WASHINGTON: 1958

FOREWORD

Minerals Yearbook, 1954, published in three volumes, includes data collected for the 1954 Census of Mineral Industries. All data collected in cooperation with Bureau of the Census are noted in either text or footnote in the commodity chapters. Unless otherwise stated the data were collected by the Bureau of Mines. When final census data become available any differences in totals will be reconciled.

Volume I includes chapters on mineral commodities, both metals and nonmetals, but exclusive of the mineral fuels. Included also are a chapter reviewing these mineral industries, a statistical summary, and chapters on mining technology, metallurgical technology, and

employment and injuries.

Volume II includes chapters on each mineral-fuel commodity, as well as chapters reviewing the industry as a whole, a statistical sum-

mary and an employment and injury presentation.

Volume III is comprised of chapters covering each of the 48 States, plus chapters on the Territory of Alaska, the Territory of Hawaii and island possessions in the Pacific Ocean, and the Commonwealth of Puerto Rico and island possessions in the Caribbean Sea, including the Canal Zone. Volume III also has a statistical summary chapter

and another presenting employment and injury data.

The data presented in the Minerals Yearbook are based largely upon information obtained from mineral producers, processors, and users, and acknowledgment is made of this indispensable cooperation given by industry. Information obtained from individuals by means of confidential surveys has been grouped to provide statistical aggregates. Data on individual producers are presented only if available from published or other nonconfidential sources, or when permission of the individuals concerned has been granted.

MARLING J. ANKENY, Director.

GEOLOGY

ACKNOWLEDGMENTS

The chapters in this volume of the MINERALS YEARBOOK were prepared by the staffs of the Division of Anthracite, the Division of Bituminous Coal, and the Division of Petroleum of the Bureau of Those chapters dealing with bituminous coal and its products were prepared under the general supervision of T. Reed Scollon, chief, Division of Bituminous Coal, and T. W. Hunter, chief, Branch of Bituminous Coal Economics and Statistics; the chapters on petroleum and related commodities were prepared under the general supervision of R. A. Cattell, chief, Division of Petroleum, and H. J. Barton, chief, Branch of Petroleum Economics; the anthracite chapter was prepared under the general direction of Joseph A. Corgan, chief, Division of Anthracite, and James A. Vaughan, commodity industry analyst; the helium chapter was prepared under the direction of C. W. Seibel, Assistant Director-Helium Activities, and Henry P. Wheeler, Jr., chief, Helium Liaison Office; and data for the Pacific coast were compiled under the direction of E. T. Knudsen, Region II.

Because of the many sources of data presented, it is impossible to give credit to each source individually, but acknowledgment is here made of the ready and willing cooperation of producers and users of fuels who supplied data and of the business press, trade associations, scientific journals, international organizations, and State and Federal The United States Department of Commerce, Bureau of the Census, furnished data on foreign trade, and the Department of State, United States Foreign Service provided information on foreign

production and developments.

The mining and geology and related departments of the respective States and Alaska have been most cooperative and have made available supplementary and verifying information with respect to production and plant operations. For their assistance the Bureau is deeply grateful, and acknowledgment is made to the following State organizations that assisted with the canvasses of bituminous coal and lignite:

Alabama: Division of Safety and Inspection, Birmingham.

Alaska: Territorial Department of Mines, Juneau.

Arizona: State mine inspector, Phoenix. Arkansas: State mine inspector, Fort Smith.

Colorado: Colorado Coal Mine Inspection Department, Denver. Georgia: Department of Mines, Mining, and Geology, State Division of Conser-

vation, Atlanta.

Illinois: State Department of Mines and Minerals, Springfield.

Indiana: Bureau of Mines and Mining, Terre Haute.

Iowa: State mine inspectors, Des Moines.

Kansas: State Mine Inspection Division, Pittsburg.

Kentucky: Kentucky Department of Mines and Minerals, Lexington. Maryland: Maryland Bureau of Mines, Westernport. Missouri: Division of Mine Inspection, Jefferson City. New Mexico: State inspector of mines, Albuquerque. North Dakota: State coal-mine inspector, Bismarck.

Ohio: Division of Mines and Mining, Ohio Department of Industrial Relations,

Oklahoma: Chief mine inspector, Oklahoma City.

Pennsylvania: Pennsylvania Department of Mines, Harrisburg.
Tennessee: Tennessee Division of Mines, Knoxville.
Utah: Safety Division, Industrial Commission of Utah, Salt Lake City.
Virginia: Division of Mines, Virginia Department of Labor and Industry, Big Stone Gap.

Washington: Chief coal-mine inspector, Department of Labor and Industries, Seattle.

West Virginia: West Virginia Department of Mines, Charleston.

Wyoming: State coal-mine inspector, Rock Springs.

Appreciation is also expressed to the Commonwealth of Pennsylvania Department of Mines, Harrisburg, and Commonwealth of Massachusetts, Division on Necessaries of Life, Boston, for assistance in acquiring data on anthracite and to the following for their assistance with the peat canvass:

Michigan: Department of Conservation, Lansing.

New Jersey: Department of Conservation and Economic Development, Bureau of Geology and Topography, Trenton.

Washington: Department of Conservation and Development, Olympia.

Credit is also due the following State organizations that assisted with the petroleum and natural-gas canvasses:

Arkansas: Arkansas Oil and Gas Commission, El Dorado.
California: California Department of Natural Resources, San Francisco. Public Utilities Commission, State of California, San Francisco.
Illinois: Oil and Gas Division, and State Geological Survey Division, Urbana.

Kansas: State Geological Survey, Lawrence.

Maryland: Department of Geology, Mines, and Water Resources, Baltimore. Michigan: Geological Survey Division, Department of Conservation, Lansing. Missouri: Division of Geological Survey and Water Resources, Department of Business and Administration, Rolla.

New York: New York State Science Service, Albany.

North Dakota: North Dakota Geological Survey, Grand Forks.

Ohio: Oil and Gas Section, Department of Natural Resources, Columbus. Tennessee: Division of Geology, Department of Conservation, Nashville. Virginia: Geological Survey Division, Department of Conservation and Development, Charlottesville.

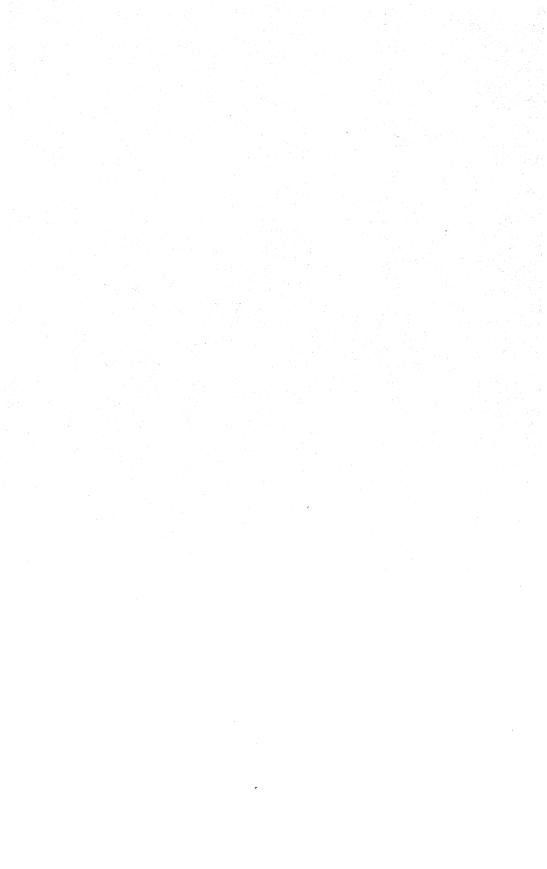

West Virginia: Geological and Economic Survey, Morgantown.

Grateful acknowledgment is made to the American Iron and Steel Institute, New York City; the Anthracite Institute, Wilkes-Barre, Pa.; the Association of American Railroads, Washington, D. C.; the Maher Coal Bureau, St. Paul, Minn.; the Ore and Coal Exchange, Cleveland, Ohio; the National Association of Packaged Fuel Manufacturers, Topeka, Kans., and the many other trade and industry associations that have provided data.

Acknowledgment is also due F. X. Jordan, Office of Oil and Gas, and James G. Kirby, Bureau of Mines, for coordination of the petroleum statistics, and to Virgil Barr and Thelma Stewart, Bureau of Mines, for review of the manuscripts upon which this volume is based to insure statistical consistency between tables, figures, and text in this volume and with similar volumes issued in former years.

PART I. GENERAL REVIEWS

Review of the Mineral-Fuel Industries in 1954

By T. W. Hunter, H. J. Barton, and J. A. Corgan

GENERAL SUMMARY

HE TOTAL production of energy in the United States in 1954 decreased 4.6 percent below 1953. The production of coal continued to decline, and the production of crude oil decreased for the first time since 1949. These decreases were partly offset by an increase in the production of natural gas. The total energy production of 35,365 trillion B. t. u. in 1954 was the lowest since 1950.

TABLE 1.-Energy produced by mineral fuels and waterpower in the United States, 1953-54

(Trillion British thermal units 1)

	1953	Per- cent of total	1954	Per- cent of total	Change from 1953 (per- cent)
Pennsylvania anthracite Bituminous coal and lignite	786 11, 981	2. 1 32. 3	739 10, 262	2.1 29.0	-6.0 -14.3
Total coal	12, 767	34. 4	11,001	31.1	-13.8
Crude petroleumNatural gas, wet	13, 671 9, 116	36. 9 24. 6	13, 427 9, 488	38. 0 26. 8	-1.8 +4.1
Total petroleum and natural gas 2	22, 787	61.5	22, 915	64.8	+.6
Total mineral fuels	35, 554 1, 522	95. 9 4. 1	33, 916 1, 449	95. 9 4. 1	-4.6 -4.8
Grand total	37, 076	100.0	35, 365	100.0	-4.6

¹ The unit heat values employed are: Anthracite, 12,700 B. t. u. per pound; bituminous coal and lignite, 13,100 B. t. u. per pound; petroleum, 5,800,000 B. t. u. per barrel; natural gas, total production ×1,075 B.t. u. minus repressuring, vent, and waste gas×1,035. Waterpower includes installations owned by manufacturing plants and mines, as well as Government and privately owned public utilities. The fuel equivalent of waterpower is calculated from the kilowatt-hours of power produced, wherever available. This method of computation is true for all public-utility plants since 1919. Otherwise, the fuel equivalent is calculated from the reported horsepower of installed water wheels, assuming a capacity factor of 20 percent for factories and mines and 40 percent for public utilities.

³ Includes gasoline, lubricants, and other products with which coal does not compete.

This drop in energy production was consistent with the 1.1-percent decline in gross national product during the year-from 364.5 billion dollars in 1953 to 360.5 billion in 1954.

As indicated in table 2, the production of bituminous coal dropped to the lowest point since the long depression of the 1930's in this The output—392 million tons—was a severe decline from the average of 522 million tons per year for the postwar period Anthracite production declined further, to the lowest out-1946-53.put since 1888. As many mines were closed, employment in the coal industry also dropped sharply and was the lowest since the turn of the century.

The general decline in business during 1954 resulted in a 0.6-percent decrease in consumption (runs to stills) of crude petroleum. downturn, in contrast with the steady gains of recent years, reflected a 1.8-percent decrease in domestic production of crude oil, a 1.3-percent increase in imports, and a 16-million-barrel (5.8-percent) decrease in stocks. The production of natural gas increased 4.1 percent, however,

in spite of the decreased business activity.

Crude-oil production was generally down throughout the country, except in the Rocky Mountain States. The increase in that area reflected the growth of pipeline outlets, as lines were extended to fields discovered and developed in recent years. Increases in natural-gas production were general among the major producing States, except for California, where there was a decrease.

The number of wells drilled for oil and gas during 1954 (52,919) established a new record and was 10 percent greater than in 1953. The percentage of oil wells completed (56.3) was slightly higher than in recent years, but the percentage of gas wells and dry holes fell slightly.

CONSUMPTION

Bituminous-coal consumption declined in 1954 in every consumer category except electric power utilities. Consumption at coke ovens and steel and rolling mills dropped 28.7 million tons. Decreases in other consumer categories were as follows: 10.4 million tons by railroads (Class I), 18.5 million tons by "other industrials," 0.2 million tons in bunker fuel used in foreign trade, 0.2 million tons at cement mills, and 8.7 million tons in retail deliveries. These declines which totaled 66.7 million tons were partly offset by an increase of 3 million tons in bituminous-coal consumption at electric power utilities. Exports of bituminous coal decreased 2.7 million tons from the 1953 level.

As the demand for industrial sizes of anthracite generally exceeds supply, the continuing recession in anthracite consumption was attributable to relatively mild weather conditions and to the inroads made in the primary anthracite-marketing areas by competitive fuels.

TABLE 3.—Consumption of bituminous coal and lignite in the United States, 1953-54, by major consumer groups

Bureau of Census, U. S. Department of Commerce.

The pattern of changes in the consumption of petroleum products during 1954 showed that consumer incomes and spending were well maintained, in spite of the drop in industrial activity. Gasoline consumption in 1954 was about 2 percent greater than in the preceding year, and use of oil for house heating increased 7.5 percent. Although railroad use of diesel fuel rose 3 percent, all other categories of industrial fuel-oil consumption were lower in 1954 than in 1953. Exports of both crude oil and products in 1954 were below those in 1953; their combined decrease was 12.5 percent. The consumption of natural gas increased substantially—5.3 percent—as the effect of the transmission lines that were extended to New England during 1953 became fully evident. Nonindustrial uses of natural gas (heating and cooking) rose 12 percent, while industrial uses, including consumption by the petroleum industry, was up only 3 percent.

EMPLOYMENT AND WORKING TIME

The average number of employees working daily in the bituminous-coal- and anthracite-mining industries declined 22.4 and 24.0 percent, respectively, in 1954 from 1953. The average daily working force in the bituminous-coal and lignite industry in 1954 totaled 227,397 men, compared with 293,106 in 1953. In the anthracite industry the decline was from 57,862 to 43,996. Because of competitive pressures for continually advancing efficiency in coal production, it is significant that the net tons mined per man-day in 1954 in the bituminous-coal and lignite industry was 9.47, compared with 8.17 in 1953. The output per man-year increased from 1,560 tons to 1,724.

In the anthracite industry the output per man-day increased from 3.28 tons in 1953 to 4.02 in 1954, owing principally to the increased percentage of strip production. The output per man per year was 659

net tons in 1954, compared with 535 in 1953.

The total employment in the petroleum industry during 1954 was 1,647,000, about 1.5 percent less than in the preceding year. Of this total, 306,200 were engaged in the production division, 222,800 in refining, 124,000 in transportation, 234,800 in wholesale distribution,

and 759,200 in retail distribution.

The average weekly hours worked in 1954 in the bituminous-coal industry decreased from 34.4 in 1953 to 32.6 in 1954. For the anthracite industry, the average weekly hours worked in 1954 was 30.0. In 1954 the bituminous-coal industry averaged 182 days of work, as against 191 days in 1953. In the anthracite industry the average

number of days worked increased from 163 to 164.

As wages strongly influence total production costs in the fuel industries, wage increases granted by the respective branches of the fuel industries are significant. In 1954 hourly earnings in the bituminous-coal industry were unchanged from 1953. In the anthracite industry hourly earnings increased 1.6 percent. In petroleum and natural-gas production they rose 2.7 percent. In absolute figures, hourly earnings in the anthracite industry were \$2.52, in the bituminous-coal industry \$2.48, and in the petroleum industry \$2.27. Because of the more regular work in the petroleum industry, weekly earnings in this industry were highest of the three—\$91.94—followed by bituminous coal with \$80.85, and anthracite with \$75.60.

¹ Revised.

FUEL PRICES

The index of wholesale prices for all commodities increased from 110.1 in 1953 to 110.3 in 1954 (see table 6). The average value per ton, f. o. b. mines, for bituminous coal declined from \$4.92 to \$4.51 and for anthracite from \$9.67 to \$8.52. The average price per barrel at the well for crude petroleum rose from \$2.68 in 1953 to \$2.78 in 1954. This increase reflected the general price increase in mid-1953, which continued in effect throughout 1954. There were no general price changes during 1954.

For natural gas the 1954 average price at the wells of 10.1 cents per

thousand cubic feet was 0.9 cent higher than in 1953.

The index of wholesale prices for petroleum and petroleum products in 1954 was 110.8 percent of the 1947-49 base and 1.7 percent below the 1953 level.

TABLE 6.—Average monthly wholesale price indexes for fuels, 1949-54 (1947-49=100)

[Bureau of Labor Statistics, U. S. Department of Labor]

	1949	1950	1951	1952	1953	1954
Gas Petroleum and petroleum products Coal. A verage index for all commodities	101. 5	98. 2	100. 7	103. 7	107. 8	108.8
	100. 1	103. 7	110. 5	109. 3	112. 7	110.8
	105. 8	106. 2	108. 4	108. 7	112. 8	106.3
	99. 2	103. 1	114. 8	111. 6	110. 1	110.3

Convenience and price are significant factors in the competition among the various fuels. Another important factor that strongly influences utilization of fuels is transportation cost. Compared with the relatively low cost of pipeline transmission of oil and natural gas, almost 80 percent of all bituminous coal is shipped via railroads at rates in 1954 that added 72 percent to the coal cost f. o. b. mines. The average railroad freight-rate charge per net ton on bituminous coal and lignite in 1954 was \$3.23, a decrease of 10 cents per ton from 1953.

Data on wholesale prices of bituminous coal for 1953 and 1954 are not fully comparable (as indicated in table 7), because the Bureau of Labor Statistics, United States Department of Labor, changed its method of collecting these data beginning with May 1954.

TABLE 7.—Comparative fuel prices, 1953-54

NATIONAL INCOME ORIGINATED, WAGES, AND SALARIES

As compared to a 1.3-percent decrease in national income originated during the year, income in the bituminous-coal and anthracite industries dropped 22.7 and 20.5 percent, respectively, below 1953. In the crude-petroleum and natural-gas industries income increased 1.6 percent.

Although total United States wages and salaries decreased 1.1 percent, wages and salaries in the bituminous-coal and anthracite industries dropped 24.1 and 22.4 percent, respectively, owing to the heavy drop in employment. In the crude-petroleum and natural-gas industries there was an increase of 4.1 percent.

ENERGY FUELS IN INTERNATIONAL TRADE

United States coal exports (bituminous and anthracite) were approximately 34 million net tons compared with 36.5 million tons in 1953—a decline of about 7 percent. Movements of bituminous coal to Canada, amounting to 15.9 million net tons, decreased sharply in comparison with 19.6 million tons shipped in 1953. Anthracite shipments to Canada were down 145,000 tons. Exports to Europe showed an appreciable increase of 2.4 million tons (2.2 million tons of bituminous and 0.2 million tons of anthracite). Asia imported 3 million tons of United States bituminous coal, 0.9 million tons less than in 1953, chiefly because of curtailed Japanese requirements for United States coal. Exports to Africa increased slightly (25,000 tons) because of Southern Rhodesia's inability to produce adequate supplies from indigenous sources. Shipments to South America were down almost 0.4 million tons, due primarily to Argentina's shift to European suppliers; however, Brazil increased its imports of bituminous coal from the United States by 262,000 tons. Exports to Chile and Uruguay decreased 57,000 and 10,000 tons, respectively.

Exports of both crude petroleum and refined products continued to drop, and the combined decrease for 1954 was 11.5 percent. Imports of crude oil and products increased only slightly (2 percent) in 1954, reflecting the relatively weak markets in this country and the continued efforts of other foreign producing countries to make up the deficit created by the shutdown of operations in Iran after nationalization. After the Iranian oil problem was solved late in 1954 and that country's substantial production was added to the world total, additional pressure to move oil to the United States was inevitable.

WORLD REVIEW

COAL

World coal production in 1954 (bituminous, anthracite, and lignite) was estimated at 1,959 million metric tons, an increase of 2 million tons over 1953. The total output on a continental basis was as follows:

North America			Million met	
South America.		 		39
Europe: Free countr	ies	 		
U. D. D. R.	and satemites			60 72
1111100				16 3
Oceania		 		3

1, 959

The 1954 output in the United States declined approximately 61 million metric tons from 1953, because of lower domestic and export demands.

The most notable production increase in 1954 took place in the U. S. S. R. and Soviet Bloc countries, where the total output was approximately 44 million tons more than in 1953, while the output in Western Europe increased about 8 million tons. In Western Europe there was a general, though slight, increase in productivity, except in the Netherlands.

Coal and lignite consumption in Western Europe amounted to about 514 million metric tons in coal equivalent in 1954, compared with 507 million tons in 1953. Coal supplied approximately 71 percent of the total energy requirements. The increased demand for coal in Europe began to assert itself in the latter half of 1953, and the generally improved economic activity remained high in 1954, particularly in the iron and steel industries.

Source: United Nations Quarterly Bulletin of Coal Statistics for Europe, Vol. III, No. 1, June 1954, and Vol. V, No. 3, December 1956.

In Asia total production in 1954 was about 8 million metric tons higher than in 1953. Production in Japan declined over 4 million tons in 1954. Taiwan, Pakistan and Malaya also reported decreases. Communist China, however increased its coal output 10 million tons. Increases in production were also reported for India, Indonesia, Korea,

Turkey, and North Vietnam.

Africa continued to increase its coal output in 1954 and produced 34 million metric tons—1 million tons more than in 1953. Most of the increase was in the Union of South Africa, where growing industrial activity has created larger energy requirements. Full productive capacity cannot be attained in the Union of South Africa and Southern Rhodesia because of a continued shortage of railroad facilities. The demand for coal continued to exceed availability in both areas.

Oceania also reported gains in coal production. Australia reported an increase of 2.4 million metric tons of bituminous coal and lignite; a large share of it was attributed to greater demand for electric power production. New Zealand reported relatively small gains in the

production of both bituminous coal and lignite.

PETROLEUM

The world output of crude petroleum in 1954—4,991 million barrels—was 4.6 percent greater than in 1953, despite the decreased United States production. World production, excluding that of the United States, was 2,675 million barrels, an increase of 10.8 percent over 1953. The proportion of total world production produced by the United States declined from 49.4 percent in 1953 to 46.4 percent in 1954, continuing the downward trend of recent years. All other major producing areas increased their production, both in actual quantities and in percentage of the world total. The percentage of the total produced in Asia (principally the Middle East) rose from 21.2 to 22.7, and the proportion produced in both South America and Europe increased slightly.

Of special significance was the return of Iranian oil to the world market in 1954. When the Iranian Government nationalized the oil industry which had been British-owned, in 1951, oil was produced only to supply local requirements. A settlement agreeable to both parties was reached late in 1954, and restoration of operations began in November. Iran produced 242 million barrels of crude oil, or 6.4 percent of the world total in 1950, before nationalization. It is expected that it will gradually regain this position during the next

2 or 3 years.

Statistical Summary of Mineral-Fuels Production

By Thelma K. Stewart

GENERAL SUMMARY

TABLES in this chapter summarize mineral-fuels production in the continental United States, defined as the 48 States and the District of Columbia, by individual fuels, both in terms of quantity and value of production. The total value of all mineral production, including mineral fuels, is also shown to provide an integrated summary of the mineral industries during 1954. For a detailed summary of all minerals other than fuels, see volume I of the Minerals Yearbook.

The value of all mineral production, by States, is given in table 3. Bituminous-coal production includes all marketable production, excluding washery and other refuse, while anthracite production is

measured at the sizing and cleaning stage.

Crude petroleum is measured at the time it is removed from the producing property, and natural-gas liquids are measured in the form in which they are shipped from the natural-gasoline or cycle plants. For precise description of the stage of measurement, see the individual commodity chapters.

World production and the proportion of the total produced by the

United States are given in table 4.

The surveys of natural-gas liquids, bituminous coal and lignite, anthracite, asphalt, and peat for 1954 were conducted jointly with the Bureau of Census, United States Department of Commerce, as a part of the Census of Mineral Industries for 1954. In all cases where applicable, any discrepancies with data published by the Bureau of the Census will be reconciled in the Minerals Yearbook, Volume II—Fuels, for 1955.

As a result of this joint effort, 11 natural-gas-liquid plants that had not been reporting to the Bureau of Mines were disclosed. Several of these were plants that dehydrate gas for pipeline movement and had not been considered natural-gasoline plants, but it developed that they do produce and ship natural-gas liquids. All these plants

are now included in the Bureau of Mines surveys.

The Census of Mineral Industries covering crude petrolum and natural gas was conducted independently of the Bureau of Mines. There are several inconsistencies between data published by Bureau of the Census and those appearing in this volume. Most of these can be explained by the fact that the Bureau of the Census did not collect data from installations with shipments valued at less than \$500, whereas Bureau of Mines reports represent complete coverage.

Coke and coal chemicals, fuel briquets and packaged fuel, and

carbon black canvasses were conducted by the Bureau of Mines.

Employment and Injuries in the Fuel Industries

By John C. Machisak

INTRODUCTION

THIS CHAPTER of the Minerals Yearbook contains injury-experience and related employment data for the coal-mining, coking, and oil and gas industries for 1954. Inasmuch as the inherent accident hazards for each of the three sections are not comparable, no attempt has been made to combine data to present an overall experience for the fuel section of the mineral industries; therefore, each industry is treated separately. The injury and employment records for the mineral industry as a whole are covered by tabulations and discussions in volume III.

COAL

The overall injury experience (fatal and nonfatal) at the Nation's coal mines was more favorable in 1954 than in the preceding year. The number of injuries, both fatal and nonfatal, was considerably less than in 1953, and the resulting injury-frequency rate per million man-hours worked dropped from 48.13 to 46.69, or 3 percent, thus

establishing a new low record for the coal-mining industry.

The total number of fatalities resulting from accidents, which were determined to be chargeable to the coal-mining industry, was 396—the lowest number recorded for any 1 year in a statistical history of the industry, covering almost three-quarters of a century. However, despite this commendable saving of life, the rate at which the deaths occurred was unfavorable. In 1953 the fatality rate—a record low—was 0.90 per million man-hours of worktime or exposure to the hazards of the industry, whereas in 1954 the rate was 1.02—an increase of 13 percent. This increase in the fatality rate was, however, due entirely to a 24-percent decrease in manpower activity. The total worktime dropped from 513.6 million man-hours in 1953 to 388.0 million man-hours in 1954.

One major disaster (a single accident in which 5 or more men are killed) occurred in a West Virginia mine as the result of an explosion; 15 underground employees and 1 surface employee were killed.

The decrease in the number of deaths in the industry was effected entirely in underground workings, where chances of death from accidents are potentially higher than in any other phase of the industry.

Accidents at surface works connected with underground mines resulted in one more death than during 1953. Fatalities associated with strippit operations increased from 21 in 1953 to 22 in 1954. The number of nonfatal injuries, or those involving loss of time beyond the day on which the injuries occurred was 17,718—27 percent less than in 1953.

Employment showed a decided decrease in 1954; an average of 283,700 men was working daily, or 19 percent less than the average daily working force in 1953. Because of the decline in the number of men working, the total worktime (man-hours) decreased 24 percent during 1954. The average miner worked a 7.82-hour shift and accumulated 1,367 hours of work in 1954.

¹ Average number of men at work each day mine was active. Because absenteeism and labor turnover are taken into consideration, this number is lower than number of men available for work, as measured by a account of names on payroll.

Bituminous-Coal Mines.—The safety record of the bituminous-coal-mining industry continued to improve in 1954, when it was the lowest of any year since complete injury data became available in 1930. The rate of 44.65 injuries (fatal and nonfatal) per million manhours for the industry was 3 percent lower than the rate of 46.15 for 1953. In all, 334 men were killed at bituminous-coal mines during 1954, at the frequency rate of 0.99 per million man-hours, which was 11 percent higher than the alltime low fatality rate of 0.89 established in 1953; however, the number of fatalities in 1954 was the lowest in the statistical history of the bituminous-coal-mining industry. Of the 334 fatalities, 291 were underground, 27 at surface operations operated in connection with underground mines, and 16 at strip-pit operations. The principal causes of underground accidents (roof falls and haulage) resulted in fewer deaths in 1954. However, the number of fatal injuries from explosions, explosives, and machinery increased. It is gratifying to report that the number of fatal injuries from falls of

Average in which operating time of each mine is weighted by average number of workers in mines.
Includes lignite.

roof, rib, or face, the greatest single cause of underground fatalities, dropped 24 percent; there were 177 in 1954 as compared with 233 in 1953, or 56 fatalities less. Underground haulage accidents caused the death of 66 men in 1954 and 78 in 1953, a decrease of 12. One major disaster (a single accident in which 5 or more men are killed) occurred in 1954, a gas and dust explosion that resulted in the death of 16 men.

The average number of men working daily at bituminous-coal mines in 1954 was 241,900, an 18-percent decline from the 1953 average employment of 295,400 men. The average number of days of employment per man declined from 191 in 1953 to 177 in 1954—a decrease of 14 days of employment per man. The total man-hours of worktime declined 24 percent, which resulted in a workyear of 1.396

hours—108 hours of work per man less than in 1953.

Anthracite Mines.—The injury rate per million man-hours (fatal and nonfatal) at Pennsylvania anthracite mines declined less than 1 percent in 1954. The combined injury rate was 60.41 in 1954 and 60.77 in 1953. A total of 62 fatalities occurred at anthracite mines in 1954—a decrease of 2 from the previous year. The fatality rate per million man-hours in 1954 (1.23) was increased 34 percent over that in 1953 (0.92). In all, 2,972 nonfatal lost-time injuries occurred, at the rate of 59.18 per million man-hours, which was slightly lower than in 1953. No major disaster occurred in this segment of the coal-mining industry during the year.

Fatal accidents at anthracite mines caused the death of 62 men—51 underground, 5 at surface operations operated in connection with underground mines, and 6 at strip mines. Falls of roof, face, or rib killed 39 men, a decline of 4 from the previous year. Only 1 death resulted from explosions—4 less than in the previous year. Haulage accidents underground were credited with the only increase over the previous year, causing six more deaths in 1954 than in 1953. Falls of roof, face, or rib, and haulage accidents were the chief sources of fatal injuries at underground anthracite mines and caused 47 (92)

percent) of the 51 fatal injuries underground.

Employment at Pennsylvania anthracite mines continued to decline in 1954. An average daily working force of 41,786 men worked 164 days, accumulating 50,222 thousand man-hours. This was a 25-percent decline in the average number of men working daily and a 28-percent drop in the total man-hours of employment from that in 1953. Each employee had an average of 1,202 man-hours of work during the year, or 42 hours less per man than in 1953.

COKE

The coke-manufacturing industry continued to improve its safety record, with a combined (fatal and nonfatal) injury-frequency rate of 4.99 per million man-hours of worktime for 1954, against a corresponding rate of 6.69 for the previous year, as shown by reports for the 21,299 active beehive and byproduct coke ovens. Reports received by the Bureau of Mines indicate a 19-percent reduction in the number of man-hours worked, as well as an 18-percent decrease in the number of employees working. The average days worked during the year were approximately the same, with an 8-hour shift. The average

worker accumulated 2,732 hours of worktime-27 hours less than

during the previous year.

Byproduct-Coke Plants.—There were 8 fatalities and 245 nonfatal disabling injuries at byproduct ovens in 1954—a 26-percent reduction in the number of fatal and nonfatal injuries. The combined rate (fatal and nonfatal) of 4.88 was 12 percent lower than the corresponding rate of 5.56 reported for 1953. There were 341 fewer ovens operated in 1954 than in 1953, and the average daily working force and number of man-hours worked each declined 15 percent. Production dropped 20 percent, while the average employee at byproduct plants worked an 8-hour shift and accumulated 2,887 hours of worktime. Byproduct ovens operated 1 day more than in 1953.

Beehive-Coke Ovens.—The beehive-coke industry again operated with a fatality-free record and reported only nine nonfatal injuries. An injury-frequency rate of 13.40 per million man-hours of worktime was 48 percent lower than in the previous year. The number of ovens operated in the beehive-coke industry for 1954 was 50 percent lower than in the previous year, and the number of workers reported declined 48 percent. Production in 1954 was 628,600 tons—a reduction of over 4 million tons from the 1953 total. The man-hours of worktime declined from 3.6 million hours in 1953 to 671,000 in 1954. The number of days active was 130 less, with each worker accumulating only 531 hours during the year, and working a 7.46-hour shift.

Average in which operating time of each plant is weighted by average number of workers in the plant.

NOTE: All data are final.

OIL AND GAS

The injury experience of the oil and gas industry in 1954 was the best for the 13-year period in which the Bureau of Mines has collected statistics. The combined frequency rate (fatal and nonfatal) of 10.51 injuries per million man-hours was 9 percent lower than in 1953, and the severity rate of 1.04 days lost per 1,000 hours worked showed a 23-percent reduction from the previous year. A total of 122 fatal and permanent total injuries was reported and 548 permanent partial and 12,248 temporary disabilities. Compared with 1953, injuries occurred less frequently in all parts of the industry except exploration and miscellaneous and were less severe than in all except production and miscellaneous. The greatest improvement in injury frequency was in drilling, although it maintained a higher rate than any other segment of the industry.

A total of 580,800 employees worked an average of 2,116 hours

each—an average of 11 hours less than in 1953.

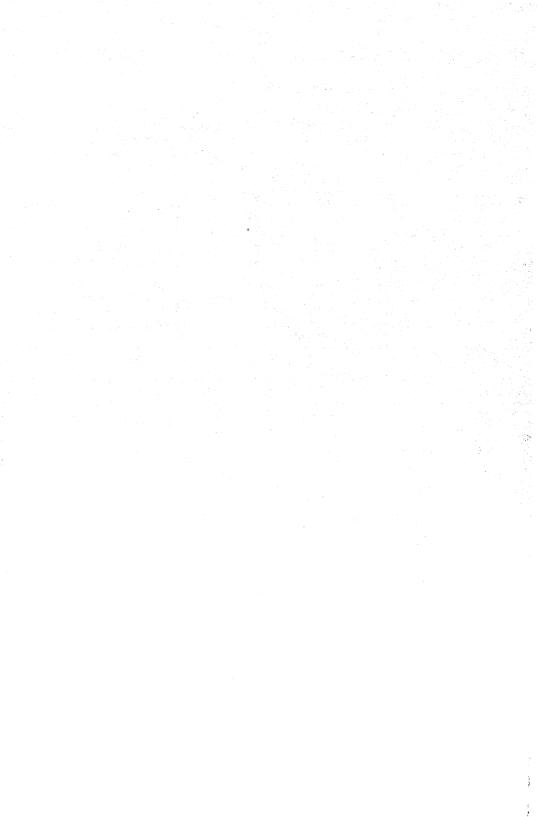

TABLE 3.—Employment and injury experience in the oil and gas industry of the United States, 1950-54

Year	Average men working	Million man- hours	Number	of injuries		y rates per nan-hours
	daily	worked	Fatal	Nonfatal	Fatal	Nonfatal

¹ Fatal and permanent total injuries combined.

CONCLUSION

The coal-mining, beehive- and byproduct-coking, and oil and gas industries all recorded new low overall frequency rates in 1954. Each industry established the best safety record since data on injuries have been compiled by the Bureau of Mines. This reduction in injury frequency resulted in approximately 8,500 fewer disabling injuries in 1954 than in 1953.

PART II. COMMODITY REVIEWS

A. Coal and Related Products Coal—Bituminous and Lignite

By W. H. Young, R. L. Anderson, and E. M. Hall

GENERAL SUMMARY

OST OF THE key items in the bituminous-coal and lignite industry declined in 1954 compared with 1953. Production, consumption, exports, average value per ton, men working, and days worked all declined; however, in the field of mechanization, the percentages mechanically loaded, mechanically cleaned, mined by auger, and mined by stripping all increased, as did production per man per

Production.—The output of soft coal in 1954—391.7 million tons was 14 percent less than the 457.3 million tons produced in 1953. The lower production in 1954 was due largely to a sharp reduction in

consumption in the United States and to a drop in exports.

Production fluctuated less during 1954 than it had for many years. There was only a slight seasonal variation in the spring, and the only major fluctuation resulted from the miners' vacation period of 10 days in midsummer. Time lost on account of strikes were the smallest since 1938—according to the Bureau of Labor Statistics, 344,000 man-days.

Trend of Employment.—The continued decrease in employment was due both to the drop in production and to the increased output per man per day in 1954 compared with 1953. The average number of men working daily at bituminous-coal and lignite mines decreased from 293,000 in 1953 to 227,000 in 1954.

Index to Capacity.—As it is impossible for all mines to operate every working day in the year, a conservative figure of 280 days for calculating potential capacity was suggested some years ago by the coal committee of the American Institute of Mining and Metallurgical Engineers. (See Minerals Yearbook, 1935, pp. 631-632.) The average output per day worked in 1954 was 2.2 million tons, which (if applied to 280 days) gives an annual potential output of 603 million tons compared with the actual production of 391.7 million tons.

Mechanization.—A greater proportion—80 percent—of coal was loaded mechanically at underground mines in the United States in 1954 than in any other year. Sales of continuous mining machines increased 50 percent over the previous year, and production at auger

mines almost doubled.

Mechanical Cleaning.—Approximately 60 percent of the soft coal mined in the United States in 1954 was mechanically cleaned. large portion of the remaining 40 percent was hand-picked and screened into various sizes at tipples with no mechanical cleaning facilities.

Consumption.—Consumption of bituminous coal and lignite in the United States declined sharply-15 percent-in 1954 from the previous year. All classes of consumers except electric power utilities used less coal in 1954. Table 53 shows trends in consumption for the major classes of consumers for 1933 to 1954.

Trends of Fuel Efficiency.—As for many years past, electric publicutility power plants chalked up new records in fuel efficiency; the poundage of coal per kilowatt-hour in 1954 was slightly less than 1.

Competition From Oil and Gas.—Soft coal continued to meet serious competition from oil and gas. The relative rate of growth of coal, petroleum, natural gas, and water-power, 1900–54, is shown graphically in figure 15. As a percentage of total energy, bituminous coal and lignite represented the smallest proportion of total energy in their history, while both petroleum and natural gas represented a higher proportion than ever before.

Electric-power utilities consumed 3 percent more bituminous coal and 13 percent more gas in 1954 than in 1953. Nineteen percent less

fuel oil was consumed in 1954 than in 1953.

Class I railroads decreased their consumption of coal 37 percent in 1954 from 1953 and their purchases of fuel oil and diesel fuel 9 percent

during the same period.

Stocks.—The reserve supply of bituminous coal and lignite in the hands of industrial consumers and retail coalyards decreased from 80.6 million tons at the beginning of 1954 to 69.2 million tons at the close. The days' supply of stocks decreased from 64 to 60. Stocks

on the upper Lake docks decreased 418,110 tons from January 1 to December 31, 1954.

SCOPE OF REPORT

As in previous years, these data include all coal produced in Alaska and in the United States except Pennsylvania anthracite. The production in Alaska is included in the total production of the United States.

Throughout this chapter all tonnage figures represent net tons of marketable coal and exclude washery and other refuse. The unit

of measurement is the net (short) ton of 2,000 pounds.

The statistics for 1954 are final and are based upon detailed annual reports of production and mine operation furnished by the producers. All but a small percentage of the output was covered by the reports submitted. For the remaining production not directly reported, which consisted chiefly of output of small mines, it has been possible to obtain reasonably accurate data from the records of the various State mine departments, which have statutory authority to require such reports, or, in a few instances, from railroad carloadings. Thus, the report represents complete coverage of all mines having an output of 1,000 tons a year or more. The report does not attempt to include many small mines that produce less than 1,000 tons a year. However, for 1954 the Bureau of the Census included reports from 643 of these small mines, whose production amounted to 365,908 tons, or less than 0.1 percent of the total United States production.

Comparability of 1954 Figures With Previous Years.—The annual canvass of bituminous coal and lignite mines for 1954 was conducted in cooperation with the United States Bureau of the Census as a part of the Census of Mineral Industries for 1954. The drafting of schedules and statistical procedures, the editing of reports, and the classification of data accorded with standards established by the Bureau of the Census. As a result of this cooperative arrangement, some items for 1954 are not strictly comparable with those for previous years.

The first instance of lack of comparability was in the definition of a mine. The Bureau of the Census defined a mine as "a working or group of workings at a given locality in which operations are conducted as a unit or are unified by common management or joint handling of some part of the mining or preparation process. Individual shafts, openings, or sites should not necessarily be considered as individual mines." The Bureau of Mines has considered individual shafts, openings, or sites as individual "mines."

There also is lack of comparability in items on employment, days worked, man-days, and output per man per day. The Bureau of the Census excluded working proprietors while the Bureau of Mines in previous years included owners, operators, or partners performing manual labor.

The joint 1954 report form requested information on loading machines "in use or available for use at the end of 1954." If a mine operated for only part of the year and was closed permanently and dismantled at the end of the year, no equipment was tabulated for that mine. The Bureau of Mines, in previous years, requested information on the number of machines in use during the period when the mine was in operation.

Includes California and Louisiana.

Somewhat less than total recorded production. See footnote 5.

THICKNESS OF BITUMINOUS-COAL AND LIGNITE SEAMS

The overall operating efficiency in bituminous-coal mining is affected by many physical conditions, such as the thickness and character of the coal seam, the dip or pitch of the seam, the depth of cover, the character of the roof and overlying strata, and mine water. Of these, the thickness of the coal seam is one of the more important

items in determining the results achieved.

The Bureau of Mines has compiled and published detailed data on thickness of seams for coal mined in 1945 2 and 1950.3 An earlier study, based on data collected by the United States Coal Commission. was made on thickness of seams in 1920.4 In the past 30 years the average seam thickness has not changed materially. The average thickness of all bituminous coal and lignite mined in 1920 was 63 inches; in 1945, 65 inches; and in 1950, 63 inches. As thick seams have been exhausted in the older fields, other thick seams have been opened in the newer fields.

Because of the importance of seam thickness in mining operations, the data for 1950, the latest year available, are summarized here. A coal seam of moderate thickness presents the least mining difficulties. Any decided thinning limits production, decreases recovery, and there-Thickening of the seam in underground mining fore increases cost. has the same effect; for, as the seam increases in thickness, it becomes necessary to maintain larger pillars, timbering becomes more difficult and finally impracticable, and roof control is almost impossible. The limited information available indicates that, for maximum recovery in underground bituminous-coal mines, the ideal thickness of seams lies between 6 and 8 feet.

The 1950 data included in the following tables were compiled from annual reports of production and mine operation submitted by bituminous-coal and lignite producers to the Bureau of Mines. Estimates were made for seam thickness not specified by the producer. estimates did not materially affect the accuracy of the final results.

Bituminous coal and lignite are mined today from seams of exceedingly variable thickness—varying from less than 2 to over 50 feet; however, a large majority of the mines produce coal from seams 3 to Table 3 presents the number of mines and production in 6 feet thick. 1950, classified by thickness. Figures are also shown separately for underground and strip mines. Coal near the surface in relatively thin seams that are not suited to underground mining frequently can be recovered by stripping. In 1950, 17 percent of strip production came from seams less than 3 feet thick, whereas only 5 percent of the underground production came from seams less than 3 feet thick.

The average thickness of seam mined varied widely, ranging from 19.2 feet in Wyoming to 1.5 in Georgia. Figure 1 shows the percentage of bituminous coal produced, by thickness of seams mined, in the 10 largest coal-producing States and the United States total in 1950.

The States are arranged in order of the percentage of output mined from seams less than 4 feet thick. Table 4 gives details by States for strip and underground mines separately. Although there was considerable variation in thickness of seams at strip and underground mines, the strip mines generally operated in thinner seams. Strip mining was carried on in 11 States in coal seams having average thicknesses less than those in the deep mines in the same States. These 11 States produced 70 percent of the total strip output in 1950.

DOMESTIC PRODUCTION

The statistics in this report combine bituminous coal and lignite. Production figures for lignite are shown separately in table 62.

The production of bituminous coal and lignite has fluctuated widely from year to year; the chief causes have been market demand and strikes. The domestic market demand is influenced primarily by general industrial conditions, but in recent years exports have had considerable effect on total production. During the last two World Wars there was an extra-heavy demand for coal. Since 1930 production has fluctuated between a low of 310 million tons in 1932 to a high of 631 million tons in 1947—the highest production on record. The long-term trend in production, particularly since 1920, has been influenced very greatly by the inroads of competitive fuels and energy, such as oil, gas, and waterpower. Strikes, as mentioned above, are also a factor. The record of average days lost per man on strike from 1899 to 1954 is shown in table 14. Within the past 10 years man-days lost by strikes have fluctuated from a low of less than one-half million in 1954 to over 19 million in 1946.

The trend of average production of bituminous coal and lignite per working day in 1945-54 is illustrated in figures 2 and 5. Production, realization, capacity, and net income of bituminous-coal and lignite

mines in 1905-54 are shown graphically in figure 3.

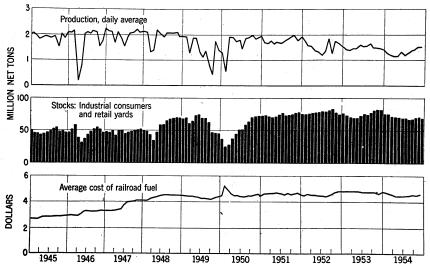

FIGURE 2.—Trends of production, stocks, and railroad-fuel prices of bituminous coal and lignite in the United States, 1945-54.

PRODUCTION BY MONTHS AND WEEKS

The figures on monthly and weekly production are estimates based upon (1) railroad carloadings of coal reported daily and weekly by all the important carriers, (2) shipments on the Allegheny and Monongahela Rivers reported by the United States Army Engineers, (3) direct reports from a number of mining companies, and (4) monthly production statements compiled by certain local operators' associations and State mine departments. In computing the estimates, allowance is made for commercial truck shipments, local sales, colliery fuel, and small truck mines producing over 1,000 tons a year. Preliminary estimates are made currently and published in the Weekly Coal Reports. These preliminary estimates have proved very reliable and for many years have been within approximately 1 percent of the final figure for total production, based upon complete coverage of all

 $^{^{\}rm l}$ Figures for 1890 to 1914, inclusive, represent fiscal year ended June 30. $^{\rm 2}$ Data not available.

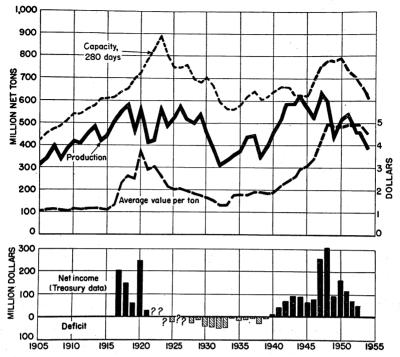

FIGURE 3.—Trends of bituminous-coal and lignite production, realization, mine capacity, and net income or deficit in the United States, 1905-54.

mines producing over 1,000 tons a year. The preliminary estimate of production for 1954 was 392 million tons, and the final figure based on the canvass was 391.7 million tons—a difference of only 0.1 percent. The preliminary estimates are later revised to agree with the final total production based on the canvass. Thus, the monthly and weekly estimates of production, summarized in tables 6–9, represent final figures and vary slightly from the preliminary figures of production published currently in the Weekly Coal Report.

Monthly and weekly production of bituminous coal and lignite varies much more than annual production. The major cause of current fluctuations in production is strikes. During periods of major strikes, approximately 80 percent of production is stopped. Even during periods of apparent labor peace, many strikes occur each year. According to the Bureau of Labor Statistics, for the past 10 years there was a low of 208 strikes in 1954 and a high of 598 strikes in

1945 in bituminous-coal and lignite mines.

In recent years the miners' vacation period has been marked by a sharp decline in production, as all miners under contract take their vacation during the latter part of June and the first few days in July. Other minor causes of current fluctuations in production included heavy snowstorms, which make it difficult for the miners to report for work.

SUMMARY BY STATES

Over a period of years there have been wide variations in production in different States. Table 10 lists production by States during the past 10 years and the year of maximum production for each State. As a background for comparison, the total production in the United States reached its peak in 1947. Georgia (a small producer) reached its peak output in 1903. Maryland (one of the oldest coal-producing States), Arkansas, and Michigan all reached their maximum production in 1907. It is most significant that nine States (including Illinois and Pennsylvania) reached their peak during World War I—1917—18. In striking contrast, Kentucky and West Virginia attained their maximum output in 1947. However, West Virginia ranked first in terms of production in 1954, followed by Pennsylvania,

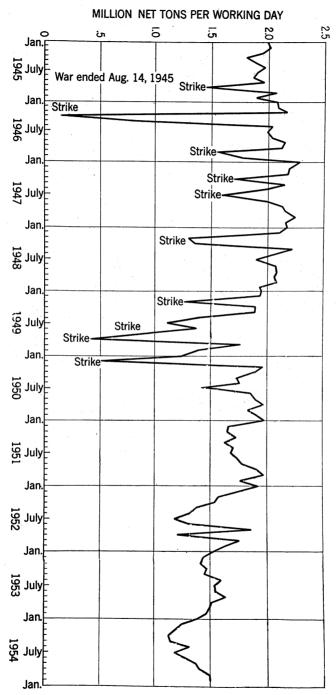

FIGURE 5.—Average production of bituminous coal and lignite in the United States per working day in each month, 1945-54.

TABLE 7.-Production of bituminous coal and lignite in the United States in 1954, by States, with estimates by months, in thousand

[Totals for year are based on final complete returns from all operators known to have produced 1,000 tons and over per year. In most instances monthly apportionment is based on current records of railroad carloadings and river shipments, supplemented by direct reports from local sources]

Included in "Other districts"; not published to avoid disclosure of individual operations. Includes districts 15, 18, 21, and 22.

Kentucky, and Illinois, in that order. The total production from the earliest record to the end of 1954, by States, is given in the last column of table 10. Here, Pennsylvania ranks first, followed by West Virginia, Illinois, and Kentucky.

Detailed statistics, by States and by Coal Act districts, are summarized in tables 11 and 12. These tables make possible easy com-

TABLE 9.—Production of bituminous coal and lignite in the United States, 1953-54, with estimates by weeks

	1953				1954		
Week ended—	Production (thousand net tons)	Maxi- mum number of work- ing days	Average production per work- ing day (thousand net tons)	Week ended—	Production (thousand net tons)	Maxi- mum number of work- ing days	Average production per work- ing day (thousand net tons)

¹ Figures represent output and number of working days in that part of the week included in the calendar year shown. Total production for the week ended January 2, 1954, was 6,790,000 net tons, and for January 1, 1955, 7,430,000 net tons.

² Average daily output for the entire week and not for working days in the calendar year shown.

Includes coal loaded at minos directly into railroad cars or river barges, hanled by trucks to railroad siding, and hauled by trucks to waterways.

Includes coal transported from mines to point of use by conveyor belts or trams, used by mine employees, taken by locomotive tenders at tipple, used at mines and all other uses at mines.

Value received or charged for coal f. o. b. mines. Includes a value for coal not sold but used by producer, such as mine fuel and coal coked, as estimated by producer at verage prices that might have been received if such commercially.

Included in lightle total. not published to avoid disclosure of individual operations.

Includes lightle in California, Montana, North Dakota, and Texas.

TABLE 12.—Number of mines, production, value, men working daily, days active, man-days, and output per man per day at bituminous-coal and lignite mines in the United States, 1954, by districts

Districts as defined in the Bituminous Coal Act of April 26, 1937 (50 Stats, 72, 91–94), and modifications thereto]

(Exclusive of mines producing less than 1,000 tons)

Includes coal loaded at mines directly into railroad ears or river barges, hauled by trucks to railroad sidings, and hauled by trucks to waterways.

Includes coal transported from mines to point of use by conveyor belts or trams, used by mine employees, taken by locomotive tenders at tipplies, used at mines, and all other uses at mines, and all other uses at mines. And all other uses at mines at mines, and all other uses at mines. Includes a value for coal not sold but used by producer, such as mine fuel and coal coked, as estimated by producer at average prices that might have been received if such coal had been sold commercially.

A finclude first coal attricts?... not published to avoid disclosure of individual operations.

Includes districts 15, 18, 21, and 22.

parisons between States and districts for such strategic items as production, number of mines, disposition of coal, average value per ton, number of men working, days worked, and output per man per day. As fluctuation seems to be the key characteristic of the soft-coal industry, it is not surprising to find wide variations among the States in most strategic items mentioned. Most variations, generally speaking, are explained in terms of physical conditions, extent of mechanization, or market demand.

NUMBER AND SIZE OF MINES

The unit in the statistical record is the mine, and operating companies are requested to make a separate report for each mine because its location is definitely known and can be related to a specific district or county; its identity can be followed through successive changes of ownership; and it is the natural operating unit from the point of view of cost, mechanical equipment, mining practice, and output per man per day. Since some companies operate two or more mines, the number of mines is much greater than the number of operating companies.

Over a period of many years, bituminous-coal and lignite mines have been increasing in size. The tendency toward larger mines has been influenced by more extensive mechanization. In 1924, when less than 1 percent of the underground production was loaded mechanically, only 18 percent of the output came from mines having an annual output of 500,000 tons and over. Thirty-one years later—by 1954—84 percent of the underground production was loaded mechanically, and 44 percent of the total production came from mines having an annual output of 500,000 tons and over. Larger stripping shovels have also influenced the development of larger mines.

Although almost half of the production of bituminous coal and lignite comes from very large mines, there are many small mines. Table 13 classifies the mines by size of output in 1954. Figure 6 shows the percentage of the number of mines and the percentage of production in each size class. It is very significant that the small mines—those producing less than 10,000 tons per year—constituted 54 percent of the total number and only 3 percent of total output. On the other hand, the large mines—those producing over 500,000 tons per year—constituted only 3 percent of the total number and 44 percent of the total production.

EMPLOYMENT AND PRODUCTIVITY

The bituminous-coal and lignite industry has become highly mechanized, mostly in the last 20 years. This has had a substantial influence on production per man per day and on the number of employees required. Roughly speaking, productivity has doubled and the number of employees has declined 50 percent in the past 20 years.

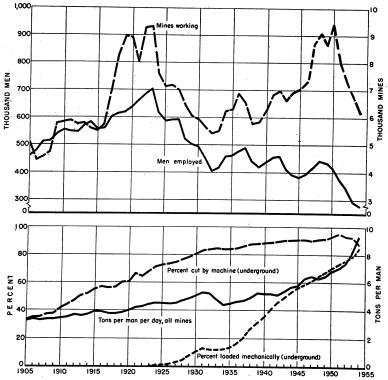

FIGURE 7.—Trends of employment, mechanization, and output per man at bituminous-coal and lignite mines in the United States, 1905-54.

UNDERGROUND MINING

Three-fourths of the bituminous coal and lignite produced is mined underground. The major tasks underground are cutting, drilling of shot holes, loading, and haulage. Loading is so important that it is given special treatment later in the section on Mechanical Loading. For many years, approximately 90 percent of the underground production has been cut by machine. The use of power drills for shot holes has increased rapidly in the past 15 years; and, by 1954, 80 percent of the production came from mines using power drills. Trolley locomotives are the principal method of underground haulage; however, in recent years the use of shuttle cars has been growing rapidly.

 $^{^{\}rm 1}$ Includes all mines using belt conveyors, other than main-slope conveyors, 500 feet long and over for underground transportation of coal.

AUGER MINING

Augers are generally used in areas where strip mining has become economically impracticable because of thick overburden. They were first used about 1945, and separate statistics on coal-recovery augers

begin with 1952.

Production at auger mines increased rapidly from less than 2 million tons in 1952 to over 4 million tons in 1954. (See table 25.) Auger mining was active in 6 States in 1954; and the sales, as reported by 4 manufacturers, indicate continued rapid growth of this type of mining. (See tables 23 and 24.) A few coal-recovery augers have been sold for underground use, but these units and the coal produced by them have been included with coal loaded mechanically underground.

 $^{^{\}mbox{\tiny 1}}$ Separate data by years and States not available.

STRIP MINING

In mining coal by stripping, the overburden above the coal seam is stripped off with large shovels or draglines, leaving the seam exposed. Then the coal is loaded (usually by smaller shovels) directly into trucks or railroad cars for haulage to tipples, railroad ramps, or the final destination. In 1954, coal was mined by stripping in every coal-producing State in the United States except Arizona, Georgia, and Utah.

Strip mines have two substantial advantages over underground mines: First, the output per man per day in strip mines more than doubles that in underground mines and second, the average value of strip coal, f. o. b. mines, is about one-third lower than that from

underground mines. (See figs. 8 and 9 and table 25.)

The rapid growth of strip mining was made possible by development of larger and improved stripping and drilling equipment and trucks. The most notable recent changes in stripping equipment have been the almost complete disappearance of steam shovels and the increased number of diesel-powered shovels and draglines and large electric shovels and draglines.

In the past 7 years the average capacity of trucks used in strip mines has increased considerably, which reduced the number required. The average distance coal was hauled from strip mines to tipples or ramps has remained approximately 4 miles during the same period.

(See tables 26–32.)

The average thickness of overburden at all bituminous-coal and lignite strip mines in the United States was 39 feet in 1950⁵ and probably averaged nearly 45 feet in 1954. Several strip mines handled an average of more than 60 feet of overburden in 1954, and a few handled over 70 feet.

⁵ Young, W. H., and Anderson, R. L., Thickness of Bituminous-Coal and Lignite Seams at All Mines and Thickness of Overburden at Strip Mines in the United States in 1950: Bureau of Mines Inf. Circ. 7642, 1952, 18 pp.

Includes gasoline shovels.
Included with diesel shovels.
Data not available.

Included in lignite total; not published to avoid disclosure of individual operations. Included in "Other States"; not published to avoid disclosure of individual operations. Includes lignite in California, Montana, North Dakota, South Dakota, and Texas. Includes Montana (bituminous), New Mexico, and Wyoming.

Includes Montana (bituminous) and New Mexico.

MECHANICAL LOADING

In the past 10 years the mechanical loading of underground bituminous coal and lignite has increased from 53 percent to 84 percent of the total output. Wage rates probably were the most important factor that caused this rapid rate of progress in mechanization; however, increased mechanization resulted in a 60-percent increase in productivity in 1954 over 1944. Although the overall mechanization showed a gradual increase during this period, the following changes occurred in the methods of loading: Mobile loading into mine cars decreased from 57 to 17 percent of the total mechanically loaded; mobile loading into shuttle cars increased from 14 to 62 percent; duckbills or other self-loading conveyors decreased from 8 to 2 percent; hand-loaded conveyors decreased from 17 to 6 percent; and continuousmining machines started in 1948 and handled 7 percent of the total mechanically loaded output in 1954. (See tables 33 and 34.)

In tables 35 and 36 certain data on mechanical loading have been arranged into three groups: (1) Continuous-mining machines, devices that mine and load the coal; (2) loading machines (mobile loading

Included in lignite total; not published to avoid disclosure of individual operations.
 Included in "Other States"; not published to avoid disclosure of individual operations.
 Includes lignite in California, Montana, North Dakota, South Dakota, and Texas.

machines, scrapers and duckbills, or other self-loading conveyors), devices that eliminate hand shoveling; and (3) hand-loaded conveyors, devices that greatly reduce the labor in hand shoveling. Most of the 17 mines listed as using continuous mining machines only, also used mobile loading machines in conjunction with the continuous mining machines. In 1954, 90 mobile loading machines were reported as used in this manner. All tonnage mined by continuous-mining machines was credited to this category, even though it may have been mined and dumped on the floor and loaded out with a mobile loading machine. Even though continuous-mining machines have been in use since 1948 and were used in 110 mines in 1954, no definite pattern in loading the coal as mined by continuous mining machines into transportation units has yet been established.

Sales of mechanical loading equipment declined in 1954 from 1953 in all items except continuous-mining machines. Shuttle-car and "mother" conveyor sales also dropped in 1954 from 1953; however, face and bridge conveyor sales increased substantially. (See tables

38-40.)

MECHANICAL CLEANING

Although mechanical cleaning of bituminous coal in the United States started about 1875, complete data begin with 1927, when 28 million tons-5 percent of the total output-was cleaned. The percentage of total production mechanically cleaned has increased each year from the previous year, except in 1945, when it remained the same. In 1954 coal mechanically cleaned composed 59 percent of the total production. The refuse handled at cleaning plants increased from 3 million tons (9 percent of the raw coal that entered the cleaning plants) in 1929 to 54 million tons (19 percent of the raw coal cleaned) This increase in refuse was due to many factors, but the main one was increased mechanization, both in underground loading and strip mining. (See tables 41 and 42.)

¹ Data not available.

¹ Includes "Bridge" conveyors and all other conveyors 10 to 100 feet long. ² Includes all haulage conveyors with capacity over 500 feet, except main-slope conveyors.

Mechanical cleaning refers to cleaning with mechanical devices that effect the separation of impurities from raw coal usually by differences in specific gravity and does not include coal that is screened only. These mechanical devices are divided into two general classes—wet and pneumatic. About 95 percent of the coal cleaned in 1954 was cleaned by various wet methods. Approximately half of all the bituminous coal cleaned in the United States is cleaned with jigs. (See table 43.) A detailed description of the various types of mechanical cleaning equipment is given in Minerals Yearbook, volume II, Fuels, 1953, pp. 94-96.

In recent years the movement of raw coal to cleaning plants has become so complicated that it is almost impossible to determine the total production of the mines that move coal to cleaning plants. new table is included in this chapter to replace the various tables in previous chapters that showed the total production at mines served by cleaning plants. In this new arrangement the coal cleaned was tabulated by types of mining under the State from which the coal was (See tables 44 and 45.) The cleaning plant has been credited to the State from which the major portion of the coal was mined.

1 All items except "Grand total production" exclude lignite and semianthracite, 1940-49. Data for 1940-45 include mines with an average daily production of 66 tons and all mines with rail or friver commeditor segardless of size. Data for 1946-54 include all mines producing 1,000 tons and over. The figures are reasonably comparable for all years.

* Because of some mines using more than 1 nothod of freatment, this total is not the findividual items.

Included in lignite total; not published to avoid disclosure of individual operations.
 Includes lignite in California, Montana, North Dakota, South Dakota, and Texas.

PRODUCTION BY STATES AND ICOUNTIES

Detailed production and employment statistics are given in table 50 for each coal-producing county in the United States from which three or more operators submitted reports for 1954. Statistics on counties with less than three reporting producers have been combined with data for other counties in the same State to avoid disclosure of individual figures, unless the operators have granted permission to publish them separately. The production of mines on the border between two States has been credited to the State from which the coal was extracted rather than to that in which the tipple was situated. If the coal was mined from lands in both States, the tonnage was apportioned accordingly.

Bituminous coal and lignite were mined in 27 States and Alaska and 348 counties in 1954. Since soft coal accounts for a very large percentage of the economic activity in many counties, the key items pertaining to the industry are published by counties. These key items—(1) method of shipping the coal, (2) value, (3) number of men working daily, (4) days worked, and (5) tons per man per day—are

very helpful in analyzing potential markets by counties.

The most striking thing about the following table is the wide variations among the several counties in the same State; not only production, but even average value and average tons per man per day, varied sharply. The differences in average value are due to quality of coal, method of transportation, or market conditions. The differences in output per man per day are caused largely by physical conditions, mining methods, and extent of mechanization.

TABLE 50.—Production, value, men working daily, days active, man-days, and output per man per day at bituminous-coal and lignite mines in the United States, 1954, by States and counties

	s or river barges y conveyor belts as at mines.	, hauled by true or trams, used	cks to railroad by mine emp	sidings, and h loyees, taken b	auled by t	rucks to wat we tenders a	srways. t tipples,	used at mines	or power
⁸ Value received or charged for coal f. o. b. mines. Includes a value for coal not sold but used by producers, such as mine fuel and coal coked, as estimated by producers at	ides a value for	coal not sold by	at used by pro	ducers, such a	s mine firel	and coal co	red. as es	timated by pro	ducers a

average prices that might have been received if such coal had been sold commercially.

In certain counties the average tons per man per day is large due to auger mining, strip mining, or mechanical loading underground.

Included in "Other counties"; not published to avoid disclosure of individual operations.

Included in lignite total; not published to avoid disclosure of individual operations.

Includes lignite in California, Montana, North Dakota, South Dakota, and Texas.

TRANSPORTATION

Within recent years the methods of shipping bituminous coal and lignite from the mines have changed radically; shipments by rail have been declining, while shipments by water and by truck have been increasing. The percentages of the total shipped by each of the latter have more than doubled in the past 20 years. A detailed analysis of the historical trends in coal transportation is given in Minerals Yearbook, volume II, 1953 (pp. 127-133).

Detailed statistics on shipments of soft coal, by individual railroads and rivers, are shown in table 52. The data include coal shipped by rail, water, and trucks and used at mines, as reported by mine operators.

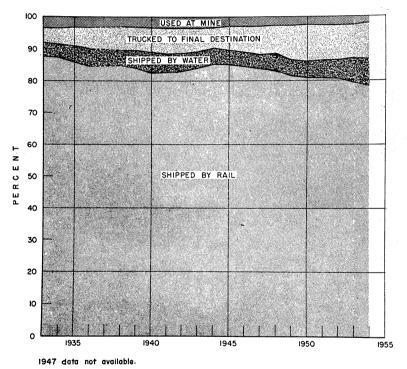

FIGURE 12.—Percentage of total production of bituminous coal and lignite 1933-54, by method of shipment from mines and used at mines.

¹ Includes coal used by mine employees, taken by locomotive tenders at tipple, used at mine for power and heat, transported from mine to point of use by conveyor or tram, made into beehive coke at mine, and all other uses at mine.

CONSUMPTION

The statistics on consumption of bituminous coal and lignite, by major consumer classes, for 1933-54, as shown in table 53, are based upon complete coverage of all consumers in each class with the exception of "Other industrials" and "Retail deliveries." The figures for each of these 2 categories are based upon a monthly sample approximating 35-percent coverage. In each instance a benchmark was established in 1943, based upon 95-percent coverage. Since 1943 data for each month have been determined by matching identicals for the last 2 months, calculating the percentage change of these identicals

for the last month from the month previous, and applying this percentage change to the published figure for the month previous. The results obtained by this procedure have been reasonably reliable over a period of years. As indicated in footnote 7 of table 53, the total of classes shown approximates total consumption and is a much more reliable figure than "calculated" consumption based on production, imports, exports, and changes in stocks, because certain significant items of stocks are not included in year-end stocks.

There have been a number of major changes in the consumption of bituminous coal and lignite during the past 20 years. From a depression level of slightly over 315 million tons in 1933, consumption expanded to a war level of almost 600 million tons in 1943. consumption of soft coal has been generally downward, reaching 363 An analysis of the different consumer classes million tons in 1954. reveals wide variations in trends. Since the close of World War II consumption by electric power utilities has doubled, coke plants and cement mills have remained steady consumers, and railroads in 1954 used only 14 percent of their wartime level. Diesel-electric locomotives have rapidly replaced coal-burning steam locomotives. Present experiments on coal-gas turbine locomotives are underway in an effort to recover the lost railroad market for coal. consumer classes all declined in coal consumed since World War II. including retail deliveries.

¹ Federal Power Commission. Represents latest available revised figures for bituminous coal and lignite

Federal Power Commission. Represents latest available revised figures for bituminous coal and lignite consumed by public-utility power plants in power generation, including a small quantity of coke.
 Bureau of Census, U. S. Department of Commerce.
 Association of American Railroads. Represents consumption of bituminous coal and lignite by class I railways for all uses, including locomotive, powerhouse, shop, and station fuel. The Interstate Commerce Commission reports that in 1954 consumption for all uses by class I line-haul railways, plus purchases for class II and class III railways, plus purchases by all switching terminal companies was 17,337,755 tons of bituminous coal and lignite.
 Includes a small amount of anthracite.
 Estimates based upon reports collected from a selected list of representative manufacturing plants.

⁴ Includes a small amount of anthracite.

⁵ Estimates based upon reports collected from a selected list of representative manufacturing plants.

⁶ Estimates based upon reports collected from a selected list of representative retailers. Includes some coal shipped by trucks from mines to final destination.

⁷ The total of classes shown approximates total consumption. It is not possible to calculate consumption closely from production, imports, exports, and changes in stocks because certain significant items of stocks are not included in year-end stocks. These items are: Stocks on Lake and Tidewater docks, stocks at other intermediate storage piles between mines and consumers, and coal in transit.

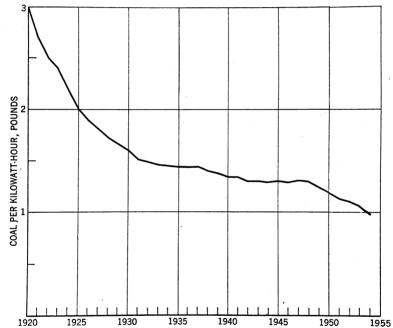

FIGURE 14.—Trend in fuel economy at electric-utility power plants in the United States, 1920-54.

RELATIVE RATE OF GROWTH OF MINERAL FUELS & WATERPOWER

In the past year industry representatives and other Government agencies have requested the Bureau of Mines to compile data on the calculated consumption of mineral energy for the continental United States and also to revise the existing energy tables published by the Bureau of Mines.

After a complete analysis of these data, it was deemed advisable to include certain items previously omitted, such as net imports of hydroelectric and net imports or net exports of the balance of petro-

leum products. The calculated consumption of energy without these data would be incomplete. In this publication these revisions have been made and these data will supersede energy tables released in the

past.

The principal changes in the production data were in the marketed production of natural gas. (See table 55.) Beginning with 1947, statistics on the marketed production of natural gas were reported on a new basis, which included the net volume stored and lost in transmission. The marketed production of natural gas was revised from 1929 through 1946 to include this estimated amount stored and lost in transmission. The revised data were published in the Minerals Yearbook in 1949. For the figures on marketed production of natural gas to be comparable for all years, further estimates on the same basis were made to 1920.

Natural-gas liquids extracted from gas used for repressuring and waste are included in the marketed production; however, no account of these liquids was considered in using 1,075 B. t. u. per cubic foot, as this factor is used for natural gas at the wellhead. Comprehensive data on compiling these energy tables were published in Weekly Coal Report 2020. The revision in the calculated consumption of natural gas in these tables results in adding to the calculated demand (loss in transmission) shown in table 8 of this report. This revision was made so that the consumption data are more reasonably correct, as gas lost in transmission and unaccounted for is an essential item to get the gas to the point of consumption.

The data on production and calculated consumption are expressed in British thermal units, because some common denominator is necessary for such unlike quantities as tons of coal, barrels of oil, and cubic feet of gas. Tables 56 and 58 summarize the equivalent of each of the fuels in trillion British thermal units. Waterpower is represented by the equivalent fuel required to perform the same work.

In converting waterpower to its equivalent of fuel required to perform the same work, the *prevailing* or average performance of all fuel-burning central electric stations for each year in question has been used. This average has declined from about 6.85 pounds of coal per kilowatt-hour in 1900 to 0.99 in 1954, which shows the influence of improved fuel efficiency.

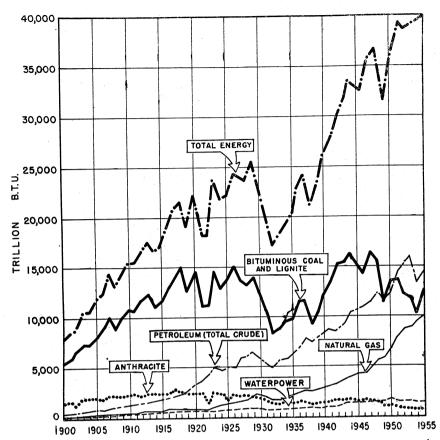

Figure 15.—Production of mineral-energy fuels and energy from waterpower in continental United States, 1900-55.

The subject of interfuel competition is exceedingly complex, and an elaborate analysis and accumulation of data not now available would be required to determine even approximately how much of any one fuel actually has been displaced either by other fuels or by waterpower. The present tables do not permit determination of such displacement, as their purpose is rather to measure the long-time trends in the total United States production and calculated consumption of energy in the continental United States.

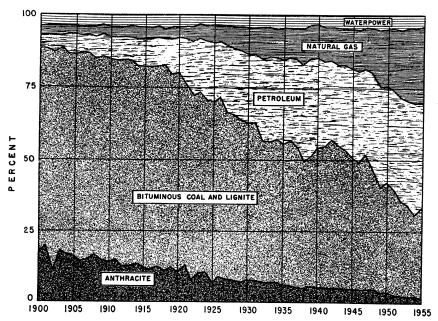

FIGURE 16.—Percentage of total production of British thermal units equivalent of mineral-energy fuels and energy from waterpower in continental United States, 1900-55.

Thousand net tons.
 Thousand barrels. Crude petroleum and commingled condensate.
 Million cubic feet. Total production minus repressuring, vent and waste.
 Million kilowatt-hours. The years 1920 to 1942, inclusive, represent the fuel equivalent of waterpower converted to kilowatt-hours at the prevailing rate of pounds of coal per kilowatt-hour at central electric stations. The years since 1942 represent production of electricity by waterpower at electric utility and industrial plants, as published by the Federal Power Commission.

1 The unit heat values employed are: Anthracite, 12,700 B. t. u. per pound; bituminous coal and lignite, 13,100 B. t. u. per pound; petroleum, 5,800 B. t. u. per barrel; natural gas, total productionX1,075 B. t. u. minus repressuring vent and waste gasX1,035. Waterpower includes installations owned by manufacturing plants and mines, as well as Government and privately owned public utilities. The finel equivalent of waterpower is calculated from the kilowatt-hours of power produced wherever available, as it is true of all publicutility plants since 1919. Otherwise, the finel equivalent is calculated from the reported horsepower of installed water wheels, assuming a capacity factor of 20 percent for factories and mines and 40 percent for public utilities.

¹ Data on consumption calculated from production minus exports plus imports, which includes shipments to noncontiguous Territories, and change in stocks. Except bituminous coal and lignite for 1933 to date, these data represent actual consumption, including a small amount of coal consumed in noncontiguous Territories.
2 Thousand net tons.
3 Thousand barrels.
4 Million cubic feet.
3 Revised.
6 Million gallons.
7 Million killowatt-hours; source, Federal Power Commission, except production for 1920–42. For these years the fuel equivalent of waterpower, converted to killowatt-hours at the prevailing rate of pounds of coal per killowatt-hour at central electric stations.

1 The heat values employed, which applied to data in table 57 are: Anthracite, 12,700 B. t. u. per pound; bituminous coal and lignite, 13,100 B. t. u. per pound; crude oil, 5,800,000 B. t. u. per barrel; weighted average British thermal units on petroleum products by using 5,248,000 gasoline, 5,670,000 kerosine, 5,825,000 distillate, 6,287,000 residual, 6,004,800 inbricants, 5,537,280 wax, 6,636,000 asphalt, and 5,796,000 miscellaneous; natural gas dry, 1,035 B. t. u. per cubic foot; natural-gas liquids weighted average British thermal units based on production; natural gasoline 110,000 B. t. u. per gallon, and LP-gas 95,500 B. t. u. per gallon. Waterpower converted to coal equivalent at the prevailing rate of PRevised.

STOCKS

Stocks of bituminous coal and lignite in the hands of industrial consumers and in retail yards in 1945–54 are shown graphically in figure 2; the wide variations from month to month are caused almost entirely by prolonged strikes. Detailed figures on tonnage of stocks and on days' supply are shown in table 59. All these figures on stocks are based on complete coverage except "Other industrials" and "Retail yards." Stocks for these two categories are based on samples, and the statistical procedure followed is the same as for calculating total consumption, as described above.

TABLE 59.—Stocks of bituminous coal and lignite in hands of commercial consumers and in retail dealers' yards in the United States, 1953-54

	Total	Days' supply at current rate of consumption on date of stocktaking

PRICES

A detailed analysis of the trend in coal prices is given in the Minerals Yearbook, volume II, 1953 (pp. 143-44). The average value of bituminous coal and lignite, f. o. b. mines, declined sharply—8 percent—in 1954 from 1953.

The producers were asked, for the first time, to report the production and total value, f. o. b. mine, of coal "sold in the open market" and "not sold in the open market" in 1954. These figures are shown, by States, in table 61. Almost one-fifth of the bituminous coal and lignite in 1954 was "not sold in the open market," and the average value of this coal was \$1.55 per ton greater than the average value of the coal "sold in the open market."

Included in lignite total; not published to avoid disclosure of individual operations.
 Included in "Other States"; not published to avoid disclosure of individual operations.
 Includes lignite in California, Montana, North Dakota, South Dakota, and Texas.
 Includes Montana (bituminous) and New Mexico.

published to avoid disclosure of individual operations. Includes lightle in California, Montana, North Dakota, South Dakota, and Texas.

Includes coal loaded at mines directly into railroad cars and hauled by trucks to railroad siding.
Includes coal used by mine employees, taken by locomotive tenders at tipple, used at mines for power and heat, made into briquets, and other uses.

FOREIGN TRADE 6

Imports of bituminous coal and lignite are very small, although exports have been an important item of foreign trade for many years, particularly since the close of World War II. A detailed analysis of exports and imports of bituminous coal and lignite is shown in Minerals Yearbook, volume II, 1953 (pp. 146–150).

Revised figure.
 Includes 33,650 tons in 1953 and 69,970 tons in 1954, representing estimated data for which district breakdown not available.

WORLD PRODUCTION

World production of anthracite and bituminous coal amounted to 1,635 million net tons in 1954 and lignite to 517 million tons, a total of 2,152 million tons. The total coal output in 1954 (including lignite), was 7 million tons less than in 1953. Of the total world coal output, 71 percent was produced in 4 countries—the United States, Russia, Germany, and United Kingdom. The United States supplied 420 million tons of bituminous coal, anthracite, and lignite, or 20 percent of the world output, in 1954.

Most coal-producing countries in Europe enjoyed slightly increased production during 1954; however, consumption requirements of the principal coal-producing countries on the European Continent exceeded available supplies. Production from the United States made up a large part of the deficit.

¹ This table incorporates a number of revisions of data published in previous Coal chapters.

Estimate.
 The production total of bituminous, anthracite, and lignite for 1954 will be compared with the Bureau of the Census total for this commodity. Differences in the totals will be adjusted or explained.
 Includes the following quantities, in thousand short tons, produced in U. S. S. R.-controlled mines: 1850, 296; 1951, 274; 1952, 279; 1953, 280; and 1954, 220 (estimated).
 Negligible.
 Year ended March 20 of year following that stated.
 Output from U. S. S. R. in Asia included with U. S. S. R. in Europe.

COAL TECHNOLOGY 7

Exploration, Geology, and Reserves.—During the year, the Federal Geological Survey was particularly active in its exploration, reserves, and coal-geology studies.8 Detailed reports were published describing the geology and coal deposits in certain coal areas in Indiana, Colorado, Wyoming, North Dakota, Kentucky, New Mexico, and Utah. The Federal Geological Survey has also published estimated coal reserves by beds and counties in categories of thickness and suitability for strip mining, which summarize the reserves of Indiana and certain coalbearing areas in Montana, North Dakota, and Alaska.

The Bureau of Mines continued its study of coking-coal estimates and published reports covering 2 counties each in Kentucky and West Virginia and 1 in Tennessee. The latter report includes preparation and carbonization studies, in addition to estimates of reserves.

The Ohio State Geological Survey has conducted coal reserve

studies on the Lower Kittanning No. 5 bed in Ohio.9

Constitution, Petrography, Properties, and Analysis.—Coal technologists in State, Federal, and educational institutions in this country and abroad were particularly active in investigating the constitution and fundamental properties of coals. During the year, a comprehensive publication by Francis 10 discussed coal, its properties and

constitution. The same writer 11 also proposed a new coal-classification system based on values of elementary analysis of humins and

chemical composition.

At Pennsylvania State University work has been in progress on the constitution of coal, the properties of coal ash with reference to fusibility, and X-ray and infrared studies of coals, products, and related substances. Data on the chemical structure of coal and the changes occurring with progressive carbonization were reported by van Krevelen.12

X-ray studies were made by numerous workers on vitrain coals. Orchin 18 indicates that basic structural units of coals are similar, although a wide variety of molecular-weight fragments exist. Differences in physical and chemical properties are explained by variations in the hydrogen bonding between the basic units that constitute the

Further progress was made in coal-constitution studies by extractive methods that avoid permanent destruction of coal substances when they are examined by pyrolytic methods. Extracts from a wide variety of coking and noncoking coals were examined by infrared spectrometer,14 and extracts of European bituminous coals 15 were appraised by several methods.

The conventional approach to coal constitutive properties by the thermal and distillation methods has shown that it is possible to recognize distinct thermal-curve types by correlation with the physical, chemical, and structural changes in the coal.16 The nature of the residual volatile matter contained in coked coal was reported by

British investigators.17

The Bureau of Mines tested the application of reflectivity techniques to petrographic analysis. Results showed a difference between those samples prepared from briquetted granules and from fractions

isolated from a single piece.

The International Standards Organization and the Bureau of Mines cooperated in continuing efforts to establish an international coalclassification system. Samples of lignites and brown coals were exchanged between a number of European countries and the United States for parallel analyses as an aid in developing an international coal-classification system for high-moisture, low-rank coals. pendently, British workers also made substantial contributions. résumé of the progress and the latest conclusions were published.18

The coal-research laboratories of the Illinois State Geological Survey established the relationship between oxidation and the coking property of an Illinois coal. Other investigations established the relationship

between the ultimate composition of coal and low-temperature oxidation at 100° C. in both open and sealed apparatus. Netherland investigators considered a se ies of fundamental basic properties of coals and thus far has reported on seven.

Interest in the feasibility of recovering germanium from coals continued. The Bureau of Mines ¹⁹ cooperated with the United States Army Signal Corps in evaluating industrial coals as a potential source

of germanium.

The Bureau of Mines and the Federal Geological Survey 20 cooperated with the Atomic Energy Commission in studying the extent and quality of the uraniferous lignites found in North and South Dakota. particularly those in Harding County, S. Dak.

Research in this country and abroad is being carried out to develop better methods for analyzing and testing coals. A critical study of the factors affecting coal calorimetry was made by English investigators.²¹

The accuracy of coal-sampling apparatus 2: 23 and the magnitude and type of errors occurring in preparing samples for coal analysis 24 25 were investigated by British and French technologists.

Underground Mining.—During 1954 considerable progress was made in reducing the production cost of raw coal by increased mechanization

and improvements in mining methods.

Continuous mining machines, which cut and remove coal from the bed without drilling and blasting, were more widely adopted. It has been estimated that, at the close of 1954, over 320 continuous-mining machines of all types were either sold or already in underground operation. These accounted for 6 percent of total underground output—a 38-percent increase over 1953.

New types of continuous miners were also presented to the industry. One of these is the "Wilcox miner," 26 which is designed to operate in 24- to 40-inch beds. The Dosco miner, 27 developed by the Dominion Coal Co. of Canada, produces coal at a high rate under severe mining conditions (steeply pitching beds). The Haarman scraper-peeler, another mechanical miner, is a recent European development. An adaptation of the scraper boxes used for loading coals in thin beds, it features improved overall safety aspects.

The American coal industry has shown strong interest in the German coal planer (plow) operating on a modified longwall face. The advantages of mechanical longwall mining over conventional mining methods are definitely appealing.

The use of air and chemical coal-breaking techniques has increased. Demonstrated late in 1953 and during 1954, chemical coal-breaking agents provide improved roof control, promoted greater safety, and increased production. Preparation-plant tests also demonstrated a definite increase in the yield of plus-6-inch lump. Known as Chemechol,29 30 electrical heat energy of about 7 seconds' duration is used to initiate a gas pressure-producing chemical reaction, which decomposes ammonium nitrate to inert gaseous compounds.

Effective reductions in total mine costs per ton were obtained by a broader application of the extensible belt conveyor, which can carry coal as far as 1,000 feet from the advancing miner, collecting and

discharging the broken coal at a fixed point.

The control of roof falls in American underground mining is still an important problem. In roof bolting, the relationship between the torque applied to the bolt and the corresponding bolt load was established. It was shown that an indicating torque wrench is accurate enough for most general practices.

Floating-platform boring for proving undersea coal reserves has been proposed. This speculative proposal is of interest, because of current successful offshore petroleum-drilling operations now in this

country.31

Although draglines continued to be favored, the application of larger capacity stripping shovels, combined with matched loading and haulage units, permitted some operators to eliminate draglines and reduce costs.

Costs of stripping by shovels and draglines were reduced by operators who employed a positive preventative maintenance program, rotated spare dragline buckets regularly, placed hard surfacing materials on wear points, and systematically changed bucket teeth.

With the large reserves of thin-cover stripping coal being rapidly used up, many large producers are confronted with the problem of handling cover that, in some instances, exceeds 80 feet. This has led to an intensive search for a stripping unit amenable to mining under these difficult conditions. As a result of this study, the stripping wheel has been developed and tested. This wheel, potentially a very significant development in mechanized mining of coal, has high capacity and can move spoil much farther than conventional shovels and smaller dragline equipment. The stripping wheel was reported to have over three times the capacity of comparable draglines or shovels.32

Considerable attention has been given to the use of ammonium nitrate as an open-pit or strip-coal mine explosive when mixed with

other constituents and used in plastic bags.

Preparation.-More critical and exacting consumer needs caused coal producers to modernize and improve their facilities, particularly in fine-coal cleaning equipment, with improved dewatering, filtering, and drying techniques.

In 1954 the Bureau of Mines station at Seattle, Wash., studied the fundamentals of particle-size behavior in heavy-medium suspensions. Performance of the heavy-medium processes, related to the density of separation, and an appraisal of coal-washing results were presented at the Second International Coal-Preparation Congress in Essen,

Germany, in September 1954.33

With increased mechanization in the coal-mining industry, the percentage of fine sizes in the coal as mined has increased, thereby accentuating the problem of coal preparation. In continuing its study of froth flotation, the Bureau of Mines investigated the relative efficiencies of vacuum and mechanical laboratory froth-flotation cells.34 It was found that the mechanical flotation cell is more efficient than the vacuum flotation cell. A study of froth flotation for cleaning fine coal, from the standpoint of a rate process, was made by English investigators.35

Additional coal-preparation studies were carried out in Europe Published test data 36 showed that the use of coal during 1954. cleaned by flotation methods resulted in coke having good mechanical properties and low phosphorus content for blast-furnace use. British investigators 37 reported possible improvements in the techniques of coal separation and washing, particularly by applying chemical

engineering practices.

Transportation.—A significant development in coal transportation was successfully carried through the pilot plant stage by the Pittsburgh Consolidation Coal Co. - hydraulic transportation by pipeline. Plans to construct a commercial pipeline were announced in October When completed, it will transport 3,600 tons of coal per day from its preparation plant at Georgetown, Ohio, to an electric-powergenerating plant at Eastlake, Ohio—a distance of 108 miles. Much original development and testing of suitable types of primary and booster pumps, materials of construction for pipelines, and problems of corrosion associated with this work were necessary.

The Bureau of Mines at Denver, Colo., in cooperation with the Texas Power & Light Co., investigated the feasibility of hydraulic transportation of a Texas lignite and a Colorado bituminous coal on a small pilot-plant scale. At Rockdale, Tex., the transportation within the plant, of minus ¼-inch natural and dried lignite using

pneumatic methods, has also been demonstrated.38

Storage of Coal.—Storage of higher rank coal seldom presents any particularly difficult problems; however, the lower rank coals, such as the subbituminous coals and lignites, are susceptible to autooxidation and spontaneous heating when not properly stored. A report published by the Bureau in 1954 39 reviews the subject in

Internat. Coal-Preparation Cong., Essen, Germany, September 20-25, 1954.

general and specifically describes the ultimate storage of 4 to 6 million tons of lignite excavated from the Garrison Dam site in North Dakota, where the Bureau of Mines cooperated with the Army

Corps of Engineers in studying storage problems.

Briquetting.—The briquetting of bituminous coal and lignite in the United States has declined in recent years. Current developments in North American coal-briquetting procedures and descriptions of a wide variety of applications have been reported in the Proceedings of the Third International Briquetting Conference 40 at Banff, Alberta, Canada, in the fall of 1953. The pelletizing of thermally pretreated lignite is of considerable interest. Investigations were carried out with varied binders to determine the effect of particle size and size distribution in achieving satisfactory agglomeration with a minimum of binder consumption.

Utilization.—Burning as Fuel. Fossil fuels abound in the United States—the largest per capita consumer of energy in the world. Notwithstanding their apparent abundance, the lavish use of power and energy is beginning to accent noticeably the depletion of certain

reserves.41 42

The growing activity in nuclear power generation has commanded increased attention from both fossil-fuel technologists 43 and fuel producers.44 The Atomic Energy Commission has estimated that, by 1975, 2 to 10 percent of the total electric energy production will be supplied from atomic sources.45 The tremendous potential of this source of energy is illustrated by the study of the radioactive excitation of carbon reputedly undertaken as a research project by the Fairchild Engine & Aeroplane Corp. 46 The cost of a nuclear power station compared to a coal-steam station of equal output, however, has been estimated to be approximately three times as great.47 This is an obvious deterrent, except where cost is not a limiting condition. It is expected that ultimate use of nuclear power generation is inevitable, but it is also anticipated that its growth will be spread over a period of years. Complacency should not exist in the field of fossil-fuel technology, because production of liquid and gaseous fuels and coal chemicals ultimately will have to substitute for natural liquid and gaseous fuels. This emphasizes the immediate necessity for a strong and continuing program of coal technological research.

The forecasts for future energy production by experts in the field and including those reported by the Paley Commission in 1952 (vol. 1, p. 120) indicate that a steady growth of electric power production is to be expected, with increase at the rate of about 6 percent a year for approximately the next 25 years. Even with the assistance from nuclear-energy electric power production, this increase will have to be met largely by coal. An overall survey of the developments in power and fuel utilization for 1954 was given in the Proceedings of the

American Power Conference.48

Several major utilities are examining the possibility of increasing thermal efficiency by operating furnaces at supercritical pressures.

A comprehensive study of the development of the cyclone burner was made by a British investigator. 49 This traces the development from the early vortex furnaces of 30 years ago to the modern Babcock & Wilcox slagging cyclone furnace. All phases of the performance, operating conditions, power requirements, position of installation, etc., were considered. Developments in the cyclone furnace and boiler

design were also reviewed by Kessler.⁵⁰

A paper by engineers of a major combusion-equipment manufacturer on progress and developments in spreader-stoker firing 51 reviewed the history of spreader-stoker firing and the development of a furnace and boiler design specifically adapted to the spreader-type stoker. New data on crossfeed firing, a method as yet little used in fuels combustion, was published by the Bureau of Mines.⁵² This gave hitherto unavailable data on a third acceptable method of fuel firing at ignition and burning rates with very high air rates that are far above those attainable with traditional grate-burning methods. The influence of coal size on combustion performance in underfeedstoker-fired boiler furnaces was also studied.53

Lignite is becoming increasingly popular in areas where it is the principal indigenous fuel for power generation. A number of plants have demonstrated that it may be prepared and burned by one of several methods, including pulverization. The fuel flexibility built into modern steam-generating units permits them to give creditable performance with fuels normally considered unsuitable by standards of past years. Studies conducted 54 at the Aurora Steam Electric Station of the Minnesota Power & Light Co. showed that it is not necessary to pulverize lignite finer than 70 percent through the 200mesh screen. The pulverized lignite had good flame stability as fired in the tangential type burners. A dual purpose application of lignite for both power generation and crude coal-chemicals production has been demonstrated by Bureau of Mines engineers and industry. 55

Performance tests were carried out in 1954 on a new high-pressure steam-turbine locomotive. The results were reported in papers presented at the 1954 Annual Meeting of the American Society of Mechanical Engineers.⁵⁶ The progress, during 1954, of research on the coal-burning gas turbine for locomotive use, in which coal-supply studies and ash-separator developments, among others, have been

considered, was also reported.⁵⁷

Though incidental to the thermal energy releasing process, the importance of the reactions of coal minerals during combustion was studied.58 The paper considered the temperatures developed in combustion systems and the primary and secondary reactions through

which coal minerals may go at elevated temperatures.

Carbonization.—A review of current coal-carbonization techniques indicates a steady trend of improvement and several well-defined advances in the industry during the past year. Because of the time required for most normal byproduct-coking operations, efforts were made to develop "rapid" carbonization processes. Fundamental studies in this field were made by British investigators. 59 A continuous-carbonization process was reported, using a traveling grate. 60 Classed as an "autogenetic" coking process, it employs restricted air admission to a horizontal layer of coal, moving on an ordinary traveling-grate stoker within a closed furnace. The process is said to transform coal to coke at 15 to 30 times the rate in conventional slot-type ovens, thus presenting low-cost possibilities. The process also appears to be amenable to a variety of coal ranks, both coking and noncoking, and can be used for producing lump chars.61

Bureau of Mines interest in developing new carbonization techniques has continued. A pilot-scale slot-type oven was developed

and tested.

At Gorgas, Ala., the Bureau of Mines, in cooperation with the Alabama Power Co., successfully initiated underground gasification of coal in place, using an electrocarbonization technique for initial opening of gasification passages through the coal beds.62 An investigation of a similar type was carried out independently at Hume, Mo. by the Hume-Sinclair Coal Co. in cooperation with the University of Missouri School of Mines and Metallurgy.63

In England, factors in coke formation were evaluated in a compre-

hensive report dealing with the problem of coking.64

Various types of modern coke ovens built under 14 principal designs were classified into a single simplified system, considering such basic features as coking chamber, method of firing, etc. ⁶⁵ Fuel technologists at Battelle Institute reviewed the progress of carbonization research with regard to the availability, treatment, and properties of coking coals and coke oven and carbonization methods.66

Gasification.—Coal gasification is of interest to many, since the estimated peak production of natural gas, in the order of 12 trillion cubic feet per year is expected to be reached by about 1960.

that time, due to the rapidly increasing population rate, production of both manufactured and natural gas may be entirely inadequate. Since coal offers the largest known resource of fossil fuel, complete conversion of coal to gas would insure a virtually unlimited supply for the foreseeable future.

The Bureau of Mines has actively continued its investigations to develop acceptable substitutes for natural gas by various methods. At the Appalachian Experiment Station, Morgantown, W. Va., the possibility of producing a high-B. t. u. gas from coal as an alternative source of pipeline fuel and the variables connected with gasification of

pulverized anthracite with oxygen and steam were studied.

Studies of the gasification of lignite in externally heated retorts were continued at the Lignite Experiment Station, Grand Forks, N. Dak. At the synthetic fuels demonstration plant formerly operated at Louisiana, Mo., data were obtained from the Koppers horizontal and a vertical slagging gasifier, operating at atmospheric pressure with An operational analysis of the units was also oxygen and steam. reported.67 British workers supplied new viewpoints on the complete gasification of coal in their papers which appeared during 1954.68 69 70 The last article in this group presents a review and discussion of past and present methods in use in Great Britain.

Synthetic Liquid Fuels.—Synthetic liquid fuels may be produced by either of two methods: (1) By direct hydrogenation of coal or (2) by using gas-synthesis procedures. The Bureau of Mines is continuing its synthetic fuel investigations of both methods in its Bruceton, Pa., and Morgantown, W. Va., laboratories. An improved, single-step coal-hydrogenation process for direct conversion to gasoline was investigated in a pilot plant. Differing from conventional hydrogenation processes, the liquid- and vapor-phase stages are combined in one unit that operates at 500° C., with a large quantity of catalyst.

Conventional gas-synthesis procedures for liquid fuels have long been studied by the Bureau of Mines. Catalyst studies and heattransfer problems in this connection are perhaps the most important and necessary single factors in conventional gas-synthesis procedures to produce liquid fuels. Iron catalysts were shown to be particularly effective in demonstration tests on a commercial-plant scale.71

By employing other variations in the Fischer-Tropsch gas-synthesis techniques and using specially treated fine iron catalysts, it was found possible to produce high yields (up to 80 percent) of products of the oxygen-rich (alcohol) variety.⁷² Normal ethyl predominated, but quantities of methyl and higher alcohols were obtained.

The new South African commercial-scale project for producing synthetic liquid fuels and chemicals was announced,73 as was British progress on the synthesis, chemistry of synthesis catalysts, and

3 Chlesinger, M. D., Benson, H. E., Murphy, E. M., and Storch, H. H. Chemicals From the Fischer-Tropsch Synthesis: Ind. Eng. Chem., vol. 46, No. 6, June 1954, pp. 1323-1326.

structure of fuel oils.74 Indian workers, reporting in British journals,75 determined equilibrium reaction rates on catalyst surfaces, the effects of feed-gas composition and space velocity, the reduction of catalyst on utilization ratio, and the nature of the oil products. Variables that affect performance of the Fischer-Tropsch synthesis, particularly the effects of diluents in the synthesis gas, were discussed by British workers.76

Chemical and Miscellaneous Uses.—Continued interest in coal-tochemicals production is encouraging and indicative of possible future wider scale use of coal. The production of much-needed aromatics from coal and coal tars is logical from theoretical considerations Since it has been established that coal has an aromatic structure, it will produce by thermal or extractive treatment, many aromatics that cannot be obtained from petroleum sources, except by extensive and circuitous processing.

The growing use of synthetic fibers of the orlon type has led to a sharp increase in demand for acetylene, used in synthesizing acryloni-The Sachse process, in which hydrocarbons such as coal and coal-tar hydrocarbon gases are partly oxidized to produce acetylene,

has been proposed to supply this demand.

Potentially, large quantities of coal tar may be produced by low-temperature carbonization of low-rank coals. Wide-scale carbonization of these coals, however, will depend, by economic necessity, upon an integrated process from which maximum return is achieved from the tar. One such outlet for the tar may be the conversion to pitches and carbons for use in electro-metallurgical industries such as the electro reduction of aluminum.

Several major power companies investigated the possibility of using waste fly ash as a pozzolanic-type admixture with normal portland cements in concrete construction and extensive work on this also was carried out by the Bureau of Reclamation, United States Department of the Interior.77 Road building materials, using bituminous shales, were studied at Iowa State College where investigations of other waste In this same category of nonfuel use of coal materials are planned. coal products, the Sinclair Coal Company investigated the preparation of a light-weight construction aggregate from spent coal shale and the University of Kentucky investigated the recovery of elemental sulfur from pyritic coal wastes.

A new mixture of coal and coal tar pitch was developed for use as

foundry mold facing and core binder compounds.

Coal—Pennsylvania Anthracite

By J. A. Corgan, J. A. Vaughan, and Marian I. Cooke

GENERAL SUMMARY

TOTAL PRODUCTION of Pennsylvania anthracite in 1954 was 29.1 million tons, a 6-percent decline from 1953. As the small decrease in exports to Canada was more than compensated for by increased shipments to Western Europe, the net decline was attributable to losses in American markets to competitive fuels and to a

relatively low demand for heat.

Although it is impossible to calculate anthracite market losses in recent years on the basis of weather conditions alone because of such contributory factors as fuel prices at the consuming level, the volume of new construction, and sales of conversion and replacement equipment, two conclusions are apparent: (1) The demand for heat in a particular space is determined by the severity of weather conditions; and (2) as Pennsylvania anthracite is predominantly a space-heating fuel, at least part of the decline in the demand for anthracite is due to the fact that the winter of 1953–54 marked the sixth successive heating season in which above-normal temperatures prevailed in the major anthra-

cite-marketing areas.

Competition was intense at the producing level throughout 1954, with the result that the f. o. b. mine-price structure was marked by instability and, in some instances, wide departures from published price lists. Under these circumstances, retail fuel dealers were reluctant to build up yard stocks, apparently preferring to operate with a low inventory while waiting for attractive wholesale price quotations to develop. This action of some dealers also undoubtedly contributed to the unstable price situation. Consequently, the average value per net ton of total production fell from \$9.67 to \$8.52 (12 percent), and the total product value declined 17 percent. The difference in the percentages of decline for total value of product and value per ton was due to the fact that average prices for the Buckwheat No. 3 (Barley) and smaller sizes, which are normally used for industrial pruposes, were practically the same as in 1953, whereas average prices for the Buckwheat No. 2 (Rice) and larger sizes, which are higher priced and comprise the bulk of total production, were considerably lower.

During 1954 producing companies used several methods to reduce production costs. As in 1953, many operators curtailed or abandoned deep-mining operations at high-cost sites and placed greater emphasis upon obtaining a proportionately larger output from surface sources. Definite trends developed also, which indicated an expansion in the purchase of run-of-mine coal for preparation from lessees and small operators without preparation facilities. Special attention was also given to increasing the efficiency of mine labor through revised work schedules and the fuller use of mechanical equipment. These efforts were effective, as is evidenced by the fact that, although the average number of men employed declined 24 percent the productivity rate increased from 3.28 to 4.02 tons per man-day, the highest on record.

Mechanical loading increased in 1954 and composed 41 percent of the total coal loaded underground compared with 38 percent in 1953. The percentage of anthracite produced underground in 1954 remained the same as in 1953—58 percent of the total—while production at strip pits and culm banks also remained relatively the same, each being less than 1 percent under the 28 and 13 percent recorded, respectively, in 1953. The recovery of coal from rivers and creeks climbed from 1 percent of the total 1953 output to approximately 3

percent of total production in 1954.

Owing to the large output of strip- and culm-bank coal, the Schuyl-kill region again led in production, with 45 percent of the total, followed by the Wyoming region, with 41 percent, and the Lehigh, with 14 percent. When compared with similar data for 1953, these figures indicate no relative change for the Schuylkill region, a 3-percent increase in the Wyoming region, and an equivalent decrease in the Lehigh. On the basis of actual tonnage in the 2 years however, 1954 production in the Lehigh region was 23 percent less than in 1953, 6 percent less in the Schuylkill, and 2 percent greater in the Wyoming. The sharp decline in production and employment in the Lehigh region was due, aside from market conditions, to the fact that a major producing company closed all operations in the spring, idling approximately 4,300 men. In June, after the operating company had failed to reach an accord with the mine workers concerning working conditions, the company withdrew from all mining activities. Subsequently, 2 lessees reopened part of the mines, 1 in October and the other in December.

At the close of the year stocks held in retail yards were estimated by the Bureau of Mines to be 34 percent (770,000 tons) less than on December 31, 1953, and producer stocks, as reported by the Anthracite Committee, declined 33 percent (623,000 tons) for the same period.

It was evident that the total demand for anthracite in 1954 was considerably stronger than was indicated by the rate of production and that, had stocks not been drawn upon so heavily, it would have proved necessary to increase production more nearly in line with 1953 to satisfy all requirements. See tables 1, 2, and 3 for summary data on the Pennsylvania anthracite industry.

SCOPE OF REPORT

The data in this chapter were collected jointly by the Bureau of Mines, United States Department of the Interior, and the Bureau of the Census, United States Department of Commerce, for the Census Year 1954. The production total (29,083,477 net tons) will be compared with the Bureau of the Census total for this commodity when it is available. Differences in the totals will be explained by appropriate textual or tabular references in the Coal—Pennsylvania Anthra-

cite chapter of Minerals Yearbook, 1955.

The Pennsylvania anthracite deposits underlie a surface area of approximately 484 square miles in the northeastern part of the State. About 181 square miles is in the Southern field, 176 in the Northern, 94 in the Western Middle, and 33 in the Eastern Middle. The coal fields are also separated into regions: The Wyoming, which extends over the same area as the Northern field; the Lehigh, which is composed of the Eastern Middle field and that portion of the Southern field east of Tamaqua; and the Schuylkill, which includes that part of the Southern field west of Tamaqua, plus the entire Western Middle field. In 1954, although fresh-mined anthracite was produced in each region and field, only seven counties—Carbon, Columbia, Dauphin, Lackawanna, Luzerne, Northumberland, and Schuylkill—contributed to the total. Berks, Lancaster, Lebanon, Northampton, and Snyder Counties produced dredge coal only in 1954. A small quantity (16,374 tons) of semianthracite mined in Sullivan County is also included. Because of this diversity of source, most of the tabular data in this chapter are presented by regions, fields, and counties.

Pennsylvania anthracite is mined or recovered at underground mines, strip pits, culm banks, and dredges. However, as anthracite is marketed only as a cleaned and sized material, the production figures reflect only those tonnages of prepared coal obtained from companies operating breakers, washeries, and dredges. A large part of the raw material processed at breakers and washeries is obtained from contractors working strip pits and culm banks and from mines not affiliated with preparation plants; therefore, these two producer categories are also canvassed annually by mail to obtain production figures on run-of-mine coal for corroboration of data supplied by the preparation plant, geographic source of output, employment, and equipment. As dredging operations are not integrated with other producing segments of the industry, the dredge operators are requested to furnish complete data on their activities to the Bureau of Mines on

a separate canvass.

The primary objective of the annual canvasses of the Pennsylvania anthracite industry is to obtain accurate measurement of production. Thanks to the splendid cooperation of the producing companies, the final nonresponse rate seldom exceeds 1 or 2 percent of the total output. To insure accuracy all schedules received are first reviewed for completeness and arithmetical balance, after which schedules submitted by companies operating preparation plants are compared with reports filed by contractors, small mines, and affiliates to determine whether adequate data have been obtained on commercial production, source, and equipment. Inadequate reporting and discrepancies in reported data are resolved by correspondence or telephone. For the small part of production on which no reports are

received, the Bureau of Mines prepares estimates based on statistics released by the Anthracite Committee and the Pennsylvania Department of Mines.

For many years the Pennsylvania Department of Mines, the Anthracite Committee, the Anthracite Institute, the Association of American Railroads, the Commonwealth of Massachusetts, the Ore and Coal Exchange, and others have cooperated wholeheartedly with the statistical program of the Bureau of Mines. Free use of data released by these agencies has been made. Sincere thanks are extended to each for continued and cordial cooperation.

As the procedures employed in collecting and processing data on the distribution of Pennsylvania anthracite differ widely from those outlined for production, a short discussion of the methods used will be found in the Distribution section. The short, or net, ton of 2,000

pounds is used throughout this chapter.

PRODUCTION, MINING METHODS, AND EQUIPMENT 1

The total production of Pennsylvania anthracite from all sources, including underground mines, strip pits, culm banks, and dredges, was 29.1 million tons in 1954, a 6-percent decline from 1953. Also included is a small tonnage (16,374 tons) of semianthracite produced in the Bernice Basin of Sullivan County. Detailed data on production and shipments by type of preparation plant and by field, region, and county of origin are presented in tables 4 to 9. Tables 10 and 11 show data on shipments by sizes and regions, in percentage of total shipments. Shipments from the Lehigh, Schuylkill, and Wyoming regions for 1890–1954 are presented graphically in figure 1.

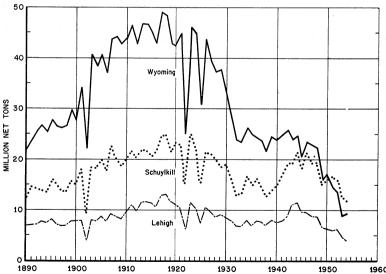

FIGURE 1.—Anthracite shipped from the Lehigh, Schuylkill, and Wyoming regions, 1890-1954.

¹ For a more detailed description of underground mining, strip-pit, culm-bank, and dredging operations the reader is referred to the Coal—Pennsylvania Anthracite chapter of Minerals Yearbook, 1953.

Quantity of Lump included is insignificant.

Underground Operations.—Because of the suspension of operations for some months at several large underground mines in the Lehigh region, the total underground production in 1954 was over 1 million tons less than in 1953. Of the 16.9 million tons produced underground in 1954, the Lehigh region contributed only 10 percent, compared with 16 percent in 1953. Conversely, the percentage contributed by the Wyoming region increased from 52 percent of the 1953 total to 56 percent and the Schuylkill from 32 percent to 34 percent. Quantitatively also, the loss in total underground output was due entirely to the decline of approximately 1.1 million tons in the Lehigh region, since an increase exceeding 100 thousand tons in the Wyoming region more than compensated for a decline of approximately 46 thousand in the Schuylkill.

Strip-Pit Coal.—On the basis of fresh-mined tonnage only, strip coal represented 42 percent of the 1954 production in the Schuylkill region, 48 percent in the Lehigh, and 19 percent in the Wyoming, compared with 46, 38, and 18, respectively, in 1953. The sharp increase in the percentages shown for the Lehigh region was due to the abrupt decline in regional output because of work disruptions at several major underground mines rather than because of any increase

² Less than 0.05 percent.

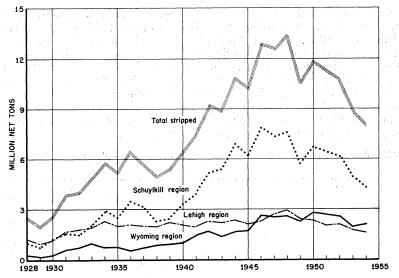

FIGURE 2.—Pennsylvania anthracite mined from strip pits, by regions, 1928-54.

in strip tonnage. In fact, the output of strip coal actually declined 171 thousand tons in the Lehigh region between 1953 and 1954. Of the 7.9 million tons produced at strip pits in 1954, 20 percent was produced in the Lehigh region, 27 percent in the Wyoming, and 53 percent in the Schuylkill, with the Wyoming the only one to show increased tonnage. Table 12 shows data on stripping operations for selected years in 1915–54 and figure 2 the trend of strip-pit production, by regions, for 1928–54.

¹ Data not available.

Culm-Bank Coal.—Production of Pennsylvania anthracite from culm and silt banks totaled 3.6 million tons in 1954, an 11 percent decline from 1953. The output of culm and silt banks represented 12 percent of the total production in 1954, compared with 13 percent in the preceding year. Of the total recovered from banks in 1954, 65 percent was obtained in the Schuylkill region, 22 percent in the Lehigh, and 13 percent in the Wyoming, reflecting a small tonnage increase in the Lehigh and rather sharp relative and absolute decreases in the other 2 regions. Details on the production of bank coal are shown, by regions and fields, in tables 13 and 14.

¹ A small quantity of culm-bank coal was put through breakers in Sullivan County.

Dredge Coal.—The production of dredge coal totaled about 726,000 tons in 1954, almost twice the output in 1953. The Susquehanna River and its tributaries provided almost all of the production, as only 16,000 tons was reported for the Lehigh River and none for the Schuylkill for the first time in many years. The abrupt increase in 1954 was attributable to the efforts of a large industrial consumer and producer to obtain a greater part of boiler-fuel requirements from lower cost sources. Increased production of river, or dredge, coal by this concern was also primarily responsible for the abrupt decline in the reported average value per ton. Details on the production of dredge coal, by rivers, are shown in tables 15 and 16.

Weekly and Monthly Data.—The Bureau of Mines regularly publishes weekly and monthly production data in a series of Weekly Anthracite Reports. The weekly data are estimated on the basis of carloading figures supplied by the Association of American Railroads, plus estimates of truck shipments, dredge coal, and colliery fuel. Monthly data in these reports include, in addition to estimates of monthly production, such related information as producer and retailer-dealer stocks, rail and truck shipments from breakers and washeries. Lake loadings and receipts, exports, imports, and price indices. Copies of these reports may be obtained by writing to the Bureau of Mines, Washington 25, D. C. The weekly and monthly data in tables 17 and 18 have been adjusted to reflect the total production figure obtained from the 1954 canvass of the producing companies.

¹ Estimated from weekly carloadings as reported by the Association of American Railroads. Adjusted to annual production total from Bureau of Mines canvass. ² Figures represent output of working days in that part of week included in the calendar year 1954. Preliminary production for week of January 1, 1955, was 549,000 tons. Revised total for week of January 2, 1954, was 422,000 tons.

¹ Production is estimated from weekly carloadings as reported by the Association of American Railroads and includes mine fuel, coal sold locally, and dredge coal.

¹ See footnote 1, table 1.

Mechanical Loading.—Of the 16.9 million tons of Pennsylvania anthracite produced at underground operations in 1954, 41 percent was mechanically loaded. Although the volume of underground production dropped over 1 million tons between the 2 years, there

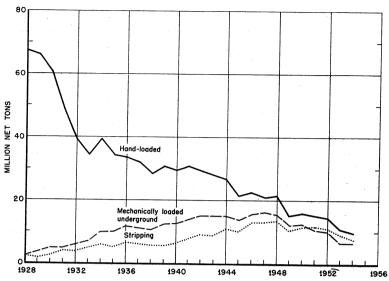

FIGURE 3.—Pennsylvania anthracite mechanically loaded, hand loaded, and stripped, 1928-54.

was a relative increase of 2 percent in mechanical loading as producing companies apparently endeavored to increase the productivity rate through greater use of available equipment. As the coal seams of the Northern field are flatter and thus more adaptable to mechanization, this field again led in mechanical loading with 89 percent of the total, followed by the Southern with 5 percent, the Western Middle with 4 percent, and the Eastern Middle with 2 percent. On a tonnage basis, the quantity mechanically loaded underground increased 8 percent in the Northern field and 1 percent in the Southern but declined 50 percent in the Eastern Middle and 36 percent in the Western Middle field because of the number and size of the underground mines closed during the year. Detailed data on underground mechanical loading are presented in tables 19 to 21. Tonnages mechanically loaded, hand loaded, and stripped are shown graphically in figure 3.

¹ As reported by Commonwealth of Pennsylvania, Department of Mines.

Cutting Machines.—Because of physical and mechanical difficulties in mining the steeply pitching seams in the Pennsylvania anthracite region, only a relatively small part of the underground production is machine-cut before blasting. Of the 96 machines reported used in

1954, all were employed in the Northern field, where the coal beds are comparatively flat. This number, of which 94 were of the "permissible" type (conforming to the safety standards established by the Bureau of Mines) and 2 were "nonpermissible," represented a sharp decline from the 135 reported for 1953. However, as the tonnage reported cut by machine increased 20 percent over 1953, it is apparent that in 1954 more effective use was made of the available machines.

Stripping Equipment.—The number of power shovels and draglines used in 1954 in stripping Pennsylvania anthracite increased over 1953, and the largest gain was reported for electric powered shovels. Details on the number of stripping machines in 1952–54, by types of power, are shown in table 22.

PRICES AND VALUE OF SALES

According to Saward's Journal, f. o. b. mine prices quoted by the industry at the close of 1954 ranged between the following limits: Broken, \$13.50-\$14.10; Egg, \$13.60-\$14.35; Stove, \$13.80-\$14.60; Chestnut, \$13.35-\$14.10; Pea, \$10.20-\$11.10; Buckwheat No. 1, \$9.40-\$9.75; Buckwheat No. 2 (Rice), \$7.80-\$8.10; and Buckwheat No. 3 (Barley), \$6.15-\$6.25. The prices quoted were for "standard" anthracite, the specifications for which are outlined in table 23. Generally, prices at the end of 1954 were about \$1.35 to \$2.20 per ton less than quotations in the latter part of October 1953 on Broken through Chestnut sizes; \$1.35 to \$1.50 less on Pea; \$0.55 to \$0.75 less on Buckwheat No. 1; \$0.30 to \$0.40 less on Buckwheat No. 2; and zero to \$0.20 more on Buckwheat No. 3. Spring discounts, which amounted to as much as \$2.00 per ton on the larger sizes down to a few cents per ton on the smaller sizes, were announced by some major producers in April 1954. In some instances, it was the intention to recover the discounts by monthly increases through September. However, owing to the increased tempo of competition at the producer level because of market conditions, the prices in effect before the issuance of spring discounts were not fully restored; in fact, in a few instances those cited above were only slightly higher than those reflecting spring discounts.

TABLE 23.—Standard anthracite specifications approved and adopted by the Anthracite Committee, effective July 28, 1947

¹ When slate content in the sizes from Broken to Chestnut, inclusive, is less than the above standards, bone content may be increased by 1½ times the decrease in the slate content under the allowable limits, but the slate content specified above shall not be exceeded in any event.

A tolerance of 1 percent is allowed on the maximum percentage of undersize and the maximum percentage of ash content.

The maximum percentage of undersize is applicable only to anthracite as it is produced at the preparation plant. Slate is defined as any material which has less than 40 percent fixed carbon.

Bone is defined as any material which has 40 percent or more, but less than 75 percent fixed carbon.

Ash determinations are on a dry basis.

During the summer and fall months of 1953 companies representing the bulk of the annual production began making strenuous efforts to combat drastic price cutting. However, in view of decreased demand and the large stocks of coal held in storage by producers at the beginning of 1954, some of which was moved at distress prices, these efforts largely failed. As a result, the average received f. o. b. mine on total production decreased from \$9.67 per ton in 1953 to \$8.52. However, the decline was not reflected equally in all sizes as the demand and prices obtained for Buckwheat No. 2 (Rice) and smaller in recent years have been relatively firmer than for the larger coals, since the greater part of the market loss to competitive fuels has been in the space-heating field, where the larger sizes are used predominantly. For example, breaker shipments of Buckwheat No. 1 and larger size decreased 9 percent from 1953, while shipments of Buckwheat No. 2 (Rice) and smaller declined 7 percent; however, the total received for breaker shipments of Buckwheat No. 1 and larger declined 20 percent while receipts from the sale of Buckwheat No. 2 (Rice) and

smaller dropped only 16 percent.

Monthly data compiled from reports published by the Bureau of Labor Statistics, United States Department of Labor, on retail prices of Pennsylvania anthracite and other fuels in selected cities are shown in table 24. For detailed information on average sales realization, see tables 25 through 27.

EMPLOYMENT

Because of such variables as the number of days worked, changes in mining methods, shifts to sources with higher output rates, etc., fluctuations in production of Pennsylvania anthracite have not always been accompanied by immediate or comparable variations in employment. Such was the case in 1954. For example, the average number of men working daily totaled 43,996, a decline of 24 percent from the 1953 work force, yet production declined only 6 percent between the 2 years. The result, of course, was a sharp improvement in output per man-day. The rate of 4.02 tons per man-day in 1954 not only far surpassed the 3.28 figure for 1953 but marked the first time in the history of the industry that the productivity rate exceeded 4 tons. Relatively higher rates of output at underground operations and strip pits were primarily responsible for the substantial increase.

In 1954, of the total labor force 62 percent was employed underground, 11 percent at strip pits, and 27 percent at culm banks, preparation plants, and other surface installations. Although these percentages indicate a relative decrease of only 2 percent in the underground force and a similar increase in surface employment, there was an actual decline of 27 percent between 1953 and 1954 in the number of men working daily underground, 22 percent at strip pits, and 18 percent at other surface facilities. Of the 1954 total labor force, 46 percent were employed in the Wyoming region, 38 percent in the Schuylkill, and 16 percent in the Lehigh. 1954 was marked by the closing of many mining operations, but the most severe from the standpoint of employment occurred in the Lehigh region, where one of the oldest and largest producing companies withdrew from mining activities. Over 4,000 men were idled in the spring, most of whom were employed in the Coaldale-Panther Valley area, and it was not until late fall that mining was resumed. However, the two new

companies formed to operate part of the properties on lease had reemployed only slightly more than one-third of the original company's labor force by the end of the year.

Detailed statistics are presented in tables 28 and 29.

See footnote 1, table 1.
 Counties producing dredge coal only.

Although the data published by the Department of Mines, Commonwealth of Pennsylvania, on the number of men affected by mines closing and opening cannot be correlated with Bureau data on employment because of differences in methods of computation, it is interesting to note that, in 1954, 79 mines were reported closed as compared with 72 in the previous year. However, whereas closures in 1953 resulted in the unemployment of 6,544, the number reached 14,045 in 1954. After allowing for the number of men employed at new mines and by the reopening of old operations, the State figures indicate a net loss of approximately 6,000 in the mine labor force in 1953 and 10,000 in 1954.

For the past few years anthracite producers have been confronted with increasingly complex economic and technical problems. face of a declining market, due primarily to the inroads made by competitive fuels, the industry has been forced to adjust its active productive capacity to a level more commensurate with demand and, at the same time, to reduce mining costs to meet competition. A study of financial reports of several major producers for 1954 indicates that, although material improvement was made in lowering production costs, the unstable price situation resulted in an unprofitable year for the industry. Measures taken by the industry in 1954 to reduce productive capacity and costs were aimed at curtailing or abandoning operations at high-cost mines, revising work schedules, and obtaining greater percentages of the total ouptut from surface sources. these measures were successful is evidenced by the improved productivity rate; yet their success, as indicated by the foregoing statistics on employment, spelled unemployment for many mine workers and further aggravation of the serious unemployment problem that has plagued the anthracite-producing region for years.

DISTRIBUTION

The Bureau of Mines has collected and published data on the distribution of Pennsylvania anthracite since the 1942-43 coal year (April 1-March 31). The data are collected on rail shipments to approximately 356 cities in 20 States and Canadian Provinces and on truck shipments by States of destination only. In contrast to the regular production statistics presented in this chapter, which are obtained by canvassing the producing companies only, the distribution data are supplied by American and Canadian wholesalers and dock operators as well as producers. This method, which permits crosschecking all returns, is believed to be the most accurate yet devised for tracing shipments from the mines to points of final destination whether moving all rail, rail-tidewater, rail-lake, or ex-dock-Results of the canvasses on distribution are published by the Bureau as mineral market reports. Copies may be obtained free by writing to the United States Department of the Interior, Bureau of Mines, Washington 25, D. C.

Owing to the increased volume of work involved in collecting and processing 1954 production data jointly with the Bureau of the Census, United States Department of Commerce, considerable time elapsed

between publication of the Minerals Yearbook 1953 and this chapter. During this interim the Bureau of Mines released Mineral Market Reports 2338 and 2451, covering the distribution of Pennsylvania anthracite for the 1953–54 and 1954–55 coal years, respectively. Shipments for each of the coal years, by States, Provinces, and countries of destination and by size of coal shipped, are summarized in tables 30 and 31.

Shipments reported to the Bureau of Mines totaled 26,620,549 net tons for the 1954–55 coal year, 8 percent less than in the 1953–54 coal year, and 21 percent less than reported for the 1952–53 year. Of the 1954–55 coal-year total, 89 percent was shipped to points in the United States, 9 percent to Canada, and 2 percent to all other countries. On a tonnage basis, 1954–55 coal-year shipments to Canada and the United States were approximately 10 percent less than in 1953–54, while exports to all other countries increased from 68,000 tons to 463,000 tons. A continuation of above-normal winter temperatures and the availability of competing fuels in Canada and the United States were undoubtedly responsible for the greater part of the decline in both countries.

Reversing the trend of recent years, the larger sizes were in relatively stronger demand in the 1954-55 coal year than the smaller sizes. For example, shipments of Pea and larger to American and Canadian destinations combined were only 8 percent less than in the preceding coal year, as contrasted with declines of 11 and 21 percent, respectively, in

shipments of Buckwheat No. 1 and smaller.

The steady increase in the percentage of anthracite shipped from the mines by truck continued during the 1954–55 coal year. Despite the decline in production the total shipped by truck climbed from 6,475,000 net tons in the 1953–54 coal year to 7,075,000 tons, an increase of 9 percent. As recently as the 1951–52 coal year, truck shipments composed only 18 percent of total shipments, yet the total indicated above for the 1954–55 coal year represented 27 percent of the total for the year. The rapid decline in the percentage of anthracite shipped by rail may well indicate that high freight rates have expanded the economic radius of the trucking area. Significantly, truck shipments to New York during the 1954–55 coal year were 26 percent higher than in 1953–54, while shipments to New Jersey increased 19 percent, Maryland 68 percent, and Pennsylvania points outside the "local sales" area 13 percent.

Data compiled monthly by the Pennsylvania Department of Mines also reflect this trend. For the year 1954, according to this source, rail shipments totaled approximately 19 million tons—13 percent less than in 1953—while truck shipments made an overall gain of 8 percent. Significantly, all of the States that are located within economical trucking distance of the mines and showed a decline in rail receipts during 1954 registered increases in trucked coal. For instance, New York, with an 18-percent decline in rail tonnage, increased truck tonnages 17 percent; New Jersey, with a 9-percent decline in rail tonnage, increased trucking volume 19 percent; and Maryland, which experienced a 14-percent decline in rail shipments, stepped up 1954 receipts of

trucked coal 66 percent. See tables 32 and 33.

 $^{^1}$ Compiled from reports of Pennsylvania Department of Mines. Does not include dredge coal. 2 Less than 0.05 percent.

Data compiled from reports of the Massachusetts Division on the Necessaries of Life and the Association of American Railroads on receipts of Pennsylvania anthracite in the New England States are presented in table 34. As indicated, rail receipts declined 9 percent between 1953 and 1954 while the tidewater movement virtually ceased, with the small import volume actually exceeding the coastwise movement.

According to reports issued by the Ore and Coal Exchange, Cleveland, Ohio, Lake Erie loadings increased 8 percent in 1954. Shipments over Lake Ontario docks were insignificant, totaling less than 2,000 tons for the year. 1954 receipts at Lake Superior ports were 37 percent higher than in 1953 and Lake Michigan, 4 percent more. Despite these increases, however, stocks were 10 percent lower at year end at Lake Superior docks and 19 percent less at docks on Lake Michigan.

CONSUMPTION

The 6-percent decline in production in 1954 was accompanied by a 4-percent decline in apparent consumption (calculated on the basis of production, imports, exports, and changes in producers' stocks). The difference was attributable largely to the fact that producers' stocks during the year decreased approximately 600,000 tons. considering that stocks in retail yards declined an additional 800,000 tons between December 31, 1953, and the same date in 1954, it is obvious that the 1,400,000-ton decline in producer and retail yard stocks played an important role in holding down 1954 output. Inferentially, therefore, had it proved necessary to meet 1954 demand entirely from production, the output undoubtedly would have more closely approximated that for 1953.

Data are not available on the consumption of all fuels in the primary anthracite market area; however, table 35 presents apparent consumption of anthracite, domestic coke, briquets, heating and range oil, and

natural gas, in terms of coal equivalent.

Consumption of anthracite by public utilities in 1954 was 12 percent under 1953, while the amount consumed by class I railroads was 16 percent less. After producing a record tonnage of oven coke in 1953, the coke industry went through a minor recession in 1954 owing to decreased demand for coke by the iron and steel industries. As a result, the quantity of anthracite mixed with bituminous coal in the manufacture of coke decreased from 275 thousand tons to 229 thousand tons, or 16 percent. The manufacture of fuel briquets also declined in 1954, with an attendant drop of 15 percent in the quantity of Pennsylvania anthracite used.

STOCKS

According to monthly estimates of the Bureau of Mines, stocks in retail dealers' yards have been declining steadily since 1952. For example, stocks in retail yards at the end of December 1954 totaled 1,495,000 net tons-34 percent less than on the same date in 1953 and 50 percent less than in 1952. On a size basis, retail stocks of Egg, Stove, and Chestnut combined dropped 36 percent between December 1953 and December 1954; Pea 28 percent; and Buckwheat No. 1 and Buckwheat No. 2 combined 34 percent. Moreover, contrary to the usual retail industry practice of stockpiling during the early spring and summer months to take advantage of the substantial discounts offered by producers, retail dealers evidenced little interest in stocking coal during the summer of 1954. As expected, retail stocks reached a low of 1.5 million tons in March and April but varied only between 1.6 and 1.8 million tons for the remainder of the year, except for December, when they again declined to the 1.5million-ton level. The comparative failure of the summer-stockpiling program was the primary reason for the low rate of production during the April-August period.

In addition to the reluctance of retail dealers to stock heavily during the warmer months, other factors have contributed also to the

decrease in retail stocks over the past few years:

(1) The actual number of retail dealers handling anthracite has been reduced substantially, either through normal attrition or by closures and consolidations brought about by decreased demand. The reduced number of dealers has resulted in a decrease in available storage space.

(2) The apparent belief of some dealers that adequate supplies of coal could be obtained from the mines on short notice, even in the

coldest months when consumption is at a peak.

(3) The desire of other dealers to keep available a large part of their storage space in order to bargain with suppliers on prices. The latter was not only particularly evident during the latter half of 1953 and throughout 1954 but was considered in industry circles to be a

factor contributing to the instability of the price structure.

At the beginning of 1954 producers had large supplies of coal in storage (1,726,000 tons at the end of January), which not only exerted an unfavorable influence on production but tended to depress the price structure. As almost 1 million tons of these stocks was Chestnut and Pea sizes, the efforts of some producers to reduce inventories by filling orders from stockpiles necessarily reduced working time, with the result that available supplies of the smaller sizes were restricted. By the end of the year producer stocks had dropped about 33 percent under December 1953.

Although total loadings over Lake Erie and Lake Ontario docks increased only about 5 thousand tons over 1953, receipts at upper Lake docks on Lake Superior and Lake Michigan increased 37 and 4 percent, respectively. Inasmuch as year-end stocks at Lake Superior docks were 10 percent less than in December 1953 and at Lake Michigan docks 19 percent less, it was apparent that the total demand for anthracite in the upper Lake region was considerably stronger than in 1052

Despite a 12-percent decline in the consumption of anthracite at electric utility plants in 1954, the public utilities slowly built up stocks throughout the year. The low point was reached in March, when a total of 2.3 million tons was reported. The year's high was for December, when the figure exceeded 2.6 million tons, or approximately 14 percent more than the same month in 1953. At the end of 1954 stocks of anthracite held by class I railroads were also higher than in the preceding coal year, totaling 77,000 tons compared with 60,000.

TECHNOLOGY

If the downward trend in the output of Pennsylvania anthracite is to be stopped or reversed, it will undoubtedly result largely from a vigorous research and development program designed to create new markets for anthracite, to provide better methods of preparing the product, and to develop more efficient mining methods. With these general objectives in mind, the Federal Bureau of Mines is conducting an extensive research program at the Bureau's laboratory at Schuyl-

During 1954 several metallurgical processes were investigated for the possible application of anthracite and for developing basic data that might create new markets. Numerous iron-smelting blast-furnace plants were visited where small quantities of lump anthracite had been used recently as furnace fuel without substantial reduction in furnace output. Anthracite has been substituted for up to 20 percent of the total fuel charge in some smaller furnaces and up to a maximum of 10 percent in larger units. The history of the use of anthracite as fuel in foundry cupolas has paralleled the experience in blast furnaces.

Anthracite was investigated as a source of additional carbon in open-hearth steel furnaces, particularly for use in cold-metal shops where hot pig iron is not available and a large part of the charge is low-carbon scrap. The volatile content of anthracite places it at a disadvantage in open hearths, however, as some of the hydrogen present may remain in the steel, while the remaining gases may cause foaming of the slag and other difficulties as metal refining proceeds. Calcination of lump anthracite to reduce the volatile content is under investigation, and this process should make anthracite suitable as an open-hearth carbon additive, creating a new market should the process prove technically and economically feasible.

The practice of admixing a small percentage of anthracite fines with coking coals, which was undertaken on a commercial scale as early as 1941, has grown to such an extent that in 1954 229,000 tons of anthracite fines was charged to coke runs. Blending small percentages of selected anthrafines with suitable coking coals permits the use of higher oven-flue temperatures, when these are not already at the maximum, and thereby increases oven-throughputs. Other advantages are improved size uniformity, no material change in coke strength and greater flexibility in bituminous-coal selection at coke-oven plants,

as anthrafines can be used to reduce the swelling characteristics of expanding coking coals. In 1954 a new fine-coal-preparation plant was placed in operation in the Eastern Middle field. This plant was designed with the blending and other specialized markets in view and was equipped to supply a well-sized, premium-quality anthrafine

product.

A technical and economic study was made on the use of anthracite for controlling frost damage to farm crops and for use in portable crop driers. A report will be released on the frost-control study, which will indicate that market potentialities for anthracite appear to range from under 100,000 tons to as much as 250,000 tons annually under severe weather conditions. During the study it was found that existing anthracite stoker and furnace equipment could be adapted to this use.

The manufacture of anthracite producer gas for industrial process heating was investigated to supply the anthracite industry, as well as manufacturers and prospective users of the equipment, with information on the performance and operating characteristics of commercial anthracite gas-producer equipment. At one shale-brick plant where field work was done, the use of anthracite producer gas reduced overall manufacturing costs, since the uniform heat obtained improved both quality and yield. The faster heating obtained with gas firing also decreased the adverse effects of seasonal weather changes on the exposed kilns. At another plant, during a 2-week observation period, 300 tons of Rice and Buckwheat No. 1 anthracite was gasified in a twin producer installation to yield about 42 million cubic feet of producer gas at 60° F. The average hot-gas efficiency of the producers was 90 to 93 percent for gas leaving the producers at an average temperature of 530° F.

Two series of tests on the gasification of pulverized anthracite with oxygen and steam were made at the Bureau's Appalachian Experiment Station, Morgantown, W. Va. One series was conducted using a 36-percent ash material in a pressure gasifier at 300 p. s. i. g. while the other tests were made in an atmospheric pressure gasifier using a 10-percent-ash coal. Additional tests were considered necessary to obtain enough data for comparison with results obtained from bituminous coals and to modify the design of the reaction chambers in both types of gasifiers to eliminate the buildup of slag when anthracite

is useď.

The relative increase in the demand for finer sizes has created new problems in sizing, screening, and desliming anthracite. The lower value of fine coal requires that preparation practices be conducted with maximum economy and efficiency. To that end, the Bureau completed a study of the commercial application of the launder screen, a device that has been used for about a half century in preparing river-coal but that has been used by other segments of the industry only since 1949 for cleaning fine sizes of anthracite.² The study demonstrated that the launder screen can be used to prepare efficiently and economically the feed to, and products from, all types of anthracite fine-coal cleaning equipment. The device is stationary, with no

² Sanner, W. S., and Clendenin, J. D., Anthracite Launder Screens; Factors in Their Design and Operation: Bureau of Mines Rept. of Investigations 5032, 1954, 32 pp.

moving parts, and is simply constructed. Thirty fine-coal cleaning plants now use these devices in preparing small coal for market.

Anthracite-crushing practices historically have been predicated on the production of a maximum quantity of the larger sizes (Egg, Stove, and Chestnut) by using toothed, double-roll crushers. As demand for the larger sizes has now declined to a point where a surplus is being produced, shortages of the smaller sizes frequently occur, particularly in the Buckwheat No. 1 and Rice range (%-%6 inch). Consequently, at the request of the industry, the Bureau of Mines has undertaken a study to determine which reduction method will yield the maximum output of Buckwheat No. 1 and Rice sizes from the larger coals. A number of non-roll-type crushers were studied, including impact, jaw, ring, and gyratory types. Of these, the gyratory type appeared to be the most efficient in recovering maximum quantities of the desired sizes. The gyratory crusher is rated at a capacity of 17 to 22 tons per hour when crushing dry limestone and will produce approximately 62 percent of Buckwheat No. 1 and Rice sizes, at 21-ton-per-hour capacity, from Chestnut size anthracite.

Experiments over a 2-year period with Bureau-owned Becorit collapsible steel props have demonstrated that definite advantages in safety, recovery, and efficiency are obtained when the roof is permitted to subside gradually and evenly over a wide area. On the basis of present knowledge, it is believed this type of roof action is attainable only by using such yielding supports with backfilling. During these experiments 25,000 tons of coal was removed, and it was found that convergence as great as 8 inches did not affect the immediate roof, and output per man-shift was increased 40 percent.

Recovery of pillar coal was 90 percent.

A vibrating-blade coal planer has been designed by the Bureau for mining and loading coal without drilling or blasting. As the machine is pulled along the face the coal is sheared from the solid by the vibrating blade, which is actuated by pneumatic hammers and falls onto a conveyor. It is planned to test the planer in an anthracite mine next year. A suitable underground site was to be prepared by the cooperating anthracite company. Installation of the machine was nearly completed by the close of the year, and testing was planned for early 1955.

Following completion in 1953 of the first cooperative experimental work with the Bureau's pneumatic packing machine, the equipment was transferred to an area where the immediate removal of coal pillars was contemplated. Over a 10-month period in 1953, 26,000 tons of breaker refuse was packed into 20 chamber voids with the machine. The material was blown from a few hundred feet to a maximum of 1,310 feet, using compressed air and a 6-inch steel discharge line.

FOREIGN TRADE

In 1954, according to data of the United States Department of Commerce, only 5,831 net tons of anthracite entered the United States for consumption. Of this total, the entire amount (except for 132 tons) was imported from Great Britain through the Massachusetts customs district. As there has been no shortage of domestic supplies in recent years, the small annual token shipments by Great Britain undoubtedly have been motivated solely by the desire of British exporters to maintain trade contacts in this country. In view of the difficulties encountered by the National Coal Board of Great Britain in meeting 1954 commitments for export tonnages because of increased demands for coal in Britain's domestic economy, it might be expected that even these small shipments will be discontinued. For detailed data see table 36.

Exports of Pennsylvania anthracite totaled approximately 2.9 million net tons in 1954, a 5-percent increase over 1953. This increase was due almost entirely to a substantial gain in shipments to Western Europe, as exports to Canada were about 6 percent less than in 1953, while total exports to Asiatic, South American, and other North American countries were relatively the same in each year.

Export data are shown in detail in table 37.

Canada imported less anthracite from all sources in 1954 than in many years owing to continuation of relatively mild weather conditions and competition from heating oil. As previously noted, imports from the United States in 1954 were about 6 percent less than in 1953; however, according to the Dominion Bureau of Statistics, imports from Great Britain declined even more sharply—from 338,856 net

tons in 1953 to 266,245 tons in 1954, a 21-percent drop.

During 1953 European coal output was generally adequate to supply demand without the importation of large tonnages from the United States; however, early in 1954 the level of industrial activity began to show definite signs of outstripping the advances in coal output. Consequently, a sharp upturn occurred in exports of anthracite to Europe in the summer and fall months. Whereas only 52 thousand net tons was shipped to Europe in 1953, the total climbed to 321 thousand tons in 1954, with clear indications that the 1955 volume would far outstrip the 1954 figure.

Although the U. S. S. R. does not publish data on foreign trade, a study of statistical releases issued by coal-importing countries indicated that Russia was an important exporter of anthracite in 1954. For instance, France, Italy, and the Netherlands, which have imported substantial quantities of Pennsylvania anthracite in the past, reported large imports of Russian anthracite in 1954. By countries, the figures follow: France, 446,745 tons; Italy, 121,236 tons; and the Netherlands, 153,661 tons.

WORLD PRODUCTION

World production of anthracite in 1954 was at relatively the same level as in 1953, since the net increase reported was both less than 1 million tons and 1 percent. The decline of approximately 1.9 million tons in the United States—the only significant decrease reported—was more than compensated for by increase in France, China, and the United Kingdom.

Although the U.S.S.R. does not publish official figures on coal production, the estimates shown in table 38, which are based on the most reliable information available, indicate that Russian output of anthracite has remained relatively stable since 1950, varying between 72.8 and 75.0 million net tons annually. In view of the steadily rising figures for total coal production in Russia during the same period, it might be concluded that the tonnages of anthracite produced either met the goals set under the various 5-year development plans or were considered adequate for all domestic and export requirements. In any event, it appears that the U.S.S.R. definitely has been placing major emphasis in recent years upon increasing output of bituminous coal for coking, chemical, and general industrial purposes while holding anthracite production fairly steady.

In Great Britain the National Coal Board made some progress in 1954 on plans to open several large new collieries in South Wales to replace many old, small, high-cost anthracite mines that have been worked beyond sound economic limits. As the mine-development work is proposed as a long-term project, however, any annual increments in output over the next few years are expected to be small.

Coke and Coal Chemicals

By J. A. DeCarlo, T. W. Hunter, and Maxine M. Otero

*

GENERAL SUMMARY

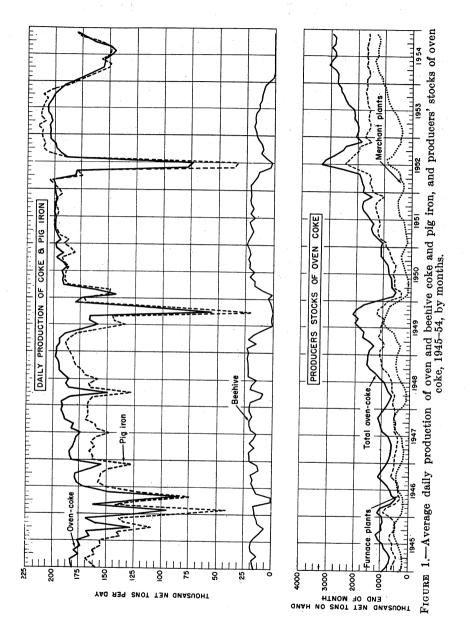

THE GENERAL decline in industrial activity in the United States during 1954 influenced coke-oven operations markedly, and output of oven and beehive coke dropped 24 percent from 1953. The drop in coke production, which began in the latter months of 1953, continued during the first half of 1954 and reached a low point in August. In September, following the upturn in pig iron and steel production, oven-coke output started to climb and increased in each succeeding month of 1954. Oven-coke plants owned and operated by iron and steel companies, classified by the Bureau of Mines as furnace plants, maintained a higher operating rate for the year than did other oven-coke plants. The rate of production for the furnace plants averaged 77 percent of capacity; whereas the nonfurnace or merchant plants operated at 61 percent. The average for all oven-coke plants was 75 percent compared with 93 percent for 1953.

Beehive-coke-oven operations did not follow the upturn in industrial activity in the latter months of 1954; consequently, the output of beehive coke was the lowest on record. Virtually all beehive-coke plants in the famous Connellsville district of Pennsylvania were idle throughout the year. The principal reasons for the closing of beehive ovens were the substantial decrease in requirements of blast-furnace coke and the expansion of carbonizing capacity of slot-type coke ovens by the iron and steel companies. Reduced requirements of blast-furnace coke resulted from (1) the low operating rates of blast furnaces and (2) a marked improvement in fuel efficiency of the furnaces. In 1954 blast furnaces producing pig iron used 67 pounds less coke per ton of pig iron produced than in 1953. Although this saving appears small, it totaled over 1.9 million tons of coke, based

on the 1954 pig-iron production.

Yields of oven and beehive coke have varied only slightly in the past 3 decades. Since 1924 oven-coke yield ranged from a high of 71.01 percent in 1944 to a low of 68.43 percent in 1932. In 1954 the yield of oven coke, exclusive of breeze, was 69.78 percent—slightly less than the 1953 average. Coke yields are influenced by the kind and condition of the coals carbonized. Low-volatile coals generally contain a higher percentage of fixed carbon than the high-volatile and consequently yield more coke. For example, the merchant plants used 28.5 percent low-volatile in their coal mixtures, and coke yield averaged 71.64 percent, whereas the furnace plants used only 21.8 percent low-volatile coal and obtained a coke yield of 69.52 in 1954. Yields of coke from beehive ovens are lower than for slot-type ovens because some of the top layer of coal in a beehive oven is burned during the coking process; consequently, the beehive-coke yield rarely exceeds 65 percent. Yield of beehive coke in 1954 dropped to 61.35 percent from 63.74 in 1953.

The annual coke capacity of slot-type coke ovens increased 337,600 tons during 1954 and totaled 78,595,600 tons at the end of the year. The 1954 gain in capacity was not as large as anticipated because the decline in demand for coke caused permanent retirement of six bat-

teries of coke ovens at merchant plants earlier than had been planned by the owners and also because construction of new ovens by iron and steel companies slackened. The annual coke capacity of slottype ovens in the iron and steel industry increased 1.7 million tons, but this gain was nearly offset by the decrease of 1.4 million tons at merchant plants. The subject of coke capacity received special attention in Government and industry in 1954. The President established a Cabinet committee on Energy Supplies and Resources Policy on July 30, 1954, to evaluate the fuel resources of the Nation and devise policy for expanding supplies. The Director of the Office of Defense Mobilization was designated chairman, and the heads of the following agencies served as members: Departments of State. Treasury, Defense, Justice, Interior, Commerce, and Labor. The White House directive outlining the committee's assignment included the following specific statements:

At the direction of the President the committee will undertake a study to evaluate all factors pertaining to the continued development of energy supplies and resources and fuels in the United States, with the aim of strengthening the national defense, providing orderly industrial growth, and assuring supplies for our expand-

ing national economy and for any future emergency.

The committee will review factors affecting the requirements and supplies of the major sources of energy including: Coal (anthracite, bituminous, and lignite, as well as coke, coal tars, and synthetic liquid fuels); petroleum and natural gas.

A task force consisting of Government and industry representatives was appointed to assist the committee. The committee submitted a report to the President in December, and the White House issued a summary in a press release on February 26, 1955. Item 11 of the press release, entitled "Mobilization Requirements for Coke," contained the following statement:

The committee believes that present and prospective rates of shutdown and dismantling of slot-type coke ovens will leave inadequate coking capacity to support full mobilization production of steel and other essential wartime industry. On the basis of national security, coke requirements can only be met if the Office of Defense Mobilization is directed to prepare plans to make the necessary arrange-

ments and tests to expand coke production rapidly in the case of an emergency.

Although delivered costs of coal fell slightly, labor costs continued to rise. The average value of coal at both oven and beehive plants was \$8.97 compared with \$9.03 for 1953. These figures are not strictly comparable, as the value in 1953 was influenced to a greater extent by the lower value for coal charged into beehive ovens, which represented 7 percent of the total quantity carbonized. In 1954 coal carbonized by beehive ovens composed only 1 percent of the total. The reported value of coal at beehive ovens was actually \$0.08 per ton higher, but this was more than offset by the decline of \$0.24 per ton for the coal delivered to oven-coke plants.

Labor costs increased slightly, according to data published by the Bureau of Labor Statistics. The average weekly and hourly earnings of production workers for "coke and other petroleum and coal products" were \$80.73 and \$1.95, respectively, compared with \$78.81 and \$1.89 in 1953. The averge hourly earnings increased \$0.06 per hour, but the average time worked decreased slightly from 41.7 hours in 1953 to 41.4 hours in 1954. According to the annual survey on employment conducted by the Bureau of Mines, employment fell in the coke industry, particularly at beehive plants. The average number of men

working at beehive plants dropped to 1,203 in 1954 from 2,429 reported in 1953, and man-hours worked receded to 576,931 from 3,580,299 in 1953. For slot-type ovens the average number of men working dropped from 21,011 employed in 1953 to 18,144 and man-hours worked fell from 61,096,328 to 52,393,761 in 1954. These data pertain to all workers in the coke industry subject to work hazards and include workers in construction, development, maintenance, and repair, as well as supervisory and technical personnel in the plants,

but do not include office workers. Production of coal chemicals depends largely on coke-oven operations, since these chemicals are made by the processing of the ammonia, tar, and light oil recovered from the gas stream. The recession in coke-oven operations reduced the output of the coal-chemical materials, and ammonia production (NH3 equivalent of all forms) fell 15 percent; crude tar, 14 percent; and crude light oil, 17 percent. Production of the various derivatives of these basic materials fluctuated The ammonia products, sulfate and liquor, decreased more widely. 13 and 35 percent, respectively. The principal light-oil derivatives benzene, toluene, and solvent naphtha-fell 20, 7, and 27 percent, respectively, while xylene output increased slightly. The main tar derivatives—creosote oil, crude chemical oil, phenol, and pitchdropped 29, 7, 9, and 15 percent, respectively. Although crude naphthalene production declined 11 percent in 1954, new facilities completed in the latter part of the year prevented a larger decrease and enabled the coke-producing companies to produce a higher quality naphthalene, pure enough to use in the manufacture of certain synthetic organic chemical intermediates, without further processing and upgrading. Before 1954 over 50 percent of the crude naphthalene produced at oven-coke plants was unsuitable for manufacturing intermediates and had to be upgraded by chemical companies. in quality of naphthalene made at coke plants was quite noticeable in 1954. Less than one-fourth of the total produced had a solidification point of less than 74° C. compared with 50 percent in 1953. It was apparent, therefore, that over three-fourths of the 1954 output of coke-oven naphthalene was used by the chemical industry without any further refinement.

Markets for most of the coal chemicals held up fairly well in 1954, and at the end of the year stocks at producing plants had changed little from those in the previous year. Prices on most of the coal chemicals remained about the same as in 1953, although prices on several commodities were reduced. Ammonium sulfate was cut \$2 to \$3 per ton by coke-oven operators around the middle of the year; this is reflected in the average value reported to the Bureau of Mines of \$0.021 per pound compared with \$0.022 in 1953. In the last quarter of 1954, benzene consumers showed some resistance to the prevailing prices, and a 4-cent-per-gallon reduction occurred in the first week of January 1955. This, however, did not affect the 1954 average value for the specification grades of benzene. Pyridine prices, which began to decline in 1953, fell further in 1954, and the refined 2° grade averaged \$0.879 per pound. However, as a whole the year was fairly good, and the total value of coal-chemical materials sold was \$292,243,755, or only 16 percent lower than the record set in

1953.

 $^{^1}$ Excludes plants retired permanently during year. 2 Included with "Undistributed" to avoid disclosure of individual company figures.

SCOPE OF REPORT

Except where otherwise noted, the statistics in this chapter are based on data voluntarily supplied to the Bureau of Mines by United States coke-producing companies. The data are confined to the products made in high-temperature slot-type and beehive-coke ovens and do not include products made by other processes (coal-gas retorts, low-temperature carbonization of coal, and carbonization of the residue from refining crude tar and petroleum). Statistics on retort and low-temperature carbonization coke in the United States are given in table 4. Production of petroleum coke totaled 4.9 million tons in 1954, and the United States Tariff Commission reported that 24,000 tons of coal-tar-pitch coke was produced.

There were 82 active oven-coke plants in the United States in 1954. operated by 45 companies. Detailed monthly and annual reports were received from every plant. In the beehive-coke industry 57 companies submitted reports on 76 plants. As submission of these reports is not mandatory, the Bureau of Mines could not obtain reports from three small beehive plants that operated spasmodically during the year. Production at these plants was estimated from railroad reports on their carloadings, and coverage of the beehive

industry is believed to be complete.

The production totals of coke, breeze, coke-oven gas, crude tar, and crude light oil for 1954 will be compared with Bureau of the Census totals for these commodities when they become available. Differences in the totals will be adjusted and explained in a subsequent

For data not collected by the Bureau of Mines but incorporated into this chapter, the Bureau of Mines is indebted to the Bureau of the Census, United States Department of Commerce, and the American Iron and Steel Institute.

Although the terms "merchant" and "furnace" plants originated in the beehive-coke industry, in this chapter this classification applies only to oven-coke plants. Furnace plants are under direct ownership of, or have a financial affiliation with, iron and steel companies whose main business is production of coke for use in their own blast furnaces. All other plants are classified as merchant and include those that manufacture metallurgical, industrial, and domestic grades of coke for sale on the open market; coke companies associated with chemical

plants; gas utilities; and those affiliated with local iron works where only a minor part (less than 50 percent of their output) is used in affiliated blast furnaces.

The Bureau of Mines does not attempt to collect statistics on the cost of manufacturing coke. Values and prices on coal, coke, and other products shown in this chapter are obtained from annual reports submitted to the Bureau of Mines by producing companies. For coke, gas, and coal chemicals sold (commercial sales) the dollar values are the amounts received for the products f. o. b. ovens. For 1954 a different procedure was used to determine the dollar value of coke-oven products used by the producing companies. The values assigned to coke, breeze, and gas used by producers are the market values of these products at producing plants rather than bookkeeping values formerly assigned according to the accounting procedures of the companies. Therefore the values of coke and breeze produced and surplus gas used by producing companies in 1954 are not comparable with those reported in preceding years.

The term "coke", as used in this chapter, refers only to the large sizes (usually one-half inch plus) from which the smaller sizes, which are known as breeze, have been screened. Metallurgical coke refers to the grades (blast furnace and foundry) used for smelting and casting ferrous metals. The standard unit of measurement in the coke industry is the net or short ton of 2,000 pounds, which is employed

throughout this chapter.

PRODUCTION BY FURNACE AND MERCHANT PLANTS

The accompanying table on the production of oven coke by furnace and merchant plants indicates the steady gain made by the furnace group in the past 5 years in relation to total output. Before World War II the merchant group produced 20 to 50 percent of the annual output of oven coke. Because of diversified interests (chemicals, gas, and domestic coke) coke production at merchant plants usually was more stable than at furnace plants where production was more closely related to trends in the steel industry. However, since World War II there has been a significant change in the pattern of fuel consumption which has had a profound effect on the demand for merchant

oven coke. Because of the widespread construction and extension of natural-gas pipelines and the tremendous increase in fuel-oil production, competition of these fuels has adversely affected the demand for coke-oven gas, coke for residential heating, and coke for chemical processing (ammonia). A balanced market for coke, gas, and coal chemicals is essential for economic operation of a merchant coke plant. Therefore, the loss of gas and coke markets made it difficult for a number of merchant plants to continue operations; consequently, production of coke and the number of active merchant plants have declined

TABLE 6.—Number and production of oven-coke plants in the United States, 1929, 1939, 1947-49 (average) and 1951-54, by types of plant

steadily in the past decade. Although production of oven coke from merchant plants has been decreasing each year, production from furnace plants has increased. Table 6 shows that production from merchant plants during 1947–49 averaged 20 percent of the total oven-coke production. Since that time the proportion of oven coke produced at merchant plants has declined steadily to 12 percent of the total in 1954, whereas the proportion of furnace coke produced increased 10 percent in the same period to 88 percent, the highest proportion on record. Although output from furnace plants was about 10 million tons less than in 1953, it nearly equaled production in 1947–49.

PRODUCTION BY STATES AND DISTRICTS

Production of oven and beehive coke, by States, is shown in table 8. The sharp reduction in output in 1954 does not reflect a trend that started at the end of World War II. A better analysis of trend is obtained by comparing 1954 State outputs with the average during 1947–49. Although the production rate of oven-coke plants was low in 1954, output in Alabama, California, Indiana, Maryland, Texas, Utah, and West Virginia either equaled or exceeded the 1947–49 average. It was quite evident, therefore, that carbonizing capacity increased in these States and that production could have been larger if more coke had been needed.

Pennsylvania—the perennial leader in coke production—again produced the largest tonnage; it comprised over one-fourth of the total oven-coke production and almost three-fourths of the beehive-coke output. Ohio barely retained second place over Indiana, and together these States produced about the same quantity as Pennsylvania. Production of oven coke in Ohio declined 3½ million tons—the largest drop among the oven-coke-producing States. The largest tonnage decrease was in Pennsylvania, where oven-coke production declined 3.2 million tons and beehive-coke output decreased 4.2 million tons. Production also decreased in Illinois, Massachusetts, and New York because a number of coke-oven batteries in these States have been permanently retired in recent years.

Production of coke, by regions, has varied little during the past several years. The Pittsburgh-Youngstown region supplied about one-third of the oven-coke production in 1954, followed by the Eastern region with 22 percent and Chicago with nearly one-fifth of the total.

As reported; quantity produced but not used undoubtedly greater. See Mineral Resources of the United States, 1922, pt. II, pp. 726-727.

NUMBER AND TYPE OF OVENS

Slot-Type Coke Ovens.—For the first time in 4 years the number of coke ovens did not increase over those active in the preceding year. In fact, the number of active ovens dropped from 15,989 ovens on January 1, 1954, to 15,891 on December 31. The reduction (98 ovens) was caused by the dismantling and permanent retirement of 866 old ovens, whereas only 768 new ovens were completed and placed in operation. Of the 866 ovens reported as abandoned 472 were dismantled for rebuilding, and 394 were retired permanently. The iron and steel companies have rebuilt old ovens at a relatively high rate since the end of World War II. On the other hand, the operators of merchant-coke plants have done little modernizing in the same period. The percentage of ovens over 25 years old at furnace plants dropped from over 40 percent of the total on December 31, 1948, to less than 33 percent on December 31, 1954. At merchant plants, however, the percentage of ovens over 25 years old has increased substantially. On December 31, 1948, only 38 percent of the ovens at merchant plants were 25 years old or more; this had risen to 64 percent at the end of 1954. Although 25 years is not the maximum life expectancy of coke ovens, past experience has shown that, generally, ovens over 25 years old become increasingly difficult to main-

¹ Includes ovens dismantled for rebuilding.

tain. The average age of ovens dismantled for rebuilding since 1948 was 27 years. Thus it is evident that the deterioration rate of ovens at merchant plants will increase substantially in the next few years unless a major rebuilding program is undertaken. However, reports submitted to the Bureau of Mines indicated that all but 44 of the 490 coke ovens under construction at the end of 1954 were at furnace plants.

Beehive Ovens.—Tables 13 and 14 show the capacity and number of ovens active in 1954. A total of 12,216 beehive ovens were in existence at 75 plants on December 31, 1954, a decrease of 2,876 ovens and 26 plants from 1953. This change was not significant, however, as operators may report certain ovens in existence one year and not the next, according to industrial activity and general business conditions. Unlike slot-type ovens, which cannot be operated intermittently without damage to brickwork, beehive ovens can easily be started or taken out of production with a minimum of damage, there-

¹ Idle and not expected to resume production; removed from list of available ovens.

fore the number of beehives in existence fluctuated widely in recent years, depending upon activity in the iron and steel industry.

The lower blast-furnace operating rates in 1954 curtailed coke requirements, and few beehive plants could continue operations. The average number of active ovens each month is given in table 14. There was little change in active ovens in the last 10 months of 1954. The December average, although slightly higher than in October and November, was less than one-third that in January.

TABLE 14.—Average number of beehive-coke ovens active in the United States in 1954, by months

CAPACITY OF OVEN-COKE PLANTS

The potential annual coke capacity of slot-type coke ovens increased slightly during 1954 and was 78,595,600 net tons at the close of the year; this was 7 percent higher than the capacity in 1949 and represented a gain of more than 1 percent annually. Whereas, the capacity of furnace oven-coke plants has increased since 1949, that of merchant plants has decreased nearly 5 percent each year in the same period.

The potential annual coke capacity reported to the Bureau of Mines by the operating companies is based on the minimum coking time necessary to produce a coke with qualities suitable for its intended use. For this reason, the potential capacity of a plant may change from year to year, depending on the age and condition of ovens, the character and quality of coal carbonized, the grade of coke required, and other economic factors. Thus the capacity reported to the Bureau of Mines may differ from the designed or rated capacity estimated by the coke-oven builder at the time of construction. For example, if a coking rate of 1 inch per hour is used to calculate the capacity (the generally accepted standard used by coke-oven builders) the capacity of slot-type coke ovens on December 31, 1954, would have been 81,684,500 net tons or 4 percent higher than the capacity reported to the Bureau of Mines. However, because of factors previously mentioned, the maximum potential capacity reported to the Bureau of Mines and shown in table 15 is probably a reliable measure of the practical operating capacity for the years given.

Table 16 shows the monthly rate of coke-oven operations for the past 5 years. The data for 1954 indicate a sharp recession in oven operations from the high rates maintained in preceding years. Operating rates dropped steadily during the first part of the year to 68 percent of capacity in August, the lowest since July 1952. The demand for coke increased in September, and coke-oven production increased accordingly in succeeding months and in December reached 84 percent, the highest for the year. This figure, however, was 12 points below the rate of production in January 1953 and 14 points below the record of June 1951.

 $^{^{1}}$ Capacity of all ovens in existence, whether active or idle, based upon maximum daily capacity times days in month.

QUANTITY AND VALUE OF COAL CARBONIZED

The quantity of coal charged into coke ovens (slot-type and bee-hive) in 1954 decreased 24 percent from 1953 and was the smallest carbonized in 8 years. Consumption of coal by slot-type ovens decreased 20.2 million tons, and consumption at beehive plants was the lowest on record. As a result, coke ovens yielded first place, among the major coal-consuming groups, to the electric-power utilities. Normally, coal consumption at coke ovens shows only small differences in seasonal consumption pattern. For example, for the 1947–49 period the fluctuation from the highest to the lowest month was only about 4 points. Beginning in the first quarter of 1954, however, the sharp recession in steel production was reflected in coking-coal consumption, which dropped from 8 million tons in January to 6.4 million in September. Consumption increased slowly but steadily in the last quarter and in December nearly equaled that in January. Anthracite fines were used at 20 oven-coke plants, and 229,373 tons was blended with bituminous coal in the coke industry in 1954.

One less State consumed coking coal in 1954, as Rhode Island consumed none after the Providence Gas Co. plant was closed in 1953. Although the geographic pattern of coking-coal consumption has been rather well established over the years, there was evidence of some shifting particularly among the States along the eastern seaboard, because of the inroads made by oil and natural gas into the markets

formerly served by coke ovens. The 1953–54 data do not illustrate this trend because of the general recession in coke production. However, if compared with 1947–49, coal consumption dropped almost 50 percent at plants along the Atlantic seaboard. Although coal-carbonizing capacity in Maryland and around Buffalo, N. Y., has increased, the gain has not offset the losses in Rhode Island, Massachusetts, eastern New York, and New Jersey, and coking-coal consumption in the eastern part of the United States has trended downward.

Pennsylvania, which lost 10,815,652 tons in coking-coal consumption from 1953, still carbonized 27 percent of the coal charged into slot-type ovens and 68 percent of the coal charged into beehives. Slot-type ovens in Ohio and Indiana together carbonized only about the same quantity as was used in all ovens in Pennsylvania, as coal consumption in Ohio fell 29 percent. Other States where over 5 million tons of coal was carbonized were Alabama, West Virginia, and

New York.

Coal costs represent 75 to 80 percent of the total coke-manufacturing costs, which, in turn, represent a substantial part of costs of making pig iron in blast furnaces. As blast furnaces use a preponderance of all coke produced in the United States, coal costs are extremely important to coke-plant and blast-furnace operators. For the first time since 1940, the reported value of coal delivered to oven-coke plants decreased slightly. In the oven-coke industry many plants are farther from the coal fields, and coal costs are much higher because of the added transportation expense. Table 20 indicates that the value of coal is much lower for Alabama and West Virginia, where the ovens are near the sources of coal, than for Indiana, Illinois, New York, and Minnesota. The differences among States are even larger when the costs of coal required for 1 ton of coke are used, because 1.43 tons of coal is required.

Although the value of coal carbonized in slot-type ovens declined in 1954, that of beehive coal continued to rise and reached \$6.44, a new high, or about twice the value reported as late as 1944. In beehive coking the yield of marketable coke is not as large as for slot-type ovens, so that more coal is required to make 1 ton of coke. This,

of course, increases the cost of coal required for each ton of beehive coke and narrows the margin in coal costs between beehive and slot-type coke ovens. For example, the difference in the average values of bituminous coal for making oven and beehive coke was \$2.56 per net ton. However, if the costs are based on the quantity of coal required

PREPARATION AND SOURCE OF COAL

Washed and Unwashed Coal.—One of the significant developments in the coke industry in the past decade has been the improvement in coal quality because of better cleaning processes and equipment. The coke industry, probably more than any other, maintains rigid specifications for the coal carbonized. In 1954, 68 percent of the bituminous coal charged into coke ovens was cleaned, compared with 28 percent in 1945. The reason for this tremendous increase is obvious, as coke quality depends to a much greater degree upon the character and quality of coal carbonized than upon oven design or carbonizing technique. Although mechanization of American bituminous-coal mines has increased productivity, it has also increased the refuse content of the coal, which has made it necessary to clean the raw coal in many areas. For example, at the end of World War II, Illinois, Indiana, Michigan, Minnesota, New Jersey, New York, and Ohio, used either small quantities of washed coal or none. In the past decade the proportion of washed coal carbonized in Illinois

increased from 22 percent in 1945 to 58 in 1954; Indiana, from less than 1 percent to 88; Michigan, from 6 percent to 46; Minnesota and New Jersey, from none to 48 percent each; New York, from 10 percent to 65; Ohio, from 25 percent to 70; Pennsylvania, from 40 percent to 74; and West Virginia, from 37 percent to 58.

All coal mined in Alabama and Colorado used to manufacture coke was washed before it was charged into ovens. Most of the cleaning or washing of coal is done at the mines, although several coke plants

operate coal-cleaning facilities adjacent to the ovens.

Source.—The bituminous-coal fields in the Appalachian region supply most of the coal carbonized in the United States. Coal fields in West Virginia and Pennsylvania supplied about three-fourths of the coking coal shipped to oven-coke plants in 1954. Of significance is the fact that the largest supplies of low-volatile coal, which is blended with high-volatile to improve the physical properties of metallurgical coke, particularly its strength, comes from these States, largely from West Virginia. The famous Pocohontas field produces some of the finest coking coal mined in the United States. portance that coke-oven operators place on the blending of low-volatile coals may be noted from the fact that coke plants in the West and on the Pacific coast ship in this type of coal from the Oklahoma-Arkansas coal fields. Kentucky has been increasing its shipments of coking coal to coke plants and supplied almost 10 million tons or 12 percent of the total quantity obtained by coke-plant operators. fields of Alabama supply the coke plants within the State, and shipments amounted to 8 percent of the United States total. Other States that contributed significant tonnages of coking coal in 1954 were Utah, Virginia, and Colorado.

The origin and destination of coking-coal shipments to oven-coke plants in 1954 are summarized in table 24. West Virginia—the leading coking-coal producer and distributor shipped coal to 17 other States. Of the total tonnage originating in this State, all but 9 percent was shipped outside the State. Pennsylvania, the perennial leader among the coal-consuming States, ranked very close to West Virginia in the quantity of coal produced in the State. However, unlike West Virginia, where only a small quantity of the coal is carbonized within the State, Pennsylvania consumed 63 percent. Kentucky, which ranked third in production, shipped virtually all of its

coal to other States, as did Virginia.

About two-thirds of the coal carbonized in slot-type coke ovens in 1954 was produced in mines owned and operated by coke-producing companies. This is known as captive coal, and its use has increased substantially in recent years. One of the reasons for the upward trend in the use of captive coal is that coke-oven operators can maintain better control of quality and be assured of an adequate supply during periods of heavy demand. Furnace plants operated by the iron and steel industry draw a greater proportion of their requirements from captive mines than do the merchant-coke plants. Merchant plants, however, have shown a larger percentage increase in the use of captive coal in the past 5 years, than have furnace plants. Captive coal obtained by merchant plants increased from 29 percent in the 1947–49 period to 42 percent for 1954. In the same period captive coal received by furnace-coke plants increased from 64 percent to 70.

Blending.—Blending or mixing various types of coal before charging it into ovens is an integral part of coal preparation at virtually all Many coke plants received coal from numerous oven-coke plants. mines and different coal-producing fields. The quality of coal varies widely from field to field and within the same field, and ample mixing facilities are necessary to obtain a uniform quality. A better coke can be obtained by a proper blend of 2, 3, or more different coals than from any 1 alone. The primary objective of blending is to produce economically a quality of coke satisfactory for the use intended. It also permits using coals that have good coking properties but may be otherwise objectionable from the standpoint of excessive ash, sulfur, or phosphorus content and cannot be used alone as a 100-percent Thus, in addition to providing a means of controlling the quality and strength of the coke and the yield of coproducts, blending permits flexible operation at oven-coke plants and use of a wider variety of coking coals. All oven-coke plants mix or blend coals before charging them into ovens; however, coal of different volatile content was mixed at only 77 of the 82 active oven-coke plants in 1954. Of these, 55 used high- and low-volatile coals; 19, high-medium-, and low-volatile; 1, high- and medium-volatile; and 2, low- and medium-volatile. Of those that did not mix coals of different volatile content, 1 plant used straight high-volatile and 4 used mediumvolatile. The proportion of the different volatile contents of coal mixed before charging into ovens varies widely from plant to plant,

CONSUMPTION OF COKE

The general decline in industrial activity in 1954 reduced coke requirements accordingly and the apparent coke consumption of the United States dropped 18,571,104 tons to 59,124,768, the lowest figure since 1946. Although consumption of coke in iron furnaces in 1954 was 7 percent lower than for the 1947–49 period, the largest decrease was in coke classified for all other purposes (table 27). In 1954 the tonnage consumed for all other purposes was almost 50 percent less than the 1947–49 average because of the loss of the home-heating and gas-manufacturing markets to natural gas and oil.

The fuel efficiency of blast furnaces continued to improve in 1954, and the quantity of coke required per ton of pig iron produced was the lowest since 1941. According to the American Iron and Steel Institute, 1,745.2 pounds of coke was needed to make 1 ton of pig iron in 1941 compared with 1,745.7 in 1954. The decline of 66.9 pounds from the 1953 rate was the largest annual decrease since 1925. Factors responsible for the decline included the improvement in quality of both coal and iron ore, expanded sintering facilities, and advancement

in operating techniques of the blast furnaces.

Data on the production and distribution of coke by major end-uses in 1954 are shown in tables 29 and 30. The format of these two tables has been revised from those of preceding years. In previous years sales of coke to financially affiliated companies were included with commercial sales. In some instances these shipments were merely intercompany transfers and the values assigned were not those prevailing on the market but values assigned according to the accounting procedures of the companies involved. Therefore, to differentiate between commercial sales and intercompany transfers the questionnaires were revised in January 1954, and intercompany transfers are no longer shown with sales but included under coke reported as used by the

producing company. In this way sales data reflect the quantity of

coke that actually changes ownership.

Table 29 shows that the furnace oven-coke plants used virtually all of the coke they produced. Although some of the merchant plants, particularly those connected with chemical works, consume most of their output, most merchant plants market virtually all of their coke. Merchant plants over the years have supplied the coke requirements of small pig-iron producers, iron foundries, nonferrous smelters, chemical processors, and fuel retailers and home owners. In 1954 the merchant oven-coke plants used 27 percent of their total distribution in their own oven operations and shipped the balance to other consumers. Of the quantity shipped to other consumers, 17 percent was sold to blast-furnace plants, 30 percent to foundries, 10 percent to other industrial plants, and 16 percent for residential heating.

Included with "Undistributed" to avoid disclosure of individual company figures.
 Sales to financially affiliated companies (formerly included under "sold") are now included with coke used by producing companies, and 1953 figures are revised accordingly.
 Includes 57 tons valued at \$721 sold to water-gas plants.

DISTRIBUTION OF OVEN AND BEEHIVE COKE

Distribution of coke and breeze shipments from producing plants in 1954, by principal end uses, and final destinations is summarized in table 31. The widespread geographic distribution of coke evidences its numerous industrial applications. The iron and steel industry is the leading consumer of coke and breeze, most of which is used for smelting iron ore in blast furnaces. Therefore, States that have blast-furnace installations were the leading consumers of coke in 1954 and were as follows: Pennsylvania, Ohio, Indiana, Alabama, and Illinois. Other States that ranked high in overall coke consumption were New York, Maryland, Michigan, and West Virginia, all of which consumed over 2 million tons. For discussion purposes, the terms "distribution" and "consumption" are synonymous in this section.

There were 18 States where coke was charged into blast furnaces; of these, Pennsylvania consumed 27 percent of the total deliveries to blast-furnace plants in the United States, Ohio 19 percent, and Indiana 12 percent. These three States thus consumed more blastfurnace coke than all 15 other States combined.

United States iron foundries are scattered widely, and foundry coke was shipped to every State, as well as the District of Columbia and a number of foreign countries, in 1954. Michigan, the center of the automobile industry and the largest producer of iron castings, led all States in foundry-coke consumption by a wide margin. The quantity of coke shipped to foundries in Michigan was equivalent to 23 percent of total shipments for this use in the United States. Ohio and Illinois followed Michigan with 10 and 9 percent, respectively, of foundry-coke shipments. Shipments of coke to producer-and water-gas

TABLE 31.—Distribution of oven and beehive coke and breeze in 1954, in net tons
[Based upon reports from producers showing destination and principal end use of coke used or sold.

Does not include imported coke, which totaled 115,781 tons in 1954]

plants continued to decline. West Virginia, which produced chemicals from the synthesis gas made from coke led all States in coke consumed in water-gas generators. Coke for other industrial uses was reported to have been shipped to every State; and Pennsylvania, New York, Ohio, and Michigan combined consumed 48 percent of the total. Use of coke for residential heating continued to decline in 1954. Coke for this purpose is seldom shipped as widely or as far as that used for industrial purposes, and most shipments are consumed near the producing plants. The total amount used for residential heating in the United States in 1954 was smaller than that consumed in New York alone in 1945.

STOCKS OF COKE AND COKING COAL

Coke.—Stocks of coke and breeze shown in tables 32 and 33 represent reserves of material at producing plants and do not include coke or breeze stocked by some producers at affiliated steel plants. though coke does not deteriorate appreciably when stocked, producers like to keep their stocks at a minimum because some degradation occurs in storing and reclaiming it. Stocks of all grades of coke increased in various amounts, whereas stocks of breeze dropped. Foundry coke at oven-coke plants more than tripled, while coke for "residential heating and other" and blast-furnace uses increased 16 and 4 percent, respectively. Table 33 shows that in 1954 stocks decreased only slightly (1,974 tons) at furnace plants but increased 277,059 tons at merchant plants. Stocks at furnace plants were equivalent to 10 days' production at the rate prevailing in December 1954, whereas merchant stocks equaled 59 days' production. Nearly all of the coke held by the furnace oven-coke plants was blast-furnace grade. Merchant-plant stocks consisted of 40 percent blast furnace, 10 percent foundry, and 50 percent all other grades. Beehive coke is rarely stocked by the producing company, which explains the small tonnage shown in table 32.

Coal.—The maintenance of adequate stocks of bituminous coal is essential to oven-coke plant operators because of the continuous nature of the carbonization process. Usually a 30-day supply is the minimum desired by most operators as a safeguard against disruption in the flow of coal to the ovens. However, coke plants on the Upper Lakes, which are supplied principally by boat, build up inventories during the shipping season for an adequate tonnage for the winter. These plants usually have stocked 4 to 5 months' supply at the end of the lake shipping season.

Stocks of bituminous coal decreased 25 percent during the year, and reserves on December 31, 1954, were the lowest in 5 years. In spite of the decline, stocks were still fairly high, and the 12.4 million tons stockpiled was adequate for 48 days' requirements at the consuming rate in December. Stocks of anthracite also declined; but the practice of using anthracite in the coking-coal admixture is not universal, and only 18 of the 82 active oven-coke plants reported anthracite

stocks.

ASSIGNED VALUE AND PRICE

The average values, at the ovens, of oven and beehive coke produced, which include coke consumed by producing companies as well as coke sold, are based on reports from the producing companies showing receipts f. o. b. plant for coke that is sold and market values assigned by producers for coke that is consumed by the producing companies. The assigned value per ton of the total coke produced and the average price f. o. b. for coke sold are shown in tables 36 and 37. The average monthly prices of furnace and foundry beehive coke and foundry oven coke in certain markets, quoted by Steel Magazine in 1954, are shown in table 38.

Before 1954 the producing companies were requested to assign only a bookkeeping value to the coke consumed by the producing companies. In 1954 the producers were requested to assign a market value at the plant to the portion of their production that they used. As a consequence, the average value of coke produced at oven coke plants shows an increase over previous years. Average prices of coke, based on commercial sales, were substantially below those reported in 1953.

For the first time the reported average price per ton of coke sold to blast-furnace plants was less for oven than for beehive coke (table 37). On the other hand, the price of oven coke sold to foundries was much greater than for beehive coke. Prices of coke sold for other industrial purposes by both oven and beehive producers were comparable, whereas the oven coke sold for residential heating was several dollars per ton higher than beehive. However, the quantity of beehive coke sold for residential heating was small.

Imports.-Imports of coke are not of great importance to the United States except to certain local areas. The quantity imported in 1954 declined 26 percent to 115,781 net tons and was less than 1 day's production in the United States. Nearly all of the coke was imported from Canada; however, 1,102 tons came from West Germany and 44 tons from the United Kingdom. Most of the Canadian coke entered the United States through the Montana-Idaho customs This district received the largest tonnage on record, which indicated that requirements of carbonaceous fuel in the Northwest and the western section of the United States were increasing. Although the Bureau does not collect precise data on the uses of imported coke in these sections, it can safely be assumed that most of it was used in smelting nonferrous metals. Imports through the Buffalo customs

¹ Figures on imports and exports compiled by Mae B. Price and Elsie D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

district were almost negligible, whereas in 1952 144,368 tons had

entered the United States through this gateway.

Exports.—Normally exports of coke are not large, except for shipments to Canada. Shortages of coke in many European countries in the postwar years resulted in larger exports to these countries. Shipments to Europe in 1951 were larger than shipments to Canada in 1954, and exports to South American countries for the three years preceding 1954 averaged around 30,000 tons annually. However, increased carbonizing capacity in Europe increased the supply of coke accordingly and lessened the need for American coke. In 1954 exports of coke to Europe were about one-third as large as in 1953, and about one-fifth as large as in 1952. The only European countries that imported coke from the United States in 1954 were Spain and Greece. Exports to South America dwindled to less than 1,000 tons. previous years Argentina and Brazil were the two largest consumers of coke in South America. Argentina did not import any from the United States in 1954 but obtained nearly all of its supply from the United Kingdom, whereas Brazil imported most of its coke from West Germany. Exports to other countries were small, although a substantial tonnage of coke was shipped to Oceania, French Pacific Islands.

TABLE 39.—Coke imported for consumption in the United States, 1952-54, by countries and customs districts

TECHNOLOGY

Extensive studies and a large amount of research were devoted to the conversion of coal into coke and coal chemicals in 1954. Bureau of Mines continued its studies on the carbonizing properties, plasticity, expansion, bulk density, and washing characteristics of coal.2 Forty-two coals from 28 beds in the Appalachian region were carbonized singly in the Bureau of Mines-American Gas Association (BM-AGA) retort. Studies were also continued on the mechanism and kinetics of coal carbonization to provide fundamental data and develop new techniques for assessing the factors that control the coking of coal. Results of research and investigative work on the effect of carbonizing temperature, bulk density, and composition of the coal blends on the yield and quality of products were summarized and published.3 Standardized operating and testing procedures were developed for use in the Tuscaloosa experimental coke oven. 4 Subsequent investigations utilizing these procedures contributed information on the effects of variations in bulk density on coking time.5 Studies on coal expansion were continued during the year and the initial phases of a long-range program on the subject were completed.6 An index of coals tested by the Bureau of Mines was prepared and published to list in one publication all of the coals on which investigations on carbonizing properties and yield of coke and coal chemicals have been made.

A 30-ton-per-hour prototype commercial fluidized-bed carbonizer was operated at Rockdale, Tex., utilizing dried lignite to produce char for firing power boilers and tars and liquid products for tests to determine characteristics and possible uses.8

Bituminous Coal Research, Inc., prepared and published an excellent summary on world coal research in 1954.9 This article described briefly some studies and research work on coal carbonization, gasification, and coal-chemical production by Federal and State agencies, universities, and individual companies. The British Coke Research Association published two pamphlets that contained extensive bibliographies, issued between January and December 1954, relating to carbonization and other subjects of interest to the coke industry.10 A similar bibliography published from June 1953 to April 1954 on coal and oil-shale pyrolysis was issued in September This review contained 160 references and covered studies and investigative work on high- and low-temperature carbonization of coals, raw materials, product and by-product characteristics and properties, coke-oven equipment and improvements, and coke analyz-

ing and testing procedures. One of the many new techologic developments reported in 1954 that created much interest was the production of synthetic ammonia, ethylene, etc., from coke-oven gas by means of low-temperature separation.¹² This method of making ammonia synthesis gas (3H₂: 1N₂) has been in operation for many years in some European countries but has not been practiced in the United States. The only coke plant in the United States where coke-oven gas is processed for the removal of hydrogen is the Belle, W. Va., plant of the Du Pont Co. However, the hydrogen is used primarily for the hydrogenation of other products and only occasionally to supplement the hydrogen from its water-gas operation used for ammonia production. In 1954 two companies operating coke ovens announced plans to use coke-oven gas as a source of hydrogen for anhydrous ammonia production. The largest cokeproducing company—The United States Steel Corp.—engaged an engineering firm in 1954 to make a study and to design a plant to cost between 18 and 20 million dollars. This company decided to build the first plant at its Geneva works in Utah and later build a similar plant at Gary, Ind. 13 The other company that was proceeding with plans to build a similar plant was the Ketona Chemical Co. This company is owned jointly by the Hercules Powder Co. and the Alabama Byproducts Corp., and the plant (at Ketona, Ala.) will use coke-oven gas made by the latter company.

The Colorado Fuel & Iron Corp., in technical collaboration with the Monsanto Chemical Co. and the Koppers Co., Inc., developed a process to make diammonium phosphate. It was claimed that this was the first commercial production of diammonium phosphate based on coke-oven ammonia and electric-furnace phosphoric acid. new fertilizer material contains about 74 percent utilizable plant nutrients compared with only 20.5 percent for ammonium sulfate. The new process closely resembles the standard sulfate recovery of ammonia from coke-oven gas, except that electric-furnace phosphoric

acid is used as the absorbent. Several other coke plants were doing research work on the same problem and planning to begin commercial

A new process for removing ammonia, hydrogen sulfide, and hydrogen cyanide from coke-oven gas using waste pickle liquor from steel plants was described. It is claimed that the equipment required for the process is relatively simple, and the cost of the installation can be repaid in a few years through the recovery of the chemical components.

A pilot-scale experimental coke oven was built and placed in operation by the Eastern Gas & Fuel Associates at its research laboratory, Everett, Mass. This oven, designed after protoypes such as those in use by the Illinois Geological Survey, the Bureau of Mines, and steel companies, is claimed to contain many modifications that

contribute to ease and convenience of operation. 16

WORLD REVIEW 17

World production of coke is shown in tables 41 and 42. includes only coke made at high temperatures in conventional slottype and beehive-coke ovens. Data on coke made from coal in all other types of carbonizing equipment, such as low-temperature carbonizers and coal-gas retorts, are summarized in table 42. In some countries coke made in slot-type and beehive-coke ovens is called hard coke, metallurgical coke, and other names. As this type of coke is generally used in industrial applications it is a fairly good barometer of the industrial activity of the producing and consuming countries.

otherwise specified, this discussion covers such coke only.

World production of coke declined slightly in 1954 from the record output of 1953, principally because of the decline in the United States. In 1954, as in prior years, the United States led all countries in coke production, but the proportion of the world total produced by the coke ovens in the United States dropped. The United States produced about 26 percent of the world total in 1954 compared with 36 percent in 1950. Although precise data on coke production in the U. S. S. R. are not available, Government estimates based on reports from various sources indicate that this country ranked second in 1954. Coke production in the U.S.S.R. has increased faster in the last 5 years than anywhere else in the world. Production in West Germany has also increased rapidly since the end of World War II. Although production there declined slightly from 1953, the rate of production was about the same as in the years preceding the outbreak of World War II. The Ruhr district in West Germany was again one of the greatest coke-producing centers in the world. Before World War II this district, which is slightly smaller than metropolitan Chicago, produced more coke than any other country of the world except the United Even in 1954, when nearly every other European country had expanded coke capacity, the production in the Ruhr exceeded that

of every country except the U.S.S.R., and was 21 percent of the total European output.

As shown in table 41, the countries of Europe produced more coke in 1954 than all other continental groups combined. The countries in

Includes breeze.

Less than 500 tons.

'Year ended June 30 of year stated.

COAL-CHEMICAL MATERIALS

GENERAL SUMMARY

Coal-chemical materials include a variety of products recovered from the gases and vapors evolved during the distillation of coal in slot-type coke ovens. The principal or basic chemical raw materials are ammonia, crude tar, crude light oil, and coke-oven gas. Coke-oven gas is not generally processed in the United States for the manufacture of chemicals, but research initiated in 1954 may make possible its extensive utilization in the future (see section on Technology). Ammonia, crude tar, and crude light oil, particularly the last two, are further processed and supply a substantial part of the coal chemicals used by American industry.

The phenomenal growth of the chemical industry in the past 2 decades has increased the requirements of chemical raw materials. Expanded markets have stimulated interest in the manufacture of coal chemicals, and coke-oven operators have installed new equipment and developed improved techniques for producing larger quantities and purer products to meet the exacting specifications for these chemicals.

Crude light oil and its derivatives were the principal revenue producers among the coal-chemical materials. Benzene—the most important of the derivatives—supplied 18 percent of the revenue obtained by coke-oven operators from the sales of all chemical materials, including coke-oven gas. Although the dollar value assigned to surplus gas (table 43) was larger, approximately two-thirds of the

² Production data for China, Mexico, Rumania, and U. S. S. R. are not available; estimates for these countries included in total.

surplus gas was used by the producing companies as boiler fuel or in steel or allied plants. Commercial sales of coke-oven gas (distributed through city mains and sold for industrial use) contributed slightly more revenue than did the commercial sales of ammonia products. Sales of crude tar and its derivatives totaled over \$50 million, most of which was supplied by the sale of crude tar itself. However, the pitch made and used by the producing companies has not been assigned a value, and pitch, which is generally used as a fuel in metallurgical furnaces, comprises a substantial part of the products obtained in processing tar. If this portion were assigned the same average unit value as that for the amount sold, the value of tar and derivatives would exceed the value contributed by the light-oil group.

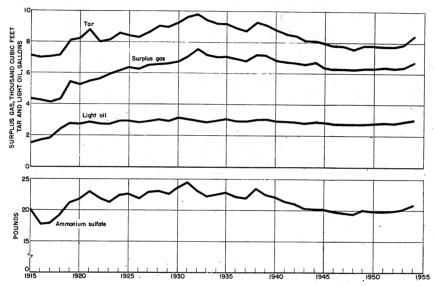

FIGURE 2.—Average yield of principal coal-chemical materials per net ton of coal carbonized in coke ovens, 1915-54. Yields of light oil and ammonium sulfate equivalent represent average for plants recovering these products.

The percentage of coal costs recovered by coal-chemical materials in 1954 increased over 1953 and equaled 38 percent of the value of coal carbonized. However, immediately before World War II the value of the coal-chemical materials used and sold was approximately 55 percent of the coal cost. Commercial sales of coke-oven gas then, however, represented about two-thirds of the value of the surplus gas and one-third of the value of all coal-chemical materials used and sold. Figure 3 illustrates the trend in values supplied by chemical materials, surplus gas, and coke and breeze. Detailed statistics on production and sales of coal-chemical materials are shown in table 43.

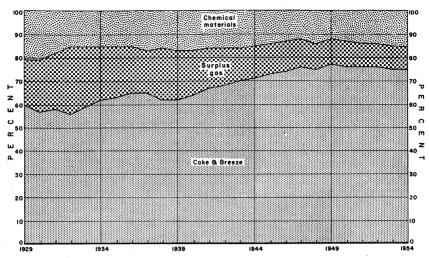

FIGURE 3.—Percentage of total value of coke-oven products from slot-type ovens supplied by coke and breeze, surplus gas, and chemical materials, 1929-54.

TABLE 43.—Coal-chemical materials produced at coke-oven installations in the United States in 1954 $^{\rm 1}$

I Includes products of tar distillation conducted by coke-oven operators under same corporate name.

Includes 28,059,083 gallons sold to affiliated companies for refining.

Water-softening point, less than 110° F.

Water-softening point, 110° to 160° F.

Water-softening point, over 160° F.

Cresols, cresylic acid, pitch coke, resin oil, road tar, tar paint, and topped or refined tar.

Includes small amount of ammonium thiocyanate.

Includes gas used for heating ovens and gas wasted.

233,983,106 gallons refined by coke-oven operators to make derived products shown.

COKE-OVEN GAS

Slot-type coke ovens produce more gas than all other types of gas-manufacturing equipment combined. After removal of ammonia, tar, and light oil approximately 17 percent by weight of the coal charged into ovens is recovered in the form of fuel gas. About one-third of the gas recovered is used to heat the ovens, and the remainder (surplus gas) is consumed by the producing companies as fuel under boilers and in integrated metallurgical operations by neighboring industrial plants, or is pumped through city mains for commercial and residential heating and cooking. The relative value of gas to cokeplant operators varies according to the type of establishment. Coke plants associated with iron and steel works can either sell some of their surplus gas to gas utilities or use the entire output in their own metallurgical furnaces, depending on business and economic conditions. In 1954 furnace plants used 90 percent of their surplus gas, mostly

in open hearths and annealing furnaces. In spite of the large proportion used by the furnace plants, they still supplied two-fifths of the total quantity of coke-oven gas distributed through city mains.

Merchant oven-coke plants do not, as a rule, have as much flexibility in their gas operations as the furnace plants do. Consequently, whenever a merchant plant loses its market for gas, continued operation is difficult. When coke plants are owned by gas utilities, the substitution of natural gas for coke-oven gas only alters the kind of gas distributed by the utilities involved. Then if continued operation of the coke ovens is not feasible, they are retired permanently or sold to other interests, if the plant is located favorably to a large coke-consuming operation, such as a blast-furnace plant. In 1954 the proportion of surplus gas sold by merchant plants was about the same as in preceding years. However, the proportion of gas sold by both merchant and furnace plants to the total surplus was less. This illustrates the continuing trend, of a declining market for coke-oven gas, which started in 1948. The average value of coke-oven gas per 1,000 cubic feet increased slightly over 1953.

CRUDE COAL TAR AND DERIVATIVES

Crude tar is a black, viscous liquid that condenses from the volatile matter during the carbonization of coal. The yield of tar varies widely among the various coke plants, depending on the kind of coal carbonized, oven temperature, completeness of tar recovery, and other factors. The yield of tar in 1954 improved markedly over 1953, rising from 7.90 gallons to 8.46 per ton of coal carbonized. This was the highest tar yield since 1941 and was no doubt caused by the general reduction in over temperatures at most plants. The accompanying table shows the high-volatile coals of the Western States rank high in tar yield, as do the coals carbonized in West Virginia and Pennsylvania. Coke plants in Pennsylvania produced 32 percent of the crude tar in 1954, whereas this State produced only 26 percent of the oven coke.

Crude tar has a high calorific content and may be used as a fuel in industrial furnaces or fractionally distilled into various tar products. Small coke plants cannot as a rule profitably erect and operate tardistilling plants. The larger coke plants usually are associated with iron and steel works and burn, sell, or distill the crude tar, depending on the economics involved. The spectacular growth of the chemicals industry in recent years has increased the requirements of coal-tar crudes and created more interest in the processing of crude tar. In 1954 several tar-distillation plants at furnace oven-coke plants began operation. In such plants the tar can be processed to remove tar acids, bases, and naphthalene, and the residue or pitch can still be utilized as fuel in metallurgical furnaces.

I Includes 5,848,047 gallons also shown under "Sold for refining into tar products."

2 Comprises 26,505,063 gallons valued at 85,062,492 sold to affiliated companies and 327,819,586 gallons valued at \$35,424,690 sold to other purchasers

Included with "Undistributed" to avoid disclosure of individual company figures.

Includes 10,990,805 gallons sold for fuel.

COKE-OVEN AMMONIA

Ammonia evolved during the carbonization of coal is recovered at coke plants either as a water solution (ammonia liquor) or as a crystallized sulfate of ammonia. At the end of 1954 it appeared that the coke industry might soon be producing another ammonia product, diammonium phosphate (see section on Technology), but no commercial output was reported in 1954. One plant which produced ammonium sulfate also made ammonium thiocyanate, but production figures for this product cannot be shown. In 1954, 80 of the 82 active oven-coke plants recovered ammonia; 67 made ammonium sulfate and 15, ammonia liquor; and 2 plants produced both sulfate and liquor. About 93 percent of the total ammonia produced was recovered as ammonium sulfate and used almost exclusively for agricultural purposes. The merchant-coke plants recover a larger proportion of their ammonia as an aqueous solution (ammonia liquor) and produced nearly two-thirds of the total liquor output in 1954. Ammonia liquor produced by coke-plant operators is utilized for chemical and agricultural purposes. Although data are not available on the quantity of ammonia liquor used for each purpose, it is estimated that over half is consumed industrially in manufacturing soda ash, ammonium chloride, and sulfuric acid.

CRUDE LIGHT OIL AND DERIVATIVES

Crude light oil was scrubbed from coke-oven gas by 77 of the 82 active oven-coke plants in 1954. Crude light oil can also be obtained by distilling crude coal tar; but this method is not practiced in the coke industry, as the yield of light oil in most instances is too small to justify the cost of separation. The light-oil yield increased almost 0.1 gallon per ton of coal carbonized and averaged 2.98 for the industry, the highest yield since 1939, when the yield was 2.99 gallons. Lower oven temperatures, improved equipment, and better coal were factors in increasing the yield. In addition to the crude light oil, 12 plants produced 2,907,059 gallons of intermediate light oil. This product, which is sold to chemical companies for processing, distills between roughly 150° and 200° C. and contains coumarone, indene, dicyclopentadiene, polyalkylbenzenes, and naphthalene. An analysis of table 52 shows that light-oil yields are related to tar yields, and the States having the highest tar yield also led in light-oil recovery.

Crude light oil is usually processed by the producing companies in integrated facilities. Most oven-coke plants have a benzol plant which fractionally distills light oil into benzene, toluene, and xylene. Saleable products recovered from the distillation usually range between 80 and 90 percent. The difference between the total of refined products and crude-light-oil input represents loss in processing and residue. The still residue in some instances is mixed with tar and used as fuel.

The principal derivative of light oil is benzene, one of our most important aromatic chemical raw materials used in the chemical industry. Roughly two-thirds of the light oil distilled is recovered as benzene. Benzene used to produce intermediate products and as a solvent must meet rigid standards and is referred to as specification

¹ Number of plants that recovered ammonia. 2 Included with "Undistributed" to avoid disclosure of individual company figures. 2 Difference between actual production of sulfate and sulfate equivalent due to transfer of liquor from Indiana for conversion into sulfate in Illinois by same producing company.

The most important grades are nitration (1° C.) and industrial (2° C.), which are used mainly for manufacturing intermediate organic chemical products; these in turn are used to manufacture resins, drugs, dyestuffs, pharmaceuticals, and explosives.

In 1954 the Chemical and Rubber Division, Business and Defense Services Administration, made a canvass of the capacity, production, and consumption of benzene, by uses. Data on capacity and production of coke-oven benzene were supplied to that agency by the Bureau Table 55 contains data compiled by BDSA on the principal uses of benzene. Styrene production consumed the largest quantity of benzene in 1954, although the total consumed was less than in 1953. The second largest use of benzene is in the production of synthetic

phenol, which increased in 1954 over 1953.

Benzene production at coke plants decreased 20 percent from 1953 because of the substantial decrease in crude-light-oil output resulting from the reduction in oven operation already mentioned in previous sections of this chapter. Although coal carbonization was the sole source of benzene during World War II and in the immediate postwar years, a large part of the 1954 supply in the United States was obtained from the cracking and re-forming of petroleum. Based on preliminary data published by the United States Tariff Commission, it appeared that about 60 percent of the benzene produced from raw materials originating in the United States came from coal.

 Excludes 14,647,521 gallons of crude light oil valued at \$3,495,456 sold as such.
 Included with "Undistributed" to avoid disclosure of individual company figures.

xylene are other light-oil derivatives that were previously produced by the carbonization of coal, but are now made chiefly from petroleum. The 33,383,028 and 9,956,303 gallons of toluene and xylene, respectively, made at coke plants in 1954 were roughly 22 and 8 percent of the total United States production of these aromatic chemicals.

Prices of the light-oil products fluctuated little from 1953, although the market quotation for benzene declined in the last several months

of the vear.

CRUDE NAPHTHALENE

The coke industry supplied the raw materials for nearly all naphthalene produced in the United States in 1954. This aromatic material, which was considered a nuisance at one time, has become one of the most important coal chemicals. The principal use of naphthalene is in manufacturing phthalic anhydride, which in turn is used to make alkyd resins and phthalate plasticizers. The alkyd resins are used mainly for automotive and other metal finishes, house and marine paints, surface coatings for military vehicles and equipment, and ammunition. Plasticized vinyl resins are the basis for vinyl film and sheets, floor coverings, coated fabrics, and inflatables. Other uses are in the manufacture of dyes, mothballs, and other insecticides, tanning agents, surfactants, oil additives, and medicinals. Naphthalene is recovered at coke plants from refining crude light oil or tar and to a smaller extent from the final coolers. The commercial grades of naphthalene are defined in terms of melting points. The crude grades range from 74° to 79° C. and are suitable for some industrial applications without further refining. Crude below 74° C. has virtually no direct commercial use and is sold by the coke-plant operators to tar refiners for upgrading or refining. In recent years several large coke plants have installed tar-refining facilities to remove naphthalene from the crude tar at the plant. Naphthalene recovered from light-oil refining, which was formerly sold to independent tar refiners for upgrading, is now processed by these companies in their new equipment. The change in quality of naphthalene produced by coke-oven operators is indicated in table 43. Over three-fourths of the crude naphthalene produced was of the better grades and was sold for direct application by the coke-oven operators.

COKE OVENS OWNED BY CITY GAS COMPANIES

(PUBLIC UTILITIES)

Data on the carbonization activities of oven-coke plants owned and operated by gas utilities are shown in table 58 which also provides comparable data for plants that are not owned by city gas companies. The manufacture of coke-oven gas by city gas companies has declined steadily in the past decade. In 1954 city gas companies produced less than 2 percent of the oven coke, 2 percent of the crude tar, 1 percent of the crude light oil, and 2 percent of the coke-oven gas produced in the United States. After the Consolidated Edison Co. of New York closed its Hunts Point, N. Y., plant in May 1954, only four coke plants were still operated by gas utilities. It appeared likely that several of these plants would also be shut down soon because the rapid increase in peak-load demands in certain areas precludes the mixing of natural gas with coke-oven gas.

Fuel Briquets and Packaged Fuel

By J. A. DeCarlo and Maxine M. Otero

GENERAL SUMMARY

RODUCTION of fuel briquets and packaged-fuel cubes or blocks continued to decline in 1954, a trend that began in 1949 for briquets and in 1941 for packaged fuel. Output of fuel briquets dropped 9 percent from 1953 and packaged fuel 3 percent; consequently, production of each of these processed fuels was the lowest in 15 years. Both fuels are used principally for space heating in the United States, and little, if any, is used industrially. The volume of production, therefore, depends on the demand of homeowners. recent years oil and natural gas have made heavy inroads into fuel markets formerly served by briquets and packaged fuel, primarily because consumer prices for briquets and packaged fuel have risen faster than natural-gas prices. The annual index of retail prices of specified fuels and electricity, published by the Bureau of Labor Statistics, show that the index number for natural gas (1947-49=100) climbed from 101.2 in 1935 to 109.3 in 1954. In this same period the index numbers for bituminous coal and anthracite, the two principal raw materials used to make briquets and packaged fuel, rose from 54.4 to 119.2 and from 58 to 128.9, respectively. The large gains in consumer prices for these solid fuels have weakened their competitive position in residential heating. A great number of handfired furnaces and other heating equipment are in use, however, for which briquets and packaged-fuel cubes are ideally suited, and the cleanliness and ease of handling still make them attractive.

Low-volatile bituminous coal was the principal raw material used in both fuel-briquet and packaged-fuel manufacture in 1954. Other raw fuels were: High-volatile bituminous coal, anthracite, semianthracite, petroleum coke, and residual carbon from the manufac-

ture of oil gas.

Briquets and packaged fuel differ widely, however, in the kind of binding material used. Petroleum asphalt is the principal binder used in making briquets, whereas starches from wheat, corn, and even potatoes are used in making packaged fuel. In the manufacture of briquets an average of 140 pounds of asphaltic binder was used per ton of raw fuel, whereas only 13 pounds of starch per ton was used in making packaged fuel. It was estimated that the briquet industry used about 105,000 tons of petroleum asphalt and packaged-fuel producers about 400 tons of starches.

The total value of briquet production declined 9 percent and of packaged fuel 5 percent from 1953, because of decreased output and a slightly lower average unit value. The value of briquets

dropped \$0.06 per ton f. o. b. plant and packaged fuel \$0.40. average unit value for packaged fuel was considerably higher than for briquets because of higher material and manufacturing costs and because of a difference in marketing methods. Nearly all packaged fuel is sold by retailers to ultimate consumers in small lots, whereas a substantial part of the fuel-briquet output is sold by producers to wholesalers and retailers.

SCOPE OF REPORT

Except where otherwise noted, the statistics in this chapter are based on data voluntarily supplied to the Bureau of Mines by the manufacturers of fuel briquets and packaged fuel within the continental limits of the United States. Data on fuel briquets have been collected and published without interruption since 1907, when the Federal Geological Survey began an annual canvass of the industry. Statistics on packaged fuel, however, go back only to 1935. Briquets made from charcoal, wood scraps, and fruit pits are not included in the Bureau of Mines review. The production totals of fuel briquets and packaged fuel for 1954 will be compared with the Bureau of the Census totals for these commodities when they become available. Differences in the totals will be adjusted or explained in a subsequent release.

In 1954 questionnaires were sent to 33 fuel-briquet plants, and returns were received from 32. In the packaged-fuel industry 50 plants were canvassed, with replies from 44. In no instance was an attempt made to estimate for the nonreporting plants. For both fuel-briquet and packaged-fuel plants the companies that did not reply were small, operating intermittently in previous years, and were assumed to be idle in 1954.

The standard unit of measurement used in this report is the short

or net ton of 2,000 pounds.

FUEL BRIQUETS CAPACITY

The annual productive capacity of the fuel-briquet industry declined slightly during 1954 and at the end of the year totaled 4,161,000 tons. The slight drop (55,000 tons) in capacity was due largely to the closing of 1 plant, which reduced the number of active plants to 25, the smallest number active since 1930. This was the 11th fuel-briquet plant to discontinue operations since December 31, 1948. Virtually all of the plants that have gone out of production have had a designed capacity of less than 25,000 tons per year, and the number of plants with less than 25,000 tons' capacity dropped from 8 in 1948 to only 1 in 1954. However, the number of larger plants, or those with a designed annual capacity of 100,000 tons or more, has not changed

during the same period. This trend has resulted in an increase in the average capacity of the industry from 130,000 tons per plant in 1948

to 166,000 tons in 1954.

The rate of operation of the larger plants is generally higher than in the smaller plants. The decline in demand for fuel briquets, however, in the past 5 years has caused the rate of production of all plants to decrease steadily. The 1954 production rate was the lowest since 1940 and was 23.2 points less than the 1950 rate and 3.2 points less than the rate in 1953 (table 3).

PRODUCTION

Production of fuel briquets in 1954 decreased 9 percent from 1953 and was the lowest since 1941. Briquets are used principally for residential heating in the United States, and monthly output varies widely during the year. Production is higher during the winter and declines during the spring and summer. The principal centers of production are the low-volatile bituminous and anthracite mining areas and the area around the docks along the Great Lakes. Low-volatile bituminous coals contain high heat values but are generally quite friable and, when mined and transported, yield a large quantity of fines. The fines can be briquetted and make an excellent fuel for either hand firing or stoker use. Areas where considerable quantities of these fines constantly accumulate are at the docks in Wisconsin and the mining districts in southeastern West Virginia. The culm banks in the anthracite-mining region of Pennsylvania also provide raw material for briquetting. Plants in Wisconsin produced about one-third and West Virginia plants about one-fourth of the total United States output in 1954; these 2 States produced 64 percent of

the national total. Missouri, using mostly low-volatile coals from West Virginia, ranked third in production, principally because of the St. Louis smoke-abatement ordinance. Other States that produced considerable quantities of briquets were Pennsylvania, Oregon, and Michigan.

TABLE 4.—Production and value of fuel briquets in the United States, 1953-54, by areas

Raw Fuels.—Briquets are produced from a wide variety of solid fuels, such as lignite char, bituminous coal, anthracite, semianthracite, petroleum coke, and residual carbon from the pyrolysis of oil. Low-volatile bituminous coal was the predominating raw material used in 1954 and represented 58 percent of the total raw fuels bri quetted. West Virginia and Wisconsin are the leading States that utilize low-volatile bituminous coal; they converted 89 percent of the total into fuel briquets. Pennsylvania anthracite, which was the leading fuel used in manufacturing briquets during World War I, ranked second in 1954, and the quantity so used was 17 percent of the total. Petroleum coke was the only raw fuel for briquetting that increased substantially in use—from 73,366 tons in 1953 to 162,744 in 1954, or 122 percent. Most of this increase occurred in the Central States bordering the large petroleum-refining center of Chicago.

Residual carbon has been converted into briquets on the west coast for many years because of the large quantities available from the manufacture of oil gas; however, as only 1 plant in Washington and 1 in Oregon report use of residual carbon, the quantity used cannot be shown separately but is included with lignite char used by

1 plant in North Dakota.

Binders.—A number of binders can be used in manufacturing fuel briquets. The principal requisites for a satisfactory binder are (1) it must be inexpensive, (2) it must be substantially water insoluble and weather resistant, and (3) it must not significantly increase the ash content of the coal or reduce its heating value. Petroleum asphalt in general, meets all of these standards and is used almost exclusively by briquet plants in the United States. Two plants making briquets from residual carbon reported that no binding material was used. Of the plants using binders, only one plant used coal-tar pitch in addition to petroleum asphalt. It was estimated that 105,000 tons of petroleum asphalt was used for briquetting in 1954.

SHIPMENTS

Fuel briquets were consumed in 35 States, the District of Columbia, Alaska, and 3 foreign countries in 1954. As it may be safely assumed that the fuel briquets are ultimately consumed in the States where shipments terminate, or the State of destination, the terms "distribution" and "consumption" are used synonymously in this chapter. As a rule, briquets are tough and strong, withstand handling and transportation, and can be shipped great distances. Wisconsin, the leading producing State, also led in consumption, and 16 percent of the total quantity distributed by the producing companies in 1954 was destined to briquet consumers in this State. Virtually all of

the briquets consumed in Wisconsin were produced within the State, whereas less than 1 percent of the total produced was consumed within West Virginia, the second largest producing State. Virginia shipped briquets to 16 other States and Canada, and 76 percent of the shipments went to Michigan, Indiana, Ohio, and Illinois. Although Missouri trailed West Virginia in production, it ranked second in consumption, principally because of the large quantities used in metropolitan St. Louis. Michigan ranked third in consumption and received 65 percent of its briquets from West Virginia. Other leading consuming States were Minnesota, Indiana, and Illinois, which together consumed 22 percent of the total distrib-Canada was the principal export market and received 8 percent of the total quantity shipped. Data collected by the Bureau of Mines on exports of briquets (table 8) differ from those compiled by the United States Department of Commerce, Bureau of the Census (table 10), because the Bureau of Mines includes briquets made from residual carbon and petroleum coke, whereas the Bureau of the Census excludes these data.

§An additional 260 tons was used by 2 producers as fuel at their plants in 1953 and 2,718 tons by 2 producers in 1954.

VALUE

The total sales value f. o. b. plants of the briquets manufactured in 1954 was \$19 million, a 9-percent decrease from 1953. "Sales value," as reported by the producing companies, varies widely because of the different local conditions under which briquets are produced and sold. The principal factors influencing the value per ton realized at any plant are costs of raw materials, labor, and price of competing fuels.

In the Eastern States nearly all of the output comes from plants in the anthracite fields of eastern Pennsylvania and the bituminous low-volatile fields of southern West Virginia, where the cost of raw fuel does not involve freight charges. This region was the only one in which the reported average value in 1954 was less than in 1953. The average unit value in the Central States increased slightly in 1954. As 78 percent of the production in this region was reported by plants along the Great Lakes, the raw fuel for these plants involves a considerable freight charge, which is reflected in higher values per ton for briquets f. o. b. plant. In the Pacific Coast States (where the raw fuels used were residual carbon from the pyrolysis of oil gas) the average per ton represented the highest values f. o. b. plant in the United States.

FOREIGN TRADE

For many years imports of fuel briquets have been small and are insignificant in the fuel economy of the United States. In 1954 only 239 tons was imported from Canada. Export data on fuel briquets were reported separately for the first time by export classification number by the Department of Commerce in 1937 and include briquets made from coal and coke only. Briquets made from other raw materials, such as petroleum coke and residual carbon, are not included. Exports of briquets, as reported by the Department of Commerce, have averaged about 6 percent of production in recent years. Canada is the principal market for American briquets and received 97 percent of the total exported in 1954. The other 3 percent went to Mexico and Chile.

TECHNOLOGY

Little was published in 1954 relating to research on the briquetting of fuels in the United States. The Fourth Biennial Briquetting Conference was held at Estes Park, Colo., on September 1–3. Representatives of producers, equipment manufacturers, asphalt suppliers, and research organizations attended. Papers were presented from the United States, Canada, Mexico, and France. A résumé of the more important papers given at this conference will be published in

the 1955 chapter.

The Central Research Establishment of the National Coal Board of Great Britain announced development of a method of briquetting coal between 250° and 450° C. by using a compound binder. This compound binder is a mixture of coal and a substance that becomes plastic at a lower temperature than the coal itself. This could be a coal tar or a coal-tar byproduct, such as pitch, or it could be a petroleum bitumen or other byproduct of petroleum, or tar and oils recovered from the distillation of wood. The amount of binder required and the initial strength of the briquets are governed chiefly by the composition of the compound binder and by the rank of coal used in it.

Much research and many worthwhile developments over the years in the fuel-briquetting field have emanated from Germany. A great deal of this work has been centered around the economic utilization of brown coal, which is quite plentiful in that country. A development that may promote the utilization of German brown coal and could be used in other countries that do not have coking coal, is the process for reducing iron ore developed by the Klockner-Humboldt-Duetz A. G. at Humboldt, Germany.³ In this process fine ore and noncoking coal are ground, mixed with binders, and briquetted. Tar pitch, asphalt, and sulfite tars have been used as binder materials. Ore, coal, and limestone are mixed with 6-percent tar and briquetted at about 3,500 p. s. i.

In 1954 the Anthracite Equipment Corp., a wholly owned subsidiary of Anthracite Institute, Wilkes-Barre, Pa., placed on the market a new type of packaged fuel for grilling, broiling, and barbecu-

ing. These briquets are made from anthracite fines, and are marketed in 2-pound packages. They are intended to be used without removal from the box, and no kindling or other starter fuel is required.

PACKAGED FUEL CAPACITY

The annual capacity of the packaged-fuel industry of the United States increased slightly in 1954 and totaled 243,300 tons. There were 37 active plants, the same number as in 1953. Packaged-fuel plants generally are small, as indicated in table 11, which shows that 25 plants had an annual capacity of less than 5,000 tons. The smaller plants were affected to a greater extent by the declining market for packaged fuel; as a result, the rate of production was lower than for the larger plants. The rate of production for the industry as a whole averaged 31.8 percent of capacity, or 2.4 points less than in 1953. The 4 largest plants, which produced about two-thirds of the total output, operated at 42.2 percent of capacity.

PRODUCTION

Production of packaged fuel fell 3 percent in 1954, as demand continued to decline. Except for a slight increase in production in Michigan and Virginia, output in the other producing States decreased 2 to 45 percent. Michigan, as usual, was the largest producer of packaged fuel, with 44 percent of the national output, followed by Ohio, Wisconsin, and Indiana. These 4 States produced 91 percent of the total. As packaged fuel is used exclusively for space heating,

⁴ Coal Age, Anthracite Packaged as Grill Briquets: Vol. 59, No. 6, June 1954, p. 142.

production is highly seasonal, and operations during the summer are quite low. Monthly output ranged from 279 tons in July to 11,772 tons in December.

Raw Fuels.—Low-volatile bituminous coal was the principal raw fuel used in the manufacture of packaged fuel in 1954. Small quantities of high-volatile bituminous coal, semianthracite, and petroleum coke were also used, but the quantity of these raw fuels amounted to only 7 percent of the total. Low-volatile coals have a high calorific value and burn with little smoke, but they are quite friable. This results in a large amount of fines in mining and shipping. For this reason, retail fuel dealers, wherever it is economical and markets exist, make packaged fuel from this fine material. Although nearly two-thirds of the plants used only yard screenings, the total raw material from this source is much smaller than the quantity obtained as screened slack direct from mines or from fines accumulated at loading and unloading terminals.

Binders.—Starches, in the form of corn or wheat flour, are the preferred binding materials for the manufacture of packaged fuel. In 1954 all of the plants used starches except one, which used petroleum asphalt. Starch is preferred because it makes a stronger cube or block than asphalt or pitch and does not add any ash or volatile matter to the product. Petroleum asphalt and coal-tar pitch do not add any ash but tend to make the packaged fuel smoky. The quantity of starch added to the raw fuel varied from 10 to 20 pounds per ton of coal and averaged 13 pounds for the industry. It was estimated that about 422 tons of starch was used in manufacturing packaged

fuel in 1954.

SHIPMENTS

Packaged fuel is generally used locally and is not transported long For the first time on record, there were no shipments by distances. A large part of the tonnage, specified as shipped by truck. was not actually loaded on trucks but was picked up by the ultimate consumers in their cars. The trend toward self-service in many fields of merchandising has also been adopted by some packaged-fuel manufacturers, and some producers have installed vending machines. It is claimed that vending machines reduce labor costs and permit the sale of packaged fuel in the evenings and at night.

VALUE

The total sales value, f. o. b. plants, of packaged fuel manufactured in 1954 decreased 5 percent from 1953 and was \$1,416,606. average sales value per ton decreased for the first time since 1940 but was still above the 1951 figure. The average value shown for packaged fuel is much higher than for fuel briquets because of higher manufacturing costs, as well as different marketing procedures. Most of the packaged-fuel production is retailed by the producing companies in small lots, and the value includes cost of raw materials and manufacturing as well as a margin of profit.

¹ Combined to avoid disclosure of individual company figures.
2 Some plants used more than 1 type of raw fuel, hence the sum of the plants exceeds the total shown.

WORLD REVIEW 5

World production of processed fuels (fuel briquets and packaged fuel) in 1954 was estimated at 117 million tons, a decline of 1 million tons from the record output of 1953. There was little change in the pattern of production established in prior years, and European countries continued to produce 95 percent of the world total. Fuel briquetting has developed faster in Europe than in other parts of the world because a large proportion of the coal supplies are of low grade, which, in their raw state, cannot be utilized economically. Briquetting of brown coal in Germany is a good example of how an inferior raw fuel can be improved. Briquetting of brown coal has been done on a large scale for many years, and the briquets have been used as railroad fuel, for electric power generation, and for residential heating and cooking. Much of the brown-coal reserves are in the central and eastern parts of Germany, and this accounts for the large amount of briquets that have always been produced in eastern Germany. Although the output of briquets in East Germany declined slightly in 1954, production has increased faster in this area than in any other part of the world, rising 43 percent in the past 5 years. Production of both hard-coal briquets and those made from brown coal have increased substantially in West Germany. Production of briquets in both zones of Germany amounted to over 72 percent of the world total. It was estimated that the Soviet Republic produced about 9,400,000 tons of briquets in 1954, which would place that country second to Germany in world production. In France production slipped a little in 1954 but was still over 7 million tons. These 3 countries produced 87 percent of the world output. The only other country that produced over 2 million tons was Japan, where fuel briquets are used for railroad fuel as well as for domestic heating and cooking. Other countries that produced over 1 million tons were: United Kingdom, United States, Belgium, Spain, and Netherlands.

⁵ Figures on world production compiled by Pauline Roberts, of the Foreign Statistics Unit, Division of Foreign Activities, Bureau of Mines.

Peat

By Eugene T. Sheridan and Maxine M. Otero

GENERAL SUMMARY

RODUCTION of peat in the United States in 1954 was 19 percent higher than in 1953 and almost double the 1947-49 average; it reached a new high of 243,257 net tons, valued at \$2,248,532. Imports increased also in 1954 and were 21 percent higher than in These substantial increases were due chiefly to expanding markets in the agricultural and horticultural fields. Peat is used as fuel in many European countries but is not so employed in the United States. In this country peat is principally a soil conditioner for lawns. gardens, golf courses, nurseries, and greenhouses and a filler in mixed fertilizers. It is also used as litter for barns and poultry yards and as packing material for plants, cut flowers, and certain vegetables.

The consumption of peat has increased greatly in the past 5 years and in 1954 was more than double the average consumption in 1947-During this period domestic production increased 85 percent; however, production of peat was not able to pace demand, and imports also increased greatly. Imports almost equaled domestic production in 1954. Most imported peat comes from West Germany and Canada.

Revised figure.

GOVERNMENT REGULATIONS

Since the physical and chemical properties of peat are so varied, no national standards have as yet been established for grading the various types. Peat is frequently sold in bulk, and 1 cubic yard ranges from 700 to 1,200 pounds in weight and from 30 to 70 percent in moisture content. Naturally, the organic-matter content of 1 cubic yard of peat will vary greatly, depending upon the moisture content. In January 1950, however, the Federal Trade Commission established trade-practice rules for the peat industry. These were designed to maintain free and fair competition in the industry and to eliminate and prevent deceptive practices in the sale of industry products. Practices deemed to be unfair are defined, and guidance is given as to the proper use of significant terms in marketing products. In addition, some State governments specify standards for peat that they purchase, and all peat procured by the Federal Government must conform to specifications defined in the Federal Stock Catalog (section IV, part 5) Q-P166-3 (November 1947).

A duty of \$0.25 per ton is levied on all imported peat moss classified as poultry and stable grade; however, peat moss imported for agri-

cultural purposes is duty free.

SCOPE OF REPORT

The Bureau of Mines compiled the statistical data presented in this chapter from producers' reports, collected jointly by the Bureau of Mines, United States Department of the Interior, and the Bureau of the Census, United States Department of Commerce, for 1954. Complete coverage of the industry was attempted, but undoubtedly there are some small operators who failed to submit reports. No attempt was made to estimate for these operations; however, the reports actually received probably represent almost complete coverage of commercial producers.

Eighty-five companies, in 21 States, submitted reports for 1954. These reports requested the name and location of the operation, production figures by types, sales by uses, and total selling price or value at the plant, by types and by uses. No information is collected on

stocks, as producers do not normally stock peat.

The production figures have not been adjusted for moisture and are on an air-dried basis only. Although peat is usually sold in bulk by cubic yard or by bale, the unit of measurement in this chapter is the net (short) ton of 2,000 pounds.

The 3-year period 1947-49 is used as a base for measuring production

and consumption trends.

RESERVES

The United States has extensive reserves of peat. Peat and muck lands total about 79 million acres ¹ and contain about 13.8 billion net tons. The northern region, which includes New England, the Middle Atlantic States, and those bordering the Great Lakes, as well as Iowa, contains 80 percent of the total deposits. Minnesota alone has 49 percent of the reserves, and Wisconsin and Michigan together have 25 percent. The Atlantic coastal region contains 20 percent of the total peat reserves, of which Florida has 14 percent. The Pacific Coast and Gulf States contain less than 1 percent of the total reserves.

The chemical and physical properties of peat vary greatly, depending upon the kinds of plants from which it was formed, on their degree of decomposition, and on climatic conditions in the area. The most extensive deposits in the United States are of the sphagnum or moss-

¹ Anderson, M. S., Blake, S. F., and Mehring, A. L., Peat and Muck in Agriculture: U. S. Dept. of Agriculture Cir. 888, October 1951. 31 pp.

261 PEAT

peat type. This type is formed from the remains of mosses, grasses, sedges, heath shrubs, and trees and is usually fibrous, elastic, and light in color. Moss peat abounds in northern Minnesota, Wisconsin, Michigan, and New England. Most of the peat found in other States of the northern region are similar in texture but are usually more fibrous. All the moss-type peats normally have a strongly acid reaction. Reed and sedge peat is formed from reeds, sedges, cattails, and other swamp plants and is found principally in shallow areas near lakes and ponds and in swampy meadows. It is also formed in the salt marshes along the New England coast. The peat of the Atlantic coastal region was formed mainly from material derived from the roots, trunks, and branches of trees and shrubs, which became mixed with the remains of leaves, ferns, and rootlets. At least half of the peat deposits in Florida are in the Everglades, and this peat is composed largely of the remains of a sedge called sawgrass.

 Exclusive of Florida.

PRODUCTION

Eighty-five companies in 21 States reported commercial production of peat in 1954; this was 17 more than in 1953. Washington produced the greatest amount of peat in 1954, supplying about 20 percent of the total production, and Florida was second with 15 percent. Production in Washington and in Florida was about one-third greater than in 1953.

Sixty percent of the peat produced was reported as peat humus. Reed or sedge composed 27 percent; peat moss, 11 percent; and "other types", 2 percent. In 1953 peat humus composed 54 percent of the total production; reed or sedge, 37 percent; and moss peat (including that listed as other types), 9 percent. About 85 percent of the peat produced was prepared for use by screening, shredding, pulverizing, or other processing.

CONSUMPTION AND USES

As in previous years, most of the peat produced in the United States was used for soil improvement. Peat used for this purpose represented 83 percent of the total quantity sold in 1954. The amount sold for soil improvement was 35 percent more than in 1953 and 46 percent more than in 1951. Peat is not a natural fertilizer but is used principally as a soil conditioner. Although some peats contain a relatively high percentage of nitrogen, it is not readily released as plant food like the "soluble nitrogen" of artificial fertilizers. however, tends to improve the physical condition of heavy-textured soils and improves their moisture-holding qualities. Sphagnum peat is especially effective for retaining water in soils.

Peat is also used as a filler and conditioner in the manufacture of mixed fertilizers. Some fertilizer materials are hygroscopic; and, to reduce stickiness and caking, dry finely-ground peat is added. The peat will absorb from the fertilizer particles some of the moisture normally absorbed from the air. It also acts as a makeweight material to fill out the fertilizer formula. Approximately 15 percent of the total amount of peat sold in 1954 went into the manufacture of

PEAT 263

fertilizers. Approximately 20 percent of the total amount sold from

1951 through 1953 was used for this purpose.

Because of its moisture-absorbing qualities and deodorizing capacity, peat is employed as litter material for poultry and as bedding for horses and cattle. A small amount is also used for packing plants, cut flowers, eggs, and other fragile materials for shipment. Some peat is used for filtering purposes, but the quantities consumed are small, and accurate figures are not available.

¹ See table 1, footnote 1.

VALUE AND PRICE

The average values of peat produced and sold are based upon producers' selling prices at the plant. Reed and sedge peats had the highest average value per ton, moss peat ranked second, and humus was third. The average value for reed and sedge peat in 1954 was \$4.56 per ton, or 52 percent higher than in 1953. Moss peat declined \$1.65 per ton or 14 percent, while humus increased \$0.56 per ton or 8 percent.

The average selling price in the United States for peat of all types in 1954 was \$9.28 per ton. This was 11 percent higher than the \$8.34 per ton in 1953. Peat sold for use as a soil conditioner brought the lowest price per ton, and peat sold for "other uses" brought the highest. Some of the peat listed as sold for "other uses" was marketed in small packages for household plants and averaged as much as \$50.00 per ton. This, of course, influenced the average for this group.

¹ Less than 1 ton.
² Due to changes in tabulating procedures by the U. S. Department of Commerce, data known not to be strictly comparable to those for earlier years.

² Figures on imports compiled by Mae B. Price and Elsie D. Page, of the Division of Foreign Activities Bureau of Mines, from records of the U. S. Department of Commerce.

PEAT 265

Department of Commerce classifies imported peat into two grades, (1) poultry and stable and (2) fertilizer. Most imported peat was "fertilizer grade", and in 1954 only 8 percent was "poultry and stable grade." Peat from West Germany constituted 58 percent of total imports, and Canada supplied 37 percent. German imports were one-fifth greater and Canadian imports one-third greater than in 1953. A small amount came from the Netherlands and insignificant amounts from Ireland, Sweden, and the United Kingdom. Imported peat is almost entirely of the moss-peat type.

TECHNOLOGY

Technological progress is greatest in those countries that are forced to use peat for fuel. For many years peat has been effectively and economically burned for steam raising in some foreign countries. The use of peat in boiler furnaces is successfully carried out in U. S. S. R., where, it is claimed, peat fuel is used to generate 30 percent of all electric energy. In U. S. S. R., Ireland, Sweden, and Germany the use of peat as a fuel has progressed from small, hand-fired furnaces using machine peat to present-day automatic furnaces using finely ground milled peat as a pulverized fuel.

The carbonization of peat to recover char, tar, and other byproducts has been studied in many countries, particularly in Ireland, Sweden, and Germany. Germany did extensive research during World War II on low-temperature carbonization of peat, and Sweden has been carrying on experiments during the past few years on this phase of peat utilization. Phenols may be extracted from peat tars, and the demand for phenols could place peat in a favorable position as a source of raw

material for the phenol-aldehyde plastics.

At the International Peat Symposium in Dublin, Ireland, in 1954, G. C. Ackroyd of the British Fuel Research Station reported that recent studies of peat wax in Britain now suggest interesting possibilities for a greater chemical utilization of this relatively abundant raw material. He stated that peat wax is a complex mixture of organic compounds of high molecular weight, and their molecular structure suggests potential chemical uses, possibly the production of plastics. D. MacDougall, also of Britain's Fuel Research Station, reported on other studies of the use of peat for gasification. Milled peat, consisting of sphagnum, cotton grass, and heather mixture, was dried to 16 percent moisture and fed with a stream of superheated steam into a gasification chamber operating at 800° C. In this process a type of gas similar to that obtained from low-grade coal was made.³

WORLD REVIEW 4

The estimated world production of peat in 1954 remained the same as in 1953, with a total of 59 million tons. Production in all countries. was essentially the same, except that production increased 19 percent in the United States and decreased 5 percent in Denmark. Production varied slightly in several other countries, but the amounts produced were insignificant.

Chemical and Engineering News, Wax from the Bogs: Vol. 32, No. 33, Aug. 16, 1954, p. 3271.
 Figures on world production compiled by Pauline Roberts of the Foreign Statistics Unit, Division of Foreign Activities, Bureau of Mines.

The U.S.S.R. produced approximately 50 million tons or 85 percent of the estimated world total. Large quantities are used in U.S.S.R. generating electric power. Ireland, the Netherlands, Germany, and Denmark together produced about 7½ million tons or 13 percent, and the remaining peat-producing areas of the world produced only 2 percent of the total.

Most of the peat produced is used for fuel purposes. Only Canada, Sweden, West Germany, and the United States use significant amounts for agricultural purposes, but these are negligible compared with

total world production.

Much peat is used in Europe as a household fuel. It is also burned effectively and economically for steam raising and for central heating in foreign countries. As stated previously under Technology, Ireland, Sweden, and U. S. S. R. have made notable advances in the use of peat for firing steam boilers, and several power plants in these countries use peat for fuel.

B. Petroleum and Related Products Carbon Black

By Donald S. Colby and Ann C. Mahoney

GENERAL SUMMARY

CARBON-BLACK shipments, which had declined in the latter part of 1953, remained low in 1954 until after settlement of the labor strike that occurred in the rubber industry in July and August.

The production of new model automobiles in the last quarter of the year spurred the demand for rubber tires and consequently the demand for carbon black. Total shipments of 1,498 million pounds for the

year were 4 percent below 1953.

Production was cut back faster than sales declined in order to reduce the large stocks of carbon black that had accumulated in 1952 and 1953. Consequently, stocks were reduced 89 million pounds in 1954.

Furnace blacks supplied over 80 percent of the shipments to rubber companies and for the first time exceeded contact blacks in quantity

exported.

Furnace blacks were preferred for use in both synthetic and natural rubber, and the increase in the ratio of natural to synthetic consumed in 1954 had no significant effect on the relative demand for furnace and contact blacks.

SCOPE OF REPORT

Annual statistics of the carbon-black industry were obtained from reports submitted to the Bureau of Mines from all operating plants in the United States by producers who represent 100 percent of commercial production. Carbon black is a very pure grade of quasi-

graphitic carbon, with particle diameters ranging from 50 to 5,000

Ångstrom units.

Export and import figures are compiled by the United States Department of Commerce. Monthly figures are based on reports prepared by the National Gas Products Association and adjusted to agree with the annual reports received by the Bureau of Mines.

Data are obtained on furnace and contact blacks, the two general types produced commercially. Substantially all contact blacks are made by the channel process. Furnace blacks are broken down into six grades: Semireinforcing Furnace (SRF), High-Modulus Furnace (HMF), Fast-Extruding Furnace (FEF), High-Abrasion Furnace (HAF), Thermal, and Other. Statistics on Superabrasion Furnace (SAF) and Intermediate-Abrasion Furnace (ISAF) are included in Other. The production and uses of the various grades are described in Minerals Yearbooks 1948 and 1949.

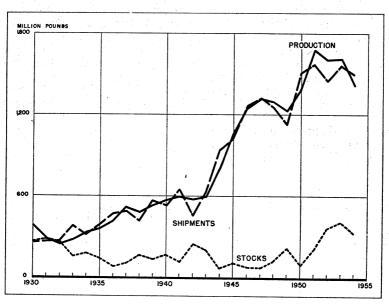

FIGURE 1.—Production, stocks, and shipments of carbon black, 1930-54.

PRODUCTION

Number and Capacity of Plants.—Four contact-type plants that produced in 1953 were idle in 1954. All were in Texas—three of them in the Panhandle. Combined capacity of these 4 plants was 119,300 pounds per day. Contact-type plants operating at the end of 1954 totaled 23, with a daily capacity of 1,134,000 pounds.

Two new oil-black furnace plants having a combined capacity of 200,000 pounds per day began operations in 1954; one was in Louisiana, the other in Oklahoma. Total number of furnace-type plants operating at the end of 1954 was 27, with a capacity of 4,157,500 pounds per day. The increase in overall furnace capacity was less than the capacity added by the new plants, because some plants

Detail will not add to totals, because some producers operate in more than 1 area.
 Partly estimated.

were producing new types of Superabrasion blacks, the processing of which results in lower yields.

Producers.—The number of carbon-black producers was reduced by 1 to 15 in 1954 with closing of the Combined Carbon Co. plant.

Method and Yield.—The production of oil and contact blacks was cut back more severely than gas-furnace-black production in 1954 partly because of the large withdrawals of channel and oil-furnace The decline in HAF production was offset by grades from stocks. increased output of Superabrasion-Furnace (SAF) and the related Intermediate-Abrasion-Furnace (ISAF) grades of oil black. The statistics of the Superabrasion grades are included in "Other" in table 4.

The yield from oil is less for the Superabrasion Furnace blacks than for the High-Abrasion Furnace grades. However, overall yield of blacks produced from oil increased from 3.68 pounds per gallon in 1953 to 3.83 pounds in 1954. Also the yield of contact black from gas increased to average 2.01 pounds per thousand cubic feet.

CONSUMPTION AND USES

Domestic sales of carbon black declined 9 percent in 1954, primarily as the result of reduced sales of new automobiles and also because of a labor strike in the rubber industry which curtailed demand for carbon black. Another factor was a decline in average loading of carbon black in rubber from 825 pounds to 807 pounds per long ton. rubber, which requires a lower loading than synthetic rubber, constituted 48 percent of the total virgin rubber consumption compared with 41 percent in 1953. Furnace black constituted 83 percent of the carbon-black sales to rubber companies compared with 82 percent in 1953.

TABLE 7 .- Sales of carbon black for domestic consumption in the United States, 1950-54, by uses, in thousand pounds

STOCKS

Total stocks declined 89 million pounds in 1954. Stocks of all grades were excessively high at the beginning of the year, and production cutbacks had been made in 1953 to permit stocks to be reduced.

VALUE

There were no open-market price changes in carbon black during 1954. The average value of furnace blacks to producers rose again in 1954, as it has each year since figures became available in 1950. This rise reflects the shift in demand to the more expensive, more highly reinforcing grades rather than the increase in value of a particular grade.

The average value of natural gas used as raw material rose sharply to 7.0 cents per thousand cubic feet, an increase of over 1.0 cent per thousand in a year. The average value of oil feedstock declined.

For explanation, see table 4.
 Adjusted figures (reclassification of grade).
 Includes thermal grade.

FOREIGN TRADE

Imports.—Imports of acetylene black from Canada declined from 10.2 ¹ million pounds in 1953 to 7.7 million in 1954. The average value increased from 15.9 cents per pound to 16.6 cents.

The United Kingdom, our only other source, provided 75,000

pounds.

Exports.—Exports of carbon black, particularly furnace-black, increased in 1954, and exports of furnace black exceeded exports of contact black for the first time. Although exports to Canada decreased 20 million pounds as the result of the operation of the first furnace-black plant in that country, increases to Australia, South America, and western Europe more than compensated for this decline.

Furnace-black exports were considerably larger than contact-black exports to Mexico, Italy, and West Germany, whereas contact-black exports predominated to the United Kingdom and Australia.

[U. S. Department of Commerce]

WORLD PRODUCTION

Carbon-black production in England reached 147 million pounds in 1954, an increase of 44 million pounds.

Production in Japan declined to 16 million pounds from 19 million ²

in 1953.

Yugoslavia produced 2 million pounds of carbon black in 1954. Carbon-black was also known to have been produced in West Germany and in Canada.

¹ Figures on imports from Canada in 1952 and 1953 have been revised. Acetylene-black imports, 1952, 8.8 million pounds valued at 15.3 cents per pound; 1953, 10.2 million pounds valued at 15.9 cents per pound. Carbon-black imports: none imported in 1952 or 1953.

² Revised figure.

Natural Gas

By Donald S. Colby, Ann C. Mahoney, and Lulie V. Harvey

GENERAL SUMMARY

ARKETED production of natural gas in the United States rose 4 percent in 1954. Consumption, however, increased over 5 percent as a result of larger withdrawals from storage and smaller transmission losses than in 1953.

Because of colder weather and a decline in industrial activity in 1954, residential use increased 12 percent and commercial use 10 percent, whereas industrial consumption increased only 4 percent.

Interstate shipments increased at a more rapid rate than marketed production in 1954. The quantity of out-of-State gas piped to California and New England continued to increase rapidly. Nevada received natural gas for the first time.

Average values, both at the wellhead and at point of consumption, continued upward in 1954 but at a somewhat slower rate than in 1953.

¹ Comprises gas sold or consumed by producers, including losses in transmission, amounts added to storage, and increases in gas in pipelines.

SCOPE OF REPORT

Data on natural-gas production, consumption, and value are collected by annual questionnaires sent to producers of oil and gas, natural-gasoline-plant operators, gas-pipeline companies, and gasutility companies. A separate report is filed by the respondent for each State in which he operates.

Volumes are reported at the pressure base selected by the reporting company; however, if the reported pressure base deviates more than 5 percent from 14.65 p. s. i. a. at 60° F., it is corrected to 14.65 p. s. i. a.

Reports are received covering approximately 75 percent of gross natural-gas production. The large number of respondents and the difficulty of contacting each small producer make direct compilation of total production impractical. The output of nonreporting producers will, in most instances, be accounted for in the purchases of reporting companies. Marketed production for each State equals consumption in the State, plus gas placed in storage, plus shipments to other States, less gas withdrawn from storage, less receipts from other States.

Gross production equals marketed production, plus the quantity repressured, plus the partly estimated quantity vented and wasted. Quantity of gas vented and wasted is compiled from data given on the reporting forms, supplemented by estimates of waste derived from figures published by Natural Gas Reserves Committee of the American Gas Association and State conservation bodies.

GOVERNMENT REGULATIONS

On March 27, 1954, President Eisenhower signed into law the Hinshaw amendment ¹ to the Natural-Gas Act. This amendment that became section 1 (c) of the act provides that any company that purchases natural gas at or within a State boundary is exempted from provisions of the act if all of the gas so purchased is consumed within that State and if the rates, services, and facilities are regulated by a State commission.

On April 15, 1954, the Federal Power Commission issued Opinion 269 in the Panhandle Eastern Pipeline Co. case, which, for the first time allowed a pipeline company to use the average field price as the value of its own production, rather than a price determined on an original cost basis.

The Supreme Court ruled on June 7, 1954,² that independent natural-gas producers selling gas in interstate commerce for resale to the ultimate consumer come within the meaning of the term "natural-gas company" as defined in the Natural Gas Act and that its sales in interstate commerce are subject to the jurisdiction of, and regulation by, the Federal Power Commission.

On July 16, 1954, the Federal Power Commission issued Order 174 designed to enforce the Supreme Court decision in the Phillips case. This order required independent producers who sell gas for interstate transmission to file existing sales contracts with the Federal Power Commission; to make no change in these rates without FPC approval; and to obtain from the FPC a certificate authorizing the sale of gas in interstate commerce before initiating such a sale.

RESERVES

The American Gas Association Committee on Natural Gas Reserves reported that estimated proved recoverable reserves of natural gas on December 31, 1954, totaled 211.7 trillion cubic feet. The estimated annual increase in reserves for 1954 was the smallest since the com-

¹ Volumes are reported at a pressure base of 14.65 p. s. i. a. and at a standard temperature of 60° F.

2 Excludes gas loss due to recovery of natural-gas liquids.

3 The net difference between gas stored in and gas withdrawn from underground storage reservoirs inclusive of adjustments and native gas transferred from other reserve categories.

4 Net production equals gross withdrawals less gas injected into producing reservoirs; changes in underground storage and gas loss due to recovery of natural-gas liquids are excluded. Fourth quarter production activated in some interprese ground storage and gas loss due to recovery of natural-gas liquids are excluded. Fourth quarter pro estimated in some instances.

Includes offshore reserves.
Includes Alabama, Arizona, Florida, Maryland, Missouri, North Dakota, and Virginia.
Nonassociated gas is free gas not in contact with crude oil in the reservoir.
Associated gas is free gas in contact with crude oil in the reservoir.
Dissolved gas is gas in solution with crude oil in the reservoir.
Gas held in underground reservoirs (including native and net injected gas) for storage purposes.

mittee began making estimates in 1946, mostly because of the downward revisions of some of the previous year's estimates.

PRODUCTION

GROSS WITHDRAWAL

Gross withdrawals of natural gas increased 3 percent in 1954. The increase was accounted for by increased production from gas wells,

Marketed production plus quantities used in repressuring, vented, and wasted.
 Gas sold or consumed by producers (see table 1, footnote 1).
 Includes gas (mostly residue) blown to the air but does not include direct waste on producing properties, except where data are available.
 Alabama, Florida, Missouri, South Dakota, and Tennessee.

as withdrawals from oil wells declined. The volume of gas vented and wasted declined sharply, chiefly in Texas. At least part of the decrease in the quantity vented in Texas can be attributed to the increase in the quantity of gas repressured in that State.

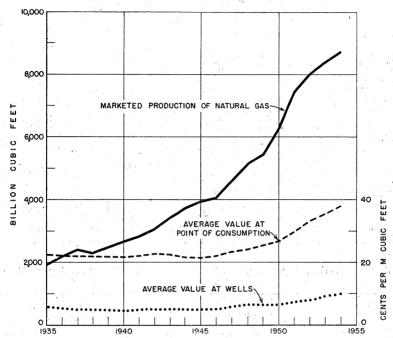

FIGURE 1.—Production and average value of natural gas in the United States, 1953-54.

STORAGE

Total withdrawals from storage increased sharply in 1954, chiefly because of the unusually cold weather in the last quarter of the year. The largest increases in withdrawals were in Michigan, Pennsylvania, and West Virginia.

The American Gas Association Committee on Underground Storage reported that on December 31, 1954, 172 storage pools were in operation, with an estimated total reservoir capacity of 1,859 billion cubic

feet. In 1953 there were 167 pools.

MARKETED PRODUCTION

The marketed production of natural gas increased 4 percent in 1954 compared with 5 percent in 1953. The lower gain in production in 1954 was not due to a reduced rate of growth of consumption but rather to a reduction in transmission losses and larger withdrawals from underground storage.

The 1.7-percent decrease in production of crude oil in 1954 was accompanied by a decline in production of oilwell gas, which would

have ordinarily gone for interruptible sales.

¹ Comprises gas either sold or consumed by producers, including losses in transmission, amounts added to storage, and increases of gas in pipelines.

² Less than \$500.

Of the smaller producing States, North Dakota and Utah had outstanding increases in marketed production as outlets for their gas became available. Production in Pennsylvania increased 38 percent as the result of the development of the Driftwood-Benezette pool.

NUMBER OF WELLS

The number of gas wells drilled in 1954 exceeded the high level attained in 1953. In Pennsylvania completions increased from 254 in 1953 to 483 in 1954. The rapid rate of development in New Mexico during 1953, when 600 gas wells were completed, was not sustained in 1954, and completions dropped to 392. There were over 70,000 producing gas wells in the United States at the end of 1954.

¹ From Oil and Gas Journal.

DEVELOPMENT AND PRODUCTION BY STATES

Kentucky.—C. D. Hunter, chief geologist, Kentucky-West Virginia Gas Co., reported that the Big Sandy gas field was extended 2 miles to the south to within 7 miles of the Pine Mountain overthrust fault. During 1954 also extensive exploration for new gas production was begun in Clay, Leslie, Breathitt and Harlan Counties, with results

favorable enough to warrant further exploration.

New Mexico.—Several discoveries of gas in the Dakota sand in northern San Juan County should stimulate exploration of this formation. The first Tertiary gas discovery in the San Juan Basin was completed in Rio Arriba County and may result in a reevaluation of the producing potentiality of the Tertiary period. Extensions were made in the Pictured Cliffs sandstone, but no outer limits have been defined. Authorization by the Federal Power Commission for the construction of a pipeline by Pacific Northwest Pipeline Corp. from

the San Juan Basin to Oregon and Washington will increase drilling

activity in the Basin.

New York.—W. L. Kreidler, senior geologist, New York State Museum and Science Service, reported that a wildcat well drilled in Ulster County near Phoenicia found gas in the Schoharie-Esopus strata. Over 30,000 acres were leased by the end of the year on the basis of this find.

North Dakota.—Wilson M. Laird, State geologist, North Dakota Geological Survey, reported that a natural-gasoline plant began operating at Tioga in 1954 to process wet gas. No pipeline outlet

was available for the dry residue gas from the plant.

Pennsylvania.—J. G. Montgomery, Jr., president, United Natural Gas Co., reported that continued intensive development of the Driftwood-Benezette Pool in Cameron, Elk, and Clearfield Counties was the most important natural-gas activity in 1954. During the year 123 producing wells were drilled in this pool, and its proved area was extended from 21,000 acres to 24,000.

INTERSTATE SHIPMENTS AND EXPORTS

Interstate shipments of natural gas increased 11 percent in 1954, the same percentage of increase as in 1953. These shipments accounted for 53 percent of marketed production in 1954 compared with 50 percent in 1953. Most of the additional shipments originated in Texas, New Mexico, and Louisiana. California consumed over 100,000 million cubic feet more out-of-State gas than in 1953. The remainder was scattered widely throughout the States.

¹ Includes exports as follows: 6,131 million cubic feet to Canada and 22,595 million cubic feet to Mexico.
³ Includes amounts consumed, stored, and lost in transmission.

Imports and Exports.—Again in 1954 the only import of natural gas was from Canada to Montana. Exports to Canada and Mexico remained substantially the same as in 1953.

PIPELINES

Certificates of public convenience and necessity for natural-gas facilities issued by the Federal Power Commission in 1954 authorized expenditure of \$452 million and included 6,392 miles of pipeline. In 1953 authorizations totaled \$726 million and included 6,800 miles of line.

One certificate to Pacific Northwest Pipeline Corp. covered a new transmission system to cost \$160 million and to include 1,900 miles of pipeline. This line will originate in the San Juan Basin of New Mexico and will serve Washington and Oregon with natural-gas for the first time. It will also serve customers along the route in Colorado, Utah, Wyoming, and Idaho. The initial daily capacity is to be 377 million cubic feet.

The Colorado Interstate Gas Co. was authorized to construct a pipeline to Denver from a connection with Pacific Northwestern near

Rock Springs, Wyo.

The Texas Eastern-Penn-Jersey Transmission Corp. was authorized to construct a line from the Oakford storage pool in Pennsylvania to a point near Lambertville, N. J., where it connects with the line of Texas Eastern Transmission Corp. The line will provide storage service for Transcontinental Gas Pipe Line Corp.

The other certificates issued were in general authorizations to tap new sources of supply and to deliver more gas to present customers.

CONSUMPTION

Consumption of natural gas in the United States increased at a slightly higher rate in 1954 than in 1953. In 1954 residential and commercial usage increased at a higher rate than in the previous year because of the colder weather in the fourth quarter. Industrial consumption did not increase as rapidly as in 1953 because of the preferential delivery to residential and commercial consumers and also because of the lower level of industrial activity in 1954.

The most rapid increases in the use of natural gas occurred in New England and the Southeastern States, where gas has only recently become available. Consumption declined in New Mexico and Okla-

homa and increased slightly in Texas.

Residential and Commercial.—The more normal cold winter weather in 1954 after the unusually warm winter in 1953 was partly responsible for the large increases in residential and commercial consumption. Residential consumption was 12 percent greater than in 1953, whereas the number of residential consumers increased only 5 percent. The average consumption of natural gas per residential consumer in 1954 was 83,500 cubic feet. In 1953 it had declined to 79,400 cubic feet from 82,000 in 1952.

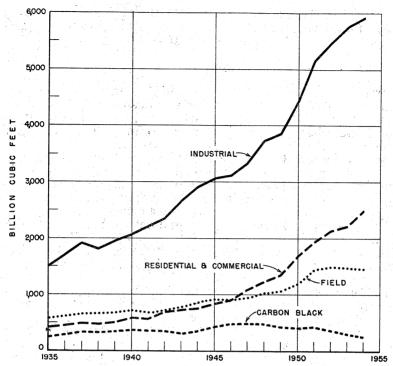

FIGURE 2.—Consumption of natural gas in the United States, 1935-54, by use.

Field.—Field use declined for the second consecutive year. The largest declines took place in Louisiana, New Mexico, and Oklahoma; use in Texas increased.

Processed for Natural-Gas Liquids.—The volume of natural gas processed for the extraction of natural-gas liquids increased 9 percent in 1954. The major increases were in Texas, New Mexico, Kentucky, and Illinois. The increases resulted from the construction of new plants and from plants erected in 1953 that operated a full year for the first time in 1954.

¹ Colorado, Montana, Nebraska, and Utah combined under "Other States" to avoid disclosure of indi-

Ohio included in Pennsylvania.

Carbon Black.—The use of gas for the production of carbon black declined again in 1954, as did the production of carbon black. with less gas consumption carbon-black production in 1954 was three times the quantity produced in 1936.

Petroleum Refineries.—The use of natural gas at petroleum refineries continued to increase in the larger gas-producing States in In California consumption declined 27 percent.

Electric Utility Plants.—The consumption of gas by electric utility plants continued upward and increased 13 percent in 1954. The increase in California was outstanding, in that electric plants in that State consumed 61 billion cubic feet more than in 1953.

Portland Cement.—The use of natural gas as fuel at portlandcement plants increased 9 percent. Natural gas was used at portlandcement plants in Ohio and South Dakota for the first time in 1954.

Natural-Gas Pipelines.—The quantity of gas used in operating natural-gas pipelines in 1954 remained substantially the same as in 1953. The trend was mainly upward in most States, with the notable exception of Oklahoma and Texas.

Other Industrial.—In 1954, "Other Industrial" use increased 8 percent, compared with an 11 percent increase in 1953 because of the necessity of diverting gas to residential users and slackening in industrial activity.

Mixed Gas.—The number of consumers of mixed gas remained substantially the same as in 1953. The quantity of natural gas consumed in mixed gas increased, because 1954 was the first full year in which natural gas was available to some New England utility companies and because colder weather prevailed.

Colorado, Montana, and Utah included in Wyoming.
 Colorado, Montana, and Utah included in Colorado.
 Michigan included in Illinois.
 Tradudae cons from transmission lines previously treater. Includes gas from transmission lines previously treated in another State. Michigan and Ohio included in Illinois. Nebraska included in Kansas. Nebraska and North Dakota included in Kansas.

TABLE 12.—Consumption of natural gas used with manufactured gas in the United States in 1954, by States ¹

Included in tables for the consumption of natural gas (tables 8-11). Converted to natural gas before the end of the year. Less than 500.

VALUE AND PRICE

The increase in the average value of natural-gas at the wellhead was less than in 1953, but the increase was far above the average for the postwar period 1946-52. In 1954 of the five largest producing States, only Oklahoma reported an increase in average value that was considerably less than the national average. The average values of residential, commercial, and industrial gas at point of consumption all

increased in 1954 but at a slower rate than in the three previous years. The overall average value at point of consumption increased at a higher rate than in 1953 because of the larger proportion of residential sales in 1954. Increases were general, except for the New England States.

TECHNOLOGY

In 1954 two significant techniques for drilling and completing gas wells were quite extensively adopted. One was the use of air or natural gas instead of mud as a drilling fluid to prevent clogging of the gas-producing strata by mud. The other technique was to fracture the producing strata by forcing sand suspended in a liquid into the formation.

WORLD REVIEW

Canada.—The estimated gross production of natural gas, less field waste, was 120.9 billion cubic feet, a 20-percent increase over 1953. Reserves totaled at least 16 trillion cubic feet.

Mexico.—The production of natural gas in Mexico remained substantially unchanged in 1954 at 93 billion cubic feet.

Italy.—The production of natural gas in Italy in 1954 totaled 104.8

billion cubic feet compared with 81.1 billion in 1953. Venezuela.—The gross production of natural gas in Venezuela was 764 billion cubic feet compared with 730 billion in 1953. total, only 24 billion cubic feet was sold away from the field.

 Total production including gas repressured and wasted.

Natural-Gas Liquids

By D. S. Colby, L. V. Harvey, A. T. Coumbe, and I. F. Avery

GENERAL SUMMARY

THE PRODUCTION of natural-gas liquids in 1954 increased 6 percent to 10.6 billion gallons. Production of liquefied petroleum (LP-) gases was 13 percent ahead of 1953. Shipments of LP-gases for both motor fuel blending and for fuel and chemical use were 12 and 11 percent, respectively, above 1953. Stocks of natural-gas liquids at plants, terminals, and refineries increased 152 million gallons during the year. Of this, 137 million gallons was an increase in stocks of LP-gases stored underground.

Sales of LP-gases, including liquefied refinery (LR-) gases, for all uses other than blending in gasoline increased 4 percent in 1954.

SCOPE OF REPORT

Annual statistics on natural-gas liquids were collected jointly by the Bureau of Mines (United States Department of the Interior) and the Bureau of the Census (United States Department of Commerce) for the Census year 1954. This joint collection covered production, value, volume of gas processed, and number and type of plants.

The monthly reports received by the Bureau of Mines provided

data on individual products, on stocks, and on uses.

Data on sales of LP-gases for fuel and chemical uses include propane, propylene, butanes, and butylenes produced both at natural-gasoline plants and at petroleum refineries but do not include liquefied-petroleum gas that is blended into gasoline motor fuel. Information is collected on an annual questionnaire received from all producers and distributors and from 90 percent of the dealers selling over 100,000 gallons of LP-gases a year. Data on small or nonreporting dealers are indirectly included in the reporting, as the sales figures of producers or distributors will reflect the operations of these dealers.

RESERVES

The American Gas Association Reserves Committee estimated the proved recoverable reserves of natural-gas liquids on December 31,

297

1954, at 5.2 billion barrels. This was a decline of 0.2 billion barrels for the year and the first decline since the committee started estimating reserves in 1946. This decline in 1954 was due primarily to downward revision of reserves in Texas, which were overestimated in 1953. Extensions and revisions in New Mexico were also considerably lower than in 1953.

¹ Comprises natural gasoline, LP-gases, and condensate.

Includes offshore reserves.
Not allocated by types, but occurring principally in column shown.

PRODUCTION

The production of natural-gas liquids increased 6 percent in 1954 compared to 7 percent in 1953. LP-gas production continued to show the highest rate of growth of the various natural-gas liquids. In 1954 it increased 13 percent. Finished-gasoline production declined 19 percent, mostly in Texas.

Beginning with 1954 statistics, isopentane has been shifted from the

LP-gas category and is included with natural gasoline.

Regionally, there were production increases in the same areas as in 1953. The National Petrochemical Co. plant in Illinois operated its first full year in 1954; moreover, the new plant capacity of El Paso Natural Gas Co. in the San Juan Basin area of New Mexico operated its first full year. North Dakota began producing natural-gas liquids with completion of a plant at Tioga.

¹ Includes 27 plants manufacturing LP-gases; 1 refrigeration-type plant each in California, Kansas, and Kentucky; and 10 refrigeration-type plants in Texas.

2 Includes combination of absorption with compression process. Includes 348 plants manufacturing LP-gases and 1 charcoal-type plant each in Ohio and West Virginia.

3 Includes 40 plants manufacturing LP-gases.

4 Included in State total production and United States total production to avoid disclosure of individual plant angestion. plant operation.

plant operation.

§ Montana, with 1 absorption plant, and Utah, with production of a small amount of drip gasoline, included with Colorado.

§ Includes some drip gasoline.

§ Michigan, with 2 compression plants and 1 absorption plant, and Ohio, with 2 absorption plants, included with Utania.

Nebraska, with 1 absorption plant, and North Dakota, with 1 absorption plant, included with Kansas. Revised.

YIELDS, PROCESSES, AND NUMBER OF PLANTS

The overall yield of natural-gas liquids recovered declined from 1.47 gallons per thousand cubic feet of gas processed in 1953 to 1.42 gallons in 1954. The reduction was entirely in the yield of heavy products; the yield of LP-gases increased 0.01 gallon to 0.70 gallon per thousand cubic feet.

Yields dropped sharply in Illinois and Kentucky, where plants were operating on lean pipeline gas. Declines, however, were general

throughout the producing States.

The number of plants operating at the end of 1954 totaled 555. The number of cycling plants and the production at cycling plants was less than in 1953. The number of compression and absorption plants and the quantity of liquids produced by them increased in 1954.

SHIPMENTS OF NATURAL-GAS LIQUIDS FROM PLANTS AND TERMINALS

Shipments of natural-gas liquids from plants and terminals in 1954 increased 5 percent compared with a 6-percent increase in 1953. Demand for both natural gasoline and LP-gases was higher than during the previous year, whereas demand for finished gasoline and con-

densate was lower.

For Motor-Fuel Use.—Total natural-gas liquids shipped for blending into motor fuel in 1954 was only 0.5 percent higher than in 1953. Production of motor fuel was less than 1 percent above the 1953 figure. The quantity of natural-gas liquids blended at refineries in 1954 was 6 percent more than in 1953. The proportion of natural-gas liquids in refinery gasoline thus increased from 9.0 percent to 9.5 percent. For the Texas Inland district this percentage jumped from 25.7 to 31.5.

For Non-Motor-Fuel Uses.—Shipments of LP-gases ¹ from plants and terminals for fuel and chemical use continued to expand. Greater quantities of ethane were shipped for uses as a chemical raw material. Approximately 129 million gallons of ethane was recovered from

natural gas in 1954.

The production of liquefied gases at refineries declined slightly.

¹ For a discussion of sales of LP-gases for fuel and chemical uses, see page 306.

SALES OF LIQUEFIED PETROLEUM GASES FOR FUEL AND CHEMICAL USE 1

Domestic sales of liquefied petroleum gases for fuel and chemical use increased only 4 percent in 1954 compared with a 10-percent increase in 1953, according to a survey made by the Branch of Petroleum Economics, Bureau of Mines. Exports of LP-gases, however, continued to expand at a high rate and were 31 percent above the 1953 total, according to the Bureau of the Census, United States Department of Commerce.

LP-gases sold to manufactured-gas companies and to synthetic rubber plants declined significantly in 1954. The quantity delivered to gas companies for distribution through mains was 14 percent lower in 1954, the same percentage decline as reported for 1953, because natural gas continued to become available in additional areas. Sales to synthetic rubber plants were off 21 percent because of curtailed production of their products.

Sales of LP-gases for domestic and commercial uses increased in 1954 but at a slightly lower rate than in 1953. Industrial plants are finding new uses for LP-gases as fuel, especially where controlled temperatures are a factor; consequently, demand for this purpose in-

creased 8 percent in 1954 or about the same as in 1953.

Chemical plants continued to consume larger quantities of LP-gases as raw material for manufacturing products. Sales of LP-gases for internal-combustion engine fuel and for "All other uses" increased 10 and 3 percent, respectively, in 1954. These increases were small compared with the very large increases reported for 1953; however, the 1953 increases reflected much broader survey coverage, as well as actual increase in sales.

¹ Data include LR-gases.

Includes LR-(liquefied-refinery) gases. Includes no LP-gases blended into gasoline but does include LP-gases used directly as a fuel for internal-combustion engines. Data include quantities sold by producers directly to consumers and all dealers' sales to consumers.

The survey covering sales of LP gases in the Pacific coast marketing area (District 5) was made by E. T. Knudsen, supervising analyst, Branch of Petroleum Economics, Region II, Bureau of Mines, San Francisco, Calif.

 Converted from pounds to gallons at 4.5 pounds per gallon.

STOCKS

Stocks of natural-gas liquids at plants and terminals increased 122 million gallons in 1954. This was the second consecutive year for which an increase of such size was reported. The increase entirely resulted from an increase in LP-gas stocks, as the increase in natural-gasoline stocks was offset by a decline in stocks of "other products." Underground stocks of LP-gases increased 141 million gallons during the year and stood at 213 million at the end of the year.

At refineries, stocks of natural-gas liquids, predominantly natural gasoline, increased 30 million gallons.

TABLE 13.—Stocks of natural-gas liquids in the United States, 1950-53, and 1954, by months, in thousand gallons

PRICES

The average posted price of grade 26-70 natural gasoline to blenders f. o. b. group 3 basis was 4.87 cents per gallon in 1954, 0.91 cent per gallon below 1953. The posted price was 5.5 cents per gallon at the beginning of the year. The first price decline came in January and the price had declined to 4.0 cents per gallon by April. Gradual increases raised the price back to 5.5 cents by October 30. Producers' realiza-

tion from all natural-gasoline sales averaged 7.24 cents per gallon in 1954 compared with 7.18 cents in 1953. The higher average realization reflected greater sales of the higher-priced grades of natural

gasoline.

The average posted price of propane, f. o. b. Houston, Tex., in 1954 was 3.28 cents per gallon, 0.74 cent per gallon below the 1953 average. The average value received by producers for all LP-gases also declined in 1954, averaging 3.44 cents per gallon, 0.64 cent per gallon less than in 1953.

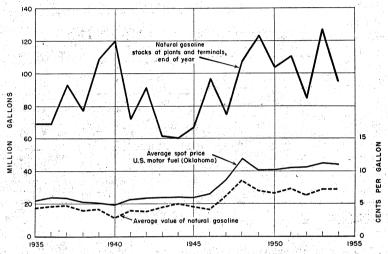

FIGURE 2.—Average value of natural gasoline, spot price of gasoline, and stocks of natural gasoline, 1935-54.

FOREIGN TRADE²

Exports of LP-gases increased 32 percent in 1954, primarily because of the much larger shipments to Mexico and Brazil. Shipments to Canada, our other major export customer, increased less rapidly, under 4 percent above 1953.

Exports of natural gasoline declined 37 percent, with only Canada receiving a substantial volume. No natural gasoline was shipped to

Europe or Australia in either 1953 or 1954.

 $^{^{2}}$ Figures on exports compiled by Mae B. Price and Elsie D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerc

Crude Petroleum and Petroleum **Products**

By Alfred G. White, Albert T. Coumbe, Donald S. Colby, and Emma M. Seelev

GENERAL SUMMARY

OTAL DEMAND 1 for petroleum and petroleum products set another record in 1954, although the 1.3-percent gain over 1953 was the smallest annual increase since 1949. Outstanding features of the petroleum situation in 1954 were the decline in exports, the smallest annual gain in gasoline demand since 1946, improvement in the demand for heating oils owing to more normal weather, and a sharp

drop in the demand for residual fuel oil.

Exports of oil fluctuate with the available supplies abroad, the competitive position of American companies in foreign markets, and problems of dollar exchange. Total exports declined over 11 percent in 1954, with a decrease of 32 percent in crude oil and 8 percent in products. The downward trend in crude exports was related to expansion of the domestic crude supply in Canada, while the decrease in product exports reflects the increase in refinery capacity, primarily in western Europe, that has taken care of the product shortage following the shutdown of the Abadan refinery in Iran in 1951.

The domestic demand for petroleum and petroleum products in continental United States increased only 1.9 percent in 1954, compared with gains of 4.4 percent in 1953, 3.4 percent in 1952, and 8.2 percent in 1951. The decline in industrial activity and fuel-oil demands that started in the latter part of 1953 continued through 1954. Furthermore, the demand for oil was affected by a greater relative increase in natural-gas supply and shifts from heavy fuel oil to coal in some areas. The relative changes by quarters, compared with 1953, indicate the trend during 1954. The 3.0-percent increase in domestic demand in the first quarter was due primarily to colder weather, resulting in a sharp increase in heating-oil requirements; the 1.7-percent decline in the second quarter marked a low level in industrial-fuel re-

¹ Certain terms, as utilized in this chapter, are more or less unique to the petroleum industry. Principal

¹ Certain terms, as utilized in this chapter, are more or less unique to the petroleum industry. Principal terms and their meaning are as follows:

Total demand.—A derived figure representing total new supply plus decreases or minus increases in reported stocks. Because there are substantial secondary and consumers' stocks that are not reported to the Bureau of Mines, this figure varies considerably from consumption.

Domestic demand.—Total demand less exports.

New supply of all oils.—The sum of crude-oil production, plus production of natural-gas liquids, plus benzol (coke-oven) used for motor fuel plus imports of crude oil and other petroleum products.

Transfers.—Crude oil conveyed to fuel-oil stocks without processing or reclassification of products from one product category to another.

All oils.—Crude petroleum, natural-gas liquids, and their derivatives.

Principal products.—Gasoline, kerosine, distillate fuel oil, and residual fuel oil.

Exports.—Total shipments from continental United States, including shipments to United States Territories and possessions.

tories and possessions.

quirements that continued through the third quarter, with a gain of only 0.4 percent, and the 5.7-percent gain in domestic demand in the fourth quarter indicated the effect of much colder weather than in the last quarter of 1953, an upward turn in industrial-fuel requirements, and a comparison with the lowest level in seasonal demand in 1953.

¹ Data, including imports and exports are for continental United States.

Total new supply of all oils amounted to 2,949 million barrels in 1954, a decline of 0.8 percent. In 1954 crude production decreased 1.7 percent, the production of light oils from natural gas gained 4.0 percent, crude-oil imports increased 1.3 percent, and product imports rose 2.4 percent. Total imports represented 13.0 percent of new supply in 1954 compared with 12.7 percent in 1953. The decline in new supply was related to a decrease of 11 million barrels in total stocks in 1954 compared with 1953 when 52 million barrels were added to stocks.

² Preliminary figures. ³ 42 gallons per barrel. ⁴ Bureau of Mines.

⁵ U.S. Department of Commerce, except Alaska and Hawaii, which are Bureau of Mines data. Exports include shipments to the Territories.

Data for 1950 not comparable with that for succeeding years; for 1951 and succeeding years definition of bulk terminals for reporting purposes was redefined as follows:

1. All bulk installations that receive their supplies by tankers, barges, or pipelines.

2. Any other storage point with a combined capacity of 50,000 barrels or more, regardless of the transpor-

tation means of products

⁷ Based upon definition of bulk terminal prior to 1951.

Data for 1952 and subsequent years excluded jet fuel.
 American Petroleum Institute.

² Preliminary figures.

DEMAND BY PRODUCTS

Since over 99 percent of the indicated consumption of crude oil in continental United States was converted into products at refineries, before sale to ultimate consumers, the analysis of demand trends involves consideration of each of the major products. The fuel oils (residual, distillate, and kerosine) compete directly with natural gas or coal in heating, cooking, and industrial uses. Gasoline is a major fuel in the transportation field. The other products serve a wide variety of uses; some compete with other oil products as fuels, and others have special uses outside the fuel field. Because of the rapid increase in the military use of jet fuel (a blend of low-grade gasoline, kerosine, and distillate), data for that product have been compiled separately since 1951.

Gasoline.—Gasoline represented 43.0 percent of the total demand for all oils in 1954 and 42.6 percent in 1953. Aviation gasolines and commercial naphthas are included in the total, but the low-grade gasoline used as a constituent of jet fuel is not. Although the total demand for gasoline set a new record in 1954, the rate of increase was only 2.3 percent, with a 9.1-percent decline in exports and a 2.7-percent increase in domestic demand. The gain of about 3 million barrels in the exports of aviation gasoline was offset by a sharp decline of 7 million barrels in the exports of other grades. In 1954, 83.3 percent of the total domestic demand for gasoline was for highway use, 5.2 percent for aviation, and 11.5 percent for other uses (including commercial naphthas, farm tractor fuel, military motor gas, other purposes, and losses). Demand for highway use increased 3.6 percent in 1954, whereas the domestic demand for aviation gasoline declined 8.1 percent because of a sharp decline in active military operations and the increased use of jet fuels.

the increased use of jet fuels.

Residual Fuel Oil.—The total demand for residual fuel oil represented 18.5 percent of the total demand for all oils in 1954, compared with 20.1 percent in 1953. Demand in 1954 declined 6.4 percent, with a 3.3-percent gain in exports and a 6.8-percent decline in domestic demand. The domestic demand for residual fuel oil is affected more by variations in industrial activity than any other oil product. Of a total decline of 38 million barrels in domestic demand in 1954, use in public utility electric plants declined 15 million barrels, railroad use dropped 12 million barrels, general manufacturing use declined 6 million, and vessel-fuel use declined 5 million barrels. The refinery production of residual has consistently declined since 1951, dropping

33 million barrels in 1954. Yields from crude oil have been declining about 1 percent a year because of improved refinery methods and the fact that residual usually sells for less than crude oil delivered at the

refinery.

Distillate Fuel Oil.—Total demand for distillate fuel oil (including light diesel oils) represented 18.6 percent of the total demand for all oils in 1954, compared with 17.8 percent in 1953, Total demand for distillate increased 5.8-percent in 1954, including a 25.1-percent decline in exports and a 7.8-percent increase in domestic demand. The main gain was in heating, owing to colder weather in 1954 than 1953, and to increased installations. Heating oils represented 57.9 percent of total domestic demand for distillate in 1954 compared with 54.7 percent in 1953. Changes in all other uses were comparatively small.

Kerosine.—The total demand for kerosine represented 4.2 percent of the total demand for all oils in both 1954 and 1953. The gain in total demand in 1954 was 1.1 percent, including a decline of 32.5 percent in exports and an increase of 3.3 percent in domestic demand. About 72 percent of the domestic sales was for use as range oil, including cooking, water heating, and small space heating. No. 1 distillate and liquefied gases can be substituted in many uses, and the increase

in electric lighting has cut into the demand for lamp oil.

Other Products.—The total demand for all other products including crude-oil exports, represented 15.7 percent of the total demand for all oils in 1954 compared with 15.4 percent in 1953. The exports of crude oil declined about 32 percent, whereas the exports of the other refined oils increased about 12 percent. The increase in the domestic demand for the other products was about 4.4 percent in 1954, including increases of 33 percent for jet fuels, 12 percent for petroleum coke, and 6 percent for asphalt and a 5 percent decline for lubricants.

Shipments to United States Territories and Possessions.—Domestic demand, as used in this chapter, relates to demand in continental United States only. Shipments from the United States to the Territories and possessions are included with exports and any foreign receipts in such areas are deleted from the total imports shown. Table 4 shows the total shipments of oil into these areas from continental

United States and from foreign countries.

The indicated new supply of all oils in the Territories and possessions decreased from 22.7 million barrels in 1953 to 22.4 million in 1954. If reexports to foreign countries are deducted, the indicated demand in these areas was about 22.3 million barrels in 1953 and 22.0 million in 1954.

WORLD OIL SUPPLY

The relative position of the United States in world production and refining of crude petroleum has continued to decline. The United States produced 46.4 percent of the total in 1954, compared with 49.4 percent in 1953. World crude production increased 4.6 percent in 1954, including a 1.7 percent decline for the United States and a gain of 10.8 percent for other countries.

Crude oil refined in the United States was 51.1 percent of the world total in 1954, compared with 54.1 percent in 1953. Total crude oil refined in 1954 increased 5.2 percent, including a 0.6 percent-decline

² Preliminary figures.

in the United States and a 12.0-percent gain in other countries. The output of refineries in West Europe increased 15 percent in 1954 compared with gains of 15 percent in 1953, 26 percent in 1952, and 44 percent in 1951. The expansion of refining in this area has been so rapid as to overcome the effect of the refinery shutdown in Iran in 1951 and to almost eliminate the need for product imports from the United States.

The domestic demand in continental United States and its Territories and possessions was 2,851 million barrels in 1954. Total foreign imports into this area amounted to 388 million barrels, while total exports to foreign countries (including reexports from the Territories) were 112 million barrels, indicating a net import of 276 million barrels, including 226 million barrels of crude oil and 50 million barrels of products in 1954.

SCOPESOF REPORT

This report deals primarily with the production, refining, distribution, and indicated consumption of crude petroleum and refined products in continental United States. The objective of the continental balance is to permit a breakdown of operations by States and districts. The increasing volume of light oils recovered from natural gas has made it necessary to include these oils with the crude-oil data, since they are either blended with refinery products or are identical with materials recovered from refinery gases. These light oils are recovered at special plants away from the oil refineries.

The major part of the data was compiled by the Bureau of Mines from detailed reports submitted, on a voluntary basis, by the companies operating various branches of the industry. Most of the data are published monthly and released about 6 weeks after the end of the month. Complete coverage, with only minor estimates, is procured for production, stocks, and refinery operations. The

Bureau of Mines uses the import data for crude oil and unfinished oils as reported by the refineries. Other product imports and all export data were taken from the records of the United States Department of Commerce.

Since it is impossible to contact many of the small producers, the only feasible method of obtaining current monthly data for crude-oil production is from reports by the pipeline companies. Their reports show, by States of origin, stocks on leases, oil taken from the leases, pipeline and tank-farm stocks, and crude deliveries. These data are cross-checked by reports of crude receipts from the refineries, by States of origin and method of transportation. These reports include information covering final receipts by boat, tank car, and trucks and cover stocks of crude oil, by States of origin, held at refineries. These data are checked further against any available current and annual production figures collected by State agencies and supplemented by estimates of unreported lease stocks. The Bureau of Mines crude-production data include some field condensate dumped in crude lines that cannot be identified when received at refineries and is included with the crude runs reported.

Monthly refinery operations reported by individual refineries show input and output and receipts, stocks at the first and end of the month, refinery production, and deliveries. Data on both product stocks at refineries and pipeline and bulk terminal stocks are collected.

Annual canvasses provide supplemental information on the value of crude petroleum at the well, the number of producing oil wells, the sales of fuel oils by uses, and refinery capacity. The table showing world production of crude oil by countries is based on monthly reports that also include additional data on crude movements and refinery operations. Data on crude reserves, wells drilled, and current prices were taken from sources indicated in the footnotes.

RESERVES

The committee on petroleum reserves of the American Petroleum Institute estimated proved reserves of crude oil in the United States on December 31, 1954, to be 29.6 billion barrels. These estimates include only oil recoverable under existing economic and operating conditions.

The increase in net crude reserves in 1954 was 616 million barrels. New reserves added in 1954 were estimated to be 2,873 million barrels, of which 538 million represented revisions of previous estimates, 1,749 million extensions of old pools, and 586 million new reserves discovered in 1954 in new fields and in new pools in old fields. The subtraction of the estimated production of 2,257 million barrels in 1954 indicates the net increase in reserves.

As of December 31, 1954, Texas had 51 percent of total estimated reserves, California 13 percent, Louisiana 10 percent, and Oklahoma

7 percent, or 81 percent for the 4 States combined.

The largest increases in reserves in 1954 were 203 million barrels for Oklahoma, 202 million for Louisiana, 65 million for Kansas, 63 million for Montana, 62 million for Mississippi, 34 million for Illinois, and 24 million for Wyoming.

Includes crude oil that may be extracted by present methods from fields completely developed or sufficiently explored to permit reasonably accurate calculations. The change in reserves during any year represents total new discoveries, extensions, and revisions, minus production.

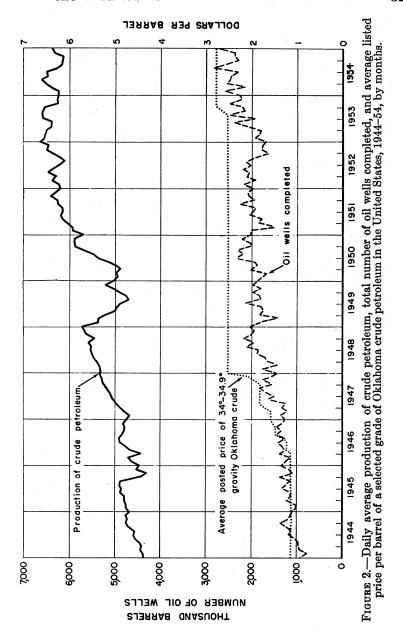

² Includes offshore reserves.
³ Includes Alabama, Florida, Missouri, Nebraska, Nevada, North Dakota, South Dakota, Tennessee, and Virginia.

CRUDE PETROLEUM SUPPLY AND DEMAND

The new supply of crude petroleum in the United States comes primarily from domestic production but has been augmented by increasing imports. The relationship of crude imports to total crude supply has risen from 7.4 percent in 1951 to 9.1 percent in 1953 and

9.4 percent in 1954.

The principal changes in total crude supply and demand in 1954, compared with 1953, were a 1.7-percent decline in crude production and a 1-3-percent increase in imports; a decline of 16.1 million barrels of total crude stocks in 1954 compared with an increase of 2.5 million in 1953; a decline of 0.7 percent in total demand for crude oil and a decrease of 0.6 percent in total crude run to stills; and a decrease of 32.0 percent in crude exports. The major part of the indicated demand for crude petroleum must be converted into products before final consumption and, in both 1953 and 1954, almost 98 percent of the total was refined and the small remainder represented exports, crude used direct for fuel, and losses.

The proper evaluation of crude production and refinery runs must take into consideration the changes in crude stocks and in refined product stocks. Production and runs were inflated above requirements in 1953 by an abnormal increase of almost 47 million barrels in product stocks compared with a gain of less than 2 million in 1954. In 1954, crude production was less than demand because of a reduction of 16 million barrels in stocks of domestic crude oil.

PRODUCTION

General

Production of crude petroleum amounted to 2,316 million barrels in 1954, a drop of about 41 million barrels or 1.7 percent less than the record established in 1953. There was no change in the rank of the 5 leading States (Texas, California, Louisiana, Oklahoma, and Kansas) that produced over 100 million barrels each and supplied 81.6 percent of total production in 1954 (table 10). Texas, with 51 percent of total crude reserves, produced 42.4 percent of the national output.

The output of the next 6 States (Wyoming, New Mexico, Illinois, Colorado, Mississippi, and Arkansas, in order of importance), producing 20 million barrels or more each, but less than 100 million, represented 14.7 percent of the national output in 1954.

These 11 States produced 96 percent of the total output in both 1954 and 1953.

¹ For detailed figures by States, 1859–1935, see Minerals Yearbook, 1937, p. 1008.

Six States (Texas, Louisiana, Oklahoma, Kansas, New Mexico, and Arkansas) issued monthly proration orders under State conservation laws to adjust production to market demand, and these States produced 71 percent of the total crude oil in 1954.

The most significant changes in production in 1954 were increases of 17 percent for Illinois, 15 percent for Colorado, 13 percent for Wyoming, 7 percent for New Mexico, and 4 percent for Kansas; whereas production declined 8 percent in Oklahoma, 4 percent in Louisiana and Texas, and 3 percent in California.

For detailed figures by States, 1859-1935, see Minerals Yearbook, 1937, p. 1008.
 Preliminary figures.
 Oklahoma included with Kansas in 1905 and 1906.
 Includes Tennessee, 1883-1907.
 Figures represent 1925-54 production only; earlier years included under "Other States."
 Figures represent 1924-54 production only; earlier years included under "Other States."
 Early production in New York included with Pennsylvania.
 Figures represent 1948-54 production only; earlier years included under "Other States."
 Includes Alaska, 1912-33; Arkansas, 1920; Michigan, 1900-19; Mississippi, 1933-35; Missouri, 1899-1911, 1913-16, 1919-23, 1932-54; New Mexico, 1913, 1919-23; Tennessee, 1916-54; Utah, 1907-11, 1920, 1924-41; Virginia, 1943-54.

The classification of fields and data may differ from other sources used in the State summaries.
 Includes revisions.
 Includes all acreage proved in Spraberry south of north line of Midland County, except Benedum, in District 7C and 8.
 Bureau of Mines data.

Crude Production by States

Colorado.—Both development and exploratory drilling increased tremendously in 1954 in Colorado, chiefly in the Denver Basin. In the Adena field alone 168 wells were drilled, and proved reserves of the field approached 60 million barrels. All discoveries in the Denver Basin were confined to the Cretaceous.

Florida.—The Sunniland field had been the only producer, but a second oil field was discovered in southern Florida. The Forty Mile

Preliminary figures.
 Includes Oak Grove area.
 Includes Athens.

Preliminary figures.
 Included in other fields.
 Includes crude oil consumed on leases and net change in stocks held on leases for entire State.

Bend field was discovered about 50 miles southeast, with production

from the same stratigraphic interval as the Sunniland field.

Illinois.—Crude-oil production in Illinois increased to the highest since 1946, primarily because of the growth of water-flood operations and improved hydraulic fracturing techniques.

Kentucky.—Activity increased in the western part of the State, and oil production increased 2 million barrels. Muhlenberg and Christian Counties were the scene of the most significant discoveries.

Louisiana.—Drilling activity in the Louisiana Gulf Coast area was about 10 percent higher in 1954 than in 1953. There was a much larger increase in offshore exploration and drilling as the result of the partial resolution of the conflicting Federal and State claims to these reserves. Thirty-four new fields were discovered in 1954, of which 8 were considered important. Four of the 8 were offshore.

In Northern Louisiana well completions increased 53 percent because of an accelerated drilling program for Annona chalk production in the Caddo-Pine Island field of Caddo Parish. Active drilling along the Wilcox, the Smackover, and the Cotton Valley areas was expected to continue because of the success achieved in 1954.

Mississippi.—Drilling increased in Mississippi, but the number of new fields discovered was less than in 1953. Probably the most important discovery was the Bolton field in Hinds County. This was the first oil find in beds of the Paluxy formation of Lower Cretaceous age.

Preliminary figures.
 Includes crude oil consumed on leases and net change in stocks held on leases for entire district.
 Includes Hemphill, Trout Creek, and Jena.
 Includes Little Creek and Summerville.

¹ Preliminary figures. ² Included with "Other fields."

2 Included in "Other fields."

Montana.—The 19 discoveries in Montana were statewide, with 7 in the Williston Basin, 7 in the central and northern parts of the State, and 5 in southern Montana. Two of these discoveries were significant. A discovery along the eastern flank of the Cedar Creek anticline focused attention on the untested northern region of the Northern Powder River Basin.

Rapid development of the East Poplar field discovered in 1952

made this the largest producer in the State.

Nevada.—The first discovery of commercial quantities of oil in Nevada was made in 1954, when the Eagle Springs field was discovered in Railroad Valley, Nye County. Production was obtained at 6,700 feet from Tertiary rhyolitic tuffs.

feet from Tertiary rhyolitic tuffs.

New Mexico.—The discovery of oil in the Queen sand in the South
Drickey field of southeastern Chaves County and at two locations
farther interest indicated that the shallow Queen sand would be

productive for several square miles.

Includes crude oil consumed on leases and net change in stocks held on leases for entire State.

¹ Included in "Other."

North Dakota.—Exploratory drilling increased in North Dakota, but the success ratio dropped from 26 percent in 1953 to 7 percent in 1954. Discoveries were mainly in the deeper part of the Williston Basin along the Nesson anticline. The Beaver Lodge and Tioga fields had been almost completely developed. Completion of a natural-gasoline plant and 3 refineries provided outlets for North Dakota production, which was over 30,000 barrels per day at the end of the year.

Ohio.—The use of hydraulic fracturing in Clinton sand wells was

successful in increasing oil production.

Texas.—West Texas.—A trend line of pre-Permian folding was established extending from the Pegasus field on the Upton-Midland County line, northwest into northeast Ector County. Considerable drilling

in this area was expected in 1955.

Panhandle.—Drilling activity in the Texas Panhandle rose to heights comparable to the boom period of 1926–29. In all, 946 wells were drilled in 1954 compared with 699 in 1953. The exploratory trend throughout the area was toward deeper productive zones. The area in northeast Hansford County was most prolific in deeper pool discoveries.

West Central.—Oil production was increased in this region by extensive development drilling and the use of sand-fracturing methods on old producing fields. The trend of Cambrian production indicated in 1953 along the eastern side of Nolan County was explored

² Monument included with Eunice. ³ Bureau of Mines figures.

Preliminary figure.

Included with "Other fields."
Includes Brock West and Lone Grove Southwest.
Includes Grief Creek.

4 Includes Hoover North, Brady Southwest, and Roady Northeast.
5 Includes Fairfax, Coon Creek, and Arcadia Northeast.

6 Revised.

¹ Includes Edmond Northwest and Lockridge Northeast,

8 Includes Munger and Munger South.

Bureau of Mines figures.
 Preliminary figure.

further. The E. A. Cambrian field was discovered in this trend, and a deeper pool test in the North Dora field in Nolan County found over 120 feet of net effective pay in the Cambrian sand.

South Texas.—The first recovery from the South Texas continental shelf was made in 1954. The discovery well was off Kleberg County

and produced from the Frio formation.

Texas Gulf.—The first sale of Federal leases off the Texas coast was held in 1954 and brought an average bonus of \$562 per acre for the 30,240 acres on which bids were received.

Utah.—The first commercial oil production from the Paradox formation was discovered at Desert Creek in the Paradox Basin in southeastern San Juan County. Exploration in the Unita Basin continued as in 1953.

¹ Preliminary figures. ² Included in "Other fields."

Wyoming.—Exploratory drilling increased only slightly, but new field wildcats were 30 percent greater than in 1953. New field discoveries in widely separated parts of the State should have encouraged exploratory drilling over a larger area. The Grieve field discovered in the southeastern part of the Wind River Basin in Natrona County was in a previously unimportant producing area. The Curtis sand may become a more favorable drilling objective in the Wind River and Big Horn Basins as a result of production obtained in the Northwest Sheldon field in Fremont County.

WELLS

The number of wells drilled in the United States, including oil and gas wells completed and dry holes, set a new record of 52,919 in 1954, an increase of 4,902 wells over 1953. The percentage of dry holes decreased from 38.4 percent of all wells drilled in 1953 to 36.2 percent in 1954. The States reporting the largest gains in the total number of wells drilled were Texas 1,895, Oklahoma 998, Illinois 969, Louisiana 797, and Colorado 624.

The total number of producing oil wells in the United States rose from 498,940 on December 31, 1953, to 511,200 on December 31, 1954, while the daily average production per well declined from 13.1 barrels

in 1953 to 12.6 barrels in 1954.

Includes crude oil consumed on leases and net change in stocks held on leases for entire State.

CONSUMPTION AND DISTRIBUTION

The total annual demand for crude oil in the United States declined in 1954 for the first time since 1949. The 0.7-percent decrease included a 2.4-percent gain in the demand for foreign crude and a 1.1percent decline in the demand for domestic crude. Foreign crude

supplied 9.3 percent of the total.

The decline in the total demand for crude oil in 1954 amounted to 19.2 million barrels, including a decline of 15.3 million in total crude runs, a drop of 6.4 million in exports, and a gain of 2.5 million barrels in crude used as fuel (transfers) and losses. The major demand for crude oil is for conversion to products at refineries (runs to stills)—98.7 percent of the total in 1954 compared with 98.6 percent The small decline in crude demand was due primarily to comparison with an inflated demand in 1953 caused by an abnormal increase in stocks of refined products.

Runs to Stills.—Total crude runs to stills declined from 7,000,000 barrels daily in 1953 to 6,958,000 in 1954, a decrease of 0.6 percent. The relative importance of the refinery districts in 1954 was indicated by the percentage of total crude runs as follows: Texas Gulf 24.3 percent, Indiana-Illinois 18.3 percent, East Coast 14.8 percent, California 14.7 percent, Oklahoma-Kansas 8.6 percent, Louisiana Gulf 8.2 percent, Rocky Mountain 3.7 percent, Texas Inland 3.4 percent, Appalachian 2.7 percent, and Arkansas-Louisiana Inland 1.3 percent. The only gains in crude runs in 1954 were in the Louisiana Gulf, Oklahoma-Kansas, Rocky Mountain, and Arkansas-Louisiana Inland districts.

Distribution.—The Bureau of Mines collects data relating to receipts of domestic and foreign crude petroleum at refineries in the United States. These receipts include the crude runs to stills, a small amount used as refinery fuel, and any increase in crude stocks at refineries. Classification of receipts, by States of origin, indicates the amount received from local production (intrastate), from other States (interstate), and receipts of imported crude. Classification by method of transportation indicates the final receipts by boat, pipeline, tank cars, and trucks. Receipts of domestic crude by boat were, in most instances, moved by pipeline from point of production to point of shipment by boat.

Receipts of domestic and foreign crude petroleum at refineries totaled 2,536.6 million barrels in 1954 and, supplemented by 5.4 million barrels from crude stocks held at refineries, provided for total crude runs of 2,539.6 million barrels and 2.4 million for fuel use or losses. Receipts of foreign crude represented 9.4 percent of the total, interstate receipts of domestic crude 37.0 percent, and intrastate

receipts 53.6 percent (table 31).

Refinery receipts of crude oil in 1954, by methods of transportation, indicated that 74.8 percent was delivered by pipeline, 23.8 percent by boat, and 1.4 percent by tank cars and trucks. The initial movement of domestic crude oil is primarily by pipeline, with a considerable subsequent movement by boat. Tank-car and truck movements

are largely local.

Receipts of crude oil by boat were 604 million barrels in 1954, which included 237 million of foreign crude, 206 million of interstate domestic crude, and 161 million of intrastate traffic. Of the total imports of foreign crude oil (including less than 3 million barrels delivered by pipeline), about 89 percent was received in the East Coast district, 8 percent in the California district, 2 percent in the Gulf Coast district, and 1 percent in Indiana-Illinois district. The major interstate boat movements of crude oil were 160 million barrels from the Gulf coast to the east coast, about 35 million barrels of interchanges between Texas and Louisiana, and 8 million barrels of river movement to Kentucky refineries. The most important intrastate receipts by boat were 67 million barrels in California, 49 million in Louisiana and Mississippi, 35 million in Texas, and 10 million in Kentucky.

¹ Preliminary figures.

Demand by State of Origin.—The detailed data on receipts of crude oil at refineries permit an analysis of the distribution of domestic crude oil by refining States and districts. Where long-distance shipments are involved and various crudes may be mixed in transit and

storage, identification by origin may be only approximate.

The indicated total demand for domestic crude oil amounted to 2,333 million barrels in 1954, a decline of 1 percent compared with 1953. Eight States had a demand of over 50 million barrels each and supplied 92 percent of the total demand for domestic crude oil in 1954. There was no change in the relative rank of these States in 1954. When total demand drops, the States with the largest surplus and widest distribution tend to show greater decreases than the States with more local-market areas.

The demand for Texas crude oil dropped 3 percent in 1954, and that State supplied only 42.6 percent of the total demand for domestic crude oil, compared with 43.4 percent in 1953. Receipts of Texas crude oil at refineries were 997 million barrels in 1954. Intrastate receipts increased 3 million barrels, and interstate receipts declined 45 million, or from 43.8 percent of total receipts in 1953 to 41.2 percent in 1954. The decrease in outside markets included declines of 32 million barrels in the Illinois-Indiana district and 19 million barrels in the East Coast district, while receipts in the Oklahoma-Kansas district rose 7 million barrels. These changes were related to the increase in the imports of foreign crude in the east coast, to the large increase in crude production in Illinois, and to a sharp decline in crude production in Oklahoma.

California ranked second as a source of domestic crude oil and furnished 15.4 percent of the total domestic demand in both 1953 and 1954; the 1-percent decrease in demand was at the same rate as the national decline. California crude was consumed in the State, except for a small export of crude, primarily to western Canada.

1 Missouri (39), Tennessee (16), and Virginia (8).
Preliminary figures.
Missouri (78), South Dakota (34), Tennessee (17), and Virginia (10).

Exports dropped from about 6 million barrels in 1953 to 2 million in 1954. The decline of almost 10 million barrels in the receipts of foreign crude was an important factor in preventing a greater decrease

in the demand for California crude oil.

Louisiana, the third ranking State, furnished 10.6 percent of the total demand for domestic crude in 1954, compared with 10.8 percent in 1953, a decline of 3 percent. Total receipts of Louisiana crude at refineries were 240 million barrels in 1954, a decline of about 8 million barrels or 3 percent. Intrastate receipts, representing 56 percent of total receipts in 1954 and 53 percent in 1953, increased about 4 million barrels, and deliveries to refineries in other States decreased 11 million barrels. The major declines in outside markets were 11 million barrels in the Texas Gulf district and 4 million in the Indiana-Illinois district, while receipts in the East Coast district increased 4 million barrels.

Oklahoma, the fourth State in importance, furnished 8.1 percent of the total demand for domestic crude oil in 1954, compared with 8.7 percent, a drop of 8 percent. Although there was no change in crude runs in Oklahoma, the intrastate deliveries fell about 3 million barrels, and receipts from Kansas and New Mexico increased. The largest decreases in shipments of Oklahoma crude to refineries in other States occurred in the Texas Gulf and Appalachian districts. The gains in the demand for Illinois and Kansas crudes replaced part of the normal market for Oklahoma crude.

Kansas ranked fifth in the demand for domestic crude oil, with 5.1 percent of the total in 1954 compared with 4.9 percent in 1953—a gain of about 3 percent. Total deliveries to refineries were 122 million barrels in 1954; 53 percent went to refineries in the State and 47 percent to refineries in other States. The interstate receipts of Kansas crude increased about 7 million barrels, including gains of 4 million in the Indiana-Illinois district, 2 million in the Appalachian district,

and 1 million in Oklahoma.

Wyoming was sixth in importance in 1954, with 4.0 percent of the total demand for domestic crude compared with 3.5 percent in 1953, a 13-percent increase in demand. The increase of about 11 million barrels in refinery receipts of Wyoming crude in 1954 included gains of 15 million barrels in receipts in the Indiana-Illinois district and about 2 million in the Rocky Mountain district—1 million in Wyoming and 1 million in other Mountain States. Receipts in the Oklahoma-Kansas district dropped about 6 million barrels. The rapid increase in the production of Wyoming crude in 1953 and 1954 has found a market by increased pipeline movements to the Indiana-Illinois district.

The demand for New Mexico crude rose from 3.0 percent of the total demand for domestic crude in 1953 to 3.3 percent in 1954, with a 9-percent gain in 1954. Since less than 6 million barrels of New Mexico crude was received by refineries within the State, the major markets were outside the State. Of the total interstate receipts of 64 million barrels in 1954, 49 million went to refineries in Texas and 12 million to refineries in the Indiana-Illinois district.

Illinois ranked eighth in the demand for domestic crude oil, with 2.9 percent of the total in 1954 and 2.5 percent in 1953, a gain of almost 16 percent. About 37 percent of the deliveries of Illinois crude was

refined in the State. The major outside markets were in the refineries in Ohio, Michigan, and Indiana. The large increase in demand in 1954 was due to comparison with low demand in 1953 (a 9-percent decline) and to the markets left open by the reduced supply of Okla-

homa crude in 1954.

The demand for Colorado crude, the ninth State in importance, has increased steadily since 1950. Colorado supplied 1.7 percent of the total demand for domestic crude in 1954 compared with 1.5 percent in 1953, a gain of 9 percent. The largest demand for Colorado crude was in the Utah refineries, but the major gain was in deliveries to refineries in Ohio, Illinois, and Michigan.

STOCKS

The total stocks of all oils declined 10.6 million barrels in 1954, which included a decline of 16.1 million in crude stocks and gains of 3.6 million in stocks of liquid derived from natural gas and 1.9 million

in stocks of refined products.

The decrease in crude stocks included a decline of 16.3 million barrels in domestic crude stocks and a gain of 0.2 million in foreign crude stocks. The principal changes in domestic crude stocks, by States of origin, were declines of 11.9 million barrels for Texas, 2.7 million for California, 2.4 million for Louisiana, and 1.7 million for Oklahoma, while the largest increase was 2.1 million barrels for Colorado. The unusual decline in crude stocks resulted in a larger relative decline in crude production than in crude demand.

To compare the indicated demand for crude oil with actual requirements, the change in product stocks must be considered. The abnormal increase of almost 47 million barrels in product stocks in 1953 inflated the indicated demand for crude oil materially above normal requirements, whereas the increase of less than 2 million barrels in product stocks in 1954 indicates a balanced relation between indicated

demand and actual requirements for crude oil.

VALUE AND PRICE

The average value of crude petroleum at the well rose from \$2.53 per barrel in 1952 to \$2.68 in 1953 and \$2.77 per barrel in 1954. The increase in the total value of crude petroleum at the well—from \$6.3 billion in 1953 to \$6.4 billion in 1954—was the result of a 41-million-barrel decline in production and an increase of 9 cents per barrel in value.

The posted prices of the representative grades of crude petroleum shown indicate some declines and no increases in posted prices during 1954. The increase in average value at the well, compared with 1953, is due to the fact that most increases in 1953 were effective for the latter half of the year only, whereas they covered a full year in 1954.

REFINED PRODUCTS GENERAL REVIEW

Petroleum reaches consumers in a variety of finished products that must be considered individually, relative to their competition with each other and with other sources of fuel and power. Important factors in analyzing trends are the annual adjustments in demand because of abnormal weather or fluctuations in industrial requirements and the causes for variations in the normal seasonal pattern of supply. Sharp variations among the major oil products occur in all these respects.

Gasoline is predominantly related to highway transport, aviation, and farm-tractor use. The demand for kerosine (a product defined as meeting lamp-oil specifications for color and flash point) has been drastically affected by the increase in electric lighting and by competition with natural gas and liquefied gases for cooking, water heating, and small-space heating. Distillate fuel oil, including light diesel oils, is used for space heating and as fuel for diesel locomotives and is

¹ Figures are on 1950 basis and comparable with preceding years.
2 Figures of stocks and demand are on new basis because of redefinition of bulk terminals. Stock figures as of Jan. 1, 1951, are as follows: gasoline, 123,702,000 barrels; kerosine, 21,430,000; distillate fuel oil, 76,021,000; residual fuel oil, 41,700,000.
3 Figures are on comparable basis with 1951.
4 Figures on 1953 basis because figures being shown separately for jet fuel, and unfinished gasoline is included with gasoline; total stocks as of Jan. 1, 1952, 134,221,000 barrels; kerosine, 26,836,000; distillate fuel oil, 86,509,000.
5 Preliminary figures.
6 Stock figures as of Jan. 1, 1953, were changed to 27.216,000 barrels for kerosine and 98,688,000 barrels for dis-

⁸ Preliminary figures.
6 Stock figures as of Jan. 1, 1953, were changed to 27,216,000 barrels for kerosine and 98,688,000 barrels for distillate fuel oil, new basis, because one company reported incorrectly.
7 Stock figure on Jan. 1, 1952 was 1,008,000 barrels included in gasoline, kerosine, and distillate fuel oil on Dec. 31, 1951.
8 Includes exports of 42,526 barrels not included in total United States exports for the year.
9 Liquefied refinery gases.
10 Liquefied petroleum gases.
11 Negative quantity; represents net excess of unfinished oils produced over unfinished oils rerun,
12 Included with gasoline (finished and natural).

replacing residual fuel oil and coal for railroad use. Residual fuel oil, a product that usually sells for less than the cost of crude oil at refineries, competes directly with natural gas and coal for heavy fuel uses. Since it cannot be moved by pipeline, distribution depends primarily on cheap water transport and limited tank-car movements that are too costly for competition in coal-producing areas, except for special uses. Liquefied gases compete with kerosine and light distillate fuel, are used as a raw material for synthetic rubber and chemical products, and may be used as a motor fuel. Jet fuels—a blend of low-grade gasoline, kerosine, and distillate fuel-are replacing aviation gasoline in military use.

The record total demand for petroleum and refined products showed a comparatively small gain of 1.3 percent in 1954, including a 11.3-percent decline in exports and a 1.9-percent gain in domestic

demand in continental United States.

The exports of refined products, after rising sharply in 1951 and 52, have continued to drop. The 8.1-percent decrease in 1954 1952, have continued to drop. resulted from the further expansion of refinery output outside the United States. Crude-oil exports showed a further decline of 31.9 percent in 1954, resulting from the increased production of foreign crude oil, particularly in Canada.

The small gain in the domestic demand for oil products in 1954 reflected the lowest annual gain in gasoline demand since 1946, a substantial increase in heating-oil requirements because of relatively colder weather than in 1953, and a sharp drop in the demand for heavy industrial fuels. The changes in domestic demand by products in 1954, compared with 1953, show a gain of only 2.7 percent for gasoline, a decrease of 6.8 percent for residual fuel, and increases of 7.8 percent for distillate fuel oil, 3.3 percent for kerosine, and 4.4 percent for other products.

The domestic demand for oil products was affected by the 3-percent increase in the marketed production of natural gas in 1954. Natural gas sold for industrial uses increased 1 percent and for residential and

commercial uses 15 percent.

The peak of the industrial and military demand for oil, resulting from the Korean hostilities, has passed. Aviation gasoline, jet fuel, distillate fuel, and residual fuel oil delivered to the armed forces in continental United States fell to 113.0 million barrels in 1954. No data were collected for military deliveries of motor gasoline or other products.

The new supply of refined products comprises the refinery output from crude oil, the recovery of light oils from natural gas, a small amount of motor benzol, and the imports of products. The quantity of crude oil refined (runs to stills) declined 0.6 percent in 1954, whereas the production of light oils increased 4.0 percent, and the import of

products increased 2.4 percent.

Total stocks of refined products increased only 1.9 million barrels in 1954 compared with an abnormal increase of 46.6 million barrels These figures indicate that crude runs were considerably above requirements in 1953 and approximated current requirements in 1954.

The yields of the various products from crude oil indicate the trend in demand for products over a number of years. The vield of gasoline

¹ Yields computed on the 1943 basis for California to compare with succeeding years.

On 1953 basis, separating jet fuel from its components.
 Preliminary figures.
 New basis, including unfinished gasoline,
 Jet fuel is included in gasoline, kerosine and distillate fuel totals.
 Conversion factors: 280 pounds of wax to the barrel; 5.0 barrels of coke to the short ton; 5.5 barrels of asphalt to the short ton; 3,600 cubic feet of still gas to the barrel.
 Negative quantity; represents net excess of unfinished oils rerun over unfinished oils produced.
 Includes losses or gains in volume during processing.

Yields computed on the 1953 basis to show jet fuel separately.
 Preliminary figures.

³ Preliminary figures.
4 Included in statistics of gasoline, kerosine, and distillate fuel oil.
5 Negative percentage; represents excess rerun over produced.
6 Less than 0.1 percent.
7 Added to finished gasoline production in computing yields after 1946.
8 Added to crude in computing yields after 1946.
9 Included in gasoline.

(naphtha included) decreased from 43.9 percent in 1953 to 43.8 percent in 1954 and was related to a moderate increase in gasoline demand as well as a decrease in gasoline stocks in 1954 compared with a large gain in 1953. The gain in distillate fuel yield, from 20.7 percent to 21.3 percent, reflected the substantial gain in demand because of colder weather and the gain in heating oil requirements. The sharp decline in residual yields reflects the decline in residual demand combined with the increase in residual imports.

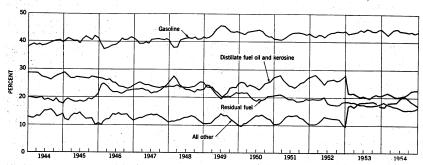

FIGURE 6.—Yields of principal products from crude runs to stills in the United States, 1945-54, by months.

The light oils from natural gas, including a small amount of cokeoven benzol blended with gasoline at refineries, contributed to the supply of other finished products. In 1954 about 63 percent of the total was used for gasoline blending or export; about 35 percent was used as liquefied gases for fuel or chemical uses, to supplement the similar output derived from still gas at refineries; and the remaining 2 percent represented distillate fuel oil and kerosine, added to the refinery output of those products by transfer as unfinished oils.

The total imports of products amounted to 144 million barrels in 1954, a gain of 2.4 percent. About 89 percent of the total was residual fuel oil coming from the Caribbean refineries to the East Coast district, where it is used for bunkering ships and as fuel for large electric and industrial plants on the seaboard. In 1954 total product imports into continental United States exceeded product exports by about 28 million barrels.

The monthly average wholesale price index for petroleum and petroleum products, compiled by the Bureau of Labor Statistics, declined from 112.7 in 1953 to 110.8 in 1954. The average value of crude oil at the well increased, but product prices in general were reduced although considerable variation by products and specified markets was shown. The average price of Regular Grade gasoline at Oklahoma refineries declined from 11.02 cents per gallon in 1953 to 10.96 cents in 1954. The tank-wagon price of kerosine at Chicago rose from 16.06 cents per gallon to 16.30 cents. The price of a selected bright stock at Oklahoma refineries declined from 20.84 cents per gallon to 17.79 cents. Bunker "C" oil at New York Harbor rose from \$2.16 per barrel in 1953 to \$2.24, and No. 2 distillate heating oil at New York declined from 9.68 cents per gallon to 9.51 cents in 1954.

Includes unfinished gasoline (net).

2 Conversion factors: 289 pounds of wax to the barrel; 5,0 barrels of coke to the short ton; 5,5 barrels of asphalt to the short ton; 3,600 cubic feet of still gas to the barrel. 3 Negative quantity; represents not excess of unfinished oils rerun over unfinished oils produced.

4 Preliminary figures.

IABLE 45.—Input and output of petroleum products at refineries in the United States, 1953-54, by districts

REFINERY CAPACITY

The total crude-oil capacity of refineries in the United States on January 1, 1955, was 8,421,000 barrels daily—an increase of 414,000 barrels daily, or 5.2 percent over 1953. The expansion program, begun in 1951, has increased total capacity by 1,457,000 barrels daily, or 21 percent, since January 1, 1951. Since actual crude runs averaged 6,958,000 barrels daily in 1954, or about 85 percent of capacity, a slower rate of expansion is indicated for several years to come. Since 1951 the largest gains, by refinery districts, have been 37 percent for the Louisiana Gulf, 31 percent for the Oklahoma-Kansas, 23 percent for the East Coast, 23 percent for the Texas Gulf, 22 percent for the Rocky Mountain, and 19 percent for the Indiana-Illinois.

¹ Includes 18,941 in 1953, 22,920 in 1954, and 34,586 in 1955 reported as inoperative without reconditioning.

AVIATION GASOLINE

The total demand for aviation grades of gasoline declined from 86.6 million barrels in 1953 to 84.1 million in 1954, a decrease of 2.8 percent. Exports increased 3.3 million barrels, while domestic demand decreased 5.8 million. Civilian deliveries increased 6.2 million barrels, whereas military deliveries declined 12.0 million barrels, chiefly because of the truce in Korea and the rapid increase in the use of jet fuels in military planes.

All data for aviation gasoline are included in total gasoline figures. "Transfers out" is rejected material returned to regular grades of gasoline. Gross production less "transfers out" equals net production

used in computing demand.

GASOLINE

Although the total demand for gasoline set another new record in 1954, the 2.3-percent gain was the smallest annual increase since 1946. Exports declined 9.1 percent, and domestic demand in continental United States increased only 2.7 percent because of a smaller annual gain for highway use, a decline in the military demand for aviation gasoline, and the curtailment of commercial demand for naphthas. Data for gasoline include aviation gasoline and naphthas.

Production.—The total production of gasoline in 1954 amounted to 1,269.1 million barrels. This included 1,115.4 million barrels produced from crude oil at a yield of 43.8 percent, 117.5 million barrels of other light oils blended at refineries, and 36.2 million barrels of other light oils blended outside refineries. Production was supplemented by importing 1.2 million barrels, and by withdrawing 2.5 million barrels from stocks of finished and unfinished gasoline. Thus the total demand for gasoline was 1,272.8 million barrels.

Yields.—The average yield of gasoline and naphtha from crude oil decreased from 43.9 percent in 1953 to 43.8 percent in 1954, owing to a small decline in gasoline stocks in 1954 compared with a large gain in 1953; to an increase in the percentage of other light oils blended with gasoline at refineries; and to the greater relative increase in

distillate-fuel demand than for gasoline.

Exports.—Gasoline exports declined from 37.9 million barrels in 1953 to 34.5 million in 1954, a drop of 3.4 million barrels, or 9.1 percent. Shipments to Territories and possessions remained at 8.0 million barrels. Reflecting the growth of aviation activity abroad, exports of aviation grades increased 3.3 million barrels to 19.2 million, whereas exports of motor gasoline, natural gasoline, and naphthas declined 6.7 million barrels. Exports of motor gasoline to West Europe have declined steadily with the expansion in refinery capacity there.

Domestic Demand.—The domestic demand for gasoline and naphthas amounted to 1,238.4 million barrels in 1954, a gain of only 2.7 percent over 1953. Totals for all uses are not available, but the demand for highway use increased 35.6 million barrels in 1954, aviation demand declined 5.8 million, demand for naphthas decreased 3.5 million, and demand for all other uses increased 6.3 million barrels.

Gasoline for civilian highway use increased 3.6 percent in 1954 (from 995.8 to 1031.4 million barrels) according to the Bureau of Public Roads, which computed use from State tax returns. These data do not include quantities of diesel fuel and fuels other than gasoline consumed that totaled 21.6 million barrels in 1953 and 24.9 million barrels in 1954. The Bureau of Mines estimated that gasoline for civilian highway use equaled 82.6 percent of the domestic demand in 1953 and 83.3 percent in 1954.

The domestic demand for aviation gasoline represented 5.2 percent

of the total domestic demand for gasoline in 1954.

No adequate data were available for motor gas for military purposes,

farm tractor and other agricultural uses, and industrial uses.

Production and Consumption by States.—Table 52, which shows gasoline production and consumption by States, provides an approximate basis on indicative areas of surplus production and deficit supply. The refinery production data were compiled by the Bureau of Mines and do not include the light oils recovered from natural gas that were blended with gasoline outside refineries. Data on consumption by States were compiled by the American Petroleum Institute and do not include commercial naphthas or off-shore military shipments. These omissions roughly offset each other.

District 1 (Atlantic Coast States and West Virginia) produced 171 million barrels of gasoline and consumed 397 million in 1954, a deficit of 226 million barrels. Receipts from district 3, including 195 million

by boat and 33 million by pipeline, partly offset the deficit.

District 2 (including refinery districts Appalachian 2 (eastern Ohio), Indiana-Illinois, and Oklahoma-Kansas) produced 388 million barrels and consumed 441 million barrels, indicating a deficit of 53 million barrels. Pipeline movements of 31 million barrels from district 3 and 3 million from district 1 partly offset this deficit, although other important supplies came by rail or river barge from district 3.

District 3 (Texas, Louisiana, Arkansas, Mississippi, Alabama, and New Mexico) produced 472 million barrels and consumed 174 million. indicating a surplus of 298 million. Of the surplus, 195 million barrels went to the east coast by boat, and 67 million barrels went into pipe-

² Figures in parentheses represent overage.

lines (33 million to district 1, 31 million to district 2, and 3 million to district 4). The rest was shipped by rail and barge to district 2 or

was exported.

District 4 (Rocky Mountain States, except New Mexico) produced 42 million barrels, received 30 million barrels from district 3, and consumed 36 million barrels. Pipeline deliveries to district 5 accounted for 4.5 million barrels; substantial rail shipments also were made to district 5.

District 5 (California, Oregon, Washington, Nevada, and Arizona) produced 159 million barrels and consumed 169 million. Most of

the deficit came by pipeline and rail from District 4.

Methods of Distribution.—Product pipelines were originally constructed to provide less expensive transportation of gasoline from Oklahoma and Texas to inland markets in the upper Middle West. Subsequently, additional lines were extended westward to Colorado, eastward into the southern half of the East Coast area, and recently from Utah to the inland markets of the upper Pacific Coast States. During the war, a product line was built from Texas to the upper East Coast but was converted to a gasline after the war. Distillate fuel oil and kerosine are being transported through the product lines at a rapidly increasing rate, without serious mixture of products at the point of contact.

In 1954 the product lines delivered about 661 million barrels representing 73 percent gasoline, 21 percent distillate fuel, 5 percent kerosine, and 1 percent liquefied gases. The gasoline delivered totaled 419 million barrels in 1953 and 484 million in 1954. The major water-borne movement of gasoline was 189 million barrels in 1953 and 195 million in 1954 transported from the Gulf Coast to the East Coast. A much smaller quantity moves by barge up the

Mississippi and Ohio Rivers.

Stocks.—Stocks of finished gasoline, as reported, include stocks held at refineries and bulk terminals and by pipelines but do not include stocks held by secondary distributors, consumers, or in military custody. There are definite normal seasonal variations in gasoline storage because of a summer peak and a winter low in demand. Stocks build up in winter, even with lower refinery yields, and are reduced sharply during the summer. This fluctuation stabilizes to some extent seasonal yields of gasoline from crude oil. Distillate fuel oil follows the reverse of this pattern, as demand is high in winter and low in summer.

Stocks of finished and unfinished gasoline declined 2.5 million barrels in 1954. Because stocks were at a relatively high level during the first half of the year and there was a smaller gain in demand than had been expected, low seasonal runs to stills followed in the third quarter, and a small seasonal increase of only 4.5 million barrels

in gasoline stocks occurred in the last quarter.

Day's supply, represented by total finished and unfinished gasoline stocks on December 31 (relative to January demand), declined to

48.7 in 1954 (table 56).

Prices.—The average posted dealer tank-wagon price for Regular Grade gasoline (exclusive of dealers' margins and sales taxes) in 50 representative cities in the United States provides an index of wholesale gasoline prices. This average increased from 15.95 cents per

gallon in 1953 to 16.19 cents in 1954. The average service-station price (exclusive of sales taxes) increased from 21.28 cents per gallon to 21.56 cents, an increase in the dealers margin from 5.33 cents in 1953 to 5.37 cents in 1954. The average service-station price to the consumer (including local, State, and Federal taxes) rose from 28.69 cents to 29.04 cents. Total taxes rose from 7.41 cents in 1953 to 7.48 cents in 1954. The average local tax remained the same at 0.09 cent per gallon, the average State taxes rose from 5.32 cents to 5.39, and there was no change in the Federal tax of 2.00 cents.

KEROSINE

Total demand for kerosine increased only 1 percent in 1954, as a gain of 3 percent in domestic demand was partly offset by the sharp 33-percent decline in exports. Domestic demand accounted for 94 percent of the total demand in 1953 and 96 percent in 1954. Production of kerosine was about one percent less than in 1953; consequently a small quantity was withdrawn from storage in order to meet requirements.

The decline in production in 1954 was due entirely to a small decline in crude runs at refineries, as there was no change in the percentage yield.

As in 1953, about 84 percent of the kerosine was produced in 4 of the 10 refinery districts. Over a third of the total was credited to the Texas Gulf Coast area, and nearly a quarter to the Indiana-Illinois-Kentucky district. Approximately 15 percent and 10 percent, respectively, came from refineries operating in the Lousiana Gulf Coast and East Coast districts. The other refinery areas produced only relatively small quantities.

A 3-percent gain in the domestic demand for kerosine in 1954 was definitely due to the colder weather that prevailed at the time. There was a 5-percent increase in the first quarter because of the unusually cold weather in January and March. The average temperature in the second quarter of 1954, measured by degree-days, was well above that for the corresponding 1953 quarter; as a result, the domestic demand was off 7 percent. Colder weather from September through December 1954 increased demands over 5 percent in the final quarters of the year.

Exports of kerosine and shipments to noncontiguous Territories continued to decline in 1954 and were off 33 percent. Although exports to the United Kingdom increased slightly, shipments to other countries declined (Canada, 0.8 million barrels in 1953 to 0.6 in 1954; India, 2.7 million barrels in 1953 to 1.5 in 1954; and Egypt, 1.9 million barrels in 1953 to 0.6 in 1954).

¹ National Petroleum News.

³ American Petroleum Institute; compiled by the Texas Co.

Year-end stocks of kerosine declined 3 percent in 1954. Inventories in the East Coast area, where over 40 percent of the stocks is usually held, dropped 13 percent; and stocks in the Indiana-Illinois-Kentucky district, which usually represent about a quarter of the total, dropped 3 percent. Increases of 1 and 50 percent were reported for the Texas Gulf Coast and the Louisiana Gulf Coast area, respectively. In the other refinery districts, where quantities of stocks held are small, increases were reported for the Oklahoma-Kansas-Missouri, Texas Inland, and Arkansas-Louisiana Inland districts, and decreases were reported for the Appalachian, Rocky Mountain, and California districts.

Kerosine stocks held at refineries, representing 40 percent of the supply, declined 7 percent during 1954, while the larger proportion reported at bulk terminals and in pipelines dropped less than 1 percent during 1954. Year-end stocks were equivalent to a 50-day supply at the January 1955 daily rate of demand, compared with a 49day supply on hand on December 31, 1953.

Preliminary figures.
 Not available

Kerosine sales increased 3 percent in 1954, mostly because of colder weather. This contrasts with a 7 percent decline in 1953. Kerosine sold for range oil (about three quarters of the total) also increased 3 percent. Sales for tractor fuel (less than 3 percent of the

total) were slightly less than in 1953. About one fourth of the total was sold for other purposes; such as, lamp fuel, insecticides, orchard heating, weed burning, and tobacco curing, and the total sold for these purposes increased 4 percent in 1954.

Sales of range oil, which is mostly kerosine plus some No. 1 fuel oil, increased approximately 3 percent in 1954. The kerosine portion of the range oil sales increased 3 percent in 1954 while the No. 1 fuel-oil portion remained virtually unchanged from 1953.

¹ Includes mostly kerosine but also a small quantity of No. 1 fuel oil.

In 1954, as in 1953, there were no important changes in representative kerosine prices. The quotation for 42°- to 44° gravity, water-white kerosine at Oklahoma refineries and intended for shipments to northern destinations was changed several times during A posting of 9.06 cents a gallon dating from late June 1953 was increased to an average of 9.18 cents in January 1954. From February through June the average price was 9.31 cents a gallon. A "low" of 9.25 cents was reached in early July, and this quotation remained in force until the second week in September. Subsequent changes in November and December resulted in a price of 9.69 cents a gallon at the year end. Many minor changes in the 1954 price for kerosine and/or No. 1 fuel oil at New York Harbor resulted in a "high" of 11 cents a gallon in late January and a "low" of 10.08 cents in July and August. The average for the year was 10.43 cents a gallon compared with 10.68 cents for 1953. The tank-wagon price

Kerosine, tank-wagon at New York City 1.

¹ Manhattan and Queens.

of 16.3 cents a gallon for kerosine in Chicago, which dated from June 1953, remained unchanged throughout 1954. Kerosine sold from tank wagons in the boroughs of Manhattan and Queens of the New York City area was marked up from 14.5 cents a gallon in November 1953, to a 1954 "high" of 15.2 cents in late January. A "low" of 14.2 cents was posted in early May, and later markups resulted in a price of 14.95 cents a gallon on December 4, 1954.

Oil companies operating in district 5 shipped 11,000 barrels of kerosine to other Western States by rail and truck in 1954 compared with 16,000 in 1953. Imports and other receipts of kerosine into the West Coast marketing area declined from 2,000 barrels in 1953 to

1,000 in 1954.

Tanker and barge shipments of kerosine from the Gulf Coast to the Atlantic seaboard, which have declined in recent years, rose to 41.4 million barrels in 1954 compared with 38.9 in 1953. Quantities loaded in Texas increased from 30.3 million barrels in 1953 to 31.7 in 1954, and those loaded in Louisiana were also larger—9.7 million

barrels in 1954 compared with 8.6 in 1953.

Barge shipments of kerosine from the Gulf Coast and Arkansas up the Mississippi River and its tributaries increased 14 percent to 5.8 million barrels in 1954. Barge shipments that originated in Texas rose from 1.6 million barrels in 1953 to 2.1 in 1954, while shipments from Louisiana totaled 2.7 million barrels in both years. Shipments credited to Arkansas were 0.8 million barrels in 1953 and 1.0 in 1954. Virtually all was shipped to district 2 (5.7 million barrels in 1954 compared with 5.0 in 1953), although small quantities went to district 1.

Tanker freight for kerosine destined for New York Harbor from the Gulf Coast continued the downward trend of recent years. The average rate for the year was 26 cents a barrel compared with 31 cents in 1953, according to Platt's Oil Price Handbook. A charge of 32.3 cents on January 1, 1954 was changed many times until it reached a "low" of 19.7 cents in July. The trend thereafter, with the coming of the heating season, was gradually upwards until the "high" of the year, 42.4 cents a barrel in this freight charge, was posted on December 21, 1954.

DISTILLATE FUEL OIL

About 99 percent of the distillate fuel-oil supply came from refineries in both 1953 and 1954, and the 1954 production was greater by 3 percent. "Transfers" from crude petroleum and imports in 1954, both minor sources of distillate fuel oils, were 24 and 5 percent, respectively, lower than the 1953 totals. A small amount was taken from storage in 1954 to meet the demand.

The overall demand for distillate fuel oil increased 6 percent in 1954. Domestic requirements were 8 percent larger in 1954, whereas exports were off 25 percent. The domestic market absorbed 96 percent of the available supply in 1954, and exports accounted for the other 4

percent.

Domestic demand for distillate fuel oil increased 8 percent in 1954, largely because of colder weather. The greater number of domestic burners in use was also a factor, although the average number in use increased only 9 percent compared with 11 percent in 1953. The

⁸ Figures not available.

weather, measured by degree-days, was 9 percent colder in the opening quarter of 1954, and the distillate-fuel-oil demand rose accordingly. The second quarter of 1954 was 9 percent warmer than the corresponding period of the previous year, and requirements for this fuel declined 2 percent. Colder weather in the second half of the year resulted in a 5-percent gain in the domestic demand for distillate fuel oil in the third quarter and a 15-percent gain in the closing 3 months.

In 1954 sales of distillate fuel oils continued the upward trend of recent years. A large net gain in sales in 1954 was mostly because of a 14-percent increase in heating-oil requirements, the result of colder weather (as measured by degree-days) and a 9-percent increase in domestic oil burners in use. Other factors were a small gain in sales of diesel fuel to railroads, and the expanding use of diesel fuel in

on- and off-highway equipment.

The lower sales of distillate fuel oils, mostly diesel grades, to vessels were more pronounced in the coastal and inland waterways traffic, as indicated deliveries in this trade declined 12 percent in 1954. Sales to vessels engaged in foreign trade were also off but to a lesser degree. Purchases by these vessels, as reported by the Bureau of the Census, United States Department of Commerce, were 9.0

million barrels in 1954, or 5 percent less than in 1953.

The Federal Power Commission reported an 8-percent decline in the consumption of diesel fuel by electric-power-generating plants from 4.8 million barrels in 1953 to 4.4 million in 1954. Manufacturedgas companies consumed only 1.5 million barrels of light fuel oils in 1954 compared with 1.9 million in 1953, according to records compiled by the American Gas Association. Thus sales of distillate fuel oil to gas and electric power plants were off 11 percent in 1954. Slightly curtailed crude-oil production and runs to stills at refineries are reflected in the small decline in the use of distillate fuel oils by oil companies.

¹ Includes diesel fuel oil.
² States are grouped according to petroleum-marketing districts rather than conventional geographic regions.

Exports of distillate fuel oil to foreign countries and shipments to noncontiguous Territories dropped sharply in 1954 as additional supplies from other world areas became available. These experts were off 25 percent in 1954 compared with a nominal 4-percent decline in 1953. The following countries showed important decreases in total exports: Netherlands Antilles, 5.0 million barrels in 1953 and 1.7 in 1954; Sweden, 1.4 in 1953 and 0.2 in 1954; and the United Kingdom, 5.7 in 1953 and 4.6 in 1954. Exports of distillate fuel oil to Canada dropped only nominally from 9.9 million barrels in 1953 to 9.7 in 1954, while quantities sent to Mexico increased from 0.4

in 1953 to 2.4 million barrels in 1954.

Although crude runs at petroleum refineries were slightly lower in 1954 than in 1953, there was a 3-percent gain in the production of distillate fuel oils because of higher percentage yield (20.7 percent in 1953 and 21.3 percent in 1954). Most refinery districts showed gains in distillate fuel oil production in 1954; however, the Texas Gulf Coast, the source of 27 percent of the total, reported a decline of 1 percent in production for the year. Production also declined 1 percent in the Texas Inland area, where about 3 percent of the distillate fuel oil is made. California, with 10 percent of total production, recorded a 5-percent decline in output. Increases in distillatefuel-oil production ranged from 2 percent for the east coast, a source of about 17 percent of this fuel, to 10 percent for the Indiana-Illinois-Kentucky group of States, which produced 16 percent of the refinery

Some pipeline companies use light crude oil as fuel, and quantities so used are considered part of the distillate-fuel-oil supply and are known as "transfers." Transfers have declined sharply in volume in recent years and there was a further decline of 24 percent in 1954. They represent less than 1 percent of the overall distillate-fuel-oil supply. Most of these "transfers" are made in the Texas Inland and the Indiana-Illinois-Kentucky refining districts. None are credited

to the east coast, Appalachian, or California areas.

Imports of distillate fuel oil, which are not an important source of supply, declined slightly (5 percent) in 1954 after having increased significantly in previous years. The quantity from the Netherlands Antilles declined from 2.3 million barrels in 1953 to 1.3 in 1954, while the quantity from Venezuela dropped even more drastically, percentage wise (from 0.6 in 1953 to 0.1 million barrels in 1954). tillate fuel oil imported from Saudi Arabia increased from 0.8 million

barrels in 1953 to 1.1 in 1954.

Year-end stocks of distillate fuel oil were off 3 percent from 1953. Quantities in the east coast area, representing over a third of the supply, declined 10 percent in 1954. There was a similar percentage loss in California, where about 11 percent of the total was held. Declines in stocks in 1954 also were reported for the Texas Inland, Louisiana Gulf, and Rocky Mountain areas; however, the quantities involved were relatively unimportant. The Texas Gulf, credited with about 13 percent of the 1954 distillate-fuel-oil stocks, and the Oklahoma-Kansas-Missouri district, with 11 percent of the total, had gains of 14 and 6 percent, respectively, during the year. late stocks in the Indiana-Illinois-Kentucky refinery district, accounting for about 18 percent of the national total, increased 1 percent in

1954. Also, there were large percentage increases in year-end inventories in the Appalachian and the Arkansas-Louisiana Inland areas, although the quanties held there were not important in volume.

About 52 percent of the distillate-fuel-oil stocks was reported held at petroleum refineries on December 31, 1954, 2 percent less than the 1953 total. Stocks held at bulk plants and in pipelines declined 5 percent during 1954.

Year-end stocks of distillate fuel oils represented a 45-day domestic supply at the January 1955 daily rate of demand, compared with a

46-day supply on hand December 31, 1953.

Rail and truck shipments of distillate fuel oil from California to other Western States comprised 458,000 barrels in 1954, slightly higher than the 1953 total (456,000 barrels). No tanker shipments of distillate fuel oils from California to the East Coast were reported in 1954, and only 6,000 barrels had been reported in 1953. Distillate fuel oil brought into the Pacific Coast marketing area, including imports, totaled 3.7 million barrels in 1954 and 2.9 million in 1953. These receipts from outside sources represented about 7 percent of the total supply in 1954 compared with 5 percent in 1953.

Distillate fuel oil shipped by tanker and barge from the Gulf Coast to ports on the East Coast increased 11 percent (from 131.7 million barrels in 1953 to 145.5 in 1954). The quantity loaded at Texas terminals increased from 106.1 million barrels in 1953 to 114.0 in 1954, while that loaded in Louisiana increased from 25.6 million in

1953 to 31.5 million barrels in 1954.

Relatively important quantities of distillate fuel oils from Texas, Louisiana, Arkansas, and Mississippi are transported up the Mississippi River and its tributaries by barge to markets in districts 1 and 2. The light fuel oil thus transported increased slightly from 7.7 million barrels in 1953 to 7.8 in 1954. The quantity loaded in Texas rose from 1.4 million barrels in 1953 to 1.8 in 1954, while that from Louisiana declined from 4.7 in 1953 to 3.9 million barrels in 1954. The quantities credited to Arkansas and Mississippi were 1.6 million barrels in 1953 and 2.1 in 1954. Most of this distillate fuel oil was unloaded in district 2—7.4 million barrels in both 1953 and 1954. Minor quantities—0.3 million barrels in 1953 and 0.4 in 1954—reached district 1. None was terminated in district 3 in either year.

The tanker rates on No. 2 distillate fuel oil shipped from Gulf ports to New York Harbor fluctuated considerably in 1954, according to Platt's Oil Price Handbook. A rate of 34.4 cents a barrel in early January slumped to a "low" of 21 cents in July. An upward trend in the fall and early winter months increased the rate to a "high" of 44.5 cents a barrel on December 21, 1954. The average for the year

was 27.7 cents a barrel, compared with 32.6 cents in 1953.

Representative distillate-fuel-oil prices in 1954 varied little from those prevailing in 1953. No. 2 straw fuel oil at Oklahoma refineries, intended for shipment to northern destinations and priced at 8.13 cents a gallon since July 1953, was increased to 8.17 cents in January 1954. Thereafter, the price fluctuated until a "high" of 8.81 cents a gallon was announced on December 30, 1954. The New York Harbor price of No. 2 distillate fuel oil—9.5 cents a gallon since November 23, 1953—was changed several times in January and

reached 10 cents at the end of the month. A "low" of 9.2 cents a gallon was posted on May 4, and again on August 9 and the "high"

of the year of 10.2 cents was posted December 7, 1954.

The price of diesel fuel at shore plants near New York Harbor varied from 9.48 cents a gallon on June 24 to 10.6 cents on December 7, 1954. Light diesel oil for ships' bunkers at New York Harbor changed from \$4.17 a barrel in January 1954 to \$3.89 in May and up to \$4.30 a barrel at the year end. Light diesel for vessels at New Orleans, La., posted at \$3.74 a barrel on June 1953, was raised to \$3.86 in October 1954 and to \$3.95 a barrel in December. The price for ships' diesel at San Pedro, Calif., which was posted at \$4.20 a barrel in late February 1953, was not changed during 1954.

RESIDUAL FUEL OIL

The overall supply of residual fuel oil in 1954 was 6 percent below the 1953 total. Production, which accounted for about three-quarters of the available quantity, was 7 percent lower, while imports, which made up a quarter of the supply, were 2 percent lower. "Transfers" or heavy crude petroleum which is used as fuel on leases or for general industrial purposes and is not relatively important in volume increased 6 percent in 1954. The domestic demand for heavy grades of fuel oil declined 7 percent. This loss in the domestic market for residual fuel oil was largely due to the sharp decline in the demand for this fuel by vessels engaged in foreign trade, by railroads, and electric-power plants. Exports of heavy fuel oils, which represent about 5 percent of total requirements, were up 3 percent in 1954. The lower demand for residual fuel oils resulted in a large increase in the quantity diverted to storage.

The recent recession in the domestic market for residual fuel oil, first evident in the final quarter of 1953, continued throughout 1954. In the first quarter of 1954 demand was off 6 percent from the corresponding 1953 quarter. In the second and third quarters, when heating requirements were not important, demand was off 11 and 10 percent, respectively. An upturn was evident in the last quarter, however, when demand was less than 2 percent smaller than in the same

quarter of 1953.

Sales of residual fuel oils, for all uses except oil-company fuel and miscellaneous uses, declined in 1954 (table 67). The 2-percent gain in the heavy fuel oils used by the oil industry was due mostly to a large increase in the California area where petroleum refineries made

a pronounced shift from natural gas to oil fuel during 1954.

The sharp decrease in the quantity of residual fuel oil sold to railroads in 1954 as in previous years was the result of the diminishing use of oil burning locomotives and the shift to diesel equipment. Heavy bunker oils delivered to vessels engaged in foreign trade declined 9 percent from 68.2 million barrels in 1953 to 62.4 million in 1954, while there was little change in the indicated quantities of 46.1 million barrels in 1953 and 46.4 million in 1954 purchased by vessels using coastal and inland waters. The 17-percent drop in sales of residual fuel oils to gas and electric power plants in 1954 was due mostly to increased use of coal and natural gas at these plants. The Federal Power Commission reported a 19-percent drop in the con-

I Represents crude oil used as fuel on leases and for general industrial purposes. Preliminary figures. ** Figures not available.

sumption of fuel oil by electric power plants from 77.4 million barrels in 1953 to 62.4 million in 1954. Also demand for heavy fuel oils by manufactured-gas companies was off 1.3 million barrels in 1954, according to statistics released by the American Gas Association.

Exports and shipments of residual fuel oil to noncontiguous Territories increased 3 percent in 1954. The more important quantities went to Canada, 5.8 million barrels; Mexico, 2.6 million; Cuba, 1.4

million; Chile, 1.9 million; and Japan, 6.3 million.

The decline (7 percent) in the production of residual fuel oil in 1954 was due almost entirely to a lower percentage yield, as there was very little change in crude runs. Both output and percentage yields were lower in all refinery districts. In the California district, which is credited with about a third of the heavy fuel oil production, the decline was only 1 percent, whereas in the Texas Gulf Coast area, with a fifth of the output, the loss was 7 percent. In the East Coast district, where approximately another fifth of the heavy fuel oil originates, the decline in output was 9 percent. The Indiana-Illinois-Kentucky district, which had about 14 percent of the production, reported a loss of 5 percent. The decline in the other refinery districts ranged from 2 percent in the Arkansas-Louisiana Inland area to 28 percent in the Appalachian district.

Heavy crude petroleum used as fuel in the oil fields and for general industrial purposes and designated as "transfers" comprised about 1 percent of the total supply and increased 6 percent in 1954. "Transfers" in California declined 4 percent, while those in other refinery

areas increased 11 percent.

Imports of residual fuel oils decreased 2 percent in 1954. Imports of heavy grades of fuel oil comprised about a quarter of the total available supply. The chief sources were Netherlands Antilles (79.4)

million barrels) and Venezuela (42.5 million barrels).

The 6-percent increase in residual fuel oil stocks was largely the result of an important increase (40 percent) in the California refinery district, where nearly three-fifths of stocks were reported at the year end. The only other refinery areas that reported gains in stocks were the Oklahoma-Kansas-Missouri and the Rocky Mountain districts, where the quantities are relatively unimportant. Stock declines in

¹ Includes some crude oil burned as fuel.
² States are grouped according to petroleum-marketing districts rather than conventional geographic regions.

1954 in areas where the quantities held are relatively large were the East Coast, down 19 percent; Indiana-Illinois-Kentucky, 18 percent;

and the Texas Gulf, where there was a 34-percent shrinkage.

Year-end stocks of heavy fuel oils held at refineries, and representing about 79 percent of the total, increased 10 percent during 1954, while those at bulk plants and in pipelines were 9 percent lower at the year end. Year-end stocks represented about a 29-day supply

at the following January daily rate of demand.

Shipments of residual fuel oils from the California refinery district totaled 21.7 million barrels. Most of this was exported to foreign countries (15.5 million barrels) or was shipped to Alaska and Hawaii (6.0 million barrels). Small quantities were distributed by rail and truck to other Western States (201 thousand barrels). There were no tanker shipments of residual fuel oil from California to the Atlantic Coast in 1952 or 1953; however, 1.6 million barrels was reported shipped in 1954 because of excessive stocks accumulated in the Pacific area and higher prices on the East Coast. Imports and other shipments of heavy fuel oils into the West Coast States increased 0.2 million barrels in 1954.

Tanker and barge shipments of residual fuel oil from the Gulf Coast to Atlantic ports decreased 9 percent in 1954. Quantities loaded at Texas terminals dropped 3.9 million barrels and those loaded in

Louisiana 2.1 million barrels in 1954.

Heavy fuel oils moved by barge up the Mississippi River and its tributaries had increased 48 percent in 1953 but declined 16 percent in 1954. Barge shipments from Texas dropped 0.5 million barrels and those from Louisiana 0.7 million barrels. Arkansas and Mississippi were credited with 47,000 barrels. Barge shipments of heavy fuel oil to district 2 increased 0.5 million barrels, and those terminated in district 1 declined 1.1 million barrels. No barge shipments were reported to district 3.

Tanker rates for Bunker "C" fuel oil on the Gulf coast-New York Harbor fluctuated considerably in 1954; however, the average for the year was 30.6 cents a barrel which was only slightly less than the 1953 average of 31.5 cents. The rate of 30.8 cents a barrel in early January 1954 dropped to 20.8 cents on June 24. An upward trend in the second half of the year brought the rate to 49.4 cents a barrel on

December 28, 1954.

There was a minor upward trend in representative prices for residual fuel oils in 1954. The posting for No. 6 grade at Oklahoma refineries intended for shipment to northern destinations was changed over 30 times during 1954. An early January price of \$1.55 a barrel was reduced in mid-July to a "low" for the year of \$1.05 a barrel. The upward trend, as the fall and winter demand became a factor, resulted in a price of \$1.55 a barrel on December 30, 1954. The posting for No. 5 grade at New York Harbor was changed only twice in 1954; it declined from \$2.77 a barrel to \$2.73 in late March and increased to \$2.87 during the first week in December. Bunker "C" heavy fuel oil at New York Harbor remained at \$2.25 a barrel until late June 1954, when it was reduced to \$2.20. It was increased to \$2.25 a barrel in September and to \$2.35 in early December. A price of \$1.95 a barrel for Bunker "C" at New Orleans, La., dating from June 1953 continued unchanged during 1954, and similarly a quotation

of \$1.80 a barrel for this grade at San Pedro, Calif., which dated from February 1953, was also maintained throughout 1954.

LUBRICANTS

The total demand for lubricating oils and greases varies greatly from year to year. The quantity of new lubricants required for automotive use varies with the number of vehicles in operation, the age of the vehicles, the improvement in the quality of lubricants that has resulted in less frequent changes of oil and greasing, and the increasing practice of reclaiming lubricating oil for reuse. Industrial uses may vary with changes in total industrial activity. No figures are available on the relative demand by uses.

The total demand for lubricants amounted to 53.6 million barrels in 1954, which included exports of 15.2 million and a domestic demand

of 38.4 million barrels.

¹ Preliminary figures.
2 Figures not available.

Production of lubricants has become less concentrated geographically, so that the relative production by refinery districts is of special interest. The important producing districts in 1954 were the Texas Gulf with 36.4 percent of the total, the East Coast with 15.9 percent, the Louisiana Gulf with 10.1 percent, the California with 9.4 percent, the Indiana-Illinois with 8.7 percent, the Appalachian with 8.1 percent, and the Oklahoma-Kansas with 7.2 percent. The largest gains in

production in 1954 were in the Texas Gulf and Louisiana Gulf, where the increase in exports was a factor.

LIQUEFIED GASES

The sale of liquefied gases for fuel, chemical, motor-fuel, synthetic rubber, and other industrial uses has expanded rapidly and these gases now rank second to kerosine in total demand. Liquefied gases are derived from two sources, production from liquids recovered from natural gas at natural gasoline and allied plants and at oil refineries from the treatment of still gas. In 1954, 72 percent of total supply came from natural gas and 28 percent from oil refineries.

The total demand for liquefied gases amounted to 120.6 million barrels in 1954, including exports of 3.9 million and a domestic demand of 116.6 million. Sales data for 1954 indicate that about 51 percent of total domestic sales was for domestic and commercial fuel uses, 21 percent for chemicals, 11 percent for internal-combustion engines, 6

percent for synthetic rubber, and 11 percent for other uses.

JET FUELS

Data on jet fuels were first collected in 1952. At present, production is primarily for military aviation, although a small quantity is exported. Jet fuel has been replacing aviation gasoline in combat planes. Extension of its use to transport or commercial planes would drastically change the pattern of aviation-fuel consumption. Jet fuels are blended at the refineries from various amounts of low-grade gasoline, kerosine, and distillate fuel. In 1954, the average blend was 70.7 percent gasoline, 21.3 percent kerosine, and 8.0 percent distillate.

Total demand for jet fuels increased 33 percent in 1954 and totaled 46.0 million barrels, including exports of 0.2 million and a domestic

demand of 45.8 million barrels.

OTHER PRODUCTS

Wax.—Wax is used primarily for waterproofing containers and paper and for candles. In 1954 the total demand for wax was 5.2 million barrels, including exports of 1.3 million and a domestic demand of 3.9 million (converted at the rate of 280 pounds to the barrel).

Coke.—Petroleum coke is a residue of cracking operations and is used for electrodes, refinery fuel, and domestic furnace fuel. Total demand was 23.0 million barrels in 1954, including exports of 3.3 million and a domestic demand of 19.7 million barrels (converted at the rate of 5.0 barrels to the short ton). Included in total production in 1954 was 9.5 million barrels (1.9 million tons) of nonmarketable catalyst coke that can be used only for refinery fuel. Since much of the increase in production has been of this low grade petroleum coke, some refineries now make coke from residual fuel oil to augment the marketable grades. Petroleum coke used as refinery fuel increased from 1.8 million short tons in 1953 to 1.9 million in 1954.

¹ Conversion factor: 5 barrels to the short ton.

Still Gas.—The production of still gas increased from the equivalent of 102.2 million barrels in 1953 to 102.6 million in 1954, or from 480 to 494 billion cubic feet. The conversion from cubic feet, as reported, to barrels is in terms of the crude-oil equivalent, not on the basis of actual heating value. Most of the still gas is consumed as refinery fuel.

¹ Conversion factor: 3,600 cubic feet to the barrel. ¹Preliminary figures.

Asphalt and Road Oil.—These products are used primarily in building materials and in road construction. In 1954 total demand for asphalt amounted to 78.5 million barrels, including exports of 1.9 million and a domestic demand of 76.6 million barrels (converted at the rate of 5.5 barrels to the short ton). The gain in domestic demand, compared to 1953, was 6 percent. The demand for road oil amounted to 7.2 million barrels in 1954. Sales of asphalt and types of products are reported in the Asphalt Chapter of the Minerals Yearbook.

Miscellaneous Oils.—The total demand for miscellaneous oils rose from 9.1 million barrels in 1953 to 10.8 million in 1954. The largest increases in production relate to specialties and others, including spray oils, aromatic tar, petrochemicals, xylene, and other products.

INTERCOASTAL SHIPMENTS

The major intercoastal movement of crude oil and products was from Gulf-coast ports to east-coast ports. The comparatively small movement of products from California to the east coast increased from 0.7 million barrels in 1953 to 2.5 million in 1954, the increase being due primarily to the gain of 1.6 million barrels in residual fuel

oil shipments.

Total Gulf-east-coast shipments amounted to 623.6 million barrels in 1954, a gain of 2.7 million including a decline of 14.5 million in crude oil and an increase of 17.2 million in products. The principal changes by products, compared with 1953, were increases of 13.8 million barrels for distillate, 6.5 million for gasoline, and 2.5 million for kerosine, while residual shipments declined 6.0 million barrels. The decline in the movement of domestic crude oil was related to a decline in total crude runs in the East Coast district combined with an increase in foreign crude runs. The increase in the product movement reflected the improved demand for light heating oils and a sharp drop in residual fuel demand.

FOREIGN TRADE 2

Foreign trade statistics in this section, as reported by the United States Department of Commerce, differ slightly from those used in other sections of this chapter. Bureau of Mines petroleum import statistics pertain to continental United States only, and its export statistics include not only foreign countries but also shipments to the Territories. Imports of crude petroleum and unfinished oils shown in table 78 are obtained by the Bureau of Mines from petroleum companies on a custody basis to balance refinery reports and therefore differ from the totals reported by the United States Department of Commerce.

Imports.—During 1954 mineral-oil imports into continental United States continued the growth trend of the postwar years and increased about 2 percent over 1953 to average 1.1 million barrels per day. Crude oil and residual fuel oil continued to be the principal oils imported, with crude petroleum amounting to 62 percent of total petroleum imports and residual fuel oil 34 percent of the total. Imported mineral oils made up 13.0 percent of the total new United States supply of petroleum in 1954 compared with 12.7 percent a year ago. The volume of imported mineral oil exceeded exports, including shipments to the Territories, by 253.9 million barrels in 1954 compared with 230.9 million barrels in 1953.

According to United States Department of Commerce statistics, crude-petroleum imports increased 2 percent over 1953. Venezuela was again the largest supplier of crude petroleum to the United States (53 percent of the total), and receipts from that source rose 9 million barrels. The countries of the Middle East supplied 32 percent of United States crude imports compared with 34 percent the previous year. Receipts from Saudi Arabia were 18 percent lower, while those from Kuwait and Iraq rose 8 and 39 percent, respectively. Receipts of Indonesian crude oils were off slightly from 1953. Im-

By F. X. Jordan, Office of Oil and Gas, U. S. Department of the Interior.

ports of crude petroleum from Canada were at the same rate as in

1953.

Lower United States industrial demand for heavy fuel oil in 1954 resulted in a 2-percent decrease in imports of residual fuel oil used as boiler fuel by industry. The Caribbean area (namely, the Netherlands Antilles and Venezuela) continued to supply the bulk of United States imports of this heavy fuel oil; Mexico shipped most of the

Imports of the lighter heating oils and diesel fuels into the continental United States decreased 4 percent, and imports into the Territories from foreign countries rose 59 percent. Refineries in the Caribbean area continued to be the primary source for these imported distillate fuel oils; the balance was supplied from the Middle

East-Bahrein Island and Saudi Arabia.

Asphalt imports, including receipts by the Territories, were 34 percent higher than in 1953; the Netherlands Antilles was the major

supplier in both years.

Imports of unfinished oils for further processing almost tripled the 1953 rate. Mexico and Kuwait, neither of which supplied unfinished oils in 1953, shipped 5 and 0.7 million barrels, respectively. Receipts of unfinished oil from Venezuela were up 85 percent, while Trinidad's shipments of unfinished oils to the United States fell 93 percent.

Exports.—United States exports of crude petroleum and refined petroleum products, including shipments to the Territories, decreased 11 percent in 1954 as foreign refinery capacity continued to increase, supplying more of the foreign refined-product requirements. petroleum refineries in Europe, Aden, India, Union of South Africa, and Australia, among others, began supplying products to local markets and, in the case of the Aden refinery, began exporting large volumes of refined products. The Abadan, Iran, plant, which produces primarily for the export market, resumed operations on a limited scale in late October 1954 and will supply increasing volumes of product for export as refinery throughout is increased.

Crude-petroleum exports from the United States were 32 percent lower and total refined-product exports 8 percent less than in 1953. Exports (including shipments to the Territories) of residual fuel oil, lubricating oil, wax, asphalt, and liquefied petroleum gases, were higher in 1954, while exports of other refined products were lower

than the previous year.

In 1954 crude-petroleum exports to all countries were lower except for nominal increases to Cuba, France, and United Kingdom. ments to Canada dropped almost 6 million barrels as the Canadian transmountain pipeline from Alberta to British Columbia completed its first full year of operation, enabling refineries on the Canadian west coast to operate on Canadian crude rather than United States Argentina's imports of United States crude decreased 44 percent; Italy took 66 percent less and Japan 16 percent less than in None was shipped to the Territories.

Continental United States exports and Territorial shipments of motor fuel (including aviation gasoline) decreased 3.6 million barrels. Country destinations of certain grades of aviation gasoline are not available for security reasons, but the amounts are included in the grand total. The limited country breakdown available indicates that smaller shipments were made to all major geographical areas, including the Territories. The largest decreases were in shipments to Canada, Cuba, the United Kingdom, Australia, and New Zealand. The Netherlands Antilles and Mexico were the only countries taking significantly larger quantities than in 1953.

Exports of kerosine dropped one-third from 1953, principally because of curtailed shipments to Egypt and India. Shipments to Mexico, Puerto Rico, Argentina, the United Kingdom, and Australia

increased moderately.

Exports of distillate fuel oil were off 25 percent from 1953 with exports generally lower to all areas except South America. The largest decreases were: Netherlands Antilles, down 3.3 million barrels; United Kingdom, 1.1 million; Sweden, 1.2 million; and Aden, Arabia, 0.7 million barrels less than in 1953. The only increase of consequence was the 2.0-million-barrel increase in shipments to Mexico. Territory shipments were 15 percent under the level of the previous year.

According to United States Department of Commerce statistics, exports and Territorial shipments of residual fuel oil were slightly above the previous year. North American countries increased takings of residual fuel oil by 0.6 million barrels, and Chile took 0.9 million barrels more than in 1953. Japan, however, took 1.4 million barrels

less, and the Territories 0.2 million less than in 1953.

Lubricating-oil shipments increased 18 percent over 1953. The destinations for certain grades of lubricating oil are not available for security reasons, but the quantities are included in the grand totals. The limited breakdown available indicates that shipments to Eastern Hemisphere countries generally increased, and Asia received 33 percent, Europe 15 percent, Africa 45 percent, and Oceania 186 percent more than in 1953. In Europe, the largest foreign market for lubricants, all countries increased imports of United States lubricants except France and the United Kingdom. India, Pakistan, Egypt, and Union of South Africa also increased imports notably, as did Australia and New Zealand. Territory receipts from the United States were off 12 percent. Total shipments to Western Hemisphere destinations were at the 1953 rates, with reduced shipments to Canada and Argentina and higher imports by Mexico and Brazil.

Among the other refined petroleum products, asphalt exports rose 9 percent. Higher shipments to Western Hemisphere countries and to Indochina more than offset the decline in shipments to Africa. Liquefied-petroleum-gas exports increased 32 percent, with notable gains in shipments to Mexico and Brazil. Exports of wax and petrolatum increased 19 and 20 percent, respectively. Petroleum-coke exports decreased 11 percent. Shipments to Japan fell 0.4 million barrels, which more than offset increases in shipment to France and Italy. Shipments of miscellaneous oils, including jet fuel, were slightly higher in 1954. Destinations of jet-fuel exports are not available for security reasons, but the quantities are included in the

grand totals.

WORLD PRODUCTION 2

World crude-oil production increased 4.6 percent in 1954 to average 13,674,000 barrels daily, even though United States production decreased from 1953. Crude-oil production in the United States was almost 2 percent below that in the previous year and represented 46.4 percent of the world total, compared with 49.4 percent in 1953. The countries of the Middle East (Bahrein Island, Iran, Iraq, Kuwait, Qatar, and Saudi Arabia) supplied 20 percent of the world total in 1954, compared with 19 percent a year earlier. Venezuela, the second largest crude-oil-producing country, furnished 14 percent of the total in both years. Crude-oil production in the Western Hemisphere rose 1 percent in 1954, compared with a 12-percent growth in Eastern Hemisphere output. On October 29, 1954, the agreement between Iran and an 8-company international consortium was approved, thereby returning Iranian oil to world markets for the first time in more than 3 years.

Canadian crude-oil production again increased notably; the Province of Alberta supplied 91 percent of total production. No major field discoveries were made in Canada during 1954. A followup of the 1953 Pembina field discovery about 65 miles southwest of Edmonton established this area as a producing field with prospects of becoming one of the largest in North America. Looping of 650 miles of the interprovincial pipeline running from Edmonton to Superior, Wis., increased daily intake capacity at Edmonton from

170,000 to 217,000 barrels.

Crude-oil production in Mexico increased almost 16 percent. The Angostura oil field (discovered in 1953), 40 miles southwest of Veracruz, and the Casa Blanca field (discovered in 1954), 8 miles northwest of Angostura, have demonstrated commercial possibilities

for a considerable area in the Veracruz vicinity.

South America increased production 7 percent over 1953, as both Venezuela and Peru reversed their production declines of a year earlier. Venezuela increased production 130,000 barrels a day to establish a new record. Bolivia nearly tripled the previous year's production. Chile raised production by over a third and late in the year placed in operation its first major oil refinery, with a capacity of 20,000 barrels a day, located near Valparaiso. In Argentina the Government oil company, Yacimientos Petroliferos Fiscales (Y. P. F.), increased oil production over 5 percent, while production of other

companies decreased 4 percent.

Western Europe raised crude-oil production significantly in 1954. Germany continued to be the largest producer and increased output 23 percent. In France the outstanding event was the discovery in March of the Parentis field, 45 miles from Bordeaux. The discovery well flowed at the rate of 3,500 barrels of oil a day. During the year 5 wells were completed (4 of which were productive), and this field accounted entirely for the 41-percent increase in France's production. Crude production in the Netherlands continued to increase, and 4 additional wells were drilled (2 of which were productive) in the Rijswijk field discovered in 1953. Yugoslavia increased production by one-fourth in 1954. In March 1954, Turkey enacted a new petro-

² By F. X. Jordan, Office of Oil and Gas, U. S. Department of the Interior.

leum law permitting private concerns to prospect for petroleum, and several oil companies have received permits to do geological

exploration work.

No reliable information is available for other countries in Eastern Europe. It is estimated from meager data that the U. S. S. R. increased production 13 percent in 1954 and that Rumanian production apparently increased about 6 percent.

Crude-oil production in Africa dropped 15 percent almost entirely because of the decline in the output from the Asl field in Egypt. Exploration activity continued to increase in Africa in 1954, and more wildcat wells were completed and more drilling rigs in operation

during the year than ever before.

Middle East production increased 13 percent to average 2.7 million barrels daily. Saudi Arabia and Kuwait, the largest producing countries, produced at almost identical rates of about 953,000 barrels daily during 1954. Iraq production continued to climb, and in December commercial output began in the Basrah Petroleum Co. new oilfield at Rumaila, about 20 miles west of the Zubair field. In Iran the consortium has set up 2 companies to operate in the country, 1 concerned with exploration and production and the other with refining. The National Iranian Oil Co. remains the Government petroleum authority. The consortium has undertaken to export 300,000 barrels of Iranian crude oil a day for the first year, after a 3-month startup period. Commercial production and export began in the neutral zone between Saudi Arabia and Kuwait in early 1954.

In the Far East the United States of Indonesia increased production by 6 percent, primarily from the southern Sumatra fields. Crude-oil production from the Vogelkop area of New Guinea was increased 131 percent because of completion in March of an 8-inch pipeline from the Mogoi field to Muturi at seaboard. British Borneo's production was slightly below that in 1953. Pakistan and Burma raised production 10 and 23 percent, respectively. Press reports from Communist China indicate a considerable increase in crude-oil output in 1954. Although discovery of crude petroleum in Western Australia was reported last year, four additional wells drilled in 1954 on the Rough

Range structure were abandoned as dry holes.

 Natural naphtha and gas oil.
 Estimate.
 U. S. S. R. in Asia (except Sakhalin) included with U. S. S. R. in Europe.

PETROLEUM TECHNOLOGY 3

EXPLORATION FOR NEW RESERVES

The oil industry continued to explore for new reserves during 1954 at a high level. The cost of exploratory drilling remained high, although it was slightly less on a footage-drilled basis than during the preceding year, principally because of improvements in drilling methods.

Exploratory drilling continued at a high rate in 1954, although slightly less exploratory footage was drilled than in 1953. Data in table 83 show the annual increases in proved reserves of total liquid

in 1954 (23.1 percent) was slightly more favorable than in 1953 (22.1 percent). However, the new proved reserves declined, compared with 1953, as did the ratio of new reserves to the exploratory footage drilled.

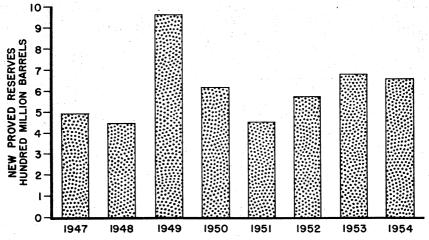

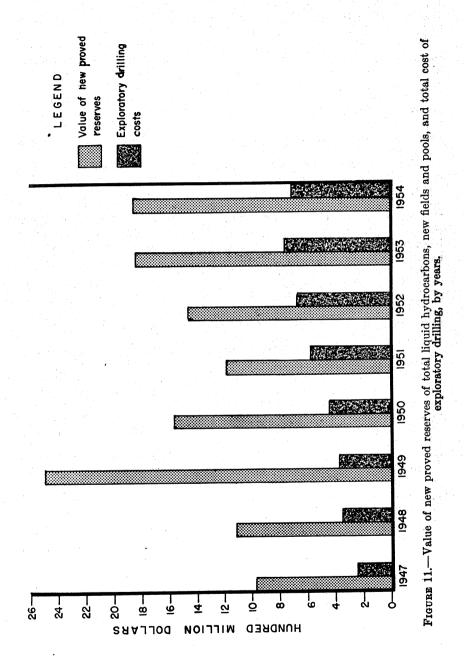

FIGURE 10.—Changes in new proved reserves of total liquid hydrocarbons, new fields and pools, and feet of exploratory drilling, by years.

DRILLING AND WELL-COMPLETION METHOD

Two changes in the development of oil production during 1954 were of both technical and economic significance to the petroleum industry. In the effort to find new fields, more deep wells were drilled than in any preceding year. More than twice as many wells (53 wells) were drilled to depths below 15,000 feet in 1954 than in either 1952 or 1953, when 24 wells were drilled annually below that depth. However, the average cost per well of deep-well drilling in

1954 was less than in 1953, and the total cost per foot of rotary drilling also was slightly less. Lower drilling cost resulted principally from improved drilling methods.

The second change in drilling procedures and the one that effected the greater economy in drilling costs was the extended use of "slimhole" drilling for moderate to deep wells. Reduced hole size was accompanied by lower costs both for drilling and for completing wells.

Figure 11 shows graphically the total cost of exploratory drilling as compared to the value of the new reserves developed from 1947 The data plotted were taken from table 83. through 1954. value of annual increases in proved reserves of total liquid hydrocarbons in new fields and in new pools per dollar expended in exploratory drilling was \$2.60 in 1954 compared with \$2.43 in 1953. highest dollar benefit on this basis for the years shown was \$6.67 for 1949, and the lowest was \$2.07 for 1951. The plotted annual increases in proved reserves do not include production figures; however, the increases shown are indicative of the profit trend. The higher costs of the increasingly difficult task of finding new oil reserves have been partly offset only through more efficient and economical practices in exploration and drilling.

Other technological improvements in drilling methods, used more extensively during 1954, included the use of air and natural gas as drilling fluids, both for drilling and coring, and the use of improved additives for drilling muds. Rotary-percussion drilling, which employs both a vertical stroke and rotary motion, was introduced on

an experimental basis in 1954.

By far the most significant new technique in well completions in 1954 was the widespread use of intentional fracturing of oil-productive formations by the injection of sand carried in a liquid, at high pressures, for increasing the flow of oil into well bores. No current figures are available for the extent of hydraulic fracturing in 1954 and the years immediately preceding. One source 8 reported only 137 hydraulic-fracturing jobs in 1949 and a total of 40,000 by January 1954, with a then current monthly average of 2,500. Another source 9 reported 5,000 fracture jobs in Oklahoma alone from January through September 1953. No data are available for the increased oil produced because of the application of hydraulic fracturing. However, several old fields in the midcontinent area have been revived because of hydraulic-fracturing methods, and much oil has been produced from formations that formerly were not considered to be economically Significant improvements in 1954 included application of hydraulic fracturing to multiple zones in one well and development of additives that permitted controlling the extent and directions of fractures.

New cement additives designed to yield low-weight, high-strength cements also were developed during 1954. High-strength wire rope for rotary-drilling lines and new finishing facilities for producing oilcountry tubular products for high strengths in deeper drilling also were introduced.

DISCOVERIES

Although no new large oil fields were discovered in 1954, production was found in three new States by land drilling. Producing wells were completed in South Dakota; in the Eagle Springs field, Nye County, Nev.; and in the Black Mesa Basin, Apache County, Ariz. New discoveries were made in four basins—the Paradox Basin, Utah; the Dalhart Basin, northwestern Texas; the Delaware Basin, West Texas; and the North Park Basin, Colorado. 10

Increased offshore exploration, made possible by improved drilling equipment and methods, and some clarification of legal questions pertaining to oil rights, resulted in the discovery of the first field off the California coast, the first 2 fields off the Texas coast, and 16 new fields off the coast of Louisiana. At least 4 of the 16 new Louisiana

fields were considered to be important.11

PRODUCTION METHODS

One of the most significant trends in oil-production methods put into more widespread practice during 1954 was the use of automatic control of pumping and separating equipment. The first completely automatic tank battery was put into service in Texas.¹² The use of automatic controls in production not only results in lower overall operating costs but also effects a saving in manpower. Sound waves were used to motivate a new deep-well pump that has been tested successfully in California.13 Greater use was made of "down-the-hole" treatment in oil-production wells with demulsifying chemicals and corrosion inhibitors. Demulsifiers and thermal demulsification units were used more extensively on many leases, particularly in the colder Extended use was made of corrosion-resections of the country. sistant and noncorrodible equipment for petroleum production, such as cement-asbestos and plastic gathering lines. Improved plastics made possible their increased use.

Reinjection of gas or water produced with crude petroleum was responsible for the continued production of significant quantities of crude petroleum. According to estimates of the Interstate Oil Compact Commission, 318 million barrels of oil was produced during 1953 by pressure maintenance. 4 This amounted to approximately 13.5 percent of the total oil produced during that year. Preliminary reports indicate that oil production by pressure maintenance for 1954 was at a continued high rate. Examples of continued successful pressure maintenance projects are the East Texas water-injection project and the successful water-injection project in the New Hope field, Franklin County, Tex. Modern and efficient operating practices

are evident in both projects.

New technological developments in repressuring partly depleted petroleum reservoirs with gas and air were continuance of the successful experimental injection of natural gas at high pressure in Block

31 field, Crane County, Tex., and the start of an experimental project in the Camp Hill field in Texas where liquefied petroleum gas is being

injected.15

Numerous new technical developments were applied to waterflood operations during 1954. This year marked the start of water injection into the Scurry Reef field in Texas—the largest potential waterflood in the United States. The deepest waterflood, in the Ellenberger formation at 13,000 feet, also was started in West Texas. The "imbibition" method of flooding low-permeability formations was continued with success in the Spraberry trend in Texas. The first large waterflood in California was started, and successful conditioning of Pacific Ocean water for flooding made available a huge potential

source of water for flooding coastal fields.

Detergents were used experimentally as flood-water additives in several field trials to increase rates of water injection and oil production. 17 Newly developed organic corrosion inhibitors and bactericides were used in many projects to minimize corrosion and prevent plugging of water-input wells. Filtration was improved in many installations by the use of element-type, diatomaceous earth filters of new design constructed from corrosion-resistant materials. Significant improvements were made on an experimental basis in the efficiency of removal of dissolved acidic gases from water by scrubbing with combustion exhaust gases and in the use of submerged burners. 18 19 fracturing was first applied on an organized basis to water-input and oil-production wells in water floods with significant increases in oil production.20

Information was released by two large oil companies in 1954 on the preliminary results of experimental laboratory and field tests of methods of increasing oil production by partial combustion of oil in place in the reservoir.^{21 22} Similar research was started by several other

production-research organizations.

CHANGES IN SOURCE OF CRUDE PETROLEUM

Deeper drilling in quest of new reserves caused much of the wildcat activity to be centered in the Gulf Coast States, the Rocky Mountain States, and California.²³ Three new States—South Dakota, Nevada, and Arizona—were introduced as producers in 1954, thus extending the range of possibilities of oil production from new areas.

Improved offshore drilling techniques, the success of some offshore drilling operations, and partial clarification of the legal questions pertaining to offshore and tidelands oil rights were responsible for

increased drilling and discoveries in offshore locations.

Figure 12 shows graphically the trends in crude oil produced by primary reservoir energy, pressure-maintenance by water injection, the injection of gas and air, and the injection of water from 1947 through 1953. Complete data are not yet available for 1954. The data from which the plots of this figure were made are only approximations, as it is impossible to separate production figures absolutely according to the method of production. However, the trends of production from projects classified as to the source of energy are clearly shown. From 1951 through 1953 total crude-oil production remained essentially constant. Oil produced by pressure maintenance by the injection of water has increased generally for the 7-year period. Oil produced by gas and air injection has increased annually, as has oil produced by waterflooding. These data also are presented in table 84.

4 Includes some gas condensate.

CONSERVATION PRACTICES

Increased production of petroleum has resulted from the conservation practices of the oil industry. This is borne out by the production increases previously cited for pressure maintenance by water injection, gas and air injection, and waterflooding. In water injection, and to a large extent in the injection of air and gas, return of those fluids to the reservoir not only has been responsible for the production of significant quantities of oil but has been instrumental in complying with State regulations governing the disposal of oilfield brines and the venting and flaring of natural gas.

Laws in some States were strengthened during 1954 to prevent further contamination of surface waters and potable-water-bearing formations by oilfield brines. Such regulations necessitate subsurface injection of the brines which, when applied to the producing formation, usually results in significant increases in oil production. Monthly proration orders were issued during 1954 by six of the major oil-producing States. Proration and other regulatory measures of oil-producing States are directed toward prevention of waste and recovery of oil at a reasonable cost while maintaining a rate of production con-

² See footnote 13, p. 121

sistent with market demand and providing for the recognition of

equities of individual owners.

The leasing and supervision of Federal lands was continued by Government agencies. An example of this action is the Indian lands in Osage County, Okla. Increased production royalties and income from the sale of leases were occasioned by the success of a large waterflood operation in the North Burbank pool, the successful use of hydraulic-fracturing methods in the completion of primary wells, and

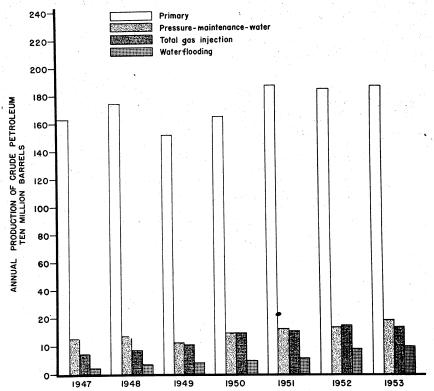

FIGURE 12.—Approximate production of crude petroleum by primary methods, pressure maintenance by water injection, total gas injection, and waterflooding, by years.

judicious management of the interests of the Osage Nation. This activity was at least partly responsible for maintaining a high rate of oil production in Oklahoma without significant new discoveries of large reserves within the State.

TRANSPORTATION AND STORAGE

Additional research was done on improved external and internal protective coatings for pipelines to minimize corrosion. A flexible external coating that will withstand cold bending of the pipe was developed. An automatic welding machine for aluminum pipe was constructed and used successfully. The use of air for testing finished

pipelines was demonstrated during 1954. Oil-field surveying methods, employing a gyroscopic compass and an inclinometer mounted

on a "go-devil," were used to locate pipelines in river beds.

Automatic control of fluid transmission, embodying the electronic "feedback" principle, was extended. Microwave relay systems were used extensively for intercommunication between pump stations and main offices. The largest oil line built by the end of 1954 was 31 inches in diameter; however, 30- to 36-inch lines are common in the gas industry. The most notable change in pipeline design has been in prime movers and pumps; for example, the gas turbine as prime mover has come into its own. Another important contribution to the natural-gas industry was publication of American Standards Association B-31, Section 8, Code on Gas Transmission and Distribution Piping Systems.

The use of gravitometers and radioactive tracers provides methods for locating the interface of different transported fluids. The radioactive tracers also provide a means of starting and stopping auto-

matic booster stations.

Tankage at pumping stations is primarily to absorb various pumping rates and to provide some control on batching and grades of oil pumped. Present tanks are all-welded structures ranging up to 200,000 barrels in capacity. Automatic welding machines have been developed to weld horizontal and vertical seams. The roofs used are floating structures that rise and fall with the liquid, minimizing corrosion and evaporation losses. In addition, tank-breathing devices, vapor-recovery systems, and plastic foam are now being used to reduce evaporation loss. Agitation by electric mixers and directional nozzles have provided effective control in the problem of the accumulation of basic sediment and water (BS&W) in tanks.

The automatic tank gage, with its associated remote-transmission system, gained widespread use and has been adopted by the oil industry for buying and selling crude oil on a mutual-agreement basis. Electrical averaging resistance thermometers have been developed to measure the average temperature of a volume of oil in a tank, making

remote transmission of temperature possible.

Underground storage of gas and liquid hydrocarbons in artificial and natural caverns has received considerable attention by the petroleum industry; however, the crude-oil-pipeline companies do not, at present, use this method of storage. Considerable evaluation has been made on plastic tanks in small sizes as a possible answer to tank corrosion and other incrustation buildup.

DEVELOPMENTS IN REFINING 25

Activity in the refining industry continued at a high level during 1954. Several process modifications and new processes were announced, more emphasis was placed on the production of light distillates, and increased interest was shown in such new possibilities as the applications of nuclear energy in refining.

Catalytic reforming is the fastest growing process in the refining industry today. After construction of the first fixed-bed hydroformer in 1939, catalytic reforming capacity increased slowly for the next 10

²⁵ By Jack E. Phillips and C. W. Kelley

years; the process was used mainly to produce toluene and other aromatics, especially during World War II. Since 1950 the process has grown rapidly and has been tremendously important to the refiners for the production of the higher octane-number gasoline demanded by the automotive industry. Domestic catalytic reforming capacity increased from 125,000 barrels daily at the end of 1951 to 600,000 barrels daily at the end of 1954, when 11 catalytic reforming processes were available to the refining industry.

In addition to its major use in the production of high-octane-number gasoline, catalytic reforming is becoming increasingly important in the production of the three major aromatics—benzene, toluene, and xylene. In 1954 approximately 280 million gallons of these aromatics was made by catalytic reforming expressly for the chemical markets. This represents about half of the total produced in the United States from all sources and compares with about 250 million gallons produced

in 1953.

Another process, introduced commercially in 1954 and designed to increase the yield of distillate products at the expense of residuum, is the Houdresid process. The first unit of this type was put into operation in March 1954. In many respects the Houdresid process resembles the Houdriflow catalytic cracking process, utilizing a downward-moving bed of synthetic or natural clay catalyst through a reaction vessel superimposed on a regenerator, wherein the catalyst is rejuvenated by burning of the deposits that accumulate on the catalyst surface. However, the process is unique in that it is the first successful application of catalytic cracking techniques to a heavy reduced crude charge stock.

Following a general trend of several years, demand for distillate products, including gasoline, increased at the expense of residual fuels. This trend was reflected processwise in the refining industry by installation of new coking units and increased charge to previously Although the familiar delayed coking processes installed units. account for essentially all of today's coking capacity, the relatively new processes of continuous contact coking and fluid coking are receiving close attention in the industry. The first of these was Fluid coking was demonproved on a commercial scale during 1953. strated commercially late in 1954 and early in 1955. Both of the new coking processes are versatile in terms of charge stock, reportedly being capable of handling residuums ranging from reduced crudes to heavy cracked tars, and both produce a coke product in the form of small granules that are withdrawn continuously from the system, thus eliminating the need for the elaborate decoking equipment of the older delayed coking processes.

Radioactivity has been widely applied in the refining industry in two distinct uses. Isotopes, such as radioactive cobalt, antimony, and zirconium, have been used for a number of years as sources of gamma rays for use in level indicating and control devices. More recently such radioactive materials have been coming into use as tracers, being incorporated into the streams of materials to be traced. By this means it is possible to measure the rate of flow in process pipes by outside measurements with Geiger counters, to check flow patterns in complex piping systems, to detect leakage from one stream to another within such equipment as heat exchangers, to measure the

thoroughness of mixing of materials in multicomponent systems, and to perform a variety of similar functions. Seeking new applications of nuclear energy, at least one petroleum company has started active investigation of the use of nuclear energy as a processing tool and plans to study such things as the influence of gamma radiation on the chemical reactions of refining and petrochemical processes.

The long-term trend toward higher octane number of motor gasoline continued. Although competition may be partly responsible for this continuing trend, the major factor is the requirement imposed by the year-to-year increase in compression ratio of the new automobile engines. Surveys by the Bureau of Mines show that since 1951 the nationwide average octane number of Premium Grade gasoline, by the research method, has increased from 90.0 to 93.6, and, for Regular Grade gasoline, has increased from 83.1 to 86.2. Corresponding increases in terms of motor-method octane number were from 82.0 to 84.5 and from 78.1 to 80.8.

Sharply increased use of jet-propelled aircraft by the Armed Forces was reflected in a comparable increase in demand for jet fuels during This trend is almost certain to be accentuated as jet-propelled civilian aircraft enter the field. At least one domestic air-transport company announced plans for putting turboprop-type aircraft into operation in 1955. Still another and potentially dominating factor in future demand for jet fuels is the probable development of turbine-driven automotive equipment. Interest within the automotive industry is sufficiently great that active competitive experimental work in the field has been undertaken by several automobile manufacturers. Major advantages of gas-turbine engines over the conventional piston types include their considerably decreased ratio of weight to power output and their suitability for operation with relatively cheap fuel. General opinion now is that the fuel for at least the first turbine-driven automobiles will be ordinarily kerosine or a blend of kerosine and heavy gasoline.

Although the demand for lubricating oils has not changed greatly during the past few years, significant changes have been made in the quality of the oils. Improved quality has been necessary to pace the more exacting requirements imposed by new and specialized industrial machinery, more powerful automotive engines operating under closer tolerances, and gas turbine engines. To improve the quality, industry, over a period of years, has devised special refining methods, such as solvent extraction, and, possibly more important, has developed many additives to impart the desired qualities to oils intended for specific uses. By the end of 1954 additives were being blended into lubricating oils of all types at a rate of almost \$150 million per year,

compared with about \$40 million per year in 1948.

Additives are generally classified into nine groups, as follows: Detergents, oxidation inhibitors, viscosity-index modifiers, pourpoint depressants, extreme-pressure lubricant agents, oiliness agents, rust inhibitors, antifoam agents, and dyes. At present, on the basis of active chemical ingredients, the quantities and values of the various types of additives being consumed in the lubricating-oil market are approximately as follows: Detergents and inhibitors are being used at a rate of 200 million pounds per year and have a value of about \$80 million; extreme-pressure gear-oil additives at 60 million pounds

and \$15 million per year; viscosity-index modifiers at 25 million pounds and \$15 million per year; and pour-point depressants at 10 million pounds and \$10 million. The remaining \$30 million is divided

among oiliness and antifoam agents and dyes.

Opinion is divided as to whether high-quality lubricating oils from petroleum will be suitable for gas-turbine-driven automotive equipment, which soon may be on the market. Mineral-oil lubricants are not considered adequate, for military jet-aircraft use, even when produced by the most advanced refining techniques and when fully fortified with the most applicable additives. Synthetic lubricants are being used to meet the stringent lubrication requirements of military jet-aircraft engines. At present the only synthetic on the market that meets military requirements, as defined in Specification MIL-L-7808, is a product containing di-iso-octyl sebacate and possibly an adipic ester; however, other synthetic lubricants are being investigated actively in Government and industry laboratories. These materials include organophosphorus compounds, silicones, silicate esters, and polyglycol esters.

Petroleum Asphalt

By Albert T. Coumbe, Ivan F. Avery, and Mildred C. Putnam

SCOPE OF REPORT

FOR THE SECOND consecutive year sales of petroleum asphalt and road oil are published by States. Data for 1953 and 1954 are comparable, to the extent that the survey for the 2 years requested the same information. However, asphalt producers were in a better position to submit a detailed breakdown of sales by States for 1954 than for 1953, the first year for which the questionnaire was revised. All respondents reported their sales by States for 1954, whereas in 1953 a few were unable to furnish this information and the Bureau of Mines estimated their distribution. Of the 89 known asphalt producers canvassed, reports were received from 87. In addition, 26 asphalt-emulsion manufacturers were asked to cooperate with the Bureau of Mines in this survey, and 23 complied. No estimates of sales of nonrespondents were made, as the volume of their business was believed to be relatively unimportant.

 Preliminary figures.

SALES

Sales of petroleum asphalt and products totaled 14.7 million short tons in 1954, a 5-percent increase over 1953. Sales of road oil remained virtually the same as in 1953—1.3 million short tons. Asphalt sales for paving purposes, such as for highways, roads on private property, sidewalks, parking areas, and airfield runways, increased from 9.2 million short tons (65 percent of the total demand in 1953) to 10.0 million (68 percent of demand in 1954). The quantity of portland cement used for such purposes is not available; however, data of the Bureau of Public Roads, United States Department of Commerce, indicate that about 7.6 million short tons of asphaltic products and 7.4 million short tons of portland cement were used for paving and maintaining public highways in 1954 and that an additional 2.4 million short tons of portland cement was used for bridges, culverts, and other structures on public highways. Quantities reported sold for roofing materials declined slightly from 3.5 million short tons in 1953 (25 percent of the total sales) to 3.3 million (22 percent of the total) in 1954. Asphalt sold for the manufacture of miscellaneous products was 1.4 million short tons in 1953 and 1.5 million in 1954, or 10 percent of the demand in both years.

The total sales of asphalt and road oil are only roughly comparable with the apparent domestic consumption shown in tables 1 and 2, because the sales of asphalt and road oil, by States and uses, are reported annually to the Bureau of Mines by the sales departments of the asphalt-producing companies and the asphalt-emulsion manufacturers, whereas the apparent domestic consumption is calculated from the production and stocks reported by the petroleum refineries of the various oil companies and the imports and exports compiled by the Bureau of the Census, United States Department of Commerce, appearing in the Monthly Petroleum Statement of the Bureau of Mines. Furthermore, the sales figures, which include emulsified asphalts, can be slightly above the apparent domestic consumption, as the emulsified asphalts may contain some water or other liquids.

FOREIGN TRADE

IMPORTS 1

Imports of asphalts, including solid and liquid petroleum asphalts and a minor quantity of natural asphalts, increased substantially in 1954 to 622,000 short tons valued at \$6.6 million compared with 464,000 short tons (revised figures) in 1953 valued at \$5.4 million. Most of the petroleum asphalts originated in the Netherlands Antilles and Venezuela, while virtually all the natural asphalts came from Trinidad and Tobago. These import figures represent quantities received in the continental United States and the noncontiguous territories; the monthly imports shown in table 1, taken from the Monthly Petroleum Statement of the Bureau of Mines, are for the continental United States only.

¹ Figures on imports and exports compiled by Mae B. Price and Elsie D. Page, of the Bureau of Mines, from records of the U. S. Department of Commerce.

TECHNOLOGY

A noteworthy advance in asphalt technology during 1954 has been the rapidly expanding use of asphalts in various types of hydraulic engineering structures. Several asphalt-lined water reservoirs of varying sizes were completed during the year, further entrenching this type of construction as a sound and economical means of providing water storage for various purposes. There has been further expansion of the construction of asphalt groins to prevent beach erosion and as a means of building up new areas of sand beaches. Properly designed, and constructed with enough asphalt cement, these asphaltic groins are proving to be a most economical solution to a long-standing engineering problem.

Another interesting development was brought to light in culmination of a 10-year study on asphalt treatment of railroad roadbeds, as reported in the February 1954 issue of the Bulletin of the American Railway Engineering Association. This report indicates that an asphalt penetration treatment and chip seal of the entire roadbed (including ties) results in substantial economies in maintenance-of-way costs. A study of equipment development suitable for rapid performance of this type of work has been initiated by The Asphalt Institute in collaboration with leading equipment manufacturers and with advice of personnel from the research staff of The Association

of American Railroads.

In the highway field the use of emulsified asphalts, further diluted with water, is being rapidly adapted to a number of applications. These diluted emulsions are being used to set up bases strong enough for use by traffic during construction and for sealing open-textured asphaltic concrete pavements. Highly diluted emulsified asphalts are being used in conventional water sprinklers to treat unsurfaced streets in some cities. This treatment minimizes dust by gradually building up an asphalt-stabilized surface through several such applications.

The asphalt industry has recognized the importance of continued research and development on the use of asphaltic materials by establishing greatly expanded laboratory facilities in the new Asphalt Institute building on the campus of the University of Maryland. A modern, well-equipped laboratory occupies almost the entire first floor of this building. The board of directors of The Asphalt Institute has approved a broad program of research and development, including the following major items:

1. Asphalt mix design.

2. Stabilization of base materials with asphalt.

3. Flexible pavement-thickness design.

4. Surfaces of airfields resistant to heat and fuel spillage.

5. Asphalt in hydraulics.

GENERAL SUMMARY

THE HELIUM ACT (50 Stat. 885; 50 U. S. C. 161, 163–166), as amended, places the responsibility for conserving, producing, and selling helium upon the Secretary of the Interior, acting through the Bureau of Mines—the only producer of helium in quantity in the world. It operates 4 plants—1 each at Amarillo and Exell, Tex.; Otis, Kans.; and Navajo (Shiprock), N. Mex.

The demand for helium has increased steadily since the decline immediately after World War II and is expected to exceed the capacity of the present plants in the near future. The Congress has appropriated \$6,000,000 for constructing a new plant. In addition to providing additional capacity to meet increased demands for helium, the new plant will enable the Bureau of Mines to better conserve the helium in the Government-owned reserves at Amarillo and Navajo.

Technologic progress was made during the year in developing methods of improving the efficiency of production at the present plants and utilizing, for helium production, helium-bearing gases that also contain high percentages of nitrogen.

All statistical data presented herein originated in the Bureau of

Mines.

PRODUCTION

The Bureau of Mines operated all 4 helium plants in 1954 to produce 190,741,361 cubic feet of helium—18 percent more than the previous record annual production, achieved in 1953. The conservation helium in the Cliffside field, which was produced and conserved by injection into the helium-bearing formation during periods when the production exceeded the demand, supplied helium during peak periods and was replenished when the demand was relatively low. During the year 784,000 cubic feet of helium was injected into the reserve and 470,000 cubic feet withdrawn, resulting in a net gain of 314,000 cubic feet of conservation helium. At the year's end 87,300,000 cubic feet of conservation helium remained in the Cliffside field.

In the 1955 Supplemental Appropriation Act the Congress provided \$6,000,000 to the Bureau of Mines for constructing a new plant to meet increasing demands for helium. Its site had not been selected

at the end of the year.

TABLE 1.—Helium production in the United States, 1921-54

Year	Active plants	Production (cubic feet)
1921-January 1929 1		46, 088, 787
1929 (April)-1942		164, 867, 140

1954	do	190, 741, 361
Total		³ 1, 485, 561, 211

No helium was produced at Government helium plants in February or March 1929. The Fort Worth plant was shut down January 10, 1929, and the Amarillo plant was not put into operation until April.
 Revised figure.
 Includes 87,294,419 cubic feet extracted at the Exell plant and injected into the Government-owned Cliffside gas field for conservation, in excess of that subsequently withdrawn.

SHIPMENTS

The 4 plants shipped 189,873,071 cubic feet of helium valued at over 3 million dollars in 1954—128,575,251 cubic feet to Federal agencies and 61,297,820 cubic feet to non-Federal customers. comprised 756 tank-car shipments, 54 trailer shipments, and 154,492 cylinder shipments.

The utilization of helium shipping containers, particularly tank cars, continued to improve throughout the year, and no serious shortage of containers occurred, even though the quantity of helium

shipped increased 20 percent over 1953.

The continuing increase in helium shipments indicated a need for additional shipping containers, and the Bureau of Mines, acting as agent for the Atomic Energy Commission, ordered 5 new helium tank cars and 5,000 standard-type cylinders. Bids for 7 additional cars for the Atomic Energy Commission and 10 cars for the Bureau of Mines were opened in December, and these cars were to be ordered early in 1955. When these cars are delivered, there will be 107 tank cars in the Government pool.

CONSUMPTION AND USES

About 67 percent of the helium shipped in 1954 went directly to Federal agencies compared with 63 percent in 1953. At least an additional 23 percent was used by private industry on Government contracts; thus, approximately 90 percent of the total consumption was for the benefit of the Government.

The Department of the Navy continued to be the largest Federal user of helium, followed by the Atomic Energy Commission, Department of the Air Force, Weather Bureau, and Department of the Army, in that order. Other Federal agencies that used moderate quantities of helium were the National Advisory Committee for Aeronautics,

the Bureau of Mines, and the National Bureau of Standards.

Helium is used directly by the Government in airships, meteorological balloons, Atomic Energy Commission and guided-missile operations, shielded-arc welding, titanium production, and many different fields of research. The principal private uses are heliumshielded arc welding, leak detection, titanium production and fabrication, as a fill gas in electronic equipment, as an inert atmosphere in the growth of germanium and silicon crystals for transistors, as a diluent with oxygen to make breathing easier for persons suffering from asthma and other respiratory ailments, as a mixture with flammable anaesthetic gases to reduce explosive hazards, and in medical and industrial research. A relatively small quantity is used to inflate toy balloons and for advertising purposes.

Private industry uses helium in producing such diverse items as airplanes, jet engines, electronic devices, farm tractors, water heaters,

refrigerators, and beer barrels.

PRICES

The Helium Act (50 Stat. 885; 50 U. S. C. 161, 163–166) provides that Federal agencies may requisition helium from the Bureau of Mines by paying proportionate shares of the expenses incident to the administration, operation, and maintenance of the Government's helium plants and properties. In the fiscal year ended June 30, 1954, the price for Federal agencies was \$14.65 per thousand cubic feet. The price for Federal agencies in the fiscal year ended June 30, 1955, was \$15.50 per thousand cubic feet.

The price to non-Federal purchasers under contracts approved before March 13, 1954, was \$13.50 per thousand cubic feet. Effective March 13, 1954, the price was increased to \$19.00 per thousand cubic feet pursuant to an amendment to the Regulations Governing the Production and Sale of Helium (30 C. F. R. 1). A charge of \$2.00 per thousand cubic feet is applicable to both of the above non-Federal prices if the helium is compressed into standard-type cylinders.

RESERVES

Helium is a constituent of the atmosphere estimated at 1 part in 185,000 to 200,000 parts of air at the earth's surface. It also is found in small quantities in radioactive rocks and in gases from some mineral springs, volcanoes, and fumeroles; but the only known substance from which helium can be extracted economically in large quantities is helium-bearing natural gas. All natural gases do not contain significant amounts of helium; usually the gases of higher helium content are found in fields that overlie buried granite ridges, such as the buried Amarillo Mountains of the Texas Panhandle, and in fields closely associated with igneous intrusions, such as the Rattlesnake field, San Juan County, N. Mex.

Government Helium Reserves.—The Government owns or otherwise controls 4 helium-bearing natural-gas deposits that are estimated to contain about 3 billion cubic feet of recoverable helium. Two of these deposits—Helium Reserve No. 1, Woodside Structure, Utah, and

Helium Reserve No. 2, Harley Dome, Utah-are on lands of the public domain. These two reserves are relatively small and have

not been used for the production of helium.

The other two Government reserves contain larger quantities of helium and are being utilized in producing helium to meet current The Government-owned Cliffside gas field, which supplies helium-bearing gas to the Amarillo, Tex., helium plant, produced about 34 million cubic feet of helium in 1954 to meet current demands. The Government-leased Rattlesnake gas field, which supplies helium-bearing gas to the Navajo (Shiprock), N. Mex., helium plant, produced about 42 million cubic feet in 1954.

Other Sources of Helium-Bearing Natural Gas.—The Bureau of Mines is extracting helium in its Exell, Tex., and Otis, Kans., plants from natural gas produced by private companies primarily for commercial sale. As this natural gas is produced and consumed as fuel whether or not the helium is removed, extracting the helium is

conservation in its truest sense.

The recoverable helium estimated to be available to the Exell and Otis plants in gas produced for fuel markets is about 7 billion cubic feet, mostly in the Channing area of the Texas Panhandle gas field, which serves the Exell plant. The helium-bearing gas available to the Otis plant has been depleted at a much faster rate but is still important because the plant facility for its recovery already exists.

În addition to the privately owned natural gas processed for helium at the Exell and Otis, Tex., plants, several other areas are known from which relatively high helium content gas is produced for fuel markets and could be made available for helium extraction. A notable example is the Keyes field of Cimarron County, Okla., a large deposit of natural gas containing about 2 percent helium by volume. from this field contains a relatively high percentage of nitrogen, however, and consequently has a relatively low B. t. u. heating value. The Bureau of Mines now is engaged in a cooperative study with a private company, which controls a large part of the field, to investigate possible methods of extracting helium and improving the heating value in a joint operation (see Technology).

In general, the percentage of helium in gas from other prospective areas is less than that in gas processed by the present plants, but the additional cost incurred in processing the leaner gas could be offset to some extent by the economies inherent in larger scale operations. Unfortunately, from a conservation viewpoint these fuel gases are in production now, and much of the helium contained therein will be lost before the helium demand becomes great enough to justify its extraction. Thus, the only helium reserves that the Nation can depend upon

for the future are those controlled by the Government.

CONSERVATION

Whenever possible, the Bureau prefers to produce helium from the helium-bearing gas available to the Exell and Otis plants rather than the reserves in the Cliffside and Rattlesnake fields serving the Amarillo and Navajo plants. Also, any production at Exell in excess of the current demand is conserved by injection into the nearby Cliffside field. Before 1953, 88,400,000 cubic feet of helium had been conserved in this manner.

455

To meet the present high demands for helium, however, the Bureau must operate all four of the plants, and the Government-owned reserves at Amarillo and Navajo are being reduced accordingly. Also, it has become necessary to use the helium conserved in the Cliffside field as an expedient in filling peak demands in excess of the combined output of the plants. Although a net gain of 314,000 cubic feet of conservation helium was achieved in 1954, it was not enough to offset the withdrawal of 1,427,981 cubic feet in 1953, and the amount of conservation helium in the Cliffside field has been reduced by more than 1 million cubic feet during the past 2 years.

Consequently, the Bureau of Mines is reducing rather than augmenting its reserves for the future. This undesirable condition will be corrected, at least temporarily, when the new plant, authorized recently by the Congress, is completed. This plant will recover additional helium from privately owned helium-bearing gas that is produced for fuel markets and will enable the Bureau of Mines to stop

depleting the Government-owned reserves.

FOREIGN TRADE

Helium is not known to be produced in commercial quantities outside the United States. Relatively small quantities of helium are exported annually, but only upon application to the Secretary of State and upon issuance by him of a license authorizing such exportation.

TECHNOLOGY

In August 1954 the Bureau of Mines agreed to undertake, in cooperation with the Colorado Interstate Gas Co. of Colorado Springs, Colo., preliminary engineering studies to determine the feasibility of a joint operation in the Keyes field of Oklahoma to process gas from that field for the extraction of helium, with a coincident improvement in the heating value of the gas. The studies indicated that a plant to accomplish the desired results is technically feasible and that the economics of such a venture depends upon the distribution of plant and gas costs between the two objectives.

The technical problems involved in removing excess nitrogen from a gas to improve its heating value also are of interest to the Bureau of Mines in connection with operation of the Amarillo plant. The Government-owned residue gas from this plant has a heating value too low to permit the ready sale of the gas in commercial fuel markets, a factor that has limited production of helium at the plant. The knowledge obtained from the Keyes studies will help the Bureau

improve this situation.

The Bureau continued its modest helium research program, aimed at providing fundamental information regarding helium and helium-bearing gas and improving the efficiency of helium production and conservation. The survey of newly discovered occurrences of natural gas to determine their helium content continued. A study of the phase relationships of natural gas from the Rattlesnake field of New Mexico was completed.

Outstanding progress was made in a detailed study of the helium-extraction cycle to determine the efficiency of heat-exchange equipment and the refrigeration cycle in general. This study has pointed out several areas where improvements in designs and techniques and increased use of instrumentation offer considerable prospect for increased output and reduced costs. These improvements will be incorporated into the design of the new plant, as well as the present plants, if subsequent investigations confirm their value and practicability.

On December 22, 1954, the Interstate Commerce Commission published a notice of intent to revise specification ICC-107A for helium tank cars by relaxing the factor of safety applicable to the steel cylinders mounted thereon. This revision, which has subsequently become effective, will permit the design and use of cars that are lighter in weight but still have greater helium capacity. The unit cost of transporting helium will thus be reduced, which will effect

a considerable saving to helium users.

Index

By Mabel E. Winslow 1

Because nearly all commodity chapters in Minerals Yearbook, volume II, follow a rather generalized outline (General Summary, Production (in certain chapters including Mining Methods), Prices, Distribution, Consumption, Stocks, Technology, Foreign Trade, and World Production), references to such data have been omitted under the various commodity headings, although they were included in past Yearbook indexes. However, outstanding new developments under Technology have been indexed, as well as some information by States and countries. Work of Government agencies most intimately associated with the mineral industries, such as the Bureau of Mines and the Geological Survey, has also been indexed.

R	Page
Page	Trade, international, in energy fuels
Railroad roadbeds, asphalt treatment 450	Trinidad, asphalts, natural, foreign trade 448
Range oil, consumption 172	Turkey, petroleum law, new 426
sales 392	
Reed peat, formation 261	Ü
production261, 262	
value 263 Rhode Island, minerals, production 15	U. S. S. R., fuel briquets, production 257
Rhode Island, minerals, production	peat, production 266 petroleum production increase 427
sales, by States	petroleum, production, increase
salient statistics 365	minerals, production 15
Rumania, petroleum, production, increase 427	petroleum, production 338
S	V
Saudi Arabia, petroleum, production, increase. 427	2000
Sedge peat, formation 261	Venezuela, natural gas, production 296 petroleum production increase 426
production 261, 262	petroleum, production, increase 426 petroleum asphalts, foreign trade 448
volua 203	Vermont, minerals, production
Semianthracite, as raw fuel for packaged fuel 255, 256	Virginia, bituminous coal, data 92
as source of fuel briquets249, 250	minerals, production15
recerves 28	Vitrain coals, X-ray studies 123
Sodium phenolate, production 229	
Solvents production 412	W
South Africa, synthetic liquid fuels, produc-	
tion130 South Carolina, minerals, production15	Washington, bituminous coal, data 92
South Dakota, lignite, data94	minerals, production 15 Waterpower, as source of energy 1,
minerals, production 15	105, 106, 107, 108
Sphagnum peat, formation 260	electricity from, calculated consumption 110, 111
Steam-turbine locomotive, high-pressure, per- formance tests	Water reservoirs, asphalt linings 450
formance tests	West Virginia, bituminous coal, data 92-93
salient statistics 365, 412	coal fines, as source of fuel briquets 248, 249
Subhituminous coal, reserves 22	minerals, production 15 Wisconsin, coal fines, as source of fuel bri-
storage 128	quets
Sulfur, production, in coke ovens 226	minerals, production
	peat, reserves260
T	Wyoming, bituminous coal, data 93
	minerals, production 15 petroleum, demand 356
Tar, average yield, in coke ovens 227	production341
crude, production 228 Tar derivatives, production 228	production
Tennessee hituminous coal, data 91	X
minerals, production15	
Texas, Amarillo helium plant, hydrogen,	Xylene, data238, 239 production229
removal 455	production
carbon black, production 269	•
lignite, data 94 minerals, production 15	$oldsymbol{Y}$
petroleum, demand 347 production 337–338, 339–340	Yard screenings, as raw fuel, for packaged
Tohogo genhalis natural toreign trade 448	Yard screenings, as raw fuel, for packaged fuel
Toluene, data	petroleum, production, increase 426
production229	l boardanil branching
