Platinum-group metals:				
Sweepings, waste, scrap ____ value__	--	$62,746	$4,144	West Germany $58,602.
Metal including alloys, unwrought and partly wrought troy ounces__	187	4,378	257	Japan 2,706; United Kingdom 1,415.
Silicon: Elemental _____	68	--		
Silver:				
Ore and concentrate value, thousands__	$3,490	$10,067	--	All to Japan.
Sweepings, waste, scrap ____ value__	$9,562	$61,700	--	Do.
Metal including alloys, unwrought and partly wrought thousand troy ounces__	1,805	1,137	689	Japan 415; United Kingdom 33.
Tin:				
Ore and concentrate _____	10	--		
Metal including alloys, semimanufactures _____	1	18	--	Saudi Arabia 9; Libya 7.
Tungsten:				
Ore and concentrate _____	1,915	1,712	25	Japan 733; West Germany 365; Sweden 273.
Metal including alloys, all forms ___	599	604	244	Japan 111; United Kingdom 72; West Germany 58.
Zinc:				
Oxides and peroxides _____	1,379	1,490	--	Japan 1,328; Sudan 159.
Metal including alloys:				
Scrap _____	84	255	NA	Philippines 100; China 50.
Unwrought _____	8,885	11,612	2,200	Japan 7,036; Pakistan 1,500.
Blue powder _____	15	38	--	Japan 20; Singapore 18.
Semimanufactures _____	16	54	1	Japan 48.
Other:				
Ash and residue containing nonferrous metals _____	1,821	2,006	--	Japan 1,917; United Kingdom 54.
Metal including alloys:				
Pyrophoric alloys _____	65	--		
Rare-earth metals _____	10	--		
Base metals including alloys, all forms _____	12	9	--	Mainly to Japan.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc _____	50	1,000	--	All to Japan.
Dust and powder of precious and semiprecious stones ____ kilograms__	1,621	1,576	--	Canada 1,415; West Germany 148.
Grinding and polishing wheels and stones _____	592	226	3	Saudi Arabia 93; Indonesia 52; Japan 39.
Asbestos, crude _____	8	30	--	All to Japan.
Boron materials: Oxide and acid____	4	--		
Cement _____ thousand tons__	2,439	4,754	--	Hong Kong 837; India 830; Saudi Arabia 500.
Clays and clay products:				
Crude:				
Bentonite _____	1,070	10	--	All to Bangladesh.
Chamotte and dinas earth____	28,010	29,335	--	Japan 29,035; China 300.
Kaolin _____	82,416	76,920	--	Japan 59,380; China 15,950.
Other _____	5,308	3,097	--	Japan 2,999.
Products:				
Nonrefractory _____	72,959	62,747	16,478	West Germany 14,053; Hong Kong 9,034.
Refractory including nonclay brick _____	13,241	15,792	2,238	Japan 11,157; Malaysia 968; Indonesia 480.
Diamond:				
Natural:				
Gem, not set or strung __ value__	$573,667	$842,788	$9,907	Japan $602,168; China $181,986.
Industrial _____ do____	$28,878	--		
Synthetic and reconstructed:				
Gem, not set or strung __ do____	$2,834	$23,233	$23,233	
Industrial _____ do____	$28,513	--		
Diatomite and other infusorial earth ___	60	120	--	All to Indonesia.
Feldspar _____	13,380	19,672	--	China 19,140; Japan 532.

See footnotes at end of table.

Table 2.—Republic of Korea: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979[r]	1980	Destinations, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Fertilizer materials, manufactured:				
Nitrogenous	474,961	635,257	NA	Philippines 226,931; Indonesia 130,000; Hong Kong 41,000.
Phosphatic	28,135	33,875	--	Japan 31,875; Fiji 2,000.
Potassic	1	--		
Other including mixed	623,366	624,253	NA	Turkey 107,982; Iran 94,000; India 29,630.
Fluorspar	470	500	--	All to Japan.
Graphite, natural	46,520	45,416	NA	Japan 26,088; China 12,565; Indonesia 4,500.
Gypsum and plasters	59,319	79,819	--	China 47,386; Japan 17,500.
Lime	544	10,873	NA	Australia 4,750; Papua New Guinea 3,045.
Magnesium materials:				
Magnesite	750	1,000	--	All to Japan.
Oxides	150	--		
Mica:				
Crude including splittings and waste	656	--		
Worked including agglomerated splittings	16	--		
Pigments, mineral: Iron oxides, processed	25	26	NA	Japan 15.
Precious and semiprecious stones except diamond:				
Natural ---------- kilograms	7	[1]25,469	299	Japan 12,372; China 10,210.
Synthetic and reconstructed value, thousands	$5,087	$6,447	$5,208	Japan $458; Hong Kong $405.
Salt and brine	399	99	2	Saudi Arabia 38; Qatar 19; United Arab Emirates 16.
Sodium and potassium compounds, n.e.s:				
Caustic potash	--	3	--	All to Sudan.
Caustic soda	--	40,307	--	Japan 24,438; Australia 11,409.
Soda ash	8,100	11,614	NA	Indonesia 7,500; Kuwait 500.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	229,831	312,483	45	Japan 310,552; China 1,886.
Worked	41,680	49,564	23	Japan 48,955; Saudi Arabia 448.
Dolomite, chiefly refractory-grade	126,657	96,400	--	All to Japan.
Gravel and crushed stone	2,772	1,873	--	Japan 1,453; China 250.
Limestone excluding dimension	10	--		
Quartz and quartzite	36,104	30,872	--	Japan 30,472; China 200; Indonesia 200.
Sand excluding metal-bearing	4,203	5,206	--	Japan 5,200.
Sulfur:				
Elemental, other than colloidal	--	1,603	--	Indonesia 1,205; Singapore 323.
Sulfuric acid	7	23	--	Libya 16; Saudi Arabia 7.
Talc including natural steatite	69,134	53,478	1,703	Japan 31,258; Thailand 6,870; Philippines 6,800.
Other:				
Crude	301,800	284,531	--	Japan 170,095; China 114,000.
Slag, dross, similar waste, not metal-bearing	72,325	53,500	--	All to Japan.
Building materials of asphalt, asbestos and fiber cements, unfired nonmetals	4,099	5,157	--	Saudi Arabia 2,049; Kuwait 938; Libya 838.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	5	--		
Coke and semicoke	1	--		
Petroleum refinery products:				
Kerosine ------ 42-gallon barrels	--	5,773	NA	NA.
Jet fuel ---------- do	--	3,520	--	All to Philippines.
Distillate fuel oil ---------- do	--	22,156	NA	NA.
Residual fuel oil ---------- do	62,937	658,294	5,874	Singapore 276,843; Thailand 254,299.
Lubricants ---------- do	27,308	74,850	186	Indonesia 4,851; Singapore 4,321; Burma 3,384.
Other:				
Liquefied petroleum gas do	229,251	132,124	--	Hong Kong 72,964; Philippines 30,044; Thailand 23,177.
Mineral jelly and wax do	6,261	6,889	NA	Japan 1,574; Hong Kong 1,573; Chile 1,180.
Nonlubricating oils do	351,725	712	--	Sudan 651; Kuwait 56.
Bitumen and other residues do	41,635	76,733	--	Indonesia 34,609; Hong Kong 22,695; Singapore 8,484.
Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals	95,621	125,447	--	Japan 91,864; China 21,209; Netherlands 5,211.

[r]Revised. NA Not available.
[1]Excludes an unreported quantity valued at $13,568.

Table 3.—Republic of Korea: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1979[r]	1980	Sources, 1980	
			United States	Other (principal)
METALS				
Aluminum:				
Ore and concentrate	1,860	2,247	--	Japan 1,370; Hong Kong 850; Sweden 27.
Oxides and hydroxides:				
For use in manufacturing	31,139	30,940	--	All from Japan.
Other	32,190	28,387	595	Japan 26,960; Taiwan 604.
Metal including alloys:				
Scrap	5,308	3,868	3,471	Japan 157; Australia 136.
Unwrought	82,803	73,821	31,332	Japan 13,645; Canada 11,982; Egypt 3,810.
Semimanufactures	19,954	19,610	2,858	Japan 7,758; France 5,278; Spain 1,663.
Antimony:				
Ore and concentrate	480	224	--	All from Thailand.
Oxides and hydroxides	80	52	--	Japan 47; United Kingdom 5.
Metal including alloys, all forms	69	NA	NA	NA.
Arsenic: Trioxide and acid	20	--		
Beryllium metal including alloys, all forms kilograms	14	1,000	--	All from Japan.
Bismuth metal including alloys, all forms do	273	NA	NA	NA.
Cadmium metal including alloys, all forms	4	NA	NA	NA.
Chromium:				
Ore and concentrate	9,344	5,264	NA	Philippines 2,355; Japan 1,919.
Oxides and hydroxides	1,213	1,147	574	Japan 362; West Germany 192.
Cobalt:				
Ore and concentrate kilograms	4	--		
Oxides and hydroxides	16	9	2	Netherlands 3; Japan 2.
Metal including alloys, all forms	70	NA	NA	NA.
Copper:				
Ore and concentrate	128,809	233,999	--	Philippines 124,358; Mexico 39,377; Canada 34,394.
Oxides and hydroxides	30	42	--	All from Japan.
Metal including alloys:				
Cement	1,848	3,341	2,135	Australia 1,132.
Scrap	51,259	19,637	15,046	Japan 2,602; United Arab Emirates 504; Kuwait 427.
Unwrought	26,277	15,471	2,020	Japan 6,156; Peru 1,371; Chile 1,170; Canada 1,026.
Semimanufactures	20,302	14,472	267	Japan 11,903; Australia 1,789.
Gold:				
Ore and concentrate value	--	$375,638	--	All from Singapore.
Metal including alloys, unwrought and partly wrought troy ounces	155,420	128,380	42,974	Japan 82,498; Singapore 1,648.
Indium metal including alloys, all forms kilograms	1,008	NA	NA	NA.
Iron and steel:				
Ore and concentrate thousand tons	7,517	9,142	--	Australia 3,883; India 2,160; Peru 1,680.
Metal:				
Scrap do	1,580	1,932	1,508	Australia 156; Japan 83; Canada 36.
Pig iron, sponge iron, powder, shot	82,681	23,434	1	India 9,983; Japan 4,598; Indonesia 4,575.
Ferroalloys	8,014	6,734	215	Japan 3,508; Norway 500; United Kingdom 118.
Steel, primary forms thousand tons	1,548	1,490	16	Japan 1,277; France 111; Australia 69.
Semimanufactures:				
Bars, rods, angles, shapes, sections	522,414	407,429	4,254	Japan 369,439; United Kingdom 23,799.
Universals, plates, sheets	429,564	449,257	1,193	Japan 442,876; Sweden 530; West Germany 526.
Hoop and strip	216,747	73,710	110	Japan 71,235; West Germany 2,042.
Rails and accessories	23,768	7,644	1,032	Japan 5,635; United Kingdom 774; France 102.
Wire	60,532	31,121	447	Japan 29,935; Norway 144; Italy 142.
Tubes, pipes, fittings	96,001	145,120	16,495	Japan 121,172; West Germany 4,899; United Kingdom 1,496.
Castings and forgings, rough	14,814	1,036	1	Japan 1,029; United Kingdom 4.

See footnotes at end of table.

Table 3.—Republic of Korea: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979[r]	1980	Sources, 1980	
			United States	Other (principal)
METALS —Continued				
Lead:				
Oxides and hydroxides	70	236	2	Mexico 187; Australia 34; Japan 13.
Metal including alloys:				
Scrap	29,437	23,388	16,281	Kuwait 4,599; Saudi Arabia 796; Canada 504.
Unwrought	19,750	20,617	2,099	Peru 7,120; Mexico 3,244; Japan 2,822.
Semimanufactures	168	150	3	Japan 109; West Germany 29.
Lithium:				
Oxides and hydroxides	35	12	11	Belgium 1.
Elemental	28	8	(1)	Mainly from Japan.
Magnesium metal including alloys:				
Unwrought including scrap	339	479	291	Japan 178; France 10.
Semimanufactures	14	14	12	Japan 2.
Manganese:				
Ore and concentrate:				
Pyrolusite	4,807	3,435	--	Singapore 2,154; Japan 1,191; Australia 90.
Other	225,829	204,765	NA	Australia 123,768; India 77,908.
Oxides and hydroxides	1,744	1,321	--	Japan 1,172; Belgium 113.
Mercury 76-pound flasks	761	836	65	Japan 756; Switzerland 14.
Molybdenum metal including alloys, all forms	9	20	3	Japan 14; West Germany 3.
Nickel:				
Oxides and hydroxides	108	102	--	Canada 77; France 10; Japan 7.
Matte, speiss, similar material	89	31	--	All from Canada.
Metal including alloys:				
Scrap	77	11	(1)	Norway 10.
Unwrought	1,927	2,777	300	Canada 1,505; Netherlands 200; Philippines 200.
Semimanufactures	727	533	72	Japan 250; West Germany 44; Australia 40.
Phosphorus: Elemental	44	879	432	Canada 396; India 30.
Platinum-group metals:				
Sweepings, waste, scrap value	$36,436	--		
Metal including alloys, unwrought and partly wrought troy ounces	99,592	75,579	25,669	West Germany 23,795; Japan 16,247.
Rare-earth metals including alloys, all forms	14	1	--	Mainly from Japan.
Selenium: Elemental	2	5	(1)	Japan 4.
Silicon: Elemental	880	603	292	France 119; Japan 91; Norway 84.
Silver:				
Sweepings, waste, scrap value	$286,405	$640,886	$5,527	Japan $635,359.
Metal including alloys, unwrought and partly wrought thousand troy ounces	876	[2]2,472	297	Japan 255; United Kingdom 14.
Tantalum metal including alloys, all forms kilograms	9	NA	NA	NA.
Tin:				
Ore and concentrate	543	331	--	Singapore 149; Malaysia 137; Indonesia 45.
Metal including alloys:				
Unwrought including scrap	6,428	1,234	1	Malaysia 781; Indonesia 354; Singapore 57.
Semimanufactures	74	95	4	Japan 66; Thailand 20.
Titanium:				
Ore and concentrate:				
Rutile	4,631	3,740	--	All from Australia.
Ilmenite	12,314	31,150	--	Malaysia 30,868; Australia 282.
Oxides and hydroxides	3,783	1,976	105	Japan 1,084; West Germany 514; Australia 122.
Metal including alloys, all forms	82	NA	NA	NA.
Tungsten:				
Ore and concentrate	--	67	--	All from Australia.
Metal including alloys, all forms	29	16	1	Japan 14.
Vanadium: Pentoxide kilograms	1,465	739	163	Japan 576.
Zinc:				
Ore and concentrate	42,601	43,760	--	Australia 37,070; Peru 6,690.
Oxides and hydroxides	413	226	40	Japan 161; West Germany 10.
Metal including alloys:				
Scrap	11,060	9,191	1,470	Japan 7,035; Australia 652.
Unwrought	3,131	1,986	--	Japan 1,254; Australia 675; Panama 37.
Blue powder	155	NA	NA	NA.
Semimanufactures	86	301	65	Japan 236.

See footnotes at end of table.

Table 3.—Republic of Korea: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979[r]	1980	Sources, 1980	
			United States	Other (principal)
METALS —Continued				
Zirconium: Ore and concentrate	1,274	1,208	--	Australia 678; Japan 275; Malaysia 255.
Other:				
Oxides, hydroxides, peroxides	174	165	1	Japan 154; Belgium 5.
Ash and residue containing nonferrous metals	22,035	28,664	--	Japan 28,629; Australia 35.
Metals:				
Alkaline-earth metals	15	14	1	Japan 10; West Germany 3.
Base metals including alloys, all forms	332	610	58	Japan 230; Belgium-Luxembourg 17.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	1,031	369	11	Japan 357.
Artificial: Corundum	8,525	9,833	6	Japan 8,922; United Kingdom 450.
Dust and powder of precious and semiprecious stones excluding diamond kilograms	4,561	2	2	
Grinding and polishing wheels and stones	733	530	36	Japan 447.
Asbestos, crude	58,616	36,787	4,728	Canada 4,817; Australia 1,326.
Barium materials:				
Barite and witherite	162	100	--	All from Thailand.
Hydroxide	59	50	(1)	Italy 18; Netherlands 18; Japan 13.
Boron materials:				
Crude natural borates	345	941	--	Peru 500; Japan 441.
Oxide and acid	2,198	1,052	943	Taiwan 68; Japan 39.
Cement	467,748	5,112	275	Japan 4,737; France 75; Singapore 25.
Chalk[3]	15	NA	--	All from West Germany.
Clays and clay products:				
Crude	51,612	54,501	23,989	Japan 25,054; Hong Kong 3,849.
Products:				
Nonrefractory	6,847	2,638	25	Japan 1,384; Italy 571; Philippines 342.
Refractory including nonclay brick	216,355	93,437	1,888	Japan 61,135; West Germany 20,352; United Kingdom 9,745.
Diamond:				
Natural:				
Gem, not set or strung value, thousands	$1,489	$1,782	$3	Japan $817; Belgium $634.
Industrial do	$1,307	$830	$600	Japan $184; United Kingdom $27.
Dust and powder do	$2,763	$2,751	$40	Japan $2,672; United Kingdom $39.
Synthetic and reconstructed:				
Gem, not set or strung do	$83	$5	$5	
Industrial do	--	$11	--	All from Japan.
Dust and powder do	$3,418	$3,019	$2,899	Japan $120.
Diatomite and other infusorial earth	58	49	49	
Fertilizer materials:				
Crude: Phosphatic thousand tons	1,845	1,670	1,512	Nauru 69; Denmark 39.
Manufactured:				
Nitrogenous	12,896	3,584	(1)	Japan 2,200; Chile 1,373.
Phosphatic	21	20	--	All from Japan.
Potassic	359,302	259,087	120	Canada 217,273; Belgium 21,500; Israel 13,702.
Other including mixed	23	38	14	Japan 20; West Germany 4.
Ammonia	19	18	1	Japan 17.
Fluorspar	11,338	21,718	--	All from Thailand.
Graphite, natural	269	322	24	Japan 246; India 30.
Gypsum and plasters	5,078	8,425	21	Morocco 8,400.
Halogens	161	125	33	Israel 47; Japan 25.
Lime	50	--		
Magnesium materials:				
Magnesite	51	123	--	All from Japan.
Oxides and hydroxides	7,683	14,004	5	Japan 13,987.
Mica:				
Crude including splittings and waste	163	134	10	India 101; Japan 17.
Worked including agglomerated splittings	74	33	(1)	Japan 32.
Pigments, mineral including processed iron oxides	1,303	1,844	315	Japan 1,383; West Germany 134.
Precious and semiprecious stones except diamond:				
Natural[4] kilograms	1,362	53,155	13,749	Japan 31,978; West Germany 4,029; Brazil 3,350.
Synthetic and reconstructed do	816	222,470	59,591	Singapore 150,000; Japan 11,211.

See footnotes at end of table.

Table 3.—Republic of Korea: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979[r]	1980	Sources, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Salt and brine	489,880	716,288	NA	Australia 539,208; Yemen Arab Republic 90,195.
Sodium and potassium compounds, n.e.s:				
Caustic potash	1,358	937	112	Japan 801.
Caustic soda	184,643	56,970	21,081	Japan 24,025; Taiwan 10,721.
Soda ash	33,148	25,406	22,006	Japan 3,400.
Stone, sand and gravel:				
Dimension stone, crude and partly worked	2,192	52,479	1	Japan 50,528; Italy 1,525.
Dolomite, chiefly refractory-grade	420	567	--	All from Japan.
Gravel and crushed rock	539	438	--	France 425; Japan 13.
Limestone excluding dimension	136,035	20,907	--	All from Japan.
Quartz and quartzite	89	96	2	Sweden 67; Belgium 18; Japan 9.
Sand excluding metal-bearing	180,727	119,474	20	Australia 92,614; Japan 21,881.
Sulfur:				
Elemental:				
Other than colloidal	582,055	519,184	--	Japan 257,767; Canada 253,481.

[1]Less than 1/2 unit.

[2]Includes reported 1,879,723 troy ounces of material listed as "sheets and strips of silver, partly worked" valued at $0.07 per troy ounce with the source listed as the region where the Korean Customs Law is enforced.

[3]Imports in 1979 were valued at $4,715; unreported quantity imported in 1980 valued at $1,000.

[4]Excludes unreported quantity valued at $486,269 in 1979 and $229,283 in 1980.

COMMODITY REVIEW

Domestic mine production met the demand for only a few mineral commodities. Although the Republic of Korea was wholly self-sufficient for limestone, mica, molybdenum, and tungsten, it was entirely dependent on imported ores and minerals such as aluminum, bituminous coal for coke, chromium, cobalt, nickel, and platinum-group metals. Moreover, the country was over 90% dependent on foreign sources of copper, iron ore, and tin. More importantly, it lacks domestic resources of oil and natural gas, driving up costs in the manufacturing sector as a result of high-priced imports.

METALS

The Government offers financial and tax concessions to industry to stockpile strategic metals. The metals stockpile was to deal with changes in market conditions as well as emergencies. During 1982, stockpile acquisition was to total 223.2 million (compared with $136.4 million in 1981), allocated as follows: aluminum, $19.2 million; lead, $4.9 million; nickel, $9.1 million; tin, $10.1 million; scrap iron, $36.5 million; coal, $35.6 million; and $107.8 million for other materials for emergency use. Materials in the latter category were to be determined after interministerial review.

South Korean capacity to produce primary nonferrous metals was largely limited to aluminum, copper, and zinc. The country's largest metal sector was iron and steel.

Aluminum.—Aluminum of Korea Ltd. (Koralu) operated the only smelter in the country, a 17,500-ton-per-year plant at Ulsan. Koralu is jointly owned by Hyundai Heavy Industries, Ltd., and Pechiney Ugine Kuhlmann of France. All of the smelter's requirements for alumina were imported from Japan. Domestic consumption for metal has been about 105,000 tons per year. To meet the shortfall in supply, the Republic of Korea imports metal and semimanufactures from Canada, France, and Japan.

Copper.—The Republic of Korea had two copper refineries, the Korea Mining & Smelter Co. at Changhang with an annual capacity of 40,000 tons, and Onsan Copper Refinery Co., Ltd., at Onsan with an annual capacity of 80,000 tons. Domestic mine production of copper continued to be small, and virtually all ore for the smelters was imported as concentrates from the Philippines, Mexico, and Canada, in order of quantity. In addition, the country imports about 50,000 tons of copper metal and semimanufactures, principally from Japan and in lesser quantities from Australia, Chile, and Peru.

Lead.—Mine output of lead from copper-zinc-lead ore and zinc-lead ore in Kyungsang averaged about 11,500 tons per year of contained lead. Lead metal was recovered by the copper smelter of Korea Mining at Changhang, which had a lead production capacity of 12,000 tons per year. Annual lead consumption was about 50,000 tons. Close to 75% of the country's supply was from imports of scrap and unwrought metal. The proposed 50,000-ton-per-year lead smelter of Korea Zinc Co. remained in the feasibility stage.

Iron and Steel.—Pohang Iron & Steel Co., Ltd. (Posco), a state-run enterprise, dominated the steel industry in the Republic of Korea. Moreover, Posco was the only integrated steelmaking facility in the country. In addition to Posco's complex at Pohang, the major iron and steel centers were located at Busan, Daegu, Inchon, Masan, Sam Cheok, Seoul, and Ulsan.[8]

The industry utilized five large blast furnaces for pig iron production. The inner volume for the two largest were 3,795 and 2,254 cubic meters. Total pig iron production capacity in 1981 was 8,019,000 tons.

Supplementing Posco's crude steel output of 8.5 million tons per year were 15 mills operating electric furnaces and 15 other installations engaged in various aspects of steel processing. For steelmaking, the industry operated 6 basic-oxygen furnaces and 39 electric arc furnaces with a combined capacity of 12,335,000 tons per year. South Korean production capacity by process as of June 1981 was as follows, in thousand tons:

Process	Capacity
Blast furnace	8,019
Basic-oxygen furnace	8,535
Electric arc furnace	3,680
Open-hearth furnace	120
Continuous casting	6,230
Slabbing and blooming	5,490
Rolling mill	13,353

Since the early 1970's, there has been spectacular growth in the iron and steel industry. Production of pig iron grew from 455,000 tons in 1973 to 7,928,000 tons in

1981; correspondingly, crude steel output increased from 1,240,000 to 10,754,000 tons. Significantly, the country is impoverished of natural resources to feed its largest metallurgical sector. Domestic production of iron ore supplied about 5% of current consumption, while the remainder was imported from Australia, Brazil, India, New Zealand, and Peru. The imports by type were 61.2% fine-size ore, 36.3% lump-size ore, and 2.5% pellets. The industry also imports about 2 million tons of iron and steel scrap annually, composed of direct receipts and metal from the country's ship-scrapping sector. Moreover, the Republic of Korea lacks resources of bituminous coal and must import the entire amount of coking coal needed by the steel industry. The country's receipts of coking coal have been from Australia, Canada, and the United States. Posco was developing a coal mine in Tanoma, Pa., to secure coal supplies and was negotiating similar arrangements in Australia and Canada.

Posco was expected to complete the expansion program for its Pohang complex, increasing annual capacity to 8.5 million tons from 5.5 million tons in early 1982. Construction of the Republic of Korea's second integrated iron and steel complex was expected to begin in July 1985. The complex, to be constructed at the southern coastal city of Kwangyang near Yosu, would have an initial rated annual capacity of 2.7 million tons of crude steel and would be under the supervision of Posco. The Government was to subsidize $280 million for developing basic groundwork—roads, railway, waterfront loading docks, and electrical and communications installations. When completed in March 1988, the complex will have facilities for producing coke, pig iron, cast iron, steel, and hot-rolled steel. It was expected that a second-stage expansion would follow, increasing the annual steel capacity at Kwangyang to 6 million tons.

Tungsten.—South Korean production of tungsten constituted about 5% of world output. The Sangdong Mine of the Korea Tungsten Mining Co., Ltd., a state-run enterprise, accounted for about 93% of national production. The remainder of the production was by Chungyang Co., Okbang Mining Co., Ltd., and other operators of small mines at Daewha, San-Nae, Ssangjon, and Wol-Ak. Korea Tungsten's mill at Sangdong had the capacity to process 2,000 tons of ore per day to produce a 70% tungsten oxide concentrate. The concentrate was shipped to the company's plant at Taegu where it was processed to produce tungsten powder and carbide and up to 2,500 tons of ammonium paratungstate.

Zinc.—The Republic of Korea had two zinc refineries, the 31,000-ton-per-year refinery of Young Poong Corp. at Sukpo and the 50,000-ton-per-year refinery of Korea Zinc Co. at Onsan. Significantly, domestic mine output accounted for about 70% of the ore requirement with the remainder imported largely from Australia. Although the South Korean metal market was small, the zinc market was relatively large at about 80,000 tons per year.

A lead-zinc deposit was discovered in North Kyongsang Province, in the Ponghwa-Ulchin area, 220 kilometers southeast of Seoul. The deposit, with estimated reserves of 6.3 million tons, reportedly has a potential value of $80 million.

Other Metals.—Bismuth and molybdenum were produced as a byproduct of tungsten processing by Korea Tungsten Mining Co., Ltd. The increase in copper refining, due to the operation of the new Onsan copper plant, resulted in higher byproduct recovery of silver and gold. A small amount of arsenic was also recovered from copper processing. Production of other metals during the year included minor amounts of antimony, manganese, and tin.

During 1980, Korea Mining Promotion Corp., a state-run enterprise, announced the discovery of a larger molybdenite deposit in Yongwol County, Kangwon Province. However, because of its low grade and the low price of molybdenum in the international market, there were no plans for a feasibility study of ore body development.

Amax Exploration Inc. of the United States and Hyundai Corp. reportedly have agreed in principle to explore jointly for molybdenum in the Republic of Korea. The initial exploration project was likely to be small scale, estimated at $400,000.

NONMETALS

Cement.—Ssangyong Cement Industrial Co., Ltd., the largest cement producer in the Republic of Korea, constituted about 42% of the total capacity in 1981. The expansion of Ssangyong's largest plant at Donghae was completed in 1980, raising capacity from 6.021 to 8.821 million tons per year. Ssangyong also has a 2,122,000-ton-per-year plant at Yeong-Weol and a 567,000-ton-per-

year plant at Mungyeon, in addition to grinding facilities at Changdong, Daegu, and Daejeon. Tong Yong Cement Manufacturing Co. Ltd. was the second largest producer with a 6,108,000-ton-per-year plant at Samcheog. Other producers of cement included, with capacities given in million tons per year, Hamil Cement Manufacturing Co., Ltd., 2.75; Sungshin Cement Industrial Co., Ltd., 2.41; Hyundai Cement Co., Ltd., 2.222; Asia Manufacturing Co., Ltd., 1.87; and Koryo Cement Manufacturing Co., Ltd., 0.587. The Sosa plant of Union Corp. had a 100-ton-per-day white cement capacity. Halla Cement Manufacturing Co. was completing the construction of its 1-million-ton-per-year plant outside of Seoul.

The expansion of the cement industry began in the 1960's. The target for cement-making was 30 million tons in 1986. However, the industry's price competitiveness has been beset with higher costs, primarily for fuel and electricity. Cement production in 1981 represented only 57% of capacity. Moreover, to reduce the dependence on oil, the industry made investments to convert as rapidly as possible to coal-fired kilns. By the end of 1981, coal accounted for 82.5% of industry capacity and was expected to increase to 86.9% by the end of 1982. To compound the difficulties, traditional export markets, such as Indonesia and Thailand, were developing their own cement industries. To overcome these problems, the cement industry was depending upon increased activity in domestic and foreign construction to improve financial performance.

Fertilizer Materials.—Manufacturers of chemical fertilizers were also adversely affected by higher energy costs and failing export markets. Although production of urea fertilizers increased 10% to 1.1 million tons in 1981, output of fused phosphate was down 23% to 93,596 tons, and production of complex fertilizers was down 16% to 1.2 million tons. Exports of fertilizers increased substantially between 1976 and 1980. Exports in 1980 were valued at $344 million but fell to $188 million in 1981.

Other Nonmetals.—The Republic of Korea was a large producer of graphite and was best known for its amorphous graphite. Production of other nonmetallic minerals included agalmatolite, andalusite, asbestos, barite, diatomaceous earth, feldspar, fluorite, salt, and talc. Cyprus Mining Co. was reportedly entering into an agreement with Ilshin Industry Co., Ltd., for joint development of talc in Yesan, South Ch'ungchiong Province.

MINERAL FUELS

There has been no commercial production of oil and natural gas in the Republic of Korea. The only indigenous fuel source was anthracite coal. Electric power generation in 1981 totaled 40,307 kilowatt-hours. Thermal powerplants accounted for 86% of the total power generated, followed by hydropower plants at 6.7%. Total electric power consumption during the year was 29,281 million kilowatt-hours. Consumption by the mining sector in 1981 totaled 715 million kilowatt-hours. The large electric power consumers were as follows, in million kilowatt-hours: primary metal producers, 4,945; textiles, 4,854; chemicals, 4,518; metal products, 2,666; and nonmetal sector, 2,642.

Petroleum's share of South Korean energy consumption was estimated at 60%. The Government's energy policy for the 1980's emphasizes a reduction in dependence on oil and the development of alternative energy sources. By 1991, a total of 11 nuclear powerplants are expected to be in operation. Also, four coal-fired electric powerplants with a combined capacity of 2 million kilowatts and a number of hydroelectric powerplants with a combined capacity of 1,950,000 kilowatts are targeted for completion by 1991. Under the proposed guidelines, South Korean dependence on oil is to be reduced to 27.6% of the total energy consumption in 1991.[9]

Coal.—Under the Government's long-term supply-demand program (1981-91), the country's demand for coal was to grow by 11.1% annually. The share of coal in total energy demand, however, was to reach 35% in 1986 and then be reduced to 32.1% in 1991.

According to MER, coal production in 1981 was the highest ever recorded in the country. Output was 5.2% more than the target set for 1981. Dai Han Coal Corp., a state-run enterprise, produced 4,883,000 tons, exceeding its target by 83,000 tons. Private mines produced 15,111,000 tons during the year. MER attributed the increase in production to the Government's efforts to boost domestic output and to the dry summer conditions in the mining area.

The Republic of Korea has been importing 6 to 7 million tons of coal annually, which includes coal for steam generation and for metallurgical coke. In 1981, the

Government authorized Dai Han Coal to be the country's sole importer of coal. Korea Electric Co. and others who have imported coal, however, will be allowed to sell imported coal in accordance with terms set by the state-run coal corporation.

In an attempt to secure foreign sources, South Korean firms have invested in the development of overseas coal projects. Posco has invested about $38 million in the development of the Mt. Thorley coal mine in Australia and was expected to begin exporting some coal in late 1982. Posco has likewise invested $68 million in the Tanoma Mine in the United States; shipments to the Republic of Korea were expected to begin in 1983. Posco has also invested in the development of the Greenhill Mine in Canada. Daesung Consolidated Coal Mining Co., Ltd., and Hyundai Corp. were developing a coal mine in Australia and were expected to begin shipping coal in 1983.

Petroleum and Natural Gas.—Exploration for oil continued on the Continental Shelf between the Republic of Korea and Japan. Following seismic surveys in 1979, test drilling in 1980 was conducted in the fifth and seventh subzones of the joint development zone. There were no indications of seabed oil. Nine additional test drillings were planned through 1987. Japanese and South Korean concessionaires were involved with subzones two through eight. Owing to the withdrawal of the Japanese applicant, subzones one and nine were to be explored later. Zapata Exploration Co. of the United States and Korea Petroleum Development Corp. completed in 1981 a 600-kilometer seismic survey southwest of Cheju Island and were to drill one well in early 1982. This area reportedly had the highest potential for commercial crude production in South Korean offshore areas.[10]

On February 26, 1981, a protocol was signed between the Governments of the Republic of Korea and Indonesia for the establishment of a 50-50 joint venture for the exploration and development of Indonesian oil resources off northwest Java. The area involved 8,000 square kilometers offshore Madura Island, and exploration and test drilling were projected to cost $60 million. Under the terms of the protocol, the contracting company for each country was to develop a master plan and set up detailed execution procedures through consultation.

In 1981, South Korean daily oil refining capacity reached 790,000 barrels. Korea Oil Corp. operated a 280,000-barrel-per-day refinery at Ulsan on the southwest coast. Homan Oil Refinery Co. completed the expansion of its refinery at Yosu to 380,000 barrels per day. The refinery of Kyung In Energy Co. had a daily refining capacity of 60,000 barrels. Kuk Dong Oil Co., Ltd., had its refinery in Pusan with a daily refining capacity of 10,000 barrels. Ssangyong Oil Refining Co. completed the construction of its 60,000-barrel-per-day refinery and began test operations in 1980. Ssangyong was a joint venture with the National Iranian Oil Corp. However, National Iranian, a state-run firm, withdrew in August 1980.

The Republic of Korea was negotiating a long-term purchase contract for Indonesian liquefied natural gas (LNG) at the rate of 1.5 million tons per year beginning in 1985. A receiving terminal for the LNG was proposed near the Pyongtaek powerplant on Asan Bay. A pipeline would link the Seoul-Inchon area with the terminal. Cost of the proposed LNG project was estimated at $785 million.

The Mineral Industry of Kuwait

By Roman V. Sondermayer[1]

As in the past, the Government-owned petroleum industry completely dominated the economy of Kuwait during 1981. The glut of oil on world markets had adverse effects on Kuwait's economy in two ways. First, Government revenues and foreign exchange earnings dropped as the result of the decision to limit crude oil production. Second, all natural gas necessary for power generation and production of petrochemicals was associated gas. Consequently, lower crude oil production resulted in lower production of natural gas, which adversely affected operation of the gas plant and petrochemical industry of Kuwait. Many commitments by Kuwait for delivery of gas and petrochemical products had to be revised downward. Premium prices made Kuwait's crude oil one of the most expensive crudes sold on the world market. During the year, resistance of buyers was mounting and the premium of $5.50 per barrel was dropped. During 1981, the Government was not encouraging development of industry in the country except where related to petroleum and natural gas. The Government of Kuwait sought to maximize its oil income. Excess capital generated by the crude oil industry was used by the Kuwaitis for investments abroad. In the United States, Kuwait Oil Corp. (KOC) concluded arrangements to buy the Santa Fe Drilling Co. of Alhambra near Los Angeles. Reportedly, Santa Fe Drilling will become a subsidiary of KOC, which will pay $51 per share for Santa Fe Drilling's outstanding shares. All necessary Kuwaiti approvals have been granted. However, the final approval for this acquisition from the appropriate Government offices in the United States had not been granted at yearend.

Principal events in the mineral industry of Kuwait were lowering of crude oil and natural gas production, expansion of ammonia-producing facilities, preparations with Saudi Arabia for construction of a cement plant, testing of two deep wells for gas, and modernization of petroleum refineries.

PRODUCTION

During 1981, according to preliminary reports, Kuwait was among the largest producers of crude oil in the world. In addition to crude oil and associated gas production, Kuwait had three petroleum refineries and one gas-processing plant in operation. Total capacity of the refineries was 594,000 barrels per day, and that of the gas plant was 3 billion cubic meters per year. Output of other minerals was minimal and had only domestic significance. The petroleum sector was Government owned or controlled, while production of other minerals was in private hands. Table 1 shows Kuwait's mineral production trends for the most recent 5-year period.

Table 1.—Kuwait: Production of mineral commodities[1]

Commodity and unit of measure	1977	1978	1979	1980[p]	1981[e]

COMMODITY REVIEW

METALS

Kuwait did not report production of metals during 1981. A project to construct an aluminum smelter using natural gas resources for generating electric power was under consideration. Implementation was uncertain at yearend. Iron and steel products were produced by the Kuwait Metal Pipe Industry. Its main product was welded pipe used by the oil industry.

NONMETALS

Ammonia.—The Petrochemical Industries Co., a wholly owned subsidiary of KOC, continued to expand its ammonia-producing facilities at the petrochemical complex at Shuaiba. Equipment for a fourth ammonia train was ordered during 1981. The new facility was planned for a capacity of 1,000 tons per day. Costs were reported at $112 million, and startup was scheduled for the second half of 1982. The new train will replace an older unit, and after completion, the capacity for production of ammonia at Shuaiba should reach 1 million tons per year.

Cement.—During 1981, most of the preliminary work necessary for construction of a 2.5-million-ton-per-year cement plant at Khuraniyah, 100 kilometers north of Dammam, Saudi Arabia, was completed. Krupp Polysius A.G. of the Federal Republic of Germany won the construction contract. The project should make Saudi Arabia, which owns 55% of the project, and Kuwait, which owns the other 45%, self-sufficient in cement.

MINERAL FUELS

Petroleum and Natural Gas.—Kuwait limited its crude oil output during 1981 in line with the policy of the Organization of Petroleum Exporting Countries (OPEC). OPEC's aim was to reduce world supplies of crude oil and consequently retard the decline of oil prices on the saturated world market. The decision affected production at the gas-processing plant at Shuaiba. The plant was forced to operate at one-half of its capacity because most of the natural gas produced in Kuwait came from gas which is produced along with oil.

During 1981, KOC continued its exploration for natural gas and crude oil. However, most exploration efforts sought natural gas. At yearend, results were inconclusive as tests were underway on gas zones in the Permian Khuff formation, reached by two deep wells. Four other areas were in various stages of exploration for crude oil and natural gas: Deep under the Burgan Field, in the Fars heavy oil formation in northern Kuwait, offshore Kuwait, and in the Neutral Zone. About five rigs were active in the country, and total drilling was estimated at about 33,000 meters.

At the beginning of 1981, the total number of wells in Kuwait capable of producing crude oil and associated gas was 556. Approximately two-thirds were out of production. Some of them were awaiting workover, but most were shut-in owing to the decision to reduce production.

In the Neutral Zone, where production was split evenly between Kuwait and Saudi

Arabia, offshore drilling totaled about 10,000 meters in 1980, the latest year for which drilling data were available. Some 410 oil wells were in production at the beginning of 1981. All associated gas produced in the Neutral Zone was flared except that used in the field. In May 1981, KOC started to work on the development of the Southern Gas Project. When completed, the facility will gather and compress associated gas from the Wafra and Khafji Fields. Kuwait expects that this previously flared gas will do much to relieve the shortage of natural gas used for making natural gas liquids at the Shuaiba gas-processing plant.

The modernization of refineries in Kuwait continued during 1981. When all refinery expansion programs are completed, Kuwait should have a refinery capacity of about 700,000 barrels per day. Completion was targeted for 1984. During the summer, a fire damaged the largest refinery in Kuwait at Shuaiba. The fire burned for a week and damaged 10 storage tanks.

The Mineral Industry of Liberia

By George A. Rabchevsky[1]

Mining remained Liberia's most important industry in 1981, although its share of the gross domestic product (GDP) has fallen steeply in recent years. In 1981, the Liberian mining and minerals industry continued the decline owing to the stagnant overall economic conditions of 1979 and disruptions following the coup of April 1980. Oil price increases, sluggish demand for iron ore, and loss of confidence among foreign investors contributed further to the decline in the GDP and in foreign currency reserve levels. Domestic production and foreign trade fell off, and all potential investments were under reconsideration by the Government.

The iron ore industry in 1981, as in the past, dominated the Liberian GDP and export earnings. Because of the political turmoil and economic uncertainty of 1980, two of the three operating iron ore mines were kept in operation largely from subsidies by the Liberian Government in 1981.

In addition to iron ore, other mineral production in Liberia included the traditional output of alluvial diamonds and gold from small mines and production from the petroleum refinery in Monrovia. Geologically, the country possesses a wide variety of minerals of potential economic value, and the Liberian Government continued to encourage exploration and mining by foreign companies, particularly in the area of diamonds and gold.

Further economic development will largely depend on the extent to which Liberia can regain the confidence of foreign investors. In view of the continuing decline in developed country markets and the uncertainty of price increases in Liberia's exports, an economic revival in Liberia does not appear likely in the near future.

PRODUCTION AND TRADE

Production of minerals in Liberia in 1977-81 is given in table 1. Production for export stemmed mainly from foreign companies attracted by generous tax relief, unrestricted transfer of profits and capital, and the sole right of exploration and development for natural resources.

The United States in 1981, as in previous years, was Liberia's preeminent trading partner and is expected to continue as a leading source of capital and technical assistance. Liberia's currency is fully convertible with the U.S. dollar with no exchange controls or restrictions on the transfer of funds, which are mostly targeted for the development of Liberia's infrastructure.

Iron ore remained Liberia's major export, accounting for over one-half of the total exports in 1981, followed by rubber and diamonds. Oil dominated domestic imports, accounting for almost 30% of the total in 1981.

COMMODITY REVIEW

METALS

Gold.—According to geological reports, gold occurrences have been found extensively in Liberia with exploitable concentrations occurring randomly, mostly in placer deposits. Most recently, however, several hard-rock concessions have also met with some success.

Exploration for gold intensified in 1981. Most of the activity was carried out in Eastern Liberia, along the Lofa River in Grand Cape Mount County by Bentley International Mining Co. on a private concession and by a team from the United Nations Revolving Fund for Mineral Exploration. Efforts to introduce modestly mechanized power shovel and crusher operations in addition to traditional washers and sluice box techniques were successful, with promising potential for future increased production.

Iron Ore.—In 1981, iron ore continued to be the most important source of foreign exchange for Liberia; all iron ore production is exported. In 1980, exports equaled 17.1 million tons valued at $313.4 million, or 52% of the value of Liberia's total exports. In 1981, iron ore exports rose to 20.4 million tons valued at $333.8 million despite the

decrease of 25% in shipments by the National Iron Ore Co. Ltd. (NIOC). With the decline in the market value of other commodities in 1981, iron ore increased its share of total export earnings for Liberia to 62%.

Following an 8.1% increase in 1980, iron ore production in 1981 remained constant at 19.6 million tons. However, the earnings of the three iron ore mining companies deteriorated appreciably owing to such factors as increased energy costs and negligible capital reinvestment, even though ore shipments increased by 3.3 million tons. The major importers of this ore in 1981 were the Federal Republic of Germany (27.3%), Italy (18.6%), France (12.1%), the United States (9.6%), and the Netherlands (7.5%). In the 1970's, Liberia shipped about 228 million tons of ore to steel plants in the European Economic Community, the United States, and Japan.

In 1981, the Lamco Joint Venture (LJV) increased its exports of iron ore to world markets to 11.5 million tons. This tonnage included 15,000 tons of pellets from stockpiles.[2] LJV's high-grade deposits at Nimba are located within the enriched portion of a banded iron formation, with the hematite and goethite ore averaging 63% Fe. The underlying itabirite at 32% Fe is not considered ore at present. In addition to the high-grade ores at Nimba, medium-grade ores of approximately 50% to 54% Fe are mined at Tokadeh, Gangra, and Yuelliton. Mining is by conventional open pit methods. Both ore and waste are taken in 10-meter benches. The slopes between berms are designed at 63° in ore and 45° in phyllite. About 80% of the ore and 70% of the waste has to be drilled and blasted. The mine, at full capacity, produces up to 13 million tons of waste and 13.5 million tons of crude ore annually, including 1.2 million tons of ore from Tokadeh. The 13.5 million tons of crude ore yields 12.7 million tons of finished products, including 4.5 million tons of washed lumps, 6.3 million tons of washed fines, and 1.9 million tons of pellets.[3]

The Bong Mining Co., Liberia's second largest iron ore mining company, established a new production high in 1981, at 8 million tons.[4] The Bong deposit consists of several narrow synclines approximately 13 kilometers long in the western part of the Bong Range. The deposit is an itabirite that has been weathered only slightly. The iron ore has a 61:39 magnetite-to-hematite ratio. The mine has a capacity of 30,000 tons of ore daily, while concentrate production averages 18,500 tons per day at an analysis of 65.5% Fe and 6.5% SiO_2. The throughput of each pellet plant is about 8,000 tons daily, providing some 6,000 tons of pellets with an average iron content of 63.5%. Concentrates and pellets are transported by rail 80 kilometers to the port of Monrovia. Storage capacity at the port is 800,000 tons of concentrates and 500,000 tons of pellets.[5]

Liberia's third largest iron ore mining company, NIOC, exported a total of 1 million tons of iron ore in 1981, all produced at its Mano River Mine.[6] The NIOC deposit at Mano River consists of six ore-bearing hills, of which four are fully developed for mining. The ore-bearing formation occurs mainly on the west-to-northwest slope of each hill. Average haulage distance from the open pit to the crusher is 4 kilometers.[7]

Reportedly, the Liberian Government was to receive $20 million in loans in 1982 from the World Bank to assist in making improvements to the Mano River iron ore mine. The loans will go toward a project costing $67.1 million, aimed at improving the mine's operating facilities and its railway links to the port of Monrovia. By the 1984 completion date, it is expected that output from the Mano River concentrator will be raised to 3.25 million tons per year.[8]

Under prevailing economic circumstances in Liberia in 1981, the outlook for significant expansion of iron mining operations appeared dim. Given the downward trends in operating results since 1978 at the Bong Mine and NIOC, both were threatened with closure. The Government of Liberia expressed hope that the LJV would proceed forthwith to expand operations at the Western Extension because high-grade deposits at Lamco's main ore body were expected to be depleted by 1986. Opening of new mines was possible at Wologisi near the Lofa River in northern Liberia and in the Bea Mountains. Though a concession was granted to the Liberian Iron and Steel Corp. in 1967, production has been delayed. The possibility of opening the new high-grade Nimba-Mifergui project in neighboring Guinea provided continuity to the Lamco operation. Nimba-Mifergui is the extension of Nimba Mountain into Guinea. Because the distance from the deposit to any port might render the project uneconomical, Mifergui has plans for the use of LJV rail and port facilities. If these various projects, together with the upgrading of the Mano Mine, come to fruition, the outlook for iron ore mining

in Liberia may not be as gloomy as would otherwise be the case.[9]

Manganese.—Reconnaissance surveys for manganese continued in 1981 by the Liberian Ministry of Lands, Mines, and Energy, with help from U.S. Peace Corps volunteer geologists. Exploration centered on the Mount Dorthrow area of Grand Gedeh County in Eastern Liberia.

Other Metals.—Efforts to bring deposits of rutile and ilmenite into production were deferred, because production reportedly would not be profitable at existing titanium ore market prices.

NONMETALS

Barite.—There was little followup activity during the year on the barite deposits northeast of Monrovia explored by the Senwein Mining Corp. in 1980.

Diamond.—Diamond deposits exist throughout Liberia. Some degree of exploration or mining was underway in each of the country's nine counties in 1981. Diamond exploration generally focused on alluvial sand and gravel deposits. The major production of diamonds in 1981 was confined to the alluvial deposits of the Lofa River Valley in the Saniquellie and Bahn Districts.

Diamonds in Liberia are mined by licensed local producers to a limited extent. Some 1,200 prospecting licenses and 1,170 mining licenses were current during 1980 and 1981. According to official trade data, diamonds account for about 7% of Liberia's exports. The value of diamonds exported in 1980 was $13.5 million, obtained mainly from small claims production. During the first 6 months of 1981, Liberia reportedly exported 143,000 carats for receipts of $10.6 million.

The long-term prospects of the Liberian diamond industry hinge on finding the geological sources of the diamonds. Potential sources still have not been extensively explored. Diamonds are closely associated with kimberlite, small dikes of which are found in Liberia, but no diamond-bearing pipes have yet been discovered.

As of July 1981, the Ministry of Lands, Mines, and Energy listed four diamond and gold concessions in Liberia: Bentley International Trading Co., Bruce J. Clayman, Weasua Mining and Development Corp., and the United Nations Revolving Fund for Mineral Exploration. Bentley International was the only one of the four listed as being in a "production phase" of operation. The concessions include land claims in Grand Gedeh, Sinoe, and Maryland Counties. Bruce Clayman had a concession for exploration on 185,000 acres along Kana Creek on the Grand Gedeh and Maryland County boundary. The Weasua Mining and Development Corp. operated in lower Lofa County, with exclusive rights to explore for gold and diamonds in a 230-square-mile area. The United Nations Fund operated in an exploration phase of its agreement in an 8,000-square-mile area of Eastern Liberia, beginning what is expected to be several years of study.

MINERAL FUELS

Petroleum.—The name of the Ministry of Lands and Mines of Liberia was changed to the Ministry of Lands, Mines, and Energy in 1981. A decree was issued giving the new ministry formal responsibility for petroleum matters, and a national energy committee was established to coordinate energy policy.

Exploration of Liberia's offshore oil potential continued in 1981. Based on encouraging results obtained from previous drilling, a contract was awarded under a $5 million World Bank loan to conduct a $3.1 million seismic survey and to reexamine past geophysical data. A French firm, Compagnie Générale de Géophysique, was awarded $1.5 million for the seismic survey, while the U.S. oil consulting firm of J.C. Ferrand of Houston, Tex., will process and interpret the data at a cost of $1.6 million.

The Liberian Petroleum Refining Co. operated a 15,000-barrel-per-day refinery at Monrovia. This Government-owned facility depends totally on imports. There is no strategic oil reserve. The plant normally attempts to maintain some reserve stock to permit orderly marketing, but owing to financial and administrative difficulties, such stocks are to all practical purposes nonexistent.

Uranium.—Exploration for uranium in 1981 was encouraged by the new Liberian Government. Active exploration for uranium was conducted by Coastal Liberian Uranium Enterprises, a subsidiary of Coastal States Gas Co. (United States). Reportedly, an airborne survey located encouraging anomalies over the 15,000-square-mile concession area.

Competitive-grade uranium deposits, of undisclosed value and quantity, were reportedly discovered in 1981 in Bong and Lofa Counties.

The Mineral Industry of Libya

By John R. Lewis[1]

Although Libya's economy remained dominated by its tremendous oil and gas reserves, they were not its only mineral resources in 1981. The iron deposit at Wadi Shati contains more than 720 million tons of 45% to 50% iron-content ore, some of which is manganiferous, which will be used as the raw material feed for the new Misratah iron and steel complex. Gypsum was present in commercial quantities; salt occurs in a number of places; and there were abundant raw materials for construction and cementmaking needs. Oil and liquefied natural gas (LNG) constituted 99.9% of Libya's exports and were responsible for the generation of about 66% of its 1981 gross national product of about $30 billion.[2] Libya's proven oil reserves in 1981 made it the ninth largest producer among the 67 oil-producing nations of the world.

Even with petroleum sales plummeting in 1981, Libya's national income exceeded expenditures by a comfortable margin, and the trade balance remained favorable.

Many Libyan contracts, worth billions of dollars, were awarded in 1981, mostly to European industrial equipment and construction firms and consortia, in furtherance of the Transformation Plan, which was aimed at diversifying the oil-based economy into the industrial and agricultural sectors.

Government Policies and Programs.—The Libyan General People's Congress, in January 1981, approved the draft of the Second Transformation Plan that takes into account the problems encountered and the delays experienced in the previous plan. Revenues from oil sales in 1981 accounted for about 66% of Libya's total income. The new plan will seek to reduce oil and gas income to about 46% of total revenue and will encourage corresponding increases from the agricultural and industrial sectors. Under the second plan, for example, the petrochemical industry is expected to rise by about 22%, while agricultural development will seek to wipe out some, if not all, of Libya's dependence on foreign food sources. Expenditures under the second plan were projected to be about $62.5 billion.

The national electrical grid system was well under way during the year. In one area, six powerplants, with total generating capacity of 40,810 megawatts, were under construction. Increasing the output from present powerplants was another goal that was well under way, and work on a whole network of electrical transmission, distribution, and feeder lines was moving ahead as was work on a large number of transformer stations throughout the more populated areas. Nine minipowerplants were well along in construction, and four desalination plants with output totaling 181 cubic meters of fresh water per day were also being built.

The U.S. Embassy in Libya was closed during 1980. On May 14, 1981, the Government of Libya announced that the 2,000 to 2,500 Americans in Libya, mostly oil and petrochemical technicians, would not be bothered because they were necessary to Libyan development. Late in December, Esso Standard Libya, Inc., and Esso Sirte, Inc., removed their corporate presence from Libya and were paid $95 million for their plants and other assets, considerably less than their reported book values. Shortly thereafter, Esso's personnel departed, and the Libya National Oil Corp. (NOC), which took over both of the Esso operations, imported 200 oil technicians from Iran's National Oil Co. to assist in keeping the plants operating while training Libyan personnel to perform these tasks.

During the summer, Libya offered a Bombay, India, firm, the Kamani Engineering Corp., a partial payment in oil for a transmission construction project upon which Kamani was bidding. The company

turned the proposal over to the state-owned Indian Oil Corp. for study. There were also indications that the Soviet Union, in an economic protocol with Libya, will provide increased technical assistance to the Libyan oil and gas industries, to pipeline gathering centers, and for the manufacture of oil well drilling equipment.

PRODUCTION AND TRADE

Exports totaled about $17 billion, and 99% of this was petroleum or its associated products. Imports, mostly food and many types of machinery, totaled $10 billion, which left a surplus balance of trade of $7 billion, somewhat less than that of preceeding years. Nonfuel minerals played a miniscule role in Libya's trade and economy during the year. The country's mineral production is shown in table 1.

Crude oil production in Libya averaged 1.8 million barrels daily in 1980. However, in 1981, the daily average production was down to 1.2 million barrels; toward the very end of the year, production may have been as low as 0.6 million barrels daily. Crude oil was produced from about 925 wells, about two-thirds of which were on some form of artificial lift. Prices for top-grade Libyan crude reached $39.90 per barrel on July 1, 1981, and remained at this level until very late in the year when, based upon action by the Organization of Petroleum Exporting Countries (OPEC), the price went down to $37.90 per barrel.

Libyan crude exports went primarily to Western Europe and the United States. In Western Europe, the Federal Republic of Germany, Spain, and Italy were the "big three," taking considerably more crude during the year than did the United States. In 1981, however, Libya exported about 130 million barrels of crude to the United States, an average of about 360,000 barrels daily and a 40% decline from that of 1980.

Despite pricing disputes that caused interruptions in LNG deliveries from Libya, Italy and Spain received nearly all exports of this product.

[e]Estimated. [p]Preliminary. [r]Revised.

[1]Table includes data available through Aug. 9, 1982.

[2]In addition to the commodities listed, a variety of construction materials (sand and gravel, crushed stone, brick, and tile) is produced, but available information is inadequate to make reliable estimates of output levels. Natural gas liquids are also produced but are blended with crude petroleum and are reported as part of that total.

[3]Series revised to exclude gas reinjected into reservoirs.

COMMODITY REVIEW

METALS

Aluminum.—During the summer of 1981, it was announced by official sources in both Libya and Yugoslavia that plans were going forward for a plant to produce aluminum from Yugoslavian alumina and petroleum coke, the latter to then be used in the aluminum smelting process.

A joint company of the Socialist People's Libyan Arab Jamahirya and the Yugoslav enterprise known as Energoinvest contracted to build adjacent facilities at a cost of $1 billion to make petroleum coke and carbon electrolytic anodes and to smelt aluminum. The location was reported by one source as Zuwarah, which is on the Mediterranean coast about 80 kilometers west of Tripoli. Another report puts the facility in the Amikat al Khams region, about the same distance east of Tripoli. Plans called for an output of about 110,000 to 120,000 tons of aluminum annually, together with electrolytic carbon anode material from 170,000 barrels annually of residual fuel oil. When it was announced, the project was targeted for completion by 1986. About 1,200 persons are to be employed. Electric power requirements will run about 240 megawatts daily at startup. A rapidly expanding electrical grid system is believed adequate for this load when it is imposed. A new 720-megawatt, oil-fired powerplant is to be built at Zuwarah as part of the overall Libyan 1981-85 plan.

Kaiser Engineers and Constructors, Inc., furnished procurement and engineering assistance to the Libyan Secretariat of Heavy Industries and will also supply construction management services during the actual work. The 2-potline smelter, each line containing 160 electrolytic pots, will be technologically supported by the National-Southwire Aluminum Co. of Hawesville, Ky. The complex will have its own Mediterranean seaport, an electrode plant, metal-casting facilities, and general plant buildings.

Iron and Steel.—Construction of the fully integrated iron and steel complex of the Libyan General Co. for Iron and Steel Projects began to get under way at Misratah during 1981. This centerpiece in Libya's 1981-85 development plans lies 225 kilometers east of Tripoli on the Mediterranean coast. Designed by MN Dastur of India, the plant will be erected in three phases with assistance from many contractors in the Federal Republic of Germany, Austria, Japan, and elsewhere. Assistance during phase two will also be extended by the Soviet Union. By the year 2005, Libya hopes to have a steel capacity of 7 to 8 million tons annually. Upon completion of phase one, however, steelmaking capacity will be 1.3 million tons per year. This phase is scheduled for completion by 1985 and will cost $3.3 billion. It will use imported iron ore. The second phase is slated for completion in 1991, will cost $1.3 billion, and will increase capacity to a reported 5 million tons per year. Libyan iron ore, hauled on the new railroad that is to be built from Sabah in the Wadi Shati iron deposit area to the Misratah area, will go into use in the complex with completion of phase two.

Many of the contracts for the components that are part of phase one were let during 1981. Everything from design, construction, delivery, and installation to operations and training of Libyan technicians was negotiated.

In the Misratah plant, the first stage of steelmaking will be direct reduction of the ore. In April 1981, a consortium headed by Korf Engineering GmbH at Duesseldorf, Federal Republic of Germany, and including Vöest-Alpine AG of Austria was awarded a $300 to $340 million contract to build two Midrex direct-reduction plants, each rated at 550,000 tons per year, to produce the highly metallized iron ore known as sponge iron. Fuel for the two units will be natural gas brought via pipeline from the Hateiba Field deep in the Sahara Desert. The output from these plants will serve as the feed for two electric steelmaking furnaces. Contracts for the two electric units were also made public during the year. One unit, to be built by Korf Engineering and Vöest-Alpine, will cost $539.3 million and will produce 670,000 tons per year of steel blooms and billets. The second contract was with Friedrich Krupp GmbH and a consortium of mainly West German firms to build a $674.2 million, 650,000-ton-per-year plant to make steel slabs and sheet metal.

A number of rolling and other type mills were also to be erected under contracts awarded during 1981. A cold-rolling mill, which will make up to 140,000 tons annually of cold-rolled sheet metal and 100,000 tons of undipped sheet metal, was to be built by Vöest-Alpine and West German companies at a cost of $360 million. Electrical facilities for this mill are to be installed by Brown Boveri & Cie. AG of Mannheim, Federal Republic of Germany, at a cost of $90 million. Hot-rolling facilities will be built by Kobe Steel Ltd. of Japan and the Marubeni Corp. A hot-rolling mill to produce from 400,000 to 580,000 tons of steel strip per year will be joined by a 400,000-ton bar and wire rod mill reported as costing from $700 to $800 million. Samsung Construction Co. of the Republic of Korea received a subcontract from Kobe Steel for some of the construction work on these two facilities. The major features of the planned infrastructure to support the Misratah iron and steel complex are detailed below.

Port.—Late in 1980, a $282 million contract was awarded to the Turkish firm, Sezai Turkes Feyzi Akkaya Insaat, to augment Mediterranean port facility work that had been started in earlier years. The new work is to be completed about midsummer 1984 and will handle the unloading of 2,000 tons per hour of iron ore or 1,300 tons per hour of coal. At some future time, the port may be enlarged to handle up to 8,000 tons of iron ore per hour. Sezai Turkes, the contractor, has been engaged to operate the port for 18 months after its completion. Dredging of the port area was subcontracted to Royal Bos Kalis Westminster of the Netherlands.

Railroad.—An all new 1,350-kilometer, standard-gauge railroad system is planned for Libya. There will eventually be three lines, converging at Misratah. The longest, Desert Line, will connect the Misratah iron and steel complex with the Sabhah area iron-mining district. A branch will extend off the Desert Line to limestone quarries at Sidadah. The iron ore rail terminal will be built near the steel mill at a place called Talut. By the year 2000, the Desert Line is expected to be handling about 12.6 million tons of cargo annually, most of which will be iron ore. Preliminary estimates indicate requirements for operation will include 18 road locomotives, 625 freight and ore-carrying hopper cars, 25 passenger coaches, 11 work-train units, and about 2,100 employees. The Desert Line, 900 kilometers in length, will not be operational before 1989 or 1990. Contracts for its construction are anticipated during 1983. A Yugoslavian firm, Projekt-Inzenjering, designed the railroad system.

Utilities.—Due for completion during 1982 are the Misratah complex's power and desalination plants. The power-generating facility, consisting of three 83.5-megawatt steam turbine-driven electric-generating units, was contracted for with Korf and Siemens AG of the Federal Republic of Germany. Electricity will be distributed on a 220-kilowatt wire system. The seawater desalination plant and water-cooling system, capable of processing 890 cubic meters of water daily, will be operated and managed by contractor-trained Libyan nationals. The water intake from the Mediterranean for this plant is to be part of the new port facility already under construction.

A water-purification plant, a repair shop, and electric transformer stations were contracted in April 1981 with a consortium led by Fiat Engineering S.p.A. and Techint Compagnia Technica Internazionale S.p.A., both of Italy.

NONMETALS

Cement.—Demand, created by vigorous construction activity in the residential, commercial, industrial, and transportation sectors, continued to encourage expansion in Libya's cement industry. Although capacity of the country's cement plants appeared to be approaching the annual requirement of 5 million tons, production itself was variously reported to be between 2 and 2.5 million tons in 1981, with the balance coming from Italy and other foreign sources.

Ample raw materials for making cement are available within the country, and although information is meager with respect to fuel used in the process, natural gas is probably predominant. Libya's cement-producing facilities are detailed in table 4.

Construction of the 1-million-ton cement plant at Derna was contracted to Mitsubishi Heavy Industries Ltd. of Japan and to Polimex Cekop, a Polish state concern. The new 1-million-ton-per-year plant at Homs will be managed, operated, and maintained by about 250 engineers and technical personnel who are employees of the Kuljian Corp. to whom a contract for these services was awarded. Kuljian was also retained to perform all required technical services in connection with planning and constructing the 500,000-ton-per-year plant at Sebha in southern Libya.

Other cement plants were under consideration for possible construction in the near future at various places in Libya. Should all of these materialize, capacity would be about 7.5 million tons annually, and Libya probably would have cement for export.

Meanwhile, a new lime plant was reported as completed at Benghazi during 1980 and operating in 1981.

Table 4.—Libya: Cement production facilities

Location	Owner	Kilns, rotary dry process	Startup	Capacity, end of 1980 (thousand tons per year)
Homs (Al-Khums), on the coast, 50 miles east of Tripoli.	National Cement & Building Materials Co.	2 1	1968 1979	1,433 1,000
Hawari, near Benghazi	Libyan Cement Co	5	1972	1,500

Zliten, 100 miles east of Tripoli.	Under construction by Kawasaki Heavy Industries.	--	Cornerstone laid in 1980; operations to begin in 1983.	1,000
Zawia, on the coast, 100 miles east of Benghazi.	Zawia Oil Refinery	--	Construction began in 1980.	100

MINERAL FUELS

Natural Gas.—Increasing use of natural gas for domestic consumption was well on the way to realization in 1981. Formerly, all natural gas production was exported as LNG or was flared. However, when the steelworks at Misratah are ready, they will be fired with natural gas from the Hateiba Gasfield, deep in the Sahara Desert. Further volumes of gas will go into feedstocks for the burgeoning petrochemical industries presently under development.

As the year began, the LNG plant at Marsa el-Brega was exporting its product at a rate of 235 million cubic feet of gas daily to Ente Nazionale Idrocarburi at Genoa, Italy, while an additional 110 million cubic feet per day was going to Gaz Natural at Barcelona, Spain. The contract price, agreed upon a year earlier, was $3.45 per million British thermal units. Early in January 1981, a price dispute surfaced. Under an OPEC-endorsed pricing policy, Libya called for an increase in LNG prices so that they would be at parity with recent crude oil price increases. Italy stood firm and refused to pay an increased price; Libya then ceased shipments to both Italy and Spain. Prompt settlement of differences and payment of a higher price to Libya by the Spanish interests resulted in little or no disruption of LNG deliveries to that country. Because other gas apparently became available to Italy, delivery of Libyan LNG was not resumed.

In September, a new gas-processing and condensate-recovery plant for the Benghazi

area was announced. The plant will use 100 million cubic feet of natural gas daily from central Libya's Messla Field. The Arabian Gulf Oil Co. awarded a $4 million contract for the plant to Worley Engineering Co., the U.S. subsidiary of William Press & Son Ltd., a British firm. Detailed engineering, procurement assistance, and inspection are expected to be completed in mid-1982. Logistics, construction management, and startup are part of phase two, for which no fixed dates were established. The contractor for phase two will also train Libyan personnel on operation of the plant and equipment maintenance.

Petroleum.—*Exploration.*—Libya's policy is to seek to replace, through new discoveries, whatever oil it produces each year. The country, therefore, has as a condition in its crude oil purchase contracts that each buyer will invest in exploration ventures within Libya's boundaries. Late in 1980, the French majority state-owned petroleum group, Elf-Aquitaine, concluded a production-sharing agreement under which it would explore for new oil in tracts totaling 15,800 square kilometers. Five separate blocks were involved; there were three onshore blocks in the Sirte Basin and one in the Hamada Plateau in the northwest part of the country about 400 kilometers southwest of Tripoli. These four blocks totaled 15,000 square kilometers. The fifth block was in western Libya's offshore waters adjoining acreage already held by Elf-Aquitaine and consisted of 800 square kilometers. However, in mid-January 1981, the Board of Directors of Elf-Aquitaine decided to postpone implementation of the exploration contract because of deteriorating relations between France and Libya over the latter's approach to the domestic affairs of Chad, its neighbor to the south and former French colony. About mid-July, the French Government decided to rescind its suspension of this and other contracts with Libya, thereby allowing, among other events, the resumption of the oil-exploration program. Two Canadian companies, in December 1981, reportedly acquired about 10% of the 5 production-sharing blocks and announced that they would perform a minimum of 7,600 line kilometers of seismic work and drill 17 exploratory wells in the ensuing 4 years.

Occidental Petroleum Corp. signed an exploration and production-sharing agreement in late 1981 for three blocks totaling approximately 10 million acres. Resolution of a continuing dispute between Malta and Libya over exploration rights on the Continental Shelf lying between the two countries was the subject of a meeting of the United Nations Security Council in late July. Evidence was presented showing that Libya has drilled about 30 offshore wells in the area and that Malta finds itself prevented from doing any drilling. The Security Council adjourned without taking any known action, nor did it set a date for a future meeting on this matter.

About 35 drilling rigs were reportedly operating in Libya in 1981, but indications of reduced exploration activity, due mainly to production cutbacks made necessary because of world oil supply-demand conditions, were beginning to be noted. Petroleum industry sources working in Libya indicated that if production improvement was not forthcoming, further cutbacks might be necessary.

Production.—For the first 4 months of 1981, Libya's crude production was running between 1.6 and 1.7 million barrels daily. A price of $39.90 per barrel, reduced from $41.00 per barrel, for top-quality Libyan crude was established in April and became effective on July 1, 1981. Responding to reduced world demand, output was down to about 1 million barrels per day by early July, to 900,000 barrels per day by the end of July, to 800,000 barrels per day in August, and some sources estimated that by September, production was down to 600,000 barrels per day, a drop of about 65% in about one-half of a year. Taken as a year's average, Libyan production was 1,117,000 barrels per day, an annual dropoff of 38.9%. By the middle of August, Libyan officials began discussing a price of $37 per barrel, and in late December, there were indications that this price had become official. There was little information available, however, as to what effect the lowered price, which was still somewhat above that being charged by OPEC nations located to the east of Libya, was having on Libya's ability to sell more crude oil.

These events led to concern in Libya that reduced petrodollar earnings would cause slowdowns both in exploration and development of Libya's oil resources as well as in the ambitious economic development of the country.

Exports.—Western Europe remained Libya's best crude oil customer in 1981, taking 48% of its crude exports. North America was Libya's second best customer, taking 35%, and Latin America was third, with 8%. Brazil's state-owned company,

Petróleo Brasileiro S.A., was increasing its liftings from Libya, owing to disruption of its regular sources by the Iraq-Iran war. Most of Libya's crude was being shipped through the port at Marsa el-Brega.

Refining.—Two refineries operated in Libya in 1981, and a large new plant was under construction. The 120,000-barrel-per-day refinery of NOC at Azzawiya satisfied most of the petroleum project needs of the country. The plant had capacities of 13,000 barrels per day in catalytic reforming and 16,000 barrels per day in catalytic hydrotreating. There was also in the NOC complex an asphalt plant with an output of 1,720 barrels per day.

In November 1981, Exxon Corp. notified the Libyan Government that it would relinquish its concessionary interests in that country. An agreement was negotiated that resulted in an orderly withdrawal from all operations along with the transfer to the Government of Libya, as of December 1, 1981, of Exxon's Libyan properties, including crude oil processing facilities and a LNG plant with associated exporting facilities. According to Exxon, this agreement resulted in a payment to the corporation that was somewhat lower than the net book value of its properties in Libya. Industry sources, in January 1982, indicated that Exxon had been paid $95 million, about $28 million less than the estimated net value.

A wholly owned subsidiary of NOC, identified as the Sirte Oil Co., was established to operate the former Esso Sirte installation, most commonly identified as the 9,500-barrel-per-day Marsa el-Brega refinery, which has catalytic reforming, hydrorefining, and hydrotreating processing facilities.

Ras Lanuf is located on the coast, not far east of Tripoli. It is here that Libya's third, and by far its largest, refinery and petrochemical complex was under development throughout 1981. The plant was owned by the Zavia Refinery Co., a subsidiary of NOC. At the outset, crude throughput capacity will be 220,000 barrels per day, but plans call for an eventual capacity of 280,000 barrels per day. Construction will be accomplished in several phases.

Work on the Ras Lanuf refining and petrochemical complexes was about on schedule during 1981. The refinery will make petroleum products for export. It will also supply raw materials for major ethylene plants, which in turn will feed a range of other petrochemical plants. A new seaport, on the Mediterranean, is being built from scratch, and adequate fresh processing water will be supplied from desalination plants, which are also under construction. Crude oil will arrive at the refinery petrochemical plant site via a new 42-inch pipeline from the producing oilfields in the desert to the south. Two entirely new towns are being built nearby to house the refinery employees and their families.

Petrochemicals.—There are two petrochemical centers in Libya. The Marsa el-Brega complex is not far south of Benghazi, on the Gulf of Sirte; a newer complex is under development at Abu Kamash, also on the coast, but far to the west, near the Tunisian border.

During 1981, demand for products from the Marsa el-Brega methanol plant were heavy enough to necessitate operating two daily shifts. In the first quarter of the year, output was 96,474 tons, about a third of the previous full year's record high production.

In September 1981, a 365,000-ton-per-year urea-based fertilizer plant was inaugurated at the Marsa el-Brega petrochemical complex. Cornerstones were also laid at the same time at Marsa el-Brega for a second urea plant, which will have a capacity of 1,750 tons per day, and for another 1,000-ton-per-day methanol plant. The urea plant, to cost $150 million, is to be built by a consortium of two Italian and one West German company.

Among numerous petrochemical units to be built at Ras Lanuf to use the ethylene feedstock that will be produced, there is a 60,000-ton-per-year low-density-polyethlene (LDP) plant. This product can withstand the temperatures of boiling water and is used for many household and industrial applications. During 1981, letters of intent worth $14.7 million were issued by the Zawiya Refinery Co. to Britain's Imperial Chemical Industries Ltd. for technology and high-pressure LDP devices and to Sim-Chem of the United Kingdom's Simon Engineering Ltd. Group for design engineering, procurement services, and a technical and advisory staff.

Transportation.—Libya's oil tanker fleet, by mid-1981, had grown to 13 ships with a total capacity of 1.2 million tons.

Early in April, at Goteborg, Sweden, the vessel *al-Gardabiya*, a 155,000-ton tanker measuring 279 meters long and 49 meters of beam, was delivered to her owners, Libya's National Corp. for Marine Transport (NCMT). She was the second of three ships of the same type built in Sweden for the NCMT. With delivery of the three tankers, Libya became the third largest Arab tanker

fleet owner.

Libya's pipeline network continued to expand during the year. It was reported in July that the Brega Petroleum Marketing Co. was to build oil storage tankage capable of holding up to 1.8 million barrels of petroleum products and a connecting pipeline system, all near Misratah, site of Libya's new steel mill complex. Construction was to be undertaken by the Republic of Korea's Samsung Construction Co. under a $75 million contract. Completion was scheduled for March 1983.

A 24-inch crude oil pipeline was also under construction from the Mobil Oil Corp. depot to the Ras Lanuf refinery, a distance of 12 kilometers. The builder was Saipem; completion was due during the summer of 1982.

The Italian construction firm, Snam Progetti S.p.A., was working on an ocean pipeline network that will feed, by 1984, into the El Sider marine terminal under construction and to be operated by the Oasis Oil Co. of Libya, Inc.

Seaport.—The NOC Ras Lanuf complex will require a new seaport to handle incoming materials and the huge volume of petroleum and petrochemical products that will be exported to world markets. A $300 million construction contract to build the port was awarded during 1980 to Hyundai Construction of the Republic of Korea. Completion was scheduled for September 1983.

Uranium.—A 400-megawatt nuclear powerplant has been in the planning stage in Libya for several years. The country has made several overtures to the Soviet Union in connection with this project. At one point, the Finnish state-owned power utility, Imatran Voima Oy (IVO), was interested in participating with the Soviet Union in the construction. In 1981, it was reported that IVO had abandoned its interest in working on this particular plant.

Libyan authorities have reportedly announced plans to mine uranium, and they claim that prospects for a viable operation are good. Meanwhile, Libya's purchases of neighboring Niger's uranium have climbed steadily. In 1978-80, acquisition totaled 788 tons. In the first 6 months of 1981, purchases from Niger were about 425 tons. Libya has only one small research reactor using, at the most, 12 kilograms of enriched uranium, and the country reportedly has no facilities for reprocessing. Therefore, the uranium can only be stored or exported. There is no available information to indicate disposition.

The Mineral Industry of Madagascar

By Kevin Connor[1]

The year 1981 brought little relief to Madagascar's economy, which continued to suffer from agricultural production problems, increasing import needs, and accumulated debt. Although there was a slowdown in 1981 in the contracting of new debts, total external debt increased from slightly over $1 billion in 1980 to $1.3 billion in 1981.[2] The service to debt ratio, which had been 4% in 1977 and 12% in 1980, rose to an estimated 30% in 1981. Despite the wide variety of large, potentially commercial mineral deposits known to exist in Madagascar, only three, chromite, graphite, and phlogopite mica, are presently being exploited. Total mineral production from these three sources accounted for less than 1% of Madagascar's gross domestic product in 1981, making the minerals industry a minor contributor to the Madagascar economy. However, as in past years, mineral production did play a somewhat greater role in terms of foreign exchange earnings, their export value accounting for approximately 4% of the country's total for the year.

Like many of the developing countries of Africa, Madagascar's need for petroleum imports is putting a sizable strain on the country's economy and is the leading cause in its growing balance-of-trade deficit. In 1981, Madagascar's petroleum trade bill increased by 33% over that of the previous year to approximately $130 million and represented 23% of Madagascar's total import costs. Madagascar's indigenous hydrocarbon deposits of tar sands, heavy oil, coal, and potential deposits of oil and gas have until recently been interesting geologically but never exploitable. However, at today's import oil prices, Madagascar has been pursuing all available avenues of domestic energy development, with petroleum exploration leading the way. In December 1981, two agreements were signed between the Government of Madagascar and Western oil companies to conduct exploratory drilling for petroleum on both offshore and onshore sites. In the area of tar sands and heavy oil deposits, Madagascar's National Military Office for Strategic Industries (OMNIS) worked in 1981 to prove the technology and economics of extracting crude oil from the island's deposits. In yet another area of energy development, construction of a large hydroelectric dam complex continued during the year, bringing the island an important step closer to energy independence. The project is the largest engineering endeavor in the island's history.

The 58-megawatt hydroelectric dam at Andekaleka, located roughly halfway between the capital city of Antananarivo and the country's principal port of Tamatave, was nearing completion at the end of 1981. The dam project, if completed on schedule during the latter part of the spring of 1982, will have cost approximately $150 million, $35 million over the original estimate. The end of 1981 marked the second full year of construction work on the project. Financing of the project has been provided by several institutions; the largest contributor was the International Development Association, with a loan of $43 million. Although the dam is small by world standards, it is expected to satisfy the electrical needs of both the Antananarivo and Tamatave areas for at least the next decade. The sophisticated dam complex has been constructed to eventually house four turbine generators, each with a generating capacity of 29 mega-

watts. The initial 58-megawatt output can be doubled to its maximum capacity in the future by installing the remaining two turbine generators. Madagascar's main sources of fuel until now have been imported oil and firewood. The new hydroelectric dam should reduce the island's fuel import bill by approximately $30 million annually.

Progress on the second phase of the expansion work to double the capacity of the Madagascar Petroleum Co. oil refinery by June 1982 was 70% completed as of the end of 1981. The new annual capacity of the plant will be 0.5 million barrels of diesel oil, 43,000 barrels of gasoline, and 20,000 tons of asphalt. The complex, which is located at Tamatave, is the only petroleum refinery within Madagascar.

PRODUCTION AND TRADE

Tonnage figures for mineral production in 1981 showed decreases for the three major minerals mined in Madagascar. Production of chromite, Madagascar's most important mineral commodity, was down by 40% from the 1980 final figure. Graphite production was down by almost 20%, and mica production was only a fraction of the 1980 total. Export earnings from mineral production trade were also considerably lower than that of 1980, with depressed international market conditions cited as the main cause.

Chromite is the most important mineral mined in Madagascar. Production, however, dropped substantially in 1981 to just under 100,000 tons, which was a 40% decrease from the 1980 tonnage. The decline was mainly due to the softening world market in steel. Part of the marketing problem for Madagascar chromite is the buyer's preference for ferrochrome, which Madagascar is presently unable to produce. A ferrochrome processing plant for Madagascar has been in the planning stage for several years, but unfortunately, technical and financial problems continue to deter its construction.

Madagascar is the world's leading producer of high-grade, natural crystalline flake graphite used in refractories, foundries, and steelmaking. All graphite production in Madagascar is by private producers. Graphite output for 1981 decreased 18% from that of 1980. A lack of foreign exchange capital to buy needed replacement parts and new equipment contributed to the decline. Mica production for 1981 was only 19% of that of 1980. Declining world markets for the resource have been cited as the reason.

The total value of 1981 imports for Madagascar was estimated at $557 million compared with only $382 million for exports. Increased import expenditures of greater than 24% over that of the previous year were attributed to domestic agricultural shortfalls in production and escalating oil prices. The majority of Madagascar's trade continued to be with the European Communities, particularly France. Trade with Africa continues to grow, as does economic relations with Japan, North Korea, and China. Trade with the United States has been declining since 1978, and continued to do so in 1981.

COMMODITY REVIEW

METALS

Chromite.—All of Madagascar's chromite was produced for export, as the country supplied approximately 2% to 3% of total world demand. Kraomita Malagasy, the Government agency responsible for all chromite mining on the island, was working with a group of technical partners from the Federal Republic of Germany, France, and Norway in 1981 to complete a ferrochrome plant feasibility study for Madagascar. Initial designs have established a 60,000-ton-per-year capacity for the plant, which would be located on the island's eastern escarpment near the town of Moramanga. However, technical problems remain to be solved before a serious decision can be made on construction of the facility. Collectively, the problems concern the suitability of Kraomita's chromite deposits for use as feedstock in a modern ferrochrome processing plant. The lumpy chromite ore most suitable for processing has yet to be produced from the main source of chromite production in Madagascar, the Andriamena Mine. Experimental ore processing was well underway in 1981, in an effort to economically bulk-produce the ore in the requisite form.

Iron Ore.—The Soalala iron ore deposit in northwest Madagascar, 150 kilometers south of the port city of Majunga, continued to be an object of in-depth study in 1981. The principal evaluator, Italsider S.p.A. of Italy, estimated ore reserves at 300 million tons with a 48% iron content. A decision on the economic viability of the project has yet to be made. However, the size of capital investment necessary to develop the mine, move the ore 150 kilometers to Majunga, and to construct port facilities there to handle the ore would be considerable. In these times of industrial austerity, construction this decade seems unlikely.

NONMETALS

Fertilizer Materials.—Construction on the Ze-Ren fertilizer plant at Tamatave continued throughout 1981 with completion scheduled for the end of 1982. The plant was designed to produce 90,000 tons of urea per year, which in turn held the potential of increasing rice production on the island by 300,000 tons per year. Madagascar, which used to be a rice exporter, had to import almost 200,000 tons of this food staple during 1981 to meet domestic needs. The estimated cost of the urea project is $65 million,

20% of which is U.S. financing from the N-Ren International Co. of the United States. This was the only U.S. investment in Madagascar as of the end of the year.

Mica.—Madagascar is currently the sole world producer of phlogopite mica, and reserves on the island are extensive. Mica production was adversely affected by competition from synthetic products in some electronic uses and by a low-cost substitute for phlogopite splittings made in India from mica scrap. About 15% of Madagascar's production is phlogopite splittings. Madagascar's mica is mainly sold to a variety of western buyers, including the United States, Japan, France, Spain, and Belgium. The drop in mica production for 1981 was attributed primarily to the surge in competition from the synthetics and substitutes.

MINERAL FUELS

Coal.—Negotiations between the Government agency OMNIS with a Belgian-French group and a British company on the development of the Sakoa coal reserves in southwest Madagascar continued in 1981. Madagascar would greatly like to see a project develop that at least might satisfy the local demand for coal for a cement plant and municipal and domestic heating uses. As is the case with many other resource sites in Madagascar, lack of infrastructure is the biggest hindrance to development of the coal. The capital outlay for the construction of mine, rail, and port facilities would be considerable and has deterred investors so far.

Petroleum.—Seeking assistance in developing a domestic petroleum industry, the Government of Madagascar negotiated a $13 million loan from the International Development Association of the World Bank (International Bank for Reconstruction and Development), in early 1980. This loan has played a key role in successfully promoting petroleum exploration within the country. Under the direction of World Bank advisors, a new petroleum code was adopted in mid-1980 by the Government, and shortly thereafter a tender was issued inviting international oil companies to bid for exploration rights. This groundwork resulted in the signing of exploration agreements between the Government of Madagascar and two U.S. petroleum companies, the Mobil Oil Corp. and Occidental Petroleum Corp., in December 1981.

Occidental was expected to begin about 18 months of seismic activities on a 5.3-million-acre block of land northwest of Tulear on the island's southwest coast, starting in late spring of 1982. Mobil negotiated for an offshore tract, and its specially equipped seismic vessel, the *T. W. Nelson*, was scheduled to arrive off Madagascar's west-central coast early in the spring of 1982 to conduct 40 to 50 days of studies. Additional seismic studies were tentatively scheduled for late 1982 or early 1983.

The two agreements signed thus far involved joint ventures with the Madagascar Government agency AKORAMA (National Enterprise for Hydrocarbons), which was officially formed in 1981 as a special petroleum company to handle state affairs in the research, exploitation, and transportation of hydrocarbons. AKORAMA is a subsidiary of the state organization OMNIS that was formed in 1975 to handle hydrocarbon development, chromite production, and potential uranium development. AKORAMA will control a 51% share in any operations developed by Mobil or Occidental, as required by Madagascar law. The oil companies assume all costs and risks prior to actual production and will have to pay taxes and royalties on any barrel of oil produced, as well as Madagascar taxes on their respective share of any profits.

In 1981, three formal bids were solicited by the Government for oil and gas exploration under the World Bank loan program. They were as follows: a January bid for geophysical operations for oil and gas prospecting in southern Tsimiroro, 450 kilometers northwest of Antananarivo; a September bid for seismic studies in the region of Morombe, on the west coast between Tulear and Morondava; and a November bid invitation to enter into joint ventures for oil exploration in the Tsimiroro area.

Aside from the agreements signed with Mobil and Occidental late in 1981, negotiations were well underway with the Amoco Oil Co., United States, by the end of the year, and an exploration-exploitation contract was expected to be signed by early spring of 1982. Also, two European oil companies were reported to be seriously negotiating exploration-exploitation agreements.

Tar Sands and Heavy Oil.—Late in 1981, OMNIS signed an agreement with the European company Compagnie Europeene de Petrole (CEP) for conducting preliminary studies on the exploitation of tar sand deposits at Bemolanga on the west coast. The reported $150 million agreement will

cover evaluating 360 square kilometers of area at Bemolanga, which is estimated to contain 3 billion tons of tar sands, 25% of which can be easily extracted. The agreement calls for 60% financing by the Government of Madagascar and 40% by CEP. This latest study followed feasibility work conducted in 1980 and 1981 under loans from the World Bank and the European Development Bank to define the preliminary reserve potential and engineering conditions necessary for exploitation. Also, feasibility work continued on evaluating the potential of the Tsimiroro heavy oil deposits, located 55 kilometers south-southwest of Bemolanga. Reserves by one estimate were placed at more than 4.5 billion barrels of oil in place at depths below 250 meters. An International Development Association-funded project in 1980-81 conducted a core drilling and chemical analysis program as a preliminary step in establishing the commerical potential of the area.

Uranium.—Madagascar possesses sizable deposits of uranium. The French Commissariat for Atomic Energy, and private mining companies, exploited deposits in the Fort Dauphine area of southern Madagascar from 1953 to 1968. Production was stopped in 1968 for political and economic reasons, but evidence indicates that only a small portion of the reserves have been exhausted. During 1981, a joint United Nations Development Program and International Atomic Energy Agency project, valued at $1.4 million, was reexamining the Fort Dauphine deposit for potential production, as well as another deposit 80 kilometers south of the capital of Antananarivo. Commercial production is not expected before 1985.

The Mineral Industry of Malaysia

By John C. Wu[1]

After a remarkable 8.2% growth in real gross national product (GNP) in 1980, the Malaysian economy managed to achieve a 6.9% growth in GNP under the adverse international environment in 1981. The slower growth in 1981 was a result of the slower expansion in agriculture and manufacturing and a negative growth of mining because of a decline in the output of tin and petroleum. The construction sector continued its strong growth stimulated by public spending on infrastructure. Malaysia's GNP, in 1970 constant dollars, was $11.6 billion in 1980 and was estimated at $12.4 billion for 1981.[2]

During 1980-81, the rate of inflation was between 6% and 9% per year, while the rate of unemployment was between 5% and 6%. Based on past records of economic growth and inflation and unemployment rates, Malaysia was rated as the third best economy in Southeast Asia after Taiwan and Singapore.

Under the fourth 5-year plan, Malaysia's gross domestic product (GDP), in millions of 1970 constant Malaysian dollars, by sector of origin for 1980 and 1985, is given in the following table:[3]

Table 1.—Malaysia: Gross domestic product, by sector of origin

(Millions of 1970 constant Malaysian dollars unless otherwise specified)

Sector of origin	1980	Share of gross domestic product (percent)	1985	Share of gross domestic product (percent)	1980-85 Average annual growth rate (percent)
Agriculture	5,809	22.2	6,720	17.8	3.0
Mining	1,214	4.6	1,607	4.3	5.8
Manufacturing	5,374	20.5	9,040	23.9	11.0
Construction	1,186	4.5	1,824	4.8	9.0
Government services	3,398	13.0	5,228	13.8	9.0
Other sectors	9,207	35.2	13,405	35.4	7.8
Total or average	26,188	100.0	37,824	100.0	7.6

For the coming 5-year period, the mining industry of Malaysia will continue to grow at between 5% and 6% annually and will contribute between 4.3% and 4.6% to Malaysia's GDP. Under the fourth 5-year plan, the Government of Malaysia has allocated about $21 million to the Departments of Geology and Mining. The corresponding budget for the two departments under the previous 5-year plan was only about $7 million.

In 1981, the mining industry remained important to the Malaysian economy. Despite its relatively insignificant contribution to the country's employment, the export earnings of tin and crude petroleum alone have contributed 32% to Malaysia's total export earnings. Other export minerals that also made contributions to export earnings were copper, bauxite, and byproduct minerals such as ilmenite, monazite, and zircon.

Malaysia was still the world's largest tin producer in 1981, despite a moderate decline in output. Its output of tin in concentrate was about 30% of the world's total, and the production of tin metal was about 35% of the world's total. In October 1981, Malaysia Mining Corp. (MMC) and Malaysian Tin Dredging (MTD) merged. The new tin mining company, also called Malaysia Mining Corp., became the world's largest tin company with a capital of $1.1 billion and controlled 38 of Malaysia's 55 dredges. Its annual tin output would represent 30% of the country's tin production.

In 1981, the State government of Sabah decided to build a $152 million copper smelter in Kota Belud in Sabah and also awarded a contract to Vöest-Alpine AG of Austria and Midrex of the United States for construction of a direct-reduction iron plant on Labuan Island.

A $350 million project was awarded by the Malaysian Government to a Japanese consortium to build a direct-reduction iron processing and electric-furnace steel complex.

The cement expansion project of the Associated Pan Malaysia Cement, Sdn. Bhd. at Rawang, Selangor, was to be built according to the schedule. A new cement company, Kedah Cement Sdn. Bhd. was established to operate a 4,000-ton-per-day, coal-fired cement plant on Langkawi Island in Kedah.

A fertilizer (ammonia-urea) complex would be built at Bintulu in Sarawak.

In the mineral fuel sector, Malaysian crude oil output dropped from an average 280,000 barrels per day in 1980 to an average 230,000 barrels per day in 1981. However, the country's oil reserves were revised from 1.8 to 2.5 billion barrels, which put Malaysia in 22d place in the world. The construction work on the $1.4 billion liquefied natural gas (LNG) plant at Bintulu was moving according to schedule. Malaysia also revised its nonassociated gas reserves from 33 to 36 trillion cubic feet.

Malaysia's export earnings declined from $12.8 billion in 1980 to an estimated $12.2 billion in 1981. Export earnings of tin, rubber, and sawed logs declined, while export earnings of palm oil, crude petroleum, and manufactured goods rose moderately. The worldwide economic recession and the oil glut weakened the international markets for most Malaysian export commodities.

Malaysia's total import bills rose from $10.7 billion in 1980 to an estimated $12.1 billion in 1981. Imports of all major items including machinery, transport equipment, and other manufactured goods increased substantially. The growth in imports reflected continued strong demand for Malaysian capital goods overseas.

Malaysia's overall merchandise trade balance has shrunk from $2.1 billion in 1980 to an estimated $0.09 billion in 1981 as a result of an 18% increase in import costs and a 0.6% decrease in export earnings.

PRODUCTION

Malaysia's tin mine output still remained the world's largest. In 1981, the tin mining industry suffered from a price reduction during the first half of the year and a 12% increase in the cost of production. The output of tin increased slightly during the second half of 1981 because of the recovery in tin prices. The output of bauxite also suffered from the depressed world market. Mine output of bauxite dropped 25% with only one mine operating in 1981.

Production of copper concentrates continued to increase in 1981, reflecting higher demand for copper ore by Japanese copper smelters and refiners. The output of iron ore increased sharply from last year with two additional mines operating in Perak.

Production of cement increased in 1981 because of increased output capacity by the Associated Pan Malaysia Cement, Sdn. Bhd., at its Rawang plant in Selangor. In mineral fuels, Malaysia was producing between 200,000 and 230,000 barrels per day of crude oil in 1981 versus an average 280,000 barrels per day in 1980 owing to the worldwide oil glut and the mandated cutback to conserve the country's limited oil reserves.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]All production is from peninsular Malaysia (Malaya) unless otherwise specified. Table includes data available through Aug. 2, 1982.

[2]In addition to the commodities listed, a variety of crude construction materials (clays, sand and gravel, and stone), salt, and fertilizers are produced, but output is not reported, and available information is inadequate to make reliable estimates of output levels.

[3]Based on export figures.

[4]Includes small amounts of tin from the smelter in Singapore.

[5]Includes production from Malaya and Sarawak.

TRADE

In 1981, exports of crude petroleum were estimated at $2.9 billion compared with $3.0 billion in 1980. Exports of tin were estimated at $1.0 billion in 1981 against $1.1 billion in 1980 owing to a decrease in tin prices. Malaysia continued to increase imports of machinery and transport equipment as well as manufactured goods. In 1981, imports of machinery and transport equipment were estimated at $4.7 billion, an increase of 15% over $4.1 billion registered in 1980. Imports of manufactured goods were estimated at $2.5 billion, a 17.7% increase over the $2.2 billion in 1980.

The Malaysian trade by major component during 1980-81 was as follows, in billion dollars:[4]

Table 3.—Malaysia: Trade by major components

(Billion U.S. dollars)

	1980	1981
Exports:		
Petroleum	3.04	2.93
Manufactured goods	2.80	2.87
Rubber	2.10	1.80
Sawed logs	1.19	1.01
Palm oil	1.14	1.25
Tin	1.14	.98
Other	1.39	1.34
Total	12.80	12.18
Imports:		
Machinery and transport equipment	4.13	4.70
Manufactured goods	2.23	2.51
Food, beverage and tobacco	1.21	1.30
Petroleum	.85	.87
Other	2.27	2.70
Total	10.69	12.08
Overall trade balance	+2.11	+.10

The overall trade balance of Malaysia shrank from $2.12 billion in 1980 to an estimated $0.09 billion in 1981, as a result of the reduction in export prices of raw materials and the continued increase in the value of imported capital goods and manufactured goods. During 1980-81, Japan, the United States, the United Kingdom, the Federal Republic of Germany, and Singapore were the major trading partners of Malaysia based on the total value of two-way merchandise trade.

Exports of Malaysian crude oil, accounting for 24% of total export value in 1980-81, went mainly to Japan, Singapore, and the United States. Exports of tin, accounting for 9% of total export value in 1980 and 8% in 1981, went principally to the Netherlands, Japan, the United States, the U.S.S.R., and India. Exports of copper concentrate and bauxite were mostly shipped to Japan.

Malaysia imported about $0.9 billion of heavier crude oil mainly from Saudi Arabia, Kuwait, and Iraq during 1980-81. Imports of capital goods and manufactured goods, valued at $6.4 billion in 1980 and over $6.9 billion in 1981, were from Japan, the United States, the United Kingdom, the Federal Republic of Germany, and Singapore.

Table 4.— Malaysia: Exports and reexports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1978	1979	Destinations, 1979	
			United States	Other (principal)
METALS				
Aluminum:

Feldspar, fluorspar, leucite	--	41	--	All to Singapore.
Fertilizer materials:				
Crude	464	520	--	Singapore 467; Brunei 53.
Manufactured	1,582	838	--	Indonesia 669; Singapore 136; Brunei 12.
Ammonia	193	437	1	Thailand 233; Singapore 200.
Gypsum and plasters	--	2	NA	NA.
Lime	22,621	18,314	NA	Singapore 18,273; Thailand 30.
Magnesite	--	26	--	All to Singapore.
Mica, worked including agglomerated splittings	2	(3)	--	All to Thailand.
Pigments, mineral: Processed iron oxides	5	22	--	Singapore 18; Indonesia 4.
Precious and semiprecious stones, except diamond:				
Natural value, thousands	$246	$318	--	Australia $147; Saudi Arabia $144.
Synthetic do	--	$280	--	All to Japan.
Salt and brine	473	793	--	Philippines 428; Indonesia 329.
Sodium and potassium compounds, n.e.s.:				
Caustic soda	5	1	--	All to Indonesia.
Soda ash	3	657	--	Republic of Korea 500; Singapore 157.
Stone, sand and gravel:				
Dimension stone, crude and worked	263	306	--	Singapore 287; Indonesia 9.
Dolomite, chiefly refractory-grade	5,550	8,327	--	Singapore 7,313; Papua New Guinea 914.
Gravel and crushed rock thousand tons	705	1,018	--	Singapore 994; Brunei 23.
Limestone, except dimension	259	489	--	All to Singapore.
Quartz and quartzite	2,747	5,010	--	Do.
Sand excluding metal-bearing	313,689	364,541	--	Singapore 269,667; Japan 76,800; Philippines 15,500.
Sulfur:				
Elemental, all forms	10	10	--	Singapore 6; Hong Kong 1.
Sulfuric acid, oleum	5	703	--	Singapore 701; Burma 2.
Talc, steatite, soapstone, pyrophyllite	114	9	--	All to Indonesia.
Other:				
Crude	--	15	--	Japan 14; Singapore 1.
Slag, dross, and similar waste, not metal-bearing	211	329	--	Singapore 137; Indonesia 33.
Building materials of asphalt, asbestos and fiber cements, unfired nonmetals	5,231	4,268	--	Singapore 2,849; Hong Kong 807; Brunei 605.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	55	10	--	All to Singapore.
Carbon black and gas carbon	1,142	3,590	--	Singapore 2,120; Indonesia 1,227; India 221.
Coal, all grades including briquets	71,701	71,438	1,755	Panama 11,282; Singapore 5,919; Republic of Korea 5,226.
Coke and semicoke	35	15	--	All to Thailand.
Hydrogen, helium, rare gases value, thousands	$10	$9	--	Singapore $8; Indonesia $1.

COMMODITY REVIEW

METALS

Aluminum.—The production of bauxite from the Telok Ramunia (Pengerang) Mine and the Sri Medan Mine (which stopped operations in March 1981) in Johore declined in 1981. A declining overseas market, particularly to Japan where most of the output was exported, was the primary cause of the reduction in mine output. In 1980, Malaysia's exports of bauxite were valued at $9.5 million, up 55% from $6.1 million in 1979. The increase in export earnings of bauxite was largely due to an increase in export quantity rather than an increase in unit value.

Copper.—Despite the depressed world copper market, copper production of Overseas Mineral Resources Development Sabah Bhd. at the Mamut Mine in Sabah increased in 1981. During 1981, the monthly production of copper ore at the mine was 500,000 tons, averaging 0.57% copper, while the monthly production of copper concentrate was 10,400 tons, grading 25% copper. The copper concentrate was exported to Japan for processing.

A $152 million copper smelter with an annual capacity of 50,000 tons of blister copper was to be built in Kota Belud in the State of Sabah. The State government of Sabah has invited bids for a turnkey smelter following a feasibility study completed by an independent consulting firm under State government supervision. The proposed copper smelter would use the copper concentrates produced from the Mamut Mine, about 112 kilometers from the proposed smelter site.[5] Until the copper smelter is completed, Malaysia will continue to export the copper concentrate to Japan. In 1980, Malaysia's output of copper concentrate was valued at $51 million.

A copper deposit was discovered by the Malaysian Geological Survey in the Pekan district of Pahang State in central Malaysia. The deposit was reportedly of a higher grade with a larger reserve than the Mamut Mine in the State of Sabah. The ore reserves and average grade of the area would be estimated after further exploration by the Malaysian Geological Survey.

Iron and Steel.—Production of iron ore increased substantially in 1981. The output of the largest mine at Gunung Jerain in Kedah accounted for about 30% of the total production; the output of seven small mines in Perak for 30%; and the output of four mines in Johore for 38%. Of 371,000 tons of iron ore produced in 1980, 97% was consumed domestically by Malayanata Steel Bhd. in Prai, and the remaining 3% was exported.

The Government of Malaysia awarded a contract to the eight-member Japanese consortium led by Nippon Steel Corp. for the construction of a direct-reduction iron processing and electric-furnace steelmaking complex at Tanjung Berhala, Trengganu, on November 9, 1981. The $350 million project was expected to be operated by a Malaysian-Japanese joint-venture company with a $109 million equity capital. The Japanese consortium reportedly was expected to take 30% of this equity capital.

Based on the terms of the contract, Nippon Steel Corp. is to engineer, supply, and build a 600,000-ton-per-year, direct-reduction plant with Daido Steel Co. to supply a 580,000-ton-per-year electric furnace; Mitsubishi Heavy Industries Ltd., a 560,000-ton-per-year billet continuous-casting machine; Chiyoda Chemical Engineering & Construction Co., the gas equipment and systems; and C. Itoh & Co., Mitsui & Co., Mitsubishi Corp., and Nittetsu Corp., the raw materials for the complex. The steelmaking complex will have an annual capacity of 600,000 tons of sponge iron, of which 560,000 tons will be for the manufacturing of steel billets, and the remainder will be for consumption by local foundry manufacturers. The complex was scheduled for completion in mid-1984 or early 1985.[6]

The Sabah State government signed a $145 million contract with Vöest-Alpine and Midrex for the turnkey construction of a 600,000-ton-per-year, direct-reduction iron plant on Labuan Island off the southwest coast of Sabah in May 1981. The construction work was expected to start in November 1981 and was scheduled for completion in early 1984. Based on the plan, all of the sponge iron produced from the plant will be exported exclusively to the steel industries of the Association of Southeast Asian Nations (ASEAN) and other Far East countries such as the Republic of Korea. The project will be operated by the Sabah Iron and Steel Sdn. Bhd., a joint-venture company owned 51% by the Sabah State government, 30% by the Heavy Industries Corp. of Malaysia, and 5% by Vöest-Alpine. The remaining 14% was expected to be taken by investors from Singapore, Thailand, Japan, and the Philippines.[7]

Tin.—Malaysia remained the world's largest tin producer in 1981. The output of

the Malaysian tin in concentrate accounted for 31% of the world's total in 1980 and about 29% in 1981. The output of the Malaysian tin metal was 36% of the world's total in 1980 and about 34% in 1981.

In 1981, the output of tin in concentrate declined slightly from that of 1980. The severe reduction in tin prices during the first half of 1981 and the rising cost of tin mining were the primary causes of the decline. The total number of active production units at the end of 1981 was 730 compared with 852 units at the end of 1980. Of the total number of production units active at the end of 1981, 617 units were gravel pumps, 57 were dredges, 33 were opencasts, 20 were underground, and 5 were other types.

Of the total tin concentrates produced in 1981, 56% was mined by gravel pumping; 29%, by dredging; 4%, by opencasting; 2%, by underground mining; and 9%, by retreatment, dulang, and other methods. Of the total concentrates produced in 1981, about 58% was from Perak; 31%, from Selangor; 4%, from Pahang; 3%, from West Persekutuan; and the remaining 4% was from Trengganu, Johore, Kedah, North Sembilan, Malacca, and Perlis.

Employment in the Malaysian tin industry dropped 12% to only 35,063 persons at the end of September 1981 from 39,720 persons at the end of the same period in 1980. Over 87% of the labor force employed by the tin mining industry was in the States of Perak and Selangor, where most of the gravel pumping and dredging mines were concentrated.

Exports of tin declined in 1980. However, because of a 12% increase in unit value in 1980, the value of tin exports increased 8.2% from $1,007 million in 1979 to $1,139 million in 1980. The value of tin exports accounted for 8.9% of the total value of Malaysia's merchandise exports in 1980. In 1981, because of the low tin prices, the value of tin exports was estimated at $978 million, a 10.3% drop from that of 1980. However, its share in the total value of merchandise exports remained at about 8%.[8]

The Government of Malaysia, in an effort to nationalize the Malaysian tin industry through MMC, has further broadened its assets base and brought about a vertical integration of its operations from exploration to production and direct marketing of tin in 1981.

In April 1981, MMC and Straits Trading Co. (STC) reached an agreement to establish a new tin smelting company, Malaysia Smelting Corp. (MSC) to operate the 60,000-ton-per-year tin smelter at Butterworth, Penang. MSC would be owned 42% by MMC and 58% by STC. The MSC was expected to smelt all tin concentrates produced by the MMC group including MTD and 15 other tin mining companies. MMC was reportedly to acquire an interest in Datuk Keramat Smelting (DKS), another major tin smelter at Georgetown on the Island of Penang with an annual capacity of 70,000 tons. DKS is owned 50.6% by Amalgamated Metal Corp., which in turn is owned 79.5% by Preussag of Hanover and 20.5% by MMC.[9]

MTD and MMC were merged into the world's largest tin mining company also called Malaysia Mining Corp. Bhd. on October 10, 1981. The newly enlarged tin mining company, with capital of $1.1 billion, will produce annually about 18,000 tons of tin, accounting for 30% of Malaysia's tin production, by controlling 38 of the country's 55 dredges. The new Malaysia Mining Corp. is owned 56.6% by Permodalan National Bhd., the Malaysian Government investment agency, 14.5% by Charter Consolidated Ltd., 3.8% by Datuk Keramat Holdings Bhd., and 25.1% by the public.[10] MMC has a marketing office in London, a new office in Japan, and was planning to open another new office in New York in the near future.

Other Metals.—Malaysia's gold production increased in 1981. Production of gold came 48% from seven small gold mines operated in the States of Pahang and Sarawak and 52% as a byproduct of tin mining operations in the Bidor area of Perak and the Kuala Lumpur area in Selangor. In 1980, gold production as a byproduct from the Mamut copper mine in Sabah amounted to about 60,800 troy ounces.[11]

Malaysia ceased production of manganese ore in July 1980. Other metallic minerals produced in Malaysia including columbite, ilmenite, monazite, scheelite, wolframite, xenotime, and zircon were recovered from tailings of dredging operations. There was small-scale mining of antimony ore from the Lucky Hill Mine in Sarawak.

NONMETALS

Cement.—Production of cement continued to increase in 1981. Malaysia's total clinker capacity has increased from 2.5 million tons in 1980 to 3.2 million tons in 1981. Malaysia's cement and clinker capacities, by company, for 1980-81 were as follows, in thousand tons:

Table 6.—Malaysia: Cement and clinker capacity, by company

(Thousand metric tons)

Company	Location	Cement capacity	Clinker capacity	
		1980	1980	1981
Associated Pan Malaysia Cement Sdn. Bhd	Kanthan, Perak	457	534	540
Do.	Rawang, Selangor	667	428	1,044
Cement Industries Malaysia, Sdn. Bhd	Kangar, Perlis	500	450	450
Cement Manufactures Sarawak, Sdn. Bhd.[1]	Pending, Kuching	260	--	--
Malaya Industrial & Mining Corp. Bhd	Batu Caves, Selangor	60	60	60
Tasek Cement, Bhd	Ipoh, Perak	1,050	1,046	1,100
Total		2,994	2,518	3,194

[1]A clinker-grinding plant.

Demand for cement in Malaysia was estimated at 2.5 to 2.6 million tons in 1980-81. Malaysia was still a cement-importing country in 1980-81.

In October 1981, Kedah Cement Sdn. Bhd., a new cement company, was established to build a 4,000-ton-per-day, coal-fired cement plant on Langkawi Island in Kedah State. The $130 million plant will be built by Ishikawajima-Harima Heavy Industries Co., Ltd., of Japan on a turnkey basis. One-half of the output will be for domestic consumption and one-half will be exported to Singapore in the form of clinker.[12]

Fertilizer Materials.—The output of chemical fertilizer remained at the 450,000-ton level in 1981. Malaysia was a net importer of fertilizer materials and chemical fertilizer. Malaysia imported phosphate rock from Togo, Jordan, and Christmas Island; urea from Indonesia, Japan, Romania, and the U.S.S.R.; ammonium nitrate and ammonium sulfate from Japan, the Republic of Korea, and Romania; and superphosphate from the United States.

A natural gas-based, ammonia-urea complex is to be built at Bintulu in Sarawak. The project is a joint ASEAN venture similar to the fertilizer complex in North Aceh of Indonesia. The total project cost was estimated at $300 million, of which about $210 million would be financed by Japan (70% from the Overseas Economic Cooperation Fund at 4% interest for 20 years, and 30% from the Export-Import Bank of Japan at 7.75% interest for 10 years), and the remaining $90 million would be contributed by Malaysia, 60%; Indonesia, Thailand, and the Philippines, 13% each; and Singapore, 1%. The fertilizer plant with an annual capacity of 272,000 tons per year of N as ammonia and 228,000 tons per year of N as urea was scheduled for completion in 1985. Stone and Webster of the United States was awarded a contract as a technical consultant to the project in late 1980. In August 1981, the Government of Malaysia, through Petroleum National Bhd. (Petronas), invited three consortia to bid for the building of the fertilizer complex at Bintulu in Sarawak. The contract was expected to be awarded in early 1982.[13]

Other Nonmetals.—To meet increasing demand for building construction materials by the expanding domestic construction industry, the output of limestone, crushed rock and granite, gravel, sand, and clay have increased substantially over the past 2 years. More than two-thirds of the limestone produced in Malaysia was used for construction purposes, and the remainder was for cement production.

Mine production of kaolin was about 46,000 tons in 1981. Of the total output, 84% was from 12 mining units operated in the Bidor area of Perak, 9% from the Jemaluang and Pontian areas of Johore, and 7% from the Cheras and Rawang areas of Selangor. About 25% of the kaolin output was exported, and the remainder was consumed domestically for fillers in rubber, paint, and plastics and for the manufacturing of floor and wall tiles, whiteware, sanitary ware, and white cement.

MINERAL FUELS

Coal.—A joint-venture company is to be established by local Malaysian interests and Kawasho Corp., a Japanese trading company (an affiliate of Kawasaki Steel Corp.), to produce coal in Selatik of Sarawak in early 1983. The Selatik (Silantek) coal deposit has been investigated several times by Nippon Coal Mining Co. and the Ataka Co. of Japan and Utah Pacific Inc. of the United States. The most recent estimate of coal reserves in Selatik was 12 million tons. Based on the plan, Kawasho Corp. will be in charge of mining operations. The coal mine output at the early stage would be about 500,000 tons

of coal per year. About 50% of the output would be exported, mainly to the Philippines, and the remainder would be consumed by the new coal-fired cement plant now under construction on Langkawi Island in the State of Kedah.[14]

Natural Gas.—Malaysia's recoverable nonassociated gas reserves were estimated at 36 trillion cubic feet (or 6 billion barrels of oil equivalent) by Petronas, the state-owned oil and gas company, in 1981. About 18 trillion cubic feet of nonassociated gas reserves in Sarawak was to be used by the LNG plant in Bintulu, Sarawak. The nonassociated gas to be used by the LNG plant would be produced from the Central Luconia Fields about 81 miles offshore Bintulu, Sarawak, at the rate of 1,250 million cubic feet per day for 20 years.

The construction work of the $1.4 billion LNG plant at Tanjong Kindurong, Bintulu, was about 76% complete for first-stage production at yearend. The construction of the LNG plant was by JGC Corp. of Japan and M. W. Kellogg (formerly Pullman Kellogg) of the United States. Under the plan, the plant was scheduled to start operations at the end of 1982 with an annual output of 1.5 million tons of LNG the first year, 3 million tons the second year, and 4.5 million tons the third year. At the end of 1985, full-capacity output is expected to reach 6 million tons of LNG per year. All of the LNG produced from the Bintulu plant will be exported to Japan beginning in 1983 under a 20-year contract. The Tokyo Electric Power Co. (taking two-thirds of the output) and the Tokyo Gas Co. are the two Japanese buyers. LNG Malaysia Sdn. Bhd., the owner and operator of the Bintulu LNG project, is owned 65% by Petronas, 17.5% by Shell Gas B.V. (a unit of the Royal Dutch/Shell), and 17.5% by Mitsubishi Corp. of Japan.[15]

The nonassociated gas from the Central Luconia Fields was also to be used as a feedstock for the ASEAN ammonia-urea plant in Bintulu, at the rate of 35 million cubic feet per day in 1985.

The remaining 18 trillion cubic feet of nonassociated gas reserves were reportedly in areas off the coast of Trengganu, of which about 17 trillion cubic feet are located in the contract area of Esso Production Malaysia Inc. and 1 trillion cubic feet in the contract area of Petronas Carigali Sdn. Bhd. The nonassociated gas from the Carigali Duyong Gasfield was to be used for firing a 450-megawatt, combined-cycle powerplant at Paka, Trengganu, at the rate of 70 million cubic feet per day in mid-1985.[16]

Malaysia's associated gas reserves were estimated at 9 trillion cubic feet in 1981. In 1980, about 260 million cubic feet per day of gas was produced. However, most of the output was flared.

Petroleum.—Malaysia's production of crude oil was from 14 oilfields in 1981. Three oilfields were in Sabah, eight in Sarawak, and three in Trengganu. Crude oil was reduced from an average of 280,000 barrels per day in 1980 to an average of 230,000 barrels per day in 1981 because of the glut in the world oil market. In 1980, Malaysia exported an average of 170,000 barrels per day of crude oil, mainly to Japan, Singapore, and the United States. Export earnings from mineral fuels rose by 52% to $3 billion in 1980 from $2 billion in 1979. In 1980, Malaysia also imported about 4 million tons of the heavier crude oil valued at $0.9 billion from Saudi Arabia, Kuwait, and Iraq to meet the requirements of its domestic refineries. Malaysia's consumption of crude oil was estimated at 7.5 million tons in 1980 and about 8.2 million tons in 1981.[17]

In 1981, Malaysia's recoverable oil reserves were revised by Petronas from 1.8 billion barrels to 2.5 billion barrels, which could last about 25 years at the present rate of production and allow Malaysia to remain a net exporter of crude oil until 1990.[18]

In late July 1981, the Government of Malaysia, through Petronas, awarded a contract to JGC Corp. and C. Itoh & Co. for design and construction of a 30,000-barrel-per-day oil refinery. The refinery would be built near Kerteh, Trengganu, about halfway between Kuala Trengganu and Kuantan. The $87 million project was expected to be completed in the first half of 1983 based on a turnkey contract. The refinery complex would have an atmospheric distillation unit, a gas-turbine, power-generation unit, storage tanks, and offsite utilities facilities including offshore shipping facilities.[19]

A $120 million project was awarded to Fluor Ocean Services Ltd. by Petronas for construction of a crude oil terminal at Trengganu. The system would have a 240,000-barrel-per-day capacity and a 45,000-barrel-per-hour tanker-loading rate and is scheduled for completion in mid-1983.[20]

The Mineral Industry of Malta

By Roman V. Sondermayer[1]

Malta remained a modest producer of limestone and salt in 1981. Some imported nonferrous metals, steel, and diamonds were worked, and the economy was heavily dependent on imported minerals and fuels to meet its requirements.

During 1981, the Government signed the first production-sharing oil exploration contract with a consortium led by Reading and Bates, Inc., of the United States. The contract covered an area of approximately 2,200 square kilometers in Block 8, Area 3, located southwest of the Island of Gozo. The contract is for 25 years, and the Government will reimburse the contractor for exploration expenses only if crude oil is discovered and commercial production starts.

In addition, another production-sharing oil exploration contract was concluded with a subsidiary of the Italian Azienda Generali Italiana Petroli S.p.A. This contract covers approximately 2,000 square kilometers in Block 3, Area 3, located northwest of Malta. Contract conditions are the same as for the previously mentioned agreement, except that drilling was to start before December 31, 1981.

[1]Less than 1/2 unit.

[2]Of the totals imported, 724 tons valued at $90,817 were reported in 1979 and 1,528 tons valued at $194,895 were reported in 1980.

[3]Excludes unreported quantities valued at $354,964 in 1979 and $287,748 in 1980.

The Mineral Industry of Mauritania

By Thomas O. Glover[1]

About one-fourth of the country's estimated $700 million[2] gross domestic product (GDP) originated in the traditional sector, principally from cereal cultivation, fishing, and livestock. The modern sector, which includes mining, transportation, and a small manufacturing sector, contributed another 20% of the total GDP, with Government and other services representing the remainder. The mining sector contributed to approximately 80% of Mauritania's foreign export revenues in 1981. Iron ore was the main industry in the country, and Mauritania's stagnant economy was directly related to depressed world iron ore markets.

The country is heavily dependent on its iron ore exports and will allocate 50% of projected investment expenditures in the next plan period to the mining sector. The mines at Kedia d'Idjill, now producing 9 million tons of iron ore annually, will be exhausted in 1990. The Guelbs project is being developed to replace this production. Total investment in the first phase of Guelbs will be $500 million, financed largely by loans from Iraq, Kuwait, Saudi Arabia, Abu Dhabi, France, Japan, the World Bank, the African Development Bank, and the Organization for Petroleum Exporting Countries Fund for International Development.

The low grade of the Guelbs iron ore will require substantial amounts of petroleum to process, adding significantly to operating costs. An oil refinery in Nouadhibou, completed in 1977, is scheduled to open next year, and consideration was being given to reopening the Akjoujt copper mine, which closed in 1978 when world copper prices fell.

PRODUCTION

Production of Mauritania's major mineral commodity, iron ore, declined slightly in 1981, mostly because of poor market conditions. Iron ore output was down 1% from 1980 but was still well above the low of 7 million tons in 1978, when the conflict with Western Sahara was at its peak. Market conditions precipitated the decline in production as well as an overall decline in export value for the year. Crude steel production, from a new scrap mill in Nouadhibou, increased slightly from 9,000 tons in 1980 to 9,100 tons of reinforcing bars in 1981. Since the closing of the Akjoujt copper mine in 1978, the only other minerals being exploited were gypsum and salt. Gypsum production decreased about 6% in 1981, and salt production remained stable.

[e]Estimated. [p]Preliminary. [r]Revised.

[1]Table includes data available through Aug. 23, 1982.

[2]In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (clays, stone, and sand and gravel) and salt presumably are produced, but output is not reported quantitatively, and available information is inadequate to make reliable estimates of output levels.

TRADE

During 1981, domestic indebtedness rose to $315 million while direct foreign aid grants declined, leaving the deficit before foreign loans at $136 million.

Iron exports from the Government-owned Société Nationale Industrielle et Minière (SNIM) mines in Zouirat in 1981 totaled 9 million tons. In 1980, SNIM exported 8.73 million tons of iron ore at an average sales price of $17.63 per ton. The European Economic Community purchased 77% of 1980 iron ore exports. SNIM exported all of its gypsum production to Senegal in 1980 at an approximate value of $440,000. A new company Société Akjoujt Minière was established to reopen the copper mines of Akjoujt, with 37.5% Mauritanian ownership, and $72 million capital. Some restoration of the old site has started, and copper exports are expected to recommence in 1984. Petroleum was brought into the country by the British Petroleum Co. under a "processing" agreement for a trial period of 1 year.

COMMODITY REVIEW

METALS

Copper.—Several studies have been conducted since 1979 concerning the feasibility of reopening the Akjoujt copper mine. The mine closed in 1978 because of heavy financial losses after being operational for 8 years. Copper oxide ores were mined and then processed to form concentrates. The treatment process used to concentrate the ore encountered technical problems, and only a limited amount of concentrate was ever produced. The copper oxide ores were nearly exhausted by 1978. Financial losses, caused by low production levels and the use of a highly energy-intensive treatment process, caused the mine to close.

The Government has attempted to attract investors to exploit the estimated 17 million tons of copper sulfide ore remaining at Akjoujt since the mine closed in 1978. The Government has received $100 million in financing from Arab countries to reopen the mine late in 1981 or early 1982, using more modern technology. Exports are expected to commence sometime in 1984.

Iron Ore.—Iron ore output declined slightly for the second consecutive year in 1981, mostly owing to the weakness of the world market for iron ore. Mining was carried out under the direction of Complexe Minière du Nord (COMINOR), which was owned entirely by SNIM. COMINOR operated three mines—Tazadit, F'Derik, and Rouessa—all in the Kedia d'Idjill deposit, near the city of Zouirat. The average grade of ore from the mines is about 65% iron. Production from these deposits began in 1960 under the direction of the Société Anonyme des Mines de Fer de Mauritanie, in which the Government held a 5% interest. The mines were nationalized in 1974, and iron ore production peaked at 11.9 million tons that year. The 1980 SNIM

annual report showed production at the Tazadit Mine of 4.41 million tons, up 20% over that of 1979. The Rouessa Mine produced 3.39 million tons of iron ore, down 13%, and the F'Derik Mine produced 1.14 million tons, down 15% from that of 1979. Stockpiled iron ore at the end of 1980 was reported at 1.2 million tons.

At the country's current rate of production, reserves at Kedia d'Idjill were expected to be depleted in the early 1990's. To ensure continued production of the country's major export, SNIM is developing the major new Guelbs iron ore project to exploit the El-Rhein and Oum Arwagen deposits. The Guelbs project is the country's top development priority. Work on the first stage of the project began in 1980.

The word Guelbs is actually applied to a group of about 25 deposits, all within a 50-kilometer radius of Zouirat. The first stage of the project was to develop the El-Rhein deposit, which contains over 260 million tons of ore, grading 35% iron. The deposit was to produce approximately 3 million tons per year in 1984 and then rise to 6 million tons per year by 1987. Included in this plan was the construction of a concentrating plant to raise the iron content to 65%. Concentration was to be dry magnetic separation, which is very important for a country with limited quantities of water. Total investment in the first stage of the project was estimated at nearly $500 million.

The second phase of the Guelbs project was centered around the Oum Arwagen deposit, where reserves were estimated at an additional 200 million tons, with an iron content of about 35%. Annual production capacity from Oum Arwagen was to be 4 million tons in 1990, rising to 6 million tons by 1992. This phase of the project, along with commissioning the second part of the concentration plant, was to take place in 1990. Concentrates from both deposits were to be transported by the 650-kilometer railroad that already links the Kedia d'Idjill deposit to Nouadhibou.

In 1981, SNIM exported 8.7 million tons of iron ore to 11 countries. The principal quantities were shipped to France, Italy, and Belgium, with less than 1 million tons going to eight other countries.

Following the startup of its first steelworks, Mauritania is now seeking quotations for the shipment of 15,000 tons per year of billets. Despite having a melting capacity of only 12,000 tons per year, the new Nouadhibou steelworks is capable of rolling up to 36,000 tons per year of rebars. The order is for 10,500 tons per year of 100-millimeter square billets and 4,500 tons per year of 80-millimeter square billets.

NONMETALS

Gypsum.—Mauritania possesses an estimated 1 billion tons of 98% pure gypsum. Since the closing of Mauritania's copper mine, the only other mining operation under SNIM's authority has been the extraction of gypsum from this deposit. The estimated 12,000 tons produced in 1981 was exported to Senegal for use in its cement plant at Rufisque. The Government hopes to expand mining operations and seek a worldwide market when the new deepwater port at Nouakchott is completed. Mauritania commenced operation of its first cement plant in 1981, producing an estimated 60,000 tons.

Phosphate.—Phosphate deposits near Mauritania's southern border are being studied to determine their economic potential. Reserves at the deposits were estimated at between 20 and 40 million tons of ore. The mining rate being considered is about 500,000 tons per year.

MINERAL FUELS

Petroleum.—In an October 1981 agreement, Mobil Oil Corp. of the United States selected two of the nine oil exploration blocks offered by the Ministry of Mines and Energy. Covering 34,000 square kilometers around Nouakchott, Mobil's acreage will be subject to a thorough seismic survey before a decision on drilling exploratory wells is taken. In November, Mobil dispatched a specially equipped ship, the Nelson, along the coastline for a preliminary geophysical appraisal.

Only 12 wildcat wells have been spudded in Mauritania's vast desert territory, and until now results have not been encouraging. Two sedimentary basins have attracted a number of international oil groups in the past: The Taoudeni Basin along the Malian frontier where Texaco Inc. and Azienda Generali Italiana Petroli S.p.A. (AGIP) were active, and the coastal or Atlantic Basin stretching from the Port of Nouadhibou southwards practically to the Senegalese border, where Amoco Oil Co. and AGIP completed an unsuccessful search. Negotiations during the first 6 months of 1982 are expected to lead to the signing of several

exploration agreements with other companies.

Refining.—Algerian technical assistance and financial aid will help bring Mauritania's new 1-million-ton-per-year refinery at Nouadhibou onstream toward the end of 1982. Completed in 1977 at a cost of $90 million, the refinery never started operations because it was designed to process only light Algerian crude oil, and until Mauritania signed a peace treaty in mid-1979 with the Algerian-backed Polisario, Algeria refused to supply crude to Mauritania.

The Algerians are supplying $20 million to refurbish the refinery, and the Jeddah-based Islamic Development Bank is to loan $10 million to finance feedstock purchases. When the refinery reaches its full production capacity of 20,000 barrels per day, about 80% of the output will be exported, as domestic consumption remains limited at 4,000 barrels per day.

Uranium.—The Mauritanian Government has disclosed the presence of a plan that is being implemented through an agreement between Mauritania and Iraq to extract uranium in Mauritania. Production is expected to begin within the next 3 years.

The Mineral Industry of Mexico

By Doris M. Hyde[1]

In 1981, Mexico maintained a strong rate of real economic growth, and it was the fourth consecutive year that the growth rate exceeded 8%. The gross domestic product (GDP) reached an estimated $239 billion,[2] as a result of high levels of public spending and strong performances in most sectors of the economy, especially petroleum. The rate of inflation in 1981 was 29%, down 1% from that of 1980.

Foreign loans were used to complement domestic resources to finance national development programs, such that by the end of 1981, Mexico's foreign debt was slightly under $50 billion. Many observers believed the Mexican peso to be overvalued by 25% to 30%, and this has made Mexican exports less competitive and imports attractively cheaper.

In 1981, Mexico ranked fourth in world production of crude oil, following the U.S.S.R., the United States, and Saudi Arabia. Although the petroleum sector accounted for only 6% of the GDP, its rapid growth rate over the past few years has affected other sectors and created a boom economy. The plentiful supply of oil for domestic development has greatly reduced constraints on growth. Petroleum export revenues have permitted increased importation of goods and services and facilitated Mexico's ability to obtain foreign loans.

The 1981 trade deficit, excluding the value added by the in-bond assembly plants, was $3.7 billion. Despite a lower rate of import growth in 1981, Mexico also experienced lower than expected income from petroleum exports as well as generally depressed world prices for some traditional exports, such as coffee, silver, and copper.

The $14.6 billion value of petroleum exports accounted for 75% of merchandise export earnings. Although this represented a 40% increase over petroleum export earnings in 1980, it was less than the $19 billion expected before market price and demand reductions.

Export earnings from nonfuel minerals were also less than anticipated. In some instances, an increasing domestic demand for minerals lessened volumes available for export. In other instances, world market prices were lower than projected. Income from silver exports was particularly disappointing as the market price dropped from an average of $20.60 per troy ounce in 1980 to $11 per troy ounce in 1981. In 1980, about one-half of the value of Mexico's nonfuel mineral exports was attributed to silver. In 1981, copper concentrate exports more than tripled those of 1980, but the associated earnings were less than double and did not compensate for the decline in silver prices.

The larger U.S. firms holding minority equity positions in Mexican mining and metals companies included AMAX, Inc., 40% interest in Cía. Fresnillo S.A. (silver); The Anaconda Company, 34% interest in Cía. Minera de Cananea (copper); ASARCO Incorporated, 34% interest in Mexico, Desarrollo Industrial Minera S.A. (copper, silver, lead, and zinc); and Texasgulf, Inc., 34% interest in Cía. Exploradora del Istmo, S.A. (sulfur).

Government Policies and Programs.—In mid-1981, the Government repealed the excess profits tax on gold and silver, first levied in January 1980 when precious metal prices reached unprecedented levels. By the time of its repeal, these prices had fallen sharply such that the tax had become largely a psychological impediment to increased mine production and investment.

Another reported Government incentive for the mining industry was to grant Certifi-

cates of Fiscal Promotion. These certificates allowed liberal tax credits to companies that increased employment, invested in additional exploration, or invested in equipment and plant facilities designed to increase production.

PRODUCTION

Mineral fuels continued to dominate Mexico's total mineral production. The production of crude oil in 1981 increased 19%, following a 33% increase in 1980. Natural gas production in 1981 increased 14% over that of 1980. Crude oil and condensate production averaged 2.3 million barrels per day during 1981. The output of refined petroleum products reached slightly less than 1.3 million barrels per day in 1981, a 10% increase over 1980 production. Petróleos Mexicanos (PEMEX) continued to use toll refining and processing facilities in Spain and France for its crude oil and also initiated new processing contracts in Italy and the United States.

The total value of production from 16 metallic and 26 nonmetallic minerals by Mexico's mining sector reached about $2.7 billion in 1980. Volumetric production gains in 1981 were not able to compensate for the generally downward trend in world market prices. As a result, the total value of production from the mining sector declined to an estimated $2.1 billion in 1981. Prominent among those minerals that declined in value was silver, whose 1980 value of $980 million fell to $550 million in 1981, despite a 12% increase in volume. Other leading minerals that were produced in greater quantity but fell in value were gold, lead, and copper.

Mexico's mining sector achieved some historic gross production records in 1981. The highest output gain was in the copper industry, which had a 30% production gain because of increased output from the La Caridad Mine. Alltime production records were also reached for iron ore, manganese, and molybdenum. Silver, barite, and phosphate rock production were the highest in the last 10 years, while gold and fluorspar production exceeded those of the last few years. Lead production gained over that of 1980 but failed to reach the higher level achieved in 1979.

[e]Estimated. [p]Preliminary. [r]Revised.

[1]Table includes data available through Sept. 14, 1982.

[2]In addition to the commodities listed, pumice and additional types of crude construction materials are produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[3]Sb content of ores for export plus Sb content of antimonial lead and other smelter products produced.

[4]Calculated white As equivalent of metallic As content of products reported.

[5]Bi content of refined metal, bullion, and alloys produced indigenously, plus recoverable Bi content of ores and concentrates exported for processing.

[6]Calculated from reported Fe content on the basis of concentrate and pellets containing 66.67% iron.

[7]Calculated from reported Mn content of mine production on the basis of ore containing 36% manganese.

[8]Estimates by the International Tin Council.

[9]Excluding that for cement production.

TRADE

Mexico's international trade in mineral commodities is given in table 2 for exports and table 3 for imports. Comparative estimates of the value of Mexico's 1980 and 1981 mineral exports follow, in millions of dollars:

	1980	1981
Total Mexican exports	$15,308	$19,379
Crude oil exports	$9,449	$13,305
Crude oil share	61.7%	68.7%
Mining, metallurgical exports	[r]$1,347	[e]$1,256
Mining, metallurgical share	[r]8.8%	6.5%

[e]Estimated. [r]Revised.

The total petroleum export values increased 40% owing to increased volumes, but the export contribution by mining and metallurgical products decreased 8%. The volume of mineral exports was up 20% for silver, 296% for copper concentrate, 66% for manganese, 14% for sulfur, and 9% for zinc concentrate. On the downward side of mineral volume exports were refined zinc, down 63%; refined lead, 9%; unrefined lead, 30%; lead concentrate, 30%; mercury, 38%; and fluorspar, 16%.

The value of Mexico's silver exports fell to an estimated $439 million, a 35% decrease from the $676 million received in 1980. This was the result of a sharp decline in world market prices. In 1981, copper export volumes more than tripled those of 1980, although their value fell short of doubling. The value of the principal nonfuel mineral exports to the United States in 1981 is shown below, in millions of dollars:

Commodity	Value
Silver	$197.6
Sulfur	108.2
Mica, quartz, feldspar, cryolite, etc	59.0
Precious metal ores and concentrates	38.2
Fluorspar	34.8
Lead and lead alloys, unwrought	25.1
Copper and copper alloys, unwrought	23.5
Sodium chloride (salt)	20.1
Ferroalloys	18.9
Copper ores and concentrates	13.7
Zinc and zinc alloys, unwrought	13.5
Total	552.6

In 1981, crude oil export volumes averaged 33% higher than the average of 827,750 barrels per day exported during 1980. Petroleum product exports were valued at $600 million, or a 53% increase over those of 1980. Petrochemical exports also increased in volume and value over those of 1980. Natural gas exports to the United States averaged 288 million cubic feet per day, for a total value of $526 million for the year. The combined value of petroleum exports reached slightly less than $14.6 billion in 1981 and represented 75% of the total value of all exports.

Mexico exported crude oil to 25 countries during 1981 and, in addition, exported only petroleum products and petrochemicals to 7 other countries. The crude oil exports were 44% Istmus light crude oil and 56% Maya heavy crude oil.

After the first semester of 1981, Mexico's prices for petroleum generally became more competitive with world market price trends. At the beginning of 1981, Istmus light crude oil was valued at about $38.50 per barrel, but at the end of the year, it had fallen to $35 per barrel. Maya heavy crude oil began the year at $34.50 per barrel but was $28.50 by the end of 1981.

Mexican imports by mineral sector are shown below, in millions of dollars:

Sector	1980	1981
Extractive:		
Crude oil and natural gas	8	8
Metallic minerals	55	58
Nonmetallic minerals	194	191
Manufacturing:		
Petroleum derivatives	292	348
Petrochemical	535	522
Metallurgy	385	574
Iron and steel	1,824	2,126
Total	3,293	3,827
Percent share of total imports	18	17

COMMODITY REVIEW

METALS

Antimony.—At the end of 1980, NL Industries, Inc., sold its 49% share in Cía. Minera Refinadora Mexicana, S.A., to LIG Overseas Ltd., a subsidiary of Lead Industries Group, Ltd., of London. LIG interest was to be managed by the firm's U.S. subsidiary, Anzon America, Inc. Minera Refinadora operated an antimony mine at Wadley and has been the major supplier of ore to Anzon's antimony oxide plant at Laredo, Tex. Anzon expected that Minera Refinadora would initiate mine expansion plans. Anzon did not plan to build an antimony oxide plant in Mexico but expected to use the increased mine production to supply its expanding Laredo antimony plant.

Copper.—An estimated 80% of Mexico's copper production originated from mines in the State of Sonora. The opportunity for Mexico to provide more of its refined copper requirements remained dependent on the completion of the Mexicana de Cobre S.A. La Caridad smelter and refinery. Until then, Mexico must import significant amounts of refined copper while exporting significant amounts of copper concentrate. In 1981, Mexico imported over 105,000 tons of copper in various forms at a cost of $230 million.

A study by the Mexican Copper Producer's Association indicated that even if 1990 production capacity reached the projected target of 380,000 tons per year, internal demand could increase at a greater rate and reach 388,000 tons or more per year.

Increased production from the La Caridad Mine near Nacozari, Sonora, was the major reason for Mexico's upswing in total 1981 copper production. Even so, La Caridad's 1981 production and export of about 450,000 tons of copper concentrate was 22% below earlier projections. The 180,000-ton-per-year smelter under construction was expected to come onstream in 1983. The La Caridad complex was also to include a 150,000-ton-per-year refinery, a wire factory, and a 1,800-ton-per-day molybdenum plant. By the end of 1981, Mexicana de Cobre, a joint venture of private Mexican interests (56%) and Government agencies (44%), had invested over $1 billion in La Caridad, and completion of the smelter and molybdenum plant was estimated to require another $500 million. The refinery cost was estimated at an additional $100 million. The high costs were attributed to inadequacies in the original design of the tailings pond and the increased cost of building the smelter. A heavy investment was also required for the development of infrastructure.

In 1981, the Cía. Minera de Cananea mine and smelter produced about 38,000 tons of blister and electrolytic copper and 353,660 ounces of silver. The company was proceeding with a major expansion project, which included opening the Kino and Colorado-Veta open pits for mining and increasing capacities at the concentrator, smelter, and electrolytic facilities.

In 1981, Atlantic Richfield Co. sold its 34% interest in Cananea to the Nacional Financiera, the Government development bank. This Government bank then had a 49% equity in Cananea, while private Mexican interests held the remainder.

Industria Minera Mexico, S.A. (IMMSA), produced about 34,000 tons of copper as a coproduct from several of its mining operations. The more important of these were the San Martin unit in Zacatecas State, Charcas unit in San Luis Potosí State, Santa Barbara unit in Chihuahua State, Tecolote unit in Sonora State, and Inguaran unit in Michoacan State. The IMMSA 42,000-ton-per-year copper smelter at San Luis Potosí also processed concentrate from other producers.

The three major copper producers mentioned above accounted for about 92% of Mexico's total mine output of copper.

Iron Ore.—Mexico's domestic iron ore production was expected to meet the needs of the Siderúrgica Mexicana (SIDERMEX) controlled steel producers until the 1990's, after which it probably would be necessary to import ore. Pellet production by the major iron ore-producing companies is shown in table 4.

Table 4.—Mexico: Pellet production of major iron ore producers

(Million metric tons)

Company (principal mines)	1979	1980	1981	Average iron content (percent)
Consorcio Minero Benito Juarez—Peña Colorado (Peña Colorado Mine)	1.9	2.1	2.4	68

Altos Hornos de México S.A. (La Perla Mine)	.3	.4	.3	63
Total	5.4	[1]5.1	6.7	

NA Not available.
[1]Incomplete.

Hojalata y Lamina, S.A. (HYSLA), the steel company of Grupo Industrial Alfa, S.A., produced about 2 million tons of iron ore from its Las Encinas Mine, Colima State. In 1981, ore reserves at Las Encinas were estimated at 24 million tons. The ore was pelletized onsite. Las Encinas ore averaged 55% iron content compared with the 47% iron content of ore HYSLA received through its 28.5% equity in the Peña Colorado Mine.

HYSLA was actively exploring for new iron ore deposits in the States of Michoacan, Chihuahua, and Guerrero. Its development of the Aguila iron deposit in Michoacan State has been delayed, and mine production was not expected to begin until 1985. This mine was expected to produce 1.5 million tons of ore per year averaging 42% iron. HYSLA plans included the construction of a second pelletizing plant at the Las Encinas site to handle the increased input. The Aguila Mine is 91 kilometers from the Las Encinas site.

The Las Hércules Mines, Coahuila State, of Fundidora de Monterrey S.A. (FMSA) were not expected to produce above minimal levels until 1983 when the 90-kilometer, 8-inch slurry pipeline from the Altos Hornos de México S.A. (AHMSA) La Perla Mine in Chihuahua State was scheduled for completion. This pipeline was to feed into a 310-kilometer, 14-inch pipeline under construction from the Las Hércules Mines to Monclova. The FMSA Cerro de Mercado Mines in Durango State were expected to close in 1983, when both of the Las Hércules Mines in Coahuila State were to be operational. The Body No. 9 Mine at Las Hércules has been operational for 10 years, but the mine called Cascolinas had not yet opened. An estimated 1.5 million tons of concentrated ore would be pumped annually from La Perla to the Las Hércules site, where 3.5 million tons of concentrated ore would be added for further transport to AHMSA facilities at Monclova. Iron ore reserves at the Las Hércules Mines were revised upwards from 53 to 85 million tons. Ore reserves at the AHMSA La Perla Mine were estimated at 46 million tons.

Iron and Steel.—Although high interest rates and shorter periods for servicing debts continued to threaten many Latin American steel expansion projects, Mexican producers have proceeded with their ambitious plans to more than double their combined installed capacity by 1990.

On the whole, the Mexican steel companies have not encountered problems in obtaining financing. Financial difficulties of the Grupo Industrial Alfa, S.A., were reportedly caused by a combination of servicing large overseas loans and the Government relaxation of some controls on the importation and commercialization of steel products. In 1981, Alfa received a $680 million loan from the Government-owned Banco National de Obras Publicas S.A. Alfa budget reductions were not expected to affect the HYSLA expansion project at Monterrey.

HYSLA, Mexico's largest private steelmaker, formed one of the three Grupo Alfa divisions. The HYSLA main steelworks had a crude steel capacity of 970,000 tons per year and was located in Monterrey. Lower capacity HYSLA steelworks have been established at Xoxtla near Puebla (500,000 tons per year) and at Mezquital near Mon-

terrey (100,000 tons per year). HYSLA combined crude steel capacity approximated 1.6 million tons per year.

The HYSLA Monterrey expansion, Project 1600, involved a two-step process to raise capacity to 1.6 million tons per year by the end of 1983 and 2 million tons per year by 1985. To accomplish this, HYSLA planned to convert its No. 3 direct-reduction plant to the new continuous direct-reduction process known as HYL III. Through this modification, the plant capacity would be increased slightly from 480,000 tons per year to 500,000 tons. A new 750,000-ton-per-year direct-reduction plant, a new electric melting shop, improvements to the hotstrip and plate mills, a continuous cold mill, and soaking pits were also scheduled as part of the expansion project. The Puebla and Mezquital plants were also programed for a combined steel capacity increase from 600,000 tons per year to 1.1 million tons per year. Total combined HYSLA capacity in 1990 was projected at 3 million tons per year.

SIDERMEX, Mexico's state steel holding company, was programing steel and direct reduction plant expansions for the companies under its control—AHMSA, FMSA, and Siderúrgica Lázaro Cárdenas-Las Truchas, S.A., also known as SICARTSA. Tubos de Acero de México S.A., also known as TAMSA, Mexico's sole producer of seamless pipe and the second largest private producer of crude steel, expected to invest $700 million by 1985 to meet increased demands from PEMEX.

Reported capacity expansions planned by public and private steel-producing companies are shown below, in thousands of tons:

Company	1981	1986	1990
SIDERMEX:			
AHMSA	3,300	4,200	4,200
FUNDIDORA	1,150	1,350	1,350
SICARTSA	900	2,800	3,200
Future plant	--	1,800	6,100
Total	5,350	10,150	14,850
HYSLA:			
Monterrey plant	1,000	2,000	2,000
Mezquital plant	100	1,000	1,000
Puebla plant	500		
Total	1,600	3,000	3,000
TAMSA	440	820	900
Others	1,100	1,600	2,000
Grand total	8,490	15,570	20,750

Lead and Zinc.—In 1981, Mexico ranked seventh in world zinc mine production and sixth in world lead mine production. The decrease in silver prices influenced associated zinc production as some companies curtailed output from mines with low-grade silver values. Lead and zinc concentrate production was expected to rise in the future as several of the larger producers complete expansion programs.

The 114,000-ton-per-year electrolytic zinc refinery of IMMSA at San Luis Potosí was not completed in 1981. A revised date for startup testing was given as October 1982.

Molybdenum.—Mexico's entire 1981 molybdenum production was from the State of Sonora. In 1981, the Cumobabi Mine of Minas Cumobabi S.A., a subsidiary of Minera Frisco S.A. de C.V., completed its first full year of operation with a production of 467 tons of molybdenum trioxide. The company was reportedly experiencing some technical difficulty separating the molybdenum from associated copper.

AMAX entered into a joint venture with Cía. Minera Fresnillo to develop a molybdenum property at Opodope, also in Sonora State. This deposit was reported to have 150 million tons of medium-grade ore reserves.

The molybdenum plant at the La Caridad copper complex was to have been operational in 1981 but was rescheduled to open in 1982.

Silver.—In 1981, Mexico was again the leading world producer of silver, and despite the continuing downward trend of world market prices, production rose to a record level. The $550 million value of 1981 production was 44% below the value of 1980

production, even though the 1981 volume was 12% higher.

Silver reserves were last estimated in 1979 at 950 million troy ounces. Precise estimates are difficult to obtain because most silver is mined as a byproduct of other metals. Total annual mining capacity in 1978 was estimated at 60 million troy ounces, but by the end of 1982, this capacity was expected to increase to 75 million troy ounces. This increased capacity was expected to come from the Real de Angeles Mine, the La Minita barite mine, the Cuale Mine, and expanded capacity at the Taxco, San Martin, Fresnillo, and Santa Barbara Mines. Annual refining capacity in 1981 was about 50 million troy ounces.

In 1981, there were about 62 companies engaged in silver mining. Of these, seven accounted for about 70% of production, and the remainder came from small- and medium-size producers. The largest private producers were Industrias Peñoles S.A. de C.V., IMMSA, Minera Frisco S.A. de C.V., Minas de San Luis S.A., Minera Mexicana Sombrerete S.A., and Cía. Minera de Cananea.

The largest silver producer was Industrias Peñoles S.A. de C.V., whose major silver-producing mines were the Fresnillo and Naica units. These two mines were operated by Cía. Fresnillo S.A., in which Peñoles held a 60% equity and AMAX held 40%. The Fresnillo group of mines produced 7.9 million troy ounces of silver and 5,600 troy ounces of gold in 1981. Peñoles owned an electrolytic refinery at Torreon, Coahuila State, where ore purchased from other Mexican producers was also refined. Peñoles treated foreign concentrates, primarily from Peru, under temporary import permits. In 1981, Peñoles refined about 35 million troy ounces of silver, of which about 12 million troy ounces originated from its own mines or from the mines of its affiliated companies.

IMMSA was Mexico's second largest silver producer. IMMSA was the largest subsidiary of the joint holding company Mexico, Desarrollo Industrial Minera S.A. (MEDIMSA), in which Asarco, of the United States has maintained a 34% interest. All of the MEDIMSA-held affiliated companies produced 18.9 million troy ounces of silver and 52,900 troy ounces of gold in 1981. IMMSA produced about 7.5 million troy ounces of silver from its own mines.

Minera Frisco S.A. de C.V., a large silver producer from its own mines, joined with Placer Development, Ltd., of Canada (34%) and the Comisión de Fomento Minera (33%) to form Minera Real de Angeles S.A. de C.V. as the operating company for the Real de Angeles silver mine in the State of Zacatecas. When fully operational, this $170 million project was expected to be the largest open pit silver mine in the world and have a production of 7 million troy ounces of silver per year. Mine development was well underway, and production was scheduled to begin in May 1982. In 1981, Frisco joined with Armco, Inc., of the United States, to form Minera Cerro de Plata S.A. de C.V. to explore for silver ore in northwestern Mexico.

Industrias Luismin S.A. de C.V., Minera Mexicana Sombrerete S.A., and Government-owned Cía. Real del Monte y Pachuca S.A. have each produced about 3 million troy ounces of silver per year, as has Cía. Minera de Cananea, a major copper producer.

A number of silver projects have been held back owing to high financing and development costs and lower than projected silver prices. The 40% excess profits tax on silver imposed in 1980 was a deterring factor to mine development. Given silver's subsequent price decline, the effect of this tax became largely psychological, and it was removed in June 1981. The unfavorable factors governing increased output, primarily silver prices, may continue to dominate company decisions on expansions and new projects. Small producers were especially susceptible to silver price declines, and many were threatened with closure.

Tungsten.—In 1981, about 250 tons of tungsten concentrate was produced in the State of Sonora, representing about 90% of Mexico's total production. Sonora's output was dominated by three companies, of which Tungsteno de Baviacora, S.A., was the largest producer. The producing companies have been seriously affected by reduced market prices and were reported as preparing to scale down their operations.

Two Canadian companies have formed a joint venture with Grupo Alfa to develop the San Alberto Mine near Alamos, Sonora State. San Alberto ore reserves were estimated at 6 million tons averaging 0.6% tungsten. Production was scheduled to begin in 1983, although the expected rate of mine output was unannounced.

NONMETALS

Barite.—The brisk demand for barite from the oil industry continued to prompt new mining investment in Mexico. Production by one of the newer companies, Government-owned Barita de Sonora S.A. de C.V., reached 500 tons of barite per day in 1980. The company estimated that production would eventually reach 300,000 tons per year. The company reported proved reserves of 15 million tons and had acquired exclusive exploration rights on a 76,800-hectare tract near Mazatan, Sonora. Barita de Sonora budgeted over $24 million for exploration work in 1982.

The other large barite producer under development in Sonora State was Minera Baucarit S.A., a privately held company formed by F.M.C. Corp. of the United States and Protexa, S.A., of Mexico. Baucarit's open pit mine, located 100 kilometers east-southeast of Hermosilla, had reported proven reserves of 20 million tons. About 475,000 tons of material was to be mined annually, including 290,000 tons of ore and 145,000 tons of waste.

In the area surrounding Tecolotlán, Jalisco State, approximately 23 barite mines were under development at a total initial investment cost of almost $3 million.

The La Minita barite mine, owned by Peñoles and located in Michoacan State near the towns of Aguililla, Taricato, and Chinicuila, initiated production in 1981. It was expected to eventually produce 240,000 tons of barite per year plus 30,000 tons of zinc concentrate, 4,000 tons of lead concentrate, and some silver. The ore averages 59% barium carbonate-barium sulfate. Barite demand by the Mexican oil industry was expected to be over 600,000 tons in 1982, well above the present production capability of the domestic producers.

Fluorspar.—Mexico retained its position as the largest fluorspar producer and in 1981 accounted for 19% of world production. A substantial volume of Mexican acid-grade fluorspar was used by four domestic plants to produce hydrofluoric acid. Mexico's sales of fluorspar by grade are shown in the following tabulation, in thousand metric tons:

	1978	1979	1980	1981
Grade:				
Submetallurgical	226	178	210	193
Metallurgical	298	278	300	307
Ceramic	45	78	104	108
Acid	490	534	492	508
Total	1,059	1,068	1,106	1,116

Mexico's major export markets continued to be the United States and Canada. Competition from South African acid-grade material and Chinese metallurgical-grade, both lower priced, has had some affect on Mexico's export sales, which declined 16% to 604,900 tons in 1981. The Instituto Mexicana de la Fluorita has set the export price for Mexican fluorite, primarily to protect the small producer.

Although there were about 140 mines producing fluorspar in Mexico, 9 of these accounted for 85% of production. Mexico's largest individual producer was Cía. Minera Las Cuevas, S.A., operating in the State of San Luis Potosí. Las Cuevas, which alone contributed 33% to Mexico's total production, planned to increase acid-grade capacity from 200,000 to 300,000 tons per year by 1983.

Phosphate Rock.—Under Mexican mining law, phosphate mining is closed to companies with foreign participation. In January 1981, phosphate production began at the new state-owned Roca Fosfórica Mexicana S.A. de C.V. (ROFOMEX) mine in Baja California. Full production of 60,000 tons per month of phosphorus pentoxide at the ROFOMEX San Juan de la Costa Mine was reportedly reached at the end of the year. All output was shipped by sea to the Fertilizantes Mexicanos S.A. plant at Lázaro Cárdenas, about 200 miles northwest of Acapulco.

The San Juan de la Costa reserves, located 35 miles north of La Paz on the Gulf of California, were reported at 45 million tons grading 18% P_2O_5. The beneficiation and concentration processes used seawater, and fresh water was used after flotation to remove chlorides. ROFOMEX, concerned with environmental effects, was experi-

menting with several different techniques to reduce the discharge of effluents into the sea.

The Santo Domingo phosphate operation on Baja California's Pacific coast, about 150 miles northwest of La Paz in the area of Bahia de Magdalena, was in the construction phase with startup scheduled for late 1982. ROFOMEX expected Santo Domingo output to reach 1.5 million tons per year by late 1983. Proven reserves at Santo Domingo were reported at 1.1 billion tons, averaging less than 5% P_2O_5. The proven reserves represented about 4% of the whole phosphate-bearing beach sand in the area. The planned mining technique was to be dredging. Although a low-grade ore, the sand-grain nature of Santo Domingo reserves offered the advantage of lower mining and processing costs.

Sulfur.—In 1981, Mexico, the biggest sulfur producer in Latin America and the fourth largest in the world, planned to raise sulfur output from 2.1 million tons in 1980 to 3.2 million tons in 1985. Sulfur was an important source of foreign exchange, and domestic needs were estimated to reach 1.8 million tons by 1985. This would leave 1.4 million tons for export. The main sulfur producers in Mexico were Azufrera Panamericana, S.A. (APSA), and Cía. Exploradora del Istmo, S.A., both state-owned companies. The two firms shared a merged management and also were responsible for the international marketing of the recovered sulfur produced by PEMEX in its refineries.

In 1981, sulfur was mined in Jaltipan, Texistepec, and Coachapa. Mesquital, a group of deposits near Minatitlan and Hidelgotilan, Veracruz, was being considered for exploitation. The newest APSA sulfur venture was the fully automated $66 million Coachapa plant that went into operation in September 1981. The plant had an initial capacity of 600,000 tons per year. APSA had also invested another $66 million in a new sulfuric acid plant in Jaltipan, Veracruz.

During the period 1977-80, the United States imported 43% of its foreign sulfur from Mexico, the second most important source after Canada.

MINERAL FUELS

In February 1981, the Mexican National Energy Plan (NEP) was passed into law. The major parts of the NEP were discussed in the 1980 Minerals Yearbook, Volume III, chapter on Mexico. An impact assessment of the NEP was difficult because it had been in effect for only a short time and was based on then-existing planning in the various energy sectors. Some of the NEP goals have shown signs of proving elusive. Namely, the readjustment of domestic fuel and electricity prices, particularly gasoline and diesel fuel, the demand for which has been increasing faster than anticipated. This has had repercussions in the refining sector where it was reported that expansion plans may need to be accelerated. The NEP was also tied to the National Industrial Development Plan and the economic and energy growth forecasted by that plan.

Regardless of whether some reevaluations or adjustment in the NEP become necessary, the plan represented an official commitment to develop all energy resources as opposed to allowing energy development to fall into overdependence on petroleum.

Coal.—Almost 100% of the coal produced in Mexico originated in the State of Coahuila. There are eight well-known coal basins in that State that contain 90% of Mexico's 2.4 billion tons of proven coal reserves—Sabinas, Las Esperanzas, Saltillo, Lampacitos, San Patricio, Las Adjuntas, Monclovia, and El Salvador.

About 44% of Mexico's producing operations have utilized longwall mining techniques, 36% utilized open pit mining, 14% involved traditional room and pillar techniques, and 6% employed other removal techniques.

In December 1981, the Comisión Federal de Electricidad, also known as CFE, inaugurated the first generating unit planned for Rio Escondido, Mexico's first large-scale coal-fired electric generating plant. This $630 million complex was designed to have four 300-megawatt generating units. The second generating unit was expected to become operational in 1982, followed by the remaining two units in 1983. The facility was under construction about 29 kilometers south of the town of Piedras Negras in Coahuila State. The facility was to service an area where electricity demands have been increasing rapidly, including Monterrey and Monclovia.

Coal to fuel the plant was to be mined from nearby underground and surface mines by the state-operated Minas Carbonifera Rio Escondido S.A. Proved noncoking steam coal reserves in the vicinity were placed at 322 million tons. Probable reserves, estimated at 600 million tons, were

considered sufficient to provide fuel for three plants the size of Rio Escondido for 30 years or more. The coal has been described as having a high-ash and low-sulfur content. Pollution controls have been incorporated into the thermoelectric facility design, and no environmental problems were anticipated. About two-thirds of the 37% ash residue expected from burning the coal was to be recovered from exhaust gases and stored for use in the cement and building-material industries. The remaining one-third of ash residue would be recovered from the bottom of the boilers. Not considered recyclable, it would be buried in designated areas to prevent wind-carried contamination.

Petroleum and Natural Gas.—The official 1980 estimate of 60 billion barrels of proved crude oil, natural gas liquids, and dry natural gas liquid equivalents was increased to 72 billion barrels in 1981. Discounted as erroneous were reports that these hydrocarbon reserves had reached 106 billion barrels. Without the dry natural gas liquid equivalent reserves, Mexico tied with Iran to rank fourth in the world in proven petroleum reserves. Higher reserve figures were generally expected to be announced in 1982, if discoveries made during 1981 in southern Mexico prove to be as large as preliminary data indicated.

The increased proven reserves were principally due to the discovery of deposits in the Gulf of Campeche, Mesozoic deposits in the Chiapas-Tabasco areas, and a re-evaluation of the paleocanal deposits of Chicontepec. The proven hydrocarbon reserve components included 48 billion barrels of crude oil, 9 billion barrels of natural gas liquids, and 15 billion barrels of dry natural gas liquid equivalent. Proven hydrocarbon reserves, by zone, are shown in table 5.

Table 5.—Mexico: Proven hydrocarbon reserves

(Million 42-gallon barrels, unless otherwise specified)

Zone	Dry natural gas (billion cubic feet)	Liquid hydrocarbons				
		Crude oil	Condensate	Dry natural gas liquid equivalent	Total 1981	Total 1980

In 1981, total crude oil production increased 19% over that of 1980, mainly because of a 21% increase in output from the Southern Zone. Within this zone, the Gulf of Campeche and the Comalcalco district were especially productive. As shown in table 6, the Southern Zone was again the predominant producing area, overshadowing the other zones with a 92% share of total crude oil production.

In 1981, natural gas production was very close to early projections of just over 4 billion cubic feet per day. Almost 17% of this gas was flared. All of the associated gas produced in the offshore Campeche fields was flared at the production site. PEMEX had almost completed a pipeline system from these wells to shore, which would allow almost all of the Campeche natural gas to be collected. Facilities to remove sulfur were under construction, as were increases in gas transmission capacities and new links in the national gas pipeline network.

PEMEX completed 342 developmental wells in 1981, of which 69 produced gas, 201 produced oil, 27 were for injection, and 45 were abandoned. Successful gas wells were drilled in the Reynosa, Monclova, Central Papaloapan, Comalcalco, and Ciudad Pemex districts. Successful oil wells were drilled in the Ebano, Cerro Azul, Poza Rica, Central Papaloapan, Nanchital, Agua Dulce, Comalcalco, and Campeche Sound districts.

In 1981, PEMEX drilled 70 exploration wells, of which 12 found natural gas, 12 encountered oil, 39 were dry holes, and 7 were stratigraphic tests. The gas discoveries were made in Reynosa, Monclova, and Comalcalco districts, and the oil discoveries were made in Monclova, Cerro Azul, Poza Rica, El Plan, Agua Dulce, and Comalcalco districts.

By the end of 1981, PEMEX estimated some type of exploration work had been carried out over 15% of Mexico, leaving to be explored 65% of the remaining land area. The remaining 20% of land area was not considered to have any potential.

New crude oil discoveries in the Chiapas, Tabasco, and Campeche Sound area lent credence to the hypothesis that Mexico's southern oil-producing region constitutes a single vast interconnected reserve system instead of separate oil-bearing areas.

Onshore wells drilled north of Cardenas were reported as encountering large reservoirs of light crude oil. The new Mora area in the State of Tabasco was designated as within the Huimanguillo oil province, which extended from the coast for 100 kilometers inland to the Chiapas Mountains. The Mora reserves were described as occurring in Upper Jurassic rocks thought to cover a surface area of 30 square kilometers and averaging 500 meters in thickness. Additional work north of Huimanguillo in an offshore area adjacent to the Arrastradero Field has reportedly established a relationship between the onshore and offshore deposits. PEMEX planned to concentrate

exploratory drilling in these areas to evaluate the potential volume of these all-important light crude oils. Most of the crude oil from the Campeche areas have been of heavy grades, and the prospect of adding significant reserves of light-grade oil was encouraging.

Gas discoveries in the Gulf of California near the mouth of the Colorado River were not scheduled for immediate development. Although they represented potentially large fields covering 40,000 square kilometers, PEMEX expected that the offshore Campeche gas pipeline completion and gas available from the onshore Huimanguillo area would assure Mexico a sufficient gas supply for the near future. Baja California and Sonora State gas requirements were expected to be met by the transmission of Mexican east coast gas through the United States and back into Mexico.

In 1981, basic petrochemical production reached 9 million tons and represented a 27% increase over that of 1980. In 1981, PEMEX had 84 petrochemical plants that produced 41 products to meet 85% of domestic demand. Additional petrochemical plants at El Tejar in Veracruz State and Morales, Tabasco 1, and Huimanguillo in Tabasco State were under construction. Two other plants, at Laguna de Ostión and Altimira, were in the engineering stages.

Uranium and Nuclear Power.—Mexico's commitment to nuclear power development became more decisive as bids were solicited for a $2 billion contract to complete the first nuclear complex near Laguna Verde in Veracruz State. The expanded capacity was expected to add about 2,400 megawatts to the 1,300 megawatts under construction at the site. Mexico's publicized plans called for the installation of 20,000 megawatts of nuclear power by the year 2000.

Uranio Mexicano, S.A., also known as URAMEX, the state-owned entity responsible for the exploration, exploitation, beneficiation, and marketing of radioactive minerals in Mexico, classified uranium reserves in three categories: proven, probable, and potential. Proven reserves were further divided into mineral and geologic reserves. Mineral reserves were those considered to be economically recoverable, and geologic reserves were those that have been measured but were not evaluated as to economic recoverability. Probable reserves were based on preliminary findings indicating the existence of mineral and/or geologic ores. Potential reserves referred solely to estimates based on indications of uranium deposits, with no regard to the current economic recoverability of the deposits.

Total proven uranium reserves were reported at 19,261 tons of yellow cake equivalent, of which 15,000 tons was considered economically recoverable. The proven reserves were distributed in the States of Chihuahua (5,092 tons), Durango (210 tons), Nuevo Leon (2,984 tons), Oaxaca (10,000 tons), Sinoloa and Baja California (500 tons), and Sonora (475 tons).

Other uranium reserves were reported as associated with the Cananea copper deposits in the State of Sonora and with the phosphate rock deposits in Baja California Sur. The Baja California Sur deposits at the San Juan de la Costa and Santo Domingo areas were considered in the potential category and have been estimated at 150,000 tons. Studies indicated that the phosphate deposits at these locations average from 100 to 120 parts per million uranium oxide. It was thought that the large-scale mining operations planned for the two deposits would make the extraction of uranium oxide economically feasible. The copper solution at the Cananea copper mine was estimated to contain 6 parts per million of uranium oxide and could result in the recovery of 80 tons per year of yellow cake.

The first uranium mining and processing operation was expected to take place in 1982 at the Los Amoles deposit in Sonora State where proven reserves were reported at 475 tons.

The Mineral Industry of Morocco

By Kevin Connor[1]

The mineral exports of Morocco contributed approximately 7% of the country's total gross national product (GNP) in 1981, which was valued at $15.1 billion. A series of problems in 1981 largely beyond Morocco's control caused early setbacks in its new 5-year development plan. They were a severe winter-spring drought, a 35% devaluation of the Moroccan dirham against the dollar, a rise in interest rates worldwide, continuing high oil import costs, and a billion-dollar-per-year military defensive effort over the disputed annexation of the Western Sahara by Morocco.[2] All of these factors combined created a 1981 trade-balance deficit of $2.1 billion;[3] which is a 50% decline from that of 1980 and a good indication of a poor year for the Moroccan economy.

Morocco's important minerals sector generally stagnated in 1981. The Minerals Production Index published by the Moroccan Government slipped 1 percentage point to 148 for the year (1969=100), reflecting flat production levels caused largely by a generally soft world market for most of the country's mineral exports. This was especially true for phosphates, Morocco's largest single export. Uncertainty among European farmers over market prices led to decreased fertilizer consumption, cutting the demand for phosphates in the country's major market. The dollar-dominated price of phosphates on the world market also led Morocco's traditional European customers to drawdown stocks to some extent in hopes that the dollar would soon devaluate relative to their currencies. Exports of most other mineral ores did no better, with the notable exceptions of zinc and barite.

In spite of overall stagnation and falling world prices in the minerals sector, Morocco continued to invest heavily in this area. Investment is estimated to have reached approximately $1 billion in 1981. With an 84% dependence on imported crude petroleum that cost about $1.75 billion for the year, Morocco embarked on major programs to search for indigenous oil deposits and develop its known large reserves of oil shale.[4] Recently reported Moroccan plans for developing its oil shale reserves include the construction of a commercial retorting plant capable of producing 70,000 barrels per day of oil by the early 1990's. Morocco's oil shale reserves are presently listed as the fourth largest in the world, after those of the Soviet Union, the United States, and Brazil. Reserve tonnages are calculated at an equivalent 23 billion barrels of oil within the country's three known major oil shale fields. Other activities in the oil shale sector are moving forward fueled by the recently announced $20 million oil shale project loan financed by the World Bank. An important gas find in the Essaouira Basin area in December 1981, drilled with World Bank financing, spurred interest by several major oil companies. Two contracts were signed recently for important offshore exploration programs.

Morocco's phosphate monopoly and largest employer and revenue generator, the Office Cherifien des Phosphates (OCP), initiated an approximate $6 billion 5-year development plan that will allow the firm to double its rock production by the end of the decade and process 30% of that production into finished products by the turn of the century. Owing to expansion efforts at the Bleida copper mine, Morocco became the Arab world's largest producer of copper. The country now also is the Arab world's only gold producer and continues to produce

10% of the world's cobalt. Coal, copper, silver, gold, and lead production are planned to increase in the coming years along with phosphate and barite. These and other expansion plans, smelting and foundry projects, and exploration efforts mean opportunities for foreign investors. The new Mining Investment Code, which should be promulgated before the end of 1982, will likely contain increased incentives for foreign investors, who are becoming increasingly interested in Morocco's mineral potential.

The United States and Moroccan Governments jointly sponsored a Mining Colloquium held in Morocco during March 1981. The colloquium provided an opportunity for exchange of information on investment potential and conditions under which investment was possible in each country. Also, the current state of mining operations and recent technological breakthroughs in each country were discussed, especially in the fields of pollution control, energy efficiency, and usage of scarce water resources in the beneficiation process.

Government Policies and Programs.—A new investment code drafted by the Moroccan Government will be implemented during 1982. The code will allow foreigners a 100% shareholding in industrial enterprises and a majority representation on the board of directors. Under the old code, foreigners were allowed a maximum of 50% shareholding in companies, and the board of directors had to have a majority of Moroccan nationals, including the chairperson. There are many benefits and tax incentives built into the new code to entice foreign investments into the more underdeveloped parts of the country. Also, to encourage labor-intensive projects that will help mitigate the country's unemployment problem, the Government will be offering a cash bonus to investors for each permanent job created by the new enterprises.

The Moroccan Parliament adopted legislation in 1981 to set up an exclusive economic zone extending to 370 kilometers off the country's coast. This legislation gave Morocco sovereign rights to the economic exploitation of mineral resources and fishing in the defined zone along both it's Atlantic and Mediterranean coastlines, including the coastal waters off Western Sahara. Previously, Morocco's claim to territorial waters extended only to a distance of 22 kilometers, and its fishing zone stretched to 130 kilometers.[5]

Responsibility for hydrocarbons exploration and development was transferred from the Moroccan Bureau de Recherches et de Participations Minières (BRPM) in April 1981 and invested in a newly formed governmental organization, the Office National de Recherches et de l'Exploitation des Petroles (ONAREP). ONAREP is responsible for oil and gas exploration as well as oil shale development and undertakes these activities through its own in-house efforts and the granting of joint-venture concessions to foreign exploration companies.

PRODUCTION AND TRADE

Morocco's minerals sector was relatively stagnant in 1981, and overall production was unchanged from that of the previous year. Exports increased only 3% on a tonnage basis, although revenue value was up 27%. This was due mainly to increased phosphate prices at the beginning of the year and the fact that all phosphate trading is done in dollars, which appreciated considerably against the Moroccan dirham. Increases in production were limited to barite, fluorine, mica, zinc, and anthracite. Moroccan barite remained high in demand because Iranian production declined seriously over the past years, as attested by the 45% increase in Moroccan production tonnage and the 33% increase in the export price attained over the 1980 price. Zinc export prices also were up, increasing an average of 45% over those of the previous year. Owing to the continued depressed state of the steel industry worldwide, iron ore production and trading were at a several-year low. Copper was another commodity that fared poorly in the marketplace this year as reflected by the 1% increase in export revenues versus the 15% increase in tonnage traded. Although anthracite production was up only 3%, the Government planned to mechanize the mine and double production over the next 3 years.

In 1981, the Moroccan Government continued to place heavy emphasis on its search for and development of, indigenous energy resources. The country's continuing heavy dependence on imported energy remains a major contributor to Moroccan economic difficulties. Imported petroleum crude amounted to $1.3 billion in 1980, or 30% of total imports. Estimates for import-

ed crude in 1981 increased to $1.75 billion. At present, domestic fuel resources only meet about 16% of the country's demands. As a result, Morocco has become intent on discovering and developing more of its own energy resources. In response to this crisis, both onshore and offshore oil exploration activities have been stepped up, with major offshore oil exploration agreements signed in 1981 with Mobil Oil Co. and Atlantic Richfield Co. (ARCO) of the United States. Using a $50 million loan from the World Bank, ONAREP conducted exploratory drilling in the Essaouira area and made a major high-pressure gas find late 1981. To exploit Morocco's oil shale reserves, estimated at well over 20 billion barrels of oil equivalent, the Government, in 1981, finalized agreements with Royal Dutch/Shell Oil Co., Davy McKee Co., Science Applications Inc., and the Tosco Corp. of the United States for developing pilot-scale retorting facilities and conducting in-depth feasibility studies for industrial-scale exploitation of the reserves.

As part of Morocco's current 5-year development plan, six new mines will be opened to boost Moroccan nonphosphate production. Three of these projects are copper mines. Of the remaining three, one will produce lead, zinc, silver, and gold; one, just lead and zinc; and the third, only silver. More than $150 million is slated over the 5-year plan period for nonphosphate mineral exploration.[6]

With a World Bank loan of $9.5 million, Morocco will carry out a pilot project to improve production from small mines in the southern Atlas region. The loan will be used by Centrale d'Achat et de Developpement de la Region Miniere du Tafilalet et de Figuig (CADETAF), an organization formed by the Government to market production from mines in Errachidia, Figuig, and part of Ouarzazate Provinces. CADETAF will acquire a mobile lead concentrator, a mobile zinc concentrator, a crushing and grinding unit, and mining equipment such as compressors, mine cars and tracks, and pumps. A study will be conducted to assess the impact of the pilot project on mining production and the income and welfare of the 7,500 miners involved in the project. The World Bank loan is for 17 years, including a grace period of 4 years, with interest at 11.6% per year.

Expansion work is continuing at the Port of Mohammedia, northwest of Casablanca, to improve handling capabilities of the port for safely accommodating ships of over 10,000 tons. The improvement work will provide the port with sheltered stations for unloading large oil tankers, which at present are susceptible at the open port to ocean surges that are considered a safety risk over one-third of the year. The expansion work, begun in mid-1980, will provide 2,600 meters of protective jetty, with six tanker sections for 10,000- to 150,000-ton ships. The estimated cost of the work is $117 million, including the construction of pipelines that will link unloading oil tankers to the Moroccan-Italian Refining Corp. (SAMIR) oil refinery, which has recently doubled its production capacity.

Morocco's OCP has reportedly signed a contract with the Soviet Union's Tsvetmetproexport under which the Soviets will loan Morocco $20 million to finance the exploitation of phosphate reserves at Meskala, in the southern part of the country. The two main areas of phosphate-bearing rocks in this region are to the north of Imi-n-Tanout on the northern slopes of the western High Atlas mountain range and still further north to the west of Chichaoua. The Soviet loan is to cover a 20-year period at 2 1/2% interest and will be paid back in phosphate rock output from the Meskala region. Development of the new mining venture will take place in three stages with production startup anticipated in 1983. The Soviet Union's interest in the Meskala deposit is enhanced by the uranium content of the rock as well as its phosphoric value.

COMMODITY REVIEW

METALS

Copper.—Among the small, new nonferrous mines scheduled for full-scale startup during the 1981-85 development plan is the Bou Gafer copper mine located in Ouarzazate Province of southern Morocco. The mine began production in 1981, and will produce 90,000 tons per year of ore when the four known deposits at the mine location are fully exploited. The Moroccan Government is supplying 10% of the total development cost of $10 million. Due onstream in 1984 is the Tizert copper mine in Agadir Province located in southwest Morocco. Development plans call for the mine to produce 84,000 tons per year of ore yielding 4,000 tons per year of concentrate containing 40% copper.[7] The Bleida copper mine in Ouarzazate Province was undergoing expansion. The Bleida ore body is about 8 kilometers long and 350 meters thick. The expansion efforts will quadruple production capacity to 300,000 tons per year of ore, which should result in about 55,000 tons of high-grade copper concentrate. Capital investment for the mine expansion project was $50 million. During the 1981-85 development plan, a related copper smelter is planned for fabrication at Agadir and will produce 50,000 tons per year of blister copper for export. Estimated foreign exchange revenues from the initial smelting operation will be $120 million per year.

Iron and Steel.—In May 1981, a contract was finalized between the Moroccan Iron and Steel Co. and Davy Loewy of Great Britain to construct a wire rod and reinforcing bar mill, outside Nador. The construction of the mill is the first step of a long-range project to build a steel fabricating complex within Morocco. The mill, preliminarily designed with a production capacity of 420,000 tons per year of finished product, was expected to come online in the latter half of 1983. The project falls within the framework of a British-Moroccan cooperative agreement. The mill construction was being financed by British credits. The total cost of the Nador iron and steel complex was estimated at $2 billion.

Lead and Zinc.—The Bou Madine multimetal mine in Errachidia Province was scheduled for startup in 1984 and will pro-

duce zinc, lead, silver, and gold metals. Production of 60,000 tons per year of ore was expected to yield 900 tons per year of 60% lead concentrate and 6,000 tons per year of 53% zinc concentrate. Total investment was estimated at $7.5 million, with the Moroccan Government contributing 15%. Development of the Sidi Lahcen operation, a lead and zinc mine in Oujda Province, continued in northwest Morocco. Plans called for production of 5,700 tons per year of lead concentrate and 3,000 tons per year zinc concentrate, starting in 1982. Development costs for the project totaled $10 million. Initial exploratory drilling of the lead and zinc deposits at Jbel Khitrem has been encouraging. Work concentrated on finding lateral and deeper seated extensions of old workings.

Silver and Gold.—The Zgounder silver mine in Ouarzazate Province was scheduled to open in 1982. Planned production was 26 tons per year of 90% concentration silver, milled from 56,000 tons of ore, by mid-1983. Capital costs for the mine were approximately $10 million. At the Tizert copper mine in Agadir Province, over 32 troy ounces of silver per ton of copper concentrate is expected to be produced when this operation goes online in 1984. The Bou Madine multimetal mine, also scheduled for a 1984 startup date, should produce 9.6 troy ounces of silver per ton of zinc concentrate processed. At the planned lead-zinc mine at Sidi Lahcen, in Oujda Province, almost 10 tons of silver production is expected from the approximately 80,000 tons of ore processed per year. The lead concentrate at this mine should produce a minor amount of silver and almost one-third of a troy ounce of gold per ton. In other new precious metals developments, BRPM opened up the Arab world's first gold mine at Tiouit near Tinherir, and exploration field work continued on a gold and silver deposit found at Bou Gafer. Additional exploration and mining of the silver deposits in central Jbilets of Roc Blanc paid off. What was earlier thought to be a depleted vein, No. 5, turned out to be a productive situation at deeper levels.

NONMETALS

Phosphate Rock.—Impressive as Morocco's plans for expanding phosphate rock mining are, OCP is concentrating primarily on the development of downstream phosphate rock to acid conversion capacity for the next several years. The focus of this effort will be in the phosphoric acid sector. The basic rationale behind the current OCP 5-year plan is to not only increase rock exports but to supply processed P_2O_5, also for export. The $2.7 billion OCP investment program, planned for completion in 1987, will substantially change the structure of the vitally important Moroccan phosphate industry. Currently, Morocco has the capacity to produce about 26 million tons of phosphate rock per year, with about three-quarters of this capacity coming from the Khouribga area. By 1985, the OCP plans to have increased capacity to 37 million tons, by expanding operations at Kouribga and Youssoufia and opening mines at Ben Guerir and Sidi Hajjaj. Long-term OCP goals include 30% total rock conversion to phosphoric acid and its derivatives by 1990.[8] This will amount to the conversion of over 10 million tons of phosphate rock production per year. In 1981, approximately 2 million tons of rock was converted into downstream products at the Safi chemical plants.

Morocco is the world's largest exporter and third largest producer of phosphate rock, accounting for over 30% and 14%, respectively, of these totals per year. Phosphate exports supply the major proportion of foreign currency earnings in Morocco and also provide a major source of tax revenue. As a user of services and a large labor employer, the phosphate industry is a powerful factor in the country's overall economy. The majority of Morocco's phosphate rock exports go to Western European fertilizer manufacturers, whose proximity give Morocco a competitive market advantage, particularly regarding freight costs. Despite falling world demand for phosphate rock, Morocco is maintaining its share of the export market. Total exports in 1981 were 15.6 million tons, down from the 16.5 million tons exported in 1980. Domestic sales were 3.5 million tons, which is a 1.1-million-ton increase over 1980 internal sales. Domestic sales of phosphate rock have increased quite rapidly in recent years, owing to its increased use in agriculture. In 1970, the domestic market accounted for only 3% of the rock production. In 1981, this figure reached over 18%.

The long-term plans stress the building of more chemical plants to produce phosphoric acid. With the rapidly rising cost of transporting high-volume, low-value rock and with increasing environmental constraints on new industrial developments in the in-

dustrialized countries, Morocco is concentrating on the manufacture and sale of finished phosphoric products on the world markets, as the United States has been doing for some years. OCP plans for the 1980's include two projects that will result in an additional 6,000 tons per day of P_2O_5 capacity for production of phosphoric acid. These plants will be located in the coastal areas of Jorf Lasfar and Nador. These projects are in addition to the expansion at Safi, where phosphoric acid capacity will stand at 4,500 tons per day processed P_2O_5 feedstock when Maroc Phosphore II comes onstream toward the end of 1982. At that time, there will be four separate operating complexes at Safi. Plans for the Maroc Phosphore III project at Jorf Lasfar include the construction of eight phosphoric acid units of 500-ton-per-day P_2O_5 capacity each. Current plans are for the plants to be brought onstream over a 3-year period, commencing in 1983. In addition to the 4,000 tons per day P_2O_5 to be processed into merchant-grade acid, OCP has decided to build units for production of superphosphoric acid and diammonium phosphate (DAP). The new port at Jorf Lasfar is expected to be completed by the end of spring 1982, whereupon work will begin on the OCP handling and storage facilities. In addition to the facilities at Jorf Lasfar, OCP plans to locate further facilities at the Moroc Phosphore IV project at Nador, in northeast Morocco. Four phosphoric acid units, each of 500-ton-per-day P_2O_5 feedstock capacity are planned, with construction to be phased in with the developments at Jorf Lasfar.

The expanded integration of Morocco's phosphate industry and the development of new port facilities clearly demonstrates OCP intentions to move away from being strictly a supplier of raw material to the world market. However, in view of the poor prevailing market conditions for phosphoric acid at present, the timing of the massive expansion plans may have to be periodically reviewed and revised.

MINERAL FUELS

Bituminous Shale.—The Royal Dutch/Shell Oil group and the Moroccan Government signed an agreement in 1981 for a three-phase joint-venture oil shale project. The first phase will cost between $40 and $50 million and will be a comprehensive survey of the shale deposits of Tarfaya conducted by Shell and the National Office of Petroleum Research and Exploitation. The second phase, if justified by the survey, would be the construction of a $450 million pilot plant. Finally, subject to successful pilot plant results, a 70,000-barrel-per-day plant costing an estimated $45 billion would be constructed and onstream as early as 1992. The Davy McKee Corp. of the United States has been awarded a contract by Morocco's BRPM to furnish project management services for the construction of a small $7 million shale oil pilot plant in the Timahdit oil shale region. The pilot plant was scheduled for completion in the latter half of 1982 and was designed to process up to 50 tons of shale per day to produce 25 barrels of shale oil. The process to be used is a semicontinuous, aboveground retort developed by the BRPM.

Also interested in the Timahdit area, the Tosco Corp. and the French bank Paribas signed an agreement in 1981 with the Moroccan Government to conduct an 18-month feasibility study of the potential commercial development of the oil shale deposits. The Timahdit deposits are located in the middle Atlas Mountains, south of the city of Fez. The region contains several billion tons of oil shale and, according to a report by Tosco, averages about 25 gallons of oil per ton. Some of the largest known oil shale deposits in the world are located in Morocco. Principal deposits are located at Tanger, Tarfaya, and Timahdit, with estimated resources of 3, 5, and 15 billion barrels, respectively. Shale grades average about 17 gallons of oil per ton.

Coal.—Anthracite production from Charbonnages du Maroc's underground mine at Jerrada in northwest Morocco increased only slightly in 1981 to 703,000 tons. The Government was mechanizing the mine and expected to increase production in 1982 to 790,500 tons. By 1984, production is hoped to be well over 1 million tons per year. The Government accorded the Jerrada coal deposits growing importance as the country turned to greater use of indigenous fuel sources for its energy needs. Of the present anthracite tonnage produced at the mine, about 80% of it is burned at the Soviet-built electrical power generation station constructed there some years ago. Two other giant power-generating facilities at Casablanca and Mohammedia are being modified to accept coal as well. The ambitious expansion program at Jerrada has led Charbonnages du Maroc to sign an exploration

contract with the Polish agency POLSERVICE and a production agreement with Westphalia of the Federal Republic of Germany.

Exploration drilling continued in 1981 for lignite in the Guercif Basin. So far only thin seams have been proven out, with thicknesses ranging from 5 to 50 centimeters. A geologic study in the Haut Aouli Basin northwest of Ghafsai discovered a number of outcroppings of quality lignite, justifying a continuation of the prospecting activities. Exploration for new anthracite reserves south of the present working at Jerrada resulted in the discovery of an estimated 50 million tons of lignite at Qued Nja.

Natural Gas.—The Government-operated ONAREP, financed with a World Bank loan of $50 million, discovered gas in the Essaouira Basin in December 1981. The well was drilled 31 kilometers east of Essaouira City, which is located on the Atlantic coast. The Meskala-101 well flowed 6 million cubic feet per day with a small amount of petroleum when last reported. Additional drilling and evaluation of the area was slated for 1982.[9]

Petroleum.—World Bank participation in onshore drilling for oil has been accompanied by increased interest on the part of major oil companies in offshore exploration along Morocco's Continental Shelf. ARCO signed a $50 million exploration contract in September 1981 for a concession in the Souss River Basin off Agadir, and Mobil negotiated a $117 million contract for a 12-year exploration lease south of the ARCO concession off Tarfaya. The Souss River Basin off Agadir is in the middle of a larger offshore basin that runs from Essaouira in the north down to Tarfaya in the south, and many of the big oil companies have expressed an interest in this almost totally unexplored area. In the meantime, Standard Oil of Indiana (AMOCO) continues to negotiate a contract for a $80 million exploration program in the Mediterranean.

The Mineral Industry of Mozambique

By Miller W. Ellis[1]

During 1981, Mozambique's mineral industry consisted chiefly of coal mining at Moatize and the production of tantalum minerals from pegmatite deposits northeast of Quelimane. A substantial amount of mineral-related income was derived from rail transport and shipping of coal and chromite from the Republic of South Africa through port facilities at Maputo, and from remittances from Mozambicans working in South African mines. Additional revenue was derived from the import and handling through Maputo, Beira, and Nacala of petroleum destined for Malawi, Swaziland, and the Republic of South Africa. The German Democratic Republic (GDR) continued to provide technical management for the Moatize coal mine and at the tantalum-mining operations and to import most of their export production.

The Government of the People's Republic of Mozambique (GPRM), controlled by the Mozambique Liberation Front, was again unable to prevent the Mozambique National Resistance Movement from repeatedly interrupting both railroad traffic from Zimbabwe to Mozambique's ports and the supply of electricity from the Cabora Bassa power dam on the Zambezi River to the Republic of South Africa. The high-tension, direct-current powerline to the major transformer station near Pretoria, in the Republic of South Africa, which also feeds Maputo, was inoperable more than 60% of 1981.

In late October, railroad traffic between Zimbabwe and Beira was halted after the bridge over the Pungwe River, 65 kilometers west of Beira, was destroyed by an explosion. The wrecked bridge, which also carried the Beira-Umtali oil pipeline, was replaced by December 18 with a pontoon structure that was subsequently washed out by floodwaters of the early rainy season. Rehabilitation of the country's railroad system was far behind schedule, largely because of a shortage of rock for ballast. Replacement of the old track with new 54-kilogram-per-meter rail on the 88-kilometer stretch from Maputo to Ressano-Garcia at the Mozambique-Republic of South Africa border, started in 1980, was rescheduled for completion by the end of 1982.

In the area of technical aid, both the GDR and Portugal have provided extensive assistance in training Mozambique students in the fields of geology and mining. Portugal also expressed interest in participating in aerial photography and in the production of marble and ornamental stone.

On June 12, 1981, a delegation from the U.S.S.R., led by the Soviet Minister of Geology, arrived in Maputo to participate in geophysical studies and prospecting operations for coal, gas, pegmatites, and gem stones. On June 18, they reassembled in Maputo for discussions of the projects and final arrangements.

On July 24, 1981, the Council of Ministers published Decree No. 10/81 providing for GPRM regulation of trade and exports of the country's natural resources. The following day, Decree No. 11/81 was published to establish the National Directorate for Geology and Mines and Protection of the Subsoil as the agency responsible for regulating and supervising mining activity in relation to gold, silver, and other precious metallic ores. The agency was to safeguard the interests of the national economy by controlling the production and commercial movement of precious metals. The Bank of Mozambique was to be the sole agent for buying or selling precious metals and the sole custodian of coins, bars, and ingots.

Early in 1981, Hunting Geology and Geophysics Ltd. of Great Britain was awarded a contract for the mineral inventory of 275,000 square kilometers, including 344,000 line kilometers of airborne magnetometer and gamma-ray spectrometer survey. LANDSAT data were to be processed and interpreted to provide base maps for compiling survey results, and provision was made for followup ground surveys as required. It was later reported that the Yugoslavian state enterprise Geozavod of Belgrade had been awarded a contract for prospecting in six of Mozambique's Provinces. Czechoslovakia was also reported as contracting to explore for iron, feldspar, gold, and tin in Nampula, Zambezia, and Niassa Provinces. The United Nations approved a $2.14 million project for detailed mineral exploration of a 15,000-square-kilometer area in Tete Province, a 6,000-square-kilometer area in Zambezia Province, and a 700-square-kilometer area in Manica Province.

Estimates of Mozambique's mineral production are listed in table 1, but reports of the country's trade were not available.

Table 1.—Mozambique: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity[2]	1977	1978	1979	1980[p]	1981[e]
METALS					
Aluminum: Bauxite, gross weight	2,000	--	--	--	--

Residual fuel oil do	1,438	1,132	236	1,332	NA
Other do	63	85	227	323	NA
Refinery fuel and losses do	299	270	128	130	NA
Total do	3,592	2,927	2,877	3,371	NA

[e]Estimated. [p]Preliminary. NA Not available.

[1]Table includes data available through July 6, 1982.

[2]In addition to the commodities listed, crude construction materials and additional varieties of gem and ornamental stones presumably are produced, chiefly for local consumption, but information is inadequate to make reliable estimates of output levels.

COMMODITY REVIEW

METALS

Iron and Steel.—Mozambique's Industrial Foundry and Rolling Mill Co. commenced production of steel ingots in July 1981, using funds from the United Nations Industrial Development Organization. Production capacity was estimated at 6,000 tons for 1982. The plant at Maputo was to reroll billets supplied by the Zimbabwe Iron and Steel Corp.

Tantalum.—In early May, the manager of Mozambique's Marropino pegmatite mine, at a meeting in Bad Harzburg in the Federal Republic of Germany, stated that the GPRM was trying to attract loans from several Western nations, including the United States. The funds were to be used to promote increased production of tantalum minerals in Mozambique. The country's potential for tantalum minerals has long been recognized as high, and its preindependence output was nearly double the 29,000 to 32,000 kilograms of tantalum minerals reportedly produced in 1981. The pegmatite deposits of Zambezia Province accounted for nearly one-half of Mozambique's mineral output in terms of value, and tantalite was its most valuable mineral export. Beryl, gem stones, bismuthinite, feldspar, mica, and other minerals were also recovered from Zambezia Province pegmatites.

NONMETALS

Cement.—Mozambique's cement industry was reportedly expanding into the export market with sales of 10,000 tons in July to Tanzania and an estimated 7,000 tons in August to Malawi. The country's three cement plants, with a total annual production of 600,000 tons, were located at Matola, Nacala, and near Dondo in Sofala Province, where the GDR was financing construction of a $1.5 million training center for cement workers.

Salt.—A newly completed salt-flat complex at Nova Mambone near Inhambane was officially opened in November 1981. The complex was built and operated by technicians from North Korea. It was the country's third largest salt production unit and was to have a capacity of 7,500 tons of salt per year by 1985. A subsurface reservoir containing 350 million cubic meters of saline water was reported to underlie part of the Gaza Province. It was estimated that 5 million tons of salt and 150,000 tons of sodium carbonate can be recovered from the reservoir.

MINERAL FUELS

Coal.—The Mozambique coal mining company, Carbonifera de Mozambique (Carbomoc), halted operation at its four mines at Moatize near Tete in December because of a shortage of explosives. Carbomoc was reported to employ 2,600 workers including 100 technical experts from the GDR. Production was reportedly meeting the goals set by the Central State Plan, but lack of railway facilities, including trucks, prevented movement of the stockpiled coal to the ports for export or for consumption in the cement plant at Dondo. Substantial numbers of railroad trucks were reportedly out of circulation because they were used as storage shelters during the rainy season. According to an agreement signed in Brazil in early October, Mozambique was to benefit from an $8.3 million coal project. The Organization of Petroleum Exporting Countries was to provide $3 million of the financing; Brazil was supplying the remaining $5.3 million, as well as providing technical expertise to assist with a project to expand Mozambique's coal output to 6 million tons of high-quality coal per year. Most of the increased production was to be exported for consumption by the Brazilian steel industry.

Substantial quantities of coal from the Republic of South Africa were exported through the Maputo coal terminal during the first 9 months of 1981. In October, a loaded railroad gondola reportedly fell through the hold of a ship loading at the terminal, and exports had not been resumed by yearend.

Petroleum and Natural Gas.—In May, a delegation of specialists from Société Nationale pour la Recherche, la Production, le Transport, la Transformation, et la Commercialisation des Hydrocarbures, the Algerian state oil enterprise, arrived in Maputo to assist the Secretariat of Coal and Hydrocarbons (SECH) to plan the resumption of exploration for petroleum and natural gas. During the 1960's and early 1970's, four groups, Mozambique Gulf Oil Co.-Mozambique Amoco Oil Co.; Sunray Mozambique Oil Co.; Société Nationale des Petroles d'Aquitaine; and Hunt Interna-

tional Petroleum Co.; had completed extensive seismic surveys and drilled 48 onshore and 12 offshore wells. Substantial gasfields were discovered in the Pande, Buzi, and Temane areas with proven and recoverable gas reserves at Pande estimated at 18 billion cubic meters and possible recoverable reserves at 60 billion cubic meters. This field was proposed as the energy source for projected industrial complexes to produce ammonium fertilizers, urea, and sponge iron, but there has been no investigation of the field since independence.

In June, contracts for extensive onshore and offshore seismic surveys were signed with a U.S. firm, Western Geophysical Co., and with the Geophysical Co. of Norway. Western Geophysical was to commence offshore surveys between Beira and Maputo with its survey vessel *Western African* in August. A Norwegian ship, *The Geco Delta*, was to undertake offshore surveys northeast of Beira to Rovuma in October. Both surveys were to extend from the coast to depths of 2,000 meters with more intensive investigation of the sea floor at depths of less than 500 meters.

At a press conference in late June SECH announced that the contractors would bear the costs of the surveys in return for the right to participate in any profits derived from the exploitation of their discoveries. The survey results were to be sold openly to interested oil companies as soon as available after survey completion in mid-1982. Regulations for the conduct of the surveys, and for subsequent negotiations and operations resulting therefrom, were drafted and published. By yearend more than 30 oil companies from Europe, the United Kingdom, and North America had expressed interest in the results.

In August, SECH announced that the Mineralimpex organization of Hungary, Compagnie Generale de Geophysique (CGG) of France, Geosource Inc. of the United States, and an Italian company had submitted proposals to evaluate the gas resources and petroleum potential of Pande, Buzi, and adjacent areas. SECH subsequently announced that CGG had been awarded a $6 million contract to assess the potential of the Pande and Buzi areas, and that a British firm, Energy Resource Consultants, and its subcontractors, Scott Pickford & Associates, had been retained by CGG.

The 300-kilometer Mozambique-Zimbabwe pipeline, from the Port of Beira to the British-owned Lonrho refinery at Feruka near the border town of Umtali, was being reconstructed and pressure-tested during 1981, but completion was delayed by destruction of the bridge over the Pungwe River west of Beira. The line, with a proposed capacity of 1.2 million tons of oil liquids per year, was expected to be used for refined motor fuels until the refinery reopens. The GPRM proposed to charge $30 per ton of oil pumped through the pipeline.

The Mineral Industry of Namibia

By George J. Coakley[1]

The mineral industry of the territory of Namibia was a major world producer of diamonds and uranium. The 23,000 to 25,000 industry workers also produced copper, lead, zinc, silver, tin, and tungsten among others. Namibia ranked as the fourth largest producer of nonfuel minerals on the African continent in terms of total value. Both the gross domestic product (GDP) and the contribution of the mining and quarrying sector to the GDP have been declining in constant dollar terms since 1978. For 1981, the GDP was estimated at $1.5 billion.[2] The mining sector made up an estimated 35% to 40% of GDP in 1981. Diamond mining, normally the major contributor to national revenues, was a disappointment; diamond revenues to the state amounted to only $44 million compared with a projected 1981 state budget estimate of $142 million. Namibia maintained a strong economic dependency on the Republic of South Africa as the latter expended over $1.15 billion in the country for 1981 including $230 million in direct aid and $460 million toward the defense of the country. Rossing Uranium Ltd. (RUL), which has had taxation deferred until it recovers its initial capital investment, is expected to be a further significant source of state revenues beginning in 1983. Most of Namibia's mineral products were produced and exported by three mining companies, Tsumeb Corp. Ltd., largely controlled by U.S. base-metal mining companies; Consolidated Diamond Mines (Pty.) Ltd. (CDM), a major subsidiary of De Beers Consolidated Mines Ltd. of the Republic of South Africa; and RUL.

From 1968 to 1978, control of mining in Namibia rested in Pretoria. In 1978, control was transferred to the Directorate of Economic Affairs, Department of Mines, Windhoek.[3]

Namibia's mining laws were fairly liberal, and foreign exploration and development was encouraged. Prospecting and mining were still governed by the Mines Works and Minerals Ordinance as enacted in 1968 with minor amendments. All mineral rights were vested in the state. The Namibian Central Government can grant exclusive rights to prospect in any defined area for any or all minerals. The prospecting grant carried with it a minimum expenditure obligation that varies with the size of the grant. Prospecting titles were easily converted to mining titles. There were no obligations to reinvest profits, recruit local personnel, process minerals locally, or restrict output volumes. The Government, however, still required a minimum of 25% local participation in large foreign mining investments.

Diamond mines paid an effective tax rate of over 60%. Uranium was taxed on a sliding scale or formula basis, similar to the system of taxing gold in the Republic of South Africa, from zero to over 70%. Other minerals, such as copper, were taxed at the normal corporate rate of 40%. Taxes were, however, further reduced in practice by substantial writeoffs on capital expenditure. Under the present system, no taxes are paid until capital investment has been fully recovered.

Mining in the former black homelands, now controlled by the second-tier "representative" governments, was formerly controlled by the South African Bantu Mining Corp. However, by AG Proclamation 57 of 1978, authority over homelands mineral

concessions was also transferred to Windhoek. Firms applying for a prospecting title in an area controlled by a black ethnic government had to agree to use local African labor, if possible, and pay 10% of any mining profit that may eventually arise from the prospecting grant to the local second-tier government. To date, these payments seemed not to have been a substantial source of revenue to second-tier governments. Companies could get prospecting rights directly anywhere in Namibia. Individuals, however, could only prospect and peg claims in their own ethnic areas.

Namibia also continued work on expanding the infrastructure of the country. Work began on dredging and deepening Walvis Bay Harbor to handle cargo ships of up to 70,000 tons. Preliminary negotiations were also underway with Botswana to build a $1 billion rail link between Walvis Bay and the huge coal deposits in the Morupule area of southern Botswana. Plans discussed involved a rail line that would run 10,000 tons of coal in unit trains and that would take 10 years to complete. Work continued on the new powerline between Windhoek and the Republic of South Africa that would hook up the Republic of South Africa to the Ruacana hydroelectric scheme and also provide cheaper electricity to southern Namibia.

PRODUCTION AND TRADE

The production statistics in table 1 were compiled largely from annual reports of some of the companies operating within Namibia. Publication of separate production statistics was suspended by the South-West African Administration in 1965. Although the country's economy depends on mineral exports, specific reporting of their magnitude and value remained unavailable and were no longer included in statistics published by the Minerals Bureau of the Republic of South Africa. The Namibian Department of Finance, however, estimated that in 1980 overall exports were 72% of gross domestic expenditure while exports were 74% of the GDP. Total exports in 1980 were estimated at $1.4 billion, with mining exports accounting for $1 billion of this figure.

Despite low world market prices, major base-metal production of copper, lead, and zinc increased from 9% to 24% over that of 1980. Estimated tin and tungsten output remained stable, while silver and uranium oxide production declined slightly. Diamond mining was hardest hit by poor demand and prices as production declined by 20% from that of 1980 and by 38% from the peak 1977 output of 1.9 million carats.

Diamonds continued to be marketed through De Beers Central Selling Organization and were exported to the Republic of South Africa and overseas. RUL uranium concentrates were exported from Walvis Bay to contract customers in Western Europe and Japan. Tsumeb's metal production was transported on the company's 640-kilometer railroad to its loading facilities at Walvis Bay for export to overseas customers. Other metal concentrates were railed to smelters and refineries in the Republic of South Africa.

Namibia's largest metal mining company, Tsumeb, produced 37,800 tons of contained lead, 30,300 tons of copper, 6,950 tons of zinc, 1.89 million troy ounces of silver, 3,800 tons of sulfur, and 1,370 tons of arsenic from four mines and three mills. The Tsumeb copper and lead smelters produced 39,719 tons of blister copper and 41,729 tons of refined lead with 66% and 75%, respectively, coming from their own operations and the remainder from toll and purchased material. The cadmium plant was shut down and the arsenic plant was operated on an intermittent basis by Tsumeb in 1981 as a cost-saving measure. Gross metal sales by Tsumeb in 1981 were just under $100 million.

Table 1.—Namibia: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity[2]	1977	1978	1979	1980[p]	1981[e]

Salt[e]	230,000	230,000	230,000	230,000	230,000
Sulfur, S content of pyritic concentrate	3,834	3,013	3,538	3,692	8,361

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Sept. 15, 1982.

[2]In addition to the commodities listed, Namibia, prior to 1967, produced bismuth concentrates, cesium ore, columbite-tantalite concentrates, gold, manganese ore, molybdenum concentrates, graphite, lime, mica, precious stones, kyanite, sillimanite, and a variety of crude construction materials (clays, stone, sand and gravel). No official statistics have been published since yearend 1966, and available information is inadequate to ascertain whether production has been continued or not, and if so, at what levels.

[3]Data are compiled from operating company reports as follows: Tsumeb Corp. Ltd. (arsenic, white, refined cadmium, mine and blister copper, mine and refined lead, mine and smelter silver, mine zinc, and pyrite concentrate); South-West Africa Co. Ltd. (SWACO) (mine lead, mine tin, mine tungsten, mine vanadium, and mine zinc); South African Iron and Steel Industrial Corp. Ltd. (ISCOR) for Imcor Zinc (Pty.) Ltd.'s Rosh Pinah Mine (mine lead and mine zinc), and for ISCOR's own Uis mine (mine tin); General Mining and Finance Corp. Ltd. for Klein Aub Koper Maatskappy Ltd.'s mine near Rehoboth (mine copper and mine silver); and Falconbridge Nickel Mines Ltd. for Oamites Mining Co. (Pty.) Ltd.'s mines (mine copper). Data from Tsumeb and Falconbridge are for calendar years; data from other companies are for fiscal years ending June 30 of that stated.

[4]White arsenic equivalent of all arsenic products reported as being produced.

[5]Figures comprise reported production of Tsumeb and Oamites plus estimates for Klein Aub and Otjihase copper mine (bought by Tsumeb in December 1980).

[6]Figures comprise reported production of Tsumeb plus estimates for Oamites, Rosh Pinah, and Klein Aub.

[7]Figures comprise reported production of Tsumeb estimates for SWACO for 1977 and 1978, as well as estimates for Rosh Pinah.

[8]Total figures reported by De Beers Consolidated Mines Ltd. in company annual reports for calendar years. Detail on gem and industrial diamonds are estimates, assuming output to be 95% gem quality.

[9]Output has not been officially reported since 1966, but presumably has continued since a number of countries record imports from "South Africa," which in total quantity considerably exceed the reported output of the Republic of South Africa and presumably include shipments from Namibia. Quantities given represent imports of the United States and the European Communities reported as originating in the Republic of South Africa, but the reader is cautioned that a portion of the material may have been mined in Zimbabwe.

COMMODITY REVIEW

METALS

Copper.—Tsumeb, Namibia's dominant copper producer, was managed and 29.6% owned by Newmont Mining Corp. of the United States. Amax, Inc., became the largest shareholder in February 1981, increasing its interest in Tsumeb to 30.2%. The British firm Selection Trust Ltd. owned 14.2% and O'okiep Copper Co. Ltd. owned 9.5%, with the remainder owned by other firms.

The largest polymetallic mine in the country was the Tsumeb Mine, north of Windhoek. Tsumeb, concentrating on higher grade areas of its mines, in 1981 mined and milled 493,708 tons of ore containing 3.60% copper, 7.32% lead, and 2.08% zinc. The 23,429 tons of copper concentrates produced averaged 35.49% copper and 33.3 troy

ounces of silver per ton. The company also operated the Matchless Mine, 42 kilometers south of Windhoek, which produced 111,247 tons of pyritic copper ore containing 2.37% copper and 11.47% sulfur in 1981. The Matchless mill generated 12,313 tons of concentrates, which contained 20.46% copper, 30.55% sulfur, and 2.5 troy ounces of silver per ton. With the exception of one new stope, all underground development work was stopped at the Matchless Mine to limit costs.

Tsumeb also produced 297,933 tons of 2.80% copper and 1.90% lead ore from its Kombat and Asis West Mines. The Kombat mill treated the ore producing 22,868 tons of concentrates with an average grade of 29.76% copper, plus lead, and 9.3 troy ounces of silver per ton.

The Tsumeb Exploration Co. Ltd. (TECO) portion of the Asis West Mine produced 12,522 tons of ore from a copper-rich portion of the mine averaging 7.54% copper and 2.31% zinc. This ore was milled at the Kombat concentrator and yielded 2,551 tons of copper concentrate containing 33.12% copper, some lead, and 8 troy ounces of silver per ton.

Under a December 1980 joint-venture agreement with Otjihase Mining Co. Ltd., Tsumeb acquired a 70% interest in Otjihase for approximately $41 million. Under the terms of the joint venture, Tsumeb agreed to reopen the mine and to make the first interest-free purchase installment 1 year after the target production rate of 65,000 tons of ore milled per month is reached, which is expected in the second quarter of 1982. The joint venture may be dissolved by mutual agreement if cash shortfalls reach defined limits or at the end of the life of the Otjihase Mine. Up to 100% of Tsumeb's undivided interest in the property could be transferred to Otjihase Mining in full settlement of any balance then outstanding on the purchase price. Subject to the fulfillment of the agreement, Otjihase Mining continued to be owned by Johannesburg Consolidated Investment Co. Ltd., which had a 49% direct interest plus an indirect interest through an associate. During restartup in 1981, Tsumeb mined and milled 206,900 tons of Ojithase ore containing 1.54% copper and 16.6% sulfur, from which 14,242 tons of copper concentrates averaging 20.2% copper and 2.2 troy ounces of silver per ton were recovered. The copper concentrates were shipped to the Tsumeb smelter, and an additional 26,800 tons of pyrite concentrates were delivered to RUL.

Tsumeb maintained exploration development drilling programs at the Tsumeb Kombat and Asis West and Otjihase Mines during the year while reducing exploration activity elsewhere in Namibia. Exploration of the Tschudi copper-silver prospect, 20 kilometers west of Tsumeb, was suspended while work continued at the Andundu gold prospect where the first four completed drill holes reported 0.26 troy ounce of gold per ton in the quartz veins, which constitute 7.7% by volume of the mineralized zone.

Ore reserves at most Tsumeb mines increased relative to 1980 levels. At the end of 1981, positive ore reserves at the Tsumeb Mine increased to 3,528,000 tons averaging 4.27% copper, 5.99% lead, and 1.77% zinc. The total reserves at the Kombat Mine area increased to 2,442,000 tons averaging 1.83% copper and 2.07% lead. Total reserves at Asis West were 1,580,000 tons averaging 5.54% copper and 2.77% lead. Proven reserves at the Matchless Mine were 371,000 tons averaging 2.22% copper. Total reserves at the Otjihase Mine remained almost unchanged at 10,117,000 tons averaging 2.23% copper.

The Oamites Mining Co. (Pty.) Ltd., jointly owned by Falconbridge Nickel Mines Ltd. of Canada (74.9%) and the International Development Corp. (IDC) of the Republic of South Africa, continued to be the country's second largest copper producer. The Oamites Mine, 55 kilometers south of Windhoek, was extracting low-grade ore by a sublevel open-stoping method. In 1981, Oamites milled 530,000 tons of ore containing 4,827 tons of recoverable copper, down 17% from the 1980 output. Silver production decreased by 13,000 troy ounces to 216,000 troy ounces in 1981. Faced with operating losses and difficult mining conditions, the company suspended operations at the nearby Swartmodder Mine in March. Production at Oamites was also reduced from 45,000 tons per month to 35,000 tons per month of ore milled. Ore reserves at the Oamites Mine at yearend were 2,027,000 tons grading 1.13% copper.

Lead and Zinc.—Two of Tsumeb's established mines produced complex ores with a mixture of lead, zinc, and copper containing other valuable constituents. The Tsumeb Mine was the country's largest lead producer and one of its two sources of zinc. The 493,708 tons of ore contained 7.32% lead and 2.08% zinc, from which the Tsumeb concentrator produced 97,970 tons of lead

concentrates that contained 31.1% lead, with 8.1% copper, 6.46% zinc, and 7.9 troy ounces of silver per ton. Its zinc concentrate weighed 1,196 tons and contained 51.94% zinc, 3.02% copper, 9.67% lead, and 10.4 troy ounces of silver per ton. Ores from the Kombat and Asis West sections of the Kombat Mine also contained lead, and the Kombat mill recovered 6,825 tons of lead concentrate with 30.5% lead, 14.0% copper, and 4.0 troy ounces of silver per ton on behalf of the parent company and 177 tons of lead concentrate containing 34.8% lead, 11.5% copper, and 4.3 troy ounces of silver per ton from Asis West ore on behalf of TECO.

The country's top zinc producer was the Rosh Pinah open pit mine in the Namib Desert, 27 kilometers north of the Orange River, operated by and for Imcor Zinc (Pty.) Ltd., a subsidiary of the South African Iron and Steel Industrial Corp. Ltd. (Iscor). Rosh Pinah Mine's capacity was 160,000 tons per month of ore. In the 1980-81 business year, 47,200 tons of 40% zinc concentrate and 20,200 tons of 45% lead concentrate were produced compared with 44,000 tons of zinc concentrate and 17,900 tons of lead concentrate in 1979-80. Both concentrates were trucked 180 kilometers to the railhead at Aus, where they were railed to Iscor's steelworks at Vanderbijlpark in the Transvaal Province of the Republic of South Africa.

Stockpiled ore at the closed Berg Aukas Mine was concentrated into zinc pellets, which were railed to Vogelstruibult in Transvaal Province, the Republic of South Africa, for further refining in the Kiln Product Ltd. smelter. Byproduct vanadium and lead may also be extracted from the Berg Aukas stockpile, which is being worked at a loss and is expected to be depleted in 1982.

Tantalum.—A subsidiary of Utah International Inc. of the United States, Southern Mining and Development Co. Ltd., carried out preliminary exploration for tantalum in 1981 and located one deposit with a potential output of 18,000 kilograms of tantalite per year.

Tin.—Most of the country's tin production continued to be derived from Iscor's Uis Mine near Brandberg, northeast of Swakopmund. The tin concentrate was shipped directly to the Vanderbijlpark Steelworks in the Republic of South Africa, where it was smelted and used to produce electrolytic tin plate for local consumption. In 1981, 1,220 tons of tin concentrate was produced, up 14% over that of 1980. Iscor reported extensive drilling at Uis proved the existence of large additional tin reserves extending the life of the mine by several decades at the present rate of production.

NONMETALS

Diamond.—Production of diamonds by CDM continued to decline as total ore treated increased to 12,540,000 tons containing 9.95 carats per 100 tons. The ore consisted of marine gravels and required the removal of 37,698,000 tons of barren sand and gravel overburden. At yearend, stripped reserves remained 6 months ahead of mining requirements. The 20% reduction in total carats produced in 1981 reflected a decision by CDM to reduce production temporarily by suspending operations at one of the four production plants, at both field screening plants, and at the 50-grid sampling plant. Mining continued to the maximum safe distance of 100 meters seaward of the high water mark, and maintenance of the seawall will continue until foreshore mining in the No. 4 plant area is completed during 1982. At that stage the bucket wheel excavator will be moved to a new site further south. CDM maintained an active diamond prospecting program in its concession areas, where it held the mineral rights until December 31, 2010. Results continued to be disappointing, with the north bank of the Orange River within Diamond Area No. 1 being the only site that showed encouraging results. In 1981, CDM contributed over $40 million to the after-tax profits of De Beers.

MINERAL FUELS

Coal.—In the early 1950's, the Anglo American Corp. Ltd. discovered coal on the north bank of the Nossob River near the Aminuis Reserve, and during 1980, its affiliated company, CDM, applied for extensive prospecting grants on both sides of the Nossob River in the Aranos area. Estimated drilled reserves of about 3 billion tons of coal have been identified to date; however, its potential exploitability may be complicated by an overburden of as much as 300 meters in some places and by an underground lake above at least part of the deposit. Exploration for coal was reported to have continued in the Etosha Pan area and along the Kaokoveld coast. The Anglo American Nossob River coal discovery and reports that another Anglo American associate, B&O Mineral Exploration, Ltd., had recently discovered coal on five adjoining farms in the southeastern corner of the

Otjiwarongo district, bordering Hereroland West, precipitated a "coal rush" and forced the Mining Commission to enforce strict requirements before granting any new concession areas.

Petroleum.—The Etosha Petroleum Co., owned by Briland Mines Ltd., has held an oil and gas exploration concession near the Angolan boundary in northern Namibia for a number of years and in February 1980 signed a letter of intent giving Superior Oil Co. a contract to execute test drilling operations over a portion of the Etosha area. Financing was reportedly arranged through Allen & Co. Inc. of New York. In 1981, Superior Oil initiated negotiations with the Administrator General of Namibia to obtain permission to search for oil along the northern perimeter of Etosha Game Park. The Government-owned Southern Oil Exploration Corp. (South-West Africa) (Pty.) Ltd. continued to be responsible for granting oil exploration concessions, and its parent company, Southern Oil Exploration Corp. (Pty.) Ltd., continued to hold offshore concessions south of Walvis Bay.

Uranium.—RUL, in which the United Kingdom's Rio Tinto Zinc Corp. Ltd. (RTZ) holds a 46.5% controlling interest, operated the Western world's largest single open pit uranium mine 65 kilometers northeast of Swakopmund. In 1981, RUL treated 14.9 million tons of ore yielding 4,681 tons of uranium oxide, down 2% from that of 1980 and still slightly short of its annual design capacity of 5,000 tons of U_3O_8. The principal ore mineral, uraninite, is ground to a pulp and treated by a sulfuric acid leach followed by ion exchange, solvent extraction, and an ammonia precipitation of the uranium oxide. RTZ reported net profits from RUL for a year, allowing for deferred taxation, of $41 million. Their partners in RUL included the General Mining and Finance Corp. Ltd. and IDC of the Republic of South Africa, Total Compagnie Minière et Nucleaire of France, and Rio Algom Mines Ltd. of Canada.

The Mineral Industry of the Netherlands

By George A. Rabchevsky[1]

The economy of the Netherlands continued to decline slowly, by more than 1% in 1981. Private consumption fell by about 3% and investments fell by about 10% of gross national product (GNP); unemployment reached about 10%, a postwar high. Even though inflation was halted somewhat, industrial output was down by approximately 3.5%, with the largest decline in natural gas.

The services sector, which in 1981 contributed a significant two-thirds of the GNP, fell less sharply, mainly because of continued rises in Government spending. The slowdown in the Netherlands' economic activity, evident since the mid-1970's, turned into a recession in the second half of 1980, which continued through 1981. An official 1981 forecast, based on the assumption of no major policy changes, projected real GNP growth in 1985 at an annual average of 1%.

PRODUCTION

Production in the metals industry was down by approximately 3% in 1981 and was at the lowest level since 1978; output was down by over 30% in the important energy sector, especially petroleum refining. Mining and natural gas output were down by over 8%.

Production of minerals for the past 5 years is given in table 1.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through July 12, 1982.

[2]In addition to the commodities listed, a variety of crude construction materials (clays, stone, and gravel) presumably is also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[3]Reported figure.

[4]In previous editions, refined lead production, both primary and secondary, was erroneously captioned as smelter lead production, and actual smelter output was unreported; these errors have been corrected in this edition.

[5]Coke oven and blast furnace gas only.

TRADE

Declining imports, improved export competitiveness, and the sharply higher prices for natural gas exports were the main causes of the 1981 surplus in the balance of payments account, the Netherlands' first since 1977. Netherlands exports accounted for over 50% of total GNP.

The Netherlands in 1981 continued to be the third largest European market for U.S. exports and was the sixth largest in the world. With the Netherlands' industrial output, investment, and consumption falling, however, the strong advances made by U.S. exports in the recent past may not be repeated in the near future. Declines in U.S. exports in the first half of 1981 were 27% in metal ores and scrap, 57% in nonferrous metals, and 23% in metal-working machinery. Gains in the same period were 31% in fertilizers and 82% in bituminous coal.

Selenium, elemental	3	2	NA	NA.
Silver metal including alloys, unwrought and partly wrought thousand troy ounces	10,100	8,127	48	Belgium-Luxembourg 2,631; France 2,020; West Germany 1,253.
Tellurium and arsenic, elemental	44	61	--	France 30; West Germany 6.
Tin:				
Oxides	8	7	--	All to Belgium-Luxembourg.
Metal including alloys:				
Scrap	513	361	--	United Kingdom 175; West Germany 128.
Unwrought	1,275	1,945	--	West Germany 1,430; Belgium-Luxembourg 368.
Semimanufactures	738	795	2	West Germany 448; Belgium-Luxembourg 124; Sweden 45.
Titanium:				
Ore and concentrate	2,599	26,386	--	West Germany 5,495; United Kingdom 4,208; Turkey 3,406.
Oxides	1,089	831	--	West Germany 243; Belgium-Luxembourg 166; Italy 149.
Metal including alloys, all forms	114	77	3	Italy 22; France 19; Belgium-Luxembourg 12.

See footnotes at end of table.

Table 2.—Netherlands: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
METALS —Continued				
Tungsten:				
Ore and concentrate	1,161	1,656	40	U.S.S.R. 939; Czechoslovakia 248; United Kingdom 140.
Metal including alloys, all forms	202	202	--	Belgium-Luxembourg 166; West Germany 16.
Zinc:				
Ash and residue containing zinc	12,359	11,854	--	Belgium-Luxembourg 5,918; West Germany 4,154; France 1,592.
Ore and concentrate	11,501	7,306	--	Belgium-Luxembourg 6,512; France 769.
Metal including alloys:				
Scrap	4,419	6,576	--	West Germany 2,822; Belgium-Luxembourg 1,994; France 1,300.
Dust (blue powder)	3,457	2,933	NA	NA.
Unwrought	136,807	163,201	9,037	West Germany 43,884; United Kingdom 34,228; France 22,816.
Semimanufactures	2,554	3,815	--	West Germany 2,616; Republic of South Africa 294; Belgium-Luxembourg 244.
Zirconium ore and concentrate	270	24,840	--	West Germany 14,227; France 4,182; United Kingdom 2,253.
Other:				
Ores and concentrates	23,363	29,159	--	West Germany 7,229; United Kingdom 4,692; Italy 4,482.
Ash and residue containing nonferrous metals	18,295	8,774	--	West Germany 4,291;United Kingdom 1,102; Belgium-Luxembourg 892.
Oxides, hydroxides, peroxides	46	51	--	France 17; United Kingdom 10; West Germany 10.
Base metals including alloys, all forms	38	21	--	Belgium-Luxembourg 7; West Germany 5.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	19,680	8,002	31	West Germany 3,430; Thailand 1,100; United Kingdom 604.
Corundum, artificial	306	411	--	Belgium-Luxembourg 170; Australia 96; West Germany 7.
Dust and powder of precious and semi-precious stones, including diamond kilograms	152	171	8	East Germany 54; Sweden 20; United Kingdom 15.
Grinding and polishing wheels and stones	3,543	4,118	18	West Germany 982; United Kingdom 819; France 677.
Asbestos, crude	56	36	NA	NA.
Barium materials:				
Barite and witherite	77,458	122,537	7,036	United Kingdom 51,722; Norway 20,589; Cameroon 16,072.
Oxides	388	603	--	Belgium-Luxembourg 237; West Germany 220.
Borates, crude, natural	369,997	400,154	--	West Germany 86,417; France 78,963; United Kindgom 55,828.
Cement	370,797	391,278	--	West Germany 181,098; Nigeria 99,766; Belgium-Luxembourg 69,653.
Chalk	25,753	26,757	--	Belgium-Luxembourg 25,313.
Clays and clay products:				
Crude:				
Bentonite	26,462	35,210	--	Belgium-Luxembourg 12,227; United Kingdom 8,050; France 4,401.
Fuller's earth, dinas earth, chamotte	3,270	2,087	--	West Germany 903; Belgium-Luxembourg 791; Nigeria 99.
Kaolin	88,931	79,203	--	Belgium-Luxembourg 67,164; West Germany 7,540.
Kyanite and sillimanite	519	1,896	--	Belgium-Luxembourg 708; West Germany 369.
Other	85,636	80,080	--	West Germany 57,212; Belgium-Luxembourg 17,211.
Products:				
Refractory including nonclay brick	34,975	33,845	17	West Germany 14,073; Belgium-Luxembourg 5,338; Italy 2,695.
Nonrefractory	833,476	852,100	269	West Germany 623,535; Belgium-Luxembourg 156,001; France 41,475.

See footnotes at end of table.

Table 2.—Netherlands: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Diamond excluding dust and powder:				
Worked:				
Gem carats	122,300	107,228	4,800	Belgium-Luxembourg 28,759 Switzerland 27,271; Israel 14,706.
Industrial do	11,468	7,994	992	Hong Kong 2,510; Japan 1,452; United Kingdom 1,113.
Unworked:				
Gem do	21,439	87,967	749	Belgium-Luxembourg 83,734; Switzerland 2,115.
Industrial do	833,999	825,518	218,321	Belgium-Luxembourg 189,291; United Kingdom 118,543; Japan 59,683.
Unsorted do	295,223	59,541	9,063	Israel 23,617; Belgium-Luxembourg 17,734; West Germany 3,580.
Diatomite and other infusorial earth	559	657	NA	France 178; Belgium-Luxembourg 160.
Feldspar, fluorspar, leucite	7,863	15,696	--	West Germany 9,229; Belgium-Luxembourg 4,914.
Fertilizer materials:				
Crude:				
Phosphatic	71,426	64,064	--	West Germany 47,113; Belgium-Luxembourg 14,170.
Other including mixed	77,507	106,894	--	Belgium-Luxembourg 83,644; West Germany 17,748.
Manufactured:				
Nitrogenous thousand tons	3,137	2,882	263	India 524; France 409; West Germany 342; Brazil 302.
Phosphatic including Thomas slag	326,500	279,071	--	France 115,762; West Germany 29,590.
Potassic	3,346	5,694	--	Nigeria 3,056; Denmark 791; Oman 642; Sudan 450.
Other including mixed thousand tons	1,077	1,033	--	France 407; West Germany 128; United Kingdom 104.
Ammonia	540,642	609,061	3,980	Belgium-Luxembourg 349,414; West Germany 69,054; France 46,730.
Graphite, natural	644	515	--	West Germany 388; East Germany 35.
Gypsum and plasters	3,475	2,170	--	Belgium-Luxembourg 1,232.
Lime	4,940	5,297	--	West Germany 3,849; Nigeria 592; Belgium-Luxembourg 449.
Magnesium materials:				
Magnesite	34,376	30,934	176	West Germany 14,362; France 3,859; Belgium-Luxembourg 2,503.
Oxide	13	85	57	Belgium-Luxembourg 1.
Mica, crude and worked	1,233	983	--	United Kingdom 220; West Germany 210; Belgium-Luxembourg 116.
Pigments, mineral, including processed iron oxide	6,567	7,488	1,654	West Germany 2,110; France 1,791; United Kingdom 619.
Precious and semiprecious stones except diamond kilograms	1,480	2,056	NA	West Germany 1,000.
Salt and brine thousand tons	2,475	2,159	30	Belgium-Luxembourg 577; West Germany 441; Finland 420.
Sodium and potassium compounds, n.e.s.:				
Caustic soda	157,193	189,748	4,318	China 70,674; Belgium-Luxembourg 17,519; Sweden 16,937.
Caustic potash	109,333	37,602	--	West Germany 33,694.
Soda ash	151,905	154,896	--	West Germany 37,548; Denmark 17,594; Belgium-Luxembourg 13,272.
Stone, sand and gravel:				
Dimension stone:				
Unworked and partly worked	5,138	7,408	--	West Germany 5,648; Belgium-Luxembourg 898.
Worked	9,579	26,949	--	Belgium-Luxembourg 19,484; West Germany 6,478.
Dolomite	10,568	15,483	--	West Germany 7,791; Belgium-Luxembourg 6,141.
Gravel and crushed stone thousand tons	4,493	4,090	--	Belgium-Luxembourg 3,757; West Germany 319.
Limestone, excluding dimension	119	59,942	--	Belgium-Luxembourg 59,893.
Quartz and quartzite	13,169	13,393	--	West Germany 10,209; Belgium-Luxembourg 1,421; Austria 746.
Sand, excluding metal-bearing thousand tons	9,304	9,341	--	Belgium-Luxembourg 8,940; West Germany 307.
Strontium material, oxide	5	329	NA	NA.

See footnotes at end of table.

Table 2.—Netherlands: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Sulfur:				
Elemental	11,015	16,038	--	Belgium-Luxembourg 15,514.
Sulfuric acid, oleum	160,579	143,341	1,107	Belgium-Luxembourg 81,570; Turkey 19,115; Mexico 10,093.
Talc and steatite	4,066	8,011	--	West Germany 4,100; Belgium-Luxembourg 1,468.
Other:				
Crude	263,859	197,104	72	West Germany 78,672; Belgium-Luxembourg 62,471; France 39,601.
Slag, dross, similar waste, not metal-bearing:				
From iron and steel manufacture	137,543	36,993	--	West Germany 28,286; Belgium-Luxembourg 7,942.
Unspecified	131,103	209,263	200	Belgium-Luxembourg 105,954; United Arab Emirates 24,075; Norway 23,848.
Building materials of asphalt, asbestos and fiber cements, unfired nonmetals[1]	17,836	14,973	--	Belgium-Luxembourg 9,454; West Germany 3,568.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	7	4,540	--	West Germany 4,535.
Carbon black	84,091	82,059	123	France 37,821; West Germany 17,555; Belgium-Luxembourg 10,379.
Coal and briquets:				
Anthracite and bituminous coal thousand tons	1,032	1,547	--	Belgium-Luxembourg 583; West Germany 409; Finland 173.
Briquets of anthracite and bituminous coal	9,862	1,702	--	Belgium-Luxembourg 1,498.
Lignite including briquets	1,259	1,689	--	Belgium-Luxembourg 1,606.
Coke and semicoke	739,373	751,921	--	France 277,284; Belgium-Luxembourg 240,188; West Germany 149,661; United Kingdom 20,812.
Gas, hydrocarbon:				
Manufactured	235,346	222,982	--	Belgium-Luxembourg 118,109; West Germany 74,919.
Natural million cubic feet	1,990,439	1,931,653	--	West Germany 910,954; France 393,760; Italy 277,652.
Hydrogen, helium, rare gases	28,371	32,745	--	West Germany 17,935; Belgium-Luxembourg 6,208; France 3,685.
Peat including briquets and litter	112,425	160,432	--	Belgium-Luxembourg 104,601; France 26,323; West Germany 25,937.
Petroleum:				
Crude 42-gallon barrels	104,878	100,079	--	Belgium-Luxembourg 65,740; West Germany 34,339.
Refinery products:[2]				
Gasoline thousand 42-gallon barrels	84,115	79,900	370	West Germany 41,535; United Kingdom 11,311; Belgium-Luxembourg 8,030.
Kerosine do	24,626	21,554	--	West Germany 9,621; Denmark 2,663; Nigeria 2,000.
Distillate fuel oil do	107,759	100,345	2	West Germany 49,331; Belgium-Luxembourg 12,152; Denmark 6,660.
Residual fuel oil do	99,956	84,491	174	United Kingdom 9,363; Belgium-Luxembourg 9,259; West Germany 8,618.
Lubricants do	4,357	4,377	21	Belgium-Luxembourg 784; United Kingdom 412; West Germany 270.
Other:				
Liquefied petroleum gas do	3,363	2,561	--	Belgium-Luxembourg 1,405; West Germany 581.
Mineral jelly and wax do	605	634	4	West Germany 197; United Kingdom 191; France 49.
Petroleum coke do	390	396	19	West Germany 205; Italy 47; France 45.

See footnotes at end of table.

[r]Revised. NA Not available.
[1]Less than 1/2 unit.
[2]May include germanium oxides.
[3]Excludes quantities valued at $24,295,985 in 1979 and $27,067,856 in 1980.
[4]Excludes quantity of gas carbon valued at $470 in 1980.
[5]Includes bunkers.

COMMODITY REVIEW

METALS

Aluminum.—The largest of the two aluminum smelting plants, that of Péchiney Nederland NV at Vlissingen, with a capacity of 170,000 metric tons, was reportedly unprofitable in 1981, because of escalating energy costs. The electricity was supplied to the smelter by the country's largest nuclear powerplant Zeeuwse Energy Co.

Iron and Steel.—Not long after joining forces with a West German company, Hoesch AG, in 1980, the giant Netherlands steel producer Estel Hoogovens BV (former-

ly Hoogovens IJmuiden BV) experienced several problems in 1981: The general crisis in the European steel industry, the inclusion of the Netherlands in the U.S. producers' suits, and the possible breakup of the Estel partnership. In 1981, the company registered a loss for the second year. State subsidy during the year amounted to about $540 million.[2] Nevertheless, in 1981 Hoogovens was one of the most modern, most efficient, and least subsidized steel producers in Europe. Hoogovens' output in 1981 was 5.2 million tons, up slightly from 5.0 million tons in 1980, while sales improved from 4.1 million tons in 1980 to 4.5 million tons in 1981. Exports to the United States accounted for about 12% to 15% of the firm's sales in 1981.

During the year, Hoogovens planned investments at its IJmuiden plant for the second-phase reconstruction of a coke battery and the completion of the 1.4-million-ton-per-year billet mill. The firm also planned to install a vacuum ladle and to build a coal injection system for two blast furnaces.

The Netherlands' electric steelmaker, Nedstaal BV, reached an agreement in 1981 with its parent company, Thyssen AG of the Federal Republic of Germany, to keep in operation the two most efficient furnaces of its four 35-ton units. Thyssen was to provide over $70 million for the modernization of Nedstaal's scrap bay and ingot stripping operation. The Netherlands Government was to provide another $40 million for the plant's electricity requirements and for compliance with environmental regulations. Over the next several years, however, the work force was slated for reduction by over one-third.

Lead.—Contributing to the growing worldwide importance of the secondary lead industry, the Netherlands reportedly produced only secondary lead in 1981, most of which was imported and refined in the country's only secondary plant, at Arnhem, owned by Billiton International Metals BV. A new 45,000-ton-per-year plant was planned to replace the old 25,000-ton plant in 1982.

Magnesium.—In 1981, Billiton Delfstoffen BV completed the construction of its magnesia-from-brines project, at Veendam in Groningen Province. The production was aimed mostly at the manufacture of refractory products. Billiton was encouraged to invest in the project because of the availability of magnesium-bearing salts in the region. In the Netherlands, large accumulations of magnesium-bearing salts occur in rock-salt strata, which form part of the Upper Permian Zechstein Basin, extending from Poland to eastern Scotland. The 100-meter saltbeds occur at depths of 1,500 to 2,000 meters. Billiton's mining concession consisted of 7,000 acres with sufficient reserves to sustain production of 100,000 tons of magnesia annually for at least 40 years. Two companies were set up to develop the deposits: Noordelijke Zoutwinning NV was to mine the rock salt, while Magnesia International BV was to reclaim salts from seawater and to manufacture the refractory magnesia. The plant was to use the conventional seawater magnesia technology with two process stages—a wet circuit involving brine purification and magnesium hydroxide precipitation, and a dry circuit involving calcination, pelletizing, and dead burning. The plant was to differ from existing central European practice, other than using brine rather than seawater feed, in that dead burning would be performed in high-temperature shaft kilns, which in 1981 were more energy efficient than the conventional rotary kilns. Harbison-Walker Refractories Co. of the United States supplied the technology for the process. The kilns were to be gas fired, using natural gas from local gasfields.

Zinc.—Billiton International Metals BV, in a joint venture with Australian Mining & Smelting, Ltd., expanded its zinc production capacity to 182,000 metric tons in 1981 from 150,000 tons in 1980. The approximate cost of the expansion of the zinc electrolysis plant was about $15 million, and the plant was to become operational in 1982.

NONMETALS

Lime.—The Netherlands does not possess sufficiently high-quality indigenous limestone for the production of quicklime or hydrated lime. Indigenous limestone and dolomite were used mainly in fertilizer, cattle feed, and aggregate applications. Only one company, CV Nekami Kalk, was actively engaged in the production and marketing of its own burnt lime in 1981. This company also sold and distributed up to 35,000 tons of various imported limestone and dolomite products in the Netherlands for special applications. Through a subsidiary, BV Nekami-Gouda, the company produced almost 90,000 tons of hydrated lime and other derived products at its plant in Gouda. All of the lime feedstock was imported from Belgium, where Nekami had another subsidiary, Chaux-Brison, S.A., based in Seilles, which quarried a high-quality 97% to 98% $CaCO_3$ Devonian limestone in

the Meuse Valley.

Salt.—Akzo Zout Chemie BV was the Netherland's largest and Europe's tenth largest chemical concern in 1981. Akzo Zout was the sole producer of salt, with mines at Hengelo, Heiligerlee, and Zuidwending. The company also sold soda ash and sodium sulfate, which it produced at its Delfzijl plant. In addition to the mine at Hengelo, Akzo Zout operated a processing plant there, which produced table salt, industrial salt, ice control salt, salt for water softening, salt licks, chlorine, and caustic soda.

In addition to the mines, there were three salt plants operating at Delfzijl in 1981, using brine from Winschoten near Groningen as raw material. The combined production from the three plants was 2 million tons annually.

MINERAL FUELS

The energy requirements of the Netherlands were heavily dependent on domestic natural gas and imported oil in 1981, as in previous years. Production of oil and gas from the North Sea in 1981, although modest, was running at a record level, and reportedly more than 300 drilling operations were planned to begin in 1982. In 1981, 29 exploratory wells were drilled onshore and 32 wells offshore — a record high to date of 61 wells. Four new gasfields and three new oilfields were discovered during the year. Drilling platforms and other U.S. equipment were used in the Netherlands in 1981, and U.S. suppliers based there and in the United States were looking toward a $1.2 billion potential opportunity in equipment sales in 1982.

The Netherlands continued to import all of its coal requirements in 1981, and in the near future coal was expected to furnish some 20% of the country's total energy needs. About 40% of electrical power will then be generated by coal, and some 20% by gas and oil. In 1981, oil and gas accounted for almost 70% in the generation of electrical power.

The Netherlands also operated several nuclear power stations, the Zeeuwse Energy Co. in Middleburg being the largest.

Coal.—Lacking domestic production, coal continued to be imported by the Netherlands in 1981, primarily from the Federal Republic of Germany. Other large foreign suppliers were the United States, Australia, Poland and the Republic of South Africa. For political reasons, coal was no longer to be imported from the Republic of South Africa in the near future. As a result of sharp increases in the price of oil and gas, the use of imported coal increased 10% in 1981. The iron and steel industry used almost 90% of it.

Coal imports for the generation of electricity are expected to rise from over 2.5 million tons to 26 million tons by the turn of the century. Substantial expansion of coal use was to be based on secure supplies through long-term contracts. In view of that, the Government in 1981 was promoting participation in overseas coal production in order to contribute to the security of supply. In this respect, a 10-year contract with Poland for the supply of 600,000 tons of steam coal annually was concluded in 1977. However, in view of the economic crisis in Poland, the supply from Poland dropped almost 50% in 1981.

Even though the last coal mine in the Netherlands ceased operation in 1974, estimated potential reserves amounted to some 2 billion tons. This low-grade coal, however, would be too expensive to recover.

A number of coal gasification pilot projects were investigated in 1981, and when implemented could increase coal imports by about 1.5 million tons annually through 1990. The demonstration stage was to be followed by the construction of three gasification units, each with an intake capacity of 2 million tons of coal annually. In 1981, Esso Nederland BV was building a $500 million gasification pilot plant in Rotterdam. It was due to be operational in 1985 and would convert 90 tons of coal daily into substitute natural gas.

The Ministry of Economic Affairs of the Netherlands updated domestic coal consumption projections as shown in the following table in thousand metric tons:

Use	1981	1990	2000
Steam coal:			
Electric power	4,400	10,000	15,000
Industry	500	4,000	13,000
Coking coal	3,200	5,000	6,000
Total	8,100	19,000	34,000

The leading coal trader in the Netherlands, the Anker Kolen Maatschappij, and the largest iron and steel company, Hoogovens, both had financial interests in U.S. coal companies. In addition, Royal Dutch/Shell had also invested up to $680 million in U.S. coal mines. At least six other Netherlands companies were interested in investments in U.S. mines and coal purchases in 1981.

Natural Gas.—Production of and exploration for natural gas in the Netherlands continued at a rapid pace in 1981. Official estimates of proven and probable natural gas reserves were revised at yearend 1980 to 77,200 billion cubic feet. Since 1975, exploration has been constant, with 6 to 8 gas wells drilled per year onshore and 17 to 18 wells per year offshore. Of the 31 exploration wells drilled in 1980, for example, 14 were successful, compared with 11 in 1979.

The Groningen onshore field, with total estimated reserves of 62,000 billion cubic feet, was the largest gasfield in the Netherlands and was capable of meeting strategic needs not only for the Netherlands but also for other European countries.

The national gas policy continued to be aimed at decreasing domestic production and supplementing it eventually with imported liquefied natural gas or pipeline gas. In addition to existing contracts with Norway, a new 20-year contract with Nigeria was under discussion. Negotiations with the U.S.S.R. for a total of 1,413 billion cubic feet annually for Western Europe were underway, of which some 177 billion cubic feet annually could be directed to the Netherlands by 1990.

Petroleum.—Traditionally an onshore gas producer, the Netherlands was beginning development of its offshore oilfields. Offshore exploration efforts increased sharply in 1981. Seven drilling rigs were operating, with almost twice as many planned for 1982. The bulk of the drilling was around the existing developments and finds that have not yet gone into production.

In 1981, Union Oil Co. of the Netherlands was developing the production of oil from its two offshore tracts in Block Q1, the Helm and Helder Fields.

The Nederlandse Aardolie Maatschappij BV, operated by Shell Nederland BV and Esso Nederland BV, also began to develop its F3 onshore tract in 1981. A pipeline was planned to carry the oil across the Wadden Zee nature preserve.

The Continental Netherland Oil Co., a unit of Conoco Inc. of the United States, was seeking permission to develop the K18 field located close to the Helm and Helder offshore areas. Agip Nederland BV continued reappraisal of its 1971 oil discovery close to NAM's F3 field, while Pennzoil Nederland Co. was planning extended production tests on an oil field in Block K10. Amoco Netherlands Petroleum Co. was drilling its P15-3 offshore well some 28 miles northwest of The Hague.

The Netherlands operated eight oil refineries in 1981, with a combined crude throughput of 1,148,000 barrels per calendar day.

The Mineral Industry of New Zealand

By Charlie Wyche[1]

New Zealand's mineral industry showed no significant change during 1981, a year when demand for its mineral products was weak in the export market. Construction materials (limestone, gravel, sand, aggregates, and clays) and aluminum were the most valuable minerals produced. This situation is changing as production of iron sands for export and the output of gas and condensate from the onshore Kapuni Field increase. This change in value will also be further enhanced as output from the offshore Maui Gasfield increases over the next few years.

Although no new mines were brought onstream in New Zealand in 1981, a major coal mine is planned at Ohinewai, near Huntly. The deposit contains about 25 million metric tons of coal and will require about 4 years to develop. A production rate of about 1 million metric tons annually is planned.

The long-projected expansion of Glenbrook steelworks, which produces steel from New Zealand's iron sand deposits, was approved and was undergoing preliminary engineering studies.

The Minister of Energy announced plans for energy development based on the country's large reserves of natural gas. The plan includes a comprehensive analysis of past and future energy supply and demand status. The plan entails a total expenditure of some $6 billion[2] over 15 years. Of this total, some $3.2 billion will be directed to powerstation development, $1.9 billion toward liquid fuels, $0.62 billion for gasfield development, and $0.30 billion for coal mine construction and expansion. New Zealand is rich in energy resources, and Government policy and development programs were being pursued as a top economic priority to ensure optimum and balanced exploitation.

The Government was actively encouraging foreign investment in the country. The Department of Trade and Industry has an investment unit that provides potential overseas investors with information on investment in New Zealand, as well as lists of New Zealand firms seeking foreign investment or joint-venture partners. U.S. firms had investments totaling $579 million in 1980; this total will be greatly increased because Mobil Oil Corp. has a 25% share in a synthetic gasoline project.

The New Zealand Government approved the construction of the world's first natural gas-to-gasoline plant using a catalytic process developed by Mobil. The contract between Mobil and the New Zealand Government was signed, and the project was scheduled for completion in 1985. The natural gas, which will be supplied by the Maui Gasfield, will enable New Zealand to produce one-half of its currently imported motor fuels.

The only export commodities of any importance were titaniferous iron sands, aluminum and aluminum alloys, and small quantities of steel products. Crude oil and refinery products were the principal commodities imported, supplying about one-third of the national energy demand. Planned development of coal, natural gas, hydroelectric power, and geothermal power was expected to reduce petroleum imports to 20% to 25% of the total energy requirement by 1990.

PRODUCTION

The value of New Zealand mine and quarry output for 1981 (metals and nonmetals) was estimated at $162 million compared with $160.2 million in 1980. Principal commodities produced in 1980 (in thousand dollars) were as follows: sand and gravel ($60,300); coal ($53,700); iron sand concentrate ($34,400); limestone for agriculture, roads, cement, and other industries ($15,400); clays for brick, tile, and pottery ($2,100); and gold ($3,800).

Natural gas production, with associated condensates, was playing an increasingly important role in New Zealand's energy program. Natural gas and some condensate were produced at the offshore Kapuni Field, and the gas was supplied to Auckland, Wellington, and the New Plymouth and Stratford power stations.

[2]Reported figure.
[3]Revised to zero.
[4]Average 57% Fe.
[5]Includes crushed rock for building aggregate, roads, and ballast.
[6]Excludes carbon dioxide component of natural gas, which is reported separately.
[7]Includes field condensate.

TRADE

According to the Department of Statistics at Wellington, principal mineral exports during fiscal year (FY) 1981 (year ending June 30, 1981) were aluminum and aluminum alloys ($220.0 million) and iron ore and concentrates ($27.6 million).

Crude petroleum, partly refined petroleum, and petroleum refinery products dominated mineral imports and were valued at $934 million in FY 1981. Iran remained the principal import source, but Kuwait and Saudi Arabia were also significant suppliers. Imports of iron and steel, mainly semimanufactures, totaled $217.8 million. Phosphate rock from Nauru, sulfur from the United States, and alumina from Australia were also imported by New Zealand during FY 1981.

The Government continued to prepare to export approximately 250,000 tons of coal annually from the Buller Coalfield located in northwest Southland. The trade, estimated at $10 million annually, would constitute the first major coal export of recent times. Probable customers are Japan, the Republic of Korea, Taiwan, Hong Kong, and Singapore.

COMMODITY REVIEW

METALS

Aluminum.—New Zealand Aluminium Smelters Ltd. (NZAS), New Zealand's only aluminum smelting operation, continued work on an expansion project that would boost its annual production capacity by 57% over the present 150,000 tons. The expansion was scheduled for completion in 1983. Comalco Ltd. of Australia, in which the U.S. firm Kaiser Aluminum & Chemical Corp. has a major interest, owned 50% of NZAS, and two Japanese firms owned the remainder. Although the smelter was the subject of some criticisms by environmentalists, NZAS had considerable support from a large majority of the residents in Southland, where the plant is located.

The New Zealand Government approved the construction of a smelter on South Island by CSR Ltd. The total cost of the smelter was estimated by CSR and partners (Swiss Aluminium Ltd. and Fletchers Holdings Ltd.) at $650 million. The plant will reportedly be one of the most modern and sophisticated smelters ever built. The first potline, which will have a capacity of 100,000 tons annually, was scheduled to come onstream in 1984 and will produce primary aluminum ingots. The second potline, which will have a similar level of output, will produce either sheet or coil aluminum alloy in continuous-strip casting. Production from the second potline should start early in 1986. NZAS output accounted for over 1% of the total world production of aluminum metal in 1981. The completion of the current expansion project and the new construction project scheduled would increase New Zealand's share of world aluminum production to about 3%.

Approximately 80% of NZAS output of 150,000 tons of aluminum was exported, and the remaining 20% was used by New Zealand fabricators to produce a wide range of aluminum products for domestic needs. Aluminum exports went primarily to Japan and Southeast Asia. Under the terms of the agreement with the New Zealand Government, the Japanese partners exported their combined 50% share.

Gold.—New Zealand's gold production continued the downward trend that began in 1977. Output by Kanieri Gold Dredging Ltd., New Zealand's principal gold producer, was 2% lower than that of 1980. The decline was attributed to the exhaustion of both the more accessible alluvial gold deposits and the ore from the zones of enrichment. Annual production was mainly confined to one dredge operating in the Taramakau River, near Kumaru, South Island. The alluvial gold mined was among the lowest grades in the world. The alluvial sands also contained 3% uranite, and tests were underway to see if the uranite could be sold as a byproduct.

The Kanieri operation is a wholly owned subsidiary of Amoil New Zealand Ltd. All gold from the Kanieri operation was purchased by the Government. Because of the high gold prices in 1981, interest in possible gold-bearing areas remained high during the past year. This has led to large-scale dredging operations being proposed for the west coast of South Island.

Mineral Resources (New Zealand) Ltd. continued exploration throughout 1981 at the Marthu Mine, North Island. Mine dumps at Union Hill were being worked, and bulk samples were evaluated. Blackwater Gold Ltd. and Carpentaria Exploration Co. Pty. Ltd. continued testing ore extensions at a former property of Blackwater Mines. Amoco Minerals New Zealand Ltd. continued prospecting in the Monowai gold area.

Iron Sands.—The mining of titanomagnetite (iron sands) was by far New Zealand's largest metallic mineral industry and was second only to sand and gravel in both tonnage and value of output. In 1980, in terms of value, iron sands accounted for 20% of all nonfuel mineral output and over 84% of all metallic ore production. Output of iron sand concentrate by the two producing companies (New Zealand Steel Mining Ltd., a wholly owned subsidiary of New Zealand Steel Ltd., and Waipipi Ironsands Ltd.) declined from the 1980 level. The decline was attributed to the cutback in steel production by the Japanese steel industry, New Zealand's principal customer. Although these two companies were the sole source of iron ore for New Zealand's iron and steel industry, about 90% of the iron sands was exported.

The iron sand deposits consist of extensive horizontal beds on or near the western coast of North Island. They range in thickness from 5 to 20 meters and contain concentrations of up to 17% titanomagnetite sand grains. The grains originated from nearby andesite volcanic formations and

were sorted and concentrated by wind, stream, and wave action. The three sand deposits that were worked commercially were at Waverley, Taharoa, and north Waikato. The Waverley deposit was being mined by Waipipi Ironsands, and the other two, by New Zealand Steel, which also owns the Glenbrook steelworks, New Zealand's only steel plant.

Steel.—New Zealand Steel produced iron sands at its Waikato North Head deposit for use in its direct-reduction steelmaking plant at Glenbrook. Taharoa provided production for export to Japanese and Republic of Korea steel mills, which used the iron sands as an additive to sinter feed material for ironmaking. The plant capacity at Waikato North Head was expanded to 250,000 tons of concentrate annually. Some 223,000 tons of raw steel was produced during 1980, and about 225,000 tons in 1981. This figure is expected to increase to about 750,000 tons annually within 10 years. A cold-rolling mill and coat line for plain and galvanized sheet were being considered. Long-range plans included a new melt shop, continuous slab facilities, and more direct-reduction kilns.

Other Metals.—The Department of Scientific and Industrial Research (DSIR) continued its investigation of black, heavy-metal beach sand deposits on the west coast of South Island. These sands contain ilmenite, monazite, zircon, and gold.

Amoco Minerals conducted airborne magnetometry on the Ceromandel Peninsula, North Island, for base metals. Otter Minerals Exploration Ltd., in partnership with Gold Mines of New Zealand Ltd., continued exploration in Nelson Province and the drilling operation on D'Urville Island. Gold Mines of New Zealand, a partnership of Australian Anglo American Corp. Ltd. and Amoil, remained active in the Raukumara, East Cape, and Kaikoura regions. Exploration in 1981, however, failed to locate an economic deposit.

NONMETALS

Asbestos.—Chrysotile asbestos, mainly associated with serpentines, occurs at a number of locations on South Island. The most significant deposits were those of the northwest Otago (Pyke River) area, but further work is required to determine the limits of mineralization. Tests of the fiber indicate that it is of favorable economic quality, but no production was reported in 1981.

Phosphates.—The most promising source of phosphate was thought to be the nodules occurring on the sea floor on the eastern half of the Chatham Rise (west of Chatham Island). Research carried out by the New Zealand Oceanographic Institute in 1979 indicated the presence of phosphorite nodules ranging from 10 to 150 millimeters. Most of these deposits were found in water from 400 to 500 meters deep, and none were found at depths less than 200 meters. The P_2O_5 values for the phosphorites generally range from 18% to 24%, with a recorded high of 27.7%. Evaluation is still continuing.

Sulfur.—In 1981, development work by Fletcher Mining Co. Ltd. on a deposit of sulfur at Rotokawa in the Taupo area, North Island, remained inactive. The deposit, with reserves estimated at 6 million tons, was mixed with pumice, and research on a separation process was not completed. The Frasch process cannot be applied here owing to the porosity of the overlying beds. Further development will await the conclusion of research and financing possibilities.

Other Nonmetals.—In 1981, serpentine was mined at Piopio (near Te Kuiti) and North Cape on North Island, and Lee Valley, Collins Valley, and Mossburn on South Island. At Lake Grassmere, in Marlborough (South Island), salt was produced by solar evaporation of seawater, and perlite was produced in the Rotorua-Taupo area.

An analysis by DSIR of beach sands on the west coast of South Island indicated reserves of over 50 million tons of ilmenite-bearing sands. DSIR was conducting extensive laboratory tests aimed at producing a synthetic rutile from the low-grade (46% TiO_2) ilmenites.

MINERAL FUELS

Coal.—New Zealand produced slightly over 2.0 million tons of coal in 1981, from some 70 mines in various fields on both the North and South Islands. Nearly 70% of the production was from open pit mines. Development work on three new coal mines was on schedule, and a major new open pit mine was planned at Ohinewai, near Huntly. Prospecting for new deposits, the Mines Div. of the Department of Energy discovered large deposits of coal on both the North and South Islands. Total recoverable coal in all categories is 3.9 billion tons, including the lignite deposits rated 50% recoverable. Of this quantity, bituminous coal totals 0.2 million metric tons; subbituminous, 0.8 mil-

lion tons; and lignite, 2.9 million tons.

In 1981, state coal mines accounted for about 65% of New Zealand output. Private production accounted for 35% of New Zealand's total mine production, primarily from small mines. However, production by the private sector is expected to drop to 15% in the 1990's as the state mines expand output. Most mine expansion plans were in the state sector, but the Government planned to fund a private joint-venture partner to develop the Greymouth Stream coal deposit on South Island. This has a potential of 2 million metric tons annually, largely for export. There are no shiploading facilities on the west coast of South Island, and development is expected to be costly.

Because the coal-exploration program over recent years has greatly increased the known reserves of coal, it was decided in late 1979 that limited amounts of coal should be exported. Coal exports totaled approximately 16,000 tons during 1980. During 1981, state coal mines intend to export a total of 250,000 metric tons. The Buller Field, South Island, will supply about 85% of the total output, principally to Japan, the Republic of Korea, and Fiji. Total exports are expected to reach 500,000 metric tons annually by 1986. There were no uses in New Zealand for high-quality coking coal, and the exports will not significantly deplete the known reserves.

Natural Gas.—The New Zealand Government approved the construction of a $1.0 billion synthetic fuels project by Mobil for the conversion of natural gas into gasoline, via the intermediate product, methanol. This would provide about 30% of New Zealand's gasoline needs by 1987. Meanwhile, the distribution network for Maui and Kapuni gas is under full-scale development. Major future users include the ammonia-urea plant at Kapuni, the methanol plant at Waitara, and the synthetic gasoline plant at Motonui.

The Government was encouraging increased exploration by foreign companies by liberalizing its handling of taxes and by allowing more writeoffs, such as exploration and development, against other operations in New Zealand. Field development costs can be written off at a rate of 20% per year, beginning in the year of the first commercial production.

Petroleum.—The Government's comprehensive petroleum-exploration policy is now in effect. In instances where the Government accepts a company's petroleum-exploration proposal, it would retain the right to acquire a 51% interest in the discovery in exchange for a 40% contribution to the exploration costs. By decreasing its contribution to the exploration costs, the Government would accept a lower share of the venture. Should either party to such an agreement decide not to contribute to the costs of a particular well, the remaining parties could proceed on a sole-risk basis. In the event of a discovery, the parties contributing to the cost of drilling would be permitted to recover 600% of their expenditures as a prior charge against first production. Royalties to be paid to the Government on oil found were set at 12.5% of the sale value. The price of indigenous oil was raised to that of world crude.

New Zealand's only known major oil resources were in the Maui and Kapuni natural gasfields. Production by Shell-BP-Todd Oil Services (in equal partnership with the Government) continues to increase over that of each previous year.

The Government approved an expansion of New Zealand's only oil refinery at Marsden Point near Whangarei. The new expanded plant will be able to handle heavier types of crude oil, allowing New Zealand to import oil from a wider range of suppliers and reduce dependency on the Middle East. It will also allow the production in New Zealand of fuels, such as aviation gasoline, that are currently imported.

Production of liquefied petroleum gas at Kapuni was maintained at a high level, but market demand still exceeded supply. An extraction plant being constructed to strip liquefied petroleum gas from the Maui gas stream was expected to be fully operational in 1982. Proposals from distributors to import liquefied petroleum gas from Australia were under consideration by the Government, but no decision was made during the year.

The Mineral Industry of Nigeria

By George A. Morgan[1]

The mineral industry continued to perform poorly in 1981. The nonfuel minerals sector was small, and output of cassiterite and columbite concentrates, the principal mineral products, was down because of poor market conditions, organizational problems, and mining difficulties. Crude oil output was also reduced mainly because of low demand and Government policy.

Plans to fund numerous projects, including infrastructure development, were dependent upon petroleum revenues. Foreign exchange earnings were being depleted after 2 consecutive years of surplus, and a deficit of $7 billion was predicted for 1982.[2] Borrowing was the method proposed to fund the deficit, but a number of projects were being postponed, and trade restrictions were to be put into effect. State governments were dependent upon Federal Government revenues for nearly all their funding needs. High levels of borrowing by Federal and State Governments limited funds to private borrowers. A 25% increase in the national minimum wage was enacted and was expected to add $3 billion to total expenditures. Any organization employing 50 or more people had to comply with provisions of the law.

Government Policies and Programs.—The Federal Government completed its goal of acquiring a controlling interest in foreign-owned companies. It continued to create new public companies to act as coordinating agencies for the mining industry, with private firms acting in the role of subsidiaries. The fourth national development plan covering 1981-85 had a provision for the investment of about $10 billion in the mining and quarrying sector.

All mineral rights were exercised through the Ministry of Mines and Power. The Geological Survey Department and the Mineral Resource Division constituted the two divisions of the Ministry.

The Government established three corporations, the Nigerian Coal Corp. (NCC), the Nigerian Mining Corp. (NMC), and the Associated Ores Mining Co. (AOMC). The NCC had the exclusive right to explore for and mine coal. The NMC had responsibility for all solid minerals except coal and iron. Its duties included research in processing technology and marketing of output. It was to compete with the private sector and could set up projects with the participation of state governments and private concerns.

The AOMC was responsible for exploration and development of iron ore. The Nigerian Steel Development Authority was dissolved, and separate steel companies were established in addition to the AOMC. All were under the Steel Department of the Executive Office of the President, which had a cabinet-level minister.

A Mines Reclamation Unit in the Ministry of Agriculture was responsible for rehabilitation of mining sites.

PRODUCTION AND TRADE

Production of metals again declined while output of nonmetallic mineral commodities, heavily dependent upon local consumption, remained stable. Emphasis was placed on obtaining foreign exchange through sales of oil and establishing local industry to in-

crease employment. The industry was estimated to employ about 60,000 workers. Eight quarrying operations were set up, seven of which were in the production stage. Three of seven clay-brick plants were in operation in Jos, Kano, and Maiduguri.

Imports were estimated to be valued at about $30 billion in 1981. Subsidies were available for exports of products from the manufacturing sector and for industries targeted for development. The Société Generale de Surveillance continued to oversee product standardization for trade. The level of imports was effectively controlled by the Government by limiting the number of import licenses. The number available for issuance was based on the level of foreign exchange.

An agreement made with the German Democratic Republic provided for the exchange of equipment for minerals and oil from Nigeria.

Port expansion continued, with Lagos, Tin Can Island, and Port Harcourt having the heaviest trade volume. The ports of Warri and Calabar were underutilized.

COMMODITY REVIEW

METALS

A preliminary study of all known gold occurrences was completed. Further evaluation was underway for targeting sites for future exploration. The Geological Survey Department reported the discovery of both copper and columbite mineralization in Bauchi State.

Columbium-Tantalum.—Columbite concentrate production by Amalgamated Tin Mines of Nigeria Ltd. (ATMN) for the 9-month period ending December 31, 1980 was 153 tons. According to the company's annual report, about 89% of the total was produced as a byproduct of cassiterite production; the remainder was from one plant working solely for columbite. In addition, 11 tons of columbite was obtained from the Odegi Mine dumps. A contract with Vestis Tin Mines Ltd., which provided for treatment and marketing of columbite from the dumps, was terminated in February 1981, owing to economic reasons.

ATMN also had an agreement with Makeri Smelting Co. Ltd. in which it sought to obtain a higher value for tantalum recovered as a byproduct.

Iron Ore.—Development of the Itape iron ore deposit continued to lag behind the planned startup of the Ajaokuta steel plant. Reserves at the banded iron ore deposit were 200 million tons, grading 35% iron. However, only $15.7 million was allocated to the Associated Ores Mining Co. to develop the deposit.

About 108,000 tons of concentrate was imported from Liberia between May and August and stockpiled for use at the Aladja steel plant. Negotiations were completed for importing concentrate from the Miferguí-Nimba deposit in Guinea. A Liberian company was contracted to transport the concentrate from Guinea to Nigeria. The concentrate would be pellitized at the Aladja plant using a Lurgi pellitizer.

Iron and Steel.—The Aladja steel plant near Warri, operated by the Government-owned Delta Steel Co., was commissioned in November. Construction was by an Austrian and West German consortium with the assistance of Metallurgical and Engineering Consultants Ltd. of India at a total cost of $1.9 billion. Steel production capacity of four electric arc furnaces was 1 million tons per year. Charge to the furnaces in-

cluded 800,000 tons per year of sponge iron from two Midrex direct-reduction units and 200,000 tons per year of scrap. About two-thirds of production would be shipped to rolling mills at Jos, Oshogbo, and Katsina. The remainder would be rolled at a light section mill nearby. Access from the plant to the harbor at Warri was via a 6.5-kilometer-long, manmade channel. Port capacity was 4 million tons per year, and it could accommodate 25,000-deadweight-ton vessels. Electricity for the plant was supplied from the Sapele power station. About 70 million cubic feet per day of natural gas will be consumed at the plant. The supply of gas was from the Warri Oilfields, where associated gas was previously flared. Iron ore concentrate requirements of 1.5 million tons per year were to be met by imports from Liberia and Guinea. Total employment was 5,400 people.

The Katsina rolling mill, one of three mills under construction in Nigeria, underwent trial rolling tests in December. Capacity of the mill was 210,000 tons per year, and the mill was to be supplied with steel billets delivered by road from the Aladja steel plant. The Jos and Oshogbo mills would also have an initial capacity of 210,000 tons per year each. Production would be 57,000 tons of coils, and the remainder, bars. Despite a work stoppage at the Jos steel mill, about 85% of the plant was completed by Julius Berger Nigeria Ltd.

Work continued on the Ajaokuta steel plant that was being built by the U.S.S.R. Blast-furnace technology would be employed, and the plant was designed to consume 200 million cubic feet per day of natural gas. Planned capacity was in excess of 1 million tons.

Despite the high cost of domestic production, the Government intended to make Nigeria self-sufficient in production of basic steel products and to protect the new industry from low-priced imports. Cost of production of 1 ton of steel billets was $880 compared with an import price of $314 per ton. Both the quantity and type of steel imported were to be limited. Domestic demand of about 3.5 million tons per year was supplied almost entirely by imports of finished and semifinished products. Four minimills produced about 90,000 tons per year of steel products.

Tin.—Output from the labor-intensive tin sector continued to decline. The Government, through the NMC, acquired a controlling interest in all major operating tin companies. The principal firms and their percentage share controlled by NMC were ATMN, 58%; Ex-lands Nigeria Ltd., 54%; Bisichi-Jantar Nigeria Ltd., 60%; and Kaduna Prospecting Nigeria Ltd., 51%.

The Government also intended to acquire a controlling interest in Makeri Smelting Co. Ltd., which received all tin concentrates for smelting. Average capacity utilization was only 20% because of the unavailability of concentrate feed. Throughput was 3,622 tons in 1980, of which 7 tons was from Niger.

The Ririwai deposit in Kano State had demonstrated reserves of 2,581,000 tons, containing 0.82% tin and 1.7% zinc, and 2.5 million tons of indicated reserves. Initial output as an underground mine commenced in 1981 at 1,000 tons per day. The operation was a joint venture between NMC and Gold and Base Metal Mines of Nigeria Ltd.

ATMN employed about 1,600 workers and reported production of 1,155 tons of concentrate in the 9-month period ending December 31, 1980. Ground instability and low recovery from the Dorowa dredge were cited as reasons for the shortfall from a predicted output of 1,269 tons. Of the total cassiterite produced by ATMN, 70% was from contract plants, 19% was from the NG8 Mine, 6% was from the dredge, and 5%, from hand-mining contractors. The poor financial condition of the company caused curtailment of prospecting and the suspension of drilling in the N'Gell basalt. Two minimum wage increases during the year adversely affected mining costs. Amalgamated Tin Mines of Nigeria (Holdings) Ltd., in its annual report, listed its share of ATMN losses at $456,000 for the year ended March 31, 1981, compared with a profit of $160,000 in the year ended March 31, 1980. The company was reappraising its continued participation in the Nigerian mining sector.

NONMETALS

Cement.—The Benue Cement Co. at Yandev was set to start up a second production line. Capacity would be raised from 1,240 to 3,010 tons per day. The plant was built by Cementia Engineering and Consulting Ltd. of Switzerland. Equipment included two 64-meter-long rotary kilns with a four-stage Humboldt preheater. Startup was dependent upon the commissioning of a new power station under construction.

Limestone.—A number of limestone deposits were evaluated for use as flux in the iron and steel industry. The Jakura deposit was worked for production of marble, and both the Ubo and Ukpilla deposits supplied limestone to the cement industry. Lime plants were reportedly planned for several deposits. The Federal Government revoked the license of the Oyo State government to operate the Igbetti marble deposit. No reason for the revocation was given.

Salt.—Two salt refineries, one at Ijoko in Ogun State and one at Oyhereki, near Sapele, in Bendel State, were under construction. Total combined capacity of the two plants was 200,000 tons per year of salt.

MINERAL FUELS

Coal.—The Government announced that it intended to establish subsidiary mining companies at all future coal-producing areas. Soviet technicians were examining the extraction of coking coal at Lafia, in Plateau State, for possible use at the Ajaokuta steel plant under construction by the U.S.S.R.

Current output has been from two underground mines and one opencast mine at Enugu in Anambra State. Recently equipped and modernized with longwall mining equipment, production at the underground mines was 91,977 tons at Onyeama Mine and 60,222 tons at Okpara Mine. Output from the Okola opencast mine was 41,025 tons. The Nigerian Cement Co. consumed 108,715 tons; the Nigerian Electric Power Authority, 11,759 tons; the Nigerian Railways, 1,779 tons; and local users, 2,883 tons. About 5,000 tons was exported to Ghana.

Natural Gas.—Natural gas production associated with crude oil output was about 2 billion cubic feet per day, most of which was flared. An agreement made with a number of European companies to guarantee purchase of gas was terminated, once again canceling plans for a natural gas liquefaction plant. Gas reserves of 75,000 billion cubic feet were considered underestimated.

Petroleum.—Sales of crude oil made up 90% of the value of exports, 80% of Government revenue, and 25% of the gross domestic product. About $24 billion was earned from oil sales in 1980.

In 1981, declining oil prices and low production levels substantially reduced revenues. In the 9-month period ending September 30, actual revenue from the sale of oil was about $6 billion below the expected level, equivalent to one-third of the 1981 budget.

The Port Harcourt refinery operated at its rated capacity of 60,000 barrels per day. The Warri and Kaduna oil refineries, each with 100,000 barrels per day capacity, actually had a combined throughput of 134,000 barrels per day.

From the inception of oil exploration in the 1960's until early 1981, 229 oilfields had been discovered. Of that number, 140 were in production, 6 had exhausted their reserves, 71 awaited integration into a gathering system, and 12 were newly discovered. Reserves were 19 billion barrels.

The Mineral Industry of Norway

By Joseph B. Huvos[1]

In 1981, Norway's industrial production, capital investment, and trade, including the production of offshore petroleum, were all below 1980 levels and the gross national product (GNP) increased only 0.7% in real terms to about $59 billion.[2] Oil exports contributed about 14% to the GNP.

Unemployment edged slightly upward to 1.3% in 1981. Although exports of petroleum, the leading export item, declined, unit export prices were higher, compensating in part for the decline. The country's mineral industry, consisting mainly of oil and gas, hydropower-based aluminum, ferroalloys, copper, and zinc, remained sluggish.

The Norwegian Government was preparing a new law for regulating exploration and exploitation of petroleum and other mineral deposits on Norway's Continental Shelf, which was to be presented to the Storting (Parliament) for consideration in 1982.

Important events in Norway's mineral industry in 1981 included stagnation in the country's petroleum output, Government approval of a gas grid in the North Sea, merger talks between the country's two largest steel firms, Government rescue of the iron mining company AS Sydvaranger, departure of Tinfos—a ferroalloy maker—from the Fesil Group, and a decision of Norsk Hydro AS to construct a nitric acid plant.

PRODUCTION

There was no important change in the production pattern of Norway's mineral industry in 1981. The production index of some selected items in the metal and mineral industry in 1980 and 1981 are shown in table 1.

Table 1.—Production indexes, metal and mineral industry

(1975=100)

	1980	1981
Oil, mining, energy	132	132
Oil production and mining	382	374
Coal	78	87
Crude oil and natural gas	458	447
Ore mining	101	104
Oil refining	83	81
Ceramics and glass	104	97
Mineral products	95	89
Iron, steel, ferroalloys	92	84
Nonferrous metals	115	114

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Aug. 9, 1982.

[2]Less than 1/2 unit.

[3]Data represent exports, presented in lieu of actual production data, which are reported in official sources as not available for publication. A part of these exports may be derived from imported materials.

[4]Excludes nepheline syenite, which is included under "Stone."

TRADE

In 1981, Norway's foreign trade balance showed an increasing surplus. Although North Sea oil prices dropped from $41 to $36 per barrel, the strengthening of the dollar compensated for some of the loss. Norway's mineral commodity trade in 1979 and 1980 is shown in tables 3 and 4.

COMMODITY REVIEW

METALS

Aluminum.—A November storm cut the power supply at Norsk Hydro's Karmöy smelter near Haugesund for 5 days causing the aluminum to freeze in the pots. This event and a very weak market caused a loss of about $10 million to the company.

Long-range plans for Norway's aluminum industry would have increased aluminum production from 700,000 to 1 million tons per year. A merger was under discussion between Aardal og Sunndal Verk AS (ASV), with its 320,000-ton-per-year plant, and DNN Aluminium AS (DNN), bringing the total capacity of the two near 500,000 tons per year.

By April 1982, a new $116 million, 80-furnace potline of 47,000 tons per year came online at ASV's aluminum smelter located on the Sogne Fjord at Höyanger. ASV's other plant at Höyanger was also producing metal from an older 20,000-ton-per-year potline, which was to be closed down for conversion to Sumimoto technology after the new potline was operating satisfactorily.

The severe slump in the primary aluminum market prompted ASV to halt preparation for a $120 million hydroelectric development on its property at Aardal. The project was to have supplied 400 million kilowatt-hours by the mid-1980's for the Aardal smelter and was to replace expensive power now bought from the Government. The company cited failure to secure adequate financing and a forecast of a mere 1% growth in the Federal Republic of Germany, ASV's most important market.

The Norwegian Government stopped preparations for modernization of the State-owned DNN aluminum plant on the Sörfjord at Odda as a result of low demand for primary aluminum. In May 1981, $10 million had been appropriated to begin a $300 million modernization of the plant. Originally planned at 90,000 tons per year, the plant's planned capacity was reduced to 60,000 tons per year owing to a lack of electric power that itself was caused by successful environmental opposition to hydroelectric development over the last 10 years. The Government wanted to gain time to reconsider the primary aluminum expansion. Meanwhile, a contractor already had started dismantling the old works, leaving only 8,000 tons per year capacity.

ASV and Elkem Spigerverket have delayed participation in the $650 million expansion of the Aluminum Company of America's Jamaican bauxite refinery. Norsk Hydro was still interested in the deal with the Jamaican Government and Alcoa.

According to original plans, Jamaica's bauxite capacity of 550,000 tons per year would have been doubled. ASV was in the meantime ready to participate in the Hunters Valley smelter project in Australia.

In 1981, Norway's aluminum industry of five companies operating eight plants had a total capacity of about 712,000 tons. The largest producer was Aardal og Sunndal Verk with plants at Aardal, Sunndalsöra, and Höyanger and a total annual capacity of 329,000 tons. Second was Mösal Aluminium AS, a subsidiary of Elkem, with plants at Mosjöen, Lista, and Farsund and a total annual capacity of 177,000 tons. Norsk Hydro's Karmöy plant with 110,000 tons per year was third, followed by Sör-Norge Aluminium AS at Husnes with 72,000 tons per year, and Det Norske Nitrid AS at Tyssedal with 24,000 tons per year.

Copper, Lead, and Zinc.—In 1981, Norway operated nine complex sulfide ore mines; among them were four copper-zinc mines: Skorovas Gruber, Skorovatn; Grong Gruber, Limingen; AS Killingdal Grubeselskap, Trondheim; and Orkla Industrier AS, Lökken Verk. There were also three copper-lead-pyrite mines: Fosdalens Bergverks AS, Malm; AS Sulitjelma Gruber, Sulitjelma; and Folldal Verk AS, Tverfjellet, Hjerkinn. There were, furthermore, two lead-copper-zinc mines: Bergverkselskapet Nord-Norge AS, Mo; and Bleikvassli Gruber, Bleikvasslia. There was also a small copper smelter at AS Sulitjelma Gruber's Sulitjelma plant.

Folldal Verk AS, a subsidiary of Borregard AS, agreed with the Amoco Minerals Co. to conduct a joint $9 million exploration program for 6 years to investigate deposits in the area of Folldal's copper-zinc mines. Tungsten and molybdenum deposits were also to be investigated.

Iron, Steel, and Ferroalloys.—The Norwegian Government established a steel commission to study the competitiveness of the country's steel industry. Based on the committee's report, merger talks continued between the country's two major steelmakers, private sector Elkem and state-owned AS Norsk Jernverk. Elkem, said to be profitable, was making rebars from local scrap near its market. Norsk Jernwerk was comparable to the best steelworks of Europe but had a cost disadvantage owing mainly to its small size of 900,000 tons per year raw steel and its ironmaking process, which consisted of electric pig iron furnaces. The company's Mo i Rana plant was in the middle of an improvement and modernization program.

The Norwegian Government agreed to rescue the state-owned mining concern Sydvaranger from the threat of bankruptcy. The company was to be released from payment of interest and amortization to the Government for 1982 and 1983. The Government was to take over credit guarantees of about $20 million and advance another $20 million to the company for modernization purposes.

Sydvaranger's Kirkenes concentrator completed major modifications to increase its capacity and to enable it to produce concentrates suitable for delivery to the direct reduction plant in Emden, Federal Republic of Germany, in which the company had a 74.9% interest. The new equipment installed at the concentrator in 1981 included a 6.5-meter-diameter ball mill and a flotation plant for upgrading magnetite concentrates.

Norway's largest iron ore mines remained as follows: Government-owned Sydvaranger's Sör Varanger Mine near Kirkenes (2.3 million tons of concentrate per year), Norsk Jernnerk's Rana Mine near Mo (1.2 million tons), and Fosdalens Bergverks AS's Verran Mine in Nord-Tröndelag (510,000 tons). Smaller mines included the privately owned AS Rödsand Mine near the west coast (150,000 tons), Elkem's Nesset Mine also on the west coast, both producing iron ore as a byproduct of vanadium, and Titania AS's Sokndal Mine in South Norway, also a byproduct iron ore producer besides ilmenite.

Union Carbide Co.'s ferromanganese plant at Sauda was acquired at midyear by Elkem, raising the latter's share in the smelter to 91%.

Associated Metals and Minerals Corp. has agreed to invest $39 million in Orkla's ferrosilicon operation at Thamshavn, which has a capacity of 60,000 tons per year of 75% ferrosilicon, although its furnaces are working, at present, below that figure.

Tinfos, a ferroalloy manufacturer, decided to leave the Fesil Group by July 1, 1982, to market independently its ferrosilicon product, together with its manganese alloys. Tinfos had a capacity of 70,000 tons per year of 75% ferrosilicon, leaving Fesil with a 200,000-ton-per-year capacity. This made Elkem Norway's largest producer with a ferrosilicon capacity of 230,000 to 245,000 tons per year. Elkem had left Fesil in 1980, in order to better control its overseas sales, after having increased its foreign

holdings. The Fesil Group was to comprise, after July 1, 1982, the Björlvefossen, Hafslund, and Ila og Lilleby companies with plants at Aalvik near Hardangerfjord, Sarpsborg near Ostfold, Trondheim and Holla on the west coast, and Finnsness near Tromsö. Tinfos meanwhile was to market its own ferrosilicon, up to 100,000 tons per year of silicomanganese, and up to 80,000 tons per year of high-carbon ferromanganese.

Magnesium.—In 1981, Norsk Hydro operated the country's only magnesium smelter at Porksgrunn, south of Oslo. Although in 1979 and 1980, production problems at the plant had led to a reduction of output below target levels, the problems were solved in 1981, resulting in about a 7% increase in output. The company reported a considerable buildup of inventories because of the generally poor economic climate.

A major modernization of the smelter, planned for 1982, was expected to result in a substantial improvement in productivity. Small old electrolytic cells were to be replaced by new larger cells, based on modern company technology, resulting in considerable energy savings.

The company's Federal Republic of Germany subsidiary, Norsk Hydro Magnesiumgesellschaft GmbH was a maker of magnesium anodes for corrosion protection. Some of the caustic magnesia produced at Porksgrunn for conversion into magnesium was sold in the free market for the processing of paper and as a cattle feed additive.

Nickel, Cobalt, Platinum-Group Metals.—In 1981, the Kristiansand, south coast, refinery of Falconbridge Nikkelverk AS, a subsidiary of Falconbridge Nickel Mines Ltd. of Canada, continued to process imported Canadian nickel matte containing cobalt and platinum.

Titania AS's Sokndal Mine on the south coast produced a nickel concentrate byproduct with 3.9% nickel, which was shipped for processing at Outokumpu Oy's Harjavalta works on the west coast of Finland.

Rare-Earth Metals.—Further investigations of the recently discovered rare-earth metals deposit at Ulefos in Telemark County were undertaken. Most of the deposits are located on land owned by the S.D. Cappelen Co., over an area of 450 acres.

Vanadium.—In 1981, the Rödsand Mine, a subsidiary of Elkem, located at Rausand, west of Molde on the Sunndalsfjord, continued to mine a titanium-magnetite deposit with a vanadium content of about 1%. The magnetite concentrate was processed at Elkem's Bremanger smelter near Svelgen into 45% to 50% ferrovanadium; capacity of the operation was about 800 tons per year of ferrovanadium. Vantite, a vanadium-titanium pig iron, was also produced.

The Rödsand iron mine had not been profitable for some years, and it was decided to remedy this by building a plant for recovering vanadium pentoxide from the ore according to the Otanmäki process, at a cost of $600,000. The magnetite concentrate produced would be sold separately.

NONMETALS

Ammonia.—In 1981, Norsk Hydro's ammonia capacity was 2.145 million tons, including capacity in the Netherlands and Qatar, to be expanded by 500,000 tons in the Netherlands in 1984. The company was also planning to build for the late 1980's another ammonia plant either in Norway, the Netherlands, or the United Kingdom.

Apatite.—Norsk Hydro acquired mining rights to the apatite deposits west of Oslofjord at Kodal, estimated to contain 70 million tons of ore graded at 17% P_2O_5 and 40% Fe_2O_3. Feasibility studies were being prepared for the deposit, said to be able to support production of 300,000 tons of concentrate per year, sufficient to cover 70% to 80% of Norsk Hydro's Norwegian fertilizer production for up to 50 years.

Cement.—Norcem, Norway's only cement manufacturer, with three cement plants and a total capacity of 3.2 million tons of cement per year, signed, through intermediaries, a contract with Ashland Coal International Ltd. of the United States for the delivery of 350,000 tons of West Virginia steam coal.

Industrial Minerals.—In 1981, Norway continued to produce significant quantities of various industrial minerals, the most important ones being limestone, olivine, ilmenite, quartz, dolomite, nepheline syenite, and feldspar. A detailed description of industrial minerals of Norway in 1981 appeared in the technical literature.[3]

Nitrogen.—Norsk Hydro has decided to invest $22 million in replacing a 40-year-old 140,000-ton-per-year nitric acid plant at Rjukan, Hordaland, which was part of an ammonia and ammonium nitrate complex. Davy McKee Co. Ltd. has been awarded a turnkey contract for their own process.

Sulfur.—Borregard AS of Sarpsborg, south of Oslo, decided to build a pyrite-

based 180,000-ton-per-year sulfuric acid plant (monohydrate) at its Sharpsborg site, where at present the company had a Dorr Oliver Inc. type 300,000-ton-per-year plant.

MINERAL FUELS

In 1981, Norway remained a net exporter of oil and gas, producing about one-quarter of Western Europe's oil output.

Electric power allocations were announced by the Government amounting to 1.4 billion kilowatt-hours until 1985, another 2 billion kilowatt-hours by 1990, but allocation of a further 4.2 million kilowatt-hours was postponed. Of a total of 3.4 billion kilowatt-hours allocated at present, 2 billion went to the aluminum industry, and 600 million kilowatt-hours, to the ferroalloy industry. Norsk Hydro's magnesium production was allotted 350 million kilowatt-hours. Total industrial energy consumption was about 30 billion kilowatt-hours per year. Industry was requesting a 75% increase of electric power allotments. Tax on electric power was increased again to a total of $120 million, which was about one-third of the total cost of power paid by industry.

Coal.—Coal production on Svalbard Island by the Government-owned Store Norske Spitsbergen Kullkompani increased slightly from the three operating mines. Two of the mines, called No. 3 and No. 7, were located at Longyearbyen. Although the coal was less than 1 meter thick in the No. 3 mine and little mechanization was possible, in the latter it was about 1.4 meters thick, allowing for some mechanization. The third mine was located at Svea where only test mining took place. Full mining was to begin in 5 to 6 years at this location, at which time Svalbard output would double to over 70,000 tons per year from reserves of about 15 million tons. In the meantime, Norcem, Norway's cement operator, planned to convert to coal and use 400,000 tons of Svalbard coal per year.

Petroleum and Natural Gas.—In 1981, oil and gas production in the Norwegian sector of the North Sea decreased temporarily by 1.4% to an oil equivalent of 48.8 million tons. This was caused by an unexpected drop in the production of the Ekofisk Field and by strikes in the industry. According to existing programs, production by 1986 is to be about 60 million tons of oil equivalent per year, but decisions to develop fields in block 30/6 and some other smaller fields could raise production to 80 million or even 90 million tons of oil equivalent per year. These development decisions would stimulate offshore capital expenditures in the range of $2 billion to $3 billion throughout the 1980's.

In 1981, the Norwegian parliament gave its backing to the construction of an 843-kilometer gas gathering pipeline that was to land Norwegian-Sector natural gas at Emden, in the Federal Republic of Germany. In a first step, the gas from the new Statvik Field in block 34/10 was to be landed in Norway at Kaarstö through a 285-kilometer 30-inch pipeline. After separation of the natural gas liquids, the dry gas was to flow from Kaarstö through a 196-kilometer 26-inch pipeline to a riser platform, to which the Heimdal Field was to be connected via a 150-kilometer 36-inch pipeline. From there the gas was to flow via a 203-kilometer 36-inch line to the Ekofisk area, from whence the gas was to flow via the existing Norpipe pipeline to Emden.

Capacity of this link to Ekofisk was to be 600 billion cubic feet per year. Cost of the project was estimated at $2.2 billion, which made it look economical in view of an annual throughput worth $1.5 billion. Snamprogetti was to be responsible for the planning, while M. W. Kellogg would handle the Kaarstö facilities. The state was to take a 60% share in the Statpipe Co. being built, Elf took 10%, Norsk Hydro 8%, Mobile 7%, Esso 5%, Shell 5%, Total 3%, and Saga 2%. Development cost of the reserves of the Statvik Field was put at $3.1 billion.

In 1981, there were seven oilfields in production on the Norwegian Continental Shelf (Ekofisk, West Ekofisk, Edda, Cod, Tor, Albuskjell, and Statfjord). The Ekofisk complex included 17 steel platforms and a concrete pumping and processing center and produced about 385,000 barrels per day, although the peak was 618,000 barrels per day. The Statfjord Field comprised two concrete platforms but a third may be added at a later date. The Statfjord Field produced 75,000 barrels per day.

There were also two oilfields under development, Valhall and Ula. The first stage of Valhall involved three steel platforms linked to the Ekofisk center and having a capacity of 95,000 barrels per day. Ula had a planned capacity of 60,000 barrels per day.

North of the 62° parallel two areas were under exploration, one west of Trondheim, Central Norway, called the Haltenbanken area, the other facing northern Norway, called the Tromsö Field. Oil and gas explo-

ration in these areas was very successful; four of the five wells drilled in the area struck oil or gas. The oil companies were pressing for extending the drilling season from the present 5 months per year to a year-round season, making more efficient operation possible. Statoil, the Norwegian state oil company, found gas in one field in the Tromsö area estimated to contain 100 billion to 200 billion cubic meters. Norsk Hydro also found gas in the same area but had not proved it to be commercial. Seismic surveys showed also similar structures in the Barents Sea, but an unresolved ownership dispute with the Soviet Union has held Norway back from exploiting it.

The Norwegian companies were considering alternate plans for the gas in the north of the country. It may be liquefied and shipped in special tankers, or be sent by pipeline through Sweden to supply the continental markets of Europe.

In 1981, two companies, AS Norske Esso and AS Norske Shell, operated four petroleum refineries, the first company at Slagen and Valloy in the Oslo Fjord with 110,000 and 4,000 barrels per day capacity, respectively, and the second at Sola and Mongstad (Stavanger and Bergen areas) having 60,000 and 90,000 barrels per day capacity, respectively.

[3]Industrial Minerals (London). December 1981, p. 34.

The Mineral Industry of Pakistan

By Suzann C. Ambrosio[1]

Pakistan's economy, particularly the mineral and industrial sectors, exhibited positive growth signs during 1980-81.[2] Real gross domestic product (GDP in constant 1960 prices) increased nearly 6% for the fourth consecutive year, and nominal gross national product (GNP) increased 20% to $28 billion during the year.[3] Despite significant gains in the production of fertilizers, cement, and other nonmetallic materials, the mineral industry continued to comprise less than 1% of the GNP. Pakistani mineral products having the highest unit value during 1981 included hydrocarbons and gem stones. The reported market value of these commodities was approximately $300 million.

The $5.8 billion Government budget was expected to increase 14% to $6.7 billion in 1981-82. Over one-half of the current expenditures were allocated to defense and debt servicing. The debt-service ratio decreased for the third consecutive year in 1981. Budget financing was expected to be divided between internal sources (65%) and external assistance (35%).

The balance of payments (BOP) improved during 1981. Exports increased in value by 26% to $2.9 billion, and imports grew 13% to $5.5 billion. The U.S. share in Pakistani trade was only 5% of exports and 11% of imports. Major Pakistani import categories continued to be petroleum, capital goods, and fertilizers.

The Arab nations continued to provide BOP support through the OPEC fund and other bilateral arrangements. Saudi Arabia was the largest contributor in 1981, followed by Japan and the Federal Republic of Germany. The multilateral aid organizations targeted aid programs toward more specific areas: The International Bank for Reconstruction and Development (World Bank)—$120 million for the development of Pakistani energy resources; United Nations—a $50 million grant to construct and equip a national training development institute in Islamabad; and the International Development Association (IDA) of the World Bank—a $25 million loan to train skilled workers. The Western industrialized countries were expected to grant a total of $1.2 billion in Afghan refugee assistance. The United States proposed a $3 billion aid package for combined military and economic assistance during 1982.

Pakistan's economic policy objectives, to promote the development of import-substitution industries and to increase exports, were complemented by demand management programs of restrained monetary supply growth and tightened credit. Inflation continued to rise, however, to approximately 11%, owing primarily to higher import prices and increased levels of worker remittances. The 1981 current account deficit of approximately $1 billion improved because of the 22% increase in worker remittances to nearly $2.2 billion. The shortfall was financed primarily through foreign capital inflows and drawdowns on the International Monetary Fund (IMF). The IMF Extended Fund Facility was to provide $1.7 billion over a period of 3 years from 1980-83. Despite general improvement trends, Pakistan's economy continued to be plagued by an investment-savings gap and growing dependence on worker remittances and foreign energy supplies.

Policies were implemented to encourage private investment and boost domestic industries. In addition to streamlining and

accelerating the investment process, the Government reduced the maximum corporate income tax rate by 5% to approximately 61% of profits. The rate of initial depreciation on plant equipment and machinery was raised from 25% to 40%.

The total gross fixed capital investment increased 12% during 1981. Public sector investment increased 11% overall, and private sector investment increased 14%, driven by a 27% increase in industrial investment. The Government continued to dominate the mineral sector, although Government investments in minerals declined 7% to $9.6 million in 1981. Conversely, private sector investment in the mineral industry increased 20% over this same period, primarily for coal and marble. Despite the fact that 85% of the coal mining properties were leased to the private sector, the public sector accounted for approximately 17% of total production during 1981.

Private industrial development was expected to be assisted by a $30 million credit approved by the IDA to finance 80 industrial projects. Although joint ventures between the Government and private companies have increased in the fertilizer and cement industries, more recently, private sector involvement has been encouraged in the hydrocarbon and gem stone sectors. In December 1981, Pakistan held an international exhibition and gem stone auction. The Gemstone Corp. of Pakistan was allowed to make direct sales to Indian gem merchants and started opening the market to other foreign and domestic private sector gem merchants.

According to the Government, major constraints in developing indigenous mineral resources were lack of exploratory equipment, insufficient geologic mapping at appropriate scale, shortage of trained and experienced personnel, and inadequate financial resources, particularly the lack of available risk capital. The United Nations Technical Cooperation Div. approved a program to strengthen the technical resources needed to explore and evaluate Pakistani mineral deposits. The $672,000 program was expected to be completed in 1983 and concentrate on copper-molybdenum deposits in Chagai and lead-zinc-barite resources in Lasbela-Khuzdar, both within the Baluchistan region. Other exploration efforts were expected to focus on hydrocarbons, chromite, iron ore, gem stones, phosphate, granite, and marble.

PRODUCTION AND TRADE

Mineral production continued to be geared toward import substitution and supplying raw materials for existing and proposed development projects. Increased output was reported for iron ore, antimony, bauxite, fertilizers, cement, barite, dolomite, limestone, fire clay, kaolin, natural gas, and refinery products. There was a decline in output of crude oil, coal, chromite, manganese, and sulfur.

Owing to the increased production efficiencies of various Government-owned plants, fertilizer production increased by 36% to approximately 600,000 nutrient tons. The Mirpur Mathelo plant, commissioned during 1980, increased urea and ammonia unit output. The Exxon Chemicals (Pakistan) Ltd. facility achieved 130% of its designed capacity. The Hazara and Fauji fertilizer plants were expected to come onstream in the near future. When completed, approximately 200,000 nutrient tons of capacity, or the equivalent of two-thirds of domestic demand, was expected to be added. Pakistan continued to import to satisfy its fertilizer deficiencies, especially urea, phosphate, and potash, from Arab countries in the Middle East.

Large increases in output were expected in the cement and iron and steel industries. Thirteen new cement plants were sanctioned by the Government. Production of iron and steel was expected to increase over the next 2 years through the commissioning of the new Pipri integrated steelworks blast furnaces Nos. 2 and 3 and billet mills. Initial output of blast furnace No. 1 in 1981 resulted in 21,000 tons of pig iron exports. All of the pig iron went to India, and negotiations were underway to sell India 50,000 tons in 1982. When the two coke oven batteries come online, approximately 215,000 tons of surplus coking coal will be available for export. Discussions about potential coke exports were being held with India, Bangladesh, Romania, and Iran.

Natural gas and other petroleum product output increased during the year. Crude oil output declined slightly, owing to declining production of the Khaur, Dhullian, Meyal, and Balkassar Oilfields. This was compensated in part by increased output of the Joya Mair, Toot, and Adhi Oilfields. There was a slight decline in total refinery product exports, mostly naphtha and furnace oil, which were sent primarily to India and

Turkey.

Despite a 13% decrease in the volume of oil imports between 1980-81, prices increased 42%, and the total oil import bill reached approximately $1.5 billion. High-quality coal imports increased 60% over that of the previous year because of expanded use for thermal power generation.

Declining production was reported for chromite and sulfur, the latter attendant with decreased oil production. Information was scarce as to why the Muslim Bagh chromite mines were not fully operable during the year. High transport costs from the mountainous area near the Afghan border to the Port of Karachi were likely a factor. Approximately 7,500 tons of chromite was exported, and 2,000 tons was sold in the local market during 1980. Development of the other known chromite deposits continued to be hampered by the economics involved in processing the relatively low-grade ores having a high alumina content.

Pakistan's mineral trade deficit was largely due to iron ore, manganese, coking coal, and crude oil imports. Until the domestic iron resources are fully developed, imports will continue to be shipped from Australia, Brazil, Canada, India, and Liberia. Mount Newman (Australia) signed a 5-year contract to supply approximately 20% of Pakistan's current iron ore needs and 40% of the lump ore requirements. The suppliers of manganese and coke imports were unknown in 1981, although most of the 1979-80 coke was imported from European countries. Kuwait and other Arab countries supplied Pakistan's crude oil requirements, plus refinery products, especially middle distillates.

The volume of mineral and mineral-related trade between Pakistan and the Middle East and the United States was expected to continue increasing. A Pakistani delegation visited various Arab countries during 1981 and was expected to develop market analyses primarily for nonmetal and construction materials exports. The United States-Pakistan Economic Council was created to promote trade between the two countries. Pakistan's trade deficit with the United States stood at $412 million in July 1981. Trade consisted primarily of manufactured products and machinery, although the potential existed to develop increased mineral trade in fertilizers, chemicals, and refined petroleum products.

Table 1.—Pakistan: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1977	1978	1979	1980[p]	1981[e]

COMMODITY REVIEW

METALS

Bauxite.—The Geological Survey of Pakistan estimated lateritic bauxite resources in excess of 70 million tons. Pakistan's Export Processing Zones Authority (EPZA), in joint participation with Saudi Arabia, was expected to finance the construction of an aluminum extrusion plant. The plantsite was located in Lhandi, near Karachi, where 200 acres was set aside for an export zone. Details on plant capacity and cost were unavailable, but the aluminum plant was expected to be the largest EPZA project, with approximately 30% of investment and profits nonrepatriable.

Chromite.—Chromite was the only commercial metallic mineral produced and exported in Pakistan during 1981. Resources were estimated at 5 million tons, with the largest known deposits located at Muslim Bagh (Baluchistan), and smaller deposits were found in Malakand, Northwest Frontier Province (NWFP), and Rash Koh, Chagai, and the Lasbela districts of Baluchistan. The Pakistan Mineral Development Corp. explored the Malakand deposits and confirmed 580,000 tons of chromite reserves. Pilot tests carried out by the Pakistan Council of Scientific and Industrial Research (PCSIR) upgraded the Malakand ores to 45% Cr_2O_3. However, tests were not successful in reducing the alumina content to the permissible limit of 10%.

The Muslim Bagh chromite mines in the Khob Valley were not fully commissioned in 1981. Investigations were underway to determine the feasibility of developing the approximately 4-million-ton deposit in conjunction with a 15,000-ton-per-year ferrochrome smelter. The Muslim Bagh ores contain a chromium-iron ratio of 3:1 to 3.6:1. The Baluchistan Development Authority reportedly initiated mining of chromite in the Lasbela area, but no other details were available.

Copper.—The Bankable Document and detailed feasibility studies were completed for the Saindak copper project in May 1980. Mountain States Mineral Enterprises of the United States submitted the final feasibility study after becoming involved in the project as consultant to Seltrust Engineering Ltd. (United Kingdom) during the preinvestment study phase. Recommendations were made to develop the south ore body at a mining rate of 12,000 tons per day. Reserves of the three adjoining Saindak copper ore bodies were estimated at 412 million tons with an average grade of 0.37%. The south ore body comprised approximately 17% of total reserves. Annual production projections were revised to 17,857 tons of blister copper, 338 tons of molybdenum concentrate, 225,220 tons of sulfuric acid, 52,337

troy ounces of gold, and 79,935 troy ounces of silver.[4]

The total cost of the project was estimated at $400 million, including a foreign exchange component of 60%. The Baluchistan Mineral Resources Development Corp. was asked by the Pakistani Ministry of Finance to prepare terms and conditions for joint venture schemes. Several international companies expressed interest, including a Canadian-French-Yugoslavian consortium and United States, British, Swedish, and Romanian firms, but no information was available on contracts and construction schedules. Tenders were offered to construct an open pit mine at the south ore body, estimated to cost $200 million. Joint venture proposals were under consideration with a projected startup in 1984-85.

The exact location of the proposed mine, mill, smelter, and steel mill was undecided by yearend 1981. A total of approximately 3,000 people were expected to be employed, and various infrastructure requirements were expected to be addressed. Investigations determined that adequate water resources were available and a 35-megawatt power station would initially facilitate the integrated mining project. A main railway line passes 20 kilometers south of Saindak, with the nearest railway station located at Koh-e-Toftan, 35 kilometers from the deposit site. In addition, a major highway parallels the main Quetta-Zahidan railroad line.

The Geological Survey of Pakistan located additional copper deposits at Dasht-i-Kain within the Chagai district and at Ann-Dhoro and Soap-Dhoro in the Lasbela district of Baluchistan. Evaluation of these new deposits were expected to occur over the next few years, with an emphasis on deposits in the Chagai district.

Iron Ore.—Pakistani iron ore reserves were estimated to exceed 400 million tons, with main deposits located in Kalabagh-Makerwal, Punjab; Langrial, Hazara district, and Chitral of NWFP; and Khuzdar, Ziarat, Chilgazi, and Nou Kundi of Baluchistan.

The Pakistan Industrial Development Corp. (PIDC) continued to explore for iron ore in the Baluchistan region in order to meet domestic steel production requirements. Approximately 18 million tons of good-quality iron ore was proved in Naukundi and Pachinkoh. The PCSIR successfully produced iron ore concentrate from indigenous resources in Pachinkoh and Chigendik. PIDC and U.S. consultants were involved in evaluating the suitability of the Naukundi iron ore for the Pakistan Steel Mills Corp. (PASMIC).

Beneficiation studies of the Chichali iron deposits in Kalabagh, Punjab region, revealed that the ore could be upgraded from 32.5% to 58% iron. The feasibility limit for commercialization and use in steel production was determined to be 62% iron metal content.

Iron and Steel.—PASMIC recently initiated the first stage of the Pipri steelworks, which are also known as the Karachi steelworks, located 40 kilometers east of Karachi at Bin Qasim. Commissioning of the two blast furnaces and billet mills was running 2 years behind schedule and exhausted the original $1.3 billion budget allocation. A $2 million loan was secured from France to import machinery for additional construction. The Soviet Union assisted the Pakistani Government with the original financing, design, and construction of the 1.1-million-ton-per-year-capacity (Linz-Donawitz process) plant.

Technical problems with the seawater pumping equipment delayed startup of the first blast furnace for 8 months, until August 1981. A fire damaged the slag production unit soon after the steelworks opened, and damages were estimated at $1 million. Despite all the problems, approximately 60,000 tons of pig iron was produced during the year. The second blast furnace was scheduled for operation in June 1982, when pig iron production was expected to more than double.

In April 1981, the steel mill's first turbogenerator was placed in service in the thermal powerplant. Rated at 55 megawatts capacity, this unit was joined, in the same month, by startup of coke oven battery No. 1, a 485,000-ton-per-year-capacity portion of the coke oven and byproduct plant. Assuming two batteries and two blast furnaces were operating, approximately 970,000 tons of coke was expected to be partially consumed, 680,000 tons by the blast furnace and 75,000 tons by the sintering plant. The balance of 215,000 tons would be available for export and domestic markets.

The 800-millimeter billet mill was scheduled for startup in March 1982, and steelmaking was expected to commence in September 1982. Phase 2 of the Pipri integrated steelworks, including production of hot sheets, cold sheets, galvanized sheets, and formed sections, was expected to be operational by 1985.

Steel projects made headway in other areas of Pakistan. A continuous caster plant was recently installed in Lahore, Punjab region. The one-strand curved mold caster was expected to produce billets from 75 by 75 millimeters to 125 by 125 millimeters. The Pakistan Industrial Credit and Investment Corp. was considering financing nearly 40% of the total cost of a steel galvanizing and iron pipe plant. The plant-site was located at the Kot Lakhpat industrial estate, near Lahore. Loans from the Industrial Development Bank of Pakistan at Peshawar were expected to facilitate construction of a steel, wire, and metal rods manufacturing unit in Lasbela.

Pakistani People's Steel Mills, the Government-owned specialty steelmaker, was shut down in 1979 because of its mounting debt of $54 million. Japanese steel experts evaluated the mills and steel stocks and suggested that the plant would not be viable without state subsidies and/or debt rescheduling. Interest was expressed by the private sector, but the Government did not make any decisions on selling or bailing out the specialty steel mills by yearend 1981.

NONMETALS

Cement.—Nine publicly operated cement plants had an installed capacity of 3.75 million tons per year in 1981. Annual consumption demand was estimated at 5 million tons and was projected to increase to 6 million tons by 1983. Expansion of the Mustehkam cement plant was expected to increase capacity to 4 million tons by yearend 1982. Three additional public sector cement projects were scheduled for completion in 1982-83, raising annual capacity by approximately 1 million tons.

The Pakistani Central Investment Promotion Committee approved private sector participation in the construction of eight new cement projects. The projects were expected to add 2.4 million tons to capacity over the next few years. Project implementation was expected to be slow because of large increased foreign exchange requirements for imported plant equipment and machinery.

Only one private sector project initiated construction by yearend 1981. The foundation was laid at the Cheerat cement factory, located 19 kilometers south of Peshawar in the NWFP. Initially, 325,000 tons was expected to be produced annually, with expansion plans set at 1 million tons. Financing was arranged through a private entrepreneur in collaboration with a French machinery and equipment firm. The Pakistani Banker's Equity was also expected to share in financing the project. Similar instances of Government participation through direct allocation of funds were expected for the Naseer Shaikh and Co. cement factory and the Fecto Ltd. cement plant, with proposed locations near Jhelum and Rawalpindi in the northern Punjab region, respectively. Each of these three projects was designed to produce approximately 300,000 tons per year of portland gray cement.

Other privately sponsored cement project proposals included Pak Land Cement located at Dhabeji, near the Port of Karachi; Dadabhoy Cement at Dadu; and Fakir Cement at Jhill Hill, Karachi, all within the Sind region. Each plant was expected to have a 300,000 ton annual capacity. Two other cement plants were to be sponsored by Arab entrepreneurs, Galadari Cement (Gulf) Ltd. at Lasbela, Baluchistan, and the Fharah cement plant at Hub Chowki, Baluchistan. Both plants had planned capacities of 600,000 tons per year.[5]

Asbestos Cement Industries Ltd. operated two plants at Karachi and Hyderabad, Sind region. Total production was rated at only 50% of installed capacity of 40,000 tons per year. Production was projected to expand through improved plant efficiencies and construction of a new asbestos cement facility, recently sanctioned by the Government for the Punjab region.

Clays.—*Kaolin.*—During 1981, the only commercially exploited deposits of kaolin (china clay) were located at Shah Dheri in Swat, NWFP. Total reserves were estimated at 4.5 million tons within the NWFP and 3.5 million tons in Nagar Paker, Sind. Recently discovered deposits in Lahore, Punjab, were evaluated by the PCSIR and the London Institute of Geological Sciences. Initial investigations proved extremely favorable and detailed feasibility studies were undertaken with technical assistance provided by the United Kingdom.

Fuller's Earth.—The Punjab Mineral Development Corp. was in the process of conducting a feasibility study to develop a fuller's earth plant. The facility was projected to cost $7 million. Operations were expected to commence by 1985 at the proposed site, Dera Ghazi Khan.

Fertilizer Materials.—In concurrence with recent successful strides to narrow the

gap between demand and domestic production, fertilizer material production increased for the fourth consecutive year and consumption declined by approximately 6% during 1981. Total production capacity achieved in 1981 was approximately 730,000 tons of nitrogenous fertilizer and 90 tons of phosphatic fertilizer.

Implementation plans continued to be made to increase the efficiency of operating plants and to expand domestic output of both nitrogenous and phosphatic fertilizers. Exxon Chemicals (Pakistan) Ltd. attained a production efficiency peak at 130% design capacity, resulting in production of 225,700 tons of fertilizer materials in 1981. Various steps implemented during the year were responsible for the increased efficiency: Ammonia converter basket and gas turbine rotor replacement, urea reactor inspections, replacement of five catalysts, and increased maintenance of the critical heat exchangers.

Progress was made on the proposed Hazara fertilizer complex. British experts were evaluating the extent and quality of phosphate deposits in the Hazara region, NWFP. The pentoxide content (P_2O_5) was estimated at 25% to 28%. The British team was expected to ascertain if the content could be raised to 30%. Preliminary reports were due in July 1981, and the final report was expected to be complete by 1983. No other detailed information on the deposits was available at yearend 1981. The National Fertilizer Corp. had the responsibility for setting up the Hazara fertilizer complex, and the Sarhad Development Authority was responsible for setting up the two mining operations near Abbattabad and Hazara.

An agreement was signed between the Fauji Fertilizer Co., Ltd., and the Kuwait Fund for Arab Economic Development in May 1981. The agreement called for a 20-year loan to assist in the execution and operation of the fertilizer project. Snamprogetti (Italy) was contracted to construct the 900-ton-per-day ammonia unit and 15,000-ton-per-day urea unit at Goth Machhi, Sind.[6]

Gypsum.—Total gypsum reserves were estimated to exceed 350 million tons. Large deposits occur in Mian Wali, Jhelum, and D. G. Khan districts in Punjab; Quetta and Sibi districts in Baluchistan; and Kohat district in NWFP. A new gypsum quarry was developed in Mian Wali with rated production capacity of 100,000 tons per year. The Government planned to triple gypsum output over a 5-year period to facilitate cement and chemical fertilizer industry expansions. The Asian Development Bank granted technical assistance to support Pakistani gypsum production goals.

Salt.—Large salt reserves located in the Punjab and NWFP were estimated to exceed 100 million tons. Salt continued to be produced from six major mines and quarries at an approximate rate of 500,000 tons per year. Three additional salt mines were expected to be opened to meet the estimated annual demand increases of 10%. Potential salt minesites were identified at Khewra, Warcha, and Kalabag, with an estimated total cost of $2 million.

The development of a 300,000-ton-per-year solution mine was under consideration. A feasibility study was near completion, and if the mine was commissioned, the salt was expected to be utilized by a nearby soda ash factory.

MINERAL FUELS

Coal.—Pakistan had approximately 480 million tons of known coal reserves in 1981, with nearly one-half of the reserves located at Lakhra, Sind. Most of Pakistani coal resources were classified as high-volatile lignitic to subbituminous, with relatively high ash and sulfur content. Proven commercial deposits were confined to the southeast foothills of the central mountain ranges. The only coal in the country possessing medium coking characteristics was located in the Sharigh Coalfield. After washing and blending with imported high-grade coking coal, the Sharigh coal was found suitable for the manufacture of metallurgical coke.

New coal deposits were discovered within the Sind and Punjab regions. The Geological Survey of Pakistan identified large quantities of good-quality coal approximately 400 kilometers northeast of Karachi at Thatta, Sind. The Thatta-Sadha Coalfield, covering over 750 square kilometers and straddling the Indus River, was expected to be inventoried by 1983. Another deposit was discovered near the border between the Jhelum and the Mian Wali districts of Punjab. The feasibility of developing a 15,000-ton-per-year mine by 1982, with an expansion potential to 50,000 tons per year, was being considered. The Provincial government allocated $3 million for additional exploration in the area. The Punjab government has also earmarked approximately $1.4 million to establish a modern mining

training institute to facilitate improvement of local coal mining practices.

The current 5-year plan (1978-83), which set the coal production target at 3 million tons, would require an approximate 50% increase in 1981 production levels. To meet the goals of the plan, objectives were set to increase production of coal to 1.7 million tons through the expansion and modernization of existing mines and development of new coalfields in the Punjab and Sind Provinces. More specifically, the plan called for expanding annual capacity at the Sharigh collieries from 50,000 to 100,000 tons by yearend 1982, construction of a 75,000-ton-per-year coal washing plant at Sharigh, expansion of the Makerwal collieries from 120,000 to 300,000 tons per year capacity, and development of the Jhimpir-Meting Coalfield within the Sind region.

The Government was also encouraging higher value uses of indigenous coal, used almost exclusively in brickkilns. Higher grade coal was imported primarily for use in thermal power generation. The Japanese International Cooperation Agency provided technical expertise in the preparation of a feasibility report for an integrated Lakhra coal mining thermal power station. The projected cost of the project, if completed in 1987, was estimated at $1.2 billion, with a foreign exchange component of $612 million. Approximately 36 million tons of reserves were proven to be of sufficient quality to feed a 200-megawatt thermal powerplant. The Pakistani Water and Power Development Authority envisioned Lakhra stage 2 in 1990 expanding capacity by 300 megawatts. The facility was designed to accommodate capacity up to 1,000 megawatts. The project continued to be delayed because of the large financial requirement and technical problems associated with the higher sulfur coals.

Natural Gas.—Recoverable reserves from dry gasfields and associated gases from the oilfields were estimated at 16 trillion cubic feet. The Oil and Gas Development Corp. recently estimated offshore resources at 8.4 billion cubic feet. At yearend 1981, the remaining marketable reserves were estimated at 13.3 trillion cubic feet, and the gas was projected to last approximately 50 years at the current production rate. Consumption during 1980-81 was 265 billion cubic feet. Natural gas supplied 35% of the total energy needs of Pakistan during 1980 and was estimated to have supplied 42% of total energy needs in 1981.

The Sui Gasfields met 80% of the total gas demand, with roughly 90% of the gas consumed by the industrial sector. Thermal power stations, fertilizer factories, and cement facilities were the three largest industrial consumers of natural gas. Large increases were reported to be consumed by the thermal-power-generation industry, owing primarily to the commissioning of the third 210-megawatt unit of the Gudu power station.

A 2-year appraisal program was launched at the Dhodak and Pirkoh Gasfields, located within the Punjab and Baluchistan regions, respectively. Objectives were set to evaluate the size of the fields and estimate the volume of gas and condensate reserves at Dhodak and the volume of gas reserves at Pirkoh. Preliminary estimates have revealed 1 trillion cubic feet of gas at Pirkoh, and six development wells were expected to be completed in the area by 1983. Pakistan signed a $55 million loan with the Asian Development Bank to develop the Pirkoh Gasfield and lay a pipeline. An 18-inch-diameter, 120-million-cubic-foot-per-day pipeline was envisioned to transport gas from Pirkoh to the Sui Field and transmission network. The initial phase of the Pirkoh gas project was expected to supply 72 million cubic feet per day by 1984.

There were five gas processing plants in Pakistan as of July 1981, with total throughput capacity of 720 million cubic feet per day. Pakistan Oilfields Ltd. initiated two refrigerated absorption plants during the year, utilizing associated gas from the Dhulian and Meyal Oilfields.

Pakistan's gas distribution network was estimated to cover 14,500 kilometers by yearend 1981. Construction work was initiated in July 1981 to lay a 12-inch-diameter, 350-kilometer pipeline from Sui Indus Right Bank pipeline to Quetta and other towns en route within Baluchistan. The Quetta gas pipeline project was estimated to cost approximately $670 million with a 51% foreign exchange component. The foreign exchange component was expected to be provided by the Kuwait Fund for Economic Assistance.

The gas transmission capacity of the Indus Right Bank pipeline was expected to be expanded from 135 million cubic feet per day. The expansion project involved the installation of mainline compressor stations at Shikarpus and Dadu and a booster station at the Sari-Hundi Gasfields.

The Hydrocarbon Development Institute of Pakistan was in the process of commis-

sioning two compressed natural gas (CNG) pilot projects. The objective was to replace gasoline and imported diesel fuel with CNG at stations in Karachi and Islamabad.

Oil.—The Pakistani Government continued to place a high priority on oil exploration and development, which was reflected in the 17% increase in the 1981-82 budget of $1.8 million. The Oil and Gas Development Corp. (OGDC), the largest Government hydrocarbon agency, was allocated 55% of the budget. OGDC drilled 7 of the 33 wells and operated 5 rigs during 1981. Other drilling was carried out by approximately 11 other public and private sector companies. A total Government investment of $2.8 million was envisioned to finance the drilling of eight exploratory wells, four development wells, and one appraisal well in 1982.

Oil was found for the first time in the lower Indus Basin, about 22 kilometers northwest of Badin, within the Sind region. The Khaskeli No. 1 well was spudded on May 14 by Union Texas Co. (United States), reaching a total depth of 2,559 meters on June 16, 1981. Union Texas, the operator for Cities Service Co. (United States) and OGDC, was expected to proceed with development drilling in 1982. The group held an 18,000-square-kilometer concession in the Thatta district of the lower Sind region. By yearend 1981, Khaskeli No. 2 was also reporting a show of oil. Union Texas planned to drill three more wells in the area.

OGDC and Pakistan Shell Petroleum Development BV agreed on a supplemental petroleum concession of 11,000 square kilometers. Under the agreement, a 4-year license was granted for the additional area. Shell was already committed to survey and drill a deep well at Pabbi Hills, NWFP.

A memorandum of understanding was signed between the Government and a group that included Occidental Petroleum Corp. for a 640-square-kilometer exploration concession in the north Potwar area of NWFP. The private sector group planned to spend $19 million in the concession for 4 years. Seismic surveys were planned, and two wildcat wells were expected to be drilled during 1982-83.

OGDC, with assistance from the Canadian International Development Agency, drilled two more wells at Dakhni and Tut within the Attock district, NWFP. Production testing was carried out at Tut No. 2, while Tut Nos. 12 and 13 were nearing their target depths by yearend 1981.

Pakistan Petroleum Ltd. (PPL) drilled six development wells during 1981. PPL, in joint participation with OGDC, conducted seismic surveys of the recently discovered (1979) Adhi Oilfield structure. Adhi No. 7 was drilled below 2,300 meters, and Adhi No. 8 was spudded on December 14, 1981, by contract drillers, Deutag Ltd. (Federal Republic of Germany). PPL agreed to transfer a concession held in the east Potwar area to OGDC. The agreement called for AMOCO Pakistan Exploration Co. and OGDC to carry out joint exploration, which included drilling three wells in the area.

Pakistan's refinery capacity was 46.8 million barrels per year in 1981, divided among Pakistan Refinery Ltd.—18.3 million barrels, National Refinery Ltd.—15.3 million barrels, and Attock Refinery Ltd.—13.2 million barrels. The Pakistan Refinery Ltd., located at Karachi, contracted with Lumus Co. Ltd. (United States) to expand annual capacity. The revamping was expected to consist of installing a vacuum distillation unit, a deasphalting unit, and a lube refinery by 1984.

An oil-product pipeline extending 865 kilometers from Karachi to Gujrat near Multan was commissioned. Oil-marketing companies obtained the products at the Gujrat Depot. An oil terminal located at Gujrat was recently constructed by the Pak-Arab Refinery Co. Operations were reported to have commenced in May 1981.

The Government commitment towards enhancing the effectiveness of the hydrocarbon sector was reflected in the establishment of a petroleum testing center in September 1981. The sponsor, Hydrocarbon Development Institute, located the center at Lahore, Punjab. In addition, the Government was expected to conduct a detailed feasibility study on the market and demand for petrochemicals.

The Mineral Industry of Peru

By Doris M. Hyde[1]

In 1981, the Peruvian economy registered a gross domestic product (GDP) of $20 billion.[2] The real growth rate of 3.9% compared favorably with the 3.1% rate achieved in 1980 but was less than that projected early in 1981. The average rate of inflation for 1981 was about 73%, but the official rate of currency devaluation was held to 45%.

The minerals sector accounted for slightly less than 9% of the GDP in 1981. The value of nonfuel mineral exports reached $1.5 billion and represented 43% of total export earnings, a decrease from its 47% contribution in 1980. There was a 20% drop in the 1981 nonfuel mineral export value from that of 1980, which was unusual for Peru but was in accord with generally depressed world metal prices and the domestic circumstances that reduced copper production.

The $684 million value of 1981 petroleum exports represented a 12% decrease from that of 1980. Nevertheless, petroleum easily maintained its newly acquired position as Peru's leading mineral foreign exchange earner because of the poor performance from the copper industry. Petroleum contributed almost 22% of the $3.2 billion value of total exports.

For the most part, all mining sectors were affected by a combination of adverse events. These included natural disasters that disrupted the transportation of minerals, supplies, and fuel, both to and from the central mining region; labor unrest; postponements of expansion plans; and cash-flow problems intensified by generally depressed market prices for metals.

The medium- and small-sized mining sectors were particularly affected by low prices for their products. To assist these companies through this critical period, the Banco Minero del Peru increased its short- and medium-term loans by almost 79%. The small-sized mining sector obtained 45% of these loans, and the medium-sized sector, 40%. Other forms of transitory credit were also made available to assist the miners with working capital.

The bank began the construction of 20 new concentrators to be situated throughout the country. These concentrators were to be rented to small operations for a maximum period of 5 years. The concentrator capacities ranged from 20 to 200 tons per day, depending on the particular needs of each region. The first of these concentrators, a 40-ton-per-day flotation plant, was inaugurated in September in the Department of Cuzco. The remainder was expected to be installed by the end of 1982.

The large-sized mining sector was also affected by adverse circumstances. Owing to labor problems at all three of its operations, Southern Peru Copper Corp. (SPCC) experienced a 15% drop in blister copper production. The work stoppage of almost 60 days was the longest in the company's history. SPCC was frustrated in its attempt to refinance the Cuajone operation. The company indefinitely postponed plans to expand production from both of its mines.

Refined copper output at the La Oroya metallurgical complex of Empresa Minera del Centro del Perú (CENTROMÍN PERÚ) was down slightly because of transportation problems caused by the aftermath of adverse weather. Copper production from the Ilo refinery of Empresa Minera del Perú (MINERO PERÚ) was reduced 11% in 1981 when the SPCC strikes curtailed blister deliveries. MINERO PERÚ also endured a short strike at its refinery. Pessimistic copper price projections were largely responsible for delaying the Ilo refinery's expansion plans.

The number of strikes in the mining sector decreased from 123 in 1980 to 37 in

1981, but the total effect was more harmful in 1981. The value of strike-lost production in 1980 was estimated at $75 million, but in 1981, with 70% fewer strikes, the lost production was valued at $100 million. Lost copper production due to the strike at SPCC was valued at $65 million.

Government Policies and Programs.—In 1981, the Government completed a series of legislative actions to reform mining and tax laws in an effort to encourage foreign investment.

The mineral marketing monopoly of Minero Perú Commercial (MINPECO) was eliminated through Legislative Decree No. 44, issued February 27, 1981. As a result, trading companies opened or reopened offices in anticipation of competing for mining sales contracts once agreements with MINPECO expire. Legally, MINPECO retained the right to market production from the three wholly state-owned enterprises. The decree established MINPECO as a limited liability company subject to the Law of Mercantile Companies.

Legislative Decree No. 35, issued February 27, 1981, modified the General Mining Law, Decree Law No. 18880. This decree altered the structure of MINERO PERÚ so that it could be operated as a limited liability company. All special mineral rights of the state were transferred to MINERO PERÚ. MINERO PERÚ may form joint ventures with private foreign and local companies to develop large mining projects as Empresas Mineras Especiales. MINERO PERÚ would retain a minimum 25% equity in these special mining companies.

Legislative Decree No. 33 exempted the mining and petroleum companies from payment of certain taxes created by Decree Laws 21528 and 21529 of 1976, including the 17.5% tax on exports and domestic sales. The decree allowed for a gradual phasing out of the export tax on a quarterly basis, with applicable taxes varying for individual mining sectors until June 30, 1983. By that date, the tax rate for the large-sized mining sector and petroleum and petroleum derivative producers was scheduled to have been reduced to 5%. Producers of silver would have had their tax reduced finally to 2%, and all other mining companies would have had their tax reduced to 3.5%.

The export tax had generated 10% of the Government's total tax revenue. To cushion the fiscal impact of the export tax reduction, a new 5% sales tax was imposed on each sale and/or export transaction of products whose prices are subject to international quotations. This new sales tax was allowed to be credited as an advance income tax payment. Small producers, gold and heavy sand-mining companies, Empresa Minera de Hierro del Perú (HIERRO PERÚ), and the Cerro Verde I operation of MINERO PERÚ were exempted from the sales tax payments.

In June, Legislative Decree No. 154 provided for a 50% reduction in the sales tax due on minerals whenever the daily international prices fell within specified ranges during 1 calendar month. The ranges were set at $9.00 to $9.50 per ounce (Handy & Harman) for silver, $0.83 to $0.88 per pound on the London Metal Exchange (LME) for copper, $0.30 to $0.33 per pound (LME) for lead, and $0.37 to $0.40 per pound (LME) for zinc. No sales tax would be paid when daily prices fell below these prices for any period exceeding 1 month.

Legislative Decree No. 109 of June 12, 1981, was the new General Mining Law, which became effective September 1, 1981. The law redefined small-sized mining, with attendant special tax benefits, by increasing the production limits from 200 to 350 tons of ore per day for metals and up to 500 tons per day for coal or nonmetals other than construction materials. As originally set forth in Legislative Decree No. 44, it eliminated the state's monopoly on the marketing of minerals and in the installation of refineries and smelters. This allowed a number of small lead-zinc smelter companies to open up operations. The new mining law also reaffirmed the special position of gold mining, redefined the role of the state-owned companies in the mining sector, redesigned the system for registering mining claims, and provided a variety of tax benefits and investment incentives. Some of the tax and investment incentives had been enacted earlier as modifications to the old mining law.

Implementing regulations for the December 1980 Petroleum Law, Decree Law 23231, were issued on March 20, 1981, as Supreme Decree No. 005-81-EM-DGH. The regulations concerned the criteria for extensive reinvestment tax credits and were generally thought to encourage increased exploration and foreign investment.

PRODUCTION

Overall, Peru's mineral production had a mixed performance in 1981. Labor problems at the SPCC Cuajone and Toquepala Mines in southern Peru was the primary reason for decreased copper production. Problems stemming from adverse weather conditions and depressed world market prices affected mineral output from producers elsewhere in Peru. CENTROMÍN PERÚ continued to produce the widest range of minerals and metals.

In 1981, CENTROMÍN PERÚ's seven mining units accounted for 8% of total mined copper production, 43% of zinc, 41% of lead, and 24% of mined silver production. CENTROMÍN PERÚ production at the La Oroya metallurgical complex is shown in table 2. Peru's refined zinc production doubled in 1981 as a result of the completion of the MINERO PERÚ Cajamarquilla zinc refinery.

The gold boom continued, and gold represented Peru's most active mineral sector. A small new gold rush occurred along the coast north of Lima near Chimbote. The Madre de Dios area in the eastern jungles, east of Cuzco and north of Puno, continued to attract mining interest.

In 1981, the average petroleum production of about 193,000 barrels per day not only failed to meet the targeted goal of 225,000 barrels but dropped slightly below the 1980 production level of 195,000 barrels. One reason for this was the failure of the consortium of Occidental Petroleum Corp.-Bridas Exploraciones y Producción of Argentina to significantly increase production from its secondary recovery program in the Talara north coastal area. In addition, production from the jungle areas was restrained from reaching its potential by problems related to transportation. The targeted production rate for 1982 was set at 230,000 barrels per day, based on anticipated improvements in the above areas.

TRADE

The Central Reserve Bank preliminary statistics on nonfuel mineral exports in 1981 indicated a total value of about $1.5 billion, a 20% decrease from the $1.8 billion record set in 1980. This substantial drop in mineral export value resulted from generally depressed world market prices for metals and a decrease in Peru's copper production.

The United States was the leading recipient of MINPECO mineral exports, importing 79% of the silver, 31% of the lead, 22% of the copper, and 19% of the zinc. Western European countries imported 31% of the copper, 27% of the lead, and 42% of the zinc exports. The Republic of Korea and Japan received about 80% of the iron ore exports.

Petroleum exports in 1981 were estimated at 54,541 barrels per day, valued at slightly under $700 million for the year. Peru expected 1982 crude oil exports to reach 85,000 barrels per day and to contribute over $1 billion to foreign exchange earnings. This export goal for 1982 remained subject to continued production increases from secondary recovery operations, the improvement of pipeline transport from the northern jungle fields, and conservative increases in domestic consumption. Domestic consumption of petroleum continued to rise at a rate of about 2% per year and in 1981 reached 138,300 barrels per day.

Through legislation enacted in 1981, MINPECO lost its monopoly in the marketing of minerals. Henceforward, MINPECO only acts on behalf of the state-owned companies plus any private companies that request its services. The change in MINPECO's status had no major affect in 1981 since all of the 1981 production had been sold prior to the legislative action.

Preliminary figures on 1981 mineral exports through MINPECO are shown in table 3.

COMMODITY REVIEW

METALS

Copper.—The 11% downturn in 1981 copper production was primarily due to labor problems and other factors related to adverse weather. Table 5 shows the principal producers of copper ores and concentrates.

Labor problems beset SPCC at all three of its operations. The Toquepala Mine was closed 56 days owing to strike activity, the Cuajone Mine lost 49 days of production owing to work stoppages, and the Ilo smelter underwent 54 days of strike activity. Labor, fuel, and maintenance costs rose significantly during the year, while the average refined copper price during 1981 was almost 77 cents per pound compared with 96 cents in 1980. In 1981, SPCC net earnings fell $65 million below the $85 million reported for 1980.

During 1981, SPCC conducted studies on all economic, technical, and legal aspects of expanding production at its two mining and concentrator operations. As a result of these studies, the company decided to delay the projects until market conditions and the financial climate improved.

SPCC continued to use the marketing services of MINPECO on a joint basis. The company planned to use MINPECO services in 1982 while continuing to establish itself as both a producer and marketer of copper.

CENTROMÍN PERÚ's Cobriza Mine copper production decreased because of labor unrest and an 18-day work stoppage caused by fuel transportation problems. The expansion work on the mine, initiated in 1977, was almost complete by the end of 1981. The new concentrator, located at Pampa de Coris on the Mantaro River, was expected to be completed by mid-1982, followed by the completion of the mine expansion project in September. This $261 million project was designed to more than triple Cobriza's annual production capacity to 205,000 tons of concentrate containing 25.4% copper. In addition, about 6 ounces of silver per ton of concentrate would be obtained. Cobriza's proven ore reserves were determined to be about 30 million tons, averaging 2.16% copper and 0.55 ounce of silver per ton. This was considered sufficient for a 10-year mine life providing additional reserves are not identified.

MINERO PERÚ maintained a normal production level at its Cerro Verde I copper mine, located 24 kilometers southwest of Arequipa in southern Peru. The company began substituting sulfuric acid produced at its new Cajamarquilla zinc refinery instead of using imported acid for leaching purposes. In 1981, the Cerro Verde project produced about 33,300 tons of copper cathodes, plus 2,450 tons of concentrate, grading 47.5% copper, from the sulfides pilot plant.

The 60 million tons of Cerro Verde I copper oxide ore reserves are underlain by 1.2 billion tons of copper sulfide ore, which MINERO PERÚ has called Cerro Verde II. Negotiations with various companies during the past 4 years to develop the Cerro Verde II project were not successful. In 1981, MINERO PERÚ decided to develop the project through engineering consultants. Accordingly, in November, Kaiser Engineers International Inc. was selected to manage the first phase of construction and development of Cerro Verde II.

The Cerro Verde II project requires expanding the Cerro Verde I Mine, the construction of a concentrating plant to treat 20,000 tons per day of copper sulfide ore, and arrangements for tailings disposal. In addition, the project entails the construction or expansion of facilities for transporting concentrate to the Port of Matarani, additional port facilities, and increased water and electrical power supplies.

The cost of Cerro Verde II was estimated at $300 million. MINERO PERÚ was negotiating for loans from Japanese sources. Construction was to start in 1982 and reach completion by the second half of 1984. Meanwhile, MINERO PERÚ began limited preparatory work to develop the mine and to prepare locations for the platforms to stockpile mined ore, the water tank, and the crushing plant.

The labor problems at SPCC operations also affected the production of refined copper at MINERO PERÚ's Ilo refinery. The lack of SPCC blister copper from August 17 to October 3 and separate strike actions by the Ilo refinery workers from October 20 to November 5 reduced output 11%, from 141,630 tons in 1980 to 125,534 tons in 1981.

At CENTROMÍN PERÚ's refinery at La Oroya, total refined copper production fell by 8%. The decrease would have been more severe except for a substantial increase in copper cathode production. The metallurgical complex encountered fuel supply and transportation problems caused by heavy rains that resulted in flooding and landslides. In 1981, CENTROMÍN PERÚ invited engineering companies to submit prequali-

fication bids for modernizing the La Oroya copper circuit. In 1981, about 45% of the copper concentrates treated at La Oroya were purchased by CENTROMÍN PERÚ from small- and medium-size mines in the region.

During 1981, progress continued on various copper projects throughout the country. Kaiser and Consultores Minero Metalúrgicos S.A. completed a feasibility study on CENTROMÍN PERÚ's Toromocho polymetallic deposit. Proven ore reserves were 354 million tons, assaying 0.75% copper and 0.36 ounce of silver per ton, plus other byproducts such as molybdenum, tungsten, zinc, and bismuth. Additional reserves of lower grade leachable ore have also been identified. The Toromocho deposit is located in the Morococha district, 142 kilometers east of Lima, and has been considered one of the more important deposits in Peru. At full production, the planned concentrator would produce 61,000 tons of copper and more than 2 million troy ounces of silver per year. The required capital investment over a 4-year construction period was estimated at $707 million. Financing arrangements have not been announced.

CENTROMÍN PERÚ was also owner of Compañia Minera Los Montes S.A., created to develop the Monterrosas copper deposit located 20 kilometers northwest of Ica in southern Peru. By the end of 1981, construction work on the mine and concentrator was nearing completion, and the project was expected to go onstream in March 1982. Initial plant capacity was 750 tons per day, with expansion capability to 1,000 tons per day. Production was estimated at 16,000 tons of copper concentrate per year, containing 25% copper and 0.26 ounce of gold per ton of concentrate. A small volume of concentrate, averaging 53% molybdenum was also programed for recovery.

The cost of the Monterrosas project was estimated at $14.2 million. Financing was obtained from the Crocker National Bank, $5 million; Corporación Financiera de Desarrollo (COFIDE), $3.6 million; the Capital Fund, $1 million; and local sources. About 80% of the investment for Monterrosas was made in local currency.

Empresa Estatal Minera Asociada Tintaya S.A. (EMATINSA), owned by MINERO PERÚ (45%), CENTROMÍN PERÚ (45%), and COFIDE (10%), obtained a total of $215 million in loans from the Export Development Corp. of Canada and a group of international banks. Construction work had been initiated in 1980, and EMATINSA expected the project to be onstream in 1984. The Canadian firm Surveyer, Nenninger and Chenevert was awarded the management services contract for this project.

The other large copper development company, Empresa Minera Especial Asociada Antamina S.R.L., was dissolved by mutual agreement of the partners in December after failing to obtain financing. The company was jointly owned by MINERO PERÚ, 51%, and Geomin of Romania, 49%. Full ownership reverted to MINERO PERÚ, although Geomin was to be reimbursed for its contributions at their nominal value. The cancellation agreement gave Geomin the option to purchase, at market prices, up to 15% of concentrate production for 15 years, whenever production begins. The future development of the Antamina copper-zinc deposit was uncertain at yearend. MINERO PERÚ was expected to create another mixed company with foreign interests. First-stage costs were estimated at $326 million for a production of 10,000 tons of copper concentrates per day.

Table 5.—Peru: Principal producers of copper ores and concentrates

(Metric tons of copper)

Company	1979	1980	1981	Change, percent (1980-81)

rRevised.

Amax Exploration, Inc., decided to withdraw from the Pashpap copper-molybdenum project. The Government, however, was expected to promote the development of the 60 million tons of ore reserves, which average 0.8% copper and 0.053% molybdenum. The Pashpap reserves are located 380 kilometers north of Lima in Ancash Department.

Gold.—Almost 60% of Peru's gold production resulted from placer mining, largely centered in the southeastern part of the country. CENTROMÍN PERÚ produced 42,425 troy ounces of refined gold at its La Oroya metallurgical complex. This output easily establishes it as Peru's single largest gold producer, although a substantial quantity of the ore processed at La Oroya was purchased from other mining companies. Minas Ocoña S.A. was the largest private gold producer with a 1981 output of 11,253 troy ounces from its underground lode mine in the district of Andaray, Department of Arequipa.

Estimated recoverable gold production by source is shown, in troy ounces, in the following table:

	1980	1981	Change, percent
In ores and concentrates	4,983	9,517	+91
Refined and in blister	57,196	55,781	-3
In placer gravels	69,960	91,597	+31
Total	132,139	156,895	+19

Source: As reported by Banco Minero del Perú.

The Banco Minero purchased 104,747 ounces of gold in 1981. The bank sold about 1,100 troy ounces domestically, a 94% decrease from that sold in 1980. Gold exports, on the other hand, reached 175,858 troy ounces, a 172% increase over that of 1980. The average price for gold in 1981 was $460 per troy ounce, a 25% decrease from the average price in 1980.

Despite the price decline, there was continued foreign and domestic interest in developing gold deposits. Some former lode gold mines were scheduled to be reopened, and many new gold-exploration claims were filed. Among the larger foreign firms reported to be planning on opening offices in Peru were Anaconda Minerals Co.; Utah International, Inc.; and Consolidated Gold Fields.

The Arias Group reopened the Salpo Mine near Quiruvilca, Department of La Libertad. The mine capacity was 100 tons per day, but a water shortage limited ore treatment to 70 tons per day, averaging 200 to 250 ounces of silver and 1.8 to 2.5 ounces of gold per ton. Development continued on the Poderosa deposit owned by an Arias Group subsidiary, Cía. Minera Poderosa S.A. This underground mine in Pataz Province, La Libertad Department, was scheduled to open in 1982. About 115,000 tons of reserves averaging 0.32 ounce of gold per ton has been identified. Another Arias Group subsidiary, Unidad Minera, completed expansion of the Farallón Mine treatment plant from 80 to 180 tons per day. Farallón ore reserves were estimated at 250,000 tons, averaging 4.2% zinc, 3.5% lead, 0.76% copper, and 0.048 ounce of gold and 4.3 ounces of silver per ton.

Compañia Aurifera Utupara S.A. resumed exploration at Utupara, Antabamba Province, Apurimac Department. Abandoned in 1960 because of difficult access and the low price of gold, construction of the new Antabamba Road and higher market prices have enhanced the mine's economic viability. The company was proceeding with infrastructural development and additional exploration. Proven and probable reserves were placed at 80,000 tons, averaging 0.5 ounce of gold and 1.5 ounces of silver per ton. Inferred reserves were estimated at 300,000 tons. Production was expected to start in 1982.

The jungle area of southeastern Peru continued to attract both Peruvian and foreign investors. Access to the various placer mines has typically required travel by air, road, water, and trail. Mines are operated under arduous working conditions.

CENTROMÍN PERÚ had the largest placer operation with claims on two blocks of 15,000 hectares each. At the Bijahual claim on the Madre de Dios River, 80 kilometers west of Puerto Maldonado, 1 million cubic meters of auriferous material has been blocked out with an average grade of 0.011 ounce of gold per cubic meter. In December 1981, a pilot plant capable of treating 12 cubic meters of material per hour was installed at CENTROMÍN PERÚ's second claim, 110 kilometers west of Puerto Maldonado on the Inambari River, where 9.8 million cubic meters of auriferous gravels have been identified with an average gold content of 0.009 ounce of gold per cubic meter. Exploration to block out additional gold reserves was continuing.

Aurifera Sur Oriente S.A. (AUSORSA) had the most successful company operation in the Madre de Dios area. In 1981, the

company had active operations in 16 concessions totaling more than 15,000 hectares in the Huepetue and Pukibe region, Manú Province. In this region, between the Huepetue River and the junction of the Colorado and Madre de Dios Rivers, AUSORSA also controlled a group of companies owning concessions covering about 36,000 hectares, of which 24,000 hectares was under a development contract with Rio Holding Co. and Rio Tinto Finance and Exploration (RIOFINEX), both subsidiaries of Rio Tinto Zinc Corp. RIOFINEX had extensive exploration efforts underway.

AUSORSA installed portable pilot plants for use at the Tigre and Choque sites of their active Huepetue region concessions. The plants consisted of simple riffles and sluices, suitable for both the region and the relatively unskilled operators. They were designed to handle 500 cubic meters of material per 24-hour feed of the black sand in which the gold is disseminated. After the washing process, mercury was added to amalgamate the gold particles and remove residual sand. The gold-mercury amalgams were burnt by a blowtorch to oxidize the mercury, leaving rough clots of gold. The concentrated gold was sent to Lima to be smelted and formed into bars. In 1981, AUSORSA produced about 2,100 ounces of gold.

The Banco Minero had established offices in the Madre de Dios area at Puerto Maldonado, Colorado, Mazuko, Huaypetue, and Laberinto to purchase gold from thousands of individual miners. These miners mostly employed the mercury and blowtorch technique for recovering the gold. They worked along the riverbanks and sandbars because land-based operations require expensive exploration and machinery for mining. A blowtorch was again used by the bank prior to weighing for purchase. The Banco Minero based its purchasing price on a weekly average of international gold prices but deducted about $58 per ounce for various expenses involved in refining, assaying, and other operating costs.

At its San Antonio de Poto gold placer deposit, Department of Puno, MINERO PERÚ planned to group hundreds of independent gold panners into cooperatives to which the miners would pay royalties. Two royalty contracts were in the final phase of preparation with the Cooperativa Aurifera de Producción Santiago de Ananea, which would transfer about 80 hectares to the cooperative. Another contract with Cooperativa Minera Ancocala was in preparation. MINERO PERÚ has divided the San Antonio deposit into four work areas where private companies may initiate operations: Arequipa Pampa, Ancocala, Huachani, and Pampa Blanca. MINERO PERÚ had been operating on a small scale at Pampa Blanca. In midyear, a small gold-washing plant was installed with a capacity of producing between 2,700 and 4,200 ounces of gold per year. This washing plant, purported to be the largest operating in Peru, encountered some problems and was modified. However, by the end of the year, the plant had operated 122 days and produced less than 129 ounces of gold.

In the latter half of 1981, a new gold boom began on the Pacific coast, about 10 kilometers north of Chimbote in the delta area of the Santa River. These deposits had been quietly worked on a small scale since their discovery in 1978. Inevitably, the location became widely known, and by midyear, the region was inundated by over 1,000 gold panners, especially around Guadalupito Beach. By the end of the year, most miners were departing as the easily reached surface sands became well worked over. A more orderly mining plan was emerging as concessions were granted, limiting the haphazard or random pattern of gold-rush-style panning.

After a short preliminary examination by geologists, the Santa River delta was thought to contain concentrations of gold, titanium, zirconium, and platinum. Gold was reportedly found throughout the land area going eastward from the coastline for about 5 kilometers to the Pan-American Highway and for about 25 kilometers in a northern direction from the mouth of the river. The depth of the gold-bearing material had not been determined, and drilling programs were planned. In November, newspaper accounts of mining activity stated that individual miners were panning between 5 and 6 ounces of gold per week using elemental panning and sluicing devices.

Iron Ore.—The possibility of recovering cobalt, copper, and nickel from HIERRO PERÚ's San Nicolás plant tailings had been under study. This potential recovery program aroused some interest in mining circles, and HIERRO PERÚ installed an experimental pilot plant. The company planned, at first, to recover only the copper, retaining the tailings for possible later extraction of cobalt and nickel. In 1981, copper concentrate recovery from the pilot plant amounted to 1,467 tons, averaging 22%

copper, of which 1,404 tons was sold to CENTROMÍN PERÚ for $331,500. Further metallurgical studies were underway.

In 1981, the beneficiation plants at San Nicolás operated at 75% of capacity because of weak market demand. HIERRO PERÚ's 1980-81 production by category is shown in the following table, in thousand metric tons:

	1980	1981	Projected 1982
Pellets	1,564	1,504	1,890
Low-silica pellets	--	193	240
High-grade sinter feed	2,800	3,359	3,460
Pellet feed in slurry form	265	202	--
Pellet feed in cake form	1,076	811	810
Total	5,705	6,069	6,400

Beneficiated iron ore exports in 1981 amounted to 5.2 million tons valued at almost $94 million.[3] The Republic of Korea purchased the major portion, 43%, overtaking Japan, which dropped to second place with 37%, while Yugoslavia purchased 18%. Smaller amounts were shipped to the United States and Argentina. Peru did not export iron ore to Romania and Czechoslovakia in 1981.

A feasibility study was underway for the construction of a plant to produce enriched iron for export using anthracite instead of coke. At a cost of $400 million, the 800,000-ton-per-year plant would enrich Marcona iron ore from 65% to 95% iron content. The project, if viable, would stimulate Peru's coal industry. The primary sources of coal for the new plant would be from mines in the Santa Valley near Chimbote. Preliminary reports indicated the plant might be located near Acari, south of San Nicolás.

Iron and Steel.—Empresa Siderúrgica del Perú (SIDERPERÚ) had a troubled year in 1981. Contracts were signed in 1980 with West German, Austrian, and Spanish firms for the installation of facilities to modernize and expand steelmaking capacity from 440,000 to 720,000 tons per year at a cost of $300 million. The contracts had not gone into effect pending the signing of relevant financing contracts. Improvements included the installation of a coal-based direct-reduction plant, an electric arc furnace, a continuous slab casting plant, and a 50-megawatt thermal powerplant.

All expansion plans were postponed after a World Bank-sponsored study that revised SIDERPERÚ's earlier feasibility study. Instead, it was recommended that the company consider a 3-year rehabilitation plan involving the repair and replacement of equipment that had been deteriorating for several years. The recommendation was to first achieve full use of present capacity, and after the modernization has been completed, steel capacity could be expected to reach 520,000 tons per year. This scaled-down program was estimated to cost $130 million, of which $87 million would be fixed investment.

The modernization program included a reorganization of the company to make it more efficient managerially and technically. A decision whether to reactivate the original expansion plan or proceed with the more modest modernization program was expected early in 1982. SIDERPERÚ has never been profitable, and losses in 1981 were estimated at $26 million. Recent losses were blamed on competition from imported steel after import duties were reduced on construction steel from 41% to 5% in mid-1980. Domestic annual steel demand was projected to reach 700,000 tons by 1985, and without the major expansion program planned earlier, major steel imports would be needed.

In 1981, by Legislative Decree No. 216, SIDERPERÚ was converted into an autonomous state company, with all shares owned by the Government. COFIDE was to control financial matters.

Lead and Zinc.—CENTROMÍN PERÚ continued to be the primary producer of lead and zinc. Its mining units contributed 41% of total lead production and 43% of total zinc. In 1981, about 20% of the lead concentrate treated at La Oroya was purchased from small- and medium-size mines. In the private sector, some producers were affected by various labor and mechanical problems.

The substantial jump in Peru's refined zinc production signaled the March 1981 startup of MINERO PERÚ's Cajamarquilla zinc refinery. By August, plant deficiencies had been corrected, and the production rate was nearing its 102,000-ton-per-year capacity. The plant also produced an estimated 125 tons of metallic cadmium and 124,000 tons of sulfuric acid. Over 84,000 tons of the sulfuric acid was shipped to MINERO PERÚ's Cerro Verde copper mine for leaching purposes. Studies were continuing to determine the best process to extract silver and lead from the residues as additional byproducts.

The major lead and zinc producers are shown in table 6, with recoverable metallic output as estimated by the Peruvian Min-

ing Society.

Cía. Minera San Ignacio de Morococha continued as the largest zinc producer in the private sector. It operated the San Vincente Mine at San Ramón, approximately 400 kilometers west of Lima. An expansion program has been underway and was scheduled for completion late in 1982. Cía. Minera Atacocha S.A., Peru's second largest lead producer, conducted geological studies to accelerate exploration opportunities. At the end of 1981, ore reserves were estimated at 3.5 million tons averaging about 4% lead, 5% zinc, and 3.3 ounces of silver and 0.01 ounce of gold per ton. MINERO PERÚ's Antamina copper-zinc project has been discussed under the section on copper.

Volcán Compañia Minera, S.A., encountered mechanical problems in 1981 that delayed completion of the Carahuacra flotation plant expansion until mid-1982. Cía. Minera Huarón, S.A., one of the oldest mining companies in Peru, also encountered mechanical difficulties at the concentrator during 1981. In addition, Huarón had transportation and shipping problems. Huarón's mines are in the central district of Huayllay, Pasco Department. Mine expansion and new exploration have been underway to increase present mine ore reserves and to allow the company to expand to other areas. This geographic expansion of activities was the basis for Huarón's 1981 decision to become a 33.3% shareholder in Extracciones y Tratamiento de Minerales, S.A. (EXTRAMIN). The other partner in EXTRAMIN was the Société Minière et Metallurgique de Penarroya, a French company. EXTRAMIN planned to process 90,000 tons of ore per year from small miners. A 300-ton-per-day portable plant was purchased for installation next year at Catac, Recuay Province, Ancash Department. The plant was expected to yield about 10,000 tons of lead-zinc-copper-silver bulk concentrate annually.

Molybdenum.—SPCC was the sole producer of molybdenum in 1982. The two smaller producers, Compañia Minera Turmalina in northern Peru and Compañia Minera San Diego in the Department of Apurimac, southeast of Lima, ceased molybdenum production because of low prices and poor long-term expectations. Taminsa S.A. continued exploration work on its Aries molybdenum deposit in Huari, Ancash Department. Although the depressed world prices for this metal has slowed exploration to some extent, Taminsa planned to apply for a $3 million loan from the Banco Minero. Taminsa expected to continue its studies using diamond drilling.

Silver.—Most of the major silver producers increased their output during 1981. Production gains were offset by a continuation of silver's downward price spiral. During 1981, the price dropped from about $16.50 per troy ounce in January to about $8.50 per troy ounce in December.

In spite of some labor unrest and adverse weather conditions, CENTROMÍN PERÚ's La Oroya refinery produced about the same quantity of refined silver as in 1980. About 52% of the silver concentrate treated at La Oroya came from small- and medium-size private producers.

Table 7 shows estimated recoverable silver from Peru's principal producers. This

table was adapted from data provided by the Peruvian Mining Society and may not conform to information obtained elsewhere.

Cía. de Minas Buenaventura, S.A., experienced some labor and weather problems during 1981, but the company still managed to increase total silver production. Buenaventura's concentrate production also contained lead, zinc, copper, bismuth, cadmium, and gold. However, about 84% of the total value of its 1981 mineral production was attributed to silver. Buenaventura's expansion of the Uchucchacua mining unit, 120 kilometers northeast of Lima, was credited as the principal reason for the increased silver production. Buenaventura continued development work at its other three mining units. At the end of 1981, ownership of the Huachocolpa unit, Huancavelica Department, was transferred to Compañia de Minas Recuperada S.A., owned 99% by Buenaventura.

At Minas de Arcata S.A., owned 51% by the Hochschild Group, plant expansion from 450 to 600 tons per day was almost completed. Arcata's 3.8-megawatt hydroelectric powerplant was expected to go onstream in mid-1982. Total ore reserves at the end of 1981 amounted to 1.8 million tons, averaging 15 ounces of silver per ton. Another Hochschild-managed company, Cía. Minera Caylloma, S.A., operated the San Cristóbal silver mine in Arequipa Department. Cía. Minera Castrovirreyna, S.A., continued development and exploration work at its three silver mining units, San Genero, Astohuaracan, and El Palomo. All of the mines are located in the Province of Castrovirreyna, Department of Huancavelica.

After a favorable study was completed by its subsidiary Consultores Minero Metalúrgicos S.A., CENTROMÍN PERÚ announced it would separate the Andaychagua Mine from its San Cristóbal production unit and develop it as an independent mining unit. Andaychagua produced silver, lead, and zinc. It is located about 10 kilometers east of San Cristóbal and 170 kilometers east of Lima. The proposed expansion project was estimated to cost $42 million. By the end of 1981, a $14 million direct loan was approved by the Inter-American Development Bank, and additional loans were expected from other sources. Proved and probable reserves at Andaychagua were placed at 1.5 million tons, averaging 1% lead, 5.7% zinc, and 5.7 ounces of silver per ton. A 1,000-ton-per-day concentrator was planned that would produce 1.5 million ounces of silver per year contained in 5,200 tons of lead concentrate and 25,400 tons of zinc concentrate. The project was scheduled for completion in 1984.

[1]Less than 1/2 unit.

Tungsten.—Production of tungsten from CENTROMÍN PERÚ's Mahr Tunnel plant at the San Cristóbal Mine continued to plummet, dropping from highest producer in 1979 to third in 1981.

At the Pasto Bueno Mine of Fermin Malaga Santolalla e Hijos Negoc. Minera, an agressive exploration and expansion program continued. By the end of 1981, the company had blocked out over 1 million tons of ore reserves, averaging 0.44% WO_3. In addition, several new exploration claims were filed for tungsten and copper ores in Pallasca Province, Ancash Department. An expansion of the copper sulfide plant from 576 to 720 tons per year was also scheduled.

Minera Regina, S.A., mining the Palca XI deposit northeast of Juliaca, Department of Puno, planned to complete its mill expansion program by the end of 1982. When

completed, capacity was expected to reach 500 tons of concentrate, averaging 70% WO_3.

Sociedad Minera Puquio Cocha S.A. used a pilot plant to recover tungsten concentrate from 50 tons per day of tailings supplied by its copper flotation plant in central Peru. The company expected to bring a 500-ton-per-day processing plant onstream in 1982.

Tungsten production by company was as follows, in metric tons of WO_3 content:

	1979	1980	1981	Change, percent (1980-81)
Malaga Santolalla	192	296	358	+21
Minera Regina, S.A.	102	145	200	+38
CENTROMÍN PERÚ	403	209	130	-38
Small producers	58	50	50	--
Total	755	700	738	+5

NONMETALS

Phosphate.—The U.S. firm Jacobs Engineering Co. proceeded with a feasibility study on the development of the Bayóvar phosphate deposit near Piura in northern Peru. The study was undertaken for Empresa Promotora Bayóvar, owned by MINERO PERÚ (60%), COFIDE (20%), and Empresa Nacional de Comercialización de Insumos (10%).

Bayóvar reserves were estimated as equivalent to 550 million tons of phosphate concentrate containing 30.5% phosphorus pentoxide and 450 million tons of brine containing 1% potassium chloride and 22% sodium chloride.

At MINERO PERÚ's Bayóvar beneficiation plant, capacity was increased to 36,000 tons per year. In 1981, actual concentrate production was about one-third of the new capacity. About 86% of production was exported to New Zealand, where it reportedly performed better than industrial superphosphates in the acid soil. New Zealand found that the Bayóvar concentrate could be used directly as a fertilizer without further treatment. In view of this finding, New Zealand has expressed an interest in participating in investments to expand present production.

MINERAL FUELS

Coal.—In 1981, the Government created a national coal company, Empresa Promotora del Carbón S.A. (PROCARBON), to promote the development and use of Peru's coal resources. PROCARBON is equally owned by four state agencies, CENTROMÍN PERÚ, MINERO PERÚ, COFIDE, and Electricidad del Peru (ELECTROPERÚ). The new company had applied for a $5 million loan from the Inter-American Development Bank. Most of the loan money was to be used for additional exploration at CENTROMÍN PERÚ's Jatunhuasi prospect, with the balance for other coal-exploration studies.

CENTROMÍN PERÚ's Jatunhuasi coal-exploration efforts have increased estimated reserves. About 300,000 tons of semibituminous coking coal has been identified. Potential reserves were still estimated at 10 to 12 million tons, averaging 30% volatile matter, 52% fixed carbon, 20% ash, and 3% sulfur. Calorific value was calculated at 11,000 British thermal units per pound. This deposit has been targeted as a priority project by PROCARBON.

The future development of MINERO PERÚ's Alto Chicama coal project remained uncertain. Financing was not obtained in 1981. Samples were gathered for combustion tests required by ELECTROPERÚ. Both ELECTROPERÚ and MINERO PERÚ planned extended feasibility studies.

The Instituto Geologico Minero y Metalúrgico was in the final phase of completing an inventory of Peru's coal resources.

Petroleum and Natural Gas.—In March 1981, Peru signed the first oil-exploration contract with a foreign company since the Belco Petroleum Corp. contract in 1973. Following lengthy negotiations, Superior Oil Co. and Petrolera General S.A., a subsidiary of Phoenix Canada Oil Co., Ltd., were awarded a 1-million-hectare concession in Block 2 in the northeastern jungle region. Block 2 is located immediately south of productive Block 1A of Occidental and east of the Santiago River. The Block 2 dimensions were altered somewhat so that an area previously explored by Petróleos del Perú (PETROPERÚ) was still reserved exclusively for its possible future exploitation. Superior holds a 90% interest in the venture, and Phoenix Canada Oil, 10%. The contract was similar to PETROPERÚ's renegotiated contract with Occidental. Superior planned a $20 million investment during the next 2 years, including the drilling of at least two wells. The first Superior Block 2 exploration well was spudded in November in the Maranon River basin.

The long-awaited final contract between PETROPERÚ and Royal Dutch/Shell was

signed in July 1981. Shell was committed to spend at least $100 million over the next 4 years in a two-stage exploration program in the southeastern jungle region. The allotted area included Lots 38 and 42, totaling 20,000 square kilometers at the southwestern corner of Loreto Department. At the end of 1981, Shell was involved in seismic exploration and was not expected to drill until 1982 or 1983.

PETROPERÚ and Belco Petroleum Corp. signed a draft agreement to explore an area off the northwestern coast. A formal contract was expected early in 1982. The new area, Block Z28, includes 3,995 square kilometers and lies immediately to the west of Belco's existing acreage in Blocks Z1 and Z2.

PETROPERÚ announced that in 1981 new discoveries had increased proven oil reserves to 840 million barrels, of which 57% was in the northeastern and central jungle areas, 30% in the northwestern coastal fields, and 13% was in Belco's Continental Shelf area. These reserves were not thought to be sufficient to ward off the prospect of Peru's becoming an importer of crude oil within the next 5 years. This prospective dependency on oil imports was the overriding basis for Peru's renewed efforts to attract foreign and national investment for oil exploration.

PETROPERÚ announced the wildcat discovery of a new field, the San Juan, in Block 8 in the northeastern jungle. This followed the late 1980 discovery of the Nueva Esperanza Field. The Nueva Esperanza well tested about 7,680 barrels per day of 45° API gravity crude oil at a depth of 10,270 feet. PETROPERÚ estimated that this field could have 20 million barrels of reserves and produce 10,000 barrels of oil per day. The San Juan well had a poor initial flow, but a confirmation well was planned for 1982.

Occidental also announced oil discoveries from two structures in the northern jungle. The more important of these was the Ceci, near the Corrientes River and close to the boundary between Blocks 1A and 1B. The Ceci No. 1 flowed 44° and 42° API gravity crude oil from two zones at a combined rate of 1,700 barrels per day from a depth of about 11,600 feet. The site is less than 8 miles from Occidental's nearest producing field. Potential reserves were not estimated pending delineation of the field. The second discovery was the Jivarito No. 1, drilled south of the Shiviyacu Field in Block 1B. The well tested at 1,200 barrels per day of 14° API gravity crude oil from a depth of about 9,600 feet. Occidental planned to drill again 6 miles south of the Jivarito discovery and to conduct additional seismic surveys.

Crude oil production failed to meet expectations in 1981. This was attributed to less-than-anticipated progress from secondary recovery projects on the northwestern coast and to oil transport problems from jungle operations. The inadequate pipeline network from the northern jungle fields inhibited production from that area. PETROPERÚ planned to initiate construction of necessary feeder lines in the near future.

The largest share of natural gas production, 36%, came from Belco's offshore operations, followed by PETROPERÚ from its northwest coastal fields.

Uranium.—No contracts for uranium exploration were issued by the Instituto Peruano de Energía Nuclear (IPEN) during 1981. Decree Law 23112, of July 9, 1980, authorized IPEN to enter into agreements with national and foreign companies for the purpose of uranium exploration and exploitation. A number of foreign companies have applied, and IPEN was expected to announce its decision in 1982. Meanwhile, the Government has reserved for itself about 400,000 hectares around Macusani and Carabaya in the Department of Puno. IPEN had initiated prospecting work in the area.

The Mineral Industry of the Philippines

By John C. Wu[1]

In 1981, the Philippines economy grew at a slower pace than in 1980. According to the Philippines National Economic Development Authority, the development target of real growth in gross national product (GNP) in 1981 was 6.5% under the 5-year Philippines development plan (1978-82). However, the real growth in the Philippines GNP in 1981 was 4.9% compared with 5.4% (revised) in 1980, and ranked fifth among the five members of the Association of Southeast Asian Nations. The Philippines GNP in 1972 constant dollars was $12.9 billion in 1981 compared with $12.3 billion in 1980.[2]

The slower growth in the Philippines economy in 1981 was caused by weakened exports, depreciated currency, mounting foreign debts, and a deteriorated balance-of-payments deficit. In 1981, despite increases in exports of coconut products and nontraditional manufactures, exports of sugar, timber, and minerals decreased because of the cutback in imports by the Philippines major trade partners—the United States and Japan. As a result, the Philippines export earnings dropped 4.3% from $4.7 billion in 1980 to $4.5 billion in 1981, while the import bills rose 9.5% from $6.38 billion in 1980 to $6.99 billion mainly because of the higher oil import bills. The Philippines external debts increased 24.7% from $12.7 billion in 1980 to $15.84 billion in 1981, while the overall balance-of-payments deficit was $560 million in 1981 compared with $381 million in 1980. However, the rate of inflation, as measured by the consumer price index, dropped to 12.5% in 1981 from 17.8% in 1980.[3]

In 1981, the mining and quarrying sector had the lowest growth rate of the major sectors in the Philippines gross domestic product (GDP). By sector, the growth rates during 1980-81 were as follows, in percent:

Sector	Growth rates	
	1980	1981
Agriculture, fishery, forestry	4.9	4.3
Mining and quarrying	4.8	1.7
Manufacturing	5.9	5.1
Construction	9.7	5.8
Electricity, gas, water	8.5	7.8
Transportation, communication, storage	4.6	4.1
Commerce	5.5	5.0
Services	5.5	4.8

The sluggish performance of the Philippines mining and quarrying industry was a result of the general downswing in metal prices caused by deepening of the worldwide economic recession and the slow growth in advanced industrial nations that cut their import demand for the Philippines mineral commodities. However, the mining industry continued to be an important sector of the Philippines economy. Its value contributed about 2.8% to the country's GDP in 1981.[4]

In 1981, the Philippines remained among the top 10 world producers of cobalt, copper, and gold. Other important metallic minerals produced by the Philippines included chromium, nickel, and silver. According to the Philippines Ministry of Natural Resources, the future development of nontraditional mineral products (nonmetallics), such as dolomite and silica, will become important in the Philippines mining sector. Under the 5-year development plan, the nonmetallic sector is to contribute at least 25% of the total mineral output value.[5]

Of the five industrial projects related to the mining sector, all except the aluminum smelter project were moving smoothly during 1981. The $373.2 million copper smelter project was proceeding smoothly and was scheduled for completion in April 1983. The $1.5 billion integrated steel mill project was

scaled down to $765 million. Instead of setting up a new steel mill complex, the Government of the Philippines has decided to modernize and expand the existing facilities of the National Steel Corp. in Iligan City on Mindanao Island. Bids on the iron-making plant have been received by the Philippines from four consortia. The rationalization and expansion of the cement industry was also proceeding on schedule. Polysius Ltd., a British subsidiary of Krupp Polysius AG Beckum of the Federal Republic of Germany, has received an order from the Philippines Cement Industry Authority to deliver nine coal-grinding plants valued at about $38.3 million. The Philippines first phosphatic fertilizer facility was moving toward actual construction work. A consortium led by Coppee-Rust of Belgium has won the contract. The plant was scheduled to come onstream in 1985, and was expected to reach full capacity in 1987. The aluminum smelter project, however, never got off the ground in 1981 because of the disagreement over pricing of the hydroelectric power between the Philippines and Reynolds Metals Aluminum Co. of the United States.

In November 1981, the Philippines Bureau of Mines and Geosciences reported that substantial heavy mineral deposits were discovered in many beach and offshore areas after aeromagnetic surveys, regional gravity surveys, sea-bottom samplings, and multispectral photography were made and studied. The important findings are as follows: (1) Heavy concentrations of detrital magnetite, chromite, gold, and ilmenite were found along the coastlines of Bascarra-Paoay, San Ildefonso-Vigau, Bauang-Santo Tomas, Carlatan-Bacnotan, and San Fabian-Dagupan; (2) placer gold deposits were discovered along the Jose Panganiban-Paracale coastline of the Bicol region; (3) silica sand deposits were found along the northern coast of Rapu-Rapu Island in the Visayas; (4) concentrations of magnetite were discovered in the Tanauan-Abuyig and Barugo-Capoocan coastal area of northern Leyte and in the San Jose-Pawig coastline of northeastern Leyte.[6]

In December 1981, the President of the Philippines ordered the establishment of a special stabilization fund to assist mining companies during periods of depressed metal prices in world markets. A $625 million industrial fund was being set aside for the exclusive use of the distressed mining industry during the 1981-83 period. About $187.5 million was to be released annually starting in 1981. Based on the proposed mechanism of disbursement, a mining company can withdraw funds whenever the prices of its mineral products fall below the trigger level. The withdrawn funds are to be repaid when prices rise.[7]

The Government of the Philippines, in an effort to encourage mineral development, announced that mining companies with large and/or newly discovered ore reserves will also be granted tax exemption. Section 53 of Presidential Decree No. 463, Executive Order No. 660, which was announced on March 4, 1980, entitled mining companies that are expanding their operations to tax exemption. The tax exemption privileges granted to new and old mines under Section 53 of Presidential Decree 463 included customs duties on imported equipment and royalties. The tax exemption privilege would be limited to 2 years from the first day of operation.[8]

The first nuclear powerplant in the Philippines resumed construction on September 15, 1980, after construction was halted for redesigning to meet additional safety requirements. The construction work was proceeding smoothly in Bagac (Borong), Bataan, about 80 kilometers west of Manila. Because of the additional safety equipment, the total cost of the project was estimated at $1.9 billion, about $800 million more than the original cost estimate. The 620-megawatt nuclear powerplant was expected to be completed by December 1983 or January 1984. Australia is reportedly expected to supply about 840 tons of U_3O_8 for the fuel requirements of the nuclear powerplant between 1985 and 1990.

PRODUCTION

The Philippines total mineral production for the first 9 months in 1981 dropped 7.8% to $1,127 million from that of the same period in 1980 as a result of the general downswing in metal prices. The output of all metallic minerals except gold and zinc declined for the first 9 months in 1981 from that of the same period in 1980.

Despite a significant drop in the output value of copper, the copper industry remained the most important sector of the Philippines mining industry. Copper pro-

ducers contributed not only copper (about 30% of the total mineral production value), but also a very significant amount of gold as a byproduct to the country's total mineral output value. Because of the lower prices and weakened demand for metals, the mine production of chromium, cobalt, copper, nickel, manganese, lead, and molybdenum were all at lower levels in 1981 than in 1980. However, mine production of gold increased significantly because of mining expansions by Benguet Corp., Atlas Consolidated Mining and Development Corp., and Apex Mining Co., Inc.

In the mineral fuels sector, the output of coal jumped by 15% in 1981 from that of 1980. It is expected that coal output will continue to increase in 1982 with the expansion of mining operations by Semirara Coal Corp. and Coalfields Mining and Industrial Corp. The Philippines crude oil production from Nido Oilfield continued to decline during 1981. However, the country's second oilfield, Cadlao, operated by Amoco Philippines Petroleum Co., started commercial operation in September 1981. By yearend, the output of two wells at Cadlao Oilfield was about 9,000 barrels per day. The third oilfield, Matinloc, operated by Cities Service Inc., is expected to start its commercial operation with an initial rate of 12,000 barrels per day in June or July 1982.

Table 1.—Philippines: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity[2]	1977	1978	1979	1980[p]	1981[e]
METALS					
Chromium: Chromite, gross weight:

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through July 9, 1982.

[2]In addition to the commodities listed, the Philippines produces platinum-group metals as byproducts of other metals, but output is not reported quantitatively and no basis is available to make reliable estimates of output levels.

[3]Reported figure.

[4]Includes "pebbles" and "soil," not further described.

[5]Excludes limestone for road construction, reported in cubic meters, which totaled 9,687 cubic meters in 1978 and 2,932 cubic meters in 1979 (other years not available).

[6]Includes materials described as: rock, crushed or broken; stones, cobbles, and boulders; rock aggregates; and broken adobe.

TRADE

In 1981, the Philippines total export earnings were estimated at $4.45 billion, a 4.3% drop from $4.65 billion registered in 1980, because of the lower world market prices of the country's export commodities. The total imports were estimated at almost $7 billion, a 9.5% jump from $6.38 billion, mainly owing to higher oil import prices. As a result, the Philippines trade deficit was pushed up by 46.2% from $1.73 billion in 1980 to $2.53 billion in 1981.

According to the latest report of the Philippines Central Bank, during the first 10 months of 1981 total mineral exports declined 25% to $756.75 million from the same period of 1980. For the same period, export earnings of copper declined 21% to $463.07 million, gold declined 31% to $135.11 million, nickel declined 32% to $90.46 million, and other metals declined 29% to $68.11 million. Among the top export-earning commodities, copper and nickel ranked third and sixth, respectively, in 1981. Other major export commodities were sugar, crude coconut oil, garments, electrical equipment (integrated circuits),

bananas, lumber, and wood products. The Philippines principal imports in 1981 were mineral fuels, nonelectrical machinery, transport equipment, base metals, electrical machinery, and appliances.

During 1981, the principal exporting partners of the Philippines were Japan, the United States, the Netherlands, the Federal Republic of Germany, and the Republic of Korea. The principal importing partners were Japan, the United States, Saudi Arabia, Kuwait, and the Federal Republic of Germany.

COMMODITY REVIEW

METALS

Aluminum.—In 1981, the proposed $773 million aluminum smelter did not get off the ground. Despite the assurance of Reynolds Aluminum Co. of the United States to finance and build the smelter, National Development Co., the investment arm of the Philippines Government, was reportedly discussing with Biliton International of the Royal Dutch/Shell Group the possibility of Biliton's partnership in the project. Because

of the cutback in new aluminum projects worldwide, caused by the reduced world demand for aluminum, both Reynolds and Biliton have not done anything other than express interest in the project.[9]

Exploration work of the bauxite deposits on Samar Island was not going well because of the deteriorated civil conditions in areas of Gandara, Matuginao, and San Jose de Bauan. However, the survey of the bauxite deposits in areas of Salcedo, Mercedes, Guian, and Concord, as well as on Batag Island, was completed by the Philippines Bureau of Mines and Geosciences in 1981. Based on the survey, the bauxite deposits in these areas were estimated at 120 million tons.

Chromium.—Mine production of both refractory and metallurgical chromite ores declined in 1981. Consolidated Mines, Inc. (the property owner), under an operating contract with Benguet Corp. (the operator), remained the single most important producer of refractory chromite ore in the Philippines, accounting for over 95% of the total refractory chromite output. In 1981, other major refractory chromite ore producers were Capital Mineral Resources and Development Co., Inc.; Pulsar Mineral Resources, Inc.; and Philchrome Mining Corp. Production of metallurgical chromite ore and concentrate was by Acoje Mining Co.; Trident Mining and Industrial Corp., which produced both ore and concentrate; and by more than eight other small ore producers led by Velore Mining Corp. and Malayan Wood Products Corp.

Consolidated Mines, Inc. (CMI), produced about 340,000 tons per year of refractory chromite concentrate from its chromite property at Coto, Masinloc, in Zambales Province under an operating contract with Benguet Corp. Under the old contract, which expired in December 1980, CMI retained 75% of the output as the property owner, while Benguet shared the remaining 25% as the mine operator.

In early 1981, a new operating contract was signed between the two companies. CMI reportedly agreed to cut its output share from 75% to only 30%, while Benguet was to retain 70%. Under the new 25-year contract, Benguet agreed to invest about $10 million to open up new reserves for a new underground chromite mining and milling operation to augment production from the existing but dwindling chromite reserves available for open pit mining. Under the new contract, the mine would expand its production capacity in 3 to 4 years. The Masinloc refractory chromite mine is the single largest and the most important source of low-silica refractory chromite in the world. In 1980, about 340,000 tons of refractory chromite concentrates were produced from the mine, of which 275,000 tons were exported mainly to the United States, Japan, and Canada.[10]

Philchrome Mining Corp., a new chromite producer, began commercial operation from its large chrome sand deposits in the southern part of Palawan Island. AMAX Inc. of the United States and Kawasaki Steel Corp. of Japan were reportedly to acquire 15% interest each in Philchrome Mining Corp. The planned output capacity was to reach 20,000 tons per year of refractory chromite for export to the United States and Japan.

Triden Mining and Industrial Corp., the second largest metallurgical chromite concentrate producer in the Philippines, completed its expansion program in early 1981, and planned to install additional equipment in two mills in Palawan to increase chromium metal recovery. The company operated two chromite concentration plants at Narra, Palawan, with an annual capacity of 96,000 tons of chromite concentrates containing about 53% chromium. Most of the output was exported under long-term contracts to Japan (imported by Mitsui and Co., Ltd.), the Federal Republic of Germany (by A. G. Metallgesellschaft), and other European countries. China was, reportedly, also an important buyer of the company's chromite concentrate.

Cobalt.—The Philippines remained one of the top six world cobalt producers in 1981; however, cobalt production of Marinduque Mining and Industrial Corp. (MMIC) declined in 1981. The reduction in cobalt output in the form of nickel-cobalt mixed sulfide was affected largely by a cutback in the output of nickel concentrate and refining operations on Nonoc Island owing to the weakened nickel prices in the world market.

For the past year, Marinduque's nickel-cobalt sulfide was shipped to Sumitomo Metal Mining Co. of Japan for refining under a long-term tolling contract. In late 1981, MMIC was reportedly negotiating with Sumitomo to amend the tolling contract, which would not expire for several years. MMIC was planning to build its own cobalt refinery, which could be completed in 1 to 2 years; however, MMIC suffered losses

of $36 million in 1980 and about $85 million in 1981 under a heavy interest repayment burden largely because of the $331 million debt financing on the Surigao nickel refinery on Nonoc Island.[11]

Copper.—The Philippines remained the world's ninth largest copper producer during the 1980-81 period. In 1980, the Philippines production of copper metal surpassed the 300,000-ton level. In 1981, because of a substantial drop in the world copper prices and increased costs of production, 7 of the 12 primary copper producers reported a decrease in output. As a result, the Philippines copper production dropped by about 5%, and total value of the copper production shrank 18% to $356 million for the first 9 months of 1981 from $435 million for the same period of 1980.

The Philippines copper production of the top 10 primary producers, during the 1980-81 period, was as follows, in thousand tons of copper metal:[12]

Company	1980	9 months	
		1980	1981
Atlas Consolidated Mining and Development Corp.	126.0	100.2	106.2
Marcopper Mining and Industrial Corp.	34.5	26.1	27.8
Benguet Corp	25.2	18.9	21.0
Marinduque Mining and Industrial Corp.	19.5	14.2	19.1
Philex Mining Corp	22.1	16.1	17.1
Lepanto Consolidated Mining Co.	15.2	12.2	11.3
CDCP Mining Corp	20.4	14.9	8.1
Western Minolco Corp	13.9	11.4	7.8
Baguio Gold Mining Co	6.1	4.6	3.9
Acoje Mining Co	3.1	2.9	1.9
Other primary and secondary producers.	19.7	17.1	2.3
Total	305.7	238.6	226.5

Other primary copper producers that reported a substantial drop in copper output were Black Mountain, Inc., and Sabena Mining Corp. In May 1981, Sabena temporarily suspended operations at its Camanlangan copper mine in New Bataan, Darao del Norte, because of lower copper prices. Two secondary producers, Zambales Base Metal, Inc., and Benguet Exploration, Inc., also reported a decline in their copper output in 1981.

In 1981, two expansion projects were completed. CDCP Mining Corp. (CDCP) has expanded its milling capacity from 15,000 to 25,000 tons of ore per day at Basay in Negros Oriental. Marinduque Mining and Industrial Corp. also completed its expansion program at Sipalay in Negros Occidental to increase milling capacity from 18,000 to 30,000 tons of ore per day. Under a joint exploration agreement, Marubeni Corp. of Japan was to invest $12.6 million in CDCP to increase its equity holding from 10.84% to 35.29%. This new capital was to be used mainly for the expansion program at Basay and underground development work. As of January 1, 1981, CDCP copper reserves at Basay were estimated at 240.7 million tons, averaging about 0.4% copper.[13]

In 1981, the Bully Bueno Mine, a new copper mine operated by Hercules Minerals and Oils, Inc., at Cacapain, Marcos, Ilocos Norte, started commercial operations. The annual output was expected to exceed 30,000 tons of 24% copper concentrate. The mine made its first shipment of copper concentrate to Japan in November. Ore reserves in the area were estimated at 13.5 million tons averaging 0.82% copper, 0.5 gram of gold, and 7.382 grams of silver per ton of ore. The mine life is expected to be 12 years at the projected milling capacity of 3,000 tons of ore per day.

The Amacan project of North Davao Mining Corp. in Masara, North Davao, was previously scheduled to start copper production in July 1981. Because of a flash flood that killed 127 people (construction crew), commercial operation was rescheduled to begin in April 1982. The milling capacity at Amacan would be 25,000 tons per day or 140,000 tons per year of 25% copper concentrate, which contains 8 to 15 grams of gold and 70 to 140 grams of silver per ton of concentrate. Ore reserves at the Amacan area were estimated at 87 million tons averaging 0.4% copper.

During 1981, several copper projects were either suspended or shelved, mostly because of the depressed world copper market. Sabena Mining Corp. suspended copper operations as well as its expansion plan at New Bataan. Marcopper suspended its San Antonio copper project near Tapian. Benguet shelved its Batangas project because of low-grade ore deposits and the high cost of land acquisition. Acoje Mining Co. closed its Barlo copper mines in Dasol, Pangasinan, at the end of 1981. The Barlo flotation mill was reportedly being sold by Acoje because of the depressed copper prices, which made it impossible to continue the commercial operations of the remaining low-grade deposits.

In late 1981, Atlas announced that it was

expanding its Lutopan underground mine at Toledo in Cebu. The $50 million expansion project would increase the output of the existing underground mine from 25,000 to 32,000 tons of ore per day by July 1984. The $50 million capital was to be financed from both external sources as well as internally generated funds.

Gold.—Despite the low price of gold in the world markets, the Philippines gold production increased in 1981. Increased gold production was largely due to extra alluvial mining operations of Atlas in Aroroy on Masbate Island, and the expanded gold mining and milling capacity of Apex in Masara, Davao del Norte. In 1981, the Philippines remained 1 of the top 10 world gold producers. Its share in the world total gold production was about 2% in 1980-81.

The Philippines gold output rose by 14.5% for the first 9 months of 1981 compared with output of the same period of 1980. Of the total output, 35% was by 7 primary gold producers and 65% was by 12 copper producers, which recovered gold as a byproduct of their copper operations. According to the Philippines Chamber of Mines, the Philippines gold production of the top 10 producers during the 1980-81 period, was as follows, in thousand troy ounces:

Company	1980	9 months	
		1980	1981
Benguet Corp. (primary and byproduct).	183.0	138.0	153.1
Atlas Consolidated Mining and Development Corp. (primary and byproduct).	150.3	110.9	145.3
Philex Mining Corp. (byproduct).	116.5	86.1	91.5
Lepanto Consolidated Mining Co. (byproduct).	58.2	46.3	46.5
Marcopper Mining Corp. (byproduct).	26.0	18.9	23.4
Apex Mining Co. Inc. (primary).	24.8	16.2	28.6
Western Minolco Corp. (byproduct).	23.4	18.9	14.6
Benguet Exploration, Inc. (primary).	11.9	8.6	8.9
Baguio Gold Mining Co. (byproduct).	11.7	8.9	7.6
Itogon-Suyoc Mines, Inc	8.9	6.5	8.0
Other primary and byproduct producers.	32.7	29.5	32.1
Total	647.4	488.8	559.6

Other gold producers were Vulcan Industrial & Mining Corp. (primary), Manila Mining Corp. (primary), Sabena Mining Corp. (byproduct, suspended operation in May 1981), Consolidated Mines, Inc. (byproduct, suspended operation in August 1980), Marinduque Mining and Industrial Corp. (byproduct), CDCP (byproduct), and Black Mountain, Inc. (byproduct).

The $29 million gold project of Philippines Eagle Mines, Inc., originally scheduled to come onstream in early 1981, was still building the processing plant at the mine site in Longos, Paracale, Camarines Norte. The plant is expected to be completed in 1982. The plant was expected to produce 44,000 ounces of gold and about 35,000 ounces of silver as a byproduct. Ore reserves were estimated at 1.56 million tons, with ore grade ranging from 0.45 to 0.55 ounce of gold per ton of ore.

In late 1981, Baguio Gold Mining Co. closed down its Santo Nino Mine in Mountain Province because of financial problems and withdrawal of Philex Mining Corp. as the company manager of the Santo Nino gold project. The project suffered from high operating costs caused by rising costs of energy and capital expenditures as well as high government royalty taxes.[14]

Iron and Steel.—San Pio Guinto Mining Corp., the only mining company engaged in the production of lump iron ore in the Philippines, produced only 4,376 tons of iron ore during the first half of 1981. The mining of magnetite sand was still restricted by the Government in 1981. Most of the Philippines iron ore requirements were imported from Australia, Brazil, and Canada.

A $7.5 million modernization project of Armco-Marsteel Alloy Corp. at its Taguig steelworks (annual capacity 70,000 tons) was started in late 1981. The project involved installation of high-technology continuous bloom-casting equipment and other support facilities. The equipment will be supplied by Concast AG of Switzerland. The project was scheduled for completion by the end of 1982. The company is a joint venture of Armco, Inc., of the United States; and Marsteel Consolidated and the Philex Mining Corp. of the Philippines. The major products of the company included specialty steel grinding balls and rods used by the domestic mining and cement industries and galvanized metal pipes consumed by the construction industry.

The plan for the development of an integrated steel mill in Misamis Oriental on Mindanao island was revised several times because of difficulties in finding the necessary financing for the project. In late 1981, the Government of the Philippines decided

to expand the existing facilities of the National Steel Corp. in Iligan City, Mindanao, in three phases. The latest proposal for the first phase called for building of a coal-based, direct-reduction, ironmaking plant; the second phase called for a steelmaking plant; and the third phase called for a rolling mill. The total cost of the project was scaled down from $1.5 billion to $765 million. Vöest Alpine AG of Austria, Kawasaki Heavy Industries of Japan with Krupp of the Federal Republic of Germany, and Davy McKee Direct Reduction Co. of the United States were reportedly the three bidders for the first phase.[15]

Nickel.—The mine output of nickel declined in 1981 because of the sluggish demand for nickel in the world market. The nickel output of MMIC dropped to 16,423 tons of refined nickel for the first 9 months of 1981 from 16,725 tons for the same period of 1980. In addition, production of mixed sulfides containing about 2,000 tons of nickel and slightly over 1,000 tons of cobalt for the first 9 months of 1980 also declined to almost 1,750 tons of nickel and nearly 825 tons of cobalt for the same period of 1981.

MMIC, in an effort to reduce operating costs, was converting from oil to coal for its nickel-refining operations on Nonoc Island in Surigao del Norte. The $123 million conversion project will reduce oil consumption of the refinery by 75% or save annually up to $50 million in energy cost upon completion of the conversion in late 1982 or early 1983.

In 1981, Rio Tuba Nickel Mining Corp., the other nickel producer in the Philippines, also reported a decline in its ore production at Bataraza in Palawan Island. Most of its nickel ore was exported to Japan.

Other Metals.—In 1981, production of manganese, lead, and molybdenum in the Philippines was at a much lower level than in 1980. MMIC and Black Mountain were the only two molybdenum producers, with MMIC accounting for over 80% of the total output. Production of lead was by Zambales Base Metals, Inc. In 1981, a new secondary lead smelter and refinery was being built in Meycawayan, Luzon. The 13,000-ton-per-year capacity lead smelter owned by the Philippines Lead Smelter Corp. was scheduled for operation in 1983. The output of unwashed manganese ore was mainly by the Associated Mining Corp. Zinc production in 1981 increased slightly from that of 1980, with Zambales Base accounting for 57% of the total, while Benguet Exploration, Inc., accounted for 43%.

Maria Cristina Chemical Corp. (MCCI), a ferroalloy producer in the Philippines, reportedly sold part of its equity holding in a new silicochromium plant at Iligan City to Nippon Kokan Kabushiki Kaisha (NKK) of Japan. In exchange, NKK was to receive about 10,000 tons of silicochromium (the total plant output) from MCCI annually. Silicochromium was shipped to the Toyama plant of NKK for processing into low-carbon chromium.

NONMETALS

Barite.—Mine Production of barite was by Falcon Minerals, Inc., the Philippines only producer of barite. The company operated its mine and milling plant in Mansalay, Oriental Mindoro. Mine output of barite declined in 1981, however, the production of barite for drilling fluid (oil well drilling mud) was being maintained at the 500-ton-per-month level. In 1980, Falcon Minerals obtained an $825,000 loan from the Private Development Corp. of the Philippines to finance the expansion program in Mansalay from 10,000 to 15,000 tons per year capacity. It is expected that production of commercial grades of varying mesh sizes and color will increase substantially for use by local paint, brake, explosive, and fiberglass industries in the coming years.

The barite ore reserves, as of December 1979, were estimated at almost 104,500 tons plus slightly over 31,000 tons of probable ore reserves.[16]

Cement.—In 1981, the Philippines cement industry consisted of 18 cement plants with 31 kilns. Although the country's total annual output capacity was 7.2 million tons, the actual cement production was about 4.2 million tons. High energy cost, outmoded equipment, and inefficient plant size were cited by the industry sources as the reasons for this low-capacity utilization. The Philippines consumed about 3.6 million tons of cement and exported about 800,000 tons to neighboring Southeast Asian countries annually.

According to the Philippines cement industry sources, the fuel cost alone accounted for 75% of the total production cost. In an effort to cut the fuel cost, the Government of the Philippines had created the National Coal Authority (NCA) to manage the so-called coal logistic system to supply

the fuel (coal) needs of cement plants as well as mines in shifting from bunker oil to coal-power generation.

The coal logistic system would include distribution of domestically produced coal through mine out-loading ports, vessels for efficient maritime movement and transportation of coal, installation of infrastructures that includes receiving, blending, and distribution terminals—six coal depots, importation of coal to be upgraded and supplement the domestic coal supply and inland transport to the end users by truck or rail. The total cost of this coal logistic system was estimated by NCA at $122 million, which includes $45 million for establishing 8 coal terminals, $8 million for 5 coal mine outloading ports, and $68 million for 12 marine vessels. The Philippines National Oil Co., (PNOC), reportedly will finance part of the cost, while NCA probably would approach the World Bank (International Bank for Reconstruction and Development) to finance the project. The whole project was expected to be completed by 1984 or 1985.

In late 1981, the Philippines Board of Investment approved two pioneer projects for coal conversion. Both Floro Cement Corp. and Iligan Cement Corp. will receive a loan from the Development Bank of the Philippines to finance their projects to convert operations from bunker to coal-fired kilns. The project of the Floro plant at Lugait, Misamis Oriental (440,000-ton-per-year capacity), was estimated at $5.8 million, while the project of the Iligan plant at Kiwalan, Iligan City (300,000-ton-per-year capacity), was at $6.6 million.

Fertilizers.—In mid-1981, the Philippines Phosphate Fertilizer Corp. (Philphos) awarded a $336 million turnkey fertilizer contract to a consortium led by Coppee-Rust of Belgium. The phosphate-fertilizer complex, to be built at Isabel City on Leyte Island, includes two units for the production of complex fertilizer (monoammonium phosphate, diammonium phosphate, and nitrogen, phosphorous, and potassium), each with a daily capacity of 1,500 tons; two phosphoric acid plants, each with a daily capacity of 600 tons; and a 550-ton-per-day sulfuric acid plant. The planned annual capacity is 350,000 tons of phosphates and 153,000 tons of ammonium sulfate. The construction work is expected to be completed by the end of 1984, but the plant operations are scheduled to come onstream in 1985.

The consortium is composed of Coppee-Rust of Belgium, which will undertake construction work on the phosphoric acid plants using the Prayon process; they will also coordinate the project. Mitsubishi Heavy Industries Ltd. of Japan will build the sulfuric acid plant using a Lurgi process using local pyrite. Dragados y Construcciones of Spain will construct the fertilizer plants, and the local contractor will be the Construction and Development Corp. of the Philippines.

Philphos, a joint-venture company, is owned 60% by the Philippines Government's National Development Corp. and 40% by Nauru Phosphate Corp. (NPC), a state-owned company of Nauru (an island nation in the Pacific). NPC has agreed to supply 300,000 tons of phosphate rock to the fertilizer plant annually. The plant requires about 1.1 million tons of phosphate ore annually. The remaining requirements of phosphate ore (800,000 tons) are expected to be supplied by Morocco and Jordan, and the anhydrous ammonia by Indonesia.[17]

MINERAL FUELS

Coal.—The Philippines coal production continued to increase in 1981. The output level reached over 373,000 tons, about 15% over that of 1980. During 1981, there were 50 coal service contractors, of which 28 were developing and producing coal, while 22 were in exploration. The major companies involved in coal development were CDCP, Marinduque Mining and Industrial Corp., and Burnett and Hallamshire of the United Kingdom.

The Philippines largest coal producer, Semirara Coal Corp. (a subsidiary of Vulcan Industrial and Mining Corp.), started a $100 million coal expansion project on Semirara Island in 1981. Vöest-Alpine AG of Austria, reportedly was to provide financing and install all mining equipment (including four bucket-wheel excavators) and facilities by 1983. The initial coal mining operation would be at the Unong Mine, one of the three mines owned and managed by Vulcan. The initial output was projected at 1,000 tons per day in 1983. By 1984, the total output of Unong Mine was expected to reach 1 million tons per year at full capacity. The Unong Mine, along with Panian and Himalian Mines, have total reserves of 105 million tons of coal. Under a long-term contract, Vulcan was to deliver annually 360,000 tons of coal to Atlas and 960,000 tons to the National Power Corp.

Coalfields Mining and Industrial Corp., a joint-venture company 50% owned by Atrium Capital Corp. (an affiliated company of the Herdis Group Co.) and 50% by J. J. Mining and Exploration Corp., was to start a $15 million coal mining and development project in Albay on Bataan Island off Legazpi. Coalfields plans to produce about 300,000 tons of coal per year by 1982 and to 500,000 tons per year by 1984. The coal reserves on Bataan Island were estimated by the NEWCO Engineering & Coal Development Co., Inc., of the United States, at about 46 million tons. Under a 10-year contract, Coalfields was to supply Atlas about 150,000 tons annually of coal beginning in April 1982.

Petroleum and Natural Gas.—During 1981, the Philippines crude oil production from Nido Oilfields declined from 3,000 barrels per day in January to about 2,600 barrels per day in October. Cities Service, the operator of Nido Oilfields, predicted that the well will be producing only about 1,700 barrels per day by December 1982. Cities Service has indicated that it probably will discontinue its operation at Nido by the end of 1982 and will focus on development at the Matinloc Field and further exploration at the Galoc Field.

In September 1981, the Philippines second offshore oilfield went into production. Cadlao Oilfields, operated by Amoco Philippines Petroleum Co. (a subsidiary of Standard Oil Co. of Indiana), started production at about 1,000 barrels per day because of bad weather and damage to some equipment. By yearend, the output of two wells at Cadlao reached 9,000 barrels per day. According to Amoco, the Cadlao Oilfields have recoverable oil reserves of about 10 million barrels with an API rating of 47°.

The Philippines third offshore oilfield, Matinloc Oilfield originally scheduled to start production in late 1981, was rescheduled by Cities Service to begin in the second quarter of 1982 at an initial production rate of 12,000 to 15,000 barrels per day. The Matinloc Oilfield with estimated oil reserves of 10 million barrels, is about 33 miles northeast of Nido Oilfields.

In August 1981, the Philippines Cities Service discovered oil at the North Galoc-1 well. The Galoc-1 well is the Philippines first oil discovery in a sandstone reservoir. The well has a yield of about 1,200 barrels of oil per day. The quality of the crude oil is between 31° to 32° API. According to Cities Service, another well called the South Galoc-1 was also discovered in a sandstone reservoir in November 1981. The South Galoc-1, about 8 miles south of the Galoc-1, contains no oil but has gas. The well tested 3.7 million cubic feet per day of natural gas and 280 barrels per day of gas condensate from two zones of a sandstone reservoir.[18]

In May 1981, Cities Service also discovered a new oil well called Tara-1, near other wells in the Matinloc, Pandau, and Libro Fields. The estimated flow rate from Tara-1 was 3,375 barrels per day. It was reported that Cities Service would concentrate on the development of the Matinloc, Pandau, and Libro Fields, and PNOC was taking over the development work on Tara-1.

The Philippines will spend $213.2 million for the development and production of oil wells in 1982. These expenditures are to be spent mainly on the Matinloc Oilfields, and about 20 oil wells scheduled for drilling in 1982.

The Mineral Industry of Poland

By Tatiana Karpinsky[1]

In 1981, a deep social and economic crisis continued to affect Poland, marked by an unbalanced market, a deep negative balance of payments, shortages in materials and technical services, a decline in industrial production, low labor productivity, and a host of unsolved social problems. By the end of 1981, the sociopolitical situation of the country had deteriorated further. A wave of tension, conflicts, and strikes were again sweeping the country. Economic difficulties grew, and strikes affected almost all industries.

On December 13, 1981, by a decree of the Council of State, martial law was introduced throughout the country, and Prime Minister Jaruzelski announced that a so-called Military Council of National Salvation (Wojskowa Rada Ocalenia Norodnogo) had been established. The Government announced that 150 enterprises had been "militarized," meaning that employees were subject to military discipline.

A decree was issued militarizing all petroleum industry centers, including all refineries and oil-processing plants and hard coal and lignite mines; powerplants and other power industry units serving these plants were also militarized.

Poland entered the crisis stage in 1979, as expressed in the decline of national income and most of the economic indicators. According to Polish sources, national income decreased 15% in 1981, compared with that of 1980, or significantly more than in the previous 2 years when the drop amounted to only a few percent. Gross industrial production decreased by 12.6% in 1981.[2]

In 1981, the shortage of coal was particularly acute and was a major handicap in other subsectors of industry. The Polish national economy was based on coal, which accounted for 70% of domestic energy.

In 1981, a shortage of electric power resulted in a decrease in output, especially of such products as electric arc furnace steel, rolled products, aluminum, soda, ammonia, lead, zinc, and cement.

In 1981, capital investment in Poland's economy decreased 15.6% compared with the 1980 level and amounted to 460 billion Polish zlotys (Z).[3] Investment in the iron and steel industry dropped sharply to only about a third of the volume of 1980, but priority in investment was given to the copper-silver industry, because foreign exchange earnings in this sector are much higher than those of the steel industry. According to the Government decision, 15 large capital projects in the steel and nonferrous sectors valued at Z133 billion were frozen and about 7 projects were trimmed back.

By decision of the Government, in November 1980, the construction of the second stage of the Katowice steel plant was discontinued, except for two tasks: The construction of the coking plant, with one-half of the original targets to be completed; and the construction of the rail heat-treatment department.[4]

In 1981, the electrical and manufacturing industries contributed 27.7% to Poland's total industrial output. The fuel industry contributed 8.8%, a decrease from 12% in 1976; the metallurgical industry, 8.7% (down from 11.5%); the chemical industry, 9.1%, and the mineral industry, 3.1%.[5]

The total number of industrial workers and employees in state enterprises in Poland was 4,744,000 in 1981. The number of workers and employees in state mineral and energy enterprises by branch for 1980 is given in table 1.[6]

Table 1.—Poland: Industrial workers and employees in 1980

Branch	Workers and employees (thousands)	Percent of total employment in all industry
Coal	412	8.7
Other fuel	50	1.0
Power	87	1.8
Ferrous metals	186	3.9
Nonferrous metals	74	1.6
Building materials	181	3.8

The mining industry's labor shortage was estimated at 19,000. During the year, 6,800 workers were trained as laborers to work in the enterprises of the Ministry of Mining.

Under the contract signed by Poland with the U.S.S.R., Polish enterprises participated in the construction of three nuclear power stations in the Soviet Union. In return, the Soviet Union is to provide Poland with 1.2 billion kilowatt-hours of electrical energy in 1984 and 2.4 billion kilowatt-hours in 1985. The total amount of electrical energy supplied to Poland under the terms of the contract is to be more than 100 billion kilowatt-hours.[7]

Poland continued to take part in the expansion of Soviet ore extraction facilities, and in return, Poland was assured additional supplies of raw materials in the 1981-85 period.[8]

Government Policies and Programs.—On January 24, 1982, the Polish Planning Commission published the first quarter revised economic plan for 1982. In comparison with the first quarter of 1981, the production in the first quarter of 1982 was planned to increase as follows: Bituminous coal, 7.4% to 44.3 million tons; sulfur, 1.1% to 1.1 million tons; and cement, 4.8% to 3.5 million tons. A decrease in output was expected for the following mineral commodities: Coke, 3.8% to 4.4 million tons; crude oil, 20.8% to 2.8 million tons; rolled steel products, 27.2% to 2.3 million tons; and copper, 5.4% to 80,000 tons.[9]

PRODUCTION

Of major importance to the development of Polish industrial production are domestic reserves of bituminous coal and lignite, copper, silver, zinc, lead, sulfur, salt, and many other minerals.

Poland has shortages of crude oil, natural gas, phosphates, potassium, salts, and metals used in alloying steel.

On December 3, 1980, the Central Committee put the Government under obligation to develop, within the framework of the preliminary 5-year plan, a 3-year plan for economic stabilization of the country. The plan for 1981 was the first stage of the 3-year program of economic stabilization. The Polish economic plan for 1981 was modest. The Government Planning Commission expected the level of industrial output in 1981 to be close to that of 1980. However, the annual report on the fulfillment of the 1981 economic plan, released early in 1982 by the main Statistical Office, showed declines in mineral production.

Table 2.—Poland: Fulfillment of 1981 economic plan

Commodity	Production (thousand metric tons)	Plan fulfillment (percent)
Bituminous coal	163,200	84.5
Natural gas	[1]6,172	97.5
Refined petroleum	13,600	84.2
Steel (crude)	15,719	80.7

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through June 23, 1982.

[2]In addition to the commodities listed, antimony, cobalt, germanium, gold, a variety of crude nonmetallic construction materials, and carbon black are also produced, but available information is inadequate to make reliable estimates of output levels. Poland may also produce alumina in small quantities, but details of such an operation, if it exists, are not available.

[3]Reported figure.

[4]Includes building gypsum, as well as an estimate for gypsum used in production of cement.

[5]Total of listed commodities only; excludes products not reported individually as well as refinery fuel and losses.

Particularly disastrous was the drop in coal production by over 30 million tons, resulting in cutbacks to industry by over 10% and by nearly 7% to the private consumer. Production decreased by about 600,000 tons owing to strikes in the mines following the imposition of martial law, chiefly at the Piast and Zeimowit Mines, where production decreases were estimated at 150,000 tons and 250,000 tons, respectively.

In 1981, the country's powerplants generated 115 billion kilowatt-hours of electrical energy, a decrease of 5.7% compared with 1980.

The first nuclear powerplant in Poland is being constructed at Zarnowice, Gdansk Province, with total designed capacity of 1,880 megawatts. The first unit of the plant is planned to start operation in 1988.

TRADE

The value of Polish exports in 1981 decreased 14.6% compared with that of 1980 and was estimated at $13.2 billion. Exports to the centrally planned economy countries decreased by 10%; exports to the market economy countries decreased by 21.3% to $5.8 billion.[10]

In 1981, the imports from the centrally planned economy countries increased 2%, compared with 1980, while imports from the market economy countries decreased by about 30%. The deficit of trade with market economy countries amounted to $78.2 million in 1981 and the deficit in trade with the centrally planned economy countries increased to $1.95 billion.

In 1981, exports by the electrical and manufacturing industries contributed about

47% of Poland's total export value; fuel and electric power, 10%; ferrous and nonferrous industry, 8%; chemical industry, 9.5%; and products of other industries, 25.5%. The share, by value, of total Polish coal exports decreased from 14% in 1980 to 10% in 1981. The import value of manufacturing and electrical industries accounted for 32%; fuel and electrical power, 20%; ferrous and nonferrous industry, 9.5%; chemical industry, 11%; and products of other industries, about 27.5%.[11]

In 11 months of 1981, in comparison with the same period of 1980, exports dropped as follows: Bituminous coal, 48%; lignite, 8%; coke, 22%; petroleum products, 49%; steel rolled products, 15%; copper, 5%; and zinc and zinc products, 52%.

In 11 months of 1981, imports of many minerals were also lower than in the same period of 1980: Crude oil, 21%; natural gas, 0.9%; petroleum products, 10%; iron ore and concentrate, 19%; pig iron, 2.2%; and steel rolled products, 0.8%.

In 1981, the Polish-Soviet trade turnover accounted for about 8.5 billion Soviet rubles (R) as compared with R8 billion in 1980. In 1981, imports from the Soviet Union increased 13.6% compared with 1980. The Soviet Union covered about 40% of import needs for raw materials, including 100% of natural gas and 75% each of crude oil and iron ore. In 1981, deliveries from the Soviet Union included 13.1 million tons of crude oil, 3 million tons of petroleum products, 5.3 billion cubic meters of natural gas, 9 million tons of iron ore, 69,000 tons of asbestos, and 53,000 tons of aluminum. The value of deliveries within the framework of participation in common capital investments in 1981 stood about R400 million, which constituted about 13% of raw material imports from the Soviet Union. These deliveries included 1 million tons of crude oil, 2.8 million cubic meters of gas, 2.5 million tons of steel-related raw materials, 42,500 tons of asbestos, and about 62,800 tons of ferroalloys. A trade agreement between the Polish and Soviet Governments for 1982 was signed in January 6, 1982, in accordance with which turnover in 1982 is to reach R8.4 billion. Deliveries of Soviet fuels and raw materials will continue to constitute not only a major, but in many cases the sole source of import supplies for the Polish economy in 1982.

Polish exports to the U.S.S.R. are to amount to R3.6 billion. In the field of raw materials the planned level of deliveries to the Soviet Union was to remain at the level of 1981, which means that they will also be considerably lower than the quantities supplied in the second half of the seventies. With regard to the negative balance of turnover in 1981, the Soviet Union granted Poland long-term credit amounting to R2.7 billion.

In 1981, Poland had an external hard currency debt of approximately $26 billion; of this amount, Government and Government-guaranteed debt was some $17 billion; private unguaranteed debt was some $9 billion. Of the $26 billion, about $20 billion was due to 16 Western countries. Polish debt to the United States totals some $3.15 billion, which is 12% of the total. Governments of 16 Western countries including the United States, the United Kingdom, France, the Federal Republic of Germany, Japan, Canada, Switzerland, and the Netherlands signed a multilateral agreement in April 1981 to reschedule 90% of the principal and interest falling due from May 1981 to December 1981. The U.S. share of this was $380 million. The official rescheduling totals $2.4 billion.

Table 4.—Poland: Apparent exports of selected mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
METALS				
Aluminum:				
Oxides and hydroxides	1	51	--	Sweden 45; Thailand 6.
Metal including alloys:				
Scrap	13,362	7,489	--	Austria 5,420; West Germany 1,482; France 220.
Unwrought	22,332	17,095	--	Hungary 15,900; West Germany 505; Sweden 284.
Semimanufactures	232	143	--	Italy 106; Denmark 18; Sweden 12.
Chromium oxides and hydroxides	596	487	--	Brazil 150; France 61; Finland 60.
Copper metal including alloys:				
Scrap	184	511	--	France 269; West Germany 214.
Unwrought[2]	133,720	144,754	--	West Germany 79,401; United Kingdom 18,440; Italy 11,013.
Semimanufactures[2]	39,471	50,056	2,983	Czechoslovakia 17,522; U.S.S.R. 6,005; Romania 5,088.
Iron and steel:				
Ore and concentrate	77,669	--		
Pyrite, roasted	8,201	11,481	--	All to Hungary.
Metal:				
Scrap	11,408	14,944	--	Netherlands 6,780; West Germany 5,645; Italy 1,727.
Pig iron	3,190	10,589	--	Pakistan 10,500; Italy 74.
Ferroalloys	--	101	--	Italy 100.
Steel, primary forms thousand tons	[3]379	215	(4)	Yugoslavia 93; Austria 31; United Kingdom 31.
Semimanufactures:				
Bars, rods, angles, shapes, sections do	[3]911	[3]1,053	15	West Germany 131; Yugoslavia 25; Finland 23.
Universals, plates and sheets do	[3]423	[3]386	55	West Germany 66; Norway 38; Sweden 33.
Hoop and strip do	[3]147	[3]168	--	Yugoslavia 35; Sweden 19.
Rails and accessories do	[3]36	[3]133	--	Singapore 15; Italy 14.
Wire do	[3]44	[3]52	2	West Germany 6; Yugoslavia 4; Hungary 3.
Tubes, pipes, fittings do	[3]110	[3]115	[5]9	East Germany 34;[2] Saudi Arabia 13; France 7.
Castings and forgings, rough do	[r]7,691	11,314	[5]286	West Germany 3,720; Sweden 2,129; Ireland 549.
Lead:				
Oxides and hydroxides	260	40	--	All to Yugoslavia.
Metal including alloys:				
Scrap	17	--		
Unwrought	[2]7,098	--		
Semimanufactures	11	--		
Molybdenum metal including alloys, all forms	5	4	--	All to Sweden.
Nickel metal including alloys:				
Scrap	11	18	--	All to Finland.
Semimanufactures kilograms	[r]345	1,390	--	France 1,000; Yugoslavia 390.
Platinum-group metals including alloys, unwrought and partly wrought value, thousands	$3,565	$1,428	--	United Kingdom $1,281; West Germany $139.
Silver:				
Waste and sweepings do	$408	$450	--	Switzerland $448.
Metal including alloys, unwrought and partly wrought[2]	347	516	46	Switzerland 158; United Kingdom 113; West Germany 109.
Tantalum metal, including alloys, all forms	--	3	--	All to West Germany.
Tin metal including alloys, scrap	36	36	--	All to United Kingdom.
Tungsten metal including alloys, all forms	12	6	--	All to Yugoslavia.
Zinc metal including alloys:				
Scrap	24	--		
Unwrought[2]	33,162	41,408	--	United Kingdom 18,664; U.S.S.R. 9,351; Hungary 8,924.
Semimanufactures[2]	4,782	4,699	[5]41	U.S.S.R. 2,955; West Germany 801; Czechoslovakia 283.
Other:				
Ash and residue containing nonferrous metal	16,362	13,493	--	Austria 8,093; West Germany 4,034; Netherlands 77.
Oxides, hydroxides, peroxides	58	11	--	Pakistan 6; Jamaica 5.
Metals:				
Metalloids	1	--		
Nonferrous alloys[2]	2,984	4,000	--	All to U.S.S.R.
Metal powder[2]	2,091	887	--	All to Czechoslovakia.

See footnotes at end of table.

Base metals including alloys, all forms	--	1	--	All to Morocco.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	2	--		
Corundum, artificial	3,073	3,291	--	West Germany 1,389; Italy 915; Austria 868.
Grinding and polishing wheels and stones	270	[6]178	--	Yugoslavia 49; Thailand 40; Austria 25.
Cement[2] thousand tons	2,044	1,890	--	West Germany 660; Spain 209; Austria 197; Ivory Coast 162.
Chalk	--	15	--	All to Jordan.
Clays and clay products:				
Crude:				
Fire clay[2]	24,333	21,631	--	Hungary 15,029; Austria 4,354.
Chamotte[2]	1,629	10,203	--	Yugoslavia 6,119; Italy 1,710; Hungary 931.
Other	8,139	496	--	Italy 203; Spain 148; West Germany 100.
Products:				
Nonrefractory	3,473	4,463	--	Sweden 3,127; West Germany 841; Finland 340.
Refractory including nonclay brick[2]	18,216	17,790	[5]9	Finland 5,375; Belgium-Luxembourg 3,424; Czechoslovakia 2,287.
Diamond:				
Gem, not set or strung value, thousands	$2	--		
Industrial do	$734	$593	--	Belgium-Luxembourg $590.
Fertilizer materials:				
Crude, nitrogenous	27	--		
Manufactured:				
Nitrogenous[2] thousand tons	365	271	--	India 60; West Germany 46; France 38; Japan 21.
Phosphatic	--	110	--	Indonesia 85; Netherlands 25.
Potassic[2]	6,762	14,000	--	All to Romania.
Other including mixed	7,476	39,707	--	Yugoslavia 24,966; Denmark 8,002; West Germany 6,316.
Ammonia	NA	12,063	--	Italy 11,993; Kenya 70.
Gypsum and plasters	161	87	--	Finland 66; Sweden 20.
Iodine	11	2	--	All to Yugoslavia.
Lime[2]	11,942	12,212	--	Hungary 10,028.
Magnesite	--	41	--	France 40.
Pigment, mineral, including processed iron oxides	102	20	--	All to Italy.
Precious and semiprecious stones value, thousands	$15	$14	$13	West Germany $1.
Salt and brine[2]	253,056	296,711	--	Sweden 183,417; Finland 62,831; France 29,038.
Sodium and potassium compounds, n.e.s.:				
Caustic potash	20	1	--	All to United Kingdom.
Caustic soda[2]	71,870	43,017	--	West Germany 11,685; Yugoslavia 5,853; Netherlands 4,448.
Soda ash[2]	123,011	141,481	--	West Germany 49,050; U.S.S.R. 26,646; Czechoslovakia 24,407.
Stone, sand and gravel:				
Dimension stone[2]	33,719	38,088	--	Netherlands 11,265; West Germany 9,714; Belgium-Luxembourg 8,666.
Dolomite, chiefly refractory-grade	--	11	--	All to West Germany.
Gravel and crushed rock[2]	457,194	291,543	--	West Germany 244,798; Finland 30,147; United Kingdom 6,888.
Limestone and dolomite	[2]9,021	3,275	--	All to West Germany.
Sand excluding metal-bearing	231,394	196,422	--	Do.
Sulfur:				
Elemental:				
Other than colloidal[2] thousand tons	3,892	3,903	--	U.S.S.R. 742; France 447; Czechoslovakia 440.
Colloidal	72	799	--	Sweden 520; Singapore 115; Sri Lanka 100.
Sulfuric acid, oleum[2]	88,310	211,729	--	U.S.S.R. 92,166; Sweden 89,437; Japan 14,308.
Other:				
Crude	6,563	[7]36	--	Denmark 22; United Kingdom 14.
Slag, dross, and similar waste, not metal-bearing	410	1,907	--	West Germany 1,203; Austria 704.
Halogens	62,611	1	--	All to Sweden.

See footnotes at end of table.

Table 4.—Poland: Apparent exports of selected mineral commodities[1] —Continued

[11]U.S. reported 42 barrels of tar exports to Poland.

COMMODITY REVIEW

METALS

Aluminum.—Production of aluminum in Poland is based on alumina imported from Hungary (70%) and from Western countries (30%). Aluminum output fell in 1981, as cutbacks ordered at the Skawina smelter were enforced. Krakow's mayor ordered the 50,000-ton-per-year smelter to idle half its pots in order to reduce hydrogen fluoride emissions. The smelter was constructed in 1952 in the valley of the Vistula River, some 14 kilometers southwest of Krakow.[12]

Copper.—In 1981, development of the copper industry continued in the Legnica-Glogow region, the sole producing area. However, in September 1981, social unrest led to a fall in production. To improve the situation an extraordinary session of the Voivodship Council was held and market supplies were slightly improved. Work discipline was a problem in the copper industry, and unauthorized absences increased by 65% from August 1, 1980, to the end of 1981. The original economic plan provided for 425,000 tons of electrolytic copper to be produced in 1980, but the output was actually 357,000 tons. The revised plan for 1981 provided for 340,000 tons of electrolytic copper to be produced, but production fell short by 13,000 tons. Production of 330,000 tons was planned for 1982, and this figure was to reach 396,000 tons in 1985, and 445,000 tons in 1990.

In 1981, Poland exported 47% of its total copper production exclusively in the form of electrolytic copper. About 52% of copper exports went to the Federal Republic of Germany as a payment for money invested in the Lubin Copper Basin, about 5% went to Belgium, 5% to France, 8% to Romania, 7% to Czechoslovakia, 6% to the United Kingdom, and smaller amounts to Sweden, Finland, Austria, Switzerland, and Iran. In 1982, exports of 165,000 tons of electrolytic copper are planned, including 145,000 tons to the market economy countries.

In 1981, the copper industry was a "priority customer" for supplies of coal, and there were no fuel shortages in the industry. The entire copper industry in the Lubin area had about 40,000 employees, 10,000 of which were underground miners. At the end of December, under martial law, the mines worked 6 days a week. In 1981, copper ore was extracted mainly from three underground mines: Rudna, Polkowice, and Lubin. A fourth mine, the Sieroszowice Mine, continued under development, although it already was producing some ore in 1981. The development of ventilation shafts at the mine was 3 months behind schedule. The largest mine, Rudna, produced about 8.5 million tons of copper ore in the same year, and the target for 1984 was 11 million tons. The Rudna Mine itself had 5,700 employees, of which 3,500 were miners. In addition to the above, an old copper mine, Konrad, produced about 1.5 million tons of ore in 1981.

In 1981, production of copper ore decreased mainly because of the introduction of work-free Saturdays and Sundays. Copper ore output in Poland planned for the 10 years (1980-90) is shown in table 6.

Table 6.—Poland: Copper ore output planned for 1980-90

(Million tons)

Mine	1980	1985	1990
Lubin	7.5	7.5	7.5
Polkowice	7.5	7.5	7.5
Rudna	11.0	11.0	12.0
Konrad	1.5	1.5	--
Sieroszowice I	1.5	5.5	5.5
Sieroszowice II	--	3.4	9.5
Total	29.0	36.4	42.0

In 1981, mining was done at a depth of 900 to 1,000 meters and was planned to go down to 1,500 meters by 1983; the average copper content was about 1.5%, and overall bed thickness ranged from 0.4 to 5.5 meters. Reserves of more than 1% copper amounted to about 1,500 million tons of copper ore. The ore-bearing deposits in the Lubin-Glogow region are in sandstone and dolomites. The main ore minerals present are sulfides, such as bornite, chalcocite, chalcopyrite, and some galena and sphalerite. Associated with copper are silver, lead, cobalt, vanadium, and various other elements. The copper deposits lie below heavy water-bearing Tertiary formations.

In 1981, smelter capacities were sufficient to reach the target of the originally planned amount of 425,000 tons of electrolytic copper per year. Smelter capacities were as follows: Legnica 60,000 tons; Glogow I 160,000 tons (two production lines); the new Glogow II 150,000 tons; and others (Trzebina, Hutnem, Szopience) about 55,000 to

60,000 tons. The Glogow II copper smelter plant was put into operation in 1978 at an estimated cost of $35 million. In 1980, it produced only 60,000 tons instead of the planned 150,000 tons.

Iron and Steel.—In 1981, steel output was planned for 17.5 million tons, but the goal was not reached. The output of rolled products was expected to decrease 0.5 million tons to about 13 million tons. This production plan was not fulfilled. In comparison with the first quarter of 1981, the production of rolled steel in the first quarter of 1982 is to decrease 27.2% to 2.3 million tons.

In 1981, consumption of steel was estimated at 15.5 million tons, reflecting a decrease of 3.7 million tons compared with the 1975 level. Slackening trends in investment activity and decline of production, both in steel sectors of the manufacturing industry, can be classified as the most significant factors working toward slowing down the growth of steel demand. Investment in the iron and steel industry decreased from Z35.8 billion in 1976 to Z20.9 billion in 1979 and to an estimated Z8.6 billion in 1981.

Poland is deficient in iron ore. During the first 11 months of 1981, imports of iron ore amounted to 14.8 million tons, a decrease of 3.5 million tons from that of the same period in 1980. About 75% of the iron ore[13] was imported from the U.S.S.R., and about 13% from Sweden and others. Norway, Brazil, and Venezuela accounted for 12%. The domestic output of low-grade siderite decreased from 529,000 tons in 1978 to 104,000 tons in 1980. Production of iron ore in 1981 was estimated at a lower level than in 1980. Imports of pig iron were about 1.4 million tons in 1981.

In 1981, there were 27 steel plants in operation, most of them located in the Upper Silesian industrial district. The largest iron and steel manufacturing plants included the Lenin steel complex in Krakow, the Katowice steel complex, and the Warsaw metal plant.

In 1981, there were 21 blast furnaces in operation with an average capacity of about 980 cubic meters. The largest units (3,200 cubic meters) operated at the Katowice steel complex. The average capacity of 16 blast furnaces of the old metal plants amounted to 539 cubic meters. The coke consumption per ton of pig iron was about 600 kilograms on the average. Poland's plans for the steel industry were to reduce open-hearth production and to increase the oxygen converter output as shown in percentages in table 7.

Table 7.—Poland: Steel production by process

(Percent)

	1976	1977	1978	1979	1980
Open-hearth	64.1	56.3	49.5	47.1	46.7
Electric	14.4	14.2	13.7	13.8	14.0
Oxygen converter	21.5	29.5	36.8	39.1	39.3

In 1980, there were 79 open-hearth furnaces in operation; 8 had a production capacity of 370 tons each, 15 had a production capacity of 100 to 200 tons, and the remainder had a production capacity of 30 to 90 tons.[14] There also were 28 electric furnaces with different capacities as shown in table 8.

Table 8.—Poland: Capacities of electric furnaces

Capacity in tons	Number of electric furnaces
5-10	6
20	4
25-30	4
50	7
140	7
Total	28

In 1981, the limited funds of the iron and steel industry were invested mainly in the completion of processing facilities including plate mills at the Beirut steel plant, small rolling mills at the Nowotko steel plant, and a cold-rolling mill at the Lenin steel plant. In 1981, planned production of crude steel at the Lenin steel complex was 6 million tons, but in view of fuel shortages, reduced shipments of iron ore, and strikes, production reached only 5 million tons. Work on the Katowice foundry was halted following an investment freeze imposed because of Poland's economic crisis. Two giant furnaces at Katowice were producing about 5 million tons of steel per year.

Lead and Zinc.—In 1981, production of zinc and lead decreased by 23% and 16%, respectively, mainly because of the reduction of the workweek to 5 days. Zinc and lead ores were mined mainly in the Olkusz district. Production of zinc and lead came from the mining and metallurgical complex in Bukowno, the Szopienice nonferrous metallurgical plant, and the Miasteczco Slaskie plant.

Poland exported an estimated 12,000 tons of zinc metal in 1981. Imports of lead metal were estimated at 4,000 tons. Hard currency shortages prevented the import of zinc and lead concentrates. On April 1, 1981, a new plant for processing battery scrap was put in operation at the Orzel Bialy mining and metallurgical combine at Pickary Slasky. About 70,000 tons of scrap is to be processed at this plant annually.

Silver.—In 1981, production of silver, a byproduct of copper production, continued to be one of Poland's major hard currency earners. Value of silver exports amounted to Z328 million in 1979 and increased in 1980 largely because of doubling of the silver price.[15]

Tin.—Further prospecting of the tin deposits near Krobica and Gierczyn (Lower Silesia), discovered in 1979, proved the ore grade of 0.2% to 0.4% tin to be economic for mining. Up to 1981, production of tin in Poland was based on imported tin ores, mainly from the United Kingdom and Indonesia.

NONMETALS

Cement.—In 1981, production of cement decreased considerably because of shortages of coal and heavy fuel oil. Following a decision of the Central Anti-Crisis Commission, production of cement was halted at two of the three plants at the Chelm cement complex, and monthly production at the complex fell from 260,000 to 270,000 tons to 40,000 tons. According to the Cement, Lime, and Gypsum Industrial Association of Opole, the cement plant there was closed because of the drastic cuts in coal supplies. The plan for the supply of coal means that it most likely will remain closed until the middle of 1982.

In 1981, only 71% of the total capacity of cement plants was used. Underutilization of productive capacity in the existing cement plants and a fuel shortage led to the new plan, with a special emphasis on modernizing existing plant facilities to reduce fuel consumption. The first stage of modernization includes reconstruction of Warta II and Kujawy cement plants, where heat consumption for the firing of clinker is to decrease from 1,800 to 1,100 kilocalories per kilogram.[16] Reconstruction is planned at the Wejherowo and Strzelce Opolskie cement plants.

Fertilizers.—During the first 11 months of 1981, in comparison with the same period of 1980, nitrogenous fertilizer production dropped 3% to 1.17 million tons (in terms of nutrient content), but production of phosphoric fertilizer increased about 2% to 796,000 tons (in terms of P_2O_5).

Fertilizer production for 1982 was planned to reach about 3.14 million tons. In 1980, export of nitrogenous fertilizers fell to 271,000 tons from 365,000 tons in 1979. This was a large reduction, compared with the 981,000 tons that was exported in 1976. Exports of nitrogenous fertilizers for 1982 are planned to reach 560,000 tons.

In 1981, about 120,000 tons of ammonia was imported from the U.S.S.R. In 1981, total imports of fertilizers increased about 20% over that of 1980. Imports of phosphate rock were supplied mainly by Morocco, the United States, and the U.S.S.R. The Soviet Union is the biggest supplier of potassic fertilizers to Poland. The 1981 shipments were estimated to be over 1.7 million tons in terms of K_2O content.

The Port of Swinoujscie was recently expanded with the introduction of a new loading base in Swinoport, III. The new facility is to handle imports of chemical raw materials for the Police chemical complex. An estimated 2 million tons of chemicals are expected to be handled by the base. The country's economic crisis and lack of raw materials caused further delays in work on the fertilizer complex at Police. The Police II plant is to produce 500,000 tons of ammonia, 400,000 tons of urea, and 823,000 tons of other fertilizers per year.

In 1981, the construction of a 250-mile gas pipeline to link the Orenburg gasline with the Police fertilizer complex was underway.[17]

The 407,000-ton-per-year ammonia plant at Wroclawek, constructed in 1972, was to undergo renovation to reach projected ammonia capacity.

Salt.—In 1981, the production of salt came from the Klodawa and Inowroclaw regions in central Poland where the deposits occur in the form of salt domes, which have cross sections of several square kilometers and reach a depth of more than 1,000 meters. Production of salt in the form of natural brine came also from rock deposits occurring along the Carpathian foreland in seams several meters thick at a depth of more than 500 meters. More than 60% of the total rock salt reserves are located in Inowroclaw and Klodawa.

In 1981, a new mine was under development at Przyma near Mogilno in the

Kujawy region because the mine at Inowroclaw, which is 50 years old, is expected to be closed in the next few years. The new mine will produce salt by solution mining by about 1986.

In 1981, the first shaft of 50 meters was put into operation at the salt mine at Siedlec near Bochnia in Tarnov Province. Brine from the new mine is to be used in the chemical industry and in production of salt. Several recently discovered deposits of salt are located in the region of Raciborz, Przemysl, and Rzeszow.

Sulfur.—In October and November 1981, sulfur production from the Grzybow, Jezierko, and Machow Mines was badly affected by strikes in the Tarnobrzeg mining region. Grzybow and Jezierko, which are Frasch mines, contributed about 90% of the total sulfur production in 1981, and Machow,which is an open pit, produced the remainder. The experimental Bazina Mine in the Preusl region produced 30,000 tons of sulfur. Domestic consumption of sulfur amounted to over 1 million tons.

Total exports of sulfur in the first 9 months of 1981 increased 5% over the level achieved during the same period in 1980 and reached 2.97 million tons. Of this total, 1.47 million tons was taken by market economy countries, a similar figure to that of 1980; Western Europe's imports of Polish sulfur fell by 22% to 968,000 tons. With the exception of Finland, all regular importers of Polish sulfur reduced their deliveries. An 84% rise in exports to Africa throughout the 9 months was achieved, with Morocco taking 213,000 tons compared with 145,000 tons in 1980, and Tunisia importing 138,000 tons compared with 46,000 tons in 1980. The high level of exports to Morocco was to cover the additional requirements of the recently completed fourth 1,500-ton-per-day sulfuric acid line of the Maroc Phosphate I plant, as well as to accumulate stocks for the startup of Maroc Phosphate II.

Exports of sulfur from Poland to centrally planned economy countries for the first 9 months of 1981 increased 9% to 1.49 million tons. Sulfur delivered to the U.S.S.R. increased from 556,000 tons in the first 9 months of 1980 to 668,000 tons over the same period in 1981.[18]

Exports of sulfur to the Soviet Union increased because large-capacity brimstone-based sulfuric acid plants, built by Polish enterprises, were brought onstream in the Soviet Union. The strong demand for Polish sulfur in the Soviet Union in 1981 also limited the extent to which Poland's Foreign Trade Enterprise Siarkopol could meet the growing sulfur demand in East Europe. Plans were to invest about Z16,500 million in the sulfur industry in the 1981-85 period. Of this Z16,500 million, about Z6,500 million is to be spent on development of a new 1-million-ton-per-year mine, Scopanie, to replace the Grzybow Mine, where output is expected to decrease from 1.4 million tons in 1981 to 250,000 tons per year in the near future. Development of the Scopanie Mine is planned to start in 1982.

MINERAL FUELS

In 1981, total primary energy production was 184.9 million tons in standard coal equivalent (SCE). This represents a decrease in total primary energy production by 14.5%, compared with the 1980 level. Coal (lignite and bituminous) contributed 93.8%; crude oil, 0.3%; natural gas, 4.4%; and others (peat, wood, and hydropower), 1.5%. Total consumption of all types of primary energy reached 200.2 tons SCE, with coal providing 78.9%; petroleum, 12.1%; natural gas, 7.6%; and others, about 1.4%. In 1981, the total apparent consumption of primary energy decreased 8.8% compared with consumption of 1980; exports decreased by 49.6%. The energy balance for 1981 and 1980 is shown in table 9.

Table 9.—Poland: Total primary energy balance[1]

(Million tons of standard coal equivalent)

	Total primary energy	Coal (lignite, bituminous) and coke	Crude oil and petroleum products	Natural gas	Others
1980:					
Production	216.3	204.2	0.5	8.4	3.2
Imports	38.8	1.0	30.7	7.1	--
Exports	35.5	33.1	2.4	--	--
Apparent consumption	219.6	172.1	28.8	15.5	3.2
1981:[e]					
Production	184.9	173.5	.5	8.1	2.8
Imports	33.2	1.0	25.1	7.1	--
Exports	17.9	16.6	1.3	--	--

[e]Estimated.

[1]One ton of standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used are from the United Nations as follows: Hard coal, 1.0; brown coal, 0.3; coke, 0.9; crude oil, 1.47; petroleum products, 1.54; natural gas (1,000 cubic meters), 1.33.

Source: Biuletyn Statystyczny (Statistical Bulletin), Warsaw, No. 12, 1981, pp. 14, 32, and 34.

Coal.—In 1981, coal output fell 12 million tons short of the planned target of 175 million tons and was 38 million tons less than in 1979 and 30 million tons less than in 1980, because miners worked only a 5-day week, involving work-free Sundays and only voluntary work on Saturdays.[19] Prior to December 13, strikes and work stoppages in mines resulted in shortfalls of some 600,000 tons of coal. Large production decreases were also noted in the last few weeks of 1981, when work was halted at the Ziemovit and Piast Mines. Export of bituminous coal amounted to 15.1 million tons in 1981, about 16 million tons less than in 1980. This entailed a loss of hard currency revenue of $1,100 million. Of the total exports, 7.2 million tons was exported to centrally planned economy countries and 7.9 million tons to developed market economy countries.[20] It was estimated that about 18 million tons of bituminous coal would be exported in 1982.

The December 13 declaration of martial law established a maximum 6-day workweek during the period of martial law. On December 31, all hard coal mines were working normally, although only on two shifts.

In 1981, there were 66 mines in operation, mainly situated in Upper Silesia. The average mining depth was estimated at about 560 meters. About 89% of the total hard coal production was obtained from mines using the longwall system of mining. The development and renovation of some hard coal mines that were started in previous years continued in 1981 (Suszec, K-1, Kaczyce, Czeczot, and Budryk Mines).

In 1981, two mines were under development in the Lublin coal basin. Work on one, however, had been suspended and work on the other was delayed because of flooding in 1980.[21]

Extraction and exports of lignite in 1981 were lower than in 1980. Exports of lignite were 1.6 million tons in 1980 compared with 3.0 million tons in 1979. In 1981, Turow opencast mine lignite output accounted for about 60% of the total lignite production. Work continued on the Turow Mine to expand its capacity and on the Konin opencast mine to develop the new Lubstow lignite deposits. A total of Z1,720 million was to be spent on the project in the near future. A new mine at Lubstow is expected to produce about 500,000 tons of lignite by yearend 1982.

The opencast brown coal mining and energy project at Belchatow continued in 1981, some 2 years behind schedule. According to M. Glanovsky, Deputy Minister of Mining and Power, the geological prospecting has proven reserves of about 1.7 billion tons of lignite. The annual output of the mine under development is to amount to about 38 million tons of lignite, which will supply the Belchatow power station with a designed capacity of 4,320 megawatts. More than 202 million cubic meters of overburden was removed at the mine and production of lignite started in 1981; final preparations were made there to put the first 360-megawatt unit into service. It is expected that in 1990, lignite production will total 140 million tons compared with

about 35 million in 1981, while the share of lignite-based energy will grow to 40%.

In 1981, about 20% of the total amount of electrical energy produced was based on the use of lignite. In 1982, lignite extraction is to increase by 1.5 million tons as a result of the commissioning of the Belchatow Basin.

Natural Gas.—Most domestic natural gas consumed was extracted from the Lubaszow Fields, but extraction of gas slightly declined compared with the level of 1980. Imports from the U.S.S.R. totaled 5.3 billion cubic meters. In 1981, new gas deposits were discovered near Nowa Sola, at a depth of about 1,000 meters. Prospecting in the region is to continue. The country purchased drilling equipment from Romania, and it was expected to drill to a depth of 6,000 to 8,000 meters. In 1980, considerable deposits of gas and oil were discovered in Karlino, Kasolin region, northwest Poland. In 1981, production of gas in the Karlino well increased from 12,000 cubic meters per day to 32,000 cubic meters per day. According to Polish sources, proved, probable, and possible gas reserves are estimated at about 200 billion cubic meters.

Petroleum.—In 1981, production of crude oil was insignificant. Petroleum supplies came from the U.S.S.R. and amounted to 13.2 million tons, including 1.1 million tons of crude oil as payment for Polish participation in the Soviet Union oil industry. Imports of petroleum products were estimated at 2.9 million tons. The Polish petroleum industry is to receive a similar amount of oil for processing in 1982. Oil imports from the Organization of Petroleum Exporting Countries were almost discontinued because of the difficult balance of payments situation.

In 1981, large crude oil deposits were discovered in the area of the Polish shelf, north of Rozewa, by the drilling platform of a joint enterprise belonging to Poland, the German Democratic Republic, and the U.S.S.R. The size of the deposits can be confirmed only by further drilling.[22]

In 1981, the Karlino oil well in the Kosalin region increased its crude oil production from 110 tons per day to 180 to 190 tons per day. If the production of oil continues at this level, the Karlino well will produce about 70,000 tons of crude oil in 1982. Some production of crude oil also came from the Krasno region in the Carpathian Mountains where new oil wells were drilled. However, workers of the Krasno oil industry went on strike in November 1981, and the production of oil considerably decreased.

In 1981, a new oil well was put into operation in the Platy region and another at Karsk near Novograd, Czczecin Province. This Province produced half of the domestic crude oil in 1981.

In 1981, the Plock refinery, together with several smaller plants, processed 13.6 million tons of crude oil. In June 1981, the Gdansk refinery resumed operations after a break of more than 1 month. The refinery processed about 2 million tons of oil in 1981. Reportedly, the prices of oil deliveries from the Soviet Union under the Intra-Comecon Agreement were raised in 1981 by 30%, but they were still about 40% below comparable world market quotations.

The Mineral Industry of Portugal

By Roman V. Sondermayer[1]

The mineral industry of Portugal remained modest by world standards. During 1981, however, the Government started to implement its plans aimed at development of the country's neglected mineral resources, hoping thereby to decrease imports of minerals and increase employment in the country. Because of budgetary restraints, however, the pace of the development would be slower than originally anticipated.

The industrial policy in the 1981-84 economic plan was intended to pave the way for entry into the European Communities and to set the framework for modernization of Portuguese industry, including mines and smelters, and for the building of a modest number of new mineral-related installations. Portugal's relative political stability, its favorable incentives, and reasonable labor rates made investing in the country an attractive opportunity.

During 1981, the extractive sector of the industry accounted for about 1% of the gross domestic product of approximately $23.9 billion.[2] The significance of the Portuguese mineral industry for the mineral supply of the world was modest, and only output of tungsten, approximately 4% of the world total, was important in the international market. The industry was also hampered by one of the most severe droughts in the past 120 years, which caused shortages of hydroelectric power and water.

Expansion of the Aljustrel pyrite mine, development of the Neves-Corvo deposit of complex sulfide ores, and development of the Moncorvo iron ore deposit were the most important events during the year in the mineral industry.

PRODUCTION

Table 1 shows trends in the production of minerals in Portugal. Most of the major mineral-producing enterprises were owned by the Government. The private sector was mostly involved in production of nonmetals. Mineral-producing facilities were outdated by world standards, but modernization and expansion of large existing installations and development of new modern ones were under study.

TRADE

Foreign trade in minerals is shown in tables 2 and 3. Imports of fuels heavily burdened the trade balance of the country.

Table 2.—Portugal: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)

Limestone, except dimension	215	131	--	Mozambique 66; Cape Verde 49.
Quartz and quartzite	3,812	1,472	--	United Kingdom 698; West Germany 395; Ireland 200.
Sand excluding metal-bearing	14,112	12,455	--	Gibraltar 11,660; Spain 700; Angola 59.
Sulfur:				
Elemental, all forms	205	83	--	Spain 40; Mozambique 22; Angola 14.
Sulfuric acid and oleum	28,649	23,895	--	Algeria 12,709; Spain 6,374; Turkey 4,618.
Talc, steatite, soapstone, pyrophyllite	18	33	--	Angola 24; Mozambique 7.
Other:				
Crude	111	159	--	Spain 113; Guinea-Bissau 24.

See footnotes at end of table.

Table 2.—Portugal: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Other —Continued				
Slag, dross, similar waste, not metal-bearing:				
From iron and steel manufacture	1,226	NA		
Unspecified kilograms	200	NA		
Oxides, hydroxides, peroxides of barium, magnesium, strontium value	$20	NA		
Building materials of asphalt, asbestos and fiber cement, unfired nonmetals	1,742	1,867	--	Guinea-Bissau 675; Cape Verde 521; France 398.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	(1)	22	--	All to Guinea-Bissau.
Carbon black	(1)	11	--	Angola 7; Guinea-Bissau 3; Mozambique 1.
Coal, all grades including briquets	11	19	--	Angola 16.
Coke and semicoke	15	20	--	All to Angola.
Hydrogen, helium, rare gases kilograms	100	NA		
Petroleum refinery products:				
Bunker deliveries:				
Gasoline, aviation thousand 42-gallon barrels	(1)	85		
Kerosine do	(1)	NA		
Jet fuel do	1,121	1,529		
Distillate fuel oil do	27	357		
Residual fuel oil do	1,136	537		
Lubricants do	142	24		
Unspecified do	405	10		
Nonbunker deliveries:				
Gasoline do	768	1,948	572	Netherlands 522; West Germany 274; France 179.
Kerosine and jet fuel do	167	100	91	Cape Verde 9.
Distillate fuel oil do	--	1,226	614	Netherlands 374; Belgium-Luxembourg 170.
Residual fuel oil do	510	2,061	607	Spain 923; Netherlands 265; United Kingdom 265.
Lubricants do	36	72	--	Spain 28; Cuba 21; United Kingdom 7.
Other:				
Liquefied petroleum gas do	11	13	--	Cape Verde 12.
Mineral jelly and wax do	15	3	--	Nigeria 1.
Unspecified do	1,599	207	--	Sweden 203; Guinea-Bissau 2.
Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals	31	621	4	Sao Tome and Principe 580; Angola 22.

NA Not available.

[1]Less than 1/2 unit.

[2]Value only reported at $1,365,000, of which $628,000 to France, $409,000 to United Kingdom, and $200,000 to United States.

[3]Value only reported at $5,341,000, of which $3,635,000 to West Germany, $1,648,000 to Belgium-Luxembourg, $37,000 to Angola, and $1,000 to United States.

[4]Value only reported at $107,454,000, all to Switzerland.

[3]Value only reported at $3,048,000, of which $2,429,000 from West Germany, $243,000 from France, $174,000 from United Kingdom, and $51,000 from United States.

[4]Excludes unreported quantity value at $319,496.

COMMODITY REVIEW

METALS

Copper.—In 1981, exploration continued and two new ore bodies, Graca and Zambujal, were delineated in the complex Neves-Corvo copper-lead-zinc deposit near Castro Verde, some 50 kilometers south-southwest of Beja and 40 kilometers southeast of Aljustrel in the Baixo Alentejo, southern Portugal. The Neves-Corvo ore bodies were located near the southeast end of the Estacao de Ourique anticlinorium and lay on the northeastern flank of the structure, dipping 10° to 30° to the northeast.

Total reserves of sulfide ores at Neves-Corvo were reported to range from 70 million tons to 100 million tons, containing 1.7 million tons of copper, 1.9 million tons of zinc, and 0.1 million tons of lead. In addition, the pyrite in the deposit contains another 0.38% copper, 0.40% zinc, and 0.31 ounce (10 grams) of silver per ton.

In addition to the massive sulfide mineralization present as stockwork in the footwall, the area of the Neves-Corvo deposit contained two types of mineralization never before identified in the Iberic Pyritic Belt. The first was layered chalcopyrite that overlaid the massive sulfides, sometimes in contact with them, but most of the time interbedded in graywackes and slates. The second was a breccia composed of chalcopyrite and pyrite in a stockwork pattern. In general, the large ore bodies at Neves-Corvo showed a core of zinc-bearing minerals with a halo of copper minerals. In certain areas, a zinc ore body was surrounded by a lead halo. A detailed description of the Neves-Corvo deposit was published.[3]

Iron and Steel.—The Moncorvo project continued in the preparatory phase during the year. Final approval from the Government was being sought and details for financing were being worked out, mostly with the World Bank. Public invitations for prequalification of companies interested in equipment supply were published by Ferromina, the operating company. The project was scheduled for startup in 1984, at an initial production of about 2 million tons of iron pellets annually.

Work on expanding capacity of the Seixal steelwork continued. Construction started at sites designated for the new blast furnace and the new steel shop. Plans call for new capacities at Seixal as follows: 1 million tons of steel, 800,000 tons of rolled products, and 1.5 million tons of iron pellets.

Pyrites.—The work on implementation of the National Plan for Utilization of Pyrites (Programa de Aproveitamento Integrado das Pirites—PAIP), continued during 1981. Aljustrel and Neves-Corvo Mines and the Sines metallurgical complex project remained the major component of the PAIP. The following completion dates for PAIP projects were targeted: The first phase of Aljustrel and Sines, 1983-84; production of copper concentrate from Neves-Corvo, 1985; startup of a copper plant at Sines, 1985-86; and the second phase of Aljustrel and Sines, 1987-88.

Tantalum.—Geomines of Belgium concluded an agreement with the Societe Nortenha of Portugal to prospect the Visiros tin-tantalite deposit. Details of the agreement were not known.

Tungsten.—The Panasqueira and Borralha Mines, situated in the central part of Portugal, remained principal producers of tungsten in Portugal. The mineralization was associated with granites related to tectonic movements of the Westphalian (Upper Carboniferous) or with granite of posttectonic effusions.

Production of the Borralha Mine declined in 1981, when compared with the output in previous years, mostly as a result of lower ore grades and labor problems. At Panasqueira, increased production was achieved by a combination of higher output resulting from mine mechanization, richer ore, and better rates of recovery in the Panasqueira mill. Geomines continued to develop the new tin and tungsten mine at Miguel Vacas.

Zinc.—The 11,000-ton-per-year zinc electrolytic plant located near the town of Barreiro, southeast of Lisbon, owned and operated by the Government-owned Quimigal-Quimica de Portugal, started normal production during 1981 although trial production had started in 1980. Only pyrite cinders were used as raw materials at Barreiro, producing zinc by the modified Zincex process. Two different types of leach liquors were obtained from roasting the pyrite by separate processes. About 60% of zinc feed was produced by using the German DHK nonvolatizing chloride roasting process. The rest of the feed was treated by the Japanese Kowa Seiko volatizing chloride roasting process. Electrowinning, melt-

ing and casting, and cationic solvent regeneration steps are the same for both circuits. Roughly 6,500 tons of zinc per year was produced from the feed of the DHK line and 4,500 tons per year of zinc was produced by the Kowa Seiko line. The detailed description of the Zincex process was published.[4]

NONMETALS

Cement.—During 1981, there were 10 plants in operation in Portugal with a total annual capacity of 6 million tons. The largest plant, with an annual capacity of 1.65 million tons, was at Outao near Setubal, and this plant was operated by the Companhia Geral de Cal e Cimento S.A.R.L.-Secil.

Other Nonmetals.—Table 1 shows production of nonmetals in Portugal during 1977-81. During 1981, no major events, by world standards, were registered.

MINERAL FUELS

The energy supply of Portugal remained almost completely dependent on imported hydrocarbons during 1981, as it was in the past. Modest quantities of anthracite were produced in northern Portugal, at the Pajao Mine, also known as the Germude Mine, by the Empresa Carbonifera do Douro S.A.R.L. In 1981, as in the past, Portugal did not produce crude oil and natural gas in its national territory. Imports of crude oil and some liquefied gas were essential to meet the country's demand.

Uranium was the only primary energy source in Portugal of economic significance. Portugal's national uranium company, Empresa National di Uranio S.A.R.L., made a decision to increase production of yellow cake U_3O_8 from 120 to 500 tons per year. During the year of review, Portugal exported all of its uranium production as yellow cake. Reports indicated stocks of about 935 tons of yellow cake were held at the end of 1981.

The Mineral Industry of Romania

By Walter G. Steblez[1]

In 1981, Romania's centrally planned economy further displayed the declining trends that marked its performance in 1980. The planned targets for the major economic indicators, with a few minor exceptions, were not met, and in some cases, output dropped below the level of the preceding year.

The net material product (gross national product minus services) was reported to have increased by only 2.1% in 1981 in comparison with that of 1980 and fell short of planned goals by about 5%. Also, net and marketable industrial production failed to reach their respective planned targets by wide margins, achieving reported growth of 4.0% versus 8.1% planned and 2.6% versus 7% planned over the 1980 level. The relative share of the fuel and metallurgical industries, including ore mining, amounted to 14.7% of the gross output of industry, and the industrial production labor force in these sectors was about 10% of the total.

Romania mined a number of ferrous, nonferrous, and nonmetallic commodities, but in many cases, domestic production was insufficient to meet the country's industrial demands, creating an import reliance for most ferrous and nonferrous metals. Although well endowed with energy resources and a developed petroleum refining industry, the country reported increasing import trends for energy raw materials owing to production shortfalls in 1981 and the preceding years. Refineries were also reported to have been operating below capacity.

Government Policies and Programs.—The inability of the Romanian economy to meet annual industrial plan objectives in 1980 and 1981 made the final outcome of the 1981-85 5-year plan, which had set high growth objectives for the period, highly uncertain. National income was planned to increase at an average annual rate of 6.1% per year, and net industrial production was planned to grow 7.1% per year. Capital investment and the foreign trade turnover were to increase 5.2% and 11.9%, respectively, each year.

A planned average 6% annual growth rate was set for the mining and extractive branches of industry, and a 7.7% annual growth rate was designated for the country's metallurgical industries.

In 1981, greater emphasis than in the past was placed on increasing reliance on domestic raw material and energy resources. Success of the entire 1981-85 5-year plan would depend upon domestic reliance of up to 82% for primary energy, 90% to 98% for coal and metallurgical coke, 100% for aluminum, and 80% to 90% for lead and zinc.

Romania's planned 1985 output of key material and energy resources is presented in table 1.[2]

Table 1.—Romania: 1980 production and 1985 production goals for key resources[1]

Commodity		1980 production	1985 goals
Bituminous shale	million tons	--	10.0
Cement	do	15.6	16.5
Chemical fertilizers (100% active substance)	thousand tons	2,455.0	4,050.0
Coal, net	million tons	35.2	85.6
Electric energy	billion kilowatts	67.5	82.5
Natural gas	billion cubic meters	28.2	31.0
Petroleum	million tons	11.5	12.5
Steel	do	13.2	18.2

[1]Scinteia (Bucharest). July 2, 1981, pp. 3-4.

Romania's river ore cargo handling and carrying capacities were also to be modernized and expanded, according to the 5-year plan. The Galati ore carrier harbor, servicing the Galati iron and steel complex, was reported to be undergoing a third development stage, which would increase its export handling capacity to 2 million tons per year.

Increased development of the mining, metallurgical, and fuel extraction industries was a key theme in the 1982 Romanian national economic plan. Measures aimed at rectifying the poor 1981 performance were to include substantial increases in geological survey work to locate new sources of fossil fuels and production increases of ferrous, nonferrous, and nonmetallic ores.

PRODUCTION

Production shortfalls in the mining, energy, and metallurgical industries were reportedly chief reasons the Romanian economy was unable to meet the 1981 planned overall output goals. Economic dislocations caused by the shortfalls were apparently severe enough to have caused censure and demotion of the Minister of Mines, Petroleum, and Geology. The Ministry was subsequently reorganized into three discrete ministerial bodies.

Among the causes of the shortfalls were mismanagement, insufficient production of mining equipment and spare parts, and the delivery of often faulty equipment. Other problems included the inefficient use of raw materials and distorted reporting of these situations to the central authorities.[3] Steel production was the only major branch of industry that recorded significant growth in 1981, although the planned target was not met by a significant margin.

[e]Estimated. [p]Preliminary. NA Not available.

[1]Includes data available through Aug. 3, 1982.

[2]In addition to the commodities listed, antimony, asbestos, gypsum, and a variety of crude construction materials are produced, but output is not reported quantitatively, and available information is inadequate to make reliable estimates of output levels.

[3]Reported figure.

[4]Romanian sources do not indicate whether refinery fuel is reported as a part of the listed product yields. Moreover, additional minor products may be produced but are not listed in official sources.

TRADE

In 1981, Romania reported a 332.4 billion lei[4] foreign trade turnover, which was aided by a broad range of commercial agreements. Apart from Romania's trade with the CMEA[5] and other socialist countries, which constituted about 41% of the total trade, 33% of the total was accounted for by trade with developed Western countries, and a substantial 26% of the total was with the developing states of Latin America, Africa, and Asia. Romania's commercial and cooperative agreements with developing countries were extensive and were particularly aimed at mining and petroleum development.

Faced with the mounting difficulties of servicing a $9.8 billion debt owed to Western banks, Romania decreased its convertible currency imports in 1981 in an effort to improve its trade balance. This resulted in a reported $300 million convertible currency surplus for the period. Total imports in 1981 decreased 7.4% while exports reportedly rose 11.3%.

Romania's main exports included petrochemicals and consumer and producer durables. The country has been a net importer of raw materials, which in 1981 included some 12.9 million tons of oil, 15 million tons of iron ore, and 3.3 million tons of metallurgical coke.

In view of its precarious balance-of-payments status, Romania's permanent representative at CMEA, Nicolai Constantin, underscored the need to effectively implement the program for inter-CMEA cooperation and economic integration that was adopted at the 25th session of CMEA 10 years previously. He particularly noted that over the 10-year period, the CMEA contribution toward fulfilling Romania's requirements for mineral raw materials, metals, and fuels declined from about 47% to 21%, necessitating purchases of these commodities with convertible rather than soft currency.

In 1981, Romania's imports of essential commodities from CMEA remained on a declining trend, and negotiations for CMEA exports of fuel and electric power to Romania were reportedly not concluded by the third quarter of 1981.

Nonferrous metals, which Romania must import owing to insufficient domestic output, were obtained in a number of buy-back arrangements with developing countries in exchange for Romanian development assistance to their respective mining enterprises. Some commodities, however, had to be purchased with hard currency.

Metals that Romania does not produce, such as nickel and cobalt, were obtained from Cuba as sinter and concentrate. In exchange, Romania, in concert with other CMEA countries, was active in upgrading Cuba's nickel-cobalt mining facilities.

Countries with which Romania conducted commercial and cooperative agreements in 1981 in mining and petroleum extraction were Chile, Peru, and Venezuela in Latin America; Angola, Mozambique, Burundi, Morocco, and Zambia in Africa; and China and Indonesia in Asia. Romania also reported negotiations conducted on cooperative mining ventures with Algeria, Egypt, Syria, Libya, Iran, and the Yemen Arab Republic.

Nonrefractory:				
Quantity	6,339	1,790	--	Saudi Arabia 781; Cameroon 754.
Value thousands	NA	$249	--	Israel $195; Cyprus $45.
Refractory	1,476	62	--	West Germany 32; Italy 20.
Diamond, industrial value, thousands	$1,050	$410	--	United Kingdom $277; Switzerland $106.
Fertilizer materials:				
Crude, nitrogenous	5,044	NA		
Manufactured:				
Nitrogenous, urea thousand tons	[2]1,023	[2]1,263	30	Turkey 143; Egypt 96; Algeria 83; undetermined 564.
Phosphatic	148,340	31,756	--	Algeria 10,500; Turkey 9,145; Hungary 7,675.
Potassic	6,350	NA		
Other including mixed thousand tons	[2]1,315	[2]1,766	--	Thailand 105; Turkey 73; Yugoslavia 31; undetermined 1,546.
Ammonia do	35,466	25,518	--	Yugoslavia 14,187; Greece 9,920.
Gypsum and plasters	28,051	28,502	--	All to Hungary.
Lime	11,146	7,692	--	Do.

See footnotes at end of table.

Table 3.—Romania: Apparent exports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980[p]	Destinations, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Pigments, mineral:				
Crude, earth colors	6	NA		
Iron oxides and hydroxides, processed	53	NA		
Precious and semiprecious stones, natural value, thousands	$3	$4	--	Italy $3; Switzerland $1.
Salt and brine thousand tons	[2]841	[2]1,025	--	Hungary 538; Yugoslavia 194; Greece 22.
Sodium and potassium compounds:				
Caustic potash	740	1,893	--	Italy 1,049; Austria 342; West Germany 202.
Caustic soda	[2]238,600	[2]248,800	--	Hungary 47,535; Yugoslavia 30,167; Egypt 19,964; undetermined 137,750.
Soda ash	[2]457,400	[2]513,000	--	Czechoslovakia 51,000; Hungary 41,230; Tunisia 30,160; undetermined 322,483.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	547	269	--	Japan 222; Austria 47.
Worked	23,351	[7]21,686	--	West Germany 17,082; Austria 2,461; Switzerland 1,402.
Gravel and crushed rock	121,428	4,457	--	All to Hungary.
Limestone excluding dimension	932	1,230	--	All to West Germany.
Sand excluding metal-bearing	20	16	--	All to Jordan.
Sulfuric acid and oleum	5,322	294	--	All to Yugoslavia.
Talc, steatite	88	145	--	All to Israel.
Other nonmetals, n.e.s.:				
Crude	1,896	1,011	--	Hungary 601; West Germany 314.
Slag, dross, similar waste, not metal-bearing	119,199	13,580	--	All to Yugoslavia.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	996	NA		
Carbon black	[2]30,200	[2]29,300	--	Poland 6,683; Sri Lanka 718; Thailand 667; undetermined 20,789.
Gas, natural million cubic feet	[2]7,063	[2]7,084	--	All to Hungary.
Peat including briquets	2,006	1,835	--	Austria 1,296; Italy 516.
Petroleum and refinery products:				
Crude thousand 42-gallon barrels	--	811	--	All to Spain.
Refinery products:				
Gasoline do	[2]20,226	[2]22,886	843	Netherlands 4,381; West Germany 3,500; France 1,686.
Kerosine and jet fuel do	([8])	21	--	Hungary 14; West Germany 7.
Distillate fuel oil do	[2]15,092	[2]19,700	--	Italy 3,739; Turkey 2,480; West Germany 2,087.
Residual fuel oil do	[2]17,005	[2]22,768	353	Italy 6,199; France 2,502; Netherlands 1,862.
Lubricants and nonlubricating oils do	[2]2,615	[2]2,164	--	Brazil 262; Italy 138; Austria 70; undetermined 1,494.
Other:				
Mineral jelly and wax do	[2]31	[2]14	--	Thailand 2; Turkey 2; Madagascar 1.
Petroleum coke do	[2]295	[2]585	--	Italy 82; undetermined 501.
Bitumen and other residues do	[2]38	[2]24	--	Austria 19.
Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals	[2]68,700	[2]57,800	([9])	Italy 17,323; France 14,931.

[p]Preliminary. [r]Revised.. NA Not available.

[1]Owing to the lack of official trade statistics published by Romania, this table should not be taken as a complete presentation of this country's mineral trade. Unless otherwise specified, these data have been compiled from United Nations information, data published by the partner trade countries, and partial official trade sources of Romania.

[2]Official Trade Statistics of Romania.

[3]Quarterly Bulletin of Steel Statistics for Europe, United Nations, New York.

[4]Destinations of steel semimanufactures exclude imports by Israel valued at $1,317,000, and Malta, valued at $413,000.

[5]May include waste and sweepings of silver.

[6]World Metal Statistics, World Bureau of Metal Statistics, London, United Kingdom.

[7]Excludes imports by Israel valued at $19,000.

[8]Less than 1/2 unit.

[9]The United States imported 851,683 barrels of naphtha.

[1]Owing to the lack of official trade statistics published by Romania, this table should not be taken as a complete presentation of this country's mineral trade. Unless otherwise specified, these data have been compiled from United Nations information, data published by the partner trade countries, and partial official trade sources of Romania.

[2]Less than 1/2 unit.

[3]Excludes exports from Israel valued at $6,000.

[4]Metallgesellschaft Aktiengesellschaft (Metallstatistik), Frankfurt am Main, West Germany.

[5]Official trade statistics of Romania.

[6]Quarterly Bulletin of Steel Statistics for Europe, United Nations, New York.

[7]Excludes exports from Norway valued at $112,000.

[8]Excludes exports from Australia valued at $1,483,000.

[9]Presumably largely bituminous; of total officially reported coal imports in 1979, 2,840,000 tons was described as washed pit coal for coke manufacture, and 1,005,000 tons was not further described. For 1980, 2,557,000 tons was described as washed pit coal and 1,395,000 tons was unspecified.

[10]Excludes portion of Japanese exports valued at $248,000.

COMMODITY REVIEW

METALS

In 1981, the Romanian steel industry employed over 119,000 production workers; nonferrous metallurgical and mining enterprises employed over 72,300 production workers. Estimated capital investment in iron mining and steel production exceeded 13 billion lei, and in the nonferrous sector, it exceeded 2.5 billion lei.

To improve the performance of the country's nonferrous mining and smelting industry, a state decree was issued establishing, on October 1, 1981, The Industrial Center for Nonferrous and Rare Metals (CIMNR). Established under the Ministry of Chemical Industry, the objectives of CIMNR were to extract aluminum, heavy metals, and rare metals from scrap and concentrate and to manufacture anodes, sulfuric acid, and other products. The following units were transferred to CIMNR:

(1) The Baia Mare, Copsa Mica, and Zlatna Metallurgical Enterprises for Nonferrous Metals as well as the Industrial School No. 3, including the Professional School for Metallurgy, were transferred from the Baia Mare Center for Ores and Nonferrous Metallurgy.

(2) The Slatina Aluminum and the Oradea Alumina Enterprises as well as the Neferal Metallurgical Enterprise, Bucharest, were transferred from the Slatina Center for Nonferrous and Rare Metals.

(3) The Tulcea Alumina Enterprise was transferred from the Tulcea Metallurgical Complex.

(4) The Moldova Noua Metallurgical Enterprise for Nonferrous Metals was transferred from the Deva Ore Center.

Aluminum.—Romania's aluminum industry was located in Slatina in Olt County. The industry's annual capacity was in excess of 250,000 metric tons, and apart from organizational changes described above, industry plans in 1981 were to maintain capacities that were already built and concentrate on increasing production efficiency as well as on the improvement and diversification of aluminum products. Reportedly, new rolling mill capacities were planned to grow by 20% to 25% in the 5-year period.

Also, a new 20,000-ton-per-year initial capacity cast components and motorcar pistons manufacturing enterprise was planned. Liquid aluminum alloys would largely be supplied from the Slatina aluminum complex.

Copper.—The main copper-producing area was in southern Banat region, in west-central Romania. The chief deposits were located along three major trends: the west Banat, the east side of the Resita geosyncline, and the Rudaria lineament.

The development of a new copper mine in the Baia de Arama area of Mehedinti County was reported. A flotation plant was begun, and initial concentrate production was scheduled for the end of 1982. The recovery of about 60,000 tons of copper from secondary sources in 1981 was also reported.

Romania was active during 1981 in a variety of international joint copper mining and mine development ventures with the major aim of assuring sources of imported copper. Among these was work conducted until the end of December on the Antamina copper-zinc deposit in Peru by the joint Romanian-Peruvian Antamina company; studies were conducted to determine whether ore production from the deposit at a rate of 10,000 to 20,000 tons per day was feasible. However, on December 13, partnership was officially dissolved owing to the venture's inability to provide necessary scheduled financing. The ownership of the mine reverted to Empresa Minera del Perú with Romania receiving nominal value compensation for its investment. Geomin of Romania will also have the option to purchase 15% of the concentrate for 15 years after production startup. The proven ore reserves at the deposit are 166 million tons, assaying 1.3% copper, 1.1% zinc, 0.48 ounce of silver per ton, and 0.04% molybdenum.

A copper exploration agreement was undertaken by the joint Romanian-Chilean company, Coemin, and other similar arrangements were reported with Mozambique and Zambia.

Gold.—Gold has been mined in Romania since antiquity. Auriferous ores were found in the country's polymetallic deposits as well as in placer beds. Romanian geologists in 1981 discovered new gold deposits that were said to have favorably increased the country's reserves of this metal. Research was planned toward extending known deposits as well as developing new regions, especially in the Apuseni Mountains, in the Banat region, and in the eastern Carpathians. During the 1981-85 5-year period, the Banat and the Fagaras Mountains would be evaluated for precious metal potential by studies of old crystalline formations and associated alluvial deposits.

Romania became a consistent exporter of gold beginning in May 1981, and in 1981 was reported to have sold 20.3 tons of gold on the Swiss market.

Iron and Steel.—A number of new installations in the iron and steel industry came onstream. A third ferrochromium furnace was put into operation at Tulcea with a 52,000-ton-per-year capacity; two additional furnaces were planned for startup in 1981 for the production of ferrosilicon. The Iasi heavy engineering complex also put into operation its first 50-ton electric-furnace shop. The shop was to be equipped with 10-, 20-, 50-, and 100-ton furnaces that would produce ingots ranging from 5 to 400 tons.

The first 350,000-ton-per-year medium sheet rolling mill was put into operation at the Calarasi iron and steel complex, completing its first stage of development. Also the construction of the No. 6 2,500-cubic-meter blast furnace was completed at the Galati iron and steel complex in 1980, and the first production of pig iron was scheduled for the second half of 1981. At the Calan metallurgical plant in Hunedoara, the first domestically produced 330,000-ton-per-year metallurgical coke battery was put into operation.

Romania's steel production, by process, was approximately 44% oxygen, 19% electric, and 37% open hearth. In 1981, about 6.4 million tons of steel was produced from recycled scrap.

In 1981, Romania had extensive trade and cooperative agreements in the iron and steel area; however, alleged dumping charges and suits were leveled against Romania by several European nations as well as the United States. The charges alleged that Romanian steel plates and pipes were sold abroad below manufacturing costs.

Lead and Zinc.—Romania continued to mine the major portion of its lead-zinc ores at the Baia Mare mining complex. The concentrate was smelted at the Copsa Mica smelting facilities in the central part of the country.

From all indications, Romania's ambitious planned production increases of 13.9% for lead and 8.9% for zinc over the 1980 level were not met, and after the installation of the electrolytic lead facilities at Copsa Mica, no new capacities were

announced for the year. Romania did, however, report a production of 11,400 tons of zinc from recycled secondary raw materials.

Silver.—Increased exploration of argentiferous ores in the Apuseni Mountains and the eastern Carpathians was undertaken by the Ministry of Geology in 1981. In Romania, silver, as well as gold, was produced in association with copper, lead, and zinc ores.

NONMETALS

Cement.—In 1981, the output of cement by the country's 12 plants actually dropped to just over the 1978 output level. Few details were provided on the industry during the year, and most of the activities within the industry were conducted abroad with the cement plants reported under construction in North Korea, Iraq, and Turkey with Romanian participation.

Clays.—Romania produced a variety of clays but was apparently unable to fully meet domestic needs for this mineral. Although the country did not publish production statistics, various foreign trade sources indicated past Romanian purchases of this commodity.

To fully meet domestic requirements, Romania's Ministry of Geology, in 1981, was directed to increase efforts aimed at finding new clay deposits, as well as other nonmetallic minerals such as talc, sands, limestones, and ornamental rocks. Refractory clays were found in the Alun region of the Padurea Craiului Mountains, as well as kaolin-bearing rocks at Stejera.

Fertilizers.—Romania's chemical industry produced a variety of simple and complex fertilizers. With an abundance of methane gas, the country has become a substantial producer of nitrogenous fertilizers. Apart from centrally planned domestic needs, nitrogenous fertilizer was exported, which in large measure helped offset the import cost of potash and phosphate rock.

Romania's agricultural and soil conditions required an average nitrogen, phosphorus, and potassium nutrients ratio (N:P:K) of 1.9:1.0:0.4. Chemical fertilizer complexes at Fagaras, Craiova, Turnu Magurele, Arad, Slobozia, Bacau, etc., were well distributed throughout agricultural regions of the country. Romania's weighted output of both simple and complex fertilizers by 1981 was as follows:

Type	Percent
Simple fertilizers:	
Superphosphate	3.4
Triple superphosphate	5.4
Carbamide	33.3
Ammonium nitrate (including nitrocalcite)	20.3
Ammonium sulfate	2.0
Total	64.4
Complex fertilizers:	
Nitrophosphates	32.6
Diammoniac phosphate	3.0
Total	35.6
Grand total	100.0

In 1981, Romania reported the startup of a 197,000-ton-per-year urea plant at Bacau in the eastern part of the country. The plant was based on Stamicarbon technology and was constructed with know-how and engineering input from Coppee-Rust.

Sulfur.—Romania's domestic production of sulfur came primarily from pyrites, although the most significant development in 1981 was the continued development at the Calimani sulfur project at Suceava. The Suceava deposit was reported to be the largest native sulfur deposit ever found in Romania. A 20-kilometer access road was under construction, and some 1,200 workers in addition to mining complex personnel were employed in the removal of rock overburden. The project called for more than 200 dump trucks, over 20 excavators, and over 30 bulldozers. The project was to come onstream late in 1981 after the removal of about 1 million cubic meters of overburden and the initial exposure of 100,000 tons of sulfur.

MINERAL FUELS

In 1981, Romania was able to meet planned objectives only for the production of methane gas. Crude petroleum output showed some gain over that of the preceding year but did not meet planned goals. Net coal production fell short of planned output requirements by over 13 million tons.

Table 5.—Romania: Primary energy balance

(Million tons of standard coal equivalent)[1]

	Total primary energy	Coal (lignite, anthracite, bituminous coke)	Crude oil and petroleum products	Natural and associated gas	Hydro-power
1980:					
Production[2]	82.3	17.0	16.9	46.9	1.5
Exports	11.7	--	11.0	.3	.4
Imports	31.9	6.2	23.5	2.0	.2
Apparent consumption	102.5	23.2	29.4	48.6	1.3
1981:					
Production[2]	82.3	16.7	17.2	46.9	e1.5
Exports	12.7	--	12.0	.3	.4
Imports	28.2	6.0	22.0	--	.2
Apparent consumption	97.8	22.7	27.2	46.6	1.3

eEstimated.

[1]1 ton of standard coal equivalent (SCE)=7,000,000 kilocalories. Conversion factors used are hard coal, 1.0; lignite and brown coal, 0.33; coke, 0.9; crude oil, 1.47; natural gas, 1.33 (per 1,000 cubic meters); and hydroelectric power, 0.123 (per thousand kilowatt-hours).

[2]Production from production table and from Anuarul Statistic Republicii Socialiste Romania, 1981, Bucharest, 1981.

Coal.—Faced with serious production shortfalls in 1981, Romania planned substantial production increases in 1982 that would set output at about 44 million tons of lignite and pit coal. By 1985, an estimated annual 96-million-ton production level was set. The Jiu Valley in Oltenia County remained the country's principal coal mining area; located in the southern Carpathian region, the Jiu Valley, with a commercial reserve base of 1 billion tons, produced 90% of Romania's lignite and about 25% of its bituminous and anthracite coal.

During the year, worker unrest was alleged at the Jiu Valley coal mining area owing to food shortages, which may have, in part, contributed to the industry's dislocations during the year.

In 1981, Romania reported the reopening of three coal mines in the Trotus Valley; the renewed operation at these mines was said to have led to discoveries of new seams that could be exploited for an estimated 15 years. It was also reported that facilities were expanded at the Leurda lignite mine in the Motru Valley that would raise output by 5,000 tons per day.

Nuclear Power.—Romania reported construction progress on the country's first nuclear powerplant at Cerna Voda. The excavation of the foundation for the Canadian-built Candu reactor was completed, and the first reactor block was scheduled for startup in 1985. Romania is the only CMEA country to have initiated its nuclear power development without resorting to Soviet technology.

Petroleum and Natural Gas.—Romania's production plan for 1982 called for the production of 12.5 million tons of crude oil and 33,000 million cubic meters of natural gas. In 1981, the industry reported a significant offshore oil discovery. The Gloria location in the Black Sea, some 30 miles offshore, was reported to contain light crude and gas in 150 feet of water. Romanian authorities expressed interest in obtaining the cooperation of U.S. oil companies to help develop the deposit, and preliminary discussions were held with Standard Oil of Indiana and Occidental Petroleum, among others.

Shale (Bituminous).—Romania's principal shale deposits, with a calorific content of 980 to 1,200 kilocalories per kilogram, were located in the southwest in Caras-Severin County. Doman and Anina, the two main deposits, were reported to contain substantial reserves, and it was planned to mine them by open pit methods; the mined product would be supplied to a planned thermoelectric power station. Shale output by 1985 was estimated at 10 million tons per year.

[4]The Romanian lei is a nonconvertible currency, whose relation to the U.S. dollar is based upon the fluctuation of the dollar-lei ratio. The rate of dollars to lei is US$1.00=Lei4.47 (official commercial rate, July 8, 1981). The conversion of Romanian national income and foreign exchange accounts into U.S. dollars was not done, owing to different criteria used in determining value in centrally planned economies as opposed to those used in market economies.

The Mineral Industry of Saudi Arabia

By Peter J. Clarke[1]

Revenues from petroleum exports, in excess of $100 billion, continued to fuel the rapid development of the Saudi economy in 1981. Production of crude oil averaged 9.945 million barrels per day during the year, up only 0.18% from the 1980 level. Petroleum revenues reached $101.2 billion[2] for 1981, up from $85 billion the year before. These revenues were the mainstay of the Saudi economy, generating 60% of the 1981 gross domestic product (GDP) of approximately $130 billion, 90% of Government revenues, and 88% of the Kingdom's total exports, valued at $115 billion in 1981. Major Saudi exports, in order of decreasing value, were crude oil, refined petroleum products, and natural gas liquids (NGL).

Economic and social development in Saudi Arabia was implemented under the guidelines of 5-year economic development programs, the third of which began in 1981. In the second 5-year plan, over 50% of the Kingdom's resources were allocated for infrastructure development to remove bottlenecks and increase the country's capacity to absorb large industrial investments. Under the first two plans, GDP has tripled, gross fixed capital formation has increased about 45% per year, and per capita income has more than doubled to the current level of about $15,000. Along with these economic developments, over 20,000 kilometers of roads, five major seaports, and three international airports were built. Electricity, telecommunications, and water distribution networks were extended to even the most remote villages. The third development plan, 1981-85, was intended to build upon these achievements, while gradually shifting the emphasis away from basic infrastructure to productive investments, such as heavy industry, agriculture, and mining. Total Government expenditures during the plan period were estimated at $236 billion, excluding military expenditures.

The largest of these investments was in the oil sector, where development of downstream processing industries was rapidly taking place. The Saudi Government has concentrated its efforts at two major industrial centers, Jubail on the East coast and Yanbu on the Red Sea. Jubail was to be the site for 2 major export-oriented oil refineries, 6 major petrochemical plants, a fertilizer plant, an iron and steel mill, secondary support industries, and a residential community for 300,000 people. Yanbu made its first step in becoming a major crude oil and NGL export terminal in 1981, with the completion of Petroline, the two parallel crude oil and NGL transpeninsular pipelines. A major crude oil and NGL loading terminal at Yanbu gave Saudi Arabia its first oil outlet on the Red Sea, thus avoiding the Persian Gulf and vulnerable Strait of Hormuz. Yanbu was also to house a NGL processing plant, an export and lube oil refinery, and a petrochemical plant. Also nearing completion was the Saudi gas system, to collect, process, and transport over 3 billion cubic feet per day of associated gas that will provide feedstock for petrochemical production, fuel for industry, power generation, and desalinization of seawater. The system was 75% complete at the end of the year. Total contracts awarded for the two industrial areas were valued at $7.8 billion in mid-1981.

The nonoil sector of the economy was also receiving considerable attention under the third 5-year plan, as part of a concerted effort by the Government to diversify the economy away from oil dependence. Growth rate of the nonoil GDP was 12% in 1981,

double the rate envisioned by the plan and about the same as in 1980. Growth in nonoil GDP was primarily a result of Government expenditures for infrastructure and basic services for Saudi Arabia's booming construction industry. The private nonoil economy also expanded rapidly in 1981, at a rate of 13%. Advances in the private sector were generated mainly by the trade and services sector, as a result of the high level of imports required by an expanding economy.

As part of its intention to develop the nonoil resources of the Kingdom, the Saudi Arabian Government issued, along with the economic plan, a 5-year mineral development plan. Development of nonfuel minerals in Saudi Arabia was under the direction of the Directorate General of Mineral Resources (DGMR). Petroleum and hydrocarbon exploitation was controlled by the General Petroleum and Mineral Organization (Petromin). Both the DGMR and Petromin were agencies of the Saudi Arabian Government. To induce foreign and domestic companies to invest in mineral development, the Kingdom offered a liberal mining code, well-established precedents for joint-venture arrangements with Petromin, interest-free loans of 50% of the capital investment with a Saudi partner, and a 5-year tax holiday. Eight mineral exploration permits were issued during the year to private companies, mostly for metallic minerals in the Arabian Shield. In addition to these companies, geologic mapping and mineral exploration was being conducted by the U.S. Geological Survey (USGS), the French Bureau de Recherches Géologiques et Minières (BRGM), Hunting Survey's Ltd. (United Kingdom), Shell Minerals Exploration-Saudi Arabia, and British Steel Corp. Two mineral projects were also nearing implementation in 1981. Consolidated Gold Fields and Petromin were going ahead with plans to develop the Mahd Adh Dhahab gold deposit in the Arabian Shield, and Saudi Arabia and Sudan were operating a pilot plant to extract several metallic minerals from the floor of the Red Sea.

The amount of revenues realized from oil exports and other sources that was not spent under the budget, or used for other purposes, constituted Saudi Arabia's petrodollar surplus. The surplus for 1981 was estimated at about $20 billion. The Saudi Arabian Monetary Agency (SAMA) was responsible for investing these surpluses to receive a maximum return. SAMA total assets at the end of 1980 were estimated at nearly $100 billion. Saudi investment income from these assets was estimated at about $5 billion in 1981. SAMA investments were mostly in Government guaranteed bonds and in blue-chip corporate securities. Estimates placed about 80% of SAMA investments in dollar-denominated securities, but with less than 50% in the United States itself.

Overall, 1981 was a year of tremendous achievement for Saudi Arabia. Its status in international financial markets was recognized in May 1981, when an agreement with the International Monetary Fund (IMF) was signed, allowing the latter to borrow up to $4.7 billion from SAMA over a period of 6 years. This effectively doubled the SAMA contribution and was considered a substantial achievement in the effort to recycle petrodollars, strengthen the IMF, and the international monetary system.

The Saudi prevailed on the Organization of Petroleum Exporting Countries (OPEC) pricing issue, for which they had fought for over a year. In October 1981 at the Geneva OPEC conference, Saudi pressure led to the unification of the OPEC pricing structure around the benchmark Arabian Light (34° API) at $34 per barrel. The Saudi had produced over 10 million barrels of oil per day and flooded world markets for most of the year to force price retrenchment by other OPEC member states. Their ability to influence the world oil market and gain acceptance of their pricing policy was a major step in the Saudi plan to become a leader of the moderate Arab world and allow OPEC to speak with a unified voice.

PRODUCTION

Production of crude oil in Saudi Arabia increased slightly in 1981, to 3.63 billion barrels. This production reflects an average daily output of nearly 10 million barrels per day. Production was raised in October 1980 from 9.5 to 10.5 million barrels per day to help supply countries left short by the loss of supplies from Iran and Iraq. Production was maintained at this level through the first 5 months of 1981, creating an oversupply situation in the world market. The Saudi used their output to prevent another round of price increases in the wake of the Iran-Iraq war, and to keep a downward

pressure on spot, or noncontract, crude oil prices. The price of Arabian Light stood at $32 per barrel from November 1980 to October 1981, when it was raised to $34 per barrel, where it remained for the rest of the year. Spot prices fluctuated slightly below the official level and reached a low of $29 per barrel by the end of the year. In October, following the OPEC conference, Saudi Arabia cut its production to 8.5 million barrels per day, where it remained through yearend.

Production of refined products continued to increase, mainly owing to the large-scale expansion program underway in the Saudi refining industry. Output of refined products averaged about 950,000 barrels per day in 1981, up 3.6% from the 1980 level. New refinery capacity was added at Riyadh, and another addition was expected in 1982 at Jeddah. Three major export refineries, at Jubail, Yanbu, and Rabigh, were to come onstream by 1985, as well as two domestic refineries and six lubrication oil refineries. With all this new capacity onstream, Saudi Arabia was to be capable of exporting over 400 million barrels per year of refined products by the mid-1980's.

The other major oil-related development in Saudi production capacity was the implementation of the massive master gas system (MGS), capable of processing 3 billion cubic feet per day of associated gas and turning it into feedstock for one of the largest petrochemical projects in the world. Saudi Arabia produced about 140 million barrels of NGL in 1981, nearly all of which was exported. When all phases of the MGS are completed, output of NGL was to more than double. Downstream processing facilities were to transform methane into ethane for use in developing the Saudi petrochemical industry.

In addition to refined products and NGL, petrochemicals represented the long-term future of the Saudi downstream processing industry. Eight petrochemical projects were to be constructed in Jubail and Yanbu by 1985, producing primary petrochemicals for the world market. The Saudi stated goal was to capture 5% of the world chemical market by 1990. To bring these projects to reality, several of the world's largest oil and chemical companies were participating as joint-venture partners. The first of these plants was due onstream in 1983.

Nonfuel mineral production in Saudi Arabia was also expanding in 1981. Production of nitrogenous fertilizer increased 4% in 1981 from the 1980 level and is scheduled to undergo large-scale expansion when the Jubail Fertilizer Co. plant comes onstream in 1983. The plant is to produce 580,000 tons per year of urea fertilizer, mainly for export. Sulfur production is also expected to increase dramatically as a byproduct of petroleum refining. Sulfur production capacity was to increase to 1.6 million tons per year by the middle of the decade.

Construction materials, mainly iron, steel, and cement, were in great demand in Saudi Arabia. To satisfy domestic requirements, the Saudi Iron and Steel Co. was constructing an 800,000-ton-per-year, direct-reduction steelworks at Jubail, to be completed by 1983. Output from the Jeddah steel rolling mill was also expanded, from 80,000 to 140,000 tons per year, in 1981. The cement industry was also given a considerable boost in 1981 through the addition of 3.8 million tons per year of new capacity. Current capacity of the cement industry was 5.2 million tons per year, but was to expand to 13 million tons per year by 1985 through the addition of four new plants. Saudi Arabia expected to be self-sufficient in iron, steel, and cement production by the mid-1980's and still have a moderate surplus for export. Total mineral production in Saudi Arabia is shown in table 1.

[3]Includes Saudi 1/2 share of production in the Kuwait-Saudi Arabia Partitioned Zone.

TRADE

Saudi balance-of-payments surplus continued to grow in 1981, led by a rise of almost 20% in the value of oil and gas exports. The merchandise trade balance showed a surplus of $76.5 billion in 1981, up 7% from the 1980 level. Oil exports, including NGL, rose by 11% in 1981 over the 1980 level. Of the total oil exports, refined products accounted for 5%; bunker fuel, 1%; and crude oil, the remaining 94%. Nonoil exports were negligible in 1981 but were to increase significantly when the petrochemical projects come onstream.

Total imports by Saudi Arabia reached $40 billion in 1981, up 22% from the 1980 level. Real growth in imports, after inflation and exchange rate adjustments, was estimated at 15%. Imports by the private sector rose 20% to $34.5 billion, representing 86% of total imports. About 80% of Saudi imports originated in 14 major industrial countries.

Oxides and hydroxides	14	20	--	Bahrain 15; Somalia 5.
Metal including alloys:				
Scrap	--	48	--	Kuwait 37; Somalia 5; Yemen Arab Republic 5.
Unwrought	47	102	--	Somalia 90; Yemen Arab Republic 6.
Semimanufactures	239	980	--	Lebanon 328; Somalia 231; Syria 111.
Other:				
Ores and concentrates	--	62	--	Kuwait 34; Jordan 27; Yemen Arab Republic 1.
Alkali, alkaline-earth, rare-earth metals	87	7	--	All to Qatar.
Metalloids	99	215	--	Lebanon 150; Jordan 64.

See footnotes at end of table.

Table 2.—Saudi Arabia: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	5	51	--	Kuwait 33; Yemen Arab Republic 18.
Grinding and polishing wheels and stones	41	16	--	Yemen Arab Republic 13; Bahrain 2; People's Democratic Republic of Yemen 1.
Asbestos, crude	83	11	--	All to Yemen Arab Republic.
Boron materials: Crude natural borates	--	3	--	Do.
Cement	4,775	27,409	--	Spain 16,200; Yemen Arab Republic 10,268; Somalia 528.
Chalk	(1)	2	--	All to Yemen Arab Republic.
Clays and clay products:				
Crude	412	226	--	Kuwait 120; United Arab Emirates 100.
Products:				
Nonrefractory	134	374	--	Yemen Arab Republic 254; Somalia 56; Bahrain 27.
Refractory including nonclay brick	109	756	--	United Arab Emirates 608; Kuwait 113; Lebanon 23.
Diatomite and other infusorial earth	771	1,284	--	Kuwait 942; Burma 140; Jordan 140.
Fertilizer materials:				
Crude:				
Nitrogenous	14,138	10,023	--	China 10,000; Yemen Arab Republic 16.
Other including mixed	156	111	--	Kuwait 60; Yemen Arab Republic 32; Netherlands 19.
Manufactured:				
Nitrogenous	94,072	170,908	4,000	Pakistan 51,617; Bangladesh 43,913; India 34,150.
Phosphatic	5,269	41,518	--	China 10,000; India 8,500; United Kingdom 6,700.
Other including mixed	115	10,001	--	Bangladesh 10,000; Yemen Arab Republic 1.
Ammonia	364	61	--	Qatar 41; Syria 12; Kuwait 8.
Gypsum and plasters	7,566	6,127	--	Kuwait 5,694; Qatar 195; Bahrain 184.
Lime	2,600	2,311	--	Yemen Arab Republic 2,018; Kuwait 92; Jordan 90.
Mica: Worked including agglomerated splittings	--	148	--	United Arab Emirates 133; Jordan 14.
Pigments, mineral: Iron oxides, processed	--	7	--	All to Kuwait.
Salt and brine	1,980	3,440	--	Kuwait 2,843; Jordan 320; Yemen Arab Republic 236.
Sodium and potassium compounds, n.e.s.:				
Caustic soda	932	135	--	Kuwait 125; United Arab Emirates 10.
Soda ash	--	3	--	All to Yemen Arab Republic.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	54	120	--	Yemen Arab Republic 83; United Arab Emirates 34.
Worked	257	1,406	--	Yemen Arab Republic 592; United Arab Emirates 359; Greece 226.
Gravel and crushed rock	133	553	--	Kuwait 488; Jordan 40; Yemen Arab Republic 14.
Sand excluding metal-bearing	142	164	--	United Arab Emirates 122; Qatar 36.
Sulfur:				
Elemental, all forms	76	126	--	Yemen Arab Republic 97; Qatar 17; Somalia 12.
Sulfuric acid, oleum	--	522	--	Qatar 515; Yemen Arab Republic 7.
Other:				
Crude	25	272	--	Kuwait 188; Yemen Arab Republic 44; Somalia 24.
Slag, dross, similar waste, not metal-bearing	--	26	--	NA.
Halogens	10	24	--	All to Kuwait.
Oxides, hydroxides, peroxides of barium, magnesium, strontium	117	--		
Building materials of asphalt, asbestos and fiber cements, unfired nonmetals	886	714	--	United Arab Emirates 407; Oman 185; Somalia 24.

See footnotes at end of table.

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	5	15	--	All to Yemen Arab Republic.
Carbon black	--	18	--	Do.
Coal:				
Anthracite and bituminous coal	1	4,301	--	Yemen Arab Republic 4,287; Lebanon 8; United Arab Emirates 6.
Lignite including briquets	--	38	--	All to Yemen Arab Republic.
Hydrogen, helium, rare gases	19	86	--	Lebanon 64; Kuwait 6.
Peat including briquets and litter	--	1	--	All to Yemen Arab Republic.
Petroleum and refinery products:				
Crude and partly refined thousand 42-gallon barrels	3,218,497	3,353,796	543,232	France 320,040; Netherlands 228,711; Italy 212,171.
Refinery products:				
Gasoline do	NA	45,245	3,623	Japan 18,428; Netherlands 4,007; Italy 3,942.
Kerosine and jet fuel do	84	164	--	Yemen Arab Republic 35; India 34; France 31; Netherlands 31.
Distillate fuel oil do	NA	4,023	--	Oman 479; United Arab Emirates 479; Brazil 361.
Residual fuel oil do	NA	38,968	--	Japan 4,327; Republic of Korea 2,022; Singapore 1,711.
Lubricants do	65	118	--	France 52; Iran 30; Somalia 27.
Other:				
Liquefied petroleum gas do	NA	90,637	1,533	Japan 63,482; Netherlands 7,381; Spain 6,868.
Mineral jelly and wax do	--	(1)	--	Mainly to Yemen Arab Republic.
Bitumen and other residues do	1	25	--	Yemen Arab Republic 24.
Total refinery products including bunkers do	177,792	179,180		
Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals	7,029	9,341	--	India 5,000; Iran 4,250.

NA Not available.

METALS —Continued				
Copper:				
Ore and concentrate	(1)	40	--	All from West Germany.
Matte and speiss	26	9	(1)	India 8.
Metal including alloys:				
Scrap	2,013	20	--	Australia 15; Japan 4.
Unwrought	87	73	13	France 38; West Germany 17.
Semimanufactures	11,222	16,633	3,896	Australia 6,054; Japan 2,951; United Kingdom 1,049.
Iron and steel:				
Ore and concentrate including roasted pyrite	115	49,128	--	India 49,127.
Metal:				
Scrap	38,471	1,198	220	Japan 317; Lebanon 61; Belgium-Luxembourg 55.
Pig iron, ferroalloys, powder, shot	52,738	57,460	418	Netherlands 14,263; Qatar 11,649; India 9,529.
Steel, primary forms	294,548	91,401	376	Japan 48,357; Republic of Korea 12,611; West Germany 4,130.
Semimanufactures:				
Bars, rods, angles, shapes, sections thousand tons	1,781	1,805	15	Japan 806; Republic of Korea 295; North Korea 90.
Universals, plates, sheets	360,765	337,379	15,758	Japan 239,237; West Germany 17,555; Greece 14,109.
Hoop and strip	8,807	9,698	268	Japan 5,136; Romania 1,037; West Germany 638.
Rails and accessories	19,112	11,492	954	West Germany 3,586; Spain 2,536; Republic of Korea 1,025.
Wire	17,752	32,060	269	West Germany 9,822; China 4,823; Republic of Korea 4,118.
Tubes, pipes, fittings	466,512	610,352	64,223	Japan 219,605; West Germany 43,538; Republic of Korea 38,990.
Castings and forgings, rough	106,979	117,776	22,010	Japan 17,485; Italy 17,438; West Germany 14,932.
Lead:				
Ore and concentrate	38	153	--	Morocco 91; Belgium-Luxembourg 44; Italy 18.
Oxides and hydroxides	43	97	(1)	West Germany 60; United Kingdom 36.
Metal including alloys:				
Scrap	374	967	459	United Kingdom 95; Kuwait 87; Lebanon 69.
Unwrought	616	1,504	31	United Kingdom 413; Kuwait 412; Lebanon 189.
Semimanufactures	2,707	3,626	151	Lebanon 1,067; West Germany 1,042; Sweden 189.
Magnesium metal including alloys:				
Scrap value, thousands	--	$3	--	All from Belgium-Luxembourg.
Unwrought and semimanufactures	90	19	10	United Kingdom 4; Bahrain 1.
Manganese:				
Ore and concentrate	2,133	--	--	
Oxides and hydroxides	73	44	--	Belgium-Luxembourg 43; West Germany 1.
Mercury 76-pound flasks	6,237	48,850	14	West Germany 38,523; United Kingdom 5,889; Italy 2,785.
Molybdenum metal including alloys, all forms	19	28	21	Italy 6.
Nickel:				
Ore and concentrate	29	36	--	All from Italy.
Matte and speiss value, thousands	$1	--		
Metal including alloys: Semimanufactures	106	200	7	Japan 138; Italy 34; West Germany 10.
Platinum-group metals including alloys, unwrought and partly wrought value, thousands	$57	$40	$13	West Germany $18; Afghanistan $5; Morocco $4.
Silver:				
Ore and concentrate[2] do	$1	--		
Waste and sweepings[2] do	$52	$59	$5	Italy $48; Czechoslovakia $5.
Metal including alloys, unwrought and partly wrought do	$1,085	$10,215	$5	Netherlands $5,410; Switzerland $1,807; Lebanon $1,663.

[1]Less than 1/2 unit.
[2]May include platinum-group metals.

COMMODITY REVIEW

METALS

Exploration and development work was being carried out in Saudi Arabia on several metallic minerals in 1981. Prospecting for metals focused primarily on two areas, base metals in the Arabian Shield in northwest Saudi Arabia and metalliferous muds on the floor of the Red Sea. In the Arabian Shield, nearly 100 prospects were identified by various organizations, including the USGS, BRGM, Rio Tinto Finance and Exploration Ltd. (Riofinex), and DGMR.

The Shield itself has evolved from a complex geologic history, the evidence for which is a rapid lateral facies variation from the Red Sea coast eastward. Mineralization in the Shield reflects the complexity of changes in the Pre-Cambrian geological environment from oceanic, to volcanic, to continental in nature. The early stages near the Red Sea contain podiform chromite deposits at the base of ophiolite complexes such as at Al Ays. In the volcanic stage further to the east, the rocks contain gold at Mahd Adh Dhahab, copper at Jebal Sayid, and iron at Wadi Sawawin. Later mineralization reflects the continental environment, with formation of alkaline granites and concentrations of rare-earth elements. The most promising prospects in the Shield, the ones that the Saudi Government planned to develop, were gold at Mahd Adh Dhahab, copper at Al Masani and the Ad-Dawadimi-Jebal Sakhen Basin, and iron ore at Wadi Sawawin.

Development work on the metalliferous muds of the Red Sea progressed during 1981, with a positive recommendation from a feasibility study carried out by Preussag (Federal Republic of Germany). Completion of the study cleared the way for construction of a pilot project to process samples brought to the surface. The project was under the direction of the Saudi-Sudanese Authority for the Exploitation of Red Sea Resources. The deposits being considered were metal-rich muds in deep brine pools of the Atlantis II Deep Basin along the center of the Red Sea floor. The muds consist of layers of sulfide minerals, mainly sphalerite and chalcopyrite, alternating with oxides and silicates. Eighteen brine pools have been identified, containing a total of 17 minerals. The minerals thought to be commercially exploitable were lead, zinc, copper, silver, platinum, and cadmium. The most promising single pool contains an estimated 2.5 million tons of zinc, 500,000 tons of copper, and 9,000 tons of silver.

Sudan and Saudi Arabia reached agreement on joint ownership of the deposits. Sudan was unable to finance any of the exploration or development costs, however, so Saudi Arabia was covering the $28 million cost of the feasibility study and the $166 million for the pilot project to mine the deposit. The project was to be implemented in four stages, the first two of which were completed in 1981. The first stage included geophysical and oceanographic surveys of the Atlantis II Basin. The second stage involved comprehensive environmental studies, development of mining and processing technology, prepilot mining tests, and training of personnel. The third stage, scheduled to start in 1982, was the pilot mining and processing stage. The mining process, developed by Orenstein and Koppel AG of the Federal Republic of Germany, was to suction pump the brine-mud mixture from the sea floor to a processing ship, most likely a refitted ore carrier. The mixture was to be processed onboard into a concentrate containing about 5% copper, 32% zinc, and 0.07% silver. The concentrate was then to be shipped by barge to a smelting-refining complex, possibly located at Yanbu. Residual slurry was to be pumped back into the sea and allowed to settle. The fourth and final stage was commercial production, scheduled to start in 1988. The estimated value of ores in the basin was over $3.5 billion, and with almost all the legal, technical, economic, and environmental studies yielding positive results, the project appeared closer than ever to realization.

Aluminum.—Saudi activity in the aluminum industry in the Middle East has been confined to participation in two major projects, both outside the Kingdom, while developing its own extrusion and fabricating facilities. The significant downturn in the metals market in 1980 led to the cancellation of plans to build a 200,000-ton-per-year aluminum smelter in the Jubail industrial zone. In 1980, Bahrain decided to expand the capacity of its aluminum smelter from 126,000 to 170,000 tons per year, and Dubai commissioned the gulf's second smelter, with a capacity of 135,000 tons per year. Saudi Arabia had acquired a 20% interest in Aluminum Bahrain (Alba) in 1978.

In February 1981, Saudi Arabia and five other Persian Gulf nations signed a joint-venture agreement to establish the Gulf Aluminum Rolling Mill Co. at a cost of about $100 million. The plant, to be located in Bahrain, was to produce 40,000 tons per year of semifabricated aluminum products to be sold mainly in the gulf area. The mill was to use primary aluminum from the Alba smelter. Equity holders in the venture were Saudi Arabia, Bahrain, Kuwait, and Iraq, 20% each, and Oman and Qatar, 10% each. Kaiser Engineering won a consulting contract for the mill late in the year, and tenders for construction of the plant were to be invited before the end of 1982.

A single aluminum extrusion plant was operating in Saudi Arabia during the year at Dammam. Aluminum Products Co. brought the 5,000-ton-per-year plant into operation in 1978. There were approximately 45 other aluminum fabricating plants operating in the Kingdom in 1981, with a combined capacity of 40,000 tons per year, most of which produced aluminum doors, windows, and household manufactures for the local market.

Copper.—Exploration work was continuing on a copper deposit in the Al-Masani area, 200 kilometers northeast of Jeddah. The Arabian Shield Development Co., a joint venture of Watts, Griffis and McQuat Ltd. (Canada) and the Saudi Arabian National Mining Co., was conducting drilling tests in the area, financed by an $11 million interest-free loan from the Saudi Ministry of Finance. The deposit contained copper, lead, zinc, silver, and gold, in a north-south trending shear zone 30 meters wide and over 5 kilometers long. Petromin indicated that exploitation of the deposit could begin by 1984.

The main Saudi consumer of copper was the Saudi Cable Co., the Kingdom's first and only electrical wire and cable manufacturing company. In 1981, NKF Groep S.V., a wholly owned subsidiary of Phillips of Holland, signed an agreement making NKF a technical partner in the company. Capacity of the plant, located in Jeddah's industrial estate, was to increase from 16,500 to 27,500 tons per year of metal wire equivalent or about 50,000 tons per year of cable. The plant manufactured building wires, low-tension power cable, bare copper wire, aluminum conductors, polyvinyl chloride-insulated copper conductors, steel tape armor, and four conductor cables. Under the expansion project, the company was to begin producing medium- and high-tension wires, insulated copper and aluminum conductors, and other products. The company's products were specially designed for Saudi Arabia's high-temperature conditions. Since opening in 1978, the company's sales have risen from $4 million in 1978 to $76 million in 1981.

Gold.—After completing the initial feasibility study, Consolidated Gold Fields (United Kingdom), in conjunction with Petromin, decided to go ahead with plans to exploit the gold deposit located at Mahd Adh Dhahab, 280 kilometers northeast of Jeddah. Consolidated Gold Fields began exploration work in the Arabian Shield in 1976, and following the discovery of gold, Petromin took a 50% share in the operation in 1979. Further exploration of the deposit revealed evidence of an open pit mine that dated back to before 1,000 B.C. Location of the ancient works led to speculation that the mine may have been King Solomon's legendary Mines of Ophir. A similar gold deposit, 1 kilometer away, had been exploited by a joint United States-Saudi partnership between 1937 and 1954. The deposit at Mahd Adh Dhahab contained an estimated 1.2 million tons of ore, containing about 1 ounce of gold per ton, 4.3 ounces of silver per ton, and 0.8% copper. The joint venture to mine the deposit appeared likely to begin development work within a year. Commercial production was scheduled to start in 1983. Output was to be 3 tons of gold and 10 tons of silver per year. The mine was expected to remain productive for 10 years. Production costs for gold were estimated at $298 per ounce.

Iron and Steel.—A full-scale feasibility study was underway during the year to determine the economic potential of the Wadi Sawawin iron ore deposit, located in northwest Saudi Arabia near the Gulf of Aqaba. The deposit has been under investigation by the British Steel Corp. (BSC) since 1978, when BSC was awarded a $15 million contract to determine the tonnage and grade of the deposit. Initial estimates indicated the presence of 250 million tons of ore containing about 42% iron, with generally high levels of silica and phosphorus. The reserves appeared sufficient to establish a large-scale mining operation, but the ore was of insufficient grade to serve as feed for a direct-reduction process. The BSC was investigating the possibility of concentrating the ore for use in developing the Saudi steel industry. The DGMR proposed to mine

25,000 tons per year of ore and beneficiate it to a 65% iron concentrate at a plant to be built near Sawawin on the Red Sea coast. Pending development of the deposit, Saudi Arabia agreed to import 1 million tons of iron ore pellets from Brazil for the planned iron and steel complex.

One of the most ambitious Saudi nonoil development projects was the construction of an 800,000-ton-per-year steelworks, to be located at the eastern industrial complex at Jubail. The project was a joint venture of the Saudi Arabian Basic Industries Corp. (SABIC), 80%, and Korf Stahl of the Federal Republic of Germany, 20%. The Saudi Iron and Steel Co. (Hadeed) was to consist of two natural gas-based Midrex direct-reduction modules, three 120-ton electric arc furnaces, three six-strand billet casters, a bar mill, and a rod mill. The Midrex direct-reduction units were to be supplied by Lurgi Chemie and Huettentechnik (Federal Republic of Germany) at a cost of $210 million. Vöest-Alpine AG (Austria) was to supply the arc furnaces and billet casters at a cost of $237 million, and a consortium consisting of Mannesmann-Damag (Federal Republic of Germany) as consortium leader, Schloemann-Siemag (Federal Republic of Germany), Redec-Daelim Saudi Arabia, and Compagnie d'Enterprises Metalliques (France) was awarded a $225 million contract to supply the two rolling mills, along with ancillary facilities and related services. The first mill was to produce 6- to 32-millimeter reinforcing bars; the other, 6- to 12-millimeter wire rod coils. The combined output of the mills, 800,000 tons per year, was to be sold mostly on the domestic market, with any surplus being exported. Hadeed was to import 1 million tons of iron ore pellets, at a cost of $50 million, from Companhia Vale de Rio Doce (Brazil) under a 5-year supply agreement. The entire complex was scheduled to begin operation in 1983.

The Jeddah steel rolling mill recommenced production of reinforcing bars after undergoing a modernization, automation, and expansion project in 1979-80. Capacity of the plant, another joint venture of SABIC and Korf-Stahl, was upgraded from 80,000 to 140,000 tons per year of steel reinforcing bars. The plant reopened in September 1981 and produced about 50,000 tons of rebars by the end of the year, and 46,000 tons of this output was sold to the domestic construction industry. Steel ingots to supply the plant were imported from Europe, pending the availability of ingots from the Jubail steel complex.

The Saudi Steel Pipe Co., a joint venture of Rabiah and Nasser Co. (Ranco), Fahd Saja Saudi Arabia, and the Korean Steel Pipe Co., brought its 70,000-ton-per-year pipe plant onstream in November 1981. The plant, located in Dammam, was built at a cost of $30.7 million and was to begin producing spiral welded pipe at full capacity in February 1982. Most of the output was to be marketed in Saudi Arabia, with the remainder on order by Iraq.

The Industrial Co. for Castings and Sanitary Fittings in Riyadh, which began operating in 1976, was increasing its capacity in 1981. The company produced mainly manhole covers and frames in gray iron. Because of increasing demand, the company ordered a 20-ton hydraulic rotary furnace for its iron foundry from Monometer. The company already operated a 5-ton rotary furnace, also obtained from Monometer.

NONMETALS

Cement.—The Saudi cement industry was expanding rapidly in 1981, with two new plants providing 3.8 million tons per year of additional capacity. The Yanbu Cement Co. brought onstream a 2-million-ton-per-year cement plant early in the year. The plant, located at Ra's Baridi, 65 kilometers north of Yanbu, was the largest cement plant in the Kingdom to date. The plant was built by KHD Industrialagen AG (Federal Republic of Germany), at a cost of $100 million. The second plant to come onstream in 1981 was the Saudi Bahraini Cement Co.'s plant at Ain-Dar. The facility, built by Ishikawajima Harima Heavy Industries Co. (Japan), was approaching full capacity by the end of the year. Also nearing completion at the end of the year was the Southern Province Cement Co.'s facility at Gizan. Fuller Co. (United States) was providing two gyratory crushers, two raw ball mills, two finish ball mills, two rotary kilns, two clinker coolers, and SF preheaters with flash calciners. The plant was to be capable of producing 1 million tons per year of cement when it comes onstream sometime in 1982. Saudi planned and operating cement plants are shown in the following table.

Table 4.—The Saudi Arabian cement industry

Operating company	Location	Current capacity (thousand metric tons per year)	Planned capacity (thousand metric tons per year)	Year commissioned
Saudi Cement Corp	Hoffuf	1,000	XX	1978
Arab Cement Co	Jeddah	600	XX	1972
Yamama Saudi Cement	Riyadh	1,000	XX	1979
Yanbu Cement Co	Ras-Baridi	2,000	XX	1981
Quasim Cement	Buraydah	600	XX	1980
Saudi Bahraini Cement Co	Ain Dar	XX	1,800	1981
Saudi-Kuwait Cement Manufacturing Co	Khursaniyah	XX	2,500	1985
Southern Province Cement Co	Gizan	XX	1,000	1982
Arab Cement Co	Rabigh	XX	1,500	1983
Total		5,200	6,800	

XX Not applicable.

Two large cement plants were both in the planning stage in 1981. The Arab Cement Co. and Kloeks Homelth of the Federal Republic of Germany signed a $264 million contract to establish a new cement plant in Rabigh. The plant was to be capable of producing 1.5 million tons per year of cement. Part of the financing for the facility came from a $120 million loan from the Saudi Industrial Development Fund. The plant was scheduled for completion in 1983. Saudi Arabia and Kuwait signed an agreement in December 1981 to establish the largest cement project in the Middle East. The plant was to produce 2.5 million tons per year of clinker, for the production of portland cement. Krupp Polysius AG (Federal Republic of Germany) won the $235 million construction contract. The project was to make both Saudi Arabia, which owns 55% of the project, and Kuwait, which owns the other 45%, self-sufficient in cement. Work on the plant, to be located at Khursaniyah, 100 kilometers north of Dammam on the Dammam-Kuwait road, was to begin in 1983.

Fertilizer Materials.—The Saudi Arabian Fertilizer Co. (SAFCO) produced a record 342,000 tons of urea fertilizer in 1981, a 4% increase over the 1980 level. About 46,000 tons was consumed in the local market, and another 16,000 tons was exported to neighboring gulf nations. The bulk of production, 272,000 tons, was exported, mainly to China, India, and Bangladesh, with smaller quantities sold to Zambia, Sudan, and Kenya. The remaining 8,000 tons was held as inventory. In February 1980, SAFCO opened a 300-ton-per-day sulfuric acid plant in Dammam to supply the local market. The plant, built by Sim Chem of the Republic of Korea at a cost of $10 million, operated at about 50% of capacity during 1981. SAFCO was owned by Petromin (45%) and other private Saudi shareholders.

Production of nitrogenous fertilizers was to more than double in Saudi Arabia when the Jubail Fertilizer Co. (SAMAD) comes onstream in January 1983. SAMAD was a joint venture of SABIC and the Taiwan Fertilizer Co. At the end of 1981, construction work on the $350 million complex was more than 50% complete, and 150 Saudi Arabian technicians were in Taiwan training to operate the complex. The Jubail fertilizer facility was to consist of a 1,000-ton-per-day ammonia plant and a 1,600-ton-per-day urea plant utilizing natural gas feedstock. Taiwan Fertilizer Co. agreed to purchase 60% of the plant's output for use in Taiwan and for marketing to other Southeast Asian countries. The remainder of the output was to be exported, either in bulk or bags, to other foreign markets. When SAMAD comes fully onstream in 1984-85, Saudi Arabia was expected to have an exportable surplus of about 300,000 tons per year of nitrogen in fertilizer.

Sulfur.—Saudi Arabia was preparing to produce another important fertilizer component, sulfur, on a large scale in 1981. With the progressive implementation of the Kingdom's huge gas-gathering scheme and the commissioning of three major export refineries, Saudi Arabia was to have the capacity to produce over 1.6 million tons of sulfur per year. Three major sour gas treatment plants were to provide the bulk of the material. The first plant, at the Berri Oilfield, was brought onstream in 1979. Approximately 300,000 tons of sulfur was recovered from associated gas at Berri in 1980, and 1981 output averaged 1,000 tons per day. Sulfur from Berri was utilized in the SAFCO acid plant at Dammam. No contract had been signed at the end of the year for international marketing of the plants' output.

A second sour gas plant was commissioned at Shedgum in March 1980. The plant

provided NGL to a fractionation plant at Ju'Aymah and had a sulfur recovery capacity of 1,200 to 1,400 tons per day. The Saudi Sulfur Co., a joint venture of the Shobokshi Group of Jeddah, Sheikh Saleh Kamel, Sheikh Adnan Samman, and Devco Overseas of the United States, signed a $300 million contract to process and market sulfur recovered from Shedgum. The operation was to recover and pelletize the sulfur and truck the pellets to Jubail, where three full-time berths were leased from the Saudi Port Authority. Sulfur was to be exported from Jubail and marketed to large fertilizer-importing countries, mainly India, Jordan, Tunisia, Italy, Pakistan, Greece, Morocco, and Thailand. Exports from Shedgum were scheduled to begin in 1982 at the rate of 650,000 to 700,000 tons per year, rising to 900,000 tons per year toward the middle of the decade.

The third major sour gas plant was completed in 1981, at Uthmaniyah. Sulfur recovery from this plant was to average 1,100 tons per day. The basic treatment facilities at Uthmaniyah were already complete, but sulfur recovery has been delayed awaiting construction of a pipeline to transport sweetened gas from Uthmaniyah to Yanbu for fractionation and liquefaction.

In addition to sulfur recovery at the sour gas plants, sulfur was to be recovered from three export refineries, all currently under construction. The joint-venture Petromin-Petrola (Greece), 325,000-barrel-per-day refinery at Rabigh was to recover 122 tons of sulfur daily by 1984. The Petromin-Shell, 250,000-barrel-per-day refinery at Jubail was to add another 300 tons per day of sulfur, and the Petromin-Mobil, 250,000-barrel-per-day refinery at Yanbu was to add still another 300 tons per day. The Mobil and Shell refineries were due onstream in 1984 and 1985, respectively.

The production and export of sulfur in Saudi Arabia was expected to rank closely behind oil, gas, and petrochemicals as the Kingdom's main source of foreign currency in the late 1980's and 1990's. Saudi Arabia was preparing to take full advantage of production and export problems in Iran, Iraq, and Poland and planned to capture a significant share of the world markets and to become a world-scale producer by 1985.

Stone (Industrial-Ornamental).—The DGMR, Petromin, and the French BRGM renewed their agreement to locate, study, and develop the mineral resources of Saudi Arabia. The joint geological venture has led to the discovery of several large deposits of limestone, clay, basalt, dolomite, and glass sand. The DGMR opened a model quarry in 1980 to demonstrate quarrying techniques and commissioned a stone cutting and polishing plant in Jeddah.

In 1981, the Saudi Consulting House conducted an economic feasibility study for the exploitation of limestone near the Jubail region. The study examined the feasibility of mining and calcining limestone and using it as a flux in the furnaces of the Jubail iron and steel complex. The limestone deposits had a thickness of up to 20 meters in certain areas, and reserves were estimated to last more than 100 years at a proposed mining rate of 100,000 tons per year. The study also included cost estimates for production and transport of limestone blocks from the quarry to the iron and steel complex at Jubail.

A joint venture was established during the year between the Retser Engineering Agency of China (40%) and Bin Ladin Organization (60%) of Saudi Arabia to develop a marble mining and processing industry in the Kingdom. The companies invested $7.6 million to set up a factory to process marble stones from a quarry 180 kilometers from Jeddah. The plant began operating in July 1981 and was capable of processing 1,000 square meters of marble per day. The company planned to expand the operation in the near future.

MINERAL FUELS

Natural Gas.—Petromin, in cooperation with Arabian-American Oil Co. (Aramco), was in the process of implementing the largest associated gas collecting and processing operation in the history of the oil industry in 1981. The project began in the early 1970's when Aramco, at the request of the Government, designed a gas treatment center to separate and utilize associated gas from the Berri Oilfield. In the midst of the Berri project, the Government decided to expand the project to other main oilfields and to collect and process over 220 billion cubic feet per year of the country's natural gas, which would have otherwise been flared. Construction and management of the scheme was awarded to Aramco, under the supervision of Petromin. During the year, the Saudi Government, which already owned 50% of the natural gas rights and gas processing facilities in the Kingdom, purchased the remaining share from Aramco for an undisclosed sum, retroactive to January 1, 1981. The sale left the Aramco part-

ners with no fixed assets in the petroleum industry in the country, except for the Trans-Arabia Pipeline (TAPline).

The MGS basically involves two stages; the first is a gas collection, desulfurization and liquefaction stage, and the second involves secondary fractionation and the production of liquefied petroleum gas (LPG). The first stage included gas collecting stations and compressing facilities at the various oilfields and pipelines to three gas-gathering stations, located at Berri, Shedgum, and Uthmaniyah. The first plant, at Berri, was designed to process 600 million cubic feet per day of associated gas from the eastern province oilfields. It went online in July 1979. Aramco awarded several units of Fluor Corp. (United States) a major contract covering engineering, procurement assistance, and construction management for a gas-collection system at Safaniya, 160 kilometers from Berri. The project was to collect previously flared gas from the Safaniya Oilfield, separate, compress, and cool the gas and pump it through a 160-kilometer pipeline to the gas-collection center at Berri. Condensate and gas receiving facilities, together with condensate stripping and product surge units, were to be added to the Berri plant. From Berri, NGL were to be transported by pipeline to a secondary treatment center at Ras Tanura where ethane and LPG were to be produced.

The second gas-gathering station, at Shedgum, began operating in March 1980. Shedgum was designed to handle 1,400 million cubic feet per day of gas from oilfields to the south of Berri in the production of sulfur and methane. Output from Shedgum was delivered to the secondary fractionation and treatment center at Ju'Aymah, where ethane and LPG were produced, while the remainder entered the transpeninsular pipeline to Yanbu. The ethane from Ju'Aymah was to serve as feedstock for the petrochemical complexes currently under construction at Jubail. Until the petrochemical projects are ready for operation, the Saudi Government planned to export NGL and to pump surplus ethane and NGL into the Qatif underground reservoir. NGL was to be pumped into the north dome of the field, and ethane, into the south dome.

The third gas-gathering station, Uthmaniyah, was completed in 1981, but had not started production at the end of the year. The plant, located southwest of Shedgum, on the western side of the Ghawar Oilfield, was designed to process 1,400 million cubic feet per day of associated gas from the Ghawar Field. NGL were then to be pipelined across the entire Arabian Peninsula along with NGL from Shedgum to the secondary fractionation and treatment center at Yanbu. Ethane and LPG output from Yanbu was to be used as feedstock for local industries and petrochemical projects at the Yanbu industrial complex. The MGS is illustrated in the following table.

Table 5.—Saudi Arabia: Master gas system

Center	Design feed capacity	Product	Volume	Startup date
Gas-gathering (million cubic feet per day):				
Berri	600	Sulfur-methane-NGL.	360,000 barrels per day NGL.	1979
Shedgum	1,400	do	NA 1,400 tons per day sulfur	1980
Uthmaniyah	1,400	do	445 million cubic feet per day methane. 325,000 barrels per day NGL.	1981
Natural gas liquid plants (thousand barrels per day):				
Ras Tanura	360 NGL	Ethane-LPG	NA	1973
Ju'Aymah	270 NGL	do	NA	1981
Yanbu	270 NGL	do	270 condensate 110 ethane 90 propane 40 butane 30 natural gasoline	1984

NA Not available.

A large portion of the LPG output from the gas project was already sold under contract up to 1985. Among the buyers of Saudi LPG were Tokyo Gas-Shell International Gas (250,000 tons per year), British Petroleum (200,000 tons per year), Mitsubishi, Mitsui, C. Itoh and Co., and Nippon Oil (250,000 tons per year each), and Dow Chemical (250,000 tons per year). Despite the number of contracts already signed, there remained some concern over the short-term surplus being generated by OPEC in LPG. Saudi Arabia, with its program still under construction, was already producing about 8 million tons per year of NGL. Another 4 million tons was to be added with the progressive implementation of MGS. Although, as of January 1, 1981, Petromin owned the entire industry, there was speculation that the Saudi Government may require the Aramco partners to purchase and market a large share of NGL and LPG. The Saudi were also having difficulty maintaining the price of LPG during the year. Prices dropped to $225 per ton for Saudi LPG from a high of $320 in 1980. Significant increases in LPG output from Shedgum and Uthmaniyah were not expected to ease the downward pressure on prices already evident in the market.

Petroleum.—*Production.*—Saudi Arabia produced approximately 3.63 billion barrels of crude oil in 1981, making it the world's second largest producer of crude oil, behind the Soviet Union, and the world's largest exporter of petroleum. Saudi crude oil output represented 21% of the market economy countries total and 68% of the Middle East total.

Aramco personnel continued to operate facilities at most oilfields and installations in Saudi Arabia, owing to the paucity of Saudi technicians. Petromin became fully responsible for administering the country's oil wealth and setting production ceilings at all oilfields. Saudi Arabia also produced oil from the offshore and onshore area of the Kuwait-Saudi Arabia Partitioned Zone, located on the southern border of Kuwait in eastern Saudi Arabia. The onshore-area oilfields in the partitioned zone were operated by Getty Oil Co. (United States) on behalf of Saudi Arabia and the Kuwait Oil Co. on behalf of Kuwait. The Arabian Oil Co., owned 60% by Saudi Arabia and 40% by Kuwait, operated the partitioned zone's offshore oilfields.

The Saudi began the year producing at their highest level ever, 10.5 million barrels per day. During the first few months of the year, the global surplus of crude oil was estimated at over 2 million barrels per day, but the Saudi maintained output at over 10 million barrels per day through June 1981. While low-priced Saudi crude was flooding the market, other OPEC producers were having difficulty maintaining customers. The Saudi share of the total Persian Gulf output was estimated at 68% in mid-1981, up from 58% in 1980.

The Saudi were in the process of expanding their crude oil output capacity from 11 to 12 million barrels per day by 1985, at a cost of about $4 to $5 billion. Although it was doubtful that this capacity would ever be used, it allowed the Saudi to alter their oil production from a minimum revenue requirement level of about 6.2 to 7 million barrels per day to a high of 12 million barrels per day. This degree of "swing capacity" was greater than most other OPEC nations' total production capacity. This put the Saudi in a position to significantly alter the world market situation, as they demonstrated thoughout most of the year. Other OPEC nations, whose production policies were determined by revenue requirements, came under strong pressure to follow the moderate lead of Saudi Arabia.

The Saudi influence within OPEC was evident in October 1981, at the OPEC ministers' conference in Geneva, Switzerland. They were able to unify the OPEC pricing structure, as had been their stated goal since the beginning of the year. The meeting brought the only price rise of the year for Arabian Light (34° API), the benchmark for OPEC, from $32 to $34 per barrel. The Saudi price rise was in return for a lowering of overpriced Gulf and North African crudes. Having achieved their objectives, the Saudi lowered production, which had drifted from July to September to about 9.6 million barrels per day, to 8.5 million barrels per day, where it remained through the end of the year.

Marketing of Saudi crude oil output was the responsibility of the producing companies, primarily Aramco and Petromin. In 1981, the major partners in Aramco exported 3.238 billion barrels of crude oil and 187 million barrels of refined products. Getty Oil Co. and the Arabian Oil Co., combined, exported 85 million barrels of crude oil and 13 million barrels of refined products. Lifting by the Aramco majors were then either resold under third-party contracts or transported into their own petroleum marketing

network. In December 1981, the Saudi Government issued an announcement stating that Petromin was the only organization authorized by the Saudi Government to carry out crude oil sales in accordance with Government policies. Petromin exported about 220 million barrels of crude oil in 1981, all of which was through direct Government deals with countries such as Turkey, Italy, Japan, Spain, Greece, Thailand, and Brazil. The remaining share of crude oil output, which belonged to Petromin, was provided as incentive crude oil for participation in the Saudi petrochemical and refining industry and as supplies to TAPline and domestic refineries.

Exploration.—By the end of 1981, Saudi crude oil reserves were estimated at 167 billion barrels, down only slightly from the 1980 figure. Of this total, proven oil reserves in Aramco concession areas were estimated at 113 billion barrels. Five new oilfields were discovered in 1980 and 1981; Jubah, Duhaynah, and Nita onshore, and Dawl and Salsal offshore. In addition, six new productive reservoirs were located in two existing fields. All of these new discoveries were located in Aramco concession areas.

In 1980, the most recent year for which exploration statistics are available, seismic surveys were conducted over a linear distance of 12,000 kilometers. Development drilling resulted in the completion of 182 wells, 114 of which were oil producing, 51 were for water or gas-liquid injection and water supply, and 18 were for observation purposes. Total footage drilled was 1,279 billion feet. In 1981, Aramco was operating 18 onshore drilling rigs and 15 onshore work-over rigs. In the offshore area, 11 drilling rigs and 1 work-over rig were in operation.

Refining.—The Saudi refining industry was undergoing a massive expansion program in 1981, which will nearly double the Kingdom's already large refining capacity by the middle of the decade. Of the five existing operating refineries in Saudi Arabia, three were owned by the independent companies; Aramco at Ras Tanura, Arabian Oil Co. at Ras-al-Khafji, and Getty Oil Co. at Mina Saud. The remaining two refineries were wholly owned by Petromin. All but 1 of the 11 new refineries were either owned completely by Petromin or were owned jointly by Petromin and various international companies. The two operating refineries owned by Petromin, at Jeddah and Riyadh, were also completing large-scale expansion projects in 1981. With all the new capacity onstream, Saudi production capacity for petroleum products was to rise from the 1981 level of 1 million barrels per day to 2.25 million barrels per day.

In 1981, Saudi Arabia produced an estimated 345 million barrels of refined products, up nearly 4% from the 1980 level. Domestic consumption averaged just under 200 million barrels, leaving the balance for export. As the new refineries come onstream within the next several years, Saudi consumption of refined products was expected to increase to nearly 500,000 barrels per day, still leaving a massive surplus for export. The Saudi, already the world's largest exporters of crude oil and close to being the world's largest exporters of refined products, were to make available to the world market another 300 million barrels per year of refined products by the mid-1980's. Saudi current and planned refining facilities are shown in table 6.

The largest Saudi refinery, Ras Tanura, processed an average of 425,000 barrels per day of crude oil and nearly 300,000 barrels per day of NGL in 1981. Production capacity at Ras Tanura, one of the world's largest refining and product loading terminals, was increased by 10,000 barrels per day through the addition of new straight-run naphtha and pentane merox extraction facilities. The new units, designed to remove organic sulfur compounds from the naphtha and pentane stream, were able to boost production of motor gasoline an average of 10,000 barrels per day in 1981.

The other major Aramco project during the year was the planned construction of the 250,000-barrel-per-day refinery at Ju'Aymah. The refinery was intended to process high-sulfur crude (27° API) from the Manifa Oilfield to supply the domestic market. Chevron Research, a subsidiary of Standard Oil Co. of California, was awarded a contract for process design of the new refinery, and Bechtel was to perform construction engineering services. Construction was to start in 1983 and be completed in 1986. Total cost of the refinery was estimated at $2.5 billion.

Table 6.—Saudi Arabia: Operating and planned oil refineries

Location	Ownership	Crude oil capacity (barrels per day)	Market	Startup date	Contractors	Cost (million dollars)
Operating refineries:						
Ras Tanura	Aramco	500,000	Domestic-export.	1945	NA	NA

NA Not available.

The two operating Petromin refineries, at Riyadh and Jeddah, were both being expanded in 1981. Chiyoda Chemical Engineering and Construction Co. and Mitsubishi Corp. (Japan) completed expansion of the Riyadh refinery from 20,000 to 120,000 barrels per day in December 1981. This refinery receives its crude oil feedstock from the Khurais Oilfield, via an 88-kilometer pipeline. The Khurais-Riyadh pipeline, completed in December 1980, had a design capacity of 300,000 barrels per day. Throughput at the end of 1981 averaged 120,000 barrels per day. Also nearing completion was the expansion project at Jeddah, raising capacity from 98,000 to 240,000 barrels per day.

Yanbu Domestic Refining Co., a subsidiary of Petromin, awarded a 5-year contract for management assistance, startup, operation, and maintenance of a new 170,000-barrel-per-day refinery at Yanbu, to FW Management Operations Ltd., a subsidiary of Foster-Wheeler Corp. (United States). The refinery was to commence operating in August 1982, utilizing a portion of the throughput of the transpeninsular crude oil pipeline.

Three major export refineries were under construction in 1981, at Jubail, Yanbu, and Rabigh. At Yanbu, Petromin and Mobil Oil Corp. (United States) were building a 250,000-barrel-per-day export refinery, at a cost of nearly $1.5 billion. Chiyoda was awarded the main contract for engineering and material and equipment procurement plus field supervision services for the 50:50 joint venture. Chiyoda awarded an $80 million subcontract to CBI Industries, a subsidiary of Chicago Bridge and Iron Co., to build storage tanks and other structures at the refinery. The project was to be completed by 1984.

The second major refinery, at Rabigh on the Red Sea coast, was a joint venture of Petromin and Petrola International Saudi Arabia (Greece). Construction began on the project in October 1981. Petrola was also awarded a $2.6 billion construction contract for the refinery, and Lummus Co. Ltd.

(United Kingdom) was to provide engineering services. Product yield from the refinery was to be 140,000 barrels per day of fuel oil, 58,000 barrels per day of naphtha, 46,000 barrels per day of diesel oil, 33,370 barrels per day of jet kerosine, and 5,000 barrels per day of LPG. The first phase of the project was to be completed by 1982.

The long-awaited construction contract for the joint Petromin-Royal Dutch/Shell export refinery at Jubail was awarded in August 1981 to a consortium of five companies composed of Ralph M. Parsons International (United States), Technip of France, and Chiyoda Chemical Engineering and Construction Co. (Japan), together with the latter two companies' Saudi subsidiaries, Technip Saudi Arabia and Chiyoda Petrostar. The $1 billion contract, to be shared equally by the three companies, involved engineering, procurement, and construction of the refinery, including a hydrocracker and benzene manufacturing facility. Badger Co. and Fluor Corp. (United States) were also providing basic engineering and process design services for the project, the total cost of which was estimated at about $2 billion. The refinery was to produce 94,000 barrels per day of naphtha, 92,000 barrels per day of gas oil, 67,000 barrels per day of high-sulfur fuel oil, and 5,000 barrels per day of benzene. Output was to be marketed jointly by Petromin and Shell. As a bonus for participating in the project, Shell was to receive "incentive" crude oil supplies beginning in 1981 at a rate of 12,000 barrels per day and rising to nearly 60,000 barrels per day by 1985. Financing for the project was to come from Petromin, 15%; Shell, 15%; commercial borrowing, 10%; and the Saudi Public Investment Fund, 60%. Commercial production was scheduled to begin in 1985.

Two major agreements involving lube oil refineries in Saudi Arabia were finalized in 1981. Arabian Chevron Overseas Ltd., a subsidiary of Standard Oil Co. of California, and Texaco Inc. joined with Petromin to build the world's largest single-train, grassroots lubrication oil refinery at Jubail. The facility, owned 50% by Petromin and 25% each by the foreign partners, was to produce 12,000 barrels per day of premium lubricating base stocks and 10,000 barrels per day of asphalt. The company was to export six different types of base oil products. Bids for design, procurement, and construction contracts were to be requested early in 1982, and the project was scheduled for completion in 1986.

The second agreement involved construction of a 5,000-barrel-per-day lubrication oil complex at Yanbu, as a 50:50 joint venture of Petromin and Ashland Oil, Inc. The plant was to utilize feedstock derived from the nearby 170,000-barrel-per-day Petromin-Yanbu refinery. Most of the plant's output was to be exported. Having signed the agreement for the refinery, Ashland became entitled to 32,000 barrels per day of incentive crude oil supplies over a 15-year period, based on its equity investment in the project.

Two other lube oil refineries in Riyadh and Jeddah were providing lubricating oils for domestic consumption in 1981. Both plants were owned by Petrolube, a joint venture of Petromin, 70%, and Mobil, 30%. In Riyadh, a 175,000-barrel-per-year lube oil blending plant was commissioned in October 1981. The plant was built by Chiyoda Petrostar, under a contract awarded in 1979. Capacity of the plant was to rise to 500,000 barrels per year in 1984. Capacity at Petrolube's refinery in Jeddah was raised from 850,000 barrels per year to 1.2 million barrels per year. The refinery produced various types of lubricants for gasoline, diesel and light turbine engines.

Petrochemicals.—The Saudi petrochemical industry was the core of one of the largest and most rapid industrialization schemes in the history of the Middle East. The Saudi were in the process of investing over $20 billion into projects that, they say, will capture 5% of the world's petrochemical market by the latter half of the decade. With other projects still far off in the planning stage, that share could increase to 15% by the year 2000. To accomplish this ambitious development program, the Saudi have attracted some of the world's largest petroleum and chemical companies to two major industrial cities, Jubail and Yanbu, through substantial incentive offers to participate with equity shares and technical know-how in the projects.

SABIC, a Government-owned industrial enterprise, was the Saudi Government's arm in implementing the plan. For each project, SABIC approached a foreign partner or consortium meeting certain criteria to form a 50:50 joint-venture company to undertake the project. In each case, financing was provided at low interest rates by the Saudi Public Investment Fund of the Ministry of Finance. The Public Investment Fund provided 60% of the cost of the project, 10% was secured from commercial bank loans,

and the remaining 30% share was provided equally by SABIC and the foreign partner. In addition to these favorable financing arrangements, the foreign partners were entitled to lift "incentive" supplies of crude oil, based on the formula of 500 barrels per day of entitlement crude oil supply per $1 million invested by the foreign partner. In the case of the SABIC-Shell Oil Co. (United States) venture, Shell was entitled to 1.3 billion barrels of oil over a 19-year period for its participation in the complex. For their part, the foreign companies were required to provide technical expertise in the chemical industry, a good record of operation, willingness to train Saudi personnel, and the capability to market most of the plants' output. Marketing was a key for SABIC to make the ventures economically viable. The foreign partner was to market, through its own channels, not less than 75% of the plant's output.

Feedstock for the plants was to be provided by the huge MGS, utilizing vast quantities of associated gas that had previously been flared. Ethane feedstock for the Jubail plants was to come from the secondary gas-fractionation centers at Ras Tanura and Ju'Aymah. Natural gas for the complex at Yanbu was to be piped from the eastern gas-gathering center at Shedgum through the recently completed transpeninsular NGL pipeline. Ethane was to then be produced at the Yanbu gas treatment facility and from there supplied to the petrochemical plant. This low-cost feedstock was a critical factor in making the plants profitable.

According to recent estimates, the Saudi plants were to be capable of producing ethylene at about 14 cents per pound and still turn a profit. In contrast, ethylene in the United States was selling, unprofitably, at about 20 to 25 cents per pound, and the United States was considered one of the world's most efficient producers. Saudi entrance into the market was coming at a time when there was already over capacity in world petrochemicals, as was demonstrated by plant closures in the United States and Europe. In some cases, as with Exxon, the foreign partner has agreed to close their obsolete plants elsewhere and use Saudi production to fill marketing channels. With so much world capacity existing on the threshold of profitability, Saudi expansion held the potential to take a significant share of the world market by forcing plant closings elsewhere and perhaps to shift the geographical center of chemical production out of the West and into the Middle East. The Saudi petrochemical industry is shown in table 7.

These major plants, all conducted on a 50:50 joint-venture basis, were essentially export-oriented operations, designed to produce primary petrochemicals for world markets. They were also to form the core of second-phase petrochemical ventures intended to serve primarily local and regional requirements. SABIC was already in the process of planning this next phase in 1981. The basic objectives of the second phase were to develop local, smaller scale industry to either provide service facilities to the large plants or to further process their output. Foreign participation in the next phase was to be limited to 20%, as opposed to 50% for the large ventures, in an attempt to establish small-scale Saudi industry.

The major developments in the petrochemical industry in 1981 mostly involved contract awards and agreement finalization. Late in 1981, construction began on the world's largest petrochemical plant in Jubail, the joint venture of SABIC and Shell Oil Co. Construction also began on the SABIC-Exxon Corp. complex at Jubail. A Japanese consortium, composed of Ishikawajima-Harima Heavy Industries and Nippon Kokan won a $193 million contract from Fluor Corp. to manufacture and assemble modules for chemical production, to be assembled at the Jubail SABIC-Shell complex. The modules were to form the basic ethylene, styrene, and crude ethanol production units at the plant. At the Eastern Petrochemical Co. (Sharq) at Jubail, Chiyoda Chemical Engineering and Construction Co. (Japan) was awarded a several-hundred-million-dollar contract to provide engineering and construction services for the $1.5 billion joint venture of SABIC and the Saudi Petrochemicals Development Corp. (SPDC), a 59-company consortium led by Mitsubishi Corp. (Japan). The Sharq project was being set up in association with another plant, Petrokemya, owned by SABIC and Dow Chemical Co. (United States). The final agreements for construction of both of these projects were signed in 1981. In December 1980, SABIC, Dow, and SPDC signed an agreement under which the two foreign companies would jointly own and share the output from the two plants. Sharq was to produce low-density polyethylene and ethylene glycol utilizing ethylene feedstock provided by Petrokemya. In return, Sharq was to supply Petrokemya with ethylene glycols.

Table 7.—Saudi Arabia: Petrochemical industry

Project	Location	Ownership	Feedstock	Products	Capacity (metric tons per year)	Startup	Cost (million)
Saudi Petrochemical Co. (SADAF)	Jubail	SABIC-Shell	Ethane	Ethylene	656,000	1985	$3,000

Pipelines.—The two parallel legs of the transpeninsular East-West pipeline were completed ahead of schedule in 1981. The crude oil line, built at a cost of $1.6 billion over 4 1/2 years, was currently capable of transporting 1.85 million barrels per day from the eastern oilfields at Abqaiq and Ghawar to Yanbu on the Red Sea coast. Mobil Overseas Pipeline Co., a subsidiary of Mobil Oil Corp. (United States), provided design, engineering and management services and was also assisting in operating the pipeline. The crude line, 1,200 kilometers long and 48 inches in diameter, had 11 pumping stations across the Arabian Peninsula. Oil was delivered to a specially designed oil port at Yanbu, which included eleven 1-million barrel storage tanks and three operational berths, capable of handling tankers between 80,000 and 500,000 tons, with simultaneous loading facilities. The first shipment of crude to be exported from Yanbu was loaded July 1, 1981. Arabian light crude oil was priced at $34.60 per barrel from Yanbu, which included 60 cents per barrel for transportation cost basically equivalent to the cost of tanker shipping the oil around the Arabian Peninsula. The Saudi Government was delaying the plan to expand the crude oil line to handle 3.7 million barrels per day. The terminal at Yanbu was the first Saudi loading facility on the Red Sea and the only outlet for crude oil that did not have to pass through the volatile Persian Gulf and the Strait of Hormuz. Most Saudi oil was still exported from the huge loading facility at Ras Tanura in the Persian Gulf. Besides providing an alternative outlet for oil exports, the pipeline was to provide crude oil supplies to the planned refineries at Yanbu and Rabigh.

Parallel to the crude oil line was the 1,700-kilometer East-West NGL pipeline, running from the Shedgum gas-gathering center in eastern Saudi Arabia to the secondary gas-fractionation center at Yanbu. The pipeline, built by Aramco at a cost of nearly $2 billion, was capable of delivering 270,000 barrels of NGL per day to Yanbu. The gas was to be used to fuel powerplants at the Yanbu industrial complex, as fuel for the pump stations positioned along the East-West pipeline, and at the NGL plant at Yanbu to provide feedstock for the petrochemical industry. The pipeline testing procedure was completed in April 1981, but the line was awaiting completion of the Yanbu NGL center before starting full-scale deliveries.

Also completed during the year was the 140-kilometer pipeline linking the Riyadh refinery to the Khurais Oilfield. The $51 million pipeline, built by Niigata Engineering Co. (Japan), was capable of delivering 300,000 barrels per day of crude oil to Riyadh. The Riyadh refinery was expanded during the year to process 120,000 barrels per day of crude oil; output of the Khurais Field was also being expanded from 50,000 to 165,000 barrels per day to supply the refinery.

A detailed engineering study for the construction of a system of refined product pipelines was completed at the end of 1981. Petromin had commissioned a group of international consulting firms to study the feasibility of building a 2,600-kilometer pipeline network to deliver refined products to a number of small towns in Saudi Arabia. According to Petromin, the study was completed and implementation of the project was awaiting allocation of appropriate funds. The system was to carry products to Riyadh, al-Qasim, al-Kharj, Najran, Diba, Tobuk, Ras Tanura, al-Hoffuf, Jubail, Jeddah, Merra, Taif, and Khamis Mushayt.

The Mineral Industry of Sierra Leone

By Ben A. Kornhauser[1]

Sierra Leone suffered economically in 1981 from various internal and external problems, many of which required considerable assistance from outside sources for their resolution. As with most developing countries, the lack of, or limited, foreign exchange prevented the purchase of supplies and goods necessary to maintain existing enterprises and precluded embarking on new ventures to improve the industrial, commercial, and transport infrastructure required to support greater economic growth.[2] Huge Government deficits amounting to about one-quarter of all expenditures planned for 1981-82 resulted from factors such as the high cost of imports (particularly oil), balance of payment deficits resulting from worldwide inflation and recession, declining export earnings, and subsidization of health care and electrical power to varying extents. Inflation during fiscal year 1981 was estimated to be 15%. As a result of these deficits, Sierra Leone applied for assistance from the International Monetary Fund (IMF), which approved a 3-year program valued at Special Drawing Rights (SDR) of $185 million, against which drawings started in April 1981. This amount was to be raised eventually to $211.5 million, equal to 400% of Sierra Leone's SDR quota of $52.9 million, once IMF confirmed additional resource commitments.[3]

The main points of the IMF stabilization program included restricted credit expansion, overall budget deficit containment, tax system reform, intensified efforts to maximize the surrender of foreign exchange receipts and to liberalize import licensing, and the continuation and expansion of production and investment programs in agriculture, mining, energy, and transportation. Among the principal investment projects in the IMF program was intensified rice production. Continuation of the World Bank's International Development Association supported agricultural projects and final negotiations for commencing the kimberlite diamond mining and the Bumbuna hydroelectric projects. The success of the 3-year program depended on maintaining exports in the face of declining output and falling prices for diamonds (the main export), as well as containing imports—that is, maintaining a slightly positive balance of payments.

Further exploitation of natural resources was the expected major benefit of the hoped-for simultaneous development of two major hydroelectric projects. These projects were the Bumbuna hydroelectric project and the Mano River Union Basin development program. The Bumbuna project was to supply power solely for Sierra Leone use and was located at Bumbuna Falls in the north-central section of the country on the Seli River. Phase one of the project was estimated to cost $376 million and was hoped to start by yearend 1981. The Mano River project, located on the Mano River bordering Sierra Leone and Liberia, was to supply power to both countries and was the largest venture attempted by the Mano River Union (MRU). Estimated cost was $277 million. The MRU was composed of Liberia, Sierra Leone, and Guinea, which joined in 1981. Funding for both projects depended primarily on receiving money from foreign countries. The electric power from these projects was to reduce oil imports and improve the profitability of present major mining operations. Bumbuna power also was to produce alumina from a recently discovered bauxite deposit in the

Port Loko area and to exploit the rich Tonkolili iron deposits, which required pelletizing to agglomerate the fines produced in separating the iron from other minerals in the deposit.[4]

The development of the road network, which attracted international aid, including a recent $10 million World Bank loan, was expected to benefit rural areas.

PRODUCTION AND TRADE

In fiscal year 1981, ending June 30, 1981, the acute shortage of foreign exchange was aggravated by the decrease in overseas earnings from diamonds and coffee, which together accounted for more than one-half of Sierra Leone's foreign exchange. The drop in prices of these products also accounted for 45% of the shortfall in fiscal export income. The value of cocoa, another major agricultural export, also declined with respect to its fiscal 1980 earnings, contributing to the shortage of foreign exchange. Although rutile production rose an estimated 50%, its increased value equaled less than 20% of the value of the diamond exports.[5] Exports of bauxite in fiscal 1981 dropped with respect to fiscal 1980, although actual production was about the same. The unreported bauxite was stockpiled until the market improves.[6] Most of Sierra Leone's bauxite production was shipped to the Federal Republic of Germany with only minor quantities to the United States.

The United States was a major receiver of Sierra Leone's diamonds, rutile, coffee, and cocoa, purchasing about 35% of that country's total exports. During 1981, the growth of U.S. exports was deterred, primarily by the strength of the U.S. dollar and the hesitancy of U.S. suppliers to ship to Sierra Leone without confirmed letters of credit.

Table 1.—Sierra Leone: Production of mineral commodities[1]

Commodity[2]	1977	1978	1979	1980[p]	1981[e]
Aluminum: Bauxite, gross weight thousand metric tons	745	716	672	766	610

Titanium: Rutile ore and concentrate, gross weight metric tons	--	--	10,000	47,497	50,795

[e]Estimated. [p]Preliminary. NA Not available.
[1]Table includes data available through Aug. 30, 1982.
[2]In addition to the commodities listed, a variety of crude construction materials (clays, sand and gravel, and stone) is produced, but output is not reported and available general information is inadequate to make reliable estimates of output levels. Sierra Leone annually refines 4,000 to 10,000 metric tons of salt from imported crude marine salt, but this is not included in the body of the table because it would represent double counting of materials credited to the country where the salt was originally collected. This output would be in addition to that reported in this table.

COMMODITY REVIEW

METALS

Bauxite.—In 1981, production of washed bauxite ore was estimated at the 1980 rate. Annual production in 1982 and thereafter was projected at 1 million tons. This increase was expected upon completion of the expansion of the Sierra Leone Ore & Metal Co. (SIEROMCO), wholly owned by Swiss Aluminium Ltd. The expanded production was to result from the completion of a new washing plant that was to reduce costs, was to have a capacity of 1 million tons per year, and was located 13 miles south of the Mokanji Hills near Moyamba in southwestern Sierra Leone. A drying plant at the port

of Nitti was expected to improve the bauxite's marketability. The planned expanded production resulted from a renegotiated agreement between SIEROMCO and the Government of Sierra Leone that increased the tax and royalty payments to the Government for the period 1978-88, but excluded Government participation in the venture.

Gold.—In August 1981, the Government made the Bank of Sierra Leone the sole purchaser and exporter of alluvial gold. By imposing few regulations on deep mining, it was hoped that investments would be encouraged in such operations that required greater capital outlays for development. The law was enacted to centralize gold export and to enable the Government to obtain the greatest amount of foreign exchange possible from alluvial mining. For the law to be effective, the gold prospector had to be offered at least the internationally established gold price and paid part of the price in a foreign exchange.[7 8]

Eurocan Ventures Ltd. (EVL) of Canada entered into a joint gold-diamond venture with Diamond Distributors Exploration Inc. (DDX) of the United States. EVL had a 60% interest in a 25.9-square-kilometer diamond-gold concession, for an initial investment of $2 million. The cost of development was to be prorated, with DDX maintaining the diamond rights. EVL completed eight drill holes and a large open pit in the Nimini Hills area in eastern Sierra Leone. The holes were drilled to varying depths, with a planned depth of 305 meters for a ninth hole then underway. Two holes had been assayed. One hole, drilled to 87 meters, had average values (including gold-bearing areas) that were of a minable open pit grade. Another hole, drilled to a depth of 57 meters, showed promising assays at three different intervals. Mineralization of the core samples from the ninth hole also showed open pit potential. A sample taken from a surface pit about 122 meters south along the strike of the two holes had a gold content of 0.3 troy ounce per ton across a 20-meter exposed span.[9]

Iron Ore.—The Marampa iron mines, which had been closed since 1975, were reopened in 1980 by the Marampa Iron Ore Mining Co. Ltd., wholly owned by the Government of Sierra Leone, which took it over from the defunct Sierra Leone Development Co. The Marampa property was operated by Austromineral KG, a subsidiary of the Austrian state-owned firm of Austro Minerals Voest Alpine AG. Funding for the operation was supplied by an Austrian Government-sponsored loan of $16 million and Government of Sierra Leone equity capital of $6 million. One-half million tons of iron ore concentrate was expected to be shipped in 1982. The mines, when operating at capacity, were expected to export 1 million tons of concentrate annually.

The Marampa Iron Ore Mining Co. Ltd. Agreements Ratification Act, 1981, delegated an exclusive managing and marketing contract to the Austromineral KG subsidiary. Under the act, the contract was to be in effect for 14 years, until December 1995. The company also was given a mining concession covering 259 square kilometers. The company's goal was the annual production of 1 million tons of salable iron ore concentrate for export.[10]

Titanium.—Rutile production in 1981 was reported at 50,795 tons, placing Sierra Leone behind Australia, the world's largest producer. The processing plant's yearly production capacity was 75,000 tons of rutile concentrate. Rutile was mined by Sierra Rutile Ltd. (SRL), which was owned by the Bethlehem Steel Corp. (85%) and Nord Resources Corp. of Ohio (15%) and began production in mid-1979. The leased area was near Gbangbima in the Moyamba and Benthe districts and was worked by Sherbo Minerals Ltd. from 1966 to 1971. The rutile was recovered by dredging alluvial sands at Mogbwembo, about 270 kilometers by road southeast of Freetown. Rutile grades averaged 2.5% TiO_2 in the topsoil and up to 3.5% TiO_2 in the basal sands and gravel, with the stratified column averaging 2.2% TiO_2 as rutile. Ilmenite, an iron titanate ($FeTiO_3$), also was produced as a byproduct of the beneficiation of the rutile. The unreported ilmenite was set aside until SRL considers it salable as is or after reprocessing.[11]

Natural rutile was used to make titanium sponge metal and was preferred for welding rod coatings. The principal use of rutile was to make titania pigment by the chloride process, which had many advantages over the sulfate process, which used ilmenite, leucoxene (another titanium mineral), and titaniferous slags. About 95% of the titanium produced was used in pigment manufacturing with the balance as titanium metal sponge, welding rod coatings, carbides for cutting tools, and in ceramics and glass. Considerable TiO_2 pigment was used in paper coating or fillers and in compounding

materials such as plastics and rubbers. The majority of the titanium metal alloys was used in aerospace systems because of their high strength-weight ratio, their strength at more elevated operating temperatures, and their excellent corrosion resistance.

NONMETALS

Cement.—A cement factory, scheduled to open in 1982, was expected to have sufficient capacity to supply the country's annual requirements of 70,000 tons and exports of 50,000 tons.[12]

Clays.—The Sierra Brick and Ceramics Factory, situated in Wellington, was still operating and reclaiming waste heat from kilns for use in dryers. An objective of the company was to produce high-quality brick at the lowest price as a means of earning foreign exchange.[13]

Diamond.—Production of alluvial diamonds by the National Diamond Mining Co. (DIMINCO) was estimated to be at 1980 levels. However, the severe drop in diamond prices greatly decreased Sierra Leone's principal source of foreign exchange. DIMINCO was owned by the Sierra Leone Government (51%) and the Sierra Leone Selection Trust (SLST), now a subsidiary of British Petroleum Ltd. (49%). Negotiations were still underway between the Government and SLST regarding the underground mining of the diamond-bearing kimberlite deposits in Kono and Tongo. An agreement was hoped for by early 1982, with exploitation starting that year. By 1984, the decline in diamond production resulting from the depletion of alluvial diamonds was expected to be reversed, but production was not expected to reach former levels. Recovery of diamonds in the kimberlite project would be more expensive. Funding of about $100 million was sought from Kuwait, the European Investment Bank, and others. The Government believed that mining in the reserve areas of the kimberlite pipes and dykes would diminish the illicit mining and diamond smuggling now prevalent in the Yengema and Tongo nonreserve areas. Resumption of the kimberlite mining would make jobs available in the Kono district.

MINERAL FUELS

Petroleum.—The *T. W. Nelson*, Mobil Oil Corp.'s sophisticated geophysical ship, returned at yearend 1981 to insure pinpointing the location for drilling offshore Turner's Peninsula in the Bonthe District for a consortium of U.S. oil companies. The consortium was searching for oil in a 73,000-square-kilometer concession belonging to Aracca Petroleum, Oxoco Petroleum, and Sundance Petroleum, with Mobil as the operating partner. The group turned over 85% of its interest to Mobil, which was bearing the entire cost of the exploration work. The test well drilling had been delayed until 1982.

The Government of Sierra Leone had been negotiating a 100% takeover of the Sierra Leone Petroleum Refining Co. (SLPRC), which was owned by the Government (50%), with remaining shares equally divided between British Petroleum, Shell Oil Co., Mobil, and Texaco Inc. If the Government became the sole owner of SLPRC, the companies were freed of an obligation to supply crude oil and platformate to the refinery in proportion to their share of the Sierra Leone market. The Government of Sierra Leone then probably had to negotiate government-to-government agreements for continuing the supply of the refinery's imported oil needs.

In December 1981, the Government acquired a 60% share in British Petroleum Co. (Sierra Leone) Ltd. which, in addition to its traditional oil business, was involved in other industrial activities.[14]

The Mineral Industry of the Republic of South Africa

By Miller W. Ellis[1]

The mineral industry continued to dominate the economy of the Republic of South Africa and mineral products accounted for more than one-half the value of the country's exports, and for 16% of its gross domestic product (GDP). In terms of U.S. dollars, the total value of mineral sales was $15.8 billion out of a GDP of $81.8 billion.[2] During 1981, the GDP grew 4.7% in real terms, about one-half the rate of increase in 1980. The gradual decline in the value of the South African rand throughout 1981 tended to neutralize the worldwide decline in the price of certain mineral commodities in terms of local currency, and thus maintained a moderately prosperous status for the country's mineral industry.

The Government-owned Industrial Development Corp. of South Africa Ltd. indirectly controlled such companies as the Phosphate Development Corp. Ltd. (Foskor), which mined and processed phosphate rock at the Palabora carbonatite deposit in eastern Transvaal Province, and the state-run Alluvial Diamond Diggings of Alexander Bay at the mouth of the Orange River. The state-controlled South African Iron and Steel Industrial Corp. Ltd. (Iscor) continued to operate its colliery, iron mines, tin mine, zinc mine, and dolomite quarries, in addition to three major production complexes. The state's exclusive control and ownership of the South African Coal, Oil and Gas Corp. Ltd. (Sasol), the country's oil-from-coal operation, ended in 1979 when the sale of shares to the public commenced, but the Government continued to play a major role during 1981 when the Sasol II plant was operational and the Sasol III unit was nearing completion.

Consolidated Gold Fields Ltd. of the United Kingdom, affiliated with Gold Fields of South Africa Ltd. (GFSA), continued to increase its shareholding in Newmont Mining Corp. of the United States which has worldwide mining interests including the Tsumeb Corp. Ltd. mines in Namibia (South-West Africa) and the O'okiep Copper Co. Ltd. and Palabora Mining Co. Ltd. mines in the Republic of South Africa.

PRODUCTION AND TRADE

The Republic of South Africa continued to lead the world in production of chromite, gem diamonds, gold, platinum, and vanadium, and was one of the three leading producers of antimony, asbestos, industrial diamond, manganese, uranium, fluorspar, and vermiculite.

Both the volume and value of gold production declined as the world gold price continued to drop. The value of the country's gold sales at $9.8 billion indicated an average price of $465 per troy ounce, nearly 25% below the record price of 1980. The value of marketed diamonds decreased, but diamond production increased nearly 12%. Coal production and exports increased substantially in both volume and value with total sales of 130 million tons worth $2.43 billion, including exports of nearly 30 million tons worth $1.12 billion. Iron ore production increased 7.6% in 1981, and the value of iron ore exported increased 14% in terms of local currency. Production and sales of both manganese ore and chromite diminished as did those of asbestos, fluorspar, and phosphate rock. Mineral products

from the Republic of South Africa were major sources of raw materials for the manufacturing industries of the United States, Western Europe, Japan, and, in some cases, Eastern Europe. Despite the generally increasing prices for many imported industrial commodities and the additional markup caused by diminished value of the local currency, the country's balance of trade had only a $1.88 billion trade deficit in 1981 in contrast to the $6.5 billion credit balance of 1980. Similarly, the increased value of exported commodities in terms of local currency stimulated trade to a substantial degree.

Despite the additional production of synthetic crude oil (syncrude) from expanded Sasol facilities, crude oil continued to be a major import commodity as did alumina, imported from Australia to supply the country's growing aluminum industry. Exports of mineral commodities from, and their imports to, the Republic of South Africa are listed in tables 2-3. Export values compared with those of domestic sales during 1979-81 are shown in table 4.

Other do	8,607	7,372	6,205		
Refinery fuel and losses do	5,624	5,700	4,015		
Total do	106,217	106,326	105,485	110,000	NA

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.
[1]Table includes data available through Sept. 15, 1982.
[2]Less than 1/2 unit.
[3]Includes osmiridium from gold ores, estimated at 2,500 troy ounces per year.
[4]Sales.
[5]Domestic sales plus exports. Production not reported.

Table 2.—Republic of South Africa: Apparent exports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
METALS				
Aluminum:				
Ore and concentrate	127	180	--	Finland 100; West Germany 69.
Oxides and hydroxides	106	244	--	All to Sweden.
Metal including alloys:				
Scrap	60	90	--	All to West Germany.
Unwrought	29,557	7,817	--	Taiwan 3,741; Japan 1,424; Thailand 599.
Semimanufactures	2,527	2,672	([2])	Japan 1,296; France 617; Brazil 410.
Antimony:				
Ore and concentrate, metal content	6,897	1,937	629	West Germany 458; Japan 446; France 355.
Oxides and hydroxides	--	6,393	6,393	
Beryllium: Ore and concentrate	34	24	24	
Chromium:				
Ore and concentrate thousand tons	[3]1,269	1,376	367	Japan 407; West Germany 224; France 87.
Oxides and hydroxides	1	2	--	All to United Kingdom.
Cobalt:				
Oxides and hydroxides	4	8	--	Spain 7; Netherlands 1.
Metal including alloys, all forms	759	35	35	
Columbium and tantalum: Concentrate kilograms	[3]4,414	[3]4,920	4,920	
Copper:				
Ore and concentrate	72,001	84,909	--	West Germany 78,323; Japan 6,586.
Matte and speiss	214	88	--	All to West Germany.
Sulfate	342	--		
Metal including alloys:				
Scrap	1,088	1,068	1	West Germany 482; Belgium-Luxembourg 252; Spain 119.
Unwrought	181,601	180,423	2,207	West Germany 62,548; Belgium-Luxembourg 43,147; Japan 32,524.
Semimanufactures	6,859	[4]2,519	1,387	United Kingdom 194; Hong Kong 182; Taiwan 171.
Iron and steel:				
Ore and concentrate thousand tons	17,079	14,286	6	Japan 6,833; West Germany 4,410; France 1,093.
Pyrites, roasted	337	--		
Metal:				
Scrap	3,296	5,974	--	Italy 1,890; Japan 1,122; Netherlands 998.
Pig iron, cast iron, powder, shot	102,208	[5]92,088	17,133	Spain 23,113; Japan 13,405; West Germany 10,899.

See footnotes at end of table.

Tin —Continued				
Metal including alloys:				
Scrap	114	(7)	--	All to Israel.
Unwrought	1,108	1,250	472	United Kingdom 360; Italy 187; France 96.
Semimanufactures	37	30	--	All to Sri Lanka.
Titanium:				
Ore and concentrate	42,845	54,367	17,152	France 20,386; Netherlands 10,406; Italy 2,672.
Slag and dross containing titanium	27,144	--		
Oxides	892	1,142	1,007	Reunion 135.
Metal including alloys, all forms	155	9	9	
Tungsten: Ore and concentrate	80	24	--	West Germany 17; Sweden 7.
Vanadium: Oxides and hydroxides	r4,406	3,949	484	Japan 3,066; France 399.
Zinc:				
Ore and concentrate	3 37,367	52,846	--	West Germany 49,414; France 2,184.
Oxides and hydroxides	38	365	--	All to Sri Lanka.
Metal including alloys:				
Scrap	17	--		
Unwrought	33	100	--	All to United Kingdom.
Semimanufactures	98	49	11	Portugal 34; United Kingdom 4.
Zirconium: Ore and concentrate	48,108	83,258	13,348	Japan 25,127; West Germany 18,511; France 6,055.
Other:				
Ores and concentrates	10,905	15,636	32	Switzerland 5,239; Greece 3,982; Canada 2,254.
Ash and residue containing nonferrous metals	70,784	202,771	54,836	Italy 76,874; France 60,288; Austria 7,332.
Oxides and hydroxides	r5,535	5,649	--	Austria 2,745; Canada 1,287; West Germany 934.
Metalloids	17,442	25,321	468	Japan 9,086; West Germany 6,004; Australia 3,960.
Alkali, alkaline-earth, rare-earth metals	--	351	351	
Base metals including alloys, all forms	17,434	12,662	395	Canada 5,494; Japan 2,498; United Kingdom 2,140.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Corundum, emery, pumice, etc	4,570	531	399	Australia 130.
Dust and powder of precious and semiprecious stones value, thousands	$14,678	$10,019	$6,035	France $3,187; West Germany $388; Sweden $258.
Grinding and polishing wheels and stones	138	76	NA	Australia 61; Hong Kong 13.
Asbestos, crude	389,470	330,730	10,260	Japan 92,685; Italy 37,389; West Germany 27,611.
Barite and witherite	25	500	--	All to Venezuela.
Boron materials: Crude, natural borates	24	--		
Cement	19,457	115,135	22	Reunion 114,546; Central African Republic 564.
Clays and clay products:				
Crude:				
Andalusite, kyanite, sillimanite	3 89,482	3 121,317	--	West Germany 49,484; Japan 15,287; Italy 14,523.
Bentonite	3 1,067	3 1,630	NA	Taiwan 68.
Chamotte earth	NA	2,868	--	All to West Germany.
Kaolin	3 1,263	3 1,798	NA	NA.
Unspecified	3 108,316	128,378	--	Japan 45,428; United Kingdom 31,484; West Germany 17,943.
Products:				
Nonrefractory	2,077	10,059	9,298	Belgium-Luxembourg 402; United Kingdom 127.
Refractory including nonclay brick	3,717	30,164	1,046	Australia 11,736; Italy 7,539; Brazil 6,185.
Cryolite and chiolite	--	351	351	
Diamond:				
Gem, not set or strung value, thousands	$981,453	$1,362,800	$730,712	Belgium-Luxembourg $111,349; Hong Kong $92,428; Japan $22,427.
Industrial do	$68,610	$74,404	$52,652	West Germany $7,386; Japan $5,827; United Kingdom $3,070.

See footnotes at end of table.

Feldspar, fluorspar, similar material	474,764	498,446	220,035	Japan 131,990; West Germany 44,369; Canada 27,507.
Fertilizer materials:				
Crude:				
Nitrogenous	15	18	--	All to Italy.
Phosphatic	65,511	108,346	--	Venezuela 89,000; United Kingdom 18,865.
Manufactured:				
Nitrogenous	71,072	20	--	All to United Kingdom.
Phosphatic	18,811	15,593	--	Sri Lanka 10,200; West Germany 5,089.
Potassic	1,929	--		
Other including mixed	6,526	14,777	--	Sri Lanka 13,761; West Germany 1,014.
Ammonia	--	1	--	All to Reunion.
Graphite, natural	359	967	378	United Kingdom 519; France 70.
Gypsum and plasters	[3]3,237	[3]1,092	NA	Japan 4.
Lime	[3]77,071	[3]78,599	NA	NA.
Magnesite	13	458	--	Austria 230; Brazil 228.
Mica: Crude including splittings and waste	2,414	1,601	3	United Kingdom 789; West Germany 463; Japan 201.
Pigments, mineral:				
Crude, natural	[3]657	[3]814	NA	Belgium-Luxembourg 297.
Iron oxides, processed	r [3]39	[3]18	--	All to Portugal.
Precious and semiprecious stones other than diamond:				
Natural value, thousands	$29,424	$13,691	$4,506	West Germany $2,713; Switzerland $2,572; Hong Kong $927.
Synthetic do	$48	$69	$9	Hong Kong $43; Canada $7; United Kingdom $7.
Pyrites, unroasted (sulfur content)	[3]2,463	[3]47,181	NA	NA.
Salt and brine	[3]53,612	[3]53,745	NA	Reunion 404; Central African Republic 400.
Sodium and potassium compounds, n.e.s.:				
Caustic potash	21	18	--	All to Canada.
Caustic soda	102	1	--	All to Reunion.
Soda ash	1,949	NA	NA	NA.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked thousand tons	[3]12	1,099	786	Italy 75; France 71; Japan 65.
Worked	[3]10,172	[3] [8]11,337	NA	United Kingdom 1,718; Netherlands 1,082.
Gravel and crushed rock	1,225	5,701	35	United Kingdom 5,638; Republic of Korea 20.
Limestone other than dimension	[3]11,681	NA	NA	NA.
Quartz and quartzite	[3]1,540	3,648	1	West Germany 2,591; Netherlands 881; United Kingdom 69.
Sand other than metal-bearing	33,110	11,540	34	Belgium-Luxembourg 10,742; Netherlands 288; West Germany 271.
Sulfur:				
Elemental:				
Crude	NA	138	--	All to Taiwan.
Refined	361	NA	NA	NA.
Sulfuric acid	NA	5	--	All to Sri Lanka.
Talc and related materials:				
Pyrophyllite (wonderstone)	[3]6,353	NA	NA	NA.
Talc	--	[3]500	NA	NA.
Vermiculite	[3]171,991	[3]156,072	NA	France 15,756; Canada 7,756.
Other: Slag, dross, and similar waste, not metal-bearing	71,244	118,725	44,923	Japan 63,412; United Kingdom 9,938.
MINERAL FUELS AND RELATED MATERIALS				
Carbon black	2,329	1,019	--	All to United Kingdom.
Coal and briquets:				
Anthracite and bituminous coal thousand tons	[3]23,341	[3]29,150	698	France 9,260; Japan 3,288; Italy 3,058.
Briquets of anthracite and bituminous coal	106,515	174	--	Sri Lanka 122; France 52.
Lignite and lignite briquets	25,591	99	77	West Germany 22.
Coke and semicoke	NA	194	--	Sri Lanka 150; Japan 44.
Peat including briquets and litter	15	39	39	

See footnotes at end of table.

Petroleum refinery products:				
Gasoline				
thousand 42-gallon barrels	840	(2)	--	All to Reunion.
Kerosine and jet fuel do	147	NA	NA	NA.
Distillate fuel oil do	503	206	--	Mainly to New Zealand.
Residual fuel oil do	253	1,038	--	Hong Kong 318; Spain 283; Belgium-Luxembourg 233.
Lubricants do	55	197	(2)	Austria 191; Reunion 5.
Other:				
Liquefied petroleum gas do	373	9	--	All to Reunion.
Mineral jelly and wax do	245	186	84	West Germany 45; Italy 14; France 12.
Petroleum coke do	1	NA	NA	NA.
Bitumen and other residues do	61	57	2	Reunion 54.
Bituminous mixtures do	1	NA	NA	NA.
Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals	5,926	7,284	--	United Kingdom 5,112; West Germany 1,717; Brazil 400.

[r]Revised. NA Not available.

[1]Because official South African trade statistics provide data only on the value of total exports of each commodity class (with no data on destinations) and not on quantity of material exported, this table has been compiled from a variety of sources including the quarterly publication "Minerals" issued by the Department of Mines (issues for 1979 and 1980) as well as official trade returns of trading partner countries. Data from "Minerals" is footnoted; other figures are compiled from a variety of sources with specifics on destination obtained from the import statistics of the countries listed.

[2]Less than 1/2 unit.

[3]Source: "Minerals" quarterly of the South African Department of Mines. Figures are shipments by producers for export and are not necessarily actual exports.

[4]Total excludes unreported quantities valued at $48,000 to Israel and $15,000 to Uruguay.

[5]Total excludes unreported quantities valued at $58,000 to Uruguay and $16,000 to Israel.

[6]May include platinum-group metals.

[7]Unreported quantity valued at $20,000.

[8]Excludes unreported quantity valued at $1,249,000 of which $1,028,000 went to the United States, $71,000 to Israel, and $64,000 to Canada.

COMMODITY REVIEW

METALS

Antimony.—Late in 1980, Consolidated Murchison Ltd. (CML), the country's only antimony producer, announced a reduction in its milling rate in view of the generally depressed world antimony market. The result was a drop of 25% in antimony produced in 1981, most in the form of concentrate which remained stockpiled on CML property at yearend. The company reported discouraging results from its program of local exploration and discontinued its exploration project in Spain, where it has decided not to exercise its options.

Approximately 388,950 tons of crude ore at a grade of 2.81% antimony was milled in 1981 to produce 16,300 tons of concentrate to which was added 300 tons of high-grade cobbed ore containing 69% antimony. The average antimony content of this mixture was 59%. Government figures indicate that the antimony contained in the concentrate was 9,810 tons, 25% less than the antimony content of the larger 1980 concentrate.

Chromite.—The nation's chromite industry suffered more from the worldwide recession than any of the country's other mining industries except diamond. Production of chromite was down 16% to less than 2.9 million tons, and exports declined 5.5% to less than 1.2 million tons. Domestic sales, largely to ferrochromium producers, were down nearly 21% to barely 1 million tons. A number of mines were shut down including three sections of the large Winterveld Mine near Steelpoort, operated by the Barlow Rand Ltd.'s subsidiary, Transvaal Consolidated Land and Exploration Co. Ltd. (TCL). The General Mining Union Corp. Group (Gencor) closed two of its mines in the Rustenburg area. Shipments of chromite through the Mozambique port of Matala near Maputo were delayed both during rail transit and at the harbor.

Western Platinum Ltd. expected to start a new 60,000-ton-per-month concentrator in early 1982 that was to treat chromite-rich platinum ore from the UG2 reef of the Bushveld Igneous Complex. The mill was slated to produce about 35,000 tons per month of 35% chromite rejects that would be stockpiled and ultimately upgraded to 42%.

Copper.—Copper production declined slightly during 1981 to just under 200,000 tons. Total sales value declined by 11% in terms of local currency, but export sales value declined 25% to $153.2 million. Palabora, a subsidiary of Rio Tinto-Zinc Corp. Ltd., remained the country's, and one of the world's, largest and most efficient copper producers. Palabora produced nearly 121,000 tons of refined copper from 100.7 million tons of its own ore, and refined 6,359 tons of copper for other producers. Byproducts included nearly 120,000 tons of magnetite, 234.2 tons of U_3O_8 concentrate, 4,941 tons of the zirconium oxide mineral (baddeleyite), and 15.5 tons of precious metal (mostly silver) in refinery tankhouse slimes. The vermiculite division recovered 175,125 tons of vermiculite byproduct from 2.1 million tons of ore. On October 1, 1981, the first stage of Palabora's electrified trolley-assist project became operational with the equipping of the 150-ton truck fleet to utilize electrical energy from lines above the steep 2.7-kilometer north ramp of the open pit. The net saving of diesel fuel from the trolley-assist system during the last quarter of 1981 was estimated at approximately $1 million. Early in 1981 the forged steel balls in one-half of the conventional ball mill circuit were replaced with high chromium steel balls. As a result, the consumption of steel balls decreased from 190 to 60 grams per ton of ore milled, and produced a grinding-cost saving of 30% despite the higher price of chromium steel balls.

At the Messina-Transvaal Development Co. Ltd. operations near the Zimbabwe border north of Palabora, 600,000 tons of 1.3% copper ore was mined and treated yielding 7,489 tons of copper in concentrate. Smelter feed included 45,000 tons of low-grade material in addition to the concentrate. Smelter output totaled 8,590 tons of copper ingot, partly from concentrate stockpiled in 1980. Copper sales of 9,427 tons realized an average of $1,644 per ton, while production cost rose to $1,742 per ton. Development work continued at the Railway lode and the Campbell shaft was extended. O'okiep, managed and 57.5% owned by Newmont Mining Corp. of the United States, also operated at a loss during 1981. O'okiep produced 1.7 million tons of 1.45% copper ore from which 68,000 tons of 32% copper concentrate was extracted. The smelter produced 22,334 tons of blister copper from O'okiep concentrate and 16,460 tons from toll concentrates. The average sales price was $1,908 per ton including about $166 for the contained gold and silver. Sinking of the shaft to develop the Carolusberg Deep ore continued to a depth of 1,615 meters, of the planned 1,690 meters. Production from the project was expected to commence before mid-1983. The proven reserves of this ore body were revised during 1981 to 15.6 million tons containing 1.99% copper. O'okiep's Carolusberg Mine became the first mine in the southern Africa region to use vertical crater retreat stoping which results in maximum safety and ore recovery in this high stress area. The cement-rockfill system in use at the nearby Hoits Mine may also be extended to the Carolusberg section in 1982.

The Prieska Copper Mines (Pty.) Ltd. (PCM), jointly owned by Anglo-Transvaal Consolidated Investment Co. Ltd. (Anglovaal) and the United States Steel Corp., mined and milled 2.76 million tons of ore from which 103,424 tons of copper (as well as zinc, lead, and iron pyrite) concentrate was recovered and smelted by O'okiep. PCM reported that 1981 profits, at $9.35 million, were less than one-half those of 1980. The Black Mountain Mineral Development Co. (Pty.) Ltd. lead-copper-zinc-silver mine, near Aggeneys in northwest Cape Province, treated 1.15 million tons of ore to recover 4,571 tons of copper in argentiferous concentrate. Black Mountain was managed by GFSA and partly owned by the Phelps Dodge Corp. of the United States.

Gold.—With the world price of gold declining well below 1980 levels throughout the year, and the rand's devaluation accentuating the rise in working costs, the Republic's gold industry continued to dominate the country's economy. Most of the gold production was managed by six large corporations: Anglo-American Corp. of South Africa Ltd. (AAC), Anglovaal, Barlow Rand Ltd., Gencor, GFSA, and Johannesburg Consolidated Investment Co. Ltd. (JCI). These six houses operated 35 gold mines and at least 2 tailings retreatment facilities. The major mines treated nearly 92 million tons of gold ore at an average grade of 0.223 troy ounce per ton, and recovered more than 20.4 million troy ounces (635 tons) of gold. Tailings treatment, small producers, and base metal mines recovered nearly 700,000 troy ounces. Production and developed ore figures for the major mines for 1979-81 are shown in table 5.

Table 5.—Republic of South Africa: Gold production and ore reserves, by producer

Producer	Production (troy ounces)			Developed ore

[1]Free State Saaiplaas and Welkom production reported with Western Holdings after merger during 1981.

Sources: Chamber of Mines of South Africa. Quarterly Analysis of Working Results, October-December 1979-81. U.S. Consulate General. Johannesburg, Republic of South Africa. State Department Airgram A-47, July 15, 1980, pp. 45-48. Supplement to the Mining Journal, London, Jan. 29, 1982, p. 15.

Each of the country's major mines continued to produce gold bullion containing 88% gold, 10% silver, and 2% base metal impurities in 26-kilogram ingots. The ingots were delivered to Rand Refining Ltd., at Germiston, where they were precisely assayed and purchased on behalf of the Reserve Bank of the Republic of South Africa. More than 100 tons of the annual gold production was minted into coins at the South African Mint in Pretoria, and sold on the world market by the International Gold Corp. (Intergold) on behalf of the Chamber of Mines of South Africa. During 1981, Intergold reported sales of 3,128,727 of the 1-ounce Krugerrand coins, 178,014 of the 1/2-ounce coins, 726,428 of the 1/4-ounce coins, 1,321,022 of the 1/10-ounce coins, as well as 18,538 2-Rand and 19,274 1-Rand coins. The total weight of gold in South African coins sold was 3.54 million troy ounces.

The average production cost per ton of ore produced and milled increased to $49.13, an increase of 18% above the 1980 figure in terms of local currency. This was equivalent to approximately $204 per troy ounce of gold recovered, while the revenue averaged about $466 per troy ounce during 1981, leaving an average profit of $262 per troy ounce. Some of the country's larger mines continued with expansion projects that were planned when the price of gold was higher. AAC merged its Free State Saaiplaas, Welkom, and Western Holdings properties in the Orange Free State, to encompass ore underlying the Erfdeel and Dank-

baarheid farms, and was contemplating the expenditure of $622 million, chiefly tax savings, for expanding the operation by the early 1990's. AAC also extended its retreatment techniques to include the old waste dumps at the Simmer and Jack property where rehabilitation work was in progress and the mine was scheduled to reopen in 1983.

GFSA arranged for its two largest and lowest cost gold producers, the East Driefontein and West Driefontein Mines to merge as Driefontein Consolidated Ltd., and to include the undeveloped North Driefontein property held by Gold Fields Mining and Development Ltd., as well as 54 hectares of neighboring ground held by Texasgulf Inc. of the United States. Texasgulf was to receive nearly 300,000 shares in the new company, but would not qualify for dividends until the operation was expanded. Early extraction of the old intermine boundary pillars was expected to produce 900,000 troy ounces of gold. The new company appeared to qualify as the world's largest and richest gold mine after recovering 2.44 million troy ounces of gold from more than 5.5 million tons of ore during 1981. The average recovery grade was 0.441 troy ounce per ton, substantially below the reserve grade of 0.543 troy ounce per ton.

Five of the country's major mines applied for state assistance because of the declining gold price during 1981. They included GFSA's Venterspost Mine, Gencor's East Rand Proprietary Mine, Anglovaal's Loraine Mine, and the independent Witwatersrand Nigel operation. These mines produced nearly 894,000 troy ounces of gold worth about $416 million and collected nearly $31 million in state assistance.

Iron Ore and Concentrate.—Production of hematitic iron ore, chiefly from Iscor's Sishen Mine in northern Cape Province, increased 9% to more than 24 million tons in 1981 while the output of magnetite ore remained constant at nearly 4.25 million tons. The value of hematite sold locally increased nearly 36% to $155 million while the value of hematite exports increased nearly 14%, in terms of local currency, to nearly $249 million. Iscor's Thabazimbi Mine in the Transvaal Province produced 2.1 million tons of the 9.4 million tons of hematite treated in Iscor's three steel mills. Of the country's 4.24 million tons of magnetite ore, 1.9 million tons was the vanadium-bearing, titaniferous magnetite from the Mapochs Mine operated by Highland Steel and Vanadium Corp. Ltd. in the Transvaal Province. Highland's 10th prereduction kiln was commissioned in June of 1981 and 3 more similar 250,000-ton-per-year kilns were to be installed before 1985. Magnetite ore continued to account for about 15% of the total iron ore production in 1981 and was chiefly used for domestic consumption. Palabora produced 120,000 tons of finished magnetite concentrate during the year.

Iron and Steel.—Iscor consumed slightly more crude ore in 1981 than in 1980, but consumption of dolomite increased by about 5%. Steel production of 6.86 million tons, was down nearly 4% from that of 1980 and consisted of 52% ingots and 48% continuously cast blooms and slabs, most of which supplied the construction and other local industries. The total net sales value was $2.26 billion, an increase of more than 3% in terms of local currency, and the net pretax profit was more than $72 million, a drop of nearly 20% in terms of local currency. Iscor's Vanderbijlpark facility accounted for about 3.5 million tons of the steel output while its Pretoria works and Newcastle works produced, 1.5 and 2.0 million tons, respectively. The quality of Iscor's railroad steel was improved during the year by the addition of a degassing plant at Pretoria. Iscor has awarded a contract to Lurgi Chemie und Huttentechnik GmbH of the Federal Republic of Germany for the construction of a four-kiln, 600,000-ton-per-year direct-reduction plant at Vanderbijlpark by 1984. A 75,000-ton-per-year plant incorporating a process developed by Direct Reduction Corp. of New York was also under construction at Germiston, by Davy McKee Ltd. of the United Kingdom, on behalf of Scaw Metals Ltd.

The corrosion-resistant 3CR12 alloy developed by the Southern Cross Steel Co. (Pty.) Ltd. of Middelburg has proven to be popular for ore chute liners, agitation leach tanks, and other installations requiring resistance to wet abrasion and corrosion and an amenability to fabrication by welding even in thicknesses as great as 20 millimeters. During 1981, a new plant was commissioned at Middelburg to increase the capacity of the meltshop from 20,000 to 200,000 tons per year and to provide additional continuous casting, as well as hot- and cold-rolling facilities.

Lead and Silver.—The country's only major lead producer, the Black Mountain Mineral Development Co. (Pty.) Ltd., managed

and 51% owned by GFSA, and 49% owned by Phelps Dodge Corp. of the United States, continued its new operation near Aggeneys in the northwestern Cape Province. Although hard hit by generally depressed nonferrous metal and silver prices, the underground operation produced and milled 1.15 million tons of complex lead-silver-copper-zinc ore during its first full year of operations. Lead concentrate containing nearly 100,000 tons of lead and more than 3 million troy ounces of silver, and copper concentrate with 4,570 tons of copper and nearly 1 million troy ounces of silver, were trucked to a shipping point on the Sishen-Saldanha Railroad and thence to Saladanha Bay for export. Zinc concentrate, with nearly 21,000 tons of zinc and about 45,000 troy ounces of silver, was shipped to the Zinc Corp. of South Africa Ltd. (ZINCOR) refinery at Springs in the Transvaal Province. ZINCOR is also a subsidiary of GFSA.

Manganese.—The worldwide slump in the steel industry was responsible for nearly a 12% drop in manganese ore production to barely over 5 million tons, with most of the decrease in the lower grade metallurgical ores. The country's largest producer continued to be the 45% state-owned South African Manganese Amcor Ltd. with its Wessels, Mamatwan, and Lohathla Mines in northern Cape Province. The other major producer, the Associated Manganese Mines of South Africa Ltd. (AMMOSAL), operated the Black Rock, N'Chwaning, and Gloria Mines, and AAC continued to manage its deep underground Middelplaats Mine, also in northern Cape Province. The Gopane Mine, the country's only source of battery-grade ore, was entirely within the Bophuthatswana Homeland. AMMOSAL was completing a major expansion program to provide additional mining capacity at its ferromanganese facilities in Transvaal Province. The country's manganese mining capacity was estimated to exceed 9 million tons per year and its ore reserves were sufficient to last for several hundreds of years. It retained its position as the world's foremost exporter of ferromanganese and electrolytic manganese metal, and as a major supplier of metallurgical ore and manganese chemicals.

Nickel and Platinum-Group Metals.—All statistics concerning the volume of these metals were classified by the Government of the Republic of South Africa. Virtually all were produced by three major companies operating a number of mines exploiting the Merensky Reef in the Bushveld Igneous Complex in Transvaal Province. Local sales of nickel were down a little more than 10% in terms of local currency with a value equivalent to slightly more than $2 million while export sales were worth nearly $66.2 million, an increase of 15% over the 1980 revenue.

Rustenburg Platinum Holdings Ltd., with its associated Matthey Rustenburg Refiners (Pty.) Ltd., continued to be the world's largest producer of platinum metal. A new base metal refinery with a capacity of 19,000 tons per year of electrolytic nickel was commissioned in October 1981. Rustenburg's precious metal refinery at Wadesville, owned jointly with Johnson Matthey and Co. of the United Kingdom, had an estimated output of 1.3 million troy ounces of platinum-group metal in 1981. Portions of Rustenburg's four mines were in the Bophuthatswana Homeland. Total production of nickel was estimated at 18,000 tons, part of which came from the new base metal refinery commissioned by Rustenburg's associate, Matthey Nickel Ltd., in October 1981.

Impala Platinum Mines (Pty.) Ltd., the country's second largest platinum-group metal producer, had an estimated production of 945,000 troy ounces of platinum-group metal. Impala's mines and most of its concentrating and smelting plants were in the Bophuthatswana Homeland. Its base and precious metal refineries were at Springs in Transvaal Province. Portions of the Impala operations were also in Bophuthatswana which reportedly mined more than 30% of the total world production of platinum.[3]

Western Platinum Ltd. (Wesplat) was building a new 60,000-ton-per-month concentrator, at a cost of $15.9 million expended in 1981, to treat platinum-chromium ore from the UG2 reef in the Bushveld Igneous Complex. The plant was expected to produce a platinum-group metals concentrate containing minor chromite, a chromite-rich (35%) reject that would be stockpiled, and tailings. The new plant was to be commissioned by mid-1982. Meanwhile Wesplat was mining nearly 122,000 tons of ore per month from the Bushveld's Merensky Reef, and milling about 110,000 tons per month to produce a sulfide concentrate with platinum-group metals and nickel. About 12,000 tons per month of the Merensky Reef ore was being stockpiled for use as a sweetener in the UG2 ore to be treated in the new

concentrator. Wesplat's Merensky Reef ore contains 6.5 grams per ton of platinum-group metal and its UG2 ore contained 4.8 grams per ton of platinum-group metal. Wesplat's production for 1981 was 132,000 troy ounces of platinum-group metal.

Tin.—World tin prices fluctuated considerably but were generally low during the first half of 1981, and rose to a record high of nearly $8.30 per pound in November. Production was somewhat lower than that of 1980, and the quantities and values of both local and export sales were substantially below those of 1980. The country's leading producer, GFSA's Rooiberg Minerals Development Co. Ltd., increased its production of tin-in-concentrate to a record 2,386 tons by retreating old tailings through the recently commissioned flotation plant at its "C" Mine. Union Tin Mines Ltd., also managed by GFSA, saw production levels decline despite retreatment of old tailings. Zaaiplaats Mining Co. Ltd., controlled by the AAC managerial subsidiary Zimro (Pty.) Ltd., was replacing old equipment in a general rehabilitation program. New tube mills replaced the old stamp battery in an attempt to increase throughput and exploit large bodies of low-grade mineralization.

Titanium, Vanadium, and Zirconium.—Ancient beach sand dunes north of Richards Bay continued to be mined by Tisand (Pty.) Ltd., and Richards Bay Iron and Titanium Ltd. smelted the ilmenite sand recovered by Tisand's floating dredges into pig iron and titanium slag. Substantial quantities of rutile, zircon, and monazite concentrates were also recovered by a land-based electromagnetic-electrostatic plant 8 kilometers from the dredging operations. The zirconium mineral, baddeleyite, was also recovered as a byproduct of phosphate and copper mining at Palabora.

The world's largest deposit of titaniferous magnetite with exploitable amounts of vanadium was mined at the Mapochs Mine operated by AAC's Highveld Steel and Vanadium Corp. Ltd. in the Steelpoort-Roossenekal area of Transvaal Province. The ores were from the Bushveld Igneous Complex and were treated in one of Highveld's eight roasting units at Witbank. Union Carbide Corp. of the United States reported reduced operations of its vanadium production facilities at Brits and Bon Accord.

Zinc.—Anglovaal's Prieska Mine continued to be the Republic's chief zinc producer from its four-product (copper, zinc, lead, and pyrite) mine at Copperton, 65 kilometers southwest of Prieska. The mine produced 125,579 tons of zinc concentrate that was transported by rail to GFSA's ZINCOR smelter-refinery near Springs in Transvaal Province. GFSA's Black Mountain operation near Aggeneys in northwesten Cape Province produced and shipped about 42,000 tons of zinc concentrate containing 20,750 tons of zinc to the Springs refinery. Iscor reported the production of 47,200 tons of zinc concentrate that was shipped from its Rosh Pinah Mine in Namibia to its Vanderbijlpark complex southwest of Pretoria for smelting and the manufacture of galvanized sheet iron and wire.

NONMETALS

Andalusite and Related Minerals.—The Republic of South Africa continued to be the world's largest producer and exporter of andalusite and sillimanite through 1981. Output of the two minerals declined 8% and 4%, respectively, during the year and export volumes and values declined 44% and 43%, respectively, for andalusite and 38% and 15%, respectively, for sillimanite. Local sale of andalusite increased 24% in volume and 46% in local currency value, while domestic sales of sillimanite declined 29% in volume, but the value in local currency increased 6%.

Weedon's Minerals (Pty.) Ltd., operating near Thabazimbi, continued as the country's largest producer of andalusite, and Pella Refractory Ores S.A. (Pty.) Ltd. and R.G. Niemoller, with mines near Aggeneys in the Namaqualand area of northwestern Cape Province, were the chief producers of sillimanite. The Hudson andalusite mine near Penge, and the Lager andalusite mine, both in the Lebowa homeland between Pietersburg and Sandton in the Transvaal Province, were sold to the Rand London Corp. during the year. The Hoogenoeg andalusite mine near Roodepoort in the Transvaal Province was acquired by a French company, Denin-Anzin Mineraux, which was improving the facilities for increased production.

Asbestos.—Production of chrysotile asbestos declined 28% as a reflection of the worldwide trend against the use of this industrial mineral. Output of the more flexible crocidolite, "blue," asbestos also decreased by 14% but output of amosite

asbestos, unique to the Republic of South Africa, increased 10% to 56,834 tons. Barlow Rand's TCL continued to acquire asbestos mines from the Swiss Eternit AG's Zimbabwean and South African subsidiary, Everite Ltd., following the acquisition of a number of crocidolite mines from Cape Industries Ltd. By midyear TCL owned 75% of the South African and world crocidolite potential. Most of the remaining crocidolite producers were held by Griqualand Exploration Ltd., a Gencor subsidiary. In the latter part of 1981, Gencor purchased all of TCL's asbestos interests for $50 million in cash and shares. Crocidolite asbestos from the Wandrag Asbestos (Pty.) Ltd., held by Duiker Exploration Ltd., a subsidiary of the Lonrho Group was marketed by Gencor's Griqualand, which thus had a monopoly on crocidolite by yearend and was able to supply the softening demand by streamlining the more profitable and closing the less profitable mines.

Gencor also owned the Msauli crysotile asbestos mine, in the Barberton district of Transvaal Province, which was plagued by production troubles throughout the year. All of the country's amosite asbestos came from the Penge Mine, operated by Egnep (Pty.) Ltd., which was included in the Cape package acquired successively by TCL and Gencor. Most of Penge's output was exported and had a value of $24 million.

Diamond.—The Republic's diamond industry[4] was the hardest hit of its diverse mineral industries with a drop of 42% to $1.86 billion in sales by the Central Selling Organization (CSO) of De Beers Consolidated Mines Ltd. This reflected a drop of 48% to $390 million in the CSO purchase price of the country's 8.1 million carats of diamonds, down 4% in quantity sold despite a 12% increase in the number of carats produced. Table 6 shows the details of marketed diamonds from various sources in the Republic of South Africa and the average sales value per carat for 1981 compared with that of 1979-80.

The Finsch Mine, 150 kilometers northwest of Kimberley in northern Cape Province, continued to be De Beers' largest producer in the Republic of South Africa since 1979, and was its second largest producer in the world, surpassed only by the Orapa Mine in neighboring Botswana. Although underground mining had started and development was continuing, most of Finsch's 4.8 million tons of ore was recovered from the 160- to 200-meter levels of the open pit, and overburden stripping of the 112- to 172-meter benches continued. Diamond recovery was greatly improved during the first full year of operation of the new treatment plant that recovered 4,463,944 carats for an average yield of 92.13 carats per 100 tons of ore, an increase of more than 50% over the 1980 recovery. On August 19, 1981, the Finsch Mine's 736-meter shaft was completed. It was the first vertical shaft sunk in the Republic of South Africa using a six-boom jumbo drill rig in place of about 40 handheld air drills, reducing the labor force on the shaft bottom by 50%. Since startup in February 1980, 52,800 cubic meters of rock has been excavated from the 9-meter-diameter shaft, and an additional 19,800 cubic meters were excavated from six hoisting stations at various levels.

Of the four kimberlite mines near the town of Kimberley in Cape Province, only the Bultfontein underground mine increased production by barely 1% over that of 1980. Bultfontein produced 663,200 tons of ore containing 40.41 carats per 100 tons from the 580- and 700-meter levels. A rim-loading section at the south of the 570-meter level was completed in December 1981. Water tunnels around the Bultfontein pipe were completed in August, and drainage holes were being drilled from the tunnels at yearend. The Bultfontein dumps yielded 367,510 carats of diamond from 1,131,400 tons of ore with a grade of 32.48 carats per 100 tons. Substantial tonnages have been added to reserves as a result of continued sampling of old dumps near Bultfontein. The Wesselton Mine production continued to be the largest of the mines near Kimberley, with 1,377,200 tons of ore which yielded 274,399 carats at a grade of 19.92 carats per 100 tons, a drop of 17% below that of 1980. Part of the drop was due to waste rock dilution from the 785-meter block cave area which accounted for 857,000 tons of ore. The mining of higher level remnants produced 520,000 tons of ore and, following additional mine development, the practice was to be extended to remnants of ore above the 713-meter level. The 920-meter haulageway was fully equipped, and development of the 920-meter sublevel cave section was continued.

At the original De Beers Mine, 127,989 carats were produced from 663,300 tons of ore at a grade of 19.30 carats per 100 tons. The ore was drawn nearly equally from the 745-meter level block cave section and from sublevel caving on the 620-meter level

where ground pressure problems were apparently obviated by orienting the development drives in an east-west direction instead of a north-south direction. Development for mining the area above the 745-meter east block cave was extended to the 585-meter level.

Table 6.—Republic of South Africa: Marketed diamond output, by Province

Province	1979		1980		1981	
	Output (carats)	Price per carat	Output (carats)	Price per carat	Output (carats)	Price per carat
Mine diamond:						
Transvaal	2,033,993	$39.60	2,342,715	$39.92	1,871,107	$28.08
Cape Province	3,680,787	45.58	3,902,256	52.04	4,693,074	27.12
Orange Free State	441,050	117.34	531,708	167.92	353,082	98.07
Total	6,155,830	48.75	6,776,679	56.94	6,917,263	31.00
Alluvial diamond:						
Transvaal	22,268	325.21	26,882	506.93	23,902	282.00
Cape Province	1,995,046	172.45	1,645,920	189.12	1,171,100	144.59
Orange Free State	7	261.80	764	115.13	127	544.64
Total	2,017,321	174.13	1,673,566	194.19	1,195,129	147.38
Grand total	8,173,151	79.70	8,450,245	84.13	8,112,392	48.14

Source: Republic of South Africa Department of Mineral and Energy Affairs, Quarterly Information Circular, Minerals, October-December 1981, p. 2. 1 Rand = US$1.149 for 1981.

The 586,000 tons of ore from the Dutoitspan Mine came from the 760-meter block cave area and yielded 98,758 carats of diamond at a grade of 16.83 carats per 100 tons. The water tunnels around the pipe were completed in July and drainage-hole drilling from the tunnels was nearly complete. The headgear and the return airways to the new ventilation shaft were completed early in the year. The shaft was to the 580-meter level by yearend and commissioning was nearly complete. Drilling and sampling of the Kamfersdam kimberlite, 5-kilometers to the north, has continued with disappointing results.

Ore production at the Premier Mine, 10 kilometers north of Pretoria in Transvaal Province, declined 16% from that of 1980 to 6.8 million tons. Ore from the underground mine, at 5.2 million tons, was slightly less than that mined in 1980, the grade was substantially lower at 28.81 carats per 100 tons, and diamond output declined nearly 3% to 1,501,157 carats. The throughput of the retreatment plant was reduced to 1.6 million tons by the fine-grained material handled, but the grade of the dump ore increased nearly 60% to 33.64 carats per 100 tons, and production of diamonds increased to 538,654 carats from this source, to achieve Premier's total of 2,039,811 carats in 1981, greater by 625 carats than that of 1980. The heavy media separation plant for fines was an improvement on the old jig plant, but harder ore has adversely affected the release and recovery of small diamonds. The No. 3 ventilation shaft was completed by June, but the underground crusher was not commissioned until December because of poor ground conditions in the crusher chamber.

The Koffiefontein Mine, 80 kilometers southeast of Kimberley in the Orange Free State, recorded a 10% drop in ore production and a 25% drop in diamond production with 3.3 million tons of ore yielding 322,635 carats of diamonds at a grade of 9.89 carats per 100 tons. Opencast mining stopped in August and underground mining failed to reach the target rate because of large boulders of hard kimberlite left in the underground haulageways from open pit haulage roads blasted in the last stages of conversion to undergroung mining.

De Beers' Namaqualand Div. recovered virtually all of the company's alluvial diamonds but production was down 15% after closure of the new Tweepad facility in June because of declining prices and demand for gem diamonds. In the Koingnass area, 1.4 million tons of ore was treated with 288,900 tons of washed gravels from the Mitchells Bay screening and washing plant, to produce 550,119 carats of diamond at an average grade of 32.81 carats per 100 tons. The decline of 13% from that of 1980 was slightly more than was envisaged when the target production was reduced by 10% in

June. Similarly, the 19% reduction in the 4.5 million tons of terrace gravel from the Buffels complex was accompanied by a 17% decrease in recovery to 622,486 carats at a grade of 13.72 carats per 100 tons. The Langhoogte Mine treated 323,500 tons of ore and recovered 41,472 carats of diamonds, 9% less than that of 1980. Overburden stripping was completed at Langhoogte. Sand removal continued in the Tweepad-Annex Kleinzee area where erection of a new 46-cubic-meter-capacity dragline for overburden stripping was nearing completion.

De Beers was continuing to evaluate diamond-bearing terrace gravels in Namaqualand and kimberlites near Venetia in northern Transvaal Province.

The Messina (Transvaal) Development Co. Ltd. paid $1.15 million on March 1, 1981, for a 72% interest in the Bobbejaan kimberlite fissure mine owned by Guniting and Mining Enterprise (Pty.) Ltd., 60 kilometers west of Warrenton in northern Cape Province. The remaining 28% interest was acquired in October. Treatment of tailings and the ore extracted during underground mine development yielded diamonds at an average rate of 13 carats per 100 tons. Production was not declared, but 3,800 carats of diamonds were sold during the year at an average price of nearly $150 per carat.

Brazil Diamante Beperk erected a new recovery plant on the farm Hondeklip south of Kleinzee on the Namaqualand coast, and two other companies, Buffels Bank Diamante Beperk and Namex (Pty.) Ltd. commissioned new plants in Namaqualand's Richtersveld area.

The Alexander Bay State Alluvial Diamond Diggings produced 125,405 carats of diamonds in 1981, 10% less than that of 1980. The sales price averaged $245 per carat and the average size stone was 0.35 carat. The cumulative weight of the larger diamonds increased 19% to 2,245.7 carats, ranging in size from 9.8 to 109.6 carats. The increase was due to the greater recovery of diamonds from the seabed where the average size was 0.70 carat. Seabed production involved 348.8 cubic meters of gravel containing 9,477.3 carats of diamonds, more than twice the quantities involved in 1980. A substantial program of plant and infrastructure rehabilitation involved the expenditures of $1.3 million for new staff housing and almost $4 million for rehabilitation of the plant during 1981.

Fluorspar.—The country's position as the world's second largest fluorspar producer was maintained in 1981 despite a 5% decline in production to 496,521 tons. Gencor's Buffalo Mine continued to be the world's largest fluorspar mine with a capacity of 240,000 tons per year. The Rand Mines Ltd. Marico operation had the capacity to produce 180,000 tons per year of acidspar, and the nearby Ottoshoop Mine, operated by Chemspar Ltd. a subsidiary of Phelps Dodge Mining Ltd., had a capacity of almost 100,000 tons per year. The Vergenoeg Mining Co. Ltd., owned by Bayer A.G., continued operation of its 115,000-ton-per-year facility at Pienaarsriver. Early in 1981, it was announced that Armco Bronne, the exploration and development subsidiary of the U.S. company, Armco Inc., would spend $27 million to develop and mine a 20-million-ton fluorite deposit near Zeerust and export 200,000 tons of fluorite per year for the U.S. steel industry. It was later announced that the project had been discontinued. Most of the country's ceramic and metallurgical grades of fluorspar were sold for consumption by the domestic refractory and steel industries. Most of the acid-grade fluorspar was exported chiefly to the United States, Japan, and the Federal Republic of Germany. Total exports declined 13% to 405,958 tons but the value increased 25% from that of 1980 to $52 million.

Phosphate.—Most of the Republic's supply of phosphate fertilizer came from the Foskor operation at the Palabora carbonatite deposit in northeastern Transvaal Province. Apatite-bearing carbonatite containing 8% to 9% phosphorus pentoxide (P_2O_5) was mined and milled to a concentrate containing in excess of 30% P_2O_5. Most of the concentrate was sold to Federale Kunsmis Ltd. and Triomf Fertilizer (Pty.) Ltd., which manufactured phosphoric acid for export. Crude phosphate rock production was down 11% to 17.7 million tons, and concentrate production dropped 18% to 2.6 million tons in 1981 from that of 1980, largely because of Foskor cutbacks following weak demand for exports of phosphoric acid, largely to Brazil. Foskor continued to receive apatite-rich overburden stripped by Palabora to facilitate mining its copper ore and the coarse, apatite-rich tailings from the Palabora concentrator which were pumped directly into the Foskor mill. Like Palabora, Foskor instituted savings of diesel fuel by installing electric trolley lines over haul roads out of its open pit. In addition to the country's phosphoric acid production,

which amounted to 229,601 tons exported in 1981, about 825,000 tons of phosphatic fertilizers, and 1,880,000 tons of various artificially mixed fertilizer blends incorporating some phosphate, were manufactured in the Republic of South Africa.

MINERAL FUELS

Coal.—The value of the Republic's coal output set a new record of more than $2.4 billion in 1981, when production of bituminous coal increased 36% to 126.36 million tons and anthractie output rose 3% to 4.02 million tons. Total coal exports increased to nearly 30 million tons worth $1.12 billion, and local sales of nearly 98 million tons had a value of $1.30 billion. More than 60% of the coal sold locally was used for coal-fired power-generating stations which supply 93% of the country's electricity. A large part of the stations was operated by the state-managed Electricty Supply Commission (Escom). Sasol's Bossjesspruit coal mine, the source of raw material for the Sasol II and III plants, achieved a production of 1 million tons of coal during July, believed to be the world's largest monthly output from an underground mine. Bossjesspruit used two 2,000-ton-per-hour belt conveyors in the haulage drift to its 11-meter-diameter service shaft. Sasol II operated at 80% of its planned capacity in January 1981.

Other coal mining achievements during the year were: A continuous drum-type miner at Escom's Matla Colliery produced 118,794 tons of coal in May; a conventional mechanized section at AAC's Kriel Colliery produced 207,393 tons of coal during August; and a longwall section at Sasol I's Sigma Colliery had an output of 210,000 tons of coal during October.

Iscor's Grootegeluk's coal mine near Ellisras in northern Transvaal Province was officially opened in April 1981 and produced just over 700,000 tons of coking coal during the remainder of the year. Grootegeluk installed in-pit crushers and conveyor systems to expedite overburden removal, and an electric trolley system over the haulage roads out of the pit to conserve diesel fuel. Grootegeluk commenced the storage of 20 million tons of middlings coal to be used by Escom in 1986. The fine coal was spread into dumps by scoop-trams, leveled, and compacted to exclude air. A number of thermocouples were buried in the dump which was covered and monitored monthly with infrared photography to reveal areas of heat buildup. The first 1-million-ton dump was completed and a 4-million-ton unit was in progress at yearend.

Iscor's Durnacol Mine produced 1.3 million tons and the company purchased 4.3 million tons of coking coal from the private sector. The AAC's subsidiary, Anglo-American Coal Corp. Ltd., was the source of 28% of the country's coal output during 1981, and by yearend was contemplating the expenditure of more than $1.5 billion to develop and equip four new mines for supplying thermoelectric power stations and for export. The Kleinkopje opencast mine of AAC's South Africa Land and Exploration Co. Ltd. was increasing production to the scheduled 4.8 million tons per year. The plan was to supply 2.5 million tons for the export market, 1.6 million tons for the Transvaal Coal Owners Association, and 700,000 tons of low-ash, metallurgical coal to Iscor during 1982. The Reitspruit Colliery, jointly owned by Barlow Rand's TCL and Shell South Africa Ltd., a subsidiary of Royal Dutch/Shell, was establishing its place as one of the largest and most mechanized of the nation's opencast collieries.

The Minister of Mineral and Energy Affairs announced that after the 44-million-ton-per-year coal export target has been achieved, probably by the mid-1980's, an export ceiling of 80 million tons per year would apply. The country's coal reserves were restated as 110,000 million tons of which 51,000 million tons was extractable.

Petroleum.—The state-owned Southern Oil Exploration Corp. (Pty.) Ltd. spent $75 million chiefly on offshore drilling of 13 drillholes with an aggregate depth of 43,988 meters plus 1 hole abandoned at 533.4 meters because of adverse water currents. Two of 4 west coast drillholes warranted drill-stem-tests as did 6 of the 10 holes drilled off Mossel Bay and the south coast. The better results were encountered 90 kilometers south of Mossel Bay where hole F-A4 cut three sandstone zones with a total permeable thickness of 14 meters, which yielded 24 million cubic feet of gas and 46 cubic meters of natural gas liquids (NGL) per day. Hole F-A5 had one 6.5-meter zone permeable with 4.4 million cubic feet of gas and 18 cubic meters of NGL, and F-A6 had 10 meters permeable in two zones with 13 million cubic feet of gas and 25 cubic meters of NGL per day. The combined fractions contained 83% methane, 6% ethane, 3% propane, and 8% of higher hydrocarbons.

Sasol II's plant was completed in 1981 and production has intermittantly exceeded 80% of its designed capacity. Sasol III was judged 90% complete by December 1, 1981, and some front-end units had been started. Production was scheduled for the second quarter of 1982. Sasol's research and development department was building a pilot plant of an improved synthesis reactor at Sasolburg, and was discussing the erection of a coal gasifer with Westinghouse Electric Corp. of the United States, as an addition to the Lurgi-Sasol gasifiers presently employed.

Uranium.—Production of uranium oxide (U_3O_8) declined less than 1% during 1981 largely due to reduced production at Gencor's West Rand Consolidated Mine, 51%; JCI's Randfontein mine, 9%; and several small producers. Increased production was recorded at AAC's Joint Metallurgical Scheme in the Orange Free State, 12%; the Ergo tailings treatment plant in the Transvaal Province, 5%; Barlow Rand's Harmony Mine, 18%; and Rio Tinto-Zinc Corp.'s Palabora Copper Mine, 62%. Production records from 1978 through 1981 are shown in table 7. West Rand Consolidated announced in July its intention to cease operating its uranium section and to concentrate on gold recovery. In August 1981, Gencor announced that its $200 million Beisa uranium mine, held and developed by Union Corp. Ltd. since 1938 and due to come onstream early in 1982, would be acquired by St. Helena Gold Mines Ltd. so that the capital outlay could be deducted from the latter's taxes. Reimbursement to Beisa was to be in preference shares issued by St. Helena that entitled the holders to 85% of Beisa's net profit after payment of royalties, taxes, capital expenditures, etc. Royalty of 15% of Beisa's gross income was payable to an AAC subsidiary and to Gencor as the most recent owners of the Beisa property.[5]

The Mineral Industry of Spain

By Roman V. Sondermayer[1]

During 1981, Spain remained mineral-poor relative to its industrial demand. Imports of mineral commodities into Spain were approximately 70% of the value of minerals, including fuels, that Spain consumed during 1981. To alleviate this dependence on foreign sources of raw materials and relieve pressure on the trade balance, the Government of Spain continued to make efforts to increase domestic production of minerals available in the country and to encourage export of these minerals.

However, Spain was an important producer and processor of certain minerals during 1981. The minerals produced in Spain with global significance were mercury, with a 24% share of world production; pyrites, with 11%; fluorspar, with 6%; and potash, with 2%. Activities of the mineral sector varied from commodity to commodity; growth was strongest in coal production, reflecting the switch to coal consumption in the country.

Activities in sectors producing and processing nonenergy minerals were partly affected by recession. Stagnation and reduced demand were characteristic of the nonfuel sector during 1981. Mineral commodities whose prices declined on world markets had the lowest level of activity.

Some commodities, such as aluminum, lead, and zinc, however, showed some improvement in their operations during 1981. These improvements resulted from efforts of the Government to foster the Plan National de Abastecimiento de Materias Primas Minerales (National Mineral Raw Materials Supply Plan).

During 1981, the economy of Spain suffered severe losses in agriculture owing to an unprecedented drought. Large imports of food put an additional burden on the trade balance. Industrial output was at the same level as that of the previous year. Unemployment was between 13% and 14% of the labor force while inflation was at 14%. The mineral industry's share in the gross national product was between 11% and 12%, including metal refining, petroleum refining, and the processing of nonmetals; however, the extractive sector's share alone was less than 1%. The mineral industry, including processing, employed about 500,000 persons during 1981.

Principal events in the mineral industry of Spain during 1981 included closing of the Aznalcóllar copper mine, development of the Sotiel copper mine, exploration of a lead and zinc deposit at La Troya, and the beginning of production at four new coal mines.

Table 1.—Spain: Principal mineral industry companies and locations, by commodity

Commodity	Major companies	Location of principal facilities
Alumina	Alúmina de España S.A	Plant at San Ciprián.
Aluminum	Aluminio Español S.A	Do.
Do	Endasa S.A	Plant at Aviles and Valladolid.
Do	Aluminio de Galicia S.A	Plant at La Coruña and Sabiñánigo.
Bituminous coal	Hunosa S.A	Mines in Asturias.
Cement	Asland S.A	5 plants.
Copper ore	Rio Tinto Minero S.A	Mines at Rio Tinto.
Copper, refined	do	Refinery at Huelva.
Ferroalloys	Soc. Espanola de Carburos Metálicos S.A	Plant at Berga.
	Hidro Nitro Espanolas S.A	Plant at Monzón.
	Ferroaleaciones Espanolas S.A	Plant at Medina del Campo.
Iron ore	Cía. Andalusa de Minas S.A	Mine at Marquesado.
Lead ores	Sociedad Minera y Metallúrgica de Peñarroya de Espana.	Mines at Mantas de los Azules, Unión.
Lead smelter	do	Smelter at Santa Lucía.
Mercury	Cousejo de Administration de Minas de Almadén.	Mines and smelter at Almadén.
Petroleum, refined	Empresa Nacional del Petróleo S.A	Refineries at Valle de Escombreras, Puertolano, and Tarragona.
Do	Cía. Esp. de Petróleos S.A	Refineries at St. Cruz de Tenerife, Algeciras.
Potash	Potasas de Navarra S.A	Mine near Pamplona.
Do	Minas de Potasas se Suria S.A	Mine near Suria.
Do	Unión Explosivos Rio Tinto S.A	Mines at Balsarney-Sallent and Cardona.
Pyrite	Tharsis Sulfur and Copper Co. Ltd	Mines at Tharsis and La Zarza.
Steel	Empresa Nacional Siderurgica S.A	Works at Aviles, Felguera, Gijón-Moreda, and Gijón-Verina.
Do	Altos Hornos de Vizcaya S.A	Work at Baracaldo-Sestao.
Zinc ore	Real Cía. Asturiana de Minas S.A	Mines at Reocín and Rubiales.
Zinc, smelter	do	Electrolytic zinc plant at San Juan de Nieva.

PRODUCTION

Latest trends in production for 1977-81 are shown in table 2.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Aug. 23, 1982.

[2]Reported figure.

[3]In previous editions, reported as "Earths, industrial, n.e.s." clay.

[4]Includes sand obtained as a byproduct of feldspar and kaolin production.

[5]Units revised.

TRADE

For the past several years, Spanish imports of minerals heavily taxed the country's balance of payments, and during 1981, this situation continued. Tables 3 and 4 show details of Spain's foreign trade in minerals, as reported by the Spanish Government.

Table 3.—Spain: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
METALS				
Aluminum:				
Ore and concentrate	1,106	6,173	--	West Germany 3,600; Portugal 2,573.
Oxides and hydroxides	69	82	--	Portugal 52; United Kingdom 12; Yugoslavia 12.
Metal including alloys:				
Scrap	684	204	1	West Germany 78; Italy 69; France 20.
Unwrought	42,870	106,782	--	France 20,889; Netherlands 17,202; Portugal 16,149.
Semimanufactures	21,755	19,495	993	Portugal 3,865; France 3,660; Japan 1,749.
Antimony:				
Oxides and hydroxides	44	44	--	All to France.
Elemental	593	370	--	Netherlands 200; Tunisia 38; France 35.
Bismuth metal including alloys, all forms	4	--		
Chromium:				
Chromite	4,099	6,267	--	Belgium 3,508; Sweden 2,754.
Oxides and hydroxides	72	533	--	Iran 440; West Germany 40; Israel 20.
Cobalt: Oxides and hydroxides	11	1	--	All to Saudi Arabia.
Copper:				
Ore and concentrate	98	--		
Matte	325	233	--	West Germany 215.
Oxides and hydroxides	92	76	21	Netherlands 54.
Sulfate	297	88	--	Netherlands 88.
Metal including alloys:				
Scrap	704	884	--	West Germany 441; France 210; Italy 95.
Unwrought	35,856	66,294	88	France 18,331; Belgium-Luxembourg 16,076; Italy 13,672.
Semimanufactures	20,065	22,505	512	Iran 5,026; Morocco 3,487; Italy 2,652.
Gold:				
Waste and sweepings ---- value	$20,318	$194,848	--	West Germany $121,838; Finland $53,416.
Metal including alloys, unwrought and partly wrought ---- thousand troy ounces	193,837	26,717	--	United Kingdom 10,610; West Germany 9,645; France 6,141.
Iron and steel:				
Ore and concentrate, except roasted pyrites thousand tons	1,995	2,088	--	Netherlands 800; Romania 475; West Germany 375.
Roasted pyrites	329,519	371,653	--	West Germany 348,950; France 22,227.
Metal:				
Scrap	172	869	79	Belgium-Luxembourg 429; Morocco 150; West Germany 138.
Pig iron including cast iron	81,993	31,291	1	Romania 10,180; Yugoslavia 9,455; Sweden 7,176.
Sponge iron, powder, shot	13,397	16,656	2	Italy 9,050; France 1,753; West Germany 1,529.
Ferroalloys:				
Ferromanganese	53,481	31,334	9,121	West Germany 9,128; Italy 3,502; Venezuela 2,004.
Other	120,350	90,069	8	West Germany 34,624; Japan 12,643; United Kingdom 9,805.
Steel, primary forms	248,421	544,839	6,844	Yugoslavia 66,799; Iran 50,232; France 39,546.

Semimanufactures:				
Bars, rods, angles, shapes, sections thousand tons	2,742	2,799	219	Iran 392; West Germany 225; Morocco 210; France 162.
Universals, plates, sheets	802,304	645,371	105,360	West Germany 70,411; Italy 45,183; Mexico 39,355; Norway 34,783.
Hoop and strip	27,172	29,981	21	Bulgaria 4,597; West Germany 3,906; Romania 3,682.
Rails and accessories	11,502	3,760	2	Saudi Arabia 2,638; Poland 845.
Wire	39,114	42,799	888	Portugal 9,312; Algeria 7,591; France 6,626.
Tubes, pipes, fittings	364,364	467,226	95,118	U.S.S.R. 51,478; France 48,759; West Germany 44,619.
Castings and forgings, rough	28,143	11,448	1,153	France 3,749; Belgium-Luxembourg 1,397; Canada 1,196.
Lead:				
Ore and concentrate	34	9,394	--	Romania 2,719; West Germany 2,284; Netherlands 2,257.
Oxides and hydroxides	20	1	--	Mainly to Guinea.
Metal including alloys:				
Scrap	--	240	--	All to Portugal.
Unwrought	19,644	7,633	--	U.S.S.R. 4,000; Belgium-Luxembourg 1,727; Italy 1,500.
Semimanufactures	1,293	3,286	217	U.S.S.R. 2,000; France 896.
Lithium: Oxides and hydroxides kilograms	--	16	--	All to Portugal.
Magnesium metal including alloys, all forms	--	2	--	Argentina 1; United Kingdom 1.
Manganese:				
Ore and concentrate	138	68	--	All to Portugal.
Oxides and hydroxides	3,000	3,202	--	France 1,393; Italy 779; U.S.S.R. 500.
Mercury 76-pound flasks	37,798	19,290	2,002	Belgium 2,901; Romania 2,495; France 2,002.
Molybdenum metal including alloys, all forms	724	10	--	West Germany 9.
Nickel:				
Ore and concentrate	--	5	--	All to United Kingdom.
Metal including alloys:				
Scrap	302	168	--	France 117; United Kingdom 39.
Unwrought	193	11	--	United Kingdom 8.
Semimanufactures	601	29	--	Algeria 11; Venezuela 6; Switzerland 2.
Platinum-group metals including alloys, unwrought and partly wrought troy ounces	47,615	9,999	--	Switzerland 5,337; West Germany 3,794.
Selenium, elemental	1	5	--	West Germany 5.
Silicon, elemental	16,464	13,667	--	Japan 8,495; France 1,902; U.S.S.R. 1,000.
Silver:				
Ore and concentrate[1]	10	27	--	All to Portugal.
Waste and sweepings[1] value	$839,741	$425,000	--	France $223,000; West Germany $193,000.
Metals including alloys, unwrought and partly wrought thousand troy ounces	3,344	184,002	--	Netherlands 176,327.
Tantalum:				
Ore and concentrate	25	56	27	West Germany 15; Netherlands 6.
Metal including alloys, all forms	4	5	--	West Germany 2; France 1.
Tin:				
Oxides and hydroxides	730	72	--	All to Portugal.
Metal including alloys:				
Scrap	94	65	--	United Kingdom 60.
Unwrought	567	229	--	Netherlands 95; United Kingdom 79.
Semimanufactures	58	259	--	Netherlands 95; United Kingdom 80; France 40.
Titanium oxides and hydroxides	12,894	11,494	2,269	France 2,858; West Germany 1,234; Italy 1,040.

Sodium compounds, n.e.s:				
Caustic potash	5,554	3,876	180	West Germany 618; Switzerland 528; Netherlands 479.
Caustic soda	115,819	92,459	--	Iraq 13,350; Portugal 12,817; Ivory Coast 5,900.
Soda ash	4,519	71,999	--	Argentina 43,754; Algeria 8,758; Italy 7,093.
Stone, sand and gravel:				
Dimension stone:				
Crude or partly worked:				
Calcareous	37,239	53,366	68	Italy 31,186; United Kingdom 11,173.
Slate	4	129	--	Andorra 79; France 50.
Other	101,901	153,266	--	Italy 129,726; France 9,934; West Germany 4,015.
Worked:				
Slate	172,093	161,490	58	France 132,619; West Germany 16,394.
Paving stone and flagstone	177	951	--	Saudi Arabia 709; Italy 174.
Other	21,864	29,753	566	West Germany 11,048; Saudi Arabia 9,098.
Dolomite, chiefly refractory-grade	105,399	75,885	--	United Kingdom 46,720; West Germany 22,000.
Gravel and crushed rock	33,992	35,658	--	Morocco 22,375; Andorra 5,519.
Limestone except dimension	99,434	5,694	--	All to Belgium.
Quartz and quartzite	333,698	357,702	--	Norway 265,884; France 59,862.
Sand excluding metal-bearing	385,786	351,491	(2)	Andorra 344,050; Portugal 7,042.
Sulfur:				
Elemental, all forms	17,733	13,257	--	Algeria 6,957; Norway 4,289; France 1,935.
Sulfuric acid	175	17,417	--	Algeria 12,736; Belgium 4,615.

See footnotes at end of table.

Table 3.—Spain: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Talc, steatite, soapstone, pyrophyllite	15,030	11,357	--	Cuba 3,400; West Germany 3,054; United Kingdom 1,840.
Other:				
Crude	535,133	563,549	752	France 180,787; Belgium 169,557; West Germany 88,571.
Slag, dross, similar waste, not metal-bearing	102,208	77,450	--	West Germany 33,131; Portugal 22,455; France 15,687.
Oxides, hydroxides, peroxides of barium, magnesium, strontium	394	49	--	Republic of South Africa 25; Canada 18.
Building materials of asphalt, asbestos and fiber cement, unfired nonmetals	38,717	41,766	217	France 20,717; Tunisia 6,236; Iceland 2,772.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	35	1	--	All to Ecuador.
Carbon black	11,577	16,221	10	Portugal 6,612; France 3,409; Morocco 2,919.
Coal and briquets:				
Anthracite and bituminous coal	14,475	17,196	--	Belgium-Luxembourg 13,725; Portugal 3,252.
Briquets of anthracite and bituminous coal	60	--		
Lignite and lignite briquets	436	28	--	All to Andorra.
Coke and semicoke	3,378	3,124	--	France 2,066; Mexico 1,000.
Gas, natural	--	21	--	Angola 14; Morocco 7.
Hydrogen, helium, rare gases	1,418	1,329	--	Belgium 979; France 123; Italy 112.
Peat including briquets and litter	163	16	--	All to Portugal.
Petroleum:				
Crude and partly refined thousand 42-gallon barrels	(2)	1,057	--	Spain 631; Libya 422.
Refinery products:				
Gasoline, aviation and motor ---do---	895	1,088	--	Italy 257; Netherlands 241; France 203.
Kerosine and jet fuel ---do---	530	560	--	Greece 165; Singapore 140; Sweden 125.
Distillate fuel oil ---do---	2,087	4,707	205	Italy 1,304; Netherlands 687; India 427.
Residual fuel oil ---do---	6,847	6,686	--	Sweden 1,052; Netherlands 789; France 274.
Lubricants ---do---	51	1,646	38	Italy 531; Mexico 224; Nigeria 202.
Other:				
Liquefied petroleum gas ---do---	29	2	--	Cape Verde 1.
Mineral jelly and wax ---do---	7	20	1	Morocco 6; Argentina 4; Portugal 2.
Petroleum coke ---do---	--	2,855	--	Italy 2,615.
Bitumen and other residues ---do---	r3,105	2,140	--	Libya 1,384; Algeria 375.
Bituminous mixtures ---do---	405	666	--	Nigeria 322; Libya 241.
Unspecified ---do---	1,294	1,572	--	All to Italy.
Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals	r180,314	207,479	26,329	Italy 62,487; Netherlands 60,890; France 42,184.

r Revised.
[1]May include platinum-group metals.
[2]Less than 1/2 unit.

Table 4.—Spain: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1979	1980	Sources, 1980	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite and concentrate	142,818	349,384	--	Guinea 187,966; Guyana 60,472.
Oxides and hydroxides	559,226	706,581	613	Guinea 273,078; Jamaica 224,528; France 94,182.
Metal including alloys:				
Scrap	4,080	5,631	1,553	Portugal 3,106; France 341.
Unwrought	7,152	3,164	511	Italy 652; Venezuela 576; West Germany 425.
Semimanufactures	14,617	16,769	3,568	West Germany 3,245; France 2,378; Belgium-Luxembourg 2,305.
Antimony:				
Ore and concentrate	664	657	--	Thailand 330; Morocco 220.
Oxides and hydroxides	242	210	--	France 105; United Kingdom 54; China 20.
Elemental	199	35	--	France 16; Czechoslovakia 12.
Arsenic: Elemental	19	18	3	Sweden 14.
Beryllium metal including alloys, all forms kilograms	10	12	--	West Germany 11.
Bismuth metal including alloys, all forms	102	72	--	Mexico 32.
Cadmium metal including alloys, all forms	(1)	10	--	All from West Germany.
Chromium:				
Chromite	117,977	84,558	--	Republic of South Africa 49,649; Turkey 17,430; Albania 9,852.
Oxides and hydroxides	135	133	1	West Germany 123; United Kingdom 9.
Metal including alloys, all forms	6	19	1	West Germany 11; United Kingdom 5.
Cobalt oxides and hydroxides	75	72	13	Belgium 28; Canada 14.
Copper:				
Ore and concentrate	191,109	204,097	--	Papua New Guinea 56,859; Mexico 43,769; Chile 43,156.
Matte	12,498	3,811	645	France 2,277; Italy 762.
Oxides and hydroxides	475	383	--	West Germany 155; Italy 87; Norway 60.
Sulfate	1,517	499	--	France 498.
Metal including alloys:				
Scrap	18,951	35,852	17,632	France 8,028; Canada 2,379; United Kingdom 1,613.
Unwrought	64,396	49,521	123	Chile 24,513; Belgium-Luxembourg 15,872.
Semimanufactures	r28,195	100,041	1,058	Austria 67,972; France 9,413; United Kingdom 4,994.
Gold:				
Ore and concentrate kilograms	350	27	NA	Republic of South Africa 11; Peru 8; Chile 6.
Waste and sweepings value, thousands	$250,768	$179,389	$6	Switzerland $120,493; United Kingdom $35,995; France $22,422.
Metal including alloys, unwrought and partly wrought thousand troy ounces	80	96	(1)	Mainly from West Germany.
Iron and steel:				
Ore and concentrate, except roasted pyrites thousand tons	5,195	4,757	--	Brazil 1,936; Venezuela 760; Liberia 654.
Roasted pyrites	--	26	--	All from France.
Metal:				
Scrap thousand tons	2,927	3,926	1,107	United Kingdom 1,861; France 393.
Pig iron including cast iron	44,312	54,163	--	Republic of South Africa 23,113; Canada 19,165; France 4,521.
Sponge iron, powder, shot	136,600	119,532	208	Canada 86,492; Venezuela 15,483; Trinidad and Tobago 10,000.
Ferroalloys	46,557	70,031	1,495	France 28,477; Republic of South Africa 22,351; Sweden 5,089.
Steel, primary forms	509,314	591,955	5	West Germany 210,764; France 185,520; Belgium-Luxembourg 69,090.
Semimanufactures:				
Bars, rods, angles, shapes, sections	172,056	201,786	352	Japan 43,929; France 33,924; West Germany 33,707.

See footnotes at end of table.

(Metric tons unless otherwise specified)

Commodity	1979	1980	Sources, 1980	
			United States	Other (principal)
METALS —Continued				
Iron and steel —Continued				
Metal —Continued				
Semimanufactures —Continued				
Universals, plates, sheets	266,890	350,537	2,575	West Germany 128,290; France 76,384; Netherlands 59,288.
Hoop and strip	66,036	84,505	108	West Germany 31,377; France 29,547; Netherlands 7,771.
Rails and accessories	2,218	2,358	--	United Kingdom 1,221; West Germany 639; Belgium-Luxembourg 345.
Wire	19,111	17,044	281	France 4,573; West Germany 4,316; Belgium-Luxembourg 3,474.
Tubes, pipes, fittings	37,561	47,329	5,196	France 13,826; West Germany 11,811; Italy 5,012.
Castings and forgings, rough	6,274	2,276	21	France 1,087; Italy 813.
Lead:				
Ore and concentrate	15,155	28,081	--	Ireland 12,063; Morocco 5,932; Denmark 5,080.
Oxides and hydroxides	109	88	--	West Germany 86.
Metal including alloys:				
Scrap	286	129	21	France 79; Guinea 20.
Unwrought	1,168	4,328	116	United Kingdom 1,307; Netherlands 1,074; West Germany 819.
Semimanufactures	69	307	110	West Germany 126; France 65.
Lithium: Oxides and hydroxides	138	127	105	Italy 15.
Magnesium metal including alloys:				
Scrap	15	30	--	Greece 17; Belgium-Luxembourg 12.
Unwrought	706	1,315	902	Norway 224; France 178.
Semimanufactures	46	39	15	West Germany 16.
Manganese:				
Ore and concentrate	487,333	432,648	3	Republic of South Africa 147,600; Australia 95,087; Gabon 82,756.
Oxides and hydroxides	1,310	637	--	Belgium 533; Ireland 100.
Metal including alloys, all forms	351	1,565	50	Portugal 1,247.
Mercury 76-pound flasks	16	26	(1)	West Germany 18; Austria 2.
Molybdenum:				
Oxides and hydroxides	--	43	9	United Kingdom 20; West Germany 14.
Metal including alloys, all forms	32	34	13	Austria 6; West Germany 6; Netherlands 6.
Nickel:				
Matte, speiss, similar materials	2,074	1,779	--	Canada 1,281; Cuba 450.
Metal including alloys:				
Scrap	32	7	7	
Unwrought	6,500	6,281	191	Canada 1,725; Cuba 1,547; Australia 771.
Semimanufactures	721	780	82	Netherlands 203; West Germany 171; France 145.
Platinum-group metals including alloys, unwrought and partly wrought thousand troy ounces	601	6,109	NA	France 4,983; United Kingdom 643; West Germany 482.
Rare-earth metals	29	46	1	Austria 22; United Kingdom 11; Brazil 10.
Selenium, elemental	42	32	--	Japan 13; United Kingdom 9; Canada 7.
Silicon, elemental	45	148	1	France 146.
Silver:				
Ore and concentrate[2]	33	71	5	Morocco 27; Chile 18; Republic of South Africa 8.
Waste and sweepings[2] value, thousands	$23,656	$86,522	$24,778	France $50,973; Switzerland $7,001.
Metals including alloys, unwrought and partly wrought thousand troy ounces	1,993	20,673	3	France 19,355; West Germany 643.

See footnotes at end of table.

Table 4.—Spain: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Sources, 1980	
			United States	Other (principal)
METALS —Continued				
Tantalum:				
Ore and concentrate	168	10	--	All from West Germany.
Metal including alloys, all forms	7	6	3	West Germany 3.
Tellurium, elemental	2	1	(1)	NA.
Tin:				
Ore and concentrate	3,263	4,363	--	United Kingdom 1,334; Thailand 1,034; Indonesia 860.
Oxides and hydroxides	301	343	--	United Kingdom 113; West Germany 107; Italy 102.
Metal including alloys, all forms	167	127	2	Malaysia 40; United Kingdom 27; West Germany 21.
Titanium:				
Ore and concentrate	162,977	134,920	2,413	Australia 65,946; Norway 64,363.
Oxides and hydroxides	2,151	2,227	137	Belgium 1,042; France 342; United Kingdom 151.
Tungsten metal including alloys, all forms	21	18	1	France 6; Austria 4; United Kingdom 3.
Uranium and thorium metals including alloys, all forms kilograms	485	165	160	France 5.
Vanadium: Oxides and hydroxides	73	282	--	Finland 150; West Germany 92.
Zinc:				
Ore and concentrate	111,703	40,192	--	Peru 21,201; Ireland 13,396.
Oxides and hydroxides	650	577	(1)	West Germany 242; Italy 140; United Kingdom 112.
Metal including alloys, all forms	3,265	1,953	1	Belgium-Luxembourg 1,255; West Germany 371.
Zirconium:				
Ore and concentrate	26,526	45,230	--	Australia 34,014; Republic of South Africa 11,151.
Metal including alloys, all forms	2	1	1	
Other:				
Ores and concentrates:				
Of molybdenum, tantalum, vanadium, zirconium	4,802	4,568	556	Australia 2,019; United Kingdom 846; Republic of South Africa 368.
Unspecified	1,179	1,845	(1)	Republic of South Africa 1,052; Australia 399; Sri Lanka 374.
Ash and residue containing nonferrous metals	46,586	51,384	17,260	France 2,722; Israel 2,535; Norway 2,080.
Oxides, hydroxides, peroxides	r1,477	1,089	171	France 469; West Germany 291.
Metals:				
Alkali and alkaline-earth	307	328	1	West Germany 288; France 36.
Pyrophoric alloys	32	26	(1)	France 21.
Base metals including alloys, all forms	r350	13,055	157	France 12,738.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	2,365	337	28	Italy 201; United Kingdom 28; France 25.
Artificial: Corundum	2,888	2,967	76	West Germany 1,074; France 986; Austria 646.
Dust and powder of precious and semiprecious stones value, thousands	$3,918	$3,764	$1,883	Ireland $1,417.
Grinding and polishing wheels and stones	1,739	1,605	--	Italy 485; Austria 271; France 263.
Asbestos, crude	74,162	67,148	361	Republic of South Africa 24,230; Canada 22,140; Zimbabwe 8,344.
Barite and witherite	2,462	849	(1)	France 838.
Boron materials:				
Crude natural borates	113,522	87,209	29,585	Turkey 54,400; France 1,923.
Oxides and acids	72	84	1	France 42; Argentina 36.
Bromine	205	256	13	Israel 160; West Germany 40.
Cement	246,184	191,849	351	Poland 147,585; United Kingdom 18,987.
Chalk	10,660	10,503	18	France 9,682; Greece 750.

See footnotes at end of table.

Table 4.—Spain: Imports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Sources, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Clays and clay products:				
Crude:				
Bentonite	35,277	31,664	5,947	Morocco 15,489; Greece 8,955.
Kaolin (china clay)	172,423	167,278	7,107	United Kingdom 117,644; West Germany 18,139; France 15,002.
Other	76,262	80,002	4,816	United Kingdom 52,881; France 12,327; Morocco 4,678.
Products:				
Nonrefractory	75,146	64,494	--	Italy 49,416; Portugal 8,880; West Germany 2,334.
Refractory including nonclay brick	35,844	36,847	813	West Germany 10,262; Italy 7,886; Austria 6,921.
Cryolite and chiolite	9,314	4,577	--	All from Denmark.
Diamond:				
Gem, not set or strung -- value, thousands	$40,339	$22,843	$700	Belgium-Luxembourg $17,990; Israel $2,080.
Industrial -- do	$2,506	$942	--	Republic of South Africa $626; Belgium-Luxembourg $160.
Diatomite and other infusorial earth	2,998	3,094	1,499	France 1,349.
Feldspar	16,256	21,408	--	France 15,662; Norway 4,151.
Fertilizer materials:				
Crude:				
Nitrogenous	46,667	49,335	1	Chile 47,192; Norway 2,142.
Phosphatic -- thousand tons	2,932	2,607	32	Morocco 2,395.
Other including mixed	3,011	1,980	1	France 1,190.
Manufactured:				
Nitrogenous	181,394	181,692	--	Netherlands 56,841; West Germany 36,541; Norway 26,920.
Phosphatic	15,552	24,606	--	Belgium-Luxembourg 14,150; Portugal 7,900.
Potassic	3,117	3,161	--	France 1,625; Israel 1,530.
Other including mixed	121,047	202,687	186,405	Finland 5,009; West Germany 4,789; Belgium-Luxembourg 2,208.
Ammonia	337,647	480,452	25,618	Mexico 129,597; U.S.S.R. 104,479; United Kingdom 51,919.
Fluorine, elemental	9,997	29	--	West Germany 15; France 8.
Fluorspar	23	62	--	France 39; Italy 23.
Graphite:				
Artificial and colloidal	3,648	2,133	216	United Kingdom 705; France 629; West Germany 206.
Natural	1,778	2,218	--	Madagascar 1,030; West Germany 402; Norway 300.
Gypsum and plasters	6,573	5,448	17	France 4,221; Morocco 786.
Iodine	146	152	9	Japan 69; Chile 48.
Lime	87	291	--	Morocco 174; France 105.
Magnesite	53,832	72,749	97	Greece 37,829; Italy 14,247; United Kingdom 8,523.
Mica, all forms	1,189	1,610	192	Austria 443; India 389; France 266.
Pigments, mineral: Iron oxides including processed	7,350	6,586	48	West Germany 5,289; France 715.
Precious and semiprecious stones except diamond:				
Natural -- value, thousands	$8,111	$5,183	--	Thailand $2,321; India $994; Brazil $383.
Manufactured -- do	$1,536	$786	$198	Austria $328; France $106.
Pyrites, unroasted	160	139	--	Italy 89; Austria 32.
Salt and brine	1,262	1,301	--	Netherlands 615; United Kingdom 419; West Germany 161.
Sodium compounds, n.e.s.:				
Caustic potash	540	226	(1)	West Germany 80; Sweden 64.
Caustic soda	146,908	145,283	1	West Germany 33,852; Belgium-Luxembourg 33,803; France 27,005.

See footnotes at end of table.

(Metric tons unless otherwise specified)

Commodity	1979	1980	Sources, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Sodium compounds, n.e.s. —Continued				
Soda ash	23,053	3,421	--	Portugal 2,143; France 625; Bulgaria 500.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked:				
Calcareous	91,780	93,817	--	Italy 59,756; Portugal 30,203.
Slate	3	(1)	--	All from West Germany.
Other	27,743	36,094	--	Finland 11,890; Republic of South Africa 10,282; Norway 6,110.
Worked:				
Slate	155	155	--	Italy 117; France 33.
Paving stone and flagstone	104	18	--	Mainly from Italy.
Other	12,783	9,719	4	Italy 6,182; Portugal 2,951.
Dolomite, chiefly refractory-grade	3,121	4,430	--	France 2,549; Norway 1,387.
Gravel and crushed rock	29,185	41,036	10	Morocco 33,321; France 7,082.
Quartz and quartzite	2,617	3,745	10	Sweden 2,392; Yugoslavia 799.
Sand excluding metal-bearing	14,692	15,530	191	Morocco 7,094; France 5,043; Belgium-Luxembourg 2,843.
Sulfur:				
Elemental:				
Other than colloidal	109,576	94,116	4,173	France 59,969; Mexico 20,909; Canada 6,925.
Colloidal	6,382	266	(1)	West Germany 242.
Sulfuric acid	251,486	71,390	6,282	France 29,164; West Germany 9,254; Poland 7,302.
Talc, steatite, soapstone, pyrophyllite	10,970	15,181	29	France 12,547; Norway 1,643.
Other:				
Crude	47,787	33,768	206	U.S.S.R. 8,836; Morocco 6,921; Greece 5,522.
Slag, dross, similar waste, not metal-bearing	6,230	14,381	--	France 11,587; Italy 1,625; West Germany 1,128.
Oxides, hydroxides, peroxides of barium, magnesium, strontium	160	242	42	Canada 105; United Kingdom 29; West Germany 25.
Building materials of asphalt, asbestos and fiber cement, unfired nonmetals	4,329	9,901	77	France 5,236; Italy 3,433.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	407	507	384	France 115.
Carbon black	18,511	14,767	1,640	France 8,836; Netherlands 1,551; West Germany 1,157.
Coal and briquets:				
Anthracite and bituminous coal thousand tons	4,192	5,678	3,014	Poland 999; Republic of South Africa 713; Australia 636.

COMMODITY REVIEW

METALS

Aluminum.—After startup in 1980, the alumina-aluminum complex, owned by Alúmina de España S.A. and the Aluminio Español S.A. at San Ciprián, had an uneventful year. Production of both alumina and aluminum was near design capacities of 800,000 and 180,000 tons, respectively.

The major producer of aluminum remained the Government-owned Empresa Nacional del Aluminio, S.A. (ENDASA), taking into account its 55% participation in Aluminio Español. During 1980, the latest year for which complete data were available, ENDASA employed 3,670 persons operating smelters at Aviles and Valladolid; utilization of the smelters was 94% of designed capacity.

Copper.—The area around Seville, in southern Spain, remained the principal producer of mined copper in Spain during 1981.

The Aznalcóllar Mine, owned by the Sociedad Andaluza de Piritas S.A., located near Aznalcóllar in the Province of Seville, was closed during the summer of 1981 because of water shortages. Aznalcóllar consists of an open pit mine with a capacity of 4 million tons of ore per year and a mill with a total capacity of 4 million tons, of which 2 million tons is treated in the pyrite circuit and 2 million tons in the pyroclastic ore circuit.

Development of the mine and construction of the mill continued at Sotiel, near Seville, southern Spain. The mine and mill were owned by the Minas de Almagrera S.A. (MASA). About 96% of MASA capital was subscribed by Institute Nacional de Industria (INI), the holding company of the Government of Spain. The mine and mill at Sotiel should become operational sometime in 1983-84. During 1981, most of the mining and milling equipment was ordered. Designed annual capacity of the mine was 600,000 tons of complex sulfide ore. The mill was designed to produce 40,000 tons of zinc concentrates with an average zinc content of 50%, 11,000 tons of copper concentrates with an average copper content of 20%, and 10,000 tons of lead concentrates with an average lead content of 50%. In addition, plans call for use of recovered pyrite in a 300,000-ton-per-year sulfuric acid plant located near the mine site.

At Rio Tinto Mines, near Seville, the most important activity continued to be expansion of the Cerro Colorado open pit mine, including the prestripping of the new Cerro Salomón pit.

Gold.—At the MASA La Lapilla gold and silver mine, in the Province of Huelva, exploration and laboratory tests for metals recovery from the ore were completed. Based on the results of the laboratory tests, planning started for construction of a beneficiation pilot plant. By yearend, no major decisions had been made relating to startup of production.

Iron and Steel.—The iron and steel sector of the industry in Spain had an uneventful year. Planning and examining ways to restructure and reorganize the steel sector to compensate for recent increases in energy and labor costs were the principal activities of the Government and private companies.

Altos Hornos de Vizcaya, S.A., operated the iron ore mines at Gallarta and Bodovalle, in Sestao, near Bilbao. Gallarta is an open pit mine that produced about 1 million tons of ore, and Bodovalle is an underground mine that produced 1.25 million tons of run-of-mine ore during 1981. The siderite concentrates were further processed in the sintering plant of the Sestao steel plant. At the common minesite, a new facility for high-intensity magnetic separation of ore in the size 0- to 1-millimeter went onstream.

In the steel sector, the major event was the Kawasaki Steel Corp. study for restructuring the integrated segment of the steel industry of Spain. The study was to be completed in 1982.

Lead.—During 1981, Exploración Minera International España S.A. continued to explore and plan for development of a complex sulfide deposit, with lead sulfide being the major component, at La Troya, near Ceraín, about 50 to 60 kilometers southwest of San Sabastián in northwestern Spain. In addition to lead, the ore from La Troya contained zinc, copper, and some precious metals.

Actual development of an underground mine and construction of a mill were to start in 1982-83. At yearend 1981, capacities of these installations had not been announced.

Tungsten.—At the Sultana tungsten-tin mine, Province of Orense, owned by MASA, geological studies, sampling, and general maintenance of stopes were underway during 1981, but production was not resumed.

In addition, some tests on beneficiation of the Sultana ore were conducted. Exploratory drilling in deeper parts of the mine was completed, and a survey of the central part of the deposit was near completion at yearend.

NONMETALS

Cement.—The cement industry had a quiet year during 1981. Spain had 54 plants, operated by 36 companies, with an aggregate annual capacity of about 44 million tons of cement. The largest company was Asland S.A. of Madrid, which operated five cement plants with a total capacity of about 6.6 million tons of cement. Spain's largest cement plants were two 2-million-ton-per-year plants, one located at Puerto Sagunto, Province of Valencia, and the other at Villaluenga de la Sagro, Province of Toledo. Both plants were owned by Asland.

MINERAL FUELS

As in the past, coal, uranium, and hydropower were the principal sources of primary energy produced in Spain during 1981. However, Spain remained heavily dependent on imported fuels, mostly petroleum, natural gas, and high-grade coals, to meet its energy demand.

The National Energy Plan (Plan Energetico National—PEN) was the governing document for the energy policy of Spain. In broad terms, the PEN provided (1) Conservation of energy through pricing and fiscal policy (Energy prices should reflect the real cost of supply, including the cost of investments; there should be a lowering of the purchase tax for small automobiles, and there should be a halt to licensing of new truck transportation companies.), (2) Increased domestic production of energy by large investments in coal and nuclear energy, and (3) Use of energy sources from reliable foreign suppliers through investments in foreign companies and by participating in exploration abroad.

Coal.—Four opencast mines, two in Teruel Province and two in Cordoba Province, started production during 1981. This accounted for most of the increased coal output.

Coal remained the most favored source of primary energy in the country, and the Government was encouraging industry to convert from liquid fuels to coal. Electric powerplants and cement factories were among the first to start using coal instead of fuel oil. Seven coal-fired electric plants were scheduled for completion in the next 3 to 4 years, replacing the oil-fired plants planned before the oil crisis.

The PEN called for domestic coal production to reach 38 million tons by 1985. This target appeared to be realistic in view of

production of about 28 million tons achieved during 1981.

To facilitate imports of coal from abroad, some seaports had to be adapted to handle large quantities of coal. To avoid labor problems with longshore workers, most of the new facilities were planned in smaller ports, avoiding the large ports of Barcelona and Bilbao. The ports at Tarragona, Almeria, and Algeciras were selected for building the new expanded and modernized installations.

A coal-importing and -exporting company was formed by the Government of Spain through its holding company, INI. The new company, Sociedad Española de Carbón Exterior, S.A. (Carboex), was organized to secure necessary coal imports, to participate in prospecting for coal abroad, and to invest in foreign coal operations. During 1981, representatives of Carboex were negotiating participation in coal-related activities in the United States, Colombia, Australia, and other countries.

The largest coal producer in the country remained the Empresa Nacional Hulleras del Norte S.A. (Hunosa). Hunosa produced approximately 5 million tons of marketable coal during 1981; about 4 million tons was produced in underground mines, and the rest was mined by opencast mining methods.

Nine large mining operations and five large coal washeries, with a total capacity of 10 million tons of run-of-mine coal, were operated by Hunosa during 1981.

Petroleum and Natural Gas.—Domestic output of both petroleum and natural gas remained small, and Spain was, as in the past, heavily dependent on imported crude oil and natural gas to meet its demand in 1981.

Exploration for liquid and gaseous hydrocarbons continued, even though results of previously drilled wells were negative. Evaluation of the Vizcaya Gasfield, offshore Bilbao, indicated reserves of natural gas of 700 billion cubic feet.

During 1981, the Government of Spain passed a decree setting up a state company that will group various state interests in the oil sector. The new entity, Instituto Nacional de Hydrocarburos (INH), was organized to coordinate purchases and refining of crude oil in Spain. The INH would operate under the jurisdiction of the Ministry of Industry and would exercise control of Empresa Nacional del Petróleo, S.A. (Enepetrol), Compañia Refinadora De Petroleos, S.A., Empresa Nacional de Investigation y Exploration de Petroleos, S.A., Hispanica de Petroleos, S.A., Empresa Nacional del Gas, S.A., and Butano, S.A.

The organization of INH, however, failed to satisfy the European Communities (EC) criteria on marketing monopolies, in that the Campsa marketing monopoly was not disbanded with the organization of INH, which was against the stipulations in Article 37 of the Treaty of Rome. In addition, INH was to give preference to Spanish refineries and would be obliged to use Spanish ships; these regulations had to be phased out before Spain could become a member of the EC.

During 1981, expansion of the refinery at Tarragona was completed. In several other refineries, construction of new catalytic cracking units were started.

Total petroleum refinery capacity available in Spain at the beginning of 1981 was 1.56 million barrels per day in 10 refineries. Three companies accounted for about 74% of the total capacity; Enepetrol with refineries at Escombreras (capacity 200,000 barrels per day), Puertollano (capacity 140,000 barrels), and Tarragona (capacity 260,000 barrels); Compañía Española de Petroleos S.A. with refineries at Santa Cruz de Tenerife (capacity 160,000 barrels per day) and Algeciras (160,000 barrels); and the Refinería de Petróleos del Norte, S.A., with a refinery at Somorrostro (capacity 240,000 barrels per day).

Uranium.—Geologists from Empressa Nacional del Uranio, S.A., conducted exploration for uranium in the Provinces of Salamanca, Cáceres, and Badajoz. In addition, areas near Soria, Molina de Aragón, and in the Tagus Basin were targets of geological exploration. At yearend, no discoveries of major new uranium deposits had been announced.

The Province of Salamanca remained the largest producer of uranium oxide (U_3O_8) in Spain with about 80% of the country's total reserves. Authorities were planning to build a new yellow cake plant with a capacity of about 800 tons of U_3O_8 per year by 1985.

The apparent slippages in construction of nuclear powerplants were a major concern of the authorities because delays in startup of nuclear plants would extend dependence on costly imported oil.

The Mineral Industry of Sudan

By Ben A. Kornhauser[1]

The mineral industry continued to be of minor significance to Sudan's estimated gross domestic product (GDP) of $4,050 million.[2] The production of mineral commodities in 1981 essentially was stagnant relative to that of 1980. Their estimated contribution, excluding refined petroleum products, was about 1% of GDP. The balance-of-payments deficit in 1981 increased to $700 million from $534 million in 1980. This deficit created a greater imbalance in foreign exchange which limited growth of the mineral industries further by restricting purchase of parts, equipment, and services.

Sudan is among the 10 oil-importing developing countries in Africa with the best potential for economic oil prospects. The new oil-field discoveries in 1981 and during last few years hold promise of improving Sudan's future economic structure. However, relatively small discoveries, which require greater investments to develop production, may reduce economic stimulus.

The Sudanese Government continued the construction of its transport infrastructure to expedite mineral and industrial development and distribution of agricultural, industrial, and mineral products. Roadbuilding was emphasized since the money required for road development has been calculated to be less than the cost of rehabilitating the railroad. The Government's allocation for roads, under its 6-year development plan (1977-78 to 1982-83), is estimated to have been exceeded by the end of the plan's third year. Except for the roads already under construction within this plan, lack of funds will limit the building of much needed roads in the future. Roads under construction are: The Wad Medani-Sennar-Kosti, Sennar-Singa-Damazin, Nyala-Kas-Zalingei, Nyala-El Fasher, and White Nile.

The Wad Medani-Sennar-Kosti road provides access from the Khartoum-Wad Medani road to the Sudanese sugar region and factories. The terminus of the road is Kosti, which is Sudan's most important river harbor, the main loading point for river transport to southern Sudan, and the site selected for Sudan's second oil refinery. The financing came from the United Kingdom and the Organization of Petroleum Exporting Countries (OPEC) Special Fund.

The Sennar-Singa-Damazin road crosses the Blue Nile Province and links it to the Gezira Province in the north. The Blue Nile Province has chromite mines and is rich in agricultural and forest resources. The road to Damazin will provide access to Roseires Dam, the country's main source of hydroelectric power. Twenty-five percent of the 258-kilometer road, which had been completed by early 1981, is being checked by the contractor, an Egyptian company, since the construction is considered below specifications.

The Nyala-Kas-Zalingei 210-kilometer road is within Southern Dorfur Province and is rich in animal and forestry resources. The road, which was expected to be asphalted in 1981 and inaugurated in mid-1982, will permit goods to move to Nyala, the railroad's most westerly point.

The Nyala-El Fasher road will link the two western provincial capitals of the Dorfur region. The road will provide access to Nyala, which is served only by Sudan Railways, and to El Fasher, which only has scheduled flights to Khartoum. The Netherlands is financing the project and supplying the equipment. However, since traffic loads are projected to be light and funds appar-

ently are unavailable for a better surface, the road will be of a raised gravel construction.

The White Nile road in central Sudan will extend southward from Khartoum in two phases. Phase One was started in 1980 and includes 152 kilometers of road, a 6-kilometer spur to the White Nile, and two ferry boats linking the spur with the town of El Dueim. The road will serve many White Nile pump-irrigation projects, which supply vegetables and dairy products to Khartoum, and will ease travel to western Sudan. In phase two of road construction, the road will continue southward to Kosti, joining the Sennar-Kosti road and the railroad. The road is being financed by the International Development Association and the Federal Republic of Germany. Construction was expected to start in 1981. Many more roads are necessary but are awaiting financing.[3]

The Port Sudan operation (World Bank part 1 project), managed by the Sea Ports Corp. of the Ministry of Transportation and started about 3 years ago, was not completed on schedule in 1981 but is expected to be finished in the second half of 1982.

PRODUCTION AND TRADE

The mining industry, on a limited scale, produced mostly chromite, gypsum, and mica. Cement production, although reduced in 1981, represented a significant part of the value of minerals in the economy.

Sudan's import trade is relatively small and is with European and nearby African and Middle Eastern countries. The dominant imports are iron and steel products, cement, fertilizers, and petroleum refinery products. However, most of the steel-mill products or semifinished materials were imported from the Far Eastern countries of Japan and the Republic of Korea. No reliable data on values were available.

In its present state of development, Sudan's small quantities of exports were mainly unprocessed raw materials or concentrates and internally generated scrap materials. These exports, mostly to Western Europe, consisted of ferrous and nonferrous scrap and locally mined chromite and manganese ores and concentrates. The imposition in early 1981 of a 5% tax on a number of exported minerals and petroleum products was expected to have a detrimental effect on Sudan's major export, chromite. With transport costs and Government royalties amounting to more than 70% of chromite prices, future production may stop if expected railway tariffs are imposed.

Table 1.—Sudan: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity[2]	1977	1978	1979	1980[p]	1981[e]

[e]Estimated. [p]Preliminary. [r]Revised.

[1]Table includes data available through July 19, 1982.

[2]In addition to the commodities listed, modest quantities of a variety of crude construction materials (including clays, stone, and sand and gravel) presumably were produced, but output is not reported quantitatively, and available information is inadequate to make reliable estimates of output levels. Crude oil was produced from several wells on a testing basis but was not being produced for domestic use or export through yearend 1980.

COMMODITY REVIEW

METALS

Chromite.—Chromite production in 1981 was estimated at 25,000 metric tons but is expected to increase within the next 5 years owing to a better transportation infrastructure. Haulage costs via the asphalt roads south to Damazin are expected to compare favorably with railroad transport. The Mitsubishi Corp. of Japan was exploring for chromite deposits in the Ingessana Hills of the Blue Nile Province. Mitsubishi is still interested in a ferrochrome production unit to supply about 20,000 tons per year instead of the 150,000 tons per year originally agreed upon with the Sudanese Government.

Copper.—The Geological and Mineral Resources Department (GMRD) and the French Bureau de Recherches Géologiques et Minières (BRGM) were still evaluating copper and tungsten prospects in the Red Sea Hills area. Saudi Arabia allocated about $11 million during 1981 to finance further prospecting by BRGM and Total Exploration, a wholly state-owned subsidiary of the French Compagnie Français des Pétroles (CFP-Total).

Gold.—A gold rush was still underway in the southeast near the borders of Kenya and Uganda. Tribespeople worked rich gold placers along the Thingaita River and bartered much of the gold for rifles from remnants of Idi Amin's army. Local and foreign companies also were exploring for gold and base-metal deposits. Minex, Inc., a subsidiary of Vam Pty. Ltd. of Australia, was prospecting for gold in the area of 36° E and the Nile. This region was considered one of Africa's most significant gold-bearing districts. By the end of 1981, Minex had discovered 30 previously unknown prospects and was examining about 50 known deposits. Mowlem-Africa Construction Co., Ltd., a joint Sudanese and British company, was evaluating the gold potential in the ancient gold mining district of Fazughli south of the Blue Nile and along the Ethiopian border. The initial assays looked promising.[4]

Metal-Rich Sediments.—According to the Saudi-Sudanese Red Sea Commission for the Exploitation of Red Sea Resources, the pilot plant for mining the metalliferous muds of the Red Sea Atlantis II Deep Basin was scheduled to be completed in 1981. By yearend 1981, the Saudi-Sudanese Red Sea Commission had spent over $300 million on the program of mining, recovering, and processing the seabed minerals identified in the sediments. Commercial production is not expected until 1988, when zinc and copper are expected to be exploited along with lead, silver, and cadmium. The mining and extractive process that was developed by Orenstein & Koppel AG of the Federal Republic of Germany, involves agitating the freed seabed muds, mixing them with seawater, and pumping the slurry to a processing ship for mineral concentration. The concentrate would be shipped by barge to a smelter-refinery, which would be constructed. The residual tailings slurry would be returned to the sea at a depth of 500 feet, where tests indicate an acceptable environmental dispersion as the residue settles onto the seabed. In 1979, the exploratory drilling ship, *Sedco*, had performed the preliminary work that led to this effort.

Radioactive Minerals.—Minex was expected to drill for radioactive minerals in its Jabal Dumbeir and Jabal Kon concessions in Kordofan. Important radioactive anomalies within syenites were discovered in the Nuba Mountains area by a West German team and a team from the University of Khartoum.

NONMETALS

Cement.—The Atbara plant of the Maspio Cement Corp. was being expanded by the addition of a 750-ton-per-day rotary kiln plus a single-stage cyclone preheater and Unax cooler. This equipment also includes a 3.2- by 9-meter raw mill and a 3.4- by 11-meter finishing mill. The modernized plant is expected to be in use in 1982.

Mica.—The Geological Survey Department of the Ministry of Energy and Mining began a pilot project in 1976 in Khartoum to produce trimmed mica. In 1978-79, as a result of this project, about 1,000 tons of scrap mica were produced along with 1 ton of hand-trimmed mica of different sizes. Owing to various contributing factors, such as poor transportation, outdated equipment, and insufficient financing, the project deteriorated and production of trimmed mica dropped significantly. In spite of this setback, it has been reported that the northern region government is interested in revitalizing the project and that some private companies are interested. By the end of 1981, 3 of the original 18 prospective sites had been worked. The Government held negotiations to sell 10,000 tons of mica at Port Sudan. The northern region government believed that an additional 4,000 tons of mica could be mined from these three sites and from new finds. Mica deposits are known to exist

on the eastern bank of the Nile in the Northern Province.[5]

MINERAL FUELS

Petroleum.—The successful discoveries of petroleum since 1979 by Chevron Oil Co. of Sudan (a subsidiary of Standard Oil Co. of California) spurred additional exploration by Chevron, Texas Eastern Corp., Union Texas Petroleum Corp. (an Allied Chemical Corp. subsidiary), Phillips Petroleum Co., and Total Exploration of France. The latter four companies were exploring the Red Sea concessions relinquished by Chevron. In 1981, Chevron increased the number of its exploratory and drilling crews in its leased areas. By the end of 1981, Chevron had completed 31 wells in its interior blocks, with a total drilled footage of 339,568. Six of these wells were new field discoveries, of which one, Tabaldi No. 1, recovered oil but was not classified as a discovery. None of the oilfields were in production. The cost of Chevron's program exceeded $300 million. This exploration pace was expected to continue in 1982. Chevron believed that Sudanese oil reserves could reach 10 billion barrels, more than the Indonesian 9.2 billion or Algerian 8.2 billion. Chevron's south fields could hold 400 million barrels, and much of the country was still to be explored. Kosti, the site of the planned Chevron refinery, also will be a large terminus for transporting products from the topping plant to the south and to oil exploration areas.

CFP-Total was exploring for oil and gas on approximately 145,000 square kilometers in the Muglad region of southern Sudan, adjoining the southeast area where Chevron made its oil discoveries at Abu Gabra, Sharaf, and Unity. CFP-Total also will explore an area offshore from Port Sudan, consisting of about 6,400 square kilometers. Texas Eastern and Union Texas, on the other hand, were exploring in northern Sudan near the Egyptian border. Texas Eastern's concession was for 26,700 square kilometers onshore and offshore from the northern Red Sea coast. Seismic work and drilling were scheduled into 1982.

Phillips Petroleum and the Government of Sudan agreed on an oil exploration contract whereby Phillips will explore 18,000 square kilometers in north-central Sudan just west of Khartoum and continuing northwesterly to a point west of Dongola. The area covers a sedimentary basin and is highly accessible all year. However, the area was considered less promising than the Red Sea or Chevron concessions. The Sudanese Government acquired a 15% equity in any production and received bonus payments exceeding $1 million for the leases.

Government negotiations were underway in 1981 regarding leases for onshore locations in the Red Sea region of northwest Sudan and for abandoned Chevron concessions in the south and west. These negotiations involved several firms including Mobil, Conoco, Sun Oil, and Trans-Pacific of Canada.

Saudi Arabia and the Federal Republic of Germany jointly planned to finance the reconstruction of the neglected Red Sea port at Sowakin at a cost of approximately $300 million to provide better service to the Shell-British Petroleum Port Sudan refinery, which will be handling Saudi-produced oil.

Refining.—A consortium, consisting of the International Finance Corp. of the World Bank, Chevron, the Sudanese Government, and the Arab Petroleum Investment Corp., established the White Nile Petroleum Co. that was arranging financing and preparing a request for a proposal package for the construction at Kosti of an oil refinery and a pipeline. The oil refinery (with a maximum capacity of 15,000 to 25,000 barrels per day) will be built on the White Nile, 275 kilometers south of Khartoum, to process the oil from Chevron's wells in the southeast areas of Abu Gabra, Sharaf, and Unity. The refinery and about 550 kilometers of 10-inch pipeline, to transport the crude from the Unity Field to the refinery, are projected to cost between $600 to $1,000 million. This project will provide products for Sudan's internal market.

The Port Sudan refinery was unable to operate at its full capacity of 1.2 million tons per year during 1981 because it was unable to obtain sufficient credit for crude from oil suppliers. To complicate matters, the oil storage at Port Sudan has a capacity of less than 50,000 tons for handling incoming deliveries.

The Mineral Industry of Sweden

By Joseph B. Huvos[1]

The recession in Sweden reached a trough in 1981, and signs of an economic upturn were visible by yearend with the stimulus to industrial production coming mainly from export demand. A 10% devaluation of the krona in September was expected to boost exports further. Sweden's gross national product in 1981 was about $123 billion,[2] a decrease in real terms of 0.8%. The balance-of-payments current-account deficit decreased in 1981 because of reduced imports. Unemployment was 2.5%, and the consumer price index rose by 12.1%.

In 1981, Sweden's mineral industry remained small but technologically advanced. The country continued to be one of the world's largest iron ore producers, and there was significant production of nonferrous metals and industrial minerals. Hydroelectric and nuclear power were abundant, but fossil fuels had to be imported.

Significant developments in Sweden's mineral industry in 1981 included commissioning of the Boliden AB Kristineberg sulfide ore mine and expansion of its Aitik copper mine, and conversion of the two Cementa AB cement plants to coal. Construction continued on the Luossavaara Kiirunavaara AB (LKAB) Viscaria copper mine and on the new Svenskst Staal AB (SSAB) ore pelletizer at Grängesberg. Government holdings in SSAB were increased, and merger talks started in the stainless steel industry. The Government's new energy bill was approved. The Stora Kopparbergs Bergslags AB (SKB) Falun open pit metal mine was closed, and plans were disclosed to close Boliden's Vassbo lead mine.

PRODUCTION

Production of mineral commodities in 1977-81 is shown in table 1.

Indices of Swedish mineral industry production in 1980-81 are shown in the following tabulation (1968=100):

Industry sector	1980	1981[p]
Iron ore mining	86	74
Nonmetallic minerals	92	81
Metal industries	118	109
Mining, quarrying, manufacturing	128	123

eEstimated. pPreliminary. rRevised. NA Not available.

[1]Includes data available through Oct. 1, 1982.

[2]In addition to the commodities listed, cobalt, nickel (as nickel sulfate), and metallic titanium are also produced, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[3]Production of sponge iron is as follows, in thousand tons: 1977—161; 1978—117; 1979—136; 1980—not available; and 1981—not available.

[4]Includes clinker as follows, in thousand tons: 1977—43; 1978—15; 1979—not available; 1980—not available; and 1981—not available.

[5]Represents material for sale, not that produced.

[6]Includes strontium minerals, unspecified minerals, and fragments of ceramic materials.

TRADE

Exports of Swedish goods declined 0.1% in 1981, and imports declined 6.5%. Sweden's principal trading partners were the countries of Western Europe. In 1981, the United States was the second largest foreign investor in Sweden, accounting for $271 million or 20% of the total. Also in 1981, the United States was the leading target of Sweden's investments abroad, with 28% of all foreign investments.

Sweden's mineral trade in 1979-80 is shown in tables 2 and 3.

Other	144,842	99,484	7,962	West Germany 34,279; Italy 20,447; United Kingdom 11,696.
Steel, primary forms	560,287	424,386	12,684	West Germany 97,774; Japan 85,998; United Kingdom 34,963.
Semimanufactures:				
Bars, rods, angles, shapes, sections	677,695	644,301	22,075	West Germany 126,282; Norway 69,467; Finland 67,298.
Universals, plates, sheets	655,966	625,568	26,637	West Germany 132,095; Norway 121,494; Denmark 71,996.
Hoop and strip	102,862	97,636	5,368	West Germany 17,606; Finland 11,162; Denmark 9,767.
Rails and accessories	30,315	37,427	--	Norway 22,705; Italy 7,988; West Germany 2,426.
Wire	77,693	65,406	6,232	West Germany 9,718; Finland 6,441; Denmark 5,932.
Tubes, pipes, fittings	256,669	230,902	11,214	West Germany 35,402; U.S.S.R. 22,782; Norway 20,508.
Castings and forgings, rough	2,543	2,239	10	Finland 713; Norway 598; Denmark 362.
Lead:				
Ore and concentrate	59,190	56,788	--	West Germany 38,662; Belgium-Luxembourg 13,765.
Oxides and hydroxides	129	181	NA	NA.
Metal including alloys:				
Scrap	36	65	--	West Germany 23; Norway 19; Denmark 12.
Unwrought	44,917	42,610	--	West Germany 18,078; Finland 10,735; Norway 3,168.
Semimanufactures	488	469	--	Finland 189; Norway 167; Saudi Arabia 57.
Magnesium metal including alloys:				
Scrap	239	307	17	West Germany 198; Denmark 65.
Unwrought	--	3	--	Mainly to Yugoslavia.
Semimanufactures	8	4	NA	Denmark 3.
Manganese:				
Ore and concentrate	164	7	--	All to North Korea.
Oxides and hydroxides	21	206	--	Denmark 200.
Metal including alloys, all forms	104	77	NA	Finland 73.
Mercury 76-pound flasks	551	841	--	Norway 725.
Molybdenum:				
Ore and concentrate	1,129	1,330	NA	West Germany 701; Netherlands 308; Japan 162.
Metal including alloys, all forms	12	2	1	United Kingdom 1.

See footnotes at end of table.

Table 2.—Sweden: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
METALS —Continued				
Nickel:				
Matte and speiss	64	--		
Metal including alloys:				
Scrap	482	503	18	Finland 171; India 171; United Kingdom 134.
Unwrought	1,516	1,906	252	Netherlands 1,311; United Kingdom 158; Spain 85.
Semimanufactures	1,406	1,347	209	France 216; West Germany 140; Italy 102.
Platinum-group metals including alloys, unwrought and partly wrought value, thousands	$6,955	$7,942	$54	United Kingdom $4,063; Finland $2,135.
Silicon, elemental do	$15,300	NA	NA	NA.
Silver:				
Ore and concentrate[2] do	--	$19	--	All to Finland.
Waste and sweepings[2] do	$19,945	$53,677	$822	United Kingdom $23,456; West Germany $22,869.
Metal including alloys, unwrought and partly wrought thousand troy ounces	7,298	7,780	NA	NA.
Tin metal including alloys:				
Scrap	8	5	--	All to Norway.
Unwrought	63	58	--	Finland 55.
Semimanufactures	47	27	--	Saudi Arabia 13; Finland 9; West Germany 2.
Titanium:				
Ore and concentrate	388	23	NA	NA.
Oxides and hydroxides	38	32	NA	Norway 19.
Metal including alloys, all forms	97	278	38	United Kingdom 147; West Germany 52.
Tungsten:				
Ore and concentrate	431	330	--	West Germany 222; India 64; Netherlands 44.
Metal including alloys, all forms	54	46	--	United Kingdom 29.
Zinc:				
Ore and concentrate	347,574	351,941	--	West Germany 77,789; Finland 73,642; Norway 68,340.
Ash and residue containing zinc	30,983	21,294	--	Norway 20,291; West Germany 513; Belgium-Luxembourg 324.
Oxides and hydroxides	486	478	NA	Norway 250; Finland 160.
Metal including alloys:				
Scrap	3,347	3,325	--	Norway 1,893; West Germany 501; Belgium-Luxembourg 350.
Unwrought	249	342	--	Norway 113; West Germany 102; Belgium-Luxembourg 49.
Semimanufactures	75	71	--	Finland 45; West Germany 15.
Zirconium metal including alloys, all forms	28	13	--	Japan 10; West Germany 3.
Other:				
Ash and residues containing nonferrous metals	r2,365	1,413	--	West Germany 460; Belgium-Luxembourg 448; United Kingdom 230.
Oxides, hydroxides, peroxides	99	200	NA	West Germany 150; United Kingdom 23; East Germany 18.
Base metals including alloys, all forms	r1,539	3160	16	United Kingdom 101.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	35	30	--	Norway 21; U.S.S.R. 7.
Artificial corundum	3,855	44	23	Norway 11.
Dust and powder of precious and semiprecious stones value, thousands	$47	$126	--	Finland $95; Denmark $28.
Grinding and polishing wheels and stones	2,447	2,512	--	Finland 331; France 292; U.S.S.R. 270; United Kingdom 270.
Asbestos, crude	112	14	--	United Kingdom 9; Switzerland 5.
Boron materials: Oxides and acids	29	47	NA	Norway 46.
Cement	165,394	348,512	85,744	Nigeria 222,067; Venezuela 35,820.
Chalk	9,309	10,210	--	Norway 3,553; Republic of South Africa 2,455; Finland 2,139.

See footnotes at end of table.

Table 2.—Sweden: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Clays and clay products:				
Crude	2,379	3,188	--	West Germany 1,065; Norway 856; Vietnam 471.
Products:				
Refractory including nonclay brick	36,742	59,057	1,080	Finland 15,790; Norway 13,514; West Germany 10,865.
Nonrefractory	28,252	23,778	250	Norway 6,687; Finland 3,430; Belgium-Luxembourg 3,351.
Cryolite and chiolite	--	2	--	Finland 1; West Germany 1.
Diamond:				
Gem, not set or strung value, thousands	$3,363	$10,197	$402	Finland $3,144; Belgium-Luxembourg $2,738; Norway $1,858.
Industrial do.	$38	$50	--	Belgium-Luxembourg $34; United Kingdom $16.
Diatomite and other infusorial earth	142	81	--	Norway 43; Yugoslavia 13; Finland 11.
Feldspar, fluorspar, etc	35,537	30,336	38	United Kingdom 11,235; East Germany 9,476; Austria 3,227.
Fertilizer materials:				
Crude:				
Nitrogenous	2,310	5,059	--	Belgium-Luxembourg 5,057.
Phosphatic	43,816	60,675	--	Norway 48,585; West Germany 6,100.
Manufactured:				
Nitrogenous	r35,313	39,084	--	NA.
Phosphatic	6,205	32,692	--	NA.
Potassic	440	--	--	
Other including mixed	8,235	8,021	18	Norway 5,169.
Ammonia	--	84	NA	NA.
Graphite, natural	47	47	36	NA.
Gypsum and plaster	--	266	--	Denmark 203; Norway 32; Finland 30.
Lime	2,292	8,092	NA	Norway 7,467.
Magnesite	551	225	--	Norway 156; Denmark 43.
Mica:				
Crude including splittings and waste	--	11	--	West Germany 5; Netherlands 2; Switzerland 2.
Worked including agglomerated splittings	1	3	NA	NA.
Pigments, mineral: Iron oxides, processed	45	70	NA	Norway 29.
Precious and semiprecious stones excluding diamond:				
Natural value, thousands	$334	$393	$3	Switzerland $112; United Kingdom $106; Australia $48.
Synthetic do.	$10,361	$13,664	$6	Ireland $13,443.
Pyrite, unroasted	7,046	84,705	--	Romania 84,382.
Salt and brine	5,037	1,475	--	Norway 840; Denmark 328; Finland 285.
Sodium and potassium compounds, n.e.s.:				
Caustic potash	3,619	3,692	NA	NA.
Caustic soda	3,765	11,940	NA	NA.
Soda ash	292	89	NA	Norway 82.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked:				
Calcareous	3,039	2,062	--	Denmark 1,220; Netherlands 648.
Slate	19,568	24,656	--	Belgium-Luxembourg 12,225; Denmark 4,639; Norway 3,664.
Other	200,455	111,921	16	West Germany 47,951; Italy 23,980; Denmark 21,114.
Worked	12,714	11,569	228	Denmark 8,666.
Dolomite, chiefly refractory-grade	4,347	36,446	--	Denmark 8,573; Netherlands 8,409; West Germany 7,793.
Gravel and crushed rock thousand tons	1,574	1,525	--	Denmark 846; West Germany 594.
Limestone excluding dimension do.	1,013	953	--	Finland 726; West Germany 114; Denmark 111.
Quartz and quartzite	141,397	103,092	1,560	Norway 85,291.
Sand excluding metal-bearing	67,624	72,259	(1)	Norway 62,855.

See footnotes at end of table.

Table 2.—Sweden: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Sulfur:				
Elemental, other than colloidal	20,597	29,513	--	United Kingdom 19,631; Netherlands 6,384; West Germany 3,015.
Dioxide	24,124	14,528	NA	Finland 5,581; Norway 4,815; West Germany 3,220.
Sulfuric acid	36,757	14,760	NA	Finland 7,967; Denmark 4,010; Norway 2,422.
Talc, steatite, soapstone, pyrophyllite	3,776	5,649	--	United Kingdom 4,391.
Other:				
Crude	7,596	9,346	--	United Kingdom 3,627; Denmark 3,009; Norway 1,901.
Slag, dross, similar waste	139,153	83,342	(1)	Finland 38,588; Norway 20,550; United Kingdom 17,398.
Oxides, hydroxides, peroxides of barium, magnesium, strontium	42	35	NA	Argentina 20.
Building materials of asphalt, asbestos and fiber cements, unfired nonmetals	3,557	4,801	NA	Norway 1,641; Finland 1,396; Hungary 735.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	76	10	--	Poland 9.
Carbon black	6,296	8,650	NA	Norway 2,991; Poland 2,513; Finland 2,244.
Coal including briquets:				
Anthracite and bituminous	24,479	3,994	--	All to Finland.
Lignite	1,000	1,129	--	All to Norway.
Coke and semicoke	26,502	114,174	--	Finland 113,994.
Hydrogen, helium, rare gases	171	580	NA	Norway 353; Finland 176.
Peat including briquets and litter	33,141	30,234	25	Denmark 15,858; Norway 10,313.
Petroleum and refinery products:				
Crude thousand 42-gallon barrels	569	646	--	All to Finland.
Refinery products:				
Gasoline do	r5,341	6,593	--	Denmark 2,618; Norway 1,321; United Kingdom 923.
Kerosine and jet fuel do	184	377	--	United Kingdom 223; France 84; Norway 60.
Distillate fuel oil do	4,602	8,318	--	Denmark 5,096; Norway 1,978.
Residual fuel oil do	12,360	17,608	--	Denmark 6,327; France 1,882; Netherlands 1,807.
Lubricants do	489	495	(1)	Norway 156; United Kingdom 94.
Other:				
Liquefied petroleum gas do	1,136	481	--	Norway 45; Denmark 36.
Mineral jelly and wax 42-gallon barrels	3,195	4,840	--	Norway 4,415.
Petroleum coke do	1,876	--		
Bitumen and other residues do	393,815	446,640	--	Denmark 248,745; Norway 94,100; Finland 73,726.
Bituminous mixtures do	34,990	34,542	(1)	Finland 7,230; Norway 4,987; Netherlands 4,436.
Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals	r207,740	166,296	--	Netherlands 129,311; Denmark 23,960.

rRevised. NA Not available.
[1]Less than 1/2 unit.
[2]May include other precious metals.
[3]Excludes silicon metal valued at $18,113,000.
[4]Excludes quantity valued at $18,662,000 distributed to the United Kingdom ($17,781,000) and France ($881,000).

Table 3.—Sweden: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1979	1980	Sources, 1980	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite	67,791	65,335	--	Australia 24,426; Greece 12,619; Guyana 9,487.
Oxides and hydroxides	199,589	235,062	48,161	Jamaica 94,774; West Germany 59,562; Panama 26,000.
Metal including alloys:				
Scrap	5,802	3,507	1,004	Norway 1,755; United Kingdom 377.
Unwrought	36,738	36,868	970	Norway 28,244.
Semimanufactures	59,377	52,012	4,733	West Germany 13,337; Norway 8,973; France 5,070.
Arsenic, all forms	--	5	2	West Germany 3.
Antimony metal including alloys, all forms	19	14	--	China 10; United Kingdom 4.
Beryllium metal including alloys, all forms value, thousands	$17	$23	$15	West Germany $8.
Cadmium metal including alloys, all forms	168	268	--	Finland 160; Norway 56; Japan 52.
Chromium:				
Chromite	665,017	332,328	--	Finland 144,059; Albania 61,075; Turkey 43,938.
Oxides and hydroxides	500	432	--	West Germany 403.
Metal including alloys, all forms	215	144	NA	United Kingdom 77; France 37; Denmark 16.
Cobalt:				
Oxides and hydroxides	4	2	--	Belgium-Luxembourg 1; France 1.
Metal including alloys, all forms	507	487	13	Belgium-Luxembourg 231; Zaire 57; Finland 47.
Copper:				
Ore and concentrate	33,153	46,870	--	Norway 26,242; Chile 10,899; Yugoslavia 5,841.

COMMODITY REVIEW

METALS

Aluminum.—Gränges Aluminium AB, one of Europe's smaller primary aluminum makers but Sweden's only one, operated its Sundsvall smelter on the east coast at near capacity but had to put on hold a project to build a new 80,000-ton-per-year smelter at Piteaa located south of Luleaa, also on the east coast.

Copper, Lead, and Zinc.—In 1981, Boliden AB remained Sweden's largest nonferrous sulfide ore mine operator, operating 15 mines, 7 ore processing plants, and 1 smelter. By yearend, the company had commissioned a new complex sulfide ore mine at Hornträsket in the Kristineberg area. Design capacity of the new mine was 70,000 tons of ore per year.

Expansion of Boliden's Aitik copper mine in the Gällivare area was completed, raising the mine's design capacity from 8 to 11.3 million tons of ore per year, but the added capacity could not be utilized during 1981 owing to mining and processing problems.

Boliden completed an extensive exploration project in the Vassbo area near Falun without finding any new ore deposits. The company was planning to close its Vassbo lead mine.

At the SKB Falun works, the company started to phase out open pit mining and increase underground operations. In 1981, the mine produced 29,000 tons of concentrates, but this was due to increase in the future, as new copper, lead, and zinc deposits had been found adjacent to the present mining areas.

LKAB continued construction of its Viscaria copper mine and processing plant located about 3 kilometers from the village of Kiruna. Full production was due to start by yearend 1983 when 1 million tons of ore were to be mined, yielding 85,000 tons of

25% concentrate containing about 12,500 tons of copper. The cost of the project was put at about $70 million. Copper concentrates were to be shipped to Finland's Outokumpu Oy Harjavalta smelter located on the west coast of Finland at Pori. AB Statsgruvor, an LKAB subsidiary, also operated sulfide ore mines at Haaksberg, Ludvika County, and at Stollberg, Smedjebacken County. The Stollberg Mine was to be closed in 1982.

Bolaget Vieille Montagne, a subsidiary of the Sté. des Mines et Fonderies de Zinc de la Vieille Montagne SA of Belgium, Sweden's only foreign owner of a mining company, improved operating techniques at its Aammebergsfeltet lead-zinc mine at Zinkgruvan, north of lake Vättern, producing almost 600,000 tons of ore in 1981. Zinc concentrate output rose substantially, accompanied by a 5% rise in the price of zinc.

Iron Ore.—In 1981, Swedish iron ore production decreased by 15%. Sweden's major iron ore producer, Government-owned LKAB, was forced to suspend production for 8 weeks in the summer. In Kiruna, production was shut down for another week in autumn, and for the next 7 weeks, production was cut to only 4 days per week. The estimated loss for the company was almost $140 million, corresponding to 30% of turnover or about $20,000 per employee.

The Swedish Parliament appropriated $250 million to meet LKAB capital requirements during 1982-84; it also set aside funds to halve the company's rail transportation costs in 1982 and decided to cut the company's work force by 1,000 by the end of 1983. The LKAB investment in iron ore mining was to be held down to about $65 million per year through 1986. By the mid-1980's, the company was to decide whether it was to go ahead with the very heavy investment required to develop lower levels in its existing mines for maintaining production. To help the industry, the Government decided to reduce the employee social security cost to 10%, from its present rate of about 40% of gross wages.

LKAB and its West European customers agreed to increase iron ore prices by 5%. Production in 1982 was to be maintained at the 1981 level. In 1981, major buyers of Swedish iron ore were Belgium-Luxembourg, 4.5 million tons; the Federal Republic of Germany, 3.5 million tons; and France, 3 million tons.

In 1981, LKAB operated four iron ore mines in Swedish Lappland: Kiruna, Svappavaara, Tuolluvaara, and Malmberget. SSAB operated two iron ore mines in the Bergslagen area in central Sweden at Grängesberg and Dannemora.

The Grängesberg Mine was in the process of modernizing its pelletizing equipment, due to start operation in 1982. The Dannemora Mine produced 550,000 tons of iron ore in 1981. Existing reserves at the mine were sufficient until the year 2000, and large additional ore reserves were discovered.

Iron and Steel.—The Swedish steel groups Fagersta AB and Uddeholm AB were in an advanced stage of talks for merging their production facilities. The companies have agreed to negotiate the formation of a jointly owned company that would take over high-speed steel production at four plants: Fagersta's Laangshytten, Oesterbruk, and Vikmanshytten works and Uddeholm's Söderfors works, all in central Sweden. Although no detailed production figures were issued, Sweden produced about 31,000 tons of high-speed steel in 1980, and Uddeholm and Fagersta were among the largest producers.

In 1981, SSAB became 75% Government-owned by the acquisition of a 25% share held by SKB. The other SSAB shareholder, Gränges-Electrolux Group, agreed to provide new funding needed by the company amounting to about $75 million.

In 1981, SSAB operated three steelworks: Luleaa in north Sweden, Oxelösund in south Sweden (both on the Baltic), and Domnarvet in central Sweden. Besides SSAB, Sweden had 28 mostly privately owned iron and steel makers, processors, ferroalloy makers, and steelworks in 1981.

Tungsten.—Increasing amounts of scheelite concentrate were produced in 1981 by Government-owned AB Statsgruvor, a subsidiary of LKAB, which operated the Yxsjöberg tungsten mine near Ljunarsberg in the Bergslagen district. The concentrates were sold in the domestic market.

NONMETALS

Apatite.—In 1981, LKAB produced 124,000 tons of apatite concentrate at its Kiruna Mine byproduct plant. Capacity of the plant was rated at 200,000 tons per year. Old iron ore tailings were enriched by froth flotation.

Asbestos.—The Swedish Government's Norrlands-Fonden discovered an anthophyllite deposit of 50 million tons, with 60% to 80% anthophyllite, at Kuekeskerp, about 100 kilometers northeast of Kiruna. The deposit was rated marginal in present

economic conditions.

Cement.—Cementa AB has successfully converted its Slite and Degerhamn cement plants from oil to coal. In 1981, the company's capacity was about 3.5 million tons per year.

Dolomite.—Enström Mineral AB continued production of white dolomite and produced over 300,000 tons in 1981.

Industrial Minerals.—The industrial mineral production of Sweden in 1981 was described in detail in the technical literature.[3]

Sulfur.—BP Raffinaderi Göteborg ordered from the Impianti Gas International a sulfur recovery plant for sour gases, rated at 2,000 tons of sulfur per year. The Göteborg plant already had an existing recovery plant of 3,000 tons of sulfur per year.

Sulfuric Acid.—In 1981, SKB produced 57,000 tons of sulfuric acid at its Falun plant in central Sweden.

Sulfuric acid used in Sweden for the production of fertilizers amounted to 245,000 tons in 1981.

MINERAL FUELS

In May, Sweden's new energy bill was approved. It included programs developed after the nuclear referendum of 1980, in particular, for energy conservation and for the decrease of oil consumption to 19 million tons of oil equivalent in 1990, two-thirds of the 1979 level; this was to be accomplished by coal and nuclear expansion, the expansion of electric power's share from 20% to 30% of the total, and the expansion of electric and district heating, particularly in combination heat and power plants.

The energy balance of Sweden in 1980 is shown in table 4.

In 1981, imported oil supplied 67% of Sweden's energy needs; imported coal, 4%; hydroelectric power, 13%; nuclear power, 6%; and wood, waste, and others, 10%. On the consumption side, space heating accounted for 44% of all energy used; industry, 38%; and transportation, 18%.

Coal.—Höganas AB discovered 20 million tons of coal in south Sweden with 0.4% sulfur and 25% ash. The coal deposit was regarded as suitable for mechanized underground mining. There were no plans to exploit it.

The energy industry planned to invest $1.1 million over the next 5 years, mostly for coal-fired power stations. In 1981, few plants were beyond the planning stage except that of the Södertalje central heating plant, southwest of Stockholm, costing $95 million and built to convert 250,000 tons of coal per year when completed by 1983.

Nuclear Power.—A uranium mining project at Pleutajokk was canceled because of uncertainty about the quantity and grade of ore. LKAB had obtained all permits for the development outside the city of Arjeplog in northern Sweden, but additional drilling revealed complex mineralization in the ore, making exploitation uneconomical. Original tests had shown 700 grams of uranium per ton.

The Swedish nuclear power utility signed a contract worth $22 million for the supply of natural uranium by Conzinc Riotinto Australia Ltd., an Australian company that owns the rich Ranger Mine near Darvin. The contract covered the period 1982-96 and was to provide Sweden with 2,400 tons of natural uranium.

In 1981, Sweden had nine operating nuclear powerplants at four locations: Oskarshamn 1 and 2; Ringhals 1, 2, and 3; Barsebeck 1 and 2; and Fosmark 1 and 2, with a total capacity of 6,455 megawatts electrical. Furthermore, three nuclear powerplants, with a total capacity of 3,025 megawatts, were under construction: Ringhals 3, Fosmark 3, and Oskarshamn 3, for commissioning in 1982, 1985, and 1986, respectively.

A central facility for nuclear waste storage was being built at Oskarshamn. Final

Table 4.—Sweden: Energy balance for 1980

(Million tons of oil equivalent)

	Total energy	Solid fuels	Petroleum and refinery products	Hydroelectric power	Nuclear power
Production[1]	16.3	3.2	--	13.1	--
Imports	39.5	1.8	31.7	--	6.0
Exports	5.0	.1	4.9	--	--
Apparent consumption	50.0	4.9	26.8	13.1	6.0

[1]Includes only primary energy.

Source: Organization for Economic Cooperation and Development Energy Report, 1980.

storage of low activity waste was planned at Fosmark.

Peat.—In 1975, Swedish mineral legislation transferred peat rights from landowners to the Government. Peat was classified as a fuel mineral, making a Government permit or concession necessary to exploit it. When oil prices rose higher in 1978-79, more interest arose in peat as a fuel. It was planned to produce about 50,000 tons of peat in 1982. In 1990, the goal for peat production according to the Government's energy bill was 4.5 million tons or 10 terawatts per year, requiring the exploitation of 16,000 hectares of peat bogs annually, which industry sources regarded as hard to achieve.

Petroleum.—In 1981, Sweden had only an insignificant production of crude oil located on Gotland Island. Most petroleum used had to be imported. Four oil companies operated six oil refineries with a total distillation capacity of 453,000 barrels per day, and there were plans to build new cracking capacity of 61,000 barrels per day at the Skandinaviska Raffinaderi AB Lysekill refinery on the Skagerrak.

The Mineral Industry of Switzerland

By Roman V. Sondermayer[1]

As in the past, Switzerland remained poor in economic mineral deposits. During 1981, many mineral deposits existed but few were in production. Domestic mineral output was limited to construction materials and salt. In addition, Switzerland was a processor of imported crude oil, alumina, and raw materials for production of iron and steel. Imports of bituminous coal, crude petroleum, natural gas, and petroleum refinery products were essential to meet the country's energy demand. Hydroelectric power and fuelwood were the primary sources of energy produced in the country.

The economic slowdown in Europe slightly affected the mineral industry of Switzerland. Construction activity suffered a lesser downturn than in other European countries; thus, the production of construction materials did not decline as elsewhere. About 2% of the gross national product can be attributed to the mineral industry. Modernization of two aluminum plants was the only significant development in the mineral industry of the country during 1981.

PRODUCTION

Salt was produced by a Government-owned monopoly; otherwise, the mineral industry of Switzerland was privately owned. Table 1 shows the latest trends in production during 1977-81.

Gas, manufactured ------ million cubic feet--	2,303	1,808	1,855	1,789	1,800

See footnotes at end of table.

Table 1.—Switzerland: Production of mineral commodities[1] —Continued

(Thousand metric tons unless otherwise specified)

Commodity[2] and unit of measure	1977	1978	1979	1980[p]	1981[e]
MINERAL FUELS AND RELATED MATERIALS —Continued					
Petroleum refinery products:					
Liquefied petroleum gas thousand 42-gallon barrels	(4)	(4)	1,229	1,199	[3]1,092
Gasoline, all kinds do	8,475	7,434	8,381	9,527	[3]10,371
Jet fuel do	1,512	1,604	1,664	1,793	[3]1,851
Kerosine do	39	--	39	44	[3]46
Distillate fuel oil do	14,278	13,457	14,696	15,527	[3]13,201
Residual fuel oil do	6,747	5,354	6,380	4,431	[3]3,615
Other refinery products do	2,103	2,265	906	798	[3]768
Refinery fuel and losses do	1,318	1,200	2,041	1,896	[3]1,766
Total do	34,472	31,314	35,336	35,215	[3]32,710

[e]Estimated. [p]Preliminary.

[1]Table includes data available through July 12, 1982.

[2]In addition to the commodities listed, a variety of crude construction materials (common clay, sand and gravel, and stone) is undoubtedly produced, but output is not reported and available general information is inadequate to make reliable estimates of output levels.

[3]Reported figure.

[4]Included in "Other refinery products."

TRADE

Tables 2 and 3 show the latest trends in foreign trade in minerals of Switzerland. It should be noted that large numbers of commodities are reexported. Fuels were the most expensive import items.

Table 2.—Switzerland: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite and concentrate kilograms	530	--	--	
Oxides and hydroxides	1,189	1,311	4	West Germany 1,095; Belgium-Luxembourg 56; Finland 22.
Metal including alloys:				
Unwrought including scrap	47,376	44,953	360	Italy 22,633; West Germany 15,920; France 2,903.
Semimanufactures	76,395	75,260	162	West Germany 13,772; France 10,483; United Kingdom 6,546.
Antimony metal including alloys, all forms kilograms	375	363	NA	NA.
Beryllium metal including alloys, all forms do	56	36	6	West Germany 26; France 1.
Chromium: Oxides and hydroxides	22	16	1	West Germany 4; Algeria 3; United Kingdom 3.
Cobalt: Oxides and hydroxides kilograms	1,531	509	--	Yugoslavia 450; West Germany 2.
Columbium and tantalum: Tantalum metal including alloys, all forms do	1,023	1,373	226	West Germany 961; France 77; Netherlands 48.
Copper:				
Sulfate	47	55	3	France 49.
Metal including alloys:				
Scrap	[r]9,285	12,075	(1)	West Germany 4,524; Austria 2,419; Hungary 1,351.
Unwrought	9,837	6,630	--	West Germany 3,498; Italy 2,221; Belgium-Luxembourg 412.
Semimanufactures	19,379	21,428	2,211	West Germany 4,854; Italy 3,459; France 2,735.
Gold metal including alloys, unwrought and partly wrought troy ounces	226,309	161,557	32	Portugal 48,612; West Germany 27,907; Iran 21,670.

See footnotes at end of table.

METALS —Continued				
Zinc:				
Oxides and hydroxides	45	43	--	West Germany 36; Yugoslavia 5.
Metal including alloys:				
Scrap	1,242	892	--	Italy 654; West Germany 116; France 96.
Unwrought	151	84	--	West Germany 82.
Blue powder	14	172	--	United Kingdom 162; Austria 9.
Semimanufactures	15	10	--	Austria 3; France 1; Iran 1; West Germany 1.
Other:				
Ores and concentrates	592	1,025	--	Austria 464; Turkey 219; Italy 100; West Germany 100.
Ash residue containing nonferrous metals	25,811	22,124	--	West Germany 11,506; Italy 4,078; Belgium-Luxembourg 3,486.
Waste and sweepings of precious metals value, thousands	$122,505	$212,194	$319	Spain $112,354; West Germany $49,614; France $43,979.
Oxides, hydroxides, peroxides	403	324	23	West Germany 168; Italy 74; Yugoslavia 11.
Metals:				
Metalloids	6,459	6,527	(1)	West Germany 5,975; United Kingdom 324; Austria 180.
Alkali, alkaline-earth, rare-earth metals kilograms	15,568	1,847	6	West Germany 107; France 73.
Base metals including alloys, all forms	167	139	36	West Germany 63; United Kingdom 6; Yugoslavia 5.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	29	19	(1)	Sweden 15.
Corundum, artificial	161	169	18	West Germany 127; France 9; Italy 7.
Dust and powder of precious and semiprecious stones kilograms	1,970	2,705	100	Italy 965; France 388; Belgium-Luxembourg 379.
Grinding and polishing wheels and stones	1,058	1,216	10	United Kingdom 310; West Germany 209; France 110.
Asbestos, crude	142	43	(1)	Italy 16; Austria 10; Barbados 7.
Barite and witherite	10	115	--	West Germany 108; Peru 5.
Boron materials:				
Crude natural borates	1	8	--	Mainly to West Germany.
Oxide and acid	5	12	(1)	Austria 6; Algeria 2; Peru 1.
Cement	28,340	30,335	--	West Germany 29,727; France 533; Austria 39.
Chalk	2,282	2,610	--	France 2,463; West Germany 108; Austria 14.
Clays and clay products:				
Crude	9,435	10,287	--	West Germany 9,689; Italy 265; Austria 160.
Products:				
Nonrefractory	46,802	53,335	36	West Germany 15,898; Italy 16,117; Austria 11,712.
Refractory including nonclay brick	1,563	2,156	(1)	Egypt 803; West Germany 542; Austria 431.
Cryolite and chiolite	1	53	--	Italy 50.
Diamond:				
Gem, not set or strung value, thousands	$1,234,023	$1,289,071	$78,983	Israel $409,891; United Kingdom $387,371; Belgium-Luxembourg $209,583.
Industrial do	$32,058	$40,721	$629	Italy $14,985; Belgium-Luxembourg $6,053; France $5,039.
Diatomite and other infusorial earth	6	19	(1)	Yugoslavia 10; France 1; Hungary 1.
Feldspar and fluorspar	255	282	--	Peru 133; Portugal 47; West Germany 47.

See footnotes at end of table.

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Fertilizer materials:				
Crude:				
Nitrogenous ____ kilograms	600	91	NA	NA.
Phosphatic ____ do	20	340	NA	France 40.
Potassic	2	24	--	Italy 20; France 1.
Manufactured:				
Nitrogenous	706	1,304	--	West Germany 1,046; Italy 80; Austria 43.
Phosphatic	4	13	--	Saudi Arabia 5; Czechoslovakia 3; Ghana 2.
Potassic	2	24	--	Italy 20; United Arab Emirates 2; France 1.
Other including mixed	1,709	2,159	(1)	West Germany 515; Ecuador 499; France 460.
Ammonia	7	47	--	Austria 40; Thailand 3; France 2.
Graphite, natural	11	10	2	Mexico 2; Peru 2; Philippines 2.
Gypsum and plasters	667	4,100	(1)	France 3,478; Austria 421; Italy 122.
Lime	1,944	2,091	--	West Germany 1,387; France 634.
Magnesite	32	35	--	Denmark 12; Peru 7; West Germany 6.
Mica:				
Crude including splittings and waste	46	117	NA	West Germany 95; Austria 9; Sweden 2.
Worked including agglomerated splittings	508	544	1	India 67; Norway 47; United Kingdom 45.
Pigments, mineral:				
Natural, crude	18	4	NA	Austria 1.
Iron oxides, processed	50	22	--	Yugoslavia 6; West Germany 4; France 2.
Precious and semiprecious stones, excluding diamond:				
Natural ____ value, thousands	$206,272	$243,384	$18,658	France $44,106; West Germany $32,530; United Kingdom $31,954.
Manufactured ____ thousand carats	262,930	219,585	4,610	West Germany 59,390; Italy 39,695; Austria 35,115; U.S.S.R. 20,000.
Salt and brine	3,459	234	--	France 214; West Germany 11.
Sodium and potassium compounds, n.e.s.:				
Caustic potash	33	127	--	Italy 100; France 14; Colombia 8.
Caustic soda	47,149	30,687	--	West Germany 18,318; Austria 10,749; France 1,092.
Soda ash	33,773	64,717	(1)	Italy 41,956; West Germany 21,544; Hungary 1,200.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	33,299	35,218	--	West Germany 20,255; Italy 9,582; France 3,781.
Worked	14,553	20,157	--	West Germany 17,078; Austria 2,490; France 174.
Dolomite, chiefly refractory-grade	8	19	--	West Germany 16; Austria 1.
Gravel and crushed rock	9,728	29,391	(1)	West Germany 23,698; France 3,665; Italy 854.
Limestone excluding dimension	--	31	--	West Germany 4; Italy 2; France 1.
Quartz and quartzite	34,441	39,356	1	Italy 37,445; West Germany 1,435; Austria 177.
Sand excluding metal-bearing	6,790	10,375	--	France 5,545; West Germany 3,101; Italy 1,191.
Sulfur:				
Elemental:				
Other than colloidal	15	20	--	All to Austria.
Colloidal	5	10	(1)	United Kingdom 3; West Germany 3; France 2.
Sulfuric acid	26,801	25,528	1	West Germany 17,473; Czechoslovakia 2,506; Italy 2,442.
Talc, steatite, soapstone, pyrophyllite	71	97	--	Austria 41; France 17; Argentina 11.

See footnotes at end of table.

Other:				
Crude	2,665	3,829	1	Austria 2,105; West Germany 1,473; France 77.
Slag, dross, similar waste, not metal-bearing:				
From iron and steel manufacture	15,128	2,674	--	All to West Germany.
Unspecified	795	1,335	--	France 909; Italy 232; West Germany 194.
Oxides, hydroxides, peroxides of barium, magnesium, strontium	22	17	(1)	Italy 6; Colombia 2; West Germany 2.
Halogens	21	27	(1)	United Kingdom 16; Romania 4; Bulgaria 1.
Building materials of asphalt, asbestos and fiber cements, unfired nonmetals	6,157	4,481	3	West Germany 1,663; Austria 736; Italy 721.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	2	--		
Carbon black	192	224	--	Czechoslovakia 84; France 45; West Germany 24.
Coal, all grades, including briquets	5,225	415	(1)	France 402; Austria 12.
Coke and semicoke	938	37	--	West Germany 26; Italy 11.
Gas, hydrocarbon, manufactured	58	95	--	France 94.
Hydrogen, helium, rare gases	53	39	(1)	Austria 18; West Germany 8; Saudi Arabia 6; Nigeria 4.
Peat including briquets and litter	2,215	1,396	--	France 814; Austria 511; West Germany 70.
Petroleum:				
Crude and partly refined 42-gallon barrels	3	17	--	Mainly to Canada.
Refinery products:				
Gasoline including natural do	31,041	92,185	(1)	Austria 91,760; Italy 183.
Distillate fuel oil do	24,760	85,198	99	Austria 55,030; Italy 21,075; West Germany 2,489.
Residual fuel oil do	104,672	132,577	--	Austria 125,525; France 7,052.
Lubricants do	28,225	37,313	107	West Germany 12,592; Italy 4,175; France 3,643.
Other:				
Liquefied petroleum gas do	194,551	119,115	--	Italy 48,310; West Germany 44,835; Austria 17,676.
Pitch and pitch coke do	142	183	82	West Germany 31; Yugoslavia 29.
Petroleum coke do	1,192	7	--	Mainly to West Germany.
Mineral jelly and wax do	4,398	1,695	2	Iraq 792; Yugoslavia 209; Colombia 156.
Bitumen and other residues and bituminous mixtures, n.e.s. do	14,710	15,353	--	Austria 11,791; West Germany 1,238; Finland 548.
White spirit do	674	727	--	Austria 643; West Germany 37; Israel 34.
Mineral tar and coal-, petroleum-, and gas-derived crude chemicals	1,169	1,139	--	West Germany 579; Italy 252; France 77.

r Revised. NA Not available.
1 Less than 1/2 unit.

COMMODITY REVIEW

METALS

Aluminum.—Work started on modification of aluminum smelters at Chippis, 30,000 tons of aluminum capacity per year and at Steg, 48,000 tons of aluminum capacity per year. Both plants were owned by Swiss Aluminium Ltd. Most of the modifications planned were to improve protection of the environment.

NONMETALS

Cement.—During 1981, the cement-producing segment of the Swiss mineral industry had an uneventful year. No new plants were commissioned, and there were no plant closures. Table 1 shows the trend of cement production for 1977-81.

The total capacity of 12 plants operating in Switzerland was 6.3 million tons. During 1981, the industry was operating at about 69% of the installed capacity. In addition, six clinker grinding plants were operational. The cement industry employed 1,405 persons, and the energy consumption amounted to about 16,000 terajoules. The switch from liquid fuels to coal continued. In 1979 about 20% of the total energy used in the cement industry was from coal, but by 1981 this figure was 67%.

Most of the cement plants used marly limestone of the Effingen beds in the Jura; various Jurassic limestones and Opalinus clays of the Aalenian were produced and added to obtain the right composition for production of portland cement.

In the Helvetic Alps, Zementstein at the Jurassic-Cretaceous boundary was another important source of raw materials for the cement industry. The Couches Rouges of the Prealps, Upper Cretaceous-Paleocene, and the Upper Jurassic-Cretaceous Maiolica and Scaglia in the southern Alps were used for cement production.

Gypsum.—The gypsum deposits of Switzerland were restricted to the Triassic formations in the Jura and in the Alps. Deposits were abundant but of rather low quality. In most deposits, primary gypsum was not preserved, and anhydrite replaced gypsum at depths between 15 to 50 meters. The Swiss gypsum industry was dominated by Gips-Union A.G., which operated three quarries in the Alps and two in the Jura Mountains.

Lime.—During 1981, the two largest producers of lime in Switzerland remained Kalkfabrik Netstal A.G. (Netstal) and Holderbank A.G. Netstal operated a 100,000-

ton-per-year plant situated at Netstal, some 30 miles southeast of Zurich. Holderbank operated its own plant at Holderbank with a capacity of 30,000 tons of lime per year. In addition, through its subsidiaries—the Kalkenfabrik Unterterzen A.G. and Société de Chaux et Ciments de la Suisse Romande—Holderbank operated plants near Unterterzen (30,000 tons per year) and Lausanne (12,000 tons per year). Limestone for production of lime was found in numerous places in the country, the purest of which was produced at St. Ursanne and near Glarus.

The Mineral Industry of Taiwan

By E. Chin[1]

Taiwan's gross national product (GNP) at current market prices was estimated at $45.1 billion[2] in 1981 compared with $44.3 billion in 1980. The net domestic product (NDP) in 1981 was $36.1 billion and was comprised as follows: Industry, $14.8 billion; commerce, $5.3 billion; Government services, $4.5 billion; agriculture and livestock, $3.5 billion; transportation and communications, $2.2 billion; real estate, $2.0 billion; money and banking, $1.6 billion; and other, $2.2 billion.[3]

Aside from construction raw materials, the only domestic mine output of significance included coal, china clay, oil and natural gas, salt, and serpentine. Output of the mining sector was valued at $708.9 million in 1981 compared with $595.9 million in 1980. The value of oil and natural gas production in 1981 was $294.7 million; coal, $183.5 million; metal mining, $148.2 million; and miscellaneous mining and quarrying, $82.5 million. Taiwan is deficient in many minerals, and domestic mine output is insignificant in terms of the world market.

Despite its dependency on foreign raw materials, Taiwan's manufacturing sector continued to grow. Total value of manufacturing was $41.5 billion in 1981 compared with $38.7 billion in 1980. Input by the major minerals sector to total manufacturing in 1981 included basic metals and metal products, $2.9 billion; chemical materials and products, $4.9 billion; nonmetallic mineral products, $1.5 billion; and petroleum and coal products, $4.7 billion.

The value of Taiwan's mine output has increased annually since 1976 resulting from higher world prices rather than the quantity of mine output. The total value of domestic mining in 1981 was less than 2% of GNP and/or NDP. Moreover, the mineral-processing sector outweighed the domestic mining sector in output value by a 20-to-1 ratio in 1981 compared with 13-to-1 a decade ago (1971).

During the past three decades, Taiwan's economic profile has changed drastically as a result of Government planning. During the 1950's, industrial production centered around goods in limited supply in the domestic market such as food products, fertilizer, and textiles. By the late 1960's and early 1970's, industrial production shifted to export products such as electronics, wood and plastic products, and optical equipment. During the 1970's, Taiwan's industrial base was geared for the manufacture of chemicals and heavy machinery. During this decade, petrochemicals, steel, and other metal production also gained prominence. For the 1980's, the Government's economic planning policies emphasized the development of precision technology industries.

The Executive Yuan approved the 4-year Economic Development Plan (1982-85) drafted by the Council for Economic Planning and Development. The 4-year plan, which stresses both growth and stability, projects an average annual growth of 8% of Taiwan's economy during the period, accompanied by an inflation rate not to exceed 7.5%. An economic growth of 7.5% was planned as a target for 1982 along with a 5.5% rise in wholesale prices. Per capita GNP was expected to reach $2,785 in 1982. The overall targets for the decade (1980-90) included a 7.9% annual economic growth rate and a 6% annual rate of increase in wholesale prices. Objectives for the 10-year period were to enhance energy efficiency, improve the industrial structure, improve

administrative efficiency and promote foreign trade, coordinate industrial and export development, and enhance efficient utilization of the work force and promote full employment.

Monthly employment in the mining and quarrying sector averaged 52,014 in 1981 compared with 1.9 million in manufacturing. Monthly earnings in the mining sector were $381 based on a monthly average of 188 working hours.

The Central Bank of China officially devalued the New Taiwan dollar from 36 to 38 per U.S. dollar, effective August 12, 1981. The Central Bank agreed to the devaluation in order to stimulate export sales by making Taiwan's export products more competitive worldwide.

PRODUCTION

In terms of value, coal, natural gas, limestone, and marble were Taiwan's leading mine products although none were significant in the world market. The other minerals mined in locally significant quantities included china clay and fire clay, dolomite, feldspar, salt, and serpentine. Taiwan also produces small amounts of gem stones, oil, and mica.[4] Metal mining output is likewise insignificant and included small quantities of copper and, periodically, iron sands. Most of the gold and silver produced was recovered as byproducts of imported copper concentrates. Taiwan is more important for its processing industries—aluminum, cement, copper, iron and steel, and petroleum refining. Aside from construction aggregates, Taiwan is virtually dependent on foreign ores and materials required by its value-added industrial sector.

Total do.	92,753	109,387	106,531	112,918	106,000

[e]Estimated. [p]Preliminary. [r]Revised.

[1]Includes data available through July 6, 1982.

[2]In addition to the commodities listed, tin and zinc may be produced, but statistical information is not available.

[3]Largely processed into natural gas liquids.

[4]Naphtha, solvent oil, and base oil.

[5]Includes liquefied petroleum gas and jet fuel among "not reported."

TRADE

Taiwan's two-way trade totaled $42.6 billion in 1981 compared with $39.5 billion in 1980. Exports increased 16.5% reaching $22.0 billion in 1981, while imports increased 9.4% to $20.6 billion. The value of total shipments to the United States was $7.9 billion; followed by Japan, $2.4 billion; Hong Kong, $1.5 billion; and the Federal Republic of Germany, $1.0 billion. Other major export destinations were Australia, Saudi Arabia, Singapore, Canada, and the United Kingdom, in that order. Japan was Taiwan's major supplier of imports, providing $5.8 billion. Receipts from the United States were $4.6 billion; Kuwait, $2.2 billion; Saudi Arabia, $1.7 billion; the Federal Republic of Germany, $0.63 billion; Australia, $0.58 billion; and Indonesia, $0.52 billion.

In 1981, Taiwan imported 17.2 million tons of crude oil, valued at $4.3 billion (about 21% of the value of total imports). Kuwait, Saudi Arabia, and Venezuela, in that order, supplied all of Taiwan's receipt of crude oil. Receipts of diesel fuel were valued at $449 million; iron and steel sheet and plate, $398 million; scrap ships and vessels, $225 million; stainless steel, $144 million; iron and steel scrap, $118 million; iron ore and concentrates, $65 million; and refined copper, $74 million. Taiwan's major export classes included food stuffs, fabric and wearing apparel, electronic and communications equipment, luggage and other travel goods, and machine tools and small machinery.[5]

Taiwan's trade posture was hampered by its high fuel import bill, a slowdown in the economies of its major export markets, and increasing competition from South Korean

exports. To enlarge its trade base, Taiwan has diversified its marketing efforts and is selling products in Africa, the Middle East, and Latin America. Taiwan lifted its trade ban with five East European countries in late 1979, and Polish ships were allowed to make regular port of calls in Taiwan. To service European trade, the Government gave approval for six European banks to set up branches in Taiwan.

Table 2.—Taiwan: Exports and reexports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
METALS				
Aluminum:				
Oxide and hydroxide	104	3,740	--	Indonesia 2,725; Republic of Korea 904.
Metal including alloys, all forms	6,943	7,456	41	Hong Kong 3,132; Japan 1,712; Indonesia 1,027.
Copper:				
Sulfate	18	195	--	Philippines 117; Indonesia 40.
Metal including alloys:				
Scrap	7,552	5,279	--	Japan 5,173.
Unwrought	236	273	--	Japan 256.
Semimanufactures	5,807	9,189	119	Singapore 3,461; Hong Kong 1,580; Malaysia 809.
Gold metal including alloys, unwrought and partly wrought troy ounces	225,666	607,070	--	Philippines 341,891; Republic of Korea 146,800.
Iron and steel metal:				
Scrap	72,065	12,863	(1)	Japan 12,022.
Pig iron, ferroalloys, similar materials	21,406	24,271	73	Japan 8,366; Indonesia 3,360.
Steel, primary forms	420,299	120,247	29	Indonesia 61,785; Malaysia 25,120; Philippines 11,636.
Semimanufactures:				
Bars, rods, angles, shapes, sections:				
Wire rod and other bars and rods	617,690	264,607	346	Hong Kong 82,153; Saudi Arabia 78,298; Malaysia 27,056.
Angles, shapes, sections	25,962	25,212	607	Saudi Arabia 5,829; Jordan 3,095; Hong Kong 2,762.
Universals, plates, sheets	266,345	161,175	1,822	Singapore 42,601; Japan 22,702; India 13,792.
Hoop and strip	4,015	3,416	86	Hong Kong 661; Indonesia 507; Jordan 450.
Rails and accessories	11,211	3,203	--	Malaysia 1,450; Singapore 1,248.
Wire	12,194	10,640	184	Hong Kong 1,985; Philippines 1,879; Thailand 1,355.
Tubes, pipes, fittings	158,480	179,754	71,101	Saudi Arabia 29,624; Hong Kong 11,173; United Arab Emirates 8,510.
Castings and forgings, rough	11,703	7,555	3,842	Japan 753; Thailand 689; Philippines 578.
Lead metal including alloys, all forms	11,423	11,895	1,128	Japan 6,446; Republic of Korea 2,060.
Magnesium metal including alloys, all forms	295	5	--	All to Malaysia.
Manganese oxides	7	(1)	--	All to Indonesia.
Nickel:				
Matte, speiss, similar materials	51	263	--	All to Japan.
Metal including alloys:				
Scrap	641	572	9	Japan 563.
Unwrought and semimanufactures	156	83	4	Japan 71.
Platinum-group metals including alloys, unwrought and partly wrought troy ounces	57,871	--		
Silver:				
Waste and sweepings kilograms	367	664	--	United Kingdom 413; West Germany 132.
Metal including alloys, unwrought and partly wrought troy ounces	22,956	1,061	--	All to Switzerland.
Tin metal including alloys, all forms	113	145	(1)	Hong Kong 90; Japan 31.
Titanium oxides	(1)	243	216	Republic of Korea 22.
Tungsten metal including alloys, all forms	10	8	--	Japan 4; West Germany 3.
Zinc:				
Oxide and peroxide	1,369	1,957	18	Japan 1,478.
Metal including alloys, all forms	597	493	68	Japan 237; Nigeria 52; Uruguay 42.
Other:				
Ash and residue containing nonferrous metals	524	761	22	Japan 456; Hong Kong 283.
Oxides, hydroxides, peroxides	91	25	--	Indonesia 22.
Metals:				
Metalloids: Silicon	17	20	--	Mainly to Malaysia.
Pyrophoric alloys kilograms	84	17	--	All to Chile.
Base metals including alloys, all forms	106	98	15	Hong Kong 43; Australia 12.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	3	19	--	Indonesia 9; Hong Kong 5; Malaysia 5.

See footnotes at end of table.

Artificial corundum	19	26	--	Indonesia 17; Republic of South Africa 6.
Dust and powder of precious and semiprecious stones including diamond kilograms	304	1,098	303	Japan 436; Hong Kong 359.
Grinding and polishing wheels and stones	2,354	2,148	434	Indonesia 401; Thailand 386; Hong Kong 210.
Barite and witherite	30	--		
Boric oxide, acid, borates, perborates	35	49	17	Republic of South Africa 17; Hong Kong 11.
Cement thousand tons	353	598	1	Hong Kong 261; Singapore 212.
Clays and clay products:				
Crude:				
Kaolin	30	--		
Bentonite	80	49	--	Nigeria 39; Malaysia 10.
Fire clay	20	--		
Other	168	178	--	Philippines 104; Singapore 40.
Products:				
Refractory (including nonclay brick)	6,371	7,488	19	Indonesia 1,758; Philippines 1,578; Singapore 1,123.
Nonrefractory	20,980	23,859	234	Hong Kong 13,926; Venezuela 3,328; Saudi Arabia 2,460.
Diamond:				
Gem, not set or strung:				
Natural thousand carats	2,675	345	5	Italy 160; Australia 135.
Manufactured do	2,455	12,410	7,440	France 1,740; New Zealand 1,220; Switzerland 770.
Industrial, natural do	(2)	3,915	3,895	Belgium 20.
Diatomite and other infusorial earth	50	184	--	Japan 178.
Feldspar and fluorspar	24	4	--	All to Indonesia.
Fertilizer materials:				
Manufactured:				
Nitrogenous	47,062	(3)	--	Do.
Potassic	--	1,000	--	All to Japan.
Other including mixed	11,382	373	5	Hong Kong 366.
Ammonia	9	144	--	Thailand 139.
Graphite, natural	615	505	--	Japan 437.
Gypsum and plasters	2,045	4 1,582	1	Indonesia 1,030; India 400.
Lime	1,682	5,247	--	Hong Kong 4,665; Nigeria 520.
Mica, all forms	112	119	--	New Zealand 51; Australia 34; United Kingdom 34.
Pigments, mineral: Processed iron oxides	93	53	--	Thailand 20; Singapore 17; Malaysia 9.
Precious and semiprecious stones except diamond:				
Natural kilograms	7,676	9,666	4,971	Italy 932; Panama 848; Switzerland 825.
Manufactured do	59,002	73,611	14,788	West Germany 30,504; United Kingdom 13,811.
Salt and brines	16,106	13,590	--	Hong Kong 10,350.
Sodium and potassium compounds, n.e.s.: Caustic soda	46,371	20,917	--	Republic of Korea 10,284; Indonesia 4,075; Philippines 3,185.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	61,884	4,367	11	Japan 3,410.
Worked	20,370	25,972	1,493	Japan 9,931; Saudi Arabia 8,057.
Dolomite, chiefly refractory-grade	80,133	93,390	--	Japan 90,550.
Gravel and crushed rock	229,082	315,349	--	Japan 314,873.
Limestone except dimension	2,388	2,416	--	Hong Kong 2,251.
Sand excluding metal-bearing	111,800	180,953	--	Japan 179,851.
Sulfur:				
Elemental:				
Other than colloidal	3,695	1,310	--	Indonesia 974; Singapore 112.
Colloidal	139	631	--	Indonesia 615.
Sulfuric acid, oleum	3,858	2,046	--	Hong Kong 1,505; Saudi Arabia 380.
Talc, steatite, soapstone, pyrophyllite	1,401	1,043	--	Thailand 264; Malaysia 230; Indonesia 178.
Other:				
Crude:				
Meerschaum, amber, jet kilograms	--	113	76	Bahrain 37.
Unspecified	552	654	--	Japan 338; Malaysia 134; Indonesia 100.
Slag, dross, and similar waste, not metal-bearing	4,608	1,573	--	Thailand 750; Indonesia 450; Japan 245.
Building materials of asphalt, asbestos and fiber cements, unfired nonmetals	2,307	338	4	Yemen 108; Thailand 94; Saudi Arabia 54.
MINERAL FUELS AND RELATED MATERIALS				
Carbon black and gas carbon:				
Carbon black	1,762	489	--	Thailand 235; Indonesia 191.
Gas carbon	11	7	--	All to Hong Kong.

See footnotes at end of table.

COMMODITY REVIEW

METALS

Aluminum.—Taiwan Aluminum Corp. (Talco), a wholly Government-owned company, operates two smelters at Kaoshiung. The older smelter, Kaoshiung I, with an annual capacity of about 35,000 tons, dates to the mid-1960's and was shut down in early 1981. Construction of Kaoshiung II, with an annual capacity of 50,000 tons, was completed in June 1980, and operated at about 60% of capacity during 1981. Shutdown of Kaoshiung I was attributed to inefficiency and pollution. Rising cost of electricity and decreased domestic demand for aluminum were cited in the curtailment in operating capacity for Kaoshiung II.

Taiwan's annual consumption of aluminum ingot was about 110,000 tons. Talco's inventory of ingot began to mount inasmuch as manufacturers were purchasing foreign metal with a distinct price advantage on the spot market. The Government banned the import of ingot in early June 1981 and partially lifted the ban in late June on the condition that users purchase 1 ton of Talco's inventory for each ton imported.

The cost per kilowatt-hour of electricity to Talco was 57 mills, compared with 70 mills in Japan, 15 mills in the United States, and about 25 mills in Western Europe. Talco maintained a cash price of $1,778 per ton of ingot, losing about $640 per ton. The construction industry accounts for about 60% of metal used in Taiwan, mostly for doors, siding, and windows. While demand in this sector was down, resurgence in construction was expected to pick up in 1982-83.

Talco has a 46,000-ton-per-year rolling mill that was built in the early 1960's and a 10,000-ton-per-year extrusion plant. A new 50,000-ton-per-year rolling mill was expected to begin operations in 1983. The $100 million rolling plant was to be equipped with a hot-rolling mill from Schloemann-Siemag AG, the Federal Republic of Germany; a cold-rolling mill from Secrim Division, Creusot-Loire, France; and additional equipment from Italy, Japan, and the United Kingdom.

Taiwan imports all of its bauxite and alumina requirements from Australia, Japan, and Malaysia. Low-grade bauxite occurs in the Tantunshan region in northern Taiwan, and in 1979 new deposits were discovered in the area with ore grade ranging from 30% to 50% Al_2O_3. The Industrial Technology Research Institute announced in September 1981 the discovery of a deposit estimated to contain 4 million tons of bauxite. A 3-million-ton bauxite deposit was found earlier in the vicinity.

Copper.—Taiwan Metal Mining Corp. (TMMC), a Government-owned company, operates an 18,000-ton-per-year copper smelter-refinery near Chinkuashih. This small plant, dating from 1947, was expanded subsequently in two stages in 1969-71 and in 1971-73. The plant uses ore and cement copper from the Chinkuashih Mine and imported concentrate and cement copper. About 90% of the copper refined is from imported material. TMMC started operation of a 50,000-ton-per-year smelter-refinery at Keeling in August 1980. This plant uses copper concentrates imported from Chile and the Philippines. With the increase in production of electrolytic copper, there was a notable increase in output of gold, silver, and sulfuric acid.

Because of falling copper prices and rising inventories, TMMC postponed the proposed expansion of its new smelter from 50,000 to 80,000 tons. The first stage of the expansion program, to begin in 1982 and be completed in 1983, was to be followed by a second-stage expansion to 130,000 tons. Annual domestic consumption of copper was about 110,000 tons.

Iron and Steel.—China Steel Corp. (CSC), a Government-owned company, operates the only integrated iron and steel mill in Taiwan at Kaohsiung. In July 1978, CSC began construction of its second-stage expansion whereby the capacity of its steelworks would be increased from 1.5 million tons of steel per year to 3.25 million tons per year in July 1982. As of the beginning of 1981, CSC had completed 51% of the phase 1, stage 2 construction of its expansion program. Cost of equipment supplied by U.S. manufacturers was valued at $250 million. Wean United Inc. was supplying a cold-rolling mill; General Electric Co. and Westinghouse Electric Corp., electric driving equipment; and Dravo Corp., sintering equipment. Overhead cranes were also to be imported from the United States. Equipment from Japan was to cost $400 million, which included a $40 million blast furnace to be supplied by Ishikawajima-Harima Heavy Industries, Inc. European companies were to supply additional equipment to cost about $150 million. When completed, new production was to be split between hot- and cold-rolled sheet.

Taiwan's consumption of steel is about 4 million tons. About two-thirds of CSC's output is consumed domestically and the remainder is exported. About 1.3 million tons is supplied by independent operators of electric furnaces, and the remainder of the nation's supply, from 1.2 to 1.4 million tons, by imports.

The Government initiated a program to consolidate the industry by offering incentives to small steelworks to merge, modernize, and expand. Companies that merge would be eligible for subsidy to install equipment to meet the statutory minimum limit of 50-ton-heat-size furnaces and 100,000-ton-per-year rolling mills. Also, merging companies would receive tax exemption for 5 years and an increase in electricity supply to match the capacity increase.

Tang Eng Iron Works Co. was expected to complete construction of its 50,000-ton-per-year stainless steel plant at Kaohsiung in May 1982, which was to be expanded later to 100,000 tons per year. Waterbury Production Machinery Corp. and General Electric Co. was providing the equipment for the plant's first phase. American Rolling Mill Corp. was assisting with the technology. Taiwan currently imports all of its requirements for stainless steel strip and sheet which totaled about 80,000 tons in 1981.

Mine output of iron ore in Taiwan is insignificant as well as sporadic. Production is limited to magnetite sand from placers between Tanshui and Wanli along the northern coast of Taiwan. Some limonite was mined in Tayiikeng, also in northern Taiwan, but there is presently no production from this source. Virtually all of Taiwan's requirement for iron ore was being met by imports of concentrates from Australia, Brazil, and the Republic of South Africa.

Zinc.—Annual demand for zinc in Taiwan was about 60,000 tons and consumption has increased yearly about 8% to 10%. TMMC's original plans for construction of a zinc smelter in northeast Taiwan was shelved in 1980. Officials of TMMC and the Government of the Republic of South Africa held discussions for Taiwan to purchase 50% equity in a South African zinc mine and for Taiwan to finance wholly the cost of constructing an 80,000-ton-per-year zinc smelter in South Africa. Consideration was also given to Taiwan's possible involvement in a copper and lead smelter in South Africa.

NONMETALS

Cement.—Taiwan's cement industry was comprised of 17 plants operated by 11 companies. Total industry capacity was about 14.5 million tons per year. Taiwan Cement Corp., the largest producer, has four plants: Kaohsiung, 1.9 million tons per year; Suao, 1.8 million tons per year; Chutung, 1.28 million tons per year; and Hualien, 290 tons per year. Asia Cement Corp. has three plants: Hsin-chu, 1.4 million tons per year, Hualein, 1.4 million tons per year, and Kuanhsi, 50 tons per year. Chia Hsin Cement Corp. has one plant at Kang Shan with an annual capacity of 1.2 million tons. These companies account for 66% of the total industry capacity for cement. Other producers were Chien Tai Cement Co., Ltd.; China Rebar Co., Ltd.; Chi-Shin Enterprise Inc.; Hsing Ta Marble and Cement Co., Ltd.; Hsin Hsin Cement Corp.; Southeast Cement Corp.; Universal Cement Corp.; and Yung Kang Industrial Development Co., Ltd. China Rebar Co., Ltd., with one plant at Tung-Shan, was to increase its capacity from 990 to 1.8 million tons per year in 1982.

Taiwan's three major producing areas were around Hsin-chu in the northwest, Taipei and Suao in the northeast, and Kaohsiung in the southwest. Except for the small operations, most of the cement plants had their own limestone quarries. Ten of the plants used oil, four used coal, and three were based on oil and coal. Total electric power consumption by the cement industry was 3,949 million kilowatt-hours in 1981.

Other Nonmetals.—There are many limestone deposits of commercial value that occur in Taiwan. The important ones are in the southwest and the east where large quarries are operated. The cement industry was the largest consumer of limestone in Taiwan followed by the sugar refining industry. Crystalline limestone, also in eastern Taiwan, is quarried for marble-decorative building stone. While most of the output is used by the cement and fertilizer industries, the production for decorative uses has grown from 193,000 cubic meters in 1971 to 3,300,000 cubic meters in 1981. Commercially important dolomite quarries are located in the Tachoshuichi stream north of Hualien. Other quarries include Hoping, Hojen, and Chungteh. However, the most important deposit is Chingchang-shan which was developed to provide dolomite for China Steel's iron and steel com-

plex in southern Taiwan. Other nonmetallic mineral production of local significance included clays, feldspar, and serpentine.

MINERAL FUELS

Taiwan produces only small quantities of coal, petroleum, and natural gas, and domestic energy output from all sources provided only 13.6% of the country's total energy supply in 1980. Taiwan's estimated total coal resources were close to 500 million tons with an estimated total recoverable reserve of 260 million tons. All of the commercially important coal deposits are in Miocene formations in northern Taiwan. Almost all of the coal mines are likewise in the north with about 70% of the workings around Keelung and Taipei. Coal mining is undertaken by different owners in small and irregular concession blocks. About 10% of the mines produce more than 3,000 tons per month while only two mines have a monthly production of over 10,000 tons. Most of the coal mines were based on slope development. In 1958, adit mining accounted for 7.7% of the total production, 3.4% in 1968, and as mining proceeded deeper, was negligible in overall production.

Domestically produced coal is used according to rank and quality; about 20% is classified as coking coal. Coal was the chief fuel in powerplants, railways, sugar mills, cement plants, ceramic kilns, and paper mills. Lesser amounts were used in fertilizer plants, aluminum smelters, textile mills, and alcohol plants. Also, household use consumes a small amount. Semi-coke produced from low-grade coking coal was more suitable for household use than raw coal.

Natural gas and small quantities of oil were produced in Taiwan since the first discovery made around the turn of the century. The important gas-producing fields included Chingtsaohu, Chinshui, Chiting, Chutung, Niushan, Pashatun, Tiehchenshan, and Yunghoshan. The major oil-producing fields were Chuhuangkeng and Tungtzechiao. The Chinese Petroleum Corp. (CPC) is the sole oil company in Taiwan and is under the supervison of the Government. CPC, which operates all of the gasfields in Taiwan, is responsible for all phases of the petroleum industry in the country from exploration, production, and refining to marketing. Because of the dim prospects of offshore finds, CPC has temporarily halted offshore exploration activities to conduct a reevaluation of its data. CPC was expected to shift gradually the focus of its domestic exploration and development program to participation in overseas projects. CPC has agreements for joint venture operations in the Philippines with Pioneer, Redeco, and Sulu Sea; in Colombia with Sunray Colombia Co.; and in Indonesia with Amoco Indonesia Petroleum.[6]

Taiwan energy supply-demand configuration was as follows, in 1,000 kiloliters of oil equivalence:

	1980	1981
Domestic production:		
Coal	1,722.9	1,684.9
Natural gas	1,958.5	1,668.9
Hydropower	728.9	1,194.3
Crude oil	211.4	182.8
Imports:		
Crude oil	20,590.6	19,878.8
Petroleum products	3,552.5	2,237.2
Coal	3,443.4	3,557.0
Nuclear	2,042.5	2,659.3
Total	34,250.7	33,063.2
Domestic consumption:		
Petroleum products	14,433.0	13,655.5
Electric power:		
Thermal	7,330.1	6,186.2
Hydropower	681.2	1,119.7
Coal and coal products	2,505.4	2,315.9
Nuclear	1,909.0	2,493.1
Natural gas	1,747.5	1,530.1
Exports:		
Petroleum products	883.9	1,199.0
Coal and coal products	5.5	7.5
Inventory adjustment	1,825.7	2,602.2
Total	31,321.3	31,109.2

In 1980, energy consumed by the energy sector was 3,939,300 kiloliters equivalent of oil; nonmetallic minerals sector, 3,517,700 kiloliters; chemicals, 2,758,900 kiloliters; metal products, 2,591,600 kiloliters; and other mining, 1,723,900 kiloliters. The industries with the fastest growing energy consumption during 1971-80 were as follows, in percents: Transportation, 16.5; miscellaneous mining, 13.2; metal products, 13.0; energy, 12.6; textiles, 11.9; agriculture, 9.6; and nonmetallic products, 8.9. Consumption of electrical energy in 1981 by select industries was as follows in million kilowatt-hours: Other chemical products, 3,949; iron and steel, 2,351; cement, 1,863; industrial chemicals, 1,181; metal products, 911; mining and quarrying, 718; aluminum, 663; and chemical fertilizers, 332.

The Mineral Industry of Tanzania

By Thomas O. Glover[1]

Diamonds continued to be the most important mineral commodity produced in Tanzania during 1981. The mineral industry contributed only a small amount to the country's real gross domestic product, estimated at $5.5 billion in 1981.[2] Nearly 90% of the value of mineral production and 50% of mineral export revenues were attributed to diamond sales.[3] Minerals produced on a small-scale basis, including cement, salt, kaolin, gypsum, and coal, were of domestic significance only. Precious stones, mica, gold, and tin comprised the majority of mineral exports during the year.

The Tanzanian Government continued to play a large role in the mineral industry sector of the economy. A new Minister of Minerals post was established, which was solely responsible for development of the minerals sector. The Minister of Minerals was responsible for (1) gathering geologic information, (2) proposing mining legislation, (3) organizing and coordinating the mining sector into several related institutions, and (4) actively pursuing mine development programs. Tanzania had a new mining act, cited as the Mining Act, 1979-No.17-12/8/79, and a new petroleum act, cited as the Petroleum Act, 1980-No.27-9/8/80. Both acts increase the role of the state in developing geological resources. The state identified many mineral-rich localities but lacked the funds to exploit them. The new Minister of Minerals was to concentrate on strengthening existing mines instead of embarking on new projects that would overstretch the meager financial resources available. He would, however, continue to encourage outside exploration and mining investment. The Geology and Minerals Exploration Division of the new ministry was responsible for carrying out geological mapping and mineral exploration programs. Petroleum exploration, development, and marketing continued to be carried out by the Tanzania Petroleum Development Corp. (TPDC) under joint-venture agreements with foreign investment companies. The State Mining Corp. (STAMICO) was responsible for exploring new mineral deposits and developing and operating new mines and mineral-related activities.

In July 1981, the Minister of Minerals presented a three-part plan concerning mining in Tanzania. A short-term plan to exploit gold, tin, gem stone, and mica deposits to solve the country's current economic problems was announced. The plan involved carrying out direct mining activity by utilizing locally available technology and minimal capital as well as completing ongoing projects that had been long overdue. Medium-term plans would concentrate on exploitation of minerals requiring moderate investment and simple technology. The Ministry's policy was to assist small-scale miners and, at the same time, open mines that would be equipped with smaller processing units that could be moved from one mining site to another. The medium-term plans were to also emphasize gold, tin, diamonds, and other minerals vital in other sectors of the economy such as coal, soda ash, kaolin, gypsum, and salt. Long-term plans included mineral projects requiring extensive studies, heavy investment, and heavy use of electrical power during both production and transportation. Long-term projects cover nickel, cobalt, copper, uranium, and iron, coal, and soda ash for export.

East and Central African countries

announced plans for a geologic, stratigraphic, and geochemical exploration program to be carried out over two areas in Zambia and Tanzania between 1982-84.

PRODUCTION AND TRADE

Having a longstanding international reputation in diamonds and with a record of supplying high-grade sheet mica, Tanzania had been looking intently at the possibilities for extending its participation in the world industrial minerals sector. This was needed to satisfy domestic needs for materials imported and to build up export markets from which foreign currency could be earned. Exploration work carried out by various organizations and state corporations demonstrated that many nonmetallic minerals were available for exploitation. Although not always proven to be large, many deposits exist as outcrops, easily amenable to small-scale mining operations. These operations could provide indicators about possible larger deposits nearby. One mineral resource, trona, was known to be present in quantities large enough to support massive extraction and refining operations. STAMICO's activities were constrained by lack of trained workers, finances, and infrastructure. To exploit the trona deposit, for example, would require massive investment, because no infrastructure existed where the trona was located.

The Government was pursuing a unified energy policy in an endeavor to diminish reliance on imported oil, the cost of which was estimated to have consumed 55% of Tanzania's export earnings in 1981, compared with 12% in 1973. As part of the Government's energy policy, existing energy-saving measures were strengthened, limited reserves of natural gas were to be tapped, and research was under way to develop a considerable hydroelectric potential. In addition, agreements for oil exploration were reached with a number of international companies in 1981. China was taking part in the construction of a thermal power station to use local coal, while a project for exploiting substantial deposits of coal at Songwe-Kiwira was under consideration.

Agrico Chemical Co. in the United States and the Tanzania Government formed a joint venture, called Kilwa Ammonia, to build a large-scale fertilizer complex at Kilwa Masoko in Tanzania. The $450 million ammonia-urea plant was to supply Tanzania with its urea fertilizer needs as well as urea for export to neighboring countries. Natural gas from Tanzania's offshore Songo Songo Field was to be used by the plant.

COMMODITY REVIEW

METALS

Gold.—The production of gold from Tanzania's Buckreef gold mine in Geita district, Mwanza region, was scheduled to begin in January 1982. The Buckreef plant could mine 250,000 tons of ore, which would be processed to yield 2 kilograms of gold per day. The Buckreef Mine was one of two producing gold mines in Tanzania. Lupa gold mine in Chunya, Mbeya region, produced alluvial gold.

Machinery was to be ordered from abroad in 1981 for two small-scale gold mines to be opened at Nzega and Kahama. Countrywide surveys identified eight areas with gold deposits, but owing to financial and work force constraints, the ministry decided to start small-scale mining in only two areas.

NONMETALS

Cement.—The Tanzania Saruji Corp.'s 800-ton-per-day Mbeya cement plant in the southwest commenced operations in 1981. Major equipment at this plant was supplied by F. L. Smidth (Denmark) and consisted of a 1,250-kilowatt raw mill; one 3.95- by 58-meter kiln with a four-stage cyclone preheater and a Unax planetary cooler; as well as an 1,820-kilowatt finish mill. Additionally, another 800-ton-per-day dry-process plant was being considered at Wazo Hills by Tanzania Saruji Corp. Kulijan Corp. was handling the conceptual design, design and engineering, construction supervision, commissioning, and initial operation of the new plant. Kulijan was also doing a feasibility study of two more cement plants. One was a one-line, 600-ton-per-day operation. The other was a two-line, 1,500-ton-per-day plant.

Diamond.—Diamond output decreased in 1981. Approximately 250,000 carats were produced at the two kimberlite mines in 1981, registering a 9% decrease below 1980 levels. Diamond continued to be the most important mineral foreign exchange earner during 1981, despite depressed world market conditions. Roughly $11.4 million in foreign exchange earnings were attributed to Tanzania's diamond industry in 1981.

Fertilizer Materials.—*Ammonium Hydroxide.*—The Tanzania Fertilizer Co. Ltd. (TFC) started production of ammonium hydroxide solution that was used in paint production, wood treatment, and other

chemical processes. The plant had capacity enough to satisfy the country's yearly demand of 2,000 liters.

Phosphate.—The foundation stone for the Minjingu phosphate mine was laid in August 1981 to officially mark the launching of the project in Hanang district, Arusha, but production was not scheduled to start until 1983. The Minjinqu deposits, discovered more than 20 years ago, have phosphate reserves to last 15 years if exploited at the rate of 100,000 tons per year. The exploitation being carried out by STAMICO with the Kone Corp. of Finland was expected to cost $22 million. The Finnish Government was to meet over one-half of this investment. TFC would save $8.5 million in foreign currency by utilizing the local phosphate mineral.

Mica.—Mica has been mined in Tanzania since the beginning of the 20th century, although the operations have always been very simple and with no mechanization. The quality of the product has always had a good standing internationally and was at one time one of the country's more important exports. Small-scale mining of mica continued at Morogoro, the Pave Mountain area, within the Karagwe district. Recent inquiries from United Kingdom mica brokers indicate that although demand for good-quality Tanzanian mica remained brisk, the problem of inadequate supply remained production oriented. Production of mica in 1981 was approximately the same as in 1980.

MINERAL FUELS

Coal.—The coal mine at Ilima reported remaining reserves of only about 70,000 tons. The operation was fairly primitive, with manually propelled carts and kerosine lamps. Across the Kiwira River was a new minesite that the Chinese finished surveying in 1980, and to which construction of a road and bridge had begun. A revised proven reserves estimate showed that close to 20 million tons were in the deposit. However, any idea of exporting the coal was canceled, as were plans for general commercial availability. The mine was now expected to produce coal only for specific projects, including a 24-megawatt power-generating facility yet to be built, a cement plant at nearby Mbeya, and the new papermill under construction at Mufindi.

Natural Gas.—Exploration for gas at Songo Songo confirmed a minimum recoverable reserve of 18.9 billion cubic meters, with another 13.9 billion cubic meters probable. The known reserves were more than sufficient to meet the needs of an ammonia-urea plant to be built nearby at Kilwa.

Petroleum.—Tanzania, assisted by the Algerian Oil Co., Sonatrach, was to start drilling a 4,000-meter (12,000-foot) exploratory well on the tiny coastal island of Mafia to determine the amount of available oil there. The project was being financed through an Algerian loan of $10 million. Tanzania was spending about one-half of its foreign exchange earnings on oil imports.

The Organization of Petroleum Exporting Countries (OPEC) Fund for International Development granted Tanzania an oil and gas exploration loan for $12 million. This loan was the first to be specifically tied to exploration for oil and gas resources and was to be complemented by $5 million in local counterpart funds generated under a previous balance-of-payments support loan.

The European Investment Bank gave Tanzania a further loan of $7.7 million for drilling operations at Songo Songo Island in the Indian Ocean. The Songo Songo scheme, which was also financed by the World Bank through the International Development Association and the OPEC special fund, was scheduled for completion by September 1982 and is expected to involve a total outlay of more than $42.5 million.

Tanzania signed two other major agreements for petroleum exploration in 1981. The first was with Shell Petroleum Development Tanzania, who agreed with the Government to explore for oil and gas in a 72,000-square-kilometer area south of Dar es Salaam. The area, which ran diagonally from Kisarawe to Songea in Southern Tanzania, excluded the coastal strip where the Italian company Azienda Generali Italiana Petroli S.p.A. was prospecting. The second agreement was between Tanzania and the Vienna-based International Energy Development Corp. (Tanzania) Ltd. (IEDC). They signed an agreement under which IEDC was to explore for oil and gas over an estimated 12,000-square-kilometer area northwest of Dar es Salaam.

Under both agreements, the exploration company was to have full responsibility for generating the capital involved. Any petroleum found in their respective exploration areas was to be shared jointly between the exploration company and TPDC.

The Mineral Industry of Thailand

By Gordon L. Kinney[1]

The 1981 economy showed signs of recovery after the recessionary trends of the second half of 1980. A bumper farm crop did not benefit the economy as much as expected because of the depressed world prices for most agricultural commodities. A liquidity crisis beginning in midyear led to a general economic slowdown. Exports grew at less-than-expected levels and imports remained high, resulting in a high balance of trade and payment deficits.[2]

The problems notwithstanding, gross national product (GNP) for 1981 was estimated at $36.6 billion[3] in current prices compared with over $32 billion in 1980.[4] Real growth in GNP was estimated at differing levels by different organizations and ranged from 6.5% to 8.0% depending on how the GNP was measured.

A high rate of inflation was a serious handicap to the Thai economy. After a 20% rate in 1980, the year opened with 4 months of even higher inflation, nearly 30%. After April the rate slowed and in August it was only 0.3%. Various estimates of the inflation rate for the whole year place the figure between 14% and 18%, still uncomfortably high. The leading cause appeared to be rising energy costs. After mostly holding the line on petroleum products during 1980, the Government was forced to increase the heavily subsidized prices an average of 20% in January 1981. Increases in electricity rates of 16% and 20% also added to the inflationary push.

In an effort to relieve the economic situation, the Government devalued the baht. The Bank of Thailand adjusted the rate downward by 1.083% in May and by another 8.7% in July. In addition, the Bank of Thailand increased its discount rates to 13.5% and 17.5%. Bank deposit rates were raised in July to 13% and 14% for 1- and 2-year deposits, respectively. Interest ceilings were also raised in July to 19% for commercial banks and 21% for finance companies. The Government also lowered corporate tax rates 5% and the tax credit for dividends was raised from 25% to 35%.

The relative importance of the mining sector in the Thai economy dropped a small amount in 1980 for the first time in several years and the small decline was expected to continue in 1981. Final figures were not available for 1981, but it was estimated that 2% of the GNP was derived from the mining and quarry sector. The decline was mostly due to the drop in value of tin exports during the year. As was normal, agriculture, manufacturing, and wholesale and retail trade were the leading sectors, contributing 26.2%, 18.7%, and 18.6%, respectively, to the GNP.[5]

The Thai Government has been trying to encourage the exploration and development of its mineral resources. It has been claimed in the past that despite theoretical encouragement, the actual practice of getting a project from paperwork through start of construction was a long, tedious, and often discouraging task. During the year, a group of American Agency for International Development officials and private businessmen were invited to Thailand to examine the problems of private investment. Their preliminary findings indicated (1) a need to clarify energy-utilization policies for investors, (2) a need to remove uncertainties in

the tax structure, (3) that Thai decision-making processes needed to be speeded up, and (4) price control policies were uncertain and needed clarification.

In another action to get mineral development moving, the Department of Mineral Resources (DMR) began to review its policies for granting exploration permits. As the law stands, once an exploration permit was issued, there was nothing to force the permit holders to begin exploring. Many people have been holding exploration rights to vast areas of land, but have done nothing about it for years. The policy prevents others genuinely interested in exploration from doing so. One change being considered was to set a time period under which the exploration activity must begin. Failure to do so would terminate the permit or a penalty fee would be owed to the Government. Another idea was to have the permits renewed each year. This would enable better records to be kept on the number of permits outstanding, who has them, and the location and the nature of the mineral to be sought. A final incentive to actual exploration would be a sharp increase in the yearly exploration and concession fees owed to the Government.

The major mining developments of the year were centered on the offshore natural gas, a probable start on the zinc project, progress toward developing a potash industry, the development of a nitrogen fertilizer complex, and possible development of the salt deposits. Also there was partial relief to previous critical cement shortages, and a second tin smelter opened during the year.

PRODUCTION

Thailand was the third largest market economy producer of tin, but production was off a small amount during 1981. The value of tin production was about $468 million, a drop of more than 16% from the 1980 level. In addition to tin, Thailand was a major world source of tantalum and columbium, mainly in the form of high-grade tin-smelter slags. Thailand also produced modest amounts of antimony, lead, manganese, tungsten, barite, and flourspar. In all, Thailand produced 35 types of ore minerals with a total value of $578 million, about 15% less than the 1980 level.

Huge deposits of salt underlay a large part of the northeast plateau area and there have been several important discoveries of potash minerals in these salt horizons. Neither the salt nor the potash was being exploited during 1981, but plans were moving along toward the eventual production of both of these minerals.

Thailand's first commercial use of the large natural gas reserves discovered several years ago in the Gulf of Thailand was in September 1981. Production began at a modest scale, but will soon become a major factor in Thailand's economy. There were plans to use the gas as either fuel or raw material in the cement, iron and steel, ammonia, potash, soda ash, liquified natural gas (LNG), and petrochemical industries. A 1981 discovery of onshore oil by Shell Exploration and Production Co. could be a great help to the Thai economy if the strike turns out to be commercially exploitable.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Includes data available through Aug. 9, 1982.

[2]Excludes columbium- and tantalum-bearing tin slags, which make Thailand the world's largest source of newly mined tantalum.

[3]Revised to zero.

TRADE

The estimated value of total trade was $18 billion in 1981, up from $15.8 billion during 1980.[6] Exports rose from $6.5 billion in 1980 to over an estimated $7.5 billion in 1981. The planned target had been well over $8 billion. The lower amount of export was attributed to the generally depressed world prices of most commodities. Imports, however, began the first 6 months of 1981 at a 20% increase over the 1980 levels.

The Government was concerned over the growing trade deficit and devaluation of the baht was initiated to boost exports and discourage imports. The Thai baht had not fluctuated more than 4% against the U.S. dollar during the past 30 years. As a result of the devaluation, the balance-of-trade deficit for 1981 was expected to be lowered by about $275 million.

By far the most important mineral export was tin, accounting for 81% of total mineral exports. Revenues from tin exports were adversely affected by the nearly 20% drop in world tin prices during 1981. Total tin exports were valued at $468 million in 1981. Other mineral exports were antimony, barite, columbium, fluorite, gem stones, lead concentrate, and tantalum. The export of tin smelter slag constituted the major source of new tantalum on the world market.

Thailand's most important mineral was crude oil, which accounted for over 31% of all imports in 1981. Because of world price increases, Thailand's oil import bill continued to rise in 1981 despite a substantial drop in the volume imported. The Government planned for the output of natural gas to substitute for a significant proportion of these oil imports in the years to come.

COMMODITY REVIEW

METALS

Iron and Steel.—Plans for major new steelmaking facilities in Thailand have been intensely debated for several years. The basic problem was what kind of facility would be economically viable in a country with no known favorable iron ores, no coking coal, high energy costs, and enthusiastic environmental groups seemingly capable of stalling any plans not meeting their approval.

Two main projects were discussed during 1980-81. One new one was proposed for the first time in 1981.

A private sector joint venture, Siam Ferro Industry Co. Ltd. was set up in 1979 to operate a proposed 400,000-ton-per-year direct-reduction (D-R) plant at Laem Chabang. The plant would use natural gas from the Gulf of Thailand and furnish its output to the Thai electric furnace operators who were dependent on scarce and expensive scrap for their operations. Increases in the Thai natural gas price, the need to change the proposed location for environmental reasons, and potential high interest charges prevented any progress toward construction during 1981.

The second project was a Government proposed 2.1-million-ton-per-year integrated steelworks. It was originally planned for Rayong Province but the same environmen-

tal problems again caused a reappraisal of the plan. As a result, the Government called for bids for a feasibility study of a plant on the west side of the Gulf of Thailand. Estel Technical Services of the Netherlands won the contract in late 1981.

The study will be in two parts. Phase one will determine site selection, prepare a general design and layout of the plant and port facilities, and make preliminary financial projections. The first phase was to be ready in 5 months. The second phase of the study will determine technical specifications of the plant based on Estel's recommendations and will be tendered separately.

The Thai Ministry of Industry was believed to favor a D-R-based plant with electric arc furnaces producing hot-rolled and cold-rolled flat products. Serious consideration of a conventional blast furnace plant was no longer likely because of the higher capital costs and nearly total raw material import requirements.

The third project under consideration would be a second integrated works with a 500,000-ton-per-year capacity. The plant would be only for nonflat products and would be planned for a 1992 startup. Considering the problems encountered with planning the other steel projects, this new idea is not likely to move beyond the planning stage for many years.

Steelmaking capability was in the hands of seven electric-furnace-based plants. The most important were: S.S. Steel Co., 160,000 tons per year; Bangkok Iron and Steel Works, Ltd., 150,000 tons per year; Siam Iron and Steel Co., 140,000 tons per year; and Bangkok Steel Industry Co., 100,000 tons per year. Total raw steel capacity was reported to have increased to 605,000 tons per year at yearend.[7]

Tantalum and Columbium.—The World Bank was reportedly considering a loan to Thai Tantalum Industries Co. Ltd. for part of the construction costs of the tin slag smelter and tantalite-columbite processing center at Phuket. The company had acquired the necessary Government approvals and investment incentives during 1980. The Government was expected to hold up to 30% of the equity in the 90% Thai-owned venture.

The plant was to produce ferrotantalum in its first stage and then to add a 300-ton-per-year tantalum oxide and columbium oxide second stage. A later third stage was proposed to produce tantalum potassium-salts. Preliminary preparations for construction were believed underway at yearend. Construction and project management contracts could be signed early in 1982.

Tin.—Tin was by far the most important mineral produced during 1981, both from the viewpoint of the number of miners employed and from the amount of foreign exchange earned by exporting the tin produced. The tin industry, however, faced increasing problems during 1981. World prices were lower than in 1980 and production dropped off enough to cause concern among Thai officials. The lowering trend in production was caused by a combination of three factors: Lowering average grade of the alluvial deposits; increasing costs of production, coupled with a high royalty rate; and the declining world price for tin, reflecting the world recession and a production surplus in the market economy countries.

The declining grade of the tin ore was in itself a complex problem. Many of the higher grade deposits both onshore and offshore have been worked for a number of years and reserves have been exploited faster than new exploration has replaced the worked out deposits. For example, nearly 60% of Thailand's tin was mined in the Andaman Sea off Phuket and Phangnga Provinces. Proved reserves in this area were being rapidly depleted, and without additional discoveries one source estimated that most mining operations in this area would have to stop in 2 or 3 years.

A continuing problem in the offshore areas has been the quasi-legal suction boats that frequently operate in the concession areas reserved for big ocean dredges. In March 1981, an estimated 200 suction boats surrounded a Billiton dredge operating under an offshore mining organization concession near Phangnga. The miners reportedly forced the dredge to temporarily stop operating. Order was restored after a series of armed clashes with the police. The small boat operators demand more areas to dredge. The Government originally allocated them 13,800 acres off Phangnga, but the miners claimed that reserves there were too poor. The problem was by no means settled by yearend.

The suction boats concentrate on mining the very profitable high-grade pockets in a given area and the operators are quite efficient at finding them. The resulting area is left with a substantially lower average tin assay per cubic meter of ore. With the high-grade pockets gone, the big commercial

dredges, operating legally, can barely work the deposit at a profit. Southern Kinta Consolidated Ltd. stopped dredging in its Kakuapa concession in 1980 because of the depletion of its reserves by the suction boats.

The environmental issue further complicates the production picture. Some of the best potential mining areas lay just off some of the best tourist beaches in the country. During the year, students from 11 universities protested any further mining development in the area, fearing damage to the famous Patong Bay beaches at Phuket Island.

The cost of producing tin concentrate has risen steadily in recent years. Spare parts, maintenance, labor, and fuel prices have all increased in the face of lowering world tin prices and a very high Government royalty. The high rate of inflation, coupled with an 8.7% devaluation of the baht in July 1981, made additional problems for the miners, especially those small operators that were working marginal onshore deposits. Even one of the large companies, Tongkah Harbour Ltd., dredging in Chalong Bay reported its costs per cubic meter mined rose 40% during 1980, the latest available figure.

The Government was not able to do much to reduce operating costs, but did make a revision of the tin royalty payments. The variable rate on the value of production was as high as 40%, depending on the value of the concentrate. In July 1981, the Ministry of Industry announced a decrease in the tin royalty by an average of 10% and the imposition of a new special fee of 5% collected on the royalty's value, to be used to benefit miners and their localities. The changes will result in an average net reduction of about 5% in the overall royalty charge.

The Government made one other concession as well. The commission paid by the suction boat operators to the tin purchasing agents for the sale of their concentrate was reduced by more than 75%. The Government refused the suction boat operators demand for more mining areas in Ta Tang and Baan Bor Daan, a guaranteed purchase price for tin concentrate, and a further royalty reduction.

Fluctuating world prices for tin have contributed to production problems. In 1980, the high price was around $19.84 per kilogram of tin. By March 1981, however, the price had dropped to around $14.55 per kilogram. Later in the year it climbed back over $17.64 per kilogram because of political factors. Decreased demand on the world market brought the price back down and the decline was continuing at yearend. A price below $15.43 per kilogram would force at least the temporary closing of several more of the marginal onshore mines. The number of suction boats operating off Phangnga Province during 1981 has reportedly dropped to about one-half the 1980 number, due to a combination of the above grade, cost, and price factors.

The Thai Government has undertaken an intensive tin survey of the Andaman Sea coastal areas from Phuket, north to the Burmese border. A preliminary survey covering about 2,200 square kilometers was completed late in 1981 and indicated the possibility of commercial tin deposits in the deeper water areas. The project was being done by DMR in collaboration with United Nations agencies and is the first such exploration in waters between 30 and 45 meters deep. The preliminary survey defined targets for the drilling program scheduled for the next few years. A total of 300 assay borings were to be completed before 1986. Favorable findings in these deeper waters could give the tin industry a much needed boost. The big contract dredges would be able to work these deeper waters with relatively little interference from the suction boat poachers. The suction boats are generally limited to waters no deeper than 20 meters because of technical and economic constraints.

Aokham Thai Ltd. and Tongkah Harbour Ltd. have started to set up a new company to explore and evaluate possible tin deposits offshore Takuapa in waters 45 to 125 meters deep, beyond the Government's 30- to 45-meter survey area. The joint venture was to be named Sea Minerals Ltd. and would have shareholders from Aokham Tin Berhad, Southern Kinta Consolidated, Aokham Thai, International Finance Corp., the Siam Commercial Bank Ltd., and probably the Government's Crown Property Bureau. An application has been made for a special prospecting licénse over the area in question. The company would be capitalized if the license is granted. No exploitation is currently underway in water of this depth.

Trial tin production began at the Thai Pioneer Enterprise Co. Ltd.'s new smelter in Feburary 1981. This, the country's second tin smelter, is located at Pathum Thani, about 40 kilometers north of Bangkok, and has a startup capacity of 3,600 tons per year

of tin ingot. The plant is designed for an eventual capacity of 6,000 tons per year. The plant had official opening ceremonies on July 30, 1981. By yearend, problems had developed over distribution of tin concentrate to the country's two operating smelters. Thai production of tin concentrate was not sufficient to keep both smelters operating at full capacity.

Construction apparently began in late spring on the country's third tin smelter. Thai Present Smelter Co. Ltd. announced the new 10,000-ton-per-year plant would be in operation in early 1983 at a site on Phuket Island. Both the location and capacity of the plant have been changed since it was originally approved by the Government in July 1977. The final location on Phuket Island puts it in direct competition for tin concentrate with the big Thaisarco smelter, also at Phuket. Thai Present took the precaution of having local miners as stockholders in the newly formed company.

Zinc.—Twelve years after it was originally proposed, Thailand's trouble-plagued plan to build a zinc refinery appeared ready to become a reality in November 1981. It was reported in late fall that construction, financing, and equity contracts were all formally signed and that construction could begin by yearend.

A new company was set up with the help of the Thai Government after a proposed Republic of Korea-Thai consortium fell through in late 1980 for lack of financing. The new venture was called Padaeng Industry Co. and will be 70% Thai owned. The major breakthrough in setting up the venture was the agreement by Belgian companies, who are supplying technology and construction expertise, to take the 30% remaining equity. The final makeup of the company will be as follows:

Participant	Share interest (percent)
Thai equity:	
Thailand Finance Ministry	20

Participation by the Mitsui Co. was particularly welcome in the project from the marketing side. Mitsui has an equity share in a Thai galvanized sheet-steel producer that will be a potential major consumer of part of the plant's output. About one-half of the plant's output should be available for export.[8]

The 60,000-ton-per-year electrolytic smelter was to cost $75 million in 1972 when originally proposed. The price has now escalated to $142 million. The plant will be located near Tak about 400 kilometers north of Bangkok near the Burma border. About 340,000 tons of high-grade zinc ore per year will be supplied from a nearby mine, which has been inactive for several years pending arrangements for the zinc smelter.

NONMETALS

Cement.—Thailand was in the middle of an ambitious cement expansion program. All of the companies were again operating at their maximum output during the year.

Two of the expansion projects came online during the year, although firm produc-

tion data was not available at yearend. Siam Cement Co. completed a large expansion project at its Ta Luang plant in Saraburi Province. Siam City Cement Co. also completed a more than 1-million-ton expansion of its Kaeng Khoi plant in Saraburi Province.

In addition, there were several other expansions or new plants under construction or planned. Of particular importance was the report that Siam Cement has let a $46 million contract to Nippon Kokan Co. of Japan to lay a 110-kilometer gas pipeline. The line will be a branch from the main Thai pipeline servicing the Bangkok area to the cement company's Ta Luang and Kaeng Khoi cement plants. The project was scheduled for completion in 1982.

Nitrogen Fertilizer.—A Scandinavian consortium consisting of Haldor Topsoe AS of Denmark, Norsk Hydro AS of Norway, and the state-run Swedyards Development Corp. of Sweden has been awarded the contract rights for the construction of a $590 million fertilizer complex in the Rayong area. As proposed, the complex will produce 1,200 tons per day of nitrogen of ammonia. Up to 900 tons per day of this nitrogen will go into production of urea and the rest will go to making ammonium phosphate.

Haldor Topsoe will provide the process and engineering for the plant. Norsk Hydro will provide management, train personnel, and handle marketing. Swedyards will build the plant in Sweden on four large floating platforms. The platforms will be barged to a prepared shallow basin at the plant site. The basin will then be filled with earth and the plant will stand on solid ground.

This will be the first nitrogenous fertilizer plant in Thailand, which presently imports all of its fertilizer needs. The cost of the plant will be financed by a reported $350 million credit, which will be guaranteed by the Swedish Government, and a $90 million loan from the Nordic Investment Bank. The remaining will be inshare capital totaling about $150 million. The Thai Government will hold 10% of the shares.

The plant will use about 65 million cubic feet of natural gas per day from the offshore gasfields. The only possible snag to the start of construction was the negotiations on the price of the Government's natural gas. Thailand agreed to supply gas at about cost price, but that term was not defined to the consortium.

Potash.—There were several projects under consideration for developing one or more of the potash deposits located in the vast salt formations of northeast Thailand.

The World Bank agreed to loan the DMR over $8 million for a feasibility study consisting of exploration and trial mining in Bamnet Narong district of Chaiyaphum Province. British and French companies will provide engineering and equipment for the project. An inclined adit will be excavated to the deposit and a continuous miner will be used for exploratory excavation in the ore body. Rock mechanics tests will assist in determining the potential mining methods and cost estimations.

During the year, the Government awarded a 3,500-square-kilometer exploration and development concession in Khon Kaen and Maha Sarakham Provinces to a consortium comprising Duval Corp., United States; CRA Exploration Pty. Ltd., Australia; and Siam Cement, Thailand. If the detailed exploration proves the economic viability of the deposit, the company proposes to invest a reported $35 million in the first-stage development and $172 million in the second stage. Late in the year, the Thai Board of Investment (BOI) agreed in principle to grant promotional privileges to this and two other potash development project plans. The BOI's action grants various tax and investment incentives to a company to help a new project along.[9]

Another joint venture, between Agrico Chemical Co. and Thai Central Chemical Co., was negotiating for exploration and development rights to a 2,333-square-kilometer area in Udon Thai Province.

The third potential concessionaire was an Amax Exploration Co.-Siam Cement joint venture. It proposed to explore and develop a 144-square-kilometer area at Wanon Niwat in Sakon Nakhon Province.

These Thai potash occurrences were the only potentially large high-grade deposits known in the Southeast Asia area. Bringing any of the deposits into production, even if abundant reserves are proved, will require unusually large capital expenditures because of the remoteness of the areas and the poorly developed infrastructure. The potential market for the potash in the Asian area was estimated as high as 6 million tons per year of marketable product.

Salt.—Plans for a $380 million rock salt and soda ash project moved forward during the year. The project would be Thailand's Association of Southeast Asian Nations

(ASEAN) contribution to the area's industrial development program. Economic viability of the soda ash plant was enhanced by the availability of natural gas. Previous plans called for use of bunker fuel oil, which would have been about 20% more expensive.

Salt will be mined near Bamnet Narong in Chaiyaphum Province and limestone will be quarried in Saraburi Province. The 400,000-ton-per-year soda ash plant probably would be located at Sattahip. Environmental groups protested the plan to site the plant at Laem Chabang, fearing potential damage to the valuable tourist beaches. It was expected that the necessary ASEAN approval for construction would be granted at an economic minister's meeting scheduled for January 1982.

MINERAL FUELS

Lignite.—The Electricity Generating Authority of Thailand continued its exploration for additional lignite reserves or new deposits and several discoveries were announced during the year.

Reserves of 78 million tons were claimed in three deposits in Lampang and Lamphun Provinces. The continued survey of the Mae Moh area revealed indicated reserves of 1,400 million tons. Thai sources reported that 450 million tons of that was usable in first-stage development and another 200 million tons would be usable in later stages. Virtually all of the Thai plans call for use of lignite for mine-mouth electric power generation as is the current use in Mae Moh and at Krabi in southern Thailand.

Malaysia announced discovery of large lignite deposits in Perlis State adjacent to Thailand's Songkhala and Satun Provinces. Malaysia apparently invited Thailand to join in a joint evaluation and development of the deposits. Thai officials were reported ready to consider the offer.

Natural Gas and Petroleum.—On September 12, 1981, the valves were opened at Ban Mabtaput to bring the first commercial natural gas production ashore from Union Oil Co. of Thailand's Erawan Gasfield. Production began 9 years after the initial discovery was made more than 400 kilometers south of Sattahip. The 425-kilometer-long, 86-centimeter-diameter, offshore portion of the pipeline was the world's longest seabed gas pipeline and cost over $500 million. Initial gas deliveries were limited to about one-half of the contracted amount because of overheating problems at the wellheads. The problem was being examined at yearend. Union Oil was to initially supply 200 million cubic feet of gas per day in 1982, and then increase to 400 million cubic feet per day in 1985. The gas was being used only for electric power generation at the Bang Pakong and South Bangkok powerplants. The domestic gas will directly replace the equivalent of 34,000 barrels per day of heavy fuel oil in 1982. By 1985, the planned gas production will be replacing about 21% of domestic oil demand.

Before production could begin, 12 offshore structures were placed and hooked up. Sixteen production wells were completed by yearend. A total of 42 wells are planned to be drilled from the 5 drilling platforms in the Erawan Field.

Offshore exploration continued during the year. Union Oil drilled nine wildcat wells during 1981. Six of the nine wells tested natural gas and condensate, and two new gasfields were established; Pladang in Block 11 and Jakrawan in Blocks 12 and 13.

Texas Pacific Thailand Inc. drilled six wells in 1981, four of which tested commercial gas. All of the strikes were in Block 15.

Only two new offshore concessions were awarded during 1981. One went to Pecten Thailand Co. which took Blocks 1, 2, and 3 in the northern section of the Gulf of Thailand. Seismic surveys were completed on these blocks in mid-November 1981 and the company intended to start drilling in Block 2 in January 1982. At least four wells were scheduled during the next 3 years.

The other was the Terramar Corp., a Denver-based firm, which won a concession located in the Andaman Sea just north of Malaysian territorial water. No seismic work had been undertaken in that particular area.

The result of the continued drilling program in the Gulf of Thailand has been to further increase the already substantial natural gas reserve figures. The Thai Department of Natural Resources now lists total reserves at 16.5 trillion cubic feet. Offshore gas reserves by field in trillion cubic feet follow:

Field	Concessionaire	Reserves
Erawan	Union Oil Co	1.8
Kaphong-Platong	do	1.3
Baanpot	do	0.8
Satun	do	3.2
Pladang	do	0.6
Jakrawan	do	1.0
Structure B	Texas Pacific Thailand Inc.	5.8
Structure 17E	do	2.0
Total		16.5

Negotiations continued between the Government and Texas Pacific on a pricing agreement for the gas that Texas Pacific Thailand Inc. has discovered in its concession areas in the Gulf of Thailand. Exploitation of the deposits cannot proceed until some equitable arrangement can be made. The problem was complicated in 1981 by the possibility of the Government allowing some of the gas to be exported. The company announced during the summer that it had reached a preliminary agreement with a Thai group of investors headed by Paul Sithi-Amunuai's group of companies and the Nissho-Iwai Corp. of Japan. The consortium was investigating the feasibility of building a LNG plant and exporting the LNG to Japan. Nissho-Iwai controls 50% of the natural gas market in Japan.

This project would be the largest industrial development in the history of the country if it were to be approved by the Government. Cost estimates for the project range as high as $3.5 billion. Approval of the project was by no means certain because of the extreme political sensitivity of the mineral exploitation industry in Thailand. The basic controversy is whether the country's natural resources should be used domestically or exported to earn foreign exchange.

Plans for a natural gas separation plant near Rayong, where the pipeline comes ashore, were delayed when the Petroleum Authority of Thailand (PTT) changed consultants for the job in March 1981. The letter of intent to Fluor Ocean Services International Inc. was cancelled because PTT felt Fluor Corp.'s cost estimates were too high. Fluor Corp. was replaced as consultant by Linde AG of the Federal Republic of Germany and construction proposals were invited in August 1981.

The plant would have the capacity to process 350 million cubic feet per day of natural gas and produce ethane, propane, butane, liquefied petroleum gas (LPG), and gasoline totaling over 860,000 tons per year.

Onshore exploration activity picked up during 1981 as two new concessions were awarded and an announcement was made of possible oil and gas discoveries.

The new concessions went to Esso Udon Corp., an Exxon Corp. subsidiary, and Phillips Petroleum Corp. Esso will explore in Udon and Loei Provinces in northeast Thailand. The Phillip's concession runs from the Esso area eastward to the Mekong River.

A gas strike was reported by Esso Exploration and Production Khorat Inc. in its first well in Thailand. The Nam Phong-1 well, located 25 kilometers north of Khon Kaen, reportedly flowed good-quality, dry-gas from below 3,100 meters. More work will be needed to determine the commercial potential of the find. Three more wells were planned for the Esso concessions. If commercial, the find could bare favorably on the development of nearby salt and potash deposits and also on local industries.

An oil strike was reported by the Thai Government at the Shell Exploration and Production Co.'s Lan Krabu-1 wildcat well in Kamphaeng Phet Province. The discovery well had a reported flow of 3,000 barrels per day of 40° API low-sulfur, high-wax crude. Several additional wells will be drilled to delineate the structure and determine if it can be developed commercially.

In February 1981, the Defense Ministry terminated the Summit Industrial Corp. lease on its Bangchak oil refinery. The company turned the plant over to the Defense Energy Department on March 31, 1981. Summit had operated the refinery since its construction in 1965 under a lease that would have expired in 1990. Later in the year the Defense Energy Department selected Lummus Operating Associates Inc. to provide management and technical advisory services for the refinery.

During 1979 and 1980, there were plans to expand all three of Thailand's refineries. In addition, there was a plan by a new firm to build a large refinery at Krabi on the Andaman Sea opposite Phuket Island. These ambitious plans were for the most part scrapped during 1981. The only positive decision during the year was approval by the Ministry of Industry for Esso Standard Thailand Corp. to debottleneck its Sriracha refinery. The project will raise the throughput capacity from about 45,000 to 60,000 or 65,000 barrels per day. At least

one other Government agency needed to approve the project before construction could begin.

The oft-delayed expansion of the Thai Refining Co. refinery at Sriracha was debated during the year but no firm decision was reached. At yearend, it appeared that the PTT would probably approve a modified expansion from 65,000 to 120,000 barrels per day instead of the 165,000 barrels per day originally planned. The expansion would consist of installing a hydrocracker and associated equipment.

Thailand's three large refineries operated entirely on imported crude oil, mostly from the Persian Gulf countries. Saudi Arabia supplied about one-half of the oil in 1981. The cost of imports for the year was estimated at $3 billion. Imports were predicted to decline in 1981 and succeeding years as the use of heavy fuel oil to power electric powerplants and furnaces is phased out in favor of the less-costly natural gas.

The Mineral Industry of Tunisia

By E. Shekarchi[1]

The year 1981 was the final year of the Fifth Development Plan (1977-81). Based on the estimates for 1981, the success of the fifth plan was due in large part to the rapid expansion of Tunisia's oil production during a period of rising international oil prices. It appeared that many of the plan's broad macroeconomic targets were met. The 5-year investment target of $10 billion was also met, representing close to 30% of the gross domestic product (GDP), as planned. The sectoral distribution of these investments, however, was significantly different than expected. While investment in agriculture, services, and infrastructure exceeded targets, capital expansion in industry was well short of the projected level. This was due primarily to the postponement of the giant Miskar offshore gas project. The employment target of the plan was nearly attained, but even so, the overall rate of unemployment was higher at the end of 1981 than it was in early 1977.

Although the Sixth Development Plan (1982-86) was still in draft form, early indications were that the investment package was to be about $20 billion,[2] twice as high in nominal terms as under the fifth plan. Major emphasis was to be placed on the expansion of the tourist, textile, and phosphate industries to increase foreign exchange earnings to compensate for the decline in oil revenues. The search for new oil reserves was to be intensified, and the Miskar Gasfield was to be exploited.

Expenditures on oil exploration and development were about $328 million in 1981 and were to increase to $414 million in 1982 as part of a campaign to restore declining crude oil output. Production was forecast to fall to 5.3 million tons by 1982 owing to declining production at the El Borma Field. It was also expected that the Tazarka offshore and Laarich onshore oilfields would come onstream later in the decade.

Output of natural gas was expected to fall from 330 million cubic meters in 1981 to 300 million cubic meters in 1982, while consumption of natural gas was predicted to rise to 450 million cubic meters. The Government planned to import 50 million cubic meters of gas from Algeria to help satisfy domestic demand. The shortfall of 100 million cubic meters in 1982 was expected to be replenished by royalty gas from the Transmed gas pipeline, which was under construction from Algeria to Italy. Investments earmarked for the natural gas sector in 1982 included $30 million for the first phase of the 300-kilometer pipeline to distribute Transmed gas within the country, and $12 million for engineering studies and preparatory work on the projected development of the offshore Miskar Field.

The most encouraging exploration results in 1981 were in the petroleum industry. Amoco Tunisian Oil Co., a joint venture of Standard Oil Co. (Indiana) and the Tunisian Government, discovered oil and natural gas 120 kilometers southwest of Gabes. The 13,000-foot wildcat well tested at rates as high as 12.6 million cubic feet of gas and 1,800 barrels of oil per day on a 1 1/2-inch choke. Tenneco Inc. reported its Houston Oil and Minerals unit found oil onshore near Sfax. During a test at 9,000 feet, oil flowed at a rate of 1,500 barrels per day through a 1/2-inch choke. Both companies anticipated more drilling and testing in 1982 before deciding the economic significance of the discovery.

Tunisia offered attractive opportunities for investment by foreign companies. Production for export purposes was to receive

tax, duty, and exchange control advantages based on the Export Industries Investment Code of 1972. Investment in the domestic market was governed by a 1974 code, which granted tax and other advantages based on the creation of employment. Export industries may be 100% foreign-owned, although companies producing for the domestic market usually had majority Tunisian equity, but this was negotiable. The Investment Promotion Agency performed surveillance over these programs and made every effort to overcome any problems. In 1981, significant amounts of U.S. capital were expended in Tunisia by U.S. oil exploration and service companies searching for new petroleum and natural gas target areas.

PRODUCTION AND TRADE

Because of increases in crude oil and phosphate prices, export receipts rose 30% above the 1980 level, to $2.7 billion, while import outlays rose only 18% to $3.9 billion in 1981. The trade deficit of $1.2 billion was somewhat less than anticipated. Tunisian exports were dominated by three products: Petroleum, textiles, and phosphate, which together accounted for about 75% of merchandise export receipts. Tunisia exported most of its own high-quality crude oil and imported lower priced oil for domestic requirements. Production of minerals, as well as exports and imports of minerals and some mineral-related semimanufactures, are presented in tables 1, 2, and 3.

COMMODITY REVIEW

METALS

Iron and Steel.—Iron ore production was primarily from the Djebel Djerissa Mine, because both the Douaria and Tamera Mines were exhausted. Although production from Djebel Djerissa was increased considerably in 1981 to supply steel industry requirements, the grade of the iron ore remained a problem. Hematite ore containing 50% to 60% iron had been mined from the two closed mines. The deposits at Djebel Djerissa Mine were largely siderite ore containing 48% iron. This ore required expensive crushing and roasting before use. Furthermore, the Arab iron and steel unions concluded that the potential for upgrading the ore by further beneficiation was extremely limited.

On the basis of domestic iron ore resources, the Société Tunisianne de Sidérurgie (STS) built up a significant steel operation, the El Fouladh works, at Menzel Bourguiba. In 1981, STS engaged in a project to double its rolled-steel-products capacity to 400,000 tons per year. However, the iron output from Tunisia had not reached a level high enough to satisfy STS demand, and it was anticipated that STS would have to seek overseas supplies of iron for its steel mill.

Lead and Zinc.—The feasibility study to upgrade the low-grade ore of the Fedj Hassene lead-zinc deposit was completed in 1981, but the results were not made public. Should the deposit be developed, it was expected that its output would compensate for declining lead-zinc production from the

country's other mines. The Société Tunisianne d'Expansion Minère (STEM) remained the only producer of lead-zinc during 1981. The smelting plants of STEM imported about 8,000 tons of lead concentrate from Morocco and about 2,500 tons from Algeria to blend with the company's concentrate. Most of the lead produced in Tunisia was consumed domestically. Some of STEM's zinc concentrate was exported to France for smelting on a barter basis.

STEM's exploration activity continued in all possible geological target areas. However, with no new finds, the company would be compelled to expand its import of lead-zinc concentrate to satisfy domestic demands.

Other Metallic Minerals.—Tunisia produced a limited amount of silver and mercury for the domestic market. Silver was produced as a byproduct from the smelting of lead and zinc. A small amount of arsenic for domestic consumption was obtained from the Tabett ben Ksouri deposits.

NONMETALS

Barite.—Barite production, which had increased every year since 1977, declined in 1981. Nearly all production was consumed domestically. Under the sixth plan, barite production was to be increased to 122,000 tons per year by the end of the plan. It was anticipated that Tunisia would supply barite for drilling mud to most of northern Africa and the Persian Gulf region.

Cement.—Although cement production in 1981 was the highest ever recorded in Tunisia, the Government had to import about 500,000 tons of cement to satisfy domestic demand. Construction of the new cement plant near Jebel Oust continued under the supervision of the Société Les Ciments Tunisians and was expected to go into production in early 1984. The cost of the plant, originally estimated at $200 million, was expected to exceed this figure by the time the plant becomes operational. The 1-million-ton-per-year production capacity of the Jebel Oust cement plant was expected to eliminate cement imports by 1984. However, with the construction industry growing at a rapid rate and the new highway network proposed in the sixth plan, it seemed likely that Tunisia would continue to import cement after that date.

The asbestos cement products plant continued production at its rated capacity of 26,000 meters of pipe per year in 1981. Most of the products of this plant were consumed domestically in irrigation and sanitation works. With the construction industry booming, it seemed likely that the capacity of this plant would have to be increased to avoid imports of pipe and attendant expenditure of hard currency.

Fertilizer Materials.—Production of phosphate rock by Cie. des Phosphates de Gafsa (CPG) leveled out in 1981 with a slight decline over 1980 output. Production was largely from the Gafsa Basin, where CPG operated six underground mines and one opencast mine. Outside of the Gafsa Basin, CPG produced phosphate from an underground mine at Kalaa Khasba. About two-thirds of the total production was consumed locally, and the remainder was exported. Under the sixth plan, Tunisia intended to expand its domestic capacity for phosphoric acid production. CPG, therefore, announced the expansion of phosphate rock mining capacity to supply domestic consumers while maintaining its position in the world market. It planned to double phosphate rock production by 1990 to 10 million tons per year. To reach this goal, CPG intended to open four new opencast mines in the Gafsa Basin. A fifth mine was to be opened at Sra Ouertane in northwest Tunisia. Not only did CPG intend to increase mine production capacity by 1990, but beneficiation capacity and transportation facilities were to be improved as well. For example, a direct rail line between Gafsa and the fertilizer plants at Gabes was to begin operation by late 1982. Indeed, it would be a challenge to accomplish all this in an area of the country where supplies of water and energy have always been problematic.

The fertilizer plant of Société Arabe des Engrais Phosphates et Azotes (SAEPA), a joint venture between the Tunisian Government and the Abu Dhabi Development Fund (40%), produced at 85% capacity during 1981. The plant produced about 400,000 tons per year of phosphoric acid, of which more than two-thirds was exported.

Tunisia exported its phosphate rock mainly to Europe, the Middle East, Latin America, and, for the first time in recent years, China.

Fluorite.—Fluorite production from the Hammam Zriba Mine increased steadily over the past few years. Most of the fluorite produced was chemical grade except a few hundred tons that were exported as metallurgical grade. Much of the production was consumed by the Société des Industries Chimiques du Fluor (SICF), which operated an aluminum fluoride plant at Gabes. SICF intended to expand its facility at Gabes and to increase mine output of fluorite to

115,000 tons per year. Behind this expansion, apparently, was the financial support of the Arab Mining Co., which had agreed to obtain up to a 28% interest in SICF.

Potassium.—A feasibility study to examine ways to exploit the potassium, magnesium, bromine, and sodium deposits in the Sebka area was completed in 1981. These deposits, situated in a dry salt lake basin on the eastern coast near Zarzis, reportedly were to be exploited in two stages. In the first stage, two plants were to be built, one for 30,000 tons of potassium chloride per year, and the other for 10,000 tons of potassium bisulfate. The cost of both plants was estimated at $22 million, and they were slated to be operational by 1987. In the second stage, new units were to be added to produce magnesium compounds and bromine products, at a cost of $92 million. No date was set for completion of the second stage.

With implementation of the potassium program, Tunisia should be able to satisfy the fertilizer needs of the country and also export potassium competitively in the international market. The constraining factor would be the availability of over 430,000 tons of phosphoric acid, which was to be manufactured in the country from indigenous phosphate rock.

MINERAL FUELS

Petroleum.—Crude petroleum production coordinated by Enterprise Tunisienne des Activites Petroliers in 1981 totaled 41 million barrels, compared with 42.6 million barrels in 1980. The expectation of the 5-year plan that 1981 would be the peak oil production year did not materialize, and no new production fields were in sight for 1982. Almost 94% of the 1981 production was from the El Borma and Ashtart Fields.

Shell Internationale Maatschappij BV (SIM) contracted to install a subsea oil production control system in the Tazerka offshore field at a depth of 820 feet. The control system was to serve eight wells and was to be equipped with a chemical-injection system designed to treat corrosion problems that might be encountered during production. SIM expected the whole system to be operational by mid-1982.

New Refinery.—In a partnership with the Governments of Iraq, Kuwait, and Saudi Arabia, the Government provided a tentative site of 1,500 hectares of land between Bizerte and Tabarka on the north coast for construction of a petroleum refinery, a 9,300-megawatt powerplant, and a deep-water port at a total cost of $1.5 billion. The designated area was to serve as a major industrial center with plans eventually to install a steel mill as well. The contracts for the construction of all these facilities was to be awarded in early 1983.

The Mineral Industry of Turkey

By Peter J. Clarke[1]

The economic reform program instituted in Turkey in January 1980 resulted in a significant improvement in most sectors of the Turkish economy in 1981. For the first time since 1974, the real growth rate of the gross national product (GNP) increased from about $39.57 billion[2] in 1980 to $41.16 billion in 1981. For the past several years, Turkey has suffered from massive balance-of-payment deficits, inflation of over 100% per year, unemployment nearing 20%, and a nearly stagnant economy. Little or no capital investment has flowed into the country during these years, serving to only worsen the general economic situation.

In January 1980, the Government instituted an economic recovery program designed to remove many of the free-market barriers in the economy, open up the productive sectors to private and foreign investment, restrict the rate of monetary growth, and trim the external deficit by promoting exports. The first half of 1980 showed little improvement, while the political problems remained in the forefront. In September 1980, the Turkish armed forces seized power, citing the inability of the elected Government to effectively govern the country. Labor disruptions were outlawed, and top priority was given to maintaining efficient operation of the country's industries. The economic reforms were kept in place, and in the last quarter of 1980, industrial production rose for the first time in 2 years. This spurt in industrial production continued through all four quarters of 1981 and was expected to continue in 1982. This growth led to a dramatic rise of 105% in industrial exports in 1981.

One of the most impressive achievements of the economic reform program has been to reduce the inflation rate from between 100% and 120% in 1979 and 1980 to below 40% in 1981. To reduce inflation, the Government first imposed credit restrictions on deficit financing and public sector spending. It then took a firm stand against expensive labor agreements and prohibited strikes. Finally, it sought and obtained nearly $1 billion in financial assistance from the Organization of Economic Cooperation and Development (OECD) nations and the International Monetary Fund (IMF) to finance imports and reduce the current account deficit. With these policies continuing through the year, inflation was expected to remain at or below 40% in 1982.

Several other reform measures were instituted as part of the recovery program to revive the sagging economy, including changes in taxation, exchange rates, interest rates, and state subsidies. Through 1980-81, tax laws had been legislated that were designed to increase Government revenues in order to reduce the deficit on the budget. The Turkish lira (LT) was devalued several times during the year, from LT94 per U.S. dollar in early 1981 to LT125 per U.S. dollar by the end of the year. The Government also removed controls on domestic bank interest rates, which increased bank deposits by about 100% over those of the previous year. While deposits increased rapidly, fixed capital investment declined owing to the high cost of credit. To further reduce its budget deficits, the Government began gradually lowering the subsidies provided for many domestically produced items, including agricultural products and fertilizer. Finally, one of the most significant reforms over the past year was the liberalization of Turkey's investment laws, including those

that apply to mining, to attract more domestic and foreign private capital into the country. The mineral sector, with tremendous foreign exchange earning potential, was only beginning to benefit from changes in the law and attitude of the country over the past 2 years.

Turkey's mineral industry provided slightly over 4% of the country's GDP in 1981. Overall mineral production increased marginally in 1981 but remained below the Government's expectation. Total mineral production was valued at nearly $4 billion, but mineral exports totaled only about 4.3% of total exports. The Government planned to increase this share to about 5% of total projected exports of $5.8 billion for 1982. To accomplish this, the Government was contemplating some sweeping changes in the laws governing the mineral industry. First, Law No. 6309, the basic mining code enacted in 1954, was in the process of being modernized. One of the primary goals of this modernization was to improve the climate for foreign and domestic private investment in the mining sector. A revised mining code was being drafted by the Ministry of Energy and Natural Resources in 1981 and was to be presented to the Consultative Assembly sometime in 1982.

Major changes were also being considered for Law No. 2172, the Mines Expropriation Law, which was passed in October 1978. This law allowed the Government to cancel private concession agreements without the consent of Parliament. In the 6 months following passage of the law, the Government canceled private concessions agreements for most boron, iron ore, and lignite mines and turned them over to the State Economic Enterprises (SEE). Boron went to Etibank, iron ore concessions were given to Turkiye Demir ve Celik Isletmeleri (Turkish Iron and Steel Works), and lignite mines were given to Turkiye Komuleri Isletmeri (TKI) (the Turkish Coal Authority), all of which were owned by the Government. The result of nationalization was an almost universal drop in production from that of the previous year. The private sector had previously accounted for 35% of boron output, 50% of iron ore output, and 30% of lignite production. The SEE, once in control of the concessions, lacked both sufficient funds to purchase new capital and the skilled personnel to efficiently operate the mines. These were, ironically, the Government's reasons for nationalizing them in the first place. Although mineral production in some areas, notably boron, has recovered, opposition to the law has remained strong. The Ministry of Energy and Natural Resources was preparing a bill to submit to the Consultative Assembly by mid-1982 that would authorize returning many of the mines to the private sector, although it was still unclear which commodities would be returned and which would be reserved for the SEE.

In June 1981, the state mining company Etibank, for the first time in its history, invited interested foreign private companies to participate in selected joint-venture projects involving mining and mineral processing. Among the projects listed were two copper projects, a new aluminum plant, and marble, perlite, and pumice projects. The petroleum industry, which was in a similar situation to the hard-rock mining sector, was also badly in need of foreign expertise and money. Petroleum production has declined steadily since 1969, and petroleum imports have expanded to over $4 billion. In 1980, the state-owned Turkiye Petrolleri Anonim Ortakliki (TPAO) was allowing foreign exploration in many regions of the country, including some on its own concessions. It was also allowing 35% of new oil production to be exported at world market prices.

These initial steps toward liberalization of restrictions on the mining and mineral fuel industries in Turkey were generally considered to be capable of initiating a strong resurgence in these sectors of the economy. Major inflows of capital were necessary to bring up Turkey's low capacity utilization factor, however, and many companies were unwilling to invest without strong guarantees against future nationalization and state interference.

PRODUCTION AND TRADE

Total output from the mineral sector in Turkey increased slightly in 1981, reversing an overall declining trend that was established in 1978-79. The increase in production across the industry averaged about 1%, but mineral production remained well below the Government's targets. Despite its rather poor performance in recent years, the overall mineral potential in Turkey was enormous. Even with inefficient operations and underutilized capacity, Turkey ranked fifth in world chromite production and second in world boron output. Substantial increases in production were registered

for several commodities during the year, such as copper, bauxite, nitrogen fertilizers, and coal. Production of most other commodities, although increasing slightly, remained low. There were several reasons for this. First, a combination of depressed demand for raw materials in Turkey, especially construction materials, owing to a stagnant domestic construction industry, and generally depressed demand for minerals worldwide held production down. Second, most of Turkey's mining operations were unable to fully utilize their processing and refining capacities. This was a result of general inefficiency of the SEE in running these operations and a lack of adequate capital investment to keep factories and machines running and up to date. Inadequate investment has plagued Turkey for several years, creating a cycle of low production levels and low export earnings, which in turn made less money available for reinvestment and capital expenditure, which further reduced production. Turkey was only beginning to pull out of this slump in 1981 under the economic recovery program instituted in January 1980.

On the more positive side, the labor actions that had forced many factories and mines to close for long periods in 1979-80 were prohibited by the military Government during the year. For the large mining ventures, this action substantially increased production levels. This was particularly true in the case of coal, where production of hard coal increased for the first time since 1974. Production of lignite also increased by almost 20%. This provided more fuel to neighboring lignite-fired thermal power stations, which allowed for greater production of electricity. Shortages of electricity has also held mineral production to low levels in recent years. Greater output from the lignite mines and more foreign currency available for fuel oil imports contributed to a significant increase in electricity production, which helped to boost the mineral sector during the year.

Of the three commodities in the mining sector that were nationalized by the Government in October 1978 (iron ore, lignite, and boron), iron ore was the only one whose production level remained below its prenationalization level. Prior to the nationalization decree, the private sector had produced about 45% to 50% of the country's iron ore from several mines around the country. Following the decree, iron ore output dropped 50%, and it has yet to increase significantly. The generally depressed state of the world iron and steel industry was partly responsible for the continued poor performance in Turkey. Also contributing to the drastic decline in iron ore production was the refusal of many of the private owners to continue to operate the mines in the 6-month period between passage of the law and the Government's actual takeover. Even after the state took over, it lacked the personnel and capital to effectively operate the mines and was forced in every case, with the exception of the two largest mines, to contract back the operation of the mines to the former private owners.

Several other commodities were able to register significant increases in production during the year. Production of blister and electrolytic copper increased an average of 44% over the 1980 level, mainly as a result of more efficient operation of the smelters and increased availability of electricity. Output from Etibank's Uludag tungsten mine increased again in 1981. After experiencing technical problems with the concentrating process from 1976 to 1979, several plant modifications and the purchase of new equipment led to increased production over the following 2 years. Etibank was operating a pilot project with a new flowsheet for concentrating the ore that could substantially increase production and recovery over the next several years. Turkey's cement industry continued its rapid expansion despite the depressed state of the domestic construction industry. Capacity of the industry was to rise 20% in the next 2 years, providing the country with an exportable surplus of cement of about 4 million tons by 1984. One of the more outstanding developments in Turkey's mineral industry was the success of the Fertilizer Rationalization and Energy Saving Project, which managed to nearly double production of nitrogenous fertilizers from 1980 to 1981. Nearly 10 million tons of fertilizer was produced during the year, exceeding the State Planning Organization's production targets. The project represented almost a complete revamp of the industry in an effort to increase efficiency, expand output, and reduce energy consumption. Further gains in production were expected as additional units are brought onstream over the next several years.

Production of crude petroleum increased slightly in 1981, in marked contrast to the previous 12 years, during which production

declined fairly steadily. Turkey was making a determined effort to increase oil production from existing fields and locate and develop new fields to reduce the awesome burden oil imports have placed on the economy over the past 3 or 4 years. It was difficult to determine whether these efforts would pay off quickly enough to offset the expected decline in production. Many of Turkey's existing wells were 10 to 20 years old and encountering water and pressure maintenance problems. Substantial results from the secondary recovery programs at the major oilfields were not expected before 1984. Production of mineral commodities in Turkey is shown in table 1.

[4]Includes Zn content of zinc and lead-zinc ores but excludes Zn content of lead ore.

Turkey's overall foreign trade disposition improved considerably in 1981, boosted by higher levels of industrial and mineral exports and by higher remittances from Turks working abroad. Even with these improvements, Turkey's balance-of-payments deficits remained as one of the country's most severe economic problems. Total exports from Turkey rose 55% from that of 1980 to about $4.5 billion in 1981. Imports, on the other hand, rose about 26% from that of 1980 to $8.7 billion in 1981, leaving a deficit in the merchandise trade balance of slightly over $4 billion.

Mineral exports increased substantially for some commodities, notably boron minerals and fertilizer, while decreasing in some others. Overall, mineral exports increased from $191 million in 1980 to $193 million in 1981. Minerals represented about 4.3% of Turkey's total exports. Exports of industrial products have shown the most dramatic growth in 1981, increasing 105% over the 1980 level. The largest growth areas were in rubber and plastics, ceramics and glass, textiles, metal products, and industrial machinery. Industrial exports were valued at about $1.7 billion in 1981. As in previous years, between 50% and 60% of Turkey's total exports were agricultural products. This share was decreasing, however, as industrial production continued to expand. Agricultural exports increased 28% in 1981 to about $2.5 billion.

Overall, Turkish exports were at record levels in 1981, which can be attributed in large part to the economic reform program. The Government placed particular emphasis on increasing industrial production, reorienting Turkish industry toward foreign markets, and maintaining realistic exchange rates. Although these policies were able to achieve a good deal of success for being in existence for only 2 years, they were unable to eliminate the most serious and persistant problem, the soaring cost of petroleum imports. Imports of crude and refined petroleum topped $4 billion in 1981, almost a 30% increase over the 1980 level. This represented an increase in consumption that was accommodated almost entirely by increased imports. Petroleum accounted for about 47% of the country's total imports.

As a result of this high level of imports, Turkey ran a large deficit in its current accounts balance, as it has every year since 1961, with the exception of 1975. The deficit was estimated at $2.8 billion, down 5% from that of 1980. The drop was due in part to increased worker remittances and balance-of-payments assistance provided by IMF and OECD. Despite its difficulty in financing these deficits, Turkey was improving its trading image overseas, mainly as a result of its economic reform program and Western support. Over the next several years, these reforms were expected to pay off in terms of improving Turkey's balance-of-payments situation, increasing domestic productivity, and reducing the country's debt. Turkey's foreign mineral trade is illustrated in tables 2 and 3.

2May include platinum-group metals.

COMMODITY REVIEW

METALS

Aluminum.—Aluminum production from the Seydisehir aluminum complex in Konya Province increased slightly from 1980 to 1981 but remained far below its design capacity. The integrated aluminum complex was designed to process 460,000 tons per year of bauxite into 200,000 tons per year of alumina to produce 60,000 tons per year of primary aluminum. Bauxite for the plant was mined at the Seydisehir Mortas Mine, near the city of Seydisehir, where reserves were estimated at 13 million tons of boehmite and gibbsite, with an Al_2O_3:SiO_2 ratio of 6.77. Some bauxite for the plant was also mined in western Anatolia, on the Aegean coast, near Mugla. Turkey reportedly possessed almost 2% of the world's reserves of bauxite, with substantial resources at Milas in Mugla Province and in the central Taurus region, near Seydisehir, which remain unexploited. Bauxite production that was not utilized at the Seydisehir complex was exported, primarily to Romania.

The Seydisehir complex and both bauxite mines were owned entirely by Etibank. The complex was built in 1973 with a $200 million loan and technical support from the Soviet Union. Production from the mine and smelter increased rapidly in the first years of operation but tumbled in 1978-80, when it operated at just above 50% capacity. The rapid decline was due to frequent power shortages at the mine and smelter caused by the lack of fuel around the country. In 1980, only two of the four potlines were able to operate on the available power. Stabilization of the economy and political scene combined with strictly enforced labor regulations led to a slight

increase in production in 1981. Turkey was negotiating with the Soviet Union in 1981 to obtain financing for expansion of Seydisehir's aluminum refining capacity to 120,000 tons per year. No agreements were signed, however, by the end of the year.

As part of the Government's efforts to attract foreign capital into the country, Etibank invited several companies to consider becoming a joint-venture partner in the country's second aluminum complex. The plant was to be located at Milas in Mugla Province on the Aegean Sea. Resources at Mugla were estimated at 28 million tons of diaspore, containing 58% Al_2O_3 and 6% to 7% SiO_2. The plant at Mugla was to produce 250,000 tons per year of alumina and 120,000 tons per year of primary aluminum. Total cost of the project was estimated at about $830 million. The foreign partner of the project would be allowed to own between 10% and 49% of the equity of the plant and was also expected to provide some direct financing as well as securing necessary loans for the foreign debt capital portion of the project. No partner had been selected by yearend 1981.

Antimony.—Antimony production remained stable in 1981, with over 27,000 tons of ore produced, yielding about 3,300 tons of concentrate containing 2,150 tons of antimony metal. Antimony was produced mainly by Ozdemir Antimuan Madenleri Ltd. Sti. from the Turhal Mine near Tokat in central Anatolia Province. Reserves at Tokat were estimated at 350,000 tons containing 12% to 14% antimony. Other small producers of antimony were Usak Mermer Sanayi ve Madencilik AS, which produced 1,000 tons per year of ore from a mine in Kutahya Province, and Ahmet UZ., which mined antimony ore from a small mine near Balikesir. Reserves at Balikesir were estimated at 300,000 tons containing 5% to 6% antimony. Reserve tonnage levels at Kutahya were not available, but the ore grade was also in the range of 5% to 7% antimony. Turkey's large reserves and current low output suggests that if demand and prices were to rise, output, especially from the Turhal Mine, could increase significantly.

Chromite.—Production of chrome ore remained at about the same level as in 1980, and Turkey held its position as the fifth largest producer of chromite in the world, supplying about 4% of the world's chromite.

Chromite deposits were widespread in Turkey, having been located in 40 of the country's 67 provinces. The major deposits were in the Provinces of Elazig in central Turkey, Bursa in northwest Turkey near the Sea of Marmara, and Mugla in southwest Turkey, with other deposits located at Eskisehir, Kutahya, and Kayseri. The chromite deposits in Turkey have been grouped into three geologic provinces. The northern Alpine ores are of the massive type and occur as small lens-shaped ore bodies with their axes parallel to the trend of the Pontus Mountains in northern Turkey. The southern Alpine province, which contains the deposits at Elazig, occur as elongated lenticular bodies that extend mostly in an east-west direction. The lenses commonly reach a depth of 120 to 150 meters and may be 100 to 300 meters in length. The third province has been termed the Middle Chrome province and is located around Kutahya and Bursa. The ore in this province occurs as banded zones, pipes, or lenses, extending to greater depths than the other two types. The Dagardi and Kavak Mines in Kutahya Province were examples of this type of deposit.

Chromite mining was carried out by many companies, the largest of which was Etibank, the state-run mining enterprise. Etibank was responsible for over one-half of the country's output of chrome ore, with a total production capacity of over 300,000 tons per year. Etibank operated mines in Mugla, Elazig, and Bursa Provinces, the largest of which were in the Guleman district in Elazig. Output from Guleman and the nearby Kefdag and Soridag Mines was fed to two concentrators at Elazig. The Sori concentrator had a capacity of 30,000 tons per year of 44% to 48% Cr_2O_3. The Kefdag concentrator treated low-grade disseminated ore from the Mount Kef region. The ore grade from the Kefdag concentrator was below expectations at about 42% Cr_2O_3, but Etibank was working on improving the grade.

Etibank's other concentrator was located at Karagedik, in Mugla Province. Output from the Uckopru, Karagedik, and Goeck Mines was processed at the Karagedik concentrator, which produced approximately 50,000 tons per year of 44% to 48% Cr_2O_3. Several other mines and a concentrator at Mugla were operated by Turk Maadin Sirketi AS, a subsidiary of Metallurg, Inc., of New York. Turk Maadin also operated the Kavak Mine and concentrator near Bursa, in Kutahya Province. Two other

small concentrators were operated by Turkish companies in the Bursa region, bringing to seven the total number of concentrators operating in the country. Chrome ore was also mined by many small one-person operations, who generally transported the ore by truck to large ports, where it was sold to exporters.

In a related development, the Mineral Research and Exploration Institute of Turkey (MTA) announced the discovery of large reserves of low-grade chromite in the Karsanti region in Adana. The initial estimate indicated at least 4 million tons of 7% chromite, but other estimates went as high as 30 million tons. Samples from the Karsanti region were being studied at MTA laboratories.

Ferrochrome.—Etibank was responsible for all ferrochrome production in the country from its two plants at Antalya and Elazig. At the Antalya Ferrochrome Works, approximately 10,000 tons of low-carbon ferrochrome was produced annually. In 1981, Etibank converted an old calcium carbide furnace into a ferrosilicon production unit, utilizing power from the regular hydroelectric supply. Production capacity at the new unit was quoted at 5,000 tons per year of FeSi with 2% carbon. The particles came in various sizes and weighed a maximum of 25 kilograms. Total capacity of the unit was equal to about one-half of Turkey's annual consumption. In an effort to encourage local consumers to purchase Etibank's FeSi, on January 10, 1981, the Turkish Government imposed a stiff tariff on imported FeSi, equivalent to almost one-fourth of the selling price of imported FeSi.

Etibank's Elazig Ferrochrome Works produced an average of 23,000 tons of high-carbon ferrochrome in 1981. Capacity of the plant, which came onstream in 1977, was 50,000 tons per year, but production has never reached the expected level. Etibank planned to expand the Elazig works to 100,000 tons per year of high-carbon ferrochrome by 1985. The expansion program, valued at $33 million, was to be undertaken by Elkem AS of Norway, providing engineering services, and Outokumpu Oy of Finland, providing process technology. Nearly two-thirds of all chromite produced in Turkey was used for the production of ferrochrome, and almost all of this production was exported. Chrome ore not used in the production of ferrochrome was usually exported as concentrate.

Copper.—Turkey's copper industry continued to experience difficulties in 1981, with production of blister copper rising by 71% but remaining below 50% of the industry's capacity. Copper was mined in three provinces in Turkey, Murgul, Kure, and Ergani, but two new deposits at Siirt Madenkoy and Rize-Cayeli were being considered for exploitation. Two companies, Etibank and Karadeniz Bakir Isletmeleri (KBI), owned 49% by Etibank, were responsible for all of the country's production of ore, concentrate, blister copper, and pyrite. Most of the refined copper was produced by private companies in and around Istanbul.

At Murgul, two open pit mines were operated by KBI, with a combined capacity of 1.2 million tons per year of 1.2% copper ore. Two concentrators were in operation at Murgul. Etibank operated a concentrator that was designed to produce 30,000 tons per year of 18% copper and 18,000 tons per year of pyrite from an annual input of 400,000 tons of ore. The KBI concentrator was designed to handle 600,000 tons per year of ore in the production of 60,000 tons of copper concentrates and 20,000 tons per year of pyrite. Output from Etibank's concentrators was delivered to Etibank's smelter at Murgul, which was designed to produce 12,000 tons per year of blister copper. Actual production in 1981 was below 8,000 tons. From Murgul, the blister was trucked to Istanbul for refining. Output from the KBI concentrator at Murgul and pyrite from Etibank's concentrator were pipelined in slurry form to Hopa, 60 kilometers north of Murgul. At Hopa, copper and pyrite were concentrated, and some of the concentrate was exported. The remaining concentrates were shipped to the KBI smelter at Samsun, for production of blister copper and byproduct sulfuric acid.

The Samsun smelter was part of the KBI Black Sea Copper Works, located in the Kure district on the coast of the Black Sea in northern Turkey. At Kure, both Etibank and KBI operated mines. Etibank's Kure Cuprous Pyrite Works consisted of the 1-million-ton-per-year open pit Asikoy Mine and a concentrator. The KBI operation consisted of the Bakibaba underground mine at Kure, also with a 1-million-ton-per-year capacity, and a concentrator and smelter located at Samsun. Output from Kure was run through Etibank's concentrator and then transported to Samsun. Etibank, with the assistance of Outokumpu Oy of Finland, was expanding mining operations at Kure in 1981. The project involved

expansion of the open pit mine, the start of underground operations, and the construction of a new concentrator. Capacity of the expanded works was to be 1.1 million tons per year of ore, yielding 100,000 tons per year of copper concentrates and 500,000 tons per year of pyrite concentrate. The KBI Samsun smelter, built in 1976, had a production capacity of 40,000 tons per year of blister copper. Output from Murgul and Hopa, as well as Kure ore, was to be used in the Samsun smelter. The Black Sea Copper Works has been unable to reach even one-half capacity since starting production, however, owing to technical problems, lack of spare parts, and labor disruptions. The smelter was built by McKee Overseas Corp., United States, with financing from the U.S. Agency for International Development (AID). With Turkey's foreign exchange earnings limited over the past several years, maintaining U.S. equipment with spare parts has made continuous operation of the smelter difficult. The Samsun smelter produced approximately 7,000 tons of blister copper in 1981, representing less than 20% capacity utilization. From Samsun, blister copper was shipped to Istanbul for refining.

At Ergani in eastern Turkey, Etibank operated an integrated copper complex consisting of a 1-million-ton-per-year mining operation, a concentrator, and a smelter. Production capacity of the Ergani concentrator was 70,000 tons per year of 14% copper concentrates, which was in turn fed to a 25,000-ton-per-year smelter. Output from the Ergani smelter was about 50% of its rated capacity in 1981. Reserves at Ergani were estimated at 20 million tons of copper-pyrite ore.

Late in 1981, Etibank announced that it was seeking foreign partners to develop two copper mining projects for which it did not have sufficient development capital. Foreign participation in the projects would represent the first private sector share in Turkey's copper industry since the majority share in KBI was nationalized in 1977. The first project was a mine to be located at Cayeli, near Trabzon on the Black Sea coast. The project was to produce 62,000 tons per year of 23% copper concentrates and a lesser amount of zinc. Etibank planned to begin construction of a pilot plant in 1982. Reserves at Cayeli were estimated at 25 million tons of copper-pyrite ore. The second project involved a mine and concentrating plant to be located at Siirt Madenkoy, in eastern Turkey. This plant was to produce about 64,000 tons per year of copper concentrates, but the whole project was still in the feasibility study stage. Reserves at Madenkoy were estimated at 15 million tons of copper ore. Fenni-Gamma, a Turkish company that owned the Cayeli deposit before Etibank took over, was investigating the possibility of mining the deposit. Fenni-Gamma was seeking both a foreign partner to start development and financial assistance from AID. Phelps Dodge Corp., United States, was also considering involvement in the project, but no definite plans were made by yearend 1981.

Iron Ore.—Production of iron ore in Turkey increased slightly in 1981 to 2.67 million tons from 2.58 million tons in 1980. Nearly 2 million tons of this output was supplied by the Divrigi Mine in central Turkey, at Sivas, Malataya. The remaining 0.5 million tons of ore was supplied by several different mines around the country. These smaller mines were nationalized in 1978 and brought under the control of the state-owned Turkish Iron and Steel Works (Turkiye Demir ve Celik Isletmeleri). Up until 1978, these mines provided between 40% and 60% of the country's iron ore output. Following nationalization, iron ore production tumbled from a high of 3.6 million tons in 1976 to below 2.6 million tons in 1980. To restore output to its previous level, the Government was preparing a bill to present to the Consultative Assembly authorizing the return of the mines to their former private sector owners. Turkey continued to import over 500,000 tons per year of iron ore, mostly from Brazil.

Government plans to develop the Hasancelebi iron ore deposit were shelved in 1981, owing to both technical and economic problems. Hasancelebi, located southwest of Divrigi, contained an estimated 300 million tons of low-grade, 15% to 30%, magnetite ore. It was determined that, because the ore grade was too low to be used as direct charge and substantial concentration would be required before converting it to pellet or sinter feed, the project was uneconomic.

Iron and Steel.—The production of iron and crude steel in Turkey declined slightly in 1981, from a high of over 2.5 million tons in 1980 to 2.4 million tons in 1981. The iron and steel industry in Turkey consisted of three large steel plants, all operated by the state-owned Turkiye Demir ve Celik Isletmeleri, seven smaller private producers, and several fabricating companies. The

three large Government steelworks were located at Karabuk, Iskenderun, and Eregli.

The largest of the three plants, and also the most profitable, was the Eregli Demir ve Celik Febrikalari T.A.S. (Eregli Iron and Steel Works Association). Eregli was the only state steel plant that had a minority share of private sector partners, including the Ankara Chamber of Commerce, Sumerbank, and others. The plant was originally established in 1960 with an 800,000 ton per year steelmaking capacity. In 1973, Nippon Kokan (Japan) expanded capacity of the plant to 1.8 million tons per year through the addition of a new blast furnace. Eregli had the highest level of capacity utilization in the Turkish steel industry from 1976 to 1981. In 1981, production from Eregli was 50% greater than in 1980, totaling well over 1 million tons.

The other two steel plants, located at Iskenderun and Karabuk, were owned entirely by the Government. The Iskenderun plant, located on the Mediterranean coast near the Syrian border, was originally built by the Soviet Union in 1970 and has experienced serious operating problems since it opened. These difficulties were caused mostly by poor management, shortages of electricity, and a work force 80% larger than was necessary for the plant to operate. In 1981, Iskenderun operated at less than 35% of design capacity. Following a series of on-again, off-again negotiations, the U.S.S.R. appeared ready to assist Turkey in expanding the capacity of the plant from the current level of 1 million tons to 2.2 million tons per year of raw steel. The expansion program was to have been carried out in 1980, but the economic crisis in Turkey and the ambivalence of the Soviets delayed implementation of the project. No date was set for completion of the expansion work.

The country's third steelworks, at Karabuk, was also preparing a modernization program in 1981. In June 1981, the World Bank provided a $70 million loan to expand and modernize Karabuk along with other industrial projects in Turkey. Romania was to supply the technical knowledge to modernize the coke ovens and replace the sinter plant and rolling mills. Capacity at Karabuk was to be raised from 600,000 to 1 million tons per year of raw steel.

In the private sector, a new specialty steel plant came onstream near the end of 1980. The plant, Asil Celik Sanayi ve Ticaret AS, was located in Orhangazi, 160 kilometers southeast of Istanbul, near the two largest automobile factories in Turkey. The plant was established by Turkey's Koc Holdings (22%), Turkiye Is Bankasi (17%), Celik Industrisi (12%), Turkiye Sinai Kalkinma Bankasi (10%), International Finance Corp. (10%), and private investors (29%). It was designed to produce 85,000 tons per year of specialty steel products aimed primarily for producing cars, tractors, and other transport machinery. The plan was to add two 45-ton electric arc furnaces in 1982.

Other large private sector steel producers in Turkey were Colakoglu Metalurji AS in Istanbul (350,000 tons per year), Metas Izmir Metalurji Fabrikasi T.A.S. in Izmir (260,000 tons per year), Istanbul Celik ve Demir Izabe Sanayii AS in Istanbul (27,000 tons per year), Elektro Metal Sanayii AS in Istanbul (30,000 tons per year), Izmir Demir Celik Sanayii AS in Izmir (600,000 tons per year), and MKEK Celik Fabrikasi in Kirikkale (20,000 tons per year).

MKEK, the Turkish Government's engineering and chemical enterprise, was nearing an agreement with the Soviet Union for the establishment of a 300,000-ton-per-year specialty steelworks at Foca. The project was originally put out to tender in 1977, but no satisfactory bids were received. In September 1980, the U.S.S.R. signed a preliminary agreement with MKEK to build the plant, and a final go-ahead was expected early in 1982.

The Turkish Government's plan to build a fourth steelworks was temporarily shelved in 1981, owing to the world steel crisis and lack of available financing. The plant, which was to be located at Sivas in eastern Anatolia, was originally intended to produce 2 million tons per year of steel utilizing domestic iron ore and coal. The plan was shelved on the advice of the World Bank, which was assisting in sorting out Turkey's financial problems.

Lead and Zinc.—The primary producers of lead and zinc ore in Turkey were Etibank and Cinko-Kursun Metal Sanayi AS (Cinkur), which was owned 47% by Etibank. At Keban near Elazig in central Anatolia, Etibank operated the Keban Lead and Zinc Works, which produced about 50,000 tons per year of lead and zinc ore, averaging 4.0% lead and 4.5% zinc. Annual output from the concentrator averaged 4,000 tons of 50% lead and 4,000 tons of 41% zinc.

Cinkur operated the only lead-zinc smelter in Turkey, located at Kayseri in central Anatolia. Cinkur operated several mines in the Zamanti area, which produced an aver-

age of 80,000 tons per year of lead-zinc ore. The Zamanti ore was concentrated and fed to the smelter, which had an annual capacity of 40,000 tons of electrolytic zinc, 6,000 tons of lead, and 150 tons of cadmium. In 1981, the Cinkur plant produced 6,000 tons of refined lead and 15,000 tons of zinc slab.

Several other smaller companies were actively mining lead and zinc deposits in the Biga Peninsula, encompassing the Provinces of Balikesir and Canakkale south of the Sea of Marmara in eastern Turkey. The Biga Peninsula contained over 200 known lead-zinc and lead-zinc-copper deposits, most of which were claimed in 100 mining or prospecting concessions. In Canakkale, Canakkale Madencelik Ltd. operated a 10,000-ton-per-year concentrator, treating lead and zinc sulfide ore from its Karundere Mine. At Balya, in Balikesir, Turker Izabe ve Rafina Sanayii AS operated two 60-ton-per-day concentrators, utilizing ore from the company's Handeresi and Halilar Mines. Also in Balikesir, Bayramoglu Madencelik ve Flutasyon Tesisi operated an 80-ton-per-day concentrator. Tailings from this company's Papazlik Mine and also from the Bayla Mines were treated by Etibank at Keban to obtain a concentrate containing 40% lead and 18% zinc. At Dursunbey in Balikesir, Andolu Maden Adi Komandit Sti. brought onstream a 60,000-ton-per-year concentrating plant. The unit treated ore from the company's Alacam Mine, where both open pit and underground operations were in progress. Also planning new operations in the Biga Peninsula were Balkesir Ararat Madencelik ve Ticaret and the Galena Mining Co., both of which owned concessions in the area.

Mercury.—Production of mercury in Turkey continued to decline in 1981, owing mainly to the depressed state of world demand. Mercury production, which dates back nearly 8,000 years, has declined steadily from a high of over 10,000 76-pound flasks in 1971 to below 4,500 76-pound flasks in 1980 and 1981. Cinnabar was mined from three main districts around Konya, Karaburun, and Aydin in southwestern Turkey. Output from these mines was delivered to two smelters, both owned by Etibank, at Halikoy and Sarayonu. Both smelters produced better than 99.99% mercury. Production capacity at Halikoy was 120 tons per year, and at Sarayonu, 80 tons per year. With demand for mercury low, some of the smelting facilities at Halikoy were converted to antimony smelting.

Tungsten.—Production of tungsten from Turkey's Uludag tungsten mine increased slightly in 1981, owing primarily to more efficient operation of the concentrating plant. The mine was located near the summit of Uludag Mountain, 42 kilometers from the town of Bursa, in northwestern Turkey. The deposit contains approximately 9.4 million tons of proven reserves and 4.9 million tons of probable reserves of both wolframite, (Fe, Mn) WO_4, and scheelite ($CaWO_4$), with an average WO_3 content of 0.5%. Mining at Uludag was by both open pit and underground methods, but the pit was closed from autumn through spring, usually about 7 months out of the year, because of poor weather and heavy snowfalls. Primary output of the mine was scheelite. Ore production in 1981 was estimated at 300,000 tons, two-thirds of which came from underground. Mining operations at the open pit were being carried out by private companies under seasonal contract from Etibank, which operated the underground mine, but Etibank planned to take over all mining operations in the near future.

The concentrator at Uludag was originally designed to treat 550,000 tons per year of both scheelite and wolframite ore, utilizing dry grinding and magnetic separation techniques for the scheelite and wet grinding and magnetic separation for the wolframite ore. The dry concentrating circuit, designed to treat 1,000 tons per day, had not come into full operation, owing to equipment problems and inadequate feed from the open pit mine. The wet grinding circuit and concentrator was being used above its rated capacity to handle both types of ore until the scheelite system could be redesigned. The flowsheet also included a flotation section following magnetic separation. The flotation section yielded a rich concentrate containing over 60% WO_3, while low-grade concentrate (20% WO_3) was obtained from the magnetic separation units. Average recovery from the entire operation was about 50%. A pilot project utilizing an "all-flotation" flowsheet design was completed in 1981, and studies were in progress to determine the feasibility of using this design to process all the Uludag ore.

NONMETALS

Barite.—Production of barite continued to expand in 1981, fueled by increased demand for high-density drilling muds from the petroleum industry. Total reserves in

Turkey were estimated at over 10 million tons in 1976, but several new discoveries since then have raised that estimate considerably. In 1976, the Government of Turkey placed a ban on the export of raw barite to increase the value of exports by forcing producers to install grinding equipment. Since 1976, grinding capacity in Turkey has risen to about 500,000 tons per year. About 90% to 95% of Turkey's barite production was exported, mostly to the U.S.S.R. and other neighboring countries. Up until about 1976, all barite was produced by private sector companies. Since that time, Etibank, the state-owned mining and minerals concern, has gradually taken a larger share of the industry. In 1980, public sector production accounted for about 60% of total output. The major barite-producing companies and their mine and grinding capacities are shown in the following table.

Company	Location, mine(s), mill(s)	Mine capacity (tons per year)	Grinding capacity (tons per year)
Bastas Barytes Industry and Trading Co. Inc.	Alanya-Sarikaraagac, Trabzon, Antalya.	150,000	120,000
Etibank	Beysehir	100,000	100,000
Barit Maden Turk AS	Marash, Adana	50,000	70,000
Polbar Baryte Industries AS	Alanya	40,000	50,000
Bager Maden Sanayive Ticaret AS	Sarikaraagac	60,000	80,000
Kimya Tesisleri Sanayi ve Ticaret AS	Silifke, Kutahya, Yarimca, Kocaeli.	30,000	100,000
Emas Industrial Minerals AS	Mas	60,000	60,000
Dolsan Dolgu Maddeleri Sanayi Kollektif Sirketi	Antalya, Eskisehir	40,000	10,000
Dunmus Yaser ve Ogullari	Beysehir	10,000	10,000
Kale Madencilik	Icel	1,000	--
Egemetal Madencilik	Mersin	1,000	--

Most of Turkey's barite deposits were located around the Sarkikaraagac, Alanya, Maras, and Konya regions. Bastas Barytes, the largest barite producer in the country, owned large deposits in Sarkikaraagac and Alanya but produced most of its raw material from a mine near Trabzon. Bastas and Kimya Tesisleri (Kimtes) both ground barites for other small producers in the country in addition to processing their own output. Although most of the barite producers in Turkey were primarily export oriented, Dolson Dolgu produced ground minerals, including barite, for Turkey's domestic market. Domestic consumption of barite averaged about 5,000 to 10,000 tons per year.

The Central Anatolian Directorate of Mining Research and Exploration announced late in 1981 that rich barite deposits had been found in the Karaman district near Konya. Tests were being conducted to determine the level of reserves and quality of the deposit. Once the tests were completed, the Government indicated it would begin exploiting the deposit.

Boron.—Production of boron minerals in Turkey increased substantially in 1981, to over 1.7 million tons from 1.2 million tons the year before. All boron output from Turkey has been produced by Etibank since 1979, when the Government nationalized all boron, lignite, and iron ore mines. Following nationalization, boron production tumbled to about 900,000 tons, and most of that was material already in accumulated stocks of the former private owners. Contrary to the Government's expectation of increasing output from the mines, Etibank produced almost no boron for the 10 months following nationalization. In 1980, Etibank was able to increase its efficiency and produce over 1 million tons, but this was still less than the mines had produced under private sector ownership. However, boron production improved substantially in 1981, reaching its highest level ever. Etibank devoted a large percentage of its resources and management skills to improving the production levels of most boron mines. This effort was designed to both prove its point that the mines had been inefficiently managed prior to nationalization and, more importantly, to generate much needed foreign exchange from boron exports. Boron mineral exports generated approximately $100 million in receipts for the Turkish Government in 1981, up nearly 40% from the 1980 level. Turkish borates were exported mainly to Western Europe, the United States, and Japan.

Turkey possessed reserves of boron minerals estimated at 490 million tons, most of which was high-quality 27% B_2O_3. This represents about 70% of the world's total reserves, with the remainder located in China and the United States. Turkey was the second largest producer of boron minerals in the world, producing about 36% of the world's total output. The United States was the world's largest producer, with about 56% of the world total.

In Turkey, Etibank mined boron from three major deposits, at Bigadic, Kirka, and Emet, all in northwest Turkey. In Bigadic, Etibank operated a 150,000-ton-per-year open pit colemanite and ulexite mine and a recently completed 150,000-ton-per-year concentrator. Output from Bigadic was either exported as concentrate and crude ore or delivered to the Bandirma facility for processing. In Emet, Etibank operated the Emet Colemanite Works, which consisted of both underground and open pit colemanite mines and a 450,000-ton-per-year concentrator. Output from the concentrator in 1981 was 400,000 tons at 40% to 47% B_2O_3. In Kirka, Etibank produced tincal at a rate of about 400,000 tons per year. In 1980, Etibank brought onstream a chemical complex at Kirka, designed to produce 180,000 tons per year of crude borax pentahydrate, 60,000 tons per year of refined anhydrous borax, and 6,000 tons per year of refined borax decahydrate. The complex was unable to operate near its rated capacity during the year and produced only a limited quantity of boron compounds.

Most of Turkey's domestically refined boron was produced at Etibank's Bandirma borax and acid plant, located on the Sea of Marmara in northwest Turkey. Annual capacity of the plant was 55,000 tons of borax decahydrate, 35,000 tons of borax pentahydrate, 25,000 tons of boric acid, 20,000 tons of sodium perborate, and 120,000 tons of sulfuric acid. Several new units were to be added to the complex over the next few years, including a 100,000-ton-per-year boric acid plant under construction by a French firm, to be completed in 1982, and a 20,000-ton-per-year hydrogen peroxide plant under construction by a Soviet company, scheduled for completion in 1985. Etibank was also planning to build a 100,000-ton-per-year borax plant in Eskisehir, to be completed in 1982. Crude and refined borates were exported mainly from the Port of Bandirma.

Cement.—Production capacity of Turkey's cement industry stood at 19.5 million tons at the end of 1981 and was scheduled to reach 22 million by the end of 1982. There were 35 operating cement factories in Turkey, 16 of which were run by the public sector, and 19, by the private sector. The public sector plants, operated by Turkiye Cimento Sanayii T.A.S. (Cisan), were mostly of relatively small size, producing between 100,000 and 500,000 tons per year of cement. The private sector plants generally had a productive capacity of 500,000 tons per year or more. The cement industry in Turkey has been in a severe slump since 1979, owing to a nearly stagnant construction industry and shortages of fuel. Cement production recovered somewhat in 1981, reaching a high of 15 million tons, while domestic demand increased only slightly, to about 13 million tons from 12 million tons in 1980. The remaining 2 million tons was exported, bringing in revenues of about $95 million.

There were five new plants under construction in Turkey in 1981, all by the public sector. The location of the new plants and their annual capacities were as follows: Samsun, 620,000 tons; Adiyaman, 610,000 tons; Diyarbakir, 610,000 tons; Siirt, 620,000 tons; and Urfa, 1 million tons of cement. All but the Urfa plant were to come into operation in 1982. Urfa was not scheduled to start production until 1984. There were no immediate expansion plans for privately owned cement plants in Turkey.

Emery.—Turkey's production of fine-grained emery increased slightly to about 44,000 tons per year in 1981. Production of emery has declined from a high of over 150,000 tons in 1973 to the current level. Most of the decline has come from the private sector operations, which produced 144,000 tons in 1974. Output has declined every year since then to the 1981 level of about 36,000 tons. Production from the public sector, carried out by Etibank, has been irregular, fluctuating between 2,000 and 10,000 tons per year from 1974 onward. Etibank's production in 1981 averaged 8,000 tons. The largest private sector producer of emery was Lutfullah E. Kitapci Mineral Co. Ltd., with a productive capacity of 70,000 tons per year from several small mines in the vicinity of Mugla. Etibank's share of emery production was derived from the Milas Mine in western Anatolia. Production capacity at the mine was 30,000 tons per year of raw emery.

Turkey produced about 60% of the world's output of emery. Most of the materi-

al was produced and exported mainly for use in abrasives in raw form, with very little processing carried out within the country. About 5,000 tons of emery powder and abrasives was exported in 1981, compared with about 34,000 tons of raw emery. Most of the output was dried, ground, bagged, and exported as unprocessed emery. Exports were delivered mainly to France, the United Kingdom, the Netherlands, and the Federal Republic of Germany.

Fertilizer Materials.—The Turkish fertilizer industry was able to achieve a dramatic increase in production in 1981, with total nitrogen content in fertilizers reaching 672,000 tons, nearly double the 1980 level. Consumption of nitrogen fertilizers in 1981 was about 810,000 tons, compared with 685,000 tons the previous year, both of which were lower than the 1979 figure of 852,000 tons. The decline in consumption was primarily a result of the higher costs. A combination of reduced Government subsidies on fertilizer and high interest rates caused farmers to cut back on purchases of fertilizer of all types. Consumption of diammonium phosphate (DAP) was lower in 1981, at 97,200 tons contained nitrogen (N), compared with 110,000 tons in 1980. Production of DAP rose from 16,800 tons N in 1980 to 57,300 tons in 1981.

This high production level of all types of fertilizer meant a substantial reduction in imports, the cost of which had been a severe drain on the Turkish economy. Imports of all types of fertilizers were 330,000 tons N in 1981, compared with 450,000 tons N in 1980. Imports of urea declined from 121,000 tons N in 1980 to just 14,000 tons N in 1981.

The dramatic turnaround in the Turkish fertilizer industry was a result of the implementation of the Fertilizer Rationalization and Energy Saving Project, which was started early in 1980 and, by the end of 1981, was reaching its second phase. The project involved a large-scale restructuring of the whole fertilizer sector in an effort to eliminate the shortages of feedstock, electricity, raw materials, and spare parts and improve the efficiency of all plants. The Turkish Government received a $110 million loan from the World Bank to finance the foreign exchange requirement of the reorganization. A further $60 million loan from the World Bank was applied for late in the year to finance the second phase. The entire revitalization program was to be completed by 1986.

The project called for plant modifications and additions, an increase in capacity utilization, improvements in energy efficiency, and a reduction in pollution across the whole industry. The first phase involved modernization of the Bandirma Gubre Fabrikalari plant at Bandirma on the Sea of Marmara in northwest Turkey. The original facilities at Bandirma consisted of a triple superphosphate plant, a 495,000-ton-per-year sulfuric acid unit, a 150,000-ton-per-year DAP unit, and a 40,000-ton-per-year nitrogen ammonium sulfate plant. Three new units were commissioned in 1981: a 145,000-ton-per-year phosphoric acid plant, a 15,000-ton-per-year DAP plant, and a 150,000-ton-per-year complex fertilizer unit.

Four other fertilizer plants were undergoing similar expansions. Gubre Fabrikalari at Iskederun planned to rehabilitate its sulfuric acid and phosphoric acid plants and add a 240,000-ton-per-year DAP plant and a new ammonium sulfate unit. Akdeniz Gubre Sanayii, which operated phosphoric acid and sulfuric acid production units at a complex in Mersin, was planning to add a 450-ton-per-day DAP unit and a 600-ton-per-day ammonium sulfate plant. Also, E.G.E. Gubre was modernizing its 350,000-ton-per-year compound fertilizer plant at Foca, and KBI, the copper company, was planning to refurbish its sulfuric acid facility at Samsun. Azot Sanayii's fertilizer plant at Samsun was also to be restructured. The complex consisted of a DAP plant and a pyrite-based sulfuric acid unit and had the capacity for both phosphoric acid and triple superphosphate production. Azot Sanayii's other lignite-based ammonia units at Kutayah, originally built in 1962, were also to be modernized. Istanbul Gubre Sanayii's plant at Izmit and Gubre Sanayii's monoammonium phosphate plant at Yarimca were also being expanded. Finally, the Toras Chemical and Fertilizer Industry Co. brought onstream a 330,000-ton-per-year monoammonium phosphate plant at Ceyhan in southern Turkey in 1981.

This almost total revamping of the industry resulted in the production of nearly 10 million tons of fertilizer materials in 1981, exceeding the Government's production target by 2%. Most of the modernization programs included construction of ancillary facilities, such as storage tanks, to prevent shortages of raw materials and feedstock.

Phosphate.—With the rest of the fertilizer industry expanding fairly rapidly, production of phosphate rock also increased in

1981. Etibank was the only producer of phosphate rock in the country from its Mazidag deposit in southeast Turkey. Reserves at Mazidag were fairly extensive, estimated at 410 million tons containing 10% to 25% P_2O_5. Operating capacity at the mine was 250,000 tons per year of phosphate rock, but Etibank was only able to produce about 100,000 tons of phosphate rock in 1981. Consumption of phosphate rock has risen sharply over the past several years, from about 650,000 tons in 1978 to about 1.2 million tons in 1981. Turkey imported nearly all of this domestic requirement in 1981. Phosphate rock was supplied by Jordan, 36%; Morocco, 30%; Tunisia, 18%; Israel, 7%; Togo, 5%; and Taiba, 4%. Imports of phosphate rock, Turkey's largest and costliest mineral import, were valued at over $30 million in 1981.

Magnesite.—Production of magnesite increased substantially in 1981, to about 880,000 tons of crude ore. About 90% of this production was supplied by four companies from deposits in the Kutayah, Konya, and Eskisehir districts. Kutayah Manyezit Isletmeleri (Kumas), Manyezit AS, and Sumerbank all produced dead-burnt magnesite, and Continental Madencilik Sanayii ve Ticaret (Comag) produced caustic-calcined magnesite.

Manyezit AS operated mines in the area between Kutayah and Eskisehir and was capable of producing 60,000 tons per year of dead-burnt magnesite, but output was well below that level. Manyezit, a subsidiary of Veitscher Magnesitwerke AG of Austria, exported most of its production to Austria. Sumerbank produced both dead-burnt magnesite and refractory bricks from its operation near Konya. The brick plant had a capacity of 26,500 tons per year of chrome-magnesite-type refractory bricks from a total sinter-magnesite capacity of 40,000 tons per year. Kumas was the country's largest producer of magnesite from its mines and facilities located near Kutayah. The company was in the process of adding a 31,000-ton-per-year brick plant to its three mines, and ore preparation and dead-burning facilities to further integrate the operation. As part of the integration plan, new machinery was to be added to the mines, the ore preparation facilities were to be modernized, and dead-burning capacity was to be increased. The expansion program was to be completed by 1983.

Comag was the country's largest producer of caustic-calcined magnesite. Ore was mined in two areas, Tavsanli and Kumbet, and calcining plants were located adjacent to both mines. Raw material for the Kumbet plant was high-grade magnesite, low in silica and iron. The calcining plant was able to produce a high-quality product, suitable for use in electrofused magnesia products.

Perlite.—Perlite production remained at about the 26,000-ton-per-year level in 1981. Etibank and Zihni International Trade and Marketing were the major producers, but Etibank operated the largest grinding and expansion plant, at Cumaovasi, Izmir. Etibank began operating the facility in 1975. Annual production capacity from the plant was about 140,000 tons of processed perlite and 50,000 to 60,000 cubic meters of expanded perlite. Raw material for the processing plant was supplied from two mines, one adjacent to the plant and one several kilometers away at Minassa. Reserves at the Cumaovasi deposit were placed at 4.5 million tons measured and another 5.6 million tons indicated. Perlite from the Minassa deposit had significantly better expansion characteristics than Cumaovasi ore. Reserves at Minassa were estimated at about 7 million tons, 3.4 million tons of which were measured.

Zihni International, a Turkish shipping, trading, and mining company, operated an open pit mine near Izmir, with a capacity of 50,000 tons of perlite ore per year. Zihni recently bought the majority of equity shares in Ege Perlit to obtain ownership of its small perlite expansion plant. Pabalk Ticaret Ltd. also operated a perlite expansion plant. Other producers of perlite, all with a capacity of 10,000 tons per year or less, were Izmir Perlite Mining and Industry Ltd., Anadolu Per-Mer Madencilik Sanayii ve Ticaret Ltd. Sti., and Durun Urun. Most of Turkey's production of perlite was used in construction materials and sold on the local market. Turkey hoped to market some of its unexpanded perlite overseas in the near future.

MINERAL FUELS

In 1981, Turkey's energy situation improved considerably, although temporary power interruptions and cutbacks were still necessary in some cases. The country's current installed electric generating capacity was 5,553 megawatts, 3,182 megawatts of which were produced by thermal (oil and coal) powerplants, and 2,351 megawatts by hydroelectric plants. About 35% of the thermal plant electricity was supplied by oil-

fired furnaces, and 65% from coal, mostly lignite. Production of electricity stood at 23 billion kilowatt-hours in 1980 and rose to 25 billion kilowatt-hours in 1981. Turkey's gross electrical energy demand stood at 27.3 billion kilowatt-hours in 1981, which led to the importation from the Soviet Union and Bulgaria of 1.89 billion kilowatt-hours of electricity. About 83.4% of Turkey's domestically produced electrical energy was supplied by the Turkish Electricity Authority (TEK), which was operated by the Government. The remainder was supplied by other domestic organizations.

Turkey's difficulties with imported oil convinced the Government that the best answer to the energy problem was to utilize the country's huge reserves of lignite to produce power. Increasing coal production capacity and building coal-fired thermal powerplants were given top priority by the Government. Of the 21 thermal powerplants that were to be completed by 1986, 1 was to use natural gas, 1 was to use diesel fuel, 1, hard coal, and the remaining 17, lignite. All these projects operating at full capacity were to provide Turkey with another 16.7 billion kilowatt-hours of electricity beyond the current level of 25 billion kilowatt-hours. Many of the planned projects have yet to be initiated, and attaining this production target seemed unlikely given the shaky state of Turkey's finances. Some projects have nearly been completed, however, and significant increases in electricity production did seem likely over the next several years.

Coal.—Turkey possessed significant reserves of both hard coal and lignite. Hard-coal reserves were estimated at 1.26 billion tons, and lignite reserves were estimated at about 7 billion tons. Production of both types increased in 1981, from 3.7 million tons of hard coal in 1980 to 7.6 million tons in 1981, and from 12.7 million tons of lignite in 1980 to over 18 million tons in 1981. TKI was the sole producer of hard coal in the country and produced about 85% of all lignite. Turkey imported about one-third of its coking coal and high-grade coke requirements, however, mostly from the United States. Imports of coking coal have averaged 925,000 tons per year over the past 4 years, costing the Government about $60 million per year. Turkey did not need to import any lignite. TKI, the coal producer, worked closely in conjunction with TEK, which was responsible for setting up thermal power stations in coal mining areas. Ten expansions or new coal-fired power projects were under construction in 1981 by TKI and TEK. Efficiency at most of the operating plants was improved in 1981, which led to an average increase in production for both hard coal and lignite of about 75%.

Hard coal was produced in the Zonguldak region by TKI. Coal has been mined in the region since 1860. The mines were operated by Eregli Komuleri Isletmeri under the authority of TKI. Coal was produced from several mines in the area, including Kandili, Kozlu, Uzulmez, and Gelik. About 2 million tons of the total output of hard coal was allocated for use as coking coal. All of this output was supplied to the Eregli steel plant, whose coking coal charging capacity was 1.5 million tons per year. Coking coal for the other steel plants was imported.

Lignite was produced in several areas in Turkey and concentrated mostly in the eastern and western parts of the country. Up until 1978, between 30% and 50% of the country's lignite production was from private sector companies. In October 1978, the Turkish Government, in an attempt to increase lignite production, nationalized nearly all of the private sector holdings. Contrary to increasing lignite production, annual output declined over 30%, mainly because the Government did not have the human or financial resources to operate the mines. Lignite production fully recovered to its highest level ever in 1981, with output reaching 18 million tons. The private sector's share in lignite production was down to about 15%.

TKI produced most of its lignite from five major lignite mining establishments, most of which were integrated with onsite thermal power stations. Production capacity at these sites alone was expected to reach 100 million tons of lignite per year by 1990. The largest of the lignite mines were located at Seyitomer, Beypazari, Soma, Afsin Elbistan, and Tunebilek, nearly all of which were undergoing some degree of expansion in 1981. Production capacity at Beypazari was to be expanded to 3 million tons per year by 1984, at a cost of $83 million. Capacity was also to be upgraded at Tunebilek to 2.05 million tons per year, at a cost of $24 million, and production from Seyitomer was to reach 2 million tons per year early in 1982, at a cost of almost $20 million. Two large projects were nearing completion late in 1981, both of which were integrated lignite mines and thermal power stations.

The Soma thermal power project (Soma Isiklar), located in far western Turkey, was to be the first of the new generation of power projects in Turkey to come online. After a 4-year delay caused by lack of financing, the first of four units was to begin producing electricity early in 1982. The entire project, once complete in 1985, was to consume over 5 million tons of lignite to produce 660 megawatts of electricity per year. The plant will supply power to the entire northwestern portion of Turkey. Lignite was also to be supplied by a second mine, Soma-Denis, located near the powerplant.

By far the largest and most ambitious of Turkey's new integrated power stations was the TKI Afsin-Elbistan project, where construction was continuing on a 20-million-ton-per-year lignite mine and a 2,400-megawatt thermal powerplant. This plant was to be the largest lignite-fueled powerplant in the world. Cost of the project, being built by Foster-Wheeler Corp., United States, and many other corporations, was estimated at over $3 billion, 60% of which required foreign financing. The first phase of the project was to come onstream late in 1982. The first phase alone was to utilize nearly 60,000 tons per day of lignite and employ about 61,000 people. The second phase involved mining an additional 20 million tons of lignite for use with four other electric generators.

These two projects were only the first on a long list of powerplants and lignite mines scheduled to come into operation before 1995. Other large projects were under construction at Mugla-Yatagan, where 3.5 million tons per year of lignite was to be fed to a thermal power station, and Sivas-Kangal, where 4.2 million tons per year of lignite was to be integrated with another powerplant. Other projects further down the line were to be located at Bursa-Orhaneli, Bursa-Keles, and Tekirdag-Saray.

Petroleum.—Turkey's petroleum situation improved somewhat in 1981, rebounding from near disaster in 1979-80, but the country continued to be plagued by massive balance-of-trade deficits caused by the high level of oil imports. Turkey imported 85 million barrels of crude oil in 1981, valued at $3.46 billion, and $613 million worth of refined oil products, bringing the country's total oil import bill to over $4 billion. The country's receipts from all its exports, on the other hand, were estimated at about $4.5 billion. Imports of petroleum represented almost 50% of the country's total imports in 1981, which were estimated at about $8.8 billion. Turkey imported 84% of its crude oil requirement in 1981, and as domestic crude oil production levels off, the share of imports was expected to increase to accommodate any increase in domestic consumption. Turkey imported almost one-half of its crude oil requirement from Iraq in 1981 through the Kirkuk Yumurtalik (Botas) pipeline. The remaining supply was derived 24% from Libya, 15% from Iran, and 13% from Saudi Arabia. This increased level of imports considerably eased the supply situation for Turkey, where for the previous 2 years, lack of fuel has caused frequent blackouts and power shortages. The recovery of Turkey's economy and the relatively soft conditions on the world oil market contributed to the overall improvement in energy supply, but the country continued to spend nearly all its foreign exchange receipts for oil imports. This situation probably will not improve during the next several years until most of Turkey's energy needs can be supplied by coal and lignite.

Production.—Turkey's domestic production of crude oil reached 16.9 million barrels in 1981, representing a 1.4% increase over the 1980 level, but still well below the 19- to 20-million-barrel level maintained from 1975 to 1979. Turkey's crude oil production has declined steadily since 1969, when it reached an alltime high of about 70,000 barrels per day, to 1980, when it reached an alltime low of 46,000 barrels per day. Combined with the slight increase in production in 1981 was a decrease in consumption, by about 2 million barrels from 1980 to 1981. As Turkey's economy begins to expand, consumption of petroleum was expected to increase fairly steeply, most of which would have to be supplied by imports. Turkey produced about 16% of its crude oil requirement in 1981.

The largest oil-producing company in Turkey was TPAO, which produced about 40% of the country's total output. N.V. Turkes Shell, a subsidiary of Shell Oil of the United States, produced about 30%, and Mobil Exploration Mediterranean Inc., a Mobil Oil Corp. U.S. subsidiary, and Ersan Sanayii both produced about 15% of the country's total. The prospects for TPAO's future appeared mixed in 1981. It was the largest company involved in oil development in the country and had the authority of the Government behind it. It also held

many of the new promising areas for oil exploration and has made several significant discoveries in the past few years. Its problems, however, stem from the age of its producing wells, which averaged well over 10 years old. If TPAO was able to bring new fields online as rapidly as it would like, the company predicted it could be producing about 25,000 barrels per day by the middle of the decade. With TPAO drilling less than 50 production wells in 1981, it seemed likely that production would continue to decrease as its older wells depleted the reservoirs over the next few years.

TPAO was in the process of implementing secondary recovery techniques at its West Raman Oilfield. Turkey's Bati Raman (West Raman) Oilfield, located in southeastern Turkey near the Bay of Iskenderun, was the country's most prolific field, producing about 7,500 barrels per day in 1981. The secondary recovery program involved pumping carbon dioxide into injection wells to boost the production level. An 81-kilometer pipeline was to be built in 1982 to transport carbon dioxide to the field. Reserves at Bati Raman were estimated at 300 million barrels, but only a fraction of this was recoverable because of the heavy weight and generally low quality of Raman oil. With the enhanced recovery program in full operation, TPAO hoped to extract up to 20,000 barrels per day from the field, but this level was unlikely before 1985.

One of the most promising TPAO discoveries in recent years was located in the southern Dincer region, where two production wells had been drilled into a field of unknown size. The first well was capable of producing about 3,400 barrels per day of crude oil, and the second was to achieve a similar flow rate. TPAO planned to drill three additional wells into the structure early in 1982, and it was hoped that output from the Guney Dincer Field would equal that of the Raman Field, and possibly surpass it by 1983.

Realizing that Turkey's oil industry was not expanding to meet the country's needs, the Government took a new approach, as part of its economic reform program of 1980, to encourage foreign participation in the industry. The idea behind the new approach was to make Turkey more attractive for oil exploration by the multinational companies, and thereby attract new technology to boost Turkey's sagging production. New decrees were issued by the Government that removed many of the disincentives of the old petroleum code. Companies were no longer required to sell all their oil production domestically at below market prices and were allowed to export 35% of oil produced from new wells at world market prices and to use receipts from this oil to repatriate capital and profits. Also, areas that had been open only to TPAO for exploration became available for lease to foreign oil companies, in joint-venture arrangements with TPAO. In 1981, over 20 foreign oil companies had discussed exploration in Turkey with TPAO, but most companies were awaiting clarification of the new decrees, including legal guarantees against nationalization and protection against currency devaluation, before beginning work.

Exploration.—The pace of exploration for oil and gas picked up somewhat in 1981, with 31 new petroleum exploration licenses issued during the year, only 7 of which went to TPAO. The majority of these licenses went to private Turkish companies, including Ersan Petroleum Corp. and Comag, the magnesite producer. Comag was to search for oil in Siirt Province under a 3-year license. Thirty-eight exploration licenses were released during the year, and another eight expired. Two hundred and two licenses were carried over by Turkish corporations during the year, and 11 licenses were renewed. Figures were not available for Turkish private sector drilling.

TPAO was the most active company involved in petroleum exploration during the year, drilling an estimated 85 exploration wells, 17 of which encountered hydrocarbons. The most promising discoveries were at Guney Dincer in the TPAO Nusaybin oil exploration field, 20 kilometers from Camurlu, near the Syrian border. TPAO was also focusing attention on the Korkandil region in the Pervari district, mainly around the towns of Baykan and Kozluk. Drilling was to begin on the Korkandil Field, where oil had been discovered several years earlier. Drilling in this area was delayed because of access problems to the field. TPAO was also exploring for oil south of the Adana petroleum region in the Mediterranean and south of the Hafay petroleum region, also in the Mediterranean, both of which were located outside of Turkish territorial waters. Onshore work was also being accelerated in southeastern Anatolia, Trakya, Adana, and the Salt Lake region of central Anatolia. TPAO also began to emphasize its exploration for natural gas reserves. Exploration for and production of

natural gas was to be encouraged for the first time in Turkey's new petroleum code. Significant reserves of natural gas were discovered by TPAO in 1980 at Thrace, where initial production from a single well flowed at 3 million cubic feet per day and has since risen to almost 6 million cubic feet per day with several new wells onstream. Natural gas production was utilized at local cement factories and for electricity production.

There were many foreign oil companies conducting exploration work in Turkey in 1981, including several U.S. companies. Shell, which produces almost one-half of Turkey's oil already, was exploring the Agachan site in the Siverek district of Urfa under two exploration permits. Other U.S. companies operating in Turkey were Phillips 66, Occidential Petroleum, Sunmark of California, and Union Texas Co. Union Texas picked up eight exploration licenses in 1981, covering about 1 million acres in Mardin, Urfa, Hakari, and Siirt Provinces. All the licenses carried 3-year terms. Other foreign companies exploring for oil in Turkey were Veba, of the Deminex group (Federal Republic of Germany), CFP-Total (France), Azienda Generali Italiani Petroli S.p.A. (AGIP) (Italy), and Salem Energy (Sweden). AGIP bought a 51% interest in Salem's production and exploration contract, offshore in Turkey's Iskenderun Bay. AGIP became operator of the concession and began drilling with the Saipem II drillship. Results of the drilling were unavailable by yearend 1981. Iskenderun Bay was considered one of the more promising areas for oil exploration in Turkey.

Refining.—Turkey's four operating oil refineries produced more than the country's requirements for gasoline and light distillates but fell short of domestic needs for diesel oil, fuel oil, and other middle and heavy distillate products. About 2 million barrels of naphtha, gasoline, kerosine, and jet fuel were exported in 1981, while about 20 million barrels of diesel oil and fuel oil had to be imported.

All four of Turkey's oil refineries were owned by the Government petroleum organization TPAO. Total crude oil throughput capacity at all the refineries was estimated at about 120 million barrels per year, but actual throughput of all four refineries was placed at 100.2 million barrels in 1981, which represents a substantial improvement over that of 1980, when refinery capacity utilization was about 75% compared with 83% in 1981. Most of the improvement resulted from a return to near full capacity of the TPAO Anadolu Tasfiyehanesi AS refinery. The plant, originally owned by Mobil Oil Corp. (United States), Royal Dutch/Shell (Netherlands), British Petroleum, and Marmara Refining, was nationalized in 1979 because it was operating below capacity. TPAO was unable to improve matters, however, and devised an agreement allowing Mobil to continue operating the refinery while using oil supplied by TPAO. Capacity at the ATAS refinery was estimated at about 90,000 barrels per day of crude oil input. TPAO also owned the Turkish Petroleum Corp.'s two refineries at Batman and Aliaga. Throughput capacity of the Batman refinery was 21,000 barrels per day, and the Aliaga facility was capable of processing 75,000 barrels per day of crude oil.

The fourth TPAO refinery was operated by Istanbul Petrol Rafinerisi Anomin Sirketi (IPRAS). The refinery, Turkey's largest, was nearing completion of an expansion project designed to raise throughput capacity from 170,000 to about 270,000 barrels per day. Although IPRAS was owned 99% by TPAO, it was given authority to operate autonomously from the state. IPRAS, in addition to operating the most efficient refinery in the country, did most of the spot market purchasing of crude oil for Turkey, imported and processed all the country's liquefied petroleum gas, and helped negotiate its long-term supply contracts.

Pipelines.—The maintenance and operation of the Iraq-Turkey pipeline took on strategic importance in 1981. Turkey received about 40% of its domestic oil requirement from Iraq through the Botas pipeline. For Iraq, the pipeline was of equal importance, it being the only operable means of exporting crude oil. Capacity of the pipeline was about 200 million barrels per year in 1981, but only about 42 million barrels of that was supplied to Turkey. The remainder was exported from the seaport of Iskenderun. Iraq was interested in increasing the flow through the pipeline to about 700,000 barrels per day to increase the country's export revenues. Further down the line was a plan to increase the capacity of the line to 1 million barrels per day through the addition of several new pumping stations. The pipeline operated fairly continuously during the year despite several instances of breakdowns and sabotage.

Turkey was also involved in negotiations

with Iran regarding the purchase of oil and the possible construction of pipeline facilities. Turkey planned to increase its purchases of Iranian oil from about 10 million barrels in 1981 to about 30 million barrels in 1982. The two countries also signed a preliminary agreement to deliver Iranian natural gas to Europe via a pipeline through Turkey. Also planned was a pipeline from northwest Iran to Turkish ports around Iskenderun. This gradual increase in supply from Iran and Iraq was a major factor in easing Turkey's petroleum situation in 1981. In light of the current glut in the world oil market, Turkey was taking advantage of both countries' growing need for export revenues and renegotiating its contracts whenever possible. Payment for oil to both countries was with goods and services as well as with foreign currency.

The Mineral Industry of the U.S.S.R.[1]

By Richard M. Levine[2]

Reported production in the ferrous metals sector either grew slowly or declined. In 1981, production of raw steel, finished rolled output, and steel pipe was less than planned, and iron ore production fell below its 1980 level. Crude oil production, including gas condensate, rose 0.9% to 4.48 billion barrels, falling slightly short of the planned target. Natural gas production rose 7% to 16.4 trillion cubic feet, compared with a planned 16.2 trillion cubic feet. Production of coal, which was to be substituted increasingly for oil as a fuel in 1981, not only fell below the planned target but declined 2%. Better results were obtained in 1981 in the production of electric energy and cement, which rose 2% each.

In 1981, production of the Ministry of Nonferrous Metallurgy increased 0.3%, which was slightly below the planned target, but labor productivity decreased 0.4% in comparison with the 1980 level. For the year, the Ministry of Ferrous Metallurgy production increased 0.5%, which was 3% below the planned target, and labor productivity dropped by 0.4%.

Indexes of several important economic indicators either failed to increase as planned or declined. According to official Soviet statistics, in 1981, national income rose 3.2%, compared with a 3.8% growth in 1980; growth did not attain the 1981 planned target of 3.4%, which was the lowest in the last decade. Industrial output rose 3.4% in 1981; this was lower than both the planned growth of 4.1% and the 1980 industrial production growth rate of 3.6%. Growth in industrial labor productivity, an important factor in achieving economic growth with the current labor shortage, rose only 2.7% compared with a planned 3.6%.

Occupying one-sixth of the world's land surface, the U.S.S.R. has large reserves and resources of many minerals and in 1981 was a significant factor in world mineral trade. The U.S.S.R. was the world's leading producer of asbestos, cement, manganese ore, petroleum, platinum-group metals, potassium salts, and steel. It occupied second place in the world, following the United States, in the production of aluminum, coal, lead, natural gas, and phosphate rock; ranked second after Canada in the production of nickel; and second after the Republic of South Africa in gold and chrome ore output.

Table 1.—U.S.S.R.: Soviet reported industrial production

(Million tons unless otherwise specified)

Commodity	1980		1981		Production change, percent	1982 planned
	Planned[1]	Reported	Planned	Reported		
Iron ore	276	245	NA	242	99.1	NA

[1]1980 planned figures, with the exception of iron ore, are the revised goals because targets for many commodities were decreased.

Government Policies and Programs.—In 1981, major emphasis was placed on the efficient use and conservation of fuel and raw materials. Savings in raw materials were considered possible at all stages of the production process. For example, in mining, up to the following amounts of raw materials were left in deposits: coal, 30% to 40% of resources; natural gas, 50%; petroleum, 70%; and iron ore, 20%.[3] At the same time, many useful ore constituents were not being recovered including antimony, bismuth, gold, tungsten, silver, and zinc.[4]

A substantial opportunity for savings existed in reducing losses of raw materials in the production, transportation, and storage processes. Reportedly, if the metal losses in metalworking were reduced by one-half, this would be equivalent to increasing the production of finished rolled metals by 10%. In nonmetallics, particularly big losses occurred at all stages of production, transport, and application of mineral fertilizer.[5]

Owing to a shift in the last two decades of mineral production to more remote areas in the east and north and to declining ore grades, the cost of mineral production rose considerably. According to Soviet calculations, the capital-output ratio for mining would increase 150% from 1965 to 1985.[6] Savings in mineral and energy resources were considered important owing both to rising domestic production costs and increased prices on the world market. In the 11th 5-year plan (1981-85), the following goals were set for reducing consumption of materials: rolled ferrous metals, 18% to 20%; steel pipes, 10% to 12%; and nonferrous metals, 9% to 11%.

Production of finished rolled steel declined from its 1978 peak, but there was growth in the output of machine building and metalworking. This created a shortage and led to an attempt to lower metal consumption. Much room for economy in the use of steel existed. Machinery and equipment were generally heavier than their Western counterparts, and their production required more fuel and energy. Furthermore, the machinery produced was not energy efficient, which led to energy losses in other economic sectors.[7]

Waste in machine building and metalworking, along with other sectors, was stimulated by the Soviet practice of measuring production in terms of the weight of output. This led to production goals being met by building heavy machinery and equipment.[8] In mining, it led to the production of low-grade ores, and in metallurgy, to the production of lower quality products.

When production was measured in ruble[9] value of output instead of tons, enterprises tended to use more expensive raw materials to increase the value of output. The introduction of the net production indicator was an attempt to eliminate this incentive by excluding from the value of output expenditures for materials and energy purchased outside the enterprise. This reform was being introduced slowly into the Ministries of Ferrous and Nonferrous Metallurgy.[10]

Increased effort was to be made to utilize and recover secondary materials. In 1981, secondary materials accounted for one-third of steel and one-fifth of nonferrous metal production. Efforts, however, to economize by using secondary materials often resulted in waste. Quotas for recycling metal were met at times by scrapping good metal and

machinery.[11]

Gas and coal were to be substituted for oil as a fuel wherever possible, and nuclear power was to be rapidly developed. In 1981, however, expansion of the nuclear power industry was not occurring as rapidly as planned.[12]

As of January 1, 1982, new wholesale prices went into effect for Soviet raw materials. The new prices were intended to fully account for the cost of raw materials and to use the profit motive to stimulate the production of priority resources and to economize on the use of resources. This was the first revision of wholesale prices since 1967. Prior to the price reform, many resources were being extracted at a loss; i.e., the extraction was subsidized.[13] Also, the number of extracted raw material components for which an enterprise would be paid was expanded to increase recovery of products. For industrial consumers, wholesale prices were set to encourage appropriate substitution. For example, prices of gas were set at an average 20% lower than those for fuel oil.

Mineral Industry Labor.—The low rate of overall growth in the Soviet industrial labor force in the 1980's, estimated at 0.7% annually, posed a serious constraint to economic growth, including mineral development. Growth in the labor force varied considerably in the different ethnic regions. Many major new mineral production areas were in the already labor-deficient regions of Siberia and the Soviet Far East, and there had not been an adequate migration of workers to these areas despite numerous wage and benefit incentives. The Soviets at times had to rely on a costly program of flying in shifts of workers for limited periods to provide labor at some mineral development sites. It was reported in the Soviet press that in West Siberia, the main source of oil and gas, 60,000 exploration workers were employed.[14]

The coal mining industry made greater use of wage incentives to attract and retain workers. In 1981, a wage increase was announced in the coal mining industry. Although miners' pay and working hours were better than the Soviet average, there were frequent complaints about having to work on free days. In addition, full-time operation hindered necessary maintenance work.

Increased use of Council of Mutual Economic Assistance (CMEA)[15] labor was being considered for mineral development, but the CMEA countries had their own labor problems and would probably not be able to supply labor in adequate measure. Owing to the problem in labor supply, the Soviets needed to increase labor productivity, which could be partially accomplished by importing state-of-the-art equipment from Western countries. The major means of acquiring hard currency to pay for this equipment was by sales of minerals to Western countries, particularly oil and gold. Sales of gas to Western Europe from the trans-Siberian pipeline, scheduled to commence in the mid-1980's, could compensate for loss of revenues from lagging oil production. The Soviets could further use the foreign exchange earned from gas sales to buy high-technology equipment to increase oil production.

Mineral Industry Technology.—Declining ore quality further increased the need for mechanization and high-technology equipment. During the 1980's, the metal content was calculated to decrease 10% to 15% in the majority of nonferrous ores and 12% to 15% in iron ores.[16] Over 60% of nonferrous metal ore was mined in open pits.

Soviet industry experienced many difficulties in supplying the mining and metallurgical sector. The Soviets had been able, at times, to develop good experimental models of needed equipment but then were either unable to introduce these items into production or produce them in quantity. No satisfactory base model for a heavy-duty bulldozer could be developed. Production of 110- to 180-ton dump trucks lagged; production of 75-ton dump trucks was insufficient, and the trucks were technologically behind foreign models.[17] In 1980, capacity of dump trucks used in nonferrous open pit mining averaged 33.8 tons, and there had been inadequate growth in dump truck capacity.[18] Production of shovels with a 12.5- to 20-cubic-meter capacity was also insufficient, and there was an inadequate supply of drilling machinery, particularly in northern areas.[19] Also lacking were small-scale mechanized devices for underground work. Lack of this equipment was blamed for declining production in the coal industry.[20]

A continued effort to improve the quantity and quality of equipment was planned for 1981-85. The production of large-diameter, multilayered steel pipeline, which was being imported from Western countries, was to receive special attention.

A major concern for mining in remote areas was the electricity supply. Also, owing to increased mining in remote areas, there

was a need for improving the quantity and quality of locomotives and freight cars, particularly specialized rolling stock for mineral transport.[21]

The Plan for 1982.—The plan called for a 3% growth of national income in 1982, which was lower than the attained growth of 3.2% in 1981. The 1982 growth-rate target for industrial production was 4.7%, which was higher than the unattained target of 4.1% in 1981, when growth was 3.4%. Capital investment in 1982 was to grow 3% as it did in 1981. The 1981 plan called for a 5% growth. Investment was to be directed toward intensive structural improvements. For example, while electric energy output was to increase only 2.6%, the growth in nuclear electric power was to increase 24%.

Investment in iron and steel was to be directed toward developing "progressive and economical" metal products. This was in keeping with the goals of the 11th 5-year plan to produce more cold-rolled sheet, improved alloys, and special steel pipes and to develop power metallurgy, oxygen converter and electric steel production, and continuous casting. The poorest performance in steel production in the past was registered in improving the assortment and quality of output. Although the steel industry had in past years fallen short by 10% to 15% in achieving investment goals, it had fallen short by 40% to 50% in achieving investment goals for diversification and improving quality.[22]

In production of nonferrous metals, emphasis was to be placed on expanding the ore base, modernization and expansion of existing enterprises, and improving extraction and processing techniques. During 1981-85, aluminum output was to increase 15% to 20%; copper production, 20% to 25%; and nickel and cobalt production, at least 30%. Increases were planned in the production of lead, magnesium, molybdenum concentrates, precious metals, tungsten, columbium (niobium), and other alloying elements.

Exploration.—In 1981, the volume of geological work accomplished for the Soviet Ministry of Geology increased 6.6% compared with that of 1980. The volume of deep drilling increased 5.2% including a 13% increase in Tyumen' Oblast'. However, growth in the volume of deep drilling was lower than planned, and deep-drilling goals for oil and gas were not met. This failure was attributed to serious organizational and planning deficiencies that resulted in insufficient equipment being supplied for winter work, particularly for the R.S.F.S.R., including Tyumen' Oblast'. The complaint was raised that inadequate technological support for geological work led to an increase in accidents.[23]

The Ministry of Geology called for an intensified search for bauxite, copper, lead, tin, and zinc and also called for a greatly intensified search for oil and gas, not only in Siberia but also in Soviet Central Asia. The intended growth in coal use necessitated increasing coal reserves in Siberia, the Soviet Far East, and Kazakhstan. Owing to fertilizer shortages, emphasis was being given to increasing reserves of phosphates and potash.

A sharp increase was called for in the volume of geological survey work, but the complaint was also raised that many major reserves waited a long time for development. Also, after development, substantial losses occurred in enrichment and processing of ores while many potential byproducts were not recovered.[24]

In the coming years, exploration was to be carried out by deep drilling and seismic sounding, particularly in the search for oil and gas deposits. The Soviets claimed to have drilled the world's deepest borehole to a depth of 10.8 kilometers in the Kola Peninsula. Despite the emphasis on deep drilling, there was little incentive for it because quota fulfillment was based on the number of meters drilled, regardless of the depth.

PRODUCTION

A Soviet decree of April 1956 classified as secret statistics on output, enterprise capacity, and production plans in physical units of output of nonferrous, precious, and rare metals and some nonmetallics. Soviet trade data on precious metals had not been available for decades, and in 1976, the Soviets stopped publishing trade statistics for nonferrous metals. Production and trade data were available for ferrous metals and some nonmetallics.

Some information was available on most mineral commodities and could be used in determining the relative size or growth of the mineral industry. However, Soviet information had to be carefully qualified. Comparisons with Western countries were difficult because Soviet statistics showed minerals produced rather than usefully consumed.

Table 2.—U.S.S.R.: Estimated[1] production of mineral commodities[2]

(Thousand metric tons unless otherwise specified)

Commodity	1977	1978	1979	1980	1981[p]

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Unless otherwise specified.

[2]Includes data available through Oct. 13, 1982.

[3]Reported in Soviet sources.

[4]Reported in United Nations sources.

[5]Estimate based on total of spiegeleisen and blast-furnace ferromanganese reported by United Nations sources.

[6]Data do not add to total shown because of independent rounding.

[7]Run-of-mine coal. The average ash content of coal shipped from mines was 20.2%, and the average calorific value was slightly more than 5,000 kilocalories per kilogram (9,000 British thermal units per pound in 1977).

[8]Not distributed by type and, therefore, not suitable for conversion to volumetric units. Data include all energy products and some nonenergy products as well as refinery fuel and exclude petrochemical feedstocks, paraffin, petroleum coke, white spirit, unspecified minor nonenergy products, and refinery losses.

TRADE

The Soviet Ministry of Foreign Trade administered all foreign trade through more than 70 foreign trade organizations. Laws of comparative advantage played less of a role in foreign trade than did Government objectives. Two major Soviet objectives were to integrate the economies of Eastern Europe with the Soviet economy and to earn sufficient hard currency to purchase essential commodities, such as grain and advanced technology and equipment.

Mineral exports were used to meet both objectives. The Soviet Union was the chief supplier of fuel and other raw materials to the CMEA states, and mineral exports were the chief source of hard currency earnings. The U.S.S.R. provided the great majority of CMEA imports of oil, gas, iron ore, pig iron, rolled ferrous metals, nonferrous metals, phosphate fertilizers, etc. The CMEA states did not pay for these imports with hard currency but rather supplied the Soviet Union with manufactured goods that were often of a higher quality than those produced domestically.

Over four-fifths of all Soviet hard-currency export earnings came from raw materials, and over one-half of the hard-currency earnings came from oil. Other significant hard-currency-earning mineral exports included chrome ore, diamonds, gold, natural gas, nickel, platinum-group metals, uranium compounds, and others. With the completion of the trans-Siberian pipeline to Western Europe in the mid-1980's, gas sales could compensate for loss of revenues from declining oil sales.

The Soviets attempted to meet their hard-currency earning goals by selling a combination of the least amount of minerals at the highest prices; many commodities exported were not actually surpluses and could easily have been consumed in the domestic economy. During periods of increased economic need, to gain entry into a market, or for political purposes, the Soviets were willing to sell in a depressed market or below the world market price.

Although a large mineral exporter, the Soviet Union was also a mineral importer. Approximately 11% of Soviet imports were minerals. For some commodities such as tin, bauxite, fluorite, and high-quality steel products, the Soviet Union did not produce enough to meet its domestic needs. For other commodities, Soviet mineral imports served to supply regions far from Soviet sources of supply, to overcome temporary supply breakdowns, or as a political gesture to help friendly countries.

In 1981, Soviet foreign trade turnover (exports plus imports) increased 17% compared with the 1980 figures. For 1981, Soviet trade turnover with developed market economy countries increased 12%; with CMEA countries, 14%; and with the developing countries, 37.5%.

Regarding major mineral exports, in 1981, Soviet oil deliveries to many Western European countries decreased. Estimated oil deliveries to the CMEA states, about 590 million barrels, were near the 1980 level. Estimated Soviet gold sales of 250 tons in 1981 approximately tripled compared with that of 1980. There was a large increase in Soviet selling in late 1981 despite the fact that the price of gold had fallen. Along with the need to buy grain owing to another poor harvest, it was speculated that these sales could have been made in part to prop up the Polish economy. The Soviet Union traditionally marketed gold in Zurich and in 1981 resumed making deliveries to London. Soviet titanium exports to the Western World continued in 1981 after speculation that the Soviet Union was going to cease exporting titanium. The Soviet Union also supplied Western European countries with enriched uranium.

Increased trade with Western Europe in 1981 was especially pronounced in the case of Finland, which became the Soviet Union's second largest market economy trading partner. The U.S.S.R. supplied Finland with crude oil, petroleum products, natural gas, nuclear fuel, coal, coke, and electricity and obtained ships and marine equipment, machinery, cables, other steel products, etc. In 1981, Finland was negotiating for the construction of a joint Soviet-Finnish nuclear powerplant to be built in Finland. The Soviets had already assisted Finland in constructing two nuclear powerplants with a capacity of 440 megawatts each.

The Federal Republic of Germany remained the Soviet Union's principal Western World trading partner. Construction of the trans-Siberian pipeline and the subsequent gas deliveries were to greatly increase the volume of Soviet-West German trade. It was foreseen that when the pipeline came onstream, it would provide a minimum of 30% of the West German natural gas requirements.

Upon completion of the pipeline, France also would be importing a sizable amount of its natural gas from the Soviet Union. Other Western European countries that were committed or were negotiating to receive gas from the pipeline included Austria, Belgium, Italy, the Netherlands, Spain, and Switzerland. The trans-Siberian pipeline was to supply Western Europe annually with 1.1 to 1.4 trillion cubic feet of natural gas.

The Federal Republic of Germany, France, and Italy were to be major suppliers of pipeline equipment, along with other Western European countries. Japan also was to be a major equipment supplier. The assistance of Western countries in the pipeline construction was considered an important factor in enabling the Soviets to meet their timetable for gas sales to Western Europe.

Trade turnover between the United States and the Soviet Union increased in 1981, with a large trade balance in favor of the United States. Corn and wheat dominated U.S. exports, and the Soviets also purchased some equipment for use on the trans-Siberian pipeline. Principal Soviet exports to the United States were mineral commodities including ammonia, chrome ore, gold, heavy and light fuel oils, naphtha, nickel, platinum-group metals, secondary aluminum, and titanium. In 1981, the United States increased exports of molybdenum concentrates to the U.S.S.R. and began exporting copper concentrate.

Table 3.—U.S.S.R.: Exports to the United States

(Million dollars)

Commodity	1980	1981
Light fuel oil, testing 25° A.P.I. or more, Saybolt Universal viscosity at 100° F of less than 45 seconds	--	80.7
Anhydrous ammonia	94.8	78.4
Nickel, unwrought	20.7	37.8
Palladium	54.6	31.1
Gold bullion, refined	85.7	21.4
Naphthas derived from petroleum, etc., n.e.s	5.0	16.6
Uranium compounds, fluorides	34.6	11.3
Heavy fuel oil, testing 25° A.P.I. or more, Saybolt viscosity at 100° F of more than 125 seconds	--	9.5
Platinum-group metals and combinations, n.e.s	5.5	6.4
Platinum sponge	4.6	4.6
Rhodium	6.3	3.5
Aluminum waste and scrap	--	3.0
Palladium bars and plates	11.7	2.8
Chrome ore:		
46% or more chromic oxide	1.7	2.8
Not over 40% chromic oxide	3.8	2.5
Titanium sponge, unwrought	2.7	1.7
Platinum bars, plates, etc	7.0	[1].6

[1]Reported figure for January-June 1981.

In 1981, sanctions previously imposed by the U.S. Government because of the Soviet invasion of Afghanistan were lifted, allowing Occidental Petroleum Corp. to continue shipments of superphosphoric acid to the Soviet Union in exchange for ammonia. At the end of 1981, the United States imposed trade sanctions against the Soviet Union in reprisal for the imposition of martial law in Poland. The sanctions affected, among others, U.S. companies supplying equipment or technology directly or indirectly for use on the trans-Siberian pipeline.

Regarding trade with Asia, Japan was the Soviet's fifth largest market economy trading partner. According to a 1981-85 trade agreement, Japanese exports to the Soviet Union were to include rolled ferrous products, tinplate, steel pipe, cable goods, other steel products, etc., while Japanese imports were to include aluminum (secondary), asbestos, chrome ore, ferroalloys, graphite, magnesium, nickel, crude oil and petroleum products, palladium, petroleum coke, pig iron, platinum, rare earths and metals, steel scrap, titanium sponge, and zinc.

In 1981, Japan agreed to a further $38.7 million loan for the development of the Neryunga coking coal complex in South Yakutia. Original loans of $450 million in 1974 to buy Japanese machinery and equipment were made with the goal of enabling the U.S.S.R. to supply 84.4 million tons of coking coal to Japan over a 16-year period, beginning with a 3.2-million-ton shipment in 1983. Owing to delays in development, deliveries might not begin on schedule.

In 1981, the Soviet Union signed a 20-year agreement with the Japanese firm Sakhalin Oil Development Corp. (SADECO) to build a $95 million plant for liquefying natural gas, and SADECO contracted to import 3 million tons of liquefied natural gas annually. Construction of the plant was scheduled to begin in 1982, but deliveries were not considered likely to begin until 1986. The U.S.S.R. was cooperating with Japan in offshore oil development off Sakhalin Island in the Sea of Okhotsk. Production from offshore wells had not yet begun.

The U.S.S.R. was replacing the United States as India's largest trading partner. In 1981, the U.S.S.R. entered into agreements to help India develop oil, coal, steel, and alumina facilities. In 1981, India was to import crude oil supplied in transfer arrangements by the U.S.S.R. from Persian Gulf sources and refined products from the U.S.S.R. A trade agreement for 1981-85 provided for India to import asbestos, fertilizers, nickel, refractories, rolled steel prod-

ucts, sulfur, and zinc. The U.S.S.R. met most of its demand for strategic-grade mica from imports from India and, according to the 1981-85 trade agreement, was also to import alumina, barite, and pig iron.

In 1981, the U.S.S.R. declared a willingness to help Pakistan develop nuclear and thermal power and to aid in oil exploration. However, the tension between Pakistan and the U.S.S.R. over the invasion of Afghanistan may have made this offer difficult to accept.

In other parts of Asia, the U.S.S.R. was the major supplier of oil to Vietnam and Kampuchea, and a portion of Soviet deliveries to Vietnam were reportedly diverted to Laos. However, consumption of oil in these Asian countries had dropped sharply since the early 1970's. In 1981, the Soviet Union and Vietnam signed a contract setting up a joint enterprise for cooperative oil and gas development on Vietnam's southern coastal shelf. No mention was made of exploration in the disputed northern waters of the Tonkin Gulf adjacent to an area in which China recently made oil and gas strikes. In addition, the Soviet Union assisted Vietnam and Laos in tin development, presumably in exchange for tin.

In Mongolia, a joint Soviet-Mongolian enterprise, Mongolsovtsvetmet, handled 92% of the output of Mongolia's mining industry. Along with copper and molybdenum, the U.S.S.R. assisted Mongolia in the development of coal, fluorite, gold, and phosphate reserves.

In the Mideast, in 1981, the Soviet Union increased its deliveries to Iran of steel and fertilizers. Soviet imports from Iran included 2.2 million tons of oil and lead-zinc and copper ores. The Soviet Union had assisted Iraq in the development of oilfields and in 1981 was assisting Iraq in maintaining oil production.

In Africa, the majority of Soviet trade was with North African countries; Libya, Algeria, Egypt, and Morocco were the leading Soviet trade partners. Angola, Mozambique, Ghana, Guinea, Nigeria, and Ethiopia were the leading trade partners in the rest of Africa. Soviet exports to Africa consisted mainly of manufactured goods, including armaments. Soviet imports were primarily agricultural products, fuels, and raw materials, including bauxite from Guinea, ores and concentrates from the Congo, nonferrous metal concentrates from Mozambique, pig iron from Algeria, fuel from Libya and Mali, and superphosphate from Morocco.

In 1981, in South America, the Soviet Union signed a contract with Brazil to purchase bauxite for its Nikolayev alumina plant on the Black Sea. The U.S.S.R. also agreed to supply Brazil with 20,000 barrels of oil per day for 5 months at a price of $35 per barrel. This agreement was to be renegotiated before the end of 1981. Soviet oil shipments represented approximately 3% of Brazil's oil imports. The Soviets were also providing technology to Brazil for a coal gasification process.

The U.S.S.R. was an important trade partner for Cuba, a Caribbean member of CMEA. Cuba was providing the U.S.S.R. with nickel and cobalt concentrates, and the U.S.S.R. was participating in their development in Cuba. In 1980, petroleum and petroleum products accounted for over 25% of Soviet exports to Cuba. Other exports included rolled steel, nonferrous metals, and fertilizers.

In 1981, the U.S.S.R. agreed to assist Cuba in the construction of a nuclear powerplant. The Soviets had been involved in aiding Cuba in nuclear research since 1967, when an agreement was concluded for installing an experimental nuclear reactor in Cuba. The Soviets had been further instrumental in establishing nuclear research centers in Cuba.

Trade with the CMEA countries comprised almost one-half of total Soviet trade turnover and was particularly important in the mineral area. Other centrally planned economy countries with which the U.S.S.R. conducted trade in mineral products included China and North Korea. In 1981, the U.S.S.R. increased its exports of pig iron, rolled steel products, and steel pipes to the centrally planned economy countries.

The German Democratic Republic was the Soviet Union's largest trade partner, and raw materials made up a large portion of exports to that country. According to a 1981-85 trade agreement, the German Democratic Republic was to import annually from the Soviet Union 140 million barrels of petroleum, 230 billion cubic feet of natural gas, 1.7 million tons of iron ore (iron content), 960,000 tons of pig iron, 130,000 tons of aluminum, 42,300 tons of copper, 1.3 million tons of coke, and 4.2 million tons of hard coal. The German Democratic Republic imported a number of other minerals from the Soviet Union such as zinc, lead, and magnesium, but figures were not reported. These planned imports from the Soviet Union during 1981-85 were to be essentially the same as the 1980 import

figures. Nevertheless, indications were that oil shipments in 1981 fell below their 1980 level of 140 million barrels.[25]

Despite shortfalls in Polish shipments, Soviet reciprocal deliveries of raw materials to Poland in 1981 remained at approximately the 1980 level. The Soviet Union supplied approximately 40% of Poland's raw material needs, including 100% of the natural gas and 75% of crude oil and iron ore. Soviet deliveries to Poland in 1981 included 96 million barrels of crude oil, 22 million barrels of petroleum products, 190 billion cubic feet of natural gas, 9 million tons of iron ore (iron content), 69,000 tons of asbestos, and 53,000 tons of aluminum. Poland, however, reduced its coal exports to the U.S.S.R. from 9.5 million tons in 1980 to 5.5 million tons in 1981. Polish sulfur exports to the U.S.S.R. reportedly increased in 1981.

Although Hungary conducted the majority of its trade with market economy countries, it was dependent on the Soviet Union for the majority of its raw material imports. Hungary imported approximately 70% of its crude oil, 40% of its natural gas, and a large percentage of its ore and metal requirements from the Soviet Union. In 1981, Hungary, as part of a continuing exchange, was to export 330,000 tons of alumina to the Soviet Union and to receive 165,000 tons of aluminum in return. Indications were that a certain amount of this aluminum was held back as a smelting fee.

Romania was the only CMEA country that did not rely on the Soviet Union for the majority of its imported raw materials; Romania also reportedly paid for Soviet oil imports in hard currency at world market prices. Soviet crude oil exports to Romania in 1981 were projected to remain at their 1980 level of 11 million barrels. The Soviet Union supplied approximately 45% of Romania's imported iron ore and 20% of its imported phosphate along with pig iron, rolled ferrous and nonferrous metals, and ferroalloys. When more complete Soviet trade data were last published in 1975, the Soviet Union was reportedly supplying Romania with asbestos, apatite, copper, and aluminum. According to a 1981-85 trade agreement, the Soviet Union was to supply Romania with apatite, asbestos, coke, coking coal, ferroalloys, iron ore, natural gas, pig iron, rolled ferrous and nonferrous metals, steel, etc. In 1981, Romania's imports of coke, coking coal, copper, and iron ore from within CMEA were expected to fall below their 1980 level.

Czechoslovakia imported almost 70% of its fuel and raw materials from CMEA countries, particularly the U.S.S.R. In 1981, Czechoslovakia was scheduled to receive from the U.S.S.R. 130 million barrels of crude oil, 307 billion cubic feet of natural gas, 8 million tons of iron ore (iron content), and 1 million tons of pig iron, along with chrome ore, manganese ore, ferrous and nonferrous metals, ferroalloys, etc. In 1981, Czechoslovakia was to export to the U.S.S.R. 300,000 tons of steel pipe, of which 120,000 tons was for use in the oil and gas industries.

The U.S.S.R. and Bulgaria also signed a trade agreement for 1981-85. The value of trade for this period was to equal 40 billion rubles. During 1976-80, the Soviet-Bulgarian value of trade was 28 billion rubles. During 1981-85, the Soviet Union was to supply Bulgaria with energy and raw materials including coal, crude oil and oil products, electric energy, iron ore, ferrous and nonferrous metals, natural gas, etc.

The Soviet Union was engaged in a number of assistance and cooperative programs with the CMEA countries. All of the East European full CMEA member countries and Cuba were developing nuclear power programs, and all except Romania were doing so with Soviet assistance. The U.S.S.R. supplied nuclear fuels to the CMEA countries and reprocessed the spent fuels. Furthermore, a number of CMEA countries were participating in nuclear development projects within the Soviet Union for which they were to receive energy in return.

The CMEA countries were also cooperating in other mineral development ventures. These included Petrobaltic, an offshore drilling consortium including the U.S.S.R., Poland, and the German Democratic Republic, organized for drilling in Baltic waters and the Kiembay asbestos complex in Orenburg Oblast', U.S.S.R., with a projected capacity of 500,000 tons per year, which was being built with a one-third investment of the CMEA countries in return for one-third of the output.

Table 4.—U.S.S.R.: Estimated production, trade, and consumption of mineral commodities in the U.S.S.R. in 1981

(Thousand metric tons unless otherwise specified)

Commodity	Production	Imports	Exports	Apparent consumption
METALS				
Aluminum:				
Bauxite	4,600	3,700	(1)	8,300

Ore and concentrate	485	NA	--	NA.
Oxides	22	20	--	Italy 18; United Kingdom 2.
Metal including alloys, all forms	4,678	2,770	1,475	West Germany 808; Italy 193; France 164.
Tungsten: Ore and concentrate	25	NA	--	NA.
Zinc:				
Ore and concentrate	--	83	--	All to West Germany.
Oxides	44	8	--	All to Saudi Arabia.
Metal including alloys:				
Blue powder	20	NA	--	NA.
Unwrought	29,894	24,875	--	Czechoslovakia 20,000; India 2,383;[5] Poland 2,164.
Semimanufactures	r90	NA	--	NA.
Other:				
Ores and concentrates	18,178	1,292	--	All to Hungary.
Ash and residues, nonferrous	r66,875	67,341	--	Austria 66,351; Japan 846.
Oxides and hydroxides	65,188	100,648	55	United Kingdom 99,635; Japan 421.
Metalloids	r2,646	2,425	1	Japan 1,990; Switzerland 218; West Germany 163.
Alkali, alkaline-earth, rare-earth metals	--	34	4	Netherlands 20; Italy 5; United Kingdom 3.
Base metals including alloys, all forms	r20,898	21,110	--	Czechoslovakia 19,000; Poland 1,628; Austria 394.
NONMETALS				
Abrasives:				
Natural: Pumice, emery, corundum, etc	r1,169	NA	--	NA.
Artificial: Corundum	1,707	1,299	--	West Germany 988; Hungary 311.
Dust and powder of precious and semiprecious stones value, thousands	r$2,122	$1,674	$205	Belgium-Luxembourg $659; Italy $340; Yugoslavia $233.
Grinding and polishing wheels and stones	r31	e13	--	Yugoslavia 8; Turkey 4.
Asbestos, crude	r234,146	315,780	--	Poland 66,898; Japan 41,703; Hungary 41,639.
Barite and witherite	294	120	--	All to Yugoslavia.
Boron materials:				
Crude, natural borates	3,215	2,778	--	All to Japan.
Oxide and acid	r12,760	r15,355	641	Japan 1,944; Hungary 1,064;[2] Italy 884.
Cement[2] thousand tons	3,084	3,245	--	Saudi Arabia 905; Hungary 505; Czechoslovakia 387.
Chalk	r196	87	--	All to Finland.
Clays and clay products:				
Crude:				
Chamotte earth	49,367	26,095	--	Poland 26,092.
Fire clay	8,297	9,239	--	Poland 8,231; Hungary 1,008.
Kaolin	38,905	32,769	--	Yugoslavia 17,112; Poland 13,210; Austria 2,402.
Unspecified	4,272	79	--	Finland 30; Algeria 26; Denmark 21.

See footnotes at end of table.

Table 6.—U.S.S.R.: Apparent exports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980[p]	Destinations, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Clays and clay products —Continued				
Products:				
Refractory[2]	129,812	120,255	--	Cuba 27,395; Romania 21,999; Bulgaria 19,436.
Nonrefractory	[r]7,800	20,687	--	Finland 20,610.
Diamond:				
Gem, not set or strung value, thousands	$314,731	$1,305,714	$3,668	United Kingdom $848,218; Belgium-Luxembourg $325,241; Japan $41,982.
Industrial do	$291	$253	--	Belgium-Luxembourg $233; United Kingdom $20.
Diatomite and other infusorial earth	114	NA	--	NA.
Fertilizer materials:				
Crude:				
Phosphatic thousand tons	3,980	3,780	--	East Germany 1,167; Poland 741; Hungary 478.
Potassic	6,014	1,077	--	All to Hungary.
Manufactured:				
Nitrogenous[2] thousand tons	2,321	2,866	--	Czechoslovakia 345; India 204; Hungary 157.
Phosphatic[2] do	638	704	--	Cuba 309; Bulgaria 183; Hungary 112.
Potassic[2] do	4,773	6,603	38	Poland 2,417; Hungary 679; Japan 426.
Other including mixed do	50	55	--	Hungary 45; Turkey 9.
Ammonia do	[r]1,339	1,825	1,000	Italy 262; Finland 162; Spain 104.
Graphite, natural	12,697	11,536	3,260	Japan 5,056; Poland 1,990; Italy 448.
Gypsum and plasters	52,578	35,205	--	Finland 20,405;[2] Sweden 14,800.[2]
Iodine	40	33	--	All to Hungary.
Lime	56	45	--	All to Saudi Arabia.
Magnesite	[r]27,311	29,402	--	Finland 8,756; Netherlands 8,568; Hungary 7,760.
Mica, worked including agglomerated splittings	--	2	--	All to Algeria.
Pigments, mineral: Iron oxides and hydroxides, processed	24	244	--	All to Yugoslavia.
Precious and semiprecious stones:				
Natural value, thousands	$10,321	$749	$82	Hong Kong $277; Austria $174; West Germany $92.
Synthetic do	$1,617	$438	$20	Austria $204; Canada $90; West Germany $49.
Pyrites, unroasted[2] thousand tons	915	911	--	Italy 391; Bulgaria 243; West Germany 101.
Salt and brine[2]	402,660	480,865	--	Hungary 179,861; Czechoslovakia 166,733; Denmark 54,602.
Sodium and potassium compounds:				
Caustic potash	--	1	--	All to Singapore.
Caustic soda	210	745	--	Turkey 743.
Soda ash	[r]48,022	43,275	--	Italy 21,822; Finland 9,961; Hungary 5,570.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	[r]19,201	22,162	--	West Germany 10,170; Italy 8,902; Japan 874.
Worked	[r]2,079	[7]1,524	(7)	Yugoslavia 1,302; Saudi Arabia 167; France 20.
Gravel and crushed rock	[r]2,515	394	--	Finland 237; Hungary 157.
Sand excluding metal-bearing	210	228	--	Algeria 117; Hungary 111.
Sulfur:				
Elemental:				
Crude	28,382	60,525	--	Hungary 37,075; Morocco 23,234.
Refined	2	NA	--	NA.
Sulfuric acid[2]	143,676	172,181	--	Czechoslovakia 138,643; Mongolia 910.
Talc, steatite, soapstone, pyrophyllite	561	(8)	(8)	
Other:				
Crude	82,876	[9]97,412	(9)	Italy 40,023; Belgium-Luxembourg 30,257; France 10,090.
Slag and dross, not metal-bearing	--	420	--	All to Yugoslavia.
Oxides and hydroxides of barium, magnesium, strontium	654	539	--	Netherlands 363; Belgium-Luxembourg 149; France 22.
Halogens	--	101	--	Hungary 100.

See footnotes at end of table.

Table 6.—U.S.S.R.: Apparent exports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980[p]	Destinations, 1980	
			United States	Other (principal)
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	--	8	--	All to France.
Carbon black[2]	102,286	103,835	(10)	Bulgaria 31,083; Hungary 19,292; Czechoslovakia 15,974.
Coal and briquets:				
Anthracite and bituminous coal thousand tons	21,730	21,334	--	Bulgaria 4,900; East Germany 3,376; Czechoslovakia 3,174.
Lignite including briquets	54,799	79,905	--	Yugoslavia 60,550; Japan 15,295; Austria 2,593.
Coke and semicoke thousand tons	[r]2,424	2,938	--	East Germany 1,156; Finland 776; Hungary 665.
Gas, natural million cubic feet	1,063,760	1,406,292	--	Czechoslovakia 293,887; Italy 240,598; East Germany 227,097.
Hydrogen, helium, rare gases	NA	2,341	--	Finland 2,118; Sweden 208.
Peat including briquets	[r]197,677	219,511	--	West Germany 71,658; Switzerland 31,504; Austria 29,183.
Petroleum:				
Crude thousand 42-gallon barrels	[r]674,880	651,465	--	East Germany 139,731; Czechoslovakia 138,202; Poland 96,285.
Refinery products:				
Gasoline do	[r]30,303	40,140	258	Netherlands 12,021; West Germany 8,773; United Kingdom 8,773.
Kerosine and jet fuel do	[r]3,689	2,570	--	Hungary 1,939; West Germany 377; Norway 123.
Distillate fuel oil do	[r]76,107	91,990	--	Switzerland 18,904; West Germany 14,033; Netherlands 11,844.
Residual fuel oil do	[r]55,015	48,621	220	Finland 8,744; Sweden 7,910; Belgium-Luxembourg 5,994.
Lubricants do	[r]2,292	2,120	--	Denmark 1,146; Austria 598; Finland 108.
Other:				
Liquefied petroleum gas do	[r]991	1,845	--	France 816;[2] West Germany 430; Hungary 219.
Mineral jelly and wax do	[r]58	42	--	Finland 38; Austria 2; Yugoslavia 2.
Nonlubricating oils do	182	1	--	All to Egypt.
Petroleum coke do	1,115	1,109	--	Japan 523; Italy 286; Spain 265.
Bitumen and other residues do	--	56	--	All to Spain.
Bituminous mixtures do	(3)	NA	--	NA.
Unspecified do	19,360	21,776	--	All to Poland.
Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals[2]	313,342	242,958	(11)	East Germany 28,190; Italy 20,730; Yugoslavia 19,932.

[p]Preliminary. [r]Revised. NA Not available.

[1]Owing to a lack of official trade data published by the U.S.S.R., this table should not be taken as a complete presentation of this country's mineral trade. Unless otherwise specified, these data have been compiled from various sources, which include United Nations information, data published by the partner trade countries, and partial official trade statistics of the U.S.S.R.

[2]Official Trade Statistics of the U.S.S.R.

[3]Less than 1/2 unit.

[4]May include other precious metals.

[5]Metallgesellschaft Aktiengesellschaft (Metallstatistics), Frankfurt am Main, Federal Republic of Germany.

[6]Excludes imports by Hungary valued at $1,142,000 and France valued at $122,000.

[7]Excludes imports by the United States valued at $13,000.

[8]1980 exports of talc were valued at $9,000, all of which were imported by the United States.

[9]Excludes imports by the United States valued at $10,000 and Japan valued at $9,000.

[10]The United States reported imports of 17 tons.

[11]The United States imported 125,000 barrels of naphtha.

Table 7.—U.S.S.R.: Apparent imports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1979	1980[p]	Sources, 1980	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite thousand tons	2,826	3,316	--	Guinea 2,500;[2] Greece 586; Jamaica 213.
Oxides and hydroxides do.	938	1,123	--	Yugoslavia 437; Hungary 387; India 80.[2]
Metal including alloys:				
Unwrought	1,028	645	--	United Kingdom 438; Norway 200.
Semimanufactures	r9,380	9,622	2	Austria 3,761; Japan 1,799; West Germany 1,481.
Antimony metal including alloys, all forms	730	600	--	All from Yugoslavia.
Bismuth metal including alloys, all forms	--	15	--	All from Japan.
Chromium: Oxides and hydroxides	--	17	--	All from Austria.
Cobalt:				
Oxides and hydroxides kilograms	--	25	--	All from Japan.
Metal including alloys, all forms	1	2	--	All from Sweden.
Copper:				
Ore and concentrate	140,316	111,378	--	Canada 80,627; Philippines 29,891.
Metal including alloys:				
Scrap	55	25	--	All from Belgium-Luxembourg.
Unwrought	14,428	9,980	--	Poland 5,698; Canada 2,331; Japan 1,945.
Semimanufactures	r20,322	20,361	2	Yugoslavia 7,278; Poland 6,005; Japan 3,369.
Iron and steel:				
Ore and concentrate	--	20,577	--	All from Norway.
Metal:				
Scrap	20,000	20,577	--	Mongolia 20,000;[3] Belgium-Luxembourg 533.
Pig iron, cast iron, powder, shot	r47,300	71,260	--	Algeria 67,683; Sweden 2,920; Japan 268.
Ferroalloys	2,998	6,975	--	North Korea 5,613;[3] Brazil 809; Canada 337.
Steel, primary forms	31,190	61,137	--	Czechoslovakia 40,000; West Germany 18,884.
Semimanufactures:				
Bars, rods, angles, shapes, sections thousand tons	r1,177	[4]1,348	(5)	Japan 367;[4] Poland 207; Spain 159.
Universals, plates, sheets do.	r2,984	2,836	--	West Germany 1,349; Belgium-Luxembourg 334; Japan 241.
Hoop and strip	303,399	[6]370,185	--	West Germany 273,972; Belgium-Luxembourg 25,895; France 13,146.
Rails and accessories	6,027	381	--	Canada 380.
Wire	33,198	r25,488	--	Belgium-Luxembourg 12,114; Yugoslavia 2,768; Italy 2,422.
Tubes, pipes, fittings thousand tons	r3,490	2,833	(5)	West Germany 861; Japan 793; Czechoslovakia 386.
Castings and forgings, rough	6,046	3,666	--	West Germany 2,115; Italy 1,525.
Lead:				
Ore and concentrate	r86,099	53,706	--	Canada 14,437; Ireland 14,417;[3] Japan 6,139.
Oxides	r1,336	5,645	--	France 2,844; West Germany 2,100; Netherlands 450.
Metal including alloys:				
Unwrought	87,605	60,513	--	Yugoslavia 13,953; Canada 11,664; United Kingdom 10,211.
Semimanufactures	r33	2,046	--	Spain 2,000; Yugoslavia 45.
Magnesium metal including alloys, unwrought	--	5	--	All from Italy.
Manganese oxides	5,367	4,082	1,048	Ireland 1,274; Greece 1,260; Spain 500.
Mercury 76-pound flasks	2	NA	--	NA.
Molybdenum:				
Ore and concentrate	3,391	326	229	Netherlands 97.
Metal including alloys, all forms kilograms	1,408	1,150	--	France 1,000; Japan 150.
Nickel:				
Matte and speiss	4,055	NA	--	NA.
Metal including alloys:				
Unwrought	10	(5)	--	All from West Germany.
Semimanufactures	42	25	(5)	West Germany 10; France 6; Italy 5.
Platinum-group metals including alloys, unwrought and partly wrought value, thousands	$1,519	$3,069	$299	West Germany $2,121; United Kingdom $649.

See footnotes at end of table.

COMMODITY REVIEW

METALS

Aluminum.—In 1981, estimated production of aluminum increased to 1.95 million tons, including 150,000 tons of secondary aluminum, and production of alumina increased to 2.8 million tons. In 1980, production of aluminum had increased 15% in comparison with that of 1975. In 1981, there was no evidence of increased production of domestic ore and concentrate, and the Soviets were trying to obtain additional foreign supplies.

The U.S.S.R. operated 14 primary reduction plants and 15 secondary aluminum plants. The rapid expansion of the aluminum industry was based on foreign technology and imported bauxite. Aluminum was produced for export as well as domestic consumption, and the U.S.S.R. exported aluminum to hard currency markets along with CMEA countries. In 1981, the U.S.S.R. increased its exports of aluminum to both centrally planned and market economy countries.

Although the Soviet Union produced large amounts of low-grade bauxite, supplies were not sufficient, and production was being developed from nepheline and alunite. Still, in 1980, over 82% of primary production was derived from bauxite, 16% from nepheline, and less than 2% from alunite. The major sources of nepheline were the apatite complex on the Kola Peninsula and Siberian nepheline syenite rock.

The Soviets imported about 40% of their bauxite and alumina requirements. Principal suppliers were Greece, Guinea, Hungary, and Yugoslavia, with imports also coming from France, Italy, Jamaica, Japan, and Turkey. Offsetting import costs was the availability of large supplies of hydroelectric power in Siberia, where most of the smelting capacity was located. The low energy costs, however, had to be calculated with respect to the higher transport costs for raw materials and output.[26]

During 1981-85, production of aluminum was to increase 15% to 20%. Growth in aluminum production was to be obtained by completing construction at the Krasnoyarsk and Regar (Tadzhik) plants, beginning operations at the Sayansk plant, and by increasing the capacity of existing potlines. Alumina production was to be increased by achieving full capacity at the Nikolayev and Achinsk alumina plants, putting into operation a new alumina shop at the Bogoslovsk aluminum plant, and transferring the bauxite supply for the Tikhvin alumina plant from depleted reserves in the Tikhvin area to the Severoonezhsk deposit.

The following developments were report-

ed in the Soviet aluminum industry in 1981. At the end of 1981, the Regar (Tadzhik) aluminum plant had prepared potline 6 to begin operations. To bring the remaining planned potlines into operation, the pace of construction work at the Regar plant would have to be increased by 50%.[27] In 1981, renovation of the potlines continued at the Bratsk aluminum plant. At the Kanaker aluminum plant, expansion and reconstruction of the foil shop was underway, and capacity of the foil shop was to increase 150%.

In late 1981, the Irkutsk aluminum plant was reportedly exceeding its production goals. A capacity increase of 20% to 25% was planned during 1981-85. The Irkutsk plant produced aluminum wire and ingots, and approximately one-third of production was exported. In 1981, the Krasnoyarsk aluminum plant was reported to have fulfilled its plan.

The long-range development program provided for a major increase in alumina production. The Nikolayev alumina plant was undergoing expansion; it used domestic and imported bauxite. The plant was to have a final capacity of 1 million tons per year, comprised of four 250,000-ton-per-year stages. In 1981, the first and second stages of the Nikolayev plant were reported to have reached capacity, and production was reported from the third stage. The fourth and last stage was still being prepared for operation in late 1981.

In 1981, the Pavlodar aluminum plant reported fulfilling its yearly output plan. During the 11th 5-year plan, production of alumina at the Pavlodar plant was to increase 2% compared with that of the 10th 5-year plan. This increase in output was to be achieved without any addition to the labor force. All necessary renovations at the Pavlodar plant to make better use of low-grade bauxite were to be completed by 1985. Despite its being called an aluminum plant, there was no indication in Soviet sources that the Pavlodar aluminum plant produced primary aluminum.

In 1981, the Achinsk alumina plant was again not achieving its production goals. The plant had not met its production goals since it went onstream 10 years earlier. The main cause of lagging production was technological problems in producing alumina from nepheline. The Achinsk plant was also faulted for inefficient pollution controls.[28]

In 1981, the Soviet Union signed contracts to buy approximately 200,000 tons of Brazilian bauxite to acquire raw materials to supply the Nikolayev plant. The U.S.S.R. agreed to help finance an alumina refinery at Visakhapatnam in India with a capacity of 600,000 to 800,000 tons per year. A percentage of the output was to go to the U.S.S.R., depending on its contribution to the financing.

Table 8.—U.S.S.R.: Estimated annual capacity of primary aluminum plants

(Thousand metric tons)

Volkhov	20
Volgograd	200
Total	2,300

[1]Not yet in operation.

Antimony.—The Kadamzhay complex in the Kirgiz S.S.R. was the principal antimony center; integrated facilities produced most of the country's refined products. Production at this complex was to have increased 50% in 1976-80. Deposits of antimony also occurred in Kazakhstan and at Sarylakh and Tazhdolinsk in Siberia. Detailed exploration was occurring at the Novoye antimony-mercury deposit in Kirgiziya. Construction was being carried out at the new Aznob Mine and mill unit at the Dzhidzhikrutskiy complex in Tadzhikistan, and the recovery of antimony from lead scrap was planned.

Arsenic.—Arsenic ore reserves are estimated at 12 million tons. Small arsenic deposits are located in Tadzhikistan; however, all Soviet arsenic output was obtained as a byproduct of smelting or roasting metallic ores. A plant to recover arsenic from sulfur was installed at the Mednogorsk copper and sulfur complex in Orenburg Oblast'.

Beryllium.—The Soviet Union ranked as one of the world's largest producers and consumers of beryl and beryllium alloys and metal. Beryllium is found in variable quantities in most pegmatites throughout

the U.S.S.R. Numerous deposits are located in the Altay, Kazakhstan, Kola Peninsula, Soviet Far East, Transbaykal, and western Ukraine. The probable level of production in 1981 was 1,800 tons of beryl (10% to 12% BeO). The recovery of beryllium from the Dzhidinsk tungsten and molybdenum ores in the Buryat A.S.S.R. was planned.

Bismuth.—In 1981, estimated production of bismuth increased to 75 tons. Bismuth was recovered as a byproduct of lead and zinc smelting in Kazakhstan and other regions; from dust and crude metal at the Balkhash, Kirovgrad, and Mednogorsk complexes; and from tungsten and molybdenum ores. Two copper-bismuth deposits (Taryzkan and Kantarkhana) were under exploitation in Tadzhikistan. The Ustarassy Mine in the Chatkal Mountains was the only enterprise mining bismuth ore, and its concentrates were sent to the Chimkent lead plant in Kazakhstan for processing. In 1981, production of bismuth at the Ust'-Kamenogorsk lead-zinc complex in Kazakhstan increased 46% compared with 1980 output; in 1980, production of bismuth at Ust'-Kamenogorsk had declined.

Chromium.—Soviet-reported production of crude chrome ore (30% to 44% Cr_2O_3) was 3.4 million tons in 1980 and decreased to 3.3 million tons in 1981. The 1981 production of marketable chrome ore (45% to 56% Cr_2O_3) was estimated at 2.4 million tons. By 1985, production of crude chrome ore was to increase to 3.8 million tons.

The U.S.S.R. was the world's second largest producer and exporter of chrome ore. Over 60% of output was consumed or stocked in the Soviet Union, and approximately three-fourths of the exports were to centrally planned economy countries. According to 1978 data, Soviet consumption of chrome ore was distributed as follows: metal production, 45%; refractories, 35%; and chemical and other products, 20%.

The Donskoye mining and concentration complex at Khrom-Tau in western Kazakhstan produced over 90% of Soviet output and was the only supplier of high-quality ore. The rest came primarily from the Saranov underground operation in the Urals. By 1985, output at the Donskoye complex was to increase 14%, raising production to 3.6 million tons per year of crude chrome ore. In January 1982, the first stage of the Molodezhnaya underground mine at the Donskoye complex was officially put into operation. The first stage was to have a capacity by 1985 of 800,000 tons per year of crude chrome ore with a Cr_2O_3 content of 45% to 51%. Ultimate capacity was to be 2 million tons per year.

Cobalt.—Cobalt production in 1981 was estimated at 3,750 tons. Production of cobalt along with nickel during 1981-85 was to increase more than 30%. Cobalt production rose 16% between 1970 and 1975 and about 10% between 1976 and 1980. Gross cobalt reserves are estimated at 100,000 tons of contained metal, found chiefly in nickel-cobalt ores and in cobalt ores of the Khovu-Aksy deposit in the Tuva A.S.S.R. north of Mongolia.

Cobalt production was concentrated at Noril'sk in East Siberia, at Monchegorsk and Pechenga on the Kola Peninsula, at the Yuzhuralnikel, Ufaley, and Rezh plants in the Urals, and at some copper plants. During 1976-80, Noril'sk became the main producer. Expansion of domestic output depended greatly on the rate of development of the Noril'sk complex. Domestic ore production was augmented by large shipments of Cuban cobalt-nickel concentrates, and the Soviets were financing the expansion of Cuban nickel production.

Copper.—In 1981, blister copper production increased to approximately 1.05 million tons, including 95,000 tons of secondary copper. This increase was due primarily to new capacities coming onstream at the Erdenet copper-molybdenum complex in Mongolia. In 1981, the United States began exporting copper concentrate to the Soviet Union.

During 1981-85, copper production was to increase 20% to 25% over the 1980 level. Blister copper was produced at 13 smelters. Secondary blister copper was produced by the Kirovgrad smelter in the Urals, by the Moscow smelting and electrolytic plant, and by several small units at secondary nonferrous plants. The country operated 40 concentrators and 11 copper refineries. Approximately 80% of all ore was mined in open pits. About 10% of the primary copper was produced as a byproduct.

The main copper ore regions are in central and eastern Kazakhstan, the eastern slope of the Ural Mountains, Uzbekistan, Transcaucasia, East Siberia, and Noril'sk. Other deposits of lesser importance are found in the North Caucasus, West Siberia, and the Kola Peninsula.

Kazakhstan contains about one-half of the total copper reserves and produced approximately 30% of the total Soviet copper output. During 1981-85, output of refined copper in Kazakhstan was to increase 15.9%. In Kazakhstan, plans called for put-

ting into operation facilities at the Dzhezkazgan complex, for developing the Boshchekul copper deposit, and for completing construction of the East Kazakhstan mining and chemical complex.

With the decline in growth in copper production in the Ural region as older mines became depleted, Kazakhstan, farther to the east, became the leading copper-producing region. However, shortages of concentrate were occurring in Kazakhstan. Problems in securing adequate raw materials led to the Balkhash complex, Kazakhstan, working under capacity. Blister copper production was at 80% of capacity and refined copper production at 77% of capacity. The results of work completed in 1981, along with plans for 1982, indicated that construction and installation work planned for 1981-85 at the Balkhash and Dzhezkazgan complexes would be one-half completed and would thus delay commissioning of planned facilities. At Balkhash, renovation of the copper smelting plant, which went into operation in 1938, and the rolling shop, which went into operation in 1941, was considered necessary.[29]

In 1981, the Dzhezkazgan mining and metallurgical complex in Kazakhstan exceeded its 1981 production quota for refined copper. During 1981-85, output of refined copper at the Dzhezkazgan complex through renovation of facilities was to increase 3.6%. At Dzhezkazgan, the first stage of the No. 3 concentration plant, two stages of Mine No. 67, and the first stages of the Annenskiy and Akchiy-Spassk Mines were to begin operation. In 1981, redevelopment of the Kounrad open pit in Dzhezkazgan Oblast', Kazakhstan, was reportedly completed; Kounrad was one of the largest copper mines in the U.S.S.R.

The Ural region was the second largest copper-producing area, with mostly copper-pyrite deposits that contain gold, silver, zinc, and other metals. There are over 100 individual pyrite deposits in the Urals. With the opening of new mines, the proportion of open pit mines in the Urals increased to approximately 75%, and the trend to open pit mining continued.

In the Ural region in Bashkiriya, the first stage of the open pit Molodezhnyy copper-zinc mine was put into operation at the Uchaly mining and beneficiation complex. The Uzel'ginskiy underground mine was also being developed at the Uchaly complex.

At the Kirovgrad copper smelting complex in the northern Urals, the 1981 production goal was lower than 1980 production, and in 1981, the work force at the smelting complex decreased. The major problem at Kirovgrad, as at the Krasnoural'sk and Karabash copper smelters in the northern Urals, was obtaining raw materials, one-third of which had to be transported from other regions.[30] Plans for the Krasnoural'sk copper smelting complex for the 1980's called for putting into operation the first stage of the Volkovskiy open pit, which was to be a major raw material supplier. Supplying Krasnoural'sk with local ore from the Volkovskiy open pit was seen as a means of alleviating the chronic ore shortage. At Krasnoural'sk, renovation was also planned for the metallurgical workshop, and renovation and expansion were planned for the main concentration plant. In 1981, the Krasnoural'sk complex reportedly exceeded its goal for copper production.

Copper production was being expanded in Siberia with the development of the Noril'sk metallurgical complex, the site of a rich copper-nickel deposit. At the Nadezhda complex at Noril'sk, which was being built with Finnish technology and equipment, construction of the No. 2 smelter was reportedly completed, with a planned capacity of 650,000 tons per year of copper concentrate. Also reported completed at Noril'sk was a 33-kilometer slurry pipeline for transporting copper-nickel concentrates. In Khabarovsk Kray in the Soviet Far East, copper production was projected to increase with the development of the Pereval'nyy Mine at the Solnechnyy complex.

Problems persisted with the development of the well-known Udokan deposit near Lake Baykal in East Siberia. Gross reserves at Udokan amount to over 700 million tons, averaging 1.5% copper (20% oxides and 80% sulfides). Years passed without any significant development, and enrichment technology for the ore was not perfected experimentally.[31] Because of the distant location, severe climate, and seismic activity, construction costs at Udokan were stated to be three times greater than normal. The Government believed that completion of the Baykal-Amur Railroad (BAM) to Chara during 1981-85 would stimulate development of the Udokan deposit. Still, production at Udokan would not begin until at least the 1990's, and Western World participation would probably be necessary.

In Mongolia, the Erdenet copper-molybdenum complex, with an annual projected capacity of 16 million tons of ore and

118,000 tons of copper in concentrate, was being developed jointly with the U.S.S.R. The ore averages 0.85% copper and 0.012% molybdenum. Construction began in 1974, and in December 1978, the first of the four stages of the complex was put into operation. In 1981, the complex was projected to produce approximately 72,000 tons of copper in concentrate. The 1980 production was approximately 44,000 tons. Concentrate from the complex was sent to the U.S.S.R. for smelting.

Gold.—Since the 1930's, there has been little Soviet statistical reporting on precious metals production, trade, stockpiles, or exploration.

Estimated Soviet gold production in 1981 was 8.43 million troy ounces. Over two-thirds of Soviet gold production came from the Soviet Far East and East Siberia (mainly from placers at Kolyma, Aldan, Dzhugdzhur, Indigirka, Yana, and Chukotka); most of the balance came from gold and mixed sulfide ores in the Urals, Tadzhikistan, Armenia, and West Siberia. Byproduct nonferrous operations produced substantial quantities of gold. The biggest source of byproduct gold was copper and lead-zinc ores.

Magadan Oblast' was the Soviet Union's main producing center with 35 placer mines, 23 dredges, over 500 sand washing rigs, and about 1,500 bulldozers. Although production in Magadan Oblast' was reported lagging for the first 9 months of 1981, by November, shortfalls had been made up at all complexes and placer mines, and the 1981 production plan for the Oblast' was expected to be fulfilled.

The first stage of the Severnaya underground mine was put into operation in 1980 in the Urals, one of the oldest gold-producing regions in the U.S.S.R., at the Berezovskiy mining complex. At the Berezovskiy complex, two mines were in operation, the Severnaya and Yuzhnaya, and all smaller mines had been eliminated or were being used for ventilation. In 1981, at Berezovskiy, renovation of the concentration plant had begun, and construction was continuing on the Severnaya Mine.

Also in 1981, a gold mining complex was reported under construction in the Toguz-Torouzkiy region, Kirgiziya. Extensive prospecting was continuing in the Asian part of the country to find new reserves.

Soviet gold sales were a principal source of hard-currency earnings. Total sales in 1981 were estimated at 8 million ounces, approximately triple 1980 sales. Owing to persistent problems in agriculture and in other areas, sales in 1982 were projected to remain at their 1981 level. Gold holdings were secret, and gold sales were carefully managed for political and economic considerations. Through the first 9 months of 1981, gold sales were approximately double their 1980 levels. However, in October 1981, sales were reported to have virtually ceased. Then in November-December 1981, the Soviets reportedly sold a very large quantity of gold (possibly 3.2 million ounces) despite the fact that the price of gold had fallen. Along with the need to pay for agricultural products, owing to the poor harvest, the late gold sales in 1981 could have been used to prop up the Polish economy.

Iron Ore.—In 1981, production of usable iron ore decreased slightly to 242 million tons. Output of pellets increased to 54.1 million tons.

The iron ore industry was characterized by concentrated production facilities, and the tendency was to further augment existing large enterprises. Eight large open pits, each with a capacity of over 20 million tons per year, accounted for 53% of iron ore extraction. Nineteen large underground mines produced approximately 80% of the underground production. Open pit mining in 1980 accounted for 84.6% of iron ore production. Large mining and concentration complexes included the Severnyy (projected capacity of 45 million tons of crude ore), the Lebedi (40 million tons), the Novo-Krivorozhsk (35 million tons), and the Sokolovo-Sarbaysk (35 million tons).

Conditions for iron ore mining worsened. Between 1975 and 1980, the average metal content of crude iron ore decreased from 33.4% to 32.3%,[32] and there was a significant increase in the depth of open pits. The number of open pits up to 200 meters deep producing over 10 million tons per year decreased 26% in 1975-80, and the percentage of ore extracted from such pits decreased from 74.1% to 58.1%. At the same time, the number of open pits more than 200 meters deep and the percentage of crude iron ore extracted from such pits increased 50%.[33] Over the last decade, the cost per ton for the extraction of usable iron ore increased approximately 40%.[34]

Exports of iron ore went principally to CMEA countries. In 1980, over 95% of Soviet iron ore exports went to CMEA countries. Although a large exporter of iron

ore, the Soviet Union had problems supplying its own plants.

The largest iron ore producing region was the Krivoy Rog Basin in the Ukraine, followed by the Kursk region, the Urals, Kazakhstan, Siberia, and the Kola Peninsula. Among iron ore producing regions, the Kursk Magnetic Anomaly (KMA) was of increasing importance both in percentage of reserves and in ore extraction. The Krivoy Rog Basin in the Ukraine, another major producing area, was declining in importance.[35] Although growth in iron ore extraction was expected from basins in the Asian part of the country including the Kustanay Basin in Kazakhstan, the Angara-Ilimsk Basin in East Siberia, and the Aldansk Basin in the Soviet Far East, principal growth in iron ore reserves was to come from the KMA, which reportedly contained proved reserves of high-grade ore totaling 27 billion tons. There were shortages of iron ore in the Urals, and over 10 million tons of ore was shipped annually to the Urals from the KMA.

The chief underground iron ore mining regions were the Krivoy Rog Basin in the Ukraine (approximately 60% of total production) and the Gornaya Shoriya in West Siberia and the Tagilo-Kuvshinskiy region of the Urals, which supplied approximately 15% each. Underground mining was conducted at 40 mines. The majority were in the Ukraine (22), in the Urals (9), and in Siberia (6). Owing to the exhaustion of reserves at the upper levels of a number of surface mines, production was projected to increasingly shift to mixed modes of mining.

As of January 1976, total iron ore reserves in place in categories $A+B+C_1+C_2$[36] were 111 billion tons averaging 34.8% iron. Over 70% of these reserves were in the European part of the country including the Urals. The iron ore reserves were distributed as follows: the Ukraine, 31%; European center, 24.4%; Urals, 15.7%; Kazakhstan, 15%; Siberia, 7.4%; northwest, 3%; Soviet Far East, 2.5%; and others, 1%. Total national reserves in categories $A+B+C_1$ were estimated at 60.2 billion tons, averaging 38% iron. This included 10.3 billion tons averaging over 55% iron that did not require dressing and 34.8 billion tons of easily dressed ore. Of total iron ore reserves in place, only 14% could be used without beneficiation, 77% required simple beneficiation, and 9% needed complex beneficiation. In 1980, more than 84% of all crude iron ore was concentrated.[37]

In 1981, construction continued on the three new large mining-concentration complexes to be built during 1981-85 at Kachar (Kazakhstan), Kostamush (Karelia), and Stoylensk (KMA). Construction of the second stage of the Mikhaylov (KMA) and Lebedi (KMA) complexes began, and there was expansion and renovation of the Kovdor (Murmansk Oblast'), Olenegorsk (Murmansk Oblast'), Tsentral'nyy (Ukraine), and Yuzhniy (Ukraine) complexes.

In 1981, at the Mikhaylov complex, the capacity for iron ore extraction increased by 2 million tons per year, reaching 37 million tons. At the Yuzhniy complex, capacities were put into operation for the extraction of 1.5 million tons per year of crude ore and the production of 400,000 tons per year of concentrate. As a result, the Yuzhniy complex's capacity reached 37 million tons per year of crude ore and 17.5 million tons per year of concentrate. At the Olenegorsk complex, new capacities were put into operation. The capacity of the Kirovogorsk open pit at Olenegorsk was reportedly expanded by 1.2 to 2.2 million tons per year of crude ore, and the concentration plant was reportedly doubled in size to produce 800,000 tons per year of concentrate. Iron ore extraction capacities were put into operation at the Azerbaydzhan, Kovdor, and Novo-Krivorozhsk complexes; at the Sheregeshskiy Mine in Kemerovskaya Oblast', Siberia; at the Irbinskiy Mine in the Khakasskaya Autonomous Oblast', Siberia; and at the Imeni V. I. Lenin mining directorate in the Krivoy Rog Basin.

Major projects scheduled to go onstream in 1982 included capacities at the Kostamush complex in Karelia, being built with the aid of Finnish companies, and at the Stoylensk complex in Belgorod Oblast' (KMA). Mining of iron ore on a limited scale started at Kostamush in 1980. The project was being built in three stages and was to have an annual capacity of 8.9 million tons of pellets from 24 million tons of crude ore. The deposit contains an estimated 1.2 to 1.5 billion tons of ore with an average iron content of 31%. Construction of the first stage began in 1977, and total construction time was to be 8 to 10 years. Finland was to buy annually up to 1.2 million tons of pellets during 1983-90.

Iron and Steel.—In 1981, production of raw steel, rolled finished steel, and steel pipe increased slightly but fell short of the

goal. Although the Soviet Union was the world's largest producer in total quantity of iron ore, coke, refractories, raw steel, and steel pipe, the country was a net importer of high-quality rolled steel products. Waste was extensive in the Soviet iron and steel industry, and only approximately 45% of the raw steel production was efficiently used in the Soviet economy.

Major problems occurred in producing the needed assortment of ferrous metal products. For example, while in 1981 the plan for finished rolled ferrous metal fell short by 6%, the plan for the production of low-alloy steel needed to reduce metal consumption was short 29%.[38] Production problems were attributed in part to the practice of registering plan fulfillment in physical units (i.e., tons), which encouraged production of simple products.

Eleven metallurgical enterprises were responsible for more than one-half the Nation's output of raw steel. The largest producer was the Magnitogorsk complex. The other 10 major producers were the Chelyabinsk works, Cherepovets works, Karaganda complex, Krivoy Rog works, Kuznetsk complex, Nizhniy Tagil complex, Novolipetsk works, West Siberia works, Zaporozhstal works, and Zhdanov "Il'ich" works.

During 1981-85, capital investment in ferrous metallurgy was to increase by approximately 40% over that of 1976-80. The share of total steel production by oxygen converter was to increase from 28.5% to 33%. Electric steel production, which in 1981 accounted for about 11% of production, was to be increased almost 60% to 22 to 23 million tons in 1985. Continuous-casting steel production was to increase to 35 to 37 million tons per year from the 16.6 million tons (11% of total steel production) produced in 1980. Emphasis also was to be placed on powder metallurgy and the production of high-quality steel pipes for gas transport.

Growth in electric steel production was to be achieved by activating capacities at existing enterprises and by putting new electric furnaces into operation at the Donetsk and Uzbek works, at the Orsko-Khalilovo and Kuznetsk complexes, and at other enterprises. The country's continuous-casting capacity was to be increased, primarily at the Cherepovets, Dzerzhinsk, and Novolipetsk enterprises.

In 1981, at the Cherepovets works, capacity of the "2000" rolling mill was to be expanded by 500,000 tons per year. At the Magnitogorsk complex, renovation of the No. 6 blast furnace was completed. The No. 8 coking battery at Magnitogorsk, with a capacity of 1 million tons per year, was officially declared in operation on the last day of 1981. It replaced a 50-year-old coking battery. The new electric pipe-welding shop at the Vyksa metallurgical plant was not put into continuous operation in 1981, and plans were for the first stage of this shop to reach its full capacity of 250,000 tons per year of large-diameter pipe for high-pressure gas transport in 1983. At the Orsko-Khalilovo complex, the electric steel shop, with two electric furnaces of 250,000 tons per year capacity each, was officially put into operation in 1980, and the first steel from furnace No. 1 was produced. At the end of 1981, the Yermakov ferroalloys plant in Kazakhstan reported that a new furnace had been put into operation and that another furnace was under construction.

At the Oskol electric steel complex in Belgorod Oblast', construction continued in 1981 of the first roasting unit with a design capacity of 2.5 million tons per year of iron pellets for steelmaking by the direct reduction process. The first stage, which was scheduled to be commissioned in 1981, was to go into operation in December 1983. The Oskol complex was to be supplied with raw material from capacities being developed at the Lebedi mining and concentration complex. A $313 million contract for a complete rolling mill at the Oskol complex was concluded with a consortium led by the Schloemann Siemag AG of the Federal Republic of Germany. The mill was to begin operation in 1985. Other West German firms had been supplying facilities for the pelletizing plant and other works.

In 1982, plans called for putting into operation a tinplate shop at the Karaganda metallurgical complex, a converter shop at the Dzerzhinsk plant, and shops for cold-rolled steel at the Magnitogorsk and Novolipetsk complexes.

Table 9.—U.S.S.R.: Crude steel production by process, in percent

Process	1980	1981
Open hearth	60.2	59.1
Oxygen converter	28.5	29.5
Electric	10.8	10.9
Bessemer	.5	.5
Total	100.0	100.0

Table 10.—U.S.S.R.: 1981 planned production of rolled finished ferrous metal at major enterprises

(Million tons)

Enterprise	Planned output
Magnitogorsk complex	11.2
Cherepovets works	10.4
Krivorozh works	8.5
Novolipetsk works	6.0
Western Siberia "Zapsib" works	4.7
Zhdanov "Azovstal" works	4.6
Karaganda complex	4.4
Nizhniy Tagil complex	4.2
Zhdanov "Il'ich" works	4.2
Chelyabinsk works	3.9
Dzerzhinsk works	3.8
Kuznetsk complex	3.4
Zaporozhye "Zaporozhstal" works	3.4
Makeyevka works	3.4
Orsko-Khalilovo complex	3.3
Kommunarsk works	3.2
Rustavi works	1.3
Amur works	1.0

Lead and Zinc.—In 1981, estimated output of primary lead at 410,000 tons remained the same, while primary zinc at 790,000 tons increased slightly compared with 1980 output. The 1981 estimated output of secondary lead increased to 220,000 tons, and the 1981 estimated output of secondary zinc remained at 80,000 tons. Lead and zinc imports were estimated to have increased in 1981. A large portion of lead and zinc exports went to the CMEA countries.

Over 10% of total lead and zinc production in 1980 was recovered as a byproduct. Of the total volume of lead produced, 35% came from secondary sources.[39] Ore reserves in 1980 were estimated at 16 million tons of contained lead and 20 million tons of contained zinc, over two-thirds of which are located in Kazakhstan, chiefly in the Altay region and the district of Karatau. There are also reserves of zinc in the Urals. Kazakhstan was the leading lead-zinc producing area, followed by the Urals, Uzbekistan, Siberia, North Caucasus, and the Ukraine. The largest part of the secondary lead was produced in shaft smelting at the "Ukrzink" plant in the Ukraine.

In recent years, production quotas for lead and zinc had not been met owing to the slow construction of new facilities, supply problems, and low metal recovery. For example, regarding lags in the construction of new mining capacity, development of the Gorevka lead and zinc deposit on the Angara River in Siberia still had not started, although exploitation of this deposit, where lead was "...practically lying on the surface..." was planned for the mid-1960's.[40]

In 1980, Kazakhstan produced over 70% of Soviet lead and approximately 50% of Soviet zinc. The 1981-85 plan for Kazakhstan was for lead production to increase 11.6%, and zinc production, 7.7%. In Kazakhstan, production of lead was to increase 12% and zinc 12.7% at the Ust'-Kamenogorsk lead-zinc complex during 1981-85, and new facilities were to be added. In 1981, the Ust'-Kamenogorsk complex reported the fulfillment of its plan for lead and zinc production. In Dzhezkazgan Oblast', Kazakhstan, plans were to increase the production of lead-zinc ore 53% during 1981-85. The Dzhezkazgan copper complex produces byproduct lead, and lead-in-concentrate output was to be raised 22% during the 11th 5-year plan.

The Zhayremsk complex was the newest lead-zinc producing enterprise in Kazakhstan; the first stage achieved its design capacity in 1978, and lead and zinc output were to increase 45% and 40%, respectively, during 1981-85, compared with that of 1976-80. Extraction of ore at the complex was to increase 50%. By 1988, the second stage of the complex was to be operating at design capacity. Construction was behind schedule at Zhayremsk, and this was foreseen as affecting commissioning of the second stage. A major problem for ore extraction at Zhayremsk was excess water in the pits, resulting in the ore freezing in winter. Plans to improve operations entailed acquiring more equipment including water pumps, 8-cubic-meter shovels, and 40- and 75-ton dump trucks.[41] Furthermore, projected targets for recovery of lead and zinc from Zhayremsk ore at the Achisay and Tekeli complexes were not being reached.[42] By 1985, a concentration plant was to be commissioned at the Zhayremsk complex along with new capacities at the Dal'nyezapad Mine and the Ushkatyn open pit. Failure to commission concentrating facilities at the Zhayremsk and Kargayly complexes in Kazakhstan resulted in ore being shipped hundreds of kilometers for processing. The commissioning of concentrating facilities at these complexes was deemed essential to overcoming this problem.[43]

At the Grekhovskiy Mine in the Zyryanov complex in Kazakhstan, which had been in operation more than 25 years, a new underground conveyor system doubled the transport capacity. In addition, an underground crushing complex was under construction,

and the ventilating system was being overhauled. A surface mine on the same deposit was being developed, along with construction of a pipeline to the concentrating plant. These improvements were projected to increase ore extraction by a minimum of 50% by 1985. The potential exploitation period for the Zyryanov deposit was extended 15 to 20 years with the detection of five new prospective mining areas.

At the Mirgalimsk deposit, which was being developed by the Achisay complex, approximately one-half of the ore was being left at higher levels, and some ore left in pillars reportedly contained two to three times more metal than ore being extracted at a depth of approximately 500 meters.[44]

The future development of the ore base in eastern Kazakhstan was of serious concern to Soviet officials. Although the output of polymetallic ores had increased fourfold in the past 10 years, the grades had dropped 40%. At the Leninogorsk mixed-sulfide complex in East Kazakhstan Oblast', production decreased 50% during 1970-79 because of ore shortages; a complaint was raised at the Leninogorsk plant about the lack of qualified basic-production workers.[45] In 1981, at the Leninogorsk complex, a new shop went into operation to process zinc concentrates. In Armenia, the Alaverdi copper complex began to recover lead from flue gases with electrostatic precipitators. An installation was to be constructed at Akhtala to upgrade this material.

Magnesium.—The 1981 estimated output of magnesium in the five operating plants increased to 78,000 tons, and production was to increase during 1981-85. The Ust'-Kamenogorsk titanium-magnesium complex in Kazakhstan exceeded its goal for magnesium production by 0.2% in 1981, and production of magnesium was to increase 40.7% in 1981-85. For this purpose, new capacities were to be put into operation at Ust'-Kamenogorsk. During 1976-80, output of magnesium at Ust'-Kamenogorsk increased 10%.

Manganese.—The 1981 Soviet manganese ore production decreased to 9.4 million tons. Expansion of the manganese industry during 1981-85 was to occur through expansion of existing enterprises as well as the construction of new enterprises. By 1985, production was to increase to 10.1 million tons.

In 1981, manganese ore capacity increased by 300,000 tons per year at the Ordzhonikidze complex in the Nikopol' Basin in the Ukraine. Nikopol' is the principal Soviet manganese basin, producing over one-half of Soviet manganese ore, but the ore, with an average grade of 26.4% manganese, is a little more than 2 meters thick and lies under about 80 meters of overburden.

Growth in manganese output during 1981-85 was to come from poorer and harder to concentrate carbonate ores.[46] During 1981-85, the Government planned to begin exploitation of the Bol'shoy Tokmak carbonate ore deposit in the Ukraine, which was to serve as a base for the construction of the Tavricheskiy mining and concentration complex in Zaporozh'ye Oblast'. The Bol'shoy Tokmak deposit was divided into northern, central, and southern sectors. Exploitation was to begin in the northern sector where the majority of reserves are concentrated. In Kazakhstan, a mine was to be developed at the Ushkatyn deposit; the output of the enterprise was intended for ferroalloy production.

The Bol'shoy Tokmak deposit is lower grade and deeper than the Nikopol' deposit, and there were unforeseen delays in bringing the deposit onstream. Lack of ore hindered production at the large ferroalloy plants in Nikopol' and Zaporozh'ye and in the entire ferrous metallurgy sector.[47]

Along with delays in bringing facilities onstream, another major cause of ore shortages was waste. Insufficient concentration and processing resulted in losses of up to one-half of the manganese in slime from concentration and in slag from metallurgical processing. The manganese content of the slag was approximately 16%, and manganese in the slag generally was not recovered. Rather high manganese-content slag was being used with asphalt for road paving, giving some roads a reddish color. An additional waste of manganese occurred during steel production. The average amount of manganese used in the Soviet steel industry was 10 kilograms per ton of steel, which was higher than in many countries. There was, furthermore, no program for secondary manganese recycling.[48]

At yearend 1969, manganese ore reserves in categories $A+B+C_1+C_2$ were estimated at 2.5 billion tons with an average manganese content of 23.0% to 26.4%, including 1.02 billion tons in the Nikopol' Basin. The Chiatura Basin in Georgia contains reserves of high-grade ore.

Two concerns, the Ordzhonikidze and Marganets, operated in the Nikopol' Basin. In 1980, there were 19 underground mines,

10 open pits, and 9 concentrators in the basin. The Chiatura Basin in 1980 had 24 mines and 8 concentrators. Approximately 80% of production from Chiatura came from underground mines.

Mercury.—In 1981, the output of mercury was estimated at 63,000 flasks (76 pounds each). Numerous mercury deposits exist, mainly in Soviet Central Asia, the Soviet Far East, and the Ukraine.

The largest Soviet mercury operation was the Khaydarkan complex in southern Kirgiziya, where mercury was mined by both underground and open pit methods. In 1981, the first output was reported at the Uluu-Too site from a new shaft of the Glubokaya mining directorate of the Khaydarkan complex. Ore was being mined at this shaft to a depth of 700 meters, and mercury production was projected to increase at Khaydarkan.

The Nikitovskiy complex in the Ukraine was the second largest mercury producer. Approximately 70% of the ore at Nikitovskiy was mined by underground, and 30%, by surface methods. Two underground mines, Second Novaya and Novozavodskaya, and the Polukupol Novyy open pit were in operation.

The small Zakarpatskiy complex processed ores from the Borkutnoye, Shayanskoye, and other small deposits in Zakarpatskaya Oblast', western Ukraine.

In the Tadzhik S.S.R., construction of the new Dzidzikrutskiy (Aznob) mercury-antimony complex was underway. Future development was planned of small deposits in the North Caucasus, at Chukotka in the Soviet Far East, and in other regions. Exploration for new deposits was continuing in Kirgiziya, the Soviet Far East, and other areas.

Molybdenum.—Output of molybdenum concentrates in 1981 was estimated to have increased to 10,900 tons of metal. In 1981, the United States increased exports of molybdenum concentrate to the U.S.S.R.

Molybdenum reserves in ore (molybdenite, copper-molybdenum, and tungsten-molybdenum ores) in the U.S.S.R. may approach 200,000 tons. Approximately 50% of the production was based on copper-molybdenum ores from Armenia, Kazakhstan, Siberia, and the Mongolian People's Republic. Approximately 30% of the production was from tungsten-molybdenum ores of Tyrny-Auz (Kabardin A.S.S.R. in the North Caucasus) and Dzhida (Buryat A.S.S.R.). The remainder came from molybdenite ore mined in Uzbekistan and Siberia. There are over 100 known deposits of molybdenum, but most are too small to be mined economically.

Armenia was one of the leading Soviet producing regions, but concentrates were shipped out of Armenia for processing. The Zangezur copper-molybdenum complex in Armenia, combining the former Kadzharan and Kafan complexes, supplied approximately 25% of the Soviet molybdenum.

The largest Soviet producer was the Sorsk complex in Krasnoyarsk Kray, which operated the Sorsk open pit. Other producers included the Tyrny-Auz tungsten-molybdenum complex, which operated the Molibden underground mine and the Mukulanskiy open pit. The Chorukhdayransk concentrator processed copper-molybdenum ores from the Chorukhdayransk and South-Yashransk deposits in the Tadzhik S.S.R. Construction of the Zhireken molybdenum complex in Chita Oblast', north of Mongolia, was being conducted. In Kazakhstan at the Akchatau mining and metallurgical complex, where production was based on tungsten-molybdenum ore, facilities were reportedly put into operation at the Yugo-Vostochniy Mine for the production of high-metal-content molybdenum concentrate. In 1981, the Akchatau complex reported exceeding its production plan. However, results of construction work indicated that development plans for the complex for 1981-85 would be only one-half fulfilled. Also, in Kazakhstan, the Balkhash mining and metallurgical complex had difficulty securing raw materials, and in 1981, capacities for processing molybdenum were only 65% utilized.[49]

The Erdenet open pit copper-molybdenum complex in Mongolia, which was being jointly developed by the U.S.S.R. and Mongolia, had an annual projected capacity of 1,000 tons of molybdenum metal from concentrate. The ore at Erdenet averaged 0.85% copper and 0.012% molybdenum. In 1981, the Erdenet complex was projected to produce 660 tons of molybdenum in concentrate; 1980 production was approximately 490 tons.[50] The concentrate was shipped to the U.S.S.R. for processing.

Nickel.—In 1981, Soviet nickel production, including production from Cuban raw material, increased to an estimated 176,000 tons. The delay in bringing production capacities onstream at Noril'sk, the site of a rich copper-nickel deposit, prevented the Soviets from attaining planned growth. The

10th 5-year plan (1976-80) called for an increase of 20% to 30% in nickel production, but the actual increase was 8.8%.[51] During the 11th 5-year plan (1981-85), production of nickel was also targeted to increase by not less than 30%, and much of this increase was to come from Noril'sk.

Known Soviet nickel reserves, almost one-half of which consist of low-grade silicate ores, are estimated not to exceed 5 million tons of contained nickel. Over 50% of the total reserve is in cupriferous pentlandites containing recoverable copper, cobalt, platinum-group metals, and some minor metals. Sulfide ores were mined in Noril'sk in Krasnoyarsk Kray (East Siberia), and in the Pechenga-Monchegorsk area in the Kola Peninsula. Oxide ores were produced in the Aktyubinsk area of the southern Urals, the Ufaley area of the central Urals, and the Ukraine.

The centers of production in order of importance were Noril'sk, the Urals, and the Kola Peninsula. There were seven smelters in operation, of which Noril'sk was the most important. Following a close second to Noril'sk were the Ufaley, Rezh, and Khalilovo smelters in the Urals. The Monchegorsk and Pechenga smelters were third, and the Pobuzhsk ferronickel plant in the Ukraine was fourth. The Soviet Union was foreseen as playing an increasing role as a nickel exporter, based on both Soviet and Cuban concentrates.

During the 11th 5-year plan, the Severonikel complex on the Kola Peninsula planned to increase nickel production by 80% based on raw materials from Noril'sk. Work on installing additional facilities at the Severonikel complex was reported.

At the Nadezhda complex in Noril'sk, the nickel flash-smelting plant, with a capacity of 550,000 tons per year of nickel concentrates and built with Finnish equipment and technology, was reportedly completed at the start of 1982. A 33-kilometer copper-nickel slurry line to Talnakh was put into operation at Noril'sk in 1981.

Soviet nickel sales to gain hard currency were partly blamed for depressed world nickel prices in 1981 as the U.S.S.R. increased its nickel exports to market economy countries. Soviet imports of Cuban nickel in nickel-cobalt concentrate were approximately 18,000 tons in 1980. The Soviet Union was assisting in Cuban nickel development, including the construction of the Punta Gorda plant in Cuba, with a capacity of 30,000 tons per year of nickel and cobalt.

Platinum-Group Metals.—The U.S.S.R. was steadily expanding its output of platinum-group metals. The 1981 output was estimated at 3.35 million troy ounces. The U.S.S.R. was one of the world's largest producers and exporters of platinum-group metals, and Soviet ore reserves are adequate for increasing production and exports for many years.

Production of platinum and platinum-group metals occurred at the Noril'sk copper and nickel complex in Krasnoyarsk Kray in East Siberia, the Severonikel and Pechenganikel complexes on the Kola Peninsula, and several smaller placer deposits in the Urals. Virtually all platinum-group metals were produced as byproducts, with over 75% coming from Noril'sk.

Production was to increase at Noril'sk in 1971-75 by 60% over the 1970 level and in 1976-80 by approximately 80% over the 1975 level. Slow construction of the Nadezhda plant at Noril'sk, however, limited production increases to 4% to 5% annually. Problems in completing construction work on schedule at the Nadezhda plant persisted in 1981.[52]

Along with attainment of capacity at the Nadezhda plant, expansion of output at Noril'sk was to accelerate with the completion of the Oktyabr' underground mine. The Oktyabr' Mine, which had been under development since 1969, was to be completed in six stages. The first four stages were in operation, and the last two were scheduled for completion during 1981-85.

Silver.—The estimated 1981 output of silver was 46.5 million troy ounces. Almost all silver was produced as a byproduct of nonferrous operations, including gold treatment plants. Production was centered in the Urals, Kazakhstan, the Soviet Far East, East Siberia, and Armenia. Complex ores in the Urals contain 0.2 to 0.4 gram of silver per ton. Production of silver was projected to increase approximately 4% in 1980-85. Some of this increase was to come from the Noril'sk complex, which produced silver. Copper-nickel enterprises on the Kola Peninsula were also producing silver.

A number of plants produced secondary silver. The Moscow plant for secondary production of precious metals was the main producer. Secondary sources included photographic film ash.

Tin.—Primary tin production in 1981 was estimated at 36,000 tons. By the mid-1980's, tin output was projected to reach 40,000

tons, based on new production from existing or developing mines in the Soviet Far East and Central Asia.

Despite Soviet policy to achieve self-sufficiency in mineral production, tin output continued to be inadequate, and imports accounted for approximately 25% of requirements. The major Soviet tin-producing areas were the Soviet Far East, Yakutia, and Transbaykal. Approximately 25% of total output was from placers, of which the Soviet northeast accounted for 75%.

Intensive exploration programs were being carried out for tin reserves. Positive results were reported in Magadan Oblast', Khabarovsk Kray, the Yakut A.S.S.R., and the Kirgiz S.S.R. In 1981, the Kirgiz Directorate for Geology planned a 3% increase in tin reserves for the Kirgiz S.S.R. Soviet gross tin reserves are currently estimated at 600,000 tons of contained metal, and the average content of tin ore ranges from 0.6% to 1% tin.

The largest tin-producing region was the Maritime Kray in the Soviet Far East. The major producer in the Maritime Kray was the Khrustal'nyy complex, which operated both lode and placer deposits. The Khrustal'nyy complex operated the Khrustal'nyy, Ege-Khaya, Imeni Lazo, Kholodnyy, and Alyaskitovyy Mines.

The largest tin producer in the U.S.S.R. was the Khingan complex, in Birobidzhan (Jewish Autonomous Oblast'), Khabarovsk Kray, of the Soviet Far East. At Khingan, renovation of the concentrator occurred in 1979, and the Berezovyy Mine and a mine near Obluchye were under development. The Solnechnyy complex in Khabarovsk Kray operated the Solnechnyy, Molodezhnyy, and Pereval'nyy Mines. At the Pereval'nyy Mine, a 7-kilometer tunnel was completed that was to serve as the main transport artery for the mine. The concentrating plant at the Solnechnyy complex was undergoing renovation, and a metallurgical plant was to be constructed.

There were three known tin refineries operating in the U.S.S.R. at Novosibirsk, Ryazan', and Podol'sk, near Moscow. Concentrates from Siberia and the Soviet Far East were sent to the Novosibirsk plant, which was the principal Soviet tin supplier.

Construction of a tin complex during 1981-85 was being planned in the Kirgiz S.S.R. on the Saryzhaz River not far from the village of Inyl'chek in Issyk-kul'skaya Oblast'.

In 1981, Bolivia was reportedly having trouble with the La Palca plant being built near Potosi with Soviet technical and financial assistance. The complaint was that the plant was causing serious contamination of agricultural land. The Soviet Union was also assisting tin development in Vietnam and Laos, presumably in exchange for tin.

Titanium.—Titanium production in 1981 was estimated to have increased to 38,500 tons. The 11th 5-year plan, 1981-85, called for an increase in titanium production. During 1976-80, production of titanium was programed to rise 40%, but during this period, production increased only 19%.[53] The industry continued to be based mainly on Ukrainian and Siberian ilmenite and rutile. Soviet reserves of TiO_2 have been estimated at approximately 10 million tons, contained in 70 million tons of ore averaging 10% to 20% TiO_2.

The Soviet Union exported titanium sponge to Western countries in 1981, and reportedly was to export titanium sponge at competitive market prices in 1982. Decreased Soviet titanium sponge trading activity in 1979 and 1980 caused confusion as reports circulated that the Soviets planned to cut off titanium exports to some Western World buyers. The Soviets claimed that they had continued to offer titanium sponge, but that importers were unwilling to meet their price. In 1981, the United States imported Soviet titanium sponge valued at $1.75 million compared with $2.7 million in 1980.

The most important sources of Soviet ilmenite are placer deposits on two right-bank tributaries of the Dnieper River in the Ukraine. Deposits with major production are the Samotkanskoye zirconium-titanium alluvial deposit; the Volchanskoye titanium deposit in Dnepropetrovsk Oblast'; the Irshanskoye, Streminogorskoye, and Zelenogorskoye titanium deposits in Zhitomirskaya Oblast'; and the Tarasovskoye deposit in Kiyevskaya Oblast'. These deposits were operated by the Verkhnedneprovskiy and Irshanskiy complexes. The Irshanskiy complex made use of dredges. Four stages of the Irshanskiy concentrator were in operation in 1980.

The Ust'-Kamenogorsk titanium-magnesium complex in Kazakhstan, a 16-year-old enterprise, planned to increase titanium production 27.1% during 1981-85. This was equivalent to the total growth in titanium output planned in Kazakhstan, in which the Ust'-Kamenogorsk complex was the only producer. In 1981, the Ust'-Kamenogorsk

enterprise exceeded its quota for titanium sponge production by 0.8%. Other major Soviet titanium producers included the Berezniki titanium-magnesium plant, the Dneprovsk titanium-magnesium plant, the Moscow titanium sponge works, and the Khar'kov plant.

Tungsten.—Production of tungsten in concentrates in 1981 was estimated to have increased by less than 2% to 8,850 tons. In 1981, Soviet tungsten production was again insufficient for domestic needs. The Soviets were reportedly seeking to purchase approximately 1,500 tons of tungsten concentrate in the fourth quarter of 1981, and there were reportedly greater than usual Soviet tungsten purchases in 1981.

Principal tungsten-producing regions were the North Caucasus, Kazakhstan, Uzbekistan, Transbaykal, and the Soviet Far East. Most of the deposits in the U.S.S.R. are low grade. The large Tyrny-Auz deposit in the North Caucasus contains both molybdenum and tungsten. The largest deposits in Kazakhstan are the Verkhne-Kayraktin tungsten and Akchatau molybdenum-tungsten deposits. There are considerable reserves of tungsten in the Ingichka deposit in Samarkand Oblast', Uzbekistan, and the Dzhida deposit in the Buryat A.S.S.R.

The main producer of tungsten concentrates is the Tyrny-Auz tungsten and molybdenum complex in the North Caucasus, where both underground and open pit methods were used. The Nal'chik plant produced tungsten metal from Tyrny-Auz concentrates. In Kazakhstan, the Akchatau mining and metallurgical complex fulfilled its production plan for 1981. However, results in 1981 indicated that construction planned for 1981-85 at Akchatau would be only one-half completed in that time.[54]

Tungsten production capacity was expanding in the Soviet Far East. At the Iul'tin complex, the only tungsten mining enterprise in Magadan Oblast', intensive improvement was reportedly carried out. During 1976-80, the Vostok tungsten mining and concentration complex was established in the Soviet Far East. Also in the Soviet Far East, the second stage of the Maritime Kray complex was under construction.

In Soviet Central Asia, tungsten development was slated for the Kirgiz S.S.R., and exploitation was reportedly beginning at an unnamed tungsten deposit in Samarkand Oblast', Uzbekistan; Samarkand Oblast' contains the large Ingichka deposit.

Vanadium.—The Soviet Union was a large vanadium producer with an estimated production in 1981 of 9,500 tons. The principal source of vanadium is as a coproduct with iron from open pits at the Kachkanar complex in Sverdlovsk Oblast' in the Urals, where expansion was planned during 1981-85. Expansion of Kachkanar was currently the only practical means for increasing vanadium production.[55] Projections indicated that increased production at Kachkanar could be achieved at the earliest by 1985.[56] Ways were being developed to extract vanadium from powerplant ash, but work was only in the research stage. The vanadium lost in powerplant ash reportedly could provide one-quarter of domestic industrial consumption.[57]

Vanadium-bearing slag was produced in the Urals at the Nizhniy Tagil metallurgical complex and the Chusovoy metallurgical plant. The Nizhniy Tagil complex, where the vanadium slag was produced in 130-ton oxygen converters, was the only modern producer. The vanadium content of the pig iron was 0.45% at Nizhniy Tagil and 0.54% at Chusovoy. After processing of the pig iron, the average V_2O_5 content of the resulting slag at Nizhniy Tagil was 21.2%, and at Chusovoy, 17.2%.

Although enlargement of the Kachkanar complex for processing from 33 to 40 million tons of iron ore annually was completed, delays in construction of facilities for additional vanadium processing at the Nizhniy Tagil metallurgical complex slowed the increase in output of vanadium products.

Minor Metals.—The Soviet Union possesses commercial deposits of all the metals that have assumed importance in modern rocketry, aircraft, and nuclear energy. However, extraction of many of the metals remained low. During 1981-85, the production of rare metals was to double in East Kazakhstan Oblast' with metallurgical facilities at Leninogorsk, Ust'-Kamenogorsk, and Zyryanovsk. The growth in extraction of rare-metal concentrates in 1979 compared with 1970 output at the Belogorsk complex in eastern Kazakhstan was 3.8% at the Ognevsk plant, 6.6% at the Belogorsk plant, and 2.37% at the central finishing plant.

The main deposits of rare metals are in Kazakhstan, Kola Peninsula, Uzbekistan, Armenia, Urals, Ukraine, Noril'sk, Transbaykal, and the Soviet Far East. Explored reserves were considered adequate to en-

sure the planned rate of growth for all rare metals during 1981-85 and for most rare metals until 1990. The limiting factor in increasing production of rare metals was construction delays.[58]

The primary sources of rhenium are molybdenite from copper-molybdenum deposits of Armenia, Kazakhstan, and East Siberia. Byproduct rhenium was recovered at the Balkhash and Dzhezkazgan complexes and the Chimkent lead plant in Kazakhstan, the Khadzharan copper-molybdenum complex in Armenia, and at the hard-alloy plant in Uzbekistan.

The selenium content in the copper-molybdenum ores of Armenia ranged from 3.6 to 10.5 grams per ton, and that of tellurium, from 1.5 to 6.2 grams per ton. There were 110 grams of selenium per ton and 40 grams of tellurium per ton in the charge of the Alaverdi metallurgical complex in Armenia.

Byproduct gallium was recovered from raw materials used to produce alumina at the Volkhov (Leningrad Oblast') and Pavlodar (Kazakhstan) aluminum plants and at the Tikhvin (Leningrad Oblast') alumina plant. The main centers of indium and thallium extraction were the Ust'-Kamenogorsk lead-zinc complex (Kazakhstan) and the Chelyabinsk zinc plant (Urals).

In 1976-80, recovery of thallium at the Chimkent lead plant in Kazakhstan increased 3.4%. The Ust'-Kamenogorsk titanium and magnesium complex in Kazakhstan began recovering scandium, and recovery of scandium and lanthanum from slime from alumina plants in the Urals was being studied. During 1976-80, output of minor metals at the Ust'-Kamenogorsk lead-zinc complex increased as follows: indium, 80%; gallium, 95%; and selenium, 70%.

The decade 1965-75 saw the start of production of rhenium in Kazakhstan at the Balkhash and Dzhezkazgan copper complexes and the Chimkent lead plant. The recovery of rhenium at the Dzhezkazgan complex increased from 3.1% in 1973 to 42.0% in the first half of 1980. The Chimkent lead plant produced thallium, tellurium, and germanium. In 1980, facilities for the production of tantalum from tailings at the Ognevsk and Belogorsk concentration plants of the Belogorsk complex in Kazakhstan were put into operation.

The Soviets claimed that the world's largest columbium and tantalum deposits lie within the boundaries of the Lovozero massif in the Kola Peninsula. Two underground mines, Karnasurt and Umbozero, were in operation at Lovozero. Smaller columbium-tantalum-bearing deposits are located in the Caucasus, Transbaykal, Ukraine, and Urals. Tantalum was produced as a byproduct at the Orlovskiy mining and concentration complex in Chitinskaya Oblast'. Soviet ilmenite concentrates contain an average of 0.12% Cb_2O_5 and 0.008% Ta_2O_5.

The Verkhnedneprovskiy complex in the Dneprovsk Oblast' in the Ukraine was exploiting an alluvial zircon deposit. The complex, brought into operation in 1969, increased production of zircon concentrate in 1980.

NONMETALS

Asbestos.—Asbestos production in 1981 was estimated at 2.11 million tons. The Soviet asbestos industry was the largest in the world. Over one-half of the production came from the Uralasbest complex in the central Urals, and over one-fourth of the output came from the Dzhetygara deposit in Kustanay Oblast', Kazakhstan. Other important producers included the Tuvaasbest complex in the Tuva A.S.S.R. in East Siberia and the Kiembay complex in Orenburg Oblast' in the southern Urals.

At the Uralasbest complex, production was reported at 1.26 million tons in 1979 and at 1.24 million tons in 1978; in 1980, three open pits produced 149 million tons of ore and overburden, producing approximately 1.19 million tons of marketable asbestos. In 1981, ore mining increased to a total of 173 million tons of ore and overburden, but production of marketable asbestos decreased to 1.16 million tons because of reduced ore grades. Construction of the No. 7 concentrator, with a capacity of 340,000 tons per year, was planned. Three concentrators were in operation.

At the Dzhetygara deposit in Kustanay Oblast', Kazakhstan, the first mill, with a capacity of 200,000 tons per year, was commissioned in 1965. During 1971-75, the mill was renovated, and production increased from 259,000 tons per year in 1970 to an estimated 350,000 tons per year in 1981. The Dzhetygara No. 2 mill, with a capacity of 400,000 tons per year, was completed in 1975 and produced an estimated 290,000 tons in 1980. Output at the Dzhetygara complex was estimated at 640,000 tons in 1981.

At the Tuvaasbest complex, the first mill was commissioned in 1964, and a second mill was commissioned in 1976. Output at

this complex in 1981 was estimated at 110,000 tons.

Construction of the Kiembay complex in Orenburg Oblast' (southern Urals) was started in 1968 and was continuing in 1981. Seven CMEA members assisted in the construction. Design capacity was 500,000 tons per year of grades III and IV from 24 million tons of ore with an average grade of 4.4%. The project was being developed in two stages of 250,000 tons per year each. The first stage was completed in December 1979 and was estimated to have produced 130,000 tons in 1981. The second stage was put into operation in December 1980 and was estimated to have produced 70,000 tons in 1981.

One-third of the output of the Kiembay complex was to be exported to the participating CMEA countries in return for their one-third investment of 106.2 million out of 300 million rubles. According to the plan, starting in 1981, about 170,000 tons of asbestos was to be exported annually to the participating countries for 12 years, after which they would be able to extend the agreement for an additional 10 years. However, this goal was not met in 1981; in December, the yearly delivery of asbestos from Kiembay to CMEA countries was reported as approximately 65,000 tons.[59]

At the Sayan asbestos deposits, on the border of Krasnoyarsk Kray and the Tuva A.S.S.R. in East Siberia, reserves were estimated at 7 million tons of asbestos. The asbestos lies at a comparatively shallow depth and was to be mined by open pit methods. Exploration was completed, and development of the Lenin complex, with a capacity of 200,000 tons per year, was underway.

Barite.—Estimated barite production in 1981 remained at 500,000 tons. About 50% of the country's barite consumption was imported, mainly from North Korea, Yugoslavia, and Bulgaria. Main centers of domestic production were Georgia, West Siberia, and Kazakhstan at the Zhayremsk mixed-sulfide complex. During 1981-85, production was to greatly increase at the Zhayremsk complex; the second stage of the complex was to achieve its design capacity in 1988. The complex fulfilled its production plan for 1976-80. The complaint was raised in 1981 that projected capacities for barite recovery from Zhayremsk ore were not being achieved at concentration plants at the Achisay polymetallic complex and the Tekeli lead-zinc complex.[60] The Zhayremsk area reportedly was extremely rich in barium sulfate, with approximately one-fourth of the world's reserves. More than 40% of the barite ore could be surface mined. In addition, rich deposits of barite were reportedly discovered in the Komi A.S.S.R., and development was underway of a 45,000-ton-per-year complex in Svanetiya, Georgia.

Diamonds.—In 1981, diamond output was estimated very roughly to have decreased to 8.5 million carats of industrial quality and 2.1 million carats of gem quality owing to more difficult mining conditions. The diamond industry was centered in Yakutia, where about 20 deposits have been discovered. Included among known producers were the Mirnyy open pit with five concentrators, the Aykhal open pit and concentrator, the Udachnaya placer mine and concentrator, and the Irelyakh placer mine with two dredges. Small quantities of gem and industrial stones were produced from the Vishera River region in Perm Oblast' (western Urals) with four dredges and two separation plants in operation at two deposits.

After fossil fuels and precious metals, diamond exports were one of the significant earners of hard currency. Gem stones were cut in Leningrad, Sverdlovsk, and Smolensk. The U.S.S.R. marketed part of its diamond output in Antwerp through a Soviet-Belgian diamond export organization, Almazyuvelirexport, in which the Soviet Union had controlling interest.

A substantial, but unknown, quantity of synthetic diamonds was produced by plants in Kiyev, Moscow, Poltava, Tashkent, and Yerevan. In 1981, at the Yerevan plant, the production of synthetic diamonds and diamond instruments increased 20% compared with 1980 output. The Kabardino-Balkar synthetic-diamond-instrument plant, Imeni Leninskogo Komsomola, was the only plant in the country producing diamond drilling instruments and rollers for accurate finishing of abrasive grinding disks. The plant, located in Terek, in 1981 reported exceeding its plan. Also, during 1976-80, production of diamond instruments in Moscow reportedly increased 16.9%.

During the 1980's, there was to be intensified geological exploration for diamonds. In 1981, diamond prospecting was reported in the European part of the U.S.S.R., including the western Ukraine and Byelorussia. In 1981, in Yakutia, the sinking of two 1,000-meter-deep shafts was started at a new diamond mine, scheduled to go into operation during 1981-85. One shaft, with

a diameter of 6.5 meters, was to be used for extraction, and the other, for ventilation. In the village of Nadezhda in the north of Yakutia, the large Nadezhda concentration plant was being renovated but was reported working at full capacity during renovation.

Fluorspar.—Despite efforts to achieve self-sufficiency, the Soviet Union remained a net importer of fluorspar, with imports providing approximately one-half of domestic consumption. Fluorspar imports came mainly from China, Mongolia, and Thailand.

Soviet production of fluorspar in 1981 was estimated at 530,000 tons. The main production areas were the Maritime Territory (Yaroslavsk deposit), Transbaykal (Kalunguy, Abagatuy, and Usugli deposits), Uzbekistan, and Kazakhstan. Small quantities were produced in Tadzhikistan and other regions. The mined ore contained 20% to 45% CaF_2. The iron and steel industry consumed more than 85% of the fluorspar, and increases in consumption had been well ahead of increases in production. During 1981-85, the Republic Ministries of Geology for Kazakhstan and Uzbekistan set goals to increase the reserves of fluorspar by 5% and 2%, respectively.

Mica.—Mica output, estimated at 47,000 tons in 1981, was inadequate to meet demand, and strategic-grade mica was imported from India. The mica industry included the following four mining and beneficiation complexes: Aldan mica (Yakutia), Karel mica (Karelia), Kovdor mica (Murmansk Oblast' on the Kola Peninsula), and Mam mica (Irkutsk Oblast').

Mamsko-Chuyskiy County in Irkutsk Oblast' contains about 75% of the country's muscovite deposits. Nine small underground mines were in operation there in 1980. Vermiculite was mined at the Kovdor mica complex in Murmansk Oblast', at the Yena, Pikolatva, and Kovdor underground mines, and a vermiculite open pit. Capacity of the concentrator at Kovdor was 56,000 tons per year. The Karel mica complex in Karelia operated the Plotina, Malinovaya Varakka, and Tedino underground mines.

In 1981, production of strategic-grade byproduct mica increased at the Ognevskiy Mine of the Belogorsk polymetallic complex in Kazakhstan. Byproduct mica production began in 1981 at the Orlovskiy lead-zinc mining complex in Chita Oblast', Siberia, where the first 200 tons were reportedly produced. Price negotiations between India and the U.S.S.R. intensified in 1981 as India again wanted a price increase for mica. The U.S.S.R. was traditionally India's largest buyer of mica, and Indian mica exports also went to the six East European CMEA states.

Mineral Fertilizers.—In 1981, output of mineral fertilizer totaled 26 million tons in nutrient content, approximately 109 million tons in bulk fertilizer, less than the 1981 target of 113.8 million tons.[61] Estimated production, in nutrient value, of nitrogen fertilizers constituted about 41%; potassium fertilizers, 33%; phosphate fertilizers, 23%; and phosphate flour, 3% of total fertilizer production. Table 11 shows production of fertilizer raw materials in 1980 and the 1985 plan targets. The Soviet mineral fertilizer industry in 1985 planned to produce 150 to 155 million tons of bulk fertilizer.

There were many problems in supplying fertilizer to farms. In 1981, there was an insufficient delivery to farms of 1.2 million tons (nutrient value) of fertilizer, including 0.2 million tons of nitrogenous, 0.1 million tons of phosphate, and 0.9 million tons of potassium fertilizers.[62] Problems in supplying fertilizer to farms occurred at every stage of the production-supply cycle. Problems caused by delays in putting production facilities into operation were compounded by problems in transport and storage.[63]

About 85% of the mineral fertilizer output was produced at enterprises subordinate to the recently created Ministry of Mineral Fertilizer Production. The rest was supplied by the Ministries of Petroleum Refining and Petrochemicals, Nonferrous Mining and Metallurgy, Ferrous Mining and Metallurgy, and others. Mineral fertilizer production was distributed to over 13 of the 15 Soviet republics.

During 1981-85, the Ministry of Fertilizer Production planned to put into operation 13 ammonia production units, each with an annual capacity of 450,000 tons. In 1981, 450,000-ton-per-year ammonia plants were put into operation at the Pridon chemical plant at Rossosh' (Voronezh Oblast') and at the Tolyatti "Azot" firm. In 1981, construction was completed of the approximately 2,400-kilometer-long Tolyatti-Odessa ammonia pipeline with an annual capacity of 2.5 million tons of liquid ammonia. The U.S. embargo of exports of superphosphoric acid to the U.S.S.R. was lifted in 1981, allowing the Occidental Petroleum Corp. to resume deliveries, for which Occidental imported ammonia in exchange.

Table 11.—U.S.S.R.: Fertilizer raw material production

(Thousand tons)

	1980	1985 (planned)
Potash ore	60,800	92,000
Apatite-nepheline ore (17.7% P_2O_5)	46,000	53,200
Sedimentary rock (13% P_2O_5)	24,800	32,100

Source: Shakhtnoye stroitel'stvo (Mine Development), Moscow. No. 12, December 1981, p. 3.

Phosphate.—The estimated 1981 output of phosphate rock totaled 73 million tons, including 47.5 million tons of apatite ore (17.7% P_2O_5) and 25.5 million tons of sedimentary rock (13% P_2O_5). Plans for 1985 called for extraction of 53.2 million tons of apatite ore and 32.1 million tons of sedimentary phosphate rock.

The main centers for phosphate production were the Apatit Association on the Kola Peninsula and phosphate deposits at Karatau in Kazakhstan. The Chilisay phosphorite basin in Aktyubinsk Oblast', Kazakhstan, was under development and was to be a major center of phosphorite production. Generally, low-grade deposits of phosphorites also occur in Upper Kama in the Urals, Yegor'yevsk and Lopatino in Moscow Oblast', Kingisepp in Leningrad Oblast', and other regions. Apatite concentrates provided the majority of all phosphate production. During 1981-85, the output of mineral fertilizers was to increase 50%, and the most rapid growth was to be for phosphorus fertilizers. Soviet exports of apatite concentrate to Western Europe have been progressively reduced in recent years.

The largest single phosphate source is the Khibiny apatite-nepheline deposit on the Kola Peninsula. Mined ore averaging 17.7% is upgraded to 39.4% P_2O_5. At the Karatau phosphate basin, in Kazakhstan, there are over 40 commercial deposits. The five largest deposits contain more than one-half of the reserves at Karatau. The 1981-85 plan called for production of phosphate rock at the Karatau Basin to increase by 50% over that of 1980.

As of January 1, 1980, reserves in place in categories $A+B+C_1$ were approximately 1.5 billion tons of P_2O_5 in 14 billion tons of ore. These reserves are in the apatite-nepheline ore of the Khibiny deposit and the phosphorites in the Karatau Basin, accounting for 37% and 26% of the reserves, respectively. The remaining reserves are the phosphorites in the European part of the country and the apatite and phosphorites in Siberia. In addition, there are approximately 550 million tons of reserves in category C_2. The majority of the reserves is low-quality ore that is difficult to process, and the ore bodies are in distant, labor-deficient areas requiring high capital investment.[64]

Increased demand for phosphate raw material necessitated both development of new capacities and increasing the volume of production at existing developments. Only 40% of the economic reserves are categorized as easy to concentrate. During the past 10 years, the average P_2O_5 content of the reserves has decreased from 14.3% to 13.1%, and the average P_2O_5 content of new deposits was only 10.8%. This was accompanied by an increase in the depth of open pits, an increase in underground extraction, and an absence of effective concentration technology for complex ores. For ore with a complex mineral composition, P_2O_5 recovery did not exceed 65% to 75%, and the average P_2O_5 content of prepared concentrate was 24% to 28%. Owing to the discovery of new apatite deposits with poor-quality ore, the P_2O_5 content of apatite ore was projected to decrease by 40% to 50% compared with that of 1975.[65]

Phosphorites from the Karatau Basin have been mined for over 40 years. During 1981-85, capacities at the Karatau complex were to increase by 8.5 million tons of ore and 2.5 million tons of concentrate. In 1981, only 57% of the ore mining capacity at the Karatau complex was being used, and capacity utilization had been declining during the past 5 years. Therefore, the building of new capacities was questioned.[66] Along with the development of the 4.75-million-ton-per-year Kok Dzhon Mine, construction of the Kok-Su Mine was planned. The first stage of Kok-Su was to begin operations during 1981-85. In the Karatau Basin, it was intended to change a number of sites to underground mining. By 1985, annual output of the Karatau complex was to exceed 20 million tons of ore.

At the Khibiny deposit on the Kola Peninsula, the Apatit firm's production of apatite concentrate was approximately 17.3 million tons in 1980 and was to increase to approximately 19 million tons by 1985. The percentage of underground mining was also to increase. In 1980, open pit mining accounted for 64% of apatite-nepheline ore extraction. For 1973-80, goals were not met

for underground mining but were surpassed for surface mining.[67] The cutoff grade of apatite-nepheline ore from open pits was 6% P_2O_5, and from underground mines, 8% P_2O_5. However, the Oshurkovskiy apatite deposit in the Buryatskaya A.S.S.R., with under 4% P_2O_5 content, was being developed. Other deposits with low P_2O_5 content to be developed included Kovdor (3% to 6% P_2O_5), Chilisay (9% to 10%), Toolse (10%), and Seligdar (6%).

The Koashva (Vostochniy) open pit, with a capacity of 7 million tons per year of ore, in Murmansk Oblast', assigned to the Apatit Association, was rescheduled for completion in 1981 after delays in 1980. The first stage, 2.4 million tons, went into operation in late 1981. In 1981, construction began on the No. 3 concentration plant at the Apatit firm. It was designed with a projected capacity of 8.8 million tons per year of apatite and was to concentrate low-quality ore from the Koashva deposit. The first stage was to go into operation during 1981-85. At the Apatit Association, development of the N'yurpakhsk open pit was underway, and the Tsentral'nyy open pit was to increase its capacity by 4 million tons to 25 million tons per year of ore. The Apatit Association also operated the Kirovskiy, Yuksporskiy, and Rasvumchorskiy Mines.

Development of the Chilisay deposit and construction of the Chilisay complex in Kazakhstan, which continued in 1981, were reported to have experienced significant delays.[68] In 1981, construction continued of the mining and concentration enterprises based on this 9% to 10% P_2O_5 phosphorite deposit.

The Seligdar apatite deposit in South Yakutia was undergoing extensive exploration. A mining-concentration complex along with a city of 50,000 inhabitants were envisioned for this deposit. Explored reserves in place at the end of 1981 consisted of 1.6 billion tons of ore, or 108.5 million tons of P_2O_5. The complex was projected to process 41 million tons of ore annually, producing more than 4 million tons of apatite concentrate and more than 13 million tons of phosphate fertilizer. This complex was to provide fertilizer for East Siberia and the Soviet Far East, which was being shipped at high cost from Karatau and the European part of the U.S.S.R.

Potassium.—The 1981 estimated output of potassium ore was 63 million tons, 8.35 million tons of K_2O equivalent. The 1985 plans called for production of 92 million tons of ore; original plan targets for 1976-80 called for potassium ore output to rise to 85 to 90 million tons by 1980. Potash exports were reported to have increased to 3 million tons of K_2O equivalent in 1981 with a 30% increase to East European markets, most noticeably to Poland. All other East European members of CMEA, except Yugoslavia, took a greater volume of potash. Potash exports to Western Europe, however, decreased. The major potash centers were Solikamsk and Berezniki on the western side of the central Urals, Soligorsk in Belorussia, and Stebnik and Kalush in the western Ukraine. Potash reserves are estimated at 3.8 billion tons of K_2O.

Potash production was administered by the All-Union Production Association Soyuzkaliy, which had five subordinate firms. During 1981-85, two new facilities were to be added to the five firms, the Novosolikamsk and the Berezniki No. 4 plants, each with two stages and capacities of 18.1 and 16.1 million tons per year, respectively. In Belorussia, which produced about 50% of the Soviet output of potash, the increase in output was to be mainly achieved by increasing extraction at the Soligorsk No. 4 complex to 17.9 million tons per year of ore. The mining depth at this complex was to reach 1,200 meters.

Plans to add new facilities were criticized because production capacities were not being fully utilized at existing enterprises.[69] For example, the Uralkaliy firm, which had a design capacity of 12 million tons of potassium fertilizer, in 1979 produced only 6 million tons, and in 1980, 8.3 million tons.[70] For 1979 and 1980, the Belaruskaliy firm did not fulfill the production plan, and production problems persisted in 1981. The Belaruskaliy firm's failure to meet production goals was attributed to production problems at the Soligorsk No. 4 complex, the first two stages of which were put into operation during 1976-80. Lagging production at Soligorsk No. 4 was blamed on delays in installing equipment along with the installation of faulty and obsolete equipment.[71] Attempts were also made to blame poor worker performance.[72]

A large potash deposit, estimated to be five times greater than the Solikamsk deposit, was reportedly discovered in Irkutsk Oblast'. The deposit, which covers an area of approximately 10,000 square kilometers, is located at a relatively shallow depth and consists of several seams 1.5 to 5 meters thick. Mining of this deposit was scheduled to start in 1985. Based on past Soviet experience, development of a mining proj-

ect, particularly in this distant region, in that period of time is doubtful.

Salt.—The Soviet Union was one of the world's leading countries for salt production, reserves, and exports. Soviet salt production in 1981 was estimated at 14.6 million tons. Exports were an estimated 500,000 tons. Over one-third of the Soviet salt production came from Lake Baskunchak in Astrakhanskaya Oblast', R.S.F.S.R., and over 40% came from the Donets Basin. The Artemsol' concern, which mined rock salt in the Donets Basin from five underground mines, was the main salt supplier. This concern had a 14,000- to 15,000-ton-per-day design capacity but was operating at approximately two-thirds capacity owing to production and transportation problems. Similar problems existed at other Soviet salt enterprises. These included Aral'sk salt, Pavlodar salt, and the Iletsk Mine. Original plans called for salt output to increase to 20 million tons by 1980, but these plans were revised to 14.7 million tons. In 1981, a salt mine at Khodzhaikan in Uzbekistan was under development along with a crushing and sorting plant with a capacity of 1 million tons per year.

Sulfur.—In 1981, estimated production of contained sulfur totaled 11.2 million tons, of which 3.6 million tons was recovered from pyrites, 3.8 million tons from native sulfur, and 3.8 million tons from other elemental sulfur sources.

The principal producers of native sulfur were Rozdol and Yavorov (western Ukraine), Gaurdak (Turkmen S.S.R.), and the Volga group of the Kuybyshev sulfur complex. Native sulfur sources are concentrated in four regions: the Carpathian, Soviet Central Asia, central Volga, and the Soviet Far East.

At the Yavorov and Gaurdak plants, where production began in 1968, approximately 30% of the output of native sulfur was produced by the Frasch process. During 1981-85, the development of mines using the Frasch process was to account for the basic growth in sulfur production. Mines using this process were to be developed at the Staroyazovskiy site of the Yavorov complex and also at the Zagaypol'skiy and Grimnovskiy sites. In 1981, the Nemirov Mine in L'vov Oblast' in the Ukraine, with a capacity of 250,000 tons per year, began production using the Frasch process.

Open pit ore extraction was to increase. At the Yavorov complex, the Tsentral'nyy open pit was to increase capacity, and the Yuzhniy open pit was to go into operation.

In 1981, approximately 1.25 million tons of sulfur was recovered from sour gas. Sulfur ore production in 1985 was to increase to 14.3 million tons.

MINERAL FUELS

Estimated primary energy production derived from fossil fuels, fuelwood, and hydroelectric and nuclear generation increased from 1,936 million tons (standard coal equivalent) in 1980 to 2,146 million tons in 1981. Total consumption of all types of primary energy increased from 1,638 million tons in 1980 to 1,862 million tons in 1981. In 1981, the U.S.S.R. produced 4.48 billion barrels of crude oil, which was slightly below the planned target but a 0.9% increase over 1980 output, and 16.4 trillion cubic feet of natural gas (planned target 16.2 trillion cubic feet), which was a 7% increase over 1980 output. Production of coal, however, which was to be increasingly substituted for oil, decreased 2% to 704 million tons of raw coal.

In addition to coal, natural gas was to be of increased importance as a substitute for oil and as a hard-currency-earning export commodity. Revenues earned from the increased sale of natural gas could be used to purchase advanced technology and equipment to increase oil production. Nuclear power was to be of increasing importance for domestic electric energy production. By 1985, nuclear power capacity was to increase by about 25,000 megawatts, raising total capacity to 40,000 megawatts, and was to provide 14.2% of the electric energy, compared with 5.6% in 1980. In 1981, expansion of nuclear power generation was not occurring as rapidly as planned.

Table 12.—U.S.S.R.: Estimated total primary energy balance in 1981

(Million tons of standard coal equivalent)

	Production	Imports	Exports	Apparent consumption
Total primary energy	2,146	30.0	314	1,862.0
Coal (lignite, anthracite, bituminous, coke)	622	16.5	23	615.5
Crude oil and petroleum products	895	8.8	221	682.8
Natural and associated gas	549	4.7	68	485.7
Peat	14	--	--	14.0
Oil shale	13	--	--	13.0
Hydropower	22	--	2	20.0
Nuclear power	7	--	--	7.0
Fuelwood	24	--	--	24.0

Coal.—In 1981, the Soviet Union produced 704 million tons of run-of-mine coal, which was 2% below 1980 production and the third successive year of decreasing production. Capacities for extracting 5 million tons of coal were put into operation in 1981. The Donets Basin was one of the major areas with slumping coal production. The decline in coal production was blamed on unfavorable mining conditions and missed deliveries of rolled steel, timber, electric motors, railroad equipment, and spare parts for mining machinery.[73] General problems that affected the development of the industry included construction delays, slow attainment of installed capacities, low level of technology and equipment, and inefficient use of labor.[74] The domestic coal supply was further hurt by a large drop in imports from Poland. The decline in coal production led to fuel shortages accompanied by some restrictions on the sale of coal to the population. Along with declining production, there was a sharp deterioration in the quality of coal.[75]

To increase worker incentives, a pay raise was announced in 1981 for coal miners. The new wage scale was to take effect in the first quarter of 1982 in the Donets, Kuznetsk, Karaganda, Ekibastuz, and Pechora coal basins, and in the remaining areas in 1983.

Output of surface-mined coal was 268 million tons (37% of the total) in 1980 and 273 million tons (39% of the total) in 1981. The 1985 plan target called for surface-mined coal output to increase to 315 million tons, 41% of the total output.

Table 13 shows 1980 coal output and planned 1985 coal output from the major basins. As can be seen from table 13, the largest planned increases among major producers were in Siberia and the Soviet Far East in the Kuznetsk, Ekibastuz, Kansk-Achinsk, and Yakutsk Basins.

There were approximately 800 underground coal mines in the Soviet Union, each with an average capacity of about 500,000 tons per year of raw coal, and in 1981, there were 73 open pits in operation, each with an average output of about 3.7 million tons of run-of-mine coal or lignite. Those open pits with the largest design capacities included the Bogatyr', 50 million tons per year; Tsentral'naya, 20 million tons per year; Irsha-Borodinskiy, 20 million tons per year; Nazarovskiy, 13 million tons per year; and Azeyskiy, 10 million tons per year.

Table 13.—U.S.S.R.: Coal production by major basins

(Million tons unless otherwise specified)

Basin	1980 production	1985 planned production	1985 planned increase over 1980, percent
Donets	204	210	3
Kuznetsk	141	154	9
Ekibastuz	66	84	27
Karaganda	48	50	4
Kansk-Achinsk	35	48	37
Pechora	28	28	0
Moscow	25	20	-20
Yakutsk	3	12	400

Ekonomicheskaya gazeta (Economic Gazette), Moscow. No. 7, February 1982, p. 1.

Despite the fact that coal mine construction was transferred directly to the Coal Ministry, construction delays persisted. Pravda stated that "it can hardly be considered normal" that the Samsonovskaya-Zapadnaya Mine had been under development for 17 years with still no end in sight. Furthermore, several mines were commissioned with considerable defects that delayed achieving design capacity. As an example, although the Dolzhanskaya Kapital'naya Mine was commissioned in 1981, it was producing far less than was planned.[76]

Coal preparation for the market did not play a great role and was generally restricted to coking coals and coal for exports. Practically all Soviet coal required beneficiation, but less than one-half was treated. Some 66 preparation plants treated coking coal, 38 plants processed anthracite, and 50 plants treated coal and lignite for powerplants. The official ash content of coal shipped to consumers was 20.3% in 1980. Approximately 20% of the coals and lignites delivered annually to powerplants were substandard. The shortage of coal beneficiation facilities forced Soviet planners to call for increasing the quantity produced.

Natural Gas.—Natural gas production had been increasing at higher than the planned rate and was in part to compensate for lagging oil production for domestic consumption and export. Natural gas production was growing 7% or more annually. In 1981, natural gas production grew 7% and totaled 16.4 trillion cubic feet or 0.2 trillion cubic feet more than planned. The 1982 production was targeted at 17.4 trillion cubic feet, and 1985 output, at 22.2 trillion cubic feet. The trans-Siberian gas pipeline to Western Europe, scheduled to go into operation during the mid-1980's, was to

supply between 1.1 to 1.4 trillion cubic feet of natural gas annually to Western Europe for at least 20 years. The sale of gas was to be an important hard-currency source, and Western World aid for pipeline construction was considered an important factor for the Soviets to achieve their hard-currency earning goals on time.

The large projected increase in natural gas production during 1981-85 was to be achieved primarily through a fivefold increase in production, compared with that of 1980, at the Urengoy Field in West Siberia. By 1985, production at Urengoy was to reach 9.7 trillion cubic feet. Total gas production in West Siberia in 1981 was 6.25 trillion cubic feet and in 1985 was projected to reach 12.7 trillion cubic feet. Output from other regions generally was not projected to increase, although production in Turkmenistan was projected to increase from 2.5 trillion cubic feet in 1980 to approximately 2.9 trillion cubic feet in 1985.

In 1981, construction was completed of the third stage of the Mubarek gas processing plant. In addition to the Urengoi-Uzhgorod export gas pipeline, by 1985, five other pipelines from West Siberia to the European part of the U.S.S.R. were to be operating. During 1981-85, a total of approximately 50,000 kilometers of gas pipeline were to be put into operation, of which the six major pipelines from West Siberia were to account for about 20,000 kilometers. Along with pipe, there was a need for hundreds of compressor stations, both of which were to be supplied, in part, from the Western World.

Natural gas was used as a fuel domestically to produce approximately 93% of the iron and steel, 95% of the mineral fertilizers, 59% of the cement, 22% of the electricity, and 37% of the thermal energy. Approximately 15% of the natural gas was used as a chemical feedstock. According to Soviet data, gas reserves in place as of January 1978 in the $A+B+C_1$ categories were about 1,000 trillion cubic feet; 15% of the reserves are in the European part of the country, 72% in Siberia and the Soviet Far East, and 13% in Soviet Central Asia, including Kazakhstan.

Petroleum.—Soviet oil production continued to increase, although not as rapidly as planned. In 1981, crude oil and gas condensate production increased 0.9% to 4.48 billion barrels, and the 1982 target was set at 4.51 billion barrels. In 1985, oil production was targeted to increase to 4.63 billion barrels, 2.8 to 2.9 billion barrels of which was to come from West Siberia. In 1981, West Siberia exceeded its production quota of 2.5 billion barrels; the Tyumen' Fields in Tyumen' Oblast', West Siberia, the major large producing area, exceeded their production quota of 2.4 billion barrels. About one-half of Tyumen's output came from the Samotlor Oilfield, the largest in West Siberia.

The 1981 increase in oil production was attributable in part to increased drilling in West Siberia. During 1981-85, plans called for drilling to increase by 70% to 80%. Goals for 1981-85 were to increase oil production, mainly in West Siberia, Kazakhstan, and the European North, and to slow the decline in output in the older producing regions.

Declines in production were occurring in the Tatar A.S.S.R., the Bashkir A.S.S.R., Kuybyshev Oblast', Perm Oblast', and Orenburg Oblast'. The most severe production declines were in the older production areas of the Ukraine, Turkemenistan, Azerbaidzhan, Belorussia, and the North Caucasus. Failure to discover significant oil reserves in East Siberia during the 1970's was a major disappointment for the Government.

The potential existed for oil production to again increase with new development occurring at a more rapid rate during the 1990's. Large portions of Siberia had not been well explored, and other discoveries were likely to be made. There was also to be an increased effort in offshore development. Western World production forecasts for the U.S.S.R. were highly speculative owing to Soviet secrecy regarding reserves, labor problems, and the need for advanced technology.

Increasing oil production in Siberia would involve tens of thousands of workers moving to remote areas in an already tight labor market. To ameliorate the labor problems, additional emphasis was put on using advanced technology and equipment to enhance labor productivity. One-third of the drilling rigs were considered obsolete.[77] Newer equipment went to Siberia, while the older equipment was concentrated in the older production areas, where production nevertheless had to be continued for production goals to be met. Soviet equipment was criticized by workers in the field for its poor quality.[78] Investment in foreign and domestic equipment was often squandered as the equipment was improperly used and maintained.

Increasing the recovery rate was a main

factor in increasing oil production. The Soviet Union claimed an average recovery of 43%, primarily using water flooding to maintain well pressure. Negative assessments of this technique by Western analysts were labeled by the Soviets as "political in character" and "miles from reality."[79] Future plans called for the recovery rate to rise 55% to 60%. Despite claims, the Soviets have acknowledged much lower rates of recovery than 43%,[80] and the planned rate of recovery of 55% to 60% was unlikely to be generally attained in operations considered commercially viable.

In 1981, full operation commenced of the Surgut-Polotsk pipeline, the longest Soviet underground oil route, supplying oil from the Tyumen' Fields to refineries in Belorussia and the Baltic Republics. Operation of these refineries was now declared assured.

Efforts were being made to economize on the use of oil. Wholesale price revisions, the first since 1967, were to reflect the increased cost of oil production. This price revision for oil was intended as an incentive for increased production and conservation. As part of the effort to economize, the oil industry was ordered to reduce losses owing to spills and pipeline mishaps.[81]

In 1981, Soviet oil deliveries to some Western World customers were reduced, while other market economy countries received increased deliveries. In 1981, indications were that oil exports to the CMEA countries were near their 1980 level of 80 million tons. A decrease in deliveries to Eastern Europe in 1982 was projected.

While the U.S.S.R. led the world in total crude oil production, it was far behind in offshore oil output, which was a very small part of total production. The offshore industry had been neglected in the 1970's with priority being given to West Siberia. Increased effort was therefore to be devoted to offshore operations. The Caspian Sea was to remain the major offshore exploration area despite a surge in exploration elsewhere on Soviet coastal shelves. Although, in 1980, the U.S.S.R. had only five mobile drill rigs, all jack up, working in the Caspian Sea, plans called for the Caspian fleet to reach 13 mobile rigs by 1985 and 23 rigs by 1990.

The Soviets were engaged in a cooperative venture with the Japanese for oil production offshore Sakhalin Island. The Soviets were also displaying an interest in cooperation with French and British companies for oil production in the Barents Sea. A joint venture with Poland and the German Democratic Republic for oil production in the Baltic Sea had been underway for several years.

The Mineral Industry of the United Arab Emirates

By Peter J. Clarke[1]

The mineral industry of the United Arab Emirates consisted primarily of the production and refining of petroleum, and the production of aluminum and cement. Despite Government efforts to diversify the economy, oil remained the driving force behind economic and social development of the seven-Emirate federation. Approximately 570 million barrels of crude oil were produced in the United Arab Emirates in 1981, of which about 535 million barrels were exported. Revenue from oil exports reached $19 billion[2] in 1981, down only 3% from 1980, despite the large 9% drop in crude oil production from the 1980 level. Combined oil and gas production accounted for about 82% of the gross domestic product in 1981, estimated at $30 billion. Abu Dhabi was by far the leading oil-producing Emirate, accounting for over 80% of the country's total oil production, followed by Dubai (19%), and Sharjah (1%). Stable oil prices and declining production levels caused a rapid dwindling of Abu Dhabi's cash surplus (oil revenues-budget expenditures) during the year, from $5 billion in 1980, to $1 billion in 1981. Despite the decline, the United Arab Emirates was able to maintain one of the world's highest per capita incomes, estimated at slightly over $21,000 in 1981, for each of the United Arab Emirates's 800,000 nationals.

Abu Dhabi's annual surplus was composed of oil revenues remaining after payment to the Federal Government (50%), local government, and to foreign governments, contribution to the Abu Dhabi Fund for Arab Economic Development, and payments made to the private purse of Sheikh Zayed of Abu Dhabi. The Federal Government invested its shares of oil revenues through the Central Bank, which was established in 1980. Abu Dhabi invested its surplus through the Abu Dhabi Investment Authority. Over 50% of the surplus was invested in dollar denominated securities, while the other half was in West German and Japanese securities. Abu Dhabi's investment income in 1981 was estimated at $1 billion.

Despite the predominance of Abu Dhabi in the United Arab Emirates overall economy, efforts were continuing in 1981 to increase the role of the Federal Government in determining economic policy and oil exploitation and marketing policy. In November 1980, the Emirates General Petroleum Corp. (EGPC) was formed to take over responsibility for marketing and distribution of petroleum products within the United Arab Emirates, and also to administer the petroleum subsidy, which amounted to about $350 million in 1981. EGPC was responsible for marketing operations in all the Emirates except for Abu Dhabi, where the Adu Dhabi National Oil Co. (ADNOC) had sole marketing authority.

In December 1980, the United Arab Emirates Central Bank was established to issue currency, regulate interest rates, and oversee the commercial banks. The rulers of Abu Dhabi and Dubai both agreed to channel 50% of their oil revenues to the Federal Government through the Central Bank to stablize the dirham and provide liquidity within the country. The most recent restriction imposed by the Central Bank in 1981 allowed foreign banks to operate only eight branches in the United Arab Emirates, thereby providing greater opportunities for local commercial banks.

The Federal Government was contemplating the establishment of an Industrial Bank in the United Arab Emirates in 1981. The bank was to be a joint venture of the United Arab Emirates Ministry of Finance

(51%) and 10 local banks and insurance companies (49%). The bank planned to lend money at low interest rates of 6% or lower to finance medium- and small-scale industrial projects, and would also carry out feasibility studies and oversee work on industrial projects. Small industrial ventures had previously been unable to obtain financing because commercial banks preferred to direct their funds into trade financing where they could receive more rapid return on their investment.

The United Arab Emirates Ministry of Planning announced its first comprehensive 5-year plan for economic and social development covering the period from 1981 to 1985. The main goals of the plan were to eliminate the chaotic planning and duplication of projects that marked the 1970's, to check inflation, and to reduce the number of foreign workers in the United Arab Emirates, which made up three-fourths of the total population. The plan projected an increase in national revenue, from $27 billion in 1981, to $34 billion by 1985. Attention was to be directed toward "Arabization" of the population, through reduction in the huge contingent of non-Arab foreign workers, diversification of the country's sources of income by raising industry's share of national income above the previous level of 5.5%, further development of the country's natural resources, including a major mineral and petroleum exploration program, and a wise investment program for the country's oil-generated financial surplus. The plan also allocated funds directly to the individual Emirates governing bodies as follows: Fujarah ($387 million), Ajman ($110 million), Ras al-Khaimah ($293 million), Umm-al-Qaiwain ($139 million), Sharjah ($217 million), Dubai ($146 million), and Abu Dhabi ($327 million).

The major infrastructure project in the United Arab Emirates centered around two main industrial areas: Ruweis in Abu Dhabi and Jebel Ali in Dubai. The Ruweis complex was the home of a major gas liquefication plant, a 120,000-barrel-per-day oil refinery, and a nitrogenous fertilizer plant. Jebel Ali contained the Dubai Aluminum Co. (Dubal), the Dubai Gas Co. (Dugas) processing plant, and a 66-berth port. Several new ports were under construction in the United Arab Emirates, including Jebel Ali, Ruweis, Fujarah Sea Port, and the already completed 35-berth facility at Port Rashid. Dubai also owned the huge Dubai Dry Dock Co., a $500 million facility that sat idle during the year.

The United Arab Emirates was conducting the third stage of its mineral survey in 1981. The survey was being conducted by Hunting Geology and Geophysics (United Kingdom), which also conducted the first two stages. The initial work had located copper deposits in Fujarah; chromite in Sharjah, Fujarah, Ras al-Khaimah, and Ajman; and asbestos in Fujarah. The third stage of the survey was to assess the quality and quantity of the discoveries and to determine the feasibility of commercial exploitation.

PRODUCTION AND TRADE

Petroleum production, mainly from Abu Dhabi, continued to dominate the mineral industry of the United Arab Emirates in 1981. Abu Dhabi produced about 420 million barrels of crude oil during the year or 80% of the total. Dubai produced about 130 million barrels, and Sharjah, 4.0 million barrels. Overall production from the United Arab Emirates declined about 8% from the 1980 level, owing to the imposition of slightly lower production ceilings by ADNOC. Production ceilings were lowered to reduce the downward pressure on crude oil prices created by oversupply conditions in world markets during the year.

Despite reduced production ceilings for the year, ADNOC, in conjunction with its foreign partners Compagnie Francaise des Petroles (CFP) (France) and Japan Oil Development Corp. (JODCO) (Japan), was in the process of expanding its crude oil production capacity from the 1.7 million barrels per day to 3 million barrels per day. The majority of the increase was to come from a huge development project at the large Upper Zakum Oilfield. Output from the field, which averaged 29,000 barrels per day in 1981, was to rise to 500,000 barrels per day by 1983. ADNOC was also developing the onshore Bu Hasa and Asab Oilfields. Production from Dubai's four offshore fields declined about 12% from the 1980 level. Although these fields did not contain large reserves, production was expected to increase in 1983 or 1984, when a large water and gas injection scheme will be implemented. Petroleum reserves in Abu Dhabi, Dubai, and Sharjah were estimated at over 40 billion barrels.

Production capacity of natural gas and natural gas liquids (NGL) was increasing nearly as rapidly as that of crude oil. Abu Dhabi Gas Industries Co.'s (GASCO) natural gas processing plant at Ruweis came on-

stream in March 1981. The plant was capable of handling 800 million cubic feet per day of associated gas from Abu Dhabi's onshore oilfields, for the production of liquefied petroleum gas (LPG) and condensates, mainly for export. Abu Dhabi's Das Island NGL plant was capable of processing another 500 million cubic feet per day of natural gas from the offshore oilfields. To supply Das Island with sufficient quantities of gas, ADNOC was completing a gas gathering project to collect, treat, and deliver 280 million cubic feet per day of associated gas from the Upper Zakum Oilfield. Abu Dhabi was also starting a program to develop its potentially huge reserves of deep nonassociated gas in 1981. Several major deep gas discoveries were made during the year, and early estimates of Abu Dhabis' possible nonassociated gas reserves were in the range from 40 to 50 trillion cubic feet.

Table 1.—United Arab Emirates: Production of mineral commodities[1]

Emirate,[2] commodity,[3] unit of measure	1977	1978	1979	1980[p]	1981[e]
ABU DHABI					
Cement, hydraulic[e] thousand metric tons	200	200	200	[r]500	700
Gas, natural:					
Gross production million cubic feet	541,760	478,617	483,809	508,445	480,000
Marketed production do.	111,876	177,914	189,286	255,594	260,000
Natural gas liquids thousand 42-gallon barrels	8,411	4,983	15,000	32,200	35,000
Petroleum:					
Crude do.	602,761	527,827	533,995	492,154	415,187
Refinery products:					
Gasoline do.	1,073	1,132	[e]1,500	1,500	6,000

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through June 1, 1982.

[2]In addition to the Emirates listed, Fujarah and Umm al-Qaiwain record no mineral production but presumably produce small quantities of crude construction materials.

[3]In addition to the commodities listed, crude construction materials such as common clays, stone, and sand and gravel presumably are produced, but output is not recorded quantitatively and general information is inadequate to make reliable estimates of output levels.

[4]No marketed production is reported; there is probably some small field use.

rRevised.

The United Arab Emirates two major nonoil minerals were aluminum and cement. Production from Dubal aluminum smelter reached its rated capacity, of 135,000 tons per year, by the end of 1981. Output for the year reached 106,000 tons of high-purity aluminum. The United Arab Emirates cement industry was also expanding rapidly during the year. Every Emirate except Umm-al-Qaiwain was to have an operating cement plant by the end of 1982. Cement production capacity was to reach 5 million tons per year by 1983, far exceeding domestic demand and providing a large surplus for export.

Abu Dhabi was to become a producer of nitrogenous fertilizer in 1983, when the Ruweis fertilizer complex is expected to come onstream. Also in the planning stage was a 500,000-ton-per-year sponge iron and steel complex. The plan was initiated by the Abu Dhabi Government to help diversify the Emirates sources of income away from dominance by petroleum. The mineral production of the United Arab Emirates is shown in table 1.

The United Arab Emirates balance of trade surplus declined for the first time in over 4 years, from a record high $12.15 billion in 1980, to $9.45 billion in 1981. The decline was due to the constant level of exports, mainly petroleum, and a significant increase in the level of imports. Imports rose from $8.65 billion in 1980 to $11 billion in 1981. The United States, the United Arab Emirates second largest trading partner behind Japan, provided $1.1 billion worth of imports, representing a 12% market share. Exports from the United Arab Emirates declined very slightly in 1981, to $20.5 billion, from a high of $20.8 billion in 1980. The drop was a direct result of the decline in petroleum revenues from $19.5 billion in 1980 to $19.0 billion in 1981. Although petroleum revenues make up the vast majority of the United Arab Emirates total exports, their actual percentage of the total has declined 1% every year since 1974. In that year, petroleum revenues accounted for 99% of total exports, and that figure has dropped to 93% in 1981. This figure represented the United Arab Emirates overall effectiveness in promoting the development of its nonoil resources.

Aluminum was the major nonpetroleum mineral export in 1981. Dubal's aluminum became available on the international market in 1980 and was traded on the London Metal Exchange (LME). Since opening in 1979, Dubal has exported over $100 million worth of high-purity aluminum. Most of its output was exported to Japan under contract to C. Itoh and Co. and Mitsui and Co.

The United Arab Emirates continued to provide a major market for U.S. and other Western goods in 1981. The United Arab Emirates was the United States third largest market among all the Arab states. Major exports to the United Arab Emirates were consumer and luxury items, oil- and gasfield machinery and services, electrical power generating equipment, food products, medical supplies, and computer systems. In return, the United States received about 8% of the United Arab Emirates oil. Other countries that imported oil from the United Arab Emirates were Japan (40%), France (10%), the Netherlands (9%), the Federal Republic of Germany (5%), and other Western European and African countries. Oil exports of the United Arab Emirates are shown in table 2.

COMMODITY REVIEW

METALS

Aluminum.—The Dubal aluminum smelter at Jebel Ali reached full-rated capacity of 135,000 tons per year in October 1981 as its third potline became fully operational. The plant produced 106,000 tons of aluminum in 1981. The smelter was 80% owned by the Dubai Government and 20% by Alusmelter Holdings, a Grand Caymen Co. owned by Southwire Co. (United States) and Selection Trust Ltd. (United Kingdom).

The smelter complex included a 515-megawatt power generating facility, a 25-million-gallon-per-day seawater desalinization plant, and the main smelter facility. Alumina for the smelter was supplied under a 10-year contract by Alcoa of Australia. The operation was powered by natural gas supplied by Dugas. The average gas input to the smelter was 100 million cubic feet per day, on which Dubal achieved an energy conversion factor of 65%, one of the highest in the world. This was achieved through a computer-controlled waste heat collection system, which served to reduce energy consumption at the water desalinization plant. Besides providing water for the smelter complex, Dubal supplied the Dubai Water Department with over 10 million gallons of water per day, for use by the population of Dubai.

Since the smelter began producing aluminum in November 1979, the company has sold over $100 million worth of high-purity (99.86%) metal. By the end of December 1981, the plant was producing above capacity, at a rate of 142,000 tons per year, with a reduced level of personnel, averaging below 1,500 workers. The combination of these factors, added to the low-cost energy supply, resulted in a metal production cost below that of many long-established smelters elsewhere in the world. The company was able to sell nearly all of its noncontracted metal at prices consistantly higher than LME levels and was not significantly hurt by a slump in the world market late in the year.[3]

Gulf Extrusions Ltd., an aluminum fabricating plant, began operating in Dubai in 1978. The plant originally imported aluminum billets from Aluminum Bahrain (Alba) but switched to Dubal feed in 1980. The company operated a single 1,600-ton press, which limited its capacity to about 3,000 tons per year of anodized architectural sections. The company was owned by the Arab Al-Ghurain Group and, like the Dubai smelter, was built by British Smelter Constructions.

The Dubai Cable Co., a joint venture of the Dubai Government and British Insulated Callender Cables (United Kingdom) began operating in October 1979. The plant was capable of producing wire, flexible conductors, insulating conductors, and polyvinyl chloride (PVC) bedding and sheath. The basic raw materials were electrical-grade copper and aluminum rod plus granular PVC supplied mainly from Europe. The plant utilized about 1,100 tons of copper, 500 tons of aluminum, 700 tons of PVC, and about 900 tons of galvanized steel wire in 1981. With greater supplies of aluminum, copper, and PVC soon to be available in the Middle East, the company planned to significantly increase its production in the future, although no timetable had been established.

It was reported in 1981 that Abu Dhabi was in the process of constructing an aluminum smelter and that construction was at an advanced stage. The smelter's initial design capacity was to be 50,000 tons per year of aluminum, with expansion planned to 150,000 tons per year. Information on the plan was very limited, and the entire project may be under review in light of the declining demand for aluminum and two viable smelters already operating in the gulf. There was no semifabricating aluminum industry in Abu Dhabi.

Iron and Steel.—There were two operating steel mills in the United Arab Emirates in 1981. The Ahli Steel Co., located in the Rashidiya industrial area of Dubai, operated a 12-ton electric arc furnace along with a two strand continuous billet caster, and a 10-ton-per-hour continuous bar mill capable of producing 36,000 tons per year of reinforcing bars, between 10 and 32 millimeters. The Abu Dhabi Steelworks operated a single 25,000-ton-per-year reroller, which began operating in 1977.

Two other steel projects were under study in 1981, both in Abu Dhabi. The Abu Dhabi Government commissioned a feasibility study for a 500,000-ton-per-year to 900,000-ton-per-year iron and steel complex to be located in the industrial city of Ruweis. The plant was to produce sponge iron from ore supplied by India. Some of the sponge iron was to be exported to India, with the re-

mainder to be used as throughput for planned electric steel furnaces. The plan was initiated by the Abu Dhabi Government, with the collaboration of Kobe Steel Co. of Japan, and Krupp GmbH and Klöckner & Co. of the Federal Republic of Germany.

Also nearing completion in 1981 was an agreement for a 50,000-ton-per-year seamless pipe mill, to be set up as a joint venture of the Government of India, and Dubai's Al-Ghurain Group. The plant was to be built in Gujarat, India, with the Al-Ghurain Group providing 40% of $125 million capital for the project. The agreement was not finalized by the end of 1981. The Gujarat pipe project came shortly after the Indian Government offered to assist Sharjah in the establishment of a direct reduction plant and steelworks. The offer was made as part of India's desire to expand its role in the Middle East. No agreement was reached with Sharjah concerning the project.[4]

NONMETALS

Cement.—The cement industry of the United Arab Emirates continued to expand in 1981, producing over 2.4 million tons of portland cement during the year. There were five operating cement plants in the federation: Abu Dhabi, Dubai, Fujarah, Ras al-Khaimah, and Sharjah. Additional plants were either being built or planned in Ajman and Ras al-Khaimah. Production of cement fell just short of domestic consumption of 2.5 million tons for the year. When all the plants under construction come into operation sometime in 1984, capacity of the cement industry will increase from the current 2.9 million tons per year to 5 million tons per year. As the contemporary wave of basic infrastructure projects are completed, domestic demand for cement was expected to hold steady or to decline, leaving a substantial surplus for export by the middle of the decade.

The Fujarah Cement Industries cement plant in Fujarah became the newest addition to the Emirates cement industry in 1981. The 500,000-ton-per-year plant was built by Voest-Alpine AG of Austria, and completed in the second half of 1981. Also nearing completion was a 500,000-ton-per-year facility in Ajman.

In Dubai, the National Cement Co. planned to double the capacity of its plant to 1-million-tons-per-year. The plant was to be converted from the current wet process to dry process technology, through which the company expected to cut energy costs by 35%. Development Consultants International (India) was preparing the feasibility study.

The Gulf Cement Co., a joint venture of the United Arab Emirates Government and Kuwait, was planning to construct a 1-million-ton-per-year cement plant in Ras al-Khaimah, principally to supply the domestic market in Kuwait. The current and planned capacities of the United Arab Emirates cement industry are shown in the following table.

Location	Operating company	Current capacity (thousand tons)	Planned capacity (thousand tons)	Year
Al Ain, Abu Dhabi	Al Ain Cement Factory	750		
Dubai	Dubai National Cement Co	500	1,000	1983
Fujarah	Fujarah Cement Industries	500		
Sharjah	Sharjah Cement Co	220		
Ras al-Khaimah	Union Cement Co	1,000		
Do	Gulf Cement Co	--	1,000	1982
Ajman	NA	--	500	1982

NA Not available.

Fertilizer Materials.—Abu Dhabi was expected to begin production of nitrogenous fertilizer sometime in 1983. A $300 million fertilizer complex was being built at the Ruweis industrial zone, under the construction management team of Mitsubishi Oil Co. and the Chiyoda Chemical Engineering and Construction Co. (Japan). The plan for the complex was initiated in 1979 by ADNOC, who signed a joint venture agreement with CFP (France). ADNOC was to own 66% of the equity, and CFP, 33%. Feasibility studies were conducted in 1979 and 1980 by Snamprogetti S.p.A. (Italy), and the construction contract was awarded in July 1980.

The plant was designed to produce 1,000 tons per day of ammonia as feed for a 1,500-

ton-per-day urea unit. Haldor Topsoe A/S, Denmark technology, was being used in the ammonia unit, and Stamicarbon's process in the urea plant. Feedstock for the plant was to be supplied from Abu Dhabi's onshore natural gasfields through a direct natural gas pipeline from Habshan. Included in the project were export terminals and a powerplant desalinization complex. Output from Ruweis was to be exported, mainly in the form of urea. The company was planning to export ammonia sometime in the future, through the addition of a 1,000-ton-per-day ammonia expansion plant.

Late in 1981, the Abu Dhabi Executive Council allocated $25 million to be used to increase the capacity of the Al-Ain compost fertilizer plant. The plant, built by Buhler A.G. (Switzerland), and Moller-Anderson & Co. (Denmark), began producing 150 tons per day of compost fertilizer in 1977. The new order would increase capacity to 225 tons per day.

The Sharjah Fertilizer plant, which came onstream in 1975, also produced chemical fertilizer for the local market. Capacity at the $5 million facility was raised from 10,000 tons per year to 35,000 tons per year in 1979.

MINERAL FUELS

Natural Gas.—The United Arab Emirates production of associated and nonassociated gas expanded rapidly in 1981 as the United Arab Emirates Government continued to promote the utilization and processing of the country's natural gas reserves. Abu Dhabi played a dominant role in natural gas development owing to its extensive reserves, estimated at around 40 trillion cubic feet, and its gas processing capacity of 1,300 million cubic feet per day.

Abu Dhabi produced associated gas from the following four onshore oilfields- in million cubic feet per day: Bu Hasa (250), Asab (250), Sahil (7), and Bab (171). The fields were linked by pipeline to the Ruweis gas processing complex, which began operating in March 1981. The $1.6 billion project was implemented by GASCO, a joint venture of ADNOC (68%), Shell Oil Co. (United States) (15%), CFP-Total (France) (15%), and Participations and Exploration Corp. (Partex) (Portugal) (2%). The Ruweis facility was designed to process 800 million cubic feet per day of associated gas in the production of 150,000 barrels per day of NGL, with a product split of 60% NGL and 40% condensates. The fractionation plant at Ruweis was designed to produce 61,000 barrels per day of propane, 62,000 barrels per day of butane, and 81,000 barrels per day of heavier hydrocarbons. The first shipment of LPG, 24,000 tons of butane and 22,000 tons of propane, was delivered to Japan in August 1981. Eight Japanese companies signed 5-year contracts for the purchase of a total of 1.49 million tons per year of GASCO's LPG output, of which 1.01 million tons per year was to be supplied from ADNOC's share, and the remaining 350,000 tons per year from the shares of CFP and Partex.

Bechtel Inc. (United States) completed engineering, procurement, and construction management for another gas processing facility, located at the Bu Hasa Oilfield. The plant was a two train NGL extraction plant capable of producing 110,000 barrels per day of raw NGL. Bechtel was also responsible for construction management at the Ruweis complex.

Abu Dhabi was also planning to increase natural gas recovery from its major offshore fields, Umm Shaif (440 million cubic feet per day), Upper and Lower Zakum (200 million cubic feet per day), and other, smaller fields (95 million cubic feet per day), in line with increased production of crude oil. Associated gas from those oilfields was processed at the Das Island Natural Gas processing plant. Das Island, which began operating in 1977, was operated by the Abu Dhabi Gas Liquefaction Co. Ltd., a joint company composed of ADNOC (51%), Mitsui (Japan) (22%), British Petroleum Co. Ltd. (BP) (United Kingdom) (16%), CFP (8%), and Bridgeston Liquefied Gas Co. Ltd. (Japan) (3%). The facility was designed to process 550 million cubic feet per day of associated gas to produce 40,000 barrels per day of LNG, 15,000 barrels per day of LPG, 4,000 barrels per day of light distillates, and 4,400 barrels per day of pelletized sulfur. The Das Island facility operated at about 79% of capacity during the year, processing about 433 million cubic feet per day of gas, mainly because not enough gas was supplied to the facility. ADNOC was in the process of solving that problem in 1981, through construction of a gas-gathering system in the Upper and Lower Zakum Oilfields.

The project, called Gas Gathering II, was to utilize all the previously flared associated gas (125 million cubic feet per day) at the oilfields. A gas treatment plant at the Zakum West supercomplex was nearing completion at the end of 1981. The facility was designed to treat, compress, cool, and

dry 280 million cubic feet per day of associated gas from the Zakum Fields and then pipe it via the Umm Shaif supercomplex gas treatment platform, to Das Island. Most of Das Island's current input was from Umm Shaif. With the Zakum Fields connected to the facility, Das Island was expected to reach capacity by mid-1982. To handle the increased output from Das Island, the British company, CBI, was in the process of building seven natural gas storage tanks. Three tanks, each with a capacity of 80,000 cubic meters, were to store liquefied natural gas, while four others, with a combined capacity of 50,000 cubic meters, were to store propane and butane. Cost of the storage tanks was estimated at $320 million.

Offshore associated gas was also processed at ADNOC's gas treatment plant at Habshan. The plant was designed to separate and treat 350 million cubic feet per day of associated gas, mainly to supply power stations in Abu Dhabi. The plant processed just over 100 million cubic feet per day in 1981. ADNOC planned to double the capacity of Habshan to 550 million cubic feet per day by 1983. Fluor Corp. (United States) was constructing the new units.

Abu Dhabi was just beginning to utilize its huge reserves of nonassociated gas in 1981. Deep nonassociated gas was discovered onshore in 1978, in the Thamama C and Thamama F Zones, underlying the Bab Oilfield. In April 1981, Fluor was contracted to develop a project to utilize gas from the Thamama C reservoir. The contract, worth $26 million, covered engineering and design specifications for production and treatment of 450 million cubic feet per day to supply projects in the Ruweis Industrial Zone, electric powerplants, a desalinization plant, and other local requirements.

Another project for the Bab Oilfield was in the planning stage in 1981. This called for the production of nonassociated wet gas from the Thamama F Zone, from which LPG and condensate would be recovered. The remaining dry gas would be reinjected into the reservoir for recycling.

Deep nonassociated gas from the Permian Khuff Formation was also discovered in several areas offshore. Deep gas was discovered offshore by the Abu Dhabi Marine Areas Operating Co. (ADMA-OPCO) in 1979 in the Umm Shaif Field at 15,000 feet. Since that time, Khuff gas has been located below the Zakum Oilfield, and exploration wells were underway onshore at Bu Hasa and Jarn Yaphour and offshore at Abu-al-Bukhoosh and Nasr. Initial results indicated that Khuff gas could be present under the entire offshore area. Work was continuing rapidly on delineating the extent of offshore gas reserves. Tentative estimates of Abu Dhabi's nonassociated gas reserves were in the range from 40 to 50 trillion cubic feet.

Petroleum.—*Abu Dhabi.*—Of the United Arab Emirates total crude oil production of nearly 550 million barrels, Abu Dhabi produced about 78%. Crude oil production in the Emirate was controlled by two major companies, both of which were majority owned subsidiaries of ADNOC, the Government-owned oil company. Production levels at all fields were set by the Minister of Petroleum in conjunction with the operating company. Abu Dhabi was planning to expand its petroleum production capacity from the current 1.7 million barrels per day to 3 million barrels per day by 1983.

The Abu Dhabi Co. for Onshore Oil Operations (ADCO) produced oil from four major onshore fields, whose production levels for 1981 were as follows: Bu Hasa (255,000 barrels per day), Asab (255,000 barrels per day), Sahil (20,000 barrels per day) and Bab (15,000 barrels per day). Also under development was the onshore Shah Field in southern Abu Dhabi, which was expected to produce 15,000 barrels per day in 1982 and 30,000 barrels per day in 1983. The major development project for the onshore oilfield was selective waterflood projects at the Asab, Bab, and Sahil Fields. The plan involved drilling 121 new production and water injection wells into various strata. At the Bu Hasa Field, 234 new wells were to be drilled, and 74 existing wells were to be worked over to increase that field's productive capacity.

ADMA-OPCO administered the Emirate's major offshore fields. These fields and their 1981 production levels were as follows: Umm Shaif (227,700 barrels per day), Upper Zakum (29,210 barrels per day), and Lower Zakum (198,316 barrels per day). Abu Dhabi's single largest development project in 1981 was the $4.8 billion Upper Zakum Development Project, which was intended to increase production from 30,000 barrels per day to 500,000 barrels per day by 1983. The project was being implemented by the Zakum Development Co., a joint venture of ADNOC and CFP (France). The Zakum Field, a complex limestone, multizone reservoir, required significant levels of water and

gas injection, for which facilities were being installed at the start of production. The initial water injection capacity at the field was to be 750,000 barrels per day, eventually rising to 1.25 million barrels per day. Output from Upper Zakum was to be exported from Zirku Island, 60 kilometers from the field. The first phase of Zirku Island, a manmade export terminal, was to be completed in 1982. This was to include two separation units, storage tanks, pumping stations, and loading installations. Phase 2 was to install new tanks and loading facilities and further increase overall handling capacity to 500,000 barrels per day.

CFP operated another Abu Dhabi offshore oilfield, at Abu-Al-Bukhoosh. Output from this field averaged 75,000 barrels per day. The Mubarraz Oil Co., a joint company of Daiyko Oil and Nippon Mining (Japan) and the Japan National Oil Corp. operated the small Mubarraz Oilfield. The field, which produced about 20,000 barrels per day in 1981, was located in Abu Dhabi's offshore area. Amerada Hess also produced about 20,000 barrels per day of crude oil from the offshore Arzanah Field.

Four other offshore fields were being developed during the year, all by the Umm Addalkh Development Co. (UDECO), a 50:50 joint company of ADNOC and JODCO. Output from all four fields was not likely to exceed 50,000 barrels per day; 25,000 from UDECO, and 25,000 from the three-field complex of Satah-Dalma-Jarnain. Reserves at the three fields were estimated to be 1 billion barrels. First production from these fields was to begin late in 1983.

Several new discoveries were made in 1981 that were likely to significantly increase Abu Dhabi's current crude oil reserves of about 30 billion barrels. The largest onshore discovery was at Zubbaya, on the coast southwest of Abu Dhabi City. The area had previously shown signs of oil potential, but new drilling by ADCO in 1981 revealed a reservoir at 9,000 feet that was much larger than originally thought. The structure was thought to extend offshore, and drilling was continuing off the coast from artificial islands.

Offshore, crude oil was discovered at Gasha by ADMA-OPCO. Test rates and depth of drill holes were unavailable, but the Gasha Field was thought to be part of the same structure as Bu-Tinah, discovered by ADMA-OPCO in 1980. The combined field was estimated to be capable of producing about 200,000 barrels per day when fully developed. Mubarraz also announced a commercial discovery in its offshore concession 140 kilometers off the coast of Abu Dhabi at wildcat No. 1. The well tested at 5,000 barrels per day of 39° to 45° API crude with a sulfur content of less than 1%, plus 24 million cubic feet per day of gas. Mubarraz planned to start commercial production from the field in 1985.

Two other discoveries, both by ADMA-OPCO in the offshore area, were at Um-al-Lulu, 15 kilometers north of Abu Dhabi City, and at Hair Dalma, east of Dalma Island. Um-al-Lulu was the larger of the two discoveries, with the well testing at 24,000 barrels per day. The ADMA-OPCO annual report for 1981 described the field as one of the largest oil-bearing formations discovered in the United Arab Emirates since the discovery of Umm Shaif and Upper Zakum.

ADNOC began exploration activity in 1980, independent of its field operators, Shell, BP, and CFP. The company was engaged in exploring five onshore and offshore areas, and preparing geophysical surveys of other areas having oil-producing potential.

Several other companies began exploration work in Abu Dhabi for the first time in 1981. Sceptre Resources (Canada) planned to spud its first wildcat on its onshore concession area "A" in eastern Abu Dhabi. The well was located 30 kilometers north of the Jarn Yaphour Oilfield. Sceptre was also conducing a seismic survey of the concession.

In May 1981, Deminex-Deutsche Erdölversorgungsgesellschaft GmbH, (Federal Republic of Germany) signed a 35-year concession agreement with the Abu Dhabi Government covering an 1,835-square-kilometer tract offshore, northwest of Abu-al-Abyad Island. Union Texas Petroleum (United States) acquired exploration rights in two concession areas. The company gained a 16% interest on a 1,500-square-kilometer tract offshore, and a 10% interest in a 7,500-square-kilometer concession onshore. Deminex operated the offshore area, and Amerada Hess, the onshore. Attock Oil Co. (United Kingdom) was also awarded a 2,500-square-kilometer concession in an Abu Dhabi offshore area. Attock agreed to spend $50 million on exploration work over an 8-year period.

Petroleum refining capacity in Abu Dhabi underwent large-scale expansion in 1981,

with the commissioning of the 120,000-barrel-per-day Ruweis refinery. The new refinery was able to satisfy domestic demand in all the Emirates, averaging 115,000 barrels per day. Plans to expand the refinery to a capacity of 300,000 barrels per day were shelved during the year, owing to softening of the market late in the year. ADNOC decided, instead, to install a 26,000-barrel-per-day hydrocracking facility at the plant to upgrade fuel oil residues into lighter products. The Ruweis refinery, built at a cost of $500 million by Snamprogetti (Italy), was expected to reach full capacity early in 1982.

Expansion of the Umm-al-Nar refinery near Abu Dhabi City was under way in 1981. Pullman Kellog Co. (United States) was awarded a contract in September 1980 to construct a new refinery adjacent to the 15,000-barrel-per-day refinery already operating at Umm-al-Nar. The new plant was to have a capacity of 60,000 barrels per day. Output from both units was to be used to satisfy domestic requirements, freeing most of the output from Ruweis for export. This new capacity was to come onstream in March 1983. Also located at Umm-al-Nar was Abu Dhabi's first lube oil blending plant. The plant was built by Balmer Laurie Co. (India) and was capable of producing 14,000 barrels per day of 50 different types of lubricants for the local market. The plant came onstream in mid-1980.

ADNOC decided in 1981 to construct a 160,000-ton-per-year petroleum coke plant in the Ruweis Industrial Area. Initial plans were to make the plant a joint venture of ADNOC and the Doha-Based Gulf Organization for Industrial Consulting. Estimated cost of the project was $220 million. The plant, the first of its type in the Persian Gulf, was designed to meet the needs of the area's two aluminum smelters at Dubal and Alba.

In 1980, Dubai opened its own natural gas processing plant. Dugas was a joint venture of the Dubai Government and Scimitar Oils Ltd., formerly known as Sunningdale Oils Ltd., of Canada. The plant was designed to handle output of about 100 million cubic feet per day of associated gas from Dubai's offshore fields. The plant, built by Hudson Engineering of Houston, Tex. (United States), was designed to produce 11,000 barrels per day of propane, 7,000 barrels per day of butane, 7,000 barrels per day of condensates, and 55 million cubic feet per day of lean residue gas. The propane, butane, and natural gasoline was sold under contract to Japanese buyers. The lean residue gas was supplied by pipeline to Dubai's aluminum smelter, to fuel the steam turbines at Dubal.

Petroleum production in Dubai came entirely from the offshore areas. The Dubai Petroleum Co. (DPC) operated four offshore oilfields: Fateh, Southwest Fateh, Falah, and Rashid. Total crude oil production in Dubai was about 112 million barrels in 1981, a 12% decline from the 1980 level. The drop was due in part to depletion of the existing fields and also was a result of sluggish demand for oil in the world market. The Falah and Rashid Fields, both discovered in the 1970's, were undergoing further development by DPC to shore up declining output.

Several foreign oil companies operated Dubai's offshore oilfields, all of which were shareholders in one of the main companies. The DPC was owned 50% by the Dubai Marine Areas, a joint company of CFP (France) and Hispanoil (Spain), 30% by Conoco (United States), and 10% by Deutsche Texaco (Federal Republic of Germany). In 1979, the Dubai Government signed an agreement to purchase about one-half of the crude oil produced by the companies at 93% of the posted price. The companies then had the right to repurchase the oil at prices set by the Government. The Government attempted to establish its own marketing agency in this manner. It was unable to sign any contracts during 1980, and Conoco repurchased 33% of the Government's share of oil. The rest was sold on the spot market. In March 1981, Idemitsu signed Dubai's first direct-deal contract for the purchase of 33,000 barrels per day of Government crude. The contract ran from April to the end of 1981 and was renewable on an annual basis.

Exploration was continuing in Dubai onshore at Jebel Ali. The consortium of Southeastern Drilling Co. and Houston Oil and Minerals Corp. a subsidiary of Teneco Inc. both of the United States, struck oil at Jebel Ali at 17,875 feet in 1980. Additional drilling was underway to determine the extent of the field. Arco-Dubai, a wholly owned subsidiary of Atlantic Richfield Co. (United States), was awarded a 760,000-acre, 35-year concession for onshore exploration in 1980. The agreement called for an initial investment of $1 million for geophysical work, and a $5 million investment in each well drilled. Arco was required to drill one well by 1983 and one well per year there-

after until 1988, if the preliminary tests were encouraging.

Sharjah.—The Emirate of Sharjah was the most recent of the seven Emirates to become an oil and gas producer. All of Sharjah's crude production, averaging 10,000 barrels per day in 1980, came from the small offshore Mubarak Field, near Abu Musa Island. The production level from the field peaked in 1975 at 38,000 barrels per day and has declined fairly rapidly since then. It was estimated that reserves at Mubarak would be exhausted by the end of the decade. The field's operator, Crescent Petroleum Corp. (United States), was in the process of installing a complex gas and water injection system. The equity shareholders in Crescent Petroleum were Buttes Gas & Oil Co. (25.7%), Ashland International Oil Co. (United States) (25%), Advance Petroleum Services Inc. (United States) (25%), Kerr McGee Corp. (United States) (12.5%), Cities Service Oil Co. (United States) (10%), and Juniper Petroleum Corp. (United States) (1.8%). Sharjah's oil revenues were based on 16.5% royalty and 77% income tax.

Sharjah's future as a petroleum producer brightened considerably in 1980 and 1981, because of two large discoveries. In 1980, oil was discovered in on offshore concession operated jointly by Forman Exploration Co. (United States) and London and Scottish Marine Oil Co. (Lasmo) (United Kingdom). The field, named Hamriyyah, was located 16 kilometers east of the Mubarak Field. The test well encountered oil and gas in two formations down to 14,300 feet. The field was deemed commercial, and additional wells were being drilled. The field was owned entirely by the Emirate of Sharjah.

The second and larger of the two finds was made in December 1980 by Amoco Sharjah Oil Co., a subsidiary of Standard Oil Co. (Indiana) (United States) at its Sajaa No. 1 well, onshore just west of the Oman Mountain Range. The well tested at 5,000 barrels per day of high-gravity crude and 50 million cubic feet per day of gas. Subsequent wells drilled by Amoco confirmed the presence of large reserves of recoverable condensate and natural gas. Amoco characterized the field as one of the largest discoveries ever made by the company. The company was implementing a five-well development plan, with potential of 250 million cubic feet per day of natural gas and 25,000 barrels per day of low-sulfur condensate by June 1982. Further expansion was planned to allow production of 80,000 barrels per day of condensate by mid-1983. Work had already started on 10 storage tanks with a capacity of 50,000 barrels each at Sajaa, and four additional 500,000 barrel tanks at Sharjah's export terminal at Hamariya were also under construction. Crude oil exports were to start in June 1982. Sharjah was also studying plans for the utilization and exploitation of natural gas from the field. As a result of the new discovery, Sharjah's crude oil reserves were estimated at 3 billion barrels.

Exploration work was continuing offshore in Sharjah. In 1981, Chieftan Development Corp. (Canada) acquired a 20% interest in a 188,500-acre concession offshore of Sharjah near Abu Musu Island, about 10 kilometers west of the Mubarak Field and 20 kilometers northwest of Dubai's Fateh Field. The concession was formerly held entirely by Meridian Oil of Australia. Chieftan was to act as operator and was committed to spend $1.47 million on exploration.

Ras al-Khaimah.—Exploration was continuing in Ras al-Khaimah, led by Gulf Ras al-Khaimah, a subsidiary of Gulf Oil Corp. (United States). Gulf was active in two offshore concession areas, the first in a 421-square-kilometer tract off Ras al-Khaimah's west coast. Participation in the concession was by Gulf, as operator (45.46%), International Petroleum Corp. (Canada) (28.33%), Chinese Petroleum Corp. of Taiwan (21.21%), and a European group, Petrokal (5%). Gulf spudded Najah No. 9, the first well on the concession, late in 1981. The concession agreement called for exploration expenditures of $20 million in 1981 and 1982, and the drilling of two exploration wells. Gulf planned to drill its second well on a separate structure early in 1982. Gulf held a second concession in Ras al-Khaimah in a joint venture with Amoco (United States). The tract was located 12 kilometers southeast of Ras al-Khaimah airport. The consortium was drilling its first test at Khatt, but no details were available.

Umm-al-Qaiwain.—Two exploration agreements were signed in 1981, covering separate concessions in the Emirate. Texaco International Exploration Co., a subsidiary of Texaco Inc. (United States), was granted a 650-square-kilometer offshore concession in December 1981. Texaco was to conduct seismic studies and drill two wells by 1984. The acreage was located southwest of the entrance to the Strait of Hormuz and about 8 kilometers east Sharjah's Mubarak Oil-

field. It was thought that Sharjah's offshore Sajaa structure might extend into Umm-al-Qaiwain, providing further incentive for Texaco's exploration efforts. A consortium consisting of Forman Exploration Co. (United States), U.S. Companies Inc. (United States), Minoco UAQ Ltd. (United States), Rimrock Offshore Ltd. (United Kingdom), and Atlantic Marine Inc. (United States) spudded their first wildcat in Umm-al-Qaiwain in October 1981. The well, located on a 50,000-acre concession, was to go to a total depth of 15,000 feet. No details on the location or results of the test well were available.

Ajman.—A consortium of Forman Exploration and Lasmo remained active on their 300-square-kilometer offshore concession. The tract was awarded in 1978, and Forman-Lasmo completed seismic work at the end of 1980. The group was preparing to spud its first well on the concession in 1981. Delhi Pacific Resources Co. (United States) reached an agreement, in principal, with Reynolds Diversified Corp. (Australia) to acquire 17.45% interest on an 85,000-acre concession offshore and onshore Ajman. No details were available on Delhi's exploration plans.

Fujarah.—Little progress has been made in oil exploration work in Fujarah since 1980. A consortium of Denison Mines Ltd. (Canada) (50%), Getty Oil Co. (United States) (15.7%), Mitsubishi (Japan) (10%), and 15 other companies have operated a 700,000-acre concession off the coast of Fujarah since 1979. A single test well was drilled on the concession in 1980, with no significant show of oil or gas. Exploration activity has subsided since that well was abandoned.

Fujarah was also preparing to open the first two berths of its new seaport. The port, which was being built by Hyundai Construction Corp. of the Republic of Korea at a cost $46 million, was to eventually operate 11 berths capable of handling imports and exports for Fujarah and other Emirates. The port was to be operated by Felixstowe Dock and Railway Co. (United Kingdom).

The Mineral Industry of the United Kingdom

By Tatiana Karpinsky[1]

The decline in output and employment evident in the United Kingdom's economy during 1980 continued in 1981. By the fourth quarter 1981, the gross domestic product (GDP) was running 5% lower, and manufacturing output was down by 14% compared with that of 1979. The number of unemployed continued to increase, reaching about 11.5% of the total work force by the end of 1981. However, there were signs that economic activity had begun to recover in the second half of 1981. The GDP rose slightly, and the indices of industrial and manufacturing output also showed a slight upward tendency. There was, in addition, a significant rise in manufacturing productivity, mainly because of the continuing fall in employment. Overseas trade figures for 1981 indicated that there was a surplus balance of payments.

PRODUCTION

Total energy production in the United Kingdom increased 3.9% in 1981 over that of 1980. Petroleum production increased 65 million barrels or 11%. Coal production dropped slightly to 126.4 million tons. Natural gas production was steady in 1981, while nuclear and hydroelectric power combined increased 4%.

The British Government's income from oil and gas, in royalties, petroleum revenue, and corporation taxes, was about $12.2 billion[2] in 1981, or 9% of the United Kingdom's total tax revenue and 2.5% of its gross national product (GNP).

The total value of gross industrial production in 1980 amounted to $157.9 billion. Mining and quarrying contributed 14% to this and 5.6% to the GNP.[3]

Production of minerals in the United Kingdom in 1977-81 is reported in table 1.

Table 1.—United Kingdom: Production of mineral commodities[1]

Metal including alloys, all forms	2,121	2,569	NA	NA.
Cobalt:				
Oxides and hydroxides	244	289	49	Belgium-Luxembourg 76; West Germany 66; Spain 19.
Metal including alloys, all forms	962	623	NA	NA.
Columbium and tantalum metal including alloys, all forms	43	34	2	West Germany 15; Belgium-Luxembourg 8.
Copper:				
Matte and cement	6	4	--	All to Switzerland.
Metal including alloys:				
Scrap	r59,593	82,903	--	West Germany 35,961; Italy 21,719; Belgium-Luxembourg 8,619.
Unwrought	r48,063	60,540	--	West Germany 17,536; Italy 12,625; France 7,475.
Semimanufactures	r118,943	119,868	3,604	Switzerland 15,098; Ireland 12,590; Netherlands 6,876.
Gold:				
Waste and sweepings value, thousands	$106,441	$91,217	--	Spain $40,920; Italy $19,034; Switzerland $14,637.
Metal including alloys:				
Bullion, refined thousand troy ounces	15,823	10,781	NA	NA.
Unwrought and partly wrought troy ounces	167,184	99,667	--	France 22,505; Belgium-Luxembourg 16,075; Switzerland 16,075.
Iron and steel:				
Ore and concentrate, except roasted pyrites	898	1,156	--	West Germany 794; Cuba 105; Ireland 94.
Metal:				
Scrap thousand tons	1,335	2,805	(1)	Spain 1,810; West Germany 328.
Pig iron, cast iron, spiegeleisen	22,536	30,245	--	Italy 15,180; Belgium-Luxembourg 11,393.
Sponge iron, powder, shot	22,098	25,543	107	West Germany 6,233; Sweden 4,011; Norway 2,087.
Ferroalloys:				
Ferromanganese	6,964	972	--	West Germany 277; France 188; Netherlands 182.
Ferrosilicon	1,782	1,353	433	West Germany 277; Italy 50.
Other ferroalloys	18,656	15,634	--	West Germany 4,846; Netherlands 1,133; Italy 997.
Steel, primary forms	482,649	242,678	13,568	Italy 116,376; West Germany 31,531; France 17,004.
Semimanufactures:				
Bars, rods, angles, shapes, sections:				
Wire rod thousand tons	451	279	2	West Germany 51; Egypt 33; Sweden 27; Belgium-Luxembourg 19.
Other bars and rods do	932	549	66	West Germany 91; France 43; Italy 37.
Angles, shapes, sections do	588	407	75	Ireland 38; India 31; Republic of Korea 30.
Universals, plates, sheets:				
Tinned plates and sheets do	244	160	--	India 32; Greece 15; Denmark 11.
Other do	1,012	497	1	West Germany 114; Ireland 38; India 19.

See footnotes at end of table.

Table 2.—United Kingdom: Exports of mineral commodities —Continued

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
METALS —Continued				
Iron and steel —Continued				
Metal —Continued				
Semimanufactures —Continued				
Hoop and strip thousand tons	135	79	4	Ireland 8; U.S.S.R. 6; Italy 5.
Rails and accessories do	105	103	5	Pakistan 24; Italy 6; Ireland 5.
Wire do	117	89	13	Canada 9; Ireland 6; Nigeria 6.
Tubes, pipes, fittings do	491	404	21	Netherlands 53; Sweden 27; U.S.S.R. 17.
Castings and forgings, rough do	112	96	33	Sweden 14; Abu Dhabi 4; France 4.
Lead:				
Ore and concentrate	5,187	3,535	--	Belgium-Luxembourg 2,788; West Germany 721.
Oxides and hydroxides	5,860	5,855	22	Ireland 2,375; Sweden 494.
Metal including alloys:				
Scrap	32,369	30,662	--	Italy 10,610; West Germany 6,728; Denmark 6,101.
Unwrought	136,549	141,825	635	West Germany 31,054; Netherlands 25,127; Portugal 11,391.
Semimanufactures	5,223	6,123	--	Ireland 1,738; Portugal 1,012.
Magnesium metal including alloys:				
Scrap	272	111	7	Italy 81; West Germany 20; Ireland 3.
Unwrought	1,075	1,167	309	France 305; Canada 193.
Semimanufactures	704	659	8	India 306; Ireland 72.
Manganese:				
Ore and concentrate	4,043	8,331	323	Republic of South Africa 2,710; Italy 1,821.
Oxides and hydroxides	1,165	2,133	20	Nigeria 841; Republic of South Africa 368; Ireland 191.
Metal including alloys, all forms	362	405	NA	NA.
Mercury 76-pound flasks	3,974	2,321	116	Belgium-Luxembourg 551; West Germany 464; Republic of South Africa 464.
Molybdenum:				
Oxides and hydroxides	381	1,937	NA	NA.
Metal including alloys, all forms	332	175	3	Netherlands 72; West Germany 31; France 30.
Nickel:				
Ore and concentrate		5	--	All to Israel.
Matte, speiss, similar materials	1,383	2,911	--	Norway 2,823; India 59.
Oxides and hydroxides	252	58	NA	NA.
Metal including alloys:				
Scrap	4,341	4,454	550	Sweden 1,455; Netherlands 804; West Germany 789.
Unwrought	14,866	10,984	--	West Germany 2,973; Belgium-Luxembourg 1,687; France 1,489.
Semimanufactures	13,098	9,136	965	France 1,853; West Germany 934; Italy 864.
Platinum-group metals including alloys, unwrought and partly wrought thousand troy ounces	3,537	1,768	418	Italy 418; Switzerland 193.
Silver:				
Ore and concentrate value, thousands	$8,629	$1,000	$95	Canada $882; Switzerland $20.
Waste and sweepings do	$25,440	$144,798	--	East Germany $40,943; Italy $28,269; Belgium-Luxembourg $19,725.
Metal including alloys:				
Refined, wrought thousand troy ounces	18,229	17,426	579	Switzerland 4,823; Sweden 4,244.
Refined, unwrought do	35,398	62,726	3,537	Switzerland 51,345; East Germany 2,894.
Other do	2,926	2,090	NA	NA.
Tin:				
Ore and concentrate	4,019	3,035	--	Spain 1,304; West Germany 1,000; Belgium-Luxembourg 500.
Oxides and hydroxides	453	431	NA	NA.
Metal including alloys:				
Scrap	22	115	--	West Germany 92; Belgium-Luxembourg 20.
Unwrought	7,458	8,234	530	U.S.S.R. 3,788; Czechoslovakia 658; Netherlands 609.
Semimanufactures	352	635	--	Netherlands 272; Italy 47; Sweden 44.
Titanium: Oxides and hydroxides	18,705	14,038	1,545	Netherlands 2,132; Hungary 1,844; West Germany 1,316.
Tungsten:				
Ore and concentrate	30	222	51	Poland 84; Netherlands 39; West Germany 31.

See footnotes at end of table.

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
METALS —Continued				
Tungsten —Continued				
Oxides and hydroxides	5	1	NA	NA.
Metal including alloys, all forms	227	333	44	West Germany 131; Netherlands 26; Italy 13.
Uranium and thorium:				
Ore and concentrate, value, thousands	--	$8	--	All to France.
Metal including alloys, all forms	11	20	NA	NA.
Zinc:				
Ore and concentrate	--	7,695	--	France 4,330; Belgium-Luxembourg 3,365.
Oxides and peroxides	10,267	9,331	168	Belgium-Luxembourg 1,340; Netherlands 1,282; Cuba 1,266.
Metal including alloys:				
Scrap	4,818	5,400	--	West Germany 3,576; Belgium-Luxembourg 727.
Blue powder	2,210	2,162	NA	NA.
Unwrought	19,119	34,468	3,661	Netherlands 10,216; France 4,403; Belgium-Luxembourg 3,331.
Semimanufactures	3,737	3,152	363	Pakistan 346.
Other:				
Ores and concentrates:				
Of molybdenum, tantalum, titanium, vanadium, zirconium	7,565	4,753	--	Belgium-Luxembourg 1,006; Spain 738; France 580.
Unspecified	396	841	83	Belgium-Luxembourg 434.
Ash and residue containing nonferrous metals	49,272	46,020	494	West Germany 21,494; Belgium-Luxembourg 7,902.
Oxides, hydroxides, peroxides	r2,025	2,101	NA	NA.
Metals:				
Metalloids	2,589	2,604	35	Denmark 1,152; Malaysia 586; West Germany 92.
Alkali, alkaline-earth, rare-earth metals	222	172	23	Poland 31; Hungary 15; Italy 15.
Pyrophoric alloys	7,574	10,325	--	West Germany 6,412; Ireland 1,236.
Base metals including alloys, all forms	r114	140	NA	NA.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	2,262	2,203	6	Libya 506; Singapore 421; West Germany 215.
Artificial: Corundum	7,171	6,744	1,665	Republic of South Africa 1,288; West Germany 1,244.
Dust and powder of precious and semi-precious stones, value, thousands	$7,805	$4,646	$689	Belgium-Luxembourg $835; West Germany $449.
Grinding and polishing wheels and stones	7,369	7,281	182	West Germany 891; Sweden 880; Italy 629.
Asbestos, crude	615	1,118	--	France 340; Italy 188; West Germany 135.
Barite and witherite	4,622	4,050	36	Norway 694; West Germany 578; Denmark 306.
Boron materials:				
Crude natural borates	140	1,517	--	Netherlands 1,399; Republic of South Africa 74.
Oxide and acid	996	1,514	37	Netherlands 1,337; France 76; Canada 36.
Cement, thousand tons	1,600	1,025	214	Nigeria 576; Ireland 102.
Chalk	60,276	57,742	--	Sweden 12,611; Nigeria 9,893; Australia 6,274.
Clays and clay products:				
Crude, thousand tons	3,111	2,957	32	West Germany 491; Italy 447; Finland 366.
Products:				
Nonrefractory	191,938	182,521	12,250	Ireland 52,754; Saudi Arabia 14,230; Netherlands 13,303.
Refractory including nonclay brick	252,611	249,937	4,025	Italy 39,031; Sweden 21,928; West Germany 16,837.
Cryolite and chiolite	7	3	NA	NA.
Diamonds: Gem, not set or strung, value, millions	$5,835	$6,568	$691	Switzerland $3,586; Belgium-Luxembourg $1,634.
Diatomite and other infusorial earth	1,098	985	2	Ireland 360; Ghana 223; Singapore 53.
Feldspar and fluorspar	28,483	59,229	--	Canada 23,556; West Germany 17,177; Norway 7,788.

See footnotes at end of table.

NONMETALS —Continued				
Fertilizer materials:				
Crude:				
Nitrogenous	230	137	--	Ireland 107; France 20.
Phosphatic	222	94	--	Australia 71; Ireland 23.
Potassic	6	35	--	Ireland 20; Bangladesh 10; France 5.
Other including mixed	2,603	2,481	93	Ireland 1,319; West Germany 662; Netherlands 111.
Manufactured:				
Nitrogenous	148,141	118,186	16	Netherlands 46,773; Ireland 25,830; Belgium-Luxembourg 22,322.
Phosphatic	41,757	25,955	--	Ireland 14,536; France 5,785.
Potassic	164,740	200,695	267	Singapore 42,889; Norway 35,807; Finland 30,345.
Other including mixed	435,267	301,952	73	Ireland 171; West Germany 57.
Ammonia	98,035	102,581	10	Spain 25,632; Ireland 16,015; Sweden 11,380.
Graphite, natural	3,158	2,081	290	France 561; Belgium-Luxembourg 218; West Germany 218.
Gypsum and plasters	17,588	17,889	777	Ireland 4,190; Saudi Arabia 2,390; Hong Kong 1,988.
Lime	42,365	32,724	--	Nigeria 7,704; Venezuela 3,499.
Magnesite	65,004	80,042	NA	NA.
Mica:				
Crude including splittings and waste	4,878	3,773	213	West Germany 706; Belgium-Luxembourg 419; Hungary 321.
Worked including agglomerated splittings	417	231	NA	NA.
Pigments, mineral: Iron oxides, processed	9,400	7,208	365	Netherlands 433; Australia 428; Italy 424.
Precious and semiprecious stones, except diamonds:				
Natural value, thousands	$90,588	$126,653	$4,369	Switzerland $73,972; West Germany $12,646.
Manufactured do.	$246	$440	$103	Spain $107; India $84; West Germany $55.
Pyrites, unroasted	13	20	--	Italy 12; France 8.
Salt and brine	424,187	393,323	19	Sweden 136,665; Nigeria 112,288.
Sodium and potassium compounds, n.e.s.:				
Caustic potash, sodic and potassic peroxides	1,588	1,618	2	Australia 674; New Zealand 420; Ireland 281.
Caustic soda	54,835	45,891	50	Nigeria 5,320; Ireland 3,903; Tanzania 3,456.
Soda ash	146,169	149,910	20	Republic of South Africa 65,203; Ireland 14,164; Sweden 11,997.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	11,077	8,368	--	West Germany 5,171; France 1,515; Ireland 610.
Worked	5,936	7,746	248	France 1,915; Belgium-Luxembourg 1,329; Australia 603.
Dolomite, chiefly refractory-grade	27,267	30,116	--	Sweden 12,765; Ireland 5,416.
Gravel and crushed rock thousand tons	6,437	6,814	1	Belgium-Luxembourg 3,171; France 1,803; Netherlands 1,121.
Limestone, except dimension	867,742	799,103	--	Belgium-Luxembourg 231,270; West Germany 227,237; Norway 179,427.
Quartz and quartzite	317	277	15	Ireland 109; Iran 43; Singapore 27.
Sand excluding metal-bearing	85,525	48,199	1	Ireland 23,843; Sweden 17,264; Norway 2,740.
Sulfur:				
Elemental:				
Other than colloidal	1,344	1,116	--	Australia 282; Ireland 228; India 161.
Colloidal	247	133	2	Ireland 50; India 21; Belgium-Luxembourg 18.
Dioxide	104	90	NA	NA.
Sulfuric acid	172,556	228,676	1	Ireland 56,271; Turkey 48,630; Greece 23,228.
Talc, steatite, soapstone, pyrophyllite	5,605	5,806	--	Belgium-Luxembourg 1,970; Nigeria 1,313; Ireland 853.
Other:				
Crude	50,480	32,620	48	West Germany 8,056; Netherlands 5,624; Sweden 2,779.
Slag, dross, similar waste, not metal-bearing:				
From iron and steel manufacture	97,677	78,935	--	West Germany 67,958; Denmark 2,433; Norway 1,971.
Unspecified	4,493	5,943	570	West Germany 2,378; Sweden 1,039.

See footnotes at end of table.

Table 2.—United Kingdom: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Other —Continued				
Oxides, hydroxides, peroxides of barium, magnesium, strontium	250	581	--	West Germany 276; Belgium-Luxembourg 100.
Halogens other than chlorine	1,824	2,026	56	France 1,010; West Germany 367; Ireland 191.
Building materials of asphalt, asbestos and fiber cements, unfired nonmetals	77,011	92,298	1,738	Ireland 21,263; Saudi Arabia 14,412; Iraq 4,603.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	3,815	2,887	--	Ireland 1,293; Kenya 491; Norway 202.
Carbon black	48,527	35,195	51	Ireland 5,845; Nigeria 4,508; France 3,858.
Coal and briquets:				
Anthracite and bituminous coal thousand tons	2,339	4,042	(1)	France 1,474; West Germany 1,145; Denmark 606.
Briquets of anthracite and bituminous coal do	174	119	--	Norway 108; Ireland 5.
Lignite and lignite briquets	5	120	--	Saudi Arabia 30; Libya 23; Norway 23.
Coke and semicoke thousand tons	721	1,164	--	West Germany 198; Norway 195; Netherlands 170.
Hydrogen, helium, rare gases	7,091	5,135	7	Ireland 2,244; Norway 597; Netherlands 554.
Peat including briquets and litter	4,542	5,105	--	France 2,138; Lebanon 592; Spain 361.
Petroleum:				
Crude and partly refined thousand 42-gallon barrels	r291,360	291,566	55,322	West Germany 83,849; Netherlands 64,649; France 21,633.
Refinery products:				
Gasoline do	r18,444	16,882	--	Ireland 5,847; Netherlands 5,445; Sweden 1,956.
Kerosine and jet fuel do	r6,441	6,090	--	Ireland 2,281; Norway 1,045; Sweden 963.
Distillate fuel oil do	39,958	37,654	--	Ireland 5,721; Denmark 4,643; Sweden 3,927.
Residual fuel oil do	23,757	35,203	170	Netherlands 8,420; Ireland 7,455; Sweden 6,399.
Lubricants do	r7,454	10,037	--	France 4,075; Netherlands 944; West Germany 738.
Other:				
Liquefied petroleum gas do	r10,322	11,839	1,189	Netherlands 2,525; Ireland 2,239; Portugal 1,404.
Mineral jelly and wax do	328	349	--	Nigeria 63; West Germany 58; Finland 28.
Bitumen and other residues and bituminous mixtures do	r1,079	910	--	Ireland 621; Iceland 66.
Petroleum coke do	r1,890	2,047	NA	NA.
Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals	302,544	222,264	5,352	Norway 59,823; Netherlands 58,320; France 20,309.

[3]Excludes quantity valued at $28,764,563 in 1979 and $39,461,026 in 1980.

COMMODITY REVIEW

METALS

Aluminum.—Production of primary aluminum, at about 340,000 tons, decreased 9% in 1981.

Imports of primary aluminum decreased 25% to 120,000 tons, of which about 50% came from Norway. Consumption of primary aluminum decreased 15% to 350,000 tons, and exports declined 17% to 100,000 tons. Production of secondary aluminum decreased by some 10,000 tons to 150,000 tons, but imports increased 25% to 6,000 tons. Consumption of secondary aluminum increased 12% to 90,000 tons, and exports declined to 60,000 tons.

British Aluminium Co. Ltd. announced at yearend that its 100,000-ton-per-year Inver-

gordon smelting plant, near Inverness, had been shut down. The smelter operated at an average 90% of capacity in 1981 and posted a first-half pretax loss of $17.4 million, compared with a profit of $14.6 million in 1980. The loss was attributed primarily to low aluminum prices and the high cost of electricity. The company's other two smelters at Lochaber and Kinlochleven, both near Fort William, Scotland, had a combined annual capacity of 50,000 tons and were still in production. At the Lochaber smelter, the company completed a major expansion, increasing production capacity by one-third to 37,000 tons per year of aluminum.

Output of the Anglesey Aluminium Ltd. primary smelter at Holyhead, North Wales, was to be reduced by cutting the number of pots onstream to approximately 200 because of the depressed market for aluminum. Anglesey, in which Kaiser Aluminum and Chemical Corp. of the United States held a 67% interest, had a design capacity of 113,000 tons per year and in 1981 was operating at about 90% capacity. The cutback action was to reduce the operating rate by about 25%.

Alcan Aluminium (United Kingdom) Ltd. reported that the Lynemouth plant commissioned the second tie line to the national grid and that a new anode handling system and a new furnace were among the major projects underway.

A new trading branch, Alaftrade, was formed by Alcan to sell ingot and semifabricated products into African and Middle East markets established by Alcan Aluminium Africa and Middle East Ltd.

Iron and Steel.—British Steel Corp. (BSC), which traditionally produced about 90% of British steel, reported a loss of $512 million before interest in the 1981-82 financial year ending April 30, against its target loss of $457 million. BSC losses in 1980-81 were $972 million. The company was expected to overrun its 1981-82 $1,482 million external financing limit (EFL) by $77 million. The EFL was expected to be reduced from $1,559 million in 1981-82 to $741 million in 1982-83. Conditions in the British iron and steel industry were abnormal during 1980 so that the usual numerical comparisons between that year and 1981 were not meaningful. In 1981, there were further falls in both apparent and estimated real consumption of steel. The domestic demand was further reduced by a net stock drawdown by consumers and steel stockholders. Production of steel in 1981 was considerably improved from the very depressed level of 1980 but was well below the output achieved in 1979.

The improvement in production was most marked in the second half of 1981. About 16% of the total steel output was produced by private concerns, showing that they were hurt less by the depressed market than BSC. In 1981, there was a small surplus of exports over imports in steel, in terms of tonnage. Investment in the iron and steel industry decreased from $37 million in 1980 to $24 million in 1981. Employment declined from 134,000 to 96,000 employees in the same period.

The British steel industry depended largely on imported iron ore, of which 13.7 million tons was purchased in 1981. About 40% of the total came from Canada, 30% from South America, and 30% from Australia, Africa, and Europe. Indigenous production of iron ore in 1981 totaled 731,245 tons with a metal content of about 21.5%, a slight decrease compared with that of 1980. For the fifth year in succession, closures of ironmaking and steelmaking facilities occurred. The closings caused a capacity reduction of about 2.5 million tons of ingot steel per year at four sites. Of the steel capacity reduction, about one-half was electric arc, the greater part of which was in the private sector. In June 1981, the Leeds Road plant of Hadfields Ltd., at Sheffield, with a capacity of 300,000 tons of crude steel, was closed down with a loss of 1,200 jobs, but Hadfields nonetheless remained a significant producer of ingots, billets, and bars.

In July 1981, Round Oak Steel Works Ltd., Brierley Hill, West Midlands, reported closure of the Level steel mill, which produced rounds, squares, and flats, and the cogging mill and partial closure of No. 2 melting shop. The number of employees was reduced from about 2,200 to 1,300.

Major developments at BSC included commissioning of a six-strand billet caster at Templeborough, an order for an eight-strand billet caster for Scunthorpe, plans for an RH degassing unit at Lackenby, and a new spun-cast iron pipe plant at Stanton and Staveley Group. Round Oak commissioned a 130-ton Asea ladle refining system. F. H. Lloyd Ltd. installed a new high-reduction mill. Darlington & Simpson Rolling Mills Ltd. went ahead with its program of modernization and automation of its rolling mills.

Lead.—In 1981, the British Government

announced that the maximum level of lead in gasoline would be reduced from 0.40 to 0.15 gram per liter by 1985.

Australian Mining and Smelting Co. Ltd., AM & S Europe Ltd. temporarily halted lead-zinc production at the Avonmouth smelter, near Bristol, late in the year because of a fault in the main blower of the Imperial smelting furnace. Supplies to customers were not expected to be affected. Britannia Refined Metals Ltd., during 1981, refined 153,323 tons of lead at its refinery at Northfleet, east of London, compared with 124,674 tons in 1980.

Rio Tinto Zinc Corp. Ltd. received permission to drill for lead-zinc near Launceston, Cornwall, and the Institute of Geological Sciences was granted permission to carry out exploratory drilling for lead, zinc, and copper in the Snowdonia National Park in North Wales.

Nickel.—A new refining plant was under construction in North Wales to recover high-purity nickel and cobalt and their salts from superalloy grindings. The refinery was to be operated by Chapman Metallurgical Ltd. The plant, based in the Clwyd district, was to cost some $2.4 million and was to start production in 1982.

The project was financed jointly by the National Research Development Corp. (part of the British Technology Group) and Technical Development Capital (part of the Finance for Industry Group) and included a contribution from the European Coal and Steel Community. By early 1983, the plant was to be in full production on a three-shift basis. Nominal capacity, on the planned one shift per day, was to be 500 tons per year of grindings and turnings, generating around 250 to 300 tons per year of nickel and cobalt. With three shifts per day, capacity would increase to 1,500 tons per year, producing about 800 to 900 tons per year of nickel and cobalt.

Tin.—In 1981, the United Kingdom was the largest producer of tin in Western Europe. Its tin mining activity was confined to Cornwall in the southwest, with minor production in neighboring Devon. Preliminary figures showed that tin metal production of 7,020 tons increased 1,190 tons in 1981. Several new and revived mining operations were developed in Cornwall and Devon despite a sharp decline in tin prices from early 1980 to mid-1981. In the latter half of 1981, the tin price increased from about $12,200 to $17,300 per ton.

In 1981, underground lode mines at South Crofty and Pendarves, belonging to South Crofty Ltd., produced 1,981 tons of tin concentrates, a decrease of 54 tons compared with that of 1980. The company was the largest British tin producer. There were plans to increase output by extending its subincline shaft, deepening the Pendarves shaft, and modernizing underground equipment and the surface mill. An exploration program on the 12,950 hectares of mineral rights owned by its subsidiary, Tehidy Minerals Co., was underway. South Crofty Ltd. was to raise production of tin by 45% over the next 5 years under a $11.7 million plan including support from the Department of Industry, the European Investment Bank, and the Barclays Bank.

At the underground lode mines at Pendeen, Geevor Tin Mines Ltd. increased its tin concentrate production (65% tin content) from 1,142 tons in 1980 to 1,344 tons in 1981. The company intended to rehabilitate the old Allen's shaft for underground mining. The subincline extension to Victory shaft became fully operational during 1980. Work began on dewatering holes to intersect the old Levant workings. It was planned to increase ore treatment capacity to 50,000 tons per year.

Rio Tinto Zinc announced for its subsidiary, Carnon Consolidated Tin Mines Ltd., a $5.7 million development program over an 18-month period at the Wheal Jane. Plans were underway to deepen the Clemow shaft and relocate the underground pumping and crushing facilities. The mine's production was estimated at 382 tons of tin concentrate during January-October 1981.

Billiton Minerals United Kingdom Ltd., a part of the Billiton International Metals Group, ceased operations at its Mount Wellington and Bissoe plants in mid-1981; the sites were put on a care and maintenance basis, and exploratory activities were to continue.

The Wheal Concord Ltd. mines near Redruth went into production in 1981, and the output of ore was expected to reach 31,200 tons per year.

The plan by Southwest Consolidated Resources Inc. to reopen the old Redmoor Mine was approved by the Government in mid-1981. The mine was expected to be in production within 3 years. The company also acquired a 30% interest from Black Rock Mineral Ventures Ltd. in an eluvial-alluvial tin prospect in Cornwall.

The significant increase in tin exploration activities and mining operations in

1981 was in contrast to the decline in the country's smelting operations. The smelter of Williams, Harvey and Co. at Bootle, Liverpool, once Europe's major tin smelting company, was finally closed at the end of June 1981, owing to a lack of concentrates and uneconomic processing of slags. The only remaining tin smelter was that of Capper Pass in North Ferriby, Yorkshire.

Titanium.—Teeside Titanium Ltd., controlled by Billiton U.K. (62.5%), Rolls Royce Ltd. (20%), and IMI Ltd. (17.5%), was planning to open a new titanium granules plant at Teeside with a designed capacity of 5,000 tons per year. The plant was scheduled to come onstream in 1983.

Tungsten.—A major project was the proposed development of a full-scale open pit mine and mill complex at the Hemerdon tungsten-tin prospect near Hemerdon, Devon, by Amax Exploration of U.K. Inc. and Hemerdon Mining and Smelting U.K. Ltd. A pilot treatment plant was constructed and operated in 1980, and evaluation continued in 1981. Planning permission to develop a mine and mill complex was awaited.

NONMETALS

Barite.—Production at the SPO Minerals Co., Ltd., Golconda barite-fluorspar-lead retreatment plant at Brassington, in Derbyshire, was affected by technical problems along with dump material that proved to be of a lower grade than forecast. The company has applied for planning permission to process barite from an old mine in Caldbeck Fells, Cumbria.

Fordamin Co. Ltd., a subsidiary of English China Clays Ltd., purchased three properties from Athole G. Allen Ltd.: The 8,000- to 10,000-ton-per-year Closehouse barite mine at Middleton-in-Teesdale, mineral leases of more than 32.4 square kilometers near Middleton-in-Teesdale, and a grinding mill at Stockton-on-Tees.

Fluorspar.—Owing to reduced demand for fluorspar, Swiss Aluminum (U.K.) Ltd. temporarily ceased development of the Burtree Pasture and Frasers Hush Mines and closed the Stanhope Burn, Cambokeels, and Broadwood operations. The Broadwood plant was operating 15% below its rated capacity of 80,000 tons per year owing to a variety of technical problems.

Laporte Industries Ltd. reported a reduced demand in 1980 for its fluorspar output at Stoney Middleton, Derbyshire. Colin Steward Ltd. commissioned its new 45,000- to 50,000-ton-per-year attrition mill and drying plant and was to process up to 20,000 to 25,000 tons per year of acid-grade fluorspar on behalf of Kaiser Aluminium (U.K.) Ltd.

Gypsum.—British Gypsum Ltd. received permission to mine its gypsum deposit at Barrow-on-Soar in Leicestershire; some 30 million tons of reserves were proven. Production was to commence by 1983, rising to full capacity around 1985. Further exploration was taking place over an area of 125.5 square kilometers throughout Great Britain.

Potash.—Cleveland Potash Ltd. announced that the Boulby Mine in Yorkshire, owned by Anglo American Corp., Ltd., of South Africa, and Charter Consolidated, Ltd., produced 509,000 tons of potash in 1980 and was scheduled to produce 395,000 tons in 1981 versus an original goal of 1 million tons. The mine was to be shut down for 3 weeks in January 1982 owing to the depressed market and imports of potassium from the German Democratic Republic. The employees at Boulby, who total 880, would be paid 80% of their basic wage during the shutdown.

MINERAL FUELS

Coal.—British production of hard coal (bituminous, semibituminous, and anthracite) at 126.4 million tons decreased 1.8 million tons in 1981. Most of the coal output came from the National Coal Board's (NCB) deep mines with about 12% produced in opencast mines. In March 1981, there were 211 NCB deep mines and 65 opencast mines in operation. During the year, the NCB closed 10 pits with a loss of 12,000 jobs. Output per workshift rose from 2.32 tons in January to 2.47 tons in November. Consumption of coal dropped from 123.5 million tons in 1980 to 118 million tons in 1981, owing to the economic recession, a reduction in steelmaking capacity, and energy conservation measures. The United Kingdom became a small net exporter of coal in 1981, reversing an 8-year trend, but export prices did not cover actual costs of production and transport. In 1981, exports reached an estimated 8.7 million tons of coal, and imports, 4.2 million tons, a 4.5-million-ton total trade surplus compared with a deficit of 3.5 million tons in 1980. Members of the European commission countries took nearly all of the United Kingdom's coal exports. Australia continued to be the principal foreign coal supplier, with shipment of 2.1 million tons in 1981, and imports of U.S. coal totaled 1.5 million tons.

In 1980-81, the income of the NCB and

two small nonmining subsidiaries amounted to $9.4 billion, which included $7.3 billion in coal sales, $251 million in coke sales, and $213 million in operating and social grants provided by the Government. Despite a trading profit and Government subsidies, the NCB still ran a deficit of $117.7 million in 1980-81. Total Government grants for operating deficits and the social costs of pit closures, primarily payments to laid-off workers, increased from $473 million in 1980-81 to $1.1 billion in 1981-82. In January 1982, the new coal industry bill set a new grant limit of $2 billion for the period 1979-84, which could be raised to $3.6 billion by Parliamentary order.

At the end of November 1981, the United Kingdom's coal stocks totaled 43.1 million tons of which 22.3 million tons was distributed to power stations, coke ovens, and other enterprises.

Coal in place in the United Kingdom was estimated at 160 to 220 billion tons, of which 45 billion tons was probably economically recoverable.

Natural Gas.—The Government withdrew its support for the $5.5 billion gas-gathering pipeline project, intended to collect and distribute gas in the United Kingdom from more than a dozen fields in the northern and central North Sea. The decision left the oil companies to arrange for gas distribution onshore. Only one independent pipeline was announced in 1981, the BP Magnus pipeline, collecting gas from the Murchison and Thistle Fields and feeding the pipeline from Brent to St. Fergus in Scotland.

In the Irish Sea, the British Gas Corp. (BGC) planned to develop its Morecambe Bay Gasfield in an attempt to get the gas onstream in the latter part of the 1983-84 winter.

Petroleum.—With a total output of 650 million barrels of crude petroleum in 1981, the United Kingdom became the fifth largest oil producer in the Western World and seventh overall, being the most important producer of high-quality light crude oil. In 1981, the United Kingdom was self-sufficient in petroleum production. Production of crude oil exceeded consumption by about 100 million barrels. Crude oil production by fields was as follows:

Field	Operator	Approximate production rate (barrels per day)
Argyll	Hamilton Bros	Temporarily shut down.
Auk	Shell-ESSO	9,100
Beatrice	British National Oil Corp. (startup in 1981).	27,800
Beryl	Mobil	97,700
Brent	Shell-ESSO	198,900
Buchan	British Petroleum (startup in 1981).	40,400
Claymore	Occidental	96,800
Cormorant, South	Shell-ESSO	20,000
Dunlin	do	89,900
Forties	British Petroleum	398,900
Heather	Unocal	33,900
Montrose	Amoco	19,400
Murchison	Conoco (80% in United Kingdom sector).	92,700
Ninian	Chevron	307,300
Piper	Occidental	199,900
Tartan	Texaco (startup in 1981).	16,200
Thistle	British National Oil Corp.	130,700

The British National Oil Co. (BNOC) marketed about two-thirds of the United Kingdom's North Sea oil output.

The Tartan Field (Texaco) came onstream in January, 180 kilometers northeast of Aberdeen, at a cost of $500 million; The Buchan Field (British Petroleum) followed in May and was found to contain more than the 7 million tons of recoverable reserves originally estimated, and the Beatrice BNOC came onstream in November. Two more fields were expected to start operations in 1982, Fulmar, 275 kilometers east of Dundee, at a cost of $1.2 billion, and North Cormorant, located in the East Shetland Basin, at a cost of $1 billion; both were operated by Shell-ESSO. Initial recoverable reserves in the Fulmar Field were estimated at 500 million barrels, with an additional 420 million barrels in the North Cormorant Field. Estimated production of the Fulmar Field was 180,000 barrels per day, and for North Cormorant, 150,000 barrels per day. The British oil industry also expected production in two smaller fields, North West Hutton and North Claymore, to begin in 1982. North West Hutton had probable reserves of 285 million barrels, and North Claymore had 30 million barrels.

Oil exploration activity in the British

North Sea, as measured by footage drilled and the number of mobile rigs in operation, was up sharply in 1981 compared with that of 1979-80. In 1981, 54 exploration wells were sunk on the United Kingdom's Continental Shelf in the North Sea, compared with 35 in 1980, and the number of drilling units increased by 6 to 26. Drilling footage from mobile rigs increased by 12% in 1981 over that of 1980.

British Petroleum, which spent $710 million on exploration in 1981 and planned to spend about $1.5 billion in 1982, reported that a typical well cost was $10 to $15 million. To develop an average oilfield, the cost was about $1 to $1.5 billion. It took 5 to 9 years to bring a proven field into production and another 6 years before the oil companies could make a profit on their investment.

The British Secretary of Energy introduced the Government's oil and gas denationalization legislation in Parliament on December 17. The bill would authorize the sale of a majority share of the exploration and production activities of BNOC, require BGC to dispose of its offshore oil holdings, and end the BGC privileged monopoly position as a buyer and seller of North Sea gas.

The Mineral Industry of Venezuela

By H. Robert Ensminger[1]

The Venezuelan economy remained substantially the same in 1981 as in 1980. The gross domestic product grew by an officially estimated 0.6% over the revised 1980 figure and amounted to $68.0 billion[2] at current prices.

Sharply rising oil prices in 1979 appeared to assure Venzuela's long-term requirements for increasing revenues. The perception that oil prices would continue to rise provided the basis for planned expenditures of approximately $20 billion to adapt the oil industry to changing domestic and world markets. A key element in the program was the development of the country's heavy oil resources, especially the Orinoco heavy oil belt. When petroleum prices reversed their upward trend. Venezuela was forced to reduce sectoral budget allocations. These budget cutbacks were also imposed on the petroleum sector, particularly the controversial Orinoco development plan.

Since heavy crude oil contains large amounts of contaminants, notably sulfur and metals, and yields large volumes of residual fuel oil that require expensive refinery upgrading, the demand for Venezuelan heavy crude was somewhat weak. This lessening of demand may have a negative impact on the national plan.

In 1981, exported petroleum and petroleum products comprised 94.4% of the total export earnings. The other mineral production provided export earnings of $847 million. The value of exported petroleum and petroleum products for 1981 increased over that of 1980; however, the volume of these same exports decreased relative to that in 1980.

Iron ore and concentrate production in 1981 fell below the level produced in 1980. An announcement was expected in early 1982 that C.V.G. Ferrominera Orinoco C.A. would close the Minorca High Iron Briquette (HIB) plant because it had been operating at 31% of capacity during 1981 and caused losses of $12 million with no prospects for improvement.

C.V.G. Siderúrgica del Orinoco, C.A. (SIDOR), produced a record 1.8 million tons of steel valued at approximately $893 million in 1981.

Venezuela's aluminum production suffered a temporary setback in 1981. The breakdown of 250 out of 720 pots at the Industria Venezolana de Aluminio (VENALUM) smelter reduced production 25%.

Interamericana de Alumina, C.A. (INTERALUMINA), planned to obtain long-term financing in 1982 to back construction of its alumina plant. Continuing questions about the viability of plans to mine bauxite have delayed the decision on the proposed Los Pijiguaos project.

The oil industry was a casualty of the budget cuts, with its original 5-year investment target of over $20 billion trimmed by 16%. What concerned segments of the oil industry was that planned investments of $5.6 billion for the development of the Orinoco heavy oil belt were halved while the other oil sectors remained virtually unchanged.

There was the likelihood that Petroleos de Venezuela, S.A. (PDVSA), which has been self-financed during the first 5 years following nationalization in 1976, would have to consider either to cut back its Orinoco heavy oil development plans or seek foreign funds through loans or direct foreign investment.

Metallgesellschaft of the Federal Republic of Germany has refused to renegotiate its alumina price agreed to in the contract with

VENALUM and has taken the issue to court.

Government Policies and Programs.—Venezuela's decision in 1981 to cut back official spending 20% over the next 5 years has left a wake of confusion and uncertainty over expansion of the State oil industry. Reduced Government spending in the heavy oil sector under the national plan reflected recognition that world oil markets are unlikely to provide substantial price increases in the immediate future. Oil income, originally forecast to reach a total of approximately $110 billion between 1981 and 1985, was subsequently projected at $98 billion.

A potential problem for the economy was the "Buy Venezuelan" decree that was instituted in 1981. It penalizes foreign imports, including those from the United States, and reduces the need for more efficient production domestically. The extent to which it will be enforced was not apparent by yearend.

The Venezuelan railroad system was being upgraded and expanded at an estimated cost of about $300 million. This included the opening of the Puerto Ordaz-Barcelona-Guanta trunkline in eastern Venezuela, a vehicular-railroad bridge spanning the Orinoco at Ciudad Guayana, and a projected bridge to Isla de Margarita on the northeast coast.

PRODUCTION

In 1981, petroleum continued as the mainstay of Venezuela's mineral production. Output for 1981 was 2.1 million barrels per day, which was 65,000 barrels less than the 1980 daily average.

The production of aluminum in 1981 fell by 4.4% compared with that of 1980. The shortfall resulted from the failure of 250 pots at the VENALUM smelter in May 1981. Aluminio del Caroni, S.A. (ALCASA) produced 111,300 tons during the year, and VENALUM produced 202,000 tons. VENALUM's production for 1982 was targeted at 228,000 tons.

All SIDOR plants increased their steel production during 1981. The production of crude steel reached a level of 1.8 million tons, an increase of almost 2% over that of 1980 and a 42% increase over that of 1979.

Gold production increased 32% over that of 1980.

Diamond production fell in both categories in 1981. Production of gem-quality diamonds fell by approximately 54% while industrial diamond production decreased by about 11%.

Table 1.—Venezuela: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through July 12, 1982.

[2]Reported figure.

[3]Data prior to 1981 was based on figures taken from the Memoria y Cuenta published annually by the Ministerio de Energia y Minas. Some of this information is not compatible with 1981 figures, but will be adjusted when more reliable data become available.

[4]From nonassociated natural gas only.

[5]Includes associated natural gas lease condensate and natural gasoline. Lease condensate is included as follows, in thousand 42-gallon barrels: 1976—1,088; 1977—1,174; 1978—1,048; 1979—1,803; 1980—1,227; and 1981—1,661. Natural gasoline is included as follows, in thousand 42-gallon barrels: 1976—283; 1977—none reported; 1978—329; 1979—255; 1980—308; and 1981—307.

[6]Liquid equivalent.

TRADE

The value of exported crude oil and refined products in 1981 was $19 billion, an increase of 5.6% over that of 1980; however, the corresponding volume decreased by 5.8%. The reduced 1981 export volume was the result of a developing worldwide oil glut, depressed economies in the industrial nations, and worldwide emphasis on conservation of energy.

In 1981, Venezuela exported approximately 147 million barrels of petroleum and refined products to the United States. This comprised about 23% of total petroleum exports and was 14% lower than that for the previous year.

The share of petroleum exports in 1981 by PDVSA subsidiary companies was as follows: Lagoven, S.A., 46%; Maraven, S.A., 31%; Corpoven, S.A., 19%; and Meneven, S.A., 4%.

In 1981, iron ore exports increased by almost 5% over those of 1980 while the U.S. share of iron ore exports increased to 44% in 1981 from 31% in 1980.

The value of steel exports increased by 36% to $94 million in 1981.

Petrochemical exports of 490,000 tons represented about 50% of the total production in 1981.

VENALUM contributed 71% of the aluminum exports while ALCASA contributed the remainder. VENALUM exported 84% of its production of aluminum while ALCASA exported 63%.

COMMODITY REVIEW

METALS

Aluminum.—The breakdown of 250 of the 720 pots at the VENALUM smelter caused a substantial loss in output of primary aluminum. Planned output for 1981 was 268,500 tons; however, output with reduced capacity declined by 25% to 202,200 tons. Sales amounted to 196,000 tons, of which 169,800 tons were exported. Exports to Japan increased to 160,000 tons in 1981 or 82% of the tonnage sold by the company.

Owing to the drop in aluminum prices on the international market, VENALUM's sales decreased to $342 million and net profit fell substantially. VENALUM's president claimed that the export subsidy to the aluminum industry was not needed and that the industry could function perfectly well without it.

Metallgesellschaft refused to renegotiate its alumina price with VENALUM and has taken the issue to court. VENALUM stated that this did not create a supply problem since it was buying alumina on the spot market for about 13% less than the Aluminum Co. of Canada international reference price.

For 1982, VENALUM projected a volume of sales of primary aluminum of 228,000 tons based on starting the year with 595 pots in operation.

By the end of May, ALCASA was the principal supplier of aluminum to the domestic market and the Andean Pact countries. The total production for the year was 111,300 tons, which represented an increase of 5% over that of 1980. Total exports amounted to 69,330 tons of which 69,100 tons were cast aluminum and 230 tons were laminated aluminum. ALCASA with its two plants, one for reduction and fabrication of aluminum in Ciudad Guayana, and the other for foil in Guacara, State of Carabobo, initiated studies directed to modifying its installed capacity for laminated products in

both plants. The total capital investment for the expansions was estimated at $378 million, of which $290 million would be spent on the plant at Ciudad Guayana and $78 million on the plant at Guacara.

INTERALUMINA planned to raise up to $400 million in long-term financing early in 1982 for completion of the 1-million-ton-per-year alumina facility currently under construction.

The reduction in Venezuela's projected oil revenues during the next few years, and the problems faced in the operation of existing aluminum plants, led the Government to sharply reduce planned investment in the aluminum sector in the period up to 1985. In the country's Sixth National Plan, covering the years 1981-85, the program envisaged in the preliminary version of the plan to increase capacity from 400,000 tons per year to 610,000 tons per year was dropped. The long-term plan to boost primary aluminum output to 1 million tons per year by 1990 remained as outlined in the preliminary plan, but until 1985, only feasibility studies and engineering design plans would be completed.

Bauxite.—Continuing doubts about project viability have delayed the final decision on initiating mining of the Los Pijiguaos bauxite project. C.V.G. Bauxita Venezolana, C.A. (BAUXIVEN), established to operate the mining project, was not allotted funds and work was limited in scope. Original plans called for BAUXIVEN to begin operations to coincide with the startup of INTERALUMINA; subsequently it appeared there will be a lag of at least 2 years because the Fondo de Inversiones (FIV) has insisted on further studies and testing of the Los Pijiguaos ore. The hesitation by FIV stemmed from a fear that it would have to subsidize the mine, if the project is not economically viable. The decision on Los Pijiguaos will essentially depend on what future the Government sees for its aluminum industry.

Iron Ore.—The iron ore mining operations were run by the Government-owned company, C.V.G. Ferrominera. The principal producing mines were Cerro Bolivar, Cerro El Pao, and Cerro Altamira. Venezuela's iron ore output in 1981 was down approximately 6% compared with that of 1980.

The Piar Div. of Ferrominera produced 75% of the iron ore. The greater part of Ferrominera's total output came from the Cerro Bolivar Mine, which had an output of 8.6 million tons in 1981. The remainder of the output came from the Cerro Altamira Mine, which was started up in 1974, closed in 1977 for lack of market demand, and reopened again in July 1980. Production from Altamira for 1981 was 3.2 million tons.

Since 1959, all ships carrying iron ore have sailed along the Rio Grande Channel, one of the major outlets of the Orinoco River Delta. One large dredger was continuously employed in keeping the channel navigable. The total channel length maintained in this manner was 341 kilometers, from Ciudad Guayana to the mouth of the river. The channel depth depends on the season. During the high water period, from June to October, the depth averages 13 meters of water and 80,000-deadweight-ton vessels can transit the channel. During the low water season, the average depth is considerably reduced and vessels can only take a 60% cargo.

At the end of 1981, Venezuela's proven iron ore reserves were estimated at 2.1 billion tons with an average grade of 63.7% iron.

Iron and Steel.—Ferrominera expected to announce in early 1982 its decision on closing down the Minorca HIB plant after months of uncertainly over its future. The reason given for the shutdown was that there has been little demand for the briquets, which are regarded as blast furnace feed. The plant produced only 200,000 tons in 1981, far below its 650,000-ton-per-year capacity. The operating loss for 1981 amounted to $12 million, bringing the cumulative loss over the last 8 years to $70 million.

In 1981, Fior de Venezuela, S.A., exported 246,000 tons of direct-reduced iron briquets from its plant in Ciudad Guayana to the United States, the German Democratic Republic, Yugoslavia, and Spain.

Gross sales of SIDOR increased during 1981 to $893 million from the sale of 1.8 million tons of products. SIDOR sold 1.5 million tons of steel on the domestic market in 1981, slightly below the amount in 1980. The company exported 400,000 tons of steel valued at about $94 million in 1981 versus the exportation of 300,000 tons valued at $69 million in 1980. Operations in 1981 resulted in a net loss of $507 million because of debt burdens.

Ferroalloys.—Negotiations were underway between Ferrosilico Venezolana, S.A. (FESILVEN), in which FIV is the major stockholder, and its foreign creditors to reschedule its foreign debt—approximately $38 million. Some of the outstanding foreign debt was expected to be paid off immediately while another part was to be converted

into medium-term debt with 10-year maturity dates. The remainder was to be converted into equity capital. Once negotiations are completed, the new shareholders would be FIV, Corporación Venezolana de Guayana, and a consortium of foreign banks.

FESILVEN has lost money since 1975, the year it was formed. It approached liquidation in 1980 in a dispute with Credit Lyonnaise of France over the payment of interest on a $13 million loan. The closure was avoided, and instead, the company expanded its operations from producing 35,000 tons of ferrosilicon in 1979 to 47,000 tons in 1980.

MINERAL FUELS

The latest figures on total energy production available are for 1980, of which petroleum comprised 83%. The total energy produced in 1980 showed a slight reduction from that of 1979, while the energy available internally from all sources increased by 11.0% over that of 1979.

Coal.—C.A. Minas de Carbon de Lobatera mines produced 44,600 tons of coal during 1981, or 99% of total production. The C.A. Minas de Naricual mine was shut down in 1981 while geologic and economic studies were being carried out.

In the early part of 1982, Carbones del Zulia, C.A., was expected to award its contract to design Venezuela's first major coal project, an open pit mine and ancillary facilities estimated to cost $200 million. The proposed mine, Paso Diablo, is to be located in the Guasare region in the State of Zulia 100 kilometers north of Maracaibo. The mine was initially scheduled to produce 4 million tons per year of steam and metallurgical coal beginning in 1986, with expansion capabilities to 6 million tons per year.

Petroleum and Natural Gas.—In 1981, the hydrocarbons industry registered a total income estimated at $19.6 billion, of which 97% was derived from export sales of crude oil and refined products. The remaining 3% of income was accounted for by the sale of refined products and natural gas on the domestic market.

The net profit of PDVSA for 1981 was $3.5 billion while the Government's share obtained through various forms of taxation was estimated to be $13.9 billion, an increase of 8.3% over that of 1980.

The budget of PDVSA during 1981 was estimated at $3.2 billion. Exploration and production expenditures accounted for 77% of the total for 1981. The objective of this allocation of funds was to increase in the shortest time, the capacity for the production of crude oil above the rate of 2 million barrels per day. Venezuela, as a member of the Organization of Petroleum Exporting Countries, followed the May 1981 recommendation to reduce production by 10% as of June 1981.

Of total reserves, an estimated 54% or 11 billion barrels was comprised of heavy crude oil of 22° API gravity or less. The Orinoco crude is typically 8° to 10° API gravity, and only 2% to 5% is recoverable by primary means. The following table[3] reflects the change in production of the various weights of crude oil from 1976 through 1982:

Table 4.—Venezuela: Daily production figures of light, medium, and heavy crude oil

(Thousand barrels per day)

	1976	1977	1978	1979	1980	1981[p]	1982[e]
Light (over 30° API gravity)	802	798	740	736	651	632	687
Medium (22° to 30° API gravity)	875	762	759	830	714	633	584
Heavy (less than 22° API gravity)	617	678	667	790	803	843	925
Total	2,294	2,238	2,166	2,356	2,168	2,108	2,196

[e]Estimated. [p]Preliminary.

At the end of June 1981, proven oil reserves totaled 20.5 billion barrels, which was a net gain of 834 million barrels over the 1980 yearend total.

In March 1981, Lagoven, S.A., a PDVSA subsidiary, awarded the first major contract for the Orinoco heavy oil belt to the Lummus Div. of Combustion Engineering Corp. The New York company will coordinate $700 million to $800 million worth of work in association with the Venezuelan firm Projectos Intergrados, C.A., over the next 8 years. The contract involves building a pilot refinery capable of handling the viscous Orinoco oil at the rate of 125,000 barrels per day and a city in the jungle for 30,000 inhabitants.

Maraven, S.A., also a PDVSA subsidiary,

let a contract to Union Oil Co. of California's Process Div. for process design work on its 360,000-barrel-per-day Cardon refinery. The contract was part of a $2.3 billion modernization of the refinery, scheduled for completion in 1985.

In October 1981, Brazil, Mexico, and Venezuela formed Latin America's first multinational oil company named PETROLATINA. It was created to explore and exploit oil resources in the Latin American region. It was intended that the company would also enter the world petroleum market in competition with the large multinational companies of the United States, the United Kingdom, the Netherlands, and other countries.

Lagoven, S.A., was embarking on a program to establish natural gas production from wells drilled in Caribbean waters. Full development was expected to take 8 to 10 years and cost $3 billion. During the past 3 years 38 wells have been drilled of which about half have produced gas. The average flow rate was 37 million cubic feet per day of gas with estimated reserves of 8 to 10 trillion cubic feet. A prefeasibility study by Société Nationale Elf Aquitaine of France stated that the fields would be attractive at one-half the reserve figure. The most promising area was north of Venezuela's Paria Peninsula, west of Trinidad and Tobago where wells reached a depth of 12,000 feet in 250 to 300 feet of water.

Meneven, S.A., awarded to Brown and Root, Inc., an $815 million contract to design and build facilities to extract liquids from natural gas and process them into propane, butane, and natural gasoline. An extraction plant with input capacity of 800 million cubic feet per day of natural gas is to be built in the State of Anzoatequi, with the 60,000-barrel-per-day processing plant to be situated near Barcelona, on the east coast.

Petrochemicals.—Petroquimica de Venezuela, S.A. (PEQUIVEN), is comprised of two basic petrochemical complexes. The older Moron complex produced nitrogen and phosphate fertilizer for the domestic market. The newer El Tablazo complex consisted of several fertilizer plants and an olefin plant. The fertilizer plants supplied the export market while the olefin plant supplied the private petrochemical sector with feedstocks for the manufacture of plastics, detergents, etc. PEQUIVEN's record sales increased by 32% to $244 million in 1981.

The Mineral Industry of Yugoslavia

By Roman V. Sondermayer[1]

Difficulties created by the world economic slowdown, as well as high prices and shortages of fuels, electric power, and foreign exchange hampered activities of the mineral industry in Yugoslavia. A number of projects started several years ago were completed or continued but no new projects of any major economic significance were started. Although the year was slow for the mineral economy, Yugoslavia maintained its position as one of the leading producers of nonferrous metals in Europe during 1981.

The more prominent minerals with Yugoslav production expressed as a percentage of 1981 world output were as follows: Antimony 2% to 3%, bauxite 3% to 4%, lead mine 3% to 4%, smelter lead 2% to 3%, magnesite 3% to 4%, bismuth 2% to 3%, mine and smelter zinc 2% to 3%, and copper ore, refined copper, and aluminum, all 1% to 2%.

In 1980, the latest year for which complete data were available, the mineral industry's share of the gross social product was 7.5% and the mineral industry employed 5.9% of the total working labor force. By sectors, the value and number of employed persons in the mineral industry are shown in the following tabulation:[2]

Branch	Million dinars	Employment, thousand persons
Coal:		
Production	16,220	54.3
Processing	1,670	3.2
Crude oil:		
Production	8,759	4.1
Processing	11,194	9.6
Iron and steel:		
Iron ore, production	940	5.0
Steel, production	18,886	53.2
Nonferrous metals:		
Production of ores	8,037	26.3
Metal, production	5,746	16.0
Metal, processing	6,105	13.9
Nonmetallics:		
Production	2,571	12.5
Processing	11,307	49.3
Sand and gravel	5,610	23.9
Construction material	18,608	73.5
Total	115,653	344.8

The major events in the mineral industry included the completion of an aluminum plant near Mostar, Bosna i Hercegovina (BiH); commissioning of additional 50,000 tons per year aluminum capacity at the Titograd Aluminum Smelter, at Titograd, Crna Gora (Montenegro); closing of a 300,000-ton-per-year alumina plant at Obrovac, Hrvatska (Croatia); and the announcement of a decision by Industrija Nafte (INA) of Zagreb, Croatia, to accept bids for joint ventures in the Yugoslav offshore of the Adriatic.

PRODUCTION

Table 1 shows the latest trends in mineral production of the country. Because of the country's economic problems, a policy of limiting investments in the mineral industry was enforced during 1981. However, efforts continued to expand existing lead and zinc mines and to develop new copper mines. The authorities hoped to correct the existing gap between smelting facilities and mine output that necessitated imports of concentrates.

Asphalt and bitumen do	3,254	3,842	4,497	NA	NA
Petroleum coke do	336	362	300	NA	NA
Total[7] do	94,870	99,565	108,525	NA	NA

[e]Estimated. [p]Preliminary. NA Not available.

[1]Table includes data available through June 18, 1982.

[2]In addition to the commodities listed, germanium, bentonite, common clay, and diatomite are also produced, and tellurium may be recovered as a copper refinery byproduct, but available information is inadequate to make reliable estimates of output levels.

[3]Reported figure.

[4]Calculated as the difference between reported total and reported primary figure.

[5]Calculated as the difference between reported total and reported secondary figure.

[6]For ore production, see under "Lead."

[7]Excludes refinery gas, which was as follows, in million cubic feet: 1977—15,351; 1978—14,086; 1979—15,050; and 1980—not available; also excludes other materials produced by and used in the refineries as fuel.

TRADE

Tables 2 and 3 show latest available figures on trade in minerals. Dependence on imports for fuels heavily taxed the country's balance of payments.

Table 2.—Yugoslavia: Exports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite	524,928	246,821	--	Czechoslovakia 128,950; Romania 77,302; East Germany 31,746.
Oxides and hydroxides:				
Alumina	395,378	213,433	--	U.S.S.R. 179,482; Czechoslovakia 19,655; Poland 14,296.
Other	68,374	439,991	--	U.S.S.R. 257,312; West Germany 85,854; Poland 85,808.
Metal including alloys:				
Scrap	352	276	--	West Germany 248; Italy 28.
Unwrought	46,180	53,872	--	East Germany 36,739; Czechoslovakia 7,037; Japan 2,628.
Semimanufactures	50,302	57,395	5,099	Czechoslovakia 15,414; East Germany 7,383; West Germany 4,828.
Antimony, regulus	975	1,055	30	U.S.S.R. 600; West Germany 225; Bulgaria 200.
Arsenic metal, all forms	52	36	14	West Germany 18; United Kingdom 4.
Cadmium metal, including alloys, all forms	133	105	60	Netherlands 21; Czechoslovakia 17; Italy 5.
Chromium:				
Chromite	10,475	11,537	--	All to Czechoslovakia.
Oxides, hydroxides, acid	125	4	--	All to Italy.
Cobalt: Oxides and hydroxides kilograms	--	50	--	All to Switzerland.
Copper:				
Ore and concentrate	--	16,131	--	Sweden 6,005; Finland 5,146; East Germany 3,979.
Sulfate	21,843	10,535	--	China 6,039; Turkey 2,000; Italy 1,042.
Metal including alloys:				
Scrap	7,948	6,129	--	Switzerland 2,324; Italy 2,128; West Germany 1,044.
Unwrought	8,356	14,334	3,641	East Germany 4,468; Sweden 2,000; United Kingdom 1,539.
Semimanufactures	29,814	34,685	2,057	U.S.S.R. 7,278; West Germany 6,304; Italy 6,141.
Iron and steel:				
Ore and concentrate	2	(1)	--	All to Hungary.
Pyrite, roasted	48,302	74,168	--	Hungary 53,515; Austria 17,537; West Germany 3,116.
Metal:				
Scrap	45,611	44,833	--	Italy 40,122; Switzerland 1,992; West Germany 1,969.
Pig iron, sponge iron, powder, shot	63,651	50,811	--	Romania 24,027; Italy 18,872; Switzerland 3,145.
Ferroalloys	148,458	120,558	39,639	Italy 29,259; Japan 12,644; Austria 12,314; Albania 4,600.
Steel, primary forms	22,494	21,406	--	Hungary 10,595; Poland 10,445; Italy 364.
Semimanufactures:				
Bars, rods, angles, shapes, sections	133,128	93,694	--	U.S.S.R. 18,453; West Germany 17,146; Albania 14,224; Bulgaria 10,760.
Universals, plates, sheets	36,691	9,659	--	Poland 1,986; Bulgaria 1,757; Turkey 1,304; West Germany 1,224.
Hoop and strip	5,403	8,598	--	Poland 5,001; Bulgaria 1,582; Romania 490; Italy 461.
Rails and accessories	32,049	14,172	--	Albania 7,723; Romania 5,344; Poland 595.
Wire	1,970	5,530	--	U.S.S.R. 2,768; Hungary 1,325; Czechoslovakia 349.
Tubes, pipes, fittings	102,247	111,321	283	East Germany 18,696; U.S.S.R. 14,361; China 13,970.
Castings and forgings, rough	4,401	4,986	--	Poland 1,200; Austria 1,083; West Germany 1,009.
Lead:				
Ore and concentrate	13,496	10,070	--	Bulgaria 8,165; Turkey 1,024; West Germany 842.
Oxides kilograms	725	1,534	--	West Germany 596; U.S.S.R. 490; Iraq 448.
Metal including alloys:				
Scrap do	--	7	--	All to Austria.
Unwrought	36,990	27,564	--	U.S.S.R. 13,953; Czechoslovakia 9,926; Austria 2,216.
Semimanufactures	2,377	1,476	--	Italy 691; France 415; Kuwait 192.
Magnesium metal including alloys:				
Scrap	5	3	--	All to Italy.
Unwrought	--	1,843	83	West Germany 911; Austria 265; Poland 126.
Semimanufactures	--	86	--	Austria 66; Poland 20.

See footnotes at end of table.

Table 2.—Yugoslavia: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
METALS —Continued				
Manganese: Ores and concentrates	922	--		
Molybdenum metal including alloys, all forms kilograms	7,135	634	--	All to West Germany.
Nickel:				
Ore and concentrate do	1,080	300	300	
Matte and speiss	--	99	--	West Germany 78; Austria 20.
Metal including alloys:				
Scrap	210	288	--	West Germany 155; Switzerland 105; Austria 20.
Unwrought	137	230	--	Austria 66; Netherlands 65; Italy 58.
Semimanufactures	27	80	--	West Germany 29; Italy 22; Austria 15.
Platinum-group metals including alloys:				
Waste and sweepings value	$34,034	$113,575	--	All to West Germany.
Unwrought and partly wrought troy ounces	64,205	4,308	3,247	United Kingdom 675; West Germany 386.
Silicon, elemental	26,496	20,437	502	U.S.S.R. 11,013; Japan 2,200; West Germany 1,900; Poland 1,568.
Silver:				
Ore and concentrate[2] kilograms	--	25	25	
Metal including alloys:				
Waste and sweepings value	$154,217	$692,713	--	All to Austria.
Unwrought and partly wrought thousand troy ounces	3,009	1,946	1,058	Czechoslovakia 586; West Germany 114; United Kingdom 94.
Tin metal including alloys:				
Unwrought	114	49	--	West Germany 29; Italy 20.
Semimanufactures	1	3	--	Albania 2.
Titanium: Oxides and hydroxides	12,132	11,353	--	East Germany 11,323; West Germany 30.
Tungsten metal including alloys, all forms kilograms	1,266	4,251	--	West Germany 3,185; Austria 1,066.
Zinc:				
Ore and concentrate	6,600	8,831	--	Bulgaria 7,492; Austria 760; Romania 579.
Oxides	1,669	193	--	Romania 175; West Germany 10; Iraq 3.
Metal including alloys:				
Scrap	25	35	--	All to Italy.
Unwrought	31,578	19,565	--	Czechoslovakia 11,044; U.S.S.R. 4,752; Hungary 3,752.
Semimanufactures	9,070	9,105	--	Czechoslovakia 5,756; West Germany 1,167; U.S.S.R. 1,090.
Other:				
Ash and residue containing nonferrous metals	23,762	31,086	--	Bulgaria 28,033; Italy 2,251; West Germany 601.
Oxides, hydroxides, peroxides of metals	92	162	--	Sweden 161.
Base metals including alloys, all forms, n.e.s	18	4	--	All to Czechoslovakia.
NONMETALS				
Abrasives:				
Natural: Pumice, emery, corundum, etc. kilograms	2,093	50	--	All to Iraq.
Artificial: Corundum	15,908	15,486	18	Romania 6,741; Italy 2,910; Czechoslovakia 1,891.
Grinding and polishing wheels and stones	2,832	2,820	48	Romania 1,200; Italy 322; Poland 286; West Germany 229.
Asbestos, crude	1,983	2,506	--	Albania 2,310; Romania 136; West Germany 50.
Barite and witherite	13,965	19,077	--	Hungary 18,929; Afghanistan 69; Libya 65.
Boron materials: Oxide and acid	542	214	--	West Germany 150; Italy 44; Czechoslovakia 20.
Cement	359,920	406,746	10,150	Egypt 151,015; Tunisia 68,800; Malta 38,100.
Chalk	2	53	--	Czechoslovakia 41; Italy 12.
Clays and clay products:				
Crude:				
Bentonite	297	1,401	--	U.S.S.R. 1,301; Albania 50; Tunisia 50.
Fire clay	18,918	12,467	--	Italy 9,082; Greece 1,681; Hungary 1,107.
Kaolin	5,618	6,587	--	Greece 6,564; U.S.S.R. 22.
Other	556	482	--	West Germany 412; Greece 50; Italy 20.
Products:				
Nonrefractory	7,698	16,241	--	U.S.S.R. 5,245; Austria 2,480; Libya 2,311; Italy 1,794.
Refractory including nonclay brick	77,120	80,674	--	Romania 23,872; U.S.S.R. 13,718; West Germany 8,000.

See footnotes at end of table.

Table 2.—Yugoslavia: Exports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Cryolite and chiolite	4	10	--	All to Malta.
Feldspar	9,695	11,498	--	Hungary 9,480; Czechoslovakia 1,340; Greece 558.
Fertilizer materials:				
Manufactured:				
Nitrogenous	46,630	60,471	--	Turkey 44,814; Ecuador 8,002; West Germany 7,100.
Phosphatic	98,787	203,469	--	Hungary 86,973; Czechoslovakia 75,755; U.S.S.R. 28,813.
Potassic	1	--	--	
Other including mixed	319,243	429,090	--	Turkey 168,940; Nigeria 109,196; Hungary 77,691.
Ammonia	20	36	--	All to Greece.
Graphite, natural	--	23	--	All to West Germany.
Gypsum and plasters	357	3,827	--	Hungary 3,814; U.S.S.R. 9.
Lime	59,319	72,158	--	Hungary 71,795; Greece 135; U.S.S.R. 131.
Magnesite	28,325	24,321	--	U.S.S.R. 7,126; Poland 5,928; Italy 4,052; Hungary 2,948.
Mica: Worked including agglomerated splittings kilograms	158	40	--	All to U.S.S.R.
Pigments, mineral: Iron oxides, processed	--	1	--	All to Hungary.
Pyrite, unroasted	75,825	67,941	--	Bulgaria 35,675; West Germany 20,129; Romania 12,074.
Salt and brine	3,078	2,812	--	Hungary 2,808; Central African Republic 4.
Sodium and potassium compounds, n.e.s.:				
Caustic potash	2,349	1,208	--	U.S.S.R. 620; France 300; Romania 128.
Caustic soda	2,102	12,044	--	Iran 3,200; Netherlands 2,414; West Germany 1,650.
Soda ash	326	2,132	--	Italy 1,632; Iran 500.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	50,151	56,354	--	Italy 30,682; Czechoslovakia 16,387; East Germany 2,564.
Worked	4,254	8,282	48	Austria 3,347; Czechoslovakia 1,980; West Germany 1,232.
Gravel and crushed rock	5,195	8,553	--	Hungary 3,505; Italy 3,365; Czechoslovakia 421.
Limestone, except dimension	3	--	--	
Quartz and quartzite	13,056	12,124	--	West Germany 11,913; East Germany 211.
Sand excluding metal-bearing	3,294	6,703	--	Albania 2,999; Greece 2,491; Libya 1,031.
Sulfur:				
Elemental:				
Other than colloidal	5,334	1,138	--	Bulgaria 1,000; Hungary 138.
Colloidal	1,209	192	--	Australia 187; Egypt 5.
Sulfuric acid	162	119	--	Italy 80; Czechoslovakia 35.
Talc, steatite, soapstone, pyrophyllite	590	810	--	All to Albania.
Other:				
Crude	1,320	4,578	--	Greece 4,159; Austria 166.
Slag, dross, and similar waste, not metal-bearing	1,506	1,384	--	Austria 1,382.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	68	123	--	East Germany 76; Libya 46.
Carbon black	87	1,414	--	Czechoslovakia 1,218; West Germany 142; East Germany 51.
Coal: Lignite including briquets	375,118	397,493	--	Austria 250,863; Czechoslovakia 74,419; Italy 43,730.
Coke and semicoke	307,538	205,319	--	Hungary 135,661; Romania 25,124; Austria 23,452.
Hydrogen, helium, rare gases	459	250	--	Austria 245.
Peat including briquets and litter	1,820	481	--	Italy 322; Austria 125.
Petroleum refinery products:				
Gasoline thousand 42 gallon barrels	4,337	3,601	(1)	Netherlands 3,569; Austria 18.
Kerosine and jet fuel do	448	220	4	United Kingdom 64; France 35; Switzerland 17.
Distillate fuel oil do	584	105	1	Austria 15; Greece 13; Panama 8.
Residual fuel oil do	269	47	--	United Kingdom 12; Malta 11; Sudan 5.
Lubricants do	349	397	(1)	Austria 293; Czechoslovakia 81; Poland 11.

See footnotes at end of table.

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
MINERAL FUELS AND RELATED MATERIALS —Continued				
Petroleum refinery products —Continued				
Other:				
Mineral jelly and wax thousand 42-gallon barrels	46	30	2	West Germany 16; Italy 10.
White spirit do	6	2	--	All to Austria.
Petroleum coke, bitumen, and other residues do	43	29	--	West Germany 22; Poland 3; Libya 1.
Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals	36,727	43,090	--	Italy 39,177; West Germany 2,218; Austria 1,688.

[1]Less than 1/2 unit.
[2]May include other precious metals.

Table 3.—Yugoslavia: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1979	1980	Sources, 1980	
			United States	Other (principal)
METALS				
Aluminum:				
Bauxite	63,883	217,595	--	Guinea 129,141; Ghana 34,300; Greece 22,404.
Oxides and hydroxides	1,367	1,285	4	West Germany 1,076; Italy 22.
Metal including alloys:				
Scrap	34	(1)	--	Mainly from West Germany and Austria.
Unwrought	41,219	58,638	1,013	U.S.S.R. 47,655; Egypt 4,901; Hungary 2,703; Romania 1,823.
Semimanufactures	8,510	8,592	109	France 3,151; West Germany 2,021; Switzerland 1,290.
Antimony:				
Ore and concentrate	3,261	4,201	--	China 2,682; Turkey 748; Morocco 670.
Regulus kilograms	--	2	--	All from United Kingdom.
Arsenic:				
Trioxide, pentoxide, acids	66	102	--	Belgium-Luxembourg 33; West Germany 31; France 26.
Metal, all forms	138	85	(1)	U.S.S.R. 50; Netherlands 20; West Germany 11.
Beryllium metal, all forms kilograms	635	97	--	West Germany 82; Switzerland 15.
Bismuth metal, all forms do	5,012	4,315	310	Belgium-Luxembourg 4,005.
Chromium:				
Chromite	297,919	278,799	--	Albania 201,115; U.S.S.R. 63,519; Iran 6,401.
Oxides, hydroxides, acid	378	784	(1)	U.S.S.R. 700; West Germany 67; Hungary 15.
Cobalt: Oxides and hydroxides	22	17	7	Belgium-Luxembourg 8; Netherlands 1.
Copper:				
Ore and concentrate	7,739	47,817	--	Mexico 20,258; Chile 14,816; Peru 9,882.
Sulfate	1,304	1,030	--	U.S.S.R. 1,010; West Germany 14.
Metal including alloys:				
Scrap kilograms	50	--		
Unwrought	36,095	50,412	4	Peru 30,751; Zambia 14,905; Chile 4,708.
Semimanufactures	5,414	2,309	32	West Germany 1,081; Poland 517; Austria 190; U.S.S.R. 132.
Iron and steel:				
Ore and concentrate thousand tons	1,060	1,640	--	Peru 617; India 600; U.S.S.R. 140; Brazil 119.
Pyrite, roasted	--	50	--	All from Romania.

See footnotes at end of table.

[2]Quantity unreported; imports valued at $481.

COMMODITY REVIEW

METALS

Aluminum.—Discovery of a new bauxite deposit, completion of a new aluminum smelter, expansion of another smelter, and the closing of an alumina plant were the highlights of the aluminum sector of the mineral industry during 1981.

A new deposit of bauxite was discovered in the vicinity of the city of Titovo Uzice in western Serbia. Reportedly, the zone of bauxite mineralization covers an area of about 30 square kilometers located on the slope of the Zlatibor Mountain, near the village of the Mackat, extending toward the villages of Nikojevici, Rozanstvo, and Sirogojno. Except for claims that the reserves of the deposit are large and that the bauxite is of good quality, specific information was not made public.

At Bacevici, near Mostar, BiH, a new 92,000-ton-per-year aluminum smelter started production in the first quarter of 1981. The plant has 256 electrolytic cells and includes an anode plant and a foundry. Technology was provided by the French concern Péchiney. The new smelter at Bacevici should reach its design capacity during 1982.

At the aluminum smelter at Titograd, Montenegro (Kombinat Aluminijuma Titograd), facilities for smelting an additional 50,000 tons per year started production at the beginning of 1981. With the new addition, the Titograd smelter has a capacity of 100,000 tons per year of aluminum metal.

The 300,000-ton-per-year alumina plant at Obrovac operated by Jadral closed down in the fall of 1981 for economic reasons. The plant was placed in standby status, and during the rest of the year, efforts were made by all concerned to find solutions for the financial problems in order to restart production sometime in the future. At yearend, it appeared that the dismantling of the factory was not being considered.

Antimony.—At Zajaca in Serbia, a facility with capacity to produce 365 tons of antimony trioxide per year started production. Plant technology was designed by Yugoslav scientists. In addition, a new zinc-antimony mine, Vinogradi, operated by the Rudarsko Metalurski Kombinat Zajaca (RMKZ) and located at the village of Rujevac near Stolica in the western part of Serbia, started production. Reserves at Vinogradi were reported at 1 million tons of antimony-zinc ore, but metal content of the ore was not reported. The nearby flotation plant at Stolica was modernized in order to recover zinc. RMKZ is the major antimony producer in Yugoslavia and operates all the new Serbian facilities.

Copper.—At the Bucim copper mine and flotation plant in Macedonia (total investment 2.5 billion dinars), the year 1981 ended with a deficit of about 400 million dinars (about U.S. $10 million). The financial difficulties resulted from a lower ore grade than expected, although mining was switched to supposedly richer ore in 1981. Apparently the grade of ore in deposits near Bucim had been overestimated. Latest reports indicated a request by the management for new investment to triple the mine and mill capacity so that the operations could become economic.

The development of the Krivelj copper mine and mill near Bor, Serbia, continued. Denver Equipment, a division of Joy Process Equipment Inc., received a large order for delivery of milling equipment for the Krivelj project. The new equipment will be installed in the second stage of mill construction at Krivelj, scheduled for production in 1983-84.

Iron and Steel.—Stagnation of the iron and steel industry was evident in 1981. Modernization of the Zeljceara Boris Kidric steel plant in Niksic, Montenegro, was the only activity of any significance. Reportedly, when completed the Boris Kidric plant will have an annual capacity of 315,000 tons per year.

Mercury.—During 1981, the possibility of restarting production of the Idria Mine in Slovenia was examined, but no decision had been made at yearend.

Nickel.—The startup of the Kavidarci (capacity 16,000 tons per year of contained nickel) ferronickel plant and nickel mine in Macedonia was delayed. Unspecified technical and financial difficulties were mentioned as the cause. The new date for the beginning of Kavadarci's production was sometime in 1982.

Development of the Glogovac ferronickel plant and nickel mines in Kosovo (also known as Kosovo plant and mines) continued during 1981. Two mines, Cikatovo near Glogovac and Glavica near Lipljan, were in the last stages of development. The first tonnage of ore was expected in late 1982 or early 1983. The ore will be used in the ferronickel plant at Glogovac. The operations of Cikatovo and Glavica mines are based on 25 million tons of ore with an average nickel content of about 1.3%. The content of gangue minerals in ore was reported as follows: Silicates 40% to 50%; iron oxide 19% to 34%; bauxite 0.5% to 5%; magnesium oxide 3.0% to 10.0%; calcium oxide 0.3% to 1.0%; chromite 0.2% to 2.0%; manganese oxide 0.2% to 0.6%. In addition, another deposit with reserves totaling 5 million tons was discovered in the same area. The grade of ore from this deposit was not reported.

Construction continued on the ferronickel plant at Glogovac (capacity 12,000 tons per year of contained nickel). The new plant was designed by experts from the U.S.S.R. and most of the equipment for the smelter will be made in the Soviet Union. All raw material used at the smelter was to be domestic except anthracite. However, it was hoped that domestic dried lignite from nearby Kosovo mines would be found to be a suitable replacement.

Total investment for the project by the large enterprise Rudarsko Hemiski Kombinat Kosovo reportedly should reach 6 billion dinars.

Titanium.—Exploration led to the discovery of titanium deposits in the Timok River in the Trgoviste area and also near Maribor in Slovenia. No details were available as to the size of the deposits or grades of ore. These two deposits are the first titanium discoveries in the country.

NONMETALS

Ammonia.—Construction continued on a 280,000-ton-per-year ammonia plant at Pancevo, Serbia. Completion of a 369,000-ton-per-year plant at Kutina, Croatia, was

delayed, and startup was planned for 1982. Both plants will use natural gas feedstock.

Asbestos.—Around Stragari, Serbia, site of an existing asbestos mine, new reserves were discovered. The quality of the asbestos was not reported but the size of the reserves was described as large enough to sustain present mine output for the next 50 years. The Rudarsko Energetsko Industrijski Kombinat Kolubara (REIK Kolubara) through its Kolubara asbestos division operates the Stragari Mine. Reports indicated that new capacity at Stragari was planned to produce 500,000 tons of asbestos ore per year equivalent to 47,000 tons of asbestos concentrates.

Bentonite.—A new bentonite deposit was discovered near Sipovo in BiH. Reserves were estimated at 1 million tons. Plans call for opening a mine with a capacity of 25,000 tons of bentonite per year.

Cement.—At Popovac, Serbia, site of an existing cement plant, an additional 800,000-ton-per-year cement plant started production in the fall of 1981. The Popovac plant, fired with fuel oil, experienced difficulties in purchasing fuel oil for its operation during the rest of the year and its output was below that planned.

Financing of new cement plants at Bela Palanka and Golubac, both in Serbia, and expansion of the Kosjeric plant in Serbia were not assured by the end of the year, but 1985 was given as the completion year for all three projects.

Fluorspar.—A deposit of fluorspar was discovered at the village of Ravnaja near Krupanj, Western Serbia. Reserves were estimated at 1 million tons of unreported grade. Apparently this is the first economic deposit of fluorspar in the country.

Lime.—In the Ba village, near the town of Ljig, Serbia, a 50,000-ton-per-year lime plant went onstream during the summer of 1981. Equipment for the plant was purchased in the Federal Republic of Germany.

Marble.—Although completed 2 years ago in Cer near Kicevo, Macedonia, a marble quarry with a plant for cutting marble remained closed after 2 months of trial production. Lack of heat in the plant was reported as the principal reason for the delay. The installation is located in an altitude 900 meters above sea level, and temperatures are too low for workers to work without heat. Responsibility for not installing heating in the plant had not been determined at yearend.

Phosphate.—Development of a phosphate mine, Lisina near Bosilegrad in Serbia, was delayed for lack of funds. Lisina will be the first phosphate mine in Yugoslavia.

MINERAL FUELS

Low-rank coals, mostly lignite, were the principal energy source produced in the country during 1981, but Yugoslavia remained greatly dependent on imported high-rank coals, crude oil, and natural gas. High prices for imported fuels continued to impact heavily the country's trade balance.

Coal.—In Serbia, the largest coal-producing state in Yugoslavia, exploration continued at the Kovin lignite deposit and the deposit at Fruska Gora, both in Vojvodina, Serbia.

A new coal deposit was discovered near Petrovac na Mlavi, eastern Serbia, with reported reserves of about 40 million tons of coking coal.

At the Bogovina Mine near Boljevac, Serbia, a new mine was planned near the existing one that it will ultimately replace. Exploratory work has confirmed about 4.4 million tons of brown coal located in the new, so-called Eastern field.

At Rosna near Pozega, Serbia, site of an old mine closed 7 years ago, new reserves of about 3 million tons were discovered. Reported to be economic, lignite production by opencast mining is possible.

At Kolubara, Serbia, a new lignite drying plant planned to start production in 1985 with an annual capacity of 855,000 tons of dried lignite. In addition, it is expected that a plant for lignite gasification, of unspecified capacity, may be built at the Kolubara Mine after 1986.

In Bosnia, the largest known coal-producing region, exploration and preparation for production continued at the Juzna Sinklinala Mine near Tuzla in BiH. Plans call for a 3-million-ton-per-year opencast mine to start production by 1986.

At the Rasa Mine in Istria, Croatia, the largest producer of bituminous coal in the country, work continued on development of a new mining field, Tupljak. Plans for the new facility have set a yearly production target of 325,000 starting in 1985. Proven reserves of bituminous coal at Tupljak were reported at 8 million tons.

Petroleum and Natural Gas.—During 1981, INA of Zagreb, Croatia, the largest crude oil producer and refiner in the country, decided to ask large foreign oil companies to bid for joint offshore ventures in the

Yugoslav area of the Adriatic. Reports indicated that concessions should be granted during the first quarter of 1982. Although joint ventures for oil and gas exploration in the Yugoslav part of the Adriatic are not a new development, INA's concessions and the size of exploration should by far exceed the area of exploration carried out in the southern part of the Adriatic by Jugopetrol-Kotor and Buttes Gas & Oil Co. of the United States.

About 10 wells were drilled on the Adriatic shores. Gas was discovered in the northern part of the Adriatic. In the Pannonian Basin, discoveries of oilbearing formations were announced below the gas formation in Boksic Lug Field, Slavonia, Croatia. In both places, details on the size of the reserves and on other specifics were not available. About 25 drilling rigs were active throughout the country, and a total of 328,575 meters were drilled.

INA's enterprise for oil and gas production, Naftaplin, produced about 62% of the total country's crude oil output. Benicanci in Slavonia remained the largest producing oilfield in Yugoslavia during 1981.

Refining capacity at the disposal of the Yugoslav petroleum industry remained the same as during 1980 (about 25.5 million tons per year). Refinery utilization was approximately 58%. Of the total crude oil processed in Yugoslavia, about 71% was imported oil. Table 3 shows details of crude oil imports.

During 1981, the last leg of the pipeline that connects the Adriatic coast at Barkar near Rijeka and the inland refineries was completed with a connection to the Lendava refinery.

Uranium.—The first nuclear powerplant in Yugoslavia started production at the end of 1981. The 615-megawatt plant, constructed by Westinghouse of the United States, is located at Krsko, Slovenia, near the border with Croatia.

Development of the first uranium mine and mill at Zirovski Vrh continued. Regular production of yellow cake was to start during 1982, and output was planned at 120 tons annually. After enrichment abroad, fuel from domestic ores should be used in the Krsko plant by 1985.

Exploration for lead and zinc led to the discovery of uranium near Probistip in Macedonia, and preparations were underway to open this, the first uranium mine in Macedonia. Data on grade of ores and size of the deposit were not made public.

---

[2]Dinar is not convertible currency. A meaningful conversion to U.S. currency is impractical. At yearend, the official exchange rate was 42 dinars = US$1.00.

The Mineral Industry of Zaire

By Miller W. Ellis[1]

In 1981, Zaire continued to be the world's leading producer of cobalt and industrial diamonds and the sixth largest producer of copper. Mineral commodity exports provided 86% of the country's $1.7 billion foreign exchange revenue, with copper accounting for $825 million; cobalt, more than $200 million; and both petroleum and diamonds more than $100 million each. Zaire's foremost mining company, La Générale des Carrières et des Mines du Zaire (Gécamines) announced a near-record year for copper production and zinc exports. Cobalt production was about the same as in 1980, but export sales slumped badly until the U.S. General Services Administration (GSA) approved the purchase of 2,359 tons for its strategic stockpile. The negotiated price was $15 per pound.

The International Monetary Fund (IMF), apparently pleased with Zaire's economic progress during 1980, discussed the granting of extended financial credit during early 1981. On June 23, it announced that an Extended Fund Facility (EFF), totaling 912 million Special Drawing Rights or $1,058 million, would be made available to Zaire during the period June 1981 through 1983 in order to promote a revival of the economy, reduce the inflation, and improve the balance of payments. This was reportedly the largest credit ever advanced to an African country by the IMF.

The EFF plans call for the country to invest some $1.6 billion in basic infrastructure within the country. Thirty-four percent was slated for the rehabilitation of facilities for the mining industry, and smaller amounts were allocated to improve port and railway facilities and distribute energy more widely. The EFF plan also encouraged a reduced role for the state in the Zairian economy, greater participation from the country's private sector, and a major effort to increase production of agricultural staple foods, as well as export crops. A further condition of the loan was that Zaire should implement an austerity program conducive to an improved balance of payments status. This included the devaluation of the Zaire on June 19 by the Zaire Executive Council. In July, the 14 lending nations (the Club of Paris) rescheduled about $350 million of Zaire debts for each of the next 2 years. Zaire's total external debt amounted to more than $5 billion, with $2.2 billion due over the next 2 years. During 1981, only $355 million was scheduled for debt servicing.

According to an extension plan of the Lome II Convention, which became applicable on January 1, 1981, the European Economic Community (EEC) was prepared to offer long-term, low-interest (1%) loans to countries that produced certain strategic minerals. Copper, cobalt, tin, and other mineral commodities were specifically included in the plan, provided they accounted for at least 15% of a country's export earnings over the preceeding 4-year period. The loans were to counter short-term problems and to maintain or increase the output of mineral commodities. The loan arrangement was known by the term, "Sysmin", to the members of the EEC. At yearend, the European Investment Bank was still considering a $50 million Sysmin loan application from Zaire. A favorable decision was expected.

In late October, the Organization of Petroleum Exporting Countries (OPEC) Fund for International Development granted Zaire a loan of $5 million to finance the rehabilitation of power generation stations and transmission lines, particularly in the Shaba region. The loan was interest free, had a 5-year grace period, a 20-year maturity date, and a nominal service charge. In

December, a French loan of $1.5 million was announced for three projects, an inventory of mineral resources, development of agriculture, and civil aviation. The Arab Bank of African Economic Development committed a $10 million loan for improvements to Zaire's river navigation and railway transport system.

In April 1981, the First State Commissioner (prime minister) Karl-I-Bond resigned and fled to exile in Belgium. N'Singa Ndjuu, executive secretary of the ruling political party, was appointed to the vacant position. In early October, President Mobutu dismissed his entire Executive Council and reappointed himself and eight of his commissioners to their former ministries. The Commissioner for Mines, Lwamba Katansi, was appointed to the Ministry of Culture and Arts, and five others were named to different ministerial posts. New appointees filled the 12 remaining ministries, including Mbenga Sandonga as Commissioner of Mines, and a new post of Deputy Prime Minister was created.

The Swiss Aluminium Co., Alusuisse, and eight other international firms signed a charter on November 24, creating a new company, Aluzaire, to build an aluminum smelter at Mwanda, north of the Zaire River mouth. The Zaire Government was to hold 15% of the consortium and was committed to arrange for a $400 million deepwater port at nearby Banana, as well as a powerline and road from Inga-Shaba to the port and refinery. Other shareholders were as follows:

Company	Country of origin	Percent ownership
Alusuisse	Switzerland	20
Energoinvest	Yugoslavia	10
Sava-Aluminio-Veneto	Italy	10
Norsk Hydro AS	Norway	10
Yoshido Kogyo KK	Japan	10
Vereinigte Aluminium Werke A.G.	Federal Republic of Germany.	10
Sumitomo Aluminium Smelting Co. Ltd.	Japan	10
Estel Aluminum BV	Belgium-Netherlands.	5

The consortium contracted to plan an $800 million aluminum plant with a capacity of 150,000 to 200,000 tons per year, complete a feasibility study in 1982, and make a final decision on starting construction by 1984. First production was projected for 1989, and expansion during the next decade could bring capacity to 600,000 tons per year. The plant was to use bauxite imported from Guinea and was to employ 2,000 workers.

Zaire's largest hydroelectric plant was the Inga II plant on the lower Zaire River west of Kinshasa with an installed capacity of 1,272 megawatts (MW) for eight 159-MW turbines. The installation was to undergo testing into early 1982 and commence supplying the powerline to Shaba as soon as the Shaban converter stations are installed and tested. Shaba's previous power source was from four hydroelectric stations installed by Union Minière du Haut-Kantanga, Gécamines' predecessor. The oldest, Francqui, built in 1930 on the Lufira River northeast of Likasi, had a capacity of 47 MW, and the nearby Bia generator, with a capacity of 77 MW, was constructed in 1945. The Delcommune dam and 120-MW powerplant on the Lualaba River north of Kolwezi were completed in 1953, and the 276-MW Le Marinel station was installed 35 kilometers downstream in 1956. These installations provided power to Shaba's copper industries and cities and enabled the electrification of much of the railway system before independence in 1960.

On August 22, a ceremony at Kolwezi marked the completion of the last pylon on a 1,700-kilometer high-voltage, direct-current powerline from Inga, near the Zaire estuary, to the Shaba region's copper-cobalt mining and refining towns. The first pylon was erected in 1974 in lower Zaire, and since that time the U.S. firm Morrison-Knudsen Co., Inc., has remained as Chief of Contracteurs Inga-Shaba (CIS). CIS was also responsible for installing and testing the converter terminals at the Shaban mining centers. Final completion of the system was set for 1983. Morrison-Knudsen was one of several U.S. companies with a total of $250 million invested in Zaire. Others included Foote Mineral Co., with investments in tin-lithium mines near Manono, and Metallurg Inc., with a pyrochlore-bearing carbonatite development at Lueshe in the Kivu region.

A free industrial zone was established around the Inga hydroelectric site on the Zaire River to include Zaire's largest powerplant and its areas of greatest underdeveloped hydroelectric potential. The organization and operation of the Inga Zone was stipulated in Statute Law No. 81-010 dated April 2, 1981.

PRODUCTION AND TRADE

Gécamines, the giant Government owned firm, continued to account for the production of all of Zaire's cadmium, cobalt, and zinc, most of its copper, and a substantial part of its gold and silver. Its operations included the smelter at the Lubumbashi (formerly Elizabethville) center 30 kilometers from its Kipushi (formerly Prince Leopold) Mine near the Zambian border. The Shituru and Panda copper-cobalt refineries and the Kakanda and Kambove Mines comprised the central group of operations of Likasi (formerly Jadotville). The Kolwezi western center of operations has been the site of most of the industry's expansion since 1975 including the new Dikuluwe and Mashamba open pits, the Dima concentrator, additional capacity at the Luilu copper-cobalt refinery, and a new flash smelter. Gécamines also produced its own limestone, lime, and cement from quarries and kilns near Kakontwe, north of Likasi, and coal from its nearby Luena Colliery. The remainder of Zaire's copper was produced and shipped as concentrate by the Japanese-operated Société de Développement Industriel et Minière du Zaire (Sodimiza) from its Musoshi concentrator near the Zambian border southeast of Lubumbashi.

A preliminary estimate of the value of Zaire's 1981 exports indicated a substantial drop in overall value owing to depressed metal prices, particularly cobalt, in a year with generally higher metal production. Copper export sales were estimated at $825 million despite a 10% increase in production. Cobalt with a value of $200 million was less than one-half the 1980 figure. The value of petroleum exports doubled to $120 million, but diamond export value was estimated at $112 million, less than one-half the 1980 figure. The value of gold production was nearly constant at $33 million, but the silver value dropped from $55 million to less than $20 million. Sales of current and accumulated zinc stocks had an estimated value of $65 million, more than four times the value of 1980 zinc sales. The total value of Zaire's mineral exports was about $1.5 billion out of a total export figure of nearly $1.75 billion. Coffee, the principal agricultural export, had an estimated export value of $180 million in 1981.

On July 2, GSA announced that the Société Zairoise de Commercialisation des Minerais (Sozacom) of Kinshasa had been selected to supply 5.2 million pounds of refined cobalt for the National Defense Stockpile at a total cost of $78 million, or $15 per pound delivered to the GSA depots in the Midwestern United States. This was the first purchase under the Strategic and Critical Minerals Stock Piling Revision Act of 1979, and the first major stockpile acquisition for a number of years. The first cobalt shipment left the Luilu refinery at Kolwezi on August 13 and was shipped from Durban Harbor in the Republic of South Africa on September 25, destined for delivery to Warren, Ohio. Despite this sale, it was estimated that stocks of Zairian cobalt held in that country and in Belgium had reached 33 million pounds by yearend, and the local production rate was deliberately reduced.

During the first 8 months of 1981, Zairian railroad exports via Zambia and the Republic of South Africa included 139,375 tons of copper, 29,753 tons of zinc, and 65,881 tons of copper concentrate. The returning railcars carried 205,600 tons of imported supplies including 40,394 tons of coke mostly from Zimbabwe's Wankie colliery, 7,178 tons of sulfur for the manufacture of sulfuric acid, 32,705 tons of coal, and 82,585 tons of maize and wheat.

Details of Zaire's 1981 mineral products are shown in table 1, and the apparent exports and imports of mineral commodities are shown tables 2 and 3, respectively.

Zairian and Tanzanian authorities discussed improvements to the TAZARA Railway and to warehouses at the port of Dar es Salaam with the intention of increasing the amount of mineral commodities exported via the barge route across Lake Tanganyika and the meter gauge railway to Dar es Salaam.

Table 1.—Zaire: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1977	1978	1979	1980[p]	1981[e]

[1]Owing to the lack of available official trade data published by Zaire, this table should not be taken as a complete presentation of mineral imports of this country. These data have been compiled from various sources which include United Nations information and data published by the trading partner countries. Unless otherwise specified, data are compiled from trade statistics of individual trading partners.

[2]Excludes exports from Japan valued at $3,000.

[3]Excludes exports from Japan valued at $1,000.

[4]Less than 1/2 unit.

[5]Excludes portion of exports from Japan valued at $4,000.

[6]Excludes exports from Canada valued at $9,000.

[7]The reported quantity of exports from Saudi Arabia valued at $23,549,000.

[8]Excludes exports from Japan valued at $62,000.

COMMODITY REVIEW

METALS

Copper, Cobalt, Zinc, and Associated Metals (Shaba region).—Gécamines production of copper increased to near-record quantities in 1981. The rate of cobalt production during the first half year was also high but was deliberately curtailed later in response to the large accumulations of cobalt stocks in Zaire, Zambia and Belgium. Gécamines' receipts of foreign exchange remittances from Sozacom were intermittent and insufficient to purchase vitally needed supplies, spare parts, and replacement equipment. At the best of times, Gécamines was allocated only 45% of the foreign exchange earned by the sale of its products by Sozacom. The Bank Commerciale du Zaire in Kinshasa received 45%, and 10% was slated directly to the Zairian Government to be applied on repayment of foreign loans. The Government reportedly levied an export tax on Gécamines products without regard to prevailing metal prices or company profitability.[2]

Sozacom announced a reduction in the price of cobalt from $25 to $20 per pound on March 2 and a further drop to $17.26 per pound in September. This price continued to be listed by both Zairian and Zambian producers through the yearend despite the GSA stockpile sale and some smaller transactions at much lower spot prices.

Completion of Gécamines' flash smelter and extensions to the Luilu refinery were put forward until 1983 when commissioning of the converters will allow power from Inga to be used in the Zairian mining centers.

Gécamines short-term planning called for the purchase of at least two new 25-cubic-yard diesel-electric shovels to speed up open pit mining and the installation of trolley-assist systems to allow the use of electric power for the 100- and 150-ton diesel-powered haulage trucks. Such systems have been tested at several South African mines and have resulted in higher speeds on steep slopes out of the mine pits, as well as substantial savings of scarce diesel fuel.

Resumption of construction work at the property held by Société Minière de Tenke-Fungurume was tentatively set for late 1982 by Compagnie Générale des Matieres Nucleaires (Cogema), an operating subsidiary of the French Bureau de Recherches Géologiques et Minières (BRGM). Cogema's holding of 26.5% originally belonged to the U.S. Amoco Minerals Co. (Standard Oil Co., Indiana). BRGM's holdings were 8.5%, with Anglo American Corp. and its Chartered Consolidated associate holding 28%, and the Zaire Government 20%. Cogema completed a feasibility study and was revising plans for the project during 1981. Startup in 1982 or 1983 at the rate of 55,000 tons of copper per year was to depend on the state of the Western economy. A substantial dependence on Gécamines smelting and refining capacity was a major factor in 1981 planning.

Sodimiza increased production of higher grade ore from its Kinsenda Mine and diminished the proportion of lower grade ore from its Musoshi Mine to the Musoshi concentrator. As a result, the 87,377 tons of concentrate contained 40.35% copper metal. Sodimiza's staff increased from 3,019 to 3,304 African and from 86 to 113 Japanese employees since 1980 because of increased production at the Kinsenda Mine. Despite the high freight cost, Sodimiza's concentrate continued to be railed through neighboring Zambia and Zimbabwe to the South African port of East London for shipment to Japan. Details of Zaire's copper production are shown in table 4.

Table 4.—Zaire: Details of 1980 copper production, by area

(Thousand metric tons)

Area	Ore	Concentrate	Copper content
MINE[1]			
Western Group:

Sodimiza	1,305	93	34.3
Total	17,337	1,836	539.5

UG Underground.
[1]Gross weight.
[2]The Kipushi ore also contained 103,500 tons of zinc, and the Kipushi concentrator produced 123,000 tons of zinc concentrate containing 67,000 tons of zinc.

Metallurgie Hoboken-Overpelt S.A. of Belgium, one of the world's largest refiners of nonferrous metals, indicated that its output of 30 tons of germanium per year was derived from Zairian raw material. In the past, much of Zaire's germanium production came from its rich and unique copper-zinc ore body at Kipushi where a germanium-rich bornite mineral, renierite, was recovered by selective mining and magnetic separation for many years. Additional germanium-rich material was included in the flue dusts from the Lubumbashi smelter and from residues from the Metalkat zinc smelter-refinery north of Kolwezi. Gécamines has not reported the recovery of germanium since 1975.

Sozacom reportedly sold a record 90,000 tons of Gécamines' zinc during 1981, including 42,000 tons from stockpiled material. Sozacom also negotiated a preferential rate for shipping 5,000 tons of zinc per month through the Republic of South Africa.

Gold.—Zaire's major gold producer continued to be the state agency Offices des Mines d'Or de Kilo-Moto (OKIMO), which operated a number of mines in the remote Haute-Zaire region near the Ugandan and Sudanese borders in northeastern Zaire. OKIMO's plans to rehabilitate its gold processing plant failed to materialize in 1981, and both the company and the Zairian Ministry of Mines were seeking outside investors to finance improvements. Clandestine gold mining and smuggling to neighboring countries were reported to have increased during 1981. OKIMO remained the only legal exporter of gold in the Haute-Zaire region. Its Kilo Mines near Bunia produced 500 to 900 troy ounces of gold per month, and the Moto operations at Watsa had an output of 2,300 to 2,700 troy ounces per month. All production was flown to Kinshasa for export. The tankhouse slimes from Gécamines cobalt-copper refineries at Likasi and Kolwezi continued to be the source of about 3,500 troy ounces of gold per year. The alluvial deposits worked by the Société Minière et Industrielle (Sominki) in the Kivu region for tin, tungsten, and tantalum minerals accounted for 15,000 troy ounces.

Manganese.—Société Minière de Kisenge (SMK), a state-owned company, operated several manganese mines near the railroad west of Kolwezi until traffic was stopped by the Angolan war of independence in 1975. Most of the stockpile of 500,000 tons of crushed carbonate ore and 700,000 tons of uncrushed ore was mined before the railway was closed. In 1980 and again in 1981, SMK shipped a total of about 10,000 tons of manganese ore on the Benguela Railroad to Angola's Lobito Bay Port on the Atlantic Ocean. The South African Manganese Amcor Ltd. approached SMK with an offer to buy up to 100,000 tons per year of Zaire's low-iron ore to blend with its own high-iron product to make a better feedstock for the production of ferromanganese. Attempts to ship manganese on southbound trains were frustrated by the demand for cars to carry the more valuable copper metal and concentrate.

Tin, Tungsten, and Columbium-Tantalum.—Société Zairetain, 50% state-owned, and 50% owned and managed by Geomines Cie., a privately owned Belgian company, continued to produce cassiterite (tin oxide) concentrates from several open pit mines near Manono. The concentrates were smelted into tin metal and tantaliferous slag at the company's Manono foundry. Zairetain and the Zairian Government have also discussed options for financing and exploiting the lithium minerals occurring with the cassiterite.

Enterprises Minière du Zaire (EMZ) was a successor to the Sermikat Pilolet Group, which operated the Mitwaba, Bukena, Kibambo, and Mkoy tin mines south of Manono prior to 1960. EMZ studied the feasibility of reopening the mines and engaged a British engineering firm, Guest, Keen, and Nettlefolds Ltd., to rehabilitate the mines, install new mining equipment, build an airstrip and transportation facilities, train staff, and operate a tin industry at about three times the rate of Zairetain's Manono operation. The EMZ properties were reported to contain wolframite as well as cassiterite.

Compagnie Française des Mines, a French Government mining company owned 69% by BRGM, was reported to have invested $14.3 million into opening up the Kania open pit tin mine south-southwest of Manono in the eastern Shaba region and was slated to produce 500 tons of tin per year starting in 1982.

Sominki, 28% Government-owned, operated one lode deposit and a number of alluvial mines in the Kivu region and continued to be Zaire's leading producer of tin and tungsten concentrates.

The U.S. company Metallurg, a major consumer of columbium (niobium), agreed to participate in 70% of a French-Belgian-Zairian consortium, Somikivu. Sominki was to hold 10% and the Zairian Government was to receive a free 20% interest in the company, which was to construct a $2.5 million pilot plant to determine the best method of extracting pyrochlore from the

Lueshe carbonatite. The Lueshe deposit was reported to contain large reserves of the mineral pyrochlore and its feasibility as a mining project was to be established by 1984. Successful pilot testing was to be followed by expenditure of as much as $50 million for a production facility that would rank as one of the world's top three sources of columbium.

NONMETALS

Diamond.—Zaire's chief producer of industrial diamonds was the Société Minière de Bakwanga (MIBA), managed and 20% owned by the Société Générale de Belgique and the Oppenheimer Group. MIBA negotiated financial backing from the International Bank for Research Development to be used for altering and expanding its concentrating facility. Additional mining equipment was needed to mine the hard kimberlite ore underlying the nearly depleted decomposed eluvial and alluvial ore.

In May, President Mobutu authorized Sozacom to commence marketing Zaire's diamond output, and on May 29, 620,000 carats of industrial diamonds were sold to Antwerp and London dealers for $6.7 million. On August 20, Meltax and Britmond/Central Selling Organization (CSO) were given 48 hours to close their diamond-buying stations in the Tshikapa vicinity and to leave the area. This broke the monopoly on the sale of Zaire's diamonds held since 1967 by Britmond-Zaire, a subsidiary of De Beers CSO, by which Britmond-Zaire received commissions of 20% including costs during 1980. Since August, records indicate that Sozacom sold more than 3.5 million carats of MIBA diamonds for under $31.3 million at prices descending from $10.81 to $7.68 per carat. Also sold were 38,277 carats of gem diamonds from Tshikapa at rates varying from $187.60 to $100 per carat.

MINERAL FUELS

Petroleum.—Crude oil production from Zaire's maritime zone increased from 18,098 barrels per day in the second quarter, to 22,568 barrels per day for September to November. Total production was estimated at 7.4 million barrels for 1981 compared with 6.5 million barrels in 1980. Most of the production came from Gulf Oil's offshore wells, but an increasing percentage was derived from wells on the Mibale structure drilled by Moanada Oil Co., a subsidiary of Cometra Oil Co. Drilling of an additional offshore well was scheduled for late December. Esso-Zaire, an affiliate of the U.S. Exxon Oil Co., completed an onshore well at Mbandaka in the Equateur region and was drilling a second near Lokolama in the Bandundu region. The company was reportedly considering seismic exploration as well as drilling in 1982-83.

The Zairian-Italian Refining Co. completed and was testing its new plant for desalinization of crude petroleum from Zaire's offshore wells so that it might be blended with lighter imported crudes and processed through the refinery at Banana. Zaire's offshore field was operated by Zaire Gulf Oil, owned 50% by U.S. Gulf Oil, 32% by a subsidiary of Teikoku Oil Co. of Japan, and 18% by the Zairian firm Soliza.

The Mineral Industry of Zambia

By Thomas Glover[1]

The mineral industry of the Republic of Zambia provided more than 95% of the country's foreign exchange credit and supported its position as the world's fifth largest producer of copper and the second largest in mine output of cobalt in 1981. Owing to many problems existing in the Zambian transportation network, transportation charges continue to be a large part of the cost of delivering copper and cobalt metal to world markets. The Benguela Railway line from Zambia thru Angola has been closed since 1975, and investment for the needed repair will be extremely high. Steps have been taken to reorganize the Tanzania-Zambia Railway (Tazara), making it possible to correct the deficit financial situation of the railway. Tazara purchased 12 new locomotives from China to add to its present stock of 97 locomotives. Cargo traffic between Dar es Salaam and Zambia has dropped 16% from that carried in 1980. The Zimbabwe route is now a significant one in the haulage of international traffic for imports and exports. This new routing has arisen because a large percentage of cargo comes from the Republic of South Africa and has the advantage of lower freight costs. Zambian miners, however, prefer to export their products through the port of Dar es Salaam rather than the South African port of East London.

The long-awaited feasibility study into the electrification of Zambia Railways has commenced. If electrification proves to be feasible, it would result in a substantial saving of foreign exchange that was being spent on importing diesel fuel for locomotives. The study, being financed under the World Bank Railway Project, will be completed in 1982.

Zambia submitted a request for financial assistance of approximately $54 million under the new mineral support scheme of the European Economic Community's Lome II Convention. The mineral support scheme aims at helping countries with short-term financial difficulties to maintain their production of certain strategic minerals. The scheme covers copper, cobalt, phosphates, manganese, bauxite, alumina, tin, and iron ore. The agreement started in 1981 and runs until 1985.

The International Monetary Fund (IMF) agreed in principle to loan Zambia approximately $800 million[2] to boost the country's troubled economy. The conditions and obligations were being negotiated.

The U.S. Export-Import Bank guaranteed a private loan of $20.5 million to Nchanga Consolidated Copper Mines, Ltd., (NCCM) to buy heavy mining equipment from the United States. In addition, the company secured two additional loans of $22.53 million each to recover copper from tailings at its Chingola Division. The two loans are a part of the $185.4 million necessary for the work on the tailings.

Zambia Industrial Mining Corp. Ltd. received a loan of $1.14 million from Romania for a second-stage development of the Mokambo copper mines near Mufulira. The work began in 1981 and was scheduled to be completed in 1982.

Zambia's two giant copper mining companies, NCCM and Roan Consolidated Mines Ltd. (RCM), will merge in early 1982 to form one company, Zambia Consolidated Copper Mines. The Zambian state holds 60% of the shares in each of the mines. The merger was aimed at rationalizing the operations of the mining industry in view of the world recession and the problems the industry has been experiencing.

PRODUCTION AND TRADE

Zambia's production of copper decreased 1% during 1981, while production of cobalt increased 20%. The grade of underground ore delivered to the mill from NCCM was 1.47% total copper and 0.097% cobalt compared with the open pit ore, which graded 2.37% copper. RCM discontinued production of leach cathode as a salable product in 1981 and is now reprocessing it to refined cathode. An acid plant is to be constructed at Chambishi to handle effluent gases from the RCM Chambishi leach-plant roasters. The new plant will enable the company to become self-sufficient in its requirements for sulfuric acid, which is presently purchased from NCCM. Table 1 shows details of Zambia's mineral production.

The economic importance of the mining sector is paramount, contributing approximately 20% of gross domestic product, one-third of Government revenues, and the bulk of foreign currency earnings. Rising fuel prices and wages, double-digit inflation, and delays in obtaining spare parts and new equipment have occurred at a time when international prices for copper have stagnated. Sixty-eight percent of the copper exported during 1980 went to five major countries. The countries were, in order of importance, Japan, France, Italy, the United States, and the Federal Republic of Germany. The value of exported copper in 1981 was $1,002 million compared with $1,279 million in 1980.

Zambia has given priority to imports for use in the mining, manufacturing, and construction industries. For the mining sector, this should reduce or eliminate production slowdowns due to delays in obtaining foreign exchange to import essential supplies and equipment.

Other do.	110	152	110	NA	NA
Refinery fuel and losses do.	383	194	128	NA	NA
Total do.	6,335	6,649	6,788	6,800	6,800

[e]Estimated. [p]Preliminary. NA Not available.

[1]Table includes data available through July 28, 1982.

[2]Includes leach cathodes.

[3]Primarily contained in blister copper and refinery muds.

[4]For all practical purposes, Zambian output of crude lead and refined lead are regarded as equal; the latter is reported, and inasmuch as no impure lead is marketable, no attempt had been made to estimate the trivial difference between the two stages of processing.

[5]Refined silver and silver contained in blister copper and refinery muds.

[6]Less than 1/2 unit.

[7]Converted from figure reported in cubic meters; believed to represent only a small part of total output.

[8]Figure for 1979 reported as cubic meters, but that for 1980 reported as metric tons; it is believed that both figures actually represent metric tons.

Table 2.—Zambia: Exports of copper, by type and destination

COMMODITY REVIEW

METALS

Copper, Cobalt, Byproduct Gold, Selenium, and Silver.—Zambia's two major mining companies treated about 30.5 million tons of ore containing about 700,000 tons of copper. Estimates of ore milled by RCM and NCCM during 1981 and the RCM ore reserve figures as published in the RCM annual report for the year ending March 31, 1981, are shown in table 5. RCM announced several development projects. At Luanshya-Baluba stage 2, the rock winding shaft was equipped, and the cage and skip compartments became operational to full depth by yearend. The foundations for the service shaft winder were completed, and construction of the hoist house and preparations for erection of the headframe are underway. At the Chibuluma Mine extension, design work and specifications for the 688-meter level crusher and pump stations at the new shaft at Chibuluma West were nearing completion with equipment orders placed. At the Chambishi Mine underground expansion, planning and feasibility studies for ore extraction above the 500-meter level at an increased rate of 230,000 tons per month by October 1981 and for continuing production below the 500-meter level were completed and approved. Detailed design for the copper tankhouse expansion at the Chambishi leach plant was completed. A cobalt metal vacuum refining plant is also being constructed at the Chambishi Mine. The recovery of gold and selenium at the RCM Ndola refinery set records in 1980 and continued at the same rate in 1981.

Table 5.—Zambia: Copper production and ore reserves, by company and mine

Company and mine	Ore mined and treated			Ore reserves		
	Gross weight (thousand metric tons)	Copper (percent)	Copper content (metric tons)	Gross weight (thousand metric tons)	Copper (percent)	Cobalt (percent)
Roan Consolidated Mines:[1]

[1]Roan Consolidated Mines Ltd.-1981 Annual Report.
[2]Stockpiled ore was used for Kalengwa mill feed.
[3]Nchanga Consolidated Copper Mines Ltd.-1981 Annual Report.

NCCM estimated ore production of 16.5 million tons was obtained equally from underground mines and open pits. Delays in the delivery of spare parts and lack of skilled and experienced maintenance staff is still causing the deterioration of plants and equipment throughout Zambia's copper belt. Copper prices remained stagnant during 1981. Zambia lowered its price of cobalt from $20 to $17.50 late in 1981. Spot markets for cobalt in the United States went to $15.00 in late 1981. In the Rokana Division, 1981 production was slightly below 1980 production. At the Mindola shaft, a prolonged overhaul of the main underground crusher severely curtailed production from the lower levels. At the central shaft, where stoping mainly depends on drawpoint loading, production was affected by low availability of loaders.

Also in the Rokana Division, copper and cobalt recovery rates improved over those of 1980. In the Chingola Division, at the Nchanga open pit, additional boreholes

were drilled to provide information for planning the future mining of cobalt-bearing ore. Despite shortages of replacement spares, underground development proceeded on schedule. Some old production areas, previously declared exhausted, were reopened successfully and have provided additional ore. In the Konkola Division surface exploration, one borehole was completed on the west limb, in the north ore body area, that intersected ore at 2.66% over a true width of 14 meters at a depth of 1,129 meters. As a result of this hole, there will be an addition to the ore reserves at the No. 3 shaft. Also at the Konkola Division, underground exploration and drilling are underway at both the north and south ore bodies. Silver production for the Broken Hill Division of NCCM totaled approximately 750,000 troy ounces.

Lead, Zinc, and Byproduct Cadmium.—Ore hoisted totaled 217,503 tons at grades of 6.4% lead and 17.7% zinc. Byproduct cadmium output totaled approximately 1 ton. The NCCM Broken Hill Division has conducted exploration programs at both its surface and underground operations yielding only low-grade mineralization to date.

NONMETALS

Cement.—A shortage of bagged cement due to the lack of paper bags became evident in late 1981. The sale of bagged cement was suspended in October 1981. Firms with bulk handling equipment were not affected.

Fertilizer Materials.—Zambia Industrial and Mining Corp. (ZIMCO) has discovered large deposits of high-grade phosphate at Kaluwe, 220 kilometers east of Lusaka, and at Petauke in the Eastern Province. Zambia now imports phosphate for manufacture of compound nitrate fertilizer at Nitrogen Chemicals of Zambia at Kafue, near Lusaka. ZIMCO is expected to start exploitation of the phosphate deposits, which are estimated at over 200 million tons, in the near future. The Zambian Government will soon start mining lime deposits in Chief Mapanza's area in the Southern Province. The lime will be used mainly for improving soil fertility.

Gem Stones (Amethyst and Emerald).—Low-grade amethyst ore was mined by Northern Minerals (Zambia) Ltd. with an alleged theft of gem production affecting 1981 sales. The Government has started mining emeralds through the Reserved Minerals Corp. in Chief Nkana's area of Ndola Rural. Production started during the first part of August 1981. Production figures are being withheld as a security matter.

MINERAL FUELS

Coal.—Production at Maamba Collieries in the Southern Province is set for a major boost following the installation of new machinery under a multimillion-dollar loan from the Africa Development Bank and the Federal Republic of Germany. The Zambian Geological Survey has recently discovered a major coal belt near Kafue National Park.

A consortium of Canadian companies will spend approximately $30 million in a 4-year oil prospecting venture that starts in the Western Province in 1982.

The Mineral Industry of Zimbabwe

By George A. Morgan[1]

The mineral industry in Zimbabwe was in broad decline throughout 1981. Production of most commodities was below previous levels. Production of gold, the second largest foreign exchange earner after tobacco, was relatively unchanged.

The industry was adversely affected by the post-Civil War and the world recessions. Other important factors contributing to the sector's downturn were increased costs, higher Government expenditures leading to tax increases, producer and investor uncertainty regarding legislation affecting marketing and production of minerals, loss of skilled personnel, and a decline in labor skills and management.

On a world scale, the major portion of minerals produced in Zimbabwe was mined from low-grade deposits with low volume of output. Previous success of the industry has been attributed to relatively low costs, including wage costs. The implementation of minimum wage levels throughout the mining sector was directly responsible for the closure of numerous small mines in the Hartley and Gatooma districts, affecting about 2,000 workers. Several mines were granted exemptions from the minimum wage provision pending investigation into their viability, but all exemptions were suspended in September. At yearend, a second higher minimum wage level was imposed. Small workers employed about 9,000 miners and were most affected by the legislation. Higher wages actually led to a fall in productivity at some workings. The Government considered taking over some mines most affected by the new wage level in order to maintain employment.

The country's two mine labor unions merged. Wildcat strikes occurred at a number of mines owing to an erosion of labor union control and external interference. The mining industry's labor force was officially reported at about 71,000. Approximately 20,000 Zimbabweans employed in the Republic of South Africa, many of them miners, were being repatriated. Planned expansion in Zimbabwe's mining sector was not sufficient to absorb them.

The Central Government Budget Account for 1981-82 allocated $5.7 million for the mining sector out of a total budget of $2,306 million.[2] Other sectors share of the budget were defense, 17%; education and culture, 16%; agriculture, 4.7%; and transportation, 3.4%. The gross national product in 1980 was $7.5 billion. A 3-year Interim Development Plan for the period 1981-84 was underway. The gross domestic product was expected to rise 8% per year; the mining sector, 8%; agriculture, 12%; and manufacturing, 11%. Wage increases from 35% in industry to 130% in commercial agriculture were to take place over a period of 3 years. The consumer price index for high-income and low-income groups increased 14.2% and 11.5%, respectively, in the period through November 1981. Foreign currency allocations came under tighter control because of the decline in mineral sector exports and continued high spending for imports. Only export-oriented firms could qualify for foreign currency allocations. In addition, allocations for the first quarter of 1982 were cut 12%.

A deficit of $433.8 million was estimated for 1981-82. The higher level of Government spending was to be paid for by a 30% increase in tax revenue. Tax measures that had an effect on mining in Zimbabwe were a 20% tax on local and foreign dividends, a capital gains tax of 30% on immovable property and marketable securities, a re-

duction in the percentage deduction of initial capital expenditures from 100% to 30% for tax purposes, a surcharge of 5% on customs duties, and an increase in sales taxes. Being considered was a proposal for the abolition of the 5% depletion allowance.

Exploration permits were granted to Shell Union Co. of Central Africa Ltd. and Cluff Mineral Exploration (Zimbabwe) Ltd. Targets included copper, lead, zinc, nickel, tungsten, gold, and molybdenum. Union Carbide Corp. began a gold exploration program and had applied for an Exclusive Prospecting Order to search for uranium and tungsten in the Zambezi Valley. It was reported that several companies had cut exploration expenditures by 50%.

Government Policies and Programs.—The creation of a Minerals Marketing Corp. (MMC) by the Government of Zimbabwe appeared likely at yearend 1981. MMC was to consist of a board of 5 to 10 members with responsibility for determining if, when, and to whom all minerals and mineral products, excluding gold and iron and steel, could be sold. It would be permitted to set stockpile levels and to withhold payment received from sales of minerals for a period of 30 days. It would also be able to seek an equity position in both new ventures and existing mining enterprises. All sales of gold were made by the Reserve Bank of Zimbabwe, and iron and steel was included under the Ministry of Industry. Several companies postponed decisions to start up new mining projects, including a primary platinum-group metal mine, pending the outcome of the new legislation.

Effective December 1981, new borrowing regulations were placed on private companies. A company must have over 85% local shareholder participation to be free of any limits on borrowing. In addition, no single shareholder who was the major shareholder may own 10% or more of the company. Previously, companies with over 50% local shareholder participation were free to borrow. The Government was expected to acquire shares in a number of mines in 1982.

PRODUCTION

The index of volume of production of minerals fell for the fifth consecutive year to 166.8 from a high of 205.8 in 1976 (1964=100). The value of crude minerals produced was estimated at $532 million compared with $614 million in 1980. This was the first decline in value of mineral production recorded from statistics available since 1964. Although the mineral raw materials sector was in general recession, the manufacturing sector continued to expand processing of mineral-related products. In the period from January to October 1981, the index of volume of production of nonmetallic mineral products was 270 (1964=100) compared with 225.8 in 1980, and the index for metals and metal products was 328 compared with 307.9. The chemical and petroleum products index of volume of production was 282, up from 234.7 in 1980. The Government has encouraged mining companies to process and upgrade their commodity to a finished product. This policy was aimed at increasing the value added and reducing the demand for imports, but also to reduce the burden on the country's transport system. No special incentives have been offered to the industry despite the encouragement.

Table 1.—Zimbabwe: Production of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1977	1978	1979	1980[p]	1981[e]

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through July 7, 1982.

[2]Smelter copper includes impure cathodes produced by electrowinning in nickel processing. Output of fire-refined copper by Messina (Transvaal) Development Corp. apparently was terminated in 1972. Refined copper output from that date to 1980 includes only electrolytic copper output by Corsyn Consolidated Mines at the Inyati Mine. Output in 1981 includes electrolytic copper from the new refinery at Messina.

[3]Includes Ni content of nickel oxide and nickel fonte.

[4]Other gem stones produced in 1981 are as follows, in kilograms: Beryl, 327; chrysoberyl, 2.

[5]Includes rough and ground quartz as well as silica sand. Quartz crystal was also produced in the amount of 3 metric tons in 1979.

[6]Data represent output by the Wankie Colliery for years ending Aug. 31 of that stated; additional output by the Radcliff plant of Risco Ltd. may total 250,000 metric tons per year of metallurgical coke and coke breeze.

TRADE

Comprehensive official trade data covering exports and imports by destination in terms of quantity and value were not available. Only quantity and value of some exported mineral items and major mineral imports by value were available. Other data on trade were provided from industry and press reports and from customs agencies of trading partner countries.

Zimbabwe has maintained a positive trade balance except for 1968. However, reduced revenue from gold sales and high import levels resulted in a negative trade balance in the period through September 1981 of $77.4 million. The export value of minerals and mineral-related products in 1980 was $723.4 million out of a total export value of $1,338.2 million. Gold sales accounted for $170.4 million in 1980. Trade data available through September 1981 indicated a mineral export value of $408 million out of a total export value of $995 million. The value of mineral-related import trade in 1980 was $385.4 million out of a total import value of about $1,200 million. For the period through September 1981, $340.1 million out of $1,074 million was mineral related. Liquid fuels continued to be the largest import item in terms of value.

The Government held talks with China, Hungary, North Korea, and Japan regarding trade agreements. Ferrochrome was the principal mineral commodity of interest in the discussions. The preferential trade agreement with the Republic of South Africa was to expire in March 1982. Discussions were held regarding a continuation of the agreement subject to renegotiation of certain elements.

Exports by rail experienced inefficiencies owing to shortages of workers, engines, and rolling stock. A rail priorities committee made decisions as to the number and destination of rail wagons to be used for exporter needs. Priority was given to exports of commodities earning the highest foreign exchange. At midyear, the country was estimated to be losing $7 million per week because of rail transport inefficiencies. Heavy backlogs of agricultural and iron and steel products occurred. At yearend 1981, the Government banned all strikes by employees of the National Railway of Zimbabwe (NRZ), including trade union action. The provisions of the Emergency Powers Act compelled all employees to place the whole of their time at the disposal of the NRZ. Only about 10% of Zimbabwean trade passed through the Mozambique ports of Beira and Maputo. The remainder was transhipped by rail and exported from ports in the Republic of South Africa. Sabotage of the rail link to Beira disrupted traffic for 3 weeks in November.

COMMODITY REVIEW

METALS

Cesium.—Zimbabwe was one of the few world producers of cesium. Output was 88 tons of pollucite in 1980 from small pegmatite ore bodies scattered throughout the country. Bikita Minerals (Pvt.) Ltd. was the principal producer with output from its deposit at Bikita. Production has been intermittent over the past 20 years because of low demand and reached a high of 281 tons in 1976.

Chromite.—The activities of the two ferrochrome producers in Zimbabwe, Union Carbide and Anglo American Corp., were in contrast during a period of higher costs, lower product prices, and uncertain market conditions.

Zimbabwe Mining and Smelting Co., a Union Carbide subsidiary, completed expansion of its ferroalloy plant at Que Que. Two new 24-megawatt furnaces, each with capacity to produce 45,000 tons per year of high-carbon ferrochrome, were added to the existing facility. Four furnaces of 7.5 to 15 megawatts with a total capacity of 90,000 tons per year and employing 1,100 people represented existing capacity. The company was deepening the shafts of the Peak and Railway Block Mines. Three small mines were being brought into operation near Selukwe, and production capacity at the Mtoroshanga Mine was expanding. When completed, the company will have five main chromite mining operations, employing over 3,500 people, located at Mtoroshanga, Darwendale, Ngesi, Lalapanzi, and Selukwe.

Rhodall, Ltd., an Anglo American subsidiary, abandoned plans to add three new ferrochrome furnaces at Gwelo because of high production costs, principally wages. Rhodall, Ltd., operated at a loss on production compared with marginal profitability at the Union Carbide plant. The company also suffered from a strike by 1,300 employees in March over the pay structure. Higher ferrochrome prices, if occurring, were expected to be offset by planned increases in wages and transportation and electricity costs. In September 1981, the Government of Zimbabwe made a request for the granting of duty-free status for shipment of low-carbon ferrochrome and ferrosilicon chrome to the United States.

Copper.—M.T.D. (Mangula) Ltd. successfully commissioned a new electrolytic refinery at Mangula. The plant had little effect on the financial position of the company, which had a loss for the first time in its history. Mining costs increased 29%, and no dividend was declared. Production declined sharply because of ore grade dilution

and lower operating efficiency. Low metal prices for copper and silver made mining operations unprofitable. The necessity to reduce the mine's dependency on borrowing may preclude payment of dividends over an extended period.

The Norah Mine, operated by M.T.D., produced mainly chalcopyrite and bornite by sublevel mining. All crushing to minus 76 millimeters was performed underground. Mill throughput was 43,000 tons per month. Main levels were set 44 meters apart with a 15° incline ramp from 5 level to the mine bottom. A conveyor system with an 18° incline moved ore from below 9 level to 850 level at 20 tons per hour.

Coronation Syndicate Ltd. produced copper at the Inyati and Muriel Mines through Corsyn Consolidated Mines Ltd. The Muriel Mine was a primary gold producer yielding 345 tons of byproduct copper in the year ending September 30, 1981. Inyati Mine, the primary copper producer, had a decline in output of almost 9% to 2,674 tons of copper. The decline was attributed to shortages of skilled personnel and spare parts, which led to plant stoppages and lower ore grades. Working costs were up 41%, mainly from higher salaries, wages, and equipment replacement. Development work in the Era section was stopped, and output was to be terminated upon depletion of payable ore grades. Only the Inyati section of the mine will be worked, which had ore reserves of 486,000 tons grading 2.38% copper. Mill throughput was 159,000 tons in 1981 compared with 193,000 tons in 1980. A further decline in throughput to 11,000 tons per month was anticipated to minimize financial losses.

Gold.—Of the 280 gold mines estimated to have operated in 1981, over 250 were small workings employing less than 20 workers. Falcon Mines, Ltd., operated the largest producer, Dalny Mine. Mill throughput for the year ending September 1981 was 242,045 tons compared with 241,550 tons in 1980. A decline in head grade from 0.198 troy ounce of gold per ton to 0.182 troy ounce per ton resulted in production of 44,111 troy ounces of gold. Working costs at the Dalny plant increased 39% to $59 per ton of ore milled. The increased costs were primarily due to a 48% rise in wages and salaries and a 29% increase in the cost of consumable supplies. Ore reserves were about 2 million tons with a gold content of 0.289 troy ounce per ton. Production from the Venice Mine, also operated by Falcon Mines, Ltd., of 5,000 tons per month was treated at the Dalny plant. An increase to 7,000 tons per month was planned for January 1982, and a new mill at the Venice Mine was to be commissioned in April. The Venice mill would treat an additional 5,000 tons of ore per month. Reserves at the Venice Mine contained 0.228 troy ounce of gold per ton, and the operation was considered marginally profitable if the price of gold fell to $385 per ounce. An increase in total mill throughput of 15% was expected in 1982. A thorough discussion of the ore characteristics, plant equipment, mill procedures, and metal recoveries at the Dalny plant was published.[3]

The annual report of Corsyn Consolidated Mines Ltd. reported a total mill throughput of 422,000 tons for the company's mills in the year ending September 30, 1981. Throughput was from four operating mines. Total gold production of 50,734 troy ounces was achieved from the following individual mines: Arcturus, 16,493 troy ounces; Mazoe, 13,696 troy ounces; Muriel, 18,615 troy ounces; and Inyati, 1,929 troy ounces. Gold content of millfeed was as follows, in troy ounces per ton: Muriel, 0.289; Arcturus, 0.151; Mazoe, 0.148; and Inyati, 0.013. Ore reserves at the Muriel Mine were 278,000 tons containing 0.440 troy ounce per ton. Airborne geophysical prospecting in the mine's vicinity yielded several anomalies for further investigation. Mill throughput at the Arcturus plant of 106,000 tons included 14,000 tons of tailings from the Mashona Kop Mine for retreatment. Ore reserves were 550,000 tons with 0.257 troy ounce of gold per ton. A new cyanide plant was commissioned at Arcturus Mine and resulted in marked improvement in recoveries. Three new shafts were completed and their commissioning was expected to reduce hoisting problems. A shaft was being sunk at the Viceroy deposit, 12 kilometers from the Arcturus Mine. Ore from the new mine will be milled at Arcturus. Reserves at the Mazoe Mine continued to decline and the production rate was reduced. Ground surveys and airborne geophysical work continued for new ore.

The Shamva Mine, operated by Attica Mines (Pvt.) Ltd., was the second largest gold-producing mine in Zimbabwe. Mill throughput was 150,000 tons per year at 0.145 troy ounce of gold per ton, yielding 17,400 troy ounces. Gold was located in tuffaceous sediments derived from the reworking of pyroclastic materials in a shallow water environment. The gold and associated sulfide mineralization were then con-

centrated in the old channels. Shamva Mine had the lowest cost per ton of ore milled of nine gold mines in the Lonrho Investment Group (Lonrho) at $30 per ton. Lonrho scheduled the opening of the Legion and Tiger Reef gold mines in 1982.

Rio Tinto Zimbabwe Ltd. (RTZ) continued infrastructure and mine development at the Renco Mine. RTZ was providing electricity, telephone service, sewage, schools, and a medical clinic. Separate housing was to be made available to all miners with families, including the lowest paid. Full operation of the mine was planned for early 1982 with a throughput of 15,000 tons per month of ore yielding over 48,000 troy ounces per year of gold. RTZ had a 56% equity in the mine; the remainder was traded on the Salisbury Stock Exchange and held by private stockholders.

Union Carbide had an expanded exploration program for gold underway and was to start up its fourth gold mine. The Sun Yat Sen Mine was put back into production following a hiatus of several years because of the Civil War.

Iron and Steel.—Production and marketing by the Zimbabwe Iron and Steel Co. Ltd. (ZISCO), formerly Rhodesia Iron and Steel Co., Ltd., also known as RISCO, were curtailed in 1981, mainly because of low market demand. Plans for installation of a continuous bloom caster and a new sinter plant to treat Ripple Creek Mine and Buchwa Mine iron ore were postponed because of cash shortages. The company requested Government approval to mothball a blast furnace. ZISCO was about 50% owned by the Zimbabwean Government. Other principal shareholders included British Steel Corp. and Tanks Consolidated Investment Ltd., both of the United Kingdom; M.T.D.; and Anglo American. Klockner and Co. Ltd. was sales agent for sales outside the home market. The home market included both domestic sales and sales to members of the Southern African Development Coordination Conference.[4] Domestic deliveries were estimated at 180,000 tons in 1981 compared with 133,545 tons in 1980. Lancashire Steel Co. received 5,000 tons of billets per month for drawing to wire products. Exports were about 210,000 tons compared with 515,297 tons in 1980. In addition to low market demand, a backlog of cargo at Maputo and sabotage of the Beira rail and bridge connection slowed exports.

Nearly all raw materials for pig iron and steel production were produced in Zimbabwe. About 2,400 tons per year of high-carbon ferromanganese was supplied by Anglo American from its plant at Gwelo.

Kew Engineering (Pvt.) Ltd. opened a new foundry in Gwelo under a subsidiary, Kew Precision Casting Co. Products included aluminum, copper, brass, mild steel, and wear-resistant steel castings. Production should replace imports of products such as drill-core bits for the mining industry.

Nickel.—Output from the smelter of Bindura Nickel Corp. in Gatooma was suspended for 8 weeks because of a furnace explosion. Sales were adversely affected by low nickel prices and unfavorable exchange rates.

Efforts were made to maintain the financial solvency of Shangani Mining Corp., Ltd., which operated the Shangani Mine. The company's cash requirement of $10.4 million was provided by its joint owners, Johannesburg Consolidated Investment Co. Ltd. and Bindura Nickel Corp. The company suffered a loss of $8.8 million in the year ending June 30, 1981. Shareholders of the company's stock were asked to exchange their holdings for shares in Bindura Nickel Corp. Ltd. In the year ending June 30, 1981, mill throughput was 746,000 tons averaging 0.55% nickel. Nickel in concentrate was 3,025 tons. Operations in the West Pit of Shangani Mine were terminated, and underground production was slowed because of complex geology and poor ground conditions. Initial planned capacity of 60,000 tons per month was reached in July. The cost per ton of ore milled was up 58% and was attributed to higher mining costs and a threefold increase in labor costs. Proved reserves were 1.23 million tons averaging 0.61% nickel. Probable and possible reserves were 15.1 million tons averaging 0.69% nickel.

Rio Tinto Zimbabwe Ltd. was drilling a nickel prospect adjacent to the inactive Lanninhurst Asbestos Mine. No indication of new ore was made.

Platinum.—Platinum-group metals (PGM) were produced as a byproduct of nickel mining. Rio Tinto Zimbabwe Ltd. developed an extraction process for Empress Mine nickel ore in 1979. Output

commenced in 1980, mainly from stockpiled material. In 1975, Rio Tinto Zimbabwe Ltd. acquired the Zinca prospect on the Great Dyke near Hartley. A pilot plant valued at $2 million was placed in operation in August 1981 to test and evaluate recovery processes. Primary recovery would be for PGM, with nickel, copper, and gold produced as byproducts. An evaluation of mining methods was underway and trial stoping was in progress. A production rate of 2 million tons per year of ore containing 3 to 5 grams per ton of PGM has been suggested. The decision to commence with the project was planned for 1982 and was dependent upon technical feasibility and the expected impact of new investment and tax codes affecting the industry.

Union Carbide operated a pilot mine at Makwira, the current site of the Zinca prospect, from 1968 to 1972, when it closed because of severe mining problems. The plant was moved to the Mimosa property on the Great Dyke near Shabani in 1974, where drilling was undertaken and a pilot shaft sunk. Because of low world metal prices and high development costs, the mine was put on a care and maintenance basis. A production rate of 2,000 tons per day of ore grading 3 to 5 grams of PGM per ton was considered necessary for profitability.

Tantalum.—Past production has included output from about 300 claims generally concentrated in 5 source areas: Kamativi, Urungwe, Mazoe, Odzi, and Victoria. Most production has been in the form of concentrates of microlite, tantalite, and simpsonite from small pegmatite ore bodies by small-workers and local syndicates. Tantalum from Kamativi was contained in tin slags. Data from small producers have generally not included concentrate grades, and byproduct from tin production was reported as Ta_2O_5 in tin slags.

The Wanroo Mine near Shamva consisted of 16 pegmatites 3 to 5 meters in width and up to 600 meters in length in a greenstone belt 700 meters wide. Albite, quartz, and lepidolite were the principal pegmatite minerals with minor quantities of fluorite, apatite, amblygonite, microlite, and cassiterite. The pegmatites were worked opencast and with shallow adits. Concentrates containing 55% to 60% Ta_2O_5 were produced. Proved ore reserves were estimated at 3,800 tons containing 0.88 kilogram of combined tantalum minerals and cassiterite per ton. Unproved reserves were estimated at 75,000 tons containing 0.88 kilogram of tantalite and cassiterite per ton.

Tungsten.—Underground development on the Bulldog claims near Umtali by Corsyn Consolidated Mines Ltd. intersected scheelite mineralization averaging 0.9% WO_2 over a 7-meter width. Determination of limits of the strike length were underway.

Uranium.—The Government announced that it intended to take equity participation at the production stage of any uranium exploitation venture. Union Carbide, Prospecting Ventures Ltd., Corsyn, and Saarberg Interplan Uran GmbH were granted prospecting rights. Saarberg Interplan Uran GmbH, under the sponsorship of the Government of the Federal Republic of Germany, had the most extensive exploration planned. Survey area was 34,000 square kilometers in northern Zimbabwe.

NONMETALS

Asbestos.—The Pangani, Vanguard, and Boss Mines, operated by Pangani Asbestos Mine (Pvt.), Ltd., were closed in May 1981. Pangani Mine depleted its ore reserves, while the Vanguard and Boss Mines were uneconomic because of high costs. Approximately 1,300 people had been employed at the mines and the blending plant.

Shabani and Mashaba Mines (Pvt.) Ltd. (SMM), the largest producer of asbestos in Zimbabwe with about 95% of total output, replaced its truck transport system at Shabani Mine with a monocable aerial ropeway. Capacity of the system was 125 tons per hour using bottom-opening buckets traveling at 185 meters per minute over 2,122 meters of ropeway.

Turnall A.C. (Pvt.), Ltd., which shut down its 25-year-old asbestos pipe plant in 1980, completed construction on a new facility. Capacity to handle and finish asbestos pipe was doubled while production capacity increased 35%. Cost of the plant was $3.22 million, and all fiber was supplied from SMM.

Barite.—Chiroswa Minerals (Pvt.) Ltd. acquired the Dodge Mine in 1978 and has held it on a care and maintenance basis. The company was actively seeking to develop the mine for production of barite and associated limestone and talc. Reserves of 650,000 tons containing 62.8% barite discovered prior to 1976 have since been estimated to be understated.

Several small-scale producers of barite sold their products to the paint and glass

industries. G & W Industries (Pvt.), Ltd., extracted small quantities from vein and stratabound deposits near Que Que.

Cement.—Two companies produced cement at two plants in Zimbabwe. Salisbury Portland Cement, Ltd. (SPC), a subsidiary of Blue Circle Ind. of the United Kingdom, had a plant at Salisbury with a 400,000-ton-per-year capacity. Output of 200,000 tons per year was from two coal-fired kilns. Limestone was supplied from a company-owned quarry at Sternblick Farm, 4 kilometers from the plant. Three types of cement were marketed: PC15 containing 15% blast furnace slag, PDFC containing 50% blast furnace slag, and portland cement. Bulk shipments of portland cement were $61 to $67 per ton, ex-plant.

The United Portland Cement Co. (Pvt.), Ltd., located in Bulawayo District, had a capacity of 400,000 tons per year and an output of 200,000 tons per year. Limestone was obtained from the Cleveland Mine in the Coleen Bawn deposit southeast of Gwanda, and clay was from the Korbut Mine near Gwanda. Production was only about 50% of capacity at both plants because of low demand.

Fertilizer Materials.—Sable Chemical Industries, located in Que Que, was the sole producer of nitrogen fertilizer. The locally owned company produced 34.5% ammonium nitrate. An ammonia synthesis plant having a 52,000-ton-per-year capacity was installed in 1972, replacing ammonia imports. Hydrogen for synthesis was produced by water electrolysis using Lurgi high-pressure water-electrolysis cells. Production was suspended briefly in February and March because of a truck shortage, and the plant was shut down in November because of boiler breakdown. Supplies to two companies producing mixed fertilizers, RFC Ltd. and Windmill (Pvt.), Ltd., were adversely affected.

The importation of 45,000 tons of nitrogenous fertilizer was authorized to make up for a shortfall caused by the addition of new farm acreage to productivity. Total combined fertilizer demand was estimated at 560,000 tons per year. The Ministry of Trade and Commerce approved an average price increase of 14% for fertilizer products. Ammonium nitrate increased from $234 per ton, ex-plant, to $260, and single superphosphate was up $37 to $163 per ton, ex-plant.

Iron Oxide Pigments.—Iron oxide pigment was produced from the Zoe Mine near Hunters Road. G & W Industrial Minerals was the principal processor of the oxide, which was hematite located in massive quartzites in faulted zones. Iron oxide content was 79%, and reserves were estimated at 25,000 tons. After grinding, the product was exported to the Republic of South Africa for staining concrete slabs and roofing tiles. Ex-plant price was $174 per ton for shipments in excess of 4 tons.

Limestone.—In addition to production of limestone at the Sternblick and Cleveland Mines for cement use, nine other mines supplied limestone and dolomite for the manufacture of lime, for use in metallurgy, or for use as a filler. The Rushinga dolomite deposit was worked by G & W Industrial Minerals (Pvt.) Ltd. at a rate of 6,000 tons per year for use as a filler. Production by Alaska Dolomite (Pvt.) Ltd. from the Springbok Mine was for agricultural use and output by Van Wyk Ventures (Pvt.) Ltd. was for use in copper smelting.

Mica.—Mitmar (Pvt.) Ltd. was the sole producer of flake and waste mica and held 100 of 300 pegmatite claims over a 500-square-kilometer area in northern Zimbabwe. The Last Hope, Turning Point, and Hendron Mines were in production. About 35,000 tons of mica dumps left in the area has been reprocessed, and several thousand tons remained. Total reserves were 47,500 tons, and production capacity was about 1,250 tons per year. Production at the Turning Point mill was designed for 150 tons per month of flake mica with two shifts. However, 75 tons was normally from mica waste dump.

Quartz (Silica).—Production was from vein, pegmatite, and alluvial quartz quarrying operations. The Lome Kop Mine near Gatooma, operated by Todoma Silica (Pvt.), Ltd., was the largest deposit with reserves of 10 million tons of high-quality quartz. Zimbabwe Base Metals Producing (Pvt.) Ltd. processed two silica grades from the Patronage Mine. Silica for use as flux in ferroalloying operations was produced by Zimbabwe Mining and Smelting Co. (Pvt.) Ltd. at the Duzi Mine near Que Que and Rhodesia Quarries Ltd. at the Broadside Mine near Gwelo. Industrial Sands Ltd. operated the Industrial Sands Mines in the Somabulla Flats at Gwelo. About 1,000 tons per month was produced for the glass industry, and 1,500 tons per month was for use in foundries and as flotation media.

The Crystal Mine in the vicinity of

Urungwe and a small mine northeast of Miami provided several tons of crystal quartz valued at $2 million. The clear, flawless, untwinned crystals were used for communications components.

Talc.—Output was mainly from two mines: The Tritan claims south of Que Que with reserves of 25,000 tons, and the Hawkshead Mine near Umtali. G & W Industrial Minerals was the principal processor, supplying three grades of ground talc for local use in filler applications, fertilizer and insecticide manufacture, and also in lump form for carving.

MINERAL FUELS

Coal.—The Government approved a coal price increase at yearend to Wankie Colliery Co. Ltd. after having denied the increase in May. The terms of the original agreement stipulated that a pretax return of 12.5% was allowed on domestic sales. All coal in Zimbabwe was owned by the Government except for Wankie, in which it was a minor shareholder. The new prices per ton of coal were as follows, ex-mine or plant: unwashed, $15.90, up 27%; washed, $21.81, up 25%; coking coal, $24.70, up 28%; and low-phosphorus coal, $81.05, up 17%.

Although total coal output declined, mine development continued and overburden removal expanded. About 7.46 million cubic meters of overburden was removed in the financial year ending August 31, 1981, compared with 7.37 million cubic meters in the previous comparable period. Production of individual mines and disposition of coal as reported in the Wankie Colliery Annual Report for 1981 is listed in the following tabulation, in tons:

	1980[r]	1981
Underground mines:		
No. 3	1,126,430	1,008,378
No. 4	--	100,006
Total	1,126,430	1,108,384
Opencast mines:		
No. 1	164,668	178,185
No. 2	259,656	254,971
No. 2A	384,689	261,757
No. 3A	--	71,669
No. 4	1,324,194	1,100,316
Total	2,133,207	1,866,598
Total mined	3,259,637	2,975,282
Discards	491,655	613,651
Salable products	2,767,982	2,361,631
Used internally	385,783	379,343
Total coal sales	2,382,199	1,982,288

[r]Revised.

Total coke production at Wankie was 193,360 tons in 1981 and 195,118 tons in 1980. Coke sales were 209,928 tons compared with 232,984 tons in 1980. Breeze coke sales were 781 tons compared with 2,179 tons in 1980. Byproducts produced were crude tar, 8,600 tons; ammonia liquor, 1,107 tons; and crude Benzol, 7,914 gallons.

New mining equipment for coal expansion was ordered, including a new walking dragline that was due for delivery and setup in April 1982.

The Mineral Industry of Other Central African Countries

By Suzann C. Ambrosio[1]

CONTENTS

CAMEROON

Crude petroleum, the only commercially exploited mineral resource in Cameroon, continued to dominate developments in the mineral industry sector. International mining concerns have expressed interest in developing Cameroon's bauxite and iron and steel potentials. Domestically, the mineral industry focused on production of fertilizers for agricultural development, infrastructure construction, and hydrocarbon development, through the nearly self-sufficient production of fertilizer materials, cement, and crude oil.

The mineral sector contributed 5.5% to the estimated 1981 gross domestic product (GDP) of $6.5 billion.[2] Petroleum exports accounted for approximately 4.5% of the 1981 GDP and exceeded coffee and cocoa exports for the second consecutive year. The trade gap widened during the fiscal year ending on July 30, 1981, owing to a 21% increase in exports and a 25% increase in imports. Offsetting these balance-of-payments difficulties, typical of developing countries' early economic stages, were increases in foreign exchange reserves to $71 million by May 1981.

The national budget for the fiscal year ending July 30, 1982, the first year of Cameroon's fifth 5-year national development plan (1981-86), increased 26% to $1.1 billion. Rising revenues from oil royalties and increased income taxes assisted financing the 25% increase in public investments, the majority of which were slated for capital works. Increasing emphasis was expected to be placed on development of the infrastructure and of the agriculture and mineral resource industries in forthcoming budgets of the 5-year plan. Although Cameroon's debt-service ratio was one of the lowest in Africa during 1981, debt-service payments increased 19% over those of 1980, representing approximately 10% of export earnings and 8% of the budget.

Europe remained Cameroon's major trading partner, importing 59% of Cameroon's exports and supplying 66% of Cameroon's imports by value. Trade with North and South America increased to 27% in 1979-80, owing primarily to rising U.S. purchases of Cameroon crude oil. The United States imported approximately 15.3 million barrels of crude oil, equivalent to just under

1% of total U.S. crude supplies during 1981. Cameroon exported nearly one-half of its petroleum output to the United States in 1981.

Systematic exploration of Cameroon's mineral resources was facilitated through aid from the European Development Fund, bilateral technical assistance agreements, and a $4.2 million multiyear effort funded by the United Nations Department of Technical Cooperation for Development. During 1981, the United Nations was investigating mineral resources in southeast Cameroon, the French Government was involved in tin and other nonferrous metals exploration in the southwestern part of the country, and the Federal Republic of Germany was lending assistance to explore uranium prospects in northern Cameroon. The World Bank expressed interest in lending petroleum exploration credits, but the Cameroon Government initially declined the offer in an effort to keep foreign debt low.

The aluminum smelter located at Edea and operated by Compagnie Camerounaise de l'Aluminium Pechiney Ugine Kuhlman underwent a 30% annual capacity expansion to 80,000 tons. Bauxite was imported from Guinea and subsequently smelted and milled into aluminum ingots and products at Edea. The plant utilized 65% of the hydroelectric power generated at Edea. Indigenous bauxite resources, located at Minim-Martap, were estimated at 1 billion tons. Studies continued to be made, but large transportation costs hindered development.

Plans were underway to expand cement output of the two existing facilities at Bonaberi and Figiul. Production capacities were expected to increase to 850,000 and 100,00 tons, respectively, by 1983. The national cement company, Les Cimenteries du Cameroun (Cimencam), projected domestic demand increases of approximately 65% to nearly 1 million tons between 1981 and 1990. The cost of the two expansion projects was estimated at $30 million.

A new company was formed, Société d'Etudes de Fer Du Cameroun (SEFERCAM), among the Cameroon Government (35%), the Bureau de Recherches Géologiques et Minières (BRGM) of France (31%), an unspecified U.S. company (24%), and Krupp GmbH of the Federal Republic of Germany (10%). The group combined efforts to conduct an 18-month prefeasibility study to exploit Cameroon's iron and steel resources. The proposed study, including technical, financial, economic, and commercial aspects, was estimated to cost $1.5 million.

A technical assistance contract was concluded by SEFERCAM and BRGM for the latter to provide technical supervision during the design and implementation phases. BRGM, in cooperation with the Cameroon Government and Krupp, was also in the process of reviewing the full potential of the 130-million-ton iron ore deposit located at Kribi. Aside from the reported valuable iron deposits, there were indications of associated titanium and uranium, and possibly cassiterite and antimony resources.

Société Nationale d'Investissement du Cameroun, the Government holding company through which the Government participated as a shareholder in roughly 80 commercial and industrial enterprises, was seeking partners to help finance and operate an 11,000-ton-per-year rebar mill. The possibility of setting up a new galvanizing plant was also under discussion. The terms of the partnership would require a 50% investment share, design and construction of the industrial unit, industrial management, and technical staff training.

In the hydrocarbon sector, Cameroon produced an average of 84,000 barrels per day of crude oil from a measured reserve base of 140 million barrels. Existing and prospective oil reserves were projected to last 25 years at current levels and allowed for a doubling of output by 1985. Crude production increased approximately 20% between 1980 and 1981. Measured natural gas reserves were reported at 7 million cubic feet. Mobil Oil Corp. and a consortium of European hydrocarbon subsidiaries identified 4 trillion cubic feet of prospective natural gas resources during 1980-81. The majority of Cameroon's oil and gas resources were offshore in the Gulf of Guinea; the northern fields were located near the town of Victoria, and the southern fields were near the town of Kribi.

A 2-year feasibility study for a proposed liquefied natural gas plant near Kribi was undertaken. SEGAZCAM, a group of five national and international hydrocarbon firms, was expected to reveal information on plant design, technical processes, construction cost, financing, and markets for export by 1983. The group consisted of the Government-owned Société Nationale des Hydrocarbures (SNH), Mobil Exploration Equatorial Africa, Total Exploration and Production Cameroon, Société Nationale

Elf Aquitaine (SNEA), and the Pecten Group. Large infrastructure and capital costs estimated at $2.7 billion have inhibited development.

Cameroon opened its first oil refinery on May 16, 1981. The 24,000-barrel-per-day facility was constructed near Victoria. Full production was expected to occur in mid-1982, and potential capacity was designed for 40,000 barrels per day. The refinery, constructed by Procon Inc. of France, was owned by SNH (66%), Total-Cíe. Française des Petroles, France (10%), and Mobil Oil Corp., Shell Oil Co., and SNEA (8% each). SNH was expected to supply 100% of the plant feedstock. The supply was expected to originate from approximately 50% of Cameroon's offshore oil entitlements, primarily from the Rio del Rey Oilfield. Cameroon's projected refined oil product surplus of mostly heavy fuel oils was expected to be exported to the Central African Republic and Chad.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Includes data available through Sept. 27, 1982.

[2]In addition to the countries listed, Equatorial Guinea and São Tomé e Principe, covered textually in this chapter, presumably produce modest quantities of a variety of crude construction materials (clays, stone, and sand and gravel) and may produce minor amounts of other mineral commodities (most notably gypsum, lime, and salt), but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[3]In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (clays, stone, and sand and gravel) presumably are produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[4]Reported figure.

CENTRAL AFRICAN REPUBLIC

Diamonds and gold were the only minerals exploited in the Central African Republic during 1981. Mineral production contributed approximately 4% to the estimated $745 million 1981 GDP.[3] Roughly two-thirds of the diamond output was gem quality, and total production was valued at approximately $25 million. Small workings of gold were valued at roughly $300,000 during the year.

Reported production of both diamond and gold declined nearly 10% betwen 1980 and 1981. It was estimated that roughly 50% of the diamond output was not reported and was illegally exported. This situation was attributed to both the Cameroon 20% diamond export tax compared with significantly lower taxes in adjacent countries, and the large number of intermediaries that resell the local prospectors' diamonds to marketing centers. This factor in combination with depressed world markets led to a 7% decline in diamond exports to approximately 24% of total exports, valued at $135.2 million in 1980. Timber and coffee were the next largest export earners, comprising another 50% of export revenues.

Investigations to develop the Nation's other mineral resources continued throughout the year. A pilot uranium plant located in France, utilizing ore from the Bakouma deposit in the Central African Republic, temporarily ceased production. Minemet, the French concern that operated the exper-

imental facility, closed operations because of low uranium prices. The Central African Republic was seeking partners to exploit the estimated 20,000 tons of uranium metal resources.

The creation of a cement facility through the development of the Fatima-Bobosa limestone deposit was one of the Government's mineral development priorities. The Nation's cement requirement, equivalent to roughly 50 million tons, was supplied by Zaire and various European countries. The indigenous limestone deposit, located south of the capital city of Bangui, was estimated to encompass a 25-kilometer stretch of limestone. Samples were taken from where the primary tributaries meet the Ubangi River. An initial sample analyzed in France indicated a 23% calcium content. Prefeasibility studies were conducted by the United Nations Development Program and a French company during the 1970's. Lack of investment capital hindered development, but the Central African Republic continued to search for and encourage foreign participation.

Small copper and iron prospects in the northwest part of the country have been periodically studied since 1962. The Romanian Government recently offered the Central African Republic additional technical assistance to evaluate the copper prospects. Both French and Romanian teams were evaluating mineralized lenses of iron in Bogoin. The French estimated iron reserves at 500,000 tons in 1962, and the Romanians, evaluating a larger area 10 years later, estimated iron reserves at 3.6 million tons. The grade ranged from 40% to 70% iron metal.

The Central African Republic Ministry of Energy and Mines continued to heavily depend on foreign assistance, since the Ministry lacked modern field and laboratory equipment. Primary ministerial responsibilities included granting diamond mining concessions and collecting mineral information. A Bureau of Statistics was created in 1981 to coordinate mineral reporting. The Government was interested in developing the analytical and research capabilities of the Ministry to further the development of mineral and energy resources.

Two hydroelectric plants with 12 megawatts of combined capacity provided electricity solely for the city of Bangui. Efforts were underway to develop additional small-scale hydroelectric potential to minimize gas and oil product imports utilized by small towns and villages. Approximately 500,000 barrels of refined products, primarily transportation-related gas, oil, and fuels, were imported. Tankers from Europe, the Middle East, and Caribbean refineries arrived at Pointe-Noire, Congo, and at Matadi, Zaire. Oil products from Pointe-Noire were hauled by train to Brazzaville, Congo, and then barged to Bangui. Products arriving at Matadi were pipelined to Kinshasa, Zaire, and then distributed by barges more than 1,000 kilometers up the Congo and Ubangi Rivers to landlocked Bangui.

Oil exploration continued in the northern part of the country near the borders with Chad. In November 1980, the Central African Hyrdocarbon Co. and the Total-Cie. Française des Petroles of France established Total Centrafricaine De Gestion (TOCAGES). The joint-venture firm was owned 51% by the Government and 19% by Total-Afrique; the remaining 30% was shared equally among Mobil Oil Corp. and Texaco Inc. of the United States and Purifna Oil Co. of Belgium. TOCAGES, with initial capitalization of nearly $700,000, started operating in 1981 as the Nation's oil-products distribution monopoly.

CHAD

The mineral industry of Chad, which previously consisted of petroleum, natron, salt, and clays, was stagnant during 1981. Natron is a hydrous sodium carbonate derived from brines and evaporite deposits at Lake Chad. War raged throughout the country, and most civilians evacuated to adjacent Central African countries. As a result, Conoco Chad (a consortium of five U.S. petroleum companies) halted exploratory oil drilling operations in the northern part of the country. The cessation of all productive industries, including agriculture, led to an economic tailspin. There was only one indication of economic normalization in Chad during 1981: The Bank of Central African States reopened its doors in August after a 17-month shutdown. The bank was a currency-issuing authority for its members of Chad, Cameroon, the Central African Republic, the Congo, and Gabon.

The 16-year Civil War tentatively ceased when in November 1981, approximately 10,000 Libyan forces withdrew from Chad and were replaced by an Organization of African Unity (OAU) peace force. The United States and France donated $12 million each in support of the OAU forces, which were projected to cost $100 million annually. A meeting was held in France during November to coordinate international reconstruction aid. Western industrialized nations and international banks focused on assistance to rehabilitate infrastructure facilities.

Discussions held at a United Nations meeting during August 1981 revealed that Chad's first 5-year plan included hydrocarbon exploration, hydroelectric potential feasibility studies at Ganthioot Falls and Legone Valley, geothermal feasibility studies in the northern part of the country, and evaluation of indigenous uranium resources.

CONGO

Increased petroleum revenues continued to support real economic growth rates in excess of 5% for the last 3 years. The share of oil receipts in the national budget increased from 41% to 70% between 1979 and 1981. The 1981 nominal GDP, estimated at $1.4 billion, and the $202 million trade surplus were largely attributed to the approximate 30% increase in petroleum output.[4] The Nation's 1981 foreign debt of $975 million consumed 20% of the budget receipts and 28% of the export earnings. The balance-of-payments situation improved owing to the growing trade surplus, increased capital account surplus, and a near doubling of foreign exchange reserves.

In the nonfuel minerals sector, output continued to be sluggish as production of copper, lead, zinc, and gold dropped off. Hydrocarbon and cement output increased during 1981. Renewed interests in the Holle potash mine and a review of the Nation's mineral resources were part of the Government's effort to diminish mineral import dependence.

Rehabilitation of the flooded Holle Mine continued to be discussed throughout 1981. United States and French firms were contemplating feasibility studies to solution-mine the carnallite. The market analysis and flow-sheet-preparation part of the study was estimated to cost $100,000. In general, the lack of capital and adequate infrastructure adversely affected even the most promising mineral resource areas.

The BRGM considered the financing and preparation of a mineral survey. An initial grant of $9,200 was set aside for a mining plan. The plan's objective was to gather, evaluate, and verify previous mineral studies. The final Holle potash report was expected to be completed in 1982. More immediate action on a cement factory proposal was also under consideration.

In April 1981, the Council of Ministers met to discuss previously completed geological and mining studies. Emphasis was placed on conducting more in-depth analyses and followup studies. Aside from hydrocarbon development, including the increased recovery of associated natural gas, the Council was interested in assessing the Nation's iron resources. Mounts Avima and Namemba, two known iron ore deposits located in the Western Sangha area, were targeted for additional investigation.

The volume of materials transported, including mineral fuels, manganese, cement, timber, and cotton, via the Congo Ocean Railway (CFCO) declined during 1981. The Compagnie Minière de l'Ogooue S.A. of Gabon (COMILOG) section of the CFCO

railroad traverses 285 kilometers from Mbinda, Gabon, through Loudima, to the Congolese coastal port Pointe-Noire. Approximately 1.5 million tons of manganese ore valued at $4.6 million was transported during 1981. The near 30% decline in volume from the previous year was due in part to a 2-week strike in Gabon by COMILOG workers in February 1981.

Five oilfields produced roughly 30 million barrels of oil during 1981. The three major producing areas were all marine fields including Loango, Emerande, and Lekouala. New reserve figures for the Lekouala and Emerande Fields were estimated at 2.2 billion and 3.7 billion barrels of oil, respectively. Other oilfields included the nearly depleted Pointe-Indienne Field, the Yanga Field which commenced production in 1981, and the newly discovered Mengo Field.

Approximately 13 million cubic feet of natural gas was produced in 1981, all of which was flared or consumed directly at the oil installations. Degassing units were added to the Lekouala Oilfield terminal late in 1981. Total potential natural gas resources were estimated at 1.7 trillion cubic feet. The Congo Government entered into a protocol agreement with Elf Congo, a subsidiary of Elf Aquitaine, France, and Azienda Generali Italiani Petroli S.p.A. (AGIP), Italy, to organize and promote natural gas exploration and development.

Natural gas was discovered 15 kilometers offshore in the Pointe-Noire deepwater section. Two test wells at Litchendjili Marine No. 2 struck gas at a depth of 2,300 meters that had a flow rate of 8.8 million cubic feet per day. The exploration permit was held by Elf Congo (65%) and AGIP (35%).

Elf Congo and AGIP have overlapping interests in both the permit areas and producing fields. Hydro-Congo, the state hydrocarbon agency, held a 20% share in each of the companies in return for granting exploration permits. Increasing levels of Government participation were indexed to production levels by means of free transfers of shares. In addition, the Congo Government joined as a minority participant in a 20% to 80% partnership with AGIP to form a research consortium called AGIP Recherches Congo (ARC). In the producing fields of Lekouala, Emerande, Pointe-Indienne, Mengo, and Yanga, Elf-Congo and AGIP were joint partners, holding respective shares of 65% to 35%. The ownership split between Elf Congo and AGIP was reversed in the Loango Field.

ARC signed an exploration agreement to prospect for oil in the southwest part of the Congo. Braspetro of Brazil signed an agreement in August 1981 with Hydro-Congo to explore for offshore liquid and gaseous hydrocarbons. A French firm, Bouygues Offshore Co., recently discovered marketable quantities of oil offshore in the Mengo Field within the Loeme permit area. The French company incorporated a company in Congo, called BOS-Congo, which was expected to install drilling platforms in Mengo during 1981. U.S. oil firms participated as minority shareholders in joint-venture exploration with Hydro-Congo and AGIP.

Large investments by Elf Congo and AGIP continued to drive exploration and production targets higher. Elf Congo invested approximately $350 million and AGIP invested $150 million during 1980-81. Congo's annual oil production targets were set at 35 million barrels for 1982 and 52 million barrels for 1984.

EQUATORIAL GUINEA

Economic stagnation continued throughout 1981 owing largely to the drastic declines in production and export of basic raw materials. Combined timber and cocoa exports dropped from approximately 40,000 tons in 1968 to 8,000 tons in 1981. The poor economic condition was boosted by assistance from the International Monetary Fund and Spanish bilateral aid programs. Plans were underway for a United Nations-sponsored International Donors Conference in April 1982. Since the 1979 coup, the new military government has encouraged Western nations to return. Promulgation and implementation of a new constitution providing for free elections was expected during 1983.

Activities in the mineral industry focused on exploration and establishing the groundwork for future exploitation. The French Government conducted 3 months of mineral research in the area of Rio Muni. Initial exploration results indicated that the majority of minerals collected were radioactive.

A new mining law, Decree No. 9, was passed on June 12, 1981. All mineral deposits whether located onshore or offshore in territorial waters were declared property of the state. Mineral substances were divided into three groups: Quarries, mines, and radioactive and strategic minerals. Foreign participation was limited through the issuance of permits for a maximum area of 150,000 hectares and a maximum time of 25 years. A model contract was attached to the decree for those interested in applying for a mining permit.

A draft petroleum law was written by Petroconsultants Inc., Switzerland, with financing provided by the International Bank for Research and Development. The final version of the law, Decree No. 7, was issued in July 1981. The new law identified areas and parameters for exploration and exploitation. Contract provisions and a seismic survey were expected to become available to bidders at a cost of approximately $350,000. Decree No. 7 was made more liberal than comparable laws in other Central African countries to attract foreign investments. Open auctions for various concessions were expected to commence late in 1982.

Empressa Guineo Española de Petróleos,

the 50:50 joint venture between Spain's Hispanoil and the Equatorial Guinean Government, obtained the Nation's first exploration lease in 1981. The 12,872-square-kilometer area was located north of the Island of Bioko, near the Nigerian and Cameroon marine oilfields. Plans were underway to operate drilling facilities by 1983-84.

Various international oil companies also expressed interest in exploring the promising Rio Del Ray area. The French firm Total-Cie. Française des Petroles, the U.S. firms Mobil Oil Corp. and Gulf Oil Co., and a small unnamed firm were considering applying for concessions.

SAO TOME E PRINCIPE

Since independence in 1979, the two islands of São Tomé e Principe have been preoccupied with establishing Government infrastructure and political stability, and pursuing agricultural development. Little progress was made in any of these areas during 1981. The Nation continued to rely heavily on assistance from the U.S.S.R., Cuba, and the German Democratic Republic, and both Western and Eastern European aid programs. The centrally planned economy countries provided mostly military and technical assistance, while the Western European agencies were involved in agricultural, health, and educational assistance for the islands. No new developments were reported in the oil and gas exploration sector by yearend 1981.

The Mineral Industry of Other East African Countries

By Kevin Connor[1]

CONTENTS

BURUNDI

The mineral industry in Burundi was a minor contributor to the country's gross domestic product (GDP), which was estimated at just $1 billion for 1981.[2] Coffee and tea continued as the Nation's major export commodities. Mineral exports consisted of small tonnages of wolframite, cassiterite, and bastnäsite. Burundi's trade balance of payments situation worsened in 1981, with import payments more than double export revenues. Petroleum imports alone equaled 46% of the export revenue total. By yearend, the only indigenous fossil fuel source to have been found in Burundi was peat, which the Government had been attempting to develop to alleviate some of the petroleum import requirements. In June 1981 the Irish Peat Development Authority, Bord na Mona, signed a 4-year contract with the Burundian Government to supply technical staff for the ongoing peat project work there. Funding for the project was provided by the U.S. Agency for International Development and the Government of Ireland. The new contract, which was an extension of ongoing peat research there, represented Burundi's increased awareness of the value of its large peat reserves for both energy and agricultural uses.

At yearend, Burundi's Ministry of Public Works and Mines was close to selecting a contractor to study the feasibility of developing Burundi's phosphate deposits. The study would determine the potential for establishing fertilizer production facilities based on the country's phosphate reserves at Matongo-Bandaga. The study's specific objectives are to prove mineral reserve tonnage and grade, draw up mining and processing facility designs, estimate capital and production costs, and conduct a regional market and distribution survey. The cost of the study was estimated at slightly over $1 million, and it should take approximately 16 months to complete. The proposed project will mark the Burundian Government's first step in its plan to exploit on a large scale its natural mineral resources for advancing its agriculture-based economy. Burundi was dependent on imports, which are expensive to transport inland from coastal ports, to supply its domestic requirements for fertilizer. It was planned that part of the fertilizer production from the

proposed facilities would be marketed to neighboring countries like Rwanda and Zaire.

Previous technical studies estimated that the Musongati nickel deposits of central Burundi contained as much as 300 million tons of reserves of this metal. To further clarify this estimate and assess the economic viability of exploiting these deposits, the Burundian Government finalized an agreement in 1981 with the International Development Association (IDA) and Finland to conduct a detailed drilling program of the Musongati deposits. The program was valued at $7.3 million, with $4 million of this funding coming as a World Bank loan. A previous study proposed a project to produce and export some 30,000 tons of ferronickel per year, but in view of the current depressed world demand for nickel, coupled with Burundi's inadequate transportation facilities, infrastructure, and land-locked position, exploitation of these deposits will probably be delayed for some time.

An important find, the rare-earth mineral europium, was discovered in high concentrations near Gakaha, Burundi, 45 kilometers southeast of Bujumbura. Large deposits of bastnäsite and monazite, which contain the 14 rare-earth minerals, are located at the Gakaha site. The discovery was made by a team of exploration scientists from the Federal Republic of Germany, who were in Burundi as part of a 3-year technical assistance project to evaluate the mineral potential of the country. The Gakaha site had been mined in the past for cerium and lanthanite, but had been dormant since suspension of the Belgian mining operation there, following independence in 1962. Besides investigating the Gakaha site with its known rare-earth deposits, the German team is evaluating tin and tungsten deposits in northern Burundi.

[e]Estimated. [p]Preliminary. NA Not available.

[1]Table includes data available through Oct. 11, 1982.

[2]In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (clays, stone, and sand and gravel) presumably are produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[3]Limited quantities of other pegmatite minerals may also be produced, but output is not reported.

[4]Reported figure.

[5]Revised to none.

[6]Data represent sales; actual production is not reported.

DJIBOUTI

The Republic of Djibouti, formerly the French Territory of Afars and Issas, gained its independence in June 1977. As in previous years, the economy of Djibouti in 1981 was based on entrepot trade through the port city of Djibouti, and along the Chemin de Fer Franco-Ethiopian railroad. Customs duties were the major contributor to the 1981 GDP. Although some mineral deposits have been identified in Djibouti, exploitation had been limited to some small sand and gravel pits for domestic construction. Based on a 1980 Iraqi loan of $25 million, engineering phase I studies were completed in 1981 on the construction of a cement plant at Mount Arrey, close to substantial limestone deposits. With both financial and technical assistance from France, geothermal wells were drilled in the Lake Assal area and were under extensive testing during 1981. No appreciable fossil fuel deposits have been found in Djibouti to date, and all petroleum product requirements were imported. Negotiations were underway in late 1981 for an estimated $25 million loan from the Saudi Fund for Development, to be used for financing highway construction projects.

ETHIOPIA

The total mineral production of Ethiopia in 1981 was estimated at a value of $44 million,[3] equal to aproximately 1% of the reported GDP of $4.25 billion. Cement production alone accounted for 50% of the mineral value, salt production for 25%, and gold for 11%. Throughout 1981, Ethiopia's balance of trade problems continued to worsen, with import costs for the country almost twice the total value of exports. In particular, petroleum import costs, which were $320 million in 1980 and represented 37% of the total value of exports, increased to $350 million in 1981, equivalent to 46% of export revenues.

Bilateral aid programs continued with various foreign governments during the year. Most notably a new multiyear agreement with Libya was finalized in August 1981, whereby Libya could contribute up to $2.5 billion in assisting Ethiopia in developing its mineral resources. According to the agreement, $500 million was to be allocated for developing the potash deposits of the Danakil Depression in northern Ethiopia. Based on a feasibility study conducted in the early 1970's, the Danakil Depression has measured high-grade reserves of 60 million tons of potash with indicated reserves estimated at 150 million tons. The tentative project was scheduled to begin in 1983, with mine production of 1.5 million tons per year of potash rock starting in 1990.

Ethiopia's gold production in 1981 was almost identical to that of 1980, which was slightly over 11,900 troy ounces. Recent installation of new hydraulic washing equipment at the Adola Goldfield should substantially increase production in 1982. Apart from gold and platinum, no other metallic mineral production was reported for the year. The copper deposit at Debarwa near Asmara, previously estimated as having 600,000 tons of high-grade ore with significant quantities of gold, silver, and zinc, remained unexploited. As part of the resource development plans of the recent Libya agreement, an updated feasibility study of this deposit was to be conducted. In Ethiopia's Sidamo region, the Canadian Javelin Co. had substantial mining concessions and concentrated in 1981 on exploration activities on proving out the nickeliferous laterite deposits in the region.

No new petroleum oil or gas finds were reported in Ethiopia in 1981. With assistance from the Soviet Union, plans were well underway in late 1981 for three exploratory well holes to be drilled in the Shilabo area in 1982. The value of the project was estimated at $21 million. Negotiations were also underway with Chevron International Oil Co., regarding Chevron's recent proposal to conduct exploration activities in western Ilubador and northern Gondor near the Sudanese border. The proposed project would begin with extensive aeromagnetic and seismic surveys, and it was estimated that no drilling would occur within the first 2 years.

LESOTHO

Lesotho, which gained its independence in 1966, is a small landlocked country surrounded by the Republic of South Africa. Lesotho's mining industry was limited in 1981 to the exploitation of diamond-bearing kimberlite pipes high in the Maluti Mountains. The industry was centered around the Letseng-la-terai operation managed by the De Beers Lesotho Mining Co., 25% of which was owned by the Lesotho Government and the remainder by De Beers Consolidated Mines Ltd. of South Africa. During 1981 the tonnage of kimberlite material mined and milled at the operation was approximately 1.9 million tons, down slightly from the 1980 figure. The recovery grade, which was already considered marginal in previous years, fell to 2.8 carats per 100 tons during 1981, for a yearly total of 52,921 carats. Production of diamonds larger than 10 carats represented 12% of the total production, compared with 13% in 1980. Because of extremely poor market conditions for diamonds in 1981 and projected for 1982, De Beers Consolidated announced late in 1981 its intention to shut down the Letseng mining operation in 1982.

Other kimberlite pipes near the Letseng operation were exploited on a smaller scale by manual labor during 1981. At two of these operations, the Liqhobong and Lemphane pits, the mine personnel were organized into cooperatives. Earnings from the diamond sales were split among the miners on a monthly basis. Early in 1981 the Lesotho Government received an approximately $500,000 foreign aid grant from the Canadian Government for purchasing additional equipment to improve and expand these two operations and others like them, in order to increase the country's diamond production. The funds will not be used to purchase industrial-type mining equipment, but will be used to continue with what are basically pick and shovel mining operations.

Outside the diamond industry, very little mineral exploitation takes place in Lesotho. The few other mineral developments are for domestic building materials and comprised small clay, sand and gravel, and stone operations. As of the end of 1981, the outlook for any other minerals exploited in Lesotho seemed poor. Coal has been found in low-grade and thin-seam conditions and uranium in trace amounts. None of the occurrences meet commercial size or grade conditions.

MALAWI

The Malawi Government enacted a new Mines and Minerals Act in March 1981 which the Government hoped will stimulate foreign interest in mineral exploration and development in the country. The only major mineral production activity for the year was the quarrying of marble and the manufacture of cement by the Portland Cement Co. Malawi Ltd. at its Changalume quarry and cement plant. The 1981 production levels of 116,000 tons of marble and 78,000 tons of cement were approximately 15% lower than 1980's reported figures. Under the new act a mining license is valid for 25 years and carries a right of renewal for 15 years under certain specified conditions. The Government recognized that major prospecting and mining ventures would involve large capital investments and provided, in the act, that at the time of granting an exclusive prospecting license, the parties involved could enter into a mining agreement. With the enactment of the new mineral legislation, the restriction on exploration for uranium in Malawi by private companies was suspended.

Malawi's migrant work force employed in Republic of South Africa mines is expected to drop to approximately 10,000 people in 1982. This figure is one-half the number of Malawians employed in that industry during 1980, and is only a fraction of the 176,000 Malawians that worked for the South African mining industry in 1974. Once a 25% portion of the mining labor force in South Africa, Malawian migrant mine workers represented less than 2% of that industry's work force in 1981 and contributed only slightly over 1% to Malawi's GDP for the year. The major reason given for the decline was that the higher unemployment rates in South Africa were leading more South Africans to apply for mining-related jobs, leaving fewer vacancies for migrants.

A 1981 Duke University geophysical study confirmed the presence of somewhat favorable conditions for the formation of oil

or gas deposits below Lake Malawi. The study findings have created an air of cautious optimism within the Malawi Government for the future prospects for indigenous energy developments in Malawi. The Shell Oil Co. of the United States has planned followup aeromagnetic surveys of the Lake Malawi area starting sometime in 1982. Core drilling in the Kapembe Hills, Ngama Coalfield, was completed in 1981, and indicated reserves are estimated at 9 million tons of coal. British Gypsum Ltd. of Great Britain registered a subsidiary company in Malawi during the year to begin mining vermiculite at Kaphirikamodzi, about 30 kilometers west-northwest of Blantyre. The plant was completed in 1981, but production rates will be well below capacity until transportation route problems for moving the vermiculite to the coast are solved.

MAURITIUS

The island of Mauritius gained its independence from Great Britain in 1968. The island's economy, which supports a population of approximately 1 million people, was dominated by the agricultural sector in 1981 as sugar production contributed over one-half of annual foreign exchange earnings. Tourism was also a major factor in the economy, and the manufacturing industry continued to grow rapidly throughout the year. Mining and mineral processing operations were all small and were limited to the production of lime and basalt stone during 1981, all of which is used for domestic purposes. In the past decade, Mauritius has become the world's third largest exporter of certain types of knitwear. Knitwear valued at $51 million was shipped to European markets in 1981. Exports of other types of manufactured goods were also rap-

idly increasing. The continued growth of the manufacturing sector was considered vital as unemployment continued to be a growing problem in Mauritius, having reached 20% by the end of 1981. The island remained dependent on imports for petroleum fuel and products, iron and steel products, cement, and a significant volume of food.

REPUBLIC OF COMOROS

The Republic of Comoros, an archipelago between Madagascar and the Mozambique coast of Africa, had negligible mineral production in 1981. Small sand and gravel operations were maintained for local construction purposes, but as of yearend 1981, no significant exploitable mineral deposits had been discovered on any of the islands. Financed by the Islamic Development Bank and the French Government, plans were being finalized in 1981 for a major expansion project for the Port of Mutsamudu on Anjouan Island. The port's jetty was to be extended to 250 meters, and the port bay was to be deepened to handle ship drafts of 9 meters, expanding the port's capability to accommodate heavy-tonnage oceangoing vessels. Under another aid agreement signed with the French Government early in 1981, funds had been allocated to improve and expand the runways of the Moroni-Hahaia International Airport on Grande Comore Island. The Republic of Comoros, like many of the developing nations of Africa, had a serious balance of trade problem in 1981, owing in large part to the high costs of petroleum imports and devaluation of the local currency against other currencies.

REUNION

Located approximately 640 kilometers east of Madagascar, Reunion is a small island of one-half million inhabitants which has been ruled as a French Overseas Department since 1946. Agriculture was the basis of Reunion's economy in 1981, with sugar production as the main activity. Tourism was also an important foreign exchange earner. Outside of sand and gravel operations for local construction, the only mineral-related activity on the island was a 200,000-ton-per-year cement clinker grinding plant at Saint Denis. Planning continued in 1981 for the construction of a new harbor and port in the Bay of Possession. If initiated, this will be the largest construction project in the island's history, with an estimated cost of $110 million.[4] Construction was planned to begin in the latter half of 1982.

RWANDA

Mineral production in 1981 accounted for approximately 1% of Rwanda's estimated $1.25 billion GDP.[5] Mineral exports remained Rwanda's third biggest foreign exchange earner, behind coffee and tea. Overall mineral production and exports declined in 1981 with the exception of gold, for which production and exportation increased 25%. Other minerals mined were cassiterite, wolframite, columbite-tantalite, and beryl.

Transportation services and infrastructure were improved during 1981 as part of a major Government construction and expansion program. Surface paving work was well underway by yearend on the roads from the capital city of Kigali south to Butare and north to Ruhengeri and on the Ruhengeri-to-Cyanika road linking Rwanda and Uganda. The total cost of the roadwork on the Kigali-Ruhengeri-Cyanika span was estimated at $40 million. As of yearend 1981, there were approximately 1,000 Belgian nationals working within Rwanda, with 20% of them involved in the mining sector.

The national tin mining company, Société Minière du Rwanda (Somirwa), reported completing construction on its 3,000-ton-per-day tin smelter complex at Kururuma during the year. Somirwa is managed and 51% owned by the Compagnie Géologique et Minière des Ingenieurs et Industriels Belges of Belgium, and 49% owned by the Rwandan Government.

As of the end of 1981 there were no facilities in Rwanda for the production or processing of petroleum or natural gas. The country imports all of its limited requirements for petroleum products in their refined form. There was no prospect in the near future that Rwanda's situation will change with respect to production of oil and natural gas, although large reserves of natural gas have reportedly been found in the vicinity of Lake Kivu. An agreement between the Governments of Rwanda, Zaire, and Burundi was reached in 1981 regarding a cooperative effort to further evaluate the development potential of these gas resources. Rwanda was involved in a preliminary feasibility study in 1981 aimed at developing large peat resources for domestic heating needs. Also in the energy sector, an agreement was reached in principle between the Governments of Rwanda, Zaire, and Burundi for constructing a 140-megawatt hydroelectric dam on the Ruzizi River. Project financing had been promised by the European Development Bank, the African Development Bank, and the Organization of Petroleum Exporting Countries.

SEYCHELLES

The Seychelles, a group of 92 coral islands 1,600 kilometers off the coast of Kenya, is a former British colony which achieved independence in 1976. The only mineral commodity to be exploited on the island in 1981 was guano. The guano is high in phosphorus and is used domestically as a fertilizer. The mineral industry contributed considerably less than 1% to the GDP, which was estimated for 1981 at $120 million.[6] The Nation's balance of payments deficit almost doubled during the year, increasing from $10.2 million in 1980 to $19.4 million in 1981. The sharp increase was attributed to a major slump in the tourist industry, the country's major foreign exchange earner, and a revaluation of the local currency by 15%. Foreign aid grants and loans amounted to $13.9 million in 1981.

After expending $35 million on three dry offshore drill holes, the AMOCO Seychelles Petroleum Co. ceased searching for oil in the Seychelles in June 1981. The exploration drilling was conducted offshore of Mahe, the Seychelles' largest island. During December 1981, U.S. AMOCO and the Seychelles Government entered into negotiations for a new oil exploration agreement, to resume active exploration operations in the Seychelles waters. In the past 2 years, AMOCO has been the only petroleum company involved in active oil exploration in Seychelles, which is forced to import all of its petroleum needs.

SOMALIA

The mineral industry sector continued to be an extremely small contributor to the Somalian economy during 1981. The GDP was $425 million for the year.[7] Mineral production in the Somali Democratic Republic was confined to small-scale mining of cassiterite tin deposits, sea salt, stone, limestone, and meerschaum. Increasing mineral development within the country was given a high priority by the Government in 1981, and a $1.5 million contract was awarded to a Brazilian state firm, Companhia de Pesquisa de Recursos Minerais, to survey the country's mineral resources.

To supply the increasing domestic market for cement and avoid increased cement imports, the Somalian Government in 1976 contracted with the Korean Government for the construction of a cement plant at Berbera in northwest Somalia. During construction of this plant, major design and contractual changes were made. The Koreans designed the plant to use a wet process with an output of 100,000 tons per year of cement. Construction of the plant was transferred to French contractors, and the plant was redesigned to use a dry process with a capacity of 300,000 tons per year of cement. Construction of the plant was scheduled for completion by the end of 1982. Near the city of Bardera in southern Somalia, a feasibility study was completed in 1981 which proposed construction of a second cement plant within the country. The additional cement capacity is needed for the construction of the $630 million hydroelectric dam on the nearby Juba Valley River. Construction activities for both of these projects were scheduled to begin in the latter half of 1982.

At the end of 1981, there were six U.S. oil companies either actively exploring for petroleum in Somalia or planning to get exploration programs underway. Oil explo-

ration efforts to date had not resulted in any positive finds. Having no known fossil fuel resources, Somalia has been heavily dependent on imported oil, with fuel imports in 1980 costing over $76 million. Late in 1981 negotiations were underway between the Governments of Somalia and Saudi Arabia for extending Somalia a grant of crude oil for the country's 1982 consumptive needs. Owing to a lack of foreign exchange capital, Somalia has had problems securing crude petroleum for its only oil refinery, Iraqsoma, located at Mogadishu. The refinery was shut down late in 1980 owing to a lack of crude oil feedstock and was dormant throughout 1981. If restarted and operated near capacity, the refinery could produce a considerable amount of fuel oil for exportation, as only 60% of the refinery's production would be needed for domestic purposes. The fuel exports could result in an estimated $25 million in revenues, which would help alleviate the country's critical shortage of foreign exchange.

International trade and trading partners did not change appreciably for Somalia in 1981. Livestock exports remained the country's greatest foreign exchange earner, comprising over 90% of the export revenues reported in 1981. The livestock exports were valued at $181 million, which was approximately 43% of the country's GDP. There was a positive change in 1981 regarding Somalia's balance of payments problems. In July 1981 Somalia officially established a two-tier exchange rate system whereby imports in categories considered nonessential were inflated 100% exchange-rate-wise to discourage their entry and purchase. Total imports for 1981 were only 87.5% of total exports, which is a considerable improvement over the 1980 figure of 170%.

SWAZILAND

Since the cessation of active iron ore mining in Swaziland during 1977, the mining sector's importance in the economy has declined. The mining sector has averaged an annual 2.2% negative growth rate since the beginning of fiscal year 1978 although it did experience a 2% positive growth in 1981 owing to expansions in coal and asbestos output. The value of mineral production in Swaziland for 1981 was approximately $23 million, which was almost 5% of the country's GDP.

In general the Swaziland economy experienced an exceptionally good year in 1981, having grown by an estimated 6.5% in real terms. The growth was due mainly to increased agricultural production, combined with increased exports of woodpulp, chemicals, and electronic equipment. Swaziland's economy was also well diversified in 1981, manufacturing contributing 25% to the country's GDP, agriculture and forestry 23%, the public sector 13%, and several other areas the remaining 39%.

The number of migrant mine workers from Swaziland working in the Republic of South Africa increased to approximately 10,000 in 1981, which was a 15% increase over 1980's total figure. However, the 1981 figure is still less than 40% of the 26,000 Swazi citizens who were employed in South African mining ventures in 1976. This downward trend is similar throughout the migrant-worker-exporting countries that have supplied laborers to the South African mines through the years. It was assumed that even though the drop in employment of Swazi migrant mine workers to the Republic of South Africa has been somewhat erratic, the decreasing employment trend will continue in the early 1980's owing to the depressed state of the mining sector there and the willingness of more South Africans to work in the mines.

Asbestos remained the main mineral foreign exchange earner in 1981 with reported revenues of almost $19 million. However, the remaining reserves at the Havelock asbestos mine, the sole asbestos mining operation in Swaziland, were almost depleted and the property will probably shut down within the next few years. Coal offered the best potential in the longer term, with reserves estimated at approximately 1 billion tons, of which 200 million tons are considered good-quality steam coal. The major coal mine in Swaziland is the Anglo American Corp. Ltd.'s Mpaka Colliery, which produced 149,000 tons of anthracite coal, or 91% of Swaziland's total production for 1981. About 30% of the coal mined during 1981 was exported to Kenya and Mozambique, with the rest consumed domestically. There is considerable expansion potential for Swaziland's export coal market. However, there are currently serious capacity problems in transporting the coal, particularly with the rail line to Mozambique's port of Maputo and the operation of the port itself. In 1981 the Swaziland Railroad Co. announced plans to build a new rail link from the Mpaka Colliery to the existing South African rail line at Komatipoort, which would take the coal to Richards Bay Port on South Africa's east coast.

UGANDA

In June 1981, the Government of Uganda took strong measures in an attempt to revitalize its economy. Actions included floating the Uganda shilling against other currencies, raising prices of agricultural crops such as coffee and cotton, and lifting restrictive price controls. The net result of these measures by yearend was some regained confidence within the international community for Uganda's ability to correct the ills of its economy, and the first signs of progress towards its economic recovery. In the mining sector the most important development during 1981 was the Government's establishment of a task force for evaluating proposals for a National Mining Corp. (Namico). Once formed, Namico was to take charge of all mining activities in the country. A bill to approve the proposed corporation was drawn up in 1981 for presentation to the 1982 session of the Ugandan Parliament.

The European Investment Bank (EIB) entered into an agreement with Kilembe Mines Ltd. in August 1981 to finance a feasibility study which will examine the prospects of rehabilitating the Kilembe copper-cobalt mine, mill, and smelter. Only a skeleton force of miners was employed during 1981, and only a minor amount of

ore was produced. Both ore and copper-cobalt concentrates were stockpiled, as the milling equipment was barely operable and the smelter required a complete rebuilding of the electric furnace before it could be expected to operate. The contract for the feasibility study was to be awarded by the spring of 1982, and once underway, the study was estimated to take 1 year to complete. A stipulation of the EIB agreement required that the study contractor must be from a European Economic Community country.

Considerable progress was reported in 1981 towards the rehabilitation of two Ugandan cement manufacturing facilities. The Federal Republic of Germany agreed in 1981 to assist with the reconstruction of the Hima cement plant. It was estimated that the plant would produce cement at near its capacity of 600 tons per day by late 1982. Part of the reconstruction work was completed by the end of 1981. The Tororo cement plant, situated on Uganda's eastern border with Kenya, produced an average of 1,000 tons per month of cement after completion of some reconstruction work in 1980 and early 1981. An agreement was signed during 1981 with the Turkish Cement Corp. to continue with rebuilding and expansion work on the plant. The rated capacity of the finished plant is 550 tons per day of cement.

The asbestos cement plant, which is part of the Tororo cement complex, produced asbestos sheets and accessories, along with pipes and pipe accessories, at about 40% of the plant's rated capacity during 1981. Production was curtailed because of a shortage of raw materials, which had to be imported into the country. Limestone, which is used in cement production, occurs in large reserves nearby the Hima and Tororo plant sites. The newest development in the cement industry during 1981 was the initiation of the Bududa cement project in Mbale district in eastern Uganda. An agreement covering the project was signed between the Ugandan Government and the Turkish Cement Corp. during the last half of 1981.

Negotiations were in the final stages at the end of 1981 for World Bank financing of a feasibility study for rehabilitating Uganda's phosphate industry. The study will examine the viability of establishing a phosphate plant and a sulfuric acid plant based on the phosphate deposits in the Sukulu Hills, 200 kilometers east of Kampala. The deposits are of high grade and close to the surface, with reserves estimated at about 200 million tons. The study is expected to take approximately 30 months to complete. The phosphate fertilizer plant at Tororo remained inoperative throughout 1981. In other mineral areas, the Bjordal Mine facilities in the Kigezi area, operating at partial capacity during 1981, produced some wolfram concentrates. However, no tungsten production figures were reported for the year. The majority of small mine operations, located mainly in western Uganda, remained shut down in 1981 owing to a lack of supplies and laborers. In past years these mines have produced gold, tungsten, tin, and beryl. The reactivation of the small mines will probably depend on the establishment and effectiveness of Namico, which would be in a much better position to mobilize the funds necessary for acquiring the supplies.

The Mineral Industry of Other West African Countries

By George A. Morgan[1]

CONTENTS

BENIN

Output of minerals was insignificant in 1981 and made a negligible contribution to the gross national product (GNP), estimated at $1.2 billion.[2] Agriculture accounted for 40% of GNP and manufacturing accounted for 10%. The chief source of income was indirect taxes levied on traffic through the Port of Cotonou, an entrepôt.

Trade statistics for Benin were incomplete and dated. Major trading partners were France and other members of the European Communities. Benin was a member of the West African Monetary Union and as such must coordinate its foreign currency, reserves, interest rate structure, and fund transfer with other member countries. Its currency, the Communauté Financière Africaine franc (CFAF), was fixed to the French franc.

Wage controls remained in effect. Private-sector minimum wages had been frozen since 1974 but were raised 15% in 1980. Public sector wages have been frozen since 1966 and were due to increase about 10% to 15%.

COMMODITY REVIEW

Cement.—Two cement plants were in operation using imported clinker. The plant of Société des Ciments du Benin (SCB) has been in operation since 1970. SCB was 80% Government controlled; the remainder was controlled by private French interests. Capacity was 240,000 tons per year, and production was about 150,000 tons in 1981.

The Société Nationale des Ciments (SONACI) was 100% Government owned. Production began in 1979 with output of 107,000 tons compared with a capacity of 200,000 tons. The company continued to experience difficulty in 1981. Output by both SCB and SONACI was distributed by the quasi-public Société Beninoise des Materiaux de Construction and the Société Provinciale de Commercialisation des Produits Manufactures.

A $125 million joint Nigerian-Benin cement project continued in the Pobe region. A clinker plant was under construction and was to utilize local limestone. Planned ca-

pacity was 500,000 tons per year.

Electric Power.—About 92% of all electric power consumed was imported through Togo from the Akasambo-Volta River hydroelectric complex in Ghana. Communauté Electrique du Benin, a joint Togolese-Benin company, provided for the transmission. Agreements permitted Benin to draw up to 25 megawatts per year for a period of 25 years.

Benin had a total generating capacity of 19.5 megawatts, consisting of two 8-megawatt diesel generators at Cotonou, a diesel generator of about 3-megawatt capacity at Parakou, and a 0.5-megawatt generator at Bohicon-Abomey.

Petroleum.—Oil was discovered in the Seme Oilfield in 1968 about 15 to 20 kilometers offshore in 30 to 50 meters of water. Exploitation of the field was being financed by a guarantee from the Norweigan Guarantee Institute for Export Credits. The guarantee required that most equipment and services be purchased in Norway.

Two storage tanks with 40,000-cubic-meter capacity each were being constructed. They will be filled with oil via a 14-kilometer, 6-inch crude oil pipeline. A 3-kilometer, 20-inch pipeline will be used for a tanker boarding facility offshore. Output of 15,000 barrels per day was planned.

Other Minerals.—Phosphate resources amounting to 4.5 million tons were located at Mekrou. No exploitation was underway. Gold, chromite, and iron mineralization have also been found in Benin.

[e]Estimated. [p]Preliminary. NA Not available.

[1]Includes data available through Oct. 12, 1982.

[2]In addition to the countries listed, The Gambia, Guinea-Bissau, and Upper Volta, which are covered in the text of this chapter, presumably produce modest quantities of a variety of crude construction materials (clays, stone, and sand and gravel) and may produce minor amounts of other mineral commodities (most notably gypsum, lime, and salt), but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[3]In addition to the commodities listed, modest quantities of unlisted varieties of crude construction materials (clays, stone, and sand and gravel) presumably are produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.

[4]Output apparently based entirely on imported clinker.

[5]Revised to zero.

[6]Products marketed under the trade names "Balifos," "Phospal," and (in 1980 only) "P 125" (the latter described as crushed aluminum phosphate).

CAPE VERDE ISLANDS

Output of mineral-related commodities in 1981 was confined to salt and construction materials. The Banque Africaine de Développment (BAD) provided $37.2 million[1] in aid for six projects involving infrastructure development. BAD was also interested in construction of a cement plant on the island of Maio. Limestone and pozzolana available locally would supply the plant.

THE GAMBIA

No mineral production of significance occurred in The Gambia in 1981. Known deposits of ilmenite, rutile, and zircon in beach sands were not mentioned for exploitation. Agriculture accounted for most of the estimated $200 million[4] GNP.

There was no oil and gas exploration activity. Chevron Overseas Petroleum Co. (United States) and Compagnie Française des Pétroles S.A. (Total) continued to hold their concessions. Their Jemmah 1 well was plugged as dry in 1979.

GUINEA

The mining sector accounted for 20% of a GNP of $1.5 billion[5] in 1981, and about 95% of export earnings. Bauxite was the principal mineral produced. Several large-scale mining projects were either proposed for study or progressed further in their realization.

Foreign exchange for the purchase of food and gasoline and for financing state-controlled industries and agricultural projects was provided by the export of mineral-related products. Foreign debt was over $1.5 billion. Approximately 50% of foreign debt was from bilateral clearing accounts with other centrally planned economies. The remainder was mainly short- and medium-term debt. The Government derived its revenue through taxes on mineral exports and gross profits. In addition, it received a share in the net profit as a joint venture partner in both Compagnie des Bauxites de Guinée (CBG) and the Société d'Économie Mixte Friguia. CBG alone provided about 75% to 80% of foreign exchange earnings.[6]

The Government attempted to reduce inefficiences in various sectors through several measures. In October, it eliminated state-holding companies and provided for separate earnings and loss statements for each company. Formerly, such reports from all companies were combined. It also created the Ministry of Small and Medium Sized Enterprises for local private enterprises, particularly those involved in diamond extraction. Credit to the private sector was increased for the first time in several years. However, the state continued to set both producer and retail prices in all sectors. It also planned to make the syli fully convertible. Currently a parallel exchange rate exists for the syli.

COMMODITY REVIEW

Bauxite and Alumina.—CBG exported about 9.3 million tons of ore in 1981 plus 113,000 tons of calcined bauxite for use in abrasives. A feasibility study was underway for increasing calcined bauxite capacity from 120,000 to 240,000 tons per year.

Exports of alumina by the Société d' Économie Mixte Friguia were about 700,000 tons. Capacity for alumina production may be increased to 1.3 million from 700,000 tons per year. Participation by foreign investors was critical to the plan.

About 90% of production by the Office des Bauxite de Kindia was exported to the U.S.S.R. under long-term agreement. The remainder was shipped to Eastern Europe to settle arrears on bilateral clearing accounts. The Soviet financed and operated company suffered power supply interruptions and materials shortages, which resulted in the loss of 3 months' output in 1981.

Diamond.—Output of diamonds was by individually licensed artisanal miners. The miners were permitted to lease small plots and to employ up to 50 workers. Output was turned over to the Central Bank for marketing through the Guinea Diamond Exchange.

The Association pour la Récherche et l'Exploitation du Diamont et de l' Or (AREDOR) was established for exploiting diamond-bearing alluvial gravels in the Kissendongou region near Sierra Leone. Participation in the company was by the Government of Guinea, 50%; Bridge Oil Ltd., 45%; Simonius Vischer, 2.5%; and Industrial Diamond Co., 2.5%. Construction of the main plant for treating 400,000 cubic meters per year by 1983 was begun. Capital requirements were $59 million. The current agreement permits Bridge Oil to purchase 70% of production and the Government 30%. If the Government does not exercise its right, the remaining partners can purchase the Government's share of output.

Iron Ore.—Agreement was reached between the Government of Guinea and United States Steel Corp. in which United States Steel would be responsible for management, operations, and engineering of the Miferguí-Nimba iron ore project near the border with Liberia.

A Kaiser Engineers and Constructors Co.

feasibility study of the project envisioned 15 million tons per year of output of natural sinter feed containing 66.5% iron. Cutoff grade from an opencast operation was to be 60% iron. A below-ground crusher would yield a minus 200-millimeter product. Secondary crushing at the surface would produce a minus 35-millimeter product. A 6.5-kilometer-long conveyor would transport crushed ore to a storage and tertiary crushing facility for final product reduction to minus 6 millimeters. Transport was to be through Liberia via a 265-kilometer-long railroad. The loading quay and ore-handling facilities at Buchanan in Liberia were being enlarged to handle the additional tonnage. An 8,000-ton-per-hour shiploader was included in the port expansion.

Cost of the project was estimated at $990 million. Canada and the International Bank for Reconstruction and Development (World Bank) were each contributing $250 million. Potential ore purchasers included Nigeria, 5 million tons; Algeria, 1.75 million tons; and Libya, 2.5 million tons.

Petroleum.—Bridge Oil reached agreement with Guinea to explore for oil and gas onshore and offshore commencing in 1983 for 3 years. The company was to invest $15 million annually, according to the terms of the agreement.

Uranium.—Exploration by the Compagnie Générale des Matières Nucléaires (COGEMA), a subsidiary of the French Bureau de Récherches Géologiques et Minières (BRGM), on sediments in the northern part of the country was completed in 1981. No commercially interesting deposits were found. Crystalline rock in the same area was to be studied by a group composed of Davy McKee Corp., Soarberg Interplan, and the Nigerian and Moroccan Governments.

GUINEA-BISSAU

Excluding some clay, stone, and gravel, there was no mineral production in Guinea-Bissau in 1981. The country had a GNP estimated at $180 million.[7] Seafood was the main export item while foodstuffs and fuel were the main import items. Few Government-controlled firms operated at a profit. Companies were asked to review their wage scales, which were considered high in view of the poor productivity. Foreign assistance for research on several minerals was underway. Libya agreed to provide petroleum technicians for training supervisory personnel in Guinea-Bissau's national oil company.

COMMODITY REVIEW

Bauxite.—Soviet assistance was to be provided for a technical-economic study of bauxite at Boe. The program was to commence in early 1982.

Petroleum.—The Government completed an assessment of possible offshore drilling zones. The decision to proceed with a request for exploration bids was based on data from research conducted between 1958 and 1973 and on a recent seismic study. The study was financed by a World Bank loan of $6.8 million. A petroleum law and tax law was to be in effect by April 1982.

Phosphate Rock.—BRGM confirmed a phosphate find in northern Guinea-Bissau and reported that it warranted further exploration. The Fonds d'Aide de Cooperation of France financed BRGM's research.

IVORY COAST

There was no nonfuel mineral production of significance in the Ivory Coast in 1981. However, a number of exploration and research programs were in progress, and several projects for exploitation of gold and diamond were likely. Oil production, which commenced in August 1980, increased, and additional oil production facilities were being built.

The overall economy continued to be depressed because of low agricultural prices and exports, increased debt, and inefficiencies in public sector companies. Both imports and exports declined. Gross domestic product (GDP) was estimated at $9.8 billion.[8] The debt service ratio continued to increase and reached 34.2% in 1981. An International Monetary Fund loan of $560 million was granted to the Ivory Coast in return for an economic readjustment program.

The Government initiated measures to either sell or abolish parastatal corporations. Other state companies were operated by private concerns on Government contract. There were no restrictions of capital

and profits of foreign companies. The investment code was liberal, and incentives of tax privileges and customs exemptions could be negotiated on a case-by-case basis.

COMMODITY REVIEW

The Société pour le Developpement Minière de la Côte d'Ivoire (SODEMI) explored for metallic sulfides, gold, and uranium in the regions of Toulepleu and Aboisso. Anomalies detected by airborne electromagnetic survey were selected for drilling. Prospecting in the vicinity of Seguela located gold and tungsten mineralization. Copper and molybdenum anomalies found by geochemical surveys in the region of Guehielbi were reported to be from disseminated sulfides, mainly pyrrhotite, with subordinate chalcopyrite and pyrite.

The Uranium Department, formerly in the Société Nationale d'Operation Petroliére de la Côte d'Ivoire, was transferred to SODEMI. The department conducted uranium prospecting in the Bouake and Boundiole regions, but with negligible results. Thorium and uranium were found in the region of Odienne. The uranium was in association with granite.

BRGM had three exploration permits. Exploration was for massive sulfides of copper, lead, zinc, and silver, as well as gold and uranium in the Birimmian volcanosedimentary basins.

Diamond.—The Compagnie des Mines et des Materiaux (COMIMAT S.A.) discovered a diamond deposit in the region of Tortiya. COMIMAT S.A. was issued a permit for exploration and was expected to commence development during 1982.

Gold.—The cost of development of a gold deposit at Ity was under study. A consortium was to exploit the deposit, commencing in 1985. The Compagnie Minière de Côte d'Ivoire (COMICI) obtained three permits to explore for gold. COMICI's primary interest was quartz veins and elluvial and alluvial material, particularly in Nero.

Petroleum.—Production from the small Belier Field commenced in August 1980 from a single offshore platform. Current capacity was not expected to exceed 15,000 barrels per day. However, the possibility of reinjection of associated natural gas may modify future recovery. Most of the oil went directly to the Ivorian Refining Co. for refining.

The Espoir Field was discovered in April 1980. It was larger than the Belier Field and would have a number of recovery wells. Output was scheduled to commence in 1982.

MALI

Production of stone, gold, and phosphate rock made a small contribution to a GNP of about $1.2 billion[9] in 1981. Exploration was targeted at several minerals, and mine production capacity increases for gold and phosphate rock were underway.

The availability and reliability of timely statistical data for Mali was poor. The latest trade data covered 1978 and indicated a trade deficit of $103 million. France was the principal trading partner followed by the Ivory Coast, Senegal, and the Federal Republic of Germany. Drought and limited water resources resulted in continued high imports of foodstuffs. Imports of oil products were a high-cost item and were transshipped through Senegal and the Ivory Coast. In conjunction with energy requirements, the World Bank allocated a loan of $3.7 million for financing research on bituminous shales in the Taodeni Basin.

COMMODITY REVIEW

Gold.—Technical assistance, which was begun in 1963 by the U.S.S.R. for gold exploration and development, resulted in the reactiviation of the Kalana Mine in the Sikasso region. An agreement signed in October between the Société Nationale de Récherches Minières (Sonarem) and the U.S.S.R. provided for a loan of about $4.35 million, payable in 10 years at 4% interest with a deferral period of 2 years. The U.S.S.R. also was to assist in the construction of a 120-kilometer-long electric transmission line linking Selingue with Kalana.

Reserves at the Kalana Mine were estimated at about 1 million troy ounces located 250 meters deep. Average grade was 0.96 to 1.28 troy ounces of gold per ton. Mine life was 15 years at a production rate of 64,300 troy ounces of gold per year. Initial production would be about 13,000 troy ounces of gold per year with byproduct silver.[10]

The Sindicat Franco-Maliende Récherches Minières, a joint-venture company including Sonarem and BRGM, was involved in gold exploration in the southeast of the country, as well as in the Kangola and Bongouni-Sikasso region.

Petroleum.—A 5-year permit to explore for oil over a 140,000-square-kilometer area in the Taodeni Basin in the north of the country was granted to Esso Oil Co.

The International Development Association (IDA) was to monitor exploration programs for oil and the evaluation of oil shale deposits. In the event exploitable oil deposits were located, IDA would establish a framework for agreement on their development.

Phosphate Rock.—The Federal Republic of Germany granted $1 million to Mali for financing a phosphate rock crushing plant

at mining operations in the Tilemsi Valley, north of Gao. Sonarem was increasing output to 10,000 tons per year and anticipated a possible future production level of 240,000 tons per year.

NIGER

Despite a loss in export earnings in 1981 due to a decline in price for uranium, the country's principal mineral product, a number of new mineral development projects were underway. These projects were expected to diversify and broaden the country's mineral industry base.

The mining sector accounted for about 12% of an estimated GDP of $2.1 billion[11] in 1981. External debt was estimated at $503.3 million. A negative balance of trade of almost $200 million was realized, and inflation was 15% to 70% in the year ending June 1981.

Planning for economic development has been based on anticipated revenue from sales of uranium. Uranium sales accounted for Niger's first 80% of total export earnings and 40% of Government revenue. The 5-year plan covering 1979-83 was released in March 1980 but was rearranged because of the shortfall in revenue, and a 10-year Program for Development of Niger was issued. The program's intent was to emphasize investment in the rural sector and the attainment of self-sufficiency in food production. The role of foreign investors and private enterprise was expanding to meet these goals.

An investment code has been in effect since 1974 and provides tax relief and tariff protection for foreign investors. Government participation in commercial ventures was common but not required by law. The country's currency was fixed against the French franc. Profits after taxes were available for full repatriation.

COMMODITY REVIEW

Cement.—A single cement plant was in operation at Malbaza near the border with Nigeria and had a total capacity of 40,000 tons per year. Limestone was supplied from a local quarry estimated to have reserves of 3.5 million tons. No firm commitment had been made for a new plant with a planned capacity of 200,000 tons per year. Local cement production was reported to supply a small percentage of domestic consumption.

Coal.—The Société Nigérienne du Charbon d'Anou Araren (SONICHAR) was created in 1977 with responsibility for developing a coal deposit at Anou Araren, about 50 kilometers east of Agadès. SONICHAR was 66% Nigerian Government owned with the remainder held by the Islamic Development Bank and domestic uranium mining companies. Production and stockpiling of coal at Anou Araren commenced in 1980. Total recoverable reserves were about 1 million tons of coal out of an estimated 6 million tons of proven reserves. Output was being consumed at a nearby powerplant. Coal production capacity was planned to be about 100 tons per day with full utilization of two turbines at the plant.

Electric Energy.—The country's first coal-fired plant went into operation in 1981. First-stage capacity was 16 megawatts and was fired by coal supplied from the nearby Anou Araren deposit. Electricity produced was consumed mainly by domestic uranium mining companies. An $11 million loan was made by the European Investment Bank for

a period of 16 years at 8% interest to complete the second stage of the powerplant. When completed total electric generating capacity would be 32 megawatts.

Iron Ore.—The United Nations Industrial Development Organization funded a study of iron ore located at Soy. About 650 million tons of oolitic hematite, grading between 48% and 53% iron, and containing about 0.5% to 0.8% phosphorus was at the deposit. Nigeria expressed some interest in the reserve, which would require complete development of a transport network for shipment to Nigeria.

Molybdenum.—Molybdenum output commenced in 1979 as a byproduct of uranium production by Compagnie Minière d'Akouta (COMINAK). The total capacity for production of molybdenum by COMINAK was 400 tons of metal in concentrates.

Phosphate Rock.—Production of phosphate came from hand operators near Takoua. A crushing plant recently installed at Takoua was capable of producing 15 tons per day of fertilizer-grade phosphate but was poorly managed and rarely operated at optimum level.

Phosphate mineralization in the vicinity of Tapoa has been the object of study for the past 10 years. A feasibility study for production from the area neared completion. Reserves were reported at 1.25 billion tons of phosphate, of which 500 million tons was considered economically exploitable. Of three ore horizons in the deposit, the uppermost averaged 22.4% P_2O_5, while the two lower horizons ranged from 27.8% to 34% P_2O_5. Nigeria expressed interest in possible development of the deposit.

Uranium.—The Government maintained its interest in uranium exploration, development, and exploitation in Niger through the Office National des Ressources Minière (ONAREM). Two companies produced uranium in 1981, COMINAK and Société des Mines de l'Aïr (SOMAIR). Participating shareholders in these two companies each had the right to export uranium in proportion to their capital participation. ONAREM had a 31% interest in COMINAK; COGEMA, France, had 34%; Overseas Uranium Resources Development, Japan, had 25%; and Empresa Nacional del Uranio, Spain, had 10%. ONAREM also had a 33% interest in SOMAIR, while COGEMA had 26.96%; Compagnie Française des Minerais de l'Uranium had 11.79%; Minatome had 7.58%; Compagnie Minière de Mokta had 7.56%; Urangesellschaft, Federal Republic of Germany, had 6.58%, and Agip Nucléaire, Italy, had 6.53%.

SOMAIR has produced uranium from the Arlit deposit in the Agadiz Basin since 1971. Uranium, as the minerals coffinite and pitchblende, was located in a 20- to 25-meter-thick horizon of clay and sandstone, grading, 0.25% U_3O_8, with overburden ranging from 35 to 50 meters thick. Production was by acid heap leaching to produce 70% uranium contained in sodium uranite. Mill throughput was about 3,000 tons per day, with a total production capacity of 2,300 tons per year of uranium.

COMINAK commenced production in 1978 from the Akouta deposit, about 20 kilometers from Arlit. Production was from an underground operation 250 meters deep in ore grading 0.4% U_3O_8. Capacity was about 2,200 tons per year of uranium in a 70% uranium-in-magnesium uranate product.

Participation in a third company, the Société Minière de Tassa N'Taghalgue (SMTT) was shared equally by ONAREM, COGEMA, and Kuwait's Foreign Trading, Contracting and Investment Co. SMTT was established in 1978 to develop the Arni deposit near Arlit. Reserves were reported at 20,000 tons of uranium in ore, grading 0.35% U_3O_8. A feasibility study was completed for an opencast operation producing 1,000 tons per year of U_3O_8.

Exports of uranium in 1981 were estimated to be as follows in tons of uranium: France, 2,293; Libya, 1,212; Japan, 816; Spain, 300; the Federal Republic of Germany, 125; and Iraq, 100.

SENEGAL

The mining sector was relatively unchanged in 1981. Mining and manufacturing accounted for about 20% of an estimated GDP of $2 billion[12] in 1981. The economy was in stagnation mainly because of the poor performance of the agricultural sector. Fish products became the largest export earner at 27% of total exports.

COMMODITY REVIEW

Cement.—Plant prices for cement increased 32% to $110 per ton. The new price included a value-added tax and a special tax.

Expansion of capacity by the Société Ouest Africaine des Ciments at Rufisque was planned. Capacity would increase to 875,000 tons per year compared with a current capacity of 360,000 tons per year. Cost of the expansion was estimated at $6.7 million.

Iron.—A feasibility study was underway regarding infrastructure and marketing requirements for development of the iron deposits located in the southeast near Faleme. The Société des Mines de Fer du Senegal Oriental was formed in 1975 to exploit the reserves. An exploration program completed in 1980 proved additional reserves. Primary magnetite ores from Farangalis and Goto may be used for production of acid and basic blast furnace pellets and direct-reduction pellets. Oxidized ores from Kondekouron, Kouroudiako, and Karakaene can be used for direct charging into blast furnaces and for sintering.

Reserves of proved magnetite ore at Farangalis and Goto were 135 million tons each, grading 45% iron. Magnetic separation was shown to yield a 68% iron ore concentrate. High-grade hematite ore reserves at Kondekouron and Kouroudiako were confirmed at 56 million tons and 26 million tons, respectively. An annual output of 12 million tons was recently estimated to be necessary for efficient utilization of rail and port capacity. Initial output would be for hematite for direct shipping and sinter feed.

Peat.—The Compagnie des Tourbieres du Senegal (CTS) was established with an initial capital of $370,000 for exploiting peat resources estimated at 50 million cubic meters. The central region of Niayes between Mboro and Lompoul has about 80% of the total peat resources. Peat was also

located at Casamome, the Sine-Saloum Rivers, and the delta region. Output was to supply two thermal powerplants of 30 megawatts capacity.

Petroleum.—Oil exploration continued in the Longo and Kafountine areas of Cassamance. The refinery at Mbou was to have an increase in capacity from 900,000 to 1,380,000 tons per year. A desulfurization unit was to be installed for utilization of lower cost, high-sulfur crude oil.

Phosphate Rock.—Production and export of phosphate has been mainly in the form of phosphate rock. Long-range plans for product upgrading were finalized with the letting of contracts for construction of sulfuric acid and phosphoric acid plants at Taiba. The sulfuric acid plant was to have a maximum capacity of 2,100 tons per day and the phosphoric acid plant was to have a maximum capacity of 800 tons per day.

A mixed fertilizer plant with a capacity of 680 tons per day of diammonium phosphate and 900 tons per day of granulated triple superphosphate was to be constructed at M'boo. Product markets were to be in West Africa and India. Exports of calcium phosphate in 1981 were mainly to the United Kingdom, France, Greece, and India. Production of aluminum phosphate was mainly for local use, although France received about 51,000 tons in 1981.

TOGO

Phosphate remained the principal mineral material produced in Togo in 1981. Poor market conditions led to a sharp reduction in production.

COMMODITY REVIEW

Cement.—Ciment du Togo's production of cement was mainly marketed locally, but about 15% was exported to neighboring countries. Cement prices, exfactory, increased to $86.42 from $73.32 per ton.[13]

The cement clinker plant at Tabligbo, jointly owned by Ghana, the Ivory Coast, and Togo, produced about 600,000 tons of clinker for cement production.

Marble.—The Société Togolaise de Marbrerie et de Materiaux, partly Government owned, mined marble from two deposits at Gnawoulou and Pagala. Operational and financial difficulties prevented full operational capacity. The company also produced burnt brick, floor brick, and tiles.

Phosphate Rock.—Output was at about 69% of capacity in 1981 because of exceptionally poor sales. Production was intentionally limited to only that quantity that could be marketed. A credit of $5.7 million was approved by the World Bank to finance engineering work on a 1,000-ton-per-day phosphoric acid plant.[14]

Salt.—Production was by the Government-owned Société des Salines du Togo. All output was sold domestically at $128 per ton.

UPPER VOLTA

Excluding production of building materials for local use, output of mineral-related commodities was negligible in 1981. A small antimony mine was operated during the year but closed at yearend because of unprofitability. Output was insignificant.

The GDP was estimated at $1.216 billion in 1981, down from $1.358 billion[15] in 1980. A negative trade balance of $252 million was reported in 1981. Petroleum product imports accounted for $50.3 million out of a total import value of $326 million. Iron and steel imports were valued at $9.1 million.

Lead, Zinc, and Silver.—A massive sulfide deposit, averaging 4% zinc, 0.6% lead, and 2.6 troy ounces of silver per ton, was discovered in the Boromo greenstone belt, about 30 kilometers northwest of Kondougou. Discovery was by a joint United Nations and Bureau Voltaique de la Geologie et des Mines exploration team.

Manganese.—The Mining Society of Kiere was formed at Bobo-Dioulasso with a capital of $300,000 for the purpose of extracting and marketing manganese from Kiere.

The Mineral Industry of the Islands of the Caribbean

By Doris M. Hyde[1]

CONTENTS

To a greater or lesser extent, the economies of the smaller Caribbean Island countries continued to have common problems. These included unemployment, inflation, foreign exchange shortages, trade deficits, and unstable world prices for their exports. Declining prices for petroleum provided some relief from scarce foreign exchange.

Overall, the mineral sector remained stable. The Amerada Hess Corp. crude oil transshipment terminal on St. Lucia was completed during 1981. However, there were no shipments during the year. No official reason was offered for the delay in opening the terminal, but it may have been related to the world surplus of crude oil that occurred in 1981. There has been no further action on the refinery, which was to complete the island's petroleum complex. During the first half of 1981, an announcement was made that a second oil transshipment terminal would be built on St. Lucia. The report indicated that the terminal was to be financed by Saudi Arabia and include underground storage. After the original announcement, no further information was made available. This terminal, like the Hess petroleum complex, may have been temporarily postponed because of the crude oil surplus.

In December 1981, there was a dedication ceremony for the opening of the small 16,000-barrel-per-day crude oil refinery on Antigua. The refinery was to undergo a 2-month breaking-in period, but it was subsequently closed by strike action.

BAHAMAS

The Bahamian gross domestic product (GDP) in 1980 was estimated at $2.1 billion at current prices. The value added by the mineral sector was reported at $222.2 million, or 11% of the total. The mineral sector was not expected to have any increased impact on the GDP in 1981. Recent Government efforts to encourage foreign investment and industrial diversification were not expected to influence the minerals sector because of resource and market limitations.

In 1980, the cost of an estimated 3.6 million barrels of imported crude oil for

local consumption (excluding bunkers) was estimated at $126 million, a 34% increase over the cost in 1979. Petroleum represented 15% of total import costs in 1980 and has been one of the factors contributing to an increasing trade deficit. In 1981, the Bahamas was accepted into the Mexico-Venezuela San Jose oil financing agreement. When final details are resolved, the Bahamas will be eligible to benefit from the low-interest loans amounting to 30% of the crude oil purchase price.

Lone Star Industries, Inc., terminated its bid to acquire a 50% interest in the Bahamas Cement Co. As announced previously, in September the Diamond Crystal Salt Co. ceased operating their salt facility on Long Island.

A 200-mile offshore economic zone was declared by the Bahamas in 1977 to protect mining and fisheries resources. This area could overlap territorial claims of the United States and other countries.

The geophysical survey conducted in the Bahamian offshore area between Andros Island, Cuba, and southern Florida was concluded. A five-member consortium composed of Getty Oil Co., British Petroleum Co. Ltd. (BP), Standard Oil Co. of California, Shell Oil Co., and Arco Oil Producing Inc. has been examining the data obtained from the survey. It was expected that portions of this area might be opened for bidding in the near future.

In late 1981, Bahamas California Oil Co. Ltd. was granted a 1-year permit to conduct geophysical surveys in parts of the Great Bahama Bank area. Natomas Petroleum Bahamas Ltd. has also applied for a permit to conduct surveys in other portions of this area.

Shortly after World War II and during the years of 1968-71, test drilling conducted off Andros, Cay Sal, Long Island, and Bimini, encountered some evidence of oil. The producing potentials were not considered great enough to justify further exploration under the prevailing economic conditions. Whether or not sufficient oil exists for commercial development today remains conjecture; although by some optimistic estimates, oil reserves of the south Florida-Bahamas Basin could amount to between 1.5 billion and 3 billion barrels.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through June 23, 1982.

[2]In addition to the countries listed, Antigua, Bermuda, Grenada, and St. Lucia presumably produced crude construction materials (clays, sand and gravel, and stone), but output is not reported and available information is inadequate to make reliable estimates of output levels. Antigua also has a petroleum refinery that was closed in 1976 but may be operational again in 1981.

[3]In addition to the commodities listed, other crude construction materials (lime, salt, and sand and gravel) may also be produced, but data on such production are not collected and available information is inadequate to make reliable estimates of output levels.

[4]Reported figure.

[5]In addition to the commodities listed, iron ore and manganese ore, both produced in significant quantities prior to the termination of publication of official statistics, presumably were produced during the period covered by this table, but available information is inadequate to make reliable estimates of output levels.

[6]Annario Estadistico de Cuba 1979 and Cuba en Cifras 1980, provide figures on nickel-cobalt content of oxide, sinter, and sulfide production using an average cobalt content in these individual products of 0.9% in total oxide, 1.1% in total sinter, and 4.5% in total sulfide, the cobalt content of reported nickel-cobalt production was determined as being 1.16% of oxide, 1.21% of sinter, and 7.56% of sulfide. The remainder of reported figures would represent the nickel content.

[7]The Dominican Republic reports gross weight of ferronickel production. When official data are not available, figures for nickel content of mine production are determined from an average of 37.4% nickel contained in ferronickel production. Nickel content of ferronickel shipments is obtained from Falconbridge Dominicana C. por A. annual reports.

[8]Revised to none.

[9]Includes crushed volcanic rock, limestone, diorite, and quartzite used for building stone, aggregate, road construction, etc.

[10]Trinidad and Tobago initiated production of pig iron and sponge iron near yearend 1980 and may also have produced a small quantity of steel, but output is not reported and available information is inadequate to make reliable estimates of output levels.

[11]Limited quantities of sulfur as a byproduct of natural gas may also be produced.

BARBADOS

In 1981, the real GDP was expected to be slightly over $4 billion,[2] indicating a 1% rate of real growth, declining from the 5% expansion experienced in 1980. The value added by the mineral sector has consistently remained well below 1%, and there is no basis for assuming more than minor fluctuations in the future.

In 1981, Barbados became one of the beneficiaries of the Mexico-Venezuela San Jose accord, which allows crude oil importing countries in the Caribbean to receive low-interest 5-year loans equivalent to the cost of 30% of the oil purchased. These loans may be converted to a 2% rate of interest, 20-year loan, if the money is used to enhance approved energy projects within the country. In addition to actively exploring and developing its own limited crude oil reserves, Barbados has strongly supported the development of alternative energy sources, especially solar. Solar energy is extensively employed for water heating in homes, and solar air-conditioning is under experimentation.

In 1981, Barbados was reported to be negotiating the exchange of limestone for steel billets from the Iron and Steel Co. of Trinidad and Tobago (ISCOTT).

The new Arawak Cement Co. plant project is jointly owned by the Governments of Barbados (51%) and Trinidad and Tobago (49%). Credit and loans totaling $80 million have been obtained to finance the construction of this 1,000-ton-per-day facility. The plant is located on the west coast of Barbados and is scheduled for completion by 1983. At full operation it is expected to produce a surplus for export.

Onshore petroleum exploration during 1981 was concentrated on deep drilling. This program did not prove successful, and shallow drilling is expected to be resumed in 1982. Some deeper drilling may also continue.

BERMUDA

Bermuda has no known official mechanism for registering production from its mineral sector. Any production would probably be in the form of small volumes of construction-oriented materials for local consumption and not of sufficient magnitude or value to warrant specific Government recordkeeping procedures.

rRevised.

[1]Bunkers originating with the Armed Forces of the United Kingdom, the North Atlantic Treaty Organization, and the United States and not listed with imports of petroleum refinery products.

[2]Less than 1/2 unit.

CUBA

Cuba entered the period of its second 5-year plan (1981-85) showing an impressive recovery from the poor economic performance experienced in 1980. In 1981, the gross national product (GNP) reached $27.4 billion,[3] indicating an overall economic growth of 12% as performance in all sectors improved. To curb import demand, maintain the balance of payments position, and decrease budgetary deficits, Cuba has planned to keep economic growth below 3% during 1982.

Administrative reforms initiated in 1980 were credited as being contributory to 1981's economic improvement. More efficient management was encouraged by keying performance measurements to profitability. Managers were judged by whether or not their enterprises were productive and profitable. Performance has been aided by other innovations, such as a new accounting system, a new salary system, a new labor law, farmer's markets, and a growing private service sector. The offering of material incentives was credited for increased labor productivity.

The trade balance during the first half of 1981 was reported as substantially positive, but it evidently deteriorated during the remainder of the year and resulted in a deficit of $1 billion. In June, Cuba and the Soviet Union signed a new Trade Turnover and Payment Protocol for the period 1981-85. The agreement provides for a 42% increase in trade volumes between the two countries compared with the previous 5-year period. Trade with market economy countries decreased 10% from 1980 as Cuba pursued its policy of maintaining a close relation between income and expenditure in convertible currencies.

In 1980, petroleum imports supplied through the U.S.S.R. accounted for almost 27% of Cuba's total import trade with that country and provided about 98% of Cuba's total oil requirements. In 1980, nickel concentrate made up 4% of Cuba's exports to the U.S.S.R.

During 1981, Cuba continued its policy of seeking investors for profit-sharing ventures. To support this policy, Cuba may take legislative action permitting the establishment of joint partnerships with foreign interests.

Czechoslovakia signed an agreement with Cuba to supply machinery and other equipment for extracting and processing chrome ores. Cuba expects to pay for the equipment by exporting chrome ore to Czechoslovakia. Chrome ore production capacity has been estimated at 100,000 tons per year, although actual production has been considerably less than this. At present, production consists mainly of refractory chrome ore containing about 38% chromic oxide. Some upgraded ore containing about 44% chromic oxide is also produced. Most of Cuba's chrome ore output is shipped through the port at Moa Bay.

Chrome podiform deposits are mined in northeastern Oriente Province in the Moa-Baracoa area. Assessed ore reserves in this area have been reported at about 6.5 million tons, and potential resources may reach 10 million tons. Another 42 million tons of lateritic deposits containing 1% to 3% chromium must await technological advances in metallurgy before development.

Cuba's nickel industry performed well in 1981, despite ongoing rehabilitation and expansion activity. Construction of the long-planned new nickel oxide plant at Las Camariocas in Holquín Province in northeast Cuba may begin in 1982. A cooperative agreement to build this plant is expected to follow an early 1982 meeting between the Council for Mutual Economic Assistance planning committee and Cuba. Construction work continued at the new Punta Gorda nickel oxide plant. This 30,000-ton-per-year plant will reportedly cost over $500 million and be operational at the end of 1983 or early 1984.

In April 1981, unconfirmed reports were widely circulated that Petróleos Mexicanos (PEMEX) had discovered crude oil about 15 miles off the Cuban coast near Havana. These reports were later denied, and no reliable information has been available as to the progress of the joint PEMEX-Cuban offshore exploration efforts.

Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals	378	[10]468	--	All from United Kingdom.

rRevised. NA Not available.

[1]Owing to a lack of official trade data published by Cuba, this table should not be taken as a complete presentation of this country's mineral imports. These data have been compiled from various sources that include United Nations information and data published by the partner trade countries. Unless otherwise specified, data are compiled from official trade statistics of individual trading partners.

[2]Source: Official Trade Statistics of Cuba.

[3]Excludes part of Japanese export valued at $576,000.

[4]Excludes part of Japanese export valued at $268,000.

[5]Source: Statistical Yearbook of the Member States of the Council for Mutual Economic Assistance, Moscow, U.S.S.R.

[6]Excludes Japanese export valued at $2,000.

[8]Less than 1/2 unit.

[9]Excludes Japanese export valued at $166,000.

[10]Excludes Canadian export valued at $22,000.

DOMINICAN REPUBLIC

A combination of adverse economic conditions resulted in a 3% real growth rate of the 1981 GDP, estimated at $3 billion. This was less than the 5% projected early in the year. The mining sector accounted for over 5% of the GDP in 1979 and over 4% in 1980. Preliminary data indicate another reduced contribution from the mining sector in 1981.

A general downtrend in the world market prices for traditional exports reduced Government revenue and foreign exchange earnings. As it became evident that 1981 income would be less than projected, the Government introduced budgetary cutbacks. The rate of inflation was held to about 8% during 1981, primarily because of stable petroleum prices and firm economic control measures.

The export value of the three major minerals, bauxite, doré, and ferronickel are shown in the following table, in millions of dollars.

Commodity	1978	1979	1980	1981[p]	1982[e]
Bauxite	$23	$21	$19	$16	$16
Doré	77	128	260	208	135
Ferronickel	75	123	101	110	70
Total	175	272	380	334	221
Share of total exports	26%	31%	39%	28%	24%

[e]Estimated. [p]Preliminary.

There was a 50% drop in the price of doré between late 1980 and mid-1981. This was partly offset by increased production. Depressed world market conditions led to lower than expected production of both ferronickel and bauxite.

In 1981, the Government imposed tight monetary and import control measures that could have a considerable impact on the economy. Overall import cost levels were down slightly in 1981, leading to an esti-

mated 10% reduction in real cost when inflation is considered. An unofficial estimate of the U.S. share of Dominican exports in 1981 was about 78%. About 53% of the Dominican Republic's imports originate in the United States.

In 1981, petroleum import costs were estimated at $558 million, an 11% increase over that of 1980. Petroleum accounted for 39% of total imports. Nevertheless, this cost was still less than projected earlier owing to reduced fuel oil requirements by the ferronickel plant and a decrease in the price of fuel oil.

The acceptance of the Dominican Republic into the Mexico-Venezuela San Jose crude oil concessional financing accord has afforded the Government some relief from energy's drain on foreign exchange. The introduction of the higher sulfur and salt content of Mexican crude oil into the refinery resulted in a lower yield of higher priced products, such as kerosine, jet fuel, gasoline, diesel oil, and liquefied petroleum gas (LPG). Yields of low-value products, such as fuel oil, were higher. Consequently, import levels of higher priced products, such as LPG and to some extent diesel fuel, were increased.

Production from the bauxite mines decreased significantly, reflecting a weak demand for aluminum in world markets and a continuing reduction in stockpiled ore. Aluminum Co. of America ships the low-grade monohydrate Dominican ore to its Point Comfort, Tex., refinery.

Expanded production at the Government-owned Rosario Dominicana S.A.'s Pueblo Viejo gold mine at Cotuí, 40 kilometers north of Santo Domingo, significantly increased the volume of doré available for export. Production in 1982 was expected to decrease, partly because of low gold and silver prices.

In early 1981, the Government signed a contract with the British firm, Davy McKee Ltd., to construct a gold and silver refinery next to the Pueblo Viejo Mine. The $5 million refinery was scheduled to open in mid-1982 with a capacity to refine 75 tons of doré annually (2.4 million troy ounces). Davy McKee will provide training and technical assistance for plant operation.

Rosario Dominicana continued gold and copper exploration work in the area south of Pueblo Viejo and north of Maimon. Rosario Dominicana also conducted gold exploration near Altagracia in the Haina River Valley, and around areas near Miches. None of these locations have been determined to have commercially exploitable gold deposits. Indications of copper have encouraged a continuation of exploration for this metal, although no deposits have been identified.

The ferronickel operation of Falconbridge Dominicana C. por A. (Falcondo) continued to operate at a loss in 1981. The company denied reports that it contemplated closing down or phasing out its plant. By the end of June, the company was operating only one of its three furnaces. Fuel requirements are estimated to account for 64% of the overall costs. In 1981, operating cash costs were estimated to be about $3.14 per pound of nickel. This does not include charges for overhead, depreciation, and other noncash costs. Full capacity operation could reduce cash costs to about $2.72 per pound of nickel. Falcondo reported a sizable net loss of about $28 million for 1981. The Government has demanded $5.4 million in back taxes due on undeclared profits in 1972 and 1973. As nickel prices continued to fall during the last half of 1981, the prospect of another complete plant shutdown became more probable. The last complete shutdown occurred during the latter half of 1980. This outlook is not encouraging for the Dominican economy from the standpoint of lost revenue, decreased availability of foreign exchange, and increased unemployment.

Falcondo reported the discovery of base metal mineralization within the Cerro Maimon concession area. Additional exploration efforts, geological studies, and drilling were underway. The area is adjacent to the Rosario Dominicana mining concession. Prospecting has identified traces of copper, lead, zinc, gold, and silver.

Douglas-Robertson and Associates of Colorado completed preliminary studies on lignite deposits in a 22-kilometer area from Sánchez to Arroyo Barril in the Samaná Peninsula. A resource base of 86 million tons was identified along with indications of some associated natural gas deposits. The Government announced that studies of 133 samples revealed that some 45 million tons of lignite having an average calorific value of 4,682 British thermal unit (Btu) per pound could be recovered. West of the Sanchez area in the Cibao region there was evidence of vast lower grade deposits.

On the southern peninsula in the eastern part of the country, evidence has been found of high-grade lignite deposits. In 1982, Rosario Dominicana, which funded the

Douglas-Robertson studies, expected to spend $1.5 million for additional exploration and studies. This work was expected to continue for 3 or 4 years.

A French Government organization and the Dominican Government have agreed to prospect for basic minerals in the western regions of the Cordillera Central adjacent to the Haitian border near Dajabon and Santiago Rodriguez. The Federal Republic of Germany's Institute of Geosciences and Natural Resources shifted its exploration from the Cordillera Central to the Cordillera Septentrional (northern range). The institute has been searching for base minerals such as copper, zinc, and lead.

A West German firm has been conducting mineral exploration for iron and titanium in the northwest, near Monte Cristi. The joint exploration by the Spanish firm Hullera Vasco-Leonesa S.A. and the Government continued in the Yujo River Basin, near Jarabacoa. The group has been searching for base metals, including gold and silver.

The United Nations has funded a petroleum resources development project and has provided technical expertise to assist the Government in establishing a laboratory and documentary library.

Canadian Superior Oil Ltd. spudded its first wildcat well, the Charco Largo No. 1, in their 735,000-acre concession in the Barahona Basin near Lake Enriquillo in the southwest region of the country. In midyear, rumors of a discovery were circulated, but a few months later a joint Government-Canadian Superior announcement revealed that commercially exploitable oil had not been found. Canadian Superior was not expected to drill again in the immediate future.

Other petroleum exploration efforts were underway in 1981. In November, Cariboil Dominicana S.A. was drilling the Candelon No. 1 well in the San Juan Basin near Elías Piña. The well has a projected total depth of 20,000 feet. This site was thought to be geologically more promising than Charco Largo. The well was not completed by year-end. Weeks Petroleum Co. reentered the Dominican exploration scene with an agreement to join a local firm, Quisqueya Oil Co., to explore the Cibao region in the north-central portion of the island. Seismic work was undertaken in 1981 and was expected to continue in 1982. Western Geophysical Co. has begun a $1 million offshore seismic exploration program in the south and southeastern areas, as well as around the Samana Peninsula.

Concessions for oil exploration have been granted on an ad hoc basis, largely free of institutional and legal guidelines. The identification of lignite reserves in the northeast and the possibility that commercial deposits of oil may be found have increased pressure on the Government to amend the 11-year-old mining law. However, action on any new mining legislation was not expected in the immediate future.

HAITI

In real terms, the economy grew by about 1% to an estimated $2 billion[4] in current prices. The value added by mining represented about 1% of the GNP in both 1980 and 1981. Both import and export levels were down in 1981, but higher prices for imports and lower earnings from exports widened the trade deficit to $133 million. Throughout the year, foreign exchange shortages occurred that strained Haiti's ability to import some essential products, such as petroleum.

Early in 1981, the Government enacted decrees prohibiting or restricting the importation of certain products and also increased the wholesale price of some items. This action along with other fiscal reforms and a proposed new investment code were expected to curb imports and improve overall future economic performance.

Haiti has not yet finalized agreements with Mexico and Venezuela for participation in the San Jose accord for financing of crude oil imports.

Reynolds Metals Co. was expected to close their Miragoâne bauxite operation by the end of 1982. Reynolds claimed the high silica content of any remaining ore has made further mining impractical, especially in view of the depressed aluminum market. Haiti has appealed to other members of the International Bauxite Association (IBA) for assistance should Reynolds leave. The IBA agreed to send a team of investigators to assess the remaining bauxite reserves in an attempt to develop some alternative options for Haiti in the event of full closure.

Under a 1980 contract with the United Nations Development Program, the gold potential of volcanic deposits in northern Haiti has been under investigation. The areas include Milot, south of Cap Haitien; and Mont Organisé and Boise de Laurence, near the border with the Dominican Republic. The $2 million evaluation project is scheduled for completion early in 1983.

In cooperation with the Institute of Geosciences and Natural Resources of the Federal Republic of Germany, a coal exploration project was initiated in September. The program is scheduled to terminate early in 1982 following the investigation of lignite deposits in the Maissade region in west-central Haiti.

Anschutz Corp. planned to commence drilling a petroleum exploration well in late 1981 or early 1982. The selected site lies in the eastern Plateau Centrale area near Lake Saumarie, directly west of an abandoned well drilled during 1981 in the Dominican Republic by Canadian Superior Oil Ltd.

JAMAICA

In real terms, the 1980 GDP decreased 5.4% from that of 1979 and represented the seventh consecutive year of economic decline. The Government initiated an economic recovery program designed to secure balance of payments assistance, increase

foreign exchange earnings, and increase new investments from domestic and foreign sources. There was a slight recovery in 1981 as the GDP reached about $3 billion,[5] and real growth was estimated at 1.5%.

In 1980, bauxite and alumina activities represented 14% of the GDP at current prices, and other mining activities accounted for less than 1%. In that year, bauxite and alumina sales were valued at $732 million and represented over 76% of total exports. Although exports of bauxite and alumina increased during the first half of 1981 over those during the same period of 1980, the industry announced a series of production cutbacks that left total 1981 bauxite production and export volumes well behind those for 1980. Alumina, on the other hand, showed a slight increase in export volume because cutbacks were not expected to have a pronounced effect until 1982.

Reduced bauxite production during 1981 and 1982 was expected to lower Government revenues from the bauxite levy and royalty payments to $198 million in 1981 and $167 million in 1982. Earlier estimates of these revenues were $222 million for fiscal year 1981 and $247 million for fiscal year 1982. If the announced sale of 1.6 million tons of bauxite to the United States for its stockpile is finalized in 1982, the bauxite revenues for that year could increase from the $167 million figure to about $211 million. Nevertheless, the prospect of losses in revenues and foreign exchange earnings caused Jamaica to undertake budgetary readjustments. The financial losses could be of sufficient magnitude to throttle Jamaica's economic recovery program.

The Government continued its efforts to secure agreements for alumina and bauxite sales. At yearend, negotiations were pending on the possible sale of 1 million tons per year of bauxite to the U.S.S.R., starting in 1982. The 1979 agreement with the U.S.S.R. for the sale of 50,000 tons of alumina per year at $180 per ton c.i.f. has undergone several contract renegotiations. The price was finally set at $205 per ton c.i.f. for the 1980 delivered volumes. The alumina price was again negotiated to $245 per ton c.i.f. in 1981.

In November 1981, it was announced that the United States would acquire a total of 1.6 million tons of bauxite from Jamaica for the National Defense Stockpile. The bauxite, valued at about $56 million, would reportedly be paid for through a combination of cash, the exchange of surplus U.S. stockpile materials, and by the barter of agricultural commodities from the U.S. Department of Agriculture stockpile. Final details were expected to be completed early in 1982. This was an auspicious sale for Jamaica in view of the production cutbacks scheduled for 1982.

In 1980, petroleum imports were valued at $418 million and accounted for 37% of total imports. In 1981, petroleum costs rose to $497 million, but their share of total imports decreased because of an overall increase in imports. Total petroleum import volumes decreased slightly in 1981, primarily because of lower domestic consumption. Consumption by the international sector—the alumina, aviation, and shipping industries—increased slightly over that of 1980. Jamaica maintained its ongoing energy conservation programs and the development of alternative energy sources.

Company contracts with the National Workers Union, which represents the bauxite workers, expired on January 31, 1981. Strikes were threatened several times throughout the year as negotiations repeatedly failed to resolve differences regarding wage increases and benefits. The year ended without settlement, and the likelihood of strike action during 1982 became a strong possibility.

Plans for doubling the 550,000-ton-per-year capacity at Jamalco's Clarendon alumina refinery were revised following the withdrawal of the three Norwegian firms from partnership negotiations. The Government subsequently announced it would reduce the proposed increase in capacity to 340,000 tons per year at a cost of $210 million. It was reported that one of the three Norwegian firms, possibly Norsk Hydro, may rejoin the venture at a later date.

The possible use of coal as an alternative energy source to petroleum continued to be considered. In 1981, the United States signed an agreement with Jamaica to finance studies on the feasibility of converting some industries from petroleum to coal. The study will include the conversion of the major energy consumers, such as the bauxite, alumina, cement, and electrical generating plants. It has been suggested that U.S. coal could be imported at a cost of about $50 per ton. One method of transportation suggested was the use of empty bauxite ore carriers returning to Jamaica.

Another opportunity to lessen petroleum dependence would be the development of domestic peat deposits. A study of these deposits indicated that they could provide

up to 40% of Jamaica's energy needs for as long as 30 years. An environmental study was underway to assess any possible ecological damage to fish-spawning areas and other forms of wildlife that might be caused by peat mining.

The best peat deposits were reported to occur in the upper Black River area in St. Elizabeth Parish, and in the swamps near Nagril along the western coast in Westmoreland Parish. The deposits were described as averaging 30 feet in thickness with the potential of yielding about 20 million tons of dried peat. Samples sent to Ireland for testing were reported to have generated 6,000 to 8,500 Btu per pound.

Jamaica's drilling program for domestic petroleum resources began in November after favorable seismic studies by the state-owned Petroleum Corp. of Jamaica and the Norwegian Government. The search is financed by a $23.5 million loan from the Inter-American Development Bank and a $7.5 million loan from the International Bank for Reconstruction and Development (World Bank). Conducted under the supervision of Petro-Canada and Parker Drilling Co., onshore drilling was underway in the western region of Jamaica. Two more onshore sites have been targeted for drilling, one in the central region and one in the eastern. Drilling was expected to reach a depth of 12,000 feet.

MARTINIQUE AND GUADELOUPE

Martinique and Guadeloupe are Overseas Departments of France. Their economies have been supported by that country.

Guadeloupe's mineral industry has been limited to the production of construction-oriented materials and pumice. There is also a small clinker grinding plant with a capacity of 250,000 tons of cement per year.

Martinique's mineral industry has been similar to that of Guadeloupe, except that it has a small petroleum refinery located at Fort de France. Crude oil has usually been imported from Venezuela and Saudi Arabia. Refinery products have been used domestically and exported to Guadeloupe.

NETHERLANDS ANTILLES

In 1981, some provisions of the pending Petroleum Protocol continued to cause disagreement within the Netherlands Antilles Cabinet. The Protocol was to be the basis for legislation to establish procedures for forming a company on each island to regulate petroleum exploration and exploitation of areas surrounding that island.

Tentative agreement had been reached by ministers on the Government-Island proportionate share of ownership and earnings of the regulating company formed by each island. Ownership of any island company would be Island Government, 90%; and Central Government, 10%. Revenues and profits would be shared 75% by the Island Government and 25% by the Central Government for a general development fund.

Disagreement surfaced when the ministers from Aruba insisted that Aruba should have full authority to decide which foreign oil companies would receive drilling rights in its territory. This was in anticipation of the decentralization expected to eventually take place under the roundtable discussions working toward full independence. The Netherlands Antilles Central Government maintained that according to the Kingdom of the Netherlands Statute all mineral wealth in the Netherlands Antilles belongs

to all the islands in common. Accordingly, one island cannot claim, while it is still a member of the group, that all of the mineral wealth in and around it is that island's patrimony only. The petroleum potential of offshore Aruba is considered the most promising because of its proximity to the Gulf of Venezuela.

Meanwhile, the Curação Island Council and the Central Government signed an agreement with BP for an option covering 50 blocks of approximately 74 square kilometers each around the Island of Curação. The option was signed under Curação Island Council legislation establishing Petrocuraçao, N.V. The company is presently wholly owned by the Curação Island Council. After Protocol passage, Petrocuraçao ownership is supposed to be adjusted to correspond with the expected 90% to 10% split on shares and the 75% to 25% division of profits with the Central Government.

BP has scheduled a series of seismic tests, after which a suitable drilling site could be selected. BP's production-sharing contract with Petrocuraçao provided for the drilling of two wells within 4 years of the agreement.

Saba Bank Resources N.V. is a state-owned corporation created to administer petroleum exploration and development in the Saba Bank area. The company has a production-sharing agreement with a group headed by Petrofina, S.A. Other members of this consortium are Cities Service Co. (50%) and Weeks Petroleum Co. (10%). The Petrofina concession area includes 14 contiguous blocks of 92 square kilometers each. After seismic testing the area in 1980, Petrofina decided to drill a wildcat well in 1982. Total depth may approach 13,500 feet as an attempt is made to penetrate buried pinnacle reefs. If a commercial deposit of oil is found, the Petrofina Group would receive 40% of total annual production. The remaining 60% of production would be divided as follows: From 0 to 24,999 barrels of oil per day, 50% to both the Government company and to the Petrofina Group; for production of more than 24,999 barrels per day, the Government would receive 80% and the consortium 20%.

In mid-December, the consortium of Union Texas Petroleum Corp. and Azienda Generali Italiana Petroli S.p.A., a subsidiary of the Italian state oil company, began their offshore exploration drilling program on Pedro Banks. Their first well was expected to reach a total depth of about 11,600 feet and cost $12 million.

TRINIDAD AND TOBAGO

Revised data indicate that in 1979, growth in the real GDP increased 17% over that of 1978. In 1980, another high growth rate of 10% was achieved as the GDP reached an estimated $6.7 billion[e] at current prices.

A decline in petroleum activities has been of considerable concern to the Government. In 1980, the petroleum sector accounted for 35% of the GDP. Petroleum also comprises the bulk of total exports—over 90% in 1980. At the end of the third quarter of 1981, many sectors of the economy were showing increases compared with the same period in 1980. The petroleum sector, which has been primarily responsible for Trinidad and Tobago's past strong economic performance, weakened as both production and refining declined. Natural gas production and consumption, on the other hand, have increased steadily. The fertilizer industry, which suffered decreased performance because of labor problems earlier in 1981, was recovering during the third quarter. New industrial developments in the iron, steel, and fertilizer industries were expected to extend future trading opportunities.

In April 1981, new legislation retroactive to January 1980 was enacted amending the Petroleum Act of 1974. The major thrust of the amendment was to provide tax relief to the oil companies. There were four major policy objectives in the bill: To promote further petroleum industry development; to enhance Government administrative control over the petroleum industry; to ensure that the state receives the maximum benefit from petroleum production and sale; and to establish a taxation policy that would be harmonious with international tax systems and allow equitable treatment for all petroleum companies operating in Trinidad and Tobago.

The tax reference price system introduced in 1974 has been replaced by a system for computing profits on the basis of realized prices. Should the Trinidad and Tobago Board of Inland Revenue determine that actual or realized prices are not realistic, it will make a determination of fair market value. Petroleum companies will now pay the normal Trinidad and Tobago corpora-

tion tax rate of 45% instead of 50%. A supplemental petroleum tax (SPT) was introduced to assure that the Government receives maximum benefit from international market price increases. The SPT, however, was declared a deductible item in computing corporate taxes. For land operations, the SPT was set at 35% of gross income. For marine operations, the SPT was established at 60% of gross income.

A system of production allowances was introduced to enhance production in smaller as well as larger fields. The percent of production allowance decreases as productive capacity of the field increases. The allowance is deductible from gross income prior to the imposition of the SPT. Other changes involved allowances for depreciation, capital expenditures, direct drilling costs, and refining investment.

The new legislation was expected to decrease Government revenues by $40 million in 1980 and 1981. This sum actually represents about 2% of taxes collected annually from the oil companies. By 1983, the incentives were expected to generate increased production, which in turn should increase Government revenues by $200 million.

COMMODITY REVIEW

Metals.—*Aluminum.*—Throughout 1981, no firm decision was made to proceed with the construction of a proposed 180,000-ton-per-year aluminum smelter. Additional engineering studies and cost analyses have been undertaken to assure the Government that the smelter will be a viable project, especially in view of the large investment required. The identification of downstream industries that could be established locally to consume part of the smelter's output was of particular interest. The U.S. companies that have been involved in the aluminum project are National Steel Corp. and Southwire Co. These two companies jointly own the National Southwire Aluminum Co. in Kentucky. Equity interests in the aluminum plant were still under negotiation, but the Government was expected to assume a 60% to 80% majority control. Alumina feedstock of about 360,000 tons per year would probably come from Jamaica and/or Guyana.

Iron and Steel.—ISCOTT continued to work toward full capacity production from its 420,000-ton-per-year direct-reduction iron (DRI) MIDREX plant.

A formal inauguration of the ISCOTT complex was held on June 27, 1981, although the first of two DRI MIDREX plants was brought onstream in the latter half of 1980. The second 420,000-ton-per-year DRI plant is scheduled to start operating in April 1982. ISCOTT estimated its total DRI output in 1982 would reach 465,000 tons, most of which would be used in the steel melt-cast shop to produce 265,000 tons of billets. The melt-cast shop's startup was in December 1980, and the wire rod mill came onstream in June 1981. The design and operation of ISCOTT facilities have been adequately described in trade magazines.[7]

Nonmetals.—*Fertilizer Materials.*— Fertilizers of Trinidad and Tobago Ltd. (FERTRIN) completed its two 272,000-ton-per-year nitrogen ammonia plants in late 1981. The inauguration of these plants brought Trinidad and Tobago's total ammonia capacity to about 1.3 million tons per year of nitrogen equivalent. FERTRIN is a joint venture of the Government (51%) and Amoco International Oil Co. (49%). FERTRIN'S investment has been estimated at $350 million.

In early 1981, construction started on a methanol plant and a urea plant, both to be located at the Point Lisas industrial center. The projects are expected to initiate production in late 1983.

The $160 million methanol plant was expected to consume about 35.3 million cubic feet of natural gas and 403 tons of carbon dioxide per day to produce 132 million gallons per year of chemical-grade methanol. A sales agreement with a West German company has already been signed, and other contracts were under final negotiation with Japanese and United States firms.

The urea plant was expected to utilize 940 tons of ammonia and 1,240 tons of carbon dioxide per day to produce 1,620 tons of urea per day. The project cost was estimated at $155 million. Final negotiations were underway for the sale of urea to Agrico Chemical Co., which also holds a 49% interest in the urea project.

Mineral Fuels.—*Natural Gas and Petroleum.*—The latest available estimate for proven natural gas reserves was 10.5 trillion cubic feet.

After 7 years of negotiations, in September the Government and Amoco Trinidad Oil Co. Ltd. reached an agreement on the sale of natural gas to the National Gas Transmission Co. (NGTC) and the Trinidad

and Tobago Electricity Commission (TTEC). Both users were paying about $0.17 per 1,000 cubic feet. Under the new agreement TTEC was to continue to pay this amount until 1983, after which it has been scheduled to pay the same rate as NGTC. The exact NGTC rate was undisclosed, but was estimated between $0.70 and $1.00 per thousand cubic feet. The agreement was to remain effective until 1990.

Amoco, the major producer of petroleum and natural gas, also agreed to renew gas exploration efforts in its Galeota concession where it has decided to install a 20-slot drilling platform.

Successful field delineation wells were drilled about 50 miles off Galeota Point by Texaco-Trinidad, Inc. Originally discovered in 1977, the gasfield is located in block 6 where water depths range between 300 and 550 feet.

The Trinidad and Tobago Oil Co., Ltd., drilled a successful wildcat, the Hibiscus No. 1, off the north coast of Trinidad and Tobago, which tested at 12 million cubic feet of natural gas per day. The well was a south offset of an earlier discovery well, the Chaconia No. 1. The area north of Trinidad and west of Tobago has been considered as having a high-risk potential because of limited information. It is also subject to the resolution of sovereignty rights between Trinidad and Tobago and neighboring island countries.

Projections for crude oil production have not been especially bright. Production has been declining in many of the offshore wells and no significant new fields have been discovered since 1972. The Government hopes that the new petroleum legislation will foster increased exploration and secondary recovery operations. The Government also has commissioned an outer ring offshore geophysical survey of Trinidad and Tobago, where water depths reach over 1,000 feet. Information from this survey may be made public in 1982.

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Cement	16	120	--	Barbados 107.
Chalk value	$2,411	$2,061	--	All to Guyana.
Clays and clay products:				
Crude	40	72	--	All to Barbados.
Products:				
Refractory including nonclay brick	39	NA		
Nonrefractory value	$30,025	$261,814	--	NA.
Diamond, gem, not set or strung carats	2	--		
Fertilizer materials:				
Natural, phosphates	5	--		
Manufactured:				
Nitrogenous	100,994	119,147	25,257	Guyana 25,725; Jamaica 22,556.
Potassic	549	17	NA	NA.
Other including mixed	9	78	--	All to St. Vincent.
Ammonia	394,678	569,724	331,259	United Kingdom 112,964; Sweden 60,526.
Gypsum and plasters value	--	$550	--	Barbados $125.
Lime do	$1,168	$441	--	Dominica $190.
Mica	2	7	--	Mainly to Guyana.
Salt and brines	25	295	(5)	Barbados 200; Grenada 90.
Sodium and potassium compounds, n.e.s.:				
Caustic soda	26	31	--	NA.
Soda ash	6	1	--	Mainly to Barbados.
Stone, sand and gravel:				
Dimension stone:				
Crude	NA	2	--	All to Grenada.
Worked value	$284	$367	--	All to Italy.
Gravel and crushed rock	NA	7	--	Grenada 6.
Quartz and quartzite value	--	$343	NA	NA.
Sand excluding metal-bearing	20	9	--	Barbados 8.
Sulfur:				
Elemental, colloidal	--	15,932	15,932	
Sulfuric acid, oleum	13	5	--	Mainly to Barbados.
Talc	3	3	--	All to Barbados.
Other:				
Crude value	$1,083	$833	NA	NA.
Building materials of asphalt, asbestos and fiber cements, unfired nonmetals	r213	2	--	Dominica 1.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	9,823	6,167	22	Guadeloupe 3,509; United Kingdom 1,082; Martinique 1,038.
Coal, all grades value	$229	--		
Hydrogen, helium, rare gases	7	1	NA	NA.
Petroleum:				
Crude and partly refined thousand 42-gallon barrels	54,282	49,601	45,678	Netherlands 375.
Refinery products:[6]				
Gasoline, motor and aviation do	8,570	9,386	3,242	Suriname 343; Guyana 299.
Kerosine do	1,598	717	--	Guyana 46; Barbados 17.
Jet fuel do	2,624	4,494	482	Barbados 308.

The Mineral Industry of Central American Countries

By H. Robert Ensminger[1]

CONTENTS

BELIZE

The Belizean economy registered a modest real growth of 1.3% during 1981. The gross domestic product (GDP), based on current prices, was $121 million[2] with an inflation rate of 10%. The country received $19 million in economic aid during 1981.

In early 1981, Belize's four commercial banks raised the interest on deposits to 15% in an effort to curb capital outflow. During 1981, the financial situation deteriorated somewhat, particularly the balance of payments. For the year the total value of imports exceeded exports by almost $38 million, while the Government continued to maintain a fairly free trade policy. Import duties and taxes averaged about 8% on essential items and 40% on nonessential ones.

The mineral activity in 1981 was limited to the production of limestone, sand and gravel, and marl.

Placid Oil Co. of Dallas, Tex., and the Anschutz Corp. of Denver, Colo., were actively engaged in oil drilling and exploration in 1981. In September, Placid began drilling off North Highway near Rancho Creek. Anschutz completed seismic exploration off the coast of the Stann Creek district. During 1981, no oil was discovered; however, at yearend, interest was undiminished.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Includes data available through Oct. 4, 1982.

[2]Ni content of sinter.

[3]Reported figure.

[4]Exports.

[5]In addition to the commodities listed, Nicaragua produces a small but undetermined quantity of cadmium contained in zinc concentrates for export.

[6]Refinery fuel is apparently included as a part of the products listed above; subtraction of the reported detail from the reported total gives a result of -7, indicating a net gain as a result of refining operations, but this cannot allow for refinery fuel.

[7]Detail adds to 7 more than this reported total (see footnote 6).

[8]Excludes approximately 8,000 cubic meters per year, apparently dimension stone.

COSTA RICA

During 1981, the GDP declined by 3.6% to an estimated $4.7 billion[3] based on current prices. A further decline in economic performance was forecast for 1982. The foreign debt for 1981 stood at $2.7 billion, an increase of approximately $700 million over the 1980 figure. The balance of payments registered a deficit of $416 million, about $237 million less than the amount for 1980. The inflation rate for 1981 was 65%, while the unemployment rate was approximately 20% of the work force.

The mineral industry was of minor significance in Costa Rica. In 1981, it contributed less than 1% to the GDP. Mineral production was limited to small amounts of gold and silver, as well as limestone and cement.

The gold was produced from the Santa Clara Mine, 40 miles from San José in Puntarenas Province. United Hearne Resources Ltd. owned 60% of the mine while Canadian Barranca Corp. owned 40%. The mine, using open pit mining on the main Mondongo zone and a cyanidation-leaching process, has been operating since February 1981. The ore reserve figure of 4.1 million tons with an average grade of 1.6 grams of gold per ton was the same as that for 1980.

Petroleum imports accounted for about 15% of the total import bill. Priority status has been given to the search for and the development of energy resources that would reduce the need for imported oil. Oil imports have been restricted to the level of the country's earnings from coffee exports.

Mexico's state oil agency, Petróleos Mexicanos, provided technical assistance to Refinadora Costarricense de Petróleo for oil exploration. Work was principally in the Baja Talamanca region, Llanuras de Santa Clara, and the Limón Basin.

The Instituto Costarricense de Electricidad announced plans to increase hydroelectric generating capacity by 60% by the end of the decade. The assessment of the geothermal resources continued around the Ricón de la Vieja and Miravalles volcanoes in the Province of Guanacaste.

Aluminios Nacionales, S.A., a subsidiary of Costarricense de Desarrollo, officially inaugurated the largest aluminum processing plant in Central America. The $28

million plant was to process annually 10,000 tons of aluminum ingots imported from the United States and Europe. An estimated 10% of the production was for domestic consumption, with the remainder destined for exportation to other Central American countries, the Caribbean, and Venezuela.

EL SALVADOR

The civil strife during 1981 continued to severely undermine the El Salvadorean economy. The high political uncertainty has resulted in the GDP falling to $3.4 billion,[4] in current prices. This represented an approximate decrease of 12% in real terms from the 1980 GDP. The balance of payments for 1981 showed a deficit of $132 million. The inflation rate was 15%, which was one-half of the 1980 rate.

The mineral industry, including production of gold, silver, cement, and limestone, contributed less than 1% to the GDP. Gold production fluctuated from about 8,700 troy ounces in 1975 to about 2,500 troy ounces in 1980. In the last decade, annual silver production varied between 112,530 and 184,870 troy ounces.

Gold was primarily produced from the San Cristobal Mine by the local company Minas San Cristobal, S.A., a wholly owned subsidiary of Javelin International Ltd., formerly Canadian Javelin Ltd.

Government involvement in the mineral industry was through the Instituto Salvadoreno de Desarrollo Industrial and the Comisión Nacional de Petróleo. Jointly they have undertaken a $1.5 million geological survey designed to locate mineral deposits of economic interest.

El Salvador's 1981 imports of crude oil declined by 2.2% from that of 1980. The country relied entirely on imported oil. The share of oil as an energy source has decreased over the last decade. The easing of this large economic burden has been achieved through agreements with the Governments of Venezuela and Mexico. Venezuela guaranteed to return 30% of the oil import costs and may help with the financing of the San Lorenzo hydroelectric project.

On March 18, 1981, the Governments of El Salvador and Mexico signed an agreement whereby El Salvador need pay only 70% of the cost of imported Mexican oil in cash. El Salvador would retain the remaining 30% due on the oil bill as a 5-year loan at 4% interest and will not need foreign exchange to cover this portion. These terms were an improvement over those granted by Venezuela, which was to supply the remaining one-half of El Salvador's petroleum and insisted on full payment 7 days in advance of shipment. Subsequently, Venezuela would return 30% of the oil bill in the form of a loan on the same repayment terms as offered by Mexico.

El Salvador had an aggressive geothermal development program underway to boost its electrical power output. During the 1970's, two 30-megawatt powerplants in the Ahuachapán Field were brought online, and a third was scheduled.

GUATEMALA

For a number of years Guatemala enjoyed one of the highest growth rates in Latin America; however, the GDP for 1981 increased less than 1% to an estimated $3.15 billion[5] in current prices. Exports for 1981 increased by about 14% over those of 1980, while imports increased only about 4%.

The small mining industry suffered a major setback with the decision to close permanently the nickel plant at El Estor, located at the western end of Lake Izabal. The reasons given for closing the plant were the depressed state of the world nickel market and the sharp increase in operating costs. The decision to close the plant was made near the end of 1981 by Inco Ltd., which held an 80% interest in the former operating company, Exploraciones y Explotaciones Mineras Izabal (Exmibal). The remaining 20% was owned by the Hanna Mining Co. of the United States. The El Estor plant had been closed on a standby basis since September 1980. The major change in operating conditions was the marked increase in the cost of oil, which accounted for approximately 60% of direct operating costs. In the laterite treatment process it was found that for each $1-per-barrel increase in the price of oil there was a corresponding increase of about $0.05 per pound of nickel produced. The El Estor plant, which was built at a total cost of $224 million, produced approximately 6,940 tons of nickel matte during the first 9 months of 1980.

With the closure of the Exmibal nickel mine, the only remaining metal mining operation of any significance in Guatemala was the Oxec underground copper mine operated by Transmetales Ltda. in Alta Verapaz Department. Underground development work was also being undertaken on the lead, zinc, and silver Ballena Montenegro and Penasco Mines in southeast Guatemala in the State of Chiquimula. The majority interest in the mines was held by Minas de Oriente S.A. (Minorsa), a 60% subsidiary of Lacana Mining Corp. of Ontario, Canada. The minority interests were held by Toho Zinc Co., Ltd., and C. Itoh & Co., Ltd., of Japan, which advanced $600,000 to fund an exploration program on Minorsa's property. The recoverable ore reserves were estimated at 2.2 million tons, averaging 2.77 troy ounces of silver per ton, 0.58% lead, and 4.28% zinc.

Stone, sand and gravel, and sulfur were produced on a limited scale in 1981. It was reported that antimony and tungsten were being mined at Ixtahuacan by Minas de Guatemala S.A.

Oil represented a valuable export commodity for Guatemala. Production from the Rubelsanto and West Chinaja Fields was about 6,600 barrels per day during 1981. It was confidently expected that this production could be raised to 10,000 to 12,000 barrels per day by the end of 1982. Société Nationale Elf Aquitaine, the French oil concern, which had been providing finan-

cial and technical assistance, was the operator of the producing fields for the Petromaya Consortium in a joint venture with Basic Resources International S.A. The Yalpemech 1 well, drilled by Hispanoil in a joint operation with Braspetro International of Brazil and Elf Aquitaine, at a final depth of 4,600 meters, was the deepest well of record drilled in Guatemala.

The Guatemalan Petroleum Bureau has estimated the probable oil reserves at 2 billion barrels compared with the previous estimate of 800 million barrels. If the estimate proves correct, Guatemala can be assured of a domestic supply of oil for many years. Most of the output of crude oil was shipped to Louisiana refineries in the United States, and the refined products were imported.

HONDURAS

The GDP for 1981 was $2.7 billion[e] at current prices, which was a slight increase over that of 1980. Honduras had a deficit in its trade balance of $139 million, while the inflation rate was 9%.

The mineral industry contributed from 2% to 3% to the country's GDP in 1981. The great bulk of the precious and base metals was produced from the El Mochito Mine near Santa Bárbara. The mine was operated by the Rosario Resources Corp. of AMAX Inc.

The El Mochito Mine was converted to a 50% open pit operation to increase profitability, while average ore grades continued to decline. During 1981, 378,000 tons of ore, grading 4.3% lead and 6.1% zinc, was mined and milled to produce 13,880 tons of lead, 17,846 tons of zinc, 1,667,000 troy ounces of silver, and 1,242 troy ounces of gold. Only zinc showed an increase over the 1980 production. Further progress was made on expanding the mine, and when completed, perhaps in 1983, the capacity could be increased from 1,200 to 2,500 tons per day.

The Texaco Inc. petroleum refinery at Puerto Cortés on the Caribbean coast was shut down from mid-September through the remainder of 1981. This action resulted from changes in refining costs due to the heavier Mexican crude oil.

The new cement plant at Piedras Azules began production in August with an annual production capacity of 400,000 tons. It was one of the country's largest projects to date, costing approximately $80 million. Firms from Japan and Spain participated in the plant's construction, while $15 million for financing came as a loan from the Venezuelan Trust Fund. The plant was expected to enable Honduras to save more than $13 million annually in imports of cement, while it generated about 350 jobs. The construction of the El Cajón hydroelectric project alone was expected to require at least 350,000 tons of cement, which would otherwise have to be imported. For its raw material, the plant utilized nearby limestone and marl deposits where measured reserves will last an estimated 40 years. In addition, the plant used a material called pozzolana, a siliceous volcanic ash, to produce a more resistant cement used in building dams and bridges.

The high cost of energy, due to the dependence on imported oil, had a very inflationary effect on the Honduran economy. The El Cajón hydroelectric powerplant under construction was expected to permit a decrease in oil imports when completed in 1983.

Exploration drilling for oil continued to be unsuccessful. A program was proposed to reevaluate the country's hydrocarbon potential with International Bank for Reconstruction and Development (World Bank) funding.

NICARAGUA

The Nicaraguan GDP for 1981 was an estimated $2.9 billion[7] at current prices, to which the mining industry contributed less than 1%. Exports rose by about 12%, and imports rose by about 1%. The trade deficit increased by approximately 4% to $393 million. The inflation rate for 1981 was about 25%. In 1981, substantial loans and grants were negotiated, notably with Mexico and Libya, but also with Venezuela, the Federal Republic of Germany, and Bulgaria.

Immediately following the revolution of 1979, the new Government nationalized the four largest gold mines, owned by two U.S. companies and one Canadian company. The U.S. companies were Rosario Resources, a subsidiary of AMAX, and ASARCO Incorporated. Negotiations for compensation to the U.S. companies were continuing. Despite predictions to the contrary, the state mining company, Nicaraguan Corp. for Mining Development (Codemina), has managed to maintain historic production levels.

In 1981, domestic mining was dominated by the production of gold and silver. The increase of 1981 gold and silver production over that of 1980 reflected the Government's determination to maximize its revenue from the extraction of these precious metals. Most of the production was from Codemina's Rosita-Siuna underground mining complex in Zelaya Department formerly operated by Rosario Mining of Nicaragua Inc., a wholly owned subsidiary of Rosario Resources Corp. The Siuna Mine, which has yielded about 50,000 ounces of gold per year, has measured and indicated reserves of

about 3.3 million tons, grading 0.095 ounce of gold per ton.

In November, the Nicaraguan Ministry of Mines and Hydrocarbons signed a cooperative agreement with the Swedish Geological Service. The agreement, worth $2.5 million, included technical assistance, creation of a mining chemical laboratory, and two mineral prospecting centers.

The Nicaraguan Government nationalized the Compañia Maritima Mundial and Oleoductos but has recognized as valid those permits for petroleum exploration held by foreign companies. However, new petroleum legislation imposing a different taxation system and modifying some of the terms of existing contracts was to have been introduced in 1981. No details were available at yearend.

Because of the political situation, there has been only limited petroleum exploration activity in Nicaragua, except for a joint offshore seismic program on the Caribbean shelf carried out in 1980 by the Chevron International Oil Co., Ltd., and Phillips Petroleum Co.

Considering the lack of any indigenous resources of oil and natural gas, priority has been given to the possible development of alternative sources of energy in the country. However, it appeared that the planned development of geothermal energy at Momotombo at Lake Managua was going to be abandoned. The project, which had been undertaken by Empresa Nacional de Luz y Fuerza at a total cost of $7.5 million, included the construction of a 35-megawatt powerplant capable of meeting about 20% of the current maximum demand for electricity.

PANAMA

After 3 years of relatively high economic growth, economic activity slowed in 1981, largely owing to the worldwide recession. In 1981, the GDP at current prices was $3.8 billion,[8] which represented a real growth rate of 3.6% over that of 1980. Inflation during 1981 was in the 7% to 10% range. The balance of payments was a negative $355 million, the highest figure recorded in recent years.

Mineral production in Panama continued to be extremely limited in 1981 and was confined almost wholly to limestone and clays.

The one mineral project considered capable of transforming the mining industry of Panama was related to the Cerro Colorado copper deposits in Chiriqui Province; however, this project had not progressed significantly by yearend. The conditions set by Río Tinto Zinc Corp. Ltd. relating to changes in the labor law have proved difficult for the Panamanian Government to accept, and by the end of 1981 no agreement had been reached. The project plans included the construction of a pilot plant and the driving of a 2,000-meter adit, followed by the development of an open pit mine and the construction of a concentrator with a capacity exceeding 100,000 tons per day of ore.

Because of the continued uncertainty over the future of the Cerro Colorado Project, the possibility for development of the extensive porphyry copper deposits farther to the northeast of Cerro Colorado near Petaquilla was of particular interest. An exploration program completed in 1976 by Panama Resources Development, a joint venture of Mitsui Mining & Smelting Co., Ltd., Dowa Mining Co., Ltd., and Mitsubishi Metal Corp., all of Japan, indicated potential reserves of 200 million tons of low-grade copper ore.

Work on the 130-kilometer transisthmian oil pipeline between Chiriqui on the Pacific coast and Bocas del Toro on the Caribbean coast started in August 1981 and was expected to be completed in late 1982, barring complications. The total estimated cost of the pipeline project was $250 million. The pipeline, located 300 kilometers west of the canal, was planned to have a throughput capacity of 700,000 barrels per day. The Panamanian Government expected to acquire 40% of the shares in the project through Corporación Financiera Nacional. The operating company would be Petroterminal Panama, S.A., a joint venture with U.S. interests. A subsidiary of Atlantic Richfield Co. has signed a 3-year agreement for the delivery of 100,000 barrels per day of Alaskan crude oil beginning in 1983.

In 1981, consumption of petroleum products for internal use declined slightly, mainly because less fuel oil was used to generate electric power. Because of higher-than-normal rains in 1981, hydroelectric generation rose from 53.1% to 70.3% of total energy consumption. In 1975, hydropower accounted for less than 10% of the total.

This pattern of declining dependence on thermal generation was expected to continue and accelerate as the large Fortuna Dam comes online in 1985 and additional alternate energy projects are carried out in future years.

The Mineral Industry of Other Areas of the Far East and South Asia

By E. Chin, Gordon L. Kinney, and John C. Wu

CONTENTS

BANGLADESH[1]

The only economically significant mineral exploited in Bangladesh during 1981 was natural gas. Nitrogenous fertilizer production was important to the agricultural sector and was totally dependent on the natural gas for fuel and raw material. Domestic cement plants were also fueled by natural gas. The flat river-delta terrain for most of Bangladesh makes the potential for discovering major mineral deposits poor. No large deposits of metal ores have been found and only in the small hilly southeastern section of the country is there even much chance of finding any. Heavy mineral sand deposits may eventually be exploited along the Chittagong coastline. There is a good potential for crude oil discoveries.

The Bangladesh economy has been heavily subsidized by billions of dollars of foreign aid since the country's inception. A World Bank report recommended total aid needs of over $2.6 billion in fiscal year (FY) 1980-81. It received commitments for barely over one-half that amount.

The Government's ambitious second 5-year development plan began in July 1, 1980, and called for a rather optimistic series of social and economic reforms that included lowering the population growth rate, cutting unemployment, greatly increasing the food supply, and accelerating the pace of economic development.

As part of the means of achieving the 5-year plan goals, the Government stated that measures had been taken to liberalize the investment incentives to both local and foreign industries. Policy has swung around in recent years to one of actively encouraging the participation of the private sector in economic development.

Despite the optimistic industrial development plans, Bangladesh's continuing extremely large trade deficit forced unwanted but necessary economic adjustments. By the end of December 1981, the original $15.5 billion plan, adopted in July 1980, had been revised to $10.9 billion.[2] The industrial sector was to drop from 18% to 15%, while the agriculture sector would be increased from 32% to 35%. The target for food production

had been 20 million tons but that was reduced to 17.5 million tons.

Another adjustment made during the year was a series of small currency devaluations. By yearend 1981, the Bangladesh currency stood devalued to the extent of nearly 19%. The spot selling rate of the dollar finished the year at taka 20.1512 against the dollar.

The electric power situation continued to hinder industrial progress. A Government official stated that industrial units suffered $5.8 million direct losses owing to power failures and load shedding during FY 1980-81. In addition, over 1 million worker hours were lost for the same reason.

Compared with that of previous years, however, the situation was relatively better and improving steadily. The Government was making every effort to increase the generating capacity and to improve the reliability and distribution of the power that was available. The official installed capacity increased to 822 megawatts in June 1980 from 718 megawatts in November 1979.[3] New units were brought online and others were refurbished during 1981 bringing the new capacity even higher, assuming none of the older obsolescent plants were withdrawn from service.

Several new projects were under construction or in late stages of design at yearend 1981. A 50-megawatt unit was to go online at the Kaptai hydroelectric plant (also referred to as Karnaphuli) by yearend 1981. Its completion would bring the plant to a capacity of 130 megawatts.

The Government has signed an agreement with the U.S.S.R. for design and technical assistance worth about $75 million for a gas-fired 210-megawatt thermal station at Ghorasal, about 50 kilometers north of Dacca. The Ghorasal powerplant had a reported capacity of 110 megawatts. One Bangladesh newspaper stated that the U.S.S.R. had signed a similar agreement last year for the same sized unit at the same plant. A 210-megawatt unit would be the largest in the country, and it is doubtful if the Soviet technicians would attempt to erect and finance two such sophisticated units simultaneously. A second 210-megawatt unit may be planned but construction probably would not begin until the first unit was installed.

The United Kingdom was to finance an expansion of the Ashuganj powerplant, about 100 kilometers northeast of Dacca. The project is to be a 90-megawatt combined cycle powerplant. This type of plant uses a natural gas fueled gas turbine to turn the generator and a conventional boiler and turbogenerator powered by the hot exhaust gases from the gas turbine.

Coal-fired units of 110 megawatts at Khulna and 60 megawatts at Chittagong were reportedly under construction with Czechoslovakian aid.

To increase efficiency and lower the overall cost of generation, a foreign contractor was constructing a 239-kilovolt double circuit transmission line for the Government. It will interconnect the gas-fueled eastern transmission network with the oil- and coal-fueled western network. The line will initially operate at 132 kilowatts and will run 153 kilometers from Tongi to Ishurdi and cost about $100 million.

The Government continued the planning for a nuclear powerplant at Roopur in Pabna District. Apparently it has decided on a capacity of 300 megawatts. The French Technocatome reactor was reportedly favored over United States, Canadian, Swedish, or Soviet plants. The restraint was financing, which Bangladesh was requesting from friendly countries and international aid agencies.

The Ministry of Finance estimated exports for FY 1980-81 would hit $758 million. This would represent a 5.5% increase over that of FY 1979-80, but a realistic comparison was difficult because of the currency changes during the year. Minerals contributed no significant part in the export earnings (less than 0.01%). Jute, jute products, tea, leather, and seafood accounted for nearly all of the exports. The export target for FY 1981-82 was proposed at $803 million.

Again in FY 1980-81, the cost of imports far exceeded the value of the exports. Total imports were expected to be about $2,424 million. Raw materials, fuel, and manufactured goods were the major imports. Most of the widening trade deficit was expected to be met by foreign aid.

COMMODITY REVIEW

Japan, the Organization of Petroleum Exporting Countries, and the International Development Bank agreed to help Bangladesh develop the Bakhrabad Gasfield just southeast of the capital city of Dacca. The project-implementing authority will be the newly formed Government-owned Bakhrabad Gas Systems Ltd., a subsidiary of the Bangladesh Oil and Gas Corp. (Petrobangla).

Under the $164 million project, four production wells will be drilled, and the original exploration well will be completed for production as well. As a result of the agreement, the first production well was spudded in May 1981. In addition to the wells, the project includes the following: gas gathering and conditioning facilities; a 177-kilometer, 61-centimeter-diameter pipeline from Bakhrabad to Chittagong; a 60-kilometer distribution system in Chittagong; and a 16-kilometer branch line to a proposed urea fertilizer plant.

At the old Titas Gasfield, the fifth production well was completed in June 1981, bringing the field's production capacity to about 150 million cubic feet per day. Three additional new production wells were to be completed by 1984. The foreign exchange component of the expansion will be financed by a loan from the Asian Development Bank.

In April 1981, the Government commissioned the 30.5-centimeter-diameter, 58-kilometer pipeline connecting the Habiganj Gasfield with the Ashuganj Fertilizer and Chemical Co. The $13 million pipeline was built by the Titas Gas Transmission and Distribution Co., a subsidiary of Petrobangla. It will supply 50 million cubic feet of gas per day to the plant at peak load. A branch pipeline connects with the Titas Gasfield distribution network and will supplement the Titas network with an additional 70 million cubic feet of gas per day. The new Habiganj pipeline complements a 25.4-centimeter branch line already existing from the Titas network to the fertilizer plant.

In addition to the developments described above, Petrobangla has been engaged in a relatively ambitious program of exploration for additional gas reserves and the hope that there is oil in some of the gas-prone geologic structures.

Petrobangla has drilled the most exploration wells in Sylhet and Comilla Districts, but seismic surveys and other exploration were being done throughout the country.

To date, 13 locations have been referred to as gasfields in the Bangladesh press, and four are actually in production. Total reserves have been quoted over a wide range of figures, often on the basis of only one exploration well per field. Over 4.5 trillion cubic feet of gas were generally considered proved, and the figure could go up above 10 trillion if Petrobangla's prognostications turn out to be correct.

The country has consumed increasing amounts of natural gas each year since 1974. Despite the steady increase, the ratio of gas consumed to total recoverable reserves is one of the lowest in the world. On a global basis about 3% of known reserves are consumed each year. In Bangladesh, however, that figure is only 0.01% of the proved reserves.

Bangladesh has been slow to utilize this valuable resource mainly because of a lack of investment captial to develop the fields and distribution network, but also because of the limited number of industries in the country that need gas for their operations.

The Government has now given priority to the development of an expanded pipeline transmission system to bring the gas to market. Through increased exploitation and improved delivery, Dacca hopes to cut back its crude oil and petroleum product import bill by as much as 75% from its present $700 million per year.

Unlike the U.S. use of gas, very little consumption is by the domestic and commercial sectors. The breakdown of gas consumption during FY 1980-81 was as follows: electric power generation, 39%; fertilizer production, 35%; other industrial users, 16%; domestic customers, 7%; and commercial users, 3%. Power, fertilizers, and new industrial users will increase consumption a great deal in the next few years as new projects are completed and begin using relatively more of the natural gas resources.

Currently there is no gas service to the western section of the country, forcing that region to rely on expensive imported oil or coal. Petrobangla was planning a $300 million project to take gas across the Jamuna River, a distributary of the Brahmaputra River, to feed the northwestern region of the country. No starting date has been announced for this project, which would require financing from abroad.

During 1981, there was no progress on a proposal to build an export-oriented liquefied natural gas (LNG) plant or to sell natural gas to India via a large pipeline.

The most important development in the fertilizer industry during 1981 was the long delayed commissioning of the Ashuganj nitrogen fertilizer plant on December 7, 1981. The plant has a design capacity of 242,000 tons per year nitrogen content of urea and cost approximately $400 million. The plant was mainly financed by foreign aid.

Production of urea fertilizer, which was scheduled to increase during the year, was adversely affected by severe mechanical

problems late in 1981 at the old 156,000-ton-per-year nitrogen urea plant at Ghorasal. The urea shortfall had to be covered by increased fertilizer imports.

In a move to gain self-sufficiency in nitrogen fertilizer production, the Government has obtained financing for two ammonium-urea complexes to be located at Chittagong. They will be based on the natural gas reserves being developed at the Bakhrabad Gasfield and will each have a capacity of 262,000 tons per year nitrogen content of urea.

The first unit, with completion planned for yearend 1983, will be financed by the International Finance Corp. and by export credits from Sweden and Denmark. Swedyards Corp. of Sweden will prefabricate the plant, which will be floated to Chittagong for erection. The Karnaphuli Fertilizer Co. has been set up to operate the plant. Formal contracts are to be signed by June 1982. Output is intended for the export market.

The second unit, to be operated by Chittagong Urea Fertilizer Ltd., was expected to be completed 2 years later with output intended for the domestic market. Cost was estimated to be $467 million with the Asian Development Bank supplying most of the foreign exchange credit.

The state-owned Bangladesh Chemical Industries Corp. contracted with a Netherlands company for construction of triple superphosphate granulation equipment at its Chittagong phosphate plant. Construction was scheduled to begin in early 1982. The 25-ton-per-hour unit will be the first such equipment in the country. The plant currently produces fertilizer in powder form which allows a high rate of waste from blowing and from washing by rain.

Plans to build a direct-reduction steel plant at Chittagong made some headway during the year. Talks between the Bangladesh Government and a group of companies led by Metallurgical and Engineering Consultants (Indian Government owned) were reportedly in final stages near yearend.[4] The plant would have a design capacity of 660,000 tons per year and was estimated to cost $180 million. India would supply the iron ore under a 50% buyback arrangement. The Indian company would supply the equipment and construct the plant, while Austrian and Japanese members would provide the technical expertise and much of the capital.

Table 1.—Other Areas of the Far East and South Asia: Production of mineral commodities[1]

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through Aug. 16, 1982.

[2]In addition to the commodities listed, other crude construction materials such as sand and gravel and other varieties of stone presumably are produced, but available general information is inadequate to make reliable estimates of output levels.

[3]Data are for years ending June 30 of that stated.

[4]Reported figure.

[5]Gross production is not reported; the quantity vented, flared, or reinjected is believed to be negligible.

[6]In addition to the commodities listed in the body and footnote 2, molybdenum production was initiated in October 1978, but output is not reported and no basis is available for reliable estimates of output levels.

[7]As reported by Statistical Office of the United Nations in 1979 Yearbook of World Energy Statistics, p. 557.

[8]Data are for the Nepalese fiscal year ending mid-July of that stated.

[9]Figure includes both gem- and industrial-grade garnet; 4,295 kilograms gem quality and 37,000 kilograms industrial quality.

[10]In addition to the commodities listed, iron ore was mined in the past and pig iron was produced at industrial facilities, but the status of these industries under prevailing conditions is not sufficiently clear to allow formulation of reliable estimates of output levels. Similarly, data on output of crude construction materials are not available, and no basis is available to make reliable estimates of output levels.

BRUNEI[5]

Brunei, little known to the world's business community, is one of the world's smallest but wealthiest states. Brunei will become independent from Britain at the end of 1983 and is expected to become a member of the Association of Southeast Asian Nations (ASEAN) by the end of 1984.

The total area of the state is only 5,765 square kilometers bordering on the northern part of Malaysia's Sarawak Province, northwest of Indonesia's Kalimantan (Borneo). The area is 3% cultivated; 22%, industry, urban, pasture, and waste; and 75%, forested. In 1981, the population was estimated at 213,000. Among them, about 52% are native Malays; 24%, Chinese; and 23%, other ethnic minorities. The labor force of the private sector totaled about 32,200 persons, of which about 30.5% were in agriculture; 32.8% in industry, manufacturing, and construction; 33.8% in trade, transport, and service; and 2.9% in other.

Brunei's gross national product (GNP) at current dollars was estimated at about $1.9 billion in 1979.[6] Its per capita GNP was the highest among the Far East and South Asian countries. The Government of Brunei imposes no personal income tax on its residents. The wealthy status of Brunei was derived mainly from its rich oil and natural gas resources.

Brunei's economy is dominated by the oil and gas industry. Over the past years, Brunei's production of oil and natural gas has helped the state to accumulate about $9 billion in foreign reserves and a surplus revenue of $2.8 billion in 1981. The output of oil and natural gas accounted for 88% of Brunei's gross domestic product (GDP), and export earnings of oil and LNG were about 98% of Brunei's total export earnings.[7] In 1981, Brunei was the world's third largest LNG exporter following Indonesia and Algeria. The Government of Brunei, in an effort to control the inflation rate, was using surplus revenues to subsidize the cost of essential foodstuffs as well as gasoline. In addition, salaries and wages were being held steady by the Government, while no tax increases on public utilities were sought.

Brunei imported about 80% of its food requirements. It also imported most of the plant equipment, capital goods, and consumer goods. As a result, most of Brunei's inflation rate was caused by imported goods. In 1981, the inflation rate in Brunei was about 10%. Because of the reduced exports of oil and LNG owing to the lower oil prices, Brunei's real GDP in constant dollars declined 20.9% in 1981.[8]

According to the state financial officer, the export earnings from oil and gas were estimated at $3.5 billion for the state in 1981. Exports of crude oil and LNG were mainly to Japan, while Brunei's imports of foods, capital goods, and consumer goods were principally from Japan, the United States, the United Kingdom, and Singapore.

COMMODITY REVIEW

Petroleum and Natural Gas.—Brunei's production of crude oil and natural gas declined in 1981. The total output of crude oil averaged 176,000 barrels per day in 1981 compared with 240,000 barrels per day in 1980, while the output of natural gas also dropped from 1,060 million cubic feet per day in 1980 to 937 million cubic feet per day in 1981. The sharp drop in the output of oil in 1981 was partially owing to the world oil glut but was largely owing to a depletion policy implemented by the Government of Brunei and the oil producer to reconcile the level of oil production with the economic needs of the Government.

Production of crude oil in Brunei was by Brunei Shell Petroleum Co., Ltd. (BSP). To increase the ultimate recovery of Brunei's oil and gas resource as well as to accelerate its program of nonassociated gas production from the West Fields and the new Gannet Field, BSP has invested a total of about $518 million in 1981 compared with $340 million in 1980 and about $260 million in 1979. Of this total expenditure in 1981, $225 million was for operation and maintenance of the company's production system, and $293 million was for enhanced oil recovery projects in the Southwest Ampa, Seria, and Champion Fields. During 1981, the company also spent about $26 million on exploration and discovered only one new oil well called Ampa West. According to the latest estimates by BSP, Brunei's recoverable oil reserves are about 1.5 billion barrels.[9]

Brunei's production of LNG was by Brunei Liquefied Natural Gas Ltd. at Lumut using the natural gas produced from the fields of the Southwest Ampa, Seria, and Champion Seven offshore complex. Under a long-term contract, Brunei is committed to supplying to Japan about 5.1 million tons of LNG annually. The Japanese importers of Brunei's LNG are Tokyo Electric Power Co., Tokyo Gas Co., and Osaka Gas Co.

According to BSP officials, the company's output will be dominated by gas rather than oil for the coming years. This is because of a long-term commitment to supply LNG to Japan for a 20-year period. To meet this export commitment, the company was accelerating its development program on nonassociated gasfields offshore in the West Fields and the new Gannet Field.

CHRISTMAS ISLAND[10]

Christmas Island is in the Indian Ocean. It is located 360 kilometers south of Java Head. The British Government sovereignty in the island was transferred to the Australian Government on October 1, 1958. The area of the island is only about 135 square kilometers. Estimated population in 1980 was 3,184. The population comprises Chinese, 1,834; Malays, 847; Europeans, 382; and others, 121.

The island's economy has been dominated for decades by the phosphate rock industry. Christmas Island was the second largest producer of phosphate rock in Asia, following China. Its output of phosphate rock accounted for 1% of the world's total in 1981. Production of phosphate rock was formerly by a shared operation between Australia and New Zealand, and the British Phosphate Commission. In 1981, a new company, the Phosphate Mining Co. of Christmas Island, was established to supersede the old British Phosphate Commission for mining and shipping the phosphate. New Zealand, reportedly, is to withdraw from the share operation, but will be allowed to import phosphate from Christmas Island in the future.

The output of phosphate ore peaked in 1974 with 1.8 million tons; since then the annual production has remained steady at about 1.3 to 1.4 million tons. The average P_2O_5 content of phosphate ore produced in 1981 was about 35.1%. In 1981, Christmas Island exported about 1.36 million tons of phosphate rock mainly to Australia and New Zealand. About 150,000 tons of phosphate dust was shipped to Malaysia and Singapore.

The Phosphate Mining Co. of Christmas Island reportedly was considering a $4.5 million[11] investment for further exploration of phosphate on the island. The phosphate reserves on the island were estimated to last for 7 more years at the current rate of production.[12]

Malaysia	111	157
New Zealand	612	602
Singapore	5	19
Total	1,360	1,638

HONG KONG[13]

Economic performance of Hong Kong as measured by the growth in real GDP was strong and impressive in 1981. Its real GDP grew 10.4% in 1981 compared with 9.8% in 1980.[14] The accelerated growth in Hong Kong's economy in 1981 was stimulated mainly by a 10.5% expansion in domestic demand and by a 7.6% real growth in exports. However, Hong Kong's economy suffered a high inflation rate of 15.5% in 1980-81 compared with a 5% average inflation rate in the 1976-79 period.

Hong Kong's GDP in 1973 constant dollars was estimated at $12.5 billion in 1981 compared with $12.7 billion in 1980.[15] In 1981, the mining and quarrying industry contributed less than 0.1% to Hong Kong's GDP. Services and manufacturing remained the dominant sectors, contributing about 85% to the total output of the economy. In 1981, out of a 2.5 million labor force in Hong Kong, only 870 persons were engaged in mining and quarrying. The overall unemployment rate of Hong Kong was at a modest 4.3% in 1981 compared with 3.8% in 1980.[16]

Feldspar, kaolin, feldspar sand (derived from washing kaolin), and cement were the mineral products produced by the mining and quarrying industry in 1981. Opencast methods were used to mine feldspar and kaolin. Most of the feldspar was exported to Taiwan, while kaolin was consumed by local industries. Cement production was by Green Island Cement Co., Ltd., owned 27.6% by the Cheung Kong Holdings, Ltd.; and Hong Kong Cement Manufacturing Co., Ltd. Green Island Cement operated a cement plant at Kowloon Bay with an annual capacity of about 2 million tons. To boost cement output by 14%, the company was building new production facilities that were scheduled for completion by the first half of 1982. Hong Kong Cement operated a 220,000-ton-per-year grinding plant in Hong Kong. A 1.5-million-ton-per-year grinding plant near Tuen Mun, to be operated by

China Cement Corp., was scheduled to come onstream in September 1982. China Cement is owned 60% by Cheung Kong Holdings, 37% by Kaiser Cement Corp. of the United States, and 3% by Japan's Onoda Cement Co.

Hong Kong's steel production was by Shun Fung Iron Works, Ltd., at Junk Bay in Kowloon with an annual capacity of about 100,000 tons. Shiu Wing Steel, Ltd., and Fuji Marden & Co., Ltd., were also locally important steel producers. The annual rolled steel capacity of Shiu Wing Steel was about 29,000 tons; and Fuji Marden, about 10,000 tons. Scrap, pig iron, and steel ingots were imported from China and Taiwan for producing iron and steel manufactures in Hong Kong.

Hong Kong imported most of its requirements for raw materials and semimanufactures to support the export-oriented light and heavy industries. In 1981, Hong Kong's merchandise imports totaled about $25 billion, of which 51.0% was raw materials and food, 26.7% was manufactured consumer goods, 14.6% was plant and capital equipment, and 7.7% was petroleum and petroleum products. In 1981, Hong Kong's total exports including reexports were about $22 billion, of which 97.6% were manufactured goods, and 2.4% were food and agricultural products. Because of the slower growth in total earnings as a result of the worldwide economic recession, Hong Kong's deficit increased to $2.9 billion in 1981 from $2.7 billion in 1980.

Based on the total trade value, Japan, China, the United States, Taiwan, Singapore, and the United Kingdom were the major trading countries for Hong Kong's imports in 1981; while the United States, China, Japan, the Federal Republic of Germany, and the United Kingdom were the major trading countries for Hong Kong's domestic exports and reexports.

Caustic potash	5	170	--	Philippines 150; Taiwan 18; Indonesia 2.
Caustic soda	750	319	--	Philippines 129; China 56; Netherlands 53; Macau 41.
Soda ash	74	7,615	--	Indonesia 7,000; China 246; Taiwan 235.
Stone, sand and gravel:				
Dimension stone, crude and worked	3,043	2,520	13	Taiwan 1,286; Philippines 541; Indonesia 355.
Gravel and crushed rock	110	1,205	--	Indonesia 1,090; China 98; Nigeria 17.
Limestone excluding dimension	85	1	--	All to Canada.
Quartz and quartzite	668	224	--	Thailand 110; Ivory Coast 61; Nigeria 30.
Sand, not metal-bearing	16	48	--	Philippines 39; Republic of Korea 5; China 4.
Sulfur:				
Elemental, all forms	--	15	--	Macau 12; China 3.
Sulfuric acid	21	26	--	Indonesia 11; Philippines 6; China 3.
Talc, steatite, soapstone, pyrophyllite	8,908	5,302	--	Indonesia 4,166; Taiwan 910; Kampuchea 107.
Other:				
Crude	603	212	--	Taiwan 206; China 6.
Ash, slag, dross, not metal-bearing	--	3,400	--	All to Taiwan.
Halogens kilograms	--	281	--	Indonesia 126; Singapore 100.
Oxides, hydroxides, peroxides of strontium and barium	10	2	--	Mainly to Indonesia.
Building materials of asphalt, asbestos and fiber cements, unfired nonmetals	653	473	--	Macau 228; Indonesia 102; China 66.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	373	23	--	All to Macau.
Carbon black and gas carbon	298	779	--	China 400; Indonesia 326; Singapore 51.
Coal, all grades including briquets	--	100	--	All to Macau.
Coke and semicoke	3	10	--	All to China.
Hydrogen, helium, rare gases value	$13,236	$14,532	--	Singapore $12,166; Vietnam $1,194; China $802.

See footnotes at end of table.

Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals	878	1,672	98	China 1,285; Japan 178; United Kingdom 83; Denmark 28.

rRevised.
1Less than 1/2 unit.
2Includes ores and concentrates of vanadium and columbium (niobium).

KAMPUCHEA[17]

Kampuchea had no significant mineral production during 1981, and given the prevailing political, economic, and military situation, there was little likelihood of major development for several years to come.

Except for the main urban center of Phnom Penh and a few other provincial centers, the economic system of the country was reduced to subsistence agriculture and barter.

Military conflict continued with sufficient frequency and vehemence to preclude any realistic plans for industrial rebuilding or the undertaking of new projects of any significant importance.

The goals for 1982 set forth by the Government reflected almost total lack of industrial or mineral production. The only nonagricultural items even mentioned were a planned catch of 60,000 tons of fish, restoration of 1,000 weaving looms, the transport of 385,000 tons of goods, and the generation of 114 million kilowatt-hours of power. The electric power plan for the entire country would equate to one powerplant of 20,000 to 25,000 kilowatts, operat-

ing at normal power factors.

The most significant mineral production may have been salt. In the first quarter of 1981, 10,700 tons of salt was produced, mostly from the evaporation pans in Kampot Province. Yearly production probably increased over the 1980 output.

One small phosphate plant was reported operational in 1981. This was the Mongkol Borei grinding plant, which had produced 700 tons of fertilizer by midyear. The plant grinds the phosphate ore for direct application to crops.

There was a small gem stone mining industry along the Thai-Kampuchea border where it meets the Gulf of Thailand. People from Thailand reportedly were crossing the border to dig for rubies in a gravel deposit. The practice was discouraged in October when a reported 30 Thai gem stone miners were killed by Vietnamese troops.

Some local production of construction materials was underway, but no estimates of production were available.

NORTH KOREA[18]

During 1961-80, Pyongyang claimed that industrial output grew at an average annual rate of 14.5% while output had jumped to 15% to 17% for the 1978-80 period. Based on projections for the 1981 budget, overall economic growth for 1981 was expected to be about 7% compared with an estimated rate of growth of 9.5% for 1980. In the first 3 years of the current economic plan, most of the objectives for industrial construction were completed. By the end of the plan period, there was to be annual production of 56 to 60 billion kilowatt-hours of electricity, 70 to 80 million tons of coal, 16 million tons of iron ore, 7.4 to 8.0 million tons of steel, 1.0 million tons of nonferrous metals, 12 to 13 million tons of cement, and 5 million tons of chemical fertilizers.[19]

The Government of North Korea has never published figures on mineral output; thus, all figures published by the U.S. Bureau of Mines and other organizations concerned with world mineral production are estimates and should generally be regarded as indicative only of the order of magnitude of production of the commodities, not as precisely computed estimates. Estimates for 1977-80 are unaltered from those published in the 1980 edition of this chapter except as noted in the following summary of 1981 production levels; the figures presented are in thousand metric tons unless otherwise specified: aluminum, primary ingot—10; cadmium, smelter output (metric tons)—150; copper, mine output, metal content—15; copper, smelter, primary and secondary—18; copper, refined, primary and secondary—22; gold, mine output, metal content (troy ounces)—160,000; iron ore, marketable, gross weight—8,000 (iron content, 3,200); pig iron—3,000; ferroalloys—120; crude steel—3,500; steel semimanufactures—3,300; silver, mine output, metal content (troy ounces)—1,550,000 (1980 revised to 1,600,000); tungsten, mine output, metal content (metric tons)—2,200; zinc, mine output, metal content—140; zinc, primary metal—120; barite—110; cement—8,000; fluorspar—40; graphite—25; lime—400; magnesite, crude—1,900; magnesite, calcined—800 (1980 revised to 800); nitrogen content of ammonia—450; phosphate rock—550; pyrites—620; salt—570; sulfur—265 (including 255 from pyrites and 10 from metallurgical byproduct); talc—170; coal—45,000 (including 36,000 anthracite, 8,800 bituminous, and 200 lignite); coke—3,000.

North Korea's leading mineral commodity mined is coal, mostly anthracite. The leading metal ore mined is magnetite. Kim Chaek is the largest iron and steel works in North Korea. The country is a significant producer of lead and zinc from mine ore and refined metal from smelters at Munpyong and Nampo. Mine production of magnesite is of world significance. Barite, mined from several locations in the western part of the country, has been exported on a long-term barter basis. Status of a 20,000-ton-per-year aluminum reduction plant installed in the 1970's remains unknown. Official data on mineral and metal production in North Korea are not available from the Pyongyang Government.[20]

The Pyongyang Government does not disseminate trade transaction data. The country's trade data were constructed from data published by North Korea's trading partners that publicly distribute their own trade information.

North Korea's foreign trade was estimated to be as follows, in million dollars:

	Exports	Imports
1970	315	395
1971	316	552
1972	386	617
1973	482	779
1974	700	1,300
1975	755	1,075
1976	555	825
1977	675	781
1978	1,027	950
1979	1,270	1,300

Starting in the mid-1970's, Pyongyang became delinquent in loan payments for plant purchases and, in some cases, was simply unable to make payments. Negotiations with creditors deferred repayment of the outstanding debts to 1983-84, with current installments covering only those loans in arrears and the interest. The country's biggest problem was to earn foreign currency to meet its obligations. In addition, Government trade representatives reportedly have approached foreign companies on setting up joint ventures in North Korea in return for a portion of the goods manufactured.[21]

To attain the output goals of the current economic plan, the Government continued the education and training of personnel in geologic expertise to insure prospecting for expanding the country's mineral reserve base, to discover new mineral deposits, and to develop new mining operations. Special efforts were to be directed to find deposits of metal ores necessary for the iron and steel industry.

Musan iron ore mines, one of the largest iron mines in North Korea, was being expanded to an annual output of 10 million tons. Experimental blasting techniques were being employed at the time to remove overburden to expose the underlying ore body. A long-distance belt-conveyor transport line was constructed, and a new ore dressing plant installed, raising ore dressing capacity 60%.

By 1984, Government plans called for an annual steel output of 7.4 to 8.0 million tons, later to be expanded by the end of the decade to 15 million tons. North Korea's largest integrated steel works are Kim Chaek and Hwanghae. Kim Chaek has two 1,000-cubic-meter blast furnaces and one 1,500-cubic-meter blast furnace. The No. 2 blast furnace was being enlarged to 1,500 cubic meters. Remodeling of the sintering furnace and modernization of the chemical shop was in progress. Conservation techniques were introduced at Kim Chaek to reduce coke consumption and overall fuel consumption. Hwanghae has three 1,000-cubic-meter blast furnaces; overhaul of furnaces Nos. 2 and 3 were completed in 1981. Production of thick plate was increased 1.3 times by changes to the rolling process. Quality control in the thin plate and wire shops raised the product utilization rate. Also, adjustments in the heating cycle reportedly reduced coke consumption per ton of steel produced while raising the fuel utilization level.

The Government's planned objective by the mid-1980's was to produce 1.5 million tons of nonferrous metals annually. North Korea was a prominent producer of lead and zinc; Komdok Mine in Tanchan was the country's largest producer. Both ore and concentrates and refined metals have been exported. Because of higher values, increased tonnages of lead and zinc metal have been exported more recently rather than concentrate. Smelter-refining facilities at Hamhung, Munchon, and Nampo produce lead and zinc metals as well as copper. Additional copper smelter facilities were at Haeju and Tanchon.

The 1984 target for annual cement production was projected at 12 to 13 million tons, which was to be expanded to 20 million tons by the end of the decade. North Korea's largest cement plants were at Chonnaeri, Madong, and Sunchon. Construction of a new plant using modern calcining technology was nearing completion. Size of plant and location were not disclosed.

The Government's target for chemical fertilizer output was projected at 5 million tons per year by 1984. Hungnam Combined Fertilizer Enterprise was the largest producer in North Korea, producing primarily nitrogenous and phosphatic fertilizers.

Lacking oil and natural gas, North Korea had coal as its chief fuel source. The country has coal resources estimated at nearly 10 billion tons; anthracite comprises 70% of the country's resources. The largest anthracite deposit, identified as the Northern Coalfield, is in South Pyongan Province, while 70% of the lignite occurrence is in the east coast district, North Hamgyong Province.

Lignite production was from wholly mechanized mines, while anthracite mines were mechanized to the extent of about 40% to 50%. The mines around Anju in the western coalfield account annually for

about 15 million tons of total production. Numerous small mines account for 20 million tons, and the remainder from mines with annual output capacity over 21 million tons in South Pyongan, North Hwanghae, North Hamgyong, South Hamgyong, and Kowon. Most of the country's output was for domestic consumption; however, some coal was exported. The bulk of the coal consumed was for steam generation and space heating.

The 1984 target output for coal was 70 to 80 million tons, to be increased to 120 million tons by 1989. To attain these goals, Government allocations to the coal sector increased 22% in 1978, 33.3% in 1979, 30% in 1980, and 25% in 1981. During this time, the mining complexes particularly at Anju, Sunchon, Tokchon, and Kujang were expanded, construction of a large colliery at Inpo was completed, and several new coal mines were commissioned.

Table 7.—North Korea: Apparent exports of mineral commodities[1]

(Metric tons unless otherwise specified)

Commodity	1979	1980[p]	Destinations, 1980	
			United States	Other (principal)
METALS				
Aluminum metal including alloys:				
Scrap	--	7	--	All to Italy.
Unwrought	--	73	--	All to Saudi Arabia.
Semimanufactures	316	2,706	--	Do.
Cadmium metal including alloys, all forms	83	55	--	All to West Germany.
Copper metal including alloys:				
Scrap	--	79	--	Do.
Unwrought	23	5	--	All to Japan.
Semimanufactures	11	5	--	All to Saudi Arabia.
Iron and steel:				
Scrap	62	1,727	--	All to Indonesia.
Pig iron, cast iron, powder, shot	51,508	66,018	--	Japan 49,349; Saudi Arabia 14,262.
Ferroalloys	3,117	7,118	--	U.S.S.R. 5,613; Japan 1,505.
Steel, primary forms	113,709	82,947	--	Greece 32,914; Thailand 29,083; Indonesia 13,584.
Semimanufactures:				
Bars, rods, angles, shapes, sections	39,149	92,256	--	Saudi Arabia 90,481; Singapore 655; Colombia 550.
Universals, plates, sheets	41,492	62,782	--	Japan 34,431; Hong Kong 8,691; Dominican Republic 5,793.
Hoop and strip	80	200	--	Sri Lanka 151; Indonesia 30; Saudi Arabia 12.
Rails and accessories	998	1	--	All to Saudi Arabia.
Wire	2,566	1,929	--	Saudi Arabia 1,769; Sri Lanka 100.
Tubes, pipes, fittings	17,398	[2]16,756	--	Saudi Arabia 15,212; Hungary 962; Dominican Republic 522.
Castings and forgings, rough	1,498	180	--	Saudi Arabia 125; Sweden 55.
Lead metal including alloys:				
Scrap	682	NA	--	NA.
Unwrought	27,355	40,719	--	Japan 22,485; West Germany 8,883; France 4,486.
Semimanufactures	4	NA	--	NA.
Silver metal including alloys, unwrought and partly wrought value, thousands	$34,099	$58,373	--	West Germany $49,573; Italy $8,783.
Tin metal including alloys, semimanufactures	--	10	--	All to Indonesia.
Tungsten metal including alloys, all forms	--	1	--	All to Japan.
Zinc:				
Ore and concentrate	64,704	54,488	--	Japan 50,717; Yugoslavia 3,771.
Metal including alloys, unwrought	51,511	49,247	--	Japan 32,110; Hong Kong 7,772; France 4,574.
Other, n.e.s.:				
Ash and residue containing nonferrous metals	4,068	4,955	--	Japan 4,835; Spain 120.
Oxides, hydroxides, peroxides	--	13	--	All to Japan.
NONMETALS				
Abrasives: Grinding and polishing wheels and stones	26	42	--	All to Saudi Arabia.
Barite and witherite	9,521	3,842	--	All to Algeria.
Cement	304,264	571,587	--	U.S.S.R. 481,000; Saudi Arabia 45,227; Hong Kong 24,233.

See footnotes at end of table.

[10]Excludes part of Japanese exports valued at $1,149,000.

LAOS[22]

The year 1981 marked the beginning of a new 5-year plan in the Lao People's Democratic Republic. Some signs of economic growth and agricultural and industrial progress were seen. For the first year in more than a decade, the Laotians were self-sufficient in food supplies. Some surplus agricultural goods were available for export, and some raw materials for industrial production were also produced. There remained an imbalance of trade, however, with the continuing necessity of exporting only raw materials and importing finished goods. The Government reported an overall increase of 8.6% in national production compared with that in 1980.

At yearend, Government officials announced that efforts to develop new mineral deposits would be stepped up. Repair and establishment of industrial enterprises would be increased, including rehabilitation of the remaining equipment at the Nam Ngum hydroelectric plant with the view toward expanding the electric power network. They further stated that repair and development of the tin mining industry at Phontiou would be continued.

Though several industrial plants encountered difficulties, including shortages of raw materials and spare parts, and lack of experience in production management, overall industrial production reportedly increased more than 13% compared with that of the previous year. Production targets for 1981 were fulfilled in the areas of electricity, coal, gypsum, and brick. It was predicted that overall national production in 1982 would increase by 16% with electric power output increasing 1%; tin production, 100%; and construction materials, by 44%.

The problem of inadequate transportation facilities continued throughout 1981. One of the main objectives of the new 5-year plan was the restoration and improvement of most of the old highway system that was destroyed or allowed to become impassible over the past decade. To this end, an agreement was signed in October 1981 between Vietnam and Laos regarding transport issues and goods exchange and payments. Highway No. 9 between Vietnam and the Phin District of Savannakhet Province was being reconstructed and was expected to eventually meet international standards.

The 250-kilometer road should greatly facilitate the transportation of exported minerals and other goods when completed.

The hydroelectric powerplant project at Nam Ngum Dam north of Vientiane continued to be one of the few foreign exchange earners for Laos. The electricity generated reportedly was 807 million kilowatt-hours during 1981, over three-fourths of which was exported to Thailand under a long standing trade agreement. During October 1981, the Electricity Generating Authority of Thailand and Lao State Electricity Enterprise concluded an agreement on a new price for the electricity exported. The new price reportedly was triple the former charges.

For many years, the Nam Ngum powerplant has operated with two functioning generators, Nos. 3 and 4, each with a 40,000-kilowatt capacity. At yearend, it was reported that generators Nos. 1 and 2, each with a 15,000-kilowatt capacity, were ready to be restarted. A fifth generator, previously believed to be under construction, was contracted for during September 1981 with the Southeast Asian affairs division of Switzerland's Motor Columbus Enterprises.[23]

COMMODITY REVIEW

During 1981, the Soviet-assisted survey and exploration of tin resources in the Pa Then Basin continued. The old established tin mine at Phontiou was known to be operating, although production figures have been unavailable for many years. Other tin deposits being surveyed included Mong Seun, Neng, and Boneng. According to the senior Soviet scientist, the occurrences were very rich, the tin content in some places reportedly being as high as 85% cassiterite. By yearend 1981, 70% of the Pa Then Basin had been surveyed. The Soviet survey was scheduled for completion in 1983.[24]

Minerals other than tin have been reported throughout the country and several were believed rich enough to be exploited if capital funding and an assured market were available. Iron deposits were known in several places, the most important being at Lalbouak and Phonlek in Xiang Khoang Province.

Gold deposits were scattered throughout the country. Copper deposits were surveyed in several locations, most notably in the Sing District, Louang Province. Gem stones were reported in Honei Sai District, including a sapphire deposit reportedly being mined with Czechoslovakian assistance. The salt farms, drilled brine wells, in the Thonlaakhom District of Vientiane Province continued in operation and supplied domestic needs.

Construction materials for local use were produced during 1981. The production of brick reportedly was increased 133% over 1980 levels. A protocol and memorandum on the construction of a brick plant, funded by the Soviet Union, were signed in Vientiane in July 1981. According to the agreement, the Soviets were to build a plant with a capacity of 7 to 12 million bricks per year.

The gypsum mining operation at the Dong Hen Quarry in southern Savannakhet Province completed its first full year of operation. The mine, run jointly by Laos and Vietnam, produced 40,500 tons during 1981. Most of the output was exported to Vietnam for use in its cement industry.

Petroleum and gas deposits were reported as being located in the Se Pon District of Savannakhet Province as a result of recent mineral surveying. Also reported were occurrences of oil shale. No plans had been made at yearend to drill or exploit these resources. Laos continued to import the small amount of petroleum products needed from Thailand and Vietnam.

In October 1981, Laos signed an agreement with the U.S.S.R. for the construction of a petroleum pipeline between the Vietnamese districts of Vinh and Vientiane. The Soviets will assist in the technical aspects of the 465-kilometer pipeline.

MONGOLIA[25]

Mongolia covers a land area of 1,564,619 square kilometers; about 89% is pasture or desert wasteland, 10% forested, and less than 1% arable. The population was estimated at 1.7 million in 1981. The total work force was about 315,000, 21.4% was in commerce and services, 21% in manufacturing, 11.9% in agricultural and fishing, 7.2% in construction, and 38.5% in government and public authorities. Mongolia is a member of the Council for Economic Mutual Assistance (CEMA). It is also a member of the Economic and Social Commission for Asia and the Pacific.

The Mongolian economy, traditionally an agrarian economy, was to transform into an

agricultural-industrial economy under the sixth 5-year plan (1976-80). During this period, Mongolia reportedly had invested over $4 billion[26] into its national economy. The Mongolian major industrial center is in Ulan Bator (the national capital) area. Three additional new industrial areas are in Darhan, Erdenet, and Choybalsan. Mongolian main industries include processing of animal products such as leather, woolen textiles, and processed meat, and mining of copper, molybdenum, fluorspar, limestone, construction aggregates, and coal. Most industries in Mongolia remained small in scale, but their share of the country's GNP has increased substantially over the past years. The output of industry accounting for 14% of the country's national income in the 1960's rose to about 30% in 1980.

Under the seventh 5-year plan (1981-85), Mongolia was to accelerate the development of the fuel and power, mining, and building industries; to extend further development of light and food industries; and to emphasize the development of state farms and the extension of the arable area. Under a new agreement signed between Mongolia and the U.S.S.R. in June 1981, the Soviet Union was to continue its technical and economic assistance to Mongolia. In the mining sector, special emphases were placed on the continuing expansion of the Erdenet copper-molybdenum mining and concentrating combine, the continuing exploration of zinc deposits in Salkhit, and the development of fluorspar mining and concentrating capacities at Boro-ondor, in southeastern Mongolia. During the 1981-85 period, Mongolia was also to complete exploration works for the copper-molybdenum deposit at Tsagaan-suvraga, coking coal deposit at Tavan-tolgoy, and the phosphate deposit at Burenhaan.

In 1980, Mongolian merchandise exports were valued at $364.7 million, and imports were valued at $495.9 million. Mongolian exports of food and agricultural products accounted for about 63.3% of total exports, while exports of minerals accounted for about 26.4%. Mongolian imports of machines and equipment, spare parts, and manufactured consumer goods accounted for over 60% of total imports. About 98% of merchandise trade was with the CEMA countries. The U.S.S.R. alone accounted for 80% of Mongolian total exports and accounted for 90% of Mongolian total imports. Mongolia has been suffering from a chronic trade deficit. However, the trade deficit decreased to about $131.2 million in 1980 from $137.4 million in 1979 because of the increased export earnings from minerals in 1980.[27]

COMMODITY REVIEW

Metals.—Mongolian mine production of copper and molybdenum at Erdenet increased substantially in 1981. The copper and molybdenum complex, initiated in 1974, is a 50-50 Soviet-Mongolian venture project. The total investment in the project was estimated at 1 billion rubles (about US$1.5 billion). The output of ore increased to about 8 million tons in 1981 from about 4 million tons in 1979. The output of ore was projected to reach 16 million tons at full capacity when the fourth phase construction work is completed in 1985.[28] The estimated mine output of contained copper and molybdenum in concentrates at Erdenet for 1979 to 1981 and projected 1985 at full capacity is as follows in tons:[29]

	1979	1980	1981	Projected 1985
Copper	21,700	44,000	71,800	118,000
Molybdenum	222	487	661	1,000

The ore reserves at Erdenet were estimated at 300 million tons, averaging 0.85% copper and 0.012% molybdenum. The existing complex at Erdenet comprised an open pit mine, a concentrator, a machine repair plant, and auxiliary shops. The complex employed about 2,600 workers; about 55% of the employees are Mongolian and the remainder are specialists from the U.S.S.R.

Nonmetals.—Mongolian cement production at Darhan was expected to increase by 18% from 177,900 tons reported in 1980. The mine production of fluorspar at Berh and two other mines continued to increase in 1981. All fluorspar produced in Mongolia was exported to the U.S.S.R. Under the seventh 5-year plan, a large fluorspar mining and concentrating combine was expected to be built at the Boro-ondor area, where a promising fluorspar deposit was discovered in recent years. To export the future output of fluorspar from the area to the U.S.S.R., a new branch line from Dalanjargalau to Boro-ondor on the Trans-Mongolian railway will also be constructed.

According to the Mongolian Planning

Commission, the Government planned to undertake further exploration work of the Burenkhan phosphate deposit discovered around Lake Khubsugul in northern Mongolia in 1964. The phosphate ore reserves in the area were estimated at 400 million tons in 1970.[30]

Mineral Fuels.—Coal production in Mongolia remained at the 4.5-million-ton level. Major coal-producing areas are around the Ulan Bator area and in Darhan. During the sixth 5-year plan (1976-80), the Nalayha Kapitalnaya Mine was expanded in the Shariyn Gol area, and a new open pit coal mine with an annual capacity of 2 million tons was being developed at Baga-Nuur. Other promising coal deposits in Mongolia include Tavan-tolgoy, Adunchulun, and Uvdun-khudag. Most of the Mongolian coal is of Permian age. About 80% of the existing coal reserves are black coal, of which about 50% can be used in the coking industry, and about 20% is brown coal.

NEPAL[31]

The mineral industry of Nepal played virtually no part in the country's economy in 1981, employing a total of only 1,200 persons. Nepal's entire industrial sector employed only about 1% of the labor force and contributed about 5% of the GDP. Most industry was oriented to the agricultural sector. The country was highly agricultural in nature and over 90% of the population was dependent on subsistence farming for its survival. Population density on the arable land was very high.

The insignificant mineral production was a reflection of the primitive state of the country's mineral development. There has been very little detailed geological exploration done in the country. However, it has a high potential for both metallic and nonmetallic mineral deposits.

High-grade copper veins have been mined since ancient times by primitive methods. Some of these mines were still worked by individuals or families and produced up to 1 ton of crudely smelted copper each year. The output went to make domestic brass utensils.

The most likely minerals for development in the near term were magnesite, lead-zinc, limestone for cement, and dimension stone. Petroleum deposits were a possibility. Exploration activity and the exploitation of any discoveries could provide employment for a substantial number of workers in the rural areas. Much of the population was only partly employed because the crowded agricultural conditions did not provide full employment on the farms.

GNP at current prices was estimated at $2.4 billion[32] for FY 1980-81.[33]

At constant 1977 prices, the economy grew about 5.5% in FY 1980-81 compared with the small decline experienced the previous year. The rise in GDP was attributable to the good food grain harvest and a generally good yield in the small cash crop harvest.

Inflation continued to be a serious problem, although moderating petroleum prices and easing of the prices of some other basic commodities dispelled thoughts that the economy was out of control. Even so, the official statistics show an increase in the cost of living of over 18%, which, though probably low, was far more realistic than previous official estimates.[34]

To increase industry and commerce, the Government turned more toward the private sector for their development. The Government rice-exporting monopoly was abolished, and trade was restored to private entrepreneurs. A new investment policy was put forth in 1981 by the Ministry of Industry, which would accord a range of generous concessions to foreign investors. Implementing legislation was pending in the National Assembly.

Future industrialization will be controlled by availability of power and the need for a ready market for the products turned out. Since the subsistence farmers have virtually no cash income, there was very little purchasing power to support import-substitution industries. Export-oriented industry faced stiff competition with the Indian market.

One bright spot for Nepal was its huge hydroelectric potential, about 80 million kilowatts of power. This amounts to 2.6% of the world total for a country occupying only 0.09% of the world land area.

During the last several years, demand for electric power, though small by any normal criterion, was well ahead of the installed capacity. Shortages have become acute, and load shedding was common during 1980 and 1981.

Work on several projects was underway during the year, and plans were progressing on others. The Government's main priority in 1981 was to complete construction on the 114-meter-high Kulekhani rockfill dam and powerplant. The dam was completed in June, and the reservoir began filling at that time. An underground powerhouse with two 30,000-kilowatt turbogenerators was completed in September, and the 6-kilometer-long headrace tunnel to the powerhouse was completed in October 1981. Power was generated on a trial basis in November. Commercial power was scheduled to be generated in the first quarter of 1982. Completion of the plant will end load-shedding in the Kathmandu-Hetauda area and also allow long needed overhauls to be performed on the major hydroelectric and diesel powerplants of the system. Total cost of the Kulekhani project was $129 million, mostly financed with foreign aid. A total of 3.5 million workdays of labor were expended on the construction.

The bulk of Nepal's current 68,000 kilowatts of installed generating capacity came from three hydroelectric plants: Trisuli, 21,000 kilowatts; Sunkosi, 10,050 kilowatts; and also the new Gandok, 15,000 kilowatts.

Several other projects have been planned and detailed feasibility studies conducted. The most promising of many was the Marsyangdi project in Tanahu District of Gandaki zone. It was first proposed seriously in 1978. The Federal Republic of Germany completed a feasibility study in 1979, but the plan was delayed until 1981 when the Government decided to go ahead with the design and survey work. Preliminary site preparation work was expected to be started early in 1982. The original capacity was set at 30,000 kilowatts but was later increased to 66,000 kilowatts. Plans called for completion in 1986.

A number of hydroelectric miniplants were being installed in the outlying districts, beyond the planned coverage of the main electric power distribution lines. The plants were engineered for the local stream conditions and range in capacity from a few tens to a few thousand kilowatts. The immediate intention was to furnish power for pumped irrigation wells. Another important purpose was to furnish an alternate domestic source of energy to the nearly universal practice of burning locally cut firewood. In the last few decades, the depletion of the forest cover on hilly terrain has led to serious runoff and soil erosion problems.

Site clearing work got underway on an Indian-aided 14,100-kilowatt hydroelectric plant at Devighat. The Prime Minister laid the cornerstone to the powerhouse in February 1981, and excavation for the headrace tunnels was underway at yearend.

At a more ambitious level, talks were proceeding favorably between India and Nepal on two major hydroelectric power projects—Pancheshwar and Karnali. These multimillion-kilowatt plants have been planned for many years, but progress in arranging for financing, construction, and control of the $1 billion projects has been slow. These plants would not only open up prospects for industrialization of Nepal but also help to tide it over the adverse balance of trade with India by exporting scores of millions of dollars worth of excess power at mutually agreed rates.

COMMODITY REVIEW

Cement.—There was a shortage of cement in Nepal again during 1981. Local production met only 15% to 20% of the domestic demand. The Himal cement plant was the only operating facility and had a capacity to produce about 160 tons per day. In recent years, the actual production has been nowhere near the rated capacity.

The Himal plant received about a $3 million loan from the Government of the Federal Republic of Germany to renovate the equipment and expand the daily capacity to 400 tons by 1984.

A modern 750-ton-per-day dry-process rotary-kiln cement plant has been under construction at Hetauda since mid-1978. It was originally scheduled for completion in 1981, but construction has been very slow and cost overruns very large. Completion of the plant was tentatively rescheduled for mid-1984.

Limestone will be supplied by a quarry at Bhaines in Makwanpur District. The stone will be transported via an aerial tramway to the plant.

In September 1978, India and Nepal agreed to set up a joint-venture company to construct a 1,500-ton-per-day cement plant at Udaypur in southeast Nepal. Plans for the project have progressed unusually slow-

ly. Feasibility studies were completed during 1979, and the findings were being studied during 1980. Construction had not begun at yearend 1981.

Magnesite.—Development work continued on the magnesite mining project. Nepal Orind Magnesite Private Ltd. (50% Nepal Government, 50% Orissa Industries Ltd. of India) was formed to exploit the large, high-grade magnesite deposit at Khari Dhunga 87 kilometers northeast of Kathmandu. Manual mining was underway during 1981, and preparations for large-scale blasting and mechanization were being carried out. Crude ore requires beneficiation by flotation to lower the silica content below 0.3%. Output of the mine will be carried via aerial tramway to Lamo Sangu where a 50,000-ton-per-year dead-burnt magnesite plant was probably already under construction. A planned 20,000-ton-per-year refractory products plant at Birganj had not been started at yearend.

Petroleum and Natural Gas.—Nepal was completely dependent on imports of refined products for its petroleum needs. Funding for petroleum exploration has been included in the Government's 5-year plans, but results have been uncertain or inconclusive until recently. In 1979 and 1980, preliminary aeromagnetic surveys were conducted by French technicians for the Nepal Department of Mines and Geology. The survey indicated the possibility of petroleum deposits in Karnali, Dhaulagiri and Gandaki zones in the hilly western regions.

As a followup in 1981, the Government was reportedly preparing to have a reconnaissance seismic survey conducted in the favorable areas. Should the surveys prove encouraging, exploration drilling would be considered for the 1984-85 period.

Japanese experts have investigated the occurrence of natural gas seeps in water wells in the Kathmandu Valley. About 1,500 million cubic feet of gas was reported in a 4-square-kilometer area at a very shallow depth—300 to 600 meters. A test hole was drilled and was yielding 6,600 cubic feet of gas per day. Tender notices for two additional wells were offered by the Department of Mines and Geology in 1981 but no qualified offers were received. A re-tender notice was published in November.

The projected flow of 21,000 cubic feet per day would meet the fuel requirements of 1,000 to 1,200 households. Even this small amount would be economically significant to the valley where the high cost of petroleum limits its use to a relatively small portion of the population.

SINGAPORE[35]

Singapore remained the most impressive country in economic performance in 1981 among the five members of ASEAN. Singapore's GDP, at 1968 factor cost, grew 9.9% in 1981 compared with 10.2% in 1980. The slower growth in 1981 was caused primarily by the reduced demand for Singapore's exports from overseas, especially from the European Economic Community. In 1981, trade, manufacturing, transport and communication, and finance and business services remained the dominant industries in the Singapore economy. Despite the continuing improvements in productivity, the country's inflation rates remained at the 8% to 8.5% level in 1980-81.

Singapore's mining industry was comprised of a small quarrying sector, several small mineral processing sectors, a very large mineral fuel refining sector, and a rapidly growing offshore oil exploration supporting sector. The activities of petroleum refining alone not only dominated the activities of the mineral industry, but also contributed substantially to the country's economy.

The activity of the quarrying sector was limited to the production of broken granite. In 1981, granite production increased sharply, reflecting strong demand for the product by the domestic construction industry. In 1981, the quarrying activity in Singapore involved 20 firms employing less than 900 workers. Its value added, estimated at $58 million,[36] accounted for 1.2% of Singapore's total value added of industrial production, which was estimated at $4.7 billion in 1981.

In Singapore, mineral processing included production of steel, nonferrous metals, and nonmetallic mineral products. In 1981, there were 17 firms engaged in ironmaking and steelmaking activities with about 1,900 workers. The value added by the iron and steel sector was estimated at $63.1 million and accounted for 1.3% of the total industrial production. The nonferrous metals sector with 12 firms employed about 390 workers. Its value, estimated at $7.8 million, accounted for less than 0.2% of the total industrial production. Nonmetallic mineral production was by 29 firms employing 1,300 work-

ers. Its value, estimated at $28.2 million, accounted for 0.6% of total industrial production.

Singapore's petroleum refining sector is the second largest after electronic products manufacturing, in terms of the value added of industrial production. The sector employed about 3,500 workers. Its value added in 1981, estimated at $841.1 million, accounted for 18% of the total industrial production. Petroleum refining in Singapore was by five refineries with a combined total capacity of 1.1 million barrels per day, which makes Singapore the third largest refining center in the world.

Singapore is the world's second largest offshore drilling rig builder, following the United States. There were five rig building yards operated in 1981. The total revenue from rig building in Singapore was estimated at about $160 million in 1981. During the 1979-80 period, of the total rig orders placed in the world, Singapore won one in every four orders. Singapore is also the leading oil tanker and rig repair and maintenance center in East Asia. In 1980, the total estimated earnings of the five repair yards in Singapore was $440 million, of which about 50% was from repair of oil tankers.

In 1981, Singapore's total export earnings were valued at $21 billion, 8.3% above that of 1980. Total imports were valued at $27.6 billion in 1981, an increase of 15% from that of 1980. As a result, the merchandise trade deficit increased to $6.6 billion in 1981 from $4.6 billion in 1980. The higher trade deficit in 1981 was due mainly to a 37.6% increase in imports of mineral fuels. Imports of mineral fuels valued at $9.4 billion accounted for 34% of Singapore's total imports, while imports of machinery and transport equipment, valued at $7.8 billion, accounted for 28.3%. Exports of mineral fuels, valued at $6.7 billion, accounted for 32% of Singapore's export earnings, while exports of machinery and transport equipment, valued at $5.6 billion, accounted for 26.6%. In 1981, based on the value of two-way trade, the major trading partners of Singapore were Japan, Malaysia, the United States, Hong Kong, the United Kingdom, and the Federal Republic of Germany.

COMMODITY REVIEW

Metals.—*Iron and Steel.*—Singapore's crude steel production was mainly by the National Iron and Steel Mills Ltd. (NISM). Its steelmaking plant at Jurong has five electric arc furnaces. The annual crude steel output capacity was about 380,000 tons. During 1981, the plant was operating near full capacity, and its output of crude steel reached 350,000 tons. The steel products by the company (bars, plate, and angles) were sold mainly to the construction industry. To meet the growing demand for the steel products from the construction industry, the company was ordering a new bar and rod mill from Danieli and Co., an Italian plant designer and builder. NISM was also undertaking a revamp of its melting works by turning the three 40- to 50-ton electromelt furnaces into an ultrahigh power unit and adding water-cooled panels and oxygen burners. As a result, the company's raw steel output capacity is expected to increase to about 550,000 tons per year by mid-1983.[37]

Nonmetals.—*Cement.*—Cement production in Singapore is basically a grinding operation using imported clinker. Combined total annual capacity of the five cement companies was 2.75 million tons at the end of 1980. During the 1980-81 period, the total annual output of cement in Singapore remained at the 1.8-million-ton-per-year level. Annual cement capacity by company and plant location was summarized as follows, in thousand tons:

Company	Location	Capacity at end of 1980
Asia Cement (Singapore) Pte., Ltd.	Jurong	450
Jurong Cement Ltd	do.	600
Pan Malaysia Cement Work (Singapore) Pte., Ltd.	do.	600
Singapore Cement Manufacturing Co.	PSA Gate 1	500
Ssangyong Cement Pte., Ltd	Jurong	600
Total		2,750

The five cement companies employed a total of 450 workers, and the value added in 1981 was estimated at $31 million.

Mineral Fuels.—*Petroleum.*—In 1980, Singapore became the world's third largest refining center and the world's second largest offshore rig building country. Most of Singapore's refineries are located on several small islands near Singapore's main island. In 1981, refining capacity by company and location was as follows, in barrels per day:

Company	Location	1981 capacity
Shell Eastern Petroleum Pte., Ltd.	Pulau Bukon	460,000
Singapore's Mobil Oil Pte., Ltd.	Singapore, Main Island.	200,000
Esso Singapore Pte., Ltd.	Pulau Ayer Chawan.	195,000
Singapore Refining Co. Pte., Ltd.	Pulau Merlimau	170,000
Singapore's BP Refinery Pte., Ltd.	Singapore, Main Island.	27,000
Total		1,052,000

The startup of a $150 million hydrocracker project of Shell Eastern Petroleum Pte., Ltd., to produce middle distillates at a 30,000-barrel-per-day capacity was postponed to the end of 1983, and the total cost of the project was revised to $280 million in 1981. Singapore Refining Co. Pte., Ltd., 40% owned by Singapore Petroleum Co. Pte., Ltd., 30% by Caltex Oil Corp. of the United States, and 30% by British Petroleum Corp., was planning to build a $65 million catalytic reformer unit to produce 12,000 barrels per day of gasoline. The unit was expected to come onstream by the end of 1982. In 1980, Esso Singapore Pte., Ltd., began a $150 million expansion and renovation program, which includes expansion of the lubricating oil plant, a product wharf handling vessels, a crude desalter, and a sulfur recovery plant. The program was expected to be completed in 1982. The $100 million visbreaker project of Singapore's Mobil Oil Pte., Ltd., was completed in 1981. The 50,000-barrel-per-day visbreaker was built by Chiyoda Chemical Engineering and Construction Co.[38]

In 1981, Compagnie Française de Petrol, a French company, joined Singapore's oil drilling and exploration supporting industry. Singapore's manufacture of oilfield equipment supply and drilling operation supporting activities were mainly by the U.S. firms Vetco Singapore Pte. Ltd., Hughes Tool Singapore Pte. Ltd., FMC Corp., Cameron Iron Works Singapore Pte. Ltd., Tri-State Oil Tool Singapore Pte. Ltd., Baker Oil (Far East) Pte. Ltd., Smith International Inc., and Hydnil Co. In oil rig construction, Bethlehem Singapore Pte. Ltd. and Marathon Letourneau Offshore Pte. Ltd. of the United States, Robin Shipyard Pte. Ltd. (Singapore-United States joint-venture company), and Far East-Lexington Shipbuilding Pte. Ltd. and Promet Pte. Ltd. of Singapore dominated the business activities. Repair and maintenance activities of oil tankers and oil rigs were by five repair yards. The Government of Singapore has a stake in four of the five repair yards. Sembawang Shipyard Pte. Ltd., Jurong Shipyard Pte. Ltd., Keppel Shipyard Pte. Ltd., and Mitsubishi Singapore Heavy Industries Pte. Ltd. are Singapore firms, while Hitachi Zosen Robin Dockyard Pte. Ltd. is a Singapore-Japanese private joint-venture company.

Oxide and hydroxide, kilograms	936	907	--	Malaysia 904.
Metal including alloys:				
Scrap	131	139	2	Taiwan 99; Japan 34.
Unwrought and semimanufactures	11,002	14,830	7,967	U.S.S.R. 2,577; Iran 984; Netherlands 775.
Titanium:				
Ore and concentrate	55	59	NA	NA.
Oxides and hydroxides	630	542	--	Malaysia 541.
Metal including alloys, all forms, kilograms	280	14	NA	NA.
Tungsten:				
Ore and concentrate	397	849	--	North Korea 270; Netherlands 270; India 110.
Metal including alloys, all forms	85	119	50	North Korea 40.

See footnotes at end of table.

Table 11.—Singapore: Exports and reexports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
METALS —Continued				
Zinc:				
Ore and concentrate ____ value__	$616	$2,335	__	All to Malaysia.
Oxides and peroxides excluding hydroxides ____	1,306	1,602	__	Japan 1,066.
Metal including alloys:				
Scrap ____	1,018	1,281	__	Taiwan 660; Japan 295.
Unwrought and semimanufactures ____	3,149	5,031	__	Malaysia 3,636; Netherlands 817.
Other:				
Ash and residue containing nonferrous metals ____	12,111	31,761	275	Malaysia 12,504; Brunei 10,074.
Oxides, hydroxides, peroxides ____	93	128	__	Malaysia 63; North Korea 12.
Metals:				
Metalloids ____	29	9	__	Malaysia 4; Taiwan 3.
Alkali, alkaline-earth, rare-earth metals ____ kilograms__	378	14,015	__	Mainly to Malaysia.
Pyrophoric alloys ____	3	6	__	Thailand 4.
Base metals including alloys, all forms ____	(1)	10	__	All to Republic of Korea.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc ____	111	60	__	Malaysia 29; India 11.
Artificial: Corundum __ kilograms__	470	136	__	All to Hong Kong.
Dust and powder of precious and semiprecious stones ____ value__	$11,155	$11,209	__	Malaysia $6,000; Japan $4,000.
Grinding and polishing wheels and stones[3] ____	431	374	__	Malaysia 295.
Asbestos, crude ____	9,535	10,461	__	Malaysia 10,407.
Boron materials:				
Crude natural borates ____	275	657	__	All to Malaysia.
Oxides and acids ____	85	204	NA	Malaysia 64; Brunei 20.
Cement ____	431,989	466,982	__	Malaysia 338,714; Sri Lanka 54,488.
Chalk ____	1,312	2,104	__	Brunei 1,811.
Clays and clay products:				
Crude:				
Bentonite ____	21,600	25,596	__	Philippines 6,972; Brunei 6,028; Thailand 3,395.
Fuller's earth ____	5,066	9,335	__	Malaysia 9,319.
Kaolin (china clay) ____	1,613	1,941	__	Malaysia 1,784.
Other ____	4,641	1,674	__	Malaysia 1,162.
Products:				
Nonrefractory[4] ____	r13,878	18,815	__	Malaysia 16,196.
Refractory including nonclay brick[5] ____	466	609	__	Malaysia 551.
Diamond:				
Gem, not set or strung value, thousands__	$6,322	$5,429	__	Hong Kong $1,866; Belgium-Luxembourg $1,079; Israel $1,072.
Industrial ____ do____	$345	$520	__	Saudi Arabia $138; Israel $136; Belgium-Luxembourg $112.
Diatomite and other infusorial earth ____	60	91	__	Malaysia 70; Philippines 19.
Feldspar and fluorspar ____	4,941	5,850	__	All to Malaysia.
Fertilizer materials:				
Crude:				
Nitrogenous ____	1	8	__	Malaysia 6; Sri Lanka 2.
Phosphatic ____	12,465	18,653	__	Malaysia 14,924; Taiwan 3,302.
Manufactured:				
Nitrogenous ____	36,701	61,916	__	Malaysia 44,035; Bangladesh 8,836.
Phosphatic ____	28,946	73,526	__	Bangladesh 30,426; China 20,300.
Potassic ____	234,167	188,654	__	Malaysia 136,676; Bangladesh 34,177.
Other including mixed ____	122,860	102,547	__	Malaysia 102,028.
Ammonia ____	381	377	__	Malaysia 290.
Graphite, natural ____	75	126	__	Malaysia 122.
Gypsum and plasters ____	1,405	1,251	__	Malaysia 952.
Lime ____	5,574	6,457	__	Malaysia 3,178; Sri Lanka 1,998.
Magnesite ____	102	337	__	Malaysia 256.
Mica, all forms ____	153	274	__	Malaysia 179; Brunei 40.
Pigments, mineral:				
Natural, crude ____	200	49	NA	NA.
Iron oxides, processed ____	427	449	__	Malaysia 424.
Precious and semiprecious stones, natural and synthetic, excluding diamond value, thousands__	$26,390	$27,847	$173	Hong Kong $25,706.
Salt and brine ____	14,131	13,695	__	Malaysia 12,699.

See footnotes at end of table.

Table 11.—Singapore: Exports and reexports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Sodium and potassium compounds, n.e.s.:				
Caustic potash	258	249	--	Malaysia 149; United Arab Emirates 30.
Caustic soda	10,893	3,509	--	Malaysia 1,963; Bangladesh 580.
Soda ash	5,939	13,139	--	Malaysia 9,424; Bangladesh 3,561.
Stone, sand and gravel:				
Dimension stone:				
Crude and partly worked	426	191	--	Malaysia 116.
Worked[6]	1,726	710	--	Malaysia 406; Brunei 76.
Dolomite, chiefly refractory-grade	2,494	40	--	Papua New Guinea 30.
Gravel and crushed rock	4,315	2,985	--	Malaysia 2,383.
Limestone except dimension	666	627	--	Malaysia 515.
Quartz and quartzite kilograms	3,484	183	NA	NA.
Sand excluding metal-bearing	1,355	583	--	Australia 91; Philippines 91; Malaysia 50.
Sulfur:				
Elemental:				
Other than colloidal	5,190	3,130	--	North Korea 1,972; Malaysia 1,141.
Colloidal, sublimed and precipitated	16,068	17,451	--	Malaysia 14,170; North Korea 2,420.
Dioxide kilograms	420	292	NA	NA.
Sulfuric acid	804	782	NA	Sri Lanka 357; Malaysia 323.
Talc, steatite, soapstone, pyrophyllite	807	554	--	Malaysia 497.
Other:				
Crude	64,165	49,207	--	Malaysia 44,505.
Slag, dross, similar waste, not metal-bearing	13,858	13,247	--	Japan 11,400.
Oxides and hydroxides of magnesium, strontium, barium	14	11	--	Malaysia 10.
Bromine, iodine, fluorine value	$12,812	$16,813	--	Brunei $7,000; Malaysia $7,000; Burma $2,000.
Building materials of asphalt, asbestos and fiber cements, unfired nonmetals	17,973	17,174	--	Malaysia 7,355; Sri Lanka 6,782.
MINERAL FUELS AND RELATED MATERIALS				
Asphalt and bitumen, natural	26,478	7,656	--	Malaysia 4,185; Burma 1,730.
Carbon black	690	687	--	Malaysia 436; Thailand 221.
Coal, all grades including briquets	1,038	1,588	--	Malaysia 991; Thailand 272.
Coke and semicoke	8,242	8,486	--	Malaysia 8,233.
Hydrogen, helium, rare gases value, thousands	$1,161	$1,498	--	Malaysia $461; Brunei $404; India $181.
Petroleum:				
Crude and partly refined thousand 42-gallon barrels	907	552	--	Malaysia 549.
Refinery products:				
Gasoline:				
Aviation do	390	511	--	Australia 133; New Caledonia 95; New Guinea 86.
Motor do	13,561	13,748	--	Malaysia 4,307; Thailand 1,889 New Zealand 1,564.
Jet fuel do	17,119	15,606	1,623	Japan 3,771; Hong Kong 2,387; New Zealand 1,747.
Kerosine and white spirits do	6,829	7,499	--	Hong Kong 2,192; Malaysia 1,435; India 1,410.
Distillate fuel oil do	30,435	33,282	--	Malaysia 8,229; Thailand 5,394; India 4,294.
Residual fuel oil do	56,929	62,108	1,827	Hong Kong 24,076; Japan 11,529; Australia 6,805.
Lubricants do	3,791	3,532	--	Thailand 830; Malaysia 804; Saudi Arabia 330.
Mineral jelly and wax do	345	263	--	Japan 54; Malaysia 25; Thailand 24.

See footnotes at end of table.

Table 11.—Singapore: Exports and reexports of mineral commodities —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
MINERAL FUELS AND RELATED MATERIALS —Continued				
Petroleum —Continued				
Refinery products —Continued				
Other:				
Naphtha, thousand 42-gallon barrels	18,779	19,167	804	Japan 12,108; New Zealand 2,577; Taiwan 1,281.
Nonlubricating oils, do.	580	472	--	Sweden 239; Thailand 110; Malaysia 72.
Petroleum coke, do.	84	21	--	Malaysia 8; Brunei 7; Oman 6.
Liquefied petroleum gas, do.	r1,024	1,699	--	Hong Kong 586; Thailand 494; Malaysia 462.
Bitumen and bituminous mixtures, n.e.s., do.	1,423	1,192	--	Australia 261; Malaysia 217; Bangladesh 128.
Unspecified, do.	r6,531	978	--	Japan 357; Philippines 328; Malaysia 103.
Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals	r4,426	4,439	--	Taiwan 2,555; Kampuchea 1,000.

rRevised. NA Not available.
[1]Less than 1/2 unit.
[2]May include platinum-group metals.
[3]Excludes quantity valued at $14,565 in 1979 and $1,868 in 1980.
[4]Excludes quantity of ceramic building bricks valued at $60,488 in 1979 and $75,191 in 1980.
[5]Excludes quantity of refractory bricks valued at $32,093 in 1979 and $299,365 in 1980.
[6]Excludes quantity valued at $115 in 1979 and $467 in 1980.

Table 12.—Singapore: Imports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1979	1980	Sources, 1980	
			United States	Other (principal)
METALS				
Aluminum:				
Ore and concentrate	11,000	400	--	All from China.
Oxides and hydroxides	7,583	8,185	216	China 5,666; Japan 2,117.
Metal including alloys:				
Scrap	334	433	--	Malaysia 342; Brunei 78.
Unwrought and semimanufactures	28,739	29,567	4,406	Australia 3,990; Japan 3,725; Malaysia 3,109; Sweden 2,106
Antimony metal including alloys, all forms	14	51	--	China 50.
Arsenic: Natural sulfides	2	10	NA	NA.
Beryllium metal including alloys, all forms, kilograms	26	20	NA	NA.
Bismuth metal including alloys unwrought, do.	2,310	45	NA	NA.
Cadmium metal including alloys unwrought	5	3	--	All from Australia.
Chromium oxides and hydroxides	163	307	78	Japan 86; Netherlands 38; Finland 36.
Cobalt:				
Oxides and hydroxides	25	3	--	Japan 2.
Metal including alloys, unwrought	2	7	--	Netherlands 4; Japan 3.
Columbium and tantalum metals including alloys, all forms, kilograms	r140	34	NA	NA.
Copper:				
Ore and concentrate	1	NA	--	NA.
Matte, value	$40	--		
Metal including alloys:				
Scrap	3,060	5,026	--	Malaysia 4,652.
Unwrought and semimanufactures	23,832	31,716	1,000	Japan 18,000; Australia 5,075; New Zealand 798.

See footnotes at end of table.

(Metric tons unless otherwise specified)

Commodity	1979	1980	Sources, 1980	
			United States	Other (principal)
METALS —Continued				
Indium metal including alloys unwrought ---------- kilograms	20,027	20	--	All from United Kingdom.
Iron and steel:				
Ore and concentrate	6,781	9,605	--	Malaysia 9,590.
Metal:				
Scrap	109,055	172,028	47,231	Australia 114,419.
Pig iron including cast iron	79,862	31,490	16,532	China 6,887; Australia 6,492.
Sponge iron, powder, shot	1,266	1,694	1,065	Japan 206.
Ferroalloys:				
Ferromanganese	6,328	3,534	--	Australia 3,154.
Other	1,409	4,878	50	Australia 3,236; Taiwan 598.
Steel, primary forms	110,990	96,377	43	Spain 30,735; Australia 20,351; Japan 15,203.
Semimanufactures:				
Bars, rods, angles, shapes, sections	246,862	444,187	4,530	Japan 252,784; West Germany 35,150; Mozambique 31,110.
Universals, plates, sheets	611,132	656,724	5,218	Japan 473,828; Republic of Korea 84,009.
Hoop and strip	30,545	24,991	842	Japan 18,227; Republic of Korea 2,661; West Germany 1,323.
Rails and accessories	34,010	25,651	32	Poland 14,891; Japan 7,906.
Wire	18,122	18,858	137	Japan 7,711; China 7,079.
Tubes, pipes, fittings	291,030	338,602	14,627	Japan 280,750; Malaysia 7,899; India 6,652.
Castings and forgings, rough	10,246	10,691	3,020	Japan 5,848; Australia 1,401.
Lead:				
Ore and concentrate	114	190	--	Thailand 114; Australia 54.
Oxides and hydroxides	497	554	--	Australia 429; West Germany 86.
Metal including alloys:				
Scrap	235	214	--	Malaysia 80; Brunei 74.
Unwrought	4,373	8,095	1	Australia 4,435; Burma 1,861; Malaysia 725.
Semimanufactures	911	856	4	Australia 653.
Magnesium metal including alloys, all forms	22	15	9	Australia 3.
Manganese:				
Ore and concentrate	33,517	60,468	--	NA.
Oxides and hydroxides	2,767	3,319	13	Ireland 1,566; China 1,047.
Mercury ---------- 76-pound flasks	116	90	34	Japan 28.
Molybdenum metal including alloys, all forms	4	3	2	NA.
Nickel metal including alloys:				
Scrap	55	237	--	Malaysia 182.
Unwrought and semimanufactures	300	1,357	19	France 1,125.
Platinum-group metals including alloys, unwrought and partly wrought troy ounces	5,466	19,290	675	Australia 3,794; West Germany 2,283.
Silver:				
Ore and concentrate[1] -- kilograms	10	434	149	Taiwan 204; United Kingdom 54.
Waste and sweepings[1] value, thousands	$138	$146	--	All from Malaysia.
Metal including alloys, unwrought and partly wrought troy ounces	809,169	741,910	57,068	Australia 208,240; Switzerland 140,113; West Germany 133,297.
Tin:				
Ore and concentrate	4,227	3,370	--	Burma 1,496; Thailand 1,404.
Oxides and hydroxides	2	6	4	NA.
Metal including alloys:				
Scrap	156	1,032	--	Australia 901; Malaysia 75.
Unwrought and semimanufactures	2,013	2,782	5	Malaysia 2,100.
Titanium:				
Ore and concentrate	r1,176	541	--	Malaysia 400; Australia 141.
Oxides and hydroxides	4,338	3,768	256	Japan 1,544; West Germany 612; United Kingdom 551.
Metal including alloys, unwrought ---------- kilograms	1,423	684	314	Japan 162.
Tungsten:				
Ore and concentrate	486	1,346	2	Burma 947; Thailand 222.
Metal including alloys, all forms	76	160	19	Republic of Korea 56; Japan 21; Austria 19.

See footnotes at end of table.

Commodity	1979	1980	Sources, 1980	
			United States	Other (principal)
METALS —Continued				
Zinc:				
Ore and concentrate	10	139	--	Burma 71; Australia 51.
Oxides and peroxides excluding hydroxides	397	531	18	United Kingdom 101; Canada 100; China 97.
Metal including alloys:				
Scrap	445	351	--	Malaysia 244; Canada 49.
Unwrought and wrought	18,038	18,482	303	Canada 8,490; Australia 4,246; China 1,362.
Zirconium ore and concentrate	377	1,102	--	Australia 1,021.
Other:				
Ash and residue containing nonferrous metals	104,240	114,052	--	Japan 100,935; Malaysia 12,501.
Oxides, hydroxides, peroxides	670	754	32	China 247; Norway 161; West Germany 94.
Metals:				
Metalloids	26	92	(2)	Japan 71; India 18.
Alkali, alkaline-earth, rare-earth metals	64	134	13	Japan 59; France 52.
Pyrophoric alloys	81	110	--	China 93; Hong Kong 10.
Base metals including alloys, all forms	8	13	--	United Kingdom 5.
NONMETALS				
Abrasives, n.e.s.:				
Natural: Pumice, emery, corundum, etc	293	298	114	India 54; Australia 51; Japan 29.
Artificial: Corundum -- kilograms	--	68	NA	NA.
Dust and powder of precious and semi-precious stones -- value	$406,358	$8,874	$874	West Germany $8,000.
Grinding and polishing wheels and stones[3]	1,456	2,062	62	Japan 731; China 514; Italy 248.
Asbestos, crude	12,008	16,661	1,748	Australia 6,198.
Barite and witherite	50,774	66,343	--	Thailand 64,574.
Boron materials:				
Crude natural borates	628	748	748	
Oxides and acids	602	175	155	NA.
Cement -- thousand tons	1,682	1,831	(2)	Japan 1,232; Republic of Korea 377.
Chalk	3,741	8,854	--	Malaysia 6,242; United Kingdom 1,584.
Clays and clay products:				
Crude:				
Bentonite	46,377	46,778	46,288	China 250.
Fuller's earth	3,187	4,856	424	West Germany 3,870.
Kaolin (china clay)	5,983	5,286	20	Malaysia 2,861; Japan 1,423; United Kingdom 832.
Other	18,307	13,753	560	Malaysia 7,662; Japan 2,807; China 1,141.
Products:				
Nonrefractory[4]	76,866	96,682	27	Italy 46,333; Japan 12,257; Spain 6,366.
Refractory including nonclay brick[5]	7,067	13,181	487	United Kingdom 5,899; Australia 3,186.
Diamond:				
Gem, not set or strung value, thousands	$36,043	$69,415	$1,914	Israel $24,285; Belgium-Luxembourg $19,082; India $14,706.
Industrial -- do	$2,015	$4,579	--	Israel $2,027; Belgium-Luxembourg $1,602.
Diatomite and other infusorial earth	657	619	356	China 130; Philippines 69.
Feldspar and fluorspar	5,829	8,312	--	India 6,972.
Fertilizer materials:				
Crude, phosphatic	17,090	20,393	--	Christmas Island 18,208; India 683.
Manufactured:				
Nitrogenous	67,219	52,169	13	U.S.S.R. 16,629; Italy 9,000; Republic of Korea 7,253.
Phosphatic	53,217	36,977	36,157	Israel 360.
Potassic	297,644	307,627	--	Canada 126,290; West Germany 51,682; Israel 46,459.
Other including mixed	119,008	139,747	21,171	West Germany 75,575; Belgium-Luxembourg 25,589.
Ammonia	542	437	114	Malaysia 134; Netherlands 48; West Germany 44.
Graphite, natural	519	572	102	China 271; Republic of Korea 140.

[1]May include platinum-group metals.
[2]Less than 1/2 unit.
[3]Excludes quantity valued at $43,656 in 1979 and $31,291 in 1980.
[4]Excludes quantity of bricks and baked clay valued at $524,865 in 1979 and $456,753 in 1980.
[5]Excludes quantity valued at $5,984,544 in 1979 and $8,297,684 in 1980.

SRI LANKA[39]

Sri Lanka was a major world producer of colored gem stones in 1981 and an important producer of heavy mineral beach sands. The only other minerals of local importance were graphite, mica, feldspar, apatite, limestone, and several of the clays. A copper-iron deposit was reported but not exploited. The mineral industry generally produced about 3% to 4% of the total value of exports; most of the mineral portion was from gems and surplus petroleum refinery products.

The Government that came to power in mid-1977 began a comprehensive program to reform the economy and to accelerate economic growth. It has taken steps to free the economy from excessive controls, to provide industries with increased incentives to produce, and to reduce consumer subsidies. The measures included unification and floating of the exchange rate; removal of exchange controls on imports; liberalization of import licensing; elimination of Government import monopolies; lifting of most price controls; guaranteed prices for certain agricultural commodities; reduction of consumer subsidies including those on rice, sugar, flour, and petroleum products; increased interest rates to promote savings; and encouragement of foreign and domestic investment.

The new fiscal program was initially very successful, but the rate of growth slowly declined. The real growth in GNP jumped from a range of 1% to 2% in the early 1970's to 8.2% in 1978, 6.3% in 1979, and 5.6% in 1980. The estimated growth had dropped to about 5.0% in 1981. The main problem apparently was that the Government was spending far more than its income, mostly on three big development projects that were turning out to be much more expensive than originally planned. By 1981, the total Government expenditures were running more than twice the total revenue.

Fiscal problems became acute as large amounts of imports were needed for the development projects, but exports, mainly agricultural products, failed to increase at the same rate. The trade deficit increased from $477 million in 1979 to $985 million in 1980. In the first 9 months of 1981 the deficit increased a further 10% over the 1980 level.

Various international funds, agencies, and individual countries have been supplying aid to finance the huge deficits and trade imbalances. The world economic situation, however, has made it more difficult to obtain the large aid grants needed to pay for the deficits. Funds that were available did not buy as much as world prices increased and the value of the Sri Lanka rupee dropped over 22% against the dollar and nearly 32% against the Japanese yen, from 1977 through 1981.

By the end of 1980, the Government had begun a series of changes and cutbacks designed to bring the economic situation back under control. Government expenditures were reduced significantly and domestic income was increased by the imposition of higher taxes. Capital expenditures on the huge Mahaweli River diversion project and the urban redevelopment project were scaled down in 1981, and the cutbacks continued in the planned fiscal year 1982 budget.

A possible indication of the effects of the new fiscal restraint was a reduction of the inflation rate from the 31% to 35% level in 1980 to about 18% in 1981.

The 147,000-ton-per-year nitrogen naphtha-based ammonia-urea plant at Sapugaskanda was finally commissioned in March 1981 after several months of trial production. The plant is to produce over 1,000 tons per day of urea for domestic consumption. It was designed and built by Kellogg Overseas Corp. and should relieve the country of the burden of importing all of its nitrogen fertilizer needs.

A large deposit of apatite was discovered in the early 1970's at Eppawala in North Central Province. Proved reserves are 25 million tons of ore grading between 34% and 38% P_2O_5. Although the ore is high in phosphorus content, its solubility is very low and it contains high levels of impurities, especially chloride. Normal methods of calcination and scrubbing do not produce a product suitable for making phosphoric acid. The search for a suitable process for economically removing the highly corrosive chloride continued during the year. A small grinding plant currently operates at the Eppawala deposit. The untreated ground apatite was used for direct crop application where farming conditions would tolerate the impurities. Only a few thousand tons was used in this manner each year.

Except for diamond, emerald, and opal, nearly all the other varieties of gem stones have been produced in Sri Lanka since ancient times. All mining is in riverbed gravels or former channels now covered by recent alluvium. The traditional mining method was for one or two workers to dig a pit in a likely looking deposit and manually pan for gem stones.

Major changes took place in the industry in 1981. Modern excavating equipment was brought into play by several companies that were awarded mining rights in the areas to be flooded by the Mahaweli River diversion program. Since about 13,000 hectares of potential gem-bearing gravels would be permanently inundated, the Government decided to invite foreign companies to bid for the mining rights and extract what gems could be obtained before the waters began to rise. The Government-owned State Gem Corp. had the option to buy all stones, and profits would be shared on an equal basis.

Neither weight of production nor value of the gem output was available in 1981. It was speculated, however, that over 1 million carats of rough stones may have been removed by the accelerated mining methods in 1981.

Sri Lanka was a major producer of high-grade natural graphite, ranking among the top 10 world producers. Total shipments of graphite in 1981 were valued at $4.5 million, a decrease of 6% in value compared with 1980 statistics. This was the third consecutive year that production has declined. To increase production, the Asian Development Bank approved technical assistance for a graphite mining project. The assistance was to formulate a program that would help produce an additional 17,000 tons of graphite ore annually. It will involve the rehabilitation and expansion of existing mines of the State Mining and Mineral Development Corp., the reopening of local abandoned mines, and the exploration and evaluation of the country's graphite potential.

Oil exploration activity was stepped up in Sri Lanka after the September 1980 Indian announcement of an oil strike in Cauvery Basin on the Indian side of Palk Strait. Gravity, magnetic, and seismic surveys were begun in late 1980 by Prakla Seismos GmbH of the Federal Republic of Germany. The surveys covered mostly Blocks 1, 2, 10, and 11 along the northwest quadrant of the island and were completed in January 1981.

Interpretation of the survey data resulted in Cities Service Sri Lanka Petroleum Corp. (Citco) choosing a drilling site, Pearl-1, in Block 11 south of Mannar Island. Drilling began on September 28, 1981, and proceeded to 3,048 meters before the well was abandoned as a dry hole. Citco then moved the jack-up drilling rig Apollo 1 to the Palk Strait, a few kilometers from the successful Indian well. The new well, Pedro 1, was drilled to 1,740 meters where it encountered what was believed to be basement rock. There was some question whether this meant no oil or whether the rock acted as a lid over a large oil reservoir. At yearend, rock samples were being analyzed to deter-

mine if the well should be drilled deeper.[40]

Several other companies hold exploration or production-sharing agreements with Ceylon Petroleum Corp. (CPC) for the offshore areas surrounding the island. Any of these could begin drilling operations in 1982 if the survey results show favorable conditions in their areas.

Discovery of even modest amounts of oil could be very important to the Sri Lanka economy. The country produced no oil or gas domestically. The cost of crude petroleum imports has become a major economic problem, increasing from $121 million in 1975 to $442 million in 1980. Expenditures for 1981 were expected to be about the same for crude oil, but refined product costs were projected to increase about 40% in 1981. In past years, some of the imported petroleum was exported in the form of bunker fuel oil, jet fuel, and naphtha. This changed in 1981 with the opening of the fertilizer plant, which uses naphtha as raw material. Increased amounts of fuel oil were scheduled for use in electric power generation as well.

Caltex Petroleum Corp. (United States) has proposed investing in a joint venture to take over the distribution of liquefied petroleum gas (LPG) in Sri Lanka. CPC produces 7,000 tons per year at its refinery in Sapugaskanda near Colombo, but demand exceeds current supply. Caltex felt that with increased storage facilities considerably more LPG would be distributed. The refinery capacity could be increased easily to 11,000 tons per year.

CPC reportedly let a contract to Ocean Resources Div. of Williams Bros. Engineering Co. (United States) for consulting services on installation of a single point mooring facility. The facility would transfer crude oil to the refinery at Sapugaskanda, which currently receives its crude oil supplies via transfer lightering barges.[41]

Coastal Corp., a Texas-based oil company, was to obtain a 25-year lease for the 1-million-ton oil storage tank farm at China Bay, Trincomalee. A new company, Coastal (Lanka) Ltd., is to be set up to recondition and operate the 99-tank facility, which was built by the British during World War II and had been unused probably since 1964. The facility would be used as a deepwater export terminal for crude and refined products.

rRevised. NA Not available.

[1]The quantities reported in this table are the total quantities reported in the official trade statistics of Sri Lanka; however, additional, unreported quantities imported by Sri Lanka are indicated in the official trade statistics only by value and have generally not been reported in this table.

[2]Less than 1/2 unit.

[3]Excludes unreported quantity valued at $51,841 imported from the United Kingdom in 1979 and unreported quantity valued at $26,736 imported in 1980.

[4]Unreported quantity valued at $41,226.

[5]Excludes unreported quantity valued at $400,326.

[6]Excludes unreported quantity valued at $2,002.

[7]May include dust and powder of diamond.

[8]Excludes unreported quantity valued at $441,985 in 1979 and $210,746 in 1980.

[9]In 1979, the quantity reported imported was valued at $593, and an unreported quantity was valued at $4,224; in 1980, the quantity reported imported was valued at $1,451, and an unreported quantity was valued at $5,603.

VIETNAM[42]

In 1981, Vietnam produced a small amount of several minerals including coal, phosphate, tin, chromite, antimony, iron ore, clays, building stone, manganese, cement, salt, graphite, and zinc. Natural gas was produced and used industrially for the first time. Coal, phosphate, tin, and chromite were produced in sufficient amounts that a surplus was available for export. There were also known deposits of bauxite, lead, silver, and titanium minerals, but their status was unknown. In past years, the mining sector accounted for up to 5% of the GNP, but Vietnam releases official figures on only a few selected commodities and seldom gives sector totals. Vietnam was not an important world producer of any mineral commodity in 1981.

Economic conditions continued to decline in 1981. Press comments, both Vietnamese and foreign, paint a picture worse than 7 years ago when the United States ended its involvement. Apparently massive Soviet aid, estimated between $3 million and $6 million per day, has not been sufficient to maintain even a Spartan standard of living for most of the population. Several reasons have been given for the problems, with high Government officials admitting that corruption, bribery, and mismanagement were prominent contributors to the country's woes. The policy of maintaining a 1-million-person military force, many of them in active conflict in Kampuchea, was extremely expensive and consumed both workers and resources that could be used domestically to help in industrial and agricultural development.

Favorable weather and Government-granted economic incentives to farmers combined to produce a record food grain harvest of over 15 million tons in 1981. Despite the good crop, total food available was not enough to feed the 55 million population. Large amounts of food had to be imported during the year, and the monthly food ration remained at a bare subsistence level. The target for 1982 food production was set at 16 million tons.

In the industrial sector, the Government gave priority to projects directly benefiting agriculture such as electric power, irrigation, coal and fertilizer production, and the transportation system. The big Pha Lai thermal powerplant was being built with Soviet aid. Its planned first-stage completion date was late 1983, and if attained, its power output would help reduce critical shortages in the Hanoi area.

In mid-1981 the state bank devalued the dong. The new equivalence was dong-9.09=US$1.00. In addition the Government banned circulation of foreign currency and imposed stricter controls on gold, silver, platinum, and diamonds. The measures failed to strengthen the dong, and on the black market the U.S. dollar was reportedly worth dong60.[43]

Major economic and technical agreements were signed with the Soviet Union during 1981. The Soviets are to assist with more than 100 industrial projects designed to increase production of electricity, fertilizers, etc. Trade between the two countries would also be greatly increased.

Official trade figures were not available, but a partial list of exports to four market economy countries showed about $50 million in 6 to 10 months of 1981 versus $51 million in the same period in 1980. Imports from the same period and countries showed a considerable rise from $138 million in 1980 to $213 million in 1981. To cut down trade deficits, the Vietnamese were striving to increase their exports wherever possible. Agricultural products and handicrafts were to furnish most of the increase. The most likely areas in the mineral sector would be coal, phosphate, and tin.

COMMODITY REVIEW

Metals.—*Tin.*—The Vietnamese, with technical and economic aid from the Soviet Union, were in the middle of modernizing and expanding their small tin industry. At least two mining areas were operating, and one was in the earliest stages of construction during 1981.

A new mining area was nearly ready to open at the old Tinh Tuc Mine in Cao Bang Province, after 3 years of construction. The mining and concentrating system, formerly manual, was mechanized and automated, and a new ore separation plant was built. The old operation was continued without interrupting the normal production rate.

The new ore processing plant will be able to recover the finer grained ore particles, formerly lost, and will recover 96% of the tin present versus 83% from the old facility. The new mechanization at the mine will presumably allow an increase in the ore production rate was well.

In Ha Tuyen Province, the Son Duong mining area was nearly ready to produce ore at two mines designed by the nonferrous metallurgical institute of the Ministry of Engineering and Metals. The mines were referred to as Khuon Phay and Bac Lung and required a capital investment of about $6 million. It was believed that Khuon Phay would eventually have a capacity of 300,000 cubic meters of ore per year. The ore grade was not revealed, but that amount of ore in neighboring countries could yield over 1,000 tons of concentrate. Construction was apparently still underway at Bac Lung. The Vietnamese press stated that after completion the Bac Lung mining zone would have a tin ore output similar to that of the Tinh Tuc Mine.

Construction of support facilities was underway at Qui Hop tin mine, also spelled Quy Hop, in Nghe Tinh Province. Construction of the mine was planned to begin in 1982 as part of the Government's industrial goal. Completion and successful operation of these new projects could greatly increase the country's tin output. Vietnam's tin consumption is not large and most of the production would be exported to furnish much needed foreign exchange.

Nonmetals.—*Cement.*—One of Vietnam's most important industrial projects was partially completed during 1981. On December 22, 1981, the first of two rotary kilns was fired on a trial basis at the Bim Son cement plant, and a 70-ton test batch was ground and bagged before the end of the year. The No. 1 production line will have a capacity of 600,000 tons per year of high-quality cement, urgently needed by the Vietnamese economy. The plant had been a showpiece of Russian-Vietnamese industrial cooperation since construction began 46 months before. The December 1981 completion date was

only accomplished by many months of maximum round-the-clock effort on the part of thousands of laborers and virtually every skilled worker who could be pressed into service. The original planned startup date was in 1980.

Reading between the lines of the Vietnamese press communiques, it was apparent that progress on the No. 2 production line, a duplicate of the No. 1 kiln, was seriously affected by the catchup work on the first kiln. The No. 2 kiln's new planned completion date was set for November 7, 1982. In addition, it was by no means certain whether the system that will supply raw materials to the kilns was ready to begin to operate in a continuous and reliable manner.

As late as October 1981, top Government officials were referring to plans insuring adequate electric power supplies, and that plans must be drawn up for the timely delivery of raw materials and transport of finished cement from the factory. A lack of reliable transport facilities has plagued the country for years and has been a major constraint to the timely completion of ambitious industrial projects. Such candid remarks as were made in late 1981 could indicate that this plant is a long way from producing 600,000 tons of cement in 1982.

Two other large rotary kiln cement plants were under construction during 1981. Both were originally scheduled for completion before yearend 1981. One was a Danish- and Japanese-aided plant at Hoang Thach, southeast of Hanoi; the other was a French-aided expansion of the old Ha Tien cement plant, 240 kilometers west of Ho Chi Minh City. Each plant will have more than a 1-million-ton-per-year capacity.

There was virtually no publicity about either of these projects during 1981. It was very likely that skilled workers and possibly equipment were borrowed from these construction sites to complete the Bim Son plant. Construction progress was probably minimal during the year, and completion of the plants was not expected until well into 1983 or beyond. The same infrastructure constraints will be encountered for these plants when completed as were mentioned for the Bim Son plant.

The Government's planned cement production for 1985 was 2.0 million tons. This may reflect a realistic belief that only the Haiphong plant (500,000 tons per year), the old Ha Tien plant (300,000 tons per year), the mini-cement plants (200,000 tons per year), and the by then completed Bim Son (1 million tons per year), actually will be in production.

Fertilizer Materials.—Workers in Ho Chi Minh City completed an organic fertilizer plant with Danish aid. The plant will convert 300,000 tons per year of dry garbage from the urban area into composted organic fertilizer. Processed organic material and green manure was extensively used throughout Vietnam both because of tradition and because chemical fertilizers were in very short supply and expensive when available.

Parts of the Soviet-aided expansion project at the Lam Thao superphosphate fertilizer plant were completed during the year, and construction continued on remaining sections. The plant was 20 years old and apparently has been poorly maintained. A constant problem of corrosion and broken equipment has adversely affected the output of the plant. The plant expansion will increase the original 200,000-ton-per-year capacity and restore the old equipment to a more reliable operating condition.

The Lam Thao superphosphate plant and the apatite grinding plants around the country were supplied with raw material from the Lao Cai apatite mine near the border with China. Lao Cai was a major apatite producer before the border hostilities in March 1979. At that time, virtually all of the mechanized equipment at the mine and much of the infrastructure supporting the operation was destroyed. Repair work has gone slowly, and production during 1981 was probably more than that in 1980 but nowhere near the former production levels. Early in 1981, there was a problem with transporting the ore out of the mining district. By midyear, however, the ore was reportedly being transported as fast as it was being extracted at the time. No official figures were released for the Lao Cai Mine's output in either 1981 or 1980.

Mineral Fuels.—*Coal.*—Coal was Vietnam's major energy source and has been, in prior years, a main source of foreign exchange through sizable anthracite exports. After a very poor year in 1980, production made a modest gain in 1981. The production goals had been revised downward very substantially during 1980, and the production level achieved in 1981 actually represented a disastrous failure of the mid-1970's Government plan to reach 10 million tons of washed coal by 1980.

Despite the construction of several new mines and the modernization of older

mines, the production levels desired have not even been approached by most of the coal industry. Some problems have been solved, and enough new capacity has begun operating to allow the production gain shown in table 1.

Two major problems, transportation and worker motivation, have not been solved and until they are solved industry in general and coal production in particular will continue to have difficulty operating smoothly.

The problem of transportation was mentioned most frequently during 1981 by Government officials. In many cases the coal has been mined but cannot be efficiently moved to its destination. Workers have difficulty getting to the mines. Several local sections of railroad were critically important but either were not completed or were built long ago and were in such poor repair as to be only marginally operable. Spare parts were in short supply so that a high proportion of rail equipment was inoperable at any given time. To speed up the movement of coal and other products, Vietnam has recently imported over an estimated $50 million worth of Indian rail equipment. In June 1981, it was expected to sign an additional agreement to import 200 to 300 new coal cars.

Waterborne coal transport suffered from the same problems. Equipment was in short supply, new barges and tugs were not completed on schedule, and maintenance of equipment was neither adequately nor quickly performed. Again, spare parts were difficult to acquire and seldom available where they were needed.

The highway sector may have been in the worst shape of all. Maintenance of a poorly engineered road network was a constant problem. Truck traffic was forced to move at very low speeds because of deterioration of road surfaces, particularly in the hilly sections of the country. This increased the turnaround time for a given trip. In turn, a larger fleet of trucks was necessary to move the required coal quotas, further aggravating the already severe vehicle maintenance problems.

Another transport problem mentioned by industry leaders was that of incorrect or irrational delivering of coal. Plants needing lump coal were sent powdered coal, while those needing powdered coal received lump coal that then had to be crushed before it could be used. Poor quality coal was delivered to cement plants, degrading the output of the kilns. These types of administrative problems were very costly and apparently accounted for a considerable waste of resources, which could be put to better use by proper planning and management in the upper levels of the coal mining organization.

The second major problem discussed in the Vietnamese press was that of motivating the work force. Several types of problems were mentioned including relative pay scales, lack of food and medical supplies, safety conditions in the mines, workers' housing and recreational facilities, inadequate job training, and lack of spare parts resulting in the workers' inability to meet production norms and hence earn bonuses.

The above problems have resulted in an excessive amount of absenteeism and workers resigning their jobs. Those that continue to work have little incentive or opportunity to increase production. The Vice Minister of Mines and Coal stated that in one 3-month period up to 32% of the workers took leave of absence and a total of nearly 2,000 workers quit their jobs, many of them were the skilled quarry workers and vehicle drivers.

Although a number of changes have been made and the industry leaders are well aware of the problems, there appeared to be very little progress during 1981 toward effectively solving these problems at the workers' level. Until most of these transport and labor troubles are solved, the production goal of 10 million tons per year will be difficult, if not impossible, to achieve.

Natural Gas and Petroleum.—Soviet technicians have been helping in the exploration for gas and oil for the last 10 years. A total of 20 wells were believed drilled in that period, mostly in a geological trough between Hanoi and the coast.

The search finally resulted in a gas discovery well in the Tien Hai District of Thai Binh Province, 95 kilometers southeast of Hanoi. The 1,200-meter-deep well was completed for production. It was then decided that a gas turbine-powered electric generator system would be the best way to quickly and economically utilize the small gas discovery.

Table 16.—Vietnam: Apparent imports of mineral commodities[1] —Continued

(Metric tons unless otherwise specified)

Commodity	1979	1980[p]	Sources, 1980	
			United States	Other (principal)
MINERAL FUELS AND RELATED MATERIALS —Continued				
Petroleum refinery products:				
Gasoline				
thousand 42-gallon barrels	1,056	166	--	All from Italy.
Kerosine 42-gallon barrels	174,965	6,402	--	Singapore 5,766; Thailand 620.
Distillate fuel oil do	734,124	NA	--	NA.
Residual fuel oil do	170,376	NA	--	NA.
Lubricants do	865,333	[6]134,484	--	Italy 104,804; Hungary 26,908.
Other:				
Liquefied petroleum gas do	10,984	NA	--	NA.
Mineral jelly and wax do	15,370	3,880	--	Japan 2,755; Hungary 905.
Nonlubricating oils do	42	NA	--	NA.
Bitumen and other residues do	110,637	111,565	--	Japan 79,992; Singapore 31,512.
Bituminous mixtures do	667	12	--	All from Belgium-Luxembourg.
Mineral tar and other coal-, petroleum-, and gas-derived crude chemicals	5,491	8,227	--	All from Japan.

[p]Preliminary. NA Not available.

[1]Owing to a lack of official trade data published by Vietnam, this table should not be taken as a complete presentation of this country's mineral trade. Unless otherwise specified, these data have been compiled from United Nations information and data published by the partner trade countries.

[2]Less than 1/2 unit.

[3]Excludes part of Japanese exports valued at $295,000.

[4]Excludes part of Japanese exports valued at $102,000.

[5]Excludes Japanese exports valued at $3,000.

[6]Excludes Japanese exports valued at $267,000.

In July 1981, the press announced that the first of five 17,000-kilowatt gas turbines had been completed and successfully tested. The plant reportedly was constructed with Soviet technical assistance in only 8 months. Commercial production of power was scheduled to begin in August 1981. Workers were making preparations for the second turbine during the same period.

Successful completion of this powerplant, the first commercial use of domestic hydrocarbons in the country, would reduce the power shortages in the Hanoi area. More importantly, it will encourage a more vigorous petroleum exploration effort on the part of Vietnam, which currently must import all of its petroleum products.

The Mineral Industry of Other Near East Countries

By Peter J. Clarke[1]

CONTENTS

AFGHANISTAN

Development of the mineral and energy resources of Afghanistan appeared to be a top priority of the Soviet-controlled Government in the country. In the Afghan Government's plan for 1980-81, the largest allocation in the development budget was for mines, industry, and energy (46.7%). In contrast, only 23.1% of the budget was allocated for agricultural development, despite the fact that the great majority of the population was dependent on farming.

The mineral industry of Afghanistan consisted of the production of natural gas, cement, coal, fertilizer materials, and rock salt. Production levels for all of these commodities were down an average of 45% from those of 1978, before the Soviet invasion. Prior to the invasion, small quantities of asbestos, barite, and talc had been produced along with about 6,000 to 7,000 kilograms per year of lapis lazuli, a semiprecious gem stone. Afghanistan had supplied about 80% of the world's output of lapis lazuli. Following direct Soviet intervention, production of these minerals declined to near zero.

Despite the drastic decline in production for most minerals, it was clear that the Afghan Government planned to exploit the country's vast array of hard rock minerals and mineral fuels. By the end of 1981, 167 Soviet-Afghan cooperation projects had been established, 76 of which, according to the Soviet News Agency, Tass, were already in operation. Soviet and Afghan geologists were also said to be conducting large-scale prospecting for petroleum and natural gas, iron ore, chrome, copper, beryl, fluorspar, lead, zinc, bauxite, lithium, tantalum, and columbium, all of which were thought to be present in the country.[2]

The largest Soviet-Afghan cooperative project in the mineral sector was a planned $600 million copper mine and smelter, to be located at Ainak, south of Kabul.[3] Reserves at the Ainak deposit were estimated at 280 million tons containing 0.7% to 1.5% copper. The feasibility study for development of the deposit was completed in mid-1981 by Machinoexport of the Soviet Union, and the project was subsequently approved by the Afghan authorities. The project was scheduled to begin operating in 1985. Soviet technicians were also examining the possibility of exploiting the Hajigak iron ore deposit, located in the Hindu Kush Mountains, 100 kilometers northwest of Kabul. Reserves at Hajigak were estimated at about 2 billion tons of 65% iron ore. The

Soviet Government was thought to be considering developing the Hajigak deposit to supply steel mills in the Tashkent region of the Soviet Union. Also being scrutinized were chromite deposits located in the southeastern portion of the country, near the Pakistan border, 200 kilometers south of Kabul. Two main deposits have been identified. The Heserak deposit in Nangarher Province contained high-grade chrome ore in a series of pockets in serpentinized rocks. The Mohammed Agha Kulanger deposit, located in the Lagor Valley in Kabul Province, contained approximately 180,000 tons of ore grading 36% to 58% Cr_2O_3 with a Cr:Fe ratio ranging from 2.52:1 to 3.57:1. Both of these deposits were being evaluated by Soviet technicians.[4]

Afghanistan's known energy resources included coal, natural gas, and crude oil. Coal production in Afghanistan came from the Karkar, Ishpushta, and Darra-i-Suf Mines. The Karkar and Ishpushta Mines were located in northeastern Afghanistan, near the towns of Pul-i-Khumri and Doab, respectively. These mines have been in continuous operation since the 1950's and were nearing depletion. The Darra-i-Suf Mine, located 160 kilometers south of Mazar-i-Sharif, and 640 kilometers by road from Kabul, was the country's largest producer. The mine, opened in 1966, contained an estimated 60 million tons of good-quality coal, some of which was suitable for coking coal. Production of coal from the Darra-i-Suf Mine has been as high as 100,000 to 150,000 tons per year, but output has declined considerably since the Soviet invasion. Whatever coal was produced in 1981 was consumed in electric-generating facilities in the Mazar-i-Sharif region.

Natural gas was Afghanistan's leading export, providing about 30% of the gross national income. About 95% of Afghanistan's production of natural gas was exported to the Soviet Union in 1981 with the remainder being used to generate electricity. The Soviet Union imported approximately 220 million cubic feet per day of natural gas from Afghanistan in 1981, worth about $114 million. Natural gas was produced from several fields, all located in northwest Afghanistan just south of the Soviet border, in Shibarghan Province. The main producing fields were the Khawaga Gogerdak Field and the Jarq-aduq Field, located within 20 kilometers of each other in southwestern Shibarghan Province. New gas treatment facilities were recently completed at both fields with Soviet technical assistance. Reserves at Gogerdak were estimated at 800 billion cubic feet of sweet gas from an upper horizon above 1,800 meters depth, and another 650 billion cubic feet of sour gas from a lower horizon at 2,200 meters depth. The gas was collected at two receiving plants, piped to a drying facility, and then exported to the Soviet Union through a 100-kilometer, 81-centimeter-diameter pipeline. Some of the gas from the Gogerdak Field had previously been used as feedstock for the Mazar-i-Sharif power and fertilizer plants. Since the Soviet invasion, however, all natural gas supplies have been diverted to the Soviet Union, and the power-plant fertilizer complex was forced to convert to coal.

The other gasfield under development in 1981 was at Jarq-aduq. The Russian firms, Technoexport and Mitpromexport orginally planned to drill 44 production wells in the field and to construct a desulfurization plant and two pipelines. One of the lines was for gas exports into the Soviet Union, and the other was to carry gas for industrial use within Shibarghan Province. Recent reports indicated that the treatment plant was completed and Jarq-aduq was producing significant quantities of gas, presumably for export into the Soviet Union. There were no indications that any gas was being diverted for consumption within the country.

Petroleum was discovered in Afghanistan as early as 1956, but it was not until the early 1970's that evaluation of the resources was carried out. Oil was encountered in exploratory wells at Angut, Aq-Darya, Bazarkami, and Oashq-oir, all in northwestern Afghanistan, in the Fariab, Jozjan, and Shibarghan Provinces. The International Bank for Reconstruction and Development (World Bank) placed Afghanistan's crude oil reserves at 70 million barrels in 1978, and the Afghan Government later revised that estimate to nearly 100 million barrels. No crude oil production was reported in 1981.

According to recent reports, Soviet and Afghan technicians were planning to construct a large refinery at Jarq-aduq.[5] Afghanistan has usually received its domestic requirements of petroleum products from the Soviet Union and Iran, but with war-related difficulties in Iran and the prominent role the Soviet Union was playing in the Afghan economy, nearly all of Afghanistan's supplies were derived from the Soviet Union. The latest figures on oil consump-

tion in the country were released in 1978, and were in the area of 250,000 tons per year of petroleum products. The chaotic situation of the country's economy and the necessity of maintaining the Soviet army have probably altered these figures significantly. The status of the planned refinery at Jarq-aduq was unavailable in 1981.

Table 1.—Other countries of the Near East: Production of mineral commodities[1]

[e]Estimated. [p]Preliminary. NA Not available.
[1]Table includes data available through Oct. 18, 1982.
[2]In addition to the commodities listed, a variety of other crude construction materials (common clays, stone, and sand and gravel) presumably is produced, but output is not reported quantitatively and available information is inadequate to make reliable estimates of output levels.
[3]Less than 1/2 unit.
[4]Includes gas reinjected into reservoirs, if any.

BAHRAIN

Production of crude oil in Bahrain declined in 1981 for the fifth consecutive year, but the drop was more than compensated for by a large increase in exports of refined petroleum products. Total receipts from the petroleum sector reached $3.88 billion, up 23% from the previous year.[e] This represented 90% of the country's total export receipts, and over 70% of the gross domestic product (GDP), estimated at $5.5 billion in 1981. Despite the overwhelming dominance of petroleum revenues in the country's national income, Bahrain has, over the last decade, achieved remarkable success in its effort to diversify the economy away from petroleum dependence. Bahrain's crude oil production has long been the lowest of all the Organization of Petroleum Exporting Countries (OPEC), averaging about 50,000 barrels per day over the last 5 years. With crude oil reserves estimated at only 223 million barrels, Bahrain could expect to exhaust its main source of income within 15 years at current production levels. This diversification effort has led to the development of a variety of enterprises ranging from heavy industry including aluminum, iron and steel, and ship repair, to a financial sector that has become one of the most successful offshore banking operations in the world.

Bahrain's economic development is based on a combination of rigidly structured semiannual Government budgets, and a strong emphasis on free enterprise and free trade. The total Government budget for 1981 was $900 million, of which 60% was allocated for capital expenditures. Only 42.5% of the total allocation was consumed for these purposes; however, and the remainder was transferred into the long-term capital account and into the annual surplus. Capital expenditures were directed mainly at expansion of the country's infrastructure. The Government budgets for 1982 and 1983 were also announced in 1981, with revenues and expenditures totaling $1.5 billion in 1982, and $1.7 billion in 1983. The budgets anticipated an annual real growth rate in the economy of between 5% and 8% per year. Bahrain's long-term capital expenditures, which were usually not included in the

Government budget, were directed toward the planned 4-million-ton-per-year iron ore pelletizing plant and construction of the $600 million causeway linking Bahrain to Saudi Arabia.

Bahrain produced approximately 46,000 barrels per day of crude oil from the Awali Field, located onshore near the center of the island. Oil was discovered at Awali in 1939, and it has been the sole source of Bahrain's oil ever since. Its age requires that secondary and tertiary recovery techniques be employed for the field to remain productive, but even with the most advanced recovery methods, recent surveys have indicated that the island's measured oil reserves could be extended to a maximum of 15 years.

Bahrain derived about one-third of its petroleum revenues from the Abu Sa'fah Oilfield, located offshore, north of Bahrain. The field was owned and operated by the Saudi Arabian Petroleum and Minerals Organization, and its oil was exported from Saudi Arabia, but as part of a joint territory deal one-half of the revenues from Abu Sa'fah's oil production goes to Bahrain. Abu Sa'fah produced about 50,000 barrels per day of oil in 1981 after peaking at about 70,000 barrels in 1978.

Bahrain's only refinery, at Sitra, produced a record 95 million barrels of petroleum products in 1981, up 5.6% from the 1980 level. Input for the 250,000-barrel-per-day refinery was supplied from Bahrain's Awali Field, by supply agreements with Saudi Arabia, and by the California Texas Petroleum Co. (Caltex), a joint venture of Chevron U.S.A. Inc. and Texaco Inc. of the United States. Saudi Arabia and Caltex each supplied 100,000 barrels per day to the refinery. Caltex input was derived from Chevron's and Texaco's crude oil entitlements in Saudi Arabia. The refinery was operated by Bapco BSC, which was owned 60% by the Bahrain Government and 40% by Caltex. In November 1981, Bapco announced that it had awarded a $36.5 million contract to Ralph M. Parsons Co., United States, to build a light isomax production unit at the refinery. This plant was the single largest item in Bapco's investment program for 1981-82. The new unit was to be composed of a new isomax reactor and a vacuum-product recovery section to turn fuel oil into diesel oil, naphtha, and sulfur. The plant was to open in mid-1983.

Caltex had originally owned the entire oil industry in Bahrain, including all oilfield assets and the petroleum refinery. Over the past 3 years, ownership and control of all oil-related operations were gradually turned over to Bahrain. Beginning in 1975, the Government of Bahrain assumed 60% ownership of the oilfield assets, and in 1976 created the Bahrain National Oil Co. (Banoco) to market refined products to local customers. One year later, the Government formed the Bahrain National Gas Co. (Banagas) to process and export liquefied petroleum gas (LPG). In 1980, the Government negotiated a 60% takeover of the Sitra refinery, through Bapco. Finally, in 1981, the Supreme Petroleum Council was established under the chairmanship of the Prime Minister to supervise and direct development of the country's resources. By January 1, 1982, Banoco was to takeover direct management of all oilfield assets. Caltex had previously operated most of the fields under agreement with Banoco. Caltex remained responsible for marketing its 100,000-barrel-per-day share of the refinery's output. The Government of Bahrain also sold Caltex 112,000 barrels per day of its refined product share to be sold through the Caltex marketing organization. The buyback arrangement was to allow Banoco time to gradually build its own marketing organization. Meanwhile, Banoco marketed about 3% of the refinery's output domestically. The country consumed approximately 2.2 million barrels of refined products in 1981. Consumption was expected to rise to over 6 million barrels per year by 1990.

In addition to managing the country's oil-producing assets, Banoco also was responsible for directing all oil and gas exploration activities. Banoco was winding up a large-scale, 18-month, $17 million seismic survey undertaken throughout offshore Bahrain by Western Geophysical Co., United States. The most promising offshore areas were north of the island, where subeconomic shows of oil and gas were discovered about 20 years ago by Caltex. Banoco planned to drill four wells in the area by mid-1982. Union Texas Oil Co. of the United States was also exploring in three blocks offshore northeast Bahrain, and was planning a test well some time in 1982. The prospects for a major discovery offshore Bahrain did not appear good, but the Government planned to maximize its use of whatever hydrocarbon resources it could locate to at least maintain the current level of production for as long as possible.

With the progressive decline in oil production, Bahrain began to focus more attention on its reserves of both associated and

nonassociated natural gas. While the production of associated gas has declined in line with crude oil production, output of nonassociated gas has continued to grow. Nonassociated gas was derived from the Permian Khuff Formation, a gas-containing strata that extends throughout much of the Middle East. The Khuff Formation was beneath the oil-producing Bahrain Formation, and wells to tap the gas commonly extended beyond 3,660 meters deep. With associated gas production leveling off at about 330 million cubic feet per day, Khuff gas was becoming an important component of the country's energy supply. Average nonassociated gas production reached 400 million cubic feet per day late in 1981. Banagas was responsible for utilizing most of the country's gas production. Banagas was composed of Banoco, 75%; Caltex, 12.5%; and the Arab Petroleum Investment Corp., 12.5%. Banagas planned to drill six producing wells into the Khuff Formation in 1982 that were expected to produce 300 million cubic feet per day of gas.

Most of Bahrain's current output of natural gas was delivered to the recently completed Banagas natural gas liquids (NGL) processing plant at Jabal. The plant, built by Japan Gasoline Co. at a cost of $72 million, began exporting NGL in March 1980. The plant was designed to utilize 100 million cubic feet per day of associated gas in the production of 280,000 tons per year of NGL, 80,000 tons per year of propane, 79,000 tons per year of butane, and 125,000 tons per year of naphtha. Caltex was responsible for overseas sales of NGL and LPG, while Banagas handled domestic distribution. Tail gas or residue gas from the plant was supplied to Aluminum Bahrain's (ALBA) smelter. ALBA received 80% of its power requirement from this tail gas, with the remaining 20% supplied directly by the country's onshore nonassociated gasfields. Of the total volume of nonassociated gas produced, about 30 million cubic feet per day was supplied to ALBA, another 90 million cubic feet per day went to Bapco, and the remainder was delivered to the aluminum extrusion plant and local power stations.

Two new petroleum-related projects were established in 1980 and 1981, under the direction of two distinct companies. The first company established was the Gulf Petrochemical Industry Co. (GPIC), a joint venture of Bahrain, Kuwait, and Saudi Arabia, all of whom owned equal shares in the project. In 1980, a contract was awarded to Wimpey Laboratories of the United Kingdom for a site survey and soil analysis for the plant, to be located on a 600,000-square-kilometer tract to be reclaimed from the sea, near Sitra. Contracts were also awarded to King Wilkinson International of the United States for a $9 million feasibility study, and Uhde of the Federal Republic of Germany for engineering and process technology. In March 1981, GPIC awarded the $80 million construction contract to Snamprogetti S.p.A. of Italy. The complex was to produce 1,100 tons per day of methanol and 1,100 tons per day of ammonia, utilizing natural gas feedstock. The plant was scheduled to go onstream in 1984. Most of the output was to be exported.

Late in 1981, the Governments of Bahrain, Kuwait, and Saudi Arabia combined again to establish the Heavy Oil Conversion Co. The company was set up to construct and manage a 50,000- to 80,000-barrel-per-day hydrocracking plant designed to convert heavy refinery oils into lighter products. A feasibility study for the project was to be completed sometime in 1982. The company was owned 40% by Bahrain, and 30% each by Saudi Arabia and Kuwait.

Perhaps the centerpiece of Bahrain's goals of diversification and decentralization is the smelter of ALBA that began operating 10 years ago. The plant has produced at its rated capacity for over 5 years, and has firmly established itself on the international market. Production capacity was increased from 122,000 to 155,000 tons per year in 1981, and was to increase to 170,000 tons per year by 1982 through the addition of a fifth and sixth potline. Most of the new output was destined for the planned aluminum rolling mill in Bahrain.

Bahrain Aluminum Co. (Balco), the marketing agency for ALBA, began to feel the effects of the downturn in the industry worldwide in 1981. Balco's earnings peaked in 1979 at $53 million, then declined to $48.5 million in 1980, and were down again to $13.2 million in 1981. The company expected to post a loss for the first quarter of 1982. ALBA was owned 57.9% by the Bahrain Government, 20% by Saudi Arabia, 17% by Kaiser Aluminum Bahrain of the United States, and 5.1% by Breton Investments of the United Kingdom. The smelter produced approximately 1.2% of the world's aluminum output in the form of ingots, rolling slabs, billets for extrusion, and liquid metal in crucibles. The minority share-

holders either exported their share of the output directly or ran the metal through the Bahrain Atomiser International aluminum powder plant, in which Breton had an interest through Eckhardtwerke A.G. of the Federal Republic of Germany.

The Bahrain Aluminum Extrusion Co., owned by the Government, increased the capacity of its extrusion plant from 3,600 to almost 5,000 tons per year in 1981 through the installation of additional anodizing facilities. Meanwhile, six regional Arab Governments have collaborated to establish the Gulf Aluminum Rolling Mill Co. to be based near ALBA in Bahrain. The project was to be designed to produce 40,000 tons per year of semifabricated aluminum products, mostly for the local market. Shareholders in the project were Bahrain, Kuwait, Saudi Arabia, and Iraq with 20% each, and Oman and Qatar with 10% each. Kaiser Engineering of the United States won a $5.3 million consultancy contract for the plant in 1981, and tenders for building the mill were to be invited by the third quarter of 1982. Aluminum ingots for the plant were to be supplied by ALBA.

Bahrain's next major industrial project planned was the Arab Iron and Steel Co.'s (AISCO) 4-million-ton-per-day iron ore pelletizing plant. AISCO was formed in 1980 to ensure adequate supplies of pelletized iron ore for the three large direct-reduction steelworks in the gulf area, in Saudi Arabia, Iraq, and Qatar. The combined capacity of these steel plants was 2.7 million tons per year of steel, which required approximately 4 million tons of pellets.

AISCO was capitalized in 1980 at $150 million. Total cost of the project was expected to be $320 million. In November 1980, Kobe Steel Ltd. of Japan was awarded the major $207 million turnkey contract for construction of the pellet plant and ancillary facilities including a 100-megawatt powerplant and a 3,000-cubic-meter-per-day seawater desalinization plant. The overall project consultant was the Kuwait Engineering Operation and Management Co.

The pellet plant itself was to consist of an iron ore drying and grinding unit; a blending and prewetting unit; a ball mill and indurating unit; a product stockpiling, reclamation, and load-out unit; and a waste reclamation plant. The plant was expected to consume 35 million cubic feet of natural gas per day. India's Kudremukh Mine was to supply 1.5 million tons per year of iron ore to the plant along with 1 million tons from Mineração Brasilieras Reunidas S.A. of Brazil and unspecified amounts from Brazil's Companhia Vale do Rio Doce and Samarco Mineração S.A. Peru's Minero Perú Commercial also was to supply 500,000 tons of iron ore per year initially, rising to 1 million tons at a later date. Construction of the plant was to begin early in 1982, and it was to be ready for commissioning sometime in 1984. Bahrain, while not announcing any plans presently, did not rule out construction of a direct-reduction plant of its own to form an integrated iron and steel project within the country.

JORDAN

Jordan's economy continued to expand in 1981, boosted by increased production of phosphate rock and unusually high levels of reexports. Jordan's mineral industry consisted of the mining of phosphate rock, petroleum refining, and the production of cement. Production of phosphate rock alone provided 5% of the country's GDP estimated at about $3 billion in 1981.[7] Mineral production was to increase substantially in 1982, with production commencing from the Dead Sea potash project and the Aqaba phosphate fertilizer complex. Also in the planning stage was a project to exploit copper deposits in the Wadi Araba region in southwestern Jordan. Total mineral production, including refined petroleum products, was valued at about $690 million in 1981, representing 22% of the GDP.

In September, the Jordan Council of Ministers approved the country's second 5-year development plan (1981-85). Total expenditures in the plan period were to reach $10 billion, with emphasis being placed on continued resource development, industry, and agriculture. Industry and mining were to contribute the bulk of the growth in the private sector, with each averaging an 18% growth rate in all of the plan years, while receiving 25% of the total investment allocated. Overall GDP was expected to grow at a real annual rate of 11% per year, reaching $4.6 billion by 1985.

Despite the strong performance in the domestic economy, Jordan's trade deficit continued to grow from $1.55 billion in 1980

to $1.88 billion in 1981. A major aim of the 5-year plan was to trim the trade deficit by promoting rapid expansion in exports of goods and services. To achieve this, the Government was planning to allocate about 48% of the current GDP toward the productive sectors of the economy, notably in the production of chemical fertilizers, a potash extraction plant, an oil refinery, phosphate production, and a cement plant. These investments were to play a vital role in modifying the structure of the Jordanian economy in favor of the commodity-producing sector rather than dependence on the services sector.

Jordan's primary heavy industry and largest export commodity was phosphate rock. Production increased substantially in 1981 to 4.2 million tons from 3.9 million tons in 1980. Exports of phosphate rock fell marginally in 1981 to 3.5 million tons, from 3.61 million tons in 1980. This was partially a result of increased consumption of phosphate rock for fertilizer within the country, and also because of a generally weak demand for fertilizer worldwide. Exports of phosphate rock brought in about $150 million in foreign exchange earnings.

Three large deposits of phosphate rock were being exploited in Jordan in 1981, at Ruseifa, El-Hasa, and Wadi-El-Abyad. Ruseifa was the oldest of the mines, having been in continuous operation since 1937. Output from the deposits, located 14 kilometers north of Amman, has been maintained at 600,000 to 1 million tons per year since 1960. The average triphosphate of lime (TPL) content at Ruseifa was 62% to 72%. At Ruseifa, the Jordan Phosphate Mines Co. (JPMC) operated an opencast mine along with a simple screening and drying operation, which yielded 66% to 68% TPL rock as well as "Jorphos," a dust from the drying plant. This dust was sold domestically as direct-application fertilizer. In June 1981, JPMC decided to replace the existing beneficiation equipment with an $18 million calcining process in order to produce a higher grade, organic-free product. The new facilities were to come onstream in 1983 and be capable of processing 1 million tons of crude rock per year.

At El-Hasa, 138 kilometers south of Amman, the JPMC was mining five separate ore bodies, using contract labor to carry out stripping operations. Phosphate ore was ripped, bulldozed, and loaded into 20-ton trucks by bucket loaders, and hauled to one of the five mobile crushing stations. The average stripping ratio was 7:1. In 1981, JPMC stripped 2 million bank cubic meters of overburden and mined about 500,000 bank cubic meters of phosphate. At El-Hasa, JPMC operated five beneficiation plants; three with an annual capacity of 500,000 tons of 73% to 75% TPL with an 18% moisture content, and two others with an 800,000-ton-per-year capacity of 73% to 85% TPL. From these plants, phosphate was fed to any of eight dryers with a total combined capacity of 4 million tons per year. From El-Hasa, phosphate was loaded into either trucks or railcars for transportation to Aqaba for export.

JPMC's newest mine came onstream in 1980 at Wadi-El-Abyad, located 20 kilometers north of El-Hasa. Proven reserves at Wadi-El-Abyad were put at 72.5 million tons, with only one of three ore bodies being exploited at the current time. Output from the mine in 1981 averaged about 1 million tons of crude phosphate rock. Beneficiation facilities at Wadi-El-Abyad consisted of two crushers and screening units, a beneficiation plant, and three dryers. The beneficiation plant consisted of three process lines with a 113-ton-per-hour rock feed capacity, and an output rating of 500,000 tons per year of 73% to 75% TPL. Output from the dryer was loaded into trucks or railcars for shipment to Aqaba. The combined output of El-Hasa and Wadi-El-Abyad, currently running at about 3.2 million tons, was to increase over 5 million tons by 1983. Most of the increase was to come from El-Hasa, where a 30.6-cubic-meter-bucket walking dragline has been installed, the first dragline in the Middle East.

Phosphate production from Jordan was to be further supplemented by the development of a fourth deposit at Ash-Shidiya, located 75 kilometers south of Ma'an and 50 kilometers northeast of Aqaba. The Shidiya deposit was one of the largest and commercially most important deposits in the country, mostly because of its proximity to the new fertilizer plant and export terminal at Aqaba. The Jordan Ministry of Trade and Industry awarded the engineering contract for development of the deposit to a consortium of French companies, led by the Société Française d'Etudes Minières. Proven reserves at Shidiya were placed at over 300 million tons of phosphate rock. Production from Shidiya was expected to reach 3 million tons per year of concentrated ore by the late 1980's.[8]

One of the reasons that increased phos-

phate rock production was important was to supply the nearly completed Jordan Fertilizer Industry Co.'s (JFI) fertilizer complex at Aqaba. The $400 million complex is composed of two 450,000-ton-per-year sulfuric acid plants, one 450,000-ton-per-year phosphoric acid plant, designed to utilize 73 to 75 bone phosphate of lime-grade phosphate rock, and two fertilizer granulation units, each capable of producing 400,000 tons per year of monoammonium or diammonium phosphate (DAP). Included in the project was a plant designed to produce 20,000 tons per year of aluminum fluoride from fluorsilicic acid. This acid is a byproduct of phosphoric acid production. JFI was also constructing storage installations for materials and products, as well as bagging equipment for DAP. A 44-megawatt electric power station was to power the complex, utilizing waste heat from steam generated in the sulfuric plant. A new marine terminal was also under construction about 15 kilometers south of Aqaba. The port consisted of a 214-meter pier for double-sided berthing, and could accommodate freighters of 30,000 deadweight tons. Startup of the fertilizer plant was scheduled for mid-1982, with commissioning expected to take 5 months. The aluminum fluoride plant was to startup in 1984.[9]

Also nearing completion in 1981 was the single largest industrial project ever undertaken in the country, the Dead Sea potash project. The $425 million facility was built for the Arab Potash Co. (APC), a joint venture of the Jordan Government (51%), the Arab Mining Co. (25%), the Islamic Development Bank (7%), the Government of Kuwait (5%), the Libyan Government (5%), and other minority shareholders. Jacobs Engineering Ltd. of the United States was responsible for engineering, design, procurement, and construction management of the project. George Wimpey and Co. of the United Kingdom built the solar evaporation ponds and surrounding dikes for $131 million, Vöest Alpine of Austria built the potash processing refinery for $107 million, and R. A. Hanson Co. of the United States supplied four laser-controlled carnallite harvesting machines for $10 million.

The potash project was located at Ghor-al-Sufi, near the Lisan Peninsula on the banks of the Dead Sea in southern Jordan. The project utilizes solar energy to evaporate Dead Sea brines. The brines are pumped onshore into a 10-kilometer-long canal that empties into several salt pans. First, common salt (NaCl) is precipitated, leaving a saturated solution of carnallite. This solution is pumped into three carnallite harvesting pans, where carnallite, a potassium chloride-magnesium chloride double salt ($KCl\text{-}MgCl\text{-}6H_2O$) is precipitated along with 15% NaCl. The carnallite is recovered using four laser-controlled harvesting machines that crawl along, semisubmerged, on wide caterpillar tracks. The machines scoop up the solids and push them into a pipeline that leads to dewatering cyclones. In this manner, about 310 tons per hour of solids are to be recovered. These are then introduced into the refinery, where sodium and magnesium chloride ores are leached out, and KCl is recrystallized, dewatered, dried, and stored. The refinery is to produce about 1.2 million tons per year of potash.

Potash was to be trucked to Aqaba for export. Marketing of the endproduct was contracted to Mitsubishi Corp. of Japan for Asia at 600,000 tons per year, Woodward and Dickerson of the United States for North and South America at 275,000 tons per year, Enterprise Minière et Chemique S.A. of France for Western Europe and Africa at 250,000 tons per year, and IMIC Holdings for Eastern Europe at 40,000 tons per year. APC was to market its share of the output in the Middle East. APC was to start production by March 1982, with exports beginning in October 1982.

Jordan's production of metals was limited to small-scale iron and steel operations. The Jordan Iron and Steel Co. operated a small electric steelworks at Zarqa that produced about 50,000 tons per year of steel reinforcing bars, mainly from scrap. The Jordan Pipes Manufacturing Co., owned 10% by France's Vallourec Group and the remainder by Jordanian interests, also operated a 120,000-ton-per-year, small-diameter welded pipe plant. The Arab Aluminum Industry Co. in Amman operated an aluminum extrusion and anodizing plant with an annual capacity of 5,000 tons.

Jordan's newest and most promising metals project was a plan to exploit the copper deposits of the Jordan Rift Valley near Wadi Araba. According to the Natural Resources Authority (NRA), the deposit contains 5 million tons of 1.36% copper in oxide ore. Relics of an ancient Iron Age copper mine have been located near the town of Etzio-Geber, near Aqaba. The deposit has been examined by the NRA, the Bureau de Recherches Géologiques et Minières (BRGM), and most recently, Seltrust Engi-

neering of the United Kingdom, who completed a feasibility study in October 1979. Seltrust was awarded another contract to do additional feasibility studies, construct a pilot plant, and do sample testing on the ore. The pilot plant was to have a 3,000-ton-per-year ore processing capacity. Based on the results of the pilot plant operation, the NRA planned to gradually expand the operation to about 9,000 tons per year by 1985. Total cost of the pilot plant, economic studies, and testing operations was estimated at $25 million. No date was available for commissioning of the plant.

Jordan's cement industry continued to expand in 1981, through the increased capacity of the Fuheis cement plant, located 25 kilometers northwest of Amman. Production capacity at Fuheis was increased from 800,000 to 1.2 million tons per year through the addition of a fifth production line at the plant. Jordan's cement consumption averaged about 1.8 million tons per year in 1981, which forced the country to import about one-third of its domestic requirement. In May 1981, the Jordan Cement Factories Co., which owned the Fuheis plant, awarded a Mitsubishi-Kobe Steel consortium of Japan a $110 million contract to build a sixth production line at Fuheis that would be capable of producing another 1 million tons per year of cement. The plant was to be completed late in 1982.

Two other cement plants were also in the planning stage, one at Rashidiyah and the other at al-Dalil. Mitsubishi was responsible for constructing the Southern Cement Works at Rashidiyah at a cost of nearly $225 million. The plant, scheduled to come onstream late in 1983, was to produce 1 million tons per year of cement, mainly for export to Saudi Arabia and Iraq. Kobe Steel, the main contractor, was providing the process technology for the plant. The al-Abyad cement plant, located in the al-Dalil region, was to produce about 100,000 tons per year of cement from raw materials located close to the plant. The project was a joint venture of Jordan and Syria through the Syrian-Jordanian Co. The cost of the plant was estimated at $54 million. No date was available for starting construction or commissioning of the plant.

Despite many years of unsuccessful petroleum exploration, the NRA continued its exploration program, concentrating on the al-Azraq region of eastern Jordan. A wildcat well was drilled to a depth of 805 meters by the Yugoslav contractor Naftagas, on behalf of the NRA. The concession was owned completely by the NRA, who contracted Naftagas and several other companies to drill the well on its behalf. The well was part of Jordan's National Independent Oil Exploration Program, which up until 1981 has concentrated only on seismic surveys. Before 1981, only four wells had been drilled based on these surveys. By mid-1982, the entire country was to have been covered by seismic surveys, with new efforts being placed on sites where potential oil-bearing formations had been located. After the Naftagas well, the NRA planned to drill several other wells in the area.

All petroleum refining in Jordan was carried out by the Jordan Petroleum Refinery Co.'s 35,000-barrel-per-day refinery at Zarqa. Output from the refinery has been running at full capacity of over 12 million barrels per year of refined products since 1979. The entire output of the plant was sold domestically. Crude oil supplies for the refinery were supplied by Saudi Arabia, through the Trans-Arabian Pipeline (TAPline). The third phase of the refinery's expansion project was underway in 1981, which was to raise input capacity to 60,000 barrels per day of crude oil. New hydrocracker and distillation units were being added by Industrialexport of Romania, along with a new LPG production plant, at a total cost of about $175 million. Increased output from the refinery was to be more than adequate to meet the country's domestic needs. The expansion project was to be completed by the end of 1982.

Also under construction at Zarqa was a small petrochemical project attached to the refinery. The unit, being built under the overall engineering contract of Rio Rodano, was designed to produce 8,000 tons per year of polyester, 4,000 tons per year of plastisizer, and 5,000 tons per year of polyvinyl chloride. The plant was to use imported phthalic anhydride, glycols, styrene monomer, and oxo-alcohols as feedstock. The project was to be completed by the end of 1982. Other projects under consideration by the Jordan Petroleum Refinery included plans to increase the crude oil pipeline capacity into the refinery, construction of six new petroleum product distribution stations, and construction of an aviation fuel pipeline and distribution center at the Queen Alia International Airport.

In addition to its newly discovered crude oil potential, Jordan also possessed about 1.3 billion tons of good quality oil shale in

the Lajjun area, near Karak in central Jordan. Klöckner Werke A.G. and Lurgi of the Federal Republic of Germany was contracted to do a $630,000, 17-month prefeasibility study for a 50,000-barrel-per-day retorting plant at Lajjun. Results of the study were not available by the end of the year.

Other mineral projects being evaluated by the NRA were several phosphate mining support projects; a bromide products and caustic soda plant based on Dead Sea brines; a magnesium and porcelain clay plant, also utilizing the waters of the Dead Sea; a potassium sulfate project; and a feldspar mining project. A general geologic survey of the kingdom was also continuing in 1981 to pinpoint important geologic areas for specific purposes, such as for mining, location of wells, and planning industrial ventures.

Table 4.—Jordan: Exports and reexports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
METALS				
Aluminum metal including alloys, all forms	1,069	800	--	Lebanon 509; Syria 124; Kuwait 106.

LEBANON

Lebanon's mineral industry did not fare particularly well in 1981, along with most of the other sectors of the economy. The period of economic expansion, which began in 1980, carried over into the first quarter of 1981, but with the outbreak of hostilities in April 1981, economic activity came to a standstill. As calm was reestablished in the third quarter, the economy began to recover as well, with industrial production increasing, spurred mostly by a miniboom in the construction sector and remittances from

Lebanese working abroad. Lebanon's GDP increased about 2.3% in 1981 from $4.08 billion in 1980 to $4.17 billion in 1981. Per capita income for 1981 was estimated at $2,200. Nearly one-half of the country's national income was supplied by Lebanese who fled during the Civil War to neighboring oil-rich Arab countries. It was estimated that remittances from these workers were averaging $150 to $200 million per month.[10]

Despite the poor security situation that prevailed during much of the year, Lebanon's exports rose about 30% in 1981 compared with that of 1980. Total exports for the year were valued at $1.3 billion. Exports, which were directed mainly toward Iraq, Saudi Arabia, Jordan, and Syria, were made up primarily of construction materials, vegetable products, chemicals, and textiles. Industrial exports were valued at $540 million, reflecting a 25% increase over that of 1980. Lebanon's industrial exports to Arab countries constituted 90% of its total industrial exports in 1981. The value of Lebanese imports declined in 1981 to $2.7 billion from $2.9 billion in 1980.

Even with exports up and imports down, Lebanon continued to run a deficit in the balance of trade, equivalent to $1.4 billion in 1981. Since the Civil War in 1975, however, the country has finished the year with a substantial surplus in the overall balance of payments. This surplus was created by remittances from Lebanese working abroad and both official and unofficial assistance to the Government, mainly from other Arab countries.

Lebanon's mineral sector consisted of refining imported petroleum and the production of cement, iron and steel products, gypsum, lime, and salt. Production of cement and salt increased in 1981, but output of refined products, iron and steel, and lime dropped considerably. The value of nonfuel mineral production in 1981 was $2.23 million.

Lebanon's two refineries at Zahrani and Tripoli operated intermittently during 1981 because of disruptions in crude oil supply and direct attacks on the refinery units or their supply lines. The Mediterranian Refining Co.'s (Medreco) refinery at Zahrani in southern Lebanon had a capacity of 17,000 barrels per day of crude oil input. The Medreco refinery was owned jointly by Caltex (50%) and Mobil Oil Corp. (50%), both U.S. companies. The refinery was shutdown in April 1981 as a result of damages sustained from air and rocket attacks around Sidon, which lies just a few kilometers north of the refinery. The refinery resumed operations in late May but was forced to shutdown several times again later in the year to repair damages or await crude oil shipments.

The Tripoli refinery, located in Tripoli in northern Lebanon, had a throughput capacity of 35,000 barrels per day of crude oil. The refinery was able to maintain fairly continuous operation, despite almost monthly interruptions in supply. The Tripoli facility was owned entirely by the Government, and its output was used to satisfy domestic requirements, while output from Medreco was either exported or sold within the country. The Government, which paid the bill for crude oil imported for the Tripoli refinery, incurred a deficit of $215 million in 1981, mainly owing to Government subsidies on petroleum products produced within the country. Also to blame was the failure of several Government departments to pay their oil bills, in particular, the Electricity Authority, which owed the Oil Ministry about $200 million. Lebanon's petroleum import bill, for both crude and refined products, reached $580 million in 1981.

One of the more interesting aspects of Lebanon's petroleum situation was its relations with the countries and companies that supply its oil. Most of the country's oil was supplied by Saudi Arabia through TAPline, which was owned and operated by TAPline Inc., a U.S. company. Late in the year, however, Iraq began to deliver oil through the Iraq Petroleum Co. (IPC) pipeline from Kirkuk, Iraq, through Bainyas, Syria, to Tripoli, Lebanon. The Tripoli spur of the pipeline had been closed since early 1976 because of disputes over transit fees. While the opening of the IPC pipeline marked a bright spot for Lebanon in 1981, its relations with TAPline were discordant. Four times in 1981, TAPline suspended deliveries of crude oil to Lebanon for unpaid bills. Saudi Arabia, at one point, stepped in to pay Lebanon's outstanding debt, but relations between TAPline and Lebanon did not improve, and the Government was constantly trying to maintain adequate supplies of crude oil and to prevent shortages of refined products within the country.

The cement industry in Lebanon fared better than most in 1981, with output reaching 2.39 million tons, an 8.6% increase over that of 1980. Cement consumption in the country averaged just over 2 million tons in 1981, leaving the balance of production

for export. Some of the cement sold locally was resold to neighboring Arab countries, however, and the total value of cement exports was estimated at $30 million. There were three cement plants operating in Lebanon in 1981, all located in Chekka. The plants were owned by private shareholders within the country. Production capacity at the Société des Ciments Libanais plant was 1.8 million tons per year. Capacity at the Cimenterie Nationale S.A.L. plant was 1 million tons per year, and at the Société Libanais des Ciments Blanc, 160,000 tons per year. Limestone and gypsum for clinker production was quarried in the country.

Lebanon also produced a small quantity of steel and fabricated aluminum, all from imported scrap and aluminum. The electric steelmaker, Lebanon Steel Mill Co. in Tripoli, had an annual capacity of 100,000 tons of reinforcing bars, and the Consolidated Steel Lebanon S.A.L. plant in Bablos-Amchit had a rerolling capacity of 180,000 tons per year of bars and 60,000 tons per year of sections. The Société Nationale des Tubes S.A.L. also produced a small quantity of galvanized steel pipe. The production of semimanufactured steel was below 200,000 tons in 1981. Two aluminum semifabricating plants also operated in Lebanon in 1981, with a combined capacity of 5,000 tons per year of extrusions and 15,000 tons per year of rolled products. The output for 1981 was estimated at 2,000 tons.

OMAN

Oman's mineral development plans centered around petroleum refining, natural gas production and processing, and copper and cement production. The most promising prospect in the nonfuel minerals sector was the copper mine and smelter complex at Sohar that was scheduled to begin production in 1982. Despite the Omani Government's attempt to diversify the economy away from petroleum dependence, revenues from oil exports remained as the single most important source of funds to drive the country's economic development. In fact, based on the most recent data available, Oman's economy was actually becoming more dependent on oil, with petroleum revenues accounting for about 72% of the 1981 GDP estimated at $5.86 billion.[11] This represented an increase of almost 4 percentage points above the 1980 level, and a full 10 percentage points above that of 1979 when oil revenues accounted for 62% of the GDP. This growing dependence on oil was because very few other commodities were produced in Oman in exportable quantities and oil production also registered its first increase in 4 years in 1981. Receipts from petroleum exports accounted for 90% of the country's export revenues.

Oman's second 5-year development plan (1981-85) was announced early in the year. The plan was expected to shape the course of economic development in the country by building upon the achievement of the first plan, which was devoted primarily to basic infrastructure. The top priorities of the second plan were to expand the network of public utilities and services to the less accessible regions of the country; to implement a large-scale program to increase the availability of water resources; to assist the private sector in promoting investment in income-generating sectors such as agriculture, fishing, mining, and heavy industry; to expand the existing low-cost housing program; to train and maximize the potential of Omani workers; and to continue to expand the country's roads, ports, and airports. The stimulation of the private sector involved the allocation of funds to small enterprises, provision of interest-free loans to joint stock companies engaged in manufacturing and mining, setting up an agriculture and fisheries credit bank, and giving direct support to farmers and fishermen. The Government also aimed at maintaining a ratio of gross fixed capital formation to GDP of 23.8%. About 65% of the investments were to be made by the Government and the remaining 35% were to be made by the private sector.

Petroleum production in Oman averaged 328,240 barrels per day in 1981, a 16% increase over the 1980 level, and the highest average annual output since 1977. This rise in production represented a significant turnaround in the country's oil industry, which, up until a few years ago, was expected to continue to produce less oil every year and exhaust its known reserves by 1995. Several moderate-sized discoveries in the late 1970's and early 1980's allowed Oman to revise its reserve estimate upward from 1.5 billion barrels in 1979 to 2.480 billion barrels in 1980, and up again to 2.484 billion barrels in 1981. Not less than five new commercial discoveries were made in 1981, which seemed likely to boost the

country's reserves even further.

The increase in production in 1981 was primarily a result of several new fields coming onstream in southern Oman, as well as the completion of a pipeline system to transport oil from the new production areas in the south into the existing network and on to the country's main export terminal at Mina-a-Fahal, just northwest of Muscat. Prior to 1980, the only oil-producing company in Oman was Petroleum Development Oman (PDO), which was owned 60% by the Oman Government, 34% by Royal Dutch/Shell of the Netherlands, 4% by Compagnie Française des Pétroles (CFP)-Total of France, and 2% by Participations and Explorations Corp. (Partex) of Portugal. PDO operated oilfields mainly in northern Oman, at Natih, Fahud, Lekhwair, and Qarn-Alam. The Qarn-Alam Field was PDO's largest, with extensions of the field reaching several kilometers to the northeast and southwest. Output from these northern fields, while still constituting the bulk of production, declined in 1981 to about 280,000 barrels per day from a high of about 370,000 barrels per day in the mid-1970's.

In 1980 and 1981, production from PDO's southern and central fields began to take up the slack in production, and a new field was brought onstream in central Oman by Essence et Lubrificants de France (Elf)-Aquitaine. Located in the Butabul region, 550 kilometers southwest of Muscat near the Saudi Arabian border, the Sahmah Field was discovered in 1979 by a consortium led by Elf-Aquitaine. Sahmah crude oil had an API gravity of 43.5°, and a sulfur content of 0.14%. Production from the field averaged 11,300 barrels per day in 1981.

The remainder of the country's production was from the southern Dhofar Province fields, most of which were discovered in the late 1970's. Production commenced in 1981 from the Marmul, Qaharie, and Birba Oilfields. Also nearing production were several small fields: Alpha, Beta, Gamma, Delta, and Rahab, all located within 20 kilometers of the main Marmul Field. These new fields in the south were connected to the main fields at Qarn-Alam by a 455-kilometer, 18-inch pipeline with a capacity of 70,000 barrels per day. Dodsal Private Ltd. of India built the line, which began operating in January 1981, under the engineering and construction management of Kellogg Continental BV. The pipeline connects with the main Qarn-Alam line, which in turn delivers oil to the main export terminal at Mina-a-Fahal.

Two other pipeline projects were underway in 1981. The Oman Construction Co. was laying a 325-kilometer-long gas pipeline to connect the Saih Nihayda Gasfield in central Oman with the main lines at Marmul. The company was also building a line to link the Rima Oilfield, which was discovered in 1980, to the main Marmul-Qarn-Alam crude line. The Rima Oilfield was located about 100 kilometers northeast of Marmul, and only about 10 to 15 kilometers east of the existing crude oil pipeline.

Exploration activity to Oman was booming in 1981, spurred by the recent success of many companies, especially in the south of the country. New exploration efforts focused mainly in blocks not held by PDO, usually in the northern and eastern part of the country. The Oman Petroleum Development Co. (OPDC), a joint venture of Nippon Oil, Teikoko Oil, Mitsui Oil Exploration, and Nissho-Iwai, all of Japan, was awarded a 15,000-square-kilometer concession in block III in central Oman in October 1981. The company was conducting a detailed geological and geophysical survey of the area, and planned to spud their first well in September 1982. OPDC pledged to spend $104 million on exploration over 6 years, and agreed to a production split of about 85:15 in favor of Oman. Elf-Aquitaine Oman, a subsidiary of Elf-Aquitaine of France was awarded a 27,000-square-kilometer onshore concession in eastern Oman. Elf-Aquitaine was to act as operator for a joint company composed of the Kuwait Petroleum Corp. and the International Energy Development Corp. and Sumitomo Petroleum Development Corp., both of Japan. Elf-Aquitaine was also active in two other concessions in eastern Oman, one of which contained the producing Sahmah Field.

Not far from Elf-Aquitaine's new concession in eastern Oman, Japex, a joint venture company composed of Japan Petroleum Exploration (85%) and C. Itoh Energy Development Corp. (15%), was awarded a 4,400-square-kilometer block by the Oman Government in July 1981. In November 1981, Indonesia Petroleum Ltd. purchased a 10% equity interest in Japex. The block is located in the Wadi Aswad region of northeastern Oman. The contract called for a minimum investment in the concession of $45 million over a 4-year period.

Amoco Oman Oil Co., a subsidiary of Standard Oil Co. of Indiana (United States) was also awarded a 49,000-square-kilometer concession in northeastern Oman, extending from the United Arab Emirates border to

Muscat. The tract was relinquished by PDO in 1970. Amoco agreed to spend $70 million on exploration over a 7-year period, with a production split of 85:15 in favor of Oman. Amoco also held an 85.5% interest with Deutsche Schachtbau (9.5%) and Wintershall A.G. of the Federal Republic of Germany in an offshore concession in southeastern Oman, extending from Masirah Island to Sauquirah Bay. Another consortium composed of the Gulf Oil Corp. (35%) and Quintana International Ltd. (35%), both of the United States, and Occidental Petroleum of Oman Ltd. (30%) spudded its fourth wildcat in the Sunaineh Concession in northwestern Oman in September 1981. One other wildcat was a gas well and the other two were dry.

While all of Oman's current production of crude oil was exported, the Government was in the process of building the country's first refinery at Mina-a-Fahal. The refinery, under construction by Mitsui of Japan, was to have a capacity of 50,000 barrels per day and was scheduled to start production in early 1983. Late in 1981, the Government established the Oman Refinery Co. Ltd. (ORC) to manage and operate the refinery. The company, owned 99% by the Ministry of Petroleum and Minerals and 1% by the Central Bank, would obtain its requirements of crude oil from PDO to meet the needs of the local market. Oman's consumption of petroleum products averaged about 11,000 barrels per day in 1981. The remainder of the refinery's output was to be exported. The Government also prohibited the importation of refined products as long as production from the refinery was sufficient to meet domestic demand. One of the first acts performed by the ORC was to contract Ashland Oil Co. of the United States to provide startup, management, and operational services for the refinery.

Oman's output of crude oil was marketed directly by the Government through PDO, by equity shareholders in the company, and by Elf-Aquitaine. Shell lifted about 165,000 barrels per day of Omani crude in 1981, 55,000 barrels per day of which was through a buyback agreement with PDO. The remaining 110,000 barrels per day was its equity share. CFP-Total and Partex lifted about 15,000 barrels per day between them, and the remaining output was sold through third party contracts to Transworld Oil Co. (90,000 barrels per day), C. Itoh and Co. (20,000 barrels per day), Gulf Oil Corp. (10,000 barrels per day), Nippon Oil through Nissho Iwai (10,000 barrels per day), Mitsui Bussan (7,000 barrels per day), and Fides Trust through Credit Suisse Banque (20,000 barrels per day). The price of Oman's crude oil started the year at $39.50 per barrel, declining to $34.50 by yearend.

Natural gas was also assuming a greater importance in Oman's economy in 1981. Associated gas produced at the country's oilfields was either used to upgrade the crude oil in the pipeline stream, used for local energy requirements, or flared. Nonassociated gas was derived primarily from the Yibal Field, located about 100 kilometers northwest of Qarn-Alam, where gas reserves were estimated at 5 trillion cubic feet. Yibal gas was liquefied at the Yibal NGL plant, the output from which was either delivered to the nearby LPG plant, or put into the Yibal-al-Ghubra pipeline. A second NGL plant was under construction at Fahud, 50 kilometers east of Yibal, and a third was planned for Lakhwair. The Yibal plant, completed in 1981, produced liquid propane and butane. The propane was utilized in cooling systems of various PDO gas plants, while the butane was purchased by the Oman National Gas Co. for bottling to meet domestic demands. Most of the output from the Yibal NGL plant was put into the 330-kilometer, 17-centimeter, Yibal-al-Ghubra pipeline. At Yibal-al-Ghubra, the gas was to fuel power generation and water desalination plants for the domestic network. The pipeline had a capacity of 130 million cubic feet per day of gas.

In December 1981, a branch of the main pipeline was completed that ran from Mureirat, which is along the Yibal-al-Ghubra pipeline, to Sohar, 250 kilometers north of Muscat. The gas pipeline, built by Dodsal of India, was designed to provide an energy source for the copper mine and refinery at Sohar and to provide gas for power generation to all the regions along the Batinah coast. Oman's effort to utilize its reserves of natural gas for domestic purposes, while saving crude oil and refined products for export, was expected to pay substantial dividends in the future. By 1985, gas consumption was expected to rise to 129 million cubic feet per day from increasing industrial demand. By that time, the savings in oil consumption was to be about 7.9 million barrels per year.

The Sohar copper mine and smelter complex was Oman's largest nonfuel mineral development project. The project was under construction by the Oman Mining Co.

(OMC), which was owned by the Government. Consultancy for the project was being handled by a team of experts from the Geological Survey division of the Australian Ministry of Trade and Resources. The company planned to mine three deposits, Lasail, Aarja, and Bayda, all located 25 kilometers west of Sohar. Reserves at the deposits were estimated at 8 million, 3 million, and 1 million tons, respectively, of 1% to 2% copper ore. The mining rate was to average 3,000 tons per day of ore, giving the mine a life of 11 to 12 years. The mining method to be used was trackless, sublevel caving, with access to the deposit by declines. Output from the mine was to be concentrated and smelted into blister copper, and then refined. OMC added the plans for the 20,000-ton-per-year electrolytic copper refinery in 1980 to allow for production of higher quality copper, and also to permit the extraction of precious metals in the anode slimes. The initial development work on the project was begun in 1979, and by 1981, several main shafts had been dug. The initial date for completion was mid-1982, but owing to time and cost miscalculations, the project would probably not commence production until mid-1983.

Oman's plans to build a steel plant have not been implemented. In 1980, Dastur Engineering of India carried out a feasibility study for a 120,000-ton-per-year rolling mill to produce bars, sections, and wire rods in the Rusayl industrial zone near Muscat. The mill was to be integrated with a gas-fired, direct-reduction sponge iron plant sometime later. Neither plan was acted upon in 1981, however, and Oman may have dropped the proposal in light of the rapid growth in regional steel production in the Middle East.

The Oman Government was also involved in the construction of a cement plant in the industrial area at Rusayl. The 600,000-ton-per-year plant was under construction by Krupp Polysius A.G. of the Federal Republic of Germany for the Oman Cement Co., a Government-owned company. Construction of the plant began in 1981, and was to be completed early in 1983. The Government also initiated a project to exploit a salt deposit at Quriyat, 60 kilometers southeast of Muscat. A $5.3 million refinery with an annual capacity of 8,000 tons of high-purity salt was to be completed in 1983.

Finally, the Oman Government, through the Ministry of Petroleum and Minerals, planned to conduct a general geological mapping program to inventory the country's mineral resource potential. Several mineral deposits have already been located in the country, including 5 to 10 million tons of podiform chromite in scattered deposits in the Oman Mountains, 8 to 10 million tons of asbestos, 10 million tons of coal, and deposits of iron, lead-zinc, and manganese. Large reserves of gypsum and limestone for possible use in the country's cement plant have also been located.

Commodity	1979	1980	Sources, 1980	
			United States	Other (principal)
NONMETALS —Continued				
Stone, sand and gravel:				
Dimension stone, crude and partly worked	1,205	2,402	--	United Arab Emirates 1,288; Italy 609; India 439.
Gravel and crushed rock	110	821	20	United Arab Emirates 662; India 138.
Limestone excluding dimension	831	1,430	3	India 1,210; United Arab Emirates 190.
Sand excluding metal-bearing	22	159	46	India 113.
Other: Building materials of asphalt, asbestos and fiber cements, unfired nonmetals	4,751	6,067	46	United Arab Emirates 3,320; India 1,599; United Kingdom 535.
MINERAL FUELS AND RELATED MATERIALS				
Petroleum refinery products:				
Gasoline thousand 42-gallon barrels	1,573	1,338	--	United Arab Emirates 901; Bahrain 436.
Kerosine and jet fuel do	803	656	(1)	Bahrain 312; United Arab Emirates 312.
Distillate fuel oil do	840	1,140	--	United Arab Emirates 522; Bahrain 334; Singapore 234.
Residual fuel oil 42-gallon barrels	13	4,003	--	United Arab Emirates 3,996; United Kingdom 7.
Lubricants do	108,507	151,389	8,904	Singapore 53,907; United Kingdom 30,240; Bahrain 24,157.
Other:				
Liquefied petroleum gas do	61,805	53,221	(1)	United Arab Emirates 51,260; India 1,195.
Mineral jelly and wax do	--	409	409	
Bitumen and other residues do	116,200	270,785	--	Bahrain 149,730; Singapore 63,824; Kuwait 32,791.

[1]Less than 1/2 unit.
[2]May include platinum-group metals.

PEOPLE'S DEMOCRATIC REPUBLIC OF YEMEN

Mineral resource development in the People's Democratic Republic of Yemen (PDRY) was only beginning in 1981. The mineral industry consisted of refining imported oil and production of salt from seawater. Still, unverified reports of a commercial oil discovery in PDRY held out the possibility of improving the country's standard of living, which was among the lowest in the region.

PDRY's economy, lacking any real industrial sector, was largely tied to agriculture and fishing. The country was a British Colony until 1967, when Yemeni nationalists wrested control of the Port of Aden and the surrounding land from the British and formed an independent nation. The withdrawal of British forces and the closure of the Suez Canal, for which Aden was a major oil-bunkering facility, left the country nearly penniless upon independence. Since that time, the Government of Aden has sought to promote the development of a balanced economy with agriculture providing a livelihood for most Yemeni, and the Port of Aden serving as the industrial center of the country. Still, with its paucity of domestic resources matched only by its shortage of a skilled work force, economic development in PDRY has been slow and difficult. PDRY's economy has remained fairly static over the past several years, due mostly to a lack of investment. Foreign trade in 1981 has been dominated by importation of crude oil, estimated at $850 million, and the export of refined products, valued at $750 million, leaving a deficit in petroleum trade of $90 million.[12] This deficit was incurred by the consumption of about 14% of the refinery's output within the country. Total exports from PDRY were valued at $800 million. About 75% of the nonoil exports were from the country's fisheries, with the remaining 25% accounted for by tobacco, coffee, and

salt. Salt was exported mostly to nearby African countries. PDRY's imports were valued at about $1.55 billion in 1981, mostly for food, cement and construction materials, and industrial raw materials. This import level left the country with a trade deficit of about $700 million. Aden's current accounts balance was rescued by remittances from Yemeni working abroad, which amounted to about $550 million in 1981, and an inflow of foreign aid, equivalent to about $90 million. This left the overall balance of payments with a deficit of about $60 million.

PDRY's short- and medium-term economic development plans were contained in the revised 1981-85 5-year economic development program. The plan was revised in October 1980 to replace the 1979-83 plan, the goals for which were considered too ambitious given the country's lack of a skilled work force. The new plan envisioned expenditures over the 5-year period of $1.68 billion. In 1981, the Government budget, through which development funds were allocated, registered expenditures of about $280 million based on revenues of about $260 million. Of the total investment spending targets of the plan, the industrial sector was to receive the largest share (32%), while transportation received 17%, agriculture 14%, fisheries 8%, building and construction 12%, and services 17%.

Recognizing the need for foreign expertise and capital for developing its resources, the centrally planned PDRY Government issued the Law for the Encouragement of Investment late in 1981. The new law was designed to encourage and protect all funds and fixed and movable property invested in the country by a foreign nation. Priorities were given to developing joint projects in cooperation with Yemeni investors. The law was developed and instituted to facilitate exploration and development of oil in the country. The urgency of law was due to the possible discovery of a commercial reservoir during the year.

Many years of exploration and prospecting may have paid off for PDRY. It was reported in Platts Oilgram that the Italian state company, Azienda Generale Italiani Petroli S.p.A. (AGIP), discovered relatively high-quality crude oil in Hadhramaut, PDRY, near the Oman border. A test well flowed at 3,000 barrels per day of light crude according to the report, and AGIP was conducting further tests to determine if the field was commercial.[13] In addition to these reports, a Kuwait newspaper reported that several Soviet companies and Braspetro, the international subsidiary of the Brazilian oil company, Petróbras Brasileira S.A., as well as AGIP, have shown that oil exists in commercial quantities in PDRY.[14] The Soviet Union, Brazil, and Italy were the only countries with companies actively exploring for oil in the country in 1981. Braspetro signed an agreement with the Yemen National Oil Co. late in the year, for sole oil and gas exploration rights over a 42,000-square-kilometer area between the Mahra and Hadhramaut Governorates. Braspetro was committed to drilling six wells in the concession area. While the news of AGIP's discovery was greeted with elation in the country, no confirmation from AGIP has been forthcoming. By the end of 1981, it was difficult to determine whether the discovery, if it actually occurred, represented the beginning of a new oil era for PDRY, as many of the country's nationals seemed to believe.

While most of the attention of the country has been focused on the development of crude oil reserves, the Aden refinery has been gradually increasing its output of refined products from an average value of $157 million in 1975-78 to about $760 million in 1981. The Aden refinery, which is owned by the Government, was originally owned and operated by British Petroleum (BP) until it was nationalized in 1977. The refinery has improved its capacity utilization factor from less than 30% to about 50% in 1981 by importing crude oil and processing it for domestic consumption and by processing oil on behalf of other customers. Throughput for the refinery in 1981 averaged about 75,000 barrels per day compared with its 150,000-barrel-per-day design capacity. Customers refining crude oil at Aden in 1981 were the Government for local consumption 10,000 barrels per day, supplied by Kuwait; the Kuwait National Petroleum Oil Co., 10,000 barrels per day; the Soviet Union, 10,000 barrels per day; Iran's National Iranian Oil Co., 40,000 barrels per day; and France's CFP-Total, 5,000 barrels per day.

Late in 1981, PDRY's Petroleum and Minerals Board (PMB) and Kuwait's Independent Petroleum Group (IPG) reached an agreement to increase the role of the Aden refinery in supplying petroleum products to the region, especially in East Africa, but also supplying any product shortages that might arise in the Middle East. The compa-

ny was to market middle distillates—heavy fuel oil, which, due to the oil hydroskimming process utilized at the refinery, represents over 50% of its output. The IPG was to also market LPG from the refinery in the same area. The agreement also called for construction of new storage tanks, cooperation on shipping services, and the preparation of a feasibility study for modernization of the refinery. The IPG also indicated its interest in undertaking petroleum exploration in PDRY.

The Aden refinery was originally intended to service East African and Middle Eastern markets, as well as to supply bunker fuel for ships transiting the Suez Canal. With the closure of the Suez Canal and the withdrawal of the British technicians, the refineries market was lost and the PDRY Government did not have the funds to modernize and stay competitive. IPG's plan, which was expected to take effect in 1982, seemed to be the first real hope of breathing new life into both the refinery and the country's economy.

PDRY's nonfuel mineral development plans have, for the most part, taken a back seat to oil exploration. The Soviet Union has been active for several years in assisting in geological exploration and mineral prospecting in the country. PDRY and the Yemen Arab Republic announced a joint geological venture late in 1981 to search for minerals and water resources. The joint project was to be financed by a $36 million grant from the Arab Fund for Social and Economic Development.

The two nonfuel mineral projects in the country that appear most likely to be undertaken involve salt and cement production. Unrefined marine salt was already produced by the General Salt Organization's facility at Khawr Maksior. The plant, located northeast of Aden, produced about 75,000 tons per year of unrefined marine salt by evaporating seawater. A small amount of this output was sold domestically, with the remainder being exported mainly to Africa. Under the 1981-85 5-year plan, the Government planned to upgrade the facility by either expanding production capacity or installing a facility to refine the salt. No definite timetable for either of these projects had been announced. The Government was also planning, within the next 5 years, to construct a 250,000- to 300,000-ton-per-year cement plant, utilizing locally quarried limestone and gypsum. The Government was in the process of locating and delineating limestone reserves in the country to supply the plant.

QATAR

The production of crude oil and natural gas continued to fuel the development of Qatar's economy in 1981, as petroleum revenues fostered an expanding nonoil industrial sector. Despite its overwhelming reliance on crude oil exports, Qatar has in the past few years become a leading regional producer of petrochemical products, fertilizer, steel, cement, and NGL. These industries were part of the Qatari Government's plan to diversify the economy away from total dependence on oil, and to develop productive industries capable of earning income on their own. Qatar's nonoil era was not expected to be as bleak as some OPEC nations, due to the presence of the huge North Field, one of the world's six largest nonassociated gasfields. This gas was to provide cheap energy to fuel Qatar's industries for many decades into the future.

Crude oil exports, valued at about $5.62 billion[15] in 1981, accounted for 94% of the country's total exports and 90% of the Government's revenues. Total revenues from oil exports declined by only 1% from 1980 to 1981, while total crude oil production declined by 14% over the same period. Qatar was able to maintain its revenues near the alltime high by holding out on price reductions for its onshore Dukhan (40° API) and offshore Marine (36° API) crude oil until about mid-1981. In January, Dukhan crude was selling for $43.92 per barrel while Marine crude was slightly lower at $43.73 per barrel. These prices reflected a $6.50 per barrel premium over the official Government sales price. As the market began to soften, Qatar eliminated the premium, and by October 1981, the official price was reduced to $35.45 for Dukhan and $35.30 for Marine.

About 90% of the country's development expenditures and domestic services were provided by the Government through the national budget. With revenues in excess of $5 billion in 1980, Government expenditures were about 60% of that level. In 1981, the Government spent even less, about $2.8

billion, while revenues were down slightly to $5.1 billion. Rather than being forced to maintain production at a certain level to fulfill budget requirements, as many other OPEC nations were, Qatar was more than happy to shut in some production and extend the life of its oil reserves. The main problem encountered by lower crude oil production was the consequent decline in associated gas output, which was used as fuel for industry, petrochemical feedstock, power generation, and water desalinization.

Crude oil production in Qatar was under the management of the Qatar General Petroleum Corp. (QGPC), which was owned by the Government. QGPC was responsible for directing oil exploration, oil and gas production, petroleum refining and marketing, and supervision of petroleum projects under construction at the Umm Said industrial zone. Total crude oil production in the country declined from an average of 473,000 barrels per day in 1980 to 402,000 barrels per day in 1981. About 97% of this output was exported, with the remainder being refined for domestic purposes. Qatar reduced its crude oil production about 18% in June 1981 in accordance with OPEC's decision to limit production to bring about equilibrium in the world oil market.

Oil was produced by QGPC from both onshore and offshore areas. All onshore oil production came from the Dukhan Field, which began producing in 1949. Production from the field declined from 228,000 barrels per day in 1980 to 210,000 barrels per day in 1981. Offshore production came from three main fields, Idd Al-Shargi, Maydan-Mahzam, and Bul Hanine. Average output from these fields averaged 192,000 barrels per day, down more than 21% from the 1980 level. QGPC contracted the operation of the onshore and offshore oilfields to service companies. The Dukhan Service Co. and a consortium composed of BP, Royal Dutch/Shell, CFP-Total, Mobil Oil, Exxon Corp., and Partex, were the main operators of the Dukhan Field, while Shell Service Co., a subsidiary of Shell Oil Co. (United States), was the main contractor for the offshore areas.

QGPC was also responsible for oil exploration within the country. In 1980, all open areas both onshore and offshore were assigned by the Government to QGCP. In 1981, QGCP began an extensive seismic survey aimed at defining new land and marine structures that show considerable oil potential. A total of 2,120 square kilometers of deep and shallow offshore areas, and 550 square kilometers of onshore areas were surveyed during the year. QGPC also drilled a total of 50 wells during the year, with the total footage drilled reaching 95,000 meters. The new well count was down three from the 1980 level. Of the wells drilled, 29 were for development purposes, 19 were for water injection, 1 was for exploration, and 1 was a gas well. An experimental project for powered water injection began in 1981 in the Dukhan Oilfield and was scheduled to run until 1983. At that time, results of the enhanced-recovery technique were to be analyzed, and a decision was to be made on whether to extend the project to the country's other fields. QGPC also announced a commercial oil strike close to the Bunduq Oilfield in the offshore area of Qatar. The Bunduq Field, which is shared jointly by Qatar and the United Arab Emirates, was shut down in 1979 owing to pressure maintenance problems. The new strike reportedly contained 40° API quality oil in commercial quantities, and the strike zone was located relatively close to the surface. No reserve figures were available by yearend. The find was made in the Arab-C zone on the Qatari side of the Bunduq Field. The Government indicated that the initial results were promising and the field was likely to add considerably to Qatar's current 4.6 billion barrels of proven oil reserves.

QGPC's crude oil output was sold mostly under quarterly contracts to the shareholders in the service companies and to Japanese contract buyers. Shareholders in Dukhan Service were entitled to lift approximately 130,000 barrels per day, while Shell Service was allocated 145,000 barrels per day. Japanese customers, Mitsubishi, Sumitomo, and Mitsui, lifted 45,000 barrels per day, 30,000 barrels per day, and 20,000 barrels per day, respectively, until spring 1981 when they reduced their liftings to 50,000 barrels per day total, owing to Qatar's high premium. Nissho-Iwai and C. Itoh each lifted 60,000 barrels per day in 1981. The remainder was sold on the spot market.

Qatar's refined product output was to be substantially increased when the country's second refinery comes onstream in 1983. The National Oil Distribution Co., which was owned by QGPC, operated an 11,000-barrel-per-day refinery at Umm Said. This refinery has been unable to satisfy Qatar's domestic requirement for petroleum products for several years, which meant substantial imports for a country that is a large

exporter of oil. To remedy the situation, Qatar awarded Technip of France a $138 million contract in October 1980 for construction of a 50,000-barrel-per-day refinery to be located at Umm Said. The contract included storage facilities for intermediate and refined products and new export facilities. The refinery was to leave a small surplus for export during the first few years of production. With the new refinery on-stream, Qatar was expected to be self-sufficient in refined products until the mid-1990's.

Qatar was beginning to rely more heavily on its reserves of natural gas rather than crude oil. Qatar produced associated and nonassociated gas from both onshore and offshore areas, and by 2000, Qatar was expected to derive 80% of its energy production from natural gas. Production of associated gas in 1981 averaged 297 million cubic feet per day, which was less than one-half the amount the Government planned to produce for use as fuel and feedstock for the industrial ventures at Umm Said. Gas from the Dukhan Field was gathered and fractionated at a central plant at Fahalil, pipelined to power generators, and then pipelined to Umm Said. Onshore gas was also earmarked for the NGL processing plant NGL I. Offshore associated gas was delivered to the parallel facility, NGL II, and also to the Qatar Petrochemical Co.'s stream crackers. Total demand for associated gas was nearly 600 million cubic feet per day, which included 150 million cubic feet per day for the Qatar Steel Co. (QASCO), 200 million cubic feet per day for the NGL plants, 100 million cubic feet per day for the fertilizer plant, and the remainder for power generation and water desalinization. The shortfall in production, which was due to Qatar's cutback in oil production, was made up by gas production from the nonassociated Khuff Field located onshore beneath the Dukhan Oilfield. While the Government of Qatar has tended to view the Khuff Field as a type of emergency energy reserve, it has been forced to tap the field in order to maintain production for the country's industrial projects. Proven reserves in the field were only 817 billion cubic feet in 1981, and at the current rate of extraction, could only be expected to last until 1990. In 1981, 150 million cubic feet per day of Khuff gas was allocated for direct use by Qatar Petrochemical Co. (QAPCO).

Qatar's two integrated NGL facilities (NGL I and NGL II) became fully operational in 1980, and produced about one-half of their rated capacity in 1981, owing mainly to inadequate supplies of associated gas. NGL I was originally commissioned in 1975 but was destroyed in an explosion in April 1977. The facility was rebuilt and commissioned in late 1980 at a cost of about $300 million. NGL I was designed to process associated gas produced onshore, while, NGL II, also completed late in 1980, was to process associated gas from offshore. NGL II was designed to process a maximum of 250 million cubic feet per day of gas from offshore, which was to be supplied by pipeline from the oilfields. Severe problems have been encountered since the gasline was commissioned in early 1980, owing to hydrogen-induced corrosion. The pipeline operated only intermittantly in 1981, and production and exports of LPG were adversely affected. LPG exports earned about $250 million during the year, which was less than one-half of the anticipated revenues. The actual full rated capacities of NGL I and II are as follows:

	NGL I	NGL II
Gas input, million cubic feet per day	340	250
Propane, tons per day	740	220
Butane, do.	470	730
Condensate, do.	370	73
Methane-enriched gas, million cubic feet per day	140	110
Ethane-enriched gas, do.	24	28

The propane, butane, and natural gasoline were for export, while ethane- and methane-enriched gas were for feedstock in the petrochemical plant. Some of the residual gas and methane was also used by the steel mill, the fertilizer plant, and other power stations. The petrochemical plant also suffered from inadequate supplies of gas during the year owing to the problems at the NGL plants.

Despite the rather dismal performance of the country's gas industry in 1981, the long-term picture appeared quite spectacular, owing to the presence of the huge North Field, formerly known as the Northwest Dome. The North Field was a nonassociated gasfield in the Permian Khuff Formation that contained measured reserves of 100 to 120 trillion cubic feet of gas and indicated reserves of 300 trillion cubic feet, which made the field possibly the largest single concentration of nonassociated gas reserves in the world. Given the size of the find, the economic progress of the entire country was to depend on the development of the field

over the next half century and beyond. With the enormous task of planning and developing the field still ahead, the Government was, understandably, moving quite cautiously. Its current shortage of gas for industry seemed somewhat ironic, however, with a field of that magnitude located just a few kilometers northwest of the country. The QGPC, which was responsible for developing the field, designed a two-phase plan. The first phase was to draw off 700 to 800 million cubic feet per day of gas to be processed for local consumption; that is, in industry, power generation, the NGL plants, and for petrochemical feedstock. The domestic requirements would eventually rise to about 1 billion cubic feet per day. The second phase of the plan would be to use another 1.0 to 1.4 billion cubic feet per day of gas to produce 6 to 7 million tons of LNG annually for export.

The initial Government plan was to have QGPC be the sole owner of the offshore production facilities, and allow foreign partners to take a 20% share in the LNG plant. The plant was to be located at Ras Laffan and connected to Umm Said by pipeline. Foreign companies, with experience in LNG plant construction, would be allowed a 15% share in the operation with the remaining 5% going to Japanese companies with experience in transportation and marketing.

QGPC estimated the cost of developing the field and processing plant at $5 to $6 billion. Foreign companies submitted proposals for developing the project in 1980, and QGPC evaluated them during the year. In 1981, the QGPC asked the interested companies to submit revised proposals that would conform to new guidelines set down by QGPC. The guidelines related to legal aspects of the partnership and project, the formation of an LNG company with its marketing and shipping costs, and the operator's fees. Companies who submitted proposals were Wintershall AG of the Federal Republic of Germany, who already held a production-sharing concession with QGPC covering the southern portion of the field; BP; Roy M. Huffington Co. of the United States; CFP; and Royal Dutch/Shell. The Japanese companies in the running for the 5% share were Mitsubishi, Mitsui, Sumitomo, C. Itoh, Marubeni, and Nissho-Iwai. Exxon was also a late comer to the main bidding when it reentered negotiations with QGPC after backing away in mid-1981.

Development of the field was not expected to begin until 1983-84, with the first gas production in phase one beginning in 1985-86. Given Qatar's expected extraction rate of 2 to 2.4 billion cubic feet per day, the measured reserve figure would give the North Field a productive life of 115 to 135 years. Using the indicated reserve figure, life of the field would range from 345 to 405 years, a statistic that is certainly not being ignored by either the oil-producing companies or oil-consuming nations of the world.

QAPCO's $770 million petrochemical complex at Umm Said came onstream in February 1981. QAPCO was a joint venture of QGPC (84%) and Charbonnages de Française (10%). The main plant was built by Technip of France under a $220 million lump-sum turnkey contract that was awarded in 1977. The main units of the plant were an ethylene steam cracker supplied by Technip; a $112 million polyethylene unit built by Coppee-Rust of Belgium; a $227 million, 50-megawatt power station supplied by Turbotechnica of Italy; and $81 million worth of storage, shiploading, and ancillary facilities built by Japan Gasoline Co. The complex utilized ethane-enriched feedstock from NGL I and II to produce a maximum of 280,000 tons per year of ethylene, 140,000 tons per year of low-density polyethylene, and 46,000 tons per year of sulfur. During the year, QAPCO produced about 110,000 tons of low-density polyethylene, 63,000 tons of ethylene, and an unspecified quantity of sulfur. About 30,000 tons of low-density polyethylene was exported. The low utilization factor was due to inadequate supplies of gas from the NGL plants.

In August 1981, QAPCO awarded Mitsui Shipbuilding of Japan a $50 million contract for process technology for a new 70,000-ton-per-year high-density polyethylene plant to be built alongside the other plant at Umm Said. The project, for which bids were invited in July 1980, was scheduled for completion in 1984. It was to use ethylene from the Umm Said complex as feedstock. Mitsui and Co. also signed a 3-year contract with QAPCO to purchase and market 35,000 tons per year of sulfur from the petrochemical project. Sulfur deliveries began in late August 1981.

The Qatar Fertilizer Co. (QAFCO) produced at about 85% of its capacity in 1981 owing to the lack of natural gas feedstock. The QAFCO complex, located at Umm Said, consisted of two twin trains for ammonia and urea production. QAFCO-1, which came onstream in 1976, could produce 900 tons

per day of ammonia and 1,000 tons per day of prilled urea. QAFCO-2 began producing in 1978, and effectively doubled the plant's capacity. Total annual output capacity of the complex, in contained nitrogen, was 488,000 tons (N) ammonia, and 304,000 tons (N) urea. The plant utilized associated gas from the Dukhan Oilfield and residual gases from the NGL plants. QAFCO was owned 70% by the Government of Qatar, 25% by Norsk Hydro AS of Norway, and 1% by Davy Powergas Ltd. and 2% by Hambros Bank, both of the United Kingdom. Qatar was also planning to build two organic fertilizer plants to be financed by an $84 million budget allocation for development in the industrial and agricultural sectors.

The Qatar National Cement Co. increased its cement production nearly 25% in 1981, to almost 200,000 tons. Demand for cement in the country was estimated at 750,000 tons annually, however, and the bulk of the country's supplies had to be imported. The Redco Cement Co. of Qatar purchased most of the country's import requirements from Arabian Bulk Trade of Saudi Arabia, who obtained most of their supplies from Japanese producers. Qatar increased its purchases of cement from 500 to 1,500 tons per day to meet the country's requirements. Current production was to increase 100,000 tons per year when a new grinding mill is installed at the National Cement plant at Umm Bab next year.

Qatar's Industrial Development Technical Center recently announced the discovery of large deposits of gypsum, celestite, and shale. The discoveries followed a comprehensive geologic survey of the country. Qatar already produced dolomitized limestone and chalk-limestone at Umm El-Afai for use in cement production at Umm Bab. Gypsum was also discovered near Al Nafkah. Building sand was also extracted and washed at a new plant near Almirkhiya.

QASCO has been one of the gulf region's prime examples of industrial diversification. QASCO was one of the first direct-reduction-based steelworks to come on-stream in the Middle East, bringing its 400,000-ton-per-year Midrex direct-reduction plant into production in 1978. The Midrex unit, located at Doha, serves two 70-ton electric arc furnaces at Umm Said. The furnaces were built by Nippon Kokan of Japan. The furnaces supplied two 4-strand continuous billet casters and a 20-strand bar mill. The billet casters and bar mill were built by Kobe Steel of Japan, which also owns a 20% share in the company. The Qatar Industrial Development Agency owned 70% of the company, and Tokyo Boeki owned the other 10%. In 1981, QASCO exceeded its rated capacity by producing 440,000 tons of direct-reduced iron and 455,000 tons of raw steel. About 12% of the plant's output was sold domestically, with about 50% exported to Saudi Arabia, 30% to the United Arab Emirates, and the balance to Iraq and other neighboring countries. Toyko Boeki was under a 10-year contract, which began in 1978, to market the plant's output. Iron ore for the plant was supplied by Brazil and Sweden, and scrap was imported from the United States.

SYRIA

Syria's mineral industry continued to prosper in 1981, in contrast to most other sectors of the Nation's economy. Major developments in the mineral sector were a slight increase in crude oil production, the first full year of operation for the new Baniyas refinery, increased production of cement and phosphate rock, and the commissioning of two new fertilizer-producing facilities at Homs. The mineral industry in Syria contributed about 15% to the country's GDP, estimated at $14.5 billion in 1981.[16] The major foreign currency earners, in order of decreasing value, were crude petroleum and phosphates, which together accounted for nearly 70% of the country's

exports valued at $2.3 billion in 1981.

The country's overall economic performance did not match that of the mineral sector. Defense expenditures, equivalent to nearly 30% of the Government's budget, continued to put a considerable strain on the economy. In 1981, the Government of Syria announced the country's fifth 5-year development plan (1981-85). Under the previous plan (1976-80), the GDP grew at an annual rate of 8%, largely owing to a high level of capital investment, usually running at 50% of the Government's total nondefense expenditures. Political instability in the region, combined with the Government's attempts to reach the development targets set under the fourth plan, led to economic problems in 1979-80. The most serious of these problems were a shortage of foreign exchange, inflation of about 20% per year, and a widening trade deficit.

To deal with the trade deficit, estimated at $1.6 billion in 1981, the Government attempted to restrict the level of imports while at the same time establishing a two-tier exchange rate in April 1981. Oil, cotton, and phosphates, which together accounted for 83% of the exports, were to be governed by the official rate of US$1.00=LS3.925, while all other exports and receipts were subject to a parallel rate, which was established by the market.

Crude oil production in Syria increased slightly in 1981 to about 164,356 barrels per day from 157,450 barrels per day in 1980. This was the first increase in crude oil output since 1976, when production averaged 191,000 barrels per day. Recoverable reserves in Syria were estimated at 3.4 billion barrels of oil, or enough to sustain production at the current level until the year 2000, barring any new discoveries. Crude oil was produced from five oilfields, Suweidiyah, Rumeilan, Karachuk, Alayan, and Jebisseh. All of the fields except Jebisseh produced an average of 20° API gravity crude containing between 4.5% and 9.5% sulfur. Crude from Jebisseh was of higher quality 40° API and low in sulfur. Production was centered on the Suweidiyah Field, which accounted for about 90% of the country's output.

Petroleum exploration efforts continued in Syria, along with the gradual implementation of secondary recovery techniques to try to arrest the country's sagging output. A major proclamation was being prepared late in 1981 to encourage oil exploration by foreign companies. The Syrian Government was expected to sign a decree that would clarify the tax exempt status of foreign oil exploration companies and their non-Syrian subcontractors. The ambiguous tax laws in Syria had forced these foreign companies to pay upwards of $4 million in local taxes while awaiting clarification of the law. The decree was expected to result in substantial rebates to the foreign companies, most of which were U.S. operated.

The major oil companies operating in Syria were the state-owned Syrian Petroleum Co. (SPC); Pecten Syria Co., a subsidiary of United States Shell; Marathon Oil Co. (United States); and the Syrian American Oil Co. (SAMOCO), a subsidiary of Coastal States Corp. of Houston, Tex. Deminex of the Federal Republic of Germany was a partner in SAMOCO's Syrian operations, and Challenger Desert Oil Co. of Panama was also involved in exploration. SAMOCO was in the process of drilling an exploration well near Deir-el-Zar in central Syria. Marathon also began drilling at a newly acquired site off the Homs-Palmyra Road. Marathon acquired the 10,000-square-kilometer tract centered around Homs in 1980. The well was the company's second and last required under their current contract.

Syria's refining industry received a considerable boost in 1981 with the commissioning of the country's second refinery, at Baniyas, on the Mediterranean coast. The 120,000-barrel-per-day refinery was built by Industrialexport of Romania, and began its trial runs late in 1980. The refinery was able to process about 30 million barrels of crude oil during the year, which respresents about a 66% capacity utilization. At the close of the year, the Syrian Ministry of Oil and Mineral Resources announced that plans were being drawn up to modify the product yield from the refinery to increase the output of light products, improve the quality of all fractions, and reduce the sulfur content of the heavier fractions.

The country's older refinery, at Homs, was capable of processing about 38 million barrels per year of crude oil. The country's output of refined products in 1981 was approximately 9.22 million tons, of which 50% was fuel oil, 21% gas oil, 8% naphtha, 6% gasoline, and 1.3% LPG. The remaining output of heavier products included 360,000 tons of asphalt and 77,000 tons of sulfur. The Homs refinery processed about 51% of the country's total in 1981, with the Baniyas refinery producing the remainder. Syria's consumption of refined products was aver-

aging about 105,000 barrels per day in 1981 or about 58% of the country's total output of refined products. The remaining production of about 28 million barrels was exported.

Syria imported about 55% of the crude oil used in its refineries in 1981. About 100,000 barrels per day of crude was imported from Iraq through the Kirkuk-Baniyas-Tripoli pipeline, and combined with approximately 66,000 barrels per day of Syrian crude for use in the Homs and Baniyas refineries. Syria was unable to process all of its crude in the refineries because of the low API gravity and high sulfur content of its oil. About 89,000 barrels per day of Syrian crude was exported in 1981, 80% of which went to Western Europe, 10% to North America, 8% to Eastern Europe, and 2% to the Middle East. Baniyas also served as the main export terminal for both Syrian and Iraqi oil. In addition to the 100,000 barrels per day of Iraqi crude that Syria consumed in its refineries, another 300,000 barrels per day came through the same pipeline to be exported from Baniyas by Syria on behalf of Iraq. The Iraqis paid Syria about $40 million in transit fees for oil pipelined to and exported from Baniyas. The pipeline operated for all of 1981, despite the deteriorating political relationship between Iraq and Syria over the Iran-Iraq war.

Syria was only beginning to utilize its reserves of associated and nonassociated natural gas in 1981. In 1980, the Syrian Oil Ministry awarded Entrepose of France a $62 million contract to utilize associated gas from the oilfields in northeast Syria for the production of industrial solvents and condensates. The gas was to be collected from nine gathering stations and pumped through 52 kilometers of pipeline to a main treatment plant. The plant was to be capable of producing 58,000 tons per year of LPG from an input of 23.3 million cubic feet per day of gas. The project, whose status was unclear in 1981, was originally scheduled for completion in 1982.

Construction of a second gas project was to start in late 1982. The Oil Ministry stated that a 50,000-ton-per-year gas liquefaction plant was to be built in the Hasakah district at al-Jibsah. The plant was to utilize nonassociated gas from several wells to be drilled in the same area. Actual construction of the plant depended on the availability and amount of gas from the wells, as well as financing and technical assistance from countries or companies familiar with gas-processing project development. SPC was also participating in a 5,500-ton-per-year sulfur plant in Roumelan, Syria. The $2 million facility was to produce 15 tons per day of sulfur from sour gas. The plant was to be completed by 1982.

Syria's most important nonfuel mineral resource was phosphate rock. Production of phosphate rock increased about 2% in 1981 from 1.32 million tons in 1980. Exports of phosphate rock also increased from 823,000 tons in 1980 to 1.1 million tons in 1981. Syria's largest deliveries were to Lebanon, which received 26% of Syria's exports, Romania (17%), Bulgaria (9%), Italy (6%), and Czechoslovakia (2%). The remaining 40% was shipped to other countries in Asia and Eastern and Western Europe. Most of the increase in exports was due to a substantial rise in the deliveries of phosphate rock to Lebanon, which nearly tripled its imports from Syria from 98,000 tons in 1980 to 279,000 tons in 1981.

Phosphate rock was mined in three areas, Al-Tadmuria, Al-Shargiya, and Khunayfis, all located just south of Palmyra in central Syria. The mines produced an average of 66% to 68% TPL rock. All phosphate production was controlled by the state-owned General Co. for Phosphates and Mines. Phosphate rock was exported from the Port of Tartous, which was capable of loading 1.5 million tons of phosphate rock per year into ships of 25,000 to 40,000 deadweight tons.

Syria's first phosphate fertilizer complex at Homs was commissioned in March 1981 and began full production in October of that year. The $180 million facility was built by Industrialexport. The plant was designed to utilize 800,000 tons per year of concentrated ore to produce 150,000 tons of phosphoric acid and 450,000 tons of triple superphosphate annually. Exports of triple superphosphate were to begin in 1982. The plant received approximately 135,000 tons of 65% to 68% TPL rock from Syria's mines in 1981.

In addition to the new phosphate fertilizer plant, Syria's second ammonia-urea fertilizer plant began test runs in January 1981. The $250 million facility was built by Creusot Loire Enterprises of France. Pullman-Kellogg of the United States was responsible for design and engineering of the ammonia unit, and Heurtey Industries of the United Kingdom built the urea plant. The new plant was built adjacent to the existing ammonia-urea plant at Homs, which has been operating since the late

1960's. The older plant was capable of producing 110,000 tons per year of nitrogenous fertilizers, while the new plant was capable of producing 1,000 tons per day of ammonia and 1,050 tons per day of urea. Both plants utilized naphtha feedstock provided by the country's oil refineries. Both facilities were under the control of the state-owned General Establishment of Chemical Industries. The new production was to satisfy the country's domestic requirement for nitrogenous fertilizer, while also providing a substantial surplus for export. Ammonia and urea were to be shipped by rail to Tartous and exported from there.

Cement production in Syria was to increase dramatically in 1982 on the heels of a 16% increase from the 1980 to 1981 levels. The 1981 increase was related to the opening of the Chaba Cement Co.'s new 400,000-ton-per-year Sheikh Said plant at Aleppo, and a 150,000-ton-per-year plant at Adra. In 1982, the Middle East's largest cement plant at Tartous was scheduled to come onstream, changing Syria from a net importer to a net exporter of cement. The plant was to consist of four production lines, each capable of producing 1,600 tons per day of finished cement. The first two lines were to become operational in 1982, and the next two the following year. In 1981, Syria produced 2.3 million tons of cement and imported 850,000 tons. Output in 1982 was expected to reach 4.5 million tons, more than enough to satisfy the domestic consumption requirement of approximately 3.2 million tons. Cement production in Syria was under the control of the state-owned Syrian State Establishment for Cement Production. Syria was also expected to eliminate the need for building stone imports, with the completion of two marble dressing plants, at al-Zobar near Latakkia, and in Damascus. The plants were capable of producing 700,000 cubic meters of building stones from domestically quarried marble.

Steel production from Syria's General Co. for Iron and Steel Products (Gecosteel) plant at Hama increased 20% in 1981 to the design capacity of 120,000 tons per year. The ministeelworks, which was commissioned in 1977, produced steel billets from direct-reduced iron and imported scrap. The steelworks consisted of two electric arc furnaces and two 2-strand continuous steel billet casting machines. The works supplied billets to Gecosteel's merchant mill adjacent to the steelworks. The company produced merchant bars and black and galvanized welded gas and water pipes. The Government was planning to double the capacity of the Hama works by 1985, expand the output of the pipe mill, and begin production of pipe fittings, all under the fifth development plan. The Government also approved, in principle, plans for the construction of an integrated steelworks based on the country's Zabadani low-grade iron ore deposits. Reserves at Zabadani were estimated at 150 million tons of hematite containing 27% to 30% Fe_2O_3. The cost of the project was estimated at $2 billion, but it was expected that this project would be deferred.

Syria's General Establishment for Industrial Engineering brought into production a 2,500-ton-per-year copper cable plant in Aleppo in 1981. The plant utilizes imported copper for cable production, which was then manufactured into telephone wire at the Damascus cable factory. ALCOM, a 100% Syrian-owned company, brought onstream a continuous aluminum slab-heating furnace at Aleppo in 1981. ALCOM previously imported aluminum sheets for producing finished products for the Syrian market, but was now able to roll its own 200-millimeter-thick slabs for the same purpose. Slabs were imported from Eastern Europe. The furnace, supplied by Mechatherm Engineering of the United Kingdom, began operating in September 1981.

YEMEN ARAB REPUBLIC

The Yemen Arab Republic was one of the most populous nations on the Arabian Peninsula, and also one of the 31 least-developed nations in the world, according to the United Nations. Despite the Government's efforts to promote the commercial and industrial sectors, the domestic economy remained largely dependent on subsis-

tence agriculture. Industry in Yemen is a relatively recent phenomenon. Ten years ago, there was no real manufacturing enterprise in the country. The Government has attempted to remedy this situation by forming public and semipublic companies to import materials for domestic consumption and to produce commodities such as cigarettes, cotton textiles, pharmaceuticals, cement, and salt. The most successful of the public companies was the Yemen Oil and Minerals Co. (Yominco), which has entered into joint ventures with several foreign companies including Hunt Oil Co. of the United States, Shell Oil, and France's BRGM. The mineral industry in the country consisted primarily of the production of gypsum, cement, and salt, with salt being the only mineral exported. Salt exports in 1981 totaled 54,000 tons.

In 1981, the Government of Yemen announced its second 5-year development plan (1981-85). Total expenditures in the plan period were predicted at $6.5 billion,[17] compared with about $3 billion allocated for the first plan. The new plan was to carry over many projects from the previous plan in the areas of infrastructure development, agriculture, education, and health care, while placing new and greater emphasis on development of the country's industrial and manufacturing sector. Allocations for public-sector industrial projects were to reach $431 million under the plan, which includes money for construction of a third cement plant, a glass factory, and a factory for producing concrete reinforcing bars.

The Yemeni economy depended on remittances from Yemenis working abroad to finance budgetary disbursements and most of the country's imports. These remittances were $950 million in 1981, which represents the second consecutive year of decline.

Another major source of Yemen's foreign exchange receipts was foreign aid, which was estimated at about $300 million. Most of the aid was supplied by Saudi Arabia, Kuwait, and other Arab states and development funds. Nearly $20 million was supplied by the United States. Yemen's exports rose slightly in 1981, but remained below $20 million. Imports, on the other hand, rose about 6% to 1.8 billion, creating a trade deficit of $1.77 billion. Remittances, foreign aid, and a small amount of capital inflows combined to reduce the overall balance of payments deficit to $150 million in 1981.

In the minerals sector, Yemen registered production of only three commodities—rock salt, gypsum, and cement. Production capacity for cement was increasing the most rapidly. The Soviet Union built a small cement plant at Banjil, north of Hodeida, in the 1960's. In 1981, the Soviets returned to expand the capacity of the plant from 80,000 to 300,000 tons per year. A second cement plant was also under construction at Amran, 50 kilometers north of the capital, Sana. The 500,000-ton-per-year plant was being built by Ishikawajima-Harima Heavy Industries, and Nissho-Iwai, both of Japan, at a cost of $110 million. The plant was due to commence production in the fall of 1982. The Government was planning to construct the country's third cement plant at Mafraq, 60 kilometers south of Ta'izz. The Government allocated money for the project in the second 5-year plan, but no tenders had been issued for construction, and no details or timetable was available by yearend. Yemen's apparent preoccupation with cement production was because local consumption had increased to over 1 million tons per year, nearly all of which had to be imported. The cost to the Government for cement imports reached $60 million in 1981.

The Yemen Salt Mining Corp. continued to mine its open pit rock salt deposit in the coastal plain adjacent to the Port of Salif. Reserves at Salif were estimated at 250 million tons of rock salt with a NaCl content of 98.23%. Salt production from the deposit generally expanded and contracted with the level of world demand, as 98% of the mine's output was exported. A private sector project was planned to refine rock salt from Salif into table salt, but no details were available as to the progress of the project. Gypsum was also recovered in association with rock salt at Salif. All of the gypsum produced was sold to the Government cement plant at Banjil. With cement capacity about to increase dramatically, output of gypsum was also expected to rise, which could in turn increase the production of rock salt.

In terms of future mineral development, BRGM was completing work on an 18-month mineral survey of much of the country. Fifteen mineral occurrences had been located by the organization including an ancient silver mine at Majma, west of Marib, that contained lead and zinc as well. A new contract was signed between BRGM and Yominco to focus new exploration efforts in areas with known mineral potential. The contract had an estimated value of $716,000. Yominco was also allocated money to develop a copper mining industry at Jamoura. The copper-cobalt-nickel deposit

had been examined by a team of Romanian geologists in 1977.

Petroleum exploration efforts continued in Yemen, despite the lack of a commercial discovery to date. Shell Oil conducted geophysical exploration operations on a 10,000-square-kilometer coastal concession on the Tihana coastal plain. Shell's exploration contract expired in 1981, and the data was given to Yominco to evaluate. The World Bank subsequently stepped in with a $9 million loan to help evaluate the data and to promote further exploration in the area. Yominco was preparing to invite bids from foreign oil companies to renew exploration at Tihana.

The other major development in the petroleum sector was the signing of a new exploration agreement between Yominco and Yemen Hunt Oil Co., a subsidiary of the Dallas-based Hunt Oil Co., of the United States. The agreement covered an area of 12,600 square kilometers in the Marib and Al-Jawf area of east-central Yemen. Hunt Oil was to spend at least $4.2 million in the first 2 years of the 6-year agreement. The company was to begin its work with a seismic survey, followed by exploratory drilling, if warranted. The Marib-Al-Jawf area was considered a promising area by both the Government and Hunt Oil, owing to the geologic character of the region, which contained salt domes and formations that correspond with oil-producing zones in other areas of the Middle East.

With no crude oil or refining capacity, the Yemen Arab Republic was forced to import all of its domestic requirements of petroleum products. Yemen imported about 6.4 million barrels of petroleum products and another 12,000 tons of LPG in 1981. All gasoline and petroleum gas was supplied by Saudi Arabia under an agreement signed in 1980, and all other refined products, including jet fuel, diesel oil, and fuel oil, were supplied by Kuwait. Late in 1981, the Islamic Development Bank supplied Yemen with a $10 million loan to purchase petroleum products from Iraq. The new supply agreement was to take effect at the beginning of 1982. Meanwhile, Yominco was planning to construct two pipelines to transport refined products around the country. The first was a 270-kilometer, 10-inch line to run from the Port of Salif, to Mabar, and then north to Sana. The other was a 105-kilometer, 8.5 centimeter line running from Mocha to Ta'izz. Both lines were still in the basic design stage. Omnium Technique des Transports of France was conducting feasibility studies for both lines, both of which were to cost $150 million.

The Mineral Industry of Other Areas of South America

By Travis Q. Lyday[1]

CONTENTS

ECUADOR

During 1981, Ecuador's gross domestic product (GDP) increased by a reported 4.8% in real terms, a slight improvement over that of 1980. In current prices, the GDP in 1981 was estimated at $13.7 billion.[2] The inflation rate increased to 15.6% according to official figures, above that of 1980.

Ecuador's production of petroleum increased 3% in 1981 compared with that of 1980. The consortium of Corporación Estatal Petrolera Ecuatoriana (CEPE), the state oil company, and Texaco, Inc., produced almost 98% of the total from their Putumayo Basin operations in Oriente, the eastern jungle region. In sharp contrast, output from the Santa Elena Peninsula Fields, where oil was first produced commercially in 1921, continued to decline, producing only 510,000 barrels, a decrease of almost 8% compared with that of 1980.

The volume of crude petroleum exports increased from 38 million barrels in 1980 to 45.7 million barrels in 1981. Although crude petroleum export revenues increased to $1.56 billion in 1981 from $1.39 billion in 1980, the average-per-barrel price declined to approximately $34.10 in 1981 from about $36.70 in 1980. Exports of crude petroleum and petroleum products accounted for about 68% of Ecuador's 1981 merchandise exports, up from 63% in 1980. The petroleum industry contributed approximately 10% to the GDP, a substantial decrease from the 16.7% in 1980.

After recording a negative growth rate in 1980 of 5%, the petroleum and mining sector increased an estimated 1% in 1981, owing, in large part, to increased petroleum production. The total production of nonfuel minerals in Ecuador was estimated to have declined in 1981, and this sector continued to be of negligible importance to the economy. Mineral industry developments continued to be constricted, in part because Ecuador has not been adequately explored but, more importantly, because the existing mining law, Ley de Fomento Minero, was considered by private sector Ecuadorean and foreign investors as offering insufficient incentives and guarantees. An early approval by Congress of the proposed mining law, under consideration for several years before being submitted in 1980 to the Office of the President, was not expected by the mining sector.

Geological and mineral reconnaissance work by various organizations and private agencies in collaboration with the Dirección General de Geología y Minas (DGGM) continued on a relatively modest scale. Development work by the DGGM continued at the Chaucha porphyry copper deposit, Loja Province, discovered a decade ago under a United Nations development program. The Chaucha represents a major potential source of copper in Ecuador, with estimated reserves of 72 million tons of ore averaging 0.7% copper and 0.02% to 0.04% molybdenum reported.

CEPE was proceeding with its ambitious program to increase, by 1988, Ecuador's petroleum refining capacity from 96,600 barrels per day to 210,000 barrels per day, the current level of crude petroleum production. Reportedly, the increase is to supply the rapidly expanding demand for gasoline, diesel fuel, and kerosine but could result in the availability for export of an estimated 50,000 barrels per day of No. 6 fuel oil.

The principal refinery, owned by CEPE and located at Esmeraldas, Esmeraldas Province, was to be increased from its current 55,600 barrels per day capacity through revamping, first to 70,000 barrels per day by 1983 and then to 90,000 barrels per day in 1987. CEPE was planning to construct a new 75,000-barrel-per-day refinery in Atahualpa, Guayas Province, scheduled for completion in 1983 or 1984. The designs for the expansion of the Esmeraldas refinery and the construction of the Atahualpa refinery were being done by UOP, Inc., of the United States. The two refineries located on the Santa Elena Peninsula, Guayas Province—the 32,000-barrel-per-day Anglo facility owned by Clyde Latino America, S.A. and CEPE, and the Petróleos Gulf del Ecuador 8,000-barrel-per-day facility owned by private sector Ecuadoreans—were to be expanded to a combined capacity of 44,000 barrels per day by 1988.

Not involved in current expansion plans was Ecuador's fourth operating refinery, located in Lago Agrio, Napo Province. Texaco, Inc., in its capacity as operator of the CEPE-Texaco consortium, operated the 1,000-barrel-per-day refinery; one-half of the output was used internally by the consortium.

Reportedly, the CEPE-Texaco consortium budgeted $133.3 million for their petroleum exploration activities in 1981, more than treble the $42.3 million spent in 1980. Offshore exploration drilling for oil began in December in the southern part of the Gulf of Guayaquil, where natural gas reserves, possibly as much as 670 million cubic feet, have been known to exist for many years. However, development of the fields has been hindered owing to disagreements between the Government and foreign consignees.

The quasi-Government Compañía Ecuadoriana de Siderúrgica S.A. (ECUASIDER) was planning the construction of a 400,000-ton direct-reduction steel mill near Puerto Bolívar, El Oro Province. The mill would use natural gas from wells in the Gulf of Guayaquil.

The long-awaited international call for tenders for the development of the San Bartolomé silver and zinc mine, located in Azuay Province, was announced in June. However, the bidding contest was declared null and void in October.

Empresa Industrias Guapán S.A.'s new 1,100-ton-per-day expansion of the Guapán cement plant in Azogues went into production late in the year. A plan to double the capacity of Cemento Selvalegre's new 345,000-ton-per-year plant near Otavalo was being considered at yearend following a feasibility study. La Cemento Nacional started a new production line at its Blanco plant, adding an additional 1,500 tons per day to its capacity. The Government increased the price of cement 50% in midyear to stimulate production to help alleviate periodic shortages.

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.
[1]Includes data available through Aug. 27, 1982.
[2]In addition to the commodities listed, a variety of crude construction materials (common clays, sand and gravel, and stone) undoubtedly were also produced, but output was not reported, and available information was inadequate to make reliable estimates of output levels.
[3]Reported figure.
[4]Gem and industrial diamond production was estimated based upon reported total production.
[5]Data represent exports.
[6]Refinery fuel apparently included with products for sale, mainly residual fuel oil and liquefied petroleum gas.
[7]Less than 1/2 unit.

FRENCH GUIANA

The mineral industry in French Guiana continued to be limited to the production of small quantities of construction materials—clays, crushed stone, and sand and gravel—used for domestic consumption and a minor amount of placer gold.

The minerals sector has not had a large role in the Nation's economy, although resources of bauxite, cinnabar, copper, low-grade iron ore, manganese, molybdenum, nickel, and tantalite are known.

No significant developments concerning the mineral industry of French Guiana during 1981 were reported.

GUYANA

The Guyanese economy continued to decline, registering a real growth of minus 0.5% in 1981. Although Guyana's economy is basically agrarian, depending mainly on sugar and rice, the production of bauxite and its processing into alumina accounted for about one-fifth of the GDP, estimated at $547 million,[3] and about 40% of total annual export earnings. However, total bauxite and alumina production not only fell almost 30% below the 1981 target of 2.3 million tons, but the 1.9 million tons produced was also below the 1980 production of 2.0 million tons.

The shortfall in output was due to several factors, including continued industrial disputes, weather difficulties, shortages of properly functioning equipment and spare parts, and technological deficiencies.

Home Oil Co. Ltd., a subsidiary of the Canadian firm Hiram Walker Resources Ltd., began drilling the first of a two-well wildcat drilling program in November on a 7,085-square-kilometer concession in the Takutu Basin. The well, the first to be drilled in the basin, is about 320 kilometers south of Georgetown near the border with Brazil. Home has a 72% interest in the concession, and Ranger Oil Ltd., of Canada, and Canadian and Oriental Oil Ltd. of Hong Kong, each own 14%. The target depth of the well was 2,440 meters.

During the year, the Government announced its intention to establish a national petroleum company to oversee exploration efforts.

Duncan Gold Resources Ltd. began exploratory drilling on its property at Omai in north-central Guyana. The Anaconda Copper Co. had explored and developed the

property previously in the late 1940's. The gold at Omai is associated with small quartz stringers in granite and has been exploited sporadically on a small scale.

Almost all of the gold produced in Guyana has been mined from alluvial or eluvial material, although there have been a few small underground operations, with working depths rarely exceeding 38 meters.

Reported gold production in 1981 increased to almost 20,000 troy ounces, 75% over that reported in 1980.

The small quantity of natural diamonds produced, reported to be 9,500 carats, was about the same as that of 1980. An estimated 40% was of gem quality. Alluvial diamonds were first discovered in Guyana in 1887, and total production since then has been in excess of 3 million carats. Peak production occurred in 1923 when 214,474 carats was recovered, but annual production has been declining almost steadily since. The diamonds, occurring in alluvial deposits within the Pakaraima Mountains in western Guyana, are recovered by hand or by suction dredging.

A comprehensive feasibility study was planned by the Bauxite Industry Development Co. to determine whether the kaolin occurring below the bauxite deposits could be mined economically. The study, focusing on the Topira bauxite mine, located near Ituni at the center of the 1,550-square-kilometer bauxite mining belt, was to be done by a consulting firm with technical assistance provided by the Inter-American Development Bank.

PARAGUAY

After decades of stagnation, Paraguay continued in 1981 to maintain an economic growth rate that is unrivaled by any other Latin American economy. The factors responsible for this unusual growth remain primarily the expansion of exportable surplus in the agricultural sector and the construction of large binational hydroelectric power projects on the Paraná River along the eastern frontier bordering Argentina and Brazil.

Paraguay's real GDP in 1981 was estimated to have increased 8.5% above that of 1980 to an estimated $5.5 billion at current prices.[4] Inflation decreased, owing to stable oil prices in 1981, to an annual rate of 15% from the 22% annual rate in 1980. The prospects for continued good growth in 1982 appeared favorable.

The construction of the Itaipú hydroelectric powerplant, located on the Paraná River approximately 8 miles upriver from the international bridge connecting Ciudad Presidente Stroessner with Foz de Iquazú, continued on schedule with about 80% of the civil works having been completed by yearend. The first electrical generation was expected to begin in mid-1983.

When the Itaipú Treaty was signed in 1973 with Brazil, the official estimated cost of the project was $2 billion. As construction of the dam progressed, the official estimated cost continued to increase at a rapid rate. In midyear, the latest official estimate of the cost was given as $12.7 billion. However, by the time the project is completed in 1988, the final cost is estimated, by sources close to the project, to be between $15 and $18 billion, owing, in part, to the burden of high interest rates that prevailed in world financial markets. Thus, the estimated cost, approximately 29 mils per kilowatt-hour, of the electrical power to be generated by Itaipú continued to rise, although still projected to be only about one-third of the cost of thermopower, approximately 96 mils per kilowatt-hour, generated in Brazil.

The plant will have an installed capacity of 14,000 megawatts, generating 80,000 gigawatt-hours of electricity per year. According to the terms of the treaty with Brazil, any power that Paraguay does not buy from Itaipú Binacional, the binational entity that will operate the Itaipú plant through joint ownership, must be sold to Brazil. Paraguay cannot sell any to a third country, and Brazil must buy all the power that is available for sale, including that portion of the share that Paraguay does not consume. Paraguay was expected to export, at least initially, almost all of its 50% share of the electricity generated at Itaipú, since the development of energy-intensive industries in Paraguay have not yet been constructed. Once completed, the energy provided by Itaipú will be equivalent to almost 500,000 barrels of fuel oil per day.

The construction of the Yacyretá hydroelectric plant, a binational project with Argentina located about 80 kilometers down the Paraná River from the towns of Encarnación and Posadas, was 3 years behind schedule by yearend. Its first power was expected to be generated in 1988, in lieu

of 1985 as originally planned. Besides providing hydroelectric energy, this project will improve navigation on the Paraná River by flooding the Apipé rapids, provide both Paraguay and Argentina with irrigation facilities, promote the fishery industry of the region, and increase tourism.

The plant will have an installed capacity of 4,000 megawatts, generating 26,000 gigawatt-hours per year. The estimated cost of the project was $10 billion.

The Yacyretá Treaty stipulates that the energy produced will be shared equally between Paraguay and Argentina, with preferential rights given to each on the purchase of the electrical energy not used by the other to meet domestic demand. Argentina must buy all of the power that is available for sale, including that portion of the share that Paraguay does not consume.

The feasibility study of the Corpus binational hydroelectric project with Argentina was scheduled to be completed in June of 1982. This project, similar to Itaipú although smaller, was to be located on the Paraná River at Itacuá, 8 miles upriver from the towns of Encarnación and Posadas. The planned installed capacity was 4,000 megawatts, the same as that of Yacyretá. However, the estimated cost for construction is only one-half, $5 billion, of that of Yacyretá owing to the more favorable condition of the damsite.

The Corpus project is almost a complement of the Yacyretá project, and its construction could depend upon Yacyretá's completion. According to preliminary estimates, Corpus could generate its first electrical power in 1992, if construction of the main civil works begins in 1986.

The Itati binational hydroelectric project, also to be executed with Argentina, was still in the prefeasibility stage in 1981. However, as it would help optimize the generating capacity at Yacyretá by regulating waterflow, it is almost certain to be built when Yacyretá is completed. The Itati project, to be located 210 kilometers downriver from Yacyretá, was projected to have an installed capacity of about 1,200 megawatts. The construction cost was estimated at $1.5 billion.

The prefeasibility study conducted by the World Bank on the possible expansion of the Petróleos Paraguayos S.A. petroleum refinery at Villa Elisa was not completed in 1981. However, construction of additional storage capacity at the refinery was awarded to Consorcio de Ingeniería Electromecánica, S.A., a private sector Paraguayan enterprise. The contract had not been signed by yearend.

The state-owned Industria Nacional del Cemento was authorized by the Government, based on feasibility studies completed in 1980, to increase the capacity of its only operating cement plant at Puerto Vallemi from 200,000 to 400,000 tons per year to meet the increasing demand of the construction industry. A contract was awarded to a French group, led by Bureau Central Pour Les Equipments Outre-Mer, for the construction of Paraguay's second cement plant. The plant, scheduled to be completed in 1984, was to be located 485 kilometers north of Asunción. Production was to be 600,000 tons of cement per year.

Aceros del Paraguay, S.A. (ACEPAR), continued its construction of Paraquay's first steel mill during 1981 at Villa Hayes, 20 kilometers north of Asunción, on the Paraguay River. The facility, consisting of one basic oxygen-process blast furnace, was scheduled to produce 100,000 tons of steel ingots, billets, bars, reinforcing rods, wire, light angles, and other construction materials beginning in 1983. ACEPAR is a joint venture comprised of Siderúrgia Paraguaya, a Paraguayan Government enterprise administered by the Ministry of Defense, 60% ownership; the Brazilian consortium Empresa Brazileña, F.L.M., 39%; and the Brazilian firm of Técnica Nacionál de Engenhariá, S.A., 1%. The latter is responsible for the construction and erection of the facility.

A mineral agreement between the Government and the U.S. firm UNC Teton Exploration Inc., a subsidiary of UNC Resources Inc., was formally accepted in late 1981. The agreement extends exclusive rights to explore and develop nonfuel minerals in the Chaco, the 24-million-hectare western region, to UNC Teton. Based on preliminary evaluations using satellite imagery, oil exploration data, and onsite geological observations, there is potential for uranium, bauxite, precious metals, and brine-associated minerals.

The Instituto de Pesquisas Tecnológicas, of São Paulo, Brazil, reportedly was contracted to survey all of Paraguay to identify valuable mineral deposits.

SURINAME

The bauxite industry continued to be the backbone of the Surinamese economy. Three companies were involved in the bauxite industry in Suriname during 1981, two of which, the Suriname Aluminum Co. (SURALCO), a wholly owned subsidiary of the Aluminum Co. of America, and Suriname N.V., Billiton Maatschappij, part of the Royal Dutch/Shell Group, have been established in the country for many years. The third company, N.V. Grassalco, the state-owned mining company, was charged with opening up the unexploited bauxite deposits in the Bakhuys region of western Suriname, although the development in that region was stymied throughout the year. SURALCO owns and operates the country's only alumina refinery and aluminum smelter, although plans have been under formulation for several years to construct a new alumina plant, to be owned by Grassalco, at Apoera on the Corantijn (Courantyne) River. The new plant would be part of the project to develop western Suriname. However, these development plans have apparently been abandoned for the near future.

Although Suriname was the world's sixth largest producer of bauxite, the worldwide recession in the aluminum industry, the growing production-cost competition from Australia, Brazil, and Guinea, and the demands for significantly higher wages by the bauxite labor union aided in decreasing the 1981 estimated production to 20% below the 1980 level. In spite of the cancellation of a 600,000-ton-per-year bauxite purchase contract by the Ormet Corp. of the United States on July 1, the United States continued to receive the major part of the bauxite mined in Suriname during 1981.

Production of alumina in 1981 was estimated to have decreased about 9% from that of 1980. However, shipments to the United States increased to 2.2 million tons, over 315% above the 1980 level, enabling the United States to replace Europe as the principal buyer of Suriname's alumina. About 90% of Suriname's alumina production was exported; the remainder was smelted at the SURALCO plant at Paranam. Production of aluminum metal decreased 24% from that of 1980 and was equal to about one-half of 1979 production.

Suriname's relatively minor gold production was mined exclusively by individual prospectors, using labor-intensive methods. Although gold mining in Suriname began more than a century ago, production has been steadily declining since about 1910, when the maximum production was about 32,000 troy ounces. The Lawa River gold deposits, discovered in 1885, have accounted for one-half of all the gold ever recovered in Suriname.

As a result of the agreement signed in 1980 between the Government of Suriname and Gulf Oil Co., Gulf began exploration drilling in the Saramaca district in mid-year. Suriname had no petroleum or natural gas production during the year. Imports of petroleum products were distributed by Esso Standard Oil, S.A., Ltd., Texaco, Inc., and Royal Dutch/Shell.

URUGUAY

Uruguay's economic growth, following the general recessionary trend that existed throughout Latin America, fell by only 1.3% in 1981, after sustaining an average annual real growth rate of 4.5% over the 6-year period ending in 1980. Owing to Uruguay's anti-inflationary policy of maintaining an overvalued exchange rate and progressive reductions in import tariffs, a further deceleration in overall economic activity was expected in 1982. The inflation rate declined again, for the third consecutive year, to 29% in 1981, according to official figures, somewhat lower than the 35% projection.

A reduction in the trade deficit to $346 million[5] in the first 10 months of 1981 from $567 million in the corresponding period of 1980 resulted from a 23% increase in exports to $994 million and a decline in imports of 2.5% to $1.34 billion. Expenditures on imported oil decreased 15% to an estimated $360 million in 1981. Crude oil imports accounted for about 27% of total imports. The Administración Nacional de Combustibles, Alcohol, y Portland (ANCAP) announced the signing of an annually renewable contract, effective on October 1, 1981, for the purchase of 10,000 barrels per day of crude petroleum from Mexico, an

estimated 25% of Uruguay's requirements.

The mineral industry was of minor importance to Uruguay's economy and continued to be concentrated in the nonmetallic sector in 1981.

Uruguay had four operating cement plants with a total production capacity of 845,000 tons per year. Two of the plants were owned by ANCAP, one located in Minas with a capacity of 240,000 tons per year and the other located in Paysandu with a capacity of 270,000 tons per year. The Paysandu plant had its annual capacity increased from 120,000 tons early in the year. The Cía. Uruguaya de Cemento Portland plant, owned by Lone Star Mining Corp. of the United States and located just outside of Montevideo, had an installed capacity of 300,000 tons per year. The fourth and smallest plant, with a capacity of 35,000 tons per year, was owned by Cía. Nacional de Cementos S.A.

Reportedly, no modification or additions to these plants were expected over the next few years.

The Mineral Industry of Other South Pacific Islands

By Charlie Wyche[1]

CONTENTS

FIJI

Principal mineral products in the Dominion of Fiji were gold, silver, pit and quarry construction materials, and cement. In 1981, the combined value of these commodities accounted for about $11.6 million,[2] over 85% of the total value of mineral output. Production of cement, sand and gravel, and quarry products increased substantially above the 1980 level.

Mining based on gold production was decreasing, and employment in the industry was declining. The better grade deposits in the one active mine were worked out, and only another 10 years' production at current rates was estimated to remain. While the high world gold price of 1979-80 led to intensive exploration, there has been little success.

High hopes were held for copper production. Exploratory results had proved sufficiently attractive for a mining agreement to be negotiated, but subsequent reports showed low-grade deposits. In view of the poor outlook for world copper prices, the project has been stopped. The prospects for domestic oil production were improved. After initially promising results, two test wells have proved inconclusive; however, another test well was being drilled. On a smaller scale, exploitable resources of marble, pumice, and phosphates have been found.

Mineral exploration has been carried out by American, Australian, British, Canadian, West German, and South African companies since the early 1960's, and a high level of activity was maintained throughout 1981. At Mount Kasi on Vanua Levu, an extensive program of geological sampling and mapping was being conducted, and drilling was taking place at some base metal prospects in the south-central parts of Viti Levu. Also, high gold values in surface samples were reported at Vuda in western Viti Levu. Total expenditures by mining companies on land-based projects exceeded $6 million in 1981.

As in previous years, most activity was on the main island of Viti Levu. However, there was an increase in previously less well prospected islands. In the Namosi district of southeast Viti Levu, exploration and development work have indicated several occurrences of porphyry copper, molybdenum, and gold mineralization. In south and central Viti Levu, geological mapping and geophysical surveys were completed over areas containing small massive sulfide copper-zinc deposits. In western Viti Levu, gold mineralization was reported and systematic sampling was commenced, but the presence of economic mineralization has yet to be demonstrated.

Table 1.—Other South Pacific Islands: Production of mineral commodities[1]

[e]Estimated. [p]Preliminary. [r]Revised. NA Not available.

[1]Table includes data available through July 26, 1982.

[2]Reported figure.

[3]Produced from an unreported amount of domestically quarried limestone.

[4]In addition to the commodities listed, crude construction materials (common clays, sand and gravel, and stone) are produced, but output is not reported quantitatively and available general information is inadequate to make reliable estimates of output levels.

[5]Data represent exports.

[6]Total cobalt content of nickel ores mined based on average nickel-cobalt ratio in metallurgical products for 1880-1972.

[7]Cobalt actually recovered for use as cobalt; excludes cobalt content of nickel-cobalt alloys and/or included in ferronickel.

[8]Nickel-cobalt content of ore produced as reported by New Caledonia's Mines Service. Of the total, about 97.323% is nickel; the balance is cobalt (based on average nickel-cobalt ratio in metallurgical products for 1880-1972).

At Mount Kasi on Vanua Levu, where gold has been mined, the diamond drilling program was completed. Again, no major new ore extensions were reported, but based on the drilling results and on detailed surveys in the area, some followup work was planned.

Four offshore oil exploration licenses were in force to U.S. oil companies in areas of the Fiji Platform known as Bligh Water,

Yasawa, Lomaiviti, and Great Sea Reef. The Mineral Resources Department's research vessel *RV Bulikula* was used on charter to carry out detailed surveys in Bligh Water. This work, together with further interpretation of geophysical and geochemical data, defined targets for a drilling program by Chevron Overseas Inc. that commenced in mid-1980.

COMMODITY REVIEW

Metals.—*Copper.*—Copper Resources Ltd. (a subsidiary of Conzinc Riotinto of Australia Ltd.) delivered a full report to the Fijian Government on the economics of the Namosi copper deposits on Viti Levu. In its report, the company informed the Government that the deposits were currently uneconomical, in view of this copper content and the current forecast for copper prices. As a result of the prefeasibility study's findings, the venturers (also including Anglo Pacific Ltd., a subsidiary of Australian Anglo American Ltd., and Preussag Fiji Ltd. of the West German Preussag Group) decided against undertaking a full feasibility study. The deposit remains a significant potential resource, and the companies have indicated to the Fijian Government that they wish to retain their special prospecting license. The study, which included diamond drilling and geological sampling, indicated an ore body of 450 million tons at 0.4% to 0.5% copper. The study also indicated that the deposit was minable by open pit methods, with a waste-to-ore ratio of about 2:1.

Gold.—Emperor Gold Mining Co. Ltd., the wholly owned operating subsidiary of Emperor Mines Ltd., mined sulfotelluride gold ores at Vatukoula on the north coast of Viti Levu. During 1981, the company employed about 700 men to mine and treat 300,000 tons of ore and recovered 30,600 troy ounces of gold and 8,060 troy ounces of silver. The high mine production as compared with that of 1980 was due to the company's decision to increase the underground work force and the absence of industrial disputes.

Emperor Mining made a complete recalculation of reserve tonnages and grade during the year; as of June 30, the total underground reserves using a cutoff grade of 0.2 ounce per ton stood at 900,000 tons of measured ore at an average grade of 0.29 ounce per ton. Indicated ore reserves totaled 187,000 tons at an average grade of 0.25 ounce per ton. Indicated reserves in the open pit amounted to 71,000 tons at an average grade of 0.20 ounce.

When gold prices reached a record high several years ago, a number of companies took out prospecting licenses and continued to work in Fiji. Altherton Antimony NL reported that the Vuda gold prospect produced an average assay of 0.20 ounce per ton of gold across a 9-meter width. Pacific Energy and Minerals Co. of Golden, Colo., continued exploring the inland areas of Viti Levu near the Vatukoula gold mine. Consolidated Goldfields of Australia was prospecting on the islands of Kadavu and Ono, where gold traces have been reported.

Nonmetals.—Emperor Gold Mines continued to produce burnt lime from its limestone quarry at Tau but did not report production. The number of sand and gravel licenses granted continued to increase.

Fiji Industries Ltd. dredged 200,000 tons of coral sand from Suva Harbor and 70,000 tons of common sand and gravel from the Rewa River and tributaries in 1981. Several tons of quarried stone were also recovered.

The Government's Mineral Resources Division continued evaluating a phosphate clay deposit on the Island of Tuvutha, where 1.5 million tons of 10% P_2O_5 was reported.

Mineral Fuels.—*Petroleum.*—Mapco Ltd. and Pacific Energy and Minerals Co. continued drilling for oil in Fiji. Drilling began in the Bligh Waters in 1980, and other areas scheduled for drilling include Yasawa, Lomaiviti, and Great Sea Reef.

Table 2.—Fiji Islands: Exports and reexports of mineral commodities

(Metric tons unless otherwise specified)

Commodity	1979	1980	Destinations, 1980	
			United States	Other (principal)
METALS				
Aluminum metal including alloys, unwrought and semimanufactures	7	17	--	New Zealand 15.
Copper metal including alloys:				
Waste and scrap	234	111	--	All to Australia.
Unwrought and semimanufactures	10	22	--	Mainly to Australia.
Gold:				
Ore and concentrate value	--	$380	--	All to Australia.
Waste and sweepings do	$17,054	$12,173	--	All to Singapore.
Bullion troy ounces	29,069	25,013	--	All to Australia.

NAURU AND KIRIBATI

The Republic of Nauru and Kiribati lies halfway between Honolulu, Hawaii, and Melbourne, Australia. Kiribati, the former British colony consisting of Ocean Island, Gilbert Islands, Line Islands, and Phoenix Islands, became independent on July 12, 1979.

Phosphate rock production by Nauru Phosphate Corp. totaled 2.0 million tons in 1981; no production was reported from Kiribati. Nauru exported 66% of its total output to Australia, 24% to New Zealand, and the remaining 10% to Japan and the Republic of Korea. The price for Nauru's phosphate generally follows Florida price trends, with allowance for quality.

As most of the phosphate was mined from between limestone pinnacles using grab buckets, methods were being investigated to recover the residual phosphate, estimated at 6% to 7% of the total.

Present reserves of phosphate rock in Nauru were estimated at 34 million tons.

NEW CALEDONIA

The French island territory of New Caledonia was the second largest producer of nickel in the market economy countries in 1981. Output of nickel by Société Métallurgique le Nickel (SLN), New Caledonia's only producer, declined in 1981 as a result of lower world demand throughout most of the year. In addition to nickel products of nickel matte and ferronickel, byproduct cobalt matte resulting from nickel smelting operations was produced by SLN. Other minerals produced in New Caledonia included chromite and pit quarry construction materials.

Nickel ore was produced at four major locations, Thio, Kouaoua, and Poro, near the east coast, and Népoui, near the west coast. Work to expand output at Népoui to 2 million tons of ore per year and at Kouaoua to 1.5 million tons per year was almost completed. Production of nickel ore totaled about 4.1 million tons in 1981.

In 1979, operations of SLN's refinery were severely affected by a fire, but it has operated normally for the past several years. The 1981 output of the metallurgical products, nickel matte and ferronickel, declined from the 1980 level.

The cobalt content of the nickel ore mined in New Caledonia during 1981 was estimated at 2,000 tons, but the total recovered metal was estimated at 150 tons. The cobalt content in either the total ore production or the nickel matte was recoverable as cobalt or cobalt chemicals.

Inco Ltd. of Canada has announced that it has agreed to develop a chromite mining and processing facility at Tiebaghi in the northern part of New Caledonia in partnership with two French companies. The two French companies are Banque de Paris and Compagnie Minière Dong-Trieu, and the venture is scheduled to start production in mid-1982. Inco will hold 55% of the equity in the new operation with Banque de Paris holding 22.5%. Dong-Trieu will be the head member of a joint company to be formed with another French concern which will hold the remaining 22.5%. The deposit was outlined by exploration work begun in 1976 by three companies, and development of the project will involve a $14 million investment.[3] Initial plans for the operation are the production of 450 tons of ore per day, which will provide feed to a nearby processing plant with an annual capacity of about 110,000 tons. The reduction plant has a capacity of about 85,000 tons annually of

chromite products.

Also, Inco, under agreement with the New Caledonian Government, continued studying the possibility of development of lateritic nickel deposits in the southern part of the island. Inco will be required to take a French partner before the project reaches the development stage.

Energy requirements were considered a potential problem since New Caledonia has no domestic energy resources. All fuel oil was imported to New Caledonia, and there were no known domestic energy resources except for the possibility of developing hydroelectric energy sources in the Plaine de Lacs area. SLN used 85% of the industrial electricity in its mining and smelting operations.

PAPUA NEW GUINEA

Papua New Guinea (PNG) has abundant mineral resources, but currently, Bougainville Copper Ltd. is PNG's only producing metal mining company. Bougainville Copper's mine at Panguna on North Solomon Island contributed significantly to Government revenues and the gross domestic product (GDP), estimated at $2.15 billion in 1981.[4] Values of 1981 output were as follows: Copper, $200 million; gold, $130 million; and silver, $8 million. Total production value of $338 million was nearly 16% of the GDP.

The only other mineral activity was the production of small quantities of limestone and sand for local use and of some alluvial gold recovered by panning in the Bulolo-Wau area. However, in addition to the Bougainville Mine, development and exploration work on two other major deposits was underway. One deposit is OK Tedi; located in the Star Mountains near the Irian Jaya border, it has large resources of copper, gold, and silver. The other, Frieda River, near Madang, has large copper resources. The principal obstacles to commercial development have been the current depressed price of copper and the difficulty of access to these remote areas.

In 1980, PNG sent a large mission to the United States to discuss newly enacted legislation relating to foreign investment guidelines for minerals and energy projects. The Government considers the development of mining and petroleum projects to be of the highest priority and welcomes foreign

investors. The basic principles of the legislation adopted were as follows:

Mineral resources belong to the people of Papua New Guinea and the Government, and the people must receive a fair price in return for extraction of the minerals.

Foreign enterprises exploiting Papua New Guinea's mineral resources deserve a reasonable return on their investment, but extraordinary gains above a reasonable return on investment will go in large part to the Government.

The Government has the right to regulate extractive enterprises so as to maximize the benefits to the local community while minimizing the potentially harmful social and economic costs.

As a result of the visit by PNG officials, the Overseas Private Investment Corp. sponsored a mission to PNG in February 1981, with representatives of 10 large U.S. corporations participating.

The climate for foreign investment in PNG is generally favorable, and the OK Tedi Copper and Gold Mine is owned by Metallgesellschaft AG (20%), BHP Australia Ltd. (30%), Amoco Minerals Co. (30%), and the PNG Government (20%). The Government reserves the right to participate as an equity partner with up to 30% interest; however, thus far it has limited its equity interest to about 20%.

Mineral and oil exploration companies have shown increasing interest in PNG during recent years. Currently, prospects for mineral development appear more promising than those for petroleum. A number of oil companies were in the initial stages of developing, but so far there are no reports of oil being found in commercial quantities.

COMMODITY REVIEW

Metals.—*Chromite.*—Development of the Ramu River chromite-nickel-cobalt deposit located 70 kilometers southwest of Madang is being assessed. The project is owned by Nord Resources (69.5%) and MIM Holdings Ltd. (30.5%). The deposit is expected to be developed in two stages, with chromite mined in the first stage and nickel and cobalt extracted in the second.

It is estimated that there are reserves of between 80 and 100 million tons of 8% to 10% chromite that occur as a lateritic-type deposit. The chromite overlies a lateritic nickel cobalt deposit with reserves put at 67 million tons of 1.14% nickel and 0.16% cobalt. When developed, the deposit could produce between 200,000 and 400,000 tons of chromite annually, and operations could begin in 2 years. Restrictions are imposed, however, by the lack of necessary infrastructure such as roads and harbor facilities.

Amax Exploration Australia Inc., a subsidiary of Amax Inc., continued evaluating chromite and other minerals in beach sands along the Marobe coast, between Salamaua and Salua. Preliminary estimates indicated reserves of 200 million tons of mineralized sands containing 1.5% chromium.

Copper.—Bougainville Copper Ltd.'s (BCL) mine at Panguna remained the only significant mining operation in Papua New Guinea. The 1981 output of all three commodities, copper, gold, and silver, was above the 1980 level. This resulted from an increase in tonnage of ore milled as ore grade declined slightly. Since 1972, the copper grade at Bougainville has fallen from 0.75% to 0.46%, and the gold grade was halved to 0.016 ounce per ton. About 38.5 million tons of ore were mined from the Panguna open pit in 1981, and the waste-to-ore ratio rose to 1.12:1. The pit was deepened by 30 meters to 445 meters above sea level, but drainage problems will prevent any further deepening of the pit until completion of the 6,400-meter drainage tunnel in 1982.

Measured reserves at Bougainville stood at 610 million tons averaging 0.43% copper and 0.015 ounce of gold per ton, and although the grade will decline further during future mining operations, it is expected to be at a reduced rate. Reserves are sufficient for the next two decades, but the company has stressed the need to explore outside its existing lease, given the long lead times to develop new ore bodies. The Government of PNG is expected to lift its present restrictions on further exploration.

In 1981, sales totaled about 160,000 tons of copper, 530,000 ounces of gold, and 1.3 million ounces of silver. Concentrates were shipped under long-term contracts to Japan, the Federal Republic of Germany, and Spain.

The feasibility study of the $1.6 billion OK Tedi Copper and Gold Mine was completed, and construction began in late 1981. Gold production is expected to commence in 1984 and copper production in 1986. An international consortium will own and operate the mine; the four partners are Dampier Mining Co., Ltd., a subsidiary of BHP Co. (30%); Mount Fubilan Development Co. Pty. Ltd., a subsidiary of Amoco Minerals Ltd. (30%); Kupferexploration GmbH, a Federal Republic of Germany group (20%); and the

PNG Government (20%). Situated near the West Irian border, the deposit has ore reserves estimated at 300 million tons. Ore grade averages 0.85% copper and 0.18 ounce per ton of gold, with some molybdenum. A hydrographic, geophysical, and geological investigation was continued of the Fly River to assess the feasibility of transporting copper concentrates from OK Tedi via barge from Kiunga on the Fly River to an as-yet-to-be-selected deepwater port on the Gulf of Papua.

Exploration also continued on the Frieda River porphyry ore body, estimated to contain 500 million tons, averaging 0.5% copper. This is a major ore body located in the Western Sepik Province about 80 kilometers northwest of OK Tedi; however, development could be hampered by its low grade. The consortium members are MIM Holdings Ltd. of Australia (30%), the Japanese consortium Furukawa & Metal Mining (25%), Norddeutsche Affinerie AG of the Federal Republic of Germany (5%), and Conzinc Riotinto Australia (CRA) (20%). The Papua New Guinea Government may opt for a 20% equity interest in the project. The Government expects to discover additional mineral deposits in the area around Frieda River. A deposit of high-grade massive sulfide minerals has been discovered a few kilometers away. This is now called the Nena Project.

On Manus Island, 360 kilometers north of the PNG mainland in the Admiralty Group, joint venture exploration by Exoil NL and Transoil NL indicated 160 million tons of ore at 0.32% copper, associated with gold, silver, and molybdenum, in ore of several known prospects. Some factors acting in favor of the Manus prospect were the limited infrastructural development required and relatively good accessibility compared with the mainland deposits. Also, the existence of a small bauxite deposit on Manus Island has been reported.

Gold and Silver.—Gold continued to be an important byproduct of BCL's Panguna copper mine. The gold production totaled about 540,300 ounces during 1981. Byproduct silver recovery was about 1.3 million ounces.

At Porgera in Papua New Guinea's central mountain range, Placer Development Ltd., MIM, and Consolidated Goldfields of Australia were engaged in a joint venture to explore and develop an alluvial gold deposit. Two zones have been explored: One was estimated to be 250 meters long, 150 meters wide, and up to 250 meters deep, with an average 0.07 ounce per ton of gold and 0.13 ounce per ton of silver. The other has a length of 420 meters, a width of 250 meters, and a depth of 240 meters and an average 0.08 ounce per ton of gold and 0.13 ounce per ton of silver. The results suggest the possibility of a large gold mine, but work was still at an early stage of development.

Mineral Fuels.—*Petroleum.*—The petroleum potential of Papua New Guinea may be considered in terms of three major sedimentary basins: The Papuan Basin, which comprises the southwestern portion of the mainland and offshore beneath the Gulf of Papua, an area of about 250,000 square kilometers; the North New Guinea Basin, almost entirely onshore in the northern mainland region and about 120,000 square kilometers in area; and the Cape Vogel Basin, predominantly offshore between the Papua Peninsula and the Trobriand Islands, an area of about 40,000 square kilometers. Prospecting continued, but no significant discoveries were reported.

The Papua New Guinea Government signed petroleum prospecting concession agreements with Gulf Oil Corp., Australian Oil Ltd., and BP Petroleum Development Australia Pty. Ltd. The concession areas involve two permits (Nos. 76 and 77). Permit No. 76 covered 7,300 square kilometers in the Western Province, and permit No. 77 covered 13,400 square kilometers in the Western and Southern Highlands Provinces. The cost of exploration over a 3-year period was estimated at $7 million. In another development, Esso Papua New Guinea Inc. announced it had spudded the Goari No. 1 well on the Paibuna River, 415 kilometers northwest of Port Moresby. Planned depth was 11,500 feet.

Recently passed legislation by the PNG Government would entitle it to receive 60% to 80% of any future revenues from oil or gas production. This would be in the form of a 1.25% royalty based on wellhead values, petroleum income tax of 50% of taxable income, a profit tax after an agreed rate of return is achieved, and a Government equity up to 22.5% with payment from the Government's share of production.

Table 7.—Papua New Guinea: Exports of copper, by destination

(Metric tons of copper content)

Destination	1979	1980
China	6,398	5,884
Germany, Federal Republic of	54,985	47,302
Japan	96,282	77,178
Spain	14,332	11,877
Total	171,997	142,241

SOLOMON ISLANDS

In 1981, the Solomon Islands' minerals output consisted of small quantities of alluvial gold and silver, valued at an estimated $675,000.[5] In addition, marine shells were harvested for lime, but production was not reported.

The International Development Association (IDA) has approved a credit of $1.5 million to the Solomon Islands to assist the Development Bank of Solomon Islands in providing finance for productive investments by indigeneous entrepreneurs during 1981-82. This is the first operation assisted by IDA in the Solomon Islands.

The Government continued to actively seek foreign investors as a major force in the country's resource development. A bauxite mine and refinery project on Rennell and Vaghena Islands have been surveyed, but temporarily shelved owing to low world bauxite prices. CRA, in partnership with Mitsui Mining and Smelting Co. Ltd. and the Solomon Islands Government, withdrew from the project, and Mitsui decided to defer further work because of the lack of market for aluminum. The project was to produce 1.5 million tons of bauxite and 600,000 tons of alumina per year from reserves estimated at 60 million tons of 45% to 50% Al_2O_3.

In addition to bauxite, other minerals known to exist in the Solomon Islands were phosphate on Bellona and Rennell, copper on Guadalcanal and Florida, nickel on Isabel, manganese on Florida, and gold on Guadalcanal. Currently, these mineral deposits were regarded as uneconomic prospects owing to the small size of known occurrences.

The Government was particularly interested in receiving proposals for prospecting for hydrocarbons both onshore and offshore. A Petroleum Act establishing the framework to enable orderly prospecting and development to be carried out by commercial companies was completed. Within the terms of the act, detailed agreements between individual companies and the Solomon Islands Government concerning work programs, expenditure levels, and the extent and nature of Government participation were considered.

TONGA ISLANDS

In 1981, minerals exploration and exploitation activities were almost exclusively concerned with sand, gravel, and other building materials obtained from beach areas and inland coral quarries. In the future, there may be other mineral potential in the country resulting from offshore petroleum exploration and the mining of manganese nodules.

Samuel Gray Oil Producers Inc. was reportedly planning to drill three offshore wells on the company's Tongan concession during 1982. Under the terms of the company's current agreement with the Tongan Government, drilling had to commence by July 1982. In July 1980, Samuel Gray Oil of Englewood, Colo., took over the Petroleum Agreement from Webb Resources of Colorado.

VANUATU (NEW HEBRIDES)

Vanuatu (formerly New Hebrides) was granted independence in July 1980. A condominium government between Britain and France had ruled the 70-island territory since 1906.

Vanuatu's only mine, located at Forari, 55 kilometers northwest of Port Vita on Vate (Efate) Island, remained closed in 1981. The mine, which produced manganese concentrate, was operated by Le Manganese de Vate and owned by Southland Mining Ltd. of Australia (87.5%) and public shareholders (12.5%). The mine is expected to reopen at about future date, although only about 120,000 tons of commercially minable reserves remain in it. The company had 100 employees, largely native Vanuatuans, and shipped a 40% to 42% manganese of metallurgical grade. The market value was $35 per ton for 40% manganese products.

Manganese concentrate was the only mineral exported in recent years, but various mineral deposits were under investigation. Samples of possolan, a consolidated volcanic ash occurring on Efate and other islands, were being evaluated in Australia and Fiji for use in cement. Surveys have taken place in recent years in search of nickel, copper, bauxite, sulfur, and zinc. None of these commodities were expected to be mined in the foreseeable future.
