chubut Prov., Argentina. *HCWS AM 53:1799(1968), 76:1985(1991)*.

38.3.4.1 Whitlockite $\text{Ca}_9(\text{Mg}, \text{Fe}^{2+})(\text{PO}_3\text{OH})(\text{PO}_4)_6$

Named in 1941 for Herbert P. Whitlock (1868–1948), mineralogist and curator of mineralogy, American Museum of Natural History, New York. Forms a series with strontiowhitlockite (38.3.4.2); see also merrillite (38.3.4.3). *HEX-R R3c*. $a = 10.330$, $c = 37.103$, $Z = 3$, $D = 3.102$. Structure: *AM 60:120(1975)*. Analogous to $\text{Ba}_3\text{P}_2\text{O}_8$, and isostructural with cerite-(Ce), whitlockite contains two types of chains, and two cation sites, one of which is partially occupied by H_2 . The phase is not equivalent to $\beta\text{-Ca}(\text{PO}_4)_2$ [*NAT(DS) 237:30(1972)*] and is distinct from the apatites. For the relationship of whitlockite to merrillite (38.3.4.3), see *EPSL:35(1977)*. *9-169(syn)*: 5.21₂ 3.45₃ 3.21₆ 2.88₁₀ 2.76₂ 2.61₇ 1.933₂ 1.728₃. Crystals usually rhombohedral, rarely tabular {0001}; coarse-granular to earthy. Colorless to white, gray, or yellowish; vitreous luster; transparent to translucent. No cleavage, uneven to sub-conchoidal fracture. $H = 5$. $G = 3.12$. DTA. Uniaxial (-); $N_0 = 1.629$, $N_E = 1.626$. There is a loss of H near 780° , complete by 1035° . Occurs with siderite, quartz, apatite, ludlamite, fairfieldite, xanthoxenite, and triphylite in pegmatite, *Palermo mine, NH*; Newry, ME; Tip Top mine, Custer, SD; Sabinas, HGO, Mexico; also at the caves at Sebduu, Oran, Algeria, and as a

WHITLOCKITE: $\text{Ca}_9(\text{PO}_4)_6\text{Mg}(\text{PO}_3\text{OH})$

The structure is composed of two chains running parallel to the c axis which contain PO_4 , (PO_3OH) groups, two different Ca sites and a (Mg,Fe) site. Ca2 on the A chain is coordinated through 6 oxygens from six different PO_4 groups on the six B chains that surround it. The A chain also contains randomly distributed octahedrally coordinated (Mg,Fe) ions, a rotated PO_4 group and half as many Ca ions (the vacant cation site is assigned as H_2) as the B chains. Ca1 on the B chain has eightfold coordination while Ca2 has either eight or nine-fold coordination relative to the rotation of the PO_3OH groups. This c axis projection illustrates the hexagonal/rhombohedral character of the structure.

component of calculus, the calcium phosphate deposit in human-animal oral cavities known as dental plaque. *HCWS DII:684, AM 45:645(1960).*

38.3.4.2 Strontiowhitlockite $\text{Sr}_9\text{Mg}(\text{PO}_3\text{OH})(\text{PO}_4)_6$

Named in 1991 after the composition and the similarity to whitlockite (38.3.4.1). *HEX-R R3c. $a = 10.644$, $c = 39.54$, $Z = 6$, $D = 3.60$. CM 29:87(1991). PD: 5.33₂ 3.29₄ 3.00₁₀ 2.66₈ 2.07₃ 1.991₃ 1.940₃ 1.783₄*. Rosettes of rounded tabular {0001} crystals up to 8 mm and in pipelike aggregates (2 mm × 20 nm) with the stem enclosing another fibrous phosphate species; flattened on {0001}. White, white streak, dull luster, translucent. Cleavage or parting {0001}. $G = 3.64$. IR. Uniaxial (-); $N_O = 1601$, $N_E = 1.598$ (589 nm). Analysis shows Ca, Ba, Mg, Mn, and Fe. Found in cavities associated with dolomite, pyrite, strontian, collinsite, and another strontium magnesium phosphate in a carbonatite vein in pyroxenites in *Kovdor deposit, Kola Penin., Russia. HCWS AM 76:2024(1991).*

38.3.4.3 Merrillite-(Ca) $(\text{Ca}, \square)_{10}\text{Mg}^{2+}_2(\text{PO}_4)_{14}$ **38.3.4.4 Merrillite-(Na) $\text{Ca}_{18}\text{Na}_2\text{Mg}^{2+}_2(\text{PO}_4)_{14}$** **38.3.4.5 Merrillite-(Y) $\text{Ca}_{16}\text{Y}_2\text{Mg}^{2+}_2(\text{PO}_4)_{14}$**

The name *merrillite* proposed in 1917 to honor George Perkins Merrill (1854–1929), meteorite specialist at U.S. National Museum, Smithsonian Institution, Washington, DC, was applied in 1977 to the anhydrous end members of calcium phosphates in extraterrestrial specimens to distinguish them from the H-containing, terrestrial whitlockite (38.3.4.1). These minerals not yet approved by IMA. *HEX-R R3c*. $a = 10.362$, $c = 37.106$, $Z = 3$ (Angra dos Reis achondrite). *EPSL 35:347(1977)*. Structure: *JSSC 10:232(1974)*, similar to $\beta\text{-Ca}_3(\text{PO}_4)_2$. *SCI 137:425(1962)*: 5.18₆ 3.43₆ 3.19₆ 2.85₁₀ 2.58₆ 1.92₅ 1.71₅ 1.54₄. Uniaxial (-); $N_0 = 1.623$, $N_E = 1.620$. Lunar merrillite-(Ca) contains Na, REE, and a vacancy instead of H_2 ; additional compositional variations detected in other extraterrestrial samples. *LS VI:646(1975)*. Reported as very small amounts of anhedral grains in the following meteorites: Kimble Co., Texas, Estacao, Allegan, Bjurbole, Homestead, New Concord, Shergotta, Waconda. Also Earth's moon, lunar sample 12032 and 12036. *HCWS DII:797, MR 2:277(1971)*.

38.3.5.1 Stanfieldite $\text{Ca}_4(\text{Mg}, \text{Fe}^{2+})_5(\text{PO}_4)_6$

Named in 1967 for Stanley Field (1875–1964), former chairman of the board, Field Museum of Natural History, Chicago. *MON Pc* or *P2/c*. $a = 17.16$, $b = 10.00$, $c = 22.88$, $\beta = 100.2^\circ$, $Z = 8$, $D = 3.15$. *SCI 158:910(1967)*. 20-223: 8.31₅ 6.01₅ 5.01₃ 3.85₆ 3.75₈ 2.82₁₀ 2.51₈ 1.870₄. See also 11-231(syn). Irregular grains up to 1 mm in diameter. Reddish to amber, clear, and transparent. No cleavage. $H = 4\frac{1}{2}$. $G = 3.15$. Biaxial (+); $N_x = 1.631$, $N_y = 1.622$, $N_z = 1.619$; $2V = 50^\circ$ (Estherville). A meteorite mineral. Mg/Fe^{2+} varies from 1.5 (Estherville) to 15 in the pallasites. Insoluble in H_2O . Found as grains along walls of cracks in the *Estherville mesosiderite meteorite*; also as thin veinlets, less than 1 mm in width, cutting the olivine in other pallasite meteorites from Santa Rosalia, Albin, Finnmarken, Imilac, Mount Verona, and Newport associated with merrillite, orthopyroxenes, and tridymite. *HCWS AM 53:508(1968)*.

38.3.6.1 Hurlbutite $\text{CaBe}_2(\text{PO}_4)_2$

Named in 1952 for Cornelius S. Hurlbut, Jr. (b.1906), professor of mineralogy, Harvard University, Cambridge, MA. *MON P2₁/c*. $a = 8.299$, $b = 8.782$, $c = 7.798$, $\beta = 90.5^\circ$, $Z = 4$, $D = 2.899$. Structure: *AM 59:1267(1974)*. Tetrahedral PO_4 groups alternate with tetrahedral BeO_4 groups linked at the vertices in a framework with Ca in seven- and nine-fold coordination in the larger openings created. 6-213: 3.67₁₀ 3.50₇ 3.28₆ 3.03₉ 2.78₉ 1.50₇ 2.40₆ 2.21₉. See also 34-1441. Short stout prismatic crystals 4–25 mm with striated faces; {001}, {110} predominate, truncated by {201}, {101}. Pale yellow, green, colorless, to gem white; white streak; vitreous to greasy luster, transparent to translucent. No cleavage, conchoidal fracture, brittle. $H = 6$. $G = 2.877$. Nonfluorescent. Biaxial (-); $\text{XYZ} = bca$; $N_x = 1.595$, $N_y = 1.601$, $N_z = 1.604$;

$2V = 70^\circ$; $r > v$, weak. Slowly soluble in acids. Found at Black Mt. pegmatite, Rumford, Oxford Co., ME; as a replacement of beryl at Beuregard pegmatite, Gilsum, Cheshire Co.; *G.E. Smith mine, Newport, Sullivan Co., NH*; Tip Top pegmatite, Custer, Custer Co., SD; Butte, MT; Otov, Czech Republic; Viitaniemi, Eräjärvi, Finland; Grand Slam, Zimbabwe. *HCWS AM 37:931(1952)*.

38.3.7.1 Stranskiite $\text{CuZn}_2(\text{AsO}_4)_2$

Named in 1960 for Iwan N. Stranski (b.1897), physicist and chemist from Berlin, Germany. *TRIC P1*. $a = 5.073$, $b = 6.669$, $c = 5.267$, $\alpha = 109.85^\circ$, $\beta = 112.14^\circ$, $\gamma = 86.88^\circ$, $Z = 1$, $D = 5.1$. *AM 63:213(1978)*. Structure: *TMPM 26:167(1979)*. Isostructural with mcbirneyite (38.3.10.1). *29-1422: 6.25₂ 4.69₂ 4.15₃ 3.91₂ 3.13₁₀ 2.79₈ 2.60₃ 2.51₆*. Radiating aggregates of tablets in subparallel arrays on chalcocite and as anhedral inclusions up to centimeter size in massive tennantite; no twinning. Blue, translucent. Cleavage $\{010\}$, perfect; $\{100\}$, good; also $\{001\}$, $\{101\}$. $H = 4$. $G = 5.23$. Nonfluorescent. Biaxial (-); $N_x = 1.795$, $N_y = 1.842$, $N_z = 1.874$; $2V = 80^\circ$. Synthesized. The ratio of Zn/Cu in natural crystals can be as low as 1.3. Found in lower oxidation zone, 950 m below the surface at the *Tsumeb mine, Tsumeb, Namibia*, intergrown with schultenite in massive tennantite and associated with adamite, ludlockite, claraite, and tsumcorite. *HCWS NW 47:376(1960)*; *BM: 236(1973)*, *660(1975)*.

38.3.8.1 Keyite $(\text{Cu,Zn,Cd})_3(\text{AsO}_4)_2$

Named in 1977 for Charles Locke Key, mineral dealer, Canton, CT, who first called attention to the mineral. *MON I2, I2/m, or Im*. $a = 11.65$, $b = 12.68$, $c = 6.87$, $\beta = 98.95^\circ$, $Z = 6$, $D = 3.495$. *MR 8:87(1977)*. *29-255: 6.41₇ 3.29₉ 3.15₆ 2.88₉ 2.80₁₀ 2.32₆ 1.700₆ 1.644₇*. Crystals $0.25 \text{ mm} \times 0.1 \text{ mm} \times 0.04 \text{ mm}$, prismatic $\{001\}$ to tabular $\{010\}$ showing $\{010\}$, $\{210\}$, $\{011\}$, $\{201\}$. Deep sky blue, pale blue streak, translucent. Cleavage $\{001\}$, good. $H = 3\frac{1}{2}$ -4. Biaxial; $Y = b$; $X \wedge c = 10\frac{1}{2}^\circ$; $N_x = 1.80$, $N_z = 1.87$; strongly pleochroic; absorption $Z > Y > X$. X, pale blue; Y, greenish blue; Z, deep blue. Readily dissolved in concentrated acids. Found in cavities in tennantite ore at *Tsumeb mine, Tsumeb, Namibia*, associated with schultenite and zincian olivenite. *HCWS AM 62:1259(1977)*.

38.3.9.1 Lammerite $\text{Cu}_3(\text{AsO}_4)_2$

Named in 1981 for Franz Lammer, chemist of Leoben, Austria, who collected the mineral. *MON P2₁*. $a = 5.079$, $b = 11.611$, $c = 5.394$, $\beta = 111.72^\circ$, $Z = 2$, $D = 5.264$. Structure: *AM 71:206(1986)*. *39-385: 4.06₃ 3.80₃ 3.07₅ 3.00₅ 2.89₁₀ 2.62₄ 2.59₄ 2.52₅*. See also *35-497*. Tabular $\{100\}$, intergrown radial aggregates. Dark green, adamantine luster, transparent. Cleavage $\{010\}$, perfect; $\{100\}$, good; $\{001\}$, trace. $H = 3\frac{1}{2}$ -4. $G = 5.18$. Biaxial (+); α parallel to b ; $Z \wedge c = 40^\circ$; $N_x = 1.89$, $N_y = 1.90$, $N_z = 1.95$; strongly pleochroic. X, pale blue; Y, sky blue; Z, pale blue-green. Associated with olivenite at *Sica Siva, Laurani, Meta*

Negra, La Paz, Bolivia, also at Tsumeb, Namibia; exhalations of Tolbachinski volcano, Kamchatka, Russia. HCWS *TMPM* 28:157(1981), *RZ* 4B:247(1985).

38.3.10.1 Mcbirneyite $\text{Cu}_3(\text{VO}_4)_2$

Named in 1984 for Alexander Robert McBirney (b.1924), volcanologist, University of Oregon. Isostructural with stranskiite (38.3.7.1). TRIC *P1*. $a = 5.342$, $b = 6.510$, $c = 5.180$, $\alpha = 88.61^\circ$, $\beta = 68.11^\circ$, $\gamma = 69.22^\circ$, $Z = 1$, $D = 4.50$. *JVGR* 33:183(1984). *PD*: 4.25₆ 4.01₈ 3.12₁₀ 2.82₁₀ 2.64₈ 2.57₆ 2.43₈ 2.31₆. See also 16-419. Anhydral crystals all less than 200 μm . Dark gray, black; metallic luster; opaque. $R = 18.5$ (470 nm), 17.5 (546 nm), 18.7 (589 nm), 20.6 (650 nm). Found as a sublimate from a fumerole in summit crater at *Izalco volcano, El Salvador*, in the outer sulfate zone ($T = 100\text{--}200^\circ$) associated with fingerite, thenardite, euchlorine, and other vanadates. HCWS *AM* 73:1495(1988).

38.4.1.1 Heterosite $\text{Fe}^{3+}(\text{PO}_4)$

Named in 1826 from the Greek for *another* because it was the second Mn-containing mineral from the same locality. See purpurite (38.4.1.2), the Mn-rich member of the series. ORTH *Pbnm*. $a = 4.786$, $b = 9.823$, $c = 5.824$, $Z = 4$, $D = 3.672$. 34-134: 4.94₆ 4.31₉ 3.46₈ 2.96₈ 2.92₈ 2.45₁₀ 2.41₄ 1.731₃. Massive. Deep rose to reddish purple; paler tints in streak, usually altered appearing dull or earthy in luster, dark brown to brown-black in color; washing in dilute acid restores color, but note solubility; subtranslucent to opaque. Cleavage {100}, good; {010}, imperfect; surfaces often curved or crinkled; uneven fracture; brittle. $H = 4\text{--}4\frac{1}{2}$. $G = 3.2\text{--}3.4$. Biaxial (+) (Limoge); $X = a$; $N_x = 1.86$, $N_y = 1.89$, $N_z = 1.91$; 2V large; strongly pleochroic; absorption $Z = Y > X$ or $Z > Y \gg X$; strong dispersion may show anomalous green interference colors. X, greenish gray, gray to rose-red; Y,Z, deep blood-red to purplish red. Easily soluble in HCl. Fe/Mn determines identification as heterosite relative to purpurite. Heterosite is the end member in the alteration of a phosphate mineral series beginning with triphylite (38.1.1.1). Alters to pitchy material, a mixture of the oxyhydroxides of Fe^{3+} and Mn^{3+} . Found at Newry, Rumford, and Peru, Oxford Co., ME; Palermo No. 1 pegmatite, Groton, Grafton Co., NH; Huntington (Norwich), MA; Branchville, Fairfield Co., CT; Bull Moose, Pleasant Valley, Tip Top, White Elephant pegmatites, Custer Co.; Gap Lode, Hill City; Dyke lode, Pennington Co., Keystone, SD; *Hureaux, St. Sylvestre, Haute-Vienne, France*; Hagendorf Süd and Hühnerkobel pegmatite, Rabenstein, Bavaria, Germany; Varutråsk, Sweden; Telírio mine, Lavro Do Enio, Galiléia, MG, Brazil; Angarf Süd, Tazenakht Plain, Morocco; Becota, Alto Ligonha, Mozambique; Okatjimukuju Farm pegmatite, Karibib; Erongo, Namibia; Bakenoje, Kazakhstan; Korgel, Laghman, Afghanistan; Euriewie Range, NSW, Australia. HCWS *DII*:675, *AM* 57:45(1972), *KT* 31:1192(1986).

38.4.1.2 Purpurite $\text{Mn}^{3+}\text{PO}_4$

Named in 1905 from the Latin *purpura*, in allusion to the color. The Mn-rich member of the series with heterosite (38.4.1.1). ORTH *Pbnm*. $a = 4.777$,

$b = 9.766$, $c = 5.824$, $Z = 4$, $D = 3.69$. $37-487$: 4.88_7 4.29_{10} 3.74_3 3.46_7 2.95_4 2.91_6 2.44_7 2.41_3 . Physical properties similar to heterosite trending toward the darker and black shades. Biaxial (+); $X=a$; $N_x = 1.85$, $N_y = 1.86$, $N_z = 1.92$ (Peru, ME); 2V moderate, 38° ; strongly pleochroic as heterosite. Soluble in HCl. The phase identified when $Mn/Fe > 1$. Secondary mineral in sequence with lithiophilite. Noted especially at Faires mine, Kings Mt., Gaston Co., NC; Custer district, Pennington Co., SD; Pala and Rincon, San Diego Co., CA; Feiteira, Portugal; Chanteloube, France; Korgal, Laghman, Afghanistan; Wodgina, WA, Australia. *hcws DII:675, KT 31:1192(1986)*.

38.4.2.1 Berlinite $AlPO_4$

Named in 1868 for N. J. Berlin (b.1812), pharmacologist of the University of Lund, Sweden. *HEX-R* $P3_121$. $a = 4.941$, $c = 10.960$, $Z = 3$, $D = 2.62$. Structure: *ZK 192:119(1990)*. $10-423$: 4.28_2 3.37_{10} 2.48_1 2.31_1 1.835_2 1.552_1 1.393_1 1.389_1 . Artificial crystals similar to quartz with $\{1011\}$, $\{0111\}$, and $\{1010\}$; natural is massive, granular. Pale rose, colorless to grayish; vitreous luster; transparent to translucent. No cleavage, conchoidal fracture. $H \approx 6\frac{1}{2}$. $G_{nat} = 2.64$, $G_{syn} = 2.56$. Uniaxial (+); $N_{O\ syn} = 1.524$, $N_{E\ syn} = 1.530$. Soluble in alkali, insoluble in cold acids. Isostructural with quartz, and $AlAsO_4$, tridymite-like and cristobalite-like polymorphs obtained on heating. Synthetic *MR 3:60(1972)*, *SPC 31:712(1986)*. Found at Inspiration mine, Gila Co., AZ; with augelite, attacolite, and other phosphates at *Vestana mine, Nastum, Kristianstad, Sweden*. *hcws DII:696, ZK 123:161(1966)*, *NBSC 539(10):3(1960)*, *MR 3:60(1972)*, *SPC 31:712(1986)*.

MONAZITE GROUP

The monazite group consists of phosphates and arsenates corresponding to the general formula

where

$A = Ce^{3+}$, La, Nd, Th^{4+} , Ca, Bi, REE

$T = P, As$

and crystallizing in the monoclinic space group $P2_1/n$.

The structure is a three dimensional framework with the cations linked through the oxygens of the tetrahedral TO_4 groups into a tight compact structure. Compare the tetragonal structures of xenotime (38.4.9.1) and zircon.

The monazite group is but one part of a ternary system $REEPO_4$ - $CaThPO_4$ - $ThSiO_4$ whose minerals have identical structures and can be thought of as a series of coupled solid solutions. For example $4+$ ions, such as Th^{4+} , may substitute for M^{3+} , i.e. Ce^{3+} , and the charge will be balanced by anionic substitution, such as SiO_4^{4-} for PO_4^{3-} . Naming the different composition species in the monazite group has followed the suggestions outlined in *AM51:152 (1966)*: the dominant element is appended to an end member

thereby minimizing the number of mineral names, i.e. monazite-(Ce), monazite-(Nd). A member of the group without analysis is usually referred to as 'monazite'. Several members of this group often form intergrowths on a sub-micron scale *MM43:1031 (1980)*.

MONAZITE: CePO₄

The three dimensional framework structure viewed down the a axis of monazite-(Ce) shows that Ce coordinates with nine oxygens CeO₉ from PO₄ groups with no channelways for H₂ or other ions.

MONAZITE GROUP

Mineral	Formula	Space Group	a	b	c	β	
Monazite-(Ce)	CePO ₄	<i>P2₁/n</i>	6.761	6.966	6.478	103.47	38.4.3.1
Monazite-(La)	LaPO ₄	<i>P2₁/n</i>	6.836	7.070	6.503	103.23	38.4.3.2
Cheralite	(Ca,Th,Ce)PO ₄	<i>P2₁/n</i>	6.751	6.962	6.468	103.88	38.4.3.3
Brabantite	CaTh(PO ₄) ₂	<i>P2₁/n</i>	6.726	6.933	6.447	103.89	38.4.3.4
Monazite-(Nd)	NdPO ₄	<i>P2₁/n</i>	6.745	6.964	6.435	103.65	38.4.3.5
Gasparite-(Ce)	CeAsO ₄	<i>P2₁/n</i>	6.937	7.137	6.738	104.69	38.4.3.6
Rooseveltite	BiAsO ₄	<i>P2₁/n</i>	6.879	7.159	6.732	104.84	38.4.4.1

Note: Members of this group with identical crystal structures and similar compositions are found together as intergrowths on a submicron scale.

38.4.3.1 Monazite-(Ce) CePO_4

Named by A. Breithaupt in 1829 from the Greek *to be solitary*, in allusion to its rare occurrence in first-known localities. Monazite group. $\text{MON } P2_1/n$. $a = 6.761$, $b = 6.966$, $c = 6.45$, $\beta = 103.47^\circ$, $Z = 4$, $D = 5.06$. Structure: *MZ 10:37(1988)*. $29-403$: 3.29_4 3.08_8 2.86_{10} 2.44_3 2.15_4 1.963_5 1.738_4 . See also *32-199(syn)*. **Physical properties:** Yellowish or reddish brown to brown, greenish, nearly white; white to pale brown streak; resinous to waxy luster, rarely adamantine, also dull to earthy; subtransparent. Crystals occasionally large and coarse. Flattened [100], or elongated [010], also prismatic or equant, wedge-shaped with development of {100} or {111}, faces sometimes striated. Twinning on {100} common, sometimes interpenetrating, also on {001}. Cleavage {100}, good; {010}, poor to good; occasionally on {110}, {101}, {011}. Quality of cleavage varies with degree of alteration; {010} cleavage sometimes perfect. Good parting on {001}, {111}. Conchoidal to uneven fracture, brittle. $H = 5$. $G = 4.6$ increases with Th content. Moderately paramagnetic. Fuses with difficulty, slightly soluble in acids. **Optics:** Biaxial (+); $X = b$; $Z \wedge c = 2-8^\circ$; $N_x = 1.774-1.800$, $N_y = 1.777-1.801$, $N_z = 1.828-1.849$, $2V = 6-19^\circ$, $r > v$ or $r < v$, faintly pleochroic, yellowish brown to colorless. Th dramatically increases RI. **Chemistry:** Heavy REE uncommon, usually

Ilmen Mountains.

New York.

Tavetsch. Twin on {100}.

Binnental. Twin on {100}.

Monazite CePO_4

Forms: $a = \{100\}$, $b = \{010\}$, $l = \{210\}$, $m = \{110\}$, $n = \{120\}$, $u = \{021\}$, $w = \{101\}$, $x = \{\bar{1}01\}$, $r = \{111\}$, $v\bar{1} = \{11\}$, $\bar{l} = \{\bar{2}11\}$, underlined letters refer to second crystal (twin).

<0.3 wt % to over 2 wt %; ThO₂ may be present to 12% grading to cheralite, Th-free material rare. U, Ca, Fe²⁺, Fe³⁺, Mg, and He may also be present. Si is usually low, occasionally to 3 wt %, but a series can extend to huttonite. *MM 43:1031(1980)*. Slowly decomposed in acids. Has been synthesized. Frequently used in radiometric dating. **Occurrence:** Common as an accessory mineral in igneous rocks, especially granite, and gneisses. Monazite may be found in detrital sands in sufficient quantities to be a commercial source of REE. Large crystals in granite pegmatites may be with allanite-(Ce), zircon, xenotime-(Y), gadolinite, samarskite-(Y), fergusonite, magnetite, apatite, columbite, ilmenite, or quartz; also with fluorite and bastnäsitate-(Ce). **Localities:** Found at Topsham, Sagadahoc Co., ME; Albany, NH; Yantic Falls, Norwich, CT; Manhattan schist, NYC; with sillimanite near Yorktown Heights, Westchester Co., NY; Boothwyn, Delaware Co., PA; with microlite at Amelia(!), VA; in sands of Brindletown Creek, Burke Co.; Polk Co.; Lincoln Co.; Silver Creek, McDowell Co.; Ellenboro, Rutherford Co.; Hiddenite, Alexander Co.; Double Shoals and Brooks Farm, Shelby, Cleveland Co.; Mars Hill, Madison Co., NC; Cowpens, Spartanburg Co.; Gaffney, Cherokee Co.; Greenville, Greenville Co., SC; beach sands in FL; sands near Centerville, Boise Co., ID; Pikes Peak batholith; pegmatites, S. Platte district, Jefferson Co., CO; Big Horn placer, WY; Elk Mt., San Miguel Co.; Harding mine(!), Taos Co.; Petaca district(!), Rio Arriba Co., NM; Snowdrift claim, Lemhi Co., ID; Southern Pacific quarry, Nuevo, Riverside Co.; Mountain Pass(!), San Bernardino Co.; Himalaya mine(!), San Diego Co., CA; Villeneuve, Ottawa Co., QUE; Parry Sound, ONT, Canada; Nordre Strømfjord, Greenland; Prince of Wales Quarry, Tintagel, Cornwall, England; granitic pegmatites at Arendal, Dillingo, Råde, Østfold, Tvedstrand, Risør in Aust-Agder, Notero on Kristiana Fiord; Hitterø Is.; Dalane No. 2, Rostadheia(!), Eptevan No. 4, Mølland No. 3, and Tveit Farm pegmatites(!), Iveland, Norway; Bjertnes, Krødern; Lilla Holma near Stromstad; Kararfvet near Falun, Kopparberg, Sweden; Sordavala and Impilaks pegmatites, Lake Ladoga, Finland; St. Christophe, near Bourg d'Oisans, Isère, France; in alpine veins with anatase, ilmenite, rutile, or titanite at Piz Blas, Val Nalps; Val Tavetsch and Wälschen Ofen, Binnatal, Valais; Val Cornera, Grisons, Switzerland; in sandstone bombs, Laacher See, Eifel district, Germany; Rauris, Salzburg, Austria; Pisek and Schüttenhofen, Bohemia, Czech Republic; Alakurtti, Chupa, Karelia; Yaurijoki(!), Murmansk Oblast; gold sands, Sanarka River, southern Ural Mts., near Miask(!); *Zlatoust, Ilmenskie Mts., Ural Mts., Russia*; Jaguarçu pegmatite, Jaguarçu; Buenopolis (twins!), MG; ES, RJ, BA; Santa Luzia, Paraíba, Brazil; Llallagua, Bolivia; Rosetta, Egypt; placer sands derived from Younger Granites, Nigeria; Van Rhyndorp, Namaqualand, South Africa; pegmatites at Ampangabe(!); Ambatofotsikely(!); Madiamby North(!); Mt. Volhambohitra(!), Ankazobe district; black sands, Manajary basin, Madagascar; sands of Embabaan district, Swaziland; Kerala (Travancore)(!), India; west coast of Sri Lanka; tin deposits of Banka and Billiton, Malaysia; Antro Creek, SA; with wolframite at Mt. Bischoff, TAS; Moolyella district, WA, Australia; Ishikawa district, Fukushima Pref.; Yamanoo, Ibar-

agi Pref.; Naegi district, Gifu Pref.; Takehara, Mie Pref.; Kotoge and Daisen, Fukuoka Pref., Japan. *HCWS DII:691*.

38.4.3.2 Monazite-(La) LaPO_4

Systematically named by Levinson in 1966. Monazite group, as described in *AM 51:152(1966)*. *MON* $P2_1/n$. $a = 6.836$, $b = 7.070$, $c = 6.503$, $\beta = 103.23^\circ$, $Z = 4$, $D = 5.08$. *35-731(syn)*: 3.53_2 3.31_9 3.12_{10} 3.01_2 2.88_4 2.21_2 2.15_4 1.981_2 . Frequently in granular masses, light brown, tan, to orange pink; twinned {100} as well as obliquely, resinous to adamantine luster. $H = 5-5.5$. Biaxial (+); $N_x = 1.785$, $N_y = 1.787$, $N_z = 1.840$; faintly pleochroic. Found at Gaya district, Bihar; Ratnapur, India; with uraninite at Shinkolobwe, Shaba, Zaire; Llallagua, Potosi, Bolivia. *HCWS DII:691*.

38.4.3.3 Cheralite $(\text{Ca,Th,Ce})\text{PO}_4$

Named in 1953 for the ancient kingdom Chera (Kerala) in southwestern India. Monazite group. *MON* $P2_1/n$. $a = 6.751$, $b = 6.962$, $c = 6.468$, $\beta = 103.88^\circ$, $Z = 4$, $D = 5.39$. *MM 43:885(1980)*. *33-1095*: 4.66_2 4.17_3 3.48_3 3.28_6 3.07_{10} 2.86_7 2.18_2 1.731_2 . Masses of rough crystals up to 2 in. across. Green, translucent. Cleavage {010}, distinct; {100}, difficult; parting {001}, poor. $H = 5$. $G = 5.28$. Biaxial (+); $X=b$; $Z \wedge c = 7^\circ$; $N_x = 1.779$, $N_y = 1.789$, $N_z = 1.816$; $2V = 18^\circ$; faintly pleochroic. X, Y , green; Z , yellowish green. Th-rich member of the monazite group, also contains some Si. Found in kaolinized pegmatite at *Kullakughi, east of Trivandrum, Travancore, India*, associated with black tourmaline (schorl), chrysoberyl, dark zircon, and smoky quartz. *HCWS AM 38:734(1953)*, *39:403(1954)*.

38.4.3.4 Brabantite $\text{CaTh}(\text{PO}_4)_2$

Named in 1980 for the locality. Monazite group. Part of a series with cheralite (38.4.3.3). Synonym: Lingaitukuang. Identical to brabanite, a REE-free cheralite. *AM 66:878(1981)*. *MON* $P2_1/n$. $a = 6.726$, $b = 6.933$, $c = 6.447$, $\beta = 103.89^\circ$, $Z = 2$, $D = 5.27$. *NJMM:247(1980)*. *31-311*: 4.14_3 3.26_7 3.06_{10} 2.84_{10} 2.42_3 2.16_3 1.945_4 1.853_4 . See also *35-465*. Elongated crystals. Gray-brown, surface alteration to reddish brown. Cleavage {100}, {001}. $H = 5.5$. $G = 5.20$. Biaxial; $N_y = 1.73$, $Z \wedge X = 0.05$. Occurs admixed with brockite in zone with microcrystalline muscovite, thorite, and uraninite in a pegmatite on the *Brabantite farm, Karibib district, Namibia*; Xingjiang, China. *HCWS AM 66:878(1981)*.

38.4.3.5 Monazite-(Nd) NdPO_4

Named in 1987 in allusion to the chemistry and relationship to monazite. Monazite group. *MON* $P2_1/n$. $a = 6.745$, $b = 6.964$, $c = 6.435$, $\beta = 103.65^\circ$, $Z = 4$, $D = 5.43$. *SMPM 67:103(1987)*. *42-1363*: 4.15_3 3.28_6 3.08_{10} 2.85_5 2.59_3 2.43_4 2.18_3 1.954_3 . Long prismatic crystals, translucent to milky but always bright rose in color. Biaxial (+); $N_x = 1.793$, $N_y = 1.795$, $N_z = 1.860$. Occurs with xenotime, gadolinite, bastnäsité, allanite, and monazite-(Ce) in

fissures and druses in aplitic to pegmatitic veins that cut schistose gneiss on moraine of the northern slope of Pta. Glogstafel, Val Formassa, Italy; as fine-grained 1 to $3\mu\text{m}$ pore fillings and fissure fillings up to $15\mu\text{m}$ in brindleyite in *Marmara bauxite deposit, Greece*. HCWS AM 68:849(1983), 73:1495(1988).

38.4.3.6 Gasparite-(Ce) CeAsO_4

Named in 1987 for G. Gaspari. Monazite group. MON $P2_1/n$. $a = 6.937$, $b = 7.137$, $c = 6.738$, $\beta = 104.69^\circ$, $Z = 4$, $D = 5.63$. SMPM 67:103(1987). PD: 3.36₈ 3.16₁₀ 3.04₃ 2.97₇ 2.71₄ 2.52₃ 2.00₃ 1.811₃. See also 15-772(syn). Alteration product as rims, or complete pseudomorphs of synchsite crystal aggregates. Light brown-red, white streak. Conchoidal to uneven fracture. $H = 4\frac{1}{2}$. Biaxial (+); $X = b$; $Z \wedge c = 4^\circ$; $N_x = 1.810$, $N_y = 1.825$, $N_z = 1.92$; $2V = 40^\circ$. Occurs associated with rutile, anatase, magnetite, hematite, synchisite-(Ce), chernovite, and cafarsite in fissures in metasedimentary rocks at *Pizzo Cervandone, a mountain on the border of Italy and Switzerland*. HCWS AM 73:1494(1988).

38.4.4.1 Rooseveltite BiAsO_4

Named in 1946 for Franklin D. Roosevelt (1882–1945), 32nd president of the United States of America. Monazite group. MON $P2_1/n$. $a = 6.879$, $b = 7.159$, $c = 6.732$, $\beta = 104.84^\circ$, $Z = 4$, $D = 7.21$. TMPM 17:65(1972). Structure: AC(B) 38:1559(1982). 25-49(syn): 4.82₄ 4.31₂ 3.33₄ 3.15₁₀ 3.02₂ 2.98₄ 2.96₇ 2.70₃. Thin botryoidal crusts, fine-grained aggregates pseudomorph after bismuthinite. Gray, adamantine luster. Brittle. $H = 4\frac{1}{2}$. $G = 6.86$. Biaxial; $N_{av} = 2.10$ –2.30. Soluble in acids. Has been synthesized. Found at Odsbach bei Oberkirsch, Black Forest, Germany; in cassiterite veinlets in rhyolite and dacite lava flows at *Santiaguillo, Macha, Potosi, Bolivia*; at San Francisco de los Andes, Cerro Negro de la Aguadata, San Juan Prov., Argentina. HCWS DII:697.

38.4.5.1 Tetraroseveltite $\beta\text{-BiAsO}_4$

Named in 1994 as the tetragonal analog of rooseveltite (38.4.4.1). TET $I4_1/a$. $a = 5.085$, $c = 11.69$, $Z = 4$, $D = 7.64$. NJMM:179(1994). Isotypic with scheelite. PD: 4.66₁ 3.07₁₀ 2.55₁ 2.23₁ 1.797₁ 1.715₁ 1.581₁ 1.551₂. Fine-grained powdery aggregates with crystals up to 3 mm. White to yellowish white, earthy. $H = 2\frac{1}{2}$. Nonfluorescent both LWUV and SVUV. Uniaxial (+); $N_{\text{mean}} = 2.20$ (Na). Synthesized. AC 1:163(1948). Oxidation product found on the fluorite–barite gangue in the *Josef mine, Moldava deposit, Krune Hory Mts., northwestern Bohemia, Czech Republic*, and associated with other secondary minerals, such as bayldonite, malachite, mimetite, presingerite, zavaritskite, bismutite, rooseveltite, mixite, wulfenite, and quartz. HCWS

38.4.6.1 Pucherite BiVO_4

Named in 1871 for the locality. One of three polymorphs of BiVO_4 . See clinobisvanite (38.4.4.2) and dreyerite (38.4.6.1). ORTH $Pnca$. $a = 5.328$, $b = 5.052$, $c = 12.003$, $Z = 4$, $D = 6.69$. CMP 41:325(1973). Structure: ZK 169:289(1984). 12-293: 4.64₅ 3.98₅ 3.50₁₀ 2.99₄ 2.70₁₀ 2.13₄ 1.992₄ 1.934₄. Small crystals,

curved faces and marked composite structure, tabular on {001} also acicular; {111} striated parallel to {001}; massive, ocherous, or coatings of minute crystals. Dark brownish red to yellowish brown, yellow streak, vitreous to adamantine luster, opaque to transparent. Cleavage {001}, perfect; subconchoidal fracture; brittle. $H = 4$. $G = 6.69$. Biaxial (-); $N_x = 2.41$, $N_y = 2.50$, $N_z = 2.51$ (Li); $2V = 19^\circ$; $r < v$, extreme; yellow brown. Soluble in HCl forming a deep red solution with evolution of Cl, which on dilution becomes green and precipitates yellow basic chloride. Changes to monoclinic form above 500° . A secondary mineral associated with bismutite and beyerite. Found as ocherous alteration products of native bismuth in pegmatite at Stewart and Pala Chief mines near Pala, San Diego Co., CA; in oxidized portions of Bi-Ag-U-Cu vein in the *Pucher shaft of the Wolfgang mine, Schneeberg, Saxony, Germany*, and from the Arme Hilfe at Ullersreuth, Thuringia; in pegmatites in Madagascar with native bismuth at Mt. Bity and with bismuthinite at Ampangabe; at Sao Jose, Brejauba, MG, Brazil. *HCWS DII:1050*.

38.4.7.1 Clinobisvanite BiVO_4

Named in 1974 for the composition and the symmetry. Other polymorphs: pucherite (38.4.5.1) and dreyerite (38.4.6.1). *MON* $I2/a$. $a = 5.186$, $b = 11.708$, $c = 5.100$, $\beta = 90.43^\circ$, $Z = 4$, $D = 6.95$. *MM* 39:847(1974). 24-688: 4.75₂ 4.67₂ 3.12₃ 3.10₁₀ 3.08₉ 2.92₂ 1.719₂ 1.717₂. See also 14-688(syn). Soft friable crusts, aggregates, reticulated plates to 0.1 mm showing multiple twinning. Yellow powder, orange aggregates, yellow streak, earthy, subvitreous luster. Cleavage {010}, perfect. Soft. $N_{\text{calc}} = 2.63$; strong dispersion. Known as synthetic material before mineral discovered and named. Found at Mutala pegmatite, Mozambique, and in several other localities such as Londonderry, Wodgina, Menzies, Westonia, and *Yinnietharp Station, Pyramid Hill, WA, Australia*, where the mineral is often intergrown with bismutite and with polymorph pucherite and on garnet in beryl-bearing spessartine pegmatites which contain bismutite, bimutoferrite, columbite, uvarovite, pyrite, leucophosphate, calcite, zircon, and triphylite. *HCWS NBSM 3:14(1964)*.

38.4.8.1 Dreyerite BiVO_4

Named in 1981 for Gerhard Dreyer, professor of mineralogy at Johannes Gutenberg University, Mainz, Germany. Xenotime group. Other polymorphs: clinobisvanite (38.4.4.2) and pucherite (38.4.5.1). *TET* $I4_1/amd$. $a = 7.303$, $c = 6.458$, $Z = 4$, $D = 6.25$. Structure: *NJMM:151(1981)*. Isostructural with zircon. 14-133: 4.84₄ 3.65₁₀ 2.91₂ 274₆ 2.59₂ 2.28₂ 1.879₅ 1.825₂. Plates parallel to (001), 20–50 μm thick to 0.5 mm in diameter. Brownish yellow to orange-yellow, yellow streak, adamantine luster. $H = 2.5$. Uniaxial (+); $N > 2.0$. O, bright yellow; E, brownish yellow. Mineral identical with synthetic *TET* BiVO_4 . Found in rhyolitic ash tuff associated with quartz, barite, hematite, native silver, bismite, and carnotite at *Hirschorn, Rheinland-Platz, Germany*. *HCWS AM 67:622(1982)*.

38.4.9.1 Ximengite BiPO_4

Named in 1990 for the locality. HEX-R $P3_121$. $a = 6.986$, $c = 6.475$, $Z = 3$, $D = 5.534$. Structure: *ZK 117:371(1962)*. *PD*: 6.05₇ 4.42₉ 3.49₉ 3.02₁₀ 2.85₆. Veinlets and as irregular aggregates of grains < 0.001–0.1 mm. Colorless, white streak, vitreous to greasy luster. Brittle. $H = 4$. Yellowish fluorescence under electron beam. Nonmagnetic. IR, DTA, TGA. Uniaxial (+); $N > 1.78$. X-ray data similar to synthetic. Inverts to monoclinic form at $\approx 1000^\circ$, then to monazite-type form. Found as an alteration of bismuthinite containing waylandite, monazite with unnamed hydrated Bi phosphates and sulfates; irregularly distributed in cassiterite–tourmaline–quartz and K-feldspar rock in tin mining district of *Ximen*, about 420 km SW Kunming, Yunnan Prov., China. HCWS *MA:4610(1990)*, *AM 76:1436(1991)*.

38.4.10.1 Lithiophosphate Li_3PO_4

Named in 1957 for the composition. ORTH $Pmn2_1$. $a = 6.116$, $b = 5.234$, $c = 4.845$, $Z = 4$, $D = 2.48$. *NBSM 25(4):21(1966)*, Structure: *SPD 23:287(1978)*. *25-1030(syn)*: 5.23₃ 3.97₁₀ 3.80₁₀ 3.55₅ 2.64₇ 2.62₄ 2.42₅ 2.32₂. Masses up to 5×9 cm. White to colorless to light rose. One excellent cleavage, one fair, about 50° apart. $H = 4$. $G = 2.46$. Luminesces turquoise-blue in X-ray beam, nonfluorescent in UV. Biaxial (+); $N_x = 1.550$, $N_y = 1.557$, $N_z = 1.567$, $2V = 69^\circ$; positive elongation. Slightly soluble in hot water, soluble in strong acids. Hydrothermal alteration product of montebrasite; weathers to mangan-apatite and davisonite. Found in Foote mine, Kings Mt., Cleveland Co., NC; Bernic Lake, MB, Canada; with montebrasite in central zone of pegmatites, Kola Penin., Russia, and with micropertthite, quartz, spodumene, beryl, tourmaline, pollucite, and epidolite. HCWS *DANS 112:124(1957)*, *AM 42:585(1957)*.

38.4.10.2 Olympite $\text{LiNa}_5(\text{PO}_4)_2$

Named to honor the Olympic Games at Moscow in 1980. ORTH $P2_12_12_1$. $a = 10.124$, $b = 14.794$, $c = 10.132$, $Z = 8$, $D = 2.71$. [*CR 39:35(1994)*] for Khibina holotype material; virtually identical to Lovozero sample. *DANS 320:499(1992)*. Structure: *SPC 37:772(1992)*. Replacement of Na by Li is limited by stability constraints; there may be a Li analog of olympite. *33-1272*: 4.18₉ 3.70₅ 3.58₆ 2.58₁₀ 2.53₇ 2.43₇ 2.39₅ 1.472₇. Oval grains up to 3 mm in diameter. Colorless, vitreous luster, translucent. Conchoidal fracture, brittle. $H \approx 4$. $G = 2.8$. Biaxial (+); $N_x = N_y = 1.510$, $N_z = 1.512$; $2V = 46^\circ$. No chemical data presented in the structure references. Readily soluble in cold water, giving strongly alkaline solution. In air, alters rapidly to sodium carbonate and hydrated sodium phosphates. Occurs in alkalic pegmatites at the Lovozero massif and at *Mt. Rasvumchorr*, *Khibina massif*, *Kola Penin.*, *Russia*, in association with sidorenkite, villiaumite, aegirine, and another sodium Mn silicate. HCWS *AM 66:438(1981)*, *ZVMO 189:476(1980)*.

38.4.10.3 Nalipoite NaLi_2PO_4

Named in 1991 for the composition: Na–Li–P–O. ORTH *Pmnb*. $a = 6.884$, $b = 9.976$, $c = 4.927$, $Z = 4$, $D = 2.612$. Structure: *CM 29:565(1991)*, *29:569(1991)*. *PD*: 4.04_4 4.00_4 3.51_{10} 3.44_7 2.83_4 2.72_3 2.49_6 2.46_6 . Anhedronal to subhedronal blocky grains to 2 mm and irregular grains to 0.2 mm. White, pale blue, to pale yellow; white streak; vitreous luster; transparent to translucent. Cleavage $\{100\}$, $\{010\}$, $\{001\}$, $\{110\}$, good, and possibly $\{101\}$. Uneven fracture, very brittle. $H = 4$. $G = 2.58$. Nonfluorescent. Biaxial (–); $XYZ = acb$; $N_x = 1.533$, $N_y = 1.540$, $N_z = 1.541$; $2V = 49^\circ$. Readily soluble in 1:1 HNO_3 , less so in 1:1 HCl , slowly in 1:1 H_2SO_4 . X-ray data similar to synthetic. Found in the sodalite–analcime–microcline xenoliths at the *Poudrette quarry in nepheline syenite of Mt. St.-Hilaire, near Montreal, QUE, Canada*. *HCWS AM 77:449(1992)*.

XENOTIME GROUP

The xenotime group are REE-containing minerals conforming to the general formula

where

REE = rare-earth element = Y, Ce, Bi

T = P, As, V, Si

and crystallize in the tetragonal space group $I4_1/amd$.

The structure is similar to monazite [ATO_4] and to zircon: rare-earth-element polyhedra are linked by TO_4 . The three-dimensional framework structure is composed of two types of chains. One type, parallel to c , consists of alternating REE-O_8 and PO_4 , and the other consists of REE-O_8 polyhedra along the a axis. All of the polyhedra are linked by shared edges. Octahedral voids form channels parallel to c .

XENOTIME GROUP

Mineral	Formula	Space group	a	c	
Xenotime-(Y)	YPO_4	$I4_1/amd$	6.878	6.036	38.4.11.1
Chernovite-(Y)	YAsO_4	$I4_1/amd$	7.039	6.272	38.4.11.2
Wakefieldite-(Y)	YVO_4	$I4/amd$	7.105	6.29	38.4.11.3
Wakefieldite-(Ce)	CeVO_4	$I4_1/amd$	7.354	6.488	38.4.11.4
Dreyerite	BiVO_4	$I4_1/amd$	7.303	6.458	38.4.8.1

*Compare clinobisvanite (38.4.7.1) and pucherite (38.4.6.11) other polymorphs of BiVO_4 . *Note*: Dreyerite is a member of the xenotime group. See clinobisvanite (38.4.7.1) and pucherite (38.4.6.1) for other polymorphs of BiVO_4 .

XENOTIME-Y YPO_4

An a_2 axis projection of the three dimensional framework structure of xenotime. Compare Zircon.

38.4.9.1 Xenotime-(Y) YPO_4

Named in 1832 from the Greek *vain* and *honor*, recalling the fact that Y in it had been mistaken for a new element. Xenotime group. TET $I4_1/amd$. $a = 6.878$, $c = 6.036$, $Z = 4$, $D = 4.277$. *MM 39:145(1973)*. Isostructural with zircon $ZrSiO_4$. *11-254*: 4.55₃ 3.45₁₀ 2.565₅ 2.44₂ 2.15₃ 1.824₂ 1.768₅ 1.725₂. See also *9-377(syn)*. Short to long prismatic [001]; equant; pyramidal; radial aggregates of coarse crystals that resemble zircon; rosettes. Often found in parallel growth with zircon. Twinning {111} rare. Yellowish brown to reddish brown, flesh-red, grayish white, wine-yellow, pale yellow, greenish; pale brown, yellowish, or reddish streak; vitreous to resinous luster; transparent to opaque. Cleavage {100}, uneven to splintery fracture, brittle. $H = 4-5$. $G = 4.4-5.1$. Paramagnetic. Uniaxial (+); $N_O = 1.721$, $N_E = 1.816$ (Na); weakly dichroic. O, pink, yellow, yellow-brown; E, brownish yellow, grayish brown, or greenish. Very lightly attacked by acids. Occurs widely as a minor accessory mineral in both acidic and alkaline igneous rocks and in large crystals in the associated pegmatites; also in mica and quartz-rich gneisses and in the quartz veinlets that form the pegmatitic portions of these rocks. Commonly associated with monazite, zircon, ilmenite, rutile, anatase, magnetite, hematite, sillimanite, feldspars, and occasionally with fergusonite and columbite-tantalites. Found in the Manhattan schist, New York City, NY; as a detrital mineral in placer gold deposits of Polk, McDowell, Burke Co., NC; in similar locations in GA and AL; at Rib Mt., Marathon Co., WI; at Snowbird mine, Mineral Co., MO; with fluorcerite and bastnäsité in Cheyenne Canyon, Pikes Peak district, El Paso Co., CO; at Evans-Lou mine, QUE, Canada. Localities

Xenotime -(Y)

Pyramidal and Prismatic habits. Forms: $a=\{110\}$, $m=\{010\}$, $r=\{121\}$, $z=\{011\}$

in Europe include the granitic pegmatites of southern Norway associated with gadolinite, polycrase-euxenite, allanite, zircon, yttrantalite, and thorite, such as at Hitterø in West-Agder, Tvedestrand, Garta, and other places near Arendal, Aust-Agder, Raade near Moss, in Osfold, at Kragerø, and Telemark; at Ytterby NE of Stockholm, Sweden; at Koralpe, Packalpe, Salzburg, Kuppergrund, Lohringer q., Rauris, Austria; at Mt. Fibria SW of St. Gotthard, in the Binnenthal, Valais, and in the Tavetschtal, Graubünden, Switzerland; at Königshain near Görlitz and with monazite at Sreiberhau, Silesia, Germany; at Bressanone, Le Chiuse, Val Masino, Italy; at Nizyunita Ohari, Marumori, Igu Co., Miyagi Pref., Japan; in the alluvial deposits of Kiracoravo, Madagascar; as an accessory mineral in granites of Cape Prov., South Africa; in Manbhum district, Bihar and Orissa Prov., India; in the river sands North Westland, New Zealand; widely distributed in the alluvial deposits at Dattas, and the Urubu pegmatite, MG, and in the diamond washings of BA, Brazil. *hcws DII:688.*

38.4.11.2 Chernovite-(Y) $YAsO_4$

Named in 1967 for Aleksandr A. Chernov (1877–1963), Russian geologist and paleontologist, Academy of Science, Komi, Syktyvkar. Xenotime group. $\text{тєт } I4_1/amd$. $a = 7.039$, $c = 6.272$, $Z = 4$, $D = 4.866$. *ZVMO 96:699(1967)*. 26-999: 4.64_4 3.50_{10} 2.47_5 2.18_3 1.801_7 1.749_4 1.455_3 1.255_3 . See also 13-429(syn). Bipyramidal crystals up to 1 mm, aggregates elongated on c with inner zone green-yellow, outer bright yellow, also colorless; vitreous luster. Cleavage $\{100\}$, indistinct. $N_{av} = 1.753$ (Binnatal), 1.783 (Russian). Contains more La-group elements (Gd, Py, Ho, Er, Yb) than xenotime. Found at *Mjarta-syn-yu R., Telops-iz E, Ural Mts., Russia*, and in the Cervandom massif, and at Binntal, Switzerland. *hcws AM 53:1777(1968)*.

38.4.11.3 Wakefieldite-(Y) YVO_4

Named in 1969 for the locality. Xenotime group. TET $I4_1/amd$. $a = 7.105$, $c = 6.29$, $Z = 4$, $D = 4.25$. AM 56:395(1971). 17-341(syn): 4.71₁ 3.56₁₀ 2.67₅ 2.52₁ 2.22₁ 1.830₅ 1.780₁ 1.481₁. Pulverulent, tiny, $<0.1 \mu\text{m}$ in length, crystal-lites have prism faces and are terminated with pyramids and basal faces reminiscent of zircon. Yellow, pale tan, translucent. $H \approx 5$. Uniaxial (+); $N_{O \text{ syn}} = 2.00$, $N_{E \text{ syn}} = 2.14$. A secondary mineral filling cavities in a pegmatite along with quartz, hellandite, cenosite, and montmorillonite at the *Evans-Lou mine, St. Pierre near Wakefield, Portland Twp., Papineau, QUE, Canada*, associated with yttrian fluorapatite, thorumgummite, or with fergusonite and xenotime. HCWS NBSM 25:59(1967), NJMM:127(1995).

38.4.11.4 Wakefieldite-(Ce) $CeVO_4$

Named "kusuite" in 1977 for the locality, later changed to wakefieldite-(Ce) to coincide with previous mineral described and the dominant rare-earth element. Xenotime group. TET $I4_1/amd$. $a = 7.354$, $c = 6.488$, $Z = 4$, $D = 4.80$. BM 109:305(1986). Structure: BM 110:657(1987). 29-398: 4.89₅ 3.68₁₀ 2.77₉ 2.59₄ 2.29₃ 1.891₇ 1.833₂ 1.638₄. See also 12-757(syn). Crystals showing $\{101\}$ to 1 mm in size. Black, rust-brown streak. No cleavage. $H = 4\frac{1}{2}$. $G = 4.76$. $N > 2.00$, yellow in transmitted light. Equal small amounts of Pb^{2+} and Pb^{4+} present but no other REE than Ce. Found in the oxidation zone of *Kusu Dept., 85 km SW of Kinshasa, Zaire*, associated with mottramite, chervetite, cuprite, diopside, heyite, malachite, plancheite, and vanadinite. HCWS BM 100:39(1977), AM 62:1058(1977).

38.4.12.1 Kosnarite $KZr_2(PO_4)_3$

Named in 1993 for Richard A. Kosnar, mineral dealer, of Black Hawk, CO. HEX-R $R3c$. $a = 8.687$, $c = 23.877$, $Z = 6$, $D = 3.206$. AM 78:653(1993). PD: 6.41₅ 4.68₅ 4.33₁₀ 3.81₉ 3.17₄ 2.93₉ 2.50₅ 1.903₅. See also 25-1206(syn), 35-756(syn). Pseudocubic rhombohedral crystals up to 0.9 mm with $\{102\}$ dominant. Pale blue to blue-green, colorless; white streak; vitreous luster; transparent. Not twinned. Cleavage $\{102\}$, perfect; conchoidal fracture; brittle. $H = 4\frac{1}{2}$. $G = 3.194$. Nonfluorescent. Uniaxial (+); $N_O = 1.656$, $N_E = 1.682$; nonpleochroic. Found in vugs with euhedral crystals of siderite, eosphorite, fluorapatite, moraesite, and quartz, part of the late-stage secondary phosphate assemblage from *Mount Mica pegmatite, Paris, and Black Mt. pegmatite, Rumford, Oxford Co., ME*; at the Wycheproof pegmatite, SA, Australia. HCWS AM 78:653(1993).

38.5.1.1 Chursinite $Hg^{1+}Hg^{2+}(AsO_4)_2$

Named in 1984 for Ludmilla A. Chursina, Russian actress. MON $P2_1/n$. $a = 8.73$, $b = 5.08$, $c = 15.64$, $\beta = 128.4^\circ$, $Z = 4$, $D = 9.05$. Structure: ZVMO 113:341(1984), AC(B) 29:1666(1973). 38-399: 3.05₁₀ 2.89₈ 2.84₇ 2.51₅ 2.46₅ 2.19₅ 2.14₅ 1.911₅. Grains to 0.2 mm. Yellow-brown to orange-brown, adamantine luster, transparent. Cleavage parallel to elongation, brittle. Sections

become covered with a blue-violet film when exposed to air. $H = 3$. $G = 9.05$. $N > 2.0$; anisotropic, dark brown to blue-green. $R = 18.5\text{--}22.8$ (460 nm), $16.1\text{--}20.4$ (546 nm), $15.8\text{--}19.7$ (540 nm), $14.5\text{--}18.5$ (656 nm). Synthesized. Found in the oxidized portion of Sb-As-Hg ores of *Khaidarken Dept., Kyrgyzstan*, associated with calomel, eglestonite, terlinguaite, corderoite, montroydite, kuzovetsovite, shakhovite, poyarkovite, and native Hg. HCWS *AM 70:871(1985)*.

38.5.2.1 Lyonsite $\text{Cu}_2^+\text{Fe}_4^{3+}(\text{VO}_4)_6$

Named in 1987 for John B. Lyons (b.1916), professor of mineralogy, Dartmouth College, Hanover, NH. ORTH *Pmcn*. $a = 10.296$, $b = 17.207$, $c = 4.910$, $Z = 2$, $D = 4.215$. Structure: *AM 72:1000(1987)*. $40\text{--}1456$: 8.79₂ 4.42₄ 3.28₁₀ 2.78₄ 2.72₄ 2.53₆ 1.591₄ 1.550₄. Euhedral, lathlike crystals up to 230 μm long. Black, dark gray streak, metallic luster, creamy white in reflected light. Cleavage $\{001\}$, good. On (010) $R = 17.5\text{--}23.1$ (481 nm), $16.6\text{--}22.3$ (547 nm), $14.7\text{--}20.7$ (591 nm), $14.4\text{--}18.8$ (644 nm). One of the several minerals sublimating from the Y fumarole of the *Izalco volcano, El Salvador*, associated with thenardite. Other vanadates: stoiberite, fingerite, mcbirneyite, ziesite, blossomite, bannermanite, and shcherbinaite. HCWS

38.5.3.1 Howardevansite $\text{NaCu}^{2+}\text{Fe}_2^{3+}(\text{VO}_4)_3$

Named in 1988 for Howard T. Evans (b.1919), mineralogist and crystallographer, U.S. Geological Survey, Reston, VA. TRIC *P1*. $a = 8.198$, $b = 9.773$, $c = 6.651$, $\alpha = 103.82^\circ$, $\beta = 101.99^\circ$, $\gamma = 106.74^\circ$, $Z = 2$, $D = 3.814$. Structure: *AM 73:181(1988)*. $42\text{--}1333$: 3.27₆ 3.17₁₀ 3.09₁₀ 2.68₆ 2.60₆ 2.05₅ 1.659₇ 1.433₆. Euhedral, tabular up to 80 μm in diameter, dominant forms (100), (010), (001), (110), (101), (101), (011). Black, red-brown streak, metallic luster. Brittle. Reflectance medium gray, moderately anisotropic. $R = 15.5\text{--}20.1$ (481 nm), $15.0\text{--}18.4$ (547 nm), $14.1\text{--}17.2$ (591 nm), $13.5\text{--}17.1$ (644 nm). Found as one of the sublimating vanadates at the fumaroles of *Izalco volcano, El Salvador*; see also lyonsite (38.5.2.1). HCWS

38.5.4.1 Ludlockite $(\text{Fe}^{2+}, \text{Pb})\text{As}_2\text{O}_6$

Named in 1970 for F. Ludlow Smith III and C. Locke Key, mineral collectors and dealers in NJ and ME. TRIC $P\bar{1}$ or *P1*. $a = 10.11$, $b = 11.95$, $c = 9.86$, $\alpha = 113.9^\circ$, $\beta = 99.7^\circ$, $\gamma = 82.74^\circ$, $Z = 9$, $D = 4.35$. *MR 8:91(1977)*. $29\text{--}774$: 10.90₆ 8.81₁₀ 4.74₆ 4.47₆ 3.33₇ 3.16₇ 2.94₉ 2.86₇. Crystals elongated [100] flattened $\{011\}$ with $\{021\}$, no terminal faces. Red, light brown streak, subadamantine luster. Sectile, flexible. Cleavage $\{011\}$, micaceous, combines with other easy $\{0kl\}$ cleavages to give fibers. Lamellar twinning on $\{011\}$. $H = 1\frac{1}{2}$. $G = 4.40$. IR, Raman suggest bonding is similar to the As-O-As bonding in claudetite. Biaxial (+); Z near a ; $N_x = 1.96$, $N_y = 2.055$, $N_z > 2.11$; optic axial plane perpendicular to $\{011\}$, pleochroic. X, yellow; Y, deep yellow; Z, orange-yellow. Readily dissolves in 1:1 HCl, HNO₃. Found with zincian siderite in a cavity of ore from the "germanite section" at *Tsumeb, Namibia*. HCWS *AM 57:1003(1972)*.

38.5.5.1 Chervetite $\text{Pb}_2\text{V}_2^{5+}\text{O}_7$

Named in 1963 for J. Chervet (1904–1962), French mineralogist. *MON P2₁/a*. $a = 13.37$, $b = 7.16$, $c = 7.11$, $\beta = 106^\circ$, $Z = 4$, $D = 6.38$. Structure: *BM 90:279(1967)*. *18-708*: 4.93₆ 4.32₅ 3.57₅ 3.44₁₀ 3.43₁₀ 3.21₈ 3.16₅ 3.08₈. Crystals up to a few centimeters showing (100), (221), (221), (001) always twinned (100), pseudomorphs after francevillite (40.2a.27.1). Cleavage {100}, {010}, doubtful. Colorless, gray, brown, white streak, adamantine luster. $H = 3$. $G = 6.31$. Biaxial (-); $N = 2.2\text{--}2.6$; $2V = 65\text{--}75^\circ$; bireflectance = 0.275; dispersion inclined weak. Found at St. Andreasberg, Harz, Germany; Vrancice, Bohemia, Czech Republic; *Mounana uranium mine, Franceville, Haut Ogooue, Gabon*; Kusu deposit, 85 km SW of Kinshasa, Zaire. *HCWS AM 48:1416(1963)*; *BM 86:117(1963)*, *88:126(1965)*.

38.5.5.2 Ziesite $\beta\text{-Cu}_2\text{V}_2^{5+}\text{O}_7$

Named in 1973 for Emanuel G. Zies (1884–1981), Geophysical Laboratory, Carnegie Institution, Washington, DC. Polymorphic with blossomite (38.5.6.1). *MON C2/c*. $a = 7.689$, $b = 8.029$, $c = 10.106$, $\beta = 110.25^\circ$, $Z = 4$, $D = 3.869$. Structure: *AM 65:1146(1980)*, *NJMM:41(1989)*. *26-569(syn)*: 5.34₈ 3.60₁₀ 3.09₁₀ 3.06₁₀ 2.30₈ 2.11₈ 2.09₈ 1.606₈. Anhedral equant crystals <200 μm in diameter. Black, reddish-brown streak (like hematite), metallic luster. No cleavage. $G_{\text{syn}} = 3.86$. Nonfluorescent. $N_{\text{mean calc}} = 2.055$. White in reflected light, approximates the reflectivity of acanthite or tetrahedrite. Nonpleochroic, moderately to strongly anisotropic. Grains often composed of several optically discontinuous regions. Found encrusting basaltic breccia fragments 1 m below the surface at the Y fumarole, one of five fumaroles at the *Izalco volcano, El Salvador*. *HCWS CR 177C:1101(1973)*.

38.5.6.1 Blossite $\alpha\text{-Cu}_2\text{V}_2^{5+}\text{O}_7$

Named for F. Donald Bloss (b.1920), professor of mineralogy, Virginia Polytechnic Institute and State University, Blacksburg, VA. Polymorphous with ziesite (38.5.5.2). The natural analog of a previously described synthetic phase and the low-temperature modification of ziesite (38.5.5.2). *ORTH Fddd*. $a = 20.676$, $b = 8.392$, $c = 6.446$, $Z = 8$, $D = 4.051$. Structure: *AM 72:397(1987)*, *AC(B) 29:2737(1973)*. *26-566(syn)*: 3.26₁₀ 3.22₈ 3.08₁₀ 2.48₈ 2.102₇ 2.096₇ 1.712₇ 1.611₇. Equant, anhedral crystals up to 150 μm . Black, red-brown streak, metallic luster, opaque, white in reflected light. Weakly to moderately anisotropic, gray to creamy brown-gray; moderate bireflectance in shades of creamy white. $R = 14.6\text{--}15.3$ (481 nm), 15.4–16.6 (547 nm), 14.8–16.7 (591 nm), 14.5–15.7 (644 nm). $N_{\text{mean}} = 2.05$. Found as a fumarolic sublimate in the Y fumarole of *Izalco volcano, El Salvador*, with shcherbinaite, bannermanite, stoiberite, fingerite, ziesite, and mcbirneyite. *HCWS CR 277C:1101(1973)*.

38.5.7.1 Simferite $\text{Li}_{0.5}(\text{Mg}_{0.5}\text{Fe}_{0.03}^{3+}\text{Mn}_{0.2}^{3+})_2(\text{PO}_4)_3$

An inadequately described mineral. ORTH *Pbnm* or *Pbn2₁*. $a = 4.747$, $b = 10.101$, $c = 5.899$, $D = 3.25$. Structure: *DANS 307:1119(1989)*. Aggregates up to 3 mm, individual crystals up to 0.1, commonly twinned. Dark red. $G = 3.22$. Biaxial; $N_x = 1.690\text{--}1.704$, $N_y = 1.702\text{--}1.716$, $N_z = 1.712\text{--}1.726$. Occurs at the contact of REE-bearing pegmatite and phlogopitized tremolitic rock in Russia. *HCWS AM 78:452(1993)*, *SPD 34:669(1989)*.

38.5.9.1 Namibite $\text{CuBi}_2(\text{VO}_4)\text{O}_2$

Named in 1981 for the country in which it was found. MON *C2/m*, *Cm*, or *C2*. $a = 11.864$, $b = 3.696$, $c = 7.491$, $\beta = 109.70^\circ$, $Z = 2$, $D = 6.76$. *SMPM 61:7(1981)*. $35\text{--}711$: 7.05_3 5.58_7 3.57_7 3.53_4 3.28_3 3.02_{10} 2.67_6 2.61_3 . Platy crystals up to 2 mm. Commonly twinned by interpenetration (011), or polysynthetic. Dark green, pistachio-green streak, translucent. Cleavage {100}, good. $H = 4\frac{1}{2}\text{--}5$. $G = 6.86$. Nonfluorescent. IR. Biaxial (-); $X \wedge a \approx 12^\circ$; $Z = b$; $N \gg 2.10$; $2V$ moderate; $Z > Y > X$; $r > v$. X, yellow-green; Y, pistachio-green; Z, dark green. Easily soluble in cold 1:10 acids. Found in cavities in drusy quartz veins at copper mine near *Khorixas* (formerly *Welwitschia*), northwestern Namibia, associated with beyerite, Bi, bismite, bismutite, and oxidized Cu minerals. *HCWS AM 67:857(1982)*.

38.5.10.1 Aerugite $(\square, \text{Ni})_9(\text{AsO}_4)_2(\text{AsO}_6)(?)$

Named in 1858 from the Greek for *copper rust*, in allusion to its appearance. See also xanthosite (38.3.2.1). HEX-R $R\bar{3}m$. $a = 5.951$, $c = 27.568$, $Z = 1$, $D = 5.772$. Structure: *AC(B) 45:201(1989)*. Structure shows layers stacked along [001]. Ni in octahedral coordination, Ni-O₆ site only partially (5/6) occupied to achieve charge balance in layers with octahedral As, As-O₆, and As in tetrahedral coordination. $18\text{--}873$: 9.19_7 5.05_8 3.76_9 2.86_8 2.49_8 2.33_8 2.06_{10} 1.485_8 . Small isolated crusts. Synthetic crystals tabular on (001). Deep blue-green. $G = 5.85$. Slowly soluble in boiling perchloric acid. Found as the crusts on walls of furnaces and with native Bi, bunsenite, at *South Terras mine, Cornwall, England*, and at *Tolgarrick Mill, St.-Stephen-in-Brnad, 5 miles W of St. Austell*, with xanthosite in comby quartz in a uranium mine with Ni-Co minerals such as rammelsberite and gersdorffite, and also erythrite, annabergite, scodorite, and pharmacosiderite; at *Johanngeorgenstadt, Saxony, Germany*. *HCWS MM 35:72(1965)*.

Hydrated Acid Phosphates, Arsenates, and Vanadates

39.1.1.1 Brushite $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$

Named in 1865 for George Jarvis Brush (1831–1912), professor of mineralogy, Yale University, New Haven, CT. Gypsum group. See gypsum (29.6.3.1). MON *C2/c*. $a = 6.361$, $b = 15.191$, $c = 5.184$, $\beta = 118.45^\circ$, $Z = 4$, $D = 2.318$. AM 76:1722(1991), Structure: ZK 181:205(1987). 11-293: 7.62₁₀ 3.80₃ 3.06₁ 2.90₁ 2.63₁ 2.53₁ 2.01₁ 1.90₁. Platy {010}; needlelike or prismatic crystals; cryptocrystalline efflorescences; earthy, powdery, foliated. Colorless to pale yellow; vitreous luster, pearly on cleavage; transparent to translucent. Cleavage {010}, {001}, perfect. $H = 2\frac{1}{2}$. $G = 2.328$. Piezoelectric. DTA. IR. MSLM 4:393,395(1974). Biaxial (+); $Z = b$; $X \wedge c = -30^\circ$; $N_x = 1.540$, $N_y = 1.546$, $N_z = 1.552$; $2V = 86^\circ$; $r > v$; crossed dispersion notable. Readily soluble in HCl. Loses all water by 100° forming monetite (37.1.1.1). Synthesized. Widespread in small amounts in sedimentary phosphate deposits, agricultural fertilizer runoff, tomb walls, and guano-bearing caves; occurs as incrustations on ancient human and animal bones and human urinary calculi. Found in Pig Hole Cave, Johns Creek Mt., Giles Co., VA; Maury formation, Dekalb Co., TN; Rock Creek, Kankakee Co., IL; Paoha Is., Mono Lake, Mono Co., CA; Rapid Creek, YK, Canada; Mona Island, PR; Sombrero Is., BVI; in guano on *Aves Island, Venezuela*; Wheal Cock, St. Just, Cornwall, England; Begues, Baix Llobregat, Catalonia region, Spain; Quercy near Limoges; on ancient human skeletons, Minerva Cave, Cevennes Mts., Hérault; Grandpré, Ardennes, France; with hydroxylapatite and taranakite in bat guano deposits from Apulian caves, southern Italy; commercially worked in a cave near Oran, Algeria; Moorba Cave, Jurien Bay, WA, Australia; Enderbury Is., Phoenix Islands. hcws DII:704, AM 41:616(1956), MSLM 4:393,395(1974).

39.1.1.2 Pharmacolite $\text{CaHAsO}_4 \cdot 2\text{H}_2\text{O}$

Named in 1800 from the Greek for *poison*, in allusion to the arsenic content. Gypsum group. See gypsum (29.6.3.1). MON *P2/m*. $a = 5.975$, $b = 15.434$, $c = 6.280$, $\beta = 114.83^\circ$, $Z = 4$, $D = 2.731$. Structure: AC(B) 25:1544(1969), but see double cell ($Z = 8$) comparison with krautite. AM 64:1248(1979). 25-138: 7.7₉ 5.1₇ 4.30₁₀ 3.08₈ 3.02₈ 2.70₉ 2.66₉ 2.48₅. Delicate silky fibers or acicular clusters; botryoidal and stalactitic; small crystals (rare) flattened on

{010}, or needle-like [001]. Colorless, whitish, grayish; vitreous luster, pearly on cleavage; transparent. Cleavage {010}, perfect; uneven fracture; flexible in thin laminae. $H = 2-2\frac{1}{2}$. $G = 2.725$. IR. MSLM 4:393(1974). Biaxial (-); $Z = b$; $X \wedge c = -29^\circ$; $N_x = 1.583$, $N_y = 1.589$, $N_z = 1.594$ (Na); $2V = 79.4^\circ$; $r > v$. Soluble in acids, insoluble in water. Dehydrates at 60° . Synthesized. Found with other arsenates, especially haidingerite, in oxidized portions of arsenical ores at White Caps mine, Manhattan, NV; with erythrite at O.K. mine, San Gabriel Canyon, Los Angeles Co., CA; at Ste.-Marie-aux-Mines (Markirch), Vosges Mts., Alsace, France; as small crystals at Jachymov, Bohemia, Czech Republic(!), at Andreasberg in the Harz, and at *Grube Anton, Wittichen, Black Forest, Germany*. *HCWS DII:706, BM 87:169(1984)*.

39.1.2.1 Fluckite $\text{CaMn}^{2+}(\text{HAsO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1980 for Pierre Fluck, mineralogist at Louis Pasteur University, Strasbourg, France. TRIC P1. $a = 8.459$, $b = 7.613$, $c = 6.968$, $\alpha = 82.21^\circ$, $\beta = 98.25^\circ$, $\gamma = 95.86^\circ$, $Z = 2$, $D = 3.11$ *BM 103:122(1980)*. Structure: *103:129(1980)*. See krautite (39.1.3.1). *33-290: 8.32₄ 7.51₁₀ 3.77₆ 3.53₉ 3.27₉ 2.98₈ 2.69₆ 2.67₄*. Radiating prismatic crystals with {100}, {110}, {010} dominant faces. Colorless to pale to deep rose. Cleavage {010}, perfect; {100}, easy; {101}, difficult. $H = 3\frac{1}{2}-4$. $G = 3.05$. DTA. Biaxial (+); $N_x = 1.618$, $N_z = 1.642$, $2V$ large. Found at the 60- and 100-m levels of the *Gabe Gottes-St. Jacques vein at Ste.-Marie-aux-Mines, Vosges Mts., Alsace, France*, associated with pharmacolite and picroparmacolite. *HCWS AM 65:1066(1980)*.

39.1.3.1 Krautite $\text{Mn}^{2+}\text{As}^{5+}\text{O}_3(\text{OH})_2 \cdot 2\text{H}_2\text{O}$

Named in 1975 for François Kraut, mineralogist at the Musée Nationale d'Histoire Naturelle, Paris. MON $P2_1/n$. $a = 8.012$, $b = 15.956$, $c = 6.801$, $\beta = 96.60^\circ$, $Z = 8$, $D = 3.274$. Structure: *AM 64:1248(1979)*. Layers of AsO_4 and MnO_6 polyhedra linked by H^+ bonds are the basic structural components, a similar structural motif to that of haidingerite (39.1.5.1) and pharmacolite (39.1.1.2). *29-888(syn): 7.99₁₀ 4.88₄ 3.86₁₀ 3.30₁₀ 3.27₁₀ 3.19₉ 2.86₄ 2.73₆*. See also *33-895*. Lamellar up to 2 mm in largest dimension and aggregates of the lamellae. Pale rose, translucent. Cleavage {010}, perfect, micaceous; {101}, good; {101}, distinct. $H = 4$. $G = 3.30$. Biaxial (+); $X = b$; $Z \wedge (101) = 16^\circ$; $N_x = 1.620$, $N_y = 1.639$, $N_z = 1.686$ (Na); $2V = 65^\circ$; positive elongation. Synthesized in 1886. Found at Sacarimb, formerly Nagyag, and Kapnik (Cavic), Transylvania, Romania. *HCWS BM 98:78(1975); AM 61:503(1976), 66:432(1981)*.

39.1.4.1 Koritnigite $\text{Zn}(\text{AsO}_3\text{OH}) \cdot \text{H}_2\text{O}$

Named in 1979 for Sigmund Koritnig (b.1912), professor, Göttingen, Germany. TRIC P1. $a = 7.948$, $b = 15.829$, $c = 6.668$, $\alpha = 90.86^\circ$, $\beta = 96.56^\circ$, $\gamma = 90.05^\circ$, $Z = 8$, $D = 3.56$. *TMPM 26:51(1979)*, Structure: *NJMA 138:316(1980)*. *34-1396: 7.90₁₀ 3.95₄ 3.83₇ 3.16₉ 2.93₄ 2.68₄ 2.46₆ 2.19₅*. Massive. Colorless, transparent. Cleavage {010}, perfect; traces of cleavage par-

allel to [001] and [100] visible on {010}. $H = 2$. $G = 3.54$. IR. Biaxial (+); $X = b$; $Z \wedge c = 22^\circ$; $N_x = 1.632$, $N_y = 1.652$, $N_z = 1.693$. Soluble in cold 1:10 HCl, HNO₃. Occurs in cavities in tennantite associated with Cu-adamite, and stranskiite at level 31 of the *Tsumeb mine*, *Tsumeb*, *Namibia*. *HCWS AM 65:206(1980)*. *AUF 31:43(1980)*.

39.1.4.2 Cobaltkoritnigite (Co,Zn)(AsO₃OH) · H₂O

Named in 1981 for the similarity to koritnigite and the composition. TRIC *P1*. $a = 7.95$, $b = 15.83$, $c = 6.67$, $\alpha = 90.86^\circ$, $\beta = 96.6^\circ$, $\gamma = 90.1^\circ$, $Z = 8$, $D = 3.44$. *NJMM:257(1981)*. *35-499*: 7.94₁₀ 7.07₂ 3.82₅ 3.25₄ 3.23₄ 3.14₇ 2.69₃ 2.46₄. Tabular crystals. Purple, vitreous luster. Cleavage {010}, perfect; {100}, good. Biaxial (+); $X \wedge b = 3^\circ$, $Y \wedge a = 12.5^\circ$; $N_x = 1.646$, $N_y = 1.668$, $N_z = 1.705$; strongly pleochroic. X, deep violet; Y, reddish violet; Z, bluish violet. Found as an alteration product of cobaltite in the Richelsdorf Mts., and by alteration of glaucodot and associated with sphaerocobaltite, erythrite, pitticite, and quartz at *Erzgebirge*, *Saxony*, *Germany*. *HCWS ZAAC 454:134(1979)*, *NJMM:237(1980)*, *AM 67:414(1982)*.

39.1.5.1 Haidingerite Ca(AsO₃OH) · H₂O

Named in 1827 for William Karl von Haidinger (1795–1871), Austrian mineralogist and geologist. ORTH *Pcnb*. $a = 6.904$, $b = 16.161$, $c = 7.935$, $Z = 8$, $D = 2.971$. Structure: *AM 64:1248(1979)*. See also *AC(B) 28:209(1972)*. *18-288*: 8.06₈ 5.25₈ 5.22₁₀ 3.84₈ 3.19₈ 3.15₈ 3.11₇ 2.96₉. Also *17-161*. Fine grained botryoidal to fibrous coatings; crystals rare equidimensional to short prismatic [001], [100]. Colorless, white; vitreous luster, pearly on cleavage; transparent. Cleavage {010}, perfect; sectile; flexible thin laminae. $H = 2-2\frac{1}{2}$. $G = 2.848$. Biaxial (+); $N_x = 1.590$, $N_y = 1.602$, $N_z = 1.638$; $2V = 58^\circ$; $r > v$. Loses water in several stages, completely dehydrated to pyroarsenate at 200°. Synthesized; Ba and Sr analogs are known. Found as an oxidation product of arsenical ores in association with pharmacolite at White Caps mine, Manhattan, NV; Schneeberg and Johanngeorgenstadt, Saxony, near Wittichen in the Black Forest, Germany; from *Jachymov*, *Zapadocesky Kraj*, *Bohemia*, *Czech Republic*. *HCWS DII:708*, *BM 89:18(1966)*.

39.1.6.1 Newberyite Mg(PO₃OH) · 3H₂O

Named in 1879 for James Cosmo Newbery (1843–1895) of Melbourne, VIC, Australia. ORTH *Pbca*. $a = 10.203$, $b = 20.678$, $c = 10.015$, $Z = 16$, $D = 2.12$. *AM 51:1755(1966)*, Structure: *TMPM 32:187(1983)*. *35-780(syn)*: 5.95₅ 4.71₅ 4.50₄ 4.15₃ 3.46₆ 3.08₅ 3.04₁₀ 2.58₃. Crystals equidimensional, short prismatic [001] or tabular {100}; {010} and {111} also seen in artificial crystals. Colorless, vitreous luster, transparent. Cleavage {010}, perfect; {001}, imperfect. $H = 3-3\frac{1}{2}$. $G = 2.10$. IR. *MSLM 4:398(1974)*. Biaxial (+); $N_x = 1.514$, $N_y = 1.517$, $N_z = 1.533$; $2V = 44.78^\circ$; $r < v$, perceptible. Scarcely soluble in cold water, readily soluble in 1:10 HCl. Dehydrates to MgHPO₄ at 130°. Synthesized. Found at Paoha Is., Mono Lake, Mono Co., CA; from mammoth

tusk with struvite and magnesite, near Dawson, YT, Canada; with collophane (carbonate-apatite) on basalt from roof of cavern on Ascension Is., southern Atlantic Ocean; as small reticulated crystals in cavities of lava tunnel filled with bat guano, Island of Reunion, Indian Ocean; from the *Skipton Caves, near Ballarat, VIC, Australia*(1), in inch-square crystals with hannayite in bat guano; as clear crystals on cracks in guano, Mejillones, Chile. *HCWS DII:709, NJMM:97(1961), BM 94:556(1971)*.

39.1.7.1 Brassite $\text{Mg}(\text{AsO}_3\text{OH}) \cdot 4\text{H}_2\text{O}$

Named in 1973 for Rejane Brasse, French chemist who synthesized the compound. ORTH *Pbca*. $a = 7.472$, $b = 10.890$, $c = 16.585$, $Z = 8$, $D = 2.326$ *BM 96:365(1973)*. Structure: *AC(B) 32:1460(1976)*. *23-1228(syn)*: 5.55₈ 5.45₈ 4.95₁₀ 3.89₈ 3.73₈ 3.30₈ 3.20₈ 3.08₁₀. See also *29-860(calc)*. Crusts and coatings on museum specimens. White, translucent. Synthetic crystals are tabular with {001} dominant, also {011}, {021}, {102} show cleavage {001}, excellent. $G = 2.28$. DTA. Biaxial (+); $XYZ = bac$; $N_x = 1.531$, $N_y = 1.546$, $N_z = 1.562$; 2V large. Occurs on specimens from *Jachymov, Bohemia, Czech Republic*; *Bieber, Saxony, Neurode, Silesia, and Wittichen, Baden, Germany*, labeled rosslerite, pharmacolite, haidingite, and "wapplerite" (= rosslerite), and is associated with arsenic, weilite, raenthalite, and micropharmacolite. *HCWS AM 60:945(1975)*.

39.1.8.1 Dorfmanite $\text{Na}_2(\text{PO}_3\text{OH}) \cdot 2\text{H}_2\text{O}$

Named in 1980 for Moisei Davidovich Dorfman (b.1908), Russian mineralogist who first reported a sodium phosphate in 1963. ORTH. $a = 10.34$, $b = 16.82$, $c = 6.60$, $Z = 8$, $D = 2.06$. *ZVMO 109:211(1980)*. *10-190(syn)*: 8.42₆ 5.28₈ 4.64₉ 3.36₁₀ 3.26₈ 2.93₄ 2.87₇ 2.74₅. Powdery aggregates. White. $H = 1-1\frac{1}{2}$. $G = 1.99$. IR, DTA. Biaxial (+); $N_x = 1.454$, $N_y = 1.461$, $N_z = 1.461$; 2V = 65°; $r > v$, weak. Very soluble in water. Found at Mt. St.-Hilaire, QUE, Canada. Formed by alteration of lomonosovite in drill cores in alkalic pegmatites of *Khibina and Lovozero massifs, Kola Penin., Russia*. *HCWS AM 66:217(1981), IGR 24:111(1982)*.

39.1.9.1 Rösslerite $\text{Mg}(\text{AsO}_3\text{OH}) \cdot 7\text{H}_2\text{O}$

Named in 1861 for Karl Rössler, of Hanau, Germany. Synonym: wapplerite. MON *C2/c*. $a = 6.692$, $b = 25.744$, $c = 11.538$, $\beta = 95.15^\circ$, $Z = 8$, $D = 1.948$. *ZK 137:194(1973)*. Structure: *AC(B) 29:286(1973)*. *26-1447(syn)*: 12.9₆ 6.43₉ 4.67₈ 4.49₉ 4.29₈ 4.08₁₀ 3.31₅ 2.86₆. Fine-grained crusts, sometimes hairlike. Small, short, prismatic crystals [001] (rare). Artificial crystals tabular {010}. Colorless, white; vitreous or dull luster; transparent. Cleavage {111}, imperfect. $H = 2-3$. $G_{\text{syn}} = 1.943$. Biaxial (+); $Z = b$; $X \wedge c = 14^\circ$; $N_x = 1.525$, $N_y = 1.53$, $N_z = 1.550$; 2V small. Readily soluble in 1:10 HCl, slightly soluble in H₂O. Crystals lose water on exposure to air becoming white, dull. Synthesized under acidic conditions. A secondary mineral with other arsenates in oxidized zones of arsenical ore deposits. Found at *Bieber, near Hanau*, with

pharmacolite and erythrite and at Sophie mine near Wittichen, at Wolfgang mine near Alpairstbach, Black Forest, *Germany*; at Jachymov, Bohemia, Czech Republic, in weathered crystals with pharmacolite and haidingerite. *HCWS DII:712*.

39.1.9.2 Phosphorrösslerite $\text{Mg}(\text{PO}_3\text{OH}) \cdot 7\text{H}_2\text{O}$

Named in 1939 for its relation to rösslerite, an arsenate, as it is the phosphate analog. *MON C2/c*. $a = 6.574$, $b = 25.36$, $c = 11.32$, $\beta = 95.18^\circ$, $Z = 8$, $D = 1.741$. *ZK 137:246(1973)*. 19-761(syn): 4.55₉ 4.42₉ 4.13₉ 4.02₉ 3.29₁₀ 2.82₁₀ 2.70₉ 2.63₉. Crystals equi-dimensional or short prismatic [100], skeletal, crusted. Rarely clear, mostly yellow due to included iron oxides and organic matter; vitreous luster when fresh, dull due to water loss. Conchoidal fracture. $H = 2\frac{1}{2}$. $G = 1.725$. Biaxial (-); $X = b$; $Z \wedge c = 6.5^\circ$; $N_x = 1.477$, $N_y = 1.485$, $N_z = 1.486$; $2V = 38.16^\circ$; $r > v$. Natural crystals more or less dehydrated to pseudomorphs of lower hydrate ($3\text{H}_2\text{O}$), lose water in dry air. Synthesized. Found in cold (10°), wet muck in abandoned Stüblau mine near *Schellfgaden, Salzburg Prov., Austria*. *HCWS DII:713*.

39.2.1.1 Hureaulite $\text{Mn}_5^{2+}(\text{PO}_3\text{OH})_2(\text{PO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1826 for the locality. *MON C2/c*. $a = 17.587$, $b = 9.127$, $c = 9.497$, $\beta = 96.68^\circ$, $Z = 4$, $D = 3.19$ *BM 99:261(1976)*. Structure: *AC(C) 43:1829(1987)*. 39-146: 8.75₄ 8.09₇ 4.55₄ 3.20₃ 3.15₁₀ 2.99₇ 2.63₄ 2.19₃. See also 16-383. Crystals short prismatic [001], sometimes tabular {100}, or equant; isolated, in groups or fascicled, also massive, compact, scaly, or imperfectly fibrous. Orange, orange-red, brownish orange, reddish to yellowish brown, violet-rose, pale rose, red, amber, also gray to nearly colorless; near-white streak; vitreous to greasy luster; transparent to translucent. Cleavage {100}, good. $H = 3\frac{1}{2}$. $G = 3.19$. Biaxial (-); $X = b$; $Z \wedge c = 75^\circ$; $N_x = 1.647$, $N_y = 1.654$, $N_z = 1.660$; $2V = 75^\circ$; $r < v$, very strong; crossed, strong; pleochroic. X, colorless; Y, yellow to pale rose; Z, reddish yellow to reddish brown. Fe^{2+} substitutes for Mn^{2+} up to at least 33% (Hureaux samples) and affects optical properties. Easily soluble in acids. Synthesized, Cd analog prepared. A secondary mineral found with fairfieldite, dickinsonite, reddingite, and eosphorite as hydrothermal alteration of lithiophilite in Branchville, CT, pegmatite, and at Strickland quarry, Portland, CT; with metastrengite, strengite, and heterosite in weathered triphylite at Palermo No. 1 and Fletcher mines, North Groton, NH; in the Black Hills at Elkhorn, Gap Lode, Hot Shot, John Ross, and Linwood pegmatites, in Custer Co. at Bull Moose Mtn., Rock Ridge, Tip Top, White Elephant mines, and in Pennington Co. at Ferguson Lode, Big Chief pegmatite, and Hesnard mine, SD; with stewartite and metastrengite in altered lithiophilite at Pala and Stewart Lithia mine, San Diego Co., CA; with rockbridgeite, cacoxenite, and vivianite in cavities in heterosite formed by alteration of triphylite in pegmatite at *Hureaux in St. Silvestre* and at *Vilate near Chanteloube, N of Limoges, Haute Vienne, France*; at Hagendorf, Hühnerkobel, Pleystein, Germany; at Vani-

trask, Sweden; at Viitanieme near Erajarvi, Finland; at Criminoso mine, Mun. Boa Vista, and at Sapucaia mine, Galileia, MG, Brazil. HCWS *DII:700*; *AM 40:50(1955)*, *58:302(1973)*, *70:395(1985)*.

39.2.1.2 Sainfeldite $\text{Ca}_5(\text{AsO}_3\text{OH})_2(\text{AsO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1964 for Paul Sainfeld (b.1916), Musée des Mineralogie, École des Mines, Paris, who collected the type material in Alsace. MON *C2/c*. $a = 18.781$, $b = 9.820$, $c = 10.191$, $\beta = 97.0^\circ$, $Z = 4$, $D = 3.027$. Structure: *BM 87:169(1964)*, *95:33(1972)*. *16-615*: 8.7_8 4.86_4 4.64_6 4.45_4 3.37_{10} 3.18_8 3.06_6 1.744_4 . Flattened rosettes or radiating crystals; elongated parallel to c , flattened on (100). Colorless to light pink, transparent. $G = 3.04$. Biaxial; $X = b$; $Y \wedge c \approx 20^\circ$; $N_x = 1.600$, $N_y = 1.610$, $N_z = 1.616$; $2V = 80^\circ$. Found at the 40-m level of the *Gabe Gottes vein*, *Ste.-Marie-aux-Mines*, *Vosges Mts.*, *Alsace*, *France*. HCWS *AM 50:806(1965)*.

39.2.1.3 Villyaellenite $\text{Mn}_5^{2+}(\text{AsO}_3\text{OH})_2(\text{AsO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1984 for Villy Aellen, director of the Natural History Museum of Geneva, Switzerland. MON *C2/c*. $a = 18.015$, $b = 9.261$, $c = 9.770$, $\beta = 96.24^\circ$, $Z = 4$, $D = 3.72$. Structure: *AM 73:1172(1988)*. *41-1455*: 8.21_5 4.45_3 3.24_4 3.21_{10} 3.13_3 3.06_7 2.98_4 2.34_3 . See also *37-344*. Rosettes of prismatic crystals elongated parallel to [001], tabular parallel to {100}, show {100}, {011}, {010}, and rarely {001}. Colorless, light pink to orange-pink; white streak; vitreous luster; transparent. Cleavage {100}, good. $H = 4$. $G = 3.20$. Biaxial (-); $X = b$; $Z \wedge c = 40^\circ$; $N_x = 1.713$, $N_y = 1.723$, $N_z = 1.729$; $2V = 70^\circ$, absorbance $Z \gg X > Y$; pleochroic. X , very pale orange-pink; Y , exceedingly pale orange-pink; Z , pale orange-pink. Soluble in HCl. Found at Sterling Hill, NJ, on calcite-bearing willemite-franklinite ore; as nearly pure end member crystals up to 4 cm length in a vug associated with ogdensburgite, arseniosiderite, adamite, and chalcophanite at Mapimi, DGO, Mexico(1). The original material from *Ste.-Marie-aux-Mines*, *Vosges Mts.*, *Alsace*, *France*, had a composition near the midpoint of the series villyaellenite-sainfeldite and was associated with fluckite (39.1.2.1). There is some question as to the degree of solid solution in the Ca-Mn series and whether type material (in Museum, Switzerland) may represent a distinct species compared to the Mexican-NJ mineral. HCWS *SMPM 64:323(1984)*, *AM 71:1547(1971)*.

39.2.2.1 Vladimirite $\text{Ca}_5(\text{AsO}_3\text{OH})_2(\text{AsO}_4)_2 \cdot 5\text{H}_2\text{O}$

Named in 1953 for the locality. MON *P2₁/c*. $a = 5.81$, $b = 10.19$, $c = 22.7$, $\beta = 82.7^\circ$, $Z = 3$, $D = 3.72$ *BM 87:169(1964)*. Structure: *ZK 157:296(1981)* on triclinic modification. *17-162*: 5.09_4 4.80_4 4.15_8 4.00_8 3.20_4 3.04_6 2.87_4 2.79_{10} . Rosettes, radiating needles; acicular. Colorless, pale rose, translucent. $G = 3.14$. Biaxial (-); $Z \wedge c = 37^\circ$; $N_x = 1.661$, $N_y = 1.656$, $N_z = 1.656$; $2V = 70^\circ$; $r > v$, strong. Found at *Vladmiriskoe*, *Altai Mts.*, *Russia*, and at Kovuaksi, Tuva Autonomous Republic, Russia; at Irhtem mine, Bou-Azzer, Morocco. HCWS *AM 50:813(1965)*; *ZVMO 82:317(1953)*, *99:362(1970)*.

39.2.2.2 Guerinite $\text{Ca}_5(\text{AsO}_3\text{OH})_2(\text{AsO}_4)_2 \cdot 9\text{H}_2\text{O}$

Named in 1961 for Henri Guerin (b.1906), French chemist who synthesized the compound. Dimorphic with ferrarisite (39.2.3.1). *MON* $P2_1/n$. $a = 17.63$, $b = 6.734$, $c = 23.47$, $\beta = 90.6^\circ$, $Z = 5$, $D = 2.74$. *BM* 87:169(1964), Structure: *AC(B)* 30:1789(1971). 26-1055: 14.0₁₀ 11.7₄ 8.7₃ 4.84₄ 3.89₈ 3.49₆ 3.01₈ 2.90₈. Spherulites and rosettes; feathery. Acicular and wedge-shaped crystals up to 0.3 mm. Colorless or white in aggregates, vitreous luster, translucent to opaque. $H = 1\frac{1}{2}$. $G = 2.76$. Biaxial (-); $N_x = 1.574$, $N_y = 1.582$, $N_z = 1.582$ (Na); $2V = 15^\circ$; $r < v$; positive elongation. Synthesized, many hydrates detected. Found at Sterling Hill Mine, Ogdensburg, Sussex Co., NJ; Gabe Gottes mine, Alsace, France; from *Daniel mine, Schneeberg, Saxony and Richelsdorf, Hesse, Germany*. *HCWS AM* 47:416(1962), 50:812(1965).

39.2.3.1 Ferrarisite $\text{Ca}_5(\text{AsO}_3\text{OH})_2(\text{AsO}_4)_2 \cdot 9\text{H}_2\text{O}$

Named in 1980 for Giovanni Ferraris (b.1937) of the Institute of Mineralogy ("G. Spezia"), University of Torino, Italy. Dimorphous with guerinite (39.2.2.2); see also sainfeldite (39.2.1.2). *TRIC* $P1$. $a = 8.294$, $b = 6.722$, $c = 11.198$, $\alpha = 106.16^\circ$, $\beta = 92.94^\circ$, $\gamma = 99.20^\circ$, $Z = 1$, $D = 2.57$ *BM* 103:533(1980). Structure: *BM* 103:541(1980). 33-280: 10.81₁₀ 6.34₃ 5.36₃ 4.73₃ 4.07₄ 3.57₄ 3.17₈ 2.83₉. Colorless, transparent, becoming white on dehydration. Biaxial (+); $X \wedge c = 17^\circ$; Z perpendicular to (110); $N_x = 1.562$, $N_y = 1.572$, $N_z = 1.585$; $2V = 83^\circ$. Dissolves readily in 1:10 HCl. Synthesized. Occurs at *Gift mine* and *Gabes Gottes, Ste.-Marie-aux-Mines, Vosges Mts., Alsace, France*, associated with picroparmacolite and raenthalite; at Anton mine, Wittichen, Baden, Germany. *HCWS AM* 66:637(1981).

39.2.4.1 Picroparmacolite $\text{Ca}_4\text{Mg}(\text{AsO}_3\text{OH})_2(\text{AsO}_4)_2 \cdot 11\text{H}_2\text{O}$

Named in 1819 for the magnesia content and the similarity to pharmacolite. See irhtemite (39.2.5.1), a lower hydrate form of the same composition. *TRIC* $P\bar{1}$. $a = 13.547$, $b = 13.500$, $c = 6.710$, $\alpha = 99.85^\circ$, $\beta = 96.41^\circ$, $\gamma = 91.60^\circ$, $Z = 2$, $D = 2.60$. Structure: *AM* 66:385(1981). 14-222: 13.50₁₀ 9.20₆ 4.84₄ 4.44₄ 3.78₆ 3.18₈ 3.066₇ 2.92₅. Small, spherical, botryoidal forms with radiating foliated structure; silky fibers or minute acicular crystals; rectangular prisms elongated on [001] with cleavages {100} and {010} perfect. White, slightly pearly luster, opaque. $G = 2.58$. IR, DTA. Formed in the oxidation zone of arsenical ore deposits, where the particular phase is dependent on the pH and Eh values of the solutions. Biaxial (+); $Y = b$; $X \wedge c \approx 37^\circ$; $N_x = 1.631$, $N_y = 1.632$, $N_z = 1.640$; $2V = 40^\circ$; $r < v$, strong. Synthesized. Found at Sterling Hill mine, Ogdensburg, Sussex Co., NJ; as a coating on dolomite in Joplin, MO; at *Ste.-Marie-aux-Mines, Vosges Mts., Alsace, France*; at Grube Anton, Heubachtal, *Richelsdorf, Hessen*, and as a recent efflorescence in mine workings at *Freiberg, Saxony, Germany*; at *Hovou-Aksi, Russia*. *HCWS DII:740; BM* 84:391(1961), 87:169(1964); *AM* 59:807(1974), 61:326(1976).

39.2.5.1 Irhitemite $\text{Ca}_4\text{Mg}(\text{AsO}_3\text{OH})_2(\text{AsO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1972 for the locality. MON. $a = 16.73$, $b = 9.48$, $c = 10.84$, $\beta = 97.25^\circ$, $Z = 4$, $D = 3.153$. *BM 95:365(1972)*. *25-158*: 9.42₃ 6.85₃ 5.35₃ 5.08₄ 3.68₄ 3.24₉ 2.97₁₀ 2.82₉. Spherulites to 1 mm in diameter. White to pale rose; colorless crystals; silky luster. $G = 3.09$. DTA. Biaxial (+); $N_x = 1.634$, $N_z' = 1.642$; negative elongation; extinction angle 25° . Dissolves in 1:10 acids. Synthesized by heating picroparmacolite. Occurs in the *Irhitem ore deposit* and Bou Azzer ore deposit, *Morocco*, associated with sainfeldite and erythrite, probably formed by dehydration of picroparmacolite. *HCWS AM 59:209(1974)*.

39.2.6.1 Chudobaite $\text{Mg}_5(\text{AsO}_3\text{OH})_2(\text{AsO}_4)_2 \cdot 10\text{H}_2\text{O}$

Named in 1960 for Karl Franz Chudoba (1898–1968), mineralogist at the University of Bonn, Germany. See geigerite (39.6.2.2), Mn analog. Some question as to whether the formula is accurate. Original description showed Na, K, and Zn as well as Mg. TRIC $P\bar{1}$. $a = 7.797$, $b = 11.440$, $c = 6.616$, $\alpha = 115.31^\circ$, $\beta = 95.77^\circ$, $\gamma = 93.87^\circ$, $Z = 1$, $D = 2.90$. *NW 63:243(1976)*. *12-643*: 10.2₁₀ 3.86₅ 3.75₅ 3.44₈ 3.27₈ 2.98₉ 2.83₅ 2.73₇. Crystals to 0.5 cm showing {100}, {010}, {001} also {110}, {120}, {180}, {101}. Pink, translucent. Cleavage {010}, perfect; {100}, imperfect. $H = 2\frac{1}{2}$ -3. $G = 2.94$. Nonfluorescent in UV. Biaxial (-); $Z \wedge c(010) = -24^\circ$; $N_x = 1.583$, $N_y = 1.608$, $N_z = 1.633$; $2V = 79^\circ$. Loses H_2O at 140° . Soluble in HCl. Found at the 1,000-m level, second oxidation zone in the *Tsumeb mine*, *Tsumeb*, *Namibia*, associated with conichalcite, cuproadamite, and zincian olivenite. *HCWS NJMM:1(1960)*; *AM 44:1323(1959)*, *45:1130(1960)*, *62:599(1977)*.

39.2.6.2 Geigerite $\text{Mn}_5^{2+}(\text{AsO}_3\text{OH})_2(\text{AsO}_4)_2 \cdot 10\text{H}_2\text{O}$

Named in 1989 for Thomas Geiger of Weisendangen, Switzerland, who studied the Falotta manganese ores. Mn^{2+} equivalent of chudobaite (39.6.2.1). TRIC $P\bar{1}$. $a = 7.944$, $b = 10.691$, $c = 6.770$, $\alpha = 80.97^\circ$, $\beta = 84.20^\circ$, $\gamma = 81.55^\circ$, $Z = 1$, $D = 3.00$. Structure: *AM 74:676(1989)*. Structure contains equal number of $[\text{AsO}_4]$ and $[\text{AsO}_3\text{OH}]$ groups sharing corners with octahedrally coordinated Mn; no cavities for acid H; one H_2O molecule not linked directly to Mn. *PD*: 10.45₁₀ 7.85₁ 4.89₁ 3.51₂ 3.34₂ 3.05₂ 3.01₂ 2.79₁. Platy, triangular crystals flattened on (010) up to 0.5 mm long. Rose red, white streak, vitreous to pearly luster. Cleavage {010}, perfect. $H = 3$. $G = 3.05$. Biaxial (-); $X \approx b$, $Y \approx a$, $Z \approx c$; on {010} $Z \wedge c = 15^\circ$; $N_x = 1.601$, $N_y = 1.630$, $N_z = 1.660$ (589 nm); $2V$ large. Weakly pleochroic, colorless to rose-red with $Z > Y \approx X$. Found in abandoned manganese mines near *Falotta*, *Oberhalberstein*, *Grisons Canton*, *Switzerland*, associated with tilasite, sarkinite, manganberzeliite, brandtite, and grischunite. *HCWS*

39.2.7.1 Lindackerite $\text{Cu}_5(\text{AsO}_3\text{OH})_2(\text{AsO}_4)_2 \cdot 8-9\text{H}_2\text{O}$

Named in 1853 for Joseph Lindacker, Austrian chemist, who made the analysis. MON. $a = 3.95$, $b = 8.02$, $c = 6.28$, $\beta = 100.5^\circ$, $Z = 1$, $D = 3.46$. *BM*

79:7(1956). 11-166: 10.2₁₀ 5.9₄ 3.95₆ 3.19₈ 3.08₆ 2.95₄ 2.86₄ 2.67₄. Minute laths grouped in rosettes or crusts. Green, greenish white, greenish blue; pale green to white streak; vitreous luster; transparent. Cleavage {010}, perfect; {100}, {001}, easy; conchoidal fracture; brittle. $H = 2-2\frac{1}{2}$, $G = 2.0-2.5$. Biaxial (+); $N_x = 1.627$, $N_y = 1.659$, $N_z = 1.729$; $2V = 68^\circ$. Dehydrates at 450° . Secondary oxidation zone mineral found at *Eliaas mine, Jachymov, Bohemia, Czech Republic*, associated with erythrite, zippeite, pitticite, annabergite, and other secondary minerals. hcws DII:1007.

39.3.1.1 Stercorite $\text{Na}(\text{NH}_4)(\text{PO}_3\text{OH}) \cdot 4\text{H}_2\text{O}$

Named in 1850 from the Latin for *dung*. Microcosmic salt. TRIC $P\bar{1}$. $a = 10.636$, $b = 6.919$, $c = 6.436$, $\alpha = 90.46^\circ$, $\beta = 98.58^\circ$, $\gamma = 109.20^\circ$, $Z = 2$, $D = 1.578$. Structure: *AC(B) 30:504(1974)*. 24-1048: 9.93₉ 6.53₁₀ 4.77₄ 4.69₃ 4.24₅ 3.66₄ 2.91₅ 2.88₅. Massive and nodular. Artificial crystals simulate monoclinic symmetry due to repeated twinning of triclinic individuals on {010}. Faces even and lustrous without reentrant angles. Crystals colorless, natural material white to yellowish, brownish; vitreous luster; transparent. No cleavage. $H = 2$. $G_{\text{syn}} = 1.574$, $G = 1.615$. Biaxial (+); $N_x = 1.439$, $N_y = 1.442$, $N_z = 1.468$; optic plane approximately perpendicular to {010}, Z approximately perpendicular to {001}; {010} may show two sets of lamellar twinning at about 90° ; $2V = 35.52^\circ$; $r > v$, strong. Soluble in cold H_2O . (NH_4) lost $\approx 200^\circ$, H_2O at higher temperatures. Synthesized from 10° to -6° by evaporation from solution. Found in a guano deposit on the *Island of Ichaboe, Namibia*; Guañape Islands, Peru. hcws DII:698.

39.3.2.1 Schertelite $\text{Mg}(\text{NH}_4)_2(\text{PO}_3\text{OH})_2 \cdot 4\text{H}_2\text{O}$

Named in 1902 for Arnulf Schertel (1841-1902) of the Freiberg Mining Academy, Saxony, Germany. ORTH $Pbca$. $a = 11.49$, $b = 23.66$, $c = 8.62$, $Z = 8$, $D = 1.84$. Structure: *AC(B) 28:683(1972)*. 16-353(syn): 5.94₁₀ 5.21₄ 4.31₂ 3.91₂ 3.46₂ 3.02₄ 2.97₅ 2.80₃. Small indistinct flat crystals. Synthetic stout rods elongated on c showing {110}, {111}; slow growth tabular on {100}. Colorless, transparent. No cleavage. $G = 1.82$. Biaxial (+); $XYZ = bca$; $N_x = 1.508$, $N_y = 1.515$, $N_z = 1.523$ (Na); optic plane {001}. Dissolves incongruently in H_2O forming struvite. H_2O lost at 120° . Synthesized. Found sparingly at *Skipit Caves, SW of Ballarat, VIC, Australia*. hcws DII:699, AM 48:635(1963).

39.3.3.1 Mundrabiliaite $\text{Ca}(\text{NH}_4)_2(\text{PO}_3\text{OH})_2 \cdot \text{H}_2\text{O}$

Named in 1983 for the locality. Dimorph of swaknoite (39.3.4.1). MON Pm , $P2$, or $P2/m$. $a = 8.643$, $b = 8.184$, $c = 6.411$, $\beta = 98.0^\circ$, $Z = 2$, $D = 2.09$. *MM 47:80(1983)*. 35-728(syn): 8.58₅ 6.32₂ 5.01₂ 4.79₁ 4.29₁₀ 3.69₁ 3.28₃ 3.10₃. Tiny crystals. Colorless, earthy. Very soft. $G = 2.05$. Biaxial (-); $N_x = 1.522$, $N_y = 1.544$, $N_z = 1.552$; extinction inclined 26° . Synthetic material: Biaxial $X = b$; $Y \wedge c = +25^\circ$; $N_x = 1.521$, $N_y = 1.542$, $N_z = 1.551$; $2V = 65^\circ$. Found in the *Petrogale Cave (31°54' S, 127°00' E) near Mundrabilia*

Station, WA, Australia, in association with other salts. *HCWS AM 69:407(1984)*.

39.3.4.1 Swaknoite $\text{Ca}(\text{NH}_4)_2 \cdot (\text{HPO}_4)_2 \cdot \text{H}_2\text{O}$

Named in 1991 for the acronym for the Suid Wes Africa Karst Navorsing Organisasie (SWAKNO), a speleological association in Namibia. Dimorph of mundrabiliaite (39.3.3.1). *ORTH.* $a = 20.959$, $b = 7.403$, $c = 6.478$, $Z = 4$, $D_{\text{syn}} = 1.89$. *BSASA 32:72(1991)*. *PD(syn)*: 10.5₅ 6.99₁₀ 4.74₄ 3.71₉ 3.65₄ 3.18₆. Commonly rosettes composed of needles up to 1 mm long, elongate [001], 10 μm wide, which show {100}, {111}, sometimes {001}. White, vitreous luster. Soft, brittle. $G = 1.91$. Soluble in H_2O . Occurs as white coating with mundrabiliaite, dittmarite, and arcanite on the dolomite walls of *Arnhem cave*, 150 km E of *Windhoek, Namibia*. *HCWS AM 78:1110(1993)*.

39.3.5.1 Hannayite $\text{Mg}_3(\text{NH}_4)_2(\text{PO}_3\text{OH})_4 \cdot 8\text{H}_2\text{O}$

Named in 1878 for James B. Hannay (b.1855), chemist, University of Manchester, England. *TRIC P1*. $a = 10.728$, $b = 7.670$, $c = 6.702$, $\alpha = 97.87^\circ$, $\beta = 96.97^\circ$, $\gamma = 104.74^\circ$, $Z = 1$, $D = 2.030$. Structure: *AC(B) 32:2842(1976)*. *16-361(syn)*: 6.96₁₀ 5.15₃ 4.64₂ 3.75₂ 3.46₇ 3.29₂ 3.13₁ 3.00₂. Small, slender crystals elongated [001], striated parallel to the same direction, may show {100}, {010}, {110}, {001}, {011}, {111}; tabular on {100} with prominent {011}, modified narrow {110}. Yellowish, translucent. Cleavage {001}, perfect; {110}, {110}, {130}, poor. $H = 1$. $G = 2.03$. Biaxial (-); $N_x = 1.504$, $N_y = 1.522$, $N_z = 1.539$; Y perpendicular to {110}; optic plane {221}; $r < v$, weak. Easily soluble in acids. Loses 21% H_2O between 100 and 115°. Found in bat guano at *Skipton Caves, SW of Ballarat, VIC, Australia*, associated with struvite, brushite, newberyite, dittmarite, and schertelite. *HCWS DII:699, AM 48:635(1963), MM 39:467(1973)*.

39.3.5.2 Francoanellite $\text{H}_6(\text{K,Na})_3(\text{Al,Fe}^{3+})_5(\text{PO}_4)_8 \cdot 13\text{H}_2\text{O}$

Named in 1976 for Franco Anelli, professor of geography, University of Bari, Italy, who discovered the cave in which the mineral was found. See taranakite (39.3.6.1) for the higher hydrate. *HEX-R R3c* or *R3c*. $a = 8.71$, $c = 82.8$, $Z = 6$, $D = 2.11$. *NJMM:49(1976)*. *29-980*: 13.75₁₀ 7.44₃ 6.86₄ 5.57₃ 4.29₃ 3.41₅ 2.81₅ 2.78₄. Nodular aggregates up to 0.2 mm diameter, pulverulent masses. Yellowish-white. Soft. $G = 2.26$. DTA. Uniaxial (+); $N_O = 1.510$, $N_E = 1.515$. Readily soluble in 1:10 HCl , HNO_3 . Loses 19% H_2O up to 200°. Hydrates to taranakite. Synthesized. Occurs at the contact of "terra rossa" with bat guano in the karst cave *Grotte di Castellana, Puglia, Italy*. *HCWS AM 44:138(1959), 61:1054(1976); NJMM:363(1979)*.

39.3.6.1 Taranakite $\text{H}_6\text{K}_3\text{Al}_5(\text{PO}_4)_8 \cdot 18\text{H}_2\text{O}$

Named in 1882 for the locality. *HEX-R R3c* or *R3c*. $a = 8.718$, $c = 95.10$, $Z = 6$, $D = 2.11$. *AM 76:1722(1991)*. Structure: *AM 61:329(1976)*. Layers of Al-PO_4 sheets perpendicular to c are separated by water molecules, cations. See fran-

coanellite (39.3.5.2), the lower hydrate. *29-981*: 15.89₁₀ 7.94₃ 7.46₃ 4.32₂ 3.59₂ 3.35₃ 3.14₃ 2.82₂. Nodular masses, claylike, pulverulent to compact, composed of fine-grained powder or pseudo-hexagonal thin colorless plates. White, gray, or yellowish white. Very soft, unctuous to the touch. $G = 2.15$. Uniaxial (-); $N_O = 1.508$, $N_E = 1.502$. Other elements detected: Na, Ca, Fe^{3+} , S, and Rb. Half H_2O lost at 100° ; easily soluble in acids. Occurs in caves or on sea coasts as a product of phosphatic solutions derived from bat or bird guano on clays or aluminous rocks. Found at Grotte de Minerve, Aude Valley, Hérault, France; at Monte Alburno, Salerno, and in the caves in the Apulian Platform, Italy; at Misserghin, Oran, Algeria; on the Island of Réunion, Indian Ocean; at Moorba Cave, Jurien Bay, WA, and Jenolan Caves, NSW, Australia; from the bird colonies at *Sugarloaves, Taranaki, New Zealand*; at Islas Leones, Patagonia, Argentina. *HCWS DII:999, MM 28:31(1947), AM 44:138(1959), 60:331(1975), 61:329(1976)*.

39.3.7.1 McNearite $NaCa_5H_4(AsO_4)_5 \cdot 4H_2O$

Named in 1981 for Elizabeth McNear, mineralogist and crystallographer, University of Geneva, Switzerland. TRIC $P1$ or $P\bar{1}$. $a = 13.50$, $b = 14.10$, $c = 6.95$, $\alpha = 90.0^\circ$, $\beta = 92^\circ$, $\gamma = 119^\circ$, $Z = 2$, $D = 2.85$. *SMPM 61:1(1981), 35-688*: 12.33₁₀ 6.94₅ 4.40₃ 3.92₆ 3.40₂ 3.12₆ 2.94₂ 2.75₄. Radiating fibers up to 2 mm length. White, pearly luster. Cleavage, perfect, parallel elongation. $G = 2.60$. Biaxial (+); $Y \wedge c = 6-22^\circ$; $N_x = 1.559$, $N_y = 1.562$, $N_z = 1.572$; $2V = 60^\circ$; positive elongation; strong dispersion. Dissolves in acids. Found in specimens from *Ste.-Marie-aux-Mines, Vosges Mts., Alsace, France*, associated with pharmacolite, guerinite, and haidingerite. *HCWS AM 67:856(1982)*.

39.3.8.1 Machatschkiite $(Ca,Na)_6(AsO_4)(AsO_3OH)_3(P,S)O_4 \cdot 15H_2O$

Named in 1977 for Felix Karl Ludwig Machatschki (1895-1976), Austrian professor of mineralogy at Tübingen, Munich, and Vienna. HEX-R $R3c$. $a = 15.127$, $c = 22.471$, $Z = 6$, $D = 2.59$. *SMPM 62:177(1982)*, Structure: *TMPM 30:145(1982), 29-296*: 8.59₁₀ 5.34₈ 3.74₇ 3.59₈ 2.86₈ 2.83₈ 2.70₈ 2.67₈. Crusts showing characteristic rhomb form {1012}. Colorless, translucent to transparent. No cleavage, conchoidal fracture. $H = 2-3$. $G = 2.50$. Uniaxial (-); $N_O = 1.593$, $N_E = 1.585$; weakly biaxial. Dissolves readily in 1:10 HCl, HNO_3 . Secondary mineral in crusts on granite with gypsum, pharmacolite, picropharmacolite, and sainfeldite at *Grube Anton, Heubachtal near Schiltach, Black Forest, Germany*. *HCWS AM 62:1260(1977), TMPM 24:125(1977), FM 59:41(1981), AM 67:418(1982)*.

39.3.9.1 Kaatialaite $Fe[H_2AsO_4]_3 \cdot 5-5.5H_2O$

Named in 1984 for the locality. MON $P2_1$ or $P2_1/m$. $a = 15.34$, $b = 19.80$, $c = 4.752$, $\beta = 91.90^\circ$, $Z = 4$, $D = 2.64$. *NJMM:337(1986)*. Structure(syn): *AC(B) 37:1402(1981), 40-475*: 9.92₈ 8.33₁₀ 7.67₈ 6.07₇ 4.47₄ 3.76₄ 3.41₆ 2.81₅. See also *43-681(syn)*. Needles to lathlike crystals up to 50 μm long, synthetic material aggregates of tabular, six-sided crystals up to 0.3 mm

across, original description powdery coatings. Greenish blue, transparent, fades to pale green, losing transparency, within months, recrystallizes to feathery aggregates of thin laths elongated parallel to c with oblique terminations. $G = 2.64$. TGA, IR. Biaxial (+); $N_x \approx N_y = 1.573$, $N_z = 1.636$; $2V = 13^\circ$. Synthetic: $Z \wedge c \approx 3^\circ$; $N_x = 1.581$, $N_{y \text{ calc}} = 1.582$, $N_z = 1.626$; positive elongation; $2V = 15^\circ$. *BSCF:2575(1972)*. Water content varies with humidity. Found as oxidation coatings with calcite, gypsum, and arsenic minerals, on lollingite in As- and Ag-containing veins in the gabbro of Nee-der-Beerbach, Odenwald, Germany; at the *Kaatiala granite pegmatite, Kuortane, western Finland*, associated with arsenolite, scorordite, and parasymplectite. *HCWS AM 69:383(1984)*.

Hydrated Normal Phosphates, Arsenates, and Vanadates

40.1.1.1 Struvite $Mg(NH_4)(PO_4) \cdot 6H_2O$

Named in 1845 for Heinrich C. G. von Struve (1772–1851), geologist and mineralogist in the Russian diplomatic service. ORTH $Pmn2_1$. $a = 6.955$, $b = 6.142$, $c = 11.218$, $Z = 2$, $D = 1.70$. NBSM 3:4(1964), AC(B) 42:253(1986). 15-762(syn): 5.91₄ 5.60₆ 4.26₁₀ 4.14₄ 2.92₅ 2.80₃ 2.69₅ 2.66₄. Usually found as distinct crystals up to 3 cm with marked hemimorphic habit, displaying variable shapes, such as equant, wedge-shaped, coffin-shaped, short prismatic, or thick tabular. Figure 40.1.1 (DII:715) illustrates the morphology and the peculiar unequal development and distribution of pyramidal and domical faces: $\{101\}$, $\{10\bar{1}\}$, $\{001\}$, $\{010\}$, $\{100\}$; tabular on $\{100\}$. Twinned on $\{001\}$, composition plane $\{001\}$, deep reentrant angles. Colorless, slightly yellowish or brown with impurities, becoming white and chalky on dehydration; vitreous luster; transparent to translucent. Cleavage $\{001\}$, good; $\{100\}$, poor; subconchoidal to uneven fracture; brittle. Piezo- and pyro-electric. $H = 2$. $G = 1.711$. Biaxial (+); $XYZ = bca$; $N_x = 1.495$, $N_y = 1.496$, $N_z = 1.504$ (Na); $2V = 37.35^\circ$; $r < v$, strong. Easily soluble in acids, very slightly soluble in water. Synthesized as large crystals. Becomes white and pulverulent on standing in dry, warm atmosphere. Formed in deposits of guano or dung, putrescent matter, canned foods, in sediments or soils by bacterial action, and as bladder and urinary concretions in humans. Found

Ballarat.

Braunschweig.

Struvite

Forms: $a = \{100\}$, $c = \{001\}$, $h = \{101\}$, $\bar{q} = \{102\}$, $s = \{011\}$, $q = \{102\}$. Underlined letters indicate faces of second (twin) crystal.

with newberyite in tooth of mammoth from Quartz Creek near Dawson, YT, Canada; originally from *Hamburg, Germany*, in a bed of peat underlying deposits of organic matter below an old church, and in cattle dung at Homburg v.d. Hohe; in sediment rich in organic remains at Liim Fjord, Denmark; in guano at Saldanha Bay, Cape Prov., South Africa; in bat guano at Skipton Caves SW of Ballarat, Australia; on the Island of Reunion, Indian Ocean. *HCWS DII:715*.

40.1.2.1 Dittmarite $\text{Mg}(\text{NH}_4)(\text{PO}_4)(\text{PO}_4) \cdot \text{H}_2\text{O}$

Named in 1887 for W. Dittmar, chemist of Glasgow, Scotland. ORTH $Pmn2_1$. $a = 5.606$, $b = 8.758$, $c = 4.788$, $Z = 2$, $D = 2.19$. *USGSPP 750A:A115(1971)*. 20-663: 8.77₁₀ 4.72₃ 4.20₂ 2.92₄ 2.80₅ 2.50₂ 2.28₁ 2.12₁. Tiny transparent orthorhombic crystals. Loses water at 100° becoming turbid. Soft. Biaxial; $N_x = 1.549$, $N_y = 1.569$, $N_z = 1.571$; $2V = 40^\circ$. Found with struvite, newberyite, hannayite, and schertelite in bat guano at *Skipton Caves, SW of Ballarat, VIC, Australia*. *HCWS DII:699, AM 57:1316(1972)*.

40.1.2.2 Niahite $(\text{Mn}^{2+}, \text{Mg}, \text{Ca})(\text{NH}_4)(\text{PO}_4) \cdot \text{H}_2\text{O}$

Named in 1983 for the locality. ORTH $Pmn2_1$. $a = 5.68$, $b = 8.78$, $c = 4.88$, $Z = 2$, $D = 2.437$. *MM 47:79(1983)*. 35-574: 8.82₁₀ 4.79₅ 4.27₆ 3.41₄ 2.85₈ 2.83₉ 2.51₃ 2.30₄. Radiating subparallel clusters, crystals to 0.5 mm. Pale orange, white streak, translucent. $H = 2$. $G = 2.39$. Biaxial (-); $N_x = 1.582$, $N_y = 1.604$, $N_z = 1.609$; $2V = 54^\circ$. Colorless in thin section. Found at *Niah Great Cave, Sarawak, Malaysia*, in soft newberyite. *HCWS*

40.1.3.1 Nastrophite $\text{Na}(\text{Sr}, \text{Ba})(\text{PO}_4) \cdot 9\text{H}_2\text{O}$

Named in 1981 for the composition. ISO $P2_13$. $a = 10.559$, $Z = 4$, $D = 2.12$. *ZVMO 110:604(1981)*. Structure: *SPD 26:1023(1981)*. 25-993(syn): 5.28₈ 4.73₈ 3.73₂ 3.52₂ 2.57₁₀ 2.07₃ 1.961₃ 1.928₃. Crystals mostly 0.2–0.5 but up to 3 mm, and irregular masses to 1 cm in diameter. Colorless, vitreous luster. Conchoidal fracture, brittle. $H = 2$. $G = 2.05$. DTA, IR. Associated with cancrinite, aegirine, vuonnemite, epistolite, mountainite, villiaumite, kogarkoite, and thermonatrite at *Alluaiv Mt., Lovozero massif, Kola Penin., Russia*, in pegmatite veins in syenites and in nepheline syenites at *Karnasurt Mt.* *HCWS AM 67:857(1982)*.

40.1.3.2 Nabaphite $\text{NaBaPO}_4 \cdot 9\text{H}_2\text{O}$

Named in 1982 for the composition. The Ba analog of nastrophite (40.1.3.1). ISO $P2_13$. $a = 10.712$, $Z = 4$, $D = 2.24$. Structure: *DANS 226:707(1982)*, *226:624(1982)*. 35-716: 5.36₈ 4.81₈ 3.79₆ 3.58₇ 2.87₉ 2.60₁₀ 2.34₆ 2.10₈. Colorless, dull vitreous luster, transparent. Cleavage (100), distinct; steplike, semi-conchoidal fracture. $H \approx 2$. $G = 2.3$. Luminesces pale white in UV. Isotropic; $N = 1.504$. Readily dehydrates in air, decomposes in cold water giving alkaline solution; soluble in 1:10 acids. Occurs in cavities in ijolite–urtite pegmatite, *Yukspor Mt., Khibina massif, Kola Penin., Russia*. *HCWS AM 68:643(1983)*.

40.1.4.1 Pottsite $\text{HPbBi}(\text{VO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1988 for the locality. TET $I4_122$. $a = 11.084$, $c = 12.634$, $Z = 10$, $D = 7.31$. *MM* 52:389(1988). *PD*: 4.62₉ 4.17₃ 3.21₄ 3.06₁₀ 2.48₄ 2.25₃ 2.18₃ 1.95₂₃. Crystals up to 1 mm long are dipyrramids, stubby prisms terminated by pyramids, {101} dominates also {110}, {101}, {211}. Bright yellow, pale yellow streak, adamantine luster, translucent. Brittle. $H = 3\frac{1}{2}$. $G = 7.0$. Uniaxial (-); $N_O = 2.40$, $N_E = 2.30$. Cloudy yellow in thin section. Occurs near Potts, Lander Co., NV, in oxide zone of tungsten mine associated with scheelite, clinobisvanite, bismutite, and vanadinite. *HCWS AM* 74:503(1989).

40.1.5.1 Mahlmoodite $\text{Fe}^{2+}\text{Zr}(\text{PO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1993 for Bertha K. Mahlmood, U.S. Geological Survey, Reston, VA. *MON P2₁c*. $a = 9.12$, $b = 5.42$, $c = 19.17$. $\beta = 94.8^\circ$, $Z = 4$, $D = 2.877$. *AM* 78:437(1993). *PD*: 9.58₈ 4.57₇ 4.38₈ 4.09₆ 3.97₄ 3.58₄ 3.16₁₀ 2.64₇. Orthogonal layer structure forms a series with many $\text{AZr}(\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$ synthetic compounds. *IC* 8:431(1969), 23:4679(1984); *JCSD*:2115(1976). Spherules of radiating thin, flat plates (<0.05 mm long), creamy white, $H \approx 3$. Uniaxial (-); $N_O = 1.652$, normal to plate <1.646. Ca, Si, and Ti also detected by microprobe. Spherulites show white core of Si-containing material. Found in vugs as last deposited species on black sodic pyroxene crystals at Wilson Springs, Garland Co., AR; Kerriac Cove, Porthtown, Cornwall, England. *HCWS*

40.2.1.1 Anapaite $\text{Ca}_2\text{Fe}^{2+}(\text{PO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1910 for the locality. TRIC $P1$. $a = 6.447$, $b = 6.816$, $c = 5.898$, $\alpha = 101.63^\circ$, $\beta = 104.24^\circ$, $\gamma = 70.76^\circ$, $Z = 1$, $D = 2.811$. Structure: *BM* 102:314(1979). 34-148: 6.39₄ 4.55₄ 3.76₁₀ 3.24₄ 3.19₅ 3.16₇ 2.88₈ 2.78₄. Tabular {110}; rosettes or crusts of subparallel crystals. Green to greenish white, white streak, vitreous luster, transparent. Cleavage {001}, perfect; {010}, distinct. Biaxial (+); $N_x = 1.602$, $N_y = 1.613$, $N_z = 1.649$; $2V = 54^\circ$; $r > v$, perceptible. Loses H_2O above 120° , altering to another hydrous calcium and ferric phosphate. Easily soluble in HCl , HNO_3 . Found at Palermo No. 1 pegmatite, Grotton, Grafton Co., NH; in well cores at Kings Co., CA; in nodular concretions in Miocene clay at Bellevor de Cerdana, Lerida, and Prats-Sampson, Spain; rims on messelite at Messel, Hesse, Germany; Allori and Castelnuovo mines, near San Giovanni, Valdarno, Firenze, Italy; in crevices in oolitic iron ore at Sheljesny Rog near Anapa, Taman Peninsula (Black Sea), Crimea, Ukraine. *HCWS DII*:731.

FAIRFIELDITE/ROSELITE GROUP

The general formula

is appropriate for several groups and subgroups of related minerals. In the fairfieldite and roselite subgroups

A = Ca,

B = Mg, Fe²⁺, Mn²⁺, Co, Ni, Zn, and

T = P or As.

The structure of the minerals in the two subgroups is dominated by chains of tetrahedra (TO₄) and octahedra [(cation-O₄(H₂O))₂] that parallel the *c* axis.

The roselite subgroup minerals, all arsenates, crystallize in the monoclinic space group P2₁/c. The AsO₄ tetrahedra and B-O₄(H₂O)₂ octahedra are interlocked into sheets parallel to (010) by Ca-O₆(H₂O) polyhedra, the direction that corresponds to the plane of perfect cleavage. Roselite is isostructural with kröhnkite, Na₂Cu(SO₄)₂ · 2H₂O, a hydrated sulfate mineral.

The fairfieldite group, which contains both phosphate and arsenate species, crystallizes in the triclinic space group P1. The B-octahedra are compressed, resulting in chain disorder, and there is different hydrogen bonding of the H₂O molecules which is expressed in a less distinct cleavage.

As might be anticipated from the structural and chemical similarities, dimorphism between the two groups is common and the following pairs have been identified (the first named is the monoclinic crystalline form followed by the triclinic modification): roselite-β-roselite, Ca₂Co(AsO₄)₂ · 2H₂O; brandite-parabrandite Ca₂Mn(AsO₄)₂ · 2H₂O; and talmessite-wendwilsonite, Ca₂Mg(AsO₄)₂ · 2H₂O. It is essential that both composition and structure be determined to assure accurate identification of a particular species.

In both subgroups elements of like size substitute one for another, for example Fe²⁺ for Mn²⁺, and though these compositional variations are small they are expressed in different optical as well as unit cell parameters.

Name	Formula	ROSELITE SUBGROUP		SPACE GROUP P2 ₁ /c		
		<i>a</i>	<i>b</i>	<i>c</i>	β	
Roselite	Ca ₂ Co(AsO ₄) ₂ · 2H ₂ O	5.801	12.989	5.617	107.42	40.2.3.1
Brandite	Ca ₂ Mn(AsO ₄) ₂ · 2H ₂ O	5.889	12.968	5.684	108.05	40.2.3.2
Zincroselite	Ca ₂ Zn(AsO ₄) ₂ · 2H ₂ O	5.832	12.889	5.644	107.72	40.2.3.3
Wendwilsonite	Ca ₂ Mg(AsO ₄) ₂ · 2H ₂ O	5.806	12.912	5.623	107.40	40.2.3.4

FAIRFIELDITE SUBGROUP SPACE GROUP P1

Name	Formula	a	b	c	α	β	γ	
Fairfieldite	$\text{Ca}_2\text{Mn}(\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$	5.79	6.57	5.51	102.25°	108.67	90.30°	40.2.2.1

Collinsite	$\text{Ca}_2\text{Mg}(\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$	5.78	6.78	5.44	97.29	108.56	107.28	40.2.2.3
Cassidyite	$\text{Ca}_2\text{Ni}(\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$	5.71	6.43	5.41	96.8	107.3	104.6	40.2.2.4
Talmessite	$\text{Ca}_2\text{Mg}(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$	5.87	6.94	5.54	92.3	108.7	108.1	40.2.2.5
Gaitite	$\text{Ca}_2\text{Zn}(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$	5.90	7.61	5.57	111.67	70.	119.47	40.2.2.6
β -Roselite	$\text{Ca}_2\text{Co}(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$	5.89	7.69	5.56	112.6	70.8	119.4	40.2.2.7
Parabrandite	$\text{Ca}_2\text{Mn}(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$	5.89	7.03	5.64	96.77	109.32	108.47	40.2.2.8

Fairfieldite and roselite should be compared with:

- 1) the brackebuschite group 40.2.8.1, where A can be Ca, Ba, Pb or Sr and in addition to P or As, T may contain V, Cr, and S;
- 2) the helmutwinklerite group 40.2.11, all arsenates (T=As) that contain only Pb, Cu, Zn and Fe in the A and B sites.
- 3) the bearthite group 41.10.3.2 where A is Ca or Sr but B contains Al and T is P.
- 4) the fornicite group 43.4.3.2 in which Pb and Cu are paired with T=As, P, S, Cr.

Note that the anion and cation associations and structural expression of the tetrahedral phosphates and arsenates of the fairfieldite/roselite subgroups are also expressed in the sulfate and silicate mineral groups and species.

40.2.2.1 Fairfieldite $\text{Ca}_2\text{Mn}(\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1879 for the locality. Fairfieldite/Roselite group. TRIC P1. $a = 5.79$, $b = 6.57$, $c = 5.51$, $\alpha = 102.25^\circ$, $\beta = 108.67^\circ$, $\gamma = 90.30^\circ$, $Z = 1$, $D = 3.095$. *NJMM:78(1957)*, *AC(B) 26:333(1970)*. $10\text{-}390: 6.40_9 \ 3.23_{10} \ 3.20_7 \ 3.03_8 \ 2.86_7 \ 2.66_7 \ 2.63_7 \ 2.46_7$. Crystals prismatic to equant, often composite; foliated to lamellar aggregates sometimes resembling gypsum; occasionally curved or fibrous; radiating masses. White, greenish white, pale straw-yellow, salmon-yellow; white streak; transparent. Cleavage {001}, perfect; {010}, good; {110}, distinct; uneven fracture; brittle. $H = 3\frac{1}{2}$. $G = 3.08$. Biaxial (+); $N_x = 1.636$, $N_y = 1.644$, $N_z = 1.654$ (Branchville); 2V very large; $r > v$, moderate. Soluble in acids. Oxidizes to white or greenish products; also found as alteration of dickinsonite, pseudomorphous after rhodochrosite. Found at Nevel quarry(1), Newry; Bennett quarry, Buckfield, Oxford Co.; with rhodochrosite, eosphorite, reddingite, and other manganese phosphates at Berry quarry, Poland, Androscoggin Co., ME; with eosphorite, triploidite, dickinsonite, reddingite, fillowite, or lithiophilite at A. N. Fillow quarry, Branchville, Redding, Fairfield Co., CT; Foote pegmatite(1), Kings Mt., Cleveland Co., NC; Tip Top mine, Custer Co., SD; White Picacho district, Yavapai Co., AZ; Mangualde, Portugal; Hühnerkobel, Rabenstein, Bavaria, Germany; Voroni'y Tundry, Kola Penin., Russia. *ncws DII:720, AM 40:828(1955)*.

40.2.2.2 Messelite $\text{Ca}_2\text{Fe}^{2+}(\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1889 for the locality. Fairfieldite/Roselite group. TRIC $P1$. $a \approx 5.8$, $b \approx 6.6$, $c \approx 5.5$, $\alpha \approx 102^\circ$, $\beta \approx 109^\circ$, $\gamma \approx 90^\circ$, $Z = 1$. *AM* 40:828(1955). 10-389: 9.00₅ 6.34₁₀ 5.07₅ 3.17₁₀ 3.02₈ 2.79₆ 2.68₈ 2.57₇. Granular, prismatic, or platy fibrous, sheaflike aggregates. Colorless, pale green to white, greenish gray; white streak; vitreous to pearly luster; transparent. Cleavage {001}, perfect; {010}, good; {110}, distinct; uneven fracture; brittle. $H = 3\frac{1}{2}$. $G = 3.16$. Found at Palermo No. 1 mine, North Groton, NH; at Cobalt, CT; at Foote mine, King's Mt., Cleveland Co., NC; with hureaulite at Bull Moose mine, and in altered triphylite at the Tip Top mine, Custer Co., as large crystals with siderite, ludlamite at Big Chief mine(1), and with triphylite at Ingersol, Dan Patch mines, Pennington Co., SD; as late hydrothermal product in granite pegmatites rimmed with anapaite near Prinz von Hesse coal mine, *Messel, Hessen, Germany*; at Lavra do Enio, Galileia, MG, Brazil. HCWS *AM* 44:469(1959), *RM* 54:255(1979).

40.2.2.3 Collinsite $\text{Ca}_2\text{Mg}(\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1927 for William Henry Collins (1878–1937), director of the Geological Survey of Canada. Fairfieldite/Roselite group. TRIC $P1$. $a = 5.734$, $b = 6.780$, $c = 5.441$, $\alpha = 97.29^\circ$, $\beta = 108.56^\circ$, $\gamma = 107.28^\circ$, $Z = 1$, $D = 2.955$. *MM* 39:577(1974). 26-1063: 5.00₄ 3.24₅ 3.14₅ 3.04₁₀ 3.02₅ 2.74₆ 2.71₈ 2.68₉. See also 27-83 (Reaphook), 35-635. Radial blades or lathlike fibers elongated [100]. Light brown, translucent, aggregates silky. Cleavage {001}, {010}, fair. $H = 3\frac{1}{2}$. $G = 2.99$. Biaxial (+); $N_x = 1.632$, $N_y = 1.642$, $N_z = 1.657$; $2V = 80^\circ$; pale yellow brown to colorless. Easily soluble in acids. Type material probably contains some Fe^{2+} . Found with dark brown, fibrous carbonatian fluorapatite at *François Lake, BC, Canada*, as concentric alternate crusts with radial fibrous structure on fragments of andesite in a veinlike deposit and associated with asphaltum. Abundant at Lavrada Ilha Taquaral, MG, Brazil, with eosphorite and other phosphates; also at Reaphook Hill, SA, and Mulgun Station, WA, Australia. HCWS *DII:722*, *AJC* 27:653(1974).

40.2.2.4 Cassidyite $\text{Ca}_2\text{Ni}(\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1967 for William A. Cassidy, who mapped Wolf Creek crater, WA, Australia, where the mineral was found. Fairfieldite/Roselite group. In a series Ni–Mg with collinsite (40.2.2.3). TRIC $P1$. $a = 5.71$, $b = 6.43$, $c = 5.41$, $\alpha = 96.8^\circ$, $\beta = 107.3^\circ$, $\gamma = 104.6^\circ$, $Z = 1$, $D = 3.26$. *AM* 52:1190(1967). 20-228: 3.49₄ 3.23₆ 3.13₅ 3.03₉ 2.70₁₀ 2.67₈ 2.23₄ 1.660₅. Crusts and small spherules. Pale to bright green, translucent. $G \approx 3.1$. Biaxial; $N_x = 1.64$, $N_z = 1.67$; optically colorless, finely fibrous, length-slow. Contains some Mg. Occurs in the cavities and cracks in weathered meteorites at *Wolf Creek, WA, Australia*. HCWS

40.2.2.5 Talmessite $\text{Ca}_2\text{Mg}(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1960 for the locality. Fairfieldite/Roselite group TRIC *P1*. $a = 5.874$, $b = 6.943$, $c = 5.537$, $\alpha = 97.3^\circ$, $\beta = 108.7^\circ$, $\gamma = 108.1^\circ$, $Z = 1$, $D = 3.42$. Structure: *BM 100:230(1977)*. *38-451*: 5.11_5 4.62_8 3.59_5 3.35_4 3.21_9 3.08_{10} 2.82_4 2.78_8 . See also *17-164*. Fine crystalline aggregates. Green, colorless, translucent. $H = 5$. $G = 3.57$. TGA. Biaxial; $N_x = 1.672$, $N_y = 1.685$, $N_z = 1.698$; $2V \approx 90^\circ$. Found at Gold Hill, UT; at Cross Creek, near Savana, BC, Canada; with barite at Luceram, Alpes-Maritimes, France; at the *Talmessi mine*, 35 miles W of Anarak, Iran, associated with dolomite; at Bou-Azzur, Morocco. HCWS *AM 45:1315(1960)*, *50:813(1965)*; *BM 83:118(1960)*, *87:169(1964)*.

40.2.2.6 Gaitite $\text{Ca}_2\text{Zn}(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1980 for Robert Irwin Gait (b.1938), curator of mineralogy, Royal Ontario Museum, Toronto, Canada. Fairfieldite/Roselite group TRIC *P1*. $a = 5.90$, $b = 7.61$, $c = 5.57$, $\alpha = 111.67^\circ$, $\beta = 70.83^\circ$, $\gamma = 119.47^\circ$, $Z = 1$, $D = 3.80$. *CM 18:197(1986)*. *33-598*: 5.05_4 3.58_4 3.35_5 3.21_5 3.08_8 2.78_{10} 2.75_7 1.72_6 . Coatings and small crystals up to 1 mm showing {010}, {001}, {011}, {001} (small). White to colorless, vitreous luster, translucent. Cleavages {010}, {001}, {011}, good but not easily observed. $H \approx 5$. $G = 3.18$. DTA. Biaxial (+); $N_x = 1.713$, $N_y = 1.730$, $N_z = 1.730$; $2V = 88^\circ$. When Zn/Mg = 1:1: Biaxial (-); $N_x = 1.689$, $N_y = 1.707$, $N_z = 1.727$; $2V = -85^\circ$. Found on prosperite, adamite, and austinite at *Tsumeb mine*, *Tsumeb*, *Namibia*. HCWS *AM 66:1274(1981)*.

40.2.2.7 β -Roselite $\text{Ca}_2\text{Co}(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1955 for its dimorphic relationship to roselite (40.2.3.1). Fairfieldite/Roselite group. TRIC *P1* or *P1*. $a = 5.89$, $b = 7.69$, $c = 5.56$, $\alpha = 112.6^\circ$, $\beta = 70.8^\circ$, $\gamma = 119.4^\circ$, $Z = 1$, $D = 3.77$. *AM 40:828(1955)*. *17-166*: 5.07_3 3.56_6 3.33_4 3.20_8 3.07_8 2.78_{10} 2.16_4 1.714_8 . Granular masses. Dark rose-red, vitreous luster, transparent to translucent. Cleavage {010}, perfect. $H = 3\frac{1}{2}$ -4. $G = 3.71$. Biaxial (-); $N_x = 1.723$, $N_y = 1.737$, $N_z = 1.756$; $2V = 80$ - 90° . Found with roselite and calcite in quartz vein at *Schneeberg*, *Saxony*, *Germany*; with erythrite at Bou-Azzur, Morocco; at *Tsumeb*, *Namibia*. HCWS *AM 45:1315(1960)*.

40.2.2.8 Parabrandtite $\text{Ca}_2\text{Mn}(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1987 to show its dimorphic relationship with brandtite. Fairfieldite/Roselite group. TRIC *P1* or *P1*. $a = 5.89$, $b = 7.03$, $c = 5.64$. $\alpha = 96.77^\circ$, $\beta = 109.32^\circ$, $\gamma = 108.47^\circ$, $Z = 1$, $D = 3.60$. *NJMM 157:113(1987)*. *40-1457*: 5.11_4 3.61_7 3.37_4 3.23_5 3.09_8 2.81_{10} 2.78_5 2.04_4 . Aggregates to 1.5 mm in diameter of crystals in parallel growth. Colorless, white streak, vitreous luster, transparent. Cleavage {010}, {110}, perfect. $H = 3$ -4. $G = 3.55$. Nonfluorescent in UV. Biaxial (+); $c = [001]$, b^* perpendicular to (010); $N_x = 1.701$, $N_y = 1.721$, $N_z = 1.751$; $2V = 79.9^\circ$; $r > v$, weak. Found in a cavity with sarkinite in a vein of primary ore containing franklinite, pink

calcite, and red willemite at *Sterling Hill mine, Sussex Co., NJ*. *HCWS AM 73:1496(1988)*.

40.2.3.1 Roselite $\text{Ca}_2(\text{Co}^{2+}, \text{Mg})(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1825 for Gustav Rose (1798–1873), professor of mineralogy, University of Berlin, Germany. Fairfieldite/Roselite group *MON P2₁c*. $a = 5.801$, $b = 12.989$, $c = 5.617$, $\beta = 107.42^\circ$, $Z = 2$, $D = 3.617$. Structure: *CM 15:36(1977)*. *29-315*: 6.44_2 5.09_2 3.75_1 3.40_3 3.35_6 3.22_8 2.99_{10} 2.76_5 . Druses or spherical aggregates of short prismatic $\{001\}$, or thick tabular $\{001\}$ crystals with large $\{122\}$, $\{122\}$. Twinned on $\{100\}$ with $\{100\}$ as composition plane, often as fourlings. *DII:724*. Dark rose-red to pink, vitreous luster, transparent to translucent. Cleavage $\{010\}$, perfect, easy. $H = 3\frac{1}{2}$. $G = 3.62$. Biaxial (-); $X = b$; $Y \wedge c = 12-20^\circ$, $Z \wedge c = -70-78^\circ$; $N_x = 1.725$, $N_y = 1.728$, $N_z = 1.735$; $2V = 60^\circ$; $r < v$, weak. X, dark rose; Y, pale rose; Z, paler rose. Indices, and deep color, vary with Co content, which substitutes for Ca and Mg and may produce zonation within crystals. Found at Molviza, Spain; at Daniel and Rappold mines, *Schneeberg, Saxony, Germany*; at Bou Azzer, Morocco(1), with β -roselite and erthyrite; at Tsumeb, Namibia. *HCWS DII:723, AM 72:217(1987)*.

Twin on $\{100\}$.

Fourling on $\{100\}$.

Roselite

Forms: $a = \{100\}$, $b = \{010\}$, $c = \{001\}$, $k = \{8.10.0\}$, $l = \{130\}$, $m = \{110\}$, $n = \{140\}$, $p = \{122\}$, $r = \{T38\}$. Underlined letters refer to faces of second crystals (twin).

40.2.3.2 Brandtite $\text{Ca}_2(\text{Mn}^{2+}, \text{Mg})(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1888 for Georg Brandt (1694–1768), Swedish chemist. Fairfieldite/Roselite group. MON $P2_1/c$. $a = 5.899$, $b = 12.968$, $c = 5.684$, $\beta = 108.05^\circ$, $Z = 2$, $D = 3.70$. *CM 15:36(1977)*. Structure: *SR III:653(1963)*. 29-348: 6.48₂ 5.15₂ 3.79₂ 3.42₃ 3.37₅ 3.24₇ 3.01₁₀ 2.27₁. Stout prismatic [001] with many prism forms visible. {100} striated [001]. Often united in radiating groups; rounded or reniform masses with radial fibrous structure. Twinning on {100} common. Colorless to white, vitreous luster, transparent to translucent. Cleavage {010}, perfect. $H = 3\frac{1}{2}$. $G = 3.67$. Biaxial (+); $X = b$; $Y \wedge c = 6^\circ$, $Z \wedge c = 84^\circ$; $N_x = 1.709$, $N_y = 1.711$, $N_z = 1.724$; $2V = 23^\circ$; $r < v$, strong. Soluble in 1 : 10 acids. Found in vug at Sterling Hill, NJ, associated with rhodochrosite, chalcopyrite, franklinite, black willemite, calcite, and sphalerite; at *Harstig mine, Pajsberg near Persberg, Varmland, Sweden*, associated with barite, calcite, sarkinite, flinkite, caryopilite, galena, and native lead; at Rappold and Daniel mines, Schneeberg, Saxony, Germany. *HCWS DII:725, AM 25:738(1952)*.

40.2.3.3 Zincroselite $\text{Ca}_2\text{Zn}(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1986 for its composition and relationship to roselite. Fairfieldite/Roselite group. MON $P2_1/c$. $a = 5.832$, $b = 12.889$, $c = 5.644$, $\beta = 107.72^\circ$, $Z = 2$, $D = 3.77$. *NJMM: 523(1986)*. 40-498: 6.44₅ 5.10₆ 3.40₅ 3.36₅ 3.22₆ 3.13₅ 3.00₁₀ 2.78₈. Aggregates up to 12 mm × 5 mm × 4 mm of intergrown lathlike crystals elongated and strongly striated [001]. Commonly twinned on (100) with {hk0} and {hkl} present. Colorless to white, translucent. Brittle. $H = 3$. $G = 3.75$. Nonfluorescent in UV. Biaxial (+); $Y = b$; $Z \wedge c = 0\text{--}5^\circ$ in acute β ; $N_x = 1.703$, $N_y = 1.710$, $N_z = 1.720$; $2V = 50^\circ$; $r < v$, strong. Found in a small cavity in oxidized copper ore at *Tsumeb mine, Tsumeb, Namibia*. *HCWS AM 73:932(1988)*.

40.2.3.4 Wendwilsonite $\text{Ca}_2\text{Mg}(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1987 for Wendell E. Wilson (b.1946), mineralogist, editor, and publisher of the *Mineralogical Record*. Fairfieldite/Roselite group. See also erythrite (40.3.6.3). MON $P2_1/c$. $a = 5.806$, $b = 12.912$, $c = 5.623$, $\beta = 107.40^\circ$, $Z = 2$, $D = 3.57$. *AM 72:217(1987)*. 41-607: 5.09₅ 3.40₃ 3.36₄ 3.23₆ 2.99₁₀ 2.77₈ 2.59₄ 2.10₃. Crystals up to 6 mm in size, stout prismatic, elongate on [100] with large {011}, {111}, narrow {110}, {010}. Twinned by reflection on {100} with {100} composition plane; lamellar parallel to {011}, {111}, {010} also possibly the result of twinning. Pale pink to intense red, pale pink streak, vitreous luster, transparent. Cleavage {010}, perfect; uneven fracture; no parting. $H = 3\text{--}4$. $G = 3.52$. Nonfluorescent. Biaxial (+); Y parallel to b ; $Z \wedge c = 92^\circ$ in obtuse β ; $N_x = 1.694$, $N_y = 1.703$, $N_z = 1.717$; $2V = 87^\circ$; $r < v$; pleochroic. X , violet pink; Y , rose pink; Z , colorless. Found at *Sterling Hill mine, Ogdensburg, NJ*, with calcite crystals on serpentine in franklinite-willemite ore; at Coahuila, COAH, Mexico; associated with tal-

messite and erythrite on altered ore and calcite gangue at Arhbar mine, Bou Azzer, Morocco. HCWS

40.2.4.1 Prosperite $\text{CaZn}_2(\text{AsO}_4)_2 \cdot \text{H}_2\text{O}$

Named in 1979 for Prosper J. Williams (b.1910), South African-Canadian mineral dealer from Toronto, Canada. MON *C2/c*. $a = 19.238$, $b = 7.731$, $c = 9.765$, $\beta = 104.47^\circ$, $Z = 8$, $D = 4.408$. *CM 17:87(1979)*. Structure: *ZK 158:33(1982)*. $33\text{-}599$: 3.86_5 3.78_7 3.36_6 3.11_8 2.99_9 2.79_5 2.72_{10} 2.61_6 . Radiating sprays of prismatic crystals up to 10 mm long and 1 mm in diameter; sheaflike subparallel aggregates. Crystals elongated parallel to [001] show {100}, {101}, {110}, {111}, {421}, {540}, {210}, {310}, {301}, {112}, {311}. White to colorless, white streak, brilliant vitreous to silky luster. $H = 4\frac{1}{2}$. $G = 4.31$. DTA. Nonfluorescent. Biaxial (+); $Y = b$; $Z \wedge c = 27^\circ$; $N_x = 1.746$, $N_y = 1.748$, $N_z = 1.768$; $2V = 34^\circ$; $r \gg v$. Found as a secondary mineral in vugs in partly altered sulfide ore at *Tsumeb mine, Tsumeb, Namibia*, associated with chalcocite, mercurian silver, cuprite, conichalcite, adamite, austinite, and koritnigite. HCWS *AM 65:208(1980)*.

40.2.5.1 Parascholzite $\text{CaZn}_2(\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1981 for its dimorphic relationship to scholzite (40.2.6.1). MON *C2/c* or *Cc*. $a = 17.864$, $b = 7.422$, $c = 6.74$, $\beta = 106.45^\circ$, $Z = 4$, $D = 3.10$. *AM 66:843(1981)*. Cell corresponds to subcell of scholzite. $35\text{-}495$: 8.55_{10} 4.53_3 4.16_5 3.41_4 3.15_2 2.80_8 2.78_4 2.59_3 . Crystals less than 1 mm, tabular, prismatic, show (100), (110), (310), (410), (001), (101), and ($\bar{1}11$); mostly polysynthetically twinned by reflection on {100} giving microscopic lamellae. White to colorless, white streak, vitreous luster. No cleavage, parting along twin composition plane {100}. $H = 4$. $G = 3.12$. DTA, TGA. Nonfluorescent. Biaxial (+); X parallel to b , $Z \wedge c = 13^\circ$; $N_x = 1.603$, $N_y = 1.588$, $N_z = 1.587$ (Na); $2V = 25^\circ$; $r > v$. Found in association with scholzite on specimens from *Hagendorf Süd and Nord, Bavaria, Germany*; probably present with scholzite everywhere. HCWS

40.2.6.1 Scholzite $\text{CaZn}_2(\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1950 for Adolph Scholz (1894-1950), mineral collector and chemist of Regensburg, Germany. Dimorphous with parascholzite (40.2.5.1). ORTH *Pbcm* or *Pbc2_1*. $a = 17.149$, $b = 22.236$, $c = 6.667$, $Z = 12$, $D = 3.110$. Structure: *AM 60:1019(1975)*, layered substructure; see also *ZK 198:239(1992)*. $27\text{-}95$: 8.65_{10} 4.56_3 4.29_4 3.71_2 3.40_3 3.33_3 2.81_6 2.27_3 . See also $13\text{-}445$ (Hagendorf), $29\text{-}1412$. Well-developed crystals up to 1 cm long with 1 mm cross section, elongated parallel to [001] showing {100}, {110}, {130}, {231}, {601}. Distinctive habits observed in close proximity; all crystals appear to include lamellae of parascholzite. White to colorless, white streak, vitreous luster. No cleavage, parting along plane of syntaxy {100} with parascholzite. $H = 4$. $G = 3.13$. Nonfluorescent. Biaxial (+); $XYZ = bac$; $N_x = 1.597$, $N_y = 1.586$, $N_z = 1.585$; $2V = 33^\circ$; $r > v$ (Reaphook). Analyses show minor

Mn, Mg, and trace Fe. Synthesized *NJMM:25(1977)*. Found as primary product of crystallization in Zn- and phosphate-bearing pegmatites at Otov, near Domazlice, Bohemia, Czech Republic; as secondary mineral from alteration of phosphates in pegmatites at *Hagendorf, Bavaria, Germany*; at Zabaiykalya, Russia; as a secondary mineral produced during weathering (with enrichment through groundwaters) of sedimentary rocks containing low-grade Zn and phosphate minerals at Richelle, Belgium, and at Reaphook Hill, Flinders Ranges, SA, Australia. *HCWS AM 36:382(1951), 66:843(1981)*.

40.2.7.1 Phosphophyllite $Zn_2(Fe^{2+}, Mn^{2+})(PO_4)_2 \cdot 4H_2O$

Named in 1920 in allusion to the phosphate composition and having a perfect cleavage. *MON P2₁/c*. $a = 10.378$, $b = 5.084$, $c = 10.553$, $\beta = 121.14^\circ$, $Z = 2$, $D = 3.058$. *JAC 9:503(1976)*. Structure: *AM 62:812(1977)*. *29-1427: 8.86₈ 4.55₂ 4.44₁₀ 3.38₆ 2.83₅ 2.82₄ 2.22₃ 1.481₃* (Potosi). See also *17-774* (Hagendorf). Thick tabular {100} with a variety of faces showing. *DII:738*. Twinned on {100} sometimes polysynthetic, also rarely on {102}. Colorless to pale bluish green; vitreous luster; transparent. Cleavage {100}, perfect; {010}, {102}, distinct; brittle. $H = 3-3\frac{1}{2}$. $G = 3.08$. Fluoresces violet in SWUV. Biaxial (-); $Z = b$; $Y \wedge c = 50^\circ$; $N_x = 1.595$, $N_y = 1.614$, $N_z = 1.616$; $2V \approx 45^\circ$; $r > v$. Soluble in acids. Found at Dunton and Bell pegmatites, Newry; Red Hill(!), Rumford, Oxford Co., ME; Palermo No. 1 pegmatite, Groton, Grafton Co., NH; in pegmatite with triplite, triphylite, sphalerite, apatite, vivianite, rockbridgeite, strengite, fairfieldite, or phosphosiderite at *Hagendorf Süd(!), near Pleystein, Oberpfalz, Bavaria, Germany*; in sharp, light green-blue crystals to 14 cm at Unificada mine, Cerro de Potosi; Siglo XX mine, Llallagua, Bolivia; Broken Hill, Zambia; Reaphook Hill, SA, Australia. *HCWS*.

BRACKEBUSHITE GROUP

The minerals in the brackebushite group conform to the general formula

where

A = Ba, Ca, Pb, Sr

B = Al, Cr^{2+} , Fe^{2+} , Fe^{3+} , Mn^{2+} , Mn^{3+} , Zn

T = As, Cr, P, S, V (and possibly Si)

and crystallize in the monoclinic system, space group $P2_1/m$.

The structure is composed of $B-(O, OH)_6$ octahedra, two nonequivalent TO_4 tetrahedra, and two different irregular polyhedra of large cations one in 6- or 8- and the other in 10- or 11-fold coordination with O, OH, or H_2O . Chains formed from the octahedra link through the apex oxygens of $TO_{4(2)}$, while the polyhedra form double chains parallel to [010] through edge-sharing with $TO_{4(1)}$. The result is a tight three-dimensional structure *TMPM 25:153(1978)*. Infrared investigations on brackebushite and gamagarite indi-

cate strong hydrogen-bonded OH which is probably the dominant species in these minerals. *AM 69:803(1984)*.

BRACKEBUSCHITE GROUP

Mineral	Formula	Space Group	a	b	c	β	
Brackebuschite	$Pb_2(Mn^{2+}, Fe^{2+})(VO_4)_2$	$P2_1/m$	8.810	6.185	7.681	111.50	40.2.8.1

Notes: Accumulating species from other classes accentuates the crystallographic similarities between different composition materials.

1. The elongate, acicular, or fibrous morphology with positive optical sign shown by these minerals is indicative of the condensed chainlike motif.
2. See also the adelite–descloisite group (41.5.1.1).
3. The tornenbohmitie minerals (52.4.5.1, and 52.4.5.2) are related.

40.2.8.1 Brackebuschite $Pb_2(Mn^{2+}, Fe^{2+})(VO_4)_2 \cdot H_2O$

Named in 1880 for Luis Brackebusch (1849–1906), professor of mineralogy, University of Cordoba, Argentina. Brackebuschite group. *MON* $P2_1/m$. $a = 8.810$, $b = 6.185$, $c = 7.681$, $\beta = 111.50^\circ$, $Z = 2$, $D = 6.11$. *MM 39:69(1973)*. *6-284*: 4.95₈ 3.25₁₀ 3.08₅ 2.98₆ 2.76₈ 2.13₄ 2.07₄ 1.720₆. Acicular [010] with {100}, {001}, striated [010], and sometimes flattened parallel to elongation; as tufts or groups of crystals; dendritic or botryoidal. Dark brown to black, yellow streak, submetallic luster, translucent to nearly opaque. $G = 6.05$. Biaxial (+); $N_x = 2.28$, $N_y = 2.36$, $N_z = 2.48$, $2V$ large; $r > v$, strong; pleochroic. X, colorless; Y, dark reddish brown; Z, clear reddish brown. Found with descloisite, vanadinite in oxidized zone of lead–zinc veins in the western part *Sierra de Cordoba, Cordoba Prov., Argentina*. *HCWS*

BRACKEBUSCHITE: $\text{Pb}_2(\text{Mn}^{2+}, \text{Fe}^{2+})(\text{VO}_4)_2 \cdot \text{H}_2\text{O}$

A 'b' axis projection two irregular A polyhedra, B-(O,OH)₂ octahedra and two non-equivalent TO₄ groups shows the three dimensional framework structure.

40.2.8.2 Arsenbrackebuschite $\text{Pb}_2(\text{Fe}^{2+}, \text{Zn})(\text{AsO}_4)_2 \cdot \text{H}_2\text{O}$

Named in 1978 in analogy to brackebuschite being the arsenic analog, but note the presence of Fe rather than Mn. Brackebuschite group. *MON* *P2/m*. $a = 7.763$, $b = 6.046$, $c = 9.022$, $\beta = 112.5^\circ$, $Z = 2$, $D = 6.54$. *NJMM:193(1976)*, Structure: *TMPM 25:153(1978)*. *29-1428*: 4.92₂ 3.68₂ 3.44₂ 3.27₉ 3.02₁₀ 3.00₁₀ 2.78₆ 2.31₃. Flat laths or platelets to 0.5 mm × 0.2 mm × 0.1 mm. Honey-yellow, light brownish-yellow streak, resinous to adamantine luster. Cleavage {010}, perfect. $H = 4-5$. Biaxial (-); $N_x' < 2.0$, $N_z' > 2.04$; pleochroic, honey-yellow to bright yellow. Occurs in the Clara mine, Black Forest, Germany, associated with anglesite, bayldonite, mimetite, and stolzite, intimately intergrown with beudantite; at *Tsumeb mine*, *Tsumeb*, *Namibia*. *HCWS AM 63:1282(1978)*.

HELMUTWINKLERITE SUBGROUP

The group can be expressed in the general formula

where

A = Pb

B = Zn, Fe²⁺, Fe³⁺, Cu

T = As,

and crystallizes in monoclinic (C2/m or C2/c) or triclinic space groups.

The general structure is a subset of the brackebuschite group. In helmutwinklerite a supercell has been determined in which the *a* axis is 4× and *b* axis is 3× the original unit cell parameters *NJMM* 446 (1985).

HELMUTWINKLERITE GROUP

Name	Formula	Space group	<i>a</i>	<i>b</i>	<i>c</i>	α	β	γ
Tsumcorite	Pb ₂ Fe ²⁺ (AsO ₄) ₂ · 2H ₂ O	C2/m	9.124	6.329	7.577		115.3	
Helmutwinklerite	PbZn ₂ (OH, H ₂ O) ₂ (AsO ₄) ₂	P $\bar{1}$, P1	22.40	22.44	7.62	70.2	70.0	69.2
Thometzekite	PbCu ₂ (AsO ₄) ₂ · 2H ₂ O							
Mawbyite	Pb(Fe _{1.5} ²⁺ , Zn _{0.5})(AsO ₄) ₂ (OH _{1.5} , H ₂ O _{0.5})	C2/c	9.05	6.277	7.580		114.7°	

40.2.9.1 Tsumcorite PbZnFe²⁺(AsO₄)₂ · H₂O

Named in 1971 for the Tsumeb Corporation. *MON* C2/*m*. *a* = 9.124, *b* = 6.329, *c* = 7.577, β = 115.3°, *Z* = 2, *D* = 5.39. *NJMM*:446(1985), Structure: *AC(B)* 29:2789(1973), in series with helmutwinklerite (40.2.11.1) and thometzekite (40.2.9.2). 25-399: 4.66₉ 3.24₁₀ 3.02₆ 2.86₉ 2.74₇ 2.57₅ 2.54₄ 2.51₄. Radiating and spherulitic fibrous crusts. Red-brown, yellow streak. *H* = 4½. *G* = 5.2. DTA. Biaxial; *N* ≈ 1.90; 2*V* ≈ 90°; dichroic, yellow to yellow-green. Dissolves in HCl. Found at the Richmond–Sitting Bull mine, Galena, Lawrence Co., SD; at the *Tsumeb mine*, *Tsumeb*, *Namibia*, in the oxidized zone associated with beudantite, anglesite, mimetite, and other arsenates; on a sample from Thasos, Greece, in the British Museum. *HCWS NJMM*:305(1971).

40.2.9.2 Helmutwinklerite PbZn₂(AsO₄)₂ · 2H₂O

Named in 1980 for Helmut G. F. Winkler (1915–1980), University of Göttingen, Germany. End member in the Zn–Cu series with thometzekite (40.2.9.3); see also tsumcorite (40.2.10.1). *TRIC* P1 or P $\bar{1}$. *a* = 22.40, *b* = 22.44, *c* = 7.62, α = 70.2°, β = 70.0°, γ = 69.2°, *Z* = 1, *D* = 5.29. *NJMM*:118(1980), 446(1985). Supercell related to tsumcorite and thometzekite. 33-781: 6.95₄

4.70₈ 3.46₄ 3.27₇ 3.08₇ 2.77₅ 2.58₁₀ 1.735₅. Crystals show {001}, {010}, {110}, {111}, pseudomonoclinic. Sky blue, vitreous to resinous luster. No cleavage. $H = 4\frac{1}{2}$. $G = 5.3$. Biaxial (+); $N_x = 1.72$, $N_y = 1.80$, $N_z = 1.98$. Dissolves in cold 10 N HCl. Found in cavities in tennantite, associated with quartz, will-emite at *Tsumeb, Namibia*. HCWS *AM 65:1067(1980)*.

40.2.9.3 Thometzekite $\text{PbCu}_2(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1985 for W. Thometzek, mining director at Tsumeb from 1912–1922. End member in the Cu–Zn series with helmutwinklerite (40.2.11.1). See also tsumcorite (40.2.10.1). Probably MON. *39-340*: 4.69₈ 4.50₅ 3.27₁₀ 3.16₄ 2.96₇ 2.87₇ 2.58₃ 2.52₇. Aggregates of tabular crystals 20 μm long and 1 μm thick. Blue-green to green, earthy. TGA. Biaxial; $N_{av} = 1.855$; light gray; wavy extinction; nonpleochroic. Some Zn and Fe also detected on microprobe analysis. Found on specimen of massive gypsum from *Tsumeb, Namibia*. HCWS *NJMM:446(1985)*, *AM 77:931(1988)*.

40.2.9.4 Mawbyite $\text{Pb}(\text{Fe}^{2+}\text{Zn})(\text{AsO}_4)_2(\text{OH})_3 \cdot \text{H}_2\text{O}$

Named in 1989 for Maurice Mawby (1904–1977) to honor his contribution to the knowledge of minerals at Broken Hill, NSW, Australia. In series with tsumcorite (40.2.9.1); pure Fe end member may be dimorphous with carminite (41.10.7.1). MON *C2/c*. $a = 9.05$, $b = 6.277$, $c = 7.580$, $\beta = 114.57^\circ$, $Z = 2$, $D = 5.53$. *AM 74:1377(1989)*. *PD*: 4.65₁₀ 4.46₈ 3.25₁₀ 3.14₃ 2.86₄ 2.72₇ 2.55₅ 2.50₃. Drusy crusts of “dogtooth” to prismatic crystals up to 0.2 mm long showing {110}, {101}, {001}; rarely tabular; hemispherical, cylindrical, and sheaflike aggregates with platy, spongy appearance. Twins V-shaped, composition plane (100). Orange brown (Zn/Fe = 1:1) to bright reddish brown (pure Fe end member), orange-yellow streak, adamantine luster, transparent to translucent. Cleavage {001}, conchoidal fracture. $H = 4$. Nonfluorescent. Biaxial; $N > 1.94 \rightarrow 2.00$ for Fe/Zn = 3:1, for Fe end member $N > 2.00$; length-fast; pleochroic, brown to reddish brown. Formation probably related to the pH of circulating waters in oxidation zone. Found at *Kintore Opencut, Broken Hill, NSW, Australia*, in the oxidized zone on spessartite, quartz rocks as a reaction halo associated with members of the corkite–beudanite series, adamite, olivenite, duftite, mimetite, balydonite, hidalgoite, pharmacosiderite, and Mn and Fe oxyhydroxides. HCWS

40.2.10.1 Wicksite $\text{NaCa}_2(\text{Fe}^{2+}, \text{Mn}^{2+})_4\text{MgFe}^{3+}(\text{PO}_4)_6 \cdot 2\text{H}_2\text{O}$

Named in 1981 for Frederick John Wicks (b.1937), curator of mineralogy, Royal Ontario Museum, Toronto, Canada. ORTH *Pbca*. $a = 12.896$, $b = 12.511$, $c = 11.634$, $Z = 4$, $D = 3.58$. *CM 19:377(1981)*. *35-512*: 3.50₂ 3.02₈ 2.91₈ 2.87₃ 2.84₃ 2.75₁₀ 2.57₄ 2.12₆. Massive; plates parallel to {010}, striated parallel to [100]. Dark blue almost black, green streak, submetallic luster. Cleavage {010}, good. $H = 4\frac{1}{2} - 5$. $G = 3.54$. Nonfluorescent. Biaxial (+); $XYZ = bac$; $N_x = 1.713$, $N_y = 1.718$, $N_z = 1.728$; $2V = 66^\circ$; $r < v$, strong; pleochroic; $X = Y > Z$. X, blue; Y, greenish blue; Z, pale yellowish brown.

May show anomalous biaxial with extinction to 5° . Found with wolfeite, atterlyite, marcite, pyrite, and quartz in nodules in *Big Fish area, YT, Canada*. Type locality at $68^\circ 28' 30''$ N, $136^\circ 29'$ W. *HCWS AM 67:1077(1982)*, *MR 17:301(1986)*.

40.2.11.1 Grischunite $\text{NaCa}_2\text{Mn}_5^{2+}\text{Fe}^{3+}(\text{AsO}_4)_6 \cdot 2\text{H}_2\text{O}$

Named in 1984 for the locality. *ORTH Pcab*. $a = 12.855$, $b = 13.487$, $c = 12.047$, $Z = 4$, $D = 4.144$. *SMPM 64:1(1984)*, Structure: *AM 72:1225(1987)*. 38-387: 6.04₃ 4.24₃ 3.62₇ 3.15₉ 3.02₈ 2.94₆ 2.84₁₀ 2.68₃. Anhedronal grains and lathlike crystals up to 1 mm elongated parallel to b . Dark red-brown, yellow-red to yellow-brown streak, vitreous luster, translucent. Cleavage (010), perfect. $H \approx 5$. $G = 3.8$. IR. Biaxial; $XYZ = bac$; $N_x = 1.784$, $N_y = 1.785$, $N_z = 1.790$; $2V = 40-50^\circ$; pleochroic; absorption $Z \approx Y \gg X$, $r \ll v$. X, yellow green; Y, yellow-brown; Z, dark red-brown. Found as an alteration product of sarkinite, with which it is intimately intergrown, in the manganese deposits near *Falotta, Oberhalbstein, Grisons Canton, Switzerland*, with brandtite, sarkinite, Mn-berzeliite, and tilasite. *HCWS AM 71:227(1986)*.

AUTUNITE GROUP

The autunite group minerals contain uranium as expressed in the formula

where

$A = \text{Ca, Ce, Ba, K, NH}_4, \text{Sr, Pb, Mg, Na, Co, Zn, or H}_3\text{O}^+$

$T = \text{P, As, V}$

$n =$ variable, related to the number of bonded and unbonded water molecules, and the cation(s) species and charge balance

and the mineral crystallize with tetragonal or pseudotetragonal monoclinic symmetry.

The structure is dominated by sheets composed of the XO_4 tetrahedral groups linked to dumbbell-shaped $(\text{UO}_2)^{2+}$ ions. The axis of the UO_2 dumbbell is perpendicular to the sheet, with the uranyl ion having an alternate upward or downward displacement from the plane of the X position atoms. The puckered $[(\text{UO}_2)(\text{TO}_2)]$ sheets are stacked perpendicular to the c axis and are separated by a layer composed of H_2O and cations, usually symmetrically arrayed, so that they form a mirror plane. This site, parallel to $\{001\}$, may also contain unbonded H_2O molecules which are easily mobilized on dehydration, and it is a locus of structural weakness, as is evident in the perfect cleavage of these minerals.

The autunite group is divided into two subgroups, autunites and meta-autunites, based on crystal structure differences initially determined on synthetic materials. *RC 57:155(1938)*. Both subgroups contain PO_4 and AsO_4

mineral species and are characterized by solid solutions for similarly charged and coordinated A cations in addition to substitution in the X site. The variable size and valence of the cations in the water layer of the structure influence not only the composition but also the stacking and bonding schemes. Members of the meta-autunite subgroup represent the lower, and often more stable, hydration states of a particular cation. *USGSB: 1036(1956), 1964(1958); AM 43:799(1958); CE 24:254(1965)*.

In the fully hydrated species (autunite, uranospinite, torbernite, etc.), the $\text{UO}_2\text{-PO}_4$ sheets have maximum separation, and the unit cell has the largest c axis. When subjected to a different temperature and humidity, the minerals dehydrate and the result is a decrease in c -axis length, but the planar character, weakness at water layers, and perfect cleavage remain.

For a specific cation there are usually multiple hydrates, and in most cases a lower hydrate is the stable phase at room temperature and humidities. Related hydrated species retain the name of the fully hydrated version; that is, autunite in lower hydrate(s) is indicated by the prefix "meta-," giving meta-autunite. In cases where there are many hydrates a roman numeral has been used, or most recently, the c -axis spacing is appended. Uranocircite I, for example, has $c = 22.6 \text{ \AA}$, or may be referred to as "uranocircite 22 \AA "; while uranocircite II, with $c = 20 \text{ \AA}$, may be called "uranocircite 20 \AA ." For this specific species even lower hydrates, meta-uranocircite I and II, have been designated.

AUTUNITE: $\text{Ca}[(\text{UO}_2)_2(\text{PO}_4)_2] \cdot 10\text{-}12\text{H}_2\text{O}$

The planar character of the $[(\text{UO}_2)_2(\text{PO}_4)_2]$ layers and cation- H_2O layers in this 'a' axis projection.

Chernikovite	$\text{H}_3\text{O}_2(\text{UO}_2)_2(\text{PO}_4)_2 \cdot 6\text{H}_2\text{O}$	<i>P4/nmm</i>	7.020		9.043	40.2a.19.1	
Trogerite	$\text{H}_2(\text{UO}_2)_2(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$	<i>P4/nmm</i>	7.16		8.80	40.2a.20	

Notes:

1. Dehydration of autunite subgroup minerals to meta-autunite subgroup results in a reduction of the *c* axis unit cell parameter (interlayer spacing), an increase in level of fluorescence under UV irradiation, and an increase in the index of refraction, often with the appearance of anomalous biaxiality. These changes indicate a departure from the *P4/nmm* pseudo-cell which usually can be verified only by detailed crystal structure determinations on rare superior quality crystals.
2. The dehydrated phases often display a grating-like twinning that appears as striae and rectangular domains parallel to (001) and (110) with the crystals resembling checkerboards under crossed polars. The twinning is due to ordering of the interlayer water.
3. Compare these minerals with the members of the carnotite group (40.2a.25-30) which have $[\text{UO}_2, \text{V}_2\text{O}_8]$ layers. The carnotites have different anion geometry.
4. See also uranophane, a hydrated silicate.

40.2a.1.1 Autunite $\text{Ca}(\text{UO}_2)_2(\text{PO}_4)_2 \cdot 10\text{--}12\text{H}_2\text{O}$

Named in 1852 for the locality. Autunite group. See meta-autunite (40.2a.1.2), sodium autunite (40.2a.5.1), *TET* $I4/mmm$. $a = 7.009$, $c = 20.736$, $Z = 2$, $D = 3.10$. *RC 57:155(1938)*, Structure: *AM 38:476(1953)*. *41-1353*: 10.4_9 5.19_7 4.93_4 3.57_{10} 3.50_4 3.32_4 2.73_4 2.07_6 . See also *12-418*. Thin tabular {001}, approaching torbernite in form and angles; subparallel growth common; scaly foliated aggregates; thick crusts with serrated surface composed of crystals standing on edge. Twinning on {110}. Oriented growth with torbernite common. Lemon yellow to greenish yellow to pale green, yellowish streak, vitreous luster to pearly on {001}, transparent to translucent. Cleavage {001}, perfect; {100}, indistinct; not brittle. $H = 2\text{--}2\frac{1}{2}$. $G = 3.15$. Strongly fluorescent yellow-green. Anomalously biaxial (-); $Z = c$; Y parallel to diagonal of plates; $N_x = 1.553$, $N_y = 1.575$, $N_z = 1.577$ (Autun); $2V = 0\text{--}53^\circ$. X, colorless to pale yellow; Y, Z, yellow to dark yellow. Biaxiality dependent on H_2O content. Small amounts of Ba and Mg substitute for Ca with trace amounts of Pb, V, and other elements. Water content decreases with mild heating formation of meta-autunite, the form always found in museum specimens. Synthesized. A secondary mineral in the zone of oxidation derived from alteration of uraninite or other uranium-containing minerals. Found in pegmatites in New England and elsewhere, including the Dunton Gem pit, Newry, ME; the Ruggles mine, Grafton Center, and the Palermo mine, N. Groton, NH; Bedford, Westchester Co., NY; Spruce Pine, Penland, and the Flat Rock mine in Mitchell Co., NC; La Sal mine, Boulder Co., CO; White Signal district, Grant Co., NM; near Keystone, Black Hills, SD; Daybreak and Triple H & J mines, Mt. Spokane, Pend Orielle Co., WA; at Redruth and St. Austell in Cornwall, England; at Sabugal SE of Guarda and at Vizeu, Portugal; at Dom Benito U deposit, Spain; at *L'Ouche de Jau, St. Symphorien, and other localities near Autun, Saône-et-Loire, France*; in the Johanngeorgenstadt district and at Falkenstein, Saxony, and the pegmatites of Hagendorf and Pleystein, Bavaria, Germany; at Ningyo Pass, Okayama/Tottori Pref., Japan; in the Shaba district, Musoni, Zaire; at Kaying-Paksing, western Siang district, Arunachal Pradesh, India; in the Flinders Ranges, SA, Australia; at Malacacheta, MG, Brazil. *hcws DII:984; USGSB 1064:160(1958); AM 45:99(1960), 46:812(1961)*.

40.2a.1.2 Meta-Autunite $\text{Ca}(\text{UO}_2)_2(\text{PO}_4)_2 \cdot 2\text{--}6\text{H}_2\text{O}$

Named in 1938 for its relation to autunite. Autunite group. Several hydrates have been described. $2\text{H}_2\text{O}$ (or 8 Å): *ORTH* $Pmmm$. $a = 6.551$, $b = 7.053$, $c = 8.164$, $Z = 1$, $D = 3.55$. *14-73*: 8.17_{10} 4.81_1 4.14_3 4.08_6 3.51_1 2.96_1 2.72_1 2.04_1 . $N_O = 1.630$, $N_E = 1.61\text{--}1.62$ (Ningyo Pass, Japan). $3\text{H}_2\text{O}$ (or 9 Å): *TET* $P4/mmm$. $a = 6.988$, $c = 8.459$, $Z = 1$, $D = 3.31$. *39-1351*: 8.46_{10} 5.39_2 4.23_2 3.62_6 3.50_2 2.62_3 2.12_4 1.601_3 . $N_O = 1.604$, $N_E = 1.596$ (Oudots mine, Saône et Loire, France, heated 2 hours at 52°). $3\text{H}_2\text{O}$ (9 Å): *TET* $P4_2$. $a = 19.72$, $c = 16.92$, $Z = 16$, $D = 3.53$. [Strong pseudocell ($a = 6.97$, $c = 8.46$) rotated 45° to true cell noted. *GSAPA 13:588(1981)*.] See also *28-*

247(syn), 12-432. Meta-autunites appear naturally, and reversibly, on slight heating or drying, and are virtually always the usual mineral form identified. Properties similar to autunite: light to dark green and yellow, vitreous luster. $H = 1$. $G = 3.44$. Uniaxial (-); $N_O = 1.604$, $N_E = 1.596$. Sr-, Co-, Fe-, Li-, and Ni-meta-autunites have been prepared. *AM* 44:702(1959), 48:1589(1963); *GSAPA* 31002:727(1983). Meta-autunite occurs at most of the localities listed for autunite and forms irreversibly when autunite is heated above $\approx 80^\circ$. Dark green (may contain admixed uraninite) meta-autunite was identified at *Day-break mine, Mt. Spokane, WA*. *HCWS* DII:985, *AM* 46:812(1961).

40.2a.1.3 Pseudoautunite $(H_3O)_4Ca_2(UO_2)_2(PO_4)_4 \cdot 5H_2O$

Named in 1964 for its similarity to autunite and meta-autunite in composition and occurrence. Composition questioned, name unacceptable. *MM* 36:1144(1968). ORTH. $a = b \approx 6.964$, $c \approx 12.85$, $Z = 2$, $D = 3.29$. *AM* 50:1505(1965). 18-1084: 6.20₁₀ 3.38₈ 3.25₁₀ 2.95₈ 2.19₈ 2.06₈ 1.915₉ 1.294₈. Fine platy, powdery crusts that consist of intergrowths of small, up to 0.1 mm, pseudo-hexagonal plates with micaceous cleavage. Pale yellow to white. $G = 3.28$. Intensely yellow-green luminescence in SWUV with persistence, weakly luminescent LWUV. DTA. Biaxial (-); $N_x = 1.541$, $N_y \text{ calc} = 1.568$, $N_z = 1.570$; plane of optic axis parallel to (001), Y perpendicular to (001); extinction parallel or 2° to (010); $r > v$, distinct. Found in fissures and cavities of albite-acmite veins in the contact zone of ultrabasic-alkalic rocks of northern Karelia, Russia, associated with oxonium pyrochlore, calcite, limonitized sulfides, and sometimes apatite. *HCWS* MG 1:31(1964).

40.2a.2.1 Uranospinite $Ca(UO_2)_2(AsO_4)_2 \cdot 10H_2O$

Named in 1873 for uranium and the Greek for *siskin*, in allusion to its composition and color. Autunite group. See meta-uranospinite (40.2a.2.2). *TET* I4/mmm. $a = 7.17$, $c = 20.61$, $Z = 2$, $D = 3.25$. *JLCM* 44:99(1976), *TMPM* 9:252(1964). 29-390(syn): 10.0₈ 5.21₈ 4.97₈ 3.62₁₀ 3.41₉ 2.93₆ 2.55₆ 2.28₆. Thin rectangular plates {001}; aggregates to 20 μ m. Lemon yellow to siskin green, pearly luster on {010}. Cleavage {001}, {100}, distinct. $H = 2-3$. $G = 3.45$. LWUV fluoresces yellow-green. DTA. Anomalously biaxial (-); $X = c$; $N_x = 1.560$, $N_y = 1.582$, $N_z = 1.587$ (Schneeberg); $2V = 0-5^\circ$; $r > v$, moderate; pleochroic. X, colorless; Y, Z, pale yellow for natural material $\approx 10H_2O$. Samples from Schneeberg often show cores of meta-zeunerite, zones of uniaxial or biaxial optics. Water content varies with humidity and temperature. Synthesized. A secondary mineral found at Honeycomb Hills, Fish Springs mining district, Juab Co., and near Pahreah in Kane Co., UT; at *Weisser Hirsch mine, Neustadt, Schneeberg, Saxony, Germany*, associated with walpurgite, meta-uranocircite, trögerite, meta-zeunerite, and at Clara Stollen Halde, Wittichen; at Radium Hill, Mount Painter, SA, Australia; as an alteration product of uraninite associated with niccolite at Solitaria mine, Argentina. *HCWS* DII:990, *USGSB* 1064:183(1958).

40.2a.2.2 Meta-uranospinite $\text{Ca}(\text{UO}_2)_2(\text{AsO}_4)_2 \cdot 6$ or $8\text{H}_2\text{O}$

Named in 1957 for its relationship to uranospinite. Autunite group. Two hydrates with different unit cell parameters have been described. $6\text{H}_2\text{O}$ (17 Å): TET $P4/nmm$. $a = 7.14$, $c = 17.00$, $Z = 2$, $D = 3.84$. *TMPM* 9:252(1965). 18-309: 8.65_{10} 5.53_8 5.08_4 4.36_4 3.67_4 3.57_{10} 3.31_9 3.00_5 . $N_z = 1.618$. $8\text{H}_2\text{O}$ (9 Å): TET $P4/nmm$. $a = 7.19$, $c = 8.81$, $Z = 1$, $D = 3.65$. *AM* 38:1159(1953). 8-319(syn): 8.85_{10} 5.57_6 5.10_7 3.74_5 3.59_9 3.34_8 2.55_5 1.804_5 . Biaxial (-); $N_x = 1.591$, $N_y = 1.619$, $N_z = 1.621$; $2V = 0-5^\circ$. Sometimes uniaxial (-); $N_O = 1.586$, $N_E = 1.560$; weakly pleochroic. X, colorless; E, pale yellow. Cleavage {001}, perfect; {100}, distinct. For other physical properties, see uranospinite (40.2a.2.1). Rehydrates easily to uranospinite. Found at Clara Stollen Halde and the *Sophia mine, Wittichen, Black Forest, Germany*. *HCWS AM* 45:254(1960).

40.2a.3.1 Uranocircite $\text{Ba}(\text{UO}_2)_2(\text{PO}_4)_2 \cdot 12$ or $10\text{H}_2\text{O}$

Named in 1877 for the composition and from the Greek for *falcon* because it was discovered at Falkenstein, Germany. Autunite group. Two hydrates have been described, both rapidly dehydrate irreversibly to meta-uranocircite. $12\text{H}_2\text{O}$ (also known as I) has $c = 22.59$ Å. $10\text{H}_2\text{O}$ (II): TET $P4/nnc$. $a = 7.01$, $c = 20.46$, $Z = 2$, $D = 3.46$ (Mentenschwand, Schneeberg, Germany). *JGLBW* 6:113(1963). 18-199: 10.14_6 5.10_{10} 2.16_5 2.04_{10} 1.645_5 1.576_5 1.527_5 1.462_6 . Crystals resemble autunite, thin tabular {001}. Yellow-green, pearly luster on {001}, transparent to translucent. Twin lamellae parallel to {100}, {010}. Cleavage {001}, perfect; {100}, {010}, distinct. $H = 2\frac{1}{2}$. $G = 3.53$. Fluoresces green. Anomalously biaxial (-); $X = c$; $N_x = 1.574$, $N_y = 1.583$, $N_z = 1.588$; $2V \approx 70^\circ$; pleochroic. X, colorless; Y, Z, pale canary yellow. Found at Cameron area, Coconino Co., AZ; at Annie Creek Mine, Lawrence Co., SD; at *Bergen, near Falkenstein in Voigtland, Saxony, Germany*, as a secondary mineral in quartz veins, and at Wolsendorf, Bavaria, with parsonsite and other secondary uranium minerals in a fluorite deposit. Reported from Rosmaneira, Spain; Srdnia Gora, Banat, Hungary; at Mounana mine, Gabon. *HCWS DII:987*.

40.2a.3.2 Meta-Uranocircite $\text{Ba}(\text{UO}_2)_2(\text{PO}_4)_2 \cdot 6$ or $8\text{H}_2\text{O}$

Named in 1982 to show relationship to uranocircite. Autunite group. Two hydrates described, $6\text{H}_2\text{O}$ or II, has been synthesized. $8\text{H}_2\text{O}$ (I, 18 Å): TET $P4_2/n$. $a = 6.953$, $c = 17.634$, $Z = 2$, $D = 3.94$. 36-407: 8.82_{10} 5.46_2 4.41_6 3.72_5 3.23_1 2.71_2 2.21_2 2.10_1 . Uniaxial (-); $N_O = 1.626$; $N_E = 1.615$. Sample from Streuber, Bergen, Germany. $6\text{H}_2\text{O}$ (II, 17 Å): TET $P4/nmm$. $a = 6.94$, $c = 16.83$, $Z = 2$, $D = 4.00$. 17-759: 8.55_{10} 5.39_7 4.91_5 4.25_6 3.61_9 3.48_5 3.21_7 2.60_4 . Uniaxial (-); $N_O = 1.626$, $N_E = 1.611$. Sample from Menzenschevand, Germany. But note the synthetic $6\text{H}_2\text{O}$ [II, 17Å(syn)]: MON (pseudo-ORTH) $P2_1/a$. $a = 9.855$, $b = 9.756$, $c = 16.84$, $\beta = 90.6^\circ$, $Z = [4]$, $D = 4.0$. 25-1468(syn): 8.34_9 5.35_3 4.27_4 4.23_4 3.60_{10} 3.47_3 3.21_3 2.61_3 . Structure of $6\text{H}_2\text{O}$ species shows corrugated UO_2PO_4 layers parallel to (001) with monoclinic

distortion. Ba is in ninefold coordination, and two of the six H₂O molecules are not bonded to Ba. *TMPM 23:183(1982)*. Platy crystals flattened on {001} with rectangular outline, subparallel aggregates, fanlike groups. Synthetic crystals to 0.6 mm, micaceous "books." Lemon-yellow, pearly luster on {001}, transparent to translucent. $G = 3.964$. Strongly fluorescent green. Easily synthesized from cation exchange starting with schoepite through chernikovite. *MM 56:367(1992)*. Found at Danvier mine, Lawrence Co., in uraniferous lignite, Slim Buttes, Harding Co., and in Chandrom formation, SD; at Kersegelac, Brittany, France; in the Wittichen district., Heubachtal, and at Schmiedestollenhalde, Germany; at Mounana, Gabon; in an alluvial deposit near Antsitabe, Madagascar; and other localities listed under uranocircite (40.2a.3.1). *HCWS USGSB 1064:211(1958)*.

40.2a.4.1 Heinrichite $\text{Ba}(\text{UO}_2)_2(\text{AsO}_4)_2 \cdot 10\text{--}12\text{H}_2\text{O}$

Named in 1958 for Eberhardt William Heinrich (1918–1991), mineralogist, University of Michigan, Ann Arbor, MI. Autunite group. See meta-heinrichite (40.2a.4.2). *TET P4/nnc*. $a = 7.13$, $c = 20.56$, $Z = 2$, $D = 3.50$. *TMPM 9:252(1965)*. *29-210(syn)*: 10.0₁₀ 5.09₇ 3.53₁₀ 3.35₈ 2.50₄ 2.25₆ 1.78₅ 1.60₇. See also 18-198. Small scaly crystals and aggregates. Oregon samples are tablets up to 1 mm long, not more than 0.1 mm thick, showing {001}, {100}, {110}. Black Forest crystals elongated, resemble bassetite (40.2a.15.1). Yellow-green; vitreous luster, pearly on cleavage; transparent to translucent. $H = 2\frac{1}{2}$. Fluoresces bright green to greenish yellow. DTA. Uniaxial (–); $N_O = 1.605$, $N_E = 1.573$ (Grube Anton); $2V = 32^\circ$ (max.). O, bright yellow; E, colorless. Readily dehydrates to meta-heinrichite (40.2a.4.2). Synthesized. Found as fracture coatings in silicified rhyolite tuff in the *White King Mine, 22 km NW of Lakeview, Lake Co., OR*; as an alteration product of pitchblende associated with zeunerite, novacekite, arseniosiderite, pitticite, and erythrite at Grube Anton, Schiltach, and Reinerzau in the Black Forest, Wittichen district, Heubachtal, Schmiedestollenhalde, Germany. *HCWS AM43:1134(1958)*.

40.2a.4.2 Meta-Heinrichite $\text{Ba}(\text{UO}_2)_2(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1958 for its relation to heinrichite. Autunite group. *TET* Space group incompletely determined, *P4₁/*. $a = 7.08$, $c = 17.66$, $Z = 2$, $D = 4.09$. *TMPM 9:252(1965)*. *24-128*: 8.90₁₀ 5.54₇ 4.99₅ 4.42₆ 3.75₈ 3.55₆ 3.28₆ 2.98₅. Yellow-green; vitreous, pearly luster. $G = 4.04$ (Oregon material dried). Uniaxial (–); $N_O = 1.641$, $N_E = 1.608$, anomalously biaxial $2V \approx 28^\circ$ (Black Forest). Found at *White King mine, Lakeview, Lake Co., OR*; at localities in Black Forest region, Germany, where heinrichite occurs. *HCWS AM 43:1134(1958)*.

40.2a.5.1 Sodium Autunite $\text{Na}_2(\text{UO}_2)_2(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1958 for its relation to autunite and the composition. Autunite group. *TET P4/nmm*. $a = 6.97$, $c = 8.96$, $Z = 1$, $D = 3.89$. *AM 43:383(1958)*. *29-1283*: 8.57₅ 3.67₁₀ 3.23₇ 2.68₈ 2.12₆ 1.639₇ 1.566₈ 1.540₈. See also 29-

1284(syn). Plates, foliated and radiating masses. Lemon yellow–lettuce yellow, pearly luster on {001}. Cleavage {001}, perfect; also {100}; brittle. $H = 2-2\frac{1}{2}$. $G = 3.584$. DTA. Strongly luminescent yellow-green. Uniaxial (-); $N_O = 1.564$, $N_E = 1.558$; after 2 days at 40° , $N_O = 1.585$, $N_E = 1.578$; weakly pleochroic. O, light yellow; E, pale yellow. Soluble in acids. Synthesized ($3H_2O$): $a = 7.00$, $c = 8.71$. *JLCM 44:99(1976)*. Found in lignite deposits in Cave Hills and Slim Buttes areas, Harding Co., SD; in granodiorite massif, *Russia*. *HCWS AM 14:7(1929)*.

40.2a.6.1 Sodium Uranospinite $(Na_2,Ca)(UO_2)_2(AsO_4)_2 \cdot 5H_2O$

Named in 1953 for the relationship to uranospinite and the composition. Autunite group. *TET P4/nmm*. $a = 7.12$, $c = 8.70$, $Z = 1$, $D = 3.80$. *AM 38:1159(1953)*. 28-1165(syn): 8.67_{10} 5.56_7 4.34_6 3.72_{10} 3.58_8 3.32_9 3.01_6 2.68_6 . See also 8-446(syn). Tablets up to 2 cm, radiating fibrous aggregates, square crystals pseudomorphic after meta-zeunerite. Lemon yellow to straw yellow; vitreous luster, pearly on {001}. Cleavage {001}, perfect; {100}, {010}, distinct. $H = 2\frac{1}{2}$. $G = 3.846$. DTA. Fluoresces light yellow-green, less bright in SWUV. Uniaxial (-); $N_O = 1.617$, $N_E = 1.586$. O, colorless; E, yellowish. May be anomalously biaxial. Synthesized: *AM 36:322(1951)*; $3.5 H_2O$: *JLCM 44:99(1976)*. Found in pitchblende-S deposits, unspecified locality *Russia*, associated with arsenopyrite, pyrite, galena, and meta-zeunerite. Sodium uranospinite is the most abundant secondary U mineral at this locality and may be replaced in part by uranophane. *HCWS AM 43:383(1958)*.

40.2a.7.1 Uramphite $(NH_4)_2(UO_2)_2(PO_4)_2 \cdot 6H_2O$

Named in 1957 for the composition. Autunite group. *TET P4/ncc*. $a = 7.02$, $c = 18.08$, $Z = 4$, $D = 3.26$. *NBS 93:557(1988)*. 42-384(syn): 9.08_{10} 5.56_2 4.35_{11} 3.80_5 3.51_2 3.28_2 2.78_3 2.16_2 . Square tablets up to 0.2 mm, rosettes, lichenlike. Bottle to pale green, vitreous luster. Cleavage distinct in two directions. $G = 3.7$. Fluoresces yellow-green. DTA. Anomalously biaxial (-); $N_x = 1.585$, $N_{y=z} = 1.564$. X, colorless; Y,Z, pale green. Soluble in 1:10 cold HCl. Synthesized. Occurs in the oxidized zone of U-coal deposits in fractures 20–30 m below the surface, *Russia*. *HCWS AM 44:464(1959)*.

40.2a.8.1 Meta-Ankoleite $K_2(UO_2)_2(PO_4)_2 \cdot 6H_2O$

Named in 1966 for the locality. Autunite group. *TET P4/nmm*. $a = 6.993$, $c = 8.891$, $Z = 1$, $D = 3.54$. *GSGB B25:49(1966)*. 19-1008: 8.92_{10} 5.47_4 4.93_5 4.32_4 3.73_7 3.49_5 3.25_6 2.95_3 . See also 29-1061(syn). Plates up to 1 mm. Yellow, translucent. Cleavage {001}, micaceous, perfect; {100}, distinct. Fluoresces yellow-green. $N_{av} = 1.580$. Synthesized ($3H_2O$): $a = 6.99$, $c = 8.89$. *JLCM 44:99(1976)*. Found in a beryl-bearing pegmatite (*Mungenyi*), Ankole district, *Uganda*, associated with muscovite and quartz; at Sebungwe district, *Zimbabwe*, associated with seriticized microcline in Karoo sandstones. *HCWS AM 52:560(1967)*.

40.2a.9.1 Abernathyite $K(UO_2)(AsO_4)_2 \cdot 3H_2O$

Named in 1956 for Jess Abernathy, operator of the mine where the mineral was found. Autunite group. TET $P4/ncc$. $a = 7.176$, $c = 18.126$, $Z = 4$, $D = 3.572$. Structure: *AM 49:1578(1964)*. $16-386$: 9.1_{10} 5.64_7 5.08_6 4.53_6 3.83_9 3.59_8 3.34_8 2.79_7 . Thick tablets up to 0.5 mm showing {100}, {110}. Yellow, vitreous luster. $H = 2-3$. $G = 3.32$. Uniaxial (-); $N_0 = 1.608$, $N_E = 1.570$. Found disseminated in uraniferous lignite in Lower Ludlow member, Fort Union formation, at Cave Hills and Slim Buttes, Harding Co., SD; at *Fuemrole mine No. 2, Temple Mt., Emery Co., UT*, associated with scorodite coating fractures in sandstone. *HCWS AM 41:82(1956)*.

40.2a.10.1 Novacekite $Mg(UO_2)_2(AsO_4)_2 \cdot 10$ or $12H_2O$

Named in 1951 for Radim Novacek (1905–1942), Czech mineralogist. Autunite group. Two hydrates known: both have been synthesized. See metanovacekite (40.2a.10.2). $12H_2O$ [I or 22 Å (syn)]: TET $P4_2/n$. $a = 14.30$, $c = 22.00$, $Z = 8$, $D = 3.13$. Anomalously biaxial (-); $N_x = 1.540$, $N_y = 1.570$, $N_z = 1.575$; $2V = 35-44^\circ$ (Grube Anton). $17-147$ (syn): 10.9_{10} 5.49_6 5.03_4 4.76_4 4.07_4 3.54_{10} 3.22_7 2.50_4 . $10H_2O$ (II or 20 Å): $P4_2/n$. $a = 7.16$, $c = 20.19$, $Z = 2$, $D = 3.28$. Anomalously biaxial (-); $N_x = 1.620$, $N_y = 1.637$, $N_z = 1.637$; $2V = 0-15^\circ$ (Schneeberg). $8-286$: 10.2_{10} 6.80_4 5.06_8 3.58_9 3.35_5 2.52_3 2.26_3 1.787_3 . But note synthetic $10H_2O$ [II or 20 Å (syn)]: TET $P4_2/n$. $a = 7.10$, $c = 20.01$. Biaxial (-); $N_x = 1.563$, $N_y = 1.591$, $N_z = 1.595$; $2V = 0-50^\circ$. $17-148$ (syn): 10.0_{10} 5.02_8 3.57_{10} 3.35_4 2.52_3 2.46_3 1.774_4 1.588_5 . Thick tablets showing {001}, rounded {h0l}, forming lamellar subparallel aggregates often intergrown with zeunerite. Light yellow, lemon yellow, greenish yellow; waxy luster; translucent. Cleavage {001}, perfect. $H = 2\frac{1}{2}$. $G = 3.25$. Fluoresces dull green. Found at Woodrow area, Laguna Res., Valencia Co., NM; at Twin Mt., Wichita Mts., near Quanah Parker Lake, Comanche Co., OK; at Aldama, CHIH, Mexico; at *Schneeberg, Saxony, Germany*, associated with zeunerite, uranophane, and a phosphatian novacekite ($a = 7.12$, $c = 20.14$, $N_{y=z} = 1.620-1.623$), and at Wittichen district, Heubachtal; crystals up to 2.5 cm at Pedra Preta(I), Brumado district, Bahia, Brazil. *HCWS AM 36:680(1951)*, *USGSB 1064:177(1958)*, *TMPM 9:111(1964)*.

40.2a.10.2 Meta-Novacekite $Mg(UO_2)_2(AsO_4)_2 \cdot 8H_2O$

Named for the relationship to novacekite I and II, being the third and lowest hydrate. Autunite group. TET $P4/n$. $a = 7.16$, $c = 8.58$, $Z = 1$, $D = 3.72$. *TMPM 9:111(1964)*. $17-152$: 8.52_{10} 4.29_5 3.57_9 3.02_4 2.53_5 2.27_4 2.14_6 1.791_5 . Rectangular plates flattened on {001}, aggregates of thin plates, crusts. Pale dull yellow, opaque. Cleavage {001}, perfect; also {010}, {110}. $H = 2\frac{1}{5}$. $G = 3.51$. DTA. Fluoresces dull green. Synthesized. Uniaxial (-); $N_0 = 1.632$, $N_E = 1.595$. Found at *Anton mine, Black Forest, Germany*; in Russia, and the localities listed under novacekite (40.2a.10.1). *HCWS JLBW 3:17(1958)*, *ZVMO 103:606(1974)*.

40.2a.11.1 Saleeite $Mg(UO_2)_2(PO_4)_2 \cdot 10H_2O$

Named for Achille Salée (1883–1932), mineralogist, Université Louvain, Belgium. Autunite group. Meta-saleeite ($8H_2O$) has been described, novacekite is the As end member. *MON* $P2_1/n$. $a = 6.951$, $b = 19.947$, $c = 9.896$, $\beta = 135.17^\circ$, $Z = 2$, $D = 3.12$ *BM 103:630(1980)*. Structure: *ZK 177:247(1986)*. $8-313$: 9.85_{10} 4.95_8 4.51_4 3.49_9 3.23_5 2.95_5 2.45_6 2.19_7 . See also $29-874(\text{syn}) = 9H_2O$: $P4/nmm$. $a = 7.047$, $c = 19.652$. $G = 3.20$. *JLCM 44:99(1976)*. Thin rectangular tablets flattened on $\{001\}$; interleaved coherently to form porous aggregates with subparallel growth; oriented parallel growth with torbernite. Pale canary yellow, lemon- or straw-yellow; transparent, translucent when partially dehydrated. Cleavage $\{001\}$, perfect; $\{010\}$, $\{110\}$, indistinct. $H = 2-3$. $G = 3.27$. Fluoresces yellow-green. Biaxial (-); $N_x = 1.559$, $N_y = 1.570$, $N_z = 1.574$ (Katanga); $2V = 61$; $r > v$, strong. O, pale greenish yellow; E, colorless. Uniaxial (-); $N_O = 1.574$, $N_E = 1.559$ (Schneeberg). Crystals show division into two or four sectors with $Z = c$ and Y perpendicular to the edge of the plate in each sector. Meta-saleeite ($8H_2O$): *TET P4/mmm*. $a = 7.22$, $c = 17.73$, $Z = 2$, $D = 3.23$. $41-389$: 8.84_{10} 6.32_4 4.55_6 4.43_4 3.78_3 3.57_4 3.35_5 3.28_3 . Yellow-green. Uniaxial (-); $N_O = 1.572$, $N_E = 1.562$ (Urucum, MG, Brazil). Found disseminated in carnotite-bearing sandstone Gull Mine, Fall River Co., and in lignite at Cave Hills and Slim Buttes, Harding Co., SD; at Sue Mine, Gila Co., AZ; at Mina da Quinta, Sabugal, Portugal (arsenic free); at Villaviejabe, Spain; found with uranophane and zeunerite at Schneeberg, Germany (contains arsenic); at *Shinkolobwe(1)*, *Shaba, Zaire*, with torbernite and dewindite; at Rum Jungle(1), Australia; at Lavra do Enio, Galileio, MG, Brazil. *HCWS DII:988*; *USGSB 1036:130(1956)*, *1064:177(1958)*.

40.2a.12.1 Seelite $Mg[UO_2(AsO_3)_x(AsO_4)_{1-x}]_2 \cdot 7H_2O$

Named in 1993 for mineral collectors Paul (1904–1982) and Hilde (1901–1987) Seel of Belgium. *MON C2/m*. $a = 18.207$, $b = 7.062$, $c = 6.661$, $\beta = 99.65^\circ$, $Z = 2$, $D = 3.60$ (Talmessi). *MR 24:463(1993)*. Structure: *AC(C) 47:2013(1991)*. Used to partition As^{3+} , As^{5+} . *AM 78:453(1993)*. *PD*: 9.05_{10} 4.85_5 4.44_8 3.99_5 3.52_6 1.92_8 . (Talmessi). Tufted spherules, rosettes of bright yellow tabular crystals; elongate $[010]$, flattened on (100) showing $\{100\}$, $\{001\}$ prism faces terminated by $\{010\}$ or $\{011\}$, $\{011\}$. Colorless streak, vitreous luster, transparent, irregular fracture. $H = 3$. $G = 3.70$. Nonfluorescent. Biaxial (-); $N_x = 1.602$ parallel to a (colorless), $N_y = 1.610$ parallel to b (yellow), $N_z = 1.753$ parallel to c (yellow), $2V_{\text{meas}} = 41^\circ$, $OAP(010) Z:c = 5^\circ$ extreme $r > v$, strongly pleochroic (Talmessi). $N_x = 1.610$, $N_y = 1.730$, $N_z = 1.740$, $2V_{\text{meas}} = 30^\circ$ (Rabejac). Found in the oxidation zones of *Talmessi mine*, 35 km W of Amarak, central Iran, and in the *Rabejac uranium deposit*, 7 km SSE of Lodeve, Hérault, France. *HCWS AM 79:1012(1994)*.

40.2a.13.1 Torbernite $\text{Cu}(\text{UO}_2)_2(\text{PO}_4)_2 \cdot 11\text{H}_2\text{O}$

Named in 1793 for Torbern Olaf Bergmann (1735–1784), Swedish chemist and mineralogist. Autunite group. See meta-torbernite (40.2a.13.2), the lower hydrate ($8\text{H}_2\text{O}$). TET $I4/mmm$. $a = 7.06$, $c = 20.5$, $Z = 2$, $D = 3.16$. *USGSB 1036:138(1956)*, *AM 42:905(1957)*. $8-360(\text{syn})$: 10.3_{10} 6.61_4 5.18_3 4.94_9 4.48_4 3.67_4 3.58_9 3.51_8 . Thin to thick tabular {001} usually square in outline, rarely pyramidal, subparallel growth common; foliated, micaceous, or scaly aggregates. Twinning on {100} rare. Parallel growth with autunite, uranospathe, zeunerite, and bassetite. Emerald to grass-green, leek-green, apple-green, or siskin-green; streak paler than color; vitreous to subadamantine luster, pearly on {001}; transparent to translucent. Cleavage {001}, perfect, micaceous; {100}, indistinct; brittle lamellae. $H = 2-2\frac{1}{2}$. $G = 3.22$. Nonfluorescent. Uniaxial (-); $N_O = 1.592$, $N_E = 1.582$. O, green; E, blue. Some As substitutes for P; Pb for Cu; very minor amounts of V, Ba, Mn detected on analysis. H_2O content varies with humidity and temperature. Torbernite deposited from aqueous solutions up to $\approx 75^\circ$, above that temperature the phase is meta-torbernite. Soluble in acids. Secondary mineral associated with autunite and other uranium minerals as an oxidation product of uraninite in gossans that also contain Cu-sulfide minerals. Found at Haddam Neck, CT, as an alteration product of uraninite in a pegmatite; in other New England pegmatites usually in association with autunite; at Spruce Pine, Mitchell Co., NC; at Hannibal mine, Terry, Lawrence Co., near Keystone, Pennington Co., SD; in the La Sal Mts., San Juan Co., and in the plateau carnotite-bearing sandstones of UT and CO; in NM in the White Signal district, Grant Co., and the San Lorenzo district, Socorro Co., NM; in Sonora, Mexico. Occurs widely at mines at Redruth, St. Austell, St. Just, St. Agnes, Cornwall(II), England; at Vizeu and Sabugal, Portugal; in Cacères Prov., Estramadura, Spain; at Cap Garonne and in the Puy de Dome district, France; at Schlaggenwald and Zinnwald, Johanngeorgenstadt and Schneeberg, Saxony, Germany; with pitchblende in vein deposits at *Joachimsthal*, *Zapadocesky Kraj*, *Bohemia*, *Czech Republic*; at Totimoto, Tamura Co., Hukusima Pref., Japan; at Kasolo, Shinkolobwe, and elsewhere in the Shaba district(I), Zaire; at Mt. Painter, Flinders Ranges, SA, Australia. *HCWS DII:981*, *USGSB 1064:170(1958)*.

40.2a.13.2 Meta-Torbernite $\text{Cu}(\text{UO}_2)_2(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1916 for the relationship to torbernite, being the lower and more stable hydrate. Autunite group. TET $P4/n$. $a = 6.969$, $c = 17.306$, $Z = 2$, $D = 3.70$. Structure: *AM 49:1603(1964)*. $36-406$: 8.66_{10} 5.43_2 4.93_2 3.68_7 3.48_2 3.23_1 2.67_1 2.17_1 . See also *16-404*. Tablets on {001}, rosettes or sheaflike aggregates of irregularly curved and composite crystals. Pale to dark green; vitreous, subadamantine luster, pearly on {001}; transparent to translucent. Cleavage {001}, perfect; brittle. $H = 2\frac{1}{2}$. $G = 3.70$. Nonfluorescent. Uniaxial (+); $N_O = 1.624$, $N_E = 1.626$; occasionally biaxial with small $2V$. O, green; E, blue. Stable phase precipitated from solutions above 75° . Soluble in acids. Synthesized. Secondary, and probably also a hydrothermal, mineral at Spruce

Pine, NC; with copper-uranium deposits in Colorado Plateau, and in uraniferous lignite at North Cave Hills, Harding Co., SD; in the San Rafael Swell, UT; in quartzite, in Wilson Creek area, Gila Co., and at Silver Bell mine, AZ; at Nicholson mine, Lake Athabasca, SAS, and at Wilberforce, ONT, Canada; at Luz del Cobra mine, San Antonio de la Huerta, SON, Mexico; at Anyiar, Spain; at Gunnis Lake mine, Calstock(!), and at Wheal Basset, Cornwall, England; at Puy de Dome and Aveyron Margabel, France; at Krinkelbachtel, Menzenschwand, and Erzgebirge, Saxony, and in the Black Forest, Germany; in Bohemia, Czech Republic; in the Piedmont of Italy at Lurisia; in the Shaba district(!), Musoni mine and Shinkolobwe, Zaire; at Chuquicamata, Antofagasta, Chile. hcws *DII:991*.

40.2a.14.1 Zeunerite $\text{Cu}(\text{UO}_2)_2(\text{AsO}_4)_2 \cdot 10\text{--}16\text{H}_2\text{O}$

Named in 1872 for Gustav Anton Zeuner (1828–1907), German physicist, director, School of Mines, Freiberg, Germany. Autunite group. TET $P4/nnc$. $a = 7.18$, $c = 21.06$, $Z = 2$, $D = 3.40$. *TMPM* 9:111(1964). 17-150: 10.3₁₀ 5.20₇ 4.98₅ 3.59₁₀ 2.39₅ 2.08₆ 1.924₆ 1.794₅. See also 4-90(syn). Rectangular tablets {001}. Pale to emerald green, transparent. $G = 3.39$. Nonfluorescent. Uniaxial (-); $N_O = 1.615$, $N_E = 1.586$. Variable water content. At 65° in air zeunerite transforms to meta-zeunerite with 8H₂O. Synthesized. Found at Centennial Eureka mine, Tintic district, and Dexter Mine, Calf Mesa, San Raphael Swell, UT; at Grandview mine, Coconino Co., AZ; at Anton mine, Black Forest, and the *Weisser Hirsch mine*, *Neustadtel*, *Schneeberg*, *Saxony*, *Germany*; at Miyosi mine, Kurasaki Co., Okayavaa Pref., Japan; at Prada Preta(!), Brumado, BA, Brazil, in crystals to 4 cm, and at other localities listed under meta-zeunerite. hcws *AM* 42:905(1957), *DII:989*.

40.2a.14.2 Meta-Zeunerite $\text{Cu}(\text{UO}_2)_2(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1937 for the relationship to zeunerite, being the lower hydrate. Autunite group. TET $P4_2/n$. $a = 7.12$, $c = 17.45$, $Z = 2$, $D = 3.85$. Structure: *AM* 49:1619(1964). See also *CJP(B)* 10:169(1960). 17-146: 8.86₁₀ 5.57₈ 5.10₆ 3.73₁₀ 3.57₇ 3.30₈ 2.98₄ 1.561₆. Tabular {001}, resembling torbernite; scaly; acute pyramidal. Forms other than {001} are striated, rough. Oriented growth parallel to axes with trogerite, uranospinite; overgrowths with meta-uranocircite. Grass- to emerald-green; vitreous luster, pearly on {001}. Cleavage {001}, perfect; {100}, distinct; uneven fracture; brittle. $H = 2\text{--}2\frac{1}{2}$. $G = 3.64$. Fluoresces yellow green. Uniaxial (-); $N_O = 1.643$, $N_E = 1.623$ (Schneeberg). O, grass-green; E, pale green. Indices vary with H₂O content. Easily soluble in acids. Does not convert to zeunerite when placed in H₂O. Synthesized. Found disseminated in uraniferous lignite in the Cave Hills and Slim Buttes areas, Harding Co., SD; with other secondary uranium minerals (i.e., torbernite, trogerite, uranospinite, walpurgite) and with erythrite and mimetite in sandstone uranium deposits of Colorado Plateau and especially at the Centennial Eureka mine, Tintic district, UT; at Grandview mine, AZ; at the Myler mine(!), Majuba Hill, Pershing Co., NV; at the Nicholson mines, Lake Atha-

basca, SAS, Canada; at Wheal Garland, Cornwall, England; with chalcophyllite, olivenite, pharmacosiderite at Cap Garonne, Var, France; at the Anton mine, Black Forest, Baden, and *Weisser Hirsch mine, Schneeberg, Saxony, Germany*, and at Joachimstal and Zinnwald, Bohemia, Czech Republic; at Cala Māstra, Island of Monte Cristo, Italy; at Baly Lo copper mine, Ashburton Downs, WA, Australia; in crystals to 3.5 cm at Pedra Preta pit(II), Brumado, Bahia, Brazil. *HCWS DII:993, USGSB 1064:215(1958), TMPM 9:111(1964)*.

40.2a.15.1 Kahlerite $\text{Fe}^{2+}(\text{UO}_2)_2(\text{AsO}_4)_2 \cdot 10\text{-}12\text{H}_2\text{O}$

Named in 1953 for Franz Kahler, geologist, with Carinthian Landesmuseum, Klagenfurt, Austria. Autunite group. TET $P4_2/n$. $a = 14.30$, $c = 21.97$, $Z = 8$, $D = 3.22$. *17-145(syn)*: 11.1₈ 5.55₅ 3.59₅ 3.53₁₀ 3.20₂ 2.53₂ 1.763₃ 1.603₄. Tabular to 2 mm showing (111), (021), (012), (011), (010). Lemon yellow, translucent. Basal cleavage. Anomalously biaxial; $N_x = 1.632$, $N_z = 1.634$; $2V = 9\text{-}33^\circ$. Found at Sophie mine, Wittichen, Germany, and at *Hüttenberg, Carinthia, Karnten, Austria*, in siderite deposit. *HCWS AM 39:1038(1954), TMPM 9:111(1964)*.

40.2a.15.2 Meta-Kahlerite $\text{Fe}^{2+}(\text{UO}_2)_2(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1964 for the relationship to kahlerite (40.2a.15.1), being the lower hydrate. Autunite group. TET $P4/nmm$. $a = 7.16$, $c = 8.62$, $Z = 1$, $D = 3.83$. *TMPM 9:111(1964)*. Synthetic: space group uncertain, probably $P4_2$. $a = 20.25$, $c = 17.20$, $Z = 16$, $D = 3.77$. *AM 71:1037(1986)*. *17-151*: 8.86₁₀ 5.07₄ 3.59₁₀ 3.03₄ 2.54₆ 2.28₆ 1.788₆ 1.608₇. See also *12-576*. Scales. Sulfur-yellow, translucent. Cleavage {001}, perfect; {100}, good. $G = 3.77$. Nonfluorescent. DTA, TGA, IR, Mossbauer. Anomalously biaxial; $N_x = 1.642$, $N_z = 1.608$; $2V$ up to 22° . X, pale yellow; Z, colorless. Both the Fe^{2+} and the Mn^{2+} end members have been synthesized as has a fully oxidized (Fe^{3+}) form (*P1* or *P1*; $a = 7.44$, $b = 9.94$, $c = 7.37$, $\alpha = 94.7^\circ$, $\beta = 102.7^\circ$, $\gamma = 90.3^\circ$, $Z = 16$, $D = 3.18$; $G = 3.19$). Found in the siderite deposit of Hüttenberg, Karnten, Austria; at *Sophia mine, Wittichen, Baden, Black Forest, Germany*. *HCWS AM 45:254(1960)*.

40.2a.16.1 Bassetite $\text{Fe}^{2+}(\text{UO}_2)_2(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1915 for the locality. Autunite group. MON $P2_1/m$. $a = 6.98$, $b = 17.07$, $c = 7.01$, $\beta = 90.5^\circ$, $Z = 2$, $D = 3.66$ (Basset). *MM 30:343(1954)*, *AM 69:967(1984)(syn)*. *7-288*: 8.59₆ 4.89₁₀ 4.24₃ 4.05₃ 3.46₁₀ 2.96₃ 2.85₂ 2.20₆. Fanlike or chessboardlike groupings of thin tablets with almost rectangular outline, flattened on {010}. Often twinned with two or more individuals arranged at 90° with {010} in common. {001} of one individual is parallel to {100} of the other with {010} the contact surface in some, and {110} against {011} in others. Yellow, transparent. Cleavage {010}, perfect; {100}, {001}, distinct. $G = 3.10$. Nonfluorescent. Mossbauer. Biaxial (-); $X = b$, $Z \wedge c = -4^\circ$; natural with low H_2O : $N_x = 1.603$, $N_y = 1.610$, $N_z = 1.617$,

$2V = 90^\circ$; synthetic: $N_x \approx 1.561$, $N_y = 1.574$, $N_z = 1.580$ (Na); $2V \approx 62^\circ$. X, pale yellow; Y,Z, deep yellow. Loses H_2O at RT with the plates breaking into four sectors with axial planes at right angles; indices of refraction and extinction angles increase to $\approx 20^\circ$. Soluble in acids. Synthesized, as has a fully oxidized (Fe^{3+}) bassetite (MON $a = 6.958$, $b = 6.943$, $c = 21.052$, $\beta = 90.92^\circ$, $Z = 2$; $G = 3.00$). Found at Fuemrol mines, Temple Mt., and Denise mine, Green River, Emery Co., UT; in the uranium-bearing quartzites of Dripping Springs, Gila Co., AZ; at the *Wheal Basset mine, Redruth, Cornwall, England*, as oriented growths with uranospathite, torbernite in pyrite-uraninite vein; at LaCrouzille, Puy de Dome, France. HCWS *DII:994*.

40.2a.16.2 Lehnerite $Mn^{2+}(UO_2)_2(PO_4)_2 \cdot 8H_2O$

Named in 1988 (reviving a name that was used in 1925 for a mineral subsequently named ludlamite) for Ferdinand Lehner (1868–1943), mineral collector of Hagendorf minerals from Pleystein, Bavaria, Germany. Autunite group. Mn^{2+} analog of bassetite (40.2a.16.1); see also fritzschite (40.2a.25.1), a manganese vanadate. MON $P2_1/n$. $a = 7.04$, $b = 17.16$, $c = 6.95$, $\beta = 90.18^\circ$, $Z = 2$, $D = 3.717$. *AUF 39:209(1988)*. *PD*: 8.56₁₀ 4.96₆ 3.50₈ 2.48₃ 2.23₇ 2.17₃ 1.746₃ 1.375₄. Pseudotetragonal prisms up to 1 mm, platy along (010) with layers perpendicular to [010], show in addition {001}, {100}, {101}, {101}. Yellow, bronze-yellow; whitish yellow streak; glassy to nacreous luster. Cleavage {010}, perfect; {101}, {101}, {100}, less perfect. $H = 2-3$. $G = 3.5$. Nonfluorescent. Biaxial (-); $X = b$; $Y \wedge a = 8-10^\circ$, $Z \wedge c = 8-19^\circ$; $N_x = 1.599$, $N_y = 1.607$, $N_z = 1.607$ (589 nm); $2V = 45^\circ$; $r > v$, strong; pleochroic, shades of yellow with Z darker than Y. Some zoning noted with extinction more oblique on outer edges of crystals, intermediate zones may be uniaxial, probably the result of variable H_2O content. Found at *Hagendorf-Süd pegmatite, Oberpfalz, Bavaria, Germany*, associated with decomposed zwieselite, corroded rockbridgeite on the 67-m level. HCWS *AM 75:221(1990)*, *75:1433(1990)*.

40.2a.17.1 Meta-Kirchheimerite $Co(UO_2)_2(AsO_4)_2 \cdot 8H_2O$

Named in 1958 for Franz Waldemar Kirchheimer (b.1911), director, Geologisches Landesamt für Württemberg-Baden, Germany. Autunite group. *TET P4/nmm*. $a = 7.17$, $c = 17.36$, $Z = 2$, $D = 3.80$. *JGLBW 3:17(1958)*. *12-586*: 8.78₁₀ 5.08₆ 4.30₆ 3.57₁₀ 3.42₅ 3.01₆ 2.52₅ 2.26₄. Crusts and tabular crystals. Pale rose, transparent. Cleavage {001}, perfect, pearly luster. $H = 2-2\frac{1}{2}$. $G = 3.33$. Uniaxial (-); $N_O = 1.644$, $N_E = 1.617$. Anomalously biaxial; Synthesized: $P4_2/m$; $a = 6.979$, $b = 16.93$. *BM 100:272(1977)*. Found at *Sophia mine, Wittichen, Black Forest, Germany*, on pitchblende. HCWS *AM 44:466(1959)*, *TMPM 9:111(1964)*.

40.2a.18.1 Meta-Lodevite $Zn(UO_2)_2(AsO_4)_2 \cdot 10H_2O$

Named in 1972 for the locality. Autunite group. *TET P4₂/n*. $a = 7.16$, $c = 17.20$, $Z = 2$, $D = 4.01$. *BM 95:360(1972)*. *25-1239*: 8.66₇ 5.09₄ 3.59₁₀

3.50₃ 2.98₆ 2.55₃ 2.29₃ 2.17₃. Crystals to 0.2 mm flattened on (001), striated parallel to [100]; aggregates. Pale yellow, vitreous luster, transparent. Cleavage {001}. Fluoresces feebly yellow-green. Anomalously biaxial (-); $N_x = 1.638$, $N_y = 1.635$, $N_z = 1.615$; $2V = 27-37^\circ$. X, Y, pale yellow; Z, brownish. Shows inclusions of pitchblende. Found at *Lodeve, Hérault*, and at *St. Martin du Bosc, France*. HCWS

40.2a.19.1 Chernikovite $(H_3O)_2(UO_2)_2(PO_4)_2 \cdot 6H_2O$

Named in 1988 for A. P. Chernikov (b.1927), Institute of Mineralogy, Geochemistry, and Rare Elements, Moscow. Autunite group. Previously synthesized [AM 40:917(1955)] and named hydrogen-autunite. TET $P4/nmm$. $a = 7.020$, $c = 9.043$, $Z = 1$, $D = 3.27$. 8-296(syn): 9.03₁₀ 5.56₅ 3.80₉ 3.51₇ 3.27₈ 2.96₆ 2.77₇ 2.16₅. See also 29-670. $4H_2O$ form, a material with high degree of proton conductivity. MRB 12:701(1977), Structure: AC(B) 34:3732(1978). Micaceous plates elongated on [010], synthetics have square or octagonal outline. Pale lemon yellow, vitreous luster, transparent. Cleavage {001}, perfect; {100}, distinct. $G_{syn} = 3.40$; Russian samples, $G = 3.259$. Fluoresces intense yellow-green. Uniaxial (-); $N_{O_{syn}} = 1.579$, $N_{E_{syn}} = 1.568$; slightly pleochroic. Synthesized from schoepite; easily transformed into parsonsite. NJMM:551(1991). Found in two localities in *Russia*; at *Perus, SP, Brazil*. HCWS MR 19:249(1988).

40.2a.20.1 Trögerite $H_2(UO_2)_2(AsO_4)_2 \cdot 8H_2O(?)$

Named in 1871 for R. Tröger, mining official at Schneeberg, Germany. Autunite group. TET $P4/nmm$. $a = 7.16$, $c = 8.80$, $Z = 1$, $D = 3.55$ (see below). 8-326(syn): 8.59₁₀ 5.50₇ 4.35₇ 3.79₉ 3.30₈ 2.70₇ 2.19₇ 2.01₇. Thin elongate tabular {001}; nonpinacoidal forms asymmetrically developed (implies monoclinic symmetry). {001} often composite and uneven, other faces small and horizontally striated; subparallel aggregates. Lemon yellow, pearly luster on {001}. Cleavage {001}, perfect, micaceous; {100}, good; also {011}. $H = 2-3$. $G = 3.55$. IR. Natural reported to be nonfluorescent. Zeunerite commonly found in parallel overgrowths with trögerite. Uniaxial (-); $N_{O_{nat}} = 1.585$, $N_{E_{nat}} = 1.630$; $N_{O_{syn}} = 1.580$, $N_{E_{syn}} = 1.620-1.624$. DANS 197:109(1971). Anomalously biaxial (-); $X = c$; $Z \wedge a = 12^\circ$; $N_x = 1.585$, $N_y = 1.624$, $N_z = 1.630$; $2V$ very small. AM 36:322(1951), 38:1159(1953). Soluble in acids. Composition close to synthetic hydrogen uranospinite, $H_2(UO_2)_2(AsO_4)_2 \cdot 10H_2O$ [DII:967, DANS 197:109(1971)], which forms as tabular, square-outline crystals that fluoresce bright lemon-green. Synthetic studies show a reversible, nonquenchable, phase transition $\approx 25^\circ$ (not dehydration) to lower symmetry (pseudotetragonal), resulting in the formation of domains with polysynthetic rectilinear twinning. AM 59:763(1974). Found at Bald Mt. district, Pennington Co., SD; with walpurgite and zeunerite in the *Walpurgis vein of the Weisser Hirsch mine, Neustadt, Schneeberg, Saxony, Germany*. HCWS DII:966.

40.2a.21.1 Przhevalskite $\text{Pb}(\text{UO}_2)_2(\text{PO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1946 for Nikolai M. Przhevalsky (1839–1888), Russian explorer. ORTH (possibly TET) $a = 7.24$, $c = 18.22$, $Z = 2$, $D = 3.38$. *AM* 43:381(1958). 29-787(syn): 9.49₅ 9.08₉ 3.61₁₀ 2.63₅ 1.960₅ 1.619₆ 1.530₆ 1.349₅. Foliated aggregates of tabular crystals to 1 mm. Bright yellow with greenish tinge; adamantine luster, pearly on cleavage {001}. Biaxial (-); $N_x = 1.739$, $N_y = 1.749$, $N_z = 1.752$; $2V \approx 30^\circ$; parallel extinction; positive elongation. X, colorless; Y, pale yellow; Z, deep yellow. Soluble in acids. Both Si and Al in analysis. Synthesized. Found in the oxidation zone of a pitchblende-sulfide deposit with torbernite, autunite, uranospinite, and hydrated iron oxides in *Russia*. *HCWS AM* 41:816(1956).

40.2a.22.1 Uranospathite $\text{HAl}(\text{UO}_2)_4(\text{PO}_4)_4 \cdot 40\text{H}_2\text{O}$

Named in 1915 for the composition and from the Greek for a *broad blade*, in allusion to the crystal habit. Autunite group. See also arsenuranospathite (40.2a.23.1). TET $P4_2/n$. $a = 7.00$, $c = 30.03$, $Z = 1$, $D = 2.49$. *MM* 42:117(1978). 31-587: 15.22₁₀ 7.60₁₀ 4.93₁₀ 4.48₆ 4.08₄ 3.50₈ 3.43₄ 2.21₆. Fan-like groups of rectangular plates and laths flattened {001}, striated parallel to elongation {010}; fibrous. Sometimes twinned on {110}, in cruciform groups. Yellow to pale green, translucent. Cleavage {001}, perfect; {100}, good; {010}, doubtful. $H = 2\frac{1}{2}$. $G = 2.50$. Fluoresces yellow-green. Anomalously biaxial (-); $N_x \approx 1.492$, $N_y = 1.511$, $N_z = 1.521$ (Na); $2V = 76^\circ$. Loses water at RT and nonhumid conditions, or in desiccator, converting to a lower hydrate that is identical with sabugalite (40.2a.24.1). Soluble in acids. Forms oriented growths with bassetite. Found at *Basset mine, Redruth, Cornwall, England*; at *Menzenschwand, Black Forest, Germany*. *HCWS DII:990*, *MM* 30:343(1954), *USGSB* 1064:194(1958), *AM* 64:465(1979).

40.2a.23.1 Arsenuranospathite $\text{HAl}(\text{UO}_2)_4(\text{AsO}_4)_4 \cdot 40\text{H}_2\text{O}$

Named for its relationship to uranospathite (40.2a.22.1) being the arsenic analog. Autunite group. TET Space group uncertain, probably $P4_2/n$. $a = 7.16$, $c = 30.37$, $Z = 1$, $D = 2.54$. *MM* 42:117(1978). 31-586: 14.6₁₀ 7.62₁₀ 5.03₈ 3.59₆ 3.49₉ 3.24₄ 2.48₂ 2.25₈. Lathlike or wedge-shaped crystals showing {100}, {010}, {110}, {001}, orthorhombic habit. White to pale yellow, translucent. Cleavage {001}, perfect; {100}, {010}, good. $H = 2$. Fluoresces greenish. Anomalously biaxial (-); $N_x = 1.538$, $N_z = 1.542$; $2V = -52^\circ$; $r > v$; straight extinction; length positive. Converts under normal room-temperature conditions to hydrate with half amount of H_2O ; a 32 H_2O phase ($a = 7.15$, $c = 20.5$, $Z = 2$, $D = 3.20$; $N_x = 1.564$, $N_y = 1.594$, $N_z = 1.596$; $2V \approx 28^\circ$; $r > v$; X, colorless; Y,Z, yellow) has been synthesized. Found at *Sophia mine, Menzenschwand, Black Forest*, and at *Wittichen, Germany*. *HCWS AM* 64:465(1979).

40.2a.24.1 Sabugalite $\text{HAl}(\text{UO}_2)_4(\text{PO}_4)_4 \cdot 16\text{H}_2\text{O}$

Named in 1951 for the locality. Autunite group, but see uranospathite (40.2a.22.1). This mineral may be "meta-uranospathite." *MON* Space group uncertain, probably $C2/m$. $a = 19.426$, $b = 9.843$, $c = 9.850$, $\beta = 96.16^\circ$, $Z = 2$, $D = 3.150$. *PCM 9:23(1983)*. Pseudotetragonal, probably isostructural with fully hydrated autunite. *39-313(syn)*: 9.63₁₀ 4.86₈ 4.55₅ 4.40₅ 3.47₉ 3.36₇ 2.45₄ 2.18₅. See also 5-107. Crusts of minute plates to 1 mm square or rectangular in shape. Yellow, translucent. Cleavage {001}. $H = 2\frac{1}{2}$. $G = 3.20$. Fluoresces bright lemon yellow in UV. IR, TGA, zeta potential. Biaxial; $N_x = 1.564$, $N_y = 1.581$, $N_z = 1.582$; $2V = 0^\circ$ to moderate. *AM 36:671(1951)*. Found in sandstone-type uranium deposits at Huskon, Arrow Head claims, near Cameron, AZ; at Happy Jack mine, White canyon, San Juan Co., UT; at Lucky Mc No. 20 mine, and in Blarco group, Fremont Co., and several claims in Johnson Co. and Crook Co., WY; at Margnac II, Haute Vienne, France; associated with meta-autunite, saleeite, phosphuranylite, milky quartz, and feldspars at *Mina de Quarta Feira, Guarda district, Sabugal, Beira Alta Prov., Portugal*, and at Kariz, Minho Parish, and at Mina de Coitos, Bandada Parish; at Pedro Alvaro, Salamanca, Spain; at Corrego Frio mine, MG, Brazil. *HCWS USGSB 1064:196(1958)*, *BGSC 60:285(1985)*.

CARNOTITE GROUP

The carnotite minerals are uranium-vandates that are chemically similar to the autunite group minerals but have a distinctive structure. They conform to the chemical formula:

The structure is layered and consists of sheets of divanadate groups (V_2O_8) composed of two pyramids (V^{5+} surrounded by 5 oxygens) joined at a common edge, and linear UO_2 groups whose axis, as in the autunite group minerals, is perpendicular to the extension of the anion group. These puckered sheets have a composition $[(\text{UO}_2)_2\text{V}_2\text{O}_8]$. Cation and water molecules occur in layers between the $[(\text{UO}_2)_2\text{V}_2\text{O}_8]$ sheets with the possibility that different hydrates are stable *Adv. ucl. End. 2:294 (1954)*. The parallelism with the autunite group is evidenced in the two species tyuyamunite, meta-tyuyamunite which have identical cation composition but are different hydrates.

CARNOTITE: $K_2(UO_2)_2(V_2O_8)_2 \cdot 1-3H_2O$

The puckered uranyl-varadate sheets effectively perpendicular to the c axis are linked through K, H_2O layers. The water content is variable. Compare autunite (40.2a.1.1).

CARNOTITE GROUP

Mineral	Formula	Space Group	a	b	c	β	
Fritzscheite	$Mn^{2+}(UO_2)_2V_2O_8 \cdot 4H_2O$	<i>Pnam</i>	10.59	8.25	15.54		40.2a.25.1

40.2a.25.1 Fritzscheite $Mn^{2+}(UO_2)_2V_2O_8 \cdot 4H_2O$

Named in 1865 for Karl Julius Fritzsche (1808–1871), German chemist. Carnotite group. ORTH *Pnam*. $a = 10.59$, $b = 8.25$, $c = 15.54$, $Z = 4$, $D = 4.39$. *BM* 93:320(1970). 23-1249(syn): 7.77₁₀ 6.52₈ 5.30₈ 4.13₉ 3.88₈ 3.65₈ 3.25₁₀ 3.00₁₀. Rectangular plates with {001} cleavage. Red-brown to hyacinth-red, vitreous to pearly luster, transparent. $H = 2-3$. Found at Autun, France; at Neuhammer, near Neudeck, Bohemia, Czech Republic; and at Steinig and *Georg Wagsfort mine, Johanngeorgenstadt, Saxony, Germany*. *HCWS DII:984*.

40.2a.26.1 Tyuyamunite $Ca(UO_2)_2V_2O_8 \cdot 5-8H_2O$

Named in 1912 for the locality. Carnotite group. ORTH *Pnna*. $a = 10.63$, $b = 8.36$, $c = 20.48$, $Z = 4$, $D = 3.4$. *AM* 39:323(1954), 41:187(1956). 6-17: 10.2₁₀ 6.62₃ 5.02₉ 4.02₂ 3.37₃ 3.20₅ 3.12₃ 2.04₄. Scales and laths flattened {001}, elongated {001}, radial aggregates. Crystal faces dull, often curved. Massive, compact to cryptocrystalline, pulverulent. Canary yellow, lemon yellow to greenish yellow; crystals adamantine pearly on {001}, massive material waxy; transparent to opaque. Cleavage {001}, perfect, micaceous; {010}, {100}, distinct; not brittle; cakes on grinding. $H \approx 2$. $G = 3.6$. DTA. Biaxial (+); $XYZ = cba$; $N_x = 1.72$, $N_y = 1.868$, $N_z = 1.953$. (Henry Mts., UT); $2V = 48^\circ$; higher indices with dehydration; $r < v$, weak. X, colorless; Y, pale canary yellow; Z, canary yellow. Some K detected in natural samples on analysis. Insoluble in 1:10 acetic acid, soluble in HCl, HNO₃, and H₂SO₄. Synthesized via substitution of Ca for K in carnotite. Found in carnotite-bearing district of the western United States, notably at Paradox Valley, Montrose Co., and at Thompson's, Grand Co., CO; at Hudspeth Co., TX; at Richardson, NW side of La Sal Mts., the Henry Mts., Garfield Co., Red Creek, Browns Park, Uinta Co., UT, often as fine-grained aggregates with fossil wood in sandstone associated with carnotite; also at Bisbee, AZ; at *Tyuya Muyun on Aravan R., 65 km SE of Fedchenko, Ferghana, Uzbekistan*, as veinlets or disseminated in limestone, in the karst caverns associated with malachite, turanite, barite, calcite, and other V minerals. *HCWS DII:1045; USGSB 1009-B(1954), 1064:248(1958)*.

40.2a.26.2 Meta-Tyuyamunite $Ca(UO_2)_2V_2O_8 \cdot 3-5H_2O$

Named in 1950 for its relationship as the lower hydrates of tyuyamunite. Carnotite group. ORTH *Pnam*. $a = 10.63$, $b = 8.36$, $c = 16.96$ ($\approx 4.5H_2O$), $Z = 4$, $D = 4.04$. (May Day mine, CO). *AM* 41:187(1956). 43-1457: 8.41₁₀ 4.20₄ 3.75₂ 3.29₃ 3.26₃ 3.06₂ 3.03₃ 2.58₄. See also 8-287. Pulverulent masses; disseminated in sandstone, limestone mixed with carnotite; radial aggregates to 3 mm on gypsum. Canary yellow, greenish yellow; adamantine luster. Cleavage {010}, {100}, distinct; not brittle. $G = 3.8-4.0$. Biaxial (-); $N_x = 1.62$, $N_y = 1.842$, $N_z = 1.899$ (May Day mine, Mesa Co., CO); X perpendicular to plate; $2V = 45^\circ$; $r < v$. X, colorless; Y, very pale canary yellow; Z, pale canary yellow. Found at over 35 localities in the Colorado Plateau area, often with carnotite and tyuyamunite, such as at the *Jo Dandy mine*,

Montrose Co., CO, Mayday or Small Spot mines, Mesa Co.; in the Shiprock and Grants districts, NM, and at other localities worldwide with tyuyamunite (40.2a.26.1). Unaltered samples of uranium minerals are good candidates for estimating the age of rocks: U–Ra analyses were made on meta-tyuyamunite. HCWS *DII:1045, AM 39:1037(1954), USGSB 1064:254(1958)*.

40.2a.27.1 Francevillite $\text{Ba}(\text{UO}_2)_2\text{V}_2\text{O}_8 \cdot 5\text{H}_2\text{O}$

Named in 1975 for the locality. Carnotite group. The Ba end member in the Ba–Pb series with curienite (40.2a.27.2). ORTH *Pcan.* $a = 10.419$, $b = 8.510$, $c = 16.763$, $Z = 4$, $D = 4.46$. *DANS 220:137(1975)*, Structure: *NJMM 552(1986)*. 21-381(syn): 8.4_{10} 5.20_6 4.26_6 4.20_4 3.30_4 3.21_4 3.00_{10} 2.13_6 . Plates exhibiting {001}, {201} and vicinal forms {111}, {221} possibly other {hkl}. Yellow, green, or orange; translucent. $G = 4.42$. Biaxial (–); $N_x = 1.945$, $N_z = 1.975$ (Na); $2V = 48^\circ$. Natural material contains Pb up to Ba/Pb 2:1. Synthesized. Found in the Otish Mts., QUE, Canada; at the South Terras mine, St. Stephen in Brannel, Cornwall, England; at the *Mounana mine, Franceville, Haut Ogooue, Gabon*, with curienite. HCWS *BM 91:453(1968)*.

40.2a.27.2 Curienite $\text{Pb}(\text{UO}_2)_2\text{V}_2\text{O}_8 \cdot 5\text{H}_2\text{O}$

Named in 1968 for Hubert Curien (b.1924), crystallographer, University of Paris (Sorbonne), France. Carnotite group. Pb end member of the Pb–Ba series with francevillite (40.2a.27.1). ORTH *Pcan.* $a = 10.42$, $b = 8.49$, $c = 16.41$, $Z = 4$, $D = 4.98$. *BM 91:453(1968)*. Structure: *BM 94:8(1971)*; see also *NJMM:552(1986)*. 22-402: 8.19_{10} 6.11_3 5.13_6 4.22_6 4.108_8 3.23_4 3.01_{10} 2.12_4 . Microcrystals show cleavage {010}. Canary yellow, translucent. $G = 4.88$. DTA. Synthesized. Biaxial; $N > 2.00$; $2V = 66^\circ$. Found as a powder on francevillite at *Mounana mine, Franceville, Haut Ogooue, Gabon*, in mineralized sulfide–uranium–vanadium deposits. HCWS *AM 54:1220(1969)*.

40.2a.28.1 Carnotite $\text{K}_2(\text{UO}_2)_2\text{V}_2\text{O}_8 \cdot 1-3\text{H}_2\text{O}$

Named in 1899 for Marie-Adolphe Carnot (1839–1920), mining engineer and chemist, France. Carnotite group. MON $P2_1/a$. $a = 10.47$, $b = 8.41$, $c = 6.91$, $\beta = 103.66^\circ$, $Z = 2$, $D = 4.91$ *AM 43:799(1948)*. Structure: *AM 50:825(1965)*. Structure similar to meta-torbernite: layers parallel to {001} composed of divanadate groups, two tetrahedra joined at common edge, linked to perpendicular, linear, UO_2 groups have composition $[(\text{UO}_2)_2\text{V}_2\text{O}_8]$. K and H_2O are found between the layers. 8-317: 6.56_{10} 4.25_3 3.53_5 3.25_3 3.12_7 2.57_2 2.16_3 1.942_2 . See 11-338(syn), anhydrous form with $c = 6.59$. Powdery or loosely coherent microcrystalline aggregates; compact; disseminated; rarely crusts of imperfect platy crystals flattened {001}, also rhomboidal {110}, lathlike [110] with {100}, {110}, or {120}; $(110) \wedge (1\bar{1}0) \approx 78^\circ$. Twinned. Bright yellow to lemon yellow, greenish yellow; dull or earthy luster, pearly and silky when coarsely crystalline. Cleavage {001}, perfect. $G = 4.70$. Biaxial (–); $XYZ = cba$; $N_x = 1.750$, $N_y = 1.925$, $N_z = 1.950$ (Long Park, CO); $2V \approx 40^\circ$; pleochroic; X, colorless; Y, Z, canary yellow. $N > 2.06$ (Olary, SA, Australia).

Indices, increase with dehydration. Small amounts of Ca, Ba, Mg, Fe^{2+} , and Na reported on analysis. Easily soluble in acids. Synthesized. Converted to tyuyamunite by treatment with calcium bicarbonate solution. Common in the plateau region of southwestern CO and in adjoining UT, AZ, and NM, disseminated in cross-bedded sandstones, concentrated around petrified or carbonized tree trunks or other vegetal matter. Formed through the action of meteoric waters on preexisting uranium–vanadium minerals; associated with tyuyamunite, volborthite, calciovolborthite, rossite, hewettite, vanoxite, pin-tadoite, uvanite, rauvite, and organic materials. Found in the Pottsville conglomerate, Jim Thorpe, Carbon Co., PA; in the Paradox Valley, Roc and La Sal creeks, Montrose Co., along the Rio Dolores SW of Gateway, Mesa Co., near Placerville and Cedar, San Miguel Co., and at Meeker, Rio Blanco Co., CO; on San Rafael Swell W of Green River, Emery Co., in the Henry Mts., Garfield Co., La Sal Mts., near Richardson, and at Thompson's, Grand Co., N of Monticello, San Juan Co., UT; at Anderson mine, AZ; at Blue Bird mine, Imperial Co., CA; in the red sandstone at Shaba, Zaire; at Radium Hill, Olary, SA, Australia. hcws *DII:1043*.

40.2a.28.2 Margaritasite $\text{Cs}_2(\text{UO}_2)_2\text{V}_2\text{O}_8 \cdot \text{H}_2\text{O}$

Named in 1982 for the locality. Carnotite group. MON $P2_1/a$. $a = 10.514$, $b = 8.425$, $c = 7.25$, $\beta = 106.01^\circ$, $Z = 2$, $D = 5.40$. *AM 67:1273(1982)*, Structure: *50:825(1965)*. *35-378*: 6.97₁₀ 3.60₇ 3.49₆ 3.34₇ 3.23₅ 3.16₅ 3.13₄ 2.70₂. See also *25-1218* (calc, no water). Aggregates up to 1 mm of fine-grained crystallites as linings surrounding relict phenocrysts. Individual tabular crystallites 1–3 μm . X-ray diffraction; Cs content distinguishes this mineral from carnotite. Yellow. Nonfluorescent. Biaxial; $N_x < 1.83$, $N_y = 2.49$, $N_z = 2.79$; $2V = 45.5^\circ$ (synthetic anhydrous analog). Some K indicated during microprobe analyses, but no evidence of a solid-solution series with carnotite from synthetic studies. Probably a hydrothermal product. Found at *Margaritas No. 2 U deposit, Sierra Peña Blanca, W of Chihuahua City, Mexico*. hcws

40.2a.29.1 Strelkinite $\text{Na}_2(\text{UO}_2)_2\text{V}_2\text{O}_8 \cdot 6\text{H}_2\text{O}$

Named in 1974 for M. F. Strelkin (1905–1965), mineralogist interested in uranium ores, Russia. Na analog of carnotite (40.2a.28.1); note difference in H_2O content. ORTH $Pnmm$ or $Pnm2$. $a = 10.64$, $b = 8.36$, $c = 32.72$, $Z = 8$, $D = 4.22$. *ZVMO 103:576(1974)*. *27-822*: 8.18₄ 7.68₁₀ 408₆ 3.95₈ 3.55₃ 3.20₅ 3.10₃ 2.01₄. Fine powdery crusts along fractures; plates nearly isometric in form up to 1.5 mm long. Gold-yellow to canary yellow, silky to pearly luster, translucent. Cleavage {001}, perfect. Weakly luminesces light green. $H = 2 - 2\frac{1}{2}$. $G = 4 - 4.2$. DTA. Biaxial (-); $XYZ = cba$; $N_x = 1.770 - 1.674$, $N_y = 1.907 - 1.855$, $N_z = 1.915 - 1.880$; $2V$ medium; pleochroic Y, yellow; Z, pale yellow. Spectrographic analyses show Ni, Co, Ti, Y, Cr, Mo, Cu, Pb, and Tl. Found in carbonaceous–siliceous shales in desert regions in *Russia*, also in effusive rocks in the arid zones associated with iron oxyhydroxides, clay minerals, quartz, and calcite. hcws *AM 60:488(1975)*.

40.2a.30.1 Vanuranylite $(\text{H}_3\text{O}, \text{Pb}, \text{k}, \text{Ca})_2(\text{UO}_2)_2\text{V}_2\text{O}_8 \cdot 4\text{H}_2\text{O}$

Named in 1965 for the composition. Carnotite group. Incompletely characterized MON Space group uncertain, probably $C2/c$. $a = 10.49$, $b = 8.37$, $c = 20.30$, $\beta = 90.0^\circ$, $Z = 4$, $D = 3.25$. *ZVMO* 94:437(1965). Name rejected as too close to vanuralite (42.11.13.1). *MM* 36:1144(1968). 19-1417: 5.3₄ 5.0₁₀ 3.43₄ 3.23₁₀ 3.12₄ 2.11₈ 2.05₅ 1.97₈. Pattern resembles tyuyamunite (40.2a.26.1). Crusts of crystals to 0.03 mm, platy, pseudo-hexagonal. Intense yellow, translucent. Cleavage {100}, perfect. $H = 2$. $G = 3.644$. DTA. Non-fluorescent. Biaxial (-); $N_x < 1.710$, $N_y = 1.92-1.95$, $N_z > 1.95$; $2V = 15^\circ$; weakly pleochroic. X, pale yellow; Y, Z, yellow. Contains some Pb, K, and Ca; detailed analysis lacking. Easily soluble in acids. Forms as crusts in fractures with uranophane and soddyite in the oxidation zone in sandstone in *Russia*. *HCWS AM* 51:1548(1966).

40.2a.31.1 Parsonsite $\text{Pb}_2(\text{UO}_2)(\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1923 for Arthur Leonard Parsons (1873-1957), mineralogist, University of Toronto, Canada. *TRIC* P1. $a = 6.849$, $b = 10.360$, $c = 6.671$, $\alpha = 101.84^\circ$, $\beta = 98.23^\circ$, $\gamma = 86.36^\circ$, $Z = 2$, $D = 6.34$. *NJMM:551* (1991), Structure: *SR* 22:422(1958). 12-259: 4.23₇ 4.16₃ 3.41₇ 3.28₁₀ 3.25₁₀ 3.16₅ 2.94₃ 2.78₄. Crusts and powdery aggregates of minute lathlike crystals which are elongated [001], flattened {010} with {001}, {101}, {100}; (001) \wedge (100) $\approx 81^\circ$, (101) \wedge (100) $\approx 132^\circ$. Pale citron yellow, subadamantine luster, transparent to translucent. No cleavage. $H = 2\frac{1}{2}-3$. $G = 5.37$. Nonfluorescent. Biaxial (-); $Y = b$; Z (or X) $\wedge c = 6-23^\circ$; $N_x \approx 1.870$, $N_z \approx 1.890$ (Ruggles). Variations in optical orientation and indices. Nonpleochroic. Soluble in acids. Synthesized with 0.5H₂O. $G = 6.29$ for anhydrous form. Found at Ruggles mine, Grafton Center, NH, with autunite and phosphuranylite; as crusts on quartz in Huachuca Mts., Cochise Co., AZ; at Lachaux, Puy de Dôme, Grury, Saône et Loire, France, with torbernite; at Wölsendorf, Bavaria, Germany, with uranocircite; at Shinkolobwe and *Kasolo, Shaba, Zaire*, associated with torbernite, kasolite, dewindite. *HCWS AM* 35:245(1950), *DII:913, USGSB* 1064:235(1958).

40.2a.32.1 Hallimondite $\text{Pb}_2(\text{UO}_2)(\text{AsO}_4)_2$

Named in 1965 for Arthur Francis Hallimond (1890-1968), British mineralogist, who contributed to the knowledge of secondary uranium minerals. *TRIC* P1. $a = 7.123$, $b = 10.469$, $c = 6.844$, $\alpha = 100.57^\circ$, $\beta = 94.80^\circ$, $\gamma = 91.20^\circ$, $Z = 2$, $D = 6.40$. *AM* 50:1143(1965). 18-706(syn): 4.41₅ 4.24₄ 3.40₁₀ 3.01₄ 2.84₉ 2.14₄ 1.736₆ 1.696₅. Small, fine-grained coatings in cavities and fractures of quartz. Crystals are up to 0.4 mm long, flattened on {110}, {100} elongated on c ; forms observed {100}, {010}, {001}, {110}, {610}, {001}, {018}, {111} with {001} striated. Oriented intergrowths with hügelite on common c axis. Yellow, pale yellow streak, subadamantine luster, transparent to translucent. No cleavage, conchoidal fracture. $H = 2\frac{1}{2}-3$. $G = 6.39$. Nonfluorescent. DTA. Biaxial (+); $N_x \approx 1.882$, $N_z \approx 1.915$; $2V = 80^\circ$; $r > v$; weakly pleochroic. Ba,

Si, Fe, Cu, Ca, Sr but no P on analysis. Synthesized. Found at the *Michael mine (Pb-Zn), Reichenbach, Black Forest, Germany*, associated with hügelite, widenmannite, weilerite, quartz, barite, mimetite, and galena. HCWS

40.2a.33.1 Ulrichite $\text{CaCu}(\text{UO}_2)(\text{PO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1988 for George Henry Frederick Ulrich (1830–1900), who contributed descriptions of minerals from VIC, Australia. *MON C2/m*. $a = 12.79$, $b = 6.85$, $c = 13.02$, $\beta = 91.03^\circ$, $Z = 4$, $D = 3.71$. *AUSM 3:125(1988)*. *PD*: 6.39_{10} 5.68_1 5.52_1 4.50_1 3.48_1 3.19_4 2.79_2 2.37_1 . Radiating sprays of acicular crystals; flat prisms, some twinned with complex pyramidal terminations. Pale apple-lime green, vitreous luster, translucent to transparent. No cleavage. $H = 3\frac{1}{2}$. Nonfluorescent. Probably biaxial (-); $N_x = 1.622$, $N_{yz} = 1.634$; length-slow; nonpleochroic. Readily soluble in 1:10 HCl, HNO_3 . Found at *Lake Boga, VIC, Australia*, with turquoise and chalcociderite in granite pegmatites associated with fluorapatite, libethenite, cyrilovite, torbernite, saleite, sampleite, and iron phosphates. HCWS *AM 75:243(1990)*.

40.2a.34.1 Triangulite $\text{Al}_3(\text{UO}_2)_4(\text{PO}_4)_4(\text{OH})_5 \cdot 5\text{H}_2\text{O}$

Named in 1982 for the triangular habit of the crystals. *TRIC P1* or *P1*. $a = 10.39$, $b = 10.56$, $c = 10.60$, $\alpha = 116.4^\circ$, $\beta = 107.8^\circ$, $\gamma = 113.4^\circ$, $Z = 1$, $D = 3.68$. *BM 105:611(1982)*. *35-577*: 7.80_{10} 4.70_3 3.87_8 3.74_2 3.63_2 3.39_2 3.15_7 2.99_5 . Aggregates of flat, triangular, or rhombohedral crystals up to 0.2 mm. Twinned about {011} and {011}. Bright yellow. $G = 3.7$. Nonfluorescent. Biaxial (+); $Z \approx [0111]$, $Y \approx [011]$, X perpendicular to [100]; $N_{x \text{ calc}} = 1.639$, $N_y = 1.665$, $N_z = 1.704$; $2V = 80^\circ$; pleochroic Y, pale green-yellow; Z, bright yellow. Found within a quartz-K-feldspar-columbite zone in a complex pegmatite associated with beryl, metamict zircon, meta-autunite, phosphuranlyte, and ranunculite at *Kobokobo, Kivu, Zaire*. HCWS *AM 69:212(1984)*.

40.3.1.1 Warikahnite $\text{Zn}_3(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1979 for Walter Richard Kahn, German mineralogist, who worked in Namibia and was interested in the crystal structures of secondary minerals. *TRIC P1* or *P1*. $a = 6.710$, $b = 8.989$, $c = 14.533$, $\alpha = 105.59^\circ$, $\beta = 93.44^\circ$, $\gamma = 108.68^\circ$, $Z = 4$, $D = 4.29$ *NJMM:389(1979)*. Structure: *TMPM 27:187(1980)*. A complicated structure in which Zn is in six-, five-, and four-fold coordination and in five different combinations with AsO_4 and H_2O . *33-1468*: 13.80_5 8.12_6 6.21_8 3.45_7 3.04_6 2.87_8 2.82_{10} 2.30_7 . Bladed crystals to 3 mm \times 0.5 mm \times 0.5 mm, elongated on a ; radiating masses. Pale yellow to colorless, transparent to translucent. Cleavage {001}, perfect; {100}, distinct. $H = 2$. $G = 4.24$. IR, TGA. Biaxial (+); $Z \wedge a = 47^\circ$; $N_x = 1.747$, $N_y = 1.753$, $N_z = 1.768$; $2V = 75^\circ$; no dispersion. Dissolves in hot HCl, HNO_3 . Occurs in the second oxidation zone at *Tsumeb mine, Tsumeb, Namibia*, on corroded tennantite associated with adamite, stranskiite, koritnigite, claudetite, tsumcorite, and ludlockite. HCWS *AM 65:408(1980)*.

PHOSPHOFERRITE GROUP

Secondary hydrated phosphates the phosphoferrite group formula can be expressed as

where

n is variable, dependent on the oxidation state of the cations, especially Fe and the temperature of formation, and crystallize in the orthorhombic space group Pbn. The structure consists of kinked edge-sharing octahedrally coordinated cations (A) that forms chains parallel to the c axis which are linked by corner sharing into sheets parallel to $\{100\}$. The sheets are held together along the c axis by $(PO_4)^{3-}$ tetrahedra.

PHOSPHOFERRITE: $(Fe^{2+}, Mn^{2+})_3(PO_4)_2 \cdot 3H_2O$

This b axis projection of phosphoferrite (all Fe^{2+}) shows tetrahedral PO_4 groups joining sheets parallel to $\{100\}$ composed of chains of octahedrally coordinated cations and water along the c axis.

PHOSPHOFERRITE Group

Mineral	Formula	Space Group	a			c
			a	b	c	
Phosphoferrite	$(\text{Fe}^{2+}, \text{Mn}^{2+})_3(\text{PO}_4)_2 \cdot 3\text{H}_2\text{O}$	<i>Pbna</i>	9.460	10.024	8.670	40.3.2.1
Kryzhanovskite	$(\text{Mn}^{2+}, \text{Fe}^{3+})_2(\text{PO}_4)_2(\text{OH})_2 \cdot 3\text{H}_2\text{O}$	<i>Pbna</i>	9.460	10.024	8.670	40.3.2.2
Reddingite	$(\text{Mn}^{2+}, \text{Fe}^{2+})_3(\text{PO}_4)_2 \cdot 3\text{H}_2\text{O}$	<i>Pbna</i>	9.49	10.08	8.70	40.3.2.3
Landesite	$(\text{Fe}^{3+}, \text{Mn}^{2+})_2(\text{PO}_4)_2(\text{OH}) \cdot 2\text{H}_2\text{O}$	<i>Pbna</i>	9.458	10.185	8.543	40.3.2.4
Garyansellite	$(\text{Mg}, \text{Fe}^{3+})_3(\text{PO}_4)_2(\text{OH})_{15} \cdot 1.5\text{H}_2\text{O}$	<i>Pbna</i>	9.452	9.890	8.198	40.3.2.5

Note: compare with vivianite group (40.3.6.1).

40.3.2.1 Phosphoferrite $(\text{Fe}^{2+}, \text{Mn}^{2+})_3(\text{PO}_4)_2 \cdot 3\text{H}_2\text{O}$

Named in 1926 in allusion to the composition. Phosphoferrite group. Part of the Fe–Mn series with reddingite. ORTH *P2na* or *Pbna*. $a = 9.460$, $b = 10.024$, $c = 8.670$, $Z = 4$, $D = 3.32$. *MM* 43:789(1980). Structure: *IC* 15:316(1976). 9-479: 4.25₇ 3.18₁₀ 2.72₈ 2.64₇ 2.41₇ 2.22₇ 1.615₇ 1.550₇. Octahedral crystals with large {111}, or tabular on {010} often in parallel groups; massive, granular, coarsely fibrous. Pale green to red-brown from alteration, vitreous to subresinous luster, transparent to translucent. Cleavage {010}, poor; uneven fracture; brittle. $H = 3-3\frac{1}{2}$. $G = 3.1$. Biaxial (+); $XYZ = abc$; $N_x = 1.672$, $N_y = 1.680$, $N_z = 1.700$; $2V = 68^\circ$; $r > v$, distinct; pleochroic (Hagendorf Fe/Mn = 2.7:1). Soluble in acids. Found at Palermo No. 1 mine, North Groton, NH; at Bull Moose mine, Custer and Dan Patch pegmatite, Keystone, SD; Hagendorf Süd, near Pleystein, Oberpfalz, Bavaria, Germany, with triploidite, ludlamite, and vivianite in pegmatite; at Lavra do Enio, Galileia, MG, Brazil. *HCWS* DII:727, *NJMA* 87:185(1954).

40.3.2.2 Kryzhanovskite $(\text{Mn}^{2+}, \text{Fe}^{3+})_2(\text{PO}_4)_2(\text{OH})_2 \cdot \text{H}_2\text{O}$

Named in 1950 for Vladimir Ilyitch Kryzhanovsky (1881–1947), curator of the Mineralogical Museum, Russian Academy of Sciences, Moscow. Phosphoferrite group. The Fe oxidized equivalent of phosphoferrite (40.3.2.1); in series with garyansellite (40.3.2.5). ORTH *Pbna*. $a = 9.460$, $b = 10.024$, $c = 8.670$, $Z = 4$, $D = 3.464$. Structure: *AM* 56:1(1971), *MM* 43:789(1980). 24-731: 5.00₇ 4.70₅ 4.25₅ 3.16₁₀ 2.72₅ 2.53₅ 2.21₅ 1.503₅. Poorly formed prismatic crystals up to 3 cm in diameter. Brown, green-brown, bronze on cleavage surfaces; yellow-brown streak; vitreous to dull luster. Cleavage {001}, perfect; uneven fracture. $H = 3\frac{1}{2}-4$. $G = 3.31$. Biaxial (+); $N_x = 1.79$, $N_z = 1.82$; $2V = 40-45^\circ$; axial plane perpendicular to (001); $r \ll v$; absorption $X > Y > Z$. X, wine-yellow; Y, orange-brown; Z, red-brown. Found with ludlamite at Palermo No. 1 pegmatite, Groton, Grafton Co., NH; Bull Moose and Tip Top pegmatites, Custer, Custer Co.; with

diadochite, hureaulite, or siderite at Big Chief pegmatite, Glendale, Pennington Co.; Dan Patch pegmatite, Keystone Co., SD; with ludlamite and arrojadite at Rapid Creek, YT, Canada; Hagendorf Süd, Bavaria, Germany; with altered triphylite in the *Kolbinsk pegmatite, Russia*; Okatjimukuju Farm pegmatite, Karibib, Namibia. *HCWS DANS 72:762(1950)*; *AM 36:382(1951)*, *59:896(1974)*.

40.3.2.3 Reddingite $(\text{Mn}^{2+}, \text{Fe}^{2+})_3(\text{PO}_4)_2 \cdot 3\text{H}_2\text{O}$

Named in 1878 for the locality. Phosphoferrite group. End member of the Mn-Fe series with phosphoferrite (40.3.2.1). ORTH *Pbna*. $a = 9.49$, $b = 10.08$, $c = 8.70$, $Z = 4$, $D = 3.262$. Structure: *MM 43:789(1980)*, *ZK 118:327(1963)*. *9-496: 4.28₇ 3.20₁₀ 2.74₈ 2.66₇ 2.42₇ 2.23₇ 1.625₇ 1.560₇*. Octahedral with large {111}, tabular {010}, often parallel groups; massive, granular, coarsely fibrous. Pinkish white or pale rose to yellowish white and colorless; vitreous to subresinous luster; translucent to transparent. Cleavage {010}, poor; uneven fracture. $H = 3-3\frac{1}{2}$, $G = 3.24$ (Mn:Fe 3:1). Biaxial (+); XYZ = abc; $N_x = 1.651$, $N_y = 1.656$, $N_z = 1.683$ (Branchville); $2V = 41^\circ$; $r > v$, distinct. X, colorless; Y, pinkish brown; Z, pale yellow. Soluble in acids. Found at Black Mt. mine, Landford, and at the Feldspar, and Paul Bennet quarries, and Nevell Tourmaline mine, Buckfield, ME; at *A.N. Fallow quarry, Branchville, Redding Twp., Fairfield Co., CT*, the alteration product of lithiophilite-triphylite. *HCWS DII:727, NJMA 87:185(1954)*.

40.3.2.4 Landesite $(\text{Fe}^{3+}\text{Mn}^{2+})_2(\text{PO}_4)_2(\text{OH}) \cdot 2\text{H}_2\text{O}$

Named in 1930 for Kenneth Knight Landes (b.1899), professor of geology, University of Michigan. Phosphoferrite group. ORTH *Pbna*. $a = 9.458$, $b = 10.185$, $c = 8.543$, $Z = 1$, $D = 3.210$. Structure: *MM 43:789(1980)*. *16-603: 5.37₆ 5.10₈ 4.73₅ 4.28₈ 3.21₁₀ 3.16₇ 3.09₅ 2.63₈*. Rough octahedral-like crystals. Dirty yellow-brown, translucent. Cleavage {010}, good; {001}, poor. $H = 3-3\frac{1}{2}$, $G = 3.026$. Biaxial (-); $N_x = 1.720$, $N_y = 1.728$, $N_z = 1.735$; X perpendicular to {001} cleavage, Z perpendicular to {010}; $2V$ large. Found as an alteration product of reddingite in granite pegmatite at *Black Mt. mine, Berry quarry, Poland, Androscoggin Co., ME*, with rhodochrosite, eosphorite, fairfieldite, lithiophilite, and apatite. *HCWS DII:729, AM 49:1122(1964)*.

40.3.2.5 Garyansellite $(\text{Mg}, \text{Fe}^{3+})_3(\text{PO}_4)_2(\text{OH})_{15} \cdot 1.5\text{H}_2\text{O}$

Named in 1984 for H. Gary Ansell, associate curator of the National Mineral Collection, Geological Survey of Canada. Phosphoferrite group. Mg analog of kryzhanovskite (40.3.2.2). ORTH *Pbna*. $a = 9.452$, $b = 9.890$, $c = 8.198$, $Z = 4$, $D = 3.154$. *AM 69:207(1984)*. *35-638: 4.93₅ 4.26₃ 3.16₁₀ 3.10₄ 2.71₆ 2.54₃ 2.21₃ 2.19₃*. Platy crystals parallel to {010} or elongate on [100] with large {111}, {011} showing. Clove-brown, brown streak, vitreous with bronze luster on cleavage surfaces. Cleavage {001}, good. $H = 4$. $G = 3.16$. DTA/TGA. Biaxial (-); XYZ = bac; $N_x = 1.733$, $N_y = 1.757$, $N_z = 1.761$; $2V = 55^\circ$; absorption $Z = X > Y$. X, reddish brown; Y, yellow;

Z, reddish brown. Found with kryzhanovskite in fractures in the *iron formations, northeastern YT, Canada*, with ludlamite, arrojadite, quartz, vivianite, meta-vivianite, and souzalite. HCWS

40.3.3.1 Parahopeite $\text{Zn}_3(\text{PO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1908 for its dimorphic relation to hopeite (40.3.4.1). TRIC $P\bar{1}$. $a = 5.768$, $b = 7.550$, $c = 5.296$, $\alpha = 93.42^\circ$, $\beta = 91.18^\circ$, $\gamma = 91.37^\circ$, $Z = 1$, $D = 3.32$. Structure: *ZK 130:261(1969)*. *39-1352*: 7.53₄ 4.44₅ 2.98₁₀ 2.88₇ 2.78₆ 2.72₅ 2.67₅ 2.51₄. See also *24-1461* and *34-156*. Crystals elongated [001], tabular {100} often as subparallel aggregates, tufted or fan-shaped. Twinning polysynthetic on {100} common. Colorless; vitreous luster, pearly on cleavage; transparent. Cleavage {010}, perfect. $H = 3\frac{1}{2}$ -4. $G = 3.31$. Biaxial (+); X near a ; $Y \wedge c$ on {100} = 30° ; $N_x = 1.614$, $N_y = 1.625$, $N_z = 1.637$; $2V \approx 90^\circ$, $r < v$. Reaphook Hill samples show zoning; center enriched in Fe and Mn, edges Mg-rich. Synthesized. Found at Hudson Bay mine, Salmo, Nelson district, BC, Canada, with hopeite, spencerite, and hemimorphite; at the Broken Hill mine, Zambia; at Reaphook Hill, SA, Australia, associated with scholzite, chalcophanite, gypsum, and hemimorphite. HCWS *DII:733*; *MM 36:621(1968)*, *39:684(1974)*.

40.3.4.1 Hopeite $\text{Zn}_3(\text{PO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1908 for Thomas Charles Hope (1766-1844), professor of chemistry, University of Edinburgh, Scotland. Dimorph of parahopeite (40.3.3.1) ORTH $Pnma$. $a = 10.594$, $b = 18.333$, $c = 5.029$, $Z = 4$, $D = 2.94$. Structure: *AM 61:987(1976)* *JSSC 93:9(1991)*. Sheets made up of zigzag chains of corner-sharing ZnO_4 parallel to c and PO_4 tetrahedra parallel to (010). The Zn atoms occupy two nonequivalent sites. Zn_1 is octahedrally coordinated with four O's from the water molecules, and two O's from PO_4 groups and is probably not fully occupied. Zn_2 is tetrahedrally coordinated. *37-465*: 9.12₆ 4.85₂ 4.57₁₀ 4.41₂ 3.46₃ 3.39₃ 2.85₇ 1.939₂. See also *33-1474(syn)*. Tabular {010} to prismatic {001} crystals that are single, tufted, or divergent aggregates, crusts, reniform masses, compact; faces development irregular; not twinned. Colorless to grayish white, pale yellow; white streak; vitreous luster, pearly on cleavage; transparent to translucent. Cleavage {010}, perfect; {100}, good; {001}, poor; uneven fracture; brittle. $H = 3\frac{1}{2}$. $G = 3.05$. Biaxial (-); $XYZ = acb$; $N_x = 1.589$, $N_y = 1.598$, $N_z = 1.599$ (Zambia); $2V = 37^\circ$; $r < v$. Optical examination of sections on {100} shows distinct zones. The zones may represent distinct crystallites within a single grain with the same composition but different hydrogen-bonding schemes. *AM 61:987(1976)*. Earlier work had proposed two polymorphs: α and β , based on the distinct stabilities on heating; that is they had different water contents. *MM 15:1(1908)*. Synthesized. Found with spencerite at Hudson Bay mine, Salmo, Nelson district, BC, Canada; associated with hemimorphite in Zn mine at *Allenberg, Moresnet district, Belgium*; at the mines named α , β , and Globe & Phoenix at Broken Hill,

Zambia, in bone breccia in a limestone cave associated with tarbuttite, hemimorphite, smithsonite, and vanadinite. HCWS *DII:734*, *MJ 7:289(1973)*, *NBSM 25(6):85(1979)*.

40.3.5.1 Ludlamite $(\text{Fe}^{2+}, \text{Mg}, \text{Mn})_3(\text{PO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1877 for Henry Ludlam (1824–1880), English mineralogist and collector. MON $P2_1/a$. $a = 10.541$, $b = 4.646$, $c = 9.324$, $\beta = 100.43^\circ$, $Z = 2$, $D = 3.176$. *AC 4:412(1951)*. *35-634*: 4.92_{10} 4.59_8 3.96_8 3.75_4 3.06_6 3.00_6 2.77_5 2.56_5 . Tabular {001}, sometimes parallel aggregates, massive, granular. Bright green to apple green, pale greenish-white streak; vitreous luster, translucent. Cleavage {001}, perfect; {100}, indistinct. $H = 3\frac{1}{2}$. $G = 3.165$. Biaxial (+); $Y = b$; $Z \wedge c = -67^\circ$; $N_x = 1.653$, $N_y = 1.675$, $N_z = 1.697$ (Cornwall); $2V = 82^\circ$, $r > v$. Soluble in acids. Found at Red Hill, Rumford, Oxford Co., ME; with phosphoferrite, triphylite, carbonate hydroxylapatite at Palermo No. 1 pegmatite, Groton, Grafton Co., NH; Victory, Big Chief, Bull Moose, Tip Top, Hesnard, Dan Patch, Etta, and Ferguson pegmatites, SD; Blackbird mine(!), Lemhi Co., ID, with vivianite; San Pedro mine, Pala, San Diego Co., CA; Rapid Creek, YT, Canada; crystals to 3 cm at San Antonio mine(!), Santa Eulalia district, CHIH, Mexico; *Wheal Jane*(!), *Kea*, near *Truro*, Cornwall, England; Brunita mine, Murcia, Spain; Stosgen, near Linz, and Hagen-dorf Süd, Bavaria, Germany; Stari Trg mine(!), Trepča, Kosovo, Serbia; Lavra do Ênio, Galiléia, MG, Brazil; Morococala(!), Dalence Prov.; to 4 cm at Huanuni(!), Oruro Dept., Bolivia; Ashio mine, Tochigi Pref., Japan. HCWS *DII:952*.

40.3.5.2 Metaswitzerite $\text{Mn}_3^{2+}(\text{PO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1986 as the stable, lower hydrate of switzerite (40.3.5.4). MON $P2_1/n$. $a = 8.496$, $b = 13.173$, $c = 17.214$, $\beta = 96.65^\circ$, $Z = 8$, $D = 2.96$. Structure: *TMPM 26:266(1979)*, *AM 71:1224(1986)*. *20-713*: 8.55_{10} 7.13_4 6.78_4 3.17_4 2.93_4 2.84_4 2.76_4 2.59_6 . Bladed crystals, micaceous masses, flattened and elongated on {100}, up to 3 mm long, showing {100}, {210}, {410}, {101}, {101}, {111}, {111}. Light to darker brown; adamantinite luster, pearly on cleavage. Cleavage {001}, perfect; {010}, fair. $H = 2\frac{1}{2}$. $G = 2.95$. Biaxial (-); $Y = b$; $Z \wedge c = 10.5^\circ$; $N_{x \text{ calc}} = 1.602$, $N_y = 1.628$, $N_z = 1.632$; $2V = 42^\circ$, $r < v$, slight. Dark brown material has $N_y = 1.666$, $N_z = 1.670$. Fe^{2+} substituting for Mn is probably responsible for the brown color and on oxidation the color darkens. Found at *Foote Mineral Co. spodumene mine*, *Kings Mt.*, *Cleveland Co.*, NC; at Viitaniemi, Finland; at Reaphook Hill, SA, Australia. HCWS

40.3.5.3 Sterlinghillite $\text{Mn}_3^{2+}(\text{AsO}_4)_2 \cdot 4\text{H}_2\text{O}$

Named in 1981 for the locality. An inadequately described mineral. Only one specimen known. *35-478*: 11.1_{10} 6.39_3 5.01_1 3.69_3 3.21_{10} 2.88_4 2.85_4 2.75_6 . Hemispherical clusters to 0.1 mm of randomly intergrown tabular crystals. White, light pink; white streak; silky to pearly luster. Cleavage

parallel to elongation. $H = 3$. $G = 2.95$. Nonfluorescent. Uniaxial (-); $N_O = 1.671$, $N_E = 1.656$. Small amounts of Zn, Mg, and Fe detected in analysis. Formed by decomposition of loellingite. Found on loellingite-franklinite-willemite-calcite ores at the *Sterling Hill mine, Ogdensburg*. HCWS *AM 66:182(1981)*.

40.3.5.4 Switzerite $(Mn^{2+}, Fe^{2+})_3(PO_4)_2 \cdot 7H_2O$

Named in 1967 for George Shirley Switzer (b.1915), mineralogist, National Museum of Natural History, Smithsonian Institution, Washington, DC. Unstable hydrate of metaswitzerite (40.3.5.2). MON $P2_1/a$. $a = 8.545$, $b = 13.164$, $c = 11.878$, $\beta = 110.12^\circ$, $Z = 4$, $D = 2.545$. *AM 71:1221(1986)*. 41-598: 11.12₁₀ 8.47₅ 3.37₉ 2.94₃ 2.35₄ 2.14₅ 1.914₂ 1.612₃. Crystals must be completely hydrated, as when exposed to air they may disintegrate explosively to meta-switzerite. Thin tabular on {001}. Pale pink, vitreous to pearly luster, translucent. Cleavage {001}, perfect; brittle. Soft. $G = 2.535$. Biaxial (-); $Z = b$; X perpendicular to (001); $N_x = 1.560$, $N_y = 1.574$, $N_z = 1.580$; $2V = 70^\circ$. Occurs at the lowest levels of the *Foote Mineral Co. mine, Kings Mt., Cleveland Co., NC*, only in freshly exposed rock. HCWS

VIVIANITE GROUP

The members of the vivianite group have a general formula

where A may be Fe^{2+} , Fe^{3+} , Mn, Mg, Zn, Co, or Ni,
X is either P or As,

and monoclinic or triclinic spacegroups.

The vivianite structure has chains of Fe octahedra and PO_4 tetrahedra that form sheets parallel to {100}. The sheets are held together by hydrogen bonding from the H_2O ligands, a weak bonding that accounts for the perfect (010) cleavage found in these minerals.

Two arsenate compositions (Fe and Zn) show polymorphism. Different hydrates are also possible and to distinguish between them the prefix 'meta' is used. In general, the lower H_2O content minerals have a triclinic rather than a monoclinic ($C2/m$ or $I2/m$) space group *CM 9:993(1968)* *BM 103:135(1980)*.

VIVIANITE: $\text{Fe}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$

In this *c* axis projection the two types of Fe sites are easily seen. Fe1 is coordinated with 4 H_2O and 2 oxygens of the $(\text{PO}_4)^{3-}$ groups. Fe2 coordinates with 2 H_2O and 4 oxygens of the $(\text{PO}_4)^{3-}$ groups and forms a double octahedra though sharing a common O—O edge. The Fe—Fe distance in the double Fe2 octahedra is only 2.96Å. Sheets of Fe1 octahedra, PO_4 tetrahedra, and the double Fe2 octahedra parallel $\{010\}$, and are held together by hydrogen bonding.

40.3.6.1 Vivianite $\text{Fe}_3^{2+}(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1817 for J. G. Vivian, English mineralogist, who discovered the mineral. Vivianite group. *MON* $C2/m$. $a = 10.086$, $b = 13.441$, $c = 4.703$, $\beta = 104.27^\circ$, $Z = 2$, $D = 2.696$. *BM* 103:135(1980). Structure: *BM* 105:147(1982). 30-662(syn): 7.93₁ 6.73₁₀ 4.90₁ 4.08₁ 3.21₂ 2.99₁ 2.96₁ 2.73₁. Prismatic {001}, also flattened {010}, rarely {100}, equant. Crystals often rounded by vicinal development into bladelike or lanceolate shapes, also as stellate groups, reniform, globular, or tabular masses or concretions, incrusting with bladed or fibrous structure, earthy, pulverulent. Twinning lamellar on {010}, corresponds \approx {304}. Colorless and transparent when fresh, becomes pale blue to greenish blue on oxidation and darkens on further exposure in air to bluish black; colorless to bluish white streak, darkening to dark blue or brown; vitreous luster, pearly on {010}, or dull and earthy; transparent to translucent. Cleavage {010}, perfect; traces on { $\bar{1}06$ }, {100}; fibrous fracture \approx perpendicular to [001]; flexible when in thin laminae; sectile. Translation gliding T(010), t{001}. $H = 1\frac{1}{2}$ -2. $G = 2.68$. Mossbauer. Biaxial (+); $X = b$; $Z \wedge c = +28\frac{1}{2}$; $N_x = 1.579$, $N_y = 1.602$, $N_z = 1.637$ (Na); $2V = 83\frac{1}{6}$, $r < v$, weak. X, blue; Y,Z, pale yellowish green. Increasing oxidation (deepening of color) increases indices, decreases birefringence and pleochroism on {010} becomes stronger. Easily soluble in acids. Easily synthesized. Small amounts of Mn^{2+} , Mg, and Ca substitute for Fe^{2+} ; amount of Fe^{3+} indicates oxidation level. Mossbauer analyses suggests that the Fe in the paired octahedra is the most resistant to oxidation. The oxidation reaction Fe^{2+} to Fe^{3+} leads to a reduction in H_2O , loss of OH^- , and changes in the hydrogen-bonding scheme. At some juncture during the loss of H bonding there would be collapse of the structure. Vivianite undergoing oxidation turns dark blue and at high Fe^{3+} content may disintegrate to a red-brown powder. *AM* 65:361(1980). There has been discussion as to whether the ferri-ferrous compositional distinctions (coupled with H_2O changes) are fully expressed by the less hydrated triclinic species meta-vivianite or whether kerchite, also triclinic, probably a more fully oxidized ferri-ferrous hydroxyphosphate, and a discredited mineral species, should be reinstated. *MM* 50:687(1986). A widespread secondary mineral, vivianite occurs in the gossan of metallic ore deposits and in pegmatites, in clays, recent alluvial, and glauconitic sediments, in pebble phosphates such as those composed of bone, in decayed wood, or in other organic sediments, such as in lignite, peat, and bog irons. It is often mistaken for turquoise as the coloring material of fossil teeth or bones. Occurs abundantly in the pegmatites in Newry, ME; at Palermo No. 1 mine, North Groton, NH; at Allentown, Shrewsbury, Monmouth Co., and Mullica Hill, Gloucester Co., NJ; in green sand at Middletown, New Castle Co., DE; at the Ideal Cement quarry, Castle Hayne, NC; at Stewart Co., GA; at Clear Springs mine, Barston, FL; at Ibex Mine, Lake Co., CO; at the Big Chief, Bull Moose, and Tip Top pegmatites, SD; in diatomite in a Tertiary lake bed near Burney, Shasta Co., CA; in bog-iron ore at Côte St. Charles, Vaufreuil Co., QUE, Canada; at the San Antonio mine, Santa Eulalia, CHIH, Mexico,

in blue-green gem-quality crystals to 8 cm(!); at Cornwall, and Millersdale, Derbyshire, England; in the coal measures, France; in the limonite ores in Amberg-Auerbach, and the pegmatites of Hagendorf, Bavaria, Germany; at Stari Trg mine, Trepca, Serbia; in the sedimentary iron ores in the Kerch and Taman Penins. on the Black Sea, Russia; as crystals at the Ashio mines(!), Shimotsuke Pref., Japan; at the Wannan R., VIC, Australia; in many localities in Bolivia, such as at Colquechaca, and the Santa Fe mine, Morocoala, at Avicaya, Ichucollo, Poopo, and Porvenienr mines, Ovuro, and in especially large crystals (to 10 cm) at the Siglo XX mine(!), Llallagua, Potosi; at Araucaí, Lavra Velha, and in Galileia, Lavra do Enio(!), at the Telido mine, and at Larada Ilha, Taquaral, MG, Brazil. *HCWS DII:742*.

40.3.6.2 Baricite $(\text{Mg}^{2+}, \text{Fe}^{2+})_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1976 for Ljudevit Baric, mineralogist, University of Zagreb, Croatia. Vivianite Group. *MON C2/m*. $a = 10.075$, $b = 13.416$, $c = 4.760$, $\beta = 104.87^\circ$, $Z = 2$, $D = 2.448$. *AM 61:1053(1976)*. *29-705*: 6.71₁₀ 3.20₄ 2.96₆ 2.70₇ 2.53₅ 2.42₃ 2.22₃ 1.676₃. Large plates up to 12 cm in maximum dimension and up to 5 cm thick. Colorless to pale blue. Cleavage {010}, perfect. $H = 1\frac{1}{2}$ –2. $G = 2.42$. Biaxial (+); $X = b$; $Z \wedge c = +32^\circ$; $N_x = 1.554$, $N_y = 1.564$, $N_z = 1.595$; $2V = 59^\circ$; $r < v$, weak. Occurs in fractures in a siderite iron formation in *Big Fish-Blow R. area, northeastern YT, Canada*. *HCWS CM 14:403(1976)*.

40.3.6.3 Erythrite $\text{Co}_3(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1832 from the Greek for *red*. The Co end member in the Co-Ni series with annabergite (40.3.6.4). Vivianite group. *MON I2/m*. $a = 10.118$, $b = 13.433$, $c = 4.762$, $\beta = 101.90^\circ$, $Z = 2$, $D = 3.14$. *NBSM 25(19):39(1970)*, *CM 9:493(1968)*. *33-413(syn)*: 7.96₃ 6.72₁₀ 4.40₂ 3.26₅ 3.23₄ 2.74₃ 2.71₂ 2.46₂. Prismatic to acicular [001], flattened {010}. Crystals deeply striated, furrowed on [001] or {010} parallel to {h0l} or {h0l}; radial or stellate groups, globular or reniform with drusy surface; coarse-fibrous, earthy, pulverulent. Crimson-red and peach-red, lighter colors indicate more Ni content, may show color banding; streak paler than color; weakly adamantine luster, pearly on {010}, dull or earthy; transparent to translucent. Cleavage {010}, perfect; {100}, {102}, indistinct; flexible in thin {010} laminae; translation gliding T{010}, t{001}; sectile. $H = 1\frac{1}{2}$ –2 $\frac{1}{2}$. $G = 3.06$ (Schneeberg). Biaxial (+); $X = b$; $Z \wedge c = +31^\circ$; $N_x = 1.629$, $N_y = 1.663$, $N_z = 1.701$ (Schneeberg); $2V$ very large; $r > v$ [may also be biaxial (-)]. X, pale pinkish; Y, pale violet; Z, red. Substitutions of Ca, Fe, Zn, and Mg have led to the description of several varieties. Synthesized. A secondary mineral usually formed by the oxidation of arsenides of Co (and Ni), erythrite is associated with symplectite, morenosite, retgersite, malachite, adamite, and scorodite. Occurs at Blackbird district, Lemhi Co., ID; at Cottonwood Canyon, Stillwater Range, NV; in the Black Hills, Yavapai Co., AZ; with annabergite in the Black Hawk district, Grant Co., NM, at the Bishop mine, E of Long Lake, Inyo Co., and mines in

San Gabriel Canyon, Los Angeles Co., CA; in the Cobalt area(1), Timiskiming district, ONT, Canada; Sara Alicia mine, Alamos, SON, Mexico; earthy varieties at Chalanches near Allemont, Isère, and at Markirch, Alsace, France; in the Heubachtal, Wittichen district, Black Forest, Baden, and at Schmiedestollenhalde, and Schneeberg, Saxony, Germany; at Joachimsthal, Bohemia, Czech Republic; at the Arhbar mine No. 4 vein, Bou Azzer, Morocco(1). HCWS *DII:747*.

40.3.6.4 Annabergite $\text{Ni}_3(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1852 for the locality. The Ni end member of the Ni-Co series with erythrite (40.3.6.3). Vivianite Group. MON *I2/m*. $a = 10.054$, $b = 13.303$, $c = 4.716$, $\beta = 102.10^\circ$, $Z = 2$, $D = 3.22$. Structure: *BM 105:332(1951)*. *34-141*(syn): 7.91₃ 6.66₁₀ 4.36₂ 3.20₄ 2.98₅ 2.72₃ 2.69₂ 2.44₂. See also *35-568*, Mg-rich mineral from Laurium, Greece. Similar in habit and physical properties to erythrite, annabergite is usually found as fine-crystalline coatings or earthy crusts. Pale rose, light gray to apple green in the highest Ni varieties. Biaxial (+); $X = b$; $Z \wedge c = +36^\circ$; $N_x = 1.622$, $N_y = 1.658$, $N_z = 1.687$; $2V = 84^\circ$; $r > v$; pleochroic. Calcian variety (Creetown, Kirkcubrightshire, Scotland) is white and pulverulent; Mg-containing varieties were among the earliest described for this mineral. Less common than erythrite, annabergite occurs with retgersite at Lovelock mine, Cottonwood Canyon, Humboldt Co., NV; at Silver Cliff, Custer Co., CO; notably at Gowganda and Keeley mine, Cobalt in the Timiskiming district, ONT, Canada; at Schneeberg and *Annaberg, Saxony, Germany; at Leogang, Salzburg, Austria*; from the Arburese mine, Gonnosfanadiga, Sardinia; Mg varieties at Sierra Carera, Almeria Prov., Spain, and at Chalanches, Isère; at the Plaka mine, Laurium, Attica, Greece(1). HCWS *DII:747*.

40.3.6.5 Köttigite $\text{Zn}_3(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1850 for Otto Köttig (b.1824), chemist of Schneeberg, Saxony, Germany. Part of a series with erythrite and annabergite. Vivianite group. MON *C2/m*. $a = 10.24$, $b = 13.405$, $c = 4.757$, $\beta = 105.21^\circ$, $Z = 2$, $D = 3.24$. Structure: *AM 64:376(1979)*. Transition metals are randomly distributed over the two octahedral sites. *33-1467*(syn): 7.97₂ 6.72₁₀ 3.23₅ 3.01₃ 3.00₄ 2.74₃ 2.71₃ 2.33₂. See also *33-430*(calc). Prismatic {001}, flattened {010}, massive, crusts with crystalline or fibrous structure. Carmine or peach blossomed, reddish-white streak, silky luster on fracture, translucent. Cleavage {010}, perfect. $H = 2\frac{1}{2}$ -3. $G = 3.33$. Biaxial (+); $X = b$; $Z \wedge c = 37^\circ$; $N_x = 1.622$, $N_y = 1.638$, $N_z = 1.671$; $2V = 74^\circ$. Soluble in acids. Synthesized. A secondary mineral that occurs at the Sterling Hill mine, Ogdensburg, Sussex Co., NJ; at the Ojuela mine, Mapimi, DGO, Mexico, in sprays of bladed crystals to 6 mm(1); and known from the alteration of smaltite and sphalerite at the *Daniel mine, Schneeberg, Saxony, Germany*. HCWS *DII:751*.

40.3.6.6 Parasymplesite $\text{Fe}_3^{2+}(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1837 from the Greek *to bring together*, in allusion to its relations to other minerals. Dimorphous with symplesite (40.3.8.1). Vivianite group. MON $C2/m$. $a = 10.335$, $b = 13.491$, $c = 4.777$, $\beta = 105.04^\circ$, $Z = 2$, $D = 3.043$. *BM 100:310(1977)*. *35-461*: 7.91₇ 6.68₁₀ 4.41₄ 3.91₃ 3.24₅ 3.01₉ 2.75₅ 2.47₄. See also *42-536*, zinc-rich mineral from Ojuela mine, Mapimi, Mexico. Spherical aggregates with coarsely fibrous, radial structure; crystals elongated [001], sometimes flattened {110}; twinned on {110}. Light green to leek-green, becoming greenish black or deep indigo-blue on oxidation, bluish-white streak, vitreous luster, transparent when fresh. Cleavage {110}, perfect, uneven fracture, brittle; translation gliding T{110}, t{001}. $H \approx 2\frac{1}{2}$. $G = 3.01$. Biaxial (-); X perpendicular to (110); $Z \wedge c = 31\frac{1}{2}^\circ$; $N_x = 1.635$, $N_y = 1.668$, $N_z = 1.702$; $2V = 86\frac{1}{2}^\circ$, $r > v$. X, deep blue; Y, nearly colorless; Z, colorless. With alteration the extinction angle increases, absorption colors go from blue to green to brown and decrease in intensity. Soluble in acids. Turns red-brown in H_2O_2 , KOH solutions. A secondary mineral associated with pharmacosiderite, scorodite, erythrite, annabergite, and iron oxyhydroxides. Found at Sterling Hill mine, Ogdensburg, Sussex Co., NJ; at Ojuela mine, Mapimi, DGO, Mexico, in crystals to 5 cm(l); at Lobenstein, and Saubach in Voigtland, with roselite at Neustädte near Schneeberg, Saxony, Germany; with quartz in cavities in hornstone at Felsobanya, Romania; at Pizzo Cipolla, Mandanici, Messina Prov., Italy; at Kiura Ohita, Japan; at the Magnet mine, TAS, Australia. *HCWS DII:752*.

40.3.6.7 Hörnesite $\text{Mg}_3(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1860 for Moritz Hoernes (1815–1868), curator of the Hof-Mineralienkabinett, Vienna, Austria. Vivianite group. MON $C2/m$. $a = 10.26$, $b = 13.44$, $c = 4.645$, $\beta = 102.41^\circ$, $Z = 2$, $D = 2.602$. *NJMM:349(1966)*. *35-856(syn)*: 7.97₃ 6.73₁₀ 4.40₅ 3.99₃ 3.21₅ 3.00₆ 2.74₄ 2.71₃. Prismatic [001] and flattened {010}, columnar, radially foliated. White, transparent, pearly on cleavage. Cleavage {010}, perfect; {100}, poor; flexible. $H = 1$. $G = 2.73$ (Jachymov). Biaxial (+); $X = b$; $Z \wedge c = 31^\circ$; $N_x = 1.563$, $N_y = 1.571$, $N_z = 1.596$; $2V = 60^\circ$. Soluble in acids. Synthesized. Found at Sterling Hill mine, Ogdensburg, Sussex Co., NJ; at Langban, Varmland, Sweden; at *Csiklova in the Banat, Romania*; and with nagyagite from Nagyag; at Jachymov, Bohemia, Czech Republic; at Fiano, near Naples, Italy, with nocerite, fluorite, and hydromagnesite in marble. *HCWS DII:755, AM 52:1588(1967)*.

40.3.6.8 Arupite $\text{Ni}_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1990 for Hans Arup (b.1928), director of the Danish Corrosion Center, Copenhagen, Denmark. Ni analog of vivianite. Vivianite group. MON $I2/m$. $a = 9.889$, $b = 13.225$, $c = 4.645$, $\beta = 102.41^\circ$, $Z = 2$, $D = 2.85$. *NJMM:76(1990)*. *33-951(syn)*: 7.77₄ 6.62₁₀ 4.81₆ 4.48₃ 3.80₅ 2.92₇ 2.68₅ 2.66₄. Earthy aggregates up to 2 mm in diameter, grains are short prisms up to 5 μm long. Sky blue to turquoise-blue, earthy luster, translucent.

$H = 1\frac{1}{2}$. Biaxial; $N_x = 1.632$, $N_z = 1.680$. X, blue; Z, colorless. Synthesized. Occurs in the weathered *Santa Catharina Ni-rich Fe meteorite* found in 1875 on the coast of southern *Brazil*, associated with honessite and reevesite. HCWS *NBSM 25(19):64(1982)*.

40.3.7.1 Bobierite $Mg_3(PO_4)_2 \cdot 8H_2O$

Named by J. Dana in 1868 for Pierre Adolphe Bobierre (1823–1881), French agricultural chemist who described the mineral. Vivianite group. MON *A2/a*. $a = 10.067$, $b = 27.926$, $c = 4.667$, $\beta = 105.01^\circ$, $Z = 4$, $D = 2.133$. Structure: *AM 71:1229(1986)*. I and II forms observed; I (mineral): unit cell data given; II (synthetic): *C2/m*, has slightly smaller unit cell dimensions. *16-330(syn)*: 8.04₂ 6.96₁₀ 3.02₁ 2.94₃ 2.81₁ 2.57₁ 2.41₁ 2.13₁. Minute acicular or fibrous crystals elongated [001] flattened {010}, rosettelike flattened aggregates, massive, lamellar. Colorless, white; weakly vitreous luster; transparent. Cleavage {010}, perfect. $H = 2-2\frac{1}{2}$. $G = 2.195$. Biaxial (+); $Y = b$; $Z \wedge c = 29^\circ$; $N_x = 1.510$, $N_y = 1.520$, $N_z = 1.543$ (Minnesota); $2V = 71^\circ$; $r < v$. Synthesized. Found on a fossil elephant tusk in Pleistocene gravel, Edgerton, Pipeston Co., MN; with apatite at *Odengården, Bramle, Norway*; at Wodgina, Pilbara district, WA, Australia; in guano on the island of Mejillones, Chile. HCWS *DII:753, AM 48:635(1963)*.

40.3.7.2 Manganese-Hörnesite $(Mn^{2+}, Mg)_3(AsO_4)_2 \cdot 8H_2O$

Named in 1951 for the composition and relationship to hörnesite. Vivianite group. MON *P2₁/c*. $a = 10.38$, $b = 28.09$, $c = 4.77$, $\beta = 105.67^\circ$, $Z = 4$, $D = 2.76$. *AM 39:159(1954)*. *8-141*: 8.19₈ 7.01₁₀ 3.25₆ 3.09₆ 3.02₇ 2.88₄ 2.72₄ 2.41₇. Needlelike crystals elongated and flattened on {010}, resembling gypsum. Radiating aggregates, stellate, up to 1 cm in diameter. White to colorless, white streak, silky luster on cleavage, transparent. Cleavage {010}, perfect; {100}, {201}, {201}, imperfect. $H = 1$. $G = 2.64$. Biaxial (+); $N_x = 1.579$, $N_y = 1.589$, $N_z = 1.609$; $2V = 65-70^\circ$. Found at Sterling Hill mine, Ogdensburg, Sussex Co., NJ; at *Långban, Varmland, Sweden*, with rhodochrosite. HCWS *AMG 1:333(1951)*.

40.3.8.1 Symplesite $Fe_3^{+}(AsO_4)_2 \cdot 8H_2O$

Named in 1837 from the Greek *to bring together*. Dimorphous with parasymphesite (40.3.6.6); see also ferrisymplesite (42.10.1.1). Vivianite group. TRIC *P1*. $a = 7.86$, $b = 9.35$, $c = 4.75$, $\alpha = 93.7^\circ$, $\beta = 98.1^\circ$, $\gamma = 106.5^\circ$, $Z = 1$, $D = 3.01$. Structure: *NJMA 138:94(1980)*, *SR 63:303(1950)*. *8-172*: 8.97₂ 7.50₂ 6.79₁₀ 5.03₁ 4.07₁ 4.01₁ 3.74₁ 3.40₁. Similar in physical and chemical properties to parasymphesite. Biaxial (-); $N_x = 1.635$, $N_y = 1.668$, $N_z = 1.702$; $2V = 87^\circ$. Found as sprays to 4 mm Ojuela mine, Mapimi, DUR, Mexico; Voigtland, Germany; at Felsobanya, Rumania, at Bou Azzer, Morocco. HCWS *DII: 752*.

40.3.8.2 Metaköttigite $(\text{Zn}, \text{Fe}^{2+}, \text{Fe}^{3+})_3(\text{AsO}_4)_2 \cdot 8\text{H}_2\text{O}$

Named in 1982 for the relationship to köttigite. The Zn analog of symplecite (40.3.8.1). Vivianite group. TRIC *P1*. $a = 7.96$, $b = 9.44$, $c = 4.72$, $\alpha = 95.6^\circ$, $\beta = 97.0^\circ$, $\gamma = 107.8^\circ$, $Z = 1$, $D = 3.03$. *NJMM:506(1982)*. 35-563: 8.90₄ 6.91₁₀ 4.99₂ 3.93₃ 3.79₂ 3.11₂ 3.00₃ 2.83₂. Minute bluish-gray crystals in oriented intergrowth on common *c* axis with köttigite. Twinned on {110}. Cleavage {110} perfect parallel to (010) cleavage of köttigite. Biaxial; $N_x = 1.648$, $N_y = 1.680$, $N_z = 1.716$; $2V = 93^\circ$; strongly pleochroic. X, dark blue; Y, yellow; Z, pale yellow. Microprobe and Mossbauer analyses showed minor Co and Fe. Found on massive samples of fine-grained goethite and smithsonite at *Ojuela mine, Mapimi, DGO, Mexico*, associated with köttigite and adamite. *HCWS AM 68:1039(1983)*.

40.3.9.1 Metavivianite $(\text{Fe}_{3-x}^{2+}, \text{Fe}_x^{3+})(\text{PO}_4)_2(\text{OH})_x \cdot 8 - x\text{H}_2\text{O}$

Named in 1974 to reflect the relationship to vivianite (40.3.6.1). Synonyms: kertschenite, oxykertschenite. Vivianite group. TRIC *P1* or *P1*. $a = 7.81$, $b = 9.08$, $c = 4.65$, $\alpha = 94.77^\circ$, $\beta = 97.15^\circ$, $\gamma = 107.37^\circ$, $Z = 1$, $D = 2.69$. *AM 50:896(1974)*. 29-1137: 8.59₄ 6.71₁₀ 4.86₄ 4.27₁ 3.87₃ 3.07₁ 2.90₂ 2.77₃. Flat prisms {110} elongated on *c*, striated parallel to *c*. Twinned on {110}, equivalent to the mirror plane {010} in (monoclinic) vivianite structure. Leek-green, opaque to translucent. Cleavage {110}, perfect. Biaxial (-); X perpendicular to (010); Y parallel to (110); $N_x = 1.579$, $N_y = 1.603$, $N_z = 1.629$; X, blue, blue-green; Y, Z, yellowish green (similar to vivianite). Metavivianite is not a dimorph of vivianite, as the oxidation of Fe is coupled with changes in H₂O content, which influences the OH⁻ and H⁺ available for bonding and the stability of the structure. See discussion under vivianite (40.3.6.1). *MM 50:687(1986)*. Occurs intimately intergrown with dark red kryzhanovskite in solution cavities in massive triphyllite boulders at *Big Chief pegmatite, Glendale, Pennington Co., SD*. *HCWS*

40.3.10.1 Volborthite $\text{Cu}_3\text{V}_2\text{O}_7(\text{OH})_2 \cdot 2\text{H}_2\text{O}$

Named in 1838 for Alexander von Volborth (1800–1876), Russian paleontologist who first noted the mineral. MON *C2, Cm* or *C2/m*. $a = 10.606$, $b = 5.874$, $c = 7.213$, $\beta = 94.9^\circ$, $Z = 2$, $D = 3.52$. *NJMM:385(1988)*. Structure: *JSSC 85:220(1990)*. Pyrovanadate ions connected by Cu octahedra into layers parallel to (001) with H₂O between the layers, similar to thortveitite. 26-1119: 7.16₁₀ 4.10₅ 3.09₅ 3.00₅ 2.89₅ 2.64₇ 2.57₇ 2.39₇. Scaly, spongy, or fibrous crusts, rosettelike aggregates, also reticulated. Scales may have triangular or hexagonal outline. Dark olive-green to yellowish green, vitreous luster, sub-translucent. Perfect cleavage one direction. $H = 3\frac{1}{2}$. $G = 3.42$. Biaxial (-); $N_x = 2.01$, $N_y = 2.04$, $N_z = 2.07$ (Uzbek); $2V$ large; $r < v$. Soluble in acids. A secondary mineral found in the sandstones at Richardson in the canyon of the Colorado R., Grand Co., UT; at Monument No. 1 mine(!), Monument Valley, Navajo Co., AZ, in a siltstone with carnotite, hewettite, metatyuyamunite, rauvite, and tyuyamunite; at *Syssersk and Nizhne Taglisk, Ural Mts.,*

Russia; at Woskressensk, Perm, and in Ferghana, Uzbekistan; at La Verde mine, Copiapo, Chile. *HCWS DII:818, AM 59:372(1974)*.

40.3.11.1 Rauenthalite $\text{Ca}_3(\text{AsO}_4)_2 \cdot 10\text{H}_2\text{O}$

Named in 1964 for the locality. TRIC $P\bar{1}$. $a = 12.564$, $b = 12.169$, $c = 6.195$, $\alpha = 89.09^\circ$, $\beta = 79.69^\circ$, $\gamma = 118.58^\circ$, $Z = 2$, $D = 2.362$. *BM 105:327(1982)*. Structure: *AC(B) 39:4(1983)*. 35-569: 10.8₁₀ 6.2₆ 5.40₄ 4.79₄ 3.95₄ 3.36₈ 2.44₇ 2.06₆. Rounded irregular polycrystalline spherulites, individual crystals flattened, prismatic. Snow white, colorless, translucent. $G = 2.36$. Biaxial (+); X, Y in plane of flattening; $Y \wedge c$ (elongation) = 5–10°; $N_{x \text{ calc}} = 1.540$, $N_y = 1.552$, $N_z = 1.570$; $2V = 85^\circ$. Found in the *Rauenthal vein system, at the 40-m level of Gabe Gottes vein, Ste.-Marie-aux-Mines, Vosges Mts., Alsace, France*. *HCWS BM 87:169(1964), AM 50:805(1965)*.

40.3.12.1 Phaunouxite $\text{Ca}_3(\text{AsO}_4)_2 \cdot 11\text{H}_2\text{O}$

Named in 1982 for the French name for the locality, *Phaunoux*. See rauenthalite (40.3.11.1). TRIC $P\bar{1}$. $a = 12.563$, $b = 12.181$, $c = 6.205$, $\alpha = 88.94^\circ$, $\beta = 91.67^\circ$, $\gamma = 113.44^\circ$, $Z = 2$, $D = 2.294$. *BM 105:327(1982)*, Structure: *AC(B) 39:4(1983)*. 41-581: 11.49₁₀ 6.23₉ 5.42₈ 3.28₉ 3.10₅ 2.96₆ 2.44₇ 2.03₆. Acicular crystals showing {100}, {010}, fan-shaped aggregates. Colorless, vitreous luster, translucent. $G = 2.28$. Biaxial (+); $N_x = 1.532$, $N_y = 1.542$, $N_z = 1.556$; $2V \approx 80^\circ$. At room temperature dehydrates slowly to rauenthalite. Found in two portions of the *Gabe Gottes vein, Ste.-Marie-aux-Mines, Vosges Mts., Alsace, France*. *HCWS AM 68:850(1983)*.

40.3.13.1 Ferrazite $(\text{Pb,Ba})_3(\text{PO}_4)_2 \cdot 8\text{H}_2\text{O} (?)$

Named in 1919 for Jorge Palmiro de Araujo Ferraz (1883–1926) of the Geological Survey of Brazil. Defined on chemical analysis of compact, dark yellowish-white disk-shaped pebbles (favas) found in the Brazilian diamond deposits near Diamantina, Brazil, but there have been no additional physical or chemical data. *HCWS AJS (4)48:353(1919)*.

VARISCITE GROUP

The members of the variscite group conform to the general formula

where

A = Al, Fe³⁺, Sc, other trivalent cations

T = P, As

and the structure is orthorhombic in space group *Pbca* or is monoclinic in space group *P2₁/n*.

The structure is built of alternate TO_4 tetrahedra and octahedrally coordinated cations that associate into a three-dimensional network. The cations have a distorted octahedral array bonding with O from four PO_4 groups and O from two water molecules. The arrangement presents limited opportunities for cleavage except where H_2O molecules are concentrated. Tilting of the tetrahedra and a somewhat different hydrogen-bonding arrangement distinguish the monoclinic from the orthorhombic subgroups.

There is complete solid solution between Fe^{3+} and Al in the PO_4 members variscite and strengite, and probably between the AsO_4 members mansfieldite and scorodite.

VARISCITE GROUP: ORTHORHOMBIC SUBGROUP

Mineral	Formula	Space Group	a	b	c	
Variscite	$\text{AlPO}_4 \cdot 2\text{H}_2\text{O}$	<i>Pbca</i>	9.822	8.561	9.630	40.4.1.1
Strengite	$\text{Fe}^{3+}\text{PO}_4 \cdot 2\text{H}_2\text{O}$	<i>Pcab</i>	10.07	9.82	8.67	40.4.1.2
Scorodite	$\text{Fe}^{3+}\text{AsO}_4 \cdot 2\text{H}_2\text{O}$	<i>Pcab</i>	9.996	10.278	8.937	40.4.1.3
Mansfieldite	$\text{AlAsO}_4 \cdot 2\text{H}_2\text{O}$	<i>Pcab</i>	10.10	9.80	8.79	40.4.1.4
Yanomantite	$\text{InAsO}_4 \cdot 2\text{H}_2\text{O}$	<i>Pbca</i>	10.446	9.068	10.345	40.4.1.5

VARISCITE GROUP: MONOCLINIC SUBGROUP

Mineral	Formula	Space Group	a	b	c	β	
Metavariscite	$\text{AlPO}_4 \cdot 2\text{H}_2\text{O}$	<i>P2₁/n</i>	5.178	9.514	8.454	90.35	40.4.3.1

Kolbeckite	$\text{ScPO}_4 \cdot 2\text{H}_2\text{O}$	<i>P2₁/n</i>	5.418	10.25	8.893	90.7	40.4.3.3

40.4.1.1 Variscite $\text{AlPO}_4 \cdot 2\text{H}_2\text{O}$

Named in 1837 for Variscia, the ancient name of the Voigtland district in Germany where the mineral was discovered. Variscite group. Two orthorhombic modifications, 10 and 20, and a monoclinic form, metavariscite (40.4.3.1), have been described. See also strengite (40.4.1.2) with which there is a series Al- Fe^{3+} , and metavariscite (40.4.3.1). ORTH *Pbca*. $a = 9.822$, $b = 8.561$, $c = 9.630$, $Z = 8$, $D = 2.59$. Structure: *AC(B) 33:263(1977)*, *JSC 32:631 (1991)*. 33-33: 5.36₇ 4.82₃ 4.26₇ 3.90₃ 3.63₂ 3.04₁₀ 2.91₅ 2.87₄ (variscite 10: *Pbca*, $a = 9.822$, $b = 8.558$, $c = 9.622$). See also 25-18 (variscite 20: *Pcab*, $a = 9.90$, $b = 9.66$, $c = 17.18$, $Z = 16$). Rare crystals octahedral {111} with {001} (= Lucin-type 10), predominantly as cryptocrystalline aggregates, fine-grained masses, nodules, veinlets or crusts, chalcedonic to opaline (= Messbach type 20). Pale to emerald-green, blue-green, to colorless; white streak; vitreous to waxy luster in the dense varieties; transparent to translucent. Cleavage {010}, good; {001}, poor; massive variscite has splintery fracture, conchoidal in glassy types. $H = 4\frac{1}{2}$. $G = 2.57$ (crystals); G lower

for microcrystalline varieties. Biaxial (-); XYZ = *acb*; $N_x = 1.563$, $N_y = 1.588$, $N_z = 1.594$ (Lucin); 2V moderate; $r < v$, weak. Crystalline Al end members insoluble in HCl, soluble in alkalis. Fe^{3+} substitution in variscite leads to higher indices of refraction. On heating green samples may turn purplish red. High-Al members typically deposited under surface conditions in cavities or breccias as the result of phosphatic meteoric waters acting on aluminous rocks. Associated minerals are wavellite, crandallite, metavariscite, apatite, chalcedony, and iron oxyhydroxides. Occurs at Moore's Mill, Cumberland Co., PA; at Carolina pyrophyllite mine and Winston-Salem, NC; at Cole Shaft, Bisbee, AZ; at the Little Green Monster mine, Fairfield(1), Utah Co., in nodules in brecciated phosphatic sediments associated with other phosphates, at Amatrice Hill, Stockton, and at Lucin, Box Elder Co., UT; at Champion mine, White Mts., Mono Co., CA; at *Messbach Plauen, Voigtland (Variscia), Thuringia, Germany*, and at Langenstriefigis, Frankenberg, Saxony; at Mixnitz, and at Brandberg, Austria; at Zeleznik, Trenice, Zajecow near St. Benigna, Bohemia, Czech Republic; at Iron Knob, Iron Monarch mine, SA, Australia; with apatite in insular rock phosphates on Clipperton Atoll in the Pacific Ocean and in the Antilles, Gran Roque Is., Venezuela; at de la Perle Island near Martinique; Malpelo Is., Colombia. *HCWS DII.756, AM 57:36(1972)*.

40.4.1.2 Strengite $Fe^{3+}PO_4 \cdot 2H_2O$

Named in 1877 for Johann August Streng (1830–1897), mineralogist, University of Giessen, Germany. Variscite group. See phosphosiderite (40.4.3.2) and AsO_4 species scorodite (40.4.1.3). ORTH *Pcab*. $a = 10.07$, $b = 9.82$, $c = 8.67$, $Z = 8$, $D = 2.90$. *NJMA 98:1(1962)*. 33-667: 5.50₉ 4.38₇ 4.00₅ 3.11₁₀ 3.00₅ 2.95₅ 2.55₅ 2.53₄. See also 15-391. Spherical and botryoidal aggregates with radial fibrous structure and drusy surface, or as crusts; rarely as fine crystals to 3 mm. Peach-blossom red, carmine, violet, colorless; white streak; transparent to translucent. Cleavage {010}, good; {001}, poor. $H = 3\frac{1}{2}$. $G = 2.87$. DTA. Biaxial (+); XYZ = *acb*; $N_x = 1.707$, $N_y = 1.719$, $N_z = 1.741$ (Pleystein); 2V small. Optics variable with Al substitution. Soluble in HCl, but not in HNO_3 . Complete series extends between Al (variscite) and Fe^{3+} (strengite) although most analyses appear to be close to end member composition. Synthesized. Surface products formed by alteration of iron-containing phosphates such as triphylite, or dufrenite, in pegmatites, also common in gossans of iron ore deposits. Associated minerals are beraunite, cacoxenite, vivianite, metastrengite, frondelite-rockbridgeite, dufrenite, microcrystalline apatite. Occurs as an oxidation product of triphylite at Palermo No. 1 mine, and Fletcher mine, North Groton, NH; at Mullica Hill, NJ; at Moor's Mill, Cumberland Co., and Noblis mine, Bearville, Lancaster Co., PA; with rockbridgeite near Midval, Rockbridge Co., VA; at Jacksonville, Calhoun Co., Indian Mt., Cherokee Co., Rock Run Station, Indian Mt., AL; in Polk Co., AR; at Woods mine, Burnett Gap, Locke Co., TN; in the Bull Moose pegmatite, Custer Co., SD(!); at Champion mine, White Mts., Mono Co., and a Mn-

rich variety at the Stewart Lithia mine, Pala, San Diego Co., CA. Al-rich varieties found at Manhattan, Nye Co., NV; at Mangualde, Beira Prov., Portugal. Also found in the *Eleonore iron mine, Giessen, near Waldgirmes, Thuringia*, alteration product at the pegmatites at Pleystein and Hagendorf, Bavaria, *Germany*; in the magnetite ore at Kirunavaara, Sweden; at the Iron Monarch mine, Iron Knob, SA, Australia; at Sapucaia Velha pegmatite, MG, Brazil. *HCWS DII:756*.

40.4.1.3 Scorodite $\text{Fe}^{3+}\text{AsO}_4 \cdot 2\text{H}_2\text{O}$

Named in 1817 from the Greek for *garlic-like*, in allusion to its odor when heated. Variscite group. See also the Al end member of the series, mansfieldite (40.4.1.4). ORTH *Pcab*. $a = 9.996$, $b = 10.278$, $c = 8.937$, $Z = 8$, $D = 3.39$. *MM 35:776(1966)*, *AC(B) 32:2891(1976)*. *37-468*: 5.61₈ 5.02₄ 4.47₁₀ 4.09₃ 3.18₉ 3.06₅ 3.00₄ 2.60₄. See also *18-654*, *26-778*. Crystals usually pyramidal {111}, tabular {001}, or prismatic [010], often aggregates as irregular groups or crusts, also massive, crystalline or porous and sinterlike, dense to earthy. Pale leek-green or gray-green to liver-brown, colorless, bluish, violet, yellow; earthy material is pale green, grayish, or brownish green; vitreous to subadamantine, subresinous luster; transparent in crystals. Cleavage {201}, imperfect; {001}, {100}, in traces; subconchoidal fracture. DTA. Biaxial (+); $XYZ = acb$; $N_x = 1.784$, $N_y = 1.795$, $N_z = 1.814$ (Durango); $2V \approx 75^\circ$; faintly pleochroic; $r > v$, strong; $Z > X, Y$. Biaxial (+); $N_x = 1.888$, $N_y = 1.895$, $N_z = 1.915$; $2V = 62^\circ$ (Japan, Al-rich). Indices, birefringence, $2V$ decrease with decreasing Fe/Al. Soluble in acids, in strong alkali mineral decomposes with separation of hydrous iron oxide. Synthesized. There is probably a complete Al-Fe series to mansfieldite, some substitution of PO_4 for AsO_4 (toward strengite). Found as a primary mineral at hydrothermal deposits such as at Saubach, Voigtland, Germany, but mostly as a secondary phase in gossans from the oxidation of arsenopyrite, or other As-containing minerals. Associated with pharmacosiderite, beudanite, vivianite, gypsum, chalcedonic quartz, iron oxyhydroxides, clays. Occurs at Sterling Hill mine, Ogdensburg, Sussex Co., NJ; at Gold Hill, Toole Co., UT; at Grandview mine, AZ; at the Mina Noche Bueno, Mazapil, ZAC(!), and similarly at the Ojuela mine, Mapimi, DGO(!), Mexico, in sharp, lustrous blue-green crystals to 3 cm; at Grube Clara, Randschlacht and Schwarzenberg, Saxony, Germany; at Kamerzesa mine, Attica, Greece; at Bhilwara district pegmatites, Rajasthan, India; at Tsumeb mine, Tsumeb, Namibia; at Preamimma mine, Callington, SA, Australia; at Geralfo Candinha mine, MG, Brazil; at Chuquicamata, Antofagasta, Chile. *HCWS DII:763*.

40.4.1.4 Mansfieldite $\text{AlAsO}_4 \cdot 2\text{H}_2\text{O}$

Named in 1948 for George Rogers Mansfield (1875-1947), geologist, U.S. Geological Survey. Variscite group. The Al end member of an Al- Fe^{3+} series with scorodite. ORTH *Pcab*. $a = 10.10$, $b = 9.80$, $c = 8.79$, $Z = 8$, $D = 3.08$. *NJMM:79(1963)*. *22-123*: 5.53₁₀ 4.92₃ 4.41₁₀ 4.02₄ 3.12₁₀ 3.00₉ 2.53₇ 2.45₄.

Spherulitic crusts made up of fibers; crusts up to 20 cm in diameter, porous, cellular masses. Light green to pale gray. $H = 3\frac{1}{2}$ -4. $G = 3.02$. Biaxial (-); $N_x = 1.627$, $N_z = 1.657$; $2V = 68^\circ$ (Oregon). Biaxial (+); $N_x = 1.622$, $N_y = 1.624$, $N_z = 1.642$; $2V = 30^\circ$; $r > v$. *AM 33:122(1948)*. Found at *Hobart Butte, Lane Co., OR*, with realgar and scorodite and intergrown with quartz and kaolinite; at Neubulach, Black Forest, Germany. *HCWS DII:763, AM 33:122(1948)*.

40.4.1.5 Yanomamite $InAsO_4 \cdot 2H_2O$

Named in 1994 for the Yanomami Indian people of the Amazon basin. Vacansite group. ORTH *Pbca*. $a = 10.446$, $b = 9.086$, $c = 10.345$, $Z = 8$, $D = 3.876$. *EJM 6:245(1994)*. *PD: 5.70₇ 4.53₁₀ 4.16₅ 3.87₆ 3.25₆ 3.11₅ 2.66₄ 2.54₄*. Idiomorphic crystals in aggregates, green-yellow, always coated with thin film of In-rich scorodite and intimately intermixed. Biaxial; $N_{mean} = 1.65$. Al and Fe^{3+} present on analysis. Appears to be cogenetic with In-bearing scorodite as an alteration of arsenopyrite and In-rich sphalerite. A secondary mineral found in the Sn deposits of *Mangabeim, Goiaa, Brazil*. *HCWS*

40.4.2.1 Koninckite $Fe^{3+}PO_4 \cdot 3H_2O$

Named in 1883 for Laurent Guillaume de Koninck (1809-1887), Belgian geologist. TET Space group unknown. $a = 11.95$, $c = 14.52$, $Z = 16$, $D = 2.625$. *BM 91:487(1968)*. *41-1489: 8.47₁₀ 6.00₁ 4.52₁ 3.85₂ 3.79₃ 3.66₁ 3.36₁ 2.99₂*. See also *22-339*. Small spherical aggregates up to 0.8 mm in diameter of radiating needles about 40 μm long terminated by an oblique plane. Yellow-white, light yellow streak, transparent. Cleavage transverse to elongation. $H = 3\frac{1}{2}$ -4. $G = 2.40$. Biaxial; $N_x = 1.645$, $N_z = 1.656$; $2V$ not very large; elongated on X. May also be isotropic, $N = 1.65$. Easily soluble in hot HCl, HNO_3 . Found at *Richelle, Visé, near Liège, Belgium*. Specimen with some Al from Nagano Pref., Japan. *HCWS DII:763*.

40.4.3.1 Metavariscite $AlPO_4 \cdot 2H_2O$

Named in 1925 for its dimorphic relationship to variscite (40.4.1.1). Variscite group. See also phosphosiderite (40.4.3.2), the Fe analog. MON $P2_1/n$. $a = 5.178$, $b = 9.514$, $c = 8.454$, $\beta = 90.35^\circ$, $Z = 4$, $D = 2.535$. *AC(B) 29:2292(1973)*. *33-32: 6.33₂ 4.76₁₀ 4.55₇ 4.23₆ 3.50₆ 2.71₉ 2.29₂ 1.585₂*. See also *15-311*. Crystals thin to thick tabular {010}, equant or slightly elongate [001] or [100] producing laths, rarely prismatic [100], also pseudo-orthorhombic, granular masses. Light green, white streak, vitreous luster, transparent, masses translucent. Cleavage {010}. $H = 3\frac{1}{2}$. $G = 2.54$. Biaxial (-); $N_x = 1.551$, $N_y = 1.558$, $N_z = 1.582$ (crystals); $2V = 55^\circ$; $r < v$. Possibly a complete isomorphous substitution to phosphosiderite. Found as crystals associated with variscite crystals in cavities of variscite nodules at *Edison-Bird mine, Utahlite Hill, Lucin, Box Elder Co., UT*; massive with variscite at *Candelaria, NV*; in phosphatized andesite on Malpelo Island, (Pacific Ocean), Colombia. *HCWS DII:767*.

40.4.3.2 Phosphosiderite $\text{Fe}^{3+}\text{PO}_4 \cdot 2\text{H}_2\text{O}$

Named in 1890 for the composition and from the Greek for *iron*. Variscite group. Also known as metastrengite, as it is the dimorph of strengite (40.4.1.2). MON $P2_1/n$. $a = 5.30$, $b = 9.77$, $c = 8.73$, $\beta = 90.6^\circ$, $Z = 4$, $D = 2.76$. AM 37:362(1952), Structure: AM 51:168(1966). A more open structure than strengite. 33-666: 4.91₃ 4.69₁₀ 4.57₂ 4.36₇ 3.61₅ 2.79₈ 2.57₄ 2.01₂. Crystals tabular {010} or stout prismatic [001], botryoidal or reniform masses, crusts with a radial fibrous structure. Light violet-pink, peach blossom red, moss green; aggregates bright rose-red to nearly colorless; vitreous to subresinous luster; translucent. $H = 3\frac{1}{2}$ -4. $G = 2.74$. Biaxial (-); $X \wedge c \approx 4^\circ$; $Y = b$; $N_x = 1.692$, $N_y = 1.725$, $N_z = 1.738$ (Na); $2V = 62^\circ$; $r > v$, very strong. Al substitutes for Fe^{3+} , a complete series to metavariscite probable. Synthesized. Found at the Fletcher and Palermo No. 1 mines, North Groton, and at Fitzgibbon mine, Alstead, NH; at Mullica Hill, NJ; at Graves Mt., GA; at Williams properties, Coosa Co., AL; at Bull Moose pegmatite, Custer, Highland Lode, Etta mine, Keystone, and White Elephant pegmatite, SD; at Stewart Lithium mine, Pala, San Diego Co., CA; at Chanteloub, France; at *Kaltenborn mine, near Eisenfeld, Siegen, Germany*, in iron ore, also in Bavaria with pharmacosiderite at Kreuzberg, Pleystein, Hagendorf, and the other pegmatites in Bavaria; at Lavra do Enio, Galileia, and Sapucaia Velha pegmatite, Galileia, MG, Brazil; El Criollo pegmatite, Argentina. hcws DII:767.

40.4.3.3 Kolbeckite $\text{ScPO}_4 \cdot 2\text{H}_2\text{O}$

Named in 1926 for Friedrich L. W. Kolbeck (1860-1943), mineralogist, Mining Academy, Freiberg, Germany, and reexamined (1959) to establish the composition. Variscite group. MON $P2_1/n$. $a = 5.418$, $b = 10.25$, $c = 8.893$, $\beta = 90.7^\circ$, $Z = 4$, $D = 2.344$. 38-431: 5.1₃ 4.78₁₀ 4.66₂ 4.44₁₀ 3.71₄ 2.88₇ 2.85₅ 2.61₅. See also 2-177. Crystals short prismatic [001] with {110}, {011}, and {001}; twinned on {100}, appearing orthorhombic. Yellowish apple-green to colorless. Cleavage {010}, distinct; conchoidal fracture; brittle. $H = 3\frac{1}{2}$ -4. $G = 2.35$. Biaxial (-); $N_x = 1.570$, $N_z = 1.610$. Synthesized. Found at Potash Sulfur Springs and Magnet Cove, AK; at Fairfield, UT; in a quartz wolframite vein in the Sadisdorf copper mine, *Schmiedeburg, Saxony, Germany*; at Klause quarry, Gleichenberg, Styria, Austria; at Felsobanya, Hungary; at Sakpur, Damnagar Talaq, Boroda, Gujarat, India; in the W-Sn ores, Tigrinoeye deposit, Silchote-Alin Range, China. hcws DII:1015, BGSa 70:1648(1959), MM 46:493(1982), DAns 322:1963(1992).

40.4.4.1 Kankite $\text{Fe}^{3+}\text{AsO}_4 \cdot 3.5\text{H}_2\text{O}$

Named in 1976 for the locality. MON. $a = 18.803$, $b = 17.490$, $c = 7.633$, $\beta = 92.71^\circ$, $Z = 16$, $D = 2.732$. MJ 12:6(1984). 29-694: 12.8₁₀ 7.56₃ 7.22₂ 4.76₄ 4.26₃ 3.70₂ 2.63₂ 2.55₂. Botryoidal coatings and crusts up to 7 mm

thick; spherules of very thin tablets less than 10 μm across. Yellowish-green, earthy, dull to vitreous luster. $H = 2\text{--}3$. $G = 2.70$. DTA, TG, IR. Biaxial; $N_{\text{max}} = 1.680$, $N_{\text{min}} = 1.664$; length-fast. Some S substitutes for As. Insoluble in H_2O but readily dissolves in 1:10 HCl. Found on the old (thirteenth- to fifteenth-century) dumps at *Kank, Kutno Hora district, Stredocesky Kraj, Bohemia, Czech Republic*; at Suzukura mine, Enzan City, Yamana-shi Pref., Japan. *HCWS NJMM:426(1976)*; *AM 62:594(1974)*, *70:220(1985)*.

40.4.5.1 Steigerite $\text{AlVO}_4 \cdot 3\text{H}_2\text{O}$

Named in 1935 for George Steiger (1869–1944), chief chemist, U.S. Geological Survey. *MON P2₁/M, P2*. $a = 11.840$, $b = 25.00$, $c = 11.040$, $\beta = 110.16^\circ$, $Z = 24$, $D = 2.58$. *ZVMO 116:100(1987)*, *AM 44:322(1959)*. *39-406: 12.52₅ 5.67₃ 3.09₄ 2.96₃ 2.93₁₀ 2.21₄ 2.18₅ 1.426₄*. See also *29-20*. Pulverulent coatings composed of fibers, gumlike masses, and occasionally flat plates. Canary-yellow to olive-green, waxy luster. $H = 2\frac{1}{2}\text{--}3$. $G = 2.56$. Biaxial (+); $N_x = 1.730$, $N_y = 1.734$, $N_z = 1.752$; $2V = 58^\circ$. Easily soluble in 1:10 acids to a deep cherry-red solution. Insoluble in H_2O . Small amounts of Cr, Fe, Ca, P, and S detected on analysis. Synthesized. Found with ferveranite and gypsum coating fractures in and around nodular concretions of corvusite in sandstone at *Sullivan Brothers claim, Gypsum Valley, San Miguel Co., CO*; at northwestern Karatau Mt. range, Kazakhstan. *HCWS DII:1049*.

40.4.6.1 Churchite-(Y) $\text{YPO}_4 \cdot 2\text{H}_2\text{O}$

Named in 1865 for Arthur Herbert Church (1834–1915), English chemist who described and analyzed the mineral. Gypsum group. Synonym: weinschenkite. *MON*. $a = 5.61$, $b = 15.14$, $c = 6.19$, $\beta = 115.3^\circ$, $Z = 4$, $D = 3.25$. *MM 30:211(1953)*, *ZK suppl. 3:258(1991)*. *8-167: 7.5₉ 4.70₆ 4.21₁₀ 3.74₆ 3.02₉ 2.82₇ 2.62₆ 2.17₆*. Crusts of subparallel platy aggregates or acicular radiating aggregates. Yellowish-gray, tinged with flesh red; vitreous luster, pearly on cleavage; transparent. Cleavage parallel to $\{010\}$, perfect; $\{100\}$, $\{001\}$, distinct. $H = 3$. $G = 3.27$. Biaxial (+); $N_x = 1.623$, $N_y = 1.631$, $N_z = 1.657$; $2V = 15^\circ$; Z perpendicular to plates. Analysis showed other rare earths Y: (Er, La, Nd, Ce) = 3:1, also Fe^{3+} , Ca, Nd-rich samples of churchite (26–42% of RE elements relative to 50% Y) were found in the mantle of weathered metamorphic rocks in Kazakhstan. Crystallites from the yellowish or pinkish-white oolitic segregations up to 12 μm long and 2 μm wide with rectangular cross section gave slightly different indices of refraction and X-ray diffraction powder pattern. *39-1385: 6.12₃ 3.49₄ 3.02₁₀ 2.82₇ 2.15₇ 1.92₃ 1.858₉ 1.743₃*. Associated minerals were apatite, fluorite, amphiboles, and acicular transparent zeolites, possibly natrolite, *DANS 268:139(1983)*. Synthesized. Found at Indian Mt., Cherokee Co., NC; at Vesuvius, Rockbridge, Co., VA; at Sausalito, CA; at Wheal Pendres tin mine, Camborne, with limonite, quartz, and barite, and at *Trefoil mine, near Bodmin, Cornwall, England*; in

Bavaria, Germany; in laterite of Chutukou, Enisei Range, Yenisei, Russia; at Mt. Weld, WA, Australia, in carbonaceous laterites where churchite occurs as void fillings in crandallite group minerals, as fine grains, or intergrown with limonite and associated with goyazite, gorceixite, florencite, crandallite, monazite, apatite, and cerianite. *HCWS DII:773, DANS 268:139(1983), MM 51:468(1987).*

RHABDOPHANE GROUP

The rhabdophane minerals are phosphate monohydrates corresponding to the general formula

where

and crystallizing in hexagonal or orthorhombic space groups.

Thy hydrated equivalents of minerals in the monazite group the rhabdophane group minerals have a very open structure formed of alternating cations and phosphate groups in columns along the *c* axis. The linkage of each column to four neighbours results in open channels with a diameter of 5.3Å along the unique hexagonal, or pseudohexagonal, direction. The channels are sites for variable amounts of the "zeolitic" water molecules *MM 48:146 (1984).*

RHABDOPHANE: - (Ce)CePO₄ · H₂O

This *c* axis projection shows the open channels and structure of rhabdophane formed from columns of alternating cation and PO₄ groups stacked along *c*. Note no water molecules are shown in this diagram.

RHABDOPHANE GROUP

Mineral	Formula	Space Group	a			b			c		
			a	b	c	a	b	c	a	b	c
Rhabdophane-(Ce)	CePO ₄ · H ₂ O	P6 ₂ 22	6.960			6.372			40.4.7.1		
Rhabdophane-(La)	LaPO ₄ · H ₂ O	P6 ₂ 22	6.98			6.39			40.4.7.2

Tristramite	(Ca,U ⁴⁺ ,Fe ³⁺)PO ₄ · H ₂ O	P6 ₂ 22	6.913			6.422			40.4.7.6		
Ningyoite	(U,Ca,Fe) ₂ (PO ₄) ₂ · 1-2H ₂ O	P222	6.78	12.10	6.38				40.4.8.1		

40.4.7.1 Rhabdophane-(Ce) CePO₄ · H₂O

Named in 1878 from the Greek *rod* and *to appear*, in allusion to the characteristic bands shown in its spectrum. Rhabdophane group. HEX P6₂22. $a = 6.960$, $c = 6.372$, $Z = 3$, $D = 4.72$. *MM* 48:146(1984), *AC* 3:339(1950). 35-61₄: 6.03₅ 4.38₅ 3.48₅ 3.01₉ 2.82₁₀ 2.35₂ 2.15₅ 1.853₅. Incrustations, botryoidal, globular or stalactitic with radiated-fibrous structure. Brown, pink, yellow-white; greasy luster; translucent. Uneven fracture. $H = 3\frac{1}{2}$, $G = 3.97$. DTA. Uniaxial (+); $N_O = 1.688$, $N_E = 1.744$ (Oberwolfach); positive elongation. Easily soluble in HCl. Analyses show distinctions among the amount and relative proportions of RE elements. Ce-rich forms from Cornwall also show Y, (Al,Fe), and Si, while samples from Oberwolfach show Nd, La, Pr, Sm, Gd, and Eu, higher indices of refraction and larger unit cell parameters. The compositional range of REE phosphates with rhabdophane type structure is probably large. See rhabdophane-(La) (40.4.7.2). Found on the *mine dumps of Fowey Consols, Cornwall, England*; at the Clara mine, Oberwolfach, Middle Black Forest, Germany, in druses on barite, fluorite, chalcopyrite, and tetrahedrite. *HCWS DII:774, CE 38:331(1978), AM 65:1065(1980), MM 47:393(1983)*.

40.4.7.2 Rhabdophane-(La) LaPO₄ · H₂O**40.4.7.3 Rhabdophane-(Nd) NdPO₄ · H₂O**

Named in 1959 to distinguish La/Nd-rich forms of rhabdophane-(Ce). Rhabdophane group. HEX P6₂22. $a = 6.98$, $c = 6.39$, $Z = 3$, $D = 3.99$. *AM* 44:633(1959). 12-277: 6.07₅ 4.40₈ 3.49₆ 3.02₁₀ 2.83₈ 2.36₄ 2.15₈ 1.859₆. See also *MM* 47:933(1983). Uniaxial (+); $N_O = 1.654$, $N_E = 1.703$. Similar in properties to Ce form. The data above from thin incrustations found at *Salisbury, CT*, which show RE elemental composition mainly of Nd, La, Y, and low Ce. High La and Nd variety also obtained from Monumental Summit, Valley Co., ID. In both localities the mineral is associated with hydrated iron hydroxides, clays, and quartz in highly weathered environments. *HCWS DII:774, USGSPP 600:B48(1964), MM 48:146(1984), AM 70:440(1985)*.

40.4.7.4 Grayite $\text{ThPO}_4 \cdot \text{H}_2\text{O}$

Named in 1957 for Anton Gray, mining engineer, advisor to U.K. Atomic Energy Authority. Rhabdophane group. **HEX** $P6_222$. $a = 6.957$, $c = 6.396$, $Z = 3$, $D = 6.41$. *USGSPP 424C:339(1961)*. *42-1389*: 6.05₂ 4.35₅ 3.46₁ 3.03₁₀ 2.82₈ 2.36₁ 2.15₈ 1.856₅. Cryptocrystalline aggregates, powdery. Dark reddish brown, resinous luster. Conchoidal fracture. $N_{\text{av}} = 1.66$ –1.69; moderately birefringent. Less than 2% RE in analyses; Pb, Ca detected. Found in lithia pegmatite, Gooddays mine, Mtoko, and the Mahaka claim, Wedza, *Zimbabwe*; in Gunnison Co., CO. *HCWS AM 47:419(1962)*.

40.4.7.5 Brockite $(\text{Ca,Th,REE})(\text{PO}_4) \cdot \text{H}_2\text{O}$

Named in 1962 for Maurice Brock of the U.S. Geological Survey, who mapped the area in which the mineral was found. Rhabdophane group. See also grayite (40.4.7.4). **HEX** $P6_222$. $a = 6.98$, $c = 6.40$, $Z = 3$, $D = 4.28$. *AM 47:1346(1962)*. *15-248*: 6.06₄ 4.37₇ 3.47₅ 3.03₁₀ 2.83₇ 2.37₃ 1.86₅ 1.69₄. Fine-grained massive aggregates and nodules up to 35 mm in diameter; radially fibrous with individuals up to 50 μm long, earthy coatings. Yellow or red-brown (from hematite stain), greasy luster, translucent. $G = 3.90$. Uniaxial (+); $N_{\text{O}} = 1.680$, $N_{\text{E}} = 1.695$. High percentage Nd relative to Ce, La, and Y in analysis. Found in inclusions of pyrite in veins of altered granitic rocks at the *Bassick mine, Wet Mts., Custer Co., CO*, with quartz, albite, hematite, and apatite, also at Hardwick and Nightingale mines with thorite and barite. *HCWS*

40.4.7.6 Tristramite $(\text{Ca,U}^{4+},\text{Fe}^{3+})\text{PO}_4 \cdot 2\text{H}_2\text{O}$

Named in 1983 for Sir Tristram, the Arthurian mythological character. Rhabdophane group. **HEX** $P6_222$. $a = 6.913$, $c = 6.422$, $Z = 3$, $D = 4.18$. *MM 47:393(1983)*. *35-613*: 5.99₄ 4.37₄ 3.46₃ 2.99₁₀ 2.83₁₀ 2.35₂ 2.14₅ 1.850₅. Acicular to fibrous crystals up to 80 μm long. Pale yellow to greenish yellow. $G = 3.8$ –4.2. Uniaxial (+); $N_{\text{O}} = 1.644$, $N_{\text{E}} = 1.664$. Found intergrown with goethite in fine fractures in mines such as *Wheal Trewavas, Breage, Cornwall, England*. *HCWS AM 69:815(1984)*.

40.4.8.1 Ningyoite $(\text{U,Ca,Fe})_2(\text{PO}_4)_2 \cdot 1-2\text{H}_2\text{O}$

Named in 1959 for the locality. Rhabdophane group. **ORTH** $P222$. $a = 6.78$, $b = 12.10$, $c = 6.38$, $Z = 3$, $D = 4.63$. *AM 44:633(1959)*. *12-273*: 5.99₄ 4.33₆ 3.38₅ 3.02₁₀ 2.81₈ 2.35₄ 2.13₈ 1.845₄. Acicular, lozenge-shaped, crystals up to 5 μm long. Brown, green-brown. $N_{\text{av}} \approx 1.64$; extinction parallel to elongation. Synthesized. $N_{\text{x}} = 1.69$ –1.70, $N_{\text{z}} = 1.70$ –1.71. X, pale green; Z, green. Found at *Ningyo-toge mine, Tottori Pref., Honshu, Japan*, where it coats pyrite and other minerals and fills cracks. *HCWS*

40.4.8.2 Lermontovite $(\text{U}^{4+})(\text{PO}_4)(\text{OH}) \cdot \text{H}_2\text{O}$

Named in 1955 for Mikhail Yurevich Lermontov (1814–1841), Russian poet. **ORTH** $P2_12_12_1$. $a = 9.72$, $b = 18.89$, $c = 10.13$, $Z = 12$, $D = 3.94$. *MZ*

5:82(1983). 41-1399: 4.87₈ 4.69₇ 4.12₈ 3.92₁₀ 3.83₈ 3.58₈ 3.29₉ 3.15₇. Radiating fibrous aggregates, botryoidal. Gray-green, dull to silky luster on fracture, transparent. Very brittle. Rapidly disintegrates in electron microscope beam. $G = 4.0-4.5$. Biaxial; $N_x = 1.686-1.690$, $N_y = 1.707$, $N_z = 1.724-1.726$; $Z = c$ = elongation parallel extinction. Analysis shows Tl in addition to U. Found under sharply reducing conditions in the hydrothermal deposits of the *Kola Penin., Russia*, associated with molybdenum sulfates, marcasite, and "thallium ochre." HCWS *AM* 43:379(1958), 69:214(1984).

40.4.8.3 Vyacheslavite $U^{4+}(PO_4)(OH) \cdot 2.5H_2O$

Named in 1984 for Vyacheslav Gavilovich Melkov (b.1911), Russian mineralogist. ORTH Space group *Cmcm*, *Cmc2₁*, or *C2cm*. $a = 6.96$, $b = 9.10$, $c = 12.38$, $Z = 6$, $D = 5.01$. *ZVMO* 113:360(1984). 38-397: 6.19₁₀ 5.03₂ 4.56₆ 4.13₆ 3.68₅ 3.04₃ 2.71₅ 2.69₇. Spherulitic aggregates of tabular crystallites, 8 μ m long, 1.5 μ m wide. Green, dark green. Cleavage {010}. $G = 4.90$. Biaxial (-); $N_x = 1.700$, $N_y = 1.728$, $N_z = 1.730$; $2V = 15^\circ$; Z perpendicular to elongation; $2V$ small; positive elongation; weakly pleochroic in greens. Some Ca detected on analysis. Found on quartz crystals associated with octahedral pyrite in *Uzbekistan*. HCWS *AM* 69:1195(1984), 70:828(1985).

40.5.1.1 Fransoletite $Ca_3Be_2(PO_4)_2(PO_3OH)_2 \cdot 4H_2O$

Named in 1983 for Andre-Mathieu Fransolet, University of Liège, France. MON $P2_1/a$. $a = 7.354$, $b = 15.07$, $c = 7.055$, $\beta = 96.41^\circ$, $Z = 2$, $D = 2.53$. Structure: *BM* 106:499(1983), *AM* 77:848(1992). 35-629: 7.52₄ 6.55₃ 4.57₃ 3.47₉ 3.32₇ 3.04₁₀ 2.60₄ 2.32₅. Crystals with mosaic texture, aggregates to 3 mm in diameter. Colorless to whitish, white streak, subvitreous luster, transparent in thin sections, otherwise turbid. Cleavage {010}, imperfect, easily produced; irregular fracture; not brittle. $H \approx 3$. Nonfluorescent. Biaxial (+); $Y = b$; $Z \wedge c = 14^\circ$; $N_x = 1.560$, $N_y = 1.566$, $N_z = 1.586$; $2V = 25^\circ$; nonpleochroic; no dispersion visible. Found in the *Tip Top pegmatite, Black Hills, near Custer, SD*, associated with beryl and other secondary minerals. See parafransoletite (38.2.9.1). HCWS

40.5.2.1 Parafransoleite $Ca_3Be_2(PO_4)_2(PO_3OH)_2 \cdot 4H_2O$

Named for its relationship to fransoletite, the dimorph. TRIC $P\bar{1}$. $a = 7.327$, $b = 7.696$, $c = 7.061$, $\alpha = 94.90^\circ$, $\beta = 96.82^\circ$, $\gamma = 101.87^\circ$, $Z = 1$, $D = 2.56$. Structure: *AM* 77:843(1992), 77:848(1992). Dominant structural elements are tetrahedral chains parallel to [100] in which four-membered rings of alternating BeO_4 and PO_4 tetrahedra link through BeO_4 tetrahedra. The chains are linked through Ca and by H bonding. The difference between the dimorphs is the placement of one of two nonequivalent Ca atoms relative to the chains. Structure similar to that of ehrleite (40.5.7.1). *PD*: 7.52₅ 3.62₈ 3.36₂ 3.03₁₀ 2.60₆ 2.49₃ 2.33₄ 1.870₃. Crystals are thin spear-shaped blades to 0.4 long, and as sheaf- and bowtielike aggregates, radial sprays to 2 mm in diameter showing subparallel crystal intergrowths. Most crystals flattened

on {010}, elongated parallel to [100], with the following forms, showing {010}, {011}, {131}, {131}, {144}; often doubly terminated and showing simple contact twinning on {010}. White, white streak, silky luster. $H = 2\frac{1}{2}$. $G = 2.54$. Nonfluorescent. Biaxial (+); $XYZ \approx abc$; $N_x = 1.562$, $N_y = 1.564$, $N_z = 1.588$; $2V_{\text{calc}} = 33^\circ$. Dissolves readily in cold 1:1 HCl. Conditions for the formation of a particular dimorph are not known. Found at the *Tip Top pegmatite, Black Hills, Custer, SD* with other secondary phosphates covering fracture surfaces in large beryl crystals and associated with mitridatite, whitlockite, montgomeryite, and also with hurlbutite, roscherite, robertsite. HCWS

40.5.3.1 Faheyite $(\text{Mg}, \text{Mn}^{2+})\text{Fe}_2^{3+}\text{Be}_2(\text{PO}_4)_4 \cdot 6\text{H}_2\text{O}$

Named in 1953 for Joseph John Fahey (1901–1980), geochemist, U.S. Geological Survey. *HEX* $P6_322$. $a = 9.43$, $c = 16.00$, $Z = 3$, $D = 2.670$. *AM* 49:395(1968). 6-109: 7.28₉ 5.72₁₀ 3.96₅ 3.24₆ 3.09₆ 3.03₆ 2.72₃ 2.67₃. Botryoidal, flat rosettes and tufts composed of individual crystals 0.08 mm long \times 0.01 mm wide and very thin, often terminated by pyramidal face giving the appearance of a pointed end. White, bluish white, brownish white. Cleavage perfect parallel to c . $H = 3$. $G = 2.66$. Uniaxial (+); $N_O = 1.631$, $N_E = 1.652$. Dissolves slowly in hot 1:10 acids. Found at Noumas mine, Blesberg, Namaqualand, Cape Prov., South Africa(1); at the *Sapucaia Velha pegmatite, Galileia, MG, Brazil*, where it coats muscovite, quartz, variscite, and frondelite and occurs with roscherite. HCWS *AM* 38:263(1953).

40.5.4.1 Gainesite $\text{Na}_2\text{Zr}_2\text{Be}(\text{PO}_4)_4 \cdot 1-2\text{H}_2\text{O}$

Named in 1983 for Richard V. Gaines (b.1917), of Earlysville, VA, economic geologist, mineralogist, and collector of pegmatite, especially Be minerals. See mccrillsite (40.5.4.2), and selwynite (40.5.4.3). *TET* $I4_1/amd$. $a = 6.567$, $c = 17.119$, $Z = 2$, $D = 2.84$. Structure: *AM* 68:1022(1983). An open-framework structure [zeolite-like] based on $\text{BeP}_4\text{O}_{16}$ clusters [similar to zunyite cluster (Si_5O_{16})], coordinated with ZrO_6 , and two Na sites, one favored by the larger alkalis (Na, K, Rb, Cs). Cation sites only partially occupied, H_2O interstitial. 35-604: 6.07₁₀ 4.24₃ 3.27₉ 3.02₅ 2.88₄ 2.17₃ 2.01₃ 1.673₃. Also 35-724. Crystals simple bipyramids up to 1 mm, {111} dominant. Pale lavender-blue, vitreous luster. Conchoidal fracture. $H = 4$. $G = 2.94$. Uniaxial (+); $N_O = 1.618$, $N_E = 1.630$. Found in small crevices in cleavelandite (albite variety) associated with roscherite and eosphorite at *Nevel Quarry (Twin Tunnels) on Pumbago Mt., Newry, Oxford Co., ME*. HCWS *CM* 32:839(1994).

40.5.4.2 Mccrillsite $\text{NaCs}(\text{Be}, \text{Li})\text{Zr}_2(\text{PO}_4)_4 \cdot 1-2\text{H}_2\text{O}$

Named to honor the McCrillis family, who have mined the Oxford Co., ME, pegmatites for over 90 years. The Cs analog of gainesite (40.5.2.1). See also wycheproofite (40.2.9.1) and selwynite (40.5.2.3). *TET* $I4_1/amd$. $a = 6.159$, $c = 17.28$, $Z = 2$, $D = 3.30$. *CM* 32:839(1994). *PD*: 6.16₉ 4.33₈ 4.10₄ 3.28₈ 3.06₁₀ 2.90₃ 1.849₃. Bipyramidal crystals up to 1.2 mm maximum dimension {111}, dominant; {001}, minor. White to colorless, white streak, vitreous

luster, translucent to transparent. No cleavage, conchoidal fracture. $H = 4-4\frac{1}{2}$. $G = 3.125$. Nonfluorescent. Uniaxial (+); $N_O = 1.634$, $N_E = 1.645$; non-pleochroic. Close to gainesite (40.5.2.1) in composition with CsO 15%, HfO₂ 2.5%. Occurs as an alteration phase in the pegmatites of *Newry quarries, Pumbago Mt., Oxford Co., ME*. HCWS *CM 30:1178(1992)*.

40.5.4.3 Selwynite $\text{NaK(Be,Al)Zr}_2(\text{PO}_4)_4 \cdot 2\text{H}_2\text{O}$

Named in 1995 for A. R. C. Selwyn, founding director of the Geological Survey of Victoria, Australia. Related to gainesite (40.5.2.1), the Na,Na member, and mccrillsite (40.5.2.2), the Na,Cs member. $I4_1/amd$. $a = 6.570$, $c = 17.142$, $Z = 2$. *CM 33:55(1995)*. *PD*: 6.16₁₀ 4.29₃ 3.29₅ 3.04₃ 2.90₂ 2.60₁ 2.43₁ 2.17₁. Irregular crusts of radiating anhedral crystals. Deep purple-blue, may weather to lavender; pale lavender streak; vitreous luster; transparent. No distinct cleavage, conchoidal fracture. $H = 4$. $G = 2.94$. Uniaxial (+); $N_O = 1.624$, $N_E = 1.636$. O, bluish lavender; E, pale bluish lavender. Small amount of Mn the probable cause of the purple-blue color. Occurs as irregular infillings in <8-mm cavities in a quartz-orthoclase-albite-muscovite-schorl pegmatite vein in Devonian granite at *Wycheproof, northwestern VIC, Australia*, closely associated with wardite and eosphorite. Other minerals present: kosnarite, wycheproofite, rockbridgeite, kidwellitelike mineral, saleeite, and montmorillonite. If weathered, the mineral remains and is associated with limonite and clays. HCWS.

40.5.5.1 Wycheproofite $\text{NaAlZr}(\text{PO}_4)_2(\text{OH})_2 \cdot \text{H}_2\text{O}$

Named for the locality, an aboriginal name. $P1$ or $P1$. $a = 10.926$, $b = 10.986$, $c = 12.479$, $\alpha = 71.37^\circ$, $\beta = 77.39^\circ$, $\gamma = 87.54^\circ$, $Z = 6$, $D = 2.81$. *MM 58:635(1994)*. *PD*: 8.87₄ 4.13₈ 3.71₇ 3.47₆ 3.24₄ 2.60₁₀. Compact aggregates of finely fibrous crystals 5–10 μm wide up to several millimeters long. Pale pink to brown-orange, colorless streak, vitreous to pearly luster, transparent. No cleavage, rough fracture. $H = 4-5$. $G = 2.83$. $N = 1.62$ (perpendicular to length), -1.64 (parallel to length); parallel extinction; length-slow; nonpleochroic. Found with a variety of other phosphates, such as wardite, eosphorite, cyrilovite, kidwell-like PO₄, rockbridgeite, leucophosphite, and saleeite, in a pegmatite vein in granite at *Wycheproof, northwestern Australia*. HCWS *AM 78:653(1978)*, *80:847(1995)*.

40.5.6.1 Ehrleite $\text{Ca}_2\text{ZnBe}(\text{PO}_4)_2(\text{PO}_3\text{OH}) \cdot 4\text{H}_2\text{O}$

Named in 1985 for Howard Ehrle of Miles City, MT, who found the holotype specimen. *TRIC P1*. $a = 7.130$, $b = 7.430$, $c = 12.479$, $\alpha = 94.31^\circ$, $\beta = 102.07^\circ$, $\gamma = 82.65^\circ$, $Z = 1$, $D = 2.62$. *CM 23:1507(1985)*. Structure: *25:767(1987)*. *38-402*: 12.41₇ 6.95₅ 6.58₃ 4.31₄ 3.16₁₀ 3.01₃ 2.72₆ 2.52₃. Thick tabular crystals up to 2 mm \times 2 mm \times 0.1 mm that show {100}, {010}, {001}. White to colorless, vitreous luster. Uneven to subconchoidal fracture, parting on (001). $H = 3\frac{1}{2}$. $G = 2.64$. Nonfluorescent. Biaxial (+); X parallel to c; $Y \wedge b = 18^\circ$, $Z \wedge a = 9^\circ$; $N_x = 1.556$, $N_y = 1.560$, $N_z = 1.580$; $2V = 62^\circ$. Soluble in cold 1:5 acids.

Found at *Tip Top mine, Custer Co., SD*, on a matrix of beryl and quartz associated with mitridatite, roscherite, hydroxyl-herderite, and goyazite-crandallite. HCWS *AM 71:1544(1986)*.

40.5.7.1 Pahasapaite $(\text{Ca,Li,K,Na},\square)_{11}\text{Li}_8\text{Be}_{24}(\text{PO}_4)_{24} \cdot 38\text{H}_2\text{O}$

Named in 1987 for the Lakota Sioux *pahasapa*, the Black Hills. iso *I23*. $a = 13.781$, $Z = 1$, $D = 2.241$. *NJMM:433(1987)*. Structure: *AM 74:1191(1989)*. An ordered (1:1) framework of $(\text{PO}_4)^3$ and $(\text{BeO}_4)^{6-}$ groups forms a structure similar to the synthetic zeolite "rho" and the faujasit group. The other cations and water are found in, or associated with, the distorted openings (cages) created by the linkages of the tetrahedral groups. *41-1384: 9.6₁₀ 5.6₁₃ 4.35₄ 3.68₉ 3.25₉ 2.94₆ 2.70₆ 2.24₄*. Euhedral crystals up to 1 mm showing {110}, {111}. Colorless, light pink, vitreous luster, transparent. No cleavage. $H = 4\frac{1}{2}$. $G = 2.28$. DTA. Isotropic; $N = 1.523$ (Na). Found at *Tip Top pegmatite mine, Custer Co., SD*, with other beryll phosphates in fractured beryl crystals. Associated minerals: montgomeryite, tiptopite, eosphoite-childrenite, and roscherite. HCWS *AM 73:1496(1988)*.

40.5.8.1 Smolianinovite $(\text{Co,Ca,Mg})(\text{Fe}^{3+},\text{Al})(\text{AsO}_4)_4 \cdot 11\text{H}_2\text{O}$

Named in 1956 for Nikolai A. Smoljaninov (1885–1957), mineralogist, Moscow University, Russia. Possibly the Co analog of the Co–Zn series with faheyite (40.5.1.1). ORTH. $a = 6.40$, $b = 11.72$, $c = 21.9$, $Z = 2$, $D = 2.2$. *MM 41:385(1977)* (Mt. Cobalt). *43-663(diffuse): 23.08₁₀ 12.00₉ 9.95₉ 7.85₁₀ 6.85₅ 4.48₅ 3.25₈ 2.89₇*. See also *43-676*. Dense aggregates of fine fibers. Yellow; earthy luster, silky on cleavage. $H = 2$. $G = 2.43$ – 2.49 . DTA. $N_{\text{av}} = 1.625$; parallel extinction; positive elongation; birefringence ≈ 0.006 . Analysis of Bou Azzer shows high Ni content. Found at Bou Azzer, Morocco; at Tsumeb, Namibia; at Mt. Cobalt, Q, Australia. HCWS *AM 42:307(1956)*, *59:1141(1974)*; *NJMM:167(1988)*.

40.5.8.2 Fahleite $\text{Zn}_5\text{CaFe}_2^+(\text{AsO}_4)_6 \cdot 14\text{H}_2\text{O}$

Named in 1988 for Rolfe Fahle of Munich, Germany, a mineral dealer specializing in Tsumeb specimens. May be the Zn analog of smolianinovite (40.5.3.1). ORTH. $a = 6.40$, $b = 11.72$, $c = 21.9$, $Z = 2$, $D = 3.16$. *NJMM:167(1988)*. *42-1417: 22.0₁₀ 11.0₁₀ 3.2₈ 2.9₅ 1.65₂*. Minute fibrous aggregates or spherules with crystals greater than 1 cm long but several microns thick, may be twisted or curved; feltlike intergrowths. Gray, straw-yellow, bright green; silky, pearly luster; transparent. Cleavage normal to fibers perfect, very soft, sectile. IR confirms presence of H_2O . All diffraction diffuse. Biaxial (+); $N_x = 1.628$, $N_y = 1.631$, $N_z = 1.656$; $2V = 39^\circ$; Z parallel to fiber length. Analysis shows some Mn. Readily soluble in cold acid. Found at *Tsumeb, Namibia*, with gypsum, smolianinovite, lavendulan, cuproadamite, conichalcite, tsumcorite, quartz, and calcite. HCWS *AM 74:501(1989)*.

40.5.9.1 Walpurgite $(\text{BiO}_4)_2(\text{UO}_2)(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1871 for the locality. TRIC *P1*. $a = 7.135$, $b = 10.462$ (corrected in 42-587), $c = 5.494$, $\alpha = 101.47^\circ$, $\beta = 110.82^\circ$, $\gamma = 88.20^\circ$, $Z = 1$, $D = 6.69$. Structure: *TMPM 30:1129(1982)*. $(\text{UO}_2)\text{O}_4$ octahedra link with AsO_4 groups to form $\text{UO}_2(\text{AsO}_4)$ chains parallel to c . Bi^{3+} in two independent sites, eight- and nine-fold coordination polygons, form $\text{Bi}_4\text{O}_4(\text{AsO}_4)_2 \cdot \text{H}_2\text{O}$ layers parallel to $\{010\}$. 42-587(calc): 10.24₁₀ 5.70₃ 3.28₆ 3.133₆ 3.129₄ 3.11₅ 3.06₆ 2.74₄. See also 8-324. Yellow, light yellow, colorless; adamantine, greasy luster. $H = 3\frac{1}{2}$. $G = 5.95$. Biaxial (-); $N_x = 1.871$, $N_y = 1.975$, $N_z = 2.005$; $2V = 52^\circ$. Some Mn, but no Co, Ni, Mg, or Si detected on analysis. Found at *Walpurgis vein, Weisse Hirsch mine, Neustädtel, Schneeberg, Saxony, Germany*, and also at Heubachtal, Wittichen district. HCWS *DII:796, USGSB 1036:149(1956)*.

40.5.9.2 Orthowalpurgite $(\text{BiO})_4(\text{UO}_2)(\text{AsO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1995 for its polymorphic relation to walpurgite (40.5.4.1). ORTH *Pbcm*. $a = 5.492$, $b = 13.324$, $c = 20.685$, $Z = 4$, $D = 6.51$. Structure: *EJM 7:1313(1995)*. Bi in fourfold (edge) and fivefold (corner) coordination with O forms Bi_8O_8 layers which are connected via $[(\text{UO}_2)(\text{AsO}_4)_2]$ chains to form a three-dimensional network. *PD*: 10.354₉ 6.659₃ 5.610₄ 3.277₆ 3.208₁₀ 3.088₈ 2.999₅ 2.852₅. Crystals up to 0.3 mm tabular on $\{010\}$ and elongate parallel to $[100]$. Yellow, transparent. Indistinct cleavage parallel to $\{001\}$, conchoidal fracture. $H = 4\frac{1}{2}$. Biaxial (+); $XYZ = cab$; $N_x = 1.91$, $N_y = 2.100$, N_z calc = 2.05; $2V = 70^\circ$. EPMA (wt %): UO_3 , 17.86; Bi_2O_3 , 64.21; As_2O_5 , 16.11; $\text{H}_2\text{O}_{\text{calc}}$, 2.43. Occurs on the dumps of a Co-Ni-Ag-Bi-U mine at *Schmiedestollen, Wittichen, Black Forest, Germany*, which was famous in the eighteenth century for native Ag occurrences. Over 150 mineral species have been found in this locality. This mineral is associated with preisingerite spherules, quartz, and tabular anatase. HCWS

40.5.10.1 Walentaite $(\text{Ca}, \text{Mn}^{2+}, \text{Fe}^{2+})\text{Fe}^{3+}(\text{AsO}_4)(\text{PO}_4)_3(\text{PO}_3\text{OH}) \cdot 7\text{H}_2\text{O}$

Named in 1984 for Kurt Walenta (b.1927), mineralogist, University of Stuttgart, Germany, who has studied many phosphate minerals. ORTH *Immm*, *Ibam*, *Ibca*, or *Imma*. $a = 26.24$, $b = 10.31$, $c = 7.38$, $Z = 1$, $D = 2.74$. *NJMM:169(1984)*. 43-680: 12.9₁₀ 9.6₁ 6.56₂ 4.82₂ 4.43₃ 3.00₅ 2.93₂ 2.78₂. Rosettelike aggregates of thin-bladed crystals $20 \mu\text{m} \times 60 \mu\text{m} \times 2 \mu\text{m}$ elongate $[001]$ flattened perpendicular to b so that $\{010\}$ dominant; coatings. Bright yellow, yellow streak, vitreous luster, translucent. Cleavage $\{010\}$, perfect; brittle. $G = 2.72$. DTA. Nonfluorescent. Biaxial (+); $XYZ = bac$; $N_y = 1.738$, $N_z = 1.779$; $Z < Y$. Y, pale yellow-green; Z, medium yellow-green. Microprobe analysis shows both As and P. Found at *White Elephant mine, Pringle, Custer Co., SD*, where primary phosphates are extensively altered. Occurs with frondelite, rockbridgeite, loellingite, spessartine, quartz, tridymite, and muscovite. HCWS *AM 69:1193(1984)*.

40.5.11.1 Canaphite $\text{CaNa}_2\text{P}_2\text{O}_7 \cdot 4\text{H}_2\text{O}$

Named in 1988 for the composition. *MON Pc*. $a = 10.529$, $b = 8.48$, $c = 5.67$, $\beta = 106.13^\circ$, $Z = 2$, $D = 2.27$. Structure: *AM 73:168(1988)*. $41-410$: 8.47₈ 5.44₈ 5.06₆ 4.36₇ 3.87₆ 3.28₆ 3.06₁₀ 2.61₉. Clusters of prismatic crystals up to 0.5 mm long [001], 100 μm wide; tabular on {010}, exhibit {010}, {001}, {100}. Colorless, white streak, vitreous luster. Cleavage {010}, perfect. $H = 2$. $G = 2.24$. Biaxial (-); $N_x = 1.496$, $N_y = 1.502$, $N_z = 1.506$; $2V = 52^\circ$. Found as coatings on stilbite at *Haledon, Passaic Co., NJ*, and at Great Notch quarry, Little Falls. *HCWS MR 16:467(1985)*.

40.5.12.1 Geminite $\text{Cu}_2\text{As}_2\text{O}_7 \cdot 3\text{H}_2\text{O}$

Named in 1990 from the Latin *gemini*, twins, in allusion to the usual character of the crystals. *TRIC P1* or *P1*. $a = 6.639$, $b = 8.110$, $c = 15.732$, $\alpha = 92.01^\circ$, $\beta = 93.87^\circ$, $\gamma = 95.02^\circ$, $Z = 4$, $D = 3.71$. *SMPM 70:309(1990)*. $44-1454$: 7.83₁₀ 4.02₃ 3.93₁₀ 3.26₇ 3.11₄ 3.07₇ 2.82₄ 2.61₅. Euhedral intergrown crystals up to 0.3 mm \times 0.06 mm. Tabular {001}, slightly elongate [100] showing {001}, {100}, {010}, {hk0}, {h \bar{k} 0}, {hk0}, {h \bar{k} 0}. Twinned polysynthetically parallel to {001}. Light green to sea-green, pale green streak, vitreous luster, transparent. Cleavage {001}, perfect; irregular fracture. $H = 3-3\frac{1}{2}$. $G = 3.70$. Nonfluorescent. IR, TGA. Biaxial (+); $X' \wedge (001) \approx 90^\circ$, $Y' \wedge a = 17-18.5^\circ$, $Z \wedge b = 13^\circ$; $N_x = 1.656$, $N_y = 1.692$, $N_z = 1.770$; $2V = 75^\circ$; $r > v$, weak. X, Y, colorless; Z, pale green to gray. Soluble in 1:10 HCl. Synthesized. Found at *Cap Garonne mine, Var, France*, on quartz associated with tennantite, covellite, chalcantite, lavendulan, antlerite, and brochantite. *HCWS AM 77:670(1992)*.

40.5.13.1 Kolovratite Zn-Ni-hydrous vanadate

Named in 1922 for Lev S. Kolovrat-Chervinsky (1884-1921), a Russian physicist. An inadequately described mineral. *15-102*: 11.6₁₀ 5.83₁₀ 3.88₁₀ 2.62₆ 2.57₆ 2.39₆ 1.52₆ 1.47₄. Incrustations and botryoidal crusts with hollow centers, fibrous felted aggregates with divergent fibers. Yellow, greenish yellow; light yellow streak; vitreous luster; transparent. Conchoidal fracture, brittle. $H = 2-3$. $N_{av} = 1.577$; parallel extinction; low birefringence. Cu, Fe, and Mn also found on analysis. Found at *Kara-Chagyr and Uch-Kurgan, Ferghana, Turkestan*, distributed in the quartz schists and carbonaceous slates. *HCWS DII:1048, CM 7:322(1962)*.

Anhydrous Phosphates, Arsenates, and Vanadates Containing Hydrogen or Halogen

41.1.1.1 Chlorophoenicite $(\text{Mn}^{2+}, \text{Mg})_3\text{Zn}_2(\text{AsO}_4)(\text{OH})_7$

Named in 1924 for the Greek for *green* and *purple-red* in allusion to the color changes of the mineral in natural and artificial light. See magnesium-chlorophoenicite (41.1.1.2), the Mg analog. MON $C2/m$. $a = 22.98$, $b = 3.32$, $c = 7.323$, $\beta = 106.0^\circ$, $Z = 2$, $D = 4.7$. CM 19:333(1981). Structure: AM 53:1110(1968). 25-1159: 6.87₅ 3.71₇ 3.11₅ 2.99₄ 2.64₁₀ 2.43₁ 1.822₂ 1.758₃. Long prismatic [010], crystals deeply striated [010], with terminal faces dull, etched, {100} relatively smooth; {h0l} faces uneven or warped. Light gray-green in natural light, pink to purple-red in strong artificial light, vitreous, translucent. Cleavage {100} good, brittle. $H = 3\frac{1}{2}$, $G = 3.46$. Biaxial (-); $N_x = 1.682$, $N_y = 1.690$, $N_z = 1.697$, $2V = 83^\circ$, $r > v$ strong. Soluble in acids. Found in massive franklinite-willemite ore at *Franklin, Sussex Co., NJ*, with calcite, leucophoenicite, tephroite, gageite, pyrochroite, and in veinlets with calcite, barite in the ore at Sterling Hill mine. HCWS DII:779.

41.1.1.2 Magnesium-chlorophoenicite $(\text{Mg}, \text{Mn}^{2+})_3\text{Zn}_2(\text{AsO}_4)(\text{OH})_7$

Named in 1935 for the composition and relationship to chlorophoenicite. MON $C2/m$. $a = 22.99$, $b = 3.236$, $c = 7.299$, $\beta = 106.5^\circ$, $Z = 2$, $D = 3.18$. JPD 2:225(1987). 38-1438: 6.98₂ 6.87₂ 3.71₅ 3.09₄ 2.98₃ 2.61₁₀ 1.756₂ 1.480₁. See also 34-190. Rosettes and radial fibrous aggregates. Colorless to white. Fibers have perfect lengthwise cleavage. $G = 3.37$. Biaxial (+); $N_x = 1.669$, $N_y = 1.672$, $N_z = 1.677$, $r < v$ strong. Spectrographic analysis shows maximum Mn found = Mg/Mn = 1.4:1.2, end member not identified in nature. Found in veinlets with zincite, willemite, haidingerite, calcite at *Franklin, Sussex Co., NJ*. HCWS DII:780, CM 19:333(1981).

41.1.1.3 Jarosewichite $\text{Mn}_5^{2+}\text{Mn}^{3+}(\text{AsO}_4)(\text{OH})_6$

Named in 1982 for Eugene Jarosewich (b. 1926), chief chemist, Department of Mineral Sciences, National Museum of Natural History, Smithsonian Institution, Washington, DC. ORTH $C_2m^2/m^2/n$, $C222$, or $Cmm2$. $a = 6.56$, $b = 25.20$, $c = 10.00$, $Z = 8$, $D = 3.70$. AM 67:1043(1982). Pronounced

substructure with $a' = 3.28$, $b' = 12.60$, $c' = 10.00$. 41-580: 6.29₂ 3.91₆ 2.67₁₀ 2.50₃ 1.788₅ 1.567₂ 1.558₃ 1.501₂. Coatings and aggregates of barrel-shaped crystals with rough irregular surfaces up to 0.5 mm long in radial divergent sprays. Flattened on a , tabular on b , dominant face is {010} with minor occurrence of {021}. Dark red, reddish-orange streak, subvitreous luster. No cleavage. $H = 4$. $G = 3.66$. Nonfluorescent. Biaxial (-); $XYZ = abc$; $N_x = 1.780$, $N_y = 1.795$, $N_z = 1.805$; $2V_{\text{calc}} = 78^\circ$; weakly pleochroic; $Z > X$. X , medium brownish red; Z , dark brownish red. Reacts with index liquids. Microprobe analysis Mn^{3+} content inferred from associated minerals, calculated. Found at *Franklin, Sussex Co., NJ*, associated with andradite, franklinite, flinkite, cahnite, and hausmannite. HCWS

41.1.2.1 Theisite $Cu_5Zn_5[(As,Sb)O_4]_2(OH)_{14}$

Named in 1982 for Nicholas J. Theis, geologist, Bendix Corp., who discovered the original sample. ORTH Pseudo hexagonal. $a = 8.225$, $b = 7.123$, $c = 14.97$, $Z = 2$, $D = 4.45$. *MM* 46:49(1982). 35-527: 14.97₉ 7.48₅ 4.11₄ 3.74₁₀ 3.00₄ 2.53₉ 1.830₅ 1.553₅. Aggregates to 2mm across. Pale blue-green, white streak, translucent luster. Cleavage (001), perfect; sectile. $H = 1\frac{1}{2}$. $G = 4.3$. Biaxial (-); $N_x = 1.755$, $N_y = 1.785$, $N_z = 1.785$; $2V = 0^\circ$; nonpleochroic. Chemical analysis shows some Sb. Found as the only mineral in thin seams at a uranium prospect near *Durango, La Plata Co., CO*, with uraninite, galena, malachite, azurite, and the secondary Cu minerals partzite, covellite, chalcocite, angleite, cerussite, zeunerite, and duftite. HCWS

41.1.3.1 Georgiadesite $Pb_{16}(AsO_4)_4Cl_{14}O_2(OH)_2$

Named in 1907 for Georgiades, director of the mine at Laurium, Greece. MON $P2_1/c$. $a = 13.803$, $b = 7.910$, $c = 10.8112$, $\beta = 102.68^\circ$, $Z = 1$, $D = 6.44$. *MM* 47:219(1983). 35-689: 6.33₃ 5.30₃ 4.03₂ 3.96₅ 3.77₃ 3.16₅ 3.10₁₀ 2.97₃. Stubby pseudo-hexagonal tablets with platy composite structure parallel to [100]. Grooved on {001}, striated on {010}. White or brownish yellow, resinous luster. No cleavage. $H = 3\frac{1}{2}$. $G = 6.30$. Biaxial (+); $N_x = 2.17$, $N_y = 2.17$, $N_z = 2.18$; $2V$ very large; $r < v$, strong. Soluble in HNO_3 . Found as coatings on altered slag at *Laurium, Greece*, with laurionite, fiedlerite, matlockite, and nealite. HCWS DII:791.

41.1.4.1 Sahlinite $Pb_{14}(AsO_4)_2O_9Cl_4$

Named in 1934 for Carl Andreas Sahlin (1861-1943), chemist and manager of the iron works at Laxa, Sweden. Kombatite (41.1.4.2) is V analog. MON $C2/c$ or Cc . $a = 12.710$, $b = 22.498$, $c = 11.360$, $\beta = 118.99^\circ$, $Z = 4$, $D = 8.096$. *NJMM*:127(1985). A pronounced pseudotetragonal subcell: $a_1 = 3.89$, $a_2 = 4.04$, $c = 22.50$, $\alpha = \beta = 90^\circ$, $\gamma = 90.5^\circ$ in which the fourfold axis is coincident with the monoclinic twofold axis. 42-600: 3.01₁₀ 2.95₁₀ 2.81₉ 2.25₇ 2.02₄ 1.754₈ 1.593₄ 1.581₄. Aggregates of thin scales up to 2 mm. Pale sulfur-yellow, translucent. Cleavage {010}, perfect. $H = 2-3$. $G = 8.00$. Biaxial (-); $X = b$; $N_x \gg 3.3$; Found at *Langban, Filipstad, Varmland, Sweden*, in a dolomite rock

with hausmannite, manganhumite, and forsterite. HCWS *DII:775, AM 71:231(1986)*.

41.1.4.2 Kombatite $\text{Pb}_{14}(\text{VO}_4)_2\text{O}_9\text{Cl}_4$

Named in 1986 for the locality. V analog of sahlinite (41.1.4.1). MON *C2/c* or *Cc*. $a = 12.552$, $b = 22.495$, $c = 11.512$, $\beta = 118.99^\circ$, $Z = 4$, $D = 7.979$. *NJMM:519(1986)*. 40-497: 3.01₁₀ 2.96₁₀ 2.81₁₀ 2.25₇ 2.01₄ 1.989₅ 1.756₇ 1.590₆. Anhedral grains 0.2 mm in diameter, mostly turbid. Bright yellow, light yellow streak, adamantine luster. Cleavage {010}, perfect. $H = 2-3$. Nonfluorescent. Biaxial (-); $N > 1.90$; nonpleochroic. Found at *Kombat mine, 78 km S of Tsumeb, Otavi, Namibia*. HCWS *AM 73:928(1986)*.

41.2.1.1 Allactite $\text{Mn}_7(\text{AsO}_4)_2(\text{OH})_8$

Named in 1884 for the Greek *to change*, in allusion to the pleochroism. MON *P2₁/a*. $a = 7.257$, $b = 6.017$, $c = 7.734$, $\beta = 111.88^\circ$, $Z = 2$, $D = 3.94$. Structure: *AM 53:733(1968)*. Edge-linked bands of double Mn^{2+}O_6 octahedra [$\text{Mn}_2^{2+}(\text{O},\text{OH})_{10}$] held together by vertex-linked Mn^{2+}O_6 octahedra form flat sheets parallel to {100}. The sheets are held together by chains of highly distorted $\text{Mn}^{2+}(\text{O},\text{OH})_6$ octahedra and AsO_4 tetrahedra parallel to {010}. 17-748: 4.95₅ 3.71₇ 3.39₅ 3.28₆ 3.23₅ 3.06₁₀ 2.93₅ 2.51₅. Elongated [010] slender prisms or tabular {100} crystals; rosette-like aggregates. Dark to light purplish red, brownish red, streak greyish to faint brown, vitreous to greasy on fracture surfaces; translucent. Cleavage {001}, distinct; uneven fracture; brittle. $H = 4\frac{1}{2}$. $G = 3.83$. Biaxial (-); $y=b$ $X \wedge c \approx 51.3^\circ$, $N_x = 1.755$, $N_y = 1.772$, $N_z = 1.774$, $2V \approx 0^\circ$ (Långban). $X = \text{blood-red}$; $Y = \text{pale yellow}$; $Z = \text{sea-green}$; $r > v$, strong at (Na) and wavelengths $> 573 \text{ m}\mu$. The crystals appear uniaxial at $573 \text{ m}\mu$ and at $< 573 \text{ m}\mu$ the axial plane is perpendicular to {010}. Easily soluble in HCl. Trace amounts ($< 0.5\%$) Ca, Fe detected. Found at Franklin and at Sterling Hill, Sussex Co., NJ with calcite, willemite, franklinite, fluorite in small veinlets in the ore; with fluorite, synadelphite, hematolite, hausmannite, pyrochroite at the *Moss mine, Nordmark, SWEDEN* and at Långban with similar minerals and native lead in veinlets and crevices *DII:785*. HCWS

41.2.2.1 Heyite $\text{Pb}_5\text{Fe}_2^{2+}(\text{VO}_4)_2\text{O}_4$

Named in 1973 for Max Hutchinson Hey (1904-1984), chemist and mineralogist, British Museum (Natural History), London, England. MON *P2₁/m*. $a = 8.910$, $b = 6.017$, $c = 7.734$, $\beta = 111.88^\circ$, $Z = 1$, $D = 6.284$. *MM 39:65(1973)*. 25-1404: 8.28₃ 4.87₅ 3.67₃ 3.25₁₀ 3.01₄ 2.97₇ 2.77₆ 2.31₄. Crystals to 0.4 mm elongated parallel to [010] or tabular parallel to [100] showing {001}, {100}, {110}, {101}. Twinned on {110}. Yellow-orange, yellow streak, translucent. $H = 4$. $G = 6.3$. Biaxial (+); $X \wedge [001] = 36^\circ$; $Y = b$; $N_x = 2.185$, $N_y = 2.219$, $N_z = 2.266$; $2V = 89^\circ$; nonpleochroic. Found on or replacing wulfenite at *Betty Jo claim, Ely, White Pine Co., NV*, with galena, chalcopyrite, pyrite, pyromorphite, crysocholla, and cerussite. HCWS *AM 59:382(1974)*.

41.3.1.1 Clinoclase $\text{Cu}_3(\text{AsO}_4)(\text{OH})_3$

Named in 1868 from the Greek *to incline* and *to break*, in allusion to the oblique basal cleavage. *MON* $P2_1/c$. $a = 7.257$, $b = 6.457$, $c = 12.378$, $\beta = 99.51^\circ$, $Z = 4$, $D = 4.42$. *MJ* 1:89(1954). Structure: *AC(C)* 46:2291(1990). 37-447: 7.17₁ 3.58₁₀ 3.14₃ 3.06₁ 2.99₁ 2.91₁ 2.39₁ 2.31₁. See also 42-1357. Crystals elongated on [010], or on [001] with {100} prominent; tabular [001], rhombohedral in aspect. Isolated crystals or aggregated as rosettes; crusts or coatings with fibrous structure. Dark greenish black to greenish blue, bluish-green streak, vitreous to pearly luster on cleavage, transparent to translucent. Cleavage {001}, perfect; uneven fracture; brittle. $H = 2\frac{1}{2}$ -3. $G = 4.38$. Biaxial (-); $Y = b$; Z near a ; $N_x = 1.756$, $N_y = 1.874$, $N_z = 1.896$; $2V = 50^\circ$; $r \ll v$. X , pale blue-green; Y , light blue-green; Z , benzol-green. Small substitution of P for As, $P/\text{As} = 1:11$. Synthesized. Found at the Mammoth mine, Tintic district, Juab Co., UT; at Majuba Hill, Pershing Co., NV; associated with olivenite and other secondary Cu minerals in *Wheal Gorland*, *Wheal Unity*, *Ting Tang* mines, and *St. Day*, *Cornwall, England*, and at *Bedford United* mines, *Tavistock, Devonshire*; at *Markirch*, in the *Vosges, France*; at *Dome Rock, SA, Australia*; at *Tsumeb mine, Namibia*. *HCWS DII:787*.

41.3.2.1 Cornetite $\text{Cu}_3(\text{PO}_4)(\text{OH})_3$

Named in 1917 for Jules Cornet (1865-1929), Belgian geologist. *ORTH* *Pbca*. $a = 10.865$, $b = 14.071$, $c = 7.098$, $Z = 8$, $D = 4.12$. 37-449: 5.07₃ 4.54₃ 4.30₆ 3.68₇ 3.18₇ 3.04₁₀ 3.03₄ 2.95₆. See also 37-483, 9-495. Short prismatic [001] to equant crystals, {210} usually rounded; crusts of minute crystals. Twinned on { $h0l$ }. Deep blue or peacock-blue to greenish blue, vitreous luster, transparent to translucent. No cleavage. $H \approx 4\frac{1}{2}$. $G = 4.10$. Biaxial (-); $XYZ = bac$; $N_x = 1.765$, $N_y = 1.81$, $N_z = 1.82$; $2V \approx 33^\circ$; nonpleochroic; $r < v$, strong. Soluble in cold HCl. Minor Fe, Mg, Al, Si, and As. Found at the *Blue Jay* and *Empire-Nevada* mines, *Yerington, NV*; at *L'Etoile du Congo mine, Elizabethville, Shaba Prov., Zaire*, associated with pseudomalachite in fine-grained argillaceous sandstone; at *Bwana M'kubwa, northern Zambia*. *HCWS DII:789, AM 35:365(1950)*.

41.3.3.1 Flinkite $\text{Mn}_2^{2+}\text{Mn}^{3+}(\text{AsO}_4)(\text{OH})_4$

Named in 1889 for Gustav Flink (1849-1931), Swedish mineralogist and collector. *ORTH* *Pnma*. $a = 9.55$, $b = 13.11$, $c = 5.25$, $Z = 4$, $D = 3.76$. *CM* 7:547(1963). Structure: *AM* 52:1603(1967). 12-400: 4.73₁₀ 4.39₁₀ 3.82₃ 3.18₈ 2.71₁ 2.66₁₀ 2.51₃ 1.538₂. Thin tabular {001}, slightly elongated {010}, crystals often rounded in [100], {001} striated parallel to [100]; featherlike aggregates. Greenish brown to dark green, vitreous to greasy luster, transparent. Brittle. $H = 4\frac{1}{2}$. $G = 3.87$. Biaxial (+); $XYZ = bca$; $N_x = 1.783$, $N_y = 1.801$, $N_z = 1.834$; $2V$ large; $r > v$, weak. X , pale brownish green; Y , yellow-green; Z , orange-brown. Soluble in HCl. Occurs at *Franklin, Sussex Co., NJ*; in veinlets in magnetite ore associated with sarkinite, brandtite, caryopillite,

nadorite, native lead, manganooan calcite, and barite at the *Harstig mine at Pajsberg, near Persberg, Varmland, Sweden*. HCWS DII:793.

41.3.4.1 Retzian-(Ce) $Mn_2^{2+}Ce(AsO_4)(OH)_4$

Named in 1894 for Anders Jahan Retzius (1742–1821), Swedish naturalist. Redefined in 1982 to accommodate the compositional variations for other rare earth elements. See retzian-(La) 41.3.4.3 and retzian-(Nd). ORTH *Pban*. $a = 5.670$, $b = 12.03$, $c = 4.863$, $Z = 2$, $D = 4.57$. *AM 67:841(1982)*. Structure: *AM 52:1603(1967)*. 20-731: 6.04₄ 4.84₄ 3.53₈ 2.72₁₀ 2.34₃ 1.895₃ 1.848₅ 1.619₄. Prismatic {001}, tabular {010}. Dark chocolate-brown to chestnut-brown, light brown streak, vitreous to greasy luster, subtranslucent. Conchoidal to uneven fracture. $H = 4$. $G = 4.15$. Biaxial (+); $XYZ = cba$; $N_x = 1.777$, $N_y = 1.788$, $N_z = 1.800$; 2V large; $Z > Y > X$; $r < v$, weak. X, colorless to orange-yellow; Y, yellowish brown to dark brown; Z, red-brown to crimson. Soluble in acids. REE analysis confirms Ce dominant over La and Nd, also present: Y, Pr, Sm, Gd, Eu. Found at Sterling Hill mine, Sussex Co., NJ; at *Moss mine, Nordmark, Varmland, Sweden*. HCWS DII:794.

41.3.4.2 Retzian-(Nd) $Mn_2^{2+}Nd(AsO_4)(OH)_4$

Named in 1982 for its relationship to retzian-(Ce) 41.3.4.1. ORTH *Pban*. $a = 5.690$, $b = 12.12$, $c = 4.874$, $Z = 2$, $D = 4.49$. *AM 67:841(1982)*. 35-686: 6.05₂ 4.89₃ 3.53₆ 3.30₁ 2.73₁₀ 1.857₃ 1.625₂ 1.463₂. Crystals and aggregates of crystals, twins, trillings, sixlings with a distinct spokelike appearance. Reddish brown to pinkish brown, color zoned with interior darker; light brown streak; vitreous luster on fracture surfaces to dull on crystal faces. No cleavage, parting along parallel growth planes, uneven fracture. $H = 3-4$. $G > 4.2$. DTA, TGA. Biaxial (+); $XYZ = cba$; $N_x = 1.774$, $N_y = 1.782$, $N_z = 1.798$; 2V = 69°; $Z > Y \gg X$; $r < v$, weak. X, yellow; Y, reddish brown; Z, brown. Microprobe analyses show $Nd > Ce$, La, Pr, low Mg, and virtually no substitutions for As. Found at *Sterling Hill mine(1), Ogdensburg, Sussex Co., NJ*, as clove-brown crystals, coating, and embedded in light brown rhodochrosite in the willemite-franklinite ore. HCWS

41.3.4.3 Retzian-(La) $Mn_2^{2+}La(AsO_4)(OH)_4$

Named in 1982 to distinguish the La-dominant retzian. ORTH *Pban*. $a = 5.670$, $b = 12.011$, $c = 4.869$, $Z = 2$, $D = 4.49$. *MM 48:533(1988)*. 38-380: 5.98₃ 4.84₃ 3.51₈ 2.72₁₀ 2.06₂ 1.848₅ 1.615₃ 1.456₄. Crystals to 0.5 mm showing {001}, {010}, {110}, {150}, pseudo-hexagonal. Reddish brown, vitreous luster. No cleavage. $H = 3-4$. $G = 4.49$. Biaxial (+); $XYZ = cba$; $N_x = 1.766$, $N_y = 1.773$, $N_z = 1.788$; 2V = 82°; weakly pleochroic; $Z > Y > X$; $r > v$, strong. Microprobe analyses show $La > Ce > Nd$ with Pr, Sm, Y plus some Mg, Zn. Found at *Sterling Hill mine, Ogdensburg, Sussex Co., NJ*, with willemite, calcite, and franklinite. HCWS *AM 67:841(1982)*.

41.3.5.1 Viitaniemiite $\text{Na}(\text{Ca}, \text{Mn}^{2+})\text{Al}(\text{PO}_4)(\text{F}, \text{OH})_3$

Named in 1981 for the locality. *MON* $P2_1$ or $P2_1/m$. $a = 6.832$, $b = 7.143$, $c = 5.447$, $\beta = 109.36^\circ$, $Z = 2$, $D = 3.242$. *AM* 66:1102(1981). Structure: *AM* 69:961(1984). 33-1226: 4.89₄ 3.22₅ 2.97₃ 2.94₆ 2.88₁₀ 2.57₄ 2.16₄ 1.915₃. Fan-shaped tabular crystals from 0.02 to 0.2 mm wide; inclusions or as rims on other minerals. Gray to white, vitreous luster. Cleavage {101}, distinct. $H = 5$. $G = 3.245$. Nonfluorescent. Biaxial (-); $Y = b$; $N_x = 1.557$, $N_y = 1.565$, $N_z = 1.571$; optic axial plane = (010); $2V = 81^\circ$. Readily dissolved by HNO_3 and H_2SO_4 . Mn-free crystals [Francon: *CM* 21:499(1983), 35-598] elongated [010], flat (100), twinned (100). Found as an inclusion in esosphorite at Viitaniemi granite pegmatite, Eräjarvi, Orivesi, Finland; at Francon quarry, Montreal, QUE, Canada, in cavities of a silicocarbonatite sill. *HCWS ZVMO* 120:74(1991).

41.3.6.1 Nacaphite $\text{Na}_2\text{Ca}(\text{PO}_4)\text{F}$

Named in 1980 for the composition. *TRIC* $P1$. $a = 10.565$, $b = 24.443$, $c = 7.102$, $\alpha = 89.99^\circ$, $\beta = 90.0^\circ$, $\gamma = 90.01^\circ$, $Z = 2$, $D = 2.88$. Structure: *DANP* 34:9(1989). Earlier investigations suggested *ORTH* space group. 33-1222: 4.00₂ 3.51₂ 3.054₄ 3.049₄ 2.65₁₀ 2.01₄ 1.762₃ 1.533₂. Inclusions about 1 mm in diameter in thermonatrite. Colorless, vitreous luster, transparent. Conchoidal fracture. $H = 3$. $G = 2.85$. IR, DTA. Biaxial (-); $N_x = 1.508$, $N_y = 1.515$, $N_z = 1.520$; $2V = 80^\circ$; $r > v$, weak. Analyses show minor K, Mn, and Sr. Occurs associated with apatite, aegirine, barytolampophyllite in ijolite pegmatite at Mt. Rasvumchorr, Khibiny massif, Kola Penin., Russia. *HCWS ZVMO* 109:50(1980), *AM* 66:218(1981).

41.3.7.1 Gerdtrammelite $\text{ZnAl}_2(\text{AsO}_4)(\text{OH})_5$

Named in 1985 for Gerd Tremmel, who first recognized the mineral. *TRIC* $P1$ or $P1$. $a = 5.169$, $b = 13.038$, $c = 4.931$, $\alpha = 98.78^\circ$, $\beta = 100.80^\circ$, $\gamma = 78.73^\circ$, $Z = 2$, $D = 3.66$. *NJMM*:1(1985). 33-373: 12.77₁₀ 4.80₄ 4.70₄ 4.22₄ 4.08₄ 3.88₅ 3.63₅ 3.14₅. Spherulitic aggregates of tabular crystals up to 3 μm . Yellowish brown to dark brown, white streak, adamantine luster, transparent. No visible cleavage or fracture. TGA. Nonfluorescent. $N_{\text{av}} = 1.73\text{--}1.74$, highly birefringent. Insoluble in HCl. Found in the deeply oxidized ore zone at Tsumeb, Namibia. *HCWS AM* 71:845(1986).

41.3.8.1 Paulkellerite $\text{Bi}_2\text{Fe}^{3+}(\text{PO}_4)_2(\text{OH})_2$

Named in 1988 for Paul Keller (b.1940), University of Stuttgart, Germany, for his contributions to the mineralogy of secondary minerals. *MON* $C2/c$. $a = 11.382$, $b = 6.690$, $c = 9.666$, $\beta = 114.73^\circ$, $Z = 4$, $D = 6.17$. *AM* 73:870(1988). 41-1468: 5.13₂ 3.91₂ 3.34₂ 3.12₁₀ 2.80₃ 2.24₂ 2.16₄ 2.04₂. Structure: Single zig-zag chains of alternating PO_4 tetrahedra and $\text{Fe}^{3+}(\text{O}, \text{OH})_6$ octahedra extend along c and form layers parallel to (100) with Bi bonding to 3 tetrahedral oxygens, 3 octahedral oxygens and one (OH) resulting in $\text{Bi}(\text{O}, \text{OH})_7$ polyhedra *AM* 73:873(1988). Compare zairite, $\text{BiFe}^{3+}(\text{PO}_4)_2(\text{OH})_2$

(41.5.12.3), a member of the crandellite group, exhibiting a different structure. 41-1468 5.13₂ 3.91₂ 3.34₂ 3.12₁₀ 2.80₃ 2.24₂ 2.16₄ 2.04₂. Wedge-shaped, euhedral, crystals with slightly curved faces up to 0.8 mm displaying {110}, {011}, and poorly developed {101}. Greenish yellow, light yellow streak, vitreous to adamantine luster, transparent. No cleavage. H = 4. Non-fluorescent. Biaxial (+); $X \wedge a = 25^\circ$ in obtuse β ; $YZ = bc$; $N_x = 1.762$, $N_y = 1.767$, $N_z = 1.825$; $2V = 37^\circ$. Found at *Neuhilf mine, Schneeberg, in the Erzgebirge area, Germany*, with native bismuth, quartz, mixed skutterudite group minerals, erythrite, and bismutoferrite. HCWS

41.4.1.1 Arsenoclasite $Mn_5(AsO_4)_2(OH)_4$

Named in 1931 from the Greek for *arsenic* and *cleavage*. ORTH $P2_12_12_1$. $a = 18.29$, $b = 5.75$, $c = 9.31$, $Z = 4$, $D = 4.21$. *AMG 4:425(1965)*, Structure: *AM 53:1539(1971)*. 20-704: 5.57₄ 4.92₄ 4.55₇ 3.06₆ 2.93₁₀ 2.84₇ 2.74₈ 1.631₅. Massive, granular. Red, translucent. Cleavage {010}, perfect. H = 5-6. $G = 4.16$. Biaxial (-); $N_x = 1.787$, $N_y = 1.810$, $N_z = 1.816$; $2V = 54^\circ$. Found at *Långban, Filipstad, Värmland, Sweden*, with calcite, sarkinite, and adelite along fissures in dolomite and associated with hausmannite. HCWS *DII:801*.

41.4.1.2 Gatehouseite $Mn_5(PO_4)_2(OH)_4$

Named in 1993 for Brian M. K. C. Gatehouse (b. 1932), crystal chemist, Monash University, Melbourne, Australia. The P analog of arsenoclasite (41.4.1.1.). ORTH $P2_12_12_1$. $a = 9.097$, $b = 55.693$, $c = 18.002$, $Z = 4$, $D = 3.854$. *MM 57:309(1993)*. *PD: 4.48_1 4.03_1 2.90_10 2.85_7 2.80_5 2.70_8 2.02_2 1.608_2*. Radiating to divergent bladed crystals up to 100 μm long, elongated on [010] showing {102}, {110}, {001}, occasionally twinned on {001}. Pale yellow to pale brownish orange, pale yellow streak, adamantine luster, transparent. Cleavage {010}, distinct; splintery fracture. H = 4. Biaxial; $N_x = 1.74$, $N_z = 1.76$; length-slow; parallel extinction; pleochroic; brown to colorless. Found as overgrowths on arsenoclasite in cavities with hematite, hausmannite, barite, and carbonates at *Iron Monarch iron ore deposit, northern Middleback Ranges, SA, Australia*. HCWS *AM 79:185(1994)*.

41.4.2.1 Cornubite $Cu_5(AsO_4)_2(OH)_4$

Named in 1959 from the Roman name for Cornwall, England. See dimorph cornwallite (41.4.3.1) and pseudomalachite, 41.4.4.1, the P analog which has two polymorphs. TRIC $P1$. $a = 6.121$, $b = 6.251$, $c = 6.790$, $\alpha = 92.93^\circ$, $\beta = 111.30^\circ$, $\gamma = 107.47^\circ$, $Z = 1$, $D = 4.85$. *FM 62:231(1984)*. Structure: *BGSF 57:119(1985)*. Sheets of edge shared $(Cu(O,OH)_6)$ octahedra parallel to (011) connect by AsO_4 groups via common corners (3 oxygens in the octahedral sheet, the fourth in the adjacent sheet) and H bonds. 38-441: 4.72₁₀ 3.49₈ 2.87₇ 2.69₉ 2.56₁₀ 2.49₁₀ 2.30₇ 1.575₇. See also 12-288, 41-1460(calc). Crystals to 0.3 mm \times 0.3 mm \times 0.05 mm thick (Reichenbach, Germany), fibrous botryoidal aggregates or porcellaneous crusts. Apple-green to dark green; vitreous, glassy luster; transparent. $G = 4.64$. Biaxial (-); $N_x = 1.87$,

$N_z = 1.90$ (Cap Garrone). *BM 84:318(1961)*. Found at Centennial mine, Eureka, Tintic district, UT; at Potts Gill, Caldbeck, Cumberland, *Wheal Carpenter, Gwinear, St. Day, Cornwall, England*, in drusy quartz associated with olivenite, malachite, cuprite, cornwallite, and liroconite; at Reichenbach, Odenwald, Hessen, Germany. *HCWS MM 32:1(1959)*.

41.4.2.2 Cornwallite $\text{Cu}_5^{2+}(\text{AsO}_4)_2(\text{OH})_2$

Named in 1847 for the locality. Dimorph of cornubite (41.4.2.1); pseudomalachite (41.4.3.1) is the P analog. *MON P2₁/a*. $a = 17.33$, $b = 5.82$, $c = 4.60$, $\beta = 92.2^\circ$, $Z = 2$, $D = 4.645$. *MM 32:1(1959)*. 39-1357: 4.81₄ 3.53₅ 3.20₅ 3.02₄ 2.89₅ 2.74₅ 2.46₅ 2.41₁₀. See also 12-287. Botryoidal crusts with radial-fibrous structure, drusy. Pale green, verdigris-green, emerald-green. Conchoidal fracture, not brittle. $H = 4\frac{1}{2}$. $G = 4.52$. Biaxial (+); $N_x = 1.796$, $N_y = 1.815$, $N_z = 1.850$; 2V small; negative elongation. Decomposed in oils containing As_2S_3 , S. Some substitution of P for As, $\text{As/P} = 7:1$. Found at Gold Hill, Tooele Co., UT; with temorite, olivenite in *Wheal Gorland, St. Day, Cornwall, England*; at Vosges, France; at Grube Clara, Rankachtal, Germany. *HCWS DII:925, AM 36:484(1951)*.

41.4.3.1 Pseudomalachite $\text{Cu}_5(\text{PO}_4)_2(\text{OH})_4$

Named in 1813 from the Greek for *false* and *malachite* because of the close resemblance to that mineral. Trimorph with reichenbachite (41.4.3.2), and ludjibaite (41.4.3.3). *MON P2₁/c*. $a = 4.473$, $b = 5.747$, $c = 17.032$, $\beta = 91.04^\circ$, $Z = 2$, $D = 4.367$. *AM 66:176(1981)*. 36-408: 4.48₁₀ 3.47₂ 3.12₂ 3.06₃ 2.98₃ 2.44₃ 2.42₂ 2.39₃. Single crystals rare, prismatic [001] usually uneven, small, or in subparallel aggregates with drusy surface or in hemispherical forms; reniform, botryoidal, massive with radial-fibrous structure and concentric banding, fibers elongated [010]; foliated, microcrystalline or dense; colloform. Twinned on {100}. Dark emerald-green to blackish green, fibrous material lighter in color, bluish green; streak paler than color; vitreous luster; translucent to subtranslucent. Cleavage {010}, distinct, but difficult; splintery fracture. $H = 4\frac{1}{2}$ -5. $G = 4.35$; fibers, $G = 4.0$. Biaxial (-); $X \wedge c = 21^\circ$; $Z = b$; $N_x = 1.789$, $N_y = 1.835$, $N_z = 1.845$ (Rheinbreitbach); 2V $\approx 50^\circ$; $r < v$, strong [also biaxial (+), $r > v$]; weakly pleochroic. X, bluish green; Y, yellowish green; Z, deep bluish green. Soluble in acids. A secondary mineral found with malachite, chrysocolla, tenorite, pyromorphite, chalcidony, and iron oxyhydroxides in the oxidized zones of Cu ore deposits. Occurs at Wheatley mines, Chester Co., and at Ecton, Perkiomen mine, Montgomery Co., PA; at Cabarrus Co., NC; in AZ at Ajo, New Cornelia mine, Lavender pit, Bisbee, Cochise Co., Harquahala mine, La Paz Co., Table Mt. mine, Mammoth Co., Silver Bell mine; at Liskeard and elsewhere in Cornwall, England; at La Coste mine Alban-la-Fraysse, Tarn Prov., France; at Ehl, near Linz, Virneberg, near Rheinbreitbach and Hirschberg, Thuringia, Germany; at Libethen and Rezbanya, Czech Republic; at Moldawa, Romania; at Mindouli, Congo Republic; in Shaba, Zaire; at Rokana mine, Zambia; at Burra, SA,

Rum Jungle, NT, and West Bogan mine, Tottenham, NSW, Australia. HCWS *DII:799, AM 35:365(1950)*.

41.4.3.2 Reichenbachite $\text{Cu}_5(\text{PO}_4)_2(\text{OH})_4$

Named in 1984 for the locality. Trimorph with pseudomalachite (41.4.3.1) and ludjibaite (41.4.3.3). MON $P2_1/a$. $a = 9.198$, $b = 10.691$, $c = 3.376$, $\beta = 92.42^\circ$, $Z = 2$, $D = 4.35$. *AM 72:404(1987)*. Structure: *62:115(1977)*. Synthetic. *40-502: 4.47₁₀ 3.13₃ 3.01₃ 2.95₂ 2.81₃ 2.41₁₀ 2.36₂ 2.24₂*. Crystals lance-shaped to 0.3 mm \times 0.3 mm \times 0.6 mm. Dark green, light green streak, vitreous luster, translucent. No cleavage, irregular fracture. $H = 3\frac{1}{2}$. Non-fluorescent. Biaxial (-); $Y = b$, $Z \wedge a = 29^\circ$; $N_x = 1.782$, $N_y = 1.833$, $N_z = 1.867$; $2V = 76^\circ$; weakly pleochroic; $r < v$, weak. X, bright emerald-green; Z, emerald-green. Synthesized. *AM 62:115(1977)*. Found in silicified barite vein at *Reichenbach, Odenwald, Germany*, associated with quartz, bayldonite, mimetite, malachite, duftite, goethite, and pseudomalachite; at Brown's prospect, Rum Jungle, NT, Australia, with pseudomalachite. HCWS *NJMM:281(1991), AM 70:881(1985)*.

41.4.3.3 Ludjibaite $\text{Cu}_5(\text{PO}_4)_2(\text{OH})_4$

Named in 1988 for the locality. TRIC $P\bar{1}$. $a = 4.446$, $b = 5.871$, $c = 8.680$, $\alpha = 103.9^\circ$, $\beta = 90.3^\circ$, $\gamma = 93.2^\circ$, $Z = 1$, $D = 4.36$. *BM 111:167(1988)*. Structure: *AM 66:169(1981)*. *PD: 4.46₁₀ 3.02₂ 2.46₅ 2.41₂ 2.35₂ 2.22₁ 2.02₂ 1.572₂*. Aggregates of blue-green blades up to 0.3 mm, white to pale blue streak, vitreous luster. Biaxial (+) [or (-)]; $N_x' = 1.786$, $N_z' = 1.840$; $2V$ large; weakly pleochroic, blue to pale blue. Found on pseudomalachite in association with libethenite in the *Ludjiba deposit, Zaire*; at Lubietova, Slovakia. HCWS *AM 73:1495(1988), NJMM:281(1991)*.

41.4.4.1 Turanite $\text{Cu}_5(\text{VO}_4)_2(\text{OH})_4$

Named in 1909 for the locality. An inadequately characterized mineral. *12-522: 7.25₈ 4.76₁₀ 2.70₄ 2.56₆ 2.47₃ 2.29₃ 2.11₃ 1.97₃*. Reniform crusts, spherical concretions of radial fibrous structure. Olive-green, translucent. $H = 5$. Biaxial (-); $N_x = 2.00$, $N_y = 2.01$, $N_z = 2.02$; $2V$ medium; positive elongation; $r > v$, strong; pleochroic: X,Y, brown; Z, green. Found with a variety of vanadium and uranium minerals in cavities in limestone at *Tyuya Muyun, Ferghana, Turan Region, Uzbekistan*. HCWS *DII:818, BM 79:219(1956)*.

41.4.5.1 Stoiberite $\text{Cu}_5(\text{VO}_4)_2\text{O}_2$

Named in 1979 for Richard Edwin Stoiber (b.1911), geologist, Dartmouth College, NH, who studied Central American volcanoes and their fumarolic deposits. MON $P2_1/n$. $a = 15.654$, $b = 6.054$, $c = 8.385$, $\beta = 102.29^\circ$, $Z = 4$, $D = 4.96$. *AM 64:941(1979)*. Structure: *AC(B) 29:1338(1973)*. *33-504: 7.92₁₀ 4.80₇ 2.76₈ 2.69₇ 2.60₇ 2.54₆ 2.10₈ 1.956₇*. Polycrystalline aggregates <100 mm in diameter, platelike {100} with striae on (100) possibly parallel to {*hll*} cleavage trace. Synthetic material may show needlelike habit. Black, red-

dish-brown streak, metallic luster, transmits light in thin sections. $G_{\text{syn}} = 5.0$. Reflected light: medium, < galena, very light gray, slightly bluish-white pleochroic. Some Cr^{6+} substitutes for V. Found at the *Y fumarole, Izalco volcano, El Salvador*, in the oxide zone coating basaltic breccia fragments. HCWS

41.4.6.1 Nealite $\text{Pb}_4\text{Fe}^{2+}(\text{AsO}_4)_2\text{Cl}_4$

Named in 1980 for Leo Neal Yedlin (1908–1977), mineral (micromount) collector of New Haven, CT. TRIC P1. $a = 6.537$, $b = 10.239$, $c = 5.582$, $\alpha = 96.20^\circ$, $\beta = 89.39^\circ$, $\gamma = 97.74^\circ$, $Z = 1$, $D = 5.88$. MR 11:299(1980). 33-755: 10.09₆ 6.48₈ 4.24₇ 3.92₅ 3.54₁₀ 3.25₆ 2.97₅ 2.78₆. Prismatic, bladed clusters tabular on {010}, elongated parallel to [001]. Orange, light orange streak, translucent. No cleavage, brittle. Nonfluorescent. Biaxial; $N > 2.00$; length-slow; nonpleochroic. Some Zn detected on microprobe analysis. Found at Cap Garonne, France and on the slags at *Laurion, Attica, Greece*. HCWS

41.4.7.1 Tancoite $\text{LiNa}_2\text{H}[\text{Al}(\text{PO}_4)_2(\text{OH})]$

Named in 1980 for the locality. ORTH Pbc. $a = 6.948$, $b = 14.089$, $c = 14.065$, $Z = 8$, $D = 2.724$. CM 18:185(1980). Structure: TMPM 31:121(1983). 33-602: 4.67₁₀ 3.41₉ 3.15₁₀ 2.48₉ 2.03₃ 1.760₄ 1.438₄ 1.429₄. Isolated crystals up to 1 mm long and druses of columnar individuals with (100), (010), (111), dominant; (021), (001), minor. Colorless to pale pink, vitreous luster. Cleavage {010}, {001}, fair; conchoidal fracture. $H = 4-4\frac{1}{2}$. $G = 2.752$. IR, DTA. Biaxial (-); XYZ = abc; $N_x = 1.541$, $N_y = 1.563$, $N_z = 1.564$; $2V = -23^\circ$, $r < v$, weak. Dissolves in 1:10 HCl, HNO_3 . Occurs in the *Tanco spodumene-bearing pegmatite mine at Bernic Lake, MB, Canada*. HCWS AM 66:1278(1981), 69:215(1984).

41.4.8.1 Reppiaite $\text{Mn}_5(\text{VO}_4)_2(\text{OH})_4$

Named in 1992 for a village near the locality. MON C2/m. $a = 9.604$, $b = 9.558$, $c = 5.393$, $\beta = 98.45^\circ$, $Z = 2$, $D = 3.91$. Structure: ZK 201:223(1992). PD: 4.76₈ 3.37₄ 3.00₃ 2.68₁₀ 2.66₅ 2.16₅ 1.565₄ 1.510₃. Minute tabular crystals flattened on (100) of irregular outline up to 50 μm thick, 300 μm diameter, striated on (100). Orange-red, orange-yellow streak, vitreous luster, transparent. No observable cleavage. $H < 3$, $\text{VHN}_{15} = 90-110$ on (100). $G = 3.92$. Nonfluorescent. Biaxial (-); $N_x = 1.893$, $N_z = 1.810$; $2V$ large; pleochroic on (100) weak yellow-orange to deep orange; medium dispersion. Some As substitutes for V. Found at *Gambalesa mine, near Reppia, Val Graveglia, Italy*, in manganese chert ores with hausmannite, tephroite, Mn-containing carbonates, and silicates. HCWS

ADELITE-DESCLOIZITE GROUP

Members of the adelite-descloizite group fall into two closely related subgroups. The general formula is

where

A = Ca, Pb

B = Co, Cu, Fe²⁺, Mg, Mn, Zn, Ni

T = As, V (and minor amounts of P in solid solution)

Both subgroups crystallize with orthorhombic symmetry. The Adelite subgroup in space group $P2_12_12_1$ and the other in space group $Pnam$.

The structure [NJMM:300(1989)] is composed of chains created from edge-sharing octahedra, BO_6 , and very distorted $A(O,OH)_8$ polyhedra linked through TO_4 into a tight three-dimensional network. The minor structural differences between members of the two subgroups are related to a shift in the position of an oxygen atom of a TO_4 group linked to the framework by a hydrogen bond. See the brackebuschite (40.2.8.1) group, which has a related structure.

ADELITE: $CaMg(OH)(AsO_4)$

An *a* axis projection of adelite shows the distorted $Ca(O,OH)_8$ polyhedra, MgO_6 octahedra and AsO_4 groups in a tight network. Distortions in the network due to OH bonding is the difference between the adelite and descloizite groups.

ADELITE SUBGROUP

Duftite- α	$\text{PbCu}(\text{OH})(\text{VO}_4)$	$Pnam$	7.788	9.223	6.001	6.57	41.5.2.5

Notes:

1. Duftite exists in two polymorphic forms, one in each subgroup.
2. Vuagnatite (52.4.2.2) and mozartite (52.4.2.1) are silicates isostructural with the group.

41.5.1.1 Adelite $\text{CaMg}(\text{AsO}_4)(\text{OH})$

Named in 1804 from the Greek for *indistinct*, for its occurrence as massive. Adelite group and subgroup. See also F end member tilasite (41.5.6.1). ORTH $P2_12_12_1$. $a = 7.525$, $b = 8.850$, $c = 5.850$, $Z = 4$, $D = 3.74$. *CM 18:191(1980)*. $24-208$: 4.96₆ 4.13₇ 3.16₁₀ 2.98₆ 2.78₆ 2.59₇ 2.33₇ 1.609₇. Crystals elongate [100], usually massive. Gray, bluish gray, yellowish gray, yellow, light green; resinous luster; transparent. Uneven to conchoidal fracture. $H = 5$. $G = 3.73$. Biaxial (+); $XYZ = acb$ (Jacobsberg); $N_x = 1.712$, $N_y = 1.721$, $N_z = 1.731$; $r < v$. Small substitutions of Pb, Mn^{2+} for Ca, Mg, P for As, F for OH. Soluble in 1:10 acids. Found in the *manganese ore deposits of Langban, Varmland, Sweden*, with sarkinite, arsenoclasite, braunite, and hedyphane; at Jacobsberg and at the Kittel mine, Nordmark, with hausmannite, magnetite, and native copper. *HCWS DII:804, AMG 4:499(1968)*.

41.5.1.2 Conichalcite $\text{CaCu}(\text{AsO}_4)(\text{OH})$

Named in 1849 from the Greek for *powder* and *lime*, in allusion to its appearance. Adelite group and subgroup. The Cu end member in Cu-Zn series with austinite (41.5.1.3). ORTH $P2_12_12_1$. $a = 7.393$, $b = 9.220$, $c = 5.830$, $Z = 4$, $D = 4.338$. *AM 56:1359(1971)*. Structure: *CM 7:561(1963)*. $37-448$: 5.78₃

4.11₃ 3.12₈ 2.89₃ 2.84₁₀ 2.60₇ 2.59₆ 2.55₅. See also 11-306. Crystals equant to short prismatic [010]; botryoidal or reniform crusts with radiating fibrous structure. Grass-green to yellowish green, pistachio-green, emerald-green; green streak; vitreous luster; subtranslucent. No cleavage, uneven fracture, brittle. $H = 4\frac{1}{2}$. $G = 4.33$. Biaxial (-) [or (+)]; $XYZ = cba$; $N_x = 1.800$, $N_y = 1.831$, $N_z = 1.846$ (Bisbee); $r > v$, strong. Y, yellow-green; Z, blue-green. Other substitutions noted: Mg for Cu, P and V for As. Fibrous varieties may show excess of H₂O. Soluble in HCl, HNO₃. A secondary mineral found in the oxidized zones of copper deposits. Occurs at Tuckers Tunnel prospect, La Plata Co., CO; at Ajo, New Cornelia mine, Bisbee, Cochise Co., Higgins mine, Shattuck shaft, Twilight claim, White-Tailed Deer mine, AZ; in the Tintic district, Juab Co., and at Gold Hill, Western Utah mine, UT; at Gallinas, Red Cloud Copper mine, and at Copper Hill, Taos Co., NM; at Bristol mine, Lincoln Co., NV, with tenorite and chrysocolla, and elsewhere in Mineral Co., and Lyon Clark Co.; at Zinc Hill mine, CA; at *Hinojosa de Cordoba, Andalusia, Spain*; at Graul near Schwarzenberg, Saxony, Germany; with tennantite at Miedzianka near Kielce, Poland; at Guchab near Otavi, Namibia; at Dome Rock, SA, Australia; at Collahuasi, Tarapaca, Chile. *ncws DII:806, AM 36:484(1951), CM 25:406(1987)*.

41.5.1.3 Austinite $\text{CaZn(AsO}_4\text{)(OH)}$

Named in 1935 for Austin Flint Rogers (1877–1957), mineralogist, Stanford University, CA. Adelite group and subgroup. The Zn end member of the Cu–Zn series with conicalcrite (41.5.1.2). ORTH $P2_12_12_1$. $a = 7.505$, $b = 9.037$, $c = 5.921$, $Z = 4$, $D = 4.323$. *AM 56:1359(1971)*. Structure: *NJMM:159(1988)*. *37-455*: 5.78₃ 4.96₅ 4.14₃ 3.17₉ 2.80₁₀ 2.64₈ 2.60₄ 2.53₄. Minute bladed or acicular crystals elongated [100], sometimes with scepterlike terminations; radially fibrous crusts and nodules. Colorless, white to pale yellowish white; subadamantine luster, to silky in fibrous aggregates. Cleavage {011}, good; brittle. $H = 4-4\frac{1}{2}$. $G = 4.13$. Biaxial (+); $XYZ = acb$; $N_x = 1.759$, $N_y = 1.763$, $N_z = 1.783$ (Na); $2V \approx 47^\circ$. Found at Sterling Hill mine, Ogdensburg, Sussex Co., NJ; at Tucker Tunnel prospect, La Plata Co., CO; at *Gold Hill, Tooele Co., UT*, with adamite, quartz, and iron oxyhydroxides; at Kanaveza mine, Attica, Greece; with barthite from Guchab, and at Tsumeb, Namibia; as fibrous veinlets with calcite and chalcedony in the Lilli mine, Lomitos, Sica Sica Prov., Bolivia. *ncws DII:809*.

41.5.1.4 Duftite- β $\text{PbCu(AsO}_4\text{)(OH)}$

Named in 1920 for G. Duft, director of mines at Tsumeb, Namibia. Adelite group and subgroup. In 1956 duftite was shown to have two forms, α and β . The β form appears to contain some Ca and may form a series with conicalcrite (41.5.1.2). See duftite- α (41.5.2.6). ORTH $P2_12_12_1$. $a = 7.49$, $b = 9.36$, $c = 5.91$, $Z = 4$, $D = 6.12$. *BM 79:7(1956)*. *PD*: 4.18₇ 3.17₁₀ 2.91₈ 2.63₉ 2.26₅ 1.868₅ 1.750₅ 1.637₇. *MM 29:609(1951)*. Found as small prismatic crystallites up to 0.05 mm; fibrous, stalactitic, mammillary. Olive-green to yellow-green,

vitreous luster. No cleavage, conchoidal fracture. $H = 4\frac{1}{2}$. $G = 5.86$. DTA. $N_{av} = 1.97$; nonpleochroic. Synthesized. Samples show intergrowth of duftite- α (end member) with calcian duftite- β . Found at Ojuela mine, Mapimi, DGO, Mexico, with adamite, wulfenite, and mimetite; at Brandy Gill, Caldebeck Falls, Cumberland, England; at Anozel, Vosges, and Cap Garonne, France, with malachite, azurite, olivenite, and mottramite; at *Tsumeb, Namibia*, as pseudomorphs of mimetite with duftite- α , malachite, bayldonite, and azurite. *HCWS MA 29:609(1951), MR 8:17(1977)*.

41.5.1.5 Gabrielsonite $PbFe(AsO_4)(OH)$

Named in 1967 for Olof Erik Gabrielson (b.1912), mineralogist, Swedish Natural History Museum, Stockholm, Sweden. Adelite group and subgroup. ORTH $P2_1m$. $a = 7.86$, $b = 8.62$, $c = 5.98$, $Z = 4$, $D = 6.69$. *AMG 4:401(1967)*. 20-583: 4.91₃ 3.93₃ 3.19₁₀ 3.07₁₀ 2.71₄ 2.65₄ 1.622₄ 1.438₄. Aggregates and masses of crude, rounded crystals up to centimeter size; nodules. Black, pale chocolate-brown streak, adamantine luster, transparent. No cleavage, brittle. $H = 3\frac{1}{2}$. $G = 6.67$. $N_{av} > 2.00$. Soluble in cold 1:1 HCl. Found with romeite, nadorite, calcite, and barite in the *Hindenburg stope at Långban, Varmland, Sweden*. *HCWS AM 53:1063(1968)*.

41.5.1.6 Tangeite $CaCu(VO_4)(OH)$

Named in 1848 for its relationship to volborthite. Adelite group and subgroup. Previously called calcivolborthite. ORTH $P2_12_12_1$. $a = 7.44$, $b = 9.24$, $c = 5.90$, $Z = 4$, $D = 3.82$. *BM 37:219(1956)*. Structure: *NJMM:300(1989)*. 31-265: 5.86₄ 4.15₈ 3.73₄ 3.14₆ 2.88₁₀ 2.60₁₀ 1.73₃ 1.61₈. Scaly aggregates, acicular crystals to 0.5 mm long, fibrous. Gray-green, yellow-green to olive-green; vitreous to pearly luster; translucent. Cleavage (010), (001). $H = 3-4$. $G = 3.75$. Biaxial (+); $N_x = 2.01$, $N_y = 2.05$, $N_z = 2.09$ (Na); $2V = 83^\circ$; nonpleochroic; positive elongation. Soluble in acids. Synthesized. A secondary mineral in sandstones and in oxidized zones of deposits containing vanadium minerals. Found with carnotite and tyuyamunite in the sandstones of southwestern CO at Naturita, Paradox Valley, and Uravan, Montrose Co., and in UT at Grand R.; at Tombstone, Cochise Co., AZ; at Mammoth copper mine, Grindstone Creek, Glenn Co., Camp Signal, San Bernardino Co., CA; at *Friedrichroda, Thuringia, Germany*, with crednerite and manganese oxides; at Tyuya Muyun, Ferghana district, Uzbekistan. *HCWS DII:317*.

41.5.1.7 Nickelaustinite $CaNi(AsO_4)(OH)$

Named in 1987 for the composition and structural relationship to austinite. Adelite group and subgroup. ORTH $P2_12_12_1$. $a = 7.455$, $b = 8.955$, $c = 5.916$, $Z = 4$, $D = 4.27$. Structure: *CM 25:401(1987)*. 41-1425: 3.15₉ 2.77₉ 2.63₁₀ 2.58₈ 2.51₈ 2.47₅ 2.34₅ 2.33₅. Fibrolamellar, flattened on (110), elongate on [001] to 0.2 mm. Yellowish green to grass-green, silky luster, translucent. Cleavage {110}, good. $H = 4$. Biaxial (-); $X = c$; $N_x = 1.770$, $N_z = 1.778$ in (110); nonpleochroic. Microprobe analysis also showed Cu, Zn, Fe, Mg, and Co.

Found on dolomite with roselite, calcite at *Bou Azzer, Morocco*. HCWS AM 73:930(1987).

41.5.1.8 Cobaltaustinite $\text{CaCo}(\text{AsO}_4)(\text{OH})$

Named in 1988 for the composition and the relationship to austinite. Adelite group and subgroup. ORTH $P2_12_12_1$. $a = 7.498$, $b = 9.006$, $c = 5.920$, $Z = 4$, $D = 4.24$. A USM 3:53(1988). PD: 4.97₃ 4.13₇ 3.16₁₀ 2.63₈ 2.60₈ 2.53₄ 2.35₃ 1.609₁₀. Coatings of crystallites up to 25 μm in diameter. Green, pale green streak, dull luster, translucent. Conchoidal fracture, brittle. $H = 4\frac{1}{2}$. Biaxial (+); $N_x = 1.777$, $N_z = 1.802$; 2V large; nonpleochroic. Possible complete solid solution Co–Cu with conichalcite (41.5.1.2). Soluble in HCl, HNO_3 . Occurs with erythrite and other arsenates at *Dome Rock copper deposit, 42 km N of Mingary, SA, Australia*. HCWS AM 74:501(1989).

41.5.1.9 Arsendescloizite $\text{PbZn}(\text{AsO}_4)(\text{OH})$

Named in 1982 to reflect the chemical and close crystallographic relationship to descloizite (41.5.2.1); the As end member of the $\text{AsO}_4\text{--VO}_4$ series. Adelite group and subgroup. ORTH $P2_12_12_1$. $a = 7.634$, $b = 9.358$, $c = 6.075$, $Z = 4$, $D = 6.57$. MR 13:155(1982). 35-668: 4.67₅ 4.23₆ 3.23₁₀ 2.88₁₀ 2.60₈ 2.09₆ 1.656₆ 1.559₈. Crystals tabular on {100} up to 1 mm \times 0.4 mm \times 0.5 mm with {101}, {110}, {100}, {111}; rosette-like aggregates. Pale yellow, white streak, brilliant subadamantine luster, transparent. No cleavage. $H \approx 4$. Biaxial (-); XYZ = bac; $N_x = 1.990$, $N_y = 2.030$, $N_z = 2.035$; 2V $\approx 30^\circ$; $r > v$. Found with willemite, chalcocite, mimetite, quartz, and goethite, on a matrix of tennantite and chalcocite at *Tsumeb mine, Namibia*. HCWS AM 68:280(1983).

41.5.2.1 Descloizite $\text{Pb}(\text{Zn,Cu})(\text{VO}_4)(\text{OH})$

Named in 1854 for Alfred Louis Oliver Legrande Des Cloizeaux (1817–1897), French mineralogist and crystallographer. Adelite group–descloizite subgroup. Zincian end member in a Zn–Cu series with mottramite (41.5.2.2). ORTH *Pnam*. $a = 7.593$, $b = 9.416$, $c = 6.057$, $Z = 4$, $D = 6.202$. MM (1956)31:289, Structure: AC(B) 35:717(1979). 12-537: 5.12₈ 4.25₆ 3.23₁₀ 2.90₈ 2.69₈ 2.62₈ 2.30₈ 1.652₈. See 31-1467, 41-1369(cuprian). Often pyramidal {111}, prismatic [001], rarely tabular {100} or short prismatic [100]. Crystal faces usually uneven and rough, subparallel growth frequent. Also as drusy crusts of intergrown crystals, stalactitic, massive with coarse fibrous structure, or massive granular, compact to friable, mammillary or botryoidal. Brownish red, orange, blackish brown; orange to brownish red streak; greasy luster; transparent to nearly opaque. Often showing zonal growth with varying color, optical properties. No cleavage, conchoidal to uneven fracture, brittle. $H = 3\text{--}3\frac{1}{2}$. $G = 6.2$. Biaxial (-); XYZ = cba; $N_x = 2.185$, $N_y = 2.265$, $N_z = 2.35$; 2V $\approx 90^\circ$ (Mammoth, AZ); , $r > v$, strong; fibers negative elongation. In addition to the complete Zn–Cu, descloizite–mottramite series, Mn and Fe^{2+} substitute (<1%) for (Zn, Cu), As for V. Trace amounts of P and Cl

are found on analysis. Easily soluble in acids. May be found as pseudomorphs after vanadinite (41.8.4.3). Secondary minerals; descloizite and mottramite may be found together in the oxidized ore zones of deposits containing vanadinite, pyromorphite, mimetite, and cerussite, and in sandstones as deposits of meteoric waters. Found with mottramite at Mammoth mine, Pinal Co., AZ; in notable deposits in Georgetown district, Grant Co., and in the Caballos Mts., Hillsboro, NM; cuprian descloizite occurs as large reniform masses and crusts in San Luis Potosi, and at the Ahumada mine, Los Lamentos, CHIH, Mexico; at Pim Hill, Shrewsbury, England; at Niederschletten, Lauterthal, Bavaria, and near Freiberg, Baden, Germany; as coatings on lava at Vesuvius, Italy; at Sah Changi mine, Iran; in large deposits (with mottramite) in sandy pockets in the limestone and dolomite at Abenab, Grootfontein(!) (Berg Aukas mine), Olifantsfontein, Guchab(!), Tsumeb, Uitsub, and elsewhere in the Otavi region, Namibia; also at Broken Hill mine, Zimbabwe; in the Katanga district, Zaire; at Itaccoambi mine, MG, Brazil; in the *Sierra de Cordoba, Argentina*. *HCWS DII:811, MM 50:137(1986), NJMM:465(1991)*.

41.5.2.2 Mottramite $\text{PbCu}(\text{VO}_4)(\text{OH})$

Named in 1876 for the locality. Adelite group descloizite subgroup. The Cu end member in the Zn-Cu series with descloizite (41.5.2.1). ORTH *Pnma*. $a = 7.711$, $b = 9.249$, $c = 6.035$, $Z = 4$, $D = 6.19$. *MM 50:137(1986)*. $43-1463$: 5.06_6 4.23_4 3.25_{10} 2.87_9 2.69_4 2.66_5 2.59_4 2.30_4 . See also *12-538*. Druses of intergrown (with descloizite) crystals often showing zones of different color and optical properties. Grass-green, olive-green to siskin-green; yellowish streak; greasy luster; transparent to opaque. $H = 3-3\frac{1}{2}$. $G = 5.9$. Biaxial (-) [or (+)]; $N_x = 2.17$, $N_y = 2.26$, $N_z = 2.32$; $2V \approx 73^\circ$ (Bisbee, AZ); , $r >$ or $<$ v , weak to strong; pleochroic: X,Y, canary to greenish yellow; Z, brownish yellow. A secondary mineral associated with descloizite and other vanadates in oxidized zones, especially sandstones. Found in the Silver Star district, MT; at Red Cloud tungsten mine, Gallinas Mt., NM; at Apache mine, and the Shattuck shaft, Bisbee, Cochise Co., the 79 mine, Gila Co., Old Yuma mine, Pima Co., Mammoth-St. Anthony mine, Tiger, and in the Tombstone district, AZ; in the Lake Valley district, Sierra Co., NM; at *Mottram-St. Andrew, Cheshire, England*; at Bena de Podru, Sassari, Sardinia; at Mouanan, Gabon; at Broken Hill mine, Zambia; with descloizite in many parts of the Tsumeb district, Namibia. *HCWS DII:811, MM 31:289(1956)*.

41.5.2.3 Pyrobelonite $\text{PbMn}(\text{VO}_4)(\text{OH})$

Named in 1919 from the Greek for *fire* and *needle*, in allusion to the color and habit. Adelite group descloizite subgroup. ORTH *Pnam*. $a = 7.644$, $b = 9.508$, $c = 6.182$, $Z = 4$, $D = 5.82$. *CM 10:117(1969)*. Structure: *AM 40:580(1955)*. *20-588*: 5.14_7 4.27_4 3.25_{10} 2.91_5 2.67_6 2.64_7 2.33_7 2.13_5 . Acicular [001]. Fire-red, orange-yellow or reddish streak, adamantine luster, transparent. $H = 3\frac{1}{2}$.

$G = 5.58$. Biaxial (-); $N_x = 2.32$, $N_y = 2.36$, $N_z = 2.37$; $2V = 29^\circ$, $r > v$. Reflectance in plane-polarized light, gray with bireflectance; under crossed polars strongly anisotropic in grays with red and orange internal reflections. Mn may substitute for Pb up to Mn/Pb 1:1. Found at Franklin, Sussex Co., NJ; at Tyloch, near South Cornelly, Mid Glamorgan, Wales, with vanadinite, manganocalcite, dolomite, and manganese oxides; at *Långban, Filipstad, Värmland, Sweden*, associated with hausmannite, pyrochroite, barite, and calcite. HCWS *MM* 41:85(1977).

41.5.2.4 Cechite $Pb(Fe^{2+}, Mn)(VO_4)(OH)$

Named in 1981 for Frantisek Cech (b.1944), mineralogist, Charles University, Prague, Czech Republic. Adelite group–Descloizite subgroup. ORTH Pnam. $a = 7.607$, $b = 9.441$, $c = 6.096$, $Z = 4$, $D = 5.99$. *NJMM:520(1981)*, Structure: *NJMM:35(1989)*. Isotypic with pyrobelonite (41.5.2.3). 35-530: 5.12₈ 4.72₄ 4.25₅ 3.35₄ 3.23₁₀ 2.91₈ 2.66₆ 2.63₈. Granular masses to 3 cm across, crystals up to 3 mm long show {110}, {010}. Black, black streak, submetallic to resinous luster. Uneven to conchoidal fracture, brittle. $H = 4\frac{1}{2}$ –5. $G = 5.88$. IR. Magnetic. In RL, blue light gives gray-white with yellowish tint, yellow light gives brown-yellow to beige. Low birefringence, anisotropic with color shift from light gray to dark gray with brownish tint. $R = 18.5, 16.0$ (460 nm), 17.6, 14.8 (540 nm); 17.7, 14.4 (580 nm); 18.9, 15.1 (660 nm). Some question about the presence and relative amounts of Fe^{3+} . Found at *Vrncice, Pribram, Stredocsky Kraj, Cechy, Bohemia, Czech Republic*. HCWS *AM* 67:1074(1982).

41.5.2.5 Duftite- α $PbCu(AsO_4)(OH)III$

Named in 1956 for its relationship to the original Duftite. See Duftite- β 42.5.1.4. Adeite group, descloizite subgroup. ORTH Pnam $a = 7.788$, $b = 9.223$, $c = 6.001$, $Z = 4$, $D = 6.57$. *BM* 79:7(1956). 41-1444 5.03₅ 4.22₆ 3.26₁₀ 2.85₇ 2.67₈ 2.58₇ 2.30₅ 1.653₆. In spheroidal fibrous aggregates to 0.5 mm; octahedra to 0.2 mm in mammillary crusts. Green-black to light green, water green, translucent to opaque. Conchoidal fracture. $H = 3$, $G = 6.40$. Biaxial (-); $N_x = 2.04$, $N_y = 2.08$, $N_z = 2.10$, $2V =$ large. Synthesized. Found at Cap Garonne, France; at *Tsumeb, Namibia* with olivenite, malachite, mottramite *MR* 8:17(1977). HCWS

41.5.3.1 Babephite $BaBe(PO_4)F$

Named in 1966 for the composition. TRIC P1. $a = 6.889$, $b = 16.814$, $c = 6.902$, $\alpha = 90.01^\circ$, $\beta = 89.99^\circ$, $\gamma = 90.32^\circ$, $Z = 8$, $D = 4.325$. *DANS* 167:93(1966). Structure: *SPC* 25:28(1980). 18-157: 3.67₆ 3.19₁₀ 2.76₈ 2.44₇ 2.76₁₀ 2.03₇ 1.516₁₀ 1.135₇. Equant or flattened tabular grains to 1 mm \times 1.5 mm. No faceted crystals seen. White, greasy luster. No cleavage. $H = 3\frac{1}{2}$. $G = 4.31$. Nonluminescent. Appears uniaxial (+); $N_{min} = 1.629$, $N_{max} = 1.632$; negative

elongation. Found in the alluvial deposits directly above a rare-metal fluorite deposit in *Siberia*, along with the heavy concentrates which contain zircon, ilmenorutile fluorite, phenakite, and scheelite. *ncws AM 51:1547(1966)*.

41.5.4.1 Herderite $\text{CaBe}(\text{PO}_4)(\text{F})$

Named in 1828 for Siegmund August Wolfgang von Herder (1776–1838), mining official in Freiberg, Saxony, Germany. The F end member (may not exist in nature) in the F–OH series with hydroxyherderite (41.5.4.2). *MON P2₁/c*. $a = 8.82$, $b = 7.70$, $c = 9.82$, $Z = 4$, $D = 2.94$. *ZK 93:146(1936)*. 6-338: 3.43₅ 3.14₁₀ 3.00₆ 2.86₈ 2.55₆ 2.26₅ 2.20₇ 1.650₅. Biaxial (–); $N_x = 1.556$, $N_y = 1.578$, $N_z = 1.589$. For properties, see hydroxyherderite. Found in the tin mines at *Ehrenfriedersdorf, Saxony, Germany*, and as a gemstone of unknown provenance from MG, Brazil. *ncws AM 37:938(1952)*.

41.5.4.2 Hydroxyherderite $\text{CaBe}(\text{PO}_4)(\text{OH})$

Named in 1894 for the composition and relationship to herderite (41.5.4.1). *MON P2₁/a*. $a = 9.789$, $b = 7.661$, $c = 4.804$, $\beta = 90.02^\circ$, $Z = 4$, $D = 3.00$. Structure: *AM 59:919(1974)*. 34-147: 3.76₂ 3.43₃ 3.14₁₀ 3.00₃ 2.87₄ 2.55₂ 2.21₃ 1.996₂. Mainly euhedral as stout prismatic [100] or [001], thick tabular {001}, pseudo-orthorhombic, or pseudo-hexagonal crystals; botryoidal or spheroidal aggregates with radial-fibrous structure. Usually twinned, although not obvious, with twin plane {001} or {100}. Colorless to pale yellow, greenish white; vitreous luster; transparent to translucent. Cleavage {110}, interrupted; subconchoidal fracture. $H = 5-5\frac{1}{2}$. $G = 2.95$. Biaxial (–); $N_x = 1.59-1.615$, $N_y = 1.61-1.634$, $N_z = 1.62-1.643$; $2V = 70^\circ$. Indices decrease with increase in F. *AM 63:913(1978)*. Soluble in acids. Little replacement of Ca by Fe, Mg, or Mn but may have some Si (toward the silicate mineral ellestadite). Found associated with quartz, albite, muscovite, and clays in pegmatite localities in ME such as Beryllium Corp. mine, Buckland, Harvard quarry, Mt. Mica mine, Bell pit, Dunton Gem, Newry mine, where it is an alteration product of beryllonite, at Paul Bennet quarry, Oxford Co., and Berry quarry, Lord Hill, near Poland, Androscoggin Co., and at Stoneham; at Charles Davis, Fletcher, Palermo No. 1 mines, North Groton, NH; at Blue Chihuahua mine, Himalya mine, San Diego Co., CA; at the pegmatites at Epprechstein or Reinersreuth, Bavaria; at Viitaniemi, Finland; in pegmatites at Mursinsk, Ural Mts., Russia; in MG, Brazil, at Lavra do Enio, Galileia, and the Xanda mine(!), Virgen da Lapa, in violet-colored crystals to 15 cm associated with lepidolite, elbaite, topaz, and microlite, and at the Golconda mine(!), Governador Voladares district, in crystals and twins to 7 cm, at Alto Bernado, Picui, and Paraiba, Brazil; also at Mursinsk, Ural Mts., Russia. *ncws DII:820*.

41.5.4.3 Väyrynenite $Mn^{2+}Be(PO_4)(OH,F)$

Named in 1954 for Heikki Allan Väyrynen (1888–1956), mineralogist and geologist, Technical High School, Helsinki, Finland. The Mn analog of hydroxylherderite (41.5.4.2). *MON P2₁/a*. $a = 5.41$, $b = 14.49$, $c = 4.73$, $\beta = 102.7^\circ$, $Z = 4$, $D = 3.23$. *ZK 112:275(1959)*. Structure: *117:16(1962)*. *12-707*: 7.25₉ 4.96₃ 4.40₆ 3.45₁₀ 2.89₉ 2.85₄ 2.66₄ 2.64₃. Rose-red to light pink, vitreous luster, transparent. Cleavage {001}, good. $H = 5$. $G = 3.183$. Biaxial (-); $N_x = 1.640$, $N_y = 1.662$, $N_z = 1.667$. *AM 39:848(1954)*. Microprobe analyses show Fe^{2+} , Ca, Be, Na, K, and Al. Euclase is the Al–Si analog. Found at the pegmatite in *Viitaniemi, Erajarvi, Finland*, associated with herderite, hurlbutite, beryllonite, microcline, muscovite, and morinitite: in the Broghul Pass area(1), northern Chitral Valley, Pakistan–Afghanistan, in crystals to 2.5 cm. *HCWS AM 41:371(1956)*, *ZK 143:309(1976)*.

41.5.4.4 Bergslagite $CaBe(AsO_4)(OH)$

Named in 1984 for the locality. *MON P2₁/c*. $a = 4.882$, $b = 7.809$, $c = 10.127$, $\beta = 90.16^\circ$, $Z = 4$, $D = 3.40$. *NJMM:257(1984)*. Structure: *ZK 166:73(1984)*. Isostructural with hydroxylherderite (41.5.4.2). *35-650*: 6.18₅ 4.88₇ 3.91₇ 3.52₈ 3.20₁₀ 3.05₇ 2.92₇ 2.41₆. Centimeter-size aggregates of elongated crystals. Colorless, whitish, or grayish; vitreous luster; translucent. No cleavage, uneven fracture. $H = 5$. $G = 3.4$. Fluoresces pale green, yellowish brown, or blue under SWUV. Biaxial (-); $XYZ = abc$; $N_x = 1.659$, $N_y = 1.681$, $N_z = 1.694$ (598 nm); $2V = 70^\circ$. Found in the *Bergslagen region, Langban, Varmland, Sweden*, in thin veins in fine-grained hematite ore associated with manganooan pyroxene, manganberzeliite, svabite, barite, and calcite. *HCWS AM 70:436(1985)*.

TILASITE GROUP

The tilasite group minerals are described by the general formula

where

- A = Na, Ca
 B = Al, Fe^{3+} , Mg
 T = As, P
 Z = F, OH

and crystallize in monoclinic space groups.

The structure is similar to titanite, $CaTiSiO_5$ (52.4.3.1) with PO_4 or AsO_4 in place of SiO_4 . The B(O, OH, F) octahedra are cross-linked by the TO_4 groups, resulting in an open-framework arrangement. Ca or Na in seven-fold coordination are located within the large cavities created.

TILASITE GROUP

Mineral	Formula	Space Group	a				β	
			a	b	c	β		
Lacroixite	NaAl(PO ₄)F	C2/c	6.414	8.207	6.885	115.47	41.5.5.1	
Durangite	NaAl(AsO ₄)F	C2/c	6.54	8.48	7.31	119.34	41.5.5.2	
Maxwellite	NaFe ³⁺ (AsO ₄)F	Aa or A2/a	7.161	8.780	6.687	114.58	41.5.5.3	
Tilasite	CaMg(AsO ₄)F	C2/c	6.688	8.944	7.570	121.17	41.5.6.1	
Isokite	CaMg(PO ₄)F	A2/a	6.909	8.746	6.518	112.2	41.5.6.2	
Panasqueiraitite	CaMg(PO ₄) (OH,F)	C2/c	6.535	8.753	7.498	121.40	41.5.6.3	

Note: In addition to titanite, Cati SiO₄O (52.4.3.1) related minerals include vuagnatite, CaAl(SiO₄)(OH) (52.4.2.2); and malayite, CaSnSiO₄O.

41.5.5.1 Lacroixite NaAl(PO₄)F

Named in 1914 for Francois Antoine Alfred Lacroix (1863–1948), French mineralogist. Tilasite group. The phosphate analog of durangite (41.5.5.2). MON C2/c. $a = 6.414$, $b = 8.207$, $c = 6.885$, $\beta = 115.47^\circ$, $Z = 4$, $D = 3.29$. CM 27:211(1989). Structure: AM 70:849(1985). 39-325: 4.73₅ 4.63₃ 3.25₂ 3.16₁₀ 2.90₁₀ 2.48₆ 2.17₄ 1.578₃. Fragments of crystals. Gray or colorless, vitreous to resinous luster, transparent. Cleavage (111), (111), indistinct. $H = 4\frac{1}{2}$. $G = 3.29$. Biaxial (-); $N_x = 1.546$, $N_y = 1.563$, $N_z = 1.580$; $2V = 89^\circ$; slight dispersion. Easily soluble in HCl, H₂SO₄. Coupled substitution of Li, OH for Na, + F noted in Buranga specimens. Found at Strickland quarry, Portland, CT; at Montebbras, France; at Jihlava, Jeclov, Konigswart, Bohemia, Czech Republic; in druses in lithium-bearing pegmatite in granite intimately mixed with viitaniemiite, its alteration product, and associated with jezekite, apatite, childrenite, roscherite, and tourmaline at Greifenstien near Ehrenfriedersdorf, Saxony, Germany; at Buranga pegmatite, Rwanda, in montebbrasite host. HCWS DII:783.

41.5.5.2 Durangite NaAl(AsO₄)F

Named in 1869 for the locality. Tilasite group. MON C2/c. $a = 6.54$, $b = 8.48$, $c = 7.31$, $\beta = 119.34^\circ$, $Z = 4$, $D = 3.616$. CM 23:241(1985). Structure (syn): ZK 99:38(1938). 35-424: 4.76₈ 3.54₄ 3.34₅ 3.24₈ 2.97₁₀ 2.56₆ 2.55₆ 1.533₄. Pyramidal crystals with {111}, {110} predominating, faces usually dull, rough. Synthetic crystals prismatic [101], or tabular with interpenetration twins on {001} common. Orange-red, light to dark, synthetics are green; cream-yellow streak; vitreous luster; translucent. Cleavage {110}, distinct; uneven fracture. $H = 5$. $G \approx 4.0$. Biaxial (-); $X \wedge c = -25^\circ$; $Z = b$; $N_x = 1.634$, $N_y = 1.673$, $N_z = 1.685$; $2V = 45^\circ$, $r > v$. Soluble in H₂SO₄. Synthesized. Found in northern Black Range, southwestern NM, in veins cutting alkali rhyolites; with amblygonite and cassiterite in pegmatite near Lake Ramsay, New Ross, Luneberg Co., NS, Canada; with cassiterite, hematite, and topaz at the Bar-

ranca tin mine, DUR, Mexico; on a joint face at the Cheesewring quarry, Linkinhorne, Cornwall, England. *HCWS DII:829*.

41.5.5.3 Maxwellite $\text{NaFe}(\text{AsO}_4)\text{F}$

Named in 1991 for Charles Henry Maxwell (b.1923), U.S. Geological Survey (Denver). Tilasite group. *MON Aa* or *A2/a*. $a = 7.161$, $b = 8.780$, $c = 6.687$, $\beta = 114.58^\circ$, $Z = 4$, $D = 3.95$. *NJMM:363(1991)*. *PD: 4.84₇ 3.64₄ 3.29₁₀ 3.04₈ 2.91₄ 2.66₃ 2.64₅ 2.61₈*. Aggregates to 3 mm of short, blocky prisms; subhedral crystals to 1 mm showing {013}, {526}, {526}, {011}. Dark red, medium to pale red-orange streak, vitreous luster, transparent. Cleavage {110}, good; irregular to conchoidal fracture. $H = 5-5\frac{1}{2}$. $G = 3.90$. Nonfluorescent. Biaxial (+); $X \wedge c = 11^\circ$; $Y = b$; $Z \wedge a = 35.5^\circ$; $N_x = 1.748$, $N_y = 1.772$, $N_z = 1.798$; $2V = 86^\circ$; $Z > X > Y$; $r > v$, strong. X, Y, medium yellow-orange; Z, dark orangish red. Slowly soluble in HCl, HNO₃, readily soluble in hot H₂SO₄. Found in the *Black Range tin district, Catron Co., NM*. *HCWS AM 77:449(1992)*.

41.5.6.1 Tilasite $\text{CaMg}(\text{AsO}_4)\text{F}$

Named in 1895 for Daniel Tilas (1712–1772), Swedish mining engineer. Tilasite group. *MON C2c*. $a = 6.688$, $b = 8.944$, $c = 7.570$, $\beta = 121.17^\circ$, $Z = 4$, $D = 3.722$. Space group revised *NJMM: 289 (1994) MR 9:385(1978)*. Structure: *AM 57:1880(1972)*. *2-485: 3.26₁₀ 3.07₁₀ 2.86₇ 2.69₁₀ 2.63₇ 2.27₈ 1.74₉ 1.69₉*. Crystals elongated [100], sometimes flattened {010}, occasionally in subparallel groups; massive. Twinning {001} common. Gray to violet-gray (Långban), olive-green to apple-green (India); resinous luster on cleavage surfaces, vitreous; translucent. $H = 5$. $G = 3.77$. India crystals piezoelectric. Biaxial (-); $X \wedge c \approx 30^\circ$; $Z = b$; $N_x = 1.640$, $N_y = 1.660$, $N_z = 1.675$; $2V = 83^\circ$; $r < v$ (India). Readily soluble in HCl, HNO₃. Found at Sterling Hill mine, Sussex Co., NJ; at White Tailed Deer mine, Bisbee, Cochise Co., AZ; as grains or veinlets with berzeliite, barite in dolomitic limestone with hausmannite at *Långban, Värmland, Sweden*; at Cherbudung, Falotta, Griesons, Binntal, Switzerland; at Kajlidongri, Jhabua State, India; at Guettera, Algeria. *HCWS DII:827*.

41.5.6.2 Isokite $\text{CaMg}(\text{PO}_4)\text{F}$

Named in 1955 for the locality. Tilasite group. *MON A2/a*. $a = 6.909$, $b = 8.746$, $c = 6.518$, $\beta = 112.2^\circ$, $Z = 4$, $D = 3.248$. *MM 56:227(1992)*. *7-406: 3.19₁₀ 3.02₁₀ 2.78₅ 2.63₁₀ 2.59₅ 2.30₈ 2.22₅ 1.720₈*. Patchy spherulitic aggregates of fibrous or platy crystals; short prismatic. White, light brown, pink. Cleavage {010}, good. $H = 5$. $G = 3.29$. Biaxial (-); $N_x = 1.590$, $N_y = 1.595$, $N_z = 1.615$; $2V = 51^\circ$. Dissolves in cold HCl. Found at Benson mines, west-central Adirondack highlands, NY, in magnetite-hematite deposits whose veins, dikes, and fractures are filled with wagnerite, replaced by isokite. Associated minerals: ankerite, dolomite, Sr- and F-containing apatite, pyrite, magnetite, ilmenite, monazite, pyrochlore, and sellaite; in the emerald mines in the

Ural Mts., Russia; in ankeritic dolomite (carbonatite), *Nkumbwa Hill, near Isoka, northern Kumbwa, Zambia*. HCWS *AM 40:776(1955)*, *MM 30:68(1955)*.

41.5.6.3 Panasqueiraite $\text{CaMg}(\text{PO}_4)(\text{OH},\text{F})$

Named in 1981 for the locality. Tilasite group. MON *C2/c*. $a = 6.535$, $b = 8.753$, $c = 7.498$, $\beta = 121.40^\circ$, $Z = 4$, $D = 3.213$. *CM 23:131(1985)*. *35-511: 3.20₇ 3.02₉ 2.78₃ 2.63₁₀ 2.58₅ 2.11₂ 1.722₄ 1.658₃*. Aggregates several centimeters in diameter with individual anhedral grains about 1 mm. Pink, white streak, vitreous luster, translucent. Cleavage {010}, poor. $H = 5$. $G = 3.27$. Nonfluorescent but cathodoluminescent in electron beam (12 kV). Biaxial (+); $X \wedge c = 22^\circ$; $Z = b$; $N_x = 1.590$, $N_y = 1.596$, $N_z = 1.616$; $2V = 51^\circ$; nonpleochroic. Occurs with thadeuite, fluorapatite, wolfeite, topaz, muscovite, sphalerite, quartz, chalcopyrite, pyrrhotite, siderite, arsenopyrite, chlorite, vivianite, and althausite in vein selvages at *Panasqueira, Portugal*. HCWS *CM 19:389(1981)*, *AM 67:859(1982)*.

41.5.7.1 Brazilianite $\text{NaAl}_3(\text{PO}_4)_2(\text{OH})_4$

Named in 1945 for the country in which it was found. MON *P2₁/n*. $a = 11.233$, $b = 10.142$, $c = 7.097$, $\beta = 97.37^\circ$, $Z = 4$, $D = 2.998$. *SMPM 41:407(1961)*. Structure: *AC(B) 30:1311(1974)*. *42-1354: 5.78₂ 5.07₁₀ 3.75₁ 3.29₁ 2.99₃ 2.87₂ 2.74₂ 2.69₃*. See also *14-379* and *27-630*(calc). Equant to short prismatic [001] with prism zone striated [001], elongated [100]; many forms showing; globular with radial-fibrous structure. Chartreuse-yellow to pale yellow, colorless streak, vitreous luster, transparent. Cleavage [010], good; conchoidal fracture; brittle. $H = 5\frac{1}{2}$. $G = 2.983$. Biaxial (+); $X \wedge c = -20^\circ$; $Y = b$; $N_x = 1.602$, $N_y = 1.609$, $N_z = 1.621$ (Na) (Brazil); $2V = 75^\circ$, $r < v$, faint. Slowly decomposed by HF and by hot H_2SO_4 . Found at the Harvard quarry and Nevel tourmaline mine, Newry, ME, G.E. Smith mine, Newport, and with whitlockite and apatite in the Fletcher mine and Palermo No. 1 mine(!), North Groton, NH; in cavities in a pegmatite near *Corrego Frio*(!) and *Lavra de Telirio*(!), *Linopolis*, also Mendes Pimental(!), *MG, Brazil*, with muscovite, albite, apatite, and tourmaline. HCWS *DII:841*.

41.5.8.1 Amblygonite $\text{LiAl}(\text{PO}_4)\text{F}$

Named in 1817 from the Greek for *blunt* and *angle*, in allusion to the appearance of crystalline samples. The F-rich member of the F-OH series with montebrasite (41.5.8.2) and the Li end member of the Li-Na series with natromontebrasite (41.5.8.3). TRIC *P1*. $a = 6.645$, $b = 7.733$, $c = 6.919$, $\alpha = 90.35^\circ$, $\beta = 117.44^\circ$, $\gamma = 91.20^\circ$, $Z = 4$, $D = 3.08$. *ZVMO 118:47(1989)*. Structure: *AM 75:992(1990)*. *22-1138: 4.64₈ 3.87₈ 3.30₅ 3.24₆ 3.15₁₀ 2.96₈ 2.38₅ 1.935₆ 1.728₅*. Equant to short prismatic [010] crystals, ordinarily rough; cleavable masses; columnar; compact. Twinning common on {111} with composition plane {111}. Twins usually tabular parallel to $\{\bar{1}11\}$ with individuals about equal in size, also tabular {110} with unequal individuals; twin {111} rare; lamellar. White to milky or creamy white, yellowish, beige,

salmon-pink, greenish, bluish, gray, occasionally colorless and water clear; vitreous to greasy luster; transparent to translucent. Cleavage {100}, perfect; {110}, good; {011}, distinct; {001}, imperfect; uneven to subconchoidal fracture; brittle. $H = 5\frac{1}{2}$ -6. $G = 3.11$. Biaxial (-); $N_x = 1.591$, $N_y = 1.605$, $N_z = 1.613$ (Na) (Utö, analysis shows Na and OH); $r > v$. Indices decrease with increasing F and Na. Soluble with difficulty in acids. Complete solid-solution series for Na-Li and F-OH, and most samples show all these elements on analysis. Usually found in Li-bearing granitic pegmatites, often as very large crystals with variable composition, even from a single site. Associated minerals: spodumene, lithiophilite-triphyllite, apatite, lepidolite, petalite, pollucite, and tourmaline. Major occurrences include transparent crystals found at New Pit, Newry(!); other forms at the many pegmatite localities in ME and NH, usually compositionally montebbrasite; giant crystals in the pegmatites of the Custer district(!), SD, and elsewhere in the Black Hills, where masses weighing hundreds of tons have been mined; at Pala, Mesa Grande, and elsewhere in San Diego Co., and San Bernardino Co., CA; at the pegmatites in the Yellowknife-Beaulieu area and in the Oiseaux R. district, MAN, Canada. In Europe the early finds were at Churgsdorf and Arnsdorf near Penig and with cassiterite at Geyer in Saxony, Germany, with several members in the series known from *Montebras, Creuse, France*; on the island of Utö near Stockholm, Sweden; at many localities in MG, Brazil, such as Araçuaí, Urubu, Itinga, Lavra de Ilha(!), Taquaral; Mendes Pimentel, Mantena. HCWS *DII:823, MM 37:414(1969)*.

41.5.8.2 Montebbrasite $\text{LiAl}(\text{PO}_4)(\text{OH})$

Named in 1872 for the locality. The (OH)-F series with amblygonite (41.5.8.1) and the Li end member in the Li-Na series with natromontebbrasite (41.5.8.3). TRIC $P1$. $a = 6.713$, $b = 7.708$, $c = 7.019$, $\alpha = 91.31^\circ$, $\beta = 117.93^\circ$, $\gamma = 91.77^\circ$, $Z = 4$, $D = 3.00$. *ZVMO 118:47(1989)*. Structure: *AM 75:992(1990)*. *12-448*: 4.68₉ 3.33₄ 3.27₅ 3.23₅ 3.20₆ 3.16₉ 2.97₁₀ 2.40₄. Habit and physical and chemical properties similar to those of amblygonite, often occurring in crystals of gigantic size and associated with lithiophilite-triphyllite, apatite, lepidolite, petalite, pollucite, and tourmaline. Composition variations between OH-F and Li-Na often detected in single locality. Biaxial (+); $N_x = 1.594$, $N_y = 1.608$, $N_z = 1.616$ (Na) (Karibib); $2V = 75^\circ$; $r < v$. (analysis shows Li/Na = 9:0.4, OH/F \approx 1:1). Found at New Pit(!), Newry, Oxford Co., ME; at Branchville and Portland, CT; at Royal Gorge, CO; as giant crystals in the pegmatites of the Custer district and in the Black Hills, Peerless, and Bob Ingersol mines(!) near Keystone, at Gaint-Volney mine near Tinton, at Beecher Lode and Tin Mt., pegmatites, SD; at Yellowknife-Beaulieu area, NWT; and at New Ross, Lunenburg Co., NS, Canada; at *Montebras, Creuse, France*; in large masses in the pegmatite at Varutrask, Sweden; in the lepidolite pegmatites at Karibib district, Namibia, with petalite; at Lemonade Springs pegmatite, Greenbushes, and at Ravensthorpe and

Ubini, WA, Australia; at Mogi das Cruzes, São Paulo, Brazil. *HCWS DII:823*, *MM 37:414(1979)*.

41.5.8.3 Natromontebrasite (Na,Li)Al(PO₄)(OH,F)

Named in 1913 for the composition and resemblance to montebrasite (41.5.8.2) and amblygonite (41.5.8.1). *P1*. $a = 5.266$ $b = 7.174$ $c = 5.042$, $\alpha = 112.3^\circ$, $\beta = 97.70^\circ$, $\gamma = 67.13$, $Z = 2$, $D = 3.31$. *44-1429*: 4.56₅ 3.34₂ 3.27₂ 3.23₃ 3.15₁₀ 2.96₁₀ 2.50₈ 2.39₃. Biaxial (+); $N_x = 1.594$, $N_y = 1.603$, $N_z = 1.615$ (Freemont, CO); 2V very large (analysis of this sample shows Na/Li = 1.69:1 and OH/F \approx 1:1). Found at Canyon City, and Eight Mile Park, Fremont Co., CO; at Jeclov, Moravia, Czech Republic; at Presidente Buena, MG, Brazil. *HCWS DII:823*.

41.5.9.1 Tavorite LiFe³⁺(PO₄)(OH)

Named in 1955 for Elysairio Tavora (b.1911), mineralogist, University of Brazil, Rio de Janeiro, Brazil. The Fe³⁺ analog of montebrasite. *TRIC P1* or *P1*. $a = 5.138$, $b = 5.307$, $c = 7.442$, $\alpha = 67.48^\circ$, $\beta = 67.72^\circ$, $\gamma = 81.98^\circ$, $Z = 2$, $D = 3.33$. *AM 40:952(1953)*, Structure: *DANP 29:27(1984)*. Tetrahedral PO₄ groups coordinate with octahedral FeO₆ groups, creating channels in which Li occurs. *41-1376*: 4.97₆ 4.77₅ 4.66₆ 3.94₄ 3.32₇ 3.27₁₀ 3.04₉ 2.46₅. Very fine grained, flakes. Yellow, green-yellow to green, dark green. $G = 3.29$. $N_{av} = 1.807$. Found at Fletcher and Palermo No. 1 mines, North Groton, NH; at pegmatite localities in SD, such as Bull Moose, Custer Mt., Elkhorn pegmatite, Tip Top and White Elephant mines; at Hagedorf, Bavaria, Germany; at *Sapucaia pegmatite, Galileia, MG, Brazil*, in veinlets and disseminated in porous triphylite and heterosite, admixed with barbosalite. *HCWS NJMM:78(1957)*.

FLORENCITE/ARSENOFLORENCITE GROUP

The Florencite/Arsenoflorencite minerals are a special set of the Crandallite subgroup with a general formula:

where

A = REE, Ba, Bi, Ca, Th, Pb, □

B = Al, Fe³⁺

T = As, P

(OH) amount depends on the charge of the A ion.

The minerals crystallize in the hexagonal-rhombohedral space group R3m. The structure *NJMM:227(1990)* resembles alunite but the tetrahedral TO₄ groups coordinated with B(O,OH)₆ polyhedra are both irregular. The apical

T-O bond of the TO_4 group is longer than the other three T-O bonds. The A ions are in 12 fold coordination in the interstices of this scaffold-like structure.

FLORENCITE/ARSENOFLORENCITE GROUP

41.5.10.1 Dussertite $\text{BaFe}_3^{3+}(\text{AsO}_4)_2(\text{OH})_5$

Named in 1925 for D. Dussert, French mining engineer. Florencite group, see crandallite subgroup 42.7.3.1. *HEX-R* $R\bar{3}m$. $a = 7.424$, $c = 17.494$, $Z = 3$, $D = 4.09$. *TMPM* 11:1215(1966). 35-621: 6.07₇ 3.72₆ 3.13₁₀ 2.58₃ 2.33₅ 2.00₆ 1.85₆ 1.560₃. Minute crystals flattened {001} grouped as rosettes or crusts. Green to pistachio-green, translucent. No cleavage. $H = 3\frac{1}{2}$. $G = 3.75$. Uniaxial (-); $N_O = 1.87$, $N_E = 1.85$ (Algeria) (occasionally biaxial, $2V = 15-20^\circ$). Occurs with arseniosiderite and carminite at Mapimi, DGO, Mexico; on spongy or lamellar quartz at *Djebel Debar, northeastern Hammam Meskhoutine, Constantine, Algeria*. *cs* *DII*:839.

41.5.10.2 Florencite-(Ce) $\text{CeAl}_3(\text{PO}_4)_2(\text{OH})_6$

Named in 1899 for William Florence (1864-1942), Brazilian mineralogist, who made a preliminary chemical analysis of the mineral. Florencite group. Compare crandallite group (42.4.3.1); see also arsenoflorencite (41.5.11.1-3), the As analog. *HEX-R* $R\bar{3}m$. $a = 6.972$, $c = 16.261$, $Z = 3$, $D = 3.73$. Structure: *NJMM*:227 (1990). 43-673: 5.65₈ 3.48₆ 2.93₁₀ 2.42₂ 2.20₃ 2.17₄ 1.886₄ 1.742₃. Sample from Backbone range, McKenzie Mts., NWT, Canada *CM* 19:535(1981). See also 8-413 (Mata dos Creoulos, Diamantina, MG, Brazil). Small rhombohedral crystals exhibiting {0221} or {1011}, pseudocubic clear, pale yellow. Luster greasy to resinous. Transparent splintery fracture. $H = 5-6$ $G = 3.586$ (Brazil). Uniaxial (+) $N_O = 1.695$, $N_E = 1.705$ (Africa). Partly soluble in HCl. Found at Kangankunde Hill, Malawi; with microcline and fluorite in pegmatite at Klein Spitzkopje, Namibia; in mica schists at Morro do Caizambu, near Ouro Preto, and as a rare constituent of the sands of Tripuhy, Ouro Preto, associated with cinnabar, monazite, and xeno-

time; in rounded grains in diamond-bearing sands from Matta de Creoulos, Rio Jequetinhonha, near Diamantina, MG, Brazil *HCWS DII:838, MM 33:281(1962)*.

41.5.10.3 Florencite-(La) $\text{LaAl}_3(\text{PO}_4)_2(\text{OH})_6$

Named in 1981 as the La end member of the florencite series. See Florencite-(Ce) 10.2. *HEX-R R3m*. $a = 6.987$, $c = 16.248$. *38-347: 5.67₉ 3.49₇ 2.93₁₀ 2.17₈ 1.884₇ 1.743₇ 1.601₇ 1.190₇*. Sample from Shituru Cu deposit, Shaba, Zaire, contains La > Ce, trace Nd *CS CM 18:301(1980)*. Physical and chemical properties as Florencite-(Ce). *HCWS*

41.5.10.4 Florencite-(Nd) $\text{NdAl}_3(\text{PO}_4)_2(\text{OH})_6$

Named in 1986 as the Nd end member of the florencite series. Florencite-group (Ce) 41.5, 10.2. *HEX-R R3m*. $a = 6.992$, $c = 16.454$. *PD 1:330(1986)*. *39-333: 5.69₉ 3.50₉ 2.95₁₀ 2.84₂ 2.19₅ 1.895₅ 1.748₆ 1.286₃*. Sample from Sausalito, Marin Co., CA. Uniaxial (+) $N_0 = 1.66-1.666$, $N_E = 1.688-1.694$. *DANS 314: 195(1990)*. *HCWS*

41.5.11.1 Arsenoflorencite-(Ce) $\text{CeAl}_3(\text{AsO}_4)_2(\text{OH})_2$

Named in 1987 for the composition and relationship to florencite. The As analog of florencite-(Ce), arsenoflorencite group. Related to the crandallite (42.7.3.1) group, with which there is limited solid solution, also isomorphous with arsenogoyazite (42.7.4.3) and with gorceixite (42.7.3.2). *HEX R R3m*. $a = 7.029$, $c = 16.517$, $Z = 3$, $D = 4.091$. *MM 51:605(1987)*. *42-1390: 3.51₆ 2.96₁₀ 2.75₃ 2.20₄ 1.905₅ 1.753₄ 1.627₃ 1.482₃*. Scalenohedral crystals showing {102}, {101}, and fragments to 0.5 mm in diameter. Colorless to light brown, clear to cloudy, translucent. No cleavage, conchoidal fracture, brittle. $H = 3$. $G = 4.096$. Nonfluorescent, no cathodoluminescence. $G = 4.096$. Uniaxial (+); $N_0 = 1.739$, $N_E = 1.745$ (589 nm). Microprobe analysis (decomposes in the microprobe beam) shows for florencite-(Ce) Ce > La, Nd with minor amounts of Pr, Gd, Sr, P, and trace amounts of Sm, S. In REE proxying for Sr, the several chemical varieties can be distinguished only by microprobe analysis. Arsenoflorencite-(Ce) is found in the sands examined from the *Kimba map-sheet area, Eyre Penin., SA, Australia*, associated with magnetite, tourmaline, garnet, sillimanite, ilmenite, apatite, zircon, spinel, and xenotime; also in sands at the NT/Q border with cassiterite, rutile, zircon, anatase, and monazite. May have inclusions and/or covering of quartz or alunite. *CS*

41.5.11.2 Arsenoflorencite-(Nd) $\text{NdAl}_3(\text{AsO}_4)_2(\text{OH})_6$

Identified and named for its relationship to arsenoflorencite and florencite arsenoflorencite group. Microprobe analysis: Nd dominant with minor amounts of Fe^{3+} , P, S, Ba, La, Ce, Pb, Pr, Ca, and Sm. *HCWS*

41.5.11.3 Arsenoflorencite-(La) $\text{LaAl}_3(\text{AsO}_4)_2(\text{OH})_6$

Identified and named for its relationship to arsenoflorencite and florencite. Arsenoflorencite group. Microprobe analysis: La dominant with minor amounts of Fe^{3+} , P, S, Ca, Sr, Ce, Nd. La-rich arsenoflorencite is found as cores of zoned crystals with florencite-(Ce), also as 30- μm irregular aggregates with arsenogoyazite, as outer zones of 5- to 10- μm grains with cores of crandallite, and with arsenoflorencite-(Nd) in the cements of a Cretaceous sandstone in drill cores from *Holicky, Stráz, and Osecná uraniumiferous deposits, northern Bohemia, Czech Republic*. Coprecipitation of the several chemical varieties of arsenoflorencite and florencite is usual. HCWS *CMG 36:103(1991)*, *AM 78:672(1993)*.

41.5.12.1 Waylandite $(\text{Bi,Ca})\text{Al}_3(\text{PO}_4,\text{SiO}_4)_2(\text{OH})_6$

Named in 1962 for Edward James Wayland, first director of the Uganda Geological Survey. Florencite group. *HEX-R R3m*. $a = 6.983$, $c = 16.175$, $Z = 3$, $D = 4.08$ *MM 50:730(1986)*. *39-367*: 5.67₈ 3.49₈ 2.94₁₀ 2.20₈ 2.17₁₀ 1.888₉ 1.743₈ 1.434₆. Massive, compact, powdery, fine-grained; grains show cyclic twinning. White, colorless, bluish; vitreous to dull luster; translucent. Uneven fracture. $G = 3.86$. Uniaxial (+); $N_0 = 1.748$, $N_E = 1.774$. Found as crystalline bands, veinlets, and crusts on a matrix of bismutite, or replacing bismutotantalite, at Restormel iron mine, Lostwithiel, and Wheal Coates, St. Agnes, Cornwall, England; at *Wampiro Hill, Busiro Co., Buganda, Uganda*; at Kobokobo pegmatite, Kivu, Kinshasa, Zaire. HCWS *AM 48:216(1963)*.

41.5.12.2 Eylettersite $(\text{Th,Pb}\square)_{1-x}\text{Al}_3(\text{PO}_4,\text{SiO}_4)_2(\text{OH})_6$

Named in 1972 for Mme Van Wambeke, the wife of the discoverer, L. Van Wambeke. Florencite group. *HEX-R R3m*. $a = 6.99$, $c = 16.70$, $Z = 3$, $D = 3.44$. *AM 56:1366(1971)*. *26-991*: 5.7₅ 3.51₆ 2.95₁₀ 2.85₂ 2.27₂ 2.19₄ 1.899₃ 1.748₂. Pulverulent nodules of creamy white, usually heavily altered. $G = 3.38$. Fluoresces brown-cream in LWUV, greenish yellow in SWUV. Radioactive, first thorium phosphate found in nature. DTA. $N_{av} = 1.635$, range depending on alteration level 1.61–1.66; nearly isotropic. Readily dissolved by H_2SO_4 . Analysis shows U, Ca, Ba, Zr, minor Sr, and Fe. Considerable cation deficiency (Th position), possibly balanced by substitution of H_4O_4 for SiO_4 . Altered specimens are found at *Kobokobo pegmatite, Kivu, Kinshasa, Zaire*, associated with feldspar, cryolite, columbite, apatite, candallite plumbogumite and phosphuranylite. HCWS *BM 95:98(1972)*, *AM 59:208(1974)*.

41.5.12.3 Zairite $\text{BiFe}_3^{3+}(\text{PO}_4)_2(\text{OH})_6$

Named in 1975 for the country of origin. The ferric iron analog of waylandite (41.5.12.1). Florencite group. *HEX-R R3m*. $a = 7.015$, $c = 16.365$, $Z = 3$, $D = 4.42$. *BM 98:351(1976)*. *29-226*: 5.71₁₀ 4.87₁ 3.50₄ 2.95₉ 2.85₁ 2.73₂ 2.16₁ 1.877₁. Small masses. Greenish, translucent. $H = 4$. Uniaxial (-); $N_{av} = 1.82$ –1.83; weakly to moderately birefringent. Found in the zone of weathering at *Eta-Etu, northern Kivu, Zaire*, where there are quartz veins

containing wolframite, mica, and other Bi-containing phosphates. *HCWS AM 62:194(1977)*.

41.5.13.1 Vesignieite $\text{BaCu}_3(\text{VO}_4)_2(\text{OH})_2$

Named in 1955 for Colonel Jean Paul Louis Vesignié (1870–1954), French mineral collector and president of the Mineralogical Society of France. Balydonite (41.5.14.1) is the Pb analog. *MON C2/c*. $a = 10.270$, $b = 5.911$, $c = 7.711$, $\beta = 116.42^\circ$, $Z = 2$, $D = 4.69$. *MM 56:67(1992)*. Structure: *AGS 64:302(1990)*. *31-136*: 3.36₃ 3.22₁₀ 2.95₄ 2.71₈ 2.56₆ 2.30₆ 1.614₄ 1.479₄. See also *12-519*. Lamellar aggregates, polysynthetically twinned, giving pseudo-hexagonal outline, up to 0.5 mm in diameter. Yellow-green to dark olive-green, vitreous luster, transparent. Cleavage {001}, good. $H = 3-4$. $G = 4.43$. Biaxial (-); $N_x = 2.053$, $N_y = 2.129$, $N_z = 2.133$. Analyses also showed minor Zn, Ni, Ag, As, Mo, Ca, Mg, K, Na, Fe^{3+} , Si, Al. Synthesized. Found as geodes in Mn ore at *Friedrichsroda, Thuringen, Germany*, with calcite and barite; at Perm, Ural Mts., Russia; at Agalik, Uzbekistan; at Shensi Prov., China. *HCWS AM 40:942(1955)*, *BM 79:219(1956)*.

41.5.14.1 Bayldonite $\text{Cu}_3\text{PbO}(\text{AsO}_3\text{OH})_2(\text{OH})_2$

Named in 1865 for John Bayldon of England. Vesignieite (41.5.13.1) the Ba, V analog. *MON A2/a*. $a = 14.083$, $b = 5.893$, $c = 10.152$, $\beta = 106.10^\circ$, $Z = 4$, $D = 5.82$. *MM 39:716(1974)*, *AC(B) 35:819(1979)*. *26-1410*: 4.52₆ 3.23₈ 3.15₁₀ 2.93₈ 2.72₆ 2.66₅ 2.48₃ 2.26₅. Minute mammillary concretions with fibrous structure, drusy surface; massive, fine-granular to powdery; crusts. Siskin-green to apple-green, yellow-green; resinous luster, subtranslucent. $H = 4\frac{1}{2}$. $G = 5.5$. IR, DTA. Biaxial (+); $X = b$, $Y \wedge$ elongation $\approx 25^\circ$; $N_x = 1.95$, $N_y = 1.97$, $N_z = 1.99$; $2V$ large; $r < v$. Soluble with difficulty in HCl. Found at *St. Day, Cornwall, England*, and at the Penberthy Creft uranium mine, Grampound Rd., St. Hilary; at several sites (i.e., Verriere, Ardilat, Rohe, Rebasse, Ceilhes) in the Herault Dept., France; at Dzeskazghan, Kazakhstan; at Tsumeb, Namibia. *HCWS DII:929, AM 66:148(1981)*.

41.5.15.1 Curetonite $\text{Ba}_4\text{Al}_3\text{Ti}(\text{PO}_4)_4(\text{O},\text{OH})_6$

Named in 1979 for Forrest Cureton, mineralogist, and Michael Cureton, of Tucson, AZ, who found the mineral. *MON P2₁/m*. $a = 6.957$, $b = 12.55$, $c = 5.22$, $\beta = 102.02^\circ$, $Z = 1$, $D = 4.31$. *MR 10:219(1979)*. *33-134*: 4.29₅ 3.29₈ 3.23₁₀ 2.99₆ 2.82₆ 2.25₆ 2.20₆ 1.686₇. Crystals up to 3 mm show {100}, {010}, {001}, {011}, {201}. Bright yellow-green to nickel-green, white streak, translucent. Polysynthetic twinning common on {100}. Cleavage {011}, good; parting on {010}. $H = 3\frac{1}{2}$. Biaxial (+); $X = b$, $Z \wedge c = 30^\circ$; $N_x = 1.676$, $N_y = 1.680$, $N_z = 1.693$; $2V = 60^\circ$; splotchy pleochroic in yellow; $X > Y = Z$; $r < v$, weak; strong inclined dispersion. Found in a barite mine at *Golconda, NV*, where barite replaces sericitic, phosphatic, and black organic cherts and shales. Massive barite is cut by veins of coarse-grained barite, euhedral adularia, and curetonite. *HCWS AM 65:206(1980)*.

41.5.16.1 Thadeuite $(\text{Ca}, \text{Mn}^{2+})(\text{Mg}, \text{Fe}^{2+}, \text{Mn}^{2+})_3(\text{PO}_4)_2(\text{OH}, \text{F})_2$

Named in 1979 for Decio Thadeu, Instituto Superior Técnico, Lisbon, Portugal, who described the geological setting. ORTH C222₁. $a = 6.412$, $b = 13.563$, $c = 8.545$, $Z = 4$, $D = 3.21$. AM 64:359(1979). Structure: AM 69:120(1982). 33-284: 3.61₂ 3.38₁₀ 3.00₃ 2.79₂ 2.63₂ 2.19₂ 1.879₁ 1.696₁. Massive, coarse-grained. Yellow-orange, white streak, vitreous luster, translucent. Cleavage {010}, good, plus another at 90°. $H = 4$. $G = 3.25$. Nonfluorescent, no cathodoluminescence. Biaxial (-); XYZ = cba; N_x calc = 1.568, $N_y = 1.597$, $N_z = 1.600$; $2V = 33^\circ$. Found intergrown with fluorapatite, danasqueiraite along the edges of hydrothermal tin-tungsten veins at *Panasqueira mine, Beira Baixa, Portugal*, associated with wolfeite, topaz, quartz, muscovite, sphalerite, chalcopyrite, pyrrhotite, siderite, arsenopyrite, chlorite, althausite, and vivianite. HCWS

41.5.17.1 Leningradite $\text{PbCu}_3(\text{VO}_4)_2\text{Cl}_2$

Named in 1990 for the city where many volcanic sublimates have been studied and described. ORTH *Ibam*. $a = 8.988$, $b = 11.083$, $c = 9.360$, $Z = 4$, $D = 4.97$. DANS 303:948(1990). PD: 5.55₅ 3.49₃ 3.42₁₀ 3.24₆ 2.76₉ 2.55₇ 2.36₇ 1.847₅. Rhombic tablets or flakes to 0.3 mm and globules up to 0.6 mm in diameter with radial or tangential orientation of crystals. Crystals show {010}, {101}, {100}, {001} with prism interfacial angle 87.9°. Red, orange-red streak, vitreous luster, transparent. Cleavage {010}, perfect; brittle. $H = 4\frac{1}{4}$. $G = 4.81$. Biaxial; XYZ = bac; N_x unknown (all grains are cleavage sections), $N_y = 2.29$, $N_z = 2.35$; $2V$ large; parallel or symmetric extinction; no dispersion; nonpleochroic. Found as a product of fumarolic activity at the *Great Tolbachik fissure eruption (1975-1976), Kamchatka, Russia*, associated with anglesite, hematite, lammerite, and tolbachite. HCWS AM 76:1434(1991).

41.5.18.1 Arctite $\text{Na}_2\text{Ca}_4(\text{PO}_4)_3\text{F}$

Named in 1981 for the arctic region, where it was found. HEX-R $R\bar{3}m$. $a = 7.078$, $c = 41.203$, $Z = 6$, $D = 3.11$. ZVMO 110:506(1981). Structure: SPD 29:5(1984). 33-1228: 13.8₂ 3.54₂ 3.43₃ 3.06₃ 2.80₃ 2.75₁₀ 2.72₂ 1.769₂. Colorless, vitreous luster. Cleavage {001}, perfect. $H \approx 5$. $G = 3.13$. Uniaxial (-); $N_0 = 1.578$, $N_E = 1.577$ (anomalously biaxial). Analyses also show Ba, K, Fe, Zr, S, Si. Insoluble in H₂O, soluble in 1:20 HCl. Found in a drill core from the valley of the *Vuonnemi R., Khibina alkaline massif, Kola Penin., Russia*, associated with rasvumite, villaumite, aegirine, and thenardite. HCWS AM 67:621(1982).

TRIPLITE-TRIPLOIDITE GROUP

The general formula for the triplite-triploidite group minerals is

where

and crystallize in the monoclinic system but appear pseudoisometric.

The structure [BM 104:677(1981)] is analogous to that of titanite, and similar to that of alluaudite (38.2.3.6) and wylieite (38.2.4.2). It is characterized by two types of chains, formed from distorted AO_6 octahedra which are connected into a three-dimensional framework by sharing vertices with TO_4 tetrahedra. One chain is parallel to b , while the chains of $[AO_4(OH)F]$ octahedra extend along the a axis.

The F/OH sites appear to have an average occupancy of 50% and could be disordered. However, OH/F ordering results in a doubling of the b unit cell axis and the different space group ($P2_1/c$) for triploidite compared with triplite ($I2/a$).

TRIPLITE: $Mn_2(PO_4)F$

A 'b' axis projection illustrates the two types of MnF_6 chains connected through PO_4 groups. One chain is parallel to 'b' the other along 'a' axis forms a tight framework,

TRIPLITE SUBGROUP

Mineral	Formula	Space Group	a				β	
			a	b	c	β		
Zweiselite	$\text{Fe}_2^{2+}(\text{PO}_4)\text{F}$	<i>I2/a</i>	12.046	6.446	9.888	107.42	41.6.1.1	
Triplite	$\text{Mn}_2^{2+}(\text{PO}_4)\text{F}$	<i>I2/a</i>	12.065	6.545	9.937	107.09	41.6.1.2	
Magniotriplite	$(\text{Mg}, \text{Fe}^{2+}, \text{Mn}^{2+})_2(\text{PO}_4)(\text{F}, \text{OH})$	<i>I2/a</i>	12.035	6.432	9.799	108.12	41.6.1.3	

TRIPLOIDITE SUBGROUP

Mineral	Formula	Space Group	a				β	
			a	b	c	β		
Wagnerite	$\text{Mg}_2(\text{PO}_4)\text{F}$	<i>P2₁/c</i>	11.945	12.717	9.70	108.18	41.6.2.1	
Wolfeite	$\text{Fe}_2^{2+}(\text{PO}_4)(\text{OH})$	<i>P2₁/a</i>	12.319	13.230	9.840	108.40	41.6.3.1	
Triploidite	$\text{Mn}_2^{2+}(\text{PO}_4)(\text{OH})$	<i>P2₁/a</i>	12.366	13.296	9.94	108.23	41.6.3.2	
Sarkinite	$\text{Mn}_2^{2+}(\text{AsO}_4)(\text{OH})$	<i>P2₁/a</i>	12.779	13.596	10.208	108.98	41.6.3.3	

Note: Three distinct cleavages are found in the triplite subgroup and reflect the chain-composed framework; triploidite subgroup minerals show acicular or fibrous morphology.

41.6.1.1 Zweiselite $\text{Fe}_2^{2+}(\text{PO}_4)\text{F}$

Named in 1841 for the locality. Triplite group and subgroup. The Fe end member of the Fe^{2+} -Mn series with triplite (41.6.1.2). See also the Mg end member magniotriplite (41.6.1.3). MON *I2/a*. $a = 12.046$, $b = 6.446$, $c = 9.888$, $\beta = 107.42^\circ$, $Z = 8$, $D = 4.00$. MM 31:587(1957). 30-654: 3.60₅ 3.38₄ 3.20₇ 3.03₉ 2.86₁₀ 2.59₃ 2.12₄ 1.986₄. See also 21-811. Dark brown. See triplite (41.6.1.2) for physical properties. Biaxial (+); $N_x = 1.680$, $N_y = 1.689$, $N_z = 1.702$; $2V_{\text{calc}} = 80^\circ$. Analyses also show Ca, Mn^{2+} , Mg, Ti. Light brown samples have higher Ca, lower indices of refraction. Found at Black Hills, SD; at Rabenstein, Zweisel, Bavaria, Germany; at Slavkov, Bohemia, and Cyrilov, western Moravia, Czech Republic. hcws DII:849.

41.6.1.2 Triplite $\text{Mn}_2^{2+}(\text{PO}_4)\text{F}$

Named in 1813 from the Greek for *threefold*, probably in allusion to the three cleavages. Triplite group and subgroup. Forms a Mn- Fe^{2+} series with zweiselite (41.6.1.1) and a Mn-Mg series with wagnerite (41.6.2.1) and magniotriplite (41.6.1.3). MON *I2/a*. $a = 12.065$, $b = 6.545$, $c = 9.937$, $\beta = 107.09^\circ$, $Z = 8$, $D = 3.61$. Structure: ZK 130:1(1969). 25-1080: 3.69₂ 3.48₂ 3.31₄ 3.05₁₀ 2.90₃ 2.88₅ 2.62₁ 2.05₆. Rough, undeveloped, massive crystals. Dark brown to chestnut-brown, reddish brown, to salmon-pink when the Mn content is high; becomes brown-black on alteration; white to brown streak; vitreous to resinous luster; subtranslucent to opaque. Cleavage {001}, good; {010}, fair; difficult to see in altered material; uneven to subconchoidal fracture. $H = 5-5\frac{1}{2}$. $G = 3.5-3.9$. Biaxial (+); $Y = b$; $Z \wedge c = -41^\circ$; $N_x = 1.643$, $N_y = 1.647$, $N_z = 1.668$; $2V = 25^\circ$ (Mica Lode, CO); $r > v$, moderate to strong; pleochroic in distinct shades of yellow-brown or reddish brown;

$X > Y, Z$. Indices decrease with increasing Mg, Ca. Soluble in acids. Fe^{2+} usually present as well as small amounts of Ca, Mg, and (OH) for F. Synthesized. A primary mineral in granite pegmatites which are phosphate-rich, associated with wolfeite, triphylite–lithiophilite, apatite, and tourmaline. Often weathers to vivianite, dufrenitellike minerals or manganese oxyhydroxides. Found in ME at Stoneham, Hebron, Mt. Apatite near Auburn; at Chatham, Branchville, and at Strickland quarry, Portland, CT; at Amelia, VA; at Elk Ridge mine, Custer Co., SD; near Aurum, Reagan district, White Pine Co., NV; at Mica Lode pegmatite, Royal Gorge, Fremont Co., and Dead Man's Gulch, Colorado Springs, El Paso Co., CO; in the Eureka district, Yavapai Co., AZ; at Pala, San Diego Co., CA. Found at Mangualda, Beira Prov., Portugal; at *Limoges near Chanteloube, Haute Vienne, France*; at Hagendorf, Kreuzberg, Pleystein, Germany; at Horrsjöberg in Värmland, Sweden, with lazulite, apatite, rutile, kyanite, and at Skruppetorp; in Moravia at Cyrillhof, Wien, Moravia, Czech Republic; in the Sn–W deposit of Tigrinoye, Sikjote Alin Range, Ural Mts., Russia; at Korgal, Laghman, Afghanistan; in the Karibib area, Namibia; in the Lomagundi district and elsewhere in Zimbabwe; at Sierra de Zapata, Catamarca Prov., Calamuchite Dept., Cordoba, Argentina. HCWS *DII:849, AM 36:256(1951), MM 31:587(1957)*.

41.6.1.3 Magniotriplite $(Mg, Fe^{2+}, Mn^{2+})_2(PO_4)(F, OH)$

Named in 1951 for its relationship chemically and crystallographically to triplite. Triplite group and subgroup. In the Mg–Mn series with triplite (41.6.1.2) and wagnerite (41.6.2.1). MON *I2/a*. $a = 12.035$, $b = 6.432$, $c = 9.799$, $\beta = 108.12^\circ$, $Z = 8$, $D = 3.68$. *BM 104:672(1981)*, Structure: *BM 104:677(1981)* (Mg \approx Fe). *F:OH=6:1 42-582: 3.59₅ 3.24₅ 3.16₇ 3.02₈ 2.86₁₀ 2.79₆ 2.73₂ 2.098₃*. See also *8-140*. Crystalline masses to 0.5 cm \times 8 cm. Reddish brown, vitreous luster. Cleavage {001}, uneven fracture. $H = 4$. $G = 3.59$. Biaxial (+); $N_x = 1.648$, $N_y = 1.653$, $N_z = 1.664$; $2V = 40^\circ$. Analyses also show minor Ca and Ti. Found at *Turkestan ridge, Kazakhstan*. HCWS *AM 37:359(1951)*.

41.6.2.1 Wagnerite $Mg_2(PO_4)F$

Named in 1821 for F. M. von Wagner (1768–1851), mining official, Munich, Germany. Triplite group and triploidite subgroup. See magniotriplite (41.6.1.3). MON *P2₁/c*. $a = 11.945$, $b = 12.717$, $c = 9.70$, $\beta = 108.18^\circ$, $Z = 16$, $D = 3.291$. *MM 56:227(1992)*. Structure: *ZK 177:15(1986)*. *42-1330: 3.29₆ 3.11₆ 2.97₁₀ 2.84₉ 2.75₃ 2.47₂ 1.557₂ 1.553₂*. Prismatic [001] with prism planes vertically striated or vicinally rounded, crystals sometimes large and coarse; rarely tabular; lenticular masses to 4 cm \times 8 cm. Yellow, grayish, flesh-red, greenish; vitreous to resinous luster, translucent to opaque in altered material. Cleavage {100}, {120}, imperfect; {001}, in traces; uneven or subconchoidal to splintery fracture. $H = 5-5\frac{1}{2}$. $G = 3.15$. Biaxial (+); $N_x = 1.585$, $N_y = 1.588$, $N_z = 1.601$; $2V = 51^\circ$; $r < v$, weak; pleochroic, colorless to pale

yellow. Soluble in acids. May contain Fe^{2+} and Ca in substitution for Mg. Synthesized. Found at Benson mine, west-central Adirondack highlands, NY, with isokite in magnetite-hematite deposits associated with sillimanite-garnet-pyroxene-rich paragneiss; at Quartzsite, AZ; at *Hollgraben, near Werfen, Salzburg, Austria*, associated with ferroan magnesite, lazulite, and chlorite; at Havredal, Porsgrund, Telemark, Norway; in lava of 1872 on Vesuvius, Italy. *HCWS DII:845; CM 10:919(1971), 12:346(1974)*.

41.6.3.1 Wolfeite $\text{Fe}_2^{2+}(\text{PO}_4)(\text{OH})$

Named in 1949 for Caleb Wroe Wolfe (1908–1980), crystallographer, Boston University, MA. Triplite group and triploidite subgroup. The Fe end member in the Fe^{2+} -Mn series with triploidite (41.6.3.2). *MON P2₁/a*. $a = 12.319$, $b = 13.230$, $c = 9.840$, $\beta = 108.40^\circ$, $Z = 16$, $D = 3.66$. *JPD 4:34(1989)*, *AM 34:692(1949)*. *41-1411*: 3.65₃ 3.38₂ 3.19₈ 3.10₁₀ 2.93₇ 2.88₃ 2.82₆ 2.57₅. See also 5-612. Massive, granular, or fibrous aggregates, elongated on [001] to 2.5 cm, showing {120}, {100}. Red-brown to clove-brown, rarely green; nearly white streak, vitreous to silky luster (fibers); transparent to translucent. Cleavage {100}, good; {010}, fair; {120}, {110}, poor; uneven fracture. $H = 4\frac{1}{2}$ -5. $G = 3.83$ (est.). Biaxial (+); $X = b$; $N_x = 1.741$, $N_y = 1.742$, $N_z = 1.746$ (Palermo); 2V moderate; faintly pleochroic; $Z > X, Y$; $r > v$, strong; marked dispersion of bisectrices. Soluble in acids. Minor amounts of Mn and Ca usually present, also Na, Li, and Zn. Reports of Fe^{3+} indicate oxidation of Fe^{2+} and mineral alteration. Found at *Palermo mine, North Groton, NH*, as the alteration product of triphylite; at Ross lode, Custer Co., SD; with triplite at Skumpetorp, Sweden; at Hagendorf-Süd, Bavaria, Germany; at Cyrillhof, Moravia, Czech Republic; at Lavra do Enio, Galileia, MG, Brazil. *HCWS DII:853*.

41.6.3.2 Triploidite $\text{Mn}_2^{2+}(\text{PO}_4)(\text{OH})$

Named in 1878 from the Greek for *form* and its resemblance to triplite in physical characters and composition. Triplite group and triplite subgroup. The Mn end member of a Mn-Fe series with wolfeite, and the OH end member of the OH-F series with triplite. *MON P2₁/a*. $a = 12.366$, $b = 13.296$, $c = 9.94$, $\beta = 108.23^\circ$, $Z = 16$, $D = 3.80$. *AM 34:692(1949)*, Structure: *ZK 131:1(1970)*. *26-1240*: 3.41₅ 3.19₈ 3.10₉ 2.94₁₀ 2.58₅ 2.31₅ 2.15₅ 1.80₆. See also 26-1239(calc). Habit and physical properties similar to Fe^{2+} end member wolfeite. Pinkish, wine-yellow to yellow-brown for material high in Mn, specific gravity, and indices of refraction lower for Mn end members. $G = 3.66$ (est.). Biaxial (+); $X = b$; $Z \wedge c = -4^\circ$; $N_x = 1.725$, $N_y = 1.723$, $N_z = 1.730$ (Branchville, CT, Mn/Fe = 3.3:1); 2V moderate; $r \gg v$. Both triploidite and wolfeite occur in granite pegmatites associated with triplite, lithiophilite, and triphilitite. Found at *Branchville, Fairfield Co., CT*, associated with eosphorite, dickinsonite, and rhodochrosite in lithiophylite; at Ross lode, SD; as an alteration of triplite at Wien, Moravia, Czech Republic. *HCWS DII:853*.

41.6.3.3 Sarkinite $Mn_2^{2+}(AsO_4)(OH)$

Named in 1885 from the Greek for *made of flesh*, in allusion to the blood-red color. Triplite group and triploidite subgroup. The As analog of triploidite (41.6.3.2). *MON P2₁/a*. $a = 12.779$, $b = 13.596$, $c = 10.208$, $\beta = 108.98^\circ$, $Z = 16$, $D = 4.20$. *MM 43:681(1969)*. *14-214*: 6.0₃ 3.48₈ 3.29₉ 3.18₁₀ 3.04₁₀ 2.90₇ 2.65₆ 2.37₃. Crystals usually thick tabular {100}, elongate [010]; short prismatic [010] or shortened on b , tabular on {100}, {001}, often uneven with {001} striated [100]; rudely spherical or granular. Flesh-red to dark blood-red, rose-red, reddish yellow to yellow; rose-red to yellow streak; greasy luster. Cleavage {100}, distinct; subconchoidal to uneven fracture. $H = 4-5$. $G \approx 4.10$. Biaxial (-); $X \wedge c = -54^\circ$; $Y = b$; $N_x = 1.793$, $N_y = 1.807$, $N_z = 1.809$; $2V = 83^\circ$; weakly pleochroic; $X > Z > Y$; no dispersion. Easily soluble in dilute acids. Very little P or Sb substitution for As, some Ca, Mg, and Fe^{2+} usually present on analysis. Found in NJ at Franklin, Sussex Co., and at Sterling Hill mine, Ogdensburg; at *Hartigen mine*(!), *Pajsberg, Sweden*, associated with native lead, bementite, brandtite, calcite, and barite; at the Sjö mine, Grythytte parish, Örebro, with magnetite, jacobsonite, and tephroite; at Langban with hausmannite and hedyphane. *HCWS DII:855, AMG 4:499(1968)*.

41.6.4.1 Satterlyite $Fe_2^{2+}(PO_4)(OH)$

Named in 1978 for Jack Satterly (b.1906), geologist at Ontario Department of Mines, Canada. Dimorph of wolfeite, 41.6.3.1, see also holtedahlite 41.6.4.2. *HEX-R P3m, P31m, P312*. $a = 11.361$, $c = 5.041$. $Z = 6$, $D = 3.60$. *CM 16:411(1978)*. *35-622* 4.49₄ 3.77₁ 3.52₅ 2.99₃ 2.84₆ 2.47₁₀ 1.885₄ 1.640₃. Grains up to $1 \times 1 \times 40$ mm elongated parallel to [0001], in radiating aggregates or nodules up to 10 cm diameter. Pale yellow to pale brown, streak pale yellow, vitreous. No cleavage. $H = 4\frac{1}{2}-5$. $G = 3.68$. Non-fluorescent. Uniaxial (-); $N_O = 1.721$, $N_E = 1.719$ dichroic when thick O=pale yellow, E=brownish-yellow, absorption $E > O$. Some Fe^{3+} detected on analysis, as are Na, Mg, Mn, trace of Si. Found in the shales along the *Big Fish R., NE YT, Canada* associated with quartz, pyrite, wolfeite, maricite *AM 64:657(1979)*.

41.6.4.2 Holtedahlite $Mg_2PO_4(OH)$

Named in 1979 for Olaf Holtedahl (1885-1975), geologist, University of Oslo, Norway. Dimorph of althausite (41.6.5.1). *HEX-R P321, P3m1, or P3m1*. $a = 11.186$, $c = 4.977$, $Z = 6$, $D = 2.936$. *LIT 12:283(1979)*. Structure: *MP 40:91(1989)*. *33-879*: 3.72₉ 3.48₅ 3.23₃ 2.95₂ 2.80₃ 2.44₁₀ 2.18₃ 1.859₃. Patches up to 0.5 cm \times 1 cm. Colorless, vitreous luster. No cleavage, uneven fracture. $H = 4\frac{1}{2}-5$. $G = 2.94$. Uniaxial (-); $N_O = 1.599$, $N_E = 1.597$. Analyses also show CO_2 , minor Na, Mn, and F. Occurs in serpentine-magnesite deposits of Tingelstadtjen at *Modum, Norway*, associated with apatite, althausite, serpentine, and talc, cut by veins of szaibelyite. *CS AM 65:809(1979)*.

41.6.5.1 Althausite $Mg_2(PO_4)(OH,O,F)$

Named in 1975 for Egon Althaus (b.1933), mineralogist, Karlsruhe University, Germany. ORTH *Pnma*. $a = 9.258$, $b = 6.054$, $c = 14.383$, $Z = 8$, $D = 2.91$. *LIT* 8:215(1975). Structure: *AM* 65:488(1980). 29-869: 3.59₁₀ 3.42₄ 3.32₉ 3.02₈ 2.89₄ 2.79₆ 2.70₃ 2.64₆. Crystals elongated on *c*, flattened on *b* show {010}, {110}, {131}. Light gray, translucent. Cleavage {001}, perfect; {101}, distinct. $H = 3\frac{1}{2}$ in *c* direction, 4 in *a*. $G = 2.97$. IR, TGA. Synthesis studies suggest complete series to the F end member. Biaxial (+); XYZ = *cba*; $N_x = 1.588$, $N_y = 1.592$, $N_z = 1.598$; $2V = 70^\circ$. Found in the serpentine-magnesite deposits of *Tingelstadtjen*, at *Modum*, Norway, and at *Overtjern* associated with apatite, talc, magnesite, and enstatite. HCWS *AM* 61:502(1976).

41.6.6.1 Olivenite $Cu_2(AsO_4)(OH)$

Named in 1824 in allusion to the color. ORTH *Pnmm*. $a = 8.615$, $b = 8.240$, $c = 5.953$, $Z = 4$, $D = 4.45$. Structure: *AC(B)* 34:715(1978), 33:2628(1977). 42-1353: 5.94₆ 4.89₈ 4.82₆ 4.20₆ 2.98₁₀ 2.66₆ 2.46₅ 2.41₄. See also 41-1354. Variable habit: elongated [100], short prismatic to acicular [001], tabular on {011}, {100}, {001}; globular, reniform with fibrous structure, fibers straight and divergent, rarely irregular, curved lamellar; massive, granular to earthy. Shades of olive-green, brownish green, straw-yellow, or grayish white; olive-green to brown streak; adamantine luster; translucent to opaque. Cleavage {011}, {110}, indistinct; conchoidal to irregular fracture. $H = 3$. $G = 3.9-4.5$. Biaxial (+) [or (-)]; $N_x = 1.772$, $N_y = 1.810$, $N_z = 1.863$ (Tintic); $2V \approx 90^\circ$; (+): $r < v$, strong; (-): $r > v$, strong. Soluble in acids and ammonia. Zn and Pb substitute for Cu. There is probably a complete solid-solution series (AsO_4-PO_4) to libethenite (41.6.6.2). A secondary mineral found in the oxidized zone of many ore deposits. Occurs in the Blackbird district, Lemhi Co., ID; in the Tintic district at American Eagle, Mammoth mines, UT, associated with clinoclase, tyrolite, and conichalcite; at New Cornelia mine, Ajo, 79 mine, Gila Co., Grand Reef mine, Graham Co., Tiger mine, Mammoth-St. Anthony, AZ; at Majuba Hill, Pershing Co., NV, with cornetite; at Yaquino Head, Newport, OR; at *Cartharrack mine*, *Gwennap*, Cornwall, and many other mines as crystals or fibrous aggregates, also at Alston Moor, Cumberland, and Tavistock, Devonshire, England; Grube Clara, Rankachtal, Germany; at Kamarezu mine, Attica, Greece; at Tsumeb, Namibia, where Zn and Fe varieties were described; at Callington, Preamimma mine, SA, and Balilo Cu mine, Ashburton Downs, WA, Australia; at Chuquicamata, Antofagasta, Chile. HCWS *DII*:859, *AM* 36:484(1951).

41.6.6.2 Libethenite $Cu_2(PO_4)(OH)$

Named in 1823 for the locality. ORTH *Pnmm*. $a = 8.062$, $b = 8.384$, $c = 5.881$, $Z = 4$, $D = 3.972$. *NJMA* 134:147(1979). Structure: *CM* 16:153(1978). 36-404: 5.81₈ 4.82₁₀ 4.76₇ 3.72₅ 2.91₈ 2.64₄ 2.63₆ 2.41₃. Short prismatic [001], slightly elongated [100], equant; crystals usually have composite structure. {110} vertically grooved or striated, {011} striated parallel to edge with

{111}. Light to dark olive-green, deep green to black-green; vitreous luster on crystal faces, greasy on fracture surfaces; translucent. Cleavage {100}, {010}, indistinct; conchoidal, uneven fracture. $H = 4$. $G = 3.97$. Biaxial (-); $N_x = 1.701$, $N_y = 1.743$, $N_z = 1.787$ (Libethen); $2V \approx 90^\circ$; $r > v$, strong; faintly pleochroic. X, pale yellowish blue; Z, pale greenish blue. Easily soluble in acids and ammonia. Synthesized. Secondary mineral in oxidized zone of Cu ore deposits with malachite, azurite, and pyromorphite. Found at Perkiomen mine, Montgomery Co., PA; at Yerrington, Lyon Co., NV; in AZ at the Clifton-Morenci district, Greenlee Co., and Silver Hill mine, Copper Creek, Pima Co., Silver Bell mine, Ray mine, Pinal Co.; at Wheal Phoenix, Cornwall, England; at Montebrias, Plateau Centrale, France; at *Libethen, near Neusohl, Stredoslovensky Kraj, Czech Republic*; at Nizhne Taglisk and Wissokaya Gora, Ural Mts., Russia; at Broken Hill mine, Rokana mine, Kabua, Zambia; at West Bogen mine, Tottenham, NSW, Australia; at Chuiquicamata, and the Mercedes mine, Coquimbo, Chile. *HCWS DII:862, BM 79:219(1956)*.

41.6.6.3 Adamite $Zn_2(AsO_4)(OH)$

Named in 1866 for Gilbert Joseph Adam (1795–1881), French mineralogist, who supplied the first specimens. *ORTH Pnm. a = 8.306, b = 8.524, c = 6.043, Z = 4, D = 4.45. AC(B) 34:715(1979)*. Structure: *AM 61:979(1976)*. 39-1354: 4.89₇ 4.25₄ 2.98₁₀ 2.70₇ 2.47₇ 2.46₆ 2.45₆ 2.42₇. See also 6-536. Radiating crusts, fan-shaped rosettes, crystals elongated parallel to [010] to 0.8 mm, showing {101}, {120}, {110}, {210}, {010}; [010] striated parallel to [101]. Light to honey- and brownish yellow, pale green, rarely colorless, white; Cu-rich bright green; Co-rich violet to rose; vitreous luster; transparent to translucent. Cleavage {101}, good; {010}, poor; brittle. $H = 3\frac{1}{2}$. $G = 4.43$. May fluoresce yellow-green. Biaxial (+); $XYZ = acb$; $N_x = 1.722$, $N_y = 1.742$, $N_z = 1.763$ (Mapimi); $2V = 88^\circ$; $r < v$, strong. Indices and color vary widely with substitutions of Cu and Co for Zn. Easily soluble in 1:10 acids. Synthesized. Secondary mineral in oxidized portions of Zn- and As-rich primary deposits. Found at Franklin, Sussex Co., NJ; at Grandview mine, AZ; at western Utah mine, Gold Hill, Clarke Mts., Tooele Co., UT; at Zinc mine, Mohawk, CA; at Ojuela mine(!), Mapimi, DUR, Mexico, associated with scorodite, mimetite, hemimorphite, calcite and "limonite"; at Cap Garonne, near Hyeres, Var, France, where cobaltian and cuproan varieties form crusts in sandstones; at Reichenbach near Lahr, Black Forest, Germany; at Mt. Valerio near Campiglia Marittima, Tuscany, Italy; at the Kamareza mine, Attica, and at Larium, Greece, filling drusy cavities in cellular smithsonite; on the Island of Thasis, Turkey; at Tsumeb(!), Namibia; at *Chanarcillo, Chile*. *HCWS DII:864*.

41.6.6.4 Eveite $Mn_2(AsO_4)(OH)$

Named in 1967 for its structural and morphological similarities to adamite. Dimorph of sarkinite (41.6.3.3). *ORTH Pnm. a = 8.57, b = 8.77, c = 6.27, Z = 4, D = 3.73. AMG 4:473(1968)*. Structure: *AM 53:1841(1968)*. 22-1166:

6.10₇ 5.09₈ 4.39₁₀ 3.14₄ 3.06₉ 2.80₅ 2.55₄ 2.53₆. Tabular, sheaflike crystals, crusts. Apple-green, white streak, translucent. Cleavage {101}, fair. $H = 4$. $G = 3.76$. Biaxial (+); $N_x = 1.700$, $N_y = 1.715$, $N_z = 1.732$; $2V = 65^\circ$; $r > v$, medium. Soluble in cold 1:1 HCl. The low-pressure form of $Mn_2(AsO_4)(OH)$. A secondary mineral found encrusting cavities and fractures in deposits containing Fe–Mn oxides and carbonates; associated minerals hausmannite, dolomite, and calcite. Found at Buckwheat open pit, Franklin, Sussex Co., NJ; at *Langban, Varmland, Sweden*. HCWS AM 55:319(1970).

41.6.7.1 Tarbuttite $Zn_2(PO_4)(OH)$

Named in 1907 for Percy Coventry Tarbutt, director of the Broken Hill Exploration Co., Zambia, who collected the first specimens. TRIC P1. $a = 5.552$, $b = 5.700$, $c = 6.471$, $\alpha = 102.7^\circ$, $\beta = 102.8^\circ$, $\gamma = 86.9^\circ$, $Z = 2$, $D = 4.11$. MM 39:684(1974). Structure: DANS 282:314(1985). 36-410: 6.17₁₀ 3.70₂ 3.09₁ 2.98₁ 2.97₁ 2.88₂ 2.78₃ 2.06₃. Equant to short prismatic [001] crystals, rounded, deeply striated; sheaflike or compact aggregates up to 5 mm; crusts. Pale shades of yellow, brown, red, green, colorless; white streak; vitreous luster, pearly on cleavage; translucent. $H = 3\frac{1}{2}$ –4. $G = 4.12$. Biaxial (-); $N_x = 1.660$, $N_y = 1.705$, $N_z = 1.713$; $2V = 50^\circ$; strong dispersion of bisectrices. Found at *Kabwe, Broken Hill mines, northwestern Zambia*, with pyromorphite, hopeite, descloizite, vanadinite, hemimorphite, cerussite, smithsonite, and "limonite"; at Reaphook Hill, SA, Australia. HCWS DII:869, ZK 123:321(1966).

41.6.7.2 Paradamite $Zn_2(AsO_4)(OH)$

Named in 1956 as the dimorph to adamite; the P analog of tarbuttite (41.6.7.1). TRIC P1. $a = 5.638$, $b = 5.827$, $c = 6.692$, $\alpha = 103.25^\circ$, $\beta = 104.37^\circ$, $\gamma = 87.92^\circ$, $Z = 2$, $D = 4.595$. SCI 123:1039(1956). Structure: AC(B) 35:720(1979). 33-1469: 6.32₇ 5.46₅ 3.70₁₀ 2.99₁₀ 2.84₁₀ 2.57₅ 2.51₅ 2.48₇. See also 12-223. Sheaflike aggregates, round striated equant crystals up to 5 mm. Pale yellow, vitreous luster, transparent. Cleavage {010}, perfect. $G = 4.55$. Biaxial (-); $N_x = 1.726$, $N_y = 1.771$, $N_z = 1.780$; $2V = 50^\circ$. Found with legrandite, plattnerite, and murchisonite at *Mapimi, DGO, Mexico*. HCWS AM 41:958(1957), 65:353(1980).

41.6.8.1 Augelite $Al_2(PO_4)(OH)_3$

Named in 1868 from the Greek for *luster*. MON C2/m. $a = 13.124$, $b = 7.988$, $c = 5.088$, $\beta = 112.25^\circ$, $Z = 4$, $D = 2.702$. SMPM 41:407(1961). Structure: AM 53:1096(1968). Al occurs in two different octahedral sites: $Al(OH)_6$ linked through sharing OH edges, and AlO_6 that link to PO_4 through sharing of corner O atoms. 34-151: 4.71₃ 4.17₃ 4.01₃ 3.52₆ 3.49₃ 3.34₁₀ 3.16₁ 2.49₁. Thick tabular {001}; prismatic to acicular [001]; thin triangular plates flattened {110}; massive. Dominant forms: {110} striated [001], {001}, {210}. Colorless to white, yellowish, pale rose; white streak; vitreous luster, pearly on {110} cleavage; transparent. Cleavage {110}, perfect; {210}, good; {001},

{101}, imperfect; uneven fracture; brittle. $H = 4\frac{1}{2}$ –5. $G = 2.696$. Biaxial (+); $N_x = 1.574$, $N_y = 1.576$, $N_z = 1.588$; $2V = 50.9^\circ$; no dispersion. Slowly soluble in hot 10 M HCl. Found at the pegmatites in Newry, ME; G.E. Smith mine, Newport, Palermo No. 1 mine, North Groton, NH; Hugo pegmatite, Keystone, SD; at Champion mine, White Mts., Mono Co., CA; at Big Fish R., YT, Canada; at *Westand iron mine, Näsrum, Kristianstad, Sweden*; from a quartz vein at Chernaya Mt. and at Starubba Mt., polar Ural Mts., Russia; at Buranga pegmatite, Rwanda; at Mbale, Uganda, with amblygonite; at Socavon mine, Oruro, with arsenopyrite, stannite, pyrite, and quartz, and at Tatasi and Portugalete, Potosi Prov., Bolivia. *HCWS DII:871*.

41.6.9.1 Arsenobismite $\text{Bi}_2(\text{AsO}_4)(\text{OH})_3$

Named in 1916 for the composition. An inadequately described mineral. ORTH 7-358: 6.06₉ 3.72₆ 3.11₁₀ 3.00₆ 2.86₅ 2.28₆ 1.997₇ 1.843₈. Cryptocrystalline aggregates, pulverulent, friable, ocherous masses. Yellowish green, yellowish brown. $H \approx 3$. $G \approx 5.7$. $N > 2.04$. Found in the oxidized ore at the 200-m level in *Mammoth mine, Tintic district, UT*; with pucherite at Schneeberg, Saxony, Germany; with bindheimite and bismutite at Tazna, Bolivia. *HCWS DII:907, AM 28:536(1943)*.

41.6.10.1 Angelellite $\text{Fe}_4^{3+}(\text{AsO}_4)_2\text{O}_3$

Named in 1959 for Victorio Angelelli (b.1908), mining geologist and director of the Geological Survey of Argentina. TRIC P1. $a = 6.461$, $b = 6.594$, $c = 5.036$, $\alpha = 106.21^\circ$, $\beta = 98.35^\circ$, $\gamma = 108.82^\circ$, $Z = 1$, $D = 4.762$. *NJMM:152(1959)*, Structure: *NJMM 132:91(1978)*. 13-121: 5.29₃ 3.15₁₀ 3.00₇ 2.96₄ 2.955₄ 2.86₅ 2.49₅ 2.07₅. Globular aggregates and crystals usually tabular with {001} dominant, other forms present {100} {021}, {101}, {031}, {111}, {101}. Blackish brown, red-brown streak, adamantine to submetallic luster, translucent. Cleavage {001}, good; conchoidal fracture; brittle. $H = 5\frac{1}{2}$. $G = 4.95$. Biaxial (+); $N_x = 2.13$, $N_y = 2.2$, $N_z = 2.40$; $Z > X$; strongly pleochroic, blood-red to red-brown; strongly anisotropic in reflected light. Some Sb on analysis. Found intergrown with hematite at *Cerro Pululul tin mine, Jujuy, Argentina*, possibly precipitated from fumarolic vapors. *HCWS AM 44:1322(1959)*.

41.6.11.1 Spodiosite $\text{Ca}_2(\text{PO}_4)\text{F}$

Named in 1872 from the Greek for *ash gray*, in allusion to the color. Inadequately described mineral. ORTH. Crystals flattened {010}, elongated [001]. Ash gray to brown, white streak, dull porcelainlike luster, vitreous. Cleavage. {010}, distinct; [001], indistinct. Biaxial (+); $N_x = 1.663$, $N_y = 1.674$, $N_z = 1.699$; $2V_{\text{calc}} = 69^\circ$; $r > v$, strong. Soluble in acids. Found at the *Nyttsta Kran mine, Filipstad, Varmland, Sweden*, and at Nordmark with serpentine, chondrodite, magnetite, and calcite. *HCWS DII:848*.

41.7.1.1 Palermoite $(\text{Sr,Ca})(\text{Li,Na})_2\text{Al}_4(\text{PO}_4)_4(\text{OH})_4$

Named in 1952 for the locality. ORTH *Imcb*. $a = 11.556$, $b = 15.84$, $c = 7.315$, $Z = 4$, $D = 3.26$. Structure: *AM 60:460(1975)*. Octahedral AlO_6 dimers form chains parallel to the a axis and connect into slabs through tetrahedral PO_4 to form the group $[\text{Al}_4^{8+}(\text{OH})_4(\text{PO}_4)_4]$ parallel to $\{010\}$. The other cations occupy openings in the structure: Li in fourfold and Sr in eightfold coordination. *18-950: 4.36₆ 3.32₅ 3.13₆ 3.09₁₀ 2.91₅ 2.60₅ 2.44₅ 1.659₅*. Fibrous aggregates; occasional small crystals show $\{001\}$, $\{010\}$, $\{011\}$, $\{130\}$, $\{110\}$, vertically striated prisms. Colorless to white; white streak; vitreous, subadamantine luster. Fibrous to subconchoidal fracture, brittle. $H = 5$. $G = 3.22$. Fluoresces white in X-ray beam. Biaxial (-); $XYZ = cab$; $c = \text{elongation}$; $N_x = 1.627$, $N_y = 1.642$, $N_z = 1.644$; $2V \approx 20^\circ$; $r < v$, moderate. Found as small crystals in cavities at the *Palermo No. 1 mine, North Groton, NH*. HCWS *AM 38:354(1953)*, *50:777(1965)*.

41.7.1.2 Bertossaite $\text{Li}_2\text{CaAl}_4(\text{PO}_4)_4(\text{OH})_4$

Named in 1966 for Antonio Bertossa, director of the Geological Survey of Rwanda. The Ca analog of palermoite (41.7.1.1). ORTH *Imaa* or *Iaa2*. $a = 11.48$, $b = 15.73$, $c = 7.23$, $Z = 4$, $D = 3.11$. *CM 8:668(1966)*. *41-1450: 4.63₆ 3.30₆ 3.10₈ 3.06₁₀ 2.88₆ 2.58₄ 2.41₆ 1.592₃*. Light pink; vitreous, glassy luster. Cleavage $\{100\}$, good; uneven to subconchoidal fracture. $H = 6$. $G = 3.10$. Biaxial (-); $X = a$, $Y = c$; $N_x = 1.624$, $N_y = 1.636$, $N_z = 1.642$; $2V_{\text{calc}} = 53^\circ$; $r < v$, moderate. Dissolves slowly in HNO_3 . Found at the *Buranga lithium pegmatite, Gatumba, Rwanda*. HCWS

41.7.2.1 Arrojadite $\text{KNa}_4\text{CaFe}_{14}^{2+}\text{Al}(\text{PO}_4)_{12}(\text{OH},\text{F})_2$

Named in 1925 for Miguel Arrojado Ribeiro Lisbõa (1872–1932), Brazilian geologist. The Fe^{2+} end member in the $\text{Fe}^{2+}\text{--Mn}^{2+}$ series with dickinsonite (41.7.2.2). MON *C2/m*. $a = 24.730$, $b = 10.057$, $c = 16.526$, $\beta = 105.78^\circ$, $Z = 4$, $D = 3.538$. Structure: A complex structure of multiple cation coordination polyhedra, some partially occupied or disordered and containing Na, Ca, K with six distinct PO_4 group sites. *AM 66:1034(1981)*. *34-149: 5.93₂ 5.55₂ 5.03₂ 3.22₅ 3.04₁₀ 2.77₃ 2.71₉ 2.55₃*. Large cleavable masses. Dark green, vitreous luster, translucent. Cleavage $\{001\}$, good; $\{201\}$, poor; uneven to subconchoidal fracture. $H = 5$. $G = 3.55$. DTA. Biaxial (-); $X = b$; $Y \wedge c = 21.5^\circ$; $N_x = 1.664$, $N_y = 1.670$, $N_z = 1.675$; $2V = 80^\circ$; $r < v$; pleochroic. X, colorless; Y, pale green; Z, pale yellow-green. The most chemically complex of primary pegmatitic phosphates, K, Ca, and Ba, may substitute for Na, although there may also be vacancies and disorder at these sites; Mn^{2+} , Mg, Al for Fe^{2+} , some Fe^{3+} , and H_2O are usually reported. Found in high-temperature ($\approx 800^\circ$) granitic pegmatites at Palermo No. 1 and No. 2 mines, Nancy No. 2, Rice mine, NH; at Victory pegmatite, Custer Co., and as large masses in the pegmatite at *Nickel Plate mine, Keystone district, Pennington Co., SD*, associated with graftonite, cassiterite, spodumene, beryl, and muscovite; at Hess

R., YT, Canada; at Serra Branca, Picui, Paraiba, Brazil. *HCWS DII:679, AM 35:59(1950), MM 43:227(1979)*.

41.7.2.2 Dickinsonite $\text{KNa}_4\text{AlMn}_{14}^{2+}(\text{PO}_4)_{12}(\text{OH}, \text{F})_2$

Named in 1878 for William Dickinson of Redding, CT, who collected the rare minerals in this locality. The Mn end member of the Mn^{2+} - Fe^{2+} series with arrojadite (41.7.2.1). *MON C2/m*. $a = 24.940$, $b = 10.131$, $c = 16.722$, $\beta = 105.60^\circ$, $Z = 4$, $D = 3.426$. Structure: *AM 66:1034(1981)*. *PD: 7.732, 5.983, 5.582, 5.063, 3.433, 3.235, 3.0610, 2.727*. Tabular {001}, often pseudorhombohedral with triangular striations on {001}; micaceous; curved lamellar, radiated stellate, disseminated scales. Olive-green, grass-green, yellowish to brownish green; nearly white streak; transparent to translucent. Cleavage {001}, perfect, micaceous; uneven fracture; very brittle. $H = 3\frac{1}{2}$ -4. $G = 3.41$. DTA shows inversion to alluaudite $\approx 500^\circ$. Biaxial (+); $X = b$; $Y \wedge c = 15^\circ$; $N_x = 1.658$, $N_y = 1.662$, $N_z = 1.671$ (Branchville); 2V moderate; $r > v$, strong; pleochroic. X, pale olive-green; Y, paler olive-green; Z, very pale yellowish green. Soluble in acids. Substitutions, especially Fe^{2+} for Mn^{2+} , common. Found at Nevel tourmaline mine, Newry, and Berry mine, Poland, ME; at Branchville, Fairfield Co., CT, associated with eosphorite, triploidite, lithiophilite, rhodochrosite, reddingite, and fairfieldite. *HCWS DII:717, AM 50:1647(1965)*.

APATITE GROUP

The apatite minerals conform to the general formula

where

A = Ca, Sr, Pb, Ba

T = P, As, or V in the traditional designation, but also Si, S, and possibly CO_3

Z = OH, F, Cl, and possibly CO_3

and crystallize with hexagonal or pseudohexagonal monoclinic symmetry.

The apatite minerals are very common, and the structure, known since 1930 [*ZK(A) 75:323(1930), 75:387(1930); AM 74:870(1989), 76:1857(1991)*], accommodates an extraordinarily wide range of both cations and anions. In fact, half the elements in the periodic table have been shown to occur in the apatites.

The dominant characteristic of the structure is the hexagonal disposition of tetrahedral groups (AsO_4 , VO_4 , or PO_4) that create the 6_3 screw axis, and the channels parallel to the unique c -axis direction in the crystals where the Z atoms are located.

There are two distinct cation sites, one connected to the tetrahedral backbone oxygens and the channels and the other related to a trigonal axis in the center of the cell. The ratio of cations in these two sites is A_3/A_2 , or more appropriately for the unit cell contents and $P6_3/m$ space group, A_6/A_4 . The cation sites can be ordered or disordered; that is, a single element can fill both sites, or both sites can be randomly occupied by a variety of cationic species, or be partially occupied, or vacant. The variations of possible coordination number and size of the two sites means that not only Ca, but many other elements, such as Pb^{2+} , Na, REE, U, and Th, may be accommodated by a general expansion of the unit cell. The distribution and occupancy of specific elements in the two distinct cation sites allows classification of the apatites into a number of subgroups.

FLUORAPATITE: $Ca_5(PO_4)_3(OH)_3$

This c axis projection shows the 6_3 screw axis of fluorapatite and the channels parallel to the unique ' c ' direction where the F atoms are located. There are two distinct cation sites, one connected to five oxygens from (PO_4) groups and the F in the channels, the other in octahedral coordination with tetrahedral backbone oxygens away from the channels (at the center of the unit cell). The variety displayed by group members show that the cation sites can be ordered or disordered, that, a single element can fill both sites, or both sites can be randomly occupied with a variety of cations, be partially occupied or vacant.

APATITE GROUP: CALCIUM PHOSPHATE SUBGROUP

Mineral	Formula	Space Group	a	c	
Fluorapatite	$\text{Ca}_5(\text{PO}_4)_3\text{F}$	$P6_3/m$	9.367	6.884	41.8.1.1
Chlorapatite	$\text{Ca}_5(\text{PO}_4)_3\text{Cl}$	$P6_3/m$	9.598	6.776	41.8.1.2
Hydroxylapatite	$\text{Ca}_5(\text{PO}_4)_3(\text{OH})$	$P6_3/m$	9.418	6.875	41.8.1.3
Carbonate-fluorapatite	$\text{Ca}_5(\text{PO}_4, \text{CO}_3)_3\text{F}$	$P6_3/m$	9.343	6.887	41.8.1.4
Carbonate-Hydroxylapatite*	$\text{Ca}_5(\text{PO}_4, \text{CO}_3)_3(\text{OH})$	$P6_3/m$	9.309	6.927	41.8.1.5

Note: *Synthetic.

The calcium phosphate apatites have Ca atoms in a trigonal array with each Ca in sixfold coordination: with five oxygens from PO_4 groups and one with the F, OH, or Cl located in the channels. Ca is also the cation in the nonequivalent second site, where it bonds to six oxygen atoms of the tetrahedral groups forming a trigonal prism. Substitution of the Z-atom position gives rise to the end members fluorapatite, hydroxylapatite, and chlorapatite. The Z site in the channelways that parallel the *c* axis affords complete and easy substitution of F for the OH. The latter is accommodated by the displacement of H either up or down in the channel but out of the plane of the trigonal (Ca) cations. The location of Cl in the channel varies with the cation and the tetrahedral group, and note that the Cl species has monoclinic rather than hexagonal symmetry. Carbonate apatite, the usual composition ascribed to biologic apatites, may have CO_3 in the T or Z sites.

APATITE GROUP: CALCIUM ARSENATE SUBGROUP

Mineral	Formula	Space Group	a	c	
Svabite	$\text{Ca}_5(\text{AsO}_4)_3\text{F}$	$P6_3/m$	9.80	6.90	41.8.3.1

Clinomimetite†	$\text{Pb}_5(\text{AsO}_4)_3\text{Cl}$	$P2_1/b$	10.180	7.46 41.8.6.1
Finnemanite*	$\text{Pb}_5(\text{As}^{3+}\text{O}_3, \square)(\text{PO}_4)_3\text{Cl}$	$P6_3/m$		

†Monoclinic polymorph of mimetite, but strongly pseudohexagonal.

*Listed chemically as an arsenite-phosphate, treated under class 43; related structurally and chemically to the apatite group.

The subset pyromorphite, mimetite, and vanadinite are respectively the phosphate, arsenate, and vanadate end members that contain $A = \text{Pb}$ and $Z = \text{Cl}$. They are found in the oxidized portions of lead deposits, and exhibit little solid solution toward the calcium phosphate apatites. That is, calcium is not found to any great extent substituting in pyromorphite, nor is much lead accommodated in the calcium phosphate apatites despite the similarities in composition, identical space group, and crystal habit. Hedyphane is an intermediate, so to speak, in the Ca–Pb cation solid-solution range. It has been shown to be an ordered structure with one cation site preferentially occupied by Ca, with Pb in the other, but there is a miscibility gap at the high-Pb end of the Pb–Ca series.

APATITE SERIES: BARIUM-CONTAINING SUBGROUP

Mineral	Formula	Space Group	a	c
Morelandite	$(\text{Ba}, \text{Ca}, \text{Pb})_5(\text{AsO}_4, \text{PO}_4)_3\text{Cl}$	$P6_3/m$	10.169	7.315 41.8.5.1
Alforsite	$\text{Ba}_5(\text{PO}_4)_3\text{Cl}$	$P6_3/m$	10.75	7.64 41.8.5.2

Phase Relations. Several of the chemical systems mentioned above have been investigated for their interesting and useful physical and chemical properties [J. R. van Wazer, *Phosphorus and Its Compounds*, John Wiley & Sons, New York, 1966; *AJS* 273:545(1973)]. Many exotic end members of the apatite group minerals have been synthesized and the ranges, and limits for cationic- and anionic-site solid solutions are now well known. The composition range of the natural apatites, though large, has some intriguing limits, and not only because of the geochemical availability of the elements. The apatite structure forms with Ca and PO_4 and AsO_4 , but a naturally occurring $\text{Ca}_5(\text{VO}_4)_3(\text{Z})$ apatite has not been described. Svabite, $\text{Ca}_5(\text{AsO}_4)_3\text{Cl}$, the arsenate analog of chlorapatite, contains very low PO_4 , and the inverse is also true: most chlorapatites contain virtually no AsO_4 .

The Pb-containing apatite subgroup members appear to prefer Cl in the Z position, with only trace amounts of F or OH. Fluorapatite and hydroxylapatite end members of the calcium phosphate apatites are very common, but chlorapatite is rare and found only in metamorphic locations, despite the availability of Cl in seawater or human serum, where precipitation of apatite dominates.

Other Structurally Related Minerals. Cesanite, a sulfate with the apatite structure, is described with the sulfates (30.3.3.1). Minerals with composite anionic groups (i.e., containing PO_4 and SO_4 or SiO_4) are described under the dominant anion group: for example, under silicates britholite-(Ce) is described. *DII:878*; W.R. Deer, R. Howie, and J. Zussman, *Rock Forming Minerals*, Vol. V, *Nonsilicates*, John Wiley & Sons, New York, 1966, pp. 323–338; *MM 57:709(1993)*; J. C. Elliott, *Structure and Chemistry of the Apatites and Other Calcium Phosphates*, Elsevier, New York, 1994.

41.8.1.1 Fluorapatite $\text{Ca}_5(\text{PO}_4)_3\text{F}$

Apatite was first named in 1788 from the Greek for *to deceive*, as members of this subset of the apatite group resemble many other common minerals (aquamarine, amethyst, olivine, fluorite, etc.) in color and habit. Fluorapatite, named in 1860 to distinguish the composition, is the F-containing end member, which forms an isomorphous series with hydroxylapatite. Apatite group. Chlorapatite, the Cl end member, does not form a continuous series. See the discussion under chlorapatite (41.8.1.2). See also carbonate-fluorapatite

Hebron, Me.

Takowaja, Ural Mts.

Hebron, Me.

St. Gotthard.

Forms a $\{11\bar{2}0\}$ c $\{0001\}$ m $\{10\bar{1}0\}$ r $\{10\bar{1}2\}$ s $\{11\bar{2}1\}$ x $\{10\bar{1}1\}$ y $\{20\bar{2}1\}$ $\mu\{21\bar{3}1\}$

(41.8.1.4) and carbonate-hydroxylapatite (41.8.1.5). $HEX P6_3/m$. $a = 9.367$, $c = 6.884$, $Z = 2$, $D = 3.18$. *AM 75:295(1990)*. 15-876: 3.44₄ 2.80₁₀ 2.77₆ 2.70₆ 2.62₃ 2.25₂ 1.937₃ 1.837₃. See also 35-496, 34-11. **Habit:** Crystals short to long prismatic [0001] with {1010}, {1011} dominant; thick tabular {0001} with {1010}, large {0001}, and other low pyramidal forms produce quite complex crystals (Figure 41.8.1.1B); massive, coarse granular to compact, sometimes globular to reniform with subfibrous, scaly, or columnar structure; stalactitic; earthy; nodular concretions. Rarely twinned, contact with twin plane {1121}, other twin planes {1010}, {1123}, {1013}. Commonly found with inclusions, such as needles of rutile where the c axes of both phases are parallel, and also monazite. Crystals often zoned from F-rich to OH-rich apatite, which may show color differences. **Physical properties:** Usually sea-green to other shades of green, blue, violet-blue, amethyst, colorless, white, yellowish, gray, brown, flesh, or rose-red. Manganoan varieties are dark green and blue-green. Violet color is lost on heating. White streak, may show bluish opalescence; vitreous luster, transparent. Cleavage of variable ease and quality; {0001}, indistinct; {1010}, in traces; conchoidal to uneven fracture; brittle. $H = 5$. $G = 3.1-3.2$. Usually fluorescent under UV, cathode, or X-radiation; phosphorescent, may be strongly thermoluminescent, not piezoelectric. Uniaxial (-); $N_O = 1.6325$, $N_E = 1.630$ (Na) (synthetic) *DII: 879*; $N_O = 1.646$, $N_E = 1.642$ (588 nm) (Zillertal). Indices highly sensitive to substitution especially OH for F (McConnell. D 1973 *Apatite*, Springer Verlag, N.Y. Colored crystals show strong to weak dichroism with absorption $E > O$: higher indices with Mn, or with OH-containing fluorapatite crystals, lower in CO_3 -containing apatites. **Chemistry:** REE, especially Ce, are common substituents for Ca, as are Mn and Sr [see below (41.8.1.6), strontium-apatite (41.8.1.7)]. An extremely wide variety of cations including both two or three positive valence states (Me^{2+} and Me^{3+} cations) have been detected on chemical analyses and many end members have been produced synthetically. However, natural crystals containing more than trace amounts of Mg and Fe^{2+} are rare, and alkalis usually occur as separate isomorphous phases with SiO_4 or SO_4 partially substituting for PO_4 . Arsenic is usually absent on analysis probably due to geochemical nonavailability, as AsO_4 forms a complete series with PO_4 (to svabite, fermorite). Synthetic studies suggest Al, Cr^{3+} , and Cr^{6+} easily fit into the anionic site in the apatite structure. **Occurrence:** Fluor- and hydroxylapatites are very common, occurring in all types of igneous rocks as accessory minerals usually in microscopic euhedral crystals; in both acidic and basic pegmatites; in magnetite deposits; in hydrothermal veins; in both regionally and contact metamorphosed rocks, especially recrystallized limestones associated with titanite, zircon, pyroxene, amphiboles, spinel, vesuvianite, and phlogopite; in talc and chlorite schists; as extensive deposits of marine origin with fine-grained massive form; as replacement beds of limestone or coral via solutions derived from guano, or as nodules disseminated in nearshore sediments, and in coal measures. **Localities:** Notable crystals of fluor- and hydroxylapatite were found in the United States at Newry(!), and Mt. Apatite(!), Auburn, ME; in the Adirondack Mts., NY,

along with magnetite; in crystalline limestones in NJ (at Franklin); at Tip Top mine, Custer Co., SD; at Clay Canyon, Fairfield, UT. Apatite has been described from Pulsifer quarry, Auburn, ME; Palermo No. 1 mine, North Groton, NH; Keystone quarry, Cornog, PA; Foote mine, Kings Mt., NC; Jeffrey quarry, Little Rock, AK; Bald Mt., Jefferson Co., MT; Hugo pegmatite, Keystone, SD; Climax mine, Lake Co., Urad mine, Clear Creek Co., and at the Pikes Peak batholith, CO; Warren mining district, Bisbee, Cochise Co., Mammoth-St. Anthony mine, Tiger, Twin Buttes mine, AZ; Harding mine, Dixon, Taos Co., NM; Champion mine, White Mts., Mono Co., Gem mine, San Benito Co., Clark, and Himalya mines, San Diego Co., CA. In Canada, fluorapatite was commonly found in the Grenville marble as irregular veins and crystals, even as large crystals(!!!; up to 200 kg) in Ottawa Co., Lanark Co., Renfrew Co., Frontenac Co., QUE. More recent finds are on the Lievre R., at Mt. St-Hilaire(!), at Yates mine, Pontiac Co., QUE; at Ottertail Range, Ice River complex, BC; at several localities in Greenland, such as Iglunguak, Narsarsuk, and Kangerdluarsuk. Fine yellow crystals were found in the magnetite deposit of Cerro Mercado(!) DGO, Mexico. In Europe F- and OH-apatites were found in andesite-tuff at Jumilla, Murcia, Spain; and more recently in Portugal at Panasqueira, at Mt. Redondo quarry. The tin veins at Tavistock, Devonshire, and Wheal Franco, Cornwall, England, and Ville-der, France, were early-noted occurrences, as were the pegmatites at Zillertal, Tyrol, Austria, and at Epprechstein and Waldstein, Fichtel Mts., the tin mines at Ehrenfriedersdorf, Saxony, Germany, and most recently at Mendig, Laacher See district; at Schwartzenstein, Salzburg, Untersulzbachtal, Austria, and at several localities in the Piedmont of Italy; at Gletch on the Rhone glacier, Switzerland; at Schlaggenwald, Czech Republic. Enormous deposits are known from the alkalic igneous rocks in the Khibina tundra, Kola peninsula(!), and from the mica schists east of Ekaterinburg(!), Ural Mts., where apatite occurs with emerald and chrysoberyl. A new deposit has been found at Slyudyanka, Siberia, Russia. The Onganja mine(!), Namibia, also has produced some fine specimens. Fluorapatite occurs in Australia at Iron Monarch mine, Iron Knob, SA; at the San Jose mine, Oruro, and the Sligo XX mine, Llallagua, Bolivia; at several mines in MG, such as Lavra do Enio, Pamaro, Santo do Encoberto, Lavra da Ilha, Virgem da Lapa, and at Paraiba and in the Brumado district, BA, Brazil. *DII:879, AM 76:1857(1991)*. Uses: The largest-volume use of apatite materials is to make the apatitic halophosphate phosphors (≈ 10 tons/day) for fluorescent lighting. The luminescence depends on the small amount (<2 wt %) of Sb^{3+} incorporated into the apatite lattice ("doping"). As of this writing the actual site(s) within the structure where Sb resides are not known. Phosphatic deposits are also mined for agricultural fertilizer and feed for animals. HCWS

41.8.1.2 Chlorapatite $\text{Ca}_5(\text{PO}_4)_3\text{Cl}$

Named in 1860 for the relationship to apatite and the composition. Apatite group. *HEX* $P6_3/m$. $a = 9.598$, $c = 6.776$, $Z = 2$, $D = 3.199$. Structure: *AM*

74:870(1989). The Cl atoms may occur above or below the mirror plane that passes through the Ca(2) triangle (see Figure 41.8.1.2). This disposition changes the Ca(2) bond lengths and effectively prohibits OH and F from occupying the centered positions in the same column. Such shifts suggest that the end member F-, OH-, and Cl-apatites are immiscible (i.e., do not have mutual solid solutions). It is possible that the Z atoms may be segregated in individual columns (producing monoclinic structure) and if the column distribution is disordered throughout the crystals, the general structure will remain hexagonal. 33-271(syn): 8.33₁ 2.86₉ 2.78₉ 2.77₁₀ 2.32₂ 2.31₂ 1.963₃ 1.836₃. Crystals pale yellow, vitreous luster, transparent; appear pinkish white with talc inclusions. H = 5. G = 3.181. Uniaxial (-); N_O = 1.6684, N_E = 1.6675 (synthetic). Many apatite analyses show very small amounts of Cl (i.e., Cl-containing fluorapatite). However, the totally Cl end member, chlorapatite, is extremely rare but has been synthesized and may show monoclinic symmetry: $P2_1/a$ with $a = 19.210$, $b = 6.785$, $c = 9.605$, $\beta = 120^\circ$; biaxial (-); N_x = 1.667, N_z = 1.665; $2V \approx 10^\circ$. Found in veins in calc-silicate rocks and marbles at *Bob's Lake, Oso Twp., Frontenac Co., Canada*, with actinolite, diopside, calcite, quartz, and talc. Other localities: Odegarden, Kragerø, Norway, where the mineral is associated with rutile, ilmenite, sphene, magnetite, pyrrhotite, hornblende, wernerite, and also at Kurokura, Kanagawa Pref., Japan, have considerably lower Cl contents. Chlorapatite has also been found in meteorites. HCWS *DII:879, CM 10:252(1970)*.

41.8.1.3 Hydroxylapatite $\text{Ca}_5(\text{PO}_4)_3(\text{OH})$

Named in 1856 to distinguish the (OH) end member of the minerals known generally as apatite. Apatite group. See fluorapatite (41.8.1.1) for general outline of habit and physical and chemical properties; see carbonate F/OH apatite for biological mineral. HEX $P6_3/m$. $a = 9.418$, $c = 6.875$, $Z = 2$, $D = 3.16$ (Holly Springs). *AM 74:870(1989)*. 9-432(syn): 3.44₄ 2.82₁₀ 2.79₆ 2.72₆ 2.63₃ 2.26₂ 1.943₂ 1.841₃. See also 24-33(calc), 34-10, 25-166. Uniaxial (-); N_O = 1.651, N_E = 1.644 (Na). High-temperatures (300–600°) and high-pressure (2 kbar) studies in the system CaO–P₂O₅–H₂O show that hydroxylapatite is stable over the pH range 4–12. The synthetic hydroxylapatite crystals are stable to temperatures in excess of 1,200° in humid environments, but lose H₂O in vacuo by 850°. *AJS 273:545(1973)*, *JPC 79:2017(1975)*. Low-temperature (<100°) precipitation of hydroxylapatite does not provide well-crystallized materials, and the assumption is that CO₂ in the environment inhibits crystal growth. The addition of F to the solution increases crystallinity and is the rationale for fluoridation, adding a few parts per million to drinking water, which appears to have the salutary effect of reducing caries in the general populace. Especially fine, clear, light yellow-green euhedral hydroxylapatite crystals are found at Holly Springs, Cherokee Co., GA.; at Eagle, CO; in the talc schists of the alpine region in Switzerland; in the Kop Dag area, Kop Daglari, Turkey; at Milgun Station, WA, Australia. HCWS *DII:879, GT 4:208(1988)*.

41.8.1.4 Carbonate-Fluorapatite $\text{Ca}_5(\text{PO}_4, \text{CO}_3)_3\text{F}$ **41.8.1.5 Carbonate-Hydroxylapatite $\text{Ca}_5(\text{PO}_4, \text{CO}_3)_3(\text{OH})$**

Named in 1906 to accommodate the intimate association of carbonate with apatite in materials that were ultrafine-grained, massive, earthy, pulverulent, or opaline, and formed as crusts, spherules, and nodules, in sedimentary horizons, as bulk phosphatic rock, or as the mineral portion of bones and teeth, all vertebrates, animal and human, both fossil and modern. *Collophane* was the original name for such a species. Francolite, named in 1859 for the locality, Wheal Franco, Devonshire, England, has been used for high-F-containing carbonate-apatites, while dahllite, named for T. and J. Dahl, Norwegian geologists and brothers [*ZK 17:426 (1890)*] is applied to carbonate-hydroxylapatite. Apatite group. *31-267*: 8.04₂ 4.04₂ 3.43₂ 3.05₄ 2.79₆ 2.69₁₀ 2.24₅ 1.783₃. See also *19-272*(syn). Soluble in HCl, HNO₃ with slight effervescence. Despite research that shows up to 6 wt % CO₂, in some carbonate-containing apatite mineral materials the actual disposition of the CO₃ group at specific site(s) in the apatite lattice is not yet known. It has been proposed that collophane and bone mineral: (1) are mixtures, the coprecipitation of CaCO₃ plus apatite; or (2) CO₃²⁻ or CO₂ may be adsorbed on the surfaces of very fine grains of F- or OH-apatite; or (3) a [CO₃-F] group substitutes for PO₄ in the structure. The last hypothesis has been supported by chemical analyses of carbonate-containing reasonably well-crystallized apatites which show greater amounts of (F,OH,Cl) than would be expected from the stoichiometric formula. *CMP 101:394(1989)*. Uniaxial (-); N_O = 1.628, N_E = 1.619 (Na); very variable; higher birefringence than that of F- and OH-apatites. Francolites were found at *Wheal Franco, Devonshire*, at Callington-Gunnislake, Cornwall, at Caldbeck Fells, Cumbria, associated with Skiddaw granites; as concretions in a light brown groundmass in argillaceous sediments with quartz, illite, pyrite, and associated with magnesian siderite at Hepworth Iron mine, Westphalia, Yorkshire, *England*. Dahllite is encountered in the skarns at Magnet Cove, AK; as fibers in Odegarden, Bamle, Norway; at the carbonatites in Palabora, northeastern Transvaal, South Africa. In addition to the fossilized animal and normal human bone samples in sedimentary horizons, there are the massive phosphorite deposits, such as the Phosphoria formation in the western United States or Florida and in Morocco and Russia. Much of the commercial phosphate material comes from these horizons and is used in the production of phosphoric acid and fertilizers, washing detergents, and animal feed. *HCWS DII:879, SCI 155:1409(1964), AM 53:445(1968), MM 41:M4(1977)*.

41.8.1.6 Belovite $(\text{Sr,Ce,Na,Ca})_5(\text{PO}_4)_3(\text{OH})$

Named in 1955 for Nikolai Vassilievich Belov (1891-1982), mineralogist and crystallographer, Institute of Crystallography, Moscow, Russia. Apatite group. One of two species that are Sr analogs of apatite. Strontium-apatite (41.8.1.7) contains > 50 at % Sr, while belovite contains < 50 at %. *HEX P6₃/m*. *a* = 9.692, *c* = 7.201, *Z* = 2, *D* = 4.131. *MZ 9:45(1987)*. *31-1350*: 3.17₇ 2.89₁₀ 2.79₇ 2.15₅ 2.01₇ 1.957₄ 1.913₇ 1.470₆. Crystals prismatic up to

2 cm showing {1010}, {0001}. Honey-yellow to light green, vitreous to greasy luster, transparent. Imperfect cleavage; irregular fracture; brittle. $H = 5$. $G = 4.19$. Uniaxial (-); $N_O = 1.660$, $N_E = 1.664$. Soluble in 1:10 HCl, HNO_3 . Contains < 50 at % Sr, with REE, Ca, and Na substitution. Occurs in central portions of the pegmatites in nepheline syenites at *Mt. Karnasurt, Lovozero massif, Kola Penin., Russia*, in ussingite with nepheline, aegirine, natrolite, and in association with minor sodalite, microcline, schizolite, erikite, murmanite, neptunite, and steenstrupine. *HCWS AM 40:367(1955)*, *DANS-ESS 142:113(1962)*.

41.8.1.7 Strontium-Apatite $(Sr,Ca)_5(PO_4)_3(F,OH)$

Named in 1962 for the composition and resemblance to the apatites. Apatite group. The name given to species with > 50 at % Sr see belovite (41.8.1.6). *HEX* $P6_3/m$. $a = 9.565$, $c = 7.115$, $Z = 2$, $D = 3.95$. Structure: *SPC 32:524(1989)*. Large ions (Sr, Ba)/(Ca, Mg, Na, Fe, Th, REE) usually have the ratio 6:4, conforming to the two possible cationic sites in the structure. *33-1348(syn)*: 3.18₂ 2.93₁₀ 2.92₁₀ 2.82₄ 2.03₃ 1.93₂ 1.81₉ 1.46₉₂. Prismatic crystals to 4 cm length, although mostly smaller 0.2 mm × 1 mm, or minute, poorly formed, oval in shape with corroded {1010}, {1011}; sugary. Pale green, pale yellow-green, colorless; vitreous to greasy luster; transparent. Imperfect cleavage parallel to prism faces, uneven fracture. $H = 5$. $G = 3.84$. Uniaxial (-); $N_O = 1.651$, $N_E = 1.637$. Soluble in acids. Microprobe analysis shows Ba, La, Ce, Pr, Nd, Sm, Eu, Gd, Tb, Dy, Er, and Yb. Synthetic studies had originally suggested a complete solid-solution Ca–Sr, but documentation of the ordering of Ca into one cation site in arsenate-containing apatites, and more recent studies of high-Ca-containing portions of the series (e.g., Ca_9Sr to Ca_6Sr_4) suggest that these compositions are usually not formed, nor have they been found in nature. The results for the Ca–Sr solid solution are similar to the range found for the Ca–Pb series, hedyphane–turneaureite. *AM 69:920(1984)*. Occurs in interstices of albite–eckermanite–aegirine veins in alkali pegmatites that cut the dunite core of the *Inaglinsky massif, southern Yakutia, Russia*, intergrown with bathysite, ramseyite, and eudialyte, and in association with microcline, batisite, innelite, and lorenzenite. *HCWS DANS 142:113(1962)*, *AM 47:808(1962)*.

41.8.2.1 Hedyphane $Ca_2Pb_3(AsO_4)_3Cl$

Named in 1830 from the Greek for *beautifully bright*, in allusion to the high luster. Apatite group. *HEX* $P6_3/m$. $a = 10.140$, $c = 7.185$, $Z = 2$, $D = 5.99$. Structure: *AM 69:920(1984)*. Structure determination confirms that Ca and Pb are regularly disposed in the two different cation structure sites. Therefore, hedyphane is an ordered intermediate species between $Ca_5(AsO_4)_3Cl$ and $Pb_5(AsO_4)_3Cl$, mimetite (41.8.4.2). *36-396*: 8.77₄ 5.07₄ 4.14₅ 3.59₇ 3.32₄ 3.01₁₀ 2.93₈ 1.94₃₈. Prismatic [0001], pyramidal to thick tabular {0001}; massive. White, yellow-white, bluish; white streak; bright, greasy to resinous luster; translucent. Cleavage {1011}, barely discernable; even fracture; brittle.

$H = 4\frac{1}{2}$, $G = 5.82$. Weak light yellow fluorescence in UV. Uniaxial (+); $N_O = 1.958$, $N_E = 1.948$ (Na); or uniaxial (-); $N_O = 2.03$, $N_E = 2.01$, both Franklin, NJ, samples. Soluble in HNO_3 . Sr, Ba, and P detected on analysis, with Sr the dominant substituent at Franklin and at Ba, Långban. A solid-solution series has been demonstrated synthetically between hedyphane-mimetite, the Ca_2Pb_3 - Pb_5 portion of the Ca-Pb system, but there is a miscibility gap in natural materials for the portion represented by hedyphane-turneureite: Ca_2Pb_3 - Ca_5 . Found at Franklin, NJ, as the most abundant nonsilicate lead mineral, occurring occasionally as fine dipyramidal or prismatic crystals(!) and associated with calcite, willemite, native copper, native lead, hancockite, rhodonite, manganaxinite, and apatite in veinlets in massive ore; at *Långban, Värmland, Sweden*, with barite, baylite, and rhodonite, as crystals coating calcite crystals in veinlets and associated with allactite and hausmannite, also at Harstig mine, Pajsberg, with tephroite and calcite in magnetite; at Tsumeb, Namibia; at Puttappi mine, Flinders Ranges, SA, Australia. ncws *DII:901*.

41.8.3.1 Svabite $Ca_5(AsO_4)_3F$

Named in 1891 for Anton Svab (1703-1768), Swedish mining official. Apatite group. $HEX P6_3/m$. $a = 9.80$, $c = 6.90$, $Z = 2$, $D = 3.708$. *DANS (1966) 166:134. 19-215: 3.99₇ 3.43₆ 2.91₁₀ 2.84₉ 2.82₉ 2.67₇ 2.23₅ 1.999₆*. Short prismatic [0001] notable hexagonal outline; massive. Colorless, yellowish white, gray, grayish green, pale lilac; vitreous to subresinous luster; transparent to translucent. Cleavage {1010}, indistinct; brittle. $H = 4-5$. $G = 3.5-3.8$ with Pb-rich samples the highest value. Fluorescent LWUV red-orange, in cathodoluminescence pale pink. DTA, Uniaxial (-); $N_O = 1.706$, $N_E = 1.698$ (Harstig). Soluble in 1:10 acids. Pb, Mg, Mn^{2+} substitute for Ca; Cl and (OH) for F, P for As with the potential for series toward fluorapatite, mimetite, or hedyphane. Found as rough hexagonal prisms with rounded terminations embedded in franklinite ore, Franklin, NJ; at *Harstig mine, Pajsberg, Värmland, Sweden*, with manganoan acmite, garnet, brandtite, sarkinite, and massive at Jakobsberg, Nordmark district, and at Långban with hematite, mica, and garnet; in contact metasomatic deposits in Siberia, and in the Ural Mts. with vesuvianite in pyroxene-garnet assemblages and in zones with spodumene, which alters to szaibelyite and brucite, Russia. ncws *DII:899*.

41.8.3.2 Turneureite $Ca_5(AsO_4)_3Cl$

Named in 1985 for Frederick Steward Turneure (1899-1986), University of Michigan, Ann Arbor. Apatite group. The Cl analog of svabite and johnbaumite, As analog of chlorapatite, and Ca analog of morelandite and mimetite. $HEX P6_3/m$. $a = 9.810$, $c = 6.868$, $Z = 2$, $D = 3.63$. *CM 23:251(1985). 33-383: 3.98₅ 3.43₆ 2.91₁₀ 2.83₉ 2.67₅ 1.995₃ 1.864₄ 1.718₃*. Prismatic crystals to 1.5 mm long, showing {1010}, {0001}; massive. Colorless, white streak, vitreous to greasy luster. No cleavage, uneven fracture. $H = 5$. $G = 3.60$. Fluorescent bright orange in SWUV. Weak phosphorescence in Franklin samples. Uniaxial

(-); $N_O = 1.708$, $N_E = 1.700$ (Na). Microprobe analysis shows Mn, P, F. Found in high-grade marble terranes (e.g., the manganese-rich siliceous marble at Balmat, St. Lawrence Co., NY) with donpeacorite, tirodite, ferrian braunite, dravite, anhydrite, and manganoan dolomite; as gray-white anhedral masses at Franklin, Sussex Co., NJ; at *Långban mine, Värmland, Sweden*(1), with calcite and andradite, in massive andradite-magnetite ore. HCWS *AM 71:1280(1980)*.

41.8.3.3 Johnbaumite $Ca_2(AsO_4)_3(OH)$

Named in 1980 for John L. Baum (b.1916), resident geologist of the New Jersey Zinc Co. and curator of the Franklin Mineral Museum, Franklin, NJ. Apatite group. As analog of hydroxylapatite and (OH) analog of svabite. HEX $P6_3/m.$ or $P6_3$. $a = 9.70$, $c = 6.93$, $Z = 2$, $D = 3.73$. *AM 65:1143(1980)*. $33-265$: 3.98_5 3.47_5 2.90_{10} 2.82_7 2.80_7 2.68_5 2.03_4 1.879_4 . Massive, anhedral grains to 8 mm. Colorless, white streak, vitreous to greasy luster on fracture surfaces, transparent. Cleavage $\{10\bar{1}0\}$, distinct. $H = 4\frac{1}{2}$. $G = 3.68$. DTA/TGA. Fluorescent pink-orange in SWUV only. Uniaxial (-); $N_O = 1.687$, $N_E = 1.684$. Microprobe analysis shows minor P, Fe^{2+} , Mg, F, Cl; also H_2O . Found at *Palmer Shaft, Franklin mine, Franklin, Sussex Co., NJ*, with yeatmanite, diopside, andradite, franklinite, native copper, and romeite. HCWS

41.8.3.4 Fermorite $(Ca,Sr)_5(PO_4,AsO_4)_3(F,OH)$

Named in 1911 for Lewis Leigh Fermor (1880-1954), director of the Geological Survey of India. Apatite group. MON $P2_1/m.$ $a = 9.594$, $b = 6.975$, $c = 9.597$, $\beta = 119.97^\circ$, $Z = 1$, $D = 3.608$. Structure: *327(1991) NJMM*: *Strongly pseudo-hexagonal*. $14-215$: 3.95_3 3.49_5 3.12_3 2.86_{10} 2.75_6 2.67_3 1.971_4 1.867_4 . Massive, granular. Pale pinkish white, white streak, greasy luster, translucent. Even fracture. $H = 5$. $G = 3.518$. Uniaxial (-); $N_{av} = 1.660$; weakly birefringent. Soluble in acids. Analysis shows significant substitution of As for P, maximum As/P = 1:1, which probably influences crystallization in monoclinic space group, minor Sr, trace H_2O . Found at *Sitapar, Chindwara district, Central Provinces, India*. HCWS *DII:904*.

41.8.4.1 Pyromorphite $Pb_5(PO_4)_3Cl$

Named in 1813 from the Greek for *fire* and *form* because after melting the mineral sample to a globule, a crystalline shape forms on cooling. Apatite group. Pyromorphite forms a complete series, P-As, with mimetite, and is the end-member name used when $P > As$. HEX $P6_3/m.$ $a = 9.976$, $c = 7.351$, $Z = 2$, $D = 7.109$. Structure: *CM 27:189(1989)*. $19-701$ (syn): 4.13_5 3.38_3 3.27_4 2.99_{10} 2.96_{10} 2.89_6 2.064_3 1.861_3 . Crystals prismatic $\{0001\}$, generally simple, showing $\{1010\}$, $\{0001\}$, $\{1011\}$; equant, barrel shaped; spindle shaped, or with cavernous terminations; rarely tabular $\{0001\}$ or pyramidal; branching groups of prismatic crystals in parallel position, tapering to a point; globular, reniform, wartlike with subcolumnar structure; granular. Crystals often

show concentric growth zones, probably due to As/P variations. Dark green to green-yellow, shades of brown, waxy yellow, orange-yellow, white, colorless; white streak; resinous luster; subtransparent to translucent. Cleavage $\{10\bar{1}1\}$ in traces, uneven to subconchoidal fracture, brittle. $H = 3\frac{1}{2}$. $G = 7.04$ (lower with substitutions). Crystals from Ems (and mimetite from Tsumeb) are piezoelectric and optically biaxial. Uniaxial (-); $N_O = 2.058$, $N_E = 2.048$ (589 nm); faintly pleochroic; biaxial when As content is high. Ca frequently substitutes for Pb, but in natural minerals a complete series to chlorapatite does not exist [see hedyphane (41.8.2.1)], minor Fe^{2+} , Cr, REE, Ba, Mn substitution reported; trace amounts of F and OH substitute for Cl. Easily synthesized below 100° . Synthetic studies concluded that a complete P-As-V solid solution was possible [AM 51:1712(1966)], but crystal structure investigations suggest that the larger VO_4 group will probably be of limited extent, especially in natural systems. Pseudomorphs of pyromorphite after galena and cerussite are common; galena may be found pseudomorphous after pyromorphite. Occurs in oxidized portions of lead deposits with mimetite, cerussite, iron oxyhydroxides, smithsonite, hemimorphite, anglesite, malachite, leadhillite, caledonite, vanadinite, wulfenite, desclozite, mottramite, and bayldonite. Found at Loudville Mine, Hampshire Co., MA; at Wheatly mines, Phoenixville, Chester Co., PA(!); in the Leadville area, CO; at the many mines in the Coeur d'Alene district(!), Shoshone Co., ID; at Bisbee, Cochise Co., and elsewhere in AZ, UT, and NM; in Canada at Mt. St.-Hilaire, QUE, and in the Moyie mines, BC; at Chihuahua, Los Lamentos, CHIH, Mexico; at mines in Cumberland, Derbyshire, Somerset, and at Bwch-Glas mine, Dyfed, Wales; at Leadhills, Wanlockhead district, Scotland; at El Horcajo, Castilla Province, Spain; at Les Farges mine, Ussel, Correze, France; in Germany at Friedrichsseggen mine, Ems, Grube Phillipseck, Munster; at lead mining areas in Russia; at Broken Hill, NSW, and in the mines at Dundas, TAS, and elsewhere in NT and SA, Australia; at Touissit mine, Oujda, Morocco; at Broken Hill mine, Zambia; at Boquira mine, BA, Brazil. *HCWS DII:889, NJMA 99:113(1963)*.

41.8.4.2 Mimetite $Pb_5(AsO_4)_3Cl$

Named in 1835 from the Greek for *imitator* because of its resemblance to pyromorphite. Apatite group. Dimorphous with clinomimetite (41.8.6.1). *HEX* $P6_3/m$. $a = 10.212$, $c = 7.419$, $Z = 2$, $D = 7.80$. Structure: *CM 29:369(1991)*. Not analogous to chlorapatite, where Ca(2) bonds to one Cl as in mimetite Pb(2) bonds to two Cl's in the Z position. *19-683(syn)*: 4.44₂ 3.36₄ 3.06₁₀ 3.01₉ 2.96₇ 2.11₃ 1.994₂ 1.905₂. See also *13-124* (P-containing species) and *19-683 (syn)*. Crystals simple barrel shapes showing $\{10\bar{1}0\}$, $\{0001\}$; botryoidal, globular, reniform, granular, rarely tabular, acicular. Pale yellow to yellowish brown, orange-yellow, orange-red, white, colorless; white streak; resinous luster; subtransparent. Zoned growth As alternates with P. Cleavage $\{10\bar{1}1\}$ in traces, subconchoidal fracture, brittle. $H = 3\frac{1}{2}$. $G = 7.28$. IR. Uniaxial/biaxial (-); $X = c$; $N_{O'} = 2.147$, $N_{E'} = 2.128$ (589

nm); $2V = 41^\circ$; $r < v$; $2V$ decreases with increasing P. Anomalous optics may denote twinning, or sector growth. Soluble in HNO_3 , KOH. Synthesized. In natural minerals there is a complete series As–P, pyromorphite–mimetite. The latter name is used when there is > 50 mol % As. Vanadinite forms a series up to $V/\text{As} = 1:1$. Ca substitutes for Pb, but see hedyphane (41.8.2.1). Less common than pyromorphite, mimetite occurs in oxidized zones of lead deposits and other formations where lead and arsenic occur. Found in association with pyromorphite at many of the lead mines in AZ, such as at Bisbee and Tombstone, and in Gila, Maricopa, Pima, and Yuma Cos., at Mammoth–St. Anthony, Tiger, and at Red Cloud Copper mine, Gallinas Mts., NM; at Santa Eulalia, CHIH, Mexico; at Millers Dale, Derbyshire, Merehead quarry, Somerset, England, with curved barrel-shaped crystals originally from Drygill, Cumberland(!), but found elsewhere; at Les Farges mine, France; at Johanngeorgenstadt, Germany; at Kamareza mine, Attica, Greece; at Seh Changi mine, Iran; at Tsumeb, Namibia; at Broken Hill, NSW, Australia. *HCWS DII:889, AM 51:1712(1966), ZK 191:125(1990)*.

41.8.4.3 Vanadinite $\text{Pb}_5(\text{VO}_4)_3\text{Cl}$

Named in 1839 for the composition. Apatite group. $\text{HEX } P6_3/m$. $a = 10.317$, $c = 7.338$, $Z = 2$, $D = 6.953$. Structure: *CM 27:189(1989)*. $43-1461$: 4.22₃ 3.40₃ 3.38₄ 3.07₉ 2.99₁₀ 2.98₈ 2.11₈ 1.976₃. See also 19-684(syn): 13-585. Crystals short to long prismatic [0001] with smooth faces, sharp edges; acicular to hairlike; occasionally, hollow prism crystals with rounded domes in parallel grouping, such as pyromorphite. Orange-red, ruby-red, brownish red, brown-yellow to pale straw-yellow; whitish-yellow streak; subresinous luster; subtransparent to nearly opaque. May be concentrically zoned with composition variations. Uneven fracture, brittle. $H = 2\frac{1}{2}-3$. $G = 6.88$, decreasing with Ca substitution. Uniaxial (-); $N_O = 2.416$, $N_E = 2.350$ (598 nm); pleochroic with $E < O$. Ca, P substitution will reduce indices. Easily soluble in HNO_3 , giving a yellow solution. Soluble in HCl, giving a green solution, deposition of lead chloride. Small amounts of Ca, Zn, Cu substitute for Pb; substantial amounts of P and As substitute for V. Synthesized. A secondary mineral found in the oxidized zones of lead deposits. Occurs in many of the mines in AZ: Apache mine, Globe, C & B mine, Gila Co., Old Yuma mine(!), Pima Co., Grey House mine, Pinal Co., Red Cloud mine(!), Rowley mine, Mammoth–St. Anthony mine, Tiger, Hamburg mine, Yuma Co.; at the Chalk Mt. mine, Churchill Co., NV; in the Hillsboro(!) and Lake Valley district(!), and Caballos Mt.(!), Sierra Co., at Red Cloud Copper mine, Gallinas Mts., NM; at Camp Signal, San Bernardino Co., and El Dorado mine, Riverside Co., CA; at Ahumada mine, Los Lamentos, CHIH, Mexico; at Leadhills, Scotland; at M'Fis and Acif mines, Morocco; at Broken Hill, Zambia; at Tsumeb, Namibia; at Proprietary mine, Broken Hill, NSW, Australia; at Itacarambi mine, MG, Brazil. *HCWS DII:895, CM 7:301(1962)*.

41.8.5.1 Morelandite (Ba,Ca,Pb)₅(AsO₄,PO₄)₃Cl

Named in 1978 for Groven C. Moreland (1912–1978), supervisor of sample preparation laboratory, National Museum of Natural History, Smithsonian Institution, Washington, DC. Apatite group. See mimetite (41.8.4.2). HEX $P6_3$ or $P6_3/m$. $a = 10.169$, $c = 7.315$, $Z = 2$, $D = 5.30$. *CM 16:601(1978)*. 31-132: 8.86₂ 5.09₃ 3.66₅ 3.18₃ 3.03₁₀ 2.97₇ 2.94₆ 1.965₃. Irregular masses. Light yellow to almost pure gray, white streak, greasy to vitreous luster, translucent. Weak cleavage parallel to {0001}. $H = 4\frac{1}{2}$. $G = 5.33$. Nonfluorescent. Uniaxial (+); $N_O = 1.880$, $N_E = 1.884$. Soluble in cold 1:1 HCl, turning opaque, chalky white, on exposure to HCl. Microprobe showed some Ca, P, minor Ca, Mn, Fe, only a trace of H₂O detected. Found at *Jakobsberg mine, near Nordmark, Sweden*. HCWS

41.8.5.2 Alforsite Ba₅(PO₄)₃Cl

Named in 1981 for John T. Alfors (b.1930), geologist, California Division of Mines and Geology. Apatite group. HEX $P6_3/m$. $a = 10.75$, $c = 7.64$, $Z = 2$, $D = 4.83$. *AM 66:1050(1981)*. 35-691(syn): 3.37₂ 3.06₁₀ 2.95₃ 2.13₄ 2.03₃ 1.928₃ 1.566₃ 1.336₃. Minute subhedral grains up to 0.2 mm but usually < 0.05 mm in diameter. Colorless, distinguished by low birefringence, high relief in thin sections. Intense violet fluorescence in 10- to 15-kV electron beam. Not fluorescent in UV. Uniaxial (-); $N_O = 1.696$, $N_E = 1.694$ (Synthetic). An accessory mineral in metamorphic rocks of *Incline, Mariposa Co., and Big Creek, Fresno Co., CA*, associated with pink gillespite, sanbornite, witherite, celsian, quartz, and fluorapatite. HCWS

41.8.6.1 Clinomimetite Pb₅(AsO₄)₃Cl

Named in 1991 for its dimorphic relationship to mimetite. Apatite group. See also finnemanite $Pb(As_5O_3)_3Cl$, and arsenite. MON $P2_1/b$. $a = 10.180$, $b = 7.46$, $c = 20.372$, $\beta = 119.88^\circ$, $Z = 4$, $D = 7.32$. Structure: *CM 29:369(1991)*. Strongly pseudohexagonal. Small changes in Pb bonding with O of PO₄ group as a result of the Cl (Z atom) position in the column are probably responsible for the monoclinicity 47-1808: 3.34₅ 3.05₁₀ 3.01₇ 2.95₇ 2.11₅ 2.00₄ 1.961₅ 1.903₅. Physical and chemical properties similar to mimetite (41.8.4.2). Spontaneous and reversible transition between $P6_3/m$ and $P2_1/b$ occurs $\approx 100^\circ$ and has been demonstrated in both natural and synthetic materials. Synthetic studies show continuous series P-As Pyromorphite-mimetite but not to V, therefore there is no series to vanadinite. $H = 3\frac{1}{2}$. $G = 7.36$. Found at *Johanngeorgenstadt, Erzgebirge, Saxony, Germany*. HCWS *NJMM:359(1968)*, 64(1969); *NJMA 113:219(1970)*.

BJAREBYITE GROUP

Bjarebyite minerals are phosphates with the general formula

where

A = Ba, Sr

B = Fe^{2+} , Mn^{2+} , Mg

C = Al, Fe^{3+}

and crystallize with monoclinic, or triclinic pseudomonoclinic, symmetry.

The structure [AM 59:567(1974)] is composed of pairs of edge-sharing octahedra $[C_2O_6(OH)_3]$ joined at the corners forming chains parallel to the *b* axis. The chains share edges with distorted pairs of BO_6 octahedra, and are bridged by PO_4 tetrahedra. The A atoms occupy holes in this framework and have 11-fold coordination.

BJAREBYITE: $BaMn_2Al_2(PO_4)_3(OH)_3$

This projection of the bjarebyite structure shows the large A ions in the interstices of a framework composed of Mn and $Al(OP,OH)_6$ Octahedra connected through PO_4 groups.

BJAREBYITE GROUP

Mineral	Formula	Space Group	a				b				c				β			
			a	b	c	β	a	b	c	β	a	b	c	β				
Kulanite*	BaFe ²⁺ Al ₂ (PO ₄) ₃ (OH) ₃	P $\bar{1}$	9.032	12.119	4.936	100.38	41.9.1.1

*Triclinic but α and γ are 90°.

41.9.1.1 Kulanite BaFe₂²⁺Al₂(PO₄)₃(OH)₃

Named in 1976 for Alan Kulan (1921–1977), who collected the first specimen. The Fe²⁺ end member of a Fe²⁺Mg series with penikisite. Bjarebyite group. TRIC P $\bar{1}$. $a = 9.032$, $b = 12.119$, $c = 4.936$, $\alpha = 90^\circ$, $\beta = 100.38^\circ$, $\gamma = 90^\circ$, $Z = 2$, $D = 3.92$. *CM 14:127(1976)*. 29-170: 8.84₆ 4.51₅ 3.58₅ 3.11₁₀ 3.04₇ 2.93₈ 2.69₆ 2.66₇. Thin tablets flattened on {101}, forming rosettes up to 3 mm × 3 mm × 0.5 mm. Blue-green, vitreous luster, translucent to transparent. $H = 4$. $G = 3.91$. DTA/TGA. Nonfluorescent. Biaxial (+); $Y \approx b$; $Z \wedge c = -8^\circ$; $N_x = 1.703$, $N_y = 1.705$, $N_z = 1.723$; $2V = 32^\circ$; $r \gg v$, very strong; pleochroic. X, brown-green; Y, green; Z, pale brown. Found with quartz, siderite, and apatite at *Rapid Creek (Cross Cut Creek), Big Fish River, YT, Canada*, associated with lazulite, wardite, vivianite, childrenite, ludlamite, metavivianite, arrojadite, augelite, and brazilianite. HCWS *IMA(abstr.):274(1986)*.

41.9.1.2 Penikisite BaMg₂Al₂(PO₄)₃(OH)₃

Named in 1977 for Gunar Penikis (1936–1979), who discovered the locality and provided the sample for analysis. The Mg end member of the Mg-Fe²⁺ series with kulanite. Bjarebyite group. TRIC P $\bar{1}$. $a = 8.999$, $b = 12.069$, $c = 4.921$, $\alpha = 90^\circ$, $\beta = 100.52^\circ$, $\gamma = 90^\circ$, $Z = 2$, $D = 3.82$. *CM 15:393(1977)*. 29-169: 8.81₆ 4.49₆ 3.09₁₀ 3.03₆ 2.92₈ 2.69₆ 2.68₆ 2.65₇. Similar to and grades into kulanite, blue-green to pale green plates in rosettes showing two cleavages {010}, {110}. DTA/TGA. Nonfluorescent. Biaxial (+); $Y = b$, $Z \wedge c = -6^\circ$ (range 0–19°); $N_x = 1.684$, $N_y = 1.688$, $N_z = 1.705$ (Na); $2V = 56^\circ$; pleochroic; $X \approx Y > Z$; $r \gg v$. X, grass-green; Y, blue-green; Z, pale pink. Found at *Rapid Creek (Cross Cut Creek), Big Fish R., YT, Canada*. HCWS

41.9.1.3 Bjarebyite (Ba,Sr)(Mn²⁺,Fe²⁺,Mg)₂Al₂(PO₄)₃(OH)₃

Named in 1973 for Gunnar Bjareby (1899–1967), Swedish-American artist, naturalist, and amateur mineralogist who collected the sample. Bjarebyite group. The name is applied to the Al end member, in which Mn > Fe, and Ba > Sr of the (Al-Fe³⁺) series with perloffite (41.9.1.4). MON P2₁/m. $a = 8.930$, $b = 12.073$, $c = 4.917$, $\beta = 100.15^\circ$, $Z = 2$, $D = 4.02$ for Fe = Mn.

MR 4:282(1973). Structure: *AM 59:567(1974)*. 29-171: 8.95₁₀ 3.12₈ 3.06₄ 2.94₄ 2.90₅ 2.71₅ 2.68₄ 1.790₄. See also 28-415(calc). Crystals complex spear-shaped up to 3 mm long, showing many forms: {001}, {100}, {010}, {110}, {120}, {111}, {121}, {131}, {141}, {411}, {211}, {021}, {011}. Forms usually pitted and etched and all negative forms missing. Emerald-green with bluish tinge, white streak, subadamantine luster, translucent. Cleavage {010}, {100}, perfect. $H = 4+$. $G = 3.95$. Biaxial (+); $N_x = 1.692$, $N_y = 1.695$, $N_z = 1.710$; $2V \approx 35^\circ$; $r > v$, strong; pleochroic, grayish tan to pale yellow-green. Microprobe analysis shows minor Ca. Found at the *Palermo No. 1 pegmatite, North Groton, NH*, as crystals in cavities between amblygonite-scorzalite and Fe-Mn oxides. Additional associated minerals: augelite, childrenite, siderite, quartz, and palermoite. *HCWS AM 59:873(1974)*.

41.9.1.4 Perloffite $Ba(Mn^{2+}, Fe^{2+})_2Fe_2^{3+}(PO_4)_3(OH)_3$

Named in 1977 for Louis Perloff (b.1907), amateur mineralogist and micro-mount collector, Tryon, NC. Bjarebyite group. The Fe^{3+} analog of bjarebyite (41.9.1.3). *MON P2₁/m*. $a = 9.223$, $b = 12.422$, $c = 4.995$, $\beta = 100.39^\circ$, $Z = 2$, $D = 3.996$. *MR 8:112(1977)*. 29-184: 5.12₃ 4.69₃ 3.17₁₀ 3.11₄ 2.98₅ 2.94₄ 2.73₈ 2.07₇. Spear-shaped crystals showing {001}, {101}, {021}, {131} to 1 mm long. Dark brown to greenish brown to black, greenish-yellow streak, vitreous to subadamantine luster. Cleavage {100}, perfect. $H \approx 5$. Biaxial (-); $X = b$; $Y \wedge c \approx 42^\circ$; $N_x = 1.793$, $N_y = 1.803$, $N_z = 1.808$; $2V = 70-80^\circ$; $r < v$, strong; pleochroic. X,Z, dark greenish brown; Y, light greenish brown. Slowly dissolved by cold 1:1 HCl. Microprobe analyses also show minor Ca, Mg, and Al. Found at *Big Chief pegmatite, Glendale, SD*, as crystals on ludlamite, hureaulite, siderite, and in vugs in ludlamite formed from the hydration of triphylite. *HCWS AM 62:1059(1977)*.

41.9.2.1 Rockbridgeite $Fe^{2+}Fe_4^{3+}(PO_4)_3(OH)_5$

Named in 1949 for the locality. The Fe^{2+} end member of the Fe-Mn²⁺ series with frondelite (41.9.2.2). See also duferenite (42.9.1.2). *ORTH Bbmm*. $a = 13.846$, $b = 16.782$, $c = 5.185$, $Z = 4$, $D = 3.60$. Structure: *AM 55:135(1970)*. Clusters of triple face-sharing octahedra of FeO_6 join through shared edges to form chains parallel to the b axis. These chains are linked to corner-sharing octahedral doublets whose composition can be expressed as $Fe_2(OH)_5O_6 + O$ from PO_4 , which also secure the cluster triplet. 34-150: 3.59₄ 3.44₄ 3.38₄ 3.19₁₀ 3.02₂ 2.42₂ 2.406₂ 1.592₂. See also 22-356. Subparallel plates {010} beveled by {100}, {110}, {001}, with a rounded dome {011}, often form sheafs or botryoidal crusts with fibrous structure. Aggregates often show color banding. Dark to olive-green; if oxidized, turns red-brown; vitreous to dull luster; subtranslucent. Cleavage {100}, excellent; {010}, good; {001}, fair; uneven fracture; brittle. $H = 4\frac{1}{2}$. $G = 3.3-3.49$ depending on Fe/Mn ratio. Biaxial (+); $X = c$; $N_x = 1.873$, $N_y = 1.880$, $N_z = 1.895$ (Rockbridge); $2V$ moderate; $r < v$; $Z > Y > X$; pleochroic. X, pale yellow-brown; Y, bluish green; Z, dark bluish green. Absorption less marked at high Fe^{3+} ;

indices increase with oxidation (Fe^{2+} to Fe^{3+}) and with increase in Fe/Mn ratio. Complete series $\text{Fe}^{2+}\text{-Mn}^{2+}$: rockbridgeite-frondelite. Small substitution of Ca, Mg for (Fe, Mn), Al for Fe^{3+} , As for P. Soluble in HCl but not in HNO_3 or H_2SO_4 . A secondary mineral earlier confused with dufrenite and found as an alteration product of triphylite or other manganese phosphates in pegmatites. Associated minerals: vivianite, strengite, metastrengite, heterosite, and goethite. Found at Palermo No. 1 and Fletcher mines, North Groton, Grafton Co., NH; with limonite at Mullica Hill, NJ; at *South Mt., near Midvale, Rockbridge Co., VA*; at Polk Co., AR; at Jacksonville, Calhoun Co., Indian Mt., Cherokee Co., AL; at Big Chief and Tip Top pegmatites, SD; at Chanteloube, France; at Kreuzberg, Pleystein, and Hagendorf, Bavaria, Germany; at Reaphook Hill, SA, Australia; at Sapucaia Velha(!), and at Lavro do Enio, Galileia, Lavra do Ilha, Taquaral, MG, Brazil. hcws AM 34:541(1949), DII:867.

41.9.2.2 Frondelite $\text{Mn}^{2+}\text{Fe}_4^{3+}(\text{PO}_4)_3(\text{OH})_5$

Named in 1949 for Clifford Frondel (b.1907), mineralogist, Harvard University, Cambridge, MA, and author of Vol. II (1956) and Vol. III (1962), 7th Edition, *Dana's System of Mineralogy*. The Mn analog of rockbridgeite. ORTH Bbmm. $a = 13.810$, $b = 16.968$, $c = 5.182$, $Z = 4$, $D = 3.55$. 35-625: 3.62₄ 3.45₃ 3.38₉ 3.19₁₀ 3.05₂ 2.42₂ 1.979₃ 1.598₂. Similar to rockbridgeite in physical and chemical properties. Biaxial (-); $X = c$; $N_x = 1.869$, $N_y = 1.880$, $N_z = 1.893$ (Sapucaia); 2V moderate; $r > v$; pleochroic. X, pale yellow-brown; Y,Z, orange-brown. Analysis shows Al, minor Ca, Mg. Occurs at Fletcher mine, North Groton, NH, with metastrengite; at Sapucaia Velha, Galileia, MG, Brazil, and localities described for dufrenite. hcws DII:867, SMPM 41:407(1961).

41.9.3.1 Griphite $\text{Mn}_4\text{Ca}_6(\text{Mn}^{2+}, \text{Fe}^{2+}, \text{Mg})\text{Li}_2\text{Al}_8(\text{PO}_4)_{24}(\text{F}, \text{OH})_8$

Named in 1891 from the Greek for *enigma*, in allusion to the chemical composition. iso Pa3. $a = 12.205$, $Z = 4$, $D = 3.65$. Structure: BM 101:543(1978). Structure resembles garnet: two interpenetrating networks one of PO_4 tetrahedra and AlO_6 octahedra that are expressed as the PO_4 tetrahedra alternating with AlO_6 octahedra and CaO_6F_2 cubes. 42-1351: 7.05₁ 3.39₁ 3.05₃ 2.96₂ 2.73₁₀ 2.49₃ 2.27₂ 1.693₁. See also 41-582. Massive, reniform. Yellow, brown, and black; resinous to vitreous luster; translucent; slightly metamict. No cleavage, conchoidal fracture, brittle. $H = 5\frac{1}{2}$. $G = 3.64$. $N_{\text{var}} = 1.63\text{-}1.66$. Readily soluble in acids. Analyses show Na, Li, Al, Mg, Fe^{3+} , H_2O . Found in masses up to 125 kg in granite pegmatite at *Everly mine, Riverton Lode, Harney City, Pennington Co., SD*; at Alberes massif, East Pyrenees, France; at Mt. Ida, NT, Australia. hcws AM 27:452(1942), BM 101:536(1978).

LAZULITE GROUP

The lazulite group are phosphate mineral with the general formula

where

A = Cu, Fe²⁺, Mg

B = Al, Fe³⁺

and the minerals crystallize in the monoclinic system.

The structure [*NJMM:410(1983)*] is made up of polyatomic triplet clusters composed of one AO₆ octahedron sandwiched by two corner-sharing BO₆ octahedra disposed in the *c*-*a* plane. The clusters are connected through the hydroxyls of the BO₆ polyhedra and the oxygens of the tetrahedral PO₄ groups into a compact network.

LAZULITE GROUP

Mineral	Formula	Space Group	<i>a</i>	<i>b</i>	<i>c</i>	β	
Lazulite	MgAl ₂ (PO ₄) ₂ (OH) ₂	<i>P2</i> ₁ / <i>c</i>	7.228	7.278	7.144	120.51	41.10.1.1
Scorzalite	Fe ²⁺ Al ₂ (PO ₄) ₂ (OH) ₂	<i>P2</i> ₁ / <i>n</i>	7.250	7.301	7.155	120.58	41.10.1.2
Hentschelite	CuFe ³⁺ (PO ₄) ₂ (OH) ₂	<i>P2</i> ₁ / <i>n</i>	7.266	7.786	6.984	117.68	41.10.1.3
Barbosalite	Fe ²⁺ Fe ³⁺ (PO ₄) ₂ (OH) ₂	<i>P2</i> ₁ / <i>n</i>	7.397	7.489	7.313	118.52	41.10.1.4

41.10.1.1 Lazulite MgAl₂(PO₄)₂(OH)₂

Named in 1795 from the old German *lazurstein*, blue stone. Lazulite group. The Mg end member in a Mg-Fe²⁺ series with scorzalite. *MON P2*₁/*c*. *a* = 7.228, *b* = 7.278, *c* = 7.144, β = 120.51°, *Z* = 2, *D* = 3.09. Structure: *NJMM:410(1983)*. 34-136: 3.24₁₀ 3.21₉ 3.15₆ 3.08₇ 2.55₄ 1.985₂ 1.572₄ 1.549₃. Crystals acute pyramidal with large {111}, {111}, small {101}, tabular on {111} or {101}; massive compact or granular. Twinning on {100} common, sometimes polysynthetic or lamellar, composition plane {001} or {100} usually shows reentrant angle, rarely on {223} and other planes. Azure-blue, sky-blue, bluish white to bluish green; white streak; vitreous luster; subtranslucent to opaque, occasionally transparent and of gem quality. *H* = 5½-6. *G* = 3.08-3.38. Biaxial (-); $X \wedge c = 9\frac{1}{2}^\circ$; *Y* = *b*; *N*_x = 1.604, *N*_y = 1.626, *N*_z = 1.637; 2*V* = 69.7°; *r* < *v*. Increase in Fe²⁺ increases indices, and birefringence, 2*V* decreases slightly. Slowly soluble in hot acids. Some Mn, Ca, Fe²⁺, Fe³⁺ (substituting for Al) reported in analyses. Occurs in aluminous high-grade metamorphic rocks with quartz as disseminated grains, in quartz veins or dikes in such rocks, in granite pegmatites. Found at Scott mine, ME; at G.E. Smith mine, Newport; Palermo No. 1 mine, North Groton, NH; with corundum at Chubbs Mt. and Chowders Mt., Gaston Co., NC; with kyanite and rutile in quartzite at Graves Mt., Lincoln Co., GA; with andalusite, rutile in garnetiferous quartzite, Markleeville, Alpine Co., and

LAZULITE: $MgAl_2(PO_4)_2(OH)_2$

This *b* axis projection of lazulite shows the intimate connections through the oxygens from the (PO_4) group and octahedrally coordinated cations. There are two $B-(O,OH)_6$ and one $A-(O,OH)_6$ octahedra in this compact structure. Compare this structure with bjarebyite (41.9.1.3).

with andalusite at Champion mine, White Mts., Mono Co.(!), CA; at Blow R. near Mt. Fitton, YT, Canada; with svanbergite at Horrsjöberg near Ny(!), with berlinite at Westana, Sweden; with wagnerite in quartz carbonate veins in clay slates near Werfen, Salzburg(!), Austria, and at Voralpe near Graz, in the Müztal, Styria; near Zermatt, Valais, Switzerland; in quartz veins in lower Triassic quartzite of Tribec, Slovakia, Czech Republic; in quartz veins on Mt. Bity and at Ranomainty SE of Betafo, and Jamalezo, Madagascar; at the Barunda pegmatite, Rwanda; as pseudomorphs with sericite after orthoclase at Real Socavon, Potosi, Bolivia; at Fazeuda Modelo, and in quartz veins with itacolomite at Dattas, MG, Brazil. *ncws DII:908; AM 47:157(1962), 67:610(1982).*

41.10.1.2 Scorzalite $Fe^{2+}Al_2(PO_4)_2(OH)_2$

Named in 1947 for Evaristo Pena Scorza (b.1899), mineralogist, Mineral Survey of Brazil. Lazulite group. The Fe^{2+} end member of the Fe^{2+} -Mg series with lazulite. *MON P2₁/n. a = 7.250, b = 7.301, c = 7.155, β = 120.58°, Z = 2, D = 3.32. Structure: AC 12:695(1959). 35-632: 6.17₂ 4.75₂ 3.25₃ 3.21₁₀ 3.15₅ 3.08₄ 2.55₂ 2.22₂. Physical properties similar to lazulite. Biaxial (-); $N_x = 1.639, N_y = 1.670, N_z = 1.680; 2V = 58.3° (Fe/Mg = 4:1); r < v; Z > Y > X$. Strongly pleochroic. X, colorless; Y, blue; Z, darker blue. High- Fe^{2+} -content samples are rare. Occurrences the same as lazulite and especially*

at Victory pegmatite, Custer Co., SD; *Corrego Frio pegmatite, MG, Brazil*. HCWS DII:908; AM 34:83(1949), 35:1(1950), 67:619(1982).

41.10.1.3 Hentschelite $\text{CuFe}_2^{3+}(\text{PO}_4)_2(\text{OH})_2$

Named in 1987 for Gerhard Hentschel (b.1930), Hessisches Landesamt für Bodenforschung, Wiesbaden, Germany. Lazulite group. MON $P2_1/n$. $a = 7.266$, $b = 7.786$, $c = 6.984$, $\beta = 117.68^\circ$, $Z = 2$, $D = 3.79$. AM 72:404(1987). Structure: AC(C) 43:1855(1987). 40-501: 4.81₅ 3.33₁₀ 3.27₅ 3.06₂ 2.40₂ 2.11₂ 1.669₂ 1.648₂. Disseminated, clusters and drusy crystals to 1 mm, showing {100}, {101}, {011}, {111}; twinned, composition plane {102}. Dark green, light green streak, vitreous luster, translucent. No cleavage, irregular fracture. $H = 3\frac{1}{2}$. Biaxial (+); $Y = b$; $X \approx [101]$; $N_x = 1.843$, $N_y = 1.848$, $N_z = 1.945$ (598 nm); $2V = 15^\circ$; $r \gg v$. Microprobe analysis shows some As, Al, minor Si. Found as replacement mineral in silicified barite veins at *Reichenbach, near Benshien, Hessen, Germany*, with mimetite, beudantite, goethite, and quartz. HCWS MM 52:408(1986).

41.10.1.4 Barbosalite $\text{Fe}^{2+}\text{Fe}_2^{3+}(\text{PO}_4)_2(\text{OH})_2$

Named in 1955 for Aliuzio Licinio de Miranda Barbosa (b.1896), geologist, Escola de Minas, MG, Brazil. Lazulite group. Dimorph of lipscombite. MON $P2_1/n$. $a = 7.397$, $b = 7.489$, $c = 7.313$, $\beta = 118.52^\circ$, $Z = 2$, $D_{(\text{recalc})} = 3.71$. Structure: AC 12:695(1959). 33-668: 4.84₆ 3.36₁₀ 3.31₈ 3.24₆ 3.16₆ 2.61₃ 2.33₄ 1.309₄. Massive, very fine-grained crystalline aggregates. Dark blue-green to black, opaque, appears dark green in thin section. $H = 6$. $G = 3.60$. Biaxial (+); $N_x = 1.77$, $N_y = 1.79$, $N_z = 1.835$; pleochroic. X, Y, dark blue-green; Z, dark olive-green. Slightly soluble in hot HCl, not soluble in 1:10 HNO_3 , H_2SO_4 ; attacked by Clerici solution. Microprobe analysis shows Mn, Mg and very minor Na, Ti. Found at Palermo No. 1 mine, North Groton, NH; at Williams property, AL; at Bull Moose pegmatite, SD; at Thackaringa pegmatite, 40 km SW of Broken Hill, NSW, Australia, where barbosalite replaces manganese oxides and is associated with wolfeite, arsenopyrite, scorodite, and quartz; at *Sapucaia pegmatite, Galileia, MG, Brazil*, with heterosite, triphylite, hureaulite, and tavorite. HCWS AM 40:952(1955), MM 43:505(1979).

41.10.2.1 Lipscombite $(\text{Fe}^{2+}, \square)\text{Fe}_2^{3+}(\text{PO}_4)_2(\text{OH})_2$

Named in 1953 for William Nunn Lipscomb (b.1909), mineralogist, University of Minnesota, MN. Dimorph of barbosalite (41.10.1.4). TET $P4_32_12$. $a = 7.310$, $c = 13.212$, $Z = 4$, $D_{\text{syn}} = 3.68$. Structure: AM 74:456(1989) (synthetic). Two disordered partially filled Fe^{2+} positions, and one Fe^{3+} position, all octahedrally coordinated $[\text{Fe}(\text{O}, \text{OH})_6]$ with O from PO_4 tetrahedra and (OH) groups. Octahedra form chains parallel to [110]. $PD(\text{syn})$: 4.82₅ 3.35₁₀ 3.30₅ 3.23₅ 3.15₄ 2.61₂ 2.32₃ 2.28₂. See also 14-569(syn), 14-310 (manganooan, Mn/Fe = 2:1; $P4_12_12$, $a = 7.40$, $c = 12.81$, $G = 3.66$). Massive. Olive-green to black, splendent. $G = 3.8$. DTA. $N = 1.67-1.80$. Manganooan (Mn^{2+}) sample

also contains Cu, Pb, Mg, Zn, Be, and Ni. Synthesized. Tetragonal-monoclinic phase change between 110 and 290°. Found at Williams property, AL; manganoan at *Sepucaia pegmatite, Galileia, MG, Brazil*, in vugs with frondelite, leucophosphite, and metastrengite. *HCWS AM 38:612(1953), 47:353(1962)*.

41.10.3.1 Jagowerite $\text{BaAl}_2(\text{PO}_4)_2(\text{OH})_2$

Named in 1973 for John Arthur Gower (1921–1972), mineralogist, University of British Columbia, Canada. TRIC $P1$ or $P1$. $a = 6.049$, $b = 6.964$, $c = 4.971$, $\alpha = 116.51^\circ$, $\beta = 86.06^\circ$, $\gamma = 112.59^\circ$, $Z = 1$, $D = 4.05$. Structure: *AM 59:291(1973)*. A network of PO_4 tetrahedra that share common corners with pairs of $\text{Al}(\text{O}, \text{OH})_6$ octahedra. *35-636: 5.53_4 3.26_6 3.14_5 3.00_{10} 2.94_3 2.91_3 2.17_3 2.02_2*. See also *26-136, 28-123(calc)*. Crystalline masses up to 2.5 cm. Light green, vitreous luster, translucent. Cleavage $\{100\}$, $\{011\}$, good; $\{021\}$, fair. $H = 4\frac{1}{2}$. $G = 4.01$. Fluoresces greenish white in LWUV. IR. Biaxial (+); $N_x = 1.672$, $N_y = 1.6923$, $N_z = 1.710$; $2V \approx 80^\circ$. Insoluble in HCl. Analyses show Fe^{3+} , S, and < 1000 ppm of Ca, Cr, Ti, V, Ta, Mn, Cu, Be, Sr, Si. Found *16 miles N of Hess River, west-central YT, Canada*. *HCWS CM 12:135(1973), AM 60:945(1975)*.

41.10.4.1 Goedkenite $(\text{Sr}, \text{Ca})_2\text{Al}(\text{PO}_4)_2(\text{OH})$

Named in 1975 for Virgil Linus Goedken (b.1940), chemist, University of Chicago, IL. Brackebuschite group. See (40.2.8.1). Close to the Sr end member of a Sr–Ca series with bearthite (41.10.4.2). MON $P2_1/m$. $a = 8.45$, $b = 5.74$, $c = 7.26$, $\beta = 113.7^\circ$, $Z = 2$, $D = 3.83$. *AM 60:957(1975)*. *29-383: 7.76_5 4.33_4 3.42_4 3.06_{10} 2.84_6 2.81_4 2.59_7 1.609_5*. Lozenge-shaped to spear-shaped crystals up to 1 mm occurring in parallel growth with $\{001\}$ bent to feathery tips, forms: $\{001\}$, $\{011\}$, $\{012\}$, $\{101\}$, $\{111\}$; tabular parallel to $\{001\}$, elongated parallel to $[100]$. Colorless to pale yellow, subadamantine luster, translucent. $H = 5$. Biaxial (+); X parallel to b ; $N_x = 1.669$, $N_y = 1.673$, $N_z = 1.692$; $2V = 45\text{--}50^\circ$. Microprobe analysis shows Sr > Ca, minor Mg, Mn, Fe, Na. Secondary mineral found at *southern wall of Palermo No. 1 pegmatite, North Groton, NH*, replacement of goyazite, palermoite, and associated with apatite, whitlockite, quartz, siderite, bjarebyite, and childrenite. *HCWS*

41.10.4.2 Bearthite $\text{Ca}_2\text{Al}(\text{PO}_4)_2(\text{OH})$

Named in 1993 for P. Bearth (1902–1989), Swiss petrologist. Brackebuschite group. See (40.2.8.1). MON $P2_1/m$. $a = 7.231$, $b = 5.734$, $c = 8.263$, $\beta = 112.57^\circ$, $Z = 2$, $D = 3.25$. Structure: *SMPM 73:1(1993)*. *PD: 4.58_2 3.05_{10} 2.87_6 2.75_3 2.63_2 2.57_4 2.44_2*. Aggregates up to 1 mm in size, consisting of flat prismatic crystals and smaller anhedral grains. Yellowish, white streak, transparent. Poor prismatic cleavage, uneven fracture. $H < 5$. Biaxial (+); X parallel to b ; $N_x = 1.662$, $N_y = 1.671$, $N_z = 1.696$; $2V = 65^\circ$; $r < v$. Microprobe analysis: Sr, Mg, Fe^{2+} , Ce, La, Si, S, F, Cl. Soluble in HCl. Synthesized.

Found in the high-pressure terranes of alpine metamorphism corroded by lazulite in concordant quartz segregations of the gneiss and schist at *Monte Rosa massif, Zermatt Valley, Switzerland*; in pyrope-phengite quartzite and in coesite-bearing metapelite in *Dora Maira massif, western Alps, Italy*. HCWS *AM 78:1314(1993)*.

41.10.4.3 Gamagarite $\text{Ba}_2(\text{Fe}^{3+}, \text{Mn}^{3+})(\text{VO}_4)_2(\text{OH})$

Named in 1943 for a ridge of hills adjacent the locality. Isostructural with brackebushite (40.2.8.1.) but contains oxidized cations: Fe^{3+} and Mn^{3+} . See also goedkenite, 41.10.4.1, bearthite, 41.10.4.2, and tsumebite, 43.4.2.1. *MON P2₁/m*. $a = 9.121$ $b = 6.142$ $c = 7.838$ $\beta = 112.88^\circ$ $Z = 2$ $D = 4.71$ (Italy). Structure: *NJMM 295 (1987)*. Chains of $(\text{Fe}, \text{Mn})\text{O}_6$ or O_8 polyhedra parallel to [010] are connected by two non-equivalent tetrahedral groups $\text{VO}_4(2)$ and $\text{VO}_4(1)$ into a framework that includes two distinct and irregular polyhedra: $\text{Ba}(\text{O}, \text{OH})_8$ and $\text{Ba}(\text{O}, \text{OH})_{11}$. $41-1413$ 3.71_2 3.30_{10} 3.07_3 3.04_5 2.80_5 2.34_3 2.16_2 1.65_{12} . Crystals prismatic, needles up to a cm long, flattened {001}. Dark brown, nearly black, streak red-brown, adamantine. Cleavages {001}. {100} distinct, {101} indistinct, brittle. Magnetic. $H = 4\frac{1}{2} - 5$ G = 4.62. Biaxial (+); $N_x 2.106$, $N_y 2.040$, $N_z 2.130$; $x \wedge c = 43^\circ$; $y = b$, elongation $2V = 46 - 62^\circ$, $r > v$ strong. Pleochroic $x = \text{red brown}$, $y = \text{very deep red-brown}$, $z = \text{light salmon buff}$. Absorption $y > x > z$. Minute opaque inclusions of hematite, sitaparite (S. Africa). Analysis: 48.3% BaO, 3.60% SrO, 7.80% Fe_2O_3 , 6.11% Mn_2O_3 , 29.05% V_2O_5 , 3.47% $\text{As}_{20}5$, H_2O by difference 1.58% (Italy). IR suggests a strong hydrogen-bonded OH, which is probably the dominant hydrogen species in this mineral, not an acid vanadate *AM 60:803 (1984)*. Found associated with sitaparite, diaspore, at *Gloucester farm, Postmasburg dist., near Gamagara Ridge, Cape Prov., South Africa*; at *Molinello, Val Graveglia, N. Appennines, E. Liguria, Italy AM 28:329 (1943)*. HCWS

41.10.5.1 Melonjosephite $\text{CaFe}^{2+}\text{Fe}^{3+}(\text{PO}_4)_2(\text{OH})$

Named in 1973 for Joseph Melon, mineralogist, University of Liege, Belgium. *ORTH Pbam*. $a = 9.542$, $b = 10.834$, $c = 6.374$, $Z = 4$, $D = 3.615$. Structure: *AM 62:60(1977)*. $25-1454$: 5.42_9 3.19_3 3.05_{10} 2.91_4 2.71_9 2.62_6 2.38_3 2.19_4 . Fibrous masses. Dark green to black, brilliant to resinous luster, translucent. Splintery cleavage along fibers, transverse imperfect; brittle. $H \approx 5$. IR. Biaxial (-); $XYZ = cab$; $N_x = 1.720$, $N_y = 1.770$, $N_z = 1.800$; $2V = 80-85^\circ$; strong dispersion; pleochroic. X, deep brown; Y, greenish brown; Z, yellow to greenish yellow. Readily dissolved by HCl. Analyses show Al, Mn, Mg, Na, Li, and traces of Pb, Mo, Ni. Found in the *Angarf-South pegmatite, Morocco*, in the zone surrounding triphylite. HCWS *BM 96:135(1973)*, *AM 60:946(1975)*.

41.10.6.1 Carminite $\text{PbFe}_2^{3+}(\text{AsO}_4)_2(\text{OH})_2$

Named in 1850 for the color. *ORTH Amaa*. $a = 16.595$, $b = 7.580$, $c = 12.295$, $Z = 8$, $D = 5.46$. *AM 44:663(1959)*. Structure: *AM 48:1(1963)*. $39-1355$: 4.58_4 3.52_5 3.23_{10} 3.04_4 2.95_5 2.72_4 2.55_{10} 1.805_3 . See also 12-278. Lathlike crystals,

flattened on {010}, elongated [001]; tufted or satiny aggregates of fine needles, massive with radiating structure; radially fibrous aggregates. Carmine-red to tile-red, reddish brown; reddish-yellow streak; vitreous luster; translucent. Cleavage {110}, distinct; brittle. $H = 3\frac{1}{2}$. $G = 4.10$ (Mapimi). Biaxial (+); $XYZ = cab$; $N_x = 2.070$, $N_y = 2.070$, $N_z = 2.080$; 2V medium; $r < v$, strong; pleochroic: X, pale yellowish red; Y, Z, dark carmine-red. Slowly soluble in HCl with separation of $PbCl_2$, completely soluble in HNO_3 . Found in the United States at Buckwheat quarry, Franklin, Sussex Co., NJ; at Eureka, NV, and Tintic district, UT; at Hingston Down Consols mine, Calstock, Cornwall, England, with scorodite, mimetite, and pharmacosiderite; at Mapimi, DUR, Mexico, with scorodite, dussertite, arsenosiderite, anglesite, and cerussite; at *Luise iron mine, Horhausen, Rhine Prov., Germany*, with beudantite and at Ems, Hesse-Nassau; at Wyloo, Ashburton district, WA, Australia; at Tsumeb, Namibia. *HCWS DII:912*.

41.10.7.1 Mounanaite $PbFe_2^{2+}(VO_4)_2(OH)_2$

Named in 1969 for the locality. TRIC P1. $a = 5.55$, $b = 7.66$, $c = 5.56$, $\alpha = 111.02^\circ$, $\beta = 112.12^\circ$, $\gamma = 94.15^\circ$, $Z = 1$, $D = 4.89$. *BM 92:196(1969)*. 22-657: 4.66₁₀ 4.56₉ 3.26₈ 2.82₈ 2.77₈ 2.60₅ 2.32₅ 1.711₆. Crystals elongated on c , tabular on [010], common forms {010}, {100}, {110}, {011}, {111}, {121}, {021}, {011}, {021}. Most crystals twinned on [001], or {111}. Reddish brown, translucent. $G = 4.85$. DTA. Biaxial; $N > 2.09$; extinction on {010} = 38° to c ; pleochroic, brown-red to brown-yellow at 90° in this orientation. Synthesized. Found at *Mounana mine, Franceville, Haute Ogooué, Gabon*, associated with goethite, francevillite, and curienite. *HCWS AM 54:1738(1969)*.

41.10.8.1 Samuelsonite $(Ca,Ba)Fe_2^{2+}Mn_2^{2+}Ca_8Al_2(PO_4)_{10}(OH)_2$

Named in 1975 for Peter B. Samuelson (b.1941), prospector, Rumney, NH. MON C2/m. $a = 18.495$, $b = 6.805$, $c = 14.000$, $\beta = 112.75^\circ$, $Z = 2$, $D = 3.355$. *AM 60:957(1975)*, Structure: *AM 62:229(1977)*. The unit $[Ca_4(PO_4)_{12}]$ forms double columns (similar units are found in the apatite structure) which are linked with chains of $[Al(OH)_2O_4]$ and cation- O_6 octahedra. 29-154: 3.39₅ 3.25₄ 3.06₁₀ 3.03₆ 2.73₅ 2.66₇ 2.56₄ 1.706₆. Crystals lamellar, bladed, lath-shaped or striated parallel to [010], prisms up to 4 cm long and 1 cm in width showing {001}, {100}, {101}, {101}, {211}, {112} with etched terminations. Colorless to pale pink stained yellow and yellow-brown, subadamantine luster. $H = 5+$. $G = 2.353$. Biaxial (+); $Z \wedge c = 22^\circ$; $N_x = 1.645$, $N_y = 1.650$, $N_z = 1.655$; 2V large. Trace quantities of Cu, Ti, Ga detected on spectrographic analysis. Found at *Palermo No. 1 mine, North Groton, NH*, embedded in black ferric and manganic oxides and in whitlockite-carbonate apatite rock; in the Buranga pegmatite, Rwanda. *HCWS*

41.10.9.1 Preisingerite $Bi_3O(OH)(AsO_4)_2$

Named in 1981 for Anton Preisinger (b.1925), mineralogist, Department of Crystallography and Structural Chemistry, University of Technology,

Vienna. TRIC $P\bar{1}$. $a = 9.993$, $b = 7.404$, $c = 6.937$, $\alpha = 87.82^\circ$, $\beta = 115.01^\circ$, $\gamma = 111.01^\circ$, $Z = 2$, $D = 7.24$. Structure: *AM 67:833(1982)*. $\text{Bi}_5\text{O}_2(\text{OH})_2$ groups link into a framework with AsO_4 tetrahedra. There are three different Bi sites. 35-543: 4.52₄ 3.28₁₀ 3.26₁₀ 3.19₈ 3.09₈ 3.02₄ 2.61₂ 1.967₃. Porous aggregates of tiny (up to 0.02 mm) tabular crystals, pulverulent masses. White to grayish white, white streak, subadamantine luster, translucent. Indistinct cleavage, conchoidal fracture, brittle. $H = 3-4$. $G \approx 6$. TGA (decomposes $\approx 400^\circ$). Biaxial (+); $N_x = 2.130$, $N_y = 2.16$ (calc), $N_z = 2.195$ (589 nm); $2V \approx 90^\circ$. Some substitutions of Pb and P. Found in weathering zones in the Mammoth mine, Tintic district, UT; Tazna, Bolivia; and at *San Francisco de Los Andes and Cerro Negro de la Aguadita, Calingasta, San Juan Prov., Argentina*, with rooseveltite. HCWS *FM 59:15(1981)*; *AM 28:536(1943)*, *67:416(1982)*.

41.10.9.2 Schumacherite $\text{Bi}_3\text{O}(\text{OH})[(\text{V},\text{P},\text{As})\text{O}_4]_2$

Named in 1983 for Friedrich Schumacher, professor, University of Freiberg and Bonn, Germany. See also preisingerite (41.10.9.1). TRIC $P\bar{1}$. $a = 10.05$, $b = 7.46$, $c = 6.90$, $\alpha = 87.7^\circ$, $\beta = 115.3^\circ$, $\gamma = 111.5^\circ$, $Z = 2$, $D = 6.90$. *TMPM 31:165(1983)*. 35-587: 6.21₄ 4.57₆ 4.13₄ 3.28₁₀ 3.19₈ 3.09₈ 3.02₄ 1.976₅. Crystals to 0.1 mm, tabular {010} showing {110}, {101}; crusts. Yellow to yellow-brown, adamantine luster, translucent. No cleavage, conchoidal fracture. $H \approx 3$. Biaxial (+); $X' \wedge c \approx 22^\circ$, $Z' \wedge a \approx 15^\circ$; $N_x > 2.20$, $N_z < 2.30-2.42$; $2V \approx 90^\circ$; optic plane approximately parallel to {111}; extinction on (010). Microprobe analyses show As, P with V/As/P highly variable, probably part of a series with preisingerite. Crystal structure change $\approx 800^\circ$, similar to preisingerite. Found as crusts on quartz-rich vein specimens from *Schneeberg, Germany*. HCWS *AM 70:438(1985)*.

41.10.10.1 Petitjohnite $\text{Bi}_3\text{O}(\text{OH})(\text{PO}_4)_2$

Named in 1993 for K. Petitjohn, a mineral collector, Odenwald, Germany, who found the mineral. The P analog of preisingerite (As) and schumacherite (V). TRIC $P\bar{1}$. $a = 9.789$, $b = 7.250$, $c = 6.866$, $\alpha = 88.28^\circ$, $\beta = 115.27^\circ$, $\gamma = 110.70^\circ$, $Z = 2$, $D = 6.99$. *NJMM:487(1993)*. *PD*: 4.44₅ 3.25₉ 3.19₁₀ 3.14₁₀ 3.03₈ 2.95₅. Crusts and small spherical aggregates with dominant forms {010}, {100}, {001}, and {101}; rotation twins on [010] with preisingerite. White to dark brown (V-bearing samples are yellow), vitreous to adamantine luster. $H = 4\frac{1}{2}$. Biaxial (+); $N_x = 2.06$, $N_z = 2.13$; $2V = 75^\circ$; $r > v$. Forms complete solid solution with preisingerite and schumacherite. Found in association with bismuthite, mixite, reichenbachite, pyromorphite, and malachite in silicified barite veins at *Gaderheim and Reichenbach, near Bensheim, Odenwald, Hesse, Germany*, and on the mine dumps on the Pucher-Schacht, Saxony. HCWS

41.10.11.1 Drugmanite $\text{Pb}_2(\text{Fe}^{3+}, \text{Al})\text{H}(\text{PO}_4)_2(\text{OH})_2$

Named in 1979 for Julien Drugman (1875–1950), Belgian mineralogist. *MON P2₁/a*. $a = 11.111$, $b = 7.986$, $c = 4.643$, $\beta = 90.41^\circ$, $Z = 2$, $D = 5.55$. *BM 111:431(1988)*. Structurally related to the silicates: gadolinite group. *33-732*: 4.63₉ 3.75₁₀ 3.35₈ 3.25₈ 2.91₉ 2.71₇ 2.39₆ 2.13₆. Platy crystals to 0.2 mm in aggregates, showing {001}, {110}. Colorless, transparent. $H < 6$. $G = 4.10$. $N_{\text{mean}} = 1.87$; $2V = 33^\circ$; X approximately perpendicular to {001}; optic axis plane = (010); $r < v$, strong. Occurs in vugs in silicified limestone at *Richelle, Belgium*. *HCWS AM 65:809(1980)*.

41.11.1.1 Trolleite $\text{Al}_4(\text{PO}_4)_3(\text{OH})_3$

Named in 1868 for Hans Gabriel Trolle-Wachtmeister (1782–1871), Swedish chemist. *MON I2/a*. $a = 18.894$, $b = 7.161$, $c = 7.162$, $\beta = 99.99^\circ$, $Z = 4$, $D = 3.08$. Structure: *AM 59:974(1974)*. Structurally similar to lazulite (41.10.1.1). *26-1009*: 6.67₄ 3.34₄ 3.21₁₀ 3.10₉ 3.08₅ 2.52₅ 1.983₄ 1.547₃. Polycrystalline nodules, lenticular masses and blebs, massive, lamellar. Pale green, vitreous luster, translucent. Indistinct cleavage in two directions at an angle of 110.9° , even to conchoidal fracture. $H = 5\frac{1}{2}$ –6. $G = 3.10$. Biaxial with optic plane parallel to best of cleavages; $2V \approx 80^\circ$; $r > v$, weak. Synthesized. High-pressure studies show trolleite relationship to berlinite (38.4.2.1), variscite (40.4.1.1), and metavariscite (40.4.3.1). Found at White Mts., Mono Co., CA; in polycrystalline nodules in kyanite-bearing specularite–muscovite–quartzite with berlinite, attacolite, pyrophyllite, augelite, and lazulite, at *Westana, Kristianstad, Sweden*. *HCWS DII:911, AM 64:1175(1979)*.

41.11.2.1 Jamesite $\text{Pb}_2\text{Zn}_2\text{Fe}_5^{2+}(\text{AsO}_4)_5\text{O}_4$

Named in 1981 for Christopher James, mining engineer, Tsumeb, Namibia. *TRIC P1*. $a = 5.622$, $b = 9.593$, $c = 10.279$, $\alpha = 109.80^\circ$, $\beta = 90.54^\circ$, $\gamma = 97.69^\circ$, $Z = 1$, $D = 5.10$. *CE 40:105(1981)*. *35-509*: 9.67₈ 4.70₈ 3.40₁₀ 3.26₈ 3.04₉ 2.92₆ 2.68₅ 2.04₆. Massive, disseminated. Reddish brown, subadamantine luster. $H \approx 3$. Biaxial (–); $Y \wedge a$ on (001) $\approx 5^\circ$; $Y \wedge a$ on (010) = 15° ; $N_x = 1.960$, $N_y = 1.995$, $N_z = 2.020$; $2V \approx 75^\circ$; $r > v$; strongly pleochroic: X, Y , pale brown; Z , deep reddish brown. Found in the oxidized zone at *Tsumeb, Namibia*. *HCWS AM 66:1275(1981)*.

41.11.3.1 Fingerite $\text{Cu}_{11}(\text{VO}_4)_6\text{O}_2$

Named in 1985 for Larry W. Finger (b.1940), mineralogist, Geophysical Laboratory, Carnegie Institute of Washington, DC. *TRIC P1*. $a = 8.158$, $b = 8.269$, $c = 8.044$, $\alpha = 107.14^\circ$, $\beta = 91.39^\circ$, $\gamma = 106.44^\circ$, $Z = 1$, $D = 4.776$. *AM 70:193(1985)*, Structure: *AM 70:197(1985)*. CuO_6 octahedrally coordinated forms a sheet with holes cross-linked by VO_4 tetrahedra and CuO_5 bipyramids. Cu sites show Jahn–Teller effect. *38-378*: 6.48₁₀ 4.74₅ 3.89₆ 3.62₆ 3.29₆ 3.04₈ 2.82₇ 2.03₇. See also *36-431*. Crystals up to 150 μm . Black, dark reddish-brown streak, metallic luster, opaque. No cleavage. Nonfluorescent. $N_{\text{mean calc}} = 2.124$. In RL in air, gray, nonpleochroic, two extinctions on

complete rotation of stage; in blue-filtered white light = 21° . Found as a fumarolic deposit at *Izalco volcano, El Salvador*, with thenardite and euchlorine. hcws

41.11.4.1 Nefedovite $\text{Na}_5\text{Ca}_4(\text{PO}_4)_4\text{F}$

Named in 1983 for E. I. Nefedov (1910–1976), Russian scientist. TRIC $P1$ or $P1$. $a = 5.401$, $b = 11.647$, $c = 16.484$, $\alpha = 134.90^\circ$, $\beta = 90.04^\circ$, $\gamma = 89.96^\circ$, $Z = 2$, $D = 3.05$. *ZVMO 112:479(1983)*. Structure: *SPD 29:700(1984)*. Pseudotetragonal: $a = 11.65$, $c = 5.40$. *37-422: 5.83_4 3.73_8 2.77_{10} 2.70_7 2.51_8 2.29_8 2.14_4 1.877_6*. Irregular grains 0.01- to 0.5-mm form aggregates to 5 mm. Colorless, vitreous luster, transparent. Conchoidal fracture. $H \approx 4\frac{1}{2}$. $G = 3.01$. Uniaxial (+); $N_O = 1.571$, $N_E = 1.590$. Insoluble in H_2O , dissolves at room temperature in 1:10 HCl with no residue. Microprobe analysis shows minor K. Found with nacaphite, adularia, alkali amphibole, and titanite in pegmatitic segregations in agpaitic nepheline syenites of the *Khibinski massif, Kola Penin., Russia*. hcws *AM 69:812(1984)*.

41.11.5.1 Atelestite $\text{Bi}_8(\text{AsO}_4)_3(\text{OH})_5\text{O}_5$

Named in 1832 from the Greek *incomplete*, presumably because its composition was unknown when first described. MON $P2_1/a$. $a = 10.88$, $b = 7.42$, $c = 6.98$, $\beta = 107.13^\circ$, $Z = 1$, $D = 6.05$. *CM 7:547(1963)*. *15-735: 6.62_2 4.23_2 3.24_{10} 3.12_4 2.73_3 2.53_2 2.20_2 2.12_2*. Minute (to 1-mm) crystals, tabular on {100}, showing {100}, {101}, {101}, {313}; the last rounded, other faces smooth and brilliant; spherical or mammillary crystalline aggregates smooth on the surface. Sulfur-yellow to yellowish green or wax-yellow, resinous to adamantine luster, transparent to translucent. $H = 4\frac{1}{2}$ –5. $G = 6.82$. Biaxial (+); $N_x = 2.14$, $N_y = 2.15$, $N_z = 2.18$ (Na) (Neuhilfe); $2V = 44^\circ$; $r < v$, strong. Easily soluble in HCl, with difficulty in HNO_3 . Found with bismutite, eulytite, and quartz at *Neuhilfe mine, Schneeberg, Germany*, and at *Neustadt*, where associated with walpurgite, torbernite, and bismutite. hcws *DII:792*.

Hydrated Phosphates, Arsenates, and Vanadates Containing Hydroxyl or Halogen

42.1.1.1 Liskeardite $(\text{Al,Fe}^{3+})_3(\text{AsO}_4)(\text{OH})_6 \cdot 5\text{H}_2\text{O}$

Named in 1878 for the locality. Probably ORTH. 11-146; 17.6₁₀ 12.2₆ 8.65₈ 7.85₆ 7.44₆ 4.25₄ 3.33₁₀ 2.37₆. Massive, thin crusts with radial fibrous structure. White to greenish, bluish, brownish white. Cleavage parallel to elongation. Soft. G = 3.10. Biaxial (+); $N_x = 1.661$, $N_y = 1.675$, $N_z = 1.689$; $2V \approx 90^\circ$. Found coating scorodite, arsenopyrite, chalcopyrite, pyrite, and quartz at *Liskeard, Cornwall, England*. Similar(?) mineral from Cap Garrone, Hyeres, Var, France, HCWS *DII:924*, *BM 75:71(1952)*.

42.1.2.1 Evansite $\text{Al}_3(\text{PO}_4)(\text{OH})_6 \cdot 6\text{H}_2\text{O}$

Named in 1864 for Brooke Evans (1797-1862), mining geologist, Birmingham, England, who brought the specimens from Romania in 1855. Massive, opaline, reniform coatings, sometimes showing concentric, colloform structure; stalactitic. Colorless to milky white, tinged with blue, green-yellow; white streak; vitreous to resinous, waxy luster; transparent to translucent. $H = 3-4$. $G = 1.8-2.2$. $N_{av} = 1.485$ (Sirk). Easily soluble in acids. Possibly amorphous. A secondary mineral found with "limonite" and allophane. Occurs at Columbiana, and Coalville, Coosa coal field, AL; at Goldberg, Custer Co., ID; in fissures in shale at Yoredale Rocks, Macclesfield, East Cheshire, England; at Teis near Vigo, Spain; at Epernay, Marne, France; in graphite deposit at Gross-Tresny, Moravia, at Litosice and Nizna-Slava, Bohemia, Czech Republic; with variscite at Vashegy, Also-Sajo(!), Verespatak, and Offenbach, Hungary; at *Mt. Zeleznik, Sirk, Com. Gomor, Slovakia*; in graphitic gneiss in the Vatoinandry district, eastern Madagascar; at Mt. Zeehan, TAS, Australia, HCWS *DII:923*.

42.2.1.1 Liroconite $\text{Cu}_2^+\text{Al}(\text{AsO}_4)(\text{OH})_4 \cdot 4\text{H}_2\text{O}$

Named in 1825 from the Greek for *pale* and *powder*, in allusion to the color of the streak. MON *I2/a*. $a = 12.664$, $b = 7.563$, $c = 9.914$, $\beta = 91.32^\circ$, $Z = 4$, $D = 3.04$. Structure: *AC(C) 49:916(1991)*. 12-526; 6.52₁₀ 6.03₈ 3.95₁ 3.91₂ 3.01₅ 2.79₂ 2.70₃ 2.21₂. Crystals thin or lenticular [001] with flat octahedral

appearance showing {001}, {010}, {100}, {110}, {011} with striations parallel to prism face edges. Sky-blue to green, vitreous luster, transparent to translucent. Cleavage {110}, {011}, indistinct; uneven to conchoidal fracture. $H = 2-2\frac{1}{2}$, $G = 2.9$. Biaxial (-); $Y = b$; $Z \wedge a = 25^\circ$; $N_x = 1.612$, $N_y = 1.652$, $N_z = 1.675$; $2V = 72^\circ$; $r < v$; nonpleochroic. Soluble in acids. P substitutes for As up to 1:4. Found in oxidized zones of copper deposits: at Cerro Gordo mine, Inyo Co., CA, with linarite and caldonite; at *Wheal Gorland* with cornubite and cornwallite, at other Redruth and St. Day areas, *Cornwall*, and in Devonshire, *England*. *HCWS DII:921, AM 36:484(1951)*.

42.2.2.1 Ranunculite $\text{HAl}(\text{UO}_2)(\text{PO}_4)(\text{OH})_3 \cdot 4\text{H}_2\text{O}$

Named in 1979 for the color (*ranunculus*, buttercup). *MON* (pseudo-ORTH) Space group unknown. $a = 11.1$, $b = 17.7$, $c = 18.0$, $\beta \approx 90^\circ$, $Z = 14$, $D = 3.39$. *MM 43:321(1979)*. $33-972$: 9.00_{10} 4.70_5 4.45_3 3.53_2 3.34_2 3.13_8 2.98_4 1.850_4 . Nodules up to 1 mm in diameter on flexible plates flattened on [010], often having rounded outline; botryoidal crusts. Gold-yellow to canary-yellow. Cleavage parallel to [001], [100] irregular. $H = 3$. $G = 3.4$. DTA. Nonfluorescent. Biaxial (-); $N_x = 1.643$, $N_y = 1.664$, $N_z = 1.670$; $2V_{\text{calc}} = 56^\circ$; extinction 20° to elongation of plates; strongly pleochroic. X, Z, pale green-yellow; Y, yellow. Slowly soluble in 1:1 HNO_3 , not in HCl. Found in the U-rich portions of the pegmatite at *Kobokobo, Kivu, Zaire*, with meta-autunite, phosphuranylite, and other aluminum-uranyl phosphates, *HCWS AM 65:407(1980)*, *BSBG 86:183(1977)*.

42.2.3.1 Veszelyite $(\text{Cu}^{2+}\text{Zn})_3(\text{PO}_4)(\text{OH})_3 \cdot 2\text{H}_2\text{O}$

Named in 1874 for A. Veszelyi (1820–1888), Hungarian mining engineer, who discovered the mineral. *MON* $P2_1/c$. $a = 9.828$, $b = 10.224$, $c = 7.532$, $\beta = 102.18^\circ$, $Z = 4$, $D = 3.42$. *BM 79:219(1956)*, Structure: *AM 59:573(1974)*. $12-525$: 7.29_3 6.96_4 4.49_2 3.64_{10} 3.48_3 2.96_3 2.77_3 2.48_3 . Short prismatic [001] and thick tabular {100}; equant or octahedral with large {100}, {011}; granular aggregates of indistinct crystals. Greenish blue to dark blue, vitreous luster, translucent. Cleavage {001}, {110}. $G = 3.4$. Biaxial (+); $Y = b$; $Z \wedge c = -35^\circ$; $N_x = 1.618$, $N_y = 1.622$, $N_z = 1.658$; $2V = 38.5^\circ$; $r < v$, weak to strong; pleochroic: X, greenish blue; Z, blue. Soluble in acids. Found with the secondary copper minerals. Occurs at Black Pine mine(!), Philipsburg, MT; at *Moravicza (Vasko) in the Banat, Romania* and at Ocna de Fier, Caras Severia; at Arakawa mine, Ugo Prov., Japan; at Broken Hill Mine, Zambia; at Kipushi, Shaba, Zaire. *HCWS DII:916*.

42.2.4.1 Kipushite $(\text{Cu}^{2+}, \text{Zn})_5\text{Zn}(\text{PO}_4)_2(\text{OH})_6 \cdot \text{H}_2\text{O}$

Named in 1985 for the locality. The P end member in the P–As series with philipsburgite (42.2.4.2). *MON* $P2_1/c$. $a = 12.197$, $b = 9.156$, $c = 10.667$, $\beta = 96.77^\circ$, $Z = 4$, $D = 3.904$. Structure: *CM 23:35(1985)*. $38-375$: 12.2_5 6.06_4 4.03_{10} 3.39_5 2.97_6 2.65_4 2.55_9 1.531_6 . Prismatic crystals, elongated aggregates to 3 mm showing {111}, {102}, {012}, {111}. Emerald-green, vitreous

luster, transparent to translucent. No distinct cleavages, uneven fracture. $H \approx 4$. $G = 3.8$. TGA. Biaxial (-); $N_x = 1.693$, $N_y = 1.738$, $N_z = 1.740$; $2V_{\text{calc}} = 23^\circ$; pleochroic: X, colorless; Y, blue; Z, bright blue. Cu/Zn varies between 2.6:1 and 1.1:1 on different grains. Found in the oxidation zone of the *Kipushi deposit, Shaba, Zaire*, with pseudomalachite, malachite, hemimorphite, pyromorphite, veszelyite, vauquelinite, libethenite, quartz, iron oxides. *HCWS AM 71:228(1986)*.

42.2.4.2 Philipsburgite $(\text{Cu}^{2+}, \text{Zn})_6(\text{AsO}_4, \text{PO}_4)_2(\text{OH})_6 \cdot \text{H}_2\text{O}$

Named in 1985 for the locality. The As analog of kipushite (42.2.4.1). *MON P2₁/c*. $a = 12.33$, $b = 9.20$, $c = 10.69$, $\beta = 96.92^\circ$, $Z = 4$, $D = 4.04$. *CM 23:255(1985)*. 38-384: 12.2₈ 6.21₄ 4.29₄ 4.05₉ 3.41₅ 2.67₆ 2.56₁₀ 1.534₆. Crystals are elongate on {010} curved with chisel-like terminations, composite faces {100} dominant; microscopic spherules with crystal terminations providing rough exterior; as druses, coatings to 0.5 mm thick. Bright emerald-green, light green streak, vitreous luster, transparent to opaque. No discernible cleavage or parting, not brittle. $H = 3-4$. $G = 4.07$. TGA. Nonfluorescent. Biaxial (-); $Z = b$, $Y \wedge c = 7^\circ$; $N_x = 1.729$, $N_y = 1.774$, $N_z = 1.775$; $2V = 16^\circ$; pleochroic. X, pale green; Y, Z, medium green; absorption $Y = Z > X$; $r \gg v$. Anomalous blue interference color when (100) in plane of microscope stage. Found in the zone of secondary minerals at the *Black Pine mine, Flink Creek Valley, John Long Mts., 14.5 km W of Philipsburg, MT*, associated with arthurite, duftite, bayldonite, tsumebite, and veszelyite and with carbonates, arsenates, sulfates, and antimonates. *HCWS AM 71:1279(1986)*.

42.3.1.1 Rusakovite $(\text{Fe}^{3+}, \text{Al})_5(\text{VO}_4, \text{PO}_4)_2(\text{OH})_9 \cdot 3\text{H}_2\text{O}$

Named in 1960 for Mikhail Petrovich Rusakov (1892-1963), geologist, Kazakhstan, Russia. 14-60: 5.17₄ 4.20₅ 3.21₁₀ 2.95₉ 2.44₈ 2.14₇ 1.569₆ 1.366₃. *ZVMO 89:440(1960)*. Reniform concretions, crusts, veinlets. Yellow-orange to reddish-yellow, ochre streak, dull luster. $H = 1\frac{1}{2}$. $G = 2.80$. DTA. $N_{\text{av}} = 1.833$. Weakly polarizing. Soluble in 1:10 acids. Found in the oxidized layers of carbonaceous shales with apatite, colophane, mica, Pb-, Zn-, and Cu-sulfides, steigerite, fervanite, satpaevite, and alvanite at *Balasauskandyk, Kara Tau, Kazakhstan*. *HCWS AM 45:1316(1960)*.

42.4.1.1 Akrochordite $\text{Mn}_4^{2+}\text{Mg}(\text{AsO}_4)_2(\text{OH})_4 \cdot 4\text{H}_2\text{O}$

Named in 1922 from the Greek for *wart*, in allusion to the form of aggregation. *MON P2₁/a*. $a = 6.832$, $b = 17.627$, $c = 5.682$, $\beta = 99.49^\circ$, $Z = 2$, $D = 3.26$. *AMG 4:425(1968)*, Structure: *AM 74:256(1989)*. 20-715: 8.79₈ 5.31₄ 4.40₁₀ 3.62₄ 3.11₄ 3.06₄ 2.75₅ 2.36₄. Wartlike or spherical aggregates of minute crystals. Red-brown with yellow tint, translucent. Cleavage {010}, perfect. $H = 3\frac{1}{2}$. $G = 3.194$. Biaxial (+); $N_x = 1.672$, $N_y = 1.676$, $N_z = 1.683$; $2V = 50^\circ$; $r < v$, strong. Easily soluble in 1:10 H_2SO_4 , giving a purple solution. Found at Sterling Hill mine, Ogdensburg, NJ; at "Japan workings," *Långban*,

Värmland, Sweden, with pyrochroite and barite in hausmannite ore. HCWS *DII:927, AM 53:1779(1968)*.

42.4.2.1 Morinite $\text{NaCa}_2\text{Al}_2(\text{PO}_4)_2(\text{F},\text{OH})_5 \cdot 2\text{H}_2\text{O}$

Named in 1891 for Mr. Morineau, director of the tin mine at Montebbras, France. (The Na end member known as jezekite, is not an accepted mineral.) MON $P2_1/m$. $a = 9.454$, $b = 10.692$, $c = 5.444$, $\beta = 105.46^\circ$, $Z = 2$, $D = 2.981$. Structure: *CM 17:93(1979)*. $33-1219(\text{calc})$: 9.11_5 4.70_7 3.75_6 , 3.47_{10} , 3.00_7 2.95_9 2.89_8 2.63_6 . See also *11-666*. Massive, prismatic crystals up to 1 cm with striated faces. Colorless, pink; white streak; vitreous luster; translucent. $H = 4\frac{1}{2}$. $G = 2.962$. Biaxial (-); $N_x = 1.551$, $N_y = 1.563$, $N_z = 1.565$; $2V = 43^\circ$. Found at Hugo mine, Keystone, SD, associated with montebraesite, apatite, augelite, wardite, crandallite, quartz, and clays; at *Montebbras, Soumans, Creuse, France*; at Viitaniemi, Finland; with viitaniemiite in the stanniferous greisens of Odinkoe, Siberia, Russia; at Broken Hill, NSW, Australia. HCWS *DII:783; AM 43:585(1958), 47:398(1962); BM 108:533(1985)*.

42.4.3.1 Tyrolite $\text{CaCu}_5(\text{AsO}_4)_2(\text{CO}_3)(\text{OH})_4 \cdot 6\text{H}_2\text{O}$

Named in 1845 for the locality. ORTH $Pmma$. $a = 10.50$, $b = 54.71$, $c = 5.59$, $Z = 8$, $D = 3.606$. *BM 59:7(1956)*. $11-348$: 28.0_{10} 14.1_8 5.60_3 5.27_4 4.85_7 4.44_5 2.98_8 2.70_8 . Fan-shaped and closely foliated aggregates, lath-shaped crystals or scales flattened on [010] and elongated [100], [001]; crusts, reniform masses with radiating fibrous structures, drusy, divergent fibers. Pale apple-green to sky-blue, paler streak, vitreous luster, translucent. Cleavage {001}, perfect; thin laminae are flexible; sectile. $H \approx 2$. $G = 3.0-3.25$. Biaxial (-); $XYZ = bca$; $N_x = 1.694$, $N_y = 1.726$, $N_z = 1.730$; $2V = 36^\circ$; $r > v$, strong. Soluble in acids and ammonia. A secondary mineral in oxidation zone of copper deposits associated with erythrite, malachite, azurite, chrysocolla, aurichalcite, cuprite, iron oxyhydroxides. Found in the Tintic district, UT, with chalcopyllite, conichalcite; at Matlock, Derbyshire, England; at Linares in the Sierra Morena, and Pennamellera, Spain; at Cap Garrone, France; at Saalfeld, Thuringia, and Bieber and Riechelsdorf, Hesse, and Schneeberg, Saxony, Germany; at *Tyrol, Austria*, in several localities such as at Kogel near Brixlegg, on the Falkenstein near Schwaz, and at Rattenberg; at Herrengrund, Hungary; at Libethen, at Pojnik near Meusohl, Czech Republic.; at Nerchinski, Transbaikalia, Russia. HCWS *DII:925*.

42.4.4.1 Clinotyrolite $\text{Ca}_2\text{Cu}_9^{2+}[(\text{As},\text{S})\text{O}_4]_4(\text{O},\text{OH})_{10} \cdot 10\text{H}_2\text{O}$

Named in 1980 for its relationship to tyrolite (42.4.3.1). MON P/a or $P2/a$. $a = 27.61$, $b = 5.56$, $c = 10.513$, $\beta = 94.0^\circ$, $Z = 2$, $D = 3.214$. *AGS 54:134(1980)*. $33-273$: 13.7_6 4.81_9 4.40_8 3.67_7 3.50_7 2.96_{10} 2.67_{10} 1.748_8 . Radiating aggregates of flaky crystals flattened parallel to (001), elongated [100]. Emerald green, silky. $G = 3.22$. IR and DTA. Biaxial (-); $Y = b$, $Z \wedge c = 7^\circ$; $N_x = 1.666$, $N_y = 1.686$, $N_z = 1.695$; $2V = 65^\circ$. Chemical analysis

46.04 CuO, 28.09 As₂O₃, 7.24 CaO, 1.28 SO₃, 17.63 H₂O. Found at *Dongchuan copper mine, Yunnan Prov., China*, with tyrolite. hcws MA:80-4909.

42.4.5.1 Dumontite $Pb_2(UO_2)_3O_2(PO_4)_2 \cdot 5H_2O$

Named in 1924 for André Hubert Dumont (1809–1857), Belgian geologist. See also hügelite (42.4.5.2). MON $P2_1/m$. $a = 8.118$, $b = 16.819$, $c = 6.983$, $\beta = 109.03^\circ$, $Z = 2$, $D = 5.66$. Structure: *BM 111:439(1988)*. Resembles Renardite (42.4.9.2) 12-158: 8.38₄ 6.14₆ 4.27₁₀ 3.74₆ 3.48₇ 3.31₆ 3.00₉ 2.95₉. Small crystals elongated [001], flattened {010}. Ochre-yellow, ochre-yellow streak. $G = 5.65$. Fluoresces greenish. Biaxial (+); XYZ = *acb*; $N_x = 1.88$, $N_z = 1.89$; 2V large; $r < v$; pleochroic. X, pale yellow; Z, deep yellow. Soluble in acids, H₂O entirely lost by 300°. Found with torbernite at *Shinkolobwe, Shaba, Zaire*. DII:928, *BM 81:63 (1958)*. hcws

42.4.5.2 Hügelite $Pb_2(UO_2)_3(AsO_4)_2(OH)_4 \cdot 5H_2O$

Named in 1913 for F. Hügel. The As analog of dumontite (42.4.5.1). MON $P2_1/m$. $a = 8.13$, $b = 17.27$, $c = 7.01$, $\beta = 109.0^\circ$, $Z = 2$, $D = 5.80$. *TMPM 26:11(1979)*. 34-1476: 4.33₆ 3.73₁₀ 3.06₉ 3.00₇ 2.89₇ 2.70₆ 2.16₆ 1.833₇. Crystals prismatic [001] to 3 mm long, showing {110}, {001}, {011}. Orange-yellow to yellow-brown, pale yellow streak, greasy to adamantine luster, transparent and translucent. $H = 2\frac{1}{2}$. $G \approx 5.1$. Biaxial (+); Y = elongation (for blue); $N_x = 1.898$, $N_z = 1.915$; 2V = 25° (at 592 μm), 25° (for red); extreme dispersion; $r \ll v$; anomalous interference colors; incomplete extinction; pleochroic. X, yellow; Y, yellow-orange; Z, colorless to pale yellow. Found at Michael mine, Weiler, and at *Reichenbach, near Lahr, Baden-Württemberg, Germany*, filling cavities with hallimondite, wiedenmanite, zeunerite, mimetite, and cerussite. hcws DII:815; *AM 47:418(1962)*.

42.4.5.3 Bergenite $(Ba,Ca)_2(UO_2)_3(PO_4)_2(OH)_4 \cdot 5H_2O$

Named in 1959 for the locality. MON $P2_1/c$. $a = 23.32$, $b = 17.19$, $c = 20.63$, $\beta = 93.0^\circ$, $Z = 18$, $D = 4.09$. *BM 104:16(1981)*. Similar to synthetic "barium phosphuranylite." *AM 41:915(1956)*. 43-668: 8.54₄ 7.73₁₀ 3.84₈ 3.74₄ 3.42₄ 3.05₆ 2.87₅ 2.83₅. See also 20-154. Thin tabular plates. Yellow, translucent. $G = 4.10$. Fluoresces pale green in SWUV and LWUV. Biaxial (-); $N_x = 1.660$, $N_y \approx 1.690$, $N_z \approx 1.698$; 2V = 45°. Found at *Streuerg, Bergen on the Trieb, Vogtland, Saxony, Germany*, associated with uranocircite, torbernite, renardite, autunite, and barium-containing uranophane. hcws *NJMM:2326(1959)*; *AM 45:909(1960)*, 66:1102(1981).

42.4.6.1 Phuralumite $Al_2(UO_2)_3(PO_4)_2(OH)_6 \cdot 10H_2O$

Named in 1979 for the composition. MON $P2_1/a$. $a = 13.836$, $b = 20.918$, $c = 9.428$, $\beta = 112.44^\circ$, $Z = 4$, $D = 3.52$. Structure: *AC(B) 35:1880(1979)*. 33-38: 10.4₁₀ 8.0₂ 5.17₇ 3.47₄ 3.40₅ 3.08₈ 2.95₂ 2.66₂. Prismatic crystals to 0.5 mm. Lemon-yellow, translucent. $H = 3$. $G = 3.5$. Nonfluorescent. Biaxial (-); X = *b*, Y ≈ elongation; $N_x = 1.559$, $N_y = 1.616$, $N_z = 1.624$; 2V = 40°;

pleochroic, colorless to pale yellow on Y and Z. Found at *Kobokobo, Kivu, Zaire*, in beryl-columbite pegmatites associated with meta-autunite, phosphuranylite, threadgoldite, and other Al- and U-containing phosphates. HCWS *BM 102:333(1979)*, *AM 65:208(1980)*.

42.4.7.1 Phurcalite $\text{Ca}_2(\text{UO}_2)_3(\text{O}_2\text{PO}_4)_2 \cdot 7\text{H}_2\text{O}$

Named in 1978 for the composition. ORTH *Pbca*. $a = 17.415$, $b = 16.035$, $c = 13.598$, $Z = 8$, $D = 4.220$. Structure: *CM 29:95(1991)*. *30-285*: 8.02_{10} 7.63_1 4.24_3 3.99_2 3.83_2 3.39_3 3.10_4 2.88_3 . See *30-384(calc)*. Tablets flattened on [010] elongated [001] up to 1 mm long. Yellow, vitreous to adamantine luster, translucent. Cleavage {001}, {010}, perfect; also {100}. $H = 3$. $G = 4.22$. Nonfluorescent. Biaxial (-); $N_x \text{ calc} = 1.690$, $N_y = 1.730$, $N_z = 1.749$; positive elongation; strongly pleochroic. X, bright yellow; Y, very pale yellow. Found at *Streuberg, Bergen, Vogtland, Saxony, Germany*. HCWS *BM 101:356(1978)*, *AM 64:243(1979)*.

42.4.8.1 Phosphuranylite

Named in 1879 for the composition. ORTH *Bmmb*. $a = 15.835$, $b = 17.324$, $c = 13.724$, $Z = 4$, $D = 4.58$. *EJM 3:69(1991)*, Structure: *AC(B) 47:439(1991)*. *19-898*: 10.4_5 7.96_8 2.86_8 4.43_8 3.87_8 3.16_{10} 3.09_{10} 2.88_{10} . Scaly coatings or crusts, tiny rectangular laths. Deep yellow to golden yellow, translucent. Cleavage {001}, perfect. $H \approx 2\frac{1}{2}$. $G = 4.10$. Biaxial (-); $N_x \text{ or } E = 1.690$, $N_y = 1.718$, $N_z \text{ or } O = 1.718$ (Flat Rock); Z perpendicular to flattening; $2V = 5-20^\circ$; $r > v$, strong; pleochroic. X, colorless to pale yellow; Y, Z, golden yellow. Easily soluble in acids. A secondary mineral associated with autunite, uranophane, beta-uranophane, opal in weathered zones of granitic pegmatites that contain uraninite. Found at Newry, ME; at Ruggles pegmatite, Grafton Center, and Palermo pegmatite, North Groton, NH; at Branchville pegmatite, Fairfield Co., CT; at Bedford, Westchester Co., NY; at *Flat Rock pegmatite, Mitchell Co., NC*; at Rosmaneira and Carrasca, Sabugal and at Urgeirica, Cannas de Senhorim, Portugal; at Wolsendorf, Bavaria, Germany; at Pamplonita, Santander do Norte, Colombia; at Saddle Ridge mine, s. Alligator R., NT, Australia; at Lavra do Enio, Galileia, at Cruzeiro mine, Sao Jose da Safira, and Lavra do Telirio, MG, Brazil. HCWS *DII:876*, *AM 39:444 (1954)*, *76:1734(1991)*, *AMG 4:267(1966)*.

42.4.9.1 Arsenuranylite $\text{Ca}(\text{UO}_2)_4(\text{AsO}_4)_2(\text{OH})_4 \cdot 6\text{H}_2\text{O}$

Named in 1958 for its relationship to phosphuranylite (42.4.8.1) as the end member. ORTH *Bmmb*. $a = 15.40$, $b = 17.40$, $c = 13.77$, $Z = 6$, $D = 4.25$. *ZVMO 87:589(1958)*. *14-268*: 8.41_8 7.72_{10} 3.85_{10} 3.42_7 3.13_8 1.778_7 1.729_7 1.612_7 . Scales, lichenlike deposits. Yellow, orange, translucent. Biaxial (-); $N_x = 1.738$, $N_y = 1.761$, $N_z = 1.774$; $2V_{\text{calc}} = 74^\circ$. Found in the oxidation zone of As-containing sulfide deposits associated with metazeunerite, uranospinite, and novacekite, replaced by schoepite and paraschoepite, Russia. HCWS *AM 44:208(1959)*.

42.4.9.2 Renardite $\text{Pb}(\text{UO}_2)_4(\text{PO}_4)_2(\text{OH})_4 \cdot 7\text{H}_2\text{O}$

Named in 1928 for Alphonse François Renard (1842–1903), mineralogist, University of Ghent, Belgium. ORTH *Bmmb*. $a = 16.01$, $b = 17.5$, $c = 13.7$, $Z = 6$, $D = 4.34$. *AM* 39:448(1954). *PD*: 10.25₅ 7.95₁₀ 5.83₆ 4.43₆ 3.96₇ 3.40₄ 3.11₉, 2.88₈. Drusy crusts of minute crystals flattened on {100}, slightly elongated {001}, showing {010}, {001}, {101}. Yellow, transparent. Cleavage {100}, perfect. $G > 4$. Biaxial (-); $\text{XYZ} = acb$; $N_x = 1.715$, $N_y = 1.736$, $N_z = 1.739$; $2V = 41^\circ$; $r > v$; pleochroic. X, Y, yellow; Z, colorless. Soluble in acids. Occurs with dewindite, dumontite, and torbernite, *Kaslo mine, Shinkolobwe, Shaba, Katanga, Zaire*. *HCWS DII:928*.

42.4.9.3 Kivuite $(\text{Th,Ca,Pb})\text{H}_2(\text{UO}_2)_4(\text{PO}_4)_2(\text{OH})_8 \cdot 7\text{H}_2\text{O}$

Named in 1958 for the locality. Incompletely described mineral. Possibly a thorian vanmeersscheite. ORTH. $a = 15.88$, $b = 17.24$, $c = 13.76$, $Z = 6$. *AM* 44:1326(1959). 13-419: 10.3₁₀ 7.96₉ 5.88₆ 4.43₆ 3.94₆ 3.86₆ 3.08₈ 2.87₈. Earthy masses, orthorhombic plates. Yellow. Nonfluorescent. Biaxial (-); $N_x = 1.618$, $N_y = 1.654$, $N_z = 1.655$; $2V = 0-5^\circ$. X, colorless; Y, Z, greenish yellow. Decomposed in HNO_3 . Found at the *Kobokobo pegmatite, Kivu, Zaire*, associated with phosphuranylite, renardite, zircon, columbotantalite, and apatite. *HCWS*

42.4.10.1 Glucine $\text{CaBe}_4(\text{PO}_4)_2(\text{OH})_4 \cdot 0.5\text{H}_2\text{O}$

Named in 1963 for the alternative name for beryllium: glucinum. 15-781: 10.8₁₀ 2.67₆ 2.41₁₀ 1.948₈ 1.529₈ 1.390₁₀ 1.229₇ 1.199₇. *ZVMO* 92:691(1963). Massive, encrusting, micron-size needles in concretions. $H = 5$. $G = 2.23-2.40$. DTA. $N_{av} = 1.555$, needles $N_{x'} = 1.547$, $N_{z'} = 1.571$; positive elongation parallel to extinction. Dissolved in 1:20 HCl. Spectrographic analysis also shows Sr, Ba, Pb, Cu, Na, Y. Associated with hydromuscovite, "limonite," quartz, moraesite, fluorite, and rutile in mica-fluorite veins, *Ural Mts., Russia*. *HCWS AM* 49:1152(1964).

42.4.11.1 Asselbornite $(\text{Pb,Ba})(\text{BiO})_4(\text{UO}_2)_6(\text{AsO}_4)_2(\text{OH})_{12} \cdot 3\text{H}_2\text{O}$

Named in 1983 for Eric Asselborn (b.1954), mineral collector and surgeon, Montrevel-en-Bresse, France. iso *Im3m* or *I432*. $a = 15.66$, $Z = 5$, $D = 5.7$. *NJMM:417(1983)*. 35-605: 6.39₈ 5.54₄ 4.52₇ 4.19₁₀ 3.69₆ 3.50₄ 3.20₈ 2.61₄. Cubic crystals up to 0.3 mm. Brown to lemon yellow, greasy to adamantine luster, translucent. TGA. $N \approx 1.9$, light yellow in thin section. Slowly soluble in 1:10 HCl. Ba increases as Pb decreases toward exterior of grains. Found in association with metauranospinite, uranophane, and uranosphaerite in quartz gangue from *Walpurgis vein, Weisser Hirsch, Neustadtel, Schneeberg, Saxony, Germany*. *HCWS AM* 69:565(1984).

42.4.12.1 Walkkilldellite $\text{Ca}_4\text{Mn}_6^{2+}(\text{AsO}_4)_4(\text{OH})_8 \cdot 18\text{H}_2\text{O}$

Named in 1983 for the dell of the Walkkill R., NJ, where the Sterling Hill mine is located. The As and Mn^{2+} analog of kittatinnyite (silicate). *HEX*. $a = 6.506$, $c = 23.49$, $Z = 4$, $D = 2.90$. *AM 68:1029(1983)*. 35-608: 11.5₁₀ 5.61₉ 4.56₄ 2.84₆ 2.75₅ 2.55₅ 2.35₄. Flattened radial clusters of platy crystals to 0.5 mm in diameter. Dark red; light orange streak; vitreous luster, resinous on fracture; translucent. Cleavage {0001}, perfect. $H \approx 3$. $G = 2.85$. Non-fluorescent. Uniaxial (-); $N_O = 1.728$; N_E ND because of thinness of plates; $O > E$; pleochroic. O, reddish orange; E, light pink-orange. Found only rarely at *Sterling Hill mine, Ogdensburg, Sussex Co., NJ*, in specimens of the typical massive franklinite-willemite ore with carbonates and adamite group minerals. *HCWS*

42.4.13.1 Althupite $\text{ThAl}(\text{UO}_2)_7(\text{PO}_4)_4\text{O}_2(\text{OH})_5 \cdot 15\text{H}_2\text{O}$

Named in 1987 for the composition. *TRIC P1*. $a = 13.504$, $b = 18.567$, $c = 10.953$, $\alpha = 95.79^\circ$, $\beta = 111.80^\circ$, $\gamma = 72.64^\circ$, $Z = 2$, $D = 3.98$. Structure: *BM 110:65(1987)*. 40-503: 10.2₁₀ 6.67₄ 5.80₅ 5.09₇ 4.91₄ 4.41₅ 4.07₄ 2.90₅. Thin tablets flattened (100), elongated {001} to 0.1 mm. Yellow, transparent. $G = 3.9$. Biaxial (-); $X \approx [100]$; $Z \wedge c = 15^\circ$; $N_x = 1.620$, $N_y = 1.661$, $N_z = 1.665$; $2V = 31^\circ$; $r < v$, strong; pleochroic: X, pale yellow; Y,Z, darker yellow. Found at *Kobokobo, Kivu, Zaire*, in a pegmatite with beryl and columbite. *HCWS AM 73:189(1988)*.

42.4.14.1 Françoisite-(Nd) $\text{Nd}[(\text{UO}_2)_3\text{O}(\text{OH})(\text{PO}_4)_2] \cdot 6\text{H}_2\text{O}$

Named in 1988 for Armand François (b.1922), geologist and director of Gecamine, Zairian mining company. *MON P2₁/n*. $a = 13.668$, $b = 15.605$, $c = 9.298$, $\beta = 112.77^\circ$, $Z = 4$, $D = 4.63$. *BM 111:443(1988)*. 42-1314: 7.79₁₀ 5.76₅ 4.44₄ 4.33₄ 3.88₅ 3.13₅ 2.87₄ 2.84₄. Aggregates of tabular (010) crystals, elongate [001], up to 0.3 mm long showing {100}, {102}; twinned on (100). Yellow, white streak, vitreous luster, translucent. Cleavage {010}, easy; uneven fracture. $H \approx 3$. $G > 4.06$. Nonfluorescent. Biaxial (-); $X = b$; $Y \wedge 3 = 14.5^\circ$, $Z \wedge a = 8.3^\circ$; $N_{x \text{ calc}} = 1.65$, $N_y = 1.74$, $N_z = 1.75$; $2V = 35^\circ$. Microprobe analyses show Y, La, Ce, Pr, Sm, Dy; gas chromatography for H_2O . Found in the *Kamoto-Est copper-cobalt deposit, 6 km W of Kolwezi, Shaba, Zaire*, in association with uraninite, schoepite, uranophane, curite, schuilingite, and kamotoite-(Y). *HCWS*

42.4.15.1 Mrazekite $\text{Bi}_2\text{Cu}_3(\text{OH})_2\text{O}_2(\text{PO}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1992 for Zdenek Mrazek (1952-1984), who suggested that this was a new mineral on samples from the ancient copper mine at Lubietova, Czech Republic. *MON P2/n*. $a = 9.065$, $b = 6.340$, $c = 21.239$, $\beta = 101.57^\circ$, $Z = 4$, $D = 5.00$. Structure: *CM 32:365(1994)*. Two independent irregular $\text{Cu}-\text{O}_6$ octahedra and tetrahedral PO_4 groups form sheets parallel to {201} which are connected by Bi and H bonds. Note: a pseudocell has been reported in *CM 30:215(1992)*. 45-1391: 7.63₈ 5.41₄ 5.20₅ 5.15₅ 3.17₄ 3.04₁₀ 3.01₆ 2.92₈.

Needles or plates elongated on b , parallel to $\{201\}$, in sheaflike aggregates up to 2 mm. Bright, cerulean blue, similar to azurite; vitreous luster; translucent. Cleavage $\{201\}$, good. $H = 2-3$. $G = 4.90$ (low due to quartz impurity). IR. Biaxial (-); $X \wedge c = 27^\circ$, $Y \wedge a = 27^\circ$, Z parallel to c ; $N = 1.86-1.879$. Found in the secondary assemblage in a quartz matrix at the *Reinera mine, Lubietová, western Slovenské Rudorhorie Mts., near Banská Bystrica, Slovakia, Czech Republic*, associated with many other arsenate and phosphate minerals: specifically, libenthenite, pseudomalachite, and euchroite. $HCWS$

42.5.1.1 Mixite $\text{BiCu}_5^{2+}(\text{AsO}_4)_3(\text{OH})_6 \cdot 3\text{H}_2\text{O}$

Named in 1880 for A. Mixa, mining official at Jachymov, Bohemia, Czech Republic. $\text{HEX } P6_3/m$. $a = 13.646$, $c = 5.920$, $Z = 2$, $D = 4.045$. *NJMM:223(1960)*, *SR 54A:250(1987)*. *13-414*: 12.0₁₀ 4.47₅ 4.18₅ 3.57₈ 2.95₇ 2.86₆ 2.70₆ 2.46₉. See also *13-413*, non-Bi-containing sample, called Chlorotile. Hairlike crystals with hexagonal outline elongated $[0001]$, deeply striated vertically; tufted groups, compact reniform spherical masses with concentric fibrous structure; cross-fiber veinlets. Emerald-green to blue-green to whitish, streak lighter in color, brilliant luster on crystals to dull on aggregates. $H = 3-4$. $G = 3.79$. Uniaxial (+); $N_O = 1.730$, $N_E = 1.810$ (Mammoth, Tintic); pleochroic. O , colorless; E , bright green. Analysis also shows Zn , Fe^{2+} , Ca , P . About 0.5 H_2O lost by heating to 175° . Found at Mammoth mine, Tintic dist., UT; at Mammoth-St Anthony mine, Tiger, AZ; with erythrite in barite at St. Anton mine, and Humbachtal, Wittichen dist.; and at Grube Clara, Rankachtal; Freundenstadt and Bulach, in Baden; and at Schneeberg, Graul, and Neustadtl, Saxony, Germany; at *Jachymov, Bohemia, Czech Republic*, with bismutite, smaltite, native bismuth; at Kamarezu mine, Attica, Greece; at Sprint Creek, SA, Australia; at Tsumeb, Namibia. $HCWS$ *DII.943*, *BM 92:420(1969)*, *NJMM:487(1991)*.

42.5.1.2 Agardite-(Y) $(\text{Y,Ca})\text{Cu}_5^{2+}(\text{AO}_4)_3(\text{OH})_6 \cdot 3\text{H}_2\text{O}$

Named in 1969 for Jules Agard, geologist, Bureau de Recherches Géologiques et Minières, Orleans, France. Agardite-(La) and agardite-(Ce) described, but no quantitative data presently available. *AM 70:871(1985)*. $\text{HEX } P6_3/m$. $a = 13.55$, $c = 5.87$, $Z = 2$, $D = 3.66$. *BM 92:420(1969)*, Structure: *AC(C) 41:161(1985)*. *25-183*: 11.7₁₀ 4.43₇ 3.54₇ 3.25₅ 2.94₈ 2.69₆ 2.56₆ 2.45₈. Rosettes, spherical aggregates, and acicular crystals to 5 mm long. Blue-green, translucent. $G = 3.72$. DTA. Uniaxial (+); $N_O = 1.701$, $N_E = 1.782$. Dissolved by HCl. REE predominate in these members of the mixite group, with names reflecting the dominant species. Found in Red Cloud fluorite mine, Gallinas Mts., NM; at *Bou Skour mine, Jebel Sarhro, Ouazazate, Morocco*, in the oxidation zone associated with azurite, malachite, cuprite, native Cu, and quartz; Laurium, Attica, Greece, associated with smithsonite, aurichalcite, hydrozincite, and cuproadamite. $HCWS$ *BM 92:420(1969)*, *AM 55:1447(1970)*, *NJMM:487(1991)*.

42.5.1.3 Goudeyite $(\text{Al},\text{Y})\text{Cu}_6^{2+}(\text{AsO}_4)_3(\text{OH})_6 \cdot 3\text{H}_2\text{O}$

Named in 1978 for Hatfield Goudey (1906–1985), mining geologist and mineral collector of San Mateo, CA. The Al analog of agardite. **HEX**. $a = 13.472$, $c = 5.902$, $Z = 2$, $D = 3.58$. *AM* 63:704(1978). 29-526: 11.63₁₀ 4.41₅ 3.53₂ 3.37₂ 3.24₅ 2.92₅ 2.68₄ 2.55₅. Hairlike hexagonal crystals 0.5 mm long (c axis), 2 μm in diameter in tufted groups, encrusting, and in cross-fiber veins. Yellow-green, translucent. $H = 3-4$. $G = 3.50$. Uniaxial (+); $N_O = 1704$, $N_E = 1.765$. O, pale yellow-green; E, green; $E > O$. Found at *Majuba Hill mine, Pershing Co., NV*. **HCWS**

42.5.2.1 Petersite-(Y) $(\text{Y},\text{Ce},\text{Nd},\text{Ca})\text{Cu}_6^{2+}(\text{PO}_4)_3(\text{OH})_6 \cdot 3\text{H}_2\text{O}$

Named in 1982 for Thomas A. Peters (b.1947) and Joseph Peters (b.1951), curators of minerals at the Paterson, NJ, museum and the American Museum of Natural History, NY, respectively. **HEX** $P6_3/m$. $a = 13.288$, $c = 5.877$, $Z = 2$, $D = 3.40$. *NJMM*:487(1991). See also 44-1434: 11.6₁₀ 4.36₅ 3.49₄ 2.88₄ 2.51₃ 2.43₆ 1.961₂ 1.742₁. Prismatic crystals showing $\{10\bar{1}0\}$, $\{0001\}$, as radiating clusters and sprays up to 0.1 mm in diameter. Yellow-green; vitreous luster on prism faces, dull on pinocoids. Brittle. $G = 3.41$. Nonfluorescent. Uniaxial (+); $N_O = 1.666$, $N_E = 1.747$; strongly dichroic; $E \gg O$. E, green; O, light yellowish green. Soluble in 1:1 HCl solution, yellow-green. Microprobe analysis also showed Ca, Fe, Ce, Nd, Sm, La. Found in minute cavities between brecciated hornfels in a traprock quarry *Laurel (Big Snake) Hill, Secaucus, Hudson Co., NJ*, on altered chalcopyrite with diadochite, chrysocolla, and hematite, and encrusting malachite and opal. **HCWS** *AM* 67:1039(1982).

42.5.3.1 Zapatalite $\text{Cu}_3^{2+}\text{Al}_4(\text{PO}_4)_3(\text{OH})_9 \cdot 4\text{H}_2\text{O}$

Named in 1972 for Emiliano Zapata (1879–1919), hero of the Mexican Revolution. **TET**. $a = 15.22$, $c = 11.52$, $Z = 6$, $D = 3.017$. *MM* 38:541(1972). 25-261: 11.6₁₀ 7.62₁₀ 6.82₂ 5.75₈ 4.58₅ 3.04₅ 2.95₄ 2.53₅. Massive. Pale blue, light blue streak, translucent. Cleavage basal, good; sectile. $H = 1\frac{1}{2}$. $G = 3.016$. Uniaxial (-); $N_O = 1.646$, $N_E = 1.635$; weakly dichroic; $E > O$; occasionally biaxial. Readily dissolves in 1:10 HNO_3 , HCl, decomposed in 20% KOH. Found at *Cerro Morita Naco, 27 km SW of Agua Prieta, SON, Mexico*, as a replacement for libethenite and pseudomalachite and may alter to chrysocolla; associated with chenevixite, alunite, and beaverite; *Villa Viciosa, Estremoz, Portugal*. **HCWS** *AM* 57:1911(1972).

42.6.1.1 Moraesite $\text{Be}_2(\text{PO}_4)(\text{OH}) \cdot 4\text{H}_2\text{O}$

Named in 1953 for Luciano Jacques de Moraes (1896–1968), Brazilian geologist and mineral collector. The P end member of a P–As series with bearsite (42.6.1.2). **MON** Cc or $C2/c$. $a = 8.553$, $b = 12.319$, $c = 7.155$, $\beta = 97.93^\circ$, $Z = 4$, $D = 1.80$. Structure: *ZK* 201:253(1992). 6-58: 7.0₁₀ 6.15₄ 4.24₆ 3.28₆ 3.02₆ 2.82₆ 2.33₄ 2.05₄. Spherulites and drusy crusts of distinct acicular or fibrous crystals to 1 mm. Needles elongated on $[001]$ show $\{110\}$, $\{111\}$; tabular

{100}, striated parallel to *c*. White, white streak, translucent. Cleavage {010}, {001}. $G = 1.805$. Biaxial (-); $Z = b$; $Y \wedge c = 11^\circ$; $N_x = 1.462$, $N_y = 1.482$, $N_z = 1.490$; $2V = 65^\circ$. Soluble in 1:10 acids. Decrepitates when heated. Found at Dunton Gem mine, Newry, ME; at Palermo No. 1, North Groton, NH; at Feldspar quarry, Londonderry, WA, Australia; at the Humanita pegmatite, Itinga, in the oxidation zone with beryl, albite, quartz, muscovite, and frondelite, and at the *Sapucaia pegmatite, Galileia, MG, Brazil*. HCWS AM 38:1126(1953), CM 25:419(1987).

42.6.1.2 Bearsite $\text{Be}_2(\text{AsO}_4)(\text{OH}) \cdot 4\text{H}_2\text{O}$

Named in 1962 for the composition, the first known Be arsenate. The As analog of moraesite (42.6.1.1). MON *C2/c* or *Cc*. $a = 8.55$, $b = 36.90$, $c = 7.13$, $\beta = 97.82^\circ$, $Z = 12$, $D = 2.199$. *ZVMO 91:442(1962)*. 15-378: 6.95₁₀ 4.23₆ 3.31₈ 3.02₆ 2.88₅ 2.15₅ 1.956₅ 1.889₅. Fine encrustations, tangled fibrous aggregates to 0.1 mm. Prismatic, longitudinally striated. White, translucent. $G > 1.8$. Biaxial (-); $Z \wedge c = 8-10^\circ$; $N_x = 1.490$, $N_y = N_z = 1.502$; $2V_{\text{calc}} = 0^\circ$. Microprobe analysis also shows Al, Fe, Ca, Mg, and Si. Found in the zone of oxidation of a polymetallic deposit that contains arsenopyrite, molybdenite, galena, pyrite, sphalerite, realgar, orpiment, and pitchblende in felsic porphyry with beryl in *Kazakhstan*, coating pharmacosiderite and arsenosiderite, and with scorodite-mansfieldite, conichalcite, and tyrolite. HCWS AM 48:210(1963).

42.6.2.1 Isoclasite $\text{Ca}_2(\text{PO}_4)(\text{OH}) \cdot 2\text{H}_2\text{O}$

Named in 1870 from the Greek for *equal* and *fracture*, in allusion to the cleavage. An inadequately described species. MON (inferred from optical properties). Dull, minute crystals, prismatic [001] and as cotton-like fibers. Colorless to snow white, vitreous to pearly luster on cleavage surfaces. Cleavage {010}, distinct. $H = 1\frac{1}{2}$. $G = 2.92$. Biaxial (+); $X = b$; $Z \wedge c$, small; $N_x = 1.565$, $N_y = 1.568$, $N_z = 1.580$; $2V$ medium. Easily soluble in acids. Found at *Jachymov, Zapadocesky Kraj, Bohemia, Czech Republic*, with chalcidony and dolomite. HCWS DII:933.

42.6.3.1 Euchroite $\text{Cu}_2^{2+}(\text{AsO}_4)(\text{OH}) \cdot 3\text{H}_2\text{O}$

Named in 1823 from the Greek for *beautiful color*. ORTH $P2_12_12_1$. $a = 10.056$, $b = 10.506$, $c = 6.103$, $Z = 4$, $D = 3.47$. AM 36:484(1951), Structure: AC(C) 45:1479(1989). 39-1358: 7.29₁₀ 5.26₇ 5.23₁₀ 5.04₇ 3.71₇ 2.83₉ 2.65₅ 2.63₅. See 4-222. Short prismatic [010] showing {110}, {302}, {201} striated parallel to [010], also {010}, {100}, {011}, {021}, {101}; equant or thick tabular {100}. Bright emerald-green or leek-green, vitreous luster, transparent to translucent. Cleavage {101}, {110}, slight; uneven to subconchoidal fracture; brittle. $H = 3\frac{1}{2}-4$. $G = 3.44$. Biaxial (+); $XYZ = cab$; $N_x = 1.695$, $N_y = 1.698$, $N_z = 1.733$; $2V = 29^\circ$; $r > v$. Weakly pleochroic. Soluble in acids. Found at Cramer Creek, Missoula Co., MT; as crystals lining crevices in mica schist at *L'ubietova, E. of Banka Bystrica, Slovakia*, with olivenite. HCWS DII:934.

42.6.4.1 Legrandite $Zn_2(AsO_4)(OH) \cdot H_2O$

Named in 1932 for Mr. Legrand, from Belgium, the mine manager who collected the original specimen. MON $P2_1/c$. $a = 12.805$, $b = 7.933$, $c = 10.215$, $\beta = 104.39^\circ$, $Z = 8$, $D = 4.01$. AM 56:1147(1971), Structure: SPC 17:747(1973). 42-1356: 6.67₆ 5.92₈ 4.20₆ 4.13₅ 4.07₁₀ 3.09₇ 3.02₅ 2.98₆. See also 16-607. Radiating aggregates of prismatic {001} crystals, up to 28 cm \times 7.5 mm (Ojuela), showing {001}, {100}, {110}, {111}. Colorless to canary yellow, vitreous luster, transparent. Cleavage {100}, fair. $H \approx 4\frac{1}{2}$. $G = 3.975$. TGA. Biaxial (+); $X = b$; $Z \wedge c = 36-40^\circ$; $N_x = 1.702$, $N_y = 1.709$, $N_z = 1.740$; $2V = 50^\circ$ (Ojuela); $r < v$; pleochroic. X, Y, colorless to yellow; Z, yellow. Contains minor Fe and Mn. Found at Ljuela mine, Mapimi, DGO., the *Flor de Pena mine*, Lampazos, NL, with siderite, mimitite, pyrite on massive sphalerite, and at Potosi mine, Sta. Eulalia, CHIH, Mexico; at Tsumeb, Namibia. ncws DII:958, AM 48:1258(1963).

42.6.4.2 Spencerite $Zn_4(PO_4)_2(OH)_2 \cdot 3H_2O$

Named in 1916 for Leonard James Spencer (1870-1959), British mineralogist, editor, and curator of minerals at the British Museum of Natural History, London, England. MON $P2_1/a$. $a = 11.191$, $b = 5.276$, $c = 10.439$, $\beta = 116.81^\circ$, $Z = 2$, $D = 3.242$. Structure: MM 38:687(1972). Zn in octahedral and tetrahedral coordination forms complex sheets with tetrahedral PO_4 groups. These layers connected by H_2O molecules. Structure explains prominent twinning. 35-631: 9.34₁₀ 4.59₂ 3.86₁ 3.49₅ 3.42₁ 3.11₁ 3.04₁ 2.33₂. See also 13-195. Crystals tabular {100}, elongated [001], often lancelike showing {102}, {001}, {101}, {121}, {221}; {h0l} striated [010] due to polysynthetic twinning with composition surface {100}. Also massive, stalactitic with columnar or platy structure. White; pearly luster on cleavages, to vitreous luster. Cleavage {100}, perfect; {010}, good; {001}, distinct. $H = 3$. $G = 3.14$. Biaxial (-); $X \approx a$; $Z = b$; $N_x = 1.586$, $N_y = 1.602$, $N_z = 1.606$; $2V = 49^\circ$; $r > v$. Polysynthetic twin lamellae show maximum extinction on {100} of $\approx 6^\circ$. Readily soluble in acids. Found with hemimorphite, hopeite, salmonite, and clay in cave in oxidized zinc ore at Hudson Bay mine, Salmo, Nelson mining district, BC, Canada. ncws DII:931.

42.6.5.1 Strashimirite $Cu_8(AsO_4)_4(OH)_4 \cdot 5H_2O$

Named in 1968 for Strashimir Dimitrov, Bulgarian petrographer. MON $P2/m$, $P2$, or Pm . $a = 9.71$, $b = 18.85$, $c = 8.94$, $\beta = 97.20^\circ$, $Z = 3$, $D = 3.76$. ZVMO 97:470(1968). 21-289: 18.7₁₀ 9.46₈ 8.97₉ 4.79₈ 4.21₈ 3.35₈ 3.13₉ 2.86₁₀. Fine platy to fibrous aggregate in spherulites to 0.5 mm. White, pale green, pearly to greasy luster. Biaxial (-); $Z \wedge$ elongation $\approx 5^\circ$; $N_x = 1.726$, $N_y \sim 1.740$, $N_z = 1.747$; $2V = 70^\circ$; positive elongation; weakly pleochroic. Y, pale yellow-green; Z, yellow-green. Microprobe analysis also shows Sb, Mn, Cd, Pb, Tl, Ba, Ca, Mg, Si, Al but no P, S, V. Found at Majuba Hill, Pershing Co.; Burrus mine, Washoe Co., NV; Gold Hill, Tooele Co., UT; Wheal Gorland and Wheal Unity, Gwennap, Cornwall, England; Horcajo mine, Ciudad Real, Spain;

Kamsdorf, Thuringia; Clara mine, Oberwolfach, Schwarzwald; Schweina, Bad Liebenstein, Germany; Novoveska Huta, Slovakia; with azurite, olivenite, malachite, or euchroite and replaces tyrolite and cornwallite at *Zapachitsa copper mine, western Stara-Planina, Bulgaria*. HCWS AM 54:1221(1969).

42.6.5.2 Arhbarite $\text{Cu}_2^{2+}(\text{AsO}_4)(\text{OH}) \cdot 6\text{H}_2\text{O}$

Named in 1982 for the locality. MON Space group unknown. $a = 16.988$, $b = 15.901$, $c = 6.100$, $\beta = 97.5^\circ$. NJMM:529(1982). 35-562: 4.57₁₀ 4.51₉ 3.72₆ 3.25₄ 2.63₄ 2.60₅ 2.47₅. Fibrous to spear-shaped crystallites 10 μm long and 2 μm wide in spherulitic aggregates to 0.3 mm. Blue, vitreous luster. IR. Biaxial; $N_x = 1.720$, $N_z = 1.740$; $\beta = 90^\circ$ (parallel and perpendicular to fiber axis), extinction 45° to length; pleochroic. X', turquoise-blue; Z', deep turquoise-blue. Found on massive dolomite associated with hematite, löllingite, pharmacolite, erythrite, talc, and mcguinnessite at *Arhbar mine, Bou-Azzer, Morocco*. HCWS AM 68:1038(1983).

42.6.6.1 Delvauxite $\text{CaFe}_4^{3+}(\text{PO}_4, \text{SO}_4)_2(\text{OH})_8 \cdot 4-6\text{H}_2\text{O}$

42.6.6.2 Borickite $\text{CaFe}_4^{3+}(\text{PO}_4, \text{SO}_4)_2(\text{OH})_8 \cdot 3.5\text{H}_2\text{O}$

Delvauxite named in 1838 for J. S. P. J. Delvaux de Feuffe (1782–1863), Belgian chemist who analyzed the mineral, and borickite for Emanuel Boricky (1840–1881), Czech petrographer. These two minerals are probably identical to one another and to picite and possibly forcherite. See *DII:935,915*. Amorphous. Concretionary or botryoidal masses, and crusts. Chestnut to red brown, yellow streak, waxy luster. Conchoidal fracture. $H = 2\frac{1}{2}$. $G \approx 2-2.5$. DTA/TCA, IR. Isotropics, $N = 1.726$ (Na) (Litosice); picite samples, $N = 1.677$. Easily soluble in HCl. Found and described as hydrous ferric phosphate at *Berneau, near Visé, Liege, Belgium*; at Leoben, Styria, Austria; at Litosice, and Zeleznik, in gossan at *Nenacovic, S of Kladno, Bohemia, Czech Republic*; in the oolitic iron ores of Kerch Penin., Russia. HCWS *TMPM* 26:79(1978), *AM* 65:813(1980).

42.6.7.1 Senegalite $\text{Al}_2(\text{PO}_4)(\text{OH})_3 \cdot \text{H}_2\text{O}$

Named in 1976 for the country in which it was found. Bolivarite (42.6.8.1) is the higher hydrate, and bulachite (42.6.7.2) is the As end member of the P–As series. ORTH $Pna2_1$. $a = 9.693$, $b = 7.596$, $c = 7.660$, $Z = 4$, $D = 2.57$. Structure: *AM* 64:1243(1979). Two types of Al–O polyhedra form infinite chains that run parallel to [101] and $[\bar{1}01]$. (PO_4) tetrahedra associate with three chains forming an open framework structure with (OH) groups at the points of chain linkage. H_2O is linked to Al, therefore not zeolitic. 36-409: 5.40₇ 4.09₆ 3.83₁₀ 3.61₆ 3.54₃ 3.21₄ 2.99₄ 2.35₃. Crystals show (100), (001), (010), (110), (210), (011), (502), (111). Colorless to pale yellow, vitreous luster. Cleavage {100}, imperfect. $H = 5\frac{1}{2}$. $G = 2.552$. IR, DTA. Nonfluorescent. Biaxial (+); $XYZ = bca$; $N_x = 1.562$, $N_y = 1.566$, $N_z = 1.587$ (Na); $2V = 53^\circ$; $r > v$, weak. Analyses also show minor Fe, trace Cu. Found in the zone of oxidation at *Kourondicko iron ore (magnetite) deposit, Falemé R. basin, eastern Senegal*,

associated with turquoise, augelite, wavellite, and crandallite. HCWS *LIT* 9:165(1976), *AM* 62:595(1977).

42.6.7.2 Bulachite $\text{Al}_2(\text{AsO}_4)(\text{OH})_3 \cdot 3\text{H}_2\text{O}$

Named in 1985 for the locality. ORTH *Pmnm*, $P2_122_1$, *Pma2*, or $Pmn2_1$. $a = 15.53$, $b = 17.78$, $c = 7.03$, $Z = 10$, $D = 2.55$. *AUF* 34:445(1983). 37-482: 8.97₇ 7.78₁₀ 7.14₅ 6.55₇ 5.92₇ 3.75₇ 3.49₈ 2.73₆. Very fine needles in radial aggregates. White, silky luster, translucent. No discernible cleavage. $H \approx 2$. $G = 2.60$. Biaxial (-); $N_x = 1.540$, $N_{y \text{ calc}} = 1.546$, $N_z = 1.548$; $2V \approx 66^\circ$; $r > v$. Found at *Neubulach, northern Black Forest, Germany*, associated with arsenocrandallite, malachite, azurite, Ba-pharmacosiderite, and goethite. HCWS *AM* 70:214(1985).

42.6.8.1 Bolivarite $\text{Al}_2\text{PO}_4(\text{OH})_3 \cdot 4-5\text{H}_2\text{O}$

Named in 1921 for Ignacio Bolivar y Urrutia (b.1850), Spanish entomologist. Amorphous. Cryptocrystalline crusts. Pale yellow-green, vitreous luster. Conchoidal fracture, brittle. $H = 2\frac{1}{2}$. $G = 2.05$. Strongly fluorescent bright green. $N = 1.506$. Feebly birefringent. $\text{Al}_2\text{O}_3/\text{P}_2\text{O}_5/\text{H}_2\text{O} = 2:1:12.5$. Found in crevices in granites near *Pontevedra, Spain*; at Kobokobo, Kivu, Zaire. HCWS *DII*:872; *MM* 32:419(1960), 38:418(1971).

42.6.9.1 Fluellite $\text{Al}_2(\text{PO}_4)(\text{OH})\text{F}_2 \cdot 7\text{H}_2\text{O}$

Named in 1824 in allusion to the composition as the discoverer overlooked the presence of phosphate. ORTH *Fddd*. $a = 8.546$, $b = 11.22$, $c = 21.158$, $Z = 8$, $D = 2.16$. *MR* 8:392(1977), Structure: *AM* 51:1579(1966). 37-450: 6.51₁₀ 4.98₁ 3.25₄ 3.09₂ 2.75₁ 2.67₁ 2.45₁ 2.16₁. See also 19-38. Crystals dipyrmidal {111}, modified by {010}. Colorless to white, vitreous luster, transparent. Cleavage {010}, {111}, indistinct. $H = 3$. $G = 2.14-2.17$. Biaxial (+); $N_x = 1.473$, $N_y = 1.490$, $N_z = 1.511$ (Stenna Gwyn); $2V$ very large; $r > v$, strong. Found at Pyrophyllite mine, Carolina Co., NC; at *Stenna Gwyn, near St. Austell, Cornwall, England*, as minute crystals on quartz with fluorite, arsenopyrite, torbernite, tavistockite, and wavellite; at the pegmatites of Kreuzberg, Pleystein, in Oberpfalz, and at Hagendorf, with phosphosiderite and strengite, as an alteration of triplite at Konigswart near Marienbad, Bavaria, Germany; at Port Chester, Woldene, Q, and at the following quarries in SA: Moculta in Angaston, St. Johns in Kapunda, and Tom's, Australia. HCWS *DII*:124.

42.6.10.1 Sengierite $\text{Cu}_2(\text{UO}_2)_2\text{V}_2\text{O}_8(\text{OH})_2 \cdot 6\text{H}_2\text{O}$

Named in 1949 for Edgar Sengier (1879-1963), executive director, Societe Generale de Belgique, Managing Director, Union Miniere du Haut-Katanga, Zaire. MON $P2_1/a$. $a = 10.599$, $b = 8.903$, $c = 10.085$, $\beta = 103.42^\circ$, $Z = 2$, $D = 4.10$. *BM* 79:219(1956), Structure: *BM* 103:176(1980). 34-172: 9.82₁₀ 5.75₄ 4.91₈ 3.74₆ 3.20₆ 3.18₆ 3.14₆ 3.09₆. See also 8-398. Crystals thin plates flattened {001} with six-sided outline show {111}, {010}, {110}, {011}.

Yellowish green, light green streak, vitreous to adamantine luster, transparent. Cleavage {001}, perfect. $H = 2\frac{1}{2}$. $G = 4.05$. TGA. Radioactive. Biaxial (-); $XYZ = cba$ $N_x = 1.77$, $N_y = 1.94$, $N_z = 1.94$; $2V \approx 37^\circ$; $r < v$, strong; pleochroic. X = blue-green; Y = olive-green; Z = yellow-green. Soluble in acids. Found at Cole shaft, Bisbee, Cochise Co., AZ; at *Luiswishi, Elizabethville-Jadotville area, Shaba, Zaire*, with volborthite, vandenbrandeite, malachite, and black oxides of Co. HCWS *DII:1047; AM 34:109(1949), 66:220(1981)*.

42.6.11.1 Tiptopite $K_2(Na,Ca)_2Li_3Be_6(PO_4)_6(OH)_2 \cdot H_2O$

Named in 1985 for the locality. HEX $P6_3$. $a = 11.655$, $c = 4.692$, $Z = 1$, $D = 2.52$. *CM 23:43(1985)*, Structure: *AM 72:816(1987)*. Isostructural with cancrinite group minerals. *38-374: 3.81₄ 3.36₅ 2.97₁₀ 2.53₉ 2.35₇ 2.22₆ 2.08₅ 1.459₆*. Prismatic needles, up to 2 mm long and 0.1 mm wide, occasionally as cavernous tubes, in radial and divergent spray fascicles. Colorless, vitreous luster, transparent. No apparent cleavage, uneven fracture, brittle. TGA. Nonfluorescent. Uniaxial (+); $N_O = 1.551$, $N_E = 1.559$ (589 nm). Microprobe and AA analyses showed Na, Ca, Mn, Al. Found in two different assemblages: (1) with whitlockite, red and yellow montgomeryite, englishite, hurlbutite, red and orange roscherite, whiteite, robertsite, fairfieldite, and fransoleite, and (2) with mitidatite, light brown to colorless montgomeryite, eosphorite-childrenite, dark olive-green roscherite, in the outer intermediate zone of the *Tip Top pegmatite, Custer, Black Hills, SD*. HCWS *AM 71:230(1986)*.

42.6.12.1 Yingjiangite $(K,Ca)(UO_2)_3(PO_4)_2(OH) \cdot 4H_2O$

Named in 1990 for the locality. ORTH $C222_1$. $a = 13.73$, $b = 15.99$, $c = 17.33$, $Z = 8$, $D = 4.17$. *AMS 10:102(1990)*. *PD: 8.03₁₀ 5.90₄ 3.99₉ 3.88₄ 3.45₄ 3.17₇ 3.10₇ 2.89₆*. Compact microcrystalline aggregates with grain size to 0.15 mm. Golden yellow to yellow, subadamantine to resinous luster, transparent to translucent. $H = 3-4$. $G = 4.15$. Fluoresces weak yellow-green. IR, DTA. Biaxial (-); $N_x = 1.669$, $N_y = 1.692$, $N_z = 1.710$; $2V = 83^\circ$; length slow; pleochroic. X, colorless; Y, light yellow; Z, yellow. Found as a secondary product in the oxidized zone containing uraninite and uranothorite in *Tongbiguan village, Yingjiang Co., Yunnan Prov., China*. HCWS *AM 76:1731(1991)*.

42.7.1.1 Childrenite $Fe^{2+}Al(PO_4)(OH)_2 \cdot H_2O$

Named in 1823 for John George Children (1777-1852), English chemist and mineralogist. Forms a Fe^{2+} - Mn^{2+} series with eosphorite (42.7.1.2). ORTH $Bba2$. $a = 10.395$, $b = 13.394$, $c = 6.918$, $Z = 8$, $D = 3.15$. *AM 35:793(1950)*, Structure: *NJMM:263(1984)*. *11-621(manganoan childrenite): 5.27₄, 4.40₃ 3.54₃ 3.39₃ 2.81₁₀ 2.42₄ 2.39₃ 1.522₄; 42-1420(strontian childrenite); 16-632(possibly a triclinic modification)*. Equant, pyramidal to short prismatic [001], thick tabular {010} or platy {100}; radial groups of distinct crystals grading into botryoidal masses or crusts with fibrous structure, also occasionally massive. Prism zone striated [001]. Brown to yellowish brown, white streak, vitreous luster, transparent to translucent. Cleavage {100}, poor; sub-

conchoidal to uneven fracture. $H = 5$. $G = 3.25$. Biaxial (-); $XYZ = bac$; $N_x = 1.649$, $N_y = 1.683$, $N_z = 1.691$; $r < v$, strong; pleochroic. X, yellow; Y, pink; Z, pale pink to colorless. Soluble in acids. A complete solid solution Fe-Mn probably exists but analyses report mostly end member; composition Ca, Sr, and occasionally Fe^{3+} are also reported. Found in mines at Black Mt., Cole, Mt. Mica, Tourmaline, near Newry, and at Paul Bennett and Berry quarries, Poland, at Ryerson Hill, and Tamminen mine, ME; at G.E. Smith, Newport, and Palermo No. 1 mine, North Groton, NH; at Branchville, CT; at Foote mine, Kings Mt., Cleveland Co., NC; at Helen Beryl mine, Custer Co., Hugo mine, Keystone Co., Pennington, SD; at *Tavistock, Devonshire, England*, and at Wheal Crebor, and the George and Charlotte mines nearby associated with siderite, quartz, pyrite, and apatite in hydrothermal veins; also at St. Austell, Cornwall, with zinnwaldite, tourmaline, and apatite; at the granitic pegmatite in Greifenstein, Ehrenfriedersdorf, Saxony, Germany, and Hagen-dorf near Pleystein, Bavaria; at Beryl mine, Sapucaia, at Larva do Enio, Galileia, and Corrego Frio, MG, Brazil. *ncws DII:936, NJMM:78(1957)*.

42.7.1.2 Eosphorite $Mn^{2+}Al(PO_4)(OH)_2 \cdot H_2O$

Named in 1878 from the Greek for *dawn-bearing*, in allusion to the pink color. The Mn end member in the Mn- Fe^{2+} series with childrenite (42.7.1.1). ORTH *Bbam*. $a = 10.436$, $b = 13.495$, $c = 6.923$, $Z = 8$, $D = 3.12$. Structure: *AC 13:384(1960)*. *36-402*: 6.75₃ 5.22₆ 4.87₃ 4.38₄ 4.13₄ 3.41₃ 2.82₁₀ 2.43₃. Short to long prismatic {001} with prism zone striated [001], twinning; radial groups, massive with coarse fibrous structure. Pink, rose-red, yellowish brown; white streak; vitreous to resinous luster; transparent to translucent. Cleavage {100}, poor; uneven fracture. $H = 5$. $G = 3.06$. Biaxial (-); $XYZ = bac$; $Z \wedge C = 5-6^\circ$, reported suggesting monoclinic rather than orthorhombic symmetry. $N_x = 1.628$, $N_y = 1.648$, $N_z = 1.657$; $2V \approx 50^\circ$; $r < v$, strong; pleochroic. X, yellow; Y, pink; Z, pale pink. Microprobe analyses show minor Ca and trace Cu. Found at many of the localities listed for childrenite especially at Newry, Poland, Buckfield, Mt. Mica, Black Mt., Hebron, ME, and at Palermo mine, North Groton, NH. Originally from *Branchville, Fairfield Co., CT*, associated with rhodochrosite, lithiophyllite, triploidite, dickinsonite in granitic pegmatite; at Hagen-dorf Süd, Oberpfalz, Germany; at Mawi Laghman, Afghanistan; at Lavra da Ilha, Taquaral, and at Mendes Pimentel, MG, Brazil. *ncws DII:936, AM 35:1793(1950), NJMM 78:(1957)*.

42.7.1.3. Ernstite $(Mn_{1-x}^{2+}Fe_x^{3+})Al(PO_4)(OH)_{2-x}O_x$

Named in 1970 for Theodor K. A. Ernst (b.1904), mineralogist, University of Erlangen, Germany. MON *C2/c* or *Cc*. $a = 13.32$, $b = 10.497$, $c = 6.969$, $\beta = 90.37^\circ$, $Z = 8$, $D = 3.086$. *NJMM:289(1970)*. *24-730*: 5.24₃ 4.36₄ 3.52₄ 2.84₃ 2.83₁₀ 2.44₅ 2.42₄ 2.00₄. Radiating aggregates to 15 mm long, crystals untwinned. Yellow-brown, translucent. Cleavage {010}, {100}, good. $H = 3-3\frac{1}{2}$. $G = 3.07$. Biaxial (-); $Z = b$; $Y \wedge c = -4^\circ$; $N_x = 1.678$, $N_y = 1.706$, $N_z = 1.721$ (Na); $r > v$; pleochroic: X, yellow-brown; Y, red-brown; Z, pale

yellow. Found as an oxidation product of eosphorite in granitic pegmatite at *Daib-East farm, Karibib, Namibia*. *HCWS AM. 56:637(1971)*.

42.7.1.4 Sinkankasite $\text{H}_2\text{Mn}^{2+}\text{Al}(\text{PO}_4)_2(\text{OH}) \cdot 6\text{H}_2\text{O}$

Named in 1984 for John Sinkankas (b.1915), Captain, U.S. Navy, and author of books on minerals and gems. *TRIC P1* or *P1*. $a = 9.58$, $b = 9.79$, $c = 6.88$, $\alpha = 108.1^\circ$, $\beta = 99.6^\circ$, $\gamma = 98.7^\circ$, $Z = 2$, $D = 2.25$. *AM 69:380(1984)*. *42-597: 9.2₁₀ 5.41₅ 5.06₆ 4.13₂ 2.94₃ 2.83₄ 2.70₄ 2.43₃*. Crystals flattened on {100}, elongated on [001], multiply twinned on {100}. Colorless, vitreous luster, transparent. Cleavage {100}, perfect but difficult; parting {100} along twin boundaries good; very brittle. $H = 4$. $G = 2.27$. Nonfluorescent. Biaxial (-); $Y \wedge c \approx 11^\circ$; $N_x = 1.511$, $N_y = 1.529$, $N_z = 1.544$; $2V_{(\text{calc})} = 84^\circ$; $r < v$. Analyses also showed Fe, Mg, Ca, minor amounts of Zn, Na, trace Si, Pb, Ti, Be, Li. Found at Palermo pegmatite, North Groton, NH; at *Barker pegmatite, SW of Keystone, Pennington Co., SD*, where it occurs as pseudomorphs after triphylite and as cavity fillings from dissolution of triphylite in quartz, microcline, albite, and muscovite rock, and associated with vivianite, hureaulite, carbonate-apatite, strengite, barbosalite, and fluellite. *HCWS*

42.7.2.1 Foggite $\text{CaAl}(\text{PO}_4)(\text{OH})_2 \cdot \text{H}_2\text{O}$

Named in 1975 for Forrest F. Fogg (b.1920), wildlife manager and micro-mount mineral collector, Penacook, NH. *ORTH A2₁22*. $a = 9.270$, $b = 21.324$, $c = 5.190$, $Z = 8$, $D = 2.771$. *AM 60:957(1975)*, *Structure: 60:965(1975)*. *29-282: 10.7₄ 6.96₅ 4.24₁₀ 4.20₅ 3.11₇ 2.69₈ 2.51₅ 2.29₄*. Spherulites, radial aggregates, and as platy (parallel to {010}, elongated parallel to [001]) crystals up to 0.2 mm, in bunches like a partly opened book. Snow white to colorless, translucent. $H \approx 4$. $G = 2.78$. Biaxial (+); $XYZ = cba$; $N_x = 1.610$, $N_y = 1.610$, $N_z = 1.611$; $2V = 40-45^\circ$. Found at *Palermo No. 1 mine, North Groton, Grafton Co., NH*, on quartz, childrenite, and siderite; at Milgun Station, WA, Australia. *HCWS*

CRANDALITE GROUP

Minerals are a subset of the ALUNITE GROUP (DANA #) with the general formula

where

A=Ca, Sr, Ba, PB

B=Al, Fe^{3+}

T=As, P

and crystallize in hexagonal/rhombohedral (R3m) or monoclinic pseudo-hexagonal (Cm) space groups. See also florencite/arsenoflorencite subgroups 41.10.5.1.

CRANDALLITE GROUP

Mineral	Formula	<i>a</i>	<i>b</i>	<i>c</i>	β
Crandallite	$\text{CaAl}_3(\text{PO}_4)_2(\text{OH})_5 \cdot \text{H}_2\text{O}$	7.005	16.192		
Gorceixite	$\text{BaAl}_3(\text{PO}_3\text{OH})(\text{OH})_6$	12.217	7.056	7.061	125.21
Goyazite	$\text{SrAl}_3(\text{PO}_4)(\text{OH})_5 \cdot \text{H}_2\text{O}$	7.021	16.505		
Lusungite	$(\text{Sr,Pb})\text{Fe}^{3+}(\text{PO}_4)_2 \cdot \text{H}_2\text{O}$	7.04	16.80		
Plumbogummite	$\text{PbAl}_3(\text{PO}_4)_2(\text{OH})_5 \cdot \text{H}_2\text{O}$	7.033	16.789		
Arsenocrandallite	$(\text{Ca,Cr})\text{Al}_3[(\text{As,P})\text{O}_4]_2(\text{OH})_5 \cdot \text{H}_2\text{O}$	7.08	17.27		
Philipsbornite	$\text{PbAl}_3(\text{AsO}_4)_2(\text{OH})_5 \cdot \text{H}_2\text{O}$	7.11	17.05		
Arsenogoyazite	$(\text{Sr,Ca,Ba})\text{Al}_3[(\text{As,P})\text{O}_4]_2(\text{OH})_5 \cdot \text{H}_2\text{O}$	7.10	17.16		
Segnitite	$\text{PbFe}^{3+}\text{H}(\text{AsO}_4)_2(\text{OH})_6$	7.359	17.113		

42.7.3.1 Crandallite $\text{CaAl}_3(\text{PO}_4)_2(\text{OH})_5 \cdot \text{H}_2\text{O}$

Named in 1917 for Milan L. Crandall, Jr., engineer, Knight Syndicate, Provo, UT. $\text{HEX-R } R\bar{3}m$. $a = 7.005$, $c = 16.192$, $Z = 3$, $D = 2.997$. Structure: *AM 59:41(1974)*. Structure resembles alunite. Sheets of corner-shared distorted Al octahedra $[\text{Al}(\text{O},\text{OH})_6]$ form six-membered trigonal rings that link with PO_4 . The sheets are stacked parallel to (0001). Ca atoms bonded to 12 (O,OH) atoms are in large cavities between the sheets. The perfect {0001} cleavage is an expression of the structure. *33-257*: 4.87_2 3.51_3 2.98_4 2.94_{10} 2.16_6 1.897_3 1.752_4 1.429_3 . See also *42-1420*, strontian crandallite; *16-632*, possibly a triclinic modification. Minute trigonal prisms terminated by {0001}, rosettes of fibers elongated perpendicular to [0001], usually massive, nodular aggregates with concentric layers composed of subparallel or matted fibers; spherules with radial fibrous structure. Yellow, yellowish white, white, gray; vitreous to dull or chalky luster; transparent to opaque. Cleavage {0001}, perfect. $H = 5$. $G = 2.92$. Uniaxial (+); $N_O = 1.618$, $N_E = 1.623$ (Fairfield, fibrous). Sr, Ba, and REE may substitute for Ca and Fe^{3+} for Al. May be found as a pseudomorph after gordonite (42.11.14.4). Crandallite is a secondary mineral that occurs in lateritic phosphate deposits and as an alteration product in pegmatites. Found at Fletcher and Palermo mines, North Groton, NH; in the phosphate deposits of the Bone Valley formation, central FL, with clays, millisite, and wavellite, and in the phosphorite unit of the Hawthorne formation; at Glass Sand quarry, Gore, VA; at Tip Top mine, Custer Co., Everly mine, Pennington Co., Hugo mine, Reyson, SD; in UT at the *Brooklyn mine, near Silver City, Tintic district, Juab Co., UT*, with quartz and barite; and at Fairfield, Utah Co., associated with deltaite, millisite, wardite, variscite, gordonite, englishite, montgomeryite, overite, sterrettite, and apatite; at Esmeralda Co., NV; at Bajo de Santa Fe, Guatemala; in alluvial sediments in Barandin, Czech Republic; at the Buranga pegmatite, Rwanda; at Iron Knob, Monarch quarry, SA, Australia; at Alto Benedito pegmatite, Picui, Paraiba, Brazil. *hows DII:835; AM 57:473(1972), 65:953(1980)*.

42.7.3.2 Gorceixite $\text{BaAl}_3(\text{PO}_4)(\text{PO}_3\text{OH})(\text{OH})_6$

Named in 1906 for Henrique Gorceix (1842-1919), first director of the School of Mines, Ouro Preto, Brazil. Crandallite subgroup forms a Ba-Sr series with goyazite (42.7.3.3). *MON Cm*. $a = 12.217$, $b = 7.056$, $c = 7.061$, $\beta = 125.21^\circ$, $Z = 2$, $D = 3.41$. *NJMM:113(1990)*, Structure: *NJMM 446(1982)*. *41-1459: 5.77₉ 3.53₆ 3.01₁₀ 2.29₄ 2.23₂ 1.920₃ 1.763₂ 1.506₂*. See also *33-130, 19-535*. Microcrystalline grains. Brown to salmon, mottled, vitreous to dull luster. Commonly found as fine-grained rolled pebbles locally called *favas*. Porcelainous fracture. $H = 6$. $G = 3.04-3.19$. Uniaxial (+); $N_O = 1.618$, $N_E = 1.625$; length-fast, undulose extinction. Ca, Ce, and Sr substitute for Ba. Found at similar localities as crandallite in NH, SD, and UT and as late-stage mineralization with fluorite, apatite, and barite in tin-tungsten deposits in the Ozarks at the Silvermine area, Madison Co., MO; at Big Fish and Hess R., YT, Canada; at Lengenbach quarry, Binn Valais, Switzerland; at Felsobanya, Baia Sprie, Romania; in the graphite deposit of Petrovskoye, Ukraine; at Dompim, Bonsa R., Gold Coast; at Oiyi district, Sierra Leone; and in Triassic gravels at Somabula, Zimbabwe; at Issineru, Mazaruni district, Guiana; in the diamond sands of *Rio Abaeto, MG, Brazil*, and at Serra de Congonhas in the Diamantina. *HCWS DII:833; AM 43:688(1958), 69:985(1984); PD 4:227(1989)*.

42.7.3.3 Goyazite $\text{SrAl}_3(\text{PO}_4)_2(\text{OH})_5 \cdot \text{H}_2\text{O}$

Named in 1884 for the state of Goias, Brazil. Crandallite group. *HEX-R R3m*. $a = 7.021$, $c = 16.505$, $Z = 3$, $D = 3.265$. *MM 47:221(1983)*. *34-152: 5.70₅ 3.51₆ 2.97₁₀ 2.77₂ 2.21₅ 1.903₂ 1.756₁ 1.457₁*. Small rhombohedral crystals, pseudocubic {1012} or tabular {0001} with rhomb faces striated horizontally; pebbles or rounded grains. Colorless, pink, honey-yellow; greasy to resinous luster on {001} pearly; transparent. Cleavage {001}, perfect. $H = 4\frac{1}{2}-5$. $G = 3.26$. Uniaxial (+); $N_O = 1.629$, $N_E = 1.639$ (Na) (Brazil). May show biaxiality with zonal growth, thick sections pleochroic. Slowly soluble in acids. Found at Black Mt., Harvard quarry, Lord Hill, Mt. Mica mine, Mt. Rubellite mine, Newry, Bell Mt., Paul Bennett, ME; Palermo mine, North Grafton, NH; Home Sweet Home mine, Park Co., CO; at Big Fish R., Rapid Creek, YT, Canada; on anhydrite in the Simplon tunnel, Switzerland; with barite, pyrite, clayey inclusions, and quartz in the limestones of Belaya Kalitva region, Donetz basin, and in the breccias of Romny and Issachki salt domes, Ukraine; at Alto Bernardino, Picui, Paraiba, in the diamond-bearing sands of *Goias, and at Serra de Congonhas, near Diamantina, MG, Brazil*. *HCWS DII:834, MJ 13:390(1987), NJMM:113(1990)*.

42.7.3.4 Lusungite $(\text{Sr,Pb})\text{Fe}_3^{2+}(\text{PO}_4)_2(\text{OH})_5 \cdot \text{H}_2\text{O}$

Named in 1958 for the Lusungu River, Zaire. Crandallite group. *HEX-R R3m*. $a = 7.04$, $c = 16.80$, $Z = 3$, $D = 4.12$. *AM 44:906(1959)*. *14-58: 5.77₉ 3.53₆ 2.98₁₀ 2.48₄ 2.26₂ 2.22₂ 2.20₁ 1.913₂*. Crusts. Yellow-brown, translucent. Found at *Kobokobo, Kivu, Zaire*, with iron oxyhydroxides, "limonite." *HCWS*

42.7.3.5 Plumbogummite $\text{PbAl}_3(\text{PO}_4)_2(\text{OH})_5 \cdot \text{H}_2\text{O}$

Named in 1832 for the Greek for *lead* for the composition and *gum* and the appearance. Crandallite subgroup. HEX-R $R3m$ $a = 7.033$ $c = 16.789$ $Z = 3$ $D = 4.025$ *NJMM 113(1990)*. $35-623$ 5.7_9 5.57_2 3.50_6 3.44_2 2.97_{10} 2.22_3 1.908_3 1.751_2 . Botryoidal, reniform, stalctitic, globular, crusts and masses with concentric structure; compact massive resembling 'gum'; radially fibrous or spherulitic; rare crystals have hexagonal outline. Greyish-white, yellowish grey to yellow to reddish brown, greenish, bluish, streak white, dull to resinous, translucent. Fracture uneven to subconchoidal, brittle. $H = 4\frac{1}{2}-5$ $G = 4.01$. Uniax $+N_0$ 1.653 N_e 1.675 may be isotropic. Soluble in hot acids, may give off organic odor. A secondary mineral often associated, and may be pseudomorphic after, pyromorphite or barite in lead deposits. Found with marcasite at Canton mine, GA; at Mine La Motte, MO; at Roughten Gill, Gry Gill, near Caldbeck, Cumberland, England with pyromorphite and mimetite; at Huelgoat, Finistere, Brittany, Nussiere near Beaujeu with pyromorphite, cerussite, anglesite, wulfenite, France; as rolled fragments (favas) with fibrous structure in diamond-bearing alluvium near Diamantina, Brazil *DII;831, MM 36:550(1967)*.

42.7.3.6 Kintoreite $\text{PbFe}_3(\text{PO}_4)_2(\text{OH},\text{H}_2\text{O})_6$

Named in 1995 for the locality. HEX-R $R3$ $a = 7.325$ $c = 16.900$ $Z = 3$ $D = 4.34$ *MM 59:143(1995)*. PD 5.96_9 3.67_6 3.07_{10} 2.97_4 2.82_4 2.54_5 2.26_5 1.979_5 . Clusters and coatings of crystals showing rhomb {112} to several mm. also globular, hemispheric, Cream, yellowish-green and brownish-yellow. Crystals translucent, vitreous to adamantine; globules transparent to translucent with waxy luster. Streak pale yellow green. Cleavage {001} good, brittle, rough fracture. $H \approx 4G > 4.2$. Uniaxial (-) N between 1.935 and 1.955; pleochroic yellow green to yellow. Some Zn, Cu, Ba, As, S, on microprobe analysis, and H_2O and CO_2 analyses to 98.9 total wt %. Occurs with segnitite, goethite, pyromorphite, mimetite, hinsdalite, libethinite and apatite in the *Kintore open pit* oxidized portion, *Broken Hill, NSW, Australia* and at the Clara mine near Oberwolfach and Igelschlatt mine near Grafenhausen, Germany. *AM 80:1073(1995)*. HCWS

42.7.4.1 Arsenocrandallite $(\text{Ca},\text{Sr})\text{Al}_3[(\text{As},\text{P})\text{O}_4]_2(\text{OH})_5 \cdot \text{H}_2\text{O}$

Named in 1981 for the composition and relation to crandallite. Crandallite group. HEX-R $R3m$. $a = 7.08$, $c = 17.27$, $Z = 3$, $D = 3.30$. *SMPM 61:23(1981)*. $35-647$: 5.84_8 5.02_3 3.55_9 2.99_{10} 2.23_4 1.919_5 1.769_6 1.302_3 . Reniform crusts, spherulitic aggregates up to 0.1 mm. Blue, bluish green; vitreous luster; translucent. No cleavage, conchoidal fracture. $H \approx 5\frac{1}{2}$. $G = 3.25$. Uniaxial; $N_{av} = 1.625$ (range 1.600–1.650). May show triangular sectors. Partially dissolved by cold 1:1 HCl or HNO_3 , and dissolves slowly in hot 1:1 HCl. Microprobe analysis shows Sr, Ba, Bi, Cu, Al, Fe^{3+} , Si. Spectrographic analysis shows Na, K, Cl. Found on dumps in the *Neubulach mining district, Black Forest, Germany*, with brochantite, chalcophyllite, parnauite, arsenosiderite,

mansfieldite, and corroded tennantite. HCWS *AM* 67:854(1982), *AUF* 30:241(1979).

42.7.4.2 Philipsbornite $\text{PbAl}_3(\text{AsO}_4)_2(\text{OH})_5 \cdot \text{H}_2\text{O}$

Named in 1982 for Helmut von Philipsborn (1892–1983), mineralogist, University of Bonn, Germany. Crandallite group. *HEX-R* *R3m* or *R3m*. $a = 7.11$, $c = 17.05$, $Z = 3$, $D = 4.33$. *NJMM:1*(1982). 35-540: 5.85₆ 5.73₂ 3.59₅ 3.54₂ 3.04₁₀ 2.87₂ 2.28₃ 1.944₃. Massive to earthy crusts of fine-grained aggregates. Grayish green. No cleavage, conchoidal fracture. $H \approx 4\frac{1}{2}$. $G > 4.1$. Isotropic; $N_{\text{av}} = 1.790$. Microprobe showed Fe^{3+} , Zn, Cu, Mn, Cr, S. Found at Tsumeb, Namibia; associated with crocoite at *Dundas district, TAS, Australia*. HCWS *AM* 67:859(1982).

42.7.4.3 Arsenogoyazite $(\text{Sr,Ca,Ba})\text{Al}_3(\text{As,P})\text{O}_4)_2(\text{OH,F})_5 \cdot \text{H}_2\text{O}$

Named in 1984 for the chemical composition and relationship with goyazite. Crandallite group. *HEX-R* *R3m* or *R3m*. $a = 7.10$, $c = 17.16$, $Z = 3$, $D = 3.33$. *SMPM* 64:11(1984). 38-386: 5.84₇ 5.03₂ 3.56₈ 3.03₁₀ 2.31₄ 2.27₄ 1.933₅ 1.777₄. Reniform crusts with rhombohedronlike crystal faces; small tabular crystals show {0001}. White, yellowish, pale green to gray-green; vitreous luster; translucent. No cleavage, conchoidal fracture. $H \approx 4$. $G = 3.35$. Isotropic; $N_{\text{av}} = 1.64$; weakly birefringent. Found at *Clara mine, Oberwolfach, Black Forest, Germany*, on quartz and barite, in association with malachite, brochantite, olivenite, Ba-pharmacosiderite, and SO_4 -free weilerite. HCWS *AM* 71:845(1986).

42.7.4.4 Segnitite $\text{PbFe}^{3+}\text{H}(\text{AsO}_4)_2(\text{OH})_6$

Named in 1992 for E. Ralph Segnit (b.1923), mineralogist and petrologist, Adelaide University, Adelaide, SA, Australia. Crandallite group. Fe^{3+} analog of philipsbornite; related to beudantite (43.4.1.1). *HEX-R* *R3m*. $a = 7.359$, $c = 17.113$, $Z = 3$, $D = 4.77$. *AM* 77:656(1992). 45-1392: 5.97₅ 3.68₄ 3.09₁₀ 2.85₂ 2.28₃ 2.25₂ 1.992₃ 1.840₃. Pseudo-octahedral crystals up to 1 mm across, as aggregates, crusts, and clusters of rhombs up to 5 mm high showing {112}, {001}. Greenish brown to yellowish brown, pale yellow streak, adamantine luster, translucent to transparent. Cleavage good on {001}, rough fracture. $H = 4$. $G > 4.2$. Found at Kintore Pit, *Broken Hill, NSW, Australia*, in the oxidized zone of the lead-zinc sulfide orebodies, where it overgrows beudantite on a matrix of goethite encrusting bluish-gray quartz and small spessartine crystals. It is also associated with mimetite, carminite, baylonite, agardite-(Y), and mawbyite. HCWS

42.7.5.1 Nissonite $\text{Cu}_2\text{Mg}_2(\text{PO}_4)_2(\text{OH})_2 \cdot 5\text{H}_2\text{O}$

Named in 1966 for William H. Nisson (1912–1965), amateur mineralogist, Petaluma, CA. *MON* *C2/c*. $a = 22.523$, $b = 5.015$, $c = 10.506$, $\beta = 99.62^\circ$, $Z = 4$, $D = 2.782$. Structure: *AM* 75:1170(1990). 40-478: 10.8₁₀ 4.36₇ 3.72₆ 2.77₁₀ 2.68₆ 2.53₆ 2.22₇ 1.859₅. Crusts or minute diamond-shaped, crystals tabular

{100}, elongated [001] showing {001}, {100}, {111}. Bluish green, translucent. Cleavage (100), fair. $H = 2\frac{1}{2}$. $G = 2.73$. Biaxial (-); $Z = b$; $Y \wedge c = 6^\circ$, $X \wedge a = 15^\circ$; $N_x = 1.584$, $N_y = 1.620$, $N_z = 1.621$; $2V_{\text{calc}} = 19^\circ$; $r > v$, very strong; pleochroic. X, colorless; Y,Z, turquoise-blue. Easily soluble in 1:10 acids. Analysis shows minor V and Fe. Found in small copper prospect in the *Franciscan formation, Panoche Valley, San Benito Co., CA*, in association with malachite, azurite, libethenite, turquoise, chrysocolla, cuprite, carite, calcite, gypsum, riebeckite, and crossite. HCWS *AM 52:927(1967)*, *PD 1:33(1986)*.

42.7.6.1 Uralolite $\text{Ca}_2\text{Be}_4(\text{PO}_4)_3(\text{OH})_2 \cdot 5\text{H}_2\text{O}$

Named in 1964 for the region (Ural Mts.) in which it was discovered. MON $P2_1/n$. $a = 6.550$, $b = 16.005$, $c = 15.969$, $\beta = 101.64^\circ$, $Z = 4$, $D = 2.197$. Structure: *EJM 6:887(1994)*. Corrugated layers of $[\text{Be}_4(\text{PO}_4)_3(\text{OH})_3]$ parallel (010). The layers consist of 4 corner-sharing $\text{Be}(\text{O},\text{OH})_4$ groups linked with PO_4 into rings with 3, 4, and 8 members (first example of a Be-Be-Be-P ring). Ca polyhedra $[\text{CaO}_5(\text{H}_2\text{O})]$ link the layers. There is one free H_2O . *PD: 7.82_6 7.12_{10} 5.59_7 3.56_7 3.20_4 3.17_4 3.03_6*. See also 16-718. Concretions, radial fibrous spherulites with diameter to 3 mm, or sheaf-like growths. Colorless to white, sometimes stained brown with iron oxides; silky needles have vitreous luster. Concretions, radial-fibrous spherulites or rare sheaflike growths. Cleavage {100}, {010}, poor. $H = 2$. $G = 2.1$. Biaxial (-); X parallel to b ; $Z \wedge a = 9^\circ$; $N_x = 1.510$ – 1.512 , $N_y = 1.525$ – 1.526 , $N_z = 1.533$ – 1.536 ; birefringence = 0.021–0.026; $2V = 66$ – 80° ; positive elongation; extinction [001] $\wedge 20^\circ$. Found in alteration sequence of beryllonite to hydroxylherderite to (brown) ferroan roscherite to white uralolite, Dunton quarry, Newry, Oxford Co., ME; Taquaral and Galileia, MG, Brazil; in late fractures with other Be-phosphates at Weinebene, Koralpe, Carinthia, Austria; in kaolin–muscovite rocks containing fluorite, beryl, apatite, crandallite, moraesite, and glucine at *Boyevka, central Ural Mts., Russia*. vk *ZVMO 93:156(1964)*, *AM 49:1776 (1964)*, *MR 9:99(1978)*.

42.7.6.2 Weinebenite $\text{CaBe}_3(\text{PO}_4)_2(\text{OH})_2 \cdot 4\text{H}_2\text{O}$

Named in 1990 for the locality. See also uralolite (42.7.6.1). MON *Cc*. $a = 11.897$, $b = 9.707$, $c = 9.633$, $\beta = 95.76^\circ$, $Z = 4$, $D = 2.17$. Structure: *EJM 4:1275(1992)*. A framework beryllophosphate (the first reported with three-membered rings) with Ca and H_2O in the cavities. *PD: 5.92_6 5.74_4 4.85_4 4.33_5 3.42_7 2.96_6 2.95_5 2.51_{10}. Platy crystals to 0.1 mm \times 0.3 mm \times 0.5 mm tabular on {001}, elongated on [100], show {001}, {001}, {010}, also {100}, {100}, {111}, {111}, {113}, {113}; xenomorphic rosettes up to 20 mm in diameter. No twinning. Colorless, white streak, vitreous luster, transparent to translucent. No cleavage, splintery fracture, brittle. $H = 3$ – 4 . $G = 2.15$. Non-fluorescent. Biaxial (+); $Z \wedge c = 42^\circ$ in acute β ; $N_x = 1.520$, $N_y = 1.520$, $N_z = 1.530$; $2V < 10^\circ$; nonpleochroic. A secondary mineral found in small fractures in a spodumene-bearing pegmatite at *Weinebebe, Koralpe, Carinthia, Austria*, associated with fairfieldite, roscherite, and uralolite. HCWS *AM 78:847(1993)*.*

42.7.7.1 Roscherite-A $\text{Ca}(\text{Mn}^{2+}, \text{Mg}, \text{Fe}^{2+}, \text{Fe}^{3+}, \text{Mn}^{3+})_2\text{Be}_3(\text{PO}_4)_3(\text{OH})_3 \cdot 2\text{H}_2\text{O}$

42.7.7.2 Roscherite-M

Named in 1914 for Walter Roscher, mineral collector of Ehrenfriedsdorf, Germany. Triclinic (A) and monoclinic (M) modifications have been described, but compositional end members not yet clearly defined. It appears that the structure responds to the amount and site occupancy of trivalent cations (e.g., Fe^{3+}), which in turn affects the OH/H₂O ratio. Structure consists of Fe-O₆ octahedral chains cross-linked with PO₄ tetrahedra with oxidation of the Fe affecting chain continuance. *TMPM* 24:169(1977). See zanzaziite (42.7.7.3). Roscherite-A: TRIC C1. $a = 15.921$, $b = 11.965$, $c = 6.741$, $\alpha = 91.07^\circ$, $\beta = 94.35^\circ$, $\gamma = 89.99^\circ$, $Z = 4$, $D = 2.89$ (high-Mn, low-Mg sample from Foote, CA). 30-173: 9.54₁₀ 5.98₉ 4.84₄ 3.35₂ 3.18₉ 3.01₄ 2.80₅ 2.65₄. Roscherite-M: MON C2/c. $a = 15.844$, $b = 11.854$, $c = 6.605$, $\beta = 95.34^\circ$, $Z = 4$, $D = 2.78$. Structure: *TMPM* 22:266(1975) (high-Mn, high-Mg sample from Lavra da Ilha). 30-172: 9.48₁₀ 5.93₈ 3.16₅ 3.14₅ 3.05₅ 2.94₄ 2.77₆ 2.63₄ (Lavra da Ilha). See also 11-355 (Fe^{3+} -containing sample from Sapucaia). Short prismatic [001], with eight- or six-sided cross section; thin tabular {001}, elongated [010] with rectangular outline due to large {100}, {010}, minor {110}; vermicular aggregates of thin plates. Dark brown to olive-green, translucent. $H = 4\frac{1}{2}$. $G = 2.77$ (Lavra) to 2.93 (Sapucaia). Biaxial (-); $X = b$; $Y \wedge c = -15^\circ$; $N_x = 1.624$, $N_y = 1.639$, $N_z = 1.643$; 2V large; crossed dispersion; $r \gg v$; abnormal interference colors; pleochroic. X, yellow to olive-green; Y, yellow-brown, greenish; Z, chestnut-brown. Soluble in acids. Mn^{2+} , Fe^{2+} form series with analyses showing Ca/Mn/Fe = 10:10:7; Fe^{3+} , Al also detected on analysis. Found at Newry and Black Mt. pegmatites, ME; at Foote mine, NC; with jezekite, lacroixite, childrenite, apatite, and tourmaline in drusy cavities in a granite at Greifenstein(!), near Ehrenfriedersdorf, Saxony, Germany; at Sapucaia pegmatite, and Lavra da Ilha, Taquaral, MG, Brazil. *HCWS DII:968*; *AM* 43:824(1958), 63:427(1978); *NBSM* 25:100(1979); *MR* 17:237(1986), 21:413(1990).

42.7.7.3 Zanzaziite $\text{Ca}_2(\text{Mg}, \text{Fe}^{2+})(\text{Mg}, \text{Fe}^{2+}, \text{Al})_4\text{Be}_4(\text{PO}_4)_6(\text{OH})_4 \cdot 6\text{H}_2\text{O}$

Named in 1990 for Pier F. Zanazzi (b. 1939), crystallographer, Università degli Studi di Perugia, Italy. See roscherite (42.7.7.1). MON C2/c. $a = 15.874$, $b = 11.854$, $c = 6.605$, $\beta = 95.35^\circ$, $Z = 2$, $D = 2.77$. *MR* 21:413(1990). *PD*: 9.50₉ 5.91₁₀ 3.16₇ 3.05₅ 2.77₅ 2.68₄ 2.20₄ 1.642₅. Barrel-shaped crystals showing {100}, {110} with {001} irregular and rounded; bladed; crystal rosettes to 4 mm. Pale to dark olive-green, zoned, white streak, vitreous to slightly pearly luster on cleavage surfaces. Cleavage {100}, good; {010}, distinct. $H = 5$. $G = 2.76$. Nonfluorescent. Biaxial(+); $X = b$; $Z \wedge [100] = 3^\circ$ in obtuse β ; $N_x = 1.606$, $N_y = 1.610$, $N_z = 1.620$; 2V = 72°. Microprobe and other analyses show minor Mn, Fe^{3+} . Found at Lavra da

Ilha, Tequaral, MG, Brazil, associated with eosphorite, wardite, roscherite, and rose quartz in pegmatite. *HCWS AM 76:1732(1991)*.

42.7.8.1 Cyrilovite $\text{NaFe}_3^{3+}(\text{PO}_4)_2(\text{OH})_4 \cdot 2\text{H}_2\text{O}$

Named in 1953 for the locality. See also wardite (42.7.8.2) the Al end member. *TET* $P_4_12_12$ or $P_4_32_12$. $a = 7.313$, $c = 19.315$, $Z = 4$, $D = 3.115$. Structure: *MP 37:1(1987)*. *31-1308*: 5.85₃ 4.85₁₀ 3.60₅ 3.19₈ 3.10₇ 2.66₈ 2.02₄ 1.553₅. See *43-672*, an Al-rich sample. Orange, orange-brown, yellow, translucent. $G = 3.088$. Uniaxial (-); $N_0 = 1.803$, $N_E = 1.769$. TGA. Analyses show K, Ca, and Al, but there is not a complete Fe^{3+} -Al solid solution to wardite (42.7.8.2). Found at Palermo No. 1 mine, North Groton, NH; at Hagendorf Süd, Bavaria, Germany; Rochefort-en-Terre, Morbihan, Bretagne, France; *Cyrilov, Velke Mezirici, western Moravia, Czech Republic*; at Iron Monarch mine, Iron Knob, SA, Australia; at Sapucaia pegmatite, Ze Berto mine, Galileia, MG, Brazil. *HCWS AM 42:204(1954)*, *BM 104:785(1981)*.

42.7.8.2 Wardite $\text{NaAl}_3(\text{PO}_4)_2(\text{OH})_4 \cdot 2\text{H}_2\text{O}$

Named in 1896 for Henry Augustus Ward (1834-1906), mineral dealer and collector, Rochester, NY. See Cyrilovite 42.7.8.1 the other Fe^{3+} end member. *TET* $P_4_12_12$. $a = 7.03$, $c = 19.04$, $Z = 4$, $D = 2.805$. Structure: *MM 37:598(1970)*. *33-1202*: 4.77₅ 4.73₁₀ 3.12₆ 3.09₈ 3.00₈ 2.83₄ 2.59₈ 2.11₄. See also *11-330*. Pyramidal {102} or {114} with {001} usually present, {102} striated horizontally, all forms except {001} are usually uneven; granular aggregates; crusts; parallel aggregates of coarse fibers; radially fibrous and concentrically banded spherulites. Blue-green to pale green to colorless, vitreous luster, transparent. Cleavage {001}, perfect. $H = 5$. $G = 2.81-2.87$. Uniaxial (+); $N_0 = 1.590$, $N_E = 1.599$ (Fairfield). Difficultly but completely soluble in acids. Found at Newry, ME; in Beryl Mt. pegmatite(!), West Andover, NH; at Hugo pegmatite, SD; in variscite nodules at *Clay Canyon, Fairfield, Utah Co.*, with millisite and crandallite, at Amatrice Hill, and Lucin, UT; at Rapid Creek(!), Big Fish R., YT, Canada, in crystals to 4 cm; as an alteration product of amblygonite at Montebras, Soumans, Dept. Creuse, France; at Iron Monarch mine, Iron Knob, SA, and Milgun Station, WA, Australia; at Lavra da Ilha(!), Taquaral, MG, Brazil. *HCWS DII:940; AM 37:849(1952)*, *42:208(1957)*.

42.7.9.1 Millisite $(\text{Na,K})\text{CaAl}_6(\text{PO}_4)_4(\text{OH})_9 \cdot 3\text{H}_2\text{O}$

Named in 1930 for F. T. Millis of Lehi, UT, who found the first specimens. *TET* $P_4_12_12$. $a = 7.00$, $c = 19.07$, $Z = 2$, $D = 2.88$. *AM 45:547(1960)*. *13-371*: 6.6₄ 4.84₁₀ 3.93₃ 3.48₃ 3.40₃ 3.09₈ 2.98₈ 2.81₈. See also *13-370*. Chalcedonic crusts or spherules with fine-fibrous structure. White to light gray, translucent. $H = 5\frac{1}{2}$. $G = 2.83$. Uniaxial (+); $N_0 = 1.602$, $N_E = 1.584$; or biaxial; negative elongation. Found with apatite and Na/K = 8:1 as microcrystalline plates growing in the cement of an altered phosphate deposit in Bone Valley, west-central FL; with dehrnite, lewistonite, and green wardite in variscite nodules

at Little Green Monster mine, *Clay Canyon, Fairfield, Utah Co., UT*; at Iron Knob, SA, Australia; at Thies, Senegal, with Na/K = 30:1. hcws *DII:941*.

42.7.10.1 Chenevixite $\text{Cu}_2\text{Fe}_2^{3+}(\text{AsO}_4)_2(\text{OH})_4 \cdot \text{H}_2\text{O}$

Named in 1866 for Richard Chenevix (1774–1830), French chemist, who in 1801 analyzed an arsenate of copper and iron from Cornwall, England. See luetheite (42.7.10.2). *MON* $P2_1/m$. $a = 15.006$, $b = 5.189$, $c = 5.724$, $\beta = 102.25^\circ$, $Z = 2$, $D = 4.594$. *MM* *41:27(1977)*. *29-553*: 7.32₄ 4.22₅ 3.56₁₀ 2.99₅ 2.59₃ 2.55₇ 2.50₄ 2.45₅. Massive, compact earthy to opaline; acicular to lathlike crystals. Greenish yellow to olive-green and dark green, yellow-green streak. Subconchoidal fracture, brittle. $H = 3\frac{1}{2}$ – $4\frac{1}{2}$. $G = 3.93$. Easily soluble in acids. Found at American Eagle, other mines in Tintic district, UT, with olivenite; at Alum Gulch, Patagonia, AZ; at Las Animas, SON, Mexico; at *Wheal Gorland, St. Day, Cornwall, England*; at Tsumeb, Namibia; at Bali Lo copper mine, Ashburton Downs, WA, Australia; at Antifagasto, Chuquicamata, Chile. hcws *DII:840*.

42.7.10.2 Luetheite $\text{Cu}_2\text{Al}_2(\text{AsO}_4)_2(\text{OH})_4 \cdot \text{H}_2\text{O}$

Named in 1977 for R. D. Luethe (b.1944), geologist at Phelps Dodge Corp., who found the mineral. The Al analog of chenevixite (42.7.10.1). *MON* $P2_1/m$ or $P2_1/c$. $a = 14.743$, $b = 5.093$, $c = 5.598$, $\beta = 101.82^\circ$, $Z = 2$, $D = 4.40$. *MM* *41:27(1977)*. *29-527*: 7.21₇ 3.50₁₀ 2.55₃ 2.51₅ 2.45₃ 1.803₅ 1.471₃ 1.270₄. Tabular crystals on {100} up to 0.2 mm. Indian-blue to greenish, translucent. Cleavage {100}, distinct; brittle. $H = 3$. $G = 4.28$. Biaxial; X parallel to [010]; $Y \wedge [001] = 10^\circ$ in obtuse β ; $N_x = 1.752$, $N_y = 1.775$, $N_z = 1.796$; $2V_{\text{calc}} = 88^\circ$; pleochroic, feebly pale blue. Found as minute crystals in silicified rhyolite porphyry with chenevixite and hematite at the Patagonia mining district, *Santa Cruz Co., AZ*. hcws *AM 62:1058(1977)*.

42.7.11.1 Olmsteadite $\text{K}_2\text{Fe}_2^{2+}(\text{Nb,Ta})(\text{PO}_4)_2\text{O}_2 \cdot 2\text{H}_2\text{O}$

Named in 1976 for Milo Olmstead, micromount mineral collector, Rapid City, SD. See johnwalkite (42.7.11.2). *ORTH* $Pb2_1m$. $a = 7.512$, $b = 10.000$, $c = 6.492$, $Z = 2$, $D = 3.41$. Structure: *AM 61:5(1976)*. Octahedrally coordinated Nb⁵⁺O and Fe²⁺O form chains parallel to c and link with PO₄ tetrahedra into an open-framework structure. K resides in a large pocket and has distorted cubic coordination with O atoms. *35-633*: 7.5₂ 6.54₂ 6.00₁₀ 4.17₃ 3.05₇ 3.00₉ 2.87₄ 2.57₃. Thick prismatic crystals up to 1 mm, thin tabular to 0.3 mm elongated parallel to [010]; showing {100}, {010}, {111}, { $\bar{1}\bar{1}\bar{1}$ }, {110}, {101}. Deep brown, red-brown, to black with bronzy surfaces; olive-green streak; subadamantine luster; translucent. Cleavage {100}, {001}, good. $H = 4$. $G = 3.36$. Biaxial (+); $XYZ = cab$; $N_x = 1.725$, $N_y = 1.755$, $N_z = 1.815$ (Big Chief); $2V \approx 60^\circ$; pleochroic. X, blue-green; Y, yellow; Z, brown $X \gg Z > Y$. Difficultly soluble in warm 1:1 HCl coloring solution, pale green, and producing a white flocculent residue. Mn²⁺ substitutes for Fe²⁺. Found as a product of hydrothermal leaching of triphylite–lithiophilite,

columbite-tantalite at *Big Chief pegmatite, near Glendale, Pennington Co., SD*, and at *Hesnard pegmatite*, probably as an oxidized form containing Fe^{3+} near Custer, Custer Co., with rockbridgeite. hcws

42.7.11.2 Johnwalkite $\text{K}(\text{Mn}^{2+}, \text{Fe}^{2+}, \text{Fe}^{3+})_2(\text{Nb}, \text{Ta})(\text{PO}_4)_2\text{O}_2 \cdot (\text{H}_2\text{O}, \text{OH})_2$

Named in 1986 for R. Johnson (b.1936) and F. Walkup (1943–1993), mineral preparators, Natural Museum of Natural History, Smithsonian Institution, Washington, DC. See olmsteadite (42.7.11.1). ORTH $Pb2_1m$. $a = 7.516$, $b = 10.023$, $c = 6.502$, $Z = 2$, $D = 3.44$. *NJMM:115(1986)*. 39-343: 7.54₃ 6.51₄ 6.01₁₀ 3.26₃ 3.05₇ 3.01₈ 2.86₇ 2.56₄. Prismatic crystals elongated on b to 6 mm in radiating aggregates. Dark reddish brown, vitreous luster, translucent. Cleavages {001}, {100}, good. $H \approx 4$. $G = 3.40$. Biaxial (+); $XYZ = cab$; $N_x = 1.748$, $N_y = 1.763$, $N_z = 1.84$; $2V = 53^\circ$; pleochroic. X, blue-green; Y, yellow to pale brown; Z, brown $X \gg Z \gg Y$. Found at *Champion mine, in the Expectation pegmatite, SE of Keystone, Pennington Co., SD*. hcws *AM 72:223(1987)*.

42.7.12.1 Upalite $\text{Al}(\text{UO}_2)_3(\text{PO}_4)_2\text{O}(\text{OH}) \cdot 7\text{H}_2\text{O}$

Named in 1979 for the composition. MON $P2_1/a$. $a = 13.704$, $b = 16.82$, $c = 9.332$, $\beta = 111.5^\circ$, $Z = 4$, $D = 3.94$. *BM 103:333(1979)*, Structure: *BM 106:333(1983)*. 35-619: 8.4₁₀ 6.03₅ 4.24₆ 4.18₈ 3.43₈ 3.17₇ 3.08₇ 2.90₈. Needles up to 0.33 mm. Amber-yellow. $G = 3.5$. Nonfluorescent. Biaxial (-); $XYZ = bac$; $N_x = 1.649$, $N_y = 1.666$, $N_z = 1.676$; $2V_{\text{calc}} = 74^\circ$; pleochroic. X, colorless; Y, Z, canary-yellow. Found with phuralumite in *beryl-columbite pegmatite at Kobokobo, Kivu, Zaire*, associated with meta-autunite, phosphuranylite, and threadgoldite. hcws *AM 65:208(1980)*.

42.7.13.1 Mundite $\text{Al}(\text{UO}_2)_3(\text{PO}_4)_2(\text{OH})_3 \cdot 5.5\text{H}_2\text{O}$

Named in 1981 for Walter Mund (1892–1956), radiochemist, University of Louvain, Belgium. ORTH $P2_1cn$ or $Pm\bar{c}n$. $a = 17.08$, $b = 30.98$, $c = 13.76$, $Z = 16$, $D = 4.295$. *BM 104:669(1981)*. Structurally related to phosphuranylite. 35-535: 7.80₁₀ 5.74₄ 4.23₃ 3.87₆ 3.37₇ 3.06₅ 3.00₄ 2.13₃. Rectangular plates flattened on {010} elongated [001]. Pale yellow, translucent. Cleavage {010}, {100}, {001}, perfect. Biaxial (-); $XYZ = bac$; $N_{x \text{ calc}} = 1.62$, $N_y = 1.682$, $N_z = 1.688$; $2V = 33^\circ$; weakly pleochroic; negative elongation. Found at *Kobokobo, Kivu, Zaire*, with phuralumite, upalite, and ranunculite. hcws *AM 67:624(1982)*.

42.7.14.1 Vanmeersscheite $\text{U}^{6+}(\text{UO}_2)_3(\text{PO}_4)_2(\text{OH})_6 \cdot 4\text{H}_2\text{O}$

42.7.14.2 Metavanmeersscheite $\text{U}^{6+}(\text{UO}_2)_3(\text{PO}_4)_2(\text{OH})_6 \cdot 2\text{H}_2\text{O}$

Named in 1982 for Maurice Van Meerssche (1923–1990), crystallographer, University of Louvain, Belgium. Vanmeersscheite: ORTH $P2_1mn$. $a = 17.06$, $b = 16.76$, $c = 7.023$, $Z = 4$, $D = 4.49$. 35-547: 8.39₁₀ 5.96₈ 5.30₅ 4.18₇ 3.91₅

3.51₅ 3.07₇ 2.89₇. Biaxial (-); N_x calc = 1.704, N_y = 1.715, N_z = 1.718; $2V = -56^\circ$. Metavanmeersscheite: ORTH *Fddd*. $a = 34.18$, $b = 33.88$, $c = 14.074$, $Z = 32$, $D = 4.49$. 35-548: 8.49₁₀ 6.01₉ 5.38₅ 4.44₄ 4.23₅ 3.52₅ 3.07₇ 2.89₆. Biaxial (-); $N_x \approx 1.67$, $N_y \approx 1.68$, $N_z \approx 1.69$; $2V = -83^\circ$. Both minerals occur as plates elongated on [001], showing {010}, {100}, {101}, {101}. Yellow, translucent. Cleavage {010}, good; {100}, less good. Both strongly fluorescent green. Found at Dunton quarry, Newry, Oxford Co., ME; *Kobokobo pegmatite, Kivu, Zaire*, associated with studtite. ncws *BM 105:125(1982)*.

42.7.15.1 Richelsdorffite $\text{Ca}_2\text{Cu}_5^{2+}\text{Sb}^{5+}(\text{AsO}_4)_4(\text{OH})_6\text{Cl} \cdot 6\text{H}_2\text{O}$

Named in 1983 for the locality. MON *C2/m*. $a = 14.079$, $b = 14.203$, $c = 13.470$, $\beta = 101.05^\circ$, $Z = 4$, $D = 3.30$. *NJMM:145(1983)*, Structure: *ZK 179:323(1987)*. 35-585: 6.80₃ 4.91₇ 4.39₆ 3.05₁₀ 2.67₅ 1.753₆ 0.834₃ 0.795₅. Spheroidal aggregates up to 0.2 mm in diameter; tabular crystals to 0.5 mm. Turquoise-blue to sky-blue, vitreous luster, translucent. Cleavage {001}, perfect. $H = 2$. $G = 3.2$. Biaxial (-); $X \wedge c$; $Y \approx$ parallel to a , Z parallel to b ; $N_x = 1.689$, $N_y = 1.765$, $N_z = 1.799$; $2V_{\text{calc}} = 69^\circ$; $r > v$. X , pale blue; Y , greenish blue; Z , light greenish blue. Readily soluble in 1:10 HCl. Microprobe analyses also show Zn, Fe. Found in Permian sandstone in *Richelsdorf Mts., Hesse, Germany*, with calcite, duftite, tirolite, and tetrahydrodrite, also in cavities in barite, as incrustations on blocks of Cu-rich schist, in cavities in quartz with calcite, tetrahydrodrite, galena, brochantite, and devillite at St. Andreasberg, Harz. ncws *AM 69:211(1984)*.

42.7.16.1 Camgasite $\text{CaMg}(\text{AsO}_4)(\text{OH}) \cdot 5\text{H}_2\text{O}$

Named in 1989 for the composition. MON *P2₁/m*. $a = 9.18$, $b = 7.63$, $c = 16.27$, $\beta = 128.0^\circ$, $Z = 4$, $D = 2.345$. *AUF 40:369(1989)*. *PD: 7.28₁₀ 6.42₁₀ 4.00₈ 3.28₈ 3.21₈ 3.02₈ 2.96₈ 2.54₈*. Crusts, crystals prismatic up to 0.15 mm, elongate [010], showing {100}, {010}, {001}. Colorless, white streak, vitreous luster, transparent to translucent. Polysynthetic twinning observed in section parallel to {010}. Cleavage {100}, {001}, good; conchoidal fracture. $H \approx 2$. $G = 2.40$. Nonfluorescent. Biaxial (+); $X = b$; Z approximately parallel to crystal edge; $N_x = 1.540$, N_y calc = 1.548, $N_z = 1.563$ (589 nm); $2V = 74^\circ$. Easily soluble in 1:10 HCl, HNO₃. Found at lower adit of the *Johann mine, Wittichen, central Black Forest, Germany*, as an intimate intergrowth with monohydrocalcite and associated with calcite, gypsum, rapidcreekite, novackite, erythrite, and hörnesite on hydrothermally altered granite with U and Co mineralization. ncws *AM 76:2021(1991)*.

42.8.1.1 Pharmacosiderite $\text{KFe}_4^{3+}(\text{AsO}_4)_3(\text{OH})_4 \cdot 6-7\text{H}_2\text{O}$

Named in 1813 from the Greek for *poison*, in allusion to the As content, and for iron, to distinguish the composition. See also alumopharmacosiderite (42.8.1.2), barium pharmacosiderite (42.8.1.3), and sodium pharmacosiderite (42.8.1.5). ISO *P43m*. $a = 7.982$, $Z = 1$, $D = 2.60$. *NJMM: 183(1984)*,

Structure: *ZK 125:192(1967)*. Zeolite-like framework of AsO_4 tetrahedra and edge-sharing $\text{Fe}(\text{OH})_3\text{O}_3$ octahedra with other cations and water molecules in channels whose smallest opening is 1.35 Å. Cations and H_2O molecules exchangeable *34-155*: 8.0₉ 4.61₁₀ 3.26₇ 2.82₇ 2.41₈ 2.30₆ 1.784₇ 1.596₆. Crystals are cubes with faces diagonally striated or replaced by vicinal trapezohedra; granular or earthy. Olive-green, honey-yellow, yellow-brown, dark brown, hyacinth-red, brown-red, grass-green, emerald-green; adamantine to greasy luster; transparent to translucent. Cleavage {001}, imperfect to good; uneven fracture; sectile. $H = 2\frac{1}{2}$. $G = 2.797$. TGA. $N = 1.693$ (Na) (Cornwall), varies with color. Anomalously biaxial (+), $r \ll v$; or biaxial (-), $r \gg v$; 2V large, weakly birefringent. May show six biaxial sectors on {001} with optical orientation of sectors varying in different specimens. Lamellar twinning parallel to sides of border sectors. Soluble in HCl. In NH_4OH green crystals turn red (take up NH_4) and back to green on reimmersion in 1:1 HCl. Cation substitution shows P for As to 1:11, Al for Fe^{3+} , Na or Ba for K. Exchange studies with Na, K, Rb, Cs, NH_4 , and HCl showed ease and parallel color changes. Zeolitic water varies from 2.4 to 7.3%, assuming four Fe in the formula unit. A secondary mineral occurring as hydrothermal deposit or oxidation product of arsenic-rich minerals, may alter to "limonite." Found at Sterling Hill mine, Ogdensburg, Sussex Co., NJ; at mines in the Tintic district, UT, with scorodite and copper arsenates derived from enargite; at Lavender pit, Bisbee, Cochise Co., AZ; at the *Carharract and Tincroft mines, Cornwall, England*, and at St. Day, Liskeard, Redruth, Calstock; at Vaulry, Puy-les-Vignes near St. Leonard, Haute-Vienne, France; at Bösensbrunn, Pöhla, and Schwarzenberg, Saxony, and Grube Clara, Rankachtel, Oberwolfach, and with scorodite in Voigtland, Germany; at Kamareza mine, Attica, Greece; at Capo Bianco, Elba, Italy; at Mouzaia, Algiers, Algeria; at Bou-Azzer, Morocco; at Tsumeb, Namibia; at Geralfo Caudinho mine, MG, Brazil; at Chuquicamata, Antofagasta, Chile. *HCWS DII:995*.

42.8.1.2 Alumopharmacosiderite $\text{KAl}_4(\text{AsO}_4)_3(\text{OH})_4 \cdot 6.5\text{H}_2\text{O}$

Named in 1981 for the relationship to pharmacosiderite and the composition. The Al analog of pharmacosiderite. iso *P43m*. $a = 7.745$, $Z = 1$, $D = 2.676$. *NJMM:97(1981)*. *35-670*: 7.77₁₀ 4.48₅ 3.87₄ 3.16₅ 2.74₆ 2.45₃ 2.34₄ 2.24₂. Polycrystalline, incrustation. White, translucent. $N = 1.565$. Transforms to AlAsO_4 at 800°. Found with blue ceruleite, green schlossmacherite, olivenite, and white mansfieldite at *Guanaco, northeastern Chile*. *HCWS AM 66:1099(1981)*.

42.8.1.3 Barium Pharmacosiderite $\text{BaFe}_8^{3+}(\text{AsO}_4)_6(\text{OH})_8 \cdot 14\text{H}_2\text{O}$

Named in 1966 for the relationship to pharmacosiderite and the composition probably P_43N , I_43M , P_42M , or I_42M . TET. Suggestion of BA ordering to give superstructures *NJMM:183(1984)*. $a = 7.97$, $c = 8.10$, $Z = 1$, $D = 3.09$. *TMPM 11:121(1966)*. *34-154*: 8.08₈ 7.95₁₀ 3.26₇ 2.83₁₀ 2.81₆ 2.55₅ 2.52₆ 2.31₅. See also *34-153*. Cubic crystals to 1 mm. Yellow-brown, translucent.

Cleavage {100}, good. $H = 2-3$. $G = 3.00$. TGA, Mossbauer. Anomalously biaxial (-); $N_x = 1.718$, $N_z = 1.728$; $2V = 0-39^\circ$; nonpleochroic. Minor Zn, trace of Al, Ca, Cu, K, Mg, P, Si detected. Readily soluble in warm 1:1 HCl. Found at Sterling Hill mine, NJ; Tintic district, UT; Cornwall, England; on limonite and barite at *Clara mine, Black Forest, Germany*, and at Scholkrippen, Spessart Mts.; Robinson's Reef mine, Port Philip, VIC, Australia. HCWS *AM 52:1585(1967)*.

42.8.1.4 Barium-alumopharmacosiderite $BaAl_4(AsO_4)_3(OH)_5 \cdot 5H_2O$

Named as the aluminium end member with barium pharmacosiderite, but see *MM 38:103(1971)*. ISO *P43m* $a = 7.7134$ $Z = 1$ $D = 3.03$ *TMPM 11:21(1966)*. 19-94 7.8₁₀ 4.46₆ 3.87₇ 3.16₇ 2.73₈ 2.44₄ 2.32₅ 2.33₄. Space group in doubt will depend on whether Ba site is ordered leading to superstructure.

42.8.1.5 Sodium Pharmacosiderite $(Na,K)_2Fe_4^{2+}(AsO_4)_3(OH)_5 \cdot 7H_2O$

Named in 1985 for the relationship to pharmacosiderite and the composition. ISO *P43m*. $a = 8.012$, $Z = 1$, $D = 2.90$. *MR 16:121(1985)*. 38-388: 7.99₁₀ 4.61₅ 4.00₄ 3.27₈ 2.83₆ 2.67₃ 2.53₅ 2.42₆. Pale green, vitreous luster, translucent. Cleavage {001}, imperfect; uneven fracture; brittle. $H \approx 3$. $N = 1.705$. Found with yellow pharmacosiderite, scodorite, arseniosiderite, a yellow member of the jarosite group in vugs formed in dissolving at *Marda, WA, Australia*. HCWS *AM 71:230(1986)*

42.8.2.1 Kidwellite $NaFe_9^{3+}(PO_4)_6(OH)_{10} \cdot 5H_2O$

Named in 1978 for Albert Lewis Kidwell (b.1919), Houston, Texas. MON *A2/M*, *Am* or *A2*. $a = 10.61$, $b = 5.15$, $c = 13.75$, $\beta = 112.64^\circ$, $Z = 2$, $D = 3.34$. *MM 42:137(1978)*. 30-1202: 9.41₁₀ 6.43₃ 4.02₄ 3.81₄ 3.41₆ 3.19₄ 3.17₄ 3.08₂. Fine feathery crystals elongated parallel to [010] in mats or wads. Pale chartreuse-green to greenish yellow, greenish white, bright yellow; silky luster; translucent. Cleavage {100}, perfect. $H = 3$. Biaxial (-); X parallel to b ; $N_x = 1.787$, $N_y = 1.800$, $N_z = 1.805$; $2V$ large; nonpleochroic. Analyses also showed Si, Al, Mg, Mn. Found at Irish Creek, Rockbridge Co., VA; at Indian Mt., AL; at *Coon Creek mine, Shady, Polk Co., AR*, associated with rockbridgeite, dufrenite, beraunite, and strengite in novaculite deposits; at Rotlaufchen mine, Waldirme, Germany. HCWS *AM 64:242(1979)*.

42.8.3.1 Schoonerite $Fe_2^{2+}ZnMn^{2+}Fe^{3+}(PO_4)_3(OH)_2 \cdot 9H_2O$

Named in 1977 for Richard Schooner (b.1925), mineral collector, Woodstock, CT. ORTH *Pmab*. $a = 11.119$, $b = 25.546$, $c = 6.437$, $Z = 4$, $D = 2.79$. *62:246(1977)*, Structure: *AM 62:250(1977)*. 29-709: 12.8₁₀ 8.35₇ 6.43₄ 5.52₃ 3.76₄ 3.18₄ 2.77₉ 1.600₄. Rosettes, mats, scales, and laths up to 2 mm long; thin tabular parallel to {010}, elongated parallel to [100], showing {001},

{010}, {100}, although most crystals are curved and crinkly. Brown to reddish brown to coppery on oxidized material, pale brown streak, vitreous luster, transparent to translucent. Cleavage {010}, micaceous; {001}, good. $H \approx 4$. $G = 2.87\text{--}2.92$. Found as part of the alteration assemblage in association with mitridatite, laueite, strunzite, whitmoreite, and Fe–Mn oxyhydroxides at *Palermo No. 1 mine, North Groton, NH*, as part of the rock alteration of pods containing triphylite, pyrite, pyrrhotite, sphalerite, galena, ludlamite, and vivianite; at Hagendorf Süd, Bavaria, Germany. HCWS

42.8.4.1 Mitridatite $\text{Ca}_2\text{Fe}_3^{2+}(\text{PO}_4)_3\text{O}_2 \cdot 3\text{H}_2\text{O}$

Named in 1914 for the locality. Forms a $\text{Fe}^{3+}\text{--Mn}^{3+}$ series with robertsite (42.8.4.2), and is the P end member of the P–As series with arseniosiderite (42.8.4.3). *MON A2/a*. $a = 17.52$, $b = 19.35$, $c = 11.25$, $\beta = 95.92^\circ$, $Z = 12$, $D = 3.249$. *AM 59:48(1974)*, Structure: *IC 16:1096(1977)*. Pronounced pseudorhombohedral cell. $26\text{--}1057$: 8.64_{10} 5.55_6 3.20_4 2.88_4 2.72_7 2.56_4 2.17_4 1.612_4 . Massive, nodules, gumlike masses; plates up to 0.2 mm show {100}, {001}, {423}. Greenish brown, deep-red to bronze-red; olive-green streak; dull to resinous luster. $H = 2\frac{1}{2}$, $G = 3.24$. Biaxial (–); X approximately perpendicular to {100}; $N_x = 1.785$, $N_y \approx N_z = 1.85$; $2V = 5\text{--}10^\circ$; extremely pleochroic. X, pale greenish yellow; Y, Z, deep greenish brown $Y, Z \gg X$. Soluble in hot acids. Found as the dull green stains, and occasionally as crystals, formed after weathering of primary phosphate-bearing pegmatites at *Palermo No. 1 mine, North Groton, NH*; at *Big Chief, Tip Top, Linwood, and White Elephant(!) pegmatites, SD*, associated with leucophosphite, hureaulite, collinsite, hydroxylapatite, whitlockite, bermanite, laueite, jahnsite, segelerite, and robertsite; in sedimentary Oolitic iron ores at *Mithridat Hill, Kerch, Crimea*, and *Taman peninsulas, Russia*, with vivianite. HCWS *DII:955*.

42.8.4.2 Robertsite $\text{Ca}_2\text{Mn}_3^{2+}(\text{PO}_4)_3\text{O}_2 \cdot 3\text{H}_2\text{O}$

Named in 1974 for Willard Lincoln Roberts (1923–1987), mineralogist, South Dakota School of Mines. Dimorph of pararobertsite (42.8.5.2), in series with arseniosiderite, mitridatite. *MON A2/a*. $a = 17.36$, $b = 19.53$, $c = 11.30$, $\beta = 96.0^\circ$, $Z = 12$, $D = 3.05$. *AM 59:48(1974)*, Structure: *IC 16:1096(1977)*. Pronounced pseudohexagonal cell. $26\text{--}1067$: 8.63_{10} 5.61_5 3.27_4 2.88_3 2.75_6 2.59_4 2.16_3 1.623_5 . Fine feathery aggregates, botryoidal with fibrous structure, plates {100} up to 5 mm in clusters to 7 cm, wedge-shaped crystals which may show {100}, {001}, {031}. Fibers resemble goethite, plates lepidocrocite. Crystals twinned by rotation perpendicular to {100} in multiples of $\pi/3$. Deep red to bronze, black; chocolate-brown streak; shiny luster; translucent. Cleavage {100}, good. $H = 3\frac{1}{2}$, $G = 3.13$. Biaxial (–); X approximately perpendicular to {100}; $N_x = 1.775$, $N_y = N_z = 1.82$; $2V \approx 8^\circ$; extremely pleochroic. X, pale reddish pink; Y, Z, deep reddish brown $Y, Z \gg X$. Found in triphylite-containing pegmatites with rockbridgeite, such as at *Tip Top(!), Linwood, White Elephant, Gap Lode, near Custer, SD*; at Hagendorf Süd, Germany. HCWS

42.8.4.3 Arseniosiderite $\text{Ca}_2\text{Fe}_3^{2+}(\text{AsO}_4)_3\text{O}_2 \cdot 3\text{H}_2\text{O}$

Named in 1842 for the composition and from the Greek for *iron*. See also mitridatite (42.8.4.1) and robertsite (42.8.4.2). MON A2/a. $a = 17.76$, $b = 19.53$, $c = 11.30$, $\beta = 96.0^\circ$, $Z = 12$, $D = 3.60$. AM 59:48(1974), Structure: IC 16:1096(1977). 26-1002: 8.84₁₀ 5.62₅ 3.28₄ 3.22₄ 2.95₅ 2.77₈ 2.21₄ 1.643₄. Massive radial-fibrous aggregates with fibers flattened {001}, easily separable; granular; pseudomorphs after siderite, scorodite. Golden-yellow, yellow-brown, reddish brown, brownish black, black; ochre-yellow streak; submetallic to silky luster; opaque except in small grains. Cleavage {001}. $H = 4\frac{1}{2}$, $1\frac{1}{2}$ in fibers. $G = 3.60$. Biaxial (-); X perpendicular to {100}; $N_x = 1.80$, $N_y = N_z = 1.88$; $2V \approx 0^\circ$; Y, extremely pleochroic. X, colorless; Y, Z, dark reddish brown $Z \gg X$. Easily soluble in hot acids. A low-temperature oxidation product of löllingite, arsenopyrite, and replaces scorodite. Found at Sterling Hill mine, Ogdensburg, and at Franklin, Sussex Co., NJ; in the Tintic district, UT; as concretions at Tagish Lake, YT, Canada; at Jesus Maria mine, Mazapil district, ZAC, Mexico, with pharmacolite, chrysocolla, and calcite and as pseudomorphs after scorodite; also at Ojuela mine, Mapimi, DUR; in the manganese deposit at *Romanèche-Thorins, Macon, Saône et Loire, France*, with quartz, goethite, romanechite, and psilomelane; at Schneeberg, Saxony, and Wittichen, Bavaria, Germany, with erythrite and roselite; as felted masses with scorodite, symplectite, pitticite, and pharmacolite on löllingite at Hüttenberg, Carinthia, Austria; at Kamare mine, Attica, Greece; at Tsumeb, Namibia. hcws DII:853.

42.8.5.1 Kolfanite $\text{Ca}_2\text{Fe}_3^{2+}\text{O}_2(\text{AsO}_4)_3 \cdot 2\text{H}_2\text{O}$

Named in 1982 for the abbreviation of Kola Filial Akad. Nauk. MON $a = 17.86$, $b = 19.66$, $c = 11.11$, $\beta = 96^\circ$, $Z = 12$, $D = 3.75$. MZ 4:90(1982). See arseniosiderite (42.8.4.3). 35-662: 8.90₁₀ 5.64₅ 3.29₉ 2.95₉ 2.72₁₀ 2.22₈ 1.646₈ 1.503₅. Massive or thin plates. Red, orange to yellow; adamantine luster. One cleavage, brittle. $H = 2\frac{1}{2}$. $G = 3.3$. Biaxial (-); $N_x = 1.810$, $N_y = 1.923$, $N_z = 1.933$, $2V = 5-7^\circ$; pleochroic. X, pale yellow; Y, Z, dark orange. Microprobe analysis shows minor P, Sb, Al, and Si. Found in hydrothermally altered granite pegmatites, *Kola Penin., Russia*, formed by alteration of holtite and associated with mitridatite, arseniosiderite, and laueite. hcws AM 68:280(1983).

42.8.5.2 Pararobertsite $\text{Ca}_2\text{Mn}_3^{3+}(\text{PO}_4)_3\text{O}_2 \cdot 3\text{H}_2\text{O}$

Named in 1989 for the demorphic relationship to robertsite. MON P2₁/c. $a = 8.825$, $b = 13.258$, $c = 11.087$, $\beta = 101.19^\circ$, (unconditional setting to compare with robertsite) $Z = 4$, $D = 3.21$. CM 27:451(1989). Pronounced subcell $b' = \frac{1}{2}b$. PD: 8.69₁₀ 5.66₆ 5.44₅ 3.18₅ 2.88₆ 2.83₅ 2.61₆ 2.16₆. Plates and clusters of plates up to 0.2 mm and < 0.02 mm thick. Tabular {100}. Red, brownish-red streak, vitreous luster, translucent. Cleavage {100}, perfect; brittle. Soft. $G = 3.22$. Nonfluorescent. Biaxial (-); $Y = b$; $Z \wedge c = 4^\circ$; $N_x = 1.79$, $N_y = 1.81$, $N_z = 1.83$; Y, pleochroic. X, yellowish brown; Y, Z, reddish

brown $Z > X$. Found on whitlockite encrusting CO_3 -apatite on quartz in secondary seams at *Tip Top pegmatite, Custer, SD*. HCWS AM 75:1211(1990).

42.8.6.1 Yukonite $\text{Ca}_2\text{Fe}_3^{3+}(\text{AsO}_4)_4(\text{OH}) \cdot 12\text{H}_2\text{O}$

Named in 1913 for the locality. An inadequately characterized mineral. Gel-like waxy aggregates, brownish-black color, and as dark-red pseudomorphs after kottingite-parasymplectite. 35-553: 5.60₈ 3.25₁₀ 2.79₈ 2.52₃ 2.33₃ 2.23₃ 1.63₄ 1.51₂. Pattern resembles arseniosiderite. Found associated with ogdensburgite at Sterling Hill mine, Ogdensburg, Sussex Co., NJ; at *Tagish Lake, YT, Canada*. HCWS CM 8:667(1966), MM 46:261(1982), AM 68:474(1983).

42.8.7.1 Mapimite $\text{Zn}_2\text{Fe}_3^{3+}(\text{AsO}_4)_3(\text{OH})_4 \cdot 10\text{H}_2\text{O}$

Named in 1981 for the mining district where it was found. MON *Cm*. $a = 11.415$, $b = 11.259$, $c = 8.661$, $\beta = 107.71^\circ$, $Z = 2$, $D = 3.02$. BM 104:582(1981), Structure: AC(B) 37:1040(1981). 35-515: 8.24₁₀ 7.83₉ 4.66₆ 3.88₅ 3.45₄ 3.33₄ 3.22₄ 2.83₄. Rectangular crystals to 3 mm, flattened {001}, bounded {110}. Polysynthetic twinning (001) with [104] pseudoaxis. Blue, blue-green, green; vitreous luster; translucent. Cleavage {001}, {010}. $H = 3$. $G = 2.95$. DTA. Biaxial (+); $Y = b$; $Z \wedge a = 13^\circ$; $N_x = 1.672$, $N_y = 1.678$, $N_z = 1.712$; $2V = 50^\circ$; $r < v$; strongly pleochroic: X, pale yellow; Y, greenish yellow; Z, deep prussian-blue. Readily soluble in 1:10 acids, fuses to a brown scoria. Some Fe^{2+} detected on analysis. Found at the *Ojuela mine, Mapimi, DUR, Mexico*, associated with scorodite, adamite, and smithsonite on "limonite" matrix. HCWS AM 67:623(1982).

42.8.8.1 Shubnikovite $\text{Cu}_8^{2+}\text{Ca}_2(\text{AsO}_4)_6(\text{OH})\text{Cl} \cdot 7\text{H}_2\text{O}$

Named in 1953 for Aleksei V. Shubnikov (1887-1971), crystallographer, Institute of Crystallography, Moscow, Russia. An inadequately described mineral. Platy, light blue, translucent. $H = 2$. Biaxial (-); $N_x = 1.640$, $N_y = N_z = 1.690$; $2V$ small; $r < v$; pleochroic: X, light blue; Y, Z, greenish blue. Found in an oxidation zone in *Russia*. HCWS ZVMO 82:311(1953), AM 40:552(1955).

42.9.1.1 Burangaite $(\text{Na,Ca})_2(\text{Fe}^{2+},\text{Mg})_2\text{Al}_{10}(\text{PO}_4)_8(\text{OH},\text{O})_{12} \cdot 4\text{H}_2\text{O}$

Named in 1977 for the locality. See also dufrenite (42.9.1.2) and natrodufrenite (42.9.1.3). MON *C2/c*. $a = 25.09$, $b = 5.048$, $c = 13.45$, $\beta = 110.91^\circ$, $Z = 2$, $D = 3.31$. BGSF 49:33(1977). 29-1190: 11.7₁₀ 4.86₄ 4.03₄ 3.32₄ 3.12₇ 3.08₉ 2.04₃ 1.675₃. Long prismatic crystals showing {301}, {102}, {104}, {101}, {223}, {331}, {223}, {311}, {401} and hourglass growth. Blue core, colorless margin. Bluish, bluish green, slightly bluish streak. Cleavage {100}, perfect. $H = 5$. $G = 3.05$. Biaxial (-); $X \wedge c = 11^\circ$ in acute β ; $Z = b$; $N_x = 1.611$, $N_y = 1.635$, $N_z = 1.643$; $2V = 58^\circ$; $r > v$; ; pleochroic. X, light blue; Y, dark blue; Z, colorless $Y > X > Z$. Found in the *Buranga pegmatite, Rwanda*, associated with bertossaite, trolleite, scorzalite (which it replaces), apatite, bjarbyite, and wardite. HCWS AM 63:793(1978).

42.9.1.2 Dufrenite $(\text{Ca}, \square) \text{Fe}^{2+} \text{Fe}_5^{3+} (\text{PO}_4)_4 (\text{OH})_6 \cdot 2\text{H}_2\text{O}$

Named in 1833 for P. A. Dufrenoy (1792–1857), French mineralogist. The Fe end member in the Fe^{2+} -Ca-Na series with burangaite (42.9.1.1) and natro-dufrenite (42.9.1.3). MON C2/c. $a = 25.84$, $b = 5.126$, $c = 13.78$, $\beta = 111.20^\circ$, $Z = 4$, $D = 3.407$. MM 54:419(1990), Structure: AM 55:135(1970). $(\text{Fe}^{2+}, \text{Fe}^{3+})-(\text{O}, \text{OH})_6$ octahedra are joined by face-sharing with PO_4 into triplets with formula $\text{Fe}_3(\text{OH})_4(\text{O}_{\text{P-group}})_8$ and via corner sharing into a second triplet $\text{Fe}_3(\text{OH})_6(\text{H}_2\text{O})_2(\text{O}_{\text{PO}_4\text{-group}})_8$ to form a slab parallel to [100]. The remainder of the structure has cavities that may be occupied, or partially occupied, by other ions, such as Ca. The PO_4 groups plus triplets along [100] account for the perfect cleavage direction and the fiber axis. 8-155: 5.05₉, 4.15₄, 3.42₉, 3.24₈, 3.17₁₀, 2.88₅, 2.44₅, 2.11₆. See also 22-1143, a Ca-containing dufrenite. Botryoidal masses and crusts with radial-fibrous structure whose surface may show drusy round-ended crystals or exfoliated terminations; rounded crystals in subparallel or sheaflike aggregates. Dark green, olive-green, to greenish black becoming reddish with oxidation; vitreous to silky luster; translucent to nearly opaque. Cleavage perfect parallel to [100], and fiber length, brittle. $H = 3\frac{1}{2}$ -4 $\frac{1}{2}$. $G = 3.1$ -3.4. Biaxial (+); $N_x = 1.837$, $N_y = 1.845$, $N_z = 1.895$ (Wheal Phoenix); 2V small; $r > v$, extreme; pleochroic. X, pale yellow-brown; Y, pale brown; Z, red-brown $Z > Y > X$. Indices increase with Fe^{3+} content. Soluble in 1:10 acids. Oxidation analogous to the triphyllite series. A secondary mineral found in gossans and in iron ore deposits. Found at Palermo No. 1, North Groton, NH; at Indian and Wolden Mts., Rock Run, Cherokee Co., AL; at Wheal Phoenix(1), Cornwall, England; at Hureaux, St. Silvester, France; at Hirschberg, Loebenstein in Thuringia, and Ullersreuth and Hauptmannsgrün near Reichenbach, Saxony, and Seigen, Westphalia, Germany; at Kangas farm, Aggeneys district, Bushmanland, South Africa. HCWS DII:873, AM 34:513(1949).

42.9.1.3 Natrodufrenite $\text{Na}(\text{Fe}^{3+}, \text{Fe}^{2+})(\text{Fe}^{3+}, \text{Al})_5(\text{PO}_4)_4 (\text{OH})_6 \cdot 2\text{H}_2\text{O}$

Named in 1982 for the relationship to dufrenite and the composition. The Na-rich end member of the Na- Fe^{2+} series with dufrenite (42.9.1.2). MON C2/c. $a = 25.83$, $b = 5.150$, $c = 13.772$, $\beta = 111.53^\circ$, $Z = 4$, $D = 3.20$. BM 105:321(1982). 35-570: 12.04₈, 5.04₆, 4.12₅, 3.40₈, 3.20₈, 3.15₁₀, 2.99₅, 2.86₅. Spheres of compact radiating fibers up to 0.5 mm in diameter. Pale blue-green, translucent. $G = 3.23$. DTA. Biaxial; $N_x = 1.756$, $N_z = 1.775$; parallel or subparallel extinction; positive elongation; pleochroic: X, pale yellow; Z, dark green. Found at Rochefort-en-Terre, France, where it occurs in a limonitic bed with cyrilovite and goethite. HCWS AM 68:1039(1983).

42.9.2.1 Souzalite $(\text{Mg}, \text{Fe}^{2+})_2(\text{Al}, \text{Fe}^{3+})_4(\text{PO}_4)_4 (\text{OH})_6 \cdot 2\text{H}_2\text{O}$

Named in 1949 for J. A. de Souza (1896–1961), director of Departamento Nacional da Producao Mineral, Brazil. Forms a Mg- Fe^{2+} series with gormonite (42.9.2.2). TRIC P1 or P1. $a = 11.74$, $b = 5.11$, $c = 13.58$, $\alpha = 90.83$,

$\beta = 99.08^\circ$, $\gamma = 90.33^\circ$, $Z = 2$, $D = 3.07$. *CM 19:381(1981)*. 33-863: 6.72₃ 4.76₆ 3.39₁₀ 3.34₃ 3.15₆ 3.06₄ 2.92₈ 2.55₉. Coarse fibrous masses. Green, dark to bluish green; vitreous luster; translucent. Polysynthetic twinning, composition plane parallel to good cleavage. Cleavage in two directions at right angles: one good, the other fair. $H = 5\frac{1}{2}$ -6. $G = 3.087$. Biaxial (-); X perpendicular to cleavage; Z || elongation; $N_x = 1.618$, $N_y = 1.642$, $N_z = 1.652$; $2V = 68^\circ$; $r \gg v$; pleochroic. X, green; Y, blue; Z, yellow. Found at Bell pit, Newry, Oxford Co., ME; Rapid Creek, Big Fish R., Blow R. area, YT, Canada, with gormanite; as hydrothermal alteration product of scorzalite at *Córrego Frio pegmatite, Linópolis district, N of Divino das Laranjeiras, MG, Brazil*. *HCWS DII:911; AM 34:83(1949), AM 55:135(1970)*.

42.9.2.2 Gormanite $Fe_3^+Al_4(PO_4)_4(OH)_6 \cdot 2H_2O$

Named in 1981 for Donald Herbert Gorman (b.1922), University of Toronto, Canada. The Fe^{2+} analog of souzalite (42.9.2.1). TRIC $P\bar{1}$ or P1. $a = 11.79$, $b = 5.11$, $c = 13.57$, $\alpha = 90.83^\circ$, $\beta = 99.25^\circ$, $\gamma = 90.08^\circ$, $Z = 2$, $D = 3.12$. *CM 19:381(1981)*. 36-403: 6.70₁₀ 4.79₆ 3.39₁₀ 3.34₇ 3.16₇ 3.13₈ 3.10₆ 2.55₇. See also 33-638. Radiating aggregates, and blades elongated parallel to [010] up to 3 mm \times 0.5 mm \times 0.1 mm, with {001} dominant, and {100}, {102}, {102}, {010}. Twinned, composition plane {001}, axis [010]. Blue-green, pale green streak, vitreous luster. Cleavage {001}, poor. $H = 4$ -5. $G = 3.13$. DTA/TGA. Nonfluorescent. Biaxial (-); X approximately perpendicular to {001}; $Z \wedge b$ (elongation) = 14° ; $N_x = 1.619$, $N_y = 1.653$, $N_z = 1.660$; $2V = 53^\circ$; pleochroic. X, colorless; Y, blue; Z, colorless $X = Z < Y$. Analyses also show Mg, Ca, Mn, Fe^{3+} . Strong chemical zoning toward souzalite. Found in outcrops of phosphate ironstone in *Rapid Creek and Big Fish areas, YT, Canada*, with quartz, siderite, ludlamite, arrojadite, kryzhanovskite, vivianite (oxidized), souzalite. *HCWS AM 67:622(1982)*.

TURQUOISE GROUP

The name *turquoise* has been in use since the sixteenth century for the blue-green mineral materials brought through Turkey to Europe from Iran (Persia). But several minerals of the group have only recently been more fully described and the distinctive end members elucidated. The general formula is

where

A = \square , Cu, Fe^{2+} , Zn

B = Al, Fe^{3+} , Cr

$x = 0$ to 2

and the minerals are usually massive botryoidal aggregates crystallizing in the triclinic space group P1.

TURQUOISE: $\text{CuAl}_6(\text{PO}_4)_4(\text{OH})_8 \cdot 4\text{H}_2\text{O}$

This *b* axis projection of turquoise shows chains (paralleling *b*) of Al (can also be Fe^{3+})- $(\text{O},\text{OH})_6$ octahedra which connect through shared vertices of two PO_4 tetrahedra. Divalent cations, such as Cu^{2+} join two or four chains, or these sites may be vacant.

The basic units of the structure [*NJMM:227(1989)*] are chains along *b* built up of alternate pairs of octahedra (either AlO_6 or Fe^{3+}O_6) joined by an edge and connected through shared vertices by two PO_4 tetrahedra. Cations in octahedral, or tetragonal dipyramidal, coordination with oxygens join two or four chains. In several of the end members, the A sites are vacant.

There is probably a continuous solid-solution series between Al and Fe^{3+} , but some Fe^{2+} is usually present. Most "turquoise" is deficient in Cu, and only a few of the materials presently called turquoise contain Cu as a principal constituent of the A site. In the $(\text{Cu},\text{Fe}^{3+})$ end member, chalcosiderite, Cu atoms alternate with a vacancy. Electrostatic equilibrium of the structure is maintained by very small differences in the coordination of the OH around the "holes." From structure determinations it appears that the Cu atoms preferentially bond with groups that have hydroxylated oxygens PO_3OH and with H_2O molecules. Planerite, whose composition shows virtually no Cu and high concentrations of acid phosphate (PO_3OH) or hydronium ions (H_3O^+), suggests a structure where acid groups balance the charge, and the bond distribution varies to accommodate the lack of A-site atoms. *ZK 121:87(1965)*, *NJMM:227(1989)*.

TURQUOISE GROUP

Mineral	Formula	Space							
		Group	a	b	c	α	β	γ	
Turquoise	$\text{CuAl}_6(\text{PO}_4)_4(\text{OH})_8 \cdot 4\text{H}_2\text{O}$	P1	7.690	9.950	7.490	110.57	115.40	68.40	42.9.3.1

Planerite	$\square\text{Al}_6(\text{PO}_4)_2(\text{PO}_3\text{OH})_2(\text{OH})_8 \cdot 4\text{H}_2\text{O}$	$\bar{P}1$	7.704	10.109	7.390	110.84	115.07	70.76	42.9.3.6

42.9.3.1 Turquoise $\text{CuAl}_6(\text{PO}_4)_4(\text{OH})_8 \cdot 4\text{H}_2\text{O}$

Named in antiquity for the "source" of the mineral materials: Turkey. Turquoise group. In Al-Fe³⁺ series with chalcosiderite (42.9.3.4). TRIC $\bar{P}1$. $a = 7.690$, $b = 9.950$, $c = 7.490$, $\alpha = 110.57^\circ$; $\beta = 115.40^\circ$, $\gamma = 68.40^\circ$, $Z = 1$, $D = 2.88$. Structure: *ZK 121:87(1965)*. 6-214: 9.09₅ 6.17₇ 4.80₆ 3.68₁₀ 3.44₇ 3.28₇ 2.91₈ 2.02₆. 25-260 (Ferrian-turquoise): 6.22₄ 4.83₅ 3.70₁₀ 3.46₇ 3.31₇ 2.93₁₀ 2.91₇ 2.54₄. Crystals are rare, short prismatic [001] with large {001}, {010}, {110}; usually massive, dense, cryptocrystalline to fine-granular; crusts, veinlets, stalactitic, concretionary. Massive turquoise is sky-blue, bluish green to apple-green, green-gray; waxy luster; subtranslucent to opaque. Crystals bright blue; white, greenish to pale green streak; vitreous luster; transparent. Cleavage {001}, perfect; fracture (of massive) conchoidal to smooth. $H = 5-6$. $G = 2.6-2.8$ (massive), 2.84 (crystals). DTA, IR, Mossbauer, ESR. *AM 64:449(1979)*, *NJMM: 469(1992)*. Biaxial (+); $N_x = 1.61$, $N_y = 1.62$, $N_z = 1.65$ (Na); $2V = 40^\circ$; $r < v$, strong; weakly pleochroic in thick grains. X , colorless; Z , pale blue or pale green. Analyses always show some Fe³⁺. Other elements found in traces (most are probably impurities): Si, Mg, Ca, Na, Ti, Mn, Ag, B, Ba, Be, Co, Cr, Ni, Pb, Sr, Zn, Zr. Soluble with difficulty in HCl, readily after low heat, which gives a blue solution when treated with ammonia. Pseudomorphs after apatite, bone, teeth, and orthoclase have been described, although fossil bone coated with a thin coating of vivianite may be mistaken for true turquoise. Synthesized from malachite. Imitation turquoise obtained through melting precipitated aluminum phosphate plus copper phosphate (Gilson turquoise), or by staining chalcedony, calcite, or glass. Natural turquoise may be treated artificially to enhance color. See *G&G 15:226(1977)*, *ZDGG 29:152(1980)*, and *JG 17:386(1981)* for studies of synthetic and imitation materials. A secondary mineral found with chalcedony, kaolin, iron oxides, and oxyhydroxides; in arid regions, turquoise forms on aluminous igneous or sedimentary rocks, probably derived from the

weathering of apatite and copper sulfides. Found in fine 1- to 2-mm crystals at Bishop mine, Lynch station, Campbell Co., VA; in crusts at Wood Copper mine, Micaville and Erin, AL; at Turquoise Chief mine, St. Kevin district, Leadville, Lake Co., the Hall mine, Villa Grove, Saguache Co., CO; at Mt. Chalchuitl, Los Cerruos, NM (originally worked by Aztecs); at New Cornelia mine, Ajo, the Cole shaft and Lavender pit, Cochise Co., on the Fort Apache Indian Res., Mineral Park mine, Mohave Co., in the Helvetia district, Santa Rita Mts., AZ; at Pilot Mt. mine, Lincoln Co., NV; at Baker, Fresno Co., CA. In Europe, crystals at Bunny mine and Stowe's mine, Wheal Phoenix, Linkinhorne, and at Hensbarrow, and at Wheal Remfry china clay pits, St. Austell Moor, Cornwall, England; as 1- to 2-mm crystals in manganiferous quartz veins at Ottré near Vielsalm, Ardennes, Belgium; crusts with wavellite at Montebrias, Creuse, France; at Jordansmühl, Silesia, Poland; at Poniklá, near Jilemnice, northern Bohemia, Czech Republic; at Olsnitz and Messbach, Vogtland, Saxony, Germany. Also from the Sinai Peninsula at Wadi Maghara, Egypt, in seams with limonite in porphyry; at two classical localities, Nishapur and Damghan, northeastern Iran, and on the southern slopes of the Ali-Mirsa-Kuh Mts. NW of Maden, Khorasan, where it is in narrow seams and irregular patches in brecciated trachyte; at Sar Chesmeh Cu-Mo porphyry in south-central Iran; in the Vathi area, Macedonia; in the Madneuli deposit, Georgia, Russia; a more greenish-blue variety from Karkaralinsk, Semipalatinsk, Siberia; in the Kara-Tube Mts. S of Samarkand, Turkestan; in the Burkantau deposit, central Kyzulkum, and the Kalmakyr deposit, Almalyk ore field, Uzbekistan; in Husei Prov., China; at Got, near Angolola, Ethiopia; crystalline materials at Grant's Lookout, Narooma, NSW, Australia; in the banded iron formation at Itatiaiuçu, and in Consecheiro Mata region, Diamantina, MG, Brazil; at Chuquicamata, Antofagasta, Chile. Used for jewelry since ancient times, a common item of barter. HCWS *DII:946*, *AM 38:9634(1953)*, *MM 40:640(1976)*, *NJMM:469(1992)*.

42.9.3.2 Coeruleolactite $(\text{Ca,Cu})\text{Al}_6(\text{PO}_4)_4(\text{OH})_8 \cdot 4-5\text{H}_2\text{O}$

Named in 1871 from the Latin *coeruleus*, blue, and *lac, lactis*, milk, in allusion to its color. Questionable mineral. Extensive search for turquoiselike material containing Ca has not been successful. Since the ionic radius of Ca^{2+} (0.99) is substantially larger than that of Cu, Zn, or Fe^{2+} , the formation of a species with such a composition is unlikely (E. E. Foord, personal communication). Possibly a mixture of a turquoise group mineral and calcite. TRIC P1. $a = 7.652$, $b = 10.153$, $c = 7.748$, $\alpha = 111.9^\circ$, $\beta = 115.9^\circ$, $\gamma = 67.6^\circ$, $Z = 1$, $D = 2.99$. *MP 6:182(1958)*, *AM 43:1224(1958)*. $12-166: 6.11_4 4.77_3 3.70_9 3.48_5 3.34_5 2.96_{10} 2.52_3 1.907_4$. Cryptocrystalline, microcrystalline, fibrous, veinlets, crusts, botryoidal aggregates. Milk-white to light blue, white streak, translucent. Uneven to conchoidal fracture. $H = 5$. $G = 2.57$. Biaxial (+) (almost uniaxial); $N_x = 1.580$, $N_z = 1.588$ (PA). Soluble in acids and alkalis. Found at General Trimble mine, East Whiteland Twp., Chester Co., PA, with variscite-L, wavellite, mataleite, gibbsite, cacozenite, and goethite in plates to

10 μm ; at Wheal Phoenix mine, Linkinhorne, Cornwall, England; in "limonite" at *Rindsberg mine, Katzenellbogen, Nassau, Germany*; at Cruzeiro mine, MG, Brazil. *HCWS DII:961, IMA:102(1986)*.

42.9.3.3 Faustite $(\text{Zn,Cu})\text{Al}_6(\text{PO}_4)_4(\text{OH})_8 \cdot 4\text{H}_2\text{O}$

Named in 1953 for George Tobias Faust (1908–1985), mineralogist, U.S. Geological Survey. Turquoise group. The Zn analog of turquoise. TRIC $P\bar{1}$. $a = 7.670$, $b = 9.890$, $c = 7.440$, $\alpha = 110.35^\circ$, $\beta = 115.60^\circ$, $\gamma = 72.80^\circ$, $Z = 2$, $D = 2.99$. *6-216*: 6.70₇ 6.14₇ 3.68₁₀ 3.44₆ 3.28₆ 2.92₆ 2.89₈ 2.05₇. Very fine grained, compact, nodular, veinlets. Apple-green to white when pure, white to pale yellow streak, waxy, dull luster. Conchoidal fracture, brittle. $H = 4\frac{1}{2}$ – $5\frac{1}{2}$. $G = 2.92$. Nonfluorescent. $N_{\text{av}} = 1.613$ (Na). Soluble in cold 1:1 HCl. Analyses show Fe^{3+} , and minor Ca, Si, V, Ca, Mg, Ba, with traces of Cr, Ti, Co, Ni, Sc, Zr, Sr, Mn, Bi. Only Ca and Fe were considered important to the chemistry of the mineral; the remainder were suggested to be impurities. *AM 38:964(1953)*. Found at *Copper King mine, Maggie Creek, Eureka Co., NV*, as apple-green veinlets in cherts and shales associated with montmorillonitic clays, quartz, kaolinite, and alunite; at Wheal Phoenix mine, Linkinhorne, Cornwall, England; in quartz veins in altered latite-andesite, Spahievo ore field, eastern Rhodope Mts., Bulgaria; cuprian faustite at Heyshapur, Iran. *HCWS GMP 16:55(1982)*.

42.9.3.4 Chalcosiderite $\text{CuFe}_6^{3+}(\text{PO}_4)_4(\text{OH})_8 \cdot 4\text{H}_2\text{O}$

Named in 1814 by J. C. Ullman from the Greek *chalcos*, copper, and *sideros*, iron. Turquoise group. The Fe^{3+} end member of turquoise. TRIC $P\bar{1}$. $a = 7.885$, $b = 10.199$, $c = 7.672$, $\alpha = 110.84^\circ$, $\beta = 115.12^\circ$, $\gamma = 67.51^\circ$, $Z = 1$, $D = 3.26$. Structure: *NJMM:227(1989)*. Pseudomonoclinic, I-centered. *37-446*: 6.39₃ 4.93₂ 3.76₁₀ 3.54₄ 3.38₄ 3.01₄ 2.95₃ 2.52₃. See also *8-127*. Crusts or sheaflike groups of distinct crystals, short prismatic [001] with large {001}, {010}, {110}, {111}. Light siskin-green to dark green, vitreous luster, transparent. Cleavage {001}, perfect; {010}, good. $H = 4\frac{1}{2}$. $G = 3.22$. IR. Biaxial (-); $N_x = 1.775$, $N_y = 1.840$, $N_z = 1.844$; $2V = 22^\circ$; $r > v$, strong, crossed; weakly pleochroic. X, colorless; Z, pale green. Some Al substitutes for Fe^{3+} , minor As, Zn detected on analysis. *ZVMO 108:701(1979)*. Occurs as a secondary mineral in the oxidized zone of copper ore deposits. Found at Cole and Shattuck shafts, Bisbee, Cochise Co., AZ; with dufrenite, andrewsite, and goethite in gossan of Wheal Phoenix mine, Cornwall, England; with pharmacosiderite at Schneckenstein, Saxony, and with dufrenite at *Siegen, Westphalia, Germany*. *HCWS DII:947, MR 12:349(1981)*.

42.9.3.5 Aheylite $(\text{Fe}^{2+},\text{Zn})\text{Al}_6(\text{PO}_4)_4(\text{OH})_8 \cdot 4\text{H}_2\text{O}$

Named in 1986 for Allen V. Heyl (b.1918), economic geologist, U.S. Geological Survey. Turquoise group. The Fe^{2+} analog of turquoise. TRIC $P\bar{1}$ or $P1$. $a = 7.408$, $b = 9.891$, $c = 7.627$, $\alpha = 110.94^\circ$, $\beta = 115.05^\circ$, $\gamma = 69.89^\circ$, $Z = 1$, $D = 2.89$. *IMMA:102(1986)*. *PD*: 6.15₄ 3.67₁₀ 3.44₄ 3.40₃ 3.27₄ 2.91₃ 2.89₇

2.02₃. Botryoidal, spheres to 2 mm of radiating concentric aggregates of crystals to 3 μm. Pale blue to blue-green, white streak, porcelaneous-subvitreous luster, translucent. Hackly and splintery fracture. Nonfluorescent. $H = 5-5\frac{1}{2}$. $G = 2.85$. Biaxial(+); $N_{\text{mean}} = 1.63$. Found at *Mira Flores mine, Huanuni district, Oruro, Bolivia*, associated with cassiterite, pyrite, quartz, sphalerite, variscite, wavellite, and vivianite. HCWS

42.9.3.6 Planerite $\square\text{Al}_6(\text{PO}_4)_2(\text{PO}_3\text{OH})_2(\text{OH})_8 \cdot 4\text{H}_2\text{O}$

Named in 1862 for D. I. Planer, director of mines, Gumeshevsk, Ural Mts., Russia. Turquoise group. TRIC $P\bar{1}$. $a = 7.704$, $b = 10.109$, $c = 7.390$, $\alpha = 110.84^\circ$, $\beta = 115.07^\circ$, $\gamma = 70.76^\circ$, $Z = 1$, $D = 2.71$. Structural data indicate vacancy for A site and some Fe^{3+} (Mossbauer) substituting for Al (B site). *IMMA:102(1986)*. 42-1318: 6.82₉ 6.20₂ 4.73₂ 3.75₁₀ 3.70₃ 3.29₁ 3.09₂ 2.55₁. Subcrystalline, botryoidal crusts. White to light green, dull luster, translucent. $H = 5$. $G = 2.68$. TGA. $N_{\text{av}} = 1.517$. Soluble in boiling NaOH. Found at General Trimble's mine, East Whiteland Twp., Chester, PA; Kelly Bank mine, Vesuvius, VA; Mauldin Mt. quarry, Mt. Ida, Montgomery Co., AR; Camelback Mt., AZ; in the *copper mines at Gumeshevsk, Ural Mts., Russia*; at Toyoda, near Kochi City, Shikoku Is., Japan, with wavellite, quartz, vermiculite, and iron hydroxides. HCWS *DII:762, NJBA 96:1(1961), JMPEG 83:141(1988)*.

42.9.4.1 Sampleite $\text{NaCaCu}_5(\text{PO}_4)_4\text{Cl} \cdot 5\text{H}_2\text{O}$

Named in 1942 by C. Hurlbut for Mat Sample, superintendent at the mine, Chuquicamata, Chile. See lavendulan (42.9.4.2), the As analog. ORTH (dipyramidal, 2/m 2/m 2/m, pseudotetragonal with $C_{\text{+et}} = \text{borth}$). $a = 9.72$, $b = 38.48$, $c = 9.67$, $Z = 8$, $D = 3.26$. *MM 42:369(1978)*. 11-349: 9.60₁₀ 6.85₇ 4.30₈ 3.89₇ 3.04₁₀ 1.79₇ 1.71₈ 1.45₇. Lathlike crystals flattened {010}, elongated {001}; wedge-shaped aggregates subparallel to [010] to 0.2 mm × 0.2 mm × 0.02 mm. Light blue to blue-green (turquoise), pearly luster on {010}, transparent. Cleavage {010}, perfect; {100}, {001}, good. $H \approx 4$. $G = 3.20$. Biaxial (-); $XYZ = bac$; $N_x = 1.625$, $N_{yz} = 1.674$; $2V = 5-10^\circ$; $r > v$; analyses also show Mg O, K₂O pleochroic. X, turquoise-green; Y, Z, benzol-green $X < Y, Z$. Easily soluble in acids. Found at Jinqemia cave, WA, Australia, formed as a reaction of CuS with guano and associated with atacamite, weddelite, gypsum, goethite, Mn oxides, birnessite, dolomite, halite, apatite, and malachite; in highly oxidized ore at Mantos Blancos with atacamite, calcite, halite, and chrysocola, and at *Chuquicamata, Chile*, with gypsum, atacamite, jarosite, and iron oxyhydroxides; as a corrosion product on old bronzes. HCWS *DII:945, BM 79:7(1956)*.

42.9.4.2 Lavendulan $\text{NaCaCu}_5(\text{AsO}_4)_4\text{Cl} \cdot 5\text{H}_2\text{O}$

Named in 1837 for the color. Sampleite (42.9.4.1) is the P analog. ORTH. $a = 9.73$, $b = 41.0$, $c = 9.85$, $Z = 8$, $D = 3.64$. *BM 79:7(1956)*. 31-1280: 9.77₁₀ 7.01₄ 4.88₅ 4.41₄ 3.11₇ 2.76₂ 2.48₂ 1.97₂. Thin botryoidal crusts of minute

radiating fibers or plates. Lavender blue, vitreous to waxy luster, translucent. $H = 2\frac{1}{2}$ -3. $G = 3.84$. DTA Biaxial (-); $N_x = 1.645$, $N_y = 1.715$, $N_z = 1.725$; Z inclined to fiber length. Analyses show some K, Co, Ni. Found at *Jachimov, Bohemia, Czech Republic*; at Laurium, Greece; at Bou Azzer, Morocco; at Alice Mary Cu mine, Rundip, High Ranges, Bali Low Cu mine, Capricorn Ranges, Francis Furnace mine, Marvel Loch, WA, and at Preamimma mine, Callington, SA, Australia; at Tsumeb, Namibia; at San Juan, Chile. *hcws DII:750, TRSSA 97:135(1973)*.

42.9.4.3 Zdenekite $\text{NaPbCu}_5(\text{AsO}_4)_4\text{Cl} \cdot 5\text{H}_2\text{O}$

Named in 1995 after Zdenek Johan (b.1935), mineralogist and director of Scientific Affairs, Bureau de Recherches Geologiques, Minières (BRGM), France. TET $P4_122$ or $P4_322$. $a = 10.066$, $c = 39.39$, $Z = 8$, $D = 4.08$. *EJM 7:553(1995)*. PD: 9.83_{10} 7.11_3 4.93_6 4.48_5 3.13_9 2.77_4 2.52_5 1.78_4 . Individual tabular tetragonal crystals up to 0.1 mm, flattened on {001}, showing {001}, {100}, and {110}; as spherules and aggregates to 0.3 mm. Intense blue color, pale blue streak, vitreous luster, translucent. Fragile, soft. Cleavage (001), perfect; irregular fracture. $G = 4.1$. Nonfluorescent in UV. Occurs at the *Cap Garonne mine, Var, France*, associated with anglesite, tsumcorite-like mineral, and olivenite in quartz conglomerate that has been mineralized with tennantite and covellite. *hcws*

42.9.5.1 Duhamelite $\text{Cu}_4\text{Pb}_2\text{Bi}(\text{VO}_4)_4(\text{OH})_3 \cdot 8\text{H}_2\text{O}$

Named in 1981 for J. E. DuHamel, geologist, Phelps Dodge Corp., who found the mineral. ORTH P . $a = 7.49$, $b = 9.66$, $c = 5.87$, $Z = 1$, $D = 5.99$. *MM 44:151(1981)*. 35-500: 5.01_4 4.83_3 4.18_2 3.49_5 3.16_7 2.95_{10} 2.64_9 1.755_3 . Prismatic crystals to 0.2 mm \times 0.4 mm and in barrel-shaped bundles. Green, yellow-green streak. Brittle. $H = 3$. $G = 5.80$. Biaxial; $N_x = 2.08$, $N_y = 2.11$ (Na); weakly pleochroic in yellows; $X = Y < Z$. Soluble in cold 1:10 HCl, HNO_3 , not in H_2O . Found with chrysocolla, malachite, fornacite, wulfenite, and bismutite in Au-bearing quartz veins cutting Precambrian greenstones 5 km SW of Payson, at *Lousy Gulch, Gila Co., AZ*. *hcws AM 67:414(1982)*.

42.9.6.1 Santafeite $\text{NaMn}_3(\text{Ca,Sr})(\text{V,As})_3\text{O}_{13} \cdot 4\text{H}_2\text{O}$

Named in 1958 for the Santa Fe Railroad Co. ORTH $B22_12$. $a = 9.239$, $b = 29.978$, $c = 6.314$, $Z = 4$, $D = 3.34$. 11-169: 14.88_{10} 7.47_5 3.66_3 3.39_3 2.91_3 2.79_4 2.70_5 1.667_4 . Small rosettes (to 4 mm in diameter) of acicular crystals radially oriented. Black, brown streak, subadamantine luster, translucent. Cleavage {010}, perfect; {110}, distinct; very brittle. $G = 3.379$. $N_{av} = 2.01$; $X = c$; pleochroic: red to yellow-brown; distinct dispersion. Small amounts of K, Fe^{3+} , Ni, Cu, U, and CO_2 as well as traces of REE in analyses. The oxidation state(s) of Mn not fully defined but Mn^{4+} appears dominant. Found on Todilto limestone in the uranium district at *Grants dist., McKinley Co., NM*. *hcws AM 43:677(1958), MM 50:299(1986)*.

42.9.7.1 Ogdensburgite $\text{Ca}_2(\text{Zn}, \text{Mn}^{2+})\text{Fe}_4^{3+}(\text{AsO}_4)_4(\text{OH})_6 \cdot 6\text{H}_2\text{O}$

Named in 1981 for the locality. ORTH *Bmmm*, *B222**. $a = 11.351$, $b = 14.837$, $c = 6.555$, $Z = 2$, $D = 3.39$. *AM 72:409(1987)*. Significant site vacancies are suggested as calculated and measured densities are vastly different. *35-518*: 14.8_{10} 7.39_2 5.30_2 4.51_3 3.28_3 2.79_2 2.73_2 2.65_4 . See also *38-482*. Rectangular blades up to 1 mm long; encrustations of thin (0.1-mm) plates (micaceous). Dark brownish red, resinous luster on cleavage surfaces, translucent. Cleavage {001}, perfect; {010}, fair; {100}, poor. $H = 2$. $G = 3.11$. Nonfluorescent. Biaxial (-); $XYZ = cba$; Y and Z parallel to {001} cleavage edges; $N_x = 1.715$, $N_y = 1.783$, $N_z = 1.785$; $2V = 5-10^\circ$; $Z > Y \gg X$; strongly pleochroic. X, yellow; Y, Z, red-brown. Found at *Sterling Hill mine, Ogdensburg, NJ*, with para-symplesite, kottigite, and other iron arsenates; at *Ojuela mine, Mapimi, DUR, Mexico*, with villyaellenite crystals(!) in vugs coated with arseniosiderite and chalcophanite in limonitic gossan that contains adamite and manganese oxides. *HCWS AM 67:858(1982)*.

42.9.8.1 Dewindtite $\text{Pb}_3(\text{UO}_2)_6\text{H}_2(\text{PO}_4)_4\text{O}_4 \cdot 12\text{H}_2\text{O}$

Named in 1922 for Jean Dewind, Belgian geologist. ORTH *Bmmb*. $a = 16.031$, $b = 17.264$, $c = 13.605$, $Z = 4$, $D = 5.12$. Structure: *EJM 2:399(1990)*. Structure contains $[\text{H}(\text{UO}_2)_3\text{O}_2(\text{PO}_4)_2]$ layers parallel to (100) connected through Pb in eightfold coordination. *39-1350*: 7.92_{10} 5.85_3 3.96_{10} 3.36_3 3.13_6 3.09_5 2.88_5 2.09_3 . Microscopic rectangular tablets flattened {100} terminated by {001}, striated [001]; pulverulent, compact. Canary-yellow, translucent. Cleavage {100}. $G = 5.03$. Fluoresces green. Biaxial (--); $XYZ = bca$; $N_x = 1.716$, $N_y = 1.736$, $N_z = 1.740$; $2V = 40^\circ$; $r < v$; nonpleochroic. Soluble in acids. Found at *Gruy, Saône-et-Loire, France*; at *Wolsendorf, Bavaria, Germany*; associated with metatorbernite and other secondary U minerals at *Kasolo, Shaba, Zaire*, and at *Shinkalobwe*. *HCWS DII:875, AM 39:444(1954)*.

42.10.1.1 Ferrisymplesite $\text{Fe}_3^{3+}(\text{AsO}_4)_2(\text{OH})_3 \cdot 5\text{H}_2\text{O}$

Named in 1924 as the oxidized equivalent of symplesite (40.3.8.1). An inadequately described mineral. *1-119(syn)*: 9.0_2 6.7_{10} 3.99_4 3.70_4 3.36_2 3.18_4 2.95_4 2.82_4 . Small irregular masses with fibrous structure. Amber-brown, resinous luster. Found intimately admixed with erythrite and anabergite at *Hudson Bay mine, Cobalt, ONT, Canada*. *HCWS DII:753, AUF 30:213(1979)*.

42.10.2.1 Wavellite $\text{Al}_3(\text{PO}_4)_2(\text{OH}, \text{F})_3 \cdot 5\text{H}_2\text{O}$

Named in 1805 for William Wavell (d.1829), physician, Horwood Parish, Devonshire, England, who discovered the mineral. ORTH *Pcmn*. $a = 9.621$, $b = 17.363$, $c = 6.994$, $Z = 4$, $D = 2.325$. Structure: *ZK 127:21(1968)*. Octahedrally coordinated Al (AlO_6) forms two distinct (Al1 and Al2) zigzag chains parallel to the c axis that are linked by phosphate tetrahedra into layers parallel to (010). Water molecules occupy cavities created. This structural configuration is responsible for the fibrous habit and the perfect

cleavages. 25-20: 8.67₁₀ 8.42₁₀ 5.65₅ 4.81₃ 3.42₄ 3.22₆ 2.57₃ 2.11₂. Crystals rare, stout to long prismatic [001], with {110} striated [001]; hemispherical or globular aggregates with radial-fibrous or stellate structure, as crusts or stalactitic, rarely chalcedonic, opaline masses. Greenish white, green to yellow, yellowish brown, brown, brownish black, blue, white, colorless; white streak; vitreous to pearly and resinous luster; translucent. Cleavages {110}, {101}, perfect; {010}, distinct; subconchoidal to uneven fracture: brittle. $H = 3\frac{1}{2}$ -4. $G = 2.36$. Biaxial (+); $XYZ = bac$; $N_x = 1.535$, $N_y = 1.543$, $N_z = 1.561$ (Cernovice); $2V \approx 71^\circ$; $r > v$, weak; $X > Z$; weakly pleochroic. X, greenish; Z, yellowish. Indices increase with increasing Fe^{3+} for Al and F for OH. Easily soluble in acids. A secondary mineral common in aluminous low-grade metamorphic rocks, in limonitic or phosphate rock deposits, and as a late-formed hydrothermal mineral in veins. Found at Amity, Orange Co., NY; at General Trimble's mine, Chester Co., Moore's Mill, Cumberland Co., Hellertown, Northampton Co., PA; at Kelly Bank mine, Vesuvius, Virginia Glass Sand Co. quarry, VA; at Carolina pyrophyllite mine, NC; at Brewer mine, Cedartown, GA; in phosphate rocks at Dunellen, Marion Co., FL; at Dug Hill, and Montgomery Co., Hot Springs, Garland Co., Magnet Cove, Hot Spring Co., in the novaculite beds, and in Silver City region, Montgomery Co., AR; near Coal City, St. Clair Co., Jacksonville, Calhoun Co., Erin, Indian Mt., Wolfden Mt., AL; at Mineral Park mine, Mohave Co., AZ; at Clonmel, County Tipperary, Tracton and Kinsale, County Cork, Ireland; in a clay slate at *High Down quarry, Barnstaple, Devonshire, England*, and at Stenna Gwyn mine, St. Austell, Cornwall; with amblygonite in tin veins at Montebrias, Creuse, France; at Langenstrieigis, Saxony, Waldgirmes, and the phosphate deposits of the Lahn-Dill region, Hesse, Nassau, Germany; at Cernovice, Zbirow, and neighboring localities in Bohemia, Czech Republic; at Kapnik, Romania; in Shaba, Zaire; at Iron Monarch quarry, Iron Knob, SA, Australia; abundant in the tin veins of Silgo XX mine, Llallagua, Bolivia, with apatite, vauxite, and paravauxite; also at Itos, Porvenir, San José mines, Oruro, Potosi. *HCWS DII:962, USGSPP 800G:53(1972)*.

42.10.3.1 Kingite $Al_3(PO_4)_2(OH,F)_3 \cdot 9H_2O$

Named in 1957 for D. King (1926-1990), geologist, Department of Mines, SA, Australia. TRIC $P\bar{1}$ or $P1$. $a = 9.15$, $b = 10.00$, $c = 7.24$, $\alpha = 98.6^\circ$, $\beta = 93.6^\circ$, $\gamma = 93.2^\circ$, $Z = 2$, $D = 2.465$. *AM 55:515(1970)*. 24-10: 9.1₁₀ 5.43₃ 5.28₅ 3.48₇ 3.45₈ 3.38₃ 3.17₄ 3.11₃. Platy or irregular crystals to 1.0 μm in nodules to 5 cm in diameter. White, translucent. $G = 2.2$. DTA. $N_{av} = 1.514$. Very minor Na, K, F detected on analysis. Dehydrates under electron beam to meta-kingite. Found coated with a brown film of goethite and talc at the phosphate deposits of *Fairview mine, Robertstown, Burra Co., SA, Australia*, associated with vivianite, fluorapatite, leucophosphite, also occurs at Clinton 100 km west-southwest of this locality. *HCWS MM 31:351(1957)*.

42.10.4.1 Gutsevichite $\text{Al}_3(\text{PO}_4)_2(\text{OH})_3 \cdot 8\text{H}_2\text{O}$

Named in 1959 for V. P. Gutsevich, geologist in Kazakhstan. iso. 14-139: 4.08₁₀ 3.51₅ 2.51₉ 1.82₈ 1.45₇. Irregular crusts and concretions. Yellow-olive to dark brown, waxy, dull luster. $H = 2\frac{1}{2}$. $G = 1.90\text{--}2.0$. DTA. N varies with color: 1.560 (yellow) to 1.60 (dark brown). Easily soluble in cold 1:10 acids. Analyses showed Mg, Ca, Ba, S, Si. Found in *northwestern Kazakhstan* as cavity fillings in zone of oxidation of V-containing shales. *ncws AM 46:1200(1961)*.

OVERITE GROUP

The overite group minerals are hydrated phosphates with the general formula

where

A = Ca, Mn, Zn

B = Mg, Fe^{2+} , Mn^{2+}

C = Al, Fe^{3+}

and a layered structure that crystallizes with orthorhombic symmetry.

OVERITE: $\text{CaMgAl}(\text{PO}_4)_2(\text{OH}) \cdot 4\text{H}_2\text{O}$

The *c* axis projection of overite shows slabs consisting of $\text{Ca}(\text{Op})_6$ alternating with $\text{Al}(\text{Op})_2(\text{OH})_4$ on $\{010\}$ and parallel layers of $\text{Mg}(\text{Op})_2(\text{H}_2\text{O})_4$.

The structure is closely related to the jahnsite–whiteite group (42.11.2.1) with octahedral corner-sharing chains of $C(O,OH)_6 + Ca(Op)_6$ forming slabs with PO_4 tetrahedra which are connected through $B(OH,H_2O)_6$ octahedra and other cations. In addition to distinctions between the several species depending on Al or Fe^{3+} content, there are variations in the general structure related to a twisting of the octahedral chains and distortion of the B-octahedra. The identification of a particular species in the overite group (and in the jahnsite–whiteite group) usually requires single-crystal structure examination.

OVERITE GROUP

Mineral	Formula	Space Group	a			b			c		
			a	b	c	a	b	c	a	b	c
Overite	$CaMgAl(PO_4)_2(OH) \cdot 4H_2O$	<i>Pbca</i>	14.723	18.746	7.107	42.11.1.1					
Segelerite	$CaMgFe^{3+}(PO_4)_2(OH) \cdot 4H_2O$	<i>Pbca</i>	14.826	18.75	7.307	42.11.1.2					
Mangano-segelerite	$CaMn^{2+}Fe^{3+}(PO_4)_2(OH) \cdot 4H_2O$	<i>Pcba</i>	14.89	18.79	4.405	42.11.1.3					
Lun'okite	$(Mn^{2+}, Ca)(Mg, Fe^{2+}, Mn^{2+})Al(PO_4)_2(OH) \cdot 4H_2O$	<i>Pbca</i>	14.95	18.71	6.96	42.11.1.4					
Wilhelmvierlingite	$CaMn^{2+}Fe^{3+}(PO_4)_2(OH) \cdot 4H_2O$	<i>Pbca</i>	14.80	18.70	7.31	42.11.1.5

42.11.1.1 Overite $CaMgAl(PO_4)_2(OH) \cdot 4H_2O$

Named in 1940 for Edwin Over (1905–1963), mineral collector at Fairfield, UT. Overite group. The Al analog of segelerite (42.11.1.2). ORTH *Pbca*. $a = 14.723$, $b = 18.746$, $c = 7.107$, $Z = 8$, $D = 2.51$. Structure: *AM 62:692(1977)*. $16-157$: 9.4_8 5.29_6 4.98_2 3.70_5 3.42_4 2.89_6 2.83_{10} 1.975_5 . Crystals flattened on {010} elongated [001] with platy to lathlike shape; subparallel growths on {010}; massive aggregates of coarse plates. Light apple-green to colorless, vitreous luster, transparent. Cleavage {010}, perfect. $H = 3\frac{1}{2}-4$. $G = 2.53$. Biaxial (-); $XYZ = cab$; $N_x = 1.568$, $N_y = 1.574$, $N_z = 1.580$; $2V = 75^\circ$; $r > v$, weak. Easily soluble in hot HNO_3 . Found in cavities in variscite nodules at *Clay Canyon, Fairfield, Utah Co., UT*, associated with crandallite, apatite. *HCWS DII:979, AM 59:48 (1974)*.

42.11.1.2 Segelerite $CaMgFe^{3+}(PO_4)_2(OH) \cdot 4H_2O$

Named in 1974 for Curt G. Segeler (1901–1989), amateur mineralogist, New York City. Overite group. See overite (42.11.1.1), the Al analog. ORTH *Pbca*.

$a = 14.826$, $b = 18.75$, $c = 7.307$, $Z = 8$, $D = 2.61$. *AM 59:48(1974)*, Structure: *AM 62:692(1977)*. *AM 26-1061*: 9.31_9 , 5.34_6 , 4.97_4 , 4.65_4 , 3.73_5 , 3.42_5 , 2.87_{10} , 2.58_4 . Crystals up to 0.5 mm striated parallel to prism length [001] with square outline showing {100}, {010}, {110}, {121}. Pale yellow-green (chartreuse) to colorless, vitreous luster, transparent. Cleavage {010}, perfect. $H = 4$. $G = 2.67$. Biaxial (-); $XYZ = bac$; $N_x = 1.618$, $N_y = 1.635$, $N_z = 1.650$; $2V$ large; pleochroic. X, Y, colorless; Z, yellow $Z > X$, Y. Found at *Tip Top pegmatite, near Custer, Custer Co., SD*; at Milgun Station, WA, Australia. HCWS

42.11.1.3 Manganosegelerite $\text{CaMn}^{2+}\text{Fe}^{3+}(\text{PO}_4)_2(\text{OH}) \cdot 4\text{H}_2\text{O}$

Named in 1992 for the composition and relationship to segelerite (42.11.1.2). Overite group. ORTH *Pbca*. $a = 14.89$, $b = 18.79$, $c = 4.405$, $Z = 8$, $D = 2.74$. *ZVMO 121:95(1992)*. *PD*: 9.39_{10} , 4.70_5 , 2.97_4 , 2.86_9 , 2.60_4 , 2.02_4 , 1.966_5 , 1.880_5 . Aggregates to 2 mm across of prismatic individuals up to 0.05 mm across. Yellow to yellow-green, yellow streak, vitreous luster, transparent in thin grains. Cleavage {001}, imperfect. $H = 3-4$. $G = 2.76$. IR shows both OH and H_2O . Biaxial (-); $YXZ = abc$; $N_x = 1.657$, $N_y = 1.668$, $N_z = 1.691$; $2V_{\text{calc}} = 70^\circ$; marked dispersion; $r < v$; pleochroic. X, yellow; Z, light yellow. Found on mitradatite in late fractures in granitic pegmatites of the *Kola Penin., Russia*, also locally developed from lunjokite, replacing it as pseudomorphs and associated with eosphorite, kingsmountite, and Mn-gordonite. HCWS *AM 79:185(1994)*.

42.11.1.4 Lun'okite $(\text{Mn}^{2+}, \text{Ca})(\text{Mg}, \text{Fe}^{2+}, \text{Mn}^{2+})\text{Al}(\text{PO}_4)_2(\text{OH}) \cdot 4\text{H}_2\text{O}$

Named in 1983 for the locality. Overite group. ORTH *Pbca*. $a = 14.95$, $b = 18.71$, $c = 6.96$, $Z = 8$, $D = 2.69$. *ZVMO 112:232 (1983)*. *37-456*: 9.39_9 , 5.15_5 , 3.48_6 , 2.92_7 , 2.81_{10} , 1.877_5 , 1.568_5 , 1.555_5 . Radiating aggregates to 1 mm; crusts. Colorless to white, yellowish, transparent. Cleavage {010}, perfect; {001}, imperfect. $H = 3-4$. $G = 2.66$. DTA, IR. Biaxial (+); $XYZ = cab$; $N_x = 1.603$, $N_y = 1.608$, $N_z = 1.616$; $2V = 70^\circ$. Found as crusts on nodules of mitradatite and in fractures in granitic pegmatites at *Lun'ok R., Kola Penin., Russia*, associated with eosphorite, laueite, and kingsmountite. HCWS *AM 69:210(1984)*.

42.11.1.5 Wilhelmvierlingite $\text{CaMn}^{2+}\text{Fe}^{3+}(\text{PO}_4)_2(\text{OH}) \cdot 2\text{H}_2\text{O}$

Named in 1983 for Wilhelm Vierling (1901-1995), Weiden, Bavaria, Germany. Overite group. Mn analog of segelerite (42.11.1.2). ORTH *Pbca*. $a = 14.80$, $b = 18.70$, $c = 7.31$, $Z = 8$, $D = 2.60$. *AM 69:568(1984)*. *38-429*: 9.34_7 , 5.00_6 , 4.67_4 , 3.44_3 , 2.86_{10} , 2.58_4 , 1.98_5 , 1.96_4 . Fine-grained radial-fibrous aggregates. Pale yellow to brownish, translucent. Cleavage {010}, perfect. $H = 4$. $G = 2.58$. IR. Biaxial (-); $XYZ = bac$; $N_x = 1.637$, $N_y = 1.664$, $N_z = 1.692$; $2V_{\text{calc}} = 45^\circ$; pleochroic. X, Y, light yellow; Z, dark yellow. Substitution of Zn for Ca detected by microprobe analysis. Found with rockbrid-

geite, zwieselite, and other secondary phosphates in the *Hagendorf pegmatite, Bavaria, Germany*. *HCWS DA 34:267(1983)*.

42.11.1.6 Kaluginite $(\text{Mn,Ca})\text{MgFe}^{3+}(\text{PO}_4)_2(\text{OH}) \cdot 4\text{H}_2\text{O}$

Named in 1991 for Aleksandr V. Kalugin (1857–1933), mineralogist, Ural Mts., Russia. Overite group. ORTH *Ccca*. $a = 15.05$, $b = 37.37$, $c = 7.18$, $Z = 16$, $D = 2.70$. *ZVMO 120:108(1991)*. 44-1403: 9.38₁₀ 4.59₅ 5.00₇ 3.52₇ 2.97₅ 2.84₉ 2.60₈ 1.88₇. Platy crystals to 1 mm, flattened {100}, elongate [001], showing {001}, {100}, {010}, {111}, {211}. Light yellowish green to greenish yellow, white streak, vitreous to greasy luster, transparent to translucent. Cleavage {010}, imperfect; uneven fracture; brittle. $H = 3\frac{1}{2}$. $G = 2.69$. Biaxial (-); $XYZ = bac$; $N_x = 1.627$, $N_y = 1.642$, $N_z = 1.658$; $2V = 90^\circ$; $r > v$; pleochroic: X, Y, colorless; Z, greenish yellow. Found in a granite pegmatite vein in *Ilmenskij National Park, Ural Mts., Russia*, associated with products of decomposition of triplite, francolite, ushkovite, matveevite, and Fe and Mn oxides. *HCWS AM 78:450(1993)*.

JAHNSITE-WHITEITE GROUP

The jahnsite-whiteite minerals are phosphate minerals whose general formula can be represented by

where

X = Ca, Mn^{2+}

A = Fe^{2+} , Mn^{2+} , Mg

B = Mg, Mn^{2+}

C = Fe^{3+} , Al

and crystallize with layered structures in the monoclinic, space group $P2/a$, although the crystals are usually twinned and appear pseudo-orthorhombic. See Overite group (42.11.1.1).

The structure [*AM 59:964(1974)*, *59:1292(1974)*] is dominated by corner-linked chains with a 7-Å repeat formed through octahedral coordination of six different and distinct cation sites. These chains form slabs parallel to {001} when connected through TO_4 tetrahedra. See also the laueite group (42.11.10.1).

The two subgroups, jahnsite and whiteite, are distinguished by the dominant element in the C site: Fe^{3+} or Al. End members are often named by adding a suffix indicating X, A, and B cations, that is, jahnsite-(CaMnMg). The familiar structural motif which produces virtually identical cell constants for the several cations in solid solution means that accurate identification of specific species requires precise crystal chemical analysis.

JAHNSITE: $\text{CaMnMgFe}_2(\text{PO}_4)(\text{OH})_2 \cdot 8\text{H}_2\text{O}$

This c axis projection of jahnsite-(CaMnMg) shows slabs paralleling {001} formed of chains with Ca in eightfold coordination, $\text{Fe}^{3+} - (\text{OH})_4(\text{O}_p)_2$ and $\text{Mn}^{2+}(\text{O}_p)_6$ connected through the tetrahedral PO_4 and with an octahedrally coordinated $\text{Mg}(\text{H}_2\text{O}, \text{O}_p)_6$ layer. The whiteite group replaces Fe^{3+} with Al. See also overite 42.11.1.1, montgomeryite 42.11.8.1 and laueite 42.11.10.1.

Notes:

1. The overite group (42.11.1.1) is a related group with the linkages of the slabs all *trans*- $[\text{Mg}(\text{O}_p)_2(\text{H}_2\text{O})_4]$, while in jahnsite they are alternately *cis* and *trans*. *AM* 62:692(1977).
2. These minerals are secondary phosphates (alteration products) found in granitic pegmatites.
3. Jahnsite (Fe^{3+} -containing species) have higher indices of refraction (1.64-1.71 and are beaxial - whereas whiteites (Al -containing species are Biaxial(+)) with indices 1.580-1.595 except Rittmanite (some Fe^{3+}) 1.62-1.65)

42.11.2.1 Jahnsite-(CaMnMg) $\text{CaMnMg}_2\text{Fe}_2^{3+}(\text{PO}_4)_4(\text{OH})_2 \cdot 8\text{H}_2\text{O}$

42.11.2.3 Jahnsite-(CaMnMn) $\text{CaMnMn}_2\text{Fe}_2^{3+}(\text{PO}_4)_4(\text{OH})_2 \cdot 8\text{H}_2\text{O}$

42.11.2.4 Jahnsite-(MnMnMn) $\text{MnMnMn}_2\text{Fe}_2^{3+}(\text{PO}_4)_4(\text{OH})_2 \cdot 8\text{H}_2\text{O}$

Named in 1974 for Richard H. Jahns (1915-1983), mineralogist and pegmatite expert, Stanford University, Palo Alto, CA. The several minerals above are the Fe^{3+} end members in the Fe^{3+} -Al series with the whiteite (42.11.3.1-3) group. Jahnsite-whiteite group. (CaMnMg): Original description of jahnsite. *MON* P2/a. $a = 14.94$, $b = 7.14$, $c = 9.93$, $\beta = 110.16^\circ$, $Z = 2$, $D = 2.715$. Structure: *AM* 59:48(1974), 59:964(1974). 26-1062: 9.27₁₀ 4.91₆ 4.63₄ 3.52₅ 2.95₅ 2.83₈ 2.58₄ 1.945₄. See also 30-265(calc). Biaxial (-); Z parallel to b; $X \wedge [001] = 18^\circ$; $N_x = 1.640$, $N_y = 1.658$, $N_z = 1.670$; 2V large; $Y \gg Z > X$; pleochroic. X, pale purple; Y, deep purplish brown; Z, greenish yellow. (CaMnFe): Fe^{2+} end member in CaMn (Fe^{2+} -Mg) series. *MON* P2/a. $a = 15.01$, $b = 7.15$,

$c = 9.87$, $\beta = 111.23^\circ$, $Z = 2$, $D = 2.88$. *MM* 42:309(1978). 30-266: 9.15₁₀ 4.96₂ 4.84₁ 4.60₄ 3.48₃ 3.45₃ 2.81₅ 1.874₂. (CaMnMn): Mn²⁺ end member in the CaMn (Mn²⁺-Mg) series. MON *P2/a*. $a = 14.887$, $b = 7.152$, $c = 9.966$, $\beta = 109.77^\circ$, $Z = 2$, $D = 2.798$. *AM* 75:401(1990). *PD*: 9.40₁₀ 5.74₂ 5.02₂ 4.70₃ 3.53₂ 3.46₂ 2.99₂ 2.87₈. (MnMnMn): Mn²⁺ end member of all jahnsite species. MON *P2/a*. $a = 15.02$, $b = 7.23$, $c = 18.75$, $\beta = 100.42^\circ$, $Z = 2$, $D = 2.90$. *GSAPA*:76A(1955), *MM* 42:309(1978). Biaxial (-); $N_x = 1.682$, $N_y = 1.695$, $N_z = 1.707$; $r > v$, strong; pleochroic. X, pale yellow-brown; Y, yellow-brown; Z, dark yellow-brown. Long to short prismatic [010] crystals with striations parallel to [010] up to 5 mm long. Often as parallel aggregates twinned by reflection on {001}, pseudo-orthorhombic appearance. Forms showing {001}, {100}, {201}, {201}, {101}, {011}, {110}, {111} with striae on {201}, {100}. Granular masses up to 5 cm across. Nut-brown, purplish brown, yellow, yellow-orange, greenish yellow. Cleavage {001}, good. $H = 4$. $G = 2.706-2.90$. The original description of jahnsite is from (CaMnMg) material found at *Tip Top pegmatite, Custer, SD*. The (CaMnFe) Fe²⁺ end member was found at *Fletcher mine, North Groton, NH*, with laueite and strunzite; the (CaMnMn) Mn²⁺ end member was found at *Mangualde pegmatite, Beira, Portugal*, and the (MnMnMn) Mn²⁺ end member of all jahnsite series minerals was found at *Stewart mine, Pala, San Diego Co., CA*. Other localities are the Palermo No. 1 mines, North Groton, NH; the White Elephant, Bull Moose, Big Chief, and Linwood pegmatites, Custer Co., SD, where they are associated with triphylite, ferrisicklerite-sicklerite series, heterosite-purpurite series, and rockbridgeite-frondelite series in vugs, which invariably contain leucophosphate, hureaulite, and may be accompanied by collinsite, hydroxylapatite, whitlockite, bermanite, laueite, mitridatite, segelerite, and robertsite; also found at Hagendorf Süd, Bavaria, Germany; at Corrego Frio mine, MG, Brazil. *HCWS AM* 62:692(1977).

42.11.3.1 Whiteite-(CaFeMg) Ca(Fe²⁺,Mn²⁺)Mg₂Al₂(PO₄)₄(OH)₂ · 8H₂O

42.11.3.2 Whiteite-(MnFeMg) (Mn²⁺,Ca)(Fe²⁺,Mn²⁺)Mg₂Al₂(PO₄)₄(OH)₂ · 8H₂O

42.11.3.3 Whiteite-(CaMnMg) CaMn²⁺Mg₂Al₂(PO₄)₄(OH)₂ · 8H₂O

Named in 1978 for John S. White, Jr. (b.1933), editor of the *Mineralogical Record* and associate curator of minerals and gems, U.S. National Museum of Natural History, Washington, DC. The minerals above are the Al end members of the whiteite series within the whiteite group. Bunched aggregates of tabular crystals (to 5 mm) to thick tabular canoe-shaped (warped) crystals (to 2 cm) showing {001}, {111} and invariably twinned by reflection on {001} producing a pseudo-orthorhombic appearance. $H = 3-4$. (CaFeMg): Original description, Ca,Fe-containing member of the series. MON *P2/a*. $a = 14.90$, $b = 6.98$, $c = 10.13$, $\beta = 113.12^\circ$, $Z = 2$, $D = 2.51$. *MM* 42:309(1978). 30-254: 9.27₁₀ 4.82₇ 4.64₇ 3.48₄ 2.94₇ 2.78₈ 1.943₅ 1.552₅. Flattened on {001} with large {001} to 5 mm in length. Tan. $G = 2.58$.

(MnFeMg): Low Ca member of the series. *MON P2/a*. $a = 14.99$, $b = 6.96$, $c = 10.14$, $\beta = 113.32^\circ$, $Z = 2$, $D = 2.62$. *MM 42:309(1978)*. *43-1467: 9.32₁₀ 5.60₃ 4.82₅ 4.64₄ 3.52₄ 3.25₄ 2.95₅ 2.78₉*. Canoe-shaped outline with {001} and {111} nearly balanced (to 1.5 cm in length). The curved aspect of {111} facets is most pronounced in Ca-poor species and gives almond-shaped cross section. Chocolate-brown. $G = 2.67$. (CaMnMg): Low-Fe²⁺, high-Ca member of the series. *MON P2/a*. $a = 14.842$, $b = 6.996$, $c = 10.109$, $\beta = 112.59^\circ$, $Z = 2$, $D = 2.64$. *CM 27:699(1989)*. Tabular pseudo-hexagonal subparallel aggregates in nodules to 0.2 mm × 0.3 mm × 0.04 mm. Pale yellow. $G = 2.81$. Biaxial (+); $N_x = 1.580$, $N_y = 1.584$, $N_z = 1.59$; $2V = 81^\circ$. Whiteite can be found at the Fletcher and Palermo mines, North Groton, NH. Whiteite-(CaMnMg) was found at the *Tip Top pegmatite, Custer, Custer Co., SD*; the original composition, whiteite-(CaFeMg), and also whiteite-(MnFeMg) were found at *Ilha de Taquaral, MG, Brazil*, associated with large childrenite-eosphorite crystals, wardite, green phase related to roscherite, upon large rose quartz crystals, and along joints and fractures in quartz and albite; at Blow R., YT, Canada. HCWS.

42.11.3.4 Rittmannite (Mn²⁺,Ca)Mn²⁺(Fe²⁺,Mn²⁺)₂(Al,Fe³⁺)₂(PO₄)₄(OH)₂ · 8H₂O

Named in 1989 for Alfred Rittman (1893–1980), German vulcanologist. Jahnsite-whiteite group whiteite subgroup. First whiteite structure type mineral with Fe²⁺ dominant in B site. *MON P2/a*. $a = 15.01$, $b = 6.89$, $c = 10.16$, $\beta = 112.82^\circ$, $Z = 2$, $D = 2.83$. *CM 27:447(1989)*. *PD: 9.38₁₀ 5.66₅ 4.93₅ 4.85₅ 4.69₇ 3.53₅ 3.46₅ 2.80₁₀*. Tabular crystals in subparallel aggregates to 0.3 mm × 0.3 mm × 0.04 mm. Pseudo-hexagonal appearance. Pale yellow, vitreous luster, translucent. $H = 3\frac{1}{2}$. $G = 2.81$. Biaxial (+); X parallel to b ; $Z \wedge c = 7^\circ$; $N_x = 1.622$, $N_y = 1.626$, $N_z = 1.654$; nonpleochroic. Analyses may also show Mg. Found in altered phosphatic nodules on kryzhanovskite, frondelite, huraeulite, and adularia in two mica pegmatites at *Mansualde, Viseu district, Beria Alta, Portugal*. HCWS

42.11.4.1 Keckite Ca(Mn²⁺,Zn)₂Fe³⁺(PO₄)₄(OH)₃ · 2H₂O

Named in 1979 for Erich Keck, collector of Hagendorf minerals. Jahnsite-whiteite group Jahnsite subgroup. *MON P2/a*. $a = 15.02$, $b = 7.19$, $c = 19.74$, $\beta = 110.30^\circ$, $Z = 2$, $D = 2.682$. *NJMA 134:183(1979)*. *33-289: 9.3₈ 4.98₅ 4.63₃ 3.51₅ 2.86₁₀ 2.59₄ 2.34₃ 1.879₄*. Aggregates of crystal plates up to 2 mm long. Brown, yellow-brown, dirty grayish brown; dull luster. Cleavage {001}, {100}. $H = 4$. $G = 2.6$. IR. Biaxial (-); $X \wedge c = 15-22^\circ$; $Z = b$; $N_y = 1.692$, $N_z = 1.699$; undulatory extinction; pleochroic: X, reddish brown; Y, yellow; Z, brighter yellow $X \gg Y > Z$. Found in the oxidation and weathering zone of phosphophyllite or rockbridgeite in *Hagendorf pegmatite, Oberfalz, Bavaria, Germany*. HCWS *AM 64:1330(1979)*.

42.11.5.1 Minyulite $KAl_2(PO_4)_2(OH,F) \cdot 4H_2O$

Named in 1933 for the locality. ORTH *Pba*2. $a = 9.337$, $b = 9.740$, $c = 5.522$, $Z = 2$, $D = 2.472$. *BM 96:67(1973)*, Structure: *AM 62:256(1977)*. Two AlO_6 octahedra share one F-vertex and two PO_4 tetrahedra, forming a dimeric cluster that links into sheets parallel to $\{001\}$. Cavities in the sheets are occupied by K^+ . Hydrogen bonds from H_2O molecules (coordinated to Al) form the only link between sheets. *37-467: 6.75₄ 5.52₁₀ 3.40₅ 3.35₆ 3.07₄ 2.68₃ 2.61₂ 2.14₃*. Radial aggregates of needles; short prismatic crystals in subparallel growth. Colorless to white, silky luster, transparent. Cleavage probably parallel to elongation, brittle. $H = 3\frac{1}{2}$. $G = 2.45$. Biaxial (+); $N_x = 1.531$, $N_y = 1.534$, $N_z = 1.538$. Traces of Fe^{3+} on analysis. Soluble in hot 1:1 acids and warm 1:10 NaOH. Synthesized below 95° . Found near *Minyulo well, Dandaragan, WA*, with dufrenite in altered outcrops of glauconite-containing phosphate beds, at Wait's quarry, Noarlunga, Moculta quarry, Angaston, SA, and with fluellite at Wolffdene quarry, Q, *Australia*. *HCWS DII:970*.

42.11.6.1 Leucophosphate $KFe_2^{3+}(PO_4)_2(OH) \cdot 2H_2O$

Named in 1932 from the Greek *leuco*, white, in allusion to the color and for the composition. The Fe^{3+} end member in the $K-NH_4$ series with spheniscidite (42.11.6.3): Tinsleyite (42.11.6.2) is the Al analog. *MON P2_{1/n}*. $a = 9.782$, $b = 9.658$, $c = 9.751$, $\beta = 102.24^\circ$, $Z = 4$, $D = 2.911$. Structure: *AM 57:397(1972)*. Tetramers of FeO_6 octahedra, clusters of composition $[Fe_4^{3+}(OH)_2(H_2O)_2(O)_{16}]$, are joined through the PO_4 groups to produce a structure with channelways where K^+ resides. *37-466: 6.77₇ 6.12₄ 5.97₁₀ 4.27₄ 3.06₇ 3.05₅ 2.91₆ 2.82₆*. See also *9-446*. Massive amorphous, tiny pseudo-orthorhombic crystallites; columnar aggregates of prismatic crystals to 1 mm. Buff, white, greenish white (purplish gray in incandescent light); chalky, translucent. Excellent cleavage parallel to (100), friable. $G = 2.948$. Biaxial (+); $X = b$, $Z \wedge c = 26^\circ$; $N_x = 1.707$, $N_y = 1.721$, $N_z = 1.739$; $2V = 62^\circ$; $r < v$, very strong. Soluble in 1:1 HCl, H_2SO_4 . Synthesized below 145° , pH 2.5–6.0, and $[PO_4]$ 1.0–3.5 M. Experiments show limited Na substitution in leucophosphate as separate Na phases form. Found at Palermo No. 1, North Groton, NH; at Tip Top mine, Custer, Custer Co., SD, with rockbridgeite; at Bomi Hill, and Bambuta, western Liberia, as a result of solutions from bat dung; at *Weelhamby Lake, Ninghanboun Hill, WA, Australia*, with variscite, chalcedony, and opal in veinlets in serpentine, presumably via solutions of bird guano on serpentine; at Sapucaia pegmatite, MG, Brazil, with cyrilovite, metastrengite, and frondelite. *HCWS DII:936, AM 42:214(1957)*.

42.11.6.2 Tinsleyite $KAl_2(PO_4)_2(OH_2) \cdot 2H_2O$

Named in 1984 for Frank C. Tinsley (b.1916), mineral collector, Black Hills specialist, of Rapid City, SD. Al analog of leucophosphate (42.11.6.1). *MON Pn*. $a = 9.602$, $b = 9.532$, $c = 5.543$, $\beta = 103.16^\circ$, $Z = 4$, $D = 2.62$. *AM 69:374(1984)*. Note space group difference from leucophosphate. *38-351:*

6.68₁₀ 5.91₈ 4.16₅ 3.72₅ 3.01₇ 2.84₅ 2.77₅ 2.62₆. Tabular on {101} prismatic crystals show {101}, {111}, {011}, {110}. Composite crystals with colorless Fe-rich leucophosphite interior and tinsleyite as the outermost zone (epitaxial). Dark violet-red, pink streak, vitreous luster, translucent. Brittle. $H \approx 5$. $G = 2.69$. Nonfluorescent. Biaxial (+); X parallel to b ; $N_x = 1.591$, $N_y = 1.597$, $N_z = 1.604$; $2V = 86^\circ$; strongly pleochroic. X, pale orange-brown; Y, light purple; Z, dark purplish red $Z > Y > X$. Microprobe analyses show Fe^{3+} , and Mn^{3+} or $4+$ oxidation state suggested because of mineral association. Found in the highly altered triphylite pods within the intermediate zone of the *Tip Top pegmatite, 8.8 km SE of Custer, Custer Co., SD*, in association with leucophosphite, robertsite, rockbridgeite-frondelite, tavorite, perthite, quartz, muscovite, fluorapatite, albite, beryl, elbaite, columbite-tantalite, carbonate-apatite, and laueite; at Sapucaia pegmatite, MG, Brazil. hcws

42.11.6.3 Spheniscidite $(NH_4, K)(Fe^{3+}, Al)_2(PO_4)_2(OH) \cdot 2H_2O$

Named in 1986 from the Latin *sphenisciformes*, to designate of the order for the animal group containing penguins. The NH_4 member in the $K-NH_4$ series with leucophosphite (42.11.6.1). MON $P2_1/n$. $a = 9.75$, $b = 9.63$, $c = 9.70$, $\beta = 102.57^\circ$, $Z = 4$, $D = 2.71$. MM 50:291(1986). 41-593: 7.62₄ 6.79₁₀ 6.09₃ 5.99₉ 4.75₄ 4.26₄ 3.36₄ 3.05₅. Fine grained ($< 200 \mu m$) micaceous aggregates. Brown, earthy, greasy luster, translucent. Soft. Cleavage {100}. DTA, IR. Biaxial (+); $X = b$; OAP perpendicular to (010); $N_{x \text{ syn}} = 1.706$, $N_{y \text{ syn}} = 1.724$, $N_{z \text{ syn}} = 1.741$; $N \approx 1.7$ in mineral with moderate birefringence. Soluble in acids, insoluble in H_2O . Analysis also shows Ca, Mg. Synthesized with $NH_4 > K$, $Fe^{3+} > Al$. Found as the rim material on phyllitic rock in ornithogenic soils (guano-containing) associated with struvite, hydroxylapatite, taranakite, and minyulite at *Elephant Island, South Shetland Is., British Antarctic Territory*. hcws

42.11.7.1 Giniite $Fe^{2+}Fe^{3+}(PO_4)_4(OH)_2 \cdot 2H_2O$

Named in 1980 by Paul Keller for his wife, Gini Keller. MON $P2/a$. $a = 14.253$, $b = 5.152$, $c = 10.353$, $\beta = 111.30^\circ$, $Z = 2$, $D = 3.42$. NJMM:561(1980). 33-669: 4.07₄ 3.36₁₀ 3.20₇ 2.80₅ 2.28₆ 2.04₇ 1.679₆ 1.604₇. Crystals to 0.5 mm \times 0.2 mm \times 0.05 mm, showing {100}, {201}, {210}, {103}, {010}. Twinned with plane {112}. Blackish green to blackish brown, olive streak, vitreous to greasy luster, translucent. No cleavage, conchoidal fracture. $H = 3-4$. $G = 3.41$. Biaxial (-); $X = c$; $N_x = 1.775$, $N_y = 1.803$, $N_z = 1.812$; $2V \approx 55^\circ$; pleochroic. X, light brown; Y, dark brown; Z, dark blue-green. Fe^{2+} and Fe^{3+} influence color and pleochroism. Found in the pegmatite at *Sandamab, near Usakos, Namibia*, associated with hureauite, tavorite, leucophosphite, and another phosphate formed by the alteration of triphylite. hcws NJMM:49(1980), AM 65:1066(1980).

MONTGOMERYITE GROUP

The montgomeryite group minerals have the general formula

where

and crystallize with monoclinic or orthorhombic space groups.

The structure is related to that of other Fe^{3+} -Al containing phosphates, and it is composed of Fe^{3+} -Al octahedra corner-linked with PO_4 tetrahedra that form chains with a 7-Å repeat (see the jahnsite-whiteite group). In montgomeryite the A site is partially occupied but ordered with the Mg cations bonded to two O(4) atoms and to four O's from H_2O molecules. The result is that there are no shared edges with other MgO_6 groups to form Mg octahedral sites. The Ca cation is located between the chains.

The space group for montgomeryite was determined to be $\text{C}2$, a subset of $\text{C}2/c$, which is probably appropriate for the other members of the group as

MONTGOMERYITE: $\text{Ca}_4\text{MgAl}_4(\text{PO}_4)_6(\text{OH})_4 \cdot 12\text{H}_2\text{O}$

A c axis projection that shows slabs composed of Ca polyhedra, $\text{Al}(\text{OH})_6$ and tetrahedral PO_4 groups. A second $\text{Ca}(\text{O}_p, \text{H}_2\text{O})$ polyhedra and $\text{Mg}(\text{H}_2\text{O})_6$ groups link the slabs. Compare with other Class 42 Type 11 structures.

well, although further detailed crystallographic work needs to be done. *AM* 59:843(1974), 61:12(1976), 77:19(1992); *DHZ* 14:231(1963); *FF* 444(1984).

42.11.8.1 Montgomeryite $\text{Ca}_4\text{MgAl}_4(\text{PO}_4)_6(\text{OH})_4 \cdot 12\text{H}_2\text{O}$

Named in 1940 for Arthur Montgomery (b.1909), mineralogist, teacher, collector, and founder of Friends of Mineralogy. He and Edwin Over mined the Fairfield, UT, phosphate deposit and recognized the mineral as new. Montgomeryite group. See kingsmountite (42.11.8.2), the Fe^{2+} end member in the Fe^{2+} -Mg series of the Al-containing members of the montgomeryite group. *MON* C2. $a = 10.004$, $b = 24.083$, $c = 6.235$, $\beta = 91.55^\circ$, $Z = 2$, $D = 2.523$. *AM* 61:12(1976), Structure: *AM* 59:843(1974). 35-624: 12.0₁₀ 6.03₂ 5.11₇ 3.13₂ 2.90₅ 2.87₃ 2.62₃ 2.58₃. See also 28-225(calc). Dark green, pale green, bright red, colorless; vitreous luster; translucent. $H = 4$. $G = 2.530$. Biaxial (-); $N_x = 1.572$, $N_y = 1.579$, $N_z = 1.582$; $2V = 75^\circ$. *MR* 14:195(1983). Microprobe analysis shows minor Mn. Found at the Tip Top pegmatite, Custer, Custer Co., SD, also at the Etta pegmatite, near Keystone, SD, replacing mitridatite; at Little Green Monster Mine, Clay Canyon, Fairfield, Utah Co., UT, with wardite, englishite, and gordonite replacing variscite, and crandallite and apatite; at Milgun Station, WA, Iron Monarch quarry, Iron Knob, SA, Australia; at Lavra da Ilha, Taquaral, Brazil. *HCWS*

42.11.8.2 Kingsmountite $(\text{Ca}, \text{Mn}^{2+})_4(\text{Fe}^{2+}, \text{Mn}^{2+})\text{Al}_4(\text{PO}_4)_6(\text{OH})_4 \cdot 12\text{H}_2\text{O}$

Named in 1979 for the locality. Montgomeryite group. The Fe^{2+} analog of montgomeryite (42.11.8.1). *MON* C2. $a = 10.029$, $b = 24.46$, $c = 6.31$, $\beta = 91.16^\circ$, $Z = 2$, $D = 2.58$. *CM* 17:579(1979). 35-694: 12.23₅ 9.30₂ 6.33₃ 5.15₁₀ 3.31₃ 2.95₄ 2.92₃ 2.62₆. Radiating plates, fibers in subparallel aggregates, spherules to 2.0 mm in diameter. White, light brown; pearly luster;

translucent. $H = 2\frac{1}{2}$. $G = 2.51$. Nonfluorescent. TGA. Biaxial (-); lath has X parallel to one edge; Y perpendicular to lath; Z \wedge elongation 35° ; $N_x = 1.575$, $N_y = 1.581$, $N_z = 1.583$, $2V = 62^\circ$. Microprobe analysis shows Mn > Fe, minor Mg. Found at *Foote Mineral Co. spodumene mine, Kings Mt., Cleveland Co., NC*, with mitridatite, birnessite; at Hagendorf pegmatite, Bavaria, Germany. hcws

42.11.8.3. Calcioferrite $\text{Ca}_4\text{Mg}(\text{Fe}^{3+}, \text{Al})_4(\text{PO}_4)_6(\text{OH})_4 \cdot 12\text{H}_2\text{O}$

Named in 1858 for the composition. The Fe^{3+} analog of montgomeryite (42.11.8.1). MON C2. $a = 10.34$, $b = 24.20$, $c = 6.31$, $\beta = 91.5^\circ$, $Z = 2$, $D = 2.65$. Sulfur-yellow, greenish yellow, siskin-green, yellowish white; sulfur-yellow to white streak, pearly luster on cleavage surfaces; translucent. Cleavage parallel to foliation perfect, second at right angles, third oblique; brittle. $H = 2\frac{1}{2}$. $G = 2.53$. Biaxial (-); $N_x = 1.572$, $N_y = 1.579$, $N_z = 1.583$; $2V = 75^\circ$. Analysis shows Cu, Al, Si, Cr. Found at *Battenberg, Bavaria, Germany*, in a bed of Tertiary clay; at *Karatay, Kazakhstan*. hcws

42.11.8.4. Zodacite $\text{Ca}_4\text{MnFe}_4^{3+}(\text{PO}_4)_6(\text{OH})_4 \cdot 12\text{H}_2\text{O}$

Named in 1988 for Peter Zodac (1894–1967), founder and editor of *Rocks and Minerals*. Montgomeryite group. The Mn and Fe^{3+} -containing end member. MON C2/c or Cc. $a = 10.152$, $b = 24.14$, $c = 6.308$, $\beta = 91.14^\circ$, $Z = 2$, $D = 2.65$. AM 73:1179(1988). 41-1454: 12.0₆ 9.38₂ 6.31₃ 5.59₂ 5.18₁₀ 3.15₄ 2.91₅ 2.66₄. Isolated crystals up to 0.2 mm, flattened, radial arrays. Light to medium yellow, tiny crystals may be colorless; light yellow to white streak; vitreous luster. Cleavage assumed parallel to {010}. $H \approx 4$. $G = 2.68$. Nonfluorescent. Biaxial (-); $X = b$; $Y \wedge c = 24^\circ$; $Z \wedge a = 23^\circ$; $N_x = 1.598$, $N_y = 1.601$, $N_z = 1.602$ (Na); weakly pleochroic. Y, very pale green; Z, pale green $Y < Z$. Found at the *Mangualde pegmatite, Beira, Portugal*, in association with jahn-site-(Mn,Mn,Mn), hureaulite, and phosphosiderite on altered varulite. hcws

LAUEITE-PARAVAUXITE GROUP

The laueite-paravauxite group of phosphate minerals contains two subgroups, plus three allied species, conforming to the formula

where

A = Mg, Fe^{2+} , Mn, Fe^{3+}

B = Al, Fe^{3+} , Cr^{3+}

$n = 5$ to 8, but is usually 8

and usually crystallize is usually with triclinic symmetry in space group $P1$ or $P1$.

The structure [laueite: *MP 38:201(1988)*; paravauxite: *NJMM:430(1969)*] comprises chains of BO_6 octahedra connected by PO_4 tetrahedra into heteropolyhedral sheets with composition $[(\text{Fe}^{3+}/\text{Al})(\text{PO}_4)_2(\text{OH})_2(\text{H}_2\text{O})_2]^{2+}$. The sheets are cross-linked of the sheets is through octahedrally coordinated cations A-O_6 . Additionally, at least two H_2O molecules are incorporated as part of the H-bonded network.

Variations in the bonding and orientation of the groups that make up the infinite chains and the associated cations give rise to different linkages and hydration states, resulting in different species, and specifically polymorphism. For example, in laueite there are two different $\text{Fe}^{3+}\text{-O}$ octahedral linkages, resulting in two types of chains. In stewartite there are three nonequivalent $\text{Fe}^{3+}\text{-O}_6$ octahedra, while pseudolaueite has all $\text{Fe}^{3+}\text{-O}_6$ octahedra equivalent, with the result chains have consistent components and configuration.

A strunzite subgroup has lower hydration states, while the paravauxite subgroup has Al-O_6 octahedra and linkages. *AM 59:1272(1974)*, *53:1025(1968)*, *54:1312(1969)*.

1. Note increase in index of refraction with Fe^{3+} and optic sign change between Ferroit ferri-strunzite.

42.11.9.1 Strunzite $Mn^{2+}Fe^{3+}(PO_4)_2(OH)_2 \cdot 6H_2O$

Named in 1958 by C. Frondel for Hugo Strunz, mineralogist (b.1910), Berlin and Regensburg, Germany. Laueite-paravauxite group strunzite subgroup. See also ferrostrunzite (42.11.9.2), ferristrunzite (42.11.9.3), and laueite (42.11.10.1). TRIC $P\bar{1}$. $a = 10.228$, $b = 9.837$, $c = 7.284$, $\alpha = 90.17^\circ$, $\beta = 98.44^\circ$, $\gamma = 117.44^\circ$, $Z = 2$, $D = 2.581$. *NJMM:222(1957)*, Structure: *TMPM (ser. 3)25:77(1978)*. 11-133: 9.02₁₀ 5.32₈ 4.50₅ 4.35₆ 3.35₄ 3.29₆

3.23₆. Tufts of hairlike or lathlike crystals flattened {010}, twinned {100}. Straw-yellow to brown-yellow, translucent. $G = 2.52$. Biaxial (-); $Z \wedge c = 10^\circ$; $N_x = 1.619$, $N_y = 1.670$, $N_z = 1.720$; $2V$ moderate; faintly pleochroic, yellow with $Z > X, Y$. Found as surface weathering product of triphylite at Nevel tourmaline mine, Newry, BB mine, Norway, Red Hill mine, Rumford, ME; Fitzgibbon mine, Alstead, Buzzo quarry, Center Strafford, G.E. Smith mine, Newport, Fletcher and Palermo No. 1 mines, North Groton, NH; at Cobalt, CT; at Mullica Hill, NJ; at Williams Property, AL; at Big Chief mine, Custer Co., Hesnard mine, Etta mine, Keystone Co., SD; as films in weathered outcrops of PO_4 rock in the Phosphoria formation, Rasmussen Valley, ID; at *Hagendorf pegmatite, Oberfalz, Bavaria, Germany*. *HCWS AM 43:793(1958)*.

42.11.9.2 Ferrostrunzite $Fe^{2+}Fe^{3+}(PO_4)_2(OH)_2 \cdot 6H_2O$

Named in 1983 for the composition and relationship to strunzite (42.11.9.1). Laueite-paravauxite group strunzite subgroup. TRIC $P\bar{1}$ or $P1$. $a = 10.23$, $b = 9.77$, $c = 7.37$, $\alpha = 89.65^\circ$, $\beta = 98.28^\circ$, $\gamma = 117.26^\circ$, $Z = 2$, $D = 2.57$. *NJMM: 524(1983)*, Structure: *NJMM 207(1992)*. There two distinct structural sites for Fe, but Mossbauer suggests some overlap of $Fe^{2+} Fe^{3+}$ in sites⁺ as $Fe^{2+}/Fe^{3+} = 0.34$. Rather than 0.50 if strictly segregated. *42-595: 8.94₈ 5.29₁₀ 4.47₃ 4.33₂ 4.24₂ 3.45₃ 3.28₄ 3.21₃*. Radiating sprays to 0.5 mm of fibrous prismatic crystals to 150 μm : flattened {100}, elongated [001]; needles to 1 mm with inclined top face. Colorless, faint straw-yellow, light brown color and streak; vitreous luster; translucent. Cleavages: parallel to length, perpendicular to optic normal, and perpendicular to $B \times a$; very brittle. $H \approx 4$. $G = 2.50$. Mossbauer. Biaxial (-); $Z \wedge c = 3-4^\circ$; $N_x = 1.628$, $N_y = 1.682$, $N_z = 1.723$; $2V = 80^\circ$; pleochroic: X, pale yellow-green; Z, pale red-yellow. Moderate and asymmetric dispersion, minimum absorption parallel to Z. No Al detected on analysis. Found at *Mullica Hill, NJ*, where the sprays encrust rockbridgeite that has replaced fossil belemnites in Cretaceous sediments; at Bethel Church, IN; at Perranporth, Cornwall, England; at Arnsberg, Sauerland, Germany. *HCWS AM 69:811(1984)*.

42.11.9.3 Ferristrunzite $Fe^{3+}Fe^{3+}(PO_4)_2(OH)_3 \cdot 5H_2O$

Named in 1987 for the composition and relationship to strunzite, the completely oxidized version. Laueite-paravauxite group strunzite subgroup. TRIC $P1$ or $P1$. $a = 10.01$, $b = 9.73$, $c = 7.334$, $\alpha = 90.5^\circ$, $\beta = 97.0^\circ$, $\gamma = 116.4^\circ$, $Z = 2$, $D = 2.55$. *NJMM:453(1987)*, Structure: *NJMM:176(1990)*. *41-1383: 8.87₈ 5.34₁₀ 4.48₂ 4.37₂ 4.20₃ 3.44₃ 3.39₃ 3.27₄*. Matted aggregates of acicular [001] crystals (to 30 μm) up to 0.5 mm long. Radiating sprays up to 2.6 mm in diameter; twinned {110}. Light brownish yellow, light yellow streak, translucent. Cleavage parallel to X-Z optic plane, good. $G = 2.5$. Biaxial (+); $Z \wedge c \approx 17^\circ$ with Z approximately parallel to elongation; $N_x = 1.664$, $N_y = 1.698$, $N_z = 1.757$; $2V = 77^\circ$; strongly pleochroic: X, greenish yellow; Z, brownish yellow. Found associated with crandallite, diadochite, allo-

phane-evansite, minyulite, strengite, phosphosiderite, cacoxenite, beraunite in argillaceous and clastic sediments exposed in a canal near *Blaton, Belgium*. *HCWS AM 74:502(1989)*.

42.11.10.1 Laueite $\text{Mn}^{2+}\text{Fe}_2^{3+}(\text{PO}_4)_2(\text{OH})_2 \cdot 8\text{H}_2\text{O}$

Named in 1954 for Max Felix Theodor von Laue (1879–1960), crystallographer, Berlin, Germany. Laue was the first to use crystals as diffraction gratings (in 1912), thus initiating a technique to study the atomic structure of crystals. Laueite–paravauxite group. See dimorph stewartite (42.11.10.2) and the closely related minerals pseudolaueite (42.11.10.3), strunzite (42.11.9.1), gordonite (42.11.14.4), and paravauxite (42.11.14.2). TRIC P1. $a = 5.28$, $b = 10.66$, $c = 7.14$, $\alpha = 107.92^\circ$, $\beta = 114.98^\circ$, $\gamma = 71.12^\circ$, $Z = 1$, $D = 2.56$. *AM 50:1884(1965)*, Structure: *AM 54:1312(1969)*. Two types of chains, $[\text{Fe}(1)\text{O}_4(\text{OH})]^{6-}$ and $[\text{Fe}(2)\text{O}_2(\text{OH})(\text{H}_2\text{O})_2]^{2-}$, are linked by PO_4 groups into sheets parallel to (010). The sheets are connected through Mn^{2+} atoms in octahedral coordination. The latter site may be partially occupied, or a portion of the Mn may be Mn^{3+} . The two remaining H_2O molecules are not coordinated to cations. *14-246: 9.91₁₀ 6.57₇ 4.95₈ 4.02₅ 3.93₅ 3.28₉ 3.12₅ 2.88₆*. Crystals to 2 mm showing {100}, {010}, {110}, {110}, {011}. Honey-brown. $H = 3$. $G = 2.46$. Biaxial (–); $N_x = 1.612$, $N_y = 1.658$, $N_z = 1.682$; $2V = 50^\circ$. Analyses also show Ca, Al, Fe^{2+} and Mg, some Mn^{3+} inferred from crystal structure determination. Found at Nevel tourmaline mine, Paul Bennet quarry, Newry, ME; at Fitzgibbon, Palermo Nos. 1 and 2, Fletcher mines, North Groton, NH; at Big Chief pegmatite, Custer Co., Hesnard, High Climb, Etta, Linwood, and White Elephant pegmatites, Keystone Co., SD; at *Hagendorf Süd pegmatite, Bavaria, Germany*; at Lavra do Enio, Galileia, MG, Brazil. *HCWS NJMA 123:148(1975)*.

42.11.10.2 Stewartite $\text{Mn}^{2+}\text{Fe}_2^{3+}(\text{PO}_4)_2(\text{OH})_2 \cdot 8\text{H}_2\text{O}$

Named in 1912 for the locality. Laueite–paravauxite group. Polymorph of laueite (42.11.10.1). TRIC P1. $a = 10.398$, $b = 10.672$, $c = 7.223$, $\alpha = 90.10^\circ$, $\beta = 109.10^\circ$, $\gamma = 71.83^\circ$, $Z = 2$, $D = 2.48$. *AM 43:1148(1958)*, Structure: *AM 59:1272(1974)*. Three nonequivalent Fe^{3+} octahedra linked through (OH) corner sharing form chains parallel to {100}. The chains are bridged by PO_4 tetrahedral groups to form sheets parallel to {010}. Mn^{2+} connects sheets. Two H_2O molecules are not directly connected to cations. *5-110: 10.0₁₀ 6.71₇ 5.86₃ 5.01₅ 3.93₅ 2.99₄ 2.652₄ 2.49₂*. Minute crystals and tufts of fibers. Brownish yellow, translucent. Cleavage {010}, perfect. $G = 2.94$. Biaxial (–); $N_x = 1.63$, $N_y = 1.658$, $N_z = 1.66$; $2V = 60^\circ$; $r < v$, strong; pleochroic: X, colorless; Y, pale yellow; Z, yellow. Found at Newry, ME; at Fletcher and Palermo no. 1 mines, North Groton, NH; at Williams Property, AL; at Tip Top pegmatite, Custer Co., and Hesnard, Linwood and White Elephant pegmatites, Keyston, SD; at *Stewart lithia mine, Pala, San Diego Co., CA*, with palaite, hureaulite as an alteration product of lithiophilite; at Chanteloube,

France; at Hagendorf Süd, Bavaria, Germany. HCWS *DII:730, NJMA 123:148(1975)*.

42.11.10.3 Pseudolaueite $\text{Mn}^{2+}\text{Fe}_2^{3+}(\text{PO}_4)_2(\text{OH})_2 \cdot 8\text{H}_2\text{O}$

Named in 1956 for the polymorphic relationship to laueite (42.11.10.1). Laueite-paravauxite group. MON $P2_1/a$. $a = 9.647$, $b = 7.428$, $c = 10.194$, $\beta = 104.63^\circ$, $Z = 2$, $D = 2.51$. NATW *43:128(1956)*, Structure: AM *54:1312(1969)*. Similar to laueite but all $\text{Fe}^{3+}\text{O}(\text{OH})_6$ octahedra are equivalent and form similar chains parallel to $\{010\}$ bridged by PO_4 tetrahedral groups into heteropolygonal sheets parallel to $\{001\}$. Mn^{2+} connects sheets into a unique three-dimensional structure. *12-294: 9.93₁₀ 5.87₇ 4.68₃ 3.91₃ 3.47₄ 3.19₃ 3.07₃ 2.55₃*. Prismatic, or thick, tabular, crystals showing $\{100\}$, $\{001\}$, $\{110\}$, $\{011\}$, $\{201\}$. Orange-yellow. $G = 2.46$. Biaxial (+); $X \wedge c = 2^\circ$; $Y \wedge a = 12^\circ$; $Z = b$; $N_x = 1.626$, $N_y = 1.650$, $N_z = 1.868$; $2V = 80^\circ$; pleochroic: X, Y, pale yellow; Z, yellow. Found at *Hagendorf, Bavaria, Germany*. Crystals may show core of stewartite and are associated with Mn and Fe oxides. HCWS AM *41:815(1956)*.

42.11.10.4 Ushkovite $\text{MgFe}_2^{3+}(\text{PO}_4)_2(\text{OH})_2 \cdot 8\text{H}_2\text{O}$

Named in 1983 for S. I. Ushkov (1880–1951), naturalist who studied the Il'men National Forest in the Ural Mts., Russia. Laueite-paravauxite group. TRIC $P1$. $a = 5.20$, $b = 10.70$, $c = 7.14$, $\alpha = 108.6^\circ$, $\beta = 106.9^\circ$, $\gamma = 72.7^\circ$, $Z = 1$, $D = 2.47$. ZVMO *112:42(1983)*. *35-685: 9.86₁₀ 6.57₈ 4.95₅ 4.85₅ 4.01₄ 3.28₆ 3.20₈ 3.12₄*. Short prismatic crystals (to 2 mm) showing (001) , (010) , $(1\bar{1}0)$ as principal faces; $\{100\}$, $\{110\}$ minor faces. Pale yellow to orange-yellow, light brown; vitreous luster to pearly on cleavage, greasy on fracture; translucent. Cleavage (010) , perfect; brittle. $H = 3\frac{1}{2}$. $G = 2.38$. IR, DTA. Biaxial (-); $N_x = 1.584$, $N_y = 1.637$, $N_z = 1.670$; $Y \wedge c = 26^\circ$; $2V = -50^\circ$; $r > v$, strong; pleochroic: X, yellow; Y, orange-yellow; Z, light brown. Dissolved by 1:10 acids. Found as the weathering product of triplite in granite pegmatites in the *Il'men Mts., Ural Mts., Russia*, associated with Mn hydroxides, francolite, mitridatite, and beraunite. HCWS AM *69:212(1984)*.

42.11.11.1 Metavauxite $\text{Fe}^{3+}\text{Al}_2(\text{PO}_4)_2(\text{OH})_2 \cdot 8\text{H}_2\text{O}$

Named in 1922 for the chemical relationship to vauxite (42.11.14.1). Laueite-paravauxite group. Dimorph of paravauxite (42.11.14.2). MON $P2_1/c$. $a = 10.23$, $b = 9.59$, $c = 6.94$, $\beta = 98.03^\circ$, $Z = 2$, $D = 2.36$. Structure: NJMA *123:148(1975)*. *33-639: 10.12₇ 5.10₅ 4.69₁₀ 4.34₈ 3.99₅ 2.76₇ 2.75₃ 2.27₃*. Prismatic to acicular $[001]$, subparallel radial aggregates. Colorless, white, pale green; vitreous luster to silky in fibers; transparent to translucent. Brittle. $H = 3$. $G = 2.345$. Biaxial (+); $X = b$; $Z \wedge c \approx 17^\circ$; $N_x = 1.550$, $N_y = 1.561$, $N_z = 1.577$ (Na). Ca and Mg may substitute for Fe. Found with vauxite, paravauxite, and wavellite in oxidation zone at *Siglo XX mine, Llallagua, Bolivia*. HCWS *DII:971*.

42.11.12.1 Gatumbaite $\text{CaAl}_2(\text{PO}_4)_2(\text{OH})_2 \cdot \text{H}_2\text{O}$

Named in 1977 for the locality. MON $P2_1/m$, $P2$, or Pm . $a = 6.907$, $b = 5.095$, $c = 10.764$, $\beta = 91.05^\circ$, $Z = 2$, $D = 2.95$. *NJMM:561(1979)*. 29-283: 6.9₅ 4.21₁₀ 3.21₅ 3.16₅ 2.77₇ 2.30₇ 2.24₁₀ 1.726₈. Sheaves and rosettes with radial fibrous structure up to 10 mm in diameter. Pure white, pearly luster, translucent. Asbestiform splinters, longitudinal cleavage, cross fractures, brittle. $H < 5$. $G = 2.92$. Nonfluorescent. IR. Biaxial (-); $Z = b$; OAP perpendicular to (010); $N_x = 1.610$, $N_y = 1.63$ _(est), $N_z = 1.639$. Found in the *Buranga pegmatite, near Gatumba, Gisenyi Prov., Rwanda*, associated with trolleite, scorzalite, apatite, bjarebyite, and a Be-phosphate. *HCWS AM 63:793(1978)*, 59:1140(1974).

42.11.12.2 Kleemanite $\text{ZnAl}_2(\text{PO}_4)_2(\text{OH})_2 \cdot 3\text{H}_2\text{O}$

Named in 1979 for Alfred William Kleeman, petrologist, University of Adelaide, SA, Australia. MON P_2 , P_{21} , P_2/M or P_{21}/M . $a = 7.29$, $b = 7.194$, $c = 9.762$, $\beta = 110.20^\circ$, $Z = 2$, $D = 2.76$. *MM 43:93(1979)*. 33-1465: 9.09₆ 5.66₅ 4.76₁₀ 3.88₅ 3.64₅ 3.33₅ 3.30₆ 3.09₈. Very small crystallites and fibers. Ochre-colored. TGA. Biaxial; $N_x = 1.598$, $N_z = 1.614$; colorless; inclined extinction to 40° of fiber axis. Coatings or thin (1 to 2 mm thick) veins on manganeseiferous iron ore at *Iron Knob, SA, Australia*. *HCWS AUSM 4:123(1989)*, *AM 64:1331(1979)*.

42.11.13.1 Vanuralite $\text{Al}(\text{UO}_2)_2(\text{VO}_4)_2(\text{OH}) \cdot 11\text{H}_2\text{O}$

Named in 1963 for the composition: vanadium and uranium. See also metavanuralite (42.11.13.2). MON $A2/a$. $a = 10.55$, $b = 8.44$, $c = 24.52$, $\beta = 103^\circ$, $Z = 4$, $D = 3.16$. *BM 93:242(1970)*. 23-769: 12.0₁₀ 6.53₄ 5.98₉ 5.14₇ 3.98₈ 3.27₅ 3.23₈ 3.18₈. Microcrystalline. Greenish yellow, translucent. $H = 2$. $G = 3.62$. Biaxial (-); $N_x = 1.65$, $N_y = 1.85$, $N_z = 1.90$; $2V = 44^\circ$. Found at *Mounana mine, Franceville, Haute Ogooue, Gabon*. *HCWS AM 48:1415(1963)*, 56:639(1971).

42.11.13.2 Metavanuralite $\text{Al}(\text{UO}_2)_2(\text{VO}_4)_2(\text{OH}) \cdot 8\text{H}_2\text{O}$

Named in 1970 as the lower hydrate of vanuralite (42.11.13.1). TRIC $P1$ or $P1$. $a = 10.46$, $b = 8.44$, $c = 10.43$, $\alpha = 75.88^\circ$, $\beta = 102.83^\circ$, $\gamma = 90^\circ$, $Z = 2$, $D = 3.66$. *BM 93:242(1970)*. 23-770: 9.92₁₀ 5.10₇ 4.17₉ 4.09₈ 3.24₈ 3.20₇ 3.16₉ 3.07₈. Greenish yellow, translucent. Stable at 20° in the relative humidity range 28-47%. Found at the *Mounana mine, Franceville, Haut Ogooue, Gabon*. *HCWS AM 56:637(1971)*.

42.11.13.3 Threadgoldite $\text{Al}(\text{UO}_2)_2(\text{PO}_4)_2(\text{OH}) \cdot 8\text{H}_2\text{O}$

Named in 1979 for Ian M. Threadgold (b.1929), University of Sydney, NSW, Australia. The P analog of metavanuralite (42.11.13.2). MON $C2/c$. $a = 20.168$, $b = 9.847$, $c = 19.719$, $\beta = 110.71^\circ$, $Z = 8$, $D = 3.33$. Structure: *TMPM 30:111(1982)*. 33-39: 9.43₁₀ 5.35₅ 4.93₄ 4.10₅ 3.73₄ 3.47₈ 3.37₆ 2.20₆. Micaceous

tabular crystals elongated on *b* to 1 mm, showing {100}, {001}, {010}, {012}. Greenish yellow, translucent. *G* = 3.4. DTA. Fluorescent green in LWUV, pale green in SWUV. Biaxial (-); *Y* = *b*; *Z* \wedge *c* = 4°; *N_x* = 1.573, *N_y* = 1.583, *N_z* = 1.588; negative elongation; 2*V* = 70°; pleochroic, pale yellow to colorless. Found at *Kobokobo, Kivu, Zaire*, with phuralumite and upalite. *hcws AC(B) 35:3017(1979), AM 65:209(1980)*.

42.11.14.1 Vauxite $\text{Fe}^{2+}\text{Al}_2(\text{PO}_4)_2(\text{OH})_2 \cdot 6\text{H}_2\text{O}$

Named in 1922 for George Vaux, Jr. (1863–1927), mineral collector, Bryn Mawr, PA. Laueite–paravauxite group, paravauxite subgroup. TRIC *P1*. *a* = 9.13, *b* = 11.59, *c* = 6.14, α = 98.3°, β = 92.0°, γ = 108.4°, *Z* = 2, *D* = 2.41. Structure: *AM 53:1025(1968)*. See also paravauxite (42.11.14.2) and metavauxite (42.11.11.1). *33-640*: 10.85₁₀ 6.07₁ 5.91₁ 5.46₂ 3.05₁ 2.96₁ 2.88₁ 2.72₁. Minute tabular {010} crystals, elongated [001] or [101], showing {010}, {110}, {101}, {130}, {211}, {132}; subparallel to radial aggregates and nodules. Sky-blue to venetian-blue, becoming greenish on exposure, white streak, vitreous luster, transparent. No cleavage, brittle. *H* = 3½. *G* = 2.39. Biaxial (+); *Z* approximately parallel to {010}; *N_x* = 1.551, *N_y* = 1.555, *N_z* = 1.562; 2*V* = 32°; *r* > *v*, strong; pleochroic. *X,Z*, colorless; *Y*, blue. Ca and Mg substitute for Fe^{2+} . Found associated with wavellite and paravauxite in the Siglo XX tin mines of *Llallagua, Potosi*, and at the Miraflores mine, Huanumi, *Bolivia*. *hcws DII:974*.

42.11.14.2 Paravauxite $\text{Fe}^{2+}\text{Al}_2(\text{PO}_4)_2(\text{OH})_2 \cdot 8\text{H}_2\text{O}$

Named in 1922 for the chemical similarity to vauxite. Polymorph of metavauxite (42.11.11.1) and vauxite (42.11.14.1). Laueite–paravauxite group, paravauxite subgroup. TRIC *P1*. *a* = 5.233, *b* = 10.541, *c* = 6.96, α = 106.9°, β = 110.8°, γ = 72.1°, *Z* = 1, *D* = 2.479. Structure: *NJMM:430(1969)*. *29-1424*: 9.89₁₀ 6.40₇ 4.93₃ 4.79₃ 3.19₃ 3.09₂ 2.85₂ 2.58₂. Short prismatic {001} to thick tabular {010}, subparallel or radial aggregates, showing {010}, {100}, {110}, {001}, {011}, {054}, {211}. Colorless to pale greenish white; white streak; vitreous luster, pearly on cleavages; transparent to translucent. Cleavage {010}, conchoidal fracture, brittle. *H* = 3. *G* = 2.36. DTA. Biaxial (+); *N_x* = 1.554, *N_y* = 1.558, *N_z* = 1.573 (Na); 2*V* medium. Minor Mg, Na, Si detected on analysis. Found with vauxite, metavauxite, and wavellite as a later secondary phosphate in the tin mine at *Llallagua, Potosi, Bolivia*, and at Oruro. *hcws DII:972, AM 47:1(1962)*.

42.11.14.3 Sigloite $\text{Fe}^{3+}\text{Al}_2(\text{PO}_4)_2(\text{OH})_3 \cdot 8\text{H}_2\text{O}$

Named in 1962 for the locality. Laueite–paravauxite group, paravauxite subgroup. Oxidized equivalent of paravauxite TRIC *P1*. *a* = 5.190, *b* = 10.419, *c* = 7.033, α = 105.00°, β = 111.31°, γ = 70.87°, *Z* = 1, *D* = 2.500. Structure: *MP 38:201(1988)*. *14-171*: 9.69₁₀ 6.46₉ 4.86₄ 4.68₄ 3.91₄ 3.23₇ 2.82₆ 2.56₅. Crystals pseudomorphous after paravauxite. Straw-yellow, light brown, translucent. Cleavage {100}, perfect; {001}. *H* = 3. *G* = 2.35. Biaxial (+);

$N_x = 1.563$, $N_y = 1.86$, $N_z = 1.619$; $2V = 76^\circ$; $r < v$. *AM 47:1(1962)*. Found at *Siglo XX mine, Llallagua, Potosi, Bolivia*, on wavellite that overgrows quartz as secondary minerals in cassiterite deposit that contains metavauxite, crandallite, and childrenite. hcws

42.11.14.4 Gordonite $MgAl_2(PO_4)_2(OH)_2 \cdot 8H_2O$

Named in 1930 for Samuel G. Gordon (1897–1952), mineralogist, Academy of Natural Sciences, Philadelphia, PA. Laueite–paravauxite group, paravauxite subgroup. See mangangordonite (42.11.14.5). TRIC *P1*. $a = 5.246$, $b = 10.532$, $c = 6.975$, $\alpha = 107.51^\circ$, $\beta = 111.03^\circ$, $\gamma = 72.21^\circ$, $Z = 1$, $D = 2.319$. Structure: *NJMM:265(1988)*. Structurally similar to paravauxite but not a series with other group members despite compositional similarities. *14-313: 9.78₁₀ 6.32₅ 4.76₅ 3.17₈ 3.07₅ 2.83₇ 2.56₆ 2.39₄*. Bundles of sheaflike aggregates with all individuals in one group similarly terminated. Crystals are prismatic [001] to platy {010}, strongly striated [001], less marked [100]. Forms {010}, {100}, {110}, {011}, {001}, rarely doubly terminated. Smoky white, colorless, occasionally tipped in green or pink; white streak; vitreous luster, pearly on {010}; transparent. Cleavage {010}, perfect; {100}, fair; {001}, poor; conchoidal fracture; brittle. $H = 3\frac{1}{2}$. $G = 2.319$. Biaxial (+); $N_x = 1.534$, $N_y = 1.543$, $N_z = 1.558$; $2V = 73^\circ$; $r > v$. Soluble in acids. Found with variscite in phosphate nodules at *Clay Canyon, Fairfield, Utah Co., UT*; at Milgun Station, WA, Australia. hcws *DII:975, AM 47:1(1962)*.

42.11.14.5 Mangangordonite $(Mn,Fe,Mg)Al_2(PO_4)_2(OH)_2 \cdot 8H_2O$

Named in 1991 for the composition and relationship to gordonite (42.11.14.4). Laueite–paravauxite group, paravauxite subgroup. TRIC *P1*. $a = 5.257$, $b = 10.363$, $c = 7.040$, $\alpha = 105.44^\circ$, $\beta = 113.07^\circ$, $\gamma = 78.69^\circ$, $Z = 1$, $D = 2.32$. *NJMM:169(1991)*, Structure: *NJMM:265(1988)*. *PD: 9.96₆ 6.39₈ 4.77₁₀ 3.90₃ 3.18₇ 2.86₅ 2.59₄ 2.12₃*. Equant to bladed crystals to 2 mm; aggregates of bladed crystals. Tabular on {010}, elongate [001] forms {010}, {100}, {110}, {011}. Colorless to faintly yellow, white streak, vitreous luster, translucent. Cleavage {010}, perfect. $H = 3$. $G = 2.36$. Biaxial(+); $Z \approx c$; (010) \wedge OAP = -45° ; $N_x = 1.556$, $N_y = 1.561$, $N_z = 1.571$; $2V = 70^\circ$; $r < v$, distinct. Reacts with microprobe beam. Found at Dunton Gem mine, Newry, ME; at *Foote Mineral Co., spodumene mine, Kings Mt., NC*, in vugs in microcline–spodumene–quartz pegmatite. hcws *AM 76:2022(1991)*.

42.11.15.1 Xanthoxenite $Ca_4Fe_2^{3+}(PO_4)_4(OH)_2 \cdot 3H_2O$

Named in 1920 in allusion to the color and possible resemblance to cacoxenite. TRIC *P1* or *P1*. $a = 6.70$, $b = 8.85$, $c = 6.54$, $\alpha = 92.1^\circ$, $\beta = 110.2^\circ$, $\gamma = 93.2^\circ$, $Z = 1$, $D = 3.38$. *MM 42:309(1978)*. *30-258: 6.27₈ 3.49₉ 3.34₄ 3.24₇ 3.14₇ 3.06₁₀ 2.97₄ 2.74₅*. Crusts and masses of distinct platy or lathlike crystals. Pale yellow to brownish yellow, dull to waxy luster, translucent. Cleavage {010}, perfect. $H \approx 2\frac{1}{2}$. $G = 2.8-2.97$. Biaxial (-); $N_x = 1.704$, $N_y = 1.715$, $N_z = 1.724$; $2V$ large; $r < v$, strong; weakly pleochroic, pale yellow to pale

lemon yellow. Found at Newry, ME; at Fletcher and Palermo No. 1 mines, North Groton, NH; at Lynwood, Tip Top, Custer Co., SD; at Hühnerkobel pegmatite, Rabenstein, Bavaria, Germany (may be stewartite); at Pribyslavice, Otov, Czech Republic; at Lavra da Ilha, Taquaral, MG, Brazil. *ncws DII:977, AM 34:692(1949)*.

42.11.16.1 Beraunite $\text{Fe}^{2+}\text{Fe}_5^{3+}(\text{PO}_4)_4(\text{OH})_5 \cdot 4\text{H}_2\text{O}$

Named in 1841 for the locality. *MON C2/c*. $a = 20.953$, $b = 5.171$, $c = 19.266$, $\beta = 90.34^\circ$, $Z = 4$, $D = 2.89$. *CM 27:441(1989)*, Structure: *ZK 201:263(1992)*. *22-631*: 10.34₁₀ 9.58₅ 7.23₅ 4.83₆ 4.42₅ 3.75₃ 3.19₄ 3.08₆. Rare crystals: tabular [100] elongated [010] striated [010]; radiated, foliated globules and crusts; radial aggregates or discoidal concretions with coarse fibrous structure. Twinned on [100], occasionally penetration twins. Reddish brown to hyacinth-red, blood-red, rarely greenish brown or dull green; yellow to olive-drab streak; vitreous to pearly luster on cleavage surfaces; translucent. Cleavage {100}, good. $H = 3\frac{1}{2}$ –4. $G = 3.00$. Biaxial (+); $Y \wedge c = 1\frac{1}{2}$ –5°; $Z = b$; $N_x = 1.775$, $N_y = 1.786$, $N_z = 1.815$ (Giessen); 2V medium large; $r > v$; pleochroic. X, Y, pale flesh; Z, carnelian red. Easily soluble in HCl. One of several phosphate minerals in secondary iron ore deposits and also an alteration product of triphylite in pegmatites. Found at Fletcher and Palermo No. 1 mines, North Groton, NH; at Mullica Hill, and Middletown, NJ; at Bachman mine, Hellertown, Northampton Co., Moore's Mills, Cumberland Co., PA; at Jacksonville, Calhoun Co., and Rock Run Station, Indian Mt., Cherokee Co., AL; at White Elephant, Custer Co., Big Chief, Hesnard, Pennington Co., SD; *Hrbek mine, Beraun, Svata Dobrotiva, Czech Republic*; at Hagendorf Süd, Hühnerkobel, Kreuzberg, Germany; at Corrego Frio, MG, Brazil. *ncws DII:959, AM 55:135(1970)*.

42.11.17.1 Bermanite $\text{Mn}^{2+}\text{Mn}_2^{3+}(\text{PO}_4)_2(\text{OH})_2 \cdot 4\text{H}_2\text{O}$

Named in 1936 for Harry Berman (1902–1944), mineralogist, Harvard University, Cambridge, MA. *MON P2₁*. $a = 5.446$, $b = 19.25$, $c = 5.428$, $\beta = 110.29^\circ$, $Z = 2$, $D = 2.867$. Structure: *AM 61:1241(1976)*. *20-712*: 9.63₁₀ 5.10₂ 4.82₃ 3.67₂ 3.26₃ 2.91₄ 2.11₁ 1.828₁. Tabular {001} to 0.5 mm; fan-shaped or subparallel rosettes of crystals; lamellar masses. Pseudo-orthorhombic, polysynthetic and other twinning. *AM 53:416(1968)*. Pale red to reddish brown, darkening on exposure; vitreous to resinous luster; translucent. Cleavage {001}, perfect; {110}, imperfect. $H = 3\frac{1}{2}$. $G = 2.85$. DTA, heated products magnetic. Biaxial (-); $X = b$; $Y \wedge c = -36\frac{1}{2}$ °; $Z \wedge a = 2$ °; $N_x = 1.690$, $N_y = 1.729$, $N_z = 1.750$; 2V = 72°; $r < v$; pleochroic. X, light red; Y, pale yellow; Z, deep red. Soluble in HNO₃. Small amounts of Fe³⁺ substitute for Mn³⁺; Mg, Ca, Na for Mn²⁺. Occurs as a secondary mineral in pegmatites. Found at Fletcher and Palermo No. 1 mines, North Groton, NH; at Williams property, Coose Co., AL; at the Bull Moose, Tip Top, and White Elephant pegmatites, Custer Co., Hesnard, Pennington Co., SD; in druzy cavities in triplite in pegmatite on *7U7 Ranch near Bagdad copper mine, 40 km W of*

Hillside, Yavapai Co., AZ, with other phosphates; at Stewart Lithia mine, San Diego Co., CA; at Mangualde, Portugal; at Hagendorf Süd, Bavaria, Germany; at the Flinders Ranges, SA, Australia; at Sapucaia, MG, Brazil; as the alteration product of triplite embedded in a black Mn deposit at El Criollo, Tanti, Cordoba, Argentina. hcws DII:967.

WHITMOREITE GROUP

The whitmoreite group minerals can be expressed by the general formula

where

A = Cu, Fe²⁺, Mn, Zn, □, and possibly some Fe³⁺

T = As, P, S

The structure [AM 59:900(1974)] is composed of octahedrally coordinated Fe sheets into slabs parallel to {100} with composition Fe₂³⁺(OH)₂(O_p)₆, (where O_p = oxygen from a phosphate group). The slabs are linked through

WHITMOREITE: Fe²⁺(H₂O)₄[Fe³⁺(OH)₂(PO₄)₂]

A c axis projection that illustrates the structure of whitmoreite: slabs of Fe₂³⁺(OH)₂(O_p)₆ and tetrahedral PO₄ groups in staggered array connected by water rich layers that contain Fe²⁺ or other elements.

the remaining PO₄ apical oxygens by [A(O_p)₂(H₂O)] octahedra. The A site may be partially occupied or contain several different ions.

WHITMOREITE GROUP

Mineral	Formula	Space Group	Space				β
			a	b	c		
Whitmoreite	Fe ²⁺ (H ₂ O) ₄ [Fe ³⁺ (OH) ₂ (PO ₄) ₂]	P2 ₁ /c	10.00	9.73	5.471	93.8	42.11.18.1
Arthurite	Cu(H ₂ O) ₄ [Fe ³⁺ (OH) ₂ (AsO ₄) ₂]	P2 ₁ /c	10.189	9.649	5.598	92.27	42.11.18.2
Ojuelite	Zn(H ₂ O) ₄ [Fe ³⁺ (OH) ₂ (AsO ₄) ₂]	P2 ₁ /c	10.247	9.665	5.569	94.37	42.11.18.3
Earlshannonite	Mn ²⁺ (H ₂ O) ₄ [Fe ²⁺ (OH) ₂ (PO ₄) ₂]	P2 ₁ /c	9.910	9.669	5.455	93.95	42.11.18.4

42.11.18.1 Whitmoreite Fe²⁺(H₂O)₄[Fe³⁺(OH)₂(PO₄)₂]

Named in 1974 for Robert W. Whitmore (b.1936), Weare, NH, micromount mineral collector and owner of the Palermo mine, NH. Whitmoreite group. MON P2₁/c. *a* = 10.00, *b* = 9.73, *c* = 5.471, β = 93.8°, *Z* = 2, *D* = 2.85. Structure: *AM* 59:900(1974). 26-1138: 10.1₁₀ 7.01₇ 4.98₇ 4.42₆ 4.21₇ 3.48₅ 2.88₅ 2.80₇. Acicular crystals parallel to [001] ≈ 10 × longer than wide, to 2 mm long, show rhomboidal cross section with {100}, {110}, {011}, {021}, {112}, usually twinned by reflection parallel to {100} imparting an orthorhombic appearance; fans or sprays, radial aggregates. Pale tan, dark brown, green-brown; vitreous to subadamantine luster; translucent. Cleavage {100}, fair. *H* = 3. *G* = 2.87. Biaxial (-); *Y* parallel to *b*, *Z* parallel to *c*; *N_x* = 1.676, *N_y* = 1.725, *N_z* = 1.745; 2*V* = 60–65°; pleochroic. *X, Y*, light green-brown; *Z*, dark greenish brown. Microprobe analyses show Mn. Found at Newry, ME; as hydrothermal alteration product of triphylite in cavities in quartz-bearing pegmatite at Palermo No. 1 mine, North Groton, NH, perched on siderite rhombs with ludlamite, strunzite, laueite, beraunite, mitridatite, and ferric oxyhydroxides, also at the Fitzgibbon pegmatite, East Alstead; at Big Chief pegmatite, near Glendale, SD; at Hagendorf Süd, Bavaria, Germany. hcws

42.11.18.2 Arthurite Cu(H₂O)₄[Fe³⁺(OH)₂(AsO₄)₂]

Named in 1964 for Arthur Edward Ian Russell (1878–1964) and W. G. Kingsbury (1906–1968), mineralogists and mineral collectors, England. Whitmoreite group. The As and Cu end member. MON P2₁/c. *a* = 10.189, *b* = 9.649, *c* = 5.598, β = 92.27°, *Z* = 2, *D* = 3.376. *MM* 33:937(1964), Structure: *NJMA* 133:291(1978). 36-400: 10.14₈ 6.98₁₀ 4.81₆ 4.30₅ 2.93₄ 2.81₅ 2.77₃ 2.71₃. See also 16-397. Thin crusts. Pale olive-green, translucent. *G* = 3.2. IR. Biaxial (+); *N_x* = 1.746, *N_y* = 1.774, *N_z* = 1.806; 2*V*_{calc} = 88°. Analyses also show P and S. Found at Mylar mine, and Copper Slope, Majuba Hill, Pershing Co., NV; at Hingston Down Consols mine, Calstock, Cornwall, England, mixed with

pharmacosiderite, scorodite, other phosphates, and quartz. HCWS *MM* 37:570(1969).

42.11.18.3 Ojuelaite $\text{Zn}(\text{H}_2\text{O})_4[\text{Fe}_2^{3+}(\text{OH})_2(\text{AsO}_4)_2]$

Named in 1981 for the locality. Whitmoreite group. The As and Zn end member. See also mapimite (42.8.7.1). MON $P2_1/c$. $a = 10.247$, $b = 9.665$, $c = 5.569$, $\beta = 94.37^\circ$, $Z = 2$, $D = 3.39$. *BM* 104:582(1981). 35-516: 10.2₇ 7.03₈ 4.83₈ 4.52₅ 4.25₁₀ 2.90₆ 2.87₉ 2.63₆. Fibers with elongation on c axis. Greenish yellow, translucent. $H = 3$. $G = 3.39$. DTA. Biaxial (+); $N_x = 1.696$, $N_y = 1.730$, $N_z = 1.798$; $2V_{\text{calc}} = 73^\circ$; extinction; fiber length parallels to pleochroic: yellow $Z = X > Y$. Soluble in 1:10 acids. Analyses show traces of Ca. Found in the oxidation zone at *Ojuela mine, Mapimi, DUR, Mexico*, associated with scorodite, adamite, smithsonite, and "limonite"; at Tsumeb mine, Namibia. HCWS *AM* 67:623(1982).

42.11.18.4 Earlishannonite $\text{Mn}^{2+}(\text{H}_2\text{O})_4[\text{Fe}_2^{3+}(\text{OH})_2(\text{PO}_4)_2]$

Named in 1984 for Earl V. Shannon (1895-1981), mineralogist and chemist at U.S. National Museum, Smithsonian Institution, Washington, DC. Whitmoreite group. The Fe^{3+} analog of whitmoreite (42.11.18.1). MON $P2_1/c$. $a = 9.910$, $b = 9.669$, $c = 5.455$, $\beta = 93.95^\circ$, $Z = 2$, $G = 2.92$. *CM* 22:471(1984). 38-364: 9.8₁₀ 6.9₈ 4.95₄ 4.38₄ 4.18₆ 3.45₆ 2.86₆ 2.79₇. Hemispheric aggregates of radial prismatic crystals to 0.5 mm length [001] showing {110}, {100}, {011}. Twinned on {100} showing parallel growth with {001} in common. Red-brown, vitreous luster, transparent. Two cleavages {100}, good; even fracture; brittle. $H = 3-4$. $G = 2.90$. Nonfluorescent. Biaxial (-); $N_x = 1.696$, $N_y = 1.745$, $N_z = 1.765$; $2V = 64^\circ$; pleochroic. X, Y, light yellow-brown; Z, yellow-brown. Microprobe analysis shows small amounts of Fe^{2+} , Al, Mg. Found on the dumps at *Foote spodumene mine, Kings Mt., Cleveland Co., NC*, associated with mitridatite, laueite, rockbridgeite, jahnsite, quartz, and Mn oxides; at Hagendorf pegmatite (bright yellow), Waidhaus, Oberpfalz, Bavaria, Germany. HCWS *AM* 70:871(1985).

42.11.19.1 Sincosite $\text{Ca}(\text{V}^{4+}\text{O})_2(\text{PO}_4)_2 \cdot 5\text{H}_2\text{O}$

Named in 1924 for the locality. TET $Pmmm$ or $P4/nmm$. $a = 8.895$, $c = 12.727$, $Z = 2$, $D = 2.970$. *AM* 70:409(1985). Isostructural with meta-autunite (40.2a.1.2). 39-318: 6.35₁₀ 3.84₃ 3.51₆ 3.19₈ 2.91₄ 2.68₅ 2.10₄ 1.264₂. Rectangular scales, or thin plates showing {001} (striated parallel to [100], {100}, possibly {110}); aggregates of stacked plates in nearly parallel position, forming scaly irregular masses; radial aggregates and nodules admixed with gypsum and carbonaceous matter. Occasionally, twinned on {110}. Leek-green, blue-green, yellow-green; green streak; vitreous to submetallic luster in altered crystals; transparent in thin crystals. Cleavage {001}, good; {100}, {110}, poor; brittle. Soft. $G \approx 2.84$. Uniaxial (-); $N_O \approx 1.680$, $N_E \approx 1.655$; may be biaxial (-) if dehydrated with $N_x = 1.675$, $N_y_{\text{calc}} = 1.690$, $N_z = 1.693$; pleochroic: O, or Z, gray-green; E, or X, colorless to pale yellow. May alter to

lower hydrate on exposure with partial oxidation of V^{4+} to V^{5+} (submetallic material). Readily soluble in dilute acids to a blue solution, insoluble in H_2O . Found in a black carbonaceous shale near *Sincos*, *Dept. Junin, Peru*, about 160 km E of Lima as small veinlets, usually parallel to bedding planes but also as irregular gypsum-bearing nodular masses in particular shale beds. *HCWS DII:1057*.

42.11.20.1 Furongite $Al_2(UO_2)(PO_4)_2(OH)_2 \cdot 8H_2O$

Named in 1976 for the poetic description of the Hunan Province, China, where the mineral was found. *TRIC P1* or *P1̄*. $a = 19.271$, $b = 14.173$, $c = 12.316$, $\alpha = 67.62^\circ$, $\beta = 115.45^\circ$, $\gamma = 94.58^\circ$, $Z = 7$, $D = 2.90$. *SMPM 65:1(1985)*, Structure: *AC(A) 37C:186(1981)*. 29-98: 10.2₁₀ 8.62₈ 5.55₃ 5.10₃ 4.31₅ 3.64₄ 3.52₃ 2.87₄. See also 44-1463. Tabular crystals; cryptocrystalline aggregates. Bright yellow to lemon yellow, vitreous luster, translucent. One perfect cleavage, two others distinct; brittle. $G = 2.82-2.90$. Radioactive. Fluoresces strong pale yellowish green. DTA, TGA, DTG. Biaxial (-); $N_x = 1.543-1.549$, $N_y = 1.564-1.567$, $N_z = 1.570-1.575$; $2V = 65^\circ$; pleochroic in yellow; oblique extinction, small angle. Found at Kobokobo, Kivu, Zaire; in the oxidation zone of an alluvial-type U deposit in Lower Cambrian carbonaceous shale, *western Hunan Prov., China*, associated with variscite, evansite, opal, halloysite, limonite, and autunite. *HCWS AM 63:425(1978)*, *73:198(1988)*.

42.11.21.1 Paulkerrite $K(Mn^{2+}, Mg)_2Fe_2^{3+}Ti(PO_4)_4(OH)_3 \cdot 15H_2O$

Named in 1984 for Paul Francis Kerr (1897-1981), mineralogist, Columbia University, New York City. Mantiennéite (42.11.21.2) is the Al analog. *ORTH Pbca*. $a = 10.49$, $b = 20.75$, $c = 12.44$, $Z = 4$, $D = 2.36$. *MR 15:303(1984)*. 38-390: 10.3₉ 7.46₈ 6.20₁₀ 5.22₂ 3.95₃ 3.75₄ 3.13₇ 2.87₄. Yellow-brown, vitreous luster, translucent. $H = 3$. $G = 2.36$. Biaxial (-); $N_x = 1.598$, $N_y = 1.624$, $N_z = 1.643$; $2V = 80^\circ$. Microprobe analysis shows Al, Mn > Mg, F. Found at *Bagdad copper mine, Hillside, Yavapai Co., AZ*. *HCWS AM 70:875(1985)*.

42.11.21.2 Mantiennéite $K(Mg, Fe^{2+})_2(Al, Fe^{3+})_2Ti(PO_4)_4(OH)_3 \cdot 15H_2O$

Named in 1984 for Joseph Mantienné (b.1929), mineralogist and collections specialist of the Bureau de Recherches Géologiques et Minières, Orleans, France. The Al end member in the Al-Fe³⁺ series with paulkerrite (42.11.21.1). *ORTH Pbca*. $a = 10.409$, $b = 20.330$, $c = 12.312$, $Z = 4$, $D = 2.25$. *BM 107:737(1984)*. 37-438: 10.18₄ 7.41₃ 6.16₁₀ 3.10₃ 3.08₆ 2.95₃ 2.84₃ 2.05₂. Spheres of radiating fibers up to 1 mm diameter. Yellow-brown, bright, translucent. Cleavage {001}, perfect; {010}, poor; brittle. $G = 2.31$. DTA, TGA. Biaxial (-); *XYZ = bca*; $N_x = 1.564$, $N_z = 1.598$; $2V \approx 55^\circ$; $r > v$, distinct; pleochroic. X, colorless; Z, very pale yellow. Contains some Mn, Ca, Na. Found in the vivianite deposit at *Anloua, Cameron*, associated with quartz, siderite, and kaolinite as the matrix of sandy layers intercalated in black shales of lacustrine origin. *HCWS AM 70:1330(1985)*.

42.11.21.3 Matveevite $\text{KTiMn}_2\text{Fe}_2^{3+}(\text{PO}_4)_4(\text{OH})_3 \cdot 15\text{H}_2\text{O}$

Named in 1991 for K. K. Matveev (1875–1954). The Mn end member in the series with paulkerrite (42.11.21.1). ORTH *Pnam* or *Pna2₁*. $a = 12.42$, $b = 20.52$, $c = 10.52$, $D = 2.40$. *ZVMO 120:108(1991)*. *44-1404*: 10.4₉ 7.50₈ 6.23₁₀ 3.15₉ 2.86₄. Isometric or thick platy crystals to 0.2 mm showing {010}, {100}, {111}. White to colorless, yellowish; white streak; vitreous luster, pearly on {010}; transparent to translucent. Cleavage {010}, perfect; uneven fracture; brittle. $H = 2\frac{1}{2}$. $G = 2.32$. Biaxial (+); $XYZ = bac$; $N_x = 1.574$, $N_y = 1.580$, $N_z = 1.618$; $2V = 44^\circ$. Found in a granitic pegmatite vein in *Ilmenskij National Park, Ural Mts., Russia*, associated with decomposition products of triplite, francolite, ushkovite, kaluninite, and Fe and Mn hydroxides. *ncws AM 78:451(1993)*.

42.11.21.4 Benyacarite $(\text{H}_2\text{O},\text{K})\text{Ti}(\text{Mn}^{2+},\text{Fe}^{2+})_2(\text{Fe}^{3+},\text{Ti})_2(\text{PO}_4)_4(\text{O},\text{F})_2 \cdot 14\text{H}_2\text{O}$

Named in 1993. An inadequately described mineral. Compare matveevite (42.11.21.3). The Mn, H₂O analog of paulkerrite (42.11.21.1). ORTH *Pbca*. $a = 10.561$, $b = 20.585$, $c = 12.51$, $Z = 4$, $D = 2.37$. Structure: *ZK 208:57(1993)*. Occurs with other phosphates and with F-rich minerals such as fluellite and pachnoite in a granitic pegmatite at *Cerro Blanco, near Tanti, Cordoba, Argentina*. *ncws AM 79:763(1994)*.

42.11.22.1 McAuslanite $\text{HFe}_3^{2+}\text{Al}_2(\text{PO}_4)_4\text{F} \cdot 18\text{H}_2\text{O}$

Named in 1988 for David A. McAuslan, exploration manager, Shell Canada Resources Ltd., who discovered the locality. TRIC *P1*. $a = 10.055$, $b = 11.568$, $c = 6.888$, $\alpha = 105.84^\circ$, $\beta = 93.66^\circ$, $\gamma = 106.47^\circ$, $Z = 1$, $D = 2.17$. *CM 26:917(1988)*. *PD*: 10.6₉ 9.53₈ 6.55₇ 5.41₂ 4.96₁₀ 4.77₂ 3.44₃ 2.81₅. Clusters up to 4 mm across of radiating bladed or fibrous crystals up to 1 mm long, 0.2 mm wide; elongate [001], showing {010}, {100}, {001}. Yellow-white, white streak, vitreous luster, translucent. Good cleavage parallel to [001], brittle. $H = 3\frac{1}{2}$. $G = 2.22$. TG/EGA. Biaxial (-); $X \wedge b = 17^\circ$ in β obtuse, $Y \wedge c = 18^\circ$ in α obtuse, $Z \wedge a = 14^\circ$ in γ obtuse; $N_x = 1.522$, $N_y = 1.531$, $N_z = 1.534$. Found as part of a complex supergene enrichment area that includes vivianite, phosphophyllite, and childrenite–eosphorite filling joints and shear zones near the surface of *East Kemptville tin mine, Yarmouth Co., NS, Canada*. *ncws AM 75:707(1990)*.

42.11.23.1 Vochtenite $(\text{Fe}^{2+},\text{Mg})\text{Fe}^{3+}[(\text{UO}_2)(\text{PO}_4)]_4(\text{OH}) \cdot 12\text{--}13\text{H}_2\text{O}$

Named in 1989 for Renard F. C. Vochten (b.1933), mineralogist, State University of Antwerp, Antwerp, Belgium. MON $a = 12.606$, $b = 19.990$, $c = 9.990$, $\beta = 102.52^\circ$, $Z = 3$, $D = 3.663$. *MM 53:473(1989)*. *42-1358*: 10.0₁₀ 4.89₅ 3.48₇ 3.33₅ 3.09₄ 2.21₄ 2.15₅ 2.11₅. Aggregates of subparallel crystals each 1 mm and pseudoquadratic in outline due to intersection of {001} and {100}. Brown, brown streak, bronzy, translucent but opaque in thick fragments. Cleavage

{010}, distinct. $H = 3$. $G = 3.650$. TGA. Massbauer Shaws $Fe^{2+} \approx Fe^{3+}$. Non-fluorescent. Biaxial (-); $X = b$; $Z \wedge c = \text{small}$; $N_x = 1.575$, $N_y = 1.589$, $N_z = 1.603$ (589 nm); $2V = 89^\circ$. Soluble in 1:1 HCl. Zeolitic H_2O is implied by the formula. Found at *Bassett mine, Redruth, Cornwall, England*. hcws AM 75:1212(1990).

42.12.1.1 Vantasselite $Al_4(PO_4)_3(OH)_3 \cdot 9H_2O$

Named in 1987 for René Van Tassel (b.1916), mineralogist of phosphate and sulfate minerals, Brussels and Louvain, Belgium. ORTH *Pman*, *Pma2*, or *P2₁am*. $a = 10.528$, $b = 16.541$, $c = 20.373$, $Z = 8$, $D = 2.312$. *BM 110:647(1987)*. Sheet structure similar to that of vashegyite (42.12.2.1) and matulaite (42.13.3.1). *42-1382*: 10.2_{10} 4.87_3 3.72_3 3.40_4 3.21_4 2.89_5 2.74_3 2.39_4 . Rosettes up to 8 mm of thin blades elongate [100], flattened {001}, terminated by {120}. White, pearly luster, translucent. Cleavage {001}, perfect. $H = 2-2\frac{1}{2}$. $G = 2.30$. TGA. Biaxial (-); $N_{x \text{ calc}} = 1.511$, $N_y = 1.560$, $N_z = 1.579$; $2V = 61^\circ$. Wet chemical and microprobe analyses show $>5\%$ (wt), $Fe_2O_3 < 0.4\%$ S. Found at *Stavelot massif, Bihain, Belgium*, on the dumps of a quartzite quarry, where it occurs in the schistosity planes or as lamellae in quartz veinlets within metapelites associated with wavellite, variscite, cacoxenite, turquoise, clinocllore, muscovite, and lithiophoite. hcws AM 73:931(1988).

42.12.2.1 Vashegyite $Al_{11}(PO_4)_9(OH)_6 \cdot 38H_2O$ or $Al_6(PO_4)_5(OH)_3 \cdot 23H_2O$

Named in 1909 for the locality. ORTH *Pna2*, *Pna2₁* $a = 10.773$ $b = 14.991$ $c = 20.626$ $Z=2$ $D=1.934$ for Al_{11} (type locality). *Pnam*, *Pna2*, $a = 10.754$ $b = 14.971$ $c = 22.675$ $Z=4$ $D=2.005$ for Al_6 (Chvaletice) *CM 21:489(1983)*. *35-704* 10.3_{10} 7.49_4 7.04_9 4.90_4 3.46_5 2.92_9 2.42_5 2.13_5 (type). See also *29-68*. *35-597* 11.3_{10} 7.50_8 6.26_7 5.39_4 3.75_4 3.30_6 2.91_9 2.83_4 . (Chvaletice). Massive, compact, porous, microcrystalline with radial fibrous structure in hemispheres. Diamond-shaped platy crystals showing {110}, {010}, {001} (Chvaletice) with irregular stacking. White, pale green to yellow, brownish, dull, opaque to subtranslucent. Cleavage {001} perfect. $H=2-3$ $G=1.93-1.99$. DTA IR. Biaxial (-) $N_x 1.470$ $N_y 1.477$ $N_z 1.482$ (Chvaletice); $xyz=cba$. Minute fibers + elongation, birefring ≈ 0.02 , $N_{av} 1.48$. Easily soluble in acids. Variable water between the sheets in the structure probably accounts for the differences in physical properties. Found in altered slate with variscite near Manhattan, Nye Co., NV; at *Zeleznik (Vashegy) mine, Sirk, R., Slovakia* with variscite, evansite; at Chvaletice, Bohemia, Czech Rep. intimately mixed with apatite, iron hydroxides; at Lavra do Enio, Galileia, MG, Brazil *DII:999, MM 39:802(1974)*. hcws

42.12.3.1 Moreauite $Al_3(UO_2)(PO_4)_3(OH)_2 \cdot 13H_2O$

Named in 1985 for Jules Moreau (b.1931), mineralogist, Catholic University, Louvain, Belgium. MON *P2₁/c*. $a = 23.41$, $b = 21.44$, $c = 18.34$, $\beta = 92.0^\circ$,

$Z = 16$, $D = 2.61$. *BM 108:9(1985)*. 39-317: 14.0₆ 11.7₈ 10.8₁₀ 9.13₇ 5.43₄ 4.51₄ 3.04₆ 2.93₇. Nodules, books of plates flattened on {100}, sometimes elongated parallel to b to 0.2 mm. Greenish yellow, vitreous luster, translucent. Cleavage {100}, good. $G = 2.64$. TGA. Biaxial (-); $X \approx a$, $Y = b$, $Z \approx c$; $N_x = 1.540$, $N_y = 1.552$, $N_z = 1.558$; $2V_{\text{calc}} = 70^\circ$; negative elongation; parallel extinction. Found at *Kobokobo, Kivu, Zaire*, associated with furongite, renunculite, and phosphosiderite. *HCWS AM 70:1330(1985)*.

42.12.4.1 Tinticite $\text{Fe}_4^{3+}(\text{PO}_4)_3(\text{OH})_3 \cdot 5\text{H}_2\text{O}$

Named in 1946 for the locality. *MON P2, Pm, or P2/m*. $a = 13.65$, $b = 6.542$, $c = 12.31$, $\beta = 91.2^\circ$, $Z = 3$, $D = 2.97$. *NJMM:446(1988)*. 8-151: 6.7₆ 6.07₆ 5.67₈ 4.56₆ 3.91₁₀ 3.28₁₀ 3.01₉ 2.96₅. See also 44-1448. Claylike earthy nodules of small ($\approx 1.5 \mu\text{m}$) platy crystals; compact porcelaneous. Cream white to slightly yellow-green, dull luster. $H \approx 2\frac{1}{2}$. $G = 2.94$. $N_{\text{av}} = 1.745$; birefringence = 0.0005. Insoluble in H_2O , H_2SO_4 , HNO_3 , slowly soluble in HCl . Found at *Tintic Standard mine, Tintic district, UT*, with jarosite, "limonite," on limestone cave wall, possibly the result of guano leaching and availability of Fe; at Gavà close to Banco and in Barcelona, Spain, where nodules up to 5 cm in diameter are covered with montgomeryite. *HCWS AM 31:395(1946)*, *MJJ 15:261(1991)*.

42.12.5.1 Tooeleite $\text{Fe}_{9-2x}^{3+}[(\text{As}_{1-x}^{5+}, \text{S}_x^{2+})\text{O}_4]_6 \cdot 5\text{H}_2\text{O}$

Named in 1992 for the county where the mineral was found. *ORTH Pbcm or Pbc2₁*. $a = 6.416$, $b = 19.45$, $c = 8.941$, $Z = 2$, $D = 4.15$. *MM 56:71(1992)*. 44-1468: 9.75₁₀ 4.48₄ 3.66₃ 3.46₃ 3.24₃ 3.21₉ 3.05₅ 2.68₄. Powdery crusts up to 10 mm thick, earthy. $H = 3$. $G = 4.23$. Biaxial (-); $N_x = 1.94$, $N_y = 2.05$, $N_z = 2.06$; $2V$ small. Microprobe analysis shows minor Mn, Al, and Mg, possible trace of Mo. Occurs in voids in massive scorodite that also contain massive jarosite in the oxidized waste dump at the *U.S. mine, Tooele Co., UT*. Tooeleite encrusts both jarosite and scorodite; other minerals present: kaatialaite, galena, sphalerite, and goethite. *HCWS*

42.13.1.1 Aldermanite $\text{Mg}_5\text{Al}_{12}(\text{PO}_4)_6(\text{OH})_{22} \cdot 32\text{H}_2\text{O}$

Named in 1981 for Arthur Richard Alderman (1901-1980), mineralogist and petrologist, University of Adelaide, SA, Australia. *ORTH $a = 15.000$, $b = 8.330$, $c = 26.60$, $Z = 2$, $D = 2.15$* . *MM 44:59(1981)*. 35-676: 13.4₁₀ 7.98₈ 5.70₃ 5.55₆ 4.96₃ 3.47₂ 2.84₅ 2.66₃. Tallike flakes only 0.1 μm thick \times 0.1 mm across. Colorless, pearly luster, translucent. $H \approx 2$. $N_{\text{av}} = 1.500$. Soluble in mineral acids. Found with fluellite in the Moculta P deposit at *Angaston, 60 km NE of Adelaide, SA, Australia*, with apatite, beraunite, cacoxenite, childrenite, crandallite, cyrilovite, dufrenite, gorceixite, leucophosphite, minyulite, rockbridgite, variscite, and wavellite. *HCWS AM 66:1099(1981)*.

42.13.2.1 Richellite $\text{Ca}_3\text{Fe}_{10}^{3+}(\text{PO}_4)_8(\text{OH})_{12} \cdot n\text{H}_2\text{O}$

Named in 1884 for the locality. Data for heated material, as original sample amorphous: TET *P4*. $a = 5.18$, $c = 12.61$, $Z = 1$, $D = 1.87$. *AM* 48:300(1963). 15-632: 5.99₆ 4.35₆ 4.14₆ 3.58₇ 3.24₁₀ 3.15₇ 2.27₆ 1.590₈. Massive, compact, or foliated; radially fibrous globules. Reddish to yellowish brown, similar streak, greasy to hornlike. $H = 2-3$. $G \approx 2$. Readily soluble in acids. Analysis shows $\approx 1\%$ HfO. Found at *Richelle, near Visé in Liège, Belgium*, associated with hallosite, allophane, and koninckite. *HCWS DII:956*.

42.13.3.1 Matulaite $\text{Ca}[\text{Al}_9(\text{H}_2\text{O})_{10}(\text{OH})_{10}(\text{PO}_4)_6]_2 \cdot 24\text{H}_2\text{O}$

Named in 1980 for Margaret Matula (b. 1925) of Allentown, PA, who found the sample. MON *P2₁/c*. $a = 20.4$, $b = 16.7$, $c = 10.6$, $\beta = 98.2^\circ$, $Z = 2$, $D = 2.33$. *AUF* 31:55(1980). 33-258: 9.96₁₀ 6.37₄ 4.83₃ 4.42₄ 3.79₃ 3.66₃ 3.07₃ 2.40₄. Small rosettes of thin tabular crystals, or botryoidal. Colorless to white, pearly luster, translucent. Cleavage {100}, perfect. $H = 1$. $G = 2.330$. Biaxial (-); $Y = b$; $Z \wedge 8^\circ$; $N_x = 1.576$, $N_z = 1.582$; $2V \approx 60^\circ$; $r < v$, strong. Analysis shows in Si, Fe^{3+} . Found at the *Bachman mine, Hellertown, PA*, as an incrustation on chert with rockbridgeite, dufrenite, cacoxenite, strengite, and wavellite; at LCA pegmatite, Gaston Co., NC; at Rotlaufchen iron mine, Waldgrimes, Germany. *HCWS AM 65:1067(1980)*.

42.13.4.1 Jungite $\text{Ca}_2\text{Zn}_4\text{Fe}_8^{3+}(\text{OH})_9(\text{PO}_4)_9 \cdot 16\text{H}_2\text{O}$

Named in 1980 for Gerhard Jung, German mineral collector who found the mineral. ORTH *Pcmm*, *Pcm2₁*, or *Pc2m*. $a = 11.98$, $b = 20.37$, $c = 9.95$, $Z = 2$, $D = 2.849$. *AUF* 31:55(1980). 35-655: 5.09₁₀ 4.91₆ 3.79₈ 3.37₁₀ 3.30₁₀ 3.08₆ 2.94₆ 1.443₈. Rosettes up to 1 cm in diameter of thin tabular, bent crystals. Dark green, yellow streak, silky to vitreous luster, translucent. Cleavage {010}, perfect. $H = 1$. $G = 2.843$. Biaxial [-(?)]; $Y = a$ $Z = C$; $N_x = 1.658$, $N_z = 1.664$; $2V \approx 60^\circ$; $r < v$, strong. Found at the *Hagendorf Süd pegmatite, Bavaria, Germany*, associated with mitridatite and Mn oxides. *HCWS AM 65:1067(1980)*.

42.13.5.1 Cacoxenite $(\text{Fe}^{3+}, \text{Al})_{25}\text{O}_6(\text{PO}_4)_{17}(\text{OH})_{12} \cdot \approx 75\text{H}_2\text{O}$

Named in 1825 from the Greek for *bad guest* because the P content interferes with the quality of iron made when the mineral occurs in limonite ore. HEX *P6₃/m*. $a = 27.559$, $c = 10.550$, $Z = 2$, $D = 2.217$. Structure: *NAT* 306:356(1983). A framework of $[(\text{Al}, \text{Fe}^{3+})_4\text{O}_6(\text{OH})_{12}(\text{PO}_4)_{17}(\text{H}_2\text{O})_{24}]$ with zeolitic water in large (14 Å) channels. *PD*: 22.0₈ 11.94₁₀ 9.83₂ 9.06₂ 6.92₃ 4.90₄ 3.35₅ 2.79₂. See also 14-331. Tiny acicular crystals [0001], sometimes with hexagonal cross section and indistinct pyramidal faces; tufted or radial aggregates; fibrous coatings; spherulitic. Yellow to brownish yellow, golden yellow, reddish or greenish yellow; silky luster; translucent. No cleavage. $H = 3-4$. $G = 2.3$. Uniaxial (+); $N_O = 1.575$, $N_E = 1.635$ (Hellertown); dichroic: O, pale yellow; E, canary-yellow to orange-yellow. Easily soluble in acids. Found at Palermo No. 1, North Groton, NH; on earthy hematite

at Antwerp, NY; at Mullica Hill, NJ; at Hellertown, Northampton Co., Moore's Mill, Cumberland Co., Noble's mine, Lancaster Co., PA; at Snow Camp, Alaman Co., NC; at Brewer mine, Cedartown, GA; at Jacksonville, Calhoun Co., Indian Mt. Iron mine, Rock Run Station, Cherokee Co., AL; at White Elephant mine, Custer Co., SD; at Tonopah, NV; at Rochefort-en-Terre, Morbihan, France; at Eleonore mine near Giessen, Rothlaufchen mine, Waldirmes, Rhine, and at the Amberg-Auerbach limonite mine, Hagen-dorf, Rabenstein, Bavaria, Germany; at *Hrbek mine, Svata Dobrotiva (St. Benigna), Bohemia, Czech Republic*; in the magnetite ore, Kirunavaara, Sweden. HCWS *DII:997; AM 35:132(1950), 51:1811(1966)*.

42.13.6.1 Ceruleite $\text{Cu}_2\text{Al}_7(\text{AsO}_4)_4(\text{OH})_{13} \cdot 12\text{H}_2\text{O}$

Named in 1900 for its color. TRIC $P\bar{1}$ or $P1$. $a = 14.359$, $b = 14.687$, $c = 7.440$, $\alpha = 96.06^\circ$, $\beta = 93.19^\circ$, $\gamma = 91.63^\circ$, $Z = 2$, $D = 2.734$. *NJMM:418(1976)*. *29-525: 7.30₈ 5.93₇ 5.65₁₀ 4.88₅ 4.76₇ 3.55₆ 3.24₅ 2.65₆*. Massive, compact, clay-like aggregates to 10 cm diameter of rodlike crystals up to 5 μm long. Turquoise blue. $H = 5-6$. $G = 2.70$. DTA. Soluble in HCl, HNO_3 , KOH, but not in H_2O . Found at the *Emma Luisa gold mine, Huanaco, Taltal Prov., Chile*; and in southern Bolivia, associated with quartz, barite, goethite, and mansfieldite. HCWS *DII:927, AM 62:598(1977)*.

42.13.7.1 Rosièresite Hydrous phosphate of Al,Pb,Cu

Named in 1910 for the locality. An inadequately described mineral. Amorphous. Opaline stalactitic masses with concentric structure. Greenish yellow, yellow, light brown, soluble in HNO_3 . $N \approx 1.50$. Found as a recent deposit in abandoned workings of Cu mine at *Rosières, Carmaux, Tarn, France*. HCWS *DII:924*.

42.13.8.1 Englishite $\text{Na}_2\text{K}_3\text{Ca}_{10}\text{Al}_{15}(\text{PO}_4)_{21}(\text{OH})_7 \cdot 26\text{H}_2\text{O}$

Named in 1930 for George L. English (1864-1944), American mineral dealer and collector. MON $A2$ or Aa . $a = 38.43$, $b = 11.86$, $c = 20.67$, $\beta = 111.27^\circ$, $Z = 8$, $D = 2.69$. Structure: *MM 40:863(1976)*. *29-1037: 17.7₉ 8.94₁₀ 5.57₆ 3.85₄ 2.96₆ 2.84₈ 2.68₆ 2.34₄*. Aggregates and layers of subparallel plates; friable puffy masses. Colorless; vitreous luster, pearly on micaceous cleavage. Cleavage $\{001\}$, perfect. $H \approx 3$. $G = 2.68$. Biaxial (-); $X = c$, $Y \approx a$, $Z \approx b$; $N_x = 1.570$, $N_z = 1.572$; $2V$ small. Found at Tip Top pegmatite, Custer Co., SD, associated with crandallite and other phosphates; at *Clay Canyon, Fairfield, Utah Co., UT*, with montgomeryite, wardite, millisite, and crandallite in variscite nodules. HCWS *DII:957, CM 22:469(1982)*.

42.13.9.1 Natrophosphate $\text{Na}_7(\text{PO}_4)_2\text{F} \cdot 19\text{H}_2\text{O}$

Named in 1972 for the composition. ISO $Fd3c$. $a = 27.755$, $Z = 32$, $D = 1.77$. Structure: *AC(B) 30:2218(1974)*. *25-831: 8.12₈ 4.94₆ 4.03₆ 3.07₆ 2.90₆ 2.68₁₀ 2.43₉ 1.950₅*. Aggregates up to 5 cm \times 3 cm. Colorless to white, vitreous to greasy luster, translucent. Cleavage $\{111\}$, perfect; conchoidal fracture.

$H = 2\frac{1}{2}$. $G = 1.71$ – 2 . Fluoresces orange (weak). Alters on contact with air, becoming covered with film of villiaumite and secondary phosphates. $N = 1.460$ – 1.462 . Spectrographic analyses showed traces of Mn, Ba, Fe, Ca, Sr. Synthesized. Found in the central cavernous zone of pegmatite in ijolite-urtite at *Yukspor Mt., Khibina massif, Kola Penin., Russia*. Nodules may be surrounded by a rim of villiaumite. HCWS *ZVMO 101:80(1972), AM 58:139(1973)*.

42.13.10.1 Phosphofibrite $\text{KCuFe}_{15}^{3+}(\text{PO}_4)_{12}(\text{OH})_{12} \cdot 12\text{H}_2\text{O}$

Named in 1984 for the composition and crystal habit. ORTH *Pbmn* or *Pnmm*. $a = 14.40$, $b = 18.76$, $c = 10.40$, $Z = 2$, $D = 2.94$. *CE 43:11(1984)*. Structurally related to kidwellite (42.8.2.1). *38-353: 9.50₁₀ 4.35₅ 3.96₄ 3.48₄ 3.23₆ 3.13₆ 2.99₅ 2.10₅*. Radial aggregates of fibrous crystals to 0.5 mm long. Yellow, yellow-green; vitreous luster; translucent. Pinacoidal cleavage, good. $H \approx 4$. $G = 2.90$. Biaxial (-); $N_x = 1.755$, $N_z = 1.790$; $2V = 40^\circ$. $R \ll V$ Soluble in cold HCl, insoluble in warm 1:10 HNO_3 . Analyses show some Al. Found at *Clara mine, Wolfach, Black Forest, Baden-Württemberg, Germany*. HCWS *AM 69:1192(1984)*.

42.13.11.1 Kamitugaite $\text{PbAl}(\text{UO}_2)_5(\text{PO}_4)_2(\text{OH})_9 \cdot 9.5\text{H}_2\text{O}$

Named in 1984 for the mining center at the locality. TRIC *P1* or *P1*. $a = 10.98$, $b = 15.96$, $c = 9.068$, $\alpha = 95.1^\circ$, $\beta = 96.1^\circ$, $\gamma = 89.0^\circ$, $Z = 2$, $D = 4.47$. *BM 107:15(1984)*. *37-425: 15.9₃ 7.95₁₀ 4.31₃ 3.97₈ 3.49₃ 3.27₄ 3.18₄ 2.88₂*. Thin plates flattened (010) to 0.5 mm, showing {100}, {101}, {001}. Yellow, transparent. Cleavage {010}, {001}, easy. $G = 4.03$. Nonfluorescent. Biaxial (-); $X \approx b^*$; $Y \wedge a \approx 2^\circ$; Z approximately perpendicular to a and b^* ; $N_{x \text{ calc}} = 1.709$, $N_y = 1.735$, $N_z = 1.744$; $2V = 60^\circ$; pleochroic. X, Y , light yellow; Z , yellow-green. Microprobe analyses also show As. Found in a quartz-albite-muscovite-beryl-columbite pegmatite associated with minor triangulite, threadgoldite, dumontite, and studtite at *Kobokobo, Kivu, Zaire*. HCWS *AM 70:437(1985)*.

42.13.12.1 Sieleckiite $\text{Cu}_3\text{Al}_4(\text{PO}_4)_2(\text{OH})_{12} \cdot 2\text{H}_2\text{O}$

Named in 1988 for Robert Sielecki (b.1958), Australian geologist. TRIC *P1* or *P1*. $a = 9.41$, $b = 7.56$, $c = 5.95$, $\alpha = 90.25^\circ$, $\beta = 91.27^\circ$, $\gamma = 104.02^\circ$, $Z = 1$, $D = 2.94$. *MM 52:515(1988)*. *PD: 9.12₅ 5.04₁₀ 4.76₂ 3.85₁₀ 3.28₃ 2.83₅ 2.46₅ 2.57₂*. Spheres up to 0.5 mm in diameter showing fine radiating fibrous structure with crystals to 100 μm long \times 2 μm wide. Deep sky-blue to royal-blue, pale blue streak, pearly luster, translucent. No cleavage, subconchoidal fracture. Not twinned. $H \approx 3$. $G = 3.02$. Nonfluorescent. Biaxial; $N = 63$ – 1.66 ; length-slow; weakly pleochroic, colorless to pale blue. Found at the *Mt. Oxide Cu mine, 150 km N of Mt. Isa, Q, Australia*, in oxidation zone of massive pyrite body that shows enrichment in chalcosite and secondary Cu minerals. Mineral in fractures in varicite boulder with turquoise, libethenite, and pseudomalachite. HCWS *AM 74:1401(1989)*.

42.13.13.1 Alvanite $(\text{Zn.Ni})\text{Al}_4(\text{VO}_3)_2(\text{OH})_{12} \cdot 2\text{H}_2\text{O}$

Named in 1959 for the composition. MON $P2_1/n$. $a = 17.808$, $b = 5.132$, $c = 8.881$, $\beta = 92.11^\circ$, $Z = 2$, $D = 2.492$. *MM* 54:609(1990), Structure: *NJMM*:385(1990). 13-386: 4.8_5 4.48_{10} 2.97_4 1.982_8 1.911_6 1.686_5 1.542_4 1.484_9 . Micaceous flakes with hexagonal form showing {001}, {010}, {100}, {101}. Light blue-green, blue-black; white streak; vitreous to pearly luster on cleavage; translucent. Cleavage {010}, perfect; also polysynthetic twinning parallel to (010). $H = 3-3\frac{1}{2}$. $G = 2.49$. Biaxial; $X \wedge$ cleavage = 14° ; $N_x = 1.658$, $N_z = 1.714$; $2V = 80-85^\circ$; $r < v$; both positive and negative elongation observed. Found at *Kurumsak ore field, Kara-Tua, Kazakhstan*. *HCWS ZVMO*:157(1959), *AM* 44:1325(1959).

Compound Phosphates, Arsenates, and Vanadates

43.1.1.1 Ardealite $\text{Ca}_2(\text{HPO}_4)(\text{SO}_4) \cdot 4\text{H}_2\text{O}$

Named in 1932 for Ardeal, the old Romanian name for Transylvania. *MON Cc*. $a = 5.726$, $b = 30.95$, $c = 6.265$, $\beta = 117.29^\circ$, $Z = 4$, $D = 2.32$. *41-585*: 7.73₁₀ 3.93₂ 3.87₄ 3.15₂ 3.08₆ 2.85₂ 2.81₃ 1.81₃. Powdery masses and crusts. Yellow to brown, pale yellow streak, earthy luster. Soft. $G = 2.30$. Biaxial (-); $N_x = 1.531$, $N_y = 1.539$, $N_z = 1.546$; $2V = 86^\circ$. Occurs in limestone caves. La Guangola, near Altamura, Italy; *Cioclovina, Transylvania, Romania*; Onino-Iwaya, Hiroshima Pref., Japan; Moorba, Jurien Bay, WA, Australia. *BM DII:1010, AM 63:520(1978), BM 105:621(1982), NJMM:461(1984)*.

BRADLEYITE GROUP

The bradleyite group minerals are carbonate-phosphate minerals of the general formula

where

$\text{M} = \text{Mg}, \text{Mn}, \text{Fe}^{2+}, \text{Sr}$

and where the structure is in a monoclinic space group.

BRADLEYITE GROUP

Mineral	Formula	Space Group	Space				β	
			a	b	c			
Bradleyite	$\text{Na}_3\text{Mg}(\text{PO}_4)(\text{CO}_3)$	$P2_1/m$	8.85	6.63	5.16	90.42	43.2.1.1	
Sidorenkite	$\text{Na}_3\text{Mn}(\text{PO}_4)(\text{CO}_3)$	$P2_1/m$	8.979	6.729	5.150	90.10	43.2.1.2	
Bonshtedtite	$\text{Na}_3\text{Fe}^{2+}(\text{PO}_4)(\text{CO}_3)$	$P2_1/m$	8.921	6.631	5.151	90.42	43.2.1.3	
Crawfordite	$\text{Na}_3\text{Sr}(\text{PO}_4)(\text{CO}_3)$	$P2_1$	9.187	6.707	5.279	89.98	43.2.1.4	

43.2.1.1 Bradleyite $\text{Na}_3\text{Mg}(\text{PO}_4)(\text{CO}_3)$

Named in 1941 for Wilmot H. Bradley (1899-1979), U.S. geologist, who investigated the Wyoming trona deposits. Bradleyite group. *MON P2₁/m*. $a = 8.85$,

SIDORENKITE: $\text{Na}_3\text{Mn}(\text{PO}_4)(\text{CO}_3)$ (Bradleyite group)

This structure can be considered as alternating layers of Na carbonate and Mn phosphate on (100), although Mn and Na are each bonded to both carbonate and phosphate groups.

$b = 6.63$, $c = 5.16$, $\beta = 90.42^\circ$, $Z = 2$, $D = 2.72$. $22-478$: 8.85_5 , 4.47_2 , 3.69_3 , 3.31_7 , 2.66_{10} , 2.58_4 , 1.84_3 , 1.66_3 . Colorless white to gray masses. $H = 3\frac{1}{2}$. $G = 2.72$. Biaxial (-); $X = b$; $Y \wedge c = 7^\circ$; $N_x = 1.487$, $N_y = 1.546$, $N_z = 1.560$; $2V = 49^\circ$; $r < v$. *Westvaco mine, Sweetwater Co., WY*, in trona deposit. *BM DII:295*.

43.2.1.2 Sidorenkite $\text{Na}_3\text{Mn}(\text{PO}_4)(\text{CO}_3)$

Named in 1979 for Alexander V. Sidorenko (1917–1982), Russian mineralogist. Bradleyite group. *MON* $P2_1/m$. $a = 8.979$, $b = 6.729$, $c = 5.150$, $\beta = 90.10^\circ$, $Z = 2$, $D = 2.98$. $33-1266$: 8.97_2 , 3.36_{10} , 2.99_1 , 2.69_2 , 2.58_1 , 1.87_1 , 1.68_2 , 1.50_1 . Prismatic crystals to 2 cm and irregular grains. Pale rose, vitreous to pearly luster. Cleavage {100}, {010}, perfect; brittle. $H = 2$. $G = 2.90$. Biaxial (-); $N_x = 1.521$, $N_y = 1.563$, $N_z = 1.585$; $2V = 68^\circ$. *Mt. Alluaiv, Lovozero massif, Kola Penin., Russia*, in syenite pegmatite. *BM ZVMO 108:56(1979), AM 64:1332(1979)*.

43.2.1.3 Bonshtedtite $\text{Na}_3\text{Fe}(\text{PO}_4)(\text{CO}_3)$

Named in 1982 for Elza M. Bonshtedt-Kupletskaya (1897–1974), Russian mineralogist. Bradleyite group. *MON* $P2_1/m$. $a = 8.921$, $b = 6.631$, $c = 5.151$, $\beta = 90.42^\circ$, $Z = 2$, $D = 3.05$. $35-678$: 8.92_2 , 4.47_1 , 3.32_{10} , 2.66_3 , 2.58_2 , 2.15_2 , 1.85_2 , 1.66_2 . Crystals up to 5 mm and fine-grained aggregates. Colorless with rose, yellow, or green tint; vitreous to pearly luster. Cleavage {100}, {010}, perfect;

brittle. $H = 4$. $G = 2.95$. Biaxial (-); $XYZ = bca$; $N_x = 1.520\text{--}1.525$, $N_y = 1.568\text{--}1.570$, $N_z = 1.591\text{--}1.597$; $2V = 68^\circ$. *Khibina and Kovdor massifs, Kola Penin., Russia*. BM *ZVMO 111:486(1982)*, *AM 68:1038(1983)*.

43.2.1.4 Crawfordite $\text{Na}_3\text{Sr}(\text{PO}_4)(\text{CO}_3)$

Named in 1994 for Adair Crawford (1748–1795), Scottish chemist, who showed in 1790 that strontianite contained a new element. Bradleyite group. MON $P2_1$. $a = 9.187$, $b = 6.707$, $c = 5.279$, $\beta = 89.98^\circ$, $Z = 2$, $D = 3.08$. *ZVMO:123: 3.35₅ 2.71₁₀ 2.65₉ 2.17₁₀ 1.89₈ 1.42₇ 1.13₆ 1.11₆*. Colorless grains to 1 mm, vitreous luster. Conchoidal fracture. $H = 3$. $G = 3.05$. Biaxial (-); $N_x = 1.520$, $N_y = 1.564$, $N_z = 1.565$; $2V = 20^\circ$. Fluoresces bright yellow-green in UV. Occurs in pegmatites in *Khibiny massif, Kola Penin., Russia*. BM *ZVMO 123(3):107(1994)*, *AM 80:1328(1995)*.

43.2.2.1 Gartrellite $\text{Pb}(\text{Cu,Fe})_2(\text{AsO}_4,\text{SO}_4)_2(\text{CO}_3,\text{H}_2\text{O})_{0.7}$

Named in 1989 for Blair Gartrell (1950–1994), Australian collector, who discovered the mineral. TRIC Probably $P1$. $a = 5.454$, $b = 7.664$, $c = 5.685$, $\alpha = 98.0^\circ$, $\beta = 110.0^\circ$, $\gamma = 111.1^\circ$, $Z = 1$, $D = 5.38$. *AM 75: 4.61₇ 3.34₇ 3.20₁₀ 2.96₁₀ 2.92₇ 2.52₆*. Fine-grained coatings and cavity fillings. Yellow to greenish yellow, yellow streak, chalky luster. Soft and friable. Biaxial; $N = 1.94\text{--}2.00$; strongly birefringent. Centennial Eureka mine, Juab Co., UT; *Ashburton Downs, WA*, and Kintore pit, Broken Hill, NSW, *Australia*. BM *AM 75:932(1990)*.

43.3.1.1 Schoderite $\text{Al}_2(\text{PO}_4)(\text{VO}_4) \cdot 8\text{H}_2\text{O}$

Named in 1962 for William P. Schoder (1900–1977), U.S. chemist. MON $P2_1$ or $P2_1/m$. $a = 16.26$, $b = 30.59$, $c = 12.56$, $\beta = 91.83^\circ$, $Z = 18$, $D = 1.95$. *34-1263: 16.3₁₀ 15.3₇ 11.2₂ 7.64₄ 5.69₃ 5.41₃ 2.89₄ 2.84₃*. Microscopic platy crystals. Yellow to yellow-orange. $H = 2$. $G = 1.92$. Biaxial (-); $X = b$; $Y \wedge c = 26^\circ$; $N_x = 1.560$, $N_y = 1.563$, $N_z = 1.565$; $2V = 42^\circ$; pleochroic. X , pale yellow; Y , deep yellow; Z , yellow. *Fish Creek Range, near Eureka, NV*; Wilson Springs vanadium deposit, Garland Co., AR. BM *AM 47:637(1962)*, *64:713(1979)*.

43.3.1.2 Metaschoderite $\text{Al}_2(\text{PO}_4)(\text{VO}_4) \cdot 6\text{H}_2\text{O}$

Named in 1962 for its relationship to schoderite. MON $P2/m$. $a = 11.4$, $b = 14.9$, $c = 9.2$, $\beta = 101.0^\circ$, $Z = 4$, $D = 1.61$. *14-217: 14.9₆ 11.1₄ 9.6₂ 8.6₁ 7.5₁₀ 5.68₁ 4.92₁ 3.02₂*. Microscopic platy crystals. Yellow-orange. $H = 2$. $G = 1.88$. Biaxial (+); $Z = c$; $Y \wedge b = 20^\circ$; $N_x = 1.598$, $N_y = 1.604$, $N_z = 1.626$; $2V = 56^\circ$. *Fish Creek Range, near Eureka, NV*. BM *AM 47:637(1962)*, *64:713(1979)*.

43.3.2.1 Embreyite $\text{Pb}_5(\text{PO}_4)_2(\text{CrO}_4)_2 \cdot \text{H}_2\text{O}$

Named in 1972 for Peter G. Embrey (b.1929), English mineralogist. MON $P2_1/m$. $a = 9.755$, $b = 8.018$, $c = 7.135$, $\beta = 103.08^\circ$, $Z = 1$, $D = 6.41$. *25-436:*

4.75₆ 3.56₃ 3.48₃ 3.17₁₀ 2.82₆ 2.21₃ 2.19₃ 1.92₅. Microscopic tabular crystals. Dull orange, yellow streak, resinous or dull luster. No cleavage, irregular fracture, brittle. $H = 3\frac{1}{2}$. $G = 6.45$. Biaxial (-); $Y = b$; $N_x = 2.20$, $N_y, N_z = 2.36$; $2V = 0-11^\circ$; pleochroic. X, honey-yellow; Y, Z, amber. *Berezov, Ural Mts., Russia*, Argent mine, Bushveld Complex, Transvaal, South Africa. BM *MM* 38:790(1972).

43.3.2.2 Cassedanneite $Pb_5(VO_4)_2(CrO_4)_2 \cdot H_2O$

Named in 1988 for Jacques P. Cassedanne (b.1928), Brazilian mineralogist. MON $A2/m$ or $A2$. $a = 7.693$, $b = 5.763$, $c = 9.795$, $\beta = 115.93^\circ$, $Z = 1$, $D = 6.45$. d_{2-1370} : 4.83₆ 3.45₂ 3.22₆ 3.15₁₀ 2.87₅ 2.83₃ 2.12₃ 1.91₃. Small platy crystals. Red-orange, resinous luster. $H = 3\frac{1}{2}$. *Beresov, Ural Mts., Russia*, in association with embreyite. BM *CR* 306:125(1988), *AM* 73:1493(1988).

BEUDANTITE GROUP

The beudantite minerals are isostructural sulfate-arsenates and sulfate-phosphates with the general formula

where

A = Ba, Ca, Pb, Sr

B = Al, Fe

X = S, As, or P

and the space group $R\bar{3}m$.

The minerals of this group are isostructural not only within themselves but also with the crandallite and the alunite groups. See the alunite group for a description of the structure.

BEUDANTITE GROUP

Mineral	Formula	Space Group	D			
			a	c		
Beudantite	$PbFe_3(AsO_4)(SO_4)(OH)_6$	$R\bar{3}m$	7.320	17.020	4.49	43.4.1.1
Corkite	$PbFe_3(PO_4)(SO_4)(OH)_6$	$R\bar{3}m$	7.220	16.660	4.42	43.4.1.2
Hidalgoite	$PbAl_3(AsO_4)(SO_4)(OH)_6$	$R\bar{3}m$	7.071	16.975	4.24	43.4.1.3
Orpheite	$Pb_2Al_3(PO_4)_4(SO_4)_2(OH)_{18}$	$R\bar{3}m$	7.016	16.730	4.02	43.4.1.4
Hinsdalite	$(Pb, Sr)Al_3(PO_4)(SO_4)(OH)_6$	$R\bar{3}m$	6.990	16.800	4.07	43.4.1.5
Svanbergite	$SrAl_3(PO_4)(SO_4)(OH)_6$	$R\bar{3}m$	6.975	16.597	3.29	43.4.1.6
Kemmlitzite	$SrAl_3(AsO_4)(SO_4)(OH)_6$	$R\bar{3}m$	7.027	16.510	3.57	43.4.1.7
Woodhouseite	$CaAl_3(PO_4)(SO_4)(OH)_6$	$R\bar{3}m$	6.979	16.214	3.02	43.4.1.8
Weilerite	$BaAl_3(AsO_4)(SO_4)(OH)_6$	$R\bar{3}m$	7.110	17.380	3.98	43.4.1.9

43.4.1.1 Beudantite $\text{PbFe}_3(\text{AsO}_4)(\text{SO}_4)(\text{OH})_6$

Named in 1826 for Francois S. Beudant (1787–1850), French mineralogist. Beudantite group. $\text{HEX-R } R\bar{3}m$. $a = 7.320$, $c = 17.020$, $Z = 3$, $D = 4.49$. 19-689; 5.99₈ 3.67₇ 3.08₁₀ 2.84₅ 2.54₅ 2.27₆ 1.98₆ 1.83₆. Rhombohedral crystals, often pseudocubic. Dark green, brown, or black; green to gray streak; vitreous to resinous luster. Cleavage {0001}, good. $H = 3\frac{1}{2}$ – $4\frac{1}{2}$. $G = 4.48$. Uniaxial (-), sometimes anomalously biaxial; $N_O = 1.957$, $N_E = 1.943$. Bisbee, Cochise Co., Tiger, Pinal Co., and Pine Grove district, Yavapai Co., AZ; Wheal Gorland, St. Day, Cornwall, England; Mine de la Garonne, Var, France; *Horhausen, Rheinland-Pfalz*, and *Dernbach, Nassau, Germany*; Kamareza mine, Laurion, Greece; Kipushi, Shaba, Zaire; Tsumeb, Namibia. *BM DII:1001, CM 26:923(1988), NJMM:27(1989)*.

43.4.1.2 Corkite $\text{PbFe}_3(\text{PO}_4)(\text{SO}_4)(\text{OH})_6$

Named in 1862 for the locality. Beudantite group. $\text{HEX-R } R\bar{3}m$. $a = 7.220$, $c = 16.660$, $Z = 3$, $D = 4.42$. 17-471: 5.86₇ 3.61₄ 3.03₁₀ 2.79₄ 2.51₃ 2.24₆ 1.96₃ 1.48₄. Small rhombohedral crystals, usually pseudocubic, and massive. Yellow to dark green, yellow to green streak, vitreous to resinous luster. Cleavage {0001}, perfect. $H = 3\frac{1}{2}$ – $4\frac{1}{2}$. $G = 4.30$. Uniaxial (-); $N_O = 1.93$; weakly birefringent. Silver Queen mine, Galena, SD; Black Pine mine, Philipsburg, MT; Frisco, Beaver Co., UT; San Felix mine, Caborca, SON, Mexico; *Glendore iron mine, Cork, Eire*; *Dernbach, Nassau, Germany*; St. Antoniodi Gennemari, Sardinia, Italy; Mt. Isa, Q, Australia; Tsumeb, Namibia. *BM DII:1002, AM 72:178(1987), NJMM:71(1987)*.

43.4.1.3 Hidalgoite $\text{PbAl}_3(\text{AsO}_4)(\text{SO}_4)(\text{OH})_6$

Named in 1953 for the locality. Beudantite group. $\text{HEX-R } R\bar{3}m$. $a = 7.071$, $c = 16.975$, $Z = 3$, $D = 4.24$. 39-1359: 5.76₄ 3.54₅ 3.00₁₀ 2.48₂ 2.26₄ 2.23₂ 1.92₄ 1.77₃. Massive. White, white streak, dull luster. $H = 4\frac{1}{2}$. $G = 3.96$. Uniaxial (+); $N_O = 1.730$, $N_E = 1.735$. Gold Hill, Tooele Co., UT; *San Pasquale mine, Zimapan mining district, HGO, Mexico*; Cap Garonne, Var, France; Kintore cut, Broken Hill, NSW, Australia; Tsumeb, Namibia. *BM AM 38:1218(1953), MR 2:212(1971)*.

43.4.1.4 Orpheite $\text{Pb}_3\text{Al}_9(\text{PO}_4)_4(\text{SO}_4)_2(\text{OH})_{18}$

Named in 1971 for Orpheus, the mythical singer of the Rhodope Mts. Beudantite group. Probably synonymous with hinsdalite. $\text{HEX-R } R\bar{3}m$. $a = 7.016$, $c = 16.730$, $Z = 1$, $D = 4.02$. 29-756: 5.66₁₀ 4.91₂ 3.50₇ 3.45₂ 2.97₁₀ 2.21₂ 1.90₄ 1.75₃. Colorless, yellow-green, pale blue, or gray; vitreous luster. Cleavage {0001}, indistinct. $H = 3\frac{1}{2}$. $G = 3.75$. Uniaxial (-); $N_O = 1.682$ – 1.704 , $N_E = 1.670$ – 1.691 . *Madjarova deposit, Rhodope Mts., Bulgaria*. *BM AM 61:176(1976)*.

43.4.1.5 Hinsdalite (Pb,Sr)Al₃(PO₄)(SO₄)(OH)₆

Named in 1911 for the locality. Beudantite group. HEX-R *R3m*. $a = 6.990$, $c = 16.800$, $Z = 3$, $D = 4.07$. 16-711: 5.7₅ 5.6₇ 3.50₄ 3.45₂ 2.96₈ 2.78₁₀ 2.22₅ 1.90₃. Pseudocubic crystals, also massive, granular. Colorless, vitreous to greasy luster. Cleavage {0001}, perfect. $H = 4\frac{1}{2}$. $G = 3.65$. Uniaxial (+); $N_O = 1.671$, $N_E = 1.689$; also anomalously biaxial. *Golden Fleece mine, Hinsdale Co., CO*; Mineral Park mine, Mohave Co., AZ; Sylvester mine, Zeehan, and Comet mine, Dundas, TAS, Australia. BM *DII:1004*; *MR 8:391(1977)*, *11:243(1980)*.

43.4.1.6 Svanbergite SrAl₃(PO₄)(SO₄)(OH)₆

Named in 1854 for Lars F. Svanberg (1805–1878), Swedish chemist. Beudantite group. HEX-R *R3m*. $a = 6.975$, $c = 16.597$, $Z = 3$, $D = 3.29$. 39-1361: 5.68₃, 3.49₂ 2.95₁₀ 2.77₃ 2.21₉ 1.89₅ 1.74₃ 1.45₄. Rhombohedral, often pseudocubic crystals, also massive. Colorless to yellow, rose, or red-brown; vitreous to adamantine luster. Cleavage {0001}, distinct. $H = 5$. $G = 3.22$. Uniaxial (+); $N_O = 1.631$ – 1.635 , $N_E = 1.646$ – 1.649 . Dover mine, near Hawthorne, Mineral Co., NV; Champion mine, White Mts., Mono Co., and Blue Bird Hill, Imperial Co., CA; Chizeuil, near Chalmoux, Saône et Loire, France; *Horrnsjöberg, Värmland*, and *Westaná, Skåne, Sweden*; Rio São Jose, BA, Brazil. BM *DII:1005*; *MR 2:225(1971)*, *8:480(1977)*.

43.4.1.7 Kemmlitzite SrAl₃(AsO₄)(SO₄)(OH)₆

Named in 1969 for the locality. Beudantite group. HEX-R *R3m*. $a = 7.027$, $c = 16.510$, $Z = 3$, $D = 3.57$. 22-1248: 5.71₇ 3.51₉ 2.96₁₀ 2.75₅ 2.20₈ 1.90₉ 1.76₈ 1.29₆. Microscopic pseudocubic crystals. Colorless to pale brown. Cleavage {0001}, indistinct. $H = 5\frac{1}{2}$. $G = 3.63$. Uniaxial (+); $N_O = 1.701$, $N_E = 1.707$. *Kemmlitz, near Oschatz, Saxony, Germany*, in kaolin deposit. BM *NJMM:201(1969)*, *AM 55:320(1970)*.

43.4.1.8 Woodhouseite CaAl₃(PO₄)(SO₄)(OH)₆

Named in 1937 for Charles D. Woodhouse (1888–1975), U.S. mineral collector. Beudantite group. HEX-R *R3m*. $a = 6.979$, $c = 16.214$, $Z = 3$, $D = 3.02$, 37-469: 5.66₂ 4.85₄ 3.49₃ 2.97₄ 2.93₁₀ 2.70₃ 2.16₅ 1.89₂. Pseudocubic and tabular crystals. Colorless to pale orange, vitreous to pearly luster. Cleavage {0001}, good. $H = 4\frac{1}{2}$. $G = 3.01$. Uniaxial (+); $N_O = 1.636$, $N_E = 1.647$. *Champion mine, White Mts., Mono Co., CA*, in vugs in quartz veins; Richelle, Belgium; Iron Knob, SA, Australia. BM *DII:1006*; *MR 8:477(1977)*, *12:106(1981)*.

43.4.1.9 Weilerite BaAl₃(AsO₄)(SO₄)(OH)₆

Named in 1961 for the locality. Beudantite group. HEX-R *R3m*. $a = 7.110$, $c = 17.380$, $Z = 3$, $D = 3.93$. 35-648: 5.84₈ 3.55₈ 3.02₁₀ 2.90₄ 2.30₆ 1.93₆ 1.77₅ 1.52₅. Spherulitic aggregates and earthy crusts. White to yellow or green. Uniaxial (+); $N_O = 1.688$, $N_E = 1.698$. *Weiler and Neubulach, Black*

Forest, Germany; Magnet mine, Dundas, TAS, Australia. BM AM 47:415(1962), 52:1588(1967); SMPM 61:23(1981).

43.4.2.1 Tsumebite $\text{Pb}_2\text{Cu}(\text{PO}_4)(\text{SO}_4)(\text{OH})$

Named in 1912 for the locality. Brackebuschite group. See (40.2.8.1). *MON* $P2_1/m$. $a = 8.69$, $b = 5.78$, $c = 7.86$, $\beta = 111.87^\circ$, $Z = 2$, $D = 6.22$. *29-568*: 4.70₃ 3.92₂ 3.24₁₀ 2.94₄ 2.90₇ 2.72₄ 2.62₃ 2.27₄. Crusts of intergrown crystals. Emerald-green, vitreous luster. Uneven fracture, brittle. $H = 3\frac{1}{2}$. $G = 6.13$. Biaxial (+); $N_x = 1.885$, $N_y = 1.920$, $N_z = 1.956$; $2V$ near 90° ; $r < v$, strong; faintly pleochroic. Morenci, Greenlee Co., and Mammoth mine, Pinal Co., AZ; Carrock Fell, Cumberland, England; Kipushi, Shaba, Zaire; *Tsumeb, Namibia. BM DII:918, AM 51:258(1966).*

43.4.2.2 Arsentsumebite $\text{Pb}_2\text{Cu}(\text{AsO}_4)(\text{SO}_4)(\text{OH})$

Named in 1935 for its relationship to tsumebite. Brackebuschite group. See (40.2.8.1). *MON* $P2_1/m$. $a = 8.85$, $b = 5.92$, $c = 7.84$, $\beta = 112.60^\circ$, $Z = 2$, $D = 6.39$. *25-456*: 4.80₇ 3.64₅ 3.25₁₀ 3.01₃ 2.96₄ 2.76₆ 2.27₃ 2.09₃. Crystalline crusts. Emerald-green, vitreous to dull luster. $G = 6.46$. Biaxial (-); $N_x = 1.970$, $N_y = 1.992$, $N_z = 2.011$; $2V = 88^\circ$; pleochroic. X, pale pistachio-green; Y,Z, bottle-green. *Tsumeb, Namibia. BM DII:918, AM 51:258(1966).*

43.4.3.1 Vauquelinite $\text{Pb}_2\text{Cu}(\text{PO}_4)(\text{CrO}_4)(\text{OH})$

Named in 1818 for Louis N. Vauquelin (1763–1829), French chemist and discoverer of chromium. Brackebuschite group. See (40.2.8.1). *MON* $P2_1/n$. $a = 13.68$, $b = 5.83$, $c = 9.53$, $\beta = 93.97^\circ$, $Z = 4$, $D = 6.18$. *13-302*: 4.73₇ 4.00₃ 3.31₁₀ 2.96₃ 2.89₆ 2.77₃ 2.31₅ 1.90₅. Small wedge-shaped crystals, also granular and compact. Green to brown color and streak, resinous to adamantine luster. Uneven fracture, brittle. $H = 2\frac{1}{2}$ –3. $G = 6.02$. Biaxial (-); $N_x = 2.11$, $N_y = 2.22$, $N_z = 2.22$; $2V$ near zero; pleochroic. X, pale green; Y,Z, pale brown. Near Benson, Cochise Co., near Wickenburg, Maricopa Co., Mammoth mine, Pinal Co., AZ; Killie mine, Spruce Mt., Elko Co., NV; Leadhills and Wanlockhead, Scotland; Pontgibaud, Puy-de-Dôme, France; *Beresov, Ural Mts., Russia; Dundas, TAS, Australia; Congonhas do Campo, MG, Brazil. BM DII:650, ZK 126:443(1968), BM 103:469(1980).*

43.4.3.2 Fornacite $\text{Pb}_2\text{Cu}(\text{AsO}_4)(\text{CrO}_4)(\text{OH})$

Named in 1915 for Lucien L. Forneau (1867–1930), French colonial governor. Brackebuschite group. See (40.2.8.1). *MON* $P2_1/c$. $a = 8.022$, $b = 5.906$, $c = 17.564$, $\beta = 110.4^\circ$, $Z = 4$, $D = 6.39$. *15-200*: 8.22₅ 4.80₉ 4.00₅ 3.31₁₀ 2.98₁₀ 2.88₁₀ 2.80₁₀ 2.71₉. Microscopic prismatic crystals. Olive-green, yellow streak. $G = 6.27$. Biaxial (+); $N_x = 2.14$, $N_z = 2.24$. Bisbee, Cochise Co., Tonopah–Belmont mine, Maricopa Co., Old Yuma mine, Pima Co., Mammoth mine, Pinal Co., and New Water Mts., Yuma Co., AZ; Cnah Khuni and Seh Cnangi mines, Iran; Smolianinova, Kirghizstan; *Djoue, Congo. BM DII:652, BM 85:309(1962), ZK 124:385(1967), MR 11:296(1980).*

43.4.3.3 Molybdoformacite $Pb_2Cu(AsO_4)(MoO_4)(OH)$

Named in 1983 for its relationship to formacite. Brackebushite group. See (40.2.8.1). MON $P2_1/c$. $a = 8.100$, $b = 6.946$, $c = 17.65$, $\beta = 109.17^\circ$, $Z = 4$, $D = 6.57$. 35-693: 4.84₅ 3.41₄ 3.32₁₀ 2.98₆ 2.94₄ 2.85₆ 2.76₆ 2.36₅. Minute lath-like crystals. Pale green, yellow streak, adamantine luster. No cleavage, conchoidal fracture. $H = 2-3$. Biaxial; $N_x = 2.05$, $N_z = 2.15$; pleochroic. X, Y, pale yellow; Z, yellow-green. Tres Hermanas Mts., Luna Co., NM; *Tsumeb, Namibia*. BM *NJMM:289(1983)*, *AM 69:567(1984)*.

43.4.4.1 Cahnite $Ca_2[B(OH)_4](AsO_4)$

Named in 1927 for Lazard Cahn (1865-1940), U.S. mineral collector and dealer. TET $I4$. $a = 7.110$, $c = 6.200$, $Z = 2$, $D = 3.16$. 13-158: 5.02₂ 4.67₂ 3.56₁₀ 2.83₂ 2.64₅ 2.51₂ 2.34₂ 1.82₆. Pseudotetrahedral crystals and cruciform twins. Colorless or white, vitreous luster. Cleavage {110}, perfect; brittle. $H = 3$. $G = 3.156$. Uniaxial (+); $N_O = 1.662$, $N_E = 1.663$; strong dispersion; shows anomalous interference colors. *Franklin, NJ*; Klodeborg mine, Arendal, Norway; Capo di Bove, near Rome, Italy; Solongo, Transbaikalia, Russia. BM *DII:386*, *MM 32:666(1960)*, *AM 46:1077(1961)*.

43.4.5.1 Seamanite $Mn_3[B(OH)_4](PO_4)(OH)_2$

Named in 1930 for Arthur E. Seaman (1858-1937), US mineralogist. ORTH $Pbnm$. $a = 7.81$, $b = 15.11$, $c = 6.69$, $Z = 4$, $D = 3.13$. 25-536: 7.55₆ 6.92₁₀ 4.20₆ 3.78₇ 3.47₆ 2.84₈ 2.50₇ 2.39₆. Acicular crystals. Pale yellow to wine-yellow. Cleavage {001}, distinct; brittle. $H = 4$. $G = 3.08$. Biaxial (+); $N_x = 1.640$, $N_y = 1.663$, $N_z = 1.665$; $2V = 40^\circ$; $r < v$. *Chicagon mine, Iron Co., MI*. BM *DII:388*, *AM 56:1527(1971)*.

43.4.6.1 Hematolite $(Mn,Mg,Al)_{15}(AsO_3)(AsO_4)_2(OH)_{23}$

Named in 1884 from the Greek for *blood*, in reference to the color. HEX-R $R3$. $a = 8.275$, $c = 36.60$, $Z = 3$, $D = 3.50$. 33-868: 12.2₄ 5.64₃ 4.22₂ 4.14₁₀ 3.42₂ 2.96₂ 2.41₂ 2.39₂. Flattened rhombohedral crystals. Blood-red, red-brown streak, vitreous to submetallic luster. Cleavage {0001}, perfect; uneven fracture; brittle. $H = 3\frac{1}{2}$. $G = 3.49$. Uniaxial (-); $N_O = 1.733$, $N_E = 1.714$. *Moss mine and Langban, Värmland, Sweden*. BM *DII:777*, *AM 63:150(1978)*.

43.4.7.1 Holdenite $(Mn,Mg)_6Zn_3(AsO_4)_2(SiO_4)(OH)_8$

Named in 1927 for Albert F. Holden (1866-1913), U.S. mining engineer and mineral collector. ORTH $Abma$. $a = 11.99$, $b = 31.46$, $c = 8.697$, $Z = 8$, $D = 4.18$. 29-903: 5.74₅ 3.58₈ 3.41₆ 2.84₁₀ 2.79₅ 2.58₈ 2.46₇ 1.53₈. Tabular crystals and fibrous veinlets. Pink to deep red, vitreous luster. Cleavage {010}, poor; subconchoidal fracture. $H = 4$. $G = 4.11$. Biaxial (+); $XYZ = cba$; $N_x = 1.769$, $N_y = 1.770$, $N_z = 1.785$; $2V = 30^\circ$; $r > v$. *Franklin and Sterling Hill, NJ*. BM *DII:775*, *AM 62:513(1977)*, *MR 12:373(1981)*.

43.4.8.1 Kolicite $Mn_7Zn_4(AsO_4)_2(SiO_4)_2(OH)_8$

Named in 1979 for John Kolic (b.1943), Franklin miner, who discovered the mineral. ORTH *Cmca*. $a = 18.59$, $b = 8.789$, $c = 12.04$, $Z = 4$, $D = 4.20$. 33-918: 4.12₁ 3.58₆ 2.97₁₀ 2.82₄ 2.61₅ 2.48₄ 2.34₄ 1.54₇. Platy aggregates. Orange, pale orange streak, vitreous luster. No cleavage, brittle. $H = 4\frac{1}{2}$. $G = 4.17$. Biaxial (-); $XYZ = bca$; $N_x = 1.779$, $N_y = 1.786$, $N_z = 1.790$; $2V = 78^\circ$; $r < v$, strong; strongly pleochroic. X, colorless or pale yellow; Y, yellow-orange; Z, pale yellow. Franklin and *Sterling Hill, NJ*. BM AM 64:708(1979), 65:483(1980).

43.4.9.1 McGovernite $Mn_9Mg_4Zn_2As_2Si_2O_{17}(OH)_{14}$

Named in 1927 for J. J. McGovern (d.1915), Franklin miner and mineral collector. HEX-R *R3c*. $a = 8.22$, $c = 205.5$, $Z = 18$, $D = 3.65$. 25-531: 4.06₃ 3.43₃ 3.24₃ 2.80₅ 2.66₆ 2.37₅ 2.35₆ 1.54₁₀. Micaceous veinlets. Red-brown, pale brown streak, vitreous to pearly luster. Cleavage {0001}, perfect. $H = 3$. $G = 3.72$. Uniaxial (+); $N_0 = 1.757$; very weakly birefringent. *Sterling Hill, NJ*. BM AM 12:373(1927), 45:937(1960), 65:957(1980), 73:1182(1988).

43.4.10.1 Kraisslite $Mn_{44}Zn_6Mg_4Fe_2(AsO_3)_4(AsO_4)_6(SiO_4)_{12}(OH)_{36}$

Named in 1978 for Frederick Kraissl (1899–1986) and Alice Kraissl (1905–1986), U.S. mineral collectors. HEX *P6₃22*. $a = 8.22$, $c = 43.88$, $Z = 1$, $D = 3.92$. 29-1432: 10.9₁ 4.39₅ 3.65₄ 3.13₂ 2.74₁₀ 2.44₆ 2.19₆ 1.22₁. Micaceous veinlets and fracture fillings. Deep copper-brown, golden brown streak, sub-metallic luster. Cleavage {0001}, perfect. $H = 3-4$. $G = 3.876$. Uniaxial (+); $N_0 = 1.805$; weakly birefringent. *Sterling Hill, NJ*. BM AM 63:938(1978), 65:957(1980).

43.4.11.1 Heneuite $Mg_5Ca(CO_3)(PO_4)_3(OH)$

Named in 1986 for Henrich Neumann (1914–1983), Norwegian mineralogist. TRIC *P1*. $a = 6.307$, $b = 10.839$, $c = 8.674$, $\alpha = 95.01^\circ$, $\beta = 93.41^\circ$, $\gamma = 101.04^\circ$, $Z = 2$, $D = 3.01$. 39-362: 3.67₄ 3.19₃ 2.88₉ 2.85₄ 2.84₄ 2.79₈ 2.70₁₀ 2.60₄. Nodular masses. Pale blue-green, white streak, vitreous luster. Cleavage {001}, good. $H = 5\frac{1}{2}$. $G = 3.016$. Biaxial (-); $N_x = 1.586$, $N_y = 1.620$, $N_z = 1.630$; $2V = 50^\circ$. *Tingelstadjern quarry, Modum, Norway*, in a serpentine-magnesite deposit. BM NJMM:343(1986), AM 73:440(1988).

43.4.12.1 Cervandonite-(Ce) $(Ce,Nd,La)(Fe,Ti,Al)_3(Si,As)_3O_{13}$

Named in 1988 for the locality. MON *Cm* (?). $a = 11.3$, $b = 19.5$, $c = 7.2$, $\beta = 121^\circ$, $Z = 6$, $D = 4.9$. SMPM 68: 5.39₈ 3.58₄ 3.25₉ 3.08₈ 2.88₁₀ 2.79₆ 2.70₅ 1.63₄. Rosettelike aggregates. Black, brown-black streak, adamantine luster. Cleavage {001}, poor; conchoidal fracture; brittle. $H = 5$. Biaxial; $N \sim 2.0$; pleochroic, yellow to brown. *Pizzo Cervandone, Alpe Devero, Italy*, in fissure veins in gneiss. BM SMPM 68:125(1988).

43.4.13.1 Attakolite (Ca,Sr)Mn(Al,Fe)₄(PO₄)₃(HSiO₄)(OH)₄

Named in 1868 from the Greek for *salmon*, in allusion to the color. MON *C2/m*. $a = 17.188$, $b = 11.477$, $c = 7.322$, $\beta = 113.83^\circ$, $Z = 4$, $D = 3.23$. 18-146: 6.57₂ 4.80₁ 4.33₃ 3.12₃ 3.08₁₀ 2.91₂ 2.87₂ 2.40₄. Massive, indistinctly crystalline. White to pale red, white streak. $G = 3.09$ – 3.23 . Biaxial (-); $Y = b$; $X \wedge a = 24^\circ$; $N_x = 1.650$, $N_y = 1.654$, $N_z = 1.661$; $2V = 75^\circ$; $r > v$. Found with berlinite and lazulite in iron ore at *Västana, Nastum, Kristianstad, Sweden*. BM *DII:845, AMG 3:537(1965), CM 8:668(1966), AM 77:1285(1992)*.

43.5.1.1 Sarmientite Fe₂(AsO₄)(SO₄)(OH) · 5H₂O

Named in 1941 for Domingo F. Sarmiento (1811–1888), Argentinian statesman. MON *P2₁/c*. $a = 6.55$, $b = 18.55$, $c = 9.70$, $\beta = 97.65^\circ$, $Z = 4$, $D = 2.58$. 22-342: 9.29₁₀ 6.13₃ 4.87₄ 4.64₉ 4.26₈ 3.43₄ 3.06₇ 2.60₅. Microscopic prismatic crystals and nodular masses. Pale yellow-orange, dull luster. $G = 2.58$. Biaxial (+); $XY = ab$; $Z \wedge c = 12^\circ$; $N_x = 1.628$, $N_y = 1.635$, $N_z = 1.698$; $2V = 38^\circ$. *Winnemucca, Humboldt Co., NV; Santa Elena mine, Barreal Dept., Argentina*. BM *DII:1013, AM 53:2077(1968)*.

43.5.1.2 Bukovskyite Fe₂(AsO₄)(SO₄)(OH) · 7H₂O

Named in 1967 for Antonin Bukovsky (1865–1950), Czech mineralogist. TRIC *P1* or *P1*. $a = 10.722$, $b = 14.079$, $c = 10.284$, $\alpha = 93.50^\circ$, $\beta = 115.96^\circ$, $\gamma = 90.27^\circ$, $Z = 4$, $D = 2.34$. Microcrystalline nodular masses. Pale yellow-green to gray-green, dull luster. $G = 2.33$. Biaxial (+); $N_y = 1.570$ – 1.582 , $N_z = 1.626$ – 1.631 . *Kank, near Kutna Hora, Czech Republic*, an alteration product of arsenopyrite. BM *AM 54:576,991(1969), NJMM:445(1986)*.

43.5.1.3 Sanjuanite Al₂(PO₄)(SO₄)(OH) · 9H₂O

Named in 1968 for the locality. TRIC *P1* or *P1*. $a = 11.314$, $b = 9.018$, $c = 7.376$, $\alpha = 93.07^\circ$, $\beta = 95.78^\circ$, $\gamma = 105.32^\circ$, $Z = 2$, $D = 1.96$. 20-47: 10.8₁₀ 8.66₃ 5.28₄ 4.43₃ 4.32₄ 4.27₃ 4.13₆ 3.45₄. Compact masses. White, white streak, silky to dull luster. $H = 3$. $G = 1.94$. Biaxial; $N_x = 1.484$, $N_z = 1.499$. *Sierra Chica de Zonda, San Juan Prov., Argentina*. BM *AM 53:1(1968), MM 53:385(1989)*.

43.5.2.1 Diadochite Fe₂(PO₄)(SO₄)(OH) · 5H₂O

Named in 1837 from the Greek for *successor*, presumably in allusion to its secondary origin. Synonym: destinezite, TRIC *P1* or *P1*. $a = 9.584$, $b = 9.748$, $c = 7.338$, $\alpha = 98.78^\circ$, $\beta = 108.00^\circ$, $\gamma = 63.87^\circ$, $Z = 2$, $D = 2.33$. 42-1364: 8.77₉ 8.27₈ 4.38₁₀ 4.08₇ 3.93₁₀ 3.21₄ 2.94₈ 2.92₄. Nodular and colloform crusts and masses. Yellow to yellow-green and brown, earthy or dull luster. $H = 3$ – 4 . $G = 2.2$. Biaxial (+); $N_x = 1.615$, $N_y = 1.627$, $N_z = 1.670$; $2V = 55^\circ$; $r < v$, strong. *New Idria mine, San Benito Co., CA; Vise, Argenteau, Belgium; Ansbach, Thuringia, Germany; Litosice, Chvaletice, Nucie, and other localities in Bohemia, Czech Republic; Leoben, Steiermark, Austria; Eisenbach, Hun-*

gary; Blyava, Ural Mts., Russia; Kara-tan, Kazakhstan; La Mure mine, Zin, Pakistan. BM *DII:1011*.

43.5.3.1 Pitticite $\text{Fe,AsO}_4\text{,SO}_4\text{,H}_2\text{O}$

Named in 1813 from Greek for *pitch*, for its resinous appearance. Amorphous. Massive and as opaline and earthy crusts. Red-brown, vitreous or resinous luster. $H = 2-3$. $G = 2.37-2.72$. $N = 1.634-1.765$. Tintic, UT; Manhattan, NV; Redruth, Cornwall, England; *Freiberg, Saxony, Germany*; Jachymov and Příbram, Bohemia, Czech Republic; Djebel Debar, Constantine, Algeria. BM *DII:1014*, *MM 46:261(1982)*.

43.5.3.2 Zykaite $\text{Fe}_4(\text{AsO}_4)_3(\text{SO}_4)(\text{OH}) \cdot 15\text{H}_2\text{O}$

Named in 1978 for Vaclav Zyka (b.1926), Czech geochemist. ORTH $P1$ or $P\bar{1}$. $a = 20.85$, $b = 7.033$, $c = 36.99$, $Z = 8$, $D = 2.51$. *29-695: 10.6₇ 10.4₁₀ 6.92₄ 5.61₄ 3.81₄ 3.52₃ 3.25₃ 2.83₄*. Nodules and cavity fillings. Gray-white, dull luster. Uneven fracture. $H = 2$. $G = 2.50$. Biaxial (-); $N_x = 1.632$, $N_z = 1.646$; $2V = 60^\circ$. *Kank, near Kutna Hora, Czech Republic*. BM *NJMM:134(1978)*, *AM 63:1284(1978)*.

43.5.4.1 Sasaite $(\text{Al,Fe})_{14}(\text{PO}_4)_{11}(\text{SO}_4)(\text{OH})_7 \cdot 84\text{H}_2\text{O}$

Named in 1978 for the South African Speleological Society. ORTH $P222$ or $Pmm2$ or $Pmmm$. $a = 10.81$, $b = 15.031$, $c = 23.064$, $Z = 1.25$, $D = 1.75$. *31-20: 11.5₁₀ 7.51₂ 7.13₂ 6.99₃ 6.30₂ 4.21₂ 3.26₂ 2.90₄*. Chalky nodules to 2 cm. White, white streak. $G = 1.75$. Biaxial (-); $XYZ = cba$; $N_x = 1.465$, $N_y = 1.473$, $N_z = 1.477$; $2V = 15^\circ$. *West Dreifontein cave, near Carlstonville, Transvaal, South Africa*. BM *MM 42:401(1978)*, *CM 21:489(1983)*.

43.5.5.1 Coconinoite $\text{Fe}_2\text{Al}_2(\text{UO}_2)_2(\text{PO}_4)_4(\text{SO}_4)(\text{OH})_2 \cdot 18\text{H}_2\text{O}$

Named in 1966 for the locality. MON $C2/c$ or Cc . $a = 12.50$, $b = 12.97$, $c = 23.00$, $\beta = 106.6^\circ$, $Z = 4$, $D = 2.85$. *25-16: 12.3₁ 11.1₁₀ 5.64₂ 5.56₄ 4.59₁ 4.31₁ 3.71₁ 3.30₂*. Aggregates of microscopic platy to lathlike grains. Pale cream-yellow. Soft. $G = 2.70$. Biaxial (-); $N_x = 1.550$, $N_y = 1.588$, $N_z = 1.590$; $2V = 40^\circ$; pleochroic. X, colorless; Y,Z, pale yellow. *Sun Valley mine, Coconino Co., and Blackwater No. 4 mine, Apache Co., AZ*; White Canyon area, San Juan Co., UT, and other localities on the Colorado Plateau; Kyzylkumi, Uzbekistan. BM *AM 51:651(1966)*, *DANS 329:792(1993)*.

43.5.6.1 Xiangjiangite $(\text{Fe,Al})(\text{UO}_2)_4(\text{PO}_4)_2(\text{SO}_4)_2(\text{OH}) \cdot 22\text{H}_2\text{O}$

Named in 1978 for the locality. MON $C2/c$ or Cc . $a = 12.54$, $b = 12.98$, $c = 23.08$, $\beta = 108.6^\circ$, $Z = 4$, $D = 2.87$. *AM 64: 11.1₁₀ 5.58₅ 4.62₆ 3.74₈ 2.94₇ 2.18₅ 2.07₅*. Microcrystalline platy aggregates. Bright yellow, pale yellow streak, silky luster. $H = 1-2$. $G = 2.9-3.1$. Biaxial (-); $N_x = 1.558$, $N_y = 1.576$, $N_z = 1.593$; $2V = 87^\circ$; weakly pleochroic, yellow. *Xiangjiang R., Hunan, China*. BM *AM 64:466(1979)*, *DANS 329:792(1993)*.

43.5.7.1 Kribergite $\text{Al}_5(\text{PO}_4)_3(\text{SO}_4)(\text{OH})_4 \cdot 4\text{H}_2\text{O}$

Named in 1945 for the locality. TRIC $P\bar{1}$ or $P1$. $a = 18.126$, $b = 13.519$, $c = 7.500$, $\alpha = 70.50^\circ$, $\beta = 117.87^\circ$, $\gamma = 136.23^\circ$, $Z = 2$, $D = 1.94$. 20-48: 11.6₁₀ 6.62₂ 5.85₁ 5.72₁ 5.37₁ 5.02₃ 2.93₁ 2.86₁. Compact veinlet. White, white streak, dull luster. $G = 1.92$. Biaxial; $N_y = 1.484$; birefringence 0.002. *Kristineberg mine, Vasterbotten, Sweden*. BM *DII:1011, MM 53:385(1989)*.

43.5.8.1 Kovdorskite $\text{Mg}_5(\text{PO}_4)_2(\text{CO}_3)(\text{OH})_2 \cdot 4.5\text{H}_2\text{O}$

Named in 1980 for the locality. MON $P2_1/c$. $a = 4.74$, $b = 12.90$, $c = 10.35$, $\beta = 102.0^\circ$, $Z = 2$, $D = 2.30$. 33-861: 7.96₁₀ 6.45₃ 5.44₅ 4.32₄ 2.82₆ 2.66₃ 2.53₃ 2.26₇. Pale rose, in part transparent. Conchoidal or uneven fracture. $H = 4$. $G = 2.60$. Biaxial (-); $Z \wedge c = 1-3^\circ$; $N_x = 1.527$, $N_y = 1.542$, $N_z = 1.549$; $2V = 80^\circ$; $r > v$, very weak. *Kovdor massif, Kola Penin., Russia*, in magnetite-forsterite rocks. BM *ZVMO 109:341(1980), AM 66:437(1981)*.

43.5.9.1 Viséite $\text{CaAl}_3(\text{PO}_3\text{OH})(\text{SiO}_3\text{OH})(\text{OH})_6$

Named in 1942 for the locality. HEX-R $R3m$. $a = 6.89$, $c = 18.065$, $Z = 3$, $D = 2.17$. 5-616: 5.68₄ 3.46₅ 2.92₁₀ 2.20₂ 1.89₃ 1.74₆ 1.20₂ 1.16₂. Botryoidal clusters and massive. Chalky white or blue. $H = 3-4$. $G = 2.2$. Isotropic; $N = 1.530$. *Champion mine, Mono Co., CA; Visé, Belgium*. BM *MA 9:88(1945), MM 41:437(1977)*.

43.5.10.1 Perhamite $\text{Ca}_3\text{Al}_7(\text{SiO}_4)_3(\text{PO}_4)_4(\text{OH})_3 \cdot 16.5\text{H}_2\text{O}$

Named in 1977 for Frank C. Perham (b.1934), U.S. geologist and pegmatite miner. HEX $P6/mmm$. $a = 7.022$, $c = 20.182$, $Z = 1$, $D = 2.53$. 29-284: 6.71₄ 6.08₅ 5.80₇ 3.51₅ 3.12₅ 3.01₄ 2.88₁₀ 1.76₅. Spherulites of platy crystals. White to pale brown, white streak, vitreous luster. Cleavage {0001}, perfect. $H = 5$. $G = 2.64$. Uniaxial (+); $N_O = 1.564$, $N_E = 1.577$; $r > v$, moderate. *Bell Pit, Newry Hill, Newry, ME*, in a pegmatite vug; Tom's quarry, Kapunda, SA, Australia. BM *MM 41:437(1977)*.

43.5.11.1 Lünebergite $\text{Mg}_3\text{B}_2(\text{OH})_6(\text{PO}_4)_2 \cdot 6\text{H}_2\text{O}$

Named in 1870 for the locality. TRIC $P\bar{1}$. $a = 6.348$, $b = 9.803$, $c = 6.298$, $\alpha = 84.46^\circ$, $\beta = 106.40^\circ$, $\gamma = 96.40^\circ$, $Z = 1$, $D = 2.204$. 25-1155: 4.98₁₀ 4.85₇ 3.23₄ 3.03₃ 2.96₆ 2.82₅ 2.51₄ 2.01₃. Flattened masses and nodules. White, white streak, vitreous to dull luster. Cleavage {010}, fair. $H = 2$. $G = 2.07$. Biaxial (-); $N_x = 1.522$, $N_y = 1.541$, $N_z = 1.549$; $2V = 63^\circ$. Occurs in marine evaporites. Permian salt basin, New Mexico and west Texas; *Lüneberg, Hannover, Germany; Bela Stena, Serbia; Kerch Penin., Ukraine; Mejillones, Tarapaca, Chile*. BM *DII:385, AM 76:1400(1991)*.

43.5.12.1 Synadelphite $\text{Mn}_9(\text{AsO}_3)(\text{AsO}_4)_2(\text{OH})_9 \cdot 2\text{H}_2\text{O}$

Named in 1884 from the Greek for *with* and *brother*, referring to its occurrence with several related minerals. ORTH $Pnma$. $a = 10.754$, $b = 18.865$, $c = 9.884$,

$Z = 4$, $D = 3.59$. *24-725*: 9.36₇ 8.72₁₀ 5.27₅ 3.84₄ 3.08₅ 2.64₉ 2.09₇ 1.60₇. Short prismatic crystals, reniform crusts, and massive. Red-brown to black, vitreous to adamantine luster. Cleavage {010}, imperfect; conchoidal to uneven fracture; brittle. $H = 4\frac{1}{2}$. $G = 3.57$. Biaxial (+); $N_x = 1.750$, $N_y = 1.751$, $N_z = 1.761$; $2V = 37^\circ$; $r > v$; pleochroic, X,Y, colorless; Z, pale brown. Sterling Hill, NJ; *Moss mine* and Langban, *Varmland, Sweden*. *BM DII:780, AM 55:2023(1970)*.

43.5.13.1 Parnauite $\text{Cu}_9(\text{AsO}_4)_2(\text{SO}_4)(\text{OH})_{10} \cdot 7\text{H}_2\text{O}$

Named in 1978 for John L. Parnau (1906–1990), U.S. mineral collector, who discovered the mineral. ORTH $P2_122$. $a = 14.98$, $b = 14.223$, $c = 6.018$, $Z = 2$, $D = 3.22$. *29-533*: 14.3₁₀ 10.4₃ 7.14₁ 6.42₁ 4.52₆ 4.00₂ 2.85₂ 2.80₁. Rosettes of lathlike crystals, and scales and crusts. Pale blue to green, pale green streak, vitreous to dull luster. $H = 2$. $G = 3.09$. Biaxial (-); XYZ = bac; $N_x = 1.680$, $N_y = 1.704$, $N_z = 1.712$; $2V = 60^\circ$; pleochroic, X, pale green; Y, yellow-green; Z, blue-green. *Majuba Hill mine, Pershing Co., NV*; Grandview mine, Cocomino Co., AZ; La Garonne, Var, France. *BM AM 63:704(1978)*.

43.5.14.1 Chalcophyllite $\text{Cu}_{18}\text{Al}_2(\text{AsO}_4)_3(\text{SO}_4)_3(\text{OH})_{27} \cdot 33\text{H}_2\text{O}$

Named in 1847 from the Greek for *copper* and *leaf*, referring to its composition and micaceous structure. HEX-R $R3$. $a = 10.77$, $c = 57.5$, $Z = 3$, $D = 2.69$. *39-1356*: 9.51₁₀ 4.76₆ 2.73₂ 2.70₃ 2.59₅ 2.34₃ 2.05₂ 1.53₂. Tabular hexagonal crystals and foliated masses. Blue-green to emerald-green, pale green streak, vitreous to pearly luster. Cleavage {0001}, perfect. $H = 2$. $G = 2.67$. Uniaxial (-); $N_O = 1.618$, $N_E = 1.552$; pleochroic, O, blue-green; E, almost colorless. Widely distributed as a secondary copper mineral. Tintic, UT; Bisbee, AZ; Majuba Hill, NV; Redruth and other localities in Cornwall, England; Cap Garonne, Var, France; Schmiederberg, Germany; Schwaz, Austria; Nizhni Tagilsk, Ural Mts., Russia; Tsumeb, Namibia; Teniente mine, near Rancagua, Chile. *BM DII:1008, ZK 151:129(1980)*.

43.5.15.1 Peisleyite $\text{Na}_3\text{Al}_{16}(\text{SO}_4)_2(\text{PO}_4)_{10}(\text{OH})_{17} \cdot 20\text{H}_2\text{O}$

Named in 1982 for Vincent Peisley (b.1941), Australian mineral collector, who discovered the mineral. MON. $a = 13.310$, $b = 12.620$, $c = 23.15$, $\beta = 110.00^\circ$, $Z = 2$, $D = 2.08$. *35-674*: 12.63₁₀ 10.85₂ 7.82₄ 7.59₃ 6.43₂ 5.41₄ 4.35₂ 4.11₂. Compact masses. White, white streak, dull luster. $H = 3$. $G = 2.12$. Biaxial; $N_{av} = 1.510$; weakly birefringent. *Tom's quarry, near Kapunda, SA, Australia*. *BM MM 46:449(1982)*.

43.5.16.1 Voggitte $\text{Na}_2\text{Zr}(\text{PO}_4)(\text{CO}_3)(\text{OH}) \cdot 2\text{H}_2\text{O}$

Named in 1990 for Adolf Vogg (b.1931), Canadian mineral collector, who discovered the mineral. MON $I2/m$. $a = 12.251$, $b = 6.557$, $c = 11.755$, $\beta = 116.12^\circ$, $Z = 4$, $D = 2.704$. *CM 28*: 10.2₁₀ 5.58₈ 5.29₃ 4.06₆ 3.89₇ 2.55₄ 2.04₄ 1.94₃. Small acicular crystals. Colorless to white, white streak, vitreous luster. Cleavage {010}, poor; brittle. $G = 2.70$. Biaxial (+); $X = b$,

$Z \wedge a = 22^\circ$; $N_x = 1.569$, $N_y = 1.594$, $N_z = 1.622$; $2V = 81^\circ$; $r < v$, strong. *Francon quarry, Montreal, QUE, Canada. BM CM 28:155(1990).*

43.5.17.1 Girvasite $\text{NaCa}_2\text{Mg}_3(\text{PO}_4)_2[\text{PO}_2(\text{OH})_2](\text{CO}_3)(\text{OH})_2 \cdot 4\text{H}_2\text{O}$

Named in 1990 for the locality. *MON P2₁/c*. $a = 6.507$, $b = 12.267$, $c = 21.403$, $\beta = 90.37^\circ$, $Z = 4$, $D = 2.529$. *42-1397*: 10.72₁₀ 3.57₈ 3.42₃ 3.08₃ 2.82₃ 2.11₃ 2.02₄. Spherulites up to 1.5 mm. White, white streak, silky to vitreous luster. Cleavage [001], perfect; very brittle. $H = 3\frac{1}{2}$. $G = 2.46$. Biaxial (-); $Y = b$; $Z \wedge a = 31^\circ$; $N_x = 1.541$, $N_y = 1.557$, $N_z = 1.565$; $2V = 60^\circ$. *Lake Girvas, Kovdor, Kola Penin., Russia, in dolomitic carbonitite. BM MZ 12(3):79(1990), AM 77:207(1992).*

43.5.18.1 Hotsonite $\text{Al}_{11}(\text{SO}_4)_3(\text{PO}_4)_2(\text{OH})_{21} \cdot 16\text{H}_2\text{O}$

Named in 1984 for the locality. *TRIC P1 or P1*. $a = 11.23$, $b = 11.66$, $c = 10.55$, $\alpha = 112.54^\circ$, $\beta = 107.53^\circ$, $\gamma = 64.45^\circ$, $Z = 1$, $D = 2.08$. *38-366*: 10.05₁₀ 8.45₄ 5.20₁ 5.01₁ 4.63₂ 4.43₁ 3.91₁ 3.67₁. White compact masses. Silky to dull luster. $H = 2\frac{1}{2}$. $G = 2.06$. Biaxial; $N_x = 1.519$, $N_z = 1.521$. *Hotson farm, Pofadder, South Africa. BM AM 69:979(1984).*

43.19.1 Quadruphite $\text{Na}_{14}\text{CaMgTi}_4(\text{Si}_2\text{O}_7)_2(\text{PO}_4)_6\text{O}_4\text{F}_2$

Named in 1992 for the Latin *quadruplex* and the element P, the quantity of PO_4 groups in the formula. *TRIC P1*. $a = 5.415$, $b = 7.081$, $c = 20.34$, $\alpha = 86.85^\circ$, $\beta = 94.40^\circ$, $\gamma = 89.94^\circ$, $Z = 1$, $D = 3.11$. *ZVMO 121:105(1992)*. *PD*: 2.88₁₀ 2.70₈ 2.64₇ 2.05₅ 1.622₄ 1.600₅. Irregular plates on {001} 1–2 mm thick and up to 3 mm across, some in epitaxial intergrowths with plates of lomonosovite, sobolevite. Light brown; white streak; vitreous luster, pearly on basal cleavage; translucent, transparent in thin sections. Brittle, step-like fracture; perfect {001}, less perfect {110}, {100} cleavages. $H = 5$. $G = 3.12$. Nonfluorescent. Biaxial (-); $N_x = 1.630$ (colorless), $N_y = 1.678$ (yellow), $N_z = 1.697$ (yellow); $2V = 62^\circ$; $r \ll v$; pronounced pleochroism. Found with K-feldspar, nepheline, sodalite, arfvedsonite, aegirine, cancrinite, analcite, albite, ussingite, makatite, grumantite, lomonosovite, vuonnemite, sobolevite, and other rare minerals at *Mount Alluaiv in the NW part of the Lovozero alkaline massif, Kola Penin., Russia. HCWS AM 78:1316(1993).*

43.20.1 Polyphite $\text{Na}_{17}\text{Ca}_3\text{Mg}(\text{Ti,Mn})_4(\text{Si}_2\text{O}_7)(\text{PO}_4)_6\text{O}_2\text{F}_2$

Named in 1992 from the Greek for *many* and the element P, indicating the quantity of PO_4 groups in the formula unit. See quadruphite (42.13.14.1), a very similar mineral and in intimate association. *TRIC P1*. $a = 5.412$, $b = 7.079$, $c = 26.56$, $\alpha = 95.21^\circ$, $\beta = 93.51^\circ$, $\gamma = 90.10^\circ$, $Z = 1$, $D = 3.00$, *ZVMO 121:105(1992)*. *PD*: 2.94₁₀ 2.70₉ 2.66₈ 2.05₈ 1.771₅ 1.730₅. Biaxial (-); $N_x = 1.600$, $N_y = 1.658$, $N_z = 1.676$. $2V = 56^\circ$. X, colorless; Y,Z, yellowish. $G = 3.07$. Found with quadruphite and other minerals in alkali pegmatites of the *Lovozero massif, Kola Penin., Russia. HCWS AM 78:1316(1993).*

Antimonates

44.1.1.1 Stibiconite $\text{Sb}^{3+}\text{Sb}_2^{5+}\text{O}_6(\text{OH})$

Named in 1832 for the composition, stibium (antimony), and from the Greek for *powder*, since it often occurs in this form. iso *Fd3m*. $a = 10.27$, $Z = 8$, $D = 5.86$. 10-388: 5.93₉ 3.09₇ 2.96₁₀ 2.57₄ 1.81₈ 1.55₆ 1.18₄ 1.15₄. Pseudomorphs after stibnite or massive. White to yellow or brown, white streak, earthy luster. $H = 3-5$. $G = 3.3-5.6$. Isotropic; $N = 1.64-2.05$. Variable composition; the cation positions may be only partially filled, and the Sb^{3+} may be partially replaced by Ca (up to 14% CaO, var. hydroromeite). Soluble in concentrated HCl + KI. A secondary mineral formed by the oxidation of stibnite and other antimony minerals; occurs in many antimony deposits throughout the world. Important localities include Manhattan, Nye Co., NV; Antimony Peak, Kern Co., CA; many localities in Mexico: El Antimonio, SON, Catorce* and Charcas*, SLP, Paletos and Mapimi, DGO, Tejocotes, OAX; Allemont, France; Moros, Zaragoza, Spain; Poggio Fuoco, Manciano, Italy; Baia Sprie, Romania; Derekdy*, Gonyuh, Turkey; Hunan*, China; Ain Kerma, Algeria; Cochabaniba*, Bolivia. BM *DI:597*, AM *37:982(1952)*.

44.1.1.2 Bindheimite $\text{Pb}_2\text{Sb}_2\text{O}_6(\text{OH})$

Named in 1868 for Johann J. Bindheim (1750-1825), German chemist, who made the first analysis on material from Nerchinsk, Siberia. iso *Fd3m*. $a = 10.47$, $Z = 8$, $D = 7.50$. 18-687: 3.03₁₀ 2.62₆ 1.85₈ 1.58₈ 1.20₄ 1.17₄ 1.07₄ 0.884₅. Massive. Yellow to brown, yellow streak, earthy luster. $H = 4-5$. $G = 4.6-5.6$. Variable composition; calcian, cuprian, and argentic varieties exist. Isotropic; $N = 1.84-1.87$. Widespread as an oxidation product of lead-antimony sulfides. Wamsley mine, Mineral Co., and Lovelock, Pershing Co., NV; Cerro Gordo mine, Inyo Co., CA; Mapimi, DGO, Mexico; Endellion, Cornwall, England; La Sanguinede, Herault, France; *Nerchinsk, Siberia, Russia*; Broken Hill and Thackaringa, NSW, Australia; Ouro Preto, MG, Brazil; Machacamarcá, Bolivia. BM *DII:1018*, MM *30:102(1953)*.

44.1.1.3 Roméite $\text{Ca}_2\text{Sb}_2\text{O}_6(\text{O},\text{OH},\text{F})$

Named in 1841 for Rome de Lisle (1736-1790), French crystallographer. iso *Fd3m*. $a = 10.26-10.31$, $Z = 8$, $D = 4.85$. 27-89: 6.0₈ 3.09₇ 2.95₁₀ 2.57₆ 1.83₈ 1.55₇ 1.18₅ 1.15₄. Small octahedral crystals, also massive. Yellow to brown,

yellow streak, vitreous to adamantine luster. Cleavage {111}, imperfect. $H = 5\frac{1}{2}$ – $6\frac{1}{2}$. $G = 4.7$ – 5.4 . Variable composition; the following varieties have been recognized: atopite (sodian), lewisite (titanian), mauzelite (plumbian), schneebergite (ferroan), and weslienite (sodian). Isotropic; $N = 1.82$ – 1.87 . An accessory mineral, usually in metamorphosed manganese ores. Franklin, NJ; Långban and Jakobsberg, Varmland, Sweden; *San Marcel mine*, Piedmont, and Schneeberg, near Vipiteno, Italy; Ngan Hui, Kwangsi, China; Miguel Burnier, MG, Brazil. *BM DII:1020*.

44.1.1.4 Monimolite $(Pb,Ca)_2Sb_2O_7$

Named in 1865 from the Greek for *stable*, because decomposed chemically with great difficulty. iso *Fd3m*. $a = 10.47$, $Z = 8$, $D = 7.50$. X-ray powder pattern identical with bindheimite (44.1.1.2). Small cubic and octahedral crystals. Yellow to brown, yellow streak, greasy to adamantine luster. Cleavage {111}, indistinct; conchoidal or splintery fracture. $H = 5$ – 6 . $G = 5.9$ – 7.3 . Isotropic; $N > 2.06$. *Harstig mine*, Varmland, Sweden. *BM DII:1023*, *MM 30:102(1953)*.

44.1.1.5 Stetefeldite $Ag_2Sb_2O_6(O,OH)$

Named in 1867 for Carl A. Stetefeld (1838–1896), German–American mining engineer. iso *Fd3m*. $a = 10.46$, $D = 5.38$. $8-12$: 3.02_{10} 2.61_7 1.85_7 1.58_7 1.51_3 1.20_5 1.17_4 0.884_5 . Massive. Yellow, blackening on exposure; yellow streak, earthy luster. $H = 3\frac{1}{2}$ – $4\frac{1}{2}$. $G = 4.6$. Isotropic; $N = 1.95$. *Belmont*, *Nye Co.*, and *Silver Peak*, *Esmeralda Co.*, NV; *Doigs*, near Mt. Monger, WA, Australia; *Huancavelica*, Peru. *BM DI:598*, *MM 30:105(1953)*.

44.1.1.6 Bismutostibiconite $Bi_2(Sb,Fe)_2O_7$

Named in 1983 for the composition. iso *Fd3m*. $a = 10.38$, $D = 6.97$. $42-591$: 3.01_{10} 2.60_7 1.83_7 1.57_7 1.50_4 1.30_3 1.19_5 1.16_5 . Massive. Yellow to brown, yellow streak, earthy luster. $H = 4$ – 5 . $G = 7.38$. Isotropic; $N = 2.09$. *Clara mine*, *Black Forest*, Germany. *BM CE 42:77(1983)*, *AM 69:1190(1984)*.

44.1.1.7 Partzite $Cu_2Sb_2O_6(OH)$

Named in 1867 for A. F. W. Partz, who discovered the mineral. iso *Fd3m*. $a = 10.25$, $Z = 8$, $D = 5.95$. $7-303$: 5.91_9 3.08_7 2.95_{10} 2.56_5 1.81_8 1.73_4 1.54_7 1.33_5 . Massive. Olive-green with black tarnish, pale green streak, earthy luster. $H = 3$ – 4 . $G = 3.0$ – 4.0 . Isotropic; $N = 1.61$ – 1.83 . *Blind Spring mining district*, *Mono Co.*, and *Benton*, *Inyo Co.*, CA; *Ashburton Downs*, WA, Australia. *BM DI:599*, *MM 30:105(1953)*, *MR 24:215(1993)*.

44.1.2.1 Ingersonite $Ca_3MnSb_4O_{14}$

Named in 1988 for F. Earl Ingerson (1906–1993), U.S. geochemist. *HEX-R* Probably *P3m*. $a = 7.287$, $c = 17.679$, $Z = 3$, $D = 5.42$. *AM 73*: 5.89_2 3.10_2 2.97_{10} 2.57_4 1.82_5 1.81_5 1.55_6 1.54_4 . Subhedral crystals to 3 mm. Yellow-

brown color and streak, vitreous luster. Cleavage {0001}, perfect. $H = 6\frac{1}{2}$. Uniaxial (-); $N_O = 1.93$, $N_E = 1.92$. *Langban, Varmland, Sweden*, a rare accessory in manganese ores. *BM AM 73:405(1988)*.

44.2.1.1 Byströmite $MgSb_2O_6$

Named in 1952 for Anders Byström (1916–1956), Swedish crystal chemist. TET $P4_2/mnm$. $a = 4.68$, $c = 9.21$, $Z = 2$, $D = 5.99$. *15-684*: 4.63₄ 4.19₇ 3.32₁₀ 2.57₉ 2.34₅ 1.73₉ 1.65₄ 1.48₄. Massive. Blue-gray color and streak, earthy luster. $H = 7$. $G = 5.7$. Uniaxial (+); $N_O = 1.908$, $N_E = 1.915$. *El Antimonio, SON, Mexico*. *BM AM 37:53(1952)*.

44.2.1.2 Ordoñezite $ZnSb_2O_6$

Named in 1955 for Ezequiel Ordoñez (1867–1950), Mexican geologist. TET $P4_2/mnm$. $a = 4.67$, $c = 9.24$, $Z = 2$, $D = 6.73$. *11-214*: 3.26₉ 2.55₈ 2.31₄ 1.72₁₀ 1.64₅ 1.39₄ 1.38₆ 1.19₆. Tetragonal crystals to 2 mm; pale to dark brown, yellow streak, adamantine luster. No cleavage, conchoidal fracture. $H = 6\frac{1}{2}$. $G = 6.635$. Uniaxial (+); $N > 1.95$. *Santín mine, GTO, and Serrita Morita, SON, Mexico*. *BM AM 40:64(1955)*.

44.2.1.3 Tripuhyite $FeSb_2O_6$

Named in 1897 for the locality. TET $P4_2/mnm$. $a = 4.63$, $c = 9.14$, $Z = 3$, $D = 6.08$. *7-349*: 3.28₁₀ 2.56₉ 2.32₄ 1.72₉ 1.64₅ 1.52₃ 1.47₄ 1.38₃. Detrital grains or massive. Yellow to brown, yellow streak, vitreous to earthy luster. $H = 7$. $G = 5.6$ – 5.8 . Anomalously biaxial (+); $N_x = 2.19$, $N_y = 2.20$, $N_z = 2.33$; 2V small; $r < v$. Mopung Hills, Churchill Co., NV; El Antimonio, SON, Mexico; Clara mine, Black Forest, Germany; Faletta, Graubunden, Switzerland; Cetine, near Siena, Italy; Hammam N'baïl, near Constantine, Algeria; *Tripuhy, MG, Brazil*; Doncellas, Jujuy, Argentina; Ashburton Downs, WA, Australia. *BM DII:1024, MM 30:107(1953), MR 24:216(1993)*.

44.3.1.1 Swedenborgite $NaBe_4SbO_7$

Named in 1924 for Emanuel Swedenborg (1688–1772), Swedish philosopher. HEX $P6_3mc$. $a = 5.42$, $c = 8.80$, $Z = 2$, $D = 4.28$. *23-656*: 4.7₇ 4.4₇ 4.2₁₀ 3.22₈ 2.72₉ 2.51₉ 2.32₉ 2.28₇. Hexagonal crystals to 8 mm. Colorless to yellow, white streak, vitreous luster. Cleavage {0001}, distinct; subconchoidal fracture. $H = 8$. $G = 4.285$. Fluorescent intense blue under SWUV, deep red under LWUV. Uniaxial (-); $N_O = 1.772$, $N_E = 1.770$. *BM Langban, Varmland, Sweden*. *DII:1027*.

44.3.2.1 Manganostibite $Mn_7Sb^{5+}As^{5+}O_{12}$

Named in 1884 for the composition. ORTH $Ibmm$. $a = 8.727$, $b = 18.847$, $c = 6.062$, $Z = 4$, $D = 5.00$. *23-1236*: 9.31₄ 4.97₆ 4.69₄ 4.38₆ 2.82₄ 2.65₁₀ 2.62₄ 2.18₅. Small rounded prismatic crystals. Black, brown streak, greasy

luster. $G = 4.949$. Biaxial (-); $N_x = 1.92$, $N_y = 1.95$, $N_z = 1.96$; 2V small. *Moss mine, Varmland, Sweden*. BM *DII:1027*, *AM 55:1489(1970)*.

44.3.3.1 Parwelite $(\text{Mn,Mg})_5\text{Sb}(\text{As,Si})_2\text{O}_{12}$

Named in 1970 for Alexander Parwel (1906–1976), Swedish chemist. MON *Aa*. $a = 9.76$, $b = 19.32$, $c = 10.06$, $\beta = 95.9^\circ$, $Z = 8$, $D = 4.69$. $\varrho_9\text{-}\varrho_{46}$: 9.65₃ 4.83₅ 3.42₅ 2.92₁₀ 2.73₁₀ 2.42₄ 2.31₃ 1.74₃. Stubby prismatic crystals to 10 mm. Yellow-brown, yellow streak, greasy luster. Cleavage {010}, fair; subconchoidal fracture. $H = 5\frac{1}{2}$, $G = 4.62$. Biaxial (+); $N_x, N_y = 1.85$, $N_z = 1.88$; 2V = 27°; $r > v$. *Långban, Varmland, Sweden*. BM *AMG 4:467(1969)*, *AM 55:323(1970)*.

44.3.4.1 Langbanite $\text{Mn}_4^{2+}\text{Mn}_5^{3+}\text{SbSi}_2\text{O}_{24}$

Named in 1887 for the locality. HEX-R *P31m*. $a = 11.563$, $c = 11.100$, $Z = 3$, $D = 4.946$. $14\text{-}195$: 2.80₈ 2.75₉ 2.55₁₀ 1.99₄ 1.67₇ 1.54₈ 1.43₅ 1.03₄. Hexagonal prismatic crystals to 1 cm. Black, brown streak, metallic luster. Cleavage {0001}, good; conchoidal fracture; brittle. $H = 6\frac{1}{2}$. $G = 4.9$. Uniaxial (-); $N_O = 2.36$, $N_E = 2.31$; weakly pleochroic, red-brown. *Langban, Varmland, Sweden*, in manganophyllite skarn; Gozaisho mine, Fukushima Pref., Japan. BM *SPC 18:320(1973)*, *AM 76:1408(1991)*, *NJMM:193(1991)*.

44.3.5.1 Katoptrite $\text{Mn}_{13}\text{Al}_4\text{Sb}_2\text{Si}_2\text{O}_{28}$

Named in 1917 from the Greek for *mirror*, in allusion to the luster on cleavages. Synonym: catoptrite. MON *C2/m*. $a = 5.617$, $b = 23.02$, $c = 7.079$, $\beta = 101.38^\circ$, $Z = 2$, $D = 4.53$. $19\text{-}274$: 8.88₇ 4.43₅ 2.96₁₀ 2.81₄ 2.60₅ 2.49₅ 2.15₃ 1.94₄. Platy crystals. Black, red-brown streak, submetallic luster. Cleavage {100}, perfect, micaceous; brittle. $H = 5\frac{1}{2}$. $G = 4.56$. Biaxial (-); $N_x = 1.92$, $N_y, N_z = 1.95$; 2V small, $r > v$; strongly pleochroic, yellow-red to red-brown. *Brattfors, Moss, and Sjö mines, Varmland, Sweden*. BM *DII:1029*, *AM 51:1494(1966)*, *NJMA 127:47(1976)*.

44.3.6.1 Yeatmanite $\text{Mn}_9\text{Zn}_6\text{Sb}_2\text{Si}_4\text{O}_{28}$

Named in 1938 for Pope Yeatman (1861–1953), U.S. mining engineer. TRIC *P1*. $a = 5.604$, $b = 11.602$, $c = 9.058$, $\alpha = 92.17^\circ$, $\beta = 100.90^\circ$, $\gamma = 77.30^\circ$, $Z = 1$, $D = 5.04$. Platy anhedral crystals to 13 mm. Clove-brown, pale brown streak, vitreous luster. Cleavage {100}, good. Brittle. $H = 4$. $G = 5.02$. Biaxial (-); $N_x = 1.864$, $N_y = 1.895$, $N_z = 1.905$; 2V = 52°; $r > v$. *Franklin and Sterling Hill, Sussex Co., NJ*. BM *AM 65:196(1980)*, *MJJ 13:53(1986)*.

44.3.7.1 Bahianite $\text{Al}_5\text{Sb}_3\text{O}_{14}(\text{OH})_2$

Named in 1976 for the locality. MON *C2/m*. $a = 9.406$, $b = 11.541$, $c = 4.410$, $\beta = 99.94^\circ$, $Z = 2$, $D = 5.26$. $\varrho_9\text{-}\varrho_2$: 4.71₇ 3.24₁₀ 3.19₁₀ 2.46₇ 2.41₇ 2.16₈ 1.65₇ 1.64₇. Water-worn pebbles (favas). Cream to tan, white streak, adamantine luster. Cleavage {100}, perfect. $H = 9$. $G = 4.89\text{--}5.46$. Biaxial (-); $N_x = 1.81$,

$N_y = 1.87$, $N_z = 1.92$; 2V large; $r > v$. *Paramirim region, BA, Brazil*. BM *NJMA* 126:113(1976), *MM* 42:179(1978).

44.3.8.1 Shakhovite $Hg_4SbO_3(OH)_3$

Named in 1980 for F. N. Shakhov (1894–1971), Russian geologist. MON *Im* $a = 4.871$, $b = 15.098$, $c = 5.433$, $\beta = 98.86^\circ$, $Z = 2$, $D = 8.35$. 37-460: 3.88₁₀ 3.33₈ 2.69₆ 2.63₅ 2.55₅ 2.03₃ 1.93₄ 1.89₃. Platy crystals to 1 mm. Yellow-green to olive-green, yellow streak, adamantine luster. $H = 3-3\frac{1}{2}$. $G = 8.38$. Probably biaxial; $N > 2.03$. *Kelyan deposit, Buryat ASSR, Russia*; *Khaidarkan deposit, Kyrgyzstan*; *Moschallandsberg, Palatinate, Germany*. BM *MM* 46:525(1982); *TMPM* 30:227(1982); *AM* 68:1041(1983), 73:1499(1988).

44.3.9.1 Cyanophyllite $Cu_5Al_2(SbO_4)_3(OH)_2 \cdot 12H_2O$

Named in 1981 for the blue color and platy form. ORTH *Pmmb*. $a = 11.82$, $b = 10.80$, $c = 9.64$, $Z = 2$, $D = 3.12$. 35-507: 9.67₆ 4.84₁₀ 2.59₆ 2.44₅ 1.92₄ 1.56₃ 1.48₃ 1.21₂. Spherulitic platy aggregates. Blue-green, blue streak, pearly to silky luster. Cleavage {001}, perfect. $H = 2$. $G = 3.10$. Biaxial (-); $X = c$; $N_x = 1.640$, $N_y = 1.664$, $N_z = 1.675$; 2V = 67°. *Clara mine, Black Forest, Germany*. BM *CE* 40:195(1981), *AM* 66:1274(1981).

44.3.10.1 Cualstibite $Cu_6Al_3(SbO_4)_3(OH)_{12} \cdot 10H_2O$

Named in 1984 for the composition. HEX-R Space group uncertain, probably *P3*. $a = 9.20$, $c = 9.73$, $Z = 1$, $D = 3.25$. 38-362: 4.89₁₀ 4.63₄ 4.17₈ 3.35₅ 2.65₇ 2.33₉ 1.79₈ 1.53₄. Microscopic trigonal crystals and massive. Blue-green, pale blue streak, vitreous luster. No cleavage, conchoidal fracture. $H = 2$. $G = 3.18$. Uniaxial (-); $N_O = 1.672$, $N_E = 1.644$; pleochroic, colorless to pale blue-green. *Clara mine, Black Forest, Germany*. BM *CE* 43:255(1984), *AM* 70:1329(1985).

44.3.11.1 Camerolaite $Cu_4Al_2(HSbO_4,SO_4)(OH)_{10}(CO_3) \cdot 2H_2O$

Named in 1991 for Michel Camerola, French mineral collector. MON Space group uncertain, probably *P2₁*. $a = 10.765$, $b = 2.903$, $c = 12.527$, $\beta = 95.61^\circ$, $Z = 1$, $D = 3.09$. 44-1441: 5.62₅ 5.16₉ 4.28₁₀ 3.57₄ 2.38₄ 2.33₄ 2.14₃ 1.92₃. Radiating fibrous aggregates to 2 mm. Blue-green, pale green streak, silky luster. Cleavage {100}, {001}, good; fibrous fracture; brittle. $G = 3.1$. Biaxial (+); $N_x = 1.626$, $N_y = 1.646$, $N_z = 1.682$; 2V = 77°; $r < v$, strong; pleochroic, colorless to blue-green. *Cap Garonne, Var, France*. BM *NJMM*:481(1991), *AM* 77:1116(1992).

44.3.12.1 Brizziite $NaSbO_3$

Named in 1994 for Giancarlo Brizzi (1936–1992), Italian mineral collector. HEX-R *R3*. $a = 5.301$, $c = 15.932$, $Z = 6$, $D = 4.95$. 9-23(syn): 5.31₁₀ 4.40₄ 3.97₄ 3.01₄ 2.65₆ 2.37₄ 1.88₄ 1.53₂. Microscopic aggregates of platy crystals. Yellow or pale pink, pearly luster. Cleavage {0001}, perfect; flexible. $VHN_{15} = 57$.

$G = 4.82$. Uniaxial (-); $N_O = 1.84$, $N_E = 1.631$. *Cetine mine, Tuscany, Italy*, an alteration product of stibnite, together with stibiconite and mopungite. *BM EM 6:667(1994)*.

Acid and Normal Antimonites and Arsenites

45.1.1.1 Reinerite $Zn_3(AsO_3)_2$

Named in 1959 for Willy Reiner (b.1904), chemist, Tsumeb Corporation, who analyzed the mineral. ORTH *Pbam*. $a = 6.092$, $b = 14.407$, $c = 7.811$, $Z = 4$, $D = 4.28$. 11-158: 4.00₁₀ 3.43₇ 3.40₇ 3.20₈ 2.64₈ 2.60₇ 2.40₇ 1.95₇. Prismatic crystals to 5 cm, also massive. Blue to yellow-green, vitreous to adamantine luster. Cleavage {110}, good; {011}, {111}, fair. $H = 5-5\frac{1}{2}$. $G = 4.27$. Biaxial (-); $N_x = 1.74$, $N_y = 1.79$, $N_z = 1.82$; $2V = 80^\circ$. Tsumeb, Namibia. BM *NJMM:160(1958)*; *AM 44:207(1959)*, *62:1129(1977)*.

45.1.2.1 Trigonite $Pb_3Mn(AsO_3)_2(AsO_2OH)$

Named in 1920 for the shape of the crystals. MON *Pn*. $a = 7.258$, $b = 6.822$, $c = 11.088$, $\beta = 94.45^\circ$, $Z = 2$, $D = 6.34$. 23-330: 4.9₆ 4.5₄ 3.65₄ 3.24₇ 3.08₉ 2.99₁₀ 2.76₄ 2.71₄. Thick tabular crystals. Yellow to brown, yellow streak, vitreous to adamantine luster. Cleavage {010}, perfect; {101}, good; uneven fracture. $H = 2-3$. $G = 6.1$. Biaxial (-); $N_x = 2.07$, $N_y = 2.10$, $N_z = 2.12$; $2V$ large, $r < v$. Langban, Varmland, Sweden. BM *DII:1032*, *TMPM 25:95(1978)*, *MA 40:1661(1989)*.

45.1.2.2 Rouseite $Pb_3Mn(AsO_3)_2 \cdot 2H_2O$

Named in 1986 for Roland Rouse (b.1943), U.S. mineralogist. TRIC *P1* or *P1*. $a = 6.36$, $b = 7.29$, $c = 5.54$, $\alpha = 97.3^\circ$, $\beta = 114.2^\circ$, $\gamma = 106.0^\circ$, $Z = 1$, $D = 5.70$. 40-472: 6.81₁₀ 3.38₆ 3.25₆ 3.06₇ 2.98₈ 2.85₉ 2.75₅ 2.02₆. Microscopic crystals. Yellow-orange, pale yellow streak, vitreous luster. Cleavage {010}, {100}, perfect. $H = 3$. $G > 4.2$. Biaxial (-); $N = 1.8-1.9$; $2V = 46^\circ$, $r > v$. Langban, Varmland, Sweden. BM *AM 71:1034(1986)*.

45.1.3.1 Asbecasite $Ca_3Be_2Si_2(Ti.Sn)(AsO_3)_6O_2$

Named in 1966 for the composition. HEX-R *P3cl*. $a = 8.364$, $c = 15.304$, $Z = 2$, $D = 3.71$. 19-87: 4.04₅ 3.84₅ 3.23₁₀ 2.41₆ 1.75₆ 1.57₇ 1.32₆ 1.15₇. Rhombohedral crystals to 5 mm. Lemon yellow, pale yellow streak, adamantine luster. Perfect rhombohedral cleavage. $H = 6\frac{1}{2}-7$. $G = 3.70$. Uniaxial (-); $N_0 = 1.86$, $N_E = 1.83$. Binntal, Switzerland, in a fissure in gneiss; Pizzo Cervandone, Italy. BM *SMPM 46:367(1966)*; *AM 52:1583(1967)*, *66:819(1981)*.

45.1.4.1 Cafarsite $(\text{Ca},\text{Mn})_8\text{Fe}_3\text{Ti}_3(\text{AsO}_3)_{12} \cdot 4\text{H}_2\text{O}$

Named in 1966 for the composition. iso $Pn\bar{3}$. $a = 15.984$, $Z = 4$, $D = 3.95$: 19-197: 9.51₄ 3.69₅ 3.15₇ 2.83₁₀ 2.75₈ 1.72₅ 1.63₆ 0.979₃. Cubo-octahedral crystals to 3 cm. Dark brown, yellow-brown streak, adamantine luster. No cleavage, conchoidal fracture, brittle. $H = 5\frac{1}{2}$ -6. $G = 3.90$. Isotropic; $N \geq 2.0$. *Binntal, Switzerland*; Pizzo Cervandone, Italy. BM *SMPM* 46:367(1966), 57:1(1977); *AM* 52:1584(1967).

45.1.5.1 Trippkeite CuAs_2O_4

Named in 1880 for the Polish mineralogist Paul Trippke (1851-1880), who discovered the mineral. TET $P4/mbc$. $a = 8.59$, $c = 5.57$, $Z = 4$, $D = 4.49$. 31-451: 6.07₆ 3.16₁₀ 3.04₅ 2.72₄ 2.53₂ 1.95₄ 1.64₃ 1.39₂. Short prismatic crystals. Blue-green, pale blue streak, adamantine luster. Cleavage {100}, perfect; {110}, good. $G = 4.8$. Uniaxial (+); $N_O = 1.90$, $N_E = 2.12$. Near *Copiapo, Chile*. BM *DII:1034*, *TMPM* 22:211(1975).

45.1.6.1 Schafarzikite FeSb_2O_4

Named in 1921 for Ferenc Schafarzik (1854-1927), Hungarian mineralogist. TET $P4/mbc$. $a = 8.59$, $c = 5.91$, $Z = 4$, $D = 5.53$. 25-1406: 3.22₄ 2.03₄ 1.67₈ 1.31₅ 1.24₄ 1.16₅ 1.05₁₀ 1.01₁₀. Prismatic crystals. Red to red-brown, brown streak, metallic luster. Cleavage {110}, perfect; {100}, good. $H = 3\frac{1}{2}$. $G = 4.3$. Uniaxial (+); $N \sim 2.1$; weakly birefringent; pleochroic, pale yellow to yellow-brown. Lac Nicolet mine, South Ham, QUE, Canada; *Pernek, Slovakia*. BM *DII:1035*, *TMPM* 22:236(1975).

45.1.7.1 Leiteite ZnAs_2O_4

Named for Luis Teixeira-Leite (b.1942), Portuguese mineral dealer, who discovered the mineral. MON $P2_1/c$. $a = 4.542$, $b = 5.022$, $c = 17.597$, $\beta = 90.81^\circ$, $Z = 2$, $D = 4.62$. 29-740: 4.83₃ 3.32₄ 3.30₃ 3.16₈ 3.13₁₀ 2.94₂ 2.18₂ 1.69₅. Cleavable masses to 7 cm. Colorless to brown, white streak, pearly luster. Cleavage {100}, perfect; cleavage lamellae flexible, inelastic. $H = 1\frac{1}{2}$ -2. $G = 4.31$. Biaxial (+); $Z \wedge c = 10^\circ$; $N_x = 1.87$, $N_y = 1.880$, $N_z = 1.98$; $2\bar{V} = 27^\circ$; $r < v$, very strong. *Tsumeb, Namibia*. BM *MR* 8(3):97(1977); *AM* 62:1259(1977), 72:629(1987).

45.1.8.1 Paulmooreite $\text{Pb}_2\text{As}_2\text{O}_5$

Named in 1979 for Paul B. Moore (b.1940), U.S. mineralogist, investigator of Langban minerals. MON $P2_1/a$. $a = 13.584$, $b = 5.650$, $c = 8.551$, $\beta = 108.78^\circ$, $Z = 4$, $D = 6.86$. 33-736: 4.26₅ 3.42₅ 3.30₁₀ 3.02₇ 2.91₈ 2.02₆ 1.77₇ 1.73₆. Small platy crystals. Colorless to pale orange, white streak, adamantine luster. Cleavage {001}, perfect; very brittle. $H = 3$. $G = 6.95$. Biaxial (+); $N > 1.9$; birefringence = 0.110; $2V = 65^\circ$; $r > v$, very strong. *Langban, Varmland, Sweden*. BM *AM* 64:352(1979), 65:340(1980).

45.1.9.1 Apuanite $\text{Fe}^{2+}\text{Fe}_4^{3+}\text{Sb}_4\text{O}_{12}\text{S}$

Named in 1979 for the locality. TET $P4_2/mbc$. $a = 8.367$, $c = 17.959$, $Z = 4$, $D = 5.23$. $33-642$: 5.90_2 4.18_2 3.17_{10} 2.98_4 2.65_2 2.43_2 1.92_5 1.65_3 . Platy crystals and massive aggregates. Black, black streak, metallic luster. Cleavage $\{110\}$, perfect. $H = 4$. $G = 5.33$. *Buca della Vena mine, Apuan Alps, Italy*. BM AM 64:1230(1979).

45.1.10.1 Versiliaite $\text{Fe}_4^{2+}\text{Fe}_8^{3+}\text{Sb}_{12}\text{O}_{32}\text{S}_2$

Named in 1979 for the locality. ORTH Space group probably *Pbam*. $a = 8.499$, $b = 8.326$, $c = 11.935$, $Z = 1$, $D = 5.20$. $33-698$: 5.94_3 3.20_{10} 3.17_{10} 2.97_8 2.68_4 2.64_2 1.95_4 1.92_3 . Platy crystals. Black, black streak, metallic luster. Cleavage $\{110\}$, perfect. $H = 4\frac{1}{2}$. $G = 5.12$. *Buca della Vena mine, Versilia valley, Apuan Alps, Italy*. BM AM 64:1230(1979).

45.1.11.1 Stibivanite-2M VOSb_2O_4

Named in 1980 for the composition. MON $C2/c$. $a = 17.989$, $b = 4.792$, $c = 5.500$, $\beta = 95.15^\circ$, $Z = 4$, $D = 5.26$. $33-122$: 4.64_6 3.50_7 3.17_7 3.00_{10} 2.11_4 2.03_3 1.87_4 1.71_3 . Radiating fibrous crystals to 2 mm. Yellow-green, white streak, adamantine luster. $H = 4$. Biaxial (-); $N_x > 1.87$, $N_z < 1.89$; $2V = 85^\circ$; $r > v$, strong; strongly pleochroic, emerald-green to olive-green. *Lake George antimony mine, NB, Canada*. BM CM 18:329(1980).

45.1.11.2 Stibivanite-20 VOSb_2O_4

Named in 1989 for the composition. ORTH *Pmcn*. $a = 17.916$, $b = 4.790$, $c = 5.509$, $Z = 4$, $D = 5.26$. CM 27: 9.00_5 4.62_5 3.63_2 3.10_{10} 2.99_7 2.51_2 1.87_5 1.75_3 . Acicular and fibrous crystals to 2 mm. Emerald green, white streak, adamantine luster. Parting parallel to c . $H = 4$. Biaxial (+); $N > 1.87$; $2V$ very small; pleochroic, emerald-green to olive-green. *Buca della Vena mine, Apuan Alps, Italy*. BM CM 27:625(1989).

45.1.12.1 Schneiderhöhnite $\text{Fe}^{2+}\text{Fe}_3^{3+}\text{As}_5\text{O}_{13}$

Named in 1973 for Hans Schneiderhöhn (1887–1962), German mineralogist. TRIC $P1$. $a = 8.924$, $b = 10.016$, $c = 9.103$, $\alpha = 59.91^\circ$, $\beta = 112.41^\circ$, $\gamma = 81.69^\circ$, $Z = 2$, $D = 4.33$. $35-462$: 7.27_{10} 4.14_7 3.93_6 3.64_8 3.35_8 2.97_{10} 2.91_{10} . Platy crystals to 7 mm. Dark brown to black, brown streak, adamantine to metallic luster. Cleavage $\{100\}$, perfect. $H = 3$. $G = 4.3$. Biaxial (+); $N_x > 2.11$, $N_z < 2.13$; pleochroic, yellow to red-brown. *Tsumeb, Namibia*. BM NJMM:517(1973), AM 59:1139(1974), CM 23:675(1985).

45.1.13.1 Fetiasite $(\text{Fe}^{2+}, \text{Fe}^{3+}, \text{Ti})_3\text{O}_2(\text{As}_2\text{O}_5)$

Named in 1994 for the composition. MON $P2_1/m$. $a = 10.614$, $b = 3.252$, $c = 8.945$, $\beta = 108.95^\circ$, $Z = 2$, $D = 4.74$. AM 79: 3.53_3 2.99_7 2.81_9 2.75_{10} 2.39_8 1.78_5 1.75_3 1.71_4 . Microscopic tabular crystals and globular aggregates. Brown to black, metallic to submetallic luster. Cleavage $\{100\}$, perfect;

uneven to conchoidal fracture. $H \approx 5$, $VHN_{50} = 440\text{--}490$. $G = 4.6$. $R = 15.3\text{--}15.8$ (546 nm). *Pizzo Cervandone, Italy*, and *Binntal, Switzerland*, in Alpine fissure veins. *BM AM 79:996(1994)*.

45.1.14.1 Ludlockite $PbFe_4^{3+}As_{10}O_{22}$

Named in 1977 for mineral dealers Ludlow Smith and Locke Key, who discovered the mineral. TRIC *P1*. $a = 10.426$, $b = 12.074$, $c = 18.349$, $\alpha = 101.84^\circ$, $\beta = 100.21^\circ$, $\gamma = 90.60^\circ$, $Z = 4$, $D = 4.37$. *29-774*: 10.9_6 8.81_{10} 4.74_6 4.47_6 3.33_7 3.16_7 2.94_9 2.86_7 . Needles to 4 mm. Red-brown, pale brown streak, subadamantine luster. Cleavage {011}, {021}, perfect. $H = 1\frac{1}{2}\text{--}2$. $G = 4.40$. Biaxial (+); $N_x = 1.96$, $N_y = 2.055$, $N_z = 2.11$; pleochroic, X, yellow; Y, deep yellow; Z, orange-yellow. *Tsumeb, Namibia*, in a cavity in sulfide ore. *BM MR 8:91(1977)*, *CM 34:79(1996)*.

Basic or Halogen-Containing Antimonites and Arsenites

46.1.1.1 Finnemanite $Pb_5(AsO_3)_3Cl$

Named in 1923 for Karl J. Finneman (1880–1953), mine worker at Långban, who recognized many new minerals. *HEX* $P6_3/m$. $a = 10.322$, $c = 7.055$, $Z = 2$, $D = 7.30$. Isostructural with apatite. $14-187$: 4.42_4 3.35_6 3.03_{10} 2.88_9 2.07_6 2.02_4 1.96_5 1.92_5 . Small prismatic crystals. Gray to black, gray streak, subadamantine luster. Cleavage $\{1011\}$, distinct. $H = 2\frac{1}{2}$. $G = 7.265$. Uniaxial (-); $N_O = 2.295$, $N_E = 2.285$. *Långban, Värmland, Sweden*; Beltana mine, near Copley, SA, Australia. *BM DII:1038, TMPM 26:95(1979)*.

46.1.2.1 Nanlingite $CaMg_4(AsO_3)_2F_4$

Named in 1976 for the locality. *HEX-R* $R3m$ or $R3m$. $a = 10.24$, $c = 25.76$, $Z = 15$, $D = 3.91$. $30-264$: 8.35_9 4.45_5 3.29_5 2.86_6 2.78_{10} 2.43_7 1.78_8 1.70_8 . Tabular crystals. Red-brown, pale yellow streak, vitreous luster. $H = 2$. $G = 3.927$. Uniaxial (-); $N_O = 1.82$, $N_E = 1.78$. *Nanling area, southern China*, in a contact zone between granite and dolomitic limestone. *BM AM 62:1058(1977)*.

46.1.3.1 Magnussonite $Mn_{10}(AsO_3)_6(OH,Cl)_2$

Named in 1956 for Nils H. Magnusson (1890–1976), Swedish geologist, who monographed the Långban deposit. *ISO* $Ia3d$. $a = 19.70$, $Z = 16$, $D = 4.61$. $10-407$: 8.01_1 4.02_1 3.13_3 2.85_{10} 2.47_3 1.74_2 1.48_1 1.42_1 . Fine-grained incrustations. Grass-green to emerald-green, white streak, vitreous luster. $H = 3\frac{1}{2}-4$. $G > 4.4$. Isotropic; $N = 1.983$. Sterling Hill, Sussex Co., NJ; Brattfors mine (a tetragonal variety, $a = 19.58$, $c = 19.72$) and *Långban, Värmland, Sweden*. *BM AMG 2:133(1956); AM 64:390(1979), 69:800(1984)*.

46.1.4.1 Stenhuggarite $CaFe^{3+}SbAs_2O_7$

Named in 1970 from the Swedish *stenhuggar* (stone)mason, referring to Brian Mason (b.1917), New Zealand–U.S. mineralogist, who worked on Långban minerals. *TET* $I4_1/a$. $a = 16.144$, $c = 10.706$, $Z = 16$, $D = 4.56$. $24-199$: 8.0_2 6.0_2 4.8_2 3.66_3 2.98_{10} 2.54_4 1.84_5 1.54_4 . Equant crystals to 3 mm. Orange, yellow streak, vitreous luster. No cleavage. $H = 4$. $G = 4.63$. Uniaxial; $N > 2.00$. *Långban, Värmland, Sweden*. *BM AMG 5:55(1970), AM 56:636(1971), AC(B) 33:1807(1977)*.

46.1.5.1 Freedite $\text{Pb}_8\text{Cu}(\text{AsO}_3)_2\text{O}_3\text{Cl}_5$

Named in 1985 for Robert L. Freed (b.1950), U.S. mineralogist. *MON* *C2/m*. $a = 13.578$, $b = 20.099$, $c = 7.465$, $\beta = 105.73^\circ$, $Z = 4$, $D = 7.43$. *39-326*: 6.51₄ 3.83₅ 3.58₄ 2.95₁₀ 2.83₈ 2.73₈ 2.10₅ 1.70₄. Radiating aggregates. Yellow-green, yellow streak, vitreous luster. Cleavage {100}, perfect. $H = 3$. $G = 7.0$. Biaxial; $N > 1.90$. *Langban, Varmland, Sweden*. *BM AM 70:845(1985)*, *TMPM 36:85(1987)*.

46.1.6.1 Nealite $\text{Pb}_4\text{Fe}(\text{AsO}_3)_2\text{Cl}_4 \cdot 2\text{H}_2\text{O}$

Named in 1980 for Neal Yedlin (1908–1977), U.S. mineralogist, who discovered the mineral. *TRIC* *P1*. $a = 6.548$, $b = 10.243$, $c = 5.587$, $\alpha = 96.2^\circ$, $\beta = 89.6^\circ$, $\gamma = 97.7^\circ$, $Z = 1$, $D = 5.89$. *33-755*: 10.09₆ 6.48₈ 4.24₇ 3.92₅ 3.54₁₀ 3.25₆ 2.97₅ 2.78₆. Microscopic prismatic or bladed crystals. Bright orange, pale orange streak, adamantine luster. No cleavage, very brittle. Biaxial; $N > 2.00$; nonpleochroic. *Laurion, Greece*, in weathered lead slag. *BM MR 11:299(1980)*, *TMPM 48:193(1993)*, *NJMM:278(1993)*.

46.2.1.1 Ecdemite $\text{Pb}_6\text{As}_2\text{O}_7\text{Cl}_4$

Named in 1877 from the Greek for *unusual*, in reference to the composition. Possibly dimorphous with heliophyllite. *TET* Space group unknown. $a = 10.80$, $c = 25.62$, $Z = 8$, $D = 7.32$. *23-343*: 3.66₈ 2.85₁₀ 2.72₈ 2.07₇ 1.92₆ 1.67₄ 1.65₅ 1.59₇. Small tabular crystals or foliated masses. Yellow, yellow streak, vitreous to greasy luster. Cleavage {100}, distinct. $H = 2\frac{1}{2}$ –3. $G = 7.14$. Uniaxial (-); $N_O = 2.32$, $N_E = 2.25$. Mammoth mine, Pinal Co., AZ; *Langban* and *Harstig* mines, *Varmland, Sweden*. *BM DII:1036*.

46.2.2.1 Heliophyllite $\text{Pb}_6\text{As}_2\text{O}_7\text{Cl}_4$

Named in 1888 from the Greek for *sun* and *leaf*, in reference to its color and structure. Possibly dimorphous with ecdemite. *ORTH* Space group unknown. $a = 10.823$, $b = 10.783$, $c = 25.580$, $Z = 8$, $D = 7.33$. *20-471*: 3.66₄ 3.19₂ 2.84₁₀ 2.06₃ 1.91₂ 1.65₃ 1.59₃ 1.25₁. Pyramidal crystals and massive, foliated or granular. Yellow, yellow streak, vitreous to greasy luster. Cleavage {011}, good. $H = 2$. $G = 6.89$. Biaxial (-); low birefringence; 2V large; $r < v$, strong. *Langban*, *Harstig*, and *Jakobsberg* mines, *Varmland, Sweden*. *BM DII:1037*.

46.2.3.1 Tomichite $(\text{V,Fe})_4\text{Ti}_3\text{AsO}_{13}(\text{OH})$

Named in 1979 for Stephan A. Tomich (b.1914), consulting geologist, Perth, WA, Australia, who discovered the mineral. *MON* *A2/m*. $a = 7.119$, $b = 14.176$, $c = 4.992$, $\beta = 105.05^\circ$, $Z = 2$, $D = 4.42$. *34-1401*: 4.94₂ 3.15₂ 3.09₄ 2.83₉ 2.66₁₀ 2.49₂ 2.02₃ 1.71₃. Tabular grains to 3 mm. Black, black streak, metallic luster. $H = 6$. $G = 4.16$. $R = 16.3$ (546 nm); anisotropic, yellow-gray to dark gray. Hemlo gold deposit, near Marathon, ONT, Canada; *Kalgoorlie, WA, Australia*. *BM MM 43:469(1979)*, *AM 72:201(1987)*.

46.2.3.2 Derbylite $\text{Fe}_4\text{Ti}_3\text{SbO}_{13}(\text{OH})$

Named in 1897 for Orville A. Derby (1851–1915), director of the Geological Survey of Brazil. MON $P2_1/m$. $a = 7.160$, $b = 14.347$, $c = 4.970$, $\beta = 104.61^\circ$, $Z = 2$, $D = 4.76$. $35\text{-}599$: 4.00_2 3.83_2 3.19_5 3.12_4 2.85_{10} 2.67_8 2.48_3 2.39_3 . Prismatic crystals to 2 mm, and detrital grains. Dark brown to black, brown streak, resinous to metallic luster. No cleavage, conchoidal fracture, very brittle. $H = 5$. $G = 4.5\text{--}4.6$. Biaxial (+); $N_x = 2.45$, $N_y = 2.45$, $N_z = 2.51$; $2V$ small. Buca della Vena mine, Apuan Alps, Italy; *Tripuhy, MG, Brazil*. BM *DII:1025, NJMA 126:292(1976), CM 21:513(1983)*.

46.2.4.1 Hemloite $(\text{Ti,V,Fe})_{12}(\text{As,Sb})_2\text{O}_{23}(\text{OH})$

Named in 1989 for the locality. Contains up to 1.4% Al_2O_3 . TRIC $P\bar{1}$. $a = 7.158$, $b = 7.552$, $c = 16.014$, $\alpha = 89.06^\circ$, $\beta = 104.32^\circ$, $\gamma = 84.97^\circ$, $Z = 2$, $D = 4.61$. *CM 27*: 3.05_7 2.92_{10} 2.80_8 2.72_9 2.67_9 2.50_7 1.77_6 1.62_6 . Microscopic subhedral to anhedral grains. Black, black streak, submetallic to metallic luster. No cleavage, irregular fracture. $H = 6\frac{1}{2}\text{--}7$. *Hemlo gold deposit, near Marathon, ONT, Canada*. BM *CM 27:427(1989)*.

46.2.5.1 Gebhardite $\text{Pb}_8\text{OCl}_6(\text{As}_2\text{O}_5)_2$

Named in 1983 for Georg Gebhard, German chemist and mineral collector. MON $P2_1/c$. $a = 6.724$, $b = 11.20$, $c = 34.19$, $\beta = 85.2^\circ$, $Z = 2$, $D = 6.07$. $35\text{-}611$: 4.55_{10} 3.34_7 3.15_8 2.28_8 2.15_6 2.07_4 1.93_8 1.74_6 . Fibrous crystal groups to 5 mm. Brown, white streak, adamantine luster. Cleavage {001}, perfect; {010}, good. $H = 3$. Biaxial (-); $N_x = 2.08$, $N_z = 2.12$. *Tsumeb, Namibia*. BM *NJMM:445(1983), AM 70:215(1985)*.

46.2.6.1 Manganarsite $\text{Mn}_8\text{As}_2\text{O}_4(\text{OH})_4$

Named in 1986 for the composition. HEX-R Space group uncertain, probably $P312$. $a = 11.451$, $c = 7.252$, $Z = 4$, $D = 3.60$. $40\text{-}484$: 5.74_3 4.49_3 3.62_5 2.66_{10} 2.24_3 1.85_7 1.65_6 1.53_4 . Hexagonal crystals to 1 mm, also massive, fine-grained. Pale pink-brown, pale pink streak, vitreous luster. Cleavage {001}, perfect. $H = 3$. $G = 3.64$. Biaxial (-); $N_x = 1.78$, N_y , $N_z = 1.81$; $2V = 28\text{--}43^\circ$; $r > v$. BM *Langban, Värmland, Sweden*. *AM 71:1517(1986)*.

46.2.7.1 Armangite $\text{Mn}_{26}\text{As}_{18}\text{O}_{50}(\text{CO}_3)(\text{OH})_4$

Named in 1920 for the composition. HEX-R $P3$. $a = 13.491$, $c = 8.855$, $Z = 1$, $D = 4.41$. $33\text{-}888$: 4.88_1 3.95_2 2.95_6 2.92_4 2.77_{10} 2.44_4 1.76_3 1.75_2 . Short prismatic crystals. Brown to black, brown streak, adamantine luster. Cleavage {001}, fair. $H = 4$. $G = 4.43$. Uniaxial (-); $N_O = 2.01$, $N_E = 1.99$. *Langban, Värmland, Sweden*. BM *DII:1031, AM 64:748(1979)*.

46.2.8.1 Dixenite $\text{Mn}_{14}\text{CuFe}(\text{AsO}_4)(\text{AsO}_3)_5(\text{SiO}_4)_2(\text{OH})_6$

Named in 1920 from the Greek for *two* and *stranger*, for the unique association of silicate and arsenite. HEX-R $R3$. $a = 8.233$, $c = 37.499$, $Z = 3$, $D = 4.38$. 35-

520: 4.10₉ 3.90₅ 2.96₈ 2.92₁₀ 2.83₅ 2.40₆ 2.37₈ 1.55₆. Micaceous plates. Red-brown, pale brown streak, resinous to submetallic luster. Cleavage {0001}, perfect. H = 3–4. G = 4.36. Uniaxial (-); N = 1.96; weakly birefringent. *Långban, Värmland, Sweden. BM AM 66:1263(1981).*

46.2.9.1 Seelite $\text{Mg}(\text{UO}_2)_x(\text{AsO}_3)_x(\text{AsO}_4)_{1-x} \cdot 7\text{H}_2\text{O}$ □ ($x = 0.7$)

Named in 1993 for Paul Seel (1904–1982) and Hilde Seel (1901–1987), U.S. mineralogists. MON $C2/m$. $a = 18.207$, $b = 7.062$, $c = 6.661$, $\beta = 99.65^\circ$, $Z = 2$, $D = 3.60$. MR 24: 9.05₁₀ 6.48₃ 5.72₃ 4.85₅ 4.44₈ 3.99₅ 3.52₆ 1.92₈. Tufted spherules of tabular crystals to 1 mm. Bright yellow, white streak, vitreous luster. Irregular fracture. H = 3. G = 3.70. Biaxial (-); $Z \wedge c = 5^\circ$; $N_x = 1.602$, $N_y = 1.737$, $N_z = 1.753$; $2V = 41^\circ$; extreme dispersion, $r > v$; strongly pleochroic. X, colorless; Y,Z, yellow. Occurs in oxidation zones of uranium deposits at Rabejc, Hérault, France, and *Talmessi, central Iran. BM MR 24:463(1993), AM 79:1012(1994).*

Vanadium Oxysalts

47.1.1.1 Rossite $\text{Ca}(\text{VO}_3)_2 \cdot 4\text{H}_2\text{O}$

Named in 1927 for Clarence S. Ross (1880–1975), mineralogist, U.S. Geological Survey. TRIC $P\bar{1}$. $a = 8.552$, $b = 8.576$, $c = 7.028$, $\alpha = 101.50^\circ$, $\beta = 114.96^\circ$, $\gamma = 103.39^\circ$, $Z = 2$, $D = 2.40$. $36\text{-}422$: 7.26_9 6.64_{10} 6.02_5 3.93_3 3.86_{10} 3.43_6 3.03_6 3.00_5 . Glassy coatings on sandstone. Yellow, yellow streak, vitreous to pearly luster. Brittle. $H = 2\text{-}3$. $G = 2.45$. Slowly soluble in water. Biaxial (-); $Y \wedge b = 45^\circ$; $N_x = 1.720$, $N_y = 1.783$, $N_z = 1.842$; $2V = 85^\circ$. Occurs in sedimentary U–V deposits of the Colorado Plateau. *Bull Pen Canyon* and *Burro mine*, *San Miguel Co.*, *Club mine*, *Montrose Co.*, *Small Spot mine*, *Mesa Co.*, *CO*; *Yellow Cat district*, *Grand Co.*, *UT*. BM *DII:1053*, *CM 7:713(1963)*, *MM 49:140(1985)*.

47.1.1.2 Metarossite $\text{Ca}(\text{VO}_3)_2 \cdot 2\text{H}_2\text{O}$

Named in 1927 as the dehydration product of rossite. TRIC $P1$. $a = 6.215$, $b = 7.065$, $c = 7.769$, $\alpha = 92.58^\circ$, $\beta = 96.39^\circ$, $\gamma = 105.47^\circ$, $Z = 2$, $D = 2.80$. $29\text{-}392$: 7.69_4 6.77_6 5.93_{10} 5.03_6 3.84_2 3.10_2 3.04_5 2.52_3 . Powdery coatings and veinlets. Pale yellow color and streak, pearly to dull luster. Biaxial (+); $N_x = 1.840$, N_y , $N_z > 1.85$; $2V$ large. Occurrence and localities as for rossite. BM *DII:1054*, *CM 6:448(1960)*.

47.1.2.1 Delrioite $\text{CaSr}(\text{VO}_3)_2(\text{OH})_2 \cdot 3\text{H}_2\text{O}$

Named in 1959 for Andres M. del Rio (1764–1849), Mexican mineralogist, who discovered vanadium in 1801. MON I/a or $I2/a$. $a = 17.170$, $b = 7.081$, $c = 14.644$, $\beta = 102.48^\circ$, $Z = 8$, $D = 3.16$. $22\text{-}528$: 6.53_{10} 4.39_6 4.19_3 3.54_8 3.26_6 2.79_6 2.57_3 2.17_5 . Radial aggregates of acicular crystals. Pale yellow-green color and streak, vitreous to pearly luster. $H = 2$. $G = 3.1$. Biaxial (-); $N_x = 1.783$, $N_y = 1.834$, $N_z = 1.866$; $2V$ medium to large; pleochroic, colorless to yellow. As coatings on sandstone, *Jo Dandy mine*, *Montrose Co.*, *CO*. BM *AM 44:261(1959)*, *55:185(1970)*.

47.1.2.2 Metadelrioite $\text{CaSr}(\text{VO}_3)_2(\text{OH})_2 \cdot \text{H}_2\text{O}$

Named in 1970 as the dehydration product of delrioite. TRIC Space group probably $P\bar{1}$. $a = 7.343$, $b = 8.382$, $c = 5.117$, $\alpha = 119.65^\circ$, $\beta = 90.27^\circ$, $\gamma = 102.82^\circ$, $Z = 2$, $D = 4.52$. $22\text{-}600$: 4.94_{10} 4.73_6 3.46_{10} 2.68_6 2.55_5 2.52_5

1.89₅ 1.86₅. Fibrous crystals intergrown with delrioite. Pale yellow-green color and streak. $H = 2$. $G = 4.3$. *Jo Dandy mine, Montrose Co., CO*. BM AM 55:185(1970).

47.1.3.1 Munirite $\text{NaVO}_3 \cdot 2\text{H}_2\text{O}$

Named in 1983 for Munir A. Khan, chairman, Pakistan Atomic Energy Commission. MON $P2_1/a$. $a = 16.72$, $b = 3.636$, $c = 8.015$, $\beta = 111.0^\circ$, $Z = 4$, $D = 2.31$. 35-615: 7.85₁₀ 6.74₅ 4.13₇ 3.30₉ 2.98₇ 2.85₃ 2.68₈ 1.82₅. Radiating fibrous aggregates. Pearly white with a tinge of apple-green. $G = 2.43$. Biaxial (-); XYZ = *cab*; $N_x = 1.692$, $N_y = 1.756$, $N_z = 1.770$; $2V = 75^\circ$. *Bhimber area, Azad Kashmir, Pakistan, on sandstone*. BM MM 47:391(1983), 52:716(1988).

47.1.3.2 Metamunirite $\beta\text{-NaVO}_3$

Named in 1991 for its relationship to munirite. ORTH $Pnma$. $a = 14.134$, $b = 3.648$, $c = 5.357$, $Z = 4$, $D = 2.92$. 32-1198(syn): 7.09₁ 5.01₁₀ 3.53₃ 3.25₂ 3.02₁ 2.95₃ 2.68₁ 2.54₁. Microscopic colorless needles. Soft, friable. $G_{\text{syn}} = 2.877$. Biaxial (+); XYZ = *acb*; $N_x = 1.780$, $N_y = 1.800$, $N_z = 1.800$; $2V = 30\text{--}40^\circ$. *Burro mine, near Slick Rock, San Miguel Co., CO, in sandstone*. BM MM 55:509(1991).

47.2.1.1 Pascoite $\text{Ca}_3(\text{V}_{10}\text{O}_{28}) \cdot 17\text{H}_2\text{O}$

Named in 1914 for the locality. MON $C2$. $a = 16.834$, $b = 10.156$, $c = 10.921$, $\beta = 93.13^\circ$, $Z = 2$, $D = 2.46$. 21-171: 8.8₆ 7.3₇ 5.5₁₀ 5.1₈ 4.67₁₀ 4.45₆ 3.34₅ 3.01₇. Granular crusts. Orange, yellow streak, vitreous to subadamantine luster. Cleavage {010}, distinct; conchoidal fracture. $H = 2\frac{1}{2}$. $G = 1.87$. Biaxial (-); $X = b$; $N_x = 1.775$, $N_y = 1.815$, $N_z = 1.825$; $2V = 50^\circ$; $r > v$, very strong; pleochroic, X, pale yellow; Y, yellow; Z, orange. Soluble in water. Widely distributed in sedimentary U-V deposits of the Colorado Plateau. Paradox Valley, San Miguel Co., Rifle, Garfield Co., Uravan, Montrose Co., CO; Grants, Valencia Co., NM; Temple Rock, Emery Co., Mi Verde mine, San Juan Co., UT; *Minasragra, Pasco Prov., Peru*. BM DII:1055, AC(A) 70:21(1966).

47.2.2.1 Hummerite $\text{K}_2\text{Mg}_2(\text{V}_{10}\text{O}_{28}) \cdot 16\text{H}_2\text{O}$

Named in 1951 for the locality. TRIC $P1$. $a = 10.81$, $b = 11.01$, $c = 8.85$, $\alpha = 106.1^\circ$, $\beta = 107.8^\circ$, $\gamma = 65.67^\circ$, $Z = 2$, $D = 2.53$. 14-155: 9.3₃ 8.2₁₀ 7.4₇ 7.0₅ 3.31₄ 3.13₄ 2.73₆ 2.11₄. Platy crusts on sandstone. Orange, yellow streak, pearly to dull luster. $H = 2$. Biaxial (-); $N_y = 1.81$; strong dispersion. Soluble in water. *Hummer mine, Montrose Co., CO*; *Gold Quarry mine, Eureka Co., NV*. BM AM 36:326(1951), 40:315(1955).

47.2.3.1 Huemulite $\text{Na}_4\text{Mg}(\text{V}_{10}\text{O}_{28}) \cdot 24\text{H}_2\text{O}$

Named in 1966 for the locality. TRIC $P\bar{1}$. $a = 11.770$, $b = 11.838$, $c = 9.018$, $\alpha = 107.22^\circ$, $\beta = 112.17^\circ$, $\gamma = 101.5^\circ$, $Z = 2$, $D = 2.40$. 18-1225: 10.6₉, 10.2₅, 9.11₅, 8.20₄, 7.61₁₀, 3.79₂, 3.06₃, 2.88₄. Granular coatings on sandstone. Yellow to orange, yellow streak, dull luster. $H = 2\frac{1}{2}$ -3. $G = 2.39$. Biaxial (-); $N_x = 1.679$, $N_y = 1.734$, $N_z = 1.742$; $2V = 20$ -25°; $r > v$, strong; pleochroic, X, pale yellow; Y, golden yellow; Z, yellow-orange. Soluble in water. *Huemul mine, Mendoza Prov., Argentina*. BM AM 51:1(1966).

47.2.4.1 Sherwoodite $\text{Ca}_9\text{Al}_2\text{V}_{28}\text{O}_{80} \cdot 56\text{H}_2\text{O}$

Named in 1958 for Alexander M. Sherwood (b.1888), chemist, U.S. Geological Survey. TET $I4_1/amd$. $a = 28.06$, $c = 13.56$, $Z = 4$, $D = 2.58$. 11-191: 12.3₁₀, 10.0₁₀, 9.3₈, 7.8₄, 7.1₄, 4.65₅, 2.61₇, 2.10₇. Equant crystals and polycrystalline aggregates. Dark blue-black, pale blue streak, vitreous to earthy luster. Subconchoidal to uneven fracture. $H = 2$. $G = 2.8$. Uniaxial (-); $N_0 = 1.765$, $N_E = 1.735$; pleochroic. O, green; E, blue. Occurs in sandstone in many U-V mines in the Colorado Plateau. *Peanut mine, Montrose Co., Matchless mine, Mesa Co., Fall Creek mine, San Miguel Co., Shadyside mine, San Juan Co., CO; Wilson Mesa, Grand Co., UT; Cerro de Pasco, Peru*. BM AM 43:749(1958), 63:863(1978).

47.3.1.1 Hewettite $\text{CaV}_6\text{O}_{18} \cdot 9\text{H}_2\text{O}$

Named in 1914 for D. Foster Hewett (1881-1971), geologist, U.S. Geological Survey. MON $P2_1/m$. $a = 12.290$, $b = 3.590$, $c = 11.174$, $\beta = 97.24^\circ$, $Z = 1$, $D = 2.67$. 35-564: 11.03₁₀, 5.63₁, 5.53₄, 3.66₁, 3.35₁, 3.09₂, 2.57₁, 2.16₃. Microscopic needles and earthy aggregates. Deep red color and streak. Silky or dull luster. Soft. $G = 2.62$. Biaxial (-); $N_x = 1.77$, $N_y = 2.18$, $N_z = 2.35$; $2V = 55^\circ$; pleochroic, orange-yellow to dark red. Slightly soluble in water. Widely distributed in U-V deposits of the Colorado Plateau. *Hummer and Jo Dandy mines, Montrose Co., Laverick Mesa, Mesa Co., CO; Grants, Valencia Co., NM; Temple Rock, Emery Co., Polar Mesa, Red Co., Cactus Rat mine, Grand Co., UT; Monument Valley, AZ; Bloomington, Bear Lake Co., ID; Gold Quarry mine, Eureka, NV; Minasragra, Peru*. BM DII:1060, CM 27:181(1989), AM 75:508(1990).

47.3.1.2 Metaheawettite $\text{CaV}_6\text{O}_{18} \cdot 3\text{H}_2\text{O}$

Named in 1914 for its relationship to hewettite. MON $P2_1/m$. $a = 12.15$, $b = 3.590$, $c = 18.44$, $\beta = 118.03^\circ$, $Z = 2$, $D = 3.05$. 33-317: 8.19₁₀, 5.36₁, 3.58₃, 3.06₂, 2.81₃, 2.30₂, 2.21₂, 2.03₁. Powdery masses or coatings. Deep red color and streak, dull luster. Soft. $G = 2.94$. Biaxial (-); $Z = b$; $N_x = 1.70$, $N_y = 2.10$, $N_z = 2.23$; $2V = 52^\circ$; pleochroic, orange-yellow to dark red. Occurrence and localities as for hewettite. BM DII:1061, AM 75:513(1990).

47.3.1.3 Barnesite $\text{Na}_2\text{V}_6\text{O}_{16} \cdot 3\text{H}_2\text{O}$

Named in 1963 for William H. Barnes (b.1903), Canadian crystal chemist. MON $P2_1/m$. $a = 12.17$, $b = 3.602$, $c = 7.78$, $\beta = 95.03^\circ$, $Z = 1$, $D = 3.23$. 16-601: 12.2₃ 7.9₁₀ 3.70₁ 3.45₄ 3.12₇ 2.92₂ 2.27₃ 1.80₃. Microscopic fibrous to bladed crystals. Dark red color and streak, adamantine luster. Soft. $G = 3.15$. Biaxial (-); $Z = b$; $X \wedge c = 5^\circ$; $N_x = 1.797$, N_y , $N_z > 2.0$; pleochroic, X, yellow; Y, orange-yellow; Z, red. *Cactus Rat mine, Grand Co., UT*. BM AM 48:1187(1963), 75:514(1990).

47.3.1.4 Hendersonite $\text{Ca}_1\text{V}_6\text{O}_{16} \cdot 6\text{H}_2\text{O}$

Named in 1962 for Edward P. Henderson (1898–1992), chemist, U.S. National Museum, who described several new vanadium minerals. ORTH $Pnam$. $a = 12.40$, $b = 3.59$, $c = 18.92$, $Z = 1$, $D = 2.80$. 15-277: 9.43₁₀ 6.20₁ 5.18₁ 4.70₂ 3.79₁ 3.11₄ 2.31₁ 2.26₂. Microscopic bladed to fibrous crystals and veinlets in sandstone. Greenish black to black, pearly to subadamantine luster. $H = 2\frac{1}{2}$. $G = 2.78$. Biaxial (-); $N_x < 2.0$, N_y , $N_z > 2.10$; 2V medium; $r > v$, weak; moderately pleochroic, X, yellow-green; Y, green; Z, brown. *J. J. mine, Montrose Co., CO*; Eastside mine, San Juan Co., NM. BM AM 47:1252(1962), 75:514(1990).

47.3.1.5 Grantsite $(\text{Na,Ca})_2\text{V}_6\text{O}_{16} \cdot 4\text{H}_2\text{O}$

Named in 1964 for the locality. MON $C2/m$. $a = 12.429$, $b = 3.604$, $c = 17.542$, $\beta = 95.33^\circ$, $Z = 2$, $D = 2.95$. 16-408: 12.4₂ 8.74₁₀ 4.37₁ 3.61₃ 3.01₁ 2.87₁ 2.73₁ 2.28₁. Microscopic fibrous to bladed crystals. Dark olive-green to green-black, silky to subadamantine luster. Soft. $G = 2.94$. Biaxial (-); $N_x = 1.82$, N_y , $N_z > 2.0$; pleochroic, X, green; Y, green-brown; Z, brown. *F-33 mine, near Grants, NM*; Golden Cycle and La Salle mines, Montrose Co., CO; Parco 25 mine, Grand Co., UT. BM AM 49:1511(1964), 75:514(1990).

47.3.2.1 Straczekite $(\text{Ca,K,Ba})\text{V}_8\text{O}_{20} \cdot 3\text{H}_2\text{O}$

Named in 1984 for John A. Straczek (b.1914), U.S. geologist. MON $C2/m$. $a = 11.679$, $b = 3.661$, $c = 10.636$, $\beta = 100.53^\circ$, $Z = 1$, $D = 3.21$. 42-598: 10.45₅ 5.74₁ 3.49₁₀ 3.26₁ 2.49₁ 1.94₃ 1.83₅ 1.80₁. Microscopic fibrous crystals forming foliated masses. Greenish-black color and streak, greasy luster. Cleavage {100}, perfect. Very soft. $G = 3.19$. Biaxial (-); $N \sim 2.0$; 2V moderate to large; slightly pleochroic, green. *Union Carbide mine, Wilson Springs, AR*; Monument No. 2 mine, Apache Co., AZ. BM MM 48:289(1984), AM 75:515(1990).

47.3.2.2 Corvusite $(\text{Na,Ca,K})\text{V}_8\text{O}_{20} \cdot 4\text{H}_2\text{O}$

Named in 1933 from the Latin *corvus*, raven, in allusion to the color. MON $C2/m$. $a = 11.706$, $b = 3.644$, $c = 11.10$, $\beta = 103.46^\circ$, $Z = 1$, $D = 3.27$. AM 75: 10.82₁₀ 3.59₁ 3.46₂ 3.26₁ 2.90₁ 2.60₁ 1.93₁ 1.82₁. Fibrous veinlets and masses. Blue-black color and streak; silky to dull luster. $H = 2\frac{1}{2}$ –3.

$G = 2.82$. Widely distributed in U–V deposits of the Colorado Plateau. Ponto No. 3 claim, Gypsum Valley, San Miguel Co., and Hummer and Club mines, Montrose Co., CO; *Jack claim*, Grand Co., and Temple Rock, Emery Co, UT; Monument No. 2 mine, Apache Co., AZ. *BM DI:603*; *AM 44:331(1959)*, *75:516(1990)*; *CM 32:339(1994)*.

47.3.2.3 Fernandinite $(Ca,Na,K)V_8O_{20} \cdot 4H_2O$

Named in 1915 for Eulagio E. Fernadini, former owner of the Minasragra deposit. *MON C2/m*. $a = 11.680$, $b = 3.654$, $c = 11.023$, $\beta = 105.00^\circ$, $Z = 1$, $D = 3.07$. *AM 75: 10.68₁₀ 5.65₁ 3.55₁ 3.48₃ 2.83₁ 2.55₁ 1.95₁ 1.84₈*. Massive with flaky crystalline surfaces. Dark green color and streak, submetallic luster. Soft. $G = 2.78$. Biaxial; $N \sim 2.05$. *Minasragra, Peru*. *BM DII:1062*; *AM 75:516(1990)*, *CM 32:339(1994)*.

47.3.2.4 Bariandite $Al_{10}V_8O_{20} \cdot 9H_2O$

Named in 1971 for Pierre Bariand (b.1933), French mineralogist. *MON C2/c*. $a = 11.70$, $b = 3.63$, $c = 29.06$, $\beta = 101.50^\circ$, $Z = 2$, $D = 2.50$. *25-1006: 14.2₁₀ 7.08₅ 5.72₇ 3.48₈ 3.43₈ 2.85₇ 1.94₇ 1.83₇*. Small fibrous crystals. Black, black streak. Cleavage {001}, perfect. $G = 2.7$. $N > 1.85$; strongly pleochroic, brown-gray. *Mounana, Gabon*, in U–V deposit in sandstone. *BM 94:49(1971)*, *MR 6:239(1975)*, *AM 75:517(1990)*.

47.3.2.5 Bokite $(Al,Fe)_{13}(V,Fe)_8O_{20} \cdot 4.7H_2O$

Named in 1963 for Ivan I. Bok (b.1898), Kazakh mineralogist. *MON C2/m*. $a = 11.85$, $b = 3.650$, $c = 11.11$, $\beta = 110.6^\circ$, $Z = 1$. *AM 75: 10.47₁₀ 3.45₃ 3.18₁ 2.91₁ 2.76₁ 2.59₁ 1.97₁ 1.82₁*. Reniform crusts with radiating fibrous structure. Black, black streak, submetallic to dull luster. One perfect cleavage. $H \sim 3$. $G = 2.97$ – 3.10 . Biaxial; $N_x = 2.01$, $N_z = 2.06$; strongly pleochroic, dirty olive to deep red-brown. Union Carbide mine, Wilson Springs, Garland Co., AR; Monument No. 2 mine, Apache Co., AZ; *Kurumsak area, Kazakhstan*. *BM ZVMO 92:51(1963)*; *AM 48:1180(1963)*, *75:517(1990)*.

47.3.2.6 Kazakhstanite $Fe_5V_{15}O_{39} \cdot 8.5H_2O$

Named in 1989 for the locality. *MON C2/m*. $a = 11.84$, $b = 3.650$, $c = 21.27$, $\beta = 100.0^\circ$, $Z = 1$, $D = 3.52$. *ZVMO 118: 10.51₁₀ 3.48₆ 3.18₂ 2.92₃ 2.76₃ 2.61₄ 2.10₂ 1.97₂*. Microscopic grains in veinlets and aggregates. Black, black streak, adamantine to dull luster. Cleavage {001}, perfect. $H = 2\frac{1}{2}$. $G = 3.4$ – 3.6 . Gold Quarry mine, Eureka Co., NV; *Northwestern Karatau, Kazakhstan*, in black shale. *BM ZVMO 118(5):95(1989)*, *AM 76:667(1991)*.

47.3.3.1 Schubnelite $Fe_2V_2O_4(OH)_4$

Named in 1970 for Henri J. Schubnel (b.1935), French mineralogist. *TRIC P1*. $a = 6.59$, $b = 5.43$, $c = 6.62$, $\alpha = 125^\circ$, $\beta = 104^\circ$, $\gamma = 84.72^\circ$, $Z = 1$, $D = 3.34$. *24-542: 6.41₈ 5.15₉ 4.47₁₀ 3.21₁₀ 3.19₉ 3.07₈ 2.73₅ 2.68₆*. Small crystalline

aggregates. Black, brown streak, adamantine luster. Soft. $G = 3.28$. Gold Quarry mine, Eureka Co., NV; *Mounana, Gabon*, on sandstone. BM *BM 93:470(1970)*, *AM 75:518(1990)*.

47.3.4.1 Fervanite $\text{Fe}_4\text{V}_4\text{O}_{16} \cdot 5\text{H}_2\text{O}$

Named in 1931 for its composition. MON Space group unknown. $a = 9.02$, $c = 6.65$, $\beta = 103.33^\circ$. *27-257*: 8.79₁₀ 6.45₉ 3.29₂ 3.22₈ 3.15₇ 2.99₅ 2.93₅ 2.91₂. Fibrous aggregates. Golden brown, adamantine luster. Biaxial (-); $N_x = 2.186$, $N_y = 2.222$, $N_z = 2.224$; 2V very small. Widely distributed in the U-V deposits of the Colorado Plateau. Wilson Springs, Garland Co., AR; Gypsum Valley, San Miguel Co., and Hummer mine, Montrose Co., CO; *Polar Mesa, Grand Co., UT*; Gold Quarry mine, Eureka Co., NV; *Mounana, Gabon*. BM *DII:1049*; *AM 44:336(1959)*, *75:518(1990)*.

47.3.5.1 Bannermanite $\text{Na}_0.7\text{V}_6\text{O}_{15}$

Named in 1983 for Harold M. Bannerman (1897-1976), U.S. economic geologist. MON *C2/m*. $a = 15.413$, $b = 3.615$, $c = 10.066$, $\beta = 109.29^\circ$, $Z = 2$, $D = 3.55$. *24-1155(syn)*: 9.49₈ 7.25₁₀ 4.75₆ 3.38₉ 3.20₇ 3.07₇ 2.92₆ 1.81₇. Microscopic lathlike crystals. Black, gray-black streak, submetallic luster. Cleavage {100}, perfect; {010}, fair; brittle. $G = 3.5$. Biaxial; $N_{\text{mean}} = 2.2$. *Izalco volcano, El Salvador*, in fumaroles. BM *AM 68:634(1983)*, *75:519(1990)*.

47.3.6.1 Melanovanadite $\text{CaV}_4\text{O}_{10} \cdot 5\text{H}_2\text{O}$

Named in 1921 for its color and composition. TRIC *P1*. $a = 6.360$, $b = 18.090$, $c = 6.276$, $\alpha = 110.18^\circ$, $\beta = 101.62^\circ$, $\gamma = 82.86^\circ$, $Z = 2$, $D = 2.53$. *39-321*: 8.4₁₀ 4.21₆ 4.12₄ 3.18₄ 3.11₅ 3.01₄ 2.97₅ 2.47₅. Prismatic crystals 1-2 mm. Black, dark red-brown streak; submetallic luster. Cleavage {010}, perfect; brittle. $H = 2\frac{1}{2}$. $G = 2.55$. Biaxial (-); $Z = b$; $Y \wedge c = 15^\circ$; $N_x = 1.73$, $N_y = 1.96$, $N_z = 1.98$; 2V medium; pleochroic, red-brown. Peanut mine, Montrose Co., CO; *Minasraga, Peru*. BM *DII:1058*, *AM 72:637(1987)*.

47.4.1.1 Satpaevite $\text{Al}_2\text{V}_8\text{O}_{37} \cdot 30\text{H}_2\text{O}$

Named in 1959 for Kanysh I. Satpaev (1899-1964), Kazakh geologist. Probably ORTH Space group unknown. *13-476*: 5.87₆ 3.91₇ 2.50₄ 2.37₉ 1.93₁₀ 1.55₆ 1.47₈ 1.27₄. Foliated masses and granular aggregates. Yellow, yellow streak, pearly to dull luster. Perfect pinacoidal cleavage. $H = 1\frac{1}{2}$. $G = 2.4$. Biaxial (+); $N_x = 1.676$, $N_y = 1.681$, $N_z = 1.690$; 2V near 70° ; weakly pleochroic. *Kurumsak, Kara-Tau, Kazakhstan*. BM *ZVMO 88(2):157(1959)*, *AM 44:1325(1959)*.

47.4.2.1 Vanalite $\text{NaAl}_3\text{V}_{10}\text{O}_{38} \cdot 30\text{H}_2\text{O}$

Named in 1962 for the composition. MON *P2/m*. $a = 12.616$, $b = 10.673$, $c = 10.923$, $\beta = 95.22^\circ$, $Z = 1$, $D = 2.15$. *25-782*: 10.7₁₀ 8.52₄ 7.90₄ 6.33₃ 5.34₃ 3.31₃ 3.12₂ 2.25₃. Microscopic wedge-shaped crystals. Yellow, yellow

streak, waxy to vitreous luster. $G = 2.3-2.4$. Biaxial; $N_x = 1.710$, $N_z = 1.735$; weakly pleochroic, yellow. *Kara-Tau, Kazakhstan*. BM *ZVMO 91:307(1962)*; *AM 48:1180(1963)*, *57:597(1972)*.

47.4.3.1 Pintadoite $\text{Ca}_2\text{V}_2\text{O}_7 \cdot 9\text{H}_2\text{O}$

Named in 1914 for the locality. Space group unknown. Thin coatings on sandstone. Yellow-green color and streak. Weakly pleochroic, yellow-green; moderately to highly birefringent. *Canyon Pintado, San Juan Co.*, and Temple Rock, Emery Co., *UT*; Bull Canyon, San Miguel Co., *CO*. BM *DII:1053*.

47.4.4.1 Rauvite $\text{Ca}(\text{UO}_2)_2(\text{V}_{12}\text{O}_{32}) \cdot 16\text{H}_2\text{O}$

Named in 1922 for its constituent elements: Ra, U, and V. Space group unknown. *8-288*: 10.7₁₀ 5.83₁ 3.87₂ 3.49₄ 2.95₅ 2.62₃ 2.22₁ 2.10₁. Dense masses and botryoidal crusts. Purple-black to blue-black, olive to yellow-brown streak. Biaxial (-); $N_{\text{mean}} = 1.88$. *Temple Rock, Emery Co., UT*. BM *DII:1058*.

47.4.5.1 Uvanite $\text{U}_2\text{V}_6\text{O}_{21} \cdot 15\text{H}_2\text{O}$

Named in 1914 for the composition. Space group unknown. *8-322*: 5.9₆ 4.6₄ 2.94₁₀ 2.24₈ 1.71₉ 1.64₄ 1.48₇ 1.12₄. Minutely crystalline masses and coatings. Yellow-brown. Two pinacoidal cleavages. Biaxial (+); $N_x = 1.817$, $N_y = 1.879$, $N_z = 2.057$; $2V = 52^\circ$; pleochroic. X, light brown; Y, dark brown; Z, yellow-green. *Temple Rock, Emery Co., UT*. BM *DII:1056*.

47.4.6.1 Vanoxite $\text{V}_6\text{O}_{13} \cdot 8\text{H}_2\text{O}$

Named in 1925 for the composition. No X-ray data. Fine-grained in sandstone. Black. *Jo Dandy claim, Montrose Co.*, and Small Spot mine, Mesa Co., *CO*. BM *DI:601*.

47.4.7.1 Doloresite $\text{H}_8\text{V}_6\text{O}_{16}$

Named in 1957 for the locality. *MON C2/m*. $a = 19.07$, $b = 2.99$, $c = 4.83$, $\beta = 90.3^\circ$, $Z = 1$, $D = 3.44$. *11-368*: 4.7₁₀ 3.83₅ 3.16₄ 2.98₂ 2.45₅ 1.93₃ 1.80₂ 1.73₁. Radiating fibrous crystals. Black, green-black streak, submetallic luster. Lamellar twinning, twin plane {100}. $G = 3.27-3.33$. Biaxial; $N_{\text{mean}} = 1.90$; pleochroic, yellow-red to red-brown. Occurs in U-V deposits of the Colorado Plateau. *Dolores R., Montrose Co.*, and Black Mama and other mines in Mesa Co., *CO*; Section 33 mine, Grants, Valencia Co., *NM*; Mi Vida mine, San Juan Co., *UT*; Monument No. 2 mine, Apache Co., *AZ*. BM *AM 42:587(1957)*, *45:1144(1960)*; *ZK 116:482(1961)*.

47.4.8.1 Simplotite $\text{CaV}_4\text{O}_9 \cdot 5\text{H}_2\text{O}$

Named in 1958 for Jack R. Simplot (b.1909) of the Simplot Mining Co., Boise, Idaho. *MON A2/m*. $a = 8.39$, $b = 17.02$, $c = 8.37$, $\beta = 90.42^\circ$, $Z = 4$, $D = 2.66$. *11-267*: 8.51₁₀ 4.26₁ 3.42₁ 3.14₂ 2.84₁ 2.62₃ 2.52₁ 1.88₁. Micaceous plates and hemispherical aggregates. Dark green, brown-black streak, vitreous luster.

Cleavage {010}, perfect. $H = 1$. $G = 2.64$. Biaxial (-); $X = b$; $Z \wedge c = 58^\circ$; $N_x = 1.705$, $N_y = 1.767$, $N_z = 1.769$; $2V = 25^\circ$; $r > v$, weak; pleochroic, X, yellow; Y,Z, green. *Sundown Claim, San Miguel Co.*, and *Peanut and J. J. mines, Montrose Co., CO*; *Vanadium Queen mine, San Juan Co., UT*. *BM AM 43:16(1958)*.

Anhydrous Molybdates and Tungstates

WOLFRAMITE GROUP

The wolframite group consists of isostructural minerals of the general formula

where

A = Mn, Fe, Zn

and the structure is in $P2/c$.

For example, the structure of ferberite, the principal member of the group, is based on W and Fe octahedra forming infinite zig-zag chains in the c axis direction. Each chain contains just one type of cation, and each octahedron is joined to the next by a common edge. Each W-octahedral chain is attached by common corners to 4 Fe chains, and each Fe chain is also surrounded by 4 W chains.

A complete solid-solution series exists between ferberite and hübnerite. Wolframite was originally considered a species name and referred to intermediate members of that series. Wolframite has been dropped as a species name but is still widely used in commerce to refer to tungsten ores and concentrates containing principally ferberite-hübnerite mineral, normally Fe rich. The nearly pure Mn end member is comparatively uncommon. Zincian members are rare, and sanmartinite has been found at only one location. Mo does not substitute for W in the structure. *ZK 127:61(1968), 144:238(1976)*.

WOLFRAMITE GROUP

Mineral	Formula	Space Group	Space					D
			a	b	c	β	D	
Hübnerite	MnWO ₄	P2/c	4.829	5.759	4.998		7.234	48.1.1.1
Ferberite	FeWO ₄	P2/c	4.72	5.70	4.96	90	7.55	48.1.1.2
Sanmartinite	(Zn,Fe)WO ₄	P2/c	4.691	5.720	4.925		7.87	48.1.2.1

48.1.1.1 Hübnerite MnWO₄

Named in 1865 for Adolph Hübner, German mining engineer of Freiberg, Saxony, who first analyzed the mineral. Wolframite group. *MON P2/c*.

HEUBNERITE: $MnWO_4$

Heubnerite contains hexagonal closest-packed layers of oxygen stacked on (100), with all cations in octahedral interstices. Double chains of W and Mn edge-sharing octahedra are parallel to the c axis.

$a = 4.829$, $b = 5.759$, $c = 4.998$, $Z = 2$, $D = 7.234$. *NBSM 25(2):24(1963)*. *13-434(syn)*: 4.84_6 3.78_6 3.70_5 3.00_{10} 2.95_9 2.88_3 2.50_5 1.73_3 . Commonly prismatic to long prismatic [001], and flattened or tabular {100}. Usually striated [001]. As groups of parallel or subparallel crystals, or as radiating groups. Twins common on {100} as contact twins. Reddish brown, yellow to reddish-brown streak, submetallic–adamantine to resinous luster. Cleavage {010}, perfect; irregular fracture. $H = 4-4\frac{1}{2}$. $G = 7.12$. Near end member hübnerite is non-magnetic. Biaxial (+); $X = b$; $Z \wedge c = 17-21^\circ$; $N_x = 2.17$, $N_y = 2.22$, $N_z = 2.32$. $2V_{calc} = 73^\circ$. X, bright yellow to orange-red; Y, greenish yellow to orange-red; Z, olive-green to brick-red. In RL, gray-white, weakly anisotropic, weakly pleochroic. Strong internal reflections, red-brown to yellow. $R = 17.9$, 14.85 (470 nm); 16.6 , 13.9 (546 nm); 16.25 , 13.65 (589 nm); 15.95 , 13.45 (650 nm). *P&J:394*. Hübnerite is most commonly found in mesothermal veins, occasionally in epithermal ones, associated with pyrite, other sulfides, rhodochrosite, fluorite, and quartz. *Erie and Enterprise veins, Ellsworth, Mammoth District, NV*. Adams mine, San Juan Co., CO(!), in good crystals. Blue Wing district, Lehmi Co., ID. Little Dragoon Mts., Cochise Co., AZ, with scheelite and fluorite. In spectacular crystals and groups with quartz crystals from the Pasto Bueno mine(!), Ancash Dept., Peru. An ore of tungsten. *RG DII:1064; ZK 125:120(1967), 144:238(1976); NJMA 113:13(1970); NJMM:477(1976)*.

48.1.1.2 Ferberite $FeWO_4$

Named in 1863 for Moritz Rudolph Ferber (1805–1875), German factory owner, amateur mineralogist, and benefactor, in Gera. Wolframite group. *MON P2/c*. $a = 4.72$, $b = 5.70$, $c = 4.96$, $\beta = 90^\circ$, $Z = 2$, $D = 7.55$. *ZK 127:61(1978)*. *21-436*: 4.69_8 3.75_6 3.65_5 2.94_{10} 2.476_6 2.470_6 2.195_5 2.189_5 .

Wolframite. Bolivia.

Wolframite. Bolivia.
Twin on {100}.**Ferberite**

Forms: $a\{100\}$, $b\{010\}$, $c\{001\}$, $r\{120\}$, $m\{110\}$, $l\{210\}$, $f\{011\}$, $y\{\bar{1}02\}$, $\omega\{111\}$, $\Delta\{112\}$, $t\{102\}$, $q\{830\}$,

Habit: Crystals commonly elongated [010] and flattened {100}. Usually striated [001], with {001} often striated [010]. Crystals often have a wedge-shaped appearance; groups of bladed crystals. Also forms excellent pseudomorphs after scheelite ("reinite"). Twins on {100} common, usually as simple contact twins; also as interpenetration twins. Twin plane {023} also common.

Physical properties: Black, black to brownish-black streak, submetallic/adamantine luster. Cleavage {010}, perfect; uneven fracture; brittle. $H = 4-4\frac{1}{2}$. $G = 7.51$. Weakly magnetic. Tests: Easily fusible. Slowly decomposed by hot concentrated H_2SO_4 or HCl; decomposed by aqua regia with separation of tungstic oxide. **Chemistry:** A complete solid-solution series exists between ferberite and hübnerite; in most commercial deposits, the mineral is an intermediate member of the series, which would formerly have been called wolframite. On the other hand, zincian members are rare and sanmartinite has been found at only one location. Mo does not substitute for W in the structure. **Optics:** $N \approx 2.40$; $X = b$; $Z \wedge c = 17-21^\circ$; pleochroic. X, red-brown; Y, red-brown; Z, red brown-black. In RL, gray-white, similar to sphalerite, with brownish-red internal reflections and weak pleochroism. $R = 18.6, 16.05$ (470 nm); 18.7, 16.0 (546 nm); 18.6, 15.8 (589 nm); 18.5, 15.55 (650 nm). *P&J.393*. **Occurrence:** Ferberite-hübnerite deposits are found in greisen or quartz-rich veins and pegmatites immediately associated with granitic intrusive rocks; in high-temperature hydrothermal ("hypothermal") veins, associated with cassiterite, arsenopyrite, apatite, tourmaline, topaz, fluorite, specular hematite, molybdenite, and bismuth; in mesothermal veins, with cassiterite and sulfides, scheelite, bismuthinite, and siderite. **Localities:** Ferberite was formerly mined in the Nederland district, Boulder Co., CO(*), where it was found in finely crystallized druses in mesothermal veins. Cave Creek district, Maricopa Co., AZ. Elizabethtown district, Colfax Co., NM. At several mines in the Black Hills, SD. It was first observed in quartz veins near *Aguilas, Sierra Almagrera, Spain*. Large deposits, often beautifully crystallized, are mined at Panasqueira, Beira Baixa, Portugal(!), associated with arsenopyrite, apatite, schorl, and quartz. In Germany at Schneeberg and Zinnwald, Saxony. Horni Slavkov, Bohemia, Czech Republic. Cornwall, England, with tourmaline in cassiterite veins. Baia Sprie, Romania(*), in good

crystals. Tae Hwa mine, Neung Am Ri, Chung Chong northern Prov., South Korea(1), and other localities on the Korean peninsula. Large numbers of rich veins are mined in Hunan and Jiangxi, China. In Bolivia at Calacalani, Colquiri(1), and with cassiterite at Viloco, near La Paz. Pseudomorphs after scheelite ("reinite") were found at Trumbull, CT, and at the Otome mine, Yamanashi Prov., Honshu, Japan(1); also in the Central African tungsten belt, especially at Gifurwe and elsewhere in Rwanda(1). Use: The principal ore of tungsten. RG *DII:1064*, *GSAM 85:223(1962)*, *NJMA 113:13(1970)*, *MR 8:393(1977)*.

48.1.1.3 Sanmartinite $(\text{Zn,Fe})\text{WO}_4$

Named in 1948 for the locality. Wolframite group. MON *P2/c*. $a = 4.691$, $b = 5.720$, $c = 4.925$, $Z = 2$, $D = 7.87$. *NSBM 25(2):40(1963)*. *15-774(syn)*: 4.69_4 3.73_4 3.62_4 2.93_{10} 2.91_9 2.86_3 2.472_4 2.464_4 . Fine-grained masses; microscopic crystals, tabular {001}. Dark brown; brownish black, resinous luster. Cleavage {010}, perfect. $G = 6.70$. FeO and MnO enter the composition to the observed extent of about 8% and 1%, respectively. Found only at *Los Cerillos, SW of San Martin, San Luis, Argentina*, in a quartz vein, as an alteration of scheelite, associated with willemite. RG *DII:1072*, *AM 33:653(1948)*, *MM 42:281(1978)*.

48.1.2.1 Scheelite CaWO_4

Named in 1821 for Karl Wilhelm Scheele (1742–1786), Swedish chemist and co-discoverer (with Priestley) of oxygen, who proved that scheelite contains tungstic oxide. TET *I4₁/a*. $a = 5.242$, $c = 11.372$, $Z = 4$, $D = 6.120$. *NBSC 539(6):23(1956)*. **Structure:** In scheelite, Ca and W form a tetragonal framework. This framework can be said to be constructed of two cubes resting one on the other. The base of the bottom cube consists of four Ca atoms at the corners and one W atom at the center; at the centers of two opposite side faces there are Ca atoms, and of the other two side faces, W atoms. The top of the bottom cube consists of four W atoms at the corners and one Ca atom at the center; this also constitutes the base of the upper cube. The upper cube is a

Scheelite

Forms: $o\{102\}$, $e\{101\}$, $\beta\{113\}$, $p\{111\}$, $k\{515\}$, $h\{313\}$, $s\{131\}$

SCHEELITE: CaWO_4

Ca atoms and WO_4 tetrahedra strictly alternate in the $[110]$ directions, but form interrupted chains in the c direction.

mirror image of the bottom cube, except rotated 90° with respect to the side face atoms. The W atoms are in tetrahedral coordination with oxygen atoms, the tetrahedra being considerably flattened in the direction of c . *DJ(1959)*, *SR 29:331(1964)*. *41-1431(syn)*: 4.77₈ 3.11₁₀ 3.07₃ 2.84₄ 2.62₂ 2.30₂ 1.928₄ 1.688₂. **Habit:** Crystals usually bipyramidal $\{011\}$ or $\{112\}$. As discrete grains; massive. Twinning on $\{110\}$ common, as penetration, or, less often, contact twins; composition plane $\{110\}$ or $\{001\}$. **Physical properties:** White, colorless, yellow, pale green, orange, and so on; white streak; vitreous/adamantine luster. Cleavage $\{101\}$, distinct; $\{112\}$, interrupted; uneven to subconchoidal fracture. $H = 4\frac{1}{2}$ -5. $G = 6.10$. Fluoresces bright blue-white under SWUV when nearly pure CaWO_4 ; the presence of even small amounts of Mo substituting for W causes the fluorescence to become yellowish, up to about 2% when the fluorescence is pure yellowish white. Above 2% Mo there is no further change in color. Thermoluminescent. **Tests:** Decomposed by HCl or HNO_3 leaving a yellow powder of hydrous tungstic oxide which is soluble in ammonia. Fusible with difficulty. **Chemistry:** A partial solid-solution series exists between scheelite and powellite, but natural material with over 4 mol % MoO_3 is not known; some older analyses show higher MoO_3 but it is not certain that only one phase was present. Nevertheless, synthetic scheelites and powellites have been prepared having a broad range of substitution, and it is probable that a complete series exists synthetically. **Optics:** Uniaxial (+); $N_O = 1.918$, $N_E = 1.935$. **Occurrence:** Scheelite is typically found in contact metamorphic deposits, especially where granitic rocks have been intruded into limestones with the formation of skarn or tectite associated with grossular, andradite, wollastonite, diopside, tremolite, vesuvianite, chalcopyrite, epidote, quartz,

pyrite, and so on. Also in high-temperature vein deposits associated with wolframite, tourmaline, apatite, fluorite, cassiterite, and arsenopyrite. Also, rarely, in certain pegmatites. Present in small amounts in some mesothermal to epithermal veins with quartz and sulfides. Alters to cuprotungstite, antho-nite, and other secondary tungsten minerals. Localities: Long Hill, near Trum-bull, CT. Many deposits have been mined in the western states, some of large size: near Bishop, Inyo Co., and at Atolia, San Bernardino Co., CA, in epither-mal veins. In NV near Mill City; at Silver Dyke near Mina, and in pegmatite with beryl, fluorite, oligoclase, and phlogopite. In AZ at the Cohen tungsten mine, E of Wilcox, Cochise Co.(1), in light brown to orange crystals up to 7 kg, and many other places in AZ. Camp Bird mine, Ouray, CO(1), in fine crystals. In a large, high-grade deposit at Canada Tungsten, Flat River valley, NWT. Well crystallized from Los Gavilanes, BCN, Mexico. *Gregers klack, Bispsberg iron mine, Säter, Dalarme, Sweden*. Estepona, Malaga, Spain(1), gemmy orange crystals to 5 cm. Knappenwand, Untersulzbachtal, Austria(1), color-less crystals with epidote. In Switzerland at Val Giuv, Tavetsch, Grisons(*), and at Kammegg, Guttannen, Uri(1), crystals to 10 cm. In Germany in fine specimens from Zinnwald, Saxony(1), and similarly from Cinovec, Bohemia, Czech Republic. Felbertal, Austria. In Italy in large fine crystals in serpentine from Traversella, Piedmont(1). At Tae Wha, Korea, in magnificent sharp brown crystals(1) up to 1 kg, associated with quartz, wolframite, and bertran-dite. From Sichuan, China(1), in rich orange crystals to 10 cm with “goshe-nite” (colorless beryl) crystals, muscovite, and quartz. Gifurve, Rwanda, and elsewhere in the Central African tungsten belt, in large crystals often pseudo-morphously altered to ferberite (“reinite”). In Brazil in large metasomatic deposits at Currais Novos, RGN, and in a hypothermal gold vein, the Morro Velho mine, Nova Lima, MG(1), in sharp orange-red crystals asso-ciated with pink apatite, pyrrhotite, siderite, dolomite, and quartz. Use: An important ore of tungsten. RG *DII:1074, AM 37:719(1952), JCP 40:504(1964)*.

48.1.2.2 Powellite CaMoO_4

Named in 1891 for John Wesley Powell (1834–1902), American explorer and geologist. TET $I4_1/a$. $a = 5.226$, $c = 11.430$, $Z = 4$, $D = 4.255$. NBSC *539(6):22(1956)*. *29-351(syn)*: 4.76_3 3.10_{10} 2.86_1 2.61_2 1.929_3 1.848_1 1.694_1 1.588_2 . Crystals pyramidal {111}; more rarely tabular {001}; also massive, with foliated structure pseudomorphous after molybdenite. White, yellow, brown, gray; subadamantine to greasy luster. Indistinct cleavage, uneven fracture. $H = 3\frac{1}{2}$. $G = 4.27$. G increases markedly with increase in W con-tent. Fluoresces creamy yellow in both SWUV and LWUV. Decomposed by HCl and HNO_3 . W may substitute for Mo up to $Mo/W = 9:1$, but a complete series to CaWO_4 does not exist in natural material. Uniaxial (+); $N_O = 1.967$, $N_E = 1.978$. Powellite is usually a secondary mineral, often formed by the alteration of molybdenite. Also sometimes formed in low-temperature hydro-thermal environments, as with zeolites in vugs in basalt or in some low-tem-

perature copper or mercury mines. More rarely formed in skarns and contact metamorphic environments with scheelite. *Peacock lode, Seven Devils district, Adams Co., ID.* In vugs in altered rhyolite at the Tonopah Divide mine, Nye Co., NV. South Hecla and Isle Royale mines, Houghton Co., MI, with native copper and epidote. Pine Creek tungsten mine, Inyo Co., CA. Huahuaxtla mercury mine, GRO, Mexico. In metasomatic deposits with scheelite and molybdenite in the Nuratinsky range, Uzbekistan. In India in vugs in trap-rock quarried on Pandulena Hill near Nasik, Maharashtra(!), with apophyllite and zeolites, forming magnificent clear sharp yellow-orange crystals up to 6 cm. In Chile at Tierra Amarilla, Atacama, in green crusts resembling smithsonite, with szenicsite. RG *DII:1079, SPC 13:414(1968)*.

48.1.3.1 Wulfenite PbMoO_4

Named in 1841 for Franz Xavier Wulfen (1728–1805), Austro-Hungarian Jesuit and mineralogist, who wrote a monograph on the lead ores of Carinthia. TET $I4_1/a$. $a = 5.435$, $c = 12.11$, $Z = 4$, $D = 6.815$. NBSC *539(7):23(1957)*. Structure: ZK *121:158(1965)*. *44-1486(syn)*: 4.96_1 3.25_{10} 3.03_2 2.72_2 2.02_2 1.921_1 1.787_1 1.653_2 . Crystals commonly square tabular {001}, often very thin, or with a flat vicinal pyramid replacing {001}; less frequently pseudo-octahedral; rarely cuboidal or short prismatic pyramidal. Sometimes shows hemimorphic habit, possibly due to twinning. Twinning on [001], common but rarely evident through the usual morphology. AM *40:857(1955)*. Also massive, granular. Yellow, orange, red, gray, brown, blue, and so on, with subadamantine to greasy luster. Cleavage {011}, distinct; {001}, {013}, indistinct; subconchoidal to uneven fracture; not very brittle. $H = 2\frac{1}{2}$. $G = 6.7-7.0$. W substitutes for Mo, with W/Mo up to at least 1:1, indicating at least a partial solid-solution series with stolzite; however, most wulfenites have only traces of W. Ca substitutes for Pb, and a partial series exists with the isostructural mineral powellite. Small amounts of V, Cr, and As may also (rarely) substitute for Mo. Uniaxial (-); $N_O = 2.405$, $N_E = 2.283$. Wulfenite is a secondary mineral found in the oxide zone of deposits of Pb- and Mo-containing minerals. When mined to the primary zone, some wulfenite deposits have shown no obvious primary Mo-containing mineral, and in these cases the Mo is thought to have been introduced by laterally moving supergene solutions that have leached traces of Mo out of the surrounding formations. Common associated minerals are mimetite, cerussite, pyromorphite, vanadinite, goethite, and manganese oxides. Found in many places in the United States: Loudville mines, MA; Wheatley mine, Phoenixville, PA; Sheman tunnel, Leadville, CO; in NM at the Stephenson–Bennett mine, Dona Ana Co.(!), and in the Hillsboro district, Sierra Co.(*); especially in AZ, where in Santa Cruz Co. it is found in spectacular large thin plates, some crystals measuring > 10 cm on edge, at the Glove mine(!), Tyndall district, and in the Palmetto district, Patagonia Mts.; in Pinal Co. abundant at the Mammoth–St Anthony mine(!), and at the Florence mine; in Yuma Co. at the Red Cloud mine(!), in large brilliant orange-red

crystals considered by many to be the world's finest, and at the Melissa mine(*); in Pima Co. at the Old Yuma mine(!) and the Total Wreck mine; in Cochise Co. in the Turquoise district, at the Silver Bill/mystery tunnel(*), Gleeson(!), in the Tombstone district(!), and at the Hilltop mine(!); in Gila Co. at the 79 mine(!) and in the Castle Dome district(*); and in Maricopa Co. at the Rowley mine(!). In UT in the Lucin district, Box Elder Co. Many localities in Mexico, especially in CHIH at Los Lamentos(!), in large toffee-colored thick square plates, at the San Carlos mine(!), at San Pedro Corralitos(!), and at the La Aurora mine, Cuchillo Parado; in SON at Cerro Prieto (= San Francisco mine), Magdalena(!), in large yellow crystals with orange-red mimetite, and at Cucurpe; and in DGO at the Ojuela mine(!), Mapimi. *Bleiberg*(!) and *Schwarzenbach*(!), *Carinthia*, *Austria*. In Slovenia at Crna(!), often twinned; and at Mezica(!)(= Mies). Příbram, Bohemia, Czech Republic. In Iran at the Tchah Mille, Tchah-Kharboze (near Anarak)(*) in fine red-orange crystals, Nakhlak, and Seh-Changi mines. Gansu Province, China, in thick dark red crystals. In Morocco at Les Dalles mine(!), Mibladen, and the Zelidja mine(!), Touissit. In Zaire at M'Fouati(!), and at Musonoi mine, Shaba. Broken Hill mine, Zambia. Tsumeb mine(!), Namibia, sometimes highly tungstenian and in a wide variety of habits and colors. In Australia at the Junction mine, Broken Hill, NSW, and a tungstenian variety ("chillagite") at the Christmas Gift mine. Use: A minor ore of lead, of decreasing importance, as it is found only in the now depleted zones of oxidation. RG *DII:1081*, *AM 51:1212(1966)*.

48.1.3.2 Stolzite PbWO_4

Named in 1845 for Joseph Alexis Stolz (1803–1896) of Teplice, Bohemia, who first drew attention to the species. Dimorphous with raspite. TET $I4_1/a$. $a = 5.462$, $c = 12.049$, $Z = 4$, $D = 8.408$. *NBSM 25(5):34(1967)*. 19-708: 3.25₁₀ 3.01₂ 2.73₃ 2.02₄ 1.931₂ 1.782₂ 1.661₄ 1.626₂. Usually pyramidal with {111} or {101}; also thick tabular {001}; infrequently prismatic. Reddish brown, yellow, red, brown, green; uncolored streak; resinous to subadamantine luster. Cleavage {001}, imperfect; {011}, indistinct; conchoidal to uneven fracture; brittle. $H = 2\frac{1}{2}$ -3. $G = 8.34$. Soluble in HCl with separation of yellow tungstic acid. Natural stolzites usually show little substitution of Mo for W. There is a partial solid-solution series from about W/Mo 1:1 to pure wulfenite, and stolzite from the Lost Gulch area, Globe District, Gila Co., AZ, contains about 9% MoO_3 , indicating that a complete series may exist. *AM 43:156(1958)*. Uniaxial (-); $N_O = 2.269$, $N_E = 2.182$ (Na). Manhan lead mine, Southampton, MA. Wheatley mine, Phoenixville, PA. Boerich claims, Dragoon Mts., and at the Reef mine, Huachuca Mts., Cochise Co., AZ. Cariboo district, BC, Canada, with scheelite and ferritungstite. *Cínovec* (*Zinnwald*), *Krusné Hory* (*Erzgebirge*), *Cechy* (*Bohemia*), *Czech Republic*. Brandy Gill lead mine, Carrock Fell, Cumberland, England. Mine de Sainte Lucie, Saint Léger de Peyres, Lozere, France(!), thin to thick tabular to 8 cm and octahedra to 10 mm. Tsumeb, Namibia(!), in crystals to 20 mm. Formerly

abundant and in large crystals (to 25 mm) at the Proprietary mine, Broken Hill, NSW, Australia(1), in a manganese gossan. Sumidoro mine, near Mariana, MG, Brazil, with raspite. RG *DII:1087*, *SPC 15:928(1971)*, *BSE 14:23(1991)*.

48.1.4.1 Raspite PbWO_4

Named in 1897 for Charles Rasp (1846–1907), German–Australian prospector, discoverer of the Broken Hill ore deposit. Dimorphous with stolzite. *MON P2₁/n*. $a = 13.555$, $b = 4.976$, $c = 5.561$, $\beta = 107.63^\circ$, $Z = 4$, $D = 8.45$. Structure: *AC(B) 33:162(1977)*. *29-784*: 3.63₁₀ 3.60₂ 3.49₄ 3.23₄ 2.92₃ 2.76₂ 2.71₆ 1.85₂. Crystals usually tabular {100}, often elongated [100] or thin tabular {101}; {100} striated parallel to [010]. Twinning on {100} common; also on {102}. Yellowish brown, light yellow, gray; adamantine luster. Cleavage {100}, perfect. $H = 2\frac{1}{2}$ –3. $G = 8.46$. Decomposed by HCl with separation of yellow tungstic acid; fusible. Biaxial (+); $Y = b$; $Z \wedge c \approx 30^\circ$; $N_x = 2.27$, $N_y = 2.27$, $N_z = 2.30$; $2V \approx 0^\circ$. *Broken Hill, NSW, Australia*, with stolzite in manganese gossan. Sumidoro mine, Municipio de Mariana, MG, Brazil, with stolzite. RG *DII:1089*.

48.2.1.1 Russellite $(\text{BiO})_2\text{WO}_4$

Named in 1938 for Arthur Russell (1878–1964), British mineralogist. *TET I42d* or *I4/amd*. $a = 5.48$, $c = 11.5$, $Z = 2$, $D = 7.40$. *MM 37:705(1970)*. *26-1044*: 3.12₁₀ 2.71₈ 1.92₈ 1.64₉ 1.58₃ 1.25₄ 1.22₃ 1.11₃. Fine-grained, compact masses. Pale yellow, yellowish green. $H = 3\frac{1}{2}$. $G = 7.35$. *Castle an Dinas mine, St. Columb Major, Cornwall, England*, associated with wolframite, topaz, Limica, tourmaline, cassiterite, bismuth, and bismuthinite. Poona, Murchison division, WA, Australia, associated with bismite, koechlinite, and bismutite in pegmatite. RG *DII:604*.

48.2.2.1 Koechlinite $(\text{BiO})_2\text{MoO}_4$

Named in 1914 for Rudolf Koechlin (1862–1939), Austrian mineralogist. *ORTH Pca2₁*. $a = 5.482$, $b = 16.199$, $c = 5.509$, $Z = 4$, $D = 8.28$. Structure: *AC(C) 40:2001(1984)*. *21-102*: 3.15₁₀ 2.75₂ 2.74₁₂ 2.70₁₂ 1.94₂ 1.92₅ 1.65₂₂ 1.63₄₂. Thin rectangular plates and laths flattened {010} and striated [010]; massive, earthy. Twin plane {101}, both contact and penetration. Greenish yellow. Cleavage {010}, perfect; very brittle. Easily soluble in HCl, with difficulty in HNO_3 . Biaxial (-); *XYZ - cab*; $N_x = 2.52$, $N_y = 2.61$, $N_z = 2.67$ (Li); weakly pleochroic; $2V$ large; $r < v$, rather strong. *Daniel mine, Schneeberg, Saxony, Germany*, in cavities in vein material composed of quartz, bismuth, and smaltite. Dunallan mine, Coolgardie, WA, Australia, as an alteration product of tetradymite, and at Bygoo, NSW, with bismocelite. RG *AM 28:536(1943)*, *DII:1092*, *NJMM:1(1951)*, *FM 60:162(1982)*.

48.2.3.1 Tungstibite (SbO)₂WO₄

Named by Walenta in 1995 for the composition. ORTH $P2_12_1$. $a = 8.59$, $b = 9.58$, $c = 6.12$, $Z = 4$. PD 3.32₁₀ 3.06₁₀ 2.98₄ 2.73₆ 2.46₅ 1.919₄ 1.829₃ 1.718₃. Forms globular aggregates to 1mm diam., composed of thin tabular crystals. Flattened (001) and elongated along one axis, sometimes spear-shaped. Green to dark green, streak greenish, luster dull to pearly, translucent to opaque. Cleavage (001) perfect, irregular fracture. $H = 2$. $G = 6.90$. Biaxial (+); $N_x = 2.285$ (dark green to brownish green), $N_y = 2.40$ (dark green), $N_z = 2.58$ (pale green to yellowish); $2V_{\text{calc}} = 82^\circ$; dispersion $r < v$, strong, $Z = c$. From the *Clara mine*, near *Oberwolfach*, central *Black Forest*, *Germany*. Associated minerals are quartz, barite, fluorite, and occasionally with tetradhite, chalcopyrite, or cervantite. *CE 55:217(1995)*.

48.3.1.1 Lindgrenite Cu₃(MoO₄)₂(OH)₂

Named in 1935 for Waldemar Lindgren (1860–1939), American mining geologist and teacher. MON $P2_1/n$. $a = 5.394$, $b = 14.023$, $c = 5.608$, $\beta = 98.5^\circ$, $Z = 4$, $D = 4.310$. *CM 6:31(1957)*. Structure: *NJMM:234(1985)*. 36-405: 4.16₅ 3.58₃ 3.52₁₀ 3.48₇ 2.78₂ 2.72₃ 2.68₄ 2.67₂. Crystals platy {010}; rarely acicular [101]. {010} striated parallel to [001]. Pistachio green, dark yellow-green; vitreous luster. Cleavage {010}, perfect; {101}, {100}, poor. $H = 4\frac{1}{2}$. $G = 4.26$. Easily soluble in HCl and HNO₃. Biaxial (-); $X \wedge c = 9^\circ$; $Z = b$; $N_x = 1.930$, $N_y = 2.002$, $N_z = 2.020$; $2V = 71^\circ$; $r > v$. Inspiration copper mine, Gila Co., AZ. Helena mine, NE of Cuprum, Seven Devils district, Adams Co., ID, with chrysocolla, brochantite, and limonite. Brandy Gill, Carrock Fell, Cumberland, England, associated with wulfenite and stolzite. *Chuquicamata*, *Antofagasta*, *Chile*, with antlerite, limonite, and hematite; also with szenicsite at *Tierra Amarilla*, *Chile*. *RG DII:1094*, *MM 30:723(1955)*.

48.3.2.1 Cuprotungstite Cu₃(WO₄)₂(OH)₂

Named in 1869 for the composition. TET Space group unknown. $a = 8.93$, $c = 14.48$, $Z = 12$, $D = 7.06$. *MM 43:448(1979)*. 34-1297: 7.76₅ 4.03₈ 3.80₈ 2.53₁₀ 2.45₄ 2.35₄ 1.73₅ 1.46₇. Microcrystalline masses and crusts. Pistachio-green to olive-green; vitreous, waxy, or earthy luster. Easily soluble in acids. Uniaxial (-); $N_0 = 2.18$, $N_E = 2.10$. Cuprotungstite is a common mineral in the oxidized zone of scheelite deposits containing primary copper sulfides. Green monster mine, near White River, Kern Co., CA. In *Mexico* from near *La Paz*, *BCS*, and abundant at the *Guadalupe* mine, *Potrero de Bojorquez*, *CHIH*. *Villa Salto*, *Sardinia*, *Italy*. *Sorpresa*, *Montoro*, *Spain*. *Mitake* mine, *Kai*, and at *Ofuku*, *Nagato*, *Japan*. At several mines in *Georgiana Co.*, *NSW*, *Australia*. *Llamuco* copper mines, near *Santiago*, *Chile*. *RG DII:1091*, *BM 92:497(1969)*, *AUM 3:61(1988)*, *AM 75:713(1990)*.

48.3.3.1 Anthoinite AlWO₃(OH)₃

Named in 1947 for Raymond Anthoine (1888–1971), Belgian mining engineer, who wrote on prospecting of alluvial deposits. TRIC $P1$ or $P1$. $a = 9.21$,

$b = 11.36$, $c = 8.26$, $\alpha = 94.75^\circ$, $\beta = 90^\circ$, $\gamma = 92.58^\circ$, $D = 4.84$. 25-1489: 5.63₁₀ 4.33₃ 4.19₈ 4.12₃ 3.97₇ 3.65₂ 3.06₇ 2.46₆. Chalky masses resembling kaolin. White, powdery luster. $H = 1$. $G = 4.8$. Slowly attacked by HCl and HNO₃. Easily soluble in strong KOH solution. *Mt. Misobo tungsten mine, Kalima district, Maniema, Zaire*, in eluvium; also quite common as an oxidation-leaching product of scheelite throughout the Central African tungsten belt. Kara mine, SSW of Burnie, TAS, Australia, as an alteration product of scheelite, associated with mpororoite. RG *DII:1097, BGSF 43:95(1970), MR 12:81(1981), MM 48:397(1984)*.

48.3.4.1 Deloryite $\text{Cu}_4(\text{UO}_2)(\text{MoO}_4)_2(\text{OH})_6$

Named in 1992 for Jean Claude Delory, French mineral collector, who found the mineral. MON *C2, Cm, or C2/m*. $a = 19.83$, $b = 6.112$, $c = 5.529$, $\beta = 103.9^\circ$, $Z = 2$, $D = 4.84$. *NJMM:58(1992)*. *PD: 4.82₈ 4.43₄ 4.28₄ 4.10₁₀ 3.73₉ 3.25₄ 2.63₄ 2.48₆*. Crystals tabular {010}, elongate [001], to max. 3 mm, in rosettes. Dark green to black, green streak, vitreous to greasy luster, transparent to nearly opaque. Cleavage {010}, {100}, perfect; {001}, good; conchoidal fracture. $H = 4$. $G = 4.9$. Nonfluorescent. Soluble in HCl. Biaxial (+); $X \wedge c = 21.9^\circ$; $Y \wedge a = 36.2^\circ$; $Z = b$; $N_x = 1.90$, $N_y = 1.93$, $N_z = 1.96$, $r > v$, strong. Found at the *Cap Garonne mine near Pradet, Var, France*, on a dendritic quartz gangue, associated with metazeunerite, atacamite, paratacamite, malachite, tourmaline, and barite. Crystallographically related to derriksite. RG *AM 77:1305(1992)*.

48.3.5.1 Szenicsite $\text{Cu}_3\text{MoO}_4(\text{OH})_4$

Named in 1994 for Terry Szenics (b.1947) and Marissa Szenics (b.1955), U.S. miners and mineral collectors, who found the mineral. ORTH *Pnmm*. $a = 8.449$, $b = 12.527$, $c = 6.067$, $Z = 4$, $D = 4.30$. *MR 25:76(1994)*. *PD: 5.06₅ 3.76₁₀ 2.77₆ 2.59₇ 2.13₃*. Bladed crystals are flattened {100}, elongate [001] up to 3 cm \times 1 cm, usually in radial aggregates. Dark green, adamantine luster. $H = 3\frac{1}{2}$ -4. $G = 4.26$. Nonfluorescent. Biaxial (+); $XYZ = bac$; $N_x = 1.886$, $N_y = 1.892$, $N_z = 1.903$; $2V = 74^\circ$, nonpleochroic, $r > v$, strong. From the *Jardinera I mine near Inca do Oro, 100 km S of Tierra Amarilla, Atacama, Chile*, where it was derived from the oxidation of bornite and molybdenite and associated with abundant green powellite, chrysocolla, brochantite, hematite, and quartz. RG *AM 79:1210(1994)*.

48.4.1.1 Sedovite $\text{U}(\text{MoO}_4)_2$

Named in 1965 for Georgii Yakolevich Sedov (1877-1914), Russian polar investigator. ORTH Space group unknown. $a = 3.36$, $b = 11.08$, $c = 6.42$, $Z = 8$, $D = 5.11$. 18-1425: 11.0₉ 5.53₈ 3.70₈ 3.37₉ 3.19₁₀ 3.06₉ 2.78₆ 2.56₆. Powdery, or radial-fibrous bundles of acicular crystals. Brown, reddish brown. Cleavage parallel to elongation. $H = 3$. $G = 4.2$. Soluble in concentrated HCl, HNO₃, and H₂SO₄ only with difficulty, on boiling. Biaxial; $Z \wedge$ elongation, 38° ; $N > 1.79$; weakly pleochroic; positive elongation. In

RL, gray with a brownish tint; strong red internal reflections; slightly anisotropic; $R = 11.8$ (589 nm). From *Russia* (?), in the supergene zone of a U-Mo deposit, associated with pitchblende, molybdenite, gypsum, wulfenite, and mourite. RG *ZVMO* 94:548(1965), *AM* 51:530(1966).

48.4.2.1 Jixianite $\text{Pb}(\text{W}, \text{Fe}^{3+})_2(\text{O}, \text{OH})_7$

Named in 1979 for the locality. iso *Fd3m*. $a = 10.359$, $Z = 8$, $D = 7.89$. *AM* 64:1330(1979). 33-760: 5.97₅ 2.98₁₀ 2.59₆ 1.83₈ 1.56₇ 1.19₅ 1.16₅ 0.997₅. Crusts or honeycomblike microcrystalline aggregates; rarely in octahedral crystals. Red; brownish red, yellow streak, resinous luster. No cleavage. $H = 3$. $G = 6.04$. Weakly magnetic. Soluble in hot concentrated H_3PO_4 , but not in other mineral acids. Isotropic; $N = 2.26-2.31$. *Jixian, Ji county, Hebei, China*, in the oxidized zone of a quartz vein containing primary wolframite, cassiterite, pyrite, chalcopyrite, and scheelite. Associated minerals are wulfenite, silver, copper, goethite, and malachite. RG

Basic and Hydrated Molybdates and Tungstates

49.1.1.1 Hydrotungstite $\text{H}_2\text{WO}_4 \cdot \text{H}_2\text{O}$

Named in 1944 for the composition. MON $P2/m$. $a = 7.379$, $b = 6.901$, $c = 3.748$, $\beta = 90.37^\circ$, $Z = 2$, $D = 4.655$. 18-1420: 6.96₁₀ 3.77₃ 3.70₃ 3.47₃ 3.31₄ 3.26₄ 2.65₁ 2.63₁. Platy microcrystals. Dark green; yellowish green, vitreous to dull luster. Cleavage {010}, imperfect. $H = 2$. $G = 4.60$. Insoluble in acids, readily soluble in NH_4OH . In CT, yields abundant water, turns yellow, then bleaches. Biaxial (+); $N_x = 1.70$, $N_y = 1.95$, $N_z = 2.04$; $2V = 52^\circ$; $r < v$; $Z > Y > X$. X, colorless; Y, yellow-green; Z, dark green. Forms from the oxidation of ferberite under acid conditions. *Calacalani mine, Oruro, Bolivia*, in crystals. Also reported from the Central African tungsten belt. RG *AM* 29:192(1944), 48:935(1963); *BGSF* 43:89(1971); *MR* 12:81(1981).

49.1.2.1 Moluranite $\text{H}_4\text{U}^{4+}(\text{UO}_2)_3(\text{MoO}_4)_7 \cdot 18\text{H}_2\text{O}$

Named in 1959 for the composition. Amorphous. 29-1371(heated): 4.17₁₀ 3.44₅ 2.58₅ 2.12₅ 2.03₅ 1.97₅ 1.31₆ 1.30₆. Colloform accumulations in fractures. Black; translucent brown in thin splinters; resinous luster. Brittle. $H = 3-4$. $G = 4$. Soluble with difficulty in acids, more easily when hot. When heated changes to iriginite. Isotropic; $N = 1.97-1.98$. In RL, light gray, similar to pitchblende. From *Russia (?)*, in thin fissures in granulated albitite, associated with molybdenite, chalcopyrite, galena, brannerite, and other U-Mo compounds. RG *AM* 43:380(1958), 45:258(1960); *ZVMO* 88:564(1959).

49.2.1.1 Ferrimolybdate $\text{Fe}_2^{3+}(\text{MoO}_4)_3 \cdot 8\text{H}_2\text{O}$

Named in 1914 for the composition. ORTH Space group unknown. 41-1388: 9.81₉ 8.24₁₀ 6.66₄ 4.16₂ 3.35₃ 3.17₂ 3.04₂ 2.78₂. Fibrous crusts; tufted aggregates; powdery, earthy; as radiating rosettes of acicular microcrystals. Canary-yellow; adamantine, or silky to earthy luster. $H = 1$. $G = 4.46$. The water content is readily lost in very dry atmospheres or above 50° and is lost in several stages. The formula may be written $\text{Fe}_2(\text{MoO}_4)_3 \cdot n\text{H}_2\text{O}$. Variation of the H_2O content also causes small variations in the physical properties and optics. Biaxial (+); $N_x = 1.79-1.81$, $N_y = 1.81-1.83$, $N_z = 1.99-2.01$; $2V = 28^\circ$; $r < v$, marked; $Z = \text{elongation}$. X, Y, colorless; Z, gray to canary-

yellow. A secondary mineral, ferrimolybdate is widespread in the oxidation zone of molybdenum-bearing deposits. Abundant at the Climax molybdenum mine, near Leadville, CO; Westmoreland, NH; Granite Hill, Cuttingsville, VT; Pioneer Mills, Cabarrus Co., NC; Red River District, Taos Co., NM; Kingman, Mojave Co., AZ; Red Mt., Ritter Range, Mojave Co., CA. In *Siberia, Russia*; Bivongi, Calabria, Italy; Pitkaranta, Lake Ladoga, Finland. In Australia at the Kingsgate, Bald Knob, and other molybdenite mines in NSW, and from Mulgine, WA. RG *DII:1095*; *AM 45:1111(1960)*, *48:14(1963)*; *BSBG 80:159(1971)*.

49.2.2.1 Umohoite $(\text{UO}_2)(\text{MoO}_4) \cdot 4\text{H}_2\text{O}$

Named in 1953 for the composition. MON *P2₁c*. $a = 6.38$, $b = 7.50$, $c = 14.30$, $\beta = 99.1^\circ$, $Z = 4$, $D = 4.93$. Also reported as ORTH; cell dimensions are somewhat variable, depending on the state of hydration and especially on the method of preparation of the sample for X-ray study. *AM 42:657(1957)*. *11-375*: 14.1_2 7.1_{10} 4.74_2 3.22_5 3.18_2 3.03_2 2.84_2 2.04_2 . Delicate rosettes of tabular plates. Blue-black; dark green, splendent luster. $G = 4.55$. Biaxial (-); $X \wedge a = 9^\circ$; $YZ = bc$; $N_x = 1.66$, $N_y = 1.831$, $N_z = 1.915$ (Na); $2V = 65^\circ$. X, dark blue; Y, light blue; Z, olive-green. *Freedom No. 2 mine, Marysvale, Piute Co., UT*. Lucky Mc mine, Gas Hills, Fremont Co., WY, with gypsum, uranium oxides, and iron sulfides in sandstone; Alyce Tolino mine, Cameron, AZ. Also found in Russia (locality unspecified). RG *AM 44:920, 1248(1959)*; *IANS, Ser. Geol.:131(1985)*.

49.2.3.1 Iriginite $(\text{UO}_2)(\text{Mo}_2^{6+}\text{O}_7) \cdot 3\text{H}_2\text{O}$

Named in 1956. MON Space group unknown. $a = 8.58$, $b = 12.87$, $c = 7.48$, $\beta = 107.67^\circ$, $Z = 3$, $D = 4.00$. *AM 49:409(1964)*. *18:1426*: 6.35_{10} 5.25_4 4.28_5 3.33_4 3.21_{10} 3.11_4 2.62_5 1.84_4 . Very fine grained, dense aggregates. Canary yellow, vitreous to dull luster. Conchoidal to uneven fracture. $H = 1-2$. $G = 3.84$. Nonfluorescent. Soluble in hot acids and in strong bases. Biaxial (+); $YZ = bc$; $N_x = 1.73$, $N_y = 1.82$, $N_z = 1.93$; $2V = 60^\circ$; parallel extinction. White River badlands, Pennington Co., SD, in sandstone. *Russia (?)*, in albite, associated with brannerite and with other U-Mo minerals. RG *BM: 81:157(1958)*; *AM 43:379(1958)*, *45:257(1960)*; *ZVMO 88:564(1959)*. *AM 79:574(1994)*.

49.2.4.1 Phyllostungstite $\text{CaFe}_3^{2+}\text{H}(\text{WO}_4)_6 \cdot 10\text{H}_2\text{O}$

Named in 1984 for the crystal habit and composition. ORTH *P222*, *Pmm2*, or *Pmmm*. $a = 7.29$, $b = 12.59$, $c = 19.55$, $Z = 3$, $D = 5.26$. *AM 71:846(1986)*. *38-381*: 6.33_7 6.01_6 4.91_6 3.25_8 3.13_{10} 2.92_7 2.45_7 1.82_8 . Crusts of tabular or scaly orthorhombic crystals, flattened {001}. Yellow, pearly luster. Cleavage {001}, perfect; irregular fracture. $H = 2$. Biaxial (-); $Z = c$; $N_x = 2.10$, $N_z = 2.185$; $2V = 18^\circ$; sometimes uniaxial. *Clara Mine, Oberwolfach, Schwarzwald, Baden-Württemberg, Germany*, as crusts on quartz associated with ferritungstite, scheelite, and pyrite. RG *NJMM:529(1984)*.

49.3.1.1 Calcurmolite $\text{Ca}(\text{UO}_2)_3(\text{MoO}_4)_3(\text{OH})_2 \cdot 11\text{H}_2\text{O}$

Named in 1962 for the composition. An inadequately characterized mineral. *AM* 49:1152(1964). 16-145: 8.34₅ 7.85₁₀ 4.29₃ 3.89₆ 3.56₃ 3.21₈ 1.99₅ 1.86₄. Prismatic crystals or massive platy aggregates. Honey-yellow. Fluoresces bright yellow-green under UV light. Biaxial (-); $N_x = 1.770$, $N_y = 1.816$, $N_z = 1.856$. X, colorless; Y, pale yellow; Z, yellow. In radial-fibrous, yellow spherulites to 3 mm at Has d'Alary and Rabejac, Lodeve, Hérault, France. From *Russia*. It forms pseudomorphs after uraninite; associated with uranophane, uranospinite, halloysite, betpakdalite, jarosite, and ferrimolybdate in the oxidation zone of a U-Mo ore deposit. RG *BM* 82:564(1959).

49.3.1.2 Tengchongite $\text{CaU}_6^{6+}\text{Mo}_2^{6+}\text{O}_{25} \cdot 12\text{H}_2\text{O}$

Named in 1986 for the locality. ORTH $A2_122$ or $C222_1$. $a = 15.616$, $b = 13.043$, $c = 17.716$, $Z = 4$, $D = 4.24$. *AM* 73:195(1988). 41-1491: 8.84₁₀ 7.66₃ 5.37₅ 4.27₅ 3.65₄ 3.38₇ 3.17₈ 2.04₄. Irregular grains, tabular {001}. Yellow, vitreous luster. Cleavage {001}, perfect. $H = 2-2\frac{1}{2}$. $G = 4.25$. Nonfluorescent. Soluble in H_2SO_4 and HNO_3 , slowly soluble in 1% HCl, insoluble in KOH solution. Biaxial (-); $N_x = 1.663$, $N_y = 1.760$, $N_z = 1.762$; $2V = 16^\circ$. *Tengchong County, Yunnan, China*, in the zone of oxidation of a uranium deposit, associated with studtite, kiviuite, and calcurmolite. RG *KT* 31:396(1986).

49.3.2.1 Cousinite $\text{Mg}(\text{UO}_2)_2(\text{MoO}_4)_2(\text{OH})_2 \cdot 5\text{H}_2\text{O}$ (?)

Named for Jules Cousin (1884-1965), Belgian, president of the Union Minière du Haut Katanga. An inadequately characterized mineral. Crystals are thin blades. Black, vitreous luster. *Shinkolobwe, Shaba, Zaire*, as an alteration product of ores containing uraninite and molybdenite. RG *AM* 44:910(1959).

49.3.3.1 Cerotungstite-(Ce) $(\text{Ce},\text{Y},\text{Nd})(\text{W}_2\text{O}_6)(\text{OH})_3$

Named in 1970 for the composition. MON $P2_1/m$. $a = 7.070$, $b = 8.700$, $c = 5.874$, $\beta = 105.45^\circ$, $Z = 2$, $D = 6.244$. *AM* 57:1558(1972). *PD*: 6.83₄ 3.41₁₀ 3.34₂ 2.63₂ 2.27₅ 1.767₂. Bladed, radiating crystals; twinning on {001}. Orange-yellow. Cleavage {100}, perfect. $H \approx 1$. Biaxial; $X = a$; Y perpendicular to {001}; $Z = b$; $N_x = 1.89$, $N_y = 1.95$, $N_z = 2.02$. *Kirwa and Nyamulilo mines, Kigezi district, Uganda*, associated with ferberite. RG *MR* 12:81(1981).

49.3.3.2 Yttrotungstite-(Y) $\text{Y}(\text{W}_2\text{O}_6)(\text{OH})_3$

Named in 1950 for the composition. MON $P2_1/m$. $a = 6.95$, $b = 8.64$, $c = 5.77$, $\beta = 104.93^\circ$, $Z = 2$. *MM* 38:261(1971). 26-1396: 6.73₇ 4.98₈ 4.69₁₀ 3.36₇ 3.26₁₀ 2.87₇ 2.79₇ 2.03₉. Earthy; as monoclinic laths, elongated [001], and flattened {100}. Always twinned on {100} to pseudo-orthorhombic symmetry. Orange yellow, earthy luster. Cleavage {010}, good; {101}, fair. $H \approx 1$. $G = 5.96$. Biaxial (-); $X \approx c$; $Z = b$; $N_x = 1.89$, $N_y = 1.98$, $N_z = 2.02$; $2V = 68^\circ$. X, pale yellow; Y, Z, dark yellow. *Kramat Pulai mine, Kinta district, Perak*,

Malaysia, associated with quartz, alumotungstite, stolzite, and raspite. RG BGSF 42:223(1970), MR 12:81(1981).

49.3.4.1 Mpororoite $\text{AlWO}_3(\text{OH})_3 \cdot 2\text{H}_2\text{O}$

Named in 1972 after the locality. TRIC $P1$ or $P\bar{1}$. $a = 9.40$, $b = 11.46$, $c = 8.20$, $\alpha = 94.33^\circ$, $\beta = 89.75^\circ$, $\gamma = 95.17^\circ$. MR 12:81(1981). 25-1496: 8.21₁₀ 6.18₂ 5.69₂ 4.73₁ 4.20₂ 4.09₂ 3.08₉ 2.36₁. Powdery, very fine grained; under SEM crystals are platy. Greenish yellow, powdery luster. Mpororo tungsten deposit, Kigezi, Uganda, as an alteration product of scheelite, associated with ferberite and ferritungstite. Kara mine, 40 km SSW of Burnie, TAS, Australia, in a similar environment but with additional associated anthoinite. RG BGSF 44:107(1972), AM 58:1112(1973), MM 48:397(1984).

49.3.5.1 Uranotungstite $(\text{Fe,Ba,Pb})(\text{UO}_2)_2(\text{WO}_4)(\text{OH})_4 \cdot 12\text{H}_2\text{O}$

Named in 1985 for the composition. ORTH $P222_1$ or $Pmm2$. $a = 9.22$, $b = 13.81$, $c = 7.17$, $Z = 2$, $D = 4.27$. AM 71:1547(1986). 41-587: 7.67₂ 6.91₁₀ 4.60₅ 3.46₃ 3.20₈ 3.04₇ 2.80₃ 2.04₁. Minute, lathlike crystals, in spherulitic aggregates. Yellow, orange, brown; dull luster. Cleavage {010}, perfect; irregular fracture. $H = 2$. $G > 4.03$. Nonfluorescent. Soluble in cold 1:1 HCl, decolorized but not dissolved by NH_3 or H_2SO_4 . Biaxial (-); $N_x = 1.682$, $N_y = 1.845$, $N_z = 1.855$; $2V = 42^\circ$. X, colorless; Y,Z, yellow; *Menzenschwand*, and *Clara Mine, Wolfach, Schwarzwald, Baden-Württemberg, Germany*, as crusts on quartz, associated with meta-uranocircite and meta-heinrichite, bergenite, schoepite, meta-zeunerite, and meta-torbernite. RG *TMPM* 34:25(1985).

49.3.6.1 Rankachite $\text{CaFe}^{2+}\text{V}_4^{5+}\text{W}_8^{6+}\text{O}_{36} \cdot 12\text{H}_2\text{O}$

Named in 1984 for the locality. ORTH $Pm\bar{m}n$. $a = 8.17$, $b = 42.02$, $c = 5.45$, $Z = 2$, $D = 4.5$. AM 70:876(1985). 38-367: 10.6₁₀ 5.44₇ 4.57₆ 4.08₆ 3.51₆ 3.26₆ 3.04₆ 2.63₆. Crusts and rosettes of acicular crystals. Dark brown, yellow, resinous to subadamantine luster. Cleavage {100} or {010}, nearly perfect; uneven fracture. $H \approx 2\frac{1}{2}$. $G > 4.03$. Biaxial (-); Y perpendicular to {100} or {010}; $Z = c$; $N_x = 1.770$, $N_y = 1.925$, $N_z = 1.970$; $2V = 58^\circ$; $r \ll v$. X,Y, yellow-brown; Z, deep reddish brown. *Clara Mine, Wolfach, Rankach Valley, Schwarzwald, Baden-Württemberg, Germany*, encrusting quartz, associated with marcasite, pyrite, and scheelite. RG *NJMM*:289(1984).

49.4.1.1 Betpakdalite $(\text{H,K})_6\text{Ca}_4\text{Fe}_6^{2+}\text{As}_4^{5+}\text{Mo}_{16}^{6+}\text{O}_{74} \cdot 28\text{H}_2\text{O}$

Named in 1961 for the locality. MON $C2/m$. $a = 19.44$, $b = 11.10$, $c = 15.25$, $\beta = 131.28^\circ$, $Z = 1$, $D = 2.70$. AM 70:1333(1985). 37-434: 11.5₄ 9.69₃ 8.91₁₀ 7.30₅ 3.65₄ 3.10₃ 3.03₃ 2.95₃. Powdery finely crystalline aggregates; also as tiny octahedral crystals with {001}, {201}, {011}. Bright lemon-yellow, greenish yellow; waxy-vitreous luster. Cleavage {001}, very good. $H = 3$. $G = 3.0$. Biaxial (+); $X \wedge c = 12^\circ$; $Y = b$; $N_x = 1.809$, $N_y = 1.821$, $N_z = 1.857$; $2V = 60^\circ$; extreme, inclined dispersion; $Z > Y > X$ (Kazakhstan). X, pale

yellow; Y, greenish yellow; Z, green. Alternatively, $N_x, N_y, N_z = 1.782, 1.797, 1.850$ (Tsumeb). *Bet-Pak-Dal desert, Kazakhstan*, in quartz-hübnerite-pyrite-arsenopyrite veins, in the oxidation zone, associated with jarosite, ferrimolybdate, opal, gypsum, and limonite. Tsumeb, Namibia, in the lower oxidation zone, with scorodite, chalcocite, powellite, adamite, and other minerals. RG *ZVMO 90:425(1961)*, *AM 47:172(1962)*, *IC 16:1096(1977)*, *NJMM:393(1984)*.

49.4.2.1 Obradovicite $H_4(K,Na)Cu^{2+}Fe_2^{3+}(AsO_4)(MoO_4)_5 \cdot 12H_2O$

Named in 1986 for Martin T. Obradovic, Chilean mineral collector from whose collection the type material came. ORTH *Pcnm* or *Pnma*. $a = 15.046$, $b = 14.848$, $c = 11.056$, $Z = 4$, $D = 3.68$. *AM 72:1026(1987)*. *40-463: 10.6₈ 8.91₁₀ 7.42₈ 5.73₅ 3.69₄ 2.97₆ 2.90₅ 2.76₅*. Crystals are platy {100}, in clusters. Pea green. No cleavage. $H = 2\frac{1}{2}$. $G = 3.55$. Nonfluorescent. Soluble in 1:1 HCl or in hot 1:1 HNO₃, insoluble in cold HNO₃, turns dull orange in 40% KOH. Biaxial (+); XYZ = bca; $N_x = 1.790$, $N_y = 1.798$, $N_z = 1.811$ (Na); $2V = 81^\circ$; extreme dispersion; $Z > X = Y$. *Chuquicamata, Antofagasta, Chile*, associated with quartz, jarosite and minor wulfenite. RG *MM 50:283(1986)*.

49.4.3.1 Melkovite $H_6CaFe^{3+}(MoO_4)_4(PO_4) \cdot 6H_2O$

Named in 1969 for Vyacheslav Gavrilovich Melkov (b. 1911), Russian mineralogist. MON Space group unknown. $a = 17.46$, $b = 18.48$, $c = 10.93$, $\beta = 94.5^\circ$, $Z = 4$, $D = 2.512$. *AM 55:320(1970)*. *23-384: 8.42₇ 3.54₉ 3.04₇ 2.92₁₀ 2.42₅ 1.99₆ 1.79₈ 1.54₅*. Powdery films and platy microcrystals. Lemon yellow; brownish yellow, dull to waxy luster. One perfect cleavage, brittle. $H = 3$. $G = 2.971$. Readily soluble in dilute acids. $N \approx 1.838$; weakly pleochroic, colorless to pale green. *Shunak Mts., Kazakhstan*, in a molybdenite-fluorite deposit, associated with powellite, iriginite, ferrimolybdate, jarosite, autunite, and limonite. RG *ZVMO 98:207(1969)*, *IGR 12:1411(1970)*, *IC 16:1096(1977)*.

49.4.4.1 Sodium Betpakdalite $(Na_2Ca)Fe_2^{3+}(As_2Mo_6O_{28}) 15H_2O$

Named in 1971 for its chemistry and similarity to betpakdalite. MON Space group unknown. $a = 11.28$, $b = 19.30$, $c = 17.67$, $\beta = 94.5^\circ$, $Z = 4$, $D = 3.32$. *AM 57:1312(1972)*. *39-398: 9.64₆ 8.73₁₀ 3.63₉ 3.24₇ 2.94₇ 2.75₇ 2.07₇ 1.84₈*. Microcrystalline or powdery films and crusts. Lemon yellow, dull luster. $G = 2.92$. Soluble in dilute mineral acids, decomposed by KOH and Na₂CO₃ solutions. Biaxial; $Z \wedge$ elongation = 38° ; $N_x = 1.792$, $N_z = 1.810$. X, pale yellow; Z, yellow. *Kazakhstan (?)*, in the zone of oxidation of a molybdenum deposit, associated with goethite, natrojarosite, gypsum, opal, and ferrimolybdate. RG *ZVMO 100:477(1971)*, *IGR 14:473(1972)*.

49.4.5.1 Mendozavilite $\text{Na}(\text{Ca},\text{Mg})_2\text{Fe}_6^{3+}(\text{PO}_4)_2(\text{P}^{5+}\text{Mo}_{11}^{6+}\text{O}_{39})(\text{OH},\text{Cl})_{10} \cdot 33\text{H}_2\text{O}$

Named in 1986 for H. Mendoza Avila, Mexican geologist, who found the first specimen. MON or TRIC Space group unknown. *41-1437*: 11.6₃ 9.46₈ 8.77₁₀ 5.44₃ 3.68₅ 3.12₄ 1.820₅ 1.552₄. Fine-grained masses. Yellow, orange; vitreous luster. $H = 1\frac{1}{2}$. $G = 3.85$. Nonfluorescent. Readily soluble in dilute mineral acids. Biaxial (+); $N_x = 1.762$, $N_y = 1.763$, $N_z = 1.766$; $2V = 5-15^\circ$; $r > v$, very strong; $Z > Y > X$. X, pale yellow. *Cumobabi molybdenum deposit, SW of Cumpas, SON, Mexico*, on quartz in a Mo-rich pegmatite, associated with paramendozavilite and other secondary Mo minerals. RG *AM 73:193(1988)*.

49.4.6.1 Paramendozavilite $\text{NaAl}_4\text{Fe}_7^{3+}(\text{PO}_4)_5(\text{P}^{5+}\text{Mo}_{12}^{6+}\text{O}_{40})(\text{OH})_{16} \cdot 56\text{H}_2\text{O}$

Named in 1986 for the similarity to mendozavilite. MON or TRIC Space group unknown. *41-1438*: 14.4₁₀ 12.9₄ 10.2₆ 9.48₁₀ 7.98₅ 7.38₇ 7.16₄ 6.56₅. Fine-grained powdery masses. Twinning polysynthetic, coincident with cleavage. Pale yellow, vitreous luster. One perfect cleavage. $H = 1$. $G = 3.35$. Readily soluble in dilute mineral acids. Biaxial (-); $N_x = 1.686$, $N_y = 1.710$, $N_z = 1.720$; $2V = 60^\circ$; extinction oblique to cleavage; $Z > Y > X$. *Cumobabi, SW of Cumpas, SON, Mexico*, associated with biotite in a biotite-rich molybdenum-bearing pegmatite, with mendozavilite and other secondary molybdenum minerals. RG *BMM 2:13(1986)*, *AM 73:194(1988)*.

49.4.7.1 Paraniite-(Y) $\text{Ca}_2\text{Y}(\text{AsO}_4)(\text{WO}_4)_2$

Named in 1992 for Fausto Parani, Italian mineral collector, who discovered the mineral. TET $I4_1/a$. $a = 5.135$, $c = 33.882$, $Z = 4$, $D = 5.95$. *SMPM 74:155(1994)*. Structurally related to scheelite, but with c tripled in paraniite-(Y), and consists of layers of composition YAsO_4 and CaWO_4 stacked in an orderly manner along [001] in a molar ratio 1:2. *PD*: 4.67₂ 3.05₁₀ 2.57₂ 1.899₃ 1.816₂ 1.671₂ 1.560₃. Crystals dipyrarnidal, elongate, to 3 mm. Creamy yellow, vitreous luster. Cleavage {001}, distinct; uneven to subconchoidal fracture. Fluoresces orange-yellow in SWUV, nonfluorescent in LWUV. Uniaxial (+); $N_0 = 1.87$, $N_E = 1.92$. Besides the content of Y_2O_3 , other REEs detected are Dy, Er, Gd, and Yb. Found in a fissure in gneiss from *Pizzo Cervandone*, from the *Alpe Devero-Ossola valley area*, on the *Italian side of the Swiss-Italian border*. RG *AM 78:452(1993)*, *80:631(1995)*.

Salts of Organic Acids

50.1.1.1 Whewellite $\text{CaC}_2\text{O}_4 \cdot \text{H}_2\text{O}$

Named in 1852 for William H. Whewell (1794–1866), English natural scientist and philosopher. *MON* $P2_1/n$. $a = 6.290$, $b = 14.583$, $c = 10.116$, $\beta = 109.47^\circ$, $Z = 8$, $D = 2.218$. Structure: *AM* 65:327(1980). 20-231(syn): 5.93₁₀ 5.79₃ 3.65₇ 2.97₅ 2.49₂ 2.36₃ 2.35₁ 2.08₁. Known only as crystals, which are usually equant or short prismatic [001]. Twinning very common; twin plane {101}, either heart-shaped or prismatic pseudo-orthorhombic. Colorless, yellowish, brownish; vitreous luster, pearly on {010}. Cleavage {101}, good; {010}, imperfect; conchoidal fracture; brittle. $H = 2\frac{1}{2}$ –3. $G = 2.23$. Insoluble in water, soluble in acids. Biaxial (+); $N_x = 1.491$, $N_y = 1.554$, $N_z = 1.650$ (Na); $2V = 84^\circ$. Whewellite is ordinarily of organic origin but has also been found as a primary hydrothermal deposit in ore veins. Type locality not known. In a septarian nodule in the bed of the Huron River, Erie Co., OH; similarly, near Havre, MT, in a septarian limestone concretion, on calcite crystals. Burgk, near Dresden, Saxony, Germany, in large crystals in a coal seam. Also with calcite and silver in a vein at Freiberg, Saxony. In lignite coal at Kladno-Pchery, and elsewhere in the Czech Republic. With tetrahedrite, carbonates, and quartz in veins of the Saint-Sylvestre mine, Urbeis, Alsace, France. In calcite veins in shale on the Yareg River, southern Timan, Russia. A common constituent of human urinary calculi. *RG* *DII*:1099; *AM* 39:208(1954), 53:455(1968).

50.1.2.1 Weddellite $\text{CaC}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$

Named in 1942 for the locality. *TET* $I4/m$. $a = 12.371$, $c = 7.357$, $Z = 8$, $D = 1.936$. Structure: *AM* 65:327(1980). 17-541(syn): 6.18₁₀ 4.42₃ 3.68₁ 2.82₁ 2.78₇ 2.41₂ 2.24₃ 1.90₂. Crystals pyramidal {101}, sometimes aggregated into groups. Colorless, white; also yellowish, brown due to included organic matter. No cleavage, subconchoidal fracture. $H = 4$. $G = 1.94$. Insoluble in water. Decomposes to CaCO_3 at about 270° . Uniaxial (+); $N_O = 1.523$, $N_E = 1.544$. *Weddell Sea, Antarctica*, as small crystals embedded in the bottom muds. Weddellite is a principal ingredient in human urinary calculi. *RG* *DII*:1101, *MM* 34:256(1965), *AC* 18:917(1965).

50.1.3.1 Humboldtine $\text{Fe}^{2+}\text{C}_2\text{O}_4 \cdot 2\text{H}_2\text{O}$

Named in 1821 for Alexander von Humboldt (1769–1859), German explorer and naturalist. *MON* $C2/c$. $a = 9.707$, $b = 5.556$, $c = 9.921$, $\beta = 104.5^\circ$. *NBSM*

25(10):24(1972). Structure: *SR 21:505(1957)*. 23-293(syn): 4.8₁₀ 4.7₆ 3.88₂ 3.60₂ 3.00₅ 2.65₃ 2.62₂ 1.82₂. Crystals prismatic {001}, or platy. Usually capillary or botryoidal forms; granular, earthy. Amber, yellow; dull to resinous luster. Cleavage {110}, perfect; {100}, {010}, imperfect. $H = 1\frac{1}{2}$ -2. $G = 2.28$. Soluble in acids; in CT, affords water. Biaxial (+); $XYZ = abc$; $N_x = 1.494$, $N_y = 1.561$, $N_z = 1.692$; 2V large. X, pale yellowish green; Y, pale greenish yellow; Z, intense yellow. Kettle point, Bosanquet Twp., ONT, Canada. *Korozluky, SW of Bilina, Bohemia, Czech Republic*, with gypsum in brown coal; also at Cermniky. In Germany at Grossalmerode, Hesse-Nassau, and in coal at Potschappel near Dresden. *RG DII:1102, PM 2:269(1957), BM 82:50(1959)*.

50.1.3.2 Glushinskite $MgC_2O_4 \cdot 2H_2O$

Named in 1960 for P. I. Glushinskii, Russian coal petrographer. *MON C2/c*. $a = 12.675$, $b = 5.406$, $c = 9.984$, $\beta = 129.45^\circ$, $Z = 4$, $D = 1.865$. *MM 43:837(1980)*. 28-625(syn): 4.89₁₀ 3.17₈ 2.55₄ 2.38₆ 2.09₄ 2.04₈ 1.863₆ 1.529₄. Minute crystals showing distorted pyramidal habit. Creamy white, colorless. $H = 2$. $G = 1.85$. Soluble in water, easily dissolved by HCl. Biaxial (-); $N_x = 1.365$, $N_y = 1.530$, $N_z = 1.595$. Mill of Johnston, near Inch, NE Scotland, on a lichen-rock interface on serpentinite. Island of Rhum, Inner Hebrides. *Russian Arctic*, in chalky clays and in Cretaceous coals. *RG ZVMO 91:204(1962); AM 47:1482(1962), 66:439(1981); MM 51:327(1987)*.

50.1.4.1 Minguzzite $K_3Fe^{3+}(C_2O_4)_3 \cdot 3H_2O$

Named in 1955 for Carlo Minguzzi (1910-1953), Italian mineralogist and professor, University of Pavia. *MON P2₁/c*. $a = 7.66$, $b = 19.87$, $c = 10.27$, $\beta = 105.1^\circ$, $Z = 4$, $D = 2.156$. Structure: *BM 81:245(1958)*. 14-720(syn): 10.2₅ 6.9₁₀ 4.96₆ 3.61₇ 3.16₅ 3.03₄ 2.67₆ 2.18₇. Tabular, minute crystals. Green, yellow-green; vitreous luster. Cleavage {010}, perfect. $G_{nat} = 2.142$, $G_{syn} = 2.092$. Easily soluble in water. Biaxial (-); $N_x = 1.498$, $N_y = 1.554$, $N_z = 1.594$; 2V = 78°. X, yellow-green; Y, Z, emerald-green. *Cape Calamita, Elba, Tuscany, Italy*, in limonite, associated with humboldtine. *ACH 10:488(1938), ANLR 18:392(1955), AM 41:370(1956)*.

50.1.5.1 Oxammite $(NH_4)_2C_2O_4 \cdot H_2O$

Named in 1870 for the composition: oxalate and ammonium. *ORTH P2₁2₁2*. $a = 8.035$, $b = 10.309$, $c = 3.801$, $Z = 2$, $D = 1.498$. *NBSC 539(7):5(1957)*. Structure: *AC(B) 28:3340(1972)*. 14-801(syn): 6.32₁₀ 3.80₇ 3.26₆ 3.06₁₀ 2.86₆ 2.67₁₀ 2.61₅ 2.59₅. Lamellar masses, pulverulent. Crystals rare; artificial crystals are sphenoidal. Colorless, yellowish white; powdery luster. Cleavage {001}, distinct. $H = 2\frac{1}{2}$. $G = 1.5$. Biaxial (-); $XYZ = cab$; $N_x = 1.438$, $N_y = 1.547$, $N_z = 1.595$ (Na); 2V = 62°; $r < v$, distinct. *Guañape Islands, Peru*, in the guano deposits, associated with mascagnite. *RG DII:1103, AM 36:590(1951)*.

50.1.6.1 Moolooite $\text{CuC}_2\text{O}_4 \cdot n\text{H}_2\text{O}$ ($n < 1$)

Named in 1986 for the locality. ORTH Space group unknown. $a = 5.35$, $b = 5.63$, $c = 2.56$, $Z = 1$, $D = 3.43$. $21-297$: 3.88_{10} 2.48_2 2.43_1 2.317_1 2.304_1 1.937_1 1.774_2 1.756_2 . As microconcretions. Blue, green; dull/waxy luster. Soluble in warm dilute HCl. $N = 1.57$ (perpendicular to elongation), $N = 1.95$ (parallel to elongation). Ste.-Marie-aux-Mines, Vosges, France. *Bunbury Well, Mooloo Downs, WA, Australia*, in quartz, associated with sampleite and liebethenite, on the outcrop of a vein bearing copper sulfides. RG *MM* 50:295(1986), *AM* 72:1025(1987).

50.1.7.1 Stepanovite $\text{NaMgFe}^{3+}(\text{C}_2\text{O}_4)_3 \cdot 8-9\text{H}_2\text{O}$

Named in 1953 for Pavel Ivanovich Stepanov (1880–1947), Russian geologist. HEX-R Space group unknown. $a = 9.28$, $c = 36.68$, $Z = 6$, $D = 1.69$. Granular aggregates, xenomorphic grains. Greenish, vitreous luster. No cleavage, irregular fracture. $H = 2$. $G = 1.69$. Soluble in water, fuses with difficulty. Uniaxial (-); $N_O = 1.515$, $N_E = 1.417$. O, yellowish green; E, colorless. *Tyllakh coal deposit, Lena River, Siberia, Russia*. RG *ZVMO* 82:311(1953); *AM* 40:551(1955), 49:442(1964).

50.1.7.2 Zhemchuzhnikovite $\text{NaMg}(\text{Al,Fe})(\text{C}_2\text{O}_4)_3 \cdot 8\text{H}_2\text{O}$

Named in 1963 for Yurii Apollonovich Zhemchuzhnikov (1885–1957), Russian geologist. HEX-R Space group unknown. $a = 16.67$, $c = 12.51$, $Z = 6$, $D = 1.66$. Crystals acicular to fibrous, [0001]. Smoky green to violet; synthetic crystals are green in daylight, amethyst violet under artificial light; vitreous luster. Cleavage {0001}, good. $H = 2$. $G = 1.69$. Soluble in water. Uniaxial (-); $N_O = 1.479$, $N_E = 1.408$. O, greenish yellow; E, reddish violet. *Chaitumusuk deposits, Lena River, Siberia, Russia*. RG *AM* 47:1483(1962), 49:442(1964).

50.1.8.1 Wheatleyite $\text{Na}_2\text{Cu}(\text{C}_2\text{O}_4)_2 \cdot 2\text{H}_2\text{O}$

Named in 1986 for the locality. TRIC *P1*. $a = 7.559$, $b = 9.665$, $c = 3.589$, $\alpha = 76.65^\circ$, $\beta = 103.67^\circ$, $\gamma = 109.1^\circ$, $Z = 1$, $D = 2.250$. *AM* 71:1240(1986). $39-1500$: 7.03_6 6.52_{10} 3.65_5 3.47_9 3.16_8 2.80_4 2.50_3 2.34_3 . Aggregates of acicular crystals. Bright blue, vitreous luster. Cleavage {100}, perfect; brittle. $H = 1-2$. $G = 2.27$. Nonfluorescent. Soluble in water. Biaxial (+); $N_x = 1.400$, $N_y = 1.499$, $N_z = 1.667$; $2V = 83^\circ$; $r < v$; $Z > Y > X$. X, colorless; Y, pale blue; Z, dark blue. *Wheatley mine, Phoenixville, Chester Co., PA*. Nishimomaki mine, Gumma, Japan. RG

50.2.1.1 Mellite $\text{Al}_2[\text{C}_6(\text{COO})_6] \cdot 16\text{H}_2\text{O}$

Named in 1793 from the Greek for *honey*, in allusion to the color. TET *I4₁/acd*. $a = 15.549$, $c = 23.209$, $Z = 8$, $D = 1.605$. Structure: *AC(B)* 29:26(1973). $42-1501$: 7.98_{10} 5.80_8 5.17_6 4.24_{10} 3.46_4 3.39_6 2.99_4 2.59_5 . Massive, nodular, as coatings. Crystals rare, prismatic [001] or pyramidal {011}. Honey-yellow, reddish, brownish, white; resinous/vitreous luster. Cleavage {011}, indistinct;

conchoidal fracture; somewhat sectile. $H = 2-2\frac{1}{2}$. $G = 1.64$. Fluoresces blue in SWUV; pyroelectric. Insoluble in water and alcohol; soluble in HNO_3 ; in CT, affords water. Uniaxial (-); $N_O = 1.539$, $N_E = 1.511$ (Na). *Arten, Thuringia, Germany*, as a secondary mineral in crevices in brown coal and lignite. Luschnitz, near Bilin, Bohemia, Czech Republic. Malowka, Bogoroditsk, Tula, Russia. With gypsum in lignitic clay, Paris basin, Seine, France. RG *DII:1104, MM 35:542(1965), PD 4:172(1989)*.

50.2.2.1 Earlandite $\text{Ca}_3(\text{C}_6\text{H}_5\text{O}_7)_2 \cdot 4\text{H}_2\text{O}$

Named in 1936 for Arthur Earland, English oceanographer. Synonym: calcium citrate. MON Space group unknown. $a = 30.94$, $b = 5.93$, $c = 10.56$, $\beta = 93.73^\circ$, $Z = 4$, $D = 1.96$. *28-2003(syn)*: 15.5₁₀ 8.5₁ 7.7₅ 6.4₁ 5.2₃ 4.74₁ 4.50₁ 3.09₁. Warty, fine-grained nodules. White, pale yellow. $G = 1.95$. $N \approx 1.56$. *Weddell Sea, Antarctica*, in oceanic bottom samples at a depth of 2,580 m. RG *DII:1105*.

50.2.3.1 Julienite $\text{Na}_2\text{Co}(\text{CNS})_4 \cdot 8\text{H}_2\text{O}$

Named in 1928 for Henri Julien (d. 1920), Belgian scientist. Synonym: sodium cobalt thiocyanate. TET $P4_2/n$. $a = 9.24$, $c = 5.57$, $Z = 1$, $D = 1.68$. Also MON $P2_1/c$. $a = 18.941$, $b = 19.209$, $c = 5.460$, $\beta = 91.63^\circ$, $Z = 4$, $D = 1.610$. *ZK 91-229(1935)*. *2-372*: 6.5₆ 4.6₆ 3.55₈ 3.23₈ 1.375₈ 1.220₈ 0.935₁₀ 0.903₁₀. Thin crusts of minute needles elongated [001]. Blue. Cleavage [001], good. $G = 1.648$. Soluble in water or alcohol, yielding a rose-colored solution. Uniaxial (+); $N_O = 1.556$, $N_E = 1.645$. *Chamitumba, near Kambove, Shaba, Zaire*, with cobaltian wad in a white talc schist. RG *DII:1106, TPM 3:376(1953)*.

50.2.4.1 Calclacite $\text{CaCl}_2 \cdot \text{Ca}(\text{C}_2\text{H}_3\text{O}_2)_2 \cdot 10\text{H}_2\text{O}$

Named in 1945 for the composition: Ca, Cl, acetate. MON $P2_1/c$. $a = 11.51$, $b = 13.72$, $c = 6.82$, $\beta = 116.7^\circ$, $Z = 2$, $D = 1.55$. Structure: *AC 11:745(1958)*. *12-869(syn)*: 8.27₁₀ 6.87₈ 6.15₅ 4.16₈ 3.24₁₀ 2.43₁₀ 2.30₈ 2.04₈. Hairlike efflorescences. White. $G = 1.5$. Biaxial (+); $Z = \text{elongation}$; $N_x = 1.468$, $N_y = 1.484$, $N_z = 1.515$; $2V = 80^\circ$. Found in oak museum cases, encrusting Ca-rich objects. The acetic acid was derived from the oak wood. RG *DII:1107*.

50.2.5.1 Kafehydrocyanite $\text{K}_4\text{Fe}^{2+}(\text{CN})_6 \cdot 3\text{H}_2\text{O}$

Named in 1973 for the composition. Natural origin in doubt. TET $I4_1/a$. $a = 9.394$, $c = 33.72$, $Z = 8$, $D = 1.89$. *25-1354*: 4.80₈ 3.62₇ 3.12₅ 2.93₁₀ 2.83₅ 2.79₅ 2.21₈ 2.10₆. Aggregates of crystallites with square and rectangular plates. Lemon yellow. Cleavage {001}, good. $H = 2-2\frac{1}{2}$. $G = 1.98$. Appreciably soluble in water. Uniaxial (+); $N_O = 1.577$, $N_E = 1.584$. *Medvezhii Log gold mine, Olkhovsk ore field, Sayan, Russia*, and in several other deposits, as stalactites in mine workings, associated with melanterite, gypsum, and various unidentified cyanides and oxalates. RG *AM 59:209(1974)*.

50.3.1.1 Kratochvilite $C_{13}H_{10}$ (Fluorene)

Named in 1937 for Joseph Kratochvil (1878–1958), Czech, professor of petrography, Charles University, Prague. ORTH $Pnma$. $a = 8.49$, $b = 5.721$, $c = 18.97$, $Z = 4$, $D = 1.197$. Structure: *SR* 19:583(1955). 28-2011(syn): 9.39₇ 4.68₁₀ 4.21₇ 3.79₅ 3.38₉ 2.54₆ 2.45₅ 2.37₅. Colorless. $G = 1.206$. Biaxial; $N_x = 1.557$, $N_y = 1.725$. From burning coal heaps in Kladno, Rozpravy, Czech Republic. *RG AM* 23:667(1938).

50.3.2.1 Ravatite $C_{14}H_{10}$

Named in 1993 for the locality. Synonym: phenanthrene. MON $P2_1$. $a = 8.392$, $b = 6.181$, $c = 9.558$, $\beta = 98.8^\circ$, $Z = 2$, $D = 1.207$. *EJM* 5:699(1993). *PD*: 9.43₁₀ 4.94₁ 4.72₁ 4.03₁ 3.37₁. Thin platelike individuals of irregular shape; aggregates form crusts generally < 1 mm thick. Colorless to white to pale gray, translucent, vitreous to waxy luster, waxlike tenacity. Cleavage {001}, perfect. $G = 1.11$. Biaxial, $N = 1.75$ – 1.95 . From *Ravat*, about 100 km N of *Dushanbe*, Northwestern *Tadzhikistan*, in a Middle Jurassic brown coal seam. Weathering of finely dispersed pyrite and the bacterial decomposition of the coal have caused lignite seams to ignite spontaneously, reaching temperatures above 800° . Ravatite forms as a sublimation product in the outer, cool zones, with liquid bitumen and rarely, native Se. *RG AM* 79:389(1994).

50.3.3.1 Simonellite $C_{19}H_{24}$

Named in 1919 for Vittorio Simonelli (1860–1929), Italian geologist and paleontologist, University of Bologna, who first observed the mineral. Synonym: 1,1-dimethyl-7-isopropyl-1,2,3,4-tetrahydrophenanthrene. ORTH $Pnaa$. $a = 9.231$, $b = 9.134$, $c = 36.01$, $Z = 8$, $D = 1.104$. 30-2001: 9.00₃ 8.21₃ 6.45₁₀ 6.11₂ 4.82₂ 4.57₂ 4.07₁ 4.05₁. *Fognano*, *Tuscany*, *Italy*. *RG ANLR* 47:41(1969), *AM* 55:1818(1970).

50.3.4.1 Fichtelite $C_{19}H_{34}$

Named in 1841 for the locality. MON $P2_1$. $a = 10.75$, $b = 7.51$, $c = 13.08$, $\beta = 126.9^\circ$, $Z = 2$, $D = 1.032$. Shining scales, flat crystals, thin layers. White, greasy luster. Brittle. $H = 1$. $G = 1.03$. Easily soluble in ether, less so in alcohol. M.P. 46° . Soluble in concentrated H_2SO_4 and in HNO_3 . Reported from Alabama in recent pine logs. *Fichtel Mts.*, *Redwitz*, *Bavaria*, *Germany*, in altered pine wood from a peat bog; also elsewhere in Germany in a similar environment. In England at Handforth in Cheshire in pine logs in moss. *RG D6:1000*, *NW* 49:9(1962).

50.3.5.1 Dinite $C_{20}H_{36}$

Named in 1852 for Olinto Dini (1802–1866), Italian teacher and professor of physics, University of Pisa. ORTH $P2_12_12_1$. $a = 12.356$, $b = 12.762$, $c = 11.427$, $Z = 1$, $D = 1.02$. *AM* 77:674(1992). *PD*: 8.92₇ 8.32₇ 7.00₈ 5.53₁₀ 5.06₁₀ 4.02₇ 3.87₅ 3.79₅. Massive, crystalline. Colorless to yellowish. No cleavage, fragile.

$G = 1.01$. Soluble in carbon tetrachloride. Found with lignite at *Castelnuovo Garfagnana, northern Tuscany, Italy*. RG *D6:1001, EM 3:855(1991)*.

50.3.6.1 Evenkite $C_{24}H_{50}$

Synonym: n-tetracosane. Named in 1953 for the locality. MON $P2_1/a$. $a = 7.52$, $b = 4.98$, $c = 32.50$, $\beta = 94^\circ$, $Z = 2$, $D = 0.926$. AM *50:2109(1965)*. *28-2004*: 4.18_{10} 3.74_9 3.02_5 2.52_7 2.25_8 2.12_6 1.91_5 1.75_6 . Pseudohexagonal tabular crystals, flattened perpendicular to c , {001}. Polysynthetic twinning. Colorless; yellowish, waxy luster. Perfect cleavage, micalike. $H = 1$. $G = 9.20$. Soluble in ether. Melting point 50.7° . Biaxial (+); $N_x = 1.504$, $N_y = 1.504$, $N_z = 1.553$. *Evenki region, Lower Tunguska River, Siberia, Russia*, in vugs in a quartz vein cutting vesicular lava, associated with chalcedony, calcite, and various sulfides. RG *DANS 88:717(1953)*, *AM 40:368(1955)*, *NJMM:19(1965)*.

50.3.7.1 Karpatite $C_{24}H_{12}$

Named in 1955 for the locality, the Carpathian mountains. Synonyms: coronene; "pendletonite." Pendletonite has been shown to be identical to karpatite, and the name *pendletonite* has been discontinued. MON $P2_1/c$ or $P2/c$. $a = 10.035$, $b = 4.695$, $c = 16.014$, $\beta = 69^\circ$, $Z = 2$, $D = 1.416$. AM *54:329(1969)*. *28-2007(syn)*: 9.44_{10} 7.43_{10} 5.09_1 4.84_1 3.96_4 3.49_6 3.03_4 1.989_1 . Acicular crystals and fibrous, radiating aggregates. Pale yellow, red-violet; vitreous luster. Cleavage {100}, {001}, {201}, perfect; flexible, almost plastic. $H < 1$. $G = 1.35-1.40$. Melts about 430° . Soluble in aniline, from which it can be recrystallized, insoluble in acids, sublimes on heating, flammable. Biaxial (-); $X = b$; $Z \wedge c = 21^\circ$; $N_x = 1.780$, $N_y = 1.977-1.982$, $N_z = 2.05-2.15$; $2V$ large; $v > r$, extreme; axial plane parallel to X . Picachos mercury mine, New Idria, San Benito Co., CA, associated with quartz and cinnabar. *Transcarpathia, Ukraine*, associated with idrialite and organic material in cavities at the contact of diorite porphyry with argillites. RG *AM 42:120(1957)*, *52:611(1967)*.

50.3.8.1 Idrialite $C_{22}H_{14}$

Named in 1832 for the locality. Synonyms: picene, "curtisite." Curtisite has been shown to be identical with idrialite, and the name *curtisite* is discontinued. ORTH Space group unknown. $a = 8.07$, $b = 6.42$, $c = 27.75$, $Z = 4$, $D = 1.29$. AM *50:2109(1965)*. *28-2006*: 7.08_2 4.94_{10} 4.43_2 4.04_6 3.40_8 2.48_3 2.06_2 1.92_1 . Tabular crystals. Light brown, pistachio-green; colorless when recrystallized and pure. Fluoresces blue-white in UV light. Soluble in chloroform, soluble in concentrated H_2SO_4 producing an intense blue-green color. M.P. 319° . Skaggs Springs, Sonoma Co., CA. *Idria, Slovenia*, in a mercury mine, mixed with cinnabar and clay. RG *NJMM:19(1965)*, *MP 40:111(1989)*.

50.4.1.1 Refikite $C_{20}H_{32}O_2$

Named in 1852 for Refik Bey (d.1865), Turkish journalist, for his interest in the sciences (he was a founder of the New Ottoman Society). Synonym: Δ 13-dihydro-*d*-pimaric acid. ORTH $P2_12_12$. $a = 10.43$, $b = 22.35$, $c = 7.98$, $Z = 4$, $D = 1.09$. *AM* 50:2110(1965). 28-2009: 11.2₁ 7.97₃ 6.09₉ 5.50₁₀ 5.20₇ 4.82₁ 4.28₂. Acicular crystals, small scales. White. Fragile, very soft. With concentrated H_2SO_4 + concentrated acetic acid produces an orange to brown solution. Soluble in ether and alcohol. M.P. 182°. *Montorio, near Feramo, Abruzzo Mts., Italy*, in lignite. In a swamp in southern Bavaria, Germany, as crystals in the fossil roots of a spruce. *RG* D6:1006, *NJMM*:19(1965).

50.4.2.1 Hoelite $C_{14}H_8O_2$

Named in 1922 for Adolf Hoel (b.1879), geologist, leader of a Norwegian expedition to Spitzbergen. Synonym: anthraquinone. MON $P2_1/c$. $a = 15.81$, $b = 3.967$, $c = 7.876$, $\beta = 102.67^\circ$, $Z = 2$, $D = 1.43$. 28-2002(syn): 7.69₉ 6.16₅ 3.84₃ 3.79₁ 3.52₁₀ 3.36₈ 3.14₁ 3.05₁. Orthorhombic needles. Yellow. $G = 1.42$. *Spitzbergen, Norway*, from a burning coal seam. *RG*

50.4.3.1 Flagstaffite $C_{10}H_{22}O_3$

Named in 1920 for the locality. Synonym: *cis*-terpin hydrate. ORTH $Fdd2$. $a = 18.60$, $b = 23.00$, $c = 10.86$, $Z = 16$, $D = 1.088$. *AM* 50:2109(1965). 28-2014: 8.72₈ 7.16₈ 5.89₅ 5.65₅ 4.88₁₀ 4.73₅ 4.36₆ 3.53₅. Well-formed prismatic crystals, with {110} and {111}; also {010} and {011}. Yellowish, resinous luster. Cleavage {110}, imperfect. $G = 1.09$. M.P. 116°. Gives a strong orange-yellow solution with concentrated H_2SO_4 . Biaxial (+); $N_x = 1.505$, $N_y = 1.512$, $N_z = 1.524$ (Na); $2V = 77^\circ$; $r > v$; optic axial plane {010}. From fossil logs near *San Francisco Peaks, N of Flagstaff, AZ*, as crystals in radial cracks in the logs. *RG* *NJMM*:19(1965).

50.4.4.1 Uricite $C_5H_4N_4O_3$

Named in 1807 for the composition. Synonym: uric acid. MON $P2_1/c$. $a = 14.44$, $b = 7.403$, $c = 6.208$, $\beta = 65.1^\circ$, $D = 1.851$. Structure: *AC* 19:286(1965). 28-2016(syn): 6.55₄ 5.63₂ 4.91₅ 3.86₄ 3.18₅ 3.093₁₀ 3.087₇ 2.87₂. White. $G = 1.851$. From guano deposits, *North Chincha Island, Peru*. Dingo Donga cave, (31°51' S, 126°44' E), WA, Australia, in guano associated with biphosphammite, brushite, and syngenite. *RG* *NBSM* 8:154(1970), *MM* 39:889(1974).

50.4.5.1 Guanine $C_5H_3(NH_2)N_4O$

Named in 1844 for its derivation from and association with guano. MON $P2_1/c$. $a = 16.510$, $b = 11.277$, $c = 3.645$, $\beta = 96.8^\circ$, $Z = 4$, $D = 1.489$. 28-2012(syn): 7.9₄ 6.32₇ 5.01₄ 3.53₅ 3.22₁₀ 2.63₅ 2.00₅ 1.80₅. White. Soft. *North Chincha Island, Peru*, in guano derived from seabirds. *Murra-el-elevyn cave, Cockabiddy Nullabor Plain, WA, Australia*, formed as a reaction to bat guano and urine

with limestone in the cave, associated with biphosphammite, hannayite, apthitalite, syngenite, monetite, whitlockite, gypsum, and organic materials. RG *MM* 39:467(1974), 39:889(1974).

50.4.6.1 Urea $\text{CO}(\text{NH}_2)_2$

Named in 1973 for the composition. TET $P4_2/m$. $a = 5.645$, $c = 4.704$, $Z = 2$, $D = 1.330$. NBSC 539(7):61(1957). Structure: AC 17:544(1964). PD 4.70₁ 3.98₁₀ 3.61₂ 3.04₃ 2.82₁ 2.52₁ 2.17₁ 1.837₁. Elongated pyramidal crystals. Pale yellow to pale brown. $G = 1.33$. Uniaxial (+); $N_O = 1.484$, $N_E = 1.603$. Toppin Hill, WA, Australia, in a cave, on guano, associated with phosphammite, weddellite, and ammonian apthitalite. RG *MM* 39:346(1973), *AM* 59:874(1974).

50.4.7.1 Acetamide CH_3CONH_2

Named in 1975 for its identity with synthetic acetamide. Synonym: ethanamide. HEX-R $R3c$. $a = 11.44$, $c = 13.50$, $Z = 18$, $D = 1.15$. 39-1851: 5.74₁₀ 3.63₁ 3.56₂ 3.32₁ 3.29₂ 2.88₃ 2.174₂ 2.166₁. Granular aggregates of crystals with a hexagonal outline, with prism {1120} prominent. Colorless, gray. Fine conchoidal fracture. $H = 1-1\frac{1}{2}$. $G = 1.17$. Volatilizes in a few hours in sunlight. Uniaxial (-); $N_O = 1.495$, $N_E = 1.460$. Lvov-Volynskii Basin, Ukraine, in waste piles from a coal shaft, in areas enriched in ammonia, shut off from oxygen and daylight. Seasonal, appearing only in dry weather. RG *ZVMO* 104:326(1975), *AM* 61:338(1976).

50.4.8.1 Kladnoite $\text{C}_6\text{H}_4(\text{CO})_2\text{NH}$

Synonym: phthalimide. Named in 1942 for the locality. MON $P2_1/c$. $a = 22.83$, $b = 7.651$, $c = 3.810$, $\beta = 91.37^\circ$, $Z = 4$, $D = 1.469$. Structure: AC(B) 28:415(1971). 28-2013(syn): 11.4₂ 6.35₉ 5.70₁₀ 5.39₁ 3.74₁ 3.38₁ 3.28₃ 3.13₁. Bladelike crystals, flattened {100}. $G = 1.47$. M.P. 234°. Biaxial (+); $Y \wedge c = 16^\circ$; $Z = b$; $N_x = 1.501$, $N_y = 1.519$, $N_z = 1.755$. Libusin, Kladno coal basin, near Prague, Czech Republic, from burning coal heaps. RG *AM* 31:605(1946).

50.4.9.1 Abelsonite $\text{NiC}_3\text{H}_{32}\text{N}_4$

Synonym: nickel porphyrin. Named in 1975 for Philip H. Abelson, president, the Carnegie Institution, Washington, DC, a pioneer in organic geochemistry. TRIC $P1$ or $P1$. $a = 8.44$, $b = 11.12$, $c = 7.28$, $\alpha = 90.88^\circ$, $\beta = 113.75^\circ$, $\gamma = 79.57^\circ$, $Z = 1$, $D = 1.45$. *AM* 63:930(1978). 30-1840: 10.9₁₀ 7.63₅ 6.63₃ 5.79₄ 5.51₃ 4.90₁ 3.77₈ 3.14₄. Aggregates of platy crystals. Pink-purple, reddish brown; submetallic/adamantine luster. Cleavage {111}; fragile. $H < 3$, very soft. $G = 1.45$. Nonfluorescent. Insoluble in H_2O and in dilute HCl

and HNO_3 , soluble in benzene and acetone. Absorption very strong, reddish brown to reddish black. The mineral is rapidly attacked by index of refraction liquids. *Green River formation, eastern Uintah Co., UT*, from a drill core at a number of locations, in fractures, associated with albite, orthoclase, pyrite, quartz, dolomite, and analcime. *RG AM 61:502(1976), SCI 223:1075(1984)*.

Insular SiO_4 Groups Only

PHENAKITE GROUP

Phenakite minerals are tectosilicates characterized by the general formula

where

$\text{R} = \text{Be}, \text{Zn}, \text{LiAl}$

and where the structure is based on a close packing of oxygens with all cations in tetrahedral coordination.

PHENAKITE: Be_2SiO_4

Be and Si tetrahedra form a triply linked framework—each oxygen is shared among two Be and one Si tetrahedra. This view shows the larger hexagonal rings and smaller rhombic rings.

PHENAKITE GROUP

Mineral	Formula	Space Group	a	c	
Phenakite	Be ₂ SiO ₄	R3	12.438	8.231	51.1.1.1
Willemite	Zn ₂ SiO ₄	R3	13.93	9.31	51.1.1.2
Eucryptite*	LiAlSiO ₄	R3	13.471	8.998	51.1.1.3

*In eucryptite, Li occupies the Si sites of phenakite, and Al and Si are disordered in the R sites. The structure is thus a tektosilicate but is retained here because of its derivation from a simpler phenakite structure.

Note: Liberite, Li₂BeSiO₄ (5.1.2.1), although stoichiometrically distinct, has a structure based on approximate close packing of oxygens with all cations in tetrahedral coordination sites.

51.1.1.1 Phenakite Be₂SiO₄

Named in 1833 by Nordenskiöld from the Greek for *deceiver*, in allusion to its being mistaken for quartz. Phenakite group. HEX-R R3. $a = 12.438$, $c = 8.231$, $Z = 18$, $D = 2.96$. $9-431$: 6.24_4 3.66_8 3.60_3 3.12_{10} 2.52_7 2.36_7 2.19_6 2.08_5 . Structure: *JPCM 14:426(1987)*. Flattened rhombohedra, often highly modified; dominant forms {1120}, {1010}, {1011}, {1232}, {1123}, {2113}, {0112}; less commonly prismatic. Penetration twins on {1010}, twin axis [0001]. Colorless, white, yellow, pale rose; vitreous luster. Cleavage {1120}, distinct; {1011}, imperfect; conchoidal fracture. $H = 7\frac{1}{2}-8$. $G = 2.98$. Uniaxial (+); $N_O = 1.654$, $N_E = 1.670$. Fusibility 7; insoluble in acids. Near the ideal composition, with little substitution. Found in granite pegmatites with microcline, topaz, quartz, and so on; also in schists; as a product of beryl alteration. At Lords Hill, Oxford Co., ME; Bald Face Mt., Carroll Co., NH; Morefield mine, Amelia Co., VA; at Rib Mt., Marathon Co., WI; at Mt. Antero, Chaffee Co.(!), as equant crystals and rare twins, and in pegmatites of the Pikes Peak granite as at Crystal Peak, near Florissant, and Harris Park, Teller Co., and Crystal Park, St. Peter's Dome, El Paso Co., CO. At Kragerø, Norway; Framont, Vosges, France; at Reckingen, Valais, Switzerland; at Tschirnitz, Silesia, and Strzegom, Wroclaw, Poland; at Rauris, Salzburg, Austria; at Ober Neusattel, Bohemia, Czech Republic. With emerald and chrysoberyl as large crystals(!) in schist at *Takovaya*, about 90 km E of Yekaterinburg, Sverdlovsk, Ural Mts., Russia, and in the Ilmen Mts., near Miask. Found in

PHENAKITE, Mt. Antero, CO.

Forms: m, {1010}; a, {1120}; x, {1232}.

the Naegi district, Gifu Pref., Japan. At Klein Spizkopje, Swakopmund, Namibia, and in the Usagara district, Tanzania; as prismatic crystals(!) at Anjanabonoina, Madagascar. At San Miguel de Piracicaba(!) as sharp, flat rhombohedra to 12 cm, and as equant transparent rhombs(!) at Marambaia, MG, Brazil. An incidental ore of beryllium and a collectors' gemstone. AR *SPC* 15:1021(1970), *MR* 9:184(1978), *PCM* 13:69(1986).

51.1.1.2 Willemite Zn_2SiO_4

Named in 1830 by Levy in honor of William I (Willem), King (1813–1840) of the Netherlands. The variety troostite was named in 1833 for Gerard Troost (1776–1850), Dutch-born American mineralogist and state geologist of Tennessee. Phenakite group. HEX-R *R3*. $a = 13.93$, $c = 9.31$, $Z = 18$, $D = 4.17$. 37-1485(syn): 4.10₂ 4.02₃ 3.49₇ 2.84₁₀ 2.63₉ 2.32₅ 1.860₄ 1.552₂. Structure: *SPC* 15:387(1970). Massive, granular, less commonly short to long prismatic to fibrous [0001]. Light green, yellow-green, yellow-brown; red-brown, colorless, blue-violet (cobaltoan); vitreous to resinous luster; translucent to transparent. Cleavage {1120}, good to poor; {0001}, poor; conchoidal to uneven fracture; brittle. $H = 5-5\frac{1}{2}$. $G = 4.05-4.20$. Uniaxial (+); $N_O = 1.691-1.714$, $N_E = 1.719-1.732$. Fluoresces bright green in LWUV and SWUV, often phosphorescent; weaker or nonfluorescent in high-purity material or with high transition-element substitution. Fusibility 3–4; gelatinizes with acids. Mn^{2+} and Fe^{2+} replace zinc (troostite); Co^{2+} occurs rarely; refractive indices increase with these substitutions. Willemite with up to 30 mol % phenakite has been prepared in the laboratory. Found in oxidized zones of zinc deposits and in metamorphosed environments; rarely in syenites. Found at Sterling Hill and *Franklin, Sussex Co., NJ*(!), where it was found six years prior to being named, both massive and in fine crystals and as large, brownish, rough crystals (troostite); in microcrystals at Mammoth–St. Anthony mine, Pinal Co, AZ, and in CO, NM, and UT; at the Cerro Gordo and Ygnacio mines, Inyo Co., CA. At the Poudrette quarry(!), Mt. St.-Hilaire, QUE, Canada. At Los Lamentos, CHIH, Mexico. At Ilimaussaq, Greenland. At *Alienberg, Moresenet, Belgium*; Långban, Varmland, Sweden; Kamareza mine, Attica, Greece. Beryllian (0.5 wt % BeO) willemite is reported from an undisclosed locality in Russia (?). At the Seh Chengi mine, eastern Iran; containing up to 25% CoO at Xingsao, Hunan, China; in Huang Hae Prov., North Korea. Near Satif, northeastern Algeria; at Mindouli, Congo; at Mumbwa and Kabuse (Broken Hill), Zambia; and at Guchab and Tsumeb, Namibia. At the Puttapa mine, Flinders Range, SA, Australia. A locally important zinc ore. AR *DT* 601(1932), *DANS* 153:681(1963).

51.1.1.3 Eucryptite $LiAlSiO_4$

Named in 1880 by Brush and Dana from the Greek for *well concealed*, in allusion to its occurrence embedded in albite. Phenakite group. HEX-R *R3*. $a = 13.471$, $c = 8.998$, $Z = 18$, $D = 2.66$. 14-667: 6.74₆ 4.20₃ 3.96₁₀ 3.89₄ 3.37₉ 2.74₈ 2.55₆ 2.38₃. Structure: *ZK* 172:147(1985). Usually massive, less

commonly in equant euhedral crystals with {1010}, {0001}, {1120}. Colorless, white, tan; vitreous luster; translucent to transparent. Cleavage {1011}, indistinct; conchoidal fracture. $H = 5\frac{1}{2}$ – $6\frac{1}{2}$. $G = 2.66$. Uniaxial (+); $N_0 = 1.572$, $N_E = 1.586$. Fluoresces pink in UV; gelatinizes in acids. In pegmatites, often as graphic intergrowths with albite derived from alteration of spodumene. From *Branchville, CT*; Center Stafford, NH; Foote mine, Cleveland Co., NC; Harding mine, Taos Co., NM. From the Tanco pegmatite, Bernic Lake, MB, Canada. From the Nanling Range, Hunan–Guangdong Prov., China. From Bikita, Zimbabwe(*), where it is mined for lithium. AR *D6 426(1892)*, AM *47:557(1962)*.

51.1.2.1 Liberite $\text{Li}_2\text{BeSiO}_4$

Named in 1964 by Chao for the component elements: lithium and beryllium. Equivalent to β - $\text{Li}_2\text{BeSiO}_4$. MON *Pn*. $a = 4.68$, $b = 4.95$, $c = 6.13$, $\beta = 90.3^\circ$, $Z = 2$, $D = 2.69$; the original description has the a and c axes reversed. 29–799(syn): 3.82₁₀ 3.71₁₀ 3.40₇ 2.59₁₀ 2.47₉ 2.35₉ 2.27₉ 2.19₇. The structure is based on close-packed oxygen with all cations in tetrahedral coordination. SR *31A:230(1966)*. Minute aggregates occasionally display pinacoidal faces. Pale yellow to brown; vitreous luster on cleavage, somewhat greasy on fractures. Cleavage {010}, perfect; {100}, {001}, distinct; brittle. $H = 7$. $G = 2.69$. Biaxial (-); $2V_{\text{calc}} = 66.3^\circ$; $N_x = 1.622$, $N_y = 1.633$, $N_z = 1.638$; $Z \wedge c(a \text{ in structure cell}) = 41^\circ$. Found with eucryptite, lepidolite, natrolite, cassiterite, and scheelite in veins cutting lepidolite–fluorite–magnetite “ribbon rock” in the *Nanling Range, Hunan–Guangdong Prov., China*. AR AM *50:519(1965)*, BM *98:6(1975)*.

51.2.1.1 Trimerite $\text{CaMn}_2\text{Be}_3[\text{SiO}_4]_3$

Named in 1890 by Flink from the Greek for *three parts*, in allusion to the optically observable radial segments. MON *P2₁/c*. $a = 8.09$, $b = 7.61$, $c = 14.06$, $\beta = 90.0^\circ$, $Z = 4$, $D = 3.47$. 17–477: 3.56₄ 2.76₁₀ 2.33₃ 2.23₃ 2.05₂ 1.89₇ 1.784₂ 1.420₃. Structure: ZK *147:46(1977)*. Crystals short prismatic to tabular, pseudo-hexagonal; twinned on {100}, {101}, and {101}, cyclic. Colorless, pink, orange-red; vitreous luster; transparent. Cleavage {001}, distinct; conchoidal fracture. $H = 6$ – 7 . $G = 3.474$. Biaxial (-); $2V = 83^\circ$; $N_x = 1.715$, $N_y = 1.720$, $N_z = 1.725$; X perpendicular to {001}; basal sections display three radial segments due to twinning. Gelatinizes with HCl. Occurs in crystals up to 10 mm as intergrowths with calcite in inclusions in a magnetite–pyroxene–garnet skarn at the *Harstigen mine, Pajsberg, Varmland, Sweden*, and similarly at Jacobsberg; also with calcite in fine-grained hematite at Langban. AR *DT:600(1932)*, VLA *2:117(1966)*.

51.2.1.2 Larsenite PbZnSiO_4

Named in 1928 by Palache et al. for Esper Signius Larsen, Jr. (1879–1961), petrologist and Professor of Geology, Harvard University. ORTH *Pnam*. $a = 8.244$, $b = 18.963$, $c = 5.06$, $Z = 8$, $D = 6.12$. 20–607(syn):

4.88₈ 4.19₆ 4.11₅ 4.03₅ 3.78₃ 3.19₁₀ 3.04₈ 2.85₉. Structure: *ZK 124:115(1967)*. Slender prismatic {001}(?), sometimes tabular {010}. White; greasy, adamantine luster; transparent. Cleavage {120}, good; brittle. $H = 3$. $G = 5.90$. Biaxial (-); $2V = 80^\circ(?)$; $N_x = 1.92$, $N_y = 1.95$, $N_z = 1.96$; $X = a$. Found in veinlets with willemite, clinohedrite, esperite, hardystonite, hodgkinsonite, and so on, in ores of *Franklin, Sussex Co., NJ*. At Tsumeb, Namibia, and at the Beltana lead-zinc deposit, Puttapa, SA, Australia. AR *AM 13:142(1928)*, *52:1077(1967)*; *MR 13:142(1982)*.

51.2.1.3 Esperite $\text{Ca}_3\text{PbZn}_4[\text{SiO}_4]_4$

Named in 1965 by Moore and Ribbe for Esper Signius Larsen, Jr. (1879–1961), petrologist and professor of geology, Harvard University. Earlier described as, and synonymous with, calcium-larsenite. MON $B2_1/m$. $a = 17.628$, $b = 8.270$, $c = 30.52$, $\beta = 90^\circ$, $Z = 12$, $D = 4.25$. *16-373*: 7.62₄ 3.36₂ 3.02₁₀ 2.96₂ 2.88₃ 2.54₇ 2.37₄ 1.944₄. Structure: *AM 50:1170(1965)*. Massive to coarse granular. White, vitreous to greasy luster. Cleavage {010} and {100}, distinct; brittle. $H = 5$. $G = 4.28$. Biaxial (-); $2V = 40^\circ$; $N_x = 1.762$, $N_y = 1.770$, $N_z = 1.774$; also $2V = 5-40^\circ$: $N_x = 1.760$, $N_y = 1.769$, $N_z = 1.769$. Fluoresces bright yellow in SWUV. Occurs with willemite, franklinite, and so on, in the zinc ores of *Franklin, Sussex Co., NJ*. AR *USGSPP 180:81(1935)*.

51.2.2.1 Sverigeite $\text{NaMn}^{2+}\text{MgSn}^{4+}\text{Be}_2(\text{OH})[\text{SiO}_4]_3$

Named in 1984 by Dunn et al. for the country of origin. ORTH *Imma*. $a = 10.815$, $b = 13.273$, $c = 6.818$, $Z = 4$, $D = 3.61$. *38-392*: 6.63₅ 5.77₇ 4.35₇ 2.98₆ 2.88₁₀ 2.83₉ 2.71₅ 2.64₆. Isolated SiO_4 tetrahedra are linked to Be tetrahedra to form three- and four-membered rings, $[\text{Be}_2\text{SiO}_8(\text{OH})]$ and $[\text{Be}_2\text{Si}_2\text{O}_{11}(\text{OH})]$, respectively, that are linked in turn to form crenulated chains parallel to [100]. Sodium is in an usual planar four-coordination. The original description interchanges a and c . Structure: *AM 74:1343(1989)*. Yellow, translucent. Cleavage {010}. $H = 6\frac{1}{2}$. $G = 3.60$. Biaxial (+); $2V = 67^\circ$; $N_x = 1.678$, $N_y = 1.684$, $N_z = 1.699$; $Z = b$; $r > v$, strong; pleochroic, $X > Y \approx Z$; yellow to pale yellow. Found in a mine dump specimen as platy aggregates with mimetite, jacobsonite, and an amphibole at the *Långban mine, Värmland, Sweden*. AR *AM 70:1332(1985)*.

OLIVINE GROUP

The olivine group minerals are isostructural silicates conforming to

where A cations are distributed between two sites:

M1 = at a center of symmetry = Zn, Ni, Mg, Fe^{2+} , Mn, Ca

M2 = on a mirror plane = Zn, Ni, Mg, Fe^{2+} , Mn, Ca

and a structure based on a hexagonal close packing of oxygen atoms.

The olivines consist of hexagonal close-packed oxygen atoms with one-half of the octahedrally coordinated sites occupied by A atoms and one-eighth of the tetrahedrally coordinated sites occupied by silicon. The A atoms do not occupy a single set of equivalent lattice positions: half are located at centers of symmetry and half are on mirror planes. The olivines contain serrated, or zig-zag, chains of two size populations of edge-sharing distorted occupied octahedra ($M1 < M2$) parallel to the c axis. They are bridged by isolated SiO_4 tetrahedra. An equivalent chain of octahedra is displaced by $b/2$.

The olivines may be divided into two subgroups: one subgroup is essentially disordered with respect to A-site occupancy, while the other is ordered. There is a large miscibility gap between ordered and disordered olivines, intermediate compositions being virtually unknown. *AM 60:292(1975)*, *68:1174(1983)*, *69:1110(1984)*; *JG 59:193(1951)*; *NJBM:205(1977)*; *RIM 5:275(1980)*; *DHZ 1A:1(1982)*.

Calcio-olivine	Ca_2SiO_4	<i>Pbnm</i>	5.06	11.28	6.78	

Notes:

1. Ringwoodite and wadsleyite are both cubic polymorphs of forsterite.
2. Bredigite and larnite are polymorphs of calcio-olivine.
3. Merwinite ($\text{Ca}_3\text{MgSiO}_4$) is related to monticellite.
4. The humite group minerals are structurally related.

51.3.1.1 Fayalite $\text{Fe}_2(\text{SiO}_4)$

Named in 1840 by Gmelin for the type locality. Olivine group. See forsterite (51.3.1.2). Very manganoan fayalite has been called knebelite and can grade into tephroite (51.3.1.4). ORTH *Pbnm*. $a = 4.756\text{--}4.817$, $b = 10.195\text{--}10.477$, $c = 5.981\text{--}6.105$, $Z = 4$; manganoan (knebelite): $a = 4.826$, $b = 10.500$, $c = 6.102$. *31-633*(magnesian fayalite): 5.21_2 3.95_2 3.54_3 2.81_{10} 2.55_6 2.49_7 2.29_3 1.77_4 ; *12-220*(manganoan): 5.31_3 4.02_2 3.58_3 3.08_2 2.86_{10} 2.59_3 2.53_8 1.79_3 ; *34-178*(syn): 3.56_6 2.83_3 2.63_3 2.565_5 2.50_{10} 1.78_8 1.77_7 1.515_3 . Forms a

complete solid-solution series with forsterite (51.3.1.2). ZnO has been observed in fayalite (10.96 wt %; Ogdensburg, NJ). *USGSP 180:(1937)*. Fe₂O₃ generally less than 2 wt %; higher amounts are due to oxidation, alteration, or inclusions of iron oxides. A complete series extends from fayalite to tephroite (51.3.1.4), with intermediate iron-rich compositions known as knebelite. Ca occupancy of M1 is unfavorable, and CaO is generally less than 0.5 wt %. Ni is preferentially partitioned to forsterite rather than fayalite and is less than 0.4 wt % in fayalite. Pale yellow to olive-green, grading to olive-brown to black, color intensifying with increasing iron contents; colorless to white streak grading to gray; oily or vitreous luster [forsterite (Fo)] grading to dull or submetallic (fayalite). Cleavage {010}, moderate; {100}, weak. $H = 6\frac{1}{2}$ -7. $G_{\text{syn}} = 4.39(\text{fayalite})$. Fluorescence (white-tan, SWUV) noted in low-iron forsterites from contact-metamorphosed deposits (e.g., Crestmore, CA; Gabbs, NV; Balmat, NY). IR spectra: *PCM 5:327(1980)* USGS OFR 87-263(1987). Biaxial; Fo₁₀₀-Fo₈₈ (+, 2V = 87-90°, r < v), Fo₈₇-Fo₀ (-, 2V = 90-74°, r > v); parallel extinction. Fe-rich fayalite is usually pleochroic: X, pale yellow; Y, orange-yellow, reddish brown; Z, pale yellow. Forsterite: $N_x = 1.635$ -1.730, $N_y = 1.651$ -1.758, $N_z = 1.670$ -1.772, $2V_z = 82^\circ(+)$ -74°(-); Fayalite: $N_x = 1.730$ -1.827, $N_y = 1.758$ -1.869, $N_z = 1.772$ -1.879, $2V_z = 74^\circ$ -46°(-). Forsterite-fayalite can be an accessory in many low-silica igneous rocks. Occasionally, iron-rich composition crystals found in granites, also late-stage cavities in extrusive rocks or in xenoliths; in some rhyolites and ash-flow tuffs. Found in many worldwide localities; only noteworthy localities are mentioned here: Hurricane Mt., Conway, Carroll Co., NH; near-end-member composition from Rockport, Essex Co., MA; Ogdensburg(!), Sussex Co., NJ; Pigeon Point, MN; Cheyenne Mt., CO; Obsidian Cliff(!), Lake of the Woods, Yellowstone Park, WY; Coso Hot Springs(!), Inyo Co., CA; Sisters Mt., McKinley Pass, ID; Salt Lake, Oahu Is., HI; Kiglapait and Nain intrusions, Labrador; Forsythe mine, Hull, QUE, Canada; Cerro de las Navajas, Mexico; Skaergaard intrusion, Kangerdlugssuaq, Greenland; Rauthaskritha, Iceland; Slavearrach, Skye Is., and Mull and Rhum Is., Scotland; Mourne Mts., Northern Ireland; Tullisenlampi, Lemi, Finland; *Fayal (Faial) Is.*, Azores; Capucin, Mt. Dore, France; Forgia Vecchia, Lipari Is., Cuddia Mida, Pantelleria Is., Italy; Künstlich, Schlakken, Germany; Dannemora, Sweden; Younger Granites, Nigeria; Bushveld complex, South Africa; Billiton, Indonesia; Broken Hill, NSW, Australia; Lake Taupo, North Island, New Zealand; Kajiya, Kanagawa-Ken, Honshu, Japan.

VK, EF

51.3.1.2 Forsterite Mg₂(SiO₄)

Named in 1824 by M. Levy for Adolarius Jacob Forster (1739-1806), noted English mineral collector. Olivine group. The original name of any olivine mineral that is definitely recognizable as an olivine from its description is chrysolite, named in 1747 by Wallerius and the name of priority use for Mg-rich compositions as early as by Dana in 1892. *Peridot ordinaire* was

FORSTERITE: Mg_2SiO_4

This view shows the edge-sharing chains of M2 octahedra, flanked by M1 octahedra. The octahedra are linked by Si tetrahedra which face alternately up and down in the *a* direction.

named by d'Argenville in 1755, and *peridot* has survived as the gem name for olivine, usually forsterite. The forsterite–fayalite series has been given names for its intermediate compositions: forsterite (90–100% Fo), chrysolite (70–90% Fo), hyalosiderite (50–70% Fo), hortonolite (30–50% Fo), ferrohortonolite (10–30% Fo), fayalite (0–10% Fo). ORTH *Pbnm*. $a = 4.756\text{--}4.817$, $b = 10.195\text{--}10.477$, $c = 5.981\text{--}6.105$, $Z = 4$, $D = 3.22$. 31-795(ferroan forsterite: $Mg_{0.64}Fe_{0.36}$): 3.92₄ 3.52₃ 2.79₁₀ 2.53₆ 2.48₆ 2.29₃ 2.27₃ 1.76₅; 34-189(syn): 3.88₈ 2.765₇ 2.51₈ 2.46₁₀ 2.27₆ 2.25₄ 1.75₇ 1.48₃. A complete solid-solution series exists between forsterite (Fo) and fayalite (Fa). Forsterites of composition $FO_{89\pm 05}$ are very common in basaltic rocks for petrogenetic reasons. Al_2O_3 contents as high as 1.68 wt % have been found in forsterite. Generally, only tenths of 1 wt % Fe_2O_3 are present in fresh olivine; larger amounts are usually due to oxidation or to the presence of minute Fe_2O_3 inclusions. Alkalis are rarely present, both 0.X wt.% or lower. Ca occupancy of M1 is unfavorable, but the content of CaO may reach several wt %. MnO content in forsterite and Fe-bearing forsterite is < 1 wt %. Ni is preferentially partitioned to forsterite relative to fayalite and reaches as much as 0.6 wt % NiO. Crystals are generally short prismatic, elongated on *c* and flattened on *b*. Depending on growth velocities and other factors, crystal habit may be dendritic, skeletal, and so on. Dominant forms are: {110}, {010}, {021}, {101}, {001}, {111}, {120}. Twinning on {011}, {012}, {031}. Pale yellow to olive-green grading to olive-brown to black, color intensifying with increasing iron content; synthetic material is colorless; colorless to white streak grading to gray; oily or vitreous luster (forsterite) grading to dull or submetallic (faya-

lite). Cleavage {100}, {010}, indistinct to good; {001}, poor to fair. $H = 6\frac{1}{2}$ -7. $G_{syn} = 3.24$. Fluorescence (white-tan, SWUV) noted in low-iron forsterites from contact-metamorphosed deposits (e.g., Crestmore, CA; Gabbs, NV; Balmat, NY). Gelatinizes in HCl. Absorption and IR spectral data: *PCM 5:327(1980)*, *DHZ 1A:200(1982)*, US6S OFR 87-263 (1987). Biaxial; XYZ = *bca*; Fo_{100} - Fo_{88} (+, $2V = 82$ - 90° , $r < v$), Fo_{87} - Fo_0 (-, $2V = 90$ - 74° , $r > v$); parallel extinction. If Fe^{2+} is only in M1, absorption is $\beta > \gamma > \alpha$; if Fe is present in both M1 and M2, absorption scheme is the same, and if Fe is present only in M2, then $\gamma > \beta > \alpha$. Forsterite: $N_x = 1.635$ - 1.730 , $N_y = 1.651$ - 1.758 , $N_z = 1.670$ - 1.722 ; $2V_z = 82^\circ$ (+)- 74° (-); Fayalite: $N_x = 1.730$ - 1.827 , $N_y = 1.758$ - 1.869 , $N_z = 1.772$ - 1.879 ; $2V_z = 74^\circ$ - 46° (-). Found in a host of intrusive and extrusive mafic and ultramafic igneous rocks, including kimberlites. Dunite is at least 90% forsterite. Present as nodules and xenoliths in various igneous rocks. Forsterite and Mg-dominant olivines are also found in thermally metamorphosed dolomitic limestones and dolomites, and calcite veins. Forsterite-fayalite can be an accessory in many low-silica igneous rocks. Manganese-bearing compositions found in manganese-bearing skarns or contact-metamorphosed manganese-bearing rocks. Found in some meteorites (e.g., pallasites = stony irons). Ubiquitous, only noteworthy localities are mentioned here: Bolton, Worcester Co., MA; Balmat, St. Lawrence Co., NY; Palisades Sill, Bergen Co., NJ; Balsam Gap(!) and Webster (dunite), Jackson Co., NC; Wichita Complex, OK; Kilbourne Hole, 20 miles SW of Las Cruces, NM; San Carlos Reservation(!), Gila Co., AZ; Gabbs, Nye Co., NV; Crestmore(!), Riverside Co., CA; Snake River plain, ID; Jumbo Mt.(!), Snohomish Co., WA; Mauna Loa, Hawaii Is., HI; crystals to 6 cm \times 20 cm \times 30 cm at the Parker mine, Notre Dame du Laus, and Oka complex, QUE, Canada; Skaergaard intrusion, Kangerdlugssuaq, Greenland; Lanzarote, Canary islands; Coire a Gretaich, Cullins and Bornas-kitaig, Skye, Scotland; Puy de la Denise(!), Puy de Dôme district, France; Traversella(!), Piedmont, *Vesuvius(!) and Monte Somma(!)*, Campania Naples, Baccano, Albani Hills, Mt. Etna, Sicily, Italy; Findelen moraine, Zermatt, Switzerland; Bellerberg, Laacher See, Dreiser Weiher, and Porstberg, Eifel district, Unkel(!), Rhine, Germany; Triblitz, Bohemia, Czech Republic; Pfunders, Tirol, Austria; Vourinos complex, Greece; Møre(!) and Snarum(!), Norway; Alnö island, Sweden; gem peridot occurs on Zabargad Is.(!) (St. John's Is.), Egypt; crystals to >10 cm from the Kovdor massif, Kola Penin.; Nikolai-Maximillian mine, Achmatovsk, and Kyshtym, Zlatoust district, Ural Mts., Russia; very fine, large crystals to 14 cm of "peridot" have recently been found near Sumpat (Suppatt), between Kamila and Naran, near Nanga Parbat, Mansehra district, NWFP, Pakistan. Crystals as heavy as >2 kg and of variable color ranging from superb green and of transparent gem quality (> 100 ct) to yellowish green and grayish green; Jacupiranga(!), São Paulo, Brazil; Nyiragongo volcano, Zaire; Ethiopia; Klaasvoogds, Cape Prov., South Africa; Salem(!), Tami Nadu, India; Sri Lanka; Mogok district. Crystallized and gem peridot occur in Myanmar (Burma); Vaitunamea, Tahiti, Society Is.; Kalka and Ewarara intrusions, Australia; Dun Mt.

(dunite), New Zealand; Vietnam; Nishinotake, Japan. Used as a minor gemstone (tumbled and faceted gems). vk, EF *G&G* 28:16(1992).

51.3.1.3 Liebenbergite Ni_2SiO_4

Named in 1973 for William Roland Liebenberg (1919–1988), South African metallurgist (ore dressing), mining official, and mineralogist. Olivine group. ORTH *Pbnm*. (Nat): $a = 4.727$, $b = 10.191$, $c = 5.955$ [*AM* 58:733(1973)]; (nat): $a = 4.731$, $b = 10.180$, $c = 5.941$ [*AM* 66:770(1981)]; (syn): $a = 4.725$ – 4.728 , $b = 10.117$ – 10.118 , $c = 5.908$ – 5.9125 [*NJBM* 30 (1963); *AC(B)* 39:692(1983)]; $Z = 4$, $D = 4.585$ – 4.60 (nat), $D = 4.92$ (syn). 15-0388 (nat): 5.09₃ 3.47₆ 2.76₉ 2.50₈ 2.44₁₀ 2.25₃ 1.74₉, 1.473₃; (syn): 4.28₂₅ 3.84₂ 3.47₉ 2.74₉ 2.55₄ 2.49₈ 2.43₁₀ 1.73₆. Ni is strongly partitioned from coexisting fluids by olivine [*NAT*:1147(1966)] and is strongly ordered into the M1 site [*AM* 60:292(1975)], potentially leading to ordered NiM_2SiO_4 intermediate compositions [*AM* 66:770(1981)]. Natural liebenbergite is fully ordered with M1 occupied only by Ni, whereas synthetic material is only partially ordered (because of rates and temperatures of equilibration). Structure of synthetic: *AC(B)* 39:692(1983). Granular (most <150 μm), yellowish green, or bright green grains to 1 mm. Cleavage {010}, good to poor; {100}, poor. $H = 6$ – $6\frac{1}{2}$. IR spectra: *PCM* 5:327(1980). Ni is a frequent minor element in forsterite in the range 0.10–0.30 wt %. *JG* 78:304(1970). End member liebenbergite not yet known. Analysis of type material (wt %): SiO_2 , 29.39; NiO , 56.32; MgO , 6.50; FeO , 4.37; CoO , 1.80. Biaxial (–); XYZ = *bca*; $N_x = 1.820$, $N_y = 1.854$, $N_z = 1.888$; $2V = 80$ – 88° ; OAP = (001); $r > v$; parallel extinction; slightly pleochroic. X, Y, colorless to pale green; Z, greenish yellow. Is variably replaced by Ni-serpentine (nepouite). Occurs in a serpentinized ultramafite containing abundant trevorite. From two assemblages variously containing bonaccordite, bunsenite, gaspéite, goethite, millerite, nepouite, nimite, reeve-site, trevorite, violarite, and willemeite. Found at the *Scotia Talc mine, Bon Accord, Barberton Mountain Land, Transvaal, South Africa*. vk, EF

51.3.1.4 Tephroite Mn_2SiO_4

Named in 1823 by Breithaupt in allusion to the ash-colored nature of the original material. Olivine group. ORTH *Pbnm*. (Nat): $a = 4.86$ – 4.908 , $b = 10.59$ – 10.772 , $c = 6.22$ – 6.302 ; (syn): $a = 4.903$, $b = 10.604$, $c = 6.258$; $Z = 4$, $D = 3.97$ (nat), $D = 4.12$ (syn). 31-0823(magnesian): 3.57₃ 3.09₂ 2.84₉ 2.58₁₀ 2.53₉ 1.79₈ 1.55₅ 1.53₅; 35-0748(syn): 3.63₅ 2.87₉ 2.69₃ 2.67₇ 2.56₁₀ 1.81₇ 1.80₃ 1.56₃; 45-1396(calcian): 4.10₁₅ 3.64₅ 2.89₈₅ 2.72₂ 2.63₈₅ 2.57₁₀ 1.82₅ 1.81₅. Twins on {110}, also polysynthetic twinning and rarely trillings. Elongated on c , sometimes on a . Dominant forms: {100}, {010}, {110}, {101}, {021}, {111}. Crystals are scarce at most deposits, tephroite being either individual grains enclosed in matrix only rarely grading to euhedral (to 2.5 cm) (Ogdensburg) or compact and massive. Elongated crystals of complex form found lining fractures. The color of the end member tephroite is variable: bluish to greenish gray, and grades to gray (daylight); with increasing ele-

mental substitutions grades to smoky gray to black, frequently brown to red or purple (incandescent light); gray streak; vitreous to subvitreous luster grading to dull; high iron compositions can have a nearly submetallic luster. Cleavage: {010}, good; {001}, moderate; {011}, poor; conchoidal fracture. $H = 5\frac{1}{2}$ –6. $G = 3.78$ –4.1. Gelatinizes in mineral acids. Optical absorption spectra: *IMA Papers and Proc., 5th Gen. Meet., Cambridge: 22–35(1968)*. IR data: *AM 49:1388(1964)*. Raman spectra: *JCS(A):1372(1969)*. Grades into fayalite with intermediate compositions called knebelite, while compositions grading to forsterite are scarce and have been termed picrotephroite. Compositions between Fo–Fa–Te have been rationalized by plots of N_y vs. d_{130} . *CM 14:479(1976)*. ZnO substitutes to 18.90 wt % (Ogdensburg), while CaO has been observed to 3.8 wt % (Japan). Both Al_2O_3 (to 0.97 wt %, Japan) and Fe_2O_3 (to 4.57 wt %) substitute in tephroite, but may be due to alteration. Ferroan tephroites tend to have a wide variety of additional substituents. Sometimes intergrown with alleghanyite. Biaxial (–); XYZ = bca; $N_x = 1.760$ –1.795, $N_y = 1.790$ –1.810, $N_z = 1.807$ –1.830; $2V = 55$ –70°. $X < Z < Y$; OAP = (001). Sometimes pleochroic; X, brownish; Y, reddish; Z, greenish blue. Also colorless to pale yellow and brownish. Z, bluish; X, pale yellow. RI values increase with increasing Fe^{2+} substitution but are greatly lowered by Mg substitution (e.g., $N_x = 1.750$, $N_y = 1.766$, $N_z = 1.779$). Mg substitution increases $2V$; $r > v$. Sometimes formed as a metasomatic reaction of rhodonite with rhodochrosite or manganoo calcite. Also suggested as a reaction of a manganoo carbonate with quartz, producing tephroite and amphibole. Found in iron- and manganese-rich ores and skarns, sometimes in late-stage veins. Sometimes found in contact-metamorphosed manganese-bearing sediments. Found frequently with manganoo calcite and with other manganese silicates, such as rhodonite, spessartine, bustamite, rarely alleghanyite, friedelite, or glaucochroite. Found with willemite and zincite ores at Franklin and Ogdensburg. Numerous worldwide localities; only localities having noteworthy material are mentioned here. Occurs at the Betts mine, Plainfield, MA; *Sterling Mine(!)*, Ogdensburg, and Mine Hill(!), Franklin, Sussex Co., NJ; Bald Knob mine, Sparta, Alleghany Co., NC; Alamo Crossing, Mohave Co., AZ; Caldwell mine, Caldwell, Mariposa Co., CA; Benallt mine, Rhiw, Carnarvonshire, Wales; Meldon, Okehampton, Devonshire, Treburland mine, Altarnun, Cornwall, England; Bonneval-sur-Arc, Haute Maurienne, France; Bjelkes, Kolegii, Loka, Nya, and Stor mines, Langban, Brattfors, Eastern Moss, and Jakobsberg mines, Nordmark, Harstigen and Pajsberg mines, Pajsberg, Värmland, Sjö mine, Grythyttan, Örebro, and Dannemora, Sweden; near Davos and St. Moritz, Switzerland; northern Appennines, Italy; near end-member composition from Möserboden, near Salzburg, Austria; Laacher See, Germany; Chvaletice, Bohemia, Czech Republic; Sebes-Cibin Mts., Romania; cuprian (to 29.6%) from Bulgaria; Primorye, Russia; Lake Balkhash, Kazakhstan; Dzhumart, Kamys, and Karadzhal deposits, central Kazakhstan; La Loma area, Santa Barbara, Antioquia Dept., Bolivia; Moanda, Gabon; Wessels mine(!), Black Rock, Kalahari Field, South Africa; Xihucum, Chanping, Beijing, China; Ikenotsura mine,

Kumamoto Pref., Kaso and Kyurazawa mines, Tochigi Pref., Hijikuzu, Tamagawa (magnesian, 6.6 wt % MgO), and Toyoguchi mines, Himegamori, Iwate Pref., Japan; calcian (3.8 wt % CaO) from Kanoiri mine, Kanuma Station, Tochigi Pref., Japan; Consolidated mine, Broken Hill and Danglemah, Tamworth district, NSW, Australia; Clark Peninsula, Wilkes Land, Antarctica; Serra do Navio, Amapa, Brazil; Andra Pradesh, India; Fotadrevo, Madagascar. *VK, EF MIN 3(1):199(1972), LIT 29:57(1992), DHZ 1A:337(1982), NJFM 159:101(1988), BNSM 17:119(1991).*

51.3.1.5 Laihunite $(\text{Fe}_{0.5}^{2+}\square_{0.5})\text{Fe}^{3+}\text{SiO}_4$

Named in 1976 for the type locality. Olivine group. May also be formulated as $(\square_x\text{Fe}_{2-3x}^{2+}\text{Fe}_{2x}^{3+}\text{SiO}_4)$. *MONO P2₁/b. (1M): a = 4.805–4.83, b = 10.189–10.27, c = 5.801–5.90, $\alpha = 90.9–91.3^\circ$ (to conform with *Pbnm* setting of olivine); (syn 2M): a = 4.81, b = 10.43, c = 5.93, $\beta = 91.0^\circ$; (syn 3M): a = 4.81, b = 10.44, c = 5.99, $\beta = 90.3^\circ$; Z = 2, D = 4.10–4.24. *AM 70:737(1985).* Superlattice reflections of 2c and 3c exist, and are called 2M and 3M, respectively (Ramsdell notation). *30–664: 3.78₆ 3.47₉ 2.78₈ 2.52₁₀ 2.405₆ 2.26₅ 1.75₇ 1.44₄*; the powder data differ from fayalite in intensity, extinction rules, and smaller d values. *AM 62:1058(1977).* A nonstoichiometric, distorted fayalite-type structure. Excess charge caused by the substitution of Fe^{3+} for Fe^{2+} is compensated at M1 by vacancies (octahedral sites). This accounts for Fe deficiency in the $\text{M}_2^{2+}\text{SiO}_4$ olivine structure. All M2 positions are occupied by Fe^{3+} , whereas M1 positions are alternately vacant and occupied by Fe^{2+} . Crystals < 1 mm thick, tabular to short, prismatic. Black, pale brown streak, metallic to submetallic luster, opaque. Weakly magnetic. Cleavage {010}, perfect; {001}, good; {100}, perfect. Microscopically twinned, and with development of antiphase domains. Intergrowths of laihunite with magnetite are frequent but not universal; also intergrown with hematite. $H = 5\frac{1}{2}–6\frac{1}{2}$. $G = 3.92–3.97$. Mossbauer spectra and magnetic and electrical properties: *AM 70:729(1985), 70:576(1985) SS 30(4):373(1995).* Thermal data: *AM 62:1058(1977), 63:424(1978).* Essentially a ferric analog of fayalite with compensating vacancies in M_1 . Analysis (wt %): SiO_2 , 31.31; Fe_2O_3 , 44.29; FeO, 23.89; MgO, 0.67; CaO, 0.34. Substitutions suggest compositions grading to magnesian or manganoan varieties [e.g., $(\text{Fe}^{2+}0.5_{0.5})(\text{Fe}^{3+}, \text{Mg}, \text{Mn})\text{SiO}_4$]. Observed substitutions (wt %) include: Al_2O_3 , 0.065; MgO, 5.91; MnO, 4.31; CaO, 0.47. Opaque in standard thin sections, brownish red when a few microns thick. Calculated refractive indices range between 2.01 and 2.04. In RL, gray to grayish black, parallel extinction, weakly anisotropic, slightly heterogeneous extinction. $R = 2.39$ (650 nm), 12.39 (589 nm), 13.43 (green); internal pleochroic reflections gray to grayish black. Laihunite plus magnetite intergrowths can form from the oxidation of fayalite, with which they can be in contact as microscopic rods or as discrete patches. Originally found in a quartz–hypersthene granulite associated with a metamorphosed banded iron deposit; laihunite was found with quartz, enstatite, and magnetite. Also reported as migmatite and/or eulysite (China). Found as inclusions in black*

fayalite with magnetite from syenite, granite, and granite pegmatites (e.g., CO). Found as individual crystals in lithophysae with tridymite, fayalite, and hematite in dacite (Japan). Found at Stove Mountain, St. Peters Dome, Crystal Park, and Cheyenne Canyon, El Paso Co., CO, Lake Albert, OR; Mourne Mts., Northern Ireland; Pantelleria Is., Sicily, Italy; *Lai-He village, Qianan Co., Liaoning Prov., Jixi Co., Anhui Prov., and Hubei Prov., China*; Kamitaga, Atami, Shizuoka Pref., Yugawara-cho, Kanagawa Pref., and Naegi, Japan. Possibly remotely sensed on Mars and Venus. *vk, EF G 1:115(1982); MJJ 11:382(1983), 12:376(1985); AM 69:154(1984)*.

51.3.2.1 Monticellite CaMgSiO_4

Named in 1831 by Brooke for Teodoro Monticelli (1759–1845), noted Italian mineralogist. Olivine group. ORTH *Pbnm*. (Syn): $a = 4.815$, $b = 11.108$, $c = 6.37$; (nat): 2.676_{10} 3.64_8 2.60_6 3.19_4 2.94_4 4.19_3 2.40_3 1.819_3 ; *35-0590(syn): 3.63_5* 3.18_3 2.93_4 2.66_{10} 2.58_6 2.40_3 1.82_6 1.59_3 . Of the two available octahedral sites, Ca atoms occupy sites on the mirror planes (M2) and Mg atoms are at the centers of symmetry (M1). Monticellite is frequently near-end-member composition, but grades toward kirschsteinite ($M_{75}K_{25}$) in rare cases (Muck). Minor substitutions observed (wt %) include Na_2O , 0.14; K_2O , 0.25; SrO , 0.08; BaO , 0.18; TiO_2 , 0.13; Al_2O_3 , 0.75; Fe_2O_3 , 1.70; MnO , 1.17. Some Crestmore material contains as much as 4.6 wt % SO_3 *BCGF 157:7(1952)*. Crystals are scarce and then usually rounded, short prismatic on c . Dominant forms: {010}, {120}, {110}, {111}, {121}, others are rare. Twinning observed on {031}. Colorless to white to gray, also greenish gray, greenish yellow, or amber yellow; white streak; vitreous to oily luster. Cleavage {010}, poor; conchoidal fracture. $H = 5\frac{1}{2}$. $G = 3.04\text{--}3.31$. IR data: *AM 49:1388(1964)*. Biaxial (-); $XYZ = bca$; $N_x = (1.641 \text{ syn}) 1.641\text{--}1.654$ (1.674 near kirschsteinite), $N_y = (1.646 \text{ syn}) 1.649\text{--}1.664$ (1.694 near kirschsteinite), $N_z = (1.652 \text{ syn}) 1.655\text{--}1.674$ (1.706 near K); $2V = (85\text{--}90^\circ \text{ syn})$, $70^\circ\text{--}90^\circ$ (decreasing with increasing Fe^{2+} or Mn substitution); colorless; OAP parallel to (001); $r > v$, parallel extinction, sometimes as optically continuous overgrowths on forsterite. Sometimes thermoluminescent. Observed to be replaced by serpentine and/or fassaitic pyroxene. Formed in skarns and marbles during high-temperature metasomatism or metamorphism. Found in some ultrabasic rocks, mellilites, peridotites, nepheline basalt, alnöite, lamprophyres, or carbonatites. Found in association with apatite, biotite, calcite, diopside, dolomite, forsterite, gehlenite, magnetite, merwinite, perovskite, scapolites, spinel, spurrite, vesuvianite, or wollastonite, rarely with clinohumite or cuspidine. Notable localities include Cascade slide(1), Essex Co., NY; Magnet Cove(1), Hot Spring Co., AR; Omaha oil field, Gallatin Co., IL; Haystack Butte, Highwood Mts., MT; Wind River Range, WY; Tres Hermanas Mts., Luna Co., NM; Crestmore(1), Riverside Co., Dewey mine, Valley Wells, Clark Mt. district, San Bernardino Co., CA; York River skarn, Bancroft, ONT, Montreal mine and Lake of Two Mountains, Oka, and Isle Cadieux, QUE, Mineral Mt. and Copper Butte, BC, Elwin Bay diatrema, NWT, Canada; Camas

Malag, Broadford, Skye Is., and Camas Mor, Muck Is., Inverness, Scotland; Carlingford district, County South, Ireland; Schälbischen Alb, Württemberg, Künstlich, Schlakken, and Dillenburg, Nassau, Germany; Monte Somma and *Mt. Vesuvius*, Naples, Campania, Italy; Toal dei Rizzoni, Mt. Monzoni, and Pesmeda Alp, Tirol, Austria; Severnyi mine, Enski district, and Kovdor massif, Murmansk Oblast, Kola Penin., Malo-Murun massif, Yakutia, Tazheran massif, Lake Baikal, and Anakit district, Lower Tunguska R., Siberia, and Zagorny massif, Kuznetsk Alatau, Akhmatovsk mine, Southern Ural Mts., Lespromkhozhnoye skarn, Patynsk, Gornaya Schoriya, and Taknakh, Russia; Hatrurim Formation, Israel; Salpetre Kop, South Africa; Borra, Visakhapatnam district, and Nanjangud, Mysore, India; Xujiachong picrite body, Jingshan Co., Hubei Prov., China; Hoki-zawa, Kanagawa Pref., Kushiro, Hiroshima Pref., Japan; Hobart, TAS, Australia. *VK, EF MIN 3(1):212(1972), DHZ 1A:352(1982).*

51.3.2.2 Kirschsteinite $\text{Ca}(\text{Fe},\text{Mg},\text{Mn})\text{SiO}_4$

Named in 1957 by Sahama and Hytönen for Egon Kirschstein, German geologist and pioneer in geological work in North Kivu, Zaire. Olivine group. *ORTH Pbnm*. (Syn): $a = 4.875$, $b = 11.159$, $c = 6.441$, $Z = 4$, $D = 3.56$. *34-0098(nat)*: 2.949_{10} $2.68_{8.5}$ 2.604_8 3.658_7 1.839_6 ; (syn): 5.58_3 3.67_4 2.96_7 2.79_3 2.68_7 2.61_{10} 1.835_9 1.61_5 . Can use d_{130} X-ray spacing to distinguish members of the monticellite-kirschsteinite series from Ca-free or Ca-poor olivine. *AM 43:862(1958)*. Type material is anhedral, but sharp translucent crystals to 1 mm are found at Mt. Nyiragongo. Yellowish to greenish gray; streak not reported, probably colorless; vitreous to oily luster presumed. Cleavage not reported, but monticellite has a poor cleavage. $H = 5.5$. $G = 3.31-3.43$. Soluble in acids. Mossbauer spectra *SSC 5:267(1967)* shows that Fe^{2+} is in a single site (M2). Extremely magnesian compositions to near monticellite occur. A subcalcic variety of kirschsteinite has been analyzed. Observed substitutions (wt %) include: TiO_2 , 0.28; Al_3O_6 , 0.71; Fe_2O_3 , 1.87; MnO , 1.65; Na_2O , 0.38; K_2O , 0.36. As much as 2.55 wt % Al_2O_3 in monticellite-kirschsteinite solid-solution series. Biaxial (-); $\text{XYZ} = bca$; $N_x = 1.674-1.696$ (Syn), $N_y = 1.694-1.734$ (Syn), $N_z = 1.706-1.743$ (Syn); $2V = 51-65^\circ$; parallel extinction. Found at the type locality in a melilite nepheline associated with clinopyroxene, apatite, biotite, combeite, gehlenite, götzenite, hornblende, kalsilite, nepheline, perovskite, and sodalite. Also with clinopyroxene, leucite, magnetite, melilite, nepheline, and pyrrhotite (Mt. Nyiragongo). Occurs in calcareous skarn xenoliths in alkali syenite (Tazheran). Observed in peridotites, meteorites, and lunar samples. Formed during underground nuclear bomb detonation. *AM 51:1192(1966)*. Found in the Minnesota River Valley, MN; magnesian from Tazheran massif, Lake Baikal region, Russia; top of Mt. Nyiragongo and northeastern Mt. Shaheru, Nyiragongo area, Kivu, Zaire; manganoan ($\text{Kr}_{55}\text{-Gl}_{45}$) from Wessels mine, Kuruman, Kalahari district, South Africa; magnesian in Angra dos Reis, Brazil, achondrite; Lewis Cliff meteorite. *VK, EF MIN 3(1):218(1972), DHZ 1A:352(1982).*

51.3.2.3 Glauchchroite $MnCaSiO_4$

Named in 1899 by Penfield and Warren from the Greek for *blue* and *color*, in allusion to the blue color of some specimens. Olivine group. ORTH $Pbnm$. $a = 4.913\text{--}4.93$, $b = 11.14\text{--}11.19$, $c = 6.488\text{--}6.60$, $Z = 4$, $D = 3.49$. 14-0376: 4.23₄ 3.69₆ 2.96₆ 2.69₈ 2.63₈ 1.85₁₀ 1.13₅ 1.11₅; Wessels mine: 5.53₄, 4.26₂ 3.02₅ 2.70₁₀ 2.58₄ 2.46₄ 1.845₅ 1.61₁₀. Ca is in M2 and Mn is in M1. *AM 63:365(1978)*. Crystals are elongated, to 1 cm prismatic on c . Forms include {100}, {010}, {110}, {120}, {103}, {021}, and others. Gray-lilac, bluish green through brown to brownish rose and red-orange, rare crystals pale pinkish lilac (Franklin); white streak; vitreous to dull (fine-grained) luster. Cleavage {100}, poor; conchoidal fracture; brittle. Twinning observed on {011} (Franklin). $H = 6$. $G = 3.41\text{--}3.48$. Moderately fusible; gelatinizes in acids, particularly HCl. Optical absorption spectra: *IMA Papers and Proc. 5th Gen. Meet., Cambridge, 1966*; *MSL:22-35(1968)*. IR spectra: *AM 49:1388(1964)*. Generally near end member with minor MgO (to 3.17 wt %, Franklin). Substitutions observed (wt %) include: Al_2O_3 , 0.5-1.85 (Wessels); PbO, 1.74 (Franklin); ZnO, 2.35; minor alkalis (Franklin). Biaxial (-); XYZ = bca ; $N_x = 1.682(1.685 \text{ syn})\text{--}1.695$, $N_y = 1.710\text{--}1.723(\text{syn})$, $N_z = 1.725\text{--}1.736(\text{syn})$; $2V = 61^\circ$; parallel extinction; $r > v$; weak or no pleochroism. Color in thin section: orange-red (Wessels) or colorless; X, Y, light yellow-orange; Z, red-orange (Wessels). Partially derived from metasomatism of manganese silicates. *AM 72:423(1987)*. Weathers to a black sooty material. Found in a manganese-rich hydrothermally worked, skarnlike assemblage (Franklin) associated with manganite, andradite, barite, bustamite, clinohedrite, diopside, franklinite, hardystonite, leucophoenicite, nasonite, willemite, or zincite. Also with calcite, andradite, diopside-hedenbergite in a dolerite-limestone skarn (Russia). With diopside, wollastonite, and other minerals in calc-silicate rocks with manganese minerals in the Wessels mine, Kalahari manganese field, South Africa. Occurs at the *Parker shaft, Franklin, Sussex Co., NJ*; Anakit skarns, Nizhnaya, Lower Tunguska R., Siberia, Russia; Wessels mine, Kuruman, Kalahari Field, South Africa; Gunning Bijih (Ertsberg) skarn, Irian Jaya, Indonesia. VK, EF *MIN 3(1):220(1972)*.

51.3.3.1 Ringwoodite Mg_2SiO_4

Named in 1969 by Binns et al. for Alfred Edward Ringwood (b.1930), petrologist, University of Canberra, Australia. iso $Fd\bar{3}m$. $a = 8.075(\text{syn } Mg_2SiO_4)$, 8.113(ferroan)-8.122(nat), 8.234(syn Fe_2SiO_4); $Z = 8$, $D = 3.90$. 21-1258(ferroan): 2.87₂ 2.45₁₀ 2.03₄ 1.56₂ 1.43₆ 1.06₁ 1.01₁ 0.828₁; 13-0230: 4.74₄ 2.91₃ 2.48₁₀ 2.06₁ 1.94₁ 1.89₁ 1.68₅ 1.58₅. Ringwoodite is a polymorph of forsterite and wadsleyite and has the normal spinel structure. See also *CJG 9:99(1990)*. The original material is a ferroan ringwoodite with 23.2-23.4 wt % FeO with no other substituents. Catherwood varies in FeO by 22.5-24.1 wt %. The name *ringwoodite* is currently applied to the entire series ($Fe_2SiO_4\text{--}Mg_2SiO_4$), but if iron-dominant material is found, nomenclature changes will

be necessary. Anhedral, purple, bluish gray, or smoky gray 100- μm grains. $G = 3.90$. Isotropic; $N = 1.768$, colorless to pale purple. Found as anhedral grains replacing ferroan forsterite or as dark veinlets in the Tenham chondrite meteorite. Presumed to exist in Earth's mantle. Also found in extraterrestrial microspherules of melt glass in a granite in western Suzhou, China. *CSB 38:1651(1993)*. Found in the Catherwood, SAS, Canada, L6 olivine-hypersthene chondrite; Peace River, AL, Canada, L6 chondrite; Coorara, WA, chondrite, and *Tenham, Australia, chondrite*; Pampa de Infierno chondrite, Argentina. *vk, EF N 221:943(1969), MIN 3(1):13(1972), GCA 46:1903(1982)*.

51.3.4.1 Wadsleyite $-(\text{Mg}, \text{Fe}^{2+})_2\text{SiO}_4$

Named in 1983 by Price et al. for A. D. Wadsley, crystallographer. *ORTH Imma*. $a = 5.70$, $b = 11.51$, $c = 8.24$, $Z = 8$, $D = 3.84$. *37-0415*: 2.89₅ 2.69₄ 2.64₃ 2.45₁₀ 2.04₈ 1.57₃ 1.55₃ 1.44₈. Polymorph of forsterite and ringwoodite. *PEPI 3:166(1970)*. Light grayish brown, translucent. Type wadsleyite is very ferroan ($\text{Mg}_{15}\text{Fe}_{0.5}\text{SiO}_4$). Analysis (wt %): Mg, 23.05; Si, 18.08; Fe varies from 16.73 to 17.78. Minor substitutions (wt %) include: Ca, 0.11; Cr, 0.07; Mn, 0.31–0.36; Ni, 0.07–0.13; Zn, 0.19. Anisotropic, fine-grained aggregates show $RI = 1.76$, low first-order interference colors. Found as microcrystalline aggregates pseudomorphing previously existing forsterite grains in veinlets in a meteorite believed to have experienced high-pressure shock. *Peace River, Alberta, Canada, L6 chondrite*. *EF CM 21:29(1983)*.

51.4.1.1 Bredigite $\text{Ca}_7\text{Mg}(\text{SiO}_4)_4$

Named in 1948 by Tilley and Vincent for Max Albrecht Bredig (b.1902), German-born American chemist, who studied polymorphism of calcium silicates. *ORTH P2nn*. $a = 10.909$, $b = 18.34$, $c = 6.739$, $Z = 4$, $D = 3.412$. *35-260(syn)*: 2.74₁₀ 2.73₁₀ 2.67₁₀ 2.23₃ 2.22₂ 1.924₃ 1.899₂ 1.562₂. The structure allegedly corresponds to that of α' - Ca_2SiO_4 ; the Ca sites, however, are not all equivalent, and the formula may be written as $(\text{Ca}, \text{Ba})\text{Ca}_{13}\text{Mg}_2(\text{SiO}_4)_8$. *AM 61:74(1976)*. Found as rounded grains, 50–100 μm ; twinned on {110}. Colorless to gray, vitreous luster. Cleavage {130}, distinct. $G = 3.40$. Biaxial (+); 2V variable; $N_x = 1.712$, $N_y = 1.716$, $N_z = 1.725$; $r < v$, weak; for Israel material $N_x = 1.695$, $N_z = 1.705$. Barium may replace up to 29% of the calcium in the larger Ca site, but overall BaO is < 0.3 wt %. Gelatinizes with acids. Found in thermally metamorphosed aureoles in intruded limestones, and in near-surface thermal metamorphism of carbonaceous limestones. With larnite at Marble Canyon, Culberson Co., TX. At *Scawt Hill, County Antrim, Northern Ireland*; Island of Muck, Inverness-shire, Scotland. In surface exposures of the Hatrurim formation at several localities in Israel. *AR MM 28:255(1948), GSIB 70:30(1977)*.

51.4.2.1 Merwinite $\text{Ca}_3\text{Mg}(\text{SiO}_4)_2$

Named in 1921 by Larsen and Foshag for Herbert Eugene Merwin (1878–1963), an American mineralogist. *MONO* $P2_1/a$. $a = 13.254\text{--}13.26$, $b = 5.293\text{--}5.301$, $c = 9.328\text{--}9.336$, $\beta = 91.9\text{--}92.8^\circ$; (syn): $a = 13.298$, $b = 5.305$, $c = 9.352$, $\beta = 92.09^\circ$; $Z = 4$, $D = 3.31\text{--}3.33$. *PD*(nat): 2.674₁₀ 2.452₈ 4.70₅ 2.652₅ 2.211₄ 2.752₄ 1.909₃ 2.031₃; 35-591(syn): 2.76₃ 2.69₁₀ 2.67₆₅ 2.65₅ 2.21₂ 2.03₁ 1.91₃₅ 1.88₂. Merwinite has a distorted glaserite-type structure. Isolated $[\text{MgO}_6]$ octahedra are linked at all apices with $[\text{SiO}_4]$ tetrahedra, showing pseudohexagonal arrangement. Ca resides within three different sites in layers slightly above and below the $[\text{MgO}_6]$ octahedral layer, one Ca site is 12-coordinated and two are ideally 10-coordinated but are frequently distorted to eight- to nine-coordinated. Noteworthy features include layers of Ca sites which are coplanar oxygen positions. *AM* 57:1355(1972). Euhedral crystals rare (to 3 mm), usually granular; may be prismatic along $[011]$ or $[0\bar{1}1]$ or tabular parallel to (100); prominent forms are: $\{211\}$, $\{011\}$, $\{001\}$, $\{101\}$; polysynthetic twinning on $\{100\}$, twin axis $[013]$, common. Colorless, white to light green; vitreous to oily luster; translucent. Cleavage $\{100\}$. $H = 6$. $G = 3.15\text{--}3.32$. IR data: *MM* 31:187(1956). Readily soluble in HCl. Essentially end-member compositions observed, with some substitution of iron to several weight percent. Biaxial (+); $N_x = 1.706\text{--}1.714$, $N_y = 1.711\text{--}1.720$, $N_z = 1.718\text{--}1.729$; $2V = 65\text{--}74^\circ$; $r > v$. Found in high-temperature, low-pressure contact zones of eruptive rocks and carbonate rocks: metamorphosed marbles, persistent to high pressures, and is associated with calcite, clintonite, gehlenite, grossular, larnite, monticellite, spinel, spurrite, vesuvianite, wollastonite, or xonotlite. The mnemonic for the order of appearance of reaction products of progressive contact metamorphism of marbles—tremolite, forsterite, diopside, periclase, wollastonite, monticellite, akermanite, spurrite, merwinite, larnite—is “Tremble, for dire peril walks, monstrous acrimony’s spurning merwinite’s laws.” *JG* 48:225(1940). A component of portland cement, also found in silicate slags. Found at Marble Canyon, Culberson Co., and in the Christmas Mountains, Brewster Co., TX; *Wet Weather quarry*, Jensen, and other quarries, *Crestmore, Riverside Co., CA*; Niehart, Little Belt Mts., MT; Guardaraya, Santa Maria, and Terneras mines, Velardeña district, DUR, and Cerro Mazahua, Susupuato district, MICH, Mexico; Camas Mòr, Muck Is., Inverness-shire, and near Kilchoan, Ardnamuvchan, Argyllshire, Scotland; Scawt Hill, Larne, County Antrim, Northern Ireland; Killala Bay, County Sligo, Ireland; Igljika deposit; Elkhovsko dist., Bulgaria; Anakit district, Lower Tunguska R., Kochumdek R. and Kuzmovka areas, Stony Tunguska R., Siberia, and Gavasai deposit, Kirghizia, Central Asia, Russia; Guneyce-Ikizdere area, Turkey; Nanjangud, Mysore, India; Hatrium Formation, Israel. vk.

GARNET GROUP

The garnet group of 15 species consists of minerals conforming to

where

A = Ca, Fe²⁺, Mg, Mn²⁺, with minor or trace amounts of Zn, Y, and Na

B = Al, Fe³⁺, Cr³⁺, V³⁺, Ti, Zr, with minor or trace amounts of Mn³⁺, Ti³⁺, Zr, and Si

T = Si, but also occasionally, Fe³⁺, Al, Ti, P, and OH

and where the mineral crystallizes close to the ideal cubic structure in space group *Iad3*.

The structure consists of a continuous network of alternating corner-sharing octahedra and tetrahedra. The oxygen framework of this arrangement also

GARNET GROUP

Mineral	Formula	Space Group	a	D	
Pyrope	Mg ₃ Al ₂ (SiO ₄) ₃	<i>Ia3d</i>	11.455	3.56	51.4.3a.1
Almandine	Fe ₃ Al ₂ (SiO ₄) ₃	<i>Ia3d</i>	11.526	4.31	51.4.3a.2

Morimotoite	Ca ₃ (Ti, Fe ²⁺ , Fe ³⁺) ₂ (Si, Fe ³⁺) ₃ O ₁₂	<i>Ia3d</i>	12.162	3.80	51.4.3c.3
Hibschite	Ca ₃ Al ₂ (Si, OH) ₃ O ₁₂ *	<i>Ia3d</i>	≈ 11.97		≈ 3.26
51.4.3d.1	Katoite				
	Ca ₃ Al ₂ (Si, OH) ₃ O ₁₂ **	<i>Ia3d</i>	12.57	2.53	51.4.3d.2

* Also rendered as Ca₃Al₂(SiO₄)_{3-x}(OH)_{2x}, 0.2 < x < 1.5.

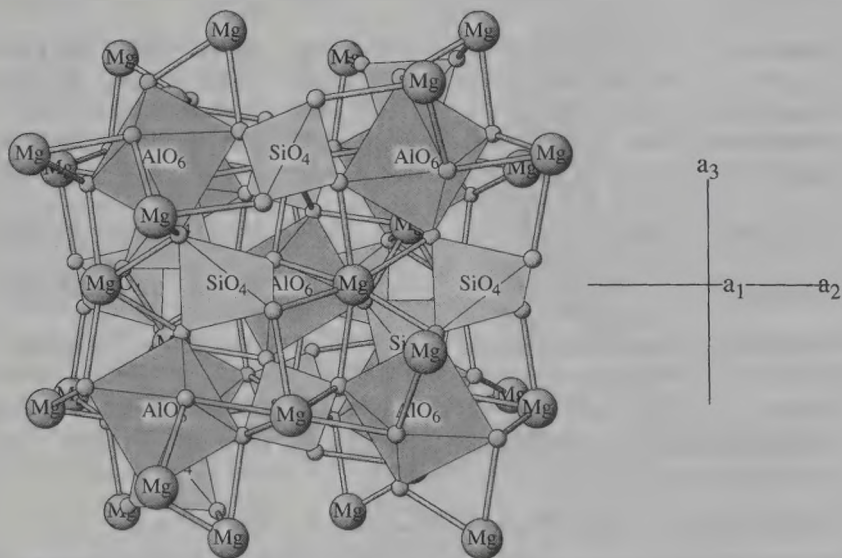

** Also rendered as Ca₃Al₂(SiO₄)_{3-x}(OH)_{2x}, 1.5 < x < 3.0.

Note: Optical data suggest that the calcium garnets are not truly cubic, due to ordering of the B cations and, perhaps, noncubic ordering of the hydroxyl groups. These garnets are orthorhombic, triclinic, or tetragonal. Ordering of Al and Fe³⁺ on the B sites and ordering of Ca and Fe²⁺ on the A sites are other causes of deviation from cubic symmetry.

encloses large voids shaped like triangular dodecahedra which contain the A sites. *EJM* 1:363(1989), *NJMA* 136:146(1979), *AM* 69:1116(1984).

51.4.3a.1 Pyrope $Mg_3Al_2(SiO_4)_3$

Named in 1803 by Werner from the Greek for *fire* and *to appear*, in allusion to its red color. Garnet group. Rhodolite is a garnet intermediate between pyrope and almandine, typically about two-thirds pyrope and one-third almandine. iso $Ia\bar{3}d$. $a = 11.455(\text{syn})$, $Z = 8$, $D = 3.56(\text{syn})$. $15-742(\text{syn})$: 2.87_6 2.56_{10} 2.44_4 2.34_2 2.25_2 1.86_2 1.59_3 1.53_5 . End-member synthetic material is colorless, but all natural material contains some Fe^{2+} , which is responsible for the characteristic red color. Colors vary depending on composition, principally substitution of Fe, Mn, Ti, Cr, and other elements. Dark red, violet-red, red, rose-red (rhodolite), and reddish orange. Some chromium-rich pyrope (generally more than 3-4 wt % Cr_2O_3) shows color change (i.e., alexandrite effect): bluish green or green in daylight or fluorescent light, reddish purple in incandescent light. Such pyrope is colored by both Cr^{3+} and Fe^{2+} and shows a change of color from purple to green when heated to about 200° . The "Alexandrite effect" is caused by a total of less than 1 wt % Cr^{3+} and V^{3+} in octahedral coordination, in conjunction with Mn^{2+} in intermediate pyrope-spessartine garnets (malaya garnets). *G&G:200(1984)*. Inert to LWUV and SWUV light. $H = 7-7\frac{1}{2}$. $G = 3.65-3.82$. IR reflectance and Raman spectra: *PCM* 17:503(1991). Dielectric constants: *AM* 77:94(1992). Pyrope from eclogites, peridotites, and kimberlites contains variable amounts of Cr. Minor amounts (usually less than several tenths of 1%) of Na and P are found in

PYROPE: $Mg_3Al_2Si_3O_{12}$

Pyrope, a structure typical of the garnet group, in perspective view approximately along an a -axis.

pyropes and other high-pressure garnets. Malaia garnet is of intermediate composition between pyrope and spessartine. Isotropic; $N = 1.714$ (syn), most natural pyropes are between 1.74 and 1.77. Colorless to shades of pink, pinkish red, and red in thin section. Pyrope is a high-pressure mineral and occurs in schists and eclogite, magmatic ultrabasic rocks, kimberlites, and peridotites. An "indicator" mineral for diamondiferous kimberlites or peridotites. Also found in alluvial deposits, and as a detrital mineral in sedimentary rocks. Widespread throughout the world; noteworthy localities include: pyrope and almandine at the Barton mine, Gore Mountain, Warren Co., NY; fine rhodolite at Mason Mt., Macon Co., NC; also on Mason's Branch as alluvial material. Sugarloaf Mtn., Jackson Co., NC. In alkalic rocks at Magnet Cove, AR. Cr-bearing (color-change) pyrope occurs in the Sloan Kimberlite diatremes, Larimer Co., In alluvial and colluvial deposits associated with kimberlite breccia pipes in northern Arizona and New Mexico (e.g., Garnet Ridge field, Apache Co., AZ; Buell Park area, Fort Defiance, McKinley Co., NM). Also in the Moses Rock and Mexican Hat fields, San Juan Co., UT. Upper Canada mine, Gauthier, ONT, Canada, Elie, Fyfehire, Scotland, UK. Classic localities in Bohemia, Czech Republic (Bohemian garnet) in the Ceske Stredohori Mts.: at Trebenice (Trebinitz); in gravels derived from weathering of serpentine derived from peridotite at Merunice (Meronitz); also at Krems near Budweis and Podsedice. The largest Bohemian pyropes are the size of pigeon or hens' eggs (Rouse Garnet, 1986). Cut stones over 10 ct are rare. Bohemian pyropes from Linhorka show the "Alexandrite effect." At Zoblitz, Saxony, and Fichtelgebirge, Bavaria, Germany. Some gem Cr-bearing, color-change pyrope on the island of Otterøy near Modle, western Norway, and at Sandvik, Gurskoy Is., western Norway. Gem material at Kimberley, South Africa; Harts Range, NT, Lowood, Q, and Bingara, NSW, Australia. Gem color-change pyrope-spessartine (malaia) garnet in the Uмба Valley region and Makonde, Tanzania; Vaal R., Transvaal, and Kimberley Cape Prov., RSA; Orissa, and in the Sittampundi complex, Salem dist., India. Color-change pyrope-almandine garnet at Ratnapura, Sri Lanka. Gem pyrope also in Burma, Brazil, and Russia. Some star (asteriated) rhodolite is known from Tanzania and India. Principal uses are as an abrasive for cutting and grinding tools and as a semiprecious gemstone. Commercial rhodolite is produced from Tanzania, Sri Lanka, Zimbabwe, and India. EF ROU (1986), DHZ 1A:468(1982).

51.4.3a.2 Almandine $\text{Fe}_3\text{Al}_2(\text{SiO}_4)_3$

Known since antiquity; described by Agricola in 1546 and by Karsten in 1800. The name is derived from the locality at Alabanda, Turkey, where garnets were cut and polished in antiquity. Garnet group. iso $Ia\bar{3}d$. $a = 11.526$ (syn), sometimes noncubic (e.g., tetragonal, $I4_1/acd$, $a = 11.6207$, $c = 11.6230$), $Z = 8$, $D = 4.318$. $9-427(\text{nat})$: 4.04_3 2.87_4 2.57_{10} 1.87_3 1.66_3 1.60_4 1.54_5 1.26_3 . Color is generally red, orange-red, or violet-red; also brown or rarely black. $H = 7\frac{1}{2}$. $G = 3.85-4.20$ for most natural samples. Soluble with difficulty

in HF; IR reflectance and Raman spectra data: *PCM 17:503(1991)*. Solid solution is common toward pyrope (51.4.3a.1) or spessartine (51.4.3a.3) (hence "pyralspite" garnets), with less common substitution to grossular (51.4.3b.2) or andradite (51.4.3b.1). Noncubic almandines are due to slight ordering between (Fe,Mn,Mg) and grandite (Ca) components. High pressure favors substantial solid solution, and relatively low temperature prevents complete disorder. *AM 77:399(1992)*. Sectorial birefringent (about 0.005) almandine-grossular garnet occurs in the Gagnon Terrane, Labrador, Canada. *CM 32:105(1994)*. This garnet also shows a split in the (400) reflection indicating a slight departure from true cubic symmetry. Isotropic; $N_{\text{syn}} = 1.830$, usually shades of red or red-orange in thin section. Report N for 75 mol.% or greater almandine garnet is between 1.813–1.785; those with high pyrope and/or grossular components have N as low as 1.766. Almandine is the typical garnet of metamorphic rocks, particularly garnet-mica schists resulting from the regional metamorphism of argillaceous sediments also found in blueschists (glaucophane-bearing). Stable over a wide range of temperature and pressure; thus found in both contact and regional metamorphic rocks. Also occurs in acid plutonic and volcanic igneous rocks as xenocrysts and as a primary magmatic constituent in lithophysal rhyolites, aplites, granites, and pegmatites. Magmatic garnets are usually almandine-spessartine. Widespread as a detrital mineral in sedimentary rocks. Occurs in Precambrian iron formations. Occurs rarely as inclusions in diamonds (almandine-pyrope-grossular) and as a constituent of eclogites (almandine-pyrope) and granulites. Also found in one lunar sample. Abundant worldwide, and only classic, well-known, and distinctive localities are mentioned here. Excellent crystals to 25 cm from pegmatic at Topsham, ME. Fine material from Russell, MA; from near Roxbury, CT, and Leiperville, PA. Occurs as large crystals to several feet across at the Barton and other mines, North Creek and Gore Mountain, Warren Co., NY; a famous 4.4-kg near-perfect trapezohedral almandine was discovered at 35th Street and Broadway in New York City and is now on display at the American Museum of Natural History. Substantial amounts of abrasive-grade almandine were produced from High Peak, Burke (Laurel Creek, Morganton), Caldwell, and Catawba Cos., NC. Huge, euhedral crystals to 30 cm found at Stony Creek, Thermal City, Rutherford Co., NC and to 10 cm from the Little Pine Mine, Redmon, Madison Co., NC. Occurs in large (to 14 lb) crystals in skarn from the Calumet mine, near Salida, Chaffee Co., CO. Asteriated "star" almandine crystals to 5 cm occurs on Emerald Creek, Fernwood, Benewah and Latah Counties., ID, and other nearby localities. Stars may be four- or six-rayed. At Orofino, Clearwater Co., ID. Occurs in lithophysal rhyolite from Ruby Mountain, Nathrop, Chaffee Co., CO, and the Thomas Range, Juab Co., UT. Also occurs as euhedral crystals (Alm₇₃Spess₂₇) to several cm in lithophysal rhyolite at Garnet Hill, near Ruth, White Pine Co., NV. A classic locality for almandine is near Fort Wrangell on the Stikine River, 1.75 miles SE of Sergief Island, AK. Crystals from this locality occur in a mica schist and are as much as 2 inches across. Albert Harbor, Baffin Island, NWT, Canada; southern Greenland in the

region east of Godthaab (e.g. Ameralik Fjord-Kangersunek Fjord) and on the west coast from Disko Bay South. Garnet masses to 25 kg have been found in the Godthaab district. Crinkle Crags, Cumbria, England; large crystals occur in pegmatite at Irchenrieth, Bavaria, Germany; also in Eppenreuth, Bavaria; in rhyolite from the Saar-Pfalz region, Germany. Noted from Obergurgl im Ötztal, and Rosstrucken, Zillertal, Tyrol, Austria. Alpe Siviglia, Val Codera, Italy. Large dodecahedral crystals occur at Falun, Sweden. From Bodø, Nordland, Norway; from Příbyslavice, Bohemia, Czech Rep. Optically anomalous material from Mt. Saroba, Kazahstan; *Alabanda, Turkey*. From granitic pegmatites (Dusso, and Shingus, Haramosh Mountains) in the Gilgit Div., NWFP, Pakistan; from Mtoko, Zimbabwe; also Ampandramaika and Ampanihy, Madagascar. Gem material is noted from Sri Lanka; Nambunju mine, Namaputa in Lindi Province, Tanzania; also from Namapura, Masasi dist., Tanzania; Zimbabwe; lower Umba Valley, Kenya; Trincomalee, Sri Lanka; a source of almandine since antiquity is Rajputana, northern India. Other Indian localities include; Meja Udaipur, Sarwak, Kishengurh; Kakoria, Jai-pur; Kondapali, Godavari dist., and Gharibpeth, Hyderabad; Bhadrachalam, central provinces; Mahanadibott, Orissa; Pallavaram, Madras; star almandine occurs in India as well as Idaho. Maude, Florence, and Hale Rivers, No. Territory; Fishery Bay, Eyre Pen., South Australia, Australia; the states of Minas Gerais (e.g. Minas Novas and Poaia, Lavra Presidente), Bahia, and Rio de Janeiro, Brazil. Principal uses are as an abrasive for cutting, grinding, and drilling tools, sandpaper, and as a semiprecious gemstone. The Barton mine supplies about 90% of all crushed garnet worldwide. *MSA RIM 5:25(1980)*, *DHZ 1A:468(1982)*, *Rouse Garnet (1986)*, *AM 73:568(1988)*.

51.4.3a.3 Spessartine $Mn_3Al_2(SiO_4)_3$

Named in 1832 by Beudant for the type locality. Garnet group. iso *Ia3d*. $a = 11.63(\text{syn})$, $11.628(\text{F-bearing})$, $11.650(\text{andradite molecule present})$, $Z = 8$, $D = 4.18$. $10-354$: 2.91_2 2.60_{10} 2.37_2 2.13_2 1.89_2 1.68_2 1.61_3 1.56_4 . F substitutes for O in Si-absent tetrahedra similar to OH substitution in hydrogrossular. *AM 75:314(1990)*. Si is 10% deficient (for material with 5.6 wt % F). Usually in solid solution principally with almandine, but spessartines with appreciable amounts of grossular also occur (to 33% of the grossular molecule). More rarely the andradite molecule may also be found. A calcian spessartine contained 2.6 wt % H_2O . *AM 58:508(1973)*. Spessartines sometimes have elevated REE contents; one from Suishoyama, Japan, has 3.2 wt % total REE and one from Pyörönmaa, Finland, has 3.35 wt % total RE_2O_3 . REEs substitute according to the following schemes: $Mn^{2+} + Si^{4+} \leftrightarrow Y^3 + Al^{3+}$ and $2Mn^{2+} \leftrightarrow Na^+ + Y^{3+}$. Vanadium (to 1.4 wt % V_2O_3) also occurs in spessartine (Fuji mine, Fukui Pref., Japan). As much as 0.36% ZnO occurs in spessartine from Franklin, NJ. Rare, color-change (alexandrite-effect) spessartine-grossular garnet exists. *G&G:100(1982)*. Very pale yellow, orange, reddish orange, orange-red, rose, hyacinth-red, and reddish

brown; the orange color is due to divalent manganese in a site with distorted cubic coordination. Sometimes confused with "hessonite," an orange grossular. Crystals may be as much as 5 in. or more across. $H = 7-7\frac{1}{4}$. $G = 3.90-4.20$. IR data: *CM 31:381(1993)*, *PCM 17:503(1990)*. Soluble with difficulty in HF. Isotropic; $N = 1.79-1.81$. Sometimes (water-bearing) weakly birefringent with a birefringence of up to 0.008. The anisotropy observed in some spessartines is believed to be due to the presence of a significant amount of the andradite molecule or ordering of Fe^{3+} in octahedral positions. *CMG 29:279(1984)*. Found in Mn-rich metamorphic rocks and in igneous rocks: most commonly in granites, aplites, and pegmatites. Pure spessartine occurs in fractionated granitic pegmatites and some metamorphic rocks. Also occurs as a lithophysal mineral in topaz-bearing rhyolites. Often occurs as etched masses in pegmatites. Occurs at many worldwide localities, only some of the best are noted here. Fine spessartine crystals to 7 cm occur in pegmatites in Leiper's quarry, Springfield Township, and the upper and lower quarries at Avondale, Delaware Co., PA. In pegmatite at the Rutherford mine, Amelia, Amelia Co., VA; the "Rutherford Lady" weighs 2829 ct and another specimen of rough spessartine from the Rutherford No. 2 mine weighs 1.34 kg (6720 ct). Also occurs at the Moorefield mine at Amelia. Occurs in the Bald Knob manganese deposit, NC. Henderson Mo porphyry deposit, Clear Creek Co., CO (F-bearing); in rhyolite at Ruby Mt., Chaffee Co., CO; in pegmatites of the Sawtooth batholith, e.g. Imogene Lake, Custer Co., ID; Victoria dist., Luna Co., NM; in rhyolite at Ash Creek, Hayden, AZ; in rhyolite from the Thomas Range, Juab Co., UT; fine orange specimen and gem quality (stones to greater than 10 ct) material occurs in several pegmatite dikes at the Little Three mine, Ramona, San Diego Co., CA; zoned almandine-spessartine and nearly pure (99.5%) spessartine occur in the Himalaya pegmatite-aplite dike system, Mesa Grande district, San Diego Co., CA; Quebec, Canada; Glen Skiag, Scotland, UK; Salm Chateau, Belgium; in alpine at Byneset, Trondheim, Norway; at *Aschaffenburg, Spessart, northwestern Bavaria, Germany*; also from Ilfeld, Germany; Tyrol, and Pfitsch, Austria; St. Marcel, Piedmont, Italy; in pegmatite at San Piero in Campo, Elba, Italy; Y-bearing at Pyörönmaa pegmatite, Kangasala, southwestern Finland; in pegmatite at Kimito, Finland; in pegmatite at Gola, Poland; in pegmatite at Budislav, Bohemia, optically anomalous spessartine occurs in hornfels east of Chvaletice, east Bohemia, also in pegmatites at Drahonín and Puklice, Moravia, Czech Republic; Ilmen Mtns. and Bagaryak, Urals, Russia; to 10 cm across from pegmatites in the Shingus area, Gilgit area, and Shigar Valley, NWF, Pakistan; fine gem-quality material occurs in metamorphic schist at Marienfluss, Namibia; clear orange material occurs in pegmatites at Tsilaizina, near Antsirabe, Madagascar; also at Maevetanana; gem-quality material (malaya garnet, ranging from ferroan spessartine to manganoan pyrope) occurs in the Umba River area, Tanzania; orange spessartine occurs in the Taita Hills, Kenya; gem-quality spessartine-pyrope occurs near Ratnapura, Sri Lanka; also in northern Burma; in pegmatite at Qibeiling mine, Altai, Xinjiang Uygur AR; China; Y-bearing in pegmatite at Suishoyama, Kawamata-

machi, Fukushima Pref., Japan; Broken Hill, NSW, Australia; in gem gravels of the Santa Maria and Abaete rivers as well as at Arassuahy, Registo and Ceara, also Rio Grande do Norte, MG, Brazil. Cubic (habit) spessartine crystals (to 2 mm) occur in pegmatite gem pockets at Linopolis, MG, Brazil. Sometimes alters to black manganese oxides and hydroxides. Principal use is as a gemstone. Malaia (also spelled Malaya) garnet is a garnet of intermediate spessartine-pyrope composition. Some malaia garnets contain trace amounts of V and Cr and are color-change garnets. A polished 708-ct red spessartine is reported from Brazil. *EF DHZ 1A:590(1982), ROU 1986.*

51.4.3a.4 Knorringite $\text{Mg}_3\text{Cr}_2(\text{SiO}_4)_3$

Named in 1968 by Nixon and Hornung for Oleg von Knorring (1915–1994), mineralogist, Leeds University, England. Expert on pegmatites and on southern Africa. Garnet group. iso *Ia3d*. $a = 11.596(\text{nat}), 11.622(\text{calc. end member})$, $Z = 8$, $D = 3.86$ (3.835 calc. end member). $35\text{-}536(\text{syn}): 2.90_8 2.59_{10} 2.47_4 2.37_4 2.27_2 1.83_2 1.61_4 1.55_6$. Subhedral, rounded grains. Blue-green to lilac(nat) or dark green(syn). $H = 7$. $G = 3.76$. Insoluble in common acids. Isotropic. $N = 1.790\text{--}1.803$ (1.875 for calc. end member). Forms a series with pyrope (51.4.3a.1). Analysis (wt.%): SiO_2 39.9, TiO_2 0.11, Al_2O_3 9.7, Cr_2O_3 17.5, Fe_2O_3 1.2, FeO 6.5, MnO 0.6, MgO 17.0, CaO 8.1. Occurs in kimberlite pipes. *Kao kimberlite, Lesotho*; as an inclusion in a type IIa diamond from a kimberlite in the Mirny area, Yakutia, Russia. *EF AM 53:1833(1968).*

51.4.3a.5 Majorite $\text{Mg}_3(\text{Fe,Al,Si})_2(\text{SiO}_4)_3$

Named in 1970 by Smith and Mason for Alan Major, who participated in studies on the synthesis of garnet from pyroxenes. Garnet group. iso. *Ia3d*. $a = 11.524(\text{at high temperature and pressure}), 11.54(\text{nat})$; transforms to TET *I4₁/a* at low temperature and pressure; $Z = 8$, $D = 4.00$. $25\text{-}843(\text{tetragonal}): 2.88_7 2.58_{10} 2.45_5 2.35_3 2.26_4 2.04_3 1.60_4 1.54_6$. End member Mg-majorite (syn) is cubic at $> 2350^\circ$ and 22 GPa but is tetragonal below this temperature, probably through ordering of octahedral Mg and octahedral Si atoms. One Si atom is in sixfold coordination. (Mg,Fe)SiO₃ pyroxenes transform to the garnet structure at high pressures. Natural majorite with $[\text{Fe}_{\text{tot}}/(\text{Mg} + \text{Fe})_{\text{tot}} \geq 0.2]$ found in meteorites is cubic. Purple-violet, colorless, or yellowish brown. No cleavage. $H = 7\text{--}7\frac{1}{2}$. Occurs as minute grains. Synthesis: *EPSL12:411(1971)*. Composition is near that of hypersthene-bronzite. SiO_2 52.0, Al_2O_3 2.6, Cr_2O_3 0.7, FeO 16.9, MgO 27.5, Na_2O 0.7, Al_2O_3 to 4.6 and CaO to 1.6. Found in the Earth's mantle and in meteorites. A product of shock transformation of olivine and pyroxene. *Coorara meteorite, Rawlina, WA, Australia*; Tenham chondrite meteorite; Catherwood chondrite meteorite; Pampa del Infierno chondrite meteorite; Peace R. meteorite, ALB, Canada. *EF DHZ 1A:512(1982), CIWY 81:279(1982), GCA 46:1903(1982), JGR(B) 86:6171 (1981), CM 21:29(1983), AM 78:1165(1993).*

51.4.3a.6 Calderite $(\text{Mn}^{2+}, \text{Ca})_3(\text{Fe}^{3+}, \text{Al})_2(\text{SiO}_4)_3$

Described in 1850 by Piddington as a massive silicon-iron-manganese rock from India; named for J. Calder. Garnet group. In 1909, Fermor used the name *calderite* for a mineral of the garnet group having the ideal composition $\text{Mn}_3\text{Fe}_2(\text{SiO}_4)_3$. iso *Ia3d*. $a = 11.81\text{--}11.82$, $Z = 8$, $D = 4.42\text{--}4.45$ (for pure calderite) and $D = 4.07$ for NAT. 10-367: 2.92₉ 2.62₁₀ 2.39₉ 1.91₈ 1.63₉ 1.57₁₀ 1.47₇ 0.97₉. Dark yellow to yellow-brown or reddish brown. $G = 4.05\text{--}4.08$. Isotropic; $N = 1.872\text{--}1.890$ (nat), and $N = 1.97$ (calc. for pure calderite). Ideal end member calderite is stable only at high pressure (>22 GPa) and low temperature. Complete solid solution exists among calderite, andradite, and spessartine. Compositions approaching ideal calderite are unknown. Some Mn is trivalent (Mn_2O_3 to 1.5 wt %); CaO to 2.7 wt %. Calderitic andradite is found in high-pressure metamorphic Fe-Mn-rich quartzites and cherts. Also in metamorphosed Mn-silicate-oxide and silicate-carbonate rocks. In areas of subduction-zone metamorphism. Found at Panoche Pass, and at the Laytonville quarry, Laytonville, CA; occurs in the Wabush iron formation, LAB, Canada; *Sausar Group at Netra, Balaghat dist. Madhya Pradesh, India*; Otjondou, Namibia; calderite and/or calderitic spessartine occurs at the Kodaira iron deposit, Fukushima Pref., Japan. Calderitic andradite occurs on Andros Island, Greece; calderitic spessartine in the Sausar Group at Chikla, Maharashtra, Katkamsandi, western India, and Tirodi, Madhya Pradesh, India; calderitic spessartine also occurs at Brezovica, Yugoslavia. EF DHZ 1A:591(1982), CMP 84:199(1983), MM 51:577(1987), ZK 189:43(1989).

51.4.3b.1 Andradite $\text{Ca}_3\text{Fe}_2^{3+}(\text{SiO}_4)_3$

Named in 1868 by Dana for J. B. d'Andrada e Silva (1763-1838), a Brazilian mineralogist, who examined and described a variety of this mineral. Garnet group. Forms two series, one with schorlomite (51.4.3c.1) and one with grossular (51.4.3b.2). Sometimes in solid solution with spessartine (51.4.3a.3) (to 11.4 wt % MnO from Pajsberg, Sweden) and uvarovite (51.4.3b.3) (to more than 3.0 wt % Cr_2O_3). May contain H_2O (as OH) as "hydroandradite" component. Some andradite from Wessels mine, South Africa, has >2 wt % H_2O . May also contain significant Mn_2O_3 (henritermierite component, CaMn^{3+}). Varieties of andradite include topazolite, which is a topaz-yellow color, and demantoid, which is yellow-green to emerald-green in color. Melanite is a titanian andradite with less than about 15 wt % TiO_2 (<1 atom of Ti) and grades into schorlomite with increasing TiO_2 content. iso *Ia3d*. $a = 12.051\text{--}12.059$ (syn), $Z = 8$, $D = 3.855$ (syn). Hydrous andradite has $a = 12.340$. Usually cubic but sometimes orthorhombic, *Fddd* or triclinic, IT, because of partial ordering of octahedral and dodecahedral cations, and of noncubic arrangement of OH groups. Other factors, such as twinning or strains at compositional boundaries, also occur. Tweedlike structure, interpreted to be an exsolution texture formed after crystal growth, is also observed in grandite garnets. AM 71:1210(1986). Distinct compositional differences exist between the Fe-richer lamellae and Fe-poorer host. Violation of *Ia3d* symmetry is

clearly evident on X-ray precession films. $10\text{-}288(\text{syn}): 3.01_6\ 2.70_{10}\ 2.46_4\ 1.96_2\ 1.67_2\ 1.61_2\ 1.32_2\ 1.20_2$; $30\text{-}253(\text{hydroxyl-bearing andradite}, 5.29\ \text{wt}\ \% \text{H}_2\text{O}^+)$. Hydrous andradite (EJM7:1221(1995)) is composed of disordered microdomains containing SiO_4 and (H_4O_4) tetrahedral units. Many different colors: brownish red, brownish yellow, brown, yellow to yellow-green (topazolite), grayish green, medium to deep green (demantoid), black (melanite). Pale yellowish green is due to Fe^{3+} in octahedral coordination; yellow to orange to black is due to charge-transfer processes involving titanium and iron. The green color of demantoid is due to low concentrations of Cr^{3+} in octahedral coordination. Vitreous to adamantine luster. $G = 3.70\text{--}4.10$; hydroxyl-bearing, $G = 3.45$. IR reflectance and Raman spectral data: US6SOF.87-263(1987) *PCM 17:503(1991)*. Mössbauer spectral data for Fe-Ti-bearing andradite: *AM 65:142(1980)*, *PCM 13:198(1986)*. Melanite contains $0.03\text{--}0.16\ \text{Ti}^{3+}/\Sigma\text{Ti}$. XPS studies confirm that Ti^{3+} is in octahedral coordination and Ti^{4+} is in octahedral and tetrahedral sites. *EJM 7:847(1995)*. Predominant substitution modes in melanite are: $^{\text{VI}}\text{Ti}^{4+} + ^{\text{VI}}\text{M}^{2+} \leftrightarrow 2^{\text{VI}}\text{M}^{3+}$ and $^{\text{VI}}\text{Ti}^{4+} + ^{\text{VI}}\text{Fe}^{3+} \leftrightarrow ^{\text{IV}}\text{Si}^{4+} + ^{\text{VI}}\text{M}^{3+}$, where $\text{M}^{3+} = \text{Fe}^{3+}$ and Al^{3+} . As much as 4 to 5.8 wt % SnO_2 has been reported in andradite-grossular garnets, and the replacement $\text{Sn}^{4+} + \text{Fe}^{2+} \leftrightarrow 2\text{Fe}^{3+}$ has been proposed. *MSA RIM 5:33(1980)*. Y_2O_3 to 3.4 wt %. Colorless to pale yellow birefringent overgrowths on melanite and schorlomite from Magnet Cove, AR, are fluorohydrograndites (F to about 1.0 wt % in grossular-rich andradite). A titanian F-bearing (1.2 wt % F) and water-bearing (2.3 wt % H_2O) andradite occurs in altered basalt, Land's End, England. *BM 109:613(1986)*. Zoning between andradite and grossular may be extreme [e.g., And_{100} (host) and $\text{And}_{50}\text{-Gros}_{50}$ (lamellae) from Crested Butte, CO]. *AM 58:840(1973)*. Isotropic; $N = 1.887(\text{syn}), 1.88\text{--}1.94(\text{nat})$. Sometimes anisotropic and biaxial. Usually, garnets near both end members (andradite and grossular, respectively) are isotropic. Anisotropy is due to formation of order-disorder growth sectors. Various degrees of Fe^{3+}/Al ordering in their octahedral cation sites are produced on the side faces of surface steps during growth. *AM 69:328(1984)*. The dispersion of demantoid is higher than that of diamond or titanite (0.057 vs. 0.044 and 0.051, respectively). Pale yellow to red-brown, rarely shades of green in thin section. demantoid is often characterized by "horse-tail" inclusions of "byssolite" (tremolite-actinolite). Some grandite garnets are iridescent, and andradite from the Adelaide mining district, near Golconda, NV, shows compositional lamellar zoning (And_{87} and And_{78} , respectively) and a moire-like type of postcrystallization exsolution texture lamellae. *AM 67:1242(1982)*, *71:123(1986)*. A hydrous andradite, $\text{Ca}_3\text{Fe}_{1.54}\text{Mn}_{0.20}\text{Al}_{0.26}(\text{SiO}_4)_{1.65}(\text{O}_4\text{N}_4)_{1.35}$, occurs at the Wessels Mine, RSA. Cornwall, Lancaster Co., PA. Mostly found in calcium and iron-rich contact-metamorphic rocks and iron-rich skarns and less commonly in alkaline igneous rocks. Also in ultrabasic rocks (Demantoid) and Ti-rich alkalic rocks (melanite). May be associated with low-temperature zeolites in cavities in basalt. In alluvial deposits. Some may be of low-temperature hydrothermal origin, such as in deep-sea sediments. Occurs in many localities

worldwide and only well-known and/or distinctive localities are listed here. In dodecahedral crystals to 13 cm at Franklin, Sussex Co., NJ. Melanite occurs at Magnet Cove, AR. Strongly compositionally zoned andradite occurs at Crested Butte, Gunnison Co., CO. At Stanley Butte, and Sierra Ancha, Graham Co., AZ. Triclinic andradite in skarn deposits in the Sonoma Range, Nevada; topazolite occurs at the green fire mine and melanite occurs near the Dallas Gem mine, San Benito Co., CA. Zoned crystals with epidote at Garnet Hill, Calaveras Co., CA. Crystals to 7 cm occur near the Jumbo Mine, Prince of Wales Is., AK. Melanite occurs in the Ice R. alkalic complex, QUE, Canada. Also from Marmorata, ONT. At Pic d'Espada and Erslios, Barèges, Hautes Pyrénées, France. *Drammen and Feiringen, Norway*. Large dodecahedral crystals at Arendal, Augst-Agder, and also Stoko, Langsundfjord Norway. At Långban, Värmland, Sweden. High-MgO-containing andradite at Sala, Sweden. At Pitkaranta, Lake Lagoda, Finland. Fine topazolite at the Mussa Alp, Ala Valley, Piedmont, Italy; also at Zermatt, Valais, Switzerland. An old classic locality is that of Knappenward, Untersuibachtal, Salzburg, Austria. Also from Pfitschtal, Tyrol, Austria. Topazolite at Schwarzenberg, Saxony, and Wurlitz, Germany. Demantoid also in Saxony. Andradite at Beitenbrunn and Schwarzenberg. Melanite at Rieden am Laacher See and Kaiserstuhl, Germany. Zr-bearing melanite-schorlomite in the Polino carbonatite, Terni, Umbria, Italy. At Pfitschtal, Trentino, Italy. Melanite at Monte Somma (Vesuvius), and in the Albanus, Rome, Italy. Demantoid at Val Malenco, (Sondrio) Frascati, Italy; also in serpentinites at Dobsina, Slovakia. At Moravicza and Dognascska, Romania. Mega Xhorid, Serifas, Greece. Demantoid (to >1 cm) in alluvial placers (Bobrovka R.) at Elizavetinskoye and in situ at Nizhni Tagil, central Ural Mts., Russia. Demantoid also in the Sysert district, near Poldnevaya, Chutosky Mtns., Chutosky Pen., Russia. Exceptionally bright black melanite crystals to 7 cm from Mina Ojos Españoles, Lazaro Cardenas, CHIH, Mexico. Olive-green crystals to 20 cm from Trapichillos, COL, Mexico. Fine melanite from Fanshan complex, Hebei Prov., China. Demantoid in Zaire. Abundant at Black Rock, RSA. Mn-bearing garnets intermediate between calderite and andradite, but closer to andradite, in metamorphosed manganese deposits at Otjosundu, Namibia, and Andros Is., Greece. Primary use is as a semiprecious gemstone, particularly topazolite and demantoid. Cut stones of demantoid >4 ct are very rare. One exceptionally fine specimen of demantoid from Val Malenco, Italy, would, if cut, yield a stone of approximately 15 ct. EF MM 36:775(1968); AM 56:1983(1971), 62:475(1977), 62:646(1977), 74:840(1989), 74:1307(1989); DHZ 1A 617(1982); ZK 158:53(1982); G&G 19:202(1983); ROU (1986); NJBM:76(1991); EJM 5:59(1993).

51.4.3b.2 Grossular $\text{Ca}_3\text{Al}_2(\text{SiO}_4)_3$

Named in 1811 by Werner in allusion to the greenish color of the gooseberry (*Ribes grossularia*). Garnet group. Generally forms in solid solution with

andradite and if Cr is present, with uvarovite. However, solid solution to varying extent occurs with other garnets. iso *Ia3d*, but many grossular garnets exhibit lowered symmetry on long range order due to order-disorder growth mechanisms. Depending on orientation, the symmetry is ORTH, MON, or TRIC. An ordered arrangement of Al and Fe³⁺ (octahedral), Ca and Fe²⁺ (dodecahedral), and/or a noncubic (OH) distribution is responsible. Sectoral twins are common: sectors contain differently ordered arrangements of Al and Fe³⁺. Changes in the ordering scheme or degree of ordering take place during growth. Strain in the crystal results from lattice mismatch, thereby reducing the symmetry from cubic. Single-crystal IR spectroscopy showed five tringent grossant andradite garnets to be cubic measurement of individual unit cells (AM 78.957 (1993). *a* = 11.851(syn), a grossular from asbestos, QUE is both TRIC (IT) (before heating): *a* 11.845, *b* 11.858, *c* 11.846, α 89.98°, β 89.96°, γ 89.97, and monoclinic (after heating): *a*11.837, *b* 11.840, *c* 11.836, α 90.01°, β 89.98°, γ 90.00. *Z* = 8, *D* = 3.59(syn). 39-368: 2.96₄ 2.65₁₀ 2.42₂ 2.32₂ 2.16₁ 1.92₂ 1.64₂ 1.58₃. Many colors, most commonly colorless, white, pink, cream, green, yellow, orange, red, cinnamon, honey, brown, and rarely black. Hessonite (or essonite) is a brownish-orange variety and tsavorite, discovered in the late 1960s (= tsavolite), is a pale to dark emerald-green variety colored by V³⁺ in octahedral coordination. *H* = 7, *G* = 3.42–3.80 (depending on composition), Hessonite is inert to LWUV and SWUV light; colorless to light green stones (including tsavorite) may fluoresce a weak to moderate orange in LW and weak yellow-orange in SW; yellow stones may fluoresce a weak orange to both LW and SW. IR and Raman spectra data: USGS of 87-263(1987) *PCM* 17:503(1991), *AM* 76:1153(1991). Isotropic; *N* = 1.734(syn). Most hessonite has *N* = 1.733–1.760, while grossular spans *N* = 1.731–1.754. *G&G* 18:204(1982). Anisotropic ugrandite garnets have a birefringence generally less than 0.005. Occasionally iridescent, with the iridescence being caused by submicroscopic twinning parallel to crystal surfaces with a periodicity of about 1000 Å. With an increase in iron content, hessonite goes from yellow to orange to red-brown. The color of tsavorite varies from pale yellow green to dark emerald green with increasing V (and some Cr) content. May contain F (e.g., 3.5 wt % in a hydrograndite on melanite from the Diamond Jo Quarry, Magnet Cove, AR). Grossular is especially characteristic of both thermally and regionally metamorphosed impure calcareous rocks, and also occurs in rocks that have undergone calcium metasomatism. *DHZ* 1A:614(1982). Also occurs in association with serpentinite and rodingites. Rarely occurs in meteorites. Ubiquitous, and only localities producing fine-quality or unusual material are mentioned here. Fine crystals to 12 cm occur at the Pitts-Tenney quarry, Minot, and red crystals to 5 cm from the Sanford deposit, York Co., ME; world-class orange crystals to 1 cm or more across at Belvidere Mtn., Lowell (Eden Mills), Lamoille Co., VT; Hunting Hill Q., Rockville, MD; Italian Mountain, Gunnison Co., CO; 2.5 mi. E of Wah Wah Summit, Beaver Co., UT; Ramona, San Diego Co., CA; hydroxyl-bearing grossular occurs at Crestmore, Riverside Co., CA; exceptional cubo-dodecahedral crystals (to 3 cm) occur at Vesper Peak, Snohomish

Co., WA; nearly pure colorless or light orange brown grossular, as well as green chromian grossular occurs at the Jeffrey mine, Asbestos, QUE in fine crystals to 3 cm; chromian grossular also occurs at the B.C. asbestos mine at Black Lake; colorless and other colors occur at the Beaver mine and other mines at Thetford, ONT; Orford nickel mine, Orford Twp., QUE; to 8 cm from the McBride property, Wakefield Twp., Hull Co., QUE; York River skarn near Bancroft, ONT, Canada; fine quality pink to red and dark cinnamon-red (due to Mn^{3+} in octahedral coordination)—pale-grey green to colorless, dodecahedral crystals to 5.5 cm occur associated with vesuvianite and wollastonite in the Las Cruces Mtns. at Sierra de la Cruz, and at Sierra Mojada at Rancho San Juan, Xalostoc, Morelos, COAH., Mexico (also occurs similarly at Lake Jaco, Chihuahua); fine material from Concepcion del Oro, Zacatecas, Mexico; Isle of Mull Scotland; Beiaren, Nordland, and Telemark, Norway; Malsjö, Varmland, Sweden; Mittagshorn, Saasthal and Zermatt, Switzerland; ambered-colored crystals from Ala Valley, Piedmont, Italy; honey-yellow octahedra (to several mm) from Elba and Monte Somma (Vesuvius), Italy; also from Monzoni, Val di Fassa, Trentino, Italy; Bellecombe, Val d'Aosta, Italy; Auerbach, Germany; Jordanow, Gleinitz, lower Silesia, Poland; Oravicza, Csiklova, Vasko and Dognaska, Romania; Kimito, Finland; *Vilui River area, Yakutia, Russia* (with vesuvianite); Achmatovsk, near Kussink, Zlatoust district, Urals, Russia; gem green tsavorite occurs in graphite-bearing gneisses and marbles associated with scapolite and epidote at the Lualenyi and Scorpion mines, near Voi, Taita Hills, Kenya (near Tsavo National Park on the Kenya-Tanzania border) and also at Kide Hill, Taita Hills District. Crystals contain as much as 1.6 wt % V_2O_5 , and rarely exceed 3 carats; the largest gem being about 20 cts. Gem tsavorite in well-formed crystals occurs at the Karo tanzanite pit in the Merelani Hills, south of Arusha and Moshi, Tanzania. Colorless, yellow and orange grossular also occurs in abundance in East Africa, e.g. Lelatima Mtns. Gem brownish-green (exterior) and yellow-green (interior) grossular (with about 20% andradite component) has been found near Diakon and Dionboko, Mali; stones over 1 carat are rare. Large yellow-green to brown grossular-andradite crystals to 14 cm in diameter occur near Sandare, Niore du Sahel, mali. The most important source of gem-quality hessonite is from gem-gravels in Sri Lanka. Fine material at the Cocoktau mine, Altai, Xinjian Uygur AR, China. *DHZ RFM 1A 468(1982), AM 69:328(1984), AM 71:779(1986), Rouse (Garnet) 1986, AM 73:568(1988), AM 74:151(1989), AM 74:859(1989)*

51.4.3b.3 Uvarovite $Ca_3Cr_2(SiO_4)_3$

Named in 1832 by Hess for Count Sergei Semeonovich Uvarov (1786–1855), a Russian nobleman, Imperial Academy of St. Petersburg. Garnet group. ISO *Ia3d*. $a = 11.999(\text{syn})$, $Z = 8$, $D = 3.85$. *11-696(syn)*: 3.00_7 2.68_{10} 2.56_2 2.45_6 2.35_3 1.95_2 1.66_3 1.60_6 . Complete solid solution exists with grossular. Some minor solid solution with andradite also occurs. Generally deep rich green in

color but may be a "rusty" green. Very dark green in large crystals. The characteristic green is due to Cr^{3+} in octahedral coordination. $H = 7\frac{1}{2}$. $G = 3.40\text{--}3.83$, depending on Cr content. Isotropic; $N = 1.865(\text{syn}), 1.80\text{--}1.87(\text{nat})$. May be slightly anisotropic. Uvarovite is associated with chromite and chromite deposits, serpentinized olivine, ultramafic rocks, and other chromium-bearing rocks. May also occur in xenoliths of calc-silicate rocks in kimberlites and in contact-metamorphic limestones and skarns. Only selected and well-documented occurrences of uvarovite are given below. Occurs in serpentinite at Wood's chrome mine, TX; Lancaster Co., PA; in serpentinite at Riddle, OR; New Idria, San Benito Co., and at least 20 other localities in CA; Kiglapait, LAB, and the Gun prospect, ITSI Mtns., Macmillan Pass, Yukon, in nephrite at Cassiar, BC, Canada; in serpentinite near Røros, Norway; at several localities in Karelia, Finland: famous from Outokumpu, where crystals to more than 2 cm across occur in skarn; some is very high in the uvarovite molecule. Also found at Kuusjarvi and Luikonlahti. Occurs at Jordanow, Silesia, Poland; from the chromium deposits of the central Ural Mts., Russia: Sysstert, Nizhni Tagil, and Mt. Saranovsk; in chromium ore near *Bissersk, near Kyshtym, NE of Zlatoust*. Associated with kammererite at the Kop Krom mine, Kop Daglari, Turkey. Occurs in the Bushveld complex, Transvaal, South Africa. Principal use is as a gemstone. Stones are usually less than several carats. EF *CM 16:205(1978), 27:565(1989)*; *DHZ 1A:642(1982)*; *ROU (1986)*.

51.4.3b.4 Goldmanite $\text{Ca}_3(\text{V,Al,Cr,Fe}^{3+})_2(\text{SiO}_4)_3$

Named in 1964 by Mocnch and Meyrowitz for Marcus Isaac Goldman (1881–1965), American sedimentary petrologist, U.S. Geological Survey. Garnet group. The vanadium analog of grossular and andradite. "Yamatoite" is the synthetic Mn analog of goldmanite but has not been discovered in nature. ISO *Ia3d*. $a = 12.070(\text{syn}), 12.01\text{--}12.06(\text{nat}), 11.947(\text{chromian}), 11.97(\text{manganooan}), Z = 8, D = 3.77. 16-714: 3.01_7 2.69_{10} 2.45_4 2.36_2 2.19_2 1.95_2 1.67_2 1.61_5$. Dark green to brownish green or grass green (highest V content), colorless streak, vitreous luster. No cleavage, brittle. $H = 7. G = 3.74\text{--}3.91$. IR data: *APM 8:265(1989)*. Contains as much as 28.7 wt % V_2O_3 and 96.3 mol %. Complete solid solution exists between grossular and goldmanite. Some have some F to 1.3 wt %, Cr_2O_3 to 10.1 wt %, MnO to 15.9 wt % ("yamatoite"). Contains some FeO and Fe_2O_3 as well. Isotropic; $N = 1.834(\text{syn})$, range for natural material is 1.792–1.834 with manganooan material having $N = 1.855$. Rarely slightly anisotropic. Occurs in vanadium-bearing sedimentary rocks or contact-metamorphosed carbonaceous and calcareous shales and sandstones; also in magnetite-bearing skarn deposits. Mn-bearing goldmanite occurs in Mn ore. In metapelite and skarn and in veins in muscovite-bearing marble. *Laguna, Grants district, NM*; Hemlo, ONT, Canada; detrital material (with maximum amount of V_2O_3 of 28.7 wt %) in the U.K. sector of the North Sea; Coat-an-Noz, Belle Isleen-Terre (Cotes du Nord), Brittany, France; Pezinok–Pernek complex, Les-

ser Carpathian Mts., Slovakia; 1- to 2-mm crystals occur at Tetetice (St Runadlo), Klatovy, Czech Republic; crystals to 2.7 mm at the Tashelginskiye magnetite deposits, Gornaya Shoriya, western Siberia, and the Mramornoye deposit, Kuznetsk-Alatau, Russia; Ishimskaya Luka, northern Kazakhstan; chromian goldmanite from the Tongshan Cu-Mo deposit, Jurong Co., Jiangsu Prov., China; manganian from Yamato mine, Kagoshima Pref., Japan; kelyphitic rims on garnet and blue zoisite from the Lualenyi mine, Kenya, are grossular-goldmanite. EF *AM* 49:644(1964), *DHZ* 1A:628,641(1982), *MM* 56:117(1992), *CM* 32:319(1994).

51.4.3c.1 Schorlomite $\text{Ca}_3(\text{Ti}^{4+}, \text{Fe}^{3+}, \text{Al})_2[(\text{Si}, \text{Fe}^{3+}, \text{Fe}^{2+})\text{O}_4]_3$

Named in 1846 by C. U. Shepard for the mineral schorl and from the Greek *homos*, the same, in allusion to its resemblance to schorl. Garnet group. Closely related to melanite (titanian andradite), andradite, and morimotoite. iso *Ia3d*. $a = 12.128(13 \text{ wt } \% \text{ TiO}_2)$, $12.17(17 \text{ wt } \% \text{ TiO}_2)$, $Z = 8$, $D = 3.84$. 33-285 (actually a melanite, with 13 wt % TiO_2): 4.29₃ 3.04₈ 2.71₁₀ 2.48₆ 2.38₂ 1.97₂ 1.68₂ 1.62₅. Fe^{3+} is in octahedral [Y] and tetrahedral [Z] sites. Fe^{2+} is in eightfold triangular dodecahedral [X] and octahedral [Y] sites. Also, Fe^{2+} [X] \leftrightarrow Fe^{3+} [Z] electron delocalization (charge transfer). Some tetrahedral Fe^{2+} replacement of Si occurs. *AM* 80:27(1995). No Ti^{3+} is present according to XANES studies. Oxygen is disordered over two positions as the result of occupancy of the Z site by cations of very different radii (Fe and Si). *CM* 33:627(1995). Black to very dark brown, dark brown streak, vitreous to metallic luster. $H = 7-7\frac{1}{2}$. $G = 3.77-3.93$. Isotropic; $N = 1.94-1.98$. Mossbauer study of natural Fe-Ti garnets: *AM* 65:142(1980). Synthetic material with composition $\text{Ca}_3\text{Ti}_2\text{Fe}_2^{3+}\text{SiO}_{12}$ is end-member composition. Highest TiO_2 content in natural schorlomite is about 27.4 wt %. Minor amounts of Al_2O_3 (to about 4 wt %) are present. Occurs principally in alkaline igneous rocks, such as syenites, ijolite, melteigite, and fenites. Found at Magnet Cove, Hot Springs Co., AR; Rainy Creek alkaline complex, Libby, MT; Oka, QUE, and crystals to more than 8 cm diameter from the Ice River alkaline complex, Yoho National Park, BC, Canada; Camphouse, Ardnamurchan, Scotland; Horningsholm, and Pottång, Alnö Is., Sweden; Iivaara and Kuusamo, Finland; Zr-bearing (to 15.8 wt % ZrO_2) from Polino carbonatite, Terni, Umbria, Italy; Podzamek, Poland; Africanda massif, Kola Penin., and Morotu, Sakhalin Is., Russia (27.4 wt % TiO_2). EF *AM* 52:773(1967), 62:475(1977), 62:646(1977); *MM* 36:775(1968); *DHZ* 1A: 468(1982).

51.4.3c.2 Kimzeyite $\text{Ca}_3(\text{Zr}, \text{Ti})_2[(\text{Si}, \text{Al}, \text{Fe}^{3+})\text{O}_4]_3$

Named in 1961 by Milton et al. for the Kimzey family, long known in connection with the mineralogy of Magnet Cove, AR. The mineral was discovered by Joe Kimzey. Garnet group. iso *Ia3d*. $a = 12.365-12.46(\text{nat})$, $12.456(\text{syn Ca-Al kimzeyite})$, $12.598(\text{syn Ca-Fe kimzeyite})$, $Z = 8$, $D = 3.96$. 13-130:

4.42₄ 3.12₆ 2.79₈ 2.54₉ 1.73₄ 1.67₁₀ 1.395₄ 1.137₄. Dark brown, light brown streak, vitreous luster. No cleavage. $H = 7$. $G = 3.94-4.00$. Dominant forms are $\{211\}$ and $\{110\}$. The end member "ferric kimzeyite" is $\text{Ca}_3\text{Zr}_2(\text{Fe}_2\text{Si})\text{O}_{12}$ and the end member kimzeyite is $\text{Ca}_3\text{Zr}_2(\text{Al}_2\text{Si})\text{O}_{12}$. Two garnets exsolve from intermediate Ca-Fe and Ca-Al compositions; below 650° , line splitting is present. *MJJ 16:371(1993)*. Isotropic, brown; $N = 1.94$. Both Al- and Fe-dominant kimzeyites occur in nature. Occurs in carbonatite at the Kimzey farm, *Magnet Cove, AR*, as crystals to 5 mm associated with calcite, apatite, monticellite, magnetite, perovskite, phlogopite, pyrite, and other minerals. In shoshonitic basalt at Stromboli, Aeolian Is., Italy. In lamprophyre dikes at the Marathon dikes, McKellar Harbor, northwestern ONT, Canada. *EF AM 46:533(1961)*, *52:773(1967)*, *56:1983(1971)*, *64:546(1979)*, *65:188(1980)*; *DHZ 1A:617(1982)*; *MM 56:581(1992)*.

51.4.3c.3 Morimotoite $\text{Ca}_3(\text{Ti,Fe}^{2+},\text{Fe}^{3+})_2(\text{Si,Fe}^{3+})_3\text{O}_{12}$

Described in 1995 by Henmi et al. and named for Nobuo Morimoto (b.1925), emeritus professor of mineralogy and crystallography, Osaka University, Japan. Garnet group. iso $Ia3d$. $a = 12.162$, $Z = 8$, $D = 3.80$. *MM 59:115(1995)*: 3.04₇ 2.72₁₀ 2.59₂ 2.48₅ 2.385_{2.5} 1.97₂ 1.69₃ 1.63₆. Detailed structure not reported. Black euhedral or subhedral grains to 15 mm with or without rims of grandite garnet; adamantine luster. No cleavage. $H = 7\frac{1}{2}$. $G = 3.75$. IR spectra are very similar to those for schorlomite. Analysis (wt %): SiO_2 , 26.9; TiO_2 , 18.5; ZrO_2 , 1.48; Al_2O_3 , 0.97; Fe_2O_3 , 11.4; FeO , 7.78; MnO , 0.23; MgO , 0.87; CaO , 31.35. The mineral is derived from andradite by the substitution $\text{Ti} + \text{Fe}^{2+} = 2\text{Fe}^{3+}$. However, as defined, morimotoite is indistinguishable from schorlomite! Isotropic; $N(D)$: $N = 1.955$. Occurs in endoskarn at *Fuka, Bitchu-Cho, Okayama Pref., Japan*. Associated with calcite, vesuvianite, grossular, wollastonite, hematite, prehnite, fluorapatite, perovskite, zircon, baddeleyite, and calzirtite. *EF*

51.4.3d.1 Hibschite $\text{Ca}_3\text{Al}_2(\text{SiO}_4)_{3-x}(\text{OH})_{4x}$ ($x = 0.2-1.5$)

Named in 1905 by Cornu for J. E. Hibsche. Garnet group. Formerly known as hydrogrossular. Synonym: Plazolite. iso. $Ia3d$. $a = 11.90-12.04$ (most samples), but as high as 12.287; $Z = 8$, $D = 3.24-3.28$ most samples, but as low as 2.92. *31-250*: 3.00₈ 2.68₁₀ 2.46₅ 2.19₅ 1.95₆ 1.73₅ 1.66₅ 1.61₈. *45-1447(nat)*: 5.01₄ 3.07₅ 2.75₁₀ 2.41₃ 2.24₆ 1.99₇ 1.70₄ 1.64₄. See also *42-570(calc. pattern)* and *3-801(Crestmore, CA)*. Structure: *NJBM 404(1983)*/*EJM1:363(1989)*. Colorless, white, gray, green to bluish green, pink. $H = 7$. $G = 3.06-3.25$. $N = 1.67-1.750$, TGA data. *BM 107:605(1984)*. Generally nonfluorescent; however, a grossular or "hydrogrossular" from Mosjoen, Nordland, Norway, shows a clear orange fluorescence in SWUV. Some S may substitute for Si. Solid solution exists with andradite (and "hydroandradite"), pyrope, and traces of the spessartine molecule may be present. Soluble in HF and with

difficulty in HCl or HNO₃. Occurs principally in rodingites, contact-metamorphosed marls, and skarn deposits. Often occurs as mantles on andradite or grossular. Nearly pure "plazolite" occurs at Crestmore, Riverside Co., CA; Ayrshire, England; Aubenas, Vivarais, France; Mariods Weisach, Northern Bavaria, Germany; S-bearing (3.1 wt % SO₃) hibschite rims occur on Ti-bearing "hydroandradite" at *Mariánska, near Ustí nad Labem, near Bohemia, Czech Republic*; Nikortzinda, Caucasus, and Lopan, Georgia, and Bug R., Russia; "hydroandradite" in the Hatrurim formation, Israel; pink and green (Cr-bearing) "hydrogrossular" (= Transvaal jade or South African jade), Buffelsfontein, Tuifontein, and Wolhuterskop farms, Rustenburg, Bushveld complex, Transvaal, South Africa; Dun Mt., Champion Creek, Waimea district, and Wairere, North Is., New Zealand; MgO-bearing (3.86 wt %) from Kushiro, Hiroshima Pref., Japan. Some material (e.g., Transvaal jade from about 40 miles W of Pretoria) is used as a gemstone; massive white material for carving comes from an unspecified locality in China. EF *AM 76:1153(1991)*, *DHZ 1A:649(1982)*, *NJBM:251(1983)*, *EJM 1:639(1989)*.

51.4.3d.2 Katoite $\text{Ca}_3\text{Al}_2(\text{SiO}_4)_{3-x}(\text{OH})_{4x}$

Named in 1984 for Akira Kato (b.1931) of the Natural Science Museum, Tokyo, former chairman of the CNMMN IMA. Garnet group. Hydrogrossular is now a group name for the hydrous garnet series hibschite-katoite. Katoite forms a series with grossular and hibschite. iso *Ia3d*. $a = 12.57(\text{syn})$, $12.358(\text{nat})$, $Z = 8$, $D = 2.76(\text{nat})$, $2.53(\text{syn})$. *38-368(nat)*: 5.05_4 3.30_3 3.09_5 2.76_{10} 2.26_6 2.00_6 1.71_3 1.65_4 . *24-217(syn)*: 5.13_9 4.44_4 3.36_6 3.14_5 2.81_8 2.30_{10} 2.04_{10} 1.68_5 . In katoite, the Si position (of grossular) is vacant, and charge balance is achieved by H atoms located slightly outside the faces of an empty O₄ tetrahedron. 4H^+ for Si^{4+} . Thin crusts, rounded microcrystals, and larger (>0.3 mm) octahedral crystals. Colorless or milky white. IR and TGA data: *BM 107:605(1984)*. Isotropic, sometimes very faintly birefringent; $N = 1.632(\text{nat})$, $1.605(\text{syn})$. Some substitution of S for Si in tetrahedral coordination. Occurs in vugs within a phonolite emplaced in argillaceous marls at *Campomorto quarry, Pietramassa, Montalto di Castro, Viterbo, Italy*. Associated with other hydrated Ca-silicates and aluminates. Also reported from basalt xenoliths at Maroldsweisach, Northern Bavaria, Germany. EF *BM 108:1(1985)*, *AM 72:756(1987)*, *CM 28:87(1990)*.

51.4.4.1 Henritermierite $\text{Ca}_3(\text{Mn,Fe,Al})_2(\text{SiO}_4)_2(\text{OH})_4$

Named in 1969 for Henri F. E. Termier (b.1897), French geologist and professor at the Sorbonne, Paris. TET *I4₁/acd*. $a = 12.39$, $c = 11.91$, $Z = 8$, $D = 3.40$. *22-150*: 6.21_3 4.92_3 4.37_6 3.09_6 2.98_6 2.75_{10} 2.52_8 1.61_5 . Each oxygen of the SiO₄ tetrahedron is shared with an MnO₄(OH) octahedron, four of the six oxygens of this octahedron being shared with SiO₄ tetrahedra while the other two are OH groups. Ca atoms lie in distorted cubic cavities. *BM*

92:126(1969). Henritermierite is tetragonal rather than cubic because of Jahn–Teller distortion along c caused by Mn^{3+} , which disrupts the cubic symmetry. Brown, clove, or apricot-brown, dark orange to red; pale brown streak; vitreous luster. No cleavage, conchoidal fracture. $G = 3.34$. Slowly dissolved by cold HCl, easily in warm HCl. HNO_3 attacks it superficially, leaving a coating of black MnO_2 . DTA and TGA show that decomposition begins at about 500° . Uniaxial (+); $N_O = 1.800$, $N_E = 1.765$. O, very pale yellow; E, lemon yellow. Sometimes anomalously biaxial (+) with a small 2V. Commonly twinned on {101}, giving four sectors. Sometimes has andradite rims. Occurs in manganese deposits. Rounded trapezohedral crystals to 3 mm in calcite-rich skarn from Långban, Värmland, Sweden; *Tachgagalt, Anti-Atlas, Morocco*; 1- to 3-mm sharp amber crystals associated with sturmanite, calcite, and andradite from the Wessels and N'Chwaning II mines, Kuruman, Kalahari manganese area, Cape Prov., South Africa. EF *BM 92:185(1969)*, *GSSA:93(1989)*, *MR 22:279(1991)*, *DHZ 1A:655(1982)*.

51.4.5.1 Wadalite $Ca_6Al_5Si_2O_{16}Cl_3$

Structure published in 1993, but origin of name not specified. ISO *I43d*. $a = 12.001$, $Z = 4$, $D = 3.06$. Powder pattern not given but is stated to be indistinguishable from grossular. $G = 3.01$. Other physical properties not given. Occurs in a skarn xenolith in two-pyroxene andesite at *Tadano, Koriyama City, Fukushima Pref., Japan*, and in skarn at the La Negra mine, Querétaro, Mexico. EF *AC(C) 49:205(1993)*.

51.5.1.1 Larnite Ca_2SiO_4

Named in 1929 by Tilley for the locality. Equivalent to β - Ca_2SiO_4 . Bredigite, which usually contains significant Mg, is its high-temperature polymorph. MON *P2₁/n*. $a = 5.48$, $b = 6.76$, $c = 9.28$, $\beta = 94.55^\circ$, $Z = 4$, $D = 3.33$. *33-302(syn)*: 2.79₁₀ 2.78₁₀ 2.75₈ 2.72₃ 2.61₄ 2.28₂ 2.19₅ 1.982₂. Structure: *AC 5:307(1952)*. Crystals tabular, subhedral, also granular and massive. Polysynthetic twinning on {100}. White, colorless; vitreous luster. Cleavage {100}, distinct. $H \approx 6$. $G = 3.28$. Biaxial (+); 2V = 60–63°; $N_x = 1.700$ –1.715, $N_y = 1.715$ –1.723, $N_z = 1.725$ –1.740 (higher values are for synthetic material); $Z = b$, $X \wedge c = 14^\circ$; $r > v$, weak. Gelatinized by dilute HCl. Occurs in contact zone of syenite-monzonite intrusion at Marble Canyon, Culberson Co., TX; similarly in the Tres Hermanas Mts., Luna Co., NM. At *Scawt Hill, near Larne, County Antrim, Northern Ireland*; at Ardnamurchan, and in metamorphosed calcitic amygdules in a plug on Mull, Scotland. In the *Hatrumim* at various localities in Israel. In a contact zone at Tokatoka, North Auckland, New Zealand. AR *MM 22:77(1929)*, *26:229(1942)*, *28:90(1947)*; *AM 51:1766(1966)*.

ZIRCON GROUP

The zircon group consists of five orthosilicate members: zircon, hafnon, thorite, thorogummite and coffinite. Behierite, (Ta, Nb)BO₄ and xenotime, YPO₄ also have the zircon structure. Zircon is a ubiquitous mineral, and xenotime is common, but the others are rare, with behierite being known from only one locality.

Name	Formula	Space Group	a(Å)	c(Å)	Z
Zircon	ZrSiO ₄	I4 ₁ /amd	6.604	5.979	4
Hafnon	HfSiO ₄	I4 ₁ /amd	6.573	5.964	4
Thorite	ThSiO ₄	I4 ₁ /amd	7.133	6.319	4
Thorogummite	(Th,U)(SiO ₄) _{1-x} (OH) _{4x}	I4 ₁ /amd	7.068	6.260	4
Coffinite	USiO ₄	I4 ₁ /amd	6.994	6.263	4
Behierite	(Ta,Nb)BO ₄	I4 ₁ /amd	6.213	5.468	4
Xenotime-(Y)	YPO ₄	I4 ₁ /amd	6.885	5.982	4

Good references for the zircon group minerals include: MSA RIM 5:67 and 113(1980), DHZ RFM 1A:418(1982).

The principal structural unit in zircon is a chain of alternating edge-sharing [SiO₄] tetrahedra and [ZrO₈] triangular dodecahedra extending parallel to *c*. The chains are joined laterally by edge-sharing dodecahedra. Octahedral voids are present but contain no cations as in the case of garnets (MSA RIM 5:67(1980)).

51.5.2.1 Zircon ZrSiO₄

Named from the Arabic *zargun*, which was derived from the Persian *zar*, gold, and *gun*, color. Known in antiquity but first modern description is that of Werner (1783). Zircon group. Synonyms: cyrtolite (high U content and metamict), hyacinth (gem variety: red-brown, etc.), malacon (high Th content and metamict). See hafnon, HfSiO₄ (51.5.2.2); thorite, ThSiO₄ (51.5.2.3); coffinite (51.5.2.4); and thorogummite (51.5.2.5). Other minerals with the zircon structure are xenotime and behierite. TET I4₁/amd. (Syn): *a* = 6.604, *c* = 5.979. JACS 50:549(1967). (Nat): *a* = 6.6042, *c* = 5.9796. AM 64:196(1979). Z = 4 *D* = 4.714. 6-266(nat): 4.43₄ 3.30₁₀ 2.52₄ 2.07₂ 1.91₁ 1.75₁ 1.71₄ 1.65₁. **Habit:** The principal structural unit in zircon is a chain of alternating edge-sharing (SiO₄) tetrahedra and (ZrO₈) triangular dodecahedra extending parallel to *c*. The chains are joined laterally by edge-sharing dodecahedra. AM 56:782(1971), 64:196(1979); CIWY 73:544(1974). Water (as OH) in zircon is in at least three sites. AM 76:1533(1991). Metamictization: AM 76:74(1991). **Physical properties:** Occurs usually in varying shades of brown, to white, yellow, orange, green, or blue. Characteristic reddish-brown color is believed due to Nb⁴⁺ ions produced by irradiation-induced reduction of Nb⁵⁺ substituting for Zr. AM 55:428(1970). Metamict varieties usually leaf green to olive or brownish green; sometimes orange. Prismatic to dipyrmidal, with {100}, {110} prisms and {101} and {112} dipyrmidals most prominent. Other forms: KL (1980), MIN 3(1):98(1972), DF (1932). Crystals to 730 cm; Twinning on {101} produces geniculate (elbow) growth twins. Twins in zircon with {011} as the composition plane and either a{100} or m{110} as the dominant prism plane. MM 39:587(1974). White streak, adamantine to oily luster. Cleavage

ZIRCON: $ZrSiO_4$

The Zr eight-cornered polyhedra share edges with Si tetrahedra to form ribbons running both parallel and perpendicular to the c axis.

{110}, imperfect; {111}, poor; conchoidal fracture; brittle. $H = 7\frac{1}{2}$ (fresh), 7(intermediate), 6-7(metamict). $G = 4.6-4.71$ (normal), 4.2-4.6(intermediate), 3.9-4.2(metamict). **Chemistry:** Slowly attacked by hot concentrated H_2SO_4 . IR: *AM 76:1533(1991)*. Raman: *JCS(A):1372(1970)*. Degree of metamictization: *EJM 7:471(1995)*. Zircon is usually luminescent and fluorescent. Fluorescence colors are orange-yellow, yellow, orange, and sometimes green under SWUV and LWUV. Always contains some Hf; normally about 1 wt %. Hf becomes progressively enriched with continued differentiation and fractionation. A complete solid-solution series exists between zircon and hafnon but not between zircon and thorite or zircon and coffinite. Water in zircon is chiefly present as (OH) and not molecular water. *AM 76:1533(1991)*, *70:1224(1985)*. The maximum amount of (OH) observed in metamict material was about 0.1 wt %. Molecular water is present in fluid inclusions. Some P substitutes for Si. REE's substitute for Zr and are dominated by the HREE's (Y-group). Other elements, such as Fe, Sn, Nb, Na, and others, are probably due chiefly to inclusions of other minerals. U and Th are often present and result in metamictization of the zircon. Total REE as much as 10 wt %, U to 7 wt %, and Th to 10 wt %. Compositional zoning is often present: several generations of zircon may be present. May be epitaxial growth with zirconium. **Optics:** Usually uniaxial (+) with very strong dispersion; $N_O = 1.960$, $N_E = 2.01$ (Na, syn). Normal zircon has $N_O = 1.924-1.934$, $N_E = 1.970-1.977$; intermediate zircon has $N_O = 1.903-1.927$, $N_E = 1.921-1.970$; metamict zircon has $N_O = 1.782-1.864$, $N_E = 1.827-1.872$. Pleochroism

is very weak; in thick sections, absorption is $N_O < N_E$. Sometimes biaxial (+); one example with $2V = 10^\circ$ had $N_x = 1.9272$, $N_y = 1.9277$, and $N_z = 1.982$, and $a = 6.67$, $b = 6.730$, $c = 6.080$. **Occurrence:** Occurs ubiquitously in small amounts in crustal igneous, metamorphic, and sedimentary rocks. Also in mantle xenoliths, lunar rocks, meteorites, and tektites. As either primary igneous crystallization product and usually euhedral, but also as xenocrysts, detrital grains, or recrystallized grains. Particularly abundant in syenitic and granitic rocks. Metamictization results in formation of amorphous glass and sometimes mixtures of cristobalite-quartz, cubic ZrO_2 , and baddeleyite (*Mon.* ZrO_2). **Localities:** Only noteworthy occurrences are given here. Alluvial sand deposits are worked for zircon (zircon sand) in the southeastern United States and other worldwide occurrences. Crystals at Litchfield, Kennebec Co., ME; Rossie, NY; Haddam, CT; Tuxedo and Hendersonville, NC; needles to 20 cm at Mellen, WI; St. Peters Dome, and Eureka Tunnel, El Paso Co., CO; Washington Pass area, Okanogan Co., WA; crystals to 15 lb at Sebastopol Twp., fine contact and interpenetrant twins from the Smart mine, Lake Clear, Eganville, Renfrew Co.; Macdonald Mine, Hybia; Hastings Co., Perth, Lanark Co., and Brudenell Township, ONT; Grenville, Argenteuil Co., Templeton, Hull Co., and Mt. St.-Hilaire, QUE, Canada; in fine crystals and twins from Mina La Panchita, Ayoquesco, OAX, Mexico; in southwestern Norway (e.g., Iveland and Langesundfjord) in zircon syenites and pegmatites; also from Seiland Is., Alta Fjord, northern Norway, in fine orange-brown crystals to 2.5 in. or more in length; Riou Pezzouliou, Expailly, Puy de Dome, France; Laacher See, Eifel, Germany; Miask, and Ilmen Mts. (to 10 lb) in the Ural Mts., and fine crystals to 5 cm at Slyudanka, Irkutsk oblast, Russia; Jemaal Kaduna, Nigeria; Mt. Ampanobe, Fianarantsoa, and Itrongay, Betroka, Madagascar; Sri Lanka, in alluvial gem gravels; Chiang Mai dist., Thailand; Tamilnad, India; multicolored gem-quality crystals to 5.5 lb from the Mud Tank area, Harts Range, NT, Australia; Pocos da Caldas, MG, and Quruipil, Goias, Brazil. Used in foundry sands, refractories, and ceramics because of its thermal properties. Lesser amounts are used for abrasives, gemstones, and the production of Zr and Hf; also for radiometric and thermoluminescence age dating. Heat treatments are used to produce blue zircons for gems. *EF EPSL* 44 390(1970), *MIN* 3(1):98(1972), *MM* 39:587(1974), *MSASC* 5: 67(1980), *DHZ* 1A:418(1982).

51.5.2.2 Hafnon $HfSiO_4$

Named in 1974 by Correia-Neves et al. for the composition, a Hf mineral; in a series with zircon, thus the similar ending. Zircon group. TET $I4_1/amd$. $a = 6.5725(\text{syn})$, $c = 5.9632(\text{syn})$, $Z = 4$, $D = 6.97$. $20\text{-}467(\text{syn})$: 4.43_6 3.29_{10} 2.64_{25} 2.51_7 2.32_2 2.06_2 1.74_2 1.70_{55} . At high pressure and temperature, transforms to the scheelite structure. Material ranges from 50:50 to nearly pure $HfSiO_4$ (1.2% ZrO_2). Uniaxial; $N = 1.946(\text{calc})$. Occurs in tantalum-bearing pegmatites, associated with cookeite and cleavelandite. Occurs in the Himalaya pegmatite-aplite dike system, Mesa Grande district, San Diego Co., CA,

as small millimeter-size amber to buff-colored crystals; at the *Morro Conca and Muiane mines, Morrúa area, Zambesia district, Mozambique*. AR CPM 48:73(1974), AM 67:804(1982).

51.5.2.3 Thorite (Th,U)SiO₄

Named in 1829 by Berzelius for the composition: contains thorium. Zircon group. See coffinite (51.5.2.4), the U dominant analog. TET $I4_1/amd$. $a = 7.1328$, $c = 6.3188$, $Z = 4$, $D = 6.67$. $11-419(\text{syn})$: 4.72_{85} 3.55_{10} $2.84_{4.5}$ 2.68_{75} 2.52_3 2.22_3 1.89_3 1.83_{65} . Voids in the structure connected parallel to c permit incorporation of molecular H₂O + metamictization. Most is partly or completely metamict. AC(B) 34:1074(1978). Yellowish gray, light olive to olive-gray, light brown, brownish yellow, pale yellow, green, orange-brown, brownish black, reddish brown, and so on; white, brown, yellow-brown streak; vitreous luster, resinous to greasy when fresh, dull when altered. To >8 cm in diameter, usually short prismatic with {110} + {111}, {100} + {101} dominant, also pyramidal {101} with prism faces small or absent, also massive, reniform masses, anhedral grains and masses. Cleavage {100}, distinct in non-metamict crystals; conchoidal fracture in metamict crystals; conchoidal to splintery fracture; brittle. $H \approx 4\frac{1}{2}$ -5, fresh, less when altered. $G = 4.1$ (with H₂O)-6.7(no H₂O) and 6.63(syn). IR data: MSASC 5:113(1980). Raman: MSASC 5:113(1980). Paramagnetic. Fresh material is insoluble in common acids, and partly metamict or completely metamict material is attacked by hot acids. Usually contains appreciable U. Other elements, such as Pb, Ca, REE (e.g. >8.1 wt % Y₂O₃), Fe and H₂O substitute. Nearly pure material occurs in the Thomas Range, Utah, as well as uranoan (about 25 wt % UO₂) thorite. Phosphatian varieties known: 13.6% P₂O₅ from Massif Central, France. Total REE's to 20 wt %. Fe in many cases is due to contamination. P₂O₅ substitutes for Si. Sulfur and arsenic also substitute: 2.17 wt % As₂O₅, 4.27 wt % S. Uniaxial (+) and isotropic; $N = 1.664$ -1.87 when isotropic and metamict; $N_0 = 1.78$ -1.827(syn), $N_E = 1.79$ -1.885(syn); $N_E > N_0$; sometimes biaxial with $2V = 5$ -6°. O, pale green; E, yellow-green. Occurs in detrital grains in Witwatersrand. Uranoan and regular variety in lithophysae of rhyolites. Widespread primary mineral. In granitic pegmatites, metasomatized zones in impure limestone, hydrothermal veins, and detrital deposits. Accessory mineral in granites and alkaline rocks. Associated with monazite, zircon, allanite, and others. In gneisenized and albitized rocks. Occurs in many worldwide localities and only a few are mentioned here: a PO₄-rich thorite occurs at the Freeman mine on Green River, Henderson Co., NC; Barringer Hill, Llano Co., TX; at St. Peters Dome, El Paso Co., and the Powderhorn Dist., Gunnison Co., CO., yellow to deep green crystals in rhyolite from the Thomas Range, UT; metamict material from the Harding Mine, Taos Co., NM; uranoan thorite occurs at Bancroft, large crystals in pegmatite at the Macdonald mine, Hybla, and in pyroxene scarn at Kemp uranium mines, Wilberforce, ONT, Canada; numerous pegmatites in Norway and Sweden: *Lomo, Brevig, Langesundfjord, Norway*; Barkevik, Iveland, Kragerø, Landsbo, and

Arendal (to >6 cm), Norway; Bjorko, Sweden; Vishneveye Gor, Ilmen Mts., Ural Mts., Batum region, Caucasus, Polar Urals, and Tongul and Krakhol massifs, western Tuva, Russia; Dara-i-Pioz, Tadzhikistan; Naegi, Gifu, Japan; fine crystals from Ambatofotsy massif, Ardrotsato, and Befarita, Madagascar; Wodgina, Western Australia. An ore of Th. *EF MIN 3(1):127(1972), CM 27:643(1989).*

51.5.2.4 Coffinite $U[SiO_4]_{1-x}(OH)_{4x}$

Named in 1956 by Stieff et al. for Reuben Clare Coffin (1886–1972), pioneer in the study of uranium deposits of the Colorado Plateau. Zircon group. TET $I4_1/amd$. $a = 6.995$, $c = 6.263$, $Z = 4$, $D = 6.9$ (for $x = 0.6$). *PD: 4.66*₁₀ *3.47*₁₀ *2.78*₂ *2.64*₅ *2.18*₂ *1.841*₂ *1.801*₅ *1.737*₂. Also *11-420(syn)* and *17-460(yttrian)*. Natural material is usually metamict. Structure: *MZ 3:81(1989)*. Most commonly as aggregates of 5- to 50- μ m grains and masses; rarely as prismatic crystals with pyramidal termination. Black, yellow to brown in thin section; brownish-black streak; dull to adamantine luster. $H = 5-6$. $G = 3.5-5.1$. Isotropic (metamict); $N = 1.64-1.92$. Uniaxial (+/-); $N_O \approx N_E \approx 1.73-1.75$. Tetrahedral $(OH)_4$ clusters replace the insular $[SiO_4]$ groups of the zircon structure, but the presence of water rather than hydroxyl ion clusters, with the formula $U[SiO_4] \cdot nH_2O$ has also been suggested. The latter view may well be valid; it is supported by chemical and IR data, but correlation of those observations with degree of crystallinity and cell size is not presented. In any given sample, both chemical interpretations may be playing a role, thus accounting for the great variation in refractive indices and the discrepancy between observed and calculated density. Thorium and RE may replace uranium; Pb present as a decay product; possible complete series with thorogummite. Other cations and anions have been observed but may represent mechanical impurities. Formed from uraninite in a supergene, reducing, alkaline environment, as found in sedimentary environments and fossil placers, by absorption of silica and hydration. Usually as aggregates of 5- to 50- μ m grains and masses; rare crystals are prismatic or prismatic-pyramidal. Found at the *La Sal No. 2 mine, Lumsden Canyon, Gateway district, Mesa Co., CO*, and throughout the uranium deposits of the Colorado plateau (AZ, CO, UT); also at the Woodrow, Crownpoint, and Jackpile mines, Valencia Co., NM, and in TX, WY, OK, and SD. Found also at Schneeberg and Marienberg, Saxony, and Wolsendorf and Pfalz, Bavaria, Germany; in Carinthia, Austria; Kovar, Poland; and in Spain, Yugoslavia, and Russia. In the fossil placers of the Dominion Reef, Witwatersrand, and other sites in South Africa; Australia. A significant ore mineral and important component of sedimentary-environment uranium deposits. *AR AM 41:675(1956), USGSB 1064(1958), CM 27:643(1989).*

51.5.2.5 Thorogummite $(Th,U,Ce)(SiO_4)_{1-x}(OH)_{4x}$

Named in 1889 by Hidden and Mackintosh for the composition and appearance and from the Latin *gummi*, gum. Zircon group. TET $I4_1/amd$. $a = 7.029-$

7.068, $c = 6.232\text{--}6.260$, $Z = 4$, $D = 5.75$; 8-440(nat uranoan): 4.7₉ 3.53₁₀ 2.82₄ 2.65₆ 2.20₄ 2.00₄ 1.82₆ 1.17₄. Black (contains U^{4+}), yellowish brown, greenish brown tan, white, greenish gray; usually fine-grained, rarely as acicular radiating crystals to 3 mm, nonmetamict to partly metamict; earthy, subvitreous to resinous luster. Conchoidal to splintery fracture. $G = 3.2\text{--}5.4$. Readily soluble in HNO_3 . Analysis (wt %), Barringer Hill: UO_2 , 22.4; ThO_2 , 41.4; Ln_2O_3 , 6.69; CaO , 0.41; SiO_2 , 13.1; PbO , 2.16; Al_2O_3 , 0.97; Fe_2O_3 , 0.85; P_2O_5 , 1.18; H_2O^+ , 7.88; H_2O^- , 1.23. Some may contain appreciable $P_2O_5 \approx 10\%$. May contain many minor and trace elements: REE, Mn, Mg, Ca, Nb, Ta, Zr, CO_2 . Some have major Fe, to $>12\%$ Fe_2O_3 . $N = 1.54\text{--}1.64$. Also given as 1.74–1.77 when metamict, and uniaxial (+) with $N_O = 1.665$, $N_E = 1.685$ to $N_O = 1.692$, $N_E = 1.710$. *USGSB: 1627(1984)*. Occurs in pegmatites. A product of alteration of primary Th minerals. Always fine-grained. Most often forms from thorite, sometimes from yttrialite, also from uraninite. Alteration: replacing thorite. Found in a large number of worldwide occurrences, only some of which are given here: *Barringer Hill pegmatite, Bluffton, Llano Co., TX*; from thorianite at Easton, PA; to 1-cm masses at Mt. St.-Hilaire, QUE, and Hybla, ONT, Canada; REE-bearing (9.15 wt % RE_2O_3) from Transbaikal, Russia; Vishnevye Mt., Ilmen Mts., Ural Mts., and Lovozero massif, Kola Penin., Russia; Haicheng Pref., southern Manchuria; Wodgina, WA, Australia; from yttrialite at Iisaka-mura, Date-gun, Fukushima Pref., Tateiwa mine, Syobu, Hozyo town, Ehime Pref., and Hayamadake, Tokiwa town, Fukushima Pref., Japan; several localities in Madagascar. *EF AM 38:1007(1953)*, *CM 27:643(1989)*.

51.5.3.1 Huttonite $ThSiO_4$

Named in 1950 for Colin Osborne Hutton (1910–1971), New Zealand–American mineralogist, Stanford University. See monazite. A dimorph of thorite. Always nonmetamict. *MON P2₁/n*. $a = 6.7759\text{--}6.80$, $b = 6.948\text{--}6.974$, $c = 6.4982\text{--}6.54$, $\beta = 104.92\text{--}104.99^\circ$, $Z = 4$, $D = 7.18(\text{syn})\text{--}7.27$. *34-188(syn)*: 4.66₄ 4.20₇ 4.04₃ 3.49₃ 3.28₆ 3.07₁₀ 2.88₃ 2.86₆. Isostructural with monazite: structure of synthetic material consists of SiO_4 monomers and a compact arrangement of edge-sharing ThO_9 polyhedra. *AC(B) 34:1074(1978)*. Colorless, white. Grains with poor development of faces, to 0.2 mm (New Zealand), {100} dominant. Imperfect cleavage on {100} and {001}, and may be parting; conchoidal fracture. $G = 7.10\text{--}7.20$. In SWUV fluoresces a dull white with a pink tinge. Unaffected by hot concentrated HCl, very finely powdered material is slowly dissolved in concentrated H_2SO_4 . Analysis (wt %): ThO_2 , 76.6; SiO_2 , 19.7; Fe_2O_3 , 1.2; Ce_2O_3 etc., 2.6. Solid solution with monazite takes place if $Th/Si + F_4 + (OH)_4$ and $(REE + Ca)/P = 1$. Substitution of Ca, F + (OH) takes place. *MM 43:1031(1980)*. Series is continuous to at least 27 wt % of Th at the monazite end and to at least 20% REE at the huttonite end. Biaxial (+); Y parallel to b , Z near c ; $N_x = 1.898\text{--}1.900(\text{syn})$, $N_y = 1.900$, $N_z = 1.922\text{--}1.930(\text{syn})$; colorless; dispersion, $r < v$, moderate. Occurs in beach sands, thought to be derived from low-grade schists or less

likely from sparsely distributed pegmatite veins. Holiday Mine, Hawthorne, Mineral CO., NV; from the val d'Aosta region, Italy; Silesia, Poland; *Gillespie's Beach, South Westland, New Zealand*; also in sands from five other beaches to the north and south of the Waikukupa R., New Zealand. EF

51.5.3.2 Tombarthite-(Y) $Y_4(\text{Si},\text{H}_4)_4\text{O}_{12-x}(\text{OH})_{4+2x}$

Named in 1968 by Neumann and Nilsson for Thomas Fredrik Weiby Barth (1899–1971), Norwegian geochemist, Oslo University. Partial substitution of 4H atoms for a Si atom. One of the ideal end members of tombarthite-(Y), $\text{YSiO}_3(\text{OH})$ can be regarded as a Y,Si analog of monazite-Ce ($Z = 1$). *MON P2₁/n*. $a = 7.12$, $b = 7.29$, $c = 6.71$, $\beta = 102.8^\circ$, $Z = 1$, $D = 3.64\text{--}3.68$. *21-1314(nat)*: 7.32₃ 6.55₁₀ 3.54₃ 3.42₈ 3.23₇ 2.97₆ 2.89₅ 2.40₄. Structure not determined. Brownish black, partly to completely metamict, masses to 1 cm wide, dull luster. $H = 5\text{--}6$. $G = 3.51\text{--}3.65$. DTA: *LIT 1:113(1968)*. Contains some MnO (to 10%), FeO (to 5.5%), CaO (to 4.9%), and ThO₂ (to 6%). $\bar{N} = 1.639$; isotropic, partly metamict. Occurs in contact with or intergrown with thalenite in a granite pegmatite at *Høgetveit, Evje, Norway*. In pegmatite at Vest-Agder, Reiersdal, Norway. A very late replacement (after britholite) mineral. EF *MIN 3(1):529(1972)*, *NGT 59:265(1979)*.

51.5.4.1 Eulytite $\text{Bi}_4[\text{SiO}_4]_3$

Named in 1827 by Breithaupt from the Greek *eulytos*, easily dissolved or fused. Synonym: eulytine. *ISO I43d*. $a = 10.3$, $Z = 4$, $D = 6.76$. *33-215(syn)*: 4.20₁₀ 3.26₉ 2.75₈ 2.57₁ 2.10₄ 2.02₄ 1.765₁ 1.670₃. Structure: *ZK 123:73(1966)*. Small, complex tetrahedral crystals with dominant {211} and {211} and less commonly {100}, {111}, {511}, {110}. Penetration twins by reflection on {100}. Also in spherical forms. White, yellow, gray, brown, colorless; adamantine luster; translucent to opaque, rarely transparent. Conchoidal fracture, brittle. Cleavage {110}, imperfect. $H = 4\frac{1}{2}$. $G = 6.1, 6.6$. Isotropic; $N = 2.05$; also anomalously uniaxial (–) with OA perpendicular to {111}; also biaxial (–) with birefringence < 0.002 . Fusibility 2, yielding yellow, then red mass, and finally metallic bismuth on charcoal with Na₂CO₃; fused mass acid soluble. Found with clinobisvanite and namibite in pegmatite at the Elizabeth R mine, Pala district, San Diego Co., CA; at the Evans–Lou mine, Hull, QUE, Canada. Complex tetrahedra (0.56 mm) and spherical aggregates (2 mm) at Buckbarrow Beck, Cumbria, England, and reported from Southwick Cliffs, near Dalbeattie, Scotland; with quartz at Johanngeorgenstadt, and with bismuth at the *Neu Glück mine, Schneeberg, Saxony, Germany*; and at Dognacska, Hungary. *AR ZK 78:136(1931)*, *106:34(1945)*; *DT:591(1932)*; *AM 28:536(1943)*; *MM 57:754(1993)*.

Insular SiO_4 Groups and O, OH, F, and H_2O

52.1.1.1 Beryllite $\text{Be}_2\text{SiO}_4(\text{OH})_2 \cdot \text{H}_2\text{O}$

Named in 1954 by Kuznenko in allusion to the beryllium content. ORTH 13-411: 4.01₁₀ 3.64₉ 3.39₇ 3.19₇ 2.90₅ 2.34₁₀ 2.12₇ 1.351₈. Also 20-166. Fibrous in spherulites and crusts. White, silky luster. $H = 1$. $G = 2.196$. Biaxial (-); $2V < 45^\circ$, $2V_{\text{calc}} = 74^\circ$; $N_x = 1.541$, $N_y = 1.553$, $N_z = 1.560$; length-slow and found at Ilimaussaq, Greenland. In alkaline pegmatites with albite and epidymite in the Lovozero massif, Kola Penin., Russia. AR AM 40:787(1955), ZMGP 1:191(1959), VMRE 2:96(1966).

52.2.1.1 Euclase $\text{BeAl}[\text{SiO}_4](\text{OH})$

Named in 1792 by Haüy from the Greek *eu* and *klasis*, good fracture, in allusion to its perfect cleavage. MON $P2_1/c$. $a = 4.632$, $b = 14.334$, $c = 4.781$, $\beta = 100.33^\circ$, $Z = 4$, $D = 3.085$. Structure: SMPM 72:159(1992). 14-65: 7.15₁₀ 3.84₃ 3.22₅ 2.77₃ 2.54₂ 2.44₃ 1.991₂ 1.880₂. Ordered Be and Si tetrahedra form composite corner-sharing chains parallel to [001]. Isostructural with väyryneite (41.5.4.3), $\text{BeMn}^{2+}[\text{PO}_4](\text{OH}, \text{F})$. The axial setting for the quoted cell is in agreement with the original description; an earlier structure paper reverses a and c . Habit commonly prismatic and striated parallel to [001] with {120}, {110}, {100}, {010} dominant; terminations complex with dominant {111}, {131}, {021}. Less commonly flattened {010}. Colorless, white, pale green, pale to deep blue, the latter often patchy; vitreous luster, sometimes pearly on cleavage; transparent to translucent. Cleavage {010}, perfect; conchoidal fracture; brittle. $H = 7\frac{1}{2}$. $G = 3.05\text{--}3.10$. Biaxial (+); $2V = 48\text{--}52^\circ$; $N_x = 1.650\text{--}1.652$, $N_y = 1.655\text{--}1.656$, $N_z = 1.671\text{--}1.672$; $Y = b$, $Z \wedge c = 42^\circ$; $r > v$; distinctly pleochroic in darker blue material. Insoluble in acids; fusibility 5.5. Minor iron and fluorine may be present. A low-temperature hydrothermal mineral in granite pegmatites and Alpine veins; also found in chlorite schist and phyllite, and as a detrital mineral. Found at the Boomer mine, Park Co., CO. At Pizzo Giubine, near St. Gothard Pass, Ticino, Switzerland; in the Austrian Alps in the Glosslockner region, and near Hochnarr, also at Sonnblick Mt., near Salzburg; at Epprechstein, Fichtelgebirge, Bavaria, Germany; at Dobschütz, near Górlitz, Silesia; Norway; in the auriferous sands of the Orenburg district (Sanarka R.), southern Ural Mts. Russia(!). Deep blue crystals(1) at the Last Hope mine, Karai, Miami district, Zimbabwe. First

brought to Europe from South America in 1785; *Villa Rica, Ouro Preto district, MG*, may be type locality; Santana do Ecoberto, Mun. São Sebastião Maranhão(1) in colorless crystals to 10 cm, and other pegmatite deposits in MG; at the Santino, Mamoés, and Amancio pegmatites (blue), near Ecuador, and at the Jacú mine, RGN, Brazil. In placer deposits in Guyana. AR *D6:508(1892)*, *ZK 117:16(1972)*, *MR 2:12(1971)*.

52.2.1.2 Clinohedrite $\text{CaZnSiO}_4 \cdot \text{H}_2\text{O}$

Named in 1898 by Penfield and Foote from the Greek for *inclined plane*, in allusion to the morphology of the point group symmetry. MON *Cc*. $a = 5.131$, $b = 15.928$, $c = 5.422$, $\beta = 103.39^\circ$, $Z = 4$, $D = 3.29$. *17-214*: 7.81₅ 3.97₅ 3.23₇ 2.76₁₀ 2.50₆ 2.47₄ 2.36₅ 1.990₄. Structure: *SP 22:614(1978)*. The classic and oft-illustrated example of point group symmetry *m*. Consequently, the original morphological indexing is retained; the transformation matrix to the structural cell is 002/020/100. Short prismatic [001] with {110}, {110}, {551}, {131} dominant; also wedge-shaped with {110}, {771}, {111}, {111} dominant; massive, granular. Colorless to white to pale amethystine, vitreous luster. Cleavage {010}, perfect. $H = 5\frac{1}{2}$. $G = 3.33$. Gelatinized in HCl; fusibility 4. Biaxial (-); $2V_{\text{calc}} = 64^\circ$; $N_x = 1.662$, $N_y = 1.667$, $N_z = 1.669$; $Y = b$; $Z \wedge c = 61^\circ$; $r > v$. Found with willemite, axinite, hancockite, and other minerals at the *Trotter mine, Franklin, Sussex Co., NJ*. AR *USGSP 180:106(1935)*, *ZK 144:377(1976)*.

CLINOHEDRITE

Clinohedrite, New Jersey. View along *b*-axis. dominant forms: *b*, {010}; *m*, {110}; *m*₁, {110}; *s*, {551}; *r*, {331}; *x*, {131}

52.2.1.3. Hodgkinsonite $\text{MnZn}_2(\text{SiO}_4)(\text{OH})_2$

Named in 1913 (Palache and Schaller) for H. H. Hodgkinson, assistant underground supervisor of Franklin mine, who discovered it in 1913. *MON P2₁/a*. $a = 8.171$, $b = 5.316$, $c = 11.761$, $\beta = 95.25^\circ$, $Z = 4$, $D = 4.07$. *35-554*: 11.8₁ 3.94₃ 3.75₄ 3.64₄ 3.24₄ 3.02₃ 2.97₈ 2.87₁₀. Structure: *ZK 119:117(1963)*. Prismatic {001} crystals with, in the structural cell, {110}, {443}, {553}, and {023} dominant. The structural c axis is $1\frac{1}{2}$ times the morphological c axis; the transformation matrix, morphology to structure, is 200/020/003. Pink to brownish pink, vitreous luster, translucent to transparent. Cleavage {001}, perfect. $H = 4\frac{1}{2}$ -5. $G = 4.06$ -4.08. Biaxial (-); $2V = 52^\circ$; $N_x = 1.724$, $N_y = 1.742$, $N_z = 1.746$; $Y = b$; $Z \wedge c = 38^\circ$; $r > v$, strong; weakly pleochroic $X = Z$, lavender; Y , pale green. Gelatinizes with acids, easily fusible. Weak pink fluorescence in LWUV. Found in rich ores at the Sterling Hill mine, Ogdensburg, and at *Franklin(1)*, *Sussex Co., NJ*. *AR USGSPP 180:108(1935)*, *MR 13:229(1982)*.

52.2.1.4 Gerstmannite $(\text{Mg},\text{Mn}^{2+})_2\text{Zn}(\text{SiO}_4)(\text{OH})_2$

Named in 1977 by Moore and Araki for Ewald Hans Gerstmann (b.1918), prominent German-American collector, of Franklin, NJ, who drew attention to the original material. *ORTH Bbcm*. $a = 8.185$, $b = 18.65$, $c = 6.256$, $Z = 8$, $D = 3.66$. *29-867*: 9.33₉ 4.81₅ 3.42₈ 2.98₆ 2.76₈ 2.60₁₀ 2.47₅ 2.33₈. Structure: *AM 62:51(1977)*. The structure consists of [(Mg,Mn)O₃(OH)₂] octahedral sheets and [ZnSiO₄] tetrahedral sheets, and may be considered a "zincosilicate." Prismatic crystals, untruncated, with {100}, {010}, {110}, forming mats and sprays up to 10 mm in length. White to pale pink, vitreous luster, transparent to opaque. Cleavage {010}, good. $H = 4\frac{1}{2}$. $G = 3.68$. Biaxial (-); $2V = 50$ -60°; $N_x = 1.665$, $N_y = 1.675$, $N_z = 1.678$; $XZ = bc$. Occurs with calcite, manganpyrosomalite, and sphalerite in veins cutting franklinite-willemite ore at the *Sterling Hill mine, Ogdensburg, Sussex Co., NJ*. *AR*

ANDALUSITE GROUP

The members of the andalusite group all share the same chemical formula,

or a minor variation of it. Although not isostructural, they are related by a common structural feature of chains of edge-sharing AlO₆ octahedra, which results in a common c -axis length of approximately 5.6 Å. The cross-linking of the chains varies in each of the species, resulting in four-, five-, and six-coordinated aluminum and a variety of structures. *AJS 271:97(1991)*, *AM 76:677(1991)*.

*Although not a member of the group in a strict sense, these minerals are related.

Notes:

1. The triple point for the three $\text{Al}_2\text{O}(\text{SiO}_4)$ polymorphs is uncertain but close to 520° and 4 kbar.
2. All the andalusite minerals are characteristic of metamorphic environments.

52.2.2a.1 Sillimanite $\text{Al}_2\text{O}(\text{SiO}_4)$

Named in 1824 by Bowen for Benjamin Silliman (1779–1864), American chemist and geologist at Yale University. Andalusite group. Fibrolite refers to the columnar to fibrous form, but is used interchangeably with sillimanite in the gem trade. Polymorphs: andalusite, kyanite. See also mullite (52.2.2a.2). ORTH *Pnma*. $a = 7.484$, $b = 7.672$, $c = 5.77$, $Z = 4$, $D = 3.239$. 38-471: 3.84₁ 3.42₁₀ 3.37₄ 2.68₂ 2.54₂ 2.42₂ 2.20₃ 1.520₁. Structure: AM 77:374(1992). The six-coordinated aluminum–oxygen chains parallel [001] and are cross-linked by four-coordinated aluminum and (SiO_4) tetrahedra. Prismatic to acicular, frequently with square cross section, {110}, striated parallel to [001] and with poor terminations; columnar to fibrous aggregates, sometimes radiating. Colorless to white; pale yellow to brown; pale blue, green, and violet; vitreous to silky luster; transparent to translucent. Cleavage {010}, perfect; uneven fracture. $H = 7$. $G = 3.23$ –3.27. Biaxial (+); $2V = 21$ –30°; $N_x = 1.654$ –1.661, $N_y = 1.658$ –1.662, $N_z = 1.673$ –1.683; $XYZ = abc$; $r > v$, moderate. Pleochroic in thick sections. X, pale yellow; Y, brown or light green; Z, dark brown or blue. Infusible and insoluble in acids. Usually close to the ideal composition, with Fe_2O_3 the only significant substituent (up to 1.5 wt %). Characteristic of high-temperature regional and thermal metamorphism of pelitic rocks; amphibolite to granulite facies. Formed with K-feldspar by breakdown of micas, and by transformation of andalusite or kyanite at high temperature and moderate pressure. Sometimes in parallel growth with andalusite; frequently associated with cordierite and corundum. Common worldwide in the appropriate metamorphic terrains (i.e., the metamorphic belts from New England to Georgia). At Chester, Middlesex Co., CT; in distinct crystals at Yorktown, Westchester Co., NY; at Chester and Mineral Hill, Delaware Co., PA; at Brandywine Springs, DE; at Culsagee mine, Macon Co., NC(1); 3 km N of Seneca, Oconee Co., SC; in Custer and Pennington Cos., SD; and the Silver Hill tin mine, Spokane Co., WA. At Romaine, QUE, Canada. At Ariege and Pontgibaud, France; in metamorphosed Ross of Mull granite, Scotland; at Lisens Alp,

SILLIMANITE: Al_2SiO_5

In sillimanite, the cross-linking Al atoms are tetrahedral, which leads to the formation of double chains running parallel to *c*. These chains consist of four-membered rings with strictly alternating Si and Al, unlike the double chains in amphibole which consist of six-membered rings.

Tyrol, Austria; at *Vltava, Susice, Czech Republic*. At Relli, Vizagapatam district, and in the Khasi Hills, Assam, India. Pale blue to violet, gemmy material from Sri Lanka, and from the Mogok district, Myanmar. In the diamond gravels of Diamantina, MG, Brazil. Used in the manufacture of mullite refractory ceramics; rarely as faceted gems and chatoyant cabochons for the gem collector. AR *NJMA* 111:74(1969), *DHZII* 1A:719(1982).

52.2.2a.2 Mullite $\text{Al}_{4+2x}\text{Si}_{2-2x}\text{O}_{10-x}$

Named in 1924 by Bowen et al. for the locality. Andalusite group. ORTH *Pbam*. $a = 7.578$, $b = 7.682$, $c = 2.886$, $Z = 1$, $D = 3.02$. 15-776(syn): 5.39₅ 3.43₉ 3.39₁₀ 2.69₄ 2.54₅ 2.21₆ 2.12₂ 1.524₃. Structure: *AM* 76:332(1991). The structure is closely related to that of sillimanite, with aluminum partially replacing silicon. Fine-grained prismatic [001]; massive (synthetic material). White, gray, pale pink; vitreous luster. Cleavage {010}, distinct. $H = 6-7$. $G = 3.11-3.26$. Biaxial (+); $2V = 20-60^\circ$; $N_x = 1.638-1.653$, $N_y = 1.642-1.657$, $N_z = 1.653-1.671$; $XYZ = abc$. Formula x has observed value of 0.17-0.59; $x = 0.25$ for commonly given $\text{Al}_6\text{Si}_2\text{O}_{13}$ (3:2 mullite, $3\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2$); natural material lies between 3:2 and 4:1. In high-temperature thermally metamorphosed argillaceous rocks. Formed by heating any of the $\text{Al}_2\text{O}(\text{SiO}_4)$ polymorphs. In argillaceous inclusion in eruptive rock on *Isle of Mull, Scotland*;

from Sithean Sluigh, Stracher, Argyllshire, Scotland; Rathlin Is., Northern Ireland; and at Maandagshoek, Transvaal, South Africa. Mullite produced artificially is an important ceramic. AR *NBSM* 25(3):3(1964); AM 66:142(1981), 71:1476(1986); *DHZII* 1A:742(1982).

52.2.2b.1 Andalusite $\text{Al}_2\text{O}(\text{SiO}_4)$

Named in 1789 by Delamethrie for Andalusia Prov., Spain; the variety chiasolite from the Greek *chiasos*, to cross, in allusion to the cross-shaped distribution of carbonaceous inclusions. Andalusite group. Polymorphs: sillimanite, kyanite. ORTH *Pnmm*. $a = 7.798$, $b = 7.903$, $c = 5.556$, $Z = 4$, $D = 3.144$. 39-376: 5.55₁₀ 4.53₈ 3.93₃ 3.52₃ 2.77₇ 2.27₃ 2.18₃ 2.17₄; the pattern for manganian andalusite is not significantly different. Structure: AM 69:513(1984). The six-coordinated aluminum–oxygen chains parallel [001] and are cross-linked by five-coordinated aluminum and (SiO_4) tetrahedra. The structure

ANDALUSITE: Al_2SiO_5

In andalusite, the cross-linking Al atoms are 5-coordinated, so andalusite is structurally intermediate between kyanite and sillimanite. All three Al_2SiO_5 polymorphs have chains of AlO_6 octahedra running parallel to c along the cell edges and at or near the center of the cell, which will be called here the "A chains." The A chains are very similar in sillimanite and andalusite, and in both the center and edge chains are linked with isolated silicate tetrahedra but otherwise are very different. In sillimanite the linking tetrahedra are in double chains consisting of four-membered rings with alternating Al and Si tetrahedra. These are the structural units in terms of strong bonds and explain why sillimanite is often fibrous. In andalusite the tetrahedral chains are replaced by pairs of AlO_5 polyhedra, and the SiO_4 tetrahedra are in quite another place. Si tetrahedra can also be considered to link the AlO_5 polyhedra into a three-dimensional framework. In kyanite the octahedral A chains are quite different from those in sillimanite and andalusite and the central chain is pushed to one side by a B layer of AlO_6 octahedra. The "central" A chain in kyanite is related to the corner ones by a center of symmetry (in the B layer) rather than by glide planes as in sillimanite and andalusite.

ANDALUSITE

Andalusite. Forms: c , {001}; m , {110}; s , {011}

is analogous to that of adamite, $Zn_2(OH)(AsO_4)$, and related species. **Habit:** Most commonly as prismatic [001] crystals of approximately square cross section with {110} and {001} dominant; chialstolite crystals often subhedral, elongated, and tapered; massive. **Twinning** on {101} uncommon. **Physical properties:** Pale to deep pink or reddish brown, white, gray, violet, yellow, green, blue; vitreous luster; transparent to opaque. Cleavage {110}, good to perfect; {100}, poor; conchoidal fracture, $H = 6\frac{1}{2}$ – $7\frac{1}{2}$. $G = 3.13$ – 3.21 . Usually biaxial (-); $2V = 73$ – 86° ; $N_x = 1.627$ – 1.637 , $N_y = 1.635$ – 1.644 , $N_z = 1.639$ – 1.650 ; $XYZ = cba$; $r < v$; weakly to strongly pleochroic. X , pale pink to red-brown; $Y \approx Z$, yellow to olive-green. Mn- and Fe-rich varieties (viridine) are light to dark green with a gray-green streak; biaxial (+); $2V = 52$ – 77° ; N_x reaching 1.679, N_z reaching 1.727; $XYZ = abc$; strongly pleochroic. $Y > Z > X$, in shades of green and yellow. Infusible and insoluble in acids. **IR Spectra:** USGS OF 87-263(1987). **Chemistry:** Mn_2O_3 and Fe_2O_3 are usually present in small amounts and may reach 4% and 20%, respectively, influencing color and optical properties. A complete series may exist between andalusite and its manganese-aluminum analog, kanonaite. A blue andalusite from Belgium contains P^{5+} (up to 0.31%) in substitution for Si^{4+} coupled with Fe^{2+} for aluminum. May contain up to 2% Cr_2O_3 . Alters readily to sericite, particularly in the chialstolite variety; may alter in part to kaolinite and/or pyrophyllite, and to kyanite paramorphs; alumina may be leached to leave a porous residue, largely quartz. **Occurrence:** Characteristic of low-grade metamorphism of pelitic sediments, primarily in contact zones, but also in regional metamorphism, and is associated with cordierite in both environments. Less commonly in granites and pegmatites, possibly through contamination by argillaceous sediments. Frequently as a detrital

Andalusite (var. chialstolite); Successive sections showing carbonaceous inclusions.

mineral in arenaceous sediments. **Localities:** Common worldwide in appropriate terrains. Noteworthy localities: fine, pink crystals(!) at Standish, and chialstolite at southern Berwick, ME; near Rye (chialstolite) and at Charleston, NH; at Westford, Middlesex Co.(!), and at Lancaster and Sterling (chialstolite), MA; in large crystals(!) at Upper Providence, Delaware Co., PA; at Altavista, Campbell Co., VA(!), in large, square crystals up to 30 cm, associated with corundum and in part replaced by sillimanite and kyanite; abundant(*) at Champion Mine, White Mts., Inyo Co., CA. Found in *Andalusia Prov., Spain*; near Var, Provence, France; blue phosphatic andalusite at Ottre, Vann-Stavelot massif, Belgium; viridine at Ultevis, Jokkmokk, Sweden; as colorless and pink crystals at Steinbach, Bavaria, and at Darmstadt, Germany; in large crystals with kyanite at Lisens Alp, Tyrol, Austria; at Mursinsk, Ural Mts., and chialstolite at Nankova, Nerchinsk district, Transbaikalia, Russia. Nearly black viridine at Manzabar, Purulia district, India; as fine gem pebbles(!) in the Ratnapura district, Sri Lanka. At Juhua-gou, near Beijing, and chialstolite in Henan Prov., China; chialstolite(!) at Mt. Howden, near Bimbowrie, SA, Australia. Chromian material from corundum-fuchsite rocks in Zimbabwe. Gem-grade stream pebbles and crystals(!) at Santa Tereza, ES, and gemmy crystals at Santa Maria, Cruzeiro Novo, MG; (viridine) with bahianite and cassiterite at Serra das Almas, Paramirim, Bahia, Brazil. **Uses:** In the manufacture of mullite ceramics; as a minor faceted gemstone notable for its strong pleochroism in red and green tones, and rarely (Brazil) as cat's-eye gems. *AR DHZII 1A:759(1982), BM 107(5):587(1984), MM 54:75(1990).*

52.2.2b.2 Kanonaite $(\text{Mn}^{3+}, \text{Al})(\text{Al}_2, \text{Mn}^{3+})\text{O}(\text{SiO}_4)$

Named in 1978 by Vran et al. for the type locality. Andalusite group. ORTH *Pnm*. $a = 7.959$, $b = 8.047$, $c = 5.616$, $Z = 4$, $D = 3.39$. $d_{2-575}: 5.66_{10}$ 4.59_6 3.99_2 2.83_4 2.52_4 2.30_2 1.513_2 . Structure: *AM 66:561(1981)*. Most of the manganese preferentially replaces six-coordinated aluminum. Greenish black, gray-green streak, vitreous luster. Cleavage {110}, poor. $H = 6\frac{1}{2}$. Biaxial (+); $2V = 53^\circ$; $N_x = 1.702$, $N_y = 1.730$, $N_z = 1.823$; $XYZ = abc$. Pleochroic; X, yellow-green; Y, blue-green; Z, deep golden yellow. The type material contains 32.2 wt % Mn_2O_3 ; the hypothetical end member would contain 44.7%. As rare porphyroblasts in gahnite-chlorite-coronadite-quartz schist at *Kanona, Serenje, Zambia*. *AR CMP 66:325(1978)*.

52.2.2b.3 Yoderite $(\text{Mg}, \text{Al}, \text{Fe})_8\text{O}_2(\text{SiO}_4)_4(\text{OH})_2$

Named in 1959 by McKie and Radford for Hatton S. Yoder (b.1921), petrologist and director of the Geophysical Laboratory, Washington, DC. Andalusite group. *MON P2*₁. $a = 8.10$, $b = 5.78$, $c = 7.28$, $\beta = 106^\circ$, $Z = 1$, $D = 3.36$. $d_{2-625}: 3.50_{10}$ 3.23_7 3.03_9 2.91_7 2.61_8 2.58_7 2.00_8 . Structure: *AM 67:76(1982)*. The high-temperature structure has the characteristic chain of edge-sharing octahedra with additional cations occupying five-fold trigonal-bipyramidal sites, plus silicon in tetrahedral sites. Found as anhedral laths up $\frac{1}{2}$ in., elon-

gated on [010]. Dark blue with pale blue streak, the color being attributed to charge transfer between Fe^{2+} and Fe^{3+} ; also emerald green; vitreous luster. Parting {001}, good; {100}, poor. H = 6. G = 3.39. Biaxial (+); $2V = 25^\circ$; $N_x = 1.689$, $N_y = 1.691$, $N_z = 1.715$; $Y = b$; $Z \wedge c \approx 7^\circ$; pleochroic, $Y > X > Z$; prussian blue to light olive-green. Iron is present in both valence states with Fe^{2+} predominant. Occurs intergrown with kyanite in quartz-kyanite-talc schist at *Mautia Hill, Kongwa, Tanzania*. AR MM 32:282(1959), NAT 210:1148 (1966), AM 76:1052(1991).

52.2.2c.1 Kyanite $\text{Al}_2\text{O}(\text{SiO}_4)$

Named in 1789 by Werner from the Greek *kuanos*, dark blue. *Cyanite* is a former spelling. Andalusite group. Synonyms: Now obsolete, *disthene*, from the Greek *dis*, two, and *sthenos*, strength, in allusion to the differing hardness as a function of orientation. Polymorphs: andalusite, sillimanite. TRIC P1. $a = 7.126$, $b = 7.852$, $c = 5.572$, $\alpha = 89.99^\circ$, $\beta = 101.11^\circ$, $\gamma = 106.03^\circ$, $Z = 4$, $D = 3.666$. 11-46: 3.35₁₀ 3.18₂ 2.70₄ 2.51₅ 2.35₄ 2.16₂ 1.960₅ 1.929₈. Structure: AM 64:573(1979). The six-coordinated aluminum-oxygen chains parallel [001] and are cross-linked by six-coordinated aluminum and (SiO_4) tetrahedra. Habit: Commonly bladed, elongated [001], and flattened {100};

KYANITE: Al_2SiO_5

Perspective view from left and below. All aluminum is in six-coordination (octahedra).

dominant forms {100} and {010}, rarely terminated, with {001} most frequent; columnar aggregates, often radiating. Twinning polysynthetic on {100} with twin axis perpendicular thereto or parallel to [010] or [001]; also multiple twins on {001}. Parallel growth with its polymorphs. **Physical properties:** Blue, green, colorless, gray due to inclusions; color often darker toward center of laths; vitreous luster; translucent to transparent. Cleavage {100}, perfect; {010}, good; parting {001}; splintery fracture. H variable, 4–5 on {100} parallel to [001], 6–7 on {100} parallel to [010], 7–7½ on {010}, 5½–6½ on {001}. $G = 3.56\text{--}3.67$. Biaxial (-); $2V = 82\text{--}83^\circ$; X approximately perpendicular {100}; $Z' \wedge c \approx 30^\circ$ on {100} and $\approx 7^\circ$ on {010}; $N_x = 1.712\text{--}1.718$, $N_y = 1.721\text{--}1.723$, $N_z = 1.727\text{--}1.734$. Weakly pleochroic (thick sections), $Z > Y > X$. IR Spectra: USGS of 87-263 (1987). **Chemistry:** Small amounts of Fe^{2+} , Fe^{3+} , and Ti may be present, the blue color being attributed to charge transfer involving these ions. Cr_2O_3 may substitute for Al_2O_3 up to 12.9 wt %, contributing green color. P^{5+} may replace silicon to a small degree. Converted to mullite and glass at $\approx 1300^\circ$. May alter to pyrophyllite, muscovite, and sericite, and may invert to andalusite or sillimanite with a change in metamorphic environment. **Occurrence:** Typically in regional metamorphism of pelitic, less commonly psammitic, rocks, and commonly used as a zonal mineral in pelitic assemblages. May be derived from pyrophyllite and paragonite, and by transformation of andalusite when thermally metamorphosed rocks are followed by regional metamorphism. May also be found in some eclogites and kyanite amphibolites. Not uncommon as a detrital mineral. **Localities:** Widespread throughout regionally metamorphosed terrains. Notable occurrences in North America are Hanover, Jaffrey, and Lyme, NH; Chester emery mines, Hampton Co., MA; Litchfield, CT; Norwich and Thetford, VT; West Bradford, Chester Co., PA (green); Broad Creek, Harford Co., MD; in Spotsylvania Co. and mined commercially at Cullen, Charlotte Co., and Willis, Buckingham Co., VA; Clubb's Mt. and Crowder's Mt., Gaston Co.(!), and gemmy green(!) in Yancy Co., NC; Graves Mt., Lincoln Co., GA. Chromian and also phosphatian, with chromian staurolite, at Cabo Ortegal, Galicia, Spain; with staurolite in paragonite schist at Pizzo Forno, Monte Camplone(!), St. Gotthard region, Switzerland; at *Zillertal*, *Austria*, and numerous localities in the Tyrol of Italy and Zillertal, Austria; at Petschau, Bohemia, Czech Republic; near Sverdlovsk, Ural Mts., and in kimberlites of Yakutia (chromian), Russia. At Balikesir, Turkey. Large gem crystals(!) at Karai, Zimbabwe. As transparent blue crystals(!) with talc at Praça Sao Paulo, Brumado, Bahia, and as gem green crystals(!) often with a blue central band at Natividade, GO; gray to black blades at Fazenda Tabatinga, São José do Jacuni; fine blue blades at Barra do Salinas; and other localities in MG, Brazil. **Uses:** In the manufacture of mullite ceramics and as a collector's gemstone. AR *NJMM* 111:74(1969); MR 5:229(1974), 9:23(1978); *DHZII* 1A:780(1982).

52.2.3.1 Staurolite $(\text{Fe}^{2+}, \text{Mg}, \text{Fe}^{3+})_4 \text{Al}_{17} \text{O}_{13} [(\text{Si}, \text{Al}) \text{O}_4]_8 (\text{OH})_3$

Although known earlier, named in 1792 by Delamethrie from the Greek *stauros*, a cross, in allusion to the common cruciform twins. Andalusite group. MON (pseudo-ORTH) $C2/m$. $a = 7.870$, $b = 16.623$, $c = 5.661$, $\beta = 90.12^\circ$, $Z = 1$, $D = 3.79$. d_{111} : 4.15₂ 3.01₃ 2.77₈ 2.69₄ 2.40₅ 2.37₄ 1.982₅ 1.968₁₀. Structure: $AC(B)$ 46:292(1990). An idealized structure may be thought of as layers lying parallel to $\{010\}$, of composition alternating between Al_2OSiO_4 (kyanite) and $\text{HFe}^{2+}\text{AlO}_4$, thus yielding a hypothetical unit cell composition of $\text{H}_2\text{Fe}_4^{2+}\text{Al}_{18}\text{Si}_8\text{O}_{48}$. Aluminum, with minor iron and magnesium, is situated in octahedral sites (M1–M3) corresponding to those of kyanite; iron is situated in additional octahedral sites (M4) and tetrahedral sites (T2) with vacancies existing in these sites and in M3; silicon and aluminum alone occupy the remaining tetrahedral sites (T1). **Habit:** Short to long prismatic $[001]$ with $\{110\}$, $\{010\}$, $\{001\}$, and equally developed $\{201\}$ and $\{2\bar{0}1\}$, resulting in pseudo-orthorhombic appearance. Twinning common on $\{031\}$, yielding cruciform penetration twins at close to 90° , and on $\{231\}$ yielding penetration twins at approximately 60° , sometimes repeated to form trillings; combined twins also known. Earlier morphological descriptions

STAUROLITE: $\text{Fe}_2\text{Al}_9\text{Si}_4\text{O}_{22}(\text{OH})_2$

Staurolite can be described broadly as slabs of Al-oxide/hydroxide parallel to (010) , held together with isolated silicate tetrahedra. There are several types of Al octahedra and several types of octahedral chains running parallel to c . Ferrous iron atoms occupy large tetrahedral sites in the middle of the slabs.

STAUROLITE

Staurolite twins: cruciform on $\{031\}$ (left); oblique on $\{231\}$. Forms: b , $\{010\}$; c , $\{001\}$; m , $\{110\}$; r , $\{201\}$ (pseudo-orthorhombic indexing).

are based on orthorhombic symmetry and doubled c axis; the transformation matrix, old to new, is 200/020/001. Staurolite-kyanite parallel growth with $c_s = c_k$ and $\{010\}_s$ parallel to $\{100\}_k$ is known. **Physical properties:** Medium to dark brown, reddish brown; colorless, gray streak; vitreous luster; transparent to opaque. Cleavage $\{010\}$, fair; conchoidal fracture. $H = 7-7\frac{1}{2}$. $G = 3.74-3.83$. Biaxial (+); $2V = 80-90^\circ$; $N_x = 1.736-1.747$, $N_y = 1.742-1.753$, $N_z = 1.748-1.761$; $XYZ = bac$; $r > v$, weak. Strongly pleochroic; X, colorless; Y, pale yellow; Z, yellow to orange. Indices increase and $2V$ decreases with increase in iron content. Cobaltoan staurolite (lusakite) is blue-black with $N_x = 1.739$, $N_y = 1.746$, $N_z = 1.753$. Strongly pleochroic; X, cobalt blue; Y, violet-blue; Z, violet. Chromian staurolite is pleochroic in green and yellow-green. Magnesian varieties fuse readily, otherwise infusible; partially decomposed by sulfuric acid. **Chemistry:** The dominant divalent, six-coordinated cation is Fe^{2+} , but it is replaceable by significant amounts of Mg, Li ($\approx 4\%$ Li_2O), and Co^{2+} . The latter, although not exceeding half of the divalent sites, is the dominant divalent cation in the variety lusakite, which, nevertheless, does not enjoy species status. Cr^{3+} may substitute (up to $\approx 6\%$ Cr_2O_3) for Al^{3+} in octahedral sites; Fe^{3+} preferentially replaces tetrahedral aluminum, as does Zn^{2+} (up to $\approx 7.5\%$). **Occurrence:** Characteristic of intermediate (amphibolite)-grade metamorphism of pelitic rocks, staurolite-almandine-kyanite being a typical assemblage. Usually develops prior to or with kyanite. Forms at lower metamorphic grade with chloritoid; also in quartz-feldspathic schist; with corundum and magnetite in emery deposits; in metamorphosed ultrabasic rocks. Alters in retrograde environments to chlorite, often granular and enclosing quartz grains. **Localities:** A widespread and often abundant mineral in the appropriate metamorphic environment. Abundant in the schists from New England to Georgia, with notable occurrences at Windham, ME; Pearl Hill(1), Fitchburg, MA; Parker mine, Cherokee Co., NC; Fannin Co., GA, commonly twinned, loose in the soil but often weathered (locally called "fairy stones"), and including zincian material. In Rio Arriba and Taos Cos., and in the Truchas Mts. (Fe- and Li-bearing), NM; at various localities in SD, AZ, and WA. Found at numerous localities in Great Britain; as large twins in the schists of Brittany, France; at Cabo Ortega, northwestern Spain (chromian and magnesian); at Mt. Campione, Switzerland(1), in schist

as long prisms with kyanite; at Mt. Greiner, Zillertal, and elsewhere in the Austrian and Italian Tyrol. In twinned crystals at Keivy, Kola Penin., Russia. As pseudomorphs after quartz, corundum, and kyanite in the Dунghai district, China. At Broken Hill, NSW, Australia (zincian); at Fiordland, New Zealand (chromian). Cobaltoan staurolite (lusakite) at a site about 120 km E of Lusaka, Zambia; in Uganda (zincian), and at Manantsahala, Madagascar (chromian). At Rubelita, MG, Brazil, as large, sharp, occasionally gemmy crystals(!), often twinned on both laws. Uses: An index mineral in the interpretation of metamorphic grade. Cruciform twins used ornamentally and as amulets. As a collector's gemstone (rarely). AR *AM* 20:316(1935), 67:292(1982), 71:1461(1986), 76:1910(1991).

52.3.1.1 Topaz $\text{Al}_2\text{SiO}_4(\text{F},\text{OH})_2$

Known since antiquity. The history of the use of the name *topaz* is both curious and confusing. According to Pliny, the Greek work *Topazos* or *Topazion* referred to an island in the Red Sea now known as Geziret Zabarget and formerly as St. John's Island, just off the south coast of Egypt. This island was and is a source of gem peridot (olivine), sometimes called chrysolite. It is probable that the gem we call peridot today was formerly called topaz ["topasius vulgaris = chrysolithos veterum," de Boot, *Gemm.* (1636)]. The first use of the name *topaz* for the species we now know by that name was by

TOPAZ: $\text{Al}_2\text{SiO}_4(\text{F},\text{OH})_2$

Topaz is similar in some respects to the Al_2SiO_5 minerals. Like kyanite, it has multiple chains of octahedra (parallel to *a*) cross-linked by Si tetrahedra. Its density is almost as great as that of kyanite.

Henckel in 1737, when he described the deposits of Saxony. The term *topaz* has commonly been applied to any yellowish gemstone, including citrine ("false topaz," "quartz topaz," "Madeira topaz"); yellow sapphire ("oriental topaz"); yellow andradite ("topazolite"); even smoky quartz ("smoky topaz"), and others. In the gem trade true topaz of a reddish orange-yellow to sherry color is often referred to as "Imperial topaz." ORTH *Pbnm* or TRIC *P1*. For F-rich topaz, Thomas Range, UT (0.1 wt % H_2O^+), $a = 4.6512(4)$, $b = 8.795(8)$, $c = 8.3993(7)$. For OH-bearing topaz, Ouro Preto, Brazil (2.6 wt % H_2O^+), $a = 4.6673(5)$, $b = 8.8415(7)$, $c = 8.3947(7)$, $Z = 4$, $D = 3.56$ (OH-free topaz), 3.37 (OH-rich topaz, 25 mol % OH for F). *GAC-MAC Ann. Meet.*, 16:A38(1991). Syn $\text{Al}_2\text{SiO}_4(\text{OH})_2$ has $a = 4.724$, $b = 8.947$, $c = 8.390$. *AM* 78:285(1993). 12-765(nat): 3.69₆ 3.195₆ 3.04₃ 2.94₁₀ 2.38₃ 2.36₄ 2.105₄ 1.67₃. Habit: Frequently in crystals prismatic to equant (with crystallographic setting $a < c < b$), with {110} or {120} predominating. Other forms present, in decreasing order of abundance, are {112}, {011}, {021}, {001}, {111}, {113}, {101}, {010}. In pegmatitic topaz {021}, {011}, {001} often prominent. Twins rare, "contact" on (010). The key structural units are crankshaft-like chains of edge-sharing $[\text{AlO}_6]$ octahedra parallel to c cross-linked by corner-sharing $[\text{SiO}_4]$ tetrahedra. Structurally related to andalusite and danburite. Orthorhombic topaz contains eight symmetry-equivalent positions for F and OH. H is disordered over these sites. Three of the eight sites (38%) are Raman active and permit substitution of OH for F. Natural topaz with more than about 30 mol % substitution of OH for F has not been found. Topaz with complete replacement of F by OH has been synthesized at high temperature (to 1000°) and pressure (55–100kb). *EOS* 71:1707(1990), *AM* 78:285(1993). In triclinic topaz, such as that from hydrothermal veins near Ouro Preto, Brazil, H associated with the hydroxyl ion is ordered on only one of the eight sites, which are otherwise symmetrically equivalent in *Pbnm* topaz. Topaz with no OH is orthorhombic but as substitution of OH for F occurs, ordering of the OH into specific sites causes a decrease in symmetry to monoclinic and then to triclinic. *MM* 43:943(1980), *CM* 28:327(1990). Two nonequivalent H positions are present in synthetic high-pressure $\text{Al}_2\text{SiO}_4(\text{OH})_2$. *AM* 79:401(1994). This is clearly seen in the OH-vibrational spectra in the mid-IR and by Raman spectra. **Physical properties:** Colorless, straw to wine-yellow, pink, blue, green, red, and rarely other colors. Most topaz is colorless, shades of blue or straw to wine yellow. Individual crystals may be multicolored. The colors of topaz are due primarily to radiation-induced color centers and/or trace levels of transition metals. White streak, vitreous luster. Cleavage {001}, perfect; subconchoidal to uneven fracture; brittle. $H = 8$. $G = 3.4\text{--}3.6$. IR data: *MG* 4:85(1973). Raman data: *JCS(A)*:1327(1969), *PCM* 15:148(1987). Rarely fluorescent yellow, white, orange, greenish yellow under both SWUV and LWUV. Pyroelectric and piezoelectric because of ordered OH for F substitution. Color is sometimes changed by heating or exposure to light due to presence of radiation-induced color centers. *NJMA* 130:288(1977). The variation of density, unit cell

parameters (particularly *b*), indices of refraction, and $2V$ for topaz are a consequence of OH for F substitution. *AM* 52:1890(1967), 56:1812(1971); *MM* 37:717(1970); *GAC-MAC Ann. Meet.*, 16:A38(1991). Partially attacked by H_2SO_4 . **Chemistry:** Topaz usually does not contain many trace or minor elements. As much as about 700 ppm Ge has been reported. More than 100 ppm each of B, Li, and Na has been reported from rhyolite-hosted topaz. Some rhyolitic topaz is pink and is colored by >600 ppm Mn. As much as several thousand ppm Cr has been reported from pink-red topaz from hydrothermal veins, and Mn^{3+} as well as Fe^{3+} may also play a role in topaz coloration. Topaz from topaz rhyolites contains less than 0.1 wt % H_2O^+ . That from pegmatites and greisens contains from 0.2 to 0.9 wt % H_2O^+ and topaz from hydrothermal veins contains from about 1.5 to 2.7 wt %. F ranges from about 20 wt % in volcanic topaz down to 15 wt % in hydrothermal vein topaz. **Optics:** Biaxial (+); XYZ = *abc*; $N_x = 1.606-1.634$, $N_y = 1.609-1.637$, $N_z = 1.616-1.644$; $2V_{z\text{ meas}} = 48-68^\circ$. For orthorhombic topaz, OAP = (010), BXA = [001]. Optics for triclinic (= optically anomalous) topaz: *MM* 43:237(1979). **Occurrence:** Topaz is a product of crystallization from F-rich vapors in rhyolites. It also crystallizes as a liquidus phase from rhyolites and certain silicic magmas known as ongonites. It is found chiefly in veins and druses in peraluminous granites, greisens, tin veins, and pegmatites. Topaz also occurs in hydrothermal veins and rarely in high-temperature sillimanite-bearing metamorphic rocks. Cr-bearing topaz is found in hydrothermal veins that transect rocks containing elevated levels of Cr or are closely associated with such rocks. **Localities:** Only noteworthy worldwide occurrences of topaz are given here. Occurs at Lord Hill, Stoneham, ME, in fine crystals; Moat Mt., and Conway region (e.g., Baldface Mt.), NH, in miarolytic cavities in granite. Unusual fine-grained, massive, low-F-bearing topaz occurs at the Brewer gold mine, Jefferson, Chesterfield Co., SC. Blue topaz occurs at the Morefield and Rutherford mines, Amelia district, Amelia Co., VA. Blue topaz(!) is found in pegmatites in the Llano uplift, Mason Co., TX. In CO in pegmatites in the Pikes Peak region (including the Lake George intrusive center, Tarryall region, and Devils Head area), and in lithophysae in rhyolite at Ruby Mt., Nathrop. In lithophysae in rhyolite from the Thomas Range, Juab Co., UT, as fine sherry-colored crystals(!!) which become colorless upon exposure to sunlight, associated with red beryl, bixbyte, pseudobrookite, and hematite. Zoned pink crystals, colored by Mn^{3+} , occur at the northern end of the Thomas Range. In pegmatites at the Little Three mine, Ramona(!), and at the Blue Lady mine, Aguanga Mt., San Diego Co., CA(!). In pegmatites of the Sawtooth Batholith, Salmon, ID. In Mexico, as orange crystals in rhyolites near Cerritos, SLP, and at Tepetate, ZAC, and in DGO. Coarse, fibrous topaz (pycnite) from Altenberg, Schneckenstein, Saxony, Germany. In Ukraine from the Volyn region(!!). In Russia in pegmatites at Miask, Ilmen Mts.(!). In superb nearly equant crystals of sky-blue color from the Alabaschka-Mursinka region, Ural Mts.(!!); from the Adun-Tschilon Mts., Nertschinsk, and Urulga R. area, Transbaikal region, Siberia. Cr-bearing,

pink to purplish-red crystals are found in placer and gem gravels derived from quartz veins as well as in the quartz veins and vugs in limestone, near Sanarka, Orenburg district, Ural Mts., Russia. Cr-bearing topaz(II) occurs at Katlang, Mardan district, Pakistan, in deep-pink gem crystals with quartz and calcite in a hydrothermal vein. The mineral occurs in fine colorless, amber-yellow, and sherry wine-colored crystals(II) in pegmatites near Shingus and Bulechi in the Gilgit area and at Niyit Bruk and Gone, near Dassu in the Skardu district. In Japan at Tanokamiyama, Omi Pref.(I). In Nigeria at Jos in veins with cassiterite and columbite. In Zimbabwe in fine blue crystals(I) at St. Ann's mine, Karoi district. In Namibia at Klein Spitzkopje, Usakos. In Brazil in fine yellow, orange, and pink to violet gem crystals(II) ("Imperial topaz") in hydrothermal veins in the Ouro Preto district, MG, associated with euclase, hematite, and rutile; also in MG abundant in the Marambaia district in fine colorless crystals(I); at Virgem da Lapa, in pegmatites in fine blue crystals(II), one of which weighed 28 kg, associated with lepidolite and herderite; and at the Fazenda do Funil, Sta. Maria da Itabira, in magnificent large crystals(II) associated with gem beryl and cassiterite. One of these crystals weighed over 270 kg and several exceeded 100 kg. Three of these crystals are on exhibit at Harvard, AMNH, and the USNM. A large crystal of Topaz, about 350 tons, was described in 1944 from the São Domingos Mine, Mugui, Espirito Santo, Brazil. Pseudomorphs are sometimes formed by hydrothermal action, causing alteration to clays or muscovite and quartz; also to fluorite, margarite, or kaolinite. Use: Principal use is as a gemstone. Irradiation (with gamma rays or with neutrons or electrons in linear accelerator facilities); treatment after cutting is commonly employed to produce "electric blue" or "London blue" stones from colorless material. Some especially large gems are: Champagne Topaz (36,853 ct), American Golden (22,875 ct), and the Brazilian Princess (21,005 ct). *EF MIN 3(1):274(1972)*, *MSASC 5:215(1980)*, *NJMM:465-470(1982)*, *DHZ 1A:801(1982)*, *AM 71:1186(1986)*, *TOPAZ 207 pp (1992)*, *MR 26:5(1995)*.

HUMITE GROUP

The humite group consists of neosilicate minerals conforming to the general formula

where

A = Mg, Ca, Mn, Fe²⁺, or Zn; n=3,5,7,9; m=1,2,3,4

CHONDRODITE: $Mg_5Si_2O_8(OH, F)_2$

Perspective view along *a*, showing the olivine and brucite layers typical of the humite group.

and where the structure is monoclinic or orthorhombic and based on hexagonal close-packed anions.

The humite group minerals (and the olivine group minerals) have structures based on hexagonal close-packed anion (O, OH, F) arrays in which one-half of the octahedral sites are filled by divalent cations. The key structural unit is a serrated chain of edge-sharing M-octahedra parallel to the *c* axis. Members with straight chains are orthorhombic, and those with diagonal chains are monoclinic. (The angle is α rather than β because of the cell orientation. The orthorhombic minerals are generally described in a nonconventional orthorhombic setting, *Pbnm*, to show the structural relationship with the olivine group.) Adjacent chains in the (001) plane are related by the translation vector *b* and are cross-linked by sharing corner with up- and down-pointing (+ and -) tetrahedra. Each (+) tetrahedron shares its three basal edges [i.e., those approximately parallel to (100)] with octahedra in the layer below, each (-) tetrahedron with octahedra in the layer above. Octahedral chains in adjacent (001) layers are related by the glide operation.

HUMITE GROUP

Mineral	Formula	Space Group	a			b		M ²⁺ / Si
			a	b	c	α		
Norbergite	Mg ₃ SiO ₄ (F,OH) ₂	<i>Pbnm</i>	4.706– 4.710	10.271– 10.275	8.727– 8.820		3:1	52.3.2a.1

COMPOSITION OF HUMITE GROUP MINERALS BASED ON THE M²⁺/SI RATIO

M ²⁺ / Si	Ca	Mg (Humite Subgroup)	Mn (Mn-Humite Subgroup)	Mn (Leucophoenicite Subgroup)
3:1		Norbergite	(unknown)	(unknown)
5:2	Reinhardbraunsite	Chondrodite	Alleghanyite	Ribbeite
7:3		Humite	Manganhumite	Leucophoenicite
9:4		Clinohumite	Sonolite	Jerrygibbsite

Notes:

- All the members of the humite group have a very limited paragenesis, and their occurrence is, with rare exceptions, restricted to metamorphosed and metasomatized limestones and dolomites and to skarns associated with ore deposits at contacts with acid and, less frequently, plutonic rocks. *DHZ 1A:337(1982)*.
- Excellent summaries of the humite group are given in *MSASC 5:231(1980)* and *DHZII 1A:377(1982)*.

52.3.2a.1 Norbergite Mg₃SiO₄(F,OH)₂

Named in 1926 by Geijer for the locality. Humite group. ORTH *Pbnm*. $a = 4.706\text{--}4.710$, $b = 10.271\text{--}10.275$, $c = 8.727\text{--}8.802$, $Z = 4$, $D = 3.14\text{--}3.19$; *11-686*(syn F end member): 4.37_3 3.06_{10} 2.64_7 2.41_3 2.34_3 2.26_7 2.23_8 1.72_5 . Structure: *AM 54:376(1969)*, *MSASC 5:231(1980)*. Crystals rare, flattened on a , typically granular no twinning observed. Light yellowish brown, white, rose, yellow; vitreous luster, uneven to subconchoidal fracture, brittle. $H = 6\text{--}6\frac{1}{2}$. $G = 3.13\text{--}3.20$. IR data: *MIN 3(1):300(1972)*; material from

many localities (e.g. Balmat, NY; Franklin and Sparta, NJ; Pargas, Finland) Balmat, NY, fluoresces bright yellow only under SWUV. Soluble in HCl, producing a silica gel. Nearly pure from Balmat, NY. Fe substitutes for Mg and OH substitutes for F. Small amounts of Fe, Mn, Al, and Ti are present in natural material. Biaxial (+); $XYZ = acb$; $N_x = 1.558-1.567$, $N_y = 1.563-1.579$, $N_z = 1.581-1.593$; $2V = 44-50^\circ$; $OAP = (001)$; $X > Y > Z$; $r > v$. X, colorless or weakly colored; Y, pale yellow, weak pale yellow; Z, colorless. Occurs in contact metasomatic rocks, Marbles Mg-rich skarns, and as a contact mineral between calcite-dolomite marble and granite. Rarely in Fe and Fe-Zn ores and Ca-rich skarn zones. Sometimes with other members of the humite group and other Mg-silicates (e.g., forsterite, diopside, phlogopite, brucite, etc). Mg-Zn skarns: Franklin, NJ. Occurs at Balmat, St. Lawrence and around Edenville, Orange Co., NY; Franklin, Sussex Co., NJ: *Ostanmossa mine, Norberg, Västmanland, Sweden*; Parainen and Pargas, Finland; Monte Sommarand, Mt. Vesuvius, Naples, Italy; Pitkyaranta, Karelia, Russia; several places, including Lyangar in Uzbekistan; Bihar, India. EF AM 64:1027(1979), 64:1156(1979), 67:538(1982), 67:545(1982); DHZ 1B:378 (1982).

52.3.2b.1 Alleghanyite $(Mn^{2+})_5(SiO_4)_2(OH,F)_2$

Named in 1932 by Ross and Kerr for the locality Humite group. See chondrodite (52.3.2b.2) (Mg-dominant analog). Polymorph: ribbeite. MON $P2_1/b$. (Nat Mg-rich): $a = 4.827$, $b = 10.613$, $c = 8.116$, $\alpha = 108.65^\circ$; (nat): $a = 4.850$, $b = 10.720$, $c = 8.275$, $\alpha = 108.64^\circ$, $Z = 2$, $D = 3.96$; for magnesian, $D = 3.75$. 43-683(nat): 3.10₁₀ 2.84₇ 2.75₄ 2.70₄ 2.59₄ 2.33₅ 1.79₆. Calc. 25-1187; Calc magnesian 39-1348. Structure (for magnesian): AM 70:182(1985). Crystals are slender, platelike, and deeply striated by twinning, usually 0.3-1 mm; also unstriated stout platy crystals, rounded, anhedral grains; twinning may be present, polysynthetic on {001}, also rarely on 015 and 035. Strawberry-pink, grayish red, clove-brown; pale pink streak; vitreous to resinous luster. Cleavage (001), good to fair; conchoidal fracture; brittle. $H - 5-5\frac{1}{2}$. $G(\text{nat}) = 3.93-4.02$, $G(\text{magnesian}) = 3.75$. Soluble in 1:1 HCl, leaving a silica gel. A high-Mg variety exists with up to 15.0 wt % MgO. The Mg-rich alleghanyite has $(Mn_{0.6}Mg_{0.4})$. Some ZnO (to ≈ 3.6 wt %) is also present. F to 3.8% for material from Sterling Hill, NJ. Near-end-member material is known from Bald Knob, NC. Biaxial (-); $X \wedge a = -35^\circ$, $Z = b$, $Y \wedge c = -35^\circ$; in the nonstandard olivine-type setting: $X \wedge b = -35^\circ$, $Z = a$, $Y \wedge c = -35^\circ$; $N_x = 1.756-1.762$, $N_y = 1.780-1.782$, $N_z = 1.792-1.793$; $2V = 70-90^\circ$; OAP perpendicular to (100); $r > v$, weak. X, brown; Y, light brown; Z, colorless. Occurs in Mn-rich skarns with other Mn-silicates and carbonates, and others. Also in Mn veins with tephroite and spessartine. Occurs at Bald Knob, Alleghany Co., NC; a high-Mg variety occurs at Sterling Hill, Ogdensburg, and Franklin, Sussex Co., NJ; Great Gossan, VA; Sunnyside mine, and Eureka Gulch, Silverton district, San Juan Co., CO; near San Jose, Santa Clara Co., and Germais

prospect, Fiddletown, Amador Co., CA; Brown Mule claim, Mason Co., WA; Benallt mine, Rhiw, Carnarvonshire, Wales; Langtan and the Brattfors mine, Nordmark, Värmland, Sweden; northern end of the Inylchek Range, south-eastern Kirgizia; several localities in Japan: Mukayama and Sono in Kyoto Pref.; Kasugi, Yamaguti Pref.; Tamagawa, Iwate. Pref., and others in Aichi, Nagano, and Tochigi Prefectures. *EF MIN* 3(1):319(1972); *MR* 15:299(1984), 12:167(1981); *AM* 70:379(1985), 68:951(1983).

52.3.2b.2 Chondrodite $(\text{Mg,Fe,Ti})_5(\text{SiO}_4)_2(\text{F,OH,O})_2$

Named in 1817 by d'Ohsson from the Greek for *granule*, in allusion to its occurrence as isolated grains. Humite group. *MON* $P2_1/b$. (Nat): $a = 4.730$, $b = 10.255$, $c = 7.867$, $\alpha = 109.0^\circ$; (nat titanian): $a = 4.727$, $b = 10.318$, $c = 7.905$, $\alpha = 109.33^\circ$; (syn F end member): $a = 4.75$, $b = 10.27$, $c = 7.80$, $\alpha = 109.2^\circ$; (syn OH end member): $a = 4.752$, $b = 10.350$, $c = 7.914$, $\alpha = 108.71^\circ$; $Z = 2$; $D = 3.38$ (titanian) and 3.18 (calc F end member). $12-527$ (nat): 4.84_3 3.56_3 3.02_4 2.76_3 2.51_4 2.29_3 2.26_{10} 1.74_7 ; $33-865$ (titanian): 3.49_6 3.03_6 2.77_5 2.68_5 2.62_7 2.52_7 2.26_8 1.74_{10} ; $14-10$ (syn F end member): 4.85_4 3.55_4 3.01_5 2.67_5 2.61_6 2.27_{10} 2.25_{10} 1.74_9 . Structure: *AM* 55:1182(1970), 63:535(1978). Ti is ordered into $M(3)$. Crystals to 2 cm or more, granular, equant, well-formed crystals, many are modified; polysynthetic twinning on $\{001\}$; titanian material appears to show more twinning, also simple, lamellar twinning on $\{001\}$, rare twinning on $\{031\}$ and $\{035\}$. Yellow, orange, brownish red, reddish or greenish brown, rarely colorless, often translucent; white-gray, yellow streak; vitreous to greasy luster. Cleavage (001), poor to good; conchoidal to uneven fracture; brittle. $H = 6-6\frac{1}{2}$. $G = 3.1-3.23$ (Tilley Foster) and 3.16 (F syn). IR data: *JRNBS* 65A:415(1961). Sometimes luminesces yellow or brown-orange, sometimes fluorescent in LWUV a yellow-white to yellow. Soluble in HCl and H_2SO_4 . May contain appreciable Ti (to $\approx 9-9.6\%$ TiO_2) (e.g., Buell Park, AZ); Franklin and Sterling Hill chondrodite contains ZnO (to 11.5% ZnO) and MnO (to 36% MnO), and grades to alleghanyite. B_2O_3 to 0.71 wt %, $M + 2(\text{OH,F}) \leftrightarrow \text{Ti} + 2(\text{O})$; $(\text{Si}_{1.88}\text{B}_{0.2})_2$ is maximum B content. Usually has $\text{F/OH} \approx 1:1$ or $> 1:1$. FeO to 10.5%. Biaxial (+); OAP perpendicular to (100); $Z = a$; $X \wedge b = 22-31^\circ$; regular range: $N_x = 1.592-1.617$, $N_y = 1.602-1.635$, $N_z = 1.621-1.646$; syn F end member: $N_x = 1.582$, $N_y = 1.594$, $N_z = 1.612$; Syn OH end members $N_x 1.630$, $N_y 1.642$, $N_z 1.658$; Tilley Foster mine: $N_x = 1.615$, $N_y = 1.627$, $N_z = 1.646$; titanian: $N_x = 1.714$, $N_y = 1.717$, $N_z = 1.750$; $X > Y \geq Z$; $r > v$ weak. X, medium yellow; Y, colorless; Z, colorless. Occurs in ultramafic rocks, serpentinite, kimberlite, ultramafic contact-metamorphic rocks, marbles. In contact silicate and carbonate rocks. Magnesian skarns. May be found with other members of the chondrodite-humite group. Occurs in many localities worldwide but only noteworthy localities are given here: Tilley Foster mine! Brewster, Putnam, and Amity, Orange Cos., NY; Franklin and Sterling Hill, and Sparta, Sussex Co., NJ; Ti-rich material from Buell Park kimberlites, AZ; Crestmore, Riverside Co., CA; Cardiff, Ont, Canada; Broadford, Skye, Scot-

land; Aker, Kareltop, and Nordmarken, Sweden; Sorfinnset and Kristiansund, Norway; *Pargas*, Hangelby, and Sibbo, *Finland*; West Tauern, Austria; Monte Somma, Vesuvius, Naples, Italy; Wunsiedel and Passau, Germany; Zlotystok, Poland; Slyudanka, Irkutsk Oblast, Russia; southern Yakutia Fe deposits; Uzbekistan; Aldan shield, Siberia; Assam, India: gemmy red crystals to 10 mm occur in the Phalaborwa Complex, South Africa; nearly pure (57 wt % MgO) material from Kamioka, Japan. Occasionally used as a gemstone (e.g., material from the Tilley Foster mine). *EF MIN 3(1):304(1972)*; *AM 64:1027(1979)*, *70:379(1985)*, *73:547(1988)*; *DHZ 1A:377(1982)*.

52.3.2b.3 Reinhardbraunsite $\text{Ca}_5(\text{SiO}_4)_2(\text{OH},\text{F})_2$

Named in 1983 by Hamm and Hentschel for Reinhard Brauns (1861–1937), former professor of mineralogy, University of Bonn. Humite group. Known earlier as synthetic “calciochondrodite.” *MON P2₁/b*. (Nat fluorian): $a = 5.052$, $b = 11.458$, $c = 8.840$, $\alpha = 108.91^\circ$, $Z = 2$, $D = 2.885$; (syn OH end member): $a = 5.076$ – 5.077 , $b = 11.448$ – 11.465 , $c = 8.915$ – 8.921 , $\alpha = 108.32$ – 108.66° , $Z = 2$, $D = 2.82$; (syn F end member): $a = 5.046$, $b = 11.492$, $c = 8.777$, $\alpha = 109.09^\circ$, $D = 2.92$. *37-414(nat fluorian)*: 3.81₄ 3.32₅ 3.04₈ 2.94₅ 2.90₈ 1.90₁₀ 1.89₅ 1.66₅. *29-380(syn OH)*: 3.83₇ 3.35₉ 3.04₁₀ 2.95₆ 2.92₉ 2.91₈ 2.78₉ 1.91₇. Structure: *TMPM 31:137(1983)* *NJBM:119(1983)*. Anhedral to subhedral grains to 3 mm across, twinning parallel to (001). Light pink to light brown, translucent to transparent, also light blue; white streak; vitreous luster. $H = 5$ – 6 . $G = 2.85$. Biaxial (–); $Z = a$, $X \wedge c = 18^\circ$; $N_x = 1.606$, $N_y = 1.617$, $N_z = 1.620$; $2V = 44$ – 50° ; $r > v$, distinct. DTA and IR data: *NJBM:119(1983)*. Soluble in HNO_3 , gelatinizes with HCl. Occurs from scoriae of a volcano. Occurs in the *Eittringer Bellerberg volcano, Mayen, Laacher See, Eifel, Germany*; in a Ca-rich xenolith at Udersdorf, Emmelberg, West Eifel. *EF*

52.3.2b.4 Ribbeite $\text{Mn}_5(\text{SiO}_4)_2(\text{OH})_2$

Named in 1987 by Peacor et al. for Paul Hubert Ribbe (b.1935), professor of mineralogy, Virginia Polytechnic Institute, Blacksburg, VA. Humite group. Dimorph: alleghanyite. *ORTH Pbnm*. $a = 4.799$ – 4.811 , $b = 10.732$ – 10.740 , $c = 15.672$ – 15.70 , $Z = 4$, $D = 3.84$ – 4.05 . *AM 72:213(1987)*. *40-491(nat)*: 2.92₇ 2.87₈ 2.82₇ 2.69₆ 2.55₈ 2.51₄ 2.36₄ 1.80₁₀. Structurally related to leucophoenicite in that it contains serrated, edge-sharing chains of Mn octahedra and two distinct types of Si tetrahedral sites: (1) a single, isolated, fully occupied Si tetrahedron, and (2) a pair of edge-sharing half-occupied Si tetrahedra, which are related by an inversion center. Ribbeite is the unit cell twinned dimorph of alleghanyite; the disordered edge-sharing tetrahedra in ribbeite are a direct consequence of mixed unit cell glide operations in alleghanyite: statistically, one-half of the glides are alternate, half are en echelon. *AM 78:190(1993)*. 0.5 mm in diameter, anhedral grains. Pink, light pink streak, vitreous luster. Cleavage not observed. $H = 5$. $G = 3.90$. Analysis (wt %): SiO_2 , 24.3; FeO , 0.3; MgO , 5.2; MnO , 65.1; CaO , 0.2; H_2O , 4.9. Biaxial

(+); XYZ = *bac*; $N_x = 1.780$, $N_y = 1.792$, $N_z = 1.808$; $2V = 81^\circ$, Na(D); $Z > X = Y$; $r > v$, moderate. X, Y, colorless; Z, light pink. Occurs at the *Kombat mine, 49 km south of Tsumet, Namibia*; from a metamorphosed Mn deposit; Cu and Pb sulfides were then deposited in essentially unmetamorphosed dolomite. Lenses of Fe and Mn oxides are present, including ribbeite. Lenses of ribbeite are up to 5 cm thick. Alleghanyite is also present. EF

52.3.2c.1 Humite (Mg,Fe)₇(SiO₄)₃(F,OH)₂

Named in 1813 by Bournon for Abraham Hume (1749–1838), English connoisseur and collector of works of art, precious stones, and minerals, and president of the Geological Society of London. Humite group. ORTH *Pbnm*. (Syn OH end member): $a = 4.735$, $b = 10.243$, $c = 20.72$; (ferroan): $a = 4.741$, $b = 10.258$, $c = 20.853$, also reported as: $a = 4.78$, $b = 10.22$, $c = 21.02$ (AM80 : 638(1995) $Z = 4$, $D = 3.20$ (syn). 12-755(syn F-member): 3.64₅ 2.69₅ 2.57₄ 2.44₇ 2.26₁₀ 2.11₄ 1.74₆ 1.48₇. Structure: Ordering of Fe and Mg. Humite group minerals often intergrown in parallel growth. AM 56:1155(1971). Granular, anhedral, well-formed crystals rare, crystals 2–10 mm, >20 forms observed, dominant: {001}, {010}, {100}, {110}, {120}; twinning present but rare. Yellow to dark orange, reddish orange; yellow to orange streak; vitreous luster. Cleavage {001}, poor. $H = 6-6\frac{1}{2}$. $G = 3.24$ (syn), 3.20–3.32(nat). IR data: JRNBS 65A(5):415(1961). EPR and Mossbauer data: CA 97(10):75846(1982). Soluble in HCl and H₂SO₄ with production of silica gel; gives up F in concentrated H₂SO₄. Manganoean humite from Franklin and Sterling Hill, NJ. Solid-solution exists between manganhumite and humite. Analysis: FeO to 7.8%, Fe₂O₃ to 2.7%, Al₂O₃ to 2.9%. Biaxial (+); XYZ = *cab*; OAP = {010}, for olivine setting; $2V = 65-84^\circ$; $N_x = 1.607-1.643$, $N_y = 1.619-1.655$, $N_z = 1.639-1.675$, F end member: $2V = 59^\circ$; syn F end member: $N_x = 1.598$, $N_y = 1.606$, $N_z = 1.630$; for syn OH end member: $N_x 1.635$, $N_y 1.640$, $N_z 1.661$, $2V_2 = 56.1^\circ$; absorption $X > Z > Y$; $r > v$, weak. X, Z, pale yellow–golden yellow; Y, colorless–pale yellow. Occurs in metamorphosed and metasomatized impure carbonate sediments adjacent to acid and less frequently alkaline plutonic rocks. Occurs at a number of worldwide localities but only selected and noteworthy localities are given here: Tilley Foster Iron Mine, Brewster, Putnam Co, NY; Franklin and Sterling Hill, Sussex Co., NJ; Skye, Scotland; South Harris, Outer Hebrides, Scotland; Monte Somma, Mt. Vesuvius, Naples, Italy; Sillböle, and Hermala and Lohja, Finland; Nordmarken, Norberg area, and The Ladu Mine, Persberg, Värmland, Sweden; Sjöffin-Syor Finset, Glomfiord, Norway; Wallis, Switzerland; Yeno-Kovdor deposit, Kola Penin., and Lesnoi-Barak pit, Kyaranta, Karelia, Russia, in marble with spinel at Anzahamarono, Malagasy Republic (Madagascar). EF MIN 3(1):309(1972); AM 64:1027(1979), 70:379(1985); MSASC 5:231(1980); DHZ 1A:376(1982); PCM 8:55(1982).

52.3.2c.2 Leucophoenicite (Mn, Ca, Mg, Zn)₇(SiO₄)₃(OH)₂

Named in 1899 by Penfield and Warren from the Greek for *pale* and *purple-red*, in allusion to its color. Humite group. Dimorph of manganhumite. *MON* $P2_1/b$. $a = 4.826-4.828$, $b = 10.842-10.85$, $c = 11.324-11.380$, $10.842-10.85$, $11.324-11.380$ $\alpha = 103.73-103.93^\circ$ $Z = 2$, $D = 4.01$. *AM* 69:546(1984): 3.64₄ 3.28₃ 2.89₁₀ 2.72₅ 2.69₉ 2.63₃ 2.45₅ 1.81₁₀; 22-1168: 4.36₅ 3.61₅ 2.88₉ 2.68₈ 2.62₄ 2.44₄ 2.36₅ 1.81₁₀. Structure: closely related to risseire. see risseire for details. *AM* 55:1146(1970). Granular crystalline masses, crystals rare, slender, prismatic, striated, elongated on a , also lath-shaped and flattened short crystals; twinning = polysynthetic on {001}. Brown, violet-red, light pink to deep pink, red-brown; white, pale pink streak; vitreous luster. Cleavage {001}, poor. $H = 5\frac{1}{2}-6$. $G = 3.85$. Gelatinizes with acids. Analysis (wt %): FeO to 0.3%; MgO, 2.7-5.5; CaO, 2.4-2.8; ZnO, 3%; ZnO to 5.4%. *USGSPP*:180(1935). Biaxial (-); X perpendicular to cleavage; $N_x = 1.751-1.760$, $N_y = 1.771-1.778$, $N_z = 1.782-1.790$; $2V = 74^\circ$; colorless or light to deep pink; $r > v$, weak. Occurs in Mn deposits (metamorphosed). In hydrothermal veins at Franklin, NJ. Occurs at the *Franklin mine, Franklin, Sussex Co., NJ*, with willemite and vesuvianite; Pajsberg, Varmland, Sweden; Val Sesia-Val Tournanche area, Italian Alps, Italy; Avontuur and Leinster basins, and Wessels mine, Kalahari Mn field, Cape Prov., South Africa; Kombat mine, Namibia. *EF AC(B)* 39:10(1983); *AM* 63:1009(1983), 69:546(1984), 70:379(1985), 71:985(1986).

52.3.2c.3 Manganhumite (Mn,Mg)₇(SiO₄)₃(OH)₂

Named in 1978 by Moore for the composition: like humite, but with predominant Mn. *ORTH Pbnm*. $a = 4.815-4.822$, $b = 10.54-10.580$, $c = 21.448-21.45$, $Z = 4$, $D = 3.84$. 33-870, *AM* 63:874(1978); 29-866, *MM* 42:133(1978); 33-870(nat): 3.74₄ 3.39₉ 2.82₆ 2.77₅ 2.64₇ 2.51₈ 1.78₁₀. Structure: magnesium-rich material was ordered with respect to distribution of Mg and Mn. *AM* 63:874(1978). Anedral, to 1 mm; Franklin material is massive, occurring in > 1-cm pieces; pale to deep brownish orange, medium brown; yellow-brown streak; subadamantine luster. Cleavage {010}, perfect. $H = 4$. $G = 3.83$. Dissolves easily in warm diluted HCl, leaving a silica gel. F absent in Swedish material, 1.2% F in Franklin material. Solid solution between Mg and Mn. Traces of CaO and FeO. Material from Bald Knob, NC, is nearly pure. Magnesian manganhumite with 14.2 wt % MgO: (Mn_{0.68}Mg_{0.30}). Biaxial (+); XYZ = cba ; $N_x = 1.761$, $N_y = 1.772$, $N_z = 1.781$; magnesian manganhumite: $N_x = 1.707$, $N_y = 1.712$, $N_z = 1.732$; $2V = 84^\circ$, $2V$ for magnesian manganhumite = 37° ; nonpleochroic, very pale orange; OAP = (010), weak absorption, pale orange; $r > v$, perceptible. Occurs as a skarn mineral with katoptrite, manganostibite, magnussonite, galaxite, etc. At Franklin and Sterling Hill, is associated with franklinite, willemite, and so on. Occurs at Franklin and Sterling Hill, Sussex Co., NJ; near-end-member composition material occurs at Bald Knob, Sparta, Alleghany Co., NC; *Brattfors mine, Nordmark, and*

Langban, Värmland, Sweden. EF MSASC 5:231(1980); MR 12:167(1981); PCM 8:167(1982); AM 68:951(1983), 70:379(1985).

52.3.2d.1 Clinohumite $(\text{Mg,Fe})_9(\text{SiO}_4)_4(\text{F,OH})_2$

Named in 1876 by Des Cloizeaux for the crystal system, monoclinic, and its position in the humite group. Humite group. MON $P2_1/b$. $a = 4.740\text{--}4.745$, $b = 10.226\text{--}10.283$, $c = 13.582\text{--}13.699$, $\alpha = 100.9\text{--}101.00^\circ$, $Z = 2$, $D = 3.38$ (Ti- and Fe-bearing) and 3.28 (normal). 33-867(titanian clinohumite calculated pattern) and 14-9(syn $\text{Mg}_9\text{F}_2\text{SiO}_4$)₄; (titanian nat): 3.71_{6,5} 2.77₉ 2.76_{4,5} 2.55₉ 2.52₉ 2.26₈ 1.75₁₀ 1.74₅; (syn F end member): 3.87₃ 3.70_{4,5} 3.49₃ 2.77₆ 2.54₆ 2.51₆ 2.26₁₀ 1.74₈. Structure: Ti substitutes into M3 site. Ordered distribution of Ti. See *CM 12:39(1973)* and *AM 63:535(1978)*. Equant, sometimes elongated on a , usually highly modified, to 1 cm; twinning on {001}, often on {011}, sometimes polysynthetically twinned on {011}, rarely on {021}, {013} as well. Yellow, brown, white, orange; streak varies from colorless to yellow, yellow-orange, honey-brown, to reddish brown; vitreous luster. Cleavage (001), poor; uneven to subconchoidal fracture; brittle. $H = 6$. $G = 3.17\text{--}3.35$. IR data: *MIN 3(1):313(1972)*. Kukh-i-Lal material is very brightly fluorescent yellow orange in SW UV, and material from Crestmore, CA and Lake Albano, Rome, Italy is moderately fluorescent yellow orange to orange. Clinohumite from alkalic and ultramafic rocks may have as much as 6% TiO_2 . There is an inverse relationship between F and Ti content. Exchange operation $\text{TiO}_2 \cdot \text{Mg}^- \text{F}^{2-}$ occurs. FeO to 11.6% in titanian clinohumite. May have minor Al, Ca, Cr, Ni, and Mn. May have BeO to 1.7%. Ti to 0.5 at % content. Total of FeO + Fe_2O_3 to 14%, MnO 1-15% max. May contain minor B: B_2O_3 to 0.8%. Biaxial (+); OAP perpendicular to (100); $X \wedge b = 7\text{--}15^\circ$ in obtuse β ; $Z = a$; for Ti-rich; $X \wedge b = 20^\circ$; (Ti- and Fe-bearing): $N_x = 1.632\text{--}1.707$, $N_y = 1.643\text{--}1.714$, $N_z = 1.664\text{--}1.734$; (syn F end member): $N_x = 1.608$, $N_y = 1.618$, $N_z = 1.636$; (Syn OH and member): $N_x = 1.638$, $N_y = 1.641$, $N_z = 1.669$; $2V = 73\text{--}88^\circ$; for Ti-rich material, $2V = 52\text{--}62^\circ$; for syn F end member, $2V = 59^\circ$ (calc. $2V = 79^\circ$); $N_x > N_y > N_z$; $r < v$, weak. X, yellow-golden yellow; Y, pale yellow; Z, colorless-pale yellow. Occurs in kimberlite, carbonatite; peridotites, metadunite, and serpentinites in orogenic belts such as the Alps, Apennines, and Ruby Range MT (Montana). Usually in metamorphosed and metasomatized limestones and dolomites and in skarns associated with ore deposits at contacts with acid and, less frequently, alkaline plutonic rocks. Also occurs in late-magmatic veins in Tertiary alkaline intrusions (e.g., Gardiner complex, Greenland). Widely distributed worldwide but only selected localities are given here: Tilley Foster iron mine, Brewster, Putnam Co., NY; titanian clinohumite in the Buell Park diatreme, AZ, and in the Moses Rock kimberlite, UT; Dillon, MT; Cotopaxi, CO; Twin Lakes, Fresno, Monterey, and Crestmore, Riverside Cos., CA; Cargill Lake, Ont., Canada; Ti-rich clinohumite from the Gardiner Plateau Complex, East Greenland; Broadford, and Camas Malag, Skye, Scotland; *Monte Somma, Mt. Vesuvius, Naples, Italy*; Nordmark and Talgruvan, Sweden; Hameenkyla, and Pargas,

Finland; Llanos de Juanar, Malaga, Spain; Ala Valley, Piedmont, Italy; Val Malenco, and Lake Albano, Rome, Italy; Laperwitzbach, Tyrol, Austria; Vuorijarvi, Karelia, Yeno-Kovdor deposits, Kola Penin., Akhmatovsk and Shishimsk mines, Chelyabinsk Oblast, southern Ural Mts., in the emerald mines of Yekaterinburg Oblast, central Ural Mts., Aldan Shield, Siberia, central Transbaikalia, Siberia, Russia; kimberlites in southern Yakutia (Ti-bearing); fine orange-brown crystals to 2 cm from Kukh-i-Lal, Pamirs, Tadzhikistan; Mt. Tanzawa, Kanagawa Pref., Japan; titanian clinohumite rims on forsterite inclusions from Morro da Mina, Jacupiranga carbonatite, São Paulo, Brazil. *EF AM 64:1027(1979)*, *MSASC 5:231(1980)*, *PCM 8:55(1982)*, *DHZ 1A:377(1982)*.

52.3.2d.2 Jerrygibbsite $(\text{Mn,Zn})_9(\text{SiO}_4)_4(\text{OH})_2$

Named in 1984 by Dunn et al. for Gerald V. Gibbs (b.1929), Virginia Polytechnic Institute, Blacksburg, VA. Humite group. Dimorphous with sonolite. ORTH $Pbn2_1$. $a = 4.85\text{--}4.875$, $b = 10.70\text{--}10.709$, $c = 28.17\text{--}28.18$, $Z = 4$, $D = 4.07$. *38-352*, *AM 69:546(1984)*; (nat): 2.87_8 2.75_5 2.70_5 2.66_3 2.56_{10} 2.36_4 1.81_{10} 1.55_3 . The structure is unit cell twinned sonolite by a $b/4$ glide plane. The structure has serrated chains of edge-sharing octahedra. *NJMM 9:410(1989)*. Massive, interlocking anhedral crystals to 0.5 mm \times 2.0 mm. Medium violet-pink, light pink streak, vitreous luster on cleavage and fracture surfaces, cleavage parallel to $\{001\}$, imperfect. $H = 5\frac{1}{2}$. $G = 4.00$. No fluorescence or cathodoluminescence. Is F-free. Analysis (wt %): $\text{SiO}_2 \approx 27.0$; $\text{FeO} \approx 0.3$; $\text{MgO} = 1.1\text{--}3.0$; $\text{CaO} = 0.4$; $\text{ZnO} = 3.2\text{--}5.3$; $\text{MnO} = 61.8\text{--}64.1$; $\text{N}_2\text{O} \approx 2$. Biaxial (-); $ZXY = abc$; $N_x = 1.772$, $N_y = 1.783$, $N_z = 1.789$; $2V = 72^\circ$; nonpleochroic, light pink; $r > v$, moderate to strong. Occurs at the *Franklin mine, Sussex Co., NJ*, with zincite, willemite, tephroite, franklinite, and other minerals. Intimately intergrown with leuco-phoenicite and also sonolite also found at the Wessels Mine, Kalahari Manganese Field, South Africa. *EF AM 70:379(1985)*.

52.3.2d.3 Sonolite $\text{Mn}_9(\text{SiO}_4)_4(\text{OH,F})_2$

Named in 1963 by Yoshinaga for the locality. Humite group. Mn analog of clinohumite. Dimorphous with jerrygibbsite. MON $P2_1/b$. $a = 4.849\text{--}4.905$, $b = 10.544\text{--}10.680$, $c = 14.022\text{--}14.333$, $\alpha = 100.3\text{--}100.97^\circ$, $Z = 2$, $D = 4.09$; high Zn (17.6 wt % ZnO): $a = 4.79$, $b = 10.51$, $c = 13.94$, $\alpha = 100.83^\circ$. Malocidelnikovskoye: 3.63_4 2.87_{10} 2.85_7 2.71_4 2.66_5 2.47_5 1.81_6 1.76_5 *22-728* (zincian): 2.82_7 2.80_5 2.59_3 2.56_4 2.45_4 2.40_4 2.30_5 1.77_{10} ; *22-725*(nat): 3.62_4 2.87_{10} 2.70_5 2.65_7 2.61_7 2.50_4 2.46_5 1.74_{10} . Structure: Majority of Mg is concentrated in M3, the smallest octahedral site. Possibly ordered distribution of Mn, Mg, and Zn. *AM 70:379(1985)*, *NJMM 9:410(1989)*, *MM 58:333(1994)*. Euhedral aggregates, anhedral masses to 2 cm at Bald Knob, tablets or equant, masses to 5–6 cm in Kirgizia; twinning, simple to polysynthetic on $\{001\}$ and $\{101\}$. Dark brown, pink, brownish pink, brownish red, brownish violet; pale reddish orange streak; striated parallel to length = $[001]$, vitreous luster. No

cleavage. $H = 5\frac{1}{2}$. $G = 3.77$ (17.6% ZnO) and $G = 3.87$ (regular). IR: *ZVMO 119:98(1990)*. Gelatinizes with acids. Three compositional groups from Franklin, NJ: (1) close to end member with minor Zn, Mg, Ca; ZnO to 4% (about 1% F is present); (2) ZnO \approx 3%, MgO = 5–8%, Fe = 1%; and (3) MgO = 16–19%, ZnO \approx 10–11%, MnO = 36–41%. F to 2%, FeO \approx 1%. ZnO to 17.6% has been found at Sterling Hill. F not found in Japanese material. F increases with increasing Mg in NJ samples. Bald Knob material is nearly pure with only traces of Fe (0.83% FeO) and Mg (0.45% MgO) present. Japanese material: to 3.6% Al₂O₃, 4.97% MgO, 1.0% CaO, 2% H₂O, 0.3% F. Discontinuous solid solution with clinohumite. *AM 70:379(1985)*. Hokkejino mine sample has appreciable Ca: (Mn₇₆ M₁₀₉ Ca₀₄Fe₀₁)₉₀ (SiO₄)₄(OH)₂. Biaxial (-); $X \wedge c = 9^\circ$; $Z = a$; $N_x = 1.695$ (zincian)–1.766, $N_y = 1.716$ (zincian)–1.783, $N_z = 1.725$ (zincian)–1.794; $2V = 70$ – 82° ; nonpleochroic, colorless; $r > v$, weak. Occurs in Mn-bearing skarn deposits, associated with other Mn minerals, such as rhodonite, spessartine, rhodochrosite, tephroite, braunite, jacobsite, and so on. Also in Mn-cherts, (e.g., Alps). Occurs at Sterling Hill, Ogdensburg, and at Franklin, Sussex Co., NJ (some is high in Mg and Zn); Bald Knob, Sparta, Alleghany Co., NC; Pennsylvania mine, San Antonio Valley, Santa Clara Co, CA; Langban and Brattfors, and Harsrigen in the Pajsberg ore field, Varmland, Sweden; Haute-Maurienne, Savoie, France; with rhodochrosite, rhodonite, and other Mn minerals from the Malocidelnikovskoye deposit, Yekaterinburg region, Ural Mts., Russia; northern end of the Inylchek Range, SE Kirgizia; Suao, Taiwan; at least 11 different localities in *Japan*: type locality is the *Sono mine, Kyoto Pref.*, Hokkejino mine, Kyoto Pref.; also Hanawa, Iwate Pref.; Takonomiya, Ibaraki Pref.; Kuratomi Mine, Oita Pref., Kaso, Totigi Pref.; Vagi, Kusugi, and Takamori in Yamaguti Pref. *EF MSASC 5:231(1980)*, *PCM 8:167(1982)*, *DHZ 1A:379(1982)*, *ZVMO 122:78(1993)*.

CHLORITOID GROUP

The chloritoid group minerals are layer-structured alumino-orthosilicates having the general formula

where

$R^{2+} = \text{Fe, Mg, Zn}$

$R^{3+} = \text{Al, Fe, Ga}$

$T = \text{Si, Ge}$

The structure consists of a brucite-type layer with two nonequivalent octahedral sites (occupied by R^{2+} and Al plus vacancies) alternating with a corundum-like layer whose octahedral sites are occupied only by R^{3+} . The two octahedral layers are joined by T^{4+} , usually silicon in isolated tetrahedral groups, and by hydrogen bonds. The distribution of R^{3+} in the layer types may best be illustrated by writing the formula as $[(R^{2+})_2R^{3+}(OH)_4][Al_3O_2][TO_4]_2$.

Triclinic and monoclinic polytypes are known for several of the species, and a centered cell is chosen for the triclinic type to maintain correspondence with the centered monoclinic cell. The monoclinic scheme can be thought of as equivalent to the triclinic cell, being twinned on {001} by a twofold screw axis parallel to [010].

Substitution of Fe^{3+} for aluminum is ordered preferentially in the larger of the octahedral sites. Complete solid solution between chloritoid and carboirite is likely. The two polytypes commonly coexist as mixed-layer phases, and they cannot generally be distinguished by optical properties because of similar orientation and frequent twinning.

MAGNESIOCHLORITOID-M: $(\text{Fe, Mg})_2\text{Al}_4\text{Si}_2\text{O}_{10}(\text{OH})_4$

Perspective view along b , and parallel to the alternating, octahedral brucite and aluminum oxide layers joined by SiO_4 tetrahedra.

CHLORITOID GROUP

*Triclinic and monoclinic polymorphs are commonly intergrown. Data are given for monoclinic or intergrowths of the two.

52.3.3.1 Chloritoid-A,M ($\text{Fe}^{2+}, \text{Mg}, \text{Mn}$)(Al, Fe^{3+})₂O[SiO₄](OH)₂

Named in 1837 by Rose in allusion to its superficial resemblance to minerals of the chlorite group. Chloritoid group. *Ottrelite*, a term now reserved for manganese-dominant chloritoids, was formerly applied to any manganoan chloritoid. The variety *sismondine* is a magnesian chloritoid. Polymorphs: The triclinic and monoclinic forms may not be polytypes in the strictest sense, there being an apparent shift in atomic positions in the successive layers; hypothetical 3T and 6H polytypes have been proposed. TRIC C1. $a = 9.46$, $b = 5.50$, $c = 9.15$, $\alpha = 97.05^\circ$, $\beta = 101.56^\circ$, $\gamma = 90.10^\circ$, $Z = 4$, $D = 3.61$. 14-344: 4.45₁₀ 3.25₆ 2.97₈ 2.77₄ 2.70₇ 2.46₉ 2.40₅ 2.14₆. MON C2/c. $a = 9.482$, $b = 5.484$, $c = 18.182$, $\beta = 101.74^\circ$, $Z = 8$, $D = 3.57$. 14-62: 4.47₁₀ 3.08₄ 2.96₉ 2.64₅ 2.37₇ 2.31₇ 2.12₄ 1.581₈. Structure: AC(B) 31:780(1975), AM 65:534(1980). The overall powder patterns of the two polymorphs are similar and may not always serve to distinguish the two forms, in part, at least, due to intergrowth and stacking faults involved. Habit: Rarely in distinct crystals. Usually tabular {001}, plates of irregular to crudely hexagonal outline often group as rosettes and as disseminated thin scales. Foliated masses with the plates often curved. Twinning common on {001}, with the individuals rotated 60° with respect to one another; the twin axes (monoclinic) are [100], [110], and [130]. Physical properties: Dark green to grayish green, translucent to opaque; vitreous to subadamantine luster, somewhat pearly {001}. Cleavage {001}, perfect but less so than in micas or chlorite; {110}, moderate; {010}, parting. Brittle and inflexible. $H = 6\frac{1}{2}$. $G = 3.51\text{--}3.80$. Biaxial (+), also reported as (-); $2V = 45\text{--}68^\circ$ but values outside this range have been reported; $Z \wedge$ perpendicular to (001)= $2\text{--}30^\circ$; $Y = b$ for most varieties, but sometimes $X = b$, and the orientation may vary within a given sample. $N_x = 1.705\text{--}1.730$, $N_y = 1.708\text{--}1.734$, $N_z = 1.712\text{--}1.740$; $r > v$, strong; anomalous interference colors. Strongly pleochroic with X, pale gray-green to green, Y, gray-blue to indigo, Z, colorless to pale yellow. The indices decrease significantly with substitution of Mg for Fe^{2+} (see magnesiochloritoid). Infusible, becoming magnetic; decomposed by sulfuric acid. Chemistry: Mn^{2+} readily replaces Fe^{2+} to form a solid solution with ottrelite; similarly substitution of Mg^{2+} yields a solid solution with magnesiochloritoid. Minor replacement of aluminum by Fe^{3+} in the brucite-like layers is common. Mn^{2+} has a distinct preference for the chloritoid structure over other associated phases. A solid solution probably exists with the isostructural, monoclinic carboirite in which Si is replaced by Ge, and Ga substitutes for part of the Al, but its existence in nature has not been established due to the low crustal abundance of Ge and the rarity of its minerals. Occurrence: Common in low to medium grade, regionally metamorphosed pelitic sediments, particularly those rich in Al and Fe^{3+} , where it is rarely free of inclusions of quartz and garnet, and is usually associated with muscovite, chlorite, garnet, and staurolite. It usually begins to form in the biotite zone, reaching its maximum development in the garnet zone and beginning to diminish in the staurolite zone. It is known from unshered, metasomatized rocks. Occurs in nonstress environments such as

pyrophyllite lenses in tuffs, rhyolites and dacites, quartz and quartz carbonate veins, hydrothermally altered lavas, and so on. The triclinic form appears to be the common one in hydrothermal, nonstress environments, and both are common in metamorphic environments. Increased stress and temperature appear to favor the monoclinic form. Localities: Widespread worldwide in the relatively common appropriate terrain. In the United States at Natick, Kent Co., RI; at the emery mines at Chester, Hampton Co., MA; Lancaster Co., PA; Deep River area, NC; Marquette Co., MI. In large embedded crystals at Vanlup, Shetland Islands, Scotland; Ottre, Ardennes, and at Salm Chateau (salmite), Belgium; at Morbihon and Ile de Croix, France; at St. Marcel, Piedmont, Italy (sismondine). At Güme Dag, east of Ephesus, Turkey. Originally (both forms) at *Kosoibrod, near Yekateriburg (Sverdlovsk), Ural Mts., Russia*. Near Hualien, Taiwan. Uses: Of no commercial value; used in the interpretation of metamorphic petrology. AR JP 2:49(1961), DHZII 1A:867(1982).

52.3.3.2 Magnesiochloritoid-A,M (Mg,Fe²⁺,Mn)(Al,Fe³⁺)₂O[SiO₄](OH)₂

Named in 1983 by Chopin et al. in allusion to the composition and its relation to chloritoid. Chloritoid group. The term *sismondine*, named for Professor Sismonda of Turin, was used for magnesian chloritoid. Triclinic and monoclinic polymorphs are commonly intergrown; data are for monoclinic, magnesiochloritoid-M, or intergrowths of the two. TRIC C1. (Syn): $a = 9.43$, $b = 5.44$, $c = 9.13$, $\alpha = 96.4^\circ$, $\beta = 101.1^\circ$, $\gamma = 90.0^\circ$; increasingly dominant and more stable with increasing temperature. MON C2/c. $a = 9.460$, $b = 5.471$, $c = 18.182$, $\beta = 101.4^\circ$, $Z = 8$, $D = 3.332$. PD: 4.46₁₀ 2.96₂ 2.46₁ 2.36₁ 2.31₁ 1.574₁ 1.482₁ 1.362₁. The two forms related as in chloritoid. Structure: PCM 18:483(1992). Dark blue, vitreous luster, translucent. Cleavage {001}, perfect. Brittle and inflexible. H = 6–7. G = 3.25. Biaxial (+); 2V = 40–50°; N_x = 1.687, N_y = 1.690, N_z = 1.702. Pleochroic, X > Y > Z; light blue to pale yellow. Found in rocks of the *Monte Rosa massif, Ghiacciaio di Verra, Mezzalama refuge, Italy*, and in the Val d'Ayas and the Palaborna mine, Val D'Aosta. From Zermatt, Valais, Switzerland. AR BM 106:715(1983), AM 73:358(1988), EJM 4:67(1992).

52.3.3.3 Ottrelite-A,M (Mn²⁺,Fe²⁺,Mg)(Al,Fe³⁺)₂O[SiO₄](OH)₂

Named in 1819 by Dethier for the type locality. Chloritoid group. The original material was probably a manganoan chloritoid; subsequent to the later naming of chloritoid, the term was used for manganoan chloritoid, and is now reserved for the Mn > Fe species. Triclinic and monoclinic polymorphs are commonly intergrown; data are for monoclinic, ottrelite-M, or intergrowths of the two. MON Cc or C2/c. $a = 9.505$, $b = 5.484$, $c = 18.214$, $\beta = 101.77^\circ$, $Z = 8$, $D = 3.49$. 39-397: 8.91₁ 4.46₁₀ 2.97₈ 2.69₄ 2.46₂ 2.44₄ 2.38₂ 1.585₄. The two polymorphs are undoubtedly related as in chloritoid. Structure: BM 101:548(1978). Green to yellow-green, vitreous to subadamantine luster,

translucent to opaque. Cleavage {001}, perfect; brittle and inflexible. $H = 6-7$. $G = 3.56$. Biaxial (+); $2V = 60-70^\circ$; $N_x = 1.709$, $N_y = 1.712$, $N_z = 1.716$, but these values clearly must be for a high-Mg phase; $X = b$; Z perpendicular to (001) = 10° ; $r > v$, strong; anomalous interference colors; pleochroic, $X > Y > Z$; olive-yellow to colorless. Infusible; soluble in sulfuric acid. Occurrence is as for chloritoid—in low- to medium-grade regional metamorphism. Found as scales and plates commonly displaying polysynthetic twinning on {001}, in metamorphic rocks of the Vann-Stavelot massif at *Ottre, Ardennes, Belgium*. The majority of other reported occurrences are chronologically early and probably represent manganoan chloritoid. AR *D6 642(1892)*, MA *30:285(1979)*.

52.3.3.4 Carboirite $Fe^{2+}(Al,Ga)_2O[(Ge,Si)_4O_4](OH)_2$

Named in 1983 by Johan *et al.* for the type locality. Chloritoid group. TRIC C1 $a = 9.513$, $b = 5.569$, $c = 9.296$, $\alpha = 96.08^\circ$, $\beta = 101.52^\circ$, $\gamma = 89.45^\circ$, $Z = 4$, $D = 3.95$ (for Ge/Si = 3:1). *35-586*: 4.79₅ 4.53₁₀ 3.02₈ 2.73₉ 2.48₉ 1.854₆ 1.608₇ 1.384₆. Pseudo-hexagonal plates {001} with {110} and {010}. Green; vitreous luster. Cleavage {001}, perfect. $H \approx 6$. Biaxial (+); $2V = 60-75^\circ$; $N_x = 1.731$, $N_y = 1.735$, $N_z = 1.740$; Y perpendicular to (010), $Z \wedge$ perpendicular to (001) = 7° ; $r > v$, strong. Strongly pleochroic. X , blue-green, Y , light blue, Z , colorless-yellow. Contains up to 30% GeO_2 and forms solid solution with chloritoid; significant gallium and zinc may substitute for Al and Fe, respectively. May be replaced, in part, by a germanium analog of lepidomelane. Found in sphalerite associated with Ge-bearing quartz in the zinc deposits at *Carboire, Ariège, central Pyrenees, France*. AR *TMPM 31:97(1983)*, MA *35:320(1984)*.

52.4.1.1 Örebroite $Mn_6(Fe^{3+},Sb^{+5},As)_2Si_2(O,OH)_{14}$

Named by Dunn *et al.* in 1986 for the locality. See welinite (52.4.1.2) and franciscanite (52.4.1.4). HEX-R P3. $a = 8.183$, $c = 4.756$, $Z = 1$, $D = 4.77$; *40-486(nat)*: 4.08₃ 3.94₂ 3.10₁₀ 2.84₅ 2.68₄ 2.33₇ 1.78₉ 1.55₅. Dark brown, reddish-brown streak, vitreous luster. No cleavage, irregular fracture. $H \approx 4$. Analysis (wt %): SiO_2 , 15.2; MnO , 54.6; MgO , 0.8; Fe_2O_3 , 9.2; Al_2O_3 , 0.3; Sb_2O_5 , 15.8; As_2O_5 , 1.6; H_2O , 2.8. Uniaxial (+); $N_O = 1.85-1.857$, $N_E = 1.87-1.875$; nonpleochroic. O,E, nearly opaque. Occurs in association with calcite in Precambrian metamorphic rocks at the *Sjö mine, Grythyttan, Örebro, Sweden*. EF *AM 71:1522(1986)*.

52.4.1.2 Welinite $Mn_6^{2+}(W^{6+},Mg)_2SiO_2(O,OH)_{14}$

Named by Moore in 1967 for Eric Welin (b.1923), mineralogist and geochronologist. HEX-R P3. $a = 8.155$, $c = 4.785$, $Z = 2$, $D = 4.41$. *20-1339(nat)*: 7.0₅ 4.07₆ 3.95₃ 3.10₈ 2.84₄ 2.33₈ 1.78₁₀ 1.54₆. Structure: *AM 53:1064(1968)*; *AKMG 4:407(1967)*, *4:459(1968)*. Up to 2-cm crystal sections. Reddish black to deep red-brown, red-brown streak, resinous luster. Poor to distinct {00.1} cleavage, brittle. $H = 4$. $G = 4.47$. Analysis (wt %): MnO ,

55.0; SiO₂, 15.7; MgO, 2.5; Fe₂O₃, 0.8; WO₃, 21.7; Sb₂O₅, 1.6; H₂O, 2.9; Σ = 100.7. Uniaxial (+); N_O = 1.864, N_E = 1.880; nonpleochroic; some grains show a small 2V while others are almost isotropic. Occurs in manganese ore associated with calcite, barite, sarkinite, and adelite. In fissures cutting hausmannite ore. Occurs at *Langban, Värmland*, and the Sjo mine, Grythyttan, Sweden. EF *MIN 3(1):95(1972)*.

52.4.1.3 Kittatinnyite $\text{Ca}_2\text{Mn}_2^{2+}\text{Mn}^{2+}\text{Si}_2\text{O}_8(\text{OH})_4 \cdot 9\text{H}_2\text{O}$

Named by Dunn *et al.* in 1983 from the Algonquin for *endless hills*, in allusion to the topography of the Franklin, NJ, area. See: walkkilldellite, the As analog (???). HEX $P6_3/mmc$, $P6_3mc$, or $P62c$. $a = 6.498$, $c = 22.78$, $Z = 2$, $D = 2.62$. $35-607$ (nat): 11.2₁₀ 5.61₆ 5.03₃ 3.80₃ 2.82₅ 2.73₆ 2.52₄ 2.28₄. Thin plates; dominant forms are {0001} and {101̄γ}, 0.2 mm in diameter, crystals 2.0 μm thick. Bright yellow, light yellow streak, vitreous luster. Cleavage {0001}, perfect; brittle. $H \approx 4$. $G = 2.61$. Nonluminescent. Uniaxial (-); N_O = 1.727, not able to measure N_E; E ≥ O. O, medium yellow; E, moderate yellow. Associated with bostwickite and carbonates at the Franklin mine, Franklin, NJ. EF *AM 68:1029(1983)*.

52.4.1.4 Franciscanite $\text{Mn}_6^{2+}(\text{V}^{5+}, \square)_2\text{Si}_2(\text{O}, \text{OH})_7$

Named in 1986 by Dunn *et al.* for the Franciscan Complex of California where it was found. Compare welinite and örebroite. HEX $P3$, $a = 8.148$, $c = 4.804$, $Z = 1$, $D = 3.93$. PD 4.07₂ 3.97₃ 3.11₉ 2.84₉ 2.67₄ 2.33₁₀ 1.785₇ 1.538₅. Cherry-red when fresh, darkening with time to a brownish red; streak brownish-red; transparent to translucent; luster vitreous; fracture uneven; $H \approx 4$, $G = 4.1$. Uniaxial (+); N_O = 1.856, N_E = 1.882, but fresh material has nominally lower indices of N_O = 1.859 (*sic*) and N_E = 1.876 suggesting that Mn²⁺ oxidizes on exposure to air; pleochroism strong with O wine red and E dark red to nearly black. Found as irregular, glassy grains up to 1.0 mm in diameter in sheared sonolite-hausmannite-gageite assemblage in chert of the Franciscan Complex, on the dump of the *Pennsylvania mine* (type material), on the southwest side of the *San Antonio Valley, Santa Clara Co., CA*. EF, RG *AM 71:1522(1986)*.

52.4.2.1 Mozartite $\text{CaMn}(\text{SiO}_4)(\text{OH})$

Named in 1993 by Basso *et al.* for Wolfgang Amadeus Mozart, the mineral having been first observed in 1991, the 200th anniversary of the composer's death, and in recognition of the association of the mineralogical sciences with his music, especially the opera "The Magic Flute." Compare vuagnatite (52.4.2.2). ORTH $P2_12_12_1$. $a = 5.838$, $b = 7.224$, $c = 8.690$, $Z = 4$, $D = 3.68$. PD : 5.56₉ 3.61₄ 3.07₇ 2.58₁₀ 2.51₆ 2.44₆ 2.20₃ 1.668₃ 1.564₅. Isostructural with vuagnatite (52.4.2.2) and the arsenates and vanadates of the adelite group. Structure: *CM 31:331(1993)*. Reddish brown, deep red; red streak; vitreous luster; transparent. $G = 3.63$. Biaxial (+); 2V = 50° (52.8_{calc}); N_x = 1.840, N_y = 1.855, N_z = 1.920; $Z = a$; length-slow. Strongly pleochroic; X, yellow-brown; Y, yellow; Z, orange-red. Water was determined by differ-

ence; minor aluminum is present and a trace of magnesium. Found as aggregates of minute anhedral crystals intergrown with pectolite and minor calcite, quartz, and hausmannite in veins cross-cutting massive beraunite at the *Cerchiara mine, near Faggiona, Val di Vara, La Spezia, eastern Liguria, Italy*. AR TN 3:9(1991).

52.4.2.2 Vuagnatite $\text{CaAl}(\text{SiO}_4)(\text{OH})$

Named in 1976 by Sarp et al. for Marc Bernard Vuagnat (b.1922) of the Department of Mineralogy, University of Geneva, who studied ophiolitic rocks. See mozartite (52.4.2.1). ORTH $P2_12_12_1$. $a = 7.055$, $b = 8.542$, $c = 5.683$, $Z = 4$, $D = 3.42$. 29-289: 3.94₄ 2.99₁₀ 2.64₇ 2.52₆. Isostructural with mozartite and the arsenates and vanadates of the adelite group. Structure: AM 61:831(1976). Anhedral grains and, less commonly, prismatic [001] crystals displaying {110}, {001}, {100}, and {010} (Turkey); also disphenoidal forms, {111}, {111} with {011} and {021} (California). Colorless, white, pale blue, to pale brown; vitreous luster; transparent to translucent. Conchoidal fracture, brittle. $H = 6$. $G = 3.20-3.42$. Biaxial (-); $2V = 44-48^\circ$; $N_x = 1.700-1.702$, $N_y = 1.724-1.726$, $N_z = 1.727-1.730$; $XYZ = cba$; $r < v$, strong. Insoluble or only slightly soluble in hot aqua regia. Found in veinlets in sheared metagabbro, mainly hydrogrossular and chlorite with minor copper and chalcocite, in the Red Mountain area, Lake and Mendocino Cos., and in a cobble from the Russian R., Mendocino Co., CA. Guatemala. Found with chantalite, prehnite, hydrogrossular, chlorite, and calcite in rodingitic dikes of the ophiolite zone at *Doganbaba, Burdur, Taurus Mts., in southwestern Turkey*. As pale blue lenses in pectolite veinlets in serpentinite at Shiraki, Toba, Mie Pref., Japan. AR AM 61:825(1976), SMPM 57:149(1977), MA 78:3469(1978).

52.4.3.1 Titanite $(\text{Ca,REE})(\text{Ti,Al,Fe})\text{SiO}_4(\text{O,OH,F})$

Named in 1795 by Klaproth in allusion to the dark brown or black color of the original specimen, and from the composition. Synonym: sphene. See vuagnatite, $\text{CaAlSiO}_4(\text{OH})$ (52.4.2.2); malayaite, CaSnSiO_5 (52.4.3.2), and the tilasite group. MON $A2/a$ and $P2_1/a$. The vast majority of samples are $A2/a$. $A2/a(\text{syn})$: $a = 7.066$, $b = 8.705$, $c = 6.561$, $\beta = 113.93^\circ$; $P2_1/a(\text{syn})$: $a = 7.069$, $b = 8.772$, $c = 6.566$, $\beta = 113.86^\circ$. AM 61:238(1976). Range: $a = 7.039-7.088$, $b = 8.643-8.740$, $c = 6.527-6.584$, $\beta = 113.74-114.15^\circ$. MSASC 5:137(1980). $Z = 4$, $D = 3.52$ (for pure CaTiSiO_5). 25-177(syn $A2/a$): 4.95₁ 3.24₁₀ 3.00₃ 2.61₃ 2.59₃ 2.27₁ 2.06₁ 1.745₁; 31-295(natural yttrian titanite): 3.60₃ 3.36₃ 3.27₉ 3.02₉ 2.92₃ 2.66₁₀ 2.07₂ 1.66₅. A reversible, displacive (second order) paraelectric-antiferroelectric phase transformation takes place upon heating from $P2_1/a$ to $A2/a$ at about 220° . AM 61:435(1976), PCM 17:591(1991). High-Al titanites are all $A2/a$ (high = $\text{Al}/(\text{Ti} + \text{Al} + \text{Fe}) \geq 0.25$). At the unit cell level, titanites are $P2_1/a$, but formation of domains due to chemical substitution in the octahedral chains causes the "average" structure to be disordered to $A2/a$. Substitution of REE's for Ca stabilize the $A2/a$ dimorph as lower substitution levels than

TITANITE(sphen): CaTiSiO_6

Like garnet, this is a framework of corner-sharing tetrahedra and octahedra (Ti) with Ca in the interstices. However, unlike garnet, some of the octahedra share corners with each other, forming chains in the a-axis direction. Ca and Si alternate in between these chains.

required for octahedral substitutions. Sometimes metamict. A natural $P2_1/a$ titanite with $\text{Al}_2\text{O}_3 = 0.07$ wt % has been reported from the Tyrol. *EJM* 3:777(1991). Titanite may be variably metamict. *AM* 76:370(1991). Generally wedge-shaped, flattened parallel to {110}, sometimes fibrous. Summary of forms found given in *DF* (1932) and *MIN* 3(1):336(1972). Simple contact and penetration twins have TP parallel to {001}, occasionally lamellar twinning on {122}. Physical Properties: Colorless, yellow, yellow-brown, green, brown, black, pink, red, blue; white to pale brown streak; vitreous to greasy luster. Cleavage {011}, imperfect to conchoidal fracture $H = 5-5\frac{1}{2}$. $G = 3.48-3.60$. IR data: *AM* 76:370(1991), *DHZ* 1A:443(1982). Raman data: *JCS(A)*:1372(1969). Thermal data: *AM* 76:370(1991). Heating restores XRD patterns but not IR patterns. Slowly attacked by HF, warm concentrated H_2SO_4 , or aqua regia. Chemistry: Can incorporate many elements other than Ca, Ti, Si, and O. An Sn content of more than 10 wt % has been reported (malayaite is the tin analog of titanite). An Sb-rich Titanite (with 12.6 wt % Sb_2O_5), equivalent to 0.165 Sb^{5+} per 1.00 Si^{4+} occurs with greenschist facies minerals in Italy (*MM* 59:717(1995)). High Al-containing titanites (formerly called grothite) occur in rocks without anorthite-rich plagioclase. Al substitution is favored by high P environments, but pressure is not the only factor. Al_2O_3 may be > 9.6 wt %, Ta_2O_5 to 16 wt %, and Nb_2O_5 to 6.5 wt %. Ferrous iron may substitute for Ca or Ti. May be enriched in both the LREE's and HREE's. *EJM* 4:307(1992). REE-bearing titanite originally called keilhauite. Substitution mechanism is: $\text{Ca}^{2+} + \text{Ti}^{4+} \leftrightarrow \text{REE}^{3+} + (\text{Fe}^{3+}, \text{Al})$. Small amounts of

Ti and Al substitute in the tetrahedral Si site. REE, Na, Th, U, etc. substitute in the seven-coordinated Ca site. OH and F replace the one O anion not bonded to Si as substitution for Ca occurs. Another important subst. scheme is $(\text{Al} + \text{Fe})^{3+} + (\text{OH}, \text{F})^{-} \leftrightarrow \text{Ti}^{4+} + \text{O}^{2-}$. Other minor substituents (generally less than 1 wt %) are Cr, V, and Sc. Highest F content is about 3 wt %. Pink, Mn-bearing titanite (called greenovite) has as much as 1 wt % MnO RSIMP 35:135 (1979). Biaxial (+); $Z \wedge c = 51^\circ$; OAP (010); $N_x = 1.843\text{--}1.950$, $N_y = 1.870\text{--}2.034$, $N_z = 1.943\text{--}2.110$; $2V_z = 17\text{--}40^\circ$. Metamict or partly metamict material has lower N's ($N_x = 1.795\text{--}1.800$, $N_z = 1.835\text{--}1.850$). Colorless, yellow, or typically clove-brown in thin section. Somewhat pleochroic. X, pale yellow; Y, brownish yellow; Z, orange-brown. $r > v$, strong; $X < YZ$. Occurrence: Occurrence: A common accessory mineral in igneous and metamorphic rocks; less common in volcanic rocks. Also in pegmatites and quartz veins, and may be hydrothermal or a detrital mineral. May alter to anatase or rutile + quartz. Other alteration products known. Localities: Noteworthy U.S. occurrences include honey-yellow crystals from Franklin, Sussex Co., NJ; as fine transparent, greenish crystals at the Tilley Foster mine, Brewster, Putnam Co., NY; as gemmy yellow-green to brown crystals(!) up to 2.5 in. long at Bridgewater Station, and upper Chichester Twp., Delaware Co., PA; black, high-Sn titanite from Kings Mt., NC; Magnet Cove, Garland Co., AR; Crestmore, Riverside Co., CA; large titanites to 15 cm \times 15 cm (usually with apatite) from several localities in ONT, Canada (e.g., Wilberforce, haliburton Co., Eganville, Renfrew Co.; Otter Lake, Turner's Island in Lake Clear; Bear Lake Road, Elliott Mine, Tory Hill, Monmouth Twp.). Also in fine black twinned crystals at Litchfield, Pontiac Co., QUE; much gem material (to 4 \times 6 \times 1.5 in in pegmatite from Pino Solo; also from El Rodeo and La Huerta, BC Norte, Mexico; Bourg d'Oisans and Isere at Maronne, France; in Norway in Aust-Agder at Arendal, and Risor, Kragerø. Nördmark, Värmland, Sweden, Laacher See, Paluensch Grund, and Eifel, Germany; Grisons, Ticino in the St. Gotthard region at Val Sella, Val Maggia, in Valais at Zermatt, Kreuzlital in Val Tavetsch, and Binnental, Switzerland; at Schwarzenstein and Rotenkopf, Zillertal, Tyrol, and Sulzbachtal, Austria; in Italy at Pfunders and in the Pfitschtal, Trentino; in Piedmont in the Ala Valley; at St. Marcel (greenovite); Val Maggia and Passodi Vize, and Monte Somma, Vesuvius. At Achmatovsk, and Saran Paul, Polarurals, Russia also from the Khibiny and Lovozero massifs, Kola Pen. Gem-quality material from Sri Lanka; Campo do Boa, Capelinha, MG, Brazil. Other noteworthy localities are in Greenland; Finland; Dassu, Pakistan; Midongy, Ambalavaokely near Betroka and Naevatanana in Madagascar (Malagasy Republic); New Zealand. Uses: Has minor use as a gemstone. EF *DAN-ESS 186:125(1969)*, *MIN 3(1):336(1972)*, *AM 61:378(1976)*, *DHZ RFM 1A 443 (1982)*.

52.4.3.2 Malayaite CaSnSiO_5

Named by Alexander and Flinterin 1965 for the country of origin. *MON A2/a*. (Nat): $a = 7.149$, $b = 8.906$, $c = 6.667$, $\beta = 113.3^\circ$. *AM 62:801 (1977)*. (Syn): $a = 7.173$, $b = 8.876$, $c = 6.688$, $\beta = 113.71^\circ$, $Z = 4$, $D = 4.49\text{--}4.56$. $25\text{--}176(\text{syn})$: 5.05_5 3.28_{10} 3.06_3 2.665_3 2.64_4 2.41_2 2.10_2 1.76_1 . Has the structure of the high-temperature form of titanite because of substitution of Sn for Ti in the $[\text{MO}_6]$ octahedra. *AM 62:801(1977)*. Wedge-shaped crystals to 3 cm. Also massive coatings. Colorless, pale yellow to orange-yellow, or tan-cream; white streak; vitreous luster. $H = 3\frac{1}{2}\text{--}4$. $G = 4.3\text{--}4.55$. Both natural and synthetic material fluoresce a bright yellowish green in SWUV. Soluble in HCl and HF. Substitution of Ti (as much as 30 mol % titanite, about 10 wt % TiO_2) for Sn. Biaxial (-); $N_x = 1.764\text{--}1.767$, $N_y = 1.783\text{--}1.785$, $N_z = 1.798\text{--}1.802$; $2V_x = 85^\circ$. Colorless to pale yellow. Associated with hydrothermal alteration of a cassiterite-quartz assemblage and associated with varlamoffite in wollastonite-diopside and other Sn-bearing skarns. Also occurs in granitic pegmatites. Found in the Himalaya and San Diego mines, Mesa Grande district, San Diego Co., CA; from the JC claims, near Dorsey Lake, Cassiar Mts., and Ti-bearing crystals to 3 cm from the Ash Mountains, Tuya Range, near McDame BC, Canada [*EG 73:269(1978)*]; essentially pure material occurs 4 km north of Ash Mountain itself; Redaven Valley, Meldon Alpe Rosso, Devonshire, England; Val Vigezzo, Novara, Piedmont, Italy; Kolyma R., and Kanonskoye deposit, Magadan oblast, Russia; *Sunsei Lah, Chenderiang, Perak, Malaysia*, and Kinta Valley, Malaysia; Pinyak mine, Thailand; Gumble, and Bourke, NSW, Australia; Toroku and Sampo mine Mirate mines, Miyazaki Pref., Okayama Pref., and several other localities, Japan [*DHZ 1A:443(1982)*]. *EF MM 35:622(1965)*, *MIN 3(1):351(1972)*, *DANS-ESS 212:126(1973)*, *JACES 59:455(1976)*, *MSASC 5:137(1980)*.

52.4.3.3 Vanadomalayaite CaVOSiO_4

Described and named in 1994 by Basso et al. for the composition. The mineral is also the V analog of titanite. *MON C2/c*. $a = 6.526\text{--}6.532$, $b = 8.691\text{--}8.692$, $c = 7.032\text{--}7.039$, $\beta = 113.88^\circ$, $Z = 4$, $D = 3.61$. *PD*: 4.90_2 3.22_{10} 2.97_7 2.61_6 2.59_4 2.27_2 2.06_2 1.64_2 . The structure is analogous to malayaite and titanite. It consists of zigzag chains of corner-sharing VO_6 octahedra running parallel to the [001] axis, cross-linked by isolated SiO_4 tetrahedra. The large cavities of the resulting framework are occupied by Ca atoms in irregular sevenfold coordination. *NJBM:489(1994)*. Subhedral crystals, prismatic, with good {110} cleavage, not exceeding 0.4 mm in size. No twinning observed. Deep red, red streak, vitreous luster. $G = 3.60$. For Na(D), $N_z = 2.105$ and $N_x \approx 1.95$. Dispersion is strong and the pleochroism varies from Z, deep greenish blue, to $X \approx Y$, brownish red-orange. The mean chemical composition is $\text{Ca}_{1.00}(\text{V}_{0.71}\text{Ti}_{0.26}\text{Fe}_{0.01}\text{Al}_{0.01})_{\Sigma 0.99}\text{OSi}_{1.01}\text{O}_4$. The mineral occurs with calcite, quartz, and haradaite in a small vein cutting ophiolitic metacherts at the *Gambatesa mine, Reppia, eastern Liguria, Italy*. *EF 16th IMA Gen. Meet. Abst.: 31-32(1994)*.

52.4.4.1 Natisite $\text{Na}_2\text{TiOSiO}_4$

Named in 1975 by Men'shikov et al. for the components: sodium, titanium, and silicon. Dimorphous with paranatisite. *TET* $P4/mmm$. $a = 6.50$, $c = 5.07$, $Z = 2$, $D = 3.15$. $29-1279$: 5.05_8 3.96_5 2.71_{10} 2.52_5 2.35_6 1.689_7 1.611_5 1.100_6 . Yellow-green to greenish gray, vitreous to adamantine luster. Cleavage $\{001\}$, perfect; $\{100\}$, less perfect. $H = 3-4$. Uniaxial (-); $N_O = 1.756$, $N_E = 1.680$. Insoluble in dilute acids, readily fusible. Found as single grains and rosettes with chkalovite, aegirine, and vuonnemite in natrolite-ussingite veins cutting alkalic rocks at *Mt. Karnarsut, Lovozero massif, Kola Penin., Russia*. *AR ZVMO 104:314(1975), AM 61:339(1976)*.

52.4.4.2 Paranatisite $\text{Na}_2\text{TiSiO}_4$

Named in 1992 by Khomyakov et al. for its relationship to natisite and the composition. *ORTH* $Pmma$. $a = 9.827$, $b = 9.167$, $c = 4.799$, $Z = 4$, $D = 3.07$. *PD*: 2.74_{10} 2.257_3 1.720_3 1.680_3 1.660_2 1.475_3 1.443_4 . Yellow to orange-brown, vitreous to subadamantine luster, transparent to translucent. $H = 5$. $G = 3.12$. Biaxial (+); $2V = 23^\circ$; $N_x = 1.740$, $N_y = 1.741$, $N_z = 1.765$; $XYZ = bac$; $r > v$, weak; Pleochroic, $X = Y > Z$; brown to yellow. Found as interstitial grains (1 mm) and aggregates (5 mm) in pegmatites on *Mt. Yukspor, Khibiny massif, Kola Penin., Russia*. *AR ZVMO 121(6):133(1992), AM 79:764(1994)*.

52.4.4.3 Yftisite-(Y) $(\text{Y,Dy,Er})_4(\text{Ti,Sn})\text{O}(\text{SiO}_4)_2(\text{F,OH})_6$

Named in 1965 by Shipovalov and also used in 1977 by Balko and Bakakin for the chemical composition (Y,F,Ti,Si). Formula is not certain because of incomplete chemical analysis, and the mineral was discredited by the CNMMN IMA in 1987. This is probably a new mineral species, but a complete chemical analysis must be done. *ORTH* $Cmcm$. $a = 14.949$, $b = 10.626$, $c = 7.043$, $Z = 4$. $33-1462(\text{nat})$: 3.73_7 3.10_{10} 2.67_{10} 1.82_9 1.77_{10} 1.71_{10} 1.56_8 1.44_8 . Infinite columns of Ti octahedra and Si tetrahedra parallel to c . Columns are linked by two seven- and eight-coordinated independent Y polyhedra. *ZSK 16:337(1975)*. 6-7 mm long. Yellowish, vitreous to greasy luster. No cleavage. $H = 3\frac{1}{2}-4$. $G = 3.96$. Biaxial (-); $N_x = 1.690$, $N_y = 1.705$, $N_z = 1.711$; birefringence = 0.021, $2V$ large; $r > v$, distinct; anomalous blue interference colors. Occurs in silicified alkalic granite, near a contact with gabbro-anorthosite, Kola Penin., Russia; also occurs at an unspecified locality in *Kazakhstan*. *EF*

52.4.5.1 Törnebohmitite-(Ce) $(\text{Ce,L a,Nd})_2\text{Al}(\text{SiO}_4)_2(\text{OH})$ **52.4.5.2 Törnebohmitite-(La) $(\text{La,Ce})_2\text{Al}(\text{SiO}_4)_2(\text{OH})$**

Named in 1921 by Geijer for Alfred Ellis Törnebohm (1839-1911), former director of the Geological Survey of Sweden. *MON* $P2_1/c$. $a = 7.383$, $b = 5.673$, $c = 16.937$, $\beta = 112.04^\circ$, $Z = 4$, $D = 5.12$. 2.82_9 2.62_4 2.18_5 2.01_6

1.783₅; 34-160(calc for Ce): 4.60₇ 3.48₄ 3.09₁₀ 2.84₄ 2.82₇ 2.63₆ 2.18₄ 2.00₃; also 37-62[La(?)]. Structure: *AM* 67:1021(1982). The structure determination is allegedly for Swedish type material in which lanthanum earth slightly exceed cerium earths. Isostructural with fornacite and related to the brackebuschite and pyrobelonite groups. 14-257(Sweden): 4.57₄ 3.50₄ 3.08₁₀. Massive or fine-grained. Bright olive-green, probably adamantine luster. Biaxial (+); 2V = 26°; N_x = 1.808, N_y = 1.812, N_z = 1.838; also N_x = 1.845, N_y = 1.852, N_z = 1.878; r < v, strong; pleochroic. X, Y > X = Z; pink or greenish yellow; Y, bluish green; Z, pink. Slowly dissolved by hot acids. Both Ce and La dominant phases occur intergrown at the type locality, and correlation of unit cell and optical data with composition is not clear. Törnebohmit (Ce) is found at the Jamestown district, Boulder Co., and at the Black Cloud pegmatite, Teuer Co., CO; at the *Bastnäs mine, Riddarhyttan, Västmanland, Sweden*; and in the Ural Mts., Russia. *AR DT* 634(1932), *AM* 51:152(1966), *USGSB* 167:192,195(1984).

52.4.6.1 Cerite-(Ce) (Ce)₆(□,Ca)(Fe³⁺,Mg)(SiO₄)₆(SiO₃OH)(OH,F)₃

Named in 1803 by Hisinger and Berzelius for the asteroid Ceres; discovered in 1801, two years before the mineral and the element cerium were named. The element Ce was discovered in this mineral. *HEX-R R3c*. *a* = 10.75–10.81, *c* = 37.71–38.29, *Z* = 6, *D* = 4.86. 11-126(nat): 3.47₄ 3.31_{3,5} 3.11₃ 2.95₁₀ 2.83₄ 2.80_{2,5} 2.69₄ 1.95₅. Nearly isostructural with whitlockite, Ca₉Mg(PO₄)₆ (PO₃OH) (□)₃. *AM* 68:996(1983). Usually fine-grained, pseudo-octahedral with {0001} + {1012}, plates, tabular on {0001}; 0.5- to 1-mm crystals at Mt. St.-Hilaire, 2–7 mm at Mt. Pass. Usually dark rose-red, also pale pink, pink, brown, yellow, green, colorless; streak greyish white; vitreous-adamantine (resinous) luster, dull when fine grained. Cleavage not apparent, uneven fracture, brittle. *H* = 5½. *G* = 4.78–4.9. Nonfluorescent. Gelatinizes with acids. Analysis: CaO, 4%; REE₂O₃, 70%; Al₂O₃, < 1%; SiO₂, 20%; H₂O, 2–5%. Uniaxial (+) and anomalously biaxial (+); N_O = 1.806–1.814, N_E = 1.808–1.820; N_x = 1.815–1.817, N_y = 1.815–1.818, N_z = 1.821–1.820; 2V small, 11–25°; r < v, very strong. O, colorless; E, pale brownish red. Occurs in pegmatite at Mt. St. Hilaire, QUE, Canada. Bands in silicate zones (skarn) of quartz-banded hematite. Originally reported in silicate skarns at Jamestown, but is actually britholite-(Ce). Fenitized pegmatites related to a Ne-syenite (Tuva). May alter to bastnaesite, lanthanite, and others. Jamestown, Boulder Co., CO; in rare-earth-bearing hydrothermal quartz-bearing carbonate veins in shonkinite at the Mountain Pass REE deposit, San Bernardino Co., CA, particularly at the Birthday claims and in vein No. 6; Mt. St.-Hilaire, and Villeneuve mine, Papineau Co., QUE, Canada; *Bastnäs, Ridarhyttan, Västmanland*, and Ostanmossa mine, Norberg, Sweden; in natrolite veins in the Lovozero massif, Kola Penin., Mochalin Log, Kushtym, Ural Mts., and Ulan-Erge massif, Sangilen, southwestern Tuva, Russia. *EF MIN* 3(1):492(1972), *ZVMO* 118:47(1989), *AM* 43:460(1958).

52.4.7.1 Afwillite $\text{Ca}_3(\text{SiO}_3)_2(\text{OH})_2 \cdot 2\text{H}_2\text{O}$

Named by Parry and Wright in 1925 for Alpheus Fuller Williams (1874–1953) of Kimberley, South Africa, manager of DeBeers Consolidated Mines and an expert on diamonds, who found the mineral. *MON* Cc, $a = 16.278$, $b = 5.632$, $c = 13.236$, $\beta = 134.90^\circ$, $Z = 4$, $D = 2.65$. $29\text{--}330$: 6.52₅, 5.06₃, 3.17₁₀, 2.83₁₀, 2.82₆ 2.73₇, 2.15₃ 1.94₃. Structure: *AC(B) 32:475(1976)*. Massive, tabular, flattened, vertically striated; crystals to 3–4 cm with masses to 11 cm, also in radial fibrous spherulites; no twinning observed; {001}, {100}, {110}, {101}, and so on. Using $a/b/c = 2.071:1:2.351$, $\beta = 98.83^\circ$, crystals are elongated parallel to {010}, tabular parallel to {101} may be prismatic, elongated on b . White to colorless, vitreous luster, transparent to translucent. Cleavage {001}, perfect; {100}, good. $H = 4\text{--}4\frac{1}{2}$. $G = 2.62\text{--}2.63$. Pyroelectric and piezoelectric; gelatinizes in HCl or H_2SO_4 . Biaxial (+); $Y = b$, $X \wedge c = 30\text{--}31^\circ$ for $a/b/c$ of 2.071:1:2.351 and $\beta = 98.83^\circ$; $N_x = 1.617\text{--}1.619$, $N_y = 1.620$, $N_z = 1.634$, colorless; $2V = 53\text{--}56^\circ$; $r < v$; positive or negative elongation. Occurs in the contact zone of eruptive rocks with sedimentary rocks and in xenoliths of sedimentary rocks in volcanic rocks. In carbonate hornfels; also in stratabound Mn deposits; may also form from tilleyite. Occurs at Crestmore in fractures associated with quartz, thaumasite, merwinite, gehlenite, and calcite. At Viterbo, Italy, associated with tobermorite, calcite, and ettringite. A hydrothermal mineral. In a dolerite inclusion at Dutoitspan. May form from spurrite. Commercial quarry, Crestmore, San Bernardino Co., CA; Scawt Hill, County Antrim, Northern Ireland; Schellkopf, near Brenk, Eifel Dist., and as Zeilberg, Maroldsweisach, Bavaria, Germany, Camponorro, Montaldo di Castro (Viterbo), Italy; Anakit, Lower Tungvskar region, Siberia, Russia; *Dutoitspan diamond mine, Kimberley, South Africa*; clear, white, prismatic crystals to 4.5 cm were found in 1989 in the Wessels mine, near Kuruman, Kalahari manganese field; Cape Prov., South Africa; Nahal Ayalon, Israel; Fuka, Bitchu, Okayama Pref., Japan. Used as an additive to portland cement. *EF MIN 3(1):233(1972)*, *RI 4:97(1982)*, *MJJ 14:279(1989)*, *MR 22:279(1991)*.

52.4.7.2 Bultfonteinite $\text{Ca}_2[\text{SiO}_3(\text{OH})]\text{F} \cdot \text{H}_2\text{O}$

Named in 1932 by Parry et al. for the type locality. *TRIC* P1. $a = 10.99$, $b = 8.18$, $c = 5.67$, $\alpha = 93.95^\circ$, $\beta = 91.32^\circ$, $\gamma = 89.85^\circ$, $Z = 4$, $D = 2.74$. $8\text{--}223$: 8.16₇ 3.51₅ 3.46₅ 2.92₁₀ 2.89₁₀ 2.83₄ 2.78₄ 1.930₈. The structural study suggests that the tetrahedral unit has the composition $[\text{SiO}_2(\text{OH}_{0.5})_2]^{3-}$. *AC 16:551(1963)*. Radiated acicular crystals; twinning on {010} and {100} common. Colorless to pink, vitreous luster, transparent. Cleavage {010}, {100}, distinct. $H = 4\frac{1}{2}$. $G = 2.73$. Biaxial (+); $2V = 70^\circ$ and on (100) = 47° ; $N_x = 1.587$, $N_y = 1.590$; $Z \wedge c$ on (010) = 28° ; $r > v$. Gelatinized by acids. Found at the Crestmore quarry, Riverside Co., CA; in the *Hatrurim* formation, Israel; at Fuka, near Bitchu, and the Mihara mine, Okayama Pref., Japan; with calcite, apophyllite, and natrolite at the *Bultfontein mine* and the *Dutoitspan* and *Jagersfontein* mines, *Kimberley, South Africa*; also in the

N'Chwaning and Wessels Mines, near Kuruman, Cape Prov. AR *MM 23:145(1932)*, AM *40:900(1955)*.

52.4.7.3 Hatrurite $\text{Ca}_3\text{O}[\text{SiO}_4]$

Named in 1977 by Gross for the locality. Corresponds to the "alite" phase of Tornebohm found in portland cement. HEX-R (or pseudo-HEX) *R3m*. $a = 7.150$, $c = 25.56$, $Z = 9$, $D = 3.02$. *16-406(syn)*: 3.07₃ 3.01₃ 2.84₇ 2.79₁₀ 2.65₁₀ 2.22₅ 1.789₅ 1.513₂. Colorless, vitreous luster. Uniaxial (-); $N_0 = 1.723$, $N_E = 1.718$; length-fast; also biaxial (-); 2V small; $N_x = 1.716$, $N_y = 1.723$, $N_z = 1.723$. Decomposed by H_2O . Found as very small; (50 μm) acicular [0001] crystals in larnite-brownmillerite-mayenite rock in the *Hatrurim* formation, exposed in the *Hatrurim syncline, west of the Dead Sea, Israel*, and elsewhere where that formation is exposed. AR *GSIB 70:35(1977)*, AM *63:425(1978)*.

52.4.7.4 Jasmundite $\text{Ca}_{11}\text{O}_2(\text{SiO}_4)_4\text{S}$

Named by Dent Glasser and Lee in 1981 for Karl Jasmund (1913-1991), director of the Mineralogical-Petrographical Institute, University of Cologne. TET *I4m2* [*AC(B) 37:803(1981)*] or *I4/mmm* [*SPC 34:40(1989)*]. $a = 10.452-10.461$, $c = 8.698-8.813$, $Z = 2$, $D = 3.01$. *33-296(nat)*: 3.24₄ 2.83₁₀ 2.76₂ 2.61₄ 1.92₂ 1.85₄ 1.70₂ 1.55₂. Two structure solutions are reported: *SPC 34(1):40(1989)*, *AC(B) 37:803(1981)*. Mostly irregular grains to several millimeters; development of {101} gives a rhombohedral appearance; pseudoisometric habit, with dominant forms {110} and {101}; {100} and {001} are subordinate. Dark brown, greenish brown, brownish green; white streak; resinous luster. No cleavage, conchoidal fracture. $H = 5$. $G = 3.03$. Soluble in dilute HCl, with slight evolution of gas. Uniaxial (-); $N_0 = 1.750$, $N_E = 1.728$ [from *33-296*]; uniaxial (+); Contains small amounts of AL, Fe and Mg. $N_0 = 1.715$, $N_E = 1.728$ (from *NJMM:337(1983)*). Optics need to be redetermined. Occurs as a constituent of metamorphosed limestone inclusions in basalt. Associated with mayenite, brownmillerite, larnite, portlandite, and ettringite. *Ettringer Feld, a lava flow of the Bellerberg volcano, Mayen, Eifel, Rheinland-Pfalz, Germany*. EF

52.4.8.1 Trimounsité-(Y) $\text{Y}_2\text{Ti}_2\text{SiO}_6$

Named in 1990 by Piret et al. for the locality. MON *P2₁/c*. $a = 12.299$, $b = 11.120$, $c = 4.858$, $\beta = 95.62^\circ$, $Z = 4$ [*EJM 2:725(1990)*], $D = 4.85$. *PD (nat)*: 3.44₉ 2.82₁₀ 2.78₄ 2.36₄ 2.12₅ 1.96₆ 1.64₆ 1.63₅. A REE silico-titanate, a nesosilicate, $\text{Y}_2\text{Ti}_2(\text{O})_5\text{SiO}_4$; structure not close to those of any other minerals. Y surrounded by seven oxygens, Ti-octahedra form $(\text{Ti}_2\text{O}_6)_n$ double chains. Prismatic to 5 mm long, elongate on [001] with {110}, {130}, {010}, {211}, {121}, {011}, striated on {110} and {130}; no twinning. Light brown, white streak, adamantine luster, translucent or slightly smoky and transparent. No cleavage, brittle. $H = 7$. $G = 5.0$. Nonfluorescent, strong bluish cathodoluminescence in electron beam. Insoluble in acids. Biaxial (-); 2V not

measurable, Na(D): all refractive indices > 2.10 ; $r > v$, strong. Occurs with allanite, bastnaesite, and other REE minerals in cavities with calcite and dolomite crystals in white dolomitic rock in a talc deposit at *Trimouns, 6 km N of Luzenac, Ariège, France*. EF

Britholite subgroup of the apatite group:

Recent structural studies (*ZK 191:249(1990)*, *AMS 12:131(1992)*, *ZK 206:233(1993)*) of britholite and related minerals indicate that there are both hexagonal and monoclinic polymorphs of both britholite-(Ce) and britholite-(Y). In addition, F-dominant analogues of both monoclinic polymorphs have been identified. Uniaxial and biaxial optics reported for britholites can be explained by the existence of the two dimorphs. A systematic study on the nomenclatures and redefinitions of "hydroxylbritholite-(Ce)", "hydroxylbritholite-(Y)", "fluorbritholite-(Ce)", "fluorbritholite-(Y)", their monoclinic dimorphs, "lessingite" and "abukumalite" is necessary.

52.4.9.1 Britholite-(Ce) (Ce,REE,Ca,Na)₅[(Si,P)O₄]₃(OH,F)

Named in 1901 by Winther from the Greek for *weight*, in allusion to its relatively high specific gravity. See the apatite group. Synonyms: beckelite, lessingite, pravdite. Melanocrite, (Ce,Ca)₅(Si,B)₃O₁₂(ON, F)hH₂O, may belong to the Apatite group. HEX $P6_3/m$ or $P6_3$. $a = 9.597-9.638$ (Sr-bearing), $c = 7.04-7.08$ (Sr-bearing), $Z = 2$, $D = 4.02-4.72$; "lessingite" (the monoclinic dimorph) is $P2_1$ and has $a = 9.580-9.628$, $b = 9.590-9.630$, $c = 6.980-7.050$, $\beta = 120.02-120.08^\circ$. $17-724$ (heated at 900°): 4.12_6 3.93_6 3.48_8 3.21_6 3.11_6 2.84_{10} 2.81_8 1.86_8 . In hexagonal britholite, there is an ordered distribution of Ca and REE's in the A1 and A2 sites: (two Ca and two La) in A1 and six La in A2. A structural formula for ordered britholite-(Ce) is (Ca,Ce)₂(Ce,Ca,Th,U,Sr)₃(SiO₄)₃(O,OH,F). In natural Monte Somma material [*EJM 1:723(1989)*], Ca²⁺ is in A1 (nine-coordinated, all Ca) and A2 (seven-coordinated) is filled by 50% REE, 25% Th, and 25% Ca. The decrease in symmetry from $P6_3/m$ to $P6_3$ is accompanied by the introduction of additional atomic sites. The Ca1 position in $P6_3/m$ corresponds to two REE positions (REE1) and (REE2), both of which have site symmetry 3. The oxygen atoms are also not related by a mirror plane. *ZK 191:249(1990)*. The change to $P2_1$ results from the shifts of all the atoms from the pseudo-hexagonal equivalent positions. Synthetic Na_{1.25}La_{8.55}Si₆O₂₄(F_{0.9}O_{1.1}) [*NJBM:311(1992)*] is $P2_1$. *CSS 9:422(1981)*, *ZK 206:233(1993)*. Pseudo-hexagonal or hexagonal prisms to 1 cm, tabular to anhedral grains, acicular needles. Elongated along c , and also tabular on {001}. Tan to dark brown, dark red, pale blue, yellow, greenish gray or brownish green; brown to very pale tan streak. Adamantine to vitreous luster. No cleavage, conchoidal to uneven fracture, brittle. $H \approx 5$. Usually G is > 3.9 (metamict or partially metamict) to 4.8. Luminesces emerald green in Hg-vapor lamp, characteristic of REE content. Occasionally, fluorescent pale blue in SWUV. Gelatinizes in acids. IR and DTA data: *MS 26:306(1972)*. The chemistry is complex, and

many substitutions occur. Often chemically zoned. "Alumo-britholite" has as much as 14.9 wt % Al_2O_3 , ThO_2 to 20.7 wt %, SrO to 6.2 wt %, P_2O_5 to 13.5 wt % or more, CaO 4.68 to 19.9 wt %, Na_2O to ≈ 2 wt %. H_2O (total) to > 10 wt % (metamict varieties). Principal substitutions are $2\text{Ca}^{2+} \leftrightarrow \text{Na}^+ + \text{REE}^{3+}$ and $\text{Ca}^{2+} + \text{P}^{5+} \leftrightarrow \text{REE}^{3+} + \text{Si}^{4+}$. Uniaxial (-) and biaxial (-); $XY = ca$; $N_O = 1.752\text{--}1.823$, $N_E = 1.748\text{--}1.817$; $2V$ to 44° , Sr-containing britholite (Khibiny) is (+), $2V \approx 0^\circ$; sometimes pleochroic. O, brown; E, colorless. Sr-containing britholite is very pale pink to colorless. Isotropic to anisotropic. May also be isotropic (i.e., metamict), with N as low as 1.72. Occurs in alkalic rocks and their cogenic pegmatites. Rarely in carbonatite complexes and lamproites. In sanidine-rich ejecta block (Monte Somma). Shonkin Sag, Montana; Rusty Gold prospect, Jamestown, Boulder Co., CO; Iron Hill, Powderhorn district, Gunnison Co., CO; Mt. St.-Hilaire (crystals to 1 cm) and Kipawa complex, and intermediate between apatite and britholite (metamict) from Oka, QUE, Canada; *Naujakasik, Ilimaussag, Greenland*; Tredaien, Norway; San Vito quarry, Monte Somma, Vesuvius, Italy; Cancarix, Albacete Prov., Spain. Kychtym, Tuva ("lessingite"), and Vishnevye Gor, Ural Mts., Khibiny massif, Kola Penin.; Kalchik R. and Priazov, Ukraine; northern Predgori Ganzurinsk Range, western Transbaikalia; Kisky massif, western Yenesei region; Kuznetsk Alatau, Berikulsk region, Russia. Borsuk, Kazakhstan; Pibnesburg complex, Rustenburg, Transvaal, South Africa; Nam Se, northern Vietnam; Madagascar. *EF VLA:297(1966)*, *JSSC 26:383(1978)*, *ZK 191:249(1990)*, *SPC 36:19(1991)*, *MM 57:203(1993)*.

52.4.9.2 Britholite-(Y) $\text{Ca}_2\text{Y}_3\text{Si}_3\text{O}_{12}(\text{OH},\text{F})$

Named in 1966 by Levinson as the Y-dominant analog of britholite-(Ce). Former name was abukumalite. See apatite group. *HEX P6₃ or P2₁*. *AMS 12:131(1992)*, *ZK 206:233(1993)*. Hexagonal material: $a = 9.39\text{--}9.44$, $c = 6.79\text{--}6.81$, $Z = 2$, $D = 4.05\text{--}4.54$. Monoclinic material: $a = 9.362$ (F-dominant analog) $\text{--}9.504$, $b = 9.364$ (F-dominant analog) $\text{--}9.414$, $c = 6.731$ (F-dominant analog) $\text{--}6.922$, $\gamma = 119.71\text{--}120.03^\circ$. *31-315(nat)*: 4 08₂₅ 3.39₃ 3.13₅ 3.09₅ 2.81₁₀ 2.75₉ 2.73₈ 1.885₃. The split of the Ca1 site in apatite into two REE_{1a} and REE_{1b} sites with different occupancies of rare-earth atoms in the monoclinic britholite structure causes the lowering of symmetry from hexagonal to monoclinic. Rounded masses to 2.5 cm; also flattened pseudo-hexagonal crystals; often metamict or partly so. Black, dark reddish brown, light tan to chocolate-brown; pale brown streak; greasy to adamantine luster. Imperfect cleavage on {0001} and {1010}, uneven to splintery or conchoidal fracture, brittle. $H = 5\text{--}6$. $G = 4.05\text{--}4.57$. Soluble in cold dilute acids. Y-group REE predominate over the Ce group. Uniaxial (-) and biaxial (-); *VLA:297(1966)* $N_O = 1.732\text{--}1.780$, $N_E = 1.728\text{--}1.783$; $2V$ to 40° ; light brown or yellowish to reddish brown. For an F-dominant sample from Fusamata: uniaxial (+); $N_O = 1.773$, $N_E = 1.777$. O, colorless-light brown; E, light brown. *US6SB1627(1984)* gives uniax (+), $N_O 1.728\text{--}1.780$, $N_O 1.730\text{--}1.783$. Found in alkalic rocks and their cogenic pegmatites. Chiefly in pegmatites with other

Y-bearing minerals and REE-bearing minerals, such as yttrialite, throgumite, tenerite, or allanite. May alter to bastnaesite and churchite. Found in the Wet Mountains, Custer and Fremont Cos., CO; Powderhorn district, Gunnison Co., CO; Reiarisdal, Vest-Agder, southern Norway (crystals to 5–20 cm); also possibly at Tvedalen, Larvik, Norway; eastern Baltic Shield, Ukraine, and Kola Penin., Russia; *Suishoyama, Fusamata, Iisaka, Kawamata-machi, Fukushima Pref., Japan.* EF *MRE II:297(1996), NJBM:311(1992).*

52.4.9.3 Fluorellestadite $\text{Ca}_5[(\text{Si},\text{P},\text{S})\text{O}_4]_2(\text{F},\text{OH},\text{Cl})$

Named in 1982 by Rouse and Dunn for Reuben B. Ellestad (1900–1993), American analytical chemist of Minneapolis, MN. F-dominant. Name also used by Chesnokov et al. [*ZVMO 116:743(1987)*]; found in nature by them. See hydroxyllestadite (52.4.9.4) and chlorellestadite (52.4.9.5) see Apatite group. *HEX* $P6_3/m$. (Nat): $a = 9.53\text{--}9.561$, $c = 6.91\text{--}6.920$, $Z = 2$, $D = 3.05\text{--}3.38$; (syn): $a = 9.423\text{--}9.442$, $c = 6.895\text{--}6.939$, $D = 3.11\text{--}3.14$. *3-708(nat)*: 3.46_3 2.86_{10} 2.80_4 2.76_6 2.66_3 2.30_3 1.97_6 1.86_6 ; *43-575*, *45-0009(syn)*: 3.45_3 2.81_{10} 2.78_4 2.71_6 2.63_3 2.26_3 1.95_3 1.85_5 . 5–8 cm long and 2–3 mm wide. Pink, bright blue to medium blue-green; white to pale blue streak. $G = 3.07$. Sometimes fluorescent; some material from Crestmore is weakly fluorescent white to blue-white or yellow-white in SWUV and shows medium white–yellow–brown fluorescence in LWUV. *ZVMO 116:743(1987)*: SO_3 , 20.75; SiO_2 , 15.30; P_2O_5 , 1.31; CO_2 , 0.66; CaO , 55.0; MnO , 0.18; MgO , 1.38; Al_2O_3 , 1.84; Fe_2O_3 , 0.11; Na_2O , 0.33; K_2O , 0.1; H_2O^+ , 0.30; F , 3.60. $\Sigma 100.86\text{--}1.52 = 9934$. Uniaxial (–); $N_O = 1.655$, $N_E = 1.650$. A skarn mineral: occurs associated with diopside, wollastonite, idocrase, monticellite, okenite, calcite, and other minerals at *Crestmore, Riverside Co., CA*; also occurs at *Kopeysk in the Chelyabinsk coal basin, southern Ural Mts., Russia* in burned fragments of petrified wood in coal dumps.. EF *AM 67:90(1982).*

52.4.9.4 Hydroxyllestadite $\text{Ca}_5(\text{SiO}_4, \text{SO}_4)_3(\text{OH}, \text{F}, \text{Cl})$

Named by Harada et al. in 1971 for the composition. See fluorellestadite (52.4.9.3) and chlorellestadite (52.4.9.5) see apatite group. *HEX* $P6_3/m$. $a = 9.491$, $c = 6.921$, $Z = 2$. Also *MON* $P2_1/m$. $a = 9.476$, $b = 9.508$, $c = 6.919$, $\gamma = 119.53^\circ$, $D = 3.08$. *25-173(nat)*: 3.46_4 2.84_{10} 2.80_5 2.74_6 2.66_5 1.96_2 1.85_5 1.48_2 . From the study of one crystal, it is not known if all hydroxyllestadite is monoclinic or if both hexagonal and monoclinic structures exist. *AC(B) 36:1636(1980)*. Anhydrous masses to 100 kg, cleavable. Pale purple, violet; vitreous luster; translucent. $H \approx 4\frac{1}{2}$. $G = 3.02$. IR, DTA, and TGA data: *AM 56:1507(1971)*. Rapidly soluble in cold, dilute HCl (1 N). Analysis (wt %), original ellestadite, Crestmore, CA: CaO , 55.2; MgO , 0.47; MnO , 0.01; CO_2 , 0.61; P_2O_5 , 3.06; SiO_2 , 17.31; SO_3 , 20.69; Al_2O_3 , 0.13; Fe_2O_3 , 0.22; F , 0.57; Cl , 1.64; H_2O^+ , 0.53; H_2O^- , 0.10; $\Sigma = 100.52 - 0.61 = 99.91$. *AM 22:977(1937)*. Analysis (wt %): CaO , 54.51; CO_2 , 1.65; SiO_2 , 17.30; SO_3 , 21.56; H_2O^+ , 2.04; H_2O^- , 0.72; minor Mn, Sr, Na, K, P, Fe, F, and Cl

present; MnO, 0.04; SrO, 0.28; Na₂O, 0.3; K₂O, 0.07; CO₂, 1.65; P₂O₅, 0.66; Fe₂O₃, 0.21; F, 0.28; Cl, 0.91. Uniaxial (-); Na(D): Na; N_O = 1.654, N_E = 1.650. Occurs at the Crestmore Quarry, Riverside Co., CA. Occurs in pre-ore skarn, associated with diopside, wollastonite, xanthophyllite, vesuvianite, and calcite at the *Chichibu mine, Saitama Pref., Japan*. An unspecified ellestradite occurs in basalt xenoliths at Marolds-Welsach, Northern Bavaria, Germany, and may be hydroxyllestadite based on the composition of assoc. minerals. EF *AM 56:1507(1971)*, *DA 46:69(1995)*.

52.4.9.5 Chlorellestadite $\text{Ca}_5(\text{SiO}_4, \text{SO}_4, \text{PO}_4)_3(\text{Cl}, \text{OH}, \text{F})$

Named in 1982 for the composition. The composition can also be rendered as Ca₁₀(SiO₄)_{3-x}(SO₄)_{3-x}(PO₄)_{2x}(Cl,OH,F)₂ (if $x = 0$: ellestadite, and if $x = 3$: apatite) *AM 67:90(1982)*. Compare: fluorellestadite (52.4.9.3) and hydroxyllestadite (52.4.9.4). See Apatite group. HEX $P6_3/m$. (Nat): $a = 9.510$, $c = 6.897$, and (syn): $a = 9.669-9.688$, $c = 6.849-6.853$, $Z = 2$, $D = 3.20$. *25-167(nat)*: 3.45₄ 2.84_{9.5} 2.80₄ 2.75₁₀ 2.65₃ 2.28₄ 1.96₃ 1.85₃ and *NJBM 7:295(1992)(syn)*. Ca₅(SO₄)_{1.5}(SiO₄)_{1.5}Cl 3.43₂ 2.87₁₀ 2.80₃ 2.79₈ 2.32₃ 1.98₃ 1.85₃ 1.13₂. Structure: *AC(B) 36:1636(1980)* analogous to that of hydroxyllestadite. Finely granular, compact aggregates < 1 mm. Pink, pale rose or orange. $G = 3.07$. IR, DTA, and TGA data: *AM 56:1507(1971)*. Rapidly soluble in cold, dilute HCl (1N). Analysis (wt %): CaO 52.69, P₂O₅ 15.9, SiO₂ 11.99, SO₃ 13.47, Cl 1.44, H₂O⁺ 0.36, H₂O⁻ 0.29, minor Sr, Fe, F, SrO 0.86, Na₂O 0.06, K₂O 0.06, CO₂ 2.18, Fe₂O₃ 0.29, F 0.43, $\Sigma = 99.57$. Uniaxial (-). N_O = 1.652-1.655, N_E = 1.649-1.650. Occurs in skarn associated with Vesuvianite, diopside, wollastonite, idocrase and pale blue calcite at the Chickibu Mine, *Takiue, Saitama Pref., Japan*. EF *AM 56:1507(1971)*, *DA 46:69(1995)*.

52.4.9.6 Mattheddleite $\text{Pb}_5(\text{SiO}_4, \text{SO}_4)_3\text{Cl}$

Named by Livingstone *et al.* in 1987 for Matthew Foster Heddle (1828-1897), Scottish mineralogist. Apatite group. HEX $P6_3/m$. $a = 9.948-10.01$, $c = 7.464-7.504$, $Z = 2$, $D = 6.86-6.96$. *41-610(nat)*: 4.31₄ 4.16₄ 3.44₂ 3.26₃ 3.00₁₀ 2.88₄ 1.88₂. Hexagonal prisms, to 3 mm, rosetiform aggregates. White (creamy), white streak, adamantine luster. *SJG 23:1(1987)*. Fluoresces dull yellow in SWUV. Analysis (wt %): PbO, 83.6; SiO₂, 7.65; SO₃, 6.00; Cl, 2.4. Uniaxial (-); (Na light): N_E = 1.999, N_O = 2.017; colorless, length-fast. Occurs with quartz and secondary minerals, including caledonite, cerussite, pyromorphite, leadhillite, susannite, and macphersonite, in an area of hydrothermal Pb-Zn mineralization. *Leadhills Dod, Strathclyde region, Lanarkshire, Scotland*. Also do the Brae Fells, Red gill, and Roughton Gill Mines, Cardbeck Fells, Cumbria, and from a number of localities in Wales. EF *U.K. jour. of Mines and Minerals, 5:21(1988)*.

52.4.9.7 Karnasurtite-(Ce) (Ce,La,Th) (Ti,Nb) (Al,Fe) (Si,P)₂O₇(OH)₄ · 3H₂O

Named in 1959 by Kuzmenko and Kozhanov for the locality. This species is considered a mineral by some sources but not by others. The mineral may be britholite-(Ce). The composition is very close to that of "hydrocerite" of Vlasov et al. Amorphous (metamict), possibly *HEX* $a = 10.6$, $c = 7.3$. *PD* (nat): no X-ray diffraction data; when heated to 900°, it gives a pattern similar to that of huttonite—ThSiO₄; (heated): 3.10₇ 2.88₇ 3.29₆ 3.49₅ 1.72₅. Grains to 1 cm diameter or aggregates of platy crystals to 10 cm × 6 cm × 2 cm. Honey yellow (fresh) to pale yellow (altered), yellowish streak, greasy luster. One good cleavage, brittle. *H* = 2. *G* = 2.89–2.95. Dehydration curve shows one-half of H₂O lost to 150°, the rest gradually to 650°. Four chemical analyses given in *AM 45:1133(1960)*; P₂O₅ to 6.8%, MgO to 3.4%, CaO to 3.2%. Uniaxial (-); *N*_O = 1.617, *N*_E = 1.595; nonpleochroic, pale yellow; parallel extinction; sometimes anomalously biaxial. Occurs in a zoned pegmatitic stock, in intermediate replacement zone of microcline. Associated with other alkalic minerals. Occurs in *Vein No. 2, Mt. Karnasurt, Lovozero massif, Kola Penin., Russia*. Also on Mt. Punkaruaiv, Lovozero massif; Red Wine alkalic complex, central LAB, Canada. *EF MIN 3(1):847(1972)*, *GSCB 294:1(1981)*, *AM 45:1133(1960)*.

52.4.9.8 Fluorbritholite-(Ce) (REE,Ca)₅(Si,P)₃O₁₂F Britholite subgroup of the apatite group

Named by Gu *et al.* in 1994 for the composition. *HEX*. *P6₃/ma* 9.537Å *c* 7.008Å *z*=2, *D*=4.66; 2.84₁₀ 2.82₃ 2.75₃ 1.87₃ (*Jour. of Wuhan Univ. of Technology*, 9(3), 9-14; abstracted in *AM 81:1013(1996)*). Pale yellow, tan, or reddish brown aggregates and patches consisting of radiating to subparallel groups; crystals are prismatic (to 0.5 mm) to equant; colorless to pale brown streak, adamantine luster, opaque to translucent, brittle, even to conchoidal fracture, perfect {0001} cleavage, *H*=5, *G*=4.66. Uniax. (-), *N*_o 1.792 *N*_e 1.786; pale yellow, nonpleochroic. Three grains analyzed, one of which has Ce>Ca (atomic): Ce₂O₃ 33.14, La₂O₃, 19.78, Pr₂O₃ 1.20, Nd₂O₃ 8.78, FeO 0.10, CaO 1.92, SrO 3.74, MnO 1.48, Na₂O 3.04, ThO₂ 1.09, U₃O₈ 0.31, SiO 16.59, Al₂O₃ 0.08, P₂O₅ 5.12, F 2.70, O for F 1.14, Σ99.20. Occurs in vugs in nepheline syenite, marble xenoliths, sodalite syenite xenoliths, and pegmatite dikes at Mont Saint-Hilaire, Quebec.

52.4.10.1 Ellenbergerite (Mg,Ti,□)₂Mg₆Al₆Si₆Si₂O₃₈H₁₀ [16th IMA Mtg :74(1994)]

Named by Chopin *et al.* in 1986 for François Ellenberger, Paris, for his geological work in the western Alps. A phosphorus-rich variety (16% P₂O₅) also was found. *HEX P6₃m*. $a = 12.25$, $c = 4.93$, $Z = 1$, $D = 3.10$ – 3.17 . 40-507(nat): 6.15₃ 3.61₇ 3.54₁₀ 3.06₇ 2.65₉ 2.34₄ 2.19₇ 1.78₄. The structure consists of single chains of face-sharing octahedra partially occupied by Mg + Ti or Zr, and double chains consisting of couples (pairs) of face-sharing octahedra occupied

by Mg + Al linked by edges along the *c* axis. Isolated SiO₄ tetrahedra interconnect the octahedral chains. *EJM* 5:819(1993). Anhedronal, rarely as prisms to 10 mm long, with hexagonal cross section. Purple to lilac Fe²⁺-Ti⁴⁺ charge transfer is responsible for color; white streak; vitreous luster; transparent. Easy fracture, brittle. H = 6½. G = 3.15–3.22. Nonfluorescent in UV, faint bluish Cl in electron beam. Analysis (wt %): SiO₂, 39.1; P₂O₅, 0.45; Al₂O₃, 25.1; TiO₂, 4.0; MgO, 22.2; FeO, 0.2; H₂O, 8.0. Original paper has range SiO₂, 32.5–38.6; P₂O₅, 0–8.3; Al₂O₃, 20.4–24.9; TiO₂, 0.5–4.1; ZrO₂, 0–3.1; MgO, 21.8–25.8; FeO, 0.15–0.43. P is incorporated by SiAl ↔ PMg. Formula also given as: [Mg, (Ti,Zr), □]₂ Mg₆(Al,Mg)₆(Si,P)₈ O₂₈(OH)₁₀. Uniaxial (-); at 589 nm: N_O = 1.6533–1.6789, N_E = 1.6538–1.6697; vividly pleochroic. O, colorless; E, colorless to deep lilac. Highest O values are for samples rich in Ti, and the color zoning is related to Ti for Zr substitution. Variations in E are more dependent on the P content. Occurs in low-temperature, high-pressure conditions in a phengite-quartzite layer of a massif in the western Alps. Occurs as inclusions in pyrope. Coesite associated. 25–30 kbar and 700–800°. *Dora-Maira massif, Parigi, near Martiniana Po, Italy*. *EF CMP* 92:316(1986), *BM* 111:17(1988).

52.4.11.1 Sitinakite Na₂KTi₄Si₂O₁₃(OH)·4H₂O

Named in 1992 by Menshikov *et al.* for the composition (Si-Ti-Na-K). TETR. P₄₂/mcm *a* 7.819-7.821A *c* 12.021-12.099A, Z=2 D=2.88; PD 7.84₁₀ 6.02₁₀ 5.04₄ 3.36₅ 3.25₈ 2.80₅ 2.61₆ 2.00₇. Structural formula: Na₂(H₂O)₂[Ti₄O₅(OH)(SiO₄)₂]K(H₂O)₂. DAN SSSR 307:114(1989). Crystals with anom. optics may be indexed on Pcc2, and symmetry reduction may be related to high concentrations of Nb, or to filling of zeolite-like channels by K and H₂O. Colorless to pale rose or dirty white. Primary hydrothermal crystals are equant to short prismatic, 1 × 1 × 2 mm with some to 3-4 mm. pseudomorphs are as much as 0.6 × 3 × 4 cm. Euhedral, pseudo-cubic. Luster vitreous, streak white. No fluorescence. Excellent {100} and fair {001} cleavage. H 4½, G 2.86. IR, DTA and TGA data given in *ZVMO* 121:94(1992).. No dissolution observed in water, HCl or HNO₃ at 25°C. Alkali sites contain Na, K, Sr, Ba and Ca and the Ti site contains Ti, Nb and Fe. Nb₂O₅ 5.1wt. %. Uniax. (+) with N_o 1.780 N_o 1.988. Anom. Biax., 2V=10–11°. Occurs on *Mount Kukisvumchorr, Khibiny massif, Kola Peninsula, Russia*; in a hydrothermal vein and in two pegmatite veins in meltigite-urtite. Assoc. with natrolite, vinogradovite, aegirine and others. Forms with vinogradovite as pseudomorphs after an unknown mineral.

Insular SiO_4 Groups and Other Anions or Complex Cations

53.1.1.1 Spurrite $\text{Ca}_5(\text{SiO}_4)_2\text{CO}_3$

Named by Wright in 1908 for Josiah Edward Spurr (1870–1950), American geologist. Synonyms: β -spurrite; α -spurrite is the high-temperature, orthorhombic form ($>1200^\circ$). See the dimorph, paraspurrite (53.1.2.1). *MON P2₁/a*. $a = 10.49$, $b = 6.705$, $c = 14.15$, $\beta = 101.3^\circ$, $Z = 4$, $D = 3.03$. *13-496(nat)*: 3.81_3 3.02_7 2.70_{10} 2.66_5 2.64_7 2.61_3 2.17_4 1.90_3 . Structure: *AC 13:434(1960)*. Granular masses, spheniscoidal masses to 15 cm; polysynthetic twinning on {001}, {101}, and {205}. White, pale blue, or yellow; white streak; vitreous luster. Cleavage {001}, distinct; {100}, poor. $H = 5$. $G = 3.00\text{--}3.02$. Thermal data: *DHZI:1B(1986)*. Green luminescence reported. *DHZI:1B(1986)*. Effervesces with dilute HCl, yielding a gelatinous silica residue. Quite pure. Traces of Al, Fe, Mg, Na, P. Biaxial (-); $X = b$, $Y \wedge a = 45^\circ$, $Z \wedge c = 33^\circ$; $N_x = 1.637\text{--}1.641$, $N_y = 1.672\text{--}1.676$, $N_z = 1.676\text{--}1.681$; colorless; $2V = 35\text{--}41^\circ$; $r > v$, weak, crossed. Occurs with hillebrandite in a contact-metamorphic limestone in Mexico, also with minerals such as larnite. In skarns. High-temperature contact metamorphism. Also in areas of spontaneous combustion of organic matter in bituminous siliceous limestones. Alteration: to scawtite. Occurs in the Little Belt Mountains, MT, and the Christmas Mountains, TX; Tres Hermanas Mountains, Luna Co., NM; Crestmore quarry, Riverside Co., CA; Scawt Hill, and Carneal, County Antrim, and Carlingford, Co. Louth, Northern Ireland; Camas Mor, Isle of Muck, and at Camphouse, Ardamur-chan, Argyllshire, Scotland; Cornet Hill, Romania; Anakit area, lower Tunguska R. and Kochumdek R. area, Siberia, Russia; Güneyce–Ikizdere area, Trabzon Prov., Turkey; Hatrurim area, Israel; Magarin area, Jordan; Kushiro, and Hirata, Hiroshima Pref., Fuka, Bicchu, Okayama Pref., Japan; Terneras mine, *Velardeña*, DUR, Cerro Mazahua, Zitacuaro, MICH, and Maconi, QUER, Mexico; Golden Gully, Tokatoka dist., New Zealand. *EF MIN 3(1):358(1972)*, *AC 13:434(1986)*.

53.1.2.1 Paraspurrite $\text{Ca}_5(\text{SiO}_4)_2\text{CO}_3$

Named in 1977 by Colville and Colville from the Greek *para*, besides, and for spurrite, a dimorphous pair. See the polymorph, spurrite (53.1.1.1). *MON*

$P2_1/a$. $a = 10.473$, $b = 6.706$, $c = 27.78$, $\beta = 90.58^\circ$, $Z = 8$, $D = 3.03$. 29-307 (nat): 6.92₈ 6.03₄ 4.62₄ 3.47₁₀ 2.72₇ 2.70₅ 2.65₄ 1.98₇. Structure is very close to that of spurrite (53.1.1.1). a and b remain essentially the same, but $c = 27.78$ and $\beta = 90.58^\circ$. In effect, paraspurrite has $2 \times d_{001}$ of spurrite (53.1.1.1). Crystals average 0.5 cm across, maximum size 2 cm; polysynthetic twinning on (001). White, white streak. Poor cleavage parallel to (001). $G = 3.00$. Quite pure: traces of Al, Fe, Mg, P. Biaxial (-); $X = b$, $Y \wedge a = 30^\circ$, $Z \wedge c = 30^\circ$; $N_x = 1.650$, $N_y = 1.672$, $N_z = 1.677$; colorless; $2V = 47^\circ$. Occurs in high-temperature contact-metamorphic rocks. Limestones. In roof pendant of siliceous carbonate rock in syenite. With gehlenite, vesuvianite, apatite, and larnite. Darwin, Inyo Co., CA; Cerro Mazahua, Zitacuaro, MICH, Mexico. EF AM 62:1003(1977).

53.1.3.1 Iimoriite-(Y) $Y_2(\text{SiO}_4)(\text{CO}_3)$

Named in 1970 by Kato and Nagashima for Satoyasu Iimorii (1885–1982), Japanese analytical chemist and REE specialist, and his son Takeo Iimorii (died in World War II), who described many REE minerals. TRIC $P1$. $a = 6.524$ – 6.573 , $b = 6.537$ – 6.651 , $c = 6.417$ – 6.454 , $\alpha = 116.36$ – 116.94° , $\beta = 92.34$ – 92.75° , $\gamma = 95.51$ – 95.92° , $Z = 2$, $D = 4.91$. 35-640(nat): 4.54₂₅ 3.30₂₅ 3.02₄ 2.95₈ 2.88₁₀ 2.84₃₅ 2.78₄ 2.70₃. All oxygen atoms in iimoriite-(Y) are bonded in anionic complexes, either SiO_4 tetrahedra or CO_3 carbonate groups. The atomic arrangement of iimoriite consists of alternating (011) slabs of orthosilicate groups and carbonate groups, with no sharing of oxygen atoms between adjacent slabs. Subhedral to anhedral grains to 0.5 mm. Buff-tan, white-pale cream, yellow; white streak; vitreous luster. One good cleavage on {011}. $H = 5\frac{1}{2}$ –6. $G = 4.47$; IR data: AM 69:196(1984). Slightly soluble in cold HCl. Kola Peninsula sample is highest in Y_2O_3 . Biaxial (-); $N_x = 1.753$ – 1.786 , $N_y = 1.820$ – 1.827 , $N_z = 1.827$ – 1.830 ; colorless; $2V = 31$ – 37° (Alaska and Kola), $2V = 5$ – 15° (Japan); OAP parallel to a cleavage. Occurs with fluorite, thalenite-(Y), keivyite-(Y), and vyuntsphakhte-(Y) in amazonite-zinnwaldite pegmatite on the Kola Peninsula. In a thorite-uraninite-bearing quartz-albite vein, Bokan Mt. In quartz-microcline pegmatite, Fukushima Pref., Japan, and the nearby Suishoyama pegmatite, as an alteration product of thalenite-(Y). Occurs at Bokan Mt., Prince of Wales Island, AK; in the Ploskogorskaya amazonite pegmatite, Keivy area, Kola Penin., Russia; Fusamata and Suishoyama, Kawatamachi, Fukushima Pref., Honshu, and Soraku, Kyoto Pref., Japan. EF AM 58:140(1973).

53.2.1.1 Saryarkite-Y $\text{Ca}(\text{Y,Th})\text{Al}_5(\text{SiO}_4)_2(\text{PO}_4,\text{SO}_4)_2(\text{OH})_7 \cdot 6\text{H}_2\text{O}$

Named in 1964 by Krol et al., but etymology not given. Synonym: saryarkite. TET $P42_12$ or $P4_22_12$. $a = 8.213$, $c = 6.55$, $Z = 4$, $D = 3.35$. 16-712: 3.45₉ 3.01₁₀ 2.83₁₀ 2.56₅ 2.36₅ 2.14₉ 1.854₁₀ 1.312₈. White, dull to greasy luster. $H = 3\frac{1}{2}$ –4. $G = 3.07$ – 3.15 . Uniaxial (+); $N_O = 1.606$, $N_E = 1.620$. Occurs as massive material at an unspecified locality (possibly Sary-Arka) in Kazakhstan (?), associated with barite, molybdenite, pyrite, hematite, and other iron

oxides in propylitized acid effusive Devonian rocks and altered granitic rocks. AR *ZVMO* 93:147(1964), *AM* 49:1775(1964).

53.2.2.1 Nagelschmidtitite $\text{Ca}_7(\text{SiO}_4)_2(\text{PO}_4)_2$

Named in 1977 by Gross for G. Nagelschmidt, who first described the synthetic compound in 1937. Probably HEX Space group unknown. (Syn): $a = 5.38$, $c = 7.10$, $Z = 1$, $D = 3.49$. β -706 (syn): 3.93_3 3.52_3 2.86_{10} 2.70_{10} 1.960_{10} 1.761_5 1.485_5 1.346_5 . Apparently consists, in part, of a mixture of two polymorphs. The clear α -phase is colorless and transparent; uniaxial (+); $N_O = 1.680$, $N_E = 1.698$; presumably close to the ideal composition. The more common, cloudy β -phase is slightly yellow to brown and translucent; uniaxial (+) to biaxial (+) with small $2V$; $N_O = 1.638$, $N_E = 1.652$. In thin section, displays a complex set of lamellae intersecting at close to 60° . The composition is deficient in phosphorus, the Si/P ratio being near 4:1 rather than 1:1; traces of Na and K are present. Occurs as anhedral grains, up to 150 μm in diameter in the lowermost part of the *Hatrum formation, Israel*, where it may constitute up to 30% of the rock and is associated with gehlenite, rankinite, perovskite, titanian andradite, and magnetite. AR *GSIB* 70:31(1977), *AM* 63:425(1978).

URANOPHANE GROUP

The uranophane minerals are hydrated uranyl silicates with the general formula

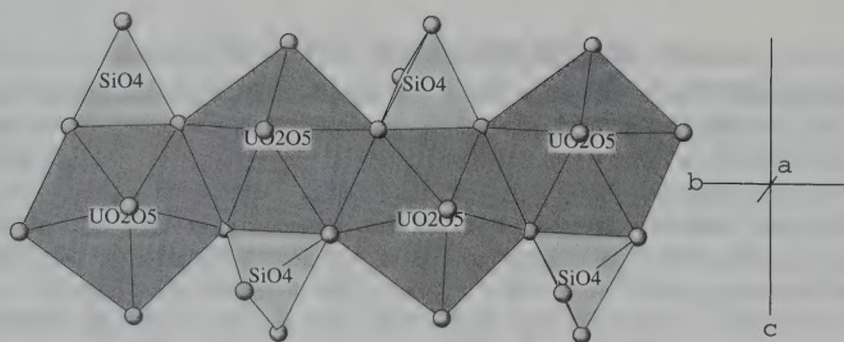

where

and with a structure based on parallel chains of composition $[\text{UO}_2\text{SiO}_4]_n^{2n}$ built of edge-sharing pentagonal bipyramidal uranium polyhedra and SiO_4 tetrahedra with a fundamental repeat distance of approximately 7 Å. In the structure, the chains are cross-linked (Si-O-U) to form sheets that are bonded to the remaining cations.

The species are not isostructural, as their symmetry and structural details are influenced by the number and nature of the associated cations as well as the orientation of the silicate tetrahedra within the chain. The chain conformation is such that in uranophane the apical oxygens of silicate tetrahedra point up along one side of the chain and down on the other; whereas in β -uranophane, the apical oxygens point alternately up and down on each side of the chain.

Except for the case of kasolite, the cations do not provide the required formal charge balance, necessitating the treatment of part of the water present as hydrogen, hydronium, or hydroxyl, the last as a substitution for a

URANOPHANE: $\text{Ca}(\text{U}(\text{OH})_2)_2(\text{SiO}_3\text{OH})_2 \cdot 4\text{H}_2\text{O}$

The uranyl silicate chain in kasolite, parallel to the $\approx 7\text{\AA}$ axis, that is common to most members of the uranophane group. In β -uranophane, silicate tetrahedra point alternately up and down on each side of the chain.

silicate apical oxygen. Structural studies suggest a variety of charge-balancing mechanisms, but the presence of either $\text{SiO}_3(\text{OH})$ tetrahedra or (H_3O) is likely. Variability in water content in analyses of these species suggests that at least part of the water may be zeolitic.

URANOPHANE GROUP

Mineral	Formula	Space Group	Axis	Chain Length (\AA)	
Kasolite	$\text{Pb}[\text{UO}_2\text{SiO}_4] \cdot \text{H}_2\text{O}$	$\text{P}2_1/a$	b	6.932	52.3.1.1

β -Uranophane**	$\text{Ca}[(\text{UO}_2)(\text{SiO}_3\text{OH})]_2 \cdot \text{H}_2\text{O}$	$\text{P}2_1/a$	a/2	6.983	53.3.1.9

* Chain conformation not yet determined. All others, except β -uranophane, have the uranophane conformation.

** Dimorph of uranophane.

Notes:

1. The same fundamental chain structure, with additional independent SiO_4 tetrahedra, appears in weeksite, haiweeite, and metahaiweeite. In weeksite the additional silicate tetrahedra are described as forming "walls" (layers?); nevertheless, these species are classified here because of the uranophane-like chains. Similar chains exist in soddyite (53.3.3.1) but with one set at 90° and cross-linked to form a three-dimensional framework.
2. See autunite for other $[\text{UO}_2\text{TO}_4]$ minerals.

53.3.1.1 Kasolite $\text{Pb}[\text{UO}_2\text{SiO}_4] \cdot \text{H}_2\text{O}$

Named in 1921 by Schoep for the type locality. Uranophane group. *MON* $P2_1/a$. $a = 6.704$, $b = 6.932$, $c = 13.252$, $\beta = 104.22^\circ$, $Z = 4$, $D = 6.534$. *29-788*: 6.51_2 6.15_4 4.21_6 3.52_6 3.24_6 3.06_8 2.92_{10} 2.18_2 . Structure: *CSC* 6:617 (1977). As elongated [010] and flattened (001) laths with {100}, {001}, {110}, {111} common, in radial clusters but sometimes isolated and doubly terminated; massive. Deep yellow to orange, subadamantine luster. Cleavage {100}, perfect; {001} and {010}, poor. $H = 4\frac{1}{2}$. $G = 5.0$. Biaxial (+); $2V = 43^\circ$; $N_x = 1.90$, $N_y = 1.91$, $N_z = 1.95$; $X = b$, $Z \wedge a = 5^\circ$. In oxidized zones of uranium ores with other secondary minerals of uranium; a constituent of the uraninite alteration product "gummitite." At the Ruggles mine, Grafton Center, NH; East Walker R. area, Lyon Co., and Goodsprings, Clarke Co., NV, and at various localities in NY, PA, UT, and AZ; Nicholson mine, Lake Athabaska, SK, and Great Bear Lake, NWT, Canada; Kersegalec, Ligud, Marbihon, and Grury, Saone-et-Loire, and Puy de Dôme, France; Norway; Italy; Franceville, Gabon; in fine but small crystals at *Kasolo*, *Shaba*, *Zaire*, and at Menda, Swambo, Luiswishi, Kasbove, Kalongwe and Musonoi. An incidental ore of uranium. *AR CR* 173:1476(1921), *MSUZ*:105(1981).

KASOLITE: $\text{Pb}(\text{UO}_2)\text{SiO}_4 \cdot \text{H}_2\text{O}$

The uranyl silicate minerals have sheets of uranyl ions (UO_2) and isolated Si tetrahedra, with Pb and water in between. U atoms are five-coordinated, and this polyhedron shares one edge with an Si tetrahedron.

53.3.1.2 Uranophane $\text{Ca}[(\text{UO}_2)(\text{SiO}_3\text{OH})]_2 \cdot 5\text{H}_2\text{O}$

Named in 1853 by Websky for the composition and from the Greek *to appear*. Synonyms: uranotile, α -uranophane, and uranophane- α . Dimorphous with β -uranophane. MON $P2_1$. $a = 15.909$, $b = 7.002$, $c = 6.665$, $\beta = 97.27^\circ$, $Z = 2$, $D_{\text{calc}} = 3.78$. 39-1360: 7.90₁₀ 3.95₉ 3.60₂ 2.63₄ 2.10₂ 1.975₅ 1.961₄ 1.771₂. Structure: $AC(C)$ 44:421(1988). As acicular crystals [010] and rosettes, frequently with tapered terminations and as fine-grained, earthy masses. Pale to canary yellow, vitreous to silky luster. Cleavage {100}, perfect; conchoidal fracture. $H = 2\frac{1}{2}$ -3. $G = 3.83$ -3.90. Biaxial (-); $2V = 37^\circ$; $N_x = 1.642$ -1.648, $N_y = 1.661$ -1.667, $N_z = 1.667$ -1.675; $X \approx a$, $Y \wedge c \approx 10^\circ$, $Z = b$; $r < v$, strong; anomalous interference colors. Variability in refractive indices may reflect loss of zeolitic water. Forms as an alteration product of uraninite, constituting much of the yellow fine-grained material adjacent to the orange-to-brown "gummite" alteration of pegmatitic uraninite. As well-crystallized needles and rosettes in oxidized uranium deposits. In pegmatites at Grafton, NH; Avondale, Delaware Co., PA; Spruce Pine district, Mitchell Co., NC; and the Black Hills, SD, as alteration haloes around uraninite and "gummite." At Lusk and Pumpkin Buttes, WY; as superb acicular crystals to 20 mm in vugs and as radial aggregate fracture coating in the Todilto limestone at Haystack Butte and adjoining areas in McKinley and Valencia Cos., NM. As silky, fibrous, radial clusters to several centimeters at the Faraday mine, Bancroft, ONT, Canada; at La Virgen Mine, Puerto del Aire, CHIH, Mexico. Occurs abundantly (uranotile) at Wolsendorf, and at Schneeberg, Saxony, Germany; at Oberpfalz; and Miedzianca (Kupferberg), Silesia, Poland. At Mt. Painter, Flinders Range, SA, Australia. At most uranium occurrences in Shaba, Zaire, as pseudomorphs after uraninite (Shinkolobwe) and as superb crystals of several centimeters and as rosettes in association with hydrated uranium oxides, kasolite, rutherfordine, and less commonly with soddyite (Kolwezi and Swambo). AR AM 24:324(1939), 40:634(1955), 66:610(1981), 71:1489(1986).

53.3.1.3 Sklodowskite $\text{Mg}(\text{H}_2\text{O})_2[\text{UO}_2\text{SiO}_4]_2 \cdot 4\text{H}_2\text{O}$

Named in 1924 by Schoep for Maria Sklodowska Curie (1867-1934), Polish-born French chemist, Nobelist in physics, 1904, and chemistry, 1911. Uranophane group. MON $C2/m$. $a = 17.382$, $b = 7.047$, $c = 6.610$, $\beta = 105.9^\circ$, $Z = 2$, $D = 3.638$. 29-875: 8.42₁₀ 5.91₅ 4.19₈ 4.00₅ 3.52₆ 3.27₇ 3.00₆ 2.87₅. Structure: CSC 6:611(1977). As acicular to fibrous [010] crystals with {100}, {001}, {301}, {011} but commonly with tapering termination; as rosettes and spherulites; massive. Pale to lemon yellow to greenish yellow, almost white in fibrous samples; vitreous luster; transparent. Cleavage {100}, perfect; conchoidal fracture. $H = 2$ -3. $G = 3.64$. Biaxial (-); $2V$ large; $N_x = 1.613$, $N_y = 1.635$, $N_z = 1.657$; $Y = b$ (elongation); $r > v$, very strong; strongly pleochroic, yellow to colorless $Z > Y > X$. In oxidation zones of uranium ores, and often replacing uraninite; commonly associated with other secondary uranium minerals. At the New Haven mine, Crook Co., WY; at Oyler Tunnel

claim, Wayne Co., and Honeycomb Hills, Juab Co., UT; at Grants, NM; at Naica, CHIH, Mexico; at *Shinkolobwe, Shaba, Zaire*, in fine, acicular crystals and as pseudomorphs after uraninite, and at Luiswishi, Musonoi, and Swambo; associated with novacekite and zeunerite at the Pedra Preta magnesite mine, Brumado, BA, Brazil(!). AR *CR 179:413(1924)*, *AM 66:610(1981)*.

53.3.1.4 Cuprosklodowskite $\text{Cu}[(\text{UO}_2)(\text{SiO}_3\text{OH})]_2 \cdot 6\text{H}_2\text{O}$

Named in 1933 by Buttgenbach in allusion to the composition and similarity to sklodowskite. Uranophane group. Synonyms: jachymovite (jachimovite). TRIC $P\bar{1}$. $a = 7.052$, $b = 9.267$, $c = 6.655$, $\alpha = 109.23^\circ$, $\beta = 89.83^\circ$, $\gamma = 110.02^\circ$, $Z = 1$, $D = 3.815$. 19-413: 8.16₁₀ 6.06₇ 4.82₉ 4 12₃ 3.53₇ 3.29₄ 2.96₄ 2.92₄. Structure: *AM 60:448(1975)*. As acicular [100] crystals with {010}, {011}, {001}, {110}; as rosettes and crystalline masses. Twins with [100] axis and (010) composition common; also with composition plane (2 $\bar{1}$ 0). Yellow-green to emerald-green, vitreous luster. Cleavage {010}, perfect; conchoidal fracture. $H = 3\frac{1}{2}$. $G = 3.83$. Biaxial (-); 2V small; $N_x = 1.655$, $N_y \approx N_z = 1.667$ $X \wedge a$ small; distinctly pleochroic. In oxidation zones of uranium ores containing copper sulfides, and in association with various secondary uranium and copper minerals. In Red Canyon and White Canyon, San Juan Co., and at Seven Mile Canyon, near Moab, Grand Co., UT; in limestone at Grants, NM; at the Nicholson mine, Lake Athabaska, SK, Canada; at Johannegeorgstadt, Saxony; at Joachimsthal (Jachymov), Czech Republic; at Amelal, Argana-Biguadine, Morocco; at *Kalongwe, Shaba, Zaire*, and as excellent acicular crystals(!) up to several centimeters long at Musonoi, and at Shinkolobwe and other sites in Shaba, Zaire, with vandenbrandeite, kasolite, sklodowskite, and malachite. AR *SGBA 56:B331(1933)*, *BM 90:259(1967)*, *AM 66:610(1981)*.

53.3.1.5 Boltwoodite $(\text{H}_3\text{O})\text{K}[\text{UO}_2\text{SiO}_4] \cdot \text{H}_2\text{O}$

Named in 1956 by Frondel and Ito for Bertram B. Boltwood (1870–1927), professor of radiochemistry, Yale University. Uranophane group. Synonym: nenadkevite. MON $P2_1$. $a = 7.073$, $b = 7.064$, $c = 6.638$, $\beta = 105.75^\circ$, $Z = 2$, $D_{\text{calc}} = 4.372$. 35-490: 6.81₁₀ 6.40₅ 3.54₇ 3.40₉ 2 95₈ 2.91₇ 1.900₆ 1.764₆. Structure: *AM 66:610(1981)*. Acicular [010]; fine, matted fibers; massive. Twinned. Light yellow, vitreous to earthy luster. Cleavage {010}, perfect; {001}, imperfect. $H = 3\frac{1}{2}$ -4. $G = 3.60$. Biaxial (-); 2V large; $N_x = 1.668$ -1.670, $N_y = 1.695$ -1.696, $N_z = 1.698$ -1.703; $Z = b$; $r < v$. Pleochroic; X, colorless, Y,Z, pale yellow. Anomalous interference colors. May have often been misidentified as uranophane. Interstitially in quartz sandstones; as an alteration product of uraninite. At Williams quarry, Easton, PA, as an alteration of thorian uraninite; Lookout No. 22 mine, Gunnison Co., CO; New Method mine and *Pick's Delta mine, Emery Co., UT*; Arandis mine, Namibia, in radial aggregates up to 2 cm long; Myponga, SA, Australia; Alto Boqueirao, Parelhas, RGN, Brazil; in the outer zones of "gummite" alteration at La Chiquita mine, Quebrado, Cordoba, Argentina. AR *SCI 124:931(1956)*, *AM 46:12(1961)*.

53.3.1.6 Sodium-Boltwoodite $(\text{H}_3\text{O})(\text{Na},\text{K})[\text{UO}_2\text{SiO}_4] \cdot \text{H}_2\text{O}$

Named in 1975 by Chernikov et al. in allusion to composition and similarity to boltwoodite. Uranophane group. ORTH $P2_12_12_1$. $a = 27.40$, $b = 7.02$, $c = 6.65$, $Z = 8$, $D_{\text{calc}} = 4.4$. 29-1044: 6.92₇ 6.71₁₀ 4.70₈ 3.49₈ 3.37₈ 3.10₈ 2.92₁₀ 1.920₇. Powdery aggregates. Pale yellow, dull luster. Perfect cleavage, reported as {010} but probably parallel [010]. $H = 3\frac{1}{2}$ -4 $G = 4.1$. Biaxial; 2V large; $N_x = 1.613$, $N_y = 1.63$, $N_z = 1.645$, also reported 1.645, 1.66, and 1.72, respectively. Pleochroic. X, colorless; Z, pale yellow. The described material contains sodium and potassium, $\text{Na}/\text{K} \approx 7:3$. An oxidation-zone mineral. Found in unspecified arid regions of the former USSR. AR DANES 221:144 (1975); AM 61:1054(1976), 66:610(1981).

53.3.1.7 Oursinite $(\text{Co},\text{Mg})(\text{H}_3\text{O})_2[\text{UO}_2\text{SiO}_4]_2 \cdot 3\text{H}_2\text{O}$

Named in 1983 by Deliens and Piret from the French *oursin*, sea urchin, in allusion to the radiating habit of the acicular crystals. Uranophane group. ORTH *Aba2* or *Abam*. $a = 12.74$, $b = 17.55$, $c = 7.050$, $Z = 4$, $D = 3.67$. 35-600: 8.73₁₀ 7.20₇ 5.16₅ 4.55₃ 4.14₇ 3.53₄ 3.27₃ 2.85₉. Structure: BM 106:305 (1983). As radiating aggregates of acicular [001] crystals of 1 mm maximum length. Pale yellow, vitreous luster, transparent to translucent. Cleavage parallel to elongation. Biaxial (-); $2V_{\text{calc}} = 76^\circ$; $N_x = 1.624$, $N_y = 1.640$, $N_z = 1.650$; $Y = c(\text{elongation})$. In oxidation zones of uranium ores at *Shinkolobwe, Shaba, Zaire*, in association with soddyite, sklodowskite, kasolite, leperonnite, bijvoetite, and other secondary uranium minerals. AR AM 69:567(1984).

53.3.1.8 Swamboite $\text{H}_6\text{U}^{6+}[\text{UO}_2\text{SiO}_4]_6 \cdot 30\text{H}_2\text{O}$

Named in 1981 by Deliens and Piret for the type locality. Uranophane group. MON $P2_1/a$. $a = 17.64$, $b = 21.00$, $c = 20.12$, $\beta = 103.4^\circ$, $Z = 6$, $D = 4.064$. 35-660: 8.67₁₀ 5.85₅ 4.76₈ 4.49₅ 4.32₈ 3.51₆ 3.26₅ 2.98₆. Structure: CM 19:553 (1981). Acicular [010] with beveled terminations. Pale yellow. $G = 4.03$. Biaxial (-); $2V = 30^\circ$ $N_x = 1.640$, $N_y = 1.661$, $N_z = 1.663$; $X \approx a$, $Y = b$, $Z \wedge c = 13^\circ$. Pleochroic; X, colorless; Y, pale yellow. As an alteration product of other uranium minerals at the Jo Mac mine, San Juan Co., UT, and at *Swambo, Shaba, Zaire*. AR

53.3.1.9 Beta-uranophane $\text{Ca}[(\text{UO}_2)(\text{SiO}_3\text{OH})]_2 \cdot \text{H}_2\text{O}$

Named in 1935 by Novacek to correspond with its polymorph, uranophane. Uranophane group. Synonyms: β -uranotile, uranophane- β . Dimorphous with uranophane. MON $P2_1/a$. $a = 13.966$, $b = 15.443$, $c = 6.632$, $\beta = 91.38^\circ$, $Z = 4$, $D = 4.117$. 8-442: 7.49₁₀ 5.04₈ 4.53₈ 3.83₉ 3.51₈ 3.17₇ 3.02₈ 2.80₉. Structure: AM 71:1489(1986). The structure is similar to that of uranophane except for the sequence of orientation of the SiO_4 tetrahedra along the chain. Acicular [100], laths; fine-grained, fibrous; massive. Twinning on {010} common. Yellow, pale yellow streak, vitreous to dull luster. Cleavage {010}, perfect; {100}, poor. $H = 2\frac{1}{2}$ -3. $G = 3.9$. Variable composition due to zeolitic water may

account for the variability in optical properties. Biaxial (-); $X = b$, $2V = 45\text{--}71^\circ$; $N_x = 1.661\text{--}1.671$, $N_y = 1.682\text{--}1.694$, $N_z = 1.689\text{--}1.702$; $Z \wedge c = 32\text{--}57^\circ$; $r > v$, strong; crossed extinction, often incomplete. Pleochroic: X, colorless; Y,Z, deep yellow. An oxidation product of uraninite found in oxidized ores and pegmatites; pseudomorphs after uraninite. May be more common than reported, due to similarity to uranophane and similarly colored uranium minerals. Newry, ME; Ruggles and Palermo mines, Grafton Center, NH; Bedford, NY; Black Hills, SD; Faraday mine, Bancroft, ONT, Canada; France; Portugal; Wolsendorf, Bavaria, Germany; *Joachimsthal (Jachymov)*, Czech Republic; Japan; Argentina. An incidental ore of uranium. AR AM 24:324(1939), 40:634(1955), 66:610(1981); GSAM 135:281(1972).

53.3.2.1 Weeksite $(K,Na)_2(UO_2)_2(Si_5O_{13}) \cdot 3H_2O$

Named in 1960 by Outerbridge et al. for Alice Dowse Weeks (1909–1991), professor of geology, Temple University. ORTH *Cmmm*. $a = 7.092$, $b = 17.888$, $c = 7.113$, $Z = 2$, $D = 3.71$. Also *Pnnb*. $a = 14.26$, $b = 35.88$, $c = 14.20$, $Z = 16$ for $K_2(UO_2)_2(Si_2O_5)_3 \cdot 4H_2O$. 12-462: 8.98₈ 7.11₁₀ 5.57₉ 3.55₇ 3.30₇ 3.20₅ 2.37₅ 2.91₆. Structure: SPD 30:435(1985). The structure consists of walls of silicate tetrahedra joined by uranophane-like chains. Small spherulites of radiating lath. Yellow, waxy to silky luster. $G \approx 4.1$. Biaxial (-); $2V \approx 60^\circ$; $N_x = 1.596$, $N_y = 1.603$, $N_z = 1.606$; XYZ = *bca*; weakly pleochroic. X; colorless; Y, pale yellow-green; Z, pale green. In opal veinlets in rhyolite; with carbonates and gypsum. Mammoth mine, near Presidio, TX; Jackpile mine, Laguna Co., NM; at Goodwill claim and *Autunite No. 8 claim*, Thomas Range, Juab Co., UT; Muggins Mountains, Yuma Co., AZ; Haiwee reservoir, Coso Mountains, Inyo Co., CA. At the Margaritas, Sierra Peña, CHIH, Mexico. From Le Bois-Noirs, Loire, France, and Russia Afghanistan, Japan and Yinnietharra, WA, Australia. AR AM 45:39(1960), 66:610(1981); ZVMO 106:553(1977).

53.3.2.2 Haiweeite $Ca(UO_2)_2Si_6O_{15} \cdot 5H_2O$

Named in 1959 by McBurney for the type locality. Synonym: ranquillite. MON *P2/c*. $a = 15.4$, $b = 7.05$, $c = 7.10$, $Z = 2$, $D = 4.88$. 12-721: 9.26₁₀ 7.97₂ 7.09₃ 4.53₈ 4.41₅ 3.54₃ 3.30₃ 3.18₄. Structure: AM 66:610(1981). Acicular, very small; spherulitic aggregates; flakes. Yellow, silky to dull luster. Cleavage {001}, good. $H = 3\frac{1}{2}$. $G = 3.35$. Biaxial (-); $2V \approx 15^\circ$ $N_x = 1.571$, $N_y = 1.575$, $N_z = 1.578$ (Haiwee res.); $N_x = 1.560$, $N_y = 1.580$, $N_z = 1.582$ (Bad Gastein); $r > v$, strong; pleochroic; $X > Z$; anomalous interference colors. A secondary, oxidation product. At Haiwee reservoir, Coso Mountains, Inyo Co., CA, in granite and voids in lake-bed sediments; in gneiss at Bad Gastein, Salzburg, Austria; Hingyotoge deposit, Tottori Pref., Japan; at Nishapur, Kuh-e-Madan, Iran; in tourmaline granite at Perus, 25 km N of São Paulo, Brazil. AR AM 44:839(1959), 54:966(1969).

53.3.2.3 Metahaiweeite $\text{Ca}(\text{UO}_2)_2\text{Si}_6\text{O}_{15} \cdot n\text{H}_2\text{O}$ $n < 5$

Named in 1959 by McBurney from the parent phase, haiweeite. *MON* $P2/c(?)$. $12-722$: 8.81₅ 6.98₁₀ 5.85₅ 4.54₄ 3.52₅ 3.28₄ 3.16₅ 2.90₅, for material heated to redness. Flakes and spherical clusters. Pale yellow to greenish yellow, pearly luster. Cleavage {100}, distinct. $H = 3\frac{1}{2}$. $G = 3.35$. Dull green in UV. Reported biaxial (+), $2V_{\text{calc}} = 21^\circ$; $N_x = 1.611$, $N_y = 1.620$, $N_z = 1.645$. A dehydration product of haiweeite; data are derived largely from laboratory-heated specimens of haiweeite. *Haiwee reservoir, Coso Mountains, Inyo Co., CA.* *AR AM* 44:839(1959).

53.3.3.1 Soddyite $(\text{UO}_2)_2\text{SiO}_4 \cdot \text{H}_2\text{O}$

Named in 1922 by Schoep for Frederick Soddy (1877–1956), British radiochemist and physicist. *ORTH Fddd*. $a = 8.32$, $b = 11.21$, $c = 18.71$, $Z = 8$, $D = 4.75$. $35-491$: 6.30₁₀ 4.81₅ 4.56₁₀ 3.35₁₀ 3.26₂ 2.99₅ 2.81₄ 2.72₁₀. Structure: *AM* 66:610(1981). Thick tabular {001} to pyramidal with {111}, {110}, {001} dominant; fibrous; massive. Cleavage {001}, perfect; {111}, good. Lemon yellow (opaque) to amber-yellow (transparent); vitreous to resinous luster, earthy. $H = 3\frac{1}{2}$. $G = 4.70$. Biaxial (-); $2V$ large. X ; $N_x = 1.650-1.654$, $N_y = 1.685$, $N_z = 1.699-1.715$ $XYZ = cba$, colorless; Y , pale yellow; Z , pale yellow-green. In oxidized uranium ores. As pseudomorphs after uraninite at Ruggles mine, Grafton Center, NH; Lucky Mc mine, Fremont Co., WY; Honeycomb Hills, UT; Jackpile mine, Laguna Co., NM; Steel City mine, Yavapai Co., AZ; in fine crystals up to 3 mm at *Shinkolobwe, Shaba, Zaire*, and at Musonoi and Kolongwe; in pegmatite at Norabees, Namaqualand, South Africa. *AR CR* 174:1066(1922), *AM* 37:386(1952), *SPD* 24:315(1980).

53.3.3.2 Uranosilite $(\text{UO}_2)\text{Si}_7\text{O}_{15}$

Named in 1983 (Walenta) in allusion to the composition. *ORTH P22₁2₁, Pmmb*, or *Pmcb*. $a = 11.60$, $b = 14.68$, $c = 12.83$, $Z = 6$, $D_{\text{calc}} = 3.25$. $37-417$: 11.6₉ 7.30₁₀ 6.19₉ 3.50₈ 3.42₆ 3.20₆ 3.08₆ 2.77₇. Minute acicular [001] crystals. Yellowish white, vitreous luster. Biaxial (-); $N_x = 1.570$, $N_z = 1.584$; Y or $Z = c$; slightly anomalous interference colors. Intimately intergrown with uranophane and studtite at *Menzeschwand, Schwarzwald, Germany.* *AR NJMM*:259(1983).

Borosilicates and Some Beryllosilicates

54.1.1.1 Grandidierite (Mg,Fe)Al₃BSiO₉

Named in 1902 by Lacroix for Alfred Grandidier (1836–1912), French explorer, who described the geography and natural history of Madagascar. ORTH *Pbnm*. $a = 10.335\text{--}10.36$, $b = 10.978\text{--}10.94$, $c = 5.75\text{--}5.760$, $Z = 4$, $D = 3.10$. 18-581(nat): 5.48₈ 5.17₁₀ 5.04₁₀ 3.71₅ 2.96₄ 2.74₈ 2.58₅ 2.17₆. The structure is related to andalusite. The only silicate in which significant amounts of Fe²⁺ are in five-fold coordination. There is a distorted trigonal bipyramid polyhedron around the (Mg,Fe) site. *AC(B)* 24:1518(1968). Prismatic crystals or grains; ≈ 0.1 mm or less, a few = 0–0.4 mm long, original Madagascar specimens to 8 cm long. Greenish blue or bluish green, pale blue-green streak, vitreous luster on cleavage. Bluish green, greenish blue, vitreous luster. Cleavage parallel to (100), good; parallel to (010), poor; uneven fracture; brittle. $H = 7\frac{1}{2}$. $G = 2.93\text{--}2.98$. IR data: *BGSF* 41:71(1969), *BM* 93:224(1970). Mössbauer data: *AM* 62:547(1977). Infusible, unattacked by acids. Analysis (wt %): MgO, 2.4–14.0; FeO, 1.1–18.5; traces of Mn, Ca; Fe₂O₃ is always very low (< 0.9 wt %), Fe²/Fe³ \approx 1:1 to 3:1, the only substitutions are Fe²⁺ \leftrightarrow Mg and Al \leftrightarrow Fe³⁺; X_{Mg} range is 0.98–0.19. Thus there are two end members: grandidierite-(Fe) and grandidierite-(Mg). Biaxial (–); XYZ parallel to *acb*; N values vary with Fe/Mg ratio: N_x = 1.587–1.602, N_y = 1.618–1.636, N_z = 1.622–1.639; $2V = 27\text{--}32^\circ$; X > Z > Y or Z > X > Y; OAP parallel to (001); r > v, moderate to strong, with some r < v. X, pale blue to blue; Y, colorless to yellow-brown; Z, very pale blue to blue-green or deep blue; iron-rich grandidierite is deeper colored. Most grandidierite occurs in ancient metamorphic terranes, in pelitic gneisses and quartzite. Also occurs in aluminous metasedimentary xenoliths in acid volcanics as well as in pegmatites. In hornfels close to intrusions: low pressure, high temperature (>600°). Stable, coexisting grandidierite–kornepupine assemblage requires high pressure and high temperature. Occurs at somewhat more than 25 worldwide localities: it occurs replacing serendibite at Russell, NY [*MM* 54:133(1990)]; with kornepupine at Opinicon Lake, southeastern ONT, and at Morton and Brewer’s Mills, ONT, Canada; Haddo House complex, northeastern Scotland; iron-rich material associated with Ti-rich dumortierite, and tourmaline at Almjotheia, 12 km N of Moi, Rogaland, and Vestpolltind, southwestern Norway; Nickenicher Sattel, Eifel, Germany;

Mount Amiata, Tuscany, and Mount Cimino, Latium, Italy; a locality in Hungary; Transbaikalia, Russia; Tizi-Ouchen, Bejaia, Algeria; Zimbabwe; Lukusuzi R. area, eastern province, Zambia; Mchinji, Malawi; with werdinite and kornerupine at Bok Se Puts, Namaqualand, and at Port Shepstone, Natal, South Africa; in cordierite and garnet in gneisses at Ihosy, southern Madagascar; also at *Fort Dauphin area, Andrahomana*; Sakatelo, Ampamatoa, Vohiboly, Sahakondro, and other localities, Madagascar; at Paderu, Vishakhapatnam district, Andhra Pradesh, India; Blanket Bay and Landing Bay, Cuvier Island, New Zealand; Maratakka, Surinam; with kornerupine at McCarthy Point and Seal Cove, Larsemann Hills, Prydz Bay, eastern Antarctica. EF *MM* 43:651(1980), 54:131(1990), 59:327(1995); *NJBA* 143:249(1982); *CMP* 98:502(1988); *AM* 75:415(1990).

54.1.2.1 Dumortierite $(\text{Al,Fe}^{3+})_7(\text{BO}_3)(\text{SiO}_4)_3\text{O}_3$ (anhydrous) and $(\text{Al}_{6.75}\square_{0.25})\text{BSi}_3[\text{O}_{17.25}(\text{OH})_{0.75}]$ (hydrous)

Named in 1881 by Gonnard and named for Vincent Eugene Dumortier (1802–1873), French paleontologist, Lyons, France. See the closely related mineral holtite (54.1.3.1). ORTH *Pmcn*. $a = 11.77\text{--}11.82$, $b = 20.18\text{--}20.25$, $c = 4.70\text{--}4.71$, $Z = 4$, $D = 3.39$. 7-71: 5.89₉, 5.84₉, 5.09₉, 3.45₇₅, 3.23₈₅, 2.93₉, 2.89₇, 2.55₁₀. Structure: *NJBA* 132:231(1978). Generally occurs as fibrous to fan-shaped radiating aggregates to >5 cm long. Acicular on c , prismatic, usually massive columnar, fibrous. Dominant forms are: {100}, {010}, {110}, {130}. May show lamellar twinning with (001) as the twin plane; also twinned on (110). Usually pink-red or blue-purple violet, but sometimes brown or greenish; white or bluish-white streak; vitreous to dull luster, sometimes silky. Cleavage {100}, distinct; {110}, imperfect; brittle. $H = 7\text{--}8$. $G = 3.25\text{--}3.41$ (high Fe). IR data and synthetic material: *CMP* 105:11(1990). Insoluble in all acids except HF. Sometimes luminescent bright blue under electron microprobe beam (e.g., Ti-bearing material from Zambia). Sometimes fluorescent blue in SWUV light. MgO to 8 wt % in dumortierite from the western Alps [see magnesioidumortierite (54.1.2.2)]. P₂O₅ to 0.5 wt %, Fe₂O₃ to 1.5 wt %, CaO to 1.0 wt %, TiO₂ to >4.6 wt %; As₂O₅ to 1.67 wt %, from Sri Lanka. The color variation (pink to blue) is possibly due to the relative concentrations of Ti and Fe and/or charge-transfer processes. Optics are variable. Biaxial (-); XYZ = cba ; $N_x = 1.659\text{--}1.686$, $N_y = 1.684\text{--}1.722$, $N_z = 1.683\text{--}1.723$; $2V = 13\text{--}52^\circ$. OAP generally parallel to (010); however, in material from Kutna Hora, Czech Republic, Riverside, CA, and Madya Pradesh, India, the OAP is (100), not (010). The pleochroic scheme is quite variable and is not due to just the variation in TiO₂ content. Examples are: X, deep blue; Y, yellow; Z, colorless; X, pink, Y, colorless, Z, colorless; X, deep purple; Y, light tan; Z, colorless. Negative elongation. Dispersion is $r < v$, medium to $r > v$, weak. A minor to major constituent in pegmatitic, aplitic, and granitic rocks. Also occurs in pneumatolytic–hydrothermal deposits and regional metamorphosed quartzites, gneisses, and granulites; in Al-rich metamorphic rocks; and in high-pressure metamorphic rocks (e.g., Alps). May alter to muscovite–ser-

icite, kaolinite; also may form pseudomorphs after andalusite. Only selected major localities are given here: Topsham and Woolwich, Sagadahoc Co., ME; Fremont Co., CO; Petaca, Rio Arriba, Co., NM., Clip, near Yuma and Quartzsite, La Paz Co., AZ; Ruby Range, east of Dillon, MT; in large quantities in Gypsy Queen Canyon, Oreana, Humboldt Co., NV; Lincoln Hill, Rochester district, Pershing Co., NV; Woodstock, WA; Corona, Riverside Co., CA; Dehesa, San Diego Co., CA; also from near Ogilby, in Imperial and Kern Cos., CA; Ashby Twp., Addington and Lennox Cos., ONT, Canada; Land's End, Cornwall, England; Aberdeen, Scotland; Mg-bearing from Bamble sector, southern Norway; with Fe-rich grandidierite at Almjotheia, Moi, Rogaland, southwestern Norway; Tvedestrand, Augst-Agder, Norway; *Beau-nan, Chaponost, near Lyon, Rhône, France*; Malsburg, Schwarzwald, Germany; in pegmatite to 5 cm long from Kank, near Kutna Hora, Czech Republic; Wolfschau, Silesia, Poland; Yelshits, Bulgaria; Mursinka, Ural Mts., Aldan and Tazhno regions, Yakutia, and Mt. Zhanet in Kounrad region of north-western Pribaikal, Russia; Lyailiyok R., Uzbekistan; Erong Mtns., Namibia, blue lapidary-quality titanian dumortierite occurs at the farm N'Rougas Suid, near Kenhardt, northern Cape Prov., South Africa; Soavina and Riamfotsi near Tananarive, and Saharina Madagascar; Nabikura mine, Yamaguchi Pref., Japan; Jaipur, Rajasthan, and Mogra Bhandara, India; Nacozari, SON, Mexico; Serra da Verada, Makoba, and Bokira, Bahia, Brazil (to 10 cm). Used as insulators and ceramics and sometimes for gemstones (cabochons). *EF MIN 3(1):329(1972)*, *NJBM:22(1979)*, *NJBA 143:249(1982)*, *AM 71:786(1986)*, *MM 55:563(1991)*, *CM 30:137(1993)*.

54.1.2.2 Magnesiodumortierite [(Mg,Ti,□)Al₄(Al,Mg)₂][Si(Si)₂O₁₅(OH)₃]B

Named in 1995 by Ferraris et al. for the compositional relationship to dumortierite. ORTH *Pmcn*. $a = 11.91$, $b = 20.40$, $c = 4.730$, $Z = 4$, $D = 3.22$. *PD(nat)*: 5.91₉ 3.47₇ 3.25₁₀ 3.09₅ 2.915₆ 2.105₉ 1.69₆ 1.345₆. *EJM 7:525(1995)*. $R = 3.1\%$. Mg is the dominant cation in the single chain of face-sharing M1 octahedra, where Ti and vacant sites are also present. With respect to dumortierite, some substitution of Al also takes place in the second face-sharing octahedron M4, but not in M3 and M2, which only share corners and edges. Occurs as mostly anhedral grains a few tens to 300 μm across. Pink to red, vitreous luster, transparent. Streak, hardness, and density could not be measured. H should be between 7 and 8. Analysis (wt %): SiO₂, 31.7; P₂O₅, 0.07; Al₂O₃, 47.3; TiO₂, 4.3; ZrO₂, 0.06; FeO, 0.09; MgO, 7.8; B₂O₃, 5.1; H₂O, 3.5. The mineral varies in composition from the Ti-free end member (Mg_{1-x},□_x)Al₂Al₄Si₃O_{17-2x}(OH)_{1+2x}B ($x \approx 0.33$) toward (Mg_{0.33}, Ti_{0.33},□_{0.33})(Al_{0.5}Mg_{0.5})₂Al₄Si₃O₁₆(OH)₂B. Biaxial (-); $X = c$; probably with $YZ = ba$; *Na(D)*: $N_x = 1.678$, $N_y = 1.700$, $N_z = 1.701$; $2V = 38.5^\circ$; $X \gg Y = Z$. X, pale pink to red; Y,Z, colorless. Color is due to Fe²⁺ → Ti⁴⁺ charge transfer. Occurs as rare inclusions in pyrope megablasts

with other magnesian minerals, such as talc, clinocllore, ellenbergerite, and kyanite in a coesite-bearing quartz-phengite-rich "white schist" within a high-pressure terrane, the *Dora-Maira massif in the western Alps, Italy*; specifically at San Giacomo near Brossasco in Val Varaita and Case Romello near Parigi (Martiniana Po) in Val Po. *EF EJM 7:167(1995)*.

54.1.3.1 Holtite (Si,Sb,As)₃B[Al₆(Al,Ta,□)O₁₅(O,OH)₂25]

Formula *MM 53:457(1989)* and (Ta,Nb,Sb,Al,Fe,Mn,Mg,Ca) Al_{6-n}{[Al,As]_k Si_{1-k}} O₄]₃ [B_{1-m}O₃][O,OH]₂₋₃, where $m+n < 1$, $k = (m+n)/3$ [*ZVMO 106:337 (1977)*] Named by Pryce in 1971 for Harold Edward Holt (1908–1967), prime minister of Australia. See dumortierite (54.1.2.1), a very closely related borosilicate. *ORTH Pnma*. $a = 4.691$, $b = 11.896$, $c = 20.383$, $Z = 4$. *MM 53:457(1989)*. *25-1209(nat)* [*MM 38:21(1971)*]: 10.3₁₀ 5.93₃ 5.89₃ 5.12₂ 5.08₃ 2.94₄ 2.36₂ 2.34₂; *ZVMO 106(3):337(1977)*: 10.26₁₀ 5.13₉, 4.27₅, 3.90₇ 3.46₆ 3.34₅, 3.23₈ 2.09₇. The structure is closely related to dumortierite but with extensive substitutions of Si by Sb in holtite. *MM 53:457(1989)*. Weak spots appear to indicate a supercell with $2a$, $2b$, c . *MM 38:21(1971)*. Fibrous, acicular prisms, pseudo-hexagonal; crystals to 3 cm × 0.8 cm; multiple twinning on {110}. Pale brownish white to brown, greenish gray, buff; vitreous to resinous or dull luster. Cleavage {010}, distinct. $H = 8\frac{1}{2}$. $G = 3.90$ (Australia) and 3.60–3.67 (Kola Peninsula). IR, DTA, TGA data: *ZVMO 106(3):337(1977)*. Fluoresces dull orange under SWUV and bright yellow in LWUV. X-ray diffraction data unchanged after heating to 1000°. Two types of holtite have been distinguished from the Kola Peninsula: holtite-I: Al₂O₃ ≈ 48%, Sb₂O₅ ≈ 7%, Ta₂O₅ ≈ 14%, Nb₂O₅ ≈ 0.2%, SiO₂ ≈ 22%, As₂O₅ ≈ 3.5%; holtite-II: Al₂O₃ = 47%, Sb₂O₅ = 20%, Ta₂O₅ ≈ 11%, Nb₂O₅ ≈ 0.2%, SiO₂ = 17.5%, As₂O₅ ≈ 2.5%. Australian material is chemically similar but with B₂O₃ = 4–5%. Biaxial (–); $X = c$, OAP = {010}; $N_x = 1.705$ –1.709 (Kola), 1.743–1.746 (Australia), $N_y = 1.728$ –1.729 (Kola), 1.756–1.759 (Australia), $N_z = 1.730$ –1.737 (Kola), 1.758–1.761 (Australia); $2V = 49$ –55° (Australia) and $2V = 20$ –30° (Kola); $r < v$. (Australia): X, shades of yellow; Y, colorless; Z, colorless. Kola holtite is nonpleochroic. Occurs in granitic pegmatites and as an alluvial mineral from pegmatites. In pollucite-bearing complex granitic pegmatites associated with albite, lepidolite, zircon, rubellite, and amblygonite. At Greenbushes as coatings on stibiotantalite and replacing tantalite. Voronyi Tundra area and Ploskogorskaya (Flat Mountain) pegmatite, Keivy, Kola Penin., Russia; *Bunbury Gully, Greenbushes, West Australia*. *EF*

DATOLITE–GADOLINITE GROUP

The datolite–gadolinite group consists of nine members plus additional species which are related but only partially accepted as members of the group. The general formula is

where

A = REE, Ca, Bi

B = Fe²⁺, Fe³⁺, Mn, Ca, □

C = Be, B

T = Si, P, As

X = O, OH, F

DATOLITE: CaBSiO₄OH

Datolite has sheets of alternating Si and B tetrahedra, with Ca in between layers. The sheets are composed of four- and eight-membered rings. The OH atoms are at the apices of the B tetrahedra.

DATOLITE-GADOLINITE GROUP

Mineral	Formula	Space Group	Crystallographic Parameters				β

The structure of gadolinite and minerals isostructural with gadolinite can be described in terms of a sheet structure built up from alternating SiO_4 and BeO_4 (or BO_4) tetrahedra. The sheet extends parallel to the (001) plane at $Z=0.5$. The rare earth and iron atoms are located at $Z=0$, and connect the sheets. The silicon atom exhibits the usual tetrahedral coordination by four oxygen atoms, O(1), O(2), O(3), and O(4). Similarly, the Be or B atom is tetrahedrally coordinated by four oxygen atoms, O(2), O(3), O(4), and O(5). These tetrahedra make corner-sharing linkages at O(2), O(3), and O(4) sites to form the sheet structure. The structure of datolite can be derived from that of gadolinite simply by replacing Be with B, Y with Ca, and O with OH. The iron site at (0,0,0) is empty in datolite. The structure of herderite is isotopic with that of datolite (*AM 69:948(1984)*).

54.2.1a.1 Datolite $\text{CaBSiO}_4(\text{OH})$ or $\text{Ca}_2(\square)\text{B}_2\text{Si}_2\text{O}_8(\text{OH})_2$

Named in 1806 by Esmark from the Greek *to divide*, in allusion to the granular character of some of its varieties. Datolite-gadolinite group. MON $P2_1/a$. $a = 9.620-9.636$, $b = 7.600-7.610$, $c = 4.820-4.835$, $\beta = 90.08-90.40^\circ$, $Z = 2$ (for 10 oxygen atoms), $D = 3.00$. *36-429(nat)*: 3.755_5 3.40_7 3.12_{10} 2.86_7 2.52_5 2.25_3 2.19_3 1.88_5 . Structure: *AM 58:909(1973)*. Generally platy to short, prismatic; crystals to 14cm in length, also equant, may occur as spherical aggregates or as massive, granular to compact and cryptocrystalline masses; dominant forms are {011} and {110}; sometimes tabular parallel to (102). Colorless, white, gray, yellowish, green, pale pink, bluish white, greenish white; white streak; vitreous to greasy luster. Cleavage (001), imperfect; uneven to conchoidal fracture; brittle. $H = 5-5\frac{1}{2}$. $G = 2.90-3.0$. Sometimes shows blue or white luminescence in SW UV. Partly soluble in HCl, HNO_3 , and H_2SO_4 . May have some MgO (to 1.3 wt %), FeO (to 0.8%), Al_2O_3 (to 0.5%), Na_2O (to 0.2%). Biaxial (-); $Y = b$, $X \wedge c = 1^\circ$, $Z \wedge a = 1-3^\circ$; $N_x = 1.623-1.626$, $N_y = 1.650-1.654$, $N_z = 1.667-1.670$; $2V = 74^\circ$; $r > v$,

weak. Occurs as a hydrothermal, postvolcanic mineral in veins and cavities in basic rocks. Often associated with calcite, prehnite, and zeolites. Also associated with danburite; in gneiss, diorite, serpentine, and other rock types. Sometimes in beds of iron ores. Occurs associated with diabase of Connecticut River valley, as at Westfield, Hampden Co., MA; in CT in Hartford Co., in large crystals at Tariffville and from near Hartford; at Meriden, New Haven Co. In New Jersey in the amygdaloidal basalts of Bergen Hill, Great Notch, Essex Co., Paterson, and Prospect Park, Passaic Co., and elsewhere, in splendid crystals and associated with various zeolites. At the Goose Creek Quarry, near Icesburg, Loudon Co., VA. Occurs in both crystalline and compact opaque varieties associated with the Keweenaw Basalts of the Michigan copper district, Keweenaw Co., MI. Clear Creek, San Benito Co., and along the Russian River, Mendocino Or., CA. Occurs at Fifeshire, Scotland; found at Andreasberg, Harz Mts., Germany, in diabase and in veins of silver ore, and at Haslach, Black Forest. From the Alpe di Siusi, Trentino; on the Seiser Alpe (Mont da Sous) and at Tiso (Theiss) northeast of Chiusa (Klausen); in geodes in amygdaloidal basalt; in granite at Baveno, Lake Maggiore; at Toggiano near Modena, Italy, in serpentine and from Serra del Zanchetti in the Apennines near Bologna in highly complex crystals. A datolite hornfels occurs at Repiste near Paskov, and veins of datolite occur at Zermanice Dam, northern Moravia, Czech Republic. Occurs at Arendal and Utø in Aust-Agder, Norway, in a bed of magnetite; fine pale blue to green crystals from Dalnegorsk, Primorsky Krai, Russia; Wessels mine, Kalahari Mn field, Cape Prov., South Africa. Fine crystals from Charcas, San Luis Potosi, Mexico; Rosebery, Montagu Co., Tasmania; Iwato Mine, Miyazaki Pref., Japan. Sometimes used as precious stone. EF

54.2.1a.2 Hingganite-(Ce) $(\text{Ce}, \text{Y})_2(\square, \text{Fe}^{2+})\text{Be}_2\text{Si}_2\text{O}_8(\text{OH}, \text{O})_2$

Named in 1987 by Miyawaki *et al.* Datolite-gadolinite group. See hingganite-(Y) (54.2.1a.3) and hingganite-(Yb) (54.2.1a.4). MON $P2_1/a$. $a = 9.996$, $b = 7.705$, $c = 4.792$, $\beta = 90.06^\circ$, $Z = 2$, $D = 4.66$. $40-1452(\text{nat})$: 6.09_5 4.80_{75} 3.16_{10} 2.87_{75} 2.58_{75} 2.565_{75} 1.99_8 . Structure is like that of gadolinite. However, the octahedral Fe site is empty or nearly so. One of the corners of the BeO_4 tetrahedra is mainly occupied by (OH) in hingganite. Idiomorphic crystals, 1–5 mm long. Light red brown. Analysis (wt %): FeO, 5.65; Y_2O_3 , 10.9; La_2O_3 , Ce_2O_3 , 16.77; Pr_2O_3 , 3.5; Nd_2O_3 , 9.79; Sm_2O_3 , 4.70; Gd_2O_3 , 4.18; Tb_2O_3 , 0.5; Dy_2O_3 , 3.82; Ho_2O_3 , 1.08; Er_2O_3 , 1.84; Yb_2O_3 , 1.00; Lu_2O_3 , 0.3; CaO, 0.39; BeO, 9.27; SiO_2 , 22.27; H_2O , 1.9. Occurs in pegmatite (drusy) associated with quartz, feldspar, mica, SnO_2 , stokesite CaF_2 , and so on. Occurs in the *Iwaguro Sekizai quarry, Tahara area, Hirukawa, Ena, Gifu Pref., Japan*. EF KZ 18:17(1987), AM 75:432(1990).

54.2.1a.3 Hingganite-(Y) $Y_2(\square)Be_2Si_2O_8(OH)_2$ or $(Y,Ce)_2(\square,Fe)_2Be_2Si_2O_8(OH)_2$

Named in 1983 by Xiaoshi *et al.* for the locality. Datolite-gadolinite group. Synonyms: yttroceberysite [*GRC 27:459(1981)*], and yberisilite *CCCM(1972)*. MON $P2_1/a$. AMS 5:289(1985). (Nat): $a = 9.895-9.930$, $b = 7.606-7.676$, $c = 4.733-4.768$, $\beta = 90.17-90.35^\circ$, $Z = 2$; 26-812(syn): $a = 9.861$, $b = 7.605$, $c = 4.720$, $\beta = 89.65^\circ$, $D = 4.53-4.72$. 26-812(syn): 3.12₈ 3.11₈ 2.84₁₀ 2.55₅ 2.54₅ 2.20₃ 2.19₃ 1.97₃. Structure is like that of gadolinite. AMS 5:289(1985), *CM 30:127(1993)*. Vacancy exists for the divalent cation site. Subhedral grains 0.1-0.2 mm, crystals to 1 mm long and fan to sheaflike aggregates to 2 mm from Zomba, Malawi; a few are stout prisms; forms developed: {011}, {111}, minor {100}. Milky white, colorless, light yellow or light green, pale blue and pale rose; white streak; vitreous to greasy luster. Uneven fracture. $H = 5-5\frac{1}{2}$, 4.08-4.57 (China). Biaxial (+); $Z \wedge c = 6-13^\circ$ in acute β , $Y = b$, $X \wedge a = 14^\circ$; $N_x = 1.744-1.748$, $N_y = 1.752-1.765$, $N_z = 1.765-1.783$; colorless; $2V = 80^\circ$; $r < v$ strong. Generally in agpaitic granitic pegmatites. Occurs in druse pegmatite with quartz, feldspar, mica, cassiterite, stokesite, fluorite, chlorite, and titanite in Japan; in a Be- and REE-bearing granophyre in Manchuria, China; in amazonite pegmatite on Kola Penin., Russia, in granite pegmatite in albitized part with muscovite, spodumene, and pyrochlore. Occurs at Trimouns, Ariège, France; Glogstafelberg, Val Formazza, Switzerland; Saga, Tvedalen, and Høydalen, Tørdal, Langesundfjord, Norway; Tuva, and Ploskogorskaya, Kola Penin., Russia; Heilongjiang, and greater Khingan area, Manchuria, China; Tahara area, Hirukawa-mura, Enagun, Gifu Pref., Japan; Zomba-Malosa complex, southern Malawi. EF *SPC 8:539(1964)*, *AM 59:700(1974)*, *DAN SSSR 270:1188(1983)*, *KZ 18:17(1987)*, *NJBM:185(1994)*.

54.2.1a.4 Hingganite-(Yb) $(Yb,Y)_2(\square)Be_2Si_2O_8(OH)_2$

Named in 1983 by Voloshin *et al.* for the relation to hingganite. Datolite-gadolinite group. MON $P2_1/a$. $a = 9.888$, $b = 7.607$, $c = 4.740$, $\beta = 90.45^\circ$, $Z = 2$, $D = 4.83$. 35-705(nat): 6.06₇, 4.76₆, 3.74₆, 3.45₆, 3.13₁₀ 2.85₁₀ 2.57₈ 2.54₈. Spherical aggregates of fine acicular crystals to 2 mm long, 0.1-0.2 mm wide. Colorless, vitreous luster, transparent. No cleavage. $H = 6-7$. IR data: *DAN SSSR 270:1188(1983)*. Analysis (wt %): Y_2O_3 , 8.56; Yb_2O_3 , 34.07; Gr_2O_3 , 8.22; Dy_2O_3 , 2.47; Lu_2O_3 , 4.50; Tm_2O_3 , 3.10; Ho_2O_3 , 1.03; CaO, 1.14; SiO_2 22.11; BeO, 10.90; H_2O , 3.74. Biaxial (+); $Z \wedge c = 23^\circ$, $X \wedge c = 20^\circ$; $N_x = 1.725$, $N_y = 1.738$, $N_z = 1.760$; $2V = 65^\circ$. OAP = (010). Occurs in an amazonite pegmatite on plumbomicrolite and violet fluorite, as a product of very late stage replacement reactions. *Ploskogorskaya, Keivy district, Kola Penin., Russia*. EF *K 28:457(1983)*.

54.2.1b.1 Bakerite $Ca_4B_5Si_3O_{15}(OH)_5$

Named in 1903 by Giles for Richard C. Baker (1858-1937), Nutfield, Surrey, one of the managing directors of Borax Consolidated Ltd. Baker provided

Giles with the material. Datolite-gadolinite group. MON $P2_1/a$. $a = 9.533-9.610$, $b = 7.569-7.596$, $c = 4.794-4.814$, $\beta = 90.00-90.41^\circ$, $Z = 1$, $D = 2.94-2.99$. *36-428(nat)*: 3.72_5 3.10_{10} 3.08_6 2.97_5 2.84_{10} 2.49_5 2.23_7 2.17_5 ; *MJJ 17:111(1994)*: 3.75_5 3.40_3 3.11_{10} 2.98_5 2.85_8 2.52_4 2.24_4 2.18_4 . The latter data while reported for bakerite are most likely from datalite. The structure has not been determined in detail. Usually massive but crystals to 0.2 mm occur as short rhombic prisms with oblique terminations or as thin diamond-shaped tablets; dominant forms are {111}, {100}, {210}, and less commonly {011}. Gray to white, colorless, sometimes greenish white, may contain clay inclusions; white streak; vitreous to porcelaneous or dull luster. No cleavage. $H = 4\frac{1}{2}$. $G = 2.88$. DTA, TG, and IR: *MJJ 17:111(1994)*. Readily soluble in hot dilute HCl. In bakerite $\text{SiO}_2/\text{B}_2\text{O}_3=1.0$. Formula also given as: $\text{Ca}_4\text{B}_4(\text{BO}_4)(\text{SiO}_4)_3(\text{OH})_3\text{H}_2\text{O}$. Biaxial (-); $Y = b$, $2V_{\text{OBS}}$ and $2V_{\text{calc}}$, $Z \wedge c = 44^\circ$; $N_x = 1.623-1.626$, $N_y = 1.635-1.648$, $N_z = 1.654-1.658$; $2V = 67^\circ$; various authors report higher $2V$'s and also optically (-), however, calculated signs is always (+)! birefringence = 0.03; negative elongation. A low-temperature hydrothermal mineral. Occurs as irregular veins in altered volcanic rocks (Inyo and Los Angeles Cos., CA); in thin veins in diabase spilite (Turkey); in slag heaps of old Fe and Cu mines (Italy); also in skarns as a vein-forming mineral (Japan). Occurs with datolite at the Sterling borax mine, Tick Canyon, Los Angeles Co., Corkscrew Canyon, Black Mts. W of *Furnace Creek District, Death Valley, Inyo Co., CA*; either bakerite or datolite occurs at Tory Hill, Bancroft, ON, Canada; Charcas, SLP, Mexico; Sivas, Golcuk Plateau, Turkey; with fluorapophyllite in veins in limestone at Fuka, Okayama Pref., Japan. *EF DII:363(1951)*; *AM 41:689(1956)*, *47:919(1962)*, *56:1109(1971)*; *MIN 3(1):395(1972)*; *RI (2):67(1985)*.

54.2.1b.2 Gadolinite-(Ce) $(\text{Ce},\text{La},\text{Nd},\text{Y})_2\text{Fe}^{2+}\text{Be}_2\text{Si}_2\text{O}_{10}$

Named in 1978 for Johan Gadolin (1760-1852), Finnish chemist and discoverer of yttrium. Datolite-gadolinite group. The Ce-dominant analog of gadolinite-(Y). MON $P2_1/a$. $a = 10.01$, $b = 7.58$, $c = 4.82$, $\beta = 90.78^\circ$, $Z = 2$, $D = 4.90$. *29-1408*, *29-1409(heated)(nat)*: 4.81_9 3.59_6 3.18_7 3.17_6 3.00_7 2.88_{10} 2.60_8 2.59_8 . Some is metamict. Irregular masses to 20 mm diameter (Norway). Black, vitreous luster. Conchoidal fracture. $G = 4.20-4.22$ (metamict, Norway). Norwegian material is chemically zoned, with higher LREE contents on the rims. Biaxial; $N_y = 1.78$. Norwegian material is olive-green. Occurs in alkalic pegmatites and alkalic granites. Pale blue nonmetamict material occurs at Liberty Bell Mountain, WA; near *Skien, Bjerkedalen valley, SW Oslo region*, Bakken quarry, Tvedalen, and Fyresdal, Telemarken, *Norway*. *EF AM 63:188(1978)*.

54.2.1b.3 Gadolinite-(Y) $\text{Y}_2\text{Fe}^{2+}\text{Be}_2\text{Si}_2\text{O}_{10}$

Named in 1800 by Klaproth for J. Gadolin (1760-1852), Finnish chemist, who first separated yttrium in 1794. Datolite-gadolinite group. MON $P2_1/a$. (Nat): $a = 10.000$, $b = 7.565$, $c = 4.768$, $\beta = 90.31^\circ$, $Z = 2$ [*AM 69:948{1984}*] and

$a = 9.900\text{--}9.970$, $b = 7.510\text{--}7.598$, $c = 4.737\text{--}4.759$, $\beta = 90.41\text{--}90.79^\circ$ (for 12 Alpine samples); (syn): $a = 9.920$, $b = 7.484$, $c = 4.747$, $\beta = 90.40^\circ$ (26-1134), $D = 4.41$. See also 22-990, 22-991. *AM 69:948(1984)(nat)*: 4.78₆ 3.14₇ 3.06₃ 2.97₅ 2.85₉ 2.84₁₀ 2.58₄ 2.56₅; 26-1134(syn): 4.74₈ 3.12₅ 3.11₅ 2.93₇ 2.82₁₀ 2.81₁₀ 2.56₆ 2.54₆. Some vacancy exists at the Fe²⁺ site. Have OH for O to compensate for the lack of (+) charge at the Fe site. REE_{2.00}Fe²⁺Be_{2.00}Si_{2.00}O_{9.72}(OH)_{0.28}. Sheets parallel to (001) plane, which is formed by corner-sharing linkages of SiO₄ and BeO₄ tetrahedra. The two REE atoms are situated between the eight-membered rings of the tetrahedra to form eight-coordinated square antiprisms. The Fe atoms are at the origins of the unit cells. *AM 69:948(1984)*, *CM 30:127(1993)*. Most common forms are {100}, {001}, {110}, {120}, {011}, prismatic or rough crystals to >20 cm, commonly in compact masses; often metamict or partly so; radioactive, contains U and Th. Pale green, green, blue-green when fresh, unaltered, and nonmetamict; black or red-brown when partly altered and metamict; greenish-gray streak; vitreous to greasy luster. No or very poor cleavage on {100}, conchoidal to splintery fracture, brittle. $H = 6\frac{1}{2}\text{--}7$. $G = 4.21\text{--}4.77$, 4.33(syn), 3.42(metamict), 4.77(fresh). IR data: *MIN 3(1):403(1972)*. Gelatinizes in acids, especially if metamict; dissolves with difficulty upon heating in HCl. Magnetic properties: *MZ 6:64(1984)*. B or Be substitution for Si is very small or non-existent. In fresh material, all Fe is Fe²⁺, and FeO >> Fe₂O₃. Ca substitutes for Fe²⁺ usually 1–2 wt % CaO, as much as 4% CaO. B substitutes for Be (as much as 4.2% and possibly 5.0% B₂O₃). Also (OH) substitutes for O. ThO₂ to >3%. One gadolinite from Kragerø (Lind Vikskollen), Norway, has about 7% CaO and 5% FeO. Metamict varieties may have several wt % each of UO₂ and ThO₂. *MIN 3(1):403(1972)*. Biaxial (+); N_y parallel to b; X \wedge c = 3–12°, Z \wedge a = 3–12°; N_x = 1.665–1.82, N_y = 1.774–1.812, N_z = 1.787–1.824; 2V = 80–85°; rarely biaxial (–), 2V = 85°; r < v; OAP = (010). X, olive; Y, Z, green in nonmetamict material, also brownish green to greenish brown. Occurs most often in alkalic granitic pegmatites or granites. Also occurs in alpine-type veins. Associated with other REE minerals and F-bearing minerals. Often partly or completely metamict. Occurs at many worldwide localities; only noteworthy localities are mentioned here. Masses to 95 kg at the Baringer Hill and Rhode Ranch pegmatites, Llano Co., TX; White Cloud mine, South Platte district, Jefferson Co., and Devils Head, Douglas Co., CO; near Kingman, Mohave Co., AZ; Golden Horn Batholith, WA; Loughborough Twp., Frontenac Co., ONT, Canada; in at least 15 locations in Sweden: Ytterby, and at Kopparberg, Brodbø, Finbo, and Korarfvet near Falun. Segregations to 500 kg from Frikstad, Iveland; nonmetamict material from Hundholmen, Tysfjord; at Hitterø and Sättersdal, Vest Agder; and Bidjovagge, Finnmark, Norway. Lovbole, Kimito, Finland. Fresh and unaltered material at several localities in the Swiss Alps: Val Vigezzo (Ossola), Rauris Valley, and Markogen pegmatite near Villach; Piz Blas, Val Nalps, Graubünden, Switzerland; Baveno, Italy; Radautal, Harz, Germany; Shklvarska-Poroma, Poland; western Keivy and Kanozero, Kola Penin., Russia. Occurs in at least 10 localities in Japan (e.g., nonmetamict material from Miyazuma, Yok-

kaichi; Takehinata, Kohu City, Yamanashi Pref.; Fusamata, Aichi Pref.; Hazumachi; Shinden, and Kurokawa, Gifu Pref.). Alto Ligonha, Mozambique. EF *AM 59:700(1974)*, *MIN 3(1):403(1972)*.

54.2.1b.4 Calciogadolinite $\text{CaREE}(\text{Fe}^{3+})\text{Be}_2\text{Si}_2\text{O}_{10}$

The name is not approved by the CNMN IMA. Datolite–gadolinite group. MON $P2_1/a$. $a = 9.988$, $b = 7.566$, $c = 4.696$, $\beta = 90.00^\circ$ for synthetic material. *AM 59:700(1967)*; $a=9.97$, $b=7.56$, $c=4.69$, $\beta=90.0^\circ$ (*CCCM1:1972*) $Z=2$. General formula: $(\text{REE}_{2-x}\text{Ca}_x)(\text{Fe}_{1-x}^{2+}\text{Fe}_x^{3+})\text{Be}_2\text{Si}_2\text{O}_{10}$ *AM 63:188(1978)*. Tadati (Tadachi) village, Nagano Pref., Japan [*CSJB 13:591(1938)*]; possible calciogadolinite with B site (Fe site) partially vacant, from Lindvikskollen, Kragerø, Norway. EF *NGT 52:197(1972)*.

54.2.1b.5 Homilite $\text{Ca}_2(\text{Fe,Mg,Mn})\text{B}_2\text{Si}_2\text{O}_{10}$

Named in 1876 by Paikjull from the Greek for *to occur together*, in allusion to its association with meliphanite. Datolite–gadolinite group. See other members of the group. MON $P2_1/a$. *AC(C) 41:13(1985)*: $a = 9.786$, $b = 7.621$, $c = 4.776$, $\beta = 90.61^\circ$, $Z = 2$, $D = 3.45$; *36-430*: $a = 9.787$, $b = 7.614$, $c = 4.780$, $\beta = 90.56^\circ$. *36-430(nat)*: 3.13_3 3.11_{10} 2.98_7 2.86_6 2.85_5 2.55_9 2.53_4 2.19_3 . The structure may be derived from datolite by placing the Fe atom in the octahedral vacancy and by charge-compensation replacement of OH^- with O^{2-} . Common forms are {001}, {100}, {110}, {210}, and {011}; often tabular parallel to c (001) or octahedral; largest crystal was ≈ 2 in. long, another weighed 50 g; twinning on (001), also on (100) and (032). Pale green, black, blackish brown; gray-white streak; resinous–vitreous luster. Distinct cleavage not developed, poor to conchoidal fracture, brittle. $H = 5$. $G = 3.28$ – 3.38 . IR data: *AM 59:700(1974)*. Readily soluble in common acids. Analysis (wt %): Na_2O , ≈ 1 ; MgO , to 0.5; Al_2O_3 , to 2.7; REE_2O_3 , to 2.5; and so on. Biaxial (+); $Z = b$, Y nearly parallel to c ($Z \wedge c = 1$ – 4° , Brogger); $N_x = 1.710$ – 1.715 , $N_y = 1.717$ – 1.725 , $N_z = 1.728$ – 1.738 ; $2V = 76$ – 80° ; $Y > X > Z$; $r > v$, distinct; OAP perpendicular to (010); strong horizontal dispersion of the bisectrix. X , bluish green; Y , medium brownish red to brownish gray; Z , smoky gray to brownish yellow. Occurs in veins in augite Ne syenite with meliphanite and also zircon, titanite, lollingite, and others. Alteration: altered material may be isotropic or anisotropic with variable optical properties. Occurs on the island of Stoko and on neighboring islands (e.g., Arø) near Brevik, Lange-sundfjord, Telemark Co., Norway. EF *GFSF 3:229(1876)*, *DS 6:505(1920)*, *MIN 3(1):399(1972)*.

54.2.1b.6 Minasgeraisite-(Y) $(\text{Y,Bi})_2\text{CaBe}_2\text{Si}_2\text{O}_{10}$

Named in 1986 by Foord *et al.* for the locality. Datolite–gadolinite group. MON $P2_1/a$. $a = 9.833$, $b = 7.562$, $c = 4.702$, $\beta = 90.46^\circ$, $Z = 2$ [*AM 71:603(1986)*], $D = 4.90$ (end member) and 4.29 (observed composition). *39-344(nat)*: 5.99_3 3.71_3 3.41_3 3.11_{10} 2.83_{10} 2.54_9 2.25_3 2.19_3 . The structure is of the gadolinite-type. Single and multiple rosettes, curved sheaves; individual crystals are 3–5

μm across, 0.2–1.0 mm across as single and multiple rosettes. Pale to medium purple, pale purple streak, earthy to subvitreous luster. One excellent cleavage, probably {100}; a second good cleavage, {001}. $H = 6\text{--}7$. $G > 4.25$. Nonfluorescent under either SWUV or LWUV. Soluble in acids, gelatinizes in hot H_2SO_4 or HCl . Is zoned into Bi-rich and lesser-Bi portions (14.7–28.5% Bi_2O_3). MnO , 2.8–3.5%; P_2O_5 , 1.2%; B_2O_3 , 1.5%. For the Bi-richest substitution, $(\text{REE}_{0.86}\text{Bi}_{0.65}\text{Ca}_{0.49})$. Rims are Bi and Mn rich. Biaxial (+); $N_x = 1.740(4)$, $N_y = 1.754(4)$, $N_z = 1.786(4)$; $2V = 50\text{--}72^\circ$, av. 68° ; $Z > Y > X$; $r > v$, very weak. X, colorless; Y, pale grayish yellow, $50\text{--}72^\circ$; Z, lavender purple. Occurs as a sparse, accessory, late-stage mineral in small druses in a zoned, complex granitic pegmatite. Associated minerals are Y-bearing milarite, muscovite, quartz, and albite. Occurs at the *Lavra de Sr. Jose Pinto, Jaguarac, Municpio de Timoteo, MG, Brazil*. EF

54.2.2.1 Hellandite-(Y) $(\text{Ca},\text{Y},\square)_6(\text{Al},\text{Fe})\text{B}_4\text{Si}_4\text{O}_{18}(\text{OH},\text{O})_4(\text{OH})_2$ or $(\text{CaY},\square)_4(\text{Y},\square)_2 \dots$

Named in 1903 by Brgger for Amund Theodor Helland (1841–1918), Norwegian geologist. Datolite–gadolinite group. Canadian material has $Y > \text{Ca}$. Tadzshikite-(Y), $\text{Ca}_3\text{Y}_2(\text{Ti}, \text{Al}, \text{Fe})\text{B}_4\text{Si}_4\text{O}_{22}$, is probably the Ti analog of hellandite-(Y). *MON P2/a*. $a = 18.824\text{--}18.99$, $b = 4.684\text{--}4.715$, $c = 10.248\text{--}10.30$, $\beta = 111.4\text{--}111.7^\circ$, $Z = 2$, $D = 3.645$. $25\text{--}184(\text{nat})$: 4.69_8 3.44_7 3.20_7 3.07_6 2.88_6 2.81_{10} 2.635_8 2.60_8 . *CM 11:760(1972)*. The main structural features are infinite silicoborate chains $[\text{Si}_4\text{B}_4\text{O}_{20}(\text{OH})_2]^{-14}$. Two such chains are parallel to c in the (010) plane, with Si and B atoms at $Y \approx \frac{1}{2}$, and are related to each other by the glide plane. Fe and Al are in octahedral coordination and Ca, Y, and REE are in square antiprismatic coordination. All are located at $Y \approx 0$ and connect the silicoborate chains. Closely related to Tadzshikite. *AM 62:89(1977)*. Prismatic to tabular. Twinning on (100). Brownish red to black, brown, sometimes colorless; vitreous luster. Cleavage (100), distinct. H between $4\frac{1}{2}$ and $5\frac{1}{2}$. $G = 3.35\text{--}3.63$. Gelatinizes with acids (metamict material). Japan: $(\text{Ca}_{5.75}\text{Y}_{3.70}\text{Nd}_{0.24}\text{Dy}_{0.21} \dots) \Sigma 10.65 (\text{Al}_{1.45}\text{Mn}_{0.45}\text{Ti}_{0.21}\text{Fe}_{0.11})_{2.22} (\text{OH})_4 [\text{Si}_8\text{B}_8\text{O}_{40}\text{O}_{22}(\text{OH})_{3.78}]$, Italy: $(\text{Ca}_{5.10}\text{Y}_{3.01}\Sigma\text{REE}_{4.56})_{9.66} (\text{Al}_{1.12}\text{Fe}_{0.89}^{II}\text{Mn}_{0.18}) \dots$, Norway: $(\text{Y}_{3.46}\text{Ca}_{3.7}\Sigma\text{REE}_{4.92})_{8.62} (\text{Al}_{0.91}\text{Fe}_{0.89}^{II}\text{Mn}_{0.18}) \dots$, Canada: $(\text{Y}_{4.62}\text{Ca}_{3.26}\Sigma\text{REE}_{6.60})_{9.86} (\text{Al}_{1.77}\text{Fe}_{0.56}^{II}\text{Mn}_{0.15})$; all on Si = 8.0 atoms. B_2O_3 is low in Norwegian and Canadian material: 5.44 atoms and 4.79 atoms instead of 8.0. H_2O goes up in this same material. Possible Mn analog at the Belo Horizonte pegmatite, Riverside Co., CA. Biaxial (–); $X = b$; $N_x = 1.656$, $N_y = 1.662\text{--}1.749$, $N_z = 1.668$; maybe metamict, with $\bar{N} = 1.75$; $2V = 87\text{--}90^\circ$. Occurs in druse pegmatite with hingganite, quartz, fluorite, chlorite, and zeolites. Colorless crystals cover hingganite (Japan). In granite pegmatites at Krager, Norway, associated with tourmaline, thorite, allanite, apatite, phenakite, and zircon. In granite at Predazzo, Italy. Belo Horizonte pegmatite, Anza, and Jensen quarry, Riverside Co., CA; Evans–Lou mine, Wakefield Lake, southern QUE, Canada; Predazzo, Trentino–alto Adige, and Lago Vico, Viterbo, Italy; *Lindvikskollen, Krager, Norway*; Trimouns Tak deposit, near Luzenac

Ariège, France; in ores of the Zaaiplaats tin mine, northern Transvaal, South Africa; Tahara area, Gifu Pref., Japan. EF *NGT* 44:35(1964), *TMPM* 10:125(1965), *MIN* 3(1):845(1972), *CM* 11:760(1972), *KZ* 18:17(1987).

54.2.2.2 Tadzhikite-(Y) $(\text{Ca,Ce})_{3-4}(\text{Y,Ce})_2(\text{Ti,Al,Fe}^{3+})\text{B}_4\text{Si}_4\text{O}_{22}(\text{O,OH})_2$ or $\text{Ca}_7\text{Y}_5(\text{Al,Ti})_2(\text{OH})_4\text{Si}_8\text{B}_8\text{O}_{44}$ or $\text{Ca}_7\text{Y}_5(\text{Al,Ti})_2\text{O}_2\text{Si}_8\text{B}_8\text{O}_{44}$

Named in 1970 by Efimov *et al.* for the locality. Datolite-gadolinite group. Hellandite is hydrated. See hellandite (54.2.2.1), the Al analog. *MON* *P2/a*. $a = 18.946\text{--}18.97$, $b = 4.71\text{--}4.714$, $c = 10.302\text{--}10.39$, $\beta = 111.6\text{--}111.8^\circ$, $Z = 2$, $D = 3.73\text{--}3.77$. *24-137*(nat): 4.97₃ 3.48₂ 2.94₃ 2.86₂₅ 2.65₁₀ 2.19₂₅ 1.91₅₅ 1.66₃. Also TRIC. Two morphological types found in tadzhikite: (1) spherulites of bent flakes not more than 1.5 cm in diameter, and (2) flattened prismatic crystals with rhombic prism and {010} pinacoid, also botryoidal, flaky, radiating lamellar, foliated masses; polysynthetic twinning present in both types, small deviations of α and γ from 90° indicate an initially monoclinic mineral that has become triclinic with the development of polysynthetic twinning; probably all monoclinic, but ordering of Ti would explain the change to triclinic symmetry. Yellowish brown to tan, beige, very pale pink and white, grayish brown to dark brown, colorless to brown; dull to pearly luster, sometimes vitreous. No cleavage is present on {100}; parting is parallel to (010). $H = 6$. $G = 3.86$ (type 1) and 3.73 (type 2). IR data: *DANS* 264:342(1982). DTA data: *DANS-ESS* 195:136(1970). Fuses at 1000° . Analysis (wt %), type 1: SiO₂, 24.7; TiO₂, 6.53; CaO, 18.3; Σ REE, 32.4; type 2: SiO₂, 23.4; TiO₂, 3.72; Al₂O₃, 2.30; CaO, 18.3; Σ REE, 34.1; Y dominant. Biaxial; $Z \wedge a = 7^\circ$, $Z \wedge b = 4^\circ$, $Z \wedge c = 25^\circ$; type 1: $N_x = 1.750\text{--}1.760$, $N_z = 1.763\text{--}1.772$; type 2: $N_x = 1.761$, $N_z = 1.772$; $2V = -88$ to $+80^\circ$ for type 1; very slightly pleochroic, nearly colorless to brown; wavy extinction. Occurs in alkalie pegmatites (former USSR and Norway) and as an accessory mineral in marble xenolith cavities (Mt. St.-Hilaire) and in igneous breccia cavities. Type 1 is in an albitized outer zone of pegmatite in the form of spherulites associated with ekanite, titanite, and eudialyte. Type 2 is in polyolithionite-quartz replacement zones in an inner blocky zone of a pegmatite with arfvedsonite-riebekite, and accessory pyrochlore and tienshanite, and stillwellite. Mt. St.-Hilaire, QUE, Canada; Tvedalen, Langesundfjord, Norway; Cimini Hills, near Rome, Lazio, Italy; *Alaisk Ridge, Dara-i-Pioz massif, Tien Shan, Tadzhikistan*. EF *AM* 62:89(1977), *DAN SSSR* 264:342(1982), *CSREM* 11:72(1987).

54.2.3.1 Cappelenite-(Y) $\text{Ba}(\text{Y,REE})_6[\text{Si}_3\text{B}_6\text{O}_{24}]\text{F}_2$

Named in 1885 by Brogger for D. Cappelen (1856-?) of Holden, Norway. Datolite-gadolinite group. *HEX-R* (trigonal) *P3*. $a = 10.67$, $c = 4.680$, $Z = 1$, $D = 4.40$. *27-47*(nat): 4.7₈ 3.48₉ 2.80₁₀ 1.94₉ 1.84₆ 1.77₇ 1.71₇ 1.66₈. See also *39-1349*(calc) pattern. Structure: *AM* 69:190(1984). B₆O₁₅ rings are linked by isolated SiO₄ tetrahedra to form a sheet perpendicular to {001}. Topologically, the mineral is *P6mm*. Pure crystals of end-member composition may

satisfy this space group. Prismatic, two principal forms $\{10\bar{1}0\}$ hexagonal prism and pyramid $\{1011\}$ or $\{1013\}$. Often doubly terminated; two crystals from Norway; one is a 2 cm \times 1.5 cm free crystal. Metamict. Reconstituted at 725° for two weeks. White, yellow-white, greenish brown; white streak. No cleavage, conchoidal fracture, vitreous luster. $H = 6$. $G = 4.20\text{--}4.40$. Readily soluble in acids. Uniaxial (-); $N_O = 1.751$, $N_E = 1.748$ (Na light); pale brownish yellow; not dichroic. Contains 0.87% ThO_2 —cause for metamict state. Substitution of Ca for Ba. Occurs in nepheline-syenite pegmatite veins associated with other alkalic minerals: wöhlerite, rosenbushite, catapleiite, lavinite, and so on. *Lille Arø island, Langesundfjord, Telemark, Norway; Kazakhstan*. EF *MRE* 2:248(1966).

54.2.3.2 Stillwellite-(Ce) (Ce,La,Th,Ca)BSiO₅

Named by McAndrew and Scott in 1955 for Frank Leslie Stillwell (1888–1963), an Australian mineralogist. Datolite-gadolinite group. $\text{HEX-R } P3_1$. $a = 6.832\text{--}6.841$, $c = 6.653\text{--}6.702$, $Z = 3$, $D = 4.76$. 25-1447(nat): 4.44₇ 3.43₁₀ 2.96₁₀ 2.71₆ 2.24₆ 2.23₆ 2.13₈ 1.86₇; 26-349(syn): 4.44₉ 3.42₉ 2.97₈ 2.91₁₀ 2.20₅ 2.13₈ 2.09₆ 1.86₁₀. Structure: *NJBM*:49(1992), *CM* 31:147(1993). Structure is probably $P3_121$ at high temperature and undergoes a ferroelectric phase transition to $P3_1$ upon cooling. Hexagonal tabular with prism $\{1120\}$ and rhombohedron $\{1011\}$; habit is very similar to quartz. Twinned on $[100]$. Crystals from Tadjikistan are as large as 5 cm \times 1 cm, and fist-size pieces exist of the Australian material. Sometimes partly metamict (e.g., Mary Kathleen mine, Mt. Isa district, Q, Australia). Streak white, dark brown, light brown, pink, maroon red, brownish yellow, and waxy white; vitreous to greasy luster (metamict material is resinous). No cleavage, subconchoidal to conchoidal fracture. $H = 5\frac{1}{2}\text{--}6\frac{1}{2}$. $G = 4.60\text{--}4.70$. No reaction in acids. IR data: *MS* 24:1(1970). Sometimes shows an alexandrite effect: pinkish tan to greenish brown. Uniaxial (+); $N_O = 1.76\text{--}1.778$, $N_E = 1.78\text{--}1.787$; negative elongation. Sometimes anomalously biaxial with $2V_2 = 0\text{--}6^\circ$. Contains as much as 5.4 wt % ThO_2 and variable amounts of CaO , minor Al_2O_3 , and sometimes minor UO_2 . Occurs with uraninite and allanite in garnet-diopside skarns formed between granodiorite and granulite. Also in magnetite ore, in pegmatites and hydrothermal veins associated with alkalic rocks, and in volcanic ejecta (syenite and sanidinite). Mineville, Essex Co., NY; Mt. St.-Hilaire, QUE, and the Desmont Mine, Bancroft, ONT, Canada; Langesundfjord area, Norway; Vico Volcano, Vetralla, Rome, Italy; Bassano Romano, Viterbo (Latium), Italy; Dara-i-Pioz, Alai Range, Tadjikistan(!); Inagli massif, southern Yakutia; Synnysh Massif, Siberia, Russia; *Mary Kathleen mine, Mt. Isa district, northwestern Q, Australia*. EF *MIN* 3(1):272(1972).

54.2.4.1 Garrelsite Ba₃NaSi₂B₇O₁₆(OH)₄

Named by Milton *et al.* in 1955 for Robert Minard Garrels (1916-1988), American geochemist and educator. Related to the gadolinite group. $\text{MON } C2/c$ a 14.639-14.655 b 8.466-8.480 c 13.460-14.438 β 114.21-114.30°, $Z=4$,

$D=3.89$. 26-1369 6.13₃ 4.23₃ 3.94₃ 3.64₈ 3.05₁₀ 2.87_{4.5} 2.03₆. The structure is a three-dimensional framework composed of silicoborate sheets and Ba-O polyhedral layers both running parallel to (001). A silicoborate with the pentaborate $[B_5O_{12}]^{9-}$ polyanion *ACB 32:824(1976)*. Steep, bipyramidal, prismatic, commonly striated (direction) crystals to 3 mm. Dominant forms are {110}, {110}, {211}, {211}, etc. Colorless to white, streak white, perfect {001} cleavage, vitreous luster, H about 6, G 3.68 (on impure material). Biaxial (-), 2V 55-72°, N_x 1.620, N_y 1.633, N_z 1.640, $Y=b$ $Z \wedge [101]$ (the edge of the {111} form) = 33°; one optic axis is nearly normal to this edge. An authigenic mineral, assoc. with nahcolite, shortite, searlesite, etc. in dolomitic shale of the Green River Formation. From several drill holes in *Uintah Co., Utah*. Also occurs in the Kramer borate deposit, Kern Co., and at Searles Lake, San Bernardino Co., CA. *USGSJR 2:213(1974)*, *SMPM 53:199(1973)*.

54.2.4.3 Okanoganite-(Y) $(Na,Ca)_3(Y,Ce)_{12}Si_6B_2O_{27}F_{14}$

Named by Boggs in 1980 for the locality. Related to the datolite group. Compare an unnamed REE-fluorosilicate from Siberia. *ZVMO 95:339(1966)*. Has Al_2O_3 and P_2O_5 and no B_2O_3 . It may be the P and Al analog of okanoganite or the same species if B, Al, and P do not occupy a separate site but only substitute for Si. HEX-R Space group unknown. $a = 10.72$, $c = 27.05$, $Z = 3$, $D = 4.37$. 35-483(nat): 4.35₄ 3.11₅ 2.97₁₀ 2.94_{9.5} 2.93₅ 2.68₃ 1.98_{3.5} 1.78_{4.5}. Structure unknown. Pseudotetrahedral crystals to 4 mm across, dominant form is {0001}, twinning: fourlings with TP {0114}, the c face of each individual forming the faces of the pseudotetrahedra, also rare interpenetration twins with the composition plane = {1012}. Rotation of 180° about a twin axis perpendicular to {0114}. Opaque white to reddish orange, light pink, yellow, tan; white streak; dull to brilliant luster. H = 4. G = 4.35. Nonluminescent. Substitutions: Ca + Th \leftrightarrow REE and Ca \leftrightarrow Na; TiO_2 , 0.7%, ThO_2 , to 3.2%, UO_2 , to 0.3%, FeO, to 2.4%, MnO, 0.5%, and so on. HREE > LREE. Uniaxial (-); wavelength used: white light; $N_O = 1.753$, $N_E = 1.740$; colorless. Occurs in isolated unaltered miarolitic cavities of an alkaline granite. Occurs with arfvedsonite, astrophyllite, bastnaesite, polythionite, zektzerite, zircon, and other minerals. Several hundred specimens found in ≈ 2 ft³ of rock. Occurs in the *Golden Horn batholith, near Washington Pass, Okanogan Co., WA*; occurs as inclusions in yttrian fluorite at Tysfjord, Norway. *EF AM 65:1138(1980)*, R. C. Boggs (1984), Ph.D. thesis, UCSB, 187 pp.

54.2.5.1 Tritomite-(Ce) $(Ce,La,Ca,Y,Th)_5(Si,B)_3(O,OH,F)_{13}$

Named in 1849 by Weibye and Berlin from the Greek for *three* and *to cut*, in allusion to the trihedral cavities left in the host rock by the crystals. Synonymous with the original tritomite. See also tritomite-(Y) (54.2.5.2). HEX $P6_3/m$. $a = 9.35$, $c = 6.88$, $Z = 2$, $D = 4.94$. 14-174: 3.44₄ 3.08₃ 2.81₁₀ 2.70₃ 1.94₃ 1.84₄ 1.74₃ 1.25₄. The morphology of the type material crystals is distinctly 3m, in the form of pseudotetrahedrons or steep trigonal pyramids with

a basal pedion. The morphological cell has six times the axial ratio of the X-ray cell that is based on a heated metamict sample. The structure is thought to be related to the apatite structure or to that of datolite. Dark brown, amber, black vitreous to resinous luster. Conchoidal fracture, brittle. $H = 5\frac{1}{2}$. $G = 4.15-4.25$ as low as 3.7. Uniaxial, but usually metamict and isotropic with $N = 1.73-1.76$ N as low as 1.69. Gelatinizes in HCl. In nepheline syenite on *Låven Island, Langesundfjord, near Brevik, Norway*, and also on Stokø and Arø, near Barkevik. *AR AM 47:9(1962), 51:152(1966)*.

54.2.5.2 Tritomite-(Y) $(Y,Ca,La,Fe^{2+},Ca)_5(Si,B,Al)_3(O,OH,F)_{13}$

Named as Spenaite in 1962 by Jaffe and Molinski Tritomite is from the Greek for *three* and *to cut*. Synonym: spenceite, named in honor of Hugh S. Spence, who collected the material in 1934. Name changed to Tritomite-(Y) in 1966. See also tritomite-(Ce) (54.2.5.1). *HEX* $P6_3/m$. $a = 9.32$, $c = 6.84$, $Z = 2$. *27-1063(heated)*: 3.16₅ 2.83₁₀ 2.73₅ 1.96₄ 1.93₄ 1.85₇ 1.76₅ 1.11₅. Irregular grains and masses, to 2.5 cm. The pattern of heated material is very similar to that of fluorapatite. Dark greenish black, reddish brown, brownish black; vitreous to resinous luster. Conchoidal fracture, brittle. $H = 5-6\frac{1}{2}$ (NJ), $3\frac{1}{2}$ (ONT). $G = 3.05$ (ONT), 3.40(NJ). Isotropic (metamict); $N = 1.63-1.685$. Found as subhedral grains with magnetite, zircon, and apatite in granite pegmatite at *Cranberry Lake, Sussex Co., NJ*; also massive in pegmatite in vuggy pyroxenite with calcite, apatite, diopside, wernerite, and fluorite in Cardiff Twp., and altered at the Faraday mine, Bancroft, Haliburton Co., ONT, Canada. *AR AM 47:9(1962), 51:152(1966); CM 12:66(1973)*.

54.2.5.3 Melanocerite-(Ce) $(Ce,Th,Ca)_5(Si,B)_3O_{12} \cdot nH_2O$ comparte tritomite-(Ce) & tritomite-(Y)

Named in 1887 (Brøgger) from the Greek meaning black and the composition. May be equivalent to tritomite-(Ce). *HEX-R* $a=9.35$ $c=6.88$ $Z=2$ $D=?$. *38-457* 3.44₄ 2.81₁₀ 1.84₄ 1.24₄ corresponding to the strongest lines of tritomite-(Ce) but commonly metamict and giving only diffuse pattern. Tabular {0001} crystals. Brown, dark brown, reddish brown, black; streak light brown; opaque to somewhat translucent; luster greasy, vireous or resinous; fracture conchoidal to uneven; $H=5-6$ $G=4.1-4.7$. Radioactive, containing up to 13.6 wt% ThO_2 ; B_2O_3 up to 4.6 wt%; in addition to the elements shown in the formula Al, Fe, Mg, Mn, Pb, Ti, Ta, and Zr may be present in significant amounts. Soluble in 1:1 HCl leaving a silica residue; also soluble in concentrated H_2SO_4 . Uniax (-) $N_o \approx 1.73$ $N_g \approx 1.72$; sometimes anomalously Biax, $2V=5-8^\circ$; metamict material isotropic with $N \approx 1.71-1.77$. Found in alkalic rocks and their cogenetic pegmatites; also in metamorphosed alkalic rocks. Sometimes altered to bastnaesite. Found at Wilberforce, ON, Canada; at Aro Island and *Kjeo Island, Barkevik, Langesundfjord, Norway*; in Russia in the Afrikanda massif, Kola Peninsula, in the Tatrsk massif, Krasnoyarsk region, and the Burpala massif, Northern Pribaikal. *ZVMO 91:573(1962), Vlasov 2:301(1966), Minerali 3-1:510(1972)*.

54.3.1.1. Vicanite-(Ce)

Described in 1995 by Maras *et al.* and named for the locality, the Vico volcanic district, Latium, Italy. Comments: cell parameters are very close to those of okanoganite-(Y). HEX.-R R3m a 10.795Å c 27.336Å $Z=3$ $D=4.73$; PD (no ICDD data) (nat.): 7.70₅ 4.42₅ 2.99₁₀ 2.95₇ 2.70₅ 1.84₅ 1.80₅ 1.69₅. Structure: the main feature is the presence of a new polyanion $(\text{Si}_3\text{B}_3\text{O}_{18})^{-15}$. It is made up of a ring of three BO_4 tetrahedra, linked via an apex to three SiO_4 tetrahedra. These polyanions are linked to each other by octahedrally coordinated Fe^{3+} , which also links isolated SiO_4 tetrahedra to form a complex layer of polyhedra perpendicular to the c direction. Both anionic and cationic interlayer positions may be vacant due to local charge balance (*EJM* 7:439(1995)). Transparent, yellowish green, anhedral grains or rare rice-grain crystals consisting of a vertical prism terminated by a pyramid, up to 0.3 mm in size, streak white, vitreous, conchoidal fracture, no cleavage, sometimes twinned giving a pseudocubic habit; non-fluorescent; $H \approx 5-6$, $D < 4.2$; IR data given. SiO_2 13.8 wt.%, Al_2O_3 0.16, TiO_2 0.14, P_2O_5 0.38, As_2O_3 4.49, Fe_2O_3 1.66, CaO 17.07, Na_2O 0.14, ThO_2 18.24, UO_2 1.96, RE_2O_3 30.98, B_2O_3 3.1, F 7.50, Σ 101.81, $\text{O}=\text{F}$ 3.16, Σ 98.65. Uniax. (-), Na(D) N_o 1.757 N_e 1.722, non-pleochroic. Occurs in small miarolytic cavities associated with other rare minerals such as thorium-rich hellandite, asbecasite, and stillwellite-(Ce), inside volcanic ejecta from a pyroclastic formation of the Vico volcanic complex at Tre Croci, Vetralla, Viterbo Prov., northern Latium, Italy. *RI* 3:207(1994).

Si₂O₇ Groups, Generally with No Additional Anions

55.1.1.1 Barylite BaBe₂Si₂O₇

Named in 1876 by Blomstrand from the Greek for *heavy*, in allusion to its high specific gravity. ORTH *Pn*2₁a. $a = 9.82\text{--}9.835$, $b = 11.65\text{--}11.67$, $c = 4.673\text{--}4.695$, $Z = 4$, $D = 3.99$. 20-119(syn): 5.81₅ 4.52₄ 3.39₉ 3.05₉ 2.99₁₀ 2.92₁₀ 2.34₄ 2.21₅. Structure: AM 62:167(1977). Colorless to white or pale blue, with {010}, {001}, {110}, and {100} dominant, tabular to bladed, elongated parallel to [001], flattened on {010}; piezoelectric; white streak; vitreous to waxy luster, sometimes dull. Cleavage (for most localities): {001}, {100}, perfect; and brittle. $H = 7$. $G = 4.02\text{--}4.07$. Some crystals (e.g., from Franklin, NJ, and Långban, Sweden) are fluorescent bluish but most are not fluorescent. Insoluble in acids. Traces of MgO, CaO to 1.8 wt %. Biaxial (–) or (+); for Långban and Seal Lake, Labrador, XYZ = bac; for Franklin, and Norwegian material, XYZ = bca; (Långban): $N_x = 1.691$, $N_y = 1.696$, $N_z = 1.703$, $2V_z = 81^\circ$; (Franklin): $N_x = 1.695$, $N_y = 1.702$, $N_z = 1.708$, $2V_x = 70^\circ$; OAP parallel to (001); $r > v$, weak to moderate or not observed. Occurs in alkalic pegmatite and miarolitic cavities at Mt. St.-Hilaire. Also in alkaline granite pegmatite at Lake George, CO. In alkaline pegmatite at Dara-i-Pioz. Contact aureoles of granites and in pegmatites. Also in nepheline syenite pegmatites and alkaline intrusions. Occurs at Franklin, NJ; in fine crystals (to > 10 cm long) with microlline, barite and fluorite in the Lake George ring-dike structure, Lake George, Park Co., CO; at Mt. St-Hilaire (very rare), QUE; in the Deadhorse Creek diatreme complex, Marathon, ONT; with eudialyte at Seal Lake, and in the Red Wine alkaline complex, central LAB, Canada; at Narsarssuk, Greenland; Bratthaggen farm, Lågen Valley, and Brevig, on Arø Island, Langesundfjord area, Norway; with hedyphane at Långban, Varmland, Sweden; above the Hackman valley on the southwestern slope of Mt. Yukspor, Khibiny massif, Kola Penin., Vishnevye Gor (Cherry Mountain), Ural Mts., Russia; Dara-i-Pioz, Tadjikistan; Pokrovo-Kirovsk, Kazakhstan. EF NGT 46:335(1966), MIN 3(1):560(1972), MZ 2:84(1980), TMPM 27:35(1980).

THORTVEITITE GROUP

The thortveitite group consists of four isostructural or nearly isostructural minerals conforming to the formula

$$\text{ABSi}_2\text{O}_7$$

A = Ca, Zr, Y, Yt, Sc

B = A

$$\text{THORTVEITITE: (Sc, Y)}_2\text{Si}_2\text{O}_7$$

Thortveitite has Si_2O_7 groups, interconnected with Sc. It is a rare example of linear Si-O-Si arrangement.

THORTVEITITE GROUP

Mineral	Formula	Space Group	a	b	c	β	
Gittinsite	$\text{CaZrSi}_2\text{O}_7$	C2	6.852	8.659	4.686	101.69	55.2.1.1
Keivyite-(Y)	$(\text{Y, Yb})_2\text{Si}_2\text{O}_7$	C2/m	6.875	8.970	4.721	101.74	55.2.1.2
Keivyite-(Yb)	$\text{Yb}_2\text{Si}_2\text{O}_7$	C2/m	6.840	8.916	4.745	102.11	55.2.1.3
Thortveitite	$(\text{Sc, Y})_2\text{Si}_2\text{O}_7$	C2/m	6.530	8.521	4.681	102.63	55.2.1.4

Note: Related structures include thalenite-(Y) (55.2.1.5), rosenhahnite (55.2.1.6), rowlandite-(Y) (55.2.1.7), and yttrialite-(Y) (55.2.1.8).

55.2.1a.1 Gittinsite $\text{CaZrSi}_2\text{O}_7$

Named in 1980 by Ansell et al. for John Gittins (1932-?), professor, Department of Geology, University of Toronto. Thortveitite group. Compare other members of the thortveitite group. MON C2. $a = 6.852\text{--}6.878$, $b = 8.659\text{--}8.674$, $c = 4.686\text{--}4.697$, $\beta = 101.69\text{--}101.74^\circ$, a sample from Mongolia has: $a = 6.895$, $b = 8.691$, $c = 4.709$, $\beta = 100.81^\circ$, $Z = 2$, $D = 3.62$. $33\text{--}322(\text{nat})$: 5.32_6 4.62_4 3.23_8 3.16_{10} 3.03_8 2.66_8 2.23_5 1.68_7 . Structure is a modification of the thortveitite structure, which involves reduction of symmetry to C2 from C2/m of thortveitite. CM 27:703(1989). Generally fine-grained, also rarely as radiating sheaves of prismatic crystals 0.1–0.3 mm long. White

or gray-white; white streak; chalky, gray-white fine-grained intergrowths with apophyllite, or vlasovite. $H = 3\frac{1}{2}$ -4 for intergrowth with apophyllite, 6 - $6\frac{1}{2}$ for mongolian material. $G=3.56$. Orange cathodoluminescence. IR spectrum is similar to that of Thortveitite. May have 0.5% Fe, to 1.3% Sn, 1.2% Pb, 0.9-1.2% MnO, $\approx 40\%$ SiO₂, $\approx 35.5\%$ ZrO₂, 1.2% HfO₂, 17% CaO. Biaxial (-); nearly parallel extinction to length of fibers, $X \wedge c = 5$ - 10° , $Y = b$, $X \wedge a = 3$ - 8° , elongation = c , Z and Y nearly perpendicular to it; $N_x = 1.720$, $N_y = 1.736$, $N_z = 1.738$; Mongolian material has $N_x = 1.716$, $N_y = 1.738$, $N_z = 1.760$; $2V = 30^\circ$; colorless. Occurs in pegmatitic lenses and gneisses of agpaite peralkaline rocks. Associated with other exotic minerals: eudialyte, elpidite, armstrongite, gadolinite-(Y), kainosite-(Y), and unnamed minerals. A rock-forming mineral at Strange Lake. May replace earlier Zr-bearing minerals similar to armstrongite. May occur with elpidite also. May be nonpseudomorphic, with quartz and allanite at Strange Lake. Alteration: Gittinsite + aegirine + Fe-oxides isomorphously replace elpidite at Strange Lake. Occurs as a rare alteration product of eudialyte in alkalic rocks at Parjarito Mountain, Mescalero Apache Indian Reservation, Otero Co., NM; an alteration product of vlasovite in nepheline-syenite pegmatites at *Kipawa River, Villedieu Twp., Temiscaming Co., Quebec, Canada*. Also in the Strange Lake complex, southeast of Lac Brisson, Quebec-Labrador, Canada; as pseudomorphs to several cm after elpidite, along with quartz, fluorite, hematite and sometimes aegirine, Khaldzan-Buregteg intrusions, Mongolian Altai, Mongolia. *CM 18:201(1980)*, *CM 30:191(1992)*, *DRAN 331:82(1993)*.

55.2.1a.2 Keiviite-(Y) (Y,Yb)₂Si₂O₇

Named in 1985 by Voloshin et al. for the area where it was found. Thortveitite group. *MON C2/m*. (Syn): $a = 6.875$, $b = 8.970$, $c = 4.721$, $\beta = 101.74^\circ$, $Z = 2$; (nat): $a = 6.845$, $b = 8.960$, $c = 4.734$, $\beta = 101.65^\circ$, $Z = 2$, $D = 4.48$. 38 - 440 (nat): 4.65_9 , 3.23_{10} , 3.04_8 , 2.28_7 ... (three weak lines have hkl values that do not fit the assumed space group); (syn): 5.38_7 , 4.62_9 , 3.25_7 , 3.22_{10} , 3.03_9 , 2.73_7 , 2.27_9 , 2.14_9 , *TJBCS 85:17(1986)*. Prismatic, 0.05-1 mm long and < 0.15 mm thick. Colorless to white, white streak, vitreous luster. No cleavage, uneven fracture. $H = 4$ -5, $VHN = 1300$. $G = 4.45$. No fluorescence, but has yellow-green cathodoluminescence. Biaxial (-); $X \wedge c = 4^\circ$, $Z = b$, $Y \wedge a = 7^\circ$; Na(D); $N_x = 1.713$, $N_y = 1.748$, $N_z = 1.758$; $2V = 56^\circ$ (calc. 55°); $r < v$. Occurs in unspecified amazonite-bearing granitic pegmatites of the *Kola Penin., Russia*, in fissures in quartz and fluorite associated with thalenite, xenotime, bastnaesite, and kuliokite-(Y). Also on keiviite-Yb. Unnamed nonmetamict REE₂Si₂O₇ minerals having the thortveitite structure were described from Norway [*NGT 51:1(1971)*] and should be either keiviite-(Y) or keiviite-(Yb): Askagen, Värmland; Högetveit, Evje, and Ivel-dal, Iveland, southern Norway; Annerød, Vaaler, Norway. *EF MZ 7:79(1985)*.

55.2.1a.3 Keiviite-(Yb) $\text{Yb}_2\text{Si}_2\text{O}_7$

Named in 1983 by Voloshin et al. for the locality. Thortveitite group. See Keiviite-(Y) (55.2.1.2). MON $C2/m$. $a = 6.840$, $b = 8.916$, $c = 4.745$, $\beta = 102.11^\circ$, $Z = 2$ [MZ 5:94(1983)], $D = 6.04$. 37-458(nat): 4.64₈ 3.24₁₀ 3.20₁₀ 3.03₉ 2.72₇ 2.67₇ 2.26₇ 2.17₆. First generation is elongated platy and prismatic crystals, and second generation is small spherulites; polysynthetic twins are common. Colorless, white streak, vitreous luster, transparent. Cleavage {110}, perfect; {001}, imperfect. $H = 5-6$. $G = 5.95$. IR data are similar to synthetic $\text{Yb}_2\text{Si}_2\text{O}_7$. Faint green cathodoluminescence. Dissolves in cold HCl. Some Y substitutes for Yb. Other HREE's are present. $\text{Yb} > \text{Er} \approx \text{Lu} > \text{Tm} > \text{Dy}$; variable Y_2O_3 , 1.0-15.4 wt %. Biaxial (-); $X = b$, $Y \wedge a = 7-8^\circ$, extinction angle of polysynthetic twins = 33° , $X \wedge c = 3-5^\circ$; $N_x = 1.723$, $N_y = 1.758$, $N_z = 1.768$; $2V = 58^\circ$; $r < v$, strong. Occurs near Keivy, Kola Penin., Russia, in amazonite pegmatite, within violet fluorite. Two generations of the mineral are present. Associated with fluorite, bastnaesite, and hingganite. EF

55.2.1a.4 Thortveitite $(\text{Sc},\text{Y})_2\text{Si}_2\text{O}_7$

Named in 1911 by Schetelig for Olaus Thortveit (1872-1917), Norwegian farmer and miner, who found the mineral. Thortveitite group. MON $C2/m$. (Nat): $a = 6.530$, $b = 8.521$, $c = 4.681$, $\beta = 102.63^\circ$, $Z = 2$, $D = 3.50$; (syn): $a = 6.508$, $b = 8.506$, $c = 4.677$, $\beta = 102.7^\circ$. 19-1125(nat): 5.18₆ 4.58₂ 3.18_{4.5} 3.14₁₀ 2.97_{6.5} 2.63₃ 2.60₅ 2.20_{2.5}; 20-1037(syn): 5.09₂ 3.13₁₀ 3.11₁₀ 2.93_{4.5} 2.58₂ 2.17₂ 2.04₂ 1.64₂. The structure consists of isolated Si_2O_7 groups. AM 73:601(1988), CM 31:337(1993). Crystals may occur singly or in radial aggregates, also flattened plates to elongate prismatic, crystals may be more than 35 cm long and 450 g in weight; {110} dominant; simple rotational twinning on (110) is common; rare twins occur on (150), and polysynthetic twinning is sometimes seen. Color is variable: white-gray, brown, gray-black, dirty green, grayish green; white-gray streak; vitreous-adamantine luster. Cleavage (110), good; uneven to conchoidal fracture; brittle. $H = 6\frac{1}{2}$. $G = 3.50-3.58$. Slightly soluble in boiling HCl and also HF. May contain > 17.7 wt % Y_2O_3 , and 10 wt % ZrO_2 . Minor substitution of Fe, Mn, Mg, Al, Hf, and Y-group REE occurs. Biaxial (-); $Y = b$, $X \wedge c = -5^\circ$; $N_x = 1.750-1.756$, $N_y = 1.789-1.793$, $N_z = 1.802-1.809$; colorless to green-brown; birefringence = 0.05; $2V = 60-70^\circ$; $r > v$, distinct. Most often occurs in granitic pegmatites, but also occurs in hydrothermal veins. Sometimes in greisens and in alaskitic granites. Occurs in commercial quantities at Crystal Mountain, Darby, Ravalli Co., MT, as millimeter-size grains included in fluorite; occurs in the Deadhorse Creek diatreme Complex, Marathon, ONT, Canada; several localities in Norway: Y-bearing from Iveland, Satersdalen, Tuftan, Frikstad; Evje, Landsverk, and Rampeitroll sinken pegmatites; Eptevann, Fen Complex, southern Norway; Bidjovagge, Finnmark, northern Norway; Kola Penin., and Tagilo-Baranchinsk massif, Ural Mts.,

Russia; central Kazakhstan; Zr-bearing from Befanamo, Madagascar; Isango mine, Kobe, Kyoto Pref., Japan. Used as an ore of scandium which is used in the metals industry and the aircraft industry. EF *MIN* 3(1):576(1972), *DAN SSSR* 318:972(1991).

55.2.1b.1 Rowlandite-(Y) (Y,TR)₄Fe(Si₂O₇)F₂

Named in 1891 by Hidden for Henry Augustus Rowland (1848–1901), American physicist, Johns Hopkins University, Baltimore, MD. TRIC *P1* or *P1*. $a = 6.59$, $b = 8.65$, $c = 5.53$, $\alpha = 99.03^\circ$, $\beta = 104.13^\circ$, $\gamma = 91.47^\circ$, $Z = 1$. 13-565(nat heated): 4.87₆ 3.59₅ 3.51₅ 3.06₁₀ 2.61₃ 2.52₃ 2.44₃ 2.08₄. The pattern is very similar, if not identical, to those for melanocerite and tritomite heated to 1000°. Structure is metamict. Heating produces multiple phases. Y₂O₃ and cristobalite and yttrialite (high-temperature form). At 950 to 1050°, both metamict and crystalline rowlandite are converted to another phase, perhaps thalenite. Is stated to be triclinic, *P1* or *P1*. Occurs as irregular masses. Grayish green, red, bluish green, greenish brown, grayish white; vitreous luster. No cleavage, conchoidal fracture, brittle. $H = 5\frac{1}{2}$. $G = 4.39$ (unheated), 4.55 (heated), and ≈ 4.57 (Russian). Three analyses (wt %): Fe is present as Fe²⁺, Y₂O₃ plus other REE, 61.9; FeO, 4.69; CaO, 0.19; UO₃, 0.40; SiO₂, 25.98; LOI, 2.01; F $\approx 5\%$. Baringer Hill: Y³⁺ + O²⁻ \leftrightarrow Fe²⁺ + F⁻, Y³⁺ + F⁻ \leftrightarrow Fe²⁺. Uniaxial (+) to biaxial (+); most has $N = 1.72$ –1.726, 1.704(isotropic), 1.76(heated). Occurs with gadolinite and yttrialite at Baringer Hill pegmatite. Also in postmagmatic veins, related to an alkaline aegirine–arfvedsonite granite. *Baringer Hill, Llano Co., TX*; *Kola Penin., Russia*; *Kazakhstan*. EF *CM* 6:576(1961), *ZVMO* 95:339(1966), *TMMAN* 21:119(1972), *MA* 27:67(1976), *MIN* 3(1):590(1972).

55.2.1b.2 Thalenite-(Y) Y₃Si₃O₁₀(OH)

Named in 1898 by Benedicks for Tobins Robert Thalen (1827–1905), Swedish physicist. Compare with members of the thortveitite group. Thalenite may include rowlandite and yttrialite. *AM* 71:188(1986). *MON* P2₁/n. $a = 10.34$ –10.38, $b = 11.09$ –11.22, $c = 7.29$ –7.33, $\beta = 96.9$ –97.3°, $Z = 4$, $D = 4.25$. 38-439(nat): 5.50₂ 3.79₂ 3.27₂ 3.16₂ 3.10₁₀ 2.81₄ 2.75₃ 2.24₃. Structure is often metamict. Cannot be reconstituted by heating. Heating dehydrates it and converts it to thortveitite. *DAN SSSR* 202:1324(1972). A fluorine-dominant thalenite was described [*MZ* 7:79(1985)] and the structure determined. *SPC* 33:356(1988). Tabular or prismatic crystals, flattened on b , and sometimes only slightly elongated on c with {010}, {120}, {121}, and {111} dominant, also compact, massive, crystals to 2 cm across, resembles quartz. Usually pink or yellowish pink, also colorless, yellowish white, cream, grayish brown to brownish black (related to Fe³⁺ content); white streak; luster is resinous on fresh fracture surface, also greasy or vitreous. No cleavage, uneven to splintery fracture, and sometimes conchoidal, brittle. $H = 6\frac{1}{2}$. $G = 4.16$ –4.41. Metamict varieties have G as low as 3.6. DTA and TGA: *VLA* 2:243(1966). *IR:MIN* 3(1):583(1972). Some is luminescent yellow under X-rays. Electro-

magnetic. Thalenite from Siberia and Sweden is dielectric. Soluble in HCl and H₂SO₄. Chemistry is summarized in *AM 71:188(1986)*, fresh material has little H₂O (0.75 wt %), fairly pure material has SiO₂, 30–32%; Fe₂O₃, 0.2–0.4; REE₂O₃, 66–69%; Al₂O₃ ≈ 0.3. Other thalenites have variable low levels of CaO, MnO, Na₂O, ThO₂, CO₂ and other elements. Biaxial (–); OAP perpendicular to (010), Y nearly parallel to *c*, [*AM 71:188(1986)*]. Biaxial (–) parallel to *b*, OAP perpendicular to *c*; N_x = 1.709–1.731, N_y = 1.716–1.739, N_z = 1.723–1.748; colorless; 2V = 65–70°, Na(D). Most often occurs in granitic pegmatites, both alkalic and subalkalic. Occurs as replacement veinlets in yttrifluorite, associated with allanite at the White Cloud pegmatite, Jefferson Co., CO, and at the Snowflake pegmatite, Teller Co., CO; Guy Hazen claims, Boulder Springs, Mojave Co., 4.5 miles S of Kingman, AZ; *Osterby pegmatite, Dalarne, Sweden*; large crystals from Åskagen, also Torsbacken, and Forskeelbak, Värmland, Sweden. Hundholmen, Tysfjord, northern Norway; Reiersdal, Vest-Agder; Høgetveit, Evje; and Iveland, Rossas Setesdalen, Norway. Pyörönmaa pegmatite, Kangasala, Finland; Keivy area, Kola Penin., and unspecified location in eastern Siberia, Russia; Suishoyama, Kawamata-machi, Fukushima Pref., and Nosen village, Yamanashi Pref., Japan. *EF NGT 59:265(1979)*.

55.2.1b.3 Yttrialite-(Y) (Y,Th)₂Si₂O₇

Named in 1889 by Hidden and Mackintosh [*AJS 38:474(1989)*] for the composition, the yttrium group REE's being the chief cations. Usually metamict; heating produces several phases. Heating for 1 hour at 1000° produces low-temperature γ-phase yttrialite. *MON P2₁/m* and *P2₁/n* (heated). (Syn): *a* = 7.34–7.50, *b* = 8.06, *c* = 5.02, β = 108.50–112.00°, Z = 2; (heated 1000°): *a* = 7.37, *b* = 8.10, *c* = 5.07, β = 108.30°. *24-1427(nat)*: 4.35₂₅ 3.31₃₅ 3.01₁₀ 2.91₄₅ 2.86₂₅ 2.81₈ 2.72₂ 1.81₂; *24-1428(syn)*: 4.67₂₅ 4.03₂₅ 3.47₂₅ 3.45₂₅ 3.05₁₀ 2.62₄ 2.07₃₅ 1.74₄. Structure: *K 16:905(1971)*. R factor between 8 and 16% on artificial material. Anhedral to subhedral masses, and equant crystals to 5 cm. Orange-yellow (when altered), olive-green, greenish and brownish black, blackish or reddish brown; greenish white or white streak; resinous and vitreous to waxy-powdery luster. No cleavage, fracture uneven to conchoidal. Brittle. H = 5½–6½. G = 4.31–4.56. G sometimes as low as 4.02. Strongly electromagnetic, forms a gel in hot HCl. IR and DTA: *AM 58:545(1973)*. Analysis (wt %): Baringer Hill: SiO₂, 30.2; Al₂O₃, 1.0; Fe₂O₃, 16.8; Y₂O₃, 32.7; Ln₂O₃, 15.8; ThO₂, 13.6; CaO, 3.1; MgO, 0.5; Na₂O, 0.3; P₂O₅, 0.3; Nb₂O₅, 0.2. Material from Iveland, Norway, has ThO₂ 6.97. Th and U substitute for REE, their higher valences being balanced by Ca, Fe²⁺, and Mn. Biaxial (–); N = 1.760 (isotropic) down to 1.660 (variable hydration); N_x = 1.731, N_y = 1.738, N_z = 1.744; 2V = 68°. Occurs in granite pegmatites, associated with gadolinite-(Y) and tenerite-(Y). Alteration: to Y-carbonates, tenerite, and others. Occurs at the Baringer Hill pegmatite, Blufton, Llano Co., TX, in masses to 10 lb; also at the nearby Rhode Ranch pegmatite; Ivedal, Iveland, southern Norway; Høgetveit, Evje, Nor-

way; and Askagen, Varmland, Sweden; Siberia; Komenono, Tateiwa Hozyo, Ehime Pref., and Yashima, Kagawa Pref.; also Fusamata and Suishoyama, Iisaka, Kawamata-machi, Fukushima Pref., Japan. EF *MRE II:243(1966)*, *NGT 51:1(1971)*, *AM 58:545(1973)*.

55.2.2.1 Keldyshite $(\text{Na}, \text{H}_3\text{O}^+)_2\text{ZrSi}_2\text{O}_7$, or $\text{Na}_{2-x}\text{H}_x\text{ZrSi}_2\text{O}_7 \cdot n\text{H}_2\text{O}$

Named in 1962 by Gerasimovskii for Mstislav Vsevolodovich Keldysh (1911–1978), Russian mathematician and former president of the USSR Academy of Sciences. Polymorph: parakeldyshite. TRIC $P\bar{1}$. $a = 9.01$, $b = 5.34$, $c = 6.96$, $\alpha = 92^\circ$, $\beta = 116^\circ$, $\gamma = 88^\circ$, $Z = 2$; $D = 3.26$; also $a = 9.31$, $b = 5.42$, $c = 6.66$, $\alpha = 94.3^\circ$, $\beta = 115.3^\circ$, $\gamma = 89.6^\circ$. *DAN SSSR 238:573(1977)*. *24-1097(nat)*: 4.16₇ 3.95₆ 2.91₁₀ 2.70₇ 2.20₆ 1.93₅ 1.70₅ 1.60₅. Note: According to *PD 2:176(1987)*, these powder data are just a poorly measured variant of *29-1293* (parakeldyshite). Grains to 4 mm, 6-mm aggregates; fine polysynthetic twinning. White, white streak, vitreous–greasy luster. Two cleavages at 90° , irregular fracture, very brittle. $H = 4$. $G = 3.30$. Decomposed by HCl , HNO_3 + H_2SO_4 . Analysis (wt %): H_2O^+ , 0.95; H_2O^- , 0.35; K_2O , 0.94; Na_2O , 16.03; $\text{FeO} + \text{Fe}_2\text{O}_3$, 0.31; TiO_2 , 0.60; ZrO_2 , 40.35; SiO_2 , 39.39 (original analysis). Biaxial (– and +); $N_x = 1.670$, $N_z = 1.710$; 2V (–): 60° red light, 78° for yellow, and 112° for blue, so the mineral is (+) in blue light; strong dispersion. Occurs at Lågendalen, near Larvik, Norway; in the *Tavaiok and Angoundasiok rivers, Mt. Alluain, Lovozero massif, Kola Penin., Russia*, with parakeldyshite, in foyaites; a primary mineral, associated with lorenzenite. EF *DANSSSR 189:166(1969)*, *MIN 3(1):595(1972)*.

55.2.2.2 Khibinskite $\text{K}_2\text{ZrSi}_2\text{O}_7$

Named in 1974 by Khomyakov et al. for the locality. See keldyshite (55.2.2.1). MON (pseudo-TRIC) $B2/m$. (Nat): $a = 19.22$, $b = 14.10$, $c = 11.10$, $\beta = 116.5^\circ$, $Z = 16$, $D = 3.33$; (syn): $a = 19.188$, $b = 14.072$, $c = 11.075$, $\beta = 117.07^\circ$. *26-0928(nat)*: 4.27₄ 2.95₇ 2.76₁₀ 2.13₅ 1.63₇ 1.595₄ 1.38₅ 1.25₅; *24-0710(syn)*: 6.38₅ 4.31₆ 4.27₃ 3.40₅ 3.00₁₀ 2.80₅ 2.77₈ 2.16₃. The structure has three nonequivalent sites for Zr and six each for Si and K. All Zr atoms are octahedrally coordinated. The K coordinations are varied, two six-coordinated, three seven-coordinated, and one eight-coordinated. *SPD 21:696 (1977)*. In 2- to 3-cm ovoids, crystals are in irregular grains to 3 mm. White (syn), pale yellowish cream or colorless (nat); vitreous, dull, or greasy luster; translucent. Cleavage (001), (100), (111), excellent; planar, steplike fracture. $H = 4\frac{1}{2}$ – $5\frac{1}{2}$. $G = 3.30$ – 3.40 . Analysis (wt %): SiO_2 , 33.8; ZrO_2 , 37.8; TiO_2 , 0.6; trace CaO ; K_2O , 27.0. Biaxial (–); OAP perpendicular to (010), $Z = b$, X and Y lie in (010); $N_x = 1.665$, $N_y = 1.715$, $N_z = 1.715$; 2V = 6 – 16° . Occurs in the *Gakman Valley, Khibiny massif, Kola Penin., Russia*, as ovoids 2–3 cm in diameter in aegirine-rich metasomatic rocks. Outer zone is eudialyte, inner zone is zircon and khibinskite. EF *ZVMO 103:110(1974)*, *DANSSSR 231:1351(1976)*.

55.2.2.3 Parakeldyshite $\text{Na}_2\text{ZrSi}_2\text{O}_7$

First described in 1972 and named in 1977 by Khomyakov for a dimorph-polymorph of keldyshite. Para = beside in Greek – associated together. A high temperature polymorph. If keldyshite is heated at 500–600°C, one obtains parakeldyshite. TRIC. $P\bar{1}$. $a = 6.629\text{Å}$, $b = 8.814$, $c = 5.434$, $\alpha = 92.70^\circ$, $\beta = 94.25^\circ$, $\gamma = 71.46^\circ$, $Z = 2$, $D = 3.40$ (synth.) and $D = 3.38\text{--}3.44$; PD 39-209 (synth.): 6.02₃ 4.23₅ 4.18₉ 3.98₁₀ 2.91₁₀ 2.71₆ 2.68₄ 2.65₉. See also PD 2:176(1987). Structure: (*Jour. Struct. Chem. (China) 11:866(1970)*). Colorless, streak white; 1–6 mm grains and masses at Mont Saint-Hilaire; vitreous; cleavage = 3 excellent to very good: {001}, {110}, {110}; H 5½–6. G 3.39; fluoresces orange-white in SW UV, strong cream fluorescence in SW. Biax. (–), $2V = 84^\circ$, $N_\alpha = 1.670$, $N_\beta = 1.692\text{--}1.697$, $N_\gamma = 1.713\text{--}1.718$; colorless; $X \approx b$, $Y \approx c$. Occurs in alkalic pegmatites in Kola Peninsula. Occurs with keldyshite in bedded in sodalite xenoliths at Mont Saint-Hilaire. Occurs at Mont Saint-Hilaire, Quebec, Canada; Lagedalen, southern Norway; Umbozero region, Lovozero Massif, Kola Peninsula, Russia; Khibiny Massif, Kola Peninsula, Russia. CM 15:102(1977), DAN SSSR 237:703(1977).

55.2.3.1 Barysilite $\text{Pb}_3\text{Mn}[\text{Si}_2\text{O}_7]_3$

Named in 1888 by Sjögren and Lundström from the Greek for *heavy* and for the composition (Si). HEX-R $R\bar{3}c$. $a = 9.821$, $c = 38.38$, $Z = 6$, $D = 6.84$. 23-404(syn): 4.57₅ 3.88₆ 3.22₅ 3.21₅ 3.16₆ 2.96₁₀ 2.77₈ 2.68₈. Structure: AC 20:357(1966). The $[\text{Si}_2\text{O}_7]$ dimers are nonlinear; the cell size for synthetic material is somewhat larger, yielding a volume greater by $\approx 7\%$. White to pinkish white, darkens on exposure to light; adamantine luster, pearly on cleavage. Cleavage {0001}, distinct; uneven fracture; brittle. H = 3. G = 6.55–6.72. Uniaxial (–); $N_O = 2.033\text{--}2.07$, $N_E = 1.015\text{--}2.05$. Gelatinizes in HCl with separation of PbCl_2 ; easily fusible. Minor substitution for Mn by Ca, Mg, and Zn. Found in thin films and veinlets in zinc ore from the Parker shaft, Franklin, Sussex Co., NJ. Found as tabular, rhombohedral crystals at Langban, and as embedded, curved lamellar masses in iron ore at the Harstig mine, Pajsberg, Varmland, Sweden. AR DT 584(1932), AM 54:510(1969), MR 4:62(1973).

55.3.1.1 Rankinite $\text{Ca}_3[\text{Si}_2\text{O}_7]$

Named in 1942 by Tilley for George Atwater Rankin (b.1884), American physical chemist, Geophysical Laboratory, Washington, DC, who first synthesized the compound. Dimorphous with kilchoanite (58.3.2.1). MON $P2_1/a$. $a = 10.557$, $b = 8.885$, $c = 7.858$, $\beta = 119.59^\circ$, $Z = 4$, $D = 2.99$. 22:539: 4.48₇ 3.84₇ 3.20₅ 3.18₈ 3.03₆ 2.90₅ 2.72₁₀ 1.819₆. Structure: MJJ 8:240(1976). Colorless to white, vitreous luster, transparent to translucent. H = 5½. G = 2.96–3.0. Biaxial (+); $2V = 60\text{--}69^\circ$; $N_x = 1.640\text{--}1.643$, $N_y = 1.644\text{--}1.647$, $N_z = 1.650\text{--}1.652$; $Y = b$, $Z \wedge c = 15^\circ$; $r > v$. Alters to its dimorph, kilchoanite. Gelatinizes with acids; infusible. Found as rounded or irregular grains, and massive in high-temperature, contact-metamorphosed limestones. Found in the Christmas Mts., Brewster Co., TX; in northern

HARDYSTONITE: $\text{Ca}_2\text{ZnSi}_2\text{O}_7$

Perspective view along *c*. The structure is analogous to that of other tetragonal members of the group except for the cation occupancy of the larger tetrahedral site.

COAH, Mexico; at *Scawt Hill, Country Antrim, Northern Ireland*; Camas Mòr, Muck, Inner Hebrides, and from Ardnamurchan, Scotland. Found in the *Hatrurim* formation, at *Hatrurim* and *Ma'aleh Adumim*, Israel; in the *Anakitisk* massif, Lower Tunguska, Siberia, Russia; at *Fuka*, *Bicchu-cho*, Okayama Pref., Japan; at *Takatoka*, New Zealand. *AR MM* 26:190(1942), 37:517(1969).

55.3.2.1 Jaffeite $\text{Ca}_6\text{Si}_2\text{O}_7(\text{OH})_6$

Named in 1989 by Sarp and Peacor for Howard Jaffe (b.1919), University of Massachusetts. Natural analog of tricalcium silicate hydrate, a component of cement. *HEX P3*. $a = 10.026$, $c = 7.482$, $Z = 2$, $D = 2.58$. 29-375(syn): 8.66₁₀ 3.28₅ 3.00₉ 2.89₇ 2.83₃ 2.47₃ 2.08₃ 1.76₃. Structure: *DAN SSSR* 219:340(1974) on synthetic material. Elongated parallel to [001], with hexagonal cross section, {0001} and {1010} only; euhedral to subhedral crystals, average length 0.4 mm, diameter 0.25 mm. Colorless, white streak, vitreous luster, transparent. Cleavage {1010}, imperfect; conchoidal fracture; brittle. $G = 2.65$. Dissolved by HCl. Analysis (wt %): CaO, 65.0; SiO₂, 24.0; H₂O, 11.0. Uniaxial (+); $N_O = 1.596$, $N_E = 1.604$; colorless; birefringence = 0.008. Occurs in a manganese deposit with defernite and hausmannite and minor brucite, and so on, in low-grade metamorphic rocks. *Kombat mine*, 49 km south of *Tsumeb*, *Namibia*; *Cerro Mazahua*, *Zitacuaro*, MICH, Mexico. *EF AM* 74:1203(1989).

MELILITE-FRESNOITE GROUPS

The melilite group consists of five isostructural tetragonal sorosilicates, having the general formula

where

The structure is characterized by two types of tetrahedral sites, double tetrahedron "paired sites" (T2) and isolated (T1) sites wherein the larger four-coordinated cations are found. There appears to be complete ordering of cations among these sites, with silicon occupying the T2 sites as long as it is the smallest of the four coordinated cations; in the synthetic boron-gehlenite, $Ca_2Si(B_2O_7)$ silicon occupies T1.

MELILITE-FRESNOITE GROUP: MELILITE SUBGROUP

Mineral	Formula	Space				
		Group	a	c	D	
Akermanite	$Ca_2Mg(Si_2O_7)$	$P4_21m$	7.835	5.010	2.944	55.4.1.1
Gehlenite	$Ca_2Al(SiAlO_7)$	$P4_21m$	7.677	5.059	3.054	55.4.1.2
Melilite*	$(Ca,Na)_2(Mg,Al,Fe)$ $[(Si,Al)_2O_7]$	$P4_21m$	7.789	5.018	3.09	55.4.1.3

*The sodium-bearing intermediate members are referred to as melilite, which does not enjoy species status. Soda-melilite (Sm), $CaNaAl(Si_2O_7)$, has been synthesized, and it is this component that substitutes in the intermediate phases. Consequently, melilite is treated here as a species.

MELILITE-FRESNOITE GROUP: FRESNOITE SUBGROUP

Mineral	Formula	Space				
		Group	a	c	D	
Fresnoite	$Ba_2TiO(Si_2O_7)$	$P4bm$	8.518	5.211	4.520	55.4.2.1
Hardystonite	$Ca_2Zn(Si_2O_7)$	$P4_21m$	7.827	5.014	3.42	55.4.2.2
Jeffreyite	$(Ca,Na)_2(Be,Al)[Si_2$ $(O,OH)_7]$	$C22_21$	14.90	40.41	2.98	55.4.2.3
Leucophanite	$CaNaBe(Si_2O_6F)$	$P2_12_12_1$ or P1	**		2.948	55.4.2.4
Meliphanite	$(Ca,Na)_2Be[(Si,Al)_2$ $O_6(F,OH)]$	I4	10.516	9.887	3.024	55.4.2.5
Gugiaite	$Ca_2Be(Si_2O_7)$	$P4_21m$	7.419	4.988	3.113	55.4.2.6

*Orthorhombic, but pseudotetragonal $a = b = 14.90$.

**Orthorhombic and triclinic cells reported with essentially identical cell constants: $a = 7.401$, $b = 7.412$, $c = 9.990$, $\alpha = \beta = \gamma = 90^\circ$.

55.4.1.1 Åkermanite $\text{Ca}_2\text{Mg}(\text{Si}_2\text{O}_7)$

Named in 1884 by Vogt for Anders Richard Åkerman (1837–1922), Swedish metallurgist. Melilite–fresnoite group. TET $P42_1m$. $a = 7.835$, $c = 5.010$, $Z = 2$, $D = 2.944$. $35\text{-}592(\text{syn})$: 5.54_1 3.72_1 3.09_2 2.87_{10} 2.48_1 2.034_1 1.776_1 1.761_2 . Structure: *NJMM*: 1(1981). Anhedronal, equant grains; massive. Twinned on {100} and {001}. Colorless, gray, green, brown; vitreous luster; translucent to transparent. Cleavage {001}, distinct; conchoidal fracture. $H = 5\text{-}6$. $G = 2.90\text{-}2.97$. Uniaxial (+), sometimes anomalously biaxial with small $2V$; $N_E = 1.638$, $N_O = 1.631$, with indices increasing and converging to 1.652 at composition $\text{Ak}_{52}\text{Ge}_{48}$; indices may increase with iron substitution, decrease and converge with substitution of sodium to 1.625 at composition $\text{Ak}_{65}\text{Sm}_{35}$; anomalous interference colors. Near-end-member åkermanite is very rare, possibly unknown in nature. Substitution of aluminum for magnesium and silicon is common, as is substitution of sodium for calcium. Ferrous and ferric iron may also replace magnesium. See the discussion of melilite (55.4.1.3). Gelatinizes with HCl. No verified natural occurrences of end-member phases; commonly found in slags and as a synthetic product. Aluminian varieties found in contact zones and meteorites. Found in the Cascade Slide xenolith, Adirondack Mts., Essex Co., NY; in the Tres Hermanas Mts., Luna Co., NM. Found in the Allende, Mexico, meteorite and other carbonaceous chondrites. From Kilchoan, Ardnamurchan, Argyllshire, Scotland, and from Scawt Hill, County Antrim, Northern Ireland. Has been reported from Vesuvius and Monte Somma, Campania, Italy; from the Wessels mine, near Kuroman, Cape Prov., South Africa. The initial description by Vogt was from a slag. AR D6:476(1892), DHZ 1B:285(1986).

55.4.1.2 Gehlenite $\text{Ca}_2\text{Al}(\text{SiAlO}_7)$

Named in 1815 by Fuchs for Adolph Ferdinand Gehlen (1775–1815), German chemist. Melilite–fresnoite group. TET $P42_1m$. $a = 7.677$, $c = 5.059$, $Z = 2$, $D = 3.054$. $35\text{-}755(\text{syn})$: 3.71_2 3.06_2 2.85_{10} 2.43_2 2.41_1 2.39_1 1.754_3 1.750_2 . Structure: *NJMA* 44:254(1982). Short prismatic to equant crystals with {100}, {001} dominant; usually as anhedronal grains; massive. Twinning on {001} and {100}. Colorless, gray, straw-yellow, brown; vitreous luster. Cleavage {001}, distinct; {110}, poor; conchoidal fracture. $H = 5\text{-}6$. $G = 3.04$. Uniaxial (–), sometimes anomalously biaxial with small $2V$; $N_O = 1.667$, $N_E = 1.657$ for pure gehlenite, and decreasing and converging to 1.652 at composition $\text{Ak}_{52}\text{Ge}_{48}$. Indices decrease with substitution of sodium and increase with substitution of iron. Complete solid solution can form with åkermanite and partial solid solution with soda melilite. Ferric and ferrous iron may also substitute as well as minor cations. Naturally occurring low-Mg gehlenites are usually low in sodium and iron content. Gelatinizes in HCl. Occurs primarily as a component of skarns formed at the contact of siliceous limestones and monzonitic to dioritic intrusives, associated with melilite, wollastonite, larnite, spinel, magnetite, and others. In chondritic meteorites. At Iron Hill, Gunnison Co., Co; in Luna Co., NM,

light brown massive; at Crestmore, Riverside Co., CA; in chondrules in the Allende meteorite, Mexico (ca. $\text{Ak}_{30}\text{Ge}_{70}$), and other carbonaceous chondrites; at Carneal and Chalk, Scawt Hill, County Antrim, Northern Ireland; at Monte Monzoni, Val di Fassa, Trentino-Alto Adige (Tyrol), Italy; at Mayen, Eifel, Germany; Oravicza, Romania; Santorini volcano, Greece; Kushiro, Tojo-cho, Hiroshima Pref., Japan. AR *D6:476(1892)*, CM *10:822(1971)*, DHZII *1B:285(1986)*.

55.4.1.3 Melilite $(\text{Ca},\text{Na})(\text{Mg},\text{Al},\text{Fe})[(\text{Si},\text{Al})_2\text{O}_7]$

Named in 1796 by Delam  therie from the Greek *meli*, honey, in allusion to the color. Melilite–fresnoite group. Synonyms: humboldtilite, velardenite. TET $P42_1m$. $a = 7.789$, $c = 5.018$, $Z = 2$, $D = 3.09$. The lattice constants vary from 7.68 and 5.06 for pure gehlenite to 7.84 and 5.01 for pure akermanite, and decrease with substitution of sodium or iron. For $\text{Ak}_{33}\text{Ge}_{33}\text{Sm}_{34}$ the constants are 7.72 and 5.04. **Habit:** Equant to short prismatic crystals with {100} and {001} dominant; laths; more commonly as anhedral grains and massive. Twinning on {001} and {100}, also on {110} and $\{1\bar{1}0\}$ on a fine scale. **Physical properties:** Colorless, pale yellow, light brown; vitreous luster; translucent. Cleavage {001}, distinct {110}; conchoidal fracture. $H = 5\text{--}6$. $G = 2.9\text{--}3.1$. Uniaxial (–); isotropic, uniaxial (+), sometimes anomalously biaxial with small $2V$; anomalous interference colors serve to distinguish from apatite; $N_O = 1.631\text{--}1.667$, $N_E = 1.638\text{--}1.657$ for sodium- and iron-free melilites, converging to 1.652 at $\text{Ak}_{52}\text{Ge}_{48}$; for gehlenite-free melilite $N_O = 1.631$, $N_E = 1.638$ decreasing and converging to 1.626 at $\text{Ak}_{64}\text{Ge}_{36}$; for low-magnesium melilite the indices decrease to $N_O = 1.639$, $N_E = 1.633$ at $\text{Ge}_{65}\text{Sm}_{35}$; iron substitution may increase the highest of these indices to about 1.675. As a result of the complex substitutions, optical properties are not diagnostic for melilite composition. **Chemistry:** Soda-melilite is present up to 40% in natural melilites. Igneous rock melilite tends to compositions near $\text{Ak}_{70}\text{Sm}_{30}$ and decrease in sodium is accompanied by decrease in magnesium; metamorphic melilites have a broader range of composition, but significant sodium is generally present. Iron is commonly present in either oxidation state producing the yellow and brown coloration. Barium, strontium, manganese, nickel, zinc, and rare earths may also be present. Gelatinizes in cold, dilute HCl. **Occurrence:** In ultrabasic igneous rocks (uncompahgrites) melilite is a dominant constituent in association with pyroxene, magnetite, perovskite, and apatite; in potassic rocks with leucite, kalsilite, and olivine; in melilitites as phenocrysts and in the groundmass; in volcanic rocks. In skarns at the contact of impure limestones and igneous intrusives, primarily monzonites and diorites, but granites as well, with typical minerals of this environment. Akermanite is considered indicative of the sanidinite metamorphic facies. Sometimes replaced by clinopyroxene; alters to calcite and diopsidic pyroxene and to bicchulite. **Localities:** Adirondack Mts., NY; Magnet Cove, AR; in Uvalde Co., TX; Iron Hill, Gunnison Co., CO; Crestmore, Riverside Co.,

CA; Oahu, HI; Oka, QUE, Canada; Velardeña, DGO, Mexico; Gardiner intrusion, Kangerlussuak, eastern Greenland; Scawt Hill and Carneal, County Antrim, Northern Ireland; Massif Centrale, France; Monte Somma, Vesuvius, and *Capo di Bove, near Rome, Italy*; Santorino volcano, Greece; Kola and Turiy Penins., and Yakutia, Russia; Lake Baga-Dzoz-Nur, Mongolia; at Hatrurim and other localities in Israel; at Kushiro, Hiroshima-ken, and other localities in Japan; Merapi, Java; Etinde, Cameroons; Nyiragongo volcano, Zaire; Mt. Elgon, Uganda; Saltpetre Kop, South Africa. See also gehlenite (55.4.1.2). AR *D6:474(1892)*, *DHZII 1B:285(1986)*, *JISI 174:121(1953)*, *AM 38:643(1953)*, *CIWY: 359(1973-74)*.

55.4.2.1 Fresnoite $Ba_2TiO(Si_2O_7)$

Named in 1965 by Alfors et al. for the locality. Melilite-fresnoite group. TET $P4bm$. $a = 8.518$, $c = 5.211$, $Z = 2$, $D = 4.520$. $22-513(\text{syn})$: 3.82_3 3.30_5 3.08_{10} 2.70_3 2.61_2 2.15_2 2.07_2 1.874_2 . Structure: *ZK 130:438(1969)*. The structure contains titanium in an unusual tetragonal-pyramidal five-coordination. Lemon- to canary-yellow, vitreous luster. Fluoresces yellow (SWUV). $H = 3-4$. $G = 4.43$. Uniaxial (-); $N_O = 1.775$, $N_E = 1.765$. E, yellow; O, colorless. Found as subhedral to euhedral grains (0.1-3 mm) in sanbornite-quartz rock and sanbornite-poor quartzite with celsian, taramellite, diopside, and pyrrhotite near contact with granodiorite at *Big Creek, Rush Creek area, Fresno Co., CA*, and from the Victor mine, Clear Creek, and the Gem mine, San Benito Co.; from the Gunn claim, near Macmillan Pass, YT, Canada; Eifel district, Germany. AR *AM 50:314(1965)*.

55.4.2.2 Hardystonite $Ca_2Zn(Si_2O_7)$

Named in 1899 by Wolff for the locality. Melilite-fresnoite group. TET $P4\bar{2}_1m$. $a = 7.827$, $c = 5.014$, $Z = 2$, $D = 3.42$. $35-745(\text{syn})$: 5.02_1 3.72_4 3.09_6 2.87_{10} 2.48_4 2.04_1 1.762_4 1.750_2 . Structure: *ZK 130:427(1969)*. The larger zinc ions are in T1. Massive, granular, and disseminated grains. White to pink or light brown with substitution of Mn or Fe, vitreous luster. Cleavage {001}, distinct; {100}, {011}, poor. $H = 3-4$. $G = 3.4$. Uniaxial (-); $N_O = 1.669$, $N_E = 1.657$. Occurs in fine-grained banded ore with willemite, rhodonite, and franklinite at *North Hill mine, Hardyston Twp., Sussex Co., NJ*. AR *USGSP 180:93(1935)*.

55.4.2.3 Jeffreyite $(Ca,Na)_2(Be,Al)[Si_2(O,OH)_7]$

Named in 1984 by Grice and Robinson for the locality. Melilite-fresnoite group. See leucophanite (55.4.2.4), meliphanite (54.4.2.5), and gugiaite (55.4.2.6). Possibly dimorphous with gugiaite and meliphanite. ORTH (pseudo-TET) $C222_1$. $a = 14.90$, $b = 14.90$, $c = 40.41$, $Z = 64$, $D = 2.98$. $38-365$: 5.00_4 2.99_9 2.77_{10} 2.54_6 2.36_4 2.23_4 1.866_4 1.755_5 . Colorless, vitreous

luster. Cleavage {001}, {110}, perfect; brittle. $H = 5$. $G = 2.99$. Biaxial (-); $2V = 40^\circ$. $N_x = 1.625$, $N_y = 1.641$, $N_z = 1.643$. Found as thin, micaceous, pseudotetragonal plates at the *Jeffrey pit*, *Asbestos*, *Richmond Co.*, *QUE*, *Canada*, in a cavity in a rodingitized dike. AR *CM 22:443(1984)*.

55.4.2.4 Leucophanite $\text{CaNaBe}(\text{Si}_2\text{O}_6\text{F})$

Named in 1840 by Esmark from the Greek for *white* and to *appear*. Melilite-fresnoite group. See jeffreyite (55.4.2.3), meliphanite (55.4.2.5), and gugiaite (55.4.2.6), to which it may have a polymorphous relationship. ORTH $P2_12_12_1$. $a = 7.401$, $b = 7.412$, $c = 9.990$, $Z = 4$, $D = 2.948$ or, as given in a later study, TRIC $P1$ with essentially identical cell constants. 18-711: 5.94_2 3.60_4 2.97_3 2.76_{10} 2.32_3 1.988_2 1.705_2 . Structure: *ZK 202:71(1992)*. Sodium and calcium are ordered in contrast to melilite; half the Si occupies the T1 site, the balance being ordered with beryllium in the T2 site as in meliphanite. Short prismatic to tabular, pseudotetragonal, spherulitic. Twinned on {001} and {110}, penetration. Colorless, pale yellow, light green; vitreous luster; transparent to translucent. Cleavage {001}, perfect; {100}, {010}, distinct. $H = 3-4$. $G = 2.96$. Biaxial (-); $2V \approx 40^\circ$; $N_x = 1.570-1.571$, $N_y = 1.594-1.595$, $N_z = 1.596-1.598$; $XYZ = cab$; $r > v$, weak. Found in nepheline-syenite pegmatites. As excellent, transparent crystal up to 4 cm at Mt. St-Hilaire, *QUE*, *Canada*; *Narssarssuk*, *Greenland*; at *Låven*, *Langesundfjord*, *Norway*, and on *Arø* and *Stokkø*, and in *Telemark* and *Tvedalen*; *Lovozero* massif, *Kola Penin.*, *Russia*. AR *D6:417(1892)*, *MA 19:267(1968)*, *CM 27:193(1989)*.

55.4.2.5 Meliphanite $(\text{Ca},\text{Na})_2\text{Be}[(\text{Si},\text{Al})_2\text{O}_6(\text{F},\text{OH})]$

Named in 1852 by Scheerer from the Greek *honey* and to *appear*. Melilite-fresnoite group. See jeffreyite (55.4.2.3), leucophanite (55.4.2.4), and gugiaite (55.4.2.6) that may have a polymorphic relationship. TET $I4$. $a = 10.516$, $c = 9.887$, $Z = 8$, $D_{\text{calc}} = 3.024$. 31-304: 3.59_4 2.96_5 2.75_{10} 2.35_4 2.34_4 2.32_4 1.978_4 1.702_5 . Structure: *AC 23:260(1967)*. Half the silicon is in the T1 site, the balance being ordered with beryllium in the T2 sites of the double tetrahedral group. Thin tabular {001} or short, square prisms; as tabular or lamellar aggregates. Yellow in various shades, less commonly red, also colorless; vitreous luster; transparent to translucent. Cleavage {010}, perfect; {001}, distinct; uneven and brittle fracture. $H = 5-5\frac{1}{2}$. $G = 3.01-3.03$. Uniaxial (+/-); $N_O = 1.611-1.664$, $N_E = 1.592-1.672$; distinctly pleochroic in dark-colored examples. Reported both as gelatinized and as insoluble in HCl. Found in nepheline-syenite pegmatite at Mt. St-Hilaire, *QUE*, *Canada*, and at *Julianehaab*, *Greenland*, but recent lists of minerals from these localities do not include it. Found at *Frederiksværn*, *Norway*, and on several islands of the *Langesundfjord*; in the *Sakhariok* massif, *Kola Penin.*, *Russia*; reported from

Gugia, China, but this may be gugiaite. AR *ZK* 16:279(1890), *D6*:418(1892), *MR* 24:60(1993).

55.4.2.6 Gugiaite $\text{Ca}_2\text{Be}(\text{Si}_2\text{O}_7)$

Named in 1962 by Peng et al. for the locality. Melilite-fresnoite group. See jeffreyite (55.4.2.3), leucophanite (55.4.2.4), and meliphanite (55.4.2.5). *TET* $P\bar{4}2_1m$. $a = 7.419$, $c = 4.988$, $Z = 2$, $D_{\text{calc}} = 3.113$. 15-199: 5.25₄ 2.97₄ 2.77₁₀ 2.36₄ 2.32₄ 2.21₄ 1.709₇ 1.485₇. Structure: *NJMA* 143:210(1982). Cation distribution is ordered with Be in T1 and Si in T2. Tabular crystals with {001}, {011}, {111}, {110}. Colorless, vitreous luster, transparent. Cleavage {100}, perfect; {001}, distinct. $G = 3.03$. Uniaxial (+); $N_0 = 1.664$, $N_E = 1.672$. At *Gugia, China*, an inadequately defined locality, in skarn with orthoclase, vesuvianite, aegerine, sphene, apatite, and prehnite. AR *SS* 11:977(1962), *AM* 48:211(1963), *VLA* 2:129(1966).

55.5.1.1 Edgarbaileyite $\text{Hg}_6^{1+}\text{Si}_2\text{O}_7$ [AM 75:1192(1990)]

Named in 1990 by Roberts et al. for Edgar H. Bailey (1914–1983), geologist and mercury commodity specialist, U.S. Geological Survey. *MON* $C2/m$, Cm , or $C2$. $a = 11.755$, $b = 7.678$, $c = 5.991$, $\beta = 111.73^\circ$, $Z = 2$ [AM 75:1192(1990)], $D = 9.13$. 45-1438(nat): 6.28₂ 3.16₁₀ 3.03₃ 2.95₃ 2.77₂ 2.72₆ 2.32₂ 1.87₄. *MR* 21:215(1990). Structure determination shows that all Hg is present as $(\text{Hg}_2)^{2+}$ dimers. Rounded to mammillary; platy, flattened on {100}; cryptocrystalline and anhedral to 0.2-mm platy crystal aggregates with {100} dominant; polysynthetic twinning with twofold rotation about c , the composition plane is {100}, polysynthetic and coherent twinning. Photosensitive; fresh—lemon yellow to orangish yellow, exposed—dark olive-green to lighter yellowish green to dark green-brown; light green streak with yellow tinge; crystals are vitreous, masses are resinous; translucent to opaque. Well-developed {100} cleavage, irregular to subconchoidal fracture. $H = 4$. $G = 9.4$. IR data for region 250–4000 cm^{-1} . Heating to low red heat destroys the structure, native Hg is liberated, and the mineral turns white. X-ray diffraction = opal-CT. Heating to 1000–1100° for 14 hours produces tridymite and cristobalite. Soluble in cold 1:10 HCl and 1:1 HNO₃. Biaxial; all $N > 2.0$ (2.10–2.58 calculated); weakly pleochroic, lemon yellow, calculated RI values yield a minimum of 2.10 at 590 nm, and a maximum of 2.58; strong absorption; $\text{VHN} = \text{VHN}_{100} = 192$; color in plane-polarized light is gray to slightly lighter gray; internal reflections pale lemon yellow; weakly to strongly bireflectant; nonpleochroic. $R_{\text{air}} = 16.1\text{--}22.8$ (470 nm), 14.5–20.9 (546 nm), 14.1–20.3 (589 nm), 13.8–19.75 (650 nm); $R_{\text{oil}} = 4.69\text{--}9.12$ (470 nm), 3.90–7.95 (546 nm), 3.65–7.50 (589 nm), 3.48–7.16 (650 nm). Occurs at the California localities as thin crusts on fracture surfaces, as disseminated rounded to mammillary masses in small cavities and as hollow mammillary nodules. At Terlingua, Brewster Co., TX, occurs as ill-formed tabular aggregates and sheaves of crys-

tals in cavities and fractures associated with HgO, terlinguaite, eglestonite, and Hg. At the *Socrates mine*, *Sonoma Co., CA*, is associated with quartz, chalcedony, native Hg, HgS, and montroydite. At the Clear Creek claim, San Benito Co., CA, associated with HgO and Hg. Also at the San Luis Mine, Huahuxtla, Guerro, Mexico. Secondary product formed most probably by reaction of native Hg and quartz. EF

Si₂O₇ with Additional O, OH, F, and H₂O

56.1.1.1 Bertrandite Be₄[Si₂O₇](OH)₂

Named in 1883 by Damour for its discoverer, the French mineralogist, Emile Bertrand (1844–1909) designer of the Bertrand lens (petrographic microscope). ORTH *Cmc*2₁. $a = 8.716$, $b = 15.255$, $c = 4.565$, $Z = 4$, $D = 2.61$. *12-452*: (nat.) 4.385₆ 4.35₄ 3.91₂ 3.81₁₀ 3.16₅ 2.54₈ 2.52₄ 2.28₂; also *17-515* (replaced by *12-542*): 4.38₁₀ 3.94₄ 3.19₉ 2.54₈ 2.28₆ 1.555₃ 1.305₄. The structure contains dimeric (Si₂O₇) and (Be₂O₆OH) groups that are linked into a three-dimensional framework through shared oxygens (AM 72:979(1987) and NJBM 13(1992)). Sphaerobertrandite and gelbertrandite are two poorly characterized varieties. Habit is predominantly tabular {001} with {001} dominant, but may be platy or prismatic. Dominant forms are {001} and {001}, and {101}, {010}, {110}, with {100} less so. May also be flattened on {100} or {010}. The earlier, morphological setting gives a c axis twice that of the X-ray cell. The hemimorphic character is not generally obvious. Twinned (polysynthetic and heart or V-shaped) on {021} and {011}; other twins occur as well. Granular aggregates, also granular, massive and earthy. Rarely in sheaves or sprays with crystals to several cm. Colorless to white, pale yellow, pale pink, light brown; streak white, transparent to translucent; luster vitreous, somewhat pearly on {001}. Cleavage {001}, perfect; {010}, {110}, good; fracture conchoidal, brittle. $H = 6\frac{1}{2}$ –7. $G = 2.57$ –2.63. Pyroelectric. Soluble in HF, H₂SO₄, and NaOH. Partly soluble in HCl. Usually contains trace minor amounts of Fe, Al, and Ca. Biaxial (–); $2V = 73$ –81; $N_x = 1.584$ –1.591, $N_y = 1.598$ –1.605, $N_z = 1.611$ –1.614; $XYZ = abc$; $r < v$ weak. Widespread but sparse in granitic pegmatites-apiaites, pneumatolitic and hydrothermal veins as a late-stage product of beryl resorption and alteration, and may form pseudomorphs after beryl. Also in W and Sn-bearing veins and greisens. A fine-grained component along with fluorite in rhyolite and tuffs, and derived sediments, e.g., Spor Mountain, Utah. Found in a wide number of world-wide localities, only noteworthy and unusual localities are mentioned here. Occurs in a number of pegmatites at Stoneham, and world-class twins are from the Hayes Ledge quarry and Waisanen quarry, Greenwood, Oxford Co. and Auburn, Androscoggin Co., ME; Strickland quarry, Portland, Middlesex Co., CT; Amelia, Amelia Co., VA; the Dan Patch pegmatite, near Keystone, and the Helen beryl mine, near Custer, SD; crystals to 1 cm or

more, assoc. with beryl and phenakite, from Mount Antero, Chaffee Co., CO; in greisen at the Boomer mine, Park Co., CO; crystals to 3-4 cm from amazonite pegmatites in the Lake George Ring, Lake George, Park and Teller Counties, CO; an ore mineral at Spor Mountain, Juab Co., UT; Mt. Wheeler tungsten deposit, White Pine Co., NV; in pegmatites of the Pala district, San Diego Co., CA; Sierra de Aguachile, Acuña, COAH., MEX; Cornwall, England; *Barbin quarries, Petit-Port, near Nantes, Loire-Atlantique, France*; St. Gotthard, Switzerland; Pizzo Marcio, Val Vigezzo, Piedmont, and from San Pietro di Campo, Elba, Italy; Henneberg, Germany; Vest-Agder, Iveland, Norway; Erajarvi, Finland; Pisek, Bohemia, Czech. Rep.; Maršíkov, Ctidružice and Rožná, Moravia, Czech Rep.: in the Altai, Urals (emerald mines) and Transbaikal regions, Russia; good crystals to 2.5 cm from Kara-Oba, Akchatau and Kounrad, Kazakhstan; as flat plates to 3 cm(!) associated with beryl, scheelite, wolframite, and dolomite in vein deposits at the Tae Hwa mine, Neung Am Ri, Chung Cheong North Prov., South Korea; Klein Spitzkopje, Namibia; as sheaves (to 5 cm) of thick, tabular crystals(!) from the Golconda mine, 30 km from Governador Valadares, and as crystals to >4 cm from Conselheiro Peno, MG, and as blocky crystals to 1.5 cm(!) at the Ermo mine, Parelahs, RGN, Brazil. Mt. Isa, Queensland, Australia. Currently, the major world source of beryllium (Spor Mountain, Juab Co., UT.) EF and AR *D6:545(1892)*, *AM 45:1300(1960)*, *MIN 3(1):627(1972)*, *MAC SC 8:135(1982)*, *PCM 13:69(1986)*.

56.1.2.1 Hemimorphite $Zn_4[Si_2O_7](OH)_2 \cdot H_2O$

Named in 1853 by Kengott for the crystal morphology, but the mineral has been known from antiquity. Synonym: calamine, which may be a corruption of Cadmia or possibly from Latin *calamus*, reed, in allusion to a stalactitic habit. ORTH *Imm2*. $a = 8.367$, $b = 10.730$, $c = 5.115$, $Z = 2$, $D = 3.484$. 5-555: 6.60₉ 5.36₅ 4.62₄ 3.30₇ 3.29₇ 3.10₁₀ 2.56₅ 2.40₅. $[Si_2O_7]$ dimers lie approximately parallel to $[010]$. ZnO_3OH tetrahedra form sheets parallel to $\{010\}$ that are cross-linked by the silicate dimers and water molecules. **Habit:** As isolated or radiating groups of distinctly hemimorphic crystals, prismatic $[001]$ and flattened to greater or lesser degree parallel to $\{010\}$. The analogous end is usually highly modified, while the antilogous end is less complex but less frequently observed due to preferential implanting on $[001]$. Dominant forms are $\{010\}$, $\{110\}$, $\{001\}$, $\{121\}$, $\{301\}$. Twinning on (001) , thus joining the antilogous ends, and not optically detectable. Also found as thick, botryoidal encrustations of thick to almost fibrous crystals; granular and massive as well. **Physical properties:** Colorless to white, less commonly, pale yellow, pale green, sky-blue, brown; vitreous luster, pearly on $\{001\}$; transparent to translucent. Cleavage $\{110\}$, perfect; $\{101\}$, good; $\{001\}$, poor; uneven fracture; brittle. $H = 4\frac{1}{2}$ -5. $G = 3.4$ -3.5. Biaxial (+); $2V = 40$ -46° $N_x = 1.614$, $N_y = 1.617$, $N_z = 1.636$ for Na_D , the indices being fairly constant; $XYZ = bac$. Strongly pyroelectric. **Chemistry:** Dehydration experiments indicate that half of the total water content is lost continuously and below 500°

HEMIMORPHITE: $Zn_4Si_2O_7(OH)_2$

Rows of disilicate groups running down the *a* axis are linked by Zn. OH atoms also are bonded to Zn. The lack of centrosymmetry is due to the silicate groups, which are all in the same orientation.

without destruction of the crystals; the balance is lost only at significantly higher temperatures. Composition is close to the ideal, but often impure, due to admixture of smithsonite, clays, and iron oxides, the last, as hematite, often staining transparent crystal to a red hue. Gelatinizes in acids. **Occurrence:** A widespread, almost ubiquitous phase in the oxidation zone of zinc deposits. **Localities:** A type locality cannot be defined. Found as thick crusts of thick crystals with notched multiple terminations at Sterling Hill, Sussex Co., NJ; at Friedensville, Lehigh Co., PA, where it was mined extensively in the past; formerly abundant and mined at Austin's mines, Wythe Co., VA; with zinc ores of the Tri-State district, especially at Granby, Newton Co., MO; in fine crystals at Elkhorn, Jefferson Co., MT; at Leadville, Lake Co., CO; at the

Hemimorphite. Forms: *a*, {100}; *b*, {010}; *c*, {001}; *m*, {110}; *t*, {301}; *i*, {031}; *v*, {12 $\bar{1}$ }.

Bunker Hill mine, Kellogg, Shoshone Co., ID; at the 79 mine, Hayden, Gila Co., AZ; from the Organ Mts., Dona Ana Co., NM; in greenish-blue mammillary forms at the Emma mine, Salt Lake Co., UT. At Mapimí, DGO, as fine white to colorless crystals, and as sky-blue botryoidal crusts at the Santo Niño mine, Guadalupe Victoria, DGO; at the El Potosí mine, Francisco Potrillo, and the San Antonio mine(!) in fine crystals to 4 cm long, Santa Eulalia, CHIH, and other localities in Mexico. Found as sky-blue and green mammillary crusts at Roughten Gill, and at Alston Moor, Cumberland, and in Derbyshire, England; from Moresnet, Belgium, and the Aachen area of Belgium and Germany; in Almeria and Santander provinces of Spain; from Mte. Agruian, Monteponi, near Iglesias, Sardinia(!); at Bleiberg and Raibl, Austria; at Dognacska, Romania; at Lavrion, Attica, Greece. At Yadz, central Iran, with hydrozincite; large crystals at Nerchinsk, Chita (Transbaikalia), Russia. At Broken Hill, NSW, Australia. In fine crystal(!) at Djebel Guerour, NW of Setif, Algeria; at Tsumeb, Namibia. Use: A minor but significant ore of zinc. AR *D6:539(1892)*, *DT 632(1932)*, *ZK 146:241(1977)*.

56.2.1.1 Junitoite $\text{CaZn}_2[\text{Si}_2\text{O}_7] \cdot \text{H}_2\text{O}$

Named in 1976 by Williams for Jun Ito (1926–1978), American mineral chemist. ORTH *Bbm2*. $a = 6.318$, $b = 12.510$, $c = 8.561$ (original setting), $Z = 4$, $D = 3.516$. *29-394*: 6.25_4 4.70_5 3.53_{10} 2.82_{10} 2.54_{10} 2.52_5 2.35_7 1.540_6 . Structure: *MM 49:91(1985)*. Structurally related to hemimorphite. Distinctly hemimorphic crystals, tabular {010} and elongated [001], 4–5 mm long and 0.5 mm thick with dominant forms {010}, {001}, {131}, {111}, {101}. Colorless to milky white. Cleavage {010}, good; {100}, {101}, poor. $H = 4\frac{1}{2}$. $G = 3.5$. Biaxial (+); $2V \approx 90^\circ$; $N_x = 1.656$, $N_y = 1.664$, $N_z = 1.672$; $r < v$, weak. Strongly pyroelectric. Found with kinoite, apophyllite, and xonotlite in a retrogressively altered tactite zone at *Christmas mine, Gila Co., AZ*. AR *AM 61:1255(1976)*.

AXINITE GROUP

Axinite group minerals have the chemical formula

where

- A = Ca, Mn
 M = Fe^{2+} , Mg, Mn
 C = Al_2

and the structure is in the triclinic space group P1.

The structure consists of Si_2O_7 groups linked in offset finite chains by BO_4 tetrahedra. The result is an Si_2O_7 group with an “apex-down” corner-shared BO_4 group. The remaining corners of this BO_4 group are shared with two

FERROAXINITE: $(\text{Fe, Mg})_2\text{Ca}_4\text{Al}_4(\text{OH})_2(\text{B}_2\text{Si}_8)\text{O}_{30}$

Axinite is not a true sheet silicate, but contains $\text{B}_2\text{Si}_8\text{O}_{30}$ units—a ring of B_2Si_4 plus pairs of Si tetrahedra branching off. These are arranged in sheets with all the cations in between. The rings are compressed laterally, and unlike standard sheet silicates, the OH atoms are not at the center of the 6-rings. As in pyroxenes and amphiboles, the Ca atoms are coordinated partly by the bases (bridging oxygens) of tetrahedra, while smaller cations are coordinated by apices (nonbridging oxygens).

additional Si_2O_7 groups. The chain narrows, but the Si_2O_4 groups share corner oxygens with a second “apex-up” borate tetrahedron, and continues with a fourth Si_2O_4 group rotated 180° with respect to the first group. The prominent motif of the structure is a $\text{B}_2\text{Si}_8\text{O}_{30}$ polyanion with a midlength six-membered ring organized in sheets. Two kinds of octahedra, also organized in sheets, separate the polyanionic $\text{B}_2\text{Si}_8\text{O}_{30}$ sheets. One type consists of relatively small edge-sharing but symmetrical octahedra with hydroxyl substituting for oxygen $[\text{AlO}_5\text{OH}]$. A larger distorted octahedron $[\text{M}^{2+}\text{O}_6]$ containing Ca^{2+} shares an edge with an $[\text{AlO}_5\text{OH}]$ octahedron. The two octahedra form a finite chain of four small $[\text{AlO}_5\text{OH}]$ octahedra terminated on both ends by large $[\text{M}^{2+}\text{O}_6]$ octahedra containing Fe^{2+} , Mn^{2+} , and Mg^{2+} . Two types of large six-membered antiprisms roughly parallel the short, essentially colinear octahedral chains. One antiprism is “isolated” and one is edge sharing.

All of the axinite minerals are [all] triclinic, P1, with dimensions approximately $a = 8.97$, $b = 9.17$, $c = 7.15$, $\alpha = 102.8^\circ$, $\beta = 98.2^\circ$, $\gamma = 88.1^\circ$. *AM* 64:635(1979), 66:428(1981); *ZK* 140:389(1974), 140:289(1974); *DHZ* 1B:603(1986); *MIN* 3(22):213(1981).

AXINITE GROUP

Mineral	Formula			Space Group	
	A	M	C		
Ferroaxinite	Ca ₂	Fe ²⁺	Al ₂	P $\bar{1}$	56.2.2.1
Magnesioaxinite	Ca ₂	Mg ²⁺	Al ₂	P $\bar{1}$	56.2.2.2
Manganaxinite	Ca ₂	Mn ²⁺	Al ₂	P $\bar{1}$	56.2.2.3
Tinzenite	CaMn	Mn ²⁺	Al ₂	P1	56.2.2.4

56.2.2.1 Ferroaxinite Ca₂FeAl₂[BSi₄O₁₅](OH)

Named in 1909 by Schaller for its chemical relationship to the axinite group (i.e., predominance of iron). Axinite group. TRIC P1. $a = 8.953\text{--}9.962$, $b = 9.190\text{--}9.203$, $c = 7.144\text{--}7.159$, $\alpha = 102.63\text{--}102.80^\circ$, $\beta = 98.08\text{--}98.19^\circ$, $\gamma = 88.18\text{--}88.24^\circ$, $Z = 2$, $D = 3.29\text{--}3.32$. $\rho_7\text{--}76$: 6.3₇ 3.68₆ 3.46₈ 3.28₆ 3.16₉ 3.00₆ 2.81₁₀ 2.16₇. Structure: ZK 140:289(1974), AM 66:428(1981). Thin wedge-shaped "axehead" crystals are common, frequently arranged in rosettes; massive ferroaxinite varies from granular replacements or in-fillings to lamellar groups of closely intergrown crystals. Usually gray to bluish gray, brown, honey-brown or violet, occasionally green; uncolored streak or extremely faintly similar to body color; vitreous luster. Cleavage {100}, good; {001}, {110}, {011}, poor; uneven to conchoidal fracture brittle. $H = 6\frac{1}{2}\text{--}7$. $G = 3.23\text{--}3.32$. Generally nonfluorescent. Intermediate compositions approaching manganaxinite are common, although a complete series could extend to magnesioaxinite. Compositions with as much as 2.4 wt % MgO are rare, but even 1.2 wt % MgO greatly affects optical properties (e.g., decreasing refractive indices). Ferroaxinite from Obira is exceptional due to a small amount of Al substituting for Si. Si- and β -deficient ferroaxinite with an excess of trivalent cations (Al,Fe) was reported from Strzegom MPOL 25:63(1994). Ti⁴⁺ to 0.19 wt % (Meldon, UK), while Na₂O to 0.33 wt % (Jokioinen, Finland) and K₂O to 0.21 wt % (Meldon, UK) have also been observed. Biaxial (-); $N_x = 1.674\text{--}1.683$, $N_y = 1.682\text{--}1.691$, $N_z = 1.685\text{--}1.694$; $2V = 67\text{--}73^\circ$. Due to the frequent substitution of Mg in iron-bearing axinites, the refractive indices overlap with that of Mn-rich axinites, which are usually Mg-poorer. Found in quartz-calcite veins, alpine-type veins, shear-zone mineralization, especially in high-grade metamorphic zones; hydrothermal metasomatism of granite or aplite, rarely in granitic pegmatites; at igneous contacts with sedimentary rocks. Can be associated with epidote-clinozoisite, grossular, vesuvianite, ilvaite, hedenbergite, hastingsite, datolite, danburite, prehnite, titanite, plagioclase, microcline, arsenopyrite, pyrite, zeolites, and others. Rarely replaced by clinocllore-chamosite and/or smectite. Occurs in many worldwide localities; notable localities include: Oxford and Franklin, and pink crystals at Bridgeville, NJ; Kibblehouse quarry, Perkiomenville, PA; Luck quarry, Goose Creek, VA; Foote quarry, Kings Mt., NC. Moosa canyon, Bonsall, San Diego Co.; Coarse Gold, Madera Co.; clear purple-brown crystals to 10 cm at the New Melones Dam(l), Calaveras Co.; at

Riverside, Stinson Beach, and Yreka, CA, Elkhorn, Jefferson Co., MT; Hope, BC, and Moneta mine, Timmins, ONT, Canada; Los Galvalontos(1) and Trinidad, Baja California; San Sebastian mine, Charcas, SLP, Mexico; Botallack mine and Roscommon Cliff, St. Just (Tremore), Bodmin, and Liskeard, Cornwall, Meldon, Okehampton, Devon, England; Jokioinen and Petsamo, Finland; Kongsberg, Buskerud, Norway; St. Christophe(1), Bourg d'Oisans and La Balme D'Auris(1), Isère (Dauphiné), France; Alpe Scopi(1), Luckmanier Pass, Berg Sroyi, and Piz Vallatcha, Grisons, Sankt Jakob, Uri, Switzerland; Freseberg and Pferdekopf, Harz Mts., Ehrenfriedersdorf and Thum, Saxony, Raudatal, Germany; Davle and Zbraslav, and Libodrice, west of Kolín, Czech Republic; Knappenwand, Tirol, Austria; Monzoni, Trentino-Alto Adige, Val Tremola, Baveno, Novara, Italy; 5- to 7-cm crystals at Val D'Ossola near Premia, Italy; Strzegom, Wroclaw, Poland; extremely fine reddish-purple brown, sharp crystals to 15 cm from the Puiva deposit, Saranpaul, Tyumen district, polar Ural Mts., and Berkutskaya Sara Kreis, Zlatoust, Ural Mts., Russia; Fazenda Baixa da Brauna(1), Santa Rosa, and Victoria da Conquista, BAH, Brazil; Colebrook Hill(1), Tasmania, and Bowling Alley Point, western New England, NSW, Australia; Obira(1), Bungo, Oita Pref., Iwatamura, Nishius, Oki Gun, Hicoga Pref., Hajikami and Yamura, Hyugo, and Toroku mine, Iwate, Miyazaki Pref., Japan. *VK, EF AM 64:635(1979), MIN 3(2):213(1981), DHZ 1B:603(1986)*.

56.2.2.2 Magnesioaxinite $\text{Ca}_2\text{MgAl}_2[\text{BSi}_4\text{O}_{15}](\text{OH})$

Named in 1975 by Jobbins et al. for its chemical relationship to the axinite group (i.e., dominance of Mg). Axinite group. *TRIC P1*. $a = 8.933$, $b = 9.155$, $c = 7.121$, $\alpha = 102.59^\circ$, $\beta = 98.28^\circ$, $\gamma = 88.09^\circ$, $Z = 2$, $D = 3.18$. Cell constants of magnesioaxinite from the type locality are anomalous for the axinite group. *AM 64:643(1979)*. $29-344$: 6.29_3 3.44_7 3.27_2 3.14_7 2.80_{10} 2.56_3 2.18_3 2.15_3 . Magnesioaxinite from the type locality is nearly end member, while analyses of the mineral from Luning, Nevada, grade from manganoean ferroan magnesioaxinite into manganoean ferroaxinite. *MR 11:13(1980)*. Crystals of magnesioaxinite are thin wedge-shaped "axeheads"; striations are common. Violet-blue to light gray-brown to pink, white streak to an extremely pale shade of its body color; vitreous luster. Cleavage {100}, good; {011}, {110}, {001}, poor; brittle. $H = 6\frac{1}{2}$. $G = 3.18-3.26$. As much as 0.13 wt % V_2O_3 is present in material from Tanzania and is responsible for the color and pleochroism. Generally fluorescent red to orange-red in both SWUV and LWUV. Biaxial (- or +); $N_x = 1.667-1.669$, $N_y = 1.673-1.675$, $N_z = 1.678-1.680$; $2V \approx 82^\circ(-)-109^\circ(+)$; $r > v$, strong; pleochroic, shades of pale blue to pale violet to pale gray. Originally identified from a faceted gemstone. First found in alluvium, later found in contact-metasomatic skarns. Associated with epidote, calcite, tremolite-actinolite, vesuvianite, and prehnite. Occurs at Luning, Mineral Co., Nevada; Arusha dist., Tanzania; London Bridge, near Queanbeyan, NSW, Australia. *VK, EF JG 14:368(1975), AM 61:503(1976), MIN 3(2):213(1981), DHZ 1B:603(1986)*.

56.2.2.3 Manganaxinite $\text{Ca}_2\text{MnAl}_2[\text{BSi}_4\text{O}_{15}](\text{OH})$

Named in 1909 by Fromme for its chemical relationship to the axinite group (i.e., predominance of manganese). Axinite group. TRIC $P\bar{1}$. $a = 7.157\text{--}7.162$, $b = 9.13\text{--}9.213$, $c = 8.938\text{--}8.978$, $\alpha = 91.80\text{--}91.87^\circ$, $\beta = 98.07\text{--}98.80^\circ$, $\gamma = 76.77\text{--}77.30^\circ$, $Z = 2$, $D = 3.31$. 27-84: 6.31₂ 3.69₁ 3.47₇ 3.44₂ 3.16₁₀ 2.89₂ 2.81₅ 2.19₂. Thin wedge-shaped "axehead" crystals are common, frequently arranged in rosettes; massive manganaxinite varies from granular replacements or in-fillings to lamellar groups of congested crystals. Usually yellow to golden brown, also gray-brown, occasionally green; uncolored streak or extremely pale, similar to body color; vitreous luster. Cleavage {100}, good; {001}, {110}, {011}, poor; brittle. $H = 6\frac{1}{2}\text{--}7$. $G = 3.30\text{--}3.36$. Frequently fluorescent red in both SWUV and LWUV. Frequently low in MgO (<0.5 wt %). Franklin, NJ, manganaxinite can have Fe_2O_3 (to 0.83 wt %), CuO (0.12 wt %), PbO (0.09 wt %), and ZnO (4.49 wt %). Biaxial (-); $N_x = 1.672\text{--}1.684$, $N_y = 1.678\text{--}1.692$, $N_z = 1.687\text{--}1.696$; $2V = 60\text{--}77^\circ$; $r < v$, strong; pleochroic, yellow-colorless to amber-pale yellow. Found in quartz-calcite veins; igneous contact zones especially with mafic rocks; occurs in some granitic pegmatites. Associated minerals include quartz, plagioclase, microcline, chamosite, spessartine, andradite, johannsensite, rhodonite, and other manganese silicates, tourmaline, datolite, also with many rare minerals. Many worldwide localities are known and only notable or unusual localities are given here: occurs at the Franklin Mine(1), Franklin, and Sterling Hill mine, Ogdensburg, NJ; Avondale, Delaware Co., Cornog, Chester Co., Easton, Northampton Co., and Camels Hump, Bethlehem, PA; McKinney mine, Mitchell Co., NC; Mitchell mine, Babbitt, MN; Iron Cap mine, Landsman Camp, Graham Co., and Huachuca Mts., Cochise Co., AZ; Consummes mine, Amador Co., Greystone mine, Genesee Valley, Plumas Co., and Little Three mine, Ramona, San Diego Co., CA; Marmora, ONT, Canada; Guadalcazar, Mexico; Aarvold Valley, Norway, Bareges, Pyrennes, France; Radaul, Germany; Monte Pù, Ligurian Apennines, Italy; Takanosu mine, Kami Kasuo, Awano-machi, Kamitsuga-gun, Tachigi Pref., Obiva mine, Bungo, Oita Pref., Anawai mine, Kochi-ken, Shikoku, Japan; Julcani mine, Julcani district, Peru. vk, EF. *MIN* 3(2):213(1981), *DHZ* 1B:603(1986).

56.2.2.4 Tinzenite $(\text{CaMn})\text{MnAl}_2[\text{BSi}_4\text{O}_{15}](\text{OH})$

Named in 1923 by Jakob for the type locality. Axinite group. Formerly called severginite (along with manganaxinite) in Russia. TRIC $P\bar{1}$. $a = 7.153\text{--}7.162$, $b = 9.103\text{--}9.184$, $c = 8.945\text{--}8.958$, $\alpha = 91.86\text{--}91.97^\circ$, $\beta = 98.31\text{--}98.68^\circ$, $\gamma = 76.97\text{--}77.29^\circ$, $Z = 2$, $D = 3.45$. 6-444: 6.30₇ 3.46₈ 3.28₆ 3.14₇ 2.98₇ 2.81₁₀ 2.17₇ 2.01₇. Structure: *PM* 42:369(1973). Mn occupies one of the two Ca positions. Thin wedge-shaped "axehead" crystals are common, frequently encased in quartz or as tightly clustered vein linings of terminated crystals. Usually light to dark yellow or orange to brownish orange, but may be orange-red or rose; colorless streak; vitreous luster. Cleavage {100}, good; {001}, {110}, {011}, poor; brittle. $H = 6\frac{1}{2}\text{--}7$. $G = 3.29\text{--}3.36$. Nonfluorescent. Near-

end-member compositions reported, minor MgO (to 0.20 wt %), FeO to 2.48 wt %. Biaxial (-); $N_x = 1.690\text{--}1.694$, $N_y = 1.697\text{--}1.701$, $N_z = 1.698\text{--}1.706$; $2V = 63\text{--}88^\circ$; $r > v$, strong; pleochroic. X, yellow-green or colorless; Y, yellow; Z, colorless to pale yellow. Found in quartz veins and in metamorphosed Mn-bearing ophiolites. Occurs at the Cassagna and Gambatesa mines, near Chiavari, Liguria, Italy; *Alpe Parsettens, near Tinzen, Val d'Err, Grisons*, and at Tinzen, Graubunden, *Switzerland*; Camis Fe-Mn deposit, central Kazakhstan, Kazakh Republic; Akatore, New Zealand. Sometimes altered to black manganese oxides. *VK, EF AM 84:635(1979)*.

56.2.3.1 Lawsonite $\text{CaAl}_2[\text{Si}_2\text{O}_7](\text{OH})_2 \cdot \text{H}_2\text{O}$

Named in 1895 by Ransom for Andrew Cowper Lawson (1861-1952), American geologist, University of California. Dimorphous with partheite. Isostructural with hennomartinite (56.2.3.2). ORTH *Ccmm*. $a = 8.795$, $b = 5.847$, $c = 13.142$, $Z = 4$, $D = 3.088$. *15-533: 4.84₆ 3.66₆ 2.73₇ 2.68₅ 2.62₁₀ 2.43₆ 2.13₆ 1.550₈*. Structure: *AM 63:311(1978)*. Calcium is in a distorted octahedral coordination with two additional, more distant oxygens; aluminum-oxygen octahedra form edge-sharing chains parallel to [010] that are bridged by the $[\text{Si}_2\text{O}_7]$ dimers. The cell is dimensionally similar to that of ilvaite and may correspond to its high-temperature orthorhombic form. Crystals tabular {010} with {010} and {101} dominant, or prismatic [010] with {101}, {011}, and {010} dominant; lamellar twinning on {101}. Data for transformation to other morphological and optical settings are inconsistent. Also as subhedral tablets, massive, and granular. Colorless, white, gray, pale blue, pinkish; vitreous to greasy luster, translucent. Cleavage {100}, {010}, perfect; {101}, imperfect. $H = 6$. $G = 3.05\text{--}3.12$. Biaxial (+); $2V = 76\text{--}87^\circ$ $XYZ = cab$; but also reported as $XYZ = abc$; $N_x = 1.663\text{--}1.665$, $N_y = 1.672\text{--}1.675$, $N_z = 1.682\text{--}1.686$; $r > v$, strong. Pleochroic in thick sections; X, light blue; Y, yellowish; Z, colorless. Insoluble in acids. Stoichiometrically close to the ideal formula with negligible substitution of Al for Si, and only minor substitution of Fe^{3+} for Al; an occurrence in the French Alps is reported with $\text{Cr}^{3+}/\text{Al} \approx 9:2$, which should properly be a distinct species. Characteristic of low-temperature metamorphism and a common component of the blueschist facies; commonly in glaucophane schists with chlorite, epidote, and pumpellyite. Found at the *Tiburón Peninsula, Marin Co., CA*, and in euhedra to 5 cm (!) near Covelo in Mendocino Co., and other localities in that state; near Darrington, Snohomish Co., WA. In a xenolith in serpentinite at Santa Clara, Cuba. At Anglesey, Wales; in recrystallized gabbro in the Roche Noire massif in the French Alps (chromian), and in other Alpine regions of Europe; in metamorphosed pillow lavas of northern Calabria, Italy; Corsica; Crete. In the Tavsanli region of northwestern Turkey; the Penzha Range, Kamchatka, eastern Russia. At Kamuikotan, Hokkaido, at Ogoose, Saitama Pref., and other sites in Japan; in New Caledonia; in the metagreywackes and slates of Maitai Valley, Nelson, New Zealand; South Shetland Is., Antarctica. *AR AJS 258:689(1960), DHZII 1B:180(1986)*.

56.2.3.2 Hennomartinitite $\text{SrMn}_2^{3+}[\text{Si}_2\text{O}_7](\text{OH})_2 \cdot \text{H}_2\text{O}$

Named in 1993 by Armbruster et al. for Henno Martin, German geologist who escaped to South West Africa during the Hitler regime; he later worked for the Geological Survey of South Africa, and subsequently became director of the Geology-Paleontology Institute, University of Göttingen. Compare lawsonite (56.2.3.1). ORTH *Cmcm*. $a = 6.245$, $b = 9.031$, $c = 13.404$, $Z = 4$, $D = 3.68$. *PD*: 4.80₂ 4.29₆ 3.37₇ 2.83₁₀ 2.81₈ 2.72₆ 2.70₁₀ 2.40₇. Structure: *EJM* 4:17(1992). Isostructural with lawsonite. Yellow-brown, vitreous luster, translucent. $H \approx 4$. Biaxial; $2V \approx 63^\circ$; $N > 1.82$; strongly pleochroic, yellowish brown to dark red-brown. Barium and ferric iron are very minor substituents for strontium and manganese, respectively. Found, with kornite, as poikiloblasts overgrowing sugilite in a felted, serandite-pectolite rock at the *Wessels mine, Kalahari manganese field, South Africa*. AR *SMPM* 73:349(1993).

56.2.3.3 Ilvaite $\text{CaFe}^{2+}\text{Fe}_2^{3+}\text{O}[\text{Si}_2\text{O}_7](\text{OH})$

Named in 1811 by Steffens for the locality (Latin *Ilva*, Elba). Synonym: lievrite. MON (below 70°) $P2_1/a$. $a = 13.010$, $b = 8.804$, $c = 5.852$, $\beta = 90.21^\circ$, $Z = 4$, $D = 4.05$. *12-149*: 7.31₇ 3.26₆ 2.87₇ 2.84₁₀ 2.72₇ 2.68₁₀ 2.18₆ 2.17₆. ORTH (above 70°) *Pnam*. $a = 13.005$, $b = 8.818$, $c = 5.853$, $Z = 4$ (transposed to agree with monoclinic cell). Structure: *ZK* 144:161(1976), 179:415(1987). Ferrous and ferric iron lie near the centers of two (A and B) tetragonally distorted octahedral sites that form, by edge sharing, double chains parallel to [001]. Calcium is seven-coordinated, and Si is in $[\text{Si}_2\text{O}_7]$ dimers. The displacive transformation from high-temperature orthorhombic to low-temperature monoclinic appears to be the result of electron ordering in the A sites. The morphological and physical property descriptions are in terms of the orthorhombic symmetry, with a and b reversed from the values above (i.e., in the traditional setting for this species). Crystals are of short to long prismatic [001] habit and frequently striated in that zone. Dominant forms are {110}, {120}, {010}, {111}, {101}, sometimes with many additional terminating forms. Coarsely crystalline, massive, and granular. Black to dark grayish black, greenish to brownish black streak, nearly opaque. Cleavage {010},

ILVAITE

Ilvaite. forms (orthorhombic indexing): b, {010}; m, {110}; s, {120}; r, {101}, o, {111}.

ILVAITE: $\text{CaFe}_3\text{OSi}_2\text{O}_7\text{OH}$

Fe^{2+} and Fe^{3+} octahedra form chains parallel to *c*, cross-linked by Ca and Si_2O_7 groups.

{001}, distinct; {100}, indistinct; brittle. $H = 5\frac{1}{2}$ –6. $G = 4.0$. Biaxial (-); $2V = 20$ – 30° ; $N_x = 1.727$, $N_y = 1.870$, $N_z = 1.853$; $XYZ = cba$; $r < v$, strong; pleochroic, $X > Y > Z$ dark green to yellow brown; but also $N_x = 1.830$, $N_y = 1.92$, $N_z = 1.925$ with the same orientation, and also $N_y = 1.89$, $N_z = 1.92$ – 1.93 with $XYZ = bac$. Gelatinizes with HCl, fusible at 2.5 to a magnetic bead. Up to ≈ 8.5 wt % MnO has been reported. Occurs in contact-metasomatic iron, zinc, and copper ores; in sodalite-syenites; and associated with zeolites. Found at Balmat, NY; North Clear Creek, Gilpin Co., CO; at the Laxey mine(!), South Mountain, Owyhee Co., ID; in the Fierro-Hanover district, Grant Co., NM; in the Dragoon Mts., Cochise Co., AZ; in Fresno, Shasta, and Sonoma Cos., CA. Found in sodalite-syenites of the Ilimaussaq complex, Julianehaab district, Greenland; at Thyrrill, Iceland; at Fossum, near Skeen, Norway. At Andreasberg, Harz; near Herborn (manganian), Hessen-Nassau; and other sites in Germany. In Italy at Mte. Mulatto near Predazzo, Trentino, in the Italian Tyrol, and at the Temperino mine, Tuscany; in large crystals(!) and aggregates with pyroxene in dolomite at Capo Calamita and *Rio Marina, Elba*; and on Seriphos, Cyclades, Greece. In lustrous black crystals(!) at the Sovietskiy mine No. 1, Dal'negorsk, Primor'ye, eastern Russia. Found at the Chichibu mine, Saitama Pref., the Hideya mine, Niigata Pref., Honshu, and other localities in Japan. At Cap Bougaroun, Constantine, Algeria. AR. *D6:541(1892)*, *SMPM 52:57(1972)*, *PCM 14:151(1987)*.

CUSPIDINE-WÖHLERITE GROUP

The cuspidine or cuspidine-wöhlerite group consists of an assortment of poorly defined minerals that may or may not have some chemical and structural similarities. Much additional work needs to be done on members of this poorly defined group.

CUSPIDINE

Foshallasite	56.2.9.3

56.2.4.1 Baghdadite $\text{Ca}_3\text{Zr}(\text{Si}_2\text{O}_7)\text{O}_2$

Named in 1986 by Al-Hermezi et al. for the city of Baghdad, Iraq. Cuspidine-wöhlerite group. See other members of the group. MON $P2_1/a$. $a = 10.36\text{--}10.42$, $b = 10.15\text{--}10.16$, $c = 7.36\text{--}7.38$, $\beta = 90.7\text{--}91.1^\circ$, $Z = 4$, $D = 3.48$. 16-0155(nat): 7.30_{4,5} 3.23₈ 3.04_{7,5} 2.98_{8,5} 2.88₇ 2.84₁₀ 2.43_{3,5} 1.70₄; 39-195(syn): 7.26₃ 3.22₁₀ 3.02₅ 2.98₅ 2.98₅ 2.86₅ 2.84₈ 1.99₃ 1.97₅. Stumpy, prismatic; to 250 μm across, very rare; twinning = contact with b as the twin axis. Colorless, vitreous luster. No cleavage. $H \approx 6$. $G = 3.46$ (syn $\text{Ca}_3\text{ZrSi}_2\text{O}_9$). Cathodoluminescence color is dull gray with a greenish tint; slowly soluble in concentrated HCl and insoluble in concentrated HNO_3 and concentrated H_2SO_4 . Analysis (wt %): SiO_2 , 29.3; ZrO_2 , 27.0; TiO_2 , 2.1; Fe_2O_3 , 0.11; Al_2O_3 , 0.03; MgO , 0.05; CaO , 41.4; Na_2O , 0.02; $\Sigma = 100.02 + \approx 0.16\%$ HfO_2 . Biaxial (+); $XZ = ca$, Y parallel to b ; $N_x = 1.652$, $N_y = 1.658$, $N_z = 1.670$; $2V = 72^\circ$; birefringence = 0.018; no dispersion. Occurs at *Dupezeh Mountain, Qala-Dizeh region, Iraq*; in melilite skarn in contact with a banded diorite. Associated with calcite, perovskite, wollastonite, and melilite. EF *DAN SSSR 142:639(1962)*, *MM 50:119(1986)*.

56.2.4.2 Burpalite $\text{Na}_2\text{CaZrSi}_2\text{O}_7\text{F}_2$

Named in 1990 by Merlino et al. for the locality. Cuspidine-wöhlerite group. Polytypes: "orthorhombic lävenite" (*DAN SSSR ESS 146:128(1966)*) and *TMMAN SSSR 24:203(1975)*. Probably a polytype of burpalite. Same locality as burpalite, same formula. $b = 10.05$, $a = 11.11$, $c = 7.23$, $\beta = 109.0^\circ$, b of burpalite = ($a \sin \beta = 10.30$). MON $P2_1/a$. $a = 10.1173$, $b = 10.4446$, $c = 7.2555$, $\beta = 90.039^\circ$, $Z = 4$ [*EJM 2:177(1990)*], $D = 3.27$. 42-1322(nat): 5.23_{2,5} 4.56_{1,5} 3.30₄ 3.20₂ 2.95₁₀ 2.87₆ 2.84_{2,5} 1.78₂; *EJM 2:177(1990)*: 3.31_m 3.03_m 2.96_{vs} 1.89_{ms} 1.79_s 1.68_m 1.56_{ms}. One of 10 possible structure types derived for the cuspidine-wöhlerite family. $R = 0.067$. Order-disorder character present. Domains with lävenite-type structure are often present in burpalite crystals. *EJM 2:177(1990)*. Platy on (010) elongated parallel to [001]; crystals to 1 mm \times 3 mm \times 5 mm, forms: {110}, {001}, {011}, {101}, and {111}. Colorless, white; vitreous luster. No cleavage, no parting, conchoidal fracture, brittle, strong tenacity. $H = 5\text{--}6$. $G = 3.33$. Glows weak yellow orange in X-rays. Decomposed by 10% HCl at 25°. Analysis (wt %): Na_2O , 13.9; CaO , 14.5; MnO , 0.6; FeO , 0.43; SiO_2 , 31.8; TiO_2 , 1.06; ZrO_2 , 31.11; Nb_2O_5 , 0.22; Y_2O_3 , 0.32; H_2O , 1.23; F , 8.1. Biaxial (-); $XYZ = bca$; $\text{Na}(D)$: $N_x = 1.627$, $N_y = 1.634$, $N_z = 1.639$; colorless, $2V = 82^\circ$; $r < v$, weak. Occurs in fenitized sandstone in the contact zone of the *Burpalinsky alkaline massif, Maygunda R., northern Transbaikal, Russia*, 120 km NE of the northern extremity of Lake Baikal. Associated minerals are albite, nepheline, aegirine, alkali amphibole, biotite, catapleiite, astrophyllite, fluorite, and accessory loparite. EF

56.2.4.3 Cuspidine $\text{Ca}_4(\text{Si}_2\text{O}_7)\text{F}_2$

Named in 1876 by Scacchi from the Latin *cuspidis*, spear, in allusion to the characteristic habit of the crystals. Cuspidine-wöhlerite group. MON $P2_1/a$. $a = 10.906\text{--}10.909$, $b = 10.521\text{--}10.547$, $c = 7.518\text{--}7.539$, $\beta = 109.3\text{--}109.6^\circ$, $Z = 4$

[*MJJ* 8:286(1977)], $D = 2.98$. 41-1474(nat): 3.26₂ 3.06₁₀ 2.95₂ 2.93₂ 2.90₃ 2.87₅ 2.02₁ 1.88₂. A sorosilicate in which Si_2O_7 groups are elongated parallel to the a axis. The Ca atoms that connect these Si_2O_7 groups have six to eight nearest neighbors of oxygen atoms. *ZVMO* 84:159(1955), *MJJ* 8:286(1977). Earthy claylike masses, fine crystals to 1 cm; twinning present on {102} and sometimes polysynthetic twinning is present. Colorless, white, pale rose, rose-red, green; white streak; vitreous luster. Cleavage {100}, good; {122}, rare. $H = 5-6$. $G = 2.97-2.99$ (Franklin). Franklin material fluoresces strong yellow to light violet in LWUV; fluorescence in SWUV is similar but weaker; Crestmore material fluoresces a weak grey-tan in SWUV and weak gray in LWUV. Soluble in HNO_3 , also soluble in HCl with production of a silica gel. Analysis (wt %): Ca, 43.8; Si, 15.25; F, 9.91; O, 30.37. Biaxial (+); $Y = b$, $X \wedge c = 5-6^\circ$ in acute angle β ; $N_x = 1.586-1.594$, $N_y = 1.589-1.596$, $N_z = 1.598-1.606(?)$; $2V = 59-71^\circ$, colorless; OAP = (010); $r > v$, moderate. Occurs in a number of environments: Precambrian zinc ore; at contact of eruptive rocks with limestone; contact-metasomatic deposits. Associated with wollastonite, garnet, diopside, monticellite, and others. Occurs on Cascade Mtn., Adirondack Mts., Essex Co., NY; at Franklin, Sussex Co., NJ; Alder dist., Custer Co., Idaho; Crestmore quarry, Riverside Co., CA; Carlingford, Ireland; Camas Malag, Skye, and Camas Mör, Muck, Scotland; Beuerberg Volcano, Mayen, Eifel, Germany; *Monte Somma, Vesuvius, Campania, Italy*; Belogorsk deposit, southern Primorye, Russia; in a kimberlite pipe at Novinka, Yakutia, Russia; Anakit massif, Lower Tunguska region, Yakutia, Russia; Fuka, near Bitchu, and in the Sanpo and Mihara mines, Kawakami, Okayama Pref., Japan; San Luis Potosi, and Cerro Mazahua, Zitacuaro, MICH, Mexico. *EF MIN* 3(1):803(1972), *CMP* 74:143(1980), *AM* 72:423(1987).

56.2.4.4 Låvenite $(\text{Na,Ca})_2(\text{Mn,Fe}^{2+},\text{Ca,Ti})(\text{Zr,Ti,Nb})\text{Si}_2\text{O}_7(\text{O,OH,F})_2$

Named in 1885 by Brøgger for the locality. Cuspidine-wöhlerite group. See baghdadite (56.2.4.1), burpalite (56.2.4.2). Ti-rich låvenite has been called titan-låvenite. *MON* $P2_1/a$. $a = 10.54-10.95$, $b = 9.86-10.01$, $c = 7.14-7.23$, $\beta = 108.1-110.3^\circ$, $Z = 4$, $D = 3.84$ (for 14-0586), also 3.50. 14-0586(nat): 6.79₃ 3.99₃ 3.22₅ 2.89₁₀ 2.81₉ 2.41₃ 2.01₃ 1.79₃. Structure: *TMPM* 28:99(1981). Elongated on c , oblique prismatic, tabular parallel to (100), to 1-2 cm; to 1-2 mm at Mt. St.-Hilaire; twinning = {100} simple, lamellar on c or perpendicular to (100). Colorless to brownish yellow to brown, brown-red, Ti-rich låvenite is orange-brown; yellow-white streak; vitreous luster. Cleavage {100}, good; uneven fracture; brittle. $H = 5\frac{1}{2}-6$. $G = 3.4-3.55$. Slowly attacked by HCl. 3-5.2% $\text{Nb}_2\text{O}_5 + \text{Ta}_2\text{O}_5$. Major feature is the range in content of Zr and Ti. ZrO_2 30.0-35.0 wt % and TiO_2 2.0-19.0 wt %, MnO to 13.0 wt %. Biaxial (-); $Z \wedge a = 40-41^\circ$, $Y = b$, $X \wedge c = 20^\circ$; $N_x = 1.645-1.728$, $N_y = 1.652-1.746$, $N_z = 1.656-1.760$; $2V = 68-86^\circ$; OAP parallel to (010); $r > v$, $v > r$, weak; pleochroic. X, colorless, pale yellow; Y, colorless, pale greenish yellow; Z, very pale yellow, golden, orange-yellow, or brownish

yellow. Absorption: $Z > Y > X$. Ti-rich lavenite has $N_x = 1.741$ and $N_z = 1.807$; X, orange-yellow; Z, dark brown. Occurs in a biotite-rich xenolith and in the contact of eudialyte-rich altered pegmatites at Mt. St.-Hilaire. In alkalic rocks and their pegmatites. In xenoliths in phonolitic pyroclastics. In nepheline syenite. Magmatic, early. Mt. St.-Hilaire, and St.-Amable sill, Varennes, and in the Montreal mine, Oka, QUE, Canada; Kangerdlugssuaq, eastern Greenland; Klein Arø, Langesundfjord, Norway; *Isle of Laven, Langesundfjord, Norway*; Mendig, Eifel region, Germany; Ischia Island, Naples, Campania, Italy; Ti-rich lavenite from Koklukhtiuai and Mt. Morua, Lovozero massif, Kovdor massif and Khibiny massif, Kola Penin., Burpala massif, northern Baikal, Siberia, Dugdinsky massif, eastern Tuva, and Ti-rich lavenite from Zaangarya, Yenesei Range, Siberia, Russia; Ile de Rouma, French Guyana; São Miguel, Azores; Ti-rich lavenite from Tenerife, Canary Islands; Serro do Tingua, MG, Brazil; 20 km N of Zomba, Chilwa Province, Malawi. EF *MIN 3(1):797(1972)*, *IGR 19:217(1977)*.

56.2.4.5 Wöhlerite $\text{NaCa}_2(\text{Zr,Nb})\text{Si}_2\text{O}_7(\text{O,OH,F})_2$

Named in 1843 by Scheerer for Friedrich Wöhler (1800–1882), German chemist and professor, Göttingen. Cuspidine-wöhlerite group. See baghdadite (56.2.4.1), burpalite (56.2.4.2), cuspidine (56.2.4.3), niocalite (56.2.4.6), and other members of the group. *MON P21*. $a = 10.823\text{--}10.869$, $b = 10.244\text{--}10.26$, $c = 7.296\text{--}7.920$, $\beta = 109.00^\circ$, $Z = 4$, $D = 3.56$. *10-0462(nat)*: 7.26₃ 5.02₃ 3.25₆ 3.00₇ 2.97₅ 2.84₁₀ 2.01₄ 1.69₄. Structure: *DAN ESS 146:128(1962)*. To 3 cm, tabular or prismatic, flattened parallel to (100); 1- to 5-mm crystals from Mt. St.-Hilaire; twinning common, parallel to (100); sometimes polysynthetic. Pale yellow–orange yellow, brown, gray; greasy to vitreous luster; transparent–translucent. Cleavage {010}, distinct; {100}, {110}, weak; conchoidal to splintery fracture; brittle. $H = 5\frac{1}{2}\text{--}6.0$. $G = 3.41\text{--}3.44$. Luminescence: some material is CL blue-green. CL is dependent on Fe content, no CL if $>1.7\%$ FeO. Soluble in HCl. Analysis (wt %) in addition to major elements: TiO₂, 0–2; MgO, 0–0.3; MnO, 0.2–1.5; FeO, 0.15–2.1; Ce₂O₃, 0.0–0.7; SrO, 0–0.4; Ta₂O₅, 0–0.45; HfO₂, 0–0.6; FO, –3.9. Biaxial (–); $c \wedge a = 45^\circ$, $Z = b$; $N_x = 1.700\text{--}1.705$, $N_y = 1.716\text{--}1.720$, $N_z = 1.726\text{--}1.728$; OAP perpendicular to (010) and almost parallel to (101); $Z > Y > X$; $2V = 71\text{--}79^\circ$; $r < v$, weak. X, colorless; Y, light yellow; Z, dark wine-yellow. Occurs in syenites, agpaite and miaskitic Ne-syenite, and their pegmatite derivatives. Also in fenites associated with alkaline massifs and in ijolite–pyroxenite, carbonatite, and silicocarbonatite. Reported from basalt, trachyte, and phonolite. Commonly found with other Nb-bearing minerals. Red Hill complex, Moultonborough, Carroll Co., NH; Magnet Cove, Hot Springs Co., AR; Prairie Lake, ONT, Mont Saint-Hilaire, and St. Lawrence pit, Oka, QUE, Canada; *Brevik, Langesundfjord, Norway*; Sangilene massif, Tuva, Khibiny massif, Kola Penin., eastern Sayan region, Yenesei region, Yakutia, and Burpala massif, northern Baikal, Siberia, Russia; Tchivira Mtns., Quilengues, Angola; Muri Mts., Guyana; from carbonatites at In Imanal and Wadi Anezrouf, Mali; Los

Islands, East Africa. EF *TMPM* 26:109(1979), *ZVMO* 109:594(1980), *CM* 27:709(1989).

56.2.4.6 Niocalite $\text{Ca}_{14}\text{Nb}_2(\text{Si}_2\text{O}_7)_4\text{O}_6\text{F}_2$

Named in 1956 by Nickel from the composition niobium and calcium. Cuspidine-wöhlerite group. *MON Pa*, previously given as $P2_1/a$: $a = 10.830$, $b = 10.420$, $c = 7.380$, $\beta = 109.67^\circ$; (Pa): $a = 10.863$, $b = 10.431$, $c = 7.370$, $\beta = 110.1^\circ$, $Z = 1$, $D = 3.30$. 11-0622 (nat): 7.31₃ 3.24₅ 3.01₁₀ 2.89₆ 2.85₆ 2.58₃ 2.43₃ 1.84₄. Structure: $P2_1/a$ *SPD* 11:197(1966) and *Pa TMPM* 30:249(1982). Niocalite is isostructural with cuspidine and lävenite, but topologically distinct from the related species wöhlerite. Crystals to 10 mm, prismatic with square cross sections; closely spaced (100–1000Å) polysynthetic twinning with (100) as the composition plane. Pale yellow, vitreous luster. Conchoidal fracture, brittle. $H = 6$. $G = 3.32$. Cathodoluminescence spectrum in *CM* 27:709(1989). Analysis (wt %): Na_2O , 0.78; K_2O , 0.02; MgO , 0.28; CaO , 47.50; SrO , $\approx 1\%$; MnO , 1.28, $\text{Al}_2\text{O}_3 + \text{RE}_2\text{O}_3 + \text{ZrO}_2$, 1.31; Fe_2O_3 , 0.54; SiO_2 , 29.7; TiO_2 , 0.22; P_2O_5 , 0.60; Nb_2O_5 , 16.56; H_2O , 0.16; H_2O^+ , none; F , 1.70. Biaxial (-); $X = b$, $Z \wedge a = 8^\circ$ in acute $\angle\beta$, $Y \wedge a = 32^\circ$; $N_x = 1.700$ –1.701, $N_y = 1.714$ –1.721, $N_z = 1.720$ –1.730; $2V = 34$ – 56° . Occurs at *Oka*, *QUE*, *Canada*, in carbonatites associated with apatite, diopside, biotite, pyrochlore, perovskite, and calcite. Early magmatic. EF *AM* 41:785(1956), *CM* 6:264(1958), *MIN* 3(1):802(1972).

56.2.4.7 Hiortdahlite $(\text{Ca},\text{Na})_3(\text{Zr},\text{Ti},\text{Nb})\text{Si}_2\text{O}_7(\text{O},\text{OH},\text{F})_2$

Named in 1889 by Brøgger for Thorstein Hallager Hiortdahl (1839–1925), Norwegian mineralogist of Christiania. Cuspidine-wöhlerite group. Merlini and Perchiazzi [*TMPM* 34:297(1985), *MP* 37:25(1987)] have distinguished two crystallographic forms of hiortdahlite, called I and II, respectively. *TRIC* Both $P1$. (I): $a = 11.012$, $b = 10.940$, $c = 7.354$, $\alpha = 109.35^\circ$, $\beta = 109.88^\circ$, $\gamma = 83.43^\circ$, $Z = 4$, $D = 3.22$; (II): $a = 11.012$, $b = 10.342$, $c = 7.359$, $\alpha = 89.91^\circ$, $\beta = 109.21^\circ$, $\gamma = 90.06^\circ$, $Z = 4$, $D = 3.287$. *CM* 12:241(1974). 27-668(type I)(nat): 3.28₄₅ 3.00₉ 2.87₁₀ 2.51₂₅ 2.03₂₅ 1.84₃ 1.80₂₅ 1.70₄. Type II has Si_2O_7 diorthogroups and two symmetry-independent octahedral walls; a wall built up by alternating Ca1-, Zr-, NaCa1-octahedra and Ca2-polyhedron parallel to (210) and another wall built up by Ca3-Ca4-Y and NaCa2-octahedra parallel to (210). To 3–4 cm, tabular parallel to (100), most common forms are {101}, {111} and {010}, {100}; polysynthetic {100} twins, twin axis coincides with vertical axis c . Light brown, honey-yellow, yellow-brown, light yellow; yellow streak; vitreous to greasy luster. Cleavage {110}, {110}, distinct; {100}, {010}, weak; brittle. $H = 5\frac{1}{2}$ –6. $G = 3.256$ (II), = 3.26(I), 3.31 (New South Wales material). Cathodoluminescence spectrum: *CM* 27:709(1989). Gelatinizes with acids. It is very difficult to distinguish minerals of the group from each other by means of powder patterns because of the similar assembly of the common structural units in all the minerals of this

family. Biaxial (+)(I), (-)(II); (I): $N_x = 1.639$, $N_y = 1.643$, $N_z = 1.646$; (II): $N_x = 1.652$, $N_y = 1.658$, $N_z = 1.665$; $2V = 80^\circ$ (I), $2V = 70^\circ$ (II); $Z > Y > X$; negative elongation; $r < v$, strong, distinctly pleochroic. X, colorless; Y, yellowish; Z, wine-yellow. Occurs in alkaline rocks and pegmatites associated with feldspar, nepheline, aegirine, meliphane, bismuth, astrophyllite, and titanite. Also in veins and in miarolitic cavities in sanidinites. Mainly in nepheline syenites and sodalite sanidinites. Kipawa R., Villedieu Township, Temiscaming Co., QUE, Canada (I and II); Kangerd-luggssvag Fjord, Greenland; *Middle Arø, Lille Arø, and Stokkø Islands, Langesundfjord, Norway*; Monte Somma, and Vesuvius, Campania, Italy; Laacher See volcanics, Eifel dist., Germany; Korgeredab massif, Sangilen, Tuva, Russia; Los Islands, East Africa; Jingera, NSW, Australia (type I). EF *MIN 3(1):815(1972)*, *CM 12:241(1974)*, *JGSA 26:81(1979)*.

56.2.4.8 Rosenbuschite $(Ca,Na)_3(Zr,Ti,Nb)Si_2O_8F$

Named in 1887 by Brögger for Karl Harry F. Rosenbusch (1836–1914), German geologist and mineralogist, Heidelberg. Cuspidine-wöhlerite group. TRIC $P\bar{1}$. *SPC 8:406(1964)*. $a = 10.12$ – 10.15 , $b = 11.29$ – 11.39 , $c = 7.27$ – 7.358 , $\alpha = 91.33$ – 92.2° , $\beta = 99.7$ – 101.15° , $\gamma = 111.6$ – 112.02° , $Z = 4$, $D = 3.27$. 14 – 447 (nat): 3.96_4 3.06_8 2.94_{10} 2.63_4 2.48_4 2.20_3 1.89_6 1.82_4 . Structure: *SPC 8:406(1964)*. This structure solution places rosenbuschite in the rinkite-seidozerite group rather than the cuspidine-wöhlerite group. *SPC 16:1026(1972)* considers götzenite and rosenbuschite isostructural. A redetermination of the structure is necessary. Acicular to prismatic, probably parallel to [010]; radial fibrous, sometimes massive, 1- to 10-mm crystals; pale yellow to beige, gray, orange; white streak; vitreous luster. Cleavage {010}, perfect, but not readily apparent; also {100}; uneven fracture; brittle. $H = 5$ – 6 . $G = 3.30$. Gelatinizes with acids. To 0.7% Nb_2O_5 , 1.2% FeO , 1.4% MnO . Biaxial (+); $Z \wedge$ perpendicular to cleavage (100) = $28\frac{1}{2}^\circ$, $X \wedge c = 0$ – 9° , parallel to length of needles; $N_x = 1.657$ – 1.678 , $N_y = 1.664$ – 1.687 , $N_z = 1.675$ – 1.705 ; $2V = 78$ – 80° ; weakly pleochroic. X, Y, colorless; Z, yellow. $Z > Y > X$. Occurs in miarolitic cavities in nepheline syenite at Mt. St.-Hilaire, QUE, Canada. On analcime crystals, as divergent sprays. Associated with natrolite, paranatrolite, calcite, wöhlerite, zircon, and aegirine. In nepheline syenites and early pegmatites in Norway and NH. Red Hill, Moultenboro, Carroll Co., NH; Ilimaussaq, Greenland; *Lille and Middle Arø Islands, and Skudesundskaar, near Brevik, Langesundfjord, Norway* in fluorite-bearing syenite; Grännal, Norra Kärr dist., Småland, Sweden, with eudialyte, fluorite and arfvedsonite; Lovozero and Khibiny massifs, Kola Penin.; Ti-rich rosenbuschite from Transangara, Yenisei Range, Tuva, Russia; 20 km N of Zomba, Chilwa Prov., Malawi. EF *NGT 42:179(1962)*, *MIN 3(1):838(1972)*.

56.2.4.9 Hainite $\text{Na}_2\text{Ca}_4[(\text{Ti,Zr,Mn,Fe,Nb,Ta})_{1.5}\square_{0.5}](\text{Si}_2\text{O}_7)_2\text{F}_4$

Named in 1893 by Blumrich for the locality. Cuspidine-wöhlerite group. See rosenbuschite (56.2.4.8) and gotzenite (56.2.5.4). TRIC *P1*. $a = 5.676$, $b = 7.259$, $c = 9.586$, $\alpha = 101.08^\circ$, $\beta = 101.14^\circ$, $\gamma = 90.27^\circ$, $Z = 1$, $D = 3.157$. $45\text{-}1453(\text{nat})$: 3.96_5 3.07_9 2.96_{10} 2.63_5 2.49_5 1.90_7 1.82_5 1.68_4 . Isostructural with gotzenite; the formula of hainite is derived from that of gotzenite by the substitution $2\text{Ca}^{2+} \rightarrow (\text{Ti,Zr})^{4+} + \square$. Needles and plates, elongate [001] with {010} + {100} modified by {110}; crystals < 1 mm long; twinning on (100), space group by analogy to gotzenite and rosenbuschite. Wine-yellow, honey-yellow, colorless; vitreous to adamantine luster. Cleavage {010} good, {100} poor; brittle. $H = 5$. $G = 3.148$. Readily soluble in diluted HCl, HF, and H_2SO_4 . Analysis (wt %): Na_2O , 7.5; CaO , 32.6; MnO , 2.2; TiO_2 , 8.3; ZrO_2 , 6.8; Ce_2O_3 , 1.10; Al_2O_3 , 0.04; Fe_2O_3 , 1.37; La_2O_3 , 0.6; Nb_2O_5 , 0.8; Ta_2O_5 , 0.3; SiO_2 , 32.1; F , 10.8; $\text{O} = \text{F}$, 4.56. Biaxial (+); $N_y \approx 1.7$; birefringence = 0.012; OAP and $B \times a$ perpendicular to (010) and oblique to (100) or Z perpendicular to (010); $r > v$, strong; weakly pleochroic. X , colorless; Z , wine-yellow. $Z > Y > X$. Occurs in cavities and groundmass of phonolite and tinguates, with aegirine. *Vrchni Hajn (formerly "Hohe Hain") near Frydlant, northern Bohemia; Krasné, Hradistě, and Kamenice, Bohemia, Czech Republic*. EF CR 308(II):1237(1989), AM 75:936(1990).

56.2.4.10 Janhaugite $(\text{Na,Ca})_3(\text{Mn,Fe}^{2+})_3(\text{Ti,Zr,Nb})_2(\text{Si}_2\text{O}_7)_2(\text{O,OH,F})_4$

Named in 1983 by Raade and Mladek for Jan Haug, Norway, an amateur mineralogist, who discovered the mineral. Cuspidine-wöhlerite group. MON $P2_1/n$. $a = 10.668$, $b = 9.787$, $c = 13.931$, $\beta = 107.82^\circ$, $Z = 4$, $D = 3.71$. $35\text{-}641(\text{nat})$: 6.65_3 3.92_4 3.20_6 2.84_{10} 2.83_9 2.78_9 2.74_4 2.72_4 . Structure: *NJBM: 7-18(1985)*. Prismatic, lamellar aggregates and sprays of prisms elongated on [001], flattened on {010} with prisms {110}, {120}, {130}, rough {001}; to 4 mm long, crystals may be curved and bent, vertically striated, sprays to 1.5 cm; twinning present, twin plane is probably {100}. Reddish brown, light brown streak, vitreous luster. Cleavage {010}, distinct; very brittle. $H = 5$. $G = 3.60$. IR data: *AM 68:1216(1983)*. Nonfluorescent. 5.00wt% Nb_2O_5 , 0.26wt% Ta_2O_5 , substitute for Ti. Biaxial (+); $X \wedge c = +15^\circ$, $Z = b$; in white light: $N_x = 1.770$, $N_y = 1.828$, $N_z = 1.910(\text{calc})$; $2V = 80^\circ$; $X < Y$, weakly pleochroic. X , nearly colorless; Y , beige; negative elongation. Occurs as an early to late magmatic mineral in pegmatites in alkaline granite. Also in miarolitic cavities, associated with pyrophanite, elpidite, monazite, and also dalyite. Fairly widespread and in places is a rock-forming constituent at *Gjerdingen, Nordmarka, northern Oslo region, Norway*. EF

56.2.4.11 Jennite $\text{Ca}_9\text{H}_2\text{Si}_6\text{O}_{18}(\text{OH})_8 \cdot 6\text{H}_2\text{O}$

Named in 1966 by Carpenter et al. for Clarence Marvin Jenni (1896–1973), American mineral collector and director of the Geological Museum, University of Missouri. Cuspidine-wöhlerite group. TRIC *P1* or *P1*. $a = 10.593$,

$b = 7.284$, $c = 10.839$, $\alpha = 99.67^\circ$, $\beta = 97.65^\circ$, $\gamma = 110.11^\circ$, $Z = 1$ [AM 62:365(1977)], $D = 2.36$. 18-1206(nat): 10.5₁₀ 6.46₅ 3.47₅ 3.29₅ 3.04₆ 2.92₈ 2.83₆ 2.66₆. Blade-shaped crystals elongated on b or platy, to 6 mm long. White. Cleavage {001}, vitreous luster. $G = 2.32$ –2.33. Material from Crestmore fluoresces a weak white in SWUV and weak to medium white in LWUV. IR and DTA data: AM 51:56(1966). Loses 7 wt % water on moderate 290° heating to give meta-jennite, $9\text{CaO} \cdot 6\text{SiO}_2 \cdot 7\text{H}_2\text{O}$, $a = 10.590$, $b = 7.278$, $c = 9.511$, $\alpha = 101.03^\circ$, $\beta = 105.74^\circ$, $\gamma = 110.10^\circ$; not considered a species. Biaxial (-); $X \wedge c = 90^\circ$, $Y \wedge b = 35$ –40°; $N_x = 1.548$ –1.552, $N_y = 1.562$ –1.564, $N_z = 1.570$ –1.571; $2V = 74^\circ$, positive elongation. A late-stage open-space filling mineral in contact rocks at Crestmore. Associated with 14-Å tobermorite and scawtite and calcite. Crestmore quarry, Riverside Co., CA; in xenoliths in basalt from Maroldsweisach, northern Bavaria, Germany; Bellerberg volcano, Mayen, Eifel dist., Bavaria; Campomorto, Montalto di Castro, Viterbo, Italy; Wessels mine, Kalahari manganese field, Cape Prov., South Africa; Fuka, Bitchu, Okayama Pref., Japan; hatrurim formation in Israel; Mina La Negra, Zimapan, Velardeña, DUR, and Cerro Mazahua, Zitacuaro, MICH, Mexico. EF MIN 3(1): 814(1972), AM 62:365(1977), MJ 14:279(1989), DA 46:69(1995).

56.2.4.12 Komarovite $(\text{H,Ca})_2(\text{Nb,Ti})_2\text{Si}_2\text{O}_{10}(\text{OH,F})_2 \cdot \text{H}_2\text{O}$

Named in 1971 by Portnov et al. for Vladimir M. Komarov (1927–1967), Russian cosmonaut, who was killed during his return flight on April 23, 1967. Cuspidine-wöhlerite group. See Na-komarovite (56.2.4.13), labuntsovite (60.1.3.2) and nenadkevichite (60.1.3.1). ORTH $a = 14.87$, $b = 12.29$, $c = 10.38$ [DANS ESS 24:248(1979)], $Z = 8$, $D = 3.04$. 25-163[ZVMO 100:599(1971)](nat): 12.3₇ 6.3₃ 5.43₃ 3.17₁₀ 3.13₄ 2.75_{2.5} 2.72_{2.5} 1.78_{4.5}. Silicified pyrochlore. Unit cells of pyrochlore and komarovite are closely related. DANS ESS 24:248(1979). Foliated, platy, filling fractures in natrolite. Pale rose, white streak, dull luster. One fair cleavage on {001}. $H = 1\frac{1}{2}$ –2. $G = 3.0$. IR data: GZ 36:54(1976). Thermal DTA: ZVMO 100:599(1971). Wet analysis (wt %): Nb_2O_5 , 47.0; TiO_2 , 2.5; SiO_2 , 23.5; Fe_2O_3 , 1.5; Al_2O_3 , 1.0; MnO , 5.0; CaO , 4.7; Na_2O , 0.85; K_2O , 0.3; H_2O , 12.0; F, 1.21. Probe analysis (wt %): Nb_2O_5 , 50.0; TiO_2 , 2.5; SiO_2 , 28.0; CaO , 6.0; Na_2O , 1.0; H_2O , 12.4; F, 1.34. Biaxial (+); $2V = 48^\circ$ XYZ = acb; $N_x = 1.730$, $N_y = 1.766$, $N_z = 1.850$. Occurs on Mt. Karnasurt, Lovozero massif, Kola Penin., Russia; in alkalic syenites associated with late albite and natrolite. EF

56.2.4.13 Na-Komarovite $(\text{Na,Ca,H})_2(\text{Nb,Ti})_2\text{Si}_2\text{O}_{10}(\text{OH,F})_2 \cdot \text{H}_2\text{O}$

Named in 1979 by Krivokoneva et al. for V. M. Komarov. Described in 1969; an incompletely described mineral. Cuspidine-wöhlerite group; the Na analog of komarovite. See komarovite (56.2.4.12), the Ca-dominant member. Probably ORTH $a = 15.00$, $b = 12.31$, $c = 10.48$, $Z = 8$, $D = 3.26$. 33-608(nat): 12.4₅ 6.39₃ 5.49_{3.5} 3.18₁₀ 3.15₅ 2.75₄ 2.74₃ 1.79₄. Silicified pyrochlore. The

unit cells of Na-komarovite and pyrochlore can be related. *DANS ESS 248:127(1981)*. $G = 3.3$. Wet analysis (wt %): Nb₂O₅, 50.2; TiO₂, 5.3; SiO₂, 16.5; RE₂O₃, 0.5; Fe₂O₃, 0.5; Al₂O₃, 1.4; CaO, 5.3; Na₂O, 13.7; H₂O, 4.6; F, 2.5. Probe analysis (wt %): Nb₂O₅, 52.0; TiO₂, 3.0; SiO₂, 24.0; CaO, 6.0; Na₂O, 8.0; H₂O, 4.6; F, 2.5. *Ilimaussaq massif, Greenland*. EF

56.2.4.14 Suolunite Ca₂Si₂O₅(OH)₂ · H₂O

Named in 1965 by Huang for the locality. Cuspidine-wöhlerite group. ORTH *Fdd2*. $a = 11.02$ – 11.15 , $b = 19.67$ – 19.82 , $c = 6.00$ – 6.08 , $Z = 8$, $D = 2.69$. *26-307(nat)*: 4.13₁₀ 3.17₈ 2.85₆ 2.68₅ 2.64₃ 2.55₄ 2.50₄ 2.24₄; *MM 48:143(1984)*: 4.13₁₀ 3.17₈ 2.85₆ 2.69₈ 2.65₆ 1.99₅ 1.85₄ 1.71₇. Structure described in two Chinese papers (1966 and 1974) listed in *MM 48:143(1984)*. Stellate concretionary aggregates, fine-grained granular masses, crystals 0.1 to 2–3 mm, bladed. Colorless, white yellow; white streak; vitreous to resinous luster. No cleavage. $H = 3\frac{1}{2}$, $G = 2.63$ – 2.68 . Distinctly piezoelectric. DTA data show a strong endotherm at 440°. *SS 23:7(1965)*. Dissolves in HCl (dilute) and leaves gelatinous silica. Analysis: SiO₂ 43.35, CaO 42.22, H₂O⁺ 14.05 fluoresces white in SWUV. Biaxial (-); XYZ = acb; N_x = 1.610–1.612, N_y = 1.620, N_z = 1.623; 2V = 30–40°. Occurs in a 2- to 3-cm vein cutting harzburgite rocks in an ultrabasic massif. Associated with faults in arid or semiarid ultramafic environments. Alteration: To calcite. Spa Kulasi, near Dobo, Bosnia (Yugoslavia); Wadi Semali, Al Khawd, near Muscat, Oman; Suolun, Mongolia, China. EF *MIN 3(1):844(1972)*.

56.2.4.15 Mongolite Ca₄Nb₆Si₅O₂₄(OH)₁₀ · 5H₂O

Named in 1985 by Vladykin et al. for the locality. Cuspidine-wöhlerite group. TET Space group unknown. $a = 7.00$, $c = 29.01$, $Z = 2$, $D = 3.51$. *39-330 [ZVMO 114:374(1985)](nat)*: 9.67_{4.5} 6.78₃ 5.82_{4.5} 3.16₁₀ 3.09_{6.5} 2.97₇ 2.90_{3.5} 2.66₄. Microflaky, mica-like aggregates, 40-μm crystals. Violet to grayish violet, silky luster. One micaceous cleavage. $H = 2$. $G = 3.15$. DTA and TGA data: *ZVMO 114:374(1985)*. Not soluble in common acids. Average of two analyses (wt %): SiO₂, 22.2; Al₂O₃, 0.83; Nb₂O₅, 52.45; MnO, 1.01; CaO, 12.88; BaO, 0.72; ZnO, 0.66; SrO, 1.97; H₂O, 7.72; minor TiO₂, MgO, Na₂O, K₂O. Uniaxial (-); N_E = 1.74, N_O = 1.80. Occurs in the *Khan-Bogdinsky massif, Gobi desert, Mongolia, China*; agpaite pegmatites in alkalic granite. Associated with quartz, arfvedsonite, aegerine. EF

56.2.5.1 Mosandrite Na(Na,Ca)₂(Ca,Ce)₄(Ti,Nb,Zr)(Si₂O₇)₂(O,F)₂F₂

Named in 1841 by Erdmann for Carl Gustav Mosander (1797–1858), Swedish chemist and mineralogist, who researched and discovered several REE elements. Formerly considered part of the rinkite group, but has been shown to be equivalent to rinkite itself. Synonyms: rinkite (now discontinued) = rinkolite = johnstrupite. *CSREM 108:249(1993)*. *MON P2₁*. $a = 5.664$ – 5.679 ,

$b = 7.412\text{--}7.437$, $c = 18.835\text{--}18.843$, $\alpha = 101.26\text{--}101.4^\circ$, $Z = 2$, $D = 3.36$. $31\text{--}313(\text{nat})$: 3.58_2 3.07_{10} 2.95_4 2.80_4 2.70_7 2.58_2 2.00_2 1.68_2 . Material from Tuva is stated to be TRIC with $a = 9.66$, $b = 5.75$, $c = 7.34$, $\alpha = 90^\circ$, $\beta = 102^\circ$, $\gamma = 101^\circ$. ZVMO 109:594(1980). Also given as TRIC (MT:1989): $a = 18.5$, $b = 7.44$, $c = 5.65$, $\alpha = 90.4^\circ$, $\beta = 91.3^\circ$, $\gamma = 102^\circ$. Structure given in CSREM 5th supplement, p. 12. Some cation ordering is present. AC(B) 27:1277(1971), SPC 36:349(1991). Prismatic (pseudohexagonal), acicular and thin tabular radiating groups, acicular parallel [100]; to 3.5 cm at Mt. St.-Hilaire. Colorless to lemon yellow, pale orange-yellow, mauve, beige, yellow-brown, brown; white streak; vitreous to resinous luster. Cleavage {001}, distinct; {010}, poor; uneven to conchoidal fracture; brittle. $H = 5$. $G = 3.29\text{--}3.46$. Nonluminescent. Gelatinizes with acids. Analysis (wt%): Ce_2O_3 8.1, Y_2O_3 0.72, La_2O_3 9.92, U_3O_8 0.33, ThO_2 1.18, Nb_2O_5 0.45, TiO_2 11.25, SiO_2 31.73, Al_2O_3 2.55, FeO 0.28, CaO 21.91, SrO 0.89, K_2O 0.84, Na_2O 4.20, F 4.72, H_2O^+ 2.71, H_2O^- 1.34. Biaxial (+); $Y = b$, $X \wedge a = 3^\circ$; $N_x = 1.643\text{--}1.665$, $N_y = 1.645\text{--}1.668$, $N_z = 1.651\text{--}1.681$; $2V = 43\text{--}80^\circ$; $Z > Y > X$; $r > v$, strong. Occurs in eudialyte-rich pegmatites, sodalite xenoliths, and nepheline syenite at Mt. St.-Hilaire. In sodalite syenites in Greenland. Occurs at Mt. St.-Hilaire, and St.-Amable sill (phonolite), Varennes, QUE, Canada; Kangerdluarssuk area, Ilimaussaq, Julianehaab district, Greenland; also at Naujakasik and Narsarsuk, Greenland; Låven, and Stokkø, near Barkevik, Langesundfjord, Norway; Khibiny and Lovozero massifs, Kola Penin., Sangilen massif, Tuva, southwest of Lake Baikal, Siberia, and central Aldan, Yakutia, Russia; Saima, Liaoning Prov., China; Pilanesberg complex, Saulspoort, South Africa. EF DAN SSSR 263:435(1982), MR 21:284(1990).

56.2.5.2 Nacareniobsite-(Ce) $\text{Na}_3\text{Ca}_3(\text{Ce},\text{La},\text{Nd})\text{Nb}(\text{Si}_2\text{O}_7)_2\text{OF}_3$

Named in 1989 by Petersen et al. for the major constituents: Na, Ca, RE, Nb, Si. Related mineral is rinkite (mosandrite): $2\text{Ca}^{2+} \leftrightarrow \text{REE}^{3+} + \text{Na}^+$. The Nb analog of $(\text{Ca},\text{Na},\text{REE})_7\text{TiSi}_4\text{O}_{14}\text{OF}_3$ (rinkite). MON P2₁/a. $a = 18.901$, $b = 5.683$, $c = 7.462$, $\beta = 101.29^\circ$, $Z = 2$, $D = 3.43$. PD(nat): 3.09_5 3.08_{10} 2.96_5 2.81_3 2.03_5 1.87_4 1.69_4 1.55_5 . Structure not yet solved, but probably isostructural with mosandrite. Rectangular, thin bladed crystals to 3 mm \times 0.4 mm \times 0.04 mm; elongated || [001]; prominent {100}, {410} and {310}; colorless, vitreous luster, transparent. Cleavage {011}, good; uneven fracture. $H = 5$. $G = 3.45$. Nonluminescent. Analysis (wt %): SiO_2 , 29.6; TiO_2 , 2.79; Nb_2O_5 , 11.61; Ta_2O_5 , 0.34; Na_2O , 10.01; CaO , 19.92; SrO , 0.27; V_2O_5 , 0.78; La_2O_3 , 4.09; Ce_2O_3 , 10.32; Pr_2O_3 , 1.42; Nd_2O_3 , 4.19; Sm_2O_3 , 0.05; F , 6.87. Biaxial (+); $XY = bc$, $Z \wedge a = 11^\circ$ in obtuse β ; $N_x = 1.6618$, $N_y = 1.6706$, $N_z = 1.6924$; $2V = 66^\circ$. Occurs in dissolution cavities in arfvedsonite-repheline syenite (lujavrite), Kvanefjeld tunnel, Ilimaussaq complex, southern Greenland. Associated with sodalite, eudialyte, and villiaumite. EF NJBM:84(1989).

56.2.5.3 Fersmanite $(\text{Ca,Na})_4(\text{Ti,Nb})_2\text{Si}_2\text{O}_{11}(\text{F,OH})_2$

Named in 1929 by Labuntsov for Alexander Yevgenievich Fersman (1883–1945), Russian mineralogist and geochemist. TRIC $P\bar{1}$ or $P1$. $a = 7.210$, $b = 7.213$, $c = 20.451$, $\alpha = 95.15^\circ$, $\beta = 95.60^\circ$, $\gamma = 89.04^\circ$, $Z = 4$, $D = 3.44$. $29\text{-}1446(\text{nat})$: 3.06_{10} 2.82_6 2.53_{35} 1.91_{25} 1.80_5 1.69_{45} 1.55_4 1.52_{55} . Structure: *SPC 29:31(1984)*. This determination indicated a monoclinic cell with $a = 10.212$, $b = 20.450$, $c = 10.198$, $\beta = 97.22^\circ$. Space group Bb or $B2/b$. It was found to be a diorthosilicate, $(\text{Ca,Na})_4(\text{Ti,Nb})_2(\text{Si}_2\text{O}_7)\text{O}_4(\text{F,OH})_2$. Pseudotetragonal, distorted crystals; euhedral crystals not common; crystals to 2–3 cm across; twinning present possibly on $\{001\}$. Dark brown, much resembling titanite, light to cinnamon brown; golden yellow; transparent to translucent, pale tan streak, vitreous luster. No cleavage, uneven fracture. $H = 5\text{--}5\frac{1}{2}$. $G = 3.44\text{--}3.46$. Soluble in acids. Main substitution scheme is $\text{CaTi} \leftrightarrow \text{NaNb}$, but some OH may replace O. Analysis: K_2O , to $\approx 1\%$; MgO , to $\approx 1\%$; SrO , to 0.5% ; FeO , to 1.4% ; Fe_2O_3 , to 3.5% ; Ta_2O_5 , to 0.8% ; F , $\approx 4\%$. Biaxial (–); $N_x = 1.873\text{--}1.886$, $N_y = 1.930$, $N_z = 1.914\text{--}1.939$; golden yellow. $2V_{\text{calc}} = 48^\circ$, also given as $0\text{--}7^\circ$. Occurs in aegirine-rich pegmatite veins in nepheline syenite assoc. with other alkalic minerals. Hydrothermal in origin. Sometimes alters to lamprophyllite. Occurs just above the *Vuonnemijok River*, on the southwestern slope of *Mt. Eveslogchorr*, *Khibiny massif*, *Kola Penin.*, *Russia*, and at a second locality about 2 km to the east; also occurs on *Mt. Yukspor* and in the apatite deposit on *Mt. Kukisvumchorr*, as well as *Mt. Kuel'por* and in the *Vorkeuai R. valley*. *EF MRE 2:564(1966)*, *MIN 3(1):353(1972)*, *CM 15:87(1977)*.

56.2.5.4 Götzenite $(\text{Ca,Na})_3(\text{Ti,Al})\text{Si}_2\text{O}_7(\text{F,OH})_2$ or $\text{Na}_2\text{Ca}_5\text{Ti}(\text{Si}_2\text{O}_7)_2\text{F}_4$

Named in 1957 by Sahama and Hytönen for Gustav Adolf Von Götzen (1866–1910), German traveler and first European to climb *Mt. Shaheru*, North Kivu, Zaire, the type locality. Synonym: calcium rinkite. See rosenbuschite (56.2.4.8) and hainite (56.2.4.9). TRIC $P1$. $a = 9.589\text{--}9.667$, $b = 7.23\text{--}7.334$, $c = 5.731\text{--}5.758$, $\alpha = 90.00\text{--}92.2^\circ$, $\beta = 100.2\text{--}101.3^\circ$, $\gamma = 99.4\text{--}101.1^\circ$, $Z = 2$, $D = 3.04$. $12\text{-}536(\text{nat})$: 3.99_2 3.10_{10} 2.99_{10} 2.65_4 2.51_3 2.26_2 1.91_5 1.69_3 . The main feature of the crystal structure of götzenite is the presence of “walls” of octahedra and eight-cornered polyhedra parallel to (100) which are connected by “ribbons” of octahedra parallel to $[010]$ and by Si_2O_7 groups. *SPC 16(6):1026(1972)*. Tablets, and prismatic, acicular parallel to $[001]$ (probably); to 1 cm long; most show lamellar polysynthetic twinning with twin axis = b and the composition plane perpendicular to (001) . *MM 31:503(1957)*. Very pale yellow, tan or off-white, colorless, white; white streak; dull, vitreous to greasy luster. Cleavage $\{100\}$, perfect; $\{001\}$, good; brittle. $H = 5\frac{1}{2}\text{--}6$. $G = 3.14\text{--}3.20$. IR data: *MIN 3(1):831(1972)*. Easily soluble in hot dilute HCl. Analysis (wt %): major Na_2O , CaO , SiO_2 , TiO_2 and F ; K_2O , $0.1\text{--}0.7$; MgO , trace to 0.6 ; SrO , to 3.8 ; MnO , to 2.1 ; FeO , to 0.5 ; Al_2O_3 , to 4.3 ; Fe_2O_3 , to 0.9 ; TR_2O_3 , to 6.4 ; ThO_2 , to 0.4 ; ZrO_2 , to 2.9 ; Nb_2O_5 +

Ta₂O₅, to 12.5; H₂O, to 2%. Biaxial (+); $X \approx c$; $Z' \wedge c \approx 58^\circ$; $N_x = 1.651$ – 1.662 , $N_y = 1.653$ – 1.665 , $N_z = 1.659$ – 1.672 ; $2V = 38$ – 74° ; $r > v$, strong; length-fast or length-slow; pleochroic, from colorless to pale yellow to pale rose. Occurs in nepheline lava (Zaire), pegmatites (Norway), and in marble xenolith cavities (Mt. St.-Hilaire) associated with pectolite and other minerals. In nepheline syenites and cogentic pegmatites, associated with other alkaline minerals. In olivine meltigeite porphyry. In sanidine–anorthoclase rocks. Occurs at Mt. St.-Hilaire, QUE, Canada; near Kirchberg, Saxony, Udersdorf, Daun, West Eifel, and Kaiserstuhl, Baden-Württemberg, Germany; to 10 cm long from near Barkevik, Langesundfjord, Norway; Sangilen massif, Tuva, southern Baikal, Azov area, Ukraine; Mt. Yukspor and Mt. Eveslogchorr, Khibiny massif, and Gornoozerna massif, Cape Turi, Kola Penin., Russia; *Nyiragongo crater, Mount Shaheru, Kivu Prov., Zaire*. EF *MIN 3(1):831(1972)*, *ZVMO 109:594(1980)*, *DHZ RFM 113:343(1986)*, *MR 21:284(1990)*.

56.2.6a.1 Seidozerite (Na,Ca)₄MnTi(Zr_{1.5}Ti_{0.5})(Si₂O₇)₂O₂(F,OH)

Named in 1958 by Semenov et al. for the locality. Calcian seidozerite has Na₂(Na,Ca)₂(Ca,Mn)TiZr₂O₂[Si₂O₇]₂(F,OH)₂. *MON P2/c*. $a = 5.53$ – 5.54 , $b = 7.10$, $c = 18.30$ – 18.36 , $\beta = 102.68$ – 102.7° , $Z = 2$, $D = 3.53$ – 3.60 . *13-576(nat)*: 2.97₁₀ 2.87₇ 2.58₄ 2.43₃ 2.25₃ 1.83₇ 1.76₃ 1.63₄. Structure: *CR DAN SSSR 122:473(1958)*; *SPC 8:406(1964)*, *10:505(1966)*, *16:1026(1972)*. Elongate on b , striated parallel to b , prismatic to fan-shaped intergrowths, equant flattened crystals to 5 cm, also spherulites, dominant forms are {001}, {100}, {203}. Brownish red, dark red, yellow to brown; strong vitreous luster. Cleavage (001), perfect; brittle. $H = 4\frac{1}{2}$. $G = 3.42$ – 3.47 . IR data: *IM: 208(1975)*, *K 6:126(1961)*. No piezoelectric effect, electromagnetic. Soluble with difficulty in HCl. Analysis (wt %): major Na₂O, MnO, SiO₂, TiO₂, ZrO₂, F; CaO, 2.8 to 9.7; FeO + Fe₂O₃, to 4.17; Al₂O₃, to 1.4; Nb₂O₅, to 0.6. Biaxial (+); $2V = 62$ – 68° ; $Z = a$, $Y \wedge c = 13^\circ$; $N_x = 1.718$ (calcian)– 1.725 , $N_y = 1.758$, $N_z = 1.772$ (calcian)– 1.830 ; OAP = (001); $X > Y > Z$; $r > v$, strong. X, dark red to reddish brown; Y, red; Z, pale yellow to yellow. Occurs in poikilitic nepheline syenite pegmatites at Lovozero. In albitized pegmatites and stringer zones and in aegirine–microcline pegmatites in the Burpala massif. Alteration to catapleite. Occurs in the *Lake Seidozero region of the Lovozero massif, Kola Penin., Russia*; Ca-rich (10% CaO) variety from the Burpala massif, northern Baikal region, and Tuva region, southern Baikal region, Siberia, Russia. EF *MS 19:131(1965)*, *MIN 3(1):835(1972)*.

56.2.6b.1 Bafertisite Ba(Fe,Mn)₂TiO(Si₂O₇)(OH,F)₂

Described in 1959 by Semenov and P'ei-Shan Chang and named for the composition: Ba, Fe (ferrum), Ti, Si. Hejtmanite is the Mn analog. *MON Cm*. $a = 10.60$, $b = 13.64$, $c = 12.47$, $\beta = 119.5^\circ$. *DANS 149:1416(1963)*. These data match the cell of *SPC 36:186(1991)*, however, the true cell may be *P2₁/m* as for hejtmanite. *EJM 4:35(1992)*. $Z = 8$. Another proposed cell

[CA 60:75(1964)] is: $a = 10.98$, $b = 6.80$, $c = 5.36$, $\beta = 94^\circ$, $P2_1/m$. Originally stated to be orthorhombic. *AM* 45:754,1317(1960). 14-541: 2.65₁₀ 2.52₃ 2.23₃ 2.11₄ 2.07₃ 1.75₃ 1.72₄ 1.57₃. Structure is related to micas. Bright red, yellowish red to light brown, or orange. Cleavage {001}, perfect; {010}, poor; brittle. $H = 5$. $G = 3.96-4.27$. IR data: *IM:208(1975)*. Mössbauer spectra: *APMA* 1:23(1982) Contains minor Nb, Al, Fe^{3+} , Mg, Ca, Na, and K. Material from Burpala massif is Mn-rich (12.8 wt % MnO). Biaxial (-); $X \wedge c = 24^\circ$ in obtuse β , $Z \wedge a = 5.5^\circ$; $N_x = 1.786-1.808$, $N_y = 1.813-1.835$, $N_z = 1.852-1.862$; $2V = 54-86^\circ$; OAP = (010); $X > Z$. X, yellow-red or brownish red; Y, yellow; Z, pale yellow or greenish yellow. Occurs in alkaline igneous rocks or in rocks associated with alkaline rocks (i.e., alkali granite and alkali syenite), hydrothermal veins associated with aegirine, fluorite, barite, and bastnaesite (Bayan Obo); in a dike of microclinized granite-aplite (Burpala massif). Fountain Quarry, Pitt County, NC, with an unidentified Ba-Ca-Mn-Fe-Ti silicate; Mn-rich variety from the Burpala massif, northern Baikal area, Russia; Tarbagata, eastern Kazakhstan; *Bayan Obo REE deposit, Inner Mongolia, Jiangsu Prov., China*. *EF TMMAN SSSR* 16:293(1965), *MIN* 3(1):635(1972), *AM* 57:1005(1972).

56.2.6b.2 Hejtmanite $Ba(Mn,Fe^{2+})_2TiO(Si_2O_7)(OH,F)_2$

Described in 1992 by Vrána et al. and named for Bohuslav Hejtman (b.1911), emeritus professor of petrology, Charles University, Prague. First found in Kirgizia but not named. The mineral is the Mn analog of bafertisite. *MON* $P2_1/m$. $a = 11.748$, $b = 13.768$, $c = 10.698$, $\beta = 112.27^\circ$, $Z = 8$, $D = 4.29$. (*EJM* 4:35(1992). Erroneously stated to be triclinic. *ZVMO* 118:81(1989). Alternative monoclinic cells are: $a = 5.361$, $b = 6.906$, $c = 12.556$, $\beta = 119.8^\circ$, $P2_1/m$ and $a = 10.723$, $b = 13.812$, $c = 12.563$, $\beta = 119.9^\circ$, *Cm*. *SPC* 36:186(1991). *EJM* 4:35(1992) and 44-1470: 5.47₃ 3.65₁ 3.45₂ 3.22₂ 2.73₁₀ 2.53₁ 2.18₂ 2.07₁. Crystals are lath-shaped to platy, or prismatic to 1 mm long. {100} prominent, elongated parallel to [001]. Brownish yellow to golden yellow, brownish-yellow streak, vitreous luster, transparent. Cleavage {100}, perfect; {0kl}, poor, parting; irregular fracture; brittle. $G = 4.02$. Biaxial (-); $X = b$, $Y \wedge c = 38^\circ$ in obtuse β , $Z \wedge a = 16^\circ$. $N_x = 1.814$, $N_y = 1.846$, $N_z = 1.867$; $2V = 76^\circ$; $Y > Z = X$. X, light green-yellow; Y, dark golden yellow; Z, light yellow. Optical orientation is different from bafertisite. Occurs in manganoan arfvedsonite crystals that are 10-30 cm across, along with albite and microcline in pegmatoid veins. Also in a rhodonite-tephroite-spessartine-quartz assemblage. Northern end of Inylchek Range, southeastern Kirgizia; *Mbolwe Hill, Mkushi River area, Central Prov., Zambia*. *EF*

LAMPROPHYLLITE GROUP

The lamprophyllite group consists of four dimensionally equivalent, and probably isostructural, species and a displacively transformed polymorph. A simplified general formula for the group is

where

A = Sr, Ba, K (12-coordinated)

B = Na, Ca, Mn, Ti^{4+} , Fe^{3+} (6-coordinated)

C = Ti^{4+} , Fe^{3+} (5-coordinated)

The structure has not been elucidated for all species. The $[Si_2O_7]$ groups are linked to tetragonal-pyramidal five-coordinated ions to form sheets, two of which are linked to either side of distorted, close-packed octahedral sheets forming triple layers similar to 2:1 phyllosilicates. The sheets are parallel to (100) with intervening 12-coordinated cations, thus accounting for the perfect {100} cleavage. Structure: *MJJ* 10:107(1980); *MZ* 12:25(1990).

LAMPROPHYLLITE: $Sr_2Na_3Ti_3(Si_2O_7)_2(OH)_4$

Si_2O_7 groups combined with Ti octahedra can be considered to form layers parallel to (100). Ti and Na form an octahedral layer joining apices of the tetrahedra, and Sr joins the back side (bases) of the tetrahedra.

LAMPROPHYLLITE GROUP

56.2.6c.1 Barytolamprophyllite **$\text{Ba}_2\text{Na}_3(\text{Fe}^{3+}, \text{Ti}^{4+})_3(\text{Si}_2\text{O}_7)_2(\text{O}, \text{OH}, \text{F})_4$**

Named in 1965 by Peng and Chang for the composition and similarity to lamprophyllite). Lamprophyllite group. Isomorphous with lamprophyllite; the existence of an orthorhombic dimorph has been suggested. MON C2/m. $a = 19.833$, $b = 7.089$, $c = 5.393$, $\beta = 96.66^\circ$, $Z = 2$, $D = 3.70$. *34-313*: 3.45₇ 3.29₅ 2.80₁₀ 2.69₅ 2.15₉ 1.790₇ 1.601₈ 1.482₉. An orthorhombic dimorph with $a = 19.32$, $b = 7.05$, $c = 5.43$ is alleged to exist at the (100) twin boundaries of the monoclinic structure. Structure: *KT 29:237(1984)*. Golden brown, light brown streak, vitreous to submetallic luster, translucent. Cleavage {100}, perfect; {011}, distinct; {010}, poor. $H = 2-3$. $G = 3.62-3.66$. Biaxial (+); $2V = 30^\circ$; $N_x = 1.742-1.743$, $N_y = 1.754$, $N_z = 1.776-1.778$ for Na_D ; $X = b$, $Z \wedge c = 6-7^\circ$ $r > v$; strongly pleochroic, $Z > Y > X$ brown to light yellow; refractive indices may decrease toward those of lamprophyllite. Sr may substitute for Ba. Found at Coyote Peak, northern Orick, Humboldt Co., CA; in the Gardiner complex, Kangerdlugssuaq, Greenland; as flakes and stellate groupings, polysynthetically twinned on (100), in nepheline-syenite of the *Lovozero massif, Khibiny, Kola Penin.*, and in the Murun massif, Yakutia, *Russia*. AR *SS 12:1827(1965)*, *AM 51:1549(1966)*.

56.2.6c.2 Delindeite $(\text{Ba}, \text{Ca})_4(\text{Na}, \text{K})_3(\text{Ti}, \text{Fe}, \text{Al})_6\text{Si}_8\text{O}_{26}(\text{OH})_{14}$

Named in 1987 by Appleman et al. for Samuel Henry deLinde (b.1923) of Mabelvale, AR, American insurance executive, mineral collector, and owner of Diamond Jo quarry. Lamprophyllite group. MON C2/m. $a = 21.617$, $b = 6.816$, $c = 5.383$, $\beta = 94.03^\circ$, $Z = 1$, $D = 3.70$. *40-1454*: 10.8₁₀ 3.54₂ 3.08₃ 2.89₃ 2.81₂ 2.75₂ 2.26₂ 2.21₁. Included here on the basis of cell constants and physical properties; structure not determined. Light pinkish gray, resinous to pearly luster. Good cleavage in one direction, brittle. $G = 3.31$. Biaxial (+); $2V_{\text{calc}} = 54^\circ$; $N_x = 1.790$, $N_y = 1.825$, $N_z = 1.982$. Found as micron-size grains and laths in spherulitic aggregates to 1 mm in diameter at the *Diamond Jo quarry, Magnet Cove, near Hot Springs, AR*. AR *MM 51:417(1987)*.

56.2.6c.3 Ericssonite $\text{BaMn}_2^{2+}\text{Fe}^{3+}\text{O}[\text{Si}_2\text{O}_7](\text{OH})$

Named in 1971 by Moore for John E. Ericsson (1803–1883), Swedish-born American engineer and inventor, designer of the iron-clad ship *Monitor*. Lamprophyllite group. Dimorphous with orthoericssonite. MON $C2/c$. $a = 20.46$, $b = 7.03$, $c = 5.34$, $\beta = 95.5^\circ$, $Z = 4$, $D = 4.38$. $29-186$: 10.1_6 5.08_5 3.51_{10} 3.40_5 2.78_6 2.03_5 1.752_6 1.597_6 . Reddish black, brown streak, submetallic luster. Cleavage $\{100\}$, perfect; $\{011\}$, distinct; very brittle. $H = 4\frac{1}{2}$. $G = 4.21$. Biaxial (+); optical properties not distinguished from those of orthoericssonite. Weakly magnetic. Massive and as embedded plates, intimately intergrown with the more abundant orthoericssonite in schefferite–rhodonite–tephroite skarn at the *Långban mine, near Filipstad, Värmland, Sweden*. AR *LIT* 4:137(1971), *AM* 56:2157(1971).

56.2.6c.4 Lamprophyllite $\text{Sr}_2\text{Na}_3\text{Ti}_3[\text{Si}_2\text{O}_7]_2(\text{O},\text{OH},\text{F})_4$

Named in 1894 by Ramsey and Hackmann from the Greek for *shining leaf*, in allusion to the luster and cleavage. Lamprophyllite group. Isomorphous with barytolamprophyllite. MON $C2/m$. $a = 19.431$, $b = 7.086$, $c = 5.386$, $\beta = 96.75^\circ$, $Z = 2$, $D = 3.54$. $17-751$: 3.73_4 3.43_6 3.27_4 2.87_4 2.77_{10} 2.66_4 2.13_5 1.479_5 . Structure: *SPD* 28:206(1983). Crystals tabular $\{100\}$ and elongated $[001]$, as isolated flakes and as stellate aggregates. Polysynthetic twinning on $\{100\}$ common. Yellow-brown, light brown streak, vitreous to submetallic luster, translucent. Cleavage $\{100\}$, perfect; $\{010\}$, poor. $H = 2-3$. $G = 3.45-3.54$. Biaxial (+); $2V = 23-41^\circ$; $N_x = 1.733$, $N_y = 1.740$, $N_z = 1.769$ for Na_D ; $X = b$, $Z \wedge c = 5-6^\circ$; $r > v$, distinctly pleochroic, $Z > Y > X$; yellow-orange to pale yellow, pleochroism serves to distinguish from astrophyllite, for which $Y > Z$. The refractive indices increase toward those of barytolamprophyllite. Ba and K may substitute for Sr, and Ca and Mn^{2+} for Na. Found in nepheline–syenites in the Bearpaw Mts., Hill Co., MT; at Mt. St.-Hilaire, Canada; Langesundfjord, Norway; *Lujavur-Urt, Kola Penin., Russia*; and Pilansberg, Transvaal, South Africa. AR *AM* 27:397(1942), *SS* 14:1829(1966).

56.2.6c.5 Orthoericssonite $\text{BaMn}_2^{2+}\text{Fe}^{3+}\text{O}[\text{Si}_2\text{O}_7](\text{OH})$

Named in 1971 by Moore from the symmetry and relationship to ericssonite. Lamprophyllite group. Dimorphous with ericssonite. ORTH $Pnmn$ or $Pn2n$. $a = 20.230$, $b = 6.979$, $c = 5.392$, $Z = 4$, $D = 4.26$. $29-185$: 5.08_6 3.61_2 3.38_{10} 2.94_1 2.82_1 2.68_3 2.54_4 2.03_1 . Reddish black, brown streak, submetallic luster. Cleavage $\{100\}$, perfect; $\{011\}$, distinct; very brittle. $H = 4\frac{1}{2}$. $G = 4.21$. Biaxial (+); $2V = 30^\circ(67^\circ_{\text{calc}})$; $N_x = 1.807$, $N_y = 1.833$, $N_z = 1.891$ (Sweden); $XYZ = bca$; $2V \approx 50^\circ(83^\circ_{\text{calc}})$; $N_x = 1.802$, $N_y = 1.840$, $N_z = 1.888$ (Japan). Strongly pleochroic; X, pale greenish tan or yellow-brown; Y, red-brown; Z, deep brown. Weakly magnetic. Massive and as embedded plates, intimately intergrown with the less abundant ericssonite in schefferite–rhodonite–tephroite skarn at the *Långban mine, near Filipstad, Värmland, Sweden*; at

the Hijikuzu mine, Iwate Pref., Honshu, Japan. *AR LIT* 4:137(1971); *AM* 56:2157(1971); *MJJ* 7:513(1975), 10:107(1980).

56.2.6c.6 Andremeyerite $\text{BaFe}(\text{Fe}, \text{Mn}, \text{Mg})\text{Si}_2\text{O}_7$

Named in 1973 by Sahama for André Marie Meyer (1890–1965), Belgian mining engineer, honorary director general of mining, who collected the original specimens in Zaire. *MON* (pseudo-ORTH) $P2_1/c$. $a = 7.488$, $b = 13.785$, $c = 7.085$, $\beta = 118.23^\circ$, $Z = 4$, $D = 4.31$ [4.14 using *BGSF* 45:1(1973)]. 26-1031: 4.63₄ 3.29₆ 3.20₂ 3.12₈ 3.06₁₀ 3.02₂ 2.81₄ 2.47₆. Structure: *AM* 73:608(1988). Related to lamprophyllite group. Prismatic, <0.2 mm long and 0.1 mm in diameter, {100} and {010} dominant, {011} and {120} also present. Always shows multiple {100} twinning. Pale emerald green. Cleavage {100}, {010}, perfect. $H = 5\frac{1}{2}$. $G = 4.15$. Contains minor amounts of K, Na, Al, Ce, N, Mg, Mn. Biaxial (+); $Z = b$, $X \wedge c = 2^\circ$ at 670 nm to 61° at 470 nm; $N_x = 1.740$, $N_y = 1.740$, $N_z = 1.760$; 2V near 0° below 490 nm, increasing to 40° at 540 nm, and decreasing again to near 0° at 585 nm; $X > Y \approx Z$; very strong dispersion. X, slight bluish green; Y, Z, colorless with faint brownish tint. Occurs in vesicles of a melilite–leucite–nephelinite block in nephelinite lava. Associated with a green Fe-rich glass and with kirschsteinite and melilite. *Nyiragongo volcano, Zaire*. *EF*

56.2.7.1 Epistolite $\text{Na}_2(\text{Nb}, \text{Ti})_2\text{Si}_2\text{O}_9 \cdot n\text{H}_2\text{O}$

Found in 1897 by Boggild and named in 1900; name originated from the Greek for *letter*, in allusion to the flat rectangular form and white color. Ideal formula is $\text{Na}_2\text{Ti}_2\text{Nb}_2(\text{Si}_2\text{O}_7)_2\text{O}_2(\text{OH})_4 \cdot 2\text{H}_2\text{O}$. Related to murmanite, considered by some sources to be the Ti-dominant analog. See murmanite (56.2.7.2). *TRIC* *P1*. $a = 5.41\text{--}5.570$, $b = 7.08\text{--}7.16$, $c = 11.821\text{--}12.10$, $\alpha = 103.05\text{--}104.39^\circ$, $\beta = 96.00\text{--}96.31^\circ$, $\gamma = 88.52\text{--}88.85^\circ$; alternate cell: $a = 5.570$, $b = 7.044$, $c = 11.821$, $\alpha = 96.53^\circ$, $\beta = 100.04^\circ$, $\gamma = 89.34^\circ$ [*MT:76(1989)*]; $Z = 2$, $D = 2.88\text{--}2.91$. 39-407(nat): 12.0₈ 5.90₇ 4.32₁₀ 2.96₉ 2.87₉ 2.71₅ 2.15₆ 1.79₇. The structure is related to that of murmanite. [*NJBA* 155:289(1986)]. Sharp, platy cleavage masses to 6 cm (Mt. St.-Hilaire); lamellar to micaceous, flattened on (001), {001} dominant; to 5 cm in length, to 10 cm in diameter and 5 mm thick in Greenland. Tan, silvery on {001}, pinkish beige, yellow-gray, white, cream-colored, brown; white streak; pearly to silky luster, vitreous to adamantine at Mt. St.-Hilaire; transparent. Cleavage {001}, perfect; one or two other good cleavages as well; *MT:76(1989)* says {100} cleavage is perfect; uneven fracture; brittle; sometimes readily scratched with a finger. $H = 2\text{--}3$; *MIN* 3(1):673(1972) says $1\text{--}1\frac{1}{2}$; $G = 2.89$ (Greenland) and 2.65 (Lovozero). Thermal data: *MIN* 3(1):673(1972), *NJBA* 155:289(1986). Nonfluorescent. Some Ca substitutes for Na. Biaxial (–), 2V = 80° , rarely (+) with 2V = 84° ; $N_x = 1.610$, $N_y = 1.650$, $N_z = 1.682$; material from Lovozero has $N_x = 1.72$ and $N_z = 1.77$ with 2V (–) of 60° , colorless; $Y = b$, $Z \wedge c = 7^\circ$; $r > v$ or $r < v$, perceptible. Occurs in pegmatites and hydrothermal veins and disseminated in lujavrite + naujaite. A rare mineral of nepheline–syenite massifs. Associated

with rare alkaline species, rinkite, and so on. Ussingite pegmatites in Lovozero. In pegmatites in nepheline-syenite in Greenland. At Mt. St.-Hilaire, some epistolite may be an alteration product of vuonnemite. Alters to leucoxene, nenadkevichite, gerasimovskite, and other minerals. Found at Mt. St.-Hilaire, QUE, Canada; *Tugtupagtakorfi*, *Kvanefjeld*, and *Taseq slope*, *Ilimaussaq intrusion*, *Julianehaab area*, southern Greenland; also at Kangerdluarssuk and Mt. Nakalik. Punkaruaiev area, Lovozero massif, Kola Penin., Russia. EF *KSM 10:96(1976)*.

56.2.7.2 Murmanite $\text{Na}_3(\text{Ti,Nb})_4(\text{Si}_2\text{O}_7)_2\text{O}_4 \cdot 4\text{H}_2\text{O}$

Named in 1923 by Fersman, apparently for the locality near Murmansk. Is a supergene, an alteration product of lomonosovite, and also is primary. TRIC *P1* or *P1* (probably *P1*). $a = 8.700$, $b = 8.728$, $c = 11.688$, $\alpha = 94.31^\circ$, $\beta = 98.62^\circ$, $\gamma = 105.62^\circ$, $Z = 2$ [*K 31:82(1986)*], $D = 2.90\text{--}3.00$. $40\text{--}479(\text{nat})$: 11.56₉ 5.81₉ 4.22₁₀ 3.76₆ 2.87₁₀ 2.64₄ 2.48₄ 1.77₄. Structure: *SPC 31:44(1986)*. $R = 9.1\%$ (anisotropic). Scaly or tabular on (001), crystals and plates to 7 cm; aggregates to 10 cm across. Pink, deep violet; cherry-red streak; pearly to submetallic luster. Three cleavages present; one is perfect (001) and micaceous parallel to tabular development of crystals. $H = 2\text{--}3$. $G = 3.34$, sometimes lower. IR, DTA, TGA data: *NJBA 155:67(1986)*. Decomposed by HCl and H_2SO_4 , leaving a silica residue. "Pink murmanite" has lower Na_2O than that of regular murmanite. It has higher MnO, TiO_2 , and Nb_2O_5 . Analysis: ZrO_2 , to $>4\%$; Fe_2O_3 , to 73.5%; MnO, to $\approx 3\%$; CaO, to $\approx 3\%$; MgO, 0.75%; Na_2O , major; $\text{TiO}_2 + \text{SiO}_2$, major; K_2O , to $\approx 1\%$; Nb_2O_5 , to $>7\%$; total $\text{H}_2\text{O} = 10\%$. Biaxial (-); $N_x = 1.682\text{--}1.735(\text{calc})$, $N_y = 1.765\text{--}1.770$, $N_z = 1.807\text{--}1.839$; $2V = 57\text{--}64^\circ$; OAP perpendicular to (001), X perpendicular to (001); $Z > Y > X$; $r < v$ or $r > v$, weak; strongly pleochroic. X, pale rose to rose; Y, light brown or light yellow-brown; Z, dark brown or brown with violet tint. Occurs in alkalic syenites and their derivative pegmatites; also in altered and sheared lava and gabbro intruded by lujavrite. A supergene alteration product of lomonosovite. Alteration: readily susceptible to alteration; sometimes to labuntsovite, also to belyankinite and other products. Occurs at Mont Saint-Hilaire, QUE, Canada; Kvanefjeld, Steenstrupsfjeld, and Skovfjord, near Ilimaussaq, Greenland; Mt. Punkaruaiev, Mt. Suoluaiev, Ninchurt, Mt. Mannekpakh, Mt. Alluaiv, Chingulusuai R., Sengischorr cirque, and other localities in the Lovozero massif, near Murmansk, Kola Penin., Russia; also in the Khibiny massif at Mt. Rasvumchorr, Mt. Rischorr, Mt. Karnasurt, Mt. Kukisvumchorr, Mt. Yukspor, and others. EF *MIN 3(1):668(1972)*, *KSM 10:96(1976)*.

56.2.8.1 Chevkinite-(Ce) $(\text{Ce,Ca,Th})_4(\text{Fe,Mg})(\text{Ti,Mg,Fe})_4\text{Si}_4\text{O}_{22}$

Named in 1839 by Rose for Konstantin Vladimirovich Tschekin (1802–1875), chief of Russian mining corps. Compare perrierite (56.2.8.3) and strontiochevkinite (56.2.8.2). Not strictly polymorphous with perrierite. Synthetics are polymorphous for certain compositions. MON *C2/m* or *P2_{1/a}* [synthetic

material is $P2_1/a$: AM 59:1277(1974)]. Natural material from Mianxi, Sichuan Prov., China, was studied by TEM techniques and SAED and CBED showed space group $C2/m$ rather than $P2_1/a$. *JCUG* 2:75(1991). This discrepancy may be due to compositional differences between synthetic and natural materials used. Heated metamict chevkinite from Zambia was refined in $P2_1/a$. *AUCG*:181(1983). $a = 13.26$ – 13.60 , $b = 5.67$ – 5.82 , $c = 11.04$ – 11.35 , $\beta = 100.53$ – 100.87° , $Z = 2$, $D = 4.88$ – 5.10 ; 42-1394(heated nat): 3.48_4 3.47_4 3.19_9 3.15_6 3.00_4 2.87_5 2.76_6 2.72_{10} ; (unheated nonmetamict): 4.61_3 3.19_8 3.15_8 2.88_7 2.76_5 2.72_{10} $2.175_{3\ 5}$ 1.98_3 . *NJBM*:358(1994). Is often metamict or partly so. Structure: AM 59:1277(1974). Anhedral to subhedral masses to 12 cm or more, or short prismatic crystals with {100}, {001}, and {201} dominant, {110} minor; elongated on b , sometimes twinned on {001}. Black, dark brown or dark reddish brown, gray-brown streak, vitreous–adamantine luster. No or very poor cleavage on (001), conchoidal fracture, brittle. $H = 5$ – 6 . $G = 4.4$ – 4.9 . Soluble in HCl, HNO₃, HF, and AR, but not in bases. Metamict material is more readily soluble. Analysis: ThO₂ to 24.2% (Ilmen Mts., Urals); Nb₂O₅ to 7.4% (Ilmen Mts., Urals); UO₂ to 2.1%; may contain elevated MnO. See perrierite (56.2.8.3) for the general formula and possible chemical substitutions. Biaxial (–); $Z = b$, $X \wedge c = 11.5$ – 25.75° in acute β ; $2V = 70^\circ$, N_x as high as 2.00 when fresh, N_z as high as 2.05 when fresh. Metamict material has N as low as 1.88. $Z > Y > X$; $r > v$. Opaque to deep reddish brown; sometimes X = very pale brown-yellow; Y = pale red-brown; Z = dark red-brown. R at four standard wavelengths is about 11%. Occurs as a minor accessory mineral in volcanic ash beds and rhyolites, but is more commonly present as an accessory mineral in alkalic or peralkaline granites, granite pegmatites, nepheline–syenites, syenites, and syenitic pegmatites. Rarely in fenites, and also carbonatites. May alter to various secondary Ti- and REE-bearing minerals. Occurs widely throughout the world, but only selected localities are given here: Stark, NH; Martin's store, Nelson Co., VA; in volcanic ash beds throughout the western United States; accessory mineral in Pikes Peak Granite, Front Range, CO; Questa, NM; Aquarius Mountains, Mohave Co., AZ; Panamint Range, Inyo Co., CA; Golden Horn Batholith, Cascades, WA; St. Kilda, Scotland; Stokkøya, Sandefjord, and Bjørkedalen in the Oslo region, Norway; Novopoltavsk, Ukraine; Khibiny and Lovozero massifs, and west Keivy region, Kola Penin., Russia; *Kuchtyim and Vishnevye Gor* (Cherry Mt.), Ilmen Mts., Ural Mts., Russia; Mianxi, Sichuan Prov. and Fujian Prov., China; Sabaragamuwa Prov., Ceylon (Sri Lanka); Mbolwe Hill, Central Prov., Zambia; Zomba and Mulanje, Chilwa Alkaline Prov., southern Malawi; Itorendrika, Betroka, and other localities in Madagascar; Kanjamali Hill, Salem district, Madras, and Orissa; Jokalandi, India; Kogendo region, Korea; Cape Ashizuri, Shikoku, Japan; southeastern Q, Australia. EF *MRE* 3:309(1966); AM 52:1094(1967), 56:307(1971); MIN 3(1):784(1972).

56.2.8.2 Strontiochevkinite

Named in 1983 by Haggerty and Mariano as the Sr-dominant analog of chevkinite. See chevkinite (56.2.8.1) perrierite (56.2.8.3). *MON* $P2_1/a$. $a = 13.56$, $b = 5.70$, $c = 11.10$, $\beta = 100.32^\circ$, $Z = 2$, $D = 5.44$. $38-443(\text{nat})$: 3.21_1 3.01_{10} 2.85_3 2.73_3 2.51_4 2.19_7 1.97_8 1.67_1 . Structure not yet determined but is of the chevkinite type. Occurs as black rounded grains to 1.5 mm in diameter. Thick parallel lamellar or interpenetration twinning present. Submetallic luster. $H \approx 5$. $G = 5.4$. Analysis (wt %): TiO_2 , 23.2; SiO_2 , 20.45; ZrO_2 , 10.3; Al_2O_3 , 0.11; FeO , 6.02; MnO , 0.08; CaO , 2.05; SrO , 19.6; BaO , 0.38; La_2O_3 , 9.18; Ce_2O_3 , 9.35. The mineral is opaque in standard thin sections. In RL, dark gray, strongly anisotropic in shades of gray with flesh-pink coloration. Deep red internal reflections. Reflectivities are 10% in air and 2% in oil. Occurs in rheomorphic fenite dikes in carbonatite, associated with lamprophyllite and strontian loparite. *Sarambi, Paraguay*. *EF CMP 84:365(1983)*.

56.2.8.3 Perrierite-(Ce)

Named in 1950 by Bonatti and Gottardi for Carlo Perrier (1886–1948), an Italian mineralogist. See chevkinite (56.2.8.1) and strontiochevkinite (56.2.8.2). Strictly speaking, chevkinite and perrierite are not polymorphs. The phase change of chevkinite to perrierite, and vice versa, is controlled primarily by composition. The two minerals do not coexist. Dimorphism occurs but only within fairly narrow chemical limits. Perrierite transforms to chevkinite with increasing temperature. *CMP 84:365(1983)*. *MON* $C2/m$. $a = 13.52-13.95$, $b = 5.62-5.73$, $c = 11.63-11.73$, $\beta = 113.3-114.5^\circ$, $Z = 2$, $D = 4.86$; $19-302(\text{nat})$: 4.10_6 3.56_8 2.99_{10} 2.96_{10} 2.84_7 2.69_6 2.18_8 1.95_8 . May be metamict or partly so. Structure: *AM 59:1277(1974)*. Anhedral masses to subhedral masses, also euhedral crystals resembling epidote with dominant forms: {001}, {100}, and {111}; twinning frequent on (001); crystal size to more than 1 cm. Brownish black or black to brownish red, brownish-gray streak, resinous to vitreous luster. No cleavage or one indistinct cleavage, uneven to conchoidal fracture, brittle. $H = 5\frac{1}{2}-6$. $G = 4.06-4.55$. Gelatinizes in HCl and dissolves in hot H_2SO_4 . General formula is $\text{A}_4^{3+}\text{B}^{2+}\text{C}_2^{+}\text{Ti}_2\text{Si}_4\text{O}_{22}$, where A = large cations: REE, Sr, Ca, Th, Na, K; B = Fe^{2+} , Mn, Mg, and sometimes Ca and C = Ti, Mg, Mn, Fe^{3+} , Fe^{2+} , Al. May contain appreciable Sc_2O_3 (to 4.17 wt %); also appreciable SrO (to 7.7 wt %); ThO_2 to >4 wt %; ZrO_2 to 5.6 wt %; may also be high in $\text{MgO} + \text{Al}_2\text{O}_3$ ($\Sigma 10$ wt %). Biaxial (-); $Z = b$, $X \wedge a = 24^\circ$ in obtuse β ; $N_x = 1.90-1.95$, $N_{y \text{ calc}} = 2.01$, $N_z = 2.02-2.06$; $2V = 60^\circ$ or less; $Z \geq Y \gg X$, very strong; $r > v$, strong. X, yellow to yellow-brown; Y, opaque to violet-red or medium red; Z, opaque to deep brown or red-brown. A minor accessory mineral (e.g., chevkinite) in volcanic ash beds, but is more commonly found in alkalic or peralkaline granites, granite pegmatites, syenites, and syenitic pegmatites. Also occurs in tuffaceous sands, as at Nettuno, Italy. Rarely in granodiorites (e.g., VA) or

anorthosite and gabbro. Alters to various secondary REE- and Ti-bearing minerals. Burley farm, NW of Amherst, and Wares Gap, Amherst Co., Chamblissburg, Bedford Co., Roseland, Nelson Co., and Hat Creek, Massie's Mills, Nelson Co., VA; many locations in the western United States in volcanic ash; Bancroft, ONT, Canada; *Nettuno, Latium, Italy*; Zr-rich from La Mola, Sabatini complex, also Monte Amiata, Tuscany, Italy; Oslo region, Norway [e.g., Storgangen (Sogndal anorthosite) and Bjørkedalen]; Manty Harju, Finland; Burpala massif, northern Baikal area (Sr-bearing), Ural Mts., and Chatkal-Kuramin Mts., Central Asia, Russia; Orlovsk Massif, Rudnyi Altai, and Tarbagata, Kentsk, Kazakhstan (scandian variety); found with apatite ores in the apatitovoye deposit Mushgay ore field, southern Mongolia; Tete, Mozambique; Salem and Bangalore, India; Shiroisi, Kobe, Ohmiya town, Kyoto Pref., Japan; Vestfold Hills, eastern Antarctica. *EF AM 52:1094(1967), 53:1558(1968), 56:307(1971); MIN 3(1):779(1972); MM 58:607(1994).*

56.2.8.4 Orthochevkinite (not approved by CNMNM IMA)

A possible orthorhombic form of chevkinite was reported by Ungemach [*BSFM 39:5-37(1916)*] and by Lacroix [*CRASP 171:594(1920)*]. Also mentioned by Lacroix [*MMAD 1: 585(1922), 3:313(1923)*]. Masses to nearly 1 kg were recovered and crystals to 10 cm. They are partly or completely metamict. Dominant forms are: {001}, {100}, {110}, {210}. Found in alkaline syenite pegmatites in the region of Ifazina-Itorendrika, with aegirine, alkali amphibole, and bastnaesite, and in granitic pegmatites of Betroka and Itron-gay. Studied by Bonatti and Gottardi [*RSMI 9:242(1953)*]. Summarized in *MIN 3(1):791(1972)*. Cell dimensions are: $a = \text{ca. } 13.6$, $b = 5.8$, $c = 22.0$. Strongest X-ray diffraction lines of unheated material [*AM 44:115(1959)*]: 4.15_{10} 3.78_7 3.54_7 2.88_4 2.70_7 2.53_4 1.69_5 1.49_4 . Heating metamict material at 700° and 1000° in nitrogen produces chevkinite. At 1000° in air, heating produces cubic CeO_2 and perrierite. This material needs to be reexamined carefully by modern methods. *EF*

56.2.9.1 Tilleyite $\text{Ca}_5\text{Si}_2\text{O}_7(\text{CO}_3)_2$

Named in 1933 by Larsen and Dunham for Cecil Edgar Tilley (1894-1973), British petrologist, Cambridge University. *MON P21a*. $a = 15.108\text{--}15.111$, $b = 10.241\text{--}10.242$, $c = 7.577\text{--}7.579$, $\beta = 105.15\text{--}105.17^\circ$ [*ZK 132:288(1970)*], $Z = 4$, $D = 2.87$. *24-184*: 3.09_{85} 3.00_{10} 2.97_{55} 2.96_4 2.50_{25} 2.10_{45} 1.91_3 1.90_{65} . See also *25-159*. Structure: *AC 6:9(1953)*, *ZK 132:288(1970)*. Usually fine-grained, to 15 cm long at Red Cap Creek; twinning = simple {100}, often lamellar $X \wedge$ twin plane $\approx 24^\circ$; not all tilleyite shows twinning. Deep gray, white, light-bluish gray, colorless; white streak; dull luster. Cleavage {201}, perfect; {100}, {010}, poor. $H = 5$. $G = 2.84$. Effervesces in HCl and forms a silica gel. Usually pure. Traces of Ti for Si and Mg for Ca, traces of Al and Fe present as well. Biaxial (+); $X \wedge c = 24^\circ$, $Y = b$, $Z \wedge \{201\}$ cleavage trace $\approx 12^\circ$; $N_x = 1.605\text{--}1.617$, $N_y = 1.626\text{--}1.635$, $N_z = 1.651\text{--}1.654$; $2V = 85\text{--}90^\circ$; $r < v$. Occurs in magmatic skarns, 800° . Marble-igneous rocks. Skarns formed

at the igneous rock-marble contact. As opposed to vein skarns-fractures in marble. In carbonate-bearing rocks of sanidinite-facies environments. Sometimes replaced by wollastonite-vesuvianite-melanite, calcite. Also foshagite and calcite. To calcite and hillebrandite, also cuspidine. North End Peak, Iron Mountain, Sierra Co., NM; Helena, MT; *Crestmore quarry, Riverside Co., CA*; Carlingford, Ireland; Camas Mor, Island of Muck, Inverness-shire, and Kilchean, Ardnamurchan, Isles of Skye and Rhum, Scotland; Cornet Hill, Romania; Anabarsky intrusive, Anakit district, Lower Tunguska region, and Kuzmovka, Stony Tunguska R., Yakutia, Russia; Guneyce-Ikizdere area, Turkey; Kushiro, Hiroshima Pref., Japan; to 25 cm from the Akagene mine, Iwate Pref., Japan; coarse-grained, 2- to 15-cm prisms from Redcap Creek, northern Q, Australia. EF *MIN 3(1):808(1972)*, *DHZ 1B 278(1986)*.

56.2.9.2 Killalaitite $\text{Ca}_3\text{Si}_2\text{O}_7 \cdot \text{H}_2\text{O}$ and $2\text{Ca}_3\text{Si}_2\text{O}_7 \cdot \text{H}_2\text{O}$

Named in 1974 by Nawaz for the locality. Cuspidine-wöhlerite group. *MON P2₁/m*. $a = 6.807$, $b = 15.459$, $c = 6.811$, $\beta = 97.76^\circ$ [*MM 41:363(1977)*], $Z = 2$ or 4; (pseudocell): $a = 6.80$, $b = 15.47$, $c = 6.82$, $\beta = 98.3^\circ$ [*CA 98:182738(1983)*] (additional very weak reflections indicating a B-centered monoclinic true cell with $2a$ and $2c$), $D = 2.88\text{--}2.94$. *29-332* (calc pattern): 3.86₂ 3.37₃ 3.09₅ 2.82₁₀ 2.71₄ 2.57₄ 2.54₃ 2.22₃. See also *26-1070(nat)*. Structure: H positions not located. $\text{Ca}_3\text{Si}_2(\text{H}_6\text{Si}_2\text{O}_7)$ (OH). *MM 41:363(1977)*. Euhedral crystals to 2 mm long; "bowtie" twinning present, penetrative. Colorless. Cleavage {100}, perfect; {010}, {001}, good. $G = 2.9$. Analysis (wt %): CaO, 57.9; SiO₂, 39.8; H₂O, 3.2 (diff). Biaxial (-); $Y = b$, $Z \wedge [001] \approx 16^\circ$, in obtuse β , $Z \wedge c = 16\text{--}19^\circ$; $N_x = 1.634\text{--}1.635$, $N_y = 1.646$, $N_z = 1.642\text{--}1.648$; $2V = 26^\circ$; elongation [010]; OAP (010). Occurs in a thermally metamorphosed limestone as a secondary mineral. In cavities and veins with calcite or awillite in spurrite-wollastonite rocks. Basalt-dolerite dikes caused the metamorphism: 350–550° in a CO₂-deficient environment. In skarns in Turkey with hillebrandite, tobermorite, and vesuvianite. Alteration to xonotlite. *Killala Bay, near Inish Crone, County Sligo, Ireland*; Guneyce-Ikizdere region, eastern Pontids, Turkey. EF *MM 39:544(1974)*.

56.2.9.3 Foshallasite $\text{Ca}_3\text{Si}_2\text{O}_7 \cdot 3\text{H}_2\text{O}$

Named in 1936 by Chirvinsky for William Frederick Foshag (1894–1956), American mineralogist, and for the mineral *centrallasite*. Cuspidine-wöhlerite group. Gyrolite has replaced the name *centrallasite*. An incompletely described mineral. Probably *MON* No X-ray diffraction data available. Scaly, sometimes as spherical aggregates, tabular parallel to {100}, elongated and striated parallel to c . White, white streak, pearly luster. Perfect tabular cleavage {100}. $H = 2\frac{1}{2}\text{--}3$. $G = 2.5$. Analysis (wt %): SiO₂, 32.65; R₂O₃, 1.89; CaO, 45.45; Na₂O, 0.40; H₂O, 0.16; ignition loss 16.66. Biaxial (-); X perpendicular to cleavage; $N_x = 1.535$, $N_y = 1.542$, $N_z = 1.549$. $2V = 12\text{--}18^\circ$. Occurs on *Mt. Yukspor, Khibiny massif, Kola Penin., Russia*; in veinlets associated with calcite and mesolite in lovchorrite, an alkaline nepheline syenite. EF

56.2.10.1 Melanotekite $\text{Pb}_2(\text{Fe}^{3+}, \text{Mn}^{3+})_2\text{O}_2(\text{Si}_2\text{O}_7)$

Named in 1880 by Lindström from the Greek *melanos* and *tektos*, black glass, from the appearance of the mineral. See kentrolite (56.2.10.2), the Mn analog. ORTH *Pbcn*. (Nat): $a = 6.992$, $b = 11.022$, $c = 10.054$; (syn): $a = 6.93$, $b = 10.98$, $c = 10.06$, $Z = 4$ [*AM 76:1389(1991)*], $D = 6.22$ (nat manganoean), 6.30 (pure Fe end member). 15-633(nat manganoean): 5.52₈ 5.03₆ 3.72₆ 3.49₈ 3.25₈ 2.91₁₀ 2.86₆ 2.73₁₀; 20-585(syn Fe): 5.49₃ 5.04₃ 3.70₃ 3.47₃ 3.24₅ 2.91₁₀ 2.86₆ 2.73₈. Structure: ferrian kentrolite done [*AM 76:1389(1991)*]. Prismatic, also massive. Blackish gray, black, synthetic pure Fe is dark brown, also reddish brown; metallic to greasy luster. Cleavable; two unequal cleavages. $H = 6\frac{1}{2}$. $G = 5.73$ –6.19. Mossbauer data: *GFF 107:221(1985)*. Decomposed by HNO_3 . Some contain Mn as a solid solution to kentrolite, as well as minor amounts of TiO_2 and Al_2O_3 . Biaxial (+); for manganoean material: $N_x = 2.12$, $N_y = 2.17$, $N_z = 2.31$; $2V = 67^\circ$; $r > v$, strong. X, nearly colorless; Y, pale reddish brown; Z, deep reddish brown. Occurs in peralkaline pegmatite at Dara-i-Pioz. In Precambrian metamorphosed Mn deposits at Långban and elsewhere in Sweden. Fine, sharp crystals of nearly end-member composition from Hillsboro, Sierra Co., NM; Cerro Gordo, Inyo Co., CA; *Langban, Värmland*, also at the Harstig mine, Pajsberg, Sweden; just about end-member composition from Jakobsberg mine, Filipstad district, Värmland, Sweden; Dara-i-Pioz, Tadzhikistan. EF *MM 58:172(1994)*.

56.2.10.2 Kentrolite $\text{Pb}_2\text{Mn}_2^{3+}\text{O}_2[\text{Si}_2\text{O}_7]$

Named in 1880 by Damour and Vom Rath from the Greek *kentron*, thorn or spike, in allusion to the crystal habit. Polymorph: melanotekite, the Fe analog. ORTH *Pbcn*. (Nat): $a = 6.961$, $b = 11.018$, $c = 9.964$; (syn.): $a = 6.98$, $b = 11.04$, $c = 9.96$, $D = 6.27$; (syn): $Z = 4$, $D = 6.26$. 20-586(nat): 5.56₆ 3.71₈ 3.51₈ 3.24₈ 2.96₅ 2.90₁₀ 2.86₁₀ 2.74₁₀; 20-587(syn): 5.52₅ 4.98₅ 3.49₅ 3.26₇ 2.89₁₀ 2.86₈ 2.84₆ 2.73₁₀. Structure is now refined to $R = 0.047$. An $[(\text{Mn}, \text{Fe})_2\text{O}_2\text{Si}_2\text{O}_7]$ fraction is the simple part, based on infinite $[\text{M}^{3+}\text{O}_4]$ edge-sharing octahedral chains parallel to $[001]$. The $6\text{S}^2\text{Pb}^{2+}$ lone-pair cations are split. *AM 76:1389(1991)*. Prismatic, also massive, sheaflike. Dark reddish brown (nat) black on surface, black (syn), also deep red; yellowish brown streak; greasy luster. Cleavage $\{110\}$, distinct; brittle. $H = 5$. $G = 6.19$ –6.2. Soluble in concentrated HCl. No reaction to KOH, NaOH, H_2O_2 , or HNO_3 . Analysis (wt %): PbO, 59.6; ZnO, 0.05; MgO, 0.05; Fe_2O_3 , 6.62; Mn_2O_3 , 13.55; Al_2O_3 , 0.30; TiO_2 , 0.38; SiO_2 , 16.45. Biaxial (+); $X = a$. $N_x = 2.10$, $N_y = 2.20$, $N_z = 2.31$; $2V = 88^\circ$; $r < v$, strong; OAP parallel to (010) . Occurs in metamorphosed Mn–Zn deposits. Near-end-member kentrolite occurs at Franklin, Sussex Co., NJ; type locality is an unspecified locality in southern Chile and/or *Langban, Värmland, Sweden*; also occurs at Jakobsberg, Filipstad, Nordmark district, and at Klintgruvan, near Krylbo, central Sweden; Pajsberg and Harstigen, Sweden; Bena de Padru near Ozieri, Sassari, Sardinia; Ushkatin mines, Atasuisk region, central Kazakhstan; very rare at Wes-

sels mine, associated with sturmanite, henritermierite, calcite, and so on, Kalahari manganese field, Cape Prov., South Africa. EF

56.2.11.1 Nasonite $\text{Pb}_6\text{Ca}_4\text{Si}_6\text{O}_{21}\text{Cl}_2$

Named in 1899 by Penfield and Warren for Frank Lewis Nason (1856–1928), American geologist, Geological Survey of New Jersey. HEX $P6_3/m$ or $P6_3$. $a = 9.94$, $c = 13.08$, $Z = 2$, $D = 5.63$. Crystals minute and rare, prismatic $\{0001\}$, with $\{10\bar{1}0\}$, $\{11\bar{2}0\}$, $\{10\bar{1}1\}$, and $\{0001\}$; usually massive, granular. White, greasy to adamantine luster. Cleavage $\{0001\}$, good, prismatic distinct. $H = 4$. $G = 5.55$. Uniaxial (+); $N_O = 1.971$, $N_E = 1.945$. Occurs in association with barysilite, datolite, prehnite, axinite, hancockite, clinohedrite, and manganophyllite below the 800 level in pilar 910, south of the Palmer shaft, and associated with glaucochroite, garnet, axinite, and barite at the Parker shaft, *Franklin, Sussex Co., NJ*; found in calcite-filled fissures with schefferite, lead, apophyllite, margarosanite, and thaumasite at Långban, Värmland, Sweden. AR *USGSPP 180:92(1935)*; *AM 36:534(1951)*, *56:1174(1971)*; *AC(B) 43:171(1987)*.

56.3.1.1 Danburite $\text{CaB}_2\text{Si}_2\text{O}_7(\text{O})$

Named in 1839 by C. U. Shepard for the locality. ORTH $Pnam$. $a = 8.038$ – 8.049 , $b = 8.752$ – 8.765 , $c = 7.730$ – 7.737 , $Z = 4$, $D = 3.00$. *29-304(nat)*: $3.65_{3,5}$ 3.57_{10} $3.44_{3,5}$ 2.96_8 2.74_7 2.73_4 2.66_6 1.44_4 . The structure consists of a tetrahedral framework of ordered B_2O_7 and Si_2O_7 groups which accommodates Ca in irregular coordination. Structurally similar to feldspars. *AM 59:79(1974)*. Habit is granular to prismatic, resembling topaz, $\{110\}$, $\{100\}$, $\{010\}$ dominant, elongated on c . Colorless, amber, yellow, pink, gray, white, yellow-brown; white streak; glassy–vitreous–greasy luster; transparent–translucent. No distinct cleavage, one very indistinct on (001) ; subconchoidal to uneven fracture. $H = 7$ – $7\frac{1}{2}$. $G = 2.97$ – 3.03 . IR data: *MS 23:359(1969)*, *PCM 14:441(1987)*. Sometimes fluorescent blue to blue-green in LWUV, with red thermoluminescence. Soluble in acids. Analysis (wt %): CaO, 22.8; B_2O_3 , 28.4; SiO_2 , 48.8. Biaxial (–); $XZ = ba$; $N_x = 1.630$, $N_y = 1.633$, $N_z = 1.635$; colorless; OAP = (001) ; $2V = 80$ – 88° ; $r < v$, strong. A contact-metamorphic mineral, occurring in moderate- to low-temperature and low-Fe-bearing conditions. Associated with calcite, datolite, and nifontovite at Charcas. Associated with axinite in Japan. In metamorphosed limestone at Danbury, CT. Also in pegmatites and greisens. In evaporites and salt domes in the Texas Gulf. In a gypsum bed in Bolivia. Occurs in dolomite marble at the extinct White's Factory excavation, *Danbury, Fairfield Co., CT*; crystals to 4 in. long at Russell, St. Lawrence Co., NY; in pegmatite at DeKalb, NY; Little 3 mine, Ramona, San Diego Co., CA; Silver Harbor, ONT, Canada; with smoky quartz in gneiss at Piz Valatscha, Val Medels, Uri, Graubunden, Switzerland; Kragerø district, Norway; with anhydrite at Zechstein, Germany; Ligurian Briançonnais, Maritime Alps, Italy; Maglovec, near Presov, Czech Republic; large crystals to >30 cm long and 10 cm wide from Dalnegorsk, Primorsky

Krai, Russia; gem-quality pebbles from marble near Mogok, Myanmar; at Maharitra on Mt. Bity, and at Imalo and Sahasonjo, Madagascar; at Obira, Bungo, Oita Pref., Japan; with axinite at the Toroku mine, Miyazake Pref., Kyushu, Japan; abundant and fine-quality prismatic crystals from lead-zinc mines at Charcas, SLP, Mexico; also from the La Sirena mine, Zimapan, Mexico; to 15 cm long in pegmatites in northern Baja California, Mexico; in evaporites and volcanic ejecta at Cochabamba, Bolivia. Minor use as a gemstone. A 138-ct pale yellow stone is in British Museum. Best faceted stones are from Burma (yellowish to brownish). *EF AUCG 1-2:111(1973)*, *NJBM: 289(1987)*.

56.3.2.1 Werdingite $(\text{Mg,Fe})_2\text{Al}_{12}(\text{Al,Fe})_2\text{Si}_4(\text{B,Al})_4\text{O}_{37}$

Named in 1990 by Moore et al. for Günter Werding (b.1929), Ruhr-University, Bochum, Germany. Related to sillimanite, mullite, and grandidierite. *TRIC P1*. $a = 7.995$, $b = 8.152$, $c = 11.406$, $\alpha = 110.45^\circ$, $\beta = 110.85^\circ$, $\gamma = 84.66^\circ$, $Z = 1$, $D = 3.07$. *PD(nat)*: 5.43₈ 5.23₁₀ 4.98₈ 3.44₃ 3.39₅ 2.71₆ 2.19₅ 1.53₄; *44-1467(syn)*: 5.44₈ 5.25₁₀ 5.03₇ 3.40₉ 3.31_{5,5} 2.72₉ 2.53₅ 2.20_{7,5}. Chains of AlO_6 octahedra parallel to c , cross-linked by Si_2O_7 groups, Al and Mg in fivefold coordination, Al and Fe tetrahedra, and B triangles. *AM 76:246(1991)*. Maximum size ≈ 3 mm; simple twins common, lamellar twins of three or four individuals also occur. Translucent—brownish yellow (honey colored); buff-white streak; vitreous luster. Conchoidal fracture. $H = 7$. $G = 3.04$. Does not fluoresce in UV. Analysis (wt %): MgO, 4.46; FeO, 5.06; Al_2O_3 , 59.49; TiO_2 , 0.05; SiO_2 , 19.83; B_2O_3 , 10.19. Biaxial (-); $X = c$; in white light: $N_x = 1.614$, $N_y = 1.646$, $N_z = 1.651$; $2V = 33^\circ$; prism elongation and the CP of simple twins are parallel to c ; $r > v$, moderately strong; horizontal dispersion present; pleochroic. X, colorless; Y, yellow; Z, colorless. Occurs in a supracrustal granulite facies gneissic sequence at *Bok Se Puts, Namaqualand, South Africa*; with sillimanite-hercynite, kornerupine, grandidierite, and Fe-Ti oxides. Alteration: grandidierite and hercynite replace werdingite. *EF*

56.4.1.1 Lomonosovite $\text{Na}_5\text{Ti}_2\text{O}_2(\text{Si}_2\text{O}_7)(\text{PO}_4)$

Named by Gerasimovskii in 1950 for Mikhail V. Lomonosov (1711–1765), Russian mineralogist and naturalist. *TRIC P1*. $a = 5.393\text{--}5.49$, $b = 7.11\text{--}7.121$, $c = 14.420\text{--}14.50$, $\alpha = 100.02\text{--}101^\circ$, $\beta = 96\text{--}96.44^\circ$, $\gamma = 90\text{--}90.44^\circ$, $Z = 2$, $D = 3.04$. *NJBA 148:83(1983)(nat)*: 4.14₆ 2.90₈ 2.83₁₀ 2.73₁₀ 2.68₆ 2.65₈ 1.77₁₀ 1.75₆; data also given on 15-155 and 17-542 for natural material. Structure: *DAN SSSR 197:81(1971)*, *235:1064(1977)*; *SPD 22:422(1977)*. Formula may also be written as $\text{Na}_2\text{Ti}_2\text{Si}_2\text{O}_9 \cdot \text{Na}_3\text{PO}_4$. Crystals to 15 cm \times 10 cm, a axis lies in the tabular direction, also lamellar and flaky aggregates; tabular crystals bound by {001}, {013}, {012}, {012}, {014}, {201}, {201}, {110}; simple contact to finely polysynthetic twinning present with (001) as the composition plane and the a axis as the twin axis. Dark brown, orange-brown, black; medium red-brown streak; vitreous-adamantine luster on cleavages, greasy on fractures.

Cleavage {001}, perfect; uneven fracture; brittle. $H = 4\frac{1}{2}$, decreasing with alteration. $G = 3.12\text{--}3.15$, lower when altered and hydrated, e.g., to 2.88. DTA, TGA, IR, Mössbauer data: *NJBA 148:83(1983)*. Contains Fe^{3+} in octahedral coordination and Fe^{2+} in two different octahedral sites. Easily soluble in HCl or H_2SO_4 , leaving a silica residue. Composition of Ilimaussaq material (avg. wt %): Na, 20.1; Ca, 0.92; Ti, 16.4; Nb, 1.73; Fe, 1.43; Mn, 0.18; Si, 10.94; P, 6.04; O, 39.7. Cinnamon-colored material from Lovozero: P_2O_5 , 12.8; $\text{Nb}_2\text{O}_5 + \text{Ta}_2\text{O}_5$, 3.0; TiO_2 , 24.4; SiO_2 , 24.1; ZrO_2 , 2.1; Fe_2O_3 , 2.4; MnO, 3.2; MgO, 0.6; CaO, 0.8; Na_2O , 26.1; H_2O , 0.3. Biaxial (-); $N_x = 1.654\text{--}1.708$, $N_y = 1.736\text{--}1.759$, $N_z = 1.764\text{--}1.778$; $2V = 56\text{--}69^\circ$; $Z > Y > X$; $r > v$, strongly pleochroic. X, nearly colorless; Y, dark brown to lilac; Z, yellowish brown. The color intensity increases with increasing content of Ti and decreasing content of Nb. For dark brown material: X, yellow to pale yellow; Y, orange-yellow or brownish yellow; Z, dark brown to violet. $P_{(001)} N_x = 38^\circ$, $N_y = 70^\circ$, $N_z = 59^\circ$. One of the optical axes lies in the $a\text{--}c$ crystallographic plane and this axis forms an angle of 74° with the a axis. The optic normal is perpendicular to the face pairs (201) and (201). Occurs in pegmatites and in several nepheline syenite varieties in the Lovozero massif; in Greenland, the mineral occurs in fine-grained lavas and in fine- to coarse-grained gabbros near the contact with intrusive nepheline syenites, composed of arfvedsonite, aegirine, microcline, and/or albite, nepheline, eudialyte, and a number of accessory minerals. Kvanefjeld area, Ilimaussaq intrusion, southern Greenland; in the Jubilee pegmatite on Mt. Karnasurt, and the Chinglusuai R., Lovozero massif, Kola Penin., Russia; also in the Khibiny massif at Mt. Yukspor, Mt. Rasvumchorr, Mt. Koashva, and Mt. Kukisvumchorr. Alters to murmanite. Beta-lomonosovite is an indefinite intermediate stage in the alteration of lomonosovite to murmanite by leaching out of PO_4 and hydration. Originally described in *DAN SSSR 142:670(1962)*. Lomonosovite may also be replaced by narsarsukite, manganeseptunite, and mountainite; sometimes replaced by bornemanite. *EF DAN SSSR 70:83(1950)*, *MIN 3(1):661(1972)*.

56.4.1.2 Polyphite $\text{Na}_{17}\text{Ca}_3\text{Mg}(\text{Ti},\text{Mn})_4[\text{Si}_2\text{O}_7]_2(\text{PO}_4)_6\text{O}_2\text{F}_6$

Named in 1992 by Khomyakov et al. from the Greek for *many*, in allusion to the many elements with multiple phosphate groups in the formula. Related to quadruphite, lomonosovite, and sobolevite. TRIC $P1$. $a = 5.412$, $b = 7.079$, $c = 26.56$, $\alpha = 95.21^\circ$, $\beta = 93.51^\circ$, $\gamma = 90.10^\circ$, $Z = 1$, $D = 3.00$. $PD: 4.37_4$ 4.13_4 2.94_{10} 2.70_9 2.66_8 2.05_8 1.77_5 1.73_5 . Structure: *DAN SSSR 294(2):357(1987)*, *ZVMO 121:105(1992)*. {001} plates, 1–2 mm and sometimes to 3 mm, epitaxially on lomonosovite (with or without sobolevite intergrowths). Light brown; tan streak; vitreous luster, pearly on cleavage to specular-metallic. Cleavage {001}, excellent; less so on {110} and {100}; brittle. $H = 5$. $G = 3.07$. Nonfluorescent. Soluble in cold 10% HCl. Analysis (wt %): Na_2O , 28.0; SrO, 0.3; BaO, 0.9; CaO, 8.3; MgO, 1.3; MnO, 5.6; FeO, 0.2; SiO_2 , 13.2; ZrO, 1.6; TiO_2 , 12.0; Nb_2O_5 , 2.7; P_2O_5 , 23.3; F, 5.1; O for F, 2.1. Biaxial (-); $N_x = 1.600$, $N_y = 1.658$, $N_z = 1.676$; $P_{(001)}: N_x = 30^\circ$, $N_y = 64^\circ$,

$N_z = 76^\circ$; $2V_{\text{obs}} = 56^\circ$, $2V_{\text{calc}} = 57^\circ$; $Z \geq Y > X$; $r < v$, strong. X, colorless; Y,Z, yellowish. Found in ultra-agpaitic pegmatitic rocks, associated with many other alkalic minerals. See also quadruphite (56.4.1.3). Found at Mt. Alluaiev, in the northern part of the Lovozero massif, Kola Penin., Russia. EF AM 78:1316(1993), MA 45:240(1994).

56.4.1.3 Quadruphite $\text{Na}_{14}\text{CaMgTi}_4(\text{Si}_2\text{O}_7)_2(\text{PO}_4)\text{O}_4\text{F}_2$

Named in 1992 by Khomyakov et al. for the Latin *quadruplex* and the element P, the quantity of PO_4 groups in the formula. TRIC P1. $a = 5.415$, $b = 7.081$, $c = 20.34$, $\alpha = 86.85^\circ$, $\beta = 94.40^\circ$, $\gamma = 89.94^\circ$ (for all acute cell), $Z = 1$, $D = 3.11$. ZVMO 121:105(1992). PD: 2.88₁₀ 2.70₈ 2.64₇ 2.05₅ 1.77₂ 1.71₃ 1.66₄ 1.600₅. Structure: MZ 9(3):28(1987) and ZVMO 121(1):105(1992). Irregular plates flattened on {001} 1–2 mm thick and up to 3 mm across, some in epitaxial intergrowths with plates of lomonosovite, and sobolevite. Light brown; white to tan streak; vitreous luster, pearly on basal cleavage to specular-metallic; translucent, transparent in thin sections. Cleavage {001}, perfect; {110}, {100}, less perfect; steplike fracture; brittle. H = 5. G = 3.12. Nonfluorescent. Soluble in cold 10% HCl. Analysis (wt%): Na_2O 28.1, SrO 0.4, BaO 1.1, CaO 5.3, MgO 1.1, MnO 4.3, FeO 0.3, SiO_2 16.5, ZrO_2 4.1, TiO_2 13.7, Nb_2O_5 3.8, P_2O_5 19.2, F 3.4, O≡F 1.4. Biaxial (-); $N_x = 1.630$, $N_y = 1.678$, $N_z = 1.697$; $2V_{\text{obs}} = 62^\circ$, $2V_{\text{calc}} = 63^\circ$; $P_{(001)}$: $N_x = 28^\circ$, $N_y = 71^\circ$, $N_z = 70^\circ$; $Z > Y > X$; $r < v$; pronouncedly pleochroic. X, colorless; Y,Z, yellow. Found in ultra-agpaitic pegmatitic rocks with K-feldspar, nepheline, sodalite, arfvedsonite, aegirine, cancrisilite, analcite, albite, ussingite, makatite, grumantite, lomonosovite, vuonnemite, sobolevite, and other rare minerals at Mt. Alluaiv in the northwestern part of the Lovozero alkaline massif, Kola Penin., Russia. EF AM 78:1316(1993), MA 45:240(1994).

56.4.1.4 Sobolevite $\text{Na}_{11}(\text{Na,Ca})_4(\text{Mg,Mn})\text{Ti}_4[\text{Si}_2\text{O}_7]_2[\text{PO}_4]_4\text{O}_3\text{F}_3$

Named in 1983 by Khomyakov et al. for Vladimir Stepanovich Sobolev (1908–1982), Russian petrologist and former president of the IMA. TRIC P1. $a = 7.078$, $b = 5.4115$, $c = 40.618$, $\alpha = 90.01^\circ$, $\beta = 93.19^\circ$, $\gamma = 90.00^\circ$, $Z = 2$, $D = 2.96$ – 3.03 . 36-439(nat): 4.29₃ 3.18₄ 2.91₅ 2.90₁₀ 2.69₇ 1.77₅ 1.72₃₅ 1.67₅. Originally described as monoclinic, but is actually triclinic. DAN SSSR 302(5):1112(1988), ZVMO 112:456(1983). Lomonosovite group. Related to polyphite, quadruphite, and lomonosovite. Brown; tan streak; metallic luster, pearly on (001), resinous. Cleavage {001}, perfect; {110}, distinct. H = $4\frac{1}{2}$ –5. G = 3.03. Nonfluorescent. Readily decomposed by cold 10% HCl. IR data: ZVMO 112:456(1983). Analysis (wt %): SiO_2 , 17.1; Na_2O , 29.7; CaO, 6.4; MgO, 0.6; TiO_2 , 15.2; Nb_2O_5 , 4.4; MnO, 4.0; Fe_2O_3 , 0.6; P_2O_5 , 19.9; F, 0.7; O for F, 0.3. Biaxial (-); $N_x = 1.627$, $N_y = 1.686$, $N_z = 1.690$; $P_{(001)}$: $N_x = 35^\circ$, $N_y = 90^\circ$, $N_z = 55^\circ$; $2V_{\text{obs}} = 29^\circ$ (Na light), $2V = 25^\circ$ (red), 33° (blue); $Z = Y > X$; $r < v$, strong. X, nearly colorless; Y,Z, yellowish brown. Found in ultra-agpaitic pegmatitic rocks associated with other alkalic mineral and rare species. Pegmatite cutting sodalite–cancrinite syenite. Associated with

lomonosovite and lamprophyllite. Found on *Mt. Alluaiev, in the northwestern part of the Lovozero massif, Kola Penin., Russia.* EF AM 76:305(1991).

56.4.2.1 Bornemanite $\text{BaNa}_4\text{Ti}_2\text{NbSi}_4\text{O}_{17}(\text{F},\text{OH}) \cdot \text{Na}_3\text{PO}_4$

Named in 1975 by Men'shikov et al. for Irina Dmitrievna Borneman-Starynkevich (b.1890), Russian mineralogist, Institute of Ore Deposits, Moscow, and student of the mineralogy of the Khibiny and Lovozero massifs. ORTH *Ibmm* or *Ibm2*. $a = 5.48$, $b = 7.10$, $c = 48.2$, $Z = 4$, $D = 3.49$. 29-1176: 24.1₁₀ 8.04₁₀ 3.44₁₀ 3.02₁₀ 2.68₈ 1.81₇ 1.610₈. Pale yellow, pearly luster, translucent to transparent. Cleavage {001}, perfect. $H = 3\frac{1}{2}$ -4. $G = 3.47$ -3.50. Biaxial (+); $2V = 40^\circ$, $2V_{\text{calc}} = 66^\circ$; $N_x = 1.682$ -1.683, $N_y = 1.687$ -1.695, $N_z = 1.718$ -1.720; $XYZ = cba$; Pleochroic; X,Y, colorless; Z, pale yellow-brown. Found as a late hydrothermal product occurring as platy aggregates up to 10 mm × 8 mm × 0.2 mm on the surface of or on cleavage cracks in lomonosovite and in natrolite in the *Yubileinaya (Jubilee) alkalic pegmatite, Mt. Karnarsut, Lovozero massif, Kola Penin., Russia.* AR ZVMO 104:322(1975), AM 61:338(1976).

56.4.3.1 Vuonnemite $\text{Na}_5\text{Nb}_2\text{Ti}^{3+}(\text{Si}_2\text{O}_7)_2\text{O}_2\text{F}_2 \cdot 2\text{Na}_3\text{PO}_4$

Named by Bussen et al. in 1973 for the locality. Related to murmanite, epitaxite, and lomonosovite. TRIC. $P\bar{1}$ $a = 5.498$ -5.50Å $b = 7.161$ -7.162Å $c = 14.440$ -14.450Å $\alpha = 92.60$ -92.63° $\beta = 95.30$ -95.33° $\gamma = 90.57$ -90.60° $Z = 1$ $D = 3.17$; PD 26-792 (nat. Kola Pen.): 7.14₆ 5.16₅ 4.77₅ 4.24₅ 3.58₆ 2.87₁₀ 2.39₅ 1.79₆; (NJB M 451(1983) (nat. Greenland): 14.35₆ 7.15₇ 4.25₁₀ 2.87₁₀ 2.77₁₀ 2.74₁₀ 2.66₆ 1.79₈. Pale yellow to lemon yellow or greenish yellow, streak white, vitreous to greasy luster, plates to 2 cm across and bladed crystals to more than 10 cm, perfect {001} cleavage and two other excellent cleavages; brittle, H 2-3 G 3.11-3.13. IR and DTA data (ZVMO 102:423(1973)). Some crystals fluoresce intense greenish yellow in SW UV or whitish with a light green hue and pale yellow or no fluorescence under LW UV. Faint bluish green phosphorescence for a short period. Decomposed by H_2O . SiO_2 22.3-22.6 wt. %, TiO_2 7.5-8.1, Al_2O_3 0.3-0.5, Nb_2O_5 23.2-27.9, FeO 0.1-0.3, MnO 0.1-0.5, MgO 0.1, CaO 0.3, Na_2O 30.2-32.0, K_2O 0.1, P_2O_5 13.1-13.5, LOI 1.0, Σ 99.7-100.1. Biax. (+), $2V = 53$ -54°, also to 86°; N_α 1.636-1.639, N_β 1.651-1.656, N_γ 1.680-1.683; $\text{OAP} = \{001\}$, $Y \wedge c$ 4°. Orientation of Ilimaussaq material: $P \wedge \alpha$ 57°, $P \wedge \beta$ 33°, and $P \wedge \gamma$ 89°, where P is the normal to the {001} cleavage plane. Occurs in albitized alkalic rocks of both the Khibiny and Lovozero massifs, assoc. with albite, microcline, nepheline, aegirine, lorenzenite, cancrinite, etc. In a transition zone between two nepheline syenites (lujavrite) in Ilimaussaq. Mont Saint-Hilaire, Quebec; Kvanefjeld plateau, Ilimaussaq intrusion, SW Greenland; Vuonnemi River, Khibiny massif, Kola Peninsula, Russia; in the Jubilee pegmatite on Mount Karnarsut, and in the Umbozero mine on Mount Alluaiev, Lovozero massif, Kola Peninsula, Russia. Zorite may replace and pseudomorph vuonnemite. EF MR 21:284(1990), Ercit and Hawthorne 1987 GAC-MAC v. 12, p.41; Ercit and Hawthorne (1990)

Insular Si_3O_{10} and Larger Noncyclic Groups

57.1.1.1 Aminoffite $\text{Ca}_3\text{Be}_2\text{Si}_3\text{O}_{10}(\text{OH})_2$

Named in 1937 for Gregori Aminoff (1883–1947), Swedish mineralogist and crystallographer, Riksmuseum, Stockholm. TET $P4_2/n$ or $I4$. $a = 9.865$, $c = 9.930$, $Z = 4$, $D = 2.90$. $23\text{-}80(\text{nat})$: 6.97_7 4.40_7 4.02_8 3.48_7 3.11_7 2.84_9 2.61_{10} 2.14_8 . Dipyramidal and flattened tablets, with $\{001\}$, $\{111\}$, $\{100\}$ common; twinning present; piezoelectric; crystals to 0.5–1.0 mm. Pale yellow or colorless, white streak, vitreous luster. Cleavage $\{001\}$, weak; conchoidal fracture. $H = 5\frac{1}{2}$. $G = 2.94\text{--}3.00$. IR data: *GZ* 36:76(1976). Not soluble in common acids. May contain some minor Na, and F. Uniaxial (–); $N_0 = 1.647\text{--}1.654$, $N_E = 1.628\text{--}1.637$; colorless; sometimes has anomalous $2V$ with $2V = 0\text{--}15^\circ$. Occurs in cavities in magnetite–limonite skarn; also in calcite veins with barite and fluorite. An accessory mineral in fluorite veins. In a contact zone between granite and marble (at Tuva), with vesuvianite, analcite, and others. *Långban, Värmland, Sweden*; in fluorite veins in the Dugdinsk Massif, Tuva, Siberia, Russia; Bayan Kol dike field. *EF MIN* 3(2):8(1981); *AM* 49:212(1964); *AC* 23:255(1967), 23:260(1967); *DANS* 209:260(1973); *GZ* 36:76(1976).

57.1.1.2 Harstigitite $\text{Ca}_6\text{Be}_4(\text{Mn,Mg})[\text{SiO}_4]_2[\text{Si}_2\text{O}_7]_2(\text{OH})_2$

Named in 1886 by Flink for the locality. ORTH $Pcmm$. $a = 13.830$, $b = 13.636$, $c = 9.793$ (original setting), $Z = 4$, $D = 3.19$. $20\text{--}200$: 4.35_4 3.22_4 2.82_5 2.79_5 2.70_{10} 2.27_5 1.790_4 1.331_4 . Structure: The structure has been related to that of aminoffite as well as that of epidote. Colorless, vitreous luster, transparent. $H = 5\frac{1}{2}$. $G = 3.16$. Biaxial (+); $2V = 52^\circ$; $N_x = 1.678$, $N_y = 1.68$, $N_z = 1.683$; $XYZ = cba$; $r < v$, weak. Prismatic $[001]$ crystals at the *Harstigen mine, Pajsberg, Värmland, Sweden*. *AR* D6:532(1892), *AM* 53:309(1968), *ZK* 177:143(1986).

57.1.2.1 Kinoite $\text{Ca}_2\text{Cu}_2(\text{Si}_3\text{O}_{10}) \cdot 2\text{H}_2\text{O}$

Named in 1970 by Anthony and Laughon for Eusebio Francisco Kino (1645–1711), Jesuit explorer of the southwestern United States. MON $P2_1/m$. $a = 6.990$, $b = 12.890$, $c = 5.654$, $\beta = 96.08^\circ$, $Z = 2$, $D = 3.19$. Structure: *AM* 56:193(1971). $23\text{--}946$: 6.44_7 4.72_{10} 3.95_3 3.14_3 3.05_3 2.32_3 2.12_4 2.07_2 . The $[\text{Si}_3\text{O}_{10}]^{8-}$ unit consists of three tetrahedra forming a roughly U-shaped

group. As small (1 mm) tabular {100} crystals elongated [001] with [001] zone striated and curved. Azure blue, light blue streak, vitreous luster, translucent to transparent. $H \approx 5$. $G = 3.16$. Biaxial (-); $2V = 68^\circ$; $N_x = 1.638$, $N_y = 1.665$, $N_z = 1.676$; $X = b$, $Z \approx c$; $r > v$. Pleochroic; X, pale green; Y, blue; Z, dark blue. Decomposed by HCl. Found enclosed in quartz and calcite at the Laurium mine and Osceola shaft, Kearsarge lode, Calumet, MI; associated with apophyllite at *Helvetia, Santa Rita Mts., Pima Co., AZ*, and with apophyllite and ruizite at the Christmas mine, Hayden, Gila Co.; at the Bawana mine, Beaver Co., UT. *AR AM 55:709(1970)*.

57.1.3.1 Trabzonite $\text{Ca}_4\text{Si}_3\text{O}_{10} \cdot 2\text{H}_2\text{O}$

Named in 1986 by Sarp and Burri for the locality. *MON P2₁ or P2₁/m*. $a = 6.895$, $b = 20.64$, $c = 6.920$, $\beta = 98.0^\circ$, $Z = 4$, $D = 3.08$. *40-513*: 5.71₃ 3.44₆ 3.06₁₀ 2.91₃ 2.85₅ 2.64₅ 2.59₉ 2.06₂. Colorless, vitreous luster. $G = 2.9$. Biaxial (+); $2V = 55^\circ$; $N_x = 1.632$, $N_y = 1.634$, $N_z = 1.640$; $Y = b$, $X \wedge c = 8^\circ$; $r > v$, weak to moderate. A retrograde mineral found as grains with rustumite, tobermorite, killalite, garnet, and molybdenite near *Ikizdere, Varda Yaylasi, near Trabzon, Turkey*. *AR AM 73:1497(1988)*.

57.1.4.1 Rosenhahnite $\text{Ca}_3\text{Si}_3\text{O}_8[(\text{OH})_{2-4x}\text{O}_x(\text{CO}_3)_x]$

Named in 1967 by Pabst et al. for Leo Rosenhahn (1904–1991), American amateur mineralogist, who found the mineral. *TRIC P1*. $a = 6.946$ – 6.962 , $b = 9.474$ – 9.492 , $c = 6.802$ – 6.812 , $\alpha = 108.82$ – $108.64(2)^\circ$, $\beta = 94.72$ – 94.85° , $\gamma = 95.72$ – $95.89(2)^\circ$, $Z = 2$, $D = 2.895$ – 2.095 . *29-378(nat)*: 3.43₃ 3.36₃ 3.20_{7.5} 3.04_{6.5} 2.97₁₀ 2.77₄ 2.66₃ 2.285₃. First studied experimentally. *AJS 261:79(1943)*. High-P polymorph of xonotlite occurring below 450° and above 20 kbar. Structure consists of $(\text{Ca}1)\text{O}_9$, $(\text{Ca}2)\text{O}_6 + (\text{Ca}3)\text{O}_7$ polyhedra and insular $[\text{Si}_3\text{O}_8(\text{OH})_2]$ groups. *NAT 241:42(1973)*, *AM 62:503(1977)*. Flat, tabular to lathlike with {010} by far most predominant, elongated parallel to c , flattened parallel to b , and breaks on {001} cleavage; maximum size of 5 mm \times 2 mm \times 1 mm, to +5 mm in Japan. Colorless to buff-white, light yellow, clear and etched; white streak. Cleavage {001}, less common on {100} and {010}. $H = 4\frac{1}{2}$ –5. $G = 2.89$. TGA: 0– 300° no loss, most water lost at 400– 600° , not much more after 600° . Russian R. material fluoresces yellowish green in SWUV, Japanese shows no fluorescence, NC material fluoresces light orangish pink in LWUV, none in SWUV. Only slightly soluble in concentrated acids. Upon heating, single crystals are converted to single crystals of wollastonite in perfect topotactic relation. Japanese has 1.6 wt % CO_2 and 0.4% FeO. CA material has traces of MgO, FeO, Na_2O , BaO (0.77%), and 1.3% CO_2 . Biaxial (-); Na(D): $N_x = 1.624$ – 1.625 , $N_y = 1.640$ – 1.641 , $N_z = 1.646$ – 1.647 ; colorless; $2V = 62$ – 64° . Detailed orientation in *AM 52:336(1967)*. Occurs in Franciscan greywacke, in veins and cavities cutting brecciated metasediments, associated with diopside, hydrogrossular, tremolite, titanite, and veins of pectolite and xonotlite. Irregular segregations intergrown with prehnite, gyrolite, apophyllite, and okenite. Also in metasomatized gabbro and rodingite in ser-

pentinite, and in limestone-contaminated granitic rock. Alteration: to opal (pseudomorphs) and to calcite and other phases. In traprock at the Durham quarry, Durham, Wake Co., NC; boulders in the Russian R. streambed, *Cloverdale, Mendocino Co., CA*; locality in Bohemia, Germany; Ozersk massif, West Baikal region, Russia; Engyoji, Kochi City, and Kushiro, Hiroshima Pref., Japan; Wairere, New Zealand. *EF AM 52:336(1967)*, *MIN 3(2):525(1981)*, *BNSM(C) 10:1(1984)*.

57.2.1.1 Tiragalloite $Mn_4AsSi_3O_{12}(OH)$

Named in 1980 for Paolo Tiragallo (b.1905). *MON P2₁/n*. $a = 6.66$, $b = 19.92$, $c = 7.67$, $\beta = 95.7^\circ$, $Z = 4$, $D = 3.86$. *33-889(nat)*: 3.26₁₀ 3.15₈ 3.03₇ 2.74₆ 2.61₇ 2.50₅ 2.49₆. Structure contains nonisolated AsO_4 groups. *AM 65:947(1980)*. Grains to 1.5 mm long, but usually (0.2–0.4 mm); symmetric twinning, twin plane coincident with cleavage plane. Orange, subadamantine luster. Cleavage {100}, good; distinct parting perpendicular to elongation. $G = 3.84$. Insoluble in HCl or H_2SO_4 , slightly soluble in HNO_3 . Analysis (wt %): SiO_2 , 32.4; MnO, 48.3; CaO, 0.75; As_2O_3 , 16.1; V_2O_5 , 1.7. Biaxial (+); $XYZ = abc$; in white light: $N_x = 1.745$, $N_y = 1.751$, $N_z = 1.760$; $2V = 38-46^\circ$; angle between α and the cleavage pole is $5-6^\circ$; positive elongation; inclined axial dispersion; nonpleochroic, orange to yellow. Occurs in veinlets cutting massive black aggregates of braunite and quartz. Occurs at an abandoned manganese mine at *Molinello, Chiavari, Val Graveglia, Liguria, Italy*. *EF AC(B) 35:2287(1979)*.

57.2.2.1 Ruizite $Ca_2Mn_2^{3+}[Si_4O_{11}](OH)_4 \cdot 2H_2O$ [*AM 70:171(1985)*] and $Ca_2Mn_2^{3+}[Si_4O_{11}(OH_2)](OH)_2(H_2O)_2$ [*TMPM 33:135(1984)*]

Named for Joe Ana Ruiz (b.1924), Mammoth, AZ, pharmacist and American amateur mineralogist, who discovered the mineral. *MON C2/m*. *AM 70:171(1985)*. $a = 9.064$, $b = 6.171$, $c = 11.976$, $\gamma = 91.38^\circ$. Also *A2*. *TMPM 33:135(1984)*. $a = 11.984$, $b = 6.175$, $c = 9.052$, $\beta = 91.34^\circ$, $Z = 2$, $D = 2.89$. *29-350(nat)*: 11.95₁₀ 5.09₅ 4.19₇ 3.64₄ 3.12₆ 2.95₄ 2.59₄ 2.13₄; *36-435(calc pattern)*: 11.97₁₀ 5.10₂ 4.20₂ 3.12₂ 2.96₁ 2.74₁₅ 2.55₁₅ 2.33₅₁. A sorosilicate with an $[Si_4O_{11}(OH)_2]$ linear cluster of corner-sharing tetrahedra. A heteropolyhedral framework of Mn octahedra and Si tetrahedra with Ca occupying the [7] coordinate interstices between the octahedral–tetrahedral sheets. Crystals show dominant forms: {001}, {201}, {201}, {111}, {110}; generally occur as spherules of radially arranged acicular crystals; 0.5- to 1.0-mm spheres, clusters to 4 mm; simple twinning common on {001}. Orange, but varies to red-brown, brown, and white; pale apricot streak. $H \approx 5$. $G = 2.89-2.90$. Solubility in cold 1:1 HNO_3 , 1:1 HCl, and 40% KOH is negligible; when heated, it readily dissolves in all three. Analysis (wt %): CaO, 20.6; Mn_2O_3 , 23.4; SiO_2 , 39.1; H_2O , 16.0. Biaxial (-); $Z \wedge [100] = 44^\circ$, in obtuse β ; $N_x = 1.663$, $N_y = 1.715$, $N_z = 1.734$; $2V = 60^\circ$; β parallel [010]; length-fast or length-slow; 1 O.A. is nearly perpendicular to {001}, crystals lying on this face do not extinguish, also because of twinning; $Y > Z > X$; $r > v$, inclined, strong.

X, pale Mars orange; Y, Mars orange; Z, Dresden yellow. Occurs at the *Christmas mine*, Gila Co., AZ, in a calc-silicate assemblage. In veinlets and on fracture surfaces in meta-limestones that have been converted to calc-silicates during contact metamorphism by a porphyry copper stock. Associated with wollastonite, grossular, diopside, and vesuvianite. Also occurs at the N'Chwaning II and Wessels mines, Kuruman, Cape Prov., South Africa, associated with inesite, orientite, quartz, datolite, and others. *EF MM 41:429(1977)*, *MR 9:137(1978)*.

57.2.3.1 Akatoreite $\text{Mn}_9^{2+}\text{Al}_2\text{Si}_8\text{O}_{24}(\text{OH})_6$

Described in 1971 by Read and Reay and named for the locality. *TRIC P1*. $a = 8.337\text{--}8.344$, $b = 10.358\text{--}10.367$, $c = 7.627\text{--}7.629$, $\alpha = 104.46\text{--}104.48^\circ$, $\beta = 93.63\text{--}93.81^\circ$, $\gamma = 103.95\text{--}104.18^\circ$; $Z = 1$, $D = 3.47\text{--}3.51$. *25-533(nat)*: 9.68₆ 4.67₁₀ 3.47₅ 3.31₉ 3.06₅ 2.87₅ 2.84₄ 2.21₈. Structure: $R = 2.9\%$, a sorosilicate with a very complex structure. *CM 31:321(1993)*. Masses or columnar aggregates; radial aggregates, or massive; crystals are prismatic, striated along [100], with {0kl} predominating; lamellar twinning with {021} twin plane. Orange-brown to orange yellow, vitreous luster. Cleavage {010}, excellent to very good; {012}, imperfect. $H = 6$. $G = 3.48$. Traces of Fe, Ca, and Mg substitute for Mn. Biaxial (+); $X \wedge \{010\} = 58^\circ$, $Y \wedge \{010\} = 30^\circ$, $Z \wedge \{P010\} = 13^\circ$. $N_x = 1.698$, $N_y = 1.704$, $N_z = 1.720$; $2V = 65^\circ$. X, colorless; Y, pale yellow; Z, canary yellow. Associated with pyroxmangite and rhodochrosite in metamorphosed limestone and chert horizons of the Haast schist group. Also associated with rhodonite, spessartine, quartz, huebnerite, albandite, tinzenite, and others. *Akatore Creek, Eastern Otago, South Island, New Zealand*; Haeste field, Norberg ore district, central Sweden. *EF NJBA 157:225(1987)*.

57.3.1.1 Zunyite $\text{Al}_{13}\text{O}_4(\text{Si}_5\text{O}_{16})(\text{OH},\text{F})_{18}\text{Cl}$

Named in 1884 by Hillebrand for the type locality. *iso F43m*. $a = 13.880$, $Z = 4$, $D = 2.89$. *14-698*: 8.07₁₀ 4.21₁₀ 4.02₆ 3.20₃ 2.84₅ 2.68₉ 2.01₅ 1.640₉. Structure: *AC(B) 38:390(1982)*. The fundamental structural element is a pentamer involving four silicon-oxygen tetrahedra sharing an oxygen each with a fifth, central one. Tetrahedra, {111} modified by {111} and {100}; sometimes pseudo-octahedral. Twinning common. Colorless, white, light grey, pinkish tan; vitreous luster; translucent to transparent. Cleavage {111}, distinct. $H = 7$. $G = 2.88$. Isotropic; $N = 1.563\text{--}1.600$, also weakly anisotropic. Infusible; insoluble in acids. Found embedded in "guitermanite" [baumhauerite (?)] as crystals up to 5 mm(l) at *Zuni mine, Anvil Mt., Silverton, San Juan Co., CO*, and in altered feldspathic rocks at Charter Oak mine, Ouray Co., and the Bonanza district, Saguache Co.; at the San Manuel mine, Pinal Co., and Big Bertha Extension mine, Yuma Co., and in the Dome Rock Mts., near Quartzsite, AZ. At the Emberton quarry, near Cockermonth, Cumberland, England. At Beni-Embarek, Algeria, and in highly aluminous shales at Post-

masburg, South Africa. As transparent crystals at Kuni, Gumma Pref., Japan at Brumado, Bahia, Brazil. AR *D6:436(1892)*; BM *85:407(1962)*, *97:271(1974)*.

57.4.1.1 Medaite (Mn,Ca)₆(V,As)Si₅O₁₈(OH)

Named in 1982 by Gramaccioli et al. for Francesco Meda (1926–1977), Turin, Italy, amateur mineralogist. MON $P2_1/n$. $a = 6.712$, $b = 28.948$, $c = 7.578$, $\beta = 95.40^\circ$, $Z = 4$, $D = 3.75$. *36-433(calc)*: 3.26₁₀ 3.16₁₀ 3.09₇ 3.01₇ 2.96₇ 2.94₇ 2.79₆ 2.61₁₀. No natural powder diffraction pattern exists because of intimate intergrowth with tiragalloite. Contains a vanadopentasilicate ion $[\text{VSi}_5\text{O}_{18}(\text{OH})]^{12-}$, comprising six tetrahedra linked together to form a chain fragment. Anedral grains to 1.5 mm long, most are 0.2–0.4 mm; twin plane is coincident with the cleavage plane. Orange-yellow to brown, dark orange, brownish red; light orange streak; subadamantine luster. Cleavage {100}, good; parting perpendicular to elongation. $G = 3.70$. Insoluble in H₂O, HCl, and HNO₃. Contains Fe, 0.3%; CaO, 1.3%; As₂O₅, 2.1%. Biaxial (+); $XYZ \approx abc$, $X \wedge$ cleavage normal = 3° ; in white light: $N_x = 1.77$, $N_y = 1.78$, $N_z = 1.80$; $2V_{\text{calc}} = 71^\circ$, $2V$ not able to be measured because of very strong absorption; positive elongation; faintly pleochroic, dark to clear orange. Occurs at *Molinello, Val Graveglia, near Chiavari, eastern Liguria, Italy*, in a manganese mine intimately associated with tiragalloite. Occurs in veinless cutting massive aggregates of quartz and braunite. Also near Lavagna, Genoa, Italy. EF *RSIMP 36:159(1980)*, *AC(B) 37:1972(1981)*, *AM 67:85(1982)*.

Insular, Mixed, Single, and Larger Tetrahedral Groups

58.1.1.1 Kornerupine $(\square, \text{Mg}, \text{Fe})(\text{Mg}, \text{Fe}, \text{Al})_9(\text{Si}, \text{Al}, \text{B})_5(\text{O}, \text{OH}, \text{F})_{22}$ MM56 : 247 (1992)

Named in 1884 by J. Lorenzen for Andreas Nikolaus Kornerup (1857–1881), Danish geologist. Space group unknown. $a = 15.999\text{--}16.117$, $b = 13.707\text{--}13.746$, $c = 6.704\text{--}6.749$; as B is substituted into kornerupine, the volume and $a + c$ parameters decrease; $Z = 4$, $D = 3.25$. 29-852(nat): 10.4₄ 7.99₃ 6.84₄ 3.35₅ 3.01₁₀ 2.62₁₀ 2.10₆ 2.08₅. Structure: *AM* 76:1824(1991). 0–0.69 B per formula unit of 22 O atoms. 0–69% occupancy of one site by B. One eightfold: five octahedral and three tetrahedral sites. *AM* 76:1824(1991). Crystals to >5 cm, rodlike to fibrous, long prisms. Dark green, sea-green, cream, white, colorless, blue, gray, pink, greenish yellow, brown, black; streak usually white; striated, with {110}, {100}, {021}; vitreous luster. Cleavage {110}, distinct prismatic; {001}, poor. $H = 6\frac{1}{2}\text{--}7.0$. $G = 3.27\text{--}3.45$. Moderately magnetic. Insoluble in common acids but soluble in HF. Formula *MM* 56:247(1992). A boron-poor variety exists, but the mineral usually has some B; up to 5.2 wt % B_2O_3 , to $\approx 15\%$ FeO, 13.4% MgO, and 0.6% F; type material has 0.5–1.44% B_2O_3 . Most localities have B-bearing material. Some Fe_2O_3 may also be present. Three localities for β -free material are known. Fe-richest material (about 15 wt % FeO) is from Port Shepstone and Homagama; Norwegian material has 20% MgO, 5.0% Fe_2O_3 . As much as 0.2 wt % BeO and 0.3 wt % Sc_2O_3 may be present. Biaxial (–); $Z = b$; $N_x = 1.660\text{--}1.682$, $N_y = 1.674\text{--}1.696$, $N_z = 1.675\text{--}1.699$; $2V = 3\text{--}48^\circ$; $r < v$, also $r > v$, weak; negative elongation; pleochroism variable. X, colorless to yellow to dark green; Y, colorless to pale brown to reddish blue; Z, light amber to light blue to dark green. Occurs in Si-poor, Mg–Al-rich gneisses. Often Precambrian in age. In aluminous upper amphibolite and granulite-facies rocks. Also in magnesian metapelites and in pegmatite. Some is alluvial. In high-grade contact- and regional metamorphic rocks. Formed with or instead of tourmaline if sufficient B is present. Associated cordierite, sapphirine, corundum, sillimanite, and others. Alteration: kornerupine may alter to a mixture of sapphirine and cordierite, gedrite \pm orthopyroxene. May replace or be replaced by grandidierite. There are 50–60 localities worldwide. Opinicon Lake and two other areas in southeastern ONT, and Lac Sainte Marie, Gati-neau Co., QUE, Canada; to more than 23 cm long from *Fiskenaesset* region,

western Greenland, some is B-poor, and to 50 cm long elsewhere in Greenland; Hullvannet, Bamble sector, southern Norway; Waldheim, Saxony, Germany; Kola Penin., Russia; Sar-e-Sang, Afghanistan; with werdingite and grandiderite at Bok se Puts, Namaqualand, Port Shepstone, KwaZulu-Natal, and from the Cavan farm, Soutpansberg district, northern Transvaal, South Africa; B-poor from Sinyoni claims, Beit Bridge, Zimbabwe; Kwale district, southern Kenya; Mautia Hill, Tanzania; Labwor Hills, Uganda; Lukusuzi, Eastern Prov., Zambia; clear, sea-green, large gem-quality crystals from Itrongay and at Betroka, Madagascar; gem gravels at Talatu Oya, eastern Khandy, Sri Lanka (Ceylon); Fe-rich material from Homagama, Sri Lanka; B-poor material from the Reynolds Range, NT, and in the Harts and Anmatjiras Ranges, Australia; with grandidierite at McCarthy Point and Seal Cove, Larsemann Hills, Prydz Bay, eastern Antarctica. Some Greenland material is of gem quality, 5.88 to 0.09 ct. Also Itrongay, Madagascar, and Sri Lanka. The largest Sri Lankan stone is 9.2 ct. *EF MIN* 3(1):290(1972); *MM* 51:695(1987), 55:563(1991), 56:247(1992), 58:27(1994), 59:163(1995), 59:327(1995); *EJM* 7:623(1995).

58.1.2.1 Davreuxite $\text{MnAl}_6\text{Si}_4\text{O}_{17}(\text{OH})_2$

Named in 1878 by De Koninck for Charles Joseph Davreux (1800–1863), Belgian pharmacist and natural scientist. *MON* $P2_1/m$. $a = 9.518$, $b = 5.753$, $c = 12.05$, $\beta = 108.0^\circ$, $Z = 2$. $37\text{--}431$: 8.51_3 5.72_4 4.29_4 3.82_3 3.51_{10} 3.10_5 2.87_6 2.84_4 . The structure consists of isolated and double, $\text{Si}_2\text{O}_6(\text{OH})$, tetrahedral silicate units. Aluminum is in six- and four-coordination, the latter forming with silicate tetrahedra, single and double chains. Aggregates of slender laminae and bundles of fine fibers [010], asbestiform. White with yellow to reddish tinge, pearly to dull luster. Cleavage {100}, good. $H = 2\text{--}3$. $G = 3.30\text{--}3.38$. Biaxial (–); $2V = 48^\circ$; $N_x = 1.660$, $N_y = 1.684$, $N_z = 1.692$; X approximately perpendicular to {100}, $Z = b$; . Magnesium and, to a lesser degree, iron may replace manganese. With quartz and pyrophyllite in low-grade metamorphosed Ordovician shales. Alters to kaolinite. At *Ottre, Stavelot massif, Ardennes, Belgium*, also at Rect, Regne, Vielsam, and Sart-Close. *AR CR(D)* 283:295(1976), *AM* 69:777(1984).

58.1.3.1 Queitite $\text{Zn}_2\text{Pb}_4[\text{SiO}_4][\text{Si}_2\text{O}_7](\text{SO}_4)$

Named by Keller et al. in honor of Clive S. Queit (b.1946), Tsumeb, Namibia. *MON* $P2_1$. $a = 11.362$, $b = 5.266$, $c = 12.655$, $\beta = 108.16^\circ$, $Z = 2$, $D = 6.07$. $33\text{--}782$: 3.77_5 3.59_5 3.18_{10} 2.99_5 2.82_5 1.635_8 1.490_6 1.486_6 . Structure: *ZK* 151:287(1980). Elongated [010], tabular {001} crystals up to $10\text{ mm} \times 3\text{ mm} \times 0.5\text{ mm}$; {001} dominant with {112}, {110}, and {101} prominent. Twinned on {100} and {001}. Colorless to pale yellow, greasy luster. Cleavage {010}, {001}, traces. $H = 4$. Biaxial (+); $2V \approx 90^\circ$; $N_x = 1.899$, $N_y = 1.901$, $N_z = 1.903$; $r > v$, strong; anomalous interference colors. Found on corroded galena, sphalerite, and tennantite with willemite, alamosite, melanotekite, and leadhillite at *Tsumeb, Namibia*. *AR AM* 65:407(1979).

EPIDOTE GROUP

The epidote group consists of 13 isostructural silicates conforming to the formula

where

A1 = Ca

A2 = Ca, REE, Pb, Sr

M1 = Al, Fe, Mn, Mg

M2 = Al

M3 = Al, Fe³⁺, Mn³⁺, Cr³⁺

and the minerals crystallize with monoclinic or orthorhombic symmetry.

The structure consists of chains of edge-sharing octahedra of two types: a single chain of M2 octahedra and a multiple or zigzag chain composed of central M1 and peripheral M3 octahedra. The chains are cross-linked by SiO₄ and Si₂O₇ groups. Finally, there remain between the chains and cross-links relatively large cavities which house the A1 and A2 cations.

Many piemontites and epidotes as named in the literature are designated incorrectly: for a discussion, see *NJBM* 8:357–366(1989). A detailed study of 23 members of the epidote group has further elucidated the effects of $\text{Al} \leftrightarrow \text{Fe}^{3+} \leftrightarrow \text{Fe}^{2+}$ substitution and the entry of REE^{3+} . *MM* 53:133(1995). In the structure of allanite and REE-bearing epidotes, the entry of trivalent REE in the A sites is balanced by the presence of divalent cations, mainly Fe^{2+} and Mg. Divalent iron in allanites occurs mainly in M3.

Mineral	Formula	Space Group	a				β

58.2.1a.1 Allanite-(Ce) $(\text{Ce}, \text{Y}, \text{Ca})_2(\text{Fe}^{2+}, \text{Fe}^{3+})\text{Al}_2(\text{SiO}_4)(\text{Si}_2\text{O}_7)(\text{O})(\text{OH})$

Named in 1810 by Thomas Thomson for Thomas Allan (1777–1833), Scottish mineralogist, who first observed the mineral. Epidote group. Synonym: orthite. Ce is the dominant REE present. MON $P2_1/m$. $a = 8.927$, $b = 5.761$,

$c = 10.150$, $\beta = 114.77^\circ$, $Z = 2$, $D = 4.11$. *25-169*: 3.53₄ 2.92₁₀ 2.89₃ 2.71₆ 2.63₄ 2.56₂ 2.18₃ 2.16₂. Also *9-474* (heated metamict allanite). REE's in larger A2 site, Ca in A1 site. *AM 56:447(1971)*. Light brown to black, light brown streak, resinous or pitchy submetallic luster. Cleavage {001}, imperfect; {100}, {110}, poor; conchoidal to uneven fracture; brittle. $H = 5-6\frac{1}{2}$. $G = 3.4-4.2$. Often metamict with even lower density. Gelatinizes with HCl. May be halogen-bearing (0.95 wt % Cl and 0.76 wt % F; e.g., Hemlo deposit). Coupled substitution $Ca + (Al + Fe^{3+}) = REE + M^{2+}$ is dominant; however, as $REE + M^{2+}$ increases, $3Ca^{2+} = 2REE^{3+} + \square$ operates. Vanadian allanite-(Ce) with about 8% V_2O_3 exists in the Hemlo gold deposit. Chromium may also substitute for Al and Fe^{3+} in allanite. MnO to 6.7 wt %, BeO to 3.8 wt %, P_2O_5 to 6.5 wt %, ThO_2 commonly to about 2 wt % and rarely to about 5%, SrO to 5 wt %, F to >1.1 wt %. One rare occurrence of Ge-bearing allanite with 10.6 wt % GeO_2 and 2.5 wt % Ge_2O_3 from a Zn deposit in the Pyrenees. Biaxial (-) or (+), majority are (-); $X \wedge c = 1-42^\circ$, $Y = b = OAP$, sometimes perpendicular to (010) = parallel to (100), $Z \wedge a = 26-67^\circ$. $N_x = 1.690-1.813$, $N_y = 1.700-1.857$, $N_z = 1.706-1.891$; $2V_x = 40-123^\circ$; $Y > Z > X$ or $Z > Y > X$; $r > v$, moderate to strong; pleochroic colors are quite variable in brown, reddish brown, yellow, green, and yellow-green. Metamict allanites are isotropic with N as low as 1.61. A common accessory mineral in many igneous rocks, particularly those that are felsic, and metamorphosed igneous rocks. Also in pegmatites, skarns, and tactites. Not common in volcanic rocks. A detrital mineral. Of the many localities, only noteworthy sites are mentioned. Franklin, NJ; Amelia, VA; Moriah, Essex Co., NY; Monroe, Orange Co., NY; large crystals to 45 cm long occur in the Pacoima pegmatite, Pacoima Canyon, Los Angeles Co., CA; Macdonald mine near Hybla, Renfrew, and Tory Hill, and vanadian varieties from Hemlo, ONT, Canada; *Avigait, eastern Greenland*; Trimouns mine, Luzenac, France; Ytterby, Riddarhyttan, and Finbo, and Mg-rich variety from Koberg mine, Bergslagen, Sweden; Hittero, Hundholmen, Iveland, and Ardendal, Norway; Vaarala, Finland; Ural Mts., and Vishnevye Mts., Russia; Sama, Madagascar. *EF AM 49:1159(1964)*, *MIN 3(1):750(1972)*, *DHZ 1B:151(1986)*, *CM 28:67(1990)*, *MM 55:497(1991)*.

58.2.1a.2 Allanite-(La) $(La, Y, Ca)_2(Fe^{2+}, Fe^{3+})Al_2(SiO_4)(Si_2O_7)(O)(OH)$

Epidote group. *Note*: Not formally approved by CNMMN IMA. *MON P21/m*. $a = 8.905-8.934$, $b = 5.699-5.760$, $c = 10.131-10.236$, $\beta = 114.9-114.97^\circ$, $Z = 2$, $D = 3.84-4.06$. *CM 30:159(1993)*: 4.74₂ 3.54₃ 3.24₅ 3.19₂ 2.94₁₀ 2.90₃ 2.73₅ 2.64₄; *45-1352*: 3.51₄₅ 2.93₃ 2.91₁₀ 2.85₅ 2.70₆ 2.69₄ 2.61₆ 2.175₂. Black, brown streak. Cleavage {100}, poor; conchoidal fracture. $H = 5-5\frac{1}{2}$. $G = 3.69-4.02$. La_2O_3 , 12.1 wt %; Ce_2O_3 , 10.9 wt %. Biaxial (+); $N_x = 1.730$, $N_y = 1.740$, $N_z = 1.770$; $2V_x = 129^\circ$. Occurs at Waterford, CT; Mitchell Twp., QUE, Canada; in skarn at Serifos Island, Cyclades, Greece; Karelia, Russia. *EF AM 51:152(1966)*.

58.2.1a.3 Allanite-(Y) $(Y, Ce, Ca)_2(Fe^{2+}, Fe^{3+})Al_2(SiO_4)(Si_2O_7)(O)(OH)$

Originally described in 1949 as lumbaardite from the Zaaiplaats tin mine, Potgietersrust district, Transvaal, South Africa. Epidote group. Unit cell given with $2a$, b , $2c$ of epidote on the basis of oscillation and Weissenberg photographs. Epidote-type pseudocell noted. Detailed structure solution not done. May be $P2$ or $P2/m$. Dark brown needles. Biaxial (+); $Y = b$; $N_x = 1.756$, $N_y = 1.761$, $N_z = 1.777$; $2V_{z\text{ meas}} = 60^\circ$, $2V_{z\text{ calc}} = 58^\circ$, $2V_z = 70\text{--}80^\circ$ for Swedish material; $r > v$, strong; $Y > Z > X$; OAP parallel to (010). X, nearly colorless; Y, amber brown; Z, tawny olive. $D_m = 3.85$, $H = 6$. In an explosion breccia in a cassiterite-bearing pipe in granite, in hydrothermally altered arkoses, and in granitic pegmatite. Reported from Asklagen, Värmland, Sweden. The mineral also occurs at Isle of Skye, Scotland. Possible allanite-(Y) occurs at Sinyaya Pala, northern Karelia, Russia. Also present at the Gole quarry, Murchison Twp., ONT, Canada. A Be- and Y-bearing (6.1 wt % Y_2O_3) allanite was reported from Skuleboda, Uddevalla, Sweden, but it contains elevated contents of water and CO_2 and is altered. *EF AM 36:381(1951)*, *48:1420(1963)*; *EPSL 48:97(1980)*; *MIN 3(1):750(1972)*; *DHZ 1B:151(1986)*.

58.2.1a.4 Clinozoisite $Ca_2(Al, Fe^{3+})Al_2(SiO_4)(Si_2O_7)(O)(OH)$

Described in 1896 by Weinschenk; name is from the crystal system, the monoclinic dimorph of zoisite, and from its resemblance to zoisite. Epidote group. *MON P2₁/m*. $a = 8.879\text{--}8.882$, $b = 5.583\text{--}5.604$, $c = 10.149\text{--}10.155$, $\beta = 115.43\text{--}115.50^\circ$, $Z = 2$, $D = 3.31\text{--}3.36$. *44-1400(nat)*: 2.89₁₀ 2.80₅ 2.68₂ 2.67₂ 2.53₂ 2.51₂ 2.39₃ 2.16₃. Only Al is present in M1 and M2, with Al, Fe, Mn, and others in M3. *AM 53:1882(1968)*. Prismatic, elongated on b , often striated, may be granular, massive, or fibrous, lamellar twinning on {100} not common. Both orthorhombic and monoclinic varieties of zoisite are considered thulite. *NJBM:325(1989)*. Colorless, pale yellow-gray, yellow-green, rose to red (rare), due to Mn^{3+} (thulite); white streak; vitreous luster. Cleavage {001}, {100}, perfect; uneven fracture. $H = 6\frac{1}{2}$. $D_m = 3.21\text{--}3.38$. Spectral data: *DHZ 1B:44(1986)*. Insoluble in HCl. Replacement of Ca by Fe^{2+} , Mn, and Ca is comparatively small. May contain many elements other than Ca, Al, Si, and O (e.g., SrO to 4.7 wt %). As much as 15.4 wt % Cr_2O_3 is present in clinozoisite from Outoukumpu, Finland. *CM 27:565(1989)*. With increasing substitution of Fe for Al, the mineral grades to epidote. Biaxial (+); $X \wedge c = 0\text{--}7^\circ$, $Z \wedge a = 18\text{--}25^\circ$, $Y = b$; $N_x = 1.670\text{--}1.718$, $N_y = 1.670\text{--}1.725$, $N_z = 1.690\text{--}1.734$; $2V_z = 14\text{--}90^\circ$, $2V$ basically correlates with Fe content; $Z \geq Y > X$; $r < v$, strong; OAP (010); usually, nonpleochroic, Mn-containing material is pleochroic in colorless–light pink. Most common in regional metamorphic rocks, particularly in greenschists–epidote–amphibolite facies. Also in pegmatites and veins. In acid igneous rocks contaminated with calc–silicate material. As an alteration product of plagioclase. Contact zones. Also in rodingites (with usually very low iron contents). Found in many localities. Typical

occurrences are at Eden Mills, VT; Allens Park, Boulder Co., CO; in the Nightingale district, Pershing Co., NV; Los Angeles Co. and elsewhere in CA; Timmins, ONT, Canada; Pinos Altos, BC, Gavilanes, BCN, Arroyo Puerto Nuevo, BCS, and Alamos, SON, Mexico; *Goslerwand, Prägratten, Tyrol, Austria*; other localities in the Tyrol and Piedmont in Switzerland, Austria, Italy, and Malagasy Republic (Madagascar). EF *DHZ 1B:44(1986)*; *MIN 3(1):724(1972)*.

58.2.1a.5 Dissakisite-(Ce) $\text{Ca}(\text{Ce},\text{La})\text{MgAl}_2(\text{SiO}_4)(\text{Si}_2\text{O}_7)\text{O}(\text{OH})$

Described in 1991 and named from the Greek for *twice over*, for an Mg analog of allanite, having been discovered twice. MON $P2_1/m$. $a = 8.91$, $b = 5.69$, $c = 10.112$, $\beta = 114.7^\circ$, $Z = 2$, $D = 3.97$. AM *76:1990(1991)*: 9.1₄ 3.50₅ 2.91₉ 2.84₅ 2.70₁₀ 2.62₆ 2.18₄ 2.14₄. Ca is ordered in A1 and lanthanides are ordered in A2. Mg and minor Fe^{2+} occupy M3, M2 is occupied only by Al. CM *30:153(1993)*. Dark brown, pale yellow-brown in thin section; vitreous luster. No cleavage observed. $G = 3.75$. No cathodoluminescence. Chromian variety from Outokumpu, Finland. Ostanmossa subaluminous ferroan dissakisite has 0.9 wt % F. Biaxial (+); Y parallel to b , $Z \wedge a = 24^\circ$ in obtuse angle β . $N_x = 1.735$, $N_y = 1.741$, $N_z = 1.758$; $2V_{z \text{ obs}} = 64^\circ$, $2V_{z \text{ calc}} = 62^\circ$; $X < Y = Z$; $r < v$, medium. X, pale brown; Y,Z, light yellow-brown. Occurs in Mg-rich metamorphic rocks such as micaceous schists, garnet–corundum gneisses, and in marble associated with calcite, phlogopite, spinel, and so on. Also in tremolite and magnesian skarn and magnetite ore. Trimoun talc deposit, Ariège, France; Ostanmossa mine, Norberg district, Sweden; Outokumpu, Finland; Fedorovskoye and Emeldzhak deposits, southern Yakutia, Russia; Donghai district, Jiangsu Prov., China; *Balchen Mountain, eastern Antarctica*. EF *CM 25:413(1987)*, *AM 73:48(1988)*.

58.2.1a.6 Dollaseite-(Ce) $\text{Ca}(\text{Ce},\text{REE})(\text{Mg})(\text{MgAl})(\text{SiO}_4)(\text{Si}_2\text{O}_7)\text{O}(\text{F})$

Named in 1988 for Wayne A. Dollase (b. 1938), American mineralogist, University of California at Los Angeles. Epidote group. Called magnesium orthite by P. Geijer [*SGU 20(4):1(1927)*]. MON $P2_1/m$. $a = 8.934$, $b = 5.721$, $c = 10.176$, $\beta = 114.31^\circ$, $Z = 2$, $D = 3.87$. *41-1469*: 9.29₂ 8.25₁ 5.13₁ 3.52₂ 2.915₁₀ 2.85₃ 2.71₇ 2.15₂. Mg is ordered over two equipoints, Ca and the REE's are ordered over two different structural sites, and F and OH are each ordered over two different sites. AM *73:838(1988)*. Brown. $G = 3.9$. Contains 3.0–3.3 wt % F. Substitution $\text{Mg} + \text{F}$ for $\text{M}^{3+} + \text{O}$ in allanite suggests that such substitutions may occur in other members of the group. Two paired substitutions in dollaseite-(Ce) are $\text{REE} + \text{Mg} \leftrightarrow \text{Ca} + \text{Al}$ and $\text{Mg} + \text{F} \leftrightarrow \text{Al} + \text{O}$. Biaxial (+); $N_x = 1.715$, $N_y = 1.718$, $N_z = 1.733$, $2V_{z \text{ calc}} = 49^\circ$. Occurs in metamorphic rocks associated with tremolite, norbergite, and calcite. *Ostanmossa mine, Norberg district, Sweden*. EF

58.2.1a.7 Epidote $\text{Ca}_2(\text{Fe}^{3+}, \text{Al})_3(\text{SiO}_4)(\text{Si}_2\text{O}_7)(\text{O}, \text{OH})_2$

Described in 1801 by Haüy and named from the Greek for *increase*, because the base of the prism has one side longer than the other. Epidote group. *MON* $P2_1/m$. $a = 8.914$, $b = 5.640$, $c = 10.162$, $\beta = 115.4^\circ$ (for 0.81 atom of Fe^{3+}); range: $a = 8.884\text{--}8.916$, $b = 5.621\text{--}5.662$, $c = 10.154\text{--}10.175$, $\beta = 115.2\text{--}115.5^\circ$, $Z = 2$, $D = 3.45$. $17\text{--}514(\text{nat})$: 4.02_5 3.40_4 2.90_{10} 2.82_4 2.69_7 2.68_{10} 2.60_5 2.46_5 ; $45\text{--}1446$: 2.90_{85} 2.69_6 2.40_{65} 1.64_{10} 1.63_6 1.46_7 1.41_6 1.40_6 . The epidote structure is summarized in *AM 56:447(1971)*. Crystals are short to long prismatic, often striated; also thick tabular or acicular. More than 200 different forms are known. Commonly massive, coarse to fine granular or fibrous. Twinning {100} lamellar, relatively common and sometimes on {001}. Green, yellow, gray, yellow-green, brownish green, greenish black, black, and bright Cr green (variety *taumawite*); the characteristic green color of epidote is associated with the presence of Fe^{3+} in M3 and is determined by $\text{O}_2 \leftrightarrow \text{Fe}^{3+}$ transfer; white-gray streak; vitreous to somewhat pearly or resinous luster. Cleavage {001}, perfect; {100}, good; conchoidal, uneven, or splintery fracture. $H = 6\frac{1}{2}$, $G = 3.38\text{--}3.49$. IR and other spectral data: *DHZ 1B:44(1986)*, *AM 76:602(1991)*. Sometimes fluorescent weak red in SWUV. Partly soluble in hot concentrated HCl, soluble in HF. May contain many elements other than Ca, Fe, Al, Si, and O. Most common are REE's, grading to allanite. Additional elemental substitutions are Mg, Mn, Sn, Sr (to 8.5 wt % SrO), and others. The variety *taumawite*, first described in 1907, is characterized by elevated Cr content. The highest reported Cr content, in epidote from Hemlo, ONT, is 11.8 Cr_2O_3 [*CM 27:565(1989)*]. A new Cr end member in the epidote group would be $\text{Ca}_2\text{Cr}(\text{Al}, \text{Fe})\text{Si}_3\text{O}_{12}(\text{OH})$. *Taumawite* should be redefined as that epidote family mineral with $X_{\text{Cr}}^{\text{opt}} = 0.33$ and $X_{\text{Al}}^{\text{opt}} = 0.67$ [*MM 51:593(1987)*]. Within epidote, there are strong site preferences for substitution of Cr, Fe, and Mn for Al. Cr has a strong preference for M1, and with substitution of V grades to mukhinite. Biaxial (-); $X \wedge c = 0\text{--}8^\circ$, $Y = b$, $Z \wedge a = 25\text{--}33^\circ$; $N_x = 1.708\text{--}1.751$, $N_y = 1.714\text{--}1.784$, $N_z = 1.718\text{--}1.797$; $2V_x = 64\text{--}90^\circ$; $r > v$, moderate to strong; usually $Y \geq Z > X$, sometimes $Z > Y > X$; pleochroism increases with Fe content. X, colorless, pale yellow, pale green; Y, yellowish green, brownish green, greenish yellow; Z, yellowish green. Other pleochroic colors as well, depending on chemical composition (e.g., Cr, V, Mn, etc.). Boundary between optically (+) clinozoisite and optically (-) epidote is between 15.0 and 15.9 mol % $\text{Ca}_2\text{Fe}_3^{++}\text{Si}_3\text{O}_{12}(\text{OH})$; about 7.7 wt % Fe_2O_3 . OAP parallel to b . For *taumawite* (Cr-epidote), $N_x = 1.695$, $N_y = 1.705$, $N_z = 1.715$; $2V_x = 40^\circ$ (note that $2V_{\text{calc}} = 90^\circ$). Epidote is a ubiquitous mineral in regional and contact-metamorphic rocks but is particularly characteristic of greenschist and epidote-amphibolite facies rocks. Also occurs in lower-grade rocks with zeolites, prehnite, pumpellyite, lawsonite, and stilpnomelane. In blueschists and eclogites as well. In metasomatic skarns, calc-silicate rocks, and epithermal ore deposits. In low-temperature veins, amygdules, fillings, and some hot-spring systems. A hydrothermal alteration product of plagioclase. Occurs as a primary magmatic mineral in some basic to

granitic rocks and pegmatites. Cr-bearing epidote occurs in contact-metamorphic rocks. Notable occurrences include: Splendid crystals from Haddam, CT. Good crystals from Calumet mine, Chaffee Co., CO, also from Garnet Hill, Calaveras County, CA. Fine, splendant crystals from the Green Monster mine, Prince of Wales Island, Sulzer, AK(1). Hemlo, ONT, Canada; Sn-bearing epidote from Land's End, Cornwall, England; beautiful crystallizations from Bourg d'Oisans, Isère, France(1); gem-quality and complex crystals from Knappenwand, Untersulzbachtal, Salzburg, and Zillertal, Tyrol, Austria(1). Traversella and Ala Valley, Piemonte, Italy; St. Gottard, Ticino, and Zermatt, Switzerland; Arendal, Norway; Zöptau, Moravia, Czech Republic; Cr-bearing material from the Outokumpu area, Finland; Achmatovsk, Kussinsk, Ural Mts., Russia; gem crystals from Gilgit, Tormiq, and Dusso, northwestern Pakistan(1); Tawmaw, Myanmar (Burma); Namibia(1). Sometimes used as a semiprecious gemstone and for lapidary purposes (unakite-epidotized granitic rocks). EF *MIN* 3(1):728(1972), *KLOK*:696(1980), *AM* 66:974(1981), *DHZ IB*:44(1986).

58.2.1a.8 Hancockite $(\text{Ca,Pb,Sr})_2(\text{Al,Fe})_3(\text{Si}_2\text{O}_7)(\text{SiO}_4)(\text{O,OH})_2$

Named in 1899 for Elwood P. Hancock (1836–1916), Burlington, NJ, a mineral collector. Epidote group. *MON* $P2_1/m$. $a = 8.958$, $b = 5.665$, $c = 10.304$, $\beta = 114.4^\circ$, $Z = 2$, $D = 4.03$. $17-212$: 4.62_3 3.49_5 3.27_3 2.91_{10} 2.81_4 2.71_4 2.18_4 1.90_4 . Pb (along with Sr and Ba) is in A2. Crystals are usually about 0.5 mm long and 0.15 mm wide, but may be as large as 2 cm \times 0.2 cm. Lathlike crystals show dominant forms {001}, {100}, {101}, {101}, {111}. Striated parallel to [010]; usually massive and masses are brownish red or maroon. Crystals are red to red-brown but may be yellowish brown to yellow-green. Vitreous luster, translucent. Cleavage {001}, perfect; uneven fracture; brittle. $H = 6\frac{1}{2}-7$. $G = 4.03$. Analysis (wt %): PbO, 18.5; SrO, 3.9 (Franklin, NJ); PbO, 32.4 (Jakobsberg, Sweden). Biaxial (-); $Y = b$; $N_x = 1.788$, $N_y = 1.810-1.825$, $N_z = 1.830$; $2V_x = 38-50^\circ$; OAP = (010); $Z > X$; $r > v$; strongly pleochroic. X, colorless, pale rose, greenish yellow; Y, pale brownish yellow to yellow; Z, pale rose, greenish yellow or green. Occurs in fractures in willemite-franklinite ore and as masses in the contact-metasomatic Zn deposit at *Franklin, Sussex Co., NJ*. Associated with garnet, hendricksite, and as inclusions in manganaxinite, datolite, willemite, and hyalophane. Also occurs in a metamorphosed manganese-iron orebody in skarns enclosed in dolomitic marble at Jakobsberg, Filipstad, Varmland, Sweden [*MM* 58:172(1994)], associated with melanotekite, garnet, and hematite. EF *AM* 56:447(1971), *MIN* 3(1):749(1972), *MM* 49:721(1985), *DHZ 1B*:44(1986).

58.2.1a.9 Khristovite-(Ce) $(\text{Ca,REE})(\text{Ce,REE})(\text{Mg,Fe,Cr,Ti,V,Al})\text{MnAl}(\text{SiO}_4)(\text{Si}_2\text{O}_7)(\text{OH})(\text{F,O})$

Described in 1991 [*SPC* 36(2):172(1991)] but not named until 1993 [*ZVMO* 122:103(1993)]. Named for Evgenia Vladimirovicha Khristova (b.1933), Rus-

sian geologist and a specialist in Tien-shan geology. Epidote group. *MON* $P2_1/m$. $a = 8.903$, $b = 5.748$, $c = 10.107$, $\beta = 113.41^\circ$, $Z = 2$, $D = 4.11$. *PD*: 9.32_2 5.23_2 4.67_2 3.52_4 2.91_{10} 2.73_7 2.63_8 1.437_2 . The Mn analog of dollaseite-(Ce), but with some differences and with Mn^{2+} predominant in M3. R = 3.5%. Prismatic crystals up to 1.5 mm long; dominant forms are {001}, {100}, and subordinate {101} and {102}. Brown to dark brown or dark grayish brown, light brown streak, vitreous luster, transparent. No cleavage observed. H = 5. G = 4.05. IR. Analysis (wt %): SiO_2 , 29.9; Al_2O_3 , 9.5; MgO, 2.7; CaO, 5.6; TiO_2 , 1.6; V_2O_5 , 1.1; Cr_2O_3 , 1.5; FeO, 1.8; MnO, 11.8; Ce_2O_3 , 13.6; La_2O_3 , 8.7; Nd_2O_3 , 4.2; Sm_2O_3 , 0.6; Dy_2O_3 , 3.1; Pr_2O_3 , 1.4; F, 2.0; $(H_2O)_{calc}$, 1.5; O for F, 0.8. MnO to 14.5 wt %. Biaxial (-); in sections perpendicular to $B \times a$, $Y \wedge$ elongation = $1.5-3^\circ$, in sections perpendicular to $B \times c$, extinction is parallel; $Y = b$; OAP is perpendicular to the elongation direction; $N_x = 1.773$, $N_y = 1.790$, $N_z = 1.803$; $2V_x = 83^\circ$; $Y > Z \gg X$; $r < v$, medium. Occurs in rhodonite in a garnet-biotite-quartz-rich exocontact of the subalkaline granites of the Inyl'chek massif, on the northern slope of the Inyl'chek Range, southwestern Tien-shan, Kirgiziya, Russia. Occurs with rhodonite, tephroite, rhodochrosite, hyalophane, barite, hejtmanite, hübnerite, and an unidentified Cl-bearing Mn-silicate. EF

58.2.1a.10 Mukhinite $Ca_2Al_2V^{3+}(SiO_4)(Si_2O_7)(O)(OH)$

Named in 1969 for Alekseia Stepanovna Mukhin (1910-1973), Russian geologist, Western Siberia Geological Administration. Epidote group. *MON* $P2_1/m$. $a = 8.90$, $b = 5.61$, $c = 10.15$, $\beta = 115.5^\circ$, $Z = 2$, $D = 3.47$. *22-1066*: 2.89_{10} 2.68_8 2.60_8 2.40_8 2.33_7 1.67_4 1.405_8 1.39_8 . A vanadian clinzoisite in which one Al is replaced by V. Brown-black, brownish-gray streak, vitreous luster. Cleavage {001}, perfect; {100}, very good; brittle. H = 8. G = 3.3. Difficultly soluble in acids. Contains 11.3 wt % V_2O_5 . Biaxial (+); $Y = b$, $Z \wedge a = 32^\circ$; $N_x = 1.723$, $N_y = 1.733$, $N_z = 1.755$; $2V_z = 88^\circ$. X, pale olive-green; Y, pale reddish brown; Z, reddish brown. Occurs with goldmanite, muscovite, and common sulfides in marble. Occurs near Lewiston, ID. *Tashelginsk iron deposit, Gornaya Shoriya, western Siberia, Russia*. EF DAN SSSR 185(6):1342(1969).

58.2.1a.11 Piemontite $(Ca,Mn)(Ca,Sr,REE)(Mn^{3+},Fe^{3+})(Al,Mn)Al(SiO_4)(Si_2O_7)(OH,F)(O)$

Named in 1853 by Kennigott for the locality. Epidote group. *MON* $P2_1/m$. $a = 8.843$, $b = 5.664$, $c = 10.150$, $\beta = 115.25^\circ$, $Z = 2$. *29-288*: 5.02_4 4.00_5 3.50_4 2.90_{10} 2.83_4 2.69_4 2.60_5 2.41_5 . Also *19-897*. The b and c dimensions increase with increasing substitution of $Mn^{3+} + Fe^{3+}$. *MM 38:64(1971)*. M2 octahedral site filled completely and uniquely by Al. M1 and M3 contain Al, Fe, Mn, and Fe and Mn preferentially occupy M3. Crystals are prismatic, elongate on b . Twinning lamellar on {001}, not common. Reddish brown, black, or red; cherry-red streak; vitreous luster. Cleavage {001}, perfect. H = 6. G = 3.38-3.61. Slowly attacked by HF only. Mn_2O_3 to 22 wt %. Composi-

tional field is large. Substitution between $\text{Ca}_2\text{Fe}^{3+}\text{Al}_2 \dots - \text{Ca}_2\text{Mn}^{3+}\text{Al}_2 \dots$ and $\text{Ca}_2\text{Mn}_2^{3+}\text{Al} \dots$. Mg may substitute as well. Some material from the type locality is strontio Piemontite because of the high SrO (12 wt %) content. Overall, on a worldwide basis, Sr is low to absent. REE-bearing (with as much as about 8 wt % total REE_2O_3) piemontites exist confirming solid solution toward manganian allanites. *EJM* 4:23(1992). REE substitution in A2 balanced by (Fe^{2+} , Mg, Mn^{2+}) substitution in the octahedral framework. Biaxial (-) and (+); $X \wedge c = 2-9^\circ$, $Y = b$, $Z \wedge a = 27-32^\circ$; $N_x = 1.730-1.794$, $N_y = 1.740-1.807$, $N_z = 1.762-1.829$; $2V_z = 64-106^\circ$; OAP parallel to (010); $r < v$, weak, to $r > v$, strong; $Z > X > Y$. X, yellow, lemon yellow, yellow-orange; Y, pale pink, amethyst, violet-pink; Z, crimson red, magenta. In low-grade regional metamorphic rocks, altered (oxidized) volcanic rocks, and as hydrothermal product in certain Mn deposits. From greenschist and blueschist facies rocks to amphibolite and occasionally, higher facies. Also a late crystallization phase in acid and intermediate volcanics. High $f\text{O}_2$ (partial pressure of oxygen) is necessary for formation. Also in pegmatites and quartz veins. Noteworthy occurrences include: Pilar, NM; San Geronio Pass, Riverside Co., CA; Glen Coe, Scotland; Haute Maurienne, France; Sorharas, Langban, and Ultevis, Sweden; *Praborna Mn mine, St. Marcel, Val d'Aosta, Piemonte*, and Monte Brugiana, Alpi Apuane, Italy; Treppes, Euboea Island, Greece; Atta, Alai range, Russia; Swat, Pakistan; Hidaka Mts., Hokkaido, and Abukuma plateau, Japan; Haast R. (Westland) and Lake Wakatipu, Otago, South Island, New Zealand; Djebel Dekhan, Egypt. Piemontite schist in New Zealand is used as an ornamental stone. *EF AM* 54:710(1969), *MIN* 3(1):744(1972), *DHZ* 1B:135(1986), *PIMA* 13:635(1986).

58.2.1a.12 Strontio Piemontite $\text{CaSr}(\text{Mn}^{3+}, \text{Fe}^{3+}, \text{Al})\text{Al}(\text{SiO}_4)(\text{Si}_2\text{O}_7)\text{O}(\text{OH}, \text{F})$

Named in 1990 as the Sr analog of piemontite. Epidote group. *MON* $P2_1/m$. $a = 8.862$, $b = 5.682$, $c = 10.191$, $\beta = 114.7^\circ$, $Z = 2$, $D = 3.73$. *PD*: 3.49₅ 2.92₁₀ 2.84₅ 2.68₄ 2.65₃ 2.60₅ 2.12₄ 1.59₅. Structure: *EJM* 2:519(1990). A(2) occupied by Sr. Prismatic, elongate on b . To 0.5 mm long. Deep red, purple-brown streak, vitreous luster. Cleavage {001}, perfect; often twinned on {100} with (010) as the TP. $H = 6$. $G = 3.65-3.73$. Biaxial (+); $Y = b$; $N = 1.763$, strongly pleochroic. X, yellow-orange; Y, violet; Z, reddish violet. In an Mn ore deposit in veinlets 3-4 mm thick cutting braunite ore. Associated with calcite, rhodochrosite, rhodonite, and ganophyllite. *Val Graveglia, Liguria, Italy*; also from the *Praborna Mn mine, St. Marcel, Val d'Aosta, Piemonte, Italy*; large masses of deep red-brown strontio Piemontite and small crystals to 1 mm occur in the Wessels mine, Kalahara manganese field, Cape Prov., South Africa, associated with pectolite. *EF EJM* 2:519(1990).

58.2.1b.1 Zoisite $\text{Ca}_2\text{Al}_3(\text{SiO}_4)(\text{Si}_2\text{O}_7)\text{O}(\text{OH})$

Named in 1805 by Werner for Siegmund Zois, Baron von Edelstein (1747-1819), Austrian natural scientist. Epidote group. *ORTH* $Pnma$. $a = 16.212$,

ZOISITE: $\text{Ca}_2\text{Al}_3\text{Si}_3\text{O}_{12}\text{OH}$

Perspective view along *b*-axis

$b = 5.559$, $c = 10.036$, $Z = 4$. *13-562(syn)*: 8.09_4 5.01_3 4.03_5 2.87_6 2.79_3 2.69_{10} 2.02_3 1.60_3 . Consists of $\text{Al}(\text{O},\text{OH})_6$ chains parallel to *b*, which are linked by SiO_4 and Si_2O_7 groups and Ca polyhedra. *AM 53:1883(1968)*. Prismatic, vertically striated, twinning not observed. Yellowish green, green, brown, blue (tanzanite), colorless, purple, gray, pink (thulite); white streak; vitreous luster, sometimes pearly on cleavage. Cleavage $\{100\}$, perfect; $\{010\}$, difficult; conchoidal to uneven fracture; brittle. $H = 6-7$. $G = 3.355$ (tanzanite), $G = 3.15$ (syn), range (nat) = 3.15–3.36. Insoluble in common acids but soluble in HF. Heat-treated tanzanite crystals become sapphire blue in color in two optical directions. Replacement of Al by Fe is very limited; rarely more than 10% of (Al,Fe) octahedra. α -Zoisite has as much as 4.0 wt % Fe_2O_3 . No Al-Fe replacement series as in epidote. There is no orthorhombic equivalent of piemontite. Thulite is a pink to rose-colored variety of zoisite and clinozoisite and has 0.05–0.9 wt % MnO. *MM 44:45(1981)*. SrO contents to 7.4 wt %. *TMPM 34:87(1985)*. Zoisite may contain some Cr (0.3–0.4 wt % Cr_2O_3). May contain some F (to 1.67 wt %). Tanzanite contains 0.2 wt % V_2O_5 . *AM 54:702(1969)*. Two varieties exist: regular (β -zoisite) and ferrian (α -zoisite). Both forms may be intergrown. Biaxial (+); $N_x = 1.685-1.705$, $N_y = 1.688-1.710$, $N_z = 1.697-1.725$; $2V_z = 0-80^\circ$ [rarely higher, to $90-120^\circ(?)$]. For tanzanite, $N_x = 1.6925$ (red-violet), $N_y = 1.6943$ (deep blue), $N_z = 1.7015$ (yellow-green), $2V_z = 53^\circ$. After heating, X, violet-red; Y,Z, deep blue. Thulite shows X, pale to medium pink; Y, colorless to pink; Z, pale yellow to yellow.

Rhombic dispersion, $r > v$ (zoisite); strong rhombic dispersion, $r \ll v$ (Fe-zoisite). For β -zoisite, XYZ = abc; ferrian zoisite, XYZ = bac. In β -zoisite, OAP is perpendicular to (100) cleavage and parallel to (010), and in ferrian zoisite, OAP is parallel to (100) cleavage. May show anomalous blue interference colors. Optically (-) zoisite with dispersion $r \gg v$ has been reported. *MM* 49:97(1985). Chiefly in regionally and, to a lesser extent, in contact-metamorphosed rocks. Also in quartz veins, pegmatites, and some eclogites. α -Zoisite is generally considered to be the high-temperature zoisite, occurring as a primary mineral in eclogitic rocks, whereas β -zoisite forms during retrograde metamorphism. Occurs at Pilar, NM (thulite); thulite occurs in at least 15 states; Ducktown, TN; thulite also occurs at Remigny, QUE, Canada; Souland and Lexviken, Norway (thulite); Vipiteno and Passiria, Italy; Gefrees, Germany; Zermatt, Switzerland; Rauris and Saualpe, Austria; Galicia, northwestern Spain; Tytyri, Lohja, Finland; Borzovka, Ural Mts., Russia (thulite); Matabatu Mts., Tanzania; gem-quality vanadian zoisite (*tanzanite*) occurs in the Merelani Hills, Tanzania; green, sharp, gemmy crystals to 6 cm from Alchuri village, between Shigar and Dassu, Baltistan, Pakistan. Also occurs (α -zoisite) near Turmik as colorless to gray crystals to several centimeters in length. Nagatoro, Saitawa Pref., Japan. Thulite is used as an ornamental stone, and tanzanite is used as a gemstone. *EF DHZ* 1B:4(1986), *MIN* 3(1):709(1972), *AJS* 264:364(1966).

PUMPELLYITE GROUP

The general formula for the pumpellyite minerals can be given as

where

W = Ca, K, Na

X = Mg, Mn^{2+} , Fe^{2+} , Al, Cr

Y = Al, Fe^{3+} , Cr, Mn^{3+} , Ti

Z = Si

and the structure is monoclinic in space group $A2/m$.

The structure [*AM* 70:1011(1985)] is related to that of the epidote group in that it contains chains of edge-sharing octahedra running parallel to the [010] direction, and these are linked laterally by independent SiO_4 tetrahedra and Si_2O_6 double tetrahedra. The octahedral chains are of two kinds not related by symmetry, one containing Al only and the other containing 50% Al, 35% Mg, and 15% Fe. There are four of the former and two of the latter in the unit cell. There are two independent Ca atoms, each in sevenfold coordination. *DHZ* 1B:1996, *CM* 12:219(1973), *LIT* 4:93(1971), *MM*:113(1953).

*Name not CNMMN IMA approved.

Notes:

1. The nomenclature for the group has been defined in two ways: see Moore (1971) and Passaglia and Gottardi (1973) in references above. The latter system is adopted here.
2. See also the related minerals sursassite (58.2.3.1) and macfallite (58.2.3.2).

58.2.2.1 Julgoldite-(Fe²⁺) Ca₂Fe²⁺(Fe³⁺, Al)₂(SiO₄)(Si₂O₇)(OH)₂ · H₂O

Named in 1971 by Moore for Julian Royce Goldsmith (b. 1918), American geochemist, University of Chicago. Pumpellyite group. Forms a series with pumpellyite-(Fe²⁺) and pumpellyite-(Mg). See other members of the group. The material from Langban is actually julgoldite-(Fe³⁺) if the nomenclature of Passaglia and Gottardi (1973) is used. A structure determination [*MM* 39:271(1973)] showed the mineral to be julgoldite-(Fe³⁺). *MON* C2/m. (Nat): *a* = 19.426, *b* = 6.047, *c* = 8.949, β = 97.58°, *Z* = 4 [*NGT* 64:251(1984)]; 23-117(calc pattern): *a* = 8.922, *b* = 6.081, *c* = 19.432, β = 97.60°, *Z* = 4, *D* = 3.55. 24-198(nat): 4.80₇ 3.84₈ 2.95₁₀ 2.78₆ 2.57₇ 2.38₅ 1.62₆ 1.52₆. 23-117 and 24-198 both actually give data for julgoldite-(Fe³⁺). *R* = 4.3%, pumpellyite type. *MM* 39:271(1973). Flat, prismatic to bladed, up to more than 10 mm long; elongated on *b* or *c*, and flattened parallel to {100}; twinning on {001} common, repeated; dominant forms are {001}, {100}, {111}. Black, greenish-olive streak with bluish tinge, almost submetallic luster. Cleavage {100}, {001}, good to perfect. *H* = 4½. *G* = 3.58–3.60. IR data: *MM* 40:761(1976). Insoluble in cold 1:1 HCl but rapidly soluble in hot 1:1 HCl, leaving a gel and a crystalline precipitate. Analysis (wt %): SiO₂, 33.1; TiO₂, 0.0; Al₂O₃, 5.9; Fe₂O₃, 21.5; FeO, 12.6; MnO, 0.2; MgO, 0.5; CaO, 20.7; Na₂O, 0.25; H₂O⁺, n.d. *NGT* 64:251(1984). Optical properties for pumpellyite-(Fe²⁺) are apparently not available. Occurs in altered or metamorphosed basalts and diabases associated with prehnite and laumontite. Occurs in fissures in Precambrian granitic gneiss (Norway). Also occurs in quartz dolerite (Scotland). Occurs in the Reydarfjordur drill hole, eastern Iceland; the Ratho and Auchinstarry quarries, near Edinburgh, Scotland; Siljan area, central Sweden; Tafjord, Sunmøre district, western Norway; Khondivili quarry, Bombay, India. *EF* *NJBM* 8:367(1989), *EJM* 2:875(1990).

58.2.2.2 Julgoldite-(Fe³⁺) $\text{Ca}_2\text{Fe}^{3+}(\text{Fe},\text{Al})_2^{3+}(\text{SiO}_4)(\text{Si}_2\text{O}_7)(\text{O},\text{OH})_2 \cdot \text{H}_2\text{O}$

Named in 1971 by Moore as oxyjulgoldite and redefined in 1973 by Passaglia and Gottardi as julgoldite-(Fe³⁺). Pumpellyite group. This name is not currently approved by the CNMMN IMA. See pumpellyite-(Mg) (58.2.2.7) for details about the name. *MON A2/m*. $a = 8.92\text{--}8.949$, $b = 6.047\text{--}6.09$, $c = 19.37\text{--}19.426$, $\beta = 97.38\text{--}97.5^\circ$, $Z = 4$, $D = 3.56\text{--}3.60$. *MM 39:271(1973)*: 4.80₇ 3.84₈ 2.95₁₀ 2.78₆ 2.57₇ 2.385₅ 1.62₅ 1.52₅. Structure: *MM 39:271(1973)*. Flat, prismatic, bladed crystals with dominant forms {100}, {111}, also {001}, {102}, {101}, and {111}, commonly striated parallel to b , elongated parallel to b , flattened parallel to a ; usually twinned on c , {001} = TP. Deep lustrous black, greenish olive with bluish tinge; almost submetallic luster. Cleavage {100}, good. $H = 4.5$. $G = 3.60$. Insoluble in cold 1:1 HCl, rapidly dissolved by hot 1:1 HCl, producing a gel. Analysis (wt %): SiO₂, 34.0; Al₂O₃, 1.3; Fe₂O₃, 29.6; TiO₂, 0.1; CaO, 22.0; MgO, 0.2; FeO, 8.7; MnO, 0.2; H₂O, 4.69. *LIT 4:93(1971)*. Also SiO₂, 32.4; Al₂O₃, 1.0; total Fe as Fe₂O₃, 40.6; CaO, 19.3. *MM 39:271(1973)*. This material may actually be julgoldite-(Fe²⁺), depending on the exact ferrous/ferric iron ratio, but structure solution has ferric iron predominant over ferrous iron. Biaxial (-); $N_x = 1.776$, $N_y = 1.814$; $2V = 50\text{--}70^\circ$, $2V_{\text{calc}} = 73^\circ$; $Z \gg Y > X$; strongly pleochroic. X, pale brown; Y, pale brownish green; Z, deep emerald-green. Occurs as cavity fillings and embedded in plates of apophyllite, in a fracture filling in hematite-magnetite ore from the Amerika stope at *Långban, Varmland, Sweden*. EF

58.2.2.3 Okhotskite-(Mg) $\text{Ca}_2(\text{Mg}, \text{Mn}^{2+})(\text{Mn}^{3+}, \text{Al}, \text{Fe}^{3+})_2(\text{SiO}_4)(\text{Si}_2\text{O}_7)(\text{OH})_2 \cdot \text{H}_2\text{O}$

58.2.2.4 Okhotskite-(Mn²⁺) $\text{Ca}_2(\text{Mn}^{2+}, \text{Mg})(\text{Mn}^{3+}, \text{Al}, \text{Fe}^{3+})_2(\text{SiO}_4)(\text{Si}_2\text{O}_7)(\text{OH})_2 \cdot \text{H}_2\text{O}$

Named in 1987 by Togari and Akasaka for the Sea of Okhotsk, along which the mine is located. Pumpellyite group. The names *okhotskite-(Mg)* and *okhotskite-(Mn)* are not yet approved by the CNMMN IMA. Compare other members of the group. A complete solid-solution series exists between pumpellyite-(Mn) and okhotskite-(Mn). *MON A2/m*. $a = 8.887\text{--}8.98$, $b = 6.000$, $c = 19.19\text{--}19.53$, $\beta = 97.08\text{--}98.1^\circ$, $Z = 4$, $D = 3.40$ and 3.58 . *42-1387 [MM 51:611(1987)](nat)*: 4.76₆ 3.87₇ 2.96₁₀ 2.72₇ 2.66₄ 2.55₄ 2.38₄ 1.81₄. Prismatic; to 0.2 mm long. Deep orange, pale orange streak, vitreous luster, transparent. One set of cleavages. $H = 6$. Mossbauer spectra: *MM 51:611(1987)*. Nonfluorescent. Biaxial (-); $Y = b$, $Z \wedge c = 9\text{--}14^\circ$ in acute β ; $N_x = 1.782$, $N_y = 1.8201$, $N_z = 1.827$; $2V = 46^\circ$; $X > Y > Z$, $X < Y < Z$ (Japan); parallel extinction; no dispersion. Distinctly pleochroic: X, light yellow-yellow; Y, light pink-deep orange; Z, rose pink-deep orange. Occurs in MnFe-oxide ores (metamorphosed). In veinlets cutting hematite ore in metamorphic rocks. Associated with pumpellyite and piemontite. Occurs at Gowari Wadhona, Madhya Pradesh, India; *Kokuriki mine, Hiyoshi, Tokoro district, eastern*

Hokkaido, Japan, associated with other Mn minerals; possibly at Ochiai mine, Japan. *EF BM 104:396(1981)*, *AM 76:241(1991)*.

58.2.2.5 Pumpellyite-(Fe²⁺)

Named by Moore in 1971 as ferropumpellyite and later redefined in 1973 by Passaglia and Gottardi. Pumpellyite group. Note that what was described as pumpellyite by Moore in 1971 is actually julgoldite-(Fe³⁺) according to the nomenclature scheme of Passaglia and Gottardi. *MON A2/m*. $a = 8.49$, $b = 5.99$, $c = 19.40$, $\beta = 100.4^\circ$, $Z = 4$, $D = 3.27$. *36-437(nat)*: 4.76₃ 4.43₃ 3.79₆ 2.91₁₀ 2.75₆ 2.66₃ 2.47₃ 2.22₄; *10-477(Pump-Mg-Fe²⁺)*: 4.38₂ 3.79₅ 2.90₁₀ 2.74₅ 2.64₃ 2.45₄ 2.21₃ 1.60₃. Twinning sometimes on {001}, CP = TP, $X \wedge TP(001) = 12^\circ$; other physical properties not given but by analogy should be similar to other members of the group. $G = 3.31$. Analysis (wt %): SiO₂, 34.83; TiO₂, 0.1; Al₂O₃, 10.10; Fe₂O₃, 18.05; FeO, 9.09; CaO, 20.5; MgO, 0.94; MnO, 0.02; Na₂O, 0.18; H₂O⁺, 5.62 (Norilsk, Russia). This analysis actually calculates to a julgoldite-(Fe)²⁺. Biaxial (+); $N_x = 1.682$, $N_y = 1.685$, $N_z = 1.694$; $2V = 56^\circ$, normally $r < v$, but in some brownish varieties and those with high RI it is $r > v$; the optical properties of members of the pumpellyite group as well as pumpellyite *sensu strictu* vary systematically with Fe²⁺ + Fe³⁺ + Mn + Cr content. They are both (+) and (-), because two orientations exist [*MM 30:113(1953)*]: (1) OAP parallel to (010); $\beta = 1.71-1.73$; $2V_x = 80-20^\circ$; $r > v$, strong; X, very pale bluish green; Y, pale to deep golden yellow. (2) OAP perpendicular to (010), Z parallel to fiber length; Z to 1.75; $2V_x = 0-60^\circ$; strong dispersion; strongly pleochroic, same as above. In very iron-rich samples, the OAP may be perpendicular to (010) or parallel to (010); $2V_x = 80-30^\circ$. Occurs in low-grade metamorphic rocks, granites, and volcanic rocks (spilites and keratophyres). Occurs at Calumet, Houghton, MI; Hicks Ranch, Sonoma Co., CA; Siljan area, central Sweden; *Långban, near Filipstad, Varmland, Sweden* (actually julgoldite); Ivakin Creek, Norilsk district, Siberia, Russia; Coloured Series, NE of Neyriz, Iran; Khondivilli Quarry, Bombay, India; East Taiwan ophiolite, Taiwan. *EF CM 12:219(1973)*; *AM 61:176(1976)*, *68:1250(1983)*; *NJBM:367(1989)*; *EJM 2:875(1990)*.

58.2.2.6 Pumpellyite-(Fe³⁺)

Named in 1973 by Passaglia and Gottardi. Pumpellyite group. *MON A2/m*. $a = 8.825$, $b = 5.945$, $c = 19.131$, $\beta = 97.45^\circ$, $Z = 4$, $D = 3.35$. *39-1368(nat)*: 4.68₅ 4.38₇ 3.79₉ 2.91₁₀ 2.90₁₀ 2.74₇ 2.52₅ 2.19₇. Physical properties not given but are presumably analogous to other members of the pumpellyite group. Analysis (wt %): SiO₂, 35.75; TiO₂, 0.12; Al₂O₃, 18.70; Fe₂O₃, 11.10; FeO, 2.80; MnO, 0.05; MgO, 3.12; CaO, 20.72; Na₂O, 0.44; H₂O⁺, 6.63. Biaxial; $N_y = 1.713$; for optics for Fe-rich varieties, see pumpellyite-(Fe²⁺)

(58.2.2.5). Occurs in metamorphic rocks. Occurs at *Långban, near Filipstad, Varmland, Sweden* (actually *julgoldite*); Bulla Stream, Val Gardena, Bolzano, Italy. EF *MM* 30:113(1953), *PM* 41:273(1972), *CM* 12:219(1973).

58.2.2.7 Pumpellyite-(Mg) $\text{Ca}_2\text{MgAl}_2(\text{SiO}_4)(\text{Si}_2\text{O}_7)(\text{OH})_2 \cdot \text{H}_2\text{O}$

Named in 1925 by Palache and Vassar for Raphael Pumpelly (1837–1923), a pioneer student of the Cu deposits of the Keweenaw Peninsula, Michigan, the locality from which it was first described. Pumpellyite group. *MON A2/m*. *AM* 70:1011(1985): $a = 8.812$, $b = 5.895$, $c = 19.116$, $\beta = 97.41^\circ$; 10-447: $a = 8.81$, $b = 5.94$, $c = 19.14$, $\beta = 97.6^\circ$; 25-156: $a = 8.820$, $b = 5.904$, $c = 19.12$, $\beta = 97.4^\circ$; $Z = 4$, $D = 3.17\text{--}3.25$. 10-447[nat pumpellyite-(Mg-Fe²⁺)]: 4.38₂ 3.79₅ 2.90₁₀ 2.74₅ 2.64₃ 2.45₄ 2.21₃ 1.60₃; 25-156[pumpellyite-(Mg)]: 4.66₂₅ 4.37₃ 3.79₃ 2.92₅₅ 2.90₁₀ 2.73₃ 2.51₃ 2.45₂₅. Structure: *AC(B)* 27:1871(1971), *AM* 70:1011(1985). Needles to plates, fibrous, flattened on {001}; twinning polysynthetic, with {100} as the twin plane, also on {001} common. Blue-green, olive green, brown, colorless; streak usually gray-green, green; vitreous luster. Cleavage (001), perfect; {100}, less so; subconchoidal fracture. $H = 5\frac{1}{2}\text{--}6$. $G = 3.18\text{--}3.2$. DTA and TGA data: *DHZ 1B*(1986). Insoluble in HCl. Analysis (wt %): Hicks Ranch, CA: Ca, 7.60; Mg, 1.60; Fe²⁺, 0.77; Fe³⁺, 0.18; Al, 10.80; Si, 11.20; H, 14.7; Calumet, MI: SiO₂, 37.18; Al₂O₃, 23.50; Fe₂O₃, 5.29; FeO, 2.09; MnO, 0.13; MgO, 3.18; CaO, 23.08; Na₂O, 0.19; H₂O⁺, 6.28; H₂O⁻, 0.06. Cr- and Ti-bearing pumpellyites occur in a metagabbro pebble (Miocene) on Chita Peninsula, Aichi Pref., Japan: Cr₂O₃ to 8 wt % and TiO₂ to 5.6 wt %. Inferred to be a pseudomorph after Cr-rich spinel; occurs with chlorite, non-Cr-bearing pumpellyite, albite, and rutile. Vanadium-bearing pumpellyite-(Mg) with 1.7 to 14 wt % V₂O₃ occurs in the Hemlo gold deposit, ONT, Canada. As much as 4.8 wt % As₂O₅ and 1.0% F are present. As substitutes for Si. V goes into pumpellyite-group minerals by $\text{Al} \leftrightarrow \text{V}$, with minor contribution from $2\text{Al}^{3+} \leftrightarrow \text{V}^{4+} + (\text{Mg}, \text{Fe})^{2+}$ or $3\text{Al}^{3+} \leftrightarrow \text{V}^{5+} + 2(\text{Mg}, \text{Fe})^{2+}$. Biaxial (+); $N_x = 1.670\text{--}1.698$, $N_y = 1.672\text{--}1.706$, $N_z = 1.684\text{--}1.720$; 2V usually $\approx 10\text{--}50^\circ$ (Calumet has 2V = 80°, and Hicks Ranch has 2V = 41°); strongly pleochoric for vanadoan (1.7–14% V₂O₃). X, colorless to weak red; Y, brown or deep brown with a violet tint; Z, pale brown. *CM* 30:153(1992). Occurs in metamorphic rocks, of hydrothermal origin. Occurs at *Calumet, Houghton Co., Keweenaw Penin., MI*; Hicks Ranch, Sonoma Co., CA; V-rich in mica schist from the main ore zone of the Hemlo gold deposit, ONT, Canada; Tiso, Bolzano, Italy; Königskopf, Germany; Jordanov, Poland; Lotru, Romania; Blagodat, Ural Mts., Russia; Luohnsha ophiolite suite, Yalu Tsampo River, southern Tibet; Witwatersrand, South Africa; Toba, Sinsen-mura, Japan; Sada mine, Takasino, Saitama Pref., Japan; Watiba, Tukikawa, Saitama Pref., Japan; Cr- and Ti-bearing from Toyoura area, Chita Penin., Minamichita-cho, Japan; Lake Wakatipu, New Zealand. EF *CM* 12:219(1973), *MJJ* 13:90(1986).

58.2.2.8 Pumpellyite-(Mn²⁺) Ca₂(Mn²⁺,Mg)(Al,Mn³⁺,Fe)₂(SiO₄)(Si₂O₇)(OH)₂ · H₂O

Named in 1981 by Kato et al., see pumpellyite-(Mg) (58.2.2.7) for origin of name. Pumpellyite group. See other members of the group. *MON A2/m*. $a = 8.923$, $b = 5.995$, $c = 19.156$, $\beta = 97.13^\circ$, $Z = 4$, $D = 3.34$. *35-0314*(nat): 4.75₆₅ 4.43₃₅ 3.84₆₅ 2.93₁₀ 2.725₉ 2.65₅₅ 2.53₅ 2.20₄₅. Platelets elongated on b , tabular to {001} or granular, crystal size to 0.1 mm. Light grayish, brownish pink; light grayish-pink streak; vitreous luster. Cleavage {001}, perfect. $H = 5$. Analysis (wt %): SiO₂, 35.66; TiO₂, 0.02; Al₂O₃, 13.40; Fe₂O₃, 2.43; Mn₂O₃, 7.74; MnO, 13.41; MgO, 0.89; CaO, 20.69; H₂O⁺, 5.75 (by difference). Biaxial (-); $N_x = 1.752$, $N_y = 1.795$, $N_z = 1.800$; $2V = 40-50^\circ$; parallel extinction; positive elongation; $B \times a$ nearly perpendicular to {001}; distinctly pleochroic. X , pale pink; Y, Z , brownish pink. Occurs in Mn-oxide ores of Precambrian pelitic and dolomitic rocks (Sausar Group, India). In braunite ore, with caryophyllite, quartz, rhodochrosite, and late calcite in Japan. Occurs in eastern Liguria, Italy; Gowari Wadhona, Madhya Pradesh, India; *Ochiai mine, Barazawa, Kohsai-cho, Yamanashi Pref., Japan*. *EF BM 104:396(1981)*, *NJBM 12:563(1983)*, *AM 76:241(1991)*.

58.2.2.9 Shuiskite-(Mg) Ca₂(Mg,Al)(Cr,Al)₂(SiO₄)(Si₂O₇)(OH)₂ · 2H₂O

Named in 1981 by Ivanov et al. for V. P. Shuisk, lithologist at the Ural Scientific Center, Yekaterinburg, Russia. Pumpellyite group. *MON A2/m*. $a = 8.897$, $b = 5.843$, $c = 19.41$, $\beta = 98^\circ$, $Z = 4$; (H₂O poor): $a = 8.780$, $b = 5.963$, $c = 19.01$, $\beta = 98.07^\circ$, $Z = 4$, $D = 3.63$. *39-1369*(nat, H₂O poor): 4.69₆ 2.88₁₀ 2.83₁₀ 2.37₆ 2.34₇ 2.09₈ 1.92₆ 0.96₆; (with H₂O): 2.90₉ 2.73₇ 2.64₅ 2.52₅ 2.46₅ 2.22₄ 1.59₁₀ 1.49₈. Prismatic radiating fibrous aggregates; at Saranov, 7 mm × 0.5 mm × 0.1 mm; twinning on (100). Dark brown with a violet tint, dark violet; light greenish-brown or grayish-green streak; vitreous luster. Cleavage {001}, perfect, or not observed; irregular and conchoidal fracture. $H = 6$. $G = 3.24-3.32$. IR data: *ZVMO 114:49(1985)*. DTA, TGA data: *ZVMO 110:508(1981)*, *114:49(1985)*. 26.5% Cr₂O₃ in Roche Noir sample, 28.6% Cr₂O₃ in Saranov sample. Some samples are H₂O poor (7.03 to 3.77 wt %). Some vacancy exists in the W site. Biaxial (-); $Z \wedge c = 0^\circ$ in zone of maximum birefringence, $Z \wedge c = 3.5-6^\circ$ in zone perpendicular to X ; (H₂O poor): $N_x = 1.755-1.772$, $N_y = 1.775-1.795$, $N_z = 1.781-1.810$; (H₂O-bearing): $2V = 40-45^\circ$, $N_x = 1.725-1.733$, $N_y = 1.762-1.772$, $N_z = 1.769-1.775$; positive elongation; $r < v$, strong; strongly pleochroic. X , violet-blue; Y , yellowish green; Z , dark violet to dark violet-rose. Occurs on fractures in chromitite. Associated with uvarovite, chromian-chlorite, and chromian-titanite. In high-pressure metamorphosed gabbro in France. At Saranovsk, in calcite veins. *Bisersk deposit, Laki Station, Gorozavod region, Perm Prov., and Saranov chromite deposit, Ural Mts. (lower water content), Russia; Roche Noir Mas-sif, French Alps, France [could be called shuiskite-(Cr)].* *EF*

58.2.3.1 Sursassite $Mn_2Al_3(SiO_4)(Si_2O_7)(OH)_3$

Named in 1926 by Jakob from *Sursass*, the name for Oberhalbstein, Switzerland. Possibly of the ardenite group. *MON* $P2_1/m$. $a = 8.704\text{--}8.885$, $b = 5.795\text{--}5.827$, $c = 9.787\text{--}9.827$, $\beta = 108.65\text{--}108.97^\circ$, $Z = 2$, $D = 3.19\text{--}3.57$. $18\text{--}1286(\text{nat})$: 4.56_5 3.72_5 2.88_7 2.82_{10} 2.66_6 2.57_7 2.44_5 2.14_6 . Also $37\text{--}479$. HRTEM studies and structure refinement show the presence of stacking disorder and intergrowth with pumpellyite. *PCM* $10:99(1984)$. Crystals are fibrous and occur in masses, elongated on b . Reddish brown to copper-colored, cinnamon-brown streak, silky to somewhat dull luster. Cleavage $\{101\}$, distinct. $G = 3.26\text{--}3.44$. Contains minor amounts of Ca, Mg, Fe. Biaxial (-); $Y = b$, $X \wedge c = 55^\circ$; $N_x = 1.720\text{--}1.736$, $N_y = 1.737\text{--}1.755$, $N_z = 1.745\text{--}1.766$; $2V = 65^\circ$; $r < v$, strong; pleochroic. X, Z , colorless to pale yellow; Y , golden to reddish brown. May show abnormal interference colors. Occurs in a glaucophane schist in George F. Canyon in the northwestern Palos Verdes Hills, CA; occurs in veinlets cutting Fe-Mn ores at the Strategic manganese mine, Plymouth, Woodstock, NB, Canada, and in cracks in radiolarian cherts of the Mn deposits of the *Val d'Err*, *Grisons*, *Graubunden*, *Switzerland*, where it occurs in Mn ores with tinzenite, parsettensite, rhodonite, quartz, albite, barite, and manganocalcite. Also occurs in the northern Apennines, Italy. *EF MIN* $3(1):768(1972)$, *RSIMP* $35:151(1979)$, *FM* $62:3(1984)$.

58.2.3.2 Macfallite $Ca_2(Mn^{3+}, Al)_3(SiO_4)(Si_2O_7)(OH)_3$

Named in 1979 for Russell P. MacFall, a dedicated amateur mineralogist. See pumpellyite (58.2.2.5 to 58.2.2.8) and sursassite (58.2.3.1). *MON* $P2_1/m$. $a = 10.235$, $b = 6.086$, $c = 8.970$, $\beta = 110.75^\circ$, $Z = 2$, $D = 3.51$. $35\text{--}471(\text{nat})$: 4.76_4 4.45_3 3.89_7 3.40_{10} 2.96_5 2.71_5 2.44_3 2.19_3 ; $42\text{--}601(\text{calc pattern})$: 4.79_8 3.92_9 2.98_{10} 2.71_5 2.68_3 2.57_7 2.45_3 2.40_5 . Structure solution gave $R = 18\%$ because structural disorder (domains, intergrowths) and/or solid solution probably affect the structure of this mineral as well as orientite and ruizite, and true single crystals of these and related compounds are encountered very infrequently. *AM* $70:171(1985)$. Acicular to elongated crystals, often in aggregates; twinning by reflection on $\{100\}$ is universal. Brown-reddish brown, maroon; brown streak with reddish tint; silky to subadamantine luster. Cleavage (001) , perfect. $H > 5$. $G = 3.43$. Analysis (wt %) (Manganese Lake material): CuO , 1.2-1.9; Al_2O_3 , 3.95-8.45; V_2O_5 , 0.0-2.2; SO_3 , 0.4-0.6. Substitutions: Cu^{2+} for Mn^{3+} , Al for Mn^{3+} , V^{5+} for Si^{4+} , S for Si^{4+} . MgO , 0.73 wt %, Al_2O_3 , 1.03 wt % in Italian material. Biaxial (-); $Z = b$; $N_x = 1.773\text{--}1.775$, $N_y = 1.795$, $N_z = 1.810\text{--}1.815$; $2V = 86^\circ$, birefringence = 0.035-0.042. X , colorless to yellow; Y , light brown; Z , brownish red to dark brown. Occurs at *Manganese Lake*, *Copper Harbor*, *Keweenaw Co.*, *MI*, in Keweenaw basalt, associated with manganite, braunite, orientite, and pyrolusite. The assemblage replaces calcite in fissures and lenses in the basalt. Occurs at the Cerchiara mine, Faggiona, eastern Liguria, Italy, in metacherts of an ophiolite sequence, interbedded layers of braunite and Mn-silicates, intergrown with orientite. *EF MM* $43:325(1979)$, *NJBM*: $455(1989)$.

58.2.4.1 Vesuvianite $(\text{Ca,Na,REE,Pb,Sb}^{3+})_{19}(\text{Al,Mg,Fe}^{3+},\text{Fe}^{2+},\text{Ti,Mn,Cu,Zn})_{13}(\text{SiO}_4)_{10}(\text{Si}_2\text{O}_7)_4(\text{B},\square)_{5}\text{O}_{68}(\text{OH,F,O})_{10}$

Described in 1795 by Werner and named for the locality. Synonym: idocrase. TET (High vesuvianite): $P4/nnc$. $a = 15.51\text{--}15.80$, $c = 11.70\text{--}11.92$, $Z = 2$, $D = 3.35$. REE-bearing (17 wt % REE_2O_3) vesuvianite from San Benito Co., CA, has the largest cell dimensions reported for natural vesuvianites. High-precision cell dimensions for low vesuvianite from Lowell (Eden Mills), VT, are: $a = 15.5498$, $b = 15.5594$, $c = 11.8276$. TET $P4/n$, $P4nc$, $P4$, and possibly as low as $P2/n$ (monoclinic). GSAPA 27(6):A-363(1995). For some vesuvianites, the sum of Y cations is >13.0 (mean sum = 13.57), $P4/nnc$, an additional site (T1) is tetrahedrally coordinated by four oxygen atoms. This site is occupied by (B,Al,Fe), which replace two H atoms at adjacent H1 positions. The substitution is accompanied by the incorporation of a vacancy at an adjacent X3 site. For B-bearing samples, $a = 15.70$, $c = 11.75$. F-bearing samples are $P4/nnc$. 38-473(Asbestos, QUE): 3.04₁ 2.95₄ 2.76₁ 2.75₁₀ 2.60₄ 2.59₆ 2.45₄ 1.76₁; 38-474(ferrian): 3.49₁ 3.01₁ 2.96₄ 2.75₁₀ 2.61₄ 2.60₆ 2.46₄ 2.13₁; also 25-145(calc pattern). High-symmetry vesuvianite has a long-range disordered structure with $P4/nnc$ average symmetry. Low symmetry vesuvianite has $P2/n$ or Pn space group symmetry, based on optical and X-ray diffraction data. Vesuvianite probably undergoes a ferroelastic phase transition at high temperature ($>500^\circ$) from a $P4/nnc$ structure to a $P2/n$ or Pn structure. Crystals containing equal volumes of oppositely ordered domains exhibit $P4/nnc$ pseudosymmetry (long-range order). SHA (second harmonic analysis) shows high vesuvianite to be centric and low vesuvianite to be acentric. Some vesuvianites exhibit weak to intense reflections, violating the various glide-plane extinctions. In addition, some vesuvianites are biaxial, indicating that they are not even tetragonal. Violations exist because of ordering of partially occupied (Y1 and X4) sites. Because of diffuseness of the violating reflections, there is domain structure. TEM studies show that there is a twin domain structure in at least some low-symmetry vesuvianites. SAED patterns are consistent with $P4/n$. Domain structure is formed by transformation twinning resulting from ordering of the disordered high-temperature structure with space group $P4/nnc$. Domains are 10–50 nm wide; some exceed 1 μm . Domain structure is often lamellar parallel to $\{001\}$. Thus the true symmetry is not tetragonal; it is probably $P2/n$ or Pn . Ordering of channel cations over nonequivalent pairs of Y1 and X4 sites cannot be the order parameter that drives the $P4/nnc \rightarrow P2/n$ transition, as it does not transform as the active irreducible representation of this transition. 010 and 011 are occupied by monovalent anions (i.e., OH, F, Cl). B-free vesuvianite has 10(H + F) with $F \geq 1.0$ atoms per formula unit. For B-bearing vesuvianite, use 19 X cations to normalize to, and for B-free vesuvianite, use 50 total cations per formula unit. T1 and T2 sites (occupied by B) are empty. Occupancy of T1 and T2 sites precludes occupancy of two H1 and H2 positions. Fe and Al can also occur at the T positions; therefore B-bearing vesuvianites usually have “excess” Y-group cation sums. EPR studies indicate that Fe^{3+}

substitutes on the fivefold-coordinated square-pyramidal Y1 site. *NJBM:264(1995)*. **Habit:** Prismatic along [001]. Forms {001}, {010}, {110}, {111}, and others. **Physical properties:** Usually green or chartreuse, but may be white, pink, yellow, yellow-brown, yellow-green, brown, red, black, purple, or blue ("cyprine"); white to pale greenish brown streak; vitreous to resinous luster. Cleavage {110}, poor; {100}, {001}, very poor; subconchoidal to uneven fracture; brittle. $H = 5-6\frac{1}{2}$. $G = 3.32-3.43$. **Chemistry:** Insoluble in common acids or partly soluble in HCl; soluble in HF. IR spectroscopy in the OH region. *CM 33:609(1995)*. Tetrahedral Z site has only Si in it, no Al substitution. X site is eight- or nine-coordinated, dominantly Ca. For B-bearing vesuvianite, $B + Mg \rightarrow 2H + Al$. B-bearing vesuvianites have much less OH (2-5 atoms per formula unit) than B-free (8.5-10 atoms per formula unit). Fe to as much as 7.4 wt % FeO, MgO to 4.75 wt %, TiO_2 to 6.7 wt %, B_2O_3 to about 4.0 wt %, BeO to 1.1 wt %, F to 3.15 wt %. Unusual Cu-bearing (to 2.2 wt % CuO) and Pb-bearing (to 2.1 wt % PbO) vesuvianite from Franklin, NJ (cyprine). Unusual bright red vesuvianite from Langban, Sweden, had 2.5 wt % Bi_2O_3 and as much as 3.8 wt % MnO. May have as much as 0.6 wt % Cr_2O_3 . ZnO to 4.5 wt % at Franklin, NJ. May also contain S (to 1.0 wt % SO_3) from Lake Jaco, Mexico. Cl to 1.2 wt %. B-bearing vesuvianite occurs at Templeton Twp., QUE, Canada; Ariccia, Italy; Lake Jaco, CHIH, Mexico; Tulare Co., CA; Achtagar R., Vilui River area, Yakutia, Russia. ThO_2 to 1.5 wt %. About 17 wt % REE_2O_3 in vesuvianite from San Benito Co., CA. An unusual Sb-bearing vesuvianite (15.5 wt % Sb_2O_3) has been reported. Low-symmetry vesuvianite has very low F and Cl contents, and high-symmetry vesuvianites have considerable F and Cl. Uniaxial (-) and (+), also anomalously biaxial (-). All B-bearing vesuvianites are (+) and all B-free samples are (-). $N_O = 1.703-1.752$, $N_E = 1.700-1.746$. An Fe- (10.9 wt % FeO + Fe_2O_3) and high-REE-containing vesuvianite (16.7 wt % REE_2O_3) has $N_O = 1.762$ and $N_E = 1.750$. The unusual Sb-bearing (15.7 wt % Sb_2O_3) vesuvianite from Sarawak, Malaysia has $N_O = 1.795$ and $N_E = 1.775$. **Optics:** Weakly dichroic, usually brownish yellow to yellowish brown, but may be green, brown, or blue. Strong dispersion. Metamict material may have N as low as 1.66. Characteristically shows abnormal interference colors in blue and brown. Three groups of vesuvianite are recognized on the basis of optical properties: (1) normal crystals showing uniform extinction and small ($0-5^\circ$) 2V; (2) blocky crystals showing irregularly shaped areas of variable birefringence in a (001) section with 2V values in the range $5-35^\circ$; and (3) sector-zoned crystals showing {001}, {101}, and {100} sectors with low (about 5°), intermediate ($20-35^\circ$), and high ($40-60^\circ$) values of 2V, respectively. The different optical types of vesuvianite arise from different relationships between the temperature range of crystallization and the temperature of the ferroelastic phase transition. **Occurrence:** A rock-forming or accessory mineral in skarns, rodingites, and altered alkali syenites. Low vesuvianite occurs in metamorphic rocks formed at $<300^\circ$ compared to those containing high vesuvianite ($400-800^\circ$). Ordering to low vesuvianite presumably takes place during crystal growth rather than by ordering transformation on cool-

ing. High vesuvianite is in skarns and calc-silicate hornfels and calc-schists. Low vesuvianite is found in veins, rodingites, and altered alkali syenites, and metamorphosed limestones. May be metamict or partly so. **Localities:** Localities for metamict material include Seward Peninsula, AK, to 1.5 cm, in nepheline syenite. Also in a skarn near Lake George, Park Co., CO; to 2-cm crystals. An alkaline pegmatite in the Tuva district, Russia, also contains metamict material. A reasonably abundant mineral that occurs worldwide; only notable localities are mentioned here. Crystals to 7 cm occur at Sanford(1), York Co., ME. Also at Auburn, Androscoggin Co., ME. Olmsteadville, NY(!); at Lowell (Eden Mills)(1), VT, associated with grossular. Be-bearing vesuvianite and "cyprine" at the Parker shaft, Franklin, Sussex Co., NJ. Rockville, Montgomery Co., MD; Magnet Cove, Garland Co., AR; Italian Mountain, Gunnison Co., CO; Crestmore quarry, Riverside Co., CA; San Benito Co., CA (REE-bearing); massive material called "californite" from localities in Siskiyou, Butte, and Fresno Cos., CA. The best "californite" is from Pulga, Butte Co. Fine vesuvianite (some of lilac-purple color) at the Jeffrey mine, Asbestos; gem material at Laurel, Argenteuil Co.; large, brownish-yellow crystals at Calumet Falls, Litchfield, Pontiac Co., and from Templeton, Ottawa Co.; as masses and minute crystals of a bright pink color at the Montreal chrome pit, Black Lake, Colerain Twp., Megantic Co., QUE, Canada. Blue, Cu-bearing (1.1% CuO) vesuvianite at Sauland, Telemark, and Eger(1), Norway; *Monte Somma, Vesuvius, Italy*. Sharp green-brown "toenails," blocky and striated crystals to 3 cm at Mt. Banchetti, Bellecombe, Aosta Valley, Italy. Transparent green or brown brilliant crystals at Mussa Alp, Ala Valley, Piedmont, Italy. Vilui River region (viluite), Yakutia, Russia; Hindubagh and Muslimbagh, Pakistan. Uses: Vesuvianite has minor use as a lapidary material and as a gemstone. *EF MIN 3(1):597(1972); DHZ 1A:699(1982); AM 76:397(1991); MP 46:163(1992); CM 30:1(1992), 30:19(1992), 30:1065(1992), 31:357(1993), 31:617(1993), 32:497(1994), 32:505(1994); MJ 17:1(1994).*

58.2.5.1 Rustumite $\text{Ca}_{10}[\text{Si}_2\text{O}_7]_2[\text{SiO}_4](\text{OH})_2\text{Cl}_2$

Named in 1965 by Agrell for Rustum Roy (b.1925), materials chemist, Pennsylvania State University. *MON C2/c. a* = 7.62, *b* = 18.55, *c* = 15.51, β = 104.35°, *Z* = 4, *D* = 2.835. *18-305:* 3.19₈ 3.03₁₀ 2.89₉ 2.75₅ 2.63₅ 1.752₇ 1.661₅ 1.613₅. Crude tabular crystals to 2 mm in length; polysynthetic twinning on {100}. Colorless to white, transparent to translucent. Cleavage {100}, poor; {010}, {001}, very poor. *G* = 2.86. Biaxial (-); 2*V* = 80°; *N_x* = 1.640, *N_{y calc}* = 1.645, *N_z* = 1.651; *X* \wedge *c* = 4-6°, *Y* = *b*. Found at the La Negra mine, Maconi, QRO, Mexico; in the skarns of *Kilchoan, Ardnamurchan, Scotland*, with akermanite, merwinite, larnite, spurrite, rankinite, and kilchoanite; Carlingford, Co. Louth, Ireland; in skarn near Güneyce-Ikizdere, Turkey. *AR MM 34:1(1965), AM 64:659(1979).*

58.2.6.1 Yoshimuraite $(\text{Ba,Sr})_2\text{Mn}_2^{2+}(\text{Ti,Fe}^{3+})\text{O}(\text{Si}_2\text{O}_7)[(\text{P,S})\text{O}_4]$
(OH)

Named by Watanabe in 1961 for Toyofumi Yoshimura (1905–1988), Japanese mineralogist and economic geologist, Kyushu University. TRIC P1. $a = 5.386$, $b = 6.999$, $c = 14.748$, $\alpha = 95.50^\circ$, $\beta = 93.62^\circ$, $\gamma = 89.98^\circ$, $Z = 2$, $D = 4.16\text{--}4.21$. $36\text{--}411(\text{nat})$: 4.89_6 3.39_3 3.32_2 $3.23_{2.5}$ 3.12_3 2.93_{10} $2.77_{3.5}$ $2.68_{2.5}$. Isostructural with innelite. The structure is strongly layered parallel to $\{001\}$, consisting of a brucite layer of MnO_6 octahedra, a layer of TiO_5 tetragonal pyramids cross-linked by Si_2O_7 groups, and a layer of edge- and face-sharing PO_4 and BaO_{11} polyhedra. Linking of all three layers along $\{001\}$ results in a mica-type structure. Si and P are well ordered and there is no sharing of tetrahedral elements between SiO_4 and PO_4 . Blades or micallike forms to 5 cm long. Polysynthetic twinning on $\{010\}$ common. Brown, orange-red, or dark brown; transparent to translucent. Cleavage $\{010\}$, perfect; $\{101\}$, $\{101\}$, distinct; brittle. $H = 4\frac{1}{2}$. $G = 4.13\text{--}4.19$. Analysis (wt %): SiO_2 , 17.2–18.25; TiO_2 , 7.47–10.0; Al_2O_3 , 0.21; Fe_2O_3 , 1.32–3.48; FeO , 1.47–3.16; MnO , 15.83–17.64; MgO , 0.31–0.56; CaO , 1.45; ZnO , 0.50; Na_2O , 0.1–0.16; K_2O , 0.01–0.03; BaO , 33.51–38.11; SrO , 3.03–4.62; P_2O_5 , 3.98–4.62; SO_3 , 3.84–5.40; Cl, 0.41; H_2O , 1.06–2.34. Biaxial (+); $N_x = 1.763\text{--}1.768$, $N_y = 1.777$, $N_z = 1.785\text{--}1.794$; $2V = 80\text{--}90^\circ$; $X < Y \leq Z$; $r > v$; x' is nearly parallel to a ; z' nearly parallel to c . X, bright yellow; Y, orange-brown; Z, brown. Occurs in coarse-grained pegmatite along the boundary between massive manganese ore and hornfels. Associated with barian K-feldspar, quartz, richterite and riebeckite, aegirine, and rhodonite. Exclusively from bedded manganese deposits (metamorphosed). Occurs exclusively at several localities in Japan: Taguchi mine, Shidara, Kitashidara-gun, Aichi Pref., Honshu; at the Noda-Tamagawa mine, Tamagawamura, Iwate Pref.; at the Hijikuzu and Tanohata mines, Iwate Pref. EF *MJJ* 2:408(1959), 3:156(1961); *JMSJ* 6:230(1963); *MSJSP* 1:74(1971); *GAC-MACP* 19:A73(1994).

58.2.6.2 Innelite $\text{Na}_2\text{Ba}_4\text{CaTi}_3\text{O}_4[\text{Si}_2\text{O}_7]_2(\text{SO}_4)$

Named in 1961 by Kravchenko et al. from the Yakut *Inneli*, the Inagli River. TRIC P1. $a = 14.76$, $b = 7.14$, $c = 5.38$, $\alpha = 90^\circ$, $\beta = 95^\circ$, $\gamma = 99^\circ$, $Z = 1$, $D = 4.08$. $15\text{--}71$: 6.31_5 5.36_5 3.92_{10} 3.04_6 2.95_6 1.964_6 1.845_6 1.735_6 . Structure: *SPC* 16:65(1971). Tabular crystals up to several centimeters. Polysynthetic twinning. Pale yellow to brown, vitreous to oily luster. Cleavage $\{010\}$, $\{110\}$, $\{101\}$, perfect; $\{001\}$, less so; brittle. $H = 5$. $G = 3.96$. Biaxial (+); $2V = 82^\circ$; $N_x = 1.726$, $N_y = 1.737$, $N_z = 1.766$; $Z = a$; $r > v$, strong. Pleochroic, $Z > Y = X$; pale yellow-brown to yellow. Anomalous blue interference colors. Nearly insoluble in acids. Found in pulaskites and aegirine-eckermannite-microcline pegmatites of the *Inagli massif*, Aldon region, and in shonkinite of the Yakutsk massif, southern Yakutia, Russia. AR *AM* 47:805(1962).

58.2.7.1 Samfowlerite $\text{Ca}_{14}\text{Mn}_3\text{Zn}_2(\text{Zn},\text{Be})_2\text{Be}_6[\text{SiO}_4]_6[\text{Si}_2\text{O}_7]_4(\text{OH},\text{F})_6$

Named in 1994 by Dunn *et al.* for Sam Fowler (1779–1844), a physician and pre-eminent figure in the history of the Franklin mining district. *MON* $P2_1/c$ $a = 9.068$, $b = 17.992$, $c = 14.586$, $\beta = 104.86^\circ$, $Z = 2$, $D = 3.31$. *PD* 2.86₁₀ 2.77₄ 2.65₅ 2.39₅ 2.27₃ 1.860₂ 1.832₃ 1.803₂. Structure: *CM* 32:43(1994). The SiO_4 and Si_2O_7 groups are isolated from one another but, together with tetrahedra occupied by beryllium and zinc, form layers roughly perpendicular to [100]. Colorless, white in aggregate, streak white, vitreous luster; cleavage not detected, but sample too small for verification of any cleavage. $H \leq 3$. $G = 3.28$. Biaxial (-); $2V = 29^\circ$; $N_x = 1.674$, $N_y = 1.680$, $N_z = 1.681$, $Y = b$, $X \wedge a = 44^\circ$, $Z \wedge c = 29^\circ$. Fluoresces very weak red in both LWUV and SWUV. Substitution of Be for Zn in a tetrahedral site is in a ratio varying from 5/8 to 3/8, suggesting that the substitution may be ordered and that the true symmetry is lower. Found as minute (0.05 mm) crystals in an andradite lined vug in franklinite-willemite ore at *Franklin, Sussex Co., N.J.* *AR CM* 32:43(1994).

58.3.1.1 Ardennite $(\text{Mn}^{2+}, \text{Ca}, \text{Mg})_4[(\text{Al}, \text{Fe}^{3+})_5\text{Mg}](\text{AsO}_4)_2(\text{Si}_3\text{O}_{10})(\text{OH})_6$

Named in 1872 by Lasaulx and Bettendorf for the locality. Ardennite group. Polytypic family includes ardennite, pumpellyite, sursassite, and one hypothetical structure type: four maximum-degree-of-order polytypes. At least two polytypes: "normal" 18.5-Å c (e.g., Alps—medium-grade metamorphic rocks), and new 37-Å c (e.g., Greece—low-grade metamorphic rocks); has both 18- and 37-Å polytypes with stacking faults present. *ORTH Pnmm*. $a = 8.692$ –8.730, $b = 5.811$ –5.828, $c = 18.521$ –18.560, $Z = 2$, $D = 3.67$ –3.72. 18-141(nat): 4.21₆ 3.76₅ 3.15₆ 2.91₇ 2.87₆ 2.57₁₀ 1.45₆ 2.245₅; 40-477(high-As): 4.28₁₅ 2.94₁₀ 2.61₇₅ 2.32₂₅ 2.26₁₅ 2.12₁₅ 2.02₂ 1.54₃; 41-1391: 3.18₃ 2.95₇ 2.91₇ 2.78₄ 2.60₁₀ 2.03₄ 1.61₃ 1.58₄ 1.46₅. The structure consists of chains of edge-sharing (Al, Mg, Fe^{3+})-octahedra connected by orthosilicate and trisilicate groups. A slightly larger tetrahedron is occupied by $\text{As}^{5+}(\text{V}^{5+})$ cations. Mn^{2+} , Ca^{2+} , and Mg^{2+} occur in the cavities of the structure in six- and sevenfold coordination. A mixed-anion silicate. Order-disorder built up from two different kinds of layers occurring in regular alternation. Linear groups of three Si-O tetrahedra (Si_3O_{10}) rather than double tetrahedra (like epidote). As and V are in an independent (As, V) O_4 tetrahedron. *AC(B)* 24:845(1968), 27:1871(1971). Prismatic blades and fibers, elongate along b , {101} dominant, crystalline aggregates and small rosettes of tapered acicular radiating crystals; to 7 mm long (New Zealand). Yellow to yellowish brown, black, yellow-green, pale golden yellow, orange; subadamantine luster. Cleavage {010}, perfect; {110}, distinct; {100}, good; very brittle. $H = 6$ –7. $G = 3.60$ –3.63. Nearly insoluble in acids. As content is variable. In Greek material, most of the As is replaced by Si. Greek material has Mn^{3+} and Mn^{2+} . Some V replaces As. One sample from Salm Chateau had 4.84 wt %

V_2O_5 and 4.14 wt % As_2O_5 . NZ material also has Mn^{2+} and Mn^{3+} ; most is Mn^{2+} . Traces of B_2O_3 (0.23 wt %) in material from Otago. Sanbagawa: CaO to 4.6 wt %, V_2O_5 to 7.3 wt %. Highest As_2O_5 from Salm-Chateau is 13.25% MgO, to 5.26 wt % from Kajlidongri, India. Biaxial (+); $Z = a$, X or $Y = b$; $N_x = 1.734\text{--}1.753$, $N_y = 1.735\text{--}1.753$, $N_z = 1.751\text{--}1.770$; 2V usually small but ranges from 0 to 70°; $r > v$ or $r < v$, strong; weakly to strongly pleochroic. X, brownish yellow; Y, golden yellow; Z, pale yellow (weak to strong). *MP 48:295(1993)* gives X parallel to b , Y parallel to a , and Z parallel to c . Vanadium-rich material from Sanbagawa, Japan has: $N_x = 1.798$ and $N_z = 1.822$. Occurs in low-pressure, low-temperature rocks; in oxidized Mn–Al-rich greenschist facies metasediments, shales, and quartz schists. Metamorphic pressure and temperature conditions span 300–400° and 2–14 kbar to 500–630° and 14–28 kbar. Associated minerals include quartz, spessartine, hematite, rutile, clinocllore, piemontite, and others. Also occurs in quartz veins. In Todilto limestone on a joint surface, with calcite and cuprosklowskite. Occurrences include: in Todilto limestone 20 miles NW of Grants, NM; Shepton Mallet, Somerset, England; best and most abundant material found at *Salm-Chateau*, also at Bihain, *Ardennes, Belgium*; Zermatt, Switzerland; Haute-Maurienne, French Alps, and Bonneval-sur-Arc, Savoie, France; Val d'Aosta, Ala Valley, Piedmont, Italy; Andros and Evvia Is., Greece; Kajlidongri mine, Jhabua district, Madhya Pradesh, India; Asemi-gawa area, Motoyama, Kochi Pref., and Ohnara, Sanbagawa, and Kamugawa, Gumma Pref., Shikoku, Japan; Arrow Junction, western Otago, New Zealand. *EF MIN 3(1):716(1972)*, *EJM 3:819(1991)*, *BNSM(C) 13:1(1987)*, *NJBA 158:89(1987)*.

58.3.1.2 Orientite $Ca_3Mn_{10}^{3+}[(SiO_4)_3(Si_3O_{10})_3(OH)_{10}] \cdot 4H_2O$

Named in 1921 by Hewett and Shannon for the locality. Ardenite group. ORTH *Bbmm* or *P2mm* [*AM 71:176(1986)*]. For *Bbmm*: $a = 9.074$, $b = 19.130$, $c = 6.121$, $Z = 4$, $D = 3.48$; for *P2mm*: $a = 9.044$, $b = 6.091$, $c = 19.031$. *NJBM:455(1989)*: $a = 6.094$, $b = 19.042$, $c = 9.026$. *41-589(calc pattern)*: 9.56₄ 4.78₄ 4.10₉ 3.97₁₀ 2.68₄ 2.61₅ 2.58₈ 2.45₄; *35-472(nat)*: 9.45₁₀ 4.74₁₀ 4.51₂₅ 4.39₁₅ 4.07₃₅ 3.27₃ 3.03₄₅ 2.70₁₅. See also *18-941*. Two structure refinements exist: *AM 70:171(1985)* and *AM 71:176(1986)*. Chains of edge-sharing Mn^{3+} octahedra run along [010] and are connected by (SiO_4) orthosilicate and (Si_3O_{10}) trisilicate groups. The mineral shows varying degrees of order. Some show $2c = 38$ Å, thus a new polytype. Thin to thick tabular parallel to {001} prisms and tabular grains. Dominant forms: {110}, {001}, {010}. Crystals to 1 mm in Italy; polysynthetic twinning. Deep red to brown, maroon; crystals are transparent reddish brown; brown streak; resinous–subvitreous luster. Cleavage or parting {001}, imperfect. $H = 4\frac{1}{2}\text{--}5$. $G = 3.33$. Soluble in hot HCl, with evolution of Cl and separation of residual insoluble silica; insoluble in HNO_3 . Manganese Lake material has 0.4–1.5 wt % V_2O_5 and Al_2O_3 is absent. Some Al_2O_3 and Fe_2O_3 in Oriente Prov. material. CuO is as high as 2.6 wt %, SO_3 is as high as 1.2 wt %. V^{5+} substitutes for Si^{3+} in tetrahedral coordination; Cu^{2+} substitutes for Mn^{3+} , and S substitutes for Si^{4+} . Italian

material has 0.89 wt % MgO, 0.4 wt % Al₂O₃. Biaxial (-); XYZ = bca; N_x = 1.756–1.765, N_y = 1.777–1.791, N_z = 1.794–1.810; 2V = 68–87°; birefringence = 0.038–0.045; OAP parallel to (001) and transverse to elongation, B × A perpendicular to (100); r < v, very strong; pleochroic. X, colorless to pale yellow; Y, reddish brown or yellow-brown; Z, deep red-brown. *NJBM:455(1989)*. *AM 46:226(1961)* gives X, red-brown; Y, yellow; Z, yellow-brown. The mineral is of low-temperature origin and low-alumina conditions, occurring with jasper, psilomelane, manganite, and barite. Occurs with manganite, braunite, macfallite, and pyrolusite, which replace calcite in fissures and lenses in Keweenaw Basalt at Lake Manganese, Copper Harbor, Keweenaw Co., MI; within volcanic breccias, tuffs, andesite, and latite at *Costa Manuel and Vicente claims, 6 miles S of Bueycito and at the Santa Rosa prospect, near Banos, Oriente Prov., Cuba*. In Mn-bearing metacherts of an ophiolite sequence at the Cerchiara mine, eastern Liguria, Italy, where the orientite is intergrown with macfallite or as lamellar intergrowths. *EF AM 46:226(1961)*.

58.3.2.1 Kilchoanite Ca₃[SiO₄][Si₃O₁₀]

Named in 1961 by Agrell and Gay for the locality. Dimorphous with rankinite (55.3.1.1). ORTH *I2cm*. *a* = 11.42, *b* = 5.09, *c* = 21.95, Z = 8, D = 3.002. *29-370(syn)*: 3.56₇ 3.07₈ 2.89₁₀ 2.68₉ 2.55₅ 2.49₅ 2.36₇ 1.964₇. Structure: *MM 38:26(1971)*. The structure contains insular [SiO₄] and insular [Si₃O₁₀] groups, in contrast with rankinite, which has only [Si₂O₇] dimers. Colorless to white, vitreous luster. G = 2.99. Biaxial (-); 2V = 60°; N_x = 1.647, N_{y,calc} = 1.649, N_z = 1.650; r > v. Anomalous interference colors. Found as a retrograde replacement of rankinite at *Kilchoan, Ardnamurchan, Scotland*; at Carlingford, County Louth, Ireland; *Hatrurim, Israel*; from a xenolith in the *Ozereskii gabbro, Priol'khonye, western Baikal, Russia*; at *Fuka, Bicchu-cho, Okayama Pref., Japan*; and at *Takatoka, New Zealand*. *AR NAT 189:743(1961)*, *DHZII 1B:272(1986)*.

Three-Membered Rings

BENITOITE GROUP

Benitoite and Catapleite structures conform to the formula

where

A = Ba, K₂, Na₂, K, Na, Ca

B = Ti, Zr, Sn

n = 0, 2, or 3

and the structure is similar or identical to the hexagonal bazirite structure. The structure of the benitoite group minerals consists of octahedrally coordinated quadrivalent cations that link (Si₃O₉) rings into an octahedral-tetrahedral framework with tubular one-dimensional cavities that contain the A cations. *NJBM:16(1987)*, *ZK 129:222(1969)*.

59.1.1.1 Bazirite BaZrSi₃O₉

Named in 1978 by Young for the composition. Benitoite group. $HEX P\bar{6}c2$. $a = 6.737\text{--}6.769$, $c = 9.997\text{--}10.020$, $Z = 2$, $D = 3.82$; (syn): $a = 6.755$, $c = 9.980$, $Z = 2$, $D = 3.85$. $29\text{--}214$ (syn): 5.82_4 3.79_{10} 3.38_4 2.92_{35} 2.80_{10} 2.21_{25} 2.01_{35} $1.60_{2.5}$. The structure is the same as that of benitoite. Octahedrally coordinated quadrivalent cations link (Si₃O₉) rings into an octahedral-tetrahedral framework with tubular one-dimensional cavities that contain the Ba cations. *NJBM:16(1987)*. {0001} + {1010}, crystals generally anhedral to subhedral, basal plates, prismatic; to 0.25 mm across and 0.65 mm long at Big Creek. Colorless. Cleavage {0001}, good. Fluoresces whitish blue in SWUV and shows bright blue cathodoluminescence under an electron beam. TiO₂ varies from 0.17 to 0.51%, also contains traces of Sn. Uniaxial (+); (nat): $N_O = 1.679$, $N_E = 1.688$; (syn): $N_O = 1.6751$, $N_E = 1.6850$; birefringence = 0.010. Occurs with celsian in metasediments, along with other Ba-silicates (CA); also with elpidite in an aegirine-riebeckite granite (Scotland). Occurs at Big Creek, Fresno Co., CA; La Madrelena mine, Tres Pozos, northern Baja California, Mexico; *Rockall Island, Inverness-shire, Scotland*. *EF MM 42:35(1978)*, *MIN 3(2):18(1981)*, *AM 69:358(1984)*.

59.1.1.2 Benitoite BaTiSi₃O₉

Named in 1907 by Louderback for the locality. Benitoite group. $HEX P6c2$. $a = 6.6409$, $c = 9.7579$, $Z = 2$, $D = 3.68$. $38\text{--}464$: 5.75_2 3.72_{10} 2.87_2 2.74_8 2.17_2 1.98_2 1.97_2 1.86_2 . Structure: *ZK 129:222(1969)*. Trigonal and hexagonal plates and platelets: {0001}, {0111}, {1011}, {1010}, {1012}, {10.1.9.10}. Rotation twins rare on {0001}. Blue to dark blue, also colorless and white (largest well-formed crystal is 5.6 cm across); rarely pink (to 2-mm crystals) or purplish blue; white streak; vitreous luster. Cleavage {1011}, imperfect; conchoidal to uneven fracture. $H = 6\frac{1}{2}$. $G = 3.64$. IR data: *TMPM 21:47(1974)*. Raman data: *JCS:1372(1969)*. Bright blue-white fluorescence under SWUV; cores fluoresce brighter than blue edges of crystals, colorless cores fluoresce dull red in LWUV and rims are nonfluorescent. Insoluble in HCl, but easily attacked by HF. Stannian benitoite with up to 4.1 wt % SnO₂ has been reported. White cores and blue rims are the same, but 0.05 wt % Fe present in deep blue material may be the chromophore. Uniaxial (+); $N_O = 1.756\text{--}1.757$, $N_E = 1.802\text{--}1.804$; strongly dichroic. O, colorless; E, deep blue to purplish blue. Occurs in natrolite with neptunite and joaquinite in hydrothermally altered serpentine (CA). Crossite inclusions are sometimes present. Occurs in pectolite in gas cavities in pseudoleucite syenite (AR). Occurs at the Diamond Jo quarry, Magnet Cove, AK; *Dallas gem mine (Victor claim), San Benito Co., CA*; Numero Uno mine (pink crystals) 6 miles W of Dallas gem mine; Rush Creek area, Fresno Co., CA (stannian benitoite); Esneux and Streupas, L'Ourthe Valley, Belgium (subsequently shown to be misidentified). Also found near Ohmi, Niigata Pref., Japan, Korea, and Texas. Used as a gemstone. Largest cut gem is 7.6 ct (USNM). Also used as a fluor-

escent standard for electron microprobes. EF *AM* 57:85(1972), *MR* 6:442(1977), *MIN* 3(2):15(1981), *LJ* 44:46, 61(1990).

59.1.1.3 Pabstite $\text{BaSnSi}_3\text{O}_9$

Named in 1965 for Adolph Pabst (1899–1990), American mineralogist, University of California, Berkeley. Benitoite group. HEX $P6c2$. (Nat): $a = 6.703$, $c = 9.824$, $Z = 2$, $D = 4.07$; (syn): $a = 6.7329$, $c = 9.8514$, $Z = 2$, $D = 4.16$ – 4.17 . 18-196(syn): 5.85₃₅ 4.93₂ 3.77₁₀ 3.37₅ 2.92₂ 2.78₉ 2.46₂ 1.99₃; 43-633(syn): 5.83₄ 3.76₁₀ 3.37₃ 2.92₂ 2.78₁₀ 1.99₂ 1.94₁ 1.88₁. Structure: *NJBM*:16(1987). Anhedral grains usually <2 mm, aggregates do not exceed 10 mm. Colorless to white, white streak, vitreous luster. $H = 6$. $G = 4.03$. Fluoresces bright blue in SWUV. Kalkar quarry sample: $\text{Ba}(\text{Sn}_{0.77}\text{Ti}_{0.23})\text{Si}_3\text{O}_9$. Uniaxial (-); $N_O = 1.685$, $N_E = 1.674$; nondichroic; birefringence = 0.011. Occurs in recrystallized siliceous limestone, associated with tremolite, witherite, Sn-bearing sulfosalts, phlogopite, diopside, and forsterite. Fracture filling and disseminated grains. *Kalkar quarry, Santa Cruz Co., CA*. EF *AM* 50:1164(1965), 69:358(1984).

59.1.1.4 Wadeite $\text{K}_2\text{ZrSi}_3\text{O}_9$

Named in 1939 by Prider for Arthur Wade (1878–1951), Australian geologist, who collected the mineral. Benitoite group. HEX $P6$ *SPC* 22:31(1977). $a = 6.926$ – 6.931 , $c = 10.177$ – 10.197 , $Z = 2$, $D = 3.11$. 35-31(syn): 5.99₈ 5.16₆ 3.88₈ 3.46₆ 2.96₈ 2.87₁₀ 2.55₅; 43-231: 6.00₄ 5.17₁ 3.89₅ 3.47₃ 3.28₂ 2.96₄ 2.87₁₀ 1.86₂. The structure is similar to that of benitoite, but in wadeite the $[\text{Si}_3\text{O}_9]$ rings do not superimpose in projection but alternately occupy different positions between the $[\text{ZrO}_6]$ octahedra to leave finite cavities for the remaining large cations. Hexagonal prismatic, tabular crystals with development of prism, basal pinacoid, and some pyramids; crystals to 3 cm in diameter at Mt. Yukspor. Colorless, light pink, lilac, white; white streak; vitreous luster. No cleavage, conchoidal fracture, brittle. $H = 5\frac{1}{2}$ – 6 . $G = 3.10$. IR data: *GZ* 36:54(1976). Shows bright blue cathodoluminescence. Nonmagnetic. Insoluble in hot acids. Contains minor TiO_2 . Uniaxial (+); $N_O = 1.624$ – 1.627 , $N_E = 1.653$ – 1.658 ; birefringence = 0.030. Occurs in leucite-bearing volcanic rocks at West Kimberly. In carbonatite veins in Kovdor massif; in albitized fenites. In nepheline syenite pegmatites on Mt. Yukspor. Partly replaced by calcite along pyramidal cleavage. Replaced by lepidomelane plus zircon or catapleiite at Mt. Yukspor. Also alters to ancylite and zeolites. Occurs at Middle Table Mt., Leucite Hills, WY; Mt. St.-Hilaire, QUE, Canada; Mts. Eveslogchorr, Marchenko, and Yukspor, Khibiny massif, and Kovdor massif, Kola Penin., and Murun massif, Aldan Shield, Yakutia, Russia; *Wolgidee Hills, West Kimberly area, WA, Australia*. EF *CM* 30:1153(1992), *CMP* 72:191(1980), *SPC* 22:31(1977).

59.1.2.1 Walstromite $\text{Ca}_2\text{BaSi}_3\text{O}_9$

Named in 1965 for Robert E. Walstrom (b.1920), American mineral collector, who discovered the mineral. See the Pb analog, margarosanite (59.1.2.3). TRIC $P\bar{1}$. *ZK 130:185(1969)* (syn, reduced cell): $a = 6.723$, $b = 9.616$, $c = 6.733$, $\alpha = 83.01^\circ$, $\beta = 77.67^\circ$, $\gamma = 69.62^\circ$, $Z = 2$, $D = 3.73$; *AM 50:314(1965)* (nat): $a = 6.743$, $b = 9.607$, $c = 6.687$, $\alpha = 69.8^\circ$, $\beta = 102.2^\circ$, $\gamma = 97.1^\circ$; $Z = 2$. *18-162(nat)*: 6.58_2 4.40_2 3.35_2 3.20_2 3.06_2 2.99_{10} 2.78_2 2.70_2 . A ring structure with Si_3O_9 rings. *AM 53:9(1968)*. Grains are from <1 to 15 mm, 3 mm average, equigranular crystals to 1.5 cm, best forms are $\{010\}$, $\{100\}$, $\{011\}$. White or colorless; white to colorless streak; subvitreous luster, pearly on cleavage surfaces. Cleavage $\{011\}$, $\{010\}$, perfect; $\{100\}$, less perfect. $H = 3\frac{1}{2}$. $G = 3.67$. IR data: *MZ 1:3(1979)*. SWUV, faint pink; LWUV, distinct pink or pinkish orange, also white and cream reported for SWUV and LWUV. Easily soluble in cold dilute acid with production of a silica gel, no reaction with bases. Contains traces of Mn, Sr, and Al. Biaxial (-); $N_x = 1.668$, $N_y = 1.684$, $N_z = 1.685$; $2V = 30^\circ$; colorless; weak dispersion. Occurs in metamorphosed metasediments. Associated with sanbornite, wollastonite, celsian, taramellite, pyrrhotite, pyrite, fresnoite, and many other Ba-silicates. In metasomatic rocks. A major constituent in some of the rocks of *Big Creek and Rush Creek areas, Fresno Co., CA*. *EF MIN 3(2):33(1981)*, *AM 69:358(1984)*.

59.1.2.2 Margarosanite $\text{Pb}(\text{Ca},\text{Mn})_2\text{Si}_3\text{O}_9$

Named in 1916 by Ford and Bradley from the Greek for *pearl* and *tablet*, in allusion to its luster and habit. See the Ba analog, walstromite (59.1.2.2). TRIC $P\bar{1}$. $a = 6.768$, $b = 9.575$, $c = 6.718$, $\alpha = 110.36^\circ$, $\beta = 102.98^\circ$, $\gamma = 83.02^\circ$, $Z = 2$, $D = 4.31$. *ZK 128:213(1969)*. Also, $a = 6.77$, $b = 9.64$, $c = 6.75$, $\alpha = 110.6^\circ$, $\beta = 102^\circ$, $\gamma = 88.5^\circ$, $D = 4.30$. *AM 48:698(1963)*. *27-79(calc pattern)*: 6.59_8 5.10_8 4.38_6 3.22_5 3.18_6 3.05_8 3.03_9 2.99_{10} ; *16-356(nat)*: 5.08_3 3.20_3 3.16_3 3.03_5 2.98_{10} 2.69_3 2.67_4 2.61_3 . Structure: *ZK 128:213(1969)*. Aggregates of flat plates or rarely in stalklike to spikelike crystals to 2 mm thick and 2 cm in diameter. Colorless, white streak, pearly luster on faces of cleavage flakes. Cleavage $\{010\}$, perfect; $\{100\}$, good; $\{001\}$, fair. $H = 2\frac{1}{2}$ -3. $G = 4.33$. IR data: *MZ 1:3(1979)*. Mn-bearing material from Franklin fluoresces pink to red or orange in SWUV; usually vivid blue-white SWUV fluorescence according to *MR 22:273(1991)*. Decomposes in HNO_3 with separation of silica. MnO to 2.2 wt %. Biaxial (-); $N_x = 1.727$ -1.729, $N_y = 1.771$ -1.773, $N_z = 1.798$ -1.807; colorless; $2V = 78$ - 83° ; $r < v$, strong. Occurs in metamorphosed Precambrian Mn deposits at *Franklin, Sussex Co., NJ*, particularly the Parker shaft and on North Mine Hill; also at Langban, and Jakoberg, Varmland, Sweden. *EF AM 49:781(1964)*, *MIN 3(2):35(1981)*, *MM 49:721(1985)*.

59.2.1.1 Umbite $\text{K}_2\text{ZrSi}_3\text{O}_9 \cdot \text{H}_2\text{O}$

Named in 1983 by Khomyakov et al. for Lake Umba, 20 km from the locality. Compare dimorph kostylevite (59.2.1.3) ORTH $P2_12_12_1$. $a = 10.208$,

$b = 13.241$, $c = 7.174$, $Z = 4$, $D = 2.79$. 35-709(nat): 6.56₆ 5.91₉ 3.31₇ 3.02₁₀ 2.87₈ 2.16₄ 1.80₈ 1.55₄. Wollastonitelike infinite chains of (Si₂₊₁O₉) with four chains bonded to one Zr-octahedron. DAN SSSR 257:622(1981). Platy, flattened on b with dominant forms: {010}, {101}, {110}, {011}. Colorless, yellow; vitreous luster. Cleavage {010}, micaceous; {100}, less perfect. $H = 4\frac{1}{2}$. $G = 2.79$. IR and thermal data: ZVMO 112:461(1983). In UV, shows a weak yellow-white photoluminescence. It is bright whitish green at the temperature of liquid nitrogen; readily decomposed by cold HCl (10%), leaving a silica skeleton. Analysis (wt %): SiO₂, 42.36; K₂O, 22.41; ZrO₂, 22.28; HfO₂, 0.43; TiO₂, 3.33; Fe₂O₃, 0.12; Na₂O, 0.16; CaO, none; H₂O, 5.03; F, 2.00. Biaxial (-); XYZ = cba ; $N_x = 1.596$, $N_{y,calc} = 1.610$, $N_z = 1.619$; $2V = 80^\circ$. Occurs in the Vuonnemiok River Valley, Khibiny massif, Kola Penin., Russia; intergrown with kostylevite and wadeite. In alkalic pegmatite. EF

59.2.1.2 Paraumbite K₃Zr₂HSi₆O₁₈ · nH₂O

Named in 1983 by Khomyakov et al. for the close structural similarity to umbite, with a and b nearly identical and c twice that of umbite. See umbite (59.2.1.1). ORTH Space group unknown. $a = 10.34$, $b = 13.29$, $c = 14.55$, $Z = 4$, $D = 2.63$. P2/cm 35-710(nat): 6.46₈ 5.95₁₀ 4.06₅ 3.34₇ 3.01₉ 2.90₇ 2.56₆ 1.83₅. Plates (pseudohexagonal); 1-2mm in sodalite xenoliths at Mt. St.-Hilaire. Colorless to very pale yellow, white to tan; white streak; vitreous to pearly luster on cleavage planes. Cleavage {010}, micaceous; {100}, less perfect. $H \approx 4\frac{1}{2}$. $G = 2.59$. Readily decomposed by cold 10% HCl. Analysis (wt %): SiO₂, 39.6; K₂O, 15.4; Na₂O, 0.1; CaO, none; ZrO₂, 27.9; HfO₂, 0.3; TiO₂, 0.9; Fe₂O₃, 0.1; H₂O, 15.73 (diff.); $n = 7$, but the calculated density corresponds to $n = 3$. Biaxial (-); XYZ = cba ; $N_x = 1.588$, $N_y = 1.601$, $N_z = 1.610$; $2V = 82^\circ$. Occurs in alkalic pegmatites along with K-feldspar and eudialyte. Eudialyte is partly replaced by wadeite, gaidonnayite, and paraumbite. Alteration: some possibly are pseudomorphs after lovozerite. Mt. St. Hilaire, QUE, Canada; Mt. Eveslogchorr, eastern Khibiny massif, Kola Penin., Russia. EF ZVMO 112:461(1983).

59.2.1.3 Kostylevite K₂ZrSi₃O₉ · H₂O

Named in 1983 by Khomyakov et al. for Yekaterina Eutikhievna Kostyleva-Labuntsova (1894-1974), Russian mineralogist. Compare the dimorph umbite. MON. P2₁/a. $a = 13.171$, $b = 11.727$, $c = 6.565$, $\beta = 105.26^\circ$, $Z = 4$ (ZVMO 112:469(1983)) $D = 2.79-2.82$; PD 37-459 (nat.): 6.42₅ 5.86₃ 5.60₆ 5.24₃ 3.34₅ 3.09₁₀ 2.86₃ 2.80₅. Structure: DAN SSSR 256:860(1981), AM 69:812(1984). Colorless, transparent; streak white, elongated on c , dominant forms: {001}, {010}, {100}, {011} + {110}; twinning on (100); vitreous; cleavage = (110) perfect; $H \approx 5$, $G = 2.74$; readily decomposed by cold 10% HCl. 2.06% TiO₂, SiO₂ 42.01%, ZrO₂ 23.90%, HfO₂ 0.61%, Fe₂O₃ 0.02%, K₂O 22.14%, $\Sigma 90.74$, Na + Ca absent. Biax. (+), $2V = 48^\circ$, $N_\alpha = 1.595$, $N_\beta = 1.598$, $N_\gamma = 1.610$; $X = b$, $Y \wedge c = 45^\circ$; dispersion = $r < v$ weak. Occurs

in the Vuonnemiok River Valley, eastern Khibiny Massif, Kola Peninsula, Russia, in alkalic pegmatite, intergrown with umbite and wadeite; assoc. with eudialyte, aegirine, and others.

59.2.2.1 Catapleiiite $(\text{Na,Ca},\square)_2\text{ZrSi}_3\text{O}_9 \cdot 2\text{H}_2\text{O}$

Named in 1850 by Weibye and Sjogren from the Greek for *wholly* and *full*, because it is always accompanied by a number of rare minerals. Benitoite group. See the dimorph, gaidonnayite (59.2.2.3). Forms a solid solution with calcium catapleiiite. MON (pseudo-HEX, pseudo-ORTH) $B2/b$. $a = 23.917$, $b = 20.148$, $c = 7.432$, $\gamma = 147.46^\circ$, $Z = 8$, $D = 2.79$. *SPC 26:808(1981)*. Also given as $I2/c$. $a = 12.779$, $b = 7.419$, $c = 20.157$, $\beta = 90.41^\circ$; (syn, stable above 140°): $a = 7.388$, $c = 10.068$. $14\text{-}297(\text{nat})$: 6.35₆ 5.37₅ 3.05₁₀ 2.96₁₀ 2.69₉ 1.97₆ 1.85₄. The structure is identical to that of wadeite: the $[\text{ZrSi}_3\text{O}_9]$ framework. In the hexagonal wadeite structure, the cavity occupied by Na is much too large to contain Na at special positions on the threefold axis, so the symmetry decreases to monoclinic. *SPC 26:808(1981)*. Forms present: {001} {100}, {103} {102}, {101}, and so on, tabular to platy crystals, generally lamellar, tabular parallel to {001}, pseudo-hexagonal edges are bound by a prism and one or more pyramids; from millimeter size to rosettes 15 cm in diameter; polysynthetic twinning, six twin laws reported, most common have the twin plane (1010) or {0001}. Tan to beige to pale gray, gray-green, brown to colorless; small crystals are pale yellow, pale orange, pink, and very pale blue-white; vitreous luster, adamantine on base. Cleavage {1010}, perfect; {1011}, {1012}, imperfect; conchoidal fracture; brittle. $H = 5\text{--}6$. $G = 2.60\text{--}2.79$. Thermal and spectral data: *DHZ 1B:364(1986)*. Dissolves in all strong acids without gelatinizing. May have >6% CaO. Trace to minor K_2O , minor FeO; $2\text{Na} \leftrightarrow \text{Ca}$; REE, and Nb_2O_5 may be present. Uniaxial (+) or biaxial (+) and (-); $N_x = 1.582\text{--}1.603$ (calcium catapleiiite), $N_y = 1.582\text{--}1.618$, $N_z = 1.600\text{--}1.639$ (calcium catapleiiite); birefringence $0.018\text{--}0.036$; $2V_z = 0\text{--}60^\circ$; most catapleiiites are (+); $Z \wedge c = 4^\circ$ in obtuse β , $Y = b$, in biaxial crystals, OAP = (010); for (-) crystals, $X = c$. For (+) crystals, Z is almost perpendicular to (001). When heated, monoclinic lamellae disappear, but reappear when cooled; $r < v$, weak. Occurs in alkaline igneous rocks and is a relatively common minor constituent in nepheline syenite pegmatites and veins. It is rarely a primary mineral and usually occurs as an alteration product of eudialyte. Occurs as pseudomorphs after dalyite and vlasovite at Strange Lake. Magnet Cove complex, Hot Springs Co., AR; Rocky Boy Stock, Bearpaw Mts., MT; Wind Mountain, Otero Co., NM; the best and largest (to >2 cm across and 15 cm long) crystals in the world are found at Mt. St.-Hilaire, QUE (this mineral and serandite are the most sought after); Strange Lake complex, QUE-LAB, Canada; Kangerdlugssuaq, eastern Greenland, and Narssarssuk, Julianehaab district, Greenland; *Låven Island, Langesundfjord area, and Bratthagen, Norway*; primary crystals from Norra Kärr complex, Sweden; Kukisvumchorr, Khibiny massif, and Lovozero massif, Kola Penin., Vishnevye Gor (Cherry Mountain), Ural Mts., and Tuva

and Aldan shields, Yakutia, Russia; 20 km N of Zomba, Chilwa Prov., Malawi; Madagascar. Minor use as a gemstone. *EF MIN 3(2):24(1981)*, *MR 21:284(1990)*, *CM 30:191(1992)*.

59.2.2.2 Calcium Catapleiiite (Ca, \square) $\text{ZrSi}_3\text{O}_9 \cdot 2\text{H}_2\text{O}$

Named in 1964 by Portnov for the composition and relationship to catapleiiite. Benitoite group. *HEX* Space group unknown, possibly $P6_3$ *mmc*. $a = 7.32$, $c = 10.15$, $Z = 2$, $D = 2.79$. *16-371(nat)*: 6.45₇ 5.40₆ 3.96₈ 3.06₈ 2.96₁₀ 1.98₈ 1.84₈ 1.74₇. The structure involves replacement of four Na atoms by two Ca atoms and two vacancies. Light yellow, yellowish white, pale yellow-cream, white; white streak; vitreous to dull luster; opaque. Cleavage present. $H = 4\frac{1}{2}$ 5. $G = 2.77$. IR and thermal data: *DAN SSSR 154:607(1964)*. Analysis (wt %), Strange Lake: SiO_2 , 44.5; ZrO_2 , 30; HfO_2 , 0.9; Al_2O_3 , 0.5; CaO , 11.0; FeO , 0.2; PbO , 0.9; Na_2O , 0.7; Burpala massif: SiO_2 , 44.5; ZrO_2 , 31.0; TiO_2 , 0.06; Al_2O_3 , 0.60; Fe_2O_3 , 0.36; CaO , 13.82; REE_2O_3 , 0.28; Na_2O , 0.32; K_2O , 0.10; H_2O^+ , 9.15; H_2O^- , 0.18. A Pb-bearing (to 11.4 wt % PbO) catapleiiite occurs as cores to rims of calcium catapleiiite at Golden Horn. Uniaxial (+); $N_0 = 1.603$, $N_E = 1.639$. Occurs at Strange Lake as a replacement of earlier-formed Zr minerals, especially vlasovite. Also occurs as euhedral grains rimmed by gittinsite. In evolved granite. In syenite pegmatites at Burpala, in cavities between microcline. In miarolitic cavity in arfvedsonite granite at Golden Horn. Occurs in the Washington Pass area, Golden Horn batholith, Okanogan Co., WA; Strange Lake complex, QUE-LAB, and with edingtonite from Ice River, BC, Canada; as Ca-rich rims on catapleiiite from Norra Karr, Sweden; and Burpala massif, northern Baikal area, Siberia, Russia. *EF DHZ 1B:364(1986)*, *CM 30:191(1992)*.

59.2.2.3 Gaidonnayite (Na, K) $_2\text{ZrSi}_3\text{O}_9 \cdot 2\text{H}_2\text{O}$

Named in 1974 by Chao and Watkinson for Gabrielle Hamburger Donnay (1920–1987), crystallographer and mineralogist, McGill University, Montreal. Benitoite group. See the dimorph, catapleiiite (59.2.2.1). Georgechaoite is the K analog. *ORTH* $P2_1nb$. $a = 11.740$ – 11.778 (potassian), $b = 12.820$ – 12.842 (potassian), $c = 6.691$ – 6.693 (potassian), $Z = 4$, $D = 2.70$. *39-353(potassian)*: 6.45₄ 5.90₈ 5.64₆ 3.12₁₀ 2.95₇ 2.83₄ 2.50₄ 1.90₄; *26-1387(regular)*: 6.42₃ 5.93₈ 5.84₈ 5.63₅ 4.31₃ 3.12₁₀ 3.09₈ 2.93₄. Powder data for K-Ca gaidonnayite: *DAN SSSR 320:1220(1991)*. Cell parameters vary linearly with K content between gaidonnayite and georgechaoite. *NGT 71:303(1991)*. Structure: *CM 23:11(1985)*. Crystals equant, blocky, tabular, and wedge-shaped, rhombic, pyramidal to 4 mm across, often striated parallel to [001], dominant forms: {010}, {120}, {011}, {100}, {001}; usually in intergrown, stacked spherical groups and druses; twinning common, [012]_{180°}, one individual appears to be rotated 90° about [100] relative to the other. White, colorless, pale yellow, to very pale brown, pale gray, gray-green; white streak; adamantine to vitreous luster. No cleavage observed, conchoidal fracture, brittle. $H = 5$. $G = 2.67$. Thermal data: *CM 12:316(1974)*. Fluoresces bright

green under SWUV and LWUV (Mt. St.-Hilaire and Norway); some nonfluorescent material has also been found. No cathodoluminescence. Gelatinizes in acids. Analysis (wt %), Potassian: Na₂O, 9.4; K₂O, 6.1; CaO, 2.1; SiO₂, 42.6; ZrO₂, 29.7; H₂O, 10.1 (Na_{1.23}K_{0.53}Ca_{0.15})_{1.91}Zr_{0.98}Si_{2.87}O_{8.73} · 2.26H₂O; minor TiO₂ substitutes for Zr, to 1.8% TiO₂; Norway: TiO₂, 1.36; Nb₂O₅, 0.68; ZnO, 0.10; Narsarsuk: CaO, 0.4; TiO₂, 0.6; Nb₂O₅, 0.9; Mt. St.-Hilaire: Na₂O, 13.1; K₂O, 2.2; SiO₂, 42.5; ZrO₂, 30.2; TiO₂, 0.42; Nb₂O₅, 3.00; H₂O, 9.25. Biaxial (-); XYZ = abc; N_x = 1.570–1.575, N_y = 1.590–1.593, N_z = 1.596–1.605; 2V = 53–59°. Occurs at *Mt. St.-Hilaire, QUE, Canada*, in altered pegmatites and rarely in miarolitic cavities in nepheline syenite and breccia cavities; also in an igneous sill in limestone. In eudialyte-rich pegmatite lenses in the Kipawa syenite complex, Villedieu Twp., Temiscamingue Co., QUE, as a late-stage alteration product of vlasovite. In a vein of aegirine syenite at Narsarsuk, southern Greenland; in nepheline syenite pegmatite at Brønnebukta, Siktesøya, Langesundfjord, Oslo region, Norway; Vuorijarvi, Karelia, Mt. Alluaiev and Mt. Karnasurt, Lovozero massif, Mt. Yukspor and Mt. Evslogchorr, Khibiny massif, Kola Penin., and K-Ca-gaidonnayite at Mt. Mannepakh, northwestern Khibiny massif, Russia; 5- to 6-mm crystals of gaidonnayite at Pocos da Caldas, MG, Brazil. *EF MIN 3(2):556(1981), GSCP 83-1A:480(1983), DANS ESS 321A:111(1994).*

59.2.2.4 Georgechaoite KNaZrSi₃O₉ · 2H₂O

Named in 1985 by Boggs and Ghose for George Y. Chao (b.1930), Canadian mineralogist. Benitoite group. See the Na analog, gaidonnayite (59.2.2.3). ORTH P2₁nb. *a* = 11.836, *b* = 12.940, *c* = 6.735, Z = 4, D = 2.69. 39-315(nat): 6.46₇ 5.95₇ 5.83₃ 5.67₅ 3.12₁₀ 2.89₂ 2.83₂ 2.20₂. Isostructural with gaidonnayite, Na₂ZrSi₃O₉ · 2H₂O. Georgechaoite shows Na/K ordering of 1:1. *CM 23:5(1985)*. Crystals to 1 mm long, forms: {010}, {011}, {100}, {100}, {101}, {101}, {120}; twinning [023]₁₈₀ observed, interpenetration twins, with a half-turn about [023], *a* axes of the two individuals are parallel, *b* axis of one individual is 14° to the *c* axis of the second. Colorless to white, white streak, vitreous luster. No cleavage, chonchoidal fracture. H = 5. G = 2.70. No UV response. Biaxial (-); XYZ = abc; N_x = 1.578, N_y = 1.597, N_z = 1.606; 2V = 67°. Associated with microcline, nepheline, analcime, aegirine, chlorite, catapleite, and monazite in miarolitic cavities in Ne-syenite at *Wind Mt., Otero Co., NM*. What has been reported [*DAN SSSR 320:1220(1991)*] as K-Ca gaidonnayite occurs as a rim of brown fine-grained aggregate around eudialyte and sometimes forms complete pseudomorphs of eudialyte; in a pegmatite vein on Mt. Mannepakh, northwestern Khibiny massif, Kola Penin., Russia. The material is fine-grained and turbid; colors are patchy from light to dark reddish brown. H = 2. Further work needs to be done on better material to confirm the identity of the mineral. *EF CM 23:1(1985)*.

59.2.2.5 Loudounite $\text{NaCa}_5\text{Zr}_4\text{Si}_{16}(\text{OH})_{11} \cdot 8\text{H}_2\text{O}$

Named in 1983 by Duan and Newbury for the locality. Not indexed, no cell data given. *35-573*(nat): 7.37₆ 5.81₅ 4.56₃ 4.06₇ 3.53₄ 2.93₁₀ 2.69₄. No structure determination or single-crystal work possible. Spherules of radiating, fibrous crystals; average spherule diameter is 0.05 mm. Have overgrowths of ancyllite. Light green, white, translucent; colorless. $H = 5$. $G = 2.48$. Luminescence: no response. Analysis (wt %): SiO_2 , 45.8; Al_2O_3 , 0.8; FeO , 2.0; MgO , 0.3; CaO , 12.1; ZrO_2 , 25.7; Na_2O , 0.2; H_2O , difference from 100.0. Biaxial with wavy extinction; $N_x = 1.536$, $N_z = 1.550$; nonpleochroic; optical orientation scheme not determined; length-slow. Associated with actinolite, chlorite, epidote, stilbite, and ancyllite in diabase. Loudounite crystallized last. Occurs at the *Goose Creek quarry, Loudoun Co.*, and at the *Fairfax quarry, Centerville, Fairfax Co., VA.* EF *CM 21:37(1983)*.

59.2.3.1 Hilairite $\text{Na}_2\text{ZrSi}_3\text{O}_9 \cdot 3\text{H}_2\text{O}$

Named in 1974 by Chao et al. for the type locality. Benitoite group. *HEX-R R32*. $a = 10.556$, $c = 15.855$, $Z = 6$, $D = 2.73$. *26-975*(nat): 6.0₆ 5.28₁₀ 3.17₅ 3.05₄ 2.99₃ 2.64₃ 2.03₃ 1.76₄. The structure consists of spiral $[\text{Si}_3\text{O}_9]$ chains rather than $[\text{Si}_3\text{O}_9]$ rings parallel to c and polyhedra of cations connecting tetrahedra in the chains. Cavities contain Na^+ and H_2O . The Na sites are partially vacant in hilairite but are fully occupied in the REE analog. *DAN SSSR 260:1118(1981)*, *SPC 37:845(1992)*. Usually short, to elongated prisms $\{1120\}$ terminated by the $\{0112\}$ rhombohedron; 0.5- to 4-mm crystals, many doubly terminated; twinning frequent on two laws: $[2201]_{180^\circ}$ and $[0001]_{180^\circ}$; may be multiply twinned according to both laws. Usually pale to dark brown, also pink or rose; white streak; vitreous to waxy luster; translucent, rarely transparent. No cleavage observed, conchoidal fracture, brittle. $H > 4$. $G = 2.72$. Nonfluorescent. Slightly attacked by 1:1 HCl and HNO_3 but not by 1:1 H_2SO_4 . At Strange Lake, some limited solid solution occurs with calciohilairite. At Mt. St.-Hilaire, minor K and Ca substitute for Na. Uniaxial (-); $N_O = 1.609$, $N_E = 1.596$. Occurs in the *Demix and Poudrette quarries, Mt. St.-Hilaire, QUE, Canada*, as an accessory mineral in miarolitic cavities and in some altered pegmatite veins, usually associated with gaidonnayite, elpidite, natrolite, microcline, aegirine, pyrite, rutile, and zircon; and as interstitial anhedral grains in granite of the Strange Lake complex, QUE-LAB. In hydrothermally altered pegmatites at Langesundfjord, Norway; in the Lovozero massif, Kola Penin., Russia. EF *CM 12:237(1974)*, *30:191(1992)*; *MZ 2:95(1980)*; *MIN 3(2):32(1981)*.

59.2.3.2 Calciohilairite $\text{CaZrSi}_3\text{O}_9 \cdot 3\text{H}_2\text{O}$

Named in 1988 by Boggs as the Ca analog of hilairite. Benitoite group. *HEX-R R32*. $a = 20.870$ -20.90, $c = 16.002$ -16.05, $Z = 24$, $D = 2.71$ -2.74. *AM 73:1191(1988)*. *41-1456*(nat): 5.99₁ 5.23₁₀ 3.20₁ 3.14₂ 3.01₃ 2.90₁ 2.61₁ 1.98₁. Structure not yet determined. Dominant forms: $\{1120\}$, $\{2\bar{1}10\}$, $\{1012\}$, $\{0112\}$, blocky, trigonal prisms; to 2 mm long; no twinning observed. Pale

blue to chalky white, white streak, vitreous luster. No cleavage, conchoidal fracture. $H = 4$. $G = 2.68$. Nonluminescent. Analysis (wt %): Na_2O , 0.2; CaO , 11.1; CuO , 0.65; FeO , 0.19; SiO_2 , 40.0; ZrO_2 , 32.6; TiO_2 , 0.06; Al_2O_3 , 1.3; H_2O , 13.8. Uniaxial (-); $N_O = 1.622$, $N_E = 1.619$. Occurs in miarolitic cavities in peralkaline granite near Liberty Bell Peak, Washington Pass area, in the *Golden Horn Batholith, northern Cascades, WA*. Associated with bastnaesite-(Ce) and malachite, quartz, and feldspar. EF

59.2.3.3 Sazykinaite-(Y) $\text{Na}_5\text{YZrSi}_6\text{O}_{18} \cdot 6\text{H}_2\text{O}$

Described in 1993 by Khomyakov et al. and named for Lyudmila Borisnova Sazykina (b.1934), Russian mineralogist and artist (using semi-precious and precious stones). The mineral is the Y-dominant analog of hilairite and calchihlairite. It is also related to komkovite. *HEX-R R32*. $a = 10.825$, $c = 15.809$, $Z = 3$, $D = 2.74$. *ZVMO 122:76(1993)*: 6.03₃ 5.40₆ 3.24₈ 3.13₉ 3.03₁₀ 2.71₂ 2.02₂ 1.805₂. Structure done ($R = 3.4\%$). *DAN SSSR 37(6):158(1992)* and *SPC 37:845(1993)*. Two alkali positions [i.e., $\text{Na}_2(\text{Na},\text{K})_3$]. Rhombohedral crystals from 0.5 to 2.0 mm across, and as complex grains showing $\{01\bar{1}2\}$. Light green to yellow, white streak, vitreous luster. Cleavage $\{0112\}$, imperfect; steplike fracture, fragile. $H = 5$. $G = 2.67$. IR, and thermal data given. Fluoresces green in UV light. Stable in water but readily soluble in 10% HCl and HNO_3 . Analysis (wt %): Na_2O , 15.2; K_2O , 3.05; Y_2O_3 , 8.7; Ce_2O_3 , 0.2; Nd_2O_3 , 0.25; Sm_2O_3 , 0.4; Eu_2O_3 , 0.2; Gd_2O_3 , 1.0; Tb_2O_3 , 0.2; Dy_2O_3 , 1.3; Er_2O_3 , 0.8; Tm_2O_3 , 0.2; Yb_2O_3 , 0.6; ThO_2 , 0.7; ZrO_2 , 10.2; TiO_2 , 1.4; SiO_2 , 40.5; Nb_2O_5 , 1.3; H_2O , 12.6. Solid solution of $\text{Y}^{3+} + \text{Na} \leftrightarrow \text{Zr}^{4+}$ is assumed. Uniaxial (-); $N_E = 1.578$, $N_O = 1.585$. Occurs in pegmatites of Koashva Mt., Khibiny alkaline massif, Kola Penin., Russia, intergrown with labuntsovite and associated with aegirine, natrolite, alkali feldspars, pectolite, alkali amphibole, astrophyllite, lomonosovite, and sphalerite. EF

59.2.4.1 Komkovite $\text{BaZrSi}_3\text{O}_9 \cdot 3\text{H}_2\text{O}$

Named in 1990 by Voloshin et al. for A. I. Komkov (1926–1987), Russian mineralogist and crystallographer. *HEX-R R32* [*DAN SSSR 320:1384(1991)*], *R3* [*ZVMO 122:76(1993)*]. $a = 10.526$, $c = 15.736$, $Z = 6$, $D = 3.31$. *42-1398(nat)*: 5.23₁₀ 3.59₈ 3.02₈ 2.96₉ 2.57₆ 2.10₆ 1.700₅ 1.55₅. Structure: *DAN SSSR 320:1384(1991)*. Equant 1–5 mm across with trigonal pyramidal faces. Brown, light brown streak, vitreous luster. No cleavage, parting on (001). $H = 3-4$. $G = 3.31$. IR and DTA data: *MZ 12:69(1990)*. Nonfluorescent, light blue cathodoluminescence. Analysis (wt %): BaO , 29; CaO , 0.04; MnO , 0.1; FeO , ≈ 0.2 ; K_2O , 0.1; ZrO_2 , 25; HfO_2 , ≈ 0.2 ; SiO_2 , 34; H_2O , ≈ 11 . Uniaxial (-); $N_O = 1.671$, $N_E = 1.644$. Occurs in carbonatites of *Vuorijarvi, Kola Penin., Russia*, in dolomite veinlets that cut pyroxenites, associated with dolomite, strontianite, phlogopite, barite, georgechaoite, and pyrite; apparently formed by alteration of catapleite. EF

Four-Membered Rings

JOAQUINITE GROUP

The joaquinite group minerals are titanosilicates conforming to the formula

where

R = Na, Fe, Ba, Ce, Sr, Mn

The structure is based on a fundamental element consisting of rings of four silicon-oxygen tetrahedra linked to octahedrally coordinated titanium to form sheets of $[Ti(Si_4O_{12})]^{4-}$ parallel to {001}. The group may be divided into two polymorphic types, monoclinic and orthorhombic. *AM 60:872(1975)*.

JOAQUINITE GROUP—JOAQUINITE SUBGROUP: MONOCLINIC

Mineral	Formula	Space Group	a	b	c	β	
Joaquinite-(Ce)	NaFe ²⁺ Ba ₂ Ce ₂ (Ti, Nb) ₂ [Si ₄ O ₁₂] ₂ O ₂ (OH, F) · H ₂ O	C2	10.516	9.686	11.833	109.67	60.1.1a.1
Strontio-joaquinite	(Na, Fe ²⁺) ₂ Ba ₂ Sr ₂ Ti ₂ [Si ₄ O ₁₂] ₂ (O, OH) ₂ · H ₂ O	C2	10.516	9.764	11.87	109.28	60.1.1a.2

JOAQUINITE GROUP—ORTHOJOAQUINITE SUBGROUP: ORTHORHOMBIC

Mineral	Formula	Space Group	a	b	c	
Orthojoaquinite-(Ce)	NaFe ²⁺ Ba ₂ Ce ₂ Ti ₂ [Si ₄ O ₁₂] ₂ O ₂ (OH) · H ₂ O	Ccmm	10.48	9.66	22.26	60.1.1b.1
Strontio-orthojoaquinite	(Na, Fe ²⁺) ₂ Ba ₂ Sr ₂ Ti ₂ [Si ₄ O ₁₂] ₂ (O, OH) ₂ · H ₂ O	Pbcm	10.517	9.777	22.392	60.1.1b.2
Bario-orthojoaquinite	Fe ₂ ²⁺ (Ba, Sr)Ti ₂ [Si ₄ O ₁₂] ₂ O ₂ · H ₂ O	Ccmm	10.477	9.599	22.59	60.1.1b.3
Byelorussite-(Ce)	NaMn ²⁺ Ba ₂ Ce ₂ Ti ₂ [Si ₄ O ₁₂] ₂ O ₂ (F, OH) · H ₂ O	Ccmm	10.492	9.640	22.266	60.1.1b.4

Note: The orthorhombic subgroup is related to the monoclinic by a transformation of cell coordinates such that $c_o \approx 2c_m \sin \beta$. The *a* and *b* axes have also been interchanged in some species, to maintain correspondence with the monoclinic subgroup.

60.1.1a.1 Joaquinite-(Ce)

Named in 1909 by Louderback for the type locality. Joaquinite group. Dimorphous with orthojaquinite-(Ce). MON C2. $a = 10.516$, $b = 9.686$, $c = 11.833$, $\beta = 109.67^\circ$, $Z = 2$, $D = 4.11$. 36-385: 4.44₇ 3.57₅ 3.30₅ 3.11₈ 2.95₉ 2.89₈ 2.78₁₀ 2.42₅. Structure: AM 60:872(1975). Honey-yellow, orange, brown; vitreous luster. Brittle. $H = 5-5\frac{1}{2}$. $G = 3.62-3.98$. Biaxial (+); $2V \approx 50^\circ$; $N_x = 1.754$, $N_y = 1.767$, $N_z = 1.823$; $XZ = ac$; $r < v$. Pleochroic, $Z > X = Y$; light yellow to colorless. Indices may be lower due to isomorphous substitution. Found at the Diamond Jo quarry, Magnet Cove, AR; as equant crystals up to 3 mm with benitoite, neptunite, and massive natrolite at *Joaquin Ridge, Diablo Range, San Benito Co., CA*, and at the Dallas Gem and Numero Uno mines in the same county; at Mt. St.-Hilaire, PQ, and with eudidymite and barylite at Seal Lake, Labrador, NF, Canada; near Kvanefjeld, Ilimaussaq, Greenland. AR AM 52:1762(1967), 57:85(1972).

60.1.1a.2 Strontiojoaquinite (Na,Fe²⁺)₂Ba₂Sr₂Ti₂[Si₄O₁₂]₂(O,OH)₂·H₂O

Named in 1982 by Wise for the composition and relationship to joaquinite-(Ce). Joaquinite group. Dimorphous with strontio-orthojaquinite. MON C2 (also reported as Primitive). $a = 10.516$, $b = 9.764$, $c = 11.87$, $\beta = 109.28^\circ$, $Z = 2$, $D = 3.68$. 36-384: 4.47₄ 4.30₃ 3.01₅ 2.97₇ 2.92₄ 2.80₁₀ 2.61₄ 2.43₄. Green to yellow-green, brown; vitreous luster. Cleavage {001}, good. $H = 5\frac{1}{2}$. $G = 3.68$. Biaxial (+); $2V = 35-45^\circ$; $N_x = 1.710$, $N_y = 1.718$, $N_z = 1.780$; $r > v$, strong. As small pseudo-orthorhombic crystals with {110}, {111}, and {001} at the *Numero Uno mine, San Benito Co., CA*. AR AM 67:809(1982).

60.1.1b.1 Orthojaquinite-(Ce) NaFe²⁺Ba₂Ce₂Ti₂[Si₄O₁₂]₂O₂(OH)·H₂O

Named in 1982 by Wise from symmetry and relationship to its dimorph, joaquinite-(Ce). Joaquinite group. ORTH Ccmm or Ccm 2₁. $a = 10.48$, $b = 9.66$, $c = 22.26$, $Z = 4$, $D = 4.14$. 26-1034: 4.43₉ 3.29₆ 3.05₄ 2.98₄ 2.94₁₀ 2.89₈ 2.61₆ 1.866₅. Light brown, vitreous luster. Cleavage {001}, good. $H = 5\frac{1}{2}$. Biaxial (+); optical properties like those of joaquinite-(Ce). Found intergrown with joaquinite-(Ce) at the *Dallas Gem mine, San Benito Co., CA*, and other nearby localities. AR AM 57:85(1972), 67:809(1982).

60.1.1b.2 Strontio-orthojaquinite (Na,Fe²⁺)₂Ba₂Sr₂Ti₂[Si₄O₁₂]₂(O,OH)₂·H₂O

Named in 1982 by Wise in keeping with its dimorph, strontiojoaquinite; earlier described but not named in 1974 by Chihara et al. Joaquinite group. ORTH Pbcm or Pbc 2 (*Pca** in original setting). $a = 10.517$, $b = 9.777$, $c = 22.392$, $Z = 4$, $D = 3.87$. PD: 5.60₃ 4.47₃ 2.97₄ 2.80₁₀, 2.61₄ 2.44₃ 2.43₂ 2.24₃. Light yellow, translucent. Cleavage {001}, good. $H = 5\frac{1}{2}$. $G = 3.62$. Optical proper-

ties not given; presumably similar to those of strontiojoaquinite. Occurs associated with other members of this group in *San Benito Co., CA*. Earlier described but not named from *Ohmi, Niigata Pref., Japan*. AR *MJJ 7:395(1974)* AM *67:809(1982)*.

60.1.1b.3 Bario-orthojoaquinite $\text{Fe}_2^{2+}(\text{Ba,Sr})_2\text{Ti}_2[\text{Si}_4\text{O}_{12}]_2\text{O}_2 \cdot \text{H}_2\text{O}$

Named in 1982 by Wise for the composition and relationship to joaquinite-(Ce). Joaquinite group. ORTH *Ccmm* or *Ccm* 2. $a = 10.477$, $b = 9.599$, $c = 22.59$, $Z = 4$, $D = 4.14$. *36-386*: 5.64₇ 4.30₆ 3.20₅ 3.00₁₀ 2.95₉ 2.94₇ 2.82₉ 2.60₅. Bipyramidal, equant crystals to 8 mm with {111} and {001} prominent. Yellow-brown, vitreous luster. Cleavage {001}, good. $H = 5-5\frac{1}{2}$. $G = 3.96$. Biaxial (+); $2V = 10-15^\circ$; $N_x = 1.735$, $N_y = 1.757$, $N_z = 1.80$; $XYZ = abc$; pleochroic, $Z > Y > X$; very pale yellow to yellow. Found in association with joaquinite-(Ce), benitoite, and natrolite at the *Dallas Gem mine, San Benito Co., CA*. AR *AM 67:809(1982)*.

60.1.1b.4 Byelorussite-(Ce) $\text{NaMn}^{2+}\text{Ba}_2\text{Ce}_2\text{Ti}_2[\text{Si}_4\text{O}_{12}]_2\text{O}_2(\text{F,OH}) \cdot \text{H}_2\text{O}$

Named in 1989 by Shpanov et al. for the type locality. Joaquinite group. ORTH *Ccmm* or *Ccm* 2. $a = 10.492$, $b = 9.640$, $c = 22.266$ (a and b transposed from structure description), $Z = 4$, $D = 4.15$. Originally reported as $P2_12_12_1$. $a = 10.57$, $b = 9.69$, $c = 22.38$, $Z = 4$, $D = 4.09$. *PD*: 4.42₆ 4.29₄ 3.30₄ 3.00₇ 2.95₆ 2.91₅ 2.78₁₀ 2.61₅. Structure: *ZK supp. 4:321(1991)*. Pale yellow to pale brown, vitreous luster. Cleavage {001}, perfect; {010}, imperfect; {100}, very imperfect. $H = 5\frac{1}{2}-6$. $G = 3.92$. Biaxial (+); $2V = 58-62^\circ$; $N_x = 1.743$, $N_y = 1.760$, $N_z = 1.820$; $XYZ = abc$. Very weakly pleochroic, $Z > Y \approx X$; colorless to very pale yellow. In metasomatized granosyenite of the *Zhitkovitscheskii horst, Homel district, Belarus (Byelorussia)*. AR *ZVMO 118(5):100(1989)*, AM *76:665(1991)*.

60.1.2.1 Baotite $\text{Ba}_4\text{Ti}_4(\text{Ti}^{4+}, \text{Nb}^{5+}, \text{W}^{6+})_4\text{Si}_4\text{O}_{28}\text{Cl}$

Named in 1959 by Peng as Pao-T'ou-K'uang (baotite by Semenov in 1961) for the locality. TRT $I4_1/a$. $a = 19.92-20.02$, $c = 5.908-6.02$, $Z = 4$, $D = 4.33$. *39-390*: 3.55₈ 3.34₅ 3.17₉ 2.89₇ 2.50₇ 2.24₁₀ 1.77₆ 1.33₆. There are two Ti sites, nonequivalent: $\text{Ba}_{4-x}\text{Ti}_4(\text{Ti}, \text{Ni}, \text{W})_{4-x}\text{Si}_4\text{O}_{28}\text{Cl}$. Vacancies exist in the Ba site and one Ti site. $2\text{Ti}^{4+} \leftrightarrow \text{Nb}^{5+} + \text{M}^{3+}$, $3\text{Ti}^{4+} \leftrightarrow \text{W}^{6+} + 2\text{M}^{3+}$, also $\text{Ti}^{4+} + \text{Ba}^{2+} \leftrightarrow \text{W}^{6+} + \square$. $\text{M}^{3+} = \text{Fe}^{3+}$, Al, Cr. Al can replace tetrahedral Si. Structure consists of $[\text{Si}_4\text{O}_{12}]$ rings and (Ti,Nb) octahedral chains. *K 14:602(1969)*. Crystals are short, equant with {110} and {011} dominant; 0.8-4 mm (MT); masses to 10 cm in China. Light brown to black, vitreous luster. Two cleavages at (110), two directions at 90° ; hackly fracture; brittle. $H = 6$. $G = 4.71-4.72$. IR data: *MZ 1:3(1979)*. As much as 6 wt % WO_3 (Pierrefitte, France); Nb is very low in French and Czech material. Nb_2O_5 to 11.5 wt % (Mongolia), Ta_2O_5 to 2.0 wt %; Czech: SiO_2 , 15.7; TiO_2 , 41.5; trace to minor amounts of Na, K, Mg, Ca, Al, Fe. Uniaxial (+);

$N_O = 1.94\text{--}1.944$, $N_E = 2.16$ to > 2.20 ; $E > O$ (Mongolia); strongly dichroic. O, brown, greenish yellow, or colorless; E, dark brown to nearly black, greenish brown, dark brownish to greenish yellow. Diamagnetic. Occurs in a base metal orebody as an accessory mineral included in alstonite and celsian, associated with common sulfides. In quartz veins with albite, aegirine, bastnaesite, and sulfides related to a monzonite intrusion at Bayan-Obo. In carbonatite (MT) with other Nb-bearing species. In metasomatites in Russia, in alkaline dikes. Occurs at Sheep Creek, Ravalli Co., MT; Dallas Gem mine, San Benito Co., CA; W-bearing material at the Garaoulere mine, Pierrefitte, Pyrenees, France; Sebkovice, western Moravia, Czech Republic and at Karlstein and Jarolden, Waloviertel, Austria, in the Bohemian massif, Czech Republic; at two unspecified localities in the western Ural Mts. and in Primorye, Russia; high-Nb bearing at *Bayan-obo REE deposit, Baotou, inner Mongolia, China*. EF *MIN 3(2):44(1981)*, *NDM 30:106(1982)*, *NJBM:31(1987)*, *MP 45:19(1991)*.

60.1.3.1 Nenadkevichite (Na,K,Ca,Ba,Mn)(Nb,Ti)(Si₂O₆)(O,OH) · 2H₂O and K-dominant analogue

Named in 1955 by Kuzmenko and Kazakova for Konstantin Antonovich Nenadkevich (1880–1963), Russian mineralogist and geochemist. Labuntsovite (Ti)–nenadkevichite series (Nb). In some samples, Ti > Nb; such material has been called “titanonenadkevichite.” Na is always > K stoichiometrically. ORTH *Pbam*. $a = 7.328\text{--}7.408$, $b = 14.123\text{--}14.198$, $c = 7.115\text{--}7.148$, $Z = 4$, $D = 2.70\text{--}2.81$. *37-484(nat)*: 7.11₁₀ 6.50₄ 5.01₄ 3.26₉ 3.18₅ 3.12₃ 2.55₄ 1.73₄. Columns formed by (Nb,Ti) octahedra with shared transvertices. The octahedral columns are linked by tetrahedral four-membered rings [Si₄O₁₂]. The statistically distributed K, Na ions and water molecules are located in the channels of the mixed framework. *AC(B) 29:1432(1973)*; *EJM 6:503(1994)*. Prismatic and tabular {100}, {010}, {011}; elongated on *c*; single crystals to 3 cm long and 4 mm thick. Colorless, white, pale pink, rose-pink, yellow, orange, and brownish red; pale pink, white streak; vitreous to pearly or dull luster. Cleavage {001}, fair; uneven fracture. Brittle. $H \approx 5$. $G = 2.73\text{--}2.97$. IR and thermal data: *MIN 3(2):64(1981)*. Readily soluble in H₂SO₄, difficultly soluble in HCl + HNO₃. Biaxial (+); $XYZ = abc$, $N_x = 1.633\text{--}1.665$, $N_y = 1.642\text{--}1.686$, $N_z = 1.738\text{--}1.785$; $2V = 19\text{--}46^\circ$; OAP = (010); pleochroic, pale rose to colorless, also brownish. X, colorless; Y, pale yellow; Z, pale rose. Occurs in altered and unaltered pegmatites and very rarely in cavities in marble xenoliths and igneous breccia at Mt. St.-Hilaire. An alteration product of epistolite. In alkaline pegmatites in Kola Penin., Russia. At Mt. St.-Hilaire, and the St.-Amable sill, Varennes, QUE, Canada; Ilimaussaq, southern Greenland; Gjerdingen, Norway; several locations in the Khibiny massif (e.g., Mt. Mannepakh), and at *Vein No. 1, Mt. Karnasurt, Lovozero massif, Kola Penin., Russia*; also in the Jubilee pegmatite on Mt. Karnasurt and Mt. Flor, Lovozero massif. EF *NJBM:49(1986)*, *MT(1989)*.

POTASSIUM ANALOGUE OF NENADKEVICHITE:

ORTH. *Fmmm*. $a = 14.72\text{\AA}$, $b = 14.20\text{\AA}$, $c = 27.87\text{\AA}$, $Z = 4$. Systematic extinctions show that the mineral can be considered as a superposition of two monoclinic diffraction patterns with a monoclinic axis parallel to axis 'b' in an orthorhombically twinned lattice and with C-centering of each monoclinic cell (*NJBM 103(1996)* and *EJM 6:503(1994)*). Colorless, transparent, mm-sized aggregates of platy/bladed crystals parallel to {001}; crystals are ≤ 0.05 mm, sometimes epitaxially overgrown on elpidite; {010}, {001}, {101} common, {012} rare, morphologically orthorhombic. Na_2O 3.75, CaO 1.04, K_2O 6.53, BaO 1.28, Ce_2O_3 0.41, Nb_2O_5 35.8, TiO_2 2.54, SiO_2 35.5, Al_2O_3 0.23, H_2O 13.4 (calc. by stoichiometry). Biax. (+), $2V_z = 55-65^\circ$, $2V_z(\text{calc.})$: 58° ; $r < v$, (Na light): $N_\alpha = 1.6386$, $N_\beta = 1.6474$, $N_\gamma = 1.7680$; $X = c$, $Y = b$, $Z = a$. The optical orientation is different from what is generally accepted for nenadkevichite: $X = a$, and $Z = c$. Occurs at Mont Saint-Hilaire, Quebec, Canada; associated with K-feldspar, aegirine, eudialyte, quartz, neptunite, elpidite, ancylite, epididymite, polyolithionite, and pyrochlore at Narssarsuk pegmatite, westernmost margin of the Igaliko complex, South Greenland; Gjerdingen, Norway; in carbonatites at Vuorijarvi, Kola Peninsula, Russia.

60.1.3.2 Labuntsovite $(K,Na,Ba)_8(Ti,Nb)_8(SiO_3)_{16}(O,OH)_{10} \cdot xH_2O$ ($x \approx 7$)

Named in 1926 by Labuntsov and described as titanoelpidite; renamed in 1955 by Semenov and Burova in honor of Aleksandr Nikolaievich Labuntsov (1884–1963) and his wife, Ekaterina Eutikhieva Labuntsova-Kostyleva, Russian mineralogists. Synonym: titanoelpidite. See nenadkevichite (60.1.3.1), the Nb end member (much more abundant at Mt. St.-Hilaire than labuntsovite). MON *C2/m*; possibly ORTH *I2/m*. $a = 15.33-15.57$, $b = 13.70-13.93$, $c = 14.14-14.33$, $\beta = 116.95-117.12^\circ$, $Z = 2$, $D = 2.87$ or 2.68 (using ideal formula and unit cell dimensions). *9-498(nat)*: 3.15_{10} 3.09_8 2.56_9 2.47_7 1.78_7 1.68_8 1.54_9 1.41_9 . A question still exists about exact symmetry. Structure needs to be redetermined. *SPC 18:596(1974)*. May be orthorhombic. *MZ 3:49(1981)*. Exact formula is also still uncertain. Prismatic to acicular on [001], sometimes flattened; crystals to $12\text{ mm} \times 3\text{ mm} \times 2\text{ mm}$, dominant forms: {001}, {110}, {011}, {010}, and {111}; spherulites to 3 cm; sometimes twinned. Pale to deep orange, rose to brownish yellow, red; white to pale orange streak; adamantine to vitreous luster. Cleavage {102}, perfect; subconchoidal fracture; brittle. $H = 6$. $G = 2.8-3.02$. IR data show presence of H_2O , H_3O^+ , and OH^- . DTA data: *MZ 3:49(1981)*. Dissolves with difficulty in HCl, HNO_3 , or H_2SO_4 , readily soluble in HF. Analysis (wt %): SiO_2 , 39.6; Al_2O_3 , 1.3; Fe_2O_3 , 1.56; Nb_2O_5 , 1.45; TiO_2 , 25.5; MgO , 0.42; MnO , 2.34; CaO , 1.19; BaO , 8.61; K_2O , 7.23; Na_2O , 3.18; H_2O , 7.91 (Lovozero). Na may be greater than K stoichiometrically, and in some samples, K may be $> Na$: potash labuntsovite. *MZ 3:49(1981)*, *MIN 3(2):68(1981)*. Nb_2O_5 to 7.27 wt

%. Biaxial (+); $Z \wedge c = 63^\circ$, $Y = b$, $X \wedge a = 27^\circ$ in the obtuse angle, $Z = c$; $N_x = 1.684\text{--}1.688$, $N_y = 1.693\text{--}1.698$, $N_z = 1.804\text{--}1.839$; $2V = 20\text{--}41^\circ$; $r > v$, distinct; OAP = (010), $Z > Y > X$; pleochroic. X, colorless or yellowish; Y, orange-yellow; Z, brownish yellow, lemon yellow, or colorless. Occurs in cavities in igneous breccia zones and in nepheline syenite and hornfels at Mt. St.-Hilaire; occasionally as epitactic overgrowth on elpidite. In druses in Khibiny (e.g., Mts. Nyorkpakh and Koashva; S. M. Kirov mine) and Lovozero massifs, associated with aegirine, nepheline, eudialyte, lorenzenite, and others. A hydrothermal alteration product of murmanite. Also in carbonatites at Kovdor; at Cape Turiy, Kola Penin. Sometimes alters to anatase. Associated with barite, gypsum, aegirine, and microcline in syenite at the Diamond Jo quarry, Magnet Cove, AR; in Green River formation at Trona, WY; Mt. St.-Hilaire, QUE, Canada; several locations in the *Khibiny massif*: Mt. Manepakh, Mt. Kukisvumchorr, and others, also in the Nyorkpakh quarry on Suoluai Mt. and on Mt. Yukspor (above the Hackman Valley); K-rich material on Mt. Evslogchorr, Kola Penin., Russia; Lovozero massif: Mt. Kuftnion, Mt. Karnasurt, Mt. Sengischorr, and several others; Kovdor massif carbonatites; Turi Cape, Kola Penin., Vuorijarvi, Karelia, Murun massif, Yakutia, and central Aldan Shield, Yakutia, Siberia, Russia. EF

60.1.4.1 Papagoite $\text{CaCu}^{+2}\text{AlSi}_2\text{O}_6(\text{OH})_3$

Named in 1960 by Hutton and Vslidis for the Papago Indian tribe that once inhabited the region in which the mining center of Ajo, AZ is situated. MON. $C2/m$. $a = 12.94\text{\AA}$, $b = 11.52\text{\AA}$, $c = 4.68\text{\AA}$, $\beta = 100.5^\circ$, $Z = 4$, $D = 3.24$; PD 13-372 (nat.): 6.33₇ 4.61₇ 4.29₉ 3.85₇ 3.44₈ 2.87₁₀ 2.80₈ 2.20₉. Structure: R = 22%! (*BM 88:119(1965)*). Needs to be redetermined. Cerulean blue; very pale blue streak, equidimensional crystals < 1 mm long, slightly flattened || to {001} with faces in the zone [010] well developed. Elongated || b , all faces in the zone [010] are striated || to the zone axis; cleavage = distinct, || to (100); H 5-5 $\frac{1}{2}$; G 3.25; TGA data (*AM 45:599(1960)*); partly soluble in boiling conc. HCl. Traces of Fe, Mn, etc. Biax. (-), $2V = 78^\circ$, $N_\alpha = 1.607$, $N_\beta = 1.641$, $N_\gamma = 1.672$; pleochroism strong: X = colorless to very pale greenish blue, Y = blue, Z = deep greenish blue; $X \wedge c = 44^\circ$, $x \wedge a = 35^\circ$, both in acute β , $Y \wedge c = 46^\circ$, Y to the perpendicular to (001) is $\approx 36^\circ$, $Z = b$; absorption, $Z > Y > X$. Dispersion = very faint $R > V$. Occurs at the *New Cornelia mine*, Ajo, Pima Co., AZ; with ajoite in metasomatically altered quartz-albite rock; dark blue inclusions in quartz crystals from the Messina mines, notably the no. 5 shaft, RSA. EF *Minerali 3(2):74(1981)*.

60.2.1.1 Kainosite-(Y) $\text{Ca}_2(\text{Y,Ce})_2\text{Si}_4\text{O}_{12}(\text{CO}_3) \cdot \text{H}_2\text{O}$

Named in 1886 by Nordenskiöld from the Greek for *unusual*, in allusion to the composition: a silicate with CO_3 . Synonym: cenosite. ORTH *Pmnb*. $a = 13.011$, $b = 14.310$, $c = 6.757$, $Z = 4$, $D = 3.54$. *NJBM 4:153(1989)*. 14-332(nat): 4.83₅ 3.45₇ 3.29₈ 3.19₈ 2.76₁₀ 2.17₇ 2.11₅ 1.93₆. The Ca and (Y,REE) polyhedra form large, alternating sheets along b . The connection, by shared edges and

corners of the polyhedra, forms large "hexagonal" holes in which the Si_4O_{12} rings and CO_3 groups are accommodated in the (001) plane across the (010) sheets. Y and Ca independently occupy two crystallographic sites. Prismatic on [001] to 8 mm, rarely to 2 cm long. {001}, {100}, {010} pinacoids and {110} prism. Elongated on *c*, also flattened on {100}; 3–5 mm long at Mt. St.-Hilaire, to several centimeters from Norway. Pale yellowish brown-brown, sometimes colorless or white, also rose-pink; white, pale rose-pink, or pale brown streak; vitreous–greasy luster, pearly on some faces. Cleavage at 90° , (100) and (010); sometimes no cleavage is developed; uneven to subconchoidal fracture; brittle. $H = 5-5\frac{1}{2}$. $G = 3.52$. IR data: *MIN 3(2):54(1981)*, *DAN SSSR 294:948(1987)*. Nonfluorescent. Soluble in acids. In HCl, gives off CO_2 . Often contains minor Na. Biaxial (-); XYZ = *cba*; $N_x = 1.658-1.667$, $N_y = 1.681-1.689$, $N_z = 1.683-1.692$; $2V = 40^\circ$; $r < v$, weak to moderate; non-pleochroic. Most often occurs in granitic pegmatites or alpine veins; also in skarns. In cavities in breccia at Mt. St.-Hilaire, and in granite at Baveno, Italy, and Golden Horn batholith, WA. Associated with quartz–feldspar–zinnwaldite; with diopside, clinocllore, magnetite, and apatite at Nordmark in an iron mine. In thorium–quartz veins at Porthill, ID. May form from yttrialite, also as pseudomorphs after yttrialite. Occurs in granite with kamphaugite-(Y) at Mount Desert Is., ME; in dikes on SR30 N of Long Lake village, NY; with epidote, fluorite, calcite and quartz; also found with calcite in galena mines at Rossie, NY; in the Cotopaxi skarn, Fremont Co., CO; at Porthill, Boundary Co., ID; the Golden Horn batholith, Okanogan Co., WA; very rare at Mt. St.-Hilaire, QUE, North Burgess Twp., Lanark Co., and Bicroft and Grayhawk mines, Bancroft, ONT, and in the Strange Lake Complex, Quebel-Labrador, Canada; *Igeltjern, Hitterö Island, Norway*; Ko mine, Nordmark, Varmland, Sweden; Mt. Blanc massif, Chamonix, Haute-Savoie, France; Baveno, Novara, Italy; Grimsel region, Aar massif, Switzerland; also in the Gotthard massif; crystals to 2 cm in the Curnera Valley, Switzerland; Itkinsk massif, western Tuva, Russia. *EF AM 49:1736(1964)*, *CM 8:1(1964)*, *DAN SSSR 294:948(1987)*.

Six-Membered Rings

BERYL GROUP

The beryl group consists of beryllium, magnesium, and iron aluminosilicate minerals. The general formula is

where

A = Be, Mg, Fe

B = Al, Sc, Fe

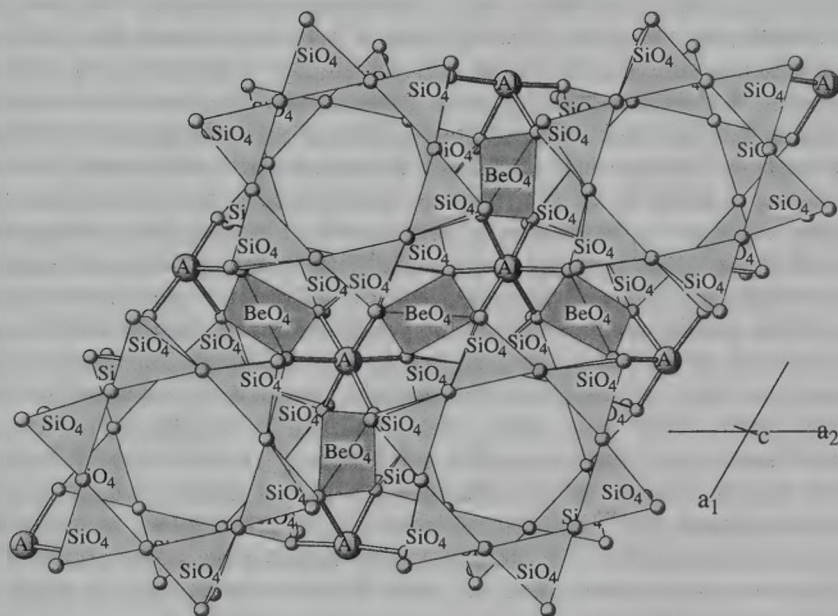

and where the mineral crystallizes in a hexagonal or in a closely related orthorhombic space group.

The principal features of the beryl structure are hexagonal rings made up of six Si-O tetrahedra. The rings have their centers on sixfold axes and are stacked above one another. Within the rings, two of the oxygen atoms in each SiO₄ are shared by the SiO₄ groups on either side, thus giving the meta-silicate ratio SiO = 1:3. The unit cell has reflection planes parallel to the base at heights of 0, *c*/2, and *c*. The hexagonal rings lie with the silicon atoms and shared oxygen atoms on these planes: between them lie Al and Be atoms, each Al coordinated with an octahedral group of six oxygen atoms on a distorted tetrahedron. In these positions they link the oxygen atoms of the Si₆O₁₈ rings, and the whole structure is linked laterally and vertically. The structure is like a honeycomb with open channels parallel to the *c* axis; no atomic center is nearer than 2.55 Å to the centers of these channels. Large alkali cations and water molecules, if present, are contained within the channels. *DHZ 1B:372(1986)*.

BERYL-CORDIERITE GROUP

Note: Indialite, cordierite, and sekaninaite are also referred to as α -cordierite, cordierite-(Mg), and cordierite-(Fe), respectively.

BERYL: $\text{Al}_2\text{Be}_3\text{Si}_6\text{O}_{18}$

61.1.1.1 Beryl $\text{Be}_3\text{Al}_2\text{Si}_6\text{O}_{18}$

Named from the Greek *beryllos*, an ancient name that was applied to many green minerals; its original significance is unknown. Beryl group. $\text{hex } P6/mcc$. $Z = 2$, $D(\text{syn}) = 2.64$, for ideal synthetic: $a = 9.208$, $c = 9.175$; natural range: $a = 9.17 - 9.28$, $c = 9.14 - 9.254$. $9-430(\text{nat})$: 7.98₉ 4.60₅ 3.99₅ 3.25₁₀ 3.01₄ 2.87₁₀ 2.52₃ 1.99₂. High-iron (6.2 wt % Fe_2O_3) beryl has $a = 9.28$, $c = 9.18$, with a significantly different powder pattern. *NJBM:193(1993)*. For: [A] $\text{X}_3\text{Y}_2\text{T}_6\text{O}_{18}$ A = \square , H_2O , OH, Na, Ca, Fe^{2+} , K, Cs, Rb, Li(?); X = B3, Al, Li, Si; Y = Al, Fe^{2+} , Mg, Fe^{3+} , Ca, Mn^{2+} , Cr^{3+} , V^{5+} , Te^{4+} , Sc; T = Si. Recent structure determinations include *CM 29:271(1991)* and *AM 78:762(1993)*. The silicate rings have a minimal opening of ~ 2.8 Å. The void between two

stacked rings is maximally $\sim 5.1 \text{ \AA} \times 5.1 \text{ \AA}$ in (0001) and $\sim 4.59 \text{ \AA}$ along *c*. The channels (A sites) within the silicate rings are ideally vacant, but alkalis, water, CO₂, and so on, can enter the site. Water and large cations such as Cs, Rb, or K occupy the central volume between adjacent rings while smaller substituents such as Na or OH occupy the minimum aperture of single rings. Additionally, water can show two orientations within the channels. *AM 53:777(1968), 69:319(1984)*. Three types of substitution are distinguished: (O) octahedral substitution of Al, (T) tetrahedral substitution of Be, and (N) limited T and O substitution. *AM 73:826(1988)*. Octahedral Al deficiency is common with divalent substitutions resulting in A site occupancy for charge compensation. Li substitution for Be in X sites appears to be inversely related to Y-site occupancy by Al (i.e., high-Al beryl tends to have significant substitution of Be by Li, while low-Al beryl tends to have X fully occupied by Be). *AM 73:826(1988)*. Al and Si may substitute in the tetrahedral Be and Si sites. *NJBM:121(1994)*. **Physical properties:** Usually tan to pale green, or pale blue, white, ideally uncolored, sky blue yellow to brown, orangy pink to rose pink, emerald green, red to purplish red, and rarely black, color names/chromophore for gem varieties include: goshenite (uncolored); aquamarine (historically green {Fe²⁺} or blue {Fe²⁺ and Fe³⁺, in channel sites and substituting for Al}; modern usage favors blue only), golden beryl or heliodor (yellow, amber, brown {Fe³⁺}), morganite (= vorobeyevite) (salmon {photosensitive} to pink {Mn²⁺}); emerald (rare vibrant green color) {usually Cr³⁺ dominant, but can have V³⁺ dominant}; blue aquamarine can be produced by heating green aquamarine; "maxixe" beryl is a blue alkali beryl, for which the cause of color is not clearly known, but may be due to CO₃⁻ color centers and/or gamma irradiation of Cs in the beryl. Color zoning frequently observed. Cleavage (0001), poor; twinning {3141}, {1120}, rare; {4041}, doubtful; brittle. *H = 7 $\frac{1}{2}$ -8*, rarely as low as ~ 7 . *G = 2.63-2.78* rarely ranging to 2.92 [high alkalis, *DHZIB(1986)*]. Insoluble in common acids, not very soluble in HF. Soluble in NaOH or KOH. Soluble in NaOH or KOH. Spectral data (IR, NMR, Raman, and others): *DHZIB:372(1986), CM 32:55(1994)*. May fluoresce white in SWUV and/or LWUV light, and the fluorescence appears to be related to primary crystal growth. Beryl crystals are ordinarily columnar hexagonal prisms with [1010] dominant in combination with a basal pinacoid {0001}. Dominant forms include {0001}, {1010}, {1011}, {1121}, with the second order prism {1120} being common only for some emeralds. Pyramidal faces are generally small. Crystals from gem pockets in evolved pegmatites can be complexly terminated and modified by a variety of pyramidal faces, commonly {1121} and {1011}; also by second order and dihexagonal prisms. Such crystals (particularly those with a high alkali content) often have a tabular habit, being greatly flattened on *c*. Etch pits, growth features on faces, dissolution tubes, and so on, are common. Pegmatite crystals frequently reach 1 m, with one crystal of 18 m \times 3.5 m (Malakialina). Organized clusters of beryl crystals are rare: in one locality in MG, Brazil, terminated crystals (to

5 cm × 1 cm) forming partly spherical clusters of well-terminated individuals. Three-dimensionally dendritic emeralds ("trapiche") from Mina Peña Blanca, Muzo (not Chivor), Colombia, were described. *AM 55:416,1808(1970)*. **Chemistry:** The BeO content of ideal beryl is 13.96 wt %, but contents between 12.5 and 13.2 wt % are common, with a low amount of 9.6 wt % due to alkali (Cs₂O to 6.7 wt %, Na₂O to 2.5 wt %, K₂O to 2.9 wt %, Li₂O to 1.3 wt %) and other substitutions. Beryls, especially from granite pegmatite miarolitic cavities, frequently have rims richer in alkalis with a consequent increase in the indices of refraction. Color zoning sometimes observed due to trace chromophores. Alkali substitution in beryl is limited to one per six Si or one divalent ion over the two octahedral sites, while Be ↔ Li is limited to 0.333 Li. *AM 73:826(1988)*. Chemical substitutions in beryl are generally either octahedral or tetrahedral; any resulting charge imbalances of one site preclude valence change in the other. Water average about 2 wt % and a maximum of about 4 wt % can be present up to one molecule per six Si: pegmatite beryl generally having 0.3–0.6 per six Si with a maximum observed in a beryl (Altai Mts.) of 0.9 H₂O. Only the red beryls from Utah rhyolite are virtually anhydrous. Observed total alkalis can amount to over 11 wt %. *CM 11:714(1973)*. Trace elements include Co, Ni, Cu; other components (wt %): P₂O₅, to 3.60; B₂O₃, to 0.39; WO₃, to 0.39; ZrO₂, 0.80; Nb₂O₅, 1.75; Ta₂O₅, to 0.72; TiO₂, 0.05; MnO, to 0.75; Sn, 1; also CO₂, He, Ar: emerald (0.14–>1.2 wt % Cr₂O₃, generally 0.2–0.3 wt % [*EP(1989)*]); some emeralds colored by as much as 0.9 wt % V₂O₃; aquamarine (0.1–0.3 wt % FeO + Fe₂O₃). FeO can be as high as 2.2 wt %, but generally under 0.5; Fe₂O₃ has been observed to 6.2 wt % but is generally under 1 wt %. MgO may be as much as 3.2 wt %. Red beryl contains elevated amounts of Fe, Mn, Ti, Cs, and other elements. *GG 20:208(1984)*. Sc can be present in sufficient quantity, resulting in the species bazzite, but Sc is generally a trace element (less than 0.1 wt %) and intermediate beryl–bazzite specimens are almost unknown. Intrachannel cation exchangeability is known. *CM 27:663(1989)*. Many studies of beryl synthesis indicate beryl stability in saturated H₂O conditions ranging from ~ 230–680° at 1 atm to ~ 500–735° at 10 kbar; also phase relations of beryl and related Be silicates have been studied. *AM 71:277(1986)*. Emerald crystals for jewelry applications have been synthesized by flux melt techniques (Chatham, San Francisco; Lennix and Gilson, France; Kyocera, Japan) and by hydrothermal methods (Linde-Regency, Biron, etc.). **Optics:** Uniaxial (–). General refractive indices of beryl have been well recorded due to the interest of the gem industry in identifying gem materials. *MR 7:211(1976)*, *EOB(1981)*. Some extreme values have also been recorded outside these values. (Low alkali, uncolored beryl): N_O = 1.568, N_E = 1.564, birefringence = 0.004; (emerald): N_O = 1.576–1.593, N_E = 1.569–1.586, birefringence = 0.005–0.007; (aquamarine): N_O = 1.575–1.585, N_E = 1.570–1.580, birefringence = 0.006; (red beryl): N_O = 1.576, N_E = 1.570, birefringence = 0.006; (high-alkali beryl): N_O = 1.585–1.598, N_E = 1.578–1.1589; (high-alkali-Fe-Mg beryl):

$N_O = 1.608$, $N_E = 1.599$; birefringence = 0.006–0.009. Length-fast with parallel extinction. Anomalous biaxial optics ($2V$ to 17°) rarely observed, due to strain. Emerald may be slightly pleochroic. Maxixe beryl has $N_O = 1.592$, cobalt blue and $N_E = 1.584$, colorless, the reverse of the normal absorption scheme. The color fades to yellowish on exposure to light or heat. **Occurrence:** Occurs principally in granite pegmatites, less common in skarns and greisens, schists and gneisses, rhyolite (only source of red beryl), hydrothermal quartz veins (especially with Sn–W–mo minerals such as cassiterite, scheelite, wolframite, and molybdenite), calcite veins (emerald—Muzo), rarely in metasomatized peridotites and nepheline syenites. Emerald occurrences are restricted to sources of available Cr and/or V, in hydrothermal veins, pegmatites cutting ultramafic rocks, and schists. Beryl can be replaced by kaolinite or muscovite, rarely chlorite or margarite; sometimes by Be silicates, principally bertrandite, rarely bavenite, and so on; Be phosphates (hydroxyl-herderite, moraesite, hurlbutite, beryllonite, etc.), usually derived from dissolution of beryl, but sometimes occurring within replacements. **Localities:** Industrial beryl: *large crystals:* Bumpus quarry, Albany, ME; Beryl Mt. mine, Acworth, McInnes mine, Rumney, NH; Bob Ingersoll No. 1 mine, Keystone, SD; A-4 mine (379.5 metric tons), Malakialina district, Malagasy; Jackalswater district, Namaqualand, South Africa. For the following varieties of beryl, only noteworthy localities are listed: *Aquamarine:* Melrose Farm, Stoneham, ME; Rice mine, Groton, NH; Beryl Hill mine, Royalston, MA; Centreville district, ID; Mt. Antero and Mt. White, Chaffee Co., CO; Chimney Rock locality, Mourne Mts., Co. Down, Northern Ireland; Nerchinsk district(!) and Adun Chilon(!) and Shergolova Gora(!), Transbaikalia, Russia; Mimoso do Sul mine, Mimoso do Sul, Salinas, and at Ponte do Reis, Fazenda do Funil, Santa Maria da Itabira, MG, Brazil; Dassu (Dusso)(!) and Shingus(!), Baltistan and Chumar Bakhoo(!), Nagar, NWF, Pakistan, and other areas around Haramosh. Jos(!), Nigeria; Kleine Spitzkopje, Namibia; Ambatoharanana, Marijao, Tongafeno locality, Tsaramanga, Malagasy; *Green beryl:* Monetnaya Dacha mine, Tshaitansk and Miass district(!), Ural Mts., Russia; Ariranhó, Rio Salinas placer(!), Barra de Salinas, Papamel placer(!), Marambaia, Mimoso do Sul mine, Mimoso do Sul, Pedroso placer, Padre Paraíso, Maxixe placer(!), Piauí valley, Resplendor(!), Rio Jequitinhonha placers (Araçuaí, Salinas, Forteleza, Jequitinhonha), Ilha Alegre, São Pedro de Jequitinhonha, Teófilo Otoni(!), MG, Brazil; Muiane, Alto Ligonha, Mozambique; Fefena, Malagasy. *High alkali and/or Fe–Mg beryl:* (6.7 wt % Cs_2O) in pegmatite at Bountiful Beryl prospect (Bluebird prospect), 15 miles S of Peach Springs, Mohave Co., AZ; Lassur mine, Ariege, France; Otov and Pisek, Bohemia; Skály, near Rýmarov, northern Moravia, Czech Republic. *Emerald:* Emerald and Hiddenite mine and Ellis mine, Hiddenite, Crabtree mine, Little Switzerland, and Turner mine, Shelby, Alexander Co., NC and mining has proceeded sporadically since that time, with much tally hoo but little

commercial success; in pegmatites at Lake Mjosa, Byrud, north of Eidsvoll, Norway (vanadian, 0.9 wt % V_2O_3); Leckbach Ravine, Habachtal, Salzburg, Austria; Marinsky, Stretensky, and Troitsky mines, Takovaya district, Ural Mts., Russia; Panjsher Valley, Kapisa district, Afghanistan; Mingora, Charbagh, Makhad, and Gujarkili in the Swat district, Khaltaro in the Gilgit district, Barang and Gandao (vanadian beryls with 0.66 wt % V_2O_3), Mohmand district, NWFP, Pakistan; Jebel Sikait localities, Egypt; Taita district, Kenya (vanadian); Zeus mine, Sandawana, Mayfield, and others, Zimbabwe; Lake Manyara mine, Manyara district, Tanzania; Kafubu, Kitwe, and Miku, Zambia; Cobra, BVD, Gravelotte, and Somerset Hill mines, Gravelotte district, Transvaal, South Africa; Leysdorp, Transvaal, South Africa; Novello claims, Victoria district, Zimbabwe (with Alexandria), Ajmer-Merwara field, India; Ankadilalana, and near Mananjary, Madagascar; Morrua area, Marropino district, Mozambique; Poona mine, Murchison Gold district, and Menzies, WA, Australia. Bode and Grota Funda mines, Carnaiba, Brumado and Salinha (vanadian), Bahia and Santana dos Ferros, Belmont, Itabira, and Capoeirana, near Nova Era, MG, and Santa Terezinha, Goias, Brazil; Chivor mine(1), Chivor, Muzo mines(1) and trapiche crystals from Mina Peña Blanca, Muzo, Buenavista mine, Ubalá, Gachalá mine(1), Vega de San Juan, and Burbar, Colombia; *Goshenite*: Tshaitansk(1) and Mursinka(1), Ural Mts., Russia; Resplendor(1), MG, Brazil; Ampangabe and Sahanivotry, Malagasy; Dassu(1), Baltistan, Pakistan. *Heliodor or golden beryl*: Trenton mine(1), Topsham, Maine; Slocum mine, East Hampton, Roebling mine, Upper Merryall, CT; NC; PA. Adun Chilon(1), Urgachen Mt., and Sherlova Gora, Transbaikalia, Russia and Wolodarsk-Wolynsk(1), Volyn, Ukraine, Zelatoya Voda, near Rangkul, Tadzikistan; Kokto-Kai, Xinjiangar, China; Magli, Nigeria; Rössing(1), Namibia; Kunar, Afghanistan. Golden beryl occurs in Brazil at Serra da Mesa, Minacu, GO; Sapucaia do Norte, M6. *Morganite and cesian beryl*: Bennett quarry(1), Buckfield, Tubbs Ledge prospect, Norway, ME; Gillette mine, Haddam, CT; Himalaya and San Diego mines, Mesa Grande and Stewart(1) and White Queen mines(1), Pala, CA; Facciatoia, Fonte del Prete, Grottia d'Oggi, Speranza, and Stabbiali quarries, San Piero di Campo, Elba, Italy I; Province, Afghanistan; Drot-Balachi, near Shengus, Gilgit-Skardu Road, NWF, Pakistan; Golconda mine, Governador Valadares, Corrego do Urucum(1), Galileia, Urubü mine(1), Teofilo Otoni, and large crystals to 25 kg from Resplendor, MG, Brazil; Muiane(1), Mozambique; Ampangabe, Anjanabonoina, Marihitra district, Tsaravovonana(1), Tsi-laizina, Vohidahy, Malagasy. *Red beryl*: Wildhorse Spring, Starvation Canyon, Topaz Valley prospects, and Pismire Wash, Thomas Range, Juab Co. and Violet claims(1), Wah Wah Mts., Beaver Co., UT; Black Mesa, Grant Co., and Paramount Canyon, Sierra Co., NM; San Luis Potosi, Mexico. *Rubidian beryl*: Mt. Mica mine, Paris, Oxford Co., ME. Uses: as an ore of Be [for beryllium copper (2% Be) and Be metal]. Also as a collectible mineral and art object, and as gemstones. The finest quality cut red beryl is >10,000/ct for stones >1ct. The separation of natural from synthetic

emerald is usually made on the basis of refractive index and specific gravity. Both are generally lower for flux synthetics than natural stones. Fluorescence and examination of inclusions under magnification are also used for this distinction. Chemical distinction [e.g., *GG 20:141(1984)*, *JG 18:530(1983)*] may also be used but involves destructive techniques. "Maxixie-type" beryl is produced by exposing pale blue beryl to gamma rays. *vk*, *EF*, *RVG AM 47:672(1962)*, *MIN 3(2):83(1981)*, *BM 105:615(1982)*, *DHZ IB:372(1986)*.

61.1.1.2 Bazzite $\text{Be}_3\text{Sc}_2\text{Si}_6\text{O}_{18}$

Described in 1915 by Artini and named for Alessandro Eugenio Bazzi (1862–1929), discoverer of the mineral. Beryl group. *HEX P6/mcc*. $Z = 2$; $D = 2.82$; (nat): $a = 9.501\text{--}9.549$, $c = 9.152\text{--}9.210$; (syn): $a = 9.552$, $c = 9.165$. *AM 53:943(1968)*. *20-165(syn): 9.15₁ 8.27₉ 4.58₃ 4.01₅ 3.31₁₀ 2.96₈ 2.58₂ 1.76₂*. Structure is of the beryl type, but with Y filled by Sc and variable amounts of Fe^{3+} and sometimes Mg. *MP 52:113(1995)*. The octahedra are strongly compressed parallel to the c axis. This results in a larger a cell dimension than for beryl. A complete series to beryl is possible, but intermediate bazzite–beryl compositions are rare. Minor substitutions of Fe^{2+} , Fe^{3+} , Al^{3+} , Na, Cs, Mn. Analysis (wt %): Cs_2O , to about 3; Fe_2O_3 , to >5.6. Crystals frequently occur as hexagonal prisms with {0001}, to several centimeters in length. Usually deep blue or shades of blue to blue-green, white streak, vitreous luster. Cleavage (0001), poor; brittle. $H = 6.5\text{--}7$. $G = 2.77\text{--}2.8$. IR spectral data: Raman spectral data: *PCM 17:395(1990)*. Insoluble in ordinary acids. Deep blue bazzite is electromagnetic. Uniaxial (–); $N_O = 1.623\text{--}1.628$, $N_E = 1.602\text{--}1.607$; dichroic; birefringence ≈ 0.02 ; $E > O$. E, azure to medium blue; O, pale greenish yellow or colorless. Cesian and ferrian bazzite has $N_O = 1.637$ and $N_E = 1.622$. Found in miarolitic granite cavities; granite pegmatite, or alpine veins frequently associated with albite, microcline, clinocllore, muscovite, bertrandite, beryl, fluorite, and rarely euclase. Occurs at the Government Pit, Albany, NY; Sugarloaf Mountain, Bethlehem, NH; Pea Ridge mine, AR; Mount Antero, Chaffee Co., CO; Hefrejern, Tørdal, Telemark, Norway; Monte Cervandone, Val Strem, Grigioni, and Pizzo Cornera, Alpe Deverno, *Baveno, Lake Maggiore, Piedmont, Italy*; Val Strem (Graubünden), Tavetsch, Oberaarkraftwerkstollen, and Grosseidelnhorn in Grimsel Pass, Bern, La Fibbia, and Monte Prosa in St. Gotthard Pass, Tessin, Furkabasistunnel, Uri–Wallis, Witen Alpstock, and Stremhörner, near Sedrun, Uri, Stollen Oberaar, Grimsel Pass, Gurtellen, Reusstal, Uri, Aushaub–Naters, Brig and Mittel Hohtenn Tunnel, Wallis, Switzerland; Grandiorbruchsteinerleinbach, Röhrenbach, Germany; Heiligenblut, Carinthia, Austria; Kent massif, central Kazakhstan; Ture Penin., Russia. *EF*, *vk AM 53:943(1968)*, *SMPM 50:445(1970)*, *CA 93:171112(1980)*, *MP 43:131(1990)*, *MIN 3(2):100(1981)*.

61.1.1.3 Indialite $Mg_2Al_4Si_5O_{18}$

Described in 1954 by Miyashiro and Iiyama and named for the country of origin. Beryl group. See the Fe-dominant analog, sekaninaite (61.2.1.2); also cordierite (61.2.1.1), the low-temperature form. Synonym: α -cordierite. *HEX* $P6/mcc$ (Na and Cs) or $P6$ [for K dominant, *AM* 77:407(1992)]. $a = 9.770\text{--}9.812$, $c = 9.345\text{--}9.365$, $Z = 2$, $D(\text{syn}) = 2.51$. $13\text{--}293(\text{syn})$: 8.48_{10} 4.89_3 4.09_5 3.38_{55} 3.14_{65} 3.03_{85} 1.875_2 1.69_3 . There is a more or less random distribution of Al and Si between the ring and linking tetrahedra. Ordering of Al and Si in all tetrahedra produces cordierite (orth *Cccm*). Pure Mg member is stable at 1 atm between 1455 and 1465°. Disordered high cordierite also crystallizes metastably below 1455° and can be retained by quenching. Short prismatic crystals. Colorless, vitreous luster. $H = 7$. $G = 2.6$. Natural material from India has the composition $(Mg_{1.40}Fe_{0.60})Al_{4.00}(Si_{4.89}Al_{0.11})O_{18}$. Uniaxial (-); $N_O = 1.526$, $N_E = 1.522$; also $N_O = 1.538$, $N_E = 1.535$, colorless or blue. Occurs in a sedimentary rock fused by the heat of a burning coal seam (India). Associated with sillimanite, spinel, and anorthite, in a polymetamorphosed pelitic rock. Intergrown cordierite and indialite occur in Japan. Bellerberg volcano, Mayen, Eifel region, Germany; *Bokaro coal field, Hazaribagh, Bihar, India*; Daimonji Yama, Kyoto Shi, Kyoto Pref., and Unazuki area, Toyama Pref., Japan. *EF CM* 15:43(1977), *CMP* 80:110(1982), *DHZ* 1B:410(1986).

LOVOZERITE GROUP

The lovozerite group minerals consist of several isotypic species with the general formula

where

A = Na, Ca, H

B = Na, H, Ca

C = H, Mn, Ca, Fe, Zr

M = Zr, Ti, Ca, Fe

and a structure the same as, or similar to, that of lovozerite-R.

The structures of the lovozerite group involve a fundamental pseudocubic block approximately 7.5 Å on edge and having $3m$ symmetry. The block contains all the components described by the general formula, with an isolated ring of six silica tetrahedra lying at the center of, and normal to, the trigonal axis of the block. The remaining cation sites, usually not fully occupied, lie at edge centers (A), face centers (B), on the triad (C), and at the corners (M) of the block.

LOVOZERITE: $(\text{Na}, \text{Ca})_2(\text{Zr}, \text{Ti})\text{Si}_6\text{O}_{18} \cdot 3\text{H}_2\text{O}$

Highly contorted six-membered silicate rings (they may look four-membered in projection) form layers parallel to (001). Layers are linked by Zr, and Na occurs both between rings in the layers and in interlayer positions.

LOVOZERITE GROUP

Mineral	Formula	Space Group	a	c	
Lovozerite	$\text{H}_4\text{Na}_2\text{Ca}(\text{Zr}, \text{Ti})[\text{Si}_6\text{O}_{18}]$	$R\bar{3}m$	10.174	13.053	61.1.2a.1
Kazakovite	$\text{Na}_6(\text{Mn}, \text{H}_2)\text{Ti}[\text{Si}_6\text{O}_{18}]$	$R\bar{3}m$	10.162	13.056	61.1.2a.2
Tisinalite	$\text{H}_3\text{Na}_3(\text{Mn}^{2+}, \text{Ca}, \text{Fe}^{2+})\text{Ti}[\text{Si}_6\text{O}_{18}] \cdot 2\text{H}_2\text{O}$	$R\bar{3}m$	10.14	13.08	61.1.2a.3
Zirsinalite	$\text{Na}_3\text{Na}_3\text{CaZr}[\text{Si}_6\text{O}_{18}]$	$R\bar{3}m$	10.29	13.11*	61.1.2a.4
Combeite	$\text{Na}_4\text{Ca}_4[\text{Si}_6\text{O}_{18}]$	$R\bar{3}m$	10.429	13.146	61.1.2a.5

*Also reported as $c = 26.31$.

The same pseudocubic blocks, with slight shifting of cation sites and consequent reduction in symmetry to $2/m$ or 2 , may be stacked in several different sequences to yield the following orthorhombic and monoclinic species.

Notes:

1. Structure determinations are lacking or only inferred for many of the species, and physical property data are lacking or incomplete, particularly for the dimorphic combeite and lovozerite.
2. Additional species, not included here, may be based on the same or similar structural elements.

SPC 35:227(1990).

61.1.2a.1 Lovozerite $\text{H}_4\text{Na}_2\text{Ca}(\text{Zr}, \text{Ti})[\text{Si}_6\text{O}_{18}]$

Named in 1939 by Gerasimovskii for the locality. Lovozerite group. Rhombohedral and monoclinic dimorphs have been reported, but their descriptions are poor and they may not be distinct phases. The names lovozerite-R (lovozerite-T) and lovozerite-M have been used for the possible dimorphs. *HEX-R R3m*. $a = 10.174$, $c = 13.053$, $Z = 3$. *28-1201*: 7.33₅ 5.27₈ 3.64₇ 3.32₇ 3.21₁₀ 2.97₅ 2.65₅ 1.826₅. Also reported as *MON C2*. $a = 10.48$, $b = 10.20$, $c = 7.33$, $\beta = 92.5^\circ$, $Z = 2$, $D = 2.63$. *PD*: 3.31₄ 3.24₅ 2.64₉ 2.57₈ 1.842₁₀ 1.543₄ 1.498₆ 1.369₄. Structure: *DANES 131:379(1960)*. Occurs as small equant crystals with pseudocubic, pseudododecahedral, or rhombohedral habit. Simple and polysynthetic twinning is common. Massive and irregular grains, and as pseudomorphs after eudialyte. Brown to black; vitreous to resinous luster; opaque, less often translucent. Cleavage undefined in two directions, brittle. $H = 5$. $G = 2.64$. Uniaxial (-); $N_0 = 1.560$, $N_E = 1.549$; also biaxial (-); $2V$ small; $N_x = 1.549$, $N_y = 1.560$, $N_z = 1.561$; weakly pleochroic. Altered material usually lighter in color and friable. Found in sodalite xenoliths at Mt. St.-Hilaire, PQ, Canada; at Ilimaussaq, Greenland; at several localities in the Khibiny massif, and the Lovozero massif, Kola Penin., Russia. *AR ZVMO 103:551(1974)*, *AM 59:633(1974)*, *MR 21:319(1990)*.

61.1.2a.2 Kazakovite $\text{Na}_6(\text{Mn}, \text{H}_2)\text{Ti}[\text{Si}_6\text{O}_{18}]$

Named in 1974 by Khomyakov et al. for Maria Efremovna Kazakova (b. 1913), Russian chemist who analyzed the material. Lovozerite group. *HEX-R R3m*. $a = 10.162$, $c = 13.056$, $Z = 3$, $D = 2.97$. *26-1385*: 3.60₇ 3.28₆ 3.17₆ 2.60₁₀ 2.52₈ 1.816₈ 1.529₆ 1.480₇. Structure: *SPD 24:132(1979)*. Rhombohedral crystals, 0.01–2.0 mm, with {1121} and {1124}. Simple and polysynthetic twinning with twin axis perpendicular to {1124}. Pale yellow, vitreous to greasy luster. Uneven to subconchoidal fracture. $H = 4$. $G = 2.84$. Uniaxial (-); $N_0 = 1.648$, $N_E = 1.625$. Disseminated in ussingite, and associated with nor-

dite, belovite, and vuonnemite in sodalite syenite at *Mt. Karnasurt, Lovozero massif, Kola Penin., Russia*. AR *ZVMO* 103:342(1974), *AM* 60:161(1975).

61.1.2a.3 Tisinalite $\text{H}_2\text{Na}_3(\text{Mn}^{2+}, \text{Ca}, \text{Fe}^{2+})\text{Ti}[\text{Si}_6\text{O}_{18}] \cdot 2\text{H}_2\text{O}$

Named in 1980 by Kapustin et al. for the composition: titanium, silicon, and sodium. Lovozerite group. HEX-R $R\bar{3}m$. $a = 10.14$, $c = 13.08$, $Z = 3$, $D = 2.682$. 33-607: 5.19₇ 3.60₁₀ 3.26₆ 3.18₈ 2.92₃ 2.59₆ 2.51₅ 1.802₅. Yellow-orange, vitreous luster. Uneven to conchoidal fracture. $H = 5$. Uniaxial (-); $N_O = 1.624$, $N_E = 1.590$ –1.592. Found as crude crystals up to 1 mm in diameter and 1 cm aggregates formed by alteration of lomonosovite and barian lamprophyllite, and associated with koashvite and shcherbakovite, in drill core from *Mt. Koashva, Khibiny massif, Kola Penin., Russia*. AR *ZVMO* 109:223(1980), *AM* 66:219(1981).

61.1.2a.4 Zirsinalite $\text{Na}_6(\text{Ca}, \text{Mn}^{2+}, \text{Fe}^{2+})\text{Zr}[\text{Si}_6\text{O}_{18}]$

Named in 1974 by Kapustin et al. for the composition: zirconium, silicon, and sodium. Lovozerite group. HEX-R $R\bar{3}m$. $a = 10.29$, $c = 13.11$, $Z = 3$, $D = 3.08$. 27-670: 4.22₄ 3.68₄ 3.33₄ 3.26₆ 2.64₉ 2.57₈ 1.842₁₀ 1.539₄. Colorless to pale yellowish gray, vitreous luster. Conchoidal fracture. $H = 5\frac{1}{2}$. $G = 2.90$. Uniaxial (-); $N_O = 1.610$, $N_E = 1.605$. Associated with aegirine, barian lamprophyllite, and lomonosovite in drill core from *Mt. Koashva, Khibiny massif, Kola Penin., Russia*. AR *ZVMO* 103:551(1974), *AM* 60:489(1975).

61.1.2a.5 Combeite $\text{Na}_4\text{Ca}_4[\text{Si}_6\text{O}_{18}]$

Named in 1957 by Sahama and Hytonen for Arthur Delmar Combe, Geological Survey of Uganda. Lovozerite group. The designations combeite-I and combeite-II are later (1990, Tamazyán and Malinkovskii). Phases I and II correspond to the high- and low-temperature polymorphs of the synthetic compound. Phase II was described in 1983 (Fischer and Tillmanns). Combeite-I: HEX-R $R\bar{3}m$. $a = 10.429$, $c = 13.146$, $Z = 3$, $D = 2.826(?)$. 25-800: 4.38₃ 3.72₅ 3.35₄ 3.30₇ 2.66₁₀ 2.61₈ 1.861₄ 1.544₂; this powder pattern is given for the original description of combeite from Zaire. Structure: *NJMM*:49(1983), *AC(C)* 43:1852(1987). Combeite II (not formally named): HEX $P3_1$. $a = 10.464$, $c = 13.176$, $Z = 3$, $D = 2.79$ for German material; this later modified to $P3_121$. No powder data are given. The difference in the two structures is that the rings are highly symmetrical in phase I but not in phase II. The morphology of crystals from both sources is trigonal or hexagonal prismatic, markedly different from the rhombohedral habit of other $\bar{3}m$ lovozerites, suggesting that phase II may be present at both localities. Colorless. No cleavage. $G = 2.84$. Uniaxial (+/-) or nearly isotropic; $N_O = 1.598$, $N_E = 1.598$. Gelatinized by hot HCl. Found at the *Meiener field, Eifel, Germany* (combeite-II), and in melilite-nephelinites from *Mt. Shaheru, Rutshuru territory, Kivu, Zaire* (combeite-I and possibly, combeite-II); at the Oldoinyo Lengai volcano, Tanzania. AR *MM* 31:503(1957), *JG* 97:367(1989).

61.1.2b.1 Imandrite $\text{Na}_{12}\text{Ca}_3\text{Fe}_2^{3+}[\text{Si}_6\text{O}_{18}]_2$

Named in 1979 by Khomyakov et al. for the locality. Lovozerite group. ORTH *Pmnn*. $a = 10.331$, $b = 10.546$, $c = 7.426$, $Z = 1$, $D = 2.92$. *PD*: 3.97₃ 3.73₅ 3.33₆ 3.29₂ 2.63₁₀ 2.59₂ 1.853₇ 1.520₅. Honey yellow, vitreous luster. $H = 4$. Biaxial (+); $2V = 75^\circ$; $N_x = 1.605$, $N_y = 1.608$, $N_z = 1.612$. Found as 1- to 3-mm anhedral, isolated grains and rims around and within fractures in eudialyte in alkalic pegmatite of the *Khibiny massif, near Lake Imandra, Kola Penin., Russia*. AR *MZ 1(1):89(1979)*, *AM 65:810(1980)*, *SPD 25:337(1980)*.

61.1.2b.2 Koashvite $\text{Na}_6(\text{Ca},\text{Mn})(\text{Ti},\text{Fe})[\text{Si}_6\text{O}_{18}] \cdot \text{H}_2\text{O}$

Named in 1974 by Kapustin et al. for the locality. Lovozerite group. ORTH *Pmnb*. $a = 10.169$, $b = 20.899$, $c = 7.335$, $Z = 4$, $D = 2.99$. *27-669*: 3.66₅ 3.57₂ 3.28₅ 2.62₄ 2.58₁₀ 1.820₇ 1.755₃ 1.294₄. Structure: *MZ 2(5):40(1980)*. Pale yellow, vitreous luster, transparent. Conchoidal fracture. $H = 6$. $G = 2.98-3.02$. Biaxial (-); $2V = 82-84^\circ$; $N_x = 1.637$, $N_y = 1.643$, $N_z = 1.648$; $r > v$, weak. Some references do not include water in the formula. In alkalic pegmatite as veinlets replacing lomonosovite and associated with pectolite, villiaumite, and tisinialite at *Mt. Koashva, Khibiny massif, Kola Penin., Russia*. AR *ZVMO 103:559(1974)*, *AM 60:487(1975)*.

61.1.2b.3 Petarasite $\text{Na}_5\text{Zr}_2[\text{Si}_6\text{O}_{18}](\text{ClOH}) \cdot 2\text{H}_2\text{O}$

Named in 1980 by Chao et al. for Peter Tarasoff (b.1934), assistant director, Noranda Research, and amateur mineralogist, Dollard-des-Ormeaux, Quebec, Canada. Lovozerite group. *MON C2/m*. $a = 10.796$, $b = 14.493$, $c = 6.623$, $\beta = 113.21^\circ$, $Z = 2$, $D = 2.86$. *33-1310*: 7.25₇ 6.09₄ 4.96₁ 4.10₁₀ 3.22₃ 3.04₃ 2.92₁₀ 1.729₂. Structure: *CM 18:503(1980)*. As short prismatic [001] crystals, 0.5 mm to 6.5 cm long. Forms {010}, {001}, {110}, {201}, and {111} dominant. Orange, orange-yellow, greenish yellow, brown, rarely rose to violet; opaque to translucent, rarely transparent. Cleavage {110}, perfect; {010}, {001}, good. $H = 5-5\frac{1}{2}$. $G = 2.88$. Biaxial (+); $2V = 29^\circ$; $N_x = 1.596$, $N_y = 1.598$, $N_z = 1.632$ (all for N_0); $X = b$, $Z \wedge c = 41.5^\circ$; $r < v$, weak, pleochroic, $Z = Y > X$; pale greenish yellow to colorless. Decomposes to parakeldyshite at 1100° . Found in interstices of biotite crystals with apatite, catapleiite, and zircon in a xenolith in nepheline syenite at the *Demix quarry, Mt. St.-Hilaire, PQ, Canada*. AR *CM 18:497(1980)*, *MR 21:329(1990)*.

61.1.3.1 Diopside $\text{Cu}_6(\text{Si}_6\text{O}_{18}) \cdot 6\text{H}_2\text{O}$

Named in 1797 by Haüy from the Greek for *through* and *to see*, in allusion to the visibility of internal cleavage planes. *HEX-R R3*. $a = 14.566$, $c = 7.778$, $Z = 3$, $D = 3.296$. *33-0487*: 7.29₈ 4.90₄ 4.06₄ 2.60₁₀ 2.44₄ 2.11₅ 1.506₄ 1.420₅. Structure: *AM 62:807(1977)*. The formula is chosen to show the six-membered ring structure. Long to short prismatic [0001], dominant forms {1120} and {0221}, {1341}; crystalline aggregates; massive. Twinning on {1011} uncommon. Bright emerald green, vitreous to greasy luster. Cleavage {1011}, perfect. Uneven to conchoidal fracture. $H = 5$. $G = 3.28-3.35$. Uniaxial (+);

**DIOPTASE**Forms: a, $\{11\bar{1}0\}$; s, $\{02\bar{2}1\}$; x, $\{13\bar{4}1\}$.

$N_O = 1.652\text{--}1.658$, $N_E = 1.697\text{--}1.709$; weakly pleochroic, $O > E$; rarely biaxial in sectors with OAP parallel to $\{1120\}$. Gelatinized in HCl. A frequent secondary mineral in many oxidized zones of copper deposits. Found at the Mammoth–St. Anthony mine, Tiger, and other localities in Pinal Co., at the Christmas mine, Gila Co., and in Cochise, Greenlee, and Yuma Cos., AZ; Soda Lake Mts., San Bernardino Co., CA; Nishapur, Iran; *Altyn Tube, Khirghiz Steppes, Kazakhstan*(!). At Reneville(!), the Sanda mine at Mindouli(!), 'Mbumba, and Pimbi, southern Congo; at Mavoyo, Angola; Guchab, Kaokoveld, and Tsumeb, Namibia, at the last in exceptional, brilliant crystals up to 5 cm long. At the Malpaso mine, Cordoba, Argentina, and at Iheca de Oro, Copiapo, Chile. An incidental ore of copper; crystal clusters used ornamentally; faceted as a collector gem. AR *D6:463(1892)*, *DANES 155:125(1964)*, *ZK 187:15(1989)*.

61.1.4.1 Baratovite $KLi_3Ca_7(Ti,Zr)_2[Si_6O_{18}]_2F_2$

Named in 1975 by Dusmatov et al. for Rauf Baratovich Baratov (b.1921), Academician and Soviet petrographer, Tadjik Academy of Sciences, Dushanbe, Tadjikistan. Compare katayamalite (61.1.4.2). MON C2/c. $a = 16.941$, $b = 9.746$, $c = 20.907$, $\beta = 112.50^\circ$, $Z = 4$, $D = 2.912$. 29-821: 4.81_1 3.54_1 3.22_{10} 3.02_1 2.41_2 1.92_2 1.60_1 1.49_1 . Structure: AM *64:383(1979)*. The structure consists of paired layers of six-tetrahedron rings linked by a layer of six-coordinated calcium; the resultant slabs are linked by the remaining cations. White; vitreous luster, pearly on $\{001\}$. Cleavage $\{001\}$, perfect. $H = 3\frac{1}{2}$. $G = 2.92$. Biaxial (+); $2V \approx 60^\circ$; $N_x = 1.672$, $N_y = 1.672$, $N_z = 1.673$; $X \wedge c = 50^\circ$; birefringence very low; $r > v$, strong. Found as platy aggregates with muscovite, ekanite, and sphene in quartz–albite–aegirine veinlets in syenite at the *Dara–Pioz alkaline massif, Alai Range, Tien Shan, Tadjikistan*. AR *ZVMO 104:580(1975)*, *AM 61:1053(1976)*.

61.1.4.2 Katayamalite $(K,Na)Li_3Ca_7Ti_2[Si_6O_{18}]_2(OH,F)_2$

Named in 1983 by Murakami et al. for Nobuo Katayama (b.1910), prominent Japanese mineralogist, University of Tokyo. See baratovite (61.1.4.1). MON C2/c. $a = 16.94$, $b = 9.72$, $c = 20.91$, $\beta = 112.4^\circ$, $Z = 4$, $D = 2.90$. 37-470: 3.23_{10} 3.06_3 2.94_3 2.90_3 2.42_3 1.933_4 1.841_2 1.382_2 . Structure: *EJM*

4:839(1992). Isostructural with baratovite and possibly a variety thereof; originally described as TRIC C1. $a = 9.721$, $b = 16.932$, $c = 19.942$, $\alpha = 91.43^\circ$, $\beta = 104.15^\circ$, $\gamma = 89.94^\circ$. As tabular {001} crystals and frequent twins on {001}. White; vitreous luster, pearly on {001}. Cleavage {001}, perfect. $H = 3\frac{1}{2}$ –4. $G = 2.91$. Biaxial (+); $2V \approx 32^\circ$; $N_x = 1.670$, $N_y = 1.671$, $N_z = 1.677$; $Y \approx b$, $Z \wedge$ cleavage $\approx 54^\circ$; $r > v$, strong. Bright blue-white fluorescence in SWUV. May be dimorphous with baratovite, but differs from the latter in the lack of zirconium and the predominance of hydroxyl ion over fluorine. Found in aegirine syenite with albite, aegirine, and pectolite on *Iwagi Islet, Ehime Pref., Japan*. AR *MJJ* 11:261(1983), 12:206(1985); AM 69:811(1984).

61.1.5.1 Odintsovite $K_2Na_4Ca_3Ti_2Be_4Si_{12}O_{38}$

Named by Konev et al. in 1995 for Prof. M. M. Odintsov (1911–1979), well-known Siberian scientist and a founder of the Institute of the Earth's Crust, Irkutsk, Russia. ORTH *Fddd* $a = 14.243\text{\AA}$ $b = 13.045\text{\AA}$ $c = 33.484\text{\AA}$ $Z = 8$ $D = 2.91$; *PD* 9.23₉ 4.15₁₀ 3.30₁₀ 3.16₁₀ 2.53₁₀ 2.42₁₀ 1.67₈ 1.63₈. Based on a crystal structure determination (K 40:253(1995); Eng. Trans. as Crystallography Reports 40:228(1995)), the structural formula is: $K_2(Na_{3.75}Li_{0.25})Ca_3(Ti_2O_2[Be_4(Si_6O_{18})_2]$. Six-membered Si-O rings, discrete Be-tetrahedra, and edge-sharing Ti-octahedra form a mixed framework with the channels extended along the two orthogonal directions. The K atoms fill the channels, with the Ca and Na atoms located between them. Transparent, pink with a brownish tint, dark red, seldom white; anhedral 0.1–1 mm grains, and aggregates of grains (0.5–4 mm) up to 7 mm. Vitreous, brittle, no cleavage observed, uneven fracture, $G = 2.94$ –2.98, $H = 5$ –5 $\frac{1}{2}$. Non-fluorescent, no thermal effects to 1000°C, and neither OH or H₂O were detected by IR. Biaxial (+), $N_\alpha = 1.630$, $N_\beta = 1.644$, $N_\gamma = 1.675$ in white light, $2V_{meas} 70^\circ$, $XYZ = abc$, $X =$ colorless, $Y = Z =$ pink. Mean analytical results: Na₂O 8.57 (wt. %), K₂O 6.86, BeO 6.75, CaO 11.51, MnO 0.05, SrO 1.21, FeO 0.42, Al O₃ 0.11, TiO₂ 11.42, SiO₂ 52.56, $\Sigma 99.46$. Occurs in a vein in alkaline syenite pegmatite and in kalsilite-syenite in the Malomurun massif (220 km south of Olekminsk), Aldan Shield, Russia. Associated minerals are: aegirine, K-feldspar, titanite, barytolamprophyllite, strontianite, wadeite, galena, and an unidentified mineral. EF ZVMO 124(5):92(1995).

61.2.1.1 Cordierite $(Mg,Fe^{2+})_2Al_3[AlSi_5O_{18}] \cdot H_2O$

Described in 1813 by Lukas and named for Pierre Louis A. Cordier (1777–1861), French mining engineer and geologist. Beryl group. Synonyms: iolite and dichroite. Dimorphous with indialite (completely disordered high-temperature form), which is truly hexagonal and is isostructural with beryl. ORTH *Cccm*. (Nat): $a = 17.088$, $b = 9.734$, $c = 9.359$ [*AM* 64:337(1979)]; (syn Mg-cordierite): $a = 17.062$, $b = 9.721$, $c = 9.339$, $Z = 4$, $D = 2.51$. 13-294(syn Mg-cordierite): 8.52₉ 8.45₁₀ 4.09₅ 3.38₅ 3.13₆ 3.04₆ 3.01₅. A framework silicate with structural channels formed by stacking of six-membered Si,Al-ordered

rings of corner-sharing tetrahedra ($\text{Si}_4\text{Al}_2\text{O}_{18}$) along the c axis. In natural specimens, these channels may contain molecules such as H_2O , CO_2 , N_2 , He, and Ar. Structurally closely related to beryl. A so-called distortion index, $\delta = 2\theta_{131} - (2\theta_{511} + 2\theta_{421})/2$, is a measure of the degree of departure from hexagonality. Maximum value for δ is about 0.31. Undergoes a first-order phase transition to indialite. *AM 68:60(1983)*. An intermediate short-range ordered domain structure exists (modulated structure). *AM 64:337(1979)*. **Habit:** Crystals are short prismatic, granular, or massive aggregates. $\{110\}$ and $\{310\}$ simple, lamellar and cyclic twinning may be present. Crystals may be several centimeters or more in size. **Physical properties:** Blue, blue-green, gray to violet; blue color is believed due to Fe^{2+} - Fe^{3+} charge transfer; white streak; vitreous-greasy luster. Cleavage $\{100\}$, moderate; $\{001\}$, $\{010\}$, poor; conchoidal to uneven fracture; brittle. $H = 7$. $G = 2.53$ - 2.65 . Spectral and thermal data: *DHZ IB:410(1986)*. **Chemistry:** Partially decomposed by acids. Mossbauer spectral studies of cordierites show that alkali-free cordierites have Fe^{2+} present in the octahedral position. Those with the largest concentrations of alkali cations display in addition a second Fe^{2+} position (i.e., channels or tetrahedral sites). *GSAAP 27(6):A-364(1995)*. IR (LIT 32:95(1994)) shows both type I and II water and CO_2 as fluid constituents in the channel sites. Substitutions of the type $\text{Be}^{2+} + \text{Na}^+ \leftrightarrow \text{Al}^{3+}$ or $\text{Na} + \text{Li} \leftrightarrow \text{Mg}$ occur. Most cordierites are rich in Mg and specimens with $\text{Fe}/(\text{Fe} + \text{Mg}) > 0.5$ are rare (sekaninaite). Fe-rich cordierites are mostly in pegmatites. $\text{FeO} \gg \text{Fe}_2\text{O}_3$; BeO to 1.77 wt %; may contain trace to minor amounts of Na and K also, CO_2 to 2.2 wt %, H_2O to 0.5 atom. Complete formula is $\text{Na}_{x+2} (\text{Mg, Fe, Mn})_{2-y} (\text{Al}_{4-x}\text{Be}_x\text{Si}_5)\text{O}_{18} \cdot n(\text{H}_2\text{O}, \text{CO}_2)$. **Optics:** Biaxial (+) or (-), most are (-); $2V_x = 35$ - 106° ; (syn Mg-cordierite): $N_x = 1.522$, $N_z = 1.527$; (nat): $N_x = 1.527$ - 1.560 , $N_y = 1.532$ - 1.574 , $N_z = 1.537$ - 1.578 . Mg-rich: X, pale yellow or green; Y, violet or violet-blue; Z, pale blue; $Y > Z > X$; $v > r$, weak; OAP = (010), XYZ = *cba*. **Occurrence:** Occurs in thermally metamorphosed rocks, particularly those derived from argillaceous sediments. Also a common product of high-grade regional metamorphism and may occur in schists, gneisses, and granulites. It may also be found in some basic igneous rocks and in some granites. In these rocks, the formation of cordierite is generally considered to be a result of assimilation of Al-rich sediments by acid or basic magmas. The mineral occurs more rarely in pegmatites and quartz veins. The most common alteration products of cordierite are chlorite-sericite aggregates (pinnite). **Localities:** Many worldwide localities. Several localities (Haddam, New London, Guilford, Plymouth) in CT; Garnet Island, NWT, Canada(!), in flawless crystals to 5 cm; notable localities include: Bodenmais and Wechselburg, Bavaria, Germany; beryllian cordierite occurs in pegmatites at Biskupice, Dolní Bory, and Vezna, Czech Republic; Orijarvi, and Pielavesi, Finland; Kragerø and Arendal, as well as the Bamble sector, Norway; Naversberg, Sweden; Cabo de Gato, Spain; gem-grade material occurs in the Sasyksky area, Muzkolsk metamorphic complex in the eastern Pamirs, SW of Rankul, Tadjikistan; Mt. Bity, Madagascar (gem material); in gem grav-

els in Sri Lanka; fine, massive, gem-quality material from the Blue Dragon mine, Orange R., Namaqualand, Cape Prov., and Guadon Farm, 70 km east of Steinkopf, North Cape, South Africa(!); White Well, WA, Australia; gem material occurs at Umburang, Paraiba, Brazil; beryllian cordierite occurs at Soto, Argentina. A nearly high cordierite is present in the Allende meteorite (chondrite), Parral, CHIH, Mexico. Uses: Cordierite (iolite) is used as a gemstone; however, most is used in ceramics applications because of its very low thermal expansion coefficient and resistance to thermal shock. Insulator for spark plugs, and refractory coating on metals for internal combustion and turbine engines. Gem material shows fine pleochroism from colorless to yellow to deep blue (when viewed perpendicular to c). The principal gem source is Madras, India; however it is produced in Sri Lanka from gem gravels; Myanmar (Burma); Tanzania, and Mr. Biry, Malagasy Republic. EF *Armbruster, 1986, Crystal Chem. of Mins.; Proc. 13th Gen. Meet. IMA:485(1986), MIN 3(2):110(1981); ZVMO 124:76(1995)*

61.2.1.2 Sekaninaite ($\text{Fe}^{2+}, \text{Mg}$) $_2\text{Al}_4\text{Si}_5\text{O}_{18}$

Named in 1975 by Stanek and Miskovsky for Josef Sekanina (b.1901), Czech mineralogist, who discovered the mineral in 1928. Beryl group. See cordierite (61.2.1.1), the Mg analogue. Much of the literature still refers to Fe-cordierite (sekaninaite) and Mg-cordierite. Cordierites with $\text{Fe}^{2+}/(\text{Fe}^{2+} + \text{Mg}) > 0.5$ are not that rare. ORTH *Cccm.* (Nat): $a = 17.186\text{--}17.230$, $b = 9.817\text{--}9.835$, $c = 9.298\text{--}9.313$; (syn): $a = 17.234$, $b = 9.824$, $c = 9.298$; BMP 11:297(1965); (syn Fe-cordierite): $a = 17.251$, $b = 9.834$, $c = 9.281$ [*AM 62:395(1977)*]; $Z = 4$, $D = 2.78$. 31-616(nat): 8.58₁₀ 4.08₆ 3.39₁₀ 3.38₁₀ 3.16₄ 3.14₆ 3.07₇ 3.04₅; 31-615(syn): 8.63₇ 8.55₇ 4.09₇ 3.39₁₀ 3.38₆ 3.14₄ 3.07₅ 3.06₅. For structural details, see cordierite (61.2.1.1). Sekaninaite has differing degrees of Al-Si order. *AM 64:337(1979)*. Mössbauer data indicate that divalent iron is strongly predominant over trivalent iron and is in the octahedral site only. The color and pleochroism of Fe-bearing cordierite and sekaninaite have been interpreted to arise from charge transfer between octahedral Fe^{2+} and channel (?), tetrahedral or octahedral Fe^{3+} . Short, prismatic, pseudo-hexagonal; twinning present on {110} and {310}; crystals may be 60–70 cm in length. Light blue to blue violet, white streak, vitreous luster. Cleavage {100}, good; indistinct parting on {001} and {010}; brittle. $H = 7\text{--}7\frac{1}{2}$. $G = 2.76\text{--}2.77$. IR, DTA, TGA data: *AM 62:395(1977)*. Other spectral data: *DHZ IB:410(1986)*. Mössbauer spectral data (CM 35:167(1997)). See *DHZ IB:410(1986)* and CM 35:167(1997) for chemical analyses. May contain some Li (0.1–0.54 wt % Li_2O), Na_2O (0.13–1.57 wt %), Ca 0.0x wt % and water (about 3%) in addition to major constituents. Li is incorporated by the substitution $\text{Li}^{\text{VI}}\text{Na}^{\text{ch}}(\text{Mg}, \text{Fe})^-$. Fe_2O_3 is probably about 0.1 wt %. Biaxial (-); $XYZ = cba$; $N_x = 1.561$, $N_y = 1.572$, $N_z = 1.576$; $2V_x = 66\text{--}68^\circ$; $Y > Z > X$; $v > r$, weak. X, colorless; Y, blue; Z, pale blue. Usually occurs in pegmatites emplaced in granulitic gneisses, but also in peraluminous granites and metamorphic xenoliths. Alters to septechamosite, andalusite, chloritoid, ferrog-

drite, and siderophyllite. *GG 34:141(1993)*. Occurs at Brockley, Rathlin Island, County Antrim, Northern Ireland; in simple beryl-columbite subtype pegmatites at *Dolní Bory, western Moravia, Czech Republic*; at Gasborn, Bergslagen, Sweden; Kemiö, Finland; in Japan, from Ide, Kyoto Pref.; Ishii, Yamaguchi Pref.; Kitasugama, Fukushima Pref.; Sasago and Doshi, Yamaguchi Pref.; and from the Hanoka mine, Kagoshima Pref. *EF AM 65:522(1980)*.

61.2.2.1 Jonesite $(\text{Na,K})_2\text{Ba}_4\text{Ti}_4[\text{AlSi}_5\text{O}_{18}]_2 \cdot 6\text{H}_2\text{O}$

Named in 1977 by Wise et al. for Francis Tucker Jones (1905–1993), Berkeley, California, mineralogist and chemical microscopist, U.S. Department of Agriculture, who first observed crystals of the species. ORTH $B22_12$. $a = 13.730$, $b = 25.904$, $c = 10.608$, $Z = 4$, $D = 3.24$. *29-983*: 13.0_{10} 3.03_4 3.01_2 2.65_3 2.60_2 2.23_2 2.16_2 2.07_2 . Laths elongated $\{001\}$ and flattened $\{010\}$ with $\{010\}$, $\{310\}$, $\{210\}$, and $\{101\}$ dominant. Colorless, vitreous luster. Cleavage $\{010\}$. $H = 3-4$. $G = 3.25$. Biaxial (+); $2V = 76-78^\circ$; $N_x = 1.641$, $N_y = 1.660$, $N_z = 1.682$; $XYZ = bac$. Fluoresces dull orange under SWUV. Found associated with neptunite and joaquinite, but not benitoite, in natrolite veins at the *Benitoite Gem mine, San Benito Co., CA*. *AR MR 8:453(1977)*.

61.2.3.1 Lourenswalsite $(\text{K,Ba})_2\text{Ti}_4(\text{Si,Al})_6\text{O}_{14}(\text{OH})_{12}$

Named in 1987 by Appleman et al. for Lourens Wals (b.1939), a leading Belgian mineral collector. Pseudo- HEX Space group unknown. $a = 5.244$, $c = 20.49$, $Z = 1$, $D = 3.199$. *40-1453*: 10.22_2 4.08_1 3.93_2 3.43_1 2.61_{10} 2.25_2 1.515_8 1.311_2 . Silver-gray to light brownish gray, pearly to dull luster. Friable; cleavage $\{001\}$, good. $G = 3.17$. Biaxial (-); $2V \approx 0^\circ$; $N_x = 1.815$, $N_y = 1.840$, $N_z = 1.840$; nonpleochroic. Formed under oxidizing conditions as rosettes of pseudo-hexagonal plates at the *Diamond Jo quarry, Magnet Cove, near Hot Springs, AR*. *AR MM 51:417(1987)*, *AM 73:1493(1988)*.

TOURMALINE GROUP

The tourmaline group is an important group of minerals corresponding to the general formula

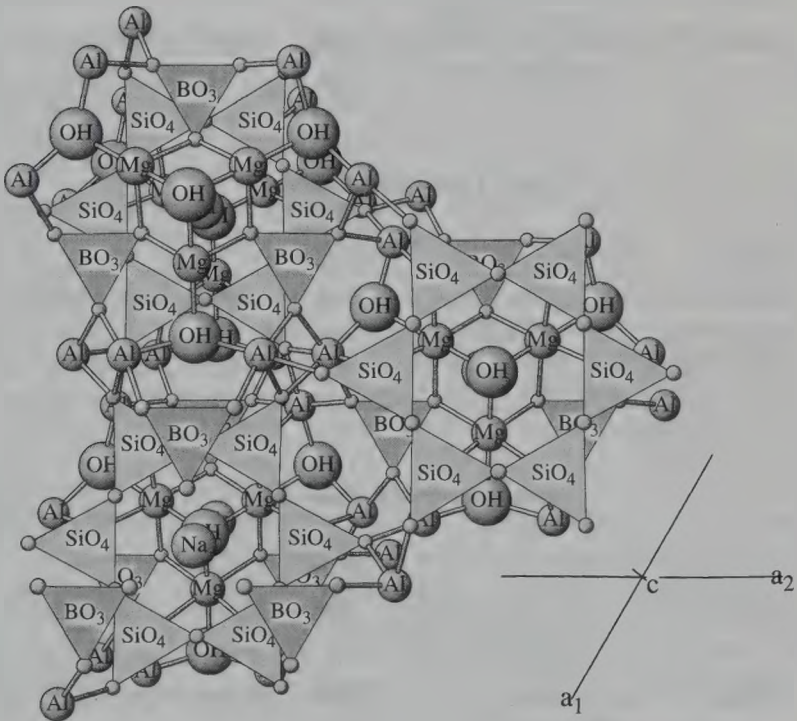

where

- X = Na, Ca, □, sometimes Mg, Fe^{2+} , Mn^{2+} , rarely K, possibly H_3O^+
 Y = Fe^{2+} , Mg, Al, Li, Fe^{3+} , Mn^{2+} , Mn^{3+} , Cr^{3+} , Ti^{4+} , Cu, Zn, trace REE
 Z = Al, Fe^{3+} , Fe^{2+} , Cr^{3+} , V^{3+} , Mn^{3+} , Ti^{3+} , Ti^{4+}
 $\text{O}_1 = \text{OH}$, O, rarely Cl
 $\text{O}_2 = \text{OH}$, F, rarely Cl
 T = Si, very minor Al and/or B, rarely very minor Ti^{4+} , P

The space group is $R\bar{3}m$, and Si and O atoms are organized into columns of six-membered hexagonal silicate rings [Si_6O_{18}]. T sites have three oxygens per tetrahedron coplanar with three oxygens of every other tetrahedron of the ring, with the tetrahedral apices toward $[0001]$. The hexagonal rings overlay three mutually edge-sharing octahedra (Y sites), both centered on the three-fold axis. Distorted triangular BO_3 groups infill indentations of the Y octahedral clusters. Large cations (Na or Ca) or vacancies occur within the hexagonal silicate rings (X site). Relatively small octahedral sites (Z sites, usually containing Al and/or Fe^{3+} but also Li) bridge the columns of silicate and borate rings and the relatively larger Y octahedral clusters.

Two halogen- or oxygen-bearing sites are significant. The O1 site occurs within the silicate ring and is centered on the threefold axis: it contains monovalent F or OH only. The O3 site contains oxygen or hydroxyl, depending on the local charge-balance requirements of the contents of the Y site.

DRAUITE: $\text{NaMg}_3\text{Al}_6(\text{BO}_3)_3\text{Si}_6\text{O}_{18}(\text{OH})_3(\text{OH})$

Drauite, a typical tourmaline, in perspective view approximately along c .

Alkali-Deficient Tourmaline Subgroup

The tourmaline group has been well studied and there are many good references. Structures: *CM* 33:849(1995), 27:199(1989); *AC(B)* 25:1524(1969); *AM* 56:101(1971), 78:433(1993), 78:1299(1993), 78:265(1993). Infrared: *K* 14:370(1969), *GCA* 48:1331(1984), *CIWYB* 62:166(1993). Composition and substitution: *DAN SSSR* 307:1461(1989); *ZVMO* 117:70(1988); *CMP* 20:235(1969), 62:109(1977). Synthetic tourmalines: *AM* 32:680(1947), 64:180(1979); *GCA* 48:1331(1984). *DTTG* 1985; *DHZ IB* 559(1986).

61.3.1.1 Foitite $\square[\text{Fe}^{2+}(\text{Al}, \text{Fe}^{3+})]\text{Al}_6(\text{BO}_3)_3\text{Si}_6\text{O}_{18}(\text{OH})_3(\text{OH})$

Named in 1993 by MacDonald et al. for Franklin F. Foit, Jr. (b.1942), mineralogist, Washington State University. *HEX-R R3m*. $a = 15.967$, $c = 7.126$, $Z = 3$, $D = 3.14$. *AM* 78:1299(1993): 6.34₈ 4.21₅ 3.99₄ 3.45₉ 2.94₇ 2.57₁₀ 2.04₃ 1.27₃. Structure is typical of that of the tourmaline group but with X-site vacancy. Prismatic crystals, generally elongated and striated along [0001], terminated, crystals to several centimeters from pegmatite, crystals less than 1 mm in veins or fillings to 1 cm from tuffs. Dark indigo with purple tints grading to black, grayish white streak, vitreous to oily luster, translucent. $H = 7$. $G = 3.17$. No cleavage, brittle. Nonfluorescent. Alkali-deficient, iron-bearing tourmaline; minor substituents include Mn, Mg, Ca, Na, Li. Foitite and foitite-related compositions have been synthesized. *AM* 64:180(1979), *GCA* 48:1331(1984). Alkali deficiency arises from coupled substitutions: $\square + \text{R}^{3+} \leftrightarrow \text{R}^+ + \text{R}^{2+}$. Uniaxial (-); (Na-light): $N_E = 1.642$, $N_O = 1.664$; strongly dichroic; $O < E$. O, pale lavender; E, dark blue. From mirolitic cavities in granite pegmatite (White Queen mine, Dobrá Voda); in mirolitic cavities in granite (Elba); found in hydrothermally altered dumortierite-bearing tuffs. *AM* 74:1317(1989). *White Queen mine, Pala, San Diego Co., CA*; Jack Creek deposit, near Basin, Jefferson County, MT; San Piero in Campo, Filone della Speranza, Elba, Italy; Dobrá Voda, Western Moravia, Czech Republic, Ben Lomond deposit, Hervey Range, Q, Australia. vk, EF

61.3.1.2 Liddicoatite $\text{Ca}(\text{Li}_{1.5}\text{Al}_{1.5})_3\text{Al}_6(\text{BO}_3)_3\text{Si}_6\text{O}_{18}(\text{OH}_{0.66}, \text{O}_{0.33})_3(\text{F})$

Named in 1977 by Dunn et al. for Richard T. Liddicoat (b.1918), gemologist and president of the Gemological Institute of America. Tourmaline group.

HEX-R $R\bar{3}m$. $a = 15.867$, $c = 7.135$, $Z = 3$, $D = 3.05$. $30-748$: 4.94_3 4.20_5 3.96_6 3.45_5 2.93_{10} 2.56_9 2.025_4 1.905_4 . Liddicoatite is isostructural with all members of the tourmaline group and indistinguishable from elbaite by XRD. Ca substitutes for Na in the X site. Charge balance is maintained by a number of substitutions: Ca by Na, Al by Li, and OH by O. End-member liddicoatite has not yet been found. Prismatic crystals, as large as $0.25\text{ m} \times 0.25\text{ m} \times 0.75\text{ m}$, generally elongated and striated along $[0001]$, sometimes acicular on large crystals due to etching. Hemimorphic, usually with pedion opposite one or two pyramids, crystals often to many centimeters; usually smoky brown, but also transparent pink or green. Color zoning is abundant at the type locality with little change in Ca/Na ratio between color zones. *AM 62:1121(1977)*. The terminations of liddicoatite are oscillatory color zoned, sometimes with adjacent pyramidal forms selectively colored. When the pyramidal end of the crystal is sliced perpendicular to the c axis, the selective internal color zones vary from triangles to triskelions. Pale brown, light pink or green, nearly white; streak lighter than mass color. $H = 7\frac{1}{2}$. $G = 3.02$. Cleavage $\{1011\}$, poor or absent; brittle. Nonfluorescent. Liddicoatite is the Ca analog of elbaite. Minor amounts of metals (generally less than 1 wt %) substitute in the Y site (e.g., Mn, Fe^{2+} , Ti^{4+} , Mg). Forms a series to elbaite and probably to olenite. Uniaxial (-); $N_O = 1.637$, $N_E = 1.621$; dichroic; $O > E$. O, dark brown, pink; E, light brown, pale pink. Color-zoned crystals reported from the Blizna graphite mine, Blizna, Bohemia, Czech Republic. Some sodian liddicoatite occurs in the Malkhan (Krasny Chikoy) pegmatite field, Transbaikalia, Russia; found in fresh pegmatite and in decomposed pegmatite-derived elluvium and alluvium, *Anjanaboinina*, *Tsilazina*, *Antsirabe*, *Madagascar (Malagasy Republic)*; individual crystals from an in situ source in an unspecified granite pegmatite in Goias, Brazil. VK, EF

61.3.1.3 Uvite $\text{CaMg}_3(\text{Al}_5\text{Mg})(\text{BO}_3)_3\text{Si}_6\text{O}_{18}(\text{OH})_3(\text{OH})$

Named in 1929 by Kunitz for the locality. Tourmaline group. HEX-R $R\bar{3}m$. $a = 15.88$, $c = 7.17$, $Z = 3$, $D = 3.01$. $29-342$: 4.23_7 3.99_7 3.49_6 2.97_{10} 2.58_9 2.04_8 1.92_6 1.46_6 . Crystals frequently equant, with one or two pyramids opposite a pedion sometimes modified by pyramid faces, to several centimeters. Green or brown to black, grayish green or grayish brown to gray streak, vitreous to oily luster, translucent. Nonfluorescent, except when low-Fe containing and then fluoresces yellow in SW UV. $H = 7\frac{1}{2}$. $G = 2.96-3.06$. No cleavage, brittle. An Mg- and Ca-bearing tourmaline with complete compositional variability to dravite (Fe^{2+}); minor substituents include Fe^{3+} , Mn^{2+} , Ti^{4+} , Na, Cr^{3+} , V^{3+} , trace Zn. Several analyses show considerable F, while most analyses have not reported on its presence. Three analyses, all of which contain enough F to dominate a site have been noted. *MR 8:100(1977)*. Uniaxial (-); $N_O = 1.634$ (low iron)- 1.668 , $N_E = 1.619$ (low iron)- 1.639 ; strongly dichroic; $O > E$. O, dark green, dark brown, yellow; E, olive-green, light brown, nearly colorless. Type material is from placer gravels; frequently found in marble associated with diopside, tremolite, phlogopite, or meionite;

sometimes with quartz. Localities include: East Hampton, Middlesex Co., CT; Canton, DeKalb, Gouverneur(1), Horicon, Macomb; Powers locality(1), Pierrepont; Actinolite locality(1), West Pierrepont, St. Lawrence and Warren Cos., NY; Franklin marble(1), Franklin, Hamburg, and McAfee, Sussex Co., NJ; Renfrew and Madoc, ONT, Canada; Santa Cruz, SON, Mexico; Hnusta, Slovakia; *Uva province, Sri Lanka*; Dnieper Basin, Russia; Uzbekistan; chromian uvite from Landani, Tanzania(1); chromian uvite from Sagaing district, Myanmar (Burma); Brumado(1), BA, Brazil, in equant to tabular crystals to 5 cm, some being transparent and shades of green to orange-red; New Zealand. VK, EF *CE* 4:208(1929).

61.3.1.4 Feruvite $(\text{Ca})\text{Fe}_3^{2+}\text{Al}_6^{3+}(\text{BO}_3)_3\text{Si}_6\text{O}_{18}(\text{OH})_3(\text{OH})$

Named in 1989 by Grice and Robinson for the compositional relationship to uvite. Tourmaline group. *HEX-R R3m*. $a = 16.012$, $c = 7.245$, $Z = 3$, $D = 3.21$. *CM* 27:199(1989): 6.43₄ 4.24₆ 4.00₆ 3.50₆ 2.98₈ 2.59₁₀ 2.05₅ 1.93₄. Subhedral crystals, generally equant, individual crystals to 2 mm. Black, gray streak, vitreous to dull luster. $H = 7$. $G = 3.21$. No cleavage, brittle. Nonfluorescent. Iron- and calcium-bearing tourmaline; major substituents include Fe^{3+} , Mg, Al, Ti^{4+} ; trace amounts of Mn, K. Type material is alkali-deficient and also strongly compositionally zoned with dravite and schorl intergrowths. Charge balance maintained by alkali deficiency and low-valence Y and Z cations. Uniaxial (-); $N_{\text{O}} = 1.687$, $N_{\text{E}} = 1.669$; strongly dichroic; $\text{O} > \text{E}$. O, very dark brown, E, light brown. In the Sullivan Pb-Ag-Zn deposit, BC; zoned crystals with feruvite cores and schor-dravite rims occur with biotite and muscovite from rare element pegmatites at Red Cross Lake, Manitoba, Canada; also in pegmatitic hydrothermally altered and tourmalinized quartz veins associated with microcline, chlorapatite, and pyrite at *Cuvier Island, New Zealand*. VK, EF

61.3.1.5 Buergerite $(\text{Na})\text{Fe}_3^{2+}\text{Al}_6(\text{BO}_3)_3\text{Si}_6\text{O}_{18}(\text{O})_3(\text{F})$

Named in 1966 by Donnay et al. for Martin J. Buerger (1903–1986), institute professor of mineralogy, MIT, pioneer of crystal structure analysis and inventor of X-ray precession camera permitting undistorted photography of the reciprocal lattice. Tourmaline group. *HEX-R R3m*. $a = 15.869$, $c = 7.188$, $Z = 3$, $D = 3.29$. 25-703: 6.33₅ 4.20₄ 3.96₅ 3.47₅ 2.95₆ 2.56₁₀ 2.03₄ 1.91₃. Structure *AC(B)* 25:1524(1969), *AM* 56:101(1971). Crystals prismatic, stout to slightly elongated, with minor striations along [001]; terminated crystals with pyramids opposite a pedion, flattened subparallel to divergent crystal clusters to several centimeters, individual crystals to 10 mm. Bronzy brown, brown streak, vitreous to oily luster. $H = 7$. $G = 3.30$. Cleavage with yellow-brown schiller, (1120), good; brittle. Nonfluorescent. A ferric iron-bearing tourmaline; minor substituents include Fe^{2+} , Ca, Mg, K, Al, Ti^{4+} , minor B for Si; aluminum analog of povondraite. Uniaxial (-); $N_{\text{O}} = 1.735$, $N_{\text{E}} = 1.655$; strongly dichroic; $\text{O} > \text{E}$; O, yellow-brown; E, very pale yellow.

Found in hydrothermally altered tuffs in clay seams in rhyolite at *Mexquitic, SLP, Mexico*. vk, EF *AM 51:198(1966)*.

61.3.1.6 Povondraite $(\text{Na})\text{Fe}_3^{2+}\text{Fe}_6^{3+}(\text{BO}_3)_3\text{Si}_6\text{O}_{18}(\text{O})_3(\text{OH})$

Named in 1993 by Grice et al. for Pavel Povondra (b.1924), mineralogist, Charles University, Prague, Czech Republic. Tourmaline group. *HEX-R R3m*. $a = 16.186$, $c = 7.444$, $Z = 3$, $D = 3.33$. *AM 78:433(1993)*: 6.63₉ 5.13₇ 4.71₇ 4.32₇ 4.05₉ 3.61₈ 3.05₉ 2.63₁₀. Structure: *AM 78:433(1993)*. Prismatic crystals, generally equant and striated along [0001], terminated crystals with pyramid opposite a pedion, poorly crystallized, flattened crystal clusters to 1 cm, individual crystals to 3 mm. Black, brown streak, vitreous to oily luster. $H = 7$. $G = 3.26$. No cleavage, brittle. Nonfluorescent. Aluminum-deficient, iron-bearing tourmaline; minor substituents include Fe^{2+} , Mg (≈ 6 wt % MgO), K, Al; trace amounts of Cu, Pb, Sn. Ferric analog of buergerite. Originally thought to be the ferric analog of dravite [i.e., ferridravite, *AM 64:945(1979)*], but Mg is not dominant in either the Y or Z site. Uniaxial (-); $N_{\text{O}} = 1.800$ (to 1.82 with highest Fe content), $N_{\text{E}} = 1.743\text{--}1.751$; strongly dichroic; O > E. O, brown to opaque; E, light brown. Found in hydrothermally altered basaltic clasts (to 10 cm) entrained within a metamorphosed evaporite [*RASPA 21:41(1994)*] associated with microcline, talc, dolomite, danburite, and rare boracite at *Cristalmuya gorge, 200 m downhill from the San Francisco asbestos mine, 50 km from Villa Tunari, Chapare Prov., Cochabamba Dept., Bolivia*. vk, EF

61.3.1.7 Olenite $(\text{Na,Ca},\square)_{1-x}(\text{Al,Li})_3\text{Al}_6(\text{BO}_3)_3(\text{Si,B})_6\text{O}_{18}(\text{O})_3(\text{OH})$

Named in 1986 by Sokolov et al. for the locality. Tourmaline group. *HEX-R R3m*. $a = 15.775\text{--}15.803$, $c = 7.079\text{--}7.086$, $Z = 3$, $D = 3.12$. *39-336*: 6.33₃ 4.18₄ 3.95₇ 3.43₈ 3.39₇ 2.92₃ 2.55₁₀ 2.02₃. Structure solution shows that B substitutes for tetrahedral Si (0.50 atoms). Acicular crystals, elongated and striated along [0001], also crystals to several centimeters from pegmatite. Pale pink, white streak, vitreous to oily luster, translucent. $H = 7$. $G = 3.01$. No cleavage, brittle. Nonfluorescent. An aluminum-rich tourmaline, can be slightly alkali-deficient; major substituents include Li for Al in Y. Minor substituents include Fe^{3+} , Mn^{2+} , Mg, Ca, K, F. Alkali deficiency in X can be compensated by Y-site low-valence substituents (e.g., Li) and by hydroxylation. *GCA 48:1331(1984)*. Many analyses (without citing specific localities) show essentially continuous solid solution with elbaite. ZnO to 3.8 wt %. *ZVMO 117:70(1988)*, *AM 73:441(1988)*. Uniaxial (-); $N_{\text{O}} = 1.654$, $N_{\text{E}} = 1.635$; dichroic; O > E. O, bright pink; E, pinkish yellow. Occurs in highly fractionated granitic pegmatites; type material is from a zone within an "elbaite" crystal. Also found within zoned crystals from Elba. Black Mountain quarry, Rumford, Oxford Co., ME; Belo Horizonte No. 1 pegmatite, Anza, Riverside Co., CA; *Decembrist pegmatite field, Olenek River Basin, Russia*; San Piero di Campo, Elba, Italy. vk, EF *ZVMO 115:119(1986)*

61.3.1.8 Elbaite $\text{Na}(\text{Li}_{0.5}\text{Al}_{0.5})_3\text{Al}_6(\text{BO}_3)_3\text{Si}_6\text{O}_{18}(\text{OH})_3(\text{F})$

Named in 1908 for the locality. Tourmaline group. *HEX-R R3m*. $a = 15.810(\text{ideal})-16.23$, $c = 7.085(\text{ideal})-7.26$, $Z = 3$, $D = 3.07$. 26-964(nat): 6.32_{2.5} 4.20₆ 3.96₈ 3.45₇ 2.93₉ 2.56₁₀ 2.03₅. **Habit:** Prismatic crystals generally elongated and striated along [0001], frequently acicular, commonly with etched terminal faces; hemimorphic, usually with pedion opposite one or two pyramids, crystals often to many centimeters; twinning rare. **Physical properties:** Usually green, frequently pink, red, or blue grading to black; sometimes brown or colorless, rarely yellow or orange, often multicolored longitudinally and/or concentrically; streak is white to very pale shade of the massive mineral; vitreous to oily luster; usually transparent to translucent. Cleavage {1120}, {1011}, poor; conchoidal fracture; brittle. $H = 7\frac{1}{2}$. $G = 3.05-3.10$ (low iron compositions). Insoluble in virtually all acids except HF; piezoelectric, pyroelectric; rarely fluorescent weak blue-white SWUV. IR data: *K 14:370(1969)*. **Chemistry:** Numerous simple trace element chromophoric octahedral substitutions (Fe^{2+} [green], Fe^{3+} [yellow], $\text{Fe}_{0.5}^{2+} \leftrightarrow \text{Fe}_{0.5}^{3+}$ [blue], Mn^{2+} [pink], Mn^{3+} [red], rarely Cu^{2+} [blue]); if present, iron in various valences generally dominates chromophoric effects, other substitutions $\text{F} \leftrightarrow \text{OH}$, $\text{Ca}_{0.5} \leftrightarrow \text{Na}$, coupled substitution $(\text{Li}_{0.5}\text{Al}_{0.5})(\text{OH})$ for $\text{Al}(\text{O})$; concentric and longitudinal color zoning common; enormously variable repeated concentric zoning along prisms with red triskelions near terminations (Antsirabé and Anjanaboina), sometimes slightly alkali deficient with increasing Al or Fe^{3+} substitution, extensive substitutions grading into schorl with increasing iron or to olenite with decreasing lithium. Analyses commonly show $\text{Li} \approx 1.3$ or fewer atoms per formula unit. *CMP 62:109(1967)*. In the elbaite-schorl series, MnO has been found to substitute into the composition, and a manganese schorl-elbaite from Tsilaisina, Madagascar, which contained about 6 wt % MnO (as much as 8.2 wt % MnO was found) was called "tsilaisite." *CE 4:208(1929)*. Recently, a yellowish-green elbaite with 8.8 wt % MnO was described. *AM 71:1214(1986)*. However, even this quantity of MnO falls short of the approximate 10.8 wt % MnO required to constitute a separate species with a majority of the Mn occupying the Y position, so the name *tsilaisite* should not be used. *AM 71:1214(1986)*. The role of radioactivity and the intensity of color was demonstrated in pink-red elbaites. *AM 73:822(1988)*. **Optics:** Uniaxial (-); $N_O = 1.619-1.620$, $N_E = 1.634-1.641$ (for colorless, pink, light green varieties, *G&G 15:19(1975)*); $N_O = 1.631-1.634$, $N_E = 1.653-1.656$ (for dark blue, dark green varieties); dichroic; $O > E$. **Uses:** The use of tourmaline as a gem dates from the sixteenth century with the discovery of green gem tourmaline, which at first was thought to be emerald, in Brazil. Any transparent tourmaline can be used as a gem, but most species are black or too dark or of unattractive colors; practically speaking, only elbaite and to a minor extent liddicoatite are used. The varietal names rubellite (for pink or red), indicolite (for blue), verdelite (for green), and achroite (for colorless) have been used in gemology, but only *rubellite* and to a minor extent *indicolite* are so used today; the terms *elbaite*,

verdelite, and *achroite* are not now used to designate gems. Some chromian uvites and some dravites make attractive gems when transparent, but they are rare. Bicolored elbaite, with pink centers and green rinds, is called "watermelon tourmaline." Generally, in late-stage cavities or cavity margins associated with lepidolite and albite in granite pegmatites; rarely from aplite, schists, or dolomites. Sometimes replaced by muscovite, lepidolite, or cookeite. **Localities:** Localities for fine quality and noteworthy material include: Dunton mine(!), Newry and Mt. Mica mine(!), Paris, Oxford Co., ME; Gillette mine, Haddam, Middlesex Co., CT; Pala Chief(!), Stewart(!), and Tourmaline Queen mines(!), Pala; Little Three mine(!), Ramona and Himalaya mine(!), Mesa Grande, San Diego Co., CA; *Grotto d'oggi, San Piero di Campo, Elba, Italy*; Lengenbach quarry, Binn, Switzerland; Penig, Saxony, Germany; Utö and Varuträsk, Sweden; Mursinka, Pervoural'sk (Shaitanka), Lipovaya, and Alabashka, Ural Mts., and Hoppevskaya Gora, Sherlovaya Gora, and Soktuj Gora prospects, Adun-Chalon Mt. district and Dorogoy-Utess prospects, Borshechovochnoi Mt. district, both near Nerchinsk, Siberia, Russia; Malkhan district, Krasny Chikoi, Transbaikalia, and Chita region, Siberia; Mawi, Korgay and Paprock, Laghman(!), and Kunar(!), Nuristan Valley, Afghanistan; Sri Lanka; Chainpur and Sankhuwa Sabha district, Nepal(!); Stak Nala(!), NWF, Pakistan; Jos(!), Nigeria; Alto Ligonha(!), Mozambique; Otjua mine(!), Karibib, and Usakos, Namibia; Anjanaboina(!) and Shatany Valley(!), Antandrokomby, Mt. Bity district, Madagascar; in MG, Brazil, at Coronel Murta(!) and at Urubu mine, Itinga (fluorescent white); Barra do Salinas(!), Salinas; Jonas mine(!), Itatiaia, Conselheiro Pena (gem rubellite crystals to 1.07 m long); Corrego Frio mine, Divino das Laranjeiras, Galileia; Golconda mine(!), Coroaci; Cruzeiro and Aricanga mines(!), São Jose da Safira; Santa Rosa mine(!), Itambacuri; Viadinho mine(!), Marilac; Xanda and Limoero mines(!), Virgem da Lapa, and in Paraíba at São Jose da Batalha (brilliant sky-blue gems colored by Cu; CuO as much as 2.4 wt %); native Cu and tenorite inclusions have been found in the cuprian elbaite [GG 30:178(1994)]; Capoeira, RGN; Gregorio pegmatite, Serra dos Quintos, RGN; Lavra da Ilha, Itinga; Novo Cruzeiro, Rodrigo Silva mine, Resplendor, Rio Doce, Santana do Encoberto. vk, EF

61.3.1.9 Dravite $\text{NaMg}_3\text{Al}_6(\text{BO}_3)_3\text{Si}_6\text{O}_{18}(\text{OH})_3(\text{OH})$

Named in 1883 by Tschermak for the locality. Tourmaline group. **HEX-R $R\bar{3}m$.** $a = 15.910$, $c = 7.210$, $Z = 3$, $D = 3.02\text{--}3.07$. 14-76: 6.38₃ 4.22₇ 3.99₉ 3.48₆ 2.96₉ 2.58₁₀ 2.04₅ 1.92₄. Vanadium-rich (4.9 wt % V_2O_3) dravite has $a = 15.960$, $c = 7.189$. PD 7:236(1992), 44-1457. Chromian dravite has $a = 15.92$, $c = 7.15$. 25-1307, 45-1340. 45-1340: 4.60₁ 4.22₁ 3.98₁₀ 3.46₁ 3.12₁ 2.95₁ 2.57₃ 1.59₁. Structure: AM 78:265(1993). Partial Z site occupancy by Mg. Small crystals and grains, usually elongated, crystals usually have one pyramid with hexagonal prism with a pedion or another pyramid; Yin-nietharra crystals show apparent, higher, nonhemimorphic, symmetry. Crystals from micrometers to many centimeters. Brown to black, pale brown to

gray streak, vitreous to oily luster, translucent. $H = 7-7\frac{1}{2}$. $G = 2.9-3.3$. No cleavage, brittle. Low iron compositions may be fluorescent SWUV yellow to orange. Magnesium- and sodium-bearing tourmaline; minor substituents include Fe^{2+} , Mn^{2+} , Ti^{4+} , Ca, Fe^{3+} , Cr^{3+} , V^{3+} . Complete compositional variability from dravite through schorl or uvite is common and that to chromdravite exists. Uniaxial (-); $N_O = 1.635$ (low iron)-1.661, $N_E = 1.610$ (low iron)-1.632; strongly dichroic; $O > E$. O, brown to yellow; E, yellow to colorless. V-rich material has $N_E = 1.646$, $N_O = 1.676$; E, light yellow green; O, medium brown. Commonly found in magnesian marbles or schists, sometimes slates, sometimes authigenic. Many worldwide localities and only localities for fine material are given here: Dunton mine(1), Newry and Black Hawk mine, Blue Hill, ME; Franconia mine(1), Franconia, Cornerstone Mountain mine, Orford, Warren, NH; Cod Fish Hill mine, Bethel, CT; McLearn mine, De Kalb, St Lawrence Co., Gomer Jones locality(1), Gouverneur, Macomb, Powers locality(1), Pierrepont, Reese locality(1), Richville, $2\frac{1}{2}$ mine, Talcville, NY; Franklin marble, Franklin, Lambertville, and Limecrest quarry, Sparta, NJ; Adams mine(1), Hiddenite and Crabtree mine, Spruce Pine, NC; Colfax, and Crestmore, Riverside Co., CA; V-rich (4.9 wt % V_2O_3) at Silver Knob, Mariposa Co., CA; Desmont mine, Monmouth, ONT, Canada; Santa Cruz(1), SON, Mexico; Bjordam mine, Bamble, Fredriksvårn, Kjenlid and Snarum, Norway; Simplon Tunnel and Feldbach, Binntal, Switzerland; Cyrilov, Moravia, Czech Republic; Prevali and Windisch Kappel, Carinthia and *Unterdrauburg, Dobrowa, Drava R., Carinthia, Austria*; chromian dravite (to 13.9 wt % (V_2O_3)) occurs in chromite ores from the Vardos area, northern Greece; green, prismatic crystals to 4.5 cm from Mikhailovskoye, Chita Oblast, Transbaikal, Russia; chromian dravite (3.70 wt % Cr_2O_3) from Sarykulboldy chrysoprase deposit, central Kazakhstan; Osarara, Narok district, Kenya; Gujarkot, Bheri zone, Nepal; chromian dravite (to 23 wt %) (V_2O_3) occurs at Nabsahi, Orissa, India; crystals to 15 cm from the prismatic crystals from Brumado, BA, Brazil. Soklich mine(1), Yinnietharra Station, WA, Australia. VK, EF MM 41:408(1977) AM 70:1(1985), DANS-ESS 315:225(1990).

61.3.1.10 Schorl $NaFe_3^{2+}Al_6(BO_3)_3Si_6O_{18}(OH)_3(OH)$

Early (1524) name, perhaps indicating *worthless*; by 1747, used specifically for a tourmaline. Tourmaline group. HEX-R $R3m$. $a = 15.992$, $c = 7.172$, $Z = 3$, $D = 3.30$. $43-1464$: 6.37₅ 4.23₅ 4.00₇ 3.47₅ 2.96₅ 2.58₁₀ 2.17₂ 2.04₄. Structure: AM 74:422(1989). Prismatic crystals, generally elongated and striated along [0001], sometimes acicular and in radial groups, terminated crystals usually with one or two pyramids opposite a pedion, crystals to many centimeters from pegmatite. Black, sometimes with very dark brown, green, or blue internal reflections, occasionally blue translucent; grayish white to bluish white streak; vitreous to oily luster. $H = 7\frac{1}{2}$. $G = 3.13$. No cleavage, brittle. Non-fluorescent. Iron- and sodium-bearing tourmaline, usually slightly alkali-deficient; minor substituents include Fe^{3+} , Mn^{2+} , Mg, Ca, Li, Cr^{3+} , Ti^{4+} . F can dominate or fill O3 site. Alkali deficiency can arise from coupled substitutions:

vacancy + $R^{3+} \leftrightarrow R^+ + R^{2+}$. *AM 74:1317(1989)*. Complete series observed with dravite/uvite or elbaite. Uniaxial (-); $N_{Eav} = 1.638$, $N_{Oav} = 1.663$; $N_O = 1.640-1.698$, $N_E = 1.622-1.675$; blue and green schorls have lower refractive indices than black schorls; strongly dichroic; $O > E$. O, gray, dark brown, blue, or green; E, light gray, brown, blue, or green. Type material believed to be from a German tin and/or tungsten deposit. Frequently found in granite pegmatite and granite. Often found in quartz veins; also greisens, schists, gneisses, phyllites; can be authigenic. Sometimes replaced by muscovite; rarely chamosite. Occurs in many worldwide localities; only well-known and notable localities are given here: Noyes and Uncle Tom Mts., Greenwood; Mount Mica and Whispering Pines(!) quarries, Paris; Hinckley prospect, Pownal; Barbour prospect, Stoneham, ME; Rice mine(!), Groton, Grafton Co., NH; Rollstone Hill quarry, Fitchburg, MA; York mine, Overlook, NY; Southern Pacific mine, Nuevo, Riverside Co.; Blue Chihuahua mine(!), Chihuahua Valley; Fano Simmons(!) and Mile Down(!) mines, Little Cahuilla Mt.; Hercules(!) and Little Three mines(!), Ramona, San Diego Co., CA; Tregarden mine, Luxulyan; Goonbarrow mine, St. Austell, and numerous other localities in Cornwall, England; Pisek, Bohemia and Dolni Bory, Moravia, Horni Bory, and Cyrilov, Moravia, Czech Republic; Vitoshka Mountain, Sofia, Bulgaria; Kaatiala, Erajarvi, Finland; Andreasberg, Saxony, Germany; Arendal, Aust-Agder, and Kragerø, Telemark, Norway; Alabashka, Mursinka district, Yekaterinburg Oblast, Russia; Dassu(!), Baltistan and Stak Nala(!), Pakistan; Paprock, Nuristan, Afghanistan; Barra do Salinas(!), Conseheiro Pena; Salinas; Divino das Larenjeiras, Galileia; Cruzeiro mine(!), São Jose da Safira, MG, Brazil. *vk, EF*

61.3.1.11 Chromdravite $NaMg_3(Cr_5^{2+}Fe^{3+})(BO_3)_3Si_6O_{18}(OH)_3(OH)$

Named in 1983 by Rumantseva for compositional relationship to dravite. Tourmaline group. *HEX-R R3m*. $a = 16.11$, $c = 7.27$, $Z = 3$, $D = 3.38$. *35-717: 6.57₅ 5.10₄ 4.31₄ 4.05₅ 3.58₈ 3.04₈ 2.62₁₀ 2.08₅*. Small crystals and grains, nearly equant, crystals to several millimeters. Dark green to black, grayish green streak, vitreous to oily luster, translucent. $H = 7$. $G = 3.39-3.40$. No cleavage, brittle. Nonfluorescent. IR data: *ZVMO 112:222(1983)*. Magnesium- and chromium-bearing tourmaline; minor substituents include Mn, Ti^{4+} , Na, V^{3+} (to 13.3 wt %). *ZVMO 114:55(1985)*. Uniaxial (-); $N_O = 1.778-1.780$, $N_E = 1.722-1.724$; strongly dichroic; $O > E$. O, dark green; E, yellow-green. Type material occurs in micaceous metasomatites associated with chromian phengite, taeniolite, vanadian muscovite, quartz, and dolomite. Found in the *Onezhkii depression, central Karelia, Russia*. *EF*

61.4.1.1 Abenakiite-(Ce) $Na_{26}REE_6(SiO_3)_6(PO_4)_6(CO_3)_6(S^{4+}O_2)O$

Named in 1994 by McDonald et al. for the Abenaki Indian tribe, which inhabited the area around the type locality. *HEX-R R3*. $a = 16.018$, $c = 19.761$, $Z = 3$, $D = 3.27$. *PD: 11.4_{7.5} 8.04_{8.5} 6.55_{8.5} 4.65_{7.5} 3.77₉ 3.59₈ 3.15₇ 2.67₁₀*. Structure: *CM 32:843(1994)*. Occurs as a single 2 mm × 1 mm

pale brown ellipsoidal grain in association with aegirine, eudialyte, manganneptunite, polyolithionite, serandite, and steenstrupine-(Ce). Also pinkish grains. White streak, vitreous luster. Cleavage {0001}, poor; conchoidal fracture; brittle. $H > 4$. $G = 3.21$. Weakly effervescent in 1:1 HCl. Nonfluorescent. Uniaxial (-); $N_O = 1.589$, $N_E = 1.586$; nonpleochroic. Occurs in a xenolith of sodalite syenite in nepheline syenite at the *Poudrette quarry, Mt. St.-Hilaire, Rouville Co., QUE, Canada*. EF

61.4.2.1 Steenstrupine-(Ce) $\text{Na}_{14}\text{Ce}_6\text{Mn}^{2+}\text{Mn}^{3+}\text{Fe}_2^{3+}(\text{Zr,Th})(\text{OH})_2(\text{PO}_4)_7(\text{Si}_6\text{O}_{18})_2 \cdot 3\text{H}_2\text{O}$

Named in 1881 by Lorenzen for Knud Johannes Vogelius Steenstrup (1842–1913), geologist, Copenhagen, Denmark. *HEX-R R3m*. $a = 10.456\text{--}10.460$, $c = 44.985\text{--}45.479$, $Z = 3$, $D = 3.63\text{--}3.67$. *41-1419(nat)*: 15.1_6 3.27_{10} 3.17_8 3.04_5 2.88_5 2.74_8 2.60_9 2.11_4 . Generally partly to completely metamict. Structure: *TMPM 31:47(1983)*. Steenstrupine can be described as a rod structure consisting of two rods having different sequences. In rod 1, T is a disordered (PO_4) group and the sequence Na1–M1–Na1 is a face-sharing octahedral trimer and M3–M2 a face-sharing octahedral dimer. A $(\text{Si}_6\text{O}_{18})$ six-membered ring occurs, with approximate point symmetry $\{C3i\}$. Steenstrupine has one of the largest unit cell volumes known for a mineral species. Crystals > 4 cm. Black to dark brown, brownish red; white, rose, or tan streak; vitreous to metallic luster or greasy and sometimes dull. Cleavage {0001}, poor; uneven to conchoidal fracture; brittle. $H = 4\text{--}5$. $G = 3.25\text{--}3.50$. IR, DTG, DTA data: *NJBA 140:300(1981)*. Not soluble in acids. A complex REE-Th silicophosphate. Analysis (wt %): Na_2O , 0.5–8.3; K_2O , 0.0–1.2; BeO , to 1.9; MgO , 0.0–1.6; CaO , 1.85–8.4; MnO , 0.0–29.0; PbO , 0.0–1.0; Al_2O_3 , 0.0–2.4; Mn_2O_3 , 0.0–6.8; Fe_2O_3 , 0.65–9.7; REE_2O_3 , to 33; SiO_2 , 7–32.4; ThO_2 , 2.1–12.1; $\text{Ta}_2\text{O}_5 + \text{Nb}_2\text{O}_5$, 0.2–4.4; P_2O_5 , 0.0–10.7; H_2O , 3.4–18.6; F, to 3.7. Uniaxial (-) or isotropic; $N_O = 1.665\text{--}1.668$, $N_E = 1.660\text{--}1.663$; colorless to pale yellow, brownish red, and yellowish brown. Pleochroism is weak in browns and yellows. Yellow-brown parallel to c and brown or dark brown perpendicular to c . A characteristic mineral of ultra-agpaitic pegmatites of nepheline syenites and sodalite syenites. Found in pegmatoid veins, and late hydrothermal veins associated with natrolite, albite, aegirine, sodalite, epistolite, and others. Often contains inclusions of other minerals. Found at Mt. St.-Hilaire, QUE, Canada; at *Tunugdliarfik, Tugtup Agtakorfia*, and nearby Igdlunguak, and Tupersuatsiak in the Ilimaussaq intrusion, southern Greenland; also in the Kangerdluarssuk area, all in the Julianehaab district; Mt. Punkaruaiev, Jubilee pegmatite on Mt. Karnasurt (Mn-rich), Mt. Nepka, Mt. Alluaiev, Mt. Sengischorr, and Kitkuai R. valley, Lovozero massif, Kola Penin., Russia. EF *M0G 167:1(1962)* *MIN 3(1):497(1972)*.

61.4.2.2 Thorosteenstrupine $(\text{Ca,Th,Mn})_3\text{Si}_4\text{O}_{11}\text{F} \cdot 6\text{H}_2\text{O}$

Named in 1963 by Kuprianova et al. from the composition: like steenstrupine, but with predominant Th. May be a mixture of ekanite $\text{ThCa}_2\text{Si}_8\text{O}_{20}$ and

cheralite $(\text{Ce,Th})\text{PO}_4$ as all X-ray lines could be indexed for these two minerals. *CM* 20:65(1982). See steenstrupine (61.4.2.1). Amorphous, recrystallizes upon heating, no ICDD data. *PD*(heated, nat): 4.08₁₀ 3.31₆ 3.25₁₀ 3.06₉ 2.84₈ 2.73₆ 2.61₁₀ 2.13₆ 1.94₇ 1.91₇ 1.79₈. Fine platy crystals 2–5 mm, sometimes to 1 cm long. Dark brown, nearly black; greasy–vitreous luster. Conchoidal fracture, brittle. $H \approx 4$. $G = 3.02$. IR and thermal data: *ZVMO* 91:325(1963). Analysis (wt %): Al_2O_3 , 0.31; Fe_2O_3 , 0.65; $\Sigma \text{Ce}_2\text{O}_3$ and Y_2O_3 , 1.12; SiO_2 , 31.87; TiO_2 , none; ThO_2 , 35.70; H_2O , 13.77; F, 2.43; P_2O_5 , none; MnO , 7.75; CaO , 8.38. $N = 1.63$ – 1.66 ; isotropic. Occurs in metasomatic veins, associated with microcline, albite, aegirine–augite, quartz, fluorite, thorite, and REE-bearing miserite. *Unspecified locality in eastern Siberia, Russia*. *EF MIN* 3(1):501(1972).

Eight-Membered Rings

62.1.1.1 Muirite $\text{Ba}_{10}\text{Ca}_2\text{Mn}^{2+}\text{TiSi}_{10}\text{O}_{30}(\text{OH},\text{Cl},\text{F})_{10}$

Named in 1965 by Alfors et al. for John Muir (1838–1914), American geologist and explorer, who made early observations in geology in the Sierra Nevada Mountains, California. TET $P4/mmm$. $a = 14.000\text{--}14.022$, $c = 5.625\text{--}5.627$, $Z = 1$, $D = 3.88$. 18-161(nat): 4.42₈ 3.73₆ 3.60₅ 3.51₆ 3.31₆ 2.91₁₀ 2.81₄ 2.74₄. Structure: *SCI 173:3961(1971)*, *DAN SSSR 221:343(1975)*. Grains to 1 mm, aggregates to 3 mm. Generally anhedral grains, but subhedral and euhedral grains to 3 mm occur. {001} + {100} dominant with lesser {110} and {h0l} forms. Orange, pale orange streak, subvitreous luster. Cleavage (001), (100), indistinct. $H \approx 2\frac{1}{2}$. $G = 3.86$. Decomposed by dilute HCl and HNO₃, grains lose their color and disintegrate to a white or colorless residue; no effect from H₂SO₄, acetic acid, or NaOH. Analysis (wt %): SiO₂, 22.15; TiO₂, 4.17; Al₂O₃, 0.53; FeO, 0.4; MnO, 2.04; MgO, 0.11; CaO, 4.67; SrO, 0.13; BaO, 59.6; K₂O, 0.1; F, 1.4; Cl, 4.5; H₂O, 1.8. Uniaxial (+); $N_0 = 1.697$, $N_E = 1.704$. O, orange; E, colorless. Anomalous interference colors. Occurs at *Rush Creek and Big Creek, Fresno Co., CA*, in metasediments surrounded by quartz diorite; in sanbornite–quartz rock. Large brown grains (to several centimeters) in sanbornite with hedenbergite, fresnoite, uvarovite, and others at the Gunn Claims, Itsy Mts., Macmillan Pass, YT, Canada. EF *MIN 3(2):43(1981)*, *AM 69:358(1984)*.

62.1.2.1 Megacyclite $\text{Na}_8\text{KSi}_9\text{O}_{18}(\text{OH})_9 \cdot 19\text{H}_2\text{O}$

Named in 1993 by Khomyakov et al. from the Greek *mega*, large, and *cyclos*, rings, in allusion to the size of the structure of insular circular radicals made of 18 SiO₄ tetrahedra. MON $P2_1/c$. $a = 24.91$, $b = 11.94$, $c = 14.92$, $\beta = 94.47^\circ$, $Z = 4$, $D = 1.87$. PD(nat): 7.42₂ 6.92₂ 4.26₆ 3.08₁₀ 2.94₇ 2.65₆ 2.40₄ 2.29₄. Structure: *K 37:334(1992)*. Anhedral grains 1–3 mm across and aggregates to 3–5 mm across. Colorless, dull vitreous luster. Cleavage {100}, excellent, {001}, less so; gradual (steplike) fracture. $H = 2$. $G = 1.82$. IR data: *ZVMO 122:125(1993)*. Relatively easily soluble in water at 25° giving an alkaline fluid. Turns white in air after prolonged exposure and with production of poorly known secondary alteration products. Analysis (wt %): H₂O, 33.2; Na₂O, 19.75; K₂O, 3.62; SiO₂, 43.4. Biaxial (–); $Y = b$, $X \wedge c = 30^\circ$; $N_x = 1.460$, $N_y = 1.478$, $N_z = 1.481$; $2V = 43^\circ$; $r > v$, strong. Occurs on *Mt.*

Rasvumchorr, Khibiny massif, Kola Penin., Russia; in veinlike bodies of pegmatitic rock. A hydrothermal mineral formed at very low temperature during final stages of crystallization. Occurs as inclusions 1–3 mm across intergrown with revdite in fenaksite–delhayelite veins. EF

Condensed Rings

63.1.1.1 Steacyite $K_{0.6-0.8}(Ca,Na)_2ThSi_8O_{20}$

Named in 1982 by Perrault and Szymanski for Harold R. Steacy (b.1923), Geological Survey of Canada, in recognition of his work on radioactive minerals of Canada. Originally described in 1970 as desourdyite, changed in 1971 to ekanite, and redefined (1982) as steacyite. Compare iraqite-La (63.1.1.2). TET $P4/mcc$. $a = 7.583$, $c = 14.763$, $Z = 2$, $D = 3.32$. 35-531 (Mt. St.-Hilaire): 5.37₁ 5.30₄ 3.38₁₀ 3.32₅ 2.64₄ 2.16₂ 2.00₃ 1.821₂; 39-408 (Guinea): 7.57₃ 7.38₃ 5.29₁₀ 3.37₁₀ 3.32₅ 2.64₈ 2.53₃ 1.99₅. Structure: $AC(B)$ 28:1794 (1972). Called ekanite in the published structure. The silicate unit is an isolated, double four-membered ring of composition $[Si_8O_{20}]^{8-}$ lying perpendicular to c . The unit cell is dimensionally equivalent to that of ekanite (72.1.1.1), whose structure can also be interpreted as having condensed four-tetrahedron rings. Isostructural with iraqite-La. Tabular {001} to prismatic [001], 1- to 3-mm crystals displaying {001}, {100}, {010}, {101}; sometimes in spherical aggregates. Cruciform twins. Dark gray, gray-brown, brown, sometimes color-zoned with darker cores; greasy-vitreous luster; transparent. $H \approx 5$. $G = 2.95$. Uniaxial (-); $N_O = 1.573$, $N_E = 1.572$. Found as an accessory mineral in pegmatite veins, marble xenoliths, hornfels, and in cavities in igneous breccia at *Mt. St.-Hilaire, QUE, Canada*; from peralkaline pegmatite of the Dara-i-Pioz massif, Tien Shan, Tajikistan; on Rouma Isle, Los Islands., Guinea. Some material designated as ekanite may actually be steacyite. AR *CM* 20:59 (1982), *NJMM*:233 (1987), *EJM* 5:971 (1993).

63.1.1.2 Iraqite-La $K(Ca,Na)_4(La,Ce,Th)_2(Si,Al)_{16}O_{40}$

Named in 1976 by Livingstone et al. for the locality. Compare ekanite (72.1.1.1) and steacyite (63.1.1.1). TET $P4/mcc$. $a = 7.61$, $c = 14.72$, $Z = 1$, $D = 3.28$. 29-995: 7.62₃ 7.36₈ 5.28₁₀ 3.40₆ 3.38₈ 3.31₁₀ 2.64₁₀ 2.17₄. Isostructural with steacyite. Pale greenish yellow, dull to pearly luster, translucent. $H = 4\frac{1}{2}$. $G = 3.27$. Uniaxial (-); $N_O = 1.590$, $N_E = 1.585$. Found in granite at dolomitic marble contact at *Shakhi-Rash Mt., Hero, Qala-Diz, northern Iraq*. AR *MM* 40:441 (1976).

MILARITE GROUP

The milarite group, also known as the osumilite group, consists of tectosilicates having the general formula

where

A = K, Na, Mg, H₂O, H₃O⁺, □, Ca, Ba

M = Mg, Ca, Fe³⁺, Ti, Sn, Fe²⁺, Al, Zr, Na, Y, REE

T2 = tetrahedral site = Al, Be, Mg, Fe, Li, B, Mn²⁺, Si, Zn

T1 = tetrahedral site = Si, Al

and the structure is a framework structure, usually hexagonal.

The structure consists of double six-membered rings of linked (Si,Al)O₄ tetrahedra (T1 tetrahedra). The double rings are linked to each other both laterally and vertically, not only by (Mg,Fe²⁺,Mn)O₄ octahedra (M sites) but also by (Al,Fe)O₄ tetrahedra (T2 tetrahedra), to produce a three-dimensionally linked framework structure. Si occurs only in ring-forming and not in linking tetrahedra. Each of the T1 tetrahedra shares three of its corners with adjacent T1 tetrahedra to form the double rings, which have approximate composition Si₁₀Al₂O₃₀. The fourth corner is shared with a T2 tetrahedron and an M octahedron. Molecules.

OSUMILITE: $KMg_2Al_3Si_{10}Al_2O_{30}$

Osumilite is similar to beryl and cordierite, but the six-membered rings are stacked in pairs along the c axis direction. There are also K atoms between silicate layers, centered on the rings.

The structure contains channels parallel to *z* which can be occupied by large cations and possibly by water molecules.

Review papers on the mineralogy of the group include: *MIN 3(2):139(1981)*, *DHZ 1B:541(1986)* and *AM 76:1836(1991)*.

63.2.1a.1 Brannockite $\text{KSn}_2\text{Li}_3\text{Si}_{12}\text{O}_{30}$

Named in 1973 by White et al. for Kent Combs Brannock (1923–1973), chemist and mineralogist, Tennessee Eastman Company, Kingsport, TN. Milarite group. *HEX P6/mcc*. *a* = 10.0167–10.002, *c* = 14.2452–14.263, *Z* = 2 [*AM 73:595(1988)*], *D* = 3.08. *26-0853(nat)*: 8.69₆ 7.14₈ 5.50₇ 4.34₈ 4.11₁₀ 2.905₉ 2.68₆ 2.50₆. A double-ring silicate. The Na site of sugilite is vacant in brannockite. *AM 73:594(1988)*. Thin hexagonal plates to 1 mm: {100}, {110}, {114}, and {001} dominant; twinning on [210] twin axis, perpendicular to (001) plane, twin plane is (210) or (140). Colorless, white streak, vitreous luster, brittle. No cleavage. *G* = 2.980. Fluoresces bright blue-white under SWUV. Contains minor Na for K. Uniaxial (–); *N*_O = 1.567, *N*_E = 1.566. Occurs in vugs and open fissures in pegmatite with bavenite, tetrawickmanite, pyrite, titanite, albite, and quartz at the *Foote mine, Kings Mt., Bessemer*

City, NC. Formed in a low-temperature hydrothermal environment. *EF MR* 4:73(1973).

63.2.1a.2 Chayesite $K(\text{Mg,Fe}^{2+})_4\text{Fe}^{3+}[\text{Si}_{12}\text{O}_{30}]$

Named in 1989 by Velde et al. for Felix Chayes (1916–1993), Geophysical Laboratory, Washington, DC. Milarite group. See roedderite (63.2.1a.14), related by the substitution $\text{Fe}^{3+} + \square = \text{Fe}^{3+} = \text{Fe}^{2+} + (\text{Na, K})$. A solid-solution series exists between the two. *HEX* Probably *P6/mcc*. $a = 10.120\text{--}10.153$, $c = 14.305\text{--}14.388$, $Z = 4$, $D = 2.68$. *45-1472(nat)*: 7.14_8 5.08_{10} 4.14_5 3.75_{10} 3.35_5 3.24_{10} 2.93_5 2.78_8 . Tabular with {0001}, {1010}, {1120}, {1012}; tabular crystals to 100 μm . Deep blue, white streak, vitreous luster, transparent. No cleavage. Analysis (wt %), Utah: SiO_2 , 69.2; Al_2O_3 , 0.20; $\text{FeO} + \text{Fe}_2\text{O}_3$, 11.5; MgO , 12.70; Na_2O , 0.31; K_2O , 5.2; MnO , 0.29; TiO_2O , 0.25; Cancarix: SiO_2 , 70.3; FeO (total Fe), 12.6; MnO , 0.2; MgO , 11.4; Na_2O , 0.04; K_2O , 4.48. Uniaxial (+); Na(D) : $N_{\text{O}} = 1.575$, $N_{\text{E}} = 1.578$. O, sky-blue; E, colorless. Occurs as a rock-forming silicate in lamproite (both Utah and Spain). Associated with potassian richterite diopside and K-feldspar. Found at *Moon Canyon, E of Francis, Summit Co., Utah*; Cancarix, Albacete Prov., Spain. *EF AM* 74:1368(1989), *MM* 58:655(1994).

63.2.1a.3 Darapiosite $\text{KNa}_2\text{Zr}[\text{Li}(\text{Mn,Zr})_2\text{Si}_{12}\text{O}_{30}]$

Named in 1975 by Semenov et al. for the locality. Milarite group. *HEX* *P6/mcc*. $a = 10.32$, $c = 14.39$, $Z = 2$, $D = 2.80$. *29-825(O assigned because of poor agreement between d_{obs} and d_{calc})(nat)*: 7.09_6 4.43_4 4.13_5 3.75_4 3.26_{10} $2.93_{6.5}$ $2.76_{4.5}$ $2.56_{5.5}$. Isometric appearing crystals to 0.5 cm across. Colorless, white, rarely brownish or bluish; white streak; oily, greasy luster. $H = 5$. $G = 2.92$. IR data: *ZVMO 104:583(1975)*. 0.90% Nb_2O_5 substitutes for Zr. Uniaxial (–); $N_{\text{O}} = 1.580$, $N_{\text{E}} = 1.575$; usually not pleochroic, a blue variety has O, violet, E, blue. Occurs at *Dara-i-Pioz, Alai Range, Tien Shan, northern Tadzhikistan*, in peralkaline rocks (massif) and their cogenetic pegmatites. Associated with aegirine, quartz, sogdianite, eudialyte, schizolite, and polyolithionite. *EF AM* 61:1053(1976).

63.2.1a.4 Eifelite $\text{KNa}_3\text{Mg}[\text{Mg}_3\text{Si}_{12}\text{O}_{30}]$

Described in 1980 and named in 1983 by Abraham et al. for the Eifel region of Germany. Milarite group. Very similar to roedderite; only chemical analyses can positively distinguish the two minerals. A complete solid-solution series exists between eifelite and roedderite, with $2\text{Na} \leftrightarrow \text{Mg}$. Roedderite is $\text{KNaMg}_5\text{Si}_{12}\text{O}_{30}$. See the milarite group minerals. *HEX* *P6/mcc*. $a = 10.137\text{--}10.150$, $c = 14.223$, $Z = 2$, $D = 2.67$. *35-588(nat)*: 7.07_5 5.11_5 4.43_6 4.14_5 3.75_9 3.26_{10} 2.91_5 2.76_5 . Eifelite has octahedral Na (six-coordinated) with eight cations per formula unit outside of the hexagonal rings; it has the highest cation occupancy of any milarite group mineral. *CMP* 82:252(1983). Hexagonal, platy to prismatic; dominant forms: {1010}, {0001}, subordinate {1120} and {1012}; euhedral crystals to 1 mm in dia-

meter. Colorless to very light yellow or green, white streak, vitreous luster. No cleavage observed. Insoluble in HCl + H₂SO₄. Analysis (wt %): SiO₂, 71.06, 69.06; TiO₂, 0.06, 0.03; Al₂O₃, 0.79, 0.57; Cr₂O₃, 0.06, 0.00; FeO, 0.48, 0.19; MnO, 0.46, 0.53; CuO, 0.08, 0.16; ZnO, 0.34, 0.43; MgO, 16.25, 15.47; K₂O, 4.18, 4.16; Na₂O, 6.48, 8.07. Uniaxial (+); N_O = 1.5430–1.5445, N_E = 1.5443–1.5458; colorless; birefringence = 0.001 compared to 0.003–0.007 for roedderite. Occurs at *Bellerberg volcano, Mayen, eastern Eifel, Germany*, in peralkaline rocks. Melt-coated cavities in gneissic xenoliths ejected in leucite-tephrite lavas. Associated with pyroxene, amphibole, tridymite, hematite, quartz, sanidine, and pseudobrookite. *EF FM 58:3(1980), DA 44:89(1993)*.

63.2.1a.5 Merrihueite (K,Na)₂(Fe,Mg)₂[(Fe,Mg)₃Si₁₂O₃₀]

Named in 1965 by Dodd et al. for Craig M. Merrihue (1936–1965), Smithsonian astrophysical laboratory. Milarite group. See roedderite (63.2.1a.14), the Na and Mg analog of merrihueite. *HEX P6/mcc.* (Nat): *a* = 10.16, *c* = 14.32, *Z* = 2 [*SCI 149:972(1965)*]; (syn): *a* = 10.222, *c* = 14.152, *Z* = 2, *D* = 2.87. *21-1270(nat)*: 7.13₈ 5.50₁₀ 5.03₃ 3.73₁₀ 3.23₉ 2.92₆ 2.77₁₀ 2.01₂; *PD(syn)*: *AC(B) 28:267(1971)*. Structure solution for synthetic material: *AC(B) 28:267(1971)*. Greenish blue. Other physical properties were not determined. Analysis (wt %): SiO₂, 61.8; Al₂O₃, 0.3; FeO, 23.7 (total Fe); MgO, 4.4; MnO, 0.5; CaO, 0.3; K₂O, 3.8; Na₂O, 2.0. Uniaxial or biaxial with 2*V* = 5–10°; N_y = 1.559–1.592; colorless to greenish blue, *N* values variable with Fe content; anomalous blues to purples in normal thin sections suggesting a low to moderate birefringence. Occurs as inclusions, to 150 μm in diameter, in clinopyroxenes in chondrite in the Mezo-Medaras chondrite, *Mezo Medaras, Transylvania, Romania*; Iwo Jima volcano, Kyushu, Japan. *EF*

63.2.1a.6 Osumilite (K,Na)(Fe,Mg)₂[(Al,Fe)₂₋₃(Si,Al)₁₂O₃₀] · nH₂O

63.2.1a.7 Osumilite-(Mg) (K,Na)(Mg,Fe)₂[(Al,Fe)₂₋₃(Si,Al)₁₂O₃₀] · nH₂O, and crystal chemical formula CA₂(T₂)₃(T₁)₁₂O₃₀, where C = K,Na, A = Fe,Mg, T₂ = Al,Fe,Mg, and T₁ = Si,Al

Named in 1953 by Miyashiro for the old province of Osumi in Sakkabira, Kyushu, Japan; osumilite-(Mg) was named by Schreyer et al. in 1983 on the basis of its composition. Milarite group. *HEX P6/mcc.* *a* = 10.08–10.17, *c* = 14.26–14.35, *Z* = 2; (osumilite): *a* = 10.150, *c* = 14.289, *Z* = 2; [osumilite-(Mg)]: *a* = 10.078, *c* = 14.319, *Z* = 2, *D* = 2.63–2.74. *25-0658(nat osumilite)*: 7.13₇ 5.53₆ 5.09₇ 4.13₈ 3.75₈ 3.22₁₀ 2.92₉ 2.77₉; *30-942[osumilite-(Mg)]*: 7.1₄ 5.01₆ 4.11₆ 3.72₆ 3.22₁₀ 2.92₆ 2.77₆ 2.53₂; *29-1016[syn osumilite-(Mg)]*: 7.18₅ 5.04₆ 4.12₄ 3.73₄ 3.58₅ 3.21₁₀ 2.92₆ 2.77₆. Structure is similar to cordierite and beryl. Channels parallel to *c* formed by a superposition of double hexagonal rings. Tetrahedral rings are linked by octahedra and additional tetrahedra. A framework rather than a ring silicate. Channels contain large cations and possibly H₂O. A tectosilicate. Possible variable Si–Al order in the double hexagonal rings of the Nain, Labrador, osumilite. *AM 73:585(1988), DHZ*

IB:541(1986). **Habit:** Prismatic to tabular, with dominant {0001}, {1010}, {1120}, {1012}; to 10 mm across in Eifel region; twinning, sometimes on (2130) Eifel. **Physical properties:** Black to deep blue—usual color, pink from Nain and Norway, some dark brown or gray or colorless. Generally no cleavage; sometimes a prismatic cleavage is present. $G = 2.64$ (osumilite), 2.63 [osumilite-(Mg)], 2.60 [osumilite-(Mg) syn]; range 2.58–2.68. IR and Mössbauer data: *AM 63:490(1978)*. **Chemistry:** Osumilite has $\text{Fe}^{2+} + \text{Fe}^{3+}$. IR work sometimes shows no H_2O . Blue color due to intervalence charge transfer between octahedral Fe^{2+} and channel Fe^{3+} . Some Fe is in the channels. Alkali position may be partly vacant when octahedral Al is present: $\text{VI Al}^{3+} + \text{XII } \square \leftrightarrow \text{VI}(\text{Mg}, \text{Fe}^{2+}) + \text{XII}(\text{K}, \text{Na})$. $\text{Si} + \text{R}^{2+} \leftrightarrow 2\text{R}^{3+}$. Mainly $(\text{Fe}^{2+} + \text{Mg}^{2+}) + \text{Si} \leftrightarrow 2\text{Al}$. As much as ≈ 11 wt % FeO in Eifel material. Typical analyses (wt %): SiO_2 , ≈ 60 –62; Al_2O_3 , 19.5–24; FeO, 0.45–10.95; MgO, 1.3–9.3; Na_2O , 0.10–1.0; K_2O , 2.4–4.3; TiO_2 , 0.02–0.80; MnO, 0.2–1.5. **Optics:** Uniaxial (+) and (–); (range): $N_O = 1.536$ –1.565, $N_E = 1.544$ –1.563; (osumilite): $N_O = 1.546$, $N_E = 1.550$; (osumilite with 12.8 wt % FeO): $N_O = 1.565$, $N_E = 1.563$; [osumilite-(Mg)]: $N_E = 1.541$, $N_O = 1.547$. O, light blue, bluish purple, or light pink; E, colorless to brown. For (+) material, sometimes metamorphic osumilites are biaxial with $2V = 13$ –40° (Nain osumilite) due to Fe in channels. One sample from the Eifel region has been reported as (–), with E blue, and O brown to olive-brown, $N_E = 1.563$, $N_O = 1.565$; osumilite-(Mg) is all (+), birefringence increases with increasing Fe in the A site; N_O increases faster than N_E , reducing the birefringence. Osumilite with >90% (Fe, Mn, Ti) in A will be (–); optical orientation scheme: E parallel to *c*; absorption = O > E; low Fe-colorless; medium Fe-pink; high Fe-blue; heating pink Nain material produced blue color. Some Fe^{2+} oxidized to Fe^{3+} , more likely charge transfer between ferrous and ferric iron, Fe^{3+} in $T_2 + \text{Fe}^{2+}$ in A. **Occurrence:** Occurs in acid volcanic rocks (e.g., rhyolite, dacite), as anhedral phenocrysts (i.e., magmatic) in the groundmass and as cavity-lining crystals associated with tridymite and quartz. Also in contact-metamorphic xenoliths in volcanic rocks (e.g., Eifel region); in fused hornfels (buchites). In high-grade contact-metamorphic aureoles. Thus conditions of crystallization range from near-solidus volcanic to granulite-facies metamorphic. Osumilite is not stable in hydrous, low-temperature conditions. Stable in anhydrous high-temperature and high-pressure conditions, and in hydrous magmas at >1 kbar. Also in the Colomera Fe-meteorite. Present in regional metamorphic rocks. Found in a trachyte flow containing sanidinite xenoliths from Italy. Rarely in volcanic ash deposits. **Alteration:** will break down retrogressively to cordierite, mica, and quartz. As of 1988, about 24 natural occurrences were known. **Localities:** Localities for osumilite include: Obsidian Cliffs and North Sister Mt., Lane Co., OR; Fe-richest material from Bellerberg volcano, Mayen, Eifel, Germany; Nickenicher Sattel volcano, Eifel region, Germany; Funtanafigu quarry, Monte Arci, Cagliari, Sardinia, Italy; in Japan at Sakkabira, Kagoshima Pref., Kyushu; Hayato-cho, Kagoshima Pref.; in volcanic ash at Izumo-zaki and Oguni, Niigata Pref., Haneyama, Oita Pref.; Asama volcano, Yamanashi Pref. Those for

osumilite-(Mg) include: Ikkinikulluit Brook, Nain complex, LAB, Canada; *Tieveragh, County Antrim, Northern Ireland*; Vikesa, Rogaland, southwestern Norway; Fosso Ricomero, Viterbo, Latium, Italy; Malyi Nepiskol volcano, Caucasus Mts., Russia; in ultrapotassic lamprophyre dike at Chili Palca Hacienda, Puno Dept., southern Peru; in Japan at Shimizu and Iriki, Kagoshima Pref.; Haneyama, Oita Pref; Akagi volcano, Gumma Pref.; Rishiri Is., Hokkaido, Japan; about six areas, including Reference Peak and Mt. Riiser-Larsen, in Enderby Land, Antarctica. Localities for which the Fe/Mg ratio is not specified include: various localities, such as Lac Ste.-Marie, QUE, in the Grenville Prov., Canada; Kuppe buchite, Blauen, Eschwege, Germany; Ruaperhu and White Is., New Zealand. EF *AM 55:875(1970)*, *73:585(1988)*; *TMPM 31:215(1983)*; *DA 44:89(1993)*; *EJM 6:657(1994)*.

63.2.1a.8 Poudretteite $\text{KNa}_2\text{B}_3\text{Si}_{12}\text{O}_{30}$

Named in 1987 by Grice et al. for the locality. Milarite group. *HEX P6/mcc*. $a = 10.239\text{--}10.253$, $c = 13.485\text{--}13.503$, $Z = 2$, $D = 2.53$. *42-1376(nat)*: 6.74₃ 5.13₁₀ 4.07₃ 3.25₁₀ 2.96₄ 2.81₆ 2.69₅ 1.82₄. Structure: *CM 25:763(1987)*. General formula: ${}^9\text{B}^{12}\text{C}^6\text{A}_2(\text{T}_2)_3(\text{T}_1)_{12}\text{O}_{30}$; the B site is empty in poudretteite. K in a [12]-coordinated C site, Na in an octahedrally coordinated A site, B in a tetrahedrally coordinated T2 site, Si in a tetrahedrally coordinated T1 site. Prismatic; short parallel to {001}; equant, deeply barrel-shaped crystals, to 5 mm long, that look like etched quartz or fluorapophyllite; no twinning observed. Colorless to very pale pink, streak white; vitreous luster. No cleavage, splintery to conchoidal fracture. $H = 5$. $G = 2.51$. No response to UV light or cathodoluminescence. Analysis (wt %): SiO_2 , 77.7; B_2O_3 , 11.4; BeO , 0.0; Li_2O , 0.0; K_2O , 5.2; Na_2O , 6.2. Uniaxial (+); (Na D): $N_{\text{O}} = 1.516$, $N_{\text{E}} = 1.532$; colorless. Occurs in cavities in marble xenoliths in nepheline-syenite at the *Poudrette quarry, Mt. St.-Hilaire, QUE, Canada*. Associated with pectolite, apophyllite, and aegirine. EF *MR 21:284(1990)*.

63.2.1a.9 Sugilite $\text{KNa}_2(\text{Fe}^{3+}, \text{Fe}^{2+}, \text{Mn}^{2+}, \text{Al})_2\text{Li}_3\text{Si}_{12}\text{O}_{30} \cdot n\text{H}_2\text{O}$

Named in 1976 by Murakami et al. for Ken-ichi Sugi (1901–1948), Japanese petrologist; found in 1944 by Sugi and Kitsuna, but not identified. Milarite group. See the other members of the milarite group. *HEX P6/mcc*. $a = 9.986\text{--}10.040$, $c = 13.936\text{--}14.062$, $Z = 2$, $D = 2.80$. *29-824(nat)*[*MJJ 8:110(1976)*]: 6.98₁ 4.32₁₀ 4.06₆ 3.50₂ 3.19₈ 2.88₅ 2.725₁ 2.50₂; Wessels mine: 4.34₁₀ 4.08₅ 3.50₃ 3.28₃ 3.25₃ 3.19₁₀ 2.87₈ 2.51₂. A double-ring silicate. Na shows disordered ninefold coordination. *AM 73:595(1988)*. Often in large compact, pure masses, and granular to prismatic; to 2 cm. Pale pink, light brownish yellow, purple: manganoan variety, reddish purple (magenta), pink, deep pink; white streak; vitreous luster. No cleavage or {0001}, poor. $H = 5\frac{1}{2}\text{--}6\frac{1}{2}$. $G = 2.73\text{--}2.79$. IR data: *G&G 23:78(1987)*. DTA data: *NJBM 10:443(1990)*. Melts at $\approx 895^\circ$ to a pale brown glass. Pink to purple color due to the presence of trivalent manganese. *MM 58:681(1994)*. Pink material is Al-rich and purple material is Fe-rich. Analysis (wt %), Wessels mine material: FeO , 0.72; Fe_2O_3 ,

10.30; Li₂O, 3.72; Indian material: Mn₂O₃ to 3.6; some H₂O⁺ is present (to about 0.9 wt %), as well as H₂O⁻; SiO₂, 68.2–73.3; Al₂O₃, 0.48–9.7; Fe₂O₃, 3.2–13.9; Na₂O, 5.5–6.2; K₂O, 3.8–4.6; MnO, 0.1–3.0; Li₂O, 3.1–4.1. Uniaxial (-); N_O = 1.579–1.611 (Mn-bearing), N_E = 1.577–1.607; generally colorless but Mn-rich material may be pale pink and pleochroic; birefringence = 0.003–0.006. Refractive indices tend to increase from Al-rich, Fe-poor to Al-poor, Fe-rich material. Occurs in stratabound metamorphosed manganese deposits (e.g., India, South Africa, and Australia) and in peralkaline igneous rocks. Also in marble xenoliths, as at Mt. St.-Hilaire, QUE, Canada. At Iwagi Islet, Japan, occurs in aegirine syenite, with albite, aegirine, pectolite, and a Ca–K–Ti silicate. In the Kalahari manganese field, Cape Prov., South Africa, with braunite, hausmannite, manganite, and others as bedded seams to 3 cm thick. Occurs at Mt. St.-Hilaire, where it is associated with poudretteite, quartz, polythionite, and pectolite; Al-bearing (to 9.7 wt % Al₂O₃) from Cerchiara mine, near Faggiona, northern Apennines, Italy; fine crystals to 6 mm long and some crystals to 2 cm across at the Wessels and N'Chwaning mines, near Kuruman, Kalahari manganese field, Cape Prov., South Africa, often intergrown with variable amounts of chalcedony; at the Hoskins mine, Grenfell, and Woods mine, 30 km NNE of Tamworth, NSW, Australia; Madhya Pradesh, India; Mn-free from *Iwagi Islet*, and Mn-bearing from the Furumiya mine, *Ehime Pref., Japan*. Massive sugilite from the Wessels mine, called “lavulite,” is used as a popular gemstone. May be partly replaced by aegirine (retrogressive reaction) and other minerals. EF *NJBM* 10:443(1990); *MM* 58:671(1994), 58:679(1994).

63.2.1a.10 Yagiite (Na,K)_{1,5}Mg₂(Al,Mg)₃(Si,Al)₁₂O₃₀ or (Na,K)₃Mg₄(Al,Mg)₆(Si,Al)₂₄O₆₀

Named in 1969 by Bunch and Fuchs for Kenzo Yagi (b.1914), professor of geology, Hokkaido University, Sapporo, Japan. Milarite group. HEX *P6/mcc*. *a* = 10.09, *c* = 14.29, *Z* = 2, or 1 [*AM* 54:14(1969)], *D* = 2.70. *21-1365*(nat): 7.12₃ 5.06_{6,5} 3.73₅ 3.57_{2,5} 3.23₁₀ 2.91₄ 2.76₅ 2.00₃. Grains < 0.8 mm. Colorless, white; vitreous luster. Analysis (wt %): SiO₂O, 61.7; Al₂O₃, 19.1; TiO₂, 0.8; FeO, 2.4; MgO, 10.5; Na₂O, 3.7; K₂O, 1.4; CaO, 0.1; Cr₂O₃, 0.1; MnO, 0.2. Uniaxial (+); N_O = 1.536, N_E = 1.544; birefringence = 0.008. O, very light blue, E, colorless. Occurs in a small 0.8-mm silicate inclusion in the *Colomera iron meteorite*. Associated with diopside, whitlockite, tridymite, and plagioclase. EF

63.2.1a.11 Dusmatovite K(K,Na,□)(Mn²⁺,Y,Zr)₂(Zn,Li)₃Si₁₂O₃₀

Described in 1995 and 1996 by Sokolova and Pautov, and Pautov and others and named for Vyacheslav Djuraevitch Dusmatov (1936–), a Russian mineralogist and geologist who has done much work at the type locality. A member of the milarite group. HEX. *P6/mcc*. *a* = 10.196, *c* = 14.284, *Z* = 2, *D* = 2.98. PD: 7.13₃ 4.15_{4,5} 3.75₅ 3.25₁₀ 2.92₄ 2.78₃ 2.55₅. Structure: *DAN* 344(5):607(1995). Dark blue, dirty blue, violet brown, streak light blue, trans-

lucent, no forms observed, no twinning observed, no cleavage, brittle, uneven fracture, non-fluorescent, $H = 4\frac{1}{2}$, $G = 2.96$. Uniax. (-), $N_O = 1.590$, $N_E = 1.586$; pleochroism strong: O = light violet, E = light blue. Analysis (wt. %): Li₂O 1.10, Na₂O 0.61, K₂O 6.16, MnO 8.78, FeO 0.45, ZnO 15.51, Mn₂O₃ 1.13, Yb₂O₃ 0.54, Y₂O₃ 1.51, SiO₂ 64.40, ZrO₂ 1.55. Occurs in a pegmatite boulder in a glacial moraine in the *Dara-i-Pioz alkaline massif, Tien Shan, Tajikistan*. Associated minerals are: quartz, microcline, aegirine, tadhikite-(Y), cesium-kupletskite, hyalotekite, betafite, and polythionite. EF Vestnik Moscow University Series 4 Geology(2):54(1996).

63.2.1a.12 Milarite $K_2Ca_4Al_2Be_4Si_{24}O_{60} \cdot H_2O$ (Z = 1) (end member), and (K,Na)Ca₂[(Be₂Al)Si₁₂O₃₀] · nH₂O (n ≈ 3/4) [AM 76:1836(1991)]

Named by Kenngott in 1870 for the locality, Val Milar, Switzerland, although the original specimen came from Val Giuf. Milarite group. $HEX P6/mcc$. $a = 10.342-10.42$, $c = 13.76-13.845$, $Z = 2$, $D = 2.56-2.61$. $12-450(nat)$ [CM 18:41(1980)]: 5.22_4 4.16_5 3.78_2 3.46_2 3.32_{10} 3.01_3 2.88_7 2.745_5 ; $35-459(nat)$: 5.20_2 4.51_4 4.14_3 3.42_2 3.31_{10} 3.01_6 2.86_7 2.73_3 ; [nat Y and HREE-rich, CM 29:533(1991)]: 6.90_4 5.17_3 4.48_3 4.13_8 3.29_{10} 2.985_4 2.87_7 2.73_3 . The structure of milarite has been well determined. There are 15 minerals with a simple four-connected three-dimensional net. Similar to that of bazzite and beryl. The difference is the number of Si₆O₁₈ rings. Bazzite has one ring while milarite has double Si₆O₁₈ rings. AM 76:1836(1991), EJM 1:353(1989). Prismatic parallel to [001], hexagonal prisms of varying length with forms: {1120}, {0001}, {1011}, {0001}; at Mt. St.-Hilaire 2-3mm, Strzegom to 4 mm, Brazil to +5 cm. Also radial fibrous aggregates. White to colorless, pale green; white streak; vitreous-silky luster (because of striations). Cleavage {0001}, indistinct; conchoidal fracture. $H = 5-6$. $G = 2.51-2.56$. IR data: AM 76:1836(1991), MM 50:271(1986). Blue-white fluorescence in SWUV (Mt. St.-Hilaire) and bright green cathodoluminescence (Strzegom); generally insoluble in common acids, some is slightly soluble in HCl, soluble in HF. Range of Be/Al proportions: (Be_{1.91}Al_{1.1}) to (Be_{2.55}Al_{0.45}) resulting from the substitution $Be^{2+} + (Na, K) \rightarrow Al^{3+} + \square$; yttrian milarite is very heterogeneous. Y + REE substitute for Ca. Y + REE increase with Be/Be + Al. $Ca^{2+} + Al^{3+} \rightarrow (Y, REE)^{3+} + Be^{2+}$. Y₂O₃ contents to ≈ 7.9 wt %. Water is present as H₂O. A simplified general formula is: $KNa_{1-x}Ca_2(Be_{3-x}Al_x)Si_{12}O_{30}[H_2O]$. Biaxial (-); $N_E = 1.529-1.552$, $N_O = 1.532-1.555$; $2V = 34^\circ$ in {0001} to 64° in {1011}; usually optically anomalous, showing biaxial character, and not truly uniaxial, showing wavy or patchy extinction, sector-zoning or moiré texture. West Věžná material shows true uniaxial optics. OAP azimuths related to the external hexagonal symmetry of the crystals. Anomalous optical properties are characteristic of milarite. Good summary in MM 50:271(1986). Possibly due to variation in channel H₂O contents. Positional disorder. Synthetic Mn-milarite is not $P6/mcc$. Twelve reflections violate the space group. SPC 22:453(1977). Occurs at Mt. St.-Hilaire on pectolite crystals in marble

xenoliths. At Strange Lake, occurs in extensively mineralized peralkaline granite. In granite pegmatite at Jaguarauçú, MG, Brazil (Y-bearing). In vugs in plutonic rocks, pegmatites, hydrothermal ore deposits, and alpine veins. A low-temperature hydrothermal mineral crystallizing in range 200–250° and at low pressures. In pegmatites at Strzegom. May form from breakdown of beryl and cordierite. Occurs in pegmatites in the Conway granite at the government pit and Moat Mt., near Conway, Carroll Co., NH; at the Foote mine, Kings Mt., Cleveland Co., NC; Mt. St.-Hilaire, QUE, and Strange Lake, QUE-LAB border, Canada; Tanno pegmatite, Chiavenna, Sondrio, Italy; Tittling, Bavaria, and Henneberg, Thuringia, Germany; Saulkopf, west Tyrol, and Habachtal, Gasteiner, Austria; Val Giuf, Grisons, Graubünden, and about 25 other localities in Switzerland, including Val Mila, Grigioni; Tysfjord, Drag, Nedre Lapplagret, Norway; Strzegom, Poland; West and East Vezna, Radkovice, and Marsíkov, Czech Republic; Yermakorsk, eastern Siberia (pink); Kola Penin., and Central Asia, Russia; Kent, central Kazakhstan; fine crystals from Rössing, Swakopmund, Namibia (gem-quality); La Valencia mine, Guanajuato, Mexico; zoned Y-bearing and Y-poor fine crystals from the Jose Pinto pegmatite, Jaguarauçú, near Coronel Fabriciano, MG, Brazil. A rare gemstone. *EF SMPM 50:445(1970)*.

63.2.1a.13 Sogdianite $(K,Na)_2(Zr,Fe,Ti)[Li_2(Li,Al)Si_{12}O_{30}]$

Named in 1968 by Dusmatov et al. for the ancient state of Middle Asia, Sogdiana. Milarite group. *HEX P6/mcc*. $a = 10.079\text{--}10.09$, $c = 13.98\text{--}14.338$, $Z = 2$, $D = 2.82$; $21\text{-}501(\text{nat})$: 4.51₆ 4.09₉ 3.52₅ 3.20₁₀ 2.90₁₀ 1.84₈ 1.52₇ 1.33₈. For structure, see osumilite (63.2.1a.6,7). Flaky grains, platy deposits to 10 cm × 7 cm × 4 cm in a vein. Violet, purple-pink, violet-pink; vitreous luster; transparent. Cleavage {0001}, perfect. $H = 6\text{--}7$. $G = 2.80\text{--}2.90$; DTA: exotherm at 950°, endotherm at 1050°. *DAN SSSR 182:137(1968)*. Analysis (wt %), Alai Range: SiO₂O, 68.83; ZrO₂, 9.78; Li₂O, 3.73; TiO₂, 2.88; Al₂O₃, 1.04; Fe₂O₃, 4.61; FeO, 1.22; MgO and MnO, traces; CaO, none; BaO, 0.32; K₂O, 4.84; Na₂O, 2.81; H₂O, none; F, none. Golden Horn has more ZrO₂ (≈ 15–18%) and less Na₂O ≈ 1.5. Uniaxial (–); $N_O = 1.608$, $N_E = 1.606$; colorless; birefringence = 0.002. Occurs in pegmatite associated with zektzerite at Washington Pass in the Golden Horn batholith, Okanogan Co., WA; in peralkaline rocks, usually in pegmatites. Associated with quartz, aegerine, REE minerals, thorite and stillwellite at *Dara-i-Pioz massif, Alai Range, Tien Shan, Tadzhikistan*. *EF GSAPA 19(7):594(1987)*, *AM 76:1836(1991)*.

63.2.1a.14 Roedderite $(Na,K)_2(Mg,Fe)_2[(Mg,Fe)_3Si_{12}O_{30}]$

Named in 1966 by Fuchs et al. for Edwin Woods Roedder (b.1919), U.S. Geological Survey, who synthesized K₂O · 5MgO · 12SiO₂. Milarite group. Forms series with eifelite and chayesite. See the other members of the group. *HEX P62c*. $a = 10.139\text{--}10.142$, $c = 14.269\text{--}14.275$, $Z = 2$, $D = 2.65$. $23\text{-}76(\text{nat})[AM 52:1519(1967)]$: 5.06₈ 4.38₉ 4.13₈ 3.73₉ 3.57₈ 3.23₁₀ 2.92₉ 2.76₉. Structure done at 100 and 300 K. An ordered arrangement of Na atoms

reduces the space group from the normal $P6/mcc$ to $P62c$. *EJM* 1:715(1989). Hexagonal tablets with dominant $\{0001\}$, $\{10\bar{1}2\}$, $\{10\bar{1}0\}$; $\{11\bar{2}0\}$ is rare. Also prismatic with same forms, and $\{10\bar{1}0\}$ dominant; to ≈ 6 mm across in Eifel region. Colorless, medium dark blue, dark green, orange, yellow. No cleavage. $G = 2.60\text{--}2.63$. Analysis (wt %), Indarch meteorite: SiO_2 , 71.0; Al_2O_3 , 0.4; MgO , 19.5; FeO , 2.0; K_2O , 3.3; Na_2O , 4.0; Eifel-Bellerberg: SiO_2 , 71; Al_2O_3 , 0.4–0.8; FeO , 0.5–2.5; MgO , 19–17.6; Na_2O , 3.5–4.0; K_2O , ≈ 4.5 ; TiO_2 , 0.03–0.12; MnO , 0.15–0.4; Cancarix, Spain: FeO , 5.8–13.9; MgO , 10.4–16.0; K_2O , 4.2–4.6; Na_2O , 0.5–2.6, and so on. K or Na may dominate in the alkali position (C site). Main substitution between chayasite and roedderite is: $(\text{K,Na}) + \text{Fe}^{2+} \leftrightarrow \square + \text{Fe}^{3+}$. Uniaxial and biaxial (+); $N_0 = 1.537$, $N_E = 1.542$; $N_x = 1.536$, $N_y \approx 1.536$, $N_z = 1.543$. O,E, colorless. Sometimes biaxial with $2V = 5\text{--}8^\circ$ (+). Occurs in peralkaline volcanic rocks and meteorites (enstatite chondrites and octahedrites). In altered gneisses in leucite tephrite lava. In xenoliths in Eifel volcanics, associated with clinopyroxene, quartz, enstatite, tridymite, hematite, amphibole, and so on. In lamproite in Spain. Occurs in the Wichita Co., KA, octahedrite meteorite; in silicate inclusions in the Canyon Diablo meteorite, AZ; from Cancarix, Albacete Prov., Spain; in the Bellerberg volcano, Mayen, east Eifel region, Germany, and at about 10 localities (e.g., Emmelberg) in the East and West Eifel region; in the *Indarch enstatite chondrite (fell April 7, 1891) in Transcaucasia, Russia*; possibly at the Wessels mine, Kuruman district, Kalahari manganese field, Cape Prov., South Africa; Qingzhen enstatite chondrite, China. *EF CMP* 82:252(1983), *DA* 44:89(1993), *MM* 58:655(1994), *METEO* 29:707(1994).

63.2.1b.1 Armenite $\text{BaCa}_2\text{Al}_6\text{Si}_9\text{O}_{30} \cdot 2\text{H}_2\text{O}$

Named in 1939 by Neumann for the locality. Milarite group. Synonym: calciocelsian (now discredited). A double-ring analog to cordierite (single six-membered ring). If heated for 4 days at $900\text{--}1000^\circ$, H_2O is expelled and optics become uniaxial with decreased refractive index values. The twinning pattern also disappears. Superstructure reflections disappear and the crystals become metrically hexagonal. However, based on order-disorder relationships in cordierite of (Si,Al), there probably is still not complete disorder of (Si,Al). So, crystals are probably still orthorhombic (*Amaa*). ORTH *Pnna*. (Nat): $a = 13.874$, $b = 18.661$, $c = 10.697$, $Z = 4$; (at 1000°): $a = 14.024$, $b = 18.383$, $c = 10.608$, $Z = 4$, $D = 2.75$ and 2.79 ; the hexagonal parameters are approximately: $a = 10.69\text{--}10.74$, $c = 13.87\text{--}13.909$. 37-432 [see *CM* 22:453(1984)]: could not resolve any splitting, also as hexagonal; 20-112(nat): 9.31_{55} 6.94_8 4.25_{65} 3.86_{10} 3.41_9 3.10_4 2.91_9 2.78_8 . 37-432 is very similar; *SMPM* 71:301(1991), best data: 9.28_3 6.93_{10} 4.26_5 3.87_3 3.86_6 3.41_3 2.91_6 2.78_5 ; also 45-1481. A double-ring silicate. Deviation from true hexagonal symmetry to orthorhombic symmetry is due to (1) ordering of H_2O and (2) partial Si-Al ordering. *SMPM* 71:301(1991), *AM* 77:422(1992). Prismatic, crystals to 1.5 cm, aggregates to several centimeters across, pseudo-hexagonal morphology formed by fine lamellar penetration twins. Gray-green to colorless, white

streak, vitreous luster. Three cleavages: {010}, {011}, distinct. $H = 7-8$. $G = 2.74-2.77$. TGA data: *NGT 21:19(1941)*. IR data: *CM 22:453(1984)*. Usually fairly pure. Traces of Na_2O and K_2O . Biaxial (-); $N_x = 1.5505-1.551$, $N_y = 1.557-1.559$, $N_z = 1.559-1.562$; colorless; $2V = 42-66^\circ$; birefringence = 0.011; also uniaxial (-): $N_O = 1.556$, $N_E = 1.550$. Occurs in Ba-rich environments. Hydrothermal veins and hydrothermally altered rocks. In sulfidic calc-silicate-rich quartz rocks (schists) and in granulitic gneisses as porphyroblasts. Low- and high-temperature environments. Occurs near Remigny, QUE, Canada; Coire Loch Kander, Scotland; *Armen mine, near Kongsberg, Norway*; Zufuru mine, southwestern Sardinia, Italy; Simplon area, Wasenalp, Vallais, Switzerland; Chvaletice, 20 km W of Pardubice, Czech Republic; Northern Dneiper region, Ukraine; Broken Hill and Purna Moota, 30 km N of Broken Hill, NSW, Australia. *EF MZ 9:83(1987)*; *MM 51:317(1987)*, *55:135(1991)*; *NJBM:49(1989)*.

Rings with Other Anions and Insular Silicate Groups

64.1.1.1 Eudialyte $\text{Ca}_6\text{Zr}_3(\square, \text{Fe})_3\text{Si}_{24}(\text{Si}_3\square)_3(\text{Ti}, \square)(\text{Nb}, \text{Al}, \square)-$
 $(\text{Fe}, \text{Mn}, \square)_3(\text{Na}, \text{K}, \text{Sr}, \text{REE}, \text{Mg})_3(\square, \text{Sr}, \text{Mg})_3(\text{Na}, \square)_{36}\text{O}_{69}/(\text{O}, \square)_6(\text{OH}, \square)_6$
 $(\text{Cl}, \square)_2$ [*SPC 33:207(1988)*]; simplified formula: $\text{Na}_{15}\text{Ca}_7\text{Fe}_3\text{Zr}_3\text{Si}$
 $(\text{Si}_3\text{O}_9)_2(\text{Si}_9\text{O}_{27})_2(\text{OH})_2\text{Cl}_2$ [*PD 5:89(1990)*]

Described in 1801 by F. Stromeyer and named from the Greek for *readily decomposable*, in allusion to its easy reaction with acids. The names *eucolite* (from T. Scheerer in 1847) (high content of heavy multivalent cations such as Fe, Mn, REE, Nb, Ca, etc., and optically negative) and *barsanovite* (a piezoelectric variety of eucolite) are synonymous with eudialyte. *HEX-R R3m* or *R3m*. $a = 13.95\text{--}14.39$, $c = 29.91\text{--}30.26$, $Z = 3$ (for simplified formula), $D = 2.67$ (REE-free). $d_{1-1465}(\text{nat}): 7.12_4 5.71_{4.5} 4.31_{5.5} 3.40_4 3.22_5 3.165_{3.5} 2.98_8 2.86_{10}$. A monoclinic variety of eudialyte was reported from Pocos da Caldas, MG, Brazil: $a = 24.641$, $b = 14.188$, $c = 21.761$, $\beta = 112.44^\circ$. *AABC 52:243(1980)*. A cyclosilicate, with both threefold (Si_3O_9) and ninefold [$\text{Si}_9\text{O}_{24}(\text{OH})_3$] rings of SiO_4 tetrahedra. *TMPM 16:105(1971)*. The structure is related to that of zeolites, in that the framework of eudialyte is the same in the different varieties, but the atoms in the zeolitic cavities are individual and influence the properties in a definite way. Differences in occupancies by heavy cations produce accentricity. *ZVMO 119:65(1990)*. *Habit*: Crystals may be as much as 8–10 cm across from the Khibiny and Lovozero massifs and also from Greenland. Crystals may be pseudo-octahedral, equant; also rhombohedral, short prismatic. Dominant forms are: {0001}, {1120}, {1010}, {1011}. *Physical properties*: Color is variable: carmine-red, orange-red, orange, pink, cherry-red, brownish red, yellowish brown, brown, yellow, violet, or green. The color appears to be controlled by the amounts of Fe^{3+} and Mn^{3+} present. White to pale pink streak, vitreous to greasy luster. Cleavage {0001}, distinct; {1120}, imperfect; {1010}, {1014}, lesser; uneven to conchoidal fracture; brittle. $H = 5\text{--}6$. $G = 2.70\text{--}3.10$. IR data (Moenke), optical absorption spectra, and Mössbauer spectra: *PCM 18:117(1991)*. Sometimes luminescent orange-red. Weakly electromagnetic, gelatinizes with acids. *Chemistry*: Fe^{2+} is responsible for the red color in eudialyte (optically +). In optically (–) eucolites, Fe^{2+} ions are in a tetragonal pyramid based on the planar quadrangle. Eucolites have Fe^{3+} as well. Eucolite has planar four- and fivefold (pyramid) Fe^{2+} . REE-free eudialyte exists. The change in optical properties may also result

from complex coupled substitutions involving Ca and REE. The chemistry varies widely. A eucolite from Tanzania had no REE, U, and Th, while a eucolite on Ascension Island had 10–12 wt % REE. Either Ce or Y group REE's may be dominant. A eudialyte from Malawi has 3.6 wt % Nb₂O₅, and 6.50 wt % MnO. A K₂O-rich (to 6.4 wt %) and H₃O⁺-bearing eudialyte was recently described from the Khibiny massif. *DAN-ESS 318:154(1993)*. **Optics:** Optical properties are variable: uniaxial (+) or (-), also isotropic; N = 1.602 (isotropic), N_O = 1.588(hydronium-bearing)–1.623, N_E = 1.594(hydronium-bearing)–1.633(optically positive eudialyte) and N_O = 1.606–1.630, N_E = 1.602–1.627(optically negative eudialyte). Birefringence = 0.00–0.02. Colorless or pleochroic with N_O pale yellow, yellowish pink, and N_E pale yellow or pink. Crystals may have (-), (+), and isotropic zones. Reversals in optic sign are induced by heating: Na-rich samples (eudialyte) become (+) and Ca-rich samples (eucolite) become (-). Eudialyte is often anomalously biaxial, but most eucolites are uniaxial. "Barsanovite" has N_x = 1.624–1.633, N_y = 1.628–1.633, N_z = 1.628–1.639, with 2V_x = 12–17°. **Occurrence:** Occurs in alkaline and peralkaline igneous rocks (e.g., Ne-syenites) and their cogenetic pegmatites. It is a primary magmatic mineral, crystallizing at >720°. Also occurs rarely in silica-saturated rocks. May alter to catapleiite, zircon, feldspar, acmite, analcime, clays, and other minerals. **Localities:** Localities include: Magnet Cove, AR; Pajarito Mt., Otero Co., NM; Cornudas Mts., NM; Bearpaw Mts., MT; in alkali granite 32 miles SSW of Farewell, AK; Mt. St.-Hilaire, and Kipawa Lake, Temiscamingue Co., QUE; Seal Lake area and Red Wine alkaline complex, LAB, Canada; *Kangerdluarssuk (Ilimaussaq)*, and to 10 cm from Naujakasik, Julianehaab district, Greenland; Langesundfjord, southern Norway; many localities in the Lovozero (e.g., Mts. Karnasurt and Vavnbed) and Khibiny (e.g., Mts. Nyorkpakhk, Kukisvumchorr, and Takhtarvumchorr) massifs (barsanovite was described from near Petrelus Mt.), the largest crystal being approx. 8 cm × 3.5 cm; Cape Turi, and crystals of an unusual green color are found in the "Mica" quarry, Kovdor massif, Kola Penin., and Tuva, and Burpala massif, Siberia, Russia; Ampasibitika, Madagascar; Oldoinjo Lengai, Tanzania; southeastern Q, Australia; Pocos da Caldas, MG, Brazil. *EF DAN SSSR 153:1164(1963)*; *MIN 3(2):227(1981)*; *MM 46:421(1982)*, *56:428(1992)*; *TMPM 32:153(1983)*; *DHZ IB(1986)*.

64.1.1.2 Alluaivite Na₉(Ca,Mn²⁺)₆(Ti,Nb)₃Si₂₆O₇₄Cl · 2H₂O

Named in 1990 by Khomyakov et al. for the location. Eudialyte group. *HEX-R R3m*. *a* = 14.046, *c* = 60.60, *Z* = 6, *D* = 2.78. *PD*: 7.14₈ 4.30₇ 3.36₅ 2.96₁₀ 2.82₁₀ 2.14₇ 1.76₈ 1.36₇. Groups of [Si₃O₉] and two types of [Si₁₀O₂₈] groups are in the structure. Irregular grains to 1 mm. Colorless to pale pink with a brownish tint, white streak, vitreous luster, transparent. Conchoidal fracture, brittle. *H* = 5–6. *G* = 2.76. IR data are similar to eudialyte. Vivid red-orange fluorescence in UV light. Mineral slowly leaches in 10% HCl, lowering the refractive index values. Analysis (wt %): Na₂O, 18.6; K₂O, 0.2; CaO, 8.6; SrO,

1.0; BaO, 0.6; MnO, 3.6; La₂O₃, 0.2; Ce₂O₃, 0.8; SiO₂, 53.3; TiO₂, 6.0; ZrO₂, 0.2; Nb₂O₅, 3.9; Cl, 0.8; H₂O, 1.7. Uniaxial (+); N_O = 1.618, N_E = 1.626; colorless. Occurs in ultra-aggaitic pegmatites, associated with nepheline, sodalite, potassium feldspar, arfvedsonite, aegirine, a cancrinite-like mineral, and others. Closely intergrown with eudialyte. *Alluav Mt., Lovozero massif, Kola Penin., Russia.* EF ZVMO 119:117(1990), DAN SSSR 312:1379(1990), AM 76:1728(1991).

64.2.1.1 Scawtite $\text{Ca}_7(\text{Si}_3\text{O}_9)_2(\text{CO}_3) \cdot 2\text{H}_2\text{O}$

Named in 1929 by C. E. Tilley for the locality. MON Space group unknown, probably *I2/m*. $a = 10.118\text{--}10.121$, $b = 15.180\text{--}15.187$, $c = 6.623\text{--}6.626$, $\beta = 100.55\text{--}100.66^\circ$, $Z = 2$, $D = 2.765$. Redetermined structure [CSB 37(11):930(1992)] indicates that the space group is *Cm* with cell dimensions: $a = 10.039$, $b = 15.194$, $c = 6.634$, $\beta = 115.64^\circ$. 31-261(nat): 3.20₆ 3.03₅ 3.02₁₀ 2.99₈ 2.96₄ 2.49₄ 2.23₄ 1.89₄. Two structure determinations [AC(B) 29:73(1973), ZC 13:195(1973)] state that the CO₃ group is disordered. However, the R factor was only 11.7%. A 1992 Chinese determination, with R = 2.2%, indicates that the CO₃ group is ordered in the structure. Platy crystals to 1.5 mm in subparallel and slightly diverging groups, also granular aggregates, seven main forms: {010}, {100}, {130}, {120}, {110}, {011}, {101}. Colorless or white, gray-white, pale flesh, shows piezoelectric effect; vitreous luster. Cleavage {010}, {001}, perfect; uneven or conchoidal fracture. $H = 4\frac{1}{2}\text{--}5$. $G = 2.71\text{--}2.73$. Some material from Crestmore fluoresces weak white in SWUV and LWUV. IR data for synthetic material: SILI 22(2):151(1978), MSLM 4:445(1974). DTA data: MIN 3(2):194(1981). Sometimes fluoresces bluish white in SW. Soluble in cold dilute HCl with formation of gelatinous residue. Analyses from four localities show variable amounts of SiO₂ and CO₂. Biaxial (+); N_x = 1.595–1.603, N_y = 1.605–1.609, N_z = 1.618–1.622; 2V = 75°; colorless, OAP parallel to (010); $Z \wedge c = 30^\circ$ [in setting of Murdoch, AM 40:505(1955)]. Forms as pseudomorphs after spurrite. Occurs in hybrid rocks formed by assimilation of limestone by dolerite. In Northern Ireland, associated with melilite, bultfonteinite, calcite, and zeolites; in North America and New Zealand, with larnite, spurrite, tobermorite, gehlenite, garnet, vesuvianite, calcite, wollastonite, and others; in Japan, with grossular, vesuvianite, and calcite. In regions of metamorphosed siliceous limestones. Alteration: to tobermorite and tacharanite. Occurs in the Little Belt Mts., MT; Crestmore quarry, Riverside Co., CA; *Scawt Hill, Co. Antrim, N. Ireland*; Ballycraig, Co. Larne, N. Ireland; Kearny, Aberdeen, Scotland; Maroldsweisach, northern Bavaria, Germany; Kansay deposit, southwestern Karamazar, Russia; Yamato and Mihara mines, and at Fuka, Bicchu, Okayama Pref., Japan; Kushiro, Hiroshima Pref., Japan; Fushan mine, Hebei, northern China; Java Sea; near Rehia, Tokatoka, New Zealand; Cerro Mazahua, Zitacuaro, Michoacan, Mexico. EF

64.2.2.1 Roebingite $\text{Pb}_2\text{Ca}_6(\text{SO}_4)_2(\text{OH})_2(\text{H}_2\text{O})_4[\text{Mn}(\text{Si}_3\text{O}_9)_2][\text{AM } 69:1173(1984)]$

Named in 1897 by Penfield and Foote for Washington Augustus Roebing (1837–1926), civil engineer and appreciative mineral collector, Trenton, NJ, a founder of the Mineralogical Society of America. *MON C2/m*. $a = 13.208$, $b = 8.287$, $c = 13.089$, $\beta = 106.65^\circ$, $Z = 2$, $D = 3.44$. *18-292(nat)*: 3.2_7 3.06_8 3.00_9 2.94_{10} 2.88_7 2.53_7 2.20_7 2.11_7 . Structure: *AM 69:1173(1984)*. Usually fine-grained, also platy, lathlike, micaceous or fibrous; dense, white nodular aggregates; Franklin—nodular masses, > 10 cm in diameter, composed of fine-grained lathlike crystals, and Langban—prismatic crystals in parallel growth. Usually white, but may be very pale pink, due to inclusions or alteration; white streak; porcelaneous. Cleavage {001}, perfect; {100}, imperfect. $H = 3$. $G = 3.43\text{--}3.50$. Gelatinizes with acids. IR and thermal data: *MM 49:756(1985)*. At least 10 chemical analyses given in the literature. Contains some SrO as well (0.7–2.8% SrO), S is as SO_3 (i.e., sulfate). Biaxial (+); $N_x = 1.64$, $N_y = 1.64$, $N_z = 1.66$; $N_x = 1.654$, $N_y = 1.660$, $N_z = 1.678$; colorless; optics need to be redetermined; plane of the cleavage contains X and Y. $2V$ small to 61° ; $r < v$, slight. Occurs in Zn–Mn ores. Precambrian metamorphosed sediments. *Franklin, Sussex Co., NJ*; Langban, Varmland, Sweden. *EF MIN 3(1):370(1972)*, *MM 46:341(1982)*, *MM 49:721(1985)*.

64.3.1.1 Taramellite $\text{Ba}_4(\text{Fe}^{3+}, \text{Ti}^{4+}, \text{Fe}^{2+}, \text{Mg}, \text{V}^{3+})_4(\text{B}_2\text{Si}_8\text{O}_{27})\text{O}_2\text{Cl}_x$ ($x = 0\text{--}1$)

Named in 1908 by Tacconi for Torquato Taramelli (1845–1922), Italian geologist. See titantaramellite (64.3.1.2) and nagashimalite (64.3.1.3), the V analog. *ORTH Pmmn*. $a = 12.125\text{--}12.217$, $b = 13.929\text{--}13.981$, $c = 7.130\text{--}7.136$, $Z = 2$. *17-479(nat)*: 3.83_5 3.68_3 3.30_4 3.16_4 3.01_{10} 2.78_3 2.58_6 2.48_5 . Main structural feature is a borosilicate radical $(\text{B}_2\text{Si}_8\text{O}_{27})^{-16}$, which is formed by the rings of four Si tetrahedra connected by a B_2O_7 group sharing two oxygen atoms with each ring. Cl atoms occur, with incomplete occupancy, between adjacent borosilicate groups. In the Rush Creek, CA, sample, the principal octahedral Me cation (titantaramellite) is Ti^{4+} ; in Candoglia, Italy, it is Fe^{3+} . *AM 65:123(1980)*. {100} dominant, tabular to equidimensional crystals, elongated parallel to c , rarely elongated on a . Bronze-purple, reddish brown, brownish violet; brown streak; vitreous or greasy luster. Cleavage {010}, perfect. $H = 5\frac{1}{2}$. $G = 3.92$. IR data: *MIN 3(2):52(1981)*. Insoluble in acids. V-rich taramellite from the Mogurazawa mine (Kiryu, Japan), became nagashimalite. See *AM 69:358(1984)* for details on chemistry. Biaxial (+); $N_x = 1.770$, $N_y = 1.774$, $N_z = 1.83$ [low Ti ($\approx 7\%$ TiO_2)]; $X = Y =$ pale pinkish or nearly colorless; $Z =$ nearly opaque (because of Fe–Ti charge-transfer processes); X is normal to the plates; XYZ parallel to cba using $a = 12 \text{ \AA}$, $b = 13.9 \text{ \AA}$, and $c = 7.1 \text{ \AA}$. $2V = 77^\circ$; $r > v$, distinct. Occurs in limestone at contact with gneiss at Candoglia. A contact-metamorphic mineral. Associated with calcite, magnetite, chalcopyrite, pyrite, pyroxene, actinolite, and celsian. With other Ba-silicates and Ba–Ti-silicates in metamorphic rocks at or close

to contacts with large granitic bodies. Sanbornite is the dominant associated mineral. Clear Creek area, San Benito Co., Tulare Co., and Trumbull Peak, Incline, Mariposa Co., CA; Ross River, and the Gun Prospect, Macmillan Pass, Itsi Mountains, YT, Canada; La Madrelena mine, Rancho Tres Pozos, La Rumarosa, Baja Norte California, Mexico; *Candoglia, Valle del Toce, Piedmont, Italy*. EF *TMPM* 25:245(1978).

64.3.1.2 Titanataramellite $\text{Ba}_4(\text{Ti,Fe}^{3+},\text{Mg,Fe}^{2+})_4(\text{B}_2\text{Si}_8\text{O}_{27})\text{O}_2\text{Cl}_x$
 $x = 0-1$, with $\text{Ti} > \text{Fe}$)

Named in 1984 by Alfors and Pabst for taramellite and dominance of Ti as the octahedral cation. See Fe-dominant taramellite (64.3.1.1) and nagashimalite (64.3.1.3), the V analog. ORTH *Pmmn*. $a = 12.053-12.220$, $b = 13.904-14.005$, $c = 7.12-7.141$, $Z = 2$. No ICDD data. See X-ray diffraction data for taramellite (64.3.1.1). Structure solution exists for titanian taramellite: *AM* 65:123(1980). Tabular to equidimensional, tabular parallel to $\{100\}$, ≈ 30 forms known, $\{100\}$ is dominant. Physical properties are as for taramellite (64.3.1.1). $H = 6$. $G = 4.00-4.05$. Heating produces no changes to 920° , changes to fresnoite at $>960^\circ$. Wet analysis (wt %): SiO_2 , 33.0; Fe_2O_3 , 6.79; FeO , 3.60; MgO , 0.55; TiO_2 , 10.63; MnO , 0.09; B_2O_3 , 3.64; Cl , 1.83; BaO , 40.45; H_2O , nil; O for Cl, 0.41; probe analysis: Al_2O_3 , 0.26; V_2O_3 , 0.37. In other samples: V_2O_5 , to 3.2%; MgO , 2.1-4.6; FeO , 1.45-5.25; eight analyses give TiO_2 , 9.10-12.53. Biaxial (+); XYZ parallel to *cba*; Big Creek: $N_x = 1.747-1.751$, $N_y = 1.756-1.761$, $N_z = 1.780$; Rush Creek: $N_x = 1.753$, $N_y = 1.757$, $N_z = 1.782$; $2V = 45-59^\circ$; pleochroic. X, Y, yellow-brown; Z, opaque. Occurs in metamorphosed limestone associated with sulfides and sulfosalts (Kalkar quarry). Victor claim is in ultramafic body in Franciscan enclaves. Others are at or close to contacts of large granitic bodies where zones or lenses within metamorphic rocks are largely Ba-silicates. Associated with sanbornite (dominant) and rare pellyite. *Rush Creek, Fresno Co.*, Big Creek, Fresno Co., Chickencoop Canyon, Tulare Co., Kalkar quarry, Santa Cruz Co., and Victor Claim, San Benito Co., CA. EF

64.3.1.3 Nagashimalite $\text{Ba}_4(\text{V}^{3+},\text{Ti})_4\text{Si}_8\text{B}_2\text{O}_{27}\text{Cl}(\text{O,OH})_2$

Named in 1980 by Matsubara and Kato for Otokichi Nagashima (1890-1969), called the "pioneer" of Japanese amateur mineralogists. See taramellite (64.3.1.1) and titanataramellite (64.3.1.2). ORTH *Pmmn*. $a = 13.937$, $b = 12.122$, $c = 7.116$, $Z = 2$, $D = 4.14$. *33-188(nat)*: 3.85₃ 3.32₂ 3.17₂ 3.03₆ 3.02₁₀ 2.79₂ 2.59₃ 1.78₂. Structure: analogous to taramellite (64.3.1.1). *MJJ* 10:131(1980). Tabular $\{001\}$, elongated on *b*, subparallel aggregates, to 1.5 cm long. Greenish black, green streak, submetallic to vitreous luster. No cleavage. $H \approx 6$. $G = 4.08$. Analysis (wt %): BaO , 41.4; V_2O_5 , 16.7; TiO_2 , 2.75; MnO , 0.48; SiO_2 , 32.4; B_2O_3 , 4.0; Cl , 1.73; H_2O , 0.77; -0.39 O for Cl. Biaxial (+); XYZ = *acb*; $N_x = 1.750$, $N_y = 1.753$, $N_z = 1.780$; $2V = 30^\circ$; $Z > Y > X$; $r > v$, strong; strongly pleochroic. X, greenish yellow; Y, green; Z, greenish brown. Occurs at the *Mogurazawa mine, Kiryu City, Gumma Pref., Japan*; in bedded

Mn ore (rhodonite, massive). Associated with rhodochrosite, barite, barian roscoelite, alabandite, and suzukiite. EF *MJJ* 10:122(1980).

64.3.2.1 Strakhovite $\text{NaBa}_3(\text{Mn}^{2+}, \text{Mn}^{3+})_4\text{Si}_6\text{O}_{19}(\text{OH})_3$

Described in 1994 by Kalinin et al. and named for Academician N.M. Strakhov (1900–1978), well-known for his work on the genesis of manganese ore deposits. ORTH *Pnma*. $a = 23.41\text{\AA}$, $b = 12.266\text{\AA}$, $c = 7.181\text{\AA}$, $Z = 4$, $D = 3.84$; PD 7.00₃ 4.58₅ 3.30₉ 3.00₁₀ 2.715₅ 2.655₁₀ 2.16₄ 1.65₅ (*ZVMO* 123:94(1994)). Structure solved to $R = 6.5\%$. Contains $[\text{Si}_4\text{O}_{12}]$ and $[\text{Si}_2\text{O}_7]$ groups (*AM* 78:675(1993)). The structure determined formula is: $\text{NaBa}_3\text{Mn}^{2+}_{2.3}\text{Mn}^{3+}_{1.7}[\text{Si}_4\text{O}_{10}(\text{OH})_2](\text{Si}_2\text{O}_7)\text{O}_2(\text{F}, \text{OH})\text{H}_2\text{O}$. Black with a greenish tint (0.2–0.4 and rarely to 0.7 mm), equant to slightly elongated grains, in thin pieces is dark olive green, sometimes occurs as well-formed crystals in druses, vitreous to greasy luster, no cleavage, brittle, $H = 5\text{--}6$, $G = 3.86$. Analysis (wt. %): SiO_2 30.03, Al_2O_3 0.23, Fe_2O_3 0.03, Mn_2O_3 11.65, MnO 14.16, CaO 0.03, Na_2O 2.85, BaO 39.2, H_2O^+ 2.40, H_2O^- 0.30, $\Sigma 100.88$. Biax. (–), $2V$ 60–65°, $N_x = 1.767$, $N_y(\text{calc.}) = 1.793$, $N_z = 1.871$ at 578 nm; biref. = 0.104, dispersion $r > v$, strong; $X = c$, $Y = b$, $Z = a$. Strong pleochroism: $X =$ light green, $Y =$ green, $Z =$ dark olive green to brown. Occurs in the *Ir-Nimi manganese deposit, on a tributary of the Udi River, on the SW side of the Taikansk Range, Russian Far East, Russia*. It occurs at the contact between braunite ore and alkali basalt. The mineral occurs in two out of 10 parts of the deposit: Djavodi and Zao-blachno. Deposit occurs in veins in early to middle Cambrian volcanic rocks. Assoc. minerals include: braunite, taikanite, namansilite, pectolite, manganeseiferous amphiboles, and others. EF

64.4.1.1 Tienshanite $\text{Na}_2\text{BaMn}^{2+}\text{TiB}_2\text{Si}_6\text{O}_{20}$

Named in 1967 by Dusmatov et al. for the locality. HEX *P6/m*. $a = 16.772$, $c = 10.434$, $Z = 6$, $D = 3.23$. 20-1291: 10.5₃ 4.19₁₀ 3.89₃ 3.47₈ 3.33₂ 3.18₉ 2.80₅ 2.42₅. Structure: *SPD* 22:544(1977). The structure contains silicate six-membered rings and layers of corner-sharing $[\text{Si}_2\text{O}_7]$ and $[\text{B}_2\text{O}_7]$ dimers. Pistachio green, vitreous luster. Cleavage $\{0001\}$, distinct; brittle. $H = 6\text{--}6\frac{1}{2}$. $G = 3.29$. Uniaxial (–); $N_0 = 1.666$, $N_E = 1.653$. The formula above is based on the original description, whereas the formula based on the brief structure description is $\text{KNa}_9\text{Ba}_6\text{Ca}_2\text{Mn}_6^{2+}\text{Ti}_6\text{B}_{12}\text{Si}_{36}\text{O}_{120}(\text{OH})_2$. Found with pyrochlore, astrophyllite, bafertisite, stillwellite, galena, sphene, and calcite, and in part replaced by datolite, in narrow veins of quartz–microcline–aegirine pegmatite cutting alkalic syenite in the *Dara-i-Pioz massif, Tien Shan, southern Tajikistan*. AR *AM* 53:1426(1968), *EJM* 5:971(1993).

64.5.1.1 Traskite $\text{Ba}_2\text{Ca}(\text{Fe}, \text{Mn}, \text{Ti})_{16}[\text{Si}_{12}\text{O}_{36}][\text{Si}_2\text{O}_7]_6(\text{O}, \text{OH})_{30}\text{Cl}_6 \cdot 14\text{H}_2\text{O}$

Named in 1965 by Alfors et al. in honor of John Boardman Trask (1824–1879), first state geologist of California. HEX *P6m2*. $a = 17.89$, $c = 12.33$, $Z = 1$, $D = 3.52$. 18-171: 15.4₅ 3.51₄ 3.27₂ 3.21₂ 3.08₃ 2.96₁₀ 2.90₂ 2.53₂. Struc-

ture: *SPD 21:426(1976)*. The structure involves a 12-tetrahedron silicate ring, and six $[\text{Si}_2\text{O}_7]$ dimers. Brownish red, pale red-brown streak, vitreous luster. Conchoidal fracture. $H \approx 5$. $G = 3.71$. Uniaxial (-); $N_O = 1.714$, $N_E = 1.702$; Pleochroic; O, brownish red; E, colorless to pale straw. Insoluble in acids. Fusibility 3.5. Found as euhedral crystals, 0.1–3 mm, with {0001} and {1010} prominent, in sanbornite-bearing metamorphic rocks along a granodiorite contact at *Big Creek and Rush Creek, Fresno Co., CA*. *AR AM 50:314(1965)*, *50:1500(1965)*.

Single-Width, Unbranched Chains, $W = 1$

PYROXENE GROUP

The pyroxene group minerals are silicates with the general formula

where

M1 = site occupied preferentially by smaller cations in nearly ideal six-coordination

M2 = site occupied preferentially by larger cations in distorted six- to eight-coordination

and an orthorhombic or monoclinic structure in which the silicate chain has a periodicity of 2, with N equal to 2, and a width of 1.

The structure consists of $(Si_2O_6)^{4-}$ chains that may be extended (nearly linear) or may be shortened by rotation of tetrahedra. The chains may be of one or two types (designated A and B), and may consist of equivalent or nonequivalent tetrahedra. For the fully extended chains, the angle $O_3-O_3-O_3$ made by the shared oxygens is 180° . Tetrahedra rotation may be in opposite senses, designated O- and S-.

In all species the chains are parallel to the c axis, and their conformation is such that the unshared, apical oxygens are on one side of the chain opposite a nearly planar arrangement of the triangular tetrahedra bases. Parallel to $\{010\}$, the chains may be joined via the M1 sites, apex to apex, to form *I-beams*. Alternatively, the chains may also be joined base to base via the M2 sites. Successive layers of I-beams parallel to $[010]$ are shifted with respect to one another by half an I-beam height in the (010) plane. The resultant staggering of the I-beams leads to the prismatic, $\{110\}$ or $\{210\}$, cleavage at approximately 93° and 87° .

Structural details vary with the cations in the M1 and M2 sites, leading to different space group symmetries. The current pyroxene classification is crystallochemical in nature. In this presentation, however, the space group symmetry is the primary factor in establishing subgroups. Note that in the subgroup tables that follow, the M2 cation is given first if it differs from M1.

For the clinopyroxene subgroup, chain shortening by rotation occurs when both M1 and M2 sites are occupied by smaller, six-coordinated divalent cations. The chains are not equivalent.

PYROXENE GROUP: $P2_1/C$ CLINOPYROXENE SUBGROUP

Mineral	Formula	Space Group	a	b	c	β	
Clinoenstatite	$Mg_2[Si_2O_6]$	$P2_1/c$	9.620	8.825	5.188	108.33	65.1.1.1
Clinoferrosilite	$Fe_2(Si_2O_6)$	$P2_1/c$	9.71	9.087	5.228	108.43	65.1.1.2
Kanoite	$MnMg[Si_2O_6]$	$P2_1/c$	9.739	8.939	5.260	108.56	65.1.1.3
Pigeonite*	$(Mg, Fe^{2+}, Ca)_2[Si_2O_6]$	$P2_1/c$	9.706	8.950	5.246	108.59	65.1.1.4

*Species status is not universally accepted.

Orthopyroxenes are dimorphous with the clinopyroxenes. In the orthopyroxenes chains are nonequivalent and rotated, and the tetrahedra are nonequivalent. The relationship of the cell constants is $a_{ortho} = 2a_{clino} \sin \beta_{clino}$, and the cell contents of the orthorhombic cell are double those of the monoclinic.

PYROXENE GROUP: ORTHOPYROXENE SUBGROUP

Mineral	Formula	Space Group	a	b	c	
Enstatite	$Mg_2[Si_2O_6]$	$Pbca$	18.235	8.818	5.179	65.1.2.1

Pyroxene Group

The structures of clinoenstatite (a), and enstatite (b) viewed along the *b*-axis. In both structures there are two types of silicate chains, SiA and SiB. In *C2/c* pyroxenes such as diopside the silicate chains are alike, SiA.

(a)

(b)

(c)

Pyroxene Group

(a) Schematic projection of the monoclinic pyroxene structure on a plane normal to *c*. (b) The same projection emphasizing the I-beam character of the chains. (c) Typical pyroxene cleavage controlled by the I-beams of (b).

Larger cations such as Ca^{2+} and Na^+ preferentially enter the M2 sites. In these structures the chains are extended, are equivalent, and the resultant symmetry is *C2/c*. There are calcium and sodium members of the subgroup, but solid solution among them is extensive. Spodumene has the same symmetry despite the small size of its cations, lithium and aluminum. Cell dimensions are not given for the intermediate species, as they vary with composition. *DHZII 2A:3(1978), AM 73:1123(1988)*.

Relationship of the unit cell of a clinopyroxene (diopside) to that of an orthopyroxene (enstatite).

or C2

*Species status is not universally accepted for these intermediate pyroxenes.

Notes:

1. The name *pyroxene* was coined by Haüy in 1799 from the Greek *pyros*, fire, and *xenos*, stranger, on the basis of his belief that these crystals in lavas were accidental inclusions of a mineral foreign to that environment. In fact, the pyroxene minerals are second only to feldspars in their role in igneous rocks. Despite his misreading of their role, Haüy must be credited for recognizing the relationship among what were previously regarded as unrelated species.
2. For the major species, composition may be described in terms of the dominant end members in the format: En (enstatite), Fs (ferrosilite), Wo (wollastonite), Di (diopside), Hd (hedenbergite), and Ae (aegirine).

65.1.1.1 Clinoenstatite Mg₂[Si₂O₆]

Named in 1906 by Wahl in allusion to its symmetry and chemical identity with enstatite. Pyroxene group. Synonym: clinohypersthene for intermediate members of the clinoenstatite-clinoferrrosilite series. Polymorphs: enstatite (orthorhombic), protoenstatite (orthorhombic). MON $P2_1/c$. $a = 9.620$, $b = 8.825$, $c = 5.188$, $\beta = 108.33^\circ$, $Z = 4$, $D = 3.19$. 35-610(syn): 3.28₃ 3.17₅ 2.98₇ 2.87₁₀ 2.54₂ 2.52₂ 2.46₃ 2.12₃. Structure: PCM 10:217(1984). Chains are of types A and B with rotations S and O, respectively. Sites M1 and M2 are both occupied by magnesium in six-coordination. Usually as rock-bound, euhedra and subhedra. Commonly displays lamellar twinning on {100}, probably as the result of inversion from protoenstatite. Colorless, yellowish to greenish brown; vitreous luster; translucent to transparent. Cleavage {110}, good to perfect. H = 5-6. Biaxial (+); $2V = 53-35^\circ$; $N_x = 1.651-1.705$, $N_y = 1.653-1.707$, $N_z = 1.660-1.727$; $X = b$, $Z \wedge c = (-)22-41^\circ$; $2V$ decreases, indices and extinction angle increase for the composition range $Es_{100}Fs_0$ to $Es_{50}Fs_{50}$. Substitution of calcium results in a decrease in $2V$ and slight increase

in refractive indices. Complete solid solution with clinoferrosilite exists; solid solution with the wollastonite molecule is limited to a few mol %; additional Ca substitution yields pigeonite, and then *C2/c* pyroxene; minor substitution of other divalent cations exists. An uncommon component of volcanic rocks and in chondritic and achondritic meteorites. Found in the Mt. Stuart batholith, Cascade Mts., WA; as phenocrysts at Cape Vogel, Papua; Bonin Is., Japan; and the Giles complex, WA, Australia. AR *ZK 114:120(1960)*, *DHZII 2A:30(1978)*.

65.1.1.2 Clinoferrosilite $\text{Fe}_2[\text{Si}_2\text{O}_6]$

Named in 1935 by Bowen in allusion to its symmetry and chemical identity with ferrosilite. Pyroxene group. Synonym: clinohypersthene for intermediate members of the clinoenstatite-clinoferrosilite series. Polymorph: ferrosilite (orthorhombic). MON $P2_1/c$. $a = 9.71$, $b = 9.087$, $c = 5.228$, $\beta = 108.43^\circ$, $Z = 4$, $D = 4.00$. *17-548(syn,calc)*: 6.47_4 4.61_6 3.35_8 3.23_8 3.03_{10} 2.91_6 2.60_3 2.59_2 . Colorless to tan, vitreous luster, translucent to transparent. Cleavage $\{110\}$, perfect. $G = 3.96$. $H = 5-6$. Biaxial (+); $2V = 34-21^\circ$; $N_x = 1.705-1.727$, $N_y = 1.707-1.753$, $N_z = 1.727-1.790$; $X = b$, $Z \wedge c = (-)41-30^\circ$; $2V$ and extinction angle decreasing, and indices increasing for the composition range $\text{Es}_{50}\text{Fs}_{50}$ to $\text{Es}_0\text{Fs}_{100}$; slight calcium substitution leads to similar changes in optical properties. The iron end member probably does not exist in nature; Mg substitutes for iron to form a complete solid solution with clinoenstatite. Occurs as acicular crystals in lithophysae in obsidian at *Obsidian Cliff, Yellowstone National Park, WY*; in the Coso Mts., Inyo Co., CA; at Hrafnntiun-uhriggur, Iceland; Lake Naivasha, Kenya. AR *IMA 334(1966)*, *DHZII 2A:30(1978)*.

65.1.1.3 Kanoite $\text{MnMg}[\text{Si}_2\text{O}_6]$

Named in 1977 by Kobayashi for Hiroshi Kano, petrologist, Akita University. Pyroxene group. Polymorphous with the hypothetical end member for donpeacorite (65.1.2.3). MON $P2_1/c$. $a = 9.739$, $b = 8.939$, $c = 5.260$, $\beta = 108.56^\circ$, $Z = 4$, $D = 3.60$. *29-865*: 3.21_{10} 3.02_9 2.92_8 2.91_9 2.57_3 2.49_4 2.14_3 1.627_4 . Light pinkish brown, vitreous luster. Cleavage $\{110\}$, perfect. $H = 6$. $G = 3.66$. Biaxial (+); $2V = 40-42^\circ$; $N_x = 1.715$, $N_y = 1.717$, $N_z = 1.728$; $Y = b$, $Z \wedge c = 48^\circ$. The composition is close to the ideal formula with $\text{Mn}_{1.00}^{2+}\text{Mg}_{0.88}\text{Fe}_{0.10}^{2+}$. Found as grains in a vein in a cummingtonite-pyroxmangite rock at the *Tatehira mine, Oshima Pref., Hokkaido, Japan*. AR *JGSJ 88:537(1977)*, *AM 63:598(1978)*.

65.1.1.4 Pigeonite $(\text{Mg},\text{Fe}^{2+},\text{Ca})_2[\text{Si}_2\text{O}_6]$

Named in 1900 by Winchell for the locality. Pyroxene group. The name *ferropigeonite* has been applied to iron-rich varieties. Polymorphs: some subcalcic augite approximates pigeonite composition. High-pigeonite (*C2/c*) and proto-pigeonite ($P2_1/c$) are high-temperature polymorphs that may exist prior to cooling. MON $P2_1/c$. $a = 9.706$, $b = 8.950$, $c = 5.246$, $\beta = 108.59^\circ$, $Z = 4$,

$D = 3.44$ for pigeonite with $\text{En}_{39}\text{Fs}_{52}\text{Wo}_9$. 13-421: 3.21₈ 3.02₁₀ 2.91₈ 2.90₁₀ 2.58₆ 1.626₆ 1.493₆ 1.391₆. Structure: *AM 55:1195(1970)*. The nonequivalent A and B chains have shared-oxygen angles of 170° and 149° and S and O rotation, respectively. M2 is a sevenfold site with occupancy (Fe,Mg,Ca); M1 is close to regular octahedral coordination with occupancy (Mg,Fe). Domain structures may develop on cooling through inversion from the equivalent-chain *C2/c* structure of high pigeonite. At decreased temperature, high-Ca pigeonite may exsolve augite.

Habit: Crystals generally rock-bound as anhedral to subhedral grains. Twinning common; simple or lamellar, on {100} or {001}. Exsolution lamella of augite parallel {001}.

Physical properties: Brown, greenish brown to black; colorless to pale green or brown in thin section; vitreous luster. Cleavage {110}, perfect; parting {100}, {010}, and {001}; uneven to conchoidal fracture; brittle. $H = 6$. $G = 3.17-3.46$.

Optics: Biaxial (+); $2V = 0-30^\circ$; $N_x = 1.682-1.732$, $N_y = 1.684-1.732$, $N_z = 1.705-1.751$; $X = b$ with OAP perpendicular to (010) but rarely $Y = b$ with OAP parallel to (010), $Z \wedge c = 32-44^\circ$; $r > v$ or $r < v$, moderate; pleochroism absent to weak, $Y > X > Z$; brown or greenish brown to colorless. Indices increase with increasing iron content; $2V$ decreases slightly with increasing iron, and at first decreases to 0° with increasing calcium and then increasing as OAP orientation changes. Distinguished from other clinopyroxenes by its small optic angle, and from orthopyroxenes by its higher birefringence and oblique extinction.

Chemistry: Calcium is present in the range Wo_{2-16} , magnesium in the range En_{25-65} , and iron in the range Fs_{65-25} . Complex concentric and sector zoning is common, and pigeonite mantled by augite is known. Increased calcium may be present at elevated temperatures but is exsolved on cooling. The total of aluminum, ferric iron, titanium, and alkalis rarely exceeds 0.2 ion per six oxygens of the formula unit. Pigeonite with 13 wt % MnO is known.

Occurrence: The dominant pyroxene in many rapidly cooled lavas and minor intrusives, particularly in andesites, dacites, and diabases, forming in the groundmass as well as phenocrysts. Relict pigeonite is often found inverted to orthopyroxene with exsolved augite lamellae. Iron-rich pigeonite is uncommon in metamorphic rocks. Also found in meteorites and Lunar materials.

Localities: Widespread throughout the world, but often inverted to orthopyroxene. A few noteworthy localities are: in diabase at Lambertsville, NJ; in a diabase pegmatite at Goose Creek, VA; in the Moore Co. meteorite, NC; in the Beaver Bay diabase at *Pigeon Point, Lake Co., MN*, and Mn-rich pigeonite as a product of prograde metamorphism in the Biwabik iron formation. In adamellite and monzonite of the Nain anorthosite massif, Labrador, NF, Canada; in the Allende, Mexico, meteorite; at Skaergaard, Kangerdlugssuaq, Greenland; in andesite from Mull, Scotland; in andesite from Weiselberg, Germany. In andesites from Hakone, and in basalt at Mihara-yama, Oshima,

Japan; Mt. Wellington, Tasmania; in numerous intrusive bodies of South Africa. In Lunar Mare basalts (Apollo 11, 12, 16).

Use: Of no economic importance, but an important phase in the study of igneous rocks. AR *DHZII 2A:162(1978)*.

65.1.2.1 Enstatite $Mg_2[Si_2O_6]$

Named in 1855 by Kenngott from the Greek for *opponent*, in allusion to its infusibility before the blowpipe. Pyroxene group. Synonym: orthoenstatite. Varietal names within the enstatite-ferrosilite series are based primarily on composition; enstatite (FS_{0-10}); *bronzite* (FS_{10-30}), in allusion to the color and luster of some examples; *hypersthene* (FS_{30-50}), from the Greek meaning *over* and *strength*, in allusion to its greater hardness than hornblende, with which it was originally confused; *ferrohypersthene* (FS_{50-70}) in *sensu strictu* a variety of ferrosilite. Polymorphs: Clinoenstatite (low temperature, monoclinic), protoenstatite (high temperature, orthorhombic). ORTH *Pbca*. $a = 18.235$, $b = 8.818$, $c = 5.179$, $Z = 8$, $D = 3.204$ (for $En_{100}Fs_0$). 19-768(syn, En_{100}): 4.41_2 3.17_7 3.15_5 2.87_{10} 2.53_2 1.518_1 1.484_2 1.411_2 . Structure: *ZK 176:159(1986)*. The unit cell parameters show approximate linear increase with Fe^{2+} substitution for Mg. The chains are of two types, both having O-rotation. The shared oxygen angles for chains A and B at room temperature are 167° and 145° , respectively. The M1 site is close to ideally octahedral; the M2 is a distorted octahedral site (4 + 2), which becomes a seven-coordinated (4 + 3) site with increasing iron substitution. Some observed lamellar structures may be due to stacking disorder developed during phase transformation rather than to twinning or exsolution. Lower-symmetry ($P2_1ca$) domains have been observed.

Habit: Rarely well crystallized as short prisms with {100} and {210} dominant with complex terminations. Commonly rock-bound in anhedral to euhedral grains. Twinning rare; lamellar with composition plane {014}; stellate with {201} as composition plane. Exsolution lamellae of diopside parallel {100} with {100} and [010] of the two phases parallel. Sometimes with kinked and displaced domains, and "hourglass" exsolution sectors.

Physical properties: Colorless, pale yellow, pale green darkening with increasing iron content to greenish brown, dark brown, to nearly black; uncolored, gray, or pale brown streak; vitreous luster, sometimes submetallic (bronzite, hypersthene) due to Schiller effect. Cleavage {210}, good to perfect; parting, {100} and {010}. $H = 5-6$. $G = 3.21-3.60$ for $En_{100}Fs_0-En_{50}Fs_{50}$.

Optics: Biaxial (+) for FS_0-FS_{12} with $2V = 50-90^\circ$; biaxial (-) for $FS_{12}-FS_{50}$ with $2V = 90-55^\circ$; $N_x = 1.649-1.710$, $N_y = 1.651-1.723$, $N_z = 1.657-1.726$ over the range 0-50 mol % Fs; dispersion weak to moderate; $r < v$ to FS_{15} , $r > v$ to FS_{50} ; $XYZ = bac$. Pleochroism absent to moderate and probably related to Ti content; X, pink to reddish browns; Z, pale to gray-green, light blue. Chatoyant, asteriated, and labradorescent examples are known, particularly in the bronzite range.

Chemistry: Complete solid solution exists with ferrosilite. Zoned crystals with Mg-richer cores are known. Other cations rarely exceed to 10 mol %.

MnO may be present up to about 2.0 wt %, higher in ferrohypersthene. NiO and Cr₂O₃ may be present up to about 1%, particularly in meteorites and peridotites. A few percent Fe₂O₃ may be present, and Al₂O₃ may reach nearly 10% in enstatites of metamorphic rocks. CaO is rarely greater than 1%, but exsolution lamellae of diopside or augite are often present and may lead to erroneously high values. TiO₂ rarely exceeds 0.5%. Alteration to serpentine or talc is common.

Occurrence: Orthopyroxenes commonly occur in basic and ultrabasic plutonic rocks, intermediate and basic volcanics, and in high-grade metamorphics of both regional and thermal origin formed from both igneous and sedimentary antecedents. Magnesium-rich orthopyroxene is probably an important component of the upper mantle, where it is associated with forsterite, diopside, spinel, and pyrope. Known also in meteorites.

Localities: Widespread throughout the world; only a few noteworthy localities are given. Enstatite: in crystals at Tilly Foster mine, Brewster, Putnam Co., NY; in large crystals(!) often altered to talc at Bamle, Telemark, Norway; at Dawros, Connemara, Ireland; mostly altered to serpentine at Baste, Harz, Germany (Schiller spar); in crystals at Alosthal, Moravia, Czech Republic; colorless(!) from Embilipitiya, and green to brown from Ratnapura, Sri Lanka; as centimeter-size crystals and platy groups(!) from Piraja, Praça São Paulo, Cabeceiras, and Cordeiros, Brumado district, BA, Brazil; in the Shallowater, TX, meteorite. Bronzite: in eucritic norite in Delaware Co., PA; from the Stillwater Complex, MT; from Mysore, India (four-ray asterism); metamorphic bronzites are found at Eilean Carrach, Ardnamurchan, Scotland, and at Pahaoja, Sotajokli, Lapland, Finland; in the Kesen chondrite, Japan. Hypersthene: in norites from Delaware Co., PA; in hypersthene-granulite at Mt. Tremblant Park, PQ, Canada; as phenocrysts in pitch stone at Holmanes, Reydarfjodor, Iceland; fine crystals at Brugard, Norway (!); as phenocrysts in andesites of several volcanoes in Japan, and in amphibolite at Hokizawa, Kanagawa Pref., Japan; in the Mt. Padbury, WA, Australia, meteorite.

Uses: Although of great petrologic significance, its only economic role is as a lapidary material. Abundant Schiller material is found in Canada; asteriated, four-ray gems are produced from Nammakal, India (black star of India); colorless to light green or brown faceted stones have been produced from Arizona, Burma, and Sri Lanka. AR *DHZII 2A:20(1978)*, *PCM 10:217(1984)*.

65.1.2.2 Ferrosilite (Fe,Mg)₂[Si₂O₆]

Named in 1935 by Bowen for the composition: ferrous silicate. Pyroxene group. Synonym: orthoferrosilite. Intermediate compositions are given the names *ferrohypersthene* (Fs₅₀₋₇₀) and *eulite* (Fs₇₀₋₉₀), a corruption of the rock name *eulysite*, from the Greek for *easily broken* or *dissolved*. Dimorphous with clinoferrosilite. ORTH *Pbca*. $a = 18.418$, $b = 9.078$, $c = 5.237$, $Z = 8$, $D = 4.00$. $21-721(\text{syn})$: 6.46₃ 4.61₉ 3.23₇ 3.00₈ 2.91₁₀ 2.59₄ 2.52₃ 1.781₂; 31-635(mag-

nesian): 3.18₁₀ 2.96₄ 2.88₅ 2.84₂ 2.72₃ 2.56₄ 2.51₃ 2.48₃. Structure: *AM 61:38(1976)*. Isostructural with enstatite, with cell constants diminishing with substitution of Mg. Usually as rock-bound grains or phenocrysts. Possibly as prismatic crystals (ferrohypersthene). Brown, greenish brown to nearly black; gray to pale brown streak; vitreous luster, less commonly pearly or submetallic on cleavage. Cleavage {210}, good; parting, {100}, {010}. $H = 5-6$. $G = 3.60-4.00$. Biaxial (-) for $Fs_{50}-Fs_{88}$ with $2V = 50-90^\circ$; biaxial (+) for $Fs_{88}-Fs_{100}$ with $2V = 90-55^\circ$; $N_x = 1.710-1.767$, $N_y = 1.723-1.770$, $N_z = 1.726-1.788$; $r < v$; $XYZ = bac$. Pleochroism absent to weak; X, pinkish brown; Z, greenish brown. Forms a complete isomorphous series with enstatite, but composition with $F_5 > 90\%$ values not known in nature. Ionic substitution is similar to that found in the enstatite half of the series; Al_2O_3 may exceed 10 wt % in some metamorphic occurrences; a few percent Fe_2O_3 may be present, usually somewhat higher than in enstatite-hypersthene and particularly in metamorphic material. Found in basic and ultrabasic plutonic rocks and in acidic to basic volcanics; also in iron-rich, high-grade metamorphics. Widespread throughout the world; only a few well-documented occurrences are given. For ferrohypersthene: in gabbro of the Guadalupe complex, CA; in rhyolite pumice at Taupo, New Zealand; in hornfels at Aavold quarry, Oslo district, Norway; Al-rich in granulite at Satnur, Mysore, India. Eulite: in granite at Rubideaux Mt., Riverside, CA; in garnet-orthopyroxene gneiss at Bear Mt., Popolopan Lake Quadrangle, NY; at an unspecified locality in the former USSR; in granulite from Broken Hill, NSW, Australia; in eulysite from Madial, Sudan. AR *DHZII 2A:20(1978)*, *MM 52:535(1988)*.

65.1.2.3 Donpeacorite (Mn,Mg)Mg[Si₂O₆]

Named in 1984 (Petersen et al.) for Donald Ralph Peacor (b.1937), Department of Geological Sciences, University of Michigan. Pyroxene group. Polymorph: clinopyroxene kanoite (65.1.1.3). ORTH *Pbca*. $a = 18.384$, $b = 8.878$, $c = 5.226$, $Z = 8$, $D = 3.403$. *38-358*: 4.03₁ 3.18₁₀ 3.09₁ 2.96₁ 2.90₆ 2.51₁ 1.495₁ 1.479₁. Manganese is ordered in the M2 site and exceeds 50% of that site occupancy. As interlocking anhedral grains, 1-3 mm in diameter, and displaying no twin or exsolution lamellae. Pale buff to yellow-orange, vitreous luster. Cleavage {210}, perfect. $H = 5-6$. $G = 3.36$. Biaxial (-); $2V = 88^\circ$; $N_x = 1.677$, $N_y = 1.684$, $N_z = 1.692$; $XYZ = bac$; pleochroism not described. Mn^{2+} makes up 56-63% of the M2 site occupancy; minor calcium, aluminum, and Fe^{2+} are present. Found with tirodite, tourmaline, ferrian beraunite, manganoo dolomite, hedyphane-like apatite, and anhydrite in a manganiferous pod of marble at the 2,500-ft level of the *Balmat No. 4 mine, Balmat, St. Lawrence Co., NY*. AR *AM 69:472(1984)*.

65.1.3a.1 Diopside CaMg[Si₂O₆]

Named in 1800 by d'Andrada from the Greek for *double* and *appearance*, in allusion to its variable appearance. Pyroxene group. Numerous varietal names

exist, of which only those utilized petrographically need be preserved: *salite* for the range $\text{Di}_{90}\text{Hd}_{10}$ – $\text{Di}_{50}\text{Hd}_{50}$ is named for Sala, Sweden; *endiopside* with excess Mg; *diallage* from Greek for *difference*, in allusion to its parting. **MON** $C2/c$. $a = 9.739$, $b = 8.913$, $c = 5.253$, $\beta = 106.02^\circ$, $Z = 4$, $D = 3.278$. *41-1370*: 3.22_5 2.99_{10} 2.94_6 2.89_3 2.56_2 2.54_2 2.51_3 2.13_2 . Structure: *AM 76:1141(1991)*. As with all $C2/c$ pyroxenes the chains are equivalent, with O-rotation and a shared oxygen angle of $\approx 166.5^\circ$. Site M1 (Mg) is octahedral; site M2 (Ca) is eight-coordinated. The cell edges a and b increase toward hedenbergite (Fe^{2+} substitution) but c remains nearly the same; all cell edges decrease toward jadeite (coupled Na–Al substitution).

Habit: Crystals equant to prismatic with $\{010\}$, $\{100\}$, $\{111\}$, $\{001\}$ dominant or with $\{110\}$ better developed than $\{100\}$ and $\{010\}$; less commonly tabular with $\{001\}$ dominant. Commonly as rock-bound, rounded grains; anhedral to euhedral. Less commonly in fibrous masses, or masses of large crystals with prominent tabular habit. Also as exsolution lamellae in pigeonite and other high-Mg pyroxenes. Simple or lamellar twinning on $\{100\}$ common.

Physical properties: White, pale to dark green, rarely violet; white to pale green streak; vitreous luster. Cleavage $\{110\}$, good to perfect; parting sometimes prominent, $\{100\}$ and $\{010\}$. $H = 5\frac{1}{2}$ – $6\frac{1}{2}$. $G = 3.22$ – 3.45 . **Optics:** Biaxial (+); $2V = 49$ – 64° , $N_x = 1.664$ – 1.697 , $N_y = 1.672$ – 1.706 , $N_z = 1.694$ – 1.728 , increasing with iron content; $Y = b$, $Z \wedge c = +35$ – 48° ; increasing with iron content; $r > v$, weak to moderate; pleochroism none to weak in iron-rich examples, $Z > Y > X$; pale brownish green to pale green. Chatoyancy, and four-ray asterism in darker varieties, hedenbergite in part.

Chemistry: A complete solid-solution series exists between diopside and hedenbergite. MnO may be present to a few percent, with ferroan diopside and hedenbergite being richer in that component, and a small amount of ZnO may also be present; at least a partial solid solution with johannsssenite and petedunnite exists. Coupled substitutions NaAl and NaFe^{3+} for CaMg involve the end-member pyroxenes jadeite and aegirine, respectively. Chrome diopside involves the coupled substitution of NaCr for CaMg and CrAl for MgSi. Endiopside contains an excess of magnesium over the ideal 1:1 Ca/Mg

Diopside

New York. Forms: $a\{100\}$, $b\{010\}$, $c\{001\}$, $u\{111\}$, $v\{221\}$, $p\{\bar{1}01\}$.

ratio. Substitution of Al for Si in the chains is usually minor and may accompany minor Ti^{4+} in the M1 site. Extensive substitution outside the diopside hedenbergite series leads to augite, omphacite, and aegirine-augite (65.1.3b.2).

Occurrence: Chrome diopside and endiopside are common pyroxenes in nodules and xenocrysts of kimberlites and alkali olivine basalts. Diopside and salite are typical of hypabyssal crystallization from alkali olivine basalt. Relatively pure diopside is found in thermally metamorphosed siliceous dolomite and in skarns; ferroan diopside occurs in similar environments. **Localities:** Diopside is of worldwide occurrence, but only a few noteworthy or well-documented localities are cited. Excellent, light green, transparent crystals(!) at De Kalb, St. Lawrence Co., and as green granules with andradite in wollastonite at Willsboro, Essex Co., and diallage and salite at Amity, Orange Co., NY; zincian salite at Franklin, Sussex Co., NJ; chromian material at Sloan II diatreme, Larimer Co., and as crystals to 3 cm with prominent {661} at Italian Mt. S of Aspen, CO; large, opaque crystals at Crestmore, CA. Found at the Jeffrey mine, Asbestos, PQ; at Birds Creek, near Bancroft, and at Dog Lake, Storrington Twp., ON, Canada. Crystals to 30 cm in the Gardiner complex, near Kangerdlugssuak Fjord, Greenland. Manganoan material at Langban, Varmland, Sweden; deep green chromian diopside from Outokumpo, Finland; as fine light green crystals(!) with grossular and clinocllore at Ala Tal and Aosta Tal, at St. Marcel (violet), and other sites in Piemonte, Italy; at Katzenbuckel, Odenwald, Germany (ferrian); and at Zillerthal, Tyrol, Austria. Found in Yakutia and at Slyudyanka, Lake Baikal, Russia [green and emerald green(!) chromian material]; dark green chatoyant and asteriated from Nammakal, Rajasthan, India; transparent yellow and chatoyant from Burma; fine, light green crystals(!) resembling those of DeKalb, NY, from the Kunlun Mts.(?), Xinjiang Uygur, China. Dark green, transparent from Taolanaro, Madagascar, and chromian from Kenya. At Setuba, and near Malacacheta, MG, Brazil (chromian). **Uses:** When transparent, the low-iron, light green (NY, China, Madagascar, Italy) and chromian, emerald green (Russia, Brazil) varieties are faceted as minor or collector's faceted gems; the dark green (hedenbergite in part) chatoyant or asteriated varieties are cut en cabochon. AR *DHZII 2A:198(1978)*; MR *15:82(1984)*, *21:535(1990)*; CE *44:299(1985)*.

65.1.3a.2 Hedenbergite $CaFe^{2+}[Si_2O_6]$

Named in 1819 by Berzelius for Ludwig Hedenberg, Swedish chemist, who analyzed and described the species. Pyroxene group. Petrographically used terms are *ferrosalite*, in use for the composition range $Di_{50}Hd_{50}-Di_{10}Hd_{90}$, and *ferrohedenbergite*; *schefferite* and *jeffersonite* have been used for manganoan and manganoan-zincian ferrosalites. MON C2/c. $a = 9.852$, $b = 9.031$, $c = 5.242$, $\beta = 104.84^\circ$, $Z = 4$, $D = 3.65$. 41-1372: 6.57_3 4.77_2 3.28_3 3.01_{10} 3.00_9 2.59_3 2.56_5 2.41_3 . Structure: ZVMO 107:113(1978). The chains are equivalent, with O-rotation and a shared oxygen angle of $\approx 164.5^\circ$. Site M1

(Fe^{2+}) is octahedral; site M2 (Ca) is eight-coordinated. The cell edges a and b decrease toward diopside (Mg substitution), but c remains nearly the same; a and b decrease toward aegirine (coupled Na/Fe^{3+} substitution) while c increases slightly. **Habit:** Crystals equant to prismatic and as rock-bound grains; essentially the same as for diopside. Simple or lamellar twinning on {100} common. **Physical properties:** Pale to dark green, brownish green, to brownish or greenish black; pale green to tan streak; vitreous to resinous luster. Cleavage {110}, good, occasionally with {100} parting. $H = 6$. $G = 3.45\text{--}3.56$. Biaxial (+); $2V = 52\text{--}64^\circ$; $N_x = 1.697\text{--}1.726$, $N_y = 1.706\text{--}1.730$, $N_z = 1.728\text{--}1.751$; $Y = b$, $Z \wedge c = 47\text{--}48^\circ$, diminishing with increasing iron; $r > v$, strong; weakly pleochroic, $Z > Y > X$, green or yellow-green to pale green or bluish green. Chatoyancy and four-ray asterism is known (in part diopside). **Chemistry:** Complete solid solution exists with diopside (65.1.3a.1). Manganese may substitute to a greater degree than in diopside, as is the case for zinc. Excess Fe^{2+} may be present in the M2 site (ferrohedenbergite). Solid solution with sodic pyroxenes, and Al substitution in the chain tetrahedral sites yields, as with diopside, augite, and aegirine-augite. **Occurrence:** Hedenbergite and manganean hedenbergite are found in limestone-dolomite skarns, thermally metamorphosed iron-rich sediments, and in metasomatically emplaced ores. Ferrohedenbergite and hedenbergite are found in quartz syenites, granophyres, and ferrodiorites. **Localities:** World-wide distribution; some notable localities are: jeffersonite and schefferite in the zinc ores of Sussex Co., NJ; in marble enclosed in anorthosite from the Ausable quadrangle, Adirondack Mts., NY; Iron Hill, Gunnison Co., CO; in the Hanover district, Grant Co., NM; fine crystal(!) at the Laxey mine, South Mt., ID. At Mt. St.-Hilaire, PQ, and ferrosalite in the Lower Wabush iron formation, Labrador, NF, Canada. Ferrohedenbergite in granophyres of the Skaergaard complex, eastern Greenland; at *Tunaberg, Sweden*, and from Langban (schefferite), the Harstig mine, Pajsberg, and at Nordmark(!); manganean at the Treburland manganese mine, Altarnun, Cornwall, England; in skarn at Tignitoio iron deposit, Elba, Italy; at Mega Xhorio, Seriphos, Greece, as prismatic crystals and as inclusions in quartz. Also in the Kola Penin., and at Dal'negorsk, Primorye, Russia; fine crystals from Skardu area, Pakistan; Andhra Pradesh, India; the Kamioka mine, Gifu Pref., Japan; and at Broken Hill, NSW, Australia. Use: Ferroan diopside and hedenbergite are cut en cabochon when they display chatoyancy or asterism. *AR DHZII 2A:198(1978), MJJ 11:84(1982)*.

65.1.3a.3 Augite ($\text{Ca}, \text{Mg}, \text{Fe}^{2+}, \text{Fe}^{3+}, \text{Al}, \text{Ti}$)₂[(Al, Si)₂O₆]

Named in 1792 by Werner from the Greek for *luster*, in allusion to the appearance of the cleavage surface. Pyroxene group. *MON C2/c*. $a = 9.707$, $b = 8.858$, $c = 5.274$, $\beta = 106.52^\circ$, $Z = 4$, $D = 3.31$ for an augite of composition $\approx \text{Na}_{0.06} \text{Ca}_{0.75} \text{Mg}_{0.79} \text{Fe}_{0.18}^{2+} \text{Mn}_{0.01} \text{Fe}_{0.09}^{3+} \text{Ti}_{0.04} \text{Al}_{0.38} \text{Si}_{1.73} \text{O}_6$; the cell constants vary considerably with composition. *41-1483*(aluminian augite): 3.22_7 2.99_{10} 2.94_6 2.90_3 2.56_4 2.53_3 2.51_5 2.13_3 . Structure: *MSASP 2:31(1969)*. The structure

is essentially like that of diopside with a shared oxygen angle in the chain of $\approx 166^\circ$. Ca is constrained to the M2 site and Al to the M1 site, but Mg and Fe^{2+} may be in either and their distribution is less ordered than in coexisting pigeonite and orthopyroxene.

Habit: Short prismatic $\{001\}$ crystals somewhat flattened $\{100\}$, with $\{110\}$, $\{100\}$, and $\{\bar{1}11\}$ dominant. Simple contact twins on $\{100\}$ common, but also lamellar; $\{001\}$ lamellar. Rock-bound anhedral to euhedral and interstitial crystals common, and as exsolution lamellae; also as large cleavable masses.

Physical properties: Greenish black to black, dark green, light to dark brown; pale brown to greenish gray streak. Cleavage $\{110\}$, good; parting $\{100\}$, $\{001\}$. $H = 5\frac{1}{2}$ –6. $G = 3.19$ –3.56. Biaxial (+); $2V = 25$ – 61° (88° reported for sodian varieties); $N_x = 1.671$ – 1.735 , $N_y = 1.672$ – 1.741 , $N_z = 1.703$ – 1.774 , the values generally increasing with increased iron; $Y = b$, $Z \wedge c = 35$ – 48° (62° reported for sodian augite); $r > v$, weak to moderate but strong in titanian augite. Weakly to moderately pleochroic, increasing with depth of color and Ti content; X, light green, yellow-green, reddish; Y, reddish, red, violet; Z, greenish yellow, reddish, violet, the reddish or violet tones being typical of titanian augite. In thin section commonly showing compositional zoning and hourglass structure.

Chemistry: Augite represents a complex solid solution involving the end members diopside, hedenbergite, jadeite, aegirine, and the Mg–Fe orthopyroxenes, as well as lesser amounts of the less common end members, but presence of high aegirine leads to aegirine–augite (65.13b.2), which is not universally accepted as a species. Al commonly substitutes for Si in the tetrahedral sites, and there is usually sufficient Al + Si to satisfy the tetrahedral sight occupancy. Fe^{3+} probably occupies tetrahedral sites in the few instances when the Al + Si sum is deficient. Na, Al, and Fe^{3+} , although almost always present, each rarely exceed 10% of the M1 + M2 cations, and titanium may be present to the same extent (titanaugite). Significant Cr_2O_3 may be present in Mg-rich augites of basic rocks. Exsolution lamellae of calcium-poor orthopyroxene or pigeonite commonly form in initially subcalcic augites of basic plutonic rocks; these are most commonly oriented parallel to $\{100\}$. Metamorphic

Augite

(a) Forms : $a, \{100\}$; $b, \{010\}$; $m, \{110\}$; $s, \{\bar{1}11\}$. (b) Contact twin on $\{100\}$.

augites may have exsolution lamellae of orthopyroxene parallel to {100} and pigeonite lamellae on irrational planes close to {100} or/and {001}.

Occurrence: Occurs in a wide variety of igneous rocks; a characteristic constituent of gabbros, dolerites, and basalts; less commonly found in ultrabasic rocks; intergrown with ilmenite in kimberlites. Titanian augite is characteristic of basic alkaline rocks. In metamorphic rocks, particularly of the granulite facies, and in metamorphosed impure and phosphatic limestones.

Localities: A ubiquitous mineral in the above-described environments. Some noteworthy and well-documented observations are: with garnet and oligoclase in granulite at Elizabethtown, NY; in crystals at Twin Peaks, Millard Co., UT. Found as crumbly crystals with scapolite in marble at La Panchita mine, near Ayoquezco, OAX, Mexico. Found as crystals and as large cleavable masses, sometimes associated with scapolite and fluorapatite, at Turner's Is., Lake Clear; the Smart mine, near Eganville; near Bancroft; and on the Cardiff property near Wilberforce, all in ON, Canada. Ferroan augite is found in the Skaergaard complex of Greenland. At Arendal, Norway, and at Ersby, near Pargas, Finland. In the Albani Mts., south of Rome, and in the lavas of Vesuvius (sometimes ferrian), Campania, Italy. In good crystals in basalt tuff SE of Teplice, Czech Republic, and in the Laacher See district of Germany. Ferrian augite is found at Khibiny, Kola Penin., and sodian augite in monzonite of Tyaki, Morotu district, Sakhalin, Russia. Common in many volcanic rocks of Japan. AR *DHZII 2A:294(1978)*, *MSARM:7(1980)*.

65.1.3a.4 Johannsenite $\text{CaMn}[\text{Si}_2\text{O}_6]$

Named in 1932 by Schaller for Albert Johannsen (1871–1962), geologist and petrologist, University of Chicago. Pyroxene group. MON *C2/c*. $a = 9.978$, $b = 9.156$, $c = 5.293$, $\beta = 105.48^\circ$, $Z = 4$, $D = 3.522$. *38-413*: 3.28_2 3.02_{10} 2.92_2 2.60_3 2.55_7 2.16_2 2.13_2 2.03_2 . Reported cell constants vary only slightly for c , but show a range for $a = 9.83$ – 9.98 and $b = 9.04$ – 9.16 . Structure: *AM 52:709(1967)*. The silicate chains are equivalent and they are slightly more kinked than in diopside with a shared oxygen angle of 163.8° ; Mn^{2+} is in site M1 with almost ideal octahedral coordination, and Ca is in M2 with an eight-fold (4 + 4) coordination. Usually massive or columnar consisting of matted, radiating, or spherulitic aggregates of prisms or fibers. Rarely in prismatic crystals. Twinning, simple or lamellar, on {100} common. Brown, gray, green, and, less commonly, colorless to bluish; often black on surface due to Mn oxides; usually colorless in thin section; translucent to opaque. Cleavage {110}, good to perfect; parting on {100} and {001}; conchoidal to splintery fracture; brittle. $H = 6$. $G = 3.37$ – 3.54 . Biaxial (+); $2V = 58$ – 72° ; $N_x = 1.699$ – 1.710 , $N_y = 1.710$ – 1.719 , $N_z = 1.725$ – 1.738 ; $X = b$, $Z \wedge c = 46$ – 55° ; $r > v$ or $r < v$, weak; ferroan material weakly pleochroic with $Z > Y > X$; the indices increase and $2V$ decreases with Fe^{2+} substitution. The chief substituents for Mn^{2+} in the M1 site are Fe^{2+} , Mg, and minor Al; those for Ca in M2 are Na and Mn^{2+} ; only minor substitution of Al for Si is reported. Characteristic of metasomatized limestones adjacent to acid and

intermediate intrusions, where it is often associated with rhodonite and bustamite, and in skarns; less commonly with calcite veins in rhyolite. Noteworthy occurrences are at Franklin, Sussex Co., NJ, with rhodonite in interstices of andradite–manganophyllite breccia; at the Star mine, Vanadium, NM, and at the Black Hole prospect, Graham Co., AZ; in the *Bohemia district, Lane Co., OR*; as veins in rhodonite at the Brown Mule claim, Mason Co., WA. Found with xonotlite and calcite at Tetela de Ocampo, PUE, Mexico; in limestone at Monte Civilliana, Recoaro, and the *Schio–Vincenti mine, Venezia, Italy*; in the Madan district of Bulgaria. Often highly altered to Mn oxides and opaline silica, it is the major component of Mn ores at Teragochi, Okayama Pref., Japan. Ferroan material with manganopyrosomalite and bustamite at Broken Hill, NSW, Australia. AR *DHZII 2A:415(1978)*.

65.1.3a.5 Petedunnite $\text{CaZn}[\text{Si}_2\text{O}_6]$

Named in 1987 by Essene and Peacor for Pete Dunn (b.1942), mineralogist, Smithsonian Institution, Washington, DC. Pyroxene group. MON *C2/c*. $a = 9.82$, $b = 9.00$, $c = 5.27$, $\beta = 105.6^\circ$, $Z = 4$, $D = 3.68$. *PD*: 6.49_1 3.02_{10} 2.96_4 2.59_3 2.54_8 2.23_1 2.14_1 2.02_3 . Dark green, vitreous luster, translucent. Cleavage {110}. $H \approx 6$. Biaxial (+); $2V = 80^\circ$; $N_x = 1.68$, $N_y = 1.69$, $N_z = 1.70$; $Y = b$, $Z \wedge c = 40^\circ$; $r > v$, strong. Pleochroic; X, Y, light yellow; Z, light green. Found in a single specimen as a mosaic of 10- to 100- μm grains that make up pseudo-single crystals, associated with calcite at *Franklin, Sussex Co., NJ*. AR *AM 72:157(1987)*.

65.1.3a.6 Esseneite $\text{CaFe}^{3+}[\text{AlSiO}_6]$

Named in 1987 by Cosca and Peacor for Eric J. Essene (b.1939), metamorphic petrologist, University of Michigan. Pyroxene group. MON *C2/c*. $a = 9.79$, $b = 8.822$, $c = 5.37$, $\beta = 105.81^\circ$, $Z = 4$, $D = 3.54$. *PD*: 3.21_2 3.00_{10} 2.96_6 2.58_3 2.55_4 2.53_7 1.545_3 1.430_2 . Reddish brown, vitreous luster, translucent. Cleavage {110}, perfect. $H \approx 6$. Biaxial (-); $2V_{\text{calc}} = 70.5^\circ$; $N_x = 1.795$, $N_y = 1.815$, $N_z = 1.825$; $Y = b$, $Z \wedge c = 9^\circ$; strong inclined dispersion; pleochroic, $Z > Y > X$, lemon yellow to apple-green. Resembles aegirine but distinguished from it by its extinction angle. Natural material has Si/Al $\approx 1.2:0.8$. Found as 2- to 8-mm grains with mullite, anorthite, and magnetite–hercynite in association with naturally combusted coal at *Durham Ranch, S of Gillette and NE of Reno Junction, WY*. AR *AM 72:148(1987)*.

65.1.3b.1 Omphacite $(\text{Ca},\text{Na})(\text{R}^{2+},\text{Al})[\text{Si}_2\text{O}_6]$

Named in 1815 by Werner from the Greek for *unripe grape*, in allusion to its usual light green color. Pyroxene group. The variety chloromelanite, named for its dark green color, lies, in part, within or close to the omphacite field. MON *C2/c*. $a = 9.561$, $b = 8.730$, $c = 5.249$, $\beta = 107.00^\circ$, $Z = 4$, $D = 3.39$. *42-568*: 4.34_5 3.14_3 2.95_{10} 2.86_{10} 2.52_3 2.51_3 2.45_4 2.09_4 . Structure: *AM 76:1141(1991)*. In addition to the *C2/c* structure, several omphacite structures have been refined in space groups *P2* and *P2/n*, the latter probably the valid

assignment. The $C2/c$ structure is essentially the same as that of other pyroxenes assigned to this space group. In the $P2/n$ structure the chains are equivalent but have two different Si sites and two distinct M1 and M2 sites; Al and Mg are ordered among the two M1 sites, Ca and Na are partially ordered among the two M2 sites. The ordering thus requires a composition close to $Di_{50}Jd_{50}$ for the $P2/n$ structure, but many omphacites ($C2/c$) are well outside this 1:1 ratio. Green to dark green, colorless in thin section; vitreous luster; translucent. Cleavage {110}, good; parting {100}. $H = 5-6$. $G = 3.16-3.43$. Biaxial (+); $2V = 56-84^\circ$; $N_x = 1.662-1.701$, $N_y = 1.670-1.712$, $N_z = 1.685-1.723$; $Y = b$, $Z \wedge c = 34-48^\circ$; $r > v$, moderate; weakly pleochroic, $Z > Y > X$, colorless to pale green, more pronounced in iron-rich varieties. The compositional field lies within the limits $(Di + Hd)_{75}Jd_{25}$, $(Di + Hd)_{60}Jd_{20}Ae_{20}$, $(Di + Hd)_{20}Jd_{60}Ae_{20}$, and $(Di + Hd)_{25}Jd_{75}$. Minor substitution of titanium and chromium occurs as well as some aluminum for silicon; only trace amounts of manganese are reported. Chloromelanite usually contains additional acmite. Omphacite is characteristic of high-pressure igneous or metamorphic environments; it is the common pyroxene of eclogites, but also occurs without garnet in glaucophane schists and amphibolites. Notable occurrences are: in the glaucophane schists of the Franciscan Formation, CA, and from kimberlite at Garnet Ridge, AZ; in eclogite of the Motagua fault, Guatemala. Found in eclogite at Naustdal and Vanelvsdalen, Norway; at Ile de Groix, France (chloromelanite); in kyanite eclogite at *Kupperbrunn, Saualpe, Austria*; in corundum and kyanite eclogites at several localities in Yakutia, Russia. Chloromelanite is found at Suberi-dani, Tokushima Prefecture, Shikoku, Japan, and in New Caledonia. Found in eclogite nodules of several kimberlite pipes of South Africa; from eclogite at Puerto Cabello, Venezuela, and Guajira Penin., Colombia. Chloromelanite finds limited use as an ornamental carving material in the Chinese tradition. AR *DHZII 2A:424(1978)*.

65.1.3b.2 Aegirine-augite $(Ca,Na)(R^{2+},Fe^{3+})[Si_2O_6]$

Species status is not universally assigned to this composition range; see also augite (65.1.3a.3) and aegirine (65.1.3c.2). The name is derived from its intermediate pyroxene composition. Pyroxene group. The pyroxene variety chloromelanite, named for its dark green color, lies in part within or close to the aegirine-augite field. MON $C2/c$. $a = 9.68-9.74$, $b = 8.79-8.94$, $c = 5.26-5.36$, $\beta = 105.0-106.85^\circ$. The powder X-ray diffraction pattern is variable and intermediate between that of ferroan augite and aegirine. Cell edges a and b decrease with higher aegirine content and c increases slightly, as does the β angle, resulting in diminished cell volume. Crystals usually rock-bound, short prismatic to acicular. Twinning on {100}, lamellar or simple, common. Dark green to black, green, yellow-green; pale yellow-green or gray-green streak; vitreous luster; translucent to opaque. Cleavage {110}, good to perfect; parting {100}; conchoidal to splintery fracture. $H = 6$. $G = 3.40-3.60$. Biaxial (-)/(+); $2V_x = 70-110^\circ$; $N_x = 1.700-1.760$, $N_y = 1.710-1.800$, $N_z = 1.730-1.813$;

$Y = b$, $X \wedge c = -(0-20^\circ)$; $r > v$, moderate to strong. Weakly to moderately pleochroic; X, bright to deep green; Y, yellow-green; Z, yellow to greenish brown. The boundary between aegirine and aegirine-augite is placed at about Ae_{80} , but alternately at the change in optic sign occurring at about Ae_{50} . Intermediate in composition between augite and aegirine; generally low in Ti, but significant Zr and minor V and Sc may be present. Chloromelanite lies, in part, within the aegirine-augite field, but most examples contain over 20 mol % each of aegirine, augite, and jadeite. A characteristic mineral of alkaline rocks, particularly syenites; also in iron-rich metasediments, and in metasomatic environments. Worldwide occurrence. Noteworthy, well-documented localities are: at Iron Hill, CO, and in shonkinite in the Bearpaw Mts., MT; in paragneiss at Seal Lake, Labrador, NF, Canada; in syenites of Greenland as at Kangerdlugssuaq. Found in aegirine granulite at Glen Lui, Aberdeenshire, Scotland; at Alnō, Sweden; in alkaline complexes of the Kola Penin., and the Ilmen Mts., Russia. In India at Harohalli, Mysore, and at Khamman, Andhra Pradesh; at the Bessi mine, Hodono, Ehime Pref., Japan. Found in iolite pegmatite, Homa Bay area, Kenya. AR *DHZII* 2A:482(1978).

65.1.3c.1 Jadeite $NaAl[Si_2O_6]$

Named in 1863 by Damour by derivation from jade, of which it is but one type; from the Spanish *piedra de yjada*, stone of the side, in reference to its alleged curative effect over kidney ailments. Pyroxene group. MON C2/c. $a = 9.418$, $b = 8.562$, $c = 5.219$, $\beta = 107.58^\circ$, $Z = 4$, $D = 3.345$. 22-1338: 4.29₄ 3.10₃ 2.92₇ 2.83₁₀ 2.49₂ 2.42₂ 2.07₃ 1.572₂. Structure: *CMP* 83:257(1983). The equivalent silicate chains are the least kinked of the clinopyroxenes with a shared oxygen angle of 174.7° . Al is in nearly ideal octahedral coordination in site M1, and the eight-coordinated M2 site has nearly equal Na-O distances. Crystals are rare in vugs in massive material as short prismatic crystals with the pinacoids dominant. Usually in compact masses of granular to short fibrous, anhedral crystals. White, colorless, pale to deep emerald-green, yellow, gray, bluish gray, lavender to violet; vitreous luster; translucent to opaque. Cleavage {110}, good; conchoidal fracture. $H = 6-7$. $G = 3.24-3.43$. Biaxial (+); $2V = 60-90^\circ$; $N_x = 1.640-1.681$, $N_y = 1.645-1.684$, $N_z = 1.652-1.692$; $Y = b$, $Z \wedge c = +35-55^\circ$; $r > v$, moderate to strong, sometimes yielding anomalous interference colors. Chromium, manganese, and ferric and ferrous iron are commonly present in small amounts and yield the brightly colored jadeite (Cr = emerald green, Mn = violet and lavender); in massive, multi-colored material the chromophore-substituted material occurs in random, irregular patches. Compositionally zoned jadeite with iron-richer cores is known. When considerable diopside is present, the term *diopside-jadeite* is often used although the composition is usually within the omphacite field. Jadeite is generally restricted to metamorphic rocks of high-pressure origin, but has also been observed in lower-pressure metamorphics. Almost invariably associated with albite, but also quartz, glaucophane, lawsonite, actinolite, and

others; found in metagreywackes where the albite content is low, it having been mostly converted to jadeite and quartz. Reported from pillow lavas and as nodules in serpentinite. Widespread in metamorphic rocks of tectonically active, subductive plate boundaries. Notable localities: found with glaucophane, lawsonite, and other minerals in the Franciscan formation, as at Clear Springs in San Benito Co., Eel R. in Trinity Co., Valley Ford in Sonoma Co., CA, both massive and in crystals; along the Motagua fault, Guatemala. Reported from Switzerland and possibly other Alpine terrains of central Europe. A violet jadeite-bearing rock is reported from Turkey, and a gray material from Pakistan. In varicolored, massive material(!) from around Tawmaw, Kachin Hills, northern Burma, in an area about 100 km NW of Moguang and lying between the Uru and Chindwin rivers; reported, but rare, with tremolite-actinolite (nephrite) from the Kunlun Mts., Xinjiang Uygur, China. Found at Kotaki, Niigata Pref., and elsewhere in Japan; at the Koesek R., Celebes. Widely used as an ornamental material to produce carved sculptures and jewelry stones. The majority of such materials derive from the Burmese occurrence; all colors, including black due to impurities, are worked, but the lavender and emerald-green materials are most highly prized for jewelry, the latter, when uniform and translucent, commanding very high prices, and commonly but not exclusively referred to as *imperial jade*; the same is also applied to any jade, jadeite or nephrite, whose provenance is attributed to the Imperial Palace, China. AR *DHZII 2A:461(1978)*, *JADE:266(1991)*.

65.1.3c.2 Aegirine $\text{NaFe}^{3+}[\text{Si}_2\text{O}_6]$

Named in 1835 by Berzelius for Aegir, the Scandinavian god of the sea, having first been observed in Norway. Pyroxene group. Synonym: acmite, named from the Greek for *point*, in allusion to its crystal habit. MON *C2/c*. $a = 9.658$, $b = 8.795$, $c = 5.295$, $\beta = 107.42^\circ$, $Z = 4$, $D = 3.577$. *31-1309*: 6.38₁₀ 4.41₂ 2.98₃ 2.91₆ 2.55₁ 2.48₁ 2.12₁ 1.730₁. Structure: *MSASP 2:31(1969)*. The silicate chains are of one type and relatively unknicked, with the shared oxygen angle being 174° . Fe^{3+} is in the almost regular octahedral M1 site, and Na is in eight-coordination (6 + 2) in the M2 site. Substitution of Ca and (Mg, Fe^{2+}) for Na and Fe^{3+} , respectively, leads to a greater kinking of the chains.

Habit: Crystals, whether free-standing or rock-bound, tend to be prismatic to decidedly acicular [001]. Crystals often reach several tens of centimeters in length. The dominant forms are {110}, {100}, and {010} terminated by {111} and often with prominent {221} and {661}, the latter resulting in the pointed habit to which the term *acmite* was originally applied; *aegirine* was originally applied to crystals with blunt terminations. The prism zone is often striated but lustrous, whereas termination faces are often etched and dull. Twinning on {100} common.

Physical properties: Dark green, reddish brown, black; the brown or yellow tones diminish with substitution of hedenbergite or diopside components; pale tan to yellow-green to pale green streak; vitreous luster. Cleavage {110}, good

to perfect; parting {100}; conchoidal fracture. $H = 6$. $G = 3.50\text{--}3.60$. Biaxial (-); $2V = 60\text{--}70^\circ$; $N_x = 1.750\text{--}1.776$, $N_y = 1.780\text{--}1.820$, $N_z = 1.795\text{--}1.836$ decreasing with Ca pyroxene substitution; $Y = b$, $X \wedge c = 0\text{--}10^\circ$; $r > v$, moderate to strong; negative elongation. Moderately pleochroic; X, emerald-green, deep green; Y, yellow to yellow-green; Z, yellow, yellow-brown, brownish green, green; the pleochroism intensifies with Ca pyroxene substitution. Distinguished from most other pyroxenes by its negative elongation and small extinction angle.

Chemistry: Complete solid solution exists with hedenbergite and diopside; aluminum content is usually low and substitution of Al for Si is very limited. Ti content is generally low, but it may occupy as much as one-fourth of the M1 site; zirconium is often present and may reach 0.65 wt % ZrO_2 . The boundary between aegirine and aegirine-augite is placed at about Ae_{80} , but alternatively, at the change in optic sign, at about Ae_{50} .

Occurrence: Aegirine, as well as aegirine-augite, are pyroxenes characteristic of alkaline igneous rocks, particularly syenites and syenite pegmatites. It is also found in alkali granites and related rocks; in metamorphosed iron-rich sediments, schists, and metasomatic environments.

Localities: Occurs worldwide in alkaline rock complexes; noteworthy and well-documented localities are: zirconian and cerian at Quincy, MA; (1) at Magnet Cove, Garland Co., AR; in the iron formation of the Cuyuna Range, MN; authigenic aegirine in the Green River formation in CO, UT, and WY. In all the rocks of Mt. St.-Hilaire, PQ, Canada, and as exceptional (1) crystals in the pegmatitic phases. In the syenite pegmatites and alkaline rocks of Greenland, particularly the Narssarsuk pegmatite (1) of the Julianehaab district. Found at *Rundemyr, Eger, near Kongsberg, Norway*. A common constituent of the alkaline complexes of the Kola Penin., Russia; at Gout Creek, Westland, New Zealand; titanian aegirine is found in NSW, Australia. Exceptional (1), lustrous, prismatic crystals often twinned and in subparallel growth from Mt. Maloosa, Zamba district, Malawi. Found in cancrinite-albite syenite at Itapurapua, SP, Brazil. AR *DHZII 2A:482(1978)*, MR *25:29(1994)*.

65.1.3c.3 Namansillite $NaMn^{3+}[Si_2O_6]$

Named in 1992 by Kalinin et al. for the composition: sodium manganese silicate. Pyroxene group. MON *C2/c*. (Syn): $a = 9.513$, $b = 8.615$, $c = 5.356$, $\beta = 105.12^\circ$, $Z = 4$, $D = 3.61$. *PD*: 6.30_6 4.31_4 2.92_{10} 2.89_9 2.59_3 2.50_3 2.07_2 1.694_2 . Structure: *AC(C) 43:605(1987)*. Red, vitreous luster, translucent. Cleavage {110}, perfect. $H = 6\text{--}7$. For Italian material, biaxial (-); $2V = 85^\circ$; $N_x = 1.750$, $N_y = 1.795$, $N_z = 1.835$; $Y = b$, $Z \wedge c = 19^\circ$; strong dispersion. Pleochroic; X, pale yellow-orange; Y,Z, red-violet. With braunite, pectolite, and K-spar as euhedral, prismatic crystals at the Cerciara mine, Val di Vera, northern Apennines, Italy, and at *Irimni braunite deposit, Taikan Mts., Khabarovsk, Russia*. Publication of the Italian occurrence, without assignment of a name, appeared prior to publication of the Russian occurrence. AR *NJMM:59(1989)*, *ZVMO 121(1):89(1992)*.

65.1.3c.4 Kosmochlor $\text{NaCr}^{3+}[\text{Si}_2\text{O}_6]$

Named in 1897 by Laspeyres from the Greek for *cosmos* and *green*, in allusion to its color and its being found in a meteorite. Pyroxene group. Synonyms: cosmochlore; ureyite, for Harold Clayton Urey (1893–1981), American chemist and Nobel laureate. MON *C2/c*. $a = 9.550$, $b = 8.712$, $c = 5.273$, $\beta = 107.44^\circ$, $Z = 4$, $D = 3.603$. *26-1484*(syn): 6.3₃ 4.35₈ 2.96₁₀ 2.87₇ 2.52₃ 2.51₄ 2.45₄ 2.10₂. Structure: *MSASP 2:31(1969)*. Dark emerald green, vitreous luster, translucent. Cleavage {110}, good; parting {001}. $H \approx 6$. Biaxial (-); $2V = 53^\circ$; $N_x = 1.740$ – 1.766 , $N_y = 1.756$ – 1.778 , $N_z = 1.762$ – 1.781 ; $Y = b$, $X \wedge c = 8$ – 22° . Pleochroic; $Z > Y > X$; yellow-green to emerald-green. In meteorite occurrences Cr^{3+} occupies 66–98% of the M1 octahedral site. Experimental work indicates that complete solid solution is possible with jadeite and with diopside. In small amounts in solid solution with jadeite and diopside, it accounts for the emerald-green color of jadeite. Found at Williams Creek, Mendocino Co., CA. Occurs rarely in the *Toluca meteorite*, *Xiquipilco*, *MEX*, *Mexico*, and in the Coahuila and Hex R. meteorites, Mexico. Reported, but not well documented, in jadeite–albite–natrolite rocks at Maw-sit-sit, upper Burma, but is unquestionably a component of emerald-green jadeites from the region. AR *DHZII 2A:520(1978)*, *AM 72:126(1987)*, *MM 52:535(1988)*.

65.1.3c.5 Natalyite $\text{Na}(\text{V}^{3+}, \text{Cr}^{3+})[\text{Si}_2\text{O}_6]$

Named in 1985 by Reznitskii et al. for Nataliya Vasil'evna Frovolva (1907–1960), Russian geologist. Pyroxene group. MON *C2/c*. $a = 9.58$, $b = 8.72$, $c = 5.27$, $\beta = 107.16^\circ$, $Z = 4$, $D = 3.55$. *31-653*: 6.24₆, 4.36₆ 2.96₁₀ 2.87₈ 2.52₁₀ 2.46₇ 2.19₆ 1.391₈. Bright yellowish green, vitreous to silky luster, translucent. Cleavage [110], good; fracture (parting ?) {001}. $H = 7$. Biaxial (-); $2V = 8$ – 12° ; $N_x = 1.741$, $N_y \approx N_z = 1.762$. Strongly pleochroic; X, greenish yellow; Y, Z, emerald-green. Karelian material is near the end-member vanadium phase. Found as 1 mm \times 0.3 mm grains associated with eskolaite–karelianite, uvarovite–goldmanite, Cr–V tourmaline, pyrite, and apatite, in Cr- and V-rich rocks of the Slyudyanka Precambrian metamorphic complex, *Lake Baikal region*, *Transbaikal*, *Russia*, and from the Onezhkii (Zaonezhki) Penin., Karelia. AR *ZVMO 114:630(1985)*, *123:55(1994)*; *AM 72:223(1987)*.

65.1.3c.6 Jervisite $\text{NaSc}[\text{Si}_2\text{O}_6]$

Named in 1982 by Mellini et al. for William P. Jervis (1831–1906), English–Italian scientist, curator of the Museo Industriale Italiano, Turin. Pyroxene group. MON *C2/c*. (Syn): $a = 9.853$, $b = 9.042$, $c = 5.312$, $\beta = 106.62^\circ$, $Z = 4$, $D = 3.29$. *35-542*: 6.51₂, 4.51₂, 3.39₂ 3.26₂ 3.04₁₀ 2.98₅ 2.54₅ 1.647₅. Structure: *AC(B) 29:2615(1973)*. Light green, vitreous luster, translucent. Cleavage {110}, perfect. Biaxial (-); $2V = \text{large}$ (56° calc). $N_x = 1.683$, $N_y = 1.715$, $N_z = 1.724$. Natural material contains 18.48% Sc_2O_3 . Found as elongated (0.2 mm) plates with cascandite, albite, orthoclase, and quartz in a vug in granite at *Cava Diverio*, *Baveno*, *Italy*. AR *AM 67:599(1982)*.

65.1.4.1 Spodumene $\text{LiAl}[\text{Si}_2\text{O}_6]$

Named in 1800 by d'Andrada from the Greek *spodumenos*, reduced to ashes, in allusion to its usual grayish-white (ash) color. Pyroxene group. Synonyms: α -spodumene and triphane, from the Greek for *three appearances*, in allusion to the cleavage and parting surfaces, the latter presently used for colorless or yellow, transparent material. Varieties: kunzite, named for American mineralogist and gemmologist George F. Kunz (1856–1932), and hiddenite, named for American mineralogist William E. Hidden (1853–1918), the latter defined as the chromian variety but often incorrectly used for pale green, chromium-free spodumene. Polymorphs: β -Spodumene and γ -spodumene exist at elevated temperatures and have structures related to keatite and high-quartz, respectively. MON $C2/c$ or $C2'$. $a = 9.45$, $b = 8.39$, $c = 5.215$, $\beta = 110.10^\circ$, $Z = 4$, $D = 3.184$. $33-876$: 6.12_4 , 4.36_4 , 4.21_8 , 3.44_4 , 3.19_4 , 2.92_{10} , 2.79_9 , 2.45_3 . Structure: *AM 60:919(1975)*. The chains are equivalent with rotation opposite to that of the other $C2/c$ pyroxenes, and a shared oxygen angle of $\approx 170.5^\circ$; in synthetic $\text{LiFe}^{3+}\text{Si}_2\text{O}_6$, the shared oxygen angle is $\approx 180^\circ$. The M1 site (Al) is octahedral; the M2 site is distorted octahedral.

Habit: Prismatic $\{001\}$, often flattened $\{100\}$; dominant forms $\{100\}$, $\{110\}$, $\{010\}$ terminated by $\{001\}$, $\{021\}$, $\{111\}$, and more complex forms. Twinning on $\{100\}$ common, often lamellar. Crystals sometimes attaining enormous size (in excess of 10 m). Often deeply etched and corroded, especially in transparent varieties, and displaying prominent etch patterns and growth hillocks. Less commonly in bladed, cleavable masses.

Physical properties: Gray, white, tan, colorless, yellow, pale green, bright green (hiddenite), pink to lilac to violet (kunzite), the latter rarely blue-gray or purple; vitreous luster. Cleavage $\{110\}$, perfect; parting $\{100\}$, common; conchoidal to splintery fracture. $H = 6\frac{1}{2}$ –7. $G = 3.03$ –3.23.

Optics: Biaxial (+); $2V = 58$ – 68° ; $N_x = 1.648$ – 1.663 , $N_y = 1.655$ – 1.669 , $N_z = 1.662$ – 1.679 ; $Y = b$, $Z \wedge c = 20$ – 26° ; $r < v$. Pleochroic in thick sections of colored varieties with $X \approx Y > Z$, purple, pink, lilac, green, to colorless.

Huntington, MA

Spodumene

Forms: $a\{100\}$, $b\{010\}$, $c\{001\}$, $m\{110\}$, $u\{120\}$, $n\{130\}$, $d\{021\}$, $p\{111\}$, $r\{\bar{2}21\}$, $t\{211\}$

Color may be fugitive in some light green and bluish gray to violet varieties; color may be intensified by irradiation but is usually fugitive.

Chemistry: The composition is usually close to the ideal, with only minor substitution in any of the cation sites. Minor iron may account for yellow, manganese for pink and violet, and chromium for deeper green varieties, but light green may be due to charge transfer between Fe^{2+} and Mn^{4+} . Some sodium may substitute for lithium despite its larger size; most other cations are present only in trace amounts.

Occurrence: Common in lithium pegmatite and associated granite and gneiss. Usually in the intermediate zone of such pegmatite as embedded prisms and laths, but also in later pneumatolitic stages, often as transparent and etched crystals. Commonly associated with lepidolite, muscovite, albite, etc. Alteration to kaolin, eucryptite, lithium mica, sericite, and others is common.

Localities: Widespread throughout the world; some notable localities are: at Branchville(!), Fairfield Co., CT, and in many pegmatites of New England; at Kings Mt., Gaston Co., and hiddenite(!) with beryl (emerald) at Stony Point, Alexander Co., NC; in crystals in excess of 10 m in length(!) at the Etta mine, Pennington Co., SD; in laths to 2 m long at the Harding mine, Dixon, Taos Co., NM; kunzite in San Diego Co., CA, particularly the Himalaya and Pala Chief mines(!). At the Tanco pegmatite, Bernic Lake, MB, Canada; in granite at Killiney Bay, near Dublin, Ireland; at Varutrask and Utö Is., Sweden. Light green hiddenite(?) at Kabbur, Hassan district, Mysore, India; kunzite(!) abundant in pegmatites of Kunar, Lagham, and Nuristan, Afghanistan; Burma; in Xinjiang and Szechuan Provs., China. Found at Katumba, Congo, and Bikita, Zimbabwe; occurs, including kunzite(!), in several pegmatites of the Malagasy Republic, particularly at Anjanaboina, Mt. Bity, and Tilapa. Fine kunzite(!) occurs in many pegmatites of MG, Brazil, particularly at Urupuca, at Lavra do Ze Mario, Corrego do Urucum, Galileia, and also as pale pink and pale green thick crystals at Resplendor. Uses: An important source of lithium. Transparent varieties, particularly pink and lavender (kunzite) and green (hiddenite), but yellow and colorless as well, are faceted as gemstones, sometimes of considerable size (>1000 ct). AR CR 278D:1541(1974); DHZII 2A:521(1978); MR 17:313(1986), 20:197(1989), 21:97(1990).

CARPHOLITE GROUP

The carpholite group minerals are isostructural and conform to the formula

where

R = Mn, Fe, Mg, Li, Ba

and crystallize in space group *Ccca*. The structure is characterized by pairs of single-chain four-coordinated silicon with periodicity 2 (approximately 5.1 Å)

lying parallel to [001] that are joined by six-coordinated aluminum into I-beams similar to those found in pyroxenes but linked through additional six-coordinated cations in a manner completely different from that of the pyroxenes, to form a structure with several large cavities which may be partially occupied by larger cations. *NJMM* 8:337(1992).

CARPHOLITE GROUP

Mineral	Formula	Space Group	a	b	c	D
Carpholite	$\text{MnAl}_2(\text{Si}_2\text{O}_6)(\text{OH})_4$	<i>Ccca</i>	13.718	20.216	5.132	3.071 65.15.1
Ferrocapholite	$(\text{Fe}, \text{Mg})\text{Al}_2(\text{Si}_2\text{O}_6)(\text{OH})_4$	<i>Ccca</i>	13.797	20.20	5.116	3.05 65.15.2
Magnesiocarpholite	$(\text{Mg}, \text{Fe})(\text{Al}, \text{Fe})_2(\text{Si}_2\text{O}_6)(\text{OH})_4$	<i>Ccca</i>	13.694	20.204	5.108	2.82 65.15.3
Balipholite	$\text{LiBaMg}_2\text{Al}_3(\text{Si}_2\text{O}_6)_2(\text{OH})_4\text{F}_4$	<i>Ccca</i>	13.587	20.164	5.144	3.403 65.15.4

Note: Although the unit cells of the carpholite minerals are dimensionally orthorhombic and the structures have been successfully refined in space group *Ccca*, optical properties and spectroscopic studies suggest that the symmetry may be only monoclinic.

CARPHOLITE: $\text{MnAl}_2(\text{Si}_2\text{O}_6)(\text{OH})_4$

Carpholite. Perspective view along c, the chain direction.

65.1.5.1 Carpholite $\text{MnAl}_2(\text{Si}_2\text{O}_6)(\text{OH})_4$

Named in 1817 by Werner from the Greek *karpheos*, straw, in allusion to its color. Carpholite group. ORTH *Ccca.* $a = 13.718$, $b = 20.216$, $c = 5.132$, $Z = 8$, $D = 3.071$. *PD*: 5.73₉ 5.13₂ 3.81₃ 3.40₄ 3.04₅ 2.62₁₀ 2.37₄ 2.05₈. Structure: *SR 45A:369(1979)*, *AM 74:1084(1989)*. Acicular to fibrous [001] radiating tufts. Straw-yellow, silky luster. Cleavage {010}, perfect; {110}, distinct. $H = 5-5\frac{1}{2}$. $G = 2.9-3.04$. Biaxial (-); $2V \approx 50^\circ$; $N_x = 1.575-1.613$, $N_y = 1.590-1.630$, $N_z = 1.594-1.635$; $XYZ = bac$; $r > v$, strong. Pleochroic, $X = Y > Z$, straw-yellow to colorless. Insoluble in acids. Mg, Fe^{2+} , K, and Li may substitute for manganese, and fluorine for hydroxyl, the substitutions accounting for the variable refractive indices. Occurs in metamorphosed shales of low grade. Found at Caldbeck Fells, Cumbria, and at several mines in Cornwall, England; at Meuville, Ardennes, Belgium; Wippura, Harz Mts., Germany; originally found with fluorite and quartz in the tin deposits of *Slavkov (Schlaggenwald)*, *Cechy (Bohemia)*, *Czech Republic*; at Radobilny, near Prilep, Macedonia, Yugoslavia; at Fukuzumi mine, Kyoto Pref., Honshu, Japan. *AR D6 549(1892)*, *DANES 195:152(1970)*, *MA 18:200(1967)*.

65.1.5.2 Ferrocapholite $(\text{Fe,Mg})\text{Al}_2(\text{Si}_2\text{O}_6)(\text{OH})_4$

Named in 1951 by de Roever for the composition and relationship to isostructural carpholite. Carpholite group. ORTH *Ccca.* $a = 13.797$, $b = 20.20$, $c = 5.116$, $Z = 8$, $D = 3.05$. *33-655*: 5.69₇ 5.04₁₀ 3.44₁ 3.36₃ 3.02₂ 2.60₂ 1.855₁ 1.680₁. Prismatic to acicular [001] crystals in aggregates to 1 cm long. Observed forms {010}, {100}, {110}. Gray-green to dark green, pale green streak, silky luster. Cleavage {010}, perfect; {110}, indistinct. $H = 5\frac{1}{2}$. $G = 3.04$. Biaxial (-); $2V = 56^\circ$; $N_x = 1.614-1.621$, $N_y = 1.630-1.636$, $N_z = 1.635-1.640$; $XYZ = bac$; $r > v$, strong. Pleochroic; X, Y, yellow-green; Z, blue-green. Found in blueschists with quartz, glaucophane, lawsonite, jadeite, and other minerals at Haute-Ubaye, French Alps, France; at Ruwi, Oman; west of Tomata, east central Celebes, Indonesia; at Diahote, New Caledonia. *AR AM 36:736(1951)*, *SMPM 57:157(1977)*, *NJMM 8:337(1992)*.

65.1.5.3 Magnesiocarpholite $(\text{Mg,Fe})(\text{Al,Fe})_2(\text{Si}_2\text{O}_6)(\text{OH})_4$

Named in 1979 by Goffe et al. for the composition and isostructural carpholite. Carpholite group. ORTH *Ccca.* $a = 13.694$, $b = 20.204$, $c = 5.108$, $Z = 8$, $D = 2.82$. *35-489(syn)*: 5.66₁₀ 5.02₂ 3.79₃ 2.73₃ 2.59₆ 2.35₂ 2.04₂ 1.848₂. Gray to green, silky luster. Cleavage {010}, perfect; {110}, indistinct. $G = 3.04$. Biaxial (+)(?); $N_x = 1.59$, $N_y = 1.60$. A poorly defined species. From *Vanois, French Alps, France*. *AR AM 65:406(1980)*, *CMP 76:260(1981)*.

65.1.5.4 Balipholite $\text{LiBaMg}_2\text{Al}_3(\text{Si}_2\text{O}_6)_2(\text{OH})_4\text{F}_4$

Named in 1974 anonymously for barium, lithium carpholite. Carpholite group. ORTH *Ccca.* $a = 13.587$, $b = 20.164$, $c = 5.144$, $Z = 4$, $D = 3.403$. *33-787*: 10.1₁₀ 6.79₁ 4.06₁₀ 3.37₉ 2.60₂ 2.52₁ 2.39₃ 2.21₁. Structure: *SS(B) 30:779(1987)*. Barium is in partial occupancy of the large cavities of the car-

pholite structure type. Yellowish white, silky luster. Cleavage {010}, perfect; {100}, {110}, distinct. $G = 3.4$. Biaxial (-); $2V = 70^\circ$; $N_x = 1.581$, $N_y = 1.596$, $N_z = 1.601$; $XYZ = bca$. Found as fibrous [001] tufts with Li-mica in miarolitic cavities in quartz at *Hsianghua area, Linwu, Hunan, China*. AR *AM* 76:338(1976).

65.1.6.1 Lorenzenite $\text{Na}_2\text{Ti}_2\text{O}_3(\text{Si}_2\text{O}_6)$

Named in 1897 by Flink for Johannes Theodor Lorenzen (1855–1884), Danish mineralogist and student of Greenland mineralogy. Synonymous with and has precedence over ramsayite. Lorenzenite group. ORTH *Pbcn*. $a = 8.713$, $b = 5.233$, $c = 14.487$, $Z = 4$, $D = 3.44$. 33-1298(syn): 5.57₃ 3.35₉ 3.25₁ 3.03₂ 2.75₁₀ 2.58₁ 2.50₁ 2.46₂; also 18-1262. Structure: *AM* 72:173(1987). The silicate structural element is a pyroxene-like chain ($W = 1$, $P = 2$) parallel to [010]. The commonly given morphological orientation differs from that of the structure cell with $a, b, c(\text{struc}) = b, c, a(\text{morph})$. As prismatic [001], flattened {100} crystals with {100}, {210}, {111} (morphological setting) prominent; also acicular and as radiating and fibrous groups. White, colorless, light blue, green, pink, pale violet, yellow-brown to dark brown; white to pale brown streak; vitreous luster, submetallic in dark brown varieties; transparent to nearly opaque. Cleavage {100}, perfect; {110}, good. $H = 6$. $G = 3.45$. Biaxial (-); $2V = 25\text{--}42^\circ$; $N_x = 1.92\text{--}1.95$, $N_y = 2.01\text{--}2.04$, $N_z = 2.02\text{--}2.06$; $XYZ = abc$; $r > v$, pleochroic, $X > Y \approx Z$; orange-yellow to pale yellow. Pale cream fluorescence in SWUV. Morphologically similar to amphiboles and vinogradovite; fibrous varieties resemble ashcroftine. Found in alkalic syenites and pegmatites. Noted from Point of Rocks near Springer, Colfax Co., NM; common at Mt. St.-Hilaire, PQ, Canada, as pink, violet, and colorless acicular crystals; and Tenerife, Canary Islands. *Narssarsuaq, Julianehaab, Greenland*; Lake Gjerdingen, Nordmark, and in the Bratthagen nepheline syenite pegmatites, Lågendalen, Oslo region, Norway; as brown, submetallic crystals(!) from Khibiny massif, Kola Penin., and the Inagli, Konder, and Murun massifs, Aldan, Yakutia, Russia. AR *DT*:692(1932), *AM* 32:59(1947), *MR* 21:319(1990).

65.1.6.2 Kukisvumite $\text{Na}_6\text{ZnTi}_4\text{Si}_8\text{O}_{24} \cdot 4\text{H}_2\text{O} (?)$

Named in 1991 by Yakovenchuk et al. for the locality. Lorenzenite group. ORTH *Pccn*. $a = 28.889$, $b = 8.604$, $c = 5.215$, $Z = 2$, $D = 2.95$. *PD*: 14.5₉ 6.42₆ 4.82₈ 4.30₅ 3.72₆ 3.61₃ 3.01₁₀ 1.604₃. Structurally and chemically related to lorenzenite, $a_k \approx 2c_l$, $b_k \approx a_l$, $c_k \approx b_l$. Colorless to silvery, transparent. Splintery fracture, breaking into fibers parallel to elongation. $H = 5\frac{1}{2}\text{--}6$. $G = 2.90$. Biaxial (-); $2V_{\text{calc}} = 77^\circ$; for Na(D): $N_x = 1.676$, $N_y = 1.746$, $N_z = 1.795$. As fan-shaped intergrowths of prismatic [001], flattened {100}, crystals up to 7 mm in an arfvedsonite-microcline pegmatite as partial to complete pseudomorphs after lamprophyllite at the *Kukisvumchorr apatite deposit, Khibiny massif, Kola Penin., Russia*. AR *MZ* 13-2:63(1991), *AM* 77:1116(1992).

65.1.6.3 Lintisite $\text{Na}_3\text{LiTi}_2\text{O}_2[\text{Si}_2\text{O}_6]_2 \cdot 2\text{H}_2\text{O}$

Named in 1990 by Khomyakov et al. from symbols of the component cations. Lorenzenite group. *MON* $C2/c$. $a = 28.583$, $b = 8.600$, $c = 5.219$, $\beta = 91.03^\circ$, $Z = 4$, $D = 2.824$. *PD*: 14.3₁₀ 6.39₅ 4.77₅ 3.69₅ 3.00₁₀ 2.74₅ 2.71₅ 1.650₅. Alternately-facing, pyroxene-like chains lie parallel to [001] in the manner of pyroxene (similar b and c axes), but with different cation coordination. The Li analog of kukisvumite, with 2Li^+ replacing Zn^{2+} , □. Occurs as fibrous to columnar aggregates up to 1.5 mm long, of acicular, [001], crystals twinned on {100}. Pale yellow; vitreous luster, pearly on cleavage; transparent to translucent. Cleavage {100}, {010}, perfect; splintery fracture. $H = 5.5$. $G = 2.77$. Biaxial (-); $2V = 85^\circ$; $N_x = 1.672$, $N_y = 1.739$, $N_z = 1.802$; $Z \wedge c = 2^\circ$, $Y = b$; $r < v$, strong; positive elongation. Weak yellow fluorescence in UV. Dehydrates in steps to yield lorenzenite pattern at 600° . Soluble with silica residue in dilute HCl. Found in nepheline-syenite pegmatites at Mt. St.-Hilaire, PQ, Canada, and *Alluaiv Mt., Lovozero massif, Kola Penin., Russia*. *AR ZVMO 119:76(1990)*, *ZK 193:137(1990)*, *AM 76:1730(1991)*.

65.1.7.1 Shattuckite $\text{Cu}_5(\text{SiO}_3)_4(\text{OH})_2$

Named in 1915 by Schaller for the type locality mine. *ORTH* $Pcab$. $a = 9.885$, $b = 19.832$, $c = 5.383$, $Z = 4$, $D = 4.128$. *20-356*: 4.97₆ 4.43₁₀ 3.64₄ 3.50₇ 3.31₅ 2.78₅ 2.74₄ 2.37₇. Structure: *AM 62:491(1977)*. The structure consists of pyroxene-type chains joined to the surface of brucite-like $(\text{CuO}_2)_n$ sheets; adjacent complex sheets are cross-linked by copper in square, four-coordination. Acicular [001], 1- to 2-mm crystals with {100}, {010}, {110} dominant; radiating, spherulitic aggregates, granular, massive. Medium to dark blue, vitreous to silky luster, translucent. Cleavage {010}, {100}, perfect. $H = 3\frac{1}{2}$. $G = 3.9-4.1$. Biaxial (+); $2V = 88^\circ$; $N_x = 1.753$, $N_y = 1.782$, $N_z = 1.815$; $XYZ = cba$ (also reported $Z \approx c$, $X = b$). Pleochroic, $Z > Y = X$; dark to light blue. Found as an alteration product of other secondary copper minerals at the Eagle Eye mine and the *Shattuck mine, Bisbee, Cochise Co., AZ*, and in the Clifton-Morenci district, Greenlee Co., the Moon-Archer mine and Potter-Cromer property, south of Wickenburg, Maricopa Co., with ajoite at the New Cornelia mine, Ajo, Pima Co., the San Manuel and Roadside mines, Pinal Co., and the New Water Mts., Yuma Co., AZ. At Tsumeb, Namibia, and reported from M'sesa and Tantara, Shaba, Zaire. *AR AM 49:1234(1964)*.

65.1.8.1 Nchwangingite $\text{Mn}_2^{2+}\text{SiO}_3(\text{OH})_2 \cdot \text{H}_2\text{O}$

Described in 1995 by Nyfeler et al., and named for the type locality, the N'chwanging mine, Kalahari manganese field, South Africa. *ORTH* $Pca2_1$ $a = 12.672\text{\AA}$, $b = 7.217\text{\AA}$, $c = 5.341\text{\AA}$, $Z = 4$, $D = 3.202$; *PD* (*AM 80:377(1995)*) (nat.): 7.22₆ 4.08₆ 3.01₁₀ 2.55₈ 2.50₆ 2.46₈ 2.44₈ 1.55₈. Structure: $R = 2.1\%$. The structure consists of double layers of laterally linked so-called truncated pyroxene-building units formed by a double chain of octahedra, topped with a Zweier single chain of Si tetrahedra. Symmetry-equivalent

units are linked laterally but turned upside down. This yields a double-layer structure with H bridges linking the layers. A striking feature of the structure is that one MnO_6 corner is formed by a water molecule. Light brown, transparent, radiating balls, to 5 mm, of needles which average $1.0 \times 0.1 \times 0.05$ mm in size; platy || (010), streak white, vitreous luster, two perfect cleavages parallel to the long axis (c axis) of the crystals, i.e. parallel to (100) and (010); no fluorescence, $G = ?$, $H = ?$. SiO_2 28.0 wt. %, Al_2O_3 0.27, FeO 0.27, MnO 60.02, MgO 1.93, CaO 0.19, H_2O not determined. Biaxial (-), $2V = 54^\circ$; $N_x = 1.681$, $N_y = 1.688$, $N_z = 1.690$, colorless, $Y = a$, $X = b$, $Z = c$. Occurs in one vug in the *N'chwaning mine, Kalahari manganese field, northern Cape Province, South Africa*; also in another vug in the Wessels mine. Associated with calcite, bultfonteinite and chlorite.

WOLLASTONITE GROUP

The wollastonite group minerals conform to the general formula

where in the simplest cases, R is a divalent cation and no OH is present, but R may also represent monovalent or trivalent cations plus vacancies. The structure is characterized by chains with $P = 3$ (≈ 7.3 Å) lying parallel to b . The conformation of the chains may be envisioned as consisting of alternating double and single tetrahedra. The species in the group are not strictly isostructural: polytypes exist, cation-site occupancies vary, and chains may shift relative to one another. *AC 12:177(1959)*, *AC(A) 37:273(1984)*.

*A monoclinic polytype has also been reported; however, it may be the result of microscale twinning. Denisovite may also be related to a possible polytype of pectolite.

WOLLASTONITE: CaSiO_3

Idealized silicate chain periodicity in pyroxenes (top), and in the wollastonite group (bottom).

65.2.1.1a Wollastonite-1A CaSiO_3

Named in 1818 by Lëman for William Hyde Wollaston (1766–1828), noted English mineralogist and chemist. Wollastonite group. Together with wollastonite-2M, it is considered the equivalent to $\alpha\text{-CaSiO}_3$, and corresponds to the originally described wollastonite. The “1A” notation refers to the polytype (single layer, triclinic) that was formerly rendered “1T.” Other polytypes are 2M, 3A, 4A, 5A, and 7A. $\beta\text{-CaSiO}_3$, pseudowollastonite, is a structurally distinct, high-temperature polymorph. TRIC $P\bar{1}$. $a = 7.926$, $b = 7.320$, $c = 7.0675$, $\alpha = 90.05^\circ$, $\beta = 95.22^\circ$, $\gamma = 103.43^\circ$, $Z = 6$, $D = 2.915$. 2θ - $372(\text{syn})$: 3.84_6 3.51_7 3.31_8 3.08_7 2.98_{10} 2.47_6 2.18_7 1.826_7 . The diffraction pattern does not allow easy distinction among polytypes, but see wollastonite-2M (65.2.1.1b). Structure: *JPCM 10:217(1984)*. The calcium ions are in two six-coordinated sites (M1 and M2) and one seven-coordinated site (M3).

Habit: Usually massive, often in coarse granular to bladed and foliated forms; fibrous. Rarely well crystallized, elongated [010] and flattened with {001} or {100} prominent, and lesser {102}, {540}, and {102}.

Physical properties: White, gray, to pale green; vitreous luster, somewhat pearly on cleavage, silky when fibrous; translucent to transparent. Cleavage {100}, perfect; {001}, {102}, good; uneven to splintery fracture. $H - 4\frac{1}{2}$ –5. $G = 2.86$ –3.09.

Optics: Biaxial (-); $2V = 36$ – 60° ; $N_x = 1.616$ – 1.631 , $N_y = 1.628$ – 1.644 , $N_z = 1.631$ – 1.646 , the indices for the pure compound being 1.618, 1.630, and

1.632, respectively, and increase with substitution of iron and manganese for calcium, and may decrease slightly due to minor hydration; $Z \wedge c \approx 36-39^\circ$, $Y \wedge b = 1-5^\circ$; $r > v$, distinct and inclined for optic plane; positive and negative elongation approximately parallel to [010]. In SWUV and LWUV may fluoresce blue-green and phosphoresce yellow. Gelatinized by HCl. Fusibility 4. Distinguished from wollastonite-2M, but with difficulty, by slight inclined extinction parallel to elongation, and from tremolite or pectolite, which are always length-slow.

Chemistry: Often very near the ideal composition. Mn^{2+} and Fe^{2+} are the most common substituents for Ca^{2+} , generally disordered among but preferentially entering the six-coordinated sites; Mn:Ca ratio of up to 1:3 has been proposed but is usually less, with increased substitution favoring the formation of bustamite. To a lesser degree, Mg^{2+} may also enter six-coordinated sites.

Occurrence: A common product of thermal metamorphism and metasomatized calcareous sediments, and representative of relatively high grade, its formation favored by increasing temperature and the escape of CO_2 from the system in accordance with the equation $CaCO_3 + SiO_2 = CaSiO_3 + CO_2$. Formed in igneous rocks primarily as a result of contamination from calcareous inclusions. In amygdules of thermally metamorphosed basalts, and in the amphibolite and granulite facies of regionally metamorphosed rocks. Rarely as a constituent of alkaline igneous rocks and carbonatites.

Localities: The commonly occurring environment of formation leads to a worldwide distribution; some notable localities are: in coarse, granular masses with andradite and diopside at Willsboro, Essex Co., and in crystals(!) at Diana, Lewis Co., NY; minor, fluorescent material at Franklin, Sussex Co., NJ; at Isle Royal, Keweenaw Co., MI; at the Christmas mine, Gila Co., and the Holbrook shaft, Bisbee, Cochise Co., AZ; at Crestmore, Riverside Co., and in Inyo and Kern Cos., CA. Found at Hermosillo, ZAC, Jalostoc, Ayala, MOR, Concepcion del Oro, ZAC, Pichucalco, CHIH, and elsewhere in Mexico. Found as massive and fibrous material at the Jeffrey mine, Asbestos, and at Grenville, Mt. St.-Hilaire, Wakefield, and the Oka carbonatite complex, PQ; in the Ice River complex, Ottertail Range, BC, Canada. In metabasalts on Mull, Scotland; at Corneal, County Antrim, Northern Ireland; at Smedsgarden Farm, Alno, Sweden, and at Pargas and Remonmaki, Finland. Good crystals(!) at Mte. Somma, Vesuvius, and Monti Peloritani, Sicily, Italy; also well-crystallized(!) at Santorini volcano, Greece; at *Dognecea*, SE of *Tinisoara*, *Banat*, *Romania*. Manganous material is found at Hijikuzu mine in Japan; found in Kenya and Tanzania, and the North and South mines, Broken Hill, NSW, Australia.

Uses: Wollastonite is used extensively in the ceramics industry because of its low fusibility, absence of volatiles, and fluxing action. Fibrous material has found increasing use as a replacement for asbestos in insulation applications.

AR *MJJ* 7:180(1973), *DHZII* 2A:547(1978).

65.2.1.1b Wollastonite-2M CaSiO₃

Named in 1935 by Peacock, the derivation being as for wollastonite-1A. Wollastonite group. Synonymous with parawollastonite, a discredited name, and included with wollastonite-1A as α -CaSiO₃. Other polytypes are 3A, 4A, 5A, and 7A. Polymorphic with pseudowollastonite. MON Space group unknown, possibly $P2_1(?)$. $a = 15.409$, $b = 7.322$, $c = 7.063$, $\beta = 95.30^\circ$, $Z = 12$, $D = 2.92$. $27-88(\text{calc})$: 3.84_2 3.52_2 3.32_3 3.09_2 2.98_{10} 2.48_2 2.18_2 1.839_2 . The diffraction pattern does not allow easy distinction among polytypes, but the weak line adjacent to the strong 3.84 \AA is alleged to be 4.07 \AA in 1A but 4.37 \AA in 2M. Structure: *ZK 174:309(1986)*. The structure is built of two units of the 1A polytype repeated along the a axis. Similar to wollastonite-1A in habit, the original description having been based on monoclinic symmetry; usually massive, granular, or fibrous. White, gray, to pale yellow; vitreous luster, somewhat pearly on cleavage, silky when fibrous; translucent to transparent. Cleavage $\{100\}$, perfect; $\{001\}$, $\{102\}$, good; uneven to splintery fracture. $H = 4\frac{1}{2}-5$. $G \approx 3.0$. Biaxial (-); $2V = 35-43^\circ$; $N_x = 1.614-1.621$, $N_y = 1.629-1.633$, $N_z = 1.631-1.635$; $Z \wedge c \approx 32^\circ$, $Y \wedge b = 0^\circ$; $r > v$, weak and distinctly inclined for optic plane; positive and negative elongation approximately parallel to $[010]$. Gelatinized by HCl, fusibility 4; distinguished from wollastonite-1A by extinction parallel to elongation, and from tremolite or pectolite, which are always length-slow. Found in the same environments as wollastonite-1A (i.e., primarily in thermally metamorphosed siliceous limestones). Found at Crestmore, Riverside Co., and several localities in the Sierra Nevada Range, CA; at Mte. Somma, Vesuvius, Italy; and at Cziklova, Banat, Romania. Its uses are essentially as those of the much more common 1A polytype, with which it is often admixed and from which it is, therefore, not separated. AR *DHZII 2A:547(1978)*.

65.2.1.1c Wollastonite-3A,4A,5A,7A CaSiO₃

Named in 1983 (3A, 4A, 5A) and 1978 (7A) by Henmi et al., the derivation being as for wollastonite-1A, the polytype notations referring to the number of 1A units repeated along the a axis. Wollastonite group. TRIC 3A: $P1$, $a = 23.2$, $b = 7.30$, $c = 7.06$, $\alpha = 90.0^\circ$, $\beta = 95.5^\circ$, $\gamma = 94.6^\circ$, $Z = 18$, $D = 2.93$; 4A: $P1$, $a = 31.2$, $b = 7.30$, $c = 7.06$, $\alpha = 90.0^\circ$, $\beta = 95.5^\circ$, $\gamma = 96.8^\circ$, $Z = 24$, $D = 2.91$; 5A: $P1$, $a = 38.6$, $b = 7.30$, $c = 7.06$, $\alpha = 90.0^\circ$, $\beta = 95.5^\circ$, $\gamma = 98.0^\circ$, $Z = 30$, $D = 2.95$; 7A: $P1$, $a = 54.3$, $b = 7.30$, $c = 7.08$, $\alpha = 90.0^\circ$, $\beta = 95.5^\circ$, $\gamma = 92.1^\circ$, $Z = 42$, $D = 2.90$. Structure: *MJJ 9:169(1978)*, *AM 68:156(1983)*. In physical appearance and optical properties, essentially indistinguishable from the more common 1A polytype. Polytypes 3A, 4A, and 5A are known only from *Kushiro, Hiroshima Pref., Japan*. Polytype 7A is known from a single sample from a skarn at *Fuka, Okayama Pref., Japan*. AR *AM 64:658(1979)*.

65.2.1.2 Bustamite $\text{Ca}(\text{Mn},\text{Fe}^{2+})(\text{SiO}_3)_2$

Named in 1826 by Brongniart for Anastasio Bustamante (1780–1853) of Mexico. Wollastonite group. TRIC $A\bar{1}$. $a = 7.736$, $b = 7.157$, $c = 13.824$, $\alpha = 90.52^\circ$, $\beta = 95.58^\circ$, $\gamma = 103.87^\circ$, $Z = 6$, $D = 3.326$. Alternative settings, only in part based on polytypes, may be found. *27-86*(syn): 3.45_5 3.24_5 3.04_5 2.99_{10} 2.73_5 2.59_5 2.42_5 1.791_8 ; *26-1066*(ferroan): 3.72_4 3.43_3 3.23_{10} 3.01_3 2.64_3 2.48_3 2.24_5 1.72_2 . Structure: *AM 48:588(1963)*. Four cation sites exist; Mn^{2+} and Fe^{2+} occupy the six-coordinated M3 site; additional Mn^{2+} next enters site M1, and then M2, both sites having 6+ coordination; site M4 is eight-coordinated and is occupied by calcium alone. Habit and physical properties relate to old morphological setting. Crystals usually tabular {001} or equant to prismatic, frequently with rounded edges and corners. Commonly massive, often compact and fibrous. Twinning on {110} rare. Light pink to brownish red, vitreous luster, translucent to transparent. Cleavage {100}, perfect; {110}, {110}, good; {010}, poor. $H = 5\frac{1}{2}$ – $6\frac{1}{2}$. $G = 3.32$ – 3.43 . Biaxial (–); $2V = 34$ – 60° ; $N_x = 1.640$ – 1.695 , $N_y = 1.651$ – 1.708 , $N_z = 1.653$ – 1.710 , the indices being lower in high Ca varieties; OAP and X approximately perpendicular to {100}; $r < v$, weak to strong with distinct crossed dispersion. Weakly pleochroic; X, Z, orange; Y, rose. The composition range approximately $\text{Ca}:(\text{Mn},\text{Fe}) = 5:1$ to $1:2$. Minor zinc may also enter the octahedral site. Typically results by metamorphism and/or metasomatism of Mn-bearing ore bodies; typical assemblages are bustamite–rhodonite–tephroite, bustamite–tephroite–calcite, and at higher grade, glaucochroite–tephroite–bustamite. Found at Franklin and Sterling Hill, Sussex Co., NJ (zincian); at *Tetelha de Xonotla, PUE, Mexico*, but this was later shown to be a mixture of johannsenite and rhodonite; at Långban, Sweden; coarsely fibrous material at Treburland mine, Altarnum, Cornwall, and at Meldon Railway quarry, Okehampton, Devon, England; as rosettes of slender needles at Culmage, Harz Mts., Germany. Found at the Nodatamagawa mine, Iwate Pref., and other sites in Japan; with the lead ores of Broken Hill, NSW, Australia; from the N'Chwaning mine, Kuroman, Cape Prov., South Africa. *AR AM 63:274(1978)*, *DHZII 2A:575(1978)*, *MM 49:37(1985)*.

65.2.1.3 Ferrobustamite $\text{Ca}(\text{Fe},\text{Ca},\text{Mn})(\text{SiO}_3)_2$

Named in 1937 by Tilley for the composition and relationship to bustamite. Wollastonite group. Original name was iron-wollastonite and later ferrowollastonite. TRIC $A1$. $a = 7.862$, $b = 7.253$, $c = 13.967$, $\alpha = 89.73^\circ$, $\beta = 95.47^\circ$, $\gamma = 103.48^\circ$, $Z = 6$, $D = 3.07$ (for the approximate composition $\text{W}_{0.82}\text{Fe}_{0.18}$). *29-336*: 7.67_2 3.84_5 3.47_6 3.27_{10} 3.05_3 2.95_2 2.70_3 2.28_6 . Structure: *AM 62:1216(1977)*. Site occupancy is as for bustamite but with $\text{Fe}^{2+} > \text{Mn}^{2+}$. Massive to coarsely fibrous. White, greenish, light brown; vitreous luster. Cleavage is as for bustamite (65.2.1.2). $H = 5$ – 6 . $G = 3.09$ – 3.39 . Biaxial (–); $2V \approx 60^\circ$; $N_x = 1.640$, $N_z = 1.653$ for composition $\text{Ca}:(\text{Fe},\text{Mn}) \approx 5:1$; the indices increase with increasing iron content and overlap those of bustamite. The iron end member is stable only above 800° and may not be found in

nature. Found in contact-metamorphic and metasomatic environments. Found around chert nodules in contact-metamorphosed dolomite at *Camas Malag, Skye, Scotland*; from Shimane, Yamaguchi, and Yoyama Prefs., Japan; and the Wessels mine, near Kuroman, Cape Prov., South Africa. *AR MM 24:569(1937)*.

65.2.1.4a Pectolite-1A $\text{NaCa}_2[\text{Si}_3\text{O}_8(\text{OH})]$

65.2.1.4b Pectolite-M2abc

Named in 1828 by Kobell from the Greek for *congealed*, in allusion to its translucent and compact appearance. Wollastonite group. The variety schizolite is manganese-rich and intermediate with serandite (65.2.1.5). Monoclinic (?) polytypes synonymous with parapectolite. The several M polytypes may arise from microscale twinning, but no data of merit provided. *TRIC P1*. $a = 7.980$, $b = 7.023$, $c = 7.018$, $\alpha = 90.54^\circ$, $\beta = 95.14^\circ$, $\gamma = 102.55^\circ$, $Z = 2$, $D = 2.906$. *33-1223*: 3.31_2 3.27_2 3.15_1 3.08_4 3.06_2 2.90_{10} 2.73_1 2.16_2 ; *33-1227*(manganoan): 3.25_3 3.23_3 3.05_4 3.01_2 2.87_{10} 2.67_1 2.55_1 2.25_2 . Structure: *ZK 146:281(1977)*. The structure is similar to that of wollastonite-1A but with a considerably shortened b axis due to hydrogen bonding within the chains parallel to b . Calcium is in distorted octahedral sites and sodium is in $3 + 5$ coordination in a distorted square antiprism configuration. Crystals elongated [010] and flattened {100} with {100} and {001} dominant; also described as prismatic [001] (Mt. St.-Hilaire); more commonly acicular in sprays or compact, radially fibrous masses. Twinning rare with [010] twin axis and composition near (100). White, pale tan, pinkish, pale blue; vitreous to silky luster. Cleavage {100}, {001}, perfect; uneven, brittle fracture. $H = 4\frac{1}{2}$ -5. $G = 2.84$ -2.90. Biaxial (+); $2V = 50$ -63°; $X \wedge c = 10$ -19°, $Y \wedge a = 10$ -16°; $N_x = 1.592$ -1.610, $N_y = 1.603$ -1.615, $N_z = 1.630$ -1.645; $Z \wedge b = 2^\circ$; $r < v$, weak to strong; indices increase beyond this range with increasing Mn content; OAP near (001). Complete isomorphous substitution on Mn for Ca forms the pectolite-serandite series; minor iron and magnesium may be present. Rare earth substitution is not uncommon in Mn-rich varieties. Partly decomposed and gelatinized by HCl. Fibrous varieties yield dangerously sharp, brittle splinters. Fusibility 2. Sometimes triboluminescent. A hydrothermal mineral typical of cavities and fracture surfaces of basic and syenitic igneous rocks; it is common in basalt cavities in association with zeolites, calcite, and quartz; also in serpentinites and mica peridotites. Found with zeolites in the Triassic Watchung basalts of northern NJ, particularly at Paterson and Bergen Hill, and also at Franklin and Sterling Hill; manganoan material in syenite at Magnet Cove, Garland Co., AR; in mica peridotite in Woodson Co., Kansas. In Canada at Thetford mines, at the Jeffrey quarry(!), Asbestos, and at Mt. St.-Hilaire(!), PQ, and in the Keweenawan traps at Lake Nipigon, ONT. Blue, compact, fibrous masses are found west of Baoruco, Dominican Republic. Occurs at Kangerdluarssuk, Julianehaab, Greenland; at Ratho quarry and near Castle Rock, near Edinburgh, Scotland; at *Mt. Baldo, Verona*, and *Mt. Monzoni, Trento, Italy*. In syenitic rocks at Yuskorlak, Kola

Penin., and veins cutting ultrabasics of the Voikaro–Syninsk massif, Polar Ural Mts., Russia; in serpentinite at Horokanai, Sorachi Pref., Japan. Compact blue material from the Dominican Republic is used as an ornamental and for cabochons and is marketed under the name *larimar*. AR D6 373(1892), ZK 144:401(1976), DHZII 2A:564(1978), AM 63:401(1978).

65.2.1.5 Serandite $\text{Na}(\text{Mn,Ca})_2[\text{Si}_3\text{O}_8(\text{OH})]$

Named in 1931 by Lacroix for J. M. Serand, West African mineral collector, who assisted in the collection of the type material. Wollastonite group. TRIC $P\bar{1}$. $a = 7.683$, $b = 6.889$, $c = 6.747$, $\alpha = 90.53^\circ$, $\beta = 94.12^\circ$, $\gamma = 102.75^\circ$, $Z = 2$, $D = 3.46$ (for a composition with $\text{Mn}:\text{Ca} \approx 11:1$). 25-723: 7.51₃ 6.72₃ 3.16₉ 2.98₁₀ 2.84₇ 2.60₄ 2.50₅ 2.19₆. Structure: AM 61:229(1976). Serandite is isostructural with pectolite, and there is a direct relationship between increasing Mn content and diminishing cell constants over the pectolite–serandite composition range. Crystals are commonly flattened {001} prisms [010] to equant, often in slightly radiating, subparallel groups. Twinning with [010] twin axis and (100) composition, both contact and penetration; also by reflection (110). Orange to pinkish orange to rose; vitreous luster, pearly on cleavage surface; transparent to translucent. Cleavage {100}, {001}, perfect. $H = 4\frac{1}{2}$ –5 $\frac{1}{2}$. $G = 3.0$ –3.4. Biaxial (+); $2V = 33^\circ$; $N_x = 1.680$, $N_y = 1.682$, $N_z = 1.705$ by extrapolation; natural material usually has decreasing indices and increasing $2V$ as calcium content increases. Complete isomorphous substitution to form the pectolite–serandite series. High-Mn members of the series commonly contain significant rare earths, with yttrium predominant for the highest-Mn members. Alters to dark brown to black birnessite; pseudomorphs of elpidite, nenadkevichite, birnessite, and rhodochrosite are known. Occurs in alkaline rocks and syenite pegmatites. Found at Point of Rocks, near Springer, Colfax Co., NM; as superb(!) salmon-pink to orange crystals to 20 cm long and in groups at Mt. St.-Hilaire, PQ, Canada. Found on Rouma, Los Is., Guinea; at the Ezuri mine, Akita Pref., and with banalsite at the Shiromaru mine, Tokyo Pref., Japan; in a phonolite dike at Mt. Goonerineggeringgi, Q, Australia. Mt. St.-Hilaire material has been fashioned into small, faceted gems for collectors. AR CR 192:187(1931), BNSM(C) 13:107(1987), MR 21:335(1990).

65.2.1.6 Cascandite $\text{Ca}(\text{Sc,Fe}^{3+})[\text{Si}_3\text{O}_8(\text{OH})]$

Named in 1982 by Mellini et al. for the composition: calcium and scandium. Wollastonite group. TRIC $P\bar{1}$. $a = 7.529$, $b = 7.051$, $c = 6.755$, $\alpha = 92.12^\circ$, $\beta = 93.67^\circ$, $\gamma = 104.65^\circ$, $Z = 2$, $D = 3.10$. 35-541: 7.22₂ 6.75₂ 4.46₂ 3.84₂ 3.62₅ 3.10₅ 2.97₅ 2.82₁₀. Structure: AM 67:604(1982). The referenced structure uses a C1 cell with $a = 9.791$, $b = 10.420$, $c = 7.076$, $\alpha = 98.91^\circ$, $\beta = 102.63^\circ$, $\gamma = 84.17^\circ$, $Z = 4$, but the cell analogous to pectolite–serandite is retained here. Calcium occupies the larger of the octahedral sites, and Sc and Fe the smaller; the site occupied by Na in pectolite–serandite is generally vacant. Crystals with maximum dimension of 0.2 mm, elongated [100] and flattened {100}; dominant forms are {001}, {100}, {120}, {530}. Pale pink,

vitreous luster. Cleavage {100}, {001}, good. Biaxial; minimum and maximum indices measured on an {001} plate are 1.663 and 1.684. Found in cavities in granite with quartz, orthoclase, albite, and jervisite at *Cava Diverio, near Baveno, Italy*. AR *AM* 67:599(1982).

65.2.1.7 Denisovite (K,Na)Ca₂[Si₃O₈(F,OH)]

Named in 1984 by Men'shikov for Aleksandr Petrovich Denisov (1918–1972), mineralogist at Geological Institute, Kola Branch, Academy of Sciences USSR, at Apatity. Wollastonite group. MON $a = 30.92$, $b = 7.20$, $c = 18.27$, $\beta = 95^\circ$, $Z = 20$, $D = 2.81$. 37-440: 3.32₁₀ 3.24₉ 3.08₈ 3.03₉ 2.79₈ 2.78₈ 2.75₁₀ 2.69₈. May be related to a possible polytype of pectolite. Parallel columnar aggregates, 10–15 cm across, consisting of acicular crystals. Greenish gray, colorless to faintly yellow; pearly luster. Cleavage or parting perpendicular to elongation. H = 4–5. G = 2.76. Biaxial (+); $2V = 20\text{--}30^\circ$; $N_x = 1.567$, $N_y = 1.568$, $N_z = 1.576$; parallel extinction; positive elongation. Found in rischorrite rocks of *Mt. Eveslogchorr and Mt. Yukspor, Khibiny massif, Kola Penin., Russia*; and in the Malyy Murun block of the Murun pluton. AR *ZVMO* 113:718(1984), *AM* 70:1329(1985), *DANS* 293:196(1987).

65.2.2.1 Foshagite Ca₄[Si₃O₉](OH)₂

Named in 1925 by Eakle for William Fredrick Foshag (1894–1956), mineralogist and former curator at U.S. National Museum, who studied the mineralogy at the type locality. TRIC P1. $a = 10.32$, $b = 7.36$, $c = 7.94$, $\alpha = 117.6^\circ$, $\beta = 104.5^\circ$, $\gamma = 90.0^\circ$, $Z = 2$, $D = 2.74$. 29-377(syn): 6.68₂ 4.96₃ 3.36₃ 2.95₁₀ 2.31₃ 2.16₃ 1.829₃ 1.746₃. Structure: *AC* 13:785(1960). The structure is related to that of wollastonite with chains parallel to b , but staggered differently. White, silky luster. H = 3(?). G = 2.36. Biaxial (+); $N_x = 1.594$, $N_y = 1.595$, $N_z = 1.598$; positive elongation. Infusible. Gelatinizes with acids. Occurs as fibers and fiber masses in contact and/or thermally metamorphosed limestones. Found at the Bingham open pit, Salt Lake Co., UT; as veins with fibers to several inches long with idocrase, thaumasite, and blue calcite at *Crestmore, Riverside Co., CA*; from Mull and Morven, Scotland; Hatrumim, Israel; Kushiro, Japan. AR *AM* 43:1(1958), *GSIB* 40:45(1977).

65.2.3.1 Hillebrandite Ca₂(SiO₃)(OH)₂

Named in 1908 for William Francis Hillebrand (1853–1925), American geochemist, U.S. Geological Survey. ORTH *Cmc*₂₁. $a = 3.6389\text{--}3.6427\text{\AA}$, $b = 16.311\text{--}16.319\text{\AA}$, $c = 11.829\text{--}11.840\text{\AA}$, $Z = 6$, $D = 2.69$. 42-538 (nat.) 4.81₃ 3.36₂ 3.03₃ 2.93₁₀ 2.84₂ 2.79₃ 2.25₂ 1.82₄. Structure: (*DAN SSSR* 123:741(1958)), (*MA* 14:179(1959)) and *AM* 80:841(1995). The structure consists of a three-dimensional network of Ca–O polyhedra that accommodates wollastonite-type Si–O tetrahedral chains. It is a natural analogue of calcium silicate hydrate phases in Portland cement. Colorless, white, faint green; streak white; radiating, fibrous crystals to 0.6 mm, elongate on b , {010} cleavage, crystal data and indices relate to a pseudo-cell, true cell is probably

monoclinic, $\beta = 90^\circ$ with doubled b , and $Z = 12$; $H = 5\frac{1}{2}$; $G = 2.66$ – 2.69 , sometimes fluorescent: weak white in SW UV and medium yellow-white in LW UV; IR data = (ZNK 5:2727(1960)); DTA (ZVMO 90:90(1961)); in HCl, separates some silica, but otherwise dissolves. Generally pure, but may contain trace to minor amounts of Fe, Al, and Mg. Biax. (-); $2V = 51^\circ$, $N_x = 1.598$ – 1.607 , $N_y = 1.603$ – 1.61 , $N_z = 1.603$ – 1.614 ; $Z = c$, (+) elongation; disper. $r < v$ strong. Shows ultra blue interference colors. Occurs in altered gabbroic rocks in Russia. In a contact zone between limestone and diorite in Mexico assoc. with wollastonite, garnet, gehlenite and spurrite. Occurs assoc. with foshagite at the Crestmore quarry, Crestmore, Riverside Co., CA; *Terner's mine, Velardena, Durango, Mexico*; Carlingford, Co. Louth, Ireland; Ozersk massif, west Baikal area, Russia; Mt. Chapchachi, West Azgir, Caspian Sea region, Kazakhstan; in the Hatrurim Formation, Israel; Güneyce-Ikizdere area, Trabzon Prov., Turkey; Nugrah, Saudi Arabia; Yamato and Mihara mines, Kushiro, Hiroshima Pref., and in the Mihari mine and at Fuka near Bicchu, Okayama Pref., Japan; N'Chwaning mine, Kalahari Mn Field, northern Cape Prov., RSA. EF *MM 30:150(1953)*.

65.2.4.1 Sorensenite $\text{Na}_4\text{SnBe}_2[\text{Si}_3\text{O}_9]_2 \cdot 2\text{H}_2\text{O}$

Named in 1965 by Semenov et al. for Henning Sørensen (b.1926), geologist, University of Copenhagen. MON *C2/c*. $a = 20.698$, $b = 7.442$, $c = 12.037$, $\beta = 117.28^\circ$, $Z = 4$, $D = 2.92$. 19-1171: 6.31₆ 3.41₈ 3.06₇ 2.96₈ 2.92₁₀ 2.84₅ 2.68₅ 2.12₄. Structure: *AC(B) 32:2553(1976)*. The silicate unit is a single chain $P = 3$, parallel to [010], similar to that of wollastonite. Colorless to pinkish altering to milky white; luster vitreous, silky. Cleavage in two directions at 63° ; brittle. $H = 5\frac{1}{2}$. $G = 2.9$. Biaxial (-); $2V$ small to 75° ; $N_x = 1.576$, $N_y = 1.581$, $N_z = 1.584$; anomalous yellow-brown and blue interference colors. Found as prismatic crystals up to $10\text{ cm} \times 1\text{ cm} \times 1\text{ cm}$ at *Nakalaq in the Ilimaussaq intrusion complex, Greenland*, with analcime, microcline, sodalite, neptunite, and aegirine in veins cross-cutting nepheline syenite; also at *Kvaneffjeld* with nepheline, analcime, and arfvedsonite. AR *AM 51:1547(1966)*.

65.3.1.1 Haradaite $\text{SrVO}(\text{SiO}_3)_2$

Named in 1974 by Watanabe et al. for Zunpei Harada (1898–1992), emeritus professor, Hakkaido University, Sapporo. See also suzukiite (65.3.1.2). ORTH *Ama2*. $a = 7.06$, $b = 14.64$, $c = 5.33$, $Z = 4$, $D = 3.80$. 18-1284(syn): 7.3₃ 3.65₄ 3.20₁₀ 2.88₉ 2.65₄ 2.55₃ 2.12₄ 2.05₄. Structure: *MJ 5:98(1967)*. The structure is characterized by an infinite kinked chain of periodicity 4 and a repeat length of 7.06 Å lying parallel to [100]. V^{4+} in square-pyramidal five-coordination bridges adjacent chains to form sheets of composition $[(\text{VO})(\text{SiO}_3)_2]^{2-}$. Anhydrous, tabular {010}, mostly 2–3 mm in diameter; massive. Emerald green, bluish green; very pale green streak; vitreous luster; translucent. Cleavage {010}, perfect; {100}, {001}, distinct; conchoidal fracture. $H = 4\frac{1}{2}$. $G = 3.80$. Biaxial (-); $2V = 75^\circ$; $N_x = 1.713$, $N_y = 1.721$, $N_z = 1.734$; $\text{XYZ} = abc$; $r < v$, strong. Strongly pleochroic; X, colorless to pale green; Y, colorless to yellow-

green; Z, bluish green. Type material contains 4.90% BaO; a complete solid solution with suzukiite is possible. Found in veinlets cutting rhodonite–manganite ores at *Yamato mine, Kagoshima Pref., Kyushu*, and at *Noda Tamagawa mine, Iwate Pref., Honshu, Japan*. AR *MJJ* 4:299(1965), *IJM*:78(1970), *AM* 56:1123(1971).

65.3.1.2 Suzukiite $\text{BaVO}(\text{SiO}_3)_2$

Named in 1982 by Matsubara et al. for Jan Suzuki (1896–1970), mineralogist and petrologist at Hokkaido University, Sapporo. See also haradaite (65.3.1.1). ORTH *Ama*2. $a = 7.089$, $b = 15.261$, $c = 5.364$, $Z = 4$, $D = 4.03$. *MJ* 11:15(1982). 35-681: 7.63₁₀ 3.82₆ 3.35₆ 3.28₃ 2.65₂ 2.39₄ 2.02₂ 1.526₂. The isostructural barium analog of haradaite with which a solid solution is possible. Small flakes {010} and aggregates. Bright green, pale green streak, vitreous luster, translucent. Cleavage {010}, perfect; {100}, {001}, distinct. $H = 4\frac{1}{2}$, $G = 4.0$. Biaxial (-); $2V \approx 90^\circ$; $N_x = 1.730$, $N_y = 1.739$, $N_z = 1.748$; strongly pleochroic, $Z > Y > X$; pale green to blue-green. Contains $\approx 3.2\%$ SrO. In massive rhodonite–rhodochrosite ore with barite, alabandite, and nagashimalite at the *Mogurazawa mine, Kiryu City, Gumma Pref., Honshu, Japan*. AR *AM* 68:282(1983).

65.3.2.1 Balangeroite $(\text{Mg,Fe}^{2+})_{21}\text{O}_3(\text{OH})_{20}[\text{Si}_4\text{O}_{12}]_2$

Named in 1983 by Compagnoni et al. for the type-locality serpentinite. See gageite (65.3.2.2a,b). MON *B2*, *Bm* or *B2/m*. (First setting): $a = 19.40$, $b = 19.40$, $c = 9.65$, $\gamma = 88.9^\circ$, $Z = 2$, $D = 3.089$. 35-567: 9.59₄ 6.77₈ 3.38₄ 3.28₄ 3.20₃ 2.71₁₀ 2.67₇ 2.52₄. Structure: *AM* 72:382(1987). An orthorhombic cell, *P****, with $a = 13.85$, $b = 13.58$, $c = 9.65$, has also been proposed and may represent a polytype. The first setting for monoclinic crystals is used to maintain correspondence with earlier orthorhombic cell of gageite. The silicate chain with $W = 1$ and $P = 4$ is kinked and lies parallel to [001], the fiber elongation. Isostructural with gageite-2M. Brown, vitreous to silky luster. $G = 2.98$. Biaxial; $N = 1.680$ perpendicular to [001]. Pleochroic; dark brown parallel to [001], yellow-brown perpendicular to [001]. Solid solution with gageite is likely. Found as fibrous to asbestiform masses associated with chrysotile, magnetite, iron–nickel, olivine, and antigorite in the *Balangero serpentinite, at the San Vittore mine, Lanzo Valley, Piemonte, Italy*. AR *AM* 68:214(1983), *EJM* 3:559(1991).

65.3.2.2a Gageite-2M $(\text{Mn,Mg})_{21}\text{O}_3(\text{OH})_{20}[\text{Si}_4\text{O}_{12}]_2$

65.3.2.2b Gageite-1A $(\text{Mn,Mg})_{21}\text{O}_3(\text{OH})_{20}[\text{Si}_4\text{O}_{12}]_2$

Named in 1911 by Phillips for Robert Burns Gage (1875–1946), Trenton, NJ, who analyzed the first sample. See balangeroite (65.3.2.1). MON *B2*, *Bm* or *B2/m*. (First setting): $a = 19.42$, $b = 19.42$, $c = 9.84$, $\gamma = 89.5^\circ$, $Z = 2$, $D = 3.599$. TRIC *P1*. $a = 14.17$, $b = 14.07$, $c = 9.84$, $\alpha = 76.5^\circ$, $\beta = 76.6^\circ$, $\gamma = 86.9^\circ$, $Z = 1$, $D = 3.61$. 20-723: 6.87₁₀ 3.44₂ 3.25₃ 2.56₈ 2.71₈ 2.61₅ 2.56₆

1.674₆ (for undifferentiated gageite). Structure: *AM* 72:382(1987). Unit cell originally described as *ORTH*, *Pnmm*, which may constitute yet another polytype. The monoclinic polytype is isostructural with balangeroite. Colorless to pink, vitreous to silky luster. $H = 3(?)$. $G = 3.58$. Biaxial (-); $N_x = 1.723$, $N_y = 1.734$, $N_z = 1.736$; $Z = c$; $r < v$, moderate; positive elongation. Infusible. Decomposed by HCl. Probable isomorphous series with balangeroite. Found as acicular crystals with a maximum 0.1 mm thickness and as fibrous aggregates in open cavities associated with late-stage, low-temperature hydrothermal activity at *Franklin, Sussex Co., NJ*. *AR AM* 53:309(1968), 54:1005(1969).

65.3.3.1 Taikanite $BaSr_2Mn_2^{3+}O_2[Si_4O_{12}]$

Named in 1985 by Kalinin et al. for the locality. *MON C2*. $a = 14.600$, $b = 7.759$, $c = 5.142$, $\beta = 93.25^\circ$, $Z = 2$, $D = 4.81$ (South Africa). 39-335: 3.44₄ 3.27₇ 3.16₅ 2.91₁₀ 2.83₉ 2.57₈ 1.946₆ 1.718₄. Structure: *AM* 78:1088(1993). The structure consists of silicate chains of periodicity 4 lying parallel to [010], linking chains of edge-sharing MnO_6 octahedra that parallel [001]; Ba^{2+} and Sr^{2+} occupy the resulting channels. The abstract for Russian type material gives *C2/m* and reverses the values of a and b . Equant, to slightly elongated grains up to 1.5 mm, and grain aggregates. Dark green, vitreous to greasy luster, translucent. Cleavage {001}, perfect; brittle, conchoidal fracture. $G = 4.72$ (Russia). For Russian material, biaxial (+); $2V = 74-80^\circ$; $N_x = 1.775$, $N_y = 1.792$, $N_z = 1.814$; $XY = ab$, $Z \wedge c = 44^\circ$; $r > v$, strong. Strongly pleochroic; X, violet to black; Y,Z, emerald-green. Occurs with braunite and manganese amphibole in the *Taikan Mts., Khabarovsk, Russia*. In a sugilite-cemented breccia of braunite and hausmannite at the Wessels mine, Kalahari manganese field, NE of Kuroman Hill, Cape Prov., South Africa. *AR ZVMO* 114:635(1985), *AM* 72:226(1987).

65.3.4.1 Batisite $(Ba)(K)(Na)_3Ti_2Si_4O_{14}$

Named in 1960 by Kravchenko et al. for the composition: containing Ba, Ti, and Si. See shcherbakovkite (65.3.4.2), the K analog. *ORTH Im2* (acentric) or *Imam* (centric). $a = 10.499$, $b = 13.913$, $c = 8.087$, $Z = 4$, $D = 3.49$. 14-636(nat): 3.4₅ 3.21₃ 2.92₁₀ 2.62₃ 2.16₅ 2.09₄ 1.68₅ 1.56₃. Structure solution obtained same residual (R) in acentric and centric space groups. *NJBM:107(1987)*. Crystals are elongated on c and flattened on b . Most abundant forms are: {001}, {010}, {100}, with lesser development of {150}, {021}, {031}, {011}, {310}. Dark brown, yellow-brown; rosy brown streak; vitreous luster. Cleavage {100}, fair; {010}, {001}, poor. $H = 6$. $G = 3.43$. IR data: *ZVMO* 93:641(1964). Insoluble in common acids. Contains minor Al_2O_3 , Nb_2O_5 , Ta_2O_5 , ZrO_2 , Fe_2O_3 , and CaO. Biaxial (+); $XYZ = abc$; $N_x = 1.728-1.730$, $N_y = 1.733-1.735$, $N_z = 1.790-1.791$; $2V = 7^\circ$; $r < v$, strong, to $r > v$, weak. X, colorless to yellow-brown; Y, yellow-brown; Z, red-brown. Occurs associated with nepheline (zeolitized), aegirine, arfvedsonite, uranothorite, lorenzenite, eudialyte, apatite, and orthoclase in nepheline-syenite pegmatite in the *Inagalinsk massif, central Aldan region*,

Russia; also occurs in fissures in two nepheline-leucite lavas at Üdersdorf and Alburg near Daun and at Liley in the west Eifel region, Germany. EF *MIN 3(1):569(1972)*, *LAP 14:14(1989)*.

65.3.4.2 Shcherbakovite $(K,Na,Ba)_3(Ti,Nb)_2(Si_2O_7)_2$

Named in 1954 by Eskova and Kazakova for Dmitrii Ivanovich Shcherbakov (1893–1966), Russian mineralogist and geochemist. *DANS 99:837(1954)*. See batisite (65.3.4.1), the Na-dominant analog. ORTH *Ima2*. $a = 10.55\text{--}10.57$, $b = 13.92\text{--}13.95$, $c = 8.10\text{--}8.12$, $Z = 4$, $D = 3.59$. *AM 70:455(1985)*, *ZVMO 93:641(1964)*. *31-1324(nat)*: 3.40_7 3.20_8 2.91_{10} 2.63_7 2.19_6 2.10_6 1.68_6 1.57_6 . Structure: *AM 70:455(1985)*. Crystals as large as $5.0\text{ cm} \times 1.5\text{ cm} \times 1.0\text{ cm}$, elongated and prismatic. Dark brown to reddish brown, rose or red-brown streak, vitreous luster. One or two good cleavages, brittle. $H = 6\frac{1}{2}$. $G = 3.34$. IR data: *IM:208(1975)*, *ZVMO 93:641(1964)*. Insoluble in HNO_3 and HCl, partly soluble in H_2SO_4 on heating. Khibiny material has minor Al, Zr, Fe, Mg, Ca. Biaxial (-); XYZ = bac; $N_x = 1.706\text{--}1.714$, $N_y = 1.745\text{--}1.746$, $N_z = 1.765\text{--}1.772$; $2V_x = 64\text{--}90^\circ$; $r < v$, distinct; positive elongation; distinctly pleochroic. $Z > Y \geq X$; X, colorless–pale yellow; Y, yellow; Z, brownish yellow or golden yellow. In pegmatite veins in alkalic rocks, also in lamproites, and kimberlites. Emmons Mesa, Zirkel Mesa, and Black Butte, Leucite Hills, WY; *Mt. Rasvumchorr, Khibiny massif, Kola Penin., Russia*; also in the dumps of the Koashva mine; Wolgidee Hills, West Kimberley region, WA, Australia. EF *MM 54:645(1990)*.

65.3.4.3 Ohmilite $Sr_3(Ti,Fe^{3+})(Si_2O_6)_2(O,OH) \cdot 2\text{--}3H_2O$

First described in 1973 by Komatsu et al.; named in 1983 by Mizota et al. for the locality. *MON P21/m*. $a = 10.979$, $b = 7.799$, $c = 7.818$, $\beta = 100.90^\circ$, $Z = 2$, $D = 3.39$. *26-1388(nat)*: 10.8_7 5.39_8 4.62_{10} 3.83_9 3.26_9 3.04_8 2.73_6 2.60_9 . Has batisite-type Si_4O_{12} chains, also found in haradaite and batisite. *AM 68:811(1983)*. Aggregates of fibers, elongate on b ; spherulites composed of radially arrayed fine needles or fibers. Fibers are $<10\ \mu\text{m}$ in length. Light pink, white streak. Cleavage $\{100\}$, perfect. $H = 3\frac{1}{2}$. $G = 3.38$. IR and thermal data: *AM 68:811(1983)*. Analysis (wt %): SiO_2 , 34.79; TiO_2 , 10.27; Fe_2O_3 , 0.20; SrO, 43.37; H_2O , 6.68. Biaxial (sign not determined); $YZ = ab$; $c \wedge Y$ not det., $N_x = 1.649$, $N_z = 1.715$; $2V$ and sign not determined because of small grain size and elongated nature parallel to $[010]$; weakly pleochroic, colorless to light pink. Occurs at *Ohmi, Niigata Pref., Japan*; in riebeckite–albite units in serpentinite. EF *MJJ 7:298(1973)*.

RHODONITE GROUP

The rhodonite group minerals, classically part of the pyroxenoids, consist of seven essentially isostructural species conforming to

RHODONITE: $MnSiO_3$

Idealized silicate chain periodicity in the rhodonite group.

where R_5 = five cation sites, three of which (M1,M2,M3) are octahedral, and two of which (M4,M5) are octahedral to eight-coordinated.

The structure is characterized by an approximately linear chain of five silica tetrahedra lying parallel to one another. All species are triclinic, and thus have no symmetry constraint to choice of unit cell. Consequently, there have been diverse cell assignments, the most common of which have been as follows:

Space Group	$a \approx$	$b \approx$	$c \approx$	$\alpha \approx$	$\beta \approx$	$\gamma \approx$	Chain Parallel to:
$C\bar{1}$	9.7	10.5	12.2	109	103	86	c
$P\bar{1}$	7.6	12.2	6.7	86	94	111	b
$P\bar{1}$	7.6	11.8	6.7	92	94	106	[110]

The first cell bears the closest relationship to the long-established morphological setting of rhodonite and babingtonite. The transformation matrix, morphology to c cell, is 010/100/002. In the species entries, the reported cell constants are those of the latest structure reference found. However, to facilitate comparison, the following table gives the constants for the last of the three settings. *DHZ II 2:586(1987)*.

RHODONITE GROUP

65.4.1.1 Rhodonite (Mn,Ca)₅(Si₅O₁₅)

Named in 1819 by Jasche from the Greek for *rose*, in allusion to its characteristic pink color. The variety fowlerite is named for Samuel Fowler. Rhodonite group. Dimorphous with hypothetical iron-free pyroxmangite (65.6.1.1). TRIC P1. $a = 7.545$, $b = 11.782$, $c = 6.663$, $\alpha = 92.69^\circ$, $\beta = 94.32^\circ$, $\gamma = 105.71^\circ$, $Z = 2$, $D = 3.55$. $13-138$: 3.34_3 3.14_3 3.10_3 2.98_7 2.92_7 2.77_{10} 2.22_2 2.18_3 . Structure: *AM 73:798(1988)*. For the given cell the [Si₅O₁₅] chains lie parallel to [110]; pairs of chains with apical oxygens pointing in opposite directions form strips parallel to (111), which in turn are joined to strips of cation polyhedra. Of the five cation sites, M1, M2, and M3 are near octahedral, M4 is highly distorted octahedral, and M5 is seven-coordinated. The last is preferentially occupied by Ca and limits the extent of its substitution. **Habit**: In the old morphological setting, crystals are commonly tabular {001} to equant with {001}, {110}, {110} dominant, but also highly modified. Crystal edges often rounded; faces often with rough or pitted surfaces. Twinning polysynthetic on (010). Granular, massive. **Physical properties**: Pink to rose-red to brownish red, often veined or coated black due to alteration; vitreous luster, somewhat pearly on cleavages. Cleavage (morph. setting) {110}, {110}, perfect at 92.5° ; {001}, good; conchoidal to uneven fracture. $H = 5\frac{1}{2}-6\frac{1}{2}$. $G = 3.55-3.76$. **Optics**: Biaxial (+); $2V = 61-87^\circ$; $N_x = 1.711-1.738$, $N_y = 1.716-1.741$, $N_z = 1.724-1.751$; $X \wedge a \approx 5^\circ$, $Y \wedge b \approx 20^\circ$, $Z \wedge c \approx 25^\circ$; $r < v$, crossed; inclined extinction in all sections. Weakly pleochroic; X, yellowish red; Y, pinkish red; Z, pale yellowish red. Refractive indices decrease with both Ca and Mg substitution; Fe substitution has little effect on indices. **Chemistry**: Some calcium is always found in substitution for manganese, but there is a discontinuity between bustamite and rhodonite, and magnesium

RHODONITE

Rhodonite, New Jersey. Forms (old morphological setting): a , {100}; c , {001}; m , {110}; M , {1 $\bar{1}$ 0}; k , {221}; n , {2 $\bar{2}$ 1}

may also substitute in small amounts as denoted by the formula $(\text{Mn,Mg})_{1-x}\text{Ca}_x(\text{SiO}_3)_2$, with $0 < x < 0.2$, with reported values having $x \approx 0.05\text{--}0.18$. Up to 43 mol % MgSiO_3 and 26 mol % FeSiO_3 have been reported, and the variety fowlerite has been reported with up to 10 mol % ZnSiO_3 . Minor Fe^{3+} has been reported, and Al levels are low. Blackens and fuses at 2.5. Alters through weathering directly, or via rhodochrosite, to pyrolusite and/or coronadite. **Occurrence:** Widespread in manganese orebodies, and is usually associated with metasomatic activity. Commonly results from contact metamorphism of rhodochrosite by metasomatic introduction of silica, or possibly by simple load-metamorphism of rhodochrosite + quartz in buried sediments. May result from the introduction of manganese into argillaceous sediments. Rarely in pegmatites, where it has probably formed by assimilation of Mn-rich country rock; in ore pockets associated with submarine extrusion of spilites and pillow lavas. As a primary gangue mineral in Pb-Zn deposits. Commonly associated with other manganese silicates, such as tephroite, johannsenite, bustamite, and pyroxmangite. **Localities:** A widespread mineral; notable localities are: in the zinc ores of Franklin, Sussex Co., NJ, in large, blocky to tabular crystals(!), often with rounded edges embedded in calcite, and as small transparent crystals in fractures with manganaxinite and willemite; also in ME, MA, MT, and CA. Magnesian rhodonite is found in regionally metamorphosed Wabush iron formation, western Labrador, NF, Canada. As brilliant crystals at the Harstig mine, Pajsberg, Sweden; brownish red material in quartzite at Simsiö, Lapua, Finland; massive at the B.R. quarry, Meldon, Okehampton, Devonshire, England; at Elbingerode, Harz, Germany; with tetrahedrite at Kapnik and Rezbanya, Hungary; extensive deposits of massive material in the Ykaterinburg district, Ural Mts., Russia. Found at several localities in Japan. Particularly noteworthy is the occurrence in the ores of Broken Hill, NSW, Australia, where gemmy crystals(!) of blocky to prismatic habit up to nearly 10 cm in length have been found. In the Kuroman manganese district of South Africa, and at Mufulira, Zambia. Gemmy crystals have been found at Morro da Mina, Conselheiro Lafaiete, MG, Brazil; in compact groups of crystals(!) to 6 cm long at Chiurocu mine, near Huanzala, Peru. **Uses:** A carving material for ornamental and decorative purposes; occasionally cut en cabochon or, less commonly, into faceted collector gems. AR *D6:378(1892)*, AC *12:182(1959)*, DHZII *2A:586(1978)*.

65.4.1.2 Babingtonite $\text{Ca}_2(\text{Fe}^{2+},\text{Mn})\text{Fe}^{3+}[\text{Si}_5\text{O}_{14}(\text{OH})]$

Named in 1824 by Levy for William Babington (1757–1833), Irish physician and mineralogist. Rhodonite group. Forms an isomorphous series with manganbabingtonite. **TRIC P1.** $a = 7.497$, $b = 12.225$, $c = 6.710$, $\alpha = 86.18^\circ$, $\beta = 93.90^\circ$, $\gamma = 112.27^\circ$, $Z = 2$, $D = 3.39$. *14-321*: 6.69₄ 4.07₄ 3.12₇ 2.95₆ 2.87₈ 2.75₁₀ 2.47₅ 2.17₆. **Structure:** *MJJ 15:8(1990)*. The structure is essentially analogous to that of rhodonite, but chain periodicity faults occur such that $P = 7$ and $P = 3$ sequences interrupt the normal $P = 5$ sequence.

Approximately 20% vacancies exist among the cation sites. Crystal habit (original morphological setting that is equivalent to original rhodonite) is as equant to short prismatic crystals with {001}, {110}, {110} dominant and modified by {100}, {010}, {221}, {221}, or tabular {001}. Dark greenish black; greenish to brownish gray streak; vitreous, splendent luster; nearly opaque. Cleavage {110}, perfect; {110}, {001}, less so; uneven fracture. $H = 5\frac{1}{2}$ –6. $G = 3.34$ –3.48. Biaxial (+); $2V = 76$ –88°; $N_x = 1.715$ –1.719, $N_y = 1.727$ –1.734, $N_z = 1.749$ –1.753; $r > v$, strong; OAP nearly normal to (001). Pleochroic; X, deep green; Y, lilac-brown; Z, pale to deep brown. Insoluble in acids. Fusibility 3. Manganese substitutes for Fe^{2+} . Occurs in cavities in granitic rocks and with zeolites in “trap rocks.” Found at Blueberry Mt., Middlesex Co., at Athol, Worcester Co., and in excellent crystals(!) at the Lane Trap Rock quarry, Westfield, Hampden Co., MA; at Wallingford, CT; at the Upper New Street quarry, Paterson, Passaic Co., NJ, and several other quarries in the region; the Goose Creek quarry, Leesburg, Loudon Co., VA. Found as distinct crystals at the *Brastad mine, near Arendal, Norway*; at Herborn, near Dillenburg, Germany; and in granite from Baveno, Novara, Italy; at the Khandivali quarry, near Bombay, Maharashtra, India. Designated the state mineral of Massachusetts. AR *D6:381(1992)*, CM *19:269(1981)*, AC(A) *37:617(1981)*.

65.4.1.3 Manganbabingtonite $Ca_2(Mn,Fe^{2+})Fe^3+[Si_5O_{14}(OH)]$

Named in 1967 by Vinogradova and Plyusinna for the composition and relationship to babingtonite. Rhodonite group. Forms isomorphous series with babingtonite. TRIC P1. $a = 7.492$, $b = 11.745$, $c = 6.701$, $\alpha = 92.54^\circ$, $\beta = 93.90^\circ$, $\gamma = 103.97^\circ$, $Z = 2$, $D = 3.33$. *42-1400*(Japan): 6.93₆ 6.67₇ 3.47₉ 3.34₄ 3.13₈ 3.02₈ 2.96₁₀ 2.45₄; *12-313*(Russia): 3.44₈ 3.10₁₀ 3.00₁₀ 2.94₁₀ 2.16₁₀ 1.654₇ 1.427₆. No structure determination, but presumably isostructural with babingtonite. Reddish brown to greenish black, vitreous luster, essentially opaque. Cleavage {001}, perfect; {110}, imperfect. $H = 6$. $G = 3.452$. Biaxial (+); $2V = 86^\circ$; $N_x = 1.716$, $N_y = 1.730$, $N_z = 1.746$; $r > v$, strong. Pleochroic; X, green; Y, pale rose; Z, rose-brown. Properties are for material with 7.9 wt % MnO and 4.5 wt % FeO. Fusibility 3. Found with epidote, calcite, and quartz at the *Rudnyi Kaskad deposit, eastern Sayan, Siberia, Russia*, and at Mitani, Kochi City, Shikoku, Japan. AR *AM 53:1064(1968)*, *BNSM(C) 15:81(1989)*.

65.4.1.4 Nambulite $(Li,Na)Mn_2^+[Si_5O_{14}(OH)]$

Named in 1972 by Yoshi et al. for Matsuo Nambu (b.1917), mineralogist, Tohoko University, Japan. Rhodonite group. Forms an isomorphous series with natronambulite. TRIC P1. $a = 7.621$, $b = 11.761$, $c = 6.731$, $\alpha = 92.77^\circ$, $\beta = 95.08^\circ$, $\gamma = 106.87^\circ$, $Z = 2$, $D = 3.55$. *29-833*(sodian): 3.34₄ 3.17₇ 3.14₅ 3.09₆ 3.07₆ 2.97₈ 2.96₁₀ 2.91₇; *27-1253*(syn, sodium-free): 3.17₆ 3.05₅ 2.95₇ 2.92₁₀ 2.70₉ 2.62₄ 2.22₅ 2.20₄. Structure: AC(B) *31:2422(1975)*. Distorted octahedral sites M1, M2, and M3 are occupied by Mn as is the seven-coordi-

nated site M4; Li and Na occupy eight-coordinated site M5. Red-brown with orange tint, pale yellow streak, vitreous to subadamantine luster, transparent to translucent. Biaxial (+); $2V = 30^\circ$; $N_x = 1.707$, $N_y = 1.710$, $N_z = 1.730$; $r > v$, weak. Found as coarse prismatic crystals, up to 8 mm, associated with albite, neotocite, and rhodochrosite in veinlets up to 5 cm thick at the *Funakozawa mine, Kitakami Mts., Iwate Pref., Japan*, and at the Gozaisho mine, Iwaki-shi, Fukushima Pref. Found as transparent, flawless crystals(1) at the Kombat mine, 37 km E of Otavi, Namibia, but these are, at least in part, natronambulite. Significant sodium is found in the natural materials. A few crystals have been faceted into collector gems. AR *MR 8:391(1977)*, *22:423(1991)*; AM *75:413(1990)*.

65.4.1.5 Natronambulite $(\text{Na,Li})\text{Mn}_4^{2+}[\text{Si}_5\text{O}_{14}(\text{OH})]$

Named in 1985 by Matsubara et al. for the composition and its relationship to nambulite, with which it forms an isomorphous series. Rhodonite group. TRIC *P1*. $a = 7.620$, $b = 11.762$, $c = 6.737$, $\alpha = 92.81^\circ$, $\beta = 95.55^\circ$, $\gamma = 106.87^\circ$, $Z = 2$, $D = 3.50$. *39-332*: 7.13₅ 6.70₄ 3.56₁₀ 3.35₄ 3.08₅ 2.97₃ 2.51₄ 2.20₂. Sodium occupies the larger M5 site. Pinkish orange, very pale orange streak, vitreous luster, translucent. Cleavage {100}, {001}, perfect. $H = 5\frac{1}{2}$ -6. $G = 3.51$. Biaxial (+); $2V = 45^\circ$; $N_x = 1.706$, $N_y = 1.710$, $N_z = 1.730$. Found as coarse-grained aggregates up to 7 mm in diameter in the dump of the *Matsumaezawa orebody, Tanohata mine, Iwate Pref., Japan*, associated with manganian aegirine, manganian arfvedsonite, rhodonite, and serandite; as transparent, flawless crystals(!) at the Kombat mine, 37 km E of Otavi, Namibia, but these are, at least in part, nambulite. AR *MJJ 12:332(1985)*; AM *72:224(1987)*, *75:413(1990)*.

65.4.1.6 Marsturite $\text{NaCaMn}_3[\text{Si}_5\text{O}_{14}(\text{OH})]$

Named in 1978 by Peacor, Dunn, and Sturman for Marion Stuart of Bellvue, ID, who has been a staunch supporter of the preservation of natural history specimens, particularly those of geological interest. Rhodonite group. TRIC *P1* or *P1*. $a = 7.70$, $b = 12.03$, $c = 6.78$, $\alpha = 85.26^\circ$, $\beta = 94.10^\circ$, $\gamma = 111.04^\circ$, $Z = 2$, $D = 3.465$. *31-585*: 3.18₄ 3.11₄ 3.00₈ 2.92₉ 2.73₁₀ 2.22₃ 1.695₃ 1.441₄. Chain-periodicity faults are probably present; probable site occupancies are: M1 and M3 = Mn; M2 = Mn,Ca; M4 = Ca; M5 = Na. Crystals are 0.5-mm laths elongated [010] and flattened on {001} with dominant {100} and {001} and crudely terminated by {010}; also as epitaxial growths on rhodonite with coincidence of all axes and the contact surface being (010) in the marsturite setting. Light pink to white, vitreous luster, transparent to translucent. Cleavage {100}, {001}, imperfect (equivalent to {110} and {110} of rhodonite). $H \approx 6$. $G = 3.46$. Biaxial (+); $2V = 60^\circ$; $N_x = 1.686$, $N_y = 1.691$, $N_z = 1.708$ for Na_D; $XZ \approx cb$; $r > v$, weak. Minor Fe^{2+} , Mg, and Zn are present. Known from only a few specimens from *Franklin, Sussex Co., NJ*, where it is found associated with rhodonite, willemite, and manganaxinite; at the Tsurumaki mine, 25 km NW of Ogaki, Gifu Pref., and the Shiromaru mine,

Hatonosu, Tokyo Pref., Japan. AR *AM* 63:1178(1978), 75:413(1990); *MR* 17:123(1986).

65.4.1.7 Lithiomarsturite $\text{LiCa}_2\text{Mn}_2[\text{Si}_5\text{O}_{14}(\text{OH})]$

Named in 1990 by Peacor et al. for the composition and relationship to marsturite. Rhodonite group. TRIC $P1$ or $P\bar{1}$. $a = 7.652$, $b = 12.119$, $c = 6.805$, $\alpha = 85.41^\circ$, $\beta = 94.42^\circ$, $\gamma = 111.51^\circ$, $Z = 2$, $D = 3.27$. *PD*: 6.79₂ 3.19₉ 3.08₅ 3.01₁₀ 2.91₉ 2.81₂ 2.77₆ 2.21₅. Structure determination incomplete, due to common chain periodicity faults. Site occupancies are: M1 and M3 = Mn; M2 = Mn,Ca; M4 = Ca; M5 = Li. Euhedral crystals, 1–3 mm in diameter, with {100}, {010}, {001}. Light pinkish brown to light yellow, vitreous luster. Cleavage {100}, {001}, good. $H = 6$. $G = 3.32$. Biaxial (-); $2V = 60^\circ$; $N_x = 1.645$, $N_y = 1.660$, $N_z = 1.666$; $X \approx b$, $Y \approx [100]$, $Z \approx c$; $r > v$, moderate. Fe^{2+} substitutes for Mn^{2+} , as does lesser Mg. Found in vugs in pegmatite at the *Foote mine, Kings Mt., NC*, with albite, fluorapatite, bavenite, brannockite, parsettenite, and tetrawickmanite. AR *AM* 75:409(1990).

65.4.2.1 Santaclaraita $\text{CaMn}_2^{2+}[\text{Si}_5\text{O}_{14}(\text{OH})](\text{OH}) \cdot \text{H}_2\text{O}$

Named in 1984 by Erd and Ohashi for the locality. TRIC $B1$. $a = 15.633$, $b = 7.603$, $c = 12.003$, $\alpha = 109.71^\circ$, $\beta = 88.61^\circ$, $\gamma = 99.95^\circ$, $Z = 4$, $D = 3.398$. *35-369*: 7.69₆ 7.04₁₀ 4.80₄ 3.85₆ 3.52₄ 3.15₈ 3.00₈ 2.20₄. Structure: *AM* 66:154(1981). Structurally related to rhodonite, but the $P = 5$ chains are shifted relative to one another; the five cation sites are six-coordinated except for M5, occupied by Ca, which is seven-coordinated as in rhodonite. One (OH) is bound to Si as in the (OH)-bearing members of the rhodonite group. Radiating lamellar aggregates of thin prismatic to tabular crystals and as individual prismatic crystals. Twinning on {100} common. Pale pink to reddish orange, vitreous luster, transparent to translucent. Cleavage {100}, {010}, good. $H = 6\frac{1}{2}$. $G = 3.31$. Biaxial (-); $2V = 83^\circ$; $N_x = 1.681$, $N_y = 1.696$, $N_z = 1.708$ for Na_D ; $r > v$, moderate; on {100} sections $Z \wedge c = 2^\circ$ and $X \wedge b = -21^\circ$; on {010} sections $Z \wedge c = 16^\circ$ and $Y \wedge a = -14.5^\circ$; pleochroic with $Y > Z > X$ in pale red tones. Chemically akin to a hydrated rhodonite, but on ignition yields bustamite. Found in masses and in vugs in pink to tan veins in Franciscan chert of the *Diablo Range, Santa Clara and Stanislaus Cos., CA*. AR *AM* 69:200(1984).

65.5.1.1 Stokesite $\text{CaSn}(\text{Si}_3\text{O}_9) \cdot 2\text{H}_2\text{O}$

Named in 1899 by Hutchinson for Sir George Gabriel Stokes (1819–1903), British mathematician and physicist, Cambridge University. ORTH *Pnna*. $a = 14.465$ – 14.485 , $b = 11.606$ – 11.630 , $c = 5.224$ – 5.250 , $Z = 4$, $D = 3.18$. *13-109*: 7.25₈ 5.82₆ 4.54₆ 3.99₁₀ 3.55₆ 3.43₈ 2.89₁₀ 1.556₇. Structure: *MM* 33:615(1963). The silicate structural element is a six-tetrahedron chain. Pyramidal to tabular, {100}, with {100}, {211}, {423} dominant, in the structure setting. The transformation matrix, original morphology to X-ray, is 010/001/100 aggregates to >3 cm across. Colorless, white, pale cream to pale blue;

vitreous luster; transparent to translucent. Cleavage {101}, perfect; {100}, imperfect. $H = 6$. $G = 3.19-3.23$. Biaxial (+); $2V = 67-70^\circ$; $N_x = 1.609-1.617$, $N_y = 1.612-1.620$, $N_z = 1.619-1.627$; $XYZ = cab$; $r < v$. Minor Mn and Fe may substitute for Sn. Found in complex granitic pegmatites and desilicated pegmatites, often in association with cassiterite in the Himalaya mine, and possibly derived from it. Occurs with cassiterite at Mesa Grande, San Diego Co., CA; at the Halvasso quarry, and at *Roscommon Cliff, St. Just, Cornwall, England* with axinite; at Ctidruzice and Vezna, Moravia, Czech Republic; Pitkaranta, Karelia, Russia; at Kerokubo, Ena, and the Iwaguro Sekizai quarry, Tuhara, Gifu Pref., Japan; in tin-rich garnet skarn at the El Hamman fluorite deposit, central Morocco; and in fine spheroidal aggregates at Corrego do Urucum, Galileia, MG, Brazil. AR, EEF *MM 32:433(1960)*, *MM 41:411(1977)*, *MR 8:294(1977)*.

65.5.2.1 Chkalovite $\text{Na}_2\text{Be}(\text{Si}_2\text{O}_6)$

Named in 1939 by Gerasimovskii for Valery Pavlovich Chkalov (1904–1938), Russian aviator who made first nonstop, polar-route flight from Moscow to the United States. ORTH *F2dd*. $a = 21.188$, $b = 21.129$, $c = 6.881$, $Z = 24$, $D = 2.68$. *42-572: 5.29₁ 4.04₁₀ 3.34₃ 3.27₃ 2.78₃ 2.49₆ 2.46₃ 1.801₂*. Structure: *DANS 248:727(1979)*. The silicate structural element is a six-tetrahedron chain linked Be-O tetrahedra to form a cristobalitelike framework. White; vitreous luster, somewhat greasy; transparent to translucent. Cleavage {001}, good; {111}, poor; conchoidal fracture. $H = 6$. $G = 2.662$. Biaxial (+); $2V = 78-81^\circ$; $N_x = 1.540-1.543$, $N_y = 1.543-1.550$, $N_z = 1.549-1.553$; $Y = c$; $r > v$. Rare at Mt. St.-Hilaire, PQ, Canada, as millimeter-size, equant, rounded crystals with villauminite, ussingite, lovozerite, and other minerals; in similar associations at Ilimaussaq, Julianehaab district, Greenland; at *Punkaruyav Mt.*, and elsewhere, in the *Lovozero massif, Kola Penin., Russia*. AR *AM 25:380(1940)*, *MR 21:303(1990)*.

65.6.1.1 Pyroxmangite $(\text{Mn,Fe}^{2+})_7[\text{Si}_7\text{O}_{21}]$

Named in 1913 by Ford and Bradley for the composition and relationship to other pyroxenoids. Polymorphic with low-Ca rhodonite. Complete isomorphous series with pyroxferroite (65.6.1.2). TRIC *P1*. $a = 6.721$, $b = 7.563$, $c = 17.380$, $\alpha = 113.17^\circ$, $\beta = 82.27^\circ$, $\gamma = 94.13^\circ$, $Z = 2$, $D = 3.77$. *29-895(syn): 4.73₄ 3.47₃ 3.04₃ 3.02₃ 2.97₁₀ 2.68₄ 2.61₃ 2.19₄*; *25-147(ferroan): 3.32₂ 3.29₂ 3.11₅ 2.95₁₀ 2.67₆ 1.168₄ 1.708₃ 1.666₂*. Structure: *AM 73:798(1988)*. The structure is characterized by chains of $W = 1$ and $P = 7$ lying parallel to c . There are seven polyhedral sites: M1, M2, and M3 are octahedral and occupied by Mn; sites M4 to M7 are distorted and contain the majority of substituting cations. A *C1* cell can be chosen so as to better correspond to the morphology. Crystals tabular to prismatic; as embedded grains; cleavable masses and compact. Pale pink to rose, often red-brown due to alteration; vitreous to pearly luster; transparent to translucent. Cleavage (morphological setting) {110}, {110}, perfect; {010}, {001}, poor. $H = 5\frac{1}{2}-6$.

PYROXMANGITE

SiO₃ chain in pyroxmangite.

$G = 3.61\text{--}3.80$. Biaxial (+); $2V = 35\text{--}45^\circ$; $N_x = 1.728\text{--}1.748$, $N_y = 1.732\text{--}1.742$, $N_z = 1.746\text{--}1.764$; $r > v$, moderate; $Z \wedge c \approx 45^\circ$ on (100) sections. Insoluble in acids; easily fusible to black bead. Complete solid solution exists with pyroxferroite. Limited substitution of Ca and Mg for Mn is common. Typical in metamorphic and metasomatic, Mn-rich assemblages. First described from Iva, Anderson Co., SC, but this occurrence is actually a Mn-rich pyroxferroite; Silverton district, San Juan Co., and the Galena district, Hinsdale Co., CO; near Boise, ID; and near Randsburg, Kern Co., CA. Found at Simsiö, Lapua, Finland; at Glen Beag, Glenelg, Scotland; and the Bernina area, Rhaetic Alps, Switzerland; from the Ajiro mine, Gifu Pref., the Taguchi mine, Aichi Pref.(!), and from pegmatite at Iwazumi-machi, Iwate Pref., and other sites in Japan. In large crystals(!) from Broken Hill, NSW, Australia. AR *MJJ 8:329(1977)*, *DHZII 2A:600(1978)*.

65.6.1.2 Pyroxferroite (Fe²⁺,Mn)₇[Si₇O₂₁]

Named in 1970 by Chao et al. for the composition and analogy with pyroxmangite (65.6.1.1), with which it forms a complete isomorphous series. TRIC P1. $a = 6.632$, $b = 7.563$, $c = 17.380$, $\alpha = 114.31^\circ$, $\beta = 82.75^\circ$, $\gamma = 94.58^\circ$, $Z = 2$, $D = 3.85$. 20-1: 6.55₃ 4.68₄ 3.09₅ 3.01₃ 2.93₁₀ 2.67₆ 2.62₃ 2.16₄. Structure: *SCI 168:364(1970)*. Yellow, light orange to orange-pink; vitreous luster; transparent to translucent. Cleavage (morphological setting) {110}, {110}, perfect; {010}, {001}, poor. $H = 5\text{--}6$. $G = 3.68\text{--}3.76$. Biaxial (+); $2V = 30\text{--}40^\circ$; $N_x = 1.746\text{--}1.756$, $N_y = 1.750\text{--}1.758$, $N_z = 1.764\text{--}1.768$. Insoluble in acids; easily fusible to a magnetic bead. Complete solid solution with pyroxmangite; Ca and Mg commonly present. Manganian material found at Iva, Anderson Co., SC, was originally described as pyroxmangite; at Vester Silfberg, Dalecarlia, Sweden; the Isanago mine, Kyoto Pref., Japan. Discovered in microgabbros of the *Sea of Tranquility, Moon*, and in the Oceanus Procellarum. AR *DHZII 2A:600(1978)*.

65.7.1.1 Alamosite PbSiO₃

Named in 1909 by Palache and Merwin for the locality. MON P2/n. $a = 12.247$, $b = 7.059$, $c = 11.236$, $\beta = 113.12^\circ$, $Z = 12$, $D = 6.32$. 29-782:

3.56₁₀ 3.53₈ 3.34₁₀ 3.25₆ 3.23₇ 2.98₇ 2.82₆ 2.30₈. Structure: *ZK 126:98(1968)*. The silicate structural element is a twisted, 12-tetrahedron chain of length 19.6 Å parallel to [101]. Crystals are fibrous to prismatic [010] in radiating groups. Colorless to white, adamantine luster, translucent to transparent. Cleavage {010}, perfect. $H = 4\frac{1}{2}$. $G = 6.49$. Biaxial (-); $2V = 25-65^\circ$; $N_x = 1.945-1.947$, $N_y = 1.955-1.961$, $N_z = 1.959-1.968$; $Y = b$, $Z \wedge c = 8^\circ$; $r < v$, strong. Fusible. Gelatinizes with acids. Only trace amounts of other constituents. Found in oxidized lead ores at Mammoth-St. Anthony mine, Pinal Co., and at the Rawhide mine, Maricopa Co., AZ; at *Alamos, SON, Mexico*; at Tsumeb, Namibia(1). AR *DT:567(1932)*, *NJMA 123:138(1974)*.

Double-Width, Unbranched Chains, $W = 2$

AMPHIBOLE GROUP

The amphibole group consists of some 70 naturally occurring inosilicate species and hypothetical end members, sharing a complex formula of

where

A = Na, K

B = Ca, Na, Mn

C = Mg, Fe²⁺, Mn, Fe³⁺, Al, Ti, Li, etc.

T = Si, Al, Be

and sharing a common structure. The name amphibole, from the Greek *amphibolos* meaning ambiguous, was coined by Haüy in 1801, and has proved to be a good choice because the complexity of the group's chemistry results in a diversity of appearances and yet a number of common characteristics.

The fundamental structural unit consists of infinite ribbons, two tetrahedrons wide, that can be envisioned as a condensation of a pair of pyroxene-type chains. The ribbon, of $W = 2$ and $P = 2$ and of composition $(Si_4O_{11})^{6-}$ lies in the b - c plane and parallel to the approximately 5.3-Å c axis common to all amphiboles. The ribbon may be viewed as a series of linked six-tetrahedron rings of ditrigonal symmetry. Of the 11 oxygens in the repeat unit, five are bridging oxygens that link the tetrahedra together and six are nonbridging, two lateral and four apical in their positions. In all the amphiboles, pairs of ribbons face one another, apex to apex, with their apical oxygens octahedrally coordinated to C cations to form I-beam units broader than, but akin to, those of the pyroxenes. The I-beams lie base to base along [100] so that the ditrigonal rings are approximately aligned from unit to unit; furthermore, they are staggered, apex plane to basal plane, along the b axis. The resultant lattice dimensions for all the monoclinic amphiboles are approximately $a \approx 9.9$ Å, $b \approx 18$ Å, $c \approx 5.3$ Å, $\beta \approx 104^\circ$.

The octahedral coordination sites (position C) between the apical, nonbridging oxygens are of three types: the two M1 and one M3 sites are

each coordinated to four apical oxygens and two (OH), whereas the two M2 sites are coordinated to four apical oxygens and two lateral oxygens of an adjacent I-beam. The two cations of position B, the M4 site, are surrounded by, but not necessarily coordinated to, two apical oxygens of one I-beam plus two lateral and four bridging oxygens of an adjacent I-beam. The M2 and M4 cations thus form the linkage between the I-beam along [010]. Finally, the A position, not always occupied, lies between the facing six-tetrahedron rings and is thus structurally surrounded by 12 bridging oxygens. This very elegant though complex structural scheme allows for the accommodation of the great diversity of the common six- and eight-coordinated cations, as well as those of higher coordination (K^+) and four-coordination (Al^{3+}, Be^{2+}).

Most of the monoclinic amphiboles crystallize in space group C_2/m , in which all the tetrahedral ribbons are alike. A few polymorphs and synthetic phases crystallize in $P2_1/m$ with a very similar structure but whose six-tetrahedron rings have near-hexagonal symmetry and the ribbons are of two types. A $P2/a$ structure with equivalent ribbons and ditrigonal rings has but one known example, joesmithite.

The orthorhombic amphiboles, $Pnma$, have cell constants related to the monoclinic amphiboles as follows: $a_o = 2a_m \sin \beta$, $b_o = b_m$, $c_o = c_m$. Dimensionally, this corresponds to a twinning on (010) on a unit cell scale, but the

TREMOLITE: $Ca_2Mg_5Si_8O_{22}(OH)_2$

Tremolite, a typical amphibole; perspective view along the double width silicate chains (parallel to c).

structure has two different ribbon coordinations. The M4 site in this structure does not readily accommodate the larger cations (i.e., Ca). Orthorhombic amphiboles crystallizing in space group *Pnmm* (protoanthophyllite) are not known in natural systems.

AMPHIBOLE GROUP: CUMMINGTONITE SUBGROUP—(Mg,Fe²⁺,Mn)₇[Si₈O₂₂](OH)₂

Leakeite	(Na, K)	Na ₂	(Mg, Fe ³⁺ , Li, Mn ³⁺)	(Si, Al) ₈	(Na, K) _A > 0.5	66.1.3c.12
Kornite	(Na, K)	Na, Li	(Mg, Mn ³⁺ , Fe ³⁺ , Li)	Si ₈		66.1.3c.13
Ungarettite	Na	Na ₂	Mn ₃ ²⁺ Mn ³⁺	Si ₉		66.1.3c.14
Fluorferroleakeite	Na	Na ₂	(Fe ₂ ²⁺ Fe ³⁺ Li)	Si ₈		66.1.3c.15

*Mg = Mg/(Mg + Fe²⁺), Fe²⁺ = Fe²⁺/(Mg + Fe²⁺), Mn = Mn/(Mn + Mg + Fe²⁺); for all other ions (Ca, Na, etc.) the value is the number of ions.

**End member whose natural occurrence is unknown or doubtful.

The presence of a variety of cation sites that can accommodate almost the full range of available cation sizes leads to extensive isomorphism. The certain establishment of immiscibility gaps for natural systems is difficult. The assignment of a specific amphibole, particularly the more varied clinoamphiboles, can be done with certainty only with a full chemical analysis. Extensive solid solution allows, in most cases, only tentative assignment on the basis of optical properties and/or X-ray diffraction. The extent of solid solution is illustrated by Figures 1a,b, which show the compositional spread for some members of the tremolite subgroup (calcic amphiboles).

The arrangement of the amphiboles into the subgroups and series reflected in the tables above is based on structural and crystallochemical considerations, but is in some respects also an artifact of convenience: considerable solid solution exists between one series and another, and even between one subgroup and another. The compositional limits in the tables are as defined by the IMA subcommittee on the amphibole group. *AM 63:1023(1978)*, *MSAMR 9A:1(1981)*.

66.1.1.1 Magnesio cummingtonite Mg₇[Si₈O₂₂](OH)₂

66.1.1.2 Cummingtonite (Mg,Fe)₇[Si₈O₂₂](OH)₂

66.1.1.3 Grunerite Fe₇[Si₈O₂₂](OH)₂

Cummingtonite named in 1824 by Dewey for the locality. Grunerite named in 1853 by Kenngott for Louis Emmanuel Gruner (1809–1883), Swiss–French

Figure 1a

The chemical variation of the calcium rich amphiboles expressed as the numbers of (Na, K) and $[Al]⁴$ atoms per formula unit.

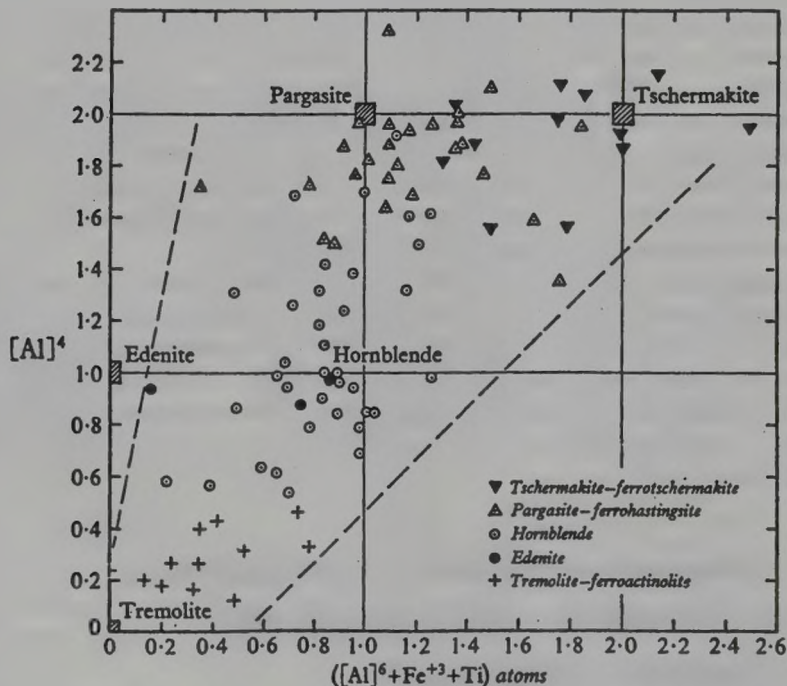

Figure 1b

The chemical variation of the calcium rich amphiboles expressed as the numbers of $([Al]⁶ + Fe³⁺ + Ti)$ and $[Al]⁴$ atoms per formula unit

chemist, who first analyzed the mineral. Magnesio-cummingtonite named in 1969 by Kisch. Synonym: amosite, an acronym for "asbestos mines of South Africa," is used for asbestiform members of this series and the gedrite series. Amphibole group, cummingtonite subgroup. Polymorphous with the magnesioanthophyllite-ferroanthophyllite series, $P2_1/m$ cummingtonite, and synthetic, orthorhombic protoanthophyllite. *MON* $C2/m$. (Magnesio-cummingtonite): $a = 9.583$, $b = 18.091$, $c = 5.315$, $\beta = 102.6^\circ$, $Z = 2$, $D = 3.18$; (cummingtonite): $a = 9.604$, $b = 18.124$, $c = 5.325$, $\beta = 102.6^\circ$, $Z = 2$, $D = 3.195$; (grunerite); $a = 9.564$, $b = 18.393$, $c = 5.339$, $\beta = 101.9^\circ$, $Z = 2$, $D = 3.54$. *17-727*(Mg-cumm.): 9.03₈ 8.30₉ 3.43₆ 3.25₈ 3.07₁₀ 2.73₇ 1.649₆ 1.406₈; *31-636*(cumm.): 9.12₅ 8.30₁₀ 4.55₄ 4.14₄ 3.26₈ 3.06₉ 2.75₇ 2.62₅; *31-631*(grun.): 9.21₅ 8.33₁₀ 3.88₅ 3.47₅ 3.07₈ 2.77₉ 2.64₇ 2.51₆. Structure: *AC 14:622*(1961). Fe^{2+} is strongly ordered in M4, the B site, as is any Ca or Na. **Habit:** Most commonly bladed, fibrous, to asbestiform; rarely displaying distinct {110} faces. Simple and lamellar twinning on (100) common. **Physical properties:** Brown to dark green, vitreous to silky luster, transparent to nearly opaque. Cleavage {110}, good to perfect at $\approx 55^\circ$. $H = 5-6$. $G = 3.10-3.60$. **Optics:** *Magnesio-cummingtonite:* Biaxial (-), (+); $2V_x = 66-97^\circ$; $N_x = 1.621$, $N_y = 1.632$, $N_z = 1.643$; $r < v$ weak; $Y = b$. Pleochroic, $X = Y$ colorless and Z pale yellow green. *Cummingtonite:* Biaxial (+), (-); $2V_z = 79-92^\circ$; $N_x = 1.632-1.662$, $N_y = 1.640-1.678$, $N_z = 1.658-1.698$; $Y = b$, $Z \wedge c = 15-21^\circ$ decreasing with Fe increase; $r > v$, weak. Pleochroism absent to weak; X, Y , colorless; Z , pale green. *Grunerite:* Biaxial (-); $2V = 82-88^\circ$; $N_x = 1.662-1.687$, $N_y = 1.678-1.709$, $N_z = 1.698-1.729$; $Y = b$; $Z \wedge c = 10-15^\circ$ decreasing with Fe increase, $r < v$, weak. Distinctly pleochroic; X, Y , very pale yellow to brown; Z , pale greenish brown. Petrographic distinction is often made at $2V = 90^\circ$. In asbestiform varieties elongation is always positive, $Z \wedge c = 0-18^\circ$, indices may increase to over 1.80, color intensified and pleochroism more distinct for samples that have been subjected to heat. Insoluble in HCl. **Chemistry:** Compositional limits are given in Amphibole group description. Magnesio-cummingtonite is likely only as a hypothetical end member; in natural occurrences, iron content is probably limited to the low-iron end of the cummingtonite range. Aluminum substitution for Si is generally less than one-eighth of the tetrahedral sites; Al and Fe^{3+} substitute to a limited degree in the C position; minor Ti may be present; Mn^{2+} may be present in significant amounts and complete series with dannemorite and tirodite is possible. Ca and Na occupy less than half the B sites. **Occurrence:** Found chiefly in contact or regionally metamorphosed basic rocks, commonly associated with hornblende and plagioclase. Cummingtonite and Ca-rich plagioclase may result from the breakdown of aluminous amphiboles. It has been reported as a primary mineral in hornblende and hypersthene dacites. Grunerite is characteristic of iron-rich siliceous sediments over a wide range of metamorphic conditions. **Localities:** Members of the series are found at numerous localities worldwide, only a few of which are noted here. *Magnesio-cummingtonite:* from Cima di Gagnone, Ticino, Switzerland, and Cooma,

NSW, Australia; occurrences with other series members from the Wabush iron formation, Labrador, NF, Canada; from *Buskerud, Kongsberg, Norway*, but appears to be outside the end-member range. *Cummingtonite*: the type material from *Cummington, Hampshire Co., MA*, is actually grunerite; abundant in the host rocks of the Homestake gold deposit, Lead, Lawrence Co., SD; Fiskenaesset, southwestern Greenland; from the Sutherland area, Scotland; from Isopää and Teisko, Finland; from Krivoi Rog, Ukraine; from Miyamori, Tochigi Pref., and the Hitachi mine, Ibaragi Pref., Japan; at the Mikouni R., Westland, and at Ringaringa, Stewart Is., New Zealand. *Grunerite*: found at Rockport, MA; with cummingtonite in the Homestake formation, Lawrence Co., and in the Rochford formation, Pennington Co., SD; and elsewhere in the United States; at *La Mallière, Collobrières, France* (type ?); at Nurmo and Vittinki, Finland; asbestiform material(*) in banded ironstones at Penge and Weltevreden districts, Transvaal, South Africa. Uses: Asbestiform varieties of this series have found extensive use as an insulating material to which, together with asbestiform gedrite, the terms *amosite* and *brown asbestos* have been applied. This application has been sharply curtailed in recent years due to the carcinogenic character of the fibers. AR *DHZI* 2:234(1963), *AM* 49:963(1964).

66.1.1.4 Tirodite $\text{Mn}_2(\text{Mg}, \text{Fe}^{2+})_5[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.1.5 Dannemorite $\text{Mn}_2(\text{Fe}^{2+}, \text{Mg})_5[\text{Si}_8\text{O}_{22}](\text{OH})_2$

Tirodite named in 1938 by Dunn and Roy and dannemorite in 1855 by Kenn-gott for their respective type localities. Amphibole group, cummingtonite subgroup. Some materials described as manganean cummingtonite may belong here. MON $C2/m$. $a = 9.606\text{--}9.64$, $b = 17.953\text{--}18.34$, $c = 5.287\text{--}5.35$, $\beta = 104.30\text{--}102.45^\circ$, $Z = 2$, $D_{\text{tir}} = 3.25$, $D_{\text{dan}} = 3.64$; tirodite with $P2_1/m$ symmetry has been reported. $PD(\text{calc tir.})$: 9.00₉ 8.28₉ 3.41₆ 3.24₆ 3.06₈ 2.96₅ 2.72₁₀ 2.51₆; $23\text{--}603(\text{tir.})$: 8.42₁₀ 4.50₂ 3.40₁ 3.27₃ 3.13₉ 2.96₁ 2.81₃ 2.71₃; $38\text{--}465(\text{dan.})$: 8.36₁₀ 3.45₂ 3.28₄ 3.09₉ 2.76₄ 2.63₂ 2.52₂ 2.20₂; cell dimensions and powder pattern spacings may be strongly affected by calcium substitution. Structure: *CM* 15:309(1977). Crystals prismatic or acicular [001]; usually in radiating or compact fibrous aggregates; twinned on {100}. Pale green, golden yellow, to reddish brown, the color being darker for Fe-rich examples; vitreous luster, sometimes silky; transparent to translucent. Cleavage {110}, perfect; parting on {001}. $H = 6\text{--}6\frac{1}{2}$. $G_{\text{tir}} = 3.07\text{--}3.13$, $G_{\text{dan}} = 3.34$. Tirodite: biaxial (+); $2V = 73\text{--}90^\circ$; $N_x = 1.630\text{--}1.638$, $N_y = 1.644\text{--}1.651$, $N_z = 1.652\text{--}1.665$; $X = b$, $Z \wedge c = 18\text{--}20^\circ$; dannemorite: biaxial (+, -); $2V_z = 89\text{--}92^\circ$; $Z \wedge c = 15\text{--}16^\circ$. A complete solid solution may exist, and apparent discontinuities in properties are probably a consequence of the small number of occurrences. Manganese, which must satisfy the condition $\text{Mn}/(\text{Mn} + \text{Mg} + \text{Fe}) \geq 0.1$, is strongly ordered in the M4 site, as is any substituting calcium. Found in manganese deposits, particularly those subject to metamorphism. Tirodite has been found at Belmont, ME; Talcville, NY; Bald Knob, Alleghany Co., NC; in the Wabush iron formation, Labrador, NF,

Canada; at Bonne-val-sur-Arc, France; Chikla, Rajasthan, and at Negpur, Maharashtra, and at *Tirodi, Madhya Pradesh, India*. Calcian material from granite pegmatite at Kamiotomo, Iwaizumi, Iwate Pref., and in contact-metamorphosed Mn ore at the Kusugi mine, Yamaguchi Pref., Japan. Danemorite is found at several localities, including *Uttersvik, in Sondermanland near Gnythyttan, Orebro*, and at *Dannemora, Uppsala, Sweden*, and at Broken Hill, NSW, Australia; from Guarultes Sao Paulo, Brazil. AR *DT:573(1932)*, *GSAM 122:397(1969)*, *BNSM 11:97(1985)*.

66.1.1.6 Magnesioclinoholmquistite $\text{Li}_2\text{Mg}_3\text{Al}_2[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.1.7 Clinoholmquistite intermediate

66.1.1.8 Ferroclinoholmquistite $\text{Li}_2\text{Fe}_3^{2+}\text{Al}_2[\text{Si}_8\text{O}_{22}](\text{OH})_2$

Clinoholmquistite named in 1965 by Ginsburg for its relationship to holmquistite. End members named in 1978 by Leake et al. Amphibole group, cummingtonite subgroup. MON $C2/m$. $a = 9.80$, $b = 17.83$, $c = 5.30$, $\beta = 109.1^\circ$, $Z = 2$, $D = 3.02$. The original paper reports space group $P2/m$ with the identical constants. 25-498(clinoholm.): 7.93₁₀ 4.40₉ 3.47₅ 2.99₁₀ 2.70₁₀ 1.61₈ 1.57₇ 1.37₉. Li^+ in the B position (M4 site). Light blue, violet; translucent. Cleavage $\{110\}$, perfect. H = 5–6. G = 3.02. Biaxial (-); $Y = b$; $2V = 55\text{--}61^\circ$; $N_x = 1.610$, $N_y = 1.627$, $N_z = 1.655$; $Z \approx c$, $X \wedge a = 15\text{--}16^\circ$. Found as prismatic crystals in pegmatite at an *unspecified locality in Siberia, Russia*. AR *AM 52:1585(1967)*.

66.1.2.1 Magnesioanthophyllite $\text{Mg}_7[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.2.2 Anthophyllite $(\text{Mg},\text{Fe}^{2+})_7[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.2.3 Ferroanthophyllite $\text{Fe}^{2+}[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.2.4 Sodium-anthophyllite $\text{Na}(\text{Mg},\text{Fe}^{2+})_7[\text{AlSi}_7\text{O}_{22}](\text{OH})_2$

Anthophyllite named in 1801 by Schumacher from the neo-Latin *anthophyllum*, clove, in allusion to its frequent clove-brown color; magnesio- and ferroanthophyllite were named in 1921 by Shannon, the latter being a hypothetical end member in current use. Amphibole group, anthophyllite subgroup. Dimorphous with corresponding members of the cummingtonite series. Protoanthophyllite is a synthetic phase with symmetry $Pnmm$. ORTH $Pnma$. (Magnesioanthophyllite): $a = 18.61$, $b = 18.01$, $c = 5.24$, $Z = 4$, $D = 2.95$; (anthophyllite): $a = 18.554$, $b = 18.026$, $c = 5.282$, $Z = 4$, $D = 3.09$. 16-401(syn Mg-anth.): 8.33₇ 4.67₂ 4.49₃ 3.66₁ 3.23₅ 3.06₁₀ 2.83₂ 1.500₂; 9-455(anth.): 8.9₃ 8.26₅ 3.65₃ 3.24₆ 3.05₁₀ 2.84₄ 2.69₃ 2.54₄; 42-455(asbestiform): 9.37₉ 9.01₅ 8.25₆ 4.59₈ 4.50₁₀ 3.23₇ 2.59₃ 2.54₅. Cell constants and powder pattern may be markedly affected by limited Na, Ca, and Al substitution. Iron preferentially enters sites M1 and M3; the structure appears to be destabilized when additional iron enters the M2

and M4 sites, resulting in cummingtonite. Structure: *ZK 188:237(1988)*. Habit: Prismatic [001] crystals rare and usually untruncated; columnar to fibrous, compact to radiating aggregates; asbestiform. Physical properties: Clove-brown to dark brown, pale green, gray, white; vitreous to silky luster; transparent to nearly opaque. Cleavage {210}, perfect at 54.5°, slightly smaller than most clin amphiboles; {010}, {100}, imperfect. $H = 5\frac{1}{2}$ –6 but often deceptively softer due to intergrowth with talc. $G = 2.85$ –3.57 increasing with iron content. Optics: For $Mg/(Mg + Fe^{2+}) = 1.0$ –0.60, biaxial (–, +); $2V_z = 111$ –78°; $N_x = 1.587$ –1.654, $N_y = 1.602$ –1.660, $N_z = 1.613$ –1.667; $XYZ = abc$; $r > v$ or $r < v$, weak; weakly pleochroic; $Z = Y > X$ or $Z > Y = X$. X, colorless to yellow-brown; Z, gray-green to brown to lilac. Change from (–) to (+) at $Mg/(Mg + Fe^{2+}) \approx 0.78$; $2V = 59^\circ$ reported in a sample with $Mg/(Mg + Fe^{2+}) = 0.62$. By extrapolation $N \approx 1.73$ for ferroanthophyllite. Sodium and calcium substitution appear to increase indices slightly, as does aluminum substituting tetrahedral sites. Chemistry: Compositional limits are given in the group description. Sodium and calcium may substitute to a limited degree in position B (M4 site). In low-aluminum varieties iron is limited to 43 mol % ferroanthophyllite, corresponding to the ratio of $(M1 + M3)/(M1 + M2 + M3 + M4)$. Aluminum may enter both tetrahedral and octahedral sites to form solid solution with members of the gedrite series. Minor titanium and manganese may be present. Occurrence: Restricted to metamorphic and metasomatic environments. Formed by Mg–Fe metasomatism or by metamorphic segregation, as evidenced by concentration in crests and troughs of minor folds. Frequent associations are with cordierite–plagioclase, with cordierite–corundum–sillimanite, with hastingsite in metagabbro, and with talc in metamorphosed ultrabasic rocks. Localities: Worldwide distribution. *Magnesioanthophyllite* is found at Edwards, St. Lawrence Co., NY, and at Vormlitjern, Søndeled, Norway. *Anthophyllite* (including undifferentiated material) is found in Macon and Yancey Cos., NC; asbestiform at Sall Mt., GA; at Cherry Creek, Madison Co., MT; as mass-fiber asbestos at Kamiah, Idaho Co., ID; as cross-fiber asbestos in serpentinite at Coffee Creek, Carville, CA; and elsewhere in the United States; with hastingsite at Hastings, ON; as long prismatic crystals at the Evans–Lou pegmatite, 20 miles N of Hull, PQ, Canada. Found at the Fiskenaesset and Sukkertoppen districts, Greenland; Kjernerud and Trondheim, Norway; Orijarvi, and at Paakkilla(*) (asbestiform), Finland; in the Outer Hebrides and at Glen Urquhart, Scotland; at Lizard, Cornwall, England; at Vedretta, Ultimo, Italy; at Miask, Ural Mts., Russia. Found with corundum and sillimanite in the anorthosite belt of the Sittampundi complex, India; at the Miyamori district, Iwate Pref., and elsewhere in Japan. Uses: Asbestiform varieties used as an insulating material. The asbestos industry does not generally differentiate asbestiform anthophyllites and gedrites. AR *DHZI 2:211(1963)*, *AM 63:1023(1978)*, *CM 21:173(1983)*.

66.1.2.5 Magnesiogedrite $\text{Mg}_5\text{Al}_2[\text{Al}_2\text{Si}_6\text{O}_{22}](\text{OH})_2$ **66.1.2.6 Gedrite** $(\text{Mg},\text{Fe}^{2+})_5\text{Al}_2[\text{Al}_2\text{Si}_6\text{O}_{22}](\text{OH})_2$ **66.1.2.7 Ferrogedrite** $\text{Fe}_5^{2+}\text{Al}_2[\text{Al}_2\text{Si}_6\text{O}_{22}](\text{OH})_2$ **66.1.2.8 Sodium-gedrite** $\text{Na}(\text{Mg},\text{Fe}^{2+})_6\text{Al}[\text{Al}_2\text{Si}_6\text{O}_{22}](\text{OH})_2$

Gedrite named in 1836 by Dufrenoy for the locality; ferrogedrite named in 1939 by Tilley; magnesiogedrite and sodium-gedrite named in 1978 by Leake. Amphibole group, anthophyllite subgroup. ORTH *Pnma*. (Magnesiogedrite): $a = 18.531$, $b = 17.741$, $c = 5.249$, $Z = 4$, $D = 3.18$; (gedrite): $a = 18.601$, $b = 17.839$, $c = 5.284$, $Z = 4$, $D = 3.20$; (ferrogedrite): $a = 18.51$, $b = 17.94$, $c = 5.315$, $Z = 4$, $D = 3.56$. 13-506(gedrite): 8.97₅ 8.27₈ 4.48₄ 3.65₄ 3.35₄ 3.23₇ 3.06₁₀ 2.50₄; 33-617(ferroged.): 8.95₁ 8.23₁₀ 4.63₁ 3.22₂ 3.04₇ 2.68₁ 2.58₁ 2.51₁. Structure: *AM 55:1945(1970)*. Aluminum plays a significant role in the silicate chains; the resultant distortion allows for a greater iron replacement than in the anthophyllite series. Occurs rarely as prismatic [001] crystals; as lamellar to fibrous aggregates; asbestiform. Pale greenish gray to brown, vitreous to silky luster, transparent to translucent. Cleavage {210}, perfect at slightly smaller angle than most clinoamphiboles; {100}, {001} imperfect. $H = 5\frac{1}{2}$ -6. $G = 3.18$ -3.57. Biaxial (+, -); $2V_z = 83$ -105°; $N_x = 1.642$ -1.694, $N_y = 1.649$ -1.710, $N_z = 1.661$ -1.722 for composition from 21 to 98 mol % of iron end member; $N_x = 1.613$, $N_y = 1.625$, $N_z = 1.634$ reported for magnesiogedrite; $XYZ = abc$; pleochroism absent to weak. Magnesiogedrite is rare or of doubtful occurrence in nature. Reported analyses of gedrites range from 21 mol % to nearly pure ferrogedrite. One to two aluminum atoms occupy tetrahedral sites, and Al is also present in octahedral coordination. Sodium is almost always present as $0.0 < \text{Na} < 0.5$ in the B position (site M4); calcium substitution is low; Mn and Fe^{3+} occupy less than one of the five C position sites. The term *ferrogedrite* has been used for gedrites with 50 mol % of the iron end member. Sodium-gedrite ($\text{Na} \geq 0.75$) is not known to occur in nature. Occurs in metamorphic and metasomatic environments similar to those for anthophyllite, but unlike it, is often associated with kyanite and garnet, an assemblage suggesting a higher-pressure field than for the anthophyllite-cordierite assemblage. Gedrite is of worldwide occurrence, the following being typical: Franklin, NC; Ruby Dam area, Madison Co., MT; Orofino, Clearwater Co., ID; Isopää, Finland; Sutherland, Scotland; gedrite at *Heas, Gedres, France*; at Schueretsky, Karelia, Russia; at Tottiyaminttam, Madras, India; at the Wakamatsu mine, Tottori Pref., and Iratsuyama, Ehime Pref., and ferrogedrite at Yakushiyama, Iwate Pref., Japan. Asbestiform material at Penge, Transvaal, South Africa. Asbestiform gedrites are used as an insulating material. In industry, gedrite asbestos is not always differentiated from anthophyllite or from "amosite" (usually cummingtonite-grunerite). *AR DHZI 2:211(1963)*, *AM 63:1023(1978)*.

66.1.2.9 Magnesioholmquistite $\text{Li}_2\text{Mg}_3\text{Al}_2[\text{Si}_6\text{O}_{22}](\text{OH})_2$ **66.1.2.10 Holmquistite** $\text{Li}_2(\text{Mg},\text{Fe}^{2+})_3\text{Al}_2[\text{Si}_6\text{O}_{22}](\text{OH})_2$ **66.1.2.11 Ferroholmquistite** $\text{Li}_2\text{Fe}_3^{2+}\text{Al}_2[\text{Si}_6\text{O}_{22}](\text{OH})_2$

Holmquistite named in 1913 by Osann for Per Johan Holmquist (1866–1946), petrologist, Stockholm, Sweden; the end members named in 1978 by Leake. Amphibole group, anthophyllite subgroup. Polymorphous with the corresponding members of the clinoholmquistite series. ORTH *Pnma*. $a = 18.254$, $b = 17.636$, $c = 5.270$, $Z = 4$, $D = 3.06$. *13-401*: 8.11₁₀ 4.43₇ 3.61₅ 3.34₆ 2.80₄ 2.54₅ 2.13₄ 1.572₄. Structure: *ZK 188:95(1989)*. Li^+ is ordered in the B position (M4 site). Sky-blue to deep violet, light bluish gray streak, vitreous luster, transparent to translucent. Cleavage {210}, perfect at $\approx 54^\circ$; partings {001}, {112}, {113}. $H = 5\frac{1}{2}$. $G = 3.06\text{--}3.13$. Biaxial (-); $2V = 44\text{--}56^\circ$; $N_x = 1.613\text{--}1.625$, $N_y = 1.634\text{--}1.645$, $N_z = 1.646\text{--}1.666$; $XYZ = abc$; pleochroic; $Z = Y > X$ or $Z > Y = X$. X, colorless to yellow-green; Z, blue to violet. Documented analyses lie between 40 and 70 mol % ferroholmquistite end member. Al in tetrahedral sites is minor. Found as prismatic to acicular [001] crystals, as sheaflike aggregates, and fibrous masses in wall rock and contact zones of lithian pegmatites with basic or ultrabasic country rock. Found in Alexander and Yancey Cos., NC; at the Harding mine, Taos Co., NM; at Barrante, PQ, Canada. Found at *Uto Is.*, *Sondermanland, Sweden*; the Kola Penin., and eastern Sayan Mts., Russia; as crystals and radiating laths(!) to 15 cm long S of Greenbushes, WA, Australia; at the Benson mine, Mtoko, Zimbabwe. AR *DHZI 2:230(1963)*, *MR 9:83(1978)*, *AM 63:1023(1978)*.

66.1.3a.1 Tremolite $\text{Ca}_2\text{Mg}_5[\text{Si}_6\text{O}_{22}](\text{OH})_2$ **66.1.3a.2 Actinolite** $\text{Ca}_2(\text{Mg},\text{Fe}^{2+})_5[\text{Si}_6\text{O}_{22}](\text{OH})_2$ **66.1.3a.3 Ferroactinolite** $\text{Ca}_2(\text{Fe}^{2+},\text{Mg})_5[\text{Si}_6\text{O}_{22}](\text{OH})_2$

Tremolite named in 1790 by Hopfner for the locality; actinolite named in 1794 by Kirwan from the Greek for *ray* in allusion to the radiating prismatic habit; ferroactinolite named in 1946 by Sundius in reference to the composition. Amphibole group, tremolite subgroup. Varietal names: byssolite from the Greek for *flax*, in allusion to the fibrous habit; hexagonite in allusion to the mistaken notion of hexagonal symmetry; nephrite from the Latin for *kidney*, in reference to its alleged beneficial effect over kidney ailments; uralite for the Ural Mountains. Synonym: Ferrotremolite is equivalent to ferroactinolite. MON *C2/m*. $a = 9.84\text{--}9.92$, $b = 18.02\text{--}18.24$, $c = 5.27\text{--}5.31$, $\beta \approx 104.7^\circ$, increasing with iron content, $Z = 4$, $D = 3.01\text{--}3.49$. *13-437*(tremolite): 8.38₁₀ 3.38₄ 3.27₈ 3.12₁₀ 2.94₄ 2.81₅ 2.71₉ 2.53₄; *41-1366*(actin.): 9.04₂ 8.42₈ 3.39₃ 3.28₅ 3.12₁₀ 2.94₄ 2.71₆ 2.53₃; *23-118*(Fe-actin.): 8.58₁₀ 4.57₂ 3.41₁ 3.16₃ 2.73₄ 2.61₂ 2.55₂ 2.03₃. Structure: *CM 14:334(1976)*. Asbestiform varieties and some nephrites display chain-width disordering. Habit: Short to long prismatic [001] when in euhedral crystals with {110}, {011}, {010}, {100}, {101} {101}

dominant; more commonly in unterminated bladed crystals or in aggregates with {110} dominant, the blades often lying near a common plane, but also as radiating groups. Magnesium-rich members may be asbestiform and the flexible fibers may exceed 25 cm in length; asbestiform actinolite fibers often isolated and brittle (byssolite); somewhat porous, matted aggregates of short asbestiform material (mountain leather, mountain cork, etc.). Both tremolite and actinolite occur in compact, tough aggregates of short, tightly interlocking fibers with a subparallel alignment to random orientation (nephrite); with pronounced parallelism and increased fiber length may display chatoyancy (cat's-eye actinolite). Twinning, simple or lamellar, on (100) common; lamellar on (001) rare. Rarely epitactically enclosing diopsidic pyroxene with common *b* and *c* axes. **Physical properties:** Colorless, white, gray, gray-green (tremolite), green to dark green and nearly black in mass (actinolite to ferroactinolite); rarely bright green due to Cr^{3+} , pink to violet due to Mn^{2+} ; vitreous luster, silky in asbestiform varieties, rarely chatoyant, dull to waxy in nephrite; transparent to translucent. Cleavage {110}, perfect; brittle to splintery fracture, fibers brittle to flexible. $H = 5-6$, perhaps $6\frac{1}{2}$ in nephrite which has a high toughness. $G = 2.89-3.44$ but mountain leather may trap air so as to float in water. **Optics:** Biaxial (-); $2V = 65-90^\circ$; $N_x = 1.598-1.684$, $N_y \approx 1.610-1.699$, $N_z = 1.622-1.702$, the upper limits interpolated; $Y = b$, $Z \wedge c = 10-21^\circ$ but asbestiform fibers may show parallel extinction; $r < v$, weak. Darker members pleochroic; *X*, pale yellow to yellow-green; *Y*, pale yellow-green to green; *Z*, pale to deep greenish blue. With increasing Fe^{2+} content the indices increase approximately linearly, while $2V$, $Z \wedge c$, and birefringence decrease. For synthetic fluortremolite the indices are $N_x = 1.581$, $N_y = 1.593$, $N_z = 1.602$. **Chemistry:** Complete isomorphism exists within the series, but there is inconsistency in the limiting compositions for the three species. The IMA Commission boundaries (1978) are given in the group description. Isomorphism between these species and other members of the tremolite subgroup occurs at least to a limited degree, but coexistence of actinolite and "hornblende" suggests a possible immiscibility gap. Aluminum is generally constrained to no more than $\frac{1}{2}$ an atom per formula unit, as is the case for Fe^{3+} ; only minor sodium is present in either the B or A position. Hydroxyl ion may be replaced by F^- , and a pure fluorine end member has been synthesized. Minor Cr^{3+} , Mn^{2+} , and Ti may be present. Ferroactinolite is relatively rare and but a few examples have been reported with >70 mol % of the iron end member. Structural water is lost between 930° and 988° . **Occurrence:** A typical product of thermal and regional metamorphism. Tremolite is an early product of thermal metamorphism of siliceous dolomites, the excess calcium appearing as calcite with the liberation of CO_2 ; at higher metamorphic grade the tremolite is unstable and diopside and, if silica is depleted, forsterite are formed. Actinolite may form in similar but ferruginous environments. Actinolite is characteristic of regionally metamorphosed (greenschist facies) ultrabasic rocks, where it is commonly associated with talc and serpentine. Actinolite may be intimately associated with hornblendes in metamorphic rocks, the compositions of the coexisting phases having cor-

responding changes in refractive index. Actinolite is also a component of some glaucophanitic regionally metamorphosed rocks. Actinolite (uralite) is also a common alteration of pyroxene in many basic rocks. Asbestiform varieties are associated with late-stage crystallization of diabase intrusives, with metamorphosed serpentinites, and in Alpine clefts. Nephrite (tremolite or actinolite jade) is commonly formed in metamorphosed ultrabasics associated with talc and serpentine, and in regionally metamorphosed terrains where dolomites have been intruded by intermediate and basic rocks. **Localities:** Tremolite and actinolite are of widespread occurrence and only a few more noteworthy localities are listed. *Tremolite* is found in dolomite at Lee, Bircher Co., MA; as white crystals and radiating aggregates at Canaan, Litchfield Co., CT. Found in NY as large, white crystals at Diana, Lewis Co.; as radiating aggregates and asbestiform at Phillipstown, Putnam Co.; at Hastings and Yonkers, Westchester Co., NY; at Rossie, at DeKalb with diopside, and manganoan tremolite (hexagonite) as pink to light violet crystalline masses at Edwards, St. Lawrence Co., NY; at Chestnut Hill, Philadelphia, and as very long, fiber masses stiffened by impregnating calcite at the Williams quarry, Easton, PA; at Sacramento Hill, Bisbee, Cochise Co., AZ; and numerous other localities in the United States. Abundant in the metamorphosed limestones of the Grenville province, eastern Canada, as at Irondale(!), Snowdon Twp., and Keller Farm, Hardwood Lake, ON, and at Calumet Falls, Litchfield Co., QUE; fluortremolite at Gatineau Park, PQ. Asbestiform and mountain leather types are found extensively in the Alps of Europe as at Bourg d'Oisans, Isere, France, at Zermatt, Valais, Switzerland, and in the Zillerthal and elsewhere in the Tyrol, Austria. Type tremolite is from *Val Tremola, St. Gotthard, Switzerland*. Large (10 cm), transparent to translucent, poorly terminated prisms(!) at Kantiwa, Noriatak, Afghanistan. Occurs as bladed crystals partly altered to talc near Chung Ju, Chung Cheon N. Prov., South Korea. Chromian material found at Dilma, eastern Sierra Leone. Found as curved crystals(!) to 20 cm in length at the Pedra Preta pit, Brumado, BA, Brazil. *Actinolite* occurs as radiating masses in the soapstone quarries at Windham, Reedsboro, and New Fane, NH; at Carlisle, Pelham, Windsor, and Lee, MA; at Mineral Hill, Delaware Co., and at Kennett, Chester Co., PA. Byssolite is abundant at the French Creek mines, St. Peters, Chester Co., PA. Found in serpentine at Bare Hills, Baltimore Co., MD; at Willis's Mt., Buckingham Co., and at the Fairfax diabase quarry (byssolite), Centreville, VA. Occurs at the New Cornelia mine, Ajo, and at Bisbee, AZ; found as 1 cm very pale green fibers (byssolite) covering areas up to 60 cm × 30 cm associated with albite, and also as parallel aggregates of fibers up to 15 cm long at New Melones Lake, Calaveras Co., CA; fine crystals(!) in talc near Wenatchee Lake, Chelan Co., WA; at Prince of Wales Island, AK. Found in the Grenville Prov. of Canada at many of the same localities as for tremolite; asbestiform at the Jeffrey quarry, Asbestos, PQ; in the Ice River Complex, Ottertail Range, BC, Canada. Occurs as dark green acicular crystals up to 15 cm long and as byssolite in dolerite at Monte Redondo, 155 km N of Lisbon, Portugal. Found in the schists of the central and eastern Alps, particularly at Greiner, in the Zil-

lerthal, at Pfitsch, and in fibrous masses (mountain leather) with epidote, in the Knappenwald, Tyrol; at Traversella, Italy. Asbestiform actinolite is found with nephrite at Fengtien, Hualien, Taiwan; occurs in glaucophane rocks in the Kanto Mts., and with coexisting hornblende in the Nakoso district, Abukuma Plateau, Japan. *Ferroactinolite* is found in the Biwabik iron formation, Mesabi district, MN; at the Tamarack mine, ID; a phase with $(\text{Fe}^{2+} + \text{Mn}) > \text{Mg}$, but $\text{Mg} > \text{Fe}^{2+}$ occurs at the Kaso mine, Tochigi Pref., Japan. *Nephrite*, both tremolitic and actinolitic, is found worldwide in regional metamorphic terrains. Many reported occurrences of nephrite, particularly of dark green or black material, are neither texturally nor mineralogically true nephrites, despite the dominance of actinolite in their makeup. Bright green to nearly black nephrite occurs in Bull Canyon, Crooks Mt., the Granite and Rattlesnake Mts., in the area between Lander and Rawlins, WY, where it is associated with feldspars, zoisite, and quartz, the last often replaced by nephritic actinolite; locally, special names have been given to “jades” containing large amounts of the associated minerals. Light to dark green pebbles and boulders are common in Mariposa (also in situ with talc), Humboldt, Trinity, and Siskiyou Cos., CA, and light green, botryoidal surface pebbles and boulders are found in Monterey and Morro Bays, in Monterey Co.; green nephrite is found along the Kobuk R., ca. 200 km from its mouth at Kotzebue Sound, AK. In Canada nephrite has been found at Milan Arm at the northern tip of NF; extensive deposits are found in BC in the Omineca Field (Mt. Ogden), the Cassiar Field (Dease Lake), and to a lesser extent at the Lillooet Field; these nephrites are in part similar to those of the Irkutsk and Taiwan, and vary from medium to deep green, sometimes with very uniform color and texture and often enclose bright green (grossular ?) and black (magnetite or chromite) spots. Found in place at Reichenstein and Jordansmühl, Silesia, and as float at Sannthal and Murthal, Styria, and at Schwemmsal, near Leipzig, Poland. Light green nephrite(!), with abundant magnetite inclusions, is found near Irkutsk, Lake Baikal region of Siberia, and white material with brown markings has recently been reported from the same region. White, pale yellow, to pale green nephrite occurs abundantly as stream boulders and in place on the north slopes and drainage of the Kun Lun Mts., between Yarkand and Khotan, Xinjiang Prov. (Chinese Turkestan), China, where it has been mined since antiquity. Medium to dark green nephrite of variable quality is found at Fengtien, Hualien, Taiwan, where it was extensively mined in the 1960s. White to light gray-green material, often with brown markings, is found in place in metamorphosed dolomite near contact with basic or intermediate metaintrusives at several localities near Chun Cheon, about 100 km N of Seoul, South Korea, the deposits probably extending through North Korea to Liaoning Prov., China; much of this has a relict granular structure characteristic of a marble, a trait that is also seen in some of the Xinjiang nephrite. Light to medium green, streaked and mottled nephrite is found near Cowell, SA, Australia; in often deeply weathered boulders at several localities, particularly the Westland Field and near Lake Wakatipu, Otago, in New Zealand, this material having been used by the Maori peoples, and forming the basis for

a distinctive, modern lapidary industry. Uses: Tremolite and, to a lesser extent, actinolite of asbestiform habit have been used as thermal insulating materials, and also as chemical filtering agents; these applications are now much curtailed due to the carcinogenic nature of the fibers. Crushed tremolite is used as a filler and whitener in construction materials. Nephrite, jade in part, has a long history of use as an ornamental material. Artifacts have been found in prehistoric sites in Switzerland and elsewhere in Europe; the carving of light-colored nephrite from Xinjiang was developed into a fine art in China and India, where objects of great delicacy or boldness have been produced, internal and surface color variation being incorporated into the design. Green nephrite, perhaps from Siberia, came late on the Chinese scene, but the abundance of material from Canada, Taiwan, New Zealand, and Wyoming has dominated present-day carving and gemstone activity; light-colored material from South Korea and Siberia is comparable in appearance to that of Xinjiang. Cabochons and small carvings have not enjoyed the popularity of the brightly colored jadeite jades, but inclusion-free, apple-green gems from Siberia or Wyoming are highly desirable. Chatoyant actinolite (nephrite) has been produced in Taiwan and to a lesser degree in British Columbia. *AR SGU* 40:1(1946), *DHZI* 2:249(1963), *MSARM* 9A:237(1981), *MR* 13:297(1982), *JADE*:208,220,296(1991).

66.1.3a.4 (Alumino)magnesiohornblende $\text{Ca}_2(\text{Mg},\text{Fe}^{2+})_4\text{Al}[\text{AlSi}_7\text{O}_{22}](\text{OH})_2$

66.1.3a.5 (Alumino)ferrohornblende $\text{Ca}_2(\text{Fe}^{2+},\text{Mg})_4\text{Al}[\text{AlSi}_7\text{O}_{22}](\text{OH})_2$

Hornblende is from an old German term, meaning *horn* and *blind* or *to deceive*, applied to a prismatic mineral occurring in ore deposits but yielding no metal. There being essentially continuous solid solution between these species and the members of the tschermakite, edenite, and pargasite series, the name has commonly been used to encompass a broader range of composition than that of hornblende *sensu strictu*. *Oxyhornblende* refers to hornblende that is (OH)-deficient and with Fe^{3+} predominating over Fe^{2+} , but also applies to most kaersutites. Amphibole group, tremolite subgroup. *MON* *C2/m*. $a \approx 9.9$, $b \approx 18.1$, $c \approx 5.31$, $\beta \approx 105^\circ$, $Z = 2$, $D = 3.02\text{--}3.23$, the cell constants increasing with iron content. *20-481*(magnesiohornblende): 8.40₁₀ 4.50₁ 3.39₁ 3.26₂ 3.10₇ 2.94₁ 2.79₁ 2.70₂; *21-149*(ferroan Mg-hornb.): 8.51₆ 3.29₃ 3.14₁₀ 2.82₂ 2.72₃ 2.61₁ 2.17₂ 1.656₂. Structure: *AM* 74:1097(1989). *Habit*: Short to long prismatic {001} when in euhedral crystals with {110}, {011}, {010}, {100}, {101}, {101} dominant, and often displaying a pseudo-hexagonal cross section; more commonly in untruncated bladed crystals, usually subparallel in gneiss or schist, or in aggregates with {110} dominant; also in radiating groups, coarse-grained cleavable masses; fibrous. Simple and lamellar twinning is common on (100). *Physical properties*: Green, dark green, brownish green to black; pale gray-green streak; vitreous luster; translucent to opaque. Cleavage {110}, perfect; brittle. $H = 5\text{--}6$. $G = 3.02\text{--}3.45$. *Optics*: Biaxial (-, +); $2V_x = 27\text{--}95^\circ$,

usually negative and large; $N_x = 1.615\text{--}1.705$, $N_y = 1.618\text{--}1.714$, $N_z = 1.632\text{--}1.730$, the indices increasing with iron content; $Y = b$, $Z \wedge c = 13\text{--}34^\circ$ generally decreasing with iron increase; $r > v$ or $r < v$. Distinctly to strongly pleochroic; $Z \geq Y > X$ or $Y > Z > X$; pale yellow-green to green to blue-green or greenish brown. *Oxyhornblende* is Biaxial (-); $2V = 60\text{--}82^\circ$, $N_y = 1.662\text{--}1.690$, $N_z = 1.672\text{--}1.730$, $N_x = 1.680\text{--}1.760$, $r < v$, $Z \wedge c = 0\text{--}18^\circ$; pleochroism strong with $Z > Y > X$, yellow to dark brown or red-brown. **Chemistry:** The relationship of hornblende composition to that of other members of the tremolite subgroup is clearly illustrated in Figures (1a, 1b); there is a near continuity between tremolite, hornblende, and pargasite series, with a lesser, but significant number of examples approaching the tschermakite and edenite series species. This diversity and continuity in composition reinforces the use of *hornblende* in its broader sense because distinctions are difficult on the basis of optical properties, requiring chemical analysis for absolute species assignment. High Ca, often in excess of two atoms per formula unit, is characteristic of hornblende in the broader sense of the term; sodium is almost invariably present, occupying the B position together with calcium and part of the A position; potassium is often present in small amount. Aluminum is almost invariably present in both four- and six-coordination. Small amounts of titanium and manganese commonly occupy part of the C position. In oxyhornblende Fe^{3+} exceeds Fe^{2+} and Al in four-coordination may be near 2, placing it near the ferritschermakite range; furthermore, (OH) is well below 2 per formula unit. A slight deficiency in (OH) is common and fluorine may replace hydroxyl. There are, however, instances of excess hydrogen; these have been variously attributed to H_2O or $(H_3O)^+$ occupying part of the A position or (OH) replacing O in the chains. Among trace elements in metamorphic hornblende, Cr and Ni decrease and Ti increases with increased metamorphic grade. **Occurrence:** Hornblende may be formed over a wide range of temperature–pressure conditions. It is a common component of intermediate members of calc-alkalic igneous rocks and is common in many hybrid rocks; it generally precedes biotite in the Bowen discontinuous reaction series. In basic igneous rocks it may appear in coronas between olivine and plagioclase. Oxyhornblende occurs in a wide variety of volcanic rocks, particularly andesite, latite, basanite, and tephrite. Hornblende is common in metamorphic rocks of the greenschist to lower granulite facies, and often constitutes the bulk of hornblende schists, hornblende gneisses, and amphibolites. With increasing metamorphism the sequence tends to be actinolite–hornblende–pargasitic hornblende–pargasite, often with the morphological sequence fibrous–acicular–prismatic. Pyroxenes of igneous rocks may undergo late-stage alteration to amphiboles, in part hornblende, that are collectively called uralite. Found also in carbonatites and marble. **Localities:** Hornblende is a common, worldwide mineral, but many reported occurrences are not supported by adequate chemical data. Localities mentioned here are but a few, chosen for their representation of modes of occurrence or exceptional size of crystals. *Magnesianhornblende* is common in the hornblende gneisses and schists throughout the Piedmont metamorphic

province of eastern PA and DE, and in metagabbros of that area; in anorthositic gneiss at South Russell, Adirondack Mts., NY; in tonalite associated with the Idaho Batholith, ID; in diorite pegmatite in San Bernardino Co., CA; in the Green River Formation, UT. Large euhedral crystals(!) and groups and coarse, cleavable masses in carbonatites at the Silver Crater mine, between Bancroft and Wilberforce, and in the Lake Clear, Kuel Lake area, Renfrew Co., ONT, Canada; in recrystallized amphibolite at Lillfjalsgruven, Sweden; in fine-grained gabbro at Garabal Hill, Argyllshire, and in injected syenite hybrid at Glenelg-Ratagain, Inverness-shire, Scotland; chromian in chromatite at Karungalpatti, Madras, India; associated with corundum (ruby)-bearing rocks in the Harts Range, NT, Australia. *Ferrohornblende* occurs as a major component of amphibolite in the Yates member of the Poorman formation, Black Hills, SD; at Barkevik and in pegmatite in the Oslo region, Norway; in chlorite-rich schist at Kyykkä, Kontiolahki, Finland; in garnet-epidote amphibolites at Achahoish, Scotland; in clinopyroxene amphibolite at Yamatama, Nokoso, Fukushima Pref., and in axinite-bearing rocks at Kannoniyama, Iwate Pref., Japan; in quartz monzonite-syenite at Sokuchankoge, Kogen-do, Korea. *Oxyhornblende* in prismatic crystals to several centimeters has been found at Korrettsberg, near Andarnach, Lacher See volcanic field, Germany. Uses: Hornblende-rich metabasalts containing significant magnetite and plagioclase and having a fine, granular texture have been used for ornamental purposes and sometimes marketed, incorrectly, as nephrite jade. AR *DHZI* 2:263(1963), *MSARM* 9A:85,325(1981), *MR* 13:201,213(1982).

66.1.3a.6 (Alumino)tschermakite $\text{Ca}_2(\text{Mg}, \text{Fe}^{2+})_3\text{Al}_2[\text{Al}_2\text{Si}_6\text{O}_{22}](\text{OH})_2$

66.1.3a.7 Ferro(alumino)tschermakite $\text{Ca}_2(\text{Fe}^{2+}, \text{Mg})_3\text{Al}_2[\text{Al}_2\text{Si}_6\text{O}_{22}](\text{OH})_2$

66.1.3a.8 Ferritschermakite $\text{Ca}_2(\text{Mg}, \text{Fe}^{2+})_3\text{Fe}_2^{3+}[\text{Al}_2\text{Si}_6\text{O}_{22}](\text{OH})_2$

66.1.3a.9 Ferroferritschermakite $\text{Ca}_2(\text{Fe}^{2+}, \text{Mg})_3\text{Fe}_2^{3+}[\text{Al}_2\text{Si}_6\text{O}_{22}](\text{OH})_2$

Named in 1945 by Winchell for Gustav Tschermak von Sesseneegg (1836–1927) Austrian mineralogist. Amphibole group, tremolite subgroup. *MON* *C2/m*. Alumino)tschermakite: $a = 9.813$, $b = 18.055$, $c = 5.321$, $\beta = 104.97^\circ$, $Z = 2$; ferrotschermakite: $a = 9.818$, $b = 18.106$, $c = 5.331$, $\beta = 105.0^\circ$, $Z = 2$, $D = 3.302$. *43-665*(ferrotschermakite): 8.40_{10} 3.39_2 3.11_3 2.94_1 2.72_5 2.60_2 2.56_3 2.34_2 . Structure: *MM* 39:36(1973). Commonly occurs as rock-bound laths or prisms with {110} dominant when euhedral; massive. Twinning on {100} common. Green, dark green, brownish green to black; pale gray-green streak; vitreous luster; translucent to opaque. Cleavage {110}, perfect; parting may develop on {001} or {100}; subconchoidal fracture; brittle. $H = 5-6$. $G = 3.13-3.35$. Biaxial (-); $2V = 60-90^\circ$; $N_x = 1.642-1.671$, $N_y = 1.648-1.688$, $N_z = 1.660-1.694$; $Y = b$, $Z \wedge c = 13-28^\circ$; indices tend to

increase with iron content while 2V and extinction angle decrease; pleochroic, $Z > Y > X$, pale yellow to green and brownish green similar to hornblende. In composition most members of this group lie between the tschermakite–hornblende–edenite limits. Sodium is invariably present to some degree, and the aluminum content is generally less than in the aluminotschermakite end member. Low (OH) content is common. Tschermakites and tschermakitic hornblendes occur in regionally metamorphosed rocks commonly of somewhat higher grade than that where common hornblende is present; they are prevalent in aluminous rocks and may be associated with kyanite. Mg-rich tschermakites are the more common, and known ferrotschermakites are close to the $\text{Fe}^{3+}\text{-Al}^{[6]}$ boundary. Widespread in occurrence but not so much so as hornblende. Some examples, supported by chemical analyses, are: in eclogite at Hurry Inlet, eastern Greenland; in kyanite–garnet–amphibolite at Glenelg, Scotland; in “hornblende” schist at Airolo, Ticino, Switzerland; Na-rich from inclusions in basalt at Saigertshausen, northern Hesse, Germany. An Al-poor ferrotschermakite from gabbrolite amphibolite at Perniö, Finland. Ferrotschermakite in banded amphibolite at Kayal, Kohistan, Pakistan. Near midpoint composition ferrotschermakite occurs in amphibolite schist from the Amanous R., northwestern Caucasus, Russia, and in medium-grained, gneissose quartz diorite at Furudono, Gosaisyo-Takanuki district, southern Abukuma Plateau, Japan; at Lake Grave, Broken Hill, NSW, Australia. *AR AM* 30:27(1945), 34:220(1949); *DHZI* 2:263(1963).

66.1.3a.10 Edenite $\text{NaCa}_2(\text{Mg}, \text{Fe}^{2+})_5[\text{AlSi}_7\text{O}_{22}](\text{OH})_2$

66.1.3a.11 Ferroedenite $\text{NaCa}_2(\text{Fe}^{2+}, \text{Mg})_5[\text{AlSi}_7\text{O}_{22}](\text{OH})_2$

Edenite named in 1839 by Glocker for the locality; ferroedenite named in 1946 by Sundius for the composition and relationship to edenite. Amphibole group, tremolite subgroup. *MON* $C2/m$. $a = 9.80\text{--}10.00$, $b = 17.95\text{--}18.22$, $c = 5.28\text{--}5.31$, $\beta = 104.4\text{--}105.5^\circ$, $Z = 2$, $D = 3.06\text{--}3.53$, cell constants and density increasing with iron content. *23-1405*: 9.01₁ 8.43₈ 4.50₁ 3.38₄ 3.27₄ 3.12₁₀ 2.80₂ 2.70₂; *31-1282(syn)*: 8.47₄ 3.38₄ 3.28₅ 3.15₁₀ 2.95₄ 2.82₄ 2.70₆ 2.59₃. Short prismatic [001] crystals with prominent {110}; massive, granular, fibrous. White, gray, pale to dark green, also brown and pale pinkish brown; vitreous luster; translucent. Cleavage {110}, perfect; parting {100} and {001}; uneven to subconchoidal fracture; brittle. $H = 5\text{--}6$. $G = 3.0\text{--}3.28$. Biaxial (–); $2V = 65\text{--}75^\circ$; $N_x = 1.634\text{--}1.666$, $N_y = 1.645\text{--}1.678$, $N_z = 1.658\text{--}1.684$; $Y = b$, $Z \wedge c = 18\text{--}32^\circ$; nonpleochroic to distinctly so with X, yellow; Y, pale green Z dark green. Mn-rich has $Z \wedge c = 33^\circ$; $N_x = 1.620$, $N_y = 1.632$, $N_z = 1.642$; $2V_{\text{calc}} = 84^\circ$. Pleochroic with X, colorless; Y, pale orange-brown; Z, pale pinkish brown. Lighter varieties easily confused with tremolite or actinolite. Minor potassium may be present in the A site. Manganese may replace magnesium, but may also occupy as much as half of the B sites. Naturally occurring, true ferroedenites are not documented by chemical analyses. Edenite occurs in metamorphic terrains and particularly in marbles, as in the Grenville series of New York

and Ontario. Noteworthy localities: *edenite* is found as brown crystals(!) to 8 cm long at Amity, and at *Edenville, Orange Co., NY*; Mn-rich with braunite in Grenville marble at the Arnold open pit, Fowler, St. Lawrence Co., NY; fibrous material with tremolite and kaolinite at the Lowell shaft, Bisbee, Cochise Co., AZ; at Spanish Peaks, Plumas Co., CA. Found in Canada at Eganville and Wilberforce, ON, and fluorine-rich edenite at Mt. St.-Hilaire, PQ, Canada. Edenitic hornblende is associated with jadeite at Kotaki, Niigata Pref., Japan. *Ferroedenite* is found at *La Tabatiere, PQ, Canada*, and in the Tibchi ring complex Nigeria. AR *DHZI 2:263(1963)*, CM *21:81(1983)*, *23:447(1988)*, AM *76:1431(1991)*.

66.1.3a.12 Pargasite $\text{NaCa}_2(\text{Mg}, \text{Fe}^{2+})_4\text{Al}[\text{Al}_2\text{Si}_6\text{O}_{22}](\text{OH})_2$

66.1.3a.13 Ferropargasite $\text{NaCa}_2(\text{Fe}^{2+}, \text{Mg})_4\text{Al}[\text{Al}_2\text{Si}_6\text{O}_{22}](\text{OH})_2$

66.1.3a.14 Magnesiohastingsite $\text{NaCa}_2(\text{Mg}, \text{Fe}^{2+})_4\text{Fe}^{3+}[\text{Al}_2\text{Si}_6\text{O}_{22}](\text{OH})_2$

66.1.3a.15 Hastingsite $\text{NaCa}_2(\text{Fe}^{2+}, \text{Mg})_4\text{Fe}^{3+}[\text{Al}_2\text{Si}_6\text{O}_{22}](\text{OH})_2$

Pargasite named in 1814 by Steinheil, hastingsite named in 1896 by Adams and Harrington, both for their localities; ferropargasite named in 1961 by Wilkinson, magnesiohastingsite named in 1928 by Billings. Amphibole group, tremolite subgroup. Currently defined nomenclature does not always agree with the original compositional descriptions; thus ferrohastingsite is equivalent to current hastingsite, and the name *hastingsite* has been used for intermediate compositions between the current pargasite and hastingsite. MON *C2/m*. $a = 9.805\text{--}9.967$, $b = 17.96\text{--}18.269$, $c = 5.302\text{--}5.347$, $\beta = 104.93\text{--}105.27^\circ$, $Z = 2$, $D = 3.18\text{--}3.54$; the lattice constants and density increase with both ferrous and ferric iron increase. *41-1430*(syn pargasite): 8.42₅ 3.36₇ 3.27₇ 3.13₁₀ 2.92₇ 2.69₇ 2.54₅ 2.34₅; *39-373*(potassian parg.): 8.47₆ 3.38₁ 3.28₃ 3.14₁₀ 2.95₁ 2.82₄ 2.39₂ 2.35₁; *26-1327*(syn Fe-parg.): 8.5₁₀ 3.40₃ 3.30₂ 3.15₈ 2.72₆ 2.61₄ 2.57₄ 2.36₃; *20-469*(hastingsite): 8.43₁₀ 3.39₅ 3.28₅ 3.13₇ 2.95₄ 2.71₆ 2.59₅ 2.56₅; *20-378*(K-, Cl-hast.): 8.52₁₀ 3.32₃ 3.16₆ 2.98₃ 2.75₃ 2.59₄ 2.37₃ 2.20₄. Structure: *EJM 3:485(1991)*. Habit: Usually as massive, bladed to fibrous cleavable masses. When well crystallized, the dominant forms are {100}, {110}, {011}, {010}. Physical properties: Light brown, brown, greenish brown to dark green and black; pale gray-green streak to brownish green in darker examples; vitreous luster. Cleavage {110}, perfect; parting on {100}, {001}; subconchoidal to splintery fracture; brittle. $H = 5\text{--}6$. $G = 3.07\text{--}3.50$. Optics: Biaxial (+, -); $2V_x = 120\text{--}0^\circ$; $N_x = 1.613\text{--}1.705$, $N_y = 1.618\text{--}1.731$, $N_z = 1.635\text{--}1.732$; $Y = b$, $Z \wedge c = 11\text{--}32^\circ$. Pleochroic. X, colorless to yellow-green; Y, light brown to green to deep greenish blue or olive-green; Z, light brown to bluish green to olive-green or smoky blue-green. Optical properties for series members, supported by selected chemical analyses, are: pargasite: biaxial (+, -); $2V_x = 120\text{--}75^\circ$; $N_x = 1.613\text{--}1.662$, $N_y = 1.618\text{--}1.673$, $N_z = 1.635\text{--}1.678$; $Z \wedge c = 13\text{--}26^\circ$; $r > v$, weak; ferroparga-

site: biaxial (-); $2V = 60-50^\circ$; $N_x = 1.669-1.697$, $N_y = 1.686-1.713$, $N_z = 1.691-1.723$; $Z \wedge c = 14-25^\circ$; magnesiohastingsite: biaxial (-); $2V = 78-68^\circ$; $N_x = 1.652-1.675$, $N_y = 1.664-1.688$, $N_z = 1.675-1.694$; $Z \wedge c \approx 30^\circ$; hastingsite: biaxial (-); $2V = 55-0^\circ$; $N_x = 1.690-1.702$, $N_y = 1.702-1.713$, $N_z = 1.705-1.730$; $Z \wedge c = 11-15^\circ$. Most pargasites are distinguishable from most other amphiboles, except cummingtonite and some ortho-amphiboles, in that they are biaxial (+), but Fe-rich pargasites are biaxial (-). **Chemistry:** Naturally occurring examples cover almost the entire compositional spectrum of the series. Mn rarely exceeds 0.5 atom per formula unit; and Ti rarely over 0.2 atom per formula unit; Pb may be present in significant amounts in the B position; K is almost always present in the A position, and K-dominant pargasite has been reported but not submitted to the IMA names committee; F is almost always present, and in type pargasite exceeds the (OH) content. **Occurrence:** Members of this series are found worldwide in a diversity of metamorphic environments and igneous rocks. **Localities:** Localities are given only for well-crystallized specimens or chemically documented examples of the varied types of occurrence. *Pargasite* has been found in hornblende-gabbro at Burlington, PA; sharp, well-terminated, brown crystals to 8 cm(!) in calcite in massive pargasite at the Jensen quarry, Riverside Co., CA; lustrous black crystals have been found near Wolfe Lake, Bedford Twp., ON, Canada; in metamorphosed limestone in the *Pargas valley, Finland*; in amphibole-rich inclusion in the Tiree marble, Tiree, Argyllshire, Scotland; in eclogite from Sau Alpe, Carinthia, Austria; with tridymite and cristobalite in druses in augite-hypersthene dacite at Ishikani-yama, Kamamoto Pref., Japan; and in an amphibole-rich layer in peridotite from Tinaquillo, Venezuela. Potassium-dominant pargasite has been reported from Einstödingen, Lützow-Holm Bay, Antarctica. *Ferropargasite* occurs in diorite porphyry in the Mt. Ellen complex, Henry Mts., Garfield Co., UT; in sodalite-syenite from Square Butte, Highwood Mts., MT; in granite from Rubideaux Mt., near Riverside, CA; and in biotite-epidote-hornblende schist at Mituisi(?), Japan. *Magnesiohastingsite* has been found in a xenolith in diorite porphyry in the Mt. Hilliers complex, Henry Mts., Garfield Co., UT; both plumbian and normal in skarns at Langban, Sweden. *Hastingsite* has been noted from hornblende granite gneiss in the Stark complex, Degrasse, Adirondack Mts., NY; in a vug in monzonite at Beaver Creek, MT (near magnesiohastingsite); in schist from Bidwell Bar; Clipper Hills quadrangle, CA; in metagabbro in *Dungannon Twp., Hastings Co., ON, Canada*, but some analyzed material from the area falls in the pargasite field; in granite at Tysfjord, Norway; in nepheline syenite from Almunge, Sweden; in rapakivi granite at Uuksonjoki, Salmi, Finland (near end member); in granite gneiss from the Goubensky massif, southern Ural Mts., Russia; and with hedenbergite, andradite, and vesuvianite at the Obira mine, Oita Pref., Kyushu, Japan. AR *DHZI* 2:264(1963); *AJS* 264:698(1966); *MM* 41:43(1977), 49:703(1985); *MR* 13:73(1982), 15:279(1984); *AM* 74:1097(1989).

66.1.3a.16 Magnesiosadanagaite $(K,Na)Ca_2(Mg,Fe^{2+},Al,Ti)_5 [(Si,Al)_8O_{22}](OH)_2$

66.1.3a.17 Sadanagaite $(K,Na)Ca_2(Fe^{2+},Mg,Al,Ti)_5 [(Si,Al)_8O_{22}](OH)_2$

Named (both) in 1984 by Shimazaki et al. for Ryoichi Sadanaga (b.1920), professor emeritus, University of Tokyo. Amphibole group, tremolite subgroup. MON $C2/m$ ($C2, Cm$). $a = 9.922-10.00$, $b = 18.01-18.06$, $c = 5.352-5.355$, $\beta = 105.30-105.55^\circ$, $Z = 2$, $D = 3.27-3.30$. $31-359$ (Mg-sad.): 7.48_{10} 3.39_4 3.28_{10} 3.15_7 2.95_5 2.77_4 2.71_6 2.16_5 . Dark brown to black, very light brown streak, vitreous luster, transparent in thin section. Cleavage $\{110\}$, perfect. $H \approx 6$. Biaxial (+); $2V_{obs} = 80-90^\circ$; $N_x = 1.673-1.674$, $N_y = 1.684-1.686$, $N_z = 1.697-1.699$; $Y = b$, $Z \wedge c = 26-28^\circ$. Pleochroic. X, colorless to pale brown; Z, brownish yellow to greenish brown. (It is noted that the higher reported indices are stated to be for magnesiosadanagaite, the Mg-richer sample.) Markedly silica deficient; the original five published analyses are all close to the midpoint of the series with $Mg/Fe^{2+} = 0.76-1.34$. *Magnesiosadanagaite* in lenses with titanian diopside (fassaite), and a similar mineral suite at *Myojin Island, Ehime Pref., Japan*. *Sadanagaite* found as grains in banded skarns and lenses in recrystallized limestones, associated with vesuvianite, spinel-hercynite, sphene, ilmenite, titanian diopside, perovskite, and apatite at *Yuge Island*, and in the Nōgō Hakusan area, Fukui Pref., Japan. AR *AM* 69:465(1984), *MM* 53:99(1989).

66.1.3a.18 Kaersutite $NaCa_2(Mg,Fe^{2+})_4Ti[Al_2Si_6O_{22}](OH)_2$

66.1.3a.19 Ferrokaersutite $NaCa_2(Fe^{2+},Mg)_4Ti[Al_2Si_6O_{22}](OH)_2$

Named in 1884 by Lorenzen for the locality. Amphibole group, tremolite subgroup. Kaersutites are usually (OH) deficient and so may be regarded as "oxyhornblendes." MON $C2/m$. $a = 9.89$, $b = 19.06$, $c = 5.315$, $\beta = 105.4^\circ$, $Z = 2$, $D = 2.94$. $17-478$: 8.38_6 3.36_6 3.26_5 3.11_8 2.93_5 2.69_{10} 2.59_5 2.55_7 . Structure: *NJMM*:137(1989). Crystals are usually short prismatic with $\{110\}$ dominant; usually as embedded euhedral to anhedral grains. Twinning on $\{100\}$ common. Dark brown to black, pale brownish gray streak, vitreous to slightly resinous luster, translucent to nearly opaque. Cleavage $\{110\}$, perfect; parting on $\{100\}$ and $\{001\}$; uneven to subconchoidal fracture. $H = 5-6$. $G = 3.2-3.3$. Biaxial (-); $2V = 66-82^\circ$; $N_x = 1.670-1.689$, $N_y = 1.690-1.741$, $N_z = 1.700-1.772$; $Y = b$, $Z \wedge c = 0-19^\circ$; $r > v$; pleochroic, $Z \geq Y > X$; pale yellow to dark reddish brown. The refractive indices and pleochroism are similar to low Ti, (OH)-deficient hornblendes. Natural occurrences of ferrokaersutites have not been documented. Titanium is an essential component, usually 0.4-1.1 atoms per formula unit; Fe^{3+} is usually low and rarely exceeds 1.0 atom per formula unit; potassium may be present in the A position; fluorine may replace hydroxyl, which is often less than 1 per formula unit. Occurs predominantly in volcanic rocks and is an abundant component of camptonites. *Kaerutite* is found as phenocrysts to 10 cm in diameter in camp-

tonite dikes near Boulder Dam, and in alkali-basalt on the San Carlos Reservation, AZ; in the Ice River Complex, Ottertail Range, BC, Canada; at *Qaersut*, *Umanq district*, *northern Greenland*; in hornblende monchiquite at Wart Holm, Copinshay, Orkney Is.; as megacrysts in rocks of the Shama volcanic field, northeastern Jordan; in monzonite at Tyaki, Morotu, Sakhalin, Russia; in a basaltic dike at Tikashi, Dōgo, Oki Is., and numerous other volcanics of Japan; as crystals at Yohodo (?), Korea; in trachybasalt at Dunedin district, New Zealand. *Ferrokaersutite* is reported from Koraput, Orissa, India. AR *DHZI* 2:321(1963), *MM* 39:390(1973).

66.1.3b.1 (Alumino)winchite $\text{CaNa}(\text{Mg}, \text{Fe}^{2+})_4\text{Al}[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.3b.2 Ferro(alumino)winchite $\text{CaNa}(\text{Fe}^{2+}, \text{Mg})_4\text{Al}[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.3b.3 Ferriwinchite $\text{CaNa}(\text{Mg}, \text{Fe}^{2+})_4\text{Fe}^{3+}[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.3b.4 Ferroferriwinchite $\text{CaNa}(\text{Fe}^{2+}, \text{Mg})_4\text{Fe}^{3+}[\text{Si}_8\text{O}_{22}](\text{OH})_2$

Named in 1906 by Fermor for Howard J. Winch, Geological Survey of India, its discoverer. Amphibole group, richterite subgroup. *MON* *C2/m*. $a = 9.834$, $b = 18.062$, $c = 5.300$, $\beta = 104.4^\circ$, $Z = 2$, $D = 2.96$. *20-1390*: 8.40₉ 4.48₇ 3.40₇ 3.12₅ 2.98₄ 2.70₁₀ 2.58₃ 2.53₉; *35-460*(potassian): 8.46₄ 3.28₈ 3.16₁₀ 2.96₄ 2.34₄ 1.916₅ 1.660₄ 1.448₅. Cobalt blue to blue-violet, pale blue-gray streak, vitreous luster, translucent. Cleavage {110}, perfect. $H = 5\frac{1}{2}$. $G = 2.97$. Biaxial (+); $2V = 82^\circ$; $N_x = 1.636$, $N_y = 1.646$, $N_z = 1.658$ (ferriwinchite); also biaxial (-); $2V = 77^\circ$; $N_x = 1.612$, $N_y = 1.623$, $N_z = 1.627$ (richterite/ferriwinchite); $Y = b$, $Z \wedge c = 18-20^\circ$; pleochroism varied with $Y > Z > X$ or, less commonly, $Z > Y > X$. Considerably lower indices, $N_x = 1.576-1.596$ and $N_z = 1.590-1.600$, have been reported for fluorine- and potassium-rich asbestiform material from Texas. Published analyses show $\text{Fe}^{3+} > \text{Al}^{6+}$, suggesting that ferririchterite may be the more common member of the series. Sodium is often relatively low within the defined range of the richterite subgroup. Manganese is commonly present up to 0.5 atom per formula unit. Later analyses of material from the type locality yield diverse results, in part ferriwinchite and in part magnesioarfvedsonite; possibly both coexist and thus suggest a miscibility gap. Occurs as prismatic crystals, blades, radiating aggregates, fibrous, and asbestiform. Asbestos from the Diablo prospect, Allammoore talc district, TX, lies in the K-richterite to K-winchite range; at ward creek, Cazadero, Sonoma Co., CA. Light blue, low-sodium richterite from Langban, Sweden, is similar to winchite-ferriwinchite. Originally found in manganese deposits at *Kajlidongri*, *Jhabua*, *Madhya Pradesh*, *India*, where amphiboles in the ferriwinchite-magnesioarfvedsonite-magnesioriebeckite appear to coexist; in granite gneiss and pegmatite (near ferribarroisite) at Chakli, Bhandara, Maharashtra, India, probably formed through incorporation of Mn from local ore deposits. A "soda tremolite" found in altered pyroxenite at Libby, MT, is intermediate between richterite and ferriwinchite. AR *MM*

14:413(1907), 40:395(1975), 50:173(1986); *DHZI* 2:352(1963); *CM* 18:101(1980).

66.1.3b.5 (Alumino)barroisite $\text{CaNa}(\text{Mg}, \text{Fe}^{2+})_3\text{Al}_2[\text{AlSi}_7\text{O}_{22}](\text{OH})_2$

66.1.3b.6 Ferro(alumino)barroisite $\text{CaNa}(\text{Fe}^{2+}, \text{Mg})_3\text{Al}_2[\text{AlSi}_7\text{O}_{22}](\text{OH})_2$

66.1.3b.7 Ferribarroisite $\text{CaNa}(\text{Mg}, \text{Fe}^{2+})_3\text{Fe}_2^{3+}[\text{AlSi}_6\text{O}_{22}](\text{OH})_2$

66.1.3b.8 Ferroferribarroisite $\text{CaNa}(\text{Fe}^{2+}, \text{Mg})_3\text{Fe}_2^{3+}[\text{AlSi}_7\text{O}_{22}](\text{OH})_2$

Named in 1922 by Murgoci with no mention of etymology, and described as intermediate between hornblende and glaucophane. Amphibole group, richterite subgroup. Allegedly synonymous with carinthine, from the locality, a term introduced by Werner in 1817. *MON C2/m*. $a = 9.90$, $b = 18.04$, $c = 5.33$, $\beta = 106.7^\circ$, $Z = 2$, $D = 3.16$. Structure: *TMPM* 6:215(1957). Blue-green, green; translucent. $G = 3.21$. Biaxial (-); $2V$ variable but small; also uniaxial (-); $Z \wedge c = 12-15^\circ$. Pleochroic; c , blue-green; b , blue to violet; a , gray-green (*Sic*). Natural occurrences falling within the current boundaries of this series are not supported by adequate chemical or physical data. *Barroisite* reported from Riffel Alp, Zermatt, Switzerland; uniaxial, from the Taunus Mts., Germany; carinthine from Sau Alpe, Carinthia, Austria. *Ferribarroisite* found at Condrey Mt., Klamath Mtns, Del Norte Co., CA; at Cauro-Bastelica, Corsica; and in the Iskou ring Complex, Air, Nigeria, close to ferribarroisite. *AR CR* 175:373,426(1922).

66.1.3b.9 Richterite $\text{Na}(\text{CaNa})(\text{Mg}, \text{Fe}^{2+})_5[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.3b.10 Ferrorichterite $\text{Na}(\text{CaNa})(\text{Fe}^{2+}, \text{Mg})_5[\text{Si}_8\text{O}_{22}](\text{OH})_2$

Richterite named in 1865 by Breithaupt for Theodor Richter (1824–1898), German mineralogist. The name *ferrorichterite* was coined in 1946 (Sundius). Amphibole group, richterite subgroup. *MON C2/m*. Richterite: $a = 9.902$, $b = 17.980$, $c = 5.269$, $\beta = 104.22^\circ$, $Z = 2$, $D = 2.87$; 25-808(syn, calc): 8.47₅ 3.39₇ 3.28₆ 3.15₆ 2.96₅ 2.71₁₀ 2.58₄ 2.53₇; 31-1082(potassian): 8.56₈ 3.39₅ 3.30₈ 3.18₁₀ 2.85₇ 2.59₄ 1.927₅ 1.663₃; ferrorichterite: $a = 9.982$, $b = 18.223$, $c = 5.298$, $\beta = 103.73^\circ$, $Z = 2$, $D = 3.46$; 26-1373(syn): 8.58₁₀ 3.43₄ 3.32₃ 3.18₇ 3.00₃ 2.74₇ 2.62₄ 2.54₅. Structure: *EJM* 4:425(1992). In ferrian richterites there are apparent vacancies in the C position, total cations being as low as 4 rather than 5. Prismatic {001}, often flattened {100} with dominant {110}, {100}, when terminated {011} and {101} are prominent; commonly in cleavable prismatic to fibrous aggregates, or as rock-bound prisms. Twinning on (100). Brown, yellow, brownish red, rose-red, pale to dark green, gray-brown; vitreous luster; transparent to translucent. Cleavage {110}, perfect; parting on {100} and {001}; uneven fracture; brittle. $H = 5-6$. $G = 2.97-3.45$. Biaxial (-); $2V = 66-87^\circ$; for Mg-rich richterites $N_x = 1.605-1.624$,

$N_y = 1.615\text{--}1.631$, $N_z = 1.622\text{--}1.641$; $Y = b$, $Z \wedge c = 15\text{--}40^\circ$; $r < v$; pleochroic; variable absorption, usually $Z > Y > X$. X , colorless, yellow to pale green or pinkish lilac; Y , pale yellow, orange, reddish, blue, pale lilac or green; Z , colorless, yellow-green, blue-green, to violet-brown. The deeper colors appear with increasing iron; for ferrian richterite indices reach $N_x = 1.685$, $N_y = 1.700$, $N_z = 1.712$, and absorption $Z > Y > X$. Magnesium-rich richterites are common, but natural occurrences of ferrichterite are not documented, although it has been synthesized. Manganese is often present, up to 1 atom per formula unit. Fluorine commonly replaces (OH), and the total of these is often significantly less than 2. In ferrian richterites the substitution of $\text{Fe}_2^{3+}\square$ for Mg_3 appears to take place. Many richterites are intermediate toward ferriwinchite, ferribarroisite, or magnesioarfvedsonite. Magnesium-rich richterites have a paragenesis similar to that of tremolite and pargasite, and occur in thermally metamorphosed limestones; also found in skarns associated with iron-manganese deposits; in carbonate veins in pyroxenites; potassium-rich richterites are found in leucite rocks, often displaying a poikilitic texture enclosing diopside and leucite. *Richterite*, intermediate with magnesioarfvedsonite, is a typical amphibole of the alkaline complex at Iron Hill, Gunnison Co., CO; in ordenite of the Leucite Hills, WY; in altered pyroxenite at Libby, MT. Fine fluorine-rich, gray-brown to nearly black crystals(!) in calcite at the Earle Farm, Wilberforce, and at Tory Hill, ON, and as small, transparent, light green crystals in breccia vugs at Mt. St.-Hilaire, PQ, Canada. In the manganese ores of *Långban and Pajsberg, Värmland, Sweden*; potassian at Murcia, Spain; in jadeite rock at Sanka, Myanmar; ferrian richterite occurs in pegmatite at Chakli, Bhandara, Maharashtra, India; potassian richterite in leucite lamproite in the West Kimberley area, WA, Australia; at Imeria, Madagascar. *Ferrichterite* found at La Tabatiere, PQ, Canada. AR *DHZI* 2:352(1963); *AM* 59:518(1974); *MR* 13:73(1982), 21:383(1990).

66.1.3b.11 Magnesio(alumino)katophorite $\text{Na}(\text{CaNa})(\text{Mg},\text{Fe}^{2+})_4\text{Al}[\text{AlSi}_7\text{O}_{22}](\text{OH})_2$

66.1.3b.12 (Alumino)katophorite $\text{Na}(\text{CaNa})(\text{Fe}^{2+},\text{Mg})_4\text{Al}[\text{AlSi}_7\text{O}_{22}](\text{OH})_2$

66.1.3b.13 Magnesioferrikatophorite $\text{Na}(\text{CaNa})\text{Mg},\text{Fe}^{2+})_4\text{Fe}^{3+}[\text{AlSi}_7\text{O}_{22}](\text{OH})_2$

66.1.3b.14 Ferrikatophorite $\text{Na}(\text{CaNa})(\text{Fe}^{2+},\text{Mg})_4\text{Fe}^{3+}[\text{AlSi}_7\text{O}_{22}](\text{OH})_2$

Named in 1894 by Brøgger from the Greek for *carrying down*, in allusion to its volcanic origin. Amphibole group, richterite subgroup. Originally cataphorite, and defined as intermediate between ferrohornblende and arfvedsonite. *MON C2/m*. $Z = 2$. Cell constants and powder X-ray diffraction data not available for chemically verified members of the series. Rose-red, dark red-brown, to

bluish back; pale tan to gray streak; translucent. Cleavage {110}, perfect; {010}, parting. $H = 5$. $G = 3.2-3.5$. Biaxial (-); $2V = 0-50^\circ$; $N_x = 1.640-1.681$, $N_y = 1.658-1.688$, $N_z = 1.660-1.692$; $X \wedge c = 30-70^\circ$; $r < v$ strong for magnesioferrikatophorite with $Y = b$, $r > v$ strong for ferrikatophorite with $Z = b$, but the exact composition at which the orientation changes is uncertain. Strongly pleochroic; $Z < Y > X$, X, yellow to light brown; Y, greenish brown to deep brown; Z, orange to greenish brown for magnesioferrikatophorite; pleochroism strong with $Z > Y > X$ in the range pale yellow through blue-green to nearly black for ferrikatophorite. The optical properties are similar to those of the eckermannite-arfvedsonite series, but extinction angles are generally larger; pleochroism in brown tones may be confused with ferrohornblende, oxyhornblende, and kaersutite. Natural occurrences of aluminokatophorites have not been observed. Katophorites are found in more basic alkaline rocks; in metamorphic environments arfvedsonite-riekbeckite are favored over katophorites. *Magnesiokatophorite* found in thealite in the Shields River basin, MT where it forms rims on aegirine and is the last ferromagnesian mineral to crystallize; at Khibiny, Kola Peninsula, Russia; at Imeria, Madagascar. *Katophorite* is found at La Tabatiere, PQ, Canada; in the *Christiania region*, Norway; the Rallier-du-Baty Peninsula, Kerguelen Is., Indian Ocean; and reported from Tawmaw, Kachin, Myanmar. *Ferrikatophorite* (actually nearer ferritaramite in composition) at Mariupol, Ukraine; in many phonolites and some trachytes of the Rungwe volcanics, Lake Nyasa, Tanzania; it is the most abundant ferromagnesian mineral in katophorite trachyte of Lake Naivasha, Kenya. AR D6 App1:14(1914), DHZI 2:359(1963).

66.1.3b.15 Magnesio(alumino)taramite $\text{Na}(\text{CaNa})(\text{Mg}, \text{Fe}^{2+})_3\text{Al}_2$
 $[\text{Al}_2\text{Si}_6\text{O}_{22}](\text{OH})_2$

66.1.3b.16 (Alumino)taramite $\text{Na}(\text{CaNa})(\text{Fe}^{2+}, \text{Mg})_4\text{Al}_2[\text{Al}_2\text{Si}_6\text{O}_{22}]$
 $(\text{OH})_2$

66.1.3b.17 Magnesioferritaramite $\text{Na}(\text{CaNa})(\text{Mg}, \text{Fe}^{2+})_3\text{Fe}_2^{2+}$
 $[\text{Al}_2\text{Si}_6\text{O}_{22}](\text{OH})_2$

66.1.3b.18 Ferritaramite $\text{Na}(\text{CaNa})(\text{Fe}^{2+}, \text{Mg})_3\text{Fe}_2^{2+}[\text{Al}_2\text{Si}_6\text{O}_{22}]$
 $(\text{OH})_2$

Named in 1923 by Morozewicz for the locality. Amphibole group, richterite subgroup. MON $C2/m$. $a = 9.923$, $b = 18.134$, $c = 5.352$, $\beta = 104.8^\circ$, $Z = 2$, $D = 3.47$ (ferritaramite). 20-734(potassian): 8.53₇ 3.29₃ 3.15₁₀ 2.73₅ 2.61₃ 2.35₃ 2.18₃ 1.44₇. Structure: CM 16:53(1978). Blue-green, translucent. Cleavage {110}, perfect; subconchoidal fracture. $H = 5-6$. Biaxial (-); $Y = b$, $Z \wedge c = 11^\circ$; $N_x = 1.684-1.705$, $N_y = 1.700-1.713$, $N_z = 1.703-1.715$; $2V = 46-54^\circ$; pleochroic. X, yellow to greenish yellow; Y, violet-gray to blue-green; Z, blue. Indices are for potassian taramite; type material is actually ferritaramite and close to ferrikatophorite; small amounts of Mn may be

present; fluorine replacement of (OH) may be significant. Occurs as rock-bound, subhedral to euhedral crystals in nepheline syenite. *Magnesiotalamite* has been found in the Nybo eclogite pod at Nordfjord, Norway. *Taramite* (near ferritaramite) in nepheline syenite at *Wali-tarama, Mariupol, Ukraine*; at the Darkainle nepheline-syenite complex, Borama district, Somalia; *potassium ferritaramite* in foyaite dike cutting nepheline-bearing gneiss at Mbozii, Tanzania, and the York Ruver area, Bancroft, ON, Canada. AR *MM* 33:1057(1964).

66.1.3c.1 Glaucophane $\text{Na}_2\text{Mg}_3\text{Al}_2[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.3c.2 Ferroglaucophane $\text{Na}_2\text{Fe}_3^{2+}\text{Al}_2[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.3c.3 Crossite $\text{Na}_2(\text{Mg},\text{Fe}^{2+})_3(\text{Al},\text{Fe}^{3+})_2[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.3c.4 Magnesioriebeckite $\text{Na}_2\text{Mg}_3\text{Fe}_2^{3+}[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.3c.5 Riebeckite $\text{Na}_2\text{Fe}_3^{2+}\text{Fe}_2^{3+}[\text{Si}_8\text{O}_{22}](\text{OH})_2$

Glaucophane named in 1845 by Hausmann from the Greek for *blue* and *to appear*, in allusion to its color; ferroglaucophane and magnesioriebeckite introduced in 1957 by Miyashiro; crossite named in 1894 by Palache for Charles Whitman Cross (1854–1949), geologist, U.S. Geological Survey; riebeckite named in 1888 by Sauer for Emil Riebeck (1853–1885), German explorer. Amphibole group, glaucophane subgroup. Possible polymorphism of glaucophane has been suggested. *MON* *C2/m*. *Z* = 2. Glaucophane: *a* = 9.531, *b* = 17.759, *c* = 5.303, β = 103.59°, *D* = 3.13; *20-453*: 8.26₁₀ 4.45₃ 3.38₃ 3.22₂ 3.06₇ 2.94₃ 2.69₆ 2.52₃; ferroglaucophane: *a* = 9.587, *b* = 17.832, *c* = 5.315, β = 103.47°, *D* = 3.224; *31-1307*: 8.31₁₀ 4.47₂ 3.23₂ 3.06₈ 2.95₁ 2.76₃ 2.70₃ 2.53₁; crossite: *a* = 9.647, *b* = 17.905, *c* = 5.316, β = 103.6°, *D* = 3.22; *20-376*: 8.95₁ 8.31₁₀ 4.87₂ 4.48₂ 3.40₂ 3.08₇ 2.71₄ 2.53₂; magnesioriebeckite: *a* = 9.700, *b* = 17.944, *c* = 5.273, β = 103.53°, *D* = 3.13; *20-656*: 8.45₁₀ 4.50₂ 3.27₃ 3.12₉ 2.89₆ 2.71₃ 2.54₁ 1.655₁; riebeckite: *a* = 9.811, *b* = 18.013, *c* = 5.326, β = 103.68°, *D* = 3.37; *19-1061*: 8.40₁₀ 4.51₂ 3.42₁ 3.27₁ 3.12₆ 2.80₂ 2.73₄ 2.18₂. Structure: *EJM* 3:485(1991). *Habit*: Crystals prismatic [001] to lathlike, often striated parallel to elongation; columnar, fibrous, granular, or massive. Simple and lamellar twinning on (100) common. Magnesioriebeckite and riebeckite may be asbestiform (crocidolite). *Physical properties*: Gray to lavender-blue (glaucophanes); light blue to blue-black (riebeckites); pale gray to bluish gray streak; vitreous luster, silky in asbestiform varieties; translucent to opaque. Cleavage {110}, good to perfect. *H* = 5–6 riebeckite possibly being the softer. *G* = 3.02–3.42. *Optics*: Glaucophane and crossite are Biaxial (-); *2V* = 0–50° decreasing with iron content; *N_x* = 1.606–1.661, *N_y* = 1.622–1.667, *N_z* = 1.627–1.670, birefringence = 0.008–0.022; *Y* = *b*, *Z* \wedge *c* = 4–14° (OAP parallel to (010)); *r* < *v* but also *r* > *v* in some crossite. Pleochroic; *Z* > *Y* > *X*, colorless to lavender-blue to blue, distinct and becoming more so with increasing iron content. Magnesioriebeckite and riebeckite

are Biaxial (-); $2V = 40-90^\circ$ increasing with iron content, less commonly Biaxial (+) with $2V$ large; $N_x = 1.654-1.701$, $N_y = 1.662-1.711$, $N_z = 1.668-1.717$; birefringence = $0.006-0.016$; $Z = b$, $X \wedge c = 3-21^\circ$ (OAP perpendicular to (010)); $r > v$ or $r < v$ strong with marked dispersion of the bisectrices leading frequently to anomalous interference colors. Pleochroism strong; $Z < Y < X$, X prussian blue to indigo and Z blue-grey to yellowish green. $1.606Z \wedge c = 4-14^\circ$ [OAP parallel to (010)]; $N_x = 1.606-1.661$, $N_y = 1.622-1.667$, $N_z = 1.627-1.670$; $2V = 0-50^\circ$ decreasing with iron content; birefringence = $0.008-0.022$; $r < v$ but also $r > v$ in some crossite; $Z > Y > X$; pleochroic from colorless to lavender-blue to blue, distinct and becoming more so with increasing iron content. Magnesioriebeckite and riebeckite are biaxial (-); $2V = 40-90^\circ$, increasing with iron content, less commonly biaxial (+) with $2V$ large, $Z = b$, $X \wedge c = 3-21^\circ$ [OAP perpendicular to (010)]; $N_x = 1.654-1.701$, $N_y = 1.662-1.711$, $N_z = 1.668-1.717$, birefringence = $0.006-0.016$, $r > v$ or $r < v$, strong with marked dispersion of the bisectrices leading frequently to anomalous interference colors; $Z < Y < X$; strongly pleochroic. X, prussian-blue to indigo; Z, blue-gray to yellowish green. The accompanying figure gives the refractive indices for this series. Asbestiform varieties usually have parallel extinction and are length-fast, distinct from other asbestiform amphiboles. **Chemistry:** Near-end-member glaucophanes do not appear to occur naturally, Fe^{2+} always being present in significant amounts, and Fe^{3+} substitution for Al generally paralleling Fe^{2+} substitution for Mg; ferroglaucophanes are all compositionally close to the glaucophane boundary. Increasing $Fe^{2+} + Fe^{3+}$ substitution leads to crossites, but few pass the midpoint between glaucophane and riebeckite. The entire range of magnesioriebeckite-riebeckite compositions is represented in

Figure A-4

Approximate refractive indices and optical orientation for the glaucophane-riebeckite series; after *CPM* 15:67(1967).

nature. Published analyses and the seemingly abrupt change in optical properties suggest a possible discontinuity between crossite and the riebeckite minerals, but this is not borne out in all occurrences. In some riebeckites the sum of B and C site occupancies is greater than 7; in others it is significantly less. Titanium is usually present as no more than 0.2 atom per formula unit, as is the case for manganese. Fluorine substitution is variable and the total of F and (OH) may be significantly less than 2 per formula unit. Asbestiform riebeckite, in part oxidized, may be partially or completely replaced by quartz with retention of the parallel fiber structure as bands of iron-rich impurities. **Occurrence:** Glaucophane and crossite occur only under the conditions of the glaucophane facies, the schists in which they occur presumably having been formed by metamorphism of sodium-rich rocks or by metasomatic addition of sodium. Commonly associated minerals in glaucophane assemblages are lawsonite, epidote, chlorite, stilpnomelane, jadeite, and almandine. In the Franciscan series of California, glaucophanic rocks are formed by retrograde metamorphism of eclogites as well as by recrystallization of sediments. Riebeckite is often of igneous origin, appearing in granites (riebeckite granites of northern Nigeria), syenites, and to a lesser extent in nepheline syenites; also in acid volcanics, particularly Na-rich rhyolites, where it may be associated with arfvedsonite and aegirine or aegerine-augite. Magnesioriebeckite forms as an authigenic mineral in the Green River formation of the western United States, where it occurs around detrital grains of brown hornblende and is associated with aegirine and shortite; and also in a low-temperature environment with opal in Permian clays of Kazakhstan. Asbestiform riebeckite (crocidolite) forms from ironstone formations with little or no addition of material under conditions of moderate temperature and pressure. **Localities:** Widespread throughout the world; only a sampling of well-documented localities follows. *Glaucophane* has been found at Iron Hill, Gunnison Co., CO; is abundant in the schists of the Coast Ranges of CA, particularly as long prisms at Laytonville; the North Cascades, WA; at Zermatt, Switzerland; at *Syra Island, Cyclades, Greece*. Found at Akuwara, Kanto Mts., Honshu; in the Kanto district, Tokushima Pref.; Horokanai, Ishikari Pref., Hokkaido; and elsewhere in Japan. Crossite occurs at *Berkeley, Alameda Co., CA*, and other areas of the Franciscan formation; also at the Dallas Gem Mine, San Benito Co., CA; at The Monument, Anglesey, Wales, and at Knockormal, Ayrshire, Scotland; in Japan at various localities as for glaucophane. *Magnesioriebeckite* occurs in the Green River formation of WY, CO, and UT; in granulite at Glen Lui, Aberdeenshire, Scotland; and at Huppu, Kanto Mts., Honshu, Japan; in *Japan*, but the exact area not specified. *Riebeckite* occurs near Quincy, Norfolk Co., MA; at Cumberland Hill, Providence, RI; St. Peters Dome, El Paso Co., CO; in crystals(!) in miarolitic cavities of the Golden Horn batholith, Okanogan Co., WA; at Narssarssuk, Greenland; in riebeckite felsite at Shetland, Scotland; and in riebeckite-aegirine granite in the Kigon Hills, Nigeria; on *Socotra Is. (Yemen), Indian Ocean*. *Crocidolite* (asbestiform riebeckite) occurs in Henan and other provinces of China; in dolerite and dolomite as long fibers (magnesioriebeckite) at Robertstown, SA, and in the Hammersley Range,

WA, Australia; in the Cape Asbestos Field, Griqualand West, South Africa(*), where it has been produced commercially on a large scale, and where occur also its silica replacements, cat's eye (blue) and tiger eye (golden brown); and at Cochabamba, Bolivia. Uses: Asbestiform varieties, principally riebeckite, marketed under the trade name Blue Asbestos, have been used extensively as a thermal insulation, although the application is diminishing due to the highly carcinogenic character of the fibers. Silica-replaced materials from South Africa have been popular lapidary materials, their natural colors grayish blue and golden brown; dyed or bleached material in straw-yellow, green, red, and other colors is readily available. AR *DHZI* 2:333(1963), *CMP* 15:67(1967), *CM* 16:187(1978), *MSARM* 9A:283(1981).

66.1.3c.6 Eckermannite $\text{Na}_3\text{Mg}_4\text{Al}[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.3c.7 Ferroeckermannite $\text{Na}_3\text{Fe}_4^{2+}\text{Al}[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.3c.8 Magnesioarfvedsonite $\text{Na}_3\text{Mg}_4\text{Fe}^{3+}[\text{Si}_8\text{O}_{22}](\text{OH})_2$

66.1.3c.9 Arfvedsonite $\text{Na}_3\text{Fe}_4^{2+}\text{Fe}^{3+}[\text{Si}_8\text{O}_{22}](\text{OH})_2$

Eckermannite named in 1942 by Adamson for Claes Walther Harry von Eckermann (1886–1969), Swedish petrologist; ferroeckermannite named in 1964 by Phillips and Layton; arfvedsonite named in 1923 by Brooke for Johan A. Arfvedson (1792–1841), Swedish chemist; magnesioarfvedsonite coined in 1957 by Miyashiro. Amphibole group, glaucophane subgroup. MON *C2/m*. $Z = 2$. Eckermannite: $a = 9.762$, $b = 17.892$, $c = 5.284$, $\beta = 103.17^\circ$, $D = 2.97$; *20-386*(syn): 8.35₄ 3.40₇ 3.25₇ 3.10₁₀ 2.97₅ 2.71₈ 2.50₆ 2.16₅; magnesioarfvedsonite: $a = 9.796$, $b = 17.932$, $c = 5.289$, $\beta = 104.99^\circ$, $D = 3.17$; *42-1369*: 8.49₆ 3.93₁ 3.39₁ 3.28₃ 3.15₁₀ 2.82₂ 2.71₂ 1.909₁; arfvedsonite: $a = 10.007$, $b = 18.077$, $c = 5.332$, $\beta = 104.10^\circ$, $D = 3.40$; *14-633*: 8.51₇ 3.42₅ 3.16₁₀ 2.73₈ 2.60₄ 2.55₃ 2.35₃ 2.19₄. Structure: *CM* 14:346(1976). Habit: Long prismatic [001] crystals, often tabular {010} or {100}, with poor to good terminations, {001} and {101}; prismatic aggregates. Crystals commonly deeply etched and striated [001]; bladed aggregates; sometimes fibrous. Twinning on (100) common. Physical properties: Blue-green (eckermannite) to greenish black, blue-black and black (arfvedsonite); pale to dark blue-gray streak; dull to vitreous luster, occasionally silky; translucent to opaque. Cleavage {110}, perfect; parting {010}; uneven fracture. $H = 5-6$. $G = 3.0-3.5$. Optics: Eckermannite is biaxial (-); $2V = 80-15^\circ$; $N_x = 1.612-1.638$, $N_y = 1.625-1.652$, $N_z = 1.630-1.654$; $Y = b$, $X \wedge c = 53-18^\circ$ [OAP parallel to (010)]; $r > v$, very strong; indices increasing while $2V$ and extinction decrease with increasing iron; $Z < Y < X$; pleochroic. X, bluish green; Z, pale yellow-green to nearly colorless. Arfvedsonite is biaxial (-); $2V = 0-50^\circ$; $N_x = 1.674-1.700$, $N_y = 1.679-1.709$, $N_z = 1.686-1.710$; $Z = b$, $X \wedge c = 0-30^\circ$ [OAP perpendicular to (010)]; $r < v$, very strong; pronounced anomalous extinction; pleochroic. X, variable absorption, usually $Z < Y < X$; blue-green to indigo; Y, gray-violet, blue to orange-yellow; Z, light yellow-green

to blue-gray. The relationships of optical properties of eckermannite–arfvedsonite to one another are similar to those of glaucophane–riebeckite, and the distinction between arfvedsonites and riebeckites may sometimes be difficult. The optical properties of magnesioarfvedsonite are intermediate to those given above, but OAP is usually perpendicular to (010). **Chemistry:** Ferroeckermannite has not been reported from natural systems, the substitution $\text{Fe}^{2+} \rightarrow \text{Mg}$ generally being accompanied by $\text{Fe}^{3+} \rightarrow \text{Al}^{[6]}$. The sum of Ca, Na, and K (normally, A and B site ions) frequently exceeds 3.0, and the total of C site ions is often significantly less than 5.0. Mn may reach ≈ 1.0 per formula unit. Fluorine substitution for (OH) is common, as is (OH) deficiency. Published analyses of members of this series are frequently intermediate with ferritaramite and members of the glaucophane–riebeckite series. **Occurrence:** Eckermannites are relatively rare, occurring in alkaline plutonic rocks and in soda-rich metamorphic environments (with jadeite). Arfvedsonites are characteristic components of alkaline plutonic rocks and their associated pegmatites. They occur in both quartz-bearing syenites and nepheline-syenites, generally forming late in their crystallization. Often associated with aegirine or aegirine–augite, the pyroxene and amphibole sometimes intergrown with their *c* axes common. They also occur as overgrowths on earlier formed hastingsites. **Localities:** *Eckermannite* occurs in a shear zone between granite and monzonite (asbestiform, soda asbestos) at Camp Albion, Boulder Co., CO; at *Norra Karr, Gränna, Sweden* (lithian); in jadeite rock at Tawmaw, Myanmar. *Magnesioarfvedsonite* occurs in the Green River formation of CO, WY, and UT; at Mt. St.-Hilaire, PQ, Canada; in shonkinite at Katzenbuckel, Odenwald, Germany; in syenite pegmatite at Mariupol, Ukraine (fluor-taramite); in albite-rich pegmatite at Lovozero, Kola Penin., Russia; and in Japan. *Arfvedsonite* occurs at Red Hill, near Moultonboro, NH; fluorine-rich arfvedsonite in pegmatite at Hurricane Mt., Carroll Co., NH; St. Peter's Dome, El Paso Co., CO; abundant as crystals(1) to 20 cm long in pegmatite dikes at Mt. St.-Hilaire, PQ, Canada; in pegmatites and related rocks at *Ilimaussaq* in crystals exceeding 20 cm, at Kangerdluarssuk, at Narssarssuk in coarse intergrown crystals in part altered to asbestiform riebeckite, and at *Tupersuatsiaat, Julianehaab district, Greenland*; in nepheline syenites and related rocks of the Langesundfjord district and Oslo region, Norway; in nepheline-syenite gneiss at Kiihtelysvaara, Finland; in nepheline-syenite at Urma-Waraka, Kola Peninsula, and in syenite at the Morotu River, Sakhalin, Russia; manganese arfvedsonite in the manganese deposits of Chikla, Bhandara, Maharashtra, India. **AR** *DHZI* 2:364(1963); **MR** 5:117(1974), 21:296(1990), **CM** 34:1011 and 1015(1996).

66.1.3c.10 Kozulite $\text{NaNa}_2\text{Mn}_4(\text{Fe}^{3+},\text{Al})[\text{Si}_5\text{O}_{22}](\text{OH})_2$

Named in 1969 by Nambu for Shukusuke Kozu (1880–1955), Japanese mineralogist, Tohoku University. Amphibole group, glaucophane subgroup. **MON** *C2/m*. $a = 9.914$, $b = 18.111$, $c = 5.308$, $\beta = 104.5^\circ$, $Z = 2$, $D = 3.36$. *25-850*: 8.51₁₀ 4.53₁ 3.40₁ 3.30₂ 3.15₆ 2.83₃ 2.72₁ 2.17₁. Structure: *AC(A)*

28:S71(1972). Reddish black, vitreous luster, transparent to translucent. Cleavage {110}, perfect. $H = 5$. $G = 3.30$. Biaxial (-); $2V = 35^\circ$; $N_x = 1.685$, $N_y = 1.717$, $N_z = 1.720$; $Y = b$, $Z \wedge c = 65^\circ$; $r > v$, weak. Pleochroic; X, yellow-brown; Y, reddish brown; Z, dark brown. Found as short prismatic to bladed crystals displaying {110}, {010}, and {011} in bedded manganese deposits in metamorphosed Cretaceous quartzite intruded by granodiorite at the *Tanahota mine, Iwate Pref., Japan*; from Woodsmine, 30 km north-northeast of Tamsworth, NSW, Australia. AR *AM 55:1815(1970)*.

66.1.3c.11 Nyböite $\text{NaNa}_2\text{Mg}_3\text{Al}_2[\text{AlSi}_7\text{O}_{22}](\text{OH})_2$

Named in 1981 by Ungaretti et al. for the locality. Amphibole group, glaucophane subgroup. MON $C2/m$. $a = 9.665$, $b = 17.752$, $c = 5.303$, $\beta = 104.11^\circ$, $Z = 2$, $D = 3.031$. Bluish, vitreous luster, translucent. Cleavage {110}, perfect; brittle. $H = 5-6$. Biaxial, indices not reported. Pleochroic; X, pale violet; Z, colorless. Found in eclogite environments, sometimes as porphyroblasts. Originally from the *Nybo pod, Nordfjord, Norway*; in eclogite from the Donghai area, Jiangsu Prov., China. AR *BM 104:400(1981)*, *EJM 4:171(1992)*.

66.1.3c.12 Leakeite $(\text{Na,K})\text{Na}_2(\text{Mg,Fe}^{3+},\text{Li,Mn}^{3+})_5$ $[(\text{Si,Al})_8\text{O}_{22}](\text{OH})_2$

Named in 1992 by Hawthorne et al. for Bernard Elgey Leake (b.1936), geologist, University of Glasgow, in recognition of his work on the chemistry of the amphiboles. Amphibole group, glaucophane subgroup. MON $C2/m$. $a = 9.822$, $b = 17.836$, $c = 5.286$, $\beta = 104.37^\circ$, $Z = 2$, $D = 3.107$. *PD*: 8.40₆ 4.46₁ 3.38₂ 3.25₂ 3.12₁₀ 2.80₅ 2.70₁ 1.431₁. Structure: *AM 77:1112(1992)*. Deep red, vitreous luster, translucent to transparent. Cleavage {110}, perfect. $H \approx 6$. $G = 3.11$. Biaxial (-); $2V = 59-71^\circ$; but reported indices compatible with biaxial (+); Na(D): $N_x = 1.667$, $N_y = 1.675$, $N_z = 1.691$; $Z = b$, $X \wedge c = +10^\circ$; $r < v$, strong; strongly pleochroic. $X \approx Y$, dark mauve to red; Z, light pink-red. Li substitution in C position is approximately 0.8; Fe^{3+} predominates over Mn^{3+} distinguishing it from kornite; some F substitutes for (OH). Occurs as prismatic grains associated with albite, braunite, and bixbyite in a dark red rock of semimetallic appearance in the metasediments of the *Kajlidongri manganese mine, Jhabua district, Madhya Pradesh, India*. AR *AM 78:733(1993)*.

66.1.3c.13 Kornite $(\text{Na,K})(\text{Na,Li})_2(\text{Mg,Mn}^{3+},\text{Fe}^{3+},\text{Li})_5$ $[\text{Si}_8\text{O}_{22}](\text{OH})_2$

Named in 1993 by Armbruster et al. for Hermann Korn (d.1946), German geologist who lived part of his life in South West Africa. Amphibole group, glaucophane subgroup. MON $P2_1/m$ or $P2/a$. $a = 9.94$, $b = 17.80$, $c = 5.302$, $\beta = 105.5^\circ$, $Z = 2$. *PD*: 8.89_M 8.43_M 5.08_M 4.44_M 3.26_S 3.13_S 2.81_S 2.55_S. The primitive lattice is based on weak reflections of the type (0k1) with k odd. Brownish lilac to dark red, vitreous luster, transparent. Biaxial (-,+); $2V_x = 88-92^\circ$; $N_x = 1.654$, $N_y = 1.675$, $N_z = 1.696$; $Y = b$, $Z \wedge c = 60-65^\circ$.

Pleochroic; X, pink; Y, dark red; Z, orange-red. Mn^{3+} is dominant over Fe^{3+} , distinguishing it, apart from the primitive lattice, from leakeite. Occurs as fine fibers with maximum length of 200 μm with hennomartinite, sugilite, and serandite–pectolite at the *Wessels mine, Kalahari manganese field, South Africa*. AR *SMPM* 73:349(1993).

**66.1.3c.14 Ungarettiite $NaNa_2(Mn_2^{2+}Mn_3^{3+})[Si_6O_{22}]O_2$
glaucophane subgroup**

Named in 1995 by Hawthorne et al. in honor of Luciano Ungaretti, Professor of Mineralogy, University of Pavia, Italy in recognition of his insights into the crystal chemistry of rock-forming minerals. MON *C2/m*. $a = 9.89$, $b = 18.04$, $c = 5.29$, $\beta = 104.6$, $Z = 2$, $D = 3.45$. *PD* 8.40₅ 4.48₅ 3.26₆ 2.99₄ 2.71₁₀ 2.59₄ 2.54₉ 2.17₃. Found as rock bound grains; extracted fragments show typical amphibole cleavage prism with irregular fracture terminations. Cherry red to very dark red, streak presumably red, vitreous luster; cleavage {110} perfect. $H \approx 6$. $G = 3.52$. Biaxial (-); $2V = 51^\circ_{obs}$, 57°_{calc} ; $N_x = 1.717$, $N_y = 1.780$, $N_z = 1.800$, $r < v$ distinct but difficult to observe due to color; $X \wedge a = -2^\circ$, $Y = b$, $Z \wedge c = 17^\circ$ in obtuse β . Pleochroic with X orange red, and $Y \approx Z$ very dark red. Near the end member composition, it is unusual in that the mid-size C cations are almost entirely manganese, and that it is an anhydrous amphibole. Found in massive silicate/Mn oxide rock associated with other Mn-bearing amphiboles (leakeite, manganian arfvedsonite, manganian katothorite), braunite, clinopyroxene, norrishite, and sometimes quartz at the *Hoskins mine, an abandoned Mn deposit, 3 km west of Grenfell, NSW, Australia*. AM 80:165(1995).

**66.1.3c.15 Fluor-ferro-leakeite $NaNa_2(Fe_2^{2+}Fe_3^{3+}Li)[Si_6O_{22}]F_2$
glaucophane subgroup**

Named in 1996 (Hawthorne et al.) for the composition and relationship to leakeite. MON *C2/m*. $a = 9.792$, $b = 17.938$, $c = 5.313$, $\beta = 103.87$, $Z = 2$, $D = 3.34$. *PD* 8.43₅ 4.48₅ 3.40₆ 3.12₃ 2.99₄ 2.71₁₀ 2.59₄ 2.54₉. Bluish-black to black; vitreous luster; cleavage {110} perfect, brittle; $H \approx 6$. $G = 3.37$. Biaxial (+); $2V = 87^\circ_{obs}$, 81°_{calc} for Na_D light; $N_x = 1.675$, $N_y = 1.683$, $N_z = 1.694$; $X \wedge c = 10^\circ$ in obtuse β , $Y = b$, $Z \wedge a = 4^\circ$ in obtuse β . Pleochroic with X very dark indigo blue, Y grey blue, and Z yellow green. X > Y > Z Potassium replaces sodium in the A position and significant Mg is present in the C positions, and (OH) replaces 30 at. % of the fluorine. Occurs as small (0.05–0.2 mm) irregular patches in the quenched groundmass as well as sparse elongate grains in peralkaline porphyry in the *Cañada Pinabete pluton, Questa, Taos Co., NM*; AM 81:226(1996).

66.1.4.1 Joesmithite $(Ca,Pb)Ca_2(Mg,Fe^{2+},Fe^{3+})_5[Be_2Si_6O_{22}](OH)_2$

Named in 1968 by Moore for Joseph Victor Smith (b.1928), professor of mineralogy, University of Chicago. MON *P2/a*. $a = 9.885$, $b = 17.875$, $c = 5.227$, $\beta = 105.67^\circ$, $Z = 2$, $D = 4.02$. *22-531*: 5.03₄ 3.70₅ 3.33₁₀ 2.90₅

2.74₅ 2.68₅ 2.56₆ 2.53₆. Structure: *MSASP 2:111(1969)*. The structure is distinct from other amphiboles in that Be is ordered into one of the four tetrahedral sites of the ribbon silicate unit, and that the A site is occupied entirely by divalent ions. Black to dark brown, pale brown streak, translucent. Cleavage {110}, perfect. $H = 5\frac{1}{2}$. $G = 3.83$. Biaxial (+); 2V large; $N_x = 1.747$, $N_y = 1.765$, $N_z = 1.78$. Pleochroic, $Y > X = Z$; olive-brown to brown. Insoluble in cold acids. Occurs as well-formed prismatic, {001}, crystals displaying {010}, {100}, {110} terminated by {011}, {112}, {113}, lining cavities in or enclosed by later calcite in a hematite-magnetite-schefferite skarn at the *Långban mine, near Filipstad, Varmland, Sweden*. *AR AM 54:577(1969)*.

66.1.5.1 Ershovite $\text{Na}_4\text{K}_3(\text{Fe,Mn,Ti})_2\text{Si}_8\text{O}_{20}(\text{OH})_4 \cdot 4\text{H}_2\text{O}$

Named in 1993 by Khomyakov et al. for Vadim Viktorovich Ershov (1939–1989), Professor and founder of the mineralogical museum at the Moscow Mining Institute, and a specialist in the area of applied geology and mining. TRIC. P1. $a = 10.244$, $b = 11.924$, $c = 5.276$, $\alpha = 103.49^\circ$, $\beta = 96.96^\circ$, $\gamma = 91.945^\circ$, $Z = 1$, $D = 2.73$; (nat.) 11.57₁₀ 3.39₂ 3.01₂ 2.99₃ 2.72₂ 2.60₃ 2.46₁ 2.16₁. Structure is related to amphibole-type (K 36:892(1991)). Olive green with a cinnamon, brownish and yellowish shading, transparent; elongate on c , 0.3–0.5 mm, aggregates to 1–3 cm, 0.1–1 × 2–3 to 3–5 × 10 mm; vitreous; excellent {100} and {010} cleavage; fibrous; $H = 2-3$; $G = 2.75$; IR data in ZVMO 122:116(1993); no UV response; readily soluble at 25°C in weak solutions of HCl, HNO₃, and H₂SO with preservation of the silicate skeleton, no change to 300°C, at 500°C is isotropic, and X-ray amorphous. SiO₂ 47.1, Na₂O 12.4, K₂O 13.6, CaO 0.1, MgO 0.5, MnO 4.7, FeO 6.1, TiO₂ 3.0, H₂O 12.5, = 100.0. Biaxial (+); 2V = 58°, 2V_{calc} = 59°; $N_x = 1.569$, $N_y = 1.574$, $N_z = 1.590$; strong pleochroism with X and Y = light green or yellow, and Z = dark olive green; angle between c and X = 86°, $Y \wedge c = 73^\circ$, $N_z = 17^\circ$, fibers have (+) elongation; absorption = Z > Y > X; disper. = moderate $r > v$. Occurs in pegmatite and pegmatitic rocks in Khibiny alkaline massif. Associated with rare alkaline minerals. Pegmatitic-hydrothermal origin. *EF Mt. Rasvumchorr and Mt. Koashva, Khibiny massif, Kola Peninsula, Russia*.

66.2.1.1 Plancheite $\text{Cu}_8(\text{Si}_4\text{O}_{11})_2(\text{OH})_4 \cdot x\text{H}_2\text{O}$

Named in 1908 by Lacroix for a Mr. Planche, who furnished the African material for study. ORTH *Pcnb*. $a = 19.043$, $b = 20.129$, $c = 5.269$, $Z = 4$, $D = 3.815$. 29-576: 10.1₁₀ 9.56₄ 6.94₇ 4.87₅ 4.06₈ 3.95₄ 3.57₃ 3.31₄. Structure: *AM 62:491(1977)*. The structure is similar to that of shattuckite (65.1.7.1) except that the chains joined to the six-coordinated copper sheets are amphibole-like. The water appears to be zeolitic with $x < 0.48$ for the structure-study material. Commonly fibrous [001]; compact radial aggregates. Pale to dark blue, silky luster. $H = 5$. $G = 3.4$. Biaxial (+); 2V = 57°; $N_x = 1.645$, $N_y = 1.660$, $N_z = 1.715$; $Z = c$. Pleochroic; Z, dark blue; X, pale blue. Indices of up to $N_x = 1.697$ and $N_z = 1.741$ have been reported, and probably reflect the variable water content. Found as an oxidation-zone mineral, as at the

Algomah mine, Ontanagon Co., MI; the Shattuck mine, Bisbee, Cochise Co.; at the Table Mt. mine with compact conichalcite, and elsewhere in Pinal Co.; and at the New Cornelia mine, Pima Co., AZ; in the Beaver Lake district, Beaver Co., UT; at Caldbeck Fells, Cumbria, and St. Austell, Cornwall, England; at the Kisanmori mine, Akita Pref., Japan. Found at *Mindouli, Renneville, Congo Republic*; at Tantara and Mindigi, near Kambove, Shaba, Zaire; at Tsumeb, Guchab, and Okatumba, Namibia. AR *BM 84:267(1961)*.

66.2.2.1 Vlasovite $\text{Na}_2\text{Zr}[\text{Si}_4\text{O}_{11}]$

Named in 1961 by Tikhonenkova and Kazakova for Kuzma Aleksevich Vlasov (1905–1964), Russian mineralogist and geochemist who studied the Lovozero massif. TRIC $P\bar{1}$ (<29°C). $a = 10.96$, $b = 10.01$, $c = 8.53$, $\alpha = 89.70^\circ$, $\beta = 100.40^\circ$, $\gamma = 90.48^\circ$, $Z = 4$, $D = 3.07$. MON $C2/c$ (>29°C). $a = 10.98$, $b = 10.00$, $c = 8.52$, $\beta = 100.40^\circ$. 39-208(syn, monoclinic): 5.44₄ 5.30₆ 5.06₇ 3.88₄ 3.67₅ 3.40₆ 3.24₁₀ 2.96₉. Structure: *DANES 141:1294(1961)*. The silicate element is a ribbon composed of four-tetrahedron rings linked by sharing an apical oxygen to form a ribbon of composition $[\text{Si}_4\text{O}_{11}]^{6-}$, distinct from the isostoichiometric amphibole ribbon. Colorless; greasy luster, vitreous to pearly on cleavage; transparent. Cleavage {010}, distinct; irregular fracture; brittle. H = 6. G = 2.97. Biaxial (-); $2V = 50-56^\circ$; $N_x = 1.607$, $N_y = 1.623$, $N_z = 1.628$; OAP parallel to (010); $r > v$, distinct. Nonfluorescent in UV, but altered material fluoresces bright orange. Up to 1.7 wt % HfO_2 is reported. Found in ejecta of peralkaline granite on Ascension Is. Large crystals (15 cm) in the Scheffield Lake complex, Villedieu Twp., PQ, Canada. Associated with feldspars, amphiboles, pyroxenes, eudialyte, apatite, and fluorite at contact of syenite pegmatite and fenite, at *Mt. Vavnbud, Lovozero massif, Kola Penin., Russia*, and in the Burpala massif, 120 km N of Lake Baikal. AR *AM 46:1202(1961)*, *MM 36:233(1967)*, *CM 12:211(1973)*.

66.3.1.1 Xonotlite $\text{Ca}_6[\text{Si}_6\text{O}_{17}](\text{OH})_2$

Named in 1866 by Rammelsberg for the type locality. Synonym: jurupaite. MON $P2/a$. $a = 17.03$, $b = 7.356$, $c = 7.007$, $\beta = 90.2^\circ$, $Z = 2$, $D = 2.705$. 29-379(calc): 7.04₆ 4.13₄ 3.56₆ 3.24₇ 3.05₁₀ 2.80₆ 2.68₅ 1.911₄. Structure: *ZK 154:271(1981)*. The silicate structural element is a ribbon of $W = 2$ and $P = 3$, formed by the condensation of two wollastonite chains sharing every third tetrahedron. Polytypes may exist. Habit is prismatic [010] with {100}, {001}, {011}, {011}, {010} prominent, but usually in compact fibrous masses. Twinned on {001}. Chalky white, colorless, pale pink, gray; dull, vitreous, or pearly luster; tough; transparent to translucent. Cleavage {001}, perfect. H = 5–6. G = 2.71. Biaxial (+); $2V$ small; $N_x = 1.583$, $N_y = 1.583$, $N_z = 1.594$; $Z = b$, OAP \approx (100); $r < v$, weak. Decomposed by acids with separation of silica. Principal occurrence is as veinlets in serpentine or in contact zones. Found at Franklin, Sussex Co., NJ; near Leesburg, Loudoun Co., VA; near Durham, NC; Isle Royale, MI; at the Christmas mine, Gila Co., AZ; and in Mendocino, Monterey, Riverside, San Francisco, and Santa

Barbara Cos., CA. Found at the Jeffrey mine, Asbestos, PQ, Canada; at Tetela de Ocampo, PUE, and *Tetela de Xonotla*, HGO, Mexico; near Yauco, Puerto Rico. At Broadford, Skye, Scotland, and at Scawt Hill, County Antrim, Northern Ireland. With kilchoanite in a xenolith in the Ozerskii gabbro, Priol'khonye, West Baikal region, Russia. As well-formed, 5- to 50- μ m crystals at Heguri, Chiba Pref., and at the Mihara mine, Okayama Pref., Japan. AR *AM* 10:12(1925), 38:860(1953); *BNSM* 1:61(1975).

66.3.1.2 Zorite $\text{Na}_6\text{Ti}_5[\text{Si}_{12}\text{O}_{34}](\text{O},\text{OH})_5 \cdot 11\text{H}_2\text{O}$

Named in 1973 by Merkov et al. from the Russian for *rosy tint of the dawn sky*. ORTH *Cmmm*. $a = 23.241$, $b = 7.238$, $c = 6.955$, $Z = 2$, $D = 2.23$. 25-1298: 11.6₈ 6.90₁₀ 3.38₈ 3.07₈ 2.98₈ 2.59₈ 1.752₈ 1.701₆. Structure: *SPC* 24:686(1979). Original description gives C^*c^* with c doubled. The silicate unit is a double chain formed by condensation of two wollastonite-like chains that are cross-linked by six-coordinated Ti to form a zeolite-like framework. The pair of wollastonitelike chains are related by a diad, as opposed to those in xonotlite, which are mirror related. Rose, vitreous luster. Cleavage {010}, {001}, perfect; {110}, good. $H = 3-4$. $G = 2.36$. Presumably biaxial. Pleochroic; X, rose; Y, colorless; Z, bluish. Found with aegirine, mountainite, and natrolite in nepheline-filled fractures and cavities in alkalic pegmatite, the same one in which ilmajokite and raite were found, in the *Jubilee pegmatite, Lovozero massif, Kola Penin., Russia*. AR *ZVMO* 102:54(1973), *AM* 58:1113(1973).

66.3.1.3 Eudidymite $\text{NaBeSi}_3\text{O}_7(\text{OH})$

Named in 1887 by Brogger from the Greek for *good* and *twin*, in allusion to its occurrence in twinned crystals. A dimorph of epididymite. MON *C2/c*. $a = 12.568-12.69$, $b = 7.37-7.375$, $c = 13.976-13.99$, $\beta = 103.7-103.78^\circ$, $Z = 8$, $D = 2.56$. 14-201(nat): 6.35₆ 3.69₅ 3.40₈ 3.16₁₀ 3.07₈ 3.00₆ 2.85₆ 2.01₅. Structure: *AM* 32:442(1947). Thin, tabular, flattened on {010}, with {010}, {100}, {001}, and others; aggregates of crystals to 5 cm from Mt. Malosa, Zomba district, Malawi; V-shaped, stellate twins that mimic maple leaves; twinning by reflection on (100). Colorless to white, pale pink; white streak; vitreous to silky luster, faint bluish iridescence, pearly on cleavage. Cleavage {001}, perfect; {100}, distinct; uneven fracture; brittle. $H = 6-7$. $G = 2.55-2.58$. Nonfluorescent. Insoluble in common acids. Be may substitute for Si and OH for O. Biaxial (+); $Y = b$, $Z \wedge c = 54-55^\circ$; $N_x = 1.544-1.545$, $N_y = 1.545-1.546$, $N_z = 1.549$; $2V = 23-30^\circ$; $r > v$, weak to distinct. Occurs in alkaline syenites and their derivative pegmatites. Associated with other alkaline minerals. Often in Na-rich parageneses. Occurs in pegmatite veins and rarely in breccia cavities at Mt. St.-Hilaire, QUE, and in the Red Wine alkaline complex, Seal Lake, central LAB, Canada; in alkalic pegmatites in the Narsarsuk area, southern Greenland; *Ovre Aro, Larvik, Langesundfjord area, Vestfold Co., Norway*; in several alkaline massifs, Kola Penin., Russia; Burpala

massif, eastern Siberia, Russia; Tallask Mts., Kirghizia; Mt. Malosa, Zomba district, Malawi. *EF MR 25:29(1994)*.

66.3.1.4 Epididymite $\text{NaBeSi}_3\text{O}_7(\text{OH})$

Named in 1893 by Flink from the Greek for *near* and *didymite*, in allusion to the fact that it is dimorphous with eudidymite. See eudidymite (66.3.1.3), the monoclinic dimorph. ORTH *Pnam*. $a = 12.49\text{--}12.74$, $b = 7.33\text{--}7.36$, $c = 13.48\text{--}13.65$, $Z = 8$, $D = 2.58\text{--}2.60$. $14\text{--}64(\text{nat})$: 6.3_7 3.65_7 3.40_{10} 3.09_{10} 2.99_{10} 2.49_7 1.80_8 1.28_8 . Structure: *AM 55:1541(1970)*. Generally fibrous, acicular, bladed, and prismatic, but may also be porcelaneous (in masses to 15 cm diameter); sometimes blocky, equant, or pseudo-hexagonal. Tabular on {001}, flattened on {001}. Dominant forms are: {001}, {110}, {010}, {100}, and others. Elongated on [010]. Frequently, polysynthetically twinned and deeply striated. Reticulate, interpenetrant, and trilling twins common, by rotation of 60° about [001]. Trillings as much as 1 cm across from Mt. St.-Hilaire. {110} and {110} are the twin planes. Crystals to 2 cm from Narsarsuk, and to 6 cm from Zomba. Colorless, white, bluish, violet or greenish; white streak; vitreous to silky luster. Cleavage {001}, perfect; {100}, micaceous and distinct; uneven to splintery fracture; brittle. $H = 6\text{--}7$. $G = 2.55\text{--}2.58$. IR data: *ZSK 8:233(1967)*. Insoluble in common acids, soluble in Hf. Analysis (wt %): K_2O , to 0.8; CaO , to 1.15; Al_2O_3 , to 1.9; traces of Fe. Biaxial (-); $X = a$, $Z = b$, $\text{OAP} = (001)$ for (-); $N_x = 1.539$, $N_y = 1.543$, $N_z = 1.544$; $2V = 0\text{--}25^\circ$. Also biaxial (+); $N_x = 1.543$, $N_y = 1.544$, $N_z = 1.546$; $2V = 22\text{--}30^\circ$. Dispersion $r > v$, weak. One of five minerals to show crossed axial plane dispersion: red light: $\text{OAP} = (001)$, $2V = 26^\circ$, violet light: $2V = 0^\circ$, dark violet light: $\text{OAP} = (010)$, $2V = 16^\circ$. Occurs in alkaline igneous rocks and their co-genetic pegmatites as a late hydrothermal mineral. May form from pre-existing Be minerals, and also may alter to bertrandite and beryllite. Localities include: near Quincy, Norfolk Co., MA; Mt. St.-Hilaire, Quebec; *Narssârssuk (Nar-sârssuk)*, Greenland; Ilímaussaq, Greenland as pseudomorphs after chkalovite; Lille Arø, Langesundfjord, Norway; Vezna, Czech Republic; as pseudomorphs after chkalovite from Mt. Alluaiv; also from Mt. Karnasurt and several other localities in the Lovozero massif, Kola Penin., Russia; Mt. Kukisvumchorr, Khibiny massif, Kola Penin., Russia; Talas Mts., Siberia, Russia; slender, prismatic to ruler-shaped crystals to 6 cm in pegmatites from Mt. Malosa, Zomba district, Malawi. *EF MM 33:450(1963)*, *CM 9:706(1969)*, *MIN 3(3):311(1981)*, *MZ 6:84(1984)*, *MR 25:29(1994)*.

66.3.1.5 Yuksporite $(\text{K,Ba})(\text{Na,Sr})\text{Ca}_2(\text{Si,Ti})_4\text{O}_{11}(\text{F,OH}) \cdot n\text{H}_2\text{O}$

Named in 1922 by Fersman for the locality. Not well characterized. Note difference between D and G. ORTH Space group unknown. $a = 24.869$, $b = 16.756$, $c = 7.057$, $Z = 9(?)$, $D = 2.79$. $41\text{--}1400$ (has $Z = 10$, $D = 2.64$) (nat): 6.22_{55} 4.18_{35} 3.19_{35} 3.10_9 3.00_9 2.915_7 2.80_{10} $2.74_{3.5}$. Platy or fibrous masses to 10 cm; forms veinlets, concretions, and nodules in feld-

spar. Pink to red or yellowish rose. $H = 5$, $G = 3.05$. IR data show that it may be related to astrophyllite group and bafertisite. Analysis (wt %): SiO_2 , 38.4; TiO_2 , 11.0; Al_2O_3 , 0.07; Fe_2O_3 , 0.75; MnO , 0.29; CaO , 18.9; SrO , 5.87; BaO , 8.60; Na_2O , 3.84; K_2O , 6.15; H_2O^+ , 2.20; F , 3.05; Cl , 0.80. Incomplete optical properties: $N_x = 1.644$, $N_z = 1.660$. $X =$ pale rose-yellow, $Y = Z =$ rose-yellow. Occurs in alkalic syenite massifs. First found on *Yukspor Mt., Khibiny massif, Kola Penin., Russia*; also on Mt. Eveslogchorr; Murun massif, Aldan Shield, Siberia, Russia. EF *MZ 7(4):74(1985)*.

66.3.3.1 Inesite $\text{Ca}_2\text{Mn}_7^+[\text{Si}_{10}\text{O}_{28}](\text{OH})_2 \cdot 5\text{H}_2\text{O}$

Named in 1887 by Schneider from the Greek for *flesh fibers*, in allusion to the color and fibrous structure. TRIC *P1*. $a = 8.889$, $b = 9.247$, $c = 11.975$, $\alpha = 88.15^\circ$, $\beta = 132.07^\circ$, $\gamma = 96.64^\circ$, $Z = 1$, $D = 3.03$. $d_{111} = 9.16_{10}$, 6.54_4 , 4.59_5 , 4.01_5 , 2.92_8 , 2.84_8 , 2.73_7 , 2.19_6 . Structure: *AM 63:563(1978)*. The chains are similar to those found in the $P = 5$ rhodonite group, but are condensed to form double-wide ribbons with unit composition $[\text{Si}_{10}\text{O}_{28}]$ that contain alternate six- and eightfold rings. These ribbons are joined to bands of edge-sharing polyhedra consisting of seven Mn octahedra and two Ca pentagonal bipyramids. Hydroxyl ion and water are not bonded to silicon. The structure is thus decidedly different from that of the $P = 5$ pyroxenoids. The habit is acicular to long prismatic $\{001\}$ with $\{100\}$ and $\{010\}$ dominant and $\{110\}$ less so, and terminated by combinations of $\{001\}$, $\{201\}$, etc., sometimes leading to acute, chisel-like crystals; as acicular, radiating aggregates. Rose to flesh-red, sometimes darkening to brown on exposure; vitreous luster; transparent to translucent. Cleavage $\{010\}$, perfect; $\{100\}$, good; brittle. $H = 6$. $G = 3.03$. Biaxial (-); $2V = 75^\circ$; $N_x = 1.618$, $N_y = 1.639$, $N_z = 1.652$; $X \wedge c = 74^\circ$, $Y \wedge c = 32^\circ$, $Z \wedge c = 62^\circ$; $r > v$, weak; nonpleochroic or only feebly so. Soluble in acids. Yields rhodonite on ignition to 800° . Inesite occurs sparsely in numerous manganese-rich environments. Found near Creede, Mineral Co., CO; with rhodochrosite and bementite in fine crystal aggregates(1) at Hale Creek, Trinity Co., CA; with bementite and hausmannite at the Crescent mine, Clallum Co., WA; at Villa Carona, DGO, Mexico. Occurs at Jacobsberg, Langban, and at the Harstig mine, Pajsberg, Sweden; embedded in calcite at *Nanzenbach, near Dillenburg, Germany*; as radial aggregates of crystals at the Kawazu, Seikoshi, and Yugashima mines, Shizuoka Pref., and the Todoroki mine, Hokkaido, Japan; as fine hemispherical masses(1) and single crystals on level 19, New Broken Hill Consolidated mine, NSW, Australia; in the Kalahari manganese field(1) in rose-red botryoidal masses, radial-fibrous spheres, and crystal groups at the Wessels and Mama Twan mines, Cape Prov., South Africa. AR *D6:564(1892)*, *AM 53:1614(1968)*.

TUHUALITE GROUP

The tuhualite group minerals are isostructural, and they have the general formula

where

A = □, Na

B = Na, K

C = Fe^{2+} , Li

D = Fe^{3+} , Zr^{4+}

and crystallize in the orthorhombic space group *Cmca*.

The silicate structural element, double that of the empirical formula, consists of a crenulated double-width chain ($W = 2$) having a periodicity of six tetrahedra ($P = 6$). Sites A, B, C, and D are nine-, ten-, four-, and six-coordinated, respectively, and not all may be occupied. In addition to the three species known for this group, there are a number of isostructural synthetic compounds: additional synthetic and natural compounds can be predicted. *AM 63:304(1978)*.

TUHUALITE: $\text{NaFe}_2(\text{Si}_6\text{O}_{15})$

This structure has extremely serpentine double chains parallel to *c*, which in turn form sheets parallel to (100). Na and Fe are both between the sheets, although the large cavities in the bends in the rings may be occupied in related minerals.

TUHUALITE GROUP

Mineral	Formula	Space Group	a			b			c		
			a	b	c	a	b	c	a	b	c
Tuhualite	$\square(\text{Na}, \text{K})^+ \text{Fe}^{2+} \text{Fe}^{3+} [\text{Si}_6\text{O}_{15}]$	<i>Cmca</i>	14.31	17.28	10.11	66.3.4.1					
Zektzerite	$\square\text{NaLiZr}[\text{Si}_6\text{O}_{15}]$	<i>Cmca</i>	14.33	17.35	10.16	66.3.4.2					
Emeleusite	$\text{Na}_2\text{LiFe}^{3+}[\text{Si}_6\text{O}_{15}]$	<i>Cmca</i>	14.004	17.337	10.072	66.3.4.3					

Note: Minerals of the milarite group are chemically analogous and essentially polymorphs of the tuhualite group, although no 1:1 correspondences in composition exist between the groups.

66.3.4.1 Tuhualite $\square(\text{Na}, \text{K})\text{Fe}^{2+}\text{Fe}^{3+}[\text{Si}_6\text{O}_{15}]$

Named in 1932 by Marshall for the locality. Tuhualite group. A composition between that of tuhualite and zektzerite may be dimorphous with sogdianite (63.2.1a.13); merrihueite (63.2.1a.5) is close in composition and may be regarded as a dimorph. ORTH *Cmca*. $a = 14.31$, $b = 17.28$, $c = 10.11$, $Z = 8$, $D = 3.03$. $10\text{-}440$: 8.62_8 7.16_{10} 5.52_8 4.85_8 4.35_8 4.32_8 3.71_8 3.47_8 . Structure: *SCI 166:1399(1969)*. The presence of both ferric and ferrous ion is evidenced by the intense absorption. Dark blue to violet-black, translucent. Cleavage {100}, {010}, {001}, good; very brittle. $H = 3\frac{1}{2}$. $G = 2.89$. Biaxial (+); $2V = 60\text{-}70^\circ$; $N_x = 1.608$, $N_y = 1.612$, $N_z = 1.621$; $r > v$, positive elongation. Pleochroic; $Z > Y > X$; deep purple, violet, and pale pink. Also given as biaxial (-); $2V = 66^\circ$; $N_x = 1.601$, $N_y = 1.605$, $N_z = 1.607$. Insoluble in acids; alters to a greenish-yellow material. In volcanic rock of *Mayor (Tuhua) Island, Bay of Plenty (Opo Bay), North Island, New Zealand*. AR *MM 31:96(1956)*, AM *41:959(1956)*.

66.3.4.2 Zektzerite $\square\text{NaLiZr}[\text{Si}_6\text{O}_{15}]$

Named in 1977 by Dunn et al. for Jack Zektzer (b.1936), mathematician and geologist of Seattle, WA, who initiated its study. Tuhualite group. A composition between that of tuhualite and zektzerite may be dimorphous with sogdianite (63.2.1a.13). ORTH *Cmca*. $a = 14.33$, $b = 17.35$, $c = 10.16$, $Z = 8$, $D = 2.80$. $29\text{-}835$: 7.19_8 4.85_{10} 4.37_5 4.34_8 4.14_5 3.48_7 3.15_8 2.67_6 . Structure: *AM 63:304(1978)*. Equant, somewhat flattened on {100}, pseudo-hexagonal crystals up to $3.7\text{ cm} \times 3.5\text{ cm} \times 1.5\text{ cm}$, with {100} and {011} dominant, modified by {001} and {010}. Colorless, white, pink, orange-tan; pearly luster on faces, vitreous on cleavage and fracture; transparent to translucent. Cleavage {100}, {010}, perfect. $H = 6$. $G = 2.79$. Biaxial (-); $2V \approx 0^\circ$; $N_x = 1.582$, $N_y = N_z = 1.584$; $XYZ = abc$; $r > v$, weak. Light yellow fluorescence in SWUV. In miarolitic cavities and as isolated grains in alkaline syenite of the Golden Horn batholith near *Washington Pass, Okanogan Co., WA*, with microcline, quartz, riebeckite, zircon, astrophyllite, elpidite, and aegirine; in *Dara-i-Pioz massif, Alai Range, Tien Shan, Tajikistan*. AR *AM 62:416(1977)*.

66.3.4.3 Emeleusite $\text{Na}_2\text{LiFe}^{3+}[\text{Si}_5\text{O}_{15}]$

Named in 1978 by Upton et al. for Charles Henry Emeleus (b.1930), British petrologist, University of Durham. Tuhualite group. ORTH (pseudo-HEX) *Cmca.* $a = 14.004$, $b = 17.337$, $c = 10.072$, $Z = 8$, $D = 2.81$ (a and c have been reversed from the original, and structure descriptions to maintain correspondence with the rest of the group; subsequent data are for the new orientation). *29-832*: 7.00₅ 4.35₁₀ 4.09₆ 3.50₇ 3.21₈ 3.19₆ 3.09₇ 2.88₆. Structure: *ZK 147:297(1978)*. Tabular {010} with {010}, {100}, {011}, {001}. Penetration trillings on {011}. Colorless to creamy pink, vitreous luster, transparent. $H = 5-6$. $G = 2.76$. Biaxial (-); 2V small; NaD: $N_x = 1.596$, $N_y = 1.597$, $N_z = 1.597$; XYZ = cab ; $r > v$, strong. Found in peralkaline rocks at *Igdlutalik, Julianehab, Greenland*. *AR MM 42:31(1978)*.

Unbranched Chains with $W > 2$

67.1.1.1 Jimthompsonite $(\text{Mg,Fe})_5[\text{Si}_6\text{O}_{16}](\text{OH})_2$

Named in 1978 by Veblen and Burnham for James Burleigh Thompson, Jr. (b.1921), American petrologist and geochemist, Harvard University, who predicted the existence of such a phase. Dimorphous with clinojimthompsonite. ORTH *Pbca*. $a = 18.626$, $b = 27.23$, $c = 5.297$, $Z = 8$, $D = 3.05$. 31-638(calc): 13.6₆ 8.81₁₀ 3.81₃ 3.25₄ 3.09₅ 2.74₃ 2.60₄ 2.55₃. Structure: AM 63:1053(1978). The structure derives from that of clinojimthompsonite by reflection across (001) such that $a_j = a_{cj} \sin \beta_{cj}$ in a relationship akin to that between clino- and orth-amphiboles. Colorless to light pinkish brown. Cleavage prismatic {210} at 38°. Biaxial (-); $2V = 62^\circ$; $N_x = 1.605$, $N_y = 1.626$, $N_z = 1.633$; XYZ = abc; $r > v$, weak. Found as radiating sprays of prismatic [001] crystals up to 5 cm long, and as parallel intergrowth on {010} with anthophyllite and cummingtonite in an ultramafic body at the *Carelton talc quarry, Chester, Windham Co., VT.* AR AM 63:1000(1978).

67.1.1.2 Clinojimthompsonite $(\text{Mg,Fe})_5[\text{Si}_6\text{O}_{16}](\text{OH})_2$

Named in 1978 by Veblen and Burnham in reference to its symmetry and its dimorph, jimthompsonite. MON *C2/c*. $a = 9.874$, $b = 27.24$, $c = 5.316$, $\beta = 109.47^\circ$, $Z = 4$, $D = 3.03$. 31-639(calc): 13.6₇ 8.81₁₀ 4.70₃ 4.04₃ 3.25₃ 3.08₆ 2.64₆ 2.51₃. Structure: AM 63:1053(1978). The silicate unit is a three-tetrahedron wide ribbon of periodicity 2 (≈ 5.3 Å) lying in the *b-c* plane and parallel to [001]. The apical oxygens of a pair of ribbons are joined by six-coordinated cations to form wide I-beam units in the manner of pyroxenes and amphiboles. Colorless to light pinkish brown. Cleavage probably at {110}. Presumably biaxial; indices not reported. Found as parallel intergrowth on {010} with anthophyllite and cummingtonite in an ultramafic body at the *Carelton talc quarry, Chester, Windham Co., VT.* AR AM 63:1000(1978).

67.1.2.1 Carlosturanite $(\text{Mg,Fe}^{2+},\text{Ti,Mn})_{21}(\text{Si,Al})_{12}\text{O}_{28}(\text{OH})_{34} \cdot \text{H}_2\text{O}$

Described in 1985 by Compagnoni et al. for Carlo Sturani (1938–1976), professor of geology, University of Turin, killed doing fieldwork. Related to serpentine group minerals. MON *Cm*. $a = 36.55\text{--}36.70$, $b = 9.31\text{--}9.41$, $c = 7.27\text{--}7.291$, $\beta = 101.05\text{--}101.1^\circ$, $Z = 1$, $D = 2.54\text{--}2.61$. 38-404(nat): 18.0₂₅

7.17₁₀ 3.64₂ 3.60₄₅ 3.40₅₅ 2.56₄ 2.54₂ 2.28₃₅. X-ray data are similar to antigorite (71.1.2a.1). Structure is somewhat disordered. A chain silicate, characterized by the presence of triple chains. *AM 70:773(1985)*. Fibrous, splintery, elongate on [010], to several cm, further crushing produces laths. Green, light brown; nearly white streak; vitreous–pearly luster. Cleavage {001}, excellent; parting on {010}; flexible. $G = 2.63\text{--}2.68$. IR, DTA, TGA data: *AM 70:767(1985)*. Complete chemical analyses exist for carlosturanite from Sampeyre and Taberg. Biaxial (+); $N_z \approx 1.54$ (Taberg) and 1.60 (Sampeyre); $2V = 35^\circ$; weakly pleochroic, orange-brown and pale orange-brown parallel and perpendicular to [010] respectively; positive elongation; parallel extinction. Occurs in low-grade metamorphic rocks in a network of veins that cross-cut antigorite–serpentinite (Sampeyre). Occurs with chrysotile, diopside, and opaques. *Sampeyre, Val Varaita, Piedmont, Italy*; various localities in the western Alps including Crissolo, Po Valley; Monte Nebin, Maira Valley; and around Viu, Viu Valley, Taberg, Sweden. *EF EJM 3:559(1991)*, *MIN 4(1):205(1992)*.

67.2.1.1 Tinaksite $K_2Na(Ca,Mn)_2(Ti,Fe)O[Si_7O_{18}(OH)]$

Named in 1965 by Rogov et al. from the symbols of some of its component elements: Ti, Na, K, and Si. See tokkoite (67.2.1.2). *TRIC P1*. $a = 10.361$, $b = 12.153$, $c = 7.044$, $\alpha = 90.79^\circ$, $\beta = 99.22^\circ$, $\gamma = 92.83^\circ$, $Z = 2$, $D = 2.84$. *18-1382*: 3.25₈ 3.09₅ 3.03₁₀ 2.95₅ 2.87₅ 2.67₄ 2.33₅ 2.00₄. Structure: *MZ 13:3(1991)*. The silicate element is a crimped band lying parallel to [001], and consisting of a pair of wollastonite-like chains joined by sharing of an oxygen, plus an additional SiO_4 tetrahedron joined to one of the chains by sharing of two oxygens. Thus $W = 5$ and $P = 3$. May also be regarded as a xonotlite chain with an appended tetrahedron sharing two oxygens. Isostructural with tokkoite. Pale yellow to pink, vitreous luster, transparent to translucent. Cleavage {010}, perfect; {110}, imperfect. $H = 6$. $G = 2.82$. Biaxial (+); $2V = 76^\circ$; $N_x = 1.593$, $N_y = 1.621$, $N_z = 1.666$; strong dispersion. Pleochroic; X, Y, colorless; Z, pale orange-yellow. Insoluble in acids. May form a solid solution with tokkoite; Mn^{2+} may substitute for Ca. Found as prismatic crystals and radiating fibrous aggregates as an accessory in K-feldspar metasomatites at the contact of limestone and the *Murun alkalic massif, near Olekminsk, Yakutia, Russia* and at Mt. Rasvumchorr, Kibiny Massif, Kola Peninsula. *AR AM 50:2098(1965)*, *ZK 189:195(1989)*.

67.2.1.2 Tokkoite $K_2Ca_4[Si_7O_{18}(OH)]F$

Named in 1986 by Lazebnick et al. for the locality. See tinaksite (67.2.1.1). *TRIC P1*. $a = 10.438$, $b = 12.511$, $c = 7.112$, $\alpha = 89.92^\circ$, $\beta = 99.75^\circ$, $\gamma = 92.89^\circ$, $Z = 2$, $D = 2.77$. *40-517*: 10.3₄ 3.34₅ 3.32₈ 3.26₅ 3.15₁₀ 3.13₈ 3.08₆ 3.04₉. Structure: *ZK 189:195(1989)*. Isostructural with tinaksite. Pale yellow to light brown, vitreous luster, transparent to translucent. Cleavage {010}, perfect; {110}, nearly so; splintery fracture. $H = 4\text{--}5$. $G = 2.76$. Biaxial; $2V = 38^\circ$; $N_x = 1.570$, $N_z = 1.577$; $Z \wedge c = 0\text{--}15^\circ$; $r < v$, weak. Found as radiating or

columnar aggregates of prismatic crystals intimately intergrown with charoite, tinaksite, and miserite in segregations with aegirine and K-feldspar in the southern part of the *Murun massif, between the Charo and Tokko rivers, Yakutia, Russia*. AR *MZ* 8:85(1986), *AM* 73:196(1988).

Structures with Chains of More Than One Width

68.1.1.1 Chesterite $(\text{Mg,Fe})_{17}[\text{Si}_4\text{O}_{11}]_2[\text{Si}_6\text{O}_{16}]_2(\text{OH})_6$

Named in 1978 by Veblen and Burnham for the type locality. A proposed but unnamed monoclinic dimorph is *MON A*/**. $a = 9.867$, $b = 45.31$, $c = 5.292$, $\beta = 109.7^\circ$, $Z = 2$. *ORTH A2₁ma*. $a = 18.614$, $b = 45.306$, $c = 5.297$, $Z = 4$, $D = 3.09$. *31-637*(calc): 11.3₄ 8.61₁₀ 3.75₃ 3.25₅ 3.08₇ 2.78₃ 2.64₃ 2.55₄. Structure: *AM 63:1053*(1978). The structure is made up of three-wide I-beams as in jimthompsonite, alternating with amphibole-like, two-wide I-beams; these lie parallel to [001] and alternate along [010]. Colorless to light pinkish brown. Cleavage prismatic, {210} at 45°. Biaxial (-); $2V = 71^\circ$; $N_x = 1.617$, $N_y = 1.632$, $N_z = 1.640$; $XYZ = abc$; $r > v$, weak. Found as radiating sprays of prismatic [001] crystals up to 5 cm long, and as parallel intergrowth on {010} with anthophyllite and cummingtonite in an ultramafic body at the *Carellon talc quarry, Chester, Windham Co., VT*. *AR AM 63:1000*(1978).

68.1.2.1 Vinogradovite $(\text{Na,Ca})_4(\text{Ti,Nb})_4\text{O}_4[\text{Si}_2\text{O}_6]_2[(\text{Si,Al})_4\text{O}_{10}](\text{H}_2\text{O,K})_3$

Named in 1956 by Semenov et al. for Aleksander Pavlovich Vinogradov (1895–1975), Russian geochemist. *MON C2/c*. $a = 24.50$, $b = 8.662$, $c = 5.211$, $\beta = 100.13^\circ$, $Z = 2$, $D = 3.15$. *PD*(type): 3.21₁₀ 3.07₁₀ 2.72₇ 2.48₆ 1.614₈ 1.558₇ 1.494₇ 1.434₇; *40-480*(Ilimaussak): 12.2₁₀ 4.49₆ 3.30₁₀ 3.22₈ 3.07₉ 3.04₅ 2.34₉ 1.476₆. Structure: *ZK 200:237*(1992). The silicate structural elements are a pair of pyroxene-like chains, $[\text{Si}_2\text{O}_6]$, and a vlasovite-like ribbon of four-tetrahedron rings linked to one another via two apical oxygens, $[\text{AlSi}_3\text{O}_{10}]$; both parallel to [001]. Spherulites and fibrous aggregates; less commonly as prismatic, [001], and/or tabular, {100}, crystals, with {310} common and terminated by {221} (these indices being different from those of the original description). Colorless, white, mauve, pink; vitreous luster, in part silky to pearly; transparent to translucent. Cleavage {010}, perfect; brittle. $H = 4$. $G = 2.88$. Biaxial (-); $2V = 41^\circ$; $N_x = 1.734$, $N_y = 1.770$, $N_z = 1.774$; $Z \wedge c = 7^\circ$, $X = b$; $r > v$. Beryllian Ilimaussak material: $2V = 81^\circ$; $N_x = 1.740$, $N_y = 1.769$, $N_z = 1.792$; $X \wedge a = 10^\circ$, $Y = b$. Beryllium may replace Si with concomitant charge balancing substitution for other cations. Found in the Green River formation, WY; at Mt. St.-Hilaire, PQ, Canada; at Ilimaussaq, Greenland; with natrolite and analcime or replacing lorenzenite

and lamprophyllite at 12 pegmatites, including those at *Takhtarvumchorr, Khibiny massif, and Nepakh, Lovozero massif, Kola Penin., Russia*. AR *AM* 42:308(1957); *MR* 8:368(1977), 10:99(1979); *NJMH* 11:481(1990).

68.1.3.1 Aërinite $\text{Ca}_4(\text{Ca,Al,Mg})_{10}(\text{Si}_{12}\text{O}_{35})(\text{OH})_{12}(\text{CO}_3) \cdot 12\text{H}_2\text{O}$

Named in 1876 by von Lasaulx from the Greek root *aer-*, alluding to atmosphere or sky and hence the color, sky blue. Revalidated in 1988. *MON* $a = 14.69$, $b = 16.87$, $c = 5.17$, $\beta = 94.75^\circ$, $Z = 1$, $D = 2.47$. *PD*: 14.7₁₀ 4.05₈ 3.80₃ 3.66₃ 3.65₃ 3.28₃ 2.81₅ 2.72₇. Blue, blue-green; translucent. $H = 3$. $G = 2.48$. Biaxial (-); $2V_{\text{calc}} = 63^\circ$; $N_x = 1.510$, $N_y = 1.560$, $N_z = 1.580$. Pleochroic; X, bright blue; $Y \approx Z$, pale beige. A hydrothermal mineral of the zeolite facies. Reported from Gunsight Mts., Pima Co., AZ. Originally described from *Casseras, Huesca, Spain*, and also Juseu and Estopinan, and from Tartaren, Lerida; as fibers with scolecite and prehnite in tholeiitic dolerite at *St.-Pandelon, Landes, France* (revalidating material); from Ourika, Morocco. AR *D6*:1025(1892), *BM* 111:39(1988), *AM* 73:1498(1988).

Chains with Side Branches or Loops

ASTROPHYLLITE GROUP

Members of the astrophyllite group conform to the formula

where

A = Na, K, Cs, Ca, H₃O

B = Fe, Mn, Mg

C = Ti, Nb, Zr

ASTROPHYLLITE

Perspective of the structure typical of the group viewed along the a-axis silicate chain.

The structure is based on infinite $(\text{Si}_4\text{O}_{12})^{10-}$ chains that are cross-linked via octahedrally coordinated cations $(\text{Ti}, \text{Zr}, \text{Nb})^{4+}$ to form sheets that lie parallel to $\{001\}$ and thus account for the micaceous habit and cleavage of the crystals. The periodicity along the chain is approximately 5.4 Å, similar to that in the pyroxenes. The chain conformation is that of a pyroxene but with additional tetrahedra joined to the outward-pointing oxygens of the core, thus yielding a branched chain about three tetrahedrons wide. The outer tetrahedra are cross-linked via the $(\text{Ti}, \text{Zr}, \text{Nb})$ octahedra to form sheets, pairs of which are joined by octahedral sheets of the B atoms to form slabs. The large A atoms lie between these slabs.

Valence changes involved in some of the substitutions cause slight deviation from the stoichiometry of the general formula.

In the following species descriptions, the unit cells of the original or structural descriptions have, wherever possible, been transposed to reflect the isotypic character. *AC 22:673(1967)*, *MM 39:97(1973)*.

ASTROPHYLLITE GROUP

Mineral	Formula			Space Group	
	A	B	C		
Astrophyllite	Na, K	Fe, Mn	Ti	$A\bar{1}$	69.1.1.1
Kupletskite	K, Na	Mn, Fe	Ti, Nb	unknown	69.1.1.2
Cesium kupletskite	Cs	Mn, Fe	Ti, Nb	$P1$ or $P1$	69.1.1.3
Niobophyllite	K, Na	Fe, Mn	Nb, Ti	$P1$ or $P1$	69.1.1.4
Zircophyllite	K, Na	Mn, Fe	Zr	unknown	69.1.1.5
Hydroastrophyllite	H_2O , K, Ca	Fe, Mn	Ti	$P1$ or $P1$	69.1.1.6
Magnesium astrophyllite	K, Na	Mg, Fe	Ti	$A2/m$ or triclinic	69.1.1.7

69.1.1.1 Astrophyllite $(\text{K}, \text{Na})_3(\text{Fe}, \text{Mn})_7\text{Ti}_2(\text{Si}_8\text{O}_{24})(\text{O}, \text{OH})_7$

Named in 1854 by Scheerer from the Greek for *star* and *leaf*, in allusion to the stellate and foliated habit. Astrophyllite group. TRIC $A1$. $a = 5.36$, $b = 11.76$, $c = 21.08$, $\alpha = 85.13^\circ$, $\beta = 90.00^\circ$, $\gamma = 103.22^\circ$, $Z = 2$, $D = 3.41$. $41-1490: 10.5_{10} 3.53_{10} 3.20_4 2.78_7 2.65_7 2.58_6 1.765_3 1.579_3$. Structure: *AC 22:673(1967)*. A primitive cell is often stated for this and other members of the group. Potassium and sodium are ordered among 13- and 10-coordinated sites and are present in approximately 2:1 ratio. As blades up to 15 cm in length and in stellate aggregates; foliated $\{001\}$ masses. Golden yellow to bronze, yellow streak, submetallic to pearly luster, translucent in thin splinters. Cleavage $\{001\}$, perfect; $\{010\}$, poor; brittle. $H = 3-4$. $G = 3.3-3.7$. Biaxial (+), less commonly (-); $2V = 70-85^\circ$; $N_x = 1.663-1.740$, $N_y = 1.691-1.746$, $N_z = 1.716-1.765$; $X \approx b$, $Z \wedge c = 3-19^\circ$; $r > v$, strong. Pleochroic, $X > Y > Z$; yellow; higher indices are concomitant with substitution of heavier atoms in B and C. Substitution of Nb^{5+} for Ti^{4+} in the C position involves vacancies in other sites. Forms a series with kupletskite. Found in nepheline

syenites, syenite pegmatites, and alkali granites and gneisses associated with albite, aegirine, arfvedsonite, nepheline, and others. At Magnet Cove, AR; St. Peter's Dome, El Paso Co., CO; Golden Horn batholith, Okanogan Co., WA. In the Red Wine complex, NF, and at Mt. St. Hilaire, PQ, Canada. At Narsarsuk, Julianehaab, and elsewhere in eastern Greenland. *Laven Is., near Brevik, Langesundfjord, Norway*; Pontevedra, Spain; October massif, eastern Azov area, and from Mt. Yukspor and Mt. Eveslogchorr, Khibiny massif, Kola Penin., Russia; at Dara-i-Pioz, Tien Shan, southern Tajikistan. At Mt. Charib, Egypt; at Iles de Los, Guinea; and Pilansberg, Transvaal, South Africa. AR *D6:719(1892)*, MZ *9(6):77(1987)*, MM *56:17(1992)*.

69.1.1.2 Kupletskite $(K,Na)_3(Mn,Fe)_7(Ti,Nb)_2[Si_8O_{24}](O,OH)_7$

Named in 1956 by Semenov for Russian geologists Boris Mikhailovich Kupletski (1894–1964) and Elsa Maximilianova Bohnshtedt Kupletskaya (1897–1974). Astrophyllite group. Probably TRIC Space group unknown. *25-6: 3.51₁₀ 3.25₁ 3.00₁ 2.76₁ 2.64₁₀ 2.57₅ 2.10₄ 1.732₄*. Tabular–acicular crystals; lamellar masses up to 2 cm consisting of platy crystals. Dark brown to black, brown streak. Cleavage {001}, perfect; also reported as {100}. $H \approx 4$. $G = 3.20-3.23$. Biaxial (-); $2V = 79^\circ$; $N_x = 1.656$, $N_y = 1.699$, $N_z = 1.731$. Forms a series with astrophyllite. Found in nepheline syenites and syenite pegmatites. Found at 3M quarry, Little Rock, Pulaski Co., AR, with aegirine, analcime, gonnardite, and eggletonite. At Mt. St.-Hilaire, PQ, Canada; in the Ilimaussaq and Werner Berg complexes, Greenland; and in the October massif, eastern Azov area, and the *Lovozero massif, Kola Penin., Russia*, associated with schizolite, neptunite, eudyalite, microcline, and nepheline. AR *DANS 108:933(1956)*, AM *42:118(1957)*, CA *65:495(1966)*, MR *21:284(1990)*.

69.1.1.3 Cesium Kupletskite $Cs_3(Mn,Fe)_7(Ti,Nb)_2[Si_8O_{24}](O,OH,F)_7$

Named in 1971 by Effimov et al. for the composition and relationship to kupletskite. Astrophyllite group. TRIC *P1* or *P1*. $a = 5.41$, $b = 11.74$, $c = 21.16$, $\alpha = 89^\circ$, $\beta = 90^\circ$, $\gamma = 102.4^\circ$, $Z = 2$, $D = 3.62$. *25-221: 10.4₁₀ 4.09₃ 3.76₃ 3.54₈ 2.79₈ 2.66₈ 2.58₆ 1.772₄*. Dull golden brown; submetallic, dull luster. Cleavage {001}, perfect. $H \approx 4$. $G = 3.68$. Biaxial (+); $2V = 75^\circ$; $N_y = 1.726$, $N_z = 1.758$; $Z = a$, $Y \wedge b \approx 9^\circ$. Pleochroic, $X < Y < Z$; yellow-green to brown. Found as rosettes of curved, platy crystals in a border-zone aegirine-bearing pegmatite in the *Alai alkalic province (Dar-i-Pioz?)*, Tajikistan. AR *DANS 197:1394(1971)*, AM *57:328(1972)*.

69.1.1.4 Niobophyllite $(K,Na)_3(Fe,Mn)_6(Nb,Ti)_2[Si_8O_{24}](O,OH)_7$

Named in 1964 by Nickel et al. in allusion to the composition and foliated character, as in astrophyllite. Astrophyllite group. TRIC *P1* or *P1*. $a = 5.391$, $b = 11.88$, $c = 21.16$, $\alpha = 95.2^\circ$, $\beta = 87.7^\circ$, $\gamma = 103.2^\circ$, $Z = 2$, $D = 3.406$. *17-742: 10.5₉ 3.74₄ 3.51₁₀ 3.26₅ 3.02₆ 2.78₈ 2.57₇ 2.48₄*. Brown. Cleavage {001}, perfect. $G = 3.42$. Biaxial (-); $2V = 60^\circ$; $N_x = 1.724$, $N_y = 1.760$, $N_z = 1.772$;

$X = b$; $Z \wedge c = 12^\circ$. Found as aggregates of {001} flakes in an albite-arfvedsonite paragneiss near Ten Mile Lake, Seal Lake area, Labrador, NF, Canada, associated with aegirine, barylite, eudidymite, neptunite, Mn-pectolite, pyrochlore, joaquinite, sphalerite, and galena. AR *CM* 8:40(1964).

69.1.1.5 Zircophyllite $(K,Na)_3(Mn,Fe)_7Zr_2[Si_8O_{24}](O,OH,F)_7$

Named in 1972 by Kapustin for the composition and foliation, as in astrophyllite. Astrophyllite group. TRIC Space group unknown. *25-856*: 9.80₄ 3.75₃ 3.50₁₀ 3.26₃ 2.80₇ 2.66₅ 2.10₅ 1.781₃. Dark brown to black, brown streak, vitreous to adamantine luster. Cleavage {001}, perfect; brittle. $H = 4-4\frac{1}{2}$. $G = 3.34$. Biaxial (-); $2V = 62^\circ$; $N_x = 1.708$, $N_y = 1.738$, $N_z = 1.747$; $r > v$, strong. Pleochroic, $X = Y < Z$; dark yellow to brown. Found as {001} platy aggregates in the natrolite zone of alkalic pegmatite at Korgereda-binsk, Tuva, Russia. AR *ZVMO* 101:459(1972), *AM* 58:967(1973).

69.1.1.6 Hydroastrophyllite $(H_3O,K,Ca)_3(Fe,Mn)_{5-6}Ti_2[Si_8O_{24}](O,OH)_7$

Named in 1974 for its composition and relationship to astrophyllite. Astrophyllite group. TRIC *P1* or *P1*. $a = 11.86$, $b = 11.98$, $c = 5.42$, $\alpha = 103.42^\circ$, $\beta = 95.15^\circ$, $\gamma = 112.20^\circ$, $Z = 1$, $D = 2.79$. *29-991*: 10.55₉ 3.51₁₀ 2.87₄ 2.78₄ 2.64₈ 2.58₅ 2.12₆ 1.768₆. Dark brown. $G = 3.15$. Biaxial (-); $2V = 40^\circ$; $N_x = 1.660$, $N_y = 1.720$, $N_z = 1.728$. Pleochroic; X, yellow; Y, orange-yellow; Z, dull yellow. Found as a weathering product in alkalic pegmatite in Szechuan Prov., China. AR *AM* 60:736(1975).

69.1.1.7 Magnesium Astrophyllite $K_2Na_2Mg_2Fe_5Ti_2[Si_8O_{24}](O,OH,F)_7$

Named in 1963 by Peng and Ma for its composition and relationship to astrophyllite. Astrophyllite group. MON *A2/m* (also reported as TRIC). $a = 10.56$, $b = 23.00$, $c = 5.35$, $\beta = 102^\circ$, $Z = 2$, $D = 3.32$. *29-1042*: 10.1₈ 3.80₆ 3.38₁₀ 3.08₅ 2.76₅ 2.55₉ 1.818₅ 1.463₇. Straw-yellow, vitreous luster. Cleavage {100}, {010}, perfect. $H = 3$. Biaxial (-); $2V \approx 82^\circ$; $N_x = 1.658$, $N_{y \text{ calc}} = 1.687$, $N_z = 1.710$; $Y = b$, $Z \wedge c \approx 5^\circ$; pleochroic in yellows. Found at an unspecified locality near Khibiny, Kola Penin., Russia. AR *SGS* 1:18(1974), *AM* 60:737(1975).

AENIGMATITE GROUP

The aenigmatite minerals, with the general formula

where

A = Ca, Na

B = Mg, Fe²⁺, Fe³⁺, Ti, Mn, Sn, Cr, Sb

T = Si, Al, Be

crystallize in space group *P1*. The crystal structure of aenigmatite group minerals is based on complex aluminosilicate chains, consisting of pyroxene-like chains with extra tetrahedra attached alternately on opposite sides, having the composition $[T_6O_{18}]_n$. The structure contains six tetrahedrally coordinated sites, seven octahedrally coordinated sites, and two 7- or 8-coordinated sites. Details of the aenigmatite structure are given in AM 56:427(1971) and CM 32:439 (1994).

AENIGMATITE: $Na_2Fe_5TiSi_6O_{20}$

This view shows the similarity to pyroxenes and amphiboles. Compare opposite. There is a chain with alternating tetrahedra like pyroxene parallel to *a*, but there are some single tetrahedra branching off from this chain; thus the structure is in some respects intermediate between pyroxene and amphibole. A unique aspect of aenigmatite is the Fe atoms in the plane of the chains, which weakly link them into sheets, and which in turn introduce nontetrahedral oxygens. There are no OH/F atoms in the center of hexagonal rings of tetrahedra as in amphiboles; the chains are not wide enough.

AENIGMATITE GROUP

Mineral	Formula	a	b	c	α	β	γ	
Aenigmatite	$\text{Na}_2\text{Fe}^{2+}\text{TiSi}_6\text{O}_{20}$	10.417	10.837	8.929	104.86	96.77	122.54	69.2.1a.1
Dorrite	$\text{Ca}_2(\text{Mg}_2\text{Fe}^{3+})(\text{Al},\text{Fe}^{3+})_4\text{Si}_2\text{O}_{20}$	10.505	10.897	9.019	106.26	95.16	124.75	69.2.1a.2

Rhonite	$\text{Ca}_2(\text{Mg},\text{Fe}^{2+},\text{Fe}^{3+},\text{Ti})_6(\text{Si},\text{Al})_6\text{O}_{20}$	10.367	10.756	8.895	105.98	96.04	124.72	69.2.1a.5
Serendibite	$(\text{Ca},\text{Na})_2(\text{Al},\text{Mg},\text{Fe}^{2+},\text{Fe}^{3+})_6(\text{Si},\text{B},\text{Al})_6\text{O}_{20}$	10.010	10.393	8.631	106.87	96.10	124.38	69.2.1a.6
Welshite	$\text{Ca}_2\text{Sb}^{5+}\text{Mg}_4\text{Fe}^{3+}\text{Si}_4\text{Be}_2\text{O}_{20}$	10.167	10.65	8.787	106.5	96.1	124.0	69.2.1a.7
Wilkinsonite	$\text{Na}_2\text{Fe}^{2+}\text{Si}_6\text{O}_{20}$	10.355	10.812	8.906	105.05	96.63	125.20	69.2.1a.8

Note: Magbasite (69.2.1.3) may be an additional member of the group. Sapphirine (69.2.1b.1) and Surinamite (69.2.1b.2) are related to the Aenigmatite Group.

69.2.1a.1 Aenigmatite $\text{Na}_2\text{Fe}_5^{2+}\text{TiSi}_6\text{O}_{20}$

Named in 1865 by Breithaupt from the Greek for *riddle*, apparently in allusion to its initial problematical nature. Aenigmatite group. See the other members of the group. TRIC P1. *CM 32:439(1994)* (conventional triclinic cell): $a = 10.417$, $b = 10.837$, $c = 8.929$, $\alpha = 104.86^\circ$, $\beta = 96.77^\circ$, $\gamma = 125.54^\circ$; (reduced triclinic cell): $a = 8.930$, $b = 9.734$, $c = 10.416$, $\alpha = 114.31^\circ$, $\beta = 96.77^\circ$, $\gamma = 64.98^\circ$; $Z = 2$, $D_{\text{syn}} = 3.87$; (syn, 700° and 1 kbar): $a = 10.35$, $b = 10.81$, $c = 8.94$, $\alpha = 105.28^\circ$, $\beta = 96.25^\circ$, $\gamma = 125.57^\circ$. *22-1453(syn)*: 8.09_{10} 3.15_{10} 2.93_7 2.70_8 2.54_8 2.41_6 2.12_7 1.62_6 ; [*CM 32:439(1994)*] (nat): 8.12_6 3.70_3 2.71_8 2.70_8 2.54_{10} 2.12_3 2.12_4 2.07_3 . Fe^{2+} and Ti occupy seven octahedral sites, M1–M7. Most Ti is in M7 (1.99 Å) and the rest is in five of the other six sites. *AM 56:427(1971)*. There are six tetrahedral sites and two seven- or eight-coordinated sites as well. Long prismatic, to > 8 cm; also as irregular segregations; twinning on {110} common, usually lamellar. Black, brown; reddish-brown streak; vitreous to greasy luster. Cleavage {010}, {100}, perfect; uneven fracture; brittle. $H = 5\frac{1}{2}$ –6. $G = 3.74$ –3.86. Insoluble in acids. Analysis (wt %): SiO_2 , 37.3–41.8; Al_2O_3 , 0.1–2.7; Fe_2O_3 , 1.3–10.0; FeO, 20.3–38.8; TiO_2 , 6.8–10.2; MnO, 0.4–4.4; MgO, 0.0–2.2; CaO, 0.0–3.7; Na_2O , 5.6–7.5; K_2O , 0.0–0.6. Ti-free aenigmatite has $(\text{Na}_2\text{Fe}_1^{2+}\text{Fe}_2^{3+}\text{Si}_6\text{O}_{20})$. Biaxial (+); $Z \wedge c = 40^\circ$; $N_x = 1.79$ –1.81, $N_y = 1.805$ –1.826, $N_z = 1.87$ –1.90; $2V = 27$ –55°; $r < v$. X, yellowish brown to reddish brown; Y, reddish brown to dark brown; Z, reddish brown to brownish black. Occurs in alkalic rocks, particularly pegmatites, also in Na-rich alkalic lavas; peralkaline to transitional lavas produced by advanced differentiation from basalts in oceanic islands and continental rift zones. Also in plutonic rocks, due to differentiation of gabbros.
