To so many fine memories of my mother, Ashraf, my father,  
Mohammad, and my brother, Mohsen, for their uncompromising  
belief in the power of education.

# About the Editor-in-Chief

---

**Hossein Bidgoli, Ph.D.**, is professor of Management Information Systems at California State University. Dr. Bidgoli helped set up the first PC lab in the United States. He is the author of 43 textbooks, 27 manuals and over five dozen technical articles and papers on various aspects of computer applications, information systems and network security, e-commerce and decision support systems published and presented throughout the world. Dr. Bidgoli also serves as the editor-in-chief of *The*

*Internet Encyclopedia* and the *Encyclopedia of Information Systems*.

The *Encyclopedia of Information Systems* was the recipient of one of the *Library Journal's* Best Reference Sources for 2002 and *The Internet Encyclopedia* was recipient of one of the PSP Awards (Professional and Scholarly Publishing), 2004. Dr. Bidgoli was selected as the California State University, Bakersfield's 2001–2002 Professor of the Year.

# Preface

---

*The Handbook of Information Security* is the first comprehensive examination of the core topics in the security field. *The Handbook of Information Security*, a 3-volume reference work with 207 chapters and 3300+ pages, is a comprehensive coverage of information, computer, and network security.

**The primary audience** is the libraries of 2-year and 4-year colleges and universities with computer science, MIS, CIS, IT, IS, data processing, and business departments; public, private, and corporate libraries throughout the world; and reference material for educators and practitioners in the information and computer security fields.

**The secondary audience** is a variety of professionals and a diverse group of academic and professional course instructors.

Among the industries expected to become increasingly dependent upon information and computer security and active in understanding the many issues surrounding this important and fast-growing field are: government, military, education, library, health, medical, law enforcement, accounting, legal, justice, manufacturing, financial services, insurance, communications, transportation, aerospace, energy, biotechnology, retail, and utility.

Each volume incorporates state-of-the-art, core information, on computer security topics, practical applications and coverage of the emerging issues in the information security field.

This definitive 3-volume handbook offers coverage of both established and cutting-edge theories and developments in information, computer, and network security.

This handbook contains chapters by global academic and industry experts. This handbook offers the following features:

- 1) Each chapter follows a format including title and author, outline, introduction, body, conclusion, glossary, cross-references, and references. This format allows the reader to pick and choose various sections of a chapter. It also creates consistency throughout the entire series.
- 2) The handbook has been written by more than 240 experts and reviewed by more than 1,000 academics and practitioners from around the world. These experts have created a definitive compendium of both established and cutting-edge theories and applications.
- 3) Each chapter has been rigorously peer-reviewed. This review process assures accuracy and completeness.
- 4) Each chapter provides extensive online and off-line references for additional readings, which will enable the reader to learn more on topics of special interest.
- 5) The handbook contains more than 1,000 illustrations and tables that highlight complex topics for further understanding.
- 6) Each chapter provides extensive cross-references, leading the reader to other chapters related to a particular topic.
- 7) The handbook contains more than 2,700 glossary items. Many new terms and buzzwords are included to provide a better understanding of concepts and applications.
- 8) The handbook contains a complete and comprehensive table of contents and index.
- 9) The series emphasizes both technical as well as managerial, social, legal, and international issues in the field. This approach provides researchers, educators, students, and practitioners with a balanced perspective and background information that will be helpful when dealing with problems related to security issues and measures and the design of a sound security system.
- 10) The series has been developed based on the current core course materials in several leading universities around the world and current practices in leading computer, security, and networking corporations.

We chose to concentrate on fields and supporting technologies that have widespread applications in the academic and business worlds. To develop this handbook, we carefully reviewed current academic research in the security field from leading universities and research institutions around the world.

Computer and network security, information security and privacy, management information systems, network design and management, computer information systems (CIS), decision support systems (DSS), and electronic commerce curriculums, recommended by the Association of Information Technology Professionals (AITP) and the Association for Computing Machinery (ACM) were carefully investigated. We also researched the current practices in the security field carried out by leading security and IT corporations. Our research helped us define the boundaries and contents of this project.

## TOPIC CATEGORIES

Based on our research, we identified nine major topic categories for the handbook.

- Key Concepts and Applications Related to Information Security
- Infrastructure for the Internet, Computer Networks, and Secure Information Transfer
- Standards and Protocols for Secure Information Transfer
- Information Warfare
- Social, Legal, and International Issues

- Foundations of Information, Computer, and Network Security
- Threats and Vulnerabilities to Information and Computing Infrastructures
- Prevention: Keeping the Hackers and Crackers at Bay
- Detection, Recovery, Management, and Policy Considerations

Although these topics are related, each addresses a specific concern within information security. The chapters in each category are also interrelated and complementary, enabling readers to compare, contrast, and draw conclusions that might not otherwise be possible.

Though the entries have been arranged logically, the light they shed knows no bounds. The handbook provides unmatched coverage of fundamental topics and issues for successful design and implementation of a sound security program. Its chapters can serve as material for a wide spectrum of courses such as:

- Information and Network Security
- Information Privacy
- Social Engineering
- Secure Financial Transactions
- Information Warfare
- Infrastructure for Secure Information Transfer
- Standards and Protocols for Secure Information Transfer
- Network Design and Management
- Client/Server Computing
- E-commerce

Successful design and implementation of a sound security program requires a thorough knowledge of several technologies, theories, and supporting disciplines. Security researchers and practitioners have had to consult many resources to find answers. Some of these resources concentrate on technologies and infrastructures, some on social and legal issues, and some on managerial concerns. This handbook provides all of this information in a comprehensive, three-volume set with a lively format.

### **Key Concepts and Applications Related to Information Security**

Chapters in this group examine a broad range of topics. Theories, concepts, technologies, and applications that expose either a user, manager, or an organization to security and privacy issues and/or create such security and privacy concerns are discussed. Careful attention is given to those concepts and technologies that have widespread applications in business and academic environments. These areas include e-banking, e-communities, e-commerce, e-education, and e-government.

### **Infrastructure for the Internet, Computer Networks, and Secure Information Transfer**

Chapters in this group concentrate on the infrastructure, popular network types, key technologies, and principles

for secure information transfer. Different types of communications media are discussed followed by a review of a variety of networks including LANs, MANs, WANs, mobile, and cellular networks. This group of chapters also discusses important architectures for secure information transfers including TCP/IP, the Internet, peer-to-peer, and client/server computing.

### **Standards and Protocols for Secure Information Transfer**

Chapters in this group discuss major protocols and standards in the security field. This topic includes important protocols for online transactions, e-mail protocols, Internet protocols, IPsec, and standards and protocols for wireless networks emphasizing 802.11.

### **Information Warfare**

This group of chapters examines the growing field of information warfare. Important laws within the United States criminal justice system, as they relate to cybercrime and cyberterrorism, are discussed. Other chapters in this group discuss cybercrime, cyberfraud, cyber stalking, wireless information warfare, electronic attacks and protection, and the fundamentals of information assurance.

### **Social, Legal, and International Issues**

Chapters in this group explore social, legal, and international issues relating to information privacy and computer security. Digital identity, identity theft, censorship, and different types of computer criminals are also explored. The chapters in this group also explain patent, trademark, and copyright issues and offer guidelines for protecting intellectual properties.

### **Foundations of Information, Computer, and Network Security**

These chapters cover four different but complementary areas including encryption, forensic computing, operating systems and the common criteria and the principles for improving the security assurance.

### **Threats and Vulnerabilities to Information and Computing Infrastructures**

The chapters in this group investigate major threats to, and vulnerabilities of, information and computing infrastructures in wired and wireless environments. The chapters specifically discuss intentional, unintentional, controllable, partially controllable, uncontrollable, physical, software and hardware threats and vulnerabilities.

### **Prevention: Keeping the Hackers and Crackers at Bay**

The chapters in this group present several concepts, tools, techniques, and technologies that help to protect information, keep networks secure, and keep the hackers and computer criminals at bay. Some of the topics discussed include physical security measures; measures

for protecting client-side, server-side, database, and medical records; different types of authentication techniques; and preventing security threats to e-commerce and e-mail transactions.

## **Detection, Recovery, Management, and Policy Considerations**

Chapters in this group discuss concepts, tools, and techniques for detection of security breaches, offer techniques and guidelines for recovery, and explain principles for managing a network environment. Some of the topics highlighted in this group include intrusion detection, contingency planning, risk management, auditing, and guidelines for effective security management and policy implementation.

## **Acknowledgments**

Many specialists have helped to make the handbook a resource for experienced and not-so-experienced readers. It is to these contributors that I am especially grateful. This remarkable collection of scholars and practitioners has distilled their knowledge into a fascinating and enlightening one-stop knowledge base in information, computer, and network security that “talks” to readers. This has been a massive effort, as well as a most rewarding experience. So many people have played a role, it is difficult to know where to begin.

I would like to thank the members of the editorial board for participating in the project and for their expert advice on selection of topics, recommendations of authors, and review of the materials. Many thanks to the more than

1,000 reviewers who provided their advice on improving the coverage, accuracy, and comprehensiveness of these materials.

I thank my senior editor, Matt Holt, who initiated the idea of the handbook. Through a dozen drafts and many reviews, the project got off the ground and then was managed flawlessly by Matt and his professional team. Many thanks to Matt and his team for keeping the project focused and maintaining its lively coverage.

Tamara Hummel, editorial coordinator, assisted the contributing authors and me during the initial phases of development. I am grateful for all her support. When it came time for the production phase, the superb Wiley production team took over. Particularly, I want to thank Deborah Schindlar, senior production editor. I am grateful for all her hard work. I thank Michelle Patterson, our marketing manager, for her impressive marketing campaign launched on behalf of the handbook.

Last, but not least, I want to thank my wonderful wife, Nooshin, and my two children, Mohsen and Morvareed, for being so patient during this venture. They provided a pleasant environment that expedited the completion of this project. Mohsen and Morvareed assisted me in sending out thousands of e-mail messages to authors and reviewers. Nooshin was a great help in designing and maintaining the authors’ and reviewers’ databases. Their efforts are greatly appreciated. Also, my two sisters, Azam and Akram, provided moral support throughout my life. To this family, any expression of thanks is insufficient.

Hossein Bidgoli  
California State University, Bakersfield

# Guide to The Handbook of Information Security

---

*The Handbook of Information Security* is a comprehensive coverage of the relatively new and very important field of information, computer, and network security. This reference work consists of three separate volumes and 207 different chapters on various aspects of this field. Each chapter in the handbook provides a comprehensive overview of the selected topic, intended to inform a broad spectrum of readers, ranging from computer and security professionals and academicians to students to the general business community.

This guide is provided to help the reader easily locate information throughout *The Handbook of Information Security*. It explains how the information within it can be located.

## Organization

This is organized for maximum ease of use, with the chapters arranged logically in three volumes. While one can read individual volumes (or articles) one will get the most out of the handbook by becoming conversant with all three volumes.

## Table of Contents

A complete table of contents of the entire handbook appears in the front of each volume. This list of chapter titles represents topics that have been carefully selected by the editor-in-chief, Dr. Hossein Bidgoli, and his colleagues on the editorial board.

## Index

A subject index for each individual volume is located at the end of each volume.

## Chapters

The author's name and affiliation are displayed at the beginning of the chapter.

All chapters in the handbook are organized in the same format:

### Title and author

### Outline

### Introduction

### Body

### Conclusion

### Glossary

### Cross-References

### References

## Outline

Each chapter begins with an outline that provides a brief overview of the chapter, as well as highlighting important subtopics. For example, the chapter "Internet Basics" includes sections for Information Superhighway and the World Wide Web, Domain Name Systems, Navigational Tools, Search Engines, and Directories. In addition, second-level and third-level headings will be found within the chapter.

## Introduction

Each chapter begins with an introduction that defines the topic under discussion and summarizes the chapter, in order to give the reader a general idea of what is to come.

## Body

The body of the chapter fills out and expands upon items covered in the outline.

## Conclusion

The conclusion provides a summary of the chapter, highlighting issues and concepts that are important for the reader to remember.

## Glossary

The glossary contains terms that are important to an understanding of the chapter and that may be unfamiliar to the reader. Each term is defined in the context of the particular chapter in which it is used. Thus the same term may be defined in two or more chapters with the detail of the definition varying slightly from one chapter to another. The handbook includes approximately 2,700 glossary terms. For example, the chapter "Internet Basics" includes the following glossary entries:

**Extranet** A secure network that uses the Internet and Web technology to connect two or more intranets of trusted business partners, enabling business-to-business, business-to-consumer, consumer-to-consumer, and consumer-to-business communications.

**Intranet** A network within the organization that uses Web technologies (TCP/IP, HTTP, FTP, SMTP, HTML, XML, and its variations) for collecting, storing, and disseminating useful information throughout the organization.

## Cross-References

All chapters have cross-references to other chapters that contain further information on the same topic. They

appear at the end of the chapter, preceding the references. The cross-references indicate related chapters that can be consulted for further information on the same topic. The handbook contains more than 1,400 cross-references in all. For example, the chapter “Computer Viruses and Worms” has the following cross references:

Hackers, Crackers and Computer Criminals, Hoax Viruses and Virus Alerts, Hostile Java Applets, Spyware, Trojan Horse Programs.

## References

The references in this handbook are for the benefit of the reader, to provide references for further research on the given topic. Review articles and research papers that are important to an understanding of the topic are also listed. The references typically consist of a dozen to two dozen entries, and do not include all material consulted by the author in preparing the chapter.

## INTRODUCTION

Cybercrime, which is essentially the use of computer technology in the commission of criminal activity, presents many challenges for the U.S. legal system. On the one hand, state and federal law adequately criminalizes most of the basic cybercrime offenses; on the other hand, there is substantial disagreement as to the penalties that are appropriate for those who commit these offenses. The disagreement over penalties is exacerbated by the fact that many offenders are juveniles; the federal system, especially, is not equipped to deal with juveniles. Charging decisions can be difficult because it is not easy to parse cybercrime into offenses: Is the dissemination of a virus that damages a million computers one crime or a million crimes? As is explained below, these are only a few of the ways in which cybercrime challenges the basic assumptions that structured traditional criminal law.

## DIFFERENCES FROM CIVIL JUSTICE SYSTEM

The criminal justice system in the United States—as elsewhere—differs from the civil justice system in several important ways. One difference is substantive: the goal of the civil justice system is to provide redress for accidental or conventional injuries or losses one “person,” which can be an individual or a corporate entity, has suffered as the result of another’s actions or failure to act (LaFave, 2003). The goal of the criminal justice system, on the other hand, is to allow the state—acting on behalf of the people in a specific society—to inflict punishment on those who inflict deliberate, serious injuries upon others. Technically, therefore, in the criminal justice system, the state is the injured party, and criminal proceedings are brought in the name of the appropriate government, which will be federal, state, or local (LaFave, 2003).

Another difference is procedural: the U.S. Constitution sets limits on what law enforcement officers can do when investigating crimes such as hacking or cyberfraud. State and federal officers must tender the *Miranda* warnings to anyone whom they take into custody for the purposes of

interrogation (LaFave, Israel, & King, 1999). The Fourth Amendment requires that they either obtain a search warrant or invoke a valid exception to the warrant requirement to search for and seize evidence of a cybercrime; so, if officers believe child pornography is located in a suspect’s computer in his or her bedroom, they must persuade a magistrate to issue a warrant allowing them to search the computer or convince the suspect to consent to such a search (consent being an exception to the warrant requirement) (LaFave et al., 1999).

There are other procedural differences that distinguish criminal trials from civil trials: In a criminal trial, the prosecution must prove its case “beyond a reasonable doubt,” which is a far more demanding standard than the “preponderance of the evidence” standard used in civil trials (LaFave et al., 1999). If the civil standard were used in a hacking prosecution, the government would only have to prove it was “more likely than not” that the defendant engaged in hacking; under the criminal standard, the government must prove beyond a reasonable doubt that the crime of hacking was committed and that it was committed by the defendant (LaFave et al., 1999). This higher standard protects those who are accused of crimes and thereby helps to avoid wrongful convictions; other rules that work to the same end are the presumption that a defendant is innocent and an indigent defendant’s right to appointed counsel (LaFave et al., 1999). The size of criminal juries also contributes to this goal; in the federal system and in most states, 12 jurors are required in criminal trials (LaFave et al., 1999). Civil trials often involve fewer jurors, frequently as few as six (LaFave et al., 1999). The size of the jury is important because studies have shown larger juries are more likely to result in fair deliberations (LaFave et al., 1999).

## BASIC INSTITUTIONAL STRUCTURE

Law enforcement in the United States takes place at three distinct levels: federal, state, and local government (LaFave et al., 1999). At the federal level, the Federal Bureau of Investigation and the Secret Service actively

pursue cybercrime investigations, but their efforts account for only a fraction of the total number of investigations; in the United States, state and federal law enforcement have traditionally been primarily responsible for pursuing criminal cases (LaFave et al., 1999). As a result, U.S. cybercrime laws can overlap: The federal system and all of the states have laws that criminalize hacking, cyberfraud, and other common cybercrimes (Ditzion, Geddes, & Rhodes, 2003). The default assumptions are that (a) state and local authorities have jurisdiction to prosecute and (b) federal authorities must be able to bring a hacking or other cybercrime case within a federal jurisdictional predicate to be able to prosecute (LaFave, 2003). The most common federal jurisdictional predicate used in cybercrime cases is an effect on interstate or foreign commerce; this is the predicate used in the general federal cybercrime statute, 18 U.S. Code §1030 (Ditzion, Geddes, & Rhodes, 2003). So, to prosecute someone for hacking in violation of §1030, federal prosecutors have to show that the hacking had an impact on interstate or foreign commerce, which is usually not difficult to do (American Bar Association Task Force, 1998).

When a cybercrime occurs, the investigation is undertaken by local, state, or federal law enforcement officers who may work in conjunction with a prosecutor and who often work in conjunction with computer forensic and other experts, such as forensic psychologists (LaFave et al., 1999). Given the complexity of cybercrime cases, these investigations are increasingly undertaken by task forces in which local, state, and federal officers collaborate with private investigators to pursue a cybercriminal (Miami Electronic Crimes Task Force, 2003). Indeed, one of the distinguishing aspects of cybercrime cases is the essential involvement of the private sector: cybercrimes are often committed against businesses, which must decide if they want to report the matter to the authorities or handle it in-house. There are disincentives for reporting a cyber-attack; aside from anything else, news that a company has been victimized by a cyberattacker can undermine confidence in the business and in its ability to protect client or customer information (Brenner & Schwerha, 2002). If a business is attacked and decides to report the matter to the authorities, it will have to decide if it wants to contact federal, state, or local authorities (Brenner & Schwerha, 2002). There are certain advantages to seeking federal prosecution; federal agencies often have more resources and expertise in dealing with computer crime, and they are not hampered by the jurisdictional impediments that confront state authorities. A federal search warrant, for example, is enforceable anywhere in the United States; a state search warrant, a New York warrant, say, is enforceable only within the state of New York.

Because cybercrime cases can be difficult to investigate and prosecute, there is an emerging emphasis on avoiding the need for both by preventing cybercrime. Prevention is a major focus of the Secret Service's Electronic Crime Task Forces and the Federal Bureau of Investigation's Infragard program. Both initiatives bring together representatives from law enforcement, the private sector, and academia to share information and resources, thereby facilitating the prevention of cybercrime and the investigation of completed cybercrimes.

## Prosecutor

The central figure in any cybercrime case is the prosecutor. In the U.S. justice system, prosecutors occupy a unique role; they serve as advocates for the state and in that sense play a role analogous to that of the defense lawyer. As advocates, defense lawyers are obliged to use every tactical advantage permitted under the law to obtain their client's acquittal, even if doing so keeps the jury from the truth (LaFave et al., 1999). Prosecutors are held to a higher standard; their duty is to ensure justice is done, not merely to win a criminal case (LaFave et al., 1999). But when a state or federal prosecutor does take a case to trial, his or her goals will generally be to obtain a conviction (LaFave et al., 1999).

Because crimes are considered a wrong against the government, prosecutions are undertaken in the name of the government, whether federal, state, or local, and victims consequently play a minor role (LaFave et al., 1999). Victims typically have little say in the charging or plea bargaining processes; their role is usually limited to that of witness (LaFave et al., 1999). Prosecutors control charging and plea bargaining; they have wide discretion in deciding (a) whether someone will be prosecuted and (b) if someone is to be prosecuted, what charges they will face (LaFave et al., 1999). In a hacking case, for instance, the prosecutor might decide not to prosecute the offender because he is a juvenile. This is particularly likely to occur in the federal system, which is not set up to deal with juvenile offenders (Esbenshade, 2002–2003). As a result, federal prosecutors tend to concentrate on adult offenders and turn juveniles over to the juvenile court of the appropriate state, pursuant to the Federal Juvenile Delinquency Act (Esbenshade, 2002–2003).

Another large class of cybercrime cases in the United States involves intellectual property (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2001): "Legal regimes have created enforceable rights in certain intangibles that have become familiar as intellectual property, including copyrights, trademarks, patents, and trade secrets" (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2001). At the federal level, various statutes are used to prosecute the unlawful appropriation of intellectual property: 18 U.S. Code §2320 makes it a crime to counterfeit trademarks. 18 U.S. Code §§1831 and §§1832 make the theft of trade secrets a federal crime. And copyright infringement is criminalized by 17 U.S. Code §506(a) and 18 U.S. Code §2319. Patent infringement "is not generally a criminal violation" (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2001). Federal law preempts state law governing copyright violations, so prosecutions can be brought only at the federal level (Nicholson et al., 2000). Federal law does not preempt state law governing trademark violations, except insofar as the state and federal statutory provisions conflict (Kahn, 2004).

In deciding whether to prosecute intellectual property crimes, such as criminal copyright infringement, federal prosecutors must consider the strength of their case, the person's culpability in connection with the crime(s), the person's history (if any) of prior criminal activity,

current federal law enforcement priorities, and the extent to which such a prosecution would deter others from engaging in similar conduct (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2001). These factors, and perhaps most notably the federal interest in protecting U.S.-based intellectual property rights, have prompted federal prosecutions of those who use the Internet to supply “warez,” that is, pirated copies of software (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2001). A study of federal cybercrime prosecutions found that in 2001 the Department of Justice declined to prosecute in 496 of 631 referred cases; 135 cases were prosecuted, resulting in 107 convictions and 28 dismissals or acquittals on all charges (National Association of Criminal Defense Lawyers, Electronic Frontier Foundation & Sentencing Project, 2003). The primary reason given for declining prosecution was lack of evidence or inadmissible evidence (National Association of Criminal Defense Lawyers, Electronic Frontier Foundation & Sentencing Project, 2003). The next most commonly cited reasons were (a) that the person would be prosecuted at the state level and (b) the lack of a federal interest in prosecuting (National Association of Criminal Defense Lawyers, Electronic Frontier Foundation & Sentencing Project, 2003).

Even when prosecutors decide to charge someone, the defense attorney may be able to arrange a plea bargain: in 1995, hacker Kevin Mitnick pled guilty to 1 of 23 counts brought against him in a North Carolina federal prosecution (Goldman, 1995). By pleading guilty, he was guaranteed a sentence of no more than 8 months and avoided prosecution on the remaining 22 counts (Goldman, 1995). Plea bargains offer defendants the opportunity to accept a lesser penalty in return for avoiding at least the possibility of a greater penalty, but they also offer certain advantages for prosecutors. Plea bargains let prosecutors resolve cases without having to go to trial, which alleviates the burden on a criminal justice system that is swamped with cybercrime and real-world crime cases; plea bargains also let prosecutors trade lesser sentences for a defendant's cooperation in prosecuting other, presumably more culpable, offenders. The potential for cooperation is one of the factors federal prosecutors consider in deciding whether to bring charges and whether to plea bargain charges that have already been brought (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2001).

As noted, law enforcement in the United States operates on three levels: local, state, and federal. This is also true for prosecutors. Local prosecutors generally operate at the county or parish level; there is typically an elected prosecutor who is usually known either as the county prosecutor or the district attorney (LaFave et al., 1999). He or she functions with the aid of a number of assistants, who are known as assistant district attorneys, deputy county prosecutors, or similar titles (LaFave et al., 1999). Moving up a tier, each state has an attorney general whose jurisdiction varies from state to state: in some states, attorney generals are authorized only to prosecute certain, specialized crimes such as antitrust or organized crime cases; in other states, attorney generals have much

more limited jurisdiction to prosecute and may be limited to substituting when a local prosecutor is disqualified (LaFave et al., 1999). Like local prosecutors, attorney generals function with the aid of assistants, who are usually known as deputy attorney generals or assistant attorney generals. Many state attorney general's offices have established cybercrime units and the National Association of Attorneys General has its own cybercrime initiative (National Association of Attorneys General—Computer Crime, 2003). Moving up to the third tier, the federal justice system is headed by an attorney general, who also functions with the aid of assistants and deputies (LaFave et al., 1999). The attorney general also heads up a nationwide organization of United States attorneys; a United States attorney is appointed for every federal judicial district in the United States; they function in a fashion analogous to county prosecutors; that is, they deal with federal crimes committed in a specified geographical area (LaFave et al., 1999). The Department of Justice, headed by the attorney general, also deals with federal crime on a more global level; the department has a specialized unit—the Computer Crime and Intellectual Property Section—which deals with cybercrime as a general phenomenon (Ditzion, Geddes, & Rhodes, 2003).

After a prosecutor has taken a case to trial and obtained a conviction or entered into a plea bargain with a defendant, the next step in the process is sentencing (LaFave et al., 1999). In all but a few U.S. jurisdictions, which allow for jury sentencing even in noncapital cases, the determination and imposition of an appropriate sentence are a matter for the court (LaFave et al., 1999). The U.S. system uses four types of sanctions: financial (fines, restitution), community release (probation, unsupervised release, house arrest), incarceration in a jail (for shorter sentences) or a prison (for longer sentences), and capital punishment (for murder) (LaFave et al., 1999). Courts can combine these sanctions; in one cybercrime case, for example, the court sentenced the defendant to 3 years' probation, a \$40,000 fine, and the payment of \$20,000 in restitution (U.S. v. Hicks, 1995). In the federal system and a number of states, sentences are determinate; that is, the offender serves the entire sentence imposed by the court (except for “good time” credit) (LaFave et al., 1999). The other states use indeterminate sentencing, in which the court sets a maximum period and a minimum period of incarceration and the state parole board decides how much time the offender will exactly serve (LaFave et al., 1999). Both systems are increasingly using sentencing guidelines, which are standards that limit the judge's discretion in imposing sentence (LaFave et al., 1999). Until recently, cybercrime offenders often received sentences of probation only, or, at most, a short period of incarceration (Beauprez, 2003). In November 2003, new sentencing guidelines went into effect in the federal system that will increase punishments in at least some cybercrime cases (Beauprez, 2003).

## Defense Attorney

The defense attorney's role is to ensure that no conviction is obtained unless (a) the prosecution proves its case

beyond a reasonable doubt or (b) the defendant accepts a plea bargain that is advantageous for him or her (LaFave et al., 1999). As noted, when charges have been brought, it is defense counsel's task to utilize every tactical advantage at his or her disposal to obtain the best outcome for the client (LaFave et al., 1999). Unlike the prosecutor, the defense attorney's advocacy is not constrained by external principles; in our adversarial system of justice, defense counsel is charged with pursuing the client's best interests without regard to other concerns (LaFave et al., 1999). That includes ensuring that the trial or the plea bargaining process is conducted in accordance with constitutional and other legal requirements; for that reason, ineffective assistance of defense counsel is a basis for setting aside a conviction (LaFave et al., 1999). But although defense counsel must represent his or her client zealously and loyally, defense attorneys, like prosecutors, are ethically obligated not to misrepresent matters of fact or law to the court, not to suborn perjury by one's client, and not to destroy, alter, or conceal evidence (American Bar Association, 2003).

The Sixth Amendment creates a right to counsel for those charged with the commission of crimes; the Supreme Court has held that this right attaches to all "critical" stages of a prosecution, such as the arraignment, plea negotiations, and trial (LaFave et al., 1999). In both the state and federal systems, defendants are represented either by privately retained attorneys or by attorneys provided by the government (LaFave et al., 1999). If a defendant cannot afford to retain private counsel, the court will arrange for appointed counsel to represent him or her (LaFave et al., 1999). States use three systems to accomplish this: in most counties, indigents are represented by public defenders—attorneys whom the county employs to represent those who cannot afford private counsel (LaFave et al., 1999). The second most commonly used system relies on private attorneys whom judges appoint to represent indigents; these private attorneys are paid at a rate determined by the local government (LaFave et al., 1999). Finally, a few counties use a system in which a private law firm or a bar association contracts with the county to provide representation for indigents (LaFave et al., 1999). In the federal system, federal public defenders represent indigents in a number of judicial districts, whereas the others rely on court-appointed private counsel (LaFave et al., 1999).

The defense of a cybercrime case is a difficult matter, because it requires special expertise as to substantive law [i.e., the offense(s) charged], procedural law (i.e., the legality of the tactics employed in the investigation), and the intricacies of computer technology. So far, there appears to be a serious scarcity of attorneys who specialize in cybercrime cases, no doubt because such cases are still relatively rare, considered in relation to the other types of criminal cases being brought. To date, many of those charged with cybercrime have relied on privately retained counsel, perhaps because hackers and others involved with computer technology are less likely to be indigent than, say, those charged with drug offenses. There have, however, been exceptions: Adrian Lamo, who became famous as the "homeless hacker," relied on a public defender when he was prosecuted federally for hacking

into systems, including the *New York Times*' computer system (Reuters Wired News, 2003).

## Adjudication

Perhaps the most critical decision the defense has to make, especially in a computer crime trial, is whether to have the case tried by a jury ("jury trial") or a judge ("bench trial"). The Sixth Amendment guarantees criminal defendants the right to trial by an impartial jury drawn from the state and district in which the crime(s) allegedly occurred (Right to Jury Trial, 2003). The right attaches when one has been charged with an offense which is punishable by a prison sentence of 6 months or more; as to crimes for which one can serve less than 6 months in prison, the right to jury trial does not attach unless the presence of additional statutory or regulatory penalties indicates that the legislature considered the offense a "serious" crime (Right to Jury Trial, 2003).

Usually, the jury in a criminal trial consists of 12 jurors, but the Supreme Court has held that 6 jurors are enough to satisfy the Sixth Amendment (Right to Jury Trial, 2003). Court rules, such as Rule 23 of the Federal Rules of Criminal Procedure, require the impaneling of 12 jurors in federal criminal trials, absent a written waiver executed by the parties and approved by the court (Right to Jury Trial, 2003). The Supreme Court has consistently held that jurors in federal criminal trials must return a unanimous verdict (Right to Jury Trial, 2003). As for state criminal trials, the jury must be unanimous if it consists of only 6 jurors; if the jury consists of 12 jurors, they can return a nonunanimous verdict (Right to Jury Trial, 2003). Traditionally, jurors were required to be purely passive spectators at a trial; they were not allowed to ask questions or otherwise participate in the proceedings (Hans, 2002). More and more, however, jurors are being allowed to ask questions, take notes, and discuss the case with each other during the trial (Hans, 2002).

A jury trial is a defendant's constitutional right, but it may or may not be the best choice, depending on the nature of the case. If the defense attorney believes the case is likely to inflame the passions of the jury against his or her client, the best course may be to ask for a bench trial. This can, for example, be an advisable tactic in a child pornography case: even though there may be valid evidentiary and/or legal reasons to acquit the accused, the jurors may be so disturbed by the images the prosecution presents that they will ignore those reasons and convict, leaving the matter to be appealed. In such an instance, the wiser course may well be for the defendant to waive his right to a jury trial and have the case tried by the court. The same can be true for crimes involving difficult legal and technical issues, such as actions under the Digital Millennium Copyright Act (*Universal City Studios, Inc. v. Corley*, 2001).

A defendant can waive his or her right to a jury trial by (a) obtaining the court's approval and the government's consent and (b) executing a written waiver that is knowing, voluntary, and intelligent (Right to Jury Trial, 2003). The government's consent is required because the Supreme Court has held that there is no constitutional right to a bench trial (Right to Jury Trial, 2003). Because

there is no constitutional right to a nonjury trial, the prosecution can, in effect, veto a defendant's wish to have his or her case heard by the court instead of a jury; all that is required is for the prosecution to refuse to consent to a bench trial (Right to Jury Trial, 2003).

Once a criminal case has been tried to its conclusion, the defendant cannot be tried again for the crimes at issue in that proceeding, as the Fifth Amendment declares that one cannot be twice "put in jeopardy" for the "same offence" (LaFave et al., 1999). The double jeopardy clause not only prevents the retrial of cases that have produced a conviction or acquittal; it can also prevent retrials after a case has been begun and is then terminated before the matter goes to the jury (LaFave et al., 1999). The basic rule is that "jeopardy" attaches (a) after the first witness has been sworn in a bench trial and (b) after the jurors have been sworn in for a jury trial (LaFave et al., 1999).

The protections of the double jeopardy clause are subject to certain exceptions: for one thing, the government may be able to re prosecute a defendant even when a trial has been dismissed after jeopardy has attached; in certain circumstances, a retrial can occur after a mistrial has been declared (LaFave et al., 1999). For another, the protection only applies to a second prosecution by the same government; consequently, it is not a violation of double jeopardy for a state to prosecute someone for crimes that were at issue in a preceding federal prosecution that produced a judgment of conviction or acquittal (LaFave et al., 1999). Perhaps the most famous instance of this, in recent years, is the state prosecution Oklahoma has brought against Terry Nichols for his role in the bombing of the Oklahoma City Federal Building; Nichols, of course, has already been prosecuted and convicted in a federal proceeding arising out of the same event (Romano, 2004).

Another important constitutional protection is the Sixth Amendment right to speedy trial. The Supreme Court has explained that this right is essential to protect at least three basic demands of justice: "(1) to prevent undue and oppressive incarceration prior to trial, (2) to minimize anxiety and concern accompanying public accusation and (3) to limit the possibilities that long delay will impair the ability of an accused to defend himself" (*Smith v. Hooy*, 1969). Indeed, this right is considered so important that the Sixth Amendment guarantee has been supplemented by statutory and rule-based protections in both the state and federal systems (LaFave et al., 1999).

## Basic Defenses

As to defending himself or herself, the substantive criminal law provides an array of theories defendants can use to argue that they should be acquitted of the charges brought against them. Analytically, these defenses fall into two categories: (1) failure of proof defenses and (2) affirmative defenses (LaFave, 2003).

Failure of proof defenses are not "true" defenses; they are merely a way of attacking the prosecution's case. As one scholar explains, a "failure of proof defense is one in which the defendant has introduced evidence at his criminal trial showing that some essential element of the crime charged has not been proved beyond a reasonable doubt" (LaFave, 2003). Because criminal liability requires

a voluntary act (*actus reus*) done with the appropriate mental state (*mens rea*), defendants often argue that they cannot be held guilty because they either were not acting voluntarily or, if they were acting voluntarily, did not possess the mental state required for the offense (LaFave, 2003). Assume, for example, that an employee of a company is charged with hacking (i.e., with unauthorized intrusion into an area of the company's computer system); the premise of the charges is that although the employee had authorized access to part of the company's computer system, he exceeded the scope of that authorized access and explored parts of the system that he was not legitimately entitled to access (*United States v. Czubinski*, 1997). Assume, further, that the charge against the employee is that he "knowingly" gained "unauthorized access" to parts of his employer's computer system. The defendant can mount a failure of proof defense by claiming that, although he did exceed the scope of his authorized access to the computer system, he did not do so "knowingly"; he could argue, for example, that he believed he had full access to the entire system because no security measures prevented his exploring parts of the system beyond those he used in the course of his everyday tasks. If the employer did not have policies that made it clear that employees were not to exceed a specifically defined scope of access to the computer system, this failure of proof defense might well work. Predicating a failure of proof defense on the theory that one was not acting voluntarily at the time the offense was committed is much more difficult when computer crimes are involved: generally speaking, claims that one was not acting voluntarily require the defendant to show that he or she was in a state of unconsciousness at the time the offense was committed; such claims rest, for example, on assertions that the defendant was sleepwalking, suffering from an epileptic seizure, or in a fugue state induced, say, by brain trauma or a reaction to medication (LaFave, 2003). Claims such as these can be credible when the offense involves simple acts, such as driving a car; they are hardly likely to be credible when the offense involves complex activity requiring the application of specialized technical knowledge and skills.

Unlike failure of proof defenses, affirmative defenses do not involve attacking the prosecution's ability to prove the elements of its case (LaFave, 2003). One who asserts an affirmative defense is, in effect, saying "yes, but . . ."; that is, the defendant is saying, in effect, "Yes, I committed the crime but there are valid reasons why I should not be held liable for doing so." The basic affirmative defenses are (a) insanity, (b) self-defense, (c) defense of others, (d) defense of property, (e) duress, and (f) choice of evils (LaFave, 2003). Insanity and duress are "excuse" defenses; one who asserts these affirmative defenses is, in essence, saying "Yes, I committed the crime but I should not be held liable" because (a) I was insane and therefore did not know right from wrong or (b) I was forced to commit the crime by threats or violence from another person (LaFave, 2003). The other four are "justification" defenses; one who asserts these affirmative defenses is, in essence, saying "Yes, I committed the crime but I did the right thing in doing so" because I acted to protect myself, to protect someone else, to protect property or to avoid some harm greater than that resulting from the commission

of this crime (LaFave, 2003). Although the prosecution bears the burden of proving every element of the crime beyond a reasonable doubt, the defendant bears the burden of producing evidence that is sufficient to raise a cognizable claim that the affirmative defense applies; a defendant must, for example, produce evidence that supports his or her claim of having acted in self-defense (LaFave, 2003).

Generally speaking, these traditional affirmative defenses tend to have little applicability in cybercrime prosecutions. One who seeks to raise an insanity defense will encounter some of the same logical obstacles as a defendant who tries to argue that he or she was not acting voluntarily at the time the crime was committed; although it might be possible to show, say, that the defendant was acting under the influence of command hallucinations when he or she hacked into NASA, both juries and judges are likely to be skeptical of such claims when the charges involve crimes the commission of which necessarily entails a course of structured, sequenced conduct. The same is true of duress: to qualify for the duress defense, a defendant must show that he or she committed the crime(s) at issue because he was forced to do so by another person, who threatened him with death or serious bodily injury if he did not comply with that person's demands (LaFave, 2003). It is, of course, quite possible that someone could use force or the threat of force to coerce a person with computer skills into hacking into a system, releasing a virus or otherwise violating state or federal cybercrime laws. The likelihood of this happening seems, however, rather remote; the duress defense is often raised when one participant in criminal activity (A) is coerced by another participant in that activity (B) to "go further" than A had intended or desires (LaFave, 2003). It is exceedingly rare for the defense to be raised in an instance of "stranger danger" (i.e., when a stranger forces an otherwise law-abiding citizen to commit a crime by using or threatening force). Because computer crimes tend, so far, to be committed by those who have no history of violent criminal activity, it is unlikely that the duress defense will be successfully asserted in cybercrime prosecutions for the foreseeable future.

It may be somewhat easier to raise a justification defense. Self-defense requires a use of "force" that the defending party deemed was necessary to protect himself or herself from another's use of force, either deadly or nondeadly (LaFave, 2003). Historically, "force" has meant physical force, but there is no reason why we could not expand the concept to encompass "virtual force" (i.e., an assault using computer technology). Even if we did so, however, the assault would have to threaten a human being with death or serious physical injury for the defending party to be able to utilize self-defense as the justification for retaliative actions; an attack focusing solely on a computer system would not suffice as the basis for invoking this defense (LaFave, 2003). In 2001, a Chinese man claimed to have hacked into a computer system in self-defense: he said he hacked into the other system because he thought the operators of that system had attacked his computer (Ying-Cheng, 2001). Even if this gentleman had been correct in that belief, he would not, under U.S. law, have been able to claim self-defense because the attack

was not a personal attack (i.e., was not directed at causing physical harm to him) (LaFave, 2003).

The same would be true if this gentleman had tried to assert the related affirmative defense of defense of others; defense of others requires that one has acted because such action was necessary to prevent another person or other persons from death or physical injury (LaFave, 2003). It is of course conceivable that such a defense could be asserted successfully in the context of a cyberassault: assume, for instance, that during the dead of winter a cyberterrorist is in the process of attacking a computer system that controls electrical power to a midwestern city; if the cyberterrorist succeeds in taking over the system and shutting down power to the city, people will be without light, heat, and other services. Many will die from exposure; others will die from panic, from their inability to gain assistance, from emergency services, and for other reasons. A computer technician discovers that the attack is in progress and knows it will succeed before he would have time to contact the authorities and secure official intervention; if this technician hacks into the cyberterrorist's computer or otherwise takes defensive measures to prevent the attack, he should be able to assert a claim of self-defense in the improbable instance he is charged with hacking into the computer which is the cyberterrorist's target. In this example, the computer technician is using a type of "force," virtual force, to prevent injury to other persons and is, therefore, justified in attacking the cyberterrorist's computer.

This brings us to defense of property; like self-defense and defense of others, defense of property has traditionally required that one use physical force. In this instance, the force is used to preserve one's possession of, or the integrity of, real or personal property (LaFave, 2003). The Chinese gentleman discussed above, who hacked into a computer system because he believed the operators of that system had attacked his system, was really asserting a defense of property theory (Ying-Cheng, 2001). He claimed he had to take affirmative action against those whom he believed were attempting to harm his computer system (Ying-Cheng, 2001). Because he believed he was acting to protect his property from unlawful conduct, he could, subject to the qualifications discussed below, assert a defense of property claim when he was charged with unlawful hacking.

The final justification defense is choice of evils. Choice of evils justifies the commission of a crime when one commits that crime to avoid a harm or evil greater than the harm or evil resulting from the commission of this offense (LaFave, 2003). The choice of evils defense would, for example, be available to one who cut a hole in a dam that was about to burst to prevent the dam from collapsing and flooding a town; the defense is available even if, by cutting the hole in the dam, the actor caused a nearby farm to flood, killing livestock or even a person (LaFave, 2003). As long as the harm sought to be avoided (i.e., flooding the town, which would cause great loss of life and property) is greater than the harm inflicted (i.e., damage to the dam plus the loss of a single life and property damage at the farm), the actor is entitled to the choice of evils defense (LaFave, 2003). This defense could therefore serve as an alternative basis for justifying the actions of the computer

technician discussed earlier: the one who frustrated the efforts of the cyberterrorist. His actions could be characterized either as defense of others (if we focus on the threat coming from another person) or as choice of evils (if we focus on the harm to be avoided versus the harm resulting from his hacking into the computer system).

As this discussion of justification defenses should demonstrate, they raise difficult issues of law and policy. When we allow someone to assert a justification defense, we are, in effect, saying that they did the right thing by taking the law into their own hands; because the legal system cannot tolerate people's taking the law into their own hands as a matter of general practice, the law imposes restrictions on the assertion of the justification defenses to ensure that they can be successfully asserted only in truly compelling cases (LaFave, 2003). The restriction that is common to all of the justification defenses is that the actor believed it was "necessary" to, in effect, take the law into his or her own hands (LaFave, 2003). "Necessary" in this context means that there were no viable, lawful alternatives (LaFave, 2003). To use the examples given above, the computer technician who hacked into a computer system to prevent the cyberterrorist's attack from succeeding would no doubt qualify for a justification defense (defense of others or choice of evils) because it seems he had no lawful alternatives; if he had contacted the authorities and asked for their assistance, the attack would have succeeded (LaFave, 2003). Conversely, the Chinese gentleman who hacked a computer system he thought was being used to attack his own system would not qualify for a justification defense because it was not "necessary" for him to take the law into his own hands; he could have gone to the authorities, reported the attacks on his system, and given them the information that led him to believe a particular computer system was being used in the attacks. The authorities could have handled matters from there.

### Hack Back Defense

The above discussion of justification defenses logically leads to the issue of vigilante action—what the law calls "self-help"—as a response to cybercrime. Some argue that because the law enforcement response to cybercrime is likely to be ineffective given the limited resources law enforcement has for this purpose plus the fact that many cybercrimes are transnational in nature, it is only reasonable to allow victims of hacking and other computer crimes to "strike back" at the offenders (Loomis, 2001). Those who advocate this approach claim that "you can't reason with attackers and you can't coddle them—the only language they understand is force" (Loomis, 2001). Those who take this position believe that if a victim strikes back at his/her attacker with sufficient force, this will deter that attacker and similarly situated attackers from launching future assaults on the victim's system (Loomis, 2001). This argument has an undeniable visceral appeal, because of the apparent impunity with which many cybercriminals operate. Indeed, it has even led to the introduction of proposed federal legislation that would legitimize self-help against those who engage in criminal copyright violations (H.R. 5211, 2002).

Society, however, cannot tolerate vigilante behavior. This was true in the 19th century, when vigilantes were active in the American West, and it is still true today (Hine, 1998). The drift toward vigilantism as a response to cybercrime is not surprising; vigilantism tends to appear in "frontier" situations (i.e., when law enforcement is ineffective or absent; Hine, 1998). This is, of course, true of cyberspace, which is often analogized to the Wild West. The problem is that although self-help can be a viscerally satisfying approach to one's victimization, it creates more problems than it solves: for one thing, vigilantes commit crimes. In the examples given in the previous section, both the computer technician who is responding to the cyberterrorist's activities and the Chinese gentleman who is responding to the attacks on his system are violating the law by hacking. It is a fundamental premise of every legal system that citizens are not privileged to commit crimes (LaFave et al., 1999). It is true that, as the previous section explained, the law does absolve citizens who take the law into their own hands under certain, very limited, situations; however, this is very different from a blanket authorization for online retaliative behavior. Aside from anything else, such behavior is objectionable because of the risks that innocent parties will be targeted for retaliation; the consequences of this risk are particularly intolerable in cyberspace, where it can be impossible to know precisely from which system an attack was launched (Loomis, 2001). It is to avoid the possibility of harm to an innocent actor that the legal system has developed a complex structure of rules and processes governing the imposition of sanctions upon those who are believed to have committed crimes (LaFave et al., 1999).

### Evidentiary Issues

Cybercrime cases present a variety of evidentiary issues, which can be broken down into two categories: (1) the process of gathering evidence and (2) the process of introducing evidence at trial.

The process of gathering evidence differs depending on whether the evidence is located in a stand-alone computer (desktop or laptop) or is on a network. If the evidence is located on a stand-alone computer, the basic principle governing law enforcement's gaining access to the evidence is the Fourth Amendment, which protects citizens from "unreasonable" searches and seizures (LaFave, Israel, & King, 1999). If a seizure is "reasonable," it does not violate the Fourth Amendment (LaFave, Israel, & King, 1999). To be "reasonable," a search or seizure conducted by law enforcement agents must be carried out either under the authority of a search warrant or under one of the exceptions to the warrant requirement, such as consent (LaFave, Israel, & King, 1999). So, assume federal agents are investigating allegations that John Doe has child pornography on his home computer. In scenario 1, they have gathered enough information to establish probable cause to believe there is child pornography on his computer. They take that information to a magistrate—in the form of an application for a search warrant and a sworn affidavit attesting to their probable cause—and obtain a warrant to search for and seize child pornography (LaFave, Israel, & King 1999). They take the warrant to John Doe's house

and conduct the search either onsite, at his home, or seize his computer and take it away for an offsite search. In scenario 2, the agents either do not have enough information to establish the probable cause they need to get a warrant or prefer to proceed without a warrant. They approach John Doe and ask him if they can search his computer; if he consents, he waives his Fourth Amendment rights and surrenders his ability to object to the search at a later date (LaFave, Israel, & King, 1999).

The process of gathering evidence is far more complex when the evidence is located on a network or on several networks (Dean, 2003). Continuing the example used above, assume the agents have received information that John Doe is corresponding online with minors whom he sends child pornography and whom he arranges to meet for the purposes of having sexual relations. The agents could proceed as outlined above with regard to evidence located on John Doe's computer, but they also need information about his e-mail contacts with the minors. To learn about that, they need information from Doe's Internet service provider (ISP). Because the Supreme Court has held that the Fourth Amendment does not apply to records held by a third party, the agents are not constitutionally required to get a warrant to obtain the information they need from the Internet service provider (LaFave, Israel, & King, 1999). But because Congress was concerned about unrestricted law enforcement access to records, it adopted a series of statutes—the Electronic Communications Privacy Act of 1986 (ECPA)—which require law enforcement to go through certain procedures to get evidence from an Internet service provider and others who provide electronic communications services (Electronic Communications Privacy Act). Under ECPA, the agents will have to use a search warrant, a subpoena, or a court order to obtain the information they need from the Internet service provider (Dean, 2003). ECPA sets up different requirements for different types of information, but the critical difference between it and the Fourth Amendment is that agents can often use either a subpoena or a court order, neither of which requires probable cause, to get the information they require (Electronic Communications Privacy Act).

The process of introducing electronic evidence, such as that described above, at trial is a very complex one which is quite beyond the scope of this chapter. Generally, for evidence to be admissible at trial it must be (a) relevant, (b) authentic, and (c) reliable (*Daubert v. Merrell Dow Pharmaceuticals, Inc.*, 1993). The issue of relevance is seldom problematic; evidence is "relevant" when it tends to prove the fact for which it is offered (i.e., child pornography was found on John Doe's computer) and when that fact is material to an element in the case (i.e., John Doe is being prosecuted for possessing child pornography; Mueller & Kilpatrick, 2003). Authenticity can be problematic, because digital evidence can be altered easily, the party offering digital evidence must be able to establish that it is what it is claimed to be (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2002). To establish this and rebut defense claims that evidence has been altered, the prosecution will typically establish a chain of custody for the evidence; that is, the prosecution will typically trace the processes that were

used to find the evidence and retrieve it from a computer or from a network (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2002). Establishing a chain of custody authenticates digital evidence by showing that it was never left unsecured in conditions that would have permitted its alteration (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2002). Reliability raises similar concerns; the defense may, for example, claim that a computer-generated record that the prosecution is offering as evidence is not reliable because the program used to create it contained serious programming errors (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2002). For the prosecution to overcome such a challenge and establish the reliability of the record in question, it will have to establish that the computer program did, in fact, meet the requisite standard of reliability (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2002).

## Sentencing

As explained, sentencing is done by a judge; in imposing sentence, a judge is guided by a set of rules that define either the required sentence or an allowable range of sentences (LaFave et al., 1999). There are four basic rationales for inflicting punishment on offenders: incapacitation (to physically prevent this person from reoffending), deterrence (to discourage this person and others from committing similar crimes), rehabilitation (to educate the person so that he/she no longer desires to commit crimes), and retribution (to retaliate for the harm the offender has caused) (LaFave, 2003). Since the 1980s, sentencing in the federal and state systems has been based on deterrence, retribution, and incapacitation, a reaction against rehabilitation, which had been the primary rationale for sentencing since the 19th century. A new approach began in the 1970s and culminated in the adoption of new sentencing provisions that emphasize the need to deter and incapacitate offenders and society's need for retribution (Vitiello, 1991).

Victims and their families have increasingly been given input into the sentencing process; the federal system and most states either permit or require the use of victim impact statements, which assess a crime's impact on the victim and the victim's family at sentencing (LaFave et al., 1999). This practice extends to cybercrime cases; in the federal system, for example, victims of criminal copyright infringement are statutorily guaranteed the right to submit a victim impact statement documenting their losses prior to sentencing (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2001).

In 2003, three groups submitted a statement to the U.S. Sentencing Commission arguing that those convicted of computer crimes are already being punished more severely than those convicted of similar crimes that do not involve the use of computer technology (National Association of Criminal Defense Lawyers, Electronic Frontier Foundation & Sentencing Project 2003). The statement argued against increasing penalties for federal computer crimes (a) because the incidence of computer crime is low, (b) because loss calculations currently in use

lead to disproportionate sentences that do not accurately reflect the offender's culpability, and (c) because harsh penalties can "chill legitimate computer research, business development, and reporting on security vulnerabilities" (National Association of Criminal Defense Lawyers, Electronic Frontier Foundation & Sentencing Project, 2003). The Sentencing Commission ultimately responded by increasing the penalties for certain of the cybercrime offenses defined by federal law (U.S. Sentencing Commission, 2003). The Commission found that the amendments reflected the "serious and risky nature of many computer offenses" (U.S. Sentencing Commission, 2003).

## RELATIONSHIP BETWEEN STATE AND FEDERAL CRIMINAL JUSTICE SYSTEMS

The United States has over 50 legal systems, each with its own definitions of "crimes." The federal system traditionally dealt with a limited set of "crimes" that protected special federal interests, such as the integrity of the currency (counterfeiting), the safety of federal officials (assassination), the viability of the taxing scheme (tax fraud), and the nation's security from its enemies (treason and espionage) (American Bar Association, 1998). There has been a tremendous expansion in federal crimes over the past century. The primary basis for this expansion has been the commerce clause of the Constitution, which lets the federal government regulate matters that can negatively affect the country's ability to sustain and engage in interstate or foreign commerce (American Bar Association, 1998). Using this power, the federal system has criminalized hacking and related crimes and has used more generic offenses (such as wire fraud and the interstate transportation of stolen property) to pursue cybercriminals (American Bar Association, 1998).

The federal government's exclusive power to criminalize conduct is limited to a few areas, including those noted above; except for these areas, both the federal and state governments can outlaw certain types of activity (American Bar Association, 1998). The drafters of the Constitution intended that criminal activity be prosecuted primarily at the state level; they saw federal criminal jurisdiction as an exception to this principle that should be carefully restricted in scope (American Bar Association, 1998). Consequently, notwithstanding the expansion in substantive federal criminal law, states still retain primary responsibility for defining and prosecuting criminal activity (American Bar Association, 1998).

Because both the federal and state governments can outlaw certain types of activity, including cybercrime, a defendant can be prosecuted by the federal government and a state government for offenses rising out of the same course of conduct; as noted, prosecutions by separate governments do not violate the prohibition on double jeopardy (LaFave et al., 1999). To prevent unfairness, the Department of Justice has adopted a policy—known as the *Petite* policy—which bars federal prosecution after a state prosecution unless certain conditions are met (LaFave et al., 1999). Basically, a subsequent federal prosecution will be barred unless the case involves a substantial federal interest that was not vindicated in the prior prosecution

and unless an assistant attorney general approves the prosecution (LaFave et al., 1999).

## CRIMINAL JUSTICE SYSTEM AND CYBERCRIME

### Federal Cybercrime Law

The basic federal cybercrime statute is 18 U.S. Code §1030. Section 1030(a) makes it a federal offense to (1) knowingly access a computer without authorization and obtain information that can be used to the disadvantage of the United States and deliver it to someone not entitled to it; (2) intentionally access a computer without authorization and obtain information contained in a financial record; (3) intentionally and without authorization access a computer used exclusively by a federal agency; (4) knowingly with the intent to defraud access a computer without authorization and obtain anything of value unless the thing obtained is only the use of the computer and does not exceed \$5,000 in any 1-year period; (5) *either* (a) knowingly cause a program, information, or code to be transmitted and intentionally damage a computer, intentionally access a computer without authorization and recklessly cause damage, *or* intentionally access a computer without authorization and cause damage *and* (b) cause or attempt to cause physical injury, modification of a medical diagnosis, loss aggregating \$5,000 in 1 year, a threat to public health or safety or damage to a computer used in furtherance of the administration of justice, national security, or national defense; (6) knowingly and with intent to defraud traffic in a password if the trafficking affects interstate commerce or the password can be used to access a federal government computer; and (7) transmit a threat to damage a computer with the intent to extort any thing of value.

Another important area is copyright law; copyright gives the author of a creative work the exclusive right to control its use for a fixed period of time (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2001). Copyright derives from the Constitution and is therefore exclusively federal (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2001). It is a crime for someone willfully to infringe a copyright for purposes of commercial advantage or private financial gain or by reproducing or distributing one or more copies of one or more copyrighted works having a total retail value in excess of \$1,000 during any 180-day period (U.S. Department of Justice Computer Crime and Intellectual Property Section, 2001).

Child pornography is another priority: federal law has long criminalized obscenity, which is considered to be outside the First Amendment's protection of free speech; in 1982, the Supreme Court held that pornography portraying minors engaging in sexually explicit activity can be criminalized even though it is not obscene (*New York v. Ferber*, 1982). The *Ferber* Court held that child pornography can be criminalized because its production inflicts physical and emotional abuse on the children involved. In 2002, the Supreme Court struck down a federal statute—18 U.S. Code §2252A—that criminalized the possession and distribution of "virtual" child pornography

(i.e., pornography created using morphed or other artificial images of children) (*Ashcroft v. Free Speech Coalition*, 2002). The Court found that the statute violated the First Amendment because (a) the material was not obscene and (b) no real children were harmed in its creation (*Ashcroft v. Free Speech Coalition*, 2002). Congress has since adopted legislation reinstating the ban on virtual child pornography; its constitutionality is uncertain (Feldmeier, 2003).

## State Cybercrime Law

Every state prohibits hacking (unauthorized access to a computer system) and cracking (unauthorized access to commit theft, damage, or other offenses) (Brenner, 2001). States tend to distinguish between basic unauthorized access (simple hacking) and unauthorized access that results in the commission of some further criminal activity, such as copying or destroying data (aggravated hacking), defining the two as distinct crimes (Brenner, 2001). They generally make simple hacking a misdemeanor and aggravated hacking a felony (Brenner, 2001).

A number of states outlaw the dissemination of viruses, worms, and other types of malware (Brenner, 2001). Many lump varieties of malware into one category: “computer contaminant” (Brenner, 2001). California, for example, defines it as “any set of computer instructions that are designed to modify, damage, destroy, record, or transmit information within a computer, computer system, or computer network without the intent or permission of the owner of the information” (California Penal Code, 2003).

States vary widely in how they criminalize the use of computers to commit traditional crimes, such as theft and forgery (Brenner, 2001). Some states outlaw computer forgery as a distinct offense. New Jersey makes it a crime to possess “forgery devices,” which include computers, computer equipment, and computer software “specifically designed or adapted to such use” (Brenner, 2001). A substantial number outlaw using computers to commit fraud. Instead of making computer fraud a separate crime, a few states increase the penalties for aggravated hacking if the offense was committed for the purpose of devising or executing a scheme to defraud (Brenner, 2001). Many states outlaw “computer theft,” which encompasses several different crimes, including information theft, software theft, computer hardware theft, and theft of computer services (Brenner, 2001). A number of states have “identity theft” or “identity fraud” statutes and some make it a crime to traffic in stolen identities (Brenner, 2001).

Cyberstalking is using computer technology to stalk or harass someone. A number of states outlaw cyberstalking (Brenner, 2001). Some criminalize “computer invasion of privacy,” which typically consists of using a computer to examine “employment, salary, credit or any other financial or personal information” pertaining to another person (Brenner, 2001). A few make it a crime to introduce false information into a computer for the purpose of “damaging or enhancing” someone’s “financial reputation” (Brenner, 2001). Some states have a “misuse of computer information” offense that prohibits copying, receiving, or using information that was obtained by violating a hacking or cracking statute (Brenner, 2001).

A surprising number of states have an “offense against computer equipment or supplies,” which consists of

modifying or destroying “equipment or supplies that are . . . intended to be used in a computer” (Brenner, 2001). A number make it a crime to deny or disrupt computer services or access to a computer and a few make it a crime to destroy computer equipment (Brenner, 2001).

## Defenses

As explained, defendants in cybercrime cases can avail themselves of traditional “failure of proof” and “affirmative defenses” to the extent the facts of the case support the assertion of such a claim. This means, for example, that one who has been charged with hacking can defend on the basis that (a) his access to the computer in question was authorized, (b) he did not know his access to the computer in question was not authorized, or (c) he knew his access to the computer in question was not authorized but believed his hacking was justified.

Cybercrime defendants also raise less traditional defenses, two of which merit discussion here. One involves the nature of theft: in an Oregon case, a defendant was charged with computer theft for copying a password file belonging to Intel, his employer; he challenged the legal sufficiency of the charge, claiming that *copying* the file did not constitute *stealing* the file (*State v. Schwartz*, 2001). He pointed out that the essence of “theft” is depriving the rightful owner of property of its possession and use and argued that because Intel still had the file he had not deprived Intel of its property (*State v. Schwartz*, 2001). The court disagreed, holding that he did commit theft, albeit theft of intangible property (*State v. Schwartz*, 2001). This argument illustrates how computer technology can challenge the assumptions that have historically animated criminal law; with intangible property, theft ceases to be a zero-sum event. Therefore, instead of drafting theft statutes to reach a deprivation of tangible property, it becomes necessary to utilize a diminution theory (i.e., that the defendant deprived the rightful owner of some quantum of the value of his property, such as the right to its exclusive use).

Another approach is the Trojan horse defense, which has been notably successful in the United Kingdom. In 2003, Aaron Caffrey, a 19-year-old British hacker, was prosecuted for launching a denial of service attack that shut down computer systems at the Port of Houston (Questions cloud cybercrime cases, 2003). His defense was that a hacker had used a Trojan horse program to take over his computer and launch the attack. Even though experts found no trace of a Trojan on the computer, a jury acquitted Caffrey of the charges against him (Questions cloud cybercrime cases, 2003). The same theory was used successfully in several child pornography prosecutions in the United Kingdom (Bean, 2003). An American accountant was acquitted of charges of filing false tax returns because he convinced the jury that a computer virus was responsible for the errors on the returns (Auditor acquitted, 2003). These cases raise a difficult issue for prosecutors: how is it possible to prove beyond a reasonable doubt that no Trojan horse or virus was responsible for the crime charged? Some argue that the solution lies in scanning the computer to determine if it contains a Trojan horse or other type of malware; if it does, then it would be necessary to determine if the malware could do what it is

claimed to have done (The Trojan horse defense in child pornography, 2003). If the computer does not contain malware capable of having committed the crime, so the argument goes, then the jury should convict (The Trojan horse defense in child pornography, 2003). Of course, Aaron Caffrey was acquitted even though experts found no trace of a Trojan on his computer. The Trojan horse and related defenses illustrate the difficulties that can be involved in presenting highly technical evidence to a lay jury; some have suggested that the solution lies in bench trials, but because of the Sixth Amendment, that option remains solely with the defendant (“Trust me, I’m an IT expert,” 2003).

### Other Problematic Areas

Clearly, the most challenging aspect of cybercrime as far as law enforcement is concerned is its pronounced tendency to cross borders, especially national borders (Brenner & Schwerha, 2002). Law is territorially based, whether it is national or the law adopted by a component state in a federal system like the United States (Brenner & Schwerha, 2002). Cybercrime’s ability to transcend national borders created problems for cybercrime investigators and prosecutors.

There are two ways to obtain evidence from another country. One is informal cooperation; the other is relying on the formal mechanisms that have traditionally been used to gather evidence (Brenner & Schwerha, 2002). A 1994 case illustrates informal cooperation: in 1994, system administrators at the Rome Air Development Center in New York found hackers had installed password sniffers on the Rome Labs networks (Brenner & Schwerha, 2002). The Air Force’s Office of Special Investigations (AFOSI) used informants to identify one of the hackers, a 16-year-old from the United Kingdom (Brenner & Schwerha, 2002). Having established a relationship with New Scotland Yard, AFOSI agents contacted them (Brenner & Schwerha, 2002). Working together, AFOSI and New Scotland Yard developed probable cause to believe evidence of the intrusions would be found at the juvenile’s home; New Scotland Yard used this information to get a warrant to search his residence (Brenner & Schwerha, 2002). They executed the warrant and seized incriminating evidence; Pryce was prosecuted and eventually pled guilty to 12 counts of hacking (Brenner & Schwerha, 2002).

Traditionally, informal cooperation depended on networking; few local police officers had the opportunity to network with officers from abroad (Brenner & Schwerha, 2002). In cybercrime cases, officers who have never had the opportunity to network with officers from other countries may find they need assistance from abroad. To meet this need, two entities—Interpol and the G8—have established 24 networks officers can use to obtain assistance from officers in other countries (Brenner & Schwerha, 2002). These networks qualify as informal cooperation because they bypass the processes discussed below (Brenner & Schwerha, 2002). As is explained below, informal cooperation is usually the most expeditious way to proceed.

The basic formal devices are requests for assistance submitted under mutual legal assistance treaties (MLATs) and letters rogatory (Brenner & Schwerha, 2002). An investigator’s first step is determining if an

MLAT encompassing the evidence to be sought is in effect between the United States and the country where the evidence is located. Using an MLAT is much faster than the letter rogatory procedure (U.S. Department of Justice, 1999). If an MLAT is in effect, the investigator must prepare a request for assistance pursuant to the treaty; it contains essentially the same information as that used for a letter rogatory, which is described below, except for the promise of reciprocity (U.S. Department of Justice, 1999). If an MLAT is not in effect, the investigator will have to resort to the letter rogatory process.

A letter rogatory is a request from a U.S. judge to a judge in another country requesting the performance of acts that would be illegal without local judicial approval (U.S. Department of Justice, 1999). The investigator must complete the letter rogatory and have it transmitted to authorities in the country from which assistance is being sought (U.S. Department of Justice, 1999). Letters rogatory are usually transmitted through diplomatic channels, which is one reason why they are such a time-consuming method of obtaining assistance; the Department of Justice warns federal prosecutors it may take a year or more to obtain assistance through a letter rogatory (U.S. Department of Justice, 1999).

Formal methods of obtaining evidence are far too time consuming to be effective in cybercrime cases, and informal methods, even when supplemented by the efforts of Interpol and the G8, can be unreliable (U.S. Department of Justice, 1999). This is part of a larger problem, namely that the laws of varying nations are inconsistent.

That was the problem in investigating the Love Bug virus, which spread around the world in May 2000 (Brenner & Schwerha, 2002). U.S. experts traced the virus to the Philippines; when FBI agents arrived there, they worked with local authorities to investigate Onel de Guzman, the primary suspect. Informal cooperation between the officers worked splendidly; the problem came with the Philippine legal system (Brenner & Schwerha, 2002). At that time, the Philippines criminal code did not criminalize hacking or the dissemination of viruses; laws to that effect were enacted after this incident. This presented several problems: investigators had difficulty getting a warrant to search de Guzman’s apartment because warrants authorize searches for evidence of “crimes” and virus dissemination was not then a crime (Brenner & Schwerha, 2002). The officers eventually got the warrant and conducted the search, but then they had to decide what to charge de Guzman with. He was charged with fraud and theft, but the charges were dismissed (Brenner & Schwerha, 2002). Because de Guzman could not be prosecuted locally, he could not be extradited for prosecution elsewhere; no one was ever prosecuted for the damage caused by the Love Bug (Brenner & Schwerha, 2002).

Many believe the only way to achieve an internationally effective response to cybercrime is to harmonize national laws so they are consistent in how they (a) define cybercrime offenses and (b) specify what law enforcement officers can and cannot do in gathering evidence in cybercrime investigations (Brenner & Schwerha, 2002). So far, the most notable achievement in this effort is the Council of Europe’s Convention on Cybercrime. Parties to the Convention, which is not limited to European nations, agree to take such “legislative or other measures” as are

necessary to outlaw certain types of computer-facilitated criminal activity (Brenner & Schwerha, 2002). They also agree to take similar measures to ensure that they can preserve and collect evidence and provide assistance in cybercrime investigations even when no MLAT is in force between the requesting country and the requested country (Brenner & Schwerha, 2002). So far, 34 countries, including the United States, Canada, and Japan, have signed the Convention (Brenner & Schwerha, 2002). It goes into effect when it has been ratified by 5 countries, 3 of which are members of the Council of Europe; it has been ratified by 3 countries, all of which are members of the Council of Europe (Brenner & Schwerha, 2002).

## CONCLUSION

Cybercrime presents challenges not only for the U.S. legal system: because cybercrime so easily and so often transcends national borders, cybercriminals can take advantage of gaps or inconsistencies in national law in an effort to evade apprehension and/or prosecution. It will not be easy to resolve the challenges cybercrime presents for the criminal justice system, here and abroad. As this chapter demonstrates, cybercrime requires the extrapolation of legal principles that were developed to deal with activity occurring in the real, tangible world; it will also, no doubt, require the articulation of new principles that are especially designed to deal with the novel ways criminal activity can manifest itself in the online world.

## GLOSSARY

**Affirmative Defense** A legal doctrine that lets a defendant avoid liability even though he or she committed a crime; self-defense is an example.

**Bench Trial** A trial in which the judge, not a jury, acts as the finder of fact; in a bench trial the judge decides whether the defendant is guilty or innocent.

**Beyond a Reasonable Doubt** The standard of proof in criminal trials; the prosecution must prove beyond a reasonable doubt that the defendant committed the crime(s) charged; if the prosecution fails the finder of fact must acquit the defendant.

**Computer Virus** Computer program code that copies itself and spreads by attaching itself to another computer program; a virus can alter or delete data or interfere with the operation of a computer.

**Council of Europe** Created in 1949, the Council of Europe brings together 45 European countries; among other things, the Council works to standardize social and legal practices across its member countries.

**Cyberstalking** The use of a computer and the Internet to stalk or harass someone, often by sending them harassing e-mails.

**Double Jeopardy** A constitutional prohibition that bars a government from trying someone more than once for the "same offence."

**G-8** The major industrial democracies (the United States, Britain, Germany, France, Japan, Italy, Canada, and Russia) have joined together to address the political and economic issues they all face; officials from the member countries meet periodically to discuss these issues and formulate policies.

**Hacking** Gaining access to a computer or computer system without authorization; hacking is analogous to trespassing in the real world.

**Intellectual Property** In most countries, laws give the creators of intangible products—such as books, movies, and software—property rights in those products; the property rights can be sold or licensed, but they have the same legal status as ownership of tangible property, such as a house or a car.

**Intellectual Property Crime** In most countries, it is a crime to take someone's intellectual property without their permission or to use intellectual property in a way that is not authorized by the owner.

**Interpol** Interpol is an international police organization that was created in 1923; it is financed by its 181 member countries and coordinates law enforcement efforts around the world.

**Jury Trial** A trial in which a group of civilians, usually twelve in number, act as the finder of fact; in a jury trial these jurors decide whether the defendant is guilty or innocent.

**Plea Bargain** An arrangement in which a defendant pleads guilty, usually to a crime of lesser severity than that charged in the indictment; typically, plea bargains include a requirement that the defendant cooperate with the government by providing evidence against others.

**Preponderance of the Evidence** The standard of proof in civil trials; in civil trials, the plaintiff must present proof that establishes that her case is "more likely than not" to be true.

**Sentencing Guidelines** Rules adopted in the federal system and in most states that guide what judges can do in sentencing someone for an offense; they tend to require that a judge impose a specific sentence, based on various factors, instead of setting a range of time someone must serve.

**Victim Impact Statement** A statement submitted as part of the sentencing process; it is designed to show how the crime impacted on the victim's life and, where appropriate, on the victim's family.

## INTRODUCTION

In the past several years, the world has come face to face with terrorists who are becoming more extreme. At the same time, the world has become increasingly dependent on using computers and networks to manage the way we work, communicate, and live. Terrorism, used throughout human history in one form or another, has found a powerful new weapon.

Although most terrorist organizations remain either national or regional, cyberspace gives them tools to become global in reach and coordination. A cyberattacked nuclear power plant meltdown, a massive air traffic control shutdown, a dam spillway opened to flood downstream cities, or other cyber-based terrorist acts could entail even greater loss of life than the September 11, 2001, attacks. Cyberterrorists—an unknown, unseen enemy who strike from anywhere, anytime, and disappear like a vapor trail and is difficult to trace and bring to justice, with devastation potentially as destructive as poison gas, deadly diseases, truckloads of explosives, and atomic radiation—may evoke even more dread and terror than the conventional terrorist.

This chapter asks whether it is reasonable to conclude that global terrorism and cyberspace will converge in this deadly intersection. It attempts to present a balanced view of what constitutes cyberterrorism and the extent of the threat. It addresses how cyberattacks are possible on physical infrastructure or other vital facilities and explores the support role of cyberspace in conventional terrorism. It discusses how government, businesses, institutions, schools and universities, private interest groups, and individuals can each play a role in combating cyberterrorism.

Academic research on cyberterrorism is in its early stages. In the fast-moving world of cyberspace, formal research lags behind current events. Information sources

for this chapter include scholarly journals and survey data where available, with up-to-date information from news reports and government or institutional Web sites.

The chapter begins by introducing potential terrorist acts and assessing sometimes confusing levels of threat. It asks whether fears of cyberterrorism are exaggerated and proceeds to formulate working definitions of cyberterrorism, which set a foundation for discussing how terrorism in cyberspace occurs and its relationships to asymmetric response and cyberwarfare. It follows this by showing some of the things individuals, companies, organizations, and government can do and how they can work together to help control the cyberterrorism threat.

## The Cyberterrorism Threat

On August 14, 2003, 50 million people in the northeastern United States lost electrical power—the biggest electrical blackout in U.S. history—including the core of America's financial network. Police responded to 80,000 emergency (911) calls on September 11, 2005 (9/11), more than double the usual number, and firefighters made more than 800 elevator rescues (Kaplan, 2003). Some in the media speculated that Al Qaeda and other terrorists were beginning a wave of cyberattacks to disable the country's physical infrastructure; 50 million victims would be a big story. It played on conspiracy theory in a post-9/11 world.

On September 14, 2004, an air traffic blackout in the Los Angeles Air Route Traffic Control Center created chaos in much of the western United States, including reported near misses and “almost near-mid-air collisions . . . as helpless controllers watched in disbelief” (Associated Press, 2004). Communication was lost with some 800 airplanes in flight (Wald, 2004). Could cyberterrorists be on the attack?

Responsible news organizations soon ruled out terrorism in both cases. The electrical blackout was attributed to faulty tree trimming and vulnerable design deficiencies in an aging grid infrastructure (Reuters, 2003). The air traffic problems resulted from neglected computer maintenance. In the long term, however, these incidents make people think: Was there a reasonable basis for concern that terrorists could compromise the power grid or other vital physical infrastructure through cyberattacks? Could they do something even worse?

## Acts That May Be Cyberterrorism

In 1996, Barry C. Collin, who takes credit for coining the term *cyberterrorism* in the mid-1980s, wrote, "This enemy does not attack us with truckloads of explosives, nor with briefcases of Sarin gas, nor with dynamite strapped to the bodies of fanatics. This enemy attacks us with ones and zeros." He listed some potentially deadly acts of the cyberterrorist:

- Remotely changing the pressure in gas lines, causing valve failures, explosion, and fire.
- Placing computerized bombs around a city, all simultaneously transmitting unique numeric patterns, each bomb receiving each other's pattern. If any of the set of bombs stops transmitting, all the others detonate simultaneously, which effectively prevents disarming any of the bombs.
- Attacking future air traffic control systems to cause civilian jets to collide.

Cyberterrorists might open a dam's spillway to inundate downstream communities or cause a meltdown of a nuclear power plant. They might cause trains to crash into each other. These "ones and zeros" attacks, Collin said, could have violent and fearful physical effects equally or more devastating than those caused by truckloads of explosives, dynamite, or poison.

Collin included several acts in cyberspace that do *not* have devastating physical effects on a large scale but clearly have the potential to create widespread chaos and fear in offices, homes, and on the streets:

- Remotely accessing the processing control systems of a cereal manufacturer to alter the formula and sicken children.
- Disrupting banks and international financial institutions and stock exchanges, with resulting loss of confidence in the economic system.
- Remotely altering formulas of medication at pharmaceutical manufacturers, resulting in ineffective or potentially harmful medications.
- Shutting down the electrical grid, causing widespread chaos.

"In effect," Collin (1996) concluded, "the cyber-terrorist will make certain that the population of a nation will not be able to eat, to drink, to move, or to live. In addition, the people charged with the protection of their nation will not have warning, and will not be able to shut down the

terrorist, since that cyber-terrorist is most likely on the other side of the world."

In 1998, Michael Vatis, director of the National Infrastructure Protection Center (NIPC), reportedly told a Senate subcommittee, "Tracing cyber-attacks is like 'tracking vapor'" (Christensen, 1999). Unknown and unseen, an enemy difficult to bring to justice connotes a lack of control that may make people more fearful.

Parks (2003) notes that attacks need not be confined to critical infrastructure, offering the example that a hacker could change the composition of vitamins at manufacture to include increasing an ingredient to a lethal level, and asks, "What if the cyber-terrorists were able to . . . attack . . . several hundreds of common products at the same time?"

Haimes (2002) separates cyberterrorism risks into three categories: (a) risk to critical cyberphysical infrastructure; (b) risk to organizational/societal infrastructures; and (c) risk to human lives and to individual property, liberty, and freedom. Physical infrastructure includes "manmade engineered systems that include telecommunications, electric power, gas and oil, transportation, water treatment plants, water distribution networks, dams, and levees." Threats include a list of potentially crippling adverse effects on society and loss of confidence in government institutions that could create chaos.

## Other Warnings about Cyberterrorism

These warnings raise questions about our vulnerability to cyberterrorism. Fears were heightened by the September 11, 2001, attacks. In December 2001, a Luntz Research survey reported that 74% of Americans were concerned that a cyberattack could target critical infrastructure assets such as telephone networks or power plants. Harris Miller, president of the Information Technology Association of America (ITAA) said, "The attacks of Sept. 11 . . . destroyed peace of mind for many people using the Internet [and] is generating high anxiety in cyberspace" (Greenspan, 2002a; CyberAtlas, 2001).

In June 2002, the *Washington Post* published an article titled "Cyber-attacks by Al Qaeda Feared, Terrorists at the Threshold of Using Internet as Tool of Bloodshed." It reported that the FBI, working with experts at the Lawrence Livermore National Laboratory, had been tracing a "suspicious pattern of surveillance against Silicon Valley computers by unknown browsers," mostly emanating from the Middle East and South Asia, targeting digital systems used to manage Bay Area utilities and other physical infrastructure. "Routed through telecommunications switches in Saudi Arabia, Indonesia and Pakistan, the visitors studied emergency telephone systems, electrical generation and transmission, water storage and distribution, nuclear power plants and gas facilities." The article said that additional information turned up on computers seized from Al Qaeda and on sympathetic Web sites. Roger Cressey, then chief of staff of the President's Critical Infrastructure Protection Board reportedly said, "Al Qaeda spent more time mapping our vulnerabilities in cyberspace than we previously thought. An attack is a question of when, not if" (Gellman, 2002).

The same article reported that in 1998 a 12-year-old hacker had taken “complete command” of Arizona’s Roosevelt Dam and the system controlling floodgates holding back 489 trillion gallons of water, enough to flood Phoenix, Mesa, and Tempe (accurate facts are given later in this chapter). In a separate incident in the early 1990s, a man reportedly had “turned his vehicle into a pirate command center” for the sewage treatment center in Queensland, Australia, and used the digital controls to release thousands of gallons of sewage into parks and streams. Manuals for the digital control systems, the article said, were available on the Web, and “nearly identical systems run [U.S.] oil and gas utilities and many manufacturing plants.” The North American power grid, described as “the most complex machine ever built,” was identified as a potential target.

In October 2001, Richard Clarke, then White House security advisor and chairman of President Bush’s Critical Infrastructure Protection Board, had claimed that cyberattacks on the nation’s critical information technology infrastructure could cause “catastrophic damage to the economy” akin to the “functional equivalent of 767’s crashing into buildings” (Johnson & Radcliff, 2001). In February 2002, testifying to the U.S. Senate, Clarke had warned, “Every sector of the U.S. economy and government has moved onto network systems . . . and nothing can operate unless the networks are functioning correctly. However, none of these things were designed with ‘security in mind’” (Wynne, 2002).

In July 2002, the U.S. Naval War College and Gartner had carried out a “digital Pearl Harbor” war game to test the vulnerability of the U.S. infrastructure to a cyberterrorist attack. In a postgame survey, 79% of the participants said that a strategic cyberattack is likely within the next 2 years (Gartner, 2002).

Clarke had used the term *digital Pearl Harbor* in 1997 during operation “Eligible Receiver,” a military exercise in which 35 hackers hired by the National Security Agency simulated attacks on the U.S. electronic infrastructure and reportedly achieved “root-level” access in 36 of the Department of Defense’s 40,000 networks, “turned off” sections of the U.S. power grid, “shut down” parts of the 9-1-1 emergency response network in Washington, DC, and other cities, and broke into computer systems aboard a Navy cruiser at sea (Christensen, 1999).

At the National Cyber Security Summit in December 2003, Secretary Tom Ridge of the Department of Homeland Security (DHS) cautioned, “A vast electronic nervous system operates much of our nation’s physical infrastructure. Everything from electricity grids to banking transactions to telecommunications depends on secure, reliable cyber networks. These networks and the infrastructures they support present an attractive target for terrorists. They know, as we do, that a few lines of code could ultimately wreak as much havoc as a handful of bombs” (CERT, 2003b).

A leading journal reported a finding by the Center for Strategic & International Studies that “all it would take to decimate the technological infrastructure of the U.S. economy is fewer than 30 computer hackers strategically placed around the world and a budget of less than

\$10 million.” It noted that research firm IDC estimated “there are 1.3 million people worldwide who possess the skills needed to launch a cyber attack” (*Information Management Journal*, 2002b).

This background, Collin’s warnings, and incidents such as the electrical grid failure in 2002 and the shutdown of the air traffic control in 2004 raise questions about our vulnerability to cyberterrorism. But a media hungry for attention, agencies seeking increased budgets, and security products vendors all have something to gain. Other voices question whether the cyberterrorism threat is exaggerated.

## Exaggerated Threats?

In an overview of the cyberterrorism threat, Lemos (2002) investigated facts surrounding the *Washington Post* story about the 12-year-old hacker who allegedly had control of Arizona’s Roosevelt Dam and its 489 trillion gallons of water. Lemos reported that the hacker was 27, not 12, and the incident occurred in 1994, not 1998. Furthermore, “While clearly trespassing in critical areas, the hacker never could have had control of any dams—leading investigators to conclude that no lives or property were ever threatened.” The Australian incident, it turns out, involved a former employee with access to a stolen copy of the control software.

Lemos (2002) notes that experts agree that it is easier to bomb a target than hack into a control system, and the results are more dramatic. He points out that the Digital Pearl Harbor exercise team determined that a successful effort would need significant resources—\$200 million, high-level intelligence, and 5 years of preparation time—and may not result in enough high-value devastation. Those same participants who predicted a likely strategic cyberattack within the next 2 years finally concluded that “such an offense could cripple communications in a heavily populated area but would not result in deaths or other catastrophic consequences.”

Denning (2001) supports that logic. “Although cyber terrorism is certainly a real possibility, for a terrorist, digital attacks have several drawbacks. Systems are complex, so controlling an attack and achieving a desired level of damage may be harder than using physical weapons. Unless people are killed or badly injured, there is also less drama and emotional appeal.”

Lemos (2002) concludes that cyberterrorism “has become a catch-all buzzword that evokes nightmare images that can be exploited to support political agendas,” including increased police power and funding for government departments and programs. He adds, “While warnings pervade government and the media, doomsday scenarios of cyberterrorism that result in massive deaths or injury remain largely the stuff of Hollywood scripts or conspiracy theory.”

The *Wall Street Journal* used the term *terrorism-industrial complex* in reporting on the Digital Pearl Harbor exercise, saying, “It is the aim of this cluster of interests both to define ‘terrorism’ as a technological problem . . . and to convince everyone that various tech tools hold great promise in combating terrorism. Billions of

dollars of federal 'homeland security' dollars are at stake" (Gomes, 2002).

Green, commenting on Richard Clarke's statements of alarm, Collin's predictions, the *Post* article, and other dire warnings says:

There's just one problem: There is no such thing as cyberterrorism—no instance of anyone ever having been killed by a terrorist (or anyone else) using a computer. Nor is there compelling evidence that al Qaeda or any other terrorist organization has resorted to computers for any serious destructive activity. . . . It is virtually impossible to use the Internet to inflict death on a large scale, and many scoff at the notion that terrorists would bother trying. (Green, 2002)

He quotes a former Clarke colleague: "Dick has an ability to scare the bejesus out of everybody."

So, should cyberterrorism be considered a serious threat?

Lemos (2002) concedes that, although Collin's more extreme scenarios are unlikely, the threat of a cyberattack is real. "Many power companies and water utilities are operated with networks of computer-controlled devices, known as supervisory control and data acquisition (SCADA) systems, which could be hacked." These systems, which can dramatically lower the cost of network maintenance, provide a window for hackers and cyberterrorists, who might use them to attack the network and the devices attached to it.

Academic researchers support the media reports and heighten the concern. "Some of these [computer hackers] are aligning themselves with terrorists like bin Laden. While the vast majority of hackers may be disinclined towards violence, it would only take a few to turn cyber terrorism into reality. Further, the next generation of terrorists will grow up in a digital world, with even more powerful and easy-to-use hacking tools" (Denning, 2001).

In a typical lottery, although the odds of winning are very low, someone eventually gets the right numbers. Hackers, even with the odds stacked against them, sometimes succeed. Cyberterrorists, using common hacking techniques or soliciting hacker help, could penetrate secure systems, too. In a comprehensive discussion of risk assessment applied to cyberterrorism, Haimes (2002) asserts that the traditional paradigm of expectancy value risk assessment does not apply to potential cyberterrorism acts. A high-probability event with a low negative effect is far different than a low probability event with a high-negative effect, even though the two might score identically in a multiplicative model. "Because terrorism is asymmetric, it defies conventional benefit-cost analysis." Thus, if the potential negative effects are devastating, it is critical to bring the probability to near zero (Haimes, 2002).

Hensgen, Desouza, Evaristo, and Kraft (2003), in a game theory article calling cyberterrorism a "bastard stepchild to physical terror attacks [in a] 'virtual,' non-real world," note that "the virtual is transformed to actual by the execution of a keystroke" (Hensgen et al., 2003).

Following the 2002 electrical grid failure, Kaplan (2003) called it an "overloaded, archaic, unevenly managed electrical-transmission system." He cited a spokesman for the North American Electric Reliability Council saying, "Hackers try to intrude on some aspect of the grid's computer network on a daily basis" (Kaplan, 2003). We could be a keystroke away from disaster. Gordon and Ford (2002) conclude, "Unless steps are taken to significantly reduce risks, disaster is inevitable."

At the National Security Summit in December 2003, Tom Ridge, Secretary of the DHS said, "Eighty-five percent of our nation's critical infrastructure, including the cyber network that controls it, is owned and operated by the private sector" (CERT, 2003b), and there is little oversight to their direct and indirect paths to the Internet. Lemos (2002) cited a survey of 50 utilities that found that 40% of water facilities allowed their operators direct access to the Internet, and 60% of them could be dialed into by modem. Even after 9/11, many of these systems have not been updated. Newer technologies, such as KVM (shared keyboard, video, mouse) that simplify network management and make SCADA attacks even more attractive, may increase the risks by encouraging wider adoption of network access.

## DEFINING CYBERTERRORISM

Definitions are required for counting and quantifying incidents of cyberterrorism, or the numbers are difficult to interpret. Laws and regulations depend on specific underlying definitions, otherwise they are unenforceable. This section explores some formal definitions used by government, private organizations, and academic researchers. Many of these definitions are inconsistent and imprecise. It gives examples of incidents in cyberspace that might be considered when defining cyberterrorism and leads to an extended definition of cyberterrorism. It also discusses how terrorists use the Internet in support roles. Multilevel operational definitions are presented, including a five-layer model. Later in the chapter, the ideas of asymmetric response and cyberwarfare are discussed in relation to the definitions.

### Definitions in Use

In the United States, government agencies implement laws by formulating regulations, which may define specific terms such as *cyberterrorism*. Ultimately, a court establishes a case law determination for a given situation. Changes require new legislation or regulations, and the process begins anew. In the coming years, cyberterrorism issues and definitions will be clarified as case law evolves, but they are likely to be made more complex as new threats and other unforeseen activities arise outside precedents.

Government departments and agencies use the term *cyberterrorism*, but none have formulated a definition that is binding outside their sphere of influence. In 2001, the NIPC called cyberterrorism an "evolving concept" and stated, "the definition of terrorism must evolve to reflect the type of activity that goes beyond traditional physical violence" (NIPC, 2001b; Vatis, 2001).

Howard Schmidt, then vice chairman of the Critical Infrastructure Protection Board, defined cyberterrorism at a conference early in 2002 as “anything that disrupts or causes mistrust about the security of computers and networks” (Moran, 2002). This is a broad definition, as terrorism is usually thought of as including some element of politically motivated coercion, intimidation, fear, confusion, uncertainty, or violence directed at civilians or other noncombatants.

In congressional testimony, J. T. Caruso, deputy executive assistant director of the FBI’s Counterterrorism and Counterintelligence unit, defined cyberterrorism as “*the use of cyber tools to shut down critical national infrastructures . . . for the purpose of coercing or intimidating a government or civilian population*” (emphasis added; Caruso, 2002; Greenspan, 2002b).

The NIPC’s Analysis and Information Sharing Unit (2001b) proposed the following:

Cyberterrorism is a criminal act perpetrated by *the use of* computers and telecommunications capabilities resulting in violence, destruction and/or disruption of services to create fear by causing confusion and uncertainty within a given population, with the goal of influencing a government or population to conform to a particular political, social, or ideological agenda. (emphasis added)

Mark Pollitt (2002), of the FBI Laboratory in Washington, DC, constructed a “working definition” as follows:

Cyberterrorism is the premeditated, politically motivated attack *against* information, computer systems, computer programs, and data which result in violence against noncombatant targets by sub national groups or clandestine agents. (emphasis added)

The definitions have important differences. The NIPC and Caruso emphasize *the use of* computers in creating terror, focusing on the act itself. Pollitt emphasizes the *target* or victim(s) of the act. They generally agree on some element of politically motivated coercion, fear, confusion, uncertainty, violence, intimidation, or intent. Gordon and Ford (2002), in a comprehensive review of government definitions, make a similar distinction between the “tool” and the “target” and introduce “the concept of ‘pure’ cyberterrorism,” which is carried out “entirely (or primarily) in the virtual world.”

Hensgen et al. (2003) in discussing definitions and game theory, include both the use of computers and the target of the act in a working definition for cyberterrorism:

A purposeful act, personally or politically motivated, that is intended to disrupt or destroy the stability of organizational or national interests, through *the use of* electronic devices which are *directed at* information systems, computer programs, or other electronic means of communications, transfer, and storage. (emphasis added)

Their definition is relatively broad. It can apply to both national and organizational interests in the virtual or physical worlds. However, it does not include elements commonly associated with terror.

More research needs to be done on establishing a definition of cyberterrorism that is consistent with definitions of conventional terrorism. Dictionary definitions of *terror* commonly include intense fear, extreme fright, dread, or panic. Terrorism includes violence or threatened violence, an ideology intended to cause harm, and some form of collective intent, usually with a political or ideological objective, directed at noncombatants.

The CIA’s Counterterrorist Center refers to Title 22 of the U.S. Code, Section 2656f(d), in defining terrorism as “premeditated, politically motivated violence perpetrated against noncombatant targets by sub national groups or clandestine agents, usually intended to influence an audience” (DCI Counterterrorist Center, CIA, 2002). The FBI defines terrorism as “the unlawful use, or threatened use, of violence by a group or individual . . . to intimidate or coerce a government, the civilian population, or any segment thereof, in furtherance of political or social objectives” (Watson, 2002). The FBI’s definition of terrorism could include *threats*, whereas the CIA specifies actual *acts*. Both involve political motivation or activities.

Dorothy Denning (2001), director of the Institute for Information Assurance, Georgetown University, offers a discussion of cyberterrorism that includes many of the elements that would lead to terror: fear, confusion, uncertainty, violence, or intimidation. “The attack should be sufficiently destructive or disruptive to generate fear comparable to that from physical acts of terrorism. Attacks that lead to death or bodily injury, extended power outages, plane crashes, water contamination, or major economic losses would be examples.”

Compared to conventional terrorism, defining cyberterrorism is complicated by the nature of cyberspace. Traditionally, laws deal with acts that are defined to occur in time and space. Acts in cyberspace may have physical effects in time and place, but some of their causal factors reside in a virtual reality, mostly independent of time and space. Defining (and prosecuting) cyberterrorism acts will need to take these factors into account, and it will take time to develop applicable case law. Many other nations have similar interpretation problems, and work needs to be done to reach international consensus. A more detailed discussion of problems in formal cyberterrorism definitions is given in the *Internet Encyclopedia* (Jaeger, 2003).

## Extended Definitions

Cyberterrorism often is defined loosely. President Clinton, in December 2000, said, “One of the biggest threats to the future is going to be cyberterrorism—people fooling with your computer networks, trying to shut down your phones, erase bank records, mess up airline schedules, do things to interrupt the fabric of life.” Clinton’s examples include many acts that do not qualify under FBI, CIA, and other definitions that include the terror component.

Gordon and Ford (2002) discuss extended definitions of cyberterrorism, which involve wide-ranging means

of using cyberspace to further terrorism. They cite self-interest motives (media attention, budget, power) in a section on “terrorism as theater.” Arguing for an extended definition, they maintain, “those who do insist on treating only ‘pure cyberterrorism’ as cyberterrorism are completely missing the true threat posed by the addition of acts in the virtual world to the terrorists’ playbook.”

Making a definition too restrictive may omit acts that should qualify. An overly broad definition, in contrast, will include so many acts that “terrorism” would become meaningless. Many ordinary crimes, vandalism, and hacking would be classified as terrorism. Even repeated “spam” might be terrorism if it intimidates or coerces people into purchasing or otherwise acting on an offer. Let us consider some examples.

In November 1999, a Tampa, Florida, man was charged in federal court with using the Internet to threaten to destroy the reputations of six young women and girls unless they engaged in phone and cybersex, charges investigated by a task force that included the FBI (FBI, 1999). Also in 1999, U.S. Web government sites were defaced in the name of China. The White House Web site was shut down for 3 days by massive amounts of e-mail. Pro-Chinese hackers hacked 165 Taiwanese Web sites to protest the Taiwanese presidential elections (Jane’s Information Group Ltd., 1999). In 2000, pro-Pakistani hackers defaced more than 500 Indian Web sites. In 2001, U.S. Web sites were attacked after a Chinese fighter jet collided with a U.S. reconnaissance plane (Tang, 2001). Pro-Korean hackers attacked computers and Web sites of various Japanese organizations following their approval of a new history textbook (NIPC, 2001a). In July 2002, CNN reported that Yale University experienced 18 unauthorized Web site log-ins—traced back to computers at Princeton (CNN.com, 2002c). The Terrorism Research Center’s Information Warfare Database lists over 50 “incidents” dating back to 1982 targeting the North American Air Defense Command, NASA, U.S. military sites, the White House, the U.S. Department of Defense, and others vital to U.S. and world security (Information Warfare Database, 2002).

These acts, and many other activities in cyberspace, are annoying and may cause monetary or other damages, but are they cyberterrorism? Some are intended to punish a country or other political entity for the purpose of influencing policy, but many do not involve large-scale or otherwise disastrous physical consequences.

In fact, only the cybersex case resulted in charges of cyberterrorism. That event had no political motivation or unauthorized break-ins, affected relatively few people, and created virtually no property damage or direct monetary losses. (The FBI called the attacks “large scale,” and Frank Gallagher, special agent in charge of the Tampa division, described them as “cyberterrorism” because of the fear created in the recipients.) The case was resolved on charges other than cyberterrorism (FBI, 1999).

There is general disagreement on whether using the Internet in a support role should be considered cyberterrorism, especially where the objective is not immediately destructive and is designed to influence public policy or further a political cause.

In a 1999 article, Denning explored how Internet users can influence public policy. She separates their usage into three categories: activism, hacktivism, and cyberterrorism. Activism refers to the normal, nondisruptive use of the Internet for persuasion or information dissemination. Hacktivism is where the activist uses hacking techniques for activities such as Web sit-ins or denial of service attacks, “with the intent of disrupting normal operations but not causing serious damage” against a target’s Internet site. Cyberterrorism refers to a “convergence of cyberspace and terrorism [that is] politically motivated [and] intended to cause grave harm such as loss of life or severe economic damage” in influencing policy (Denning, 1999).

### Support for Conventional Terrorism

Many experts believe that the most likely future attack scenario is for the cyberterrorists’ bits and bytes to be combined with terrorists’ bombs. This leads us to consider extended definitions of cyberterrorism, including support for conventional terrorism.

Gellman (2002) quotes Ronald Dick, then director of the FBI’s NIPC, “The event I fear most is a physical attack in conjunction with a successful cyber-attack on the responders’ 911 system or on the power grid,” meaning that “the first responders couldn’t get there . . . and water didn’t flow, hospitals didn’t have power. Is that an unreasonable scenario? Not in this world. And that keeps me awake at night.”

The Digital Pearl Harbor study group dealing with the electrical network “envisioned a two-pronged attack: first, the physical destruction of key transmission bottlenecks, followed by sabotage through the Internet of the digital systems that allow supervisors to switch transmission flows, . . . thus blocking them from restarting the power after the attack” (Kaplan, 2003). With simultaneous attacks on water, rail, highway, air traffic, and other physical infrastructure and digital control systems, the cyberterrorist would compound and prolong physical attacks. Disruptions of banks, stock exchanges, and pharmaceutical and food manufacturing and distribution would compound the effects.

At the 2003 National Cyber Security Summit, Amit Yoran (2003), then director of the National Cyber Security Division of the DHS, warned “America’s economic engine is fueled by efficiency . . . though the use of technology. . . . When we look at the vulnerability of cyberspace, there’s no doubt in my mind that what we’ve seen so far in attacks is just the early stage of what could become a critical national weakness—if we don’t aggressively address it.”

Does the use of cyberspace to support conventional terrorism qualify as cyberterrorism? To the extent that it is premeditated, politically motivated, perpetrated against noncombatant targets to influence an audience, there is a reasonable argument for including such activity.

### Communication in Terrorism

Under broad definitions, communication between terrorists and other cyberspace support for terrorist acts may be considered forms of cyberterrorism. The Web is a fast,

easy, cheap, and powerful communication tool. Just as businesses, governments, military forces, and other individuals use the Internet to communicate and transfer files, so do terrorists. A December 2003 Al Qaeda video appeared on the Web to recruit new terrorists (Arena, 2003), and terrorists have used the Web for disseminating information about the Iraq war.

In February 2003, a University of Idaho graduate student was arrested and charged in U.S. district court with using his computer expertise between 1994 and 2003 to foster terrorism. Specifically, *United States of America vs. Sami Omar Al-Hussayen* charged that he “provided and conspired with others to provide material support and resources . . . by, among other things, creating and maintaining internet websites and other internet media designed to recruit mujahideen and raise funds for violent jihad in Israel, Chechnya and other places” (details are on [www.findlaw.com](http://www.findlaw.com)).

After a 7-week trial and 7 days of deliberations, Al-Hussayen was found not guilty on three terrorism counts and a mistrial was declared on several other counts. The government agreed to drop the remainder of the charges after the defendant agreed to deportation to Saudi Arabia.

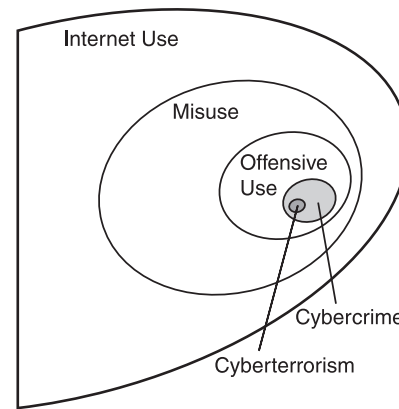

As early as 1999, Denning concluded, “It appears that virtually every terrorist group is on the Web,” such groups are actively establishing alliances and coalitions via the Web, and this support role is the most common use of the Web in terrorism. She adds, “Forcing them off the Web is impossible, because they can set up their sites in countries with free-speech laws.”

Cyberspace can become a conduit for terrorist intelligence gathering and calls-to-action, often using unprotected, hacked computers as open relays, planting spy devices, and reading the contents of computer hard drives in homes, businesses, or institutions anywhere in the world (security is covered in other chapters of this *Handbook*). Some of this activity is criminal, even if it does not result in terrorism.

## A Five-Level Operational Model

Although a formal definition of cyberterrorism may remain obscure, it is useful to address the problem with a multilevel operational model that describes behavior. Tavani and other writers on ethics in cyberspace have separated cyberspace activities into variations of subsets, such as cybervandalism, cybertrespass, and cyberpiracy. Together, these activities capture a part of cyberterrorism, at least in the extended definition, but they are only elements in the destructive acts described by Collin and others. (Cybercrime, cybervandalism, hacking, and related topics are covered in other chapters of this *Handbook*.)

Conway (2002) described a general three-tiered schema, categorizing “fringe” activity on the Internet as “use, misuse, and offensive use.” Use is normal and legal Internet usage—the same for terrorists as for anyone else—similar to Denning’s activism. Misuse includes acts that disrupt or otherwise compromise other sites, including protests and vandalism typically associated with hackers. Most of the incidents described in this chapter fall

**Figure 1:** Categories of Internet usage related to terrorism.

into this category, similar to Denning’s hacktivism. Offensive use entails actual damage, theft, fraud, extortion, or commercial espionage. Not all of these offensive uses are crimes. Some of them may be cyberterrorism.

Expanding Conway’s general schema would include two additional subsets of offensive use: cybercrime and a subset of that, cyberterrorism. Cybercrime would be criminal acts using cyberspace that can be prosecuted. Cyberterrorism would include crimes with political motivations, grave harm, severe economic damage, and so on, consistent with dictionary definitions of terrorism, definitions of cyberterrorism in common use, and Denning’s operational hierarchy (see Figure 1).

Many of what would be misuse and offensive use “incidents” are tracked by the Carnegie Mellon CERT Coordination Center. The incidents counts have increased exponentially since 1988 (CERT, 2004b) (see Figure 2).

Cyberterrorists seldom would engage in ordinary misuse or offensive use, unless such use supported their larger goals, as the potential risk of discovery would be counterproductive. Conversely, ordinary use of the Internet by terrorists to communicate and coordinate activities that support conventional terrorism is likely to be common.

## HOW CYBERTERRORISM OCCURS

This section outlines how the convergence of the physical and virtual worlds creates vulnerabilities to cyberterrorism. It presents some of the tools and techniques available to cyberterrorists. It addresses the distributed nature of the generally unregulated Internet, which increases its vulnerability and creates limitations to how regulation can be applied. It discusses the concept of asymmetric response, its role in cyberwarfare, and its relationship to cyberterrorism.

### Convergence of the Physical and Virtual Worlds

Cyberspace is a virtual world of combinations of ones and zeros with no appreciable mass, time, or space. Digits can represent the physical world but are not the physical object(s). With the attachment of stimuli and sensory interface devices, however, the flow of ones and zeros can

Number of Incidents

**Figure 2:** Number of incidents (from [www.cert.org/stats/](http://www.cert.org/stats/)). Asterisk indicates the 2003 estimate is based on 137,529 incidents reported through Q3.

control physical objects that exist in time and space. “It is now the intersection, the convergence, of these two worlds that forms the vehicle of cyberterrorism, the new weapon that we face” (Collin, 1996).

Collin (1996) discusses activities in the physical world that intersect with cyber-based systems through these vulnerable convergence points. Examples include food and pharmaceutical processing plants, electric and natural gas utilities, train crossings and traffic control systems, air traffic control systems, virtually all modern military equipment, and military, public safety, and civilian communications. Using readily available digital tools and freely available information from Internet Web sites, the cyberterrorist may exploit this “point of convergence” to achieve one or more of three goals: destruction, alteration, or acquisition and retransmission.

An electronic signal can be attacked if its rule-based behavior of ones and zeros can be determined and accessed. When remote administration of the physical device is used, illustrated by the discussion of SCADA devices at the beginning of this chapter, the Internet can be a conduit to the target device through standardized Internet rules [Internet protocols (IPs) and transmission or transfer control protocols (TCPs)] that enable worldwide communication. Each device has a unique IP address. Once terrorists access the IP address and learn the rules controlling the device itself, they have the potential to control it through cyberspace.

Hackers and terrorists may not need to know details of the physical structures in which the ones and zeros reside—usually a computer or system of computers with its associated network—or even the physical location of the device itself. If they know the processes used to maintain and control its action(s), the IP or other electronic address “where” it resides in cyberspace, and how its internal structure responds to electronic stimuli, the device is vulnerable.

The Internet was designed to be decentralized and unregulated, except through technical protocols, so there is little control over individual installations. There are no effective committees with official authority or tracking oversight based on content (although some countries such as China and France have laws regulating forbidden content). The terrorists’ servers can reside in any country, sometimes in difficult-to-discover physical locations, and they can be moved easily.

**Vulnerabilities: External, Internal, Other**

Kevin Mitnick, “the condor,” is perhaps the world’s most notorious cybercriminal and the first to appear on the FBI’s Most Wanted list. Mitnick stole tens of thousands of credit card numbers and copied millions of dollars worth of computer software beginning in the 1980s. He eventually served 5 years in prison and now is a consultant (Meriwether, 1995; Sargent, 2001).

Mitnick breaks vulnerability into four “access points”: host, network, physical security, and people. He says the most common sources of vulnerability today are unpatched and misconfigured systems, their associated networks, and insufficient systems management education (*eWeek*, 2003). Hosts and networks can be protected with firewalls, improved passwords, encryption, and other technological shields, discussed later in this chapter and elsewhere in this book.

Mitnick says that systems operators—particularly those controlling physical infrastructure with SCADA devices—need more education, training, and awareness of the issues. “Unfortunately, a lot of enterprises believe that buying a firewall or an [intrusion detection system] is all they need to do. And they’re lulled into a false sense of security.” He is concerned that companies and organizations are not making the required commitment to long-term security. “A lot of our clients want a one-time . . . test to satisfy an auditor . . . or to get buy-in to get a security budget.”

The 2004 “State of the CIO” survey found that the highest *technology* priority, after enhanced system performance, was ensuring data security and integrity. Data security did not make the top 10 of the CIO’s *management* priorities (*CIO Magazine*, 2004).

In 2004, Deloitte’s annual Global Security Survey of worldwide financial services firms reportedly found that 83% of respondents “acknowledged that their systems had been compromised in the past year, compared to only 39% in 2002.” However, although 59% of the respondents “indicated security is a key part of their solution, only 10% . . . reported that their general management perceives security as a business enabler” (CCNMatthews, 2004).

Hinde (2003) supports the idea that technical solutions and other measures to keep outsiders from unauthorized access is only one part of the problem. “Internal security breaches and backdoors are a growing problem. Insider hacking represents about 70% of all malicious attacks, and costs US business over \$1 billion annually in damages,” he says. “Firewalls will not help against this.” He recommends a 10-point plan for implementing an advanced intrusion detection system (IDT) that would address both internal and external threats.

There are conflicting estimates. The Carnegie Mellon CERT Coordination Center reports that a *CSO* magazine survey found 71% of attacks coming from outsiders, compared with 29% from insiders. Hackers were listed as the greatest security threat, followed closely by current or former employees or contractors (CERT, 2004a).

The CERT Center has tracked technical vulnerabilities since 1995. They have shown exponential growth until 2002, but there has been a gradual decline since then (CERT, 2004b) (see Figure 3).

Physical network architecture is vulnerable to traditional terrorism from the outside, too. In 2002, a story about Internet physical vulnerability reported how in San Jose, California, “any visitor can walk into the building and board the elevator unchallenged” and exit on the fifth floor location of MAE West, one of “about a dozen major U.S. peering points . . . where the wires of thousands of data networks intersect [in a] clustering effect” (Wylie, 2002). In a facility of this kind, a well-placed bomb might be coordinated with a cyberattack. Physical security at

this and many similar facilities has been upgraded, but other locations have not.

## Tools of Cyberterrorists

Hackers and cyberterrorists use similar tools and techniques: hardware, sophisticated software, and detailed knowledge of the technology, the targets, and the procedures used to maintain and control operations at target sites.

Today, hacking tools are more powerful, easier to use, and more plentiful than ever. Hacking software and documentation are easily obtained on the Internet. In discussing “the democratization of hacking,” Christensen (1999) said, “The tools of mayhem are readily available. There are about 30,000 hacker-oriented sites on the Internet, bringing hacking—and terrorism—within the reach of even the technically challenged.” He quotes a manager of technical security at a company that does business with the Pentagon: “You no longer have to have knowledge, you just have to have the time.”

Hacking into secure sites may simply mean millions of iterations of new trial-and-error algorithms that ultimately discover the target device’s secret passwords or defeat its other protective barriers. Even with a low probability of success, the documented cases of unauthorized entry are common.

In tracking attack sophistication versus intruder technical knowledge, Lipson (2002) asserts that in 1980, attack sophistication was low, but it required high intruder knowledge. By 2000, attack sophistication had become high, but the required intruder knowledge was low, and there was “widespread availability of exploit tools.” An excellent graphic is included, showing the development of this relationship over time (Lipson, 2002).

Hackers typically work alone, but can gain power by working together. Obtaining the knowledge, hardware, software, and access to targets in cyberspace can be complex. Specialists can focus on a tiny problem that unlocks success in the broader venture. Acting together, even informally in loosely knit alliances, cyberterrorists can defeat barriers that would be impossible for any single individual. Networks of cyberterrorist hackers working together, perhaps in widely separated parts of the world, may one day unlock the keys to making Collin’s doomsday scenarios reality.

## BGP Tables, DNS Poisoning, and DDoS

Vulnerabilities exist in network traffic routing and in methods to track users. Snyder (2002) points out that the entire Internet depends on huge border gateway protocol (BGP) tables that detail the more than 100,000 routes information can travel. BGP4 is the protocol used to exchange routing information among providers and to propagate external routing information through autonomous networks. BGP-speaking routers “peer” with each other to exchange information about routes and improve data flow efficiency:

In the early days, these tables were validated against routing registries that ensured bogus information could not be injected into the tables.

Vulnerabilities

**Figure 3:** Number of vulnerabilities (from www.cert.org/stats/). Asterisk indicates 2004 estimate is based on 1,740 vulnerabilities reported through Q2.

Nowadays, that doesn't happen. Keeping those routing registries updated and synchronized is just too expensive and inconvenient. The lack of a global routing registry means that it's fairly easy to create routes to nowhere. . . . If a determined attacker were to start injecting routes into the BGP tables, the ripple effects could be enormous. . . . [It] could cripple routers around the world.

Craig Labovitz, a border gateway protocol researcher, reportedly identified a 1997 event where a "serious weakness was discovered" by a network technician who changed two lines of code and "nearly brought down the global network" (Lemos, 2002).

The University of Oregon Route Views Project studies variations in core route table sizes and growth rates through regular BGP sessions with many routers spread throughout the world. They found that the number of routes in the Internet increased from approximately 15,000 in 1994 to approximately 115,000 by mid-2002, magnifying their vulnerability (Meyer, 2002).

Chakrabarti and Manimaran (2002), in their comprehensive taxonomy of Internet infrastructure security, say, "So far, the research in Internet security primarily focused on securing the information rather than securing the infrastructure itself." They note that attacks on BGP tables could create a "large amount of service disruption" and

"are very difficult to detect because the attacker is hidden," adding, "Such service disruption has already been noticed with . . . routing flaps due to Nimbda/Code Red" (their taxonomy discusses domain name system (DNS) hacking, routing table poisoning, packet mistreatment, and denial of service (DoS), using "masquerading," "cache poisoning," and other techniques).

Reviewing the DHS's National Strategy to Secure Cyberspace, Fisher (2003b) says, "While there is considerable space given to the need for reducing the number of vulnerabilities in . . . BGP (border gateway protocol), the Domain Name System and IP, the strategy makes little mention of how to go about fixing these problems, a key shortcoming."

Attacks on the are common. In March 2003, after Al-Jazeera's Web site showed pictures of dead or captured soldiers in Iraq, hackers posted the U.S. flag and the message "Let Freedom Ring" on Al-Jazeera's site. The suspected technique is called "DNS poisoning," which fools traffic-directing computers across the Internet (Associated Press, 2003a). A creative cyberterrorist might combine an attack on the DNS servers with BGP routing. If it is possible to use BGP tables to redirect messages by acquisition and retransmission to random or unknown locations, it might be possible to redirect them to a specific destination—its own control station—where the terrorist might alter the message contents and redirect it, thus taking control of critical physical devices without discovering

the secret passwords and other barriers to these devices. A technique of this kind is unlikely but perhaps not impossible.

Internet DNS servers track users, referencing millions of user names. It is common to “ping” these and other address nodes by sending packets with a short query message that maintains communication with them and detects abnormalities. Normally, this traffic is minimal.

DoS attacks use packet flooding to overwhelm servers. In distributed denial of service attacks (DDoS), once a vulnerable computer is compromised, the worm infects that target, randomly or systematically selects new targets, and resends the exploit and propagation code to that host, which in turn launches coordinated attacks from their distributed locations.

On October 21, 2002, an estimated 6,000 computers worldwide swamped the Internet’s 13 root servers in Japan, Europe, and the United States that control most of the Net’s traffic. Eight were disabled to some degree. This massive “ping flooding” was part of a DDoS attack, “the biggest ever hacking attack on the Internet” (Naraine, 2002; Vickers, 2002).

These relatively new and effective tools in the cyberterrorist’s toolkit are difficult to track. In the old days, it was possible to trace a message or command back to a guilty IP address. Today, with distributed attacks, the offending packets may originate in an otherwise innocent computer. (Details of DoS and DDoS attacks are in other chapters in this *Handbook*.)

The attacks may have resulted in no direct or lasting damage, but they are unsettling. One expert maintains that although there were few direct effects on Internet users, “as nations and critical infrastructure become more dependent on computer networks for their operation, new vulnerabilities are created—a massive electronic Achilles’ heel” (Lewis, 2002).

On January 25, 2003, much of the Internet was shut down with a similar attack that used the “Slammer” worm (discussed later in this chapter and in other chapters of this *Handbook*). A security firm official predicted, “Slammer variants could emerge which are capable of being used in a blended threat scenario alongside physical attacks by radicals. This could achieve a significant multiplier effect” to prolong or worsen conventional terrorist attacks (Greenspan, 2003b).

## RMA and Asymmetric Response

Asymmetric response (one sided; does not follow “rules”) is a way for the weak to attack the strong. A rag-tag, poorly trained militia that is no match for a powerful state’s army may use guerilla tactics, sneak attacks, bombings, or sniper attacks to harass and demoralize the superior force. As the balance tilts more and more toward the camp of the powerful adversary, asymmetric response becomes more likely. It can be highly effective, as witnessed by Russia’s withdrawal from Afghanistan and the United States’ departure from Somalia.

The industrialized nations have highly developed electronic infrastructure that drives knowledge-based economies and gives them advantages in business, government, and military power. Loren Thompson, a defense

analyst with the Lexington Institute in Arlington, Virginia, says, “Warfare is less and less about pushing men and machines around the battlefield and more and more about pushing electrons and photons” (CNN, 2003a). Attacking those assets through cyberspace, as a guerilla army might use suicide bombers and beheadings, to the degree that it creates chaos and panic, can be cyberterrorism.

The National Intelligence Council (NIC) has predicted asymmetric responses to an expected overwhelming military superiority brought about by a paradigm shift in the nature of warfare. This “revolution in military affairs” (RMA) will employ “a small, information-intensive, professional armed force [as] the model for a 21st century military,” largely based on strength in information technology and smart weaponry (NIC, 1999). In October 2003, ministers from 19 NATO nations met to discuss “transformation of their armies” and held an exercise named Dynamic Response ’07, designed to help formulate such a force of 5,000 international troops by October 2006 (CNN, 2003b).

When the U.S. military captured Saddam Hussein, they used digital technology, the Force 21 Base and Command Brigade and Below (FBCB2) system, for commanders to monitor and direct equipment and other war assets in real time. The Army Battle Command System (ABCS) helped run the war room to monitor the big picture. Voice radio, Internet controllers, and the global positioning system (GPS) added efficiency (Van Marsh, 2004). This expensive technology saves lives and gives the military a significant tactical advantage in physical warfare. Cyberterrorism—as an asymmetric response—may be the only way for an opposing force to counteract this overwhelming advantage.

Overill (2003), discussing the nature of asymmetric information warfare, observes that “the cost of defending an asset from attack is many orders of magnitude greater than the cost of attacking it.” Regan (1999) points out, “Cyberterrorism allows terrorists...to inflict damage with no harm to themselves and little chance of being caught. It is a way for the ‘weak’ to attack the ‘strong.’”

The Associated Press reported that then-White House Technology Advisor Richard Clarke warned a Senate Judiciary subcommittee on cyberterrorism, “A serious cyber-attack is almost inevitable because it is cheaper and easier for a foreign country or a terrorist group than a physical attack” (Holland, 2002).

## Cyberspace Warfare

Governments are becoming more interested in electronic warfare. In 2002, in testimony before a Senate Judiciary subcommittee on cyberterrorism, Richard Clarke named Iran, Iraq, North Korea, China, Russia, and other countries as “already having people trained in Internet warfare” (Holland, 2002). Previously, the NIC (1999) had said, “Iraq and Iran are examples of states that will likely explore the usefulness of information technology in pursuit of asymmetric conflict... including through the employment of information warfare and cyberterrorism.”

The United States is not backing away from defensive—or offensive—use of cyberspace warfare tools. Fisher (2003a) cites the National Strategy to Secure Cyberspace:

“When a nation, terrorist group or other adversary attacks the United States through cyberspace, the U.S. response need not be limited to criminal prosecution. The United States reserves the right to respond in an appropriate manner, including through cyber warfare. The United States will be prepared for such contingencies.”

The *Washington Post* reported that President Bush signed a National Security Presidential Directive 16 in July 2002, under which “The United States would launch cyber-attacks against enemy computer networks.” The article said, “The Pentagon has stepped up development of cyber-weapons, envisioning a day when electrons might substitute for bombs and allow for more rapid and less bloody attacks on enemy targets” (Rasmussen, 2003). Mark (2003) reports that “the Pentagon is actively developing cyber-weapons to disable enemy radar, electrical grids and telephone systems.”

In the 2003 buildup to the Iraq war, a CNN article had predicted a “fierce cyber war,” saying, “Imagine Iraqi commanders getting misleading text messages on their cell phones. They appear to contain orders from Saddam Hussein but are actually sent by the U.S. military in disguise, directing Iraqi troops to a trap.” CNN likened this to the Civil War, when signal flag messages were diverted, and in World War II, when German forces were deceived by “leaking” battle plans involving nonexistent troops. The article concluded that “the Internet makes deceptions easier” (CNN, 2003a).

## SPONSORS AND SUPPORT

Terrorism traditionally has been sponsored by nations who provide financial resources and a safe haven. Cyberterrorism requires less funding. It uses fewer physical assets, so it is more mobile and can cross physical borders or operate simultaneously in many locations. Thus, nations that sympathize with cyberterrorists can support them without becoming a sponsor in the traditional sense. This section addresses different forms of terrorist groups and explores what it means to sponsor them in cyberspace. Cyberterrorism is an international issue, and perspectives from other parts of the world are explored.

### Cyberterrorism Sponsors

Hackers and cyberterrorists can operate out of almost any physical location on Earth. Many undeveloped or emerging nations have daunting problems such as hunger, disease, political unrest, or traditional war, often to the extent that they are unable to address security issues or exert effective control over cyberspace. Although the number of computers may be relatively few in these countries, many offer adequate electronic infrastructure and sometimes—knowingly or not—harbor terrorists.

In simpler times, conventional terrorists required a sponsoring organization, often state sponsorship, to obtain sufficient funding and connections. Traditional organizations and state sponsors had a fixed infrastructure. They were comparatively easy to monitor to determine who was pulling strings and causing consequences. Today, terrorists can pursue extreme agendas with more powerful tools than ever before, leaving no easy-to-follow trail.

Low-cost cyberspace tools reduce the need for large-scale money transfers, and because physical currency need not be exchanged, following a money trail is more complex.

CNN quotes M. J. Gohel of the Asia-Pacific Institute in London, who describes many of these terrorist organizations as “autonomous with their own leadership, with their own funding, their own personnel. And they have their own plots, as it were. But they’re all bonded together by a common ideology” (Arena, 2003). This fragmentation makes them and their funding difficult to track.

Caruso separated the international terrorist threat into three categories: (a) traditional, clearly defined terrorist organizations; (b) the radical international jihad movement; and (c) state sponsors of international terrorism, specifically identifying Iran, Iraq, Sudan, and Libya (Iraq subsequently has changed governments, and Libya has taken steps to limit terrorism; this list will likely undergo continual change). Many of the terrorist groups are not identified with a sponsoring country (Caruso, 2002).

Cyberterrorists acting alone or in small groups can pursue extreme agendas either through volunteer labor or by relatively small amounts of money disbursed from wealthy individuals, foundations, fund raising organizations, or almost any rogue country’s intelligence unit. Regan (1999) quotes Dr. Harvey Kushner, chairman of the criminal justice department at Long Island University:

We have moved away from state-sponsored terrorism. The old model of the hierarchical or “organized crime” group, no longer exists. These days, terrorists move in loose groups, constellations with free-flowing structures. So these days terrorism—both the traditional kind and cyberterrorism—is more the act of the freelancer or the individual. This is true both internationally and nationally.

The Associated Press, reporting on a London-based study, quotes author Kevin Rosser, “What we’re beginning to see is a much more disparate movement of people who are sometimes coordinating and sometimes not, but who are inspired by the example of Al Qaeda, . . . so we see the threat becoming much more elusive and . . . much harder to track” (Associated Press, 2003b). However, if these groups coalesce into relationships with each other through Al Qaeda or other known organizations, better visibility could result, and tracking, with worldwide participation, could become more effective.

### The Worldwide Perspective

Although there are differences between the way individual nations and the world community view cyberterrorism, there is general agreement that it is a global problem. Nations have become more aware of their vulnerability and are beginning to work together to counter the threat.

In 2003, European Union (EU) ministers agreed to “require all 15 EU member states to adopt a new criminal offence: illegal access to, and illegal interference with an information system,” recommending “jail terms of at least two years in serious cases” (*The Information Management Journal*, 2003).

A Manila conference of Southeast Asian telecommunications ministers reported “facing a computer security threat following the 11 September terror attacks in the United States.” They implemented “stricter measures to counter cyberterrorism” and “urged the United Nations to come up with a universally accepted definition” (BBC Worldwide Monitoring, 2002).

The United Nations (UN) understands the cyberterrorism connection. “The same Internet that has facilitated the spread of human rights and good governance norms has also been a conduit for propagating intolerance and has diffused information necessary for building weapons of terror” (Annan, 1999). Following the September 11, 2001, attack on the World Trade Center, the 56th regular session of the UN General Assembly declared that cyberspace threats are a weapon against UN goals and unanimously passed a resolution condemning terrorism and cyberterrorism.

On November 23, 2001, the first-ever international treaty on criminal offenses committed against or with the help of computer networks was signed in Budapest, Hungary, by 26 member states of the Convention on Cyber-crime, a part of the Council of Europe. Four non-members who helped draft the document, Canada, Japan, South Africa, and the United States, also signed to pursue “a common criminal policy aimed at the protection of society against cyber-crime” (Convention on Cyber-crime, 2001a). Christian Kruger, deputy secretary general of the council, announced that “the Convention would give national legal systems ways of reacting together to crimes committed against or through computer networks, especially those related to terrorism” (Convention on Cyber-crime, 2001b).

Although struggling to cooperate, some nations of the world are reluctant to give up sovereignty. Beyond prosecuting international war criminals charged with physical atrocities, international justice efforts have made only minimal progress. International law and bilateral treaties rarely adjudicate conflicts between companies, individual entities, or public/private disputes. Entities such as the World Trade Organization set rules for engaging in trade and commerce, but their judicial branch only settles differences in trade matters between nations. Formal international agreements usually deal with physical presence and events, not cyberspace activities.

Many developed nations have their own international security agencies, many of which operate anywhere in the world—and often in the virtual world. Nations with such agencies generally work with each other through informal agreements. Since the mid-1990s, cooperation has been on the upswing, and the 9/11 attacks and other international terrorism incidents have added urgency. Although it is rarely discussed publicly, this is a very active area of international relations.

## CONTROLLING CYBERTERRORISM

This section begins with general strategies for fighting back against unauthorized attacks, including cyberterrorism. Subsections follow that focus on specific actions that government, businesses, organizations, higher education institutions, and individuals can do. Privacy concerns,

especially where government regulations may limit freedom of speech or use confidential information, are addressed.

## General Strategies

Many general steps can be taken by individuals, businesses, organizations, and government to reduce the risk of unauthorized intrusion into computer systems and electronically controlled infrastructure. Many of these are technical. Scholarly journals have raised issues of how we view the problem strategically.

Overill discusses the “protect, detect, and react” paradigm and outlines strategic issues associated with various types of reactive strategy. He separates defenses into technical possibilities, legal aspects, and ethical considerations. Technical responses range from benign (notifying the system operator) to aggressive (launch a retaliatory malicious software strike). Many of these are becoming part of built-in computer system “active defense” capabilities in organizational settings (Overill, 2003).

Marcella, Roth, and Espersen (2003) advocate moving “from a reactive posture to a proactive approach to crisis management,” adding, “Assessing an organization’s weaknesses may require the assessor . . . to think like a cyber criminal or terrorist might think.” If management has not established a formal crisis management team, they say, “internal auditors . . . can come together as a proactive team to assist in mitigating exposures.”

Although these strategies apply primarily in organizational settings, individuals and other noninstitutional users can take steps to help prevent unauthorized entry into their computer systems that could be used in DDoS attacks or other cyberattack activities. The National Cyber Security Alliance (NCSA) is a public/private partnership sponsored by computer hardware and software companies, ISPs, and others “focused on promoting cyber security and safe behavior online.” The NCSA issues guidelines directed toward individuals, home users, and small businesses. It sponsors an October National Cyber Security Awareness Month (see <http://www.staysafeonline.info>). Their 10-point guidelines include operating systems upgrades and patches, antivirus software, password protocols, and other safeguards that most Internet users can apply. Some of these are simple enough to be applied by nontechnical users, whereas others require the guidance of information technology (IT) or other professionals.

## Information Technology Professionals

Large business and government organizations usually have IT professionals that make critical decisions about safeguarding their computer systems from cyberattacks and how much information flexibility is built into their systems. Too much filtering screens out important information, whereas too little may risk penetration by intruders. Those that maintain systems connected to SCADA systems controlling vital infrastructure have a higher stake in cybersecurity.

In a journal article overview of how IT professionals can help safeguard their organizations, Hinde (2003) points out that “it may be difficult to differentiate between legitimate operations, intrusive marketing, hacker

mischievous, competitor attack, criminal activity and cyberterrorism,” concluding that “for a truly secure computer, ban users and connectivity.” He gives nine technical steps IT professionals can take to “become proactive in defending our computer systems,” including IDSs and lock downs.

IT professionals install patches for viruses and worms such as “SQL Slammer” and the “W.32.Bugbear.” On January 25, 2003, many of the more than 200,000 computers running Microsoft SQL Server 2000 were vulnerable to the Slammer attack that severely disrupted Internet traffic because required “patches” had not been installed (Fisher, 2003b). Dow Jones reported that Slammer was responsible for “generating a billion attacks an hour at its peak” and “is so virulent that a vulnerable machine—one that hasn’t been patched for a particular flaw—is compromised within three minutes of coming online.”

In December 2002, Fisher reported, “Security researchers have discovered a set of vulnerabilities in . . . the SSHv2 protocol that could give an attacker the ability to execute code on remote machines. The new flaws are especially dangerous in that they occur before authentication takes place. Attackers could, in some cases, run code on remote machines or launch denial-of-service attacks” (Fisher, 2002). IT professionals implement protective actions against such security flaws.

IT professionals also can help provide feedback to software vendors. In 2002, an average of 50 new software vulnerabilities were reported per week, and a SANS (SysAdmin, Audit, Network, Security) Institute official was quoted as saying, “What this illustrates is that a program that expects end users to patch their systems is futile,” adding, “The only solutions are to make software developers, such as Microsoft, responsible for supplying safe, automatic updates or for companies to do much more aggressive filtering of traffic into their networks” (Richmond, 2003).

The Microsoft patches reportedly “were so difficult to install or so poorly publicized that some of Microsoft’s own database administrators failed to install them.” Database administrators “were required to manually stop each instance of the software running in their organizations, rename or remove some files, and paste the patch files into various directories in each instance.” Microsoft released a self-installing patch in November 2002, shortly after the October 21, 2002, attack that swamped the Internet’s 13 root servers in Japan, Europe, and the United States, “but it was given only to customers who contacted Product Support Services” (Vaas, 2003). In 2004, Microsoft released Service Pack 2 for XP that has been widely used and closes many of the potential illicit access points.

Professional IT organizations such as the ITAA helped formulate the National Strategy to Secure Cyberspace and participated in the National Cyber Security Summit. ITAA publishes newsletters and maintains an Information Sharing and Analysis Center (ISAC) to disseminate security information among its members and help organizations that do not have adequate resources to maintain their own security. It helped establish the I-ACERT security certification program (Miller, 2003).

The National Cyber Security Division of the DHS works with IT professionals in businesses, universities, and other

organizations to promote the new IPv6 Internet protocol, which comes with an improved security framework promising fewer networking vulnerabilities (Fisher & Carlson, 2003). Anticipating its adoption, the updated IPv6 protocol is being implemented by many operating systems, some of which have already begun shipping.

Michael Rasmussen (2003), vice president for Standards and Public Policy for the Information Systems Security Association, says “If we can build the ideal and perfect IT security architecture—we will still have information security and privacy incidents. That is because we have people involved who are human, make mistakes, and succumb to greed and other motives.” Regardless of how good technical security becomes, there will always be the chance of human error or inside complicity allowing access to secure IT resources.

## Business and Industry

Some companies control vital physical infrastructure and have much to lose through cyberattacks, but there is wide variation in how they have taken protective action—and their attitudes toward the problem. Prior to 9/11, many companies were not taking effective steps to protect themselves from cyberattacks, and many were not sharing what they learned. Often, from a purely business point of view, it makes more sense for a company to deal with the issue internally than to report it to police or other investigative agencies. “Corporate leaders, in many instances, simply never tell the outside world they’ve been victimized, to avoid spooking investors or customers” (O’Connor, 2000).

An April 2002 CNN.com report on the seventh annual Computer Crime and Security Survey noted, “About 90 percent of the respondents detected a security breach within the last 12 months. However, only 34 percent reported the intrusions to law enforcement officials.” It added, “There is much more illegal and unauthorized activity going on in cyberspace than corporations admit to their clients, stockholders and business partners or report to law enforcement.” It quoted an FBI assistant director, “Now, more than ever, the government and private sector need to work together to share information and be more cognizant of information security so that our nation’s critical infrastructures are protected from cyber-terrorists” (Sieberg, 2002).

Some companies have been lax in applying even modest protective measures. In February 2002, Richard Clarke, then the White House advisor on Cyberspace Security, gave the U.S. Senate a figure that has been widely quoted as short of meeting the need for security. “In the private sector,” said Clarke, “the amount of money spent on IT security is roughly .0025% of total revenue. That is less than the amount of money spent on coffee in the same companies” (Wynne, 2002). New figures show that is changing.

In October 2002, the Associated Press reported on the W.32.Bugbear virus, calling it “the worst computer security outbreak in the world” (Associated Press, 2002a). Once a computer is infected, the hacker can steal and delete information. The worm lasted well into 2003 because many users did not realize that their computer was infected. Incidents such as these, although destructive in

the short term, have a beneficial effect in prodding laggard businesses. "The expectation is that shareholders will eventually hold boards accountable for security breaches, and, in turn, boards will hold security officials responsible" (Carlson, 2002b).

A leading journal reported that a 2004 *CSO* magazine survey found that "online criminals... cost business an estimated \$666 million in 2003." In a reversal of earlier surveys, 40% named outside hackers as the biggest cybersecurity threat, compared with 28% citing internal threats, such as disgruntled employees. The magazine concluded, "Auditing firms should include cybersecurity readiness as part of the criterion for determining whether companies have adequate internal and financial safety controls" (*The Information Management Journal*, 2004).

Many CIOs dispute Collin's or Clarke's extreme threat scenarios against physical infrastructure attacks. For example, Berinato examines safeguards in place at the Massachusetts Water Resource Authority (MWRA) and concludes that a cyberterrorist would need to penetrate firewalls and SCADA control barriers through two "very narrow access points," have insider knowledge of how the system operates, and then successfully "plant surreptitious code that would allow remote control of the chemical distribution or even the flow of water itself" and assume that the changes would go undetected long enough to have severe negative effects. An MWRA director calls them "ridiculous barriers." The article concludes, "The real threat is to critical data, not to property" (Berinato, 2002).

In recent years, companies have increased IT spending, much of it for improved security against viruses and worms (discussed elsewhere in this *Handbook*), aimed at loss of valuable data of computing systems. The 2004 "State of the CIO" survey shows that IT headcount increased in 37% of firms and decreased in only 17%. IT's budget as a percentage of organizational revenue ranged from 13.8% for financial firms down to 2.6% for manufacturers, with an average of 5.6% for all firms. The highest technology priority, after enhanced system performance, was ensuring data security and integrity (*CIO Magazine*, 2004).

Haimes (2002) and others emphasize a "holistic" approach to cyberthreats, using systems analysis that includes understanding the system's nature and improving the decision-making process. *The Information Management Journal* (2002a) reports that experts recommend educating personnel, establishing a crisis management team, and enforcing a "total risk management program."

Part of the holistic approach is to become more conscious of all types of threats. The journal points out, "A corporate Web site is a virtual gold mine for competitive intelligence gatherers." Especially when companies control SCADA devices or other physical infrastructure, cyberterrorists can use that information to help plot attacks. Preventive measures include using search engines to periodically check on who is linking to your company's site, not revealing too much information on job postings, and keeping "to a minimum the strategic information filed with government agencies" (*The Information Management Journal*, 2002c).

Companies face a balancing act in information sharing. They want to avoid the bad publicity associated with having had their systems and facilities compromised by a cyberterrorist; they want to protect proprietary information from scrutiny by agencies that would turn it into public record through the Freedom of Information Act; they are concerned that if they work too closely with competitors, they may be accused of antitrust violations; and many fear that they will be required to spend more time on assessment and managing security than on productive work.

Although America's largest buyer—the federal government—has no power to directly force business and industry into cooperation, it is using its purchasing power to force better security standards, establish configuration benchmarks, and encourage information sharing and cooperation through the National Cyber Security Summit and other initiatives (Fisher & Carlson, 2003). The National Strategy to Secure Cyberspace business sector strategy calls for a heightened awareness and responsibility within companies and promotes company-wide corporate security councils to integrate all aspects of security, including cybersecurity—a mostly voluntary emphasis. Some say it should be mandatory.

In the United States and many other economically advanced countries, 70% of the GNP is services. Although most large, information-intensive organizations have their own IT resources, many smaller entities cannot justify maintaining technical staffs, so it makes sense to outsource. In the past several years, an entire service industry has grown up around the idea of helping companies with cybersecurity.

Creating an internal security unit may be costly, require the recruitment of specialized personnel, entail substantial start-up time, and risk isolation from new developments. Service providers have highly trained people able to leverage their information and knowledge over several businesses.

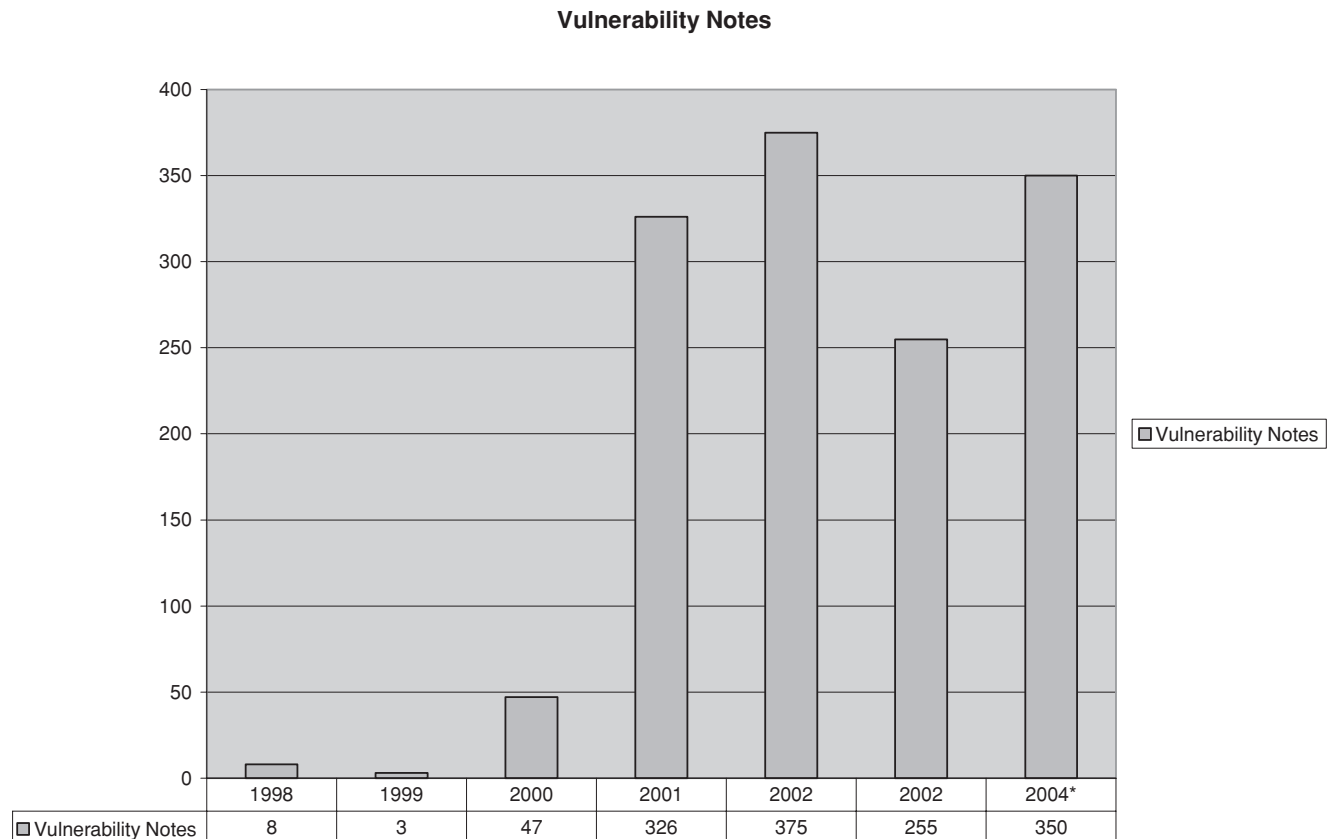

Companies are investing in software, firewalls, virtual private networks (only minimally connected to the Internet), and other security components with a high services content. Global investment in e-security services were expected to total \$14.5 billion in 2005, with North America accounting for 58% of the global total (McMahon, 2002). Some of these service companies have evolved as for-profit branch organizations of private interest groups that disburse information or other resources for counteracting cyberterrorism.

## Government

The 9/11 attack was a "wakeup call" that helped galvanize support around the world for stronger government measures against terrorism, including cyberterrorism. In the United States, these include protection of government cyberspace activities, proactive coordination, and aggressive laws allowing an expansion of wiretapping and other surveillance.

## Introspection and Protection

Compared to private business, government security has lagged. An ITAA survey in September 2002 found that 77% of respondents felt the private sector was more advanced

**Figure 4:** Vulnerability notes (from [www.certs.org/stats/](http://www.certs.org/stats/)). Asterisk indicates the 2004 estimate is based on 175 notes reported through Q2.

in hardening information systems than the public sector (Miller, 2003). This may be explained, in part, because “Government . . . staffs are paid less and don’t have access to the latest software and hardware defenses” (Weiss, 2001).

In December 2002, President Bush signed the Federal Information Security Management Act (FISMA), which mandates that government agencies develop annual reports and risk assessments, configuration guidelines, continuity plans, security policies, and inventories of systems. Graded A–F on the security state of their cybersystems, including software security, employee training, and other factors, most agencies failed.

Agencies counter that the grades are “unfair” because “the self-evaluation the agencies must perform can cost hundreds of thousands of dollars, depending on the size of the network,” and they simply have had “difficulty finding money in their budgets to comply” (Fisher & Carlson, 2003).

The situation is improving. In 2003, although the government received an overall D grade, it was up from an overall F in 2002. In 2003, 14 of the 24 agencies that were evaluated improved their year-over-year scores, although the DHS still received a failing grade. The Nuclear Regulatory Commission improved to an A from a C, and the National Science Foundation improved to an A- from a D- (Greenspan, 2003a).

Successful attacks on U.S. government systems are declining, having peaked in 2001 (Greenspan, 2003a). The

Cert Center publishes vulnerability notes that capture similar incidents. These increased dramatically in 2001, but have been relatively steady since then (CERT, 2004b) (see Figure 4).

### Coordination

In September 2002, a draft of the President’s National Strategy to Secure Cyberspace addressed ISPs, wireless networks, and other information security points of convergence for business and home Internet users. A final plan was released in February 2003. The report included 60 recommendations for government, companies, institutions, and individuals in the United States and other nations, including five priorities: (a) a national cyberspace security response system, (b) threat and vulnerability reduction, (c) security awareness and training, (d) securing government cyberspace, and (e) international cooperation (Fisher, 2003a).

Recommendations for government included improving federal cybersecurity, early warning and crisis management plans, and partnering to help develop new security technologies in science and industry. It “strives to ensure that any interruptions will be infrequent, brief, manageable, geographically isolated, and minimally detrimental to the welfare of the United States” (Porteus, 2002).

Many of these initiatives were merged into the DHS, established in November 2002. The DHS absorbed 22 federal agencies, including five cybersecurity offices and

programs, and expanded the government's powers to obtain information from telephone and Internet service providers. About \$3 billion was reserved for technology in the DHS 2003 and 2004 budgets, each approximately \$30 billion. "One important DHS priority will be to examine the vulnerabilities found in security systems. The emphasis will be on catastrophic terrorism—threats to the security of our homeland that could result in large-scale loss of life as well as triggering major economic repercussions" (DHS, 2003).

In December 2003, the DHS and leading industry associations, including the U.S. Chamber of Commerce, the Business Software Alliance, the ITAA, and TechNet, hosted the National Cyber Security Summit. This "first forum of its kind since the release of the President's Strategy" brought together leaders from the public and private sectors to "support the National Cyber Security Division's efforts to improve the security of cyberspace, to strengthen the country's ability to prevent and respond to cyber attacks, and to cultivate and sustain a public-private partnership for cyber-security" (CERT, 2003a).

The government continues to pursue public/private cyberspace security initiatives, including ISACs such as CERT for "sharing information on cyber-attacks, vulnerabilities, countermeasures, and best practices" (ISAC, 2003). The ISACs deal with telecommunications, financial, chemical, energy, information technology, water, transportation, aviation, and food (Porteus, 2003). Other government activities include collaborating with organizations developing the more powerful and secure IPv6 Internet protocol, sponsoring simulations such as Digital Pearl Harbor, promoting ties with legitimate businesses investigating potential security risks, and improving surveillance.

### Surveillance and Investigation

On October 26, 2001, the Patriot Act (Providing Appropriate Tools Required to Intercept and Obstruct Terrorism) was signed into law by President Bush. Tracking cyberterrorists and terrorists in cyberspace is a key objective of the act, which gives authorities broad powers to investigate terrorism. That same month, the President's Critical Infrastructure Protection Board was created. The Patriot Act is being reviewed by Congress in 2005, and it is likely it will be continually modified in future years.

In a broad sense, cyberspace surveillance systems are weapons that rely on prevention rather than actively destabilizing terrorist networks. The FBI was already experimenting with a controversial electronic surveillance system called Carnivore, which looked for suspicious activity in cyberspace, and had other tools under development. Through the Patriot Act, the DHS has been assigned additional powers of obtaining investigatory information from ISPs and other cyberspace service providers.

Opponents of these systems maintain that they are intrusive and do not warrant the increased invasion of privacy. The uses of commercial databases in data collection, along with many of the new surveillance tools, DHS reporting requirements for ISPs and other cyberspace service providers, and increased aggressive investigatory techniques, are being challenged by the American Civil Liberties Union (ACLU) and privacy organizations

(discussed later in this chapter and in other chapters in this *Handbook*).

The government maintains that the Patriot Act of 2001 and other surveillance and investigative powers have materially improved security and prevented attacks in both government and private entities. In December 2002, FBI Director Robert Mueller reported that in the period of just over a year since the World Trade Center attack, "tens of attacks, probably close to a hundred around the world" have been detected and stopped through improved surveillance (Associated Press, 2002b).

At the end of 2003, increased cyberspace "chatter" by suspected international terrorists triggered additional security at airports and other vulnerable points. Such "data mining" from programs similar to the FBI's Carnivore project is designed to identify potential threats using cyberspace patterns—which we might call *cybermetrics* or digital forensics.

The government has been aggressive in investigating other potential security threats. In late August 2002, the Associated Press reported an FBI raid on the offices of a San Diego consulting firm, which claimed that, motivated to expose a need for better security, it had "identified 34 military sites where it said network security was easily compromised" (CNN.com, 2002d).

On December 5, 2002, federal agents raided a Quincy, Massachusetts, company "that provides critical software to major U.S. agencies and is suspected of having ties to Osama bin Laden and Al Qaeda terrorists. . . . Officials suspected 'back doors' may have been built into the software to enable terrorist access to federal computers." Customers included the Department of Energy, the FBI, the U.S. Air Force, the Naval Air Systems Command, the Federal Aviation Administration, the House of Representatives, and NATO (Fox News, 2002).

In 2004, inbound international airline traffic was repeatedly interrupted for additional passenger screenings, based on intelligence information. In January 2004, the United States began photographing and fingerprinting noncitizens entering the country, implementing the U.S. Visitor and Immigrant Status Indicator Technology (US-VISIT), which uses "biometrics"—technology that identifies people using digitized biological traits. That program was extended to other nations in September 2004. The proposed new Computer Assisted Passenger Pre-Screening (CAPPS-2) and Automated Commercial Environment (ACE) were designed to use digital technology to collect and analyze data. Although these programs are not specifically targeted at cyberterrorists, data from them could be cross referenced with information about individuals engaged in cyberterrorist activities.

### Legal and Privacy Concerns

Privacy advocates and cyberterrorism fighters often are on a collision course. One side is for maximizing personal liberties, whereas the other wants to minimize terrorism. It is probably impossible to satisfy both sides. Other nations face similar issues.

Rowland, discussing a balance between anonymity and "strategic lawsuits against public participation" (SLAPPs), points out that U.S. and international laws in this area have only recently begun to consider the issue in cyberspace (cyberSLAPPs). She asks, "To what

extent will the law protect those who use anonymity . . . to enable them to engage in public debate without the fear of reprisal and recrimination?" When it is relatively easy to hide an identity in cyberspace and asymmetric response is potentially devastating, "the fear of cyberterrorism . . . provides another rationale for intervention and regulation" (Rowland, 2003). That debate will continue.

For years, the FBI and CIA were constrained in what they could do with respect to human intelligence—actual agents on the street. In response, they developed Carnivore, Magic Lantern, and other electronic surveillance technologies to monitor worldwide telephone conversations, e-mail, and other correspondence, all of which are intrusive.

A May 2004 magazine reported that the General Accounting Office (GAO) "enumerates nearly 200 data mining initiatives in operation or in the works," and many of these "rely on data purchased from the commercial sector" (Carlson, 2004). The Pentagon's Total Information Awareness project—renamed Terrorism Information Awareness (TIA)—was blocked in Congress following privacy objections (TIA details are on the DARPA Web site, [www.darpa.mil](http://www.darpa.mil)). There are critics on both sides.

The ACLU and small but vocal private interest groups argue that electronic eavesdropping and the Patriot Act and other new antiterrorism laws violate fundamental rights guaranteed by the Constitution and the Bill of Rights, especially when they purchase data from commercial firms. They contend that the resulting loss of freedom is not worth the security benefits, the ends do not justify their means, and the government has too much power over individuals.

The other side argues that the National Strategy to Secure Cyberspace is not forceful enough, and we need more laws and regulations allowing increased oversight. Mark Rosh, formerly the Justice Department's top computer crimes prosecutor said, "You need to put some teeth into some of the proposals" (CNN.com, 2002a). Many who advocate more aggressive government monitoring recommend that private-sourced data be integrated into government surveillance programs.

Former Justice Department attorney Orrin Kerr maintains, "The law is a lot more balanced than people thought. The government ended up introducing a law that didn't really take any major steps." Under the Patriot Act, noncitizens are investigated by intelligence agencies with broad powers, but citizens are handled by the FBI, which is much more restricted. They can monitor online communications, but as with wiretapping or other surveillance, agents must get judicial permission to obtain message content (Borland & Bowman, 2002).

The new strategy, new laws, and new technology increase government and companies' ability (and perhaps willingness) to collect personal data. In an interview with the *Boston Globe*, Richard Hunter discussed companies' data collection policies and excerpts from his book, *World Without Secrets*: "Information is constantly recorded and made available to almost anyone who wants it, regardless of intent. . . . The amount of information that's out there, and readable, is already huge" (Denison, 2002). Companies already have most of the data, and the government can get it.

Data that the government controls is subject to the Privacy Act of 1974 and other restrictions, and information brokers have generally resisted selling to federal law enforcement agencies. Although the numbers are still low, as of 2002, it was reported, "The FBI's use of commercial databases has grown 9,600 percent over the last decade" (Carlson, 2002a).

## Institutions, Organizations, and Conferences

Not-for-profit and private institutions typically do not have the same security needs as commercial companies. It would be rare for them to have control over nuclear power plants, electrical grids, dams, or other vital infrastructure. However, in many cases they hold considerable financial and information resources that may be vulnerable to cybercrime and terrorism, especially with extended definitions.

Although institutions seldom have enough in-house expertise to combat potential cyberterrorism, many of the security techniques companies are using apply equally to institutions. They are good candidates for private security firms, but resource constraints make it difficult to afford the needed services. This is an area that will benefit from closer attention.

Not-for-profit and private institutions are included in government initiatives such as the National Strategy to Secure Cyberspace. Many private and semiprivate groups that combat cybercrime and cyberterrorism now are connected in some way to the DHS. In addition, many operate programs to disseminate information about potential cyberterrorist threats. For example, the Carnegie Mellon Software Engineering Institute's CERT Coordination Center, which tracks cyberspace "incidents" and "vulnerabilities," publishes a stream of security notes designed to help businesses, organizations, educational institutions, government, and technical individuals. Organizations without full-time IT staffing can access these reports on the Internet and use them as indicators for when to consider contracting for needed services. Security notes rose dramatically beginning in 2001 (CERT, 2004b).

The SANS Institute together with the FBI publishes a top 20 list of security threats. The list is "especially intended for those organizations that lack the resources to train, or those without technically advanced security administrators" (Wagner, 2002).

The Critical Infrastructure Protection Project (CIP), part of the George Mason University School of Law, is associated with the DHS and over 30 local, state, and national associations, including the Association of Metropolitan Water Agencies (AMWA), the North American Electric Reliability Council (NERC), and the ITAA. It publishes reports to Congress and a monthly newsletter, *The CIP Report*, for constituents "who have an interest in critical infrastructure protection."

The NIC publishes papers on global trends under the aegis of the National Foreign Intelligence Board and the Director of Central Intelligence, sometimes together with other government or private centers. It sponsors conferences such as the Future Threat Technologies Symposium and The Global Course of the Information Revolution: Technological Trends (NIC, 2000). The National Infrastructure Protection Center (NIPC) and the

National Association of State Chief Information Officers (NASCIO) have partnered to form an ISAC “to disseminate intelligence quickly and prevent unauthorized and destructive infiltrations” (Greenspan, 2002b).

Some of these conference organizations sell business services to commercial, nonprofit, and government entities. Many participate in, sponsor, or promote conferences that call attention to cyberterrorism issues and cybercrimes. Some have become partnered with the DHS or otherwise help in implementing the National Strategy to Secure Cyberspace and other governmental programs. In all, they are an important component in counteracting cyberterrorism.

### Higher Education Institutions

Higher education institutions have many of the same resources and opportunities as other organizations. In addition, they usually have considerable in-house expertise. Colleges and universities were Internet pioneers. Long before the graphical World Wide Web existed and before business was allowed to use the Internet for commercial purposes, the academic community was file sharing and facilitating group research using the Internet.

Many higher education institutions became leaders in developing security skills and experience with the UNIX operating system and its associated Internet protocols, TCP/IP. Individuals in higher education have a tradition of working long and hard in making UNIX and Internet tools robust—often with little or no compensation. Many of them are working on cyberterrorism issues.

Today, public and private universities, community colleges, and specialized institutions such as the American Military University develop innovative technologies and popular new courses to counteract terrorism and cyberterrorism. In a letter to alumni, John Hennessy, President of Stanford University said, “Professor William Perry, former Secretary of Defense, was one of the many faculty members who made extraordinary efforts to accommodate students in oversubscribed classes. Bill’s class on ‘Technology in National Security’ swelled from an enrollment of 145 in the fall of 2000 to 329 students this past year!” (Hennessy, 2002).

In September 2002, it was reported that Congress approved National Science Foundation (NSF) grants for 7 large projects and 240 smaller projects. Between \$500,000 and \$13.5 million will go to each recipient organization, many of which are higher education institutions (Legon, 2002b). Many of these support antiterrorism initiatives.

### Small Business and Individuals

In the past several years, the number of individuals using cyberspace has skyrocketed, and they are included in the National Strategy to Secure Cyberspace and other cooperative initiatives. E-mail is the most common application, and many users participate in chat rooms, instant messaging, or contribute Web content through Web logs (blogs) and other forums.

Most individuals become exposed to hackers or cybercriminals—not cyberterrorists—through credit card fraud, identity theft, or property crimes. Programs such as ISpyNOW, SpyBuddy, and Cute Spy enable hackers to

monitor computer keystrokes and create logs that pick up e-mail messages, passwords, and other confidential information. Some can be installed remotely, potentially through back doors. Programs such as SpyCop have been used to detect the spy, tell when it was installed, and optionally disable it.

Many small business and individuals use digital cable or DSL lines for high-speed access through an ISP, often remaining connected 24 hours per day. Hackers can gain access to connected computers that have no firewall or if the firewall is ineffective against “back door” access points. Home and small business users may lack the technical expertise to configure these access points to protect against intrusion. The “I Love You” virus caused an estimated \$4 billion in damages to individuals and international systems (Information Warfare Database, 2000). Hackers also plant worms or other invasive programs to hijack the computer and use it to send spam or to carry out DDoS or other forms of cyberattacks, a potential contributor to cyberterrorism.

*PC Magazine* listed 10 “bad guys” of cyberspace, including DDoS attacks, worms, viruses, e-mail attachments, open network or TCP ports, and “persistent connections” (usually 24/7). The article gives often-attacked filenames, discusses strengths and weaknesses of hardware or software firewalls, offers nine safety tips, details specific information about instant messaging hazards, and names vulnerable ports hackers exploit (Karagiannis & Sarrel, 2002). These data are somewhat more detailed than the NCSA guidelines (see <http://www.staysafeonline.info>).

The National Strategy to Secure Cyberspace makes simple recommendations to private users to regularly update antivirus and operating systems, turn off computers at night, and install firewall software or physically disconnect when offline. In addition, the strategy recommends that users apply caution in opening e-mail attachments that may contain viruses, worms, or other invasive components. Other common preventive measures include using strong passwords that mix characters and numbers, disabling unnecessary applications and services, maintaining proper browser security settings, and relentless vigilance.

## WHO WILL WIN THE BATTLE OF CYBERTERRORISM?

This chapter is about the terrorist threat as it can best be seen from today, with the benefit of no hindsight. A long struggle with cyberterrorism may be just beginning. It could be a battle of minimization, not elimination. In the days following the 9/11 attacks, Secretary of Defense Donald Rumsfeld said of the war on terrorism:

The cold war, it took 50 years, plus or minus. It did not involve major battles. It involved continuous pressure. It involved cooperation by a host of nations. And when it ended, it ended not with a bang, but through internal collapse. It strikes me that might be a more appropriate way to think about what we are up against here. (*World Almanac and Book of Facts*, 2002)

Richard Clarke adds, "We reserve the right to respond in any way appropriate: through covert action, through military action, any one of the tools available to the president" (Holland, 2002). This could indicate the future of counteracting cyberterrorism.

IT professionals in government, business, institutions, schools and universities, and private interest groups are interconnected through cyberspace. Each will play a role in combating cyberterrorism. Many government programs have been designed to bring these groups together, help secure systems from outside attack, monitor internal usage, and detect suspicious activity. Working together, they will become more effective in counteracting cyberterrorism.

In the coming years, cyberterrorists will have more powerful tools at their disposal. At the same time, government, businesses, institutions, and individuals will work together to craft strategies to counteract it. Although that effort seems to be making progress in protecting critical infrastructure, networks, and computer systems, continued vigilance will be required as terrorists obtain new tools.

How actively should governmental intervention policies regulate vulnerabilities in cyberspace? Parks (2003) takes the aggressive position, suggesting codification and compliance. "When we were approaching Y2K, also known as 'the end of the world,' the federal government required that all public companies disclose to their shareholders what measures had been taken to prevent predicted disruptions and failures in their systems, [and we] should implement information security regulations along those same lines." Others advocate cooperative, voluntary approaches that can react quickly to flexible threats and conditions, without rigid legal requirements.

People will need to learn to live with cyberterrorism and minimize its impact. Some individuals have resigned themselves to some loss of freedoms to counteract terrorist threats. Others have remained committed to preserving individual privacy. This will be an important issue in the next several years.

One thing seems clear: as cyberterrorism becomes increasingly global, governments worldwide and international governing organizations will need to participate in what is almost certain to be a long-term commitment. Balancing control with individual rights will take on an increasingly global perspective, and what was initially perceived to be a threat may become an opportunity to establish increased overall cooperation.

The strong level of disagreement between extreme points of view, such as those of Richard Clarke, who predicts doom and gloom, and opponents who do not see great danger, is an obstacle to effective policy. At least, in our changing environment, it should make people think and debate. Hopefully, the dialectic will lead to effective solutions.

## GLOSSARY

- 9/11** The World Trade Center and Pentagon attacks, which occurred on September 11, 2001.
- 24/7** An activity that can occur 24 hours per day 7 days per week, as do many broadband Internet connections.

**Asymmetric Response** A one-sided response and a generic explanation why cyberterrorists behave as they do. Unable to achieve their objectives through conventional means, an extremist may strike against the "enemy" with a one-sided act of terror.

**Border Gateway Protocol (BGP)** Tables that detail the more than 100,000 routes information can travel over the Internet. BGP routers exchange information about routes and improve data flow efficiency.

**Cybercrime** Activity in cyberspace usually associated with fraud, commercial espionage, or theft of intellectual property, identity, or private data that can result in loss of data or corruption of computer files.

**Cyberspace/Digital World/Virtual World** The world of discrete mathematical values, usually ones and zeros at its lowest level, that powers computers and networks and can be used to represent the physical world. It is generally outside time and space, unless it is applied to a physical object through an interface to the analog world.

**Cyberterrorism** An evolving body of activity that includes both acts *in* cyberspace and *using* cyberspace tools to create fear or panic, often done by subnational groups or clandestine agents and directed toward intimidating or coercing a government or some segment of the noncombatant civilian population, usually in furtherance of political or social objectives; differs from hacking and cybervandalism in its intent and the degree of severity of the attacks.

**Denial of Service (DoS) Attack** A condition under which a Web site or other Internet resource is disabled by an attack from an overwhelming number of inbound messages. A distributed denial of service (DDoS) attack has the inbound messages coming from multiple computers.

**Department of Homeland Security (DHS)** Signed into law in November 2002, the DHS absorbed 22 federal agencies, including five cybersecurity offices and programs.

**Graphical User Interface (GUI)** Typically used to describe the graphical interface between a computer's display and the internal hardware workings or the interface between a computer's display and images served up on the Web.

**Hacker** A person who gains unauthorized entry into computers or other digital devices through cyberspace, usually for the purpose of minor damage or annoyance, such as defacement of a Web site or observation of data.

**Hardware** Physical devices that process mathematical ones and zeros. Hardware has an interface to the physical world, such as a keyboard or monitor display. SCADA devices include hardware.

**Information Sharing and Analysis Centers (ISACs)** Formal or informal groups that share information on cyberattacks, vulnerabilities, countermeasures, and information services best practices relating to telecommunications, financial, chemical, energy, information technology, water, transportation, aviation, food, and so on.

**Physical World/Analog World** The world of physical objects and forces in time and space. The analog world

is continuous. It can be represented in cyberspace by devices that use digital ones and zeros.

**SCADA Systems** Supervisory control and data acquisition systems used in networks of digital computer-controlled devices for physical infrastructure.

**Software** Programming code that, at its basic level, delivers ones and zeros that can be used to control the operation and function of hardware devices, including SCADA systems.

**Transmission Control Protocols/Internet Protocols (TCPs/IPs)** The set of rules by which the Internet operates and communicates among devices.

**World Wide Web (a.k.a. Web)** The graphical overlay that resides on top of the Internet and allows graphics to be served and browsed.

## WHAT IS ONLINE STALKING?

### Definition

What is online stalking, often referred to as *cyberstalking*? The answer depends on whom you ask—there is no agreed upon definition. The term is usually defined based on an analogy to the crime of traditional stalking. Traditional stalking involves a form of repeated harassment that generally involves following the victim. It is harassment that leaves the victim with the fear that he or she will be physically harmed. Because “stalking” is an emotionally charged term, and one that often has specific legal implications, it is important to define the term properly.

“Cyberstalking” does not refer to annoying e-mail. It does not apply to irritating instant messages. It does not refer to defamatory message board posts. It does not refer to identity theft. All of these types of behavior, however, may fit into an overall pattern of conduct exhibited by stalkers. Online stalking is conduct similar to traditional stalking but carried out online. For instance, sending e-mail messages detailing the recipient’s day-to-day activities and implying or threatening harm to the recipient may be a case of online stalking.

Various countries and states may have laws against stalking specifically or against various actions that may be part of a stalker’s course of conduct. Service providers also may be willing to help customers who are being stalked online, or they may be willing to terminate the service of their own customers who are stalking others. Conduct that is merely irritating, however, may simply be seen as a natural part of life, and complaints about such conduct often will not be taken seriously by the law or a service provider.

### What Is “Traditional” Stalking?

“Stalking” as a distinctly defined crime is fairly new, first appearing in the statute books in the early 1990s. It generally involves repeated contact with the victim—contact that makes the victim fear for his or her physical safety. An example of a stalking statute (California Civil Code, 2001) provides the following:

(a) A person is liable for the tort of stalking when the plaintiff proves all of the following elements of the tort:

- (1) The defendant engaged in a pattern of conduct, the intent of which was to follow, alarm, or harass the plaintiff. In order to establish this element, the plaintiff shall be required to support his or her allegations with independent corroborating evidence.
- (2) As a result of that pattern of conduct, the plaintiff reasonably feared for his or her safety, or the safety of an immediate family member. For purposes of this paragraph, “immediate family” means a spouse, parent, child, any person related by consanguinity or affinity within the second degree, or any person who regularly resides, or, within the six months preceding any portion of the pattern of conduct, regularly resided, in the plaintiff’s household.
- (3) One of the following:
  - (A) The defendant, as a part of the pattern of conduct specified in paragraph (1), made a credible threat with the intent to place the plaintiff in reasonable fear for his or her safety, or the safety of an immediate family member and, on at least one occasion, the plaintiff clearly and definitively demanded that the defendant cease and abate his or her pattern of conduct and the defendant persisted in his or her pattern of conduct.
  - (B) The defendant violated a restraining order, including, but not limited to, any order issued pursuant to Section 527.6 of the Code of Civil Procedure, prohibiting any act described in subdivision (a).

Stalkers are generally motivated by a desire to control their victims. Stalking is seen as a problem because it implies an intentional and concerted effort to place the victim in fear of bodily harm rather than mere casual but unwelcome contact. Thus, accidentally running into a former boyfriend at a restaurant may be an annoyance but such an encounter by itself would not constitute stalking.

Conversely, running into a former boyfriend every night in the parking lot of a different restaurant, as if he is following the woman around and waiting in the dark, could indicate conduct venturing into the realm of stalking. Stalking laws generally will not provide a remedy for the accidental encounter, but they will assist where there is a pattern of activity intended to instill a sense of fear in the victim. (Check with local legal authorities to determine what conduct is prohibited and what remedies are available in your local area.)

### How Does Online Stalking Differ from Traditional Stalking?

Online stalking is a form of harassment, but it is more pointed, as is traditional stalking. It occurs through the use of a computer, and it may have more specific motivations than other forms of harassment. One way in which traditional stalking differs from online stalking is in some jurisdictions' specific requirement that the stalker "follow" the victim. How do you follow someone around in cyberspace? Such a spatial requirement may preclude the application of a specific stalking statute to online-only conduct. Second, because stalking statutes generally require a fear of bodily harm, it is less likely that an e-mail message will convey the same fear that a personal encounter would create. With an e-mail message, there is no way to know if the sender is even on the same continent as the recipient, much less a legitimate threat. Online stalking may lack the immediacy that is present with "real-world" encounters. For electronically received communications, a threat of harm may be more remote or less reasonable than, for example, a personal encounter. Additionally, online stalking adds a level of anonymity that may be missing in a real-life encounter. This anonymity also may have the side effect of emboldening stalkers who are more willing to attack or harass than they would be if their conduct was more readily traceable.

### Why Does the Definition Matter?

Harassing conduct may be annoying, but it is conduct for which there are only limited remedies available under the law. Although, on the one hand, the extent or availability of any remedy varies depending on applicable laws in your country or state of residence, as a general rule you have no right to be protected from being annoyed—especially when the source of your annoyance is someone else's protected speech. Stalking, on the other hand, may be a criminal offense in many jurisdictions for which there are specific legal remedies. The law does not punish the speech *per se*, but punishes the use of speech as a weapon intended to cause harm in much the same way as hate speech or defamation may be outlawed because of the harm it causes rather than for the substance of the message. Stalking is essentially seen as a form of assault rather than an attempt to communicate.

The law is slow to keep up in many areas with changing technology, including in the area of addressing aspects of online harassment. Traditional stalking law may not help a victim if the online conduct does not fit within a particular statute's definition of stalking. Thus a statutory

definition of stalking affects whether a particular stalking law applies to the unwelcome conduct. An example of an online-specific law is Illinois' Cyberstalking (2001) law, which reads as follows:

#### Sec. 12-7.5. Cyberstalking.

- (a) A person commits cyberstalking when he or she, knowingly and without lawful justification, on at least 2 separate occasions, harasses another person through the use of electronic communication and:
  - (1) at any time transmits a threat of immediate or future bodily harm, sexual assault, confinement, or restraint and the threat is directed towards that person or a family member of that person, or
  - (2) places that person or a family member of that person in reasonable apprehension of immediate or future bodily harm, sexual assault, confinement, or restraint.
- (b) As used in this Section: "Harass" means to engage in a knowing and willful course of conduct directed at a specific person that alarms, torments, or terrorizes that person. "Electronic communication" means any transfer of signs, signals, writings, sounds, data, or intelligence of any nature transmitted in whole or in part by a wire, radio, electromagnetic, photoelectric, or photo-optical system. "Electronic communication" includes transmissions by a computer through the Internet to another computer.
- (c) Sentence. Cyberstalking is a Class 4 felony. A second or subsequent conviction for cyberstalking is a Class 3 felony.

However, even in the absence of a specific online stalking law, there may be other less obvious laws that provide a remedy, as well as technical options that also provide an adequate remedy to online harassment.

Defining conduct as stalking is also important because it provides a means to frame the discussion. Stalking is a concept that many people have encountered, at least via the media, and can therefore understand. By framing the online conduct in terms of traditional stalking, it may produce greater sensitivity to the effects of the unwelcome conduct. Merely calling the police and telling them that you are "receiving unwelcome instant messages" may be greeted with the suggestion that you simply turn off your computer. Obviously, such a dismissive reaction will not be of much comfort to a victim, because it shows no acknowledgment of the real harm that can result from a stalker's interests. If the police do not understand what an instant message is, at least they can be educated to the point that they understand the message sender could be a legitimate stalker intent on causing the same harm that any other stalker sending the same message via a more traditional medium could intend.

### Who Is a Stalker?

A 2002 unscientific study done by Working to Halt Online Abuse (WHOA), an organization started by a former online stalking victim, describes the profile of an online stalker as follows:

- Seventy-one percent of cases reported to WHOA involved female victims, although there is no indication if women are harassed more frequently or are instead more likely to seek help with harassment.
- Forty-nine percent of people who contacted WHOA for help reported their ages as between 18 and 30.
- Fifty-two percent of cases reported to WHOA involved harassment by a male, 35% of the harassers were female, and 13% were of unknown gender.
- More than half of those reporting to WHOA had some previous contact with their harassers, most commonly as a result of a prior relationship or due to an online encounter.
- Nearly 2% of all online harassment (as distinguished from other contact) began via e-mail.
- Thirty-four percent of online stalking cases reported to WHOA included some form of offline harassment as well.

The study is unscientific because the responses are self-selected responses of those who decided to contact the organization. In the absence of scientifically valid survey data, however, it provides useful anecdotal information that helps define the problem.

What motivates a stalker? As discussed by Howard (1999) in *Cyber-Stalking: Obsessional Pursuit and the Digital Criminal*, there are four basic types of cyberstalkers:

1. **Simple Obsessional:** The largest category; typically involves a victim and a perpetrator who have a prior relationship. This group also poses the biggest threat to the victim. The motivation behind the stalking is often to restart a relationship—or seek revenge for the ending of a relationship—through the inducement of fear.
2. **Love Obsessional:** Such stalkers generally have no prior relationship with the victim. Victims are often encountered through the media or the Internet. A large percentage of such stalkers may be suffering from a mental disorder. A typical example of a love obsessional stalker is the “obsessed fan” of a celebrity.
3. **Erotomaniac:** Similar to the love obsessional category, these stalkers go a step further and possess the delusion that their target is in love with them.
4. **False Victimization Syndrome:** This group accuses another person of stalking, either real or imaginary, to foster sympathy and support from those around them.

## HOW MUCH OF A PROBLEM IS ONLINE STALKING?

Online stalking earns media attention, but how serious is the problem? This question is open to debate. A 1999 report prepared by the U.S. Department of Justice (1999), and later reports that merely respun the same content, stated that the problem is pervasive and, using “back of the envelope,” calculations theorized that online stalking could be a crime with tens or hundreds of thousands of victims. The report, however, is sparse in actual support for these claims. In fact, it even cites a study conducted at the University of Cincinnati, of which the authors have

stated does not measure the statistics that the Department of Justice cites the study to support (Koch, 2000). Essentially, there are no empirical scientific studies or data as to the scope of the problem.

Although the media, legislatures, and other interested groups may provide more than a fair amount of hype for the topic, online stalking and other forms of online harassment are a legitimate concern, especially for victims. As more and more daily activities move online, a statistical analysis is not required to see that more harassing conduct likely will move online as well—an assumption supported at least by anecdotal evidence.

## Examples of Online Stalking

Andrew Archambeau has the distinction of being the first person convicted of “cyberstalking,” although his actions extended into the “real world” as well (Eckenweiler, 1996). The real-world aspects of his conduct are rarely mentioned in discussions of online stalking, however; only the fact that he harassed his victim by e-mail is discussed at any length. Archambeau had met a woman through a video dating service in early 1994, and they went out on two dates. Apparently he thought more of the relationship than she did, because she sent him an e-mail message saying that she did not want to see him again. Over the next few weeks, he sent her approximately 20 e-mail messages and also left her telephone messages (including one saying, “I stalked you for the first time today”). Requests to leave her alone were ignored. Unfortunately for him, he lived across the street from the school where she worked, thus making it appear that he was waiting outside her workplace. After he ignored a police warning to leave her alone, criminal charges were filed against him for violating Michigan’s stalking law. After mounting an unsuccessful challenge to the statute’s constitutionality, he finally pleaded no contest (Ellison & Akdeniz, 1998). Archambeau’s conduct was obviously objectionable, and even absent the e-mail messages sent to his victim, he may have run afoul of the stalking law because of his real-world actions.

Another incident that had a much stronger online component, yet still included a variety of real-world contacts involved two law students at the University of Dayton who had begun dating. The woman decided to end the relationship, but the man wasn’t willing to accept this proposition. Over winter break, he began sending his former love interest notes about how he was starving himself to death, including the details of the pain he was to suffer in the process. The two reconciled—briefly. After recovering from a suicide attempt provoked when the woman broke off the relationship a second time, Mr. Davis, the former boyfriend, sent the woman numerous e-mail messages stating that he had been researching her hometown and regularly spending time in a park near her apartment. The notes did not contain explicit threats of harm, but Davis’s tone “fluctuated between despair over the breakup, anger, threats to commit suicide, a desire to see [the woman] in pain, and blaming [her] for ruining Davis life” (*Dayton v. Davis*, 1999). Davis also included in his e-mail messages information that led to the belief that he had been watching the woman, such as knowing what she

had watched on television, as well as a link to the Web site he had created. Davis Web site “portrayed, among other things, the image of [her] head transforming into a skull amidst flames, dripping blood, and charging horses ridden by robed skeletons. Interspersed with these images were quotations from the Bible and other sources in which the common theme was love, death, and destruction. On another Web page, Davis had posted pictures of [her] home town . . . although when questioned . . . Davis denied ever having been to the town” (*Dayton v. Davis*). Davis was charged by the authorities with violating the Ohio State law against menacing by stalking (R.C. 2903.211) and aggravated menacing R.C.G.O. 135.05(A). He defended himself by arguing that he had never actually threatened the woman. The court found that he had still succeeded in knowingly placing her in fear of serious physical harm, as evidenced in part by her moving out of her apartment and eventually transferring schools. Intentionally creating such fear, rather than making threats, is what the statutes prohibited. Davis was convicted and sentenced to 180 days in detention.

The first person convicted under the California state online stalking statute was Gary S. Dellapenta (Miller & Maharaj, 1999), a 50-year-old security guard who decided to generate some unwanted notoriety for his former girlfriend. In this case, the stalker’s conduct was purely online, although it generated real-world consequences. Dellapenta posted messages on America Online and sent e-mail messages purportedly from the woman stating that she had “rape fantasies”—and soliciting assistance in living out those fantasies. The messages included her home telephone number, address, and instructions on how to disable her home security system. Six people decided to take up “her” offer and dropped by her apartment (she was not physically harmed by these visitors). Criminal charges were brought against Dellapenta for stalking, computer fraud, and solicitation of sexual assault, and he was sentenced to 6 years incarceration (Brenner, 2001). A similar false impersonation case in Korea that involved the culprit forging offers of sexual services in the name of the victim resulted in a warrant for the arrest of a man on criminal slander charges (Soh-Jung, 2001).

*People v. Kochanowski* (2000) involved a man who asked a coworker to help set up a Web site. The site contained suggestive photographs of his former girlfriend, along with her address and telephone numbers. The page also contained what the court described as “express references to intimate body parts and attributed to [the girlfriend] an infatuation with sex” (*People v. Kochanowski*, p. 462). The woman then began receiving disturbing calls at work. The court found that the former boyfriend was guilty of violating the New York statute prohibiting “aggravated harassment” [New York State Penal Law §240.30(1)] that prohibited certain intentionally annoying or alarming communications. Kochanowski argued in his defense that he had not made the alarming calls, which would have been a violation of a protective order the woman had obtained prohibiting the man from communicating with her. The court found it sufficient under the aggravated harassment statute, however, that he had intentionally caused such alarming communications to be made by others (although the court did not

find the specific terms of the protection order violated by Kochanowski’s Web site).

Other examples demonstrate the international reach of online harassment—it may be just as easy to stalk someone on the other side of the planet as it is to stalk someone up the street. In the case of Rhonda Bartle, international online harassment did lead to an attempted real-world encounter (Hubbard, 2001). Bartle, a New Zealand author, started exchanging e-mail messages with Peggy Phillips, an American writer living in California. When the 84-year-old Phillips showed that she was interested in a deeper relationship than Ms. Bartle wanted, Ms. Bartle decided to end the relationship. Ms. Phillips commented about feeling suicidal and then took a plane to New Zealand. Bartle told the local taxi company not to take anyone to her house. When Phillips attempted to order a cab, the taxi company called the police, who then served Phillips with a trespass notice. After returning home, Phillips continued sending her unwanted e-mail messages (which, for the most part, were automatically filtered out of Bartle’s e-mail). Because New Zealand did not have online stalking laws at the time, Bartle contacted the Orange County, California, police in an effort to have them enforce the California law against Phillips. (Unfortunately, news accounts did not state whether this proved productive.) Australian courts have also been faced with a jurisdictional fight over where an online stalking case can be heard against an Australian man who stalked a Canadian actress by e-mail (Cant, 2001).

## WHAT CAN YOU DO IF YOU ARE A VICTIM?

According to information provided to members of the CyberAngels who may assist victims of online stalking:

The victim is often embarrassed and does not seek help till the situation becomes out of hand. Why do you think this happens? They often know the stalker in some way. May even have had a relationship with them to some degree. Maybe online boyfriend and girlfriend. Maybe the victim had sought out the person first. Maybe they have given personal identifying information that has come back to haunt them. So they are embarrassed and ashamed and don’t know what to do. The victim naturally will try to reason with the stalker, to get them to back off. It rarely works. Any attention given to a stalker is still attention and empowers them. If they can’t have your love they will take your hate, anger and fear. (CyberAngels, n.d.)

In other words, asking a stalker to stop is not likely to be effective—although it is the first place to start. One of the most important things a victim can do is to document the situation. Save e-mail messages. Capture chat sessions. Document everything. Although the details on how to capture this information are beyond the scope of this article, the need is clear. This information is what allows you to make a case—be it with a service provider,

law enforcement, or in court. Beyond this basic record keeping, there are a few places to seek help.

### Service Providers and Technical Fixes

One remedy that may be available is to have the Internet access of a stalker eliminated. According to WHOA's statistics, most frequently cases reported to the organization were resolved after complaints to the sender's Internet service provider (ISP; WHOA, 2002). The vast majority of ISPs have some sort of "terms of service" agreement or "acceptable use policy." These are generally contracts with the service providers and their users that restrict the use of the service providers' systems. Although these policies generally do not create a legal remedy on behalf of a victim, they do provide a means for the service provider to terminate someone who is abusing people via the service provider's system. A service provider is often willing to terminate "problem users" because it does not want to be seen as contributing to the continuation of abusive activities, it actively wants such conduct removed from the Internet, or it simply does not want the hassle of dealing with a user who generates complaints and the possibility of (expensive) legal hassles. As a result, if a victim can trace a stalker back to his or her Internet service provider, it is always sensible to look at the service provider's Web site to see if the provider has an acceptable use policy or terms of service agreement that is being violated by the stalker's actions. This policy then can be brought to the service provider's attention when describing the actions of the provider's user. In the course of dealing with a stalker, however, although this line of action may be effective, having his or her Internet access shut down is likely to provoke anger, possibly producing more harmful behavior in the end (either through a different service provider or through real-world contacts) rather than eliminating the threat altogether.

Tracing the source of online harassment may be straightforward, or it may be almost impossible. A harasser may make no effort to hide his or her identity or the service provider being used to originate harassing messages. In such a case, contacting a service provider is a fairly simple process. In addition to looking to see if the provider has a Web site with contact information, many providers maintain an e-mail account intended for abuse complaints—generally in the form of "abuse@[serviceprovider.com]" or the like. In addition, the domain name registration for a service provider will usually have contact information. Domain name registration information can be checked from a Web site such as <http://www.allwhois.com/>.

It may not be easy to track the source of harassing communications because of the ease of anonymously communicating on the Internet. In addition to services that specifically provide for anonymous communication by stripping identifying information from e-mail messages and other public posts, it is also possible to forge routing information. Although tracing such forgeries is beyond the scope of this article and techniques change with advances in the technology involved, good resources can be found online. (For e-mail, see the SPAM-L FAQ in the Further Reading section.) Of course, even if you can trace a

message back to its source, it may be the case that the originating account was opened with false information.

If one can identify a service provider but not the real name of the user, the provider is not likely to be helpful in turning over its user's identity. Often a service provider will insist on some sort of subpoena or court order before turning over identity or contact information about one of its users, even in a case where it is willing to cancel that same user's account. (Some jurisdictions make it relatively easy to file a suit or otherwise compel the release of information possessed by an ISP that identifies a harasser. Some jurisdictions will allow the filing of a "John Doe" lawsuit for the purpose of discovering who the true target of the suit should be.) It is worth noting that in some jurisdictions the service provider may be immune from any liability itself for harboring an online stalker, but this is not likely to extend to protections from criminal liability where it is earned, and it does not mean a service provider is exempt from turning over useful information when presented with a court order.

In some cases a remedy can be obtained by the victim simply changing e-mail addresses. However, this will obviously not be effective in cases where there is ongoing contact between the victim and the stalker, either in the offline world or in some online forum where the stalker will be able to learn the victim's new contact information.

Without resorting to help from a service provider, there are some steps that victims can take for themselves. The most obvious is to avoid unwanted contact. Delete or "kill file" messages from the stalker, either manually or through an automatic filter that most popular e-mail programs and newsreaders allow users to establish. Avoid logging on to chat rooms at times when the stalker is likely to be logged on as well.

### The Law

If you are being stalked, a typical response is to call the police. For traditional stalking, this may result in gaining the assistance one needs to stop the stalker's conduct. According to WHOA's (2002) statistics, referring a matter to law enforcement was the most frequent solution to a stalking incident if contacting a service provider or changing e-mail addresses proved insufficient. Unfortunately, in the case of online stalking, the response from the police is not always useful. Many people who call the police are unable to obtain redress for their problem. As found in the Department of Justice (1999) report, training of law enforcement officers to handle online stalking is erratic and, in large measure, insufficient. Depending on location, the type of law enforcement to contact may vary—for instance, are state or federal authorities the best resource? In the United States, a victim could try contacting the local or state police, the Federal Bureau of Investigation, or the Secret Service—all of which may handle some types of online crimes. The amount of coordination and awareness between law enforcement groups is growing. The level of technical sophistication and resources devoted to computer crime-related issues is also improving. In some cases, such improvements are required by legislation. Often the agency contacted may not know how to help but will know to whom the victim should be referred.

Victims who do not get a knowledgeable response may want to try a different law enforcement entity.

Another concern with contacting law enforcement is a matter of resource allocation. Simply put, law enforcement resources are limited, and there may be no one capable of taking time to help a victim of online harassment if other matters that affect more than a single victim or that appear likely to result in more immediate harm are consuming available resources. There may also be a lack of investigative tools with which to pursue a matter even if there is sufficient interest in the case.

Finally, contacting law enforcement may result in either a very public or a very private investigation. The fact that a police report has been filed, for instance, is a matter of public record in many jurisdictions and may attract media attention. Conversely, the details of an investigation undertaken by law enforcement may be confidential, even from the victim who reported the incident and stands to benefit from the results of any investigation. An investigation by law enforcement is generally out of the hands of the victim because it becomes the government's rather than the victim's case.

Another means of using the law to provide a remedy is through the hiring of a private attorney. The ability of an attorney to provide assistance will be dictated by where the victim and the stalker are located. This will determine, in part, the applicable laws, which will determine if a "private cause of action" exists. In other words, an individual generally cannot sue someone for violating a criminal law. Generally, only the government can sue someone to enforce the criminal law. Some statutes do, however, provide a private cause of action or some other civil remedy that will allow a victim to go after a stalker directly, without assistance from the government. The results of such a suit could include injunctive relief which, for example, would require the stalker to leave the victim alone or provide for recovery of monetary damages.

What kinds of laws are there? As mentioned, traditional stalking laws may apply to cyberstalking cases. These are generally criminal statutes that require law enforcement assistance. These statutes generally require multiple incidents of harassment that cause the victim to fear for his or her physical safety. Sometimes the safety of family members is also covered under these statutes. The statute may also dictate a specific behavioral requirement, such as the stalker's having physically followed the victim. Some jurisdictions have expanded or clarified their laws in recent years to provide a remedy specific to online stalking. These laws may acknowledge certain harmful uses of technology in defining the offense or merely serve to remove obstacles contained in traditional stalking statutes containing physical requirements that do not apply in the online world.

Some jurisdictions address stalking-like behavior with traditional harassment law or laws prohibiting intimidation. Harassment and intimidation laws may cover a broader range of conduct than traditional stalking laws, but they may have other sorts of obstacles to overcome to ensure that only egregious conduct is prohibited as unlawful harassment. Hurdles, for example, may include requirements that a harasser has the intent to cause harm, or they may require a certain level of damage before

providing a remedy. These statutes may be technology dependent, such as harassing telephone call statutes, although use of modems to connect to the Internet may fit within the statutes' coverage.

If messages from a stalker contain actual threats, many jurisdictions have statutes that provide a remedy for the transmission of credible threats. One famous online "stalking" case, the "Jake Baker" case (*U.S. v. Alkhabaz*, 1997), involved a student at the University of Michigan who posted to Usenet news a piece of "erotic fiction" describing the sexual torture of a woman, a woman who was given the name of one of his classmates. The man was arrested and initially held in jail as a threat to society pending a psychiatric evaluation. The court held that the man's actions were not criminal, because no evidence was presented that his actions were anything more than a sick fantasy. Because there was no evidence that he would really act out his fantasy, there was no credible threat, and thus the federal statute at issue was not violated. Some jurisdictions may have different standards for threats made to certain types of people, such as the U.S. prohibition of threats made against the president (18 U.S.C. §871).

Statutes that address specific conduct such as identity theft, false attribution of origin of the messages, or eavesdropping may also come to bear in a cyberstalking case. Some "common law" concepts—traditional legal concepts that have evolved through court decisions and for which there may be no statute—may also provide a mechanism for legally attacking a stalker. For instance, assault (where a victim is placed in fear of bodily injury); intentional infliction of emotional distress; or, depending on the particular actions, defamation, trespass, or fraud-type arguments may also allow for a remedy. Depending on the law of a particular jurisdiction, "family law" remedies such as restraining orders and orders of protection, often aimed at keeping away ex-spouses or love interests, may be relevant.

## CONCLUSION

Online stalking is a problem of unknown proportions. Just as traditional stalking is a concern for its victims, however, so, too is the online equivalent. As more people live more of their lives online, all forms of online crime are likely to increase. Although this will produce more claims of online stalking and other forms of online harassment, it will also force law enforcement to be more prepared to address the needs of victims. In the case of legislators, they will also be required to ensure that the laws have evolved to address the concerns of victims—without having undue impact on legitimate, but perhaps heated, interactions. Because of the international nature of the Internet, cooperation between governments will be essential to address foreign harassers. Efforts are already being put into place to aid in the international enforcement of criminal laws, as evidenced by the Council of Europe's Cybercrime Convention (Howard, 1999) that requires all signing countries to outlaw certain types of objectionable conduct and to provide international assistance in enforcing other countries' laws that prohibit this minimum level of criminal conduct. It is reasonable to expect that the more egregious forms

of online stalking are likely to be sufficient to result in some degree of international cooperation.

## GLOSSARY

**Acceptable Use Policy** An Internet service provider's rules describing what one of its customers may and may not do with or through the provider's computer system.

**Criminal Lawsuit** A lawsuit brought by the government against an individual. Unlike a private or civil lawsuit, a criminal lawsuit could involve jail time or other more serious sanctions depending on what remedies are contained in the applicable law.

**Cyberstalking** Another name for online stalking (see below).

**Harass** To engage in an intentional course of conduct directed at a specific person that alarms, torments, or terrorizes that person.

**Injunctive Relief** Relief granted by a court to a victim that generally orders another person not to do something, such as ordering a stalker to stay away from a victim, or to do something, such as remove objectionable material from a Web site.

**John Doe Lawsuits** Lawsuits filed against an unknown person. Once the lawsuit is filed, the party filing the suit can try to obtain more information on the person being sued.

**Kill Files** Filters in many e-mail programs that are used to block messages sent from people or addresses listed in the kill file (also called bozo filters). These are used so that e-mail or other electronic communications from a harasser can be deleted by the victim before they appear in the inbox.

**Online Stalking** A form of computer-mediated harassment analogous to traditional stalking.

**Private Cause of Action or Private Right of Action** The ability to sue a person engaging in objectionable conduct without the need for government involvement to enforce the law.

**Restraining Orders** Orders issued by a judge that may prohibit someone from contacting another person. What these orders may cover varies by jurisdiction.

**Stalking** A form of harassment generally targeted at a specific individual that causes fear of physical harm. As a legal term, this definition varies by jurisdiction.

## INTRODUCTION

In today's society, computer systems are valuable, and often invaluable, for innumerable business and personal uses. Computer systems and networks are also very tempting as targets, shown by statistics that track the frequency and prevalence of cybercrimes. For example, Symantec Corporation estimates that organizations were hit by an average of 11 attacks daily during the first half of 2004 (Turner, 2004).

Part of the temptation is the ease of electronic attacks. Although not every attack takes advantage of vulnerabilities, it is widely known that computer systems have numerous vulnerabilities. In early 2004, about 48 new vulnerabilities were discovered weekly on average (Turner, 2004). Moreover, 96 percent of them were serious enough to be rated as moderately or highly severe. Attackers are keenly aware of new vulnerabilities because it takes time for organizations to set up adequate protection, e.g., software patching. In early 2004, exploits for new vulnerabilities appeared on average only 5.8 days after announcement of the vulnerability.

Electronic attacks have also become easier since virtually all computers are interconnected by the Internet or private networks. Moreover, mobile and handheld devices with Internet connectivity have steadily grown in popularity. This extensive network environment facilitates remote attacks and makes attacks more difficult to track to their sources. The growing number of networked machines also means more targets to attract attacks.

This chapter gives an overview of electronic attacks, highlighting the basic steps involved in attacks seeking to compromise computer systems. Most of the emphasis here is on network-enabled attacks, but this is not meant to imply that all electronic attacks are carried out through the network. This chapter also describes

large-scale attacks such as viruses, worms, denial of service, and spam.

## Types of Attackers

Attackers can be categorized in a number of different ways. One distinction often made is the relationship of the attacker to the target, either internal or external. Insider attacks from within an organization are believed to be the most common and most critical in past years. A commonly cited statistic in the late 1990s attributed 70 percent of all attacks to insiders. Insiders have certain advantages that can increase the likelihood of a successful attack, such as the trust of an organization and knowledge regarding systems and their defenses. However, with ubiquitous network connectivity today, external attacks are more likely than ever before (CERT, 2004).

Attackers can also be categorized as either amateurs or professionals. Many people probably visualize an attacker as the stereotypical male teenage "hacker" or "script kiddie" with too much free time. This stereotype has been perpetuated by fictional characters in films such as *War Games* as well as real-life arrested hackers. For example, the most recent case was the arrest of 18-year-old Sven Jaschan in May 2004. He is being prosecuted for writing the four most damaging worms of 2004, including the Netsky and Sasser worms, which accounted for 70 percent of the worms received in the world in the first half of 2004 (Sophos, 2004).

While teenage vandals are undoubtedly responsible for a substantial fraction of electronic attacks, it appears from recent trends that cybercrimes are being increasingly carried out by professionals and organized crime. Professional crimes tend to be more sophisticated and larger scale than amateur crimes. Attacks designed for identity theft and profit are becoming more prevalent. There are

growing number of channels used for buying and selling lists of compromised computers and stolen identity data. Other professionals known to be involved in electronic attacks include national governments, military agencies, and industrial spies.

## Attacker Goals and Motivations

The motivations for electronic attacks depend on the attacker. Because there are many different types of attackers, motivations can be almost anything, ranging from fun and fame to extortion, profit, espionage, revenge, or a political agenda.

The stereotypical teenage hacker is believed to be usually interested in gaining fame or notoriety. For example, according to some media accounts, Sven Jaschan appeared primarily motivated by curiosity and perhaps good intentions, writing Netsky. A worm to combat two other worms, MyDoom and Bagle.

On the other hand, messages encoded in the Bagle worm suggested that its authors were professionals motivated by profit. This is supported by the worm's actions, including installation of backdoors for remote access (Symantec, 2004).

An increasingly common goal is invasion of privacy or theft of confidential data. This is evident from the escalation of spyware and phishing attacks (described later in this chapter).

## Attack Targets

An electronic attack will have specific targets depending on the attacker's goals. The target could be particular information on a single machine, or the target could be as broad as the entire network infrastructure.

A recent survey showed that 70 percent of organizations were hit by some type of electronic attack (CERT, 2004). E-commerce was the most frequently targeted sector; as many attackers now are motivated by financial gain (Turner, 2004).

## Attack Phases

An electronic attack is commonly carried out through a progression of steps, analogous to the steps of a physical attack (Chirillo, 2002; McClure, Scambray, and Kutz, 2001; Skoudis, 2002). The first step is reconnaissance to collect the necessary intelligence in preparation of the actual attack. The second step is the actual attack, which could have many different goals. During and after the attack, the attacker may try to take actions to avoid detection.

## RECONNAISSANCE PHASE

If an attacker wants to compromise a specific computer system, it would obviously be wise to prepare for an attack by first discovering everything possible about the target. The reconnaissance phase can reveal a variety of information—account names, addresses, operating systems, perhaps even passwords—that could increase the success of an attack. Moreover, most reconnaissance techniques are not viewed as malicious or illegal, and may be carried out without a high risk of alarming a potential target.

As one might imagine, many different reconnaissance techniques are possible, and attackers do not follow a unique sequence of steps. Here we outline three general steps to progressively discover more information about a potential target.

## Footprinting

The initial step in discovery is called footprinting, fingerprinting, or enumeration. An abundance of information is readily available on the Web. These databases can be interrogated by a number of utilities such as *nslookup* or *dig*.

The whois databases contain information about the assignment of Internet addresses, registration of domain names, and individual contacts. Domain names such as *www.mycompany.com* are registered through the Internet Network Information Center (InterNIC), a consortium of several companies and the U.S. government. For a domain name, the InterNIC whois database can provide the registrant's name and address, domain servers, and contact information.

For information about ownership of ranges of IP addresses, the American Registry for Internet Numbers (ARIN) database provides a mechanism for finding contact and registration information for resources including IP addresses, autonomous system numbers, and registered organizations in the Americas. European IP address assignments can be discovered from Réseaux IP Européens Network Coordination Centre (RIPE NCC). Likewise, Asian IP address assignments are maintained by the Asia Pacific Network Information Center (APNIC).

Another useful database is the domain name system (DNS). DNS is a hierarchy of servers used to associate domain names, IP addresses, and mail servers. The hierarchy extends from the root DNS servers down to DNS servers for individual organizations and networks. These DNS servers contain information about other low-level DNS servers and IP addresses of individual hosts.

## Scanning

Armed with information gained from footprinting, an attacker may know names and addresses for potential targets, and perhaps specific host system information. Footprinting is similar to looking up names and numbers in a telephone book. Scanning is a more active step to learn about potential targets from their responses. There are many different ways to conduct scans.

**War Dialing.** The most primitive though still useful type of scanning is war dialing. War dialers are simply automated machines for dialing a set of phone lines to find accessible modems. A telephone number within an organization is usually easy to find through the Internet or telephone books, then an attacker could dial a surrounding range of numbers. The results will reveal phone lines with modems. War dialers can include a nudging function that sends a predefined string of characters to a modem to see how it responds. The response may reveal the lack of a password, the type of platform, and perhaps a remote access program (e.g., the popular *pcAnywhere*).

Although war dialers have been in use for decades, they can still be effective in attacks when a modem is not properly secured. Obviously, modems without password protection are completely vulnerable. In addition, modems can be attacked by guessing the password (see the section below on password attacks). A successful attack through an unsecured modem can lead to compromise of an entire organization's network, effectively bypassing firewalls and other sophisticated defenses.

**Ping Sweeps.** Internet control message protocol (ICMP) is part of the Internet protocol to enable notification of troubles and other control functions. Ping consisting of a pair of ICMP messages called Echo Request and Echo Reply are designed to verify that a specific host is operational. An IP-addressable host should reply to an ICMP Echo Request with an ICMP Echo Reply.

Ping is frequently used by attackers to scan a block of IP addresses for live hosts. Any number of tools can easily perform a ping sweep. However, since ping sweeps can be noticed, organizations will sometimes block ICMP messages. TCP packets to well known ports will also work, prompting a TCP SYN-ACK reply.

**Network Mapping.** Traceroute is a widely used utility for mapping a network topology. It cleverly takes advantage of the time-to-live (TTL) field in the IP packet header. The TTL field is set to the maximum time allowed for delivery of an IP packet. Each router decrements the TTL field by the time spent by the packet in that router, but routers typically forward packets quickly and are then forced to decrement the TTL by the minimum unit of one. Thus, the TTL field essentially serves as a hop count, where each router decrements the TTL field by one. If the TTL field reaches a value of zero, a router should discard the packet and send an ICMP Time Exceeded message back to the source IP address in the discarded packet.

Traceroute sends out a series of UDP packets, starting with a TTL field value of one and incrementing the value by one for each successive packet. When ICMP Time Exceeded messages are returned, they reveal the addresses of routers at various distances. An example of traceroute is shown in Figure 1. Similarly, ICMP messages could be used instead of UDP packets.

**Port Scanning.** TCP and UDP packets are sent to and received at specific ports indicated in the TCP and UDP headers. The headers allow a range of 65,535 TCP and 65,535 UDP ports. Certain "well known" port numbers are pre-assigned to common protocols. For example, Web servers listen for HTTP requests on TCP port 80. The other ports may be used dynamically as needed.

An attacker is very often interested to discover which ports are open on a potential target, i.e., which services are listening. However, probing every possible port manually would be very tedious. A port scanner is an automated tool for sending probes to a set of specific ports to see which ports are open. An example of a port scan is shown in Figure 2.

**Operating System Detection.** Knowledge of a host's operating system and its version is valuable to attackers

because specific vulnerabilities are known for different operating systems. One technique used by attackers is TCP stack fingerprinting, implemented in the popular Nmap tool. While the TCP protocol is standardized in terms of its three-way connection establishment handshake, the standards do not cover responses to various illegal combinations of TCP flags. Operating systems can differ in their implementations of responses to illegal TCP packets. The idea of TCP stack fingerprinting is to probe for these differences with various illegal TCP packets until the operating system, even its particular version, can be identified (Fyodor, 2002).

**Scanning Tools.** Plenty of free and commercial scanning tools are available. Many of these are used for legitimate purposes by system administrators.

Sam Spade is a combination of useful reconnaissance tools, wrapped behind a Windows graphical user interface, including ping, whois, IP block whois (ARIN database query), nslookup, traceroute, and a function to verify email addresses on a specific mail server. A version of Sam Spade is available as a Web-based tool. Many other Web-based scanning tools can be found easily, such as a Web portal run by Mixer that includes ping, traceroute, whois, and port scans.

Other examples of free toolkits include CyberKit and Cheops. Cheops is a popular, easy-to-use tool for network mapping that automatically draws out a network topology based on discovered hosts and distances; it also discovers active services through port scanning and identifies operating systems by TCP stack fingerprinting.

An example of a commercial tool, NetScanTools Pro includes ping, port scans, traceroute, netscanner (ping sweep), custom ICMP packet generation, whois, nslookup, IP packet capturing, email address validation, and operating system identification. It uses an unusual method for operating system identification based on observing responses to four types of ICMP messages and variations of them. WildPackets' iNetTools is another commercial tool providing many of the functions as other scanners.

Finally, probably the most widely used tool for port scanning is the open-source Nmap shown in Figure 3. Nmap is perhaps the most capable port scanner, providing options for many different types of scans. Possible scans include TCP Connect, TCP SYN, TCP FIN, Xmas Tree, Null, TCP ACK, and UDP. Other interesting options in Nmap include: scanning for RPC (remote procedure calls) services on a target machine; sending decoy scans with fake source addresses; sending scans with different timing options to avoid detection; and identifying a computer's operating system via TCP stack fingerprinting.

## Vulnerability Scanning

Using general network scanning, an attacker can discover a broad range of information about a potential target, such as host addresses, network topology, open ports, and operating systems. The next step in reconnaissance is to scan for specific vulnerabilities that might be exploited for an attack. It is possible to manually scan for vulnerabilities, but would be obviously time consuming to check

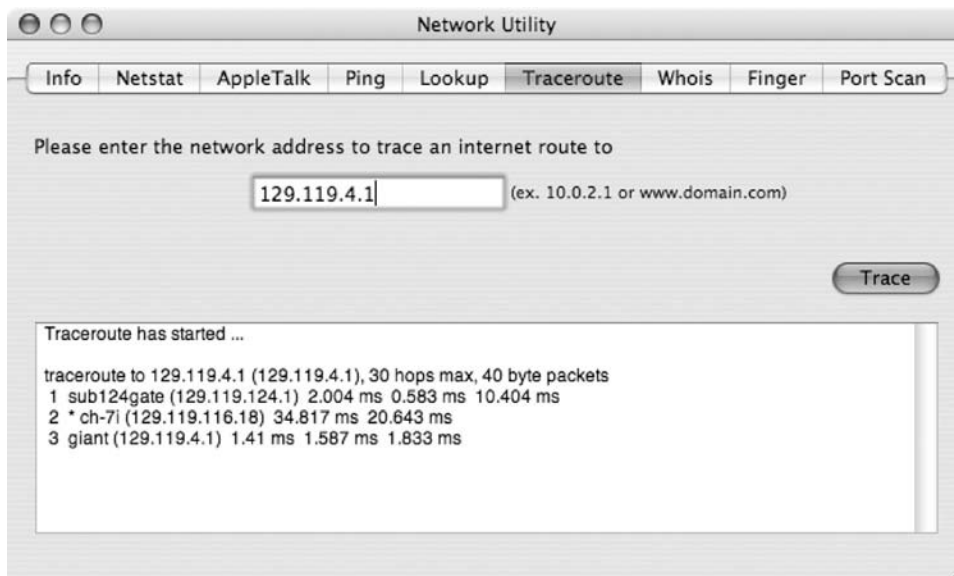

Figure 1: Example of traceroute output.

many machines for hundreds or thousands of vulnerabilities. Many automated vulnerability scanners are available and often used by system administrators to evaluate the security of an internal network.

**Types of Vulnerabilities.** Several types of vulnerabilities are usually sought by scanners:

- Default configuration weaknesses: Many operating systems and service applications ship with default accounts and passwords. These are intended to help ease the installation process, or simplify troubleshooting in case of lost passwords. Naturally, default passwords should be changed but are sometimes overlooked or ignored. Attackers look for the existence of default configurations

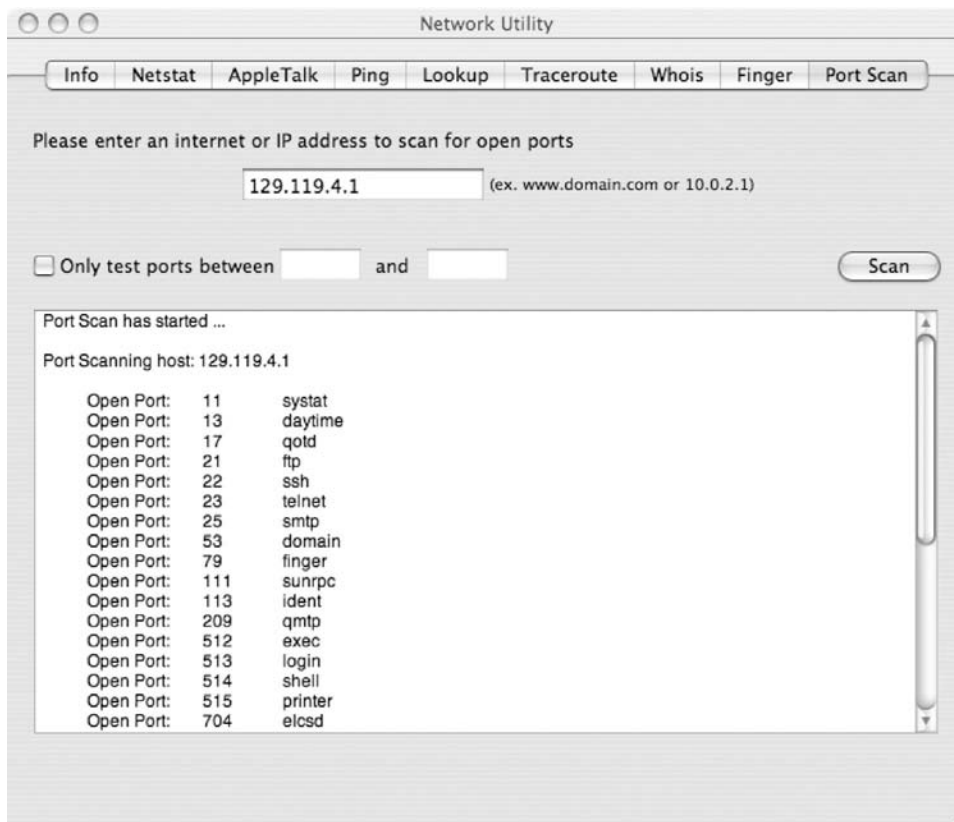

Figure 2: Example of a port scan.

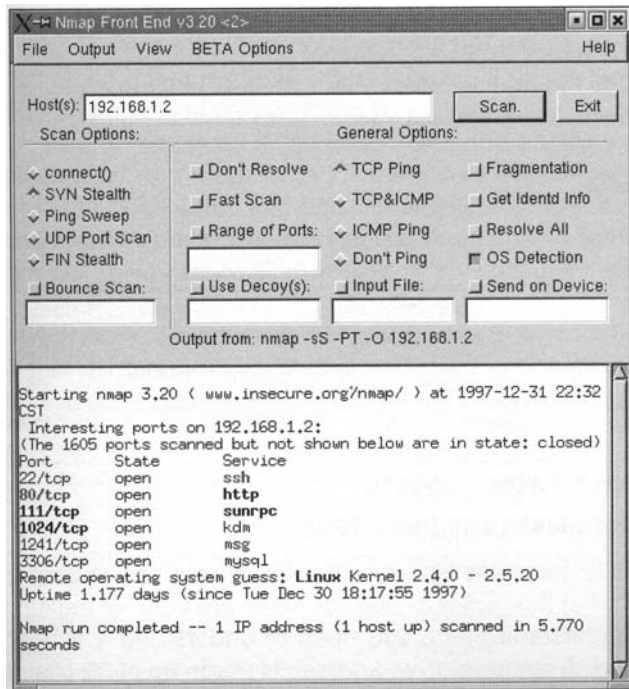

Figure 3: Nmap graphical user interface.

because they offer an easy way to compromise a system.

- Misconfiguration errors: Networking equipment requires expertise to configure properly. Obviously, incorrect configuration settings can defeat any security offered by networking equipment. An example is a misconfigured firewall that could be too permissive in allowing incoming packets.
- Well-known system vulnerabilities: New vulnerabilities are being constantly discovered in operating systems and applications. The most critical are often published by vendors with a patch. However, it requires a great deal of time and effort for organizations or individuals to keep up with security bulletins and patches. The time between the publication of a security vulnerability and the installation of patches leaves a window of opportunity for attackers to exploit that vulnerability.

**Vulnerability Scanning Tools.** A vulnerability scanner is an automated program generally consisting of a vulnerability database to check; a user interface to allow control of the scanner; scanning engine to send and receive packets; knowledge base to track the current scan; and a recording and reporting tool (Skoudis, 2002). Many open-source and commercial vulnerability scanners can be found easily.

Most vulnerabilities scanner operate in a similar way. They first discover live hosts within a given address range using ping or similar utility. Then they run a basic set of scans to discover open ports and active services running on the hosts. Based on this information, they proceed to more customized probes for vulnerabilities. In the final step, they generate output in the form of a report. Some vulnerabilities scanners include a function for network mapping as a byproduct.

The Security Administrator's Tool for Analyzing Networks (SATAN) was an early well-known vulnerability scanner developed in 1995. While SATAN is still freely available, it has two updated descendents, the open-source Security Auditor's Research Assistant (SARA) and the commercial Security Administrator's Integrated Network Tool (SAINT). SARA enhances SATAN's security engine and program architecture by providing an improved user interface and up-to-date vulnerability tests. SARA can discover information about hosts by examining various network services. It can also find potential security flaws, such as misconfigured network services, well-known system vulnerabilities, or poorly chosen policies. It can generate a report of these results or execute a rule-based program to investigate any potential security problems.

Nessus is a popular open-source vulnerability scanner. It works in a client-server architecture, where the client and server may run on the same machine. The client consists of a tool for user configuration and a tool for recording and reporting results. The server consists of a vulnerability database, a knowledge base to keep track of the current scan, and a scanning engine. Nmap is included as the built-in port scanning tool. The vulnerability database is designed to be modular in the form of plug-ins, each plug-in to check for a specific vulnerability. Nessus contains over 500 plug-ins, and a large user base continually contributes new ones. Vulnerabilities are rated and classified into categories such as finger abuses, Windows-related vulnerabilities, backdoors, CGI (common gateway interface) abuses, RPC vulnerabilities, firewall misconfigurations, remote root access, FTP, and SMTP (mail server vulnerabilities).

Commercial vulnerability scanners include TigerTools' TigerSuite Pro, McAfee's CyberCop ASaP, ISS's Internet Scanner, eEye Digital Security's Retina Network Security Scanner, and Cisco Systems' Secure Scanner.

## ATTACK PHASE

The actual attack phase can take many different forms and serve different purposes, such as stealing confidential data, tampering with the integrity of data, compromising the availability of a resource, or obtaining unauthorized access to a system. As mentioned previously, these specific attack types can be directed at either specific targets or the general network infrastructure. Quite often, large-scale, indiscriminate attacks have the effect of widespread disruption of computers and networks, even if that is not the real intent. They have widespread effects because they are carried out through a network toward a large number of targets.

The major types of attack covered here include sniffing, session hijacking, password attacks, exploits, social engineering attacks, Trojan horses, spyware and adware, viruses and worms, spam, and denial-of-service (DoS) attacks. The list is not meant to be exhaustive, but rather highlights of important attack types seen today.

These attack types are not mutually exclusive—in fact, many times they are combined in so-called blended threats. For example, social engineering can be a component of many e-mail worms. Some spyware is included

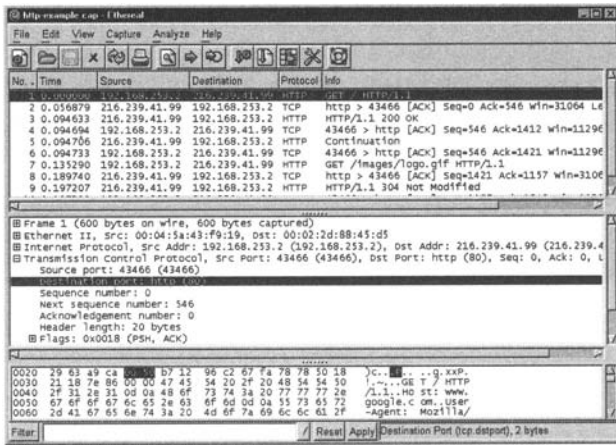

Figure 4: Example of Ethereal output.

as a Trojan horse in seemingly harmless software. Viruses can spread via spam, and so forth.

## Sniffing

Sniffing is a form of passive attack that enables the compromise of confidential information. Sniffers, traditionally used by network administrators for traffic monitoring and LAN troubleshooting, have become one of the most commonly used attack tools. An example from the Ethereal sniffer is shown in Figure 4. On a LAN, hosts see all traffic broadcast on the LAN medium but normally ignore the packets that are addressed to other hosts. A sniffer program puts the network interface of a host into promiscuous mode to capture all packets seen at the interface. Thus, the sniffer can eavesdrop on everything transmitted on the LAN including user names, passwords, DNS queries, e-mail messages, and all types of personal data.

Many free and commercial sniffers are available, including tcpdump, windump, Snort, Ethereal, Sniffit, and dsniff.

## Session Hijacking

Session hijacking is a combination of sniffing and address spoofing that enables the compromise of a user's remote login session, thus providing an attacker unauthorized access to a machine with the privileges of the legitimate user. Address spoofing in IP is quite simple because the sender of an IP packet writes in the IP source address in the packet header. Attackers can send packets with any fake IP source address.

If a user is currently engaged in an interactive login session (e.g., through telnet, rlogin, FTP), a session hijacking tool allows an attacker to steal the session. When most hijack victims see their login session disappear, they usually just assume that the cause is network trouble and try to login again, unaware of the hijacking attack.

Popular session hijacking tools include Juggernaut and Hunt. The hijacking attack begins with the attacker sniffing packets of an interactive session between two hosts, carefully noting the TCP sequence numbers of all packets. To hijack the session, the attacker injects packets with a source address spoofing one of the hosts. The proper TCP

sequence numbers must be used for the attack to work, because the receiving host must be convinced to accept the faked packets from the attacker.

## Password Attacks

Password attacks enable unauthorized access to a machine or other resource with the privileges of the user associated with the compromised password. Passwords continue to be very frequently used for access control, despite their major weakness: if a password is guessed, an attacker could gain complete access. The most well-protected systems could be compromised by a single weak password. Understandably, many attacks are often directed at guessing or bypassing passwords.

The easiest passwords to guess are the default passwords installed by many operating systems and service applications. Extensive lists of default accounts and passwords are not hard to find by searching on the Web, and sometimes they are overlooked or ignored by system administrators.

Another easy password attack is a dictionary attack that, as the name suggests, takes advantage of the natural human instinct to choose passwords that are common words or names. The chance of finding passwords that are common words may not be as likely as in the past though, because modern systems are usually programmed with rules to prevent users from choosing easily guessable passwords. More sophisticated hybrid password guessing tools combine dictionary attacks with limited brute-force attacks. They begin with guesses of common words but then methodically add characters to words to form new guesses.

The most powerful password attacks, called password cracking, can be performed if the attacker can obtain the password file (Shimonski, 2002). Computer systems store a list of user accounts and passwords in a password file, but the information is encrypted or hashed for protection against attackers. If an attacker can obtain the password file, the attacker has the advantage of time (translating into more CPU cycles) to crack the passwords by brute force (i.e., attempting all possible combinations of legal characters). A few examples of password cracking tools include John the Ripper, Cain and Abel, Crack, Lincrack, L0phtcrack, Nutcracker, PalmCrack, and RainbowCrack.

A variation and extension of password attacks involves guessing usernames as well as passwords. Even if an attacker does not know a username associated with a given resource prior to beginning a password attack, many systems include commonly named accounts such as "Administrator" or "Guest". Automated attacks in particular, such as self-propagating worms, can incorporate password attacks that will guess both usernames and passwords when attempting to compromise a resource.

## Exploits

Exploits of vulnerabilities are a means of attack that enable unauthorized access to a system. Vulnerabilities are continuously discovered in operating systems and application software. A vulnerability is a description of a problem, which is not dangerous in and of itself. The danger comes when an exploit is written that takes advantage

of a vulnerability to compromise the security of the operating system or application. Usually vulnerabilities are announced at the same time with a patch for fixing the vulnerability. A vendor has knowledge of the vulnerability but holds the information from the public at large until there is a fix for the problem. However, the vulnerability is sometimes announced prior to a patch, in which case there is an important race to devise and distribute a patch prior to the creation of an exploit taking advantage of that vulnerability. In general, the time between the announcement of a vulnerability and the appearance of a corresponding exploit is shrinking (Turner, 2004).

One of the most common types of exploit, used particularly often by worms, is a buffer overflow attack. Attackers are drawn to this exploit because many applications and operating systems do not perform proper bounds checking and are thus vulnerable to a buffer overflow. Furthermore, if successful, a buffer overflow attack could lead to complete control of a target machine.

A well-known instance is a stack-based buffer overflow, or “smashing the stack” (AlephOne, 1996). During a function call, various pieces of data are pushed onto the program stack: function-call arguments, return pointer, frame pointer, and local variables. Normally, at the end of the function call, the pieces of data are popped off the stack, and the return pointer is used to resume execution of the main program. A stack-based buffer overflow depends on inputting more data than expected into the local variables. The excess data is written into the allocated buffer space and then overwritten onto the frame pointer and return pointer. If the excess data can be crafted carefully enough, the overwritten return pointer can be made to point back into the stack somewhere in the data input by the attacker. Hence, when the main program resumes execution, the attacker’s data (malicious code) will be run.

It might be observed that a buffer overflow attack requires careful coding and significant technical knowledge about the target processor architecture. Hence, buffer overflow attacks are not easy to craft from scratch, but pre-written exploits can be found and used even by novice attackers.

## Social Engineering

Social engineering is a time-tested, low-tech approach that continues to be effective for both the reconnaissance and the actual attack phases. A social engineering attack refers to a human interaction where social skills are used to trick the victim into a compromising action, such as revealing personal information or opening an infected e-mail message. Social engineering can be combined with many of the other attack types to compromise security for just about any purpose. Although social engineering attacks are simple in concept, they can be surprisingly effective if executed well.

In the past, the telephone was a favorite avenue for social engineering attacks. Attackers would call an organization posing to be an employee, customer, supplier, or auditor, trying to obtain proprietary information. Today, many social engineering attacks are carried out through e-mail, due to the low risk and low cost of mass e-mailing. Also, e-mail works across different computing platforms

and various types of devices (including handheld mobile devices). E-mail became the preferred medium after the success demonstrated by mass e-mailing viruses, such as the 2000 Love Letter and 2001 Anna Kournikova viruses. E-mail viruses typically offer a provocative reason to entice the recipient into opening (executing) an e-mail attachment, which results in a virus infection. More recently, e-mails might pretend to be security bulletins, bounced e-mail, notifications from an ISP or system administrator, or other official-looking messages.

Recently, a type of social engineering attack called phishing (password harvesting fishing) has escalated in frequency. Phishing attacks begin with e-mail seemingly from a reputable credit card company or financial institution that requests account information, often suggesting that there is a problem with an account or a transaction. These e-mails are carefully crafted to appear official and often include corporate graphics. The e-mails typically include a link directing the victim to a Web site that appears to be genuine, but is actually a facsimile. The purpose of the Web site is to capture any account or personal information submitted by the victim. An example of a phishing e-mail appearing to be sent from eBay is shown in Figure 5.

## Trojan Horses

Trojan horses are malicious programs that appear to be benign (analogous to the Greek wooden horse in the Trojan War). The purpose of the disguise is to entice a user into installing and executing the program. If executed, Trojan horses are capable of doing anything that other programs can do, running with the privileges of the associated user. Similar and related to social engineering attacks, Trojan horses can be combined with many of the other attack types to compromise security for just about any purpose. Today, Trojan horses are distributed by any number of stealthy ways including virus and worm payloads, peer-to-peer file sharing, and Web site downloads. Victims are often unaware of their installation.

The most worrisome Trojan horse may be backdoor programs, sometimes called remote access Trojans (RATs) because backdoors allow an attacker to remotely access a victim’s machine. Backdoors circumvent the usual access control security (e.g., login with password). Many backdoor Trojans are known and some are promoted for legitimate administrative uses, including Sub7, Back Orifice 2000, and Virtual Network Computer (VNC).

## Adware and Spyware

Adware is software to monitor and profile a user’s online behavior, typically for the purposes of targeted marketing. Adware is often installed at the same time as other software programs; when this occurs without the user’s knowledge, the adware (and the software with which it is bundled) is an instance of a Trojan horse. Even when the user is alerted to the presence of the adware (often buried in the ignored licensing agreement), adware can represent an attack on the privacy of the user and the confidentiality of the user’s data when information about the user is communicated back to a marketing organization. Adware is primarily an annoyance,

 To:

Figure 5: A fraudulent phishing e-mail pretending to be from eBay.

sometimes causing pop-up marketing windows during Web surfing.

A more serious and growing concern is another type of software that profiles and records a user's activities, called spyware. Similar to adware, spyware can sometimes be installed with a user's or system administrator's knowledge. For example, commercial versions of spyware are sold as means to monitor and regulate the online actions of children or an organization's employees. Often though, spyware can be installed stealthily on a machine as a Trojan horse or as part of a virus or worm compromise. Spyware can record keystrokes (also known as keystroke loggers), Websites visited, passwords, screenshots, and virtually anything done on a computer. After capturing data, spyware can communicate the stolen data by various channels (e.g., e-mail, FTP, upload to the Web, or Internet Relay Chat) to an attacker. Spyware, like adware, is an attack on user privacy, but spyware is also more likely to compromise confidential data for identity theft.

## Viruses and Worms

Viruses and worms are software with the key characteristic of self-replication (Grimes, 2001; Harley, Slade, & Gattiker, 2001). While there is some debate and blurring of distinctions between viruses and worms, common traditional definitions are the following:

- Viruses are program code that replicate by modifying (infecting) a normal program or file with a copy of itself.

- Worms are stand-alone programs that replicate by spreading copies of themselves to other systems through a network.

Traditional viruses are not complete programs themselves. When the host program or file is executed, the virus code is executed and takes over control to copy itself to other files. Usually human action is needed to execute the host program, so viruses are sometimes characterized as requiring human action to replicate. Although viruses were far more common than worms around ten years ago, worms have become predominant in the past few years. The increase in worms has coincided with the growth of computer networks. Today virtually all computers are connected to private networks or the Internet, which is an environment naturally friendly to worms. In particular, the widespread popularity of e-mail has made it easier for worms to spread across different computing platforms. E-mail continues to be the most popular vector for worm propagation today, though typically e-mail worms require user intervention to propagate.

Viruses have evolved in their complexity over the years, often in response to countermeasures put in place by anti-virus vendors. The first viruses often simply added their code to either the beginning or the end of the host file. In order to evade simple detection, viruses later began to intersperse their code throughout the host file. Another technique that viruses have adopted to evade detection is to encrypt their code within each host file instance, thus

making it more difficult for a signature of the virus to be developed. When antivirus programs began keying on the decryption algorithm as the signature, viruses became polymorphic, changing their decryption algorithm with each copy. Taking it one step further, some viruses have become metamorphic, i.e., they change their logic (not just the decryption algorithm) with each infection instance.

Worms that are standalone files have not had to evolve in the same way as file-infecting viruses. Functionally, a worm program must carry out a few specific steps to spread to another target after infection of a victim host.

First, an algorithm chooses candidates for the next targets. The simplest algorithm, which is used by quite a few worms, is to choose an IP address (32-bit number) at random. This is not efficient because the IP address space is not populated uniformly. More sophisticated target selection algorithms choose addresses within the same networks as the victim because local networks have shorter propagation delays to allow faster spreading. Other target selection algorithms may choose targets discovered from a victim's e-mail address book, mail server, DNS server, or countless other ways.

Second, many (but not all) worms will perform scanning of selected targets, for the same purpose as scanning done by human attackers. Scanning prompts responses from the potential targets that indicate whether the worm's programmed exploits can be successful. This process identifies suitable targets among the selected candidates.

The third step is the actual exploit or attack to compromise a suitable target. A common attack is to send e-mail to the target, usually carrying an infected attachment that has to be executed. More sophisticated e-mail worms are activated when their message is just previewed or read. Other worms might attack via file sharing, password guessing, or any number of exploits. It is also common for worms to combine multiple exploits or propagation vectors (blended threats) to increase the likelihood of success and rate of spreading.

The fourth step after successfully gaining access is to transfer a copy of the worm to the target. Depending on the exploit, a copy of the worm might have been transferred during the exploit (e.g., by e-mail). However, some exploits only create a means of access, such as a backdoor or shell. The worm takes advantage of the access to transfer a copy of itself via any number of protocols including FTP, TFTP, or HTTP.

An optional last step is execution of the worm's payload, if there is one. The payload is the part of the worm's program that is directed at an infected victim and not related to its propagation. The payload could be virtually anything, and not necessarily destructive. In recent cases, payloads have included: opening backdoors allowing remote access; installing spyware; downloading worm code updates from the Internet; or disabling antivirus software.

Both viruses and worms are becoming easier to generate with the introduction of virus and worm toolkits. For example, the VBSWG (Visual Basic Script Worm Generator) toolkit simplified the process of creating e-mail worms for attackers—the Anna Kournikova worm in 2001

was produced using this toolkit. Other toolkits are easily found searching the Internet. Toolkits enable advances in malicious code technology to become commodities, easily reused by less experienced attackers for their own purposes.

Finally, there is a convergence occurring between viruses, worms, and other forms of malicious code. For example, there are instances of malicious code that both infect files like a virus and drop standalone copies of itself like a worm. Viruses and worms often possess characteristics of a Trojan horse, especially when they use social engineering to trick a user into aiding propagation. And viruses and worms can be used to enable the other forms of attack discussed next, both spam and denial of service (DoS) attacks.

## Spam

Spam, the e-mail equivalent of unsolicited junk mail, has been a growing problem over the past few years. E-mail addresses are harvested from the Internet or generated randomly. They typically advertise a product, service, or investment scheme (which may well turn out to be fraudulent). E-mail is an attractive advertising medium in economic terms. Spammers can send enormous volumes of e-mail at much less cost than postal mail. The necessary equipment is modest: a PC, software, and an Internet connection. Even if the response rate is very small, a sizable profit can be made easily.

At the very least, spam wastes network resources (bandwidth, memory, server processing) and necessitates spam filtering at ISPs and organizations. It also wastes users' time to read and delete. The seriousness of the problem has steadily grown as the volume of spam has escalated.

A growing concern with spam is evidence of collaboration between spammers, virus/worm writers, and organized crime. A substantial number of worms have been used as a delivery vehicle for Trojan horses that set up "bots." Bots listen for instructions from a remote attacker or allow backdoor access. A number of bots under coordinated control is a bot net. Bot nets are being used for distributed DoS attacks or spamming. Moreover, spam is increasingly being used for phishing (as described earlier). Phishing attacks attempting identity theft with increasing sophistication suggests the involvement of organized crime.

## Denial of Service

Most people tend to think of DoS attacks as flooding, but at least four types of DoS attacks can be identified:

- starvation of resources (e.g., CPU cycles, memory) on a particular machine
- causing failure of applications or operating systems to handle exceptional conditions, due to programming flaws
- attacks on routing and DNS
- blocking of network access by consuming bandwidth with flooding traffic.

There are numerous examples of DoS attacks. A “land attack” is an example of starvation. On vulnerable machines with Windows NT before service pack 4, the land attack would cause the machine to loop, endlessly consuming CPU cycles. The “ping of death” is an ICMP Echo Request message exceeding the maximum allowable length of 65,536 bytes. It caused earlier operating systems to crash or freeze (that programming flaw has been remedied in later operating systems).

The “Smurf” attack is an example of an indirect flooding attack, where the ICMP protocol is abused to cause many response packets to be sent to a victim machine in response to a broadcast packet. It is indirect because real attacker’s address is not seen in any packets. It is also interesting as an example of amplification: a single attacker’s packet is multiplied into many packets by the recipients of the broadcast.

The most harmful flooding attacks take advantage of amplification through a distributed DoS (DDoS) network (Dittrich, 2004). A famous DDoS attack occurred in February 2000 against several Web sites including Yahoo, eBay, e\*Trade, and others. Examples of automated DDoS tools include Trin00, TFN (tribe flood network), TFN2K, and Stacheldraht. In addition, viruses and worms have been known to infect victims with DDoS agents.

DDoS attacks generally proceed in two phases. The first phase is stealthy preparation of the DDoS network. The attacker attempts to compromise a large number of computers, often home PCs with a broadband connection, by installing a DDoS agent (i.e., a Trojan horse). DDoS tools such as Trin00 and TFN set up a two-level DDoS network. A small fraction of compromised machines are designated as “masters”, waiting for commands from the attacker. The remainder of compromised machines are “daemons” waiting for commands from masters. The daemons carry out the actual flooding attack to a specified target.

## DETECTION AVOIDANCE PHASE

During reconnaissance or an attack, an attacker would naturally prefer to avoid detection, which could trigger defensive actions. After a successful attack gaining access or control of a target, an attacker would like to hide evidence of the attack.

## Evading Intrusion Detection Systems

Intrusion detection systems (IDSs) are designed to alert system administrators about any signs of suspicious activities. They are analogous in function to burglar alarms, a way to react in case intruders are able to penetrate preventive defenses (e.g., firewalls). Network-based IDSs monitor the network traffic and might be a stand-alone device or integrated in firewalls or routers. Host-based IDSs are processes that run on hosts and monitor system activities. IDSs are now commonly used by organizations. Naturally, an intelligent attacker would want to avoid detection by IDSs.

Without special precautions, an attacker could be easily detected by an IDS during reconnaissance because scanning tools are noisy. A port scan might involve thousands of packets, while a vulnerability scan could involve

hundreds of thousands of packets. These scans may have an obvious impact on normal traffic patterns in a network. Moreover, these scans are exactly the signs that IDSs are designed to look for.

Most commercial IDSs attempt to match observed traffic against a database of attack signatures (i.e., misuse detection). Hence, an attacker could try to evade a signature match by changing the packets or traffic pattern of an attack. One approach to changing the appearance of an attack is to take advantage of IP fragmentation. An IDS must be able to reassemble fragments in order to analyze an attack. An IDS without the capability for fragment reassembly could be evaded by simply fragmenting the attack packets. An IDS might also be overwhelmed by a flood of fragments or unusual fragmentation.

IDS evasion is also possible at the application layer. For example, an IDS may have a signature for attacks against known weak CGI scripts on a Web server. An attacker may try to evade this signature by sending an HTTP request for a CGI script, but the HTTP request is carefully modified to not match the signature but still run on the Web server.

Another strategy for evading detection by IDSs, or other monitoring products, is to simply overload them with common, unimportant events to mask the actual attack. “Flying under the radar” of an IDS is easy to do when thousands of meaningless port scans and ping sweeps are filling the operators’ consoles and logs, while a more sophisticated attack is executed.

## Covering Up

Covering up evidence after an attack is particularly important if an attacker wants to maintain control of the victims. One of the obvious methods is to change the system logs on the victim’s computers. Unix machines keep a running system log about all system activities, which can be viewed by system administrators to detect signs of intrusions. Likewise, Windows NT/2000/XP systems maintain event logs including logins, file changes, communications, and so on.

An attacker needs to gain sufficient access privileges, such as root or administrator, to change the log files. It is unwise to simply delete the logs because their absence would be noticed by system administrators searching for unusual signs. Instead, a sophisticated attacker will try to carefully edit system logs to selectively remove suspicious events, such as failed login attempts, error conditions, and file accesses.

## Rootkits

Rootkits are known to be one of the most dangerous means for attackers to cover their tracks. Rootkits are obviously named for the root, the most prized target on Unix systems because the root user has complete system access. If an attacker has gained root access, it is possible to install a rootkit designed to hide signs of a compromise by selectively changing key system components. The rootkit cannot be detected as an additional application or process; it is a change to the operating system itself. For example, Unix systems include a program *ifconfig* that can show the status of network interfaces, including interfaces in

promiscuous mode (or a sniffer). A toolkit could modify *ifconfig* to never reveal promiscuous interfaces, effectively hiding the presence of a sniffer. Another program *find* is normally useful to locate files and directories. A toolkit could modify *find* to hide an attacker's files.

Kernel-level rootkits have evolved from traditional rootkits. In most operating systems, the kernel is the fundamental core that controls processes, system memory, disk access, and other essential system operations. As the term implies, kernel-level rootkits involve modification of the kernel itself. The deception is embedded at the deepest level of the system, such that no programs or utilities can be trusted any more.

## Covert Channels

Although logs and operating systems can be modified to escape detection, the presence of a system compromise might be given away by communications. For example, system administrators might recognize the packets from an attacker trying to access a backdoor. Clearly, an attacker would prefer to hide his communications through covert channels.

A common method used to hide communications is tunneling, which essentially means one packet encapsulated in the payload of another packet. The outer packet is the vehicle for delivery through a network; the receiver has to simply extract the inner packet. The outer packet is usually IP for routing through the Internet. Also, ICMP messages and HTTP messages have been used. Since the inner packet has no effect on network routing, any type of packet can be carried by tunneling.

## CONCLUSION

Computer systems are common targets for a wide range of electronic attacks. Instead of an exhaustive catalog, this chapter has attempted a quick tour of the most pressing types of attacks in preparation for later chapters with more details.

An understanding of attacks is necessary in order to design strong electronic defenses. This chapter has not addressed electronic defenses, which will be covered by other chapters. We have seen that attacks can be viewed as a sequence of phases proceeding from reconnaissance to attack to covering up. An understanding of the methods and tools used in each attack phase can be helpful in fortifying cyber defenses.

## GLOSSARY

- Adware** A type of software to monitor and profile a user's online behavior.
- Backdoor** A means for an attacker to remotely access a system.
- Buffer overflow** An attack on programs without bounds checking that allows arbitrary attack code to be executed remotely on a target system.
- Denial of service** A type of attack on the proper operation of a system or service through exhaustion of system resources, exhaustion of bandwidth, exploitation of programming bugs, or attacks on routing and DNS.

- Firewall** A security system intended to protect an organization's internal network against threats from an external network, using configurable filtering rules.
- Footprinting** The initial process of discovering and identifying potential targets.
- Intrusion detection system** A device to monitor network traffic or system activities to search for signs of intrusions.
- Pfishing** A social engineering attack luring e-mail victims to a fake Website for the purpose of stealing personal data, such as account passwords.
- Port scan** A probe to TCP or UDP ports to discover whether a service is listening.
- Reconnaissance** The process of collecting information about potential targets in preparation for an attack.
- Rootkit** Tools to change system components to evade detection of an intrusion.
- Session hijacking** An attack to eavesdrop on an active session and take over control by impersonating one of the hosts.
- Sniffer** A program to passively intercept and copy network traffic typically on LANs.
- Social engineering** An attack attempting to persuade or trick victims into a compromising action, such as revealing
- Spam** Unsolicited junk e-mail, usually sent in bulk to many addresses.
- Spyware** A type of software to attack privacy by stealing personal data.
- Trojan horse** A program appearing to be useful but actually containing malicious functions.
- Virus** Program code that executes during the execution of an infected host program to copy itself to other programs.
- Vulnerability** A weakness or flaw that may be exploited by an attack to compromise a system or service.
- Worm** A self-replicating program that automatically attempts to copy itself to other systems across a network.

## INTRODUCTION

Warfighting, as experienced on today's battlefields, demands that soldiers have not only timely information but also the ability to move that information from place to place. Weapon systems and decision-making commanders, using this information, may be constrained by *communications bandwidth and data-flow rates*. Soldiers require large communications "pipes." It may be difficult to predict the precise nature of the future battlefield, but we may be certain that it will continue to be built on a complex array of digital and analog communication networks. Those networks will integrate hardwired and wireless links, as well as satellite and line-of-sight signals. Whereas infantry-based armies of the ancient world depended on roads and couriers to move messages, future armies will rely on redundant communications networks to move their messages (Leonard, 2000).

Protecting one's own information, while trying to capture information from the enemy, is the crux of information warfare (IW). This modern type of warfare may be thought of in terms of "command, control, communications, computers, intelligence and recognition" or C4IR. The aspects of command and control (C2), embodied in this acronym, involve opposing forces attacking each other's information systems and processes while protecting their own. This is the foundation of information

warfare; the intent is to create a condition in which the friendly side can obtain, assess, and disseminate important information to perceive the battlefield, control its forces effectively, and act decisively while denying the enemy to do likewise.

Probably the greatest amount of skepticism, regarding the future of information warfare, concerns the vulnerability of information technologies to actions by the enemy. This is especially true with *wireless* communications links because the extent of their operations has no borders; they are inherently insecure. The fear of someone hacking into battlefield computer networks, jamming a key signal node, or spoofing our vital GPS position-location devices is borne of a healthy regard for the extreme complexity of digitization and the use of commercial off-the-shelf (COTS) products. For example, the U.S. Army's combat divisions employ a vast array of computers, communications, sensors, and networks to achieve situational awareness and information dominance. With this complexity, comes vulnerability (Nichols & Lekkas, 2001).

This chapter focuses on the wireless side of warfare. We consider the *uniqueness* of wireless information warfare (WIW). Sources, taxonomies, and defenses of WIW are examined. We also incorporate a real attack/defense (A/D) scenario on a corporate "soft" target to emphasize the security concerns and the role of wireless information links.

## DEFINITION OF WIRELESS INFORMATION WARFARE

To understand WIW, it is first necessary to define the broader category of information warfare (IW). Information warfare has been defined in numerous ways by entities such as the United States Joint Chiefs of Staff (JCS) and the United States Department of Defense (DoD) and by experts such as Edward Waltz. Edward Waltz explains that IW covers the acquisition, processing, and dissemination of information or the exploitation of information to achieve dominant awareness in the battlespace (Waltz, 1998). The JCS expands on the definition to state that “Information warfare includes actions taken to preserve the integrity of one’s own information systems from exploitation, corruption, or disruption, while at the same time exploiting, corrupting or destroying an adversary’s information systems and in the process achieving an information advantage in the application of force” (JCS, 2004). The DoD definition continues the expansion to include the effect on processes and networks, in this definition of IW: “Actions taken to achieve information superiority by affecting adversary information, information-based processes, information systems, and computer-based networks while defending one’s own information, information-based processes, information systems, and computer-based networks” (Office of the Under Secretary of Defense for Acquisition and Technology, 1996).

Waltz uses the term *battlespace* in his definition of IW and although this term brings up military images, it should be recognized that the term *applies equally well* to military, commercial, and, to a lesser degree, private interactions with the outside environment. When such interactions occur via wireless means (e.g., radio, cellular phones, wireless networks, and wireless modems), then IW has entered the wireless arena and become WIW.

A former DoD definition of IW also delineates three central aspects of IW conflicts at the national level: information dominance, information attack, and information protection. DoD Directive Number 8100.2, April 14, 2004, specifically considers all of these aspects in terms of wireless technology, development, and deployment in detail (DoD, Number 8100.2, 2004).

Because of the complexity of both wireless communications and information warfare and definitions, background information and classification taxonomies for both of these topics are discussed in the following sections.

## TAXONOMIES OF INFORMATION WARFARE

The three primary classifications of IW covered in this document include classifications based on domains of information aggression; classifications based on confidentiality, integrity, and availability; and classifications based on exploitation and attack/defense. Each of these taxonomies is described below.

Information warfare taxonomies provide a framework to develop and categorize the elements of a given attack or defense plan, including the countermeasures, their

respective countercountermeasures, and the effects of both on the target systems. Evaluation of the effects on target systems is particularly important on wireless systems, because wireless systems include an additional area of impact—*degradation of performance*. Blocking or jamming a wireless system degrades system information performance (technical degradation or destruction) and effectiveness (utility or impact on downstream users of the information system under attack). Simple overloading can cause collisions in the delivery system.

Commercial firms and the public sector have a major impact on the development of IW concepts and IW weapons (e.g., countermeasures and countercountermeasures), partly because very few information-related technologies are export controlled in the United States or elsewhere. Information technologies include products or techniques such as network computing, intelligent mobile agents to autonomously operate across networks, multimedia data presentation and storage, and push/pull information dissemination. Information creation technologies are capable of creating synthetic and deceptive virtual information (e.g., morphed video, fake imagery, and duplicate virtual realities). Information security technologies include survivable networks, multilevel security, network and communications security, digital signatures, public key infrastructure (PKI), authentication technologies, wireless security end-to-end firmware, ASICS, and software. By understanding a taxonomy of IW it becomes possible to identify when and how to use the above tools and technologies that are so readily available.

### Classification by Domain of Information Aggression

Waltz presents a taxonomy based on domains of information aggression. Information resources may be attacked and must be defended across all three of these domains: national, corporate, and private. Table 1 provides specific examples of information warfare within each domain.

### Classification by Confidentiality, Integrity, and Availability

An alternative taxonomy may be constructed based on information warfare objectives, targets, attack objectives, countermeasures, and the responses of the targeted information infrastructures, all of which affect the capability of the information infrastructure to maintain the confidentiality, integrity, and availability of the data involved. Figure 1 shows the standard confidentiality, integrity, availability (CIA) requirements, and the associated objective of the countermeasures for each security requirement (Waltz, 1998).

The required security capability of any information system is to ensure the confidentiality, the integrity, and the availability of the information stored, used, or transmitted on the system. Any given IW operation on a wireless infrastructure or transmission vehicle may involve single, multiple, or complex combinations of specific tactical elements to achieve the basic IW objectives of disruption of availability, corruption of integrity, and exploitation of confidentiality.

**Table 1** Taxonomy of Domains of Information Aggression

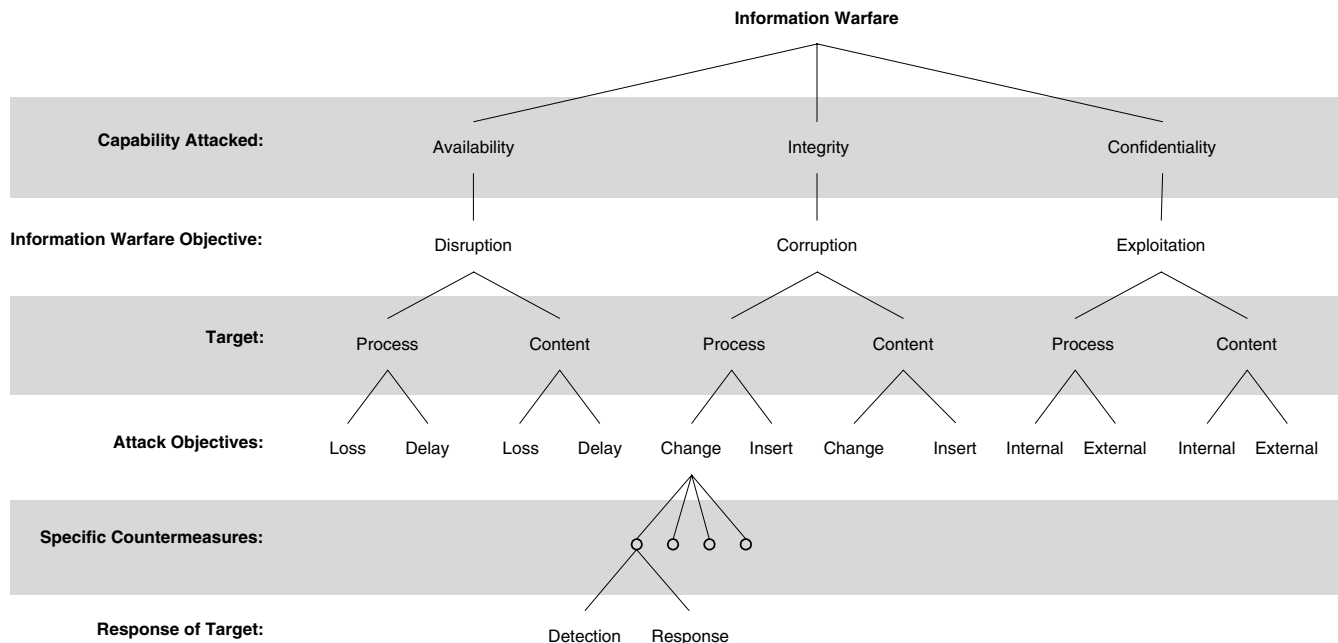

Domains of Conflict	Representative Examples
National (global, public, military sector)	Network warfare Economic warfare Political warfare Command-and-control warfare
Corporate (business sector)	Network-based information espionage, sabotage, and source intelligence Inside-agent espionage or sabotage Precision physical attack on information systems (EMP, etc.) Destruction of magnetic media Notebook computer theft Exploitation of former employees and competitor product, analysis Competitor trash capture and analysis Arson, other nonprecision attacks on information systems
Private (personal sector)	E-commerce fraud Net impersonation, spoofing, e-mail harassment, spamming Wiretapping and cell phone intercept Bank card impersonation, bank card and credit card theft Telephone harassment, "shoulder surfing," and PIN capture Credit card and database theft Computer destruction

Reprinted with permission from Waltz, Edward (1998), *Information Warfare: Principles and Operations*, Artech House, Norwood MA.

- **Disruption:** Disruption of information or denial-of-service (DoS) may be achieved by causing a loss or temporary delay in the information content or services. Jamming, overloading, and electromagnetic (EM) or physical destruction of wireless links or processors are examples of countermeasures (i.e., attacks) in this category.
- **Corruption:** Corruption of integrity may include changing (e.g., replacing or removing) or inserting

information to achieve effects such as deception, disruption, or denial. Examples of specific countermeasures in this category include viruses with corruption engines and payloads, database worms, man-in-the-middle (MIM) attacks on cryptographic protocols, and sensor spoofers.

- **Exploitation:** Exploitation of confidentiality may be accomplished at external levels (passive observation) or internal levels (gaining access to internal sensitive

**Figure 1:** Classification by confidentiality, integrity, and availability [reprinted with permission from Waltz, E. (1998) *Information Warfare: Principles and Operations*, Artech House, Norwood, MA].

information or services by breaching security services) to gain information intended to remain confidential.

These objectives are achieved by targeting a process or the content via a specific tactical element of attack objective. To achieve the attack objective, specific countermeasures (e.g., attacks) are selected and applied. As seen in Figure 1, the degree of effect of each countermeasure may be categorized by the response of the targeted information system, in terms of the detection of the attack and the response to the attack, as follows.

- **Detection:** (1) undetected by the target, (2) detected on occurrence, or (3) detected at some time after the occurrence.
- **Response:** (1) no response (unprepared), (2) initiate audit activities, (3) mitigate further damage, (4) initiate protective actions, or (5) recover and regroup.

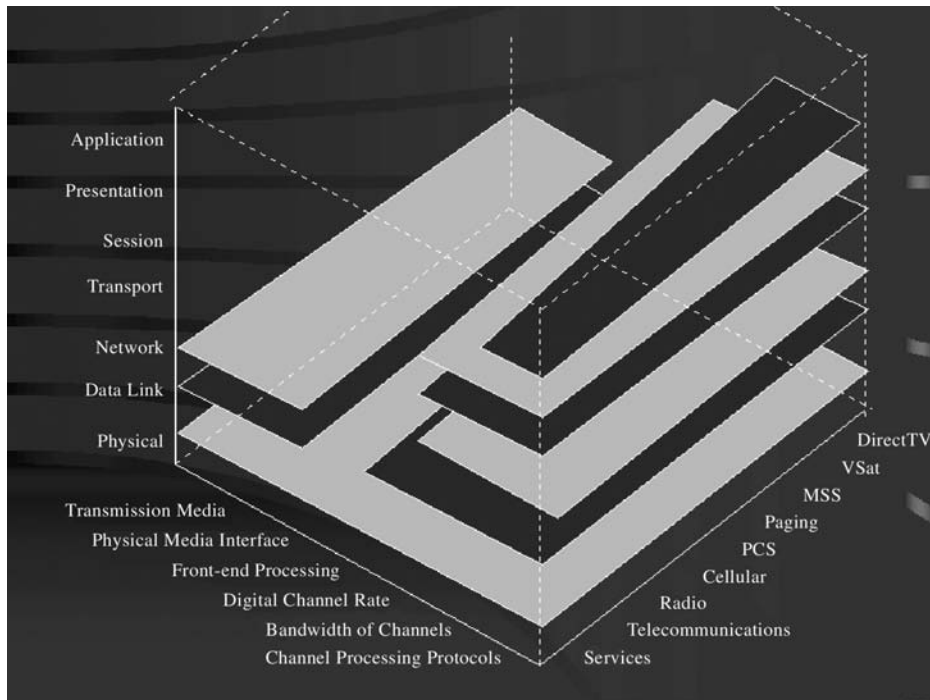

From the standpoint of a wireless system and infrastructure, this taxonomy includes only the *first effects*. One attack, even undetected, may have minor or political consequences, whereas another attack may bring immediate and cascading (second- and third-order) consequences. Figure 2 shows the interrelationships among the transmitting media ( $x$  axis), network layers ( $y$  axis), and major wireless services ( $z$  axis). It is conceivable that an attack at the lower intersecting layers could devastate the communication defenses of a given country because their services are not protected at the lower levels and multiple services

are available (not separated) on the same computer systems (Nichols & Lekkas, 2001).

## Relationship to Asymmetric Warfare

Figure 2 illustrates the importance and complexity of the concept of asymmetric warfare applied in the wireless arena. To fully understand its implications, we must make the mental bridge from the art and science of war in the kinetic world (where attrition is a prime driving force) to war in the digital world (in which a multitude of interrelated effects reign). Because information and knowledge are so critical for making good and timely decisions, the asymmetric tool of *information operations* will supplant the heavy reliance on traditional kinetic (bullets, bombs, and attrition) perspectives of conflict in the 20th century. Military and commercial services must prepare for future conflicts and transformation of war having an invisible, intangible, cerebral nature. People must consider and decide what information they need to make decisions faster and better than their enemies. People will need to determine how they access and use information and how they relate to the ends they seek—they must understand how to collect, process, and visualize information for its maximum usefulness. Autonomous intelligence agents (“cyberbots”) will provide the help that cyberstrategists need to identify critical variables and potential second- and third-order effects (Hall, 2003).

New opponents will increasingly use asymmetric strategy, tools, and tactics. They will design their actions to lead to effects (outcomes) that cut across social, political,

**Figure 2:** Interrelationships among the major wireless services, transmitting media, and network layers. [Reprinted with permission from Nichols, Randall K., Daniel J. Ryan and Julie J. C. H. Ryan (2000). *Defending Your Digital Assets against Hackers, Crackers, Spies and Thieves*, New York, McGraw Hill.]

military, commercial, financial, informational, and ecological systems. Their goal is to create the greatest second- and third-order effects possible, effects that eventually cause the country's will to implode. Asymmetric warfare involves intangibles—achieving offsets through surprise, shock, and ability to *influence information sources* to create aggregate effects in command and control systems, decision making of leaders, and the will of the public to support them (Hall, 2003).

Turning to Figure 2 again, and thinking about the asymmetric foes of the future, the author asserts that they will perform a sophisticated analysis of the stronger opponent's centers of gravity. They will seek to affect those centers of gravity indirectly but with significant impact, thereby affecting command and control (C2) to the point of decision—paralysis and creating conditions that make responses oscillate between impossible and inappropriate. Such an effort would be particularly powerful if the opponent timed such activities to occur at the moment of maximum vulnerability. An example of this idea would be to attack or manipulate a place (physical or more likely cyberspace) in which a confluence of communications, collection, automation, thinking and planning, and decision making occurs and whose role in activities is so important that if lost or adversely affected would seriously jeopardize security.

The United States has many vulnerability centers of gravity ranging from military command posts and headquarters to state and local emergency operations centers to incident command centers. Many of these vulnerabilities have arisen because of the need for mobility and wireless devices in the military. The situation is graver in the commercial organizations. Profit economics has tended to push commercial operations to group their wireless services (e.g., telecommunications, paging, cellular, radio, and TV) on the same enterprise servers and switches. Wireless security requires thoughtful analysis and involves many layers of defense. In general, it is not understood or performed competently. Knock out an enterprise server which coordinates multiple services and a foe brings on the second- and third-order effects that cascade and provide leverage (Nichols & Lekkas, 2002).

Wireless information operations could very well be the centerpiece of future asymmetric warfare and conflict. Why? People are more dependent on information and attendant communications to move the information, manipulate the data, and turn the information into learning. We are becoming wireless junkies, carrying multiple devices, requiring constant connections to the Web for our business, military, economic, and personal decisions. Wireless is the very reason we are so mobile and a prime reason we are so vulnerable. Adaptive foes cannot help but notice these vulnerabilities and will come at them with guile, cunning, and force.

### Classification by Exploitation and Attack/Defense

An alternate classification of IW explores the two main operational objectives that can be applied to wireless systems: (1) exploitation of information and (2) attack and defense of information.

Information exploitation operations are defined as the acquisition, transmission, storage, or transformation of information that enhances the employment of military forces. This objective is the same for commercial and private forces to a lesser degree or scope. Two actions are possible: (1) direct, such as interception of adversary communications to locate or extract information, or (2) indirect, such as surveillance and reconnaissance sensors with subsequent intelligence analysis (e.g., from eyes in the sky to private eyes).

Attack and defense of information objectives have four categories that apply to wireless systems (especially infrastructure): (1) deception, (2) security, (3) electronic warfare, and (4) information corruption, as defined below:

- **Deception:** misleading the enemy about actual capabilities and intentions. It is indirectly accomplished by conducting misleading (military, commercial, illegal) operations that hint at incorrect future plans or intentions. For example, millions of wireless messages were sent out over-the-air (OTA) before the Normandy invasion and a month-long electronic warfare campaign was carried out prior to the ground engagement by a coalition of troops during the first Gulf War.
- **Security:** fundamental measures used to keep the enemy from learning our capabilities or intentions. May be applied directly as defensive countermeasures such as INFOSEC countermeasures designed to deny direct access to wireless (or wired) networks or may be applied indirectly such as COMSEC and CI.
- **Electronic warfare:** the denial of accurate information to the enemy (or target) using the electromagnetic spectrum. Electronic warfare (EW) is accomplished directly by using electromagnetic energy to couple deceptive information into an information system. It can also be accomplished indirectly via jamming or by deceiving a radar or RF sensor through the transmission of spurious waveforms to affect the receiver. Another method is to knock out the synchronization of a cryptographic transmission over a wireless media.
- **Information corruption:** a potentially devastating attack because it is normally done without visibly changing the physical entity within which it resides. This is a direct attack using malicious logic by penetrating security boundaries of an associated wireless (or wired) network to gain unauthorized access. The effect is a force multiplier if the target relies on the corrupted information (Ryan, 2000).

## TAXONOMIES OF WIRELESS NETWORKS

The primary *raison d'être* for wireless communications is to enable mobility. Mobility means different things in the commercial and military worlds. Within the commercial/Internet community, the current notion of supporting host (user) mobility is via "mobile IP." Mobile IP supports host "roaming," where a roaming host may be connected through various means to the Internet. However, at no time is a host more than "one hop" (i.e., a wireless link, dial-up modem line, etc.) from a fixed network.

Supporting host mobility requires address management and protocol interoperability enhancements, but core network functions such as routing still occur within the fixed network.

The military vision of mobile IP is to support host mobility in wireless networks via mobile routers. Such networks are envisioned to have dynamic, rapidly changing mesh topologies consisting of bandwidth-constrained wireless links. These characteristics create a set of underlying assumptions for protocol design, which differs from those used for the higher speed, fixed topology Internet. These assumptions lead to somewhat different solutions for implementing core network functionality such as routing, resource reservation, and most importantly security (Feldman, 1998). Frater and Ryan (2001) provide recent treatment of the subject.

Two classification schemes for the mobility aspect of communications systems/networks are the network architecture classification and the mobility classification.

## Network Architecture Classifications

Wireless networks fall into four categories based on characteristics of the supporting infrastructure and network architecture:

**Wireless systems with a fixed supporting infrastructure.** (Most existing wireless systems fall into this category.) A mobile user connects to a base station, access point, or satellite gateway; the remainder of the communications path (assuming mobile-to-fixed communications) passes over wired networks. Wired connections refer to anything that is not wireless, including the twisted pair wiring in telephone local loops, coaxial cable, and optical fibers. Examples include cellular phone systems, cordless phones, and some satellite networks. In the case of the cellular and cordless phones, the path from a mobile user to the public switched network (or vice versa) involves one wireless “hop” (transmission/reception pair). Cellular telephony requires a fixed supporting infrastructure that includes base stations and landlines that connect the base stations to each other and to the rest of the public switched network (PSN). For a small satellite terminal, such as the mobile phones used with the geostationary American Mobile Satellite (AMSAT), a mobile user connects to a gateway in two hops—one hop up to the satellite repeater and a second hop down to the gateway terminal (Earth station). The gateway provides a connection into the PSN.

**Wireless systems in which users communicate directly through a satellite or satellites.** Military satellite networks such as the Defense Satellite Communications System (DSCS) use large satellite terminals. Mobile terminals having sufficient EIRP (effective isotropic radiated power) and G/T (ratio of antenna gain to effective system noise temperature) and lying within the same satellite antenna footprint can communicate directly to one another through the satellite repeater via two hops. Until recently, communications between small mobile satellite terminals required four hops—two hops to reach a satellite hub and another two hops (again using

the satellite as a repeater) to reach the destination terminal. Access to a gateway is required when a connection is being established for purposes of authentication and authorization.

**Wireless data networks that are fully mobile (i.e., any supporting infrastructure) is also mobile.** No such commercial wireless data networks currently exist. The U.S. military is currently investigating wireless network concepts involving repeaters on UAVs (unmanned aerial vehicles). A major advantage of the UAV-based relays over satellites is that they can be moved to any location where communications are needed. Furthermore, UAV relays would probably be under the control of the theater commander, whereas satellites are not. Geostationary satellites may be moved to support a local surge in demand (or to fill a void caused by the failure of another satellite), but this is generally not standard practice and should not be counted on (because of the expenditure of station-keeping fuels, reduction in the useful lifespan of the satellite, and the impact on the other users of the satellite; Feldman, 1998). Another concept involves cellular base stations on mobile vehicles; each vehicle would carry an antenna on a tall (e.g., 10-m-high) mast and would provide connectivity to users in its vicinity. High-capacity microwave trunks could be used to interconnect the mobile base stations, which would be necessary to provide connectivity to users served by different base stations. The high-capacity trunks would form a mobile network backbone; mobile-to-mobile connections would involve a single hop into or out of the backbone at each end. The base station vehicles would move with their forces but might have to stop moving to operate.

**Wireless systems with no supporting infrastructure other than the mobile nodes themselves.** Such fully mobile networks are called either mobile peer-to-peer networks or mobile mesh networks. New technologies such as Bluetooth and WiFi extend this taxonomy.

## Mobility Classifications

Wireless can also be classified based on the *extent of mobility*. Consider the general problem of providing connectivity to mobile users through a supporting infrastructure of base stations. One could use a single base station capable of covering the entire area or a number of base stations, each covering a smaller area. To make a network with multiple base stations perform like a network with only a single base station, one must interconnect the base stations and design the network so that connections are maintained when users move across the boundaries of base station coverage regions (“cells”). The transfer of user connections from one base station to another is called a handover. Base stations must track mobile user locations even when they are not connected so that connections can be established at any time. All of this implies considerable complexity. Cellular telephone networks best illustrate untethered mobility with a fixed base station infrastructure.

Cordless telephones represent an extreme form of tethered mobility in which the handset can only be used near

a specific base station (i.e., it cannot communicate with other base stations). Using a single base station to cover the entire area of interest offers significant advantages in terms of reduced protocol complexity (no need for handovers) and reduced computational load. However, several major drawbacks outweigh these benefits:

- As the size of the area to be covered increases, the required base station antenna height increases (to achieve line-of-sight to the mobile users). If the area to be covered is sufficiently large, then it might be necessary to put the base station on a satellite.
- As the size of the area to be covered grows, the EIRP requirements of the base station and of the mobile users increase.
- In a military network, a single base station that covers a large area becomes a critical node, as well as a high-value (and highly visible) asset that can be an attractive target for the enemy.

## UNIQUE ASPECTS OF WIRELESS INFORMATION WARFARE

Traditional threats to wireless communications exist in three areas: (1) interception, (2) illegal access to mobile services, and (3) interference in wireless networks. Interception attacks include data interception on the air interface, loss of confidentiality of user data, loss of confidentiality of signaling information, and loss of confidentiality of user identity information. Illegal access to mobile services generally revolves around some scheme to masquerade or impersonate a subscriber while using system services. Interference in wireless networks includes jamming, denial of service, and radio frequency disruption (Nichols & Lekkas, 2001). Because wireless networks have significant vulnerabilities, the question of wireless security naturally arises.

### Why Is Wireless Security Different?

There are *five fundamental differences* for wireless services: (1) bandwidth, (2) allowable error rates, (3) latency, (4) variability, and (5) power constraints. Many of these differences are seen at the network levels. Wireless networks are generally based on mobile devices that communicate via an electromagnetic transmission and reception method: (1) radio-frequency (RF) networks [HF, VHF, UHF (3MHz–3GHz)], (2) satellite communications (SAT) [SHF, EHF (3–300 GHz)], and (3) infrared (IR) (IrDA).

Wireless networks are generally characterized by low quality of service (QoS). Many employ small size devices with low power and low bandwidth options. Wireless networks are relatively more unreliable than wired networks, as packet losses occur more frequently in wireless networks. They exhibit high latency and variability because of retransmissions. Network limitations necessitate efficient communications and security protocols. Wireless designers consider a whole battery of variables in their designs: user expectations, interference, error rates, throughput, protocol overhead, compression, latency, battery life and energy-saving protocols, unknown network connectivity, “out of coverage,” “one way coverage,” chatty

applications/protocols, and “keep-alive messages.” The Internet has made the problem more complex, because wired Internet protocols (e.g. IPSec, SSL, or SSH) are typically not optimized for wireless networks. They are too chatty and carry too much overhead and the timeouts are too tight (Nichols & Lekkas, 2001).

We must recognize that secure mobile devices will have the following:

- Relatively low computing power (compared to desktop PCs).
- Limits on the type of cryptographic algorithms a device can support.
- Limited storage capacity.
- Power conservation requirement (imposed by functionality limitations).
- Fundamental restrictions on: bandwidth, error rate, latency, and variability.
- Small footprint and compact Input/Output interfaces:
- Limited display capabilities (graphical user interfaces are a challenge to implement across multiple display form factors).
- Limits on usability and user experience issues.
- Throughput sensitivities to protocol overhead and compression.

Most existing security technologies, protocols, and standards have been designed for the wired/high bandwidth environment. In many cases, they are not well suited for the wireless mobile environment because they have too much overhead and exhibit tight timeouts. Thus we redefine successful implementation of wireless security to mean: (1) adaptation and integration of existing solutions and infrastructure, (2) promotion of consistency and interoperability among a diverse spectrum of mobile and wireless devices, and (3) provision for a high level of security without detrimental impact on the user experience. In a wireless network, security features greatly differ between each of the protocol stacks, and security policy implementation and enforcement are dependent on the carrier. For example, Table 2 lists some representative differences/features in the OSI layer implementation used by wireless.

The bearer layers are used to secure the OTA link to prevent eavesdropping threats. The transport layer incorporates security for goals of confidentiality and authentication. However, the implementation is discontinuous because of the numerous transition points between wireless and wired protocols. Application level security provides for access control, authentication, confidentiality, and nonrepudiation.

Designing security into wireless services means that we require wireless communications/transactions to exhibit high levels of authentication, confidentiality, data integrity, and nonrepudiation. Companies offering wireless services infrastructure must provide customers high levels of assurances that their communications/transactions are secure. This becomes a nontrivial challenge when dealing with an assortment of networks, protocols, and devices.

**Table 2** Representative Differences and Features of Wireless OSI Layer Implementations

Layer	Representative Differences and Features
Physical	Provides signal scrambling for over-the-air (OTA) eavesdropping protection, using current technologies based on splitting the bit stream into small fragments called radio frames and then applying some form of frequency based scrambling technique. The radio frames travel on a spread spectrum of frequencies where each fragment is identified by a digital code known only to the device and the base station and no other device can receive the transmissions. For each connection, there are billions of code combinations available (example: CDMA network security).
Data Link and Network	Some protocols such as CDPD and GSM provide data confidentiality in these layers. CDPD applies encryption to each segmented datagram(s) prior to transmission. GSM uses a SIM (subscriber identity module) card to store a symmetric key known only to the mobile and the authentication center (AuC) at the carrier site. The key is used in both authentication and ciphering TDMA frames prior to transmission.
Transport	Secure Socket Layer (SSL): used extensively in Internet applications to secure TCP/IP connections. Public keys (e.g., RSA) are used to exchange a session key (e.g., RC4 or other algorithms) for bulk encryption. Incorporates an elaborate session/connection management protocol for session establishment, resumption, and termination. Designed for high-bandwidth connections; it is not optimized for high-latency networks. Enables client and server authentication via X.509 certificates. Unfortunately X.509 certificates have a large footprint and require significant computing power to process. SSL is not well suited for wireless applications.
Application	Application specific user authentication User ID and password Challenge-response authentication protocols Biometrics Message integrity Hashing of a shared secret and some message specific data to produce a unique MAC. (SHA1, MD5) Application level encryption: RC5, Triple 3DES, Rijndael, and so on Application level digital signatures for non-repudiation and authentication. (PKI), RSA, ECDSA (ECC).

Translating into mobile end-to-end security requirements, there must be confidentiality between mobile device and organization/user. Organizations must be able to authenticate sensitive transactions that have been signed by the user of the mobile device and vice versa. In addition, no intermediate entity (such as a mobile operator/carrier or middle-tier service provider) should be able to view, intelligently hear, alter, or store any of the confidential data/voice elements that make up the message or transaction. End-to-end security entails protecting voice/data with minimal cost, delay, complexity, and bandwidth overhead. Mobile and base stations must authenticate each other and allow distinct keys in a variety of environments. Two-way authentication is more effective using end-to-end encryption. Because no one organization can control the entire infrastructure, end-to-end connectivity needs to be independent of the underlying infrastructure. More and more functionality needs to be moved from the core and the perimeters of the networks to the edge devices. This needs to be done within a spectrum of emerging standards (IEEE 802.1b and family, wireless application protocol, WEP, Bluetooth, Future narrow band digital terminal, and so on (Nichols & Lekkas, 2001). Noonan provides a capable framework for hardening network wireless infrastructures from hacking (Noonan, 2004).

## Performance Measures and Key Design Trade-Offs

The performance of a communications system depends on design parameters whose values can be selected by the system designer and environmental parameters over which the designer may have no control. The relationship between these parameters and performance metrics of interest is usually complex. Changing any single design parameter tends to affect all performance metrics and simultaneously changing multiple designs parameters typically affects performance metrics in ways that cannot be predicted from knowledge of the single parameter effects alone.

The goal of the design process is to select the design parameters that achieve specific performance levels (or the best performance possible) subject to constraints on system cost. Cost is commonly viewed as a major performance metric. Speed to deploy and/or market is another constraint. Some of the choices the designer must make are essentially discrete or integer valued, that is, a selection among a small (or at least finite) set of alternatives. The three-way divide among narrowband, direct sequence spread spectrum, and frequency hop spread spectrum is an example of a situation wherein such a choice must be

made. Other design parameters are essentially real valued. For example, antenna size and transmitter output power can take on values from a continuum. Performance requirements of communications networks may also depend on a variety of other factors, including the types and quantities of traffic to be carried, the required availability and responsiveness of the system, the operating environment, and acceptable costs for the infrastructure and user equipment segments of the network. Some performance measures are specific to certain types of networks, or to certain types of traffic, and are inappropriate in other contexts.

Feldman (1998) shows why the wireless system design problem is difficult, for several reasons:

1. The designer is faced with a huge design space (each design parameter can be thought of as one dimension in a multidimensional space). Exhaustive exploration of this space is typically impractical. Thus, the designer must rule out many alternatives early in the design process based on experience to consider a smaller, more manageable set of alternatives that can be evaluated via simulation.
2. Current simulation tools at best tend to accurately model either the ISO physical layer (layer 1) on a single-link basis or the middle ISO layers (2–4) for networks involving multiple nodes but not both at the same time.
3. Even without detailed modeling of the physical layer, high-fidelity simulations of large networks tend to require large amounts of computation. One cannot scale down networks for purposes of performance evaluation because the behavior of networks involving small numbers of nodes may be very different.
4. The external environment in which a system must operate is often highly uncertain. Terrain type, presence of interfering equipments, jamming, and other external factors can all impact performance, but are difficult to accurately characterize and model. In the case of jamming, uncertainty about the threat is a major issue.

Military and commercial communications systems designers tend to choose different design approaches and thus reach different results primarily because (1) the expected operating environments are different, (2) the business practices and economics (including economies of scale) are different, and (3) robustness against jamming and low probability of detection (LPD) are of concern only for the military.

### Military-Unique System Requirements

The military has unique requirements that drive the design of military communications systems toward solutions that are markedly different from commercial systems. The most important of these involve (1) low probability of detection, (2) resistance to jamming, (3) *precedence* and *perishability*, (4) electromagnetic compatibility, (5) interoperability with legacy systems, and (6) security.

**Low probability of detection (LPD):** This is critical for activities such as reconnaissance because it reduces the

risks to forward spotters, and it is important in any situation where the enemy might employ direction-finding equipment to advantage.

**Resistance to jamming:** Although jamming of mission critical communications may have significant cost in both the commercial and military sectors, it is in the military arena that lives and equipment are most likely to hang in the balance and drive the need for jamming resistant communications.

**Precedence and perishability:** Military networks must be able to offer different grades of service to traffic based on *precedence level* (*priority*), which indicates importance, and *perishability*, which indicates when the information must be received to be of value. Optimal handling of precedence and perishability information is especially important when a network becomes congested. In packet-switched networks (Internet) network status and control information are not privileged. In general, commercial providers have rejected the idea of different grades of service. Commercial vendors do not provide for either precedence or perishability. Guaranteed QoS makes sense for wired networks with stable topologies and constant link capacities but is almost certainly unrealistic for fully mobile wireless networks, even without the added factor of hostile enemy actions such as destruction of nodes and jamming of links. Furthermore, guaranteed QoS requires admission control, which is unacceptable on the battlefield, except as a last resort. In critical situations, the ability to get something intelligible through in a timely fashion is probably the most important tactical user communication requirement.

**Electromagnetic compatibility:** For some military platforms, for command posts and for vehicles moving in formation, electromagnetic compatibility (EMC) can be a problem because of interference between equipment operating in close proximity (possibly on the same platform). This is the so-called co-site interference problem.

**Interoperability with legacy systems:** The military tends to retain computer and communications equipment in the inventory for relatively long periods. In the commercial world, users are expected to upgrade or replace equipment every 2–4 years. Because volumes of military systems tend to be much smaller than those of commercial systems, the costs of R&D, software, and testing have a much greater impact on the final per-unit cost of military systems than they do for commercial products. These higher costs in turn force the military to try to retain the systems for as long as possible. In addition, spectral efficiency is much more important to the commercial designer because of the cost factor. Higher spectral efficiencies tend to reduce the cost of equipment (Feldman, 1998).

Differences in frequencies of operation, waveforms, modulation and error control coding protocols, and message formats prevent the different military systems (e.g., radios) from interoperating. Interoperability is a prevalent problem in separate-service efforts that do not address the need for communications interoperability between services and between our allies for joint

and combined operations. The opposite is often true with commercial radios and upgrades.

Because cryptographic and ECCM algorithms in tactical radios have been implemented in hardware, and because the relevant devices and specifications are generally not made available to our allies, encrypted and jam-resistant tactical communications are problematic for combined operations.

Part of the solution for this problem may be software-based encryption; this permits one to change not only the keys but also the underlying algorithms. Software-based encryption is practical except perhaps at the highest data rates. Secrecy with respect to the encryption algorithms used in tactical radios is almost certainly a mistake. If we trust the algorithms, then there can be no harm in making them public. If we do not trust them, then scrutiny by academic researchers is one of the best ways to find flaws. This same basic reasoning about the secrecy of encryption algorithms can be applied to the pseudorandom sequence generators used in frequency hopping and direct sequence spread spectrum, but it does not apply to ECCM algorithms in general. The ECCM algorithms are not available to allies or enemies alike (Nichols & Lekkas, 2001).

**Security:** Security is often cited as an additional military-unique performance requirement. This is not accurate, however, because the business world is becoming increasingly concerned about the protection of information, and widespread commercial use of strong encryption and authentication (digital signatures) is increasing. There are, however, requirements unique to the military. Even if all user data are encrypted, transmission security is needed to protect traffic. Without this, an eavesdropper could perform traffic analysis. The commercial world rarely worries about this, even if data are protected by encryption. Secure multicast with frequent changes of multicast group membership may require mechanisms that are more complex for key generation, distribution, and authentication. The commercial world also needs to solve the problem of authenticating users who join a multicast, otherwise it would be impossible to have private conferences, pay-per-view events, and the like. However, the military authentication requirements are more complex. Military wireless networks must be capable of surviving in the event of the capture of equipment and software by the enemy (Feldman, 1998).

## SECURE COMMUNICATIONS SYSTEM DESIGN

The integration of security features into developing communications systems is by no means limited to encryption and key management. Beginning with denial of physical access to facilities and direct observation of critical displays of information (e.g., monitors, control panels, cipher mechanisms, even user keyboards and other input devices), proximity detection devices and alarm/alert systems are of primary importance. Design includes tamper-proof manufacturing techniques, automatically zeroizing of circuits processing sensitive databases (e.g., encryption

keying devices), and specification of trusted systems and software in accordance with established operational procedures. Truly trusted systems must be designed at the factory, secured during transit, assembled/installed within a secured area, and maintained by specially cleared personnel. The design must accommodate configuration management of its hardware and software components as well as sustain periodic security audits.

## OFFENSIVE INFORMATION OPERATIONS

Offensive information operations are malevolent acts conducted to meet the strategic, operational, or tactical objectives of authorized government bodies; legal, criminal, or terrorist organizations; corporations; or individuals. The operations may be legal or illegal, ethical or unethical, and may be conducted by authorized or unauthorized individuals. The operations may be performed covertly, without notice to the target, or they may be intrusive, disruptive, and even destructive. The effects on information may bring physical results that are lethal to humans. Waltz defines offensive operations as uninvited, unwelcome, unauthorized, and detrimental to the target; therefore, we use the term *attack* to refer to all such operations (Waltz, 1998).

For these reasons, this section must be considered within the context of *understanding offense to prepare for defense*: an understanding of the attacks it must face must precede security design. This section precedes the final section on defensive operations, developing the spectrum of attacks, whereas the next provides the complementary elements of protection and reaction.

Offensive information attacks have two basic functions: (1) to *capture* or (2) to *affect* information. Information may refer to processes or to data/information/knowledge content. These functions are performed together to achieve the higher level operational and perceptual objectives. Functions, measures, tactics, and techniques of offensive operations relating to the wireless component of IW are of immediate interest.

**Functions:** The fundamental functions (capture and affect) are used to effectively gain a desired degree of control of the target's information resources. Capturing information is an act of theft of a resource if captured illegally. Affecting information is an act of intrusion with intent to cause unauthorized effects, usually harmful to the information owner. The functional processes that *capture and affect information* are called *offensive measures*, designed to penetrate operational and defensive security measures of the targeted information system (Waltz, 1998).

**Tactics:** The operational processes employed to plan, sequence, and control the countermeasures of an attack. These tactics consider tactical factors, such as attack objectives, desired effects (e.g., covertness, denial or disruption of service and destruction, modification, or theft of information), degree of effects, and target vulnerabilities.

**Techniques:** The technical means of capturing and affecting information of humans—their computers,

communications, and supporting infrastructures—are described as techniques. In addition to these dimensions, other aspects, depending on their application, may characterize the information attacks.

**Motive:** The attacker’s motive may be varied (e.g., ideological, revenge, greed, hatred, malice, challenge, and theft). Though not a technical characteristic, motive is an essential dimension to consider in forensic analysis of attacks.

**Invasiveness:** Attacks may be passive or active. Active attacks invade and penetrate the information target, whereas passive attacks are noninvasive, often observing behaviors, information flows, timing, or other characteristics. Most cryptographic attacks may be considered passive relative to the sender and receiver processes but active and invasive to the information message itself.

**Effect:** The effects of attacks may vary from harassment to theft, from narrow, surgical modification of information to large-scale cascading of destructive information that brings down critical societal infrastructure.

**Ethics and legality:** The means and the effects may be legal or illegal, depending on current laws. The emerging opportunities opened by information technology have outpaced international and U.S. federal laws to define and characterize illegal attacks. Unlike real property, information is a property that may be shared, abused, or stolen without evidence or the knowledge of the legitimate owner (Nichols, Ryan, & Ryan, 2000). There are two issues of concern in the wireless arena. These are the network (computer) attacks and attacks on protective cryptography.

### Taxonomy of Attack Operations

The following may be considered malevolent at the functional level (Waltz, 1998)

- Target level of the IW model: perceptual, information, or physical
- Attack category: capture or affect

The attack matrix is divided into the two avenues of approach available to the attacker:

1. **Direct, or internal, penetration attacks:** Where the attacker penetrates a communication link, computer, or database to capture and exploit internal information, or to modify information (add, insert, delete) or install a malicious process.
2. **Indirect, or external, sensor attacks:** Where the attacker presents open phenomena to the system’s sensors or information to sources (e.g., media, Internet, and third parties) to achieve counterinformation objectives. These attacks include insertion of information into sensors or observation of the behavior of sensors or links interconnecting fusion nodes.

The object of attack defines two categories of attacks that affect information:

1. **Content attacks:** The content of the information in the system may be attacked to disrupt, deny, or deceive the user (a decision-maker or process). Content attacks are focused on the real-time data and the derived information
2. **Temporal attacks:** The information process may be affected such that the timeliness of information is attacked. Either a delay in the receipt of data or insertion of false data and passed on as legitimate.

Components of Howard’s process-based taxonomy are presented in Table 3 (reported in Waltz, 1999).

Howard constructed the taxonomy such that any simple attack can be categorized as a process, composed of the flow through the elements in the taxonomy (Howard

**Table 3** Howard’s Process-Based Taxonomy

Taxonomy	Description
Attackers	Six categories of attackers are identified: hackers, spies, terrorists, corporate, criminals, and vandals.
Tools	The levels of sophistication of use of tools to conduct the attack are identified.
Access	The access to the system is further categorized by four branches.
	Vulnerability exploited      Design, configuration (of the system), and implementation bugs are all means of access that may be used.
	Level of intrusion      The intruder may obtain unauthorized access, but may also proceed to unauthorized use, which has two possible subcategories.
	Use of processes      The specific process or service used by the unauthorized user is identified as this branch of the taxonomy.
	Use of information      Static files in storage or data in transit may be the targets of unauthorized use.
Results	Four results are considered: denial of service, theft of service, corruption of information, or theft (disclosure) of information.
Objectives	The objective of the attack (often closely correlated to the attacker type).

& Longstaff, 1998). Illustrated is the process thread of a network attack (state-supported agents are attackers) in which distributed (multiple-site) tools are used to exploit implementation vulnerabilities to gain use of the system. A specific system process is used to corrupt information in data packets in transit through the targeted computer to achieve a political objective of the supporting nation state.

This taxonomy clearly distinguishes the source (who), the objective (why), and the result (what) from the means (how). Each of these components is required to effectively detect, understand, and respond to attacks. The taxonomy is useful for real-time detection systems and is necessary for investigation and prosecution of attackers.

## Cryptographic Attacks

The most devastating attacks on a wireless system are those that compromise the cryptographic security of the system or network. The analysis and “breaking” of encryption is performed to penetrate cryptographic information security to

- Gain one-time access to information that has been encrypted (this information may represent knowledge, electronic funds, certification, or many other information representations)
- Commit one-time security forgery (e.g., to create a secure authentication)
- Spoof a user by presenting a valid authentication intercepted and copied from a valid user
- Fully understand an encryption and keying process to permit repeated and full access to traffic on the targeted system

Cryptanalysis attacks seek to locate vulnerabilities of the general cryptographic system. A fundamental tenet of cryptographic algorithm design is that a strong algorithm’s security rests entirely in the key and not the design details of the algorithm. A general rule of encryption security—Kerchoffs principle—is to assume that the attacker may know the encryption/decryption algorithms, but the system must remain secure by the strength of the method and security of the key. Cryptographic attacks against strong, known cryptosystems therefore seek to acquire or guess keys and understand the algorithms of unknown cryptosystems as follows:

- Key management systems are attacked to acquire keys or reduce the search space for brute force key searches.
- Key generators that format key variables and the distribution systems may be exploited if weaknesses occur in their design, implementation, or security.
- Random number generators that randomly select seed numbers to generate keys may be exploitable if they are pseudorandom and a repetitive (deterministic) characteristic can be identified. If deterministic sequences can be identified, key sequences can be predicted.
- Encryption system may be attacked if any portion of the path (plaintext or ciphertext) can be intercepted to perform an analysis.

Chapters “Public Key Algorithms” and “Elliptic Curve Cryptography” provide a description of the most basic cryptographic attack techniques, which include cryptanalysis and deception methods. Methods for attacking symmetric and asymmetric encryption systems differ. They are covered adequately in Chapters “Digital Watermarking and Steganography” and “Forensic Computing.” Chapter “Side-Channel Attacks” discusses interesting wireless threats and cryptographic attacks.

## DEFENSIVE INFORMATION OPERATIONS

Defensive information measures are also referred to as information assurance. Information operations protect and defend information and information systems by ensuring their availability, integrity, authentication, confidentiality, and nonrepudiation. This includes providing for the restoration of information systems by incorporating protection, detection, and reaction capabilities.

This definition distinguishes protection of the infrastructure by prevention of unauthorized access or attack (proactive measures) and defense of the infrastructure by detecting, surviving, and responding to attacks (reactive measures). The assurance includes the following component properties and capabilities (collectively known as CIA):

- Availability provides assurance that information, services, and resources will be accessible and usable when needed by the user.
- Integrity assures that information and processes are secure from unauthorized tampering (e.g., insertion, deletion, destruction, and replay of data) via methods such as encryption, digital signatures, and intrusion detection.
- Authentication assures that only authorized users have access to information and services on the basis of controls: (1) authorization (granting and revoking access rights), (2) delegation (extending a portion of one entity’s rights to another), and (3) user authentication (reliable corroboration of a user; and data origin). (This is a mutual property when each of two parties authenticates the other.)
- Confidentiality protects the existence of a connection, traffic flow, and information content from disclosure to unauthorized parties.
- Nonrepudiation assures that transactions are immune from false denial of sending or receiving information by providing reliable evidence that can be independently verified to establish proof of origin and delivery.
- Restoration assures information and systems can survive an attack and that availability can be resumed after the impact of an attack.

Information assurance includes the traditional functions of information security (INFOSEC), which is defined at two levels. At the policy level, INFOSEC is the system of policies, procedures, and requirements to protect information that, if subjected to unauthorized disclosure, could reasonably be expected to cause damage. At the

technical level, INFOSEC includes measures and controls that protect the information infrastructure against:

- Denial of service
- Unauthorized (accidental or intentional) disclosure
- Modification or destruction of information infrastructure components and data

INFOSEC includes consideration of hardware and software functions, characteristics, features, operational procedures, accountability procedures, and access controls at the central computer facility, remote computer, and terminal facilities; management constraints; physical structures and devices; and personnel and communication controls needed to provide an acceptable level of risk for the infrastructure and for the data and information contained in the infrastructure.

INFOSEC includes the totality of security safeguards needed to provide an acceptable protection level for an infrastructure and for data handled by an infrastructure. INFOSEC includes five components within communications security (COMSEC): emanations security (EMSEC), electronics security (ELSEC), transmission security (TRANSEC), computer security (COMPUSEC), and cryptographic security (COMSEC).

More recently, the aspect of survivability (the capacity to withstand attacks and functionally endure at some defined level of performance) has been recognized as a critical component of defenses included under the umbrella of INFOSEC and information assurance.

## WIW IN PRACTICE: VULNERABILITIES OF A SUBURBAN HOSPITAL

To put theory into practice, an assault on a suburban hospital (a vital commercial target) is presented in this section. This assault involves a unique hopping attack across the hospital's wireless local area network (WLAN). The assault incorporated three separate wireless attack scenarios. A "soft" commercial target was deliberately chosen to remind the reader that WIW applies to more than just military targets. *WIW may be described in terms of military goals and objectives but in practice, it can be used just as effectively in the private theater. The attack described is feasible and remarkably effective on both private sector and military installations.* The target hospital is a full service regional 1000-bed medical center that serves a major county in a U.S. state, providing services of all types, including cardiac, respiratory, and organ transplant operations, maternity and pediatric care, emergency treatment, and outpatient services. To protect the facility, we have removed pertinent identifications from this chapter (references to people, locations, and certain applications software). We have advised the security officers at this installation, prior to publication of our findings, of the vulnerabilities in their system. We have been advised that appropriate measures have been put in place to hamper these attack scenarios. Our purpose is to show that WIW is a highly effective means of leveraging effort in terms of damage to the target (in *any* arena employing wireless devices and communications).

## Security Measures for the Hospital

The hospital administrators are acutely aware of the precariousness of the open environment of a major hospital. Their primary attention is focused on three aspects of protection: (1) physical security, (2) personnel security, and (3) information security. These three aspects when integrated complement each other and provide a cumulative level of protection.

The main threat to the hospital is not focused on external or internal forces, though these areas are a primary concern. The hospital administration views the main daily threat to its information systems as a potential inability to keep up with maintenance and service to the information systems that support its health and life-saving mission. The largest part of the information management annual budget is for repair costs, supplies, and maintenance. The attitude of the administrators is that the information technology is mainly a means of functioning. The most recent risk assessments emphasized personnel and physical security as the primary countermeasures to human initiated attacks on the system. However, threats to information systems have been implemented regarding physical, personnel, and information processing and storage.

Hospital administrators are responsible for protecting patients' medical records as required by the Health Insurance Portability and Accountability Act (HIPAA). Although the primary intent of HIPAA is to improve access to health insurance, it is also concerned with healthcare fraud and abuse. One of its most important tenets for healthcare providers is proscriptions on how medical information may be used, disclosed, and accessed. The healthcare provider is responsible for the safeguarding of medical information while it is being stored and/or transmitted. There are significant penalties, both civil and criminal for the most severe cases of negligence or abuse (e.g., fines up to \$250,000 and 10 years imprisonment). Violation of HIPAA provisions may result in potential financial losses and may damage the hospital's standing within the community it serves and within the medical community. It is important that hospital administrators realize that the security and privacy issues of HIPAA impact both the business processes of the medical center operation and the information systems used therein.

## Target Wireless Operations

Each physician's area and nurses' station area is configured for wireless LAN operation. Use of 802.11g standards allows maximum usage of this feature, which is identification (ID) and password protected. The system transmitter-receiver supports bandwidth up to 54 Mbps and operates in the 2.4-GHz frequency range as an FCC Part 15 (low powered, unlicensed device). The radiating elements are fixed length whip antennas, vertically polarized, affording coverage over practically all of the hospital (including the cafeteria) except for the information systems area. Access to the Internet from an individual's laptop is accomplished by using a removable network card compatible with 802.11g standards. The hospital is transitioning toward replacing laptops with hand held wireless PDA type devices and Tablet PCs for e-mail, messaging, and paging. Physicians, nurses, and other essential personnel were the

first to be equipped with these devices, which affected a savings over separate pager, cell phone, and laptop costs. This move to a smaller size form-factor increases the problems with theft, loss through neglect, and unauthorized use when left unattended.

When using the WLAN, security is provided in primarily in two ways. The first is media access control (MAC) address access control lists. The MAC of the wireless network adapter used by a computer must be in the access point (AP) MAC database before the computer is allowed to connect to the AP (and therefore the WLAN). In addition, use of 64-bit (or 128-bit) wireless encryption protocol (WEP) provides for confidentiality of data as they traverse the WLAN. The newer Wi-Fi Protected Access (WPA) is planned as a near future upgrade, but no resources have been allocated for its purchase, installation, and maintenance at this time. Voice-over Internet protocol (VoIP) is not currently available in the hospital, mainly because of the adequacy of the present phone system; in any event, use of VoIP will increase the security challenges significantly.

The wireless transceivers (AP and antennae) are scattered in strategic areas of the hospital, including the cafeteria. They are categorized as “low” and “high” powered. Between buildings, the hospital uses a laser transmission and receiving system in a line-of-sight arrangement. The data rate is high, about 100 Mbs, thus allowing a seamless interconnection of information systems without reverting to cable with its attendant problems, such as deterioration due to aging. This system’s reliability has been proven in the past 3 years since its installation.

### VLAN Operations and Servers

The hospital operates an intranet that is divided into four subnets using virtual local area networks (VLAN). The VLAN supports approximately 240 users. Three of the VLANs are intentionally kept nonspecific in terms of functionality, thus the failure of a single subnet will not wipe out a given hospital function. Historically, the hospital has added additional VLANs as the existing systems exceeded their capacity. All of the VLANs are protected by a single LAN firewall. Access to particular servers is controlled by particular VLANs and thus there is some sharing of resources across the different VLANs. All workstations are connected to a 100-MB backbone to the servers located in a secure separate facility. Two of the VLANs have Internet capability as well as availability of a virtual private network (VPN) capability.

The hospital requires many different types of servers on its network: an e-mail server, Internet servers, a fire-wall server, database servers, and application servers are spread out across various floors. The hospital uses a heterogeneous network with five different types of Unix (SCO, Solaris AIX, HP-UX, and Linux), as well as three other operating systems (Windows, Novell, and Tandem).

Main servers carry the hospital core applications previously described. Department servers are used for nonstandard applications, such as tracking physicians’ certifications. Because of the integration of these systems, medical information constantly flows across the network.

### The Wireless Attacks

In this A/D simulation, the attack team (AT) posed as highly motivated and highly skilled terrorists with multiple objectives. The AT members are considered “long-term” assets whose objectives are to continue small, focused attacks against specialized targets to reduce public confidence in the infrastructure and public institutions. The AT does not mind being electronically “seen” because they want publicity related to how often/easy these attacks were, but they do not want to be “caught” (e.g., arrested). The AT is much more experienced than the average hacker or script-kiddie, who uses tools prescribed by more experienced people.

The AT attacks perpetrated against this hospital follow a standard methodology recognized within rogue groups of hackers, and professional penetration testers, as the “de facto” process for finding and exploiting vulnerabilities. This process may be used in both the logical/cyberenvironment and the physical world. Figure 3 illustrates the process flow, which is described below (Scambray, McClure, & Kurtz, 2001).

- **Footprinting:** This step includes target address range and naming acquisition as part of the overall information gathering process; the attacker attempts to gather as much data about the IT devices, network, and infrastructure as possible.
- **Scanning:** This step includes target assessment and identification of listening services and possible security vulnerabilities that may allow system access.
- **Enumeration:** This step includes more in-depth probing of systems and devices to identify valid user accounts and poorly protected resource shares.

Adapted from *Hacking Exposed: Network Security Secrets and Solutions Second Edition*, by Stuart McClure, Joel Scambray, and George Kurtz. Osborne/McGraw-Hill 2002

Figure 3: De facto methodology for wireless hacks.

- **Gaining Access:** This step is the exploitation of vulnerabilities to access the target once enough information has been gathered.
- **Escalating Privilege:** Once initial access is achieved the attacker attempts to gain full control of the system (administrator or root access).
- **Pilfering:** This step involves gathering information on a compromised system to gain access to other systems.
- **Covering Tracks:** This step involves backing out of a system leaving no proof that malicious activity occurred.
- **Creation of Backdoors:** This step involves leaving methods of gaining privileged access to systems for future actions on compromised systems.
- **Denial of Service:** This step involves preventing access to a target system, device, or service.

Each of the process flow items may be repeated in a “loop” fashion to continue building upon previous attacks. For example, once access is gained to a device more information about the system may produce additional vulnerabilities. Therefore, the attacker may go back to the footprinting, scanning, or enumeration phases. For each target, specific vulnerability *types* are targeted using automated and manual methods. Generally, the vulnerability types fall into eight categories:

1. **Kernel Flaws:** The kernel is the core of an operating system; it enforces the overall security model for the system. Any security flaw that occurs in the kernel puts the entire system in danger.
2. **Buffer Overflows:** A buffer overflow occurs when programs do not adequately check input for appropriate length, usually because of poor programming practice. When this occurs, arbitrary code can be introduced into the system and executed with the privileges of the running program. This code often can be run as root on Unix systems and SYSTEM on Windows systems.
3. **Symbolic Links:** A symbolic link or symlink is a file that points to another file. Often there are programs that will change the permissions of a file. If these programs run with privileged permissions, a user could strategically create symlinks to trick these programs into modifying or listing critical system files.
4. **File Descriptor Attacks:** File descriptors are nonnegative integers that the system uses to keep track of files rather than using specific filenames. Certain file descriptors have implied uses. When a privileged program assigns an inappropriate file descriptor, it exposes that file to compromise.
5. **Race Conditions:** Race conditions can occur when a program or process has entered into a privileged mode but before the program or process has given up its privileged mode. A user can time an attack to take advantage of this program or process while it is still in the privileged mode. If an attacker successfully manages to compromise the program or process during its privileged state then the attacker has won the “race.” Common race conditions include signal handling and core file manipulation.
6. **Configuration Management:** File and directory permissions control which users and processes have access to what files and directories. Appropriate permissions are critical to the security of any system. Poor permissions could allow any number of attacks, including the reading or writing of password files or the addition of allowable hosts and users in access control databases or list files (e.g., rhost files). Configuration management includes the documentation of removing/disabling/changing default accounts and passwords.
7. **Trojans:** Trojan programs include programs such as BackOrifice, NetBus, and SubSeven or they can be custom built. Kernel root kits could also be employed once access is obtained to allow a backdoor into the system at anytime.
8. **Social Engineering:** Social engineering is the technique of using persuasion and/or deception to gain access to, or information about, information systems. It is typically implemented through human conversation or other interaction. The usual medium of choice is telephone but can also be e-mail or even face to face. Social engineering generally follows two standard approaches. In the first approach the attacker (or the information assurance tester) poses as a user experiencing difficulty and calls the organization’s help desk to gain information on the target network or host, obtain a login ID and credentials, or get a password reset. The second approach is to pose as the help desk and call a user to get the user to provide his/her user id(s) and password(s). This technique can be extremely effective.

In practical example, we follow three different basic scenarios (e.g., attack vectors): (1) remote attacks on a wireless network, (2) attacks via trusted agents, and (3) attacks via public access pathways. Each scenario contains several different and specific methods of achieving the attack goal.

## EXAMPLE ATTACK: REMOTE ATTACK ON A WIRELESS NETWORK (VLAN HOPPING)

Many risks are associated with this attack scenario, including being spotted by hospital employees/patrons, detection by IT staff (because of the amount of probes/scans), and detection by passing police patrols. This attack scenario required the attack team to spend considerable time performing a site survey of the hospital (i.e., war driving/walking); the AT started with the footprinting process to bound the scope of our attack by detecting all devices, which gave us the sum of all possible targets of evaluation (TOE). To do this the AT used specialized hardware and software to monitor the 802.11 frequency spectrum—in this case, a 15-db directional yagi antenna, a 5-db omnidirectional antenna, a laptop running Fedora Core 1 Linux (<http://fedora.redhat.com/>), a PCMCIA Orinoco-based 802.11 Network Interface Card (NIC), and the wireless application Kismet (<http://www.kismetwireless.net/>). The site survey first involved patrolling the outside perimeter of the hospital in

Figure 4: Hospital AP and associated ranges.

a car equipped with the magnetic mount omnidirectional antenna. After using the omnidirectional antenna to survey all the operating wireless devices, the AT used the 15-db directional yagi antenna to probe further into the hospital (for interior devices). Figure 4 shows the approximate range of each one of the wireless devices that we were able to find; each name (color) represents a different hospital AP and the circles represent the range of the signal. Of the 85 access points listed in this image, at least 9 were APs unprotected by wired equivalency protocol (WEP).

Additionally, the AT pinpointed those devices identified with the omni that have the greatest number of clients so they could capture the highest number of Internet protocol packets; the more packets captured, the faster the AT could crack the hospital WEP protections. During this step, the team also captured all traffic between the detected APs and client devices and downloaded the AP

router tables using Kismet. To do this the AT was required to spend more time sniffing the network to gain the AP service set identifier (SSID) because the hospital had the AP set not to broadcast their SSID (the AT must have the SSID to connect to the AP later and attack internal devices). Capturing all the data traffic also allowed the AT to determine which devices were “static” or generally present on the network, which devices were AP/routers/repeaters, and which devices were transient clients (roaming doctors, nurses, etc.). In this step, the AT also built a logical diagram of the TOE; they gathered as much data about the wireless IT devices, network, and infrastructure as possible. The intent was to determine the interconnection and dependencies of devices.

When the AT finished the footprinting step, it tried unsuccessfully to connect to multiple APs. Because the AT had already cracked the hospital WEP key, it knew that MAC (media access control) filtering was enabled.

Only specified wireless clients were allowed to connect to a given AP. To bypass this protection the team picked the MAC of several authorized transient clients and connected once the transient devices disconnected from the network or moved to another AP. The AT then began the scanning step using NMAP (<http://www.insecure.org>) in “paranoid mode” with packet fragmentation (to help with IDS evasion) to identify logical ports and services available on each internal device connected to the AP (e.g., the wireless devices used by doctors and nurses). [The AT was aware that the hospital IDS might see the scan traffic and alert the sysadmins, who would in turn kick the MAC off the network. However, it should be noted that this did not occur. It is arguable that a better approach would be to deploy a passive network enumerator such as p0f found at <http://lcamtuf.coredump.cx/p0f.shtml>. However, passive enumerators such as p0f do not have as large an OS “fingerprint” database (because there is a smaller user base) and are not as accurate as active tools; therefore they are a tool of last resort]. The AT also started sniffing the traffic between AP and client devices to look for username/password combinations traversing the network unencrypted (using dsniff); they also cataloged associated vulnerabilities they found for later exploitation. To accomplish the scanning step the AT used tools such as nessus, superscan, nmap, and other general-purpose automated vulnerability tools so that they could identify vulnerable interfaces, such as WWW, FTP, SMB, and NETBIOS. Again, the AT was concerned about detection, so they also used the passive RNA scan to identify vulnerable interfaces. For the enumeration step the AT began in-depth probing of devices to determine accounts and poorly protected resources (e.g., file systems and network shares). During this stage tools such as smbgetusers, smbfff, nikto, whisker, and other specialized-/single-purpose tools were used. It was during this step in which it was determined that the hospital AP were acting as network bridges between the wireless network and the hospital local area network (LAN); once they had access to the AP the team was able to connect to the “wired” hospital network segments and numerous VLANs.

Once the AT finished the enumeration step, it had a baseline of possible targets and attack vectors for devices connected to the hospital wireless network. Their first attempt at attacking the attached systems was to probe the network segments looking for devices, which could be classified as some type of a server. Regrettably, each time the AT scanned a server their connection to the server was abruptly broken.

The AT assumed that the hospital has some sort of IDS/IPS protecting the servers. Therefore, the AT began concentrating on other devices such as portable monitoring stations, laptops, PDA/PED, and some mobile workstations. Here they used username/passwords obtained via our sniffer on the wireless network and root-level exploits (such as the RPC-DCOM vulnerability that allowed us administrator access to an unpatched Windows 2000/XP workstation). The AT systematically performed a search of storage devices (local and networked shares) for .doc, .xls, .jpg, .wpd, and so on and cataloged the directory trees; this information will be

used for further exploitation/access and possible social engineering.

For each workstation compromised, the AT also introduced a backdoor (Trojan) and key-logger package. The purpose was to gather additional usernames/passwords for other systems; whenever someone used our compromised systems to access another area, the key-loggers captured their username and password (even if the system is on another “wired” segment or VLAN). Once the AT finished attacking the Windows-based workstations, the team began application-level attacks against Linux/Unix servers with the purpose of introducing malicious code into the hospital network (including viruses, rootkits, and key loggers). In particular, they attacked the hospital e-mail server by attempting to send unauthenticated e-mail to hospital employees.

The AT purpose was twofold: (1) to impersonate hospital help desk/system administrators with the goal of using e-mail to perform password harvesting from users and (2) to introduce both destructive and nondestructive viruses/worms into the hospital systems via the primary e-mail server. For their first goal, the AT exploited vulnerabilities in the hospital e-mail server in which no authentication was required to send e-mail to anyone within the hospital domain. The AT was successful in this endeavor and gained multiple passwords from almost a dozen users before system administrators notified their users.

For the second goal the AT attempted to use the same vulnerability in the e-mail server to attach a virus to an e-mail prior to sending it out to hospital users; they were unsuccessful in this attack because the hospital had an antivirus program for e-mail servers installed on the system. However, while doing the enumeration of the internal network VLAN on which the AT were connected (via the AP and compromised hosts) the AT discovered a Solaris and HP-UX computer that had the POSTFIX mail transport agent (MTA) enabled with a default configuration. Using these computers the AT were able to successfully send out e-mail to domain users containing viruses and use these systems to send e-mails for password harvesting.

The last attack using the wireless system was a two-stage attack to gain access to sensitive and protected systems; the first stage was done earlier where the team gained administrative-level access to a Windows 2000/XP system on the LAN. The second stage of the attack was to use that system to gain access to the VLAN containing sensitive systems. To accomplish this, the AT installed a Trojan and specialized tools on the workstation that enabled them to launch attacks directly from the workstation targeting the VLAN switches. The AT used tools to sniff the wired network to find the VLAN switches and created a logical map. Once they had the TOE identified, the AT began scanning with Nmap, SNMPwalk, and so on to identify vulnerable ports and services. It was able to find multiple switches with default simple network management protocol (SNMP) interfaces (community names). The AT then used these interfaces to change the switch configurations so that the VLAN is supertrunked across interfaces (the VLAN the AT computer is connected to now has access to all VLANs). Once the team had access to the protected VLAN, they were able to identify a

vulnerable Windows 2000 server with generic cardiology software containing doctor id numbers, patient records, and other sensitive information.

## Attack via Trusted Agents

This scenario uses vulnerabilities found in the hospital IT interconnections to trusted sources such as remote employees, state/local systems, and transient employees (such as interns and volunteers). Each attack vector within this scenario required multiple stage attacks, each one building upon the previous until the result is gained (access to the internal hospital systems). Again, the intent is to determine the interconnection and dependencies of devices. For this scenario the AT extensively researched public information sources such as the hospital Web site (including the teaching/research areas), doctors associated with the hospital, and federal/state/local programs related to hospitals and hospital research. The attack team attempted to determine what the physical and logical bounds are of IT devices and what security controls may be in place for those devices. It used the information to determine where IT devices are located (what doctor's offices, where students and researches keep their laptops, etc.).

The attack scenario involved multiple preparatory stages of research before launching the footprinting, scanning, and enumeration activities. The first stage was defining the targets: the AT scoured the hospital public Web pages, newsgroups, and university pages for information. The AT was looking for any information that could tell them which doctors were related to the hospital, how interns/volunteers work at the hospital, and what types of research are performed. For the second preparatory stage of the attack, they did the same thing for the doctor's offices (including physical reconnaissance) and university-based research areas (areas on the university campus that dealt with work performed at the hospital). The third and final preparatory stage required team members to "interview" interns, volunteers, and nurses (at related doctor's offices) to gather information. Interviews took the form of casual chitchat and "formal" interviews for the "purpose" of writing school reports or newspaper articles.

Once the AT finished the research stage, it used the information to begin footprinting, scanning, and enumeration of the federal, state, and local government interconnects. The interconnects include fractional T1, 56k leased lines, and dial-up connections to federal, state, and local government agencies. The AT was able to gain very little information about the systems associated with the interconnects; either no information was available about the systems on the other end (e.g., they had their banners turned off) or the connections were repeatedly dropped. Attempting to identify vulnerabilities on these connections was an arduous task and each time the team failed.

Next, the AT began targeting remote access for doctors. It started this attack by performing information gathering off the hospital Web site (i.e., they manually scoured the site looking for doctor names, addresses, and phone numbers). The AT then performed Internet searches on those doctors to find personal or doctor office Web sites; each

site was then scanned/enumerated for vulnerabilities. The original plan dictated that once these attack vectors have been attempted they would then begin site reconnaissance of the doctor's offices to determine the possibility of a wireless Ethernet attack or physical break-in and local compromise of computers, which may provide information/access to hospital systems. However, during the enumeration of the public hospital Web site the AT found numerous entry points for remote access. Of these, the AT found a custom portal (a Web page created by hospital IT staff), which allowed access to the generic remote access application. The portal was vulnerable to a cross-site-scripting attack (XSS), which then allowed the team read access to doctor and patient records contained in the remote access software.

The AT's last effort in attacking via trusted agents was to surreptitiously obtain an intern laptop from the intern "sleep room." Although this was extremely risky, an AT member was able to dress in hospital "scrubs" and walk freely into the room itself. The AT person spent several hours posing as an external exchange student (a student from a different hospital and school) visiting the teaching hospital for a 2-day "familiarity" tour. During this visit, the AT member spent time talking to other interns gaining their trust and eventually asked to borrow one of the intern's computers when the intern went back to work. Once the AT intruder had access to the system, he booted into a bootable operating environment (Knoppix-STD), copied off all documents and data (including password files, etc.) onto an external USB drive and installed a keylogger/Trojan with the ability to send information to the AT via its own e-mail engine.

## Attack via Public Access Pathways

The AT used public Internet interfaces and remote access gateways to perform these attacks. When the AT members first began the footprinting, scanning, and enumeration steps against the public Web servers, their connections were dropped and eventually the team could no longer connect to the servers with those IP addresses. From this, the AT determined that some type of IDS/IPS was in place, which prevented initial attempts. Because of this, the AT changed the settings on their tools to "IDS Evasion" so that the scanning process would not be detected as quickly. This worked for a time but the AT found it was still being detected and eventually dropped/blocked from connecting. After several days of no activity, the AT launched a distributed denial of service (DoS) attack against the primary Web server. While this attack was being performed, the AT began footprinting, scanning, and enumerating the other servers. Because the system administrators and IDS/IPS were busy tracking the DoS, the team was able to continue uninterrupted. The AT performed the same basic process of scanning and enumerating these access paths as in prior scenarios in order to find vulnerabilities and exploit them. The AT used information from the other scenarios, including all hospital owned/related IP address space information, and footprinted all devices associated with the address space. Once the devices were footprinted, the AT began the scanning and enumeration process and attempted to exploit vulnerabilities such as

cross-site scripting (XSS), application-level vulnerabilities, and weak passwords.

The AT's first attack was again focused on the public hospital Web server. Here it found another custom portal allowing access into the remote access application. Because the AT was only able to obtain read access to an application on the Web server (the remote access application), the AT was unable to introduce any malicious code onto the server.

The AT again accessed the hospital e-mail server, this time from the Internet, and was able to send out e-mail posing as system administrators and help desk employees. Although the system administrators caught on to this faster this time, the AT was still able to get passwords from a couple of users. However, the users changed their passwords before the AT could take advantage of the vulnerability.

Last, the AT tried to gain access to protected systems by using VLAN exploitations against the switches and routers facing the Internet. Each time their connections were dropped/blocked and eventually the AT could not connect using their IP addresses. The AT assumed that the hospital IDS/IPS had automatically detected their exploits and was configured to drop the connection, and then the IP altogether, after successive malicious attempts.

## EXAMPLE DEFENSE: METHODS OF DEFENSE

The defense team (DT) reviewed the AT findings, failures, and successes and recommended the following computer security countermeasures be installed or hardened.

### Host-Based Intrusion Detection System (h-IDS)

Host-based intrusion detection system upgrades and installation were deemed an effective method of intrusion detection as compared to network-based intrusion detection systems. This is based partly on the fact that data transmitted over the hospital information system are encrypted; therefore, network-based IDS will not be as effective in identifying intrusion signatures. By configuring IDS in host-based mode, activities of each host (e.g., the various hospital servers) can be monitored. IDS within the IS has been configured to monitor the following (Peikari & Fogie, 2002):

#### In packet level

- Unexpected signature
- TCP/IP violations
- Packets of unusual size
- Low TTL (time-to-live)
- Invalid checksum

#### In application level

- CPU usage
- Disk activity
- User login

- File activity
- Number of running services
- Number of running applications
- Number of open ports
- Log file size

When any abnormality is detected, an alert should be sent to the centralized console in real time. This method has high sensitivity but unfortunately generates a great deal of data. It is important to carefully craft detection signatures to weed out what are called "false positives."

Other properties of IDS are log file monitoring and integrity monitoring. Log file monitoring that is used is Swatch (Simple Watcher; <http://www.SourceForge.net>), which can scan log entries and report in real time. An integrity monitor watches key system structures for change. For example, a basic integrity monitor uses system files or registry keys as "bait" to track changes by an intruder. The integrity monitor software used is Tripwire (<http://www.tripwire>), which can monitor the following (Peikari & Fogie, 2002):

- File additions, deletions, or modifications
- File flags (hidden, read-only, archive, and so on)
- Last access time
- Last write time
- Create time
- File size
- Hash checking

In addition, IDS can be configured for signature scanning and anomaly detection. The hospital now uses Snort for much of their IDS signature scanning (Snort 2.0). Caswell has written an excellent reference on Snort 2.0 (Caswell, Beale, Foster, & Posluns, 2003). Anomaly detection involves establishing a baseline of normal system or network activity and then sounding an alert when a deviation occurs. Because network traffic is constantly changing, such a design lends itself more to host-based IDS rather than network IDS (Peikari & Fogie, 2002): Snort also serves as an intrusion prevention system (IPS). At the time of detection, the system administrator can use Snort to block suspect IP addresses and kill the connections.

To maximize the effectiveness of a monitoring infrastructure, the DT recommended that everything be centralized within a few servers. This means using software that is modular enough to allow for different types of monitoring. Some of the most common programs used for this type of centralized monitoring include "HP OpenView" (Hewlett-Packard), "Netcool" (Micromuse), "Big Brother" (Quest Software), "WhatsUp Gold" (Ipswitch), and "Nagios" (Nagios). It was recommended that the system administrator plug in only those monitoring tools required by the hospital security policies to develop modules to accommodate needs (Liska, 2002) and to provide a means for real-time audit log monitoring.

### Firewall

In addition to the host-based IDS, the DT recommends that the network be protected by firewalls that are

configured in “invisible” mode. This set up adds another layer of security to the network. The disadvantage to a typical firewall is that it is a destination on the network. A traditional firewall has a public and a private network, so it has addresses that can be attacked. An intruder can attempt to launch a DoS attack against the firewall directly. If the firewalls are set up so that if the firewall application crashes, the server underneath simply becomes a router—directing traffic from the public to the private network, which introduces great vulnerability. If an attacker successfully launches a DoS attack against the firewall and is able to crash the application, that attacker now has full access to the network. The invisible mode helps to counteract some of these vulnerabilities and exhibits the following advantages (Liska, 2002):

- It is more difficult to build a network map, because the firewall does not provide an attacker with an IP address, therefore it is more difficult to find vulnerable devices on the network.
- The lack of a public IP address also makes it more difficult for an attacker to determine the type of firewall in place—making it harder to exploit weaknesses in the firewall.
- It is easier to add a firewall to an existing network, because invisible mode requires no change in network settings.

The main disadvantage to this mode is the increased difficulty in network troubleshooting. The firewalls act as a device on the network that is directly impacting traffic but do not show up as network nodes. This can sometimes create confusion and make spotting network problems more difficult. Firewall software used in the target hospital information systems are Checkpoint FW-1, Raptor, and Netscreen.

The hospital is using a hybrid system because it offers both packet filtering and a proxy firewall. Additional features suggested and recommended for the firewall are as follows (Bhasin, 2002):

- Incorporate tunneling functionality to implement a site-to-site encryption solution
- Log the activities of the network so that administrators can track events of the day
- Inclusion of built-in high-availability and graceful degradation to handle network risks that may arise due to unexpected breakdowns; this feature enables firewalls to transfer their operations to backup firewalls if there is a breakdown.
- Inclusion of mechanisms that can trap intruders; one such mechanism is the use of a honey pot, which entices intruders by displaying data that is not valid.

## Defenses for Wireless Networks

Attacks are performed systematically. There are steps that an attacker takes to gain access over the network eventually. There are countermeasures in place, which may safeguard the information system in each level. These

countermeasures may result in either the attacker running out of resources or becoming psychologically discouraged in pursuing his or her attacks against the target.

Physical security measures represent a first line of defense against physical surveillance by any attacker who attempts to roam around the hospital either during business hours or during nonbusiness hours. In either case, the physical security such as security guards and surveillance cameras may spot him. Security personnel patrol hospital premises on a regular basis. Any suspicious activity will be reported to the security office of the hospital. Depending on the circumstances, local law enforcement may be contacted. Closed circuit cameras are present both in the hospital and in the parking lot. Any suspicious activity spotted by the surveillance will be reported to the security office. The physical countermeasures will provide means to limit access to the hospital information system. This is called threat decomposition.

The data transmitted over the network are encrypted as an additional line of defense. Unfortunately, the data on a given machine are not encrypted, which is vulnerability. If an attacker cannot access the physical machine, he has to break many security measures to get access to the machine. The most common countermeasures in place for wireless networks are WEP and MAC address filtering. WEP is based on four 64-bit (or one 128-bit) encryption keys, which is not strong encryption per se. Coupled with MAC address filtering, it adds another layer to the security. WEP is a shared key protocol meaning both ends of the link use the same key. In WEP mode, a packet is added to the data called integrity check value (ICV) and the packet is encrypted via an RC4 encryption method. Key IDs (for decryption) and initialization vector (IV) are added to the packet in unencrypted form and sent to the receiver (Edney & Arbaugh, 2003). Hospital policies require daily review of audit logs to detect any malicious activities. In case of malicious activity detection, system administrators are charged with changing the WEP keys and blocking all the MAC addresses until the spoofed MAC has been detected and blocked.

Considering the mechanics of WEP, it is not a secure protocol. WEP is vulnerable to many attacks.

- **Challenge Response Mechanism:** WEP authentication relies on a challenge/response mechanism. First, the AP sends a random string of numbers. Second, the mobile device encrypts the string and sends it back. Third, the AP decrypts the string and compares it to the original string. It can then choose to accept the device and send a success message. The key used for this process is the same WEP key used for encryption. The operation does not authenticate the access point to the mobile device. Therefore, a rogue access point can pretend it was able to check the encrypted string and send a success message without ever knowing the key. There is no token provided to validate subsequent transactions, making the whole authentication process rather ineffective. In addition, during authentication the access point sends a random string of 128 bytes. The mobile station encrypts the string and sends it back. WEP encryption involves generating a sequence of pseudorandom bytes called the

key stream and XOR-ing it with the plaintext. So anyone watching this transaction now has the plaintext challenge and the encrypted response. Therefore, simply by XOR-ing the two together, the attacker has a copy of the RC4 random bytes (Edney & Arbaugh, 2003).

- **Frame Capture:** An attacker with a wireless sniffer that is able to capture all the frames sent between an access point and a mobile device. At the time of log in, the server sends a login message and a legitimate user enters a username and password. The attacker cannot see the file because it is encrypted; however, at a later time, the attacker can send a copy of the message the legitimate user sent to the server (replay). The access point passes the message to the login server, which accepts it as a valid log in, because it was encrypted by the correct key. The attacker can thus successfully log into the network and the server. WEP has no inherent protections against a replay attack (Edney & Arbaugh, 2003).
- **Direct Key Attack:** This is a weakness inherent in RC4 encryption, which is often referred to as a “weak key” vulnerability. WEP does not protect against this weakness. An attacker can directly attack a WEP encryption key and, within a short period, reconstructs the key.

The following are a list of methods to protect against WEP vulnerabilities. However, these methods are not perfect. WEP is still far from a reliable security countermeasure.

- Use of a combination of SSID (with broadcast disabled), WEP, and MAC address filtering to secure wireless network.
- Segmentation of wireless LAN traffic. If possible, all access points plug into the same switch or group of switches. Keeping WLAN traffic segmented in this manner helps to limit the damage an attacker can do, if the WLAN security is breached (Liska, 2002).
- Changing of WEP keys on a periodic basis or whenever the system administrator detects probing into the network.
- Limitations on the number of copies of a message that can be accepted. This is a function of the wireless security protocol.
- Termination of the wireless network when not in use.
- Changing of all the hardware default passwords like routers and switches.
- Modification of WEP key lengths from 64 bits to 128 bits.

It should be expected that a determined attacker would break WEP and get access to the wireless network. The countermeasures in place to protect the wireless network will likely fail. However, other countermeasures in place will assist in protecting the network and detecting the attacker.

To better secure the wireless network, an upgrade of the hardware and software to WAP or even better to RSN (robust security network) is recommended. Another technique, which can add security to the network, is the use of

a DMZ (demilitarized zone). By doing this, WLAN is in a semitrusted zone that is expected to be attacked by hackers. By operating with the mentality that the WLAN could already be owned, a more appropriate plan can be taken about who and what is allowed to access the internal network. However, although this type of protection can help protect internal resources, it will not protect the wireless network users. Therefore, the DMZ should be just one part of a wireless security plan (Peikari & Fogie, 2002).

Configuring access points to use RADIUS/LEAP to authenticate users can further enhance wireless network security. A user connects to an access point and the network card authenticates using SSID, WEP, or both. A RADIUS request is then forwarded from the access point to a RADIUS server. The RADIUS server authenticates the user, who is now able to pass traffic across the network. For redundancy, a second RADIUS server can be added to the access point. If the primary server fails, users will be automatically forwarded to the secondary server (Liska, 2002). Using RADIUS in conjunction with a VPN is a powerful, but expensive, solution to the problems associated with WEP. In this configuration, the 802.11 link is used simply as a transport mechanism. Network access, user authentication, and data encryption are handled by the VPN.

## Defense against Information Pilfering

An attacker can penetrate the network by breaking WEP and spoofing a MAC address and start probing the network. Correct IDS monitoring configuration will detect these probes. Assuming the attacker gains access to the network via a spoofed MAC address, if the attacker attempts during business hours to probe the IS, his behavior may deviate from the norms. Because the legitimate user is using his or her account to perform daily activities, there are chances that an attacker can be detected by employees or system administrators because of unfamiliar behavior. Each user will only have access to particular sections of the IS. Unusual behavior such as accessing areas where the user would not normally access may cause an IDS alarm if the traffic patterns are unusual enough. If an attacker attempted to perform his probing at night, it would be easier for system administrators to detect the probe via time restricted login policies and the typically lower amounts of network traffic. As expected, appropriate monitoring policies that are enforced present a formidable deterrence to an attacker. All server activities are monitored because of hospital policy. As a result, an attacker will have a hard time searching through network and local shares to catalog directory trees. If the spoofed MAC address is not permitted to perform these activities, the IDS will set a flag to the system administrator in real time. The system administrator will detect and block the IP address and kill the connection. Therefore, for this attack, the countermeasures in place will effectively defend against the attack and the attacker will be stopped.

In our example, however, the AT occupied the system administrators with the DoS attack on the primary Web server and has already gained access to the secondary Web server. The IDS has been distracted by the DoS attack. Thus, the system administrator has ignored

the activity logs on the secondary Web server. The attacker can continue his DoS attack on the primary server and possibly keep his activities on the secondary server undetected. Therefore, the attacker may be successful in his attack.

### Defense against Malicious Code Introduction

In this attack, the attacker tries to introduce malicious code into the system by installing RAT backdoors. There are countermeasures in place to prevent the attacker from succeeding in this attack. The attacker can get access to the primary mail server and sends out e-mail from that server because the mail server does not require SMTP authentication. While the attacker uses the mail server to send out his e-mail with malicious codes as attachment, the antivirus software installed on the mail server (Sophos mail server A-V software) will detect and stop the e-mail. There are especially virulent attacks possible and the DT was familiar with Young and Yung's work on Malicious CryptoVirology (Young & Yung, 2004)

There are different methods to secure mail servers in the hospital (Liska, 2002).

- To enhance the security of an MTA (mail transfer agent), the system administrator should limit the range of IP addresses that can use MTA as a mail relay. An MTA cannot be closed off to all outside connections, because it has to be reachable by other servers that are sending legitimate mail to users on the network. Only users within the hospital network should be able to send e-mail to remote mail servers using the MTA. The administrator should use the domain name as the determining factor, allowing users to relay mail through the mail server if the "from address" matches the hospital's domain name. However, it is too easy to bypass this security measure by forging the originating address in the mail program.
- Another method of MTA security is POP-before-relay. Before a user can connect to send mail, he or she must first connect to the POP mail server and authenticate against it. If authentication is successful, that user's IP address will be allowed to relay for a set period, usually 5–15 min.
- All the unnecessary accounts on the mail server have to be removed. In addition, the number of accounts on the mail server has to be restricted. Administrator should create a group on the mail server that is reserved for mail users. The group should have no access privileges to the server, only the ability to check e-mail. If the mail group is tightly controlled, with very restricted access, then none of the users should be able to cause any damage to the server.
- To increase security for the mail servers, the hospital mail server can be switched from mail authentication to authenticated post office protocol (APOP). APOP functions in the same manner as POP mail, but it encrypts the user's password using the MD5 one-way hash algorithm. APOP also requires a separate authentication database, so that even if a user's password is compromised, an attacker will not be able to gain access to the rest of the network.
- A more secure solution for POP or IMAP (Internet message access protocol) sessions is to connect over a TLS (transport layer security) session. TLS is a form of encryption, based on Netscape's SSL. A certificate is generated and submitted to a certificate authority. Afterward, the certificate is installed on the mail server. The mail clients are configured to use TLS (or SSL, depending on the client) encryption when connecting to the mail server. Using this method, not only is the password encrypted, but the entire session is encrypted as well. This provides the greatest level of security. TLS-encrypted POP and IMAP sessions operate in the same manner that HTTPS-based encryption does. The disadvantage of TLS encryption for POP or IMAP is the extra load of the network by continuously encrypting and decrypting POP or IMAP sessions. To solve this problem, a larger-user network with TLS should implement an SSL accelerator from Intel, Nortel, and Cisco. Using an SSL accelerator in conjunction with TLS authentication of POP or IMAP sessions will increase security without negatively affecting the server's performance.
- The hospital's policy must implement restrictive mail scanning. Currently, all the attachments of the e-mails are scanned for viruses or worms. Hospitals should also scan e-mails for UBE (unsolicited bulk e-mail, also referred to as SPAM). The administrator has to perform checks to determine false-positive and false-negative rates by using UBE scanning. In addition, the system administrator should review blacklists that are publicly available to set restrictions for receiving e-mails. Hospitals can stipulate policies for content scanning to assure avoidance of information theft by hospital employees.

### Attacker Identification

Pipkin provides the following advice on attacker identification:

A system that has been compromised is likely to be attacked again. Monitoring the restored systems will help verify that the improvements deter future attacks and can assist in the gathering of information about the attacker if he returns. The monitoring should include the services that were compromised, the processes that were used to compromise the system originally, and the connections for other systems that were compromised. The restored system should be placed at the highest level of monitoring for a period of time after the attack to help restore confidence in the system. (Pipkin, 2002).

### Defense from Attack via Trusted Agents

These attacks are performed remotely. The hospital cannot control the access points that an attacker uses to penetrate into the hospital information system because there is no control of those resources from the hospital. If an attacker can break into the third-party machine and gain access to the hospital's system, he can easily bypass all the security measures in the hospital.

## Defense against Remote Doctor Offices

The DT noted that remote access to the hospital information system was gained through Web-based one-way SSL. Remote connections are based on username and password. There are computer policies that passwords have to contain a certain number of letters and numbers. System administrators can program the “passfilt.dll” file in Windows NT or 2000 to increase the security of passwords. In addition to creating policies for passwords, the hospital information system is equipped with “Passfilt Pro (Altus Net)” software, which increases the security of the passwords on the network so the attacker cannot brute-force the passwords or, if he does, it will take him a much longer time to break the password. However, if the attacker again gains access and harvests the password from the remote machine, he can easily bypass the SSL and all the password protection countermeasures. In this attack, the attacker will gain access to the system and break into the remote machine. He will obtain the password and gain access from the hospital remote access system. Because the attacker intrudes as a legitimate user, countermeasures fail to prevent or detect intrusion and his presence is undetected.

To mitigate the risk of intrusion via remote connections, the hospital can upgrade the system to robust authentication methodology. The hospital IS can be accessed remotely via hardware token VPN or usage of PKI. Either method requires a token for the user to access the network remotely. The hospital can implement products such as “RSA SecureID (RSA)” for remote connection.

## Defenses against Attacks via Public Access Pathways

In this scenario, the attacker is taking advantage of one of the weakest links in the hospital information system: Web servers. With the present architecture of the Web servers in the hospital, the attacker can easily gain access to the IS. The only countermeasures on the Web servers are IDS and firewalls. The attacker can bypass the firewall, create a distraction for the IDS, and bypass the IDS as well. In this scenario, the attacker realizes that Web servers are protected by IDS. Thus, he will run a DoS attack on the primary Web server. The effort of the system administrators will be focused on blocking and stopping the DoS attack and bringing the system back online. Meanwhile, the attacker has gained access to the secondary Web server and accessed the databases.

There are architectures and methodologies that can improve the security of the Web servers (Liska, 2002).

- The Web server should be a single-use server. Only personnel who absolutely need access should have it. A staging server can be used for further restricting access to the actual Web server. The staging server is a replica of the Web server. It should have the same operating system, same patches, same file structure, and all of the same software as the Web server. Content destined for the Web server is loaded to the staging server and then pushed to the Web server using software like “RedDot

Solution’s Content Management Server (CMS) (Red-Dot).” Different users or departments in the hospital are given accounts on the staging server. The accounts are used to upload content to the staging server. The content is pushed from the staging server to the actual Web server using a separate account to which the users do not have access. The Web server is configured to only allow the staging account access from the IP address of the staging server. The staging server should be placed on a separate VLAN than the Web server. The staging server should be part of a private VLAN that is not accessible through the firewall. This will prevent an attacker who does gain access to the Web server from getting to the staging server and using it to launch additional attacks. Because the staging server is the only machine that will send content to the Web server, hospital administrators can restrict the ways of accessing the server. Content can be uploaded using either Secure Copy (SCP) or Secure FTP (SFTP). Standard FTP ports should be disabled on the server. If other forms of access are required, they should only be allowed from the staging server, and those ports should be blocked to the server through the firewall.

- Content on the Web server should be stored on a separate partition from the operating system files. The default files from programs installed to assist in serving Web pages (i.e., Apache, Internet Information Server, and ColdFusion programs) should be deleted. If the content of a Web site is largely static, there should be restriction on HTML pages and setting the file permissions as readable but not writable and not executable. If Web site content is dynamic and database driven, the files will have to be readable and executable but not writable.
- One of the weaknesses for the Web servers is possible exploitation of cross-site scripting (XSS). The hospital should implement script security to mitigate this vulnerability. This can be performed by three computer policies: A script should never accept unchecked data; all inputs should be validated; scripts should not rely on path information assembled from the server. “Administrator should hard code data paths directly into the scripts. Hard coding path information into a script prevents an attacker from manipulating the PATH variable to display files on the web server” (Liska, 2002). (It is arguable that the trade-off between security and usability will tip the scale in favor of usability in many situations. A more reasonable approach might be teach the hospital’s developers to code securely or to use a Web-based application scanner or red-team to audit the Web applications.)
- Clustering and network load balancing: A cluster is a series of servers that act as a single server. The servers communicate either with each other or with a cluster controller to process requests as they are made. The cluster is assigned an IP address. The individual servers are also assigned unique IP addresses, which allow for server management and communication between the servers. Clusters add security to the Web server by increasing its availability and by increasing the difficulty of launching an attack against the server. Each time a request

to the Web site is made a different server may respond to the request. An attacker engaged in a complicated break-in attempt will need to restart the process each time a request is made because there is no way to guess which server will respond. If a private network is used to maintain the servers, there is no public address for the attacker to complete an attack. It provides extra time for the administrator to catch the alarm, track down the attacker, and stop the attack before it is successful. Network load balancing uses a switched device [such as "Cisco CSS11500 (Cisco)," "Nortel Network Alteon 184 (Nortel)," "Extreme Network SummitPx1 (Extreme)," or "F5 Network BIG-IP 5000 (F5)"] to direct traffic between multiple servers. Web site requests are forwarded to the appropriate server based on load balance. If a server fails, it is taken out of service rotation by the load balancer and an alert is generated. No traffic is lost as the load balancer simply redirects requests to another server. It is recommended that two network balancers be used in a pair. In case the first one is down from a DoS attack, the second one directs the traffic. The advantage of using clustering and network load balancing is that even if the site is offline because of a DoS attack, the Web server is secure.

## Incident Response

After the system administrator stops the DoS attack, blocks the IP address, and kills the connection, it is time for the incident response process: isolating the system, securing the system, data integrity check and recovery, repairing the vulnerability, system recovery, monitoring for additional signs of attacks, gathering information (counterintelligence), and documentation.

The system administrator (SA) examines other systems for any unusual activity. The SA correlates the attack time logs with databases access times. He or she will notice unauthorized activities on the secondary server. Thus, the SA will isolate the Web server, run integrity checks on the databases on the secondary Web server, and compare it with backup results to determine any modification. Again, if there have been alterations, entire databases will be recoverable from backups. As a minimum, however, the confidentiality of the data has been compromised. The secondary Web server will stay offline until the vulnerability is fixed and the data has been recovered.

Principle of least privilege (access as well as trust relationships with other servers/network resources), shutting down unneeded services, removing all data not needed on public servers, and replacing default scripts, accounts, and so on move the Web root to a different partition to avoid directory transversal attacks are all potential solutions that could be implemented.

To mitigate this risk, the hospital can implement more secure Web server architecture as mentioned above. Another recommended solution would be running vulnerability assessments on the server periodically or after any major change. The hospital can use vulnerability scanners such as Retina (eEye), NetRecon (Symantec), ISS Internet Scanner (ISS), Cybercop Scanner (Network Associates), The Open Source Nessus Project (Nessus), and Whisker (Open Source).

## Defense against VLAN Hopping

On this attack, the DT noted that the attacker would gain access to the system and exploit the VLAN hopping vulnerability. The access entry for the AT for the target hospital was the cardiology system. The system administrator could catch the attacker on the VLAN via h-IDS and audit log monitoring. He can detect the attacker and can block the IP address and kill the connection. However, detection is often too late and comes after there has been an information leak in the system. As a minimum, information confidentiality has been breached. The integrity of data should be checked in the incident response process.

Once the security incident has been determined, the severity of the security incident has to be reported to the incident response team (team consists of system administrators). The incident should be communicated to management immediately. Computer-based communications such as e-mail, electronic notes, or instant messaging programs should not be used, because they may not be secure. Management should be contacted via telephone, pager, or in person. Because the hospital information is sensitive, in a security incident situation, law enforcement (FBI) will also be informed.

Because an intrusion has occurred through the cardiology system, the system cannot be trusted anymore. The network that the attacker has compromised should be blocked to outside access. Network connections to the system and any other remote connections that can be used to provide access to the intruder must be removed. It is critical to kill the attacker's connection and block the IP address before he or she can try to cover his or her tracks by destroying the file systems of the machine. The services for the network must be blocked to stop attacker to gain access to other systems.

After the SA stops the DoS attack, Snort anomaly detector will identify the IP address of the attacker. Snort is IPS as much as it is IDS. The IP address of the attacker will be blocked and the connection will be terminated. Therefore, the attacker will be stopped from accessing to the other VLANs. The defense on this attack depends on the speed of stopping the DoS attack and identifying the attacker's IP address on the secondary attack. Time is a critical factor in this defense. If the attacker is undetected for long time, he or she will gain access to more VLANs and it is harder to identify the damages. After the attacker is stopped, data integrity checks have to be practiced to assure no data modification. In practice the VLAN hopping attack is devastating and is undetected until the end game.

## CONCLUSIONS

The author chose a commercial entity rather than a military target for our attack via wireless media. It was felt that this would provide an instructive example to which most readers can relate. WIW attacks and defenses represent trade-offs in security. Perhaps the two best books on the subject are by wireless experts Nichols and Lekkas (Nichols & Lekkas, 2001) and by cryptography guru Bruce Schneier (Schneier, 2003). The former book focuses on the methodologies for designing secure wireless communications systems. There is a special section on security

for WIW embedded systems. The latter book details not only the cryptography trade-offs involved but looks at the entire security process holistically. The same processes that are used in a military arena apply to commercial theaters too—and perhaps more effectively. The results of the AT/DT WIW hospital scenario bear out the security best practices espoused in these aforementioned references.

The results of the hospital attacks and defenses above prove that a defense in depth implementation can be very useful in keeping out the wireless hackers. However, it also proves that a determined enough hacker with extensive resources will work long enough to find the weak links in the system. Arquilla warned that networks would become the next battlefield (Arquilla & Ronfeldt, 2001). Networks are ubiquitous. They are also the wireless hackers' playground.

Security is not 100% effective in preventing all vulnerabilities from being exploited by determined hackers—especially in wireless based networks. There are always new vulnerabilities from the evolution of software and hardware to newer versions. In our example, critical systems and network that are used for hospitals cannot afford to be slack with security measures as lives are dependent on the security of the network. It is not inconceivable that a hacker could gain access to the systems that nurses use to consult on what medications to give to their patients.

The AT executed essentially three attacks. The first attack (via VLAN hopping) showed the ease with which the AT was able to map the wireless access points for a hospital. The hospital security management should conduct a risk assessment of the hospital networks to determine the vulnerabilities in the hospital network. Through the analysis, they will have better knowledge of the priority vulnerabilities that need mitigation and will be able to spend their security budget more wisely. Although this attack was shown to not totally succeed, it could very well succeed where the network administrators are less aware of and less trained in security. Furthermore, a huge amount of *information* was developed. Clearly, WEP is inadequate for decent degree of security, but it is better than no wireless security at all. The advent of the WPA using the 802.11x standard would afford a definite improvement in securing WLANs that should be implemented as soon as possible. A wireless IDS using passive sensors would also be another important consideration for organizations as upgrades are considered.

The second attack (via trusted agents) showed that they succeed in some of the stages of the attack dealing directly with people but they fail to gain the necessary access to the network. The conclusion here is the same as for the first attack, *information* gained helped the AT to be successful on the final breach of the network.

The third attack (via public access pathways) showed the AT succeeding in gaining access through the Web server. The hospital needs to beef up the Web security as there are medical databases with Web access that are weak points to the network as discussed in the introduction.

The attack successes came about as a direct result of the effectiveness of the VLAN hopping technique. The defense successes were directly attributable to the defense-in-depth principle. This bifunctionality is the nub of WIW. Attackers are able to access the various wireless nodes in

the system, crack the weak cryptography or identify the APs, develop a TOE and from that exploit the weakest links to the heart of the network. The defenders must develop a defense in depth, be always monitoring activities, prepare to respond to incidents and constantly upgrade their systems to improve their security posture.

Other possible scenarios might have included Software Defined Radio technology with user enable programming and dual/triple mode chipsets that could permit security breaches between media domains, real problems that were not included in this scenario of a typical hospital found in a large city area at this time mainly because they would not typically be found in an urban hospital at this time. In the near future, however, as businesses increase their security awareness, the impact of these and emerging technologies will have to be considered.

## GLOSSARY

**Access Point (AP)** A hardware device or software that acts as a communication hub for users of a wireless device to connect to a wired LAN. APs are important for providing heightened wireless security and for extending the physical range of service, a wireless user has access to.

**Analog** A characteristic of a circuit or device having an output that is proportional to the input.

**Asynchronous Transfer Mode (ATM)** A technique for dispatching data in packets or cells of a fixed size over a network. The advantage is that video, audio, and files can be transmitted over the same network without one type of data transmission seizing the line for an excessive time.

**Asymmetric Warfare** The strategy, tactics, and tools a weaker adversary uses to offset the superiority of a foe by attacking the stronger force's vulnerabilities, using both direct and indirect approaches to hamper vital functions or locations for the explicit purpose of seeking and exploiting advantages.

**Attack/Defense Scenario (A/D)** a team simulation pedagogical tool that allows a team to explore wireless network construction, information systems, and information assurance. Teams construct networks, impose policies, and explore cyber intrusion techniques. Team members role-play both attacker and defender positions for a chosen wireless target. Teams explore interrelationships between people, procedures, hardware, software, and data and how each of these factors impacts on the target wireless network design and security. The A/D deliverable is an After Action Report which represents the group's collective evaluation on the success or failure of the attack and defense in depth. Attacks and defenses are normally multi-tiered.

**Authenticated Post Office Protocol (APOP)** A post office protocol (see POP), which encrypts the user's password using the MD5 one-way hash function.

**Cellular Digital Packet Data (CDPD)** An open data transmission specification supporting access up to 19.2 KB to the Internet as well as other packet switched networks in the 800–900-MHz band.

**Cellular Phones** A mobile radiotelephone, usually hand held, used in an area divided into small sections

(cells), each with its own fixed base-station transmitter/receiver allowing access to the public telephone system. These may use analog or digital transmission techniques. Base stations support handovers so that users can move from one cell (region supported by a given base station) to another cell.

**CI** The abbreviation for counterintelligence.

**Code Division Multiple Access (CDMA)** A digital wireless technology that uses a spread spectrum technique to scatter a radio signal across a wide range of frequencies. CDMA is a 2G technology. WCDMA, a 3G technology, is based on CDMA.

**Command, Control, Communications, Computers, Intelligence, and Recognition (C4IR)** Integrated systems of doctrine, procedures, organizational structures, personnel, equipment, facilities, communications, intelligence, and identification designed to support a commander's exercise of command and control across the range of military operations.

**Commercial-off-the-Shelf (COTS)** An item, such as software or hardware, available for sale in the private sector and usually immediately available.

**Communications Security (COMSEC)** The protection resulting from all measures designed to deny unauthorized persons information of value that might be derived from the possession and study of telecommunications, or to mislead unauthorized persons in their interpretation of the results of such possession and study. Communications security includes cryptosecurity, transmission security, emission security, and physical security of communications security materials and information. (a) Cryptosecurity: The component of communications security that results from the provision of technically sound cryptosystems and their proper use. (b) Transmission security: The component of communications security that results from all measures designed to protect transmissions from interception and exploitation by means other than cryptanalysis. (c) Emission security: The component of communications security that results from all measures taken to deny unauthorized persons information of value that might be derived from intercept and analysis of compromising emanations from cryptoequipment and telecommunications systems. (d) Physical security: The component of communications security that results from all physical measures necessary to safeguard classified equipment, material, and documents from access thereto or observation thereof by unauthorized persons.

**Computer Security (COMPUSEC)** The protection resulting from all measures to deny unauthorized access and exploitation of friendly computer systems.

**Confidentiality, Integrity, and Availability (of Data) (CIA)** Factors of a data processing system and its files that must be protected. Confidentiality protects the existence of a connection, the traffic flow, and information content from disclosure to unauthorized parties. Integrity is the assurance that information and processes are secure from unauthorized modifications by use of cryptography, digital signatures, and intrusion detection. Availability is the degree that information, data processes, and resources are usable when needed.

**Cordless Phones** For most types of cordless phones, a single base station supports each mobile user. A user cannot move from one base station to another while a call is in progress.

**Cross-Site Scripting (XSS)** A security breach that takes advantage of dynamically generated Web pages. In an XSS attack, a Web application is sent with a script that activates when it is read by an unsuspecting user's browser or by an application that has not protected itself against cross-site scripting. Because dynamic Web sites rely on user input, a malicious user can input malicious script into the page by hiding it within legitimate requests. Common exploitations include search engine boxes, online forums, and public-accessed blogs. Once XSS has been launched, the attacker can change user settings, hijack accounts, poison cookies with malicious code, expose SSL connections, access restricted sites and even launch false advertisements. The simplest way to avoid XSS is to add code to a Web application that causes the dynamic input to ignore certain command tags.

**Cryptanalysis** The steps and operations performed in converting encrypted messages into plain text without initial knowledge of the key employed in the encryption.

**Cryptography** The science that deals with hidden, disguised, or encrypted communications. It includes communications security and communications intelligence.

**Deception** Those measures designed to mislead the enemy by manipulation, distortion, or falsification of evidence to induce the enemy to react in a manner prejudicial to the enemy's interests.

**Denial of Service (DoS)** A loss of the ability of a data processing system to provide satisfactory service with respect to confidentiality, integrity, and/or the availability of its data. This loss may be temporary, as in a delay, or it may be long lasting enough have a catastrophic effect on an enterprise.

**Digital** Description of or relating to a device that can read, write, or store information that is represented in numerical form.

**EIRP** Equivalent isotropically radiated power. EIRP represents the total effective transmit power of the radio, including gains that the antenna provides and losses from the antenna cable. In the United States, the FCC (Federal Communications Commission) defines power limitations for wireless LANs in FCC Part 15.247. Part 15.247 provides details on limitations of EIRP.

**Electromagnetic Compatibility (EMC)** Ability of systems, equipment, and devices that use the electromagnetic spectrum to operate in their intended operational environments without suffering unacceptable degradation or causing unintentional degradation because of electromagnetic radiation or response. It involves the application of sound electromagnetic spectrum management; system, equipment, and device design configuration that ensures interference-free operation; and clear concepts and doctrines that maximize operational effectiveness.

**Electronic Counter Counter Measures (ECCM)** Term used as an alternative to "electronic protection." ECCM

- is to ensure continued friendly use of the electromagnetic spectrum despite adversaries, electronic attack (EA) and electronic support (ES). Countering EA efforts is the focus of electronic protection although some electronic protection techniques are also designed to make adversary ES more challenging.
- Electronics Security (ELSEC)** Protection resulting from all measures designed to deny unauthorized persons information of value that might be derived from their interception and study of noncommunications electromagnetic radiations (e.g., radar).
- Electronic Warfare** Denial of accurate information to an unauthorized party by use of the electromagnetic spectrum.
- Emanations Security (EMSEC)** Control of electromagnetic emissions that may compromise internal information.
- Exploitation** Taking full advantage of any information that has come to hand for tactical, operational, or strategic purposes.
- Firewall** A system, hardware or software based, that is designed to block unauthorized access to or from a specified network. Its effectiveness is dependent on the degree of proper configuration.
- Forward Line of Own Troops (FLOT)** A line that indicates the most forward positions of friendly forces in any kind of military operation at a specific time. The forward line of own troops (FLOT) normally identifies the forward location of covering and screening forces. The FLOT may be at, beyond, or short of the forward edge of the battle area. An enemy FLOT indicates the forwardmost position of hostile forces.
- Global System for Mobile (communications) (GSM)** The most widely used of the three digital wireless telephone technologies (TDMA, GSM, and CDMA), and it supports voice, data, text messaging, and cross-border roaming. The SIM (subscriber identification module), a removable plastic card that contains a users data, is an essential element in a GSM network.
- Handover** A transfer of a user connection or function from one base station to another.
- Health Insurance Portability and Accountability Act of 1996 (HIPAA)** A federal law that allows persons to qualify immediately for comparable health insurance coverage when they change their employment relationships. Title II, Subtitle F, of HIPAA gives Health and Human Services, the federal department that has overall responsibility for implementing HIPAA, the authority to mandate the use of standards for the electronic exchange of health care data; to specify what *medical* and *administrative code sets* should be used within those standards; to require the use of national identification systems for health care patients, providers, payers (or plans), and employers (or sponsors); and to specify the types of measures required to protect the security and privacy of personally identifiable health care information. Also known as the Kennedy-Kassebaum Bill, the Kassebaum-Kennedy Bill, K2, or Public Law 104-191.
- Information Based Warfare (IBW)/Information Operations (IO)** Actions taken to affect adversary information and information systems while defending one's own information and information systems.
- Information Security (INFOSEC)** The protection of information and information systems against unauthorized access or modification of information, whether in storage, processing, or transit, and against denial of service to authorized users. Information security includes those measures necessary to detect, document, and counter such threats. Information security is composed of computer security and communications security.
- Information Warfare (IW) Definition I** Information operations (IO) conducted during time of crisis or conflict to achieve or promote specific objectives over a specific adversary or adversaries. IW actions may induce denial of service, corruption of data, and/or exploitation of the information obtained.
- Information Warfare (IW) Definition II** Actions taken to achieve information superiority by affecting adversary information, information-based processes, information systems, and computer-based networks while defending one's own information, information-based processes, information systems, and computer-based networks. (DoD96, 1996)
- Information Warfare (IW) Definition III** The offensive and defensive use of information and information systems to deny, exploit, corrupt, or destroy, and adversary's information, information-based processes, information systems, and computer-based networks while protecting one's own. Such actions are designed to achieve advantages over military or business adversaries. (Goldberg, 2001)
- Internet Message Access Protocol (IMAC)** An agreed-on format for transmitting e-mail data between two devices.
- Intrusion detection System (IDS)** Inspects all inbound and outbound network activity and identifies suspicious patterns that may indicate a network or system attack from someone attempting to break into or compromise a system. A secure form is the h-IDS or host based IDS, which allows online monitoring of activities.
- Line-Sight Radios** Connections are limited to line of sight because of operation at frequencies above HF, the need for high data rates, lack of hardware and protocol support for multihop transmission, or some combination of these factors. There are two types: (1) fixed or transportable, high capacity systems for point-to-point trunking (multiple streams of data and digital voice are multiplexed together over a single connection) and (2) mobile, semimobile (stop to transmit or receive), or transportable low-capacity radios that are designed primarily for handling single two-way (typically push-to-talk), voice connections.
- Low Probability of Detection (LPD)** A relative indication of a poor chance of an event being noticed.
- Mail Transfer Agent (MTA)** Software used by the mail server.
- Media Access Control (MAC)** A system of addressing defined by IEEE that uniquely identifies each node of a network.
- Mobility** Ability of a host (user) of a network to connect in various ways, such as by using a roaming host or routers.
- Over The Air (OTA) (or Over-The-Air)** A standard for the transmission and reception of application-related

information in a wireless communications system. The standard is supported by Nokia, SmartTrust, and others.

OTA is commonly used in conjunction with the Short Messaging Service, which allows the transfer of small text files even while using a mobile phone for more conventional purposes. In addition to short messages and small graphics, such files can contain instructions for subscription activation, banking transactions, ringtones, and Wireless Access Protocol settings. OTA messages can be encrypted to ensure user privacy and data security.

**Packet Radio Networks** The radios in these networks are digital and exchange information in a store-and-forward fashion, so that a source and destination that are not able to communicate directly may nevertheless be able to exchange information. Packets are routed through the network, and may take one or more hops to reach the destination.

**Pagers** These include conventional pagers, alphanumeric pagers, and two-way pagers.

**Peer-to-peer network** A system in which each workstation has equivalent capabilities and responsibilities rather than certain computers dedicated to performing tasks for others (as in a client server system).

**Post Office Protocol (POP)** An older format for transmitting e-mail data between two devices.

**Precedence** A designation assigned to a message by the originator to indicate to communications personnel the relative order of handling and to the addressee the order in which the message is to be noted. Time standards are specified for each precedence's processing. The most immediate to least designations are as follows: flash, immediate, priority, and routine.

**Quality of Service (QoS)** A relative measure of satisfaction of an act performed for a user

**Radio Frequency Identification Devices (RFID)** Devices, passive or active, that are typically attached to objects for purposes of inventory, location, and/or description of contents (for containers). The RFID responds to queries.

**RC4** A stream cipher developed by RSA laboratories circa 1987.

**Satellite Earth Terminals** In a satellite link, one of the nonorbiting communications stations that receives, processes, and transmits wireless signals between itself and a satellite. Note: Earth terminals may be mobile, fixed, airborne, or waterborne.

**Secure Set Identifier (SSID)** A 32-character stream included in a packet header that functions as a password, differentiating one WLAN from another. Because an SSID can be sniffed in plain text from a packet, it does not supply any security to the network. Also known as *network name*.

**Security (of Information)** With respect to classified matter, the condition that prevents unauthorized persons from having access to official information that is safeguarded in the interests of national security.

**Social Engineering** Deceptive techniques involved by persons pretending to have authorization to obtain information or entry into a facility for which they are not authorized.

**Subscriber Identification Module (SIM)** A removable plastic card that contains a user's data, usually for security purposes to confirm the user is authorized to access a system or data files.

**Target** A file, device, or any type of location to which data is moved or copied (including the entire enterprise system or backbone of communications).

**Targets of Evaluation (TOE)** the explicit enumeration of all possible wireless targets of interest to an attack team. TOE also defines the spectrum of wireless targets that must be considered by a defense team. In essence the TOE defines the scope of wireless warfare for both teams.

**Taxonomy** The study of the general principles of scientific classification.

**Tethered Mobility** A condition in which a system can only be used within a given range of a specific node (e.g., a cordless telephone)

**Time Division Multiple Access (TDMA)** A technology used in digital cellular telephone communication to divide each cellular channel into three time slots to increase the amount of data that can be carried. GSM and D-AMPS use TDMA in one form or another.

**Transmission Security (TRANSEC)** The protection of transmissions ("externals") from traffic analysis, disruption, and imitative deception typically by encryption means. See Communications Security (COMSEC).

**Trojan** A malicious program that presents itself as being of a nondestructive nature. A characteristic that distinguishes them from viruses is that Trojans do not replicate themselves.

**Unsolicited Bulk E-mail (UBE)** Commonly known as a type of spam.

**Virtual Local Area Network (VLAN)** A network of computers that behave as if they are connected to the same wire even though they may actually be physically located on different segments of a LAN. VLANs are configured through software rather than hardware, which makes them extremely flexible. One of the biggest advantages of VLANs is that when a computer is physically moved to another location, it can stay on the same VLAN without any hardware reconfiguration.

**Virtual Private Network (VPN)** A network in which some of the parts are connected using the public Internet, but the data sent across the Internet are encrypted, so the entire network is virtually private. An example might be a company network where there are offices in different cities. Using the Internet, the offices merge their networks into one network. The data are encrypted to ensure that only the offices can see the data on the Internet link.

**Virus** Apparently innocuous program or other software that, when loaded, becomes destructive in nature. Viruses replicate. They are created for a specific destructive purpose.

**Wi-Fi Protective Access (WPA)** An interim standard (to be replaced by IEEE 802.11i) that is an improvement over the security features of WEP, including improved data encryption and user authentication.

**Wired Equivalency Privacy (WEP)** A security protocol for WLANs defined in the 802.11b standard and

designed to provide the same level of security as that of a wired LAN, usually through encrypting data.

**Wireless Information Warfare (WIW)** Information warfare focusing on data processed over radio and light systems.

**Wireless Local Area Network (WLAN)** A local area network that employs radio waves instead of wires to transmit and receive data. It enables fast data transmission through a wireless connection at relatively low cost. Particularly suitable for organizations such as hospitals and schools as well as businesses; also refers to wireless networks between computers within one building or a group of buildings. WLANs may use infrared or radio techniques. The IEEE standard for WLANs is 802.11. Well-known further WLAN proposals come from the competing groups Bluetooth and Home-RF.

**Wireless Modems** A modem that accesses a private wireless data network or a wireless telephone system.

**Wireless Security Implementation** (1) Adaptation and integration of existing wireless solutions and infrastructure; (2) promoting consistency and interoperability among a diverse spectrum of mobile and wireless devices; (3) providing a high level of security without detrimental impact on the user experience. In a wireless network, security features greatly differ between each of the protocol stacks, and security policy implementation and enforcement are dependent on the carrier (Nichols & Lekkas, 2001).

Technologies for Computer Network Defense	95		

## INTRODUCTION

Computer network operations (CNO) is primarily about the management of computer and networks within a corporate environment so as to allow the organization to maintain/achieve a competitive advantage. Within a commercial organization CNO is used to refer to the ability to access information hosted on information systems in a timely manner so as facilitate the functioning of the organization.

When this definition is applied to information security and information assurance we can interpret CNO as follows:

Computer network operations are about identifying cyber-based attacks targeted against your information technology infrastructure. This is achieved through a process of data integration and data function of security related information from multiple disparate heterogeneous systems.

To understand information security and how it relates to electronic commerce we need to have a precise set of definitions as to what we mean by: threat, threat agent, and vulnerability (Denning, 1999; Waltz, 1998).

- Threat. The *Concise Oxford Dictionary* defines the word *threat* as follows:

Declaration of intention to punish or hurt; menace of bodily hurt or injury to reputation or property, such as may restrain a person's freedom of action; indication of something undesirable coming.

For the purposes of this report threat is a function of an adversary's motivation, their capability, the opportunity, and the impact that a successful attack would have on an organization.

Threat = Function (Motivation, Capability, Opportunity, Impact)

Each of the terms utilized in the threat function are defined as follows:

- Motivation. The *Concise Oxford Dictionary* defines the word motivation as follows:

Supply a motive to cause a person to act in a particular way. In the context of a threat, motivation is considered to be identification of both the reasons why someone would launch an attack and a measure of the degree to which the attack would be pressed home.

For the purpose of this chapter we consider motivation to be the degree to which an aggressor is prepared to implement a threat. The motivational factors are the specific real-world elements that drive a hacker to consider penetrating a computer system. There are a variety of features that are worth considering in the question of motivation. First, motivation provides the *impetus* for the hacking attempts; it determines how persistent the hacker will be in his or her attempts; it determines how much effort (time, money) the hacker is prepared to expend on the attempt. It determines, in short, just how much we should be concerned about the hacker. This aspect is examined further below.

A second feature of importance in motivation is the *continuity* that it implies. A strong and focused motivation—say in pursuit of animal rights or Irish liberation—will suffuse much of the individual's offensive activity. A recreational motivation will lead predominantly to a recreational approach to hacking attempts—though it is of course important to understand that recreational motivations can easily translate under certain circumstances such as duress into more sinister activities. This indeed leads to the third important feature of the motivation, which we can classify as its *flavor*. For example, is the hacker motivated by the opportunity for financial gain? Is the motivation ideological, personal, or even trivial in nature? Is the hacker (like Levin) perhaps motivated by external coercion? This flavor of motivation is important because it has a bearing on persistence, but also because it has a bearing on the selection criteria that the individual will apply (Jones, Kovacich, & Luzwick, 2002). Levin was reputed to be the principle author of a successful attack against Citibank (Neumann, 1995).

Motivational factors in and of themselves cannot be *detected* by intrusion detection systems technology—at least, not with the current state of the art. However, important motivational elements can be observed in the records that are collected and maintained by a variety of network security systems; they represent important information that can and should be analyzed. Abstracting such profiles is part and parcel of the objective of this new-generation IDS technology, allowing confident identification of individuals to be supported (Rehman, 2003).

Capability. The *Concise Oxford Dictionary* defines the word capability as meaning the power to do something. In terms of information security the term capability is used as a measure of (1) the availability of a number of tools and techniques to implement an attack and the ability to use the tools and techniques correctly and (2) the availability of education and training to support the correct use of various tools and techniques.

For the purposes of this chapter we use the term *capability* to mean the degree to which an aggressor is able to implement a threat.

- Opportunity. The *Concise Oxford Dictionary* defines the word opportunity as meaning, a favorable occasion for action. Sun Tzu stated: “The good fighters of old first put themselves beyond the possibility of defeat, and then waited for an opportunity of defeating the enemy” (Griffith, 1971).

Consequently, for a threat agent to bring its capability to bear against a target they must have the correct conditions to do so, and for their capabilities to be effective and have an impact on the target, the target must be vulnerable to attack.

- Impact. The term *impact* is used to denote the concept of effect that an attack can have against a computer-based system, company, individual, and so on. The measurement of an attack can be made in direct and indirect terms. For example, we can measure impact directly as follows: duration of unavailability of service/drop in share price and loss of commercial confidence/loss of trust.
  - Threat agent. The term *threat agent* is used to denote an individual or group that can manifest a threat.
- Vulnerability. The *Concise Oxford Dictionary* defines the term *vulnerability* as “susceptible to damage.” Vulnerability has been defined as follows: (1) a point where a system is susceptible to attack, (2) a weakness in the security system that might be exploited to cause harm or loss, or (3) some weakness of a system that could allow security to be violated.

A threat agent is an individual or organization that has the potential to realize a threat against a specific target. Consequently, threats and threat agents are unique to the target and must be considered in the context of the environment, be that commercial or political that the target functions in. Modern threat agents such as hackers, organized crime, terrorists, and so on have all adopted and utilized computer network operations to help them achieve their objectives.

## NETWORK DEFENSE AND NETWORK ATTACK

To understand network defense or network attack we must first develop an understanding of what we mean by network and security. The term network is used to denote a TCP/IP infrastructure.<sup>1,2</sup> In the area of information security (IS) and information assurance (IA) there are two basic models of security that allow us to understand and implement information assurance. The first model is called the confidentiality, integrity, and availability (or CIA) model. This basic model defines security in simple terms (Pfleeger & Pfleeger, 2003).

Confidentiality means that the assets of the system are accessed only by authorized parties. Another aspect in confidentiality is that the traffic flow is also protected by any kind of “outside” analysis. This requires that an attacker will not be able to identify any asset in a transaction, such as the sender, the receiver, and the context. Integrity means that the assets of the system can be modified by authorized parties only and in authorized ways. Here there is a concept of “inside” and “outside” integrity. We not only want the “outsiders” not to be able to modify system data but also the insiders not to be able to participate in any sort of malicious operations with the system data. Availability means that the assets of a system are always available to the authorized parties. Having one or two of the above goals achieved is relatively easy. The difficulty lies in achieving all three of them as each one is going “against the other” in some sort of manner.

The second model defines information security in terms of detect, deter, protect, react, and recover (DDPRR). Detect means the ability to identify an attack whether it is a cyber-based intrusion or social engineering. Deter means the ability to show that this system is well protected and monitored so try some place else. Most hackers are opportunistic and once they realize that a system is protected they will move onto the next target. Protect means the ability to know what assets we possess and what assets we need to defend. React means that once an attack is detected, we have the ability to respond in a defensive manner to safeguard the asset. Defense actions can include actions such as redefining the rules on a firewall or phoning the police. Recovery is the ability to take an asset that has been compromised by an intruder and restore that asset to a safe and secure state. So, for example, it can mean taking a computer system and formatting the hard disk, reinstalling the operating system, and applying all of the security patches to bring the system into a secure state.

Computer network operations encompasses computer network attack (CNA) and computer network defense (CND). The term *computer network attack* is used to mean the art by which a computer network is subverted via cyber means, whereas the term computer network defense refers to how a computer network is protected from a computer network attack (Blyth & Kovacich, 2001).

NATO, Europe, the United States, and Canada now view computer network operations as an integral part

<sup>1</sup> See *The Handbook of Information Security, Volume I, Key Concepts, Infrastructure, Standards and Protocols*. Chapter 37, “Internet Architecture.”

<sup>2</sup> See *The Handbook of Information Security, Volume I, Key Concepts, Infrastructure, Standards and Protocols*. Chapter 38, “TCP/IP.”

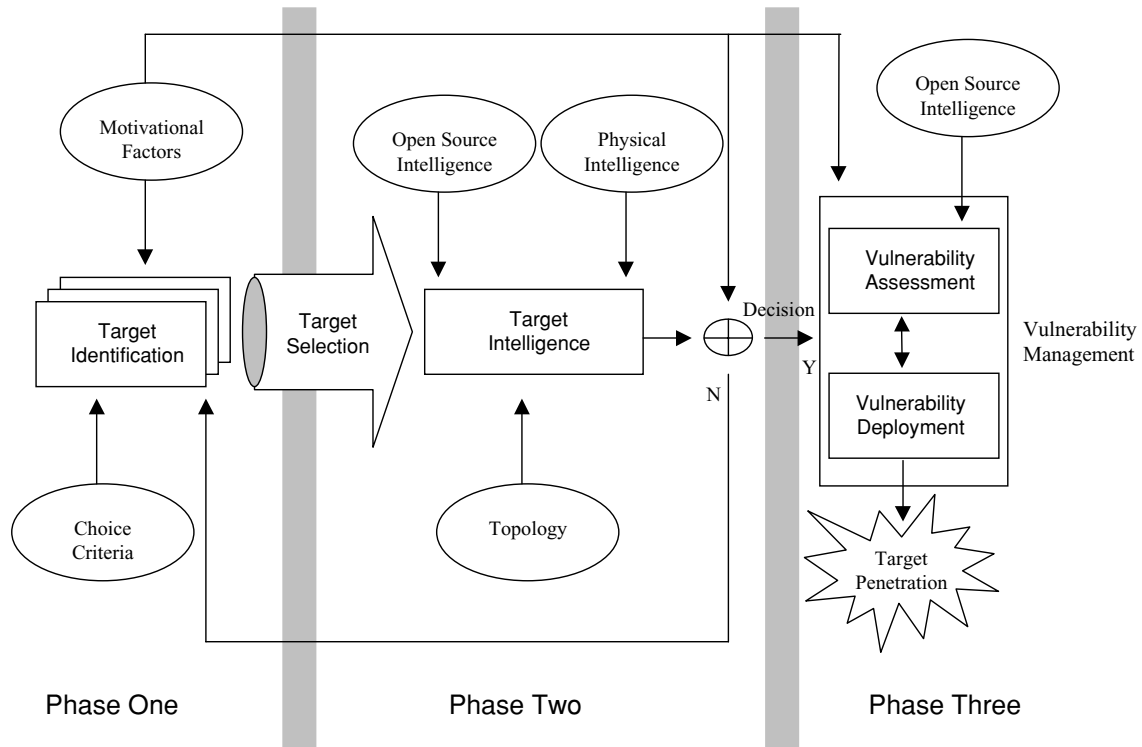

Figure 1: The CNA process.

of military operations during peacetime, war, and crisis. Within the commercial sector, the rise in extortion and industrial espionage attacks targeted against corporate IT infrastructure has resulted in the need for organizations to protect themselves. This process of protection is not the simple deployment of technology such as intrusion detection systems and firewall; rather, it is a process that centers on the role and function of the individual within the organization and makes use of technology, policy, and education/awareness (Rathmell, 2001). It is also reputed that both Korea and Israel have this capability.

## A MODEL OF COMPUTER NETWORK ATTACK

Threat agents when employing CNA will operate in a characteristic fashion, performing a set of analytic, probing, and exploitive behavior with computer systems or networks.<sup>3</sup> This behavior is identifiable and, to an extent, predictable. Within this element of the work package, the authors have constructed a general-purpose model of hackers' activity—a model that can be applied not simply to the recreational, low-skill "Kiddie Script" hacker aimlessly exploring computer networks but also to the more determined professional criminal. Central to this model is the recognition of a sequence of activities, but crucially incorporating a sense of *expenditure* on the part of the intruder—in terms of time, equipment, finance, and commitment. Using this model, we can address the most fundamental of our questions for consideration: "How do hackers penetrate computer networks and systems?"

<sup>3</sup> See *The Handbook of Information Security, Volume III, Threat, Vulnerabilities, Prevention, Detection and Management*.

Figure 1 provides a flowcharted model for the individual decision points and activities that are common to all intrusion attempts.

The CNA process model is a simple, general-purpose one, in which hackers of any persuasion perform a series of increasingly refined actions against an increasingly focused set of target computer systems. Figure 1 shows the basic process that an intruder would go through when penetrating a system. This process is divided up into three distinct phases. The first phase is concerned with the processes by which an intruder identifies and selects the machine(s) and network(s) to be penetrated. The second phase is concerned with the processes by which an intruder would gather intelligence about the machine(s) and network(s) to be penetrated. Phase three is concerned with the processes by which a computer system is penetrated. This phase involves the selection and deployment of a set of vulnerabilities against a set of target machine(s) and network(s).

### Target Identification

The world contains untold millions of computer systems, each of which might be a potential target for a hacker, depending on the criteria that the hacker applies in selecting computers for attention.

For some hackers, every one of these millions of systems is indeed a potential target: they are as likely to attack any one as any other, with a selection criterion that is essentially opportunistic. For others, the total set of systems can be more finely subdivided into systems in which they have a very specific interest and a determination to perform a more focused sequence of activities.

In the target identification section of the model, we uncover the decisions and activities the hacker has applied

in uncovering the specific types of computer system of interest to them: all government computers, computers belonging to animal testing organizations, Irish republican newspaper sites, all banking computer networks, and so on. This represents a subdivision of the universal set of computers, with decisions made by the hacker based on two important elements: (1) their determination to penetrate the computer and (2) the specific criteria to be applied.

## Motivational Factors

The motivational factors are the specific real-world elements that drive a hacker to consider penetrating a computer system. Analysis of computer criminals suggests that the primary motivations include the following, sometimes in combination (Blyth & Kovacich, 2001; Jones et al., 2002):

- The need to resolve intense personal problems such as job-related difficulties, mental instability, debt, drug addiction, loneliness, jealousy, and the desire for revenge
- Peer pressure and other challenges, for example, among malevolent hackers
- Idealism and extreme advocacy, for example, by espionage agents and terrorists
- Financial gain

There are a variety of features that are worth considering in the question of motivation. Firstly, motivation provides the *impetus* for the hacking attempts; it determines how persistent the hacker will be in his attempts; it determines how much effort (time, money) the hacker is prepared to expend on the attempt. It determines, in short, just how much we should be concerned about the hacker. This aspect is examined further below.

A second feature of importance in motivation is the *continuity* that it implies. A strong and focused motivation—say, in pursuit of animal rights or Irish liberation—will suffuse much of the individual's offensive activity. A recreational motivation will lead predominantly to a recreational approach to hacking attempts—although it is of course important to understand that recreational motivations can easily translate under certain circumstances such as duress into more sinister activities.

This indeed leads to the third important feature of the motivation, which we can classify as its *flavor*. For example, is the hacker motivated by the opportunity for financial gain? Is the motivation ideological, personal, or even trivial in nature? Is the hacker (like Levin) perhaps motivated by external coercion? This flavor of motivation is important not only because it has a bearing on persistence but also because it has a bearing on the selection criteria that the individual will apply.

Motivational factors in and of themselves cannot be detected by IDS technology—at least, not with the current state of the art. However, important motivational elements can be observed in the records that are collected and maintained by a variety of network security systems: they represent important information that can and should be analyzed. Abstracting such profiles is part and

parcel of the objective of this new-generation IDS technology, allowing confident identification of individuals to be supported.

## Choice Criteria

Driven by the motivation factors, hackers will apply their individual choice criteria to the universal set of computer systems, abstracting the (possibly still large) set of targets in which they have an interest. The choice criteria have several aspects to them.

First, there is the question of criteria *freedom*: does the hacker in fact have any say in the specific criteria applied, or is the choice predetermined by an external agency? Again, this element of target selection can be observed as a feature that we can think of as *persistence*: how determined does the intruder seem to be in the face of real or perceived security measures?

Second, there is the question of criteria *flexibility*: will the selected set of targets evolve over time, perhaps compromising choice as the difficulty of hitting specific targets becomes obvious—or are the criteria immutable?

Third, what is the *breadth* of criteria? How many systems are considered? Where are they located? How are the choice criteria effectively articulated?

Self-evidently, there is an interaction between motivational and choice aspects, leading to the determination, the persistence, the precision, and so on with which the hacker approaches the subsequent stages of his activity. The target identification stage provides the hacker with a set of potential victims to be considered: a set from which the specific targets are then selected.

## Target Selection and Intelligence

The selection of specific targets from the broad set of potential victims is driven by a variety of elements. First and most obviously, there is an opportunistic element to even the most highly focused attacks: a range of systems might be scanned in a particular order or a more intelligent set of choices might be made, based on what intelligence the hacker gathered about the system. Some of this intelligence is also available to the *defender* of the system, although it is unlikely that more than a subset of this will be feasibly obtained by the IDS itself.

## Open Source Intelligence

Hackers will attempt to perform a review of open source material in an attempt to gather intelligence on the network topology for a target organization or network. This can include such diverse elements as newsgroup postings referring to problems operating a particular type of computer and evidence showing with whom the employees of the target normally communicate. For example, a hacker could:

- Perform a Web search on related names and terms using Web search engines
- Analyze postings by users of target systems and target organizations on Usenet
- Analyze various open source exploit databases
- Analyze various other open source material

- Use remote domain name system (DNS) mining tools
- Connect to various computer underground servers and acquire the password file for the target system

It should be noted that from the perspective of an outsider penetrating a computer network, a review of open source literature is an activity that an intrusion detection system is unlikely to detect. However, from the perspective of an employee within an organization, it is possible that by logging all out-bound traffic an administrator would be able to identify an insider accessing various types of open source intelligence. This type of analysis of traffic generated by employees within a system can be used as an early-warning system.

The creation of a global information infrastructure (GII) means that a threat agent can mount a computer network attack against a target from any place on the planet. Understanding the CNA process model can allow us to create an understanding of how to implement computer network defense. Standards such as Common Criteria and BS 7799/ISO-17799 allow administrators to deploy technologies within a network environment that will stop, delay, hinder, or detect an attack.

## Deploying/Exploiting a Vulnerability

Within the context of computer network operations, a threat to a system can be defined as follows (Summers, 1997): "Some weakness of a system that could allow security to be violated."

Vulnerability assessments are concerned with the identification of the weakness that may be exploited. In general, vulnerabilities exist throughout the information systems processes, software, hardware, information, business processes, and people. Software can be vulnerable to interruption of execution, deletion, interception of software in transit, and modification. Hardware is vulnerable to theft and interruption of service. Finally, information is vulnerable to interruption (loss), interception, modification, and fabrication. In essence, there are seven types of vulnerabilities that can exist in any system, and these are as follows:

1. **Physical Vulnerabilities:** intruders can break into computing facilities. Once in they can sabotage and vandalize computers and steal hardware, diskettes, printouts, and so on.
2. **Natural Vulnerabilities:** computers may be vulnerable to natural disasters and to environmental threats. Disasters such as fire, flood, earthquakes, and power loss can wreck your computer and destroy information.
3. **Hardware/Software Vulnerabilities:** certain kinds of hardware and software failures can compromise the security of a computer system. Software failures of any kind may cause systems to fail and may open up systems to penetration or make systems so unreliable that they cannot be trusted.
4. **Media Vulnerabilities:** disk packs and tapes can be stolen or damaged by such mundane perils as dust and ballpoint pens.

**Table 1** External Misuse

Mode of Misuse	Description
Visual spying	Observation of keystrokes or screen.
Misrepresentation	Deceiving operators and users.
Physical scavenging	Dumpster diving for printouts, floppy disks, and so on.

5. **Emanation Vulnerabilities:** all electronic equipment emits radiation that can be intercepted.
6. **Communication Vulnerabilities:** if your computer is attached to a network then its message can be intercepted and possibly modified or misrouted.
7. **Human Vulnerabilities:** the people who administer and use your computer facilities represent the greatest vulnerability of all. They may be vulnerable to greed, revenge, blackmail, and the like.

With regard to computer network operations these vulnerabilities can manifest themselves via the following types of misuse.

External misuse of an information system is related to the creation, manipulation, and destruction of information by a user within the organization. This type of misuse forces one to examine how, when, where, and by whom information is created, manipulated, and destroyed. This type of analysis is primarily concerned with the physical environment within which the users execute the business processes. Generally nontechnological and unobserved, external misuse is physically removed from computer and communications facilities. It has no direct observable effects on the systems and is usually undetectable by the computer information assurance systems. Types of external misuse are listed in Table 1 and include the following:

- **Visual spying:** for example, remote observation of typed key strokes or screen images.
- **Deception:** various forms of deception external to computer systems and telecommunications. For example, social engineering (having one act in a manner conducive to another's needs; e.g., release their password).
- **Physical scavenging:** for example, collection of waste paper or other externally accessible computer media, so-called dumpster diving.

Hardware misuse of an information system is primarily concerned with the information assurance of the physical devices that form the physical infrastructure of the organization's information system. Table 2 shows types of misuse. It is important to note that this type of misuse also includes theft of removable storage media such as printout and electromagnetic tapes and other electronic removable media. In essence there are two types of hardware misuse: passive and active.

- **Passive Hardware Misuse.** This tends to have no immediate side effect on hardware or software behavior and includes the following:

**Table 2** Hardware Misuse

Mode of Misuse	Description
Logical scavenging	Examining discarded/stolen media.
Eavesdropping	Intercepting electronic or other information.
Interference	Jamming, electronic or otherwise.
Physical attack	Damaging or modifying equipment or power.
Physical removal	Removing equipment and storage media.

- Logical scavenging (such as the examination of discarded computer media)
- Electronic or other types of eavesdropping that intercept signals, generally unbeknownst to the victims; for example, picking up emanations, known as TEM-PEST (telecommunications electronics material protected from emanating spurious transmissions)
- Planting a spy-tap device in a terminal, workstation, mainframe, or other hardware subsystem.
- **Active Hardware Misuse.** This generally has noticeable effects and includes the following:
  - Theft of computing equipment and physical storage media
  - Hardware modifications, such as internally planted Trojan horse hardware devices
  - Physical attacks on equipment and media, such as interruption of power supplies. This type of attack can also make use of electromagnetic pulse (EMP) weapons

Masquerading misuse of an information system is primarily concerned with the authentication of information, its source, its destination, and its users. Masquerading attacks, listed in Table 3, include the following:

- **Impersonation of the identity of some other individual or computer subject.** For example, using a computer identifier and password to gain access to a computer system. The computer identifier and password may belong to a person or a computer demon.

**Table 3** Masquerading

Mode of Misuse	Description
Impersonation	Using false identities external to the computer system
Piggybacking attacks	Usurping communication lines and workstations
Spoofing attacks	Using playback, creating bogus nodes and systems
Network weaving	Masking physical whereabouts or routing

**Table 4** Pest Programs

Mode of Misuse	Description
Trojan horse attacks	Implanting malicious code, sending letter bombs.
Logic bombs	Setting up time or event bombs.
Virus/worms attacks	Attaching to programs and replicating.

- **Piggyback attacks.** For example, an unauthorized user may hijack a communication channel to a computer.
- **Spoofing attacks.** For example, using the identity of another machine on a network to gain unauthorized access. Types of attacks include IP spoofing, machine spoofing, and demon spoofing.
- **Playback attacks.** For example, the playback of network traffic in the attempt to recreate a transaction.
- **Network weaving to hide physical whereabouts.** A person connects through several machines to a target machine.

Pest programs, briefly described in Table 4 are primarily concerned with the availability of information systems services, and the expected behavior of services.

- **Trojan Horse:** a Trojan horse is an entity (typically a program, but not always) that contains code or something interpretable as code that, when executed, will have undesirable effects, such as the clandestine copying of information or the disabling of the information system.
- **Letter bomb:** a letter bomb is a peculiar type of Trojan horse attack whereby the harmful agent is not contained in a program but rather is hidden in a piece of mail or information. The harmful agent usually consists of special characters that are only meaningful to a particular mail agent. This bomb is triggered when it is read as a piece of electronic mail.
- **Logic bomb:** a logic bomb is a Trojan horse in which the attack is detonated by the occurrence of some specified logical event such as the first subsequent login by a particular user.
- **Time bomb:** a time bomb is a logic bomb in which the attack is detonated by the occurrence of some specified time-related logic event (e.g. the next time the date is 18 December).
- **Virus/worms:** viruses and worms often attack the Internet and other networks. For example: in May 2000, the "I Love You" e-mail virus was released. When the worm executes, it will search for certain types of files and make changes to those files depending on the type of file. For files on fixed or network drives, it will take the following steps: Files with the extension *vbs* or *vbe* are overwritten with a copy of the virus, and files with the extension *mp3*, *mp2*, *js*, *jse*, *css*, *wsh*, *sct*, *jpg*, *jpeg*, or *hta* are overwritten with a copy of the virus and the extension is changed to *vbs*.

Because the modified files are overwritten by the worm code rather than being deleted, file recovery is difficult and

**Table 5** Bypasses

Mode of Misuse	Description
Trapdoor attacks	Utilizing existing flaws in the system and misconfigured network programs
Authorization attacks	Password cracking and so on

may be impossible. By May 10, 2000, it was estimated that the viruses had infected 600,000 machines in the United States alone and had cost American business \$2.5 billion in damages and lost income.

Bypasses, listed in Table 5, are a type of misuse of an information system primarily concerned with authorization and configuration management. A *trapdoor* is an entry path that is not normally expected to be used. There are several types of trapdoors:

- Inadequate identification, authentication, and authorization of users, tasks, and systems (e.g., the Sendmail debug option that was used by the Internet worm)
- Improper initialization; many bypasses are enabled by systems being incorrectly configured, so that when they are initialized IA features can be bypassed
- Improper finalization; when a program terminates it must ensure that it disposes of all secure information properly—if not, improper finalization occurs
- Incomplete or inconsistent authentication and validation can be caused by improper argument validation (e.g., the Internet worm used a bug in the *get* function located in the finger demon to gain root access); the bug was that the *get* function did not do a bounds check on the number of arguments
- Improper encapsulation of the internals of a system can allow a user to access information or functions that they are not authorized to access

Authorization attacks are attacks where an attacker attempts to guess a user's password. This type of attack can be computerized and tools such as John-the-Ripper and L0pht-Crack have been developed. It is estimated that L0pht-Crack can perform a complete search of the Windows NT password search space on a 1.0-GHz PC in 3 and a half days.

Active misuse of an information system is primarily concerned with modifying information or entering false or misleading information. Table 6 describes types of active misuse. The following are also examples of active misuse:

**Table 6** Active Misuse

Mode of Misuse	Description
Basic active attack	Creating, modifying, entering false or misleading information
Incremental attack	Using salami attacks
Denial of service	Perpetrating saturation attacks

**Table 7** Passive Misuse

Mode of Misuse	Description
Browsing	Making random and selective searches
Inference, aggregation	Exploiting database inferences and traffic analysis
Covert channels	Exploiting covert channels or other information leakage

- A box office supervisor cancelled tickets, which had been sold, and then later resold the tickets, keeping the cash. The box office supervisor falsified the audit trail, but this was detected after problems with the software were investigated. The employee was prosecuted and given six months' imprisonment.
- The World Wide Web provides a vehicle through which organizations and people can communicate and disseminate information. Hundreds, if not thousands, of businesses and government agencies have had their Web sites attacked. The general effect of unauthorized alteration of a Web site is a loss of public confidence in the agency's ability to protect its information systems and often a public relations nightmare.

In addition, this type of misuse is concerned with the denial of service (DOS). For example, a company that specializes in trading on the Internet is exposed to the threat that if the Internet connection is lost then the ability for the company to conduct business is lost and the supply chain is broken.

Passive misuse of an information system is primarily concerned with exploiting the information within the system so as to conduct analysis and make inferences about the existence of sensitive information. Table 7 lists types of passive misuse.

Inactive misuse of an information system is primarily concerned with willfully failing to perform expected duties or committing errors of omission. Table 8 describes inactive misuse.

Indirect misuse of an information system is primarily concerned with preparing for subsequent misuses, as in offline preencryption matching, factoring large numbers to obtain private keys, autodialer scanning. Table 9 describes indirect misuse.

## TECHNOLOGIES FOR COMPUTER NETWORK DEFENSE

The three most common types of technologies that get deployed to protect a computer network from attack are intrusion detection systems, firewalls, and honey-pots.

**Table 8** Inactive Misuse

Mode of Misuse	Description
Inactive misuse	Willfully failing to perform expected duties, or committing errors of omission

Table 9 Indirect Misuse

Mode of misuse	Description
Indirect misuse	Preparing for subsequent misuses, as in offline preencryption matching, factoring large numbers to obtain private keys, autodialer scanning

- Intrusion detection systems come in two flavors: misuse detection and anomaly detections. Misuse detection makes use of expert system technology to detect attack. This type of technology is very good at detecting known forms of attack and thus has a very low false positive rate, whereas it is very poor at detecting new forms of attacks. Anomaly detection focuses on the rule of statistics to the identification of an attack and makes use of key technologies such as byzantine network, neural network, and genetic algorithms. Such technologies are very good at identifying new attacks but can generate a lot of false positive assessments when identifying known attacks.
- The most common forms of firewalls on a network will be either a packet filtering firewall or a proxy firewall. A packet filtering firewall uses the contents of the TCP/IP packet to decide if a packet is allowed onto the network or not. A proxy firewall uses a proxy service to relay messages to systems located behind the firewall that are not visible inform of the firewall. Computer network defense will make use of vast quantities of audit data such as IDS logs, firewall logs, router logs, and other system type logs. Technologies such as INCH, IODEF, and IDMEF are all XML-based solutions to the problem of data integration, data fusion, and data sharing (Rehman, 2003).
- The development of deception technologies such as honey-pots and honey-nets are designed to divert an attack from a critical part of the network to a non-critical part of the network. The goal when deploying these technologies is to tempt a threat agent into wasting time, money, and other precious resources into trying to compromise systems that have no impact on the

effectiveness in operational terms of the organization. In fact, while a threat agent is attacking a honey-pot, a defending organization can deploy a set of countermeasures to apprehend the threat agency.

### SURVIVABILITY

Survivability is about detecting, recovering, and tolerating an attack. In terms of computer network defense (CND) it means defense in depth. Figure 2 illustrates this principle. The threat is made manifest via a threat agent and the attack is detected. The detection process can involve technologies such as intrusion detection systems (e.g., Snort) or the simple education of users to look for erroneous behavior. Once an attack is detected, the computer system then has to operate while under attack.

The computer system is required to recover from the attack and mount a defensive response. As in many countries, such as the UK, United States, Canada, Australia, and New Zealand, where hacking is illegal, it is a point of legal, ethical, and moral debate as to under what conditions it is acceptable to mount an offensive response. A defensive response can mean reconfiguring a firewall in real time to stop an intruder from penetrating a network further or deploying technologies that aid in deceiving an intruder and thus luring the attacker away from the real system (Blyth & Kovacich, 2001).

### DECEPTION

Deception in information security is something that is now starting to attract attention (Grazioli & Jarvenpaa, 2003). Technologies such as honey-potting have matured and commercial products are now available. The model of using deception in information security is based on the concept of defense in depth. When using deception in computer network operations we should implement deception in layers, understand that intruders will fall prey to deception differently, depending on their knowledge, experience, capabilities, determination, resources, and so on and deploy deception accordingly, and use the information gathered in an intelligence gathering capacity to

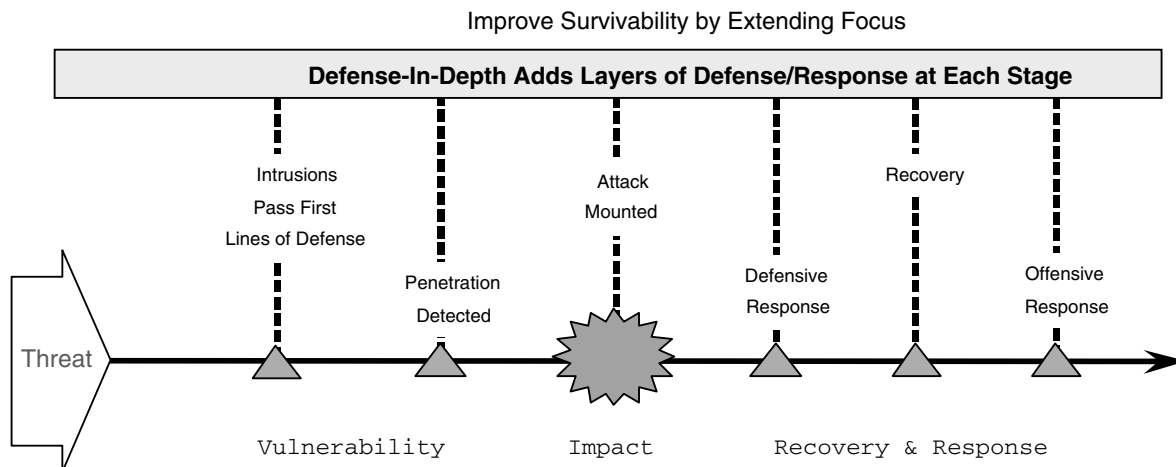

Figure 2: Survivability.

understand intentions, interests, capabilities, and modus operandi.

When using deception in information security the goal is to increase the survivability of your critical information systems by allowing an adversary to expend time and resources attacking false systems. From a defensive point of view our goal is to protect our own command and control systems, as the loss of these systems could function as a force multiplier for an adversary.

When deploying deception we need to appreciate that deception will affect different people in different ways, consequently we need to understand the following: what deception can mean and how and why deception works on different types of people.

The *Concise Oxford English Dictionary* defines the term *deception* as meaning “Deceiving or being deceived; thing that deceives, trick, sham” and defines the term *deceives* as “persuade of what is false, mislead purposely.”

In terms of information assurance the goals of using deception are as follows (Dearth, 1998; Gerwehr & Glenn, 2000):

- *To condition a target's belief*
- *To influence the target's actions*
- *For the deceiver to benefit from the target's actions*

The most common form of this type of information assurance activity is called perception management and propaganda (Waltz, 1998). The goal of perception management is to control the way that an adversary sees the world through their belief system. Propaganda is using information to convince people that your view of the world is the correct view of the world. Propaganda is not new and forms part of commercial advertising that we see on television and the Internet today. Many terrorist organizations make use of the Internet as a tool for propaganda (Johnson, Grazioli, & Berryman, 2001). The problem that many governments now face is that the Internet allows people direct access to a population. Before the Internet a government could disrupt radio signals, but censorship on the Internet is a far more difficult subject.

The goal of using deception in a defensive capacity is to control and direct the actions of an adversary so as to protect your own assets and ensure that mission/safety critical information systems are protected and continue to function while under attack. An example of using computer-based deception would be to create a fake network and IP addresses space within which an adversary would seek to find nonexistent information. Consequently, by getting the adversary to seek for nonexistent information, we are forcing them to commit their resources to an activity that will fail; thus we are weakening our opponent. In addition, we can also monitor the activities of the adversary and use this monitoring as a vehicle for gathering intelligence on their capabilities. We may also wish to create fake network and vulnerable computer systems as a mechanism for leaking information to an adversary that we would wish them to have. Thus intelligence and counterintelligence have a role to play in any deception operation.

## DECEPTION TAXONOMY

The following is a taxonomic framework that can be used to develop an understanding of the way in which cyberdeception can function:

- Feint, diversion, display, decoy, dummy, camouflage, concealment, cover, mimicry, spoofing, dazzling, sensory-saturation, disinformation, and conditioning
- Static, dynamic, adaptive, and premeditated
- Host-based and network-based
- Offensive deception operations and defensive deception operations
- Phases of a deception operation
- Dissimulation and simulation
- Deceit, denial, disruption, distraction, and development

We now examine each of these in turn in more detail. The types of deception acts that can be used in information warfare are as follows:

1. **Feint/diversion.** The aim of a feint/diversion attack is to overload another network service while attacking another. For example, a feint/diversion attack would begin to deploy resources in mounting an attack against it. The attack could be anything from intelligence gathering to denial of service, including mounting a denial of service attack against one server while using a specific root-level remote exploit against another.
  - On January 10, 1992, ABC's "Nightline" reported that a virus had been shipped in a printer to the Iraqi government. The virus named AF/91 never existed and was part of a disinformation campaign designed to stop the Iraqi government from using computer equipment.
2. **Display/decoy/dummy.** The aim of a display/decoy/dummy attack is to induce a belief in an adversary that they have correctly identified your main networks and servers.
3. **Camouflage/concealment/cover.** The aim of a camouflage, concealment, and cover attack is either to insert information into an adversary's information system without them realizing it or to covertly observe an adversary without them realizing it. For example, directing a network based attack via a compromised third party.
4. **Mimicry/spoofing.** The aim of a mimicry/spoofing attack is to induce a belief in an adversary that they have received information from an agent, when in fact the agent did not send it. Examples of mimicry and spoofing attacks include the following:
  - Sending fake e-mails and reports from a person/agent
  - Creating a fake node on a network using IP spoofing. This type of attack was used by Mitnick against Shimomura (Shimomura & Markoff, 1996)
5. **Dazzling/sensory-saturation.** The aim of a dazzling/sensory-saturation attack is to overload the sensing capability and processes capability of adversaries with so much data that they are blinded for a period of time.

6. Disinformation. The aim of a disinformation attack is to provide an adversary with false information from a credible in such a manner so as to influence/control their behavior. Sun Tzu (Griffith, 1971), talks about such stratagems such as providing agents with deliberately false information. Modern examples include the following:

- On December 16, 1999, federal prosecutors charged two men with posting false messages about a company on Internet bulletin boards in an effort to bolster the company's stock prices. The pair were accused of posting phony stories over a 2-day period in November about NEI Webworld, a Dallas-based printing services company. The bogus postings pushed the price of NEI's stock up from 13 cents to more than \$15 per share.

7. Conditioning. The aim of a conditioning attack is to induce a belief in an adversary that is incorrect. For example, making a server unstable by resetting it, thus conditioning the administrator into believing that there is some hardware fault.

The static, dynamic, adaptive, and premeditated types of deception that can be used in information assurance are as follows:

1. Static deception is where a deception method is in place irrespective of state activity or history of either deceiver or target.
2. Dynamic deception is where the deceiver employs a deception method when a strict set of circumstances occurs.
3. Adaptive deception is where a deception method is triggered as in dynamic deception, but the method or triggering event may be modified by feedback.
4. Premeditated deception is where a deception method is designed and implemented by the deceiver based on experience, knowledge of own vulnerabilities/strengths, and observations of the target.

The host-based and network-based types of deception that can be used in information warfare are as follows:

1. Host-based deception is deception that is based on a target computer that an intruder has access to. This type of deception can include modification of tools such as ls and ps on UNIX to provide false information (Cheswick, 1992) or the creation and location of false information on the computer so as to misinform an adversary (Stoll, 1989).
2. Network-based deception is deception that makes use of a computer network or computer system to create the illusion of a fake computer network. For example, simulating multiple operating systems on a single computer.

The types of offensive deception operations and defensive deception operations that can be used in information security are as follows:

1. Offensive deception is where a deception method is designed to enhance the effectiveness of offensive acts

while reducing an adversary's effectiveness in both offense and defense.

2. Defensive deception is where a deception method is utilized that is designed to enhance the effectiveness of defensive acts while reducing an adversary's effectiveness in both offense and defense.

With regard to information security the phases of a deception operation can be viewed as being cyclic in nature progressing through seven stages/phases defined as follows:

1. Phase/Stage 1: Defining and reviewing operational objectives that the deception operation is required to achieve.
2. Phase/Stage 2: Evaluating your own and the adversary's capabilities and other situational factors. This will draw on intelligence gathered in other operations. In a commercial setting it could include market research and competitive analysis. From a computer-based perspective it could include a technical assessment of an adversary's capability and resource utilization.
3. Phase/Stage 3: Developing the concept of operations and set of actions that will implement the operation and achieve the objectives defined in Phase/Stage 1.
4. Phase/Stage 4: Allocation of resources required. This could include physical resources such as people, technologies, finances, and computers, but it could also include logical resources such as information.
5. Phase/Stage 5: Coordinating the plan relative to other plans. Often a deception operation will form part of a larger strategic plan of a campaign. Thus, to avoid it adversely interacting with other operations it needs to be coordinated and synchronized with other plans.
6. Phase/Stage 6: Performing a risk and feasibility assessment. This involves assessing the potential for success and failure and examining the strategies and costs that need to be put in place to ensure success. The assessment can also include a calculation of the cost if the deception operation fails. Cost can be calculated not only in monetary value but also in the loss of prestige and trust.
7. Phase/Stage 7: Review adherence to strategic and tactical objectives. The deception operation needs to be viewed as integrated into a strategic whole if the strategic objectives are to be achieved.

We can also view deception in terms of dissimulation and simulation.

1. The term *dissimulation* is used to refer to the concept of hiding the real. Dissimulation includes the following:
  - Masking: hiding some or all of the real target by making it invisible to an adversary's sensor capability.
  - Repackaging: hiding the real target by disguising it so that the adversary's sensor capability sees the repackaged artifact.
  - Dazzling: hiding the real target by confusing/overloading an adversary's sensor capability.
2. The term *simulation* is used to refer to the concept of showing the false. Simulation includes the following:

- **Mimicking:** showing false to adversary's sensor capability through imitation.
- **Inventing:** showing false by creating a different reality for an adversary's sensor capability to detect.
- **Decoying:** showing false by diverting the attention of an adversary's sensor capability.

We can also view deception in terms of deceit, denial, disruption, distraction, and development.

- **Deceit** is fabricating, establishing, and reinforcing incorrect or preconceived beliefs, or creating erroneous illusions.
- **Denial** is masking operations for protection or to achieve surprise in an attack operation.
- **Disruption** is creating confusion and overload in the decision making process.
- **Distraction** is moving the focus of attention toward deceptive actions or a way from authentic actions.
- **Development** is creating a standard pattern of behavior to develop preconceived expectations for subsequent exploitation.

In general terms, however, deception is used to encompass a number of concepts concern with misinformation and perception management. In military terms deception is used to *camouflage, conceal, deceive, imitate, disinform, keep secret, secure, feint, and divert*. But how are these concepts being embraced within modern military doctrine and information warfare?

## STRATEGIES AND POLICIES FOR COMPUTER NETWORK OPERATIONS

Strategies for CNO and in particular CND must function at the strategic, tactical, and operational levels. At the strategic level, we must focus on developing an understating of the risks and threats faced both in terms of CND and CAN (Rathmell, 2001). Questions arise about the capabilities and motivations of threat agents faced. At the strategic level both the attacker and defender must build strategic alliance with other parties.

In tactical terms, there is a need to focus on the clear identification of operational procedures and responsibilities, along with system planning and acceptance and business continuity planning (Pfleeger & Pfleeger, 2003). These must be tested and continually revised if they are to be effective. Whereas at the operational level we must focus on the use and deployment of up-to-date technologies and systems to hinder an attack.

## IMPLEMENTING COMPUTER NETWORK OPERATIONS

When we consider CNO at an international level we can use the security models of CIA and DDPRR to create a framework within which a integrate approach can be formulated.

- **Deterrence:** Multilateral initiatives to deter a threat agent from mounting a CNA. Such an approach must include

the harmonizing of cybercrime legislation and the sharing of evidence and intelligence.

- **Prevention:** Multilateral initiatives to prevent CNA by promoting the correct specification, design, implementation, and deployment of secure systems. Such an approach must include the sharing of security related information such as vulnerabilities and patches. Deception technologies such as honey-pots also allow for an attack to be diverted to a fake target thus preventing the attack on the real target.
- **Detection:** Multilateral initiatives to detect CNA that focus on enhanced cooperation of organization and agencies at both a professional and technical level. The development and deployment of intrusion detection systems and deception technologies such as honey nets allow for an intruder to be detected.
- **Reaction:** Multilateral initiatives to react and survive a CNA. Such initiatives must include the creation of computer network infrastructure that is capable of surviving and tolerating attacks. Initiatives must also include cooperation among criminal justice agencies, government agencies, and the public.

In short, for CNO to function we require an integrated approach that supports cooperation and the exchange of information across organization and political boundaries.

## GLOSSARY

**Capability** The ability of an adversary to perform an action.

**Computer Network Attack** The art of breaking into a computer network.

**Computer Network Defense** The art of defending against someone breaking into a computer network.

**Computer Network Operations** Both computer network attack and computer network defense.

**Computer Security** The protection resulting from all measures to deny unauthorized access and exploitation of friendly computer systems.

**Confidentiality, Integrity, and Availability (of data)**

Factors of a data processing system and its files that must be protected. Confidentiality protects the existence of a connection, the traffic flow, and information content from disclosure to unauthorized parties. Integrity is the assurance that information and processes are secure from unauthorized modifications by use of cryptography, digital signatures, and intrusion detection. Availability is the degree that information, data processes, and resources are usable when needed.

**Cryptanalysis** The steps and operations performed in converting encrypted messages into plain text without initial knowledge of the key employed in the encryption.

**Cryptography** The science that deals with hidden, disguised, or encrypted communications. It includes communications security and communications intelligence.

**Deception** Those measures designed to mislead the enemy by manipulation, distortion, or falsification of evidence to induce the enemy to react in a manner prejudicial to the enemy's interests.

**Denial of Service** A loss of the ability of a data processing system to provide satisfactory service with respect to confidentiality, integrity, and/or the availability of its data. This loss may be temporary, as in a delay, or it may be long-lasting enough have a catastrophic effect on an enterprise.

**Exploit** A specific technique that allows for the security of a system to be compromised.

**Information-Based Warfare/Information Operations** Actions taken to affect adversary information and information systems while defending one's own information and information systems.

**Information Security** The protection of information and information systems against unauthorized access or modification of information, whether in storage, processing, or transit and against denial of service to authorized users. Information security includes those measures necessary to detect, document, and counter such threats. Information security is composed of computer security and communications security.

**Information Warfare Definition I** Information operations conducted during time of crisis or conflict to achieve or promote specific objectives over a specific adversary or adversaries. Information warfare actions may induce denial of service, corruption of data, and/or exploitation of the information obtained.

**Information Warfare Definition II** Actions taken to achieve information superiority by affecting adversary information, information-based processes, information systems, and computer-based networks while defending one's own information, information-based processes, information systems, and computer-based networks.

**Information Warfare Definition III** The offensive and defensive use of information and information systems to deny, exploit, corrupt, or destroy an adversary's information, information-based processes, information systems, and computer-based networks while protecting one's own. Such actions are designed to achieve advantages over military or business adversaries.

**IP** The Internet protocol.

**Risk** The level of threat posed by an adversary.

**Security (of Information)** With respect to classified matter, the condition that prevents unauthorized persons from having access to official information that is safeguarded in the interests of national security.

**Social Engineering** Deceptive techniques involved by persons pretending to have authorization to obtain information or entry into a facility for which they are not authorized.

**Threat** A function of motivation, capability, opportunity, and impact that describes a threat agent.

**Threat Agent** A hacker, cracker, criminal, spy, and so on.

**Transmission Control Protocol**

**Trojan** A malicious program that presents itself as being of a nondestructive nature. A characteristic that

distinguishes them from viruses is that Trojans do not replicate themselves.

**Vulnerability** A method that allows for the security of a system to be compromised.

## INTRODUCTION

The term *electronic protection* has been used inconsistently in the literature to mean several things related to information security. We interpret it here in the strict sense of methods of protecting information systems from attacks that do not require an electrical or software connection to the target but exploit electromagnetic effects of electronics. Unfortunately, electrical connections to a target system are not necessary to have serious security problems. We do not consider here other important aspects of this considered elsewhere in the *Handbook*, such as radio frequency and wireless communications security, wireless information warfare, hacking techniques in wireless networks, mobile devices and protocols, and smart card security. We also do not consider primarily nonelectronic physical attacks on computer systems and networks such as explosions of conventional munitions (see Physical Security Threats).

The two main threats addressed by electronic protection are people trying to steal your secrets (spies) and people trying to vandalize your hardware or prevent it from working (saboteurs). These threats are more associated with military information systems than civilian systems and are particularly serious in battlefield situations (Friedman, 1983), so much of the research has been done by military organizations. Spies in a military setting are trying to get intelligence, and if they get it from electronic signals, they are doing signals intelligence (SIGINT; Zorpette, 2002). But spying and sabotage are also an increasing problem for businesses; secrets of competitors can be worth considerable money and effort. Incidents may be underestimated because it is of little advantage for either the military or business to report them. Electronic spying and sabotage are usually illegal; in the United States, U.S. Code Section 2511 prohibits real-time acquisitions of electronic communications in transit, and many countries have similar laws. But this has not stopped determined spies when key government, military, or business secrets are at stake.

Like all security measures, electronic protection must be cost-effective. One needs to assess the likelihood of an attack and how serious the results of that attack might be. It is thus important to do a risk assessment (see Risk Assessment and Risk Management) before committing to the protection methods to be discussed.

## ELECTRONIC EMANATIONS FROM COMPUTER TECHNOLOGY

We first consider the problem of information leakage from a computer system or network through the electromagnetic radiation it produces. This has been termed *emanations security* or *emissions security* in the military literature.

### The Physics of Electronic Emanations

It was discovered in the 19th century by Oersted, Faraday, and Henry and formulated in Maxwell's equations that changing electrical currents induce changing magnetic fields and magnetic fields induce changing currents. Computers use patterns in currents for operations and communication. These changes induce a changing magnetic field that propagates as an electromagnetic wave through surrounding space. This field can be picked up by electrical conductors in the vicinity, and in bad cases can impede operations of other electronic devices via *electromagnetic interference*. Thus an antenna with an amplifier can pick up a considerable amount of signal from a nearby computer and can reconstruct the generating electrical signals. Electromagnetic signal strength or intensity is the amplitude of the electromagnetic field waveform at some point in space (also called the electric flux density) and is the major factor affecting detectability of the signal. Signal intensity generally decreases as the square of the distance from the radiation source. Bugging devices within computers can pick up signals more successfully than remote ones can.

Electronic protection has not improved as the speed of computer technology has increased. With clock times now below nanoseconds, computers are radiating signals whose base frequencies are in the range of microwave radiation. As with microwave ovens, microwaves have good penetrating power for many kinds of materials. (The higher the frequency, the more energy the radiation has; however, penetration ability varies considerably with the chemistry of the material.)

Matters are made worse by the use of abrupt changes between two levels of voltage in digital hardware. The more abrupt a transition, the more high-frequency components in its spectrum. A sine wave has only one frequency; a square wave consisting of alternation between two voltages has a frequency spectrum of odd multiples of a base frequency where the amplitude of the components is inversely proportional to the frequency. High-frequency components of a waveform are refracted less by materials than low-frequency components, making them easier to detect if they are not absorbed. Furthermore, materials that one frequency poorly penetrates may be much more transparent to another—and the harmonics of an abrupt transition can be significant over quite a range of frequency. A spy may need only find one frequency to recognize the transition of a digital signal.

Several additional factors affect the intensity of signals emanating from a computer system:

- Higher currents produce stronger signals than lower currents. Most parts of computers run on relatively low currents, but an important exception is a cathode ray monitor, which requires hundreds of volts. Consequently, their screen images are easier to detect than most computer signals.
- Slower signals are often easier to detect than faster signals because they stand out better from the background noise. Therefore cables connecting to a modem are more susceptible to eavesdropping than a cable to a fast digital telephone line. However, faster signals may also radiate better.
- Periodic signals are easier to detect than irregular or one-time signals because signal energy can be summed for corresponding parts of each period, greatly helping detection. Important periodic signals occur in many places in computers, especially in the central processing unit (CPU) cycle, the monitor screen refresh process, and the loop that monitors the keyboard for key depressions.
- “Unbalanced” signals are easier to detect than balanced signals. Signals are balanced when pairs of opposite currents occur on adjacent wires. Balance is a problem for some kinds of cables.
- Many sophisticated techniques from electrical engineering can help detect signals in the presence of noise, even nonrandom noise (Garth & Poor, 1994).
- Electronic circuits have resonant frequencies. An external signal can be broadcast to a computer system to induce it to resonate at one its natural frequencies. This has the effect of modulating normal signals of the computer, making them easier to detect by demodulation.

However, the effect is weak and it is difficult to control what kind of information you obtain.

- If a spy can plant a Trojan horse on a computer system, it could deliberately create periodic loops in code to make stronger electromagnetic signals, providing a covert channel for transmission of information (see Side Channel Attacks).

## Electronic Eavesdropping Technology

An electronic eavesdropper uses bugs consisting of the following:

- A device for picking up signals, as large as possible and as close as possible to the source while maintaining concealment; this can be an antenna at a distance or an induction loop around an electronic component
- An amplifier for the signals from the antenna
- A receiver (electronic filtering to extract the signal from the noise); the emanations of a computer are not designed for easy separation like radio stations are, but good filters can be effective
- Either a recording device (which may be hard to conceal given the amount of data recorded) or a retransmission device; retransmission is commonly by radio at a specific frequency, but could also be done by digitizing and connecting to a computer network (if the signal picked up is video, it could be retransmitted to another screen nearby).

Bug technology continues to decrease in size for the same performance (Murray, 2003). Intelligence agencies use bugs camouflaged as all kinds of everyday objects, so do not expect them to be easy to recognize. They may not need to be camouflaged much anyway—most people rarely look inside the cabinet of their computer. Even chips could be bugs because many computers leave empty slots during manufacture to permit later expansion. Good places to put bugs are on the display and keyboard drivers to enable reading of everything the user is doing. People who like to be suspicious have claimed bugs are widespread (Thomas, 2004), but one must be skeptical of much of what one reads about bugs on the Internet.

## Points of Weakness for Electromagnetic Emanations in Computer Systems

We enumerate here some particular sources of signals that spies could exploit for electronic eavesdropping.

### Cathode Ray Monitors

The traditional television-style monitor screen is a big source of emanations. Van Eck (1985) stimulated a great deal of interest by showing how easy it was to duplicate the display of a traditional cathode ray monitor on a nearby monitor using just the radiated signal. Reception is aided by high currents used by such devices. In addition, screen display follows a consistent periodic sequence: Each line of the screen is drawn from side to side, and the standard VGA format uses exactly 480 lines with exactly 640 pixels per line. This means one can reconstruct the screen signal by an easy guess as to the vertical sync (the time to draw all

lines) and the horizontal sync (the time to draw one line) (Kuhn & Anderson, 1998). Liquid-crystal displays such as those found in most laptops do not use this mechanism but still give some weaker emanations nonetheless, especially the back-lit ones common today.

### Keyboard

Another weakness is the keyboard-handling software. Usually the keys are sampled periodically by a keyboard driver to see if they have been depressed. This produces a near-periodic signal that can be compared between cycles to detect key depressions. However, it involves transitory changes and lower currents than those of the monitor.

### Cables

Electrical cables connecting a computer to other devices can be a source of signal because of their similarity to antennas (which are long wires, too). Cables can use higher currents than CPUs because of the need to reduce transmission losses. Modem cables in particular are desirable targets because of their low data rates and the possibility of picking up passwords and keys in the clear. Furthermore, modems often use serial (one-at-a-time) character transmission, which reduces the number of signals that need to be distinguished by the eavesdropper.

Most cables are shielded to reduce the electromagnetic interference on their signal from other devices. (Exceptions include many telephone cables that are unshielded twisted pairs.) This means that the main conductor is surrounded but separated from an electrically conductive covering that carries the ground (or comparison) voltage. In principle, this should reduce emanations substantially. But in practice, not all cables are properly grounded (grounding can be difficult), not all shielding is effective (good cabling costs money), and there is a source of signal at each end where the cable connects to other electronics. Smulders (1990) showed a surprising ability to pick up signals from a modem cable with a standard radio receiver.

### Power and Ground Voltages

Electrical devices using varying amounts of power create transients in the power and ground connections that they use. The effect is visible on any device sharing the same power connections, as within a building. This effect is often seen when large motors turn on and can be seen to a lesser extent with computer peripherals, especially a cathode ray monitor. But the signals produced are very noisy because everything attached to the power line or ground can also produce an effect.

### Magnetic Disks

Magnetic hard disks rotate continually even when not being read. If the disk head remains over a particular track on the disk, it will generate a periodic signal representing the bits on that track. But this is uninteresting data most of the time, and the signal may be so weak because of shielding that it would be easier to directly connect to the associated computer system.

### Optical Signals

Light is also electromagnetic and we need to prevent reading of computer screens through windows with

telescopes. Just ensuring that the screen is unreadable at a reasonable distance is insufficient with cathode ray monitors, because the changes over time in the total diffused light from a monitor can carry enough information to enable reconstruction of characters (Kuhn, 2002). Many computers and peripherals also have light-emitting diodes (LEDs) intended to give operators a simple summary of what the devices are doing. However, LEDs can switch on and off at a rate up to 10 ns, far beyond what people can detect, and this could be a covert channel to signal information to a confederate (Loughry & Umpruss, 2002).

### Error Correction

Detected electromagnetic emanations have considerable noise, because the transmission of information is neither engineered nor intended. A variety of error-correction methods can be used by the eavesdropper. Conventional electronic filtering can be done when the signal has a primary frequency, or a strong known unwanted frequency can be filtered out. Video signals have a variety of specialized correction techniques that have been developed to aid copying of video. Research in optical character reading (Liu, Babad, Sun, & Chan, 1991) has developed a variety of robust techniques for correcting noisy images of characters.

As for digital data, error-correcting codes and checksums in network transmissions can be picked up by the eavesdropper to correct some reception errors (Forouzan, 2003). But even without such codes, a spy eavesdropping on text can exploit knowledge of an alphabet or language used to rule out most errors. For instance for English, 20,000 words is a common vocabulary size for a native speaker, and the average word is eight letters long. Yet there are 200 billion possible eight-letter words, so most of the one-character errors in interpreting an eight-letter English word are easy to correct. Kukich (1992) gives a comprehensive overview of algorithms for such corrections. For other kinds of data, knowledge of the typical symbols can be formulated from experience (Moulin & O'Sullivan, 2003).

The frequent predictability of software can be exploited by an eavesdropper. For instance, encryption algorithms often start execution with the same sequence of code; an eavesdropper could learn to recognize the signals corresponding to that code and then zero in on the plaintext key typed next. The eavesdropper could learn the necessary patterns by obtaining and running their own copy of the encryption software.

## REDUCING THE THREAT OF ELECTRONIC EMANATIONS

In the face of these threats, several techniques can prevent or reduce eavesdropping, as summarized in Table 1.

The most obvious techniques are concealment of the emanations themselves by reducing their intensity. This was the idea behind the TEMPEST standards adopted by the U.S. government in the 1960s to reduce emanations from their important computers (McNamara, 2004). Although the quantitative details of TEMPEST

**Table 1** Summary of the Suitability of Electronic Protection Methods for Attack Targets

Threat	Monitor	Keyboard	Cables	Power and Ground	Disks	Optical Signals
<b>Electromagnetic shielding</b>	Yes	Yes	Yes	No	Yes	No
<b>Source Suppression</b>	Yes	No	Yes	Yes	No	Yes
<b>Noise generation and encryption</b>	Yes	Yes	Yes	Yes	Yes	Yes
<b>Signal irregularity</b>	Yes	Yes	Yes	Yes	No	Yes
<b>Deliberate deception</b>	Yes	No	Yes	No	Yes	Yes
<b>Bug detectors</b>	Yes	Yes	Yes	Yes	Yes	No

specifications are still secret (i.e., they are classified), the basic principles are available in the open literature. TEMPEST has not been as important since a 1991 report of the U.S. Central Intelligence Agency concluded it was not cost-effective, especially within the United States in protecting against foreign spies. TEMPEST hardware for computers, peripherals, and cables typically costs two to three times that of equivalent unprotected commercial hardware. There are so many software-based ways of stealing secrets that electronic eavesdropping is less threatening than it once was. Nonetheless, TEMPEST standards are still important for U.S. military and diplomatic computers that have important secrets.

## Electromagnetic Shielding

Electromagnetic emanations can be reduced or even suppressed entirely by use of appropriate electromagnetic shielding. Gauss's law says the surface integral of a closed contour surrounding an object is only proportional to the charge enclosed. If that contour is unbroken and electrically conductive, an internal electrical field with no net charge will cancel itself out so there will be no net electrical field outside the contour. This also means that any electrical charge on a closed conductive surface resides entirely on the outside of the surface.

Therefore, to eliminate emanations, we should put computers in metal boxes (Faraday cages) made of conductive materials such as copper, aluminum, or steel. A variety of materials and forms (solid metals, conductive coatings, adhesive foils, conductively filled materials, etc.) suffice (Molyneux-Child, 1997). However, perfect protection assumes the conductive enclosure is unbroken. Because there usually must be gaps for ventilation, power lines, keyboards, and network connections, these gaps may permit signals to leak out (Warne & Chen, 1992). Consequently, significant gaps must be minimized. A key factor is the ratio of the diameter of the gap to the wavelength of the signal frequency one wishes to suppress (Hoffman Enclosures Inc., 2003). As a rule of thumb, it has been suggested this should be 1/10th or less to prevent significant radiation from escaping, and 1/100th to provide 60-db reduction (Molyneux-Child, 1997). Waveguides in the form of conductive pipes through the gaps can further reduce the emanations at these gaps, as can making the gaps into meandering channels. Power lines through these gaps can be filtered, and fiber optic cables through the gaps can supply communications signals without providing an electro-

magnetic channel. Monitor screens can be coated with a conductive film, but keyboards are tricky to protect. A number of vendors supply such specialized hardware. Such shielding is difficult to do on laptop computers, where weight and space are at a premium.

To simplify construction, the conducting box is often constructed with a grid of wires like a cage. This works well if the gaps between the wires fulfill the wavelength constraints, and it permits better ventilation than a closed surface. Rooms and even buildings can be built using these conductive grids (Hemming, 1992).

Cables provide special problems for shielding because an unshielded and unbalanced electrical cable can be much like an antenna. Fiber optic cables are the best solution although they are more expensive per unit length than electrical cables. They have no electromagnetic emanations along their bodies because they are coated to prevent the escape of light. Their only weakness is on their ends where light is converted to and from electrical signals. Long fiber optic cables such as long-distance telephone lines also need to be periodically boosted electronically along their length, and the booster is susceptible to eavesdropping.

Optical signals from cathode ray monitors and LEDs can be suppressed by covering room windows and otherwise controlling their light, even the reflected light. Kuhn (2002) also suggests increasing light noise by using significant broad-frequency illumination for the computer room by incandescent or high-frequency fluorescent lights to cover the frequencies of the monitor light. Good design for LEDs should ensure they do not change any faster than humans can follow them.

## Source Suppression

Another goal should be to reduce emanations from the computer itself. A good compact design of the machine will help. This means a relatively small chassis and short cables to reduce electrical dipoles that cause emanations. Devices used to measure electromagnetic interference can help locate possible emanation problems (Masuda et al., 2003). Generally speaking, the intensity of a signal decreases as the square of the distance from the source, so one can estimate how close an enemy must be to pick up a signal.

For conventional electrical cables of either the twisted-pair or coaxial type, ferrite beads or disks on the ends can reduce emanations. Ferrites are ferromagnetic materials

that dissipate high-frequency magnetic fields as small amounts of heat with magnetic eddy currents. They are useful for frequency over 100 MHz, in the range of computer signals, but require some care to use effectively because they must be matched to appropriate electrical hardware. In-line capacitors can also achieve the effects of ferrite beads but can involve more power dissipation.

Because high frequencies tend to be easier to pick than low frequencies, it is desirable to lower the high-frequency emanations by slowing the switching times between low and high voltages in signals. This is difficult with the CPU but makes sense for the cables, particularly the video and keyboard cables that do not need fast transition times. This can be done by running the signals through a suitably designed low-pass filter, something done routinely to reduce electromagnetic interference. Kuhn and Anderson (1998) also designed special "Tempest fonts" for monitor screen display that have reduced high-frequency components but are still legible, making them harder for an eavesdropper to pick up.

Another approach to source suppression is to move the source about as in a mobile device. That way any fixed-location eavesdropper cannot obtain all the information. But this is possible only with a few applications.

## Noise Generation and Encryption

Another way to make eavesdropping more difficult is to broadcast noise at the same time. Noise can be just many signals at the same time. It is difficult to eavesdrop on a single computer in a busy office with many computers, and similarly, it is difficult to eavesdrop on the signals of a CPU because there are so many in a small space. Noise, however, can create electromagnetic interference if too strong. Realism requires that noise start and stop and eavesdropping could be done while it is off. Also, it is important to create sufficiently complex noise that cannot be easily filtered out. Analog white noise, for instance, noise of a uniform mixture of frequencies, is just added to the frequencies already present and its uniform height can be easily subtracted from the frequency spectrum. So digital noise is needed that looks like real computer operations from a number of simultaneous sources. Even noise sources that are obviously fake can create a difficult combinatorial problem for the attacker in assigning bits to each signal if the sources are located near one another.

The effect of noise can be created by omitting error-correcting bits transmitted in network protocols so attackers have a more difficult time fixing errors in reception. Because their error rate will be higher than that of the system they are monitoring, this creates added problems for them. However, this may give only a mild effect and also hurts the system if its own error rate is nonnegligible. So it is hard to justify against rare threats.

A systematic way to accomplish noise is to encrypt much of the digital activity of the computer. This is a good practice for files and network communications anyway when secrecy is important, so it can be extended to other aspects of the computer when electromagnetic emanations are a concern. Strong encryption methods are now easily available (see PKI and PGP). Unfortunately,

the keyboard depressions and the monitor display cannot ultimately be encrypted, so other techniques are necessary for them. It will help to avoid displaying passwords and keys on the screen because the screen contents are easy to pick up. Steganography is not as useful as encryption because activities and files are difficult to conceal completely.

Even when data are encrypted, spies may learn something from when and where it is being used. Spies can do traffic analysis to determine the flow of information between sites; for a hierarchical organization, this may be sufficient to identify the flow of information. To prevent this, it is useful to send dummy (noise) messages periodically between sites; if an equal number of messages are sent between each pair of sites on the average, a spy cannot infer any structure of the sites.

## Signal Irregularity

Because eavesdropping is easier with periodic signals, another idea is to insert deliberate random delays in transmission of signals to avoid periodicity. This can be done by changing the operation of the lowest layers of the OSI network transmission protocols (Forouzan, 2003), the physical and data link layers. Because slow transmissions such as those with keyboards, monitors, and modems are the easiest to eavesdrop, and the EIA-232 (also called RS-232) protocol and associated cable hardware are used for these on most computers, it is desirable to add irregularity to that protocol. Transmissions with EIA-232 can be synchronous (with a clock signal) or asynchronous (without); synchronous transmissions are paradoxically best suited to creating irregularity because the clock signal can be supplied irregularly to indicate when the signal level should be sampled.

Irregularity can also be created at higher levels of network protocols. At the data link layer, gaps in time between bursts of data (frames) can be made random. Although bursts may be deciphered, it will be hard to string them into packets, particularly when similar signals on other electronic equipment are being generated at the same time. Buffering at the receiving end can regularize the data as needed to enable normal computer operations. Asynchronous transfer mode (ATM), important for the Internet, already supports irregular handling of its small packets.

Random delays can also be done in drawing the screen of the monitor. Also, the monitor does not need to draw the lines on the screen in vertical order but could draw them in an order determined by a secret time-varying key. Then an eavesdropper not knowing the key would see only a scrambled mess. But they could try orders at random until they hit on the right one because 480 lines in the standard VGA format is not many. Similarly, keyboard sampling to recognize key depressions could randomly delay between cycles and does not need to check the keys in the same order every time. Keyboard rates now are so slow compared to CPU processing times that a more complex keyboard-sampling method makes no difference to interaction speed. As for periodicity of a magnetic disk, the disk head can be moved when not in use to a blank portion of the disk.

Trojan horses that deliberately create periodic signals to facilitate eavesdropping can be found by the usual methods for finding Trojan horses (see Trojan Horse Programs) such as comparing checksums on executables to previous checksums and looking for statistically anomalous run-time behavior. Their broadcast may be detected by monitoring the emanations of the hardware for unusual frequencies.

## Deliberate Deception

Deception is a classic military technique for exploiting modest resources for a major gain. Deception could be done in electronic emanations to plant disinformation with the eavesdropper. For instance, dummy computers could transmit false information made especially easy (in intensity or accessibility) for the eavesdropper to pick up. This is easiest if one can replay old signals that are no longer secret, with date and detail changes. Routine data such as transmission headers are easy to fake.

Deception can help confirm eavesdropping. One can plant some information and see if an eavesdropper reacts; if they do, then deception can be tailored to them more specifically. Counterintelligence uses methods like these. Honeypots (see Use of Deception Techniques: Honeypots and Decoys) also use deception to collect information about attackers and their attacks. They can pretend to have resources that attackers want such as unencrypted (but ineffective) passwords to waste the time of the attacker. Deception can often be more effective than concealment because the enemy can recognize that you are concealing something and redouble his or her efforts to get it, whereas deception may make him or her go away.

## Bug Detectors

If eavesdropping is suspected, one can try to locate the eavesdropping hardware and remove it (Ferrand, 1988; Tolces, 1986). If the countermeasures discussed have already been employed, any useful bug must be nearby. A variety of electronic bug detectors are available, but a purchaser must be cautious because there is much competition among vendors and little regulation. Some vendors promise more than they can deliver, and some are outright scams. Careful testing of products is essential.

There are two approaches to bug detection. One is to focus on the eavesdropping device itself. Because nearly all use electronics, one can exploit properties of electronics. For one thing, they dissipate some heat, so an infrared camera may be able to see bugging devices hidden unexpectedly in everyday objects such as light fixtures and telephones. Another idea is to take advantage of the nonlinearity of many transistors by irradiating the area with a strong microwave signal and looking for distinctive reradiation patterns at different frequencies than the excitation (Yost, 1985). This is usually what is meant by sweeping an area for bugs. It requires a very pure frequency generation because the detectable signals can be small, and good amplification for the sensitive signals after filtering out the excitation signal. Almost any bug will need to contain transistors, but this will not work for MOSFET

circuits nor transistors with very small input leads. It will also not find bugs next to legitimate electronic hardware nor those electromagnetically shielded.

Another approach is to focus on bug transmissions. Because most bugs collect too much data to store at the bug (concealment is important, and the bug may need to remain untouched in place a long time to prevent suspicion), retransmission of data by electromagnetic waves to a more convenient location is usual. So frequency-scanning bug detectors, or frequency analyzers, look for unusual frequencies in the electromagnetic spectrum that could represent bug transmissions. It helps that it is easier for a spy to use off-the-shelf hardware for transmitters and receivers to take advantage of frequently used parts of the spectrum. These include the citizen's band at 25–50 MHz, the frequency modulation radio band at 88–120 MHz, the police band at 150–174 MHz, and the gap between UHF and VHF television at around 470 MHz (Yost, 1985); the antenna size required ranges from a few feet for the first to an inch for the last. So a bug detector frequency scanner should focus on those ranges. Techniques for detecting signals in nonrandom noise can help (Garth & Poor, 1994). Additional tricks may be necessary to detect signals of highly motivated adversaries such as military enemies (Stephens, 1996).

Spies can use several additional techniques to conceal bug transmissions: (1) a wide-spectrum broadcast, (2) frequency hopping in the broadcast, (3) double modulation using subcarrier frequencies, and (4) frequencies close to legitimate signals such as radio stations ("snuggling"). But each of these leaves clues in the frequency spectrum. Wide-spectrum and frequency-hopping behavior will give a distinctive "smear" pattern; double modulation will give two equal peaks; and snuggling will give two distinct but very close peaks. It may help to keep records of the frequencies observed at a location to better notice changes created by new transmissions, analogously to using checksums for detecting changes to a file system. Frequency detection is not foolproof as it does not work when bug is turned off; a bug could be designed for only occasional transmissions.

Bugs can also be detected by nonelectronic inspection by noticing unusual changes to objects, such as repair work or abrasions where none should be expected, new objects or building materials, and so on. Counterintelligence training (Shulsky, 1993) provides many suggestions.

## PROTECTING AGAINST OFFENSIVE SIGNALS

Now let us turn to the use of electromagnetic signals as weapons against computer systems for sabotage or harassment.

### Damage Mechanisms for Electromagnetic Signals

A disadvantage of the decreasing size of computer and network hardware is that they are becoming increasingly vulnerable to electronic attacks as they become less able to dissipate large amounts of power. So a high voltage

suddenly created within modern circuitry can more easily create permanent damage. High voltages induce high current flows that can melt electrical conductors, causing electrical breaks or shorts deep inside chips that are virtually impossible to repair. This heat can also melt the packaging and create toxic fumes or start fires. In addition, even moderate levels of heat can destroy the essential dielectric properties of the semiconductors that are the building blocks of integrated circuits, making them useless.

Several methods can damage circuitry without a direct electrical connection. High-frequency electromagnetic waves can be used that have powerful penetration capabilities. A short burst of such frequencies can be created by a nuclear explosion high in the atmosphere, an electromagnetic pulse (U.S. Government Printing Office, 1998). Such pulses are serious threats to international security because they can destroy digital hardware over a wide area. Smaller pulses can also be created from spark gaps, and they can be effective against specific targets.

Microwave radiation can also be used to attack computer hardware. Because microwave ovens can cook food, higher power microwaves can be focused to overheat particular targets. Such weapons can be either narrow band or broadband. Narrow band can be more effective if one knows the natural frequencies of an electronic device and can stimulate the device at those frequencies, amplifying the damage, but that requires detailed knowledge of the device. The former Soviet Union is alleged to have been the world leader in developing offensive electromagnetic weapons as an inexpensive way to attack the combat systems of the more technologically advanced West.

### Countermeasures for Damaging Electromagnetic Signals

The same electromagnetic shielding discussed above as a protection against spying can also protect against electromagnetic attacks, as Gauss's law applies to both incoming and outgoing signals (Kopp, 1997; Podgorski, 1990). But for perfect protection, the device must be perfectly enclosed in a conductive material. If there are any gaps in the surrounding material, they will permit penetration by radiation of frequencies less than the width of the gap unless countermeasures are used. Centimeter-sized gaps are sufficient for microwaves, but not for the X rays and gamma rays that occur with a nuclear explosion. More complex shielding designs can address this. Press (1990) proposes convoluted corridors that twist and turn for the necessary gaps as a way to significantly attenuate radiation traversal.

Shielding can also be at the level of the integrated circuit. "Radiation-hardened" integrated-circuit chips are available for military and space applications (Hughes & Benedetto, 2003) to protect against high-frequency radiation. They cost 10–1,000 times more than regular hardware because of their difficulty of manufacture but provide a number of techniques for protecting the chip. These include special thinness of the circuit layers (to reduce the effect of charged layers), extra width of critical electrical channels, fabrication at lower temperatures to reduce chemical weaknesses that radiation can exploit

and more complex design methods. However, they are generally designed for continuous radiation (as in nuclear and space applications) rather than for the short pulses of radiation typical of an attack.

Traditional methods of electronic protection against voltage spikes (because of lightning, power problems, etc.) can also provide some protection for electronic circuitry if they are significantly upgraded from usual practice. Press (1990) recommends protection for up to 10,000 volts on power lines and 20,000 volts on phone lines (albeit for only a few nanoseconds); special devices such as varistors can accomplish that. A fuse is the oldest and most familiar method, but is no protection for a voltage surge over every conductor. Fuses must also be replaced once they have been blown and must be chosen to have a faster delay than the damage time of the circuit they are protecting. Circuit breakers involve a gap across which a high-voltage spike could jump, so they are not appropriate for powerful electromagnetic attacks. Fiber optic cables are useful along input lines because they cannot be overloaded.

Surge protectors and transient protection devices are another traditional way of protecting electronic equipment against current spikes on its power or signal lines. They use large resistors to dissipate energy as heat and capacitors to even out the current supplied to a device. However, capacitors become less effective the higher the frequency of the signal they are protecting against, and they cannot react effectively against a nuclear electromagnetic pulse. Surge protectors have a rated delay, and useful ones need to have delays on the order of picoseconds.

As with emanations protection, the danger decreases with the square of the distance from the source. Thus if you can keep your enemy outside a given perimeter around your computer systems, you can estimate the closest they could get, the strength of their electromagnetic weapons, the strength of your protections, and the possible damage.

### Electromagnetic Noise to Interfere with Computer Systems

Another way to interfere with electronics is to deliberately produce electromagnetic interference to impede operations. Jamming is an example, where supplying a strong signal at the same frequency as a narrow band signal such as radio will prevent listeners from receiving the signal. Jamming works best with analog voltages, where adding to an existing signal changes the meaning of the signal. This could affect the video monitor of a computer or analog input devices. But it is less a problem for digital communications where there are only two voltage levels, because moderate noise does not increase ambiguity unless it changes the voltage enough to go from low to high or vice versa. This inherent noise protection is, in fact, a main justification for the shift from analog to digital electronics that has been occurring since the mid-1950s. Some protection against electronic noise can be obtained by filtering it out using appropriate circuitry. If the noise has distinctive frequencies, appropriate electronic filters can be designed, even automatically, in response to observed signals.

## CONCLUSION

Electronic threats to computer systems and networks are often overlooked in the concerns over the myriad of security problems with the new software technologies. Nonetheless, electromagnetic threats remain serious problems for high-security systems, and everyone concerned with information security should be aware of them and the variety of measures available to combat them.

## GLOSSARY

**Bug Detector** Electronic device for detecting electronic or audio eavesdropping devices.

**Counterintelligence** Methods used to impede the collection by your enemy of intelligence about you.

**EIA-232** Commonly used physical-level network protocol and associated hardware specifications for slow communications like those for keyboards, monitors, and modems; originally called RS-232.

**Electromagnetic Interference** Electromagnetic waves that are sufficiently strong to induce significant voltages and thereby interfere with operations of electronic devices.

**Electromagnetic Pulse** A burst of high-voltage electromagnetic radiation, created by a special device or a nuclear explosion.

**Electromagnetic Shielding** Electrically conductive material placed around electronic devices to reduce their electromagnetic emanations and reduce their susceptibility to electromagnetic pulses.

**Electronic Filter** An electronic device that amplifies some frequencies more than others, useful in reducing electromagnetic emanations.

**Emanations (Emissions) Security** Issues in the protection of computers and networks from eavesdropping on the electromagnetic signals they inadvertently generate.

**Faraday Cage** Perfect electromagnetic shielding with no gaps.

**Ferrites** Ferromagnetic materials which can be used for reducing high-frequency magnetic fields.

**Ground** The comparison voltage for electronic circuitry, usually electrically connected to the earth through an electrical plug and appropriate building wiring.

**Intelligence** Information about an enemy obtained by surreptitious means.

**Signals Intelligence (SIGINT)** Gathering of intelligence data by intelligence agencies from electromagnetic signals.

**Source Suppression** Reduction of electromagnetic emanations from a computer or network by reducing its generated signals.

**TEMPEST** Secret U.S. Government standards for computer hardware with reduced electromagnetic emanations, used for military and diplomatic systems.

## INTRODUCTION

As society increasingly relies on digitally stored and accessed information, traditional information security technologies, policies, management, and practices are found more and more limited in satisfying the security and assurance needs of modern information systems and applications, for several reasons. In general, addressing only the protection of information against unauthorized disclosure, transfer, modification, or destruction, traditional information security cannot deliver the level of information assurance that modern applications require. In particular, first, as applications increasingly rely on digitally stored and accessed information, they increasingly rely on the availability of this information and the reliability of the corresponding information system. However, availability and reliability are largely neglected by traditional information security.

Second, although information confidentiality, privacy, and integrity protection are certainly crucial in meeting the security needs of modern applications, not all attacks can be prevented and some attacks do succeed. (Readers can refer to Volume III of this handbook for a detailed discussion of the threats and vulnerabilities to modern information systems.) These attacks can cause substantial confidentiality and privacy loss (via unauthorized disclosure of information), substantial integrity loss (via unauthorized modification of information), substantial availability/reliability loss and serious denial-of-service (via destruction of some critical components of the information system), and substantial nonrepudiation loss (via destruction of evidence and audit data). When applications were lightly dependent on digitally stored and accessed information, such information security losses might be able to be tolerated. But as applications increasingly rely on digitally stored and accessed information, such security losses can be disastrous and may no longer be able to be tolerated. Hence, another fundamental limitation of traditional information security is how to address these successful attacks or intrusions.

As a result, to meet the security and assurance needs of modern information systems and applications, a broader perspective is introduced, saying that, in addition to preventing information from being disclosed, modified, or destroyed, intrusions should be detected; countermeasures (e.g., responses) to intrusions should be planned and deployed in advance; security and fault tolerance mechanisms should work together to ensure confidentiality, privacy, integrity, nonrepudiation, authenticity, availability, and reliability in the presence of attacks; and the damage caused on the information and the information system should be repaired and restored (or recovered). In this literature, this is referred to as *information assurance*. For example, from the military perspective, information assurance must address the delivery of authentic, accurate, secure, reliable, timely information, regardless of threat conditions, within the distributed and heterogeneous computing and communication environment.

The basic meaning of information assurance is well captured by the definition from the *National Information Systems Security Glossary*, which is as follows:

**Information Assurance (IA):** Information operations that protect and defend information and information systems by ensuring their availability, integrity, authentication, confidentiality, and non-repudiation. This includes providing for restoration of information systems by incorporating protection, detection, and reaction capabilities. [*National Information Systems Security (INFOSEC) Glossary, NSTISSI No. 4009, Aug. 1997*]

Compared with the concepts of information security and information systems security, whose definitions are quoted below, it is not difficult to see that the concept of information assurance is much broader than that of information security. In particular, (a) the focus of information security is on protection or prevention, whereas the focus

of information assurance is on integration of protection, detection, and reaction; (b) intrusion detection and reaction are not a major concern of information security, but they are certainly crucial for information assurance; (c) attack recovery or restoration may be a topic out of the scope of information security, but it is certainly a critical component of information assurance; (d) the goal of information security technologies is to prevent attacks from happening, whereas the goal of information assurance is to ensure that even if some attacks intrude into an information system, certain levels of availability, integrity, authentication, confidentiality, or nonrepudiation can still be guaranteed.

**Information security:** The protection of information against unauthorized disclosure, transfer, modification, or destruction, whether accidental or intentional.

**Information systems security (INFOSEC):** [The] protection of information systems against unauthorized access to or modification of information, whether in storage, processing or transit, and against the denial of service to authorized users, including those measures necessary to detect, document, and counter such threats.

It is no doubt that information assurance involves many disciplines and has a variety of aspects, such as the policy, legal, ethical, social, management, evaluation, and technical aspects of information assurance. Compared with traditional information security practices, information assurance involves not only the design and development of a variety of new security technologies but also a variety of emerging policy, legal, ethical, social, economical, management, evaluation, and assurance issues as information assurance evolves people's practices of information security in an ever quicker pace. Nevertheless, to make this chapter more tangible, it focuses primarily on the technical aspect of information assurance, though some relevant policy, management, and evaluation issues are also addressed. Readers can refer to Security Policy Guidelines and Security Policy Enforcement for a detailed discussion on the policy aspect. Readers can refer to Managing a Network Environment for detailed discussion on the management aspect. Readers can refer to Common Criteria for detailed discussion on the evaluation aspect. Readers can refer to the Social and Legal Issues part of Volume II for a detailed discussion on the social, ethical, and legal aspects of IA.

The rest of this chapter is organized as follows. Overview of Information Assurance Technologies presents an overview of IA technologies. Three generations of IA technologies are identified and summarized. Third generation IA technologies are classified into two categories: intrusion masking technologies and defense in depth technologies. In Section 3, we survey intrusion masking technologies. In Section 4, we survey defense in depth technologies. In Section 5, we conclude the chapter.

## OVERVIEW OF INFORMATION ASSURANCE TECHNOLOGIES

In this section, we give a comprehensive overview of information assurance technologies, with a focus on the emerging third generation information assurance technologies and their relation with more established intrusion prevention and detection IA technologies.

### Three Generations of IA Technologies

In general, existing IA technologies can be "clustered" into three generations as shown below. There is a natural evolution or maturing that has occurred in the IA community, and these generations offer evidence of the evolution.

- **First generation: prevent intrusions.** The goal is to prevent attacks from succeeding. The representative technologies are trusted computing base, access control and physical security, multiple levels of security, and cryptography.
- **Second generation: detect intrusions.** Because not all attacks can be prevented, intrusions will occur. Hence, the goal of second generation IA technologies is to detect intrusions. Some representative technologies are firewalls, intrusion detection systems, and boundary controllers.
- **Third generation: operate through attacks (or survivability).** Because some attacks will succeed, we need the third generation IA technologies. The goal is to enable information systems to continue delivering essential services with security assurance in the presence of sustained attacks. Some representative technologies are real-time situation awareness and response, real-time trade-off of performance, functionality and security, intrusion tolerance, and graceful degradation. It should be noticed that the third generation IA technologies are not simply focusing on the availability domain; their dimensions are much broader. In particular, without delivering such security assurance as confidentiality (privacy), integrity, authenticity and nonrepudiation, essential services cannot be continuously delivered under sustained attacks. In general, survivability means not only availability under attacks but also confidentiality (privacy), integrity, authenticity, and nonrepudiation under attacks. Moreover, in many situations, survivability implies reliability.

It should be noticed that among the three generations of IA technologies, each generation is crucial in achieving the goals of information assurance, and no one can replace another. (The second generation IA technologies do not subsume the first generation IA technologies, and the third generation IA technologies do not subsume the second generation IA technologies either.) In particular, the first generation IA technologies build the foundation for information assurance because without strong protection of information confidentiality, privacy, integrity, authenticity, and nonrepudiation, there can be too many successful attacks for the information system to survive, which in fact makes survivability infeasible. Moreover,

intrusion prevention, intrusion detection, and intrusion tolerance (or survivability) actually share primarily the same goal (i.e., to ensure the information confidentiality, privacy, integrity, availability, authenticity and nonrepudiation in the face of attacks). A highly trusted and assured information system should be able to prevent as many attacks as possible from breaking into the system, detect the attacks that could not be prevented with accuracy and agility, and robustly operate through and recover from these successful attacks without losing availability, reliability, and accountability. Second, the third generation IA technologies are largely dependent on the second generation IA technologies, because many third generation IA technologies assume that the intrusions can be detected in a timely manner with good accuracy (e.g., low false positive rate and false negative rate).

Nevertheless, in this chapter we focus on the third generation IA technologies, because the first and second generation IA technologies are well covered by the other chapters of this handbook. In particular, we survey the technologies for developing survivable (networked) information systems. Readers can refer to Secure Public Networks, IPsec, SSL/TLS, Secret Key Cryptography, Database Security, Medical Record Security, Access Control: Principles and Solutions, PGP (Pretty Good Privacy), P3P (Platform for Privacy Preferences Project), Anonymity and Identity in the Internet, Privacy Law, Privacy Issues in Wired and Wireless Networks, and Medical Record Security for detailed discussions of first generation IA technologies. Readers can refer to Intrusion Detection: Detection Technology and Techniques, Intrusion Detection Systems Basics, Host-Based Intrusion Detection Systems, and Network-Based Intrusion Detection Systems for detailed discussions of second generation IA technologies.

### Third Generation IA Technologies

Related to the fault tolerance concept and drawing from that discipline is the area of intrusion tolerance or survivability. Intrusion tolerance is emerging as one of the most important R&D areas in cyberoperations today because the systems and networks we depend on must continue to operate through intrusions and keep operating, although in a degraded mode, in spite of a sequence of successful cyberattacks.

### Classification of Survivability Technologies

We can classify existing survivability technologies into two categories: intrusion masking and defense in depth. Note that well-known intrusion tolerance projects include the MAFTIA (Information Society Technologies, 2004) and OASIS (Information Processing Technology Office, 2004) projects.

#### Intrusion Masking

From the design perspective, one system design can be inherently much more *attack resilient* than another. The goal of intrusion masking is to redesign a regular vulnerable computer system with enough redundancy so that the new survivable design can function correctly even when part of the system is hacked. In this sense, we say the new

survivable design can *mask* intrusions. Techniques in this category focus on how to enhance the inherent resilience of a secure system, and their effectiveness is typically much less sensitive to the agility and accuracy of intrusion detection than pragmatic, run-time intrusion response techniques. General principles in developing attack-resistant designs include but are not limited to (a) redundancy and replication (b) diversity (c) randomization (d) fragmentation and threshold cryptography and (e) increased layers of indirections. Techniques in this perspective include but not limited to Byzantine intrusion masking techniques (Castro & Liskov, 1999; Malkhi, Merritt, Reiter, & Taubenfeld, 2003; Schneider, 1990; Sekar, Bendre, & Bollineni, 2001) that follow the redundancy and replication principle, threshold-cryptography-based attack resilient systems (Jing et al., 2003; Zhou, Schneider, & Renesse, 2002; Wylie et al., 2000) that follow the fragmentation principle, multipath routing (Vutukury & Garcia-Luna-Aceves, 2001) that follow the redundancy principle, and resilient overlay networks (Anderson, Balakrishnan, Kaashoek, & Morris, 2001) that follow the “increased layers of indirections” principle.

#### Defense in Depth

Instead of redesigning a system, the goal of defense in depth technologies is to arm the system with a set of attack that threat response facilities that, with the help of the intrusion detection, can respond to intrusions in such a way that the system can operate through attacks. Technologies in this category include (a) *boundary controllers* such as firewalls and access control (b) *intrusion detection* and (c) *threat/attack/intrusion response*. It is well known that boundary controllers cannot prevent every attack.

*Intrusion detection* (Lee, Stolfo, & Mok, 1999; Lunt, 1993; Jukherjee, Heberlein, & Levitt, 1994; Ning, Cui, & Reeves, 2002; Sekar et al., 2001; Debar, Cadier, & Wespi, 1999) is a key part of many survivable systems, but existing intrusion detection technologies in general suffer the high false positive (negative) rate problem, especially when the detection is anomaly based or specification based. Because intrusion detection techniques cannot guide us to respond to intrusions, existing defense-in-depth technologies focus on intrusion response, which can be classified into three categories as follows:

*Type 1: Reactive response.* Techniques in this category are activated only when an intrusion is identified and their effectiveness is highly dependent on the accuracy and latency of intrusion detection. For example, attack recovery techniques (Ammann, Jajodia, & Liu, 2002; Liu, Ammann, & Jajodia, 2000; Yu, Lium, & Zang, 2004) belong to this category. If the detection is quick and accurate, then the contaminated part of the system can be quickly repaired without causing serious integrity degradation. However, if there are many false alarms, a lot of clean elements could be corrupted by wrong “repairs.” Some other Type 1 techniques include but are not limited to reactive one-phase damage containment techniques, detection-based (firewall) reconfiguration techniques, and patching techniques.

*Type 2: Proactive response.* Techniques in this category are activated in a proactive manner based on suspicious

activities (or signs) before an intrusion is confirmed. Although proactive response may consume more resources, it may immunize the system from the damage caused by many attacks. Moreover, many proactive response mechanisms are transparent to users. Type 2 techniques include but are not limited to isolation (Liu, Jajodia, & McCollum, 2000), multiphase damage containment (Liu & Jajodia, 2001), and sandboxing (Malkhi & Reiter, 2000).

*Type 3: Adaptive response.* Feedback-based adaptation is a nice feature of many survivable systems, where the defense posture (i.e., security mechanism configuration) of the system is dynamically adjusted based on the changing environment. Adaptive response addresses the reconfigurable computing and communication aspect of survivable information systems. Type 3 techniques include but are not limited to the OASIS Willard project and adaptive ITDB (Luenam & Liu, 2002).

Because intrusion detection makes the system attack aware but not attack resilient, that is, intrusion detection itself cannot maintain confidentiality, integrity, and availability of information in the face of attacks, intrusion response is crucial in building survivable systems. Moreover, because the fundamental sciences, principles, and arts of survivable systems and networks are almost the same, we do not address systems and networks separately; instead, we focus on these common sciences, principles, and arts. Finally, malicious code defense is an important aspect of IA, but this aspect is not addressed in this chapter.

## Survivability versus Fault Tolerance

As a core concept of the third generation IA technologies, survivability (Ellison et al., 1999) builds on the top of several related fields of study (e.g., security, fault tolerance, safety, reliability) and introduces new concepts and principles. In particular, because many survivability technologies are motivated by fault tolerance technologies, people may wonder about the differences between these two fields. In the following, we highlight three major differences between survivability and fault tolerance.

First, in fault tolerance, failures randomly happen; but in security, attacks are typically intentional and do not randomly happen. Moreover, attacks are more intelligent and active (i.e., more intentional and better planned) than failures, so more proactive tolerance techniques are needed for survivability.

Second, intrusion detection is typically much more complicated than failure detection. This is why there are so many new research challenges in intrusion detection.

Third, in the literature of fault tolerance, intrusions in many cases are modeled and tolerated as Byzantine faults, or arbitrary faults. Therefore, if a system is Byzantine fault tolerant, it is able to tolerate intrusions in some degree. BFT (Castro & Liskov, 1999), a practical Byzantine fault tolerant system, can tolerate both faults and intrusions. However, it should be noticed that not all damages to the system are caused by faults and not all intrusions can be modeled as Byzantine faults. For example, successful intrusions at the application level (e.g., corrupted transactions of database systems) and data corruption usually do not appear as faults and cannot be handled by Byzantine fault tolerance.

## INTRUSION MASKING TECHNOLOGIES

In this section, we survey four representative intrusion masking technologies, namely survivable storage systems, intrusion masking distributed computing, attack resistant certification authority, and survivable network systems.

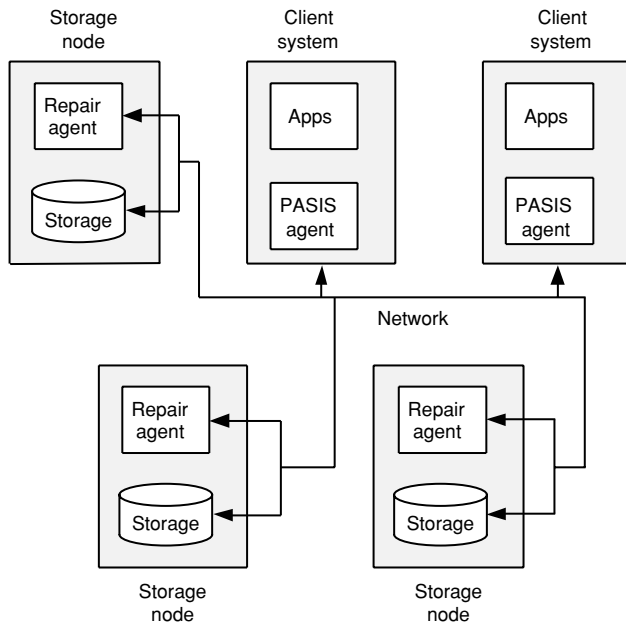

### Survivable Information Storage Systems

As society increasingly relies on digitally stored and processed information, supporting the availability, integrity, and confidentiality of this information is crucial. We need systems in which users can securely store critical information, ensuring that it persists, is continuously accessible, cannot be destroyed, and is kept confidential. A *survivable storage system* would provide these guarantees over time and despite malicious compromises of storage node subnets.

In Deswarte, Blain, and Favre (1991) and Wylie et al. (2000), how to build a survivable distributed information storage system (e.g., a distributed file storage system) has been investigated. Current distributed file systems are not survivable; whenever a node is hacked, the attacker can not only know the content of the files stored on that node but also modify or destroy them. In Deswarte, Blain, and Favre (1991), a fragmentation-based survivability design is proposed, where (a) every file is fragmented into a set of *fragments* before it is stored on a storage node (b) fragments are replicated to yield more availability and (c) fragment *replicas* of a file are carefully scattered across the network of storage nodes in such a way that when a node is broken, the attacker can never get a complete set of the fragments for this file. Moreover, to prevent the attacker from getting partial information about the file from the fragments he captures after breaking into a node, each file is encrypted before fragmentation and the ciphertext fragments are made interdependent on each other (using such technique as CBC mode encryption), and the ensemble order among the fragments for the file is kept confidential. In this way, when the attacker captures a set of encrypted fragments, even if he or she knows the key, he or she is still unable to decrypt these fragments (in most cases).

In Wylie et al. (2000), a different secret-sharing-based survivable design, called PASIS, is proposed, although the goal is also to develop a survivable information storage system. The PASIS architecture, shown in Figure 1, flexibly and efficiently combines decentralized storage systems, data redundancy and encoding, and dynamic self-maintenance to achieve survivable information storage. A PASIS system applies threshold cryptography schemes (Shamir, 1979) to spread information across a decentralized collection of storage nodes. Client-side agents communicate with the collection of storage nodes to read and write information, hiding decentralization from the client system. Automated monitoring and repair agents on storage nodes provide self-maintenance features.

In particular, in PASIS an  $m - n$  secret sharing scheme is used to break a data object (e.g., a file) into  $n$  shares so that (a) every shareholder (i.e., a storage node) has one of the shares (b) any  $m$  of the shareholders can reconstruct the object but (c) a group of fewer than  $m$  shareholders cannot gain any information about the object. Note that

**Figure 1:** The PASIS architecture. Client systems and storage nodes are attached to the network. Client applications interact with a PASIS storage system through a PASIS agent. Storage devices and repair agents that monitor system status comprise the storage nodes.

a share in Wylie et al. (2000) and a fragment in Deswarte, Blain, and Favre (1991) are very different. A (cleartext) fragment can tell the attacker partial information about the corresponding data object, but a share could tell the attacker nothing about the data object. This nice property of secret-sharing schemes allows PASIS to achieve the same amount of security as Deswarte, Blain, and Favre (1991) without doing any encryption.

Correspondingly, the read and write operations need to be redesigned in PASIS. In particular, when a client reads a file, first, the client will look up, in the directory service, the names of the  $n$  shares that comprise the file. Second, the client sends read requests to at least  $m$  of the  $n$  storage nodes. Third, the client collects the responses. Fourth, the client reconstructs the file. Conversely, when a client writes a file, the client needs to a set of operations similar to those involved in a read except that the write operation does not complete until at least  $n - m + 1$  (or  $m$ , whichever is greater) storage nodes have stored their shares.

In summary, the PASIS architecture illustrates the following ideas in building survivable storage systems. First, use *decentralized storage systems* to partition information among nodes. "Using data distribution and redundancy schemes commonly associated with disk array systems such as RAID (redundant array of independent disks) ensures scalable performance and fault tolerance" (Wylie et al., 2000). "Elimination of single failure points provides a starting point for developing survivable storage systems" (Wylie et al., 2000).

Second, exploit *data redundancy and encoding*. Threshold or secret-sharing schemes provide both information confidentiality and availability. "These schemes encode,

replicate, and divide information into multiple pieces (or shares) that can be stored at different storage nodes" (Wylie et al., 2000). The system can only construct the information when enough shares are available. Third, perform *dynamic self-maintenance*. "Over time, all systems need maintenance. Truly survivable systems automatically perform some self-maintenance includes regular monitoring for potential problems, such as failed or compromised nodes, performance bottlenecks, and denial-of-service attacks" (Wylie et al., 2000).

Finally, accomplish good trade-offs among information confidentiality, information availability, and storage requirements. Different threshold schemes will yield different confidentiality, availability, and storage requirements trade-offs. For example, as  $n$  increases, information availability increases (it is more probable that  $m$  shares are available), but the storage required for the information increases (more shares are stored) and confidentiality decreases (there are more shared to steal).

### Intrusion Masking Distributed Computing

As businesses and applications are becoming more and more distributed (on the Internet), distributed computing and distributed software are more and more popular. To satisfying the IA needs of these distributed businesses and applications, survivable distributed computing is in urgent need. Nevertheless, distribution of computing can make information systems more vulnerable because the hacker will have more choices regarding where and when to enforce the attack; and any local breach may lead to serious global compromise through the interdependencies among distributed operations.

Distributed software is often structured in terms of clients and services. Each service comprises one or more servers and exports operations that clients invoke by making requests. Although using a single centralized server is the simplest way to implement a service, the resulted service can only be as secure and reliable as that server. If this level of fault and intrusion tolerance is unacceptable, then multiple servers that fail independently must be used. Usually, replicas of a single server are executed on separate processors of a distributed system, and protocols are used to coordinate client interactions with these replicas. Moreover, to make a replicated system more resilient to attacks, various *diversifying* technologies such as diverse operating systems can be used.

The *state machine (replication) approach* (Schneider, 1990) is a general method for implementing an intrusion-masking service by replicating servers and coordinating client interactions with server replicas. In this approach, an intrusion-masking server (modeled as a state machine) is implemented by replicating that server (i.e., both services and data) and running a (server) *replica* on each of the nodes in a distributed system. In the state machine approach, given the same sequence of requests (from probably a set of clients) to each replica, a group of non-faulty replicas that start consistent (i.e., having the same state) will remain consistent (after the sequence of requests are processed). Hence, when a group of server replicas is serving a set of clients, if the requests of the

clients can be delivered to the replicas in such a way that the same sequence of requests will always be received by each replica, then if the group has  $2t + 1$  replicas, it can mask  $t$  intruded replicas, because each client can use majority voting to identify both the correct and the malicious responses.

Ensuring that the same sequence of requests (i.e., the same messages and the same order) will be delivered to each replica is, however, fairly difficult, because of the complexities of the networking environment and the fact that any node or (communication) link in a distributed system could be faulty or vulnerable. For one example, if we let a replica be the (designated) *sender* that transmits the clients' messages (or requests) to the other replicas, then if the sender is faulty, the group of replicas can receive inconsistent requests. Conversely, even if the sender is not faulty, communication failures can still cause replicas to receive inconsistent or differently ordered requests. For another example, if we let each client directly send its requests to each replica, then even if nothing is faulty, two replicas could receive two requests from two clients, respectively, in different orders, because of delay and competition. According to Schneider (1990), two requirements need to be satisfied to achieve this goal: (a) *consistency*, whereby every nonfaulty server replica receives every request, and (b) *total order*, whereby every nonfaulty replica processes the requests it receives in the same relative order. Developing the protocols that can satisfy these two requirements has raised a tremendous amount of interests, and fortunately as a result, a family of reliable totally ordered group communication services that can satisfy the two requirements are developed (e.g., Reiter, 1994). And these protocols (or services) have naturally become a key component of a typical implementation of the state machine approach. Because the state machine approach can handle arbitrary Byzantine faults such as software bugs, operator mistakes, and malicious attacks, the corresponding systems (services) built using this approach are also called Byzantine fault tolerant distributed systems (services). Nevertheless, to guarantee correctness and security, in general these reliable totally ordered group communication services require that fewer than one-third of replica group members be faulty. Therefore, a survivable distributed computing system built using the state machine approach actually uses  $3k + 1$  or more server replicas to mask  $k$  intruded replicas.

Although many solutions for state machine replication have been proposed, state machine replication has not been widely deployed in the real world primarily because of the fact that most of these solutions have significant performance overhead (another reason might be that once one replica is compromised, it is fairly easy to compromise the remaining replicas). To mitigate this problem, in Castro and Liskov (1999) a new practical algorithm for state machine replication called *BFT* is proposed, which can be used to build highly survivable systems that tolerate Byzantine faults. BFT shows how to build Byzantine fault tolerant systems that can be used in practice to implement real services because they do not rely on unrealistic assumptions and they perform well. Many existing solutions for state machine replication rely on *synchrony*

assumption for correctness (i.e., rely on known bounds on message delays and process speeds, which is dangerous in the presence of malicious attacks). An attacker may compromise the safety of a service by delaying nonfaulty nodes or the communication between them until they are tagged as faulty and excluded from the replica group. Such a denial of service attack is generally easier than gaining control over a nonfaulty node.

In contrast, BFT works in *asynchronous* environments such as the Internet, it incorporates mechanisms to defend against Byzantine faulty replicas, and it recovers replicas proactively. The recovery mechanism allows the algorithm to tolerate any number of faults over the lifetime of the system provided less than *one-third* of the replicas become faulty within a small window of vulnerability. The window may increase under a denial of service attack but the algorithm can detect and respond to such attacks and it can also detect when the state of a replica is corrupted by an attacker. BFT has been implemented as a generic program library with a simple interface. The BFT library provides a complete solution to the problem of building real services that tolerate Byzantine faults. The library is used to implement the first Byzantine fault tolerant NFS file system, BFS. The BFT library and BFS perform well because the library incorporates several important optimizations. The most important optimization is the use of symmetric cryptography to authenticate messages. Public key cryptography, which was the major bottleneck in previous systems, is used only to exchange the symmetric keys. The performance results show that BFS performs 2% faster compared to 24% slower than production implementations of the NFS protocol that are not replicated. Therefore, the BFT library is believed to be able to be used to build practical systems that tolerate Byzantine faults. Accordingly, in Yu, Liu, and Zhang (2003) BFT is extended to build practical Byzantine fault tolerant two-phase commit protocols (BFT-2PC) to tolerate both malicious coordinator and malicious participants in distributed transaction processing.

Finally, although BFT is quite efficient when the replica group is relatively small, BFT may not scale well for large groups. To improve scalability, a technology called *Byzantine Quorum* is proposed (Malkhi & Reiter, 1998), where quorum replication techniques are applied to achieve Byzantine fault tolerance in asynchronous systems. This technology may provide more scalability because each operation is processed by only a subset of replicas instead of every replica. Nevertheless, this approach to scalability is fairly expensive: it requires  $n > 4f + 1$  to tolerate  $f$  faults; each replica needs a copy of the state; and the load of each replica decreases slowly with  $n$  (it is  $O(1/\sqrt{n})$ ).

### Attack Resistant Certification Authority

In a public key infrastructure, a *certificate* specifies a binding between a name and a set of attributes especially the public key. Certificates are the core of PKI technologies. "Over time, public keys and attributes can change: a private key might be compromised, leading to selection of a new public key, for example. The old binding and any certificate that specifies that binding then become

invalid.” A certification authority (CA) attests to the validity of bindings by issuing digitally signed certificates that certify these bindings and by providing a means for clients to check the validity of certificates. “With an on-line CA, principals can check the validity of certificates just before using them” (Zhou et al., 2002). An online CA needs not only to be secure (the CA’s private key cannot be compromised) but also to be available and reliable, which is exactly the goal of survivable CA.

COCA (Cornell certification authority) (Zhou et al., 2002) is a fault tolerant and secure online certification authority that has been built and deployed both in a local area network and on the Internet. Extremely weak assumptions characterize environments in which COCA’s protocols execute correctly: no assumption is made about execution speed and message delivery delays (i.e., COCA assumes asynchrony, channels are expected to exhibit only intermittent reliability and with  $3t + 1$  COCA servers up to  $t$  may be faulty or compromised). These extremely weak assumptions inversely make COCA extremely resilient to malicious attacks. COCA is the first system to integrate a Byzantine quorum system (Malkhi & Reiter, 1998; used to achieve availability and scalability) with threshold cryptography and proactive recovery (used to defend against mobile adversaries which attack, compromise, and control one replica for a limited period of time before moving on to another). In addition to tackling problems associated with combining fault tolerance and security, COCA develops new proactive recovery protocols and gives a quantitative evaluation on its cost and effectiveness.

The idea of COCA has four major aspects. First, the CA service is supported by a set of replicated COCA servers, but the private key of the CA service (namely the signing key) is held by no COCA server. Instead, different shares of the key are stored on each of the servers, and threshold cryptography is used to construct signatures on responses and certificates. To sign a message from a client, each COCA server generates a *partial signature* from the message and that server’s share of the service private key, some COCA server combines these partial signatures and obtains the signed message. In this way, even when several COCA servers are compromised, the private key will still not be disclosed if the number of compromised servers is below the threshold of the scheme.

Second, to be resilient to server failures and provide more availability, every client request is processed by multiple servers and every certificate is replicated on multiple servers. (Note that COCA supports two types of requests: a query request retrieves a certificate, whereas an update request creates, updates, or invalidates a certificate.) The replication is managed as a dissemination Byzantine quorum system (Malkhi & Reiter, 1998), where servers are organized by COCA into sets, called *quorums*, and, accordingly, each client request is processed by a quorum instead of every replica server. However, because a client making a request cannot authenticate messages from a COCA server (because in COCA clients do not know server public keys) and therefore cannot determine whether a quorum of servers has processed that request. COCA let some servers become *delegates* for each request. A delegate presides over the processing of a client request and

Figure 2: Overview of client request processing in COCA.

assembles the needed partial signatures from other COCA servers. A client request is handled by  $t + 1$  delegates to ensure that at least one of the delegates is correct.

Figure 2 gives a high-level overview of how COCA operates by depicting one of the  $t + 1$  delegates and the quorum of servers working with that delegate to handle a client request. The figure shows a client making its request by sending a signed message to  $t + 1$  COCA servers. Each server that receives this message assumes the role of delegate for the request. A delegate engages a quorum of servers to handle the request and constructs a response to the request based on the responses (i.e., partial signatures) received from that quorum. The delegate then assembles these responses into a signature signed by the CA service. After receiving this signature, the client checks that the response is correctly signed by the service and incorrectly signed responses will be discarded.

Third, a mobile adversary might compromise  $t + 1$  servers over a period of time and, in doing so, collect the  $t + 1$  shares of the service private key. To counter this attack, COCA employs a proactive secret-sharing (PSS) protocol to refresh these shares, periodically generating a new set of shares for the service private key and deleting the old set. New shares cannot be combined with old shares to construct signatures. Fourth, to support the asynchrony assumption, COCA develops an asynchronous PSS protocol.

COCA is motivated by an earlier work denoted  $\Omega$  (“Omega”) (Reiter, Franklin, Lacy, & Wright, 1996).  $\Omega$  is a survivable key management service for open networks whose goal is to provide flexible and powerful interfaces to meet the demands of an ever widening range of applications.  $\Omega$  provides the flexibility of an online server without incurring the fault tolerance or security vulnerabilities usually associated with such servers.  $\Omega$  is built on top of the Byzantine quorum technology, but it does not involve threshold cryptography. Finally, in addition to distributed survivable CA such as COCA and  $\Omega$ , in Jing et al. (2003) a centralized attack resilient CA called ARECA is proposed that is built on the top of threshold cryptography and a new *two-phase signature generation* technique.

## Survivable Network Systems

In Anderson et al. (2001) resilient overlay network architectures are addressed. A “Resilient Overlay Network (RON) is an architecture that allows distributed Internet applications to detect and recover from path outages and periods of degraded performance within several seconds, improving over today’s wide-area routing protocols that take at least several minutes to recover” (Anderson et al., 2001). “A RON is an application-layer overlay on top of the existing Internet routing substrate. The RON nodes monitor the functioning and quality of the Internet paths among themselves, and use this information to decide whether to route packets directly over the Internet or by way of other RON nodes, optimizing application-specific routing metrics” (Anderson et al., 2003). It is clear that a RON can mask such attacks as distributed denial of service attacks and attacks on routers and physical communication links.

Results from two sets of measurements of a working RON deployed at sites scattered across the Internet demonstrate the benefits of the RON architecture. For instance, over a 64-hr sampling period in March 2001 across a 12-node RON, there were 32 significant outages, each lasting over 30 min, over the 132 measured paths. RON’s routing mechanism was able to detect, recover, route around all of them, in less than twenty seconds on average, showing that its methods for fault (and intrusion) detection and recovery work well at discovering alternate paths in the Internet. Furthermore, RON was able to improve the loss rate, latency, or throughput perceived by data transfers; for example, about 5% of the transfers doubled their TCP throughput and 5% of transfers saw their loss probability reduced by 0.05.

RON node is sufficient to overcome faults or intrusions and improve performance in most cases. These improvements, particularly in the area of fault detection and recovery, demonstrate the benefits of moving some of the control over routing into the hands of end systems.

## DEFENSE IN DEPTH TECHNOLOGIES

Compared with intrusion masking technologies, where many attacks may be masked without causing any system security (e.g., integrity and availability) degradation, defense in depth technologies usually would introduce certain level of system security degradation. Conversely, the advantage of defense in depth technologies is that (a) they do not require the system to be redesigned and can be directly applied to legacy systems and (b) their overhead is typically smaller than intrusion masking technologies.

The key issues and problems in developing defense in depth technologies are as follows:

- How to quickly *contain/isolate* the intrusions so that their infection will not be too serious to operate through.
- How to quickly distinguish the damaged part for the undamaged part of the system.
- How to quickly repair the contaminated part of the system without bringing it offline.
- How to handle the impact of false alarms, undetected intrusions, and the detection latency.

- How to make the intrusion response facilities adaptive and proactive.
- How to validate the cost effectiveness of defense in depth technologies.

In the rest of this section, we break the possible defense in depth technologies into subsections. In the first subsection, we discuss phases of in-depth defense. In the second subsection, we use an intrusion tolerant database system to illustrate some important techniques of defense in depth.

## Phases of Defense in Depth

In the literature, defense in depth is usually referred to as information warfare defense. Information warfare defense does everything possible to prevent attacks from succeeding, but it also assumes that not all attacks will be averted at the outset. This places increased emphasis on the ability to live through and recover from successful attacks. Information warfare defense must consider all phases of the attack and recovery process. These phases, and the activities that occur in each, are proposed in Ammann, Jajodia, McCollum, and Blaustein (1997) and quoted as follows:

- *Prevention*: the defender puts protective measures in place.
- *Intelligence gathering*: the attacker observes the system to determine its vulnerabilities and find the most critical functions or data to target.
- *Attack*: the attacker carries out the resulting attack plan.
- *Detection*: the defender observes symptoms of a problem and determines that an attack may have taken place or be in progress.
- *Containment*: the defender takes immediate action to eliminate the attacker’s access to the system and to isolate or contain the problem, preventing it from spreading further.
- *Damage assessment*: the defender determines the extent of the problem, including failed functions and corrupted data.
- *Reconfiguration*: the defender may reconfigure to allow continued operation in a degraded mode while recovery proceeds.
- *Repair*: the defender recovers corrupted or lost data and repairs or reinstalls failed system functions to reestablish normal operations.
- *Fault treatment*: to the greatest extent possible, the defender identifies weaknesses exploited in the attack and takes steps to prevent a recurrence.

Some phases, such as prevention, intelligence gathering, detection, containment, reconfiguration, and repair, lend themselves to automated mechanisms and support within the system being attacked. Others, such as fault treatment and some aspects of damage assessment, typically require human intervention.

It should be noticed that the above phases are motivated by the life cycle of fault tolerance. Fault tolerance

is a natural approach for dealing with information attacks because it is designed to address system loss, compromise, and damage during operation. Traditional fault tolerance approach phases include detection, containment, adaptation, and recovery. Fault semantics for information attacks differ from the traditional fault tolerance model because in such cases faults are intentionally introduced and malicious, and some attacks may be disguised to appear like normal operations. Therefore, semantics for countermeasures must differ correspondingly, as mentioned under.

The information warfare defender's goal is to keep the system operating to support as much critical processing as possible, even if the system is contaminated (or infected) by an attack. One way to ensure continued service is to explicitly address integrity losses caused to the systems in the presence of information warfare attacks. To some degree, real systems lack integrity most of the time. These integrity losses do not always prevent the systems from achieving their critical objectives. The challenge in information warfare is to anticipate acceptable integrity losses and design systems to operate in these degraded modes.

## Survivable Database Systems

Existing survivable database technologies can be roughly broken into two categories: *transaction-based* database survivability (Ammann et al., 2002; Liu et al., 2004; Smirnov & Chiueh, 2004), which enables a database to operate through attacks via identifying and "rolling back" malicious and affected transactions, and *data-object-based* database survivability (Panda & Giordano, 1998), which enables a database to operate through attacks via identifying and repairing each corrupted data object. In this section, we use ITDB (Intrusion Tolerant Data Base) to illustrate the design principles of survivable database systems.

ITDB (Ammann et al., 2002; Liu, 2002; Liu et al., 2000a, 2000b, 2004) is a transaction-level self-healing database framework. Because preventing malicious transaction from being executed is in general not a realistic solution, ITDB focuses on how to enable a database to *heal* itself under sustained malicious transaction attacks in such a way that the database can continue delivering (to a large extent valid) transaction-processing services in the face of such attacks.

ITDB focuses on the intrusions enforced by authorized but malicious transactions. ITDB views a database as a set of data *objects*. At a moment, the *state* of the database is determined by the values of these objects. The database is accessed by transactions for the ACID properties. A *transaction* is a partial order of *read* and *write* operations that either *commits* or *aborts*. The execution of a transaction usually transforms the database for one state to another. Moreover, ITDB models the (usually concurrent) execution of a set of transactions by a structure called a *history*.

ITDB focuses on the *damage* caused by malicious, committed transactions. Because an *active*, malicious transaction will not cause any damage before it commits (due to the *atomicity* property), it is theoretically true that if we can detect every malicious transaction before

it commits, then we can roll back the transaction before it causes any damage. However, this "perfect" solution is not practical for two reasons. First, transaction execution is, in general, much quicker than detection, and slowing down transaction execution can cause very serious denial of service. For example, the Microsoft SQL Server can execute over 1000 (TPC-C) transactions within 1 s, whereas the average anomaly *detection latency* is typically in the scale of minutes or seconds (because of the difficulty of anomaly detection).

Hence ITDB is motivated by the following practical goal: "After the database is damaged, locate the damaged part and repair it as soon as possible, so that the database can continue being useful in the face of attacks." In other words, ITDB wants to provide sustained levels of data integrity and availability to applications in the face of attacks. The major components of ITDB are shown in Figure 3. Note that all operations of ITDB are on-the-fly without blocking the execution of (most) normal user transactions. The job of the *intrusion detector* is to identify malicious transactions. In the rest of this section, we give an overview of the jobs that the other ITDB components do.

The complexity of ITDB is mainly caused by a phenomenon called *damage spreading*. In a database, the results of one transaction can affect the execution of some other transactions. Informally, when a transaction  $T_i$  reads an object  $x$  updated by another transaction  $T_j$ ,  $T_i$  is directly *affected* by  $T_j$ . If a third transaction  $T_k$  is affected by  $T_i$ , but not directly affected by  $T_j$ ,  $T_k$  is indirectly affected by  $T_j$ . It is easy to see that when a (relatively old) transaction  $B_i$  that updates  $x$  is identified malicious, the damage on  $x$  can spread to every object updated by a *good* transaction that is affected by  $B_i$ , directly or indirectly. The job of the *damage assessor* is to identify every affected good transaction. The job of the *damage repairer* is to recover the database from the damage caused on the objects updated by malicious transactions as well as affected good transactions. In particular, when an affected transaction is located, the damage repairer builds a specific *cleaning* transaction to clean each object updated by the transaction (and not cleaned yet). Cleaning an object is simply done by restoring the value of the object to its latest undamaged version. This job gets even more difficult as the execution of new transactions continues because the damage can spread to new transactions and cleaned objects can be redamaged. Therefore, the main objective of ITDB is to guarantee that damage spreading is (dynamically) controlled in such a way that the database will not be damaged to a degree that is useless.

The developers of ITDB believe the single most challenging problem in developing practical, cost-effective self-healing database systems (e.g., ITDB) is that during the detection latency, a tremendous amount of damage spreading can be caused. This is because of the fact that intrusion detection is in general much slower than transaction processing. So when a malicious transaction is detected, a lot of affected transactions may have already been committed. Therefore, a practical, cost-effective self-healing database system must be able to live with substantially longer detection latency relative to transaction processing.

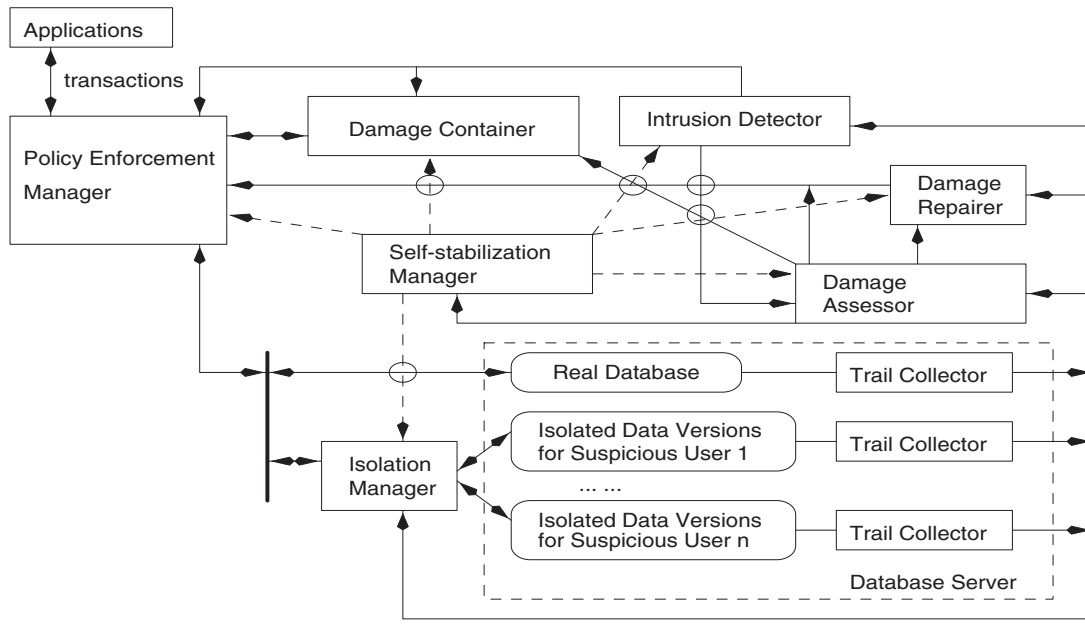

Figure 3: The ITDB architecture.

A unique technical contribution of ITDB is that it can live with long detection latency without suffering serious damage spreading. Allowing long detection latency not only lowers ITDB's requirement on detection agility, but also indirectly lowers ITDB's requirements on detection rate and false alarm rate, because in many cases, longer detection latency can lead to higher detection rate and lower false alarm rate.

However, living with long detection latency is not an easy task. In ITDB, the impact of detection latency is threefold as follows: (1) during the detection latency, the damage can spread to many objects; (2) a significant *assessment latency* can be caused, and during the assessment latency the damage can further spread to many more objects; (3) significant assessment latency can cause ineffective—to some degree at least—damage containment. These three aspects of impact can cause the database to be too damaged to be useful. The job of the isolation manager and the damage container is to mitigate this impact.

It is easy to see that if every malicious transaction  $B_i$  can be identified just after it commits, very little damage can spread, and damage assessment can be done quickly. However, with significant detection latency, when  $B_i$  is identified, in the history there can already be many good transactions following  $B_i$  and many of them may have already been affected by  $B_i$ . Damage assessment at this situation can cause substantial delay, because as shown in (Ammann et al., 2002) damage assessment can spend substantial computation time to scan a long subhistory log for identifying the affected transactions.

Significant assessment latency could cause ineffective damage confinement. At first glance, it seems that to prevent damage spreading during repair, containing the damage that is located by the damage assessor is a good idea. However, in this approach damage will not be contained

until an object is identified by the damage assessor as damaged. Hence damage containment depends on damage assessment. As a result, when there is a significant latency in locating a damaged object  $x$ , during the latency many new transactions may read  $x$  and spread the damage on  $x$  to the objects updated by them. As a result, when  $x$  is confined many other objects may have already been damaged, and the situation can feed on itself and become worse because as the damage spreads the assessment latency could become even longer. This clearly contradicts with our original motivation of damage containment.

ITDB tackles the three challenges through two novel techniques: attack isolation and multiphase damage containment. Although working toward the same goal, the isolation manager and the damage container take two very different approaches. And these two approaches compensate each other. In particular, the damage container takes a novel *multiphase* damage containment approach that first instantly contains the damage that might have been caused by an intrusion as soon as the intrusion is identified and then tries to uncontain the objects that are previously contained by mistake. Multiphase damage containment can ensure that no damage will spread during the assessment latency, although with some availability lost. However, the damage container can do nothing to reduce the damage caused during the detection latency. In contrast, the isolate manager can reduce the damage caused during the detection latency (thus it indirectly reduces the damage caused during the assessment latency) by isolating the execution of a *suspicious* transaction that is very likely to cause damage later on. Isolation immunizes the database from the damage caused by the set of suspicious transactions without sacrificing substantial availability, because if an isolated user turns out to be innocent, most—if not all—of his or her updates can be merged back to the real database.

Finally, the job of the *self-stabilization manager* (SSM) is to dynamically reconfigure the other ITDB components based on (a) the current attacks, (b) the current workload, (c) the current system state, and (d) the current defense *behavior* of ITDB, in such a way that stabilized levels of data integrity and availability can be provided to applications in a cost-effective way. Factors (a), (b), and (c) are called the *environment* of ITDB. The jobs of the *policy enforcement manager* (PEM) are to proxy user transactions and enforce systemwide intrusion tolerance policies. For example, a policy may require the PEM to reject every new transaction submitted by a user as soon as the intrusion detector finds that a malicious transaction is executed by the user. Intrusion response policies and security manager interfaces are certainly a crucial aspect of ITDB. In summary, ITDB develops a family of novel defense in depth techniques, such as on-the-fly attack recovery, multiphase damage containment, attack isolation, and rule-based adaptive intrusion tolerance.

From the self-healing perspective, ITDB considers recovery from malicious but committed transactions. Traditional recovery mechanisms do not address this problem, except for complete *rollbacks* to a previous *checkpoint*, which undo the work of good transactions as well as malicious ones, and compensating transactions, whose utility depends on application semantics. ITDB develops two attack recovery mechanisms: on-the-fly repair and history rewriting. For on-the-fly repair, instead of rolling back the database to the latest checkpoint, the *write-read dependency* between transactions is analyzed on the fly to determine which good transactions are affected by a bad transaction, directly or indirectly. Then a specific *cleaning transaction* is composed to clean the infection caused by each malicious or affected transaction, and the concurrency control algorithm is adapted in such a way that new user transactions can be executed simultaneously together with cleaning transactions without affecting the correctness of repair. Finally, when an on-the-fly repair terminates with all the damage repaired, ITDB can detect the termination in a timely manner.

For history rewriting, ITDB rewrites execution histories for the purpose of backing out malicious transactions (Liu et al., 2000b). Good transactions that are a directly or indirectly, by malicious transactions complicate the process of backing out undesirable transactions. The prefix of a rewritten history produced by the algorithm serializes exactly the set of unaffected good transactions. The suffix of the rewritten history includes special state information to describe a good transactions as well as malicious transactions. ITDB can extract additional good transactions from this latter part of a rewritten history. The latter processing saves more good transactions than is possible with a dependency graph based approach to recovery.

Finally, in Yu et al. (2004), a self-healing workflow system is proposed. Compared with ITDB, Yu et al. (2004) considers more types of dependency relations and introduces a set of theorems to trace damage spreading, construct repairing tasks, and create execution orders between recovery and normal tasks in such a way that correct, on-the-fly workflow attack recovery can be achieved.

## CONCLUSION

As society increasingly relies on digitally stored and accessed information, applications have increasingly higher requirements on supporting the availability, integrity, and confidentiality of this information, and traditional information security technologies are increasingly limited in satisfying the security requirements of applications because of their inability to survive successful attacks. As a result, information assurance technologies are introduced to not only prevent information from being disclosed, modified, or destroyed, but also detect intrusions and operate through attacks in such a way that a certain level of information security can be ensured in the presence of attacks. In this chapter, we survey the natural evolution of information assurance technologies. Three generations of IA technologies are summarized, and the newest generation of IA technologies is discussed in detail. In summary, this chapter takes the first steps to give a comprehensive overview of the scope of IA technologies, the relation between the emerging survivability technologies and the more established IA technologies such as information security and intrusion detection technologies, the characteristics of survivability technologies, and the representative ideas, principles, and techniques of survivable systems development.

Although a variety of emerging IA technologies have been developed recently to ensure a certain level of information security in the presence of attacks for applications, existing IA technologies are still at their earlier stage and limited in many aspects, and advanced IA technologies have not been widely deployed in the real world so far. Hence, a lot of existing new IA technologies and practices are yet to come. Here we mention several new research and development directions in IA technologies, which are illustrated as follows:

- The *threat* aspect of survivability. Without a tangible and accurate threat model, a highly assured information system cannot be developed. To build a good threat model, both the system's vulnerabilities and the attacks' characteristics (e.g., intent) are crucial. Some preliminary research has been done in analyzing the attacker's intent and strategies (e.g., Liu & Zang, 2003), but more research is certainly needed. Risk analysis is a relevant topic and readers can refer to Risk Assessment and Risk Management for information on this topic.
- Survivability requirements analysis. Without a clear specification of the users' *survivability requirements*, a survivable system may either overreact to attacks (and threats) or be not proactive enough, and the effectiveness of survivability mechanisms could not be well evaluated. Survivability requirements analysis is a challenging problem, especially when quantitative requirement specifications are expected.
- Survivability *metrics* and measurements. Information assurance metrics are scarce and qualitative. Given the need to determine the information assurance posture for a given organization under given conditions, users in the field require a means to determine the relative degree of assurance associated with the information assets under their control. Likewise, developers of survivable systems

require metrics to measure the degree to which they are employing engineering practices during the system development process. The use of IA metrics would permit establishing trust in a system built from untrusted components, determining sufficient levels of security for the specific tactical situation and condition, and assessing system vulnerabilities. IA metrics enable quantitative tradeoffs between security and performance (degradation).

- *Service survivability*. Existing IA technologies largely focus on system survivability, but in many cases system survivability does not imply service survivability, and additional service survivability facilities and controls are needed. Service survivability are application oriented and at a higher level than system survivability.
- *Wireless Information assurance*. A key piece of the large-scale information enterprise is the wireless information assurance segment. Wireless networks must exhibit the same functional and IA attributes as wired networks. They must be protected; attacks against these networks must be detected; specifics of successful attacks must be assessed and finally appropriate responses must be carried out. As we move to more and more wireless components becoming a part of the larger network and as wireless networks proliferate, we need to be aware that these networks, if improperly understood and configured, could provide a “back-door” into our protected wired enterprise. Intrusion detection for wireless networks must be addressed as well as recovery of wireless services after adversary disruption/denial destruction of friendly networks.
- Using intrusion tolerant middleware (Courtney et al., 2003; Ramasamy, Pandey, Lyons, Cukier, & Sanders, 2002; Singh, Cukier, & Sanders, 2003) to facilitate the development of intrusion tolerant applications. In this way, developers may be relieved from substantial IA design and development issues.

## ACKNOWLEDGMENT

This work was supported by NSF ANI-0335241, NSF CCR-0233324, and Department of Energy Early Career PI Award.

## GLOSSARY

**Assurance** (a) The degree of confidence that a target of evaluation adequately fulfills the security requirements. (b) A measure of confidence that the security features and architecture of an automated information system accurately mediate and enforce the security policy. Note: The two main aspects of assurance are effectiveness and correctness or development and evaluation assurance.

**Authenticity** The ability (a) to establish the validity of a claimed identity and (b) to provide protection against fraudulent transactions by establishing the validity of a message, station, individual, or originator.

**Availability** (a) The ability to access a specific resource within a specific time frame as defined within the IT product specification. (b) The ability to use or access

objects and resources as required. The property relates to the concern that information objects and other system resources are accessible when needed and without undue delay. (c) The prevention of the unauthorized withholding of information or resources.

**Byzantine Fault Tolerance** A Byzantine fault is one in which a component of some system not only behaves erroneously but also fails to behave consistently when interacting with other components. Correctly functioning components of a Byzantine fault tolerant system will be able to reach the same group decisions regardless of Byzantine faulty components.

**Certificate** A certificate is a document that attests to the truth or ownership of something. A digital certificate is a digital document that serves the same purpose. Most specifically, it attests to the truth that you are who you say you are and that you own the particular public key specified in the certificate.

**Certification Authority** A trusted third party who confirms the identity of an organization or individual (an entity).

**Confidentiality** Assurance that information is not disclosed to inappropriate entities or processes.

**Fault Tolerance** The ability of a system or component to continue normal operation despite the presence of hardware or software faults.

**Integrity** (a) Correctness and appropriateness of the content and/or source of a piece of information. (b) The prevention of the unauthorized modification of information. (c) Sound, unimpaired, or perfect condition.

**Intrusion Detection** A security service that monitors and analyzes system events to find and provide real-time or near-real-time attempt warnings to access system resources in an unauthorized manner. This is the detection of break-ins or break-in attempts by reviewing logs or other information available on a network.

**Nonrepudiation** An attribute of communications that seeks to prevent future false denial of involvement by either party. *Nonrepudiation with proof of origin* provides the recipient of data with evidence that proves the origin of the data.

**Survivability** The ability of a network computing system to provide essential services in the presence of attacks and failures and recover full services in a timely manner.

**Vulnerability** A hardware, firmware, communication, or software flaw that leaves a computer processing system open for potential exploitation, either externally or internally, thereby resulting in risk for the owner, user, or manager of the system.

## INTRODUCTION

Modern business is all but dependent upon information technology (IT), and reliance on the exchange of electronic information is rapidly becoming entrenched in our day-to-day personal lives (e.g., through the Internet, wireless devices, and other interactive means of data transfer). To an ever greater degree, business relies on technologies that connect with its customers, and with other businesses, for example, to streamline supply routes, control inventory, and minimize time to market, exchange services and products in business-to-business trade platforms, enhance distribution channels, boost sales through e-commerce, improve fulfillment operations, and enrich customer databases with valuable information concerning customer spending patterns and the like. There are, in fact, companies, such as Axiom Corporation, Abacus Direct, Equifax, Experian, and InfoUSA, that focus on compiling and aggregating consumer-related data.

The Internet has been the foremost catalyst of this business evolution, precipitating a global interconnectivity of computer systems that permits ready access by businesses and individuals to vast amounts of corporate and consumer information, which, thanks to advancements in IT, are becoming increasingly easy to access, search, and retrieve. A by-product of this evolving global electronic business model is the interdependence on the access to and sharing of data. IT—through software applications, hardware and communications equipment, networking systems, and the many related services—facilitates this access to and sharing of data.

### Rethinking the Security of Data in Light of Modern IT

Modern IT, and particularly the Internet, has caused a rethinking of how corporate data and personal information

should be handled. Most of that information is now in electronic form. It is quite common now for a business's key information to reside in an electronic data format, sometimes never being transformed into paper hardcopy at all. Because it can be easily accessed, copied, and widely distributed in electronic form, via the Internet for example, and often as easily as by typing a few keystrokes, concerns of security are greater than ever. With the efficiencies brought about by modern IT have come greater risks—risks that often involve undesired, or even illegal, use of, access to, and disclosure of sensitive data.

Public awareness of these risks, at least with regard to personal information, has raised the bar for information security by putting pressures on business to assure consumers of the security of their information. To allay consumer concern, many Web sites display a privacy policy aimed at reassuring consumers hesitant about uploading their personal information online and have taken steps to secure that data. Today's business also operates with an understanding that a security breach could cause echoing negative public relations. For example, *In the Matter of Eli Lilly and Co.* (2002), Eli Lilly had offered users of several drugs, including the antidepressant medication Prozac, an e-mail reminder service that would allow each user to receive personal e-mail messages to remind them to take or refill their medication. On June 27, 2001, Lilly sent an e-mail to all 669 subscribers of the e-mail service, but listed each of their e-mail addresses in the "To:" field of the e-mail, thereby unintentionally disclosing to each individual subscriber the e-mail addresses of all other subscribers. Lilly's privacy policy included statements such as "Eli Lilly and Company respects the privacy of visitors to its Web sites, and we feel it is important to maintain our guests' privacy as they take advantage of this resource." The Federal Trade Commission (FTC) alleged that Lilly's claim of privacy and confidentiality was deceptive because it "failed to maintain or implement internal

measures appropriate under the circumstances to protect sensitive consumer information,” as evidenced by its June 27, 2001, disclosure.

Public concern has also prompted lawmakers to enact legislation affecting how certain personal information is handled. Those laws can impact a business’s implementation of IT, can create regulatory compliance obligations, and may pose the potential for liability to third parties if the data are mishandled. The new regulatory environment and its corporate compliance issues, coupled with corporate concern for negative public relations, the potential for civil liability, and the heightened risks brought about by advancements in IT, have caused businesses to pay closer attention to IT security practices and to look at how IT may be used to both satisfy compliance obligations and minimize liability.

## WHAT IS AT RISK?

### Corporate Data and Personal Information

Corporate data are often a valuable asset. Trade secrets, confidential business information such as customer lists, and other sensitive business information such as internal operating procedures are guarded with great care, are protected from unauthorized disclosure to outsiders, and should be secured.

Additionally, the personal information of employees and consumers (sometimes referred to in legal texts as nonpublic personal information, personally identifiable information, or simply personal data), such as contact information, financial data and transaction records, and personal health information, is generally viewed as private and confidential to the individual and therefore protected against unauthorized access by and disclosure to third parties. It is not uncommon for a business to invest in the security of human management and payroll systems to ensure adequate protection of information about employees. Nor is it unusual for a business to safeguard consumer information, not only because its unauthorized disclosure may pose a risk of regulatory noncompliance, but also because such information may be considered a valuable asset, the disclosure of which could result in a competitive loss in the marketplace.

#### Nature of the Data

Data of little commercial value, or that are not highly private to an individual, may pose little risk. However, data that may pose a distinct risk if subject to a security breach, and that may result in liability, could include sensitive information such as the following:

1. Company trade secrets, which may include customer lists or business methods. Rights in trade secrets are governed by state law (*Roton Barrier, Inc. v. Stanley Works*, 1996). The Restatement of Torts acknowledges that a customer list may be a trade secret (see Restatement of Torts §757, Comment b). A business must protect the secrecy of a trade secret to retain its trade secret status (see *Defiance Button Machine Co. v. C&C Metal Products Corp.*, 1985, in which rights in a customer list were forfeited because information was not kept confidential).

2. Information that may not necessarily be a trade secret, but which a business nonetheless considers to be confidential (e.g., price lists, internal policy manuals) and does not want disclosed to certain other parties (e.g., competitors) or publicly (see *Overholt Crop Insurance Service Co. v. Travis*, 1991, in which the court enforced a company’s rights in its customer information that had been revealed under a confidential relationship, even if the information was “technically not a trade secret”).
3. Confidential information of a business partner, of a contracting entity, or of a business customer and of which an organization is in possession and for which the organization has agreed to keep confidential (e.g., through a contract, such as a nondisclosure agreement).
4. Information collected from or about a consumer (such as contact information, demographic information, transaction records, credit report data, purchasing habits, or Web site surfing activity), which may be subject to:
  - (a) Specific laws governing redisclosure and use of consumer information, such as financial information and medical records. Examples of such laws include the Financial Services Modernization Act of 1999 (more commonly known as the Gramm-Leach-Bliley Act or GLB), which governs the protection of “personally identifiable financial information,” and the Health Insurance Portability and Accountability Act (HIPAA), which governs the protection of “protected health information.” In Europe, the Data Protection Directive (1995) governs generally the protection of “personal data.”
  - (b) More general consumer protection laws governing personal information of consumers. Examples of such laws include the Federal Trade Commission Act (FTCA, 1914) and individual state consumer protection laws.
  - (c) A commitment by the business to keep the consumer’s information private, such as in a Web site privacy policy or in a legally required privacy notice (such as a GLB notice).

In many instances, the nature of the data will determine whether certain statutory or regulatory obligations are triggered and thus whether the data are subject to regulatory compliance requirements (e.g., HIPAA pertains only to “protected health information,” a statutorily defined term). The nature of the data may affect the risk in two ways: (1) highly sensitive data, such as trade secrets, customer credit card information, and consumer financial account information, will be a target for hackers, increasing the likelihood of unauthorized disclosure by intrusion, and (2) in the event of a breach, more sensitive data may pose a greater degree of harm and perhaps result in a public relations fiasco as well.

#### Attendant Risks

It is important to understand how the data are used and what therefore could happen to them (or, if a breach has occurred, what has happened to the data). Key to this understanding is knowing how the data are gathered,

transmitted, used, and stored and where in that process the data might be (or have been) compromised in one way or another. This exercise pinpoints where the integrity of those data may be (or was) compromised.

Why is this important? Certain regulatory obligations specifically address the handling of data (e.g., GLB prohibits an unauthorized disclosure to a nonaffiliated third party). In terms of devising an appropriate compliance program, it is necessary to understand fully how the data are to be used, and what access, use, and disclosure restrictions need to be placed on those data. Moreover, the potential for liability to others will depend to a large extent on how the data are handled (e.g., liability might attach under a negligence theory if the data were handled in an unreasonable fashion). The implementation of appropriate IT infrastructure and data security policies and procedures can often help to satisfy compliance obligations and to mitigate the potential for liability.

At the preventive stage, there are several security considerations, the evaluation of which provides a good framework for assessing and testing security controls:

*Physical security.* Physical security refers to the security measures in place to prevent unauthorized physical entry to the location at which computer equipment is located and may include such relatively simple measures as locked entryways and access to central computing rooms via authorized identification card only or more sophisticated measures such as biometric screening systems such as fingerprint or retinal scan recognition. Ordinarily, locked entryways and access restricted to authorized identification cards would suffice, but other measures may be considered when highly sensitive data are at issue.

*Technical security.* Technical security encompasses the use of logical security, which includes implementation of hardware and software designed specifically to secure data. Logical security has been defined as “security measures for controlling access to electronic information resources through logical means (e.g., via software or network controls), procedural controls related to software development and change control, security of data, communications, and reduction of risk from harmful and intrusive computer software.” See “University of Central Florida” (2001). It contemplates controls within software that limit access by a secure means of authentication and authorization. Logical security includes issuance and maintenance of user identifications and corresponding passwords and other software-related protocols for identifying authenticity. Extranets, virtual private networks, and remote access typically employ varying degrees of logical security. Logical security also involves securing networks and securely integrating applications and systems by using software and hardware designed specifically to secure or otherwise prevent risk to data. Examples include software firewalls, virus and monitoring applications, and hardware firewalls and routers. Software that is implemented should be regularly updated (e.g., with current security patches). Virus scanning software should be regularly updated with current virus definitions. Technical security may also include adequate contingency plans, including routine backup and archiving of data, to minimize the risk in the event of data loss.

*Personnel and administrative security (employee and consultant policies and procedures).* The nature of the data may warrant that they be accessed by a limited number of personnel having higher security clearance. Moreover, personnel with access should be trained as to the business’ policies and procedures with regard to the use and disclosure of such data. There should also be fail checks built into the system, or some sort of counterintelligence mechanisms, to identify individuals who may not follow procedures or who may, themselves, seek to access, copy, steal, or release data improperly. Background checks may be made on persons being considered for hire as employees or to be retained as consultants who are expected to have access to sensitive data or to the systems that store or transmit such data. Adequate training and ongoing support may minimize the risk of data being inadvertently deleted or altered by human error or ignorance. Adequately trained personnel should administer the business’ security policies and procedures.

*Operational security.* The overall operations of the business should be guided by a security policy that takes into account the unique risks and vulnerabilities associated with the attendant business practices, which will include several of the foregoing security concerns. Certain laws (e.g., GLB) require a business to implement a security program suitable for its size, business practices, risks, and vulnerabilities.

As shown below, failures in the foregoing may lead to regulatory noncompliance and also may give rise to third-party liability. Security breaches that may trigger regulatory obligations, or generate the potential for third-party liability, include unauthorized access, use, or disclosure of data or systems and destruction, loss, or corruption of data.

**Unauthorized Access, Use, and Disclosure.** Information of a sensitive nature—for example, corporate trade secrets, confidential information of a business partner, or personal information of consumers—poses a distinct risk of liability if it is not properly safeguarded. Most organizations recognize that this information should be kept confidential. Not all organizations, however, appreciate how their IT infrastructure and policies impact the potential for liability.

Liability may arise when the information is accessed by an unauthorized person, such as a hacker. A common fear in the corporate sector is that an intruder will infiltrate the organization’s systems and steal valuable data. The intruder, who may be an outsider, a contractor, or even an internal employee, may seek to blackmail the organization, threatening to publicly disclose the data unless the organization pays a sum of money. At times, a business may want to avoid the negative implications of a public disclosure and heed the intruder’s demands. Other times, law enforcement will intervene, but the intruder is not always apprehended, and the news of the security breach may not be well received by customers or shareholders. In other instances, the hacker may, unbeknownst to the business, use or sell the stolen information for illegitimate purposes, such as identity theft.

Although the threat of an intruder is typically recognized by an organization’s risk management, liability

for unauthorized access, use, or disclosure of data may arise in other contexts, such as with inadvertent disclosures caused by human error or by a technology snafu. For example, data may be misdirected or transferred to the wrong destination (e.g., in e-mail) or unintentionally released or displayed (e.g., on a Web site), any of which could result from technological failure or human oversight.

Employee unawareness of legal obligations may also lead to regulatory noncompliance and third-party liability. An employee may not know that certain data should not be disclosed. For example, under GLB, a financial institution may not use or disclose nonpublic personal information except as set forth in the institution's privacy notice, and then, in certain regards, only to the extent that the consumer has not opted out of specific disclosures. If, for example, the marketing arm of a firm has access to customer information, such as via the firm's customer relations management software, but has not been informed of the regulatory restrictions, or of any consumer opt-outs, it might improperly share the data with third parties in marketing campaigns in violation of GLB. Personnel not familiar with the applicable data restrictions might unwittingly misuse the data, causing an organization to be noncompliant with regulatory requirements.

In other situations, an organization may contract to use data for certain limited purposes, such as in a data supply agreement or in a service provider relationship in which either the service provider or the customer commits contractually to limit its use and disclosure of the data it receives. Usage or disclosure of the data outside the contract parameters may result in a breach of the contract. Proper IT implementation and practices, including adequate personnel training and education, should help to avoid such problems.

There are also risks associated with unauthorized access to computer systems, even where data are not accessed or compromised. For example, a denial of service attack could render business operations ineffective, creating potential business loss and third-party liability. Unauthorized access to a network could likewise create potential losses and liability.

**Corruption, Destruction, or Loss of Data.** Liability may also arise from the corruption, destruction, or loss of data. Where a business has contracted with another to process certain data, implicit in which is the maintenance or preservation of those data, or where a business expressly agrees to preserve data (such as where a contract contemplates routine backup of data), the corruption or loss of those data may lead to contractual liability. Adequate procedures with respect to the handling of the data, as well as backup and disaster recovery practices, should mitigate the potential for such loss.

Data may be destroyed, lost, or corrupted due to a number of factors, including viruses, Trojan horses, worms, or other harmful software code; ill-intentioned efforts by intruders; software errors, malfunctions and bugs; failed hardware or media; telecommunications glitches and failure; noncompliance with internal procedures; or natural disaster, terrorism, an act of God, or other force majeure events. None of the foregoing may be absolutely

avoidable, but the likelihood of an occurrence, or of data being destroyed, lost, or corrupted in the event of an occurrence, may be mitigated by proper precautionary measures. Many businesses employ a backup regimen, for example. The procedures vary from company to company, depending upon the nature and value of the data and the attendant risks. It is fairly common for a business to employ a nightly backup of all transactions that occurred during the day onto tapes that are stored offsite periodically. Certain data may warrant more elaborate, and costly, backup procedures involving duplicate or redundant systems that copy data daily, hourly, or at other assigned times or that mirror data immediately. Frequent backups should lessen the amount of data that could be lost and would therefore need to be restored, thus reducing the potential for liability.

When data are destroyed, lost, or corrupted, a business faces both (1) additional costs and expenses for its internal efforts, and perhaps for external services to assist, in restoring the data and (2) potential liability to third parties, such as, for example, where the security of the data was entrusted to that party and the data cannot be fully restored or cannot be restored in a timely manner, causing an interruption in the other party's business operations. Steps taken to avoid events that may compromise the data will obviously lessen a business's risk. Moreover, adequate backup and disaster recovery programs will minimize the extent of data lost, and thus the potential financial exposure, in the event that data are compromised.

### Risks Incumbent With the Internet and Subcontracting

The makeup of an organization's IT infrastructure may impact the risk of a security breach and the potential for liability. It may also affect the organization's regulatory compliance. The IT upon which a business depends typically involves a mix of internal technology, such as owned or leased computer equipment and networking systems, licensed or proprietary software, and IT personnel responsible for the smooth operation of the business's IT systems and, to a varying degree, technology solutions offered by one or more IT service providers, such as managed network servicers, telecommunications providers, application service providers, hosting companies, and outsourcing providers. Many of those services are provided remotely, through the Internet, or otherwise contemplate access via the Internet. How an organization's IT infrastructure is deployed may influence whether a particular statutory or regulatory obligation is triggered and may affect the potential for third-party liability.

### Web Sites and the Internet

An overriding consideration in any legal assessment is whether the data are collected from or accessible to the outside. Where an organization collects information through a Web site or stores data on a server connected to the Internet, the potential for unauthorized access and disclosure to someone outside the organization may be greater than with a closed system. Furthermore, data that are transmitted or stored unencrypted are at greater risk if intercepted or otherwise accessed by an intruder.

Consumer data collected via a Web site may also subject a business to certain obligations under consumer protection laws, or perhaps contractual liability under the business's own privacy policy if the terms in that policy are not followed.

### Outsourcing and Subcontracting

Utilizing third-party service providers may be an attractive option where such providers are, given the efficiencies created by their niche expertise or their economies of scale, capable of providing a service at reduced costs when compared with supporting the service in-house. In other instances, there may be no alternative to engaging an IT service provider, as is typically the case with a telecommunications provider. Furthermore, vendors that concentrate on providing a particular service may have expertise in an area that may be difficult to replicate in-house. A hosting company is a good example. Many hosting companies maintain large server farms on which they host many Web sites for their customers. A hosting company often negotiates favorable terms with hardware and software providers, and with an Internet Service Provider (ISP) or telecommunications provider for Internet access, and can build those savings into its offering to its customers. A hosting company can also reduce costs by using shared servers and allocating personnel to multiple accounts.

When IT is handled primarily in-house, the organization has direct control over its IT operations and can usually achieve an acceptable comfort level with its risk and liability assessments by review and enforcement of its own internal policies and procedures, and through the periodic undertaking of internal compliance audits. However, when a business elects to engage a third-party vendor to provide certain of its IT services, a number of legal issues arise that are more difficult to assess. When certain aspects of the IT program are outsourced or otherwise entrusted to a third party, direct control over some or all of the IT operations, and the security of its data, is lost. The business is then dependent, to an extent, on the vendor (and its subcontractors) to ensure that adequate security policies and procedures are in place, monitored, and enforced (e.g., to meet the business's regulatory obligations and to minimize the potential for liability).

Allowing third parties access to corporate and personal data and the business's IT systems obviously poses a level of risk that should be considered when looking to engage any vendor. Some amount of due diligence should be conducted to gain a satisfactory level of comfort with the vendor (e.g., reference checks, background checks, and Dunn & Bradstreet financial checks). Moreover, the contract between the vendor and the customer should clearly spell out the expectations of the parties, including who is responsible for what (e.g., in the event of a security breach), how data are to be handled (e.g., which restrictions attach to which data), which types of security are to be implemented, and who is liable for what. In certain instances, engaging a subcontractor will trigger regulatory obligations with regard to the subcontract itself (e.g., HIPAA requires that a subcontractor sign a business associate agreement that must satisfy certain express regulatory requirements).

Service provider contracts will often attempt to disclaim liability for these types of events (e.g., in a force majeure clause, in general or specific disclaimers, in disclaimers of damages, or in limitations of liability). From the customer's perspective, such disclaimers may be acceptable so long as they are qualified as being outside the service provider's reasonable control, not reasonably avoidable with proper due diligence and foresight, and the contract elsewhere affirmatively requires the provider to undertake steps to maintain the security and integrity of the data.

## STATUTORY AND REGULATORY COMPLIANCE

### The Impact of the Law: Determining Regulatory Obligations and Assessing the Potential for Liability

Security breaches may pose liability under a number of different legal theories, depending upon the nature of the data and the circumstances surrounding the breach. They may also create noncompliance situations with regulatory obligations, subjecting the organization to penalties and possible enforcement actions by government regulators. This section looks at statutory and regulatory obligations and the potential for liability for failures to comply with those obligations. The remainder of this chapter looks at the potential for third-party liability under contract and tort theories.

As an introduction, it is worthy to note that there is a body of decisional law in the United States premised upon an individual's right to privacy in certain information. It has been held, for example, that an individual has a constitutional right to privacy in the very intimate aspects of his or her personal life, such as with certain medical information. It has also been held that an individual may maintain an action in tort for an invasion of his or her privacy, which could, for example, include the privacy of financial information. See *McNally v. The Pulitzer Publishing Co.* (1976), which differentiated between the constitutional right of privacy and the common law right recognized by state tort law. The failure to safeguard such information may give rise to claims of a violation of either a constitutional right or of a tort involving the invasion of privacy. Although possible claims in tort are discussed in a later section of this chapter, the concept of this right to privacy has influenced, and continues to influence, the development of statutes and regulations that impose upon organizations an obligation to safeguard certain personal information.

### Damages

Certain statutes may provide for statutory remedies (e.g., a dollar figure for violations or treble damages). To the extent that a statute imposes a duty to maintain the security of data, and allows a private claim to be brought for a breach of that statutory duty, unless otherwise provided in the statute, the claimant will likely need to demonstrate that he or she suffered some actual damage to recover under the statute (*Doe v. Chao*, 2004). In the *Doe v. Chao*

case, the plaintiff alleged a violation of the Privacy Act of 1974, which requires federal agencies not to disclose data, because the Department of Labor had disclosed his Social Security number on public documents. The Privacy Act states that a claimant who suffered damages as a result of a violation of the act may receive “actual damages sustained by the individual . . . but in no case shall a person entitled to recovery receive *less than* the sum of \$1,000” (5 U.S.C. §552a(g)(4)(A)). In declining to award the statutory \$1,000, the Court held that the plaintiff’s assertions “that he was ‘torn . . . all to pieces’ and ‘greatly concerned and worried’ because of the disclosure of his Social Security number and its potentially ‘devastating’ consequences” was insufficient to establish that he had, in fact, suffered actual damage (2004 U.S. LEXIS at \*8).

In many instances, it may be difficult for a claimant to establish any damages arising from an unauthorized disclosure of his or her personal information. This topic is further addressed in the discussion about remedies under the next section of this chapter. It would be ill-advised, however, to assume that damages may never be assessed in respect of disclosures of consumer data.

## Legislative Developments

The growing concern for privacy in recent years has prompted legislative action both in the United States and abroad requiring organizations to protect the privacy of personal information. The statutory approach in the United States is often referred to as sectoral in nature because the laws are drawn along industry lines; that is, they pertain to specific information gathered by organizations in specific industries (namely financial and medical). Unlike the Data Protection Directive, for example, which has been adopted in European countries and which imposes restrictions on the collection, use, and disclosure of personal information generally, regardless of the context of the relationship in which the information was collected—whether financial, medical, or otherwise, the United States has no comparable broad stroke law that restricts generally the collection, use, or disclosure of personal information (see Data Protection Directive, 1995).

The U.S. approach, therefore, creates one anomaly in that the same information collected via different relationships could in one instance be subject to statutory and regulatory restrictions and in another instance not be regulated at all. Moreover, in some instances the information could be subject to more than one statutory scheme (e.g., information might fall under both HIPAA and GLB, raising the issue of which regulation should govern—GLB regulators have addressed this by suggesting that the applicable regulation be the one more protective to the consumer). See Privacy of Consumer Financial Information; Final Rule, 65 Fed. Reg. 35,164 (2000). Whether specific information is governed by regulation requires a thorough understanding of the statutory scheme.

### U.S. Federal Law

Two U.S. federal statutes that directly address IT security are the Financial Services Modernization Act of 1999 (more commonly known as the GLB) and HIPAA (1996). These two statutes, and their accompanying regulations,

focus on the privacy of certain personal information, but also specifically address the security of data. Neither statute concerns corporate data (e.g., corporate trade secrets or confidential information), unless that information includes the personal information of individuals that is protected by the statute. The following takes a close look at the regulatory obligations imposed on data security by these statutes, but by no means is an exhaustive review of all the regulations. Neither statute allows for a civil cause of action (enforcement would be brought by the applicable federal agency or state authority), but the security requirements set out in the regulations might reflect standards that a court could consider in addressing a liability claim brought by a private party.

**GLB.** Although it is limited to “nonpublic personal information” collected by “financial institutions,” GLB is a good example of statutory and regulatory initiatives that directly impact IT operations and data security procedures. It is worthy to note that GLB applies broadly to many businesses that handle financial data in one way or another and not just banks. GLB was enacted in 1999.

#### What Are Financial Institutions?

GLB applies only to financial institutions, a term broadly defined by the statute. The term *financial institution* means “any institution the business of which is engaging in financial activities as described in section 1843(k) of title 12” (Financial Services Modernization Act, 1999, 15 U.S.C. §6809(3)(A)). 12 U.S.C. §1843(k) describes a long list of activities as being financial in nature. 12 U.S.C. §1843(k) includes a list of entities that includes the more traditional financial institutions, such as lending institutions, banks, insurance companies, underwriters, investment companies, financial advisors, and funds and broker-dealers. In addition to the traditional financial activities identified in 12 U.S.C. §1843(k), the term *financial activities* includes activities that the Federal Reserve Board has found, by regulation, order, or interpretation, to be either closely related to banking (12 U.S.C. §1843(k)(4)(F)) or usual in connection with the transaction of banking or other financial operations abroad (12 U.S.C. §1843(k)(4)(G)).

Activities that are “closely related to banking” are identified at 12 C.F.R. §225.28 and 12 C.F.R. §225.86(a), and include, in certain circumstances, brokering or servicing loans; leasing real or personal property (or acting as agent, broker, or adviser in such leasing) without operating, maintaining, or repairing the property; appraising real or personal property; check guaranty, collection agency, credit bureau, and real estate settlement services; providing financial or investment advisory activities including tax planning, tax preparation, and instruction on individual financial management; management consulting and counseling activities (including providing financial career counseling); courier services for banking instruments; printing and selling checks and related documents; community development or advisory activities; selling money orders, savings bonds, or traveler’s checks; and providing financial data processing and transmission services, facilities (including hardware, software,

documentation, or operating personnel), databases, advice, or access to these by technological means.

Activities that are “in connection with the transaction of banking or other financial operations abroad” are identified at 12 C.F.R. §211.5(d) and 12 C.F.R. §225.86(b), and include leasing real or personal property (or acting as agent, broker, or adviser in such leasing), where the lease is functionally equivalent to an extension of credit; acting as fiduciary; providing investment, financial, or economic advisory services; and operating a travel agency in connection with financial services.

Given the broad definition of financial institution, many organizations that were not traditionally thought of as financial institutions may nonetheless be subject to GLB and therefore required to comply with its security and privacy regulations.

#### Who Are the Regulators?

GLB provides the statutory framework but instructs the relevant federal and state agencies and authorities to promulgate regulations governing the application of the statute for those entities within their respective jurisdictions. Accordingly, the Securities and Exchange Commission (SEC) issued a Privacy Rule that incorporates its Security Rule (17 C.F.R. §248.30) and implements GLB’s statutory requirements with regard to the entities governed by the SEC (investment advisers registered with the SEC, brokers, dealers (broker-dealers), and investment companies (funds); 17 C.F.R. Part 248; See Final Rule: Privacy of Consumer Financial Information (Regulation S-P) (SEC), 65 Fed. Reg. 40,334 (2000)). Similarly, the various banking agencies—the Federal Reserve System, Federal Deposit Insurance Corporation, Office of Comptroller of the Currency, Department of the Treasury, and the Office of Thrift Supervision, Department of the Treasury—issued a Joint Privacy Rule and Joint Security Guidelines (12 C.F.R. Part 40) governing the various banking institutions under their jurisdiction. The National Credit Union Administration (NCUA) issued regulations (12 C.F.R. Parts 716 and 741) governing credit unions that it regulates. For insurance companies, GLB regulations are implemented by the applicable state insurance department or authority of the state in which the person is domiciled. The National Association of Insurance Commissioners has proposed a model regulation for adoption by the states (See *What’s happening with privacy*, n.d.).

For all those entities that do not otherwise fall under the jurisdiction of the federal agencies identified above, or the state insurance departments or authorities, but nevertheless are financial institutions under the broad statutory definition of that term, GLB authorizes the FTC to regulate such entities with regard to GLB compliance. The FTC issued its Privacy Rule (16 C.F.R. Part 313) and Security Rule (16 C.F.R. Part 314) in 2000.

#### Restrictions on Handling of Data

GLB limits the disclosure of nonpublic personal information. Nonpublic personal information is defined as “personally identifiable financial information provided by a consumer to a financial institution resulting from any transaction with the consumer or any service performed

for the consumer or otherwise obtained by the financial institution” (Financial Services Modernization Act, 1999, 15 U.S.C. §6809(4)(A)). This is broadly construed to “encompass any information that ‘is requested by a financial institution for the purpose of providing a financial product or service,’ 65 Fed. Reg. at 33,658, inasmuch as all such information can be fairly characterized as ‘relating to finance and financiers’” (*Trans Union LLC v. Federal Trade Commission*, 2002). Accordingly, information collected in connection with a financial transaction would be subject to GLB’s security and privacy requirements, even if the information itself is not necessarily financial in nature (nonpublic personal information would therefore include, e.g., any name, address, telephone number, e-mail address, Social Security number, contact information, or other information supplied by a consumer in connection with an application for a financial product or service).

Precisely how GLB limits the use of nonpublic personal information can be a bit complicated under the statutory and regulatory scheme. In essence, however, GLB requires a financial institution to disclose clearly to consumers in a privacy notice its policies and procedures with regard to the collection, use, and disclosure of nonpublic personal information. The notice must clearly indicate what information is collected, how it is used, and to whom it is disclosed and, in certain instances, the consumer must be afforded an opportunity to opt out of disclosures of the information to nonaffiliated third parties. The institution must ensure that it complies with its notice and any opt-out elections made by a consumer. Failure to do so may result in a regulatory enforcement action and civil penalties.

#### Security Obligations

GLB requires each agency to establish appropriate standards relating to administrative, technical, and physical safeguards:

- to ensure the security and confidentiality of customer records and information;
- to protect against any anticipated threats or hazards to the security or integrity of such records; and
- to protect against unauthorized access to or use of such records or information which could result in substantial harm or inconvenience to any customer (Financial Services Modernization Act, 1999, 15 U.S.C. §6801(b)).

Each agency issued its own security guidelines or regulations. The following outlines the security guidelines promulgated by the banking agencies. The FTC’s security rule is found at 16 C.F.R. §314; the Securities and Exchange Commission’s security rule is included in its privacy regulations (Regulation S-P) at 17 C.F.R. §248.30.

A financial institution must develop and implement “a comprehensive written information security program that includes administrative, technical, and physical safeguards” (a) designed to protect the security and confidentiality of “customer information” and (b) to assess, manage and control risks pertaining to the institution’s “customer information systems” (12 C.F.R. Part 30, Appendix B, ¶ II.A-C). Customer information is “any record

containing nonpublic personal information, as defined in §40.3(n) of this chapter, about a customer, whether in paper, electronic, or other form, that is maintained by or on behalf of the bank” (12 C.F.R. Part 30, Appendix B, ¶ I.C.2.c). This includes “data, files, or other information” about the consumer. It includes records that may contain other than nonpublic personal information, even records that contain very little nonpublic personal information. Records that contain little nonpublic personal information are still customer information under the guidelines; this fact may be a factor in determining the appropriate level of protection. See Interagency Guidelines Establishing Standards for Safeguarding Customer Information (Banking Agencies), 66 Fed. Reg. 8,618 (2001). “Customer information systems” are “any methods used to access, collect, store, use, transmit, protect, or dispose of customer information.” This includes “electronic or physical” methods. A “financial institution’s responsibility to safeguard customer information continues through the disposal process” (12 C.F.R. Part 30, Appendix B, ¶ I.C.2.d).

The guidelines do not impose specific requirements in terms of the administrative, technical, and physical safeguards to be adopted by an organization. They are, instead, intended to be flexible, permitting an institution to develop a program “appropriate to the size and complexity of the bank and the nature and scope of its activities” (12 C.F.R. Part 30, Appendix B, ¶ II.A).

#### Assess Risks

The guidelines allow an organization latitude in developing an information security program appropriate for its business. The organization must assess the risks that customer information may be compromised (e.g., disclosed, misused, altered, or destroyed), taking into consideration internal and external threats, the likelihood and potential damage of these threats (including the sensitivity of the customer information), and the arrangements in place to control the risks. There is no requirement that all organizations afford the same degree of protection to all customer information. Rather, the guidelines permit the organization “the discretion to determine the levels of protection necessary for different categories of information” (Interagency Guidelines Establishing Standards for Safeguarding Customer Information (Banking Agencies), 66 Fed. Reg. 8,621 (2001)).

For example, sensitive data that are stored on or transmitted through “systems that are accessible through public telecommunications networks...may require more and different protections, such as encryption, than if it were located in a locked file drawer” (Interagency Guidelines Establishing Standards for Safeguarding Customer Information (Banking Agencies), 66 Fed. Reg. 8,621 (2001)). Such data may include customer account numbers and access codes because they are more at risk of being targeted by a hacker and their disclosure would cause the customer considerable harm.

#### Manage and Control Risks

The information security program must be appropriate for an organization’s activities, considering the risks stated above. A number of security measures that are to

be considered and, if appropriate, adopted are identified at 12 C.F.R. Part 30, Appendix B, ¶ III.C.1.a through h. They include the following:

1. Access controls (e.g., passwords for customers to access their information electronically, identification criteria to be used by employees before providing account information, procedures to guard against pretext calling).
2. Access restrictions at physical locations (to permit access by authorized personnel only to computer facilities, record storage facilities, etc.).
3. Encryption of customer information (in electronic format while in transit or while residing on electronic storage devices, in either case where access may be gained by unauthorized individuals).
4. Review of updates and upgrades to customer information systems (to ensure continued integrity of the financial institution’s information security program).
5. Dual control procedures, segregation of duties, and employee background checks for employees with responsibilities for or access to customer information. Dual control procedures “refers to a security technique that uses two or more separate persons, operating together to protect sensitive information. Both persons are equally responsible for protecting the information and neither can access the information alone.” (Interagency Guidelines Establishing Standards for Safeguarding Customer Information (Banking Agencies), 66 Fed. Reg. 8,622 (2001)).
6. Monitoring of customer information systems (to detect attempted and actual attacks and intrusions).
7. Response procedures (specifying actions to take when it is suspected or verified that unauthorized individuals have accessed the financial institution’s customer information systems, including, when appropriate, reports to law enforcement and regulatory agencies).
8. Contingency plans and measures to protect against loss of or damage to customer information (e.g., due to fire, water damage, or technological failures).

The information security program should include training “designed to train employees to recognize, respond to, and report unauthorized attempts to obtain customer information” (12 C.F.R. Part 30, Appendix B, ¶ III.C.2). Staff should be properly informed about the organization’s procedures for reporting suspicious activities (such as suspicious activity reports [SARs]) and other federal reporting requirements. An institution regulated by the FRS must file an SAR with the Financial Crimes Enforcement Network of the Department of the Treasury “when it detects a known or suspected violation of Federal law, or a suspicious transaction related to a money laundering activity or a violation of the Bank Secrecy Act” (12 C.F.R. §208.62). The NCUA also requires federally insured credit unions to file similar reports (see 12 C.F.R. §748.1(c)).

#### Systems Testing

An information security program should include regular testing of key controls, systems, and procedures. There is no requirement that an organization apply specific tests

to evaluate the key control systems of its program; the organization must determine the frequency and nature of the testing based on its risk assessment. The tests should be conducted or reviewed by independent third parties or by staff independent of those that develop or maintain the security programs or operate the customer information systems.

#### Adjustments to Security Program

Adjustments should be made to the information security program “as necessary to reflect changes in both internal and external conditions” (Interagency Guidelines Establishing Standards for Safeguarding Customer Information (Banking Agencies), 66 Fed. Reg. 8,623 (2001); see 12 C.F.R. Part 30, Appendix B, ¶ III.E). An organization must adjust, as appropriate, the program “in light of any relevant changes in technology, the sensitivity of its customer information, and internal or external threats to information security” (12 C.F.R. Part 30, Appendix B, ¶ III.E). This would include analyzing the risks to customer information posed by new technology before adopting that technology to ascertain whether any adjustments to the security program are necessary. The program should also be adjusted to reflect an organization’s “own changing business arrangements, such as mergers and acquisitions, alliances and joint ventures, outsourcing arrangements, and changes to customer information systems” (12 C.F.R. Part 30, Appendix B, ¶ III.E).

#### Service Providers and Subservicers

An organization may, in the course of its business, outsource certain business functions or otherwise engage service providers to handle certain business operations that would necessarily require or permit their access to customer information. Such activities create additional risks to the security and confidentiality of the information and, to protect against such risks, the “institution must take appropriate steps to protect information that it provides to a service provider, regardless of who the service provider is or how the service provider obtains access” (Interagency Guidelines Establishing Standards for Safeguarding Customer Information (Banking Agencies), 66 Fed. Reg. 8,618 (2001)). An organization is responsible for customer information accessed by its service providers. Service providers are broadly defined and include “any person or entity that maintains, processes, or otherwise is permitted access to customer information through its provision of services directly to the bank” (12 C.F.R. Part 30, Appendix B, ¶ I.C.2.e). A service provider does not include a person or entity, such as a subservicer, that indirectly provides services to a financial institution. A subservicer that is retained by a primary service provider would not be a service provider to the organization that engaged the primary service provider, because it has no contractual relationship with the subservicer. A subservicer is “any person who has access to an institution’s customer information through its provision of services to the service provider and is not limited to mortgage subservicers” (Interagency Guidelines Establishing Standards for Safeguarding Customer Information (Banking Agencies), 66 Fed. Reg. 8,619, fn. 8 (2001)).

An organization must exercise due diligence in selecting a service provider, which would include a review of the (a) measures taken by a service provider to protect customer information and (b) controls the service provider has in place to ensure that any subservicer used by the service provider will be able to meet the objectives of the guidelines. An organization should enter into a contract with its service providers that requires the provider to implement appropriate security measures designed to meet the objectives of the guidelines.

An organization must exercise an appropriate level of oversight over each of its service providers to ensure that the provider is implementing the security measures for which it has been contracted. The oversight responsibilities should be consistent with the organization’s own risk assessment procedures. Not all outsourcing arrangements need be monitored or monitored in the same fashion. Where, for example, a service provider is also a regulated financial institution or subject to other legal and professional standards that require it to safeguard customer information, it may be reasonable to rely on the fact that the provider must comply with such restrictions, and therefore it may not be necessary to provide as much oversight.

The service provider may be monitored through periodic review of audits, summaries of test results or other equivalent measures of the service provider. The contract with the service provider should call for the receipt of copies of audits and test result information adequate to confirm that the service provider is implementing security measures consistent with the provider’s contractual obligations. A contract may call for the service provider to submit to periodic audits of its security measures.

#### Liability and Enforcement Actions

The banking rule is not intended to impose absolute liability for a financial institution that has a security breach. This is evident in the qualification in 12 C.F.R. Part 30, Appendix B, ¶ II.B that a security program is to be *designed* to accomplish the statutory objectives set out at 15 U.S.C. §6801(b).

Under certain of the guidelines, if an agency determines that an organization has failed to satisfy the security standards set forth in the guidelines, the agency may request the institution to submit a compliance plan that sets out the steps it will take to correct the deficiency and how long those steps will take. If the organization fails to submit or implement a compliance plan, the agency shall, by order, require the institution to correct the deficiency and may take further actions. If the organization fails to comply with an order, the agency may seek enforcement and a civil money penalty in court.

**HIPAA.** HIPAA was enacted in August 1996. In accordance with HIPAA, the United States Department of Health and Human Services (HHS) promulgated regulations titled Standards for Privacy of Individually Identifiable Health Information (the HIPAA Privacy and Security Rule), which became effective in April 2003 and established national standards for the privacy and security of health information (45 C.F.R. Parts 160 and 164. See 65 Fed. Reg. 82462; 67 Fed. Reg. 53182).

### Who and What Are Regulated by HIPAA?

HIPAA applies to covered entities, which include health plans, health care clearinghouses, and certain health care providers. A health plan is an individual or group plan that provides, or pays the cost of, medical care. Health plans include group health plans, health insurance issuers, health maintenance organizations, Parts A and B of the Medicare program, a Medicaid program, Medicare supplemental insurers, and certain long-term care insurers. A health care clearinghouse is an entity that processes, or facilitates the processing of, health information into a standard format or standard data elements, receives health information in a standard format and process, or facilitates the processing of that information into a nonstandard format or nonstandard content. A health care provider is broadly defined and includes all persons and organizations who furnish, bill, or are paid for providing health care, services, or supplies related to the health of an individual, in the normal course of business. If the health care provider transmits health information electronically in connection with certain transactions, it is a covered entity under the HIPAA Privacy and Security Rule.

HIPAA pertains to protected health information (PHI), which includes medical records and other health information that identifies or could be used to identify an individual, regardless of its form (electronic, paper, or oral), that are created or received by a covered entity or its business associate. PHI includes, for example, any information about payment for health care.

### Outsourcing and Vendors

The HIPAA Privacy and Security Rule imposes specific regulatory obligations on outsourcing and other vendor relationships. Where a covered entity engages a third-party contractor, HIPAA requires the covered entity to secure specific contractual commitments from the contractor, which the HIPAA Privacy and Security Rule refers to as a "business associate" (45 C.F.R. §160.103). A business associate may be a subcontractor, an outsourcer or any party that (a) performs a function or activity on behalf of the covered entity and that function or activity involves the use or disclosure of PHI (for example, claims processing, data analysis, utilization review, and billing functions) or (b) provides certain specified services to a covered entity (namely legal, actuarial, accounting, consulting, data aggregation, management, administrative, accreditation or financial services).

The HIPAA Privacy and Security Rule requires covered entities to have business associates execute a business associate agreement. Among other things, the business associate agreement may not permit the business associate to use or disclose PHI in any manner that would violate the HIPAA Privacy and Security Rule if done by the covered entity, must limit the use of PHI only for the purpose for which the business associate is engaged, and must provide assurances that the business associate will safeguard the PHI from misuse. For example, the business associate agreement must

- Require the business associate to use appropriate safeguards to prevent the unauthorized use or disclosure of PHI (the HIPAA Privacy and Security Rule does

not define the appropriate safeguards; 45 C.F.R. § 164.504(e)(2)(ii)(B)).

- Report to the covered entity any unauthorized use or disclosure of PHI of which it becomes aware (45 C.F.R. § 164.504(e)(2)(ii)(C)).
- Ensure that any agents of the business associate, including any subcontractor, to whom the business associate provides PHI agree to the same conditions and restrictions that apply to the business associate with respect to the PHI (45 C.F.R. § 164.504(E)(2)(ii)(D)).
- Permit access to PHI to satisfy the covered entity's obligations to allow individuals to amend their PHI or to provide individuals with an accounting of the disclosures of their PHI (45 C.F.R. § 164.504(e)(2)(ii)(E)-(G)).
- Return or destroy all PHI received from or created or received by the business associate on behalf of the covered entity or ensure its continued protection upon the termination of the contract (45 C.F.R. § 164.504(e)(2)(ii)(I)).

The business associate agreement may permit the business associate to disclose PHI as required by law (e.g., court orders, court-ordered warrants, a civil or an authorized investigative demand, subpoenas or summonses issued by a court, a governmental or tribal inspector general or an administrative body authorized to require the production of information, Medicare conditions of participation with respect to health care providers participating in the program, and statutes or regulations that require the production of such information if payment is sought under a government program), so long as the business associate obtains certain assurances from the person to whom the PHI is disclosed.

### Security

HIPAA imposes general requirements on covered entities to maintain the security of PHI. For example, the HIPAA Privacy and Security Rule requires covered entities to

- Ensure the confidentiality, integrity, and availability of all electronic PHI the covered entity creates, receives, maintains, or transmits.
- Protect against any reasonably anticipated threats or hazards to the security or integrity of such information.
- Protect against any reasonably anticipated uses or disclosures of such information that are not permitted or required under the rule (45 C.F.R. §164.306(a)).

As with GLB, HIPAA allows flexibility in determining the approach to ensuring security. The following factors must be considered in devising a security program appropriate for a particular organization:

- The size, complexity, and capabilities of the covered entity.
- The covered entity's technical infrastructure, hardware, and software security capabilities.
- The costs of security measures.
- The probability and criticality of potential risks to electronic PHI (45 C.F.R. §164.306(b)(2)).

The HIPAA Privacy and Security Rule implements these statutory requirements by setting out a fairly lengthy list of administrative, physical, technical, and organizational safeguards that a covered entity must institute (or, in certain instances, must consider instituting) to protect the integrity of PHI. Those safeguards are detailed at 45 C.F.R. §§164.308-164.314 and include the following:

#### Administrative Safeguards

*Risk analysis.* Conduct accurate and thorough assessment of the potential risks and vulnerabilities to the confidentiality, integrity, and availability of electronic PHI held by the covered entity.

*Risk management.* Implement security measures sufficient to reduce risks and vulnerabilities to a reasonable and appropriate level.

*Information system activity review.* Implement procedures to regularly review records of information system activity, such as audit logs, access reports, and security incident tracking reports.

*Assigned security responsibility.* Identify the security official who is responsible for the development and implementation of the policies and procedures required by the rule.

*Workforce security.* Implement policies and procedures to ensure that all members of the workforce have appropriate access to electronic PHI and to prevent those workforce members who do not have access from obtaining access to electronic PHI.

*Security awareness and training.* Implement a security awareness and training program for all members of the workforce (including management).

*Protection from malicious software.* Procedures for guarding against, detecting, and reporting malicious software (e.g., viruses, worms, or Trojan horses).

*Log-in monitoring.* Procedures for monitoring log-in attempts and reporting discrepancies.

*Password management.* Procedures for creating, changing, and safeguarding passwords.

*Security incident procedures.* Implement policies and procedures to address security incidents.

*Response and reporting.* Identify and respond to suspected or known security incidents; mitigate, to the extent practicable, harmful effects of security incidents that are known to the covered entity and document security incidents and their outcomes.

*Contingency plan.* Establish (and implement as needed) policies and procedures for responding to an emergency or other occurrence (for example, fire, vandalism, system failure, and natural disaster) that damages systems that contain electronic PHI.

*Data backup plan.* Establish and implement procedures to create and maintain retrievable exact copies of electronic PHI.

*Disaster recovery plan.* Establish (and implement as needed) procedures to restore any loss of data.

*Emergency mode operation plan.* Establish (and implement as needed) procedures to enable continuation of critical business processes for protection of the security of electronic PHI while operating in emergency mode.

*Testing and revision procedures.* Implement procedures for periodic testing and revision of contingency plans.

*Applications and data criticality analysis.* Assess the relative criticality of specific applications and data in support of other contingency plan components.

#### Physical Safeguards

*Facility access controls.* Implement policies and procedures to limit physical access to its electronic information systems and the facility or facilities in which they are housed, while ensuring that properly authorized access is allowed.

*Facility security plan.* Implement policies and procedures to safeguard the facility and the equipment therein from unauthorized physical access, tampering, and theft.

*Access control and validation procedures.* Implement procedures to control and validate a person's access to facilities based on their role or function, including visitor control and control of access to software programs for testing and revision.

*Maintenance records.* Implement policies and procedures to document repairs and modifications to the physical components of a facility that are related to security (for example, hardware, walls, doors, and locks).

*Workstation use.* Implement policies and procedures that specify the proper functions to be performed, the manner in which those functions are to be performed, and the physical attributes of the surroundings of a specific workstation or class of workstation that can access electronic PHI.

*Workstation security.* Implement physical safeguards for all workstations that access electronic PHI to restrict access to authorized users.

*Device and media controls.* Implement policies and procedures that govern the receipt and removal of hardware and electronic media that contain electronic PHI into and out of a facility and the movement of these items within the facility.

#### Technical Safeguards

*Unique user identification.* Assign a unique name or number for identifying and tracking user identity.

*Emergency access procedure.* Establish (and implement as needed) procedures for obtaining necessary electronic PHI during an emergency.

*Automatic logoff.* Implement electronic procedures that terminate an electronic session after a predetermined time of inactivity.

*Encryption and decryption.* Implement a mechanism to encrypt and decrypt electronic PHI.

*Audit controls.* Implement hardware, software, or procedural mechanisms that record and examine activity in information systems that contain or use electronic PHI.

#### Organizational Safeguards

*Business associate contracts.* The contract between a covered entity and a business associate must provide that the business associate will do the following:

- Implement administrative, physical, and technical safeguards that reasonably and appropriately protect the confidentiality, integrity, and availability of the electronic PHI that it creates, receives, maintains, or transmits on behalf of the covered entity.

- Ensure that any agent, including a subcontractor, to whom it provides such information agrees to implement reasonable and appropriate safeguards to protect it.
- Report to the covered entity any security incident of which it becomes aware.
- Authorize termination of the contract by the covered entity, if the covered entity determines that the business associate has violated a material term of the contract.

The HIPAA Privacy and Security Rule also requires a covered entity to designate a privacy official responsible for the development and implementation of its PHI policies and procedures. Those policies and procedures must be updated as necessary and appropriate to comply with changes in the law, including any changes in the HIPAA Privacy and Security Rule. A covered entity's workforce must be trained about its policies and procedures with respect to PHI, as necessary and appropriate for the workforce members to carry out their duties. A covered entity must have and enforce appropriate sanctions against members of its workforce who fail to comply with its privacy and security policies and procedures.

HHS may pursue violations of HIPAA and the HIPAA Privacy and Security Rule. Violations carry a civil penalty of not more than \$100 for each such violation, except that the total amount imposed on the person for all violations of an identical requirement or prohibition during a calendar year may not exceed \$25,000.

**Other Laws.** Other U.S. statutes are relevant to the discussion of IT security insofar as they may impose obligations with regard to data security or give rise to liability in the event of a security breach. Given that steps to ensure privacy of information in electronic format will depend, in large part, upon adequate information security measures, some laws may indirectly impact IT security by imposing obligations to maintain the privacy of personal information.

#### Consumer Protection Laws

##### Federal Trade Commission Act

Consumer protection law at the U.S. federal level may be found in the Federal Trade Commission Act (1914). Under Section 5 of the FTCA, the FTC is authorized to take action against businesses involved in unfair or deceptive acts or practices in or affecting commerce. The FTC is permitted a fair amount of latitude under the FTCA in determining what constitutes "unfair or deceptive acts or practices." (See *FTC v. Colgate-Palmolive Co.*, 1965: "This statutory scheme necessarily gives the Commission an influential role in interpreting §5 [of the FTCA as to what are deceptive practices] and in applying it to the facts of particular cases arising out of unprecedented situations . . . the Commission is often in a better position than are courts to determine when a practice is 'deceptive' within the meaning of the Act.")

The FTC has taken the position that a misrepresentation as to the handling of personal information is a violation of Section 5 of the FTCA. For example, in the complaint filed by the FTC in *In the Matter of Geocities*

(1998), the FTC alleged, "The acts and practices of respondent as alleged in this complaint [that Geocities misrepresented its information collection practices] constitute unfair or deceptive acts or practices in or affecting commerce in violation of Section 5(a) of the Federal Trade Commission Act" (Complaint at ¶ 20). Geocities had allegedly misrepresented that the personal information it collected from its users would not be disclosed to third parties without the user's consent when Geocities actually disclosed it to third-party marketers.

The FTC may consider a promise to safeguard personal information—in a Web site privacy policy or in some other commitment made by a company—as a representation by that company that the personal information will be safeguarded in the manner promised. For example, in *In the Matter of Guess?, Inc.*, the FTC asserted that

since at least October 2000, Guess' Web site has been vulnerable to commonly known attacks such as "Structured Query Language (SQL) injection attacks" and other web-based application attacks. Guess' online statements reassured consumers that their personal information would be secure and protected. The company's claims included "This site has security measures in place to protect the loss, misuse, and alteration of information under our control" and "All of your personal information, including your credit card information and sign-in password, are stored in an unreadable, encrypted format at all times." In fact, according to the FTC, the personal information was not stored in an unreadable, encrypted format at all times and Guess' security measures failed to protect against SQL and other commonly known attacks. In February 2002, a visitor to the Web site, using an SQL injection attack, was able to read in clear text credit card numbers stored in Guess' databases, according to the FTC.

The FTC alleged that Guess misrepresented "the extent to which it maintains and protects the security of personal information collected from or about consumers" (*In the Matter of Guess?, Inc.*, 2003).

In *In the Matter of Microsoft Corporation* (2002), the FTC asserted that Microsoft's Passport service "collects personal information from consumers and allows them to sign in at any participating website with a single name and password." According to the FTC, "Microsoft's Passport privacy policies included statements such as, 'Passport achieves a high level of Web Security by using technologies and systems designed to prevent unauthorized access to your personal information.'" After an investigation, the FTC alleged, among other things, that "Microsoft falsely represented that [i]t employs reasonable and appropriate measures under the circumstances to maintain and protect the privacy and confidentiality of consumers' personal information." (See also Muris, 2001, who stated, "Having encouraged commercial Web sites to post these notices, the FTC needs to ensure compliance. Privacy promises made offline should be held to the same standard.")

The failure to comply with such a representation in a privacy policy may be declared a violation of the FTCA for which the FTC may take action. Under the FTCA, the FTC may seek preliminary and permanent injunctive relief to remedy “any provision of law enforced by the Federal Trade Commission” whenever the FTC has “reason to believe” that a party “is violating, or is about to violate” a provision of law enforced by the FTC (15 U.S.C. §53(b)).

If the conduct were such as “a reasonable man would have known under the circumstances was dishonest or fraudulent,” the FTC may also pursue consumer redress in the form of “rescission or reformation of contracts, the refund of money or return of property, the payment of damages, and public notification respecting the rule violation or the unfair or deceptive act or practice,” or such other “relief as the court finds necessary to redress injury to consumers or other persons, partnerships, and corporations resulting from the rule violation or the unfair or deceptive act or practice” (15 U.S.C. §57b). Under the FTCA, the FTC may also seek civil penalties when the violator had “actual knowledge or knowledge fairly implied on the basis of objective circumstances that such act is unfair or deceptive and is prohibited by such [unfair or deceptive acts or practices] rule” under Chapter 2 of the FTCA (15 U.S.C. §45(m)(1)). The civil penalty is capped at \$10,000 per violation.

#### Electronic Communications Privacy Act

An amendment to the Wiretap Act, the Electronic Communications Privacy Act (ECPA, 1986) prohibits anyone from intentionally accessing, using, or disclosing stored communications, such as e-mail or stored voice messages, without authorization. Violations of the ECPA are punishable by fines, imprisonment, or both. The ECPA allows for a civil cause of action and recovery of actual damages but not less than \$1,000 per violation of the statute, plus the costs and reasonable attorneys’ fees in pursuing the action. If the violation were willful or intentional, the court may assess punitive damages (18 U.S.C. §2707(c)).

The ECPA also expressly prohibits providers of “electronic communication” or “remote computing services” from knowingly divulging the contents of a communication in electronic storage, except under certain enumerated circumstances (18 U.S.C. §2702(a)). The following disclosures are excepted from the statutory prohibition: (a) to intended recipients and their agents; (b) with the consent of the originator or the recipient of the communication, and in the case of remote computing services, the subscriber to the service; (c) to a person employed or authorized to forward the communication to its destination; (d) as necessarily incident to providing a service or to protecting the rights or property of the service provider; (e) to a law enforcement agency, if the communication was inadvertently obtained and appears to pertain to criminal activity; and (f) as otherwise authorized by law (18 U.S.C. §2702(b)).

Electronic communication services are defined as “any service which provides to users thereof the ability to send or receive wire or electronic communications” (e.g., an ISP) or telephone company that offers digital services (18 U.S.C. §2510(15)). Remote computing services are defined

as “the provision to the public of computer storage or processing services by means of an electronic communications system” (e.g., application service providers and certain Web-based services that provide services to the public; 18 U.S.C. §2511(2)).

The ECPA does not address security of data per se; however, to the extent it prohibits certain disclosures, organizations must be cognizant that such disclosures are not intentionally or knowingly made without authorization (e.g., providers of electronic communication or remote computing services need to ensure that such disclosures are not knowingly made unless expressly permitted by the ECPA). Where, for example, an employee or agent intentionally or knowingly discloses a stored communication (e.g., because he or she did not appreciate the restrictions on disclosure of such information or otherwise failed to follow privacy or security procedures), under certain circumstances the act of the employee or agent may be imputed to the employer, in which event the employer could be liable under the ECPA.

In *Muskovich v. Crowell* (1996), the court held that a telephone company did not knowingly disclose an unlisted telephone number (which the court assumed fell within the definition of electronic communication). There, an MCI employee, in violation of MCI’s employee policies, obtained a subscriber’s unlisted number and made a number of harassing phone calls to her. Finding that “the term knowingly means that the Defendant was aware of the nature of the conduct, aware of or possessing a firm belief in the existence of the requisite circumstances and an awareness of or a firm belief about the substantial certainty of the result,” the court held that since “MCI trained Crowell in policies requiring confidentiality of customer information and prohibiting profanity and personal use of company facilities, services or customer information” and the defendant “violated MCI’s express policies by making personal use of confidential information he obtained from customer records,” without MCI’s actual knowledge, MCI had not violated the ECPA by knowingly disclosing such information (*Id.* at \*12-14).

The Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism Act (USA Patriot Act) amended the ECPA to expressly allow organizations to cooperate with law enforcement as part of a legitimate investigation and to permit the voluntary disclosure of stored communications in certain instances. The ECPA also permits the disclosure of stored communications with the consent of the originator or addressee of the stored communication. Such consent may be obtained, for example, through an appropriate employee manual, workplace policy, terms of use, or other agreement with the originator of the stored communication.

#### Sarbanes-Oxley Act

The Sarbanes-Oxley Act (SOX) was enacted in July 2002 in response to the corporate accounting scandals in the 1990s. The law has far-reaching implications on the disclosures and accounting practices of public companies and applies generally to companies (whether organized in the United States or elsewhere) that have registered

equity or debt securities with the SEC under the Securities Exchange Act (SEA). Although SOX does not directly impose security requirements, it requires, among other things, that chief executive officers (CEOs) and chief financial officers (CFOs) of public companies provide a written statement with each periodic report certifying that the report fully complies with the requirements of Section 13(a) or 15(d) of the SEA and that the information contained in the report fairly presents, in all material respects, the financial condition and results of operations of the company. A CEO or CFO who provides such certification knowing that the report does not meet those standards may be fined up to \$1 million, imprisoned for up to 10 years, or both. A CEO or CFO who willfully provides the certification knowing that the report does not meet those standards may be fined up to \$5 million, imprisoned for up to 20 years, or both.

SOX also requires, through SEC rules, that the principal executive officers and principal financial officers of public companies certify the following in each annual and quarterly report:

1. the certifying officer has reviewed the report;
2. based on the knowledge of the officer, the report does not contain a material misstatement or material omission and the financial statements and other financial information included in the report fairly present, in all material respects, the financial condition and results of the operations of the company; and
3. each certifying officer (a) is responsible for establishing and maintaining effective internal controls; (b) has designed such internal controls to ensure that material information relating to the company is made known to him or her; (c) has evaluated the effectiveness of those controls as of a date no more than 90 days before filing the report; (d) has presented in the report his or her conclusions about the effectiveness of those controls; (e) has disclosed to the outside auditors and to the audit committee any significant deficiencies in those controls and any fraud involving management or other employees who have a significant role in the company's internal controls; (f) has identified to the outside auditors any material weaknesses in those controls; and (g) has stated in the report whether or not there were significant changes in the internal controls that could affect those controls, including any corrective actions.

SOX therefore imposes upon the directors and officers of a public company direct responsibility for corporate accounting practices and reporting and oversight over the company's internal controls relating thereto. The requirements placed upon directors and officers by SOX have had an indirect impact on security measures as increasingly auditing firms and other entities realize that the integrity of financial data cannot be ensured without an adequate security program and periodic audits thereof. SOX should therefore indirectly impact a company's use of IT by creating incentives to deploy adequate IT security solutions, and internal control measures, that will ensure and protect the integrity of corporate data comprising the company's SEC disclosures and reporting.

Furthermore, to the extent that any business maintains records in electronic format, and the data in those records is used in preparing corporate tax filings or SEC disclosures, the business may be required to later reproduce those data to support the accounting in the tax filings or the representations made in the disclosures. Accordingly, adequate safeguards should be undertaken to protect the integrity of that data.

#### Uniform Computer Information Transactions Act

The Uniform Computer Information Transactions Act (UCITA, 1999) was drafted by the National Conference of Commissioners on Uniform State Laws (NCCUSL) and was originally proposed as an amendment to the Uniform Commercial Code (UCC) in the form of a new article (UCC Article 2B). Fundamental disagreement over the substance of the language caused the project to be dropped as a proposed amendment to the UCC and recast as a stand-alone model act that could be adopted by each of the states. Approved by NCCUSL on July 29, 1999, only two states—Virginia and Maryland—have adopted UCITA as state law, and each has adopted the model act with some modifications.

Although UCITA attempted to establish uniform laws governing the licensing and use of software, it has been criticized on a number of grounds. For example, UCITA essentially validates shrink-wrap or click-through licenses—the standard, take-it-or-leave-it licenses that are often tied to software. A trap for any business would be the downloading and installation by employees of software onto company computers, where the software is accompanied by click-through licensing terms. In such instances, the business could be subject to those terms, even though the terms were not formally reviewed and accepted by the legal department.

UCITA also validates stop code, or software code, mechanisms that may deactivate the functionality of the software automatically over time, switch off use of the software for other reasons (e.g., if installed on a replacement computer), or otherwise allow the vendor to shut down the software remotely through a back door (e.g., through an Internet connection). The implications of such stop code are obvious, particularly where incorporated within mission critical software.

Anyone doing business in a jurisdiction that has recognized UCITA should consider the implications of that act. Furthermore, in negotiating any licensing or IT agreement, the parties should also be aware of a contract clause that attempts to apply any or all of the provisions of UCITA to the terms of the agreement.

#### Computer Fraud and Abuse Act

The Computer Fraud and Abuse Act (CFAA, 1986) is intended to reduce hacking of commercial computer systems and prohibits, among other things, anyone from intentionally accessing a computer without authorization and thereby improperly obtaining information from the computer (18 U.S.C. §1030 *et seq.*). The CFAA applies to computers (a) storing certain financial information, (b) storing information from any department or agency of the United States, and (c) used in interstate or foreign commerce or communication (18 U.S.C. §1030(a)(2)).

Violation of the CFAA is punishable by imposition of a fine, imprisonment, or both (18 U.S.C. §1030(c)). The CFAA permits, under certain circumstances, a person damaged by reason of a violation of the CFAA to bring a civil cause of action for compensatory damages and injunctive or other equitable relief (18 U.S.C. §1030(g)).

Although the CFAA requires intent to access a computer without authorization, instances may arise in which, for example, overzealous employees seek, intentionally, to obtain information from competitors to obtain a competitive advantage in the marketplace or in which a software tool is used, intentionally, to crawl, mine, or extract data from Web sites and databases available online, however, in doing so circumvent authorization requirements for legitimate access to that data. Such conduct could run afoul of the CFAA and risk civil liability, in addition to fines and, in certain instances, imprisonment of the violator.

#### Other U.S. Federal Statutes

Other U.S. statutes that impact data security from one angle or another (some of which apply only to government agencies) and are worth mentioning include the following:

1. The Privacy Act of 1974 which, in relevant part, provides that “no [government] agency shall disclose any record which is contained in a system of records by any means of communication to any person, or to another agency” (5 U.S.C. §552a).
2. The Computer Security Act of 1987 (amended by the Clinger-Cohen Act of 1996 and the E-Government Act of 2002), which requires the government to promulgate standards for computer security, train relevant employees in computer security and establish plans for the security and privacy of computer information. In relevant part, the act requires that

each federal agency shall provide for the mandatory periodic training in computer security awareness and accepted computer security practice of all employees who are involved with the management, use or operation of each Federal computer system within or under the supervision of that agency . . . [and] establish a plan for the security and privacy of each Federal computer system . . . that is commensurate with the risk and magnitude of the harm resulting from the loss, misuse, or unauthorized access to or modification of the information contained in such system. (40 U.S.C. §1441)

3. The Clinger-Cohen Act (1996; formerly known as the Information Technology Management Reform Act), which directs executive agencies of the government to establish the position of chief information officers (CIO) and places responsibility on the CIO for

providing advice and other assistance to the head of the executive agency and other senior management personnel of the executive agency to ensure that information technology is acquired and information resources

are managed for the executive agency . . . ; developing, maintaining, and facilitating the implementation of a sound and integrated information technology architecture for the executive agency; and promoting the effective and efficient design and operation of all major information resources management processes for the executive agency, including improvements to work processes of the executive agency. (40 U.S.C. §1401)

4. The Trade Secrets Act (2000), which criminalizes unauthorized government disclosure of trade secrets.
5. The Uniform Trade Secrets Act (1985), which has been adopted by a majority of the states in one form or another and which protects certain confidential information receiving the status of a trade secret under the terms of the act.
6. The Fair Credit Reporting Act (1970), which limits the disclosure and use of certain credit information appearing on a consumer’s credit bureau report.
7. The Children’s Online Privacy Protection Act (1998), which prohibits the online collection and use of information from children under the age of 13 without parental consent.
8. The Controlling the Assault of Non-Solicited Pornography and Marketing Act of 2003, which places certain restrictions on the transmittal of commercial e-mail.

See *Cobell v. Norton* (2001).

**U.S. State Laws.** There is a growing trend among the states, undoubtedly prompted by increasing public concern for such things as identity theft and misuse of private information, to enact privacy laws that would supplement the protections afforded by federal law. California, for example, has enacted a number of privacy-driven statutes, among them being the California Information Practices Act.

#### California Information Practices Act

California passed a unique law, effective July 1, 2003, requiring notification of security breaches. An amendment to the California Information Practices Act (2003), and titled Notice of Security Breach, the law requires any business or California state agency that maintains unencrypted computerized data that include personal information to notify any California resident of a security breach involving his or her personal information (CA Civil Code §§1798.29 and 1798.82–1798.84). The purpose of the law is to give affected individuals the opportunity to take steps to protect themselves from identity theft.

Under the California Act, personal information refers to “an individual’s first name or first initial and last name in combination with any one or more of the following data elements, when either the name or the data elements are not encrypted” (CA Civil Code §1798.82(e)):

- Social Security number.
- Driver’s license number or California identification card number.

- Account number, credit or debit card number, in combination with any required security code, access code, or password that would permit access to an individual's financial account.

“Breach of the security of the system’ means unauthorized acquisition of computerized data that compromises the security, confidentiality, or integrity of personal information maintained by the person or business” (CA Civil Code §1798.82(d)). The law states that

any person or business that *conducts business in California*, and that owns or licenses computerized data that includes personal information, shall disclose any breach of the security of the system following discovery or notification of the breach in the security of the data to any resident of California whose unencrypted personal information was, *or is reasonably believed to have been*, acquired by an unauthorized person. (CA Civil Code §1798.82(a); emphasis added)

Because the law applies to any business or person that *conducts business in California*, it has the potential to affect many businesses located outside the state of California (i.e., even if the business does not have a physical presence within the state), particularly companies that conduct business through a Web site via the Internet. Furthermore, because the law requires a business to notify affected individuals if a security breach is *reasonably believed* to have occurred, businesses that believe they may have been subject to a breach will need to make a prompt assessment of the situation to determine whether notification is required under the law.

To the extent applicable, the owner or licensee of the information must also be notified (CA Civil Code §1798.82(b)). For example, where a data processor or outsourcer is handling data on behalf of another organization and the data processor's systems are breached, and the other organization is deemed the owner of the data, the data processor will need to notify the organization of the security breach. The statute allows for a private cause of action, thus permitting those who have been injured by a violation of the statute to seek redress in a lawsuit (CA Civil Code §1798.84).

Because many organizations shy away from public disclosure of security breaches, largely because of the public relations fallout, the California law has caused a fair amount of commotion. The law will require, at least when the personal information of California residents is concerned, that organizations immediately notify such individuals (and perhaps the organization's business associates, if they own the data) when there is reason to believe that their personal information has been compromised due to a breach of the organization's (or its subcontractor's) IT systems. At least one lawsuit, seeking class action status, has been filed under the California law (see *Hamilton v. Microsoft Corp.*, 2003). The complaint alleged that Microsoft's response to security vulnerability, in respect of its Windows operating system and other software

products, is not sufficient to protect important and vital information and data.

#### State Consumer Protection Laws

Given its limited resources, the FTC has not often pursued privacy violations of the sort mentioned in the foregoing section. State attorneys general may pursue claims under state consumer protection laws whether or not the FTC pursues the matter under the FTCA. For example, in the FTC Toysmart action (*Federal Trade Commission v. Toysmart.com, LLC*, 2000), the FTC proposed a settlement with Toysmart, but the attorneys general of 47 states rejected that settlement, filing an objection to the FTC's application to enter the settlement (see *In re Toysmart.com, LLC*, 2000).

There are a number of state consumer protection laws that resemble the FTCA in addressing false, misleading, or deceptive business practices. In some states, the language of the state consumer protection law parallels that of Section 5 of the FTCA. See *Vermont v. International Collection Service, Inc.* (1991), in which “fourteen states have adopted this version [of the Unfair Trade Practices and Consumer Protection Law as proposed by the FTC], commonly known as the mini-FTC act.” State consumer protection laws are typically enforced by the office of the state attorney general but may allow for a private cause of action by consumers. See *Florez v. Linens 'n Things, Inc.* (2003), in which California consumer protection law permits private action regarding retailer's collection of personal information from customer.

Attorneys general have already shown an indication that they will pursue action where the security of personal information is compromised. For example, the New York State Office of the Attorney General (NYOAG) announced a multistate agreement with technology publisher Ziff Davis Media Inc. to “redress an Internet security breach that exposed the personal information of thousands of magazine subscribers online.” According to the NYOAG,

a magazine promotion Ziff Davis ran on its website in November of [2001]...allowed a computer file of approximately 12,000 subscription orders for Electronic Gaming Monthly to be accessed by anyone surfing the Internet. Personal data was exposed, including credit card information, which resulted in some subscribers becoming victims of identity theft.

The NYOAG noted that Ziff Davis's “privacy policy promised reasonable security, but it was not effective in this case” (Office of New York State Attorney General Eliot Spitzer, 2002).

In October 2003, the NYOAG settled a claim against Victoria's Secret Direct, LLC that the company's Web site allowed users to view online order information of other users, including personal information such as name, billing address, and items ordered. The NYOAG noted that

the published privacy policy for Victoria's Secret indicated that: “Any information you provide to

us at this site when you establish or update an account, enter a contest, shop online or request information . . . is maintained in private files on our secure web server and internal systems. . . .” (Office of New York State Attorney General Eliot Spitzer, 2003)

Where a private cause of action is allowed, an aggrieved consumer may sue to recover his or her damages or, if permitted by the statute, statutory damages, treble damages, or both.

**Foreign Laws.** The security of data may be impacted by laws outside the United States. For example, the European Union follows a Data Protection Directive that imposes various limitations and restrictions on the access, use, and disclosure of personal information (European Parliament, 1995). The Data Protection Directive is implemented as national law by the member countries of the European Union. The directive requires certain security measures to be taken:

1. The organization having control of the personal data (the controller) must implement appropriate technical and organizational measures to protect personal data against accidental or unlawful destruction or accidental loss and against unauthorized alteration, disclosure or access, in particular where the processing involves the transmission of data over a network, and against all other unlawful forms of processing. Having regard to the state of the art and the costs of their implementation, such measures shall ensure a level of security appropriate to the risks represented by the processing and the nature of the data to be protected (European Parliament, 1995, Article 17, ¶ 1).
2. The “controller must, where processing is carried out on his behalf, choose a processor who provides sufficient guarantees in respect of the technical security measures and organizational measures governing the processing to be carried out and must ensure compliance with those measures” (European Parliament, 1995, Article 17, ¶ 2).
3. The carrying out of processing by a processor must be governed by a contract binding the processor to the controller and stipulating in particular that (i) the processor shall act only on instructions from the controller, and (ii) the obligations set out in paragraph 1 above shall also apply to the processor (European Parliament, 1995, Article 17, ¶ 3).

The Data Protection Directive also restricts the transfer of certain information outside the European Union to countries that do not provide adequate safeguards to ensure the privacy and security of the data. See European Parliament (2002). As of March 2004, the United States was not considered to be a country that provides adequate safeguards. Thus, under the directive, personal data (e.g., employee data collected by human resource departments, customer information, and prospective client lists) cannot normally be transferred from the European office of a company to its U.S. office or to any other person or entity

in the United States. There are three mechanisms in place, however, to legally effectuate such a transfer:

1. Where the individual consents to the transfer of his or her data.
2. Where the parties enter into a contract incorporating model clauses approved by the European Commission in which the transferee agrees to safeguard the data in accordance with those clauses (see “Model contracts,” n.d.).
3. For data transferred to the United States, where the U.S.-based business registers for and adheres to the Safe Harbor, a set of rules developed by the U.S. Department of Congress and approved by the European Commission (see “Safe harbor overview,” n.d.).

Under certain local European laws, the transfer of personal data must be registered with a designated local authority. The failure to adhere to the restrictions of the Data Protection Directive could result in a violation of European law.

## CONTRACTUAL LIABILITY

Liability may arise under a breach of contract claim. There are at least two distinct categories of contracts that could be impacted by a security breach:

1. Business-to-business contracts, such as vendor agreements, outsourcing agreements, facility management agreements, independent contractor agreements, application service provider agreements, service bureau agreements, transaction fulfillment agreements, hosting agreements, co-location agreements, and agreements for contingency planning, backup, and disaster-recovery services—in all of which one party is being entrusted with responsibility for, or has access to, sensitive data of the other party.
2. Consumer contracts, which may arise in varying contexts, such as through a Web site click-through agreement, privacy policy, terms of use, subscriber agreement or user agreement, or, perhaps, where statutorily mandated, such as for financial information governed by GLB and health information covered by HIPAA or in any other context in which an organization has made a representation to the consumer with respect to the privacy or security of his or her personal information.

### Requirements of a Binding Contract

There must be mutual intent of the parties for there to be a binding contract, including an offer, acceptance, and consideration. See generally, Restatement (Second), Contracts, ch. 3, 4; see also *Maher v. United States* (2002). These requirements are almost always satisfied with a written agreement signed by at least two parties, particularly in a commercial setting in which the agreement is usually entered into by relatively sophisticated parties and often reviewed by attorneys. Although a contract need not necessarily be in writing to be binding, it is customary for many to be written instruments.

In the absence of an express agreement, a promise may nonetheless be enforceable under the theory of promissory estoppel or implied contract.

The elements of promissory estoppel are: (1) a promise unambiguous in its terms; (2) reliance on such promise by the party to whom it is made; (3) this reliance is expected and foreseeable by the party making the promise; and (4) the one to whom the promise is made must rely on the promise to his injury. (*Cohabaco Cigar Co. v. United States Tobacco Co.*, 1999)

A “standardized contract, which, imposed and drafted by the party of superior bargaining strength, relegates to the subscribing party only the opportunity to adhere to the contract or reject it” is referred to as a contract of adhesion (*Armendariz v. Foundation Health Psychcare Services*, 2000) (citations and internal quotation omitted); see also *Farnsworth on Contracts* §4.26 (2001). (“The form may be a take-it-or-leave-it proposition, often called a contract of adhesion, under which the only alternative to complete adherence is outright rejection.”) An online agreement, for example, may be a contract of adhesion since the end user may either accept or reject it, but has no power to negotiate its terms (*Comb v. PayPal, Inc.*, 2002, for reviewing online agreement in terms of a contract of adhesion). If there were unequal bargaining power in the formation of a contract, as is true with a contract of adhesion, courts are likely to interpret any ambiguity in the contract against the drafter and in favor of the nondrafting party (*Farnsworth on Contracts* §4.26 (LEXIS 2001); *Comb*, 2002, 218 F. Supp. 2d at 1172). Furthermore, the fact that a contract is one of adhesion may sway the court that a provision of the contract is unconscionable and thus unenforceable (*Comb*, 2002, 218 F. Supp. 2d at 1172).

There is case law that supports the view that a cause of action may be maintained in contract for an unauthorized disclosure of personal information. For example, in *Peterson v. Idaho First National Bank* (1961), the Idaho Supreme Court dismissed the plaintiff’s invasion of privacy claim but held open the possibility that the bank had breached an implied contractual duty of confidentiality. In that case, the plaintiff’s manager had asked the bank to inform him when any of his employees did anything to discredit his company. A bank official informed the manager that the plaintiff had written several bad checks. The plaintiff brought suit against the bank for its unauthorized disclosure of his personal information. The court focused on the relationship of the parties and the nature of the information in finding that “it is implicit in the contract of the bank with its customer or depositor that no information may be disclosed by the bank or its employees concerning the customer’s or depositor’s account, and that, unless authorized by law or by the customer or depositor, the bank must be held liable for breach of the implied contract” (*Id.* at 290; see also *Barnett Bank of West Fla. v. Hooper*, 1986, acknowledging that a bank may have an implied contractual duty not to disclose information regarding a customer’s account absent special circumstances such as fraud; and *Suburban Trust Co. v. Waller*, 1979,

recognizing a bank’s implied contractual duty to keep private information concerning its customer’s account).

## Remedies

### Damages

In a breach of contract action, the normal remedy for the aggrieved party is to recover his or her actual damages attributable to the breach. Where personal information has been disclosed due to a security breach, it may, however, be difficult to quantify the damages. In fact, a consumer may have no provable damages. For example, it has been held that a person suffered no quantifiable damage when his personal information was sold to third parties for marketing purposes (*Dwyer v. American Express Co.*, 1995, in which the plaintiffs did not suffer damages by credit card company’s disclosure of cardholders’ credit card purchases and contact information; and *Smith v. Chase Manhattan Bank, USA, N.A.*, 2002: “Thus, the ‘harm’ at the heart of this purported class action, is that class members were merely offered products and services which they were free to decline. This does not qualify as actual harm.”).

However, if the disclosure results in identity theft, there could be some level of real damages incurred. A survey by CalPIRG and the Privacy Rights Clearinghouse in May 2000 found that the average consumer identity theft victim spends 175 hours and \$800 resolving identity theft problems and that it takes 2 to 4 years for victims to resolve all the resulting problems (“Identity theft,” n.d.). Thus, there could be a quantifiable amount of actual damages in which a breach results in the disclosure of personal information of many individuals. Furthermore, it would be naïve to assume that any unauthorized disclosure of personal information would result in no damage, especially in light of the changing legal climate concerning the privacy and security of such information.

Consumer harm aside, in the commercial context the disclosure or loss of corporate data could have a substantial financial impact. For example, an unauthorized disclosure of trade secrets or customer information could put a business at a significant competitive disadvantage and, in some cases, ruin the business. Most commercial contracts will contain disclaimers of certain damages and limitations of liability. Depending on which side of the contract you are on, this may or may not be reassuring. For example, many contracts disclaim liability for consequential damages. Whereas direct, or compensatory, damages usually equate to the amount of money to put the aggrieved party in as good a position had the breaching party not breached (e.g., the amount of money that a customer had agreed to pay), indirect, or consequential, damages reflect the natural and probable consequences flowing from the breach and can be significantly more than the direct damages. Examples of damages that, depending upon the nature of the contract, tend to be consequential in nature include lost profits, loss of business, and loss of goodwill.

Damages that are consequential may not be recoverable if the parties have contracted to exclude them from liability in the event of a breach. Thus, if the disclosure of a trade secret or some other confidential information causes a business to lose a competitive edge in the marketplace,

results in a public relations fiasco possibly driving down the stock, or if the loss or corruption of data leads to a loss of business or loss of clients, to the extent the damages are consequential in nature, the injured party may not be able to recover. Some contracts, however, exclude from the disclaimer of damages certain breaches of the contract or conduct of a party, such as a breach of an obligation to maintain the confidentiality of confidential information, a breach of a security requirement, or for reason of a party's negligence, recklessness, willful misconduct, or intentional conduct. Such exceptions could allow for recovery for such losses under certain circumstances.

Additionally, commercial contracts often limit the amount of liability to a dollar figure or a fixed amount, such as the total fees paid or a multiple thereof. Some contracts will limit the amount to the fees paid during a particular term of the contract, such as 1 year preceding the accrual of the claim. Unless there is an express carve out from the limitation of liability, the dollar cap would typically apply to any claim under the contract, including a claim for breach of confidentiality or breach of security (unless, for example, the applicable jurisdiction recognizes a tort claim for gross negligence or willful misconduct in such instance or otherwise, for public policy reasons, would disregard the contractual limitation of liability given the reckless or intentional conduct of the breaching party). The limitation of liability and disclaimers of damages are therefore very important aspects of any IT-related contract because, depending on which side of the contract a person is on, these clauses will greatly impact his or her financial risk in the event of a security breach. Accordingly, the precise wording of these clauses should be carefully considered during the contract negotiations.

Many contracts also include some type of indemnity, which can likewise affect financial liability arising from a security breach. For example, a clause that requires Party A to indemnify Party B for third-party claims arising out of a breach of a representation or warranty, or for Party A's or its subcontractors' negligence, recklessness, or willful misconduct, could make Party A contractually obligated to defend, indemnify, and hold harmless Party B should Party B become involved in a claim based on Party A's unauthorized disclosure of Party B's confidential information. The indemnity there could be triggered where, for example, the contract contained a representation or warranty regarding the confidentiality, privacy, or security of information or a representation or warranty against viruses, Trojan horses, worms, or other malicious code. It could also be triggered if Party A were negligent in, for example, exercising adequate safeguards to protect the information (e.g., in failing to use suitable firewalls or encryption, failing to screen employees and subcontractors and to do background checks, failing to provide adequate employee training, or failing to utilize reasonable physical and logical security).

Where there is a stream of providers of technology services, it is wise to ensure that the contractual chain is not broken at some point, thereby exposing one party to unnecessary liability. It is not at all uncommon to have various contracts and subcontracts involving multiple

providers of IT services. In many instances, it is desirable to have the contracts contain similar obligations—particularly concerning liability—flowing upstream. For example, a provider that assumes responsibility to its customer in a contract, and then subcontracts out some or all of its obligations to another party, should take care to ensure that the contract with its subcontractor contains obligations similar to those in its customer contract. If there are gaps in the contractual obligations, the provider may, in the event of a breach, find itself in between its customer and its subcontractor with no contractual recourse against its subcontractor. This is particularly acute when the provider has agreed to indemnify its customer, but has failed to secure the same indemnity from its subcontractor. If, for example, the subcontractor releases customer data without authorization, thereby triggering the provider's indemnity to its customer, the provider may have to indemnify its customer, but not have a reciprocal right to obtain indemnity from the subcontractor. Thus, to the extent feasible, contractual obligations, particularly those affecting liability (e.g., indemnities, warranties, and disclaimers), should flow upstream.

It is worth noting that the value of any indemnity is tied directly to the financial wherewithal of the party giving it. That is, if the indemnifying party should become insolvent, the indemnity may be worthless. The contracting parties may therefore wish to explore, in addition to an indemnity provision, specific insurance commitments in the agreement.

It is also prudent to recognize downstream liability. For example, a provider of certain data may restrict the usage of data it provides to another service provider which, in turn, may offer those data bundled with other products and services to an end user. The end user may be bound, through its contract with the service provider, to adhere to the data provider's restrictions. In the absence of such a contract, the data may be protected by copyright or other intellectual property rights. Accordingly, the end user should be aware of potential liability it faces for any misuse of the data.

### Equitable Relief

Equitable relief may be available where damages will not adequately compensate the injured party. If there is a contract, a court may order that the nonbreaching party specifically perform its obligations under the contract (see *Marquardt and Roche/Meditz and Hackett, Inc. v. Riverbend Executive Center, Inc.*, 2003, in which “the specific performance remedy is a form of injunctive decree in which the court orders the defendant to perform the contract”). In the context of a promise not to disclose personal information, a court may order the business to perform its promise not to disclose the information or to cease an ongoing disclosure. The burden rests with the party seeking equitable relief to show that there is no adequate remedy at law (see *Marquardt*, 74 Conn. App. at 421, 812 A.2d at 182, in which “a party seeking injunctive relief has the burden of alleging and proving irreparable harm and lack of an adequate remedy at law”).

As a practical matter, to prevent the business from disclosing the information while the merits of the case are adjudicated, the claimant would seek interim relief in the

form of a preliminary injunction. To obtain a preliminary injunction, the claimant must show that he or she will be irreparably harmed if the action is not enjoined (*Chicago Research & Trading v. New York Futures Exchange, Inc.*, 1982, in which “injunctive relief will be afforded only in those extraordinary situations where the plaintiff has no adequate remedy at law and such relief is necessary to avert irreparable injury.”).

## Web Sites

The Internet presented a new twist to traditional contract theory. In the online context, such as with a Web site terms of use, there is a written document (albeit in electronic form) but no signatures by the parties (at least not in the traditional penmanship sense; there may be electronic signatures for purposes of logging a transaction). Nonetheless, a business that posts an online terms of use or privacy policy on its Web site may be bound to the promises made in those terms or that policy. A terms-of-use or privacy policy may be a binding contract, enforceable by the customer against the organization that posted the terms or policy on its Web site. The enforceability of an online contract depends essentially upon basic contract principles. An online contract has been held enforceable (see *Hughes v. America Online, Inc.*, 2002, in which enforcing forum selection clause in an online click-through terms-of-service agreement; see also *Comb v. PayPal, Inc.*, 2002, in which a binding online agreement may shown by the assent of the parties).

The FTC has urged businesses to clearly inform consumers of their information collection practices. See, for example, FTC’s Fair Information Practice Principles (n.d.). Although posting a privacy policy on a Web site is not legally required, it has become common practice. A carefully drafted privacy policy might be considered a proper means of disclosing to consumers a business’s information collection, use, and disclosure practices and thereby fend off claims by consumers that they were unaware that, by uploading their personal information to a Web site, the information would be used or disclosed in various ways. In that regard, so long as the privacy policy accurately reflects an organization’s practices, and the organization follows those practices, the policy might be used as a means to head off potential consumer confusion and complaints. An organization must, however, adhere to the statements in its policy. (According to Simpson, 2001, “Amazon.com and its Alexa Internet subsidiary probably made deceptive statements about their privacy practices...[by] surreptitiously collecting personal data on customers through its Alexa system, which is designed to assist shopping and other activities online.”)

## Terms of Use and Privacy Policies

As a general principle, a Web site agreement will be enforceable against the end user if there is mutuality, that is, if the end user has assented to its terms. Courts have enforced online terms of service where the end user had to view the terms and affirmatively accept them (e.g., by clicking an I Accept button). The evolving case law indicates that where a business seeks to enforce its online terms against the end user, it must demonstrate that the

end user affirmatively assented to the terms. See, for example, *Hughes v. America Online, Inc.*, 2002, which upheld the forum selection clause in a click-wrap agreement governing use of an e-mail service; *Groff v. America Online, Inc.*, 1998, which enforced the click-through choice of law clause in online terms of service agreement where user clicked “I agree” not once but twice; and *Caspi v. Microsoft Network, LLC*, 1999, which enforced forum selection clause in a click-through agreement for use of Internet service. See also *Stomp, Inc. v. Neato*, 1999, which commented that “‘clickwrap agreement’ allows the consumer to manifest its assent to the terms of a contract by ‘clicking’ on an acceptance button on the website.”

Conversely, it would appear evident that the terms should be enforceable against the owner of the Web site who actually posted them. Under basic contract theory, the posted terms would, in essence, be an offer of a contract. If the end user accepts, there should be a binding contract. The end user, however, must have accepted the terms for them to be binding. See, for example, *Gibson v. United States*, 2003, in which elements of a contract must be shown to be entitled to a reward; and *Otsworth v. The Florida Bar*, 1999, in which an offer for a reward is contractual and a “claimant must allege ‘knowledge of existence of the offer of reward’ to be entitled to the benefits of such reward.” It has been held that an individual need only have been aware of the terms, and not have relied upon a particular term or even have read the terms, of a contract for it to be binding upon him or her (*Reuben H. Donnelley Corp. v. American Protective Services Corp.*, 1986, in which “this court agrees and holds that APS [American Protective Services] cannot avoid the contracts on the basis that it chose not to read them”). Where a Web site has posted terms, and an end user alleges he or she was aware of the terms, the owner of the Web site will be hard pressed to argue that it is not contractually bound to those terms. If a terms-of-use or privacy policy makes overly broad claims about maintaining the privacy or ensuring the security of personal information, it is conceivable that an end user may bring a breach-of-contract claim if there is a security breach that discloses his or her personal information. Identity theft resulting from an unauthorized disclosure is one area of significant concern and may generate such claims.

Two important considerations regarding privacy policies are (1) amendments to a privacy policy and (2) the sale of assets that include information collected under an existing privacy policy. If an organization desires to amend the terms of a privacy policy, and wishes the amendment to apply retroactively to information it had collected under the earlier privacy policy, it should notify all those whose information it had already collected of the amendment. This may be done by e-mail or, perhaps, by posting notice of the amendment on its Web site, so long as the organization has reason to believe that the affected individuals will receive notice in that manner. If an individual objects to his or her information being used in the manner set forth in the amendment, the organization should respect the individual’s request and take appropriate measures, such as removing his or her information from the database or otherwise tagging that information for restricted use or disclosure. In addition to raising

contracting concerns (e.g., such as an unconscionable term in a contract of adhesion), a failure to follow these steps could run afoul of the FTCA or state consumer protection laws as improper use of a consumer contract or possibly a misrepresentation to the consumer.

Where assets subject to purchase in a business transaction include information collected under an existing privacy policy, the acquiring business may have difficulty obtaining the information if it were collected under a privacy policy that indicated that such information would not be disclosed to third parties. For example, in 2000 the FTC and state attorneys general attempted to block the transfer of customer information collected by failed online toy retailer Toysmart.com LLC in a bankruptcy asset sale because the company had collected the information under a privacy policy that stated that personal information “is never shared with a third party.” In response to the Toysmart matter, many businesses amended their privacy policies to state that they could transfer information in event of bankruptcy or an acquisition, merger, or sale of the company’s assets. The FTC has indicated that a business obtaining such personal information should continue to respect the commitments made in the privacy policy under which the information was collected, unless it seeks to amend the terms of the privacy policy.

### Privacy Seal Programs

Some private companies offer, for a fee, to certify that a privacy policy and the privacy practices of a business are trustworthy. Two companies that maintain seal programs are TRUSTe and BBBonline. If the policy and practices are certified, the business is permitted to display the sponsor’s privacy seal. An organization may enter into an agreement with the sponsor of a seal program to display the seal on its Web site. The agreement will likely require, in addition to compliance with the organization’s own posted policies and procedures, adherence to certain other policies regarding personal information that is required by the seal sponsor. Should the organization fail to comply with the terms of its agreement with the sponsor, due to a security breach or otherwise, it may find itself in breach of its contractual obligations to the sponsor. For example, in the Toysmart bankruptcy, TRUSTe intervened to enjoin the sale of Toysmart’s customer list, asserting that the sale would be in breach of its seal licensing agreement with Toysmart. See *Objection of Trusted Universal Standards In Electronic Transactions (TRUSTe) To Motion To Approve Stipulation, In re Toysmart.com, LLC, 2000*.

## TORT LIABILITY

A tort is “a legal wrong committed upon the person or property independent of contract” (Garner, 1983). In certain instances, the law will impose upon a person a duty of care. If the person fails to fulfill that duty, he or she may be liable to another person who has suffered damage as a result of the failed duty. Liability under tort theory may apply where there is no contract between two parties. Negligence, gross negligence, willful misconduct, and strict liability are common tort theories of liability.

## Elements of a Tort

A party may be liable under a tort theory if

- the law recognizes a duty of care (e.g., to maintain the security of data or to prevent security breaches);
- there is a breach of that duty;
- there is a proximate relationship between the breach of the duty and the injury; and
- actual loss or damage is incurred as a result of the breach.

There is presently no clearly established duty of care with regard to the security of data under tort law. A leading case discussing when a tort duty should be imposed is *United States v. Carroll Towing Co., Inc.*, 1947. That case assessed whether a duty should be imposed based upon several factors: (1) the probability that harm will occur, (2) the gravity of the resulting harm, and (3) the burden of adequate precautions (*Id.* at 173). Under that rationale, a duty should exist if the probability of harm occurring and the magnitude of that harm outweigh the burden of avoiding the harm.

A handful of cases may offer guidance as to whether there exists such a duty. For example, in the banking context, it has been held that a bank has a duty to keep certain information confidential (*DJowharzadeh v. City Nat’l Bank & Trust Co.*, 1982). In that case, a bank customer provided to the bank’s loan officer certain confidential information about a proposed real estate purchase, which the loan officer then disclosed to other individuals who used the information to the customer’s detriment. Stating that the “customer’s cause of action is, with these special facts, properly framed in terms of tortious conduct,” the court held that the “bank’s relationship to a loan applicant implicitly imposes the duty to keep the contents of loan applications confidential. This duty has existed traditionally and continues to exist, if not specifically in the law books, at least in the mind of the public in general and within the banking community in particular” (*Id.* at 620).

On the other hand, in *Stevens v. First Interstate Bank of California* (2000), the court held that a bank does not have a duty to safeguard personal information. In that case, the court framed the issue as follows:

Where a third party misappropriates personal or credit information that a depositor had provided to a bank, and that misappropriation is the result of the bank’s failure to adequately protect the information from such misappropriation, is the bank liable for the depositor’s resulting emotional distress? (*Id.* at 285–286)

Viewing the bank–customer relationship in that case as “more analogous to a merchant–customer relationship in which the customer, in transacting a credit card or other noncash purchase, provides certain information to the merchant,” the court concluded that the relationship between the parties had no element of a trust in it (e.g., in holding money in trust for someone) and, therefore, did not give rise to a duty on the part of the bank to protect the information from misappropriation (*Id.* at 288).

At least one case has found a duty to secure sensitive records accessible via the Internet under the theory that the party responsible for trust fund records had a fiduciary duty to protect them from unauthorized disclosure (*Cobell v. Norton*, 2001). In *Cobell*, the Department of the Interior (DOI) held or created in systems managed and administered by the Bureau of Indian Affairs Office of Information Resources Management certain Indian trust funds and individual Indian trust records. The information was kept on systems that were accessible to the Internet without firewalls, encryption, or other means of reasonable security. In a scathing report, the special master criticized the DOI for failing to employ adequate safeguards and recommended that the court intervene to take control over the DOI's IT systems. The special master found that the DOI had a fiduciary duty to safeguard information relating to the trust and that the DOI had derogated that duty by failing to implement satisfactory IT security safeguards (*Id.* at \*141).

The fiduciary relationship in the *Cobell* case arose because of the special nature of the data—trust fund records—the special duty for which was already well established in common law. See *Rippey v. Denver U.S. Nat. Bank* (1967), in which “it is generally agreed that a trustee owes a duty to his beneficiaries to exercise such care and skill as a man of ordinary prudence would exercise in safeguarding and preserving his own property.” Absent such a relationship, however, it is not clear that a duty would exist to safeguard sensitive information such as names, addresses, telephone numbers, or Social Security numbers. The lack of clear precedent either way—whether in favor of a duty or declining to recognize any duty—renders the notion of a tort claim for data security somewhat uncertain. The issue will undoubtedly present itself, and may, for example, arise in the context of an individual whose personal information was allegedly not adequately safeguarded, for example, after he or she uploaded that information through a Web site.

## What Is Reasonable?

Were a court to find that a tort duty exists, the duty of care could vary depending upon the circumstances. Generally, however, the law will apply a duty to exercise *reasonable* care. A person who fails to exercise a reasonable duty of care is said to have been negligent. In tort cases, courts routinely determine what is reasonable under the circumstances drawing upon what has been learned in past cases and evidence offered in the current case. The oft-quoted measure in assessing reasonableness is what would a reasonable person have done under the circumstances. Of course, the issue of reasonableness is often open to debate and the subject of intense disagreement during a litigation.

Perhaps one of the most significant hurdles in a claim of negligence regarding data security is ascertaining what would be reasonable. Many people—courts included—lack a good understanding of the technical nuances that comprise IT and information security. A genuine lack of familiarity with the subject makes it extraordinarily difficult to assess reasonableness because one would have to defer to others' experiences as to what may or may not

be reasonable on an otherwise foreign subject. Moreover, like IT in general, security technologies are ever in flux, rapidly changing as computer technologies change. What may be reasonable one day may not be a short time later.

There is also a wide range of security needs, depending upon the nature of the data and the perceived risks. For example, sensitive personal information that a business considers a valuable asset and that represents a would-be target for thieves might require greater levels of security than similar, but less sensitive, information of little interest to hackers. Thus, there could be widely divergent security standards that are, nonetheless, reasonable under differing circumstances.

Because there are many differing approaches to security, the idea of one reasonable standard that could be applied across the board may be difficult to accept. Indeed, a single common standard for data security might even prove undesirable insofar as it could actually make hacking easier if would-be hackers knew that most security systems adhered to a similar common technical standard. However, it may be prudent to have certain general principles governing policies and procedures regarding security, but allow the technical implementation of security devices, applications, and systems to differ across individual business enterprises. Following the example in the HIPAA Privacy and Security Rule, for example, it may be acceptable to establish administrative, physical, technical, and organizational standards for safeguarding data, leaving the implementation of those standards to each organization (this, of course, would not completely solve the issue as there would still need to be some level of determination as to whether the standards were reasonably implemented within the parameters established).

For torts commonly seen by courts, there is ample case law to draw upon in assessing what would be reasonable. Where there is no well-established standard, as appears currently true for data security, a court may look to several factors in its attempt to assess what would have been reasonable under the circumstances. For example, a court may consider an argument concerning the costs to implement certain levels of security in relation to the risks involved. A plaintiff may be able to proffer a convincing argument that, where the risks substantially outweigh the costs or where the costs are relatively insignificant to a corporate budget, a business acted unreasonably in not applying more rigid, but costly, security protocols. A court may also entertain expert testimony concerning the security policies and procedures of other similarly situated organizations, the thinking being that if certain policies and procedures are being exercised by a number of a defendant's counterparts, it would be reasonable for the defendant to have followed similar policies and procedures.

A court may also consider industry standards to the extent there is some agreement within an industry as to what those standards are. In this regard, a court may look to examples in organizations that proffer security standards or otherwise audit security risks. It may also consider evidence of relevant statutory language and the requirements set out in regulatory pronouncements, such as GLB and HIPAA, that speak to the security of data.

## Establishing a Standard

A judicially construed standard may be drawn from various sources. The following offers examples of sources that could be given weight in arriving at such a standard.

### Statutes and Regulations

A statute that was enacted in 2002, the Federal Information Security Management Act (FISMA), may provide guidance as to what steps an organization should take in safeguarding. FISMA applies to government agencies and is therefore binding upon them. It is not binding upon private sector companies, but its principles may serve to establish standards applicable to private business. FISMA was enacted to

- (1) provide a comprehensive framework for ensuring the effectiveness of information security controls over information resources that support Federal operations and assets;
- (2) recognize the highly networked nature of the current Federal computing environment and provide effective government wide management and oversight of the related information security risks, including coordination of information security efforts throughout the civilian, national security, and law enforcement communities; (3) provide for development and maintenance of minimum controls required to protect Federal information and information systems; [and] (4) provide a mechanism for improved oversight of Federal agency information security programs. See 44 U.S.C. § 3541(1)-(4).

It is intended to provide a framework for government agencies to improve security and risk management processes by mandating reporting on security compliance with a set of standard internal controls. FISMA makes government agencies accountable for implementing defensible security measures and requires greater reporting on these security activities. The intent is to show government regulators an agency's security benchmark, how each agency is progressing against this benchmark, and how they continue to improve agency security measures on a year-over-year basis.

Among other things, FISMA focuses on (1) developing and overseeing the implementation of information security policies; (2) requiring agencies to identify and provide information security protections commensurate with the risk and magnitude of the harm resulting from the unauthorized access, use, disclosure, disruption, modification or destruction of information or information systems used by or on behalf of an agency (including systems operated by agency contractors); and (3) coordinating the development of standards and guidelines under the National Institute of Standards and Technology (NIST) Act with agencies and offices operating or exercising control of national security systems (including the National Security Agency) to ensure, to the maximum extent feasible, that such standards and guidelines are complementary with standards and guidelines developed for national security systems (see 44 U.S.C. §3543(1)-(3)). FISMA requires that each federal enterprise information security

program be placed under the CIO and mandates an independent information security program audit function which is assigned to each agency's Office of Inspector General. Because the program is placed under the CIO, it can be fully and completely integrated into the budget process to ensure that information security is adequately addressed throughout the life cycle of any and all IT-related programs. This framework allows for budget integration and independent audit functions and, by way of such, is intended to result in an effective security program.

Other statutes, such as GLB and HIPAA, which outline requirements for information security, might also be considered in developing broader security standards for corporate and personal information.

### Government and Industry Standards

The Bush administration outlined a plan to enhance security of IT systems known as *The National Strategy to Secure Cyberspace* (2003). In conceptual terms, it articulates five national priorities for security; identifies eight major actions and initiatives to reduce threats and related vulnerabilities; identifies four major actions and initiatives for awareness, education, and training; identifies five major actions and initiatives for the securing of governments' cyberspace; and identifies six major actions and initiatives to strengthen U.S. national security and international cooperation. Although the concepts are general in nature, and are not necessarily binding on anyone (they are set out in a strategy), they may be one of several things that factor into broad security standards.

In December 2003, the president signed Homeland Security Presidential Directive-7 (HSPD-7) titled "Critical Infrastructure Identification, Prioritization, and Protection." Based on that directive, the Department of Homeland Security has chartered the National Cyber Security Division (NCSA), and that office is responsible for implementing the national strategy. NCSA chartered the U.S. Computer Emergency Response Team (US CERT).

Guidance may also be gleaned from organizations that propose standards for IT security. For example, Statement on Auditing Standards (SAS) No. 70 is an auditing standard developed by the American Institute of Certified Public Accountants (AICPA). SAS 70 requires service organizations to disclose their control activities and processes to their customers and their customers' auditors in a uniform reporting format. The purpose of an SAS 70 examination is for a service organization to have its control objectives and control activities examined by an independent accounting and auditing firm that will issue an auditor's opinion ("About SAS 70," n.d.).

Implementation and Security Risk Analysis ISO 17799 is a detailed security standard offered by the International Organization for Standardization (ISO). ISO is a non-governmental organization that develops standards for a variety of applications, particularly technical standards. ISO 17799 is intended to counteract interruptions to business activities and to critical business processes from the effects of major failures or disasters. It sets out a number of standards concerning business continuity planning, system access control, system development and maintenance, physical and environmental security, compliance, personnel security, security organization, computer and

operations management, asset classification and control, and security policies ("ISO 17799: What Is It?" n.d.).

Another agency that promulgates guidelines relevant to IT security is the NIST. NIST "works with industry, research, and government organizations to make [information] technology more usable, more secure, more scalable, and more interoperable than it is today" (*Cobell v. Norton*, 2001, \*34, fn. 21, quoting Dr. William O. Mehuron, "Information Technology Laboratory: What ITL Does," n.d.). Pursuant to the Information Technology Management Reform Act (Public Law 104-106), the secretary of commerce approves standards and guidelines that are developed by the NIST for federal computer systems. These standards and guidelines are issued by NIST as the Federal Information Processing Standards (FIPS) for government use. "NIST develops FIPS when there are compelling federal government requirements such as for security and interoperability and there are no acceptable industry standards or solutions" (*Cobell*, 2001, at \*35, fn. 22, citing "General Information," n.d.). NIST standards are now mandated for federal agencies by FISMA.

The Computer Emergency Response Team Coordination Center (CERT/CC), a federally funded research and development center operated by Carnegie Mellon University, also provides a great deal of information regarding systems security and vulnerability (see <http://www.cert.org>). CERT/CC offers a method for evaluating security risks, security practices that an organization can implement (including evaluating security architecture to detect and respond to intrusions), and training courses for managers and technical personnel. The security practices developed by CERT/CC and other organizations may prove helpful in assessing what practices an organization should reasonably undertake to safeguard data. CERT/CC has a relationship with the US CERT.

### Security Certifications

There are also organizations that offer to audit and certify IT systems from a security standpoint. For example, SysTrust is a certification program sponsored by the AICPA that is intended to audit and certify IT systems for availability, security, integrity, and maintainability (see "What is SysTrust," 2001). TruSecure is a private company that also offers a security certification program ("TruSecure Programs," n.d.). The knowledge and efforts of these organizations may help contribute to a standard.

The foregoing provides only a few possible examples from which to draw upon a legal standard for IT security. In developing a legal standard for any duty of care, a court, for example, may look to one or more of the above, or to other resources, in formulating what is reasonable and appropriate under the circumstances.

### Damages

The damages typically recoverable for a tort are those that are reasonably foreseeable and are proximately caused by the act or omission of the wrongdoer. Some jurisdictions do not permit a tort plaintiff to recover economic losses in the absence of physical damage. This economic loss rule was typically applied to claims for pain and suffering or emotional distress where there was, in fact, no

actual physical harm. In the case of unauthorized disclosure of information, the rule might prohibit recovery of any damages, because the loss would be essentially economic in nature without any underlying physical harm. Nonetheless, a number of courts now recognize an exception to this rule. See, for example, *People Express Airlines v. Consolidated Rail Corp.* (1985). Given the climate for data privacy and security, it would not be surprising for the exception to apply to security breaches. Whether the damages are quantifiable is another issue (as discussed above), but one not to be lightly taken.

## CONCLUSION

Advancements in IT are rapidly changing the way business is done and how we conduct our personal lives. IT has, in many ways, made the world a smaller place by making information readily accessible. As a result, sensitive corporate and personal information, in electronic form, is at all times vulnerable to compromise, whether by human error, technical fault, ill-intent, or otherwise. Organizations that rely on or process such data may have legal obligations to maintain the security of the data and may face potential liability in the event of a security breach.

Given the increasing concern among businesses, consumers, and lawmakers for hackers, breaches of data systems and networks, identity theft, and the security of information generally, it is prudent to take steps to review existing security practices and to anticipate the potential for liability under current and evolving laws. Because data security is a relatively new area for the law, an organization would do well to keep advised of statutory, regulatory, judicial, and other legal developments as they arise, and to adapt its security practices accordingly. The risk of regulatory noncompliance and of potential third-party liability may be mitigated by the implementation of adequate IT infrastructure and practices based on a proper understanding of the legal framework affecting an organization.

## GLOSSARY

**Application Service Provider** A business that offers remote access to and use of software application services, often through the Internet.

**Click-wrap Agreement** An agreement setting forth the terms and conditions for use of intellectual property or a service (e.g., a Web site), which must be assented to by the user by an affirmative action such as clicking an I Accept button or the equivalent.

**Confidential Information** Any information deemed confidential and having pecuniary value and that is protected from unauthorized disclosure to others.

**Customer Relations Management Software** Software designed to aggregate, compile, organize and sort data relating to a business's customers.

**Equitable Relief** Relief in the form of an injunction or specific performance, instead of money damages, that may be ordered by a court.

**European Commission (formally the Commission of the European Communities)** The executive of the European Union, whose primary roles are to propose

and enact legislation and to act as guardian of the treaties that provide the legal basis for the European Union.

**Federal Trade Commission (FTC)** U.S. federal agency established in 1914 by the Federal Trade Commission Act to enforce, among other things, federal consumer protection laws by investigating complaints against individual companies.

**Financial Services Modernization Act of 1999 (more commonly known as the Gramm-Leach-Bliley Act [GLB])** U.S. federal legislation enacted in 1999 governing the privacy and security of personally identifiable financial information.

**Force Majeure** An act of God or an event outside the reasonable control of a person or entity.

**Health Insurance Portability and Accountability Act (HIPAA)** U.S. federal legislation enacted in 1996 governing the privacy and security of health information.

**Hosting Company** A business that offers services that host Web sites on computer servers and keep those Web sites available for access through the Internet.

**Information Technology (IT)** The technology required for processing information and the use of computers and computer software to convert, store, protect, process, transmit, and retrieve information.

**Internet Service Provider (ISP)** A business that offers users access to the Internet and related services.

**Managed Network Servicer** A business that manages and oversees an organization's computer networks.

**Outsourcing** The act of a business in subcontracting to a third party the responsibilities for certain services or equipment, which may include computer systems or software or the responsibilities for operating and maintaining such computer systems or software.

**Privacy Policy** A disclaimer placed on a Web site informing users about how the website collects, uses and shares the user's personal information.

**Privacy Seal** A seal of approval issued by a private company, which may be displayed on a Web site, certifying that the Web site has agreed to adhere to certain standards for the privacy and security of data transferred through the site.

**Risk Management** The total process of identifying, controlling, and mitigating risks.

**Security Certification** A certification issued by a private auditing firm certifying that an IT system adheres to certain minimum security requirements.

**Terms of Use** A set of rules set up by the owner of intellectual property or a service (e.g., a Web site) to govern its use and is often a contract between the owner and the user.

**Tort** Under common law, a civil wrong for which the law provides a remedy.

**Trade Secret** A confidential practice, method, process, design, or other information used by a company to compete with other businesses, which is protected from general disclosure to others.

**Uniform Commercial Code (UCC)** One of the uniform acts, dealing with sales and commercial transactions, that attempts to harmonize the law of the 50 U.S. states.

**Web Site** A collection of Web pages accessible via hypertext transfer protocol through the Internet.

## INTRODUCTION

Early on, the threat posed by hackers, crackers, and computer criminals was comparatively minor. For starters, most people lacked sufficient access to the new information technologies to be affected in any significant way by computer crime. Equally important, most computer intruders lacked the skills and expertise to do significant damage to affected individuals.

Much has changed in the past 20 to 25 years. An ever-increasing number of people are coming to rely on e-mail, Web access, and other digital information technologies for social, personal, and commercial purposes, and those who lack direct access to these technologies frequently depend on commercial and governmental institutions that incorporate these technologies into key operations. In consequence, the increasing number of computer intrusions implicates, at least indirectly, the interests of the vast majority of people in the industrial world and a growing number of people in the developing world.

Moreover, computer criminals have been developing a more sophisticated (and dangerous) palate of tools for committing intrusions. Partly because computer technologies are so sophisticated, computer criminals tend to be more intelligent and more focused than other criminals. Not surprisingly, they have worked hard to hone their skills at breaking into computer systems and concealing their presence in those systems.

These efforts have paid off. Over time, scripts and programs have been improved to automate more and more of the various processes involved in staging a digital attack or intrusion. These new technologies can employ multiple attack vectors, install backdoors, disable antivirus and firewall software, disable and wipe log files, alter the

operating system to run them at every reboot, and do all of this in a matter of seconds.<sup>i</sup>

The result is that hackers, crackers, and computer criminals now pose a serious threat to individuals, commercial firms, and state institutions. Because sophisticated intruders can command hundreds of thousands of computers to stage attacks against innocent persons and institutions, they can cause catastrophic harm. A sustained attack taking down a commercial Web site, for example, can result in the loss of millions of dollars in revenue—and potentially the loss of jobs. It is not overstating matters to characterize computer crime as one of the most important problems facing law enforcement today.

## DEFINITIONS AND EXAMPLES

### Defining the Terms: Hacking and Cracking

The words “hacker” and “cracker” are contentious terms, meaning different things to different people. Many people in the programming community, especially those who were programming in the seventies and eighties, view the word “hacker” as a term of approbation. Indeed, the original *Hacker’s Dictionary*<sup>ii</sup>, maintained for years by students at the Massachusetts Institute of Technology (MIT), defines “hacker” in terms that naturally lend themselves to such an interpretation:

<sup>i</sup> To get a sense for how much the computer criminal’s tools and tactics have improved, consider this: ten years ago, it would take an expert hacker weeks, and even months, to break into several hundred systems; today, an expert hacker can compromise many more computers in a matter of days. For an example of the former, see Mann and Freedman (1998).

<sup>ii</sup> <http://www.dourish.com/goodies/jargon.html>

**HACKER** n. 1. A person who enjoys learning the details of programming systems and how to stretch their capabilities, as opposed to most users who prefer to learn only the minimum necessary. 2. One who programs enthusiastically, or who enjoys programming rather than just theorizing about programming. 3. A person capable of appreciating hack value (q.v.). 4. A person who is good at programming quickly. Not everything a hacker produces is a hack. 5. An expert at a particular program, or one who frequently does work using it or on it; example: “A SAIL hacker”. (Definitions 1 to 5 are correlated, and people who fit them congregate.) 6. A malicious or inquisitive meddler who tries to discover information by poking around. Hence “password hacker”, “network hacker”.

According to the first five clauses of this early definition, the term “hacker” is used to pick out a class of people with a variety of intellectual virtues, including special expertise in computer and network systems. On this usage, the term applies only to persons of distinction—whether in virtue of their special skills or in virtue of their passion for intellectual pursuits. Indeed, as defined here, the term’s connotation is sufficiently positive that it was bestowed as an honor: to be a hacker was to possess extraordinary programming ability and intellectually virtuous character traits.

Definition 6 comes closest to expressing the current use of the term “hacker” that is now irrevocably associated with computer crime. A hacker, on this usage, is a malicious or inquisitive meddler who pokes around to discover information. The use of “malicious,” “meddler,” and “poking around,” at the very least, evokes the contemporary idea that a hacker is someone who intrudes upon the computer systems and networks of other people.

The different definitions reflect the history of hacking and the associated terms, which arguably extend as far back as the mainframe computer. Taken together, the various historical treatments of hacking distinguish a number of different classes or generations of persons who have been characterized as hackers. These classes include (1) the original MIT hackers who worked with mainframe computers in the 1950s and 1960s; (2) the hardware hackers of the so-called personal computer revolution of the 1970s; (3) the software hackers of the 1980s who developed new architectures for computer games; (4) so-called microserfs who have abandoned the original hacking culture to join large corporate firms as programmers and developers; (5) open source programmers; (6) hacktivists who commit computer intrusions for the purpose of advancing social and political causes; and (7) the hackers and crackers who commit computer intrusions for other malicious and nonmalicious purposes.<sup>iii</sup>

But, for better or worse, Definition 6 comes closest to capturing the meaning of the word as currently used in

the community at large. Although many persons in the computer industry continue to use the term “hacker” to pick out programmers of distinction, the term “hacker” is now used by most persons only to pick out persons who intrude upon systems and machines belonging to other people without any meaningful authorization (whether through the consent of the owners or through the legal process). Anyone who trespasses upon someone else’s system or network qualifies under this definition as a hacker according to this common usage.

In consequence, the term has lost its normative connotations (at least outside the computer industry). To the general population, it no longer connotes either expertise in programming or intellectual virtue of any kind. The media, for example, typically use the term, to the chagrin of many who lament these changes in conventional usage, to refer to the most unskilled intruders, including so-called script kiddies who simply take the most primitive hacking tools off the Web and use them without any understanding or creativity.

Even so, many persons attempt to distinguish intrusions motivated by malicious purposes (e.g., to destroy someone else’s files) from intrusions motivated by benign purposes (e.g., to investigate security flaws in some operating system). Hacking that is motivated by a malicious intent to cause damage or harm is called “cracking” (or “black-hat hacking”).<sup>iv</sup> Persons who distinguish hacking from cracking reserve the term “hacking” (or “white-hat hacking”) for intrusions not associated with destructive or malicious purposes.

## Motivations and Examples

Given the problems associated with hacking and cracking, it is important to understand the motivations of those who engage in such behaviors. Hacking and cracking, by definition, involve unauthorized intrusions upon the computers (and hence property) of other persons; as such, these behaviors are fairly characterized as antisocial. As is true of other antisocial behaviors, the problems associated with computer misconduct cannot be successfully addressed without some understanding of what motivates it.

### Fame

It is not surprising that one very common motivation for hacking and other forms of computer misconduct is a desire for fame and notoriety. Fame and notoriety, after all, are common motivations in many other walks of life. Given the amount of media attention devoted to successful large-scale computer attacks and to such hacker celebrities as Kevin Mitnick, it is clear that hacking, cracking, and computer crimes are all viable paths to fame.

Hackers motivated by such considerations are primarily concerned with achieving recognition within the hacker community and have publicized their exploits among fellow hackers in a variety of ways. Early hackers, for example, discussed their exploits on special bulletin boards or print publications devoted to hacking, such

<sup>iii</sup> These classifications owe to several different historical treatments of hacking. See Levy (1984), Taylor (1999), and Taylor and Jordan (2004). I am indebted to an anonymous reviewer for drawing my attention to the importance of this point.

<sup>iv</sup> The term *cracking* is sometimes used to refer to people who produced high-quality programs for circumventing copywrite-protection technologies. See, for example, *Interview with Mike Hudack* (n.d.)

as 2600. Contemporary hackers can discuss their exploits on Web logs (blogs) and in Internet chat rooms. In both cases, the idea was to find a comparatively private forum in which hacker exploits could be shared among a sympathetic community without incurring a risk of prosecution.

Even so, a hacker's desire for fame sometimes proves to be his or her undoing.<sup>v</sup> As former Justice Department Internet crimes prosecutor Marc Zwillinger put it, "[For t]he kind of people who do this, fame and notoriety are the primary motivation. They don't derive financial benefit from releasing a worm. If they can't claim credit, what's the point?"<sup>vi</sup> Indeed, many hackers who would otherwise have gotten away with their attacks have been caught because they claimed credit for an attack on a bulletin board or in a chat room.

### Curiosity

Some intrusions are motivated by nothing more sophisticated than curiosity. Robert Tappan Morris wrote and released the first Internet worm in 1998 simply to satisfy curiosity. Morris did not intend the damage the worm eventually caused and did not anticipate that many sites would choose to shut off their Internet connections entirely because of the ensuing disruption to affected systems.<sup>vii</sup> Indeed, he had no developed sense of what the worm would do or how people might respond: he released the worm, in essence, just to see what would transpire.

### Boredom

A desire to relieve boredom is another common motivation. Adrian Lamo wandered through the networks of WorldCom, Microsoft, Excite@Home, Yahoo!, and the *New York Times* partly out of boredom. Lamo entered a variety of networks, sometimes gaining access to sensitive information. After entering the *New York Times* network, he viewed employee records and Social Security numbers, as well as accessed the contact information for the newspaper's sources and columnists, including former U.S. president Jimmy Carter, former Marine colonel Oliver North, and hip-hop artist Queen Latifah. Somewhat sheepishly, Lamo attributed his behavior to boredom: "I was looking for something to do."<sup>viii</sup>

### Intellectual Challenge

One of the most widely cited motivations, and the one most typically associated with the stereotype of the hacker as a social nerd, is the intellectual challenge involved in finding a way into a system. For example, Kevin Mitnick stole the source codes for Sun Microsystems' operating system, Nokia's cell phones, and Motorola's cell phones. In testimony before the U.S. Senate Committee on Governmental Affairs, Mitnick explained his motivations as follows:

My motivation was the quest for knowledge, the intellectual challenge, the thrill and also the escape from reality—kind of like somebody

<sup>v</sup> It is worth noting, despite the use of "his or her" in this context, that the world of computing technology has been largely dominated by males. This is no less true of the hacking community: hackers are nearly always male.

<sup>vi</sup> See "Few Clues in Web Worm Whodunit" (2003).

<sup>vii</sup> See [ftp://coast.cs.purdue.edu/pub/doc/morris\\_worm/](ftp://coast.cs.purdue.edu/pub/doc/morris_worm/)

<sup>viii</sup> Lemos (2001).

who chooses to gamble to block out things that they would rather not think about. My hacking involved pretty much exploring computer systems and obtaining access to the source code of telecommunication systems and computer operating systems, because my goal was to learn all I can about security vulnerabilities within these systems.<sup>ix</sup>

Such motivations presumably echo the intentions of many younger hackers who are eager to learn more about the relevant technologies, as well as to improve their own skills.

### To Help Secure Systems

Hackers are sometimes motivated by a desire to improve the security of affected systems. For example, when the MSBlaster worm infected millions of computers in 2001, an unknown hacker wrote and released a counterworm that attempted to install a patch disabling MSBlaster. Although this counterworm was christened the Good Samaritan Worm for the salutary motivations of its creator, many experts feared that it might have more undesirable than desirable effects.

Indeed, computer intruders frequently lament that their victims do not seem to welcome their assistance. For example, an anonymous intruder to the National Aeronautics and Space Administration (NASA) expressed disappointment when his help was not accepted:

I would email the system administrators sometimes and tell them that their computers were vulnerable. I would tell them how to break in, and how to fix the problems. I'd give them advice, and they would never follow it. Three weeks later I would go in and I *still* had access to their computers.<sup>x</sup>

These hackers believe that their efforts are legitimate because they are motivated by the best of intentions—the desire to help secure systems.

### Financial Gain

Not surprisingly, some intrusions are motivated by financial gain. In 1994, Russian Vladimir Levin used stolen passwords to transfer an estimated \$10 million out of Citibank into accounts around the world. Levin reportedly used stolen account names and passwords to make the transfers. All but \$400,000 was recovered.<sup>xi</sup>

Russian hackers Vasily Gorshkov and Alexey Ivanov broke into a number of corporate networks and Internet

<sup>ix</sup> <http://www.pbs.org/wgph/pages/frontline/shows/hackers/whoare/testimony.html> Mitnick turned out to be a master at using information to trick employees at these companies into giving him full access to the systems that contained the source code he sought (see the Social Engineering section for a discussion of such tactics). Mitnick went on to say, "The human side of computer security is easily exploited and constantly overlooked. Companies spend millions of dollars on firewalls, encryption, and secure access devices and it's money wasted because none of these measures address the weakest link in the security chain: the people who use, administer, operate and account for computer systems that contain protected information." *Id.*

<sup>x</sup> *Id.*

<sup>xi</sup> See <http://www.pbs.org/wgph/pages/frontline/shows/hackers/whoare/notable.html>

service providers, looking for credit card numbers.<sup>xii</sup> If they were unsuccessful in finding credit card numbers, they would extort money from the victims to “fix” the holes. But if they were successful, they would use the numbers to purchase nonexistent items they sold on eBay, subsequently laundering the purchases through PayPal and fake e-mail accounts. The two reportedly caused an aggregate loss of more than \$25 million.<sup>xiii</sup>

The U.S. Federal Trade Commission reported that, in 2003, \$437 million was lost in online fraud.<sup>xiv</sup> These losses resulted from identity theft involving stolen credit cards and attacks aimed at inducing individuals, by fraudulent means, into giving out personal and financial information.<sup>xv</sup>

Financially motivated distributed denial of service attacks (DDoS) have also increased.<sup>xvi</sup> These attacks, which frequently involve a large number of innocent agent machines, threaten to deny customers access (or deny service) to online materials and services unless victims pay a substantial sum. Many attacks have affected online transaction-processing services<sup>xvii</sup>; the British Association of Real-time Gambling Operators (ARGO) reported, for example, that their members had paid over \$73 million to extortionists between January and June 2004.<sup>xviii</sup> There is even a case (the first of its kind) in the United States involving someone allegedly hired to attack business competitors.<sup>xix</sup> This trend is growing at an alarming rate worldwide and is becoming a major focus of international law enforcement resources.

### Political Activism (Hacktivism)

Some unauthorized intrusions are motivated by political and expressive purposes. In 1999, political activists sought to buttress the protests against the World Trade Organization (WTO) by striking at the WTO Web site. U.K.-based E-hippies, an activist group, attempted to shut down a WTO Web site hosted by Conxion by overwhelming it with requests for information. Similarly, in early 2000, a number of activists launched similar attacks against a variety of commercial Web sites, including Amazon.com and eBay.com, as a means of protesting the increasing commercialization of the Web. These self-styled activists viewed their attacks as a form of civil disobedience justified by the justice of the causes they sought to advance. These politically motivated attacks have come to be known as hacktivism.

### Revenge

Some unauthorized intrusions are motivated as revenge for some sort of perceived slight.<sup>xx</sup> Convinced that he was

not being fairly compensated, Roger Duronio resigned from his position at Paine Webber as a system administrator. He planted a logic bomb (i.e., a program designed to take malicious action at a particular point in time) on 1,000 of PaineWebber's approximately 1,500 networked computers around the country, attempting to profit from the resulting damage.<sup>xxi</sup> Duronio purchased \$21,000 of put options on stock in UBS, the parent company of PaineWebber, in the hope that the logic bomb would cause the value of UBS stock to drop, thereby increasing the value of his options. Although the logic bomb was successfully activated on March 4, 2002, causing an estimated \$3 million in damages to PaineWebber, the anticipated drop in the price of UBS's stock did not occur.<sup>xxii</sup>

## TACTICS, TECHNOLOGIES, AND TECHNIQUES

Hackers, crackers, and computer criminals have a growing palate of tactics and technologies that can be used to achieve their purposes. Common tactics include sniffers that harvest passwords from unsuspecting computer users connecting over the network; stepping stones that conceal the ultimate source of an intrusion; and stolen disk space to serve as caches for, among other things, attack programs, password files, or stolen credit card numbers. Attackers often use more than one of these tactics depending on their skill sets, timelines, and available bandwidths for targeting hosts. These and other tactics are discussed below.

### Sniffers

Sniffers are the digital analog to wiretap devices in the telecommunications context. Whereas a wiretap is a physical device that records the analog transmissions of voice communications over a telephone line, a sniffer is a program that allows one to “see” and record the packets of data that contain the communication between people using computers. Just as a wiretap must be placed on one of the lines being monitored, sniffing can occur only on local area network segments (which include aggregator switches and backbone networks).<sup>xxiii</sup> It is not possible either to sniff traffic from multiple network hops (i.e., network interconnections) away from the target network or to tap a phone line physically located inside a building that the would-be wiretapper cannot enter.

Computer criminals frequently use sniffers to harvest passwords from unsuspecting computer users connecting over the network. These passwords can subsequently be used to gain access to valuable information that is stored on the user's network in e-mail and other files. Passwords can be obtained by sniffing the traffic associated with login authentication or by looking for passwords transmitted as part of text messages, such as e-mail, chat, or instant messages. (For this reason, users should be wary of transmitting very sensitive information on any channel that does not encrypt the transmissions.)

## Internet Protocol Spoofing

The exchange of data between computers on the Internet is made possible through the use of various protocols. These protocols are layered in what is known as a stack, with lower level protocols handling transmission over physical media or wireless transmission and higher level protocols responsible for routing packets between networks. The latter eventually leads up to application-level protocols or higher.

For example, applications that use the Internet for communication rely on either the unreliable datagram protocol (UDP), which is used for quick but unreliable transmissions, or the transmission control protocol (TCP), which is used for more reliable transmissions. Applications using UDP typically send simple request/reply packets (somewhat like electronic versions of postcards) without the overhead associated with ensuring that packets actually make it from one computer to the intended destination. Applications that must ensure the integrity of the data being transferred can use TCP, which manages the process of establishing connections by tracking the number of bytes sent and received through use of sequence numbers and by checking to ensure they are transmitted without error through the use of checksums. This is part of the state information about transmissions maintained by the TCP portion of the TCP/Internet protocol (IP) stack.

Both TCP and UDP rely on a lower level routing protocol to get packets from one Internet host to another (sometimes through a dozen or more intermediary routers) known as the IP. Communication at the IP layer is handled by transmitting individual packets of data (known as datagrams) from sender to receiver and back again. Packets in transit are identified by several attributes, specified by fields in the packet's header, including their source and destination IP addresses. IP addresses are 4-byte values that are represented by dotted quads that consist of four decimal values between 0 and 255 separated by periods; these addresses specify the locations, so to speak, of the various computers and networks making up the Internet (an example of a dotted quad IP address is 192.168.0.1).

As may be evident, the exclusive use of numeric IP addresses for users to identify computers on the Internet is impractical in one important respect: sequences of up to 12 digits separated by three decimal points are very difficult for people to remember. To circumvent the need for people to remember these source addresses, methods of mapping names to IP addresses were developed. The Internet relies today on the domain name system (DNS) to map these decimal sequences to more easily remembered names. For example, the MIT computer housing the GNU Open Source software repository in California is named "prep.ai.mit.edu" in DNS and has the IP address 199.232.41.9. (The trailing period is just there to make that a valid English sentence. IP addresses do not end in periods.)

Unfortunately, the most widely used version of the Internet protocol (IPv4)<sup>xxiv</sup> is vulnerable to being exploited because IPv4 lacks any mechanism for guaranteeing the

reliability of source addresses. It is possible for someone to generate a series of bytes forming a valid IP packet, inject it into the network, and route it to some unknowing receiving host. For example, a computer that tries to communicate with prep.ai.mit.edu might wind up exchanging information with a computer pretending to be 199.232.41.9.<sup>xxv</sup>

The problem is that it is quite difficult for a user to ascertain whether he or she is connecting to the intended source or to an imposter. File transfer protocol (FTP), Telnet,<sup>xxvi</sup> and hypertext transfer protocol (HTTP) browsers provide no way for the user to determine that he or she is not connecting to some imposter site. With some basic protocols (UDP services, for example, or the Berkeley "r" utilities), especially on TCP/IP stacks using predictable sequence numbers, someone can forge an entire series of packets and, as long as they reach the victim host before replies reach the host being faked, the victim will respond to them.

This unreliability in the validity of IP source addresses leads to several types of spoofing attacks. Blind spoofing attacks generally target stateless protocols, such as UDP, that do not employ any mechanism for authenticating clients or servers.<sup>xxvii</sup> These attacks are typically staged from one or more network hops from the targeted network and proceed by forging packets that make it appear that the targeted network is communicating with some acceptable host network; they are characterized as blind because they do not require that the attacker have visibility of the packets being sent back and forth to trick the target host.<sup>xxviii</sup>

Another common use of IP spoofing is in connection with denial of service (DoS) attacks. As will be discussed in more detail in the Denial of Service section, a DoS attack attempts to shut down a targeted network by overwhelming it with more traffic than it can handle. Perpetrators of such an attack frequently spoof a source address on the packets to either make it more difficult for the victim to identify the flooding hosts or make it more difficult for network operators to find and clean up the affected host.

## Session Hijacking

Intruders can take over a user's session by deflecting traffic from its intended destination and interjecting their own

---

writing, IPv6 is still not in widespread use in the United States, although it is becoming very popular in some Asian and European countries.

<sup>xxv</sup> There are various types of attacks that involve IP spoofing, some more difficult than others, depending on where the attacker is located—in network terms—in relation to the victim. For more on IP spoofing attacks, see <http://www.securityfocus.com/infocus/1674>.

<sup>xxvi</sup> Even though clear-text password vulnerabilities have existed in programs such as FTP and Telnet for decades, some vendors still distribute these programs in their operating systems, and some people still continue to use them. This is most common behind firewalls or in home local area network environments, where users believe they are secure. Many sites ban these programs by policy and instead try to provide users with cryptographically secure services that do not expose passwords on the network, such as SSH or SSL.

<sup>xxvii</sup> Some protocols don't keep any state whatsoever and, in consequence, may respond to a reply that is received by a system that never even initiated a request. One such attack on the address resolution protocol compromises the mapping of IP addresses to the physical (e.g., Ethernet or MAC) addresses of network cards.

<sup>xxviii</sup> A more complex nonblind spoofing attack is described below in the Session Hijacking section.

<sup>xxiv</sup> The newest version of the Internet Protocol, Version 6 (IPv6), includes features for cryptographic authentication and encapsulation that are intended to make address forgery and sniffing attacks impossible. As of this

traffic into the user's stream of communication. For example, someone making a connection to an FTP server or using Telnet will likely have an account on the server that would not exist if someone was simply impersonating the server. To circumvent this obstacle, intruder tools have been developed that act as a man in the middle and relay all traffic to and from the real server until the victim has logged in. The attacker can then interject packets into the stream with the client's forged source address and effectively take over the session.

This tactic has come to be known as *session hijacking*. By displacing the victim's traffic with his or her own, the attacker hijacks the victim's session. The victim will notice that the session has hung or died and may simply kill the session and start again, thinking that some relevant application has malfunctioned.

Simple forms of session hijacking can be defeated by using more secure communication methods, such as Secure Socket Layer (SSL) or SSH, which employ cryptographic certificate or key pair mechanisms to verify the authenticity of one or both ends of the connection and which encrypt the content of the communication. This effectively defeats the simple forms of session hijacking because, in ordinary cases, the attacker will not have access to the proper keys to get past the encryption used.

Certain man-in-the-middle attacks on SSL and SSH remain possible, but these can succeed only if users ignore warnings that encryption keys have changed since their last use or that certificates either do not match expectations or are not signed by proper certificate authorities. The weakest point is the first time a user connects to a site using a new SSL certificate or uses a new client to connect to an SSH server; at this point, the user must verify that a fingerprint matches to determine whether he or she is connecting to the real server or whether he or she is being tricked by a man-in-the-middle attack. Many users are not trained to do this fingerprint verification, and many sites do not provide users with a secure means to verify the fingerprint in the first place. Thus, even though strong encryption is available, it may be used improperly and only provide a false sense of security and be easily defeated by an intruder.

## Buffer Overflows

Buffer overflows take advantage of a decades-old class of programming errors involving low-level languages such as C that use pointers to data structures in memory and do not take into consideration the size of those data structures. Programmers frequently make themselves vulnerable by defining a buffer to be of some small, fixed size—say 32 bytes—and then calling a function to read an arbitrary amount of data from a network socket. This programming error enables an intruder to attack by feeding a much larger amount of data into the socket, say 4,096 bytes, which effectively overwrites the 32 bytes (typically located on the stack, surrounded by other variables such as function call return addresses, frame pointers, etc.). This makes it possible for the intruder to inject binary machine language code and manipulate return addresses on the stack, tricking the computer into executing code that the intruder has injected.

Buffer overflow conditions can be identified by examining source code, by writing programs to generate large strings and examining their effect on a program using a debugger or by reverse-engineering the program using a disassembler. When, for example, Microsoft confirmed that source code to parts of its Windows NT and 2000 operating systems had been leaked on the Internet, the immediate fear of many security experts was that this would result in a slew of new exploits.

## John the Ripper and Password-Cracking Techniques

A variety of techniques have been used to store passwords on systems for the purpose of authenticating users. For example, the UNIX operating system formerly combined the user's password and a two character "salt" to produce a scrambled string, which was stored on the system in a file visible to all applications and users.<sup>xxx</sup> The system would authenticate the user by combining the same two salt characters with the password provided by the user; if the result was the same as the stored string, then the same password was given.<sup>xxx</sup> If not, access was denied. The encrypted passwords were deemed to be safe in visible form, since computers at the time were not sufficiently powerful to attack the encryption mechanism or to use brute-force methods to try to determine the passwords (an attack known as password cracking). More recently, systems use hashing algorithms<sup>xxxi</sup>, such as Message Digest 5 (MD5), that produce output with a much larger number of bits, making brute-force comparisons against longer pass phrases much more difficult.

John the Ripper is one of the most commonly used password cracking programs. Its popularity derives from its flexibility in handling many types of password hashing or encrypting mechanisms, its dictionary-attack techniques, and its functions for restarting interrupted sessions. It operates by detecting weak UNIX passwords and is compatible with a variety of different platforms, including DOS, Win32, BeOS, and Open VMS.

John the Ripper's core strength rests in using predefined dictionaries of words that are algorithmically permuted in ways commonly used by people choosing passwords, such as replacing letters such as "O," "A," and "S" with the digits "0," "4," and "5"; adding digits or punctuation as a prefix or suffix to words, and so forth. By allowing the selection of targeted dictionaries, an attacker

<sup>xxxix</sup> For a discussion of how Unix passwords are encrypted, the role of a salt value in password encryption, weaknesses in the original crypt algorithm, password cracking attacks, and some proposed ways to harden Unix passwords, see "The Ambitious Amateur vs. crypt(3) or Pondering the Lifespan of Visible Passwords against Brute Force Attack," <http://personal.stevens.edu/~khockenb/crypt3.html>

<sup>xxx</sup> At the time, programmers believed that the algorithm was sufficiently complex that no risk would result from allowing all users to see the encrypted password.

<sup>xxxi</sup> Hash functions take a variable length input and convert it to a fixed length output. The kinds of hash functions used for passwords are known as cryptographic hash functions. Properly used, such functions should make it difficult for an attacker to find the same input (i.e., the user's password or pass-phrase) that resulted in the hash value stored in the password hash file. For more details, see [http://en.wikipedia.org/wiki/Cryptographic\\_hash\\_function](http://en.wikipedia.org/wiki/Cryptographic_hash_function)

can increase the likelihood of cracking weak user passwords. For example, if an attacker knows the password file comes from a system used by chemists, he or she can increase the chances of cracking the system's passwords by using a dictionary that includes chemical terms, names of famous chemists, and chemical companies (over one, say, that includes European poets or figures in African history). Dictionaries exist for all common fields of study and professions—hence the common admonishment to refrain from using words or names found in dictionaries or encyclopedias, even if they are foreign words or names.

There are a number of defenses against password cracking. Systems can defend against such attacks by securing the password hash file, requiring that users select hard-to-guess passwords and change them frequently, or using some form of *second-factor authentication* mechanisms (i.e., adding to the username or password another authentication challenge, such as a one-time password or key fob or card that generates random numbers).

In any event, intruders can obtain passwords without attempting to decrypt them or reverse hashing functions (assuming this is even theoretically possible). In many cases, they can simply attack the password authentication mechanism itself (i.e., the login/password challenge presented by the system) by attempting to predict a person's choice of password (people are not very good at generating randomness in passwords) or by taking advantage of weaknesses in the hashing algorithms themselves. The simple dictionary attack similar to the one used by John the Ripper, if targeted and sorted according to the frequency of occurrence of commonly used terms, can often break passwords in seconds.<sup>xxxii</sup>

These kinds of attacks (which do not require access to the stored password file) are becoming very popular against Windows computers running Windows remote access services, file-sharing services, as well as against SSH servers on non-Windows platforms. Programs such as Phatbot<sup>xxxiii</sup> implement remote dictionary-based attacks against Windows computers using over 100 popularly chosen passwords.<sup>xxxiv</sup> It is very successful in identifying hosts using these weak passwords. Informing users how

<sup>xxxii</sup> Sadly, many people do not try to choose passwords that either have the appearance of randomness or are hard-to-guess words or phrases. One recent study showed that the most frequently used password is "password." See, e.g., bCentral (2005) <http://www.bcentral.co.uk/issues/technology/networks/securityconsiderations.msp>

<sup>xxxiii</sup> LurHQ (2005) <http://www.lurhq.com/phantbot.html>

<sup>xxxiv</sup> One version of Phatbot uses the following list of passwords: admin, Admin, password, Password, 1, 12, 123, 1234, beer, !@#\$, asdfgh, !@#%\$, !@#%\$^, !@#%\$^&, !@#%\$^&\*, WindowsXP, windows2k, windowsME, windows98, windoze, hax, dude, owned, lol, ADMINISTRATOR, rooted, noob, TEMP, share, r00t, freak, ROOT, TEST, SYSTEM, LOCAL, SERVER, ACCESS, BACKUP, computer, fucked, gay, idiot, Internet, test, 2003, 2004, backdoor, whore, wh0re, CNN, pwned, own, crash, passwd, PASSWD, iraq, devil, linux, UNIX, feds, fish, changeme, ASP, PHP, 666, BOX, Box, box, 12345, 123456, 1234567, 12345678, 123456789, 654321, 54321, 111, 000000, 00000000, 11111111, 88888888, fanny, pass, passwd, database, abcd, oracle, sybase, 123qwe, fool, server, computer, Internet, super, 123asd, ihavenopass, West, godblessyou, enable, xp, 23, 2002, 2600, 0, 110, 2525, newfy, 111111, 121212, 123123, 1234qwer, 123abc, 007, alpha, 1776, newfie, patrick, pat, root, sex, god, foobar, 1778, a, aaa, abc, test, temp, win, pc, asdf, secret, drugs, qwer, yxcv, zxcv, home, xxx, owner, login, Login, west, Coordinatore, Administrador, Verwalter, Ospite,

to form strong passwords can prevent Phatbot from entering systems using this method.

Up to this point, this portion of the chapter has discussed only tools and techniques for gaining entry to a computer system. In addition to gaining entry, it should come as no surprise that attackers typically wish to maintain access to the system they have compromised by avoiding detection over time as well as minimizing the chances they will be caught if and when they are detected. To accomplish these goals, the attackers must destroy evidence of the intrusion, conceal their presence in the system, and hide their true locations and identities. The next section discusses some of these techniques.

## Postintrusion Concealment Using Rootkits

Rootkits are programs designed to conceal an intruder and his or her files, directories, or programs by making an operating system lie to its owner. The term *root* relates to the system administrator account, but also serves as a verb in the hacker vernacular referring to the act of gaining system administrator rights on a system ("Betty rooted that Unix system"). The term *kit* refers to the programs that are bundled by an attacker into a neat and easy-to-distribute and install package form (often a *tar* archive file).

Rootkits come in a few distinct types:

1. Straight replacements of, or modifications to, basic operating system programs that are designed to filter out strings based on rules or configuration;
2. Kernel modules that are loaded into the running operating system kernel that perform filtering and privilege escalation at a level below the operating system commands; and
3. Modifications to the kernel's run-time memory that alter system call tables, execution paths within system calls, or the return values of security checks to bypass intended access control mechanisms.

Rootkits elevate privileges on demand, provide continual unfettered (and nonlogged) access, and conceal the intruder's presence in a computer system. Although these methods generally leave some kind of trace in the system's file system,<sup>xxxv</sup> they all make the job of intrusion response

administrator, Default, administrador, admins, teacher, student, superman, wmd, supersecret, kids, penis, wwwadmin, database, changeme, dope, test123, user, private, 69, root, 654321, xxyyzz, asdfghjkl, mybaby, vagina, pussy, leet, metal, work, school, mybox, box, werty, baby, porn, homework, secrets, x, z, bong, qwertyuiop, secret, Administrateur, abc123, password123, red123, qwerty, admin123, zxcvbnm, poiuytrewq, pwd, pass, love, mypc, texas, Texas, Washington, washington, Tennessee, tennessee, jackdaniels, whisky, whiskey, azerty, poiut, mouse, ordinateur, souris, imprimeur, cederom, cédérom, bière, biere, moonshine, athlon, oil, opteron, écran, ecran, reseau, carte, merde, mince, ami, amie, copin, copine, 42, harry, dumbledore, hagrid, potter, hermine, hermine, gryffindor, azkaban, askaban, cauldron, buckbeak, hogwarts, dementor, quidditch, madre, switch, mypass, pw. It also attempts to use an empty password, which also is a surprisingly popular choice of passwords, even for the administrator account.

<sup>xxxv</sup> Nevertheless, it is important to note that modifications of kernel memory space are considerably less likely to leave detectable traces than the other methods.

more difficult because the system appears completely normal to the unwitting system owner or administrator. In many cases, the presence of a rootkit can be confirmed only by monitoring and analyzing network traffic from outside the system, as the intruder must get packets over the network to remotely control the computer.

## Log Alteration

Once inside a computer system, attackers will often begin by disabling, deleting, or modifying logs to eliminate traces of their break-in and subsequent access to the system. A computer system contains two basic types of logs that intruders can alter to eliminate evidence of their presence in the system:

1. Binary logs that require a program or special application programming interface (API) to process and convert the logs to human readable text form. Examples of binary log files are Windows Event logs and Unix *wtmp/utmp/lastlog* files.
2. Text logs from services and applications that have already been converted to human readable form and simply need to be viewed. Examples of text log files are Apache Web server *access\_log* and Unix *syslog* log files.

## Use of Stepping Stones

The concept of a stepping stone is helpfully explained in terms of a physical analogy. If someone wishes to move from a point on one side of, say, a placid Japanese water garden to a point on the other side, he or she must find a series of solid and dry stones that can be used to step or hop from one side to the other. These *stepping stones* provide a safe path from one point to another point. If the number and proximity of these stepping stones is great enough, a person can make repeated trips across the water using different combinations of stones such that the path is not predictable and is possibly never repeated in the exact same sequence. Like physical stepping stones, digital stepping stones make it possible for a user to move from one machine location on the Internet to another.

The analogy, however, breaks down in one crucial respect. Digital stepping stones are used for the purpose of concealing the starting point of an intruder's path—and not for the purpose of moving from one location to another. Unlike physical stepping stones, digital stepping stones are not bound by physical constraints of movement; an attacker can conceivably move from any stone to any other stone—including from starting stone to destination stone; this means that intermediate stones are not necessary to enable the user to travel from a starting location to the final destination.

Digital stepping stones conceal the starting point of an attack from the ultimate victim.

To compromise a machine or network for use as a stepping stone, the attacker must gather intelligence about it.<sup>xxxvi</sup> A sophisticated attacker will typically spend considerable time reconnoitering a network to identify its

structure, the trust relationships<sup>xxxvii</sup> between hosts, the points of vulnerability, and the alarms and access controls in place. These efforts aim at identifying weaknesses that can be exploited to use the machine or network as a stepping stone.

Intruders sometimes exploit trust relationships between systems by gaining access (frequently through firewalls) to a host within the network perimeter and then masquerading as a trusted insider to hop from this system to other systems. If an attacker can install the SucKIT rootkit on a Linux server, for example, he or she can do two things: (1) harvest passwords by sniffing terminal sessions after they have been decrypted (i.e., even SSH sessions will be sniffed and passwords logged) and (2) use the back doors provided by SucKIT and bundled intruder tools to bounce from this system to others on the network.

Unfortunately, most networks have neither flow-level monitoring capabilities that detect new services showing up on a compromised host (e.g., the back doors) nor mechanisms for detecting and correlating connections involving the stepping stone (i.e., coming in from and bouncing to other systems). This typically means the operators or network administrators at a site have no idea when, how, or from where they are being attacked.

It is worth noting that stepping stones are frequently located in countries other than the ultimate target of the attack. For example, an attacker might start in the United States, bounce through a system in South Korea or Germany (both in different time zones and with different native languages), and then come back into the United States to a stepping stone within another network, moving finally into the targeted system. These stepping stones can literally be anywhere in the world, making it nearly impossible to tell where the attack originates. Four, five, or even more hops are feasible if the network latency is sufficiently low that keystroke delay does not become an issue. As network bandwidth increases worldwide, the attacker's ability to maintain anonymity and untraceability over the Internet also improves.

## Antiforensics

As a general matter, forensic science is concerned with identifying and classifying information that will assist in investigating crimes. *Computer forensics* is concerned with gathering information about computers that will provide or lead to information about computer crimes. One of the first published white papers on computer forensics, "Basic Steps in Forensic Analysis of Unix Systems," explains the term "computer forensics" as follows:

<sup>xxxvii</sup> A trust relationship is formed between two systems when there is a shared authentication mechanism, like the same login name and password, or some other means of getting from one system to another. Trust is also found in external access control mechanisms, such as hardware or software firewalls. When trust relationships exist, an attacker who gains access to a single account on a single host may have actually gained access to hundreds or even thousands of other systems that trust the initially compromised host. In addition to the added reach of the intrusion, these trust relationships make great stepping stones to make it harder to detect or trace the attacker, and to make it easier to extend the attacker's reach into the network as if he or she were now an insider (which, for all intents and purposes, he or she now is.)

<sup>xxxvi</sup> The same, of course, is true about the ultimate target of an attack.

The science [of computer forensics involves] methodical, premeditated actions to gather and analyze evidence. The technology, in the case of computers, are programs that suite particular roles in the gathering and analysis of evidence. The crime scene is the computer and the network (and other network devices) to which it is connected.<sup>xxxviii</sup>

Accordingly, computer forensics is concerned with the preservation and analysis of the available data for the purpose of allowing a victim of computer attack to determine the extent of damage or intrusion and to take actions to remediate and bring back under the victim's control all computer and network resources compromised by the attacker. Computer forensics can either be employed by official law-enforcement agencies or by the victim in gathering information about a computer attack. In every case, however, it is concerned with determining the facts about the attack.

Antiforensics measures, in contrast, seek to alter evidence on a computer system to defeat defensive incident-response and law-enforcement investigations; such measures may include destroying existing evidence or planting false evidence. Although it is very difficult to go entirely undetected on a computer system,<sup>xxxix</sup> an attacker with full control of a computer and its operating system kernel can affect all time stamps, attributes, and memory contents. This can make it significantly more difficult for victims and law enforcement to detect intrusions and determine their ultimate sources.

Some techniques that have been discussed publicly and implemented include the following:

1. Deletion of all *i-node* attributes (including file name). I-nodes are data structures in Unix file systems that articulate the attributes of files, such as the file's owner, permissions, time stamps, location of blocks on a disk holding the file contents, and so forth. Directory entries then associate file names, and implicitly the path to the file within the file system (e.g., `/home/users/bob/foo.tar.gz`), to the blocks on the disk where the contents of that file are stored. File systems, such as the Linux EXT3 file system, destroy the information that links the I-node to the blocks on the disk holding the file contents, but leave the file name, ownerships, time stamps, and so forth intact. Antiforensics tools wipe out these data to eliminate as much

information as possible about the files that have been deleted.<sup>xli</sup>

2. Encryption provides a means of concealing the true contents of a file. Most computer users are familiar with encryption as a means of hiding a password or an e-mail message from unintended eyes. But programs can also be encrypted, a feature that enables an attacker to defeat analysis of surface features (e.g., embedded strings, command prompts) and of the program while it runs using debuggers. Encryption can also effectively lock the program so that it can be run only by someone who knows a password. By encrypting portions of the program on disk, only to decrypt them at run time, and by exploiting other weaknesses in debugging APIs (e.g., the `ptrace` system call) and debugging applications (such as GNU, `gdb`, or `objdump`), attackers can make it more difficult to analyze or control the execution of malicious programs.<sup>xlii</sup>
3. Kernel-system call-table modification can be used to conceal running programs, stored files, and network connections and to disable logging. By affecting the operating system's functioning at the level of the kernel's own memory image, rather than through replacement of programs that implement external commands, these measures make possible more comprehensive concealment. Taking over the `exec` system call, for example, can allow an attacker to control which programs are run, thereby providing one behavior for normal accounts and giving elevated privileges for special accounts. The SucKIT rootkit, described earlier, implements these features.

## Covert Channels

The use of *covert channels* is intended to conceal the attacker's use of a compromised computer. Although an attacker can hide his or her presence within a computer system without much trouble, the act of communicating with the compromised system requires transmission of packets to and from that compromised system. In cases where these transmissions pass through other network devices not under the attacker's control, the attacker's use of the compromised computer can, in principle, be detected (by, e.g., a network operator, a security operator, an investigator, or even another attacker) while communications are in transit on the network. A covert channel is a mechanism for concealing the attacker's traffic by either hiding it or making it appear legitimate to third parties.

The Department of Defense's Trusted Computer System Evaluation Criteria defines a "*covert channel*" as "any communications channel that can be exploited by a process to transfer information in a manner that violates the system's security policy."<sup>xliii</sup> In practical terms, covert channels involve the use of some communication method that avoids the standard methods supported by the system

<sup>xxxviii</sup> See <http://staff.washington.edu/dittrich/misc/forensics/>. The authors go on to describe the job of the computer forensic scientist as follows: "Your job, as a forensic investigator, is to do your best to comb through the sources of evidence—disc drives, log files, boxes of removable media, whatever—and do two things: make sure you preserve as much of this data in its original form, and to try to re-construct the events that occurred during a criminal act and produce a meaningful starting point for police and prosecutors to do their jobs."

<sup>xxxix</sup> The reason for such difficulties is that computer intrusions necessarily involve changes to the system that leave traces, and the operating system must have some visibility of these changes to continue running the attacker's programs while functioning in a stable manner. To eliminate every single change to the system is nearly impossible, but it is certainly possible to hide from all but the most skilled system administrators and incident responders.

<sup>xli</sup> The grugq's *The Defiler's Toolkit* implements these techniques. See <http://www.phrack.org/phrack/59/p59-0x06.txt>

<sup>xlii</sup> Programs like TESO's *burneye* encryption engine and Neel Mehta's and Shaun Clowes's *shiva* (see <http://www.securiteam.com/tools/5XP041FA0U.html>) implement these techniques.

<sup>xliii</sup> See Department of Defense (1985) <http://www.radium.nssc.mil/tpep/library/rainbow/5200.28-STD.html>

and does so in a way that avoids logging or detection. For example, files may be transferred out of a system by encoding them in packets using the TCP sequence number or ID fields.<sup>xliii</sup>

These techniques make it difficult for victims and law enforcement to detect malicious software. The operation of malicious software blends in with normal traffic, getting lost in the massive volume of traffic on large networks. If network operators have little understanding of what normally flows over their networks, these techniques can be highly effective. (For example, there are 255 possible IP protocol values, only about half of which are even defined at this time, yet most networks route all of them. Some network monitoring tools will only look for TCP, UDP, ICMP (Internet Control Message Protocol), and Multicast, and lump everything else into one bucket called "other.")

Covert channels pose unique difficulties for anti-intrusion efforts. First, they are quite easy to use. Second, they can be implemented in many ways that use a forged source address together with directly routed traffic between sender and receiver to bounce packets off a third-party computer as a means of concealing the true source of network traffic (such as implemented by Simple Nomad's ncovert tool, released at BlackHat 2003).

## Viruses, Trojan Horses, and Worms

Viruses, Trojan horses, and worms are malicious programs that pose a growing problem for computer users.<sup>xliv</sup> A *virus* is a program that infects computers by attaching itself to programs accessed by the affected computer (from its own file storage system or from remotely mounted file systems on a file server or network storage device).<sup>xlv</sup> Viruses are usually contrived to inflict damage on the victim while distributing themselves to as many other victims as possible through one or more available *infection vectors*, such as e-mail attachments or the boot block on removable media.

As the name suggests, a *Trojan horse* is an innocent-looking program that performs malicious functions that alter the victim's system without his or her knowledge. For example, an attachment to an e-mail message that purports to be a screen saver but actually creates a back door on the system through which it installs malicious software is a Trojan horse. Unlike viruses, Trojan horses generally attempt to deceive the user into running the attachment and hence rely on a form of social engineering (described in the next section).

<sup>xliii</sup> See, for example, Rowland (1996).

<sup>xliv</sup> Not every such program is motivated by a malicious purpose. Some viruses, Trojan horses, and worms have been developed to serve some legitimate purposes. For example, system administrators at the Xerox Palo Alto Research Center (PARC) developed a worm that would, among other things, clean up the Altos computers on their network. Unfortunately, such salutary intentions can have very bad results, as the users of PARC's network found out one morning in 1978 when a worm written by two PARC administrators rendered all 100 workstations useless due to a bug in the worm. See Lemos (2001) [http://ecoustics-cnet.com.com/Year+of+the+Worm/2009-1001\\_3-254061.html](http://ecoustics-cnet.com.com/Year+of+the+Worm/2009-1001_3-254061.html) and Hiltzik (1999).

<sup>xlv</sup> Viruses can also infect documents that support macro languages (which effectively incorporate programs into those documents).

A *worm* is a program that compromises a system by way of a remotely accessible vulnerability and then uses the infected host to distribute the worm to other hosts with the same vulnerability. Worms are usually malicious, but there have been worms, like the so-called Good Samaritan Worm, that attempted to close some existing vulnerability in compromised machines.

Attackers will sometimes use combinations of these programs to compromise a site. In cases where a direct attack against a firewall is not possible but e-mail is allowed into the site, an attacker can, for example, send e-mail messages to victims inside the network with an attachment containing a program that makes a connection to the attacker's Web site. If the victim opens the attachment, the connection is treated by the firewall as a legitimate connection initiated by the victim inside the network; in this way, attackers can circumvent the network's firewall protection to achieve a connection to the computer inside the firewall.

Another way to combine these tools begins with the release of a worm that opens a back door in infected machines. The attacker can then use a scanner or other malicious software to find and use these systems at a later date. An example of this is the program Phatbot, which looks for and takes control of systems infected by Bagle or MyDoom viruses.

## Social Engineering

Although the term *social engineering* has a number of meanings,<sup>xlvi</sup> crackers use it to refer to social mechanisms (e.g., threats or fraudulent misrepresentations) that deceive a victim into doing what the attacker wants him or her to do. One especially effective form of social engineering is a *phishing scam*.<sup>xlvii</sup> Phishing involves the transmission of a message reporting to be from a security department of a popular bank, online auction site (such as eBay), or other online financial service (such as PayPal). The message claims that hackers have broken into the victim's account and that the victim must connect to the site to verify his or her personal information. The Web site is designed to appear legitimate to induce the victim to disclose information that can be used to steal his or her identity. In some cases, the attacker's site will even link back to the legitimate site for any number of subpages other than the authentication page, which is redirected to a Web server under the control of the attacker.

## Denial of Service

A *denial of service attack* is a digital attack calculated to crash or shut down a Web site, server, or network either by exploiting a vulnerability in the system or by overwhelming it with more traffic than it can handle (e.g., in the form of sham requests for information).<sup>xlviii</sup> DoS attacks are distinguished from many of the attacks described previously in that they are directed not at the confidentiality or

<sup>xlvi</sup> It is sometimes used, for example, to refer to the use of the law to encourage socially desirable practices and attitudes among citizens.

<sup>xlvii</sup> US-CERT (2004) <http://www.us-cert.gov/cas/tips/ST04-014.html>

<sup>xlviii</sup> For a more complete description of denial of service, see Mirkovic, Dietrich, Dittrich, and Reiher (2005).

integrity of information systems, but rather at the availability of information systems. The point is not to gather confidential information, but instead to shut down the target and render its contents unavailable to its legitimate users.

The most potent form of a DoS attack is a *distributed denial of service* (DDoS) attack. DDoS attacks are usually staged from a large number of innocent machines that have been compromised without the owners' knowledge. Attackers install on these machines special attack software designed to overwhelm the target Web site, network, or server with requests for information; the attack is launched from these machines when the programs are simultaneously activated.

The use of compromised agent machines in DDoS attacks not only allows the attacker to direct more force at the target than could be deployed through a simple DoS attack, but also makes the identity of the culpable attacker much more difficult to ascertain. The use of innocent agent machines interposes, as it were, a layer of insulation between the target and the culpable attacking party, making it more difficult for the victim or law enforcement agencies to trace the attack path back to the originating source.

It is worth noting that DDoS attacks frequently employ a form of IP spoofing. Some DDoS programs forge a large number of random addresses, thereby making the attack appear to the user as if it came from everywhere on the Internet. Sites that do not filter packets, leaving their network with addresses that do not exist within the network (*egress filtering*), or do not filter packets entering their network with addresses from inside the network (*ingress filtering*) are particularly vulnerable and can make an attacker's job much easier by making it harder for a victim to trace the ultimate sources of the attack.

Unfortunately, the intensity of DDoS attacks has increased dramatically since they first appeared on the Internet landscape in 1999. Although the first DDoS attacks involved no more than 2,000 to 5,000 compromised attacking computers<sup>xlix</sup>, more recent DDoS attacks have involved as many as just under half a million hosts.<sup>1</sup> The increasing number of attacking machines makes these latter DDoS attacks particularly effective in making unavailable the contents of target sites.

## THE COMMON MORALITY ON HACKING AND CRACKING

This section considers whether and to what extent various types of computer intrusions by private persons<sup>li</sup> are ethically permissible according to what Bernard Gert, in an influential article on computer ethics, calls the "common

morality."<sup>liii</sup> The common morality, as Gert defines it, is "the [shared] *moral system* that people use . . . in deciding how to act when confronting moral problems and in making their moral judgments" (Gert, 1999, p. 58). As Gert points out, there is much more agreement among persons in any given culture on moral issues than there is disagreement; though it is quite natural to focus energy on what we disagree upon, "such controversial matters form only a very small part of those matters about which people make moral decisions and judgments" (Gert, 1999, p. 57).

This section attempts to identify those principles of the common morality that are relevant with respect to evaluating the various computer intrusions. Such principles include general norms protecting moral rights to property, privacy, intellectual property, autonomy, and free speech as well as certain norms encouraging the promotion of such social benefits as knowledge. Accordingly, the analysis in this section purports, following Gert, to be grounded in principles that are widely accepted in cultures such as this one—though some of these principles, such as those protecting intellectual property, have themselves come under increasing scrutiny within the past few years.

This is, of course, not the only worthwhile framework for evaluating ethical issues. There is a wide variety of general theoretical approaches to ethics, which include deontological ethical theories such as Kantian theories, virtue theories, theories of care, and an array of utilitarian theories (including hedonistic, preference, and welfare versions of act and rule utilitarianism). There is also a wide variety of more specific approaches to computer ethics—including Deborah Johnson's *global information ethics*, James Moor's *just consequentialism*, and Luciano Floridi's *conception of information as having moral standing*. But none of these frameworks, as is evident from the sheer number of them, commands general assent among either theorists or informed laypersons.

Fortunately, these theoretical approaches tend to agree on most moral principles. All mainstream theoretical approaches, deontological and consequentialist, afford substantial moral protection to our interests in life, liberty, property, physical security, and privacy. Indeed, the vast majority of these are fairly characterized as defining moral rights to life, liberty, property, physical security, and privacy that can be justifiably infringed only by reference to some other right that is at least as important. Accordingly, insofar as these theories all agree on these widely accepted principles of the common morality, hacking and cracking can be fruitfully evaluated by appealing to principles of the common morality.<sup>liiii</sup>

Two final preliminary observations are in order. First, as articulated here, the common morality may presuppose a deontological (or duty-based) framework. Many theorists think that act utilitarianism is inconsistent with the existence of rights as this notion is commonly understood. On this line of reasoning, any act that maximizes utility

<sup>xlix</sup> The first public analyses of DDoS attack tools were published by David Dittrich in December 1999. See <http://staff.washington.edu/dittrich/misc/trinoo.analysis.txt>; <http://staff.washington.edu/dittrich/misc/tfn.analysis.txt>; and <http://staff.washington.edu/dittrich/misc/stacheldraht.analysis.txt>.

<sup>1</sup> See <http://www.securityfocus.com/news/8573>.

<sup>li</sup> Public acts (i.e., those performed by state agencies) raise radically different issues. States are frequently permitted to do things that private individuals are not—such as incarcerating persons.

<sup>lii</sup> See Gert (1999).

<sup>liiii</sup> The arguments in this section parallel those made by Spafford in his classic article "Are Computer Hacker Break-ins Ethical?" (2001). Though Spafford does not explicitly characterize his analysis as grounded in the common morality (not surprising given that Spafford's article was written long before Gert's), he relies on principles that he takes to be largely uncontroversial among all but act-utilitarian theories.

is morally required by utilitarianism regardless of what kind of interest it might infringe. Critics of act utilitarianism have, for example, charged that killing an innocent person would wrongly be required by act utilitarianism if doing so were, all things considered, to maximize utility in a particular situation.

It is not entirely clear whether this criticism succeeds, as some act utilitarians deny these counterexamples, but the following analysis presupposes in any event that morality affords strong protection to our interests in life, liberty, property, physical security, and privacy. To the extent that act utilitarianism is inconsistent with the existence of moral rights and, as seems clear, the common morality presupposes the existence of moral rights (such as rights to life and liberty), the analysis of the common morality is deontological in character in the sense that it presupposes that our ethical principles are grounded in general rules that establish at least some duties that cannot justifiably be infringed to secure some set of desirable consequences.<sup>liv</sup>

Second, many of the principles of the common morality are directly challenged by hackers through their activities; hackers, for example, reject traditional views regarding the protection of property<sup>lv</sup> and privacy rights that ground many of the arguments that will be described further. Even so, it is important to realize that the burden rests on dissenters to make some sort of articulate case for rejecting these principles precisely because the various moral theories all tend to agree on these ordinary views.<sup>lvi</sup> Because there is so much agreement on the basic principles, it is not enough simply to deny them.

In any event, the analysis in this section should be understood as a plausible attempt to identify the implications of these common commitments. Because the analysis here does not seek to defend these common

commitments or the moral theories that validate them, it cannot provide the final word. It is safe to say that the debate will continue.

## The Case against Cracking

The moral case against cracking is straightforward according to the common morality.<sup>lvii</sup> Cracking involves unauthorized computer intrusions that are intended to cause harm or damage to the victims. According to the common morality, it is wrong for one person to deliberately cause harm to another person. Indeed, as Gert (1999) points out, many of our more specific moral commitments (as well as those commitments identified by most general theories) could be summed up in the rule “Do not cause harm.”

Of course, the rule “Do not cause harm” is not absolute.<sup>lviii</sup> Although there are certain principles that can rebut the presumption of impermissibility, these principles do not apply to cracking in ordinary cases. For example, principles allowing punishment of wrongdoing do not apply because they justify only the state in carrying out a punishment; punitive measures by private individuals are almost universally condemned in Western cultures as wrongful vigilantism. Likewise, the principles that allow use of force in self-defense are clearly inapplicable in ordinary cases of cracking because those cases are not responses to attacks on others.

Nevertheless, principles of common morality allow for the possibility that cracking might be morally justified in highly exceptional cases if done without malicious purpose to bring about a great moral good. For example, someone who knows that stolen sensitive information about persons is about to be wrongfully published on a known terrorist Web site might, according to the common morality, be justified in attempting to destroy that information as a means of preventing the great harm that would result—provided that there is no other way to prevent the harm.

But it is doubtful that any cracking case has involved circumstances like the highly unusual ones described here. Indeed, such cases are sufficiently exceptional that it is reasonable to conclude that ordinary cracking is always wrong under the common morality—and the extent of the wrong is determined in part by the extent of the harm that is actually caused and in part by the extent of the harm that is intended by the cracker. The more malicious the intent, the worse the moral transgression involved in cracking. The garden-variety cracker, then, is guilty of committing a serious moral wrong under the common morality.

## The Case against Hacking

The case against hacking seems no less straightforward under the common morality. Although the more malicious

<sup>liv</sup> It is worth noting that this does not imply that all moral rules are absolute. Some deontologists, like Kant, have taken this position; Kant, for example, believed that it is always wrong to lie—even when necessary to save someone’s life. See, for example, Immanuel Kant, *Groundwork for the Metaphysics of Morals*; available at <http://www.swan.ac.uk/poli/texts/kant/kantcon.htm>. Most deontologists, however, have taken the position that less important duties are qualified by more important duties when they conflict. Thus, for example, if the duty to respect property comes into conflict with the duty to refrain from deliberately killing innocent persons, the former is qualified by the latter. The rule defining the duty to respect property is limited by the rule defining the duty not to kill innocent persons. See, for example, Ross (1930). As the latter view seems more in line with the common morality, I will presuppose it.

<sup>lv</sup> The term *property* here should not be construed as including intellectual property. It is meant here to pick out only concrete entities, such as land and computers, that are traditionally thought to receive moral protection.

<sup>lvi</sup> There have been various attempts to describe a hacker ethic, but these attempts have not really engaged the basic assumptions about property and privacy. Some of these efforts, as discussed further, are intended to justify certain intrusions by describing their benefits and motivations. But these arguments generally assume that such considerations win out over any moral interests people might have in their property and privacy. What is needed, however, is a sustained defense of this assumption.

Indeed, it is worth noting that much that has been written about the hacker ethic has been concerned to describe a work ethic that involves a profound commitment of time and energy to understanding hard and soft computing technologies. See, for example, chapter 1 in Himanen (2001). These efforts, however, do not even purport to engage these assumptions, which have nothing to do with describing a work ethic.

<sup>lvii</sup> Two preliminary observations about usage should be made at the outset. First, this entry uses *hacker* and related terms to refer to persons who commit unauthorized intrusions and the intrusions themselves. Second, as used here, the terms *hacker* and *hacking* encompass only unauthorized computer intrusions *not* intended to cause damage, whereas *cracker* and *cracking* encompass only unauthorized computer intrusions intended to cause damage.

<sup>lviii</sup> See Note 52, above.

intrusions involve serious transgressions because of the harm they are intended to cause, all unauthorized intrusions are morally objectionable because they wrongfully impinge upon the morally protected interests of their victims.

First, unauthorized intrusions impinge upon property interests that are clearly legitimate under the common morality. Someone who gains access to my computer without my permission has gained access to a physical entity in which I have a legitimate property interest; it is, after all, my computer—and I have, at the very least, a presumptive moral right, under the common morality, to exclude other people from appropriating my computer.<sup>lix</sup> Indeed, an unauthorized entry into some other person's network seems straightforwardly analogous to a trespass onto the real property of another person. According to the common morality, such trespass is morally wrong regardless of whether it results in damage because it violates the owner's property right to exclude other people from the use of his or her belongings.<sup>lx</sup>

Second, unauthorized intrusions can result in harm even when they are not intended to do so. Even skillful hackers who intend no damage can inadvertently cause significant damage to files and programs in which the victim has legitimate property interests under the common morality. The likelihood of causing such accidental damage is an additional factor that supports thinking that hacking is morally wrong.

Third, unauthorized intrusions impinge upon privacy interests that are clearly legitimate under the common morality.<sup>lxi</sup> Someone who gains access to my computer without permission is gaining access to space in which I have a legitimate privacy interest. If it is true that I may legitimately exclude others from use of an access to my computer, then it is not unreasonable to regard my computer as a private space in which I can store sensitive information. Even benign intrusions impinge, then, upon these legitimate privacy interests.

Accordingly, the common morality seems straightforwardly to condemn even benign intrusions because they impinge upon legitimate privacy and (physical) property interests—and this is true regardless of whether any actual damage is caused to the victim or the victim's property.

## Hacker Attempts to Justify Hacking

Not everyone is convinced that hacking is wrong. Many hackers believe that, at the very least, nonmalicious intrusions are morally permissible and have offered a number of arguments purporting to justify such intrusions (and hence to qualify or limit the rules governing property and privacy rights). Some argue, for example, these intrusions are justified because they result in an increase in humanity's stock of knowledge about the relevant technologies. Others argue that any barriers to information are morally

illegitimate and hence deserve no respect. This section explains and critically evaluates these arguments under the common morality.

### The Social Benefits of Benign Intrusions

Hackers argue that benign intrusions increase our technological knowledge in a couple of ways. First, by gaining insight into the operations of existing networks, hackers develop a base of knowledge that can be used to improve those networks. Second, the break-ins themselves call attention to security flaws that could be exploited by crackers or, worse, cyberterrorists. Thus, electronic trespass is distinguished from other forms of trespass in that it inevitably conduces to the public's benefit.

Neither consideration, however, justifies benign intrusions under the common morality. Even if the privacy and property interests of computer owners might sometimes yield to such considerations, these arguments are problematic because these social benefits can be achieved in other ways that do not infringe upon any legitimate interests.

Hackers can, for example, develop the techniques that enable them to break into other systems in settings where the consent of all parties has been obtained. In cases where hackers seek entry to the machines of ordinary users, they can solicit the consent of other like-minded users to allow them to attempt to circumvent the relevant security measures. In cases where hackers seek entry to the machines of large commercial users, they can seek employment at those firms or provide advice to employees of those firms.<sup>lxii</sup> It seems impermissible to infringe privacy and property interests to achieve benefits that can be achieved without infringing those interests.

Moreover, the social benefits arguments fail to take into account the social costs of hacking. The continuing threat of hacker attacks force companies to invest capital into security that they would otherwise invest in more productive areas. Hacker attacks may contribute to improving security technologies, but these technologies could arguably be developed at a much lower cost if hackers would cooperate with companies in developing these technologies—instead of forcing companies to develop them in an ongoing process of having to defend against such attacks.

There is, however, a deeper problem with these arguments. According to the common morality, the privacy and property interests of computer owners rise to the level of moral rights.<sup>lxiii</sup> But it is part of the very concept of a right that the infringement (as opposed to violation) cannot be justified by an appeal to the resulting good. The mere fact that someone could do a lot of social good by stealing, say, a billion dollars from Bill Gates cannot justify stealing that sum if Gates has a property right in that money. As Ronald Dworkin famously puts the point, rights trump consequences.<sup>lxiv</sup>

<sup>lix</sup> It should be noted that a computer is physical property and not intellectual property; for this reason, the argument does not rely on any contested claims about intellectual property.

<sup>lx</sup> Eugene Spafford, for example, characterizes hackers as "trespassers" and "burglars," which presupposes that hackers are violating property rights of some kind. See Spafford (1992, pp. 335, 340).

<sup>lxi</sup> See, e.g., Spafford (1992, p. 336).

<sup>lxii</sup> As Spafford (1992, p. 337) puts this point, "People wishing to report a problem with the security of a system need not exploit it to report it. . . . [O]ne does not set fire to the neighborhood shopping center to bring attention to a fire hazard in one of the stores."

<sup>lxiii</sup> It should be noted that this argument will not satisfy an act utilitarian who takes the position that there are no moral rights.

<sup>lxiv</sup> See, for example, Dworkin (1978).

The social benefits arguments, then, fail because they are the wrong kind of arguments under the common morality. The property and privacy rights that computer owners have in their machines can justifiably be infringed by an unauthorized intrusion only if required to secure some more important right that outweighs those privacy and property rights. If rights trump consequences, then hackers must identify some stronger right that justifies an intrusion: the appeal to social benefits, by itself, is insufficient to do so. Such an argument is considered in the next section.

### Benign Intrusions as Free Expression

Hackers have also attempted to defend benign intrusions as free expression. On this line of reasoning, hacking is sometimes justifiable as an exercise of the moral right to free expression; in certain circumstances, hackers are morally entitled to intrude upon the computers of others—as long as they do nothing reasonably calculated to cause harm. The assumption here is that the hacker's right to free speech is more important than and hence qualifies (or limits) the victim's privacy and property rights.

### The Free Flow of Information

This line of argument is grounded in the idea that the moral right to free expression is such that there should be no restrictions on the free flow of information; as this latter idea is sometimes put, information *wants* to be—or, better, *ought* to be—free.<sup>lxv</sup> If, on this reasoning, it is true that any restrictions on the free flow of information are morally wrong in virtue of violating the right to free expression, then security measures designed to keep hackers out of networks violate their rights to free expression because they inhibit the free flow of information.<sup>lxvi</sup> As long as hackers do no harm, it is morally permissible for them to intrude into networks to gain information.<sup>lxvii</sup>

The claim that there are no morally legitimate restrictions on the free flow of information is inconsistent with two widely accepted principles of the common morality. First, it is inconsistent with there being a right to informational privacy that entitles persons to exclude others from information in which they have a reasonable expectation of privacy; efforts that exclude others from information, by definition, impede the free flow of information.<sup>lxviii</sup>

Second, it is inconsistent with the claim that people have at least some moral right to control the disposition of their intellectual creations.<sup>lxix</sup> On this line of analysis, people have some intellectual property interest in their creations because such creations are the result of their labor and express their personality.<sup>lxx</sup> If, as most people

believe, at least one of these commonly held judgments is correct,<sup>lxxi</sup> then it is false that the right of free expression entails that there are no legitimate restrictions on the flow of information.

But even if it were true that there are no legitimate restrictions on the free flow of information, it doesn't follow that, as an ethical matter, people have *carte blanche* to get information. For example, it would clearly be wrong, under the common morality, for someone to break into my house to gain information about what books I buy. Similarly, if hacking violates the legitimate property interests of a person in his or her computer, then it is wrong regardless of whether the hacker is otherwise entitled to information on the victim's computer.

### Hacking as Political Activism

Mark Manion and Abby Goodrum argue that politically motivated hacking is morally justifiable as civil disobedience as long as it results in neither harm to the victims nor profit to the hackers.<sup>lxxii</sup> If civil disobedience is morally justifiable to protest against injustice, it is sometimes justifiable to commit benign intrusions to protest injustice.<sup>lxxiii</sup> Insofar as it is permissible to stage a sit-in in a commercial or governmental building to protest, say, laws that violate human rights, Manion and Goodrum argue that it is sometimes permissible to benignly intrude upon commercial or government networks to protest such laws.

The problem with this argument is that hacking is not like ordinary civil disobedience in one very important respect under the common morality. Benign and malicious digital intrusions tend to inflict significantly greater harm than sit-ins or other ordinary forms of civil disobedience. For example, a DDoS attack that shuts down a large commercial Web site can result in millions of dollars in losses to that site and potentially in losses of livelihoods and it seems clear, under the common morality, that the infliction of such harms on ordinary people cannot be justified as a form of political activism or expression.

Here it is important to note that civil disobedience is typically motivated by a moral view that is deeply contested in the culture; in many cases, the view motivating civil disobedience is one that is held by a small percentage of people in the culture. Because there is no reliable way to determine which side of the view is correct, there are moral limits on what sorts of harm or inconvenience can justifiably be inflicted on persons who are not morally responsible for the policy being protested. Hacking that can result in the loss of jobs is always problematic, but is especially so when grounded in views that have not been adequately defended—as is all-too-frequently the case.

<sup>lxv</sup> See, for example, Barlow (n.d.). For a detailed analysis and criticism of this idea, see Himma (in press).

<sup>lxvi</sup> For a critical discussion of this claim, see Spafford (1992, pp. 41–47).

<sup>lxvii</sup> Accordingly, this argument does not even address, much less justify, cracking.

<sup>lxviii</sup> See Spafford (1992, p. 336).

<sup>lxix</sup> It is important to note, however, that the idea that people have intellectual property rights in various kinds of content has become increasingly controversial in recent years. For this reason, it is not entirely clear whether there is something fairly characterized as a *common morality* on this issue. Nonetheless, I include the argument here for the sake of completeness.

<sup>lxx</sup> For a discussion of these views, see, for example, Hughes (1988).

<sup>lxxi</sup> There is, of course, much controversy about whether and to what extent intellectual property rights are morally legitimate. See, for example, Hettinger (1989).

<sup>lxxii</sup> See Manion and Goodrum (2000). Though Manion and Goodrum do not explicitly refer to the common morality, their argument purports to be grounded in widely shared moral judgments about certain kinds of cases and is also fairly characterized as an argument that appeals to the common morality.

<sup>lxxiii</sup> Civil disobedience is typically justified as a form of political expression, a means of expressing one's political conscience and of bringing unpopular political ideas to the attention of an unsympathetic populace and government. See, for example, Dworkin (1978, chap. 9).

Thus, hacktivism will generally be unjustified under the common morality because there are no widely accepted principles that allow persons to inflict great harm on ordinary innocent parties as a means of expressing a political view or protesting injustice.

### Benign Intrusions as Avoiding Waste

Hackers have also defended benign intrusions on the grounds that they make use of computing resources that would otherwise go to waste. On this line of reasoning, it is morally permissible to do what is needed to prevent valuable resources from going to waste; benign hacking activity is justified on the strength of a moral principle that condemns squandering valuable resources in a world of scarcity in which there are far more human wants than resources to satisfy them.

This argument also fails under the common morality. According to ordinary judgments, if one person has a property right in some object X, it is wrong for other persons to appropriate X without permission to prevent X from being wasted. As Spafford aptly puts this point:

I am unable to think of any other item that someone may buy and maintain, only to have others claim a right to use it when it is idle. For instance, the thought of someone walking up to my expensive car and driving off in it simply because it is not currently being used is ludicrous. Likewise, because I am away at work, it is not proper to hold a party at my house because it is otherwise not being used. The related positions that unused computing capacity is a shared resource, and that my privately developed software belongs to everyone, are equally silly (and unethical) positions.<sup>lxxiv</sup>

If such reasoning is correct, hacking cannot be justified under the common morality to prevent waste.

## THE LEGALITY OF HACKING

Whatever doubts one might have about whether some intrusions are ethically permissible, most are unambiguously prohibited by the law in most Western industrialized nations. This section discusses the law of the United States, Canada, and the European Union.

### The United States

The primary federal law in the United States that covers unauthorized access and damage to computer systems is the Computer Fraud and Abuse Act (CFAA; i.e., 18

<sup>lxxiv</sup> Spafford (1992, p. 340). Nevertheless, it is worth noting that the law sometimes permits a person to take possession of property through a wrongful act of trespass. According to the law of adverse possession, a person may come into possession of land by openly and notoriously occupying the land in a way that is clearly adverse to the owner's interests for an extended period of time; if the owner takes no action to halt the adverse possession, the land becomes the trespasser's after the end of the prescribed period (which may vary from one jurisdiction to the next). The justification for this rather counterintuitive law is that the community has an interest in ensuring that a scarce resource like land does not lie fallow. See, for example, <http://www.propertylawuk.net/adversepossessionquarters.html> for a discussion of these interesting issues.

U.S.C. §1030.)<sup>lxxv</sup> The CFAA defines a number of crimes. Of particular relevance is Section 1030(a)(5), which provides as follows:

Whoever . . . (A)(i) knowingly causes the transmission of a program, information, code, or command, and as a result of such conduct, intentionally causes damage without authorization, to a protected computer; (ii) intentionally accesses a protected computer without authorization, and as a result of such conduct, recklessly causes damage; or (iii) intentionally accesses a protected computer without authorization, and as a result of such conduct, causes damage; and (B) by conduct described in clauses (i), (ii), or (iii) of subparagraph (A), caused (or in the case of an attempted offense, would, if completed, have caused)—(i) loss to 1 or more persons during any 1-year period . . . aggregating at least \$5,000 in value; (ii) the modification or impairment, or potential modification or impairment, of the examination, diagnosis, treatment, or care of 1 or more individuals; (iii) physical injury to any person; (iv) a threat to public health or safety; or (v) damage affecting a computer system used by or for a government entity in furtherance of the administration of justice, national defense, or national security . . . shall be punished as provided in subsection (c) of this section.

Subsection (c) authorizes fines and imprisonment of up to 20 years for specified violations of the quoted provision.

Although the relevant provisions apply only to protected computers, the definition of protected computers is potentially quite broad. In particular, the category of protected computers includes government computers and computers used by financial institutions, but also includes any "computer . . . used in interstate or foreign commerce or communication." Construed literally, this latter provision would include any computer used to send an e-mail from a person in one state to a person in another state or used to access any Web page published on a server physically located in a different state from the user. If so, this would include the vast majority of computers capable of being hacked because they are connected to a network; it is hard to imagine that any person who is connected to a network long enough to be hacked has not used his or her computer in one of these ways.

Although this subsection clearly applies to intrusions that cause or are intended to cause significant damage, it also potentially applies to benign intrusions. All that is required for liability is that the user gain unauthorized access to a machine that causes specified kinds or levels of damage. As long as the intrusion is deliberate and unauthorized, the damage need not be intended. Since even

<sup>lxxv</sup> The Department of Justice maintains a Web page that lists recent computer crime cases. This site is primarily concerned with violations of the CFAA (18 U.S.C. §1030). But there is some information at the bottom of the page on other laws that were cited in various cases. See <http://www.cybercrime.gov/cccases.html>

benign intrusions run an obviously foreseeable risk of causing significant damage to protected machines, hackers can be held liable under this act for recklessly causing damage during a putatively benign intrusion.

In addition, benign intrusions may also violate legal rights to privacy—though such violations are perhaps more likely to give rise to civil, rather than criminal, liability—or state laws that criminalize unauthorized computer intrusions. Indeed, a growing number of states are enacting statutes that criminalize various forms of computer misuse which include, but are not limited to, unauthorized computer intrusions.

The relevant federal privacy statutes in the United States are collectively known as the Electronic Communications Privacy Act (or ECPA, for short). The ECPA is made up of the Wiretap Statute (18 U.S.C. §§2510-22), the Pen Register/Trap and Trace Statute (18 U.S.C. §3121) and the Stored Communications Statute (18 U.S.C. §2701). These statutes were further amended in 2001 by the Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism (USA PATRIOT) Act. The most likely to be used for prosecuting computer intrusions involving sniffers or keystroke monitors would be the Wiretap Statute.

As described earlier, a recent trend in computer crime is the use of very large (using perhaps as many as half a million compromised computers<sup>lxxvi</sup>) DDoS networks to cause disruption of online gambling sites in the United Kingdom to extort money from these sites. A total of \$73 million were lost to extortion by these online gambling sites in the first part of 2004.<sup>lxxvii</sup> Three suspects were arrested by the British National High Tech Crime Unit in June 2004 for these attacks.<sup>lxxviii</sup> Had the victims been in the United States, such attacks could violate several other federal statutes, such as the following:

- 18 U.S.C. §1951—Extortion that affects commerce
- 18 U.S.C. §875—Threats transmitted in interstate commerce
- 18 U.S.C. §876—Mailing threatening communications
- 18 U.S.C. §877—Mailing threatening communication from a foreign country
- 18 U.S.C. §880—Receipt of the proceeds of extortion

Other possible violations of law include the following acts. Using a sniffer to steal account and password combinations for the purpose of using these stolen accounts can be prosecuted under the Fraud and Related Activity in Connection with Access Devices Statute (18 U.S.C. §1029). The willful and malicious destruction of data or systems used for communications can be prosecuted under the Communication Lines, Stations, or Systems Statute (18 U.S.C. §1362).<sup>lxxix</sup>

<sup>lxxvi</sup> According to ARGO, 518,000 IP addresses were implicated in DDoS attacks associated with extortion demands. See <http://www.apig.org.uk/ARGO%20Evidence.doc>

<sup>lxxvii</sup> See Bullough (2004) [http://www.usatoday.com/tech/news/internetprivacy/2004-07-28-russian-hackers\\_x.htm](http://www.usatoday.com/tech/news/internetprivacy/2004-07-28-russian-hackers_x.htm)

<sup>lxxviii</sup> See [http://zdnet.com.com/2100-1105\\_2-5278046.html](http://zdnet.com.com/2100-1105_2-5278046.html)

## Canada

Section 342.1 of the Canadian Consolidated Statutes and Regulations defines the general framework that applies to hacker attacks. In particular, Subsection (1) provides the following:

Every one who, fraudulently and without colour of right (a) obtains, directly or indirectly, any computer service, (b) by means of an electromagnetic, acoustic, mechanical or other device, intercepts or causes to be intercepted, directly or indirectly, any function of a computer system, (c) uses or causes to be used, directly or indirectly, a computer system with intent to commit an offence under paragraph (a) or (b) or an offence under section 430 in relation to data or a computer system, or (d) uses, possesses, traffics in or permits another person to have access to a computer password that would enable a person to commit an offence under paragraph (a), (b) or (c) is guilty of an indictable offence and liable to imprisonment for a term not exceeding ten years, or is guilty of an offence punishable on summary conviction.

On its face at least, Section 342.1 seems to create a more stringent standard protecting against unwanted computer intrusions. In contrast to the U.S. Computer Crime and Fraud Act, Section 342.1 lacks a damage requirement and hence appears to prohibit both malicious and benign computer intrusions.

In addition, Section 430 of the Canadian criminal law prescribes penalties for the crime of mischief, which occurs when one party, without authorization, intentionally damages, destroys, or renders less valuable the property of another person. Subsection 1.1 specifically defines damage to data as criminal mischief subject to specified penalties:

Every one commits mischief who willfully (a) destroys or alters data; (b) renders data meaningless, useless or ineffective; (c) obstructs, interrupts or interferes with the lawful use of data; or (d) obstructs, interrupts or interferes with any person in the lawful use of data or denies access to data to any person who is entitled to access thereto.

Section 430 (1.1), then, creates additional liability for malicious intrusions (i.e., cracking) that result in damage.

## The European Union

The Council of Europe has demonstrated a firm commitment to adopting a unified approach to dealing with computer misuse. On November 8, 2001, the Committee of Ministers of the Council formerly adopted the Convention on Cybercrime, which states guidelines for the various members of the European Union in formulating laws

Intellectual Property Section Web page of the Department of Justice and <http://www.cybercrime.gov>

regarding computer misuse.<sup>lxxx</sup> The council observes the following in an explanatory note:

The fast developments in the field of information technology have a direct bearing on all sections of modern society. The integration of telecommunication and information systems, enabling the storage and transmission, regardless of distance, of all kinds of communication opens a whole range of new possibilities. . . . By connecting to communication and information services users create a kind of common space, called "cyber-space", which is used for legitimate purposes but may also be the subject of misuse. These "cyber-space offences" are either committed against the integrity, availability, and confidentiality of computer systems and telecommunication networks or they consist of the use of such networks or their services to commit traditional offences. . . . The criminal law must therefore keep abreast of these technological developments which offer highly sophisticated opportunities for misusing facilities of the cyber-space and causing damage to legitimate interests.<sup>lxxxii</sup>

Section 1 of Chapter II of the convention states guidelines for formulating substantive criminal law as it pertains to unauthorized access of computers, unauthorized interception of data, data interference, system interference, misuse of computing devices, computer fraud, child pornography, and copyright infractions. Article 2 of the convention is of particular relevance for this entry as it defines the relevant guidelines for criminalizing unauthorized access to computers and associated technologies. Article 2 provides as follows:

Each Party shall adopt such legislative and other measures as may be necessary to establish as criminal offences under its domestic law, when committed intentionally, the access to the whole or any part of a computer system without right. A Party may require that the offence be committed by infringing security measures, with the intent of obtaining computer data or other dishonest intent, or in relation to a computer system that is connected to another computer system.<sup>lxxxiii</sup>

Insofar as the defining characteristic of a hacker attack is the attempt to gain unauthorized access, Article 2 purports to guide the adoption of criminal laws regarding hacker attacks. The clear intent, of course, is that unauthorized intrusions be prohibited by law.

Presumably, every member nation of the European Union already has laws on the books prohibiting hacking activities. Although these laws probably differ in particulars, it is reasonable to think that they satisfy the spirit of Article 2's general call to prohibit unauthorized intrusions.

## CONCLUSIONS

It is reasonable to hypothesize that incidents of computer misconduct will continue to increase as hackers, crackers, and computer criminals progress in developing more sophisticated and destructive techniques and technologies for intruding upon and attacking the computers and networks of innocent persons. These new techniques will, in turn, give rise to new ethical issues and policy challenges as lawmakers struggle to keep abreast with the latest technologies. Unfortunately, at this time, legislators, policy makers, and law enforcement agencies have not been able to keep pace with the increasing incidence of hacking, cracking, and computer crimes. This chapter has attempted to provide an overview of the relevant technological, ethical, and legal challenges posed by the problem of computer crime.

## GLOSSARY

**Agent Machines** Machines belonging to innocent parties that are compromised by an attacker and used to stage a digital attack or intrusion of some kind.

**Antiforensics** Measures that seek to alter evidence on a computer system to defeat defensive incident-response and law-enforcement investigations; such measures may include destroying existing evidence or planting false evidence.

**Cracker** Someone who trespasses onto the computers or networks of other persons without authorization and with an intent to harm.

**Cybercrime** Criminal activity that involves unauthorized use of computer technology in an essential way.

**Cyberterrorism** Hacking activity that attempts to harm innocent persons and thereby create a general sense of fear or terror among the general population for the purpose of achieving a political agenda.

**Denial of Service** A digital attack that is calculated to shut down a Web site, server, or network, usually by overwhelming it with sham requests for information.

**Digital Intrusion** An act intended to gain unauthorized access to the digital contents (e.g., files or programs) of another person. Such access can be for comparatively benign purposes (e.g., merely to look at files) or for malicious purposes (e.g., to destroy files).

**Hackers** Persons who attempt to gain unauthorized entry to network servers or other computers. Hacking is usually distinguished from cracking in that the latter, unlike hacking activity, is intended to cause harm to innocent persons.

**Intrusion Response** Measures adopted by the victim of a digital intrusion intended to investigate, repel, or punish the intrusion.

**Internet Protocol (IP) Spoofing** The use of a false IP address for the purpose of deceiving the user about the source of incoming packets.

**Logic Bomb** A program designed to take malicious action at a particular point in time.

**Rootkits** Programs designed to conceal an intruder and his or her files, directories, or programs by making an operating system lie to its owner.

**Session Hijacking** Hijacking that occurs when an intruder deflects traffic from the user's intended

<sup>lxxx</sup> Council of Europe (2001).

<sup>lxxxii</sup> Council of Europe (2001).

<sup>lxxxiii</sup> See Council of Europe (2001).

destination and interjects its own traffic into the user's stream of communication.

**Sniffers** Programs that are designed to monitor network traffic on local area network segments.

**Stepping Stones** Chains of login sessions across multiple computers, often in different countries and time zones.

**Trojan Horse** A program that appears innocuous, but actually performs malicious functions that alter the victim's system without his or her knowledge.

**Virus** A malicious program (i.e., one intended to cause damage) that infects computers by attaching itself to programs accessed by the affected computer and attempts to distribute itself to as many other victims as possible through one or more available infection vectors, such as e-mail attachments.

**Worms** Programs that compromise a system by way of a remotely accessible vulnerability and then use the infected host to distribute the worm to other hosts with the same vulnerability.

## INTRODUCTION

Elsewhere (Jordan & Taylor, 2004; Taylor, 1999; Taylor, 2001), we have provided detailed accounts of both hacking and the attendant phenomenon of hacktivism. The purpose of this chapter is to provide a more succinct account of the way in which the key attributes of hacking have been adopted by new social movements that have pressed them into the service of the burgeoning antiglobalization movement. In carrying out this task, we will explore the points of contact and divergence that exist between traditional hacking and the recent emergence of hacktivism, the latter defined as the deployment of hacking tactics within the context of an explicit political agenda. Although hackers tend to be much more politically motivated than their hacker predecessors, their innovative acts are in fact very much in keeping with the original hacker ethic of using technology in the most ingenious manner possible. Hacking has, almost from its first emergence, been marked by a certain politics. However, this politics has revolved around the problem of the freedom of information and access to technology. The innovative feature of hacktivism is the way it takes this preexisting hacker ethic and applies it to the field of specific social protest movements whose concerns are not solely technological. Because hacktivism attempts to wrest control of the technologies of globalization from the hands of the state and corporations and to turn them against the very order that developed and deployed them, it can be said, to continue a trend in computer culture which, from the 1960s onward, hacktivists have sought to challenge the assumption that technology is intrinsically the tool of capitalism and the state.

This chapter begins with an introduction to the key ethical aspects of hacking and offers a schema that traces the evolution of hacking as a concept and practice through various generations. Although a more traditional and apparently politically neutral hacking culture is still extant, we will show how hacktivism, under the impetus of the antiglobalization movement, has emerged as a separate and distinct practice. Despite the common perception of hacking as a computer-related act, the term in its earliest use described a particular, playfully innovative,

and irreverent attitude toward any technology or associated system. The gradual reduction of the term solely to the field of computing is, it will be argued, commensurate with apparent erosion of the hacker ethic as reflected in Microsoft's corporate co-optation of gifted programmers and their culture, a takeover whose stakes are encapsulated in the term *microserfs*. From a radical political perspective, the microserf generation is shown to represent a particularly low point, and the political nature of hacktivism, as described through the notion of electronic civil disobedience and examples of specific hacktivist groups, is presented as a revival of hacking's early political promise. The uses to which these groups put the hacker ethic is then contrasted with the open-source (OS) movement, which despite lacking hacktivism's clear agenda, nevertheless retains a strong fidelity to the original aims of hacking. The chapter concludes with an analysis of the global trends that hacktivism and the OS movement simultaneously challenge and utilize.

## THE CULTURE AND FOUNDING ETHICS OF HACKING

Access to computers—and anything which might teach you something about the way the world works—should be unlimited and total. Always yield to the Hands-On Imperative!

All information should be free  
Mistrust Authority—Promote Decentralisation  
Hackers should be judged by their hacking,  
not bogus criteria such as  
degrees, age, race, or position.  
You can create art and beauty on a computer.  
Computers can change your life for the better.  
(Levy, 1984, pp. 40–45)

So runs Levy's (1984) summary of the hacker ethic. First-hand research among various groups of hackers (Taylor, 1999) suggests that central beliefs in the overarching value of technological ingenuity and a fascination with the innate complexity of systems should be added to Levy's

ethical commandments. It is important to emphasize that it is only in relatively recent years that hacking became associated just with computers. When carrying out firsthand empirical research, hackers provided examples of their favorite hacks that included a number of different artifacts ranging from coffee machines to parking meters and a diverse range of systems encompassing the abstractions of the legal establishment (from a hacker who worked on his own legal defense in jail) and the labyrinthine practicalities of phone networks. Perhaps at its most basic level the term invokes a sense of *bricolage*, that is, a sort of creative or Puckish tinkering with technologies and systems so that they exhibit proprieties and display functions beyond those intended by the designers.

Himanen (2001) offers another perspective on the hacker ethic, arguing that hackers can be distinguished from their ambient culture by their overdeveloped work ethic. They have broken with the Protestant work ethic, in which regulated labor as the cornerstone of a virtuous life finds its reward in material remuneration and a clear conscience. Hackers, although by no means adverse to work, labor in a nonalienated fashion; their hours are irregular and determined by the waxing and waning of their own interest rather than by external dictates. Hackers do not value labor in itself, but rather their specific labor; their enthusiasm is not for the material rewards of work, but for the task itself. In this light, hacking at its most basic level is a joyous, playful, or creative activity. In this respect, the work ethic of the hacker is close to that of the creative artist or the academic, both of whom (ideally) work for the sake of the work (Moody, 2002, p. 154). But in the case of the latter there is a tendency toward individualism, an autonomous even solipsistic aspect that is absent in hacking. Such a formulation may appear paradoxical, given the popular image of the hacker as a socially maladroit loner, happier with code than people. Yet, although this stereotype is not without a grain of truth, it nonetheless fails to recognize the deeply social nature of hacking. To quote Marvin Minsky, "Contrary to popular belief, hackers are more social than other people" (as cited in Himanen, 2001, p. 52). Hackers, although perhaps solitary as individuals, are as a group or collective highly social. Peer recognition, and a desire to produce tools that are socially useful, is the lifeblood of their endeavor. Thus, hackers harness the traits of creativity and enthusiasm associated with highly individualized forms of production toward communal or collaborative projects. This social aspect is perhaps most clear in the activities of the open-source/free software communities but can be observed even in the more questionable activities of hackers.

All these ethical values emerged in the earliest days of computing and are perhaps most readily associated with Levy's further classification of the first three generations of hackers:

*"True" hackers:* these pioneers made their name experimenting with the large mainframe computers at such U.S. universities as the Massachusetts Institute of Technology during the 1950s and 1960s.

*Hardware hackers:* these were the entrepreneurial innovators of the 1970s who played a key role in making

computing accessible to the masses by both facilitating and promoting the personal computing revolution and its much smaller, decentralized computing hardware.

*Game hackers:* in the 1980s, building upon the hardware successes of the personal computer (PC) revolution, the game hackers were responsible for the development of popular gaming software applications.

In view of the development of computer culture since Levy's analysis, four additional categories should be added to these earlier generations:

*Hacker/cracker:* from the mid-1980s to the present day, these terms are used (frequently interchangeably) to describe a person who illicitly breaks into other peoples' computer systems. The choice of term tends to vary depending upon the moral interpretation used by a commentator for acts that tend to be essentially the same. *Hacker*, for example, tends to be used by those sympathetic to the values of the computer underground, whereas *cracker* tends to be used by those who have a much sterner interpretation, such as the computer security industry that has grown up over time in response to such unsolicited intrusions.

*Microserfs:* this is the phrase used in Douglas Coupland's novel (1995) of the same name to describe those computer programmers, who, while exhibiting various obsessive and independent-minded traits of the hacker subculture, nevertheless became sucked into the corporate world of bonds and the desire to vest them.

*Open source/free software hackers:* A breed of hacker who self-consciously differentiates themselves from the both the corporate microserf and the deviant cracker. Based primarily around the open source GNU/Linux operating system, they can be seen as a return to the original spirit of the 1960s and 1970s. Indeed, there is a direct link in the form of Richard Stallman, whom Levy described in his 1984 volume as *the last hacker*. Stallman, in particular through the concept of *copyleft* and its adoption by Linus Torvalds, has operated as an intergenerational bridge, perpetuating the original hacker ethic. Unlike hacktivists, the open-source community are political by circumstance rather than by choice, that is, to the degree that their working methodology proves a challenge to the monopolistic agenda of Microsoft and the like.

*Hacktivism:* the mid-1990s marked a pivotal point at which previous, largely apolitical hacking activity was incorporated into a much more overtly political form. The political activity of the previous generations tended to be limited to securing freer access to computing facilities rather than questioning too deeply the political purposes for which the equipment could be used. The rise of hacktivism fundamentally changed this political blind spot and continues to integrate global networks of information technologies to object against the perceived excesses of global capitalism.

It should be noted that these generations represent a conceptual schema and that the real history of hacking and hacktivism is inevitably more complex, offering overlaps

and concurrencies that problematize a simple subdivision of hacking into the previous generations. Notwithstanding these limitations, the schema nevertheless provide a useful overview of the way in which there has been a move away from, and then a return (in the form of open source and free software) to, key aspects of the original hacker ethic:

engagement with systems  
hands-on curiosity applied to *any* technology  
a desire to reverse the original purposes of an artifact or system.

Before looking at the sophisticated and self-reflexive politics of hacktivism that has sought to revisit and reapply these values, it is necessary to trace the decline in the political potential of early hacker groups and their subsumption within the corporate takeover of the information revolution.

## FROM HACKING TO MICROSERFDOM

These were the radical or guerrilla hackers, who were destined to give the computer a dramatically new image and a political orientation it could never have gained from Big Blue [IBM] or any of its vassals in the mainstream of the industry. At their hands, information technology would make its closest approach to becoming an instrument of democratic politics. (Roszak, 1986, p. 138)

In support of the above claim from Roszak, it is possible to trace a line of influence from the radicalized student population of the 1960s to the computer culture of the 1970s, for instance at the University of California Berkeley, famous as a breeding ground for both hackers and radical politics. This impression is reinforced by a number of influential texts, for instance Ivan Illich's *Tools for Conviviality* (1973) and Ted Nelson's *Computer Lib/Dream Machines* (1974). Both books made an explicit connection between an emancipatory politics and an emancipated technology. Nelson's text, in appearance a sort of smazidat publication resembling the *Whole Earth Catalog*, was particularly prophetic. It offered the nebulous but inspiring vision of a *hypertextual* (this term's first appearance) system called Xanadu that would connect every document with every other document in a universal database. Perhaps more important was the fact that Nelson's vision was couched in a revolutionary rhetoric that argued that computing should be accessible to all and not the preserve of corporations or academics. Nelson's text thus assigned the hobbyist and the underground hacker "a noble role in the battle for humanity's future and recruited them for the rebellion they were witnessing on their college campuses" (Wolf, 1995, p. 8). Similarly, Illich argued for the liberation of the design of technology so that the principles were accessible to all, the *convivial* tool aimed to dissolve the distinction between user and producer. His thesis inspired members of the Homebrew Computer Club, such as Lee Felstein, whose "TV Typewriter or Tom Swift Terminal" was an early attempt to hack a monitor/interface

using a keyboard and television and produce a "convivial cybernetic device" inspired by Illich's vision of a convivial technology (Levy, 1984, p. 210; see also Felsentein, 1995) and in this manner Illich's ideas were part of the matrix that spawned the PC revolution.

Thus, on the one hand, a hacker's belief in the ingenious use of technology offered an immediate potential for countercultural activity. If you see subversion in every object placed before you, it is likely that you will develop tendencies that can easily be viewed as subversive by those in authority. On the other hand, however, any radicality within the early generations tended to be mostly confined to issues of access. In other words, hackers could be radical but only tended to be so to gain time for hands-on experimentation with the artifacts and systems that they loved so much. The early radical wing of the hacking ethos was reflected in the advent of the *Youth International Party Line* an underground newsletter run by Abbie Hoffman established in 1971 and which changed its name in September 1973 to the *Technological American Party* (TAP). Newsletters were produced that vividly manifested the ubiquity of the pure hacker hands-on imperative with their raft of detailed technical information on such issues as how to phone-phreak (obtain free phonecalls through the technical manipulation of the phone system) and reengineer a large range of artifacts and techniques including burglar alarms, lock picking, pirate radio, and gas and electric meters.

TAP ceased publication in 1984, but its mantle was quickly assumed with the launch of the phone-phreak/hacker magazine *2600* whose anti-Big Brother government bent was immediately indicated by the editor's choice of the nom de plume Emmanuel Goldstein (the oppressed protagonist of George Orwell's *1984*). Meanwhile, in 1981 in Europe, a German hacker group established the Chaos Computer Club. It directly expressed the digitally correct implications of the original hacker ethic, "All information wants to be free," in the following declaration:

A development into an "information society" requires a new Human Right of worldwide free communication. The Chaos Club...claims a border-ignoring freedom of information which deals with the effects of technologies on human society and individuals. It supports the creation of knowledge and information in this respect. (As cited in Bowcott and Hamilton, 1990, p. 53.)

We shall see in our subsequent discussion of hacktivism how this emphasis upon the primacy of informational flows lies behind the major schism between human rights and digital rights-orientated hacktivists (see Jordan & Taylor, 2004, for more details). Notwithstanding this perennial tension with the computer counterculture between radical politics and pragmatic issues of access, the first and second generations both exhibited a form of electronic populism. Their subversive desire to hack and the attempt to make technology more universally available were complementary facets of the same hacker agenda.

The earliest hackers had noncorporatist values to the extent that they inhabited cloistered university

environments and were motivated by pure intellectual curiosity rather than business applications. With the more outward-looking second generation of hackers, a certain explicit anticorporate ethos, as evinced in the names of some of the early start-up companies such as the *Itty-Bitty Machine Company* (a parody of IBM) and *Kentucky Fried Computers* (Jordan & Taylor, 2004, p. 142). Likewise, the Apple computer company chose its symbol because of its “whole earth” connotations. This countercultural spirit was not to last, however, and the initial socially liberating potential of such computers increasingly became subordinated to their status as mere commodities: “all the bright possibilities seem so disturbingly compatible with corporate control and commercial exploitation” (Jordan & Taylor, p. 155). This corporate appropriation of the original hacker ethic was most dramatically illustrated by Apple’s famous 1984 television commercial (directed by Ridley Scott) that culminated with the anti-Orwellian image of a woman sprinting across the screen to launch a huge hammer at a menacingly glowering Big Brother.

As computing technology developed within the ever-widening circles of commercially sponsored dissemination, the commodity view of information gained pace over the countercultural desire for a more politically engaged democracy fueled by the exponential increase in the accessibility of information. Thus the perennial tension between hacking’s potential radicalism and the affinity of its code-loving tendencies to economic libertarianism was increasingly resolved in favor of the latter: the countercultural hopes pinned upon the computer as vehicle for antiestablishment values floundered as the *wunderkinds* of the 1970s became the software giants of the 1980s. Given the intrinsically commercial dimension of their activity, the second generation of game hackers was naturally primed to take advantage of the subsequent dot-com boom, whereas the third generation of crackers/hackers increasingly found an outlet for their idiosyncratic skills in the deliberately collegiate atmosphere of Microsoft’s headquarters. The early hackers’ desire to promote free access to computers and information as a means of facilitating an informed, and thereby empowered, demos had quickly retreated to a self-serving concern with access to computing for its own sake.

Thus the youthful, antiauthoritarian attitudes within the early generations of hacking were soon sublimated into a frustrated desire to consume computing resources (see Taylor, 1999, pp. 53–56) such that teenage hackers came to “resemble an alienated shopping culture deprived of purchasing opportunities more than a terrorist network” (Ross, 1991, p. 90). The nadir of this process was vividly portrayed in Douglas Coupland’s (1995) geist-busting “factional” account of the lifestyles of the young programmers working at Microsoft’s Seattle headquarters in *Microserfs*. The hacker/cyberpunks’ willingness to immerse themselves in the labyrinthine matrices of code was easily co-opted to the creation of a particularly extreme form of *homo economicus*:

In the 1980s corporate integration punctured the next realm of corporate life invasion at “campuses” like Microsoft and Apple—with the next level of intrusion being that borderline

between work and life blurred to the point of unrecognizability. *Give us your entire life or we won’t allow you to work on cool projects.* In the 1990s, corporations don’t even hire people anymore. People become their own corporations. It was inevitable. (Coupland, p. 211 [emphasis in the original].)

Microsoft’s subsumption of hacker culture has been so successful because traits such as “high productivity, maverick forms of creative work, energy, and an obsessive identification with on-line endurance (and endorphin highs)” (Ross, 1991, p. 90) from the outset blurred the boundaries between work and play, labor and creativity. Thus it engineered an environment in which these qualities, which might have proved problematic in a traditional structure, served solely to valorize “the entrepreneurial codes of silicon futurism” (Ross, p. 90). In this manner, hacking’s apparent political potential was diffused and business as usual had restabilized its hegemony. This was arguably because an essential part of the specific act of hacking is its love of the technical means rather than the political or philosophical end. Thus, although the hacking mentality could theoretically be applied to a multitude of artifacts, in practice it was limited to the joy of the hack and the technological means by which it is effected. In other words, an appreciation of the relation of the hacked artifact to the overarching technological system and the possibility of hacking as a subversive intervention in this system tends to be an underdeveloped dimension of hacking.

Similarly, from a political point of view, such a close attachment to the technological system results in a necessary convergence with the aims of the wider social systems that sustain it; to quote the Critical Art Ensemble (CAE),

The hacker is generally obsessed with efficiency and order. In producing decentralized technology, a fetish for the algorithmic is understandable and even laudable; however, when it approaches a totalising aesthetic, it has the potential to become damaging to the point of complicity with the state (1994, p. 137).

This was demonstrated in one of the authors’ (Taylor, 1999) early research into the original hacking communities where, in addition to the moral judgments about hacking made by external groups such as the computer security industry and law enforcement officers, hackers themselves readily expressed their ethical disapproval of those who engaged in destructive acts of electronic trespass. This was because it drew attention to, and thereby endangered, their otherwise harmless engagement with both artifacts and systems. Put another way, hackers did not want to alienate themselves unnecessarily from the society upon which they were dependent for their technological sandpits. Thus, in confirmation of the manner in which many hacker traits appear fundamentally ambiguous with respect to the wider political questions, the peculiar mixture of individuality and communality that characterized hacking culture proved a limitation on its political possibilities. Thus, while hacking produced novel forms of collective endeavor (e.g., live-in mini-gangs, conferences,

chat room groups), the narrow activity itself remained fundamentally solitary, even solipsistic.

This is reflected in some of the cultural aspects of the early hacker communities. For example, the Electronic Frontier Foundation (EFF) was an interest group that although not specifically devoted to hacking per se, was, as its name suggests, closely akin to the hacker demand for unfettered access to the digital plains. This appeal to imagery of the Wild West tapped into a deep stratum of the American psyche and finds its echo in the influential fictional genre of cyberpunk that gave us the epochal term *cyberspace*, wherein suitably glamorized hacker protagonists are referred to as *console cowboys*. These tropes of rugged individualism in both cyberpunk depictions and organizations such as the EFF indicate how readily the original hacker ethic was elided with a libertarian, laissez-faire economic ideology. Rather than the socially inclusive dream of an informatically enabled populace that motivated some of those involved in the first wave of the PC revolution, computer networks were increasingly seen as an unprecedented, technologically facilitated opportunity to create virtual social conditions unencumbered by the regulatory weight of real-world government interference. Thus, the key significance of hacktivism and elements of the free software movement is the way in which they, by virtue of a reassertion of a revised set of countercultural values, challenge this apparently total surrender of every aspect of social life to the values of the market. Moreover, this challenge does not occur outside of the market, but rather within the context of the technologies that have played no small role in creating this situation.

## HACKTIVISM, TACTICAL MEDIA, AND THE VIRTUAL SIT-IN

As hackers become politicized and as activists become computerized, we are going to see an increase in the number of cyber-activists who engage in what will become more widely known as Electronic Civil Disobedience. The same principles of traditional civil disobedience, like trespass and blockage, will still be applied, but more and more these acts will take place in electronic or digital form. The primary site for Electronic Civil Disobedience will be in cyberspace (Wray 1998: 3).

As with the hackers before them, there are competing definitions of which activities and people deserve the terms *hacktivism* and *hacktivists*. The conceptual categories offered in this chapter thus inevitably involve simplification of blurred, if not contested, terminological boundaries. Thus, there may be examples of online individuals or groups who use hacking techniques for destructive activities while claiming a political motivation and as a consequence various interpretations can be made as to whether such people should be classed as *hacktivists*, *hackers*, or even the pejorative term *crackers*. Denning's comprehensive analysis of hacktivism provides a useful distinction between it, an online activism that simply uses new technologies, and the more sinister cyberterrorism: "Activism refers to normal, non-disruptive use

of the Internet in support of an agenda or cause... hacktivism refers to the marriage of hacking and activism... cyberterrorism refers to the convergence of cyberspace and terrorism" (Denning, 1999, p. 2). Recently, within the post-9/11 context, the Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism (USA PATRIOT) Act has collapsed hacktivism, cyberterrorism, and the more traditional activities of crackers. All, in the eyes of U.S. law at least, can constitute cyberterrorism, and because that act allows for the extradition of cyberterrorists thus defined, it has implications for any group considering adopting hacktivist strategies.

Out of these definitions this chapter focuses on the fusion of hacking and activism and its points of contact with the free software movement, which in concert offer the most theoretically interesting and legitimate direct challenge to the commercial paradigms that have dominated the Internet in recent years. In view of this terminological uncertainty, *tactical media* is a useful generic phrase that can be used largely synonymously with hacktivism, the following definition of which is offered by the Critical Art Ensemble:

The term "tactical media" refers to a critical usage and theorization of media practices that draw on all forms of old and new, both lucid and sophisticated media, for achieving a variety of specific noncommercial goals and pushing all kinds of potentially subversive political issues. (The organizers of the 1993 Amsterdam event Next Five Minutes, as cited in CAE, 1994, p. 5.)

The definition by some of its practitioners (one of whose number has been recently detained under the USA PATRIOT Act, see [www.caedefensefund.org](http://www.caedefensefund.org)) demonstrates its fidelity to the original hacking ethic's emphasis upon the ingenious reappropriation of *any* technological artifact or system. The other key feature of this definition is the inclusive phrase of "a variety of specific noncommercial goals." This is the main unifying feature of hacktivists: their self-reflexive political perspective. Again, in keeping with the original hacking ethic, they seek imaginative methods to reengineer the purpose of a system: in this case the global capitalist system of communication and commodity flows. They also reengineer concepts of protest so that conventional notions of civil disobedience are redesigned for the digital age. Most prominent among these techniques is that of the *virtual sit-in*:

A virtual sit-in is little more than a collective, simultaneous requesting of a Web site. If one requests a Web site faster than it can be transferred and built up on the end user's screen, the server receives, on the one hand, a message telling it that the first request is no longer valid, and on the other hand, the new request. Scripts running on one's own computer or on go-between servers automate this process, and after a certain number of requests, the server under attack begins to suffer under the strain. One has to differentiate very specifically between knocking out a server

for private motives and a political action openly disrupting a Web site for clearly formulated reasons and for a limited time. That's when it becomes comparable to a warning strike during wage negotiations, a means of civil disobedience signalling that one side has the willingness and courage to fight (Grether, 2000, p. 5).

A practical example of this theory of electronic civil disobedience was provided in 1998 when a group known as the Electronic Disturbance Theater (EDT) coordinated a series of Web sit-ins in support of the Zapatistas, a Mexican antigovernment group largely made up of indigenous people from the Chiapas region. The sit-ins used an automated piece of software called Flood Net. The idea behind this program is that once downloaded onto a computer, it helps users to automatically connect their computer to constantly request access to a preselected Web site and renew the request every 7 seconds. If thousands of people use Flood Net on the same day, the combined effect of such a large number of activists will severely disrupt the operations of a particular site. The particular way in which Flood Net was used illustrates the important distinction to be made between pure hacktivism and the early hacking mentality that arguably lives on in the form of digitally correct hacktivism (see Jordan & Taylor, 2004). The overriding concern of digitally correct hacktivism is the maintenance of bandwidth functionality and the technical elegance of a hack. In contrast, the political success and strength of the Flood Net action was the very fact that it was not a highly sophisticated and largely automated program. It was relatively simple from a technological point of view and this meant that it required the mass participation of willing volunteers. This gave it a political credibility it would not otherwise have had. Before moving on to analyze further the political motivations and implications of hacktivism, it is helpful at this point to review some brief examples of hacktivist groups and their actions.

## FURTHER EXAMPLES OF HACKTIVIST ACTIONS

### Electronic Pressure Group Actions: The Etoy Campaign

Despite all the naysaying, the Net is offering individuals new opportunities to take action and giving ideas a better shot at taking hold. It allows and even encourages cooperation in virtual groups, and in the best of situations, a self-organizing countermatrix as well that can make short work of a highly organized and powerful corporation (Grether, 2000, para. 2).

Grether (2000) provides a full account of the 1999 Etoy campaign by activists created in response to the court action initiated by a commercial company in an attempt to remove an art collective's Web site domain name (*etoy*) because it was too close to their own (*etoys*). The company's action was implemented despite the fact the art collective had been operating under its name first and generated enough online ill will to generate a highly coordinated

campaign that incorporated various hacktivist (e.g., the Flood Net program) and public relations initiatives (e.g., mass mailings, countercourt actions, satirical mirror Web sites). The campaign was successful and the company was forced to retreat from its aggressively litigious stance. The incident illustrated the extent to which online actions can produce an unprecedentedly effective degree and speed of coordination constituting an important, new countervailing power to corporate influence.

### Culture Jamming

One two-dollar can of spray can reverse a hundred-thousand-dollar media campaign (Rushkoff, 1994, p. 281).

Although usually considered separately, culture jamming fits enough of this chapter's schematic requirements to be considered a form of hacktivism. Its basic purpose is to hack the symbolic codes of what its practitioners perceive to be an excessively commodified culture. It can be considered as a semiotic form of aikido, in so far as it seeks to use a minimum of effort to turn the strength of commercial culture back on itself (see also Klein, 2001, pp. 279–309). The Adbusters group, for example, uses techniques known as billboard banditry and subvertising to make small, but hugely significant, changes to hugely expensive advertising campaigns. One vivid example of this technique was the use of cheap spray cans on the giant billboard figures of gamine Calvin Klein models. In this case culture jammers used the hacker technique of reverse engineering to give the models on the posters "zipper mouths" and blacked out eyeballs and a consequently skeletal appearance. As the above quote demonstrates, this practice is not intrinsically technological; nevertheless, the new media and the algorithmic manipulability that underwrites them provide a range of novel possibilities for culture jamming. Thus, common hacktivist tactics such as *Web redirects*, in which Web sites are hijacked and their users redirected to politically significant sites (for instance Nike.com redirected to a site concerned with worker's rights), and *Web site defacements*, such as those that proliferated at the start of the Iraq war and around the long-running Palestinian–Israel conflict, which were directed at a range of targets (Al Jazeera, the U.S. military, etc.) by a range of interest groups (both for and against the action and its various participants) (Allen & Demchack, 2003), can be seen as examples of technologically driven forms of culture jamming.

To this cultural jamming we might also add forms of intervention at the level of both software and hardware. In the case of hardware, this can take the form of a reverse engineering of artifacts that deliberately shut out or artificially delimit the options of their users. For instance, Microsoft's entry in the game console market, the X-Box, contained a fairly decent Windows-only computer. Users, through the addition of a mod chip, were able to release this computer, install an alternative operating system, and use it in a manner of their choosing. Such hacking is political only to the extent that it asserts a freedom to modify over a proprietorial vision of technology, in the case of a joint project carried out by CAE and the

Carbon Defense League, a similar technological detournement of the Nintendo Game Boy was implemented for explicitly political purposes, in this case to draw attention to the ideological programming inherent in game design ([http://www.carbondefense.org/writing\\_4.html](http://www.carbondefense.org/writing_4.html)).

Perhaps of greater significance than this reverse engineering are attempts to develop forms of software that challenge or embody political positions, examples of which might include programs such as *Freenet*—an entirely decentered and encrypted person-to-person network whose *raison d'être* is the prevention of any form of control or censorship, which attempts to enshrine at the level of code the values of free speech—and a range of software developed to override attempts by various governments and other organizations to delimit access to the Internet on the behalf of their populations. On a more general level, the proliferation of hacks to evade state and commercial control over the flow and ownership of data, software, and hardware can be seen as a form of cultural jamming in that they attempt to preserve the decentralized free flow of information that for many is the Net's most important dimension (Deibert, 2003).

### Precision Targeted Satire: RTMark and the Yes Men

To restate a situationist expression, rather than “fighting alienation with alienated methods” (bureaucracy, political parties, militancy, deferment of pleasure), one uses derision, irony, laughter—all underground strategies which undermine the process of normalization and domestication which are the goals of the guarantors of the external and hence abstract order. (Maffesoli, 1996, p. 50)

The emphasis upon performance has been given a sustainedly satirical treatment by such groups as RTMark and The Yes Men. RTMark's name stems from the phrase *registered trademark* and its distinctive mode of operation rests upon its pastiche of corporate organizational forms. For example, in an imitation of the conventional stock market, it offers investments in imaginative stocks. The investments are made in the form of such countercultural stunts as the switching of the voice boxes in GI Joes and Barbie dolls by a group calling themselves the Barbie Liberation Organisation. The Yes Men have recently released an independent film of their stunts and have particularly focused their attentions upon the global economic policies of the World Trade Organization by misleadingly carrying out satirical presentations at various high-profile public events while pretending to be World Trade Organization representatives. Another example of this precision-directed satire was offered by re-code.com, which aimed at exposing the fallacy of the empowered consumer (perpetrated by sites such as priceline.com). It lets consumers dictate the price of purchase by providing users of the online site with the ability to access and manipulate the barcodes of popular products sold. Users were able to modify, download, and print barcodes that could then be attached to their item of choice. Although the creators of this site stressed that its purpose is solely

satirical, a number of companies, including Wal-Mart, took a less charitable view of its activities and currently re-code.com is the subject of a legal action.

### OPEN SOURCE AND FREE SOFTWARE: THE REBIRTH OF THE HACKING ETHIC?

Within the context of the issues under discussion, the emergence in the 1990s of the free software/open-source movement both confirms and consolidates many of the trends displayed by hacktivism, while also highlighting the perennial problems that plague the politicization of hacking. As stated above, the free software movement serves as a bridge between the ideals of the early generation of hackers and a new movement that has emerged in direct response to the increasing commodification of software and the Internet. We have spoken of tactical media as a synonym for hacktivism, and in this light, hacktivism can be seen as operating at the level of the message rather than the medium. In contrast, free software offers the possibility of an intervention in the structure of the medium because it renders the medium's design political. However, the politics of free software are a fraught matter, not least because the movement contains within itself a number of conflicting tendencies. Unlike hacktivism, which is irreducibly political, the politics of free software are in some respects extrinsic, that is to say the result of its context rather than a product of an explicit agenda. This resembles the problems faced by the first generations of hackers, with their predominant concern over the question of access, and like that generation the resolution of its immediate arena of conflict would possibly neutralize any wider political charge that the movement might possess. Certainly there are hackers among this community who see their work in political terms, not only as a challenge to the proprietorial model and monopolistic ethos of Microsoft and the like but also as a defense and assertion of fundamental freedom. But equally many of those who contribute to the project regard it simply in terms of an effective means for software design.

As a result, in 1998 the movement fractured into two factions when the Open Source Initiative, led by Eric Raymond, split from Richard Stallman's Free Software Foundation. The former claims to offer open-source software without “ideological tub-thumping” and a “losing attitude and symbolism” (<http://www.opensource.org/advocacy/faq.html>), arguing that OS is primarily a successful methodology for the development of software and as such is entirely compatible with the aims of big business. It has deliberately sought to meliorate those aspects of the movement that prove objectionable to corporate clients (not least a propensity toward long hair, beards, woolly hats, and comic T-shirts). In contrast, the free software faction has upheld the original hacker ethic and remains firm in the belief that free software partakes of a fundamental intellectual freedom. It argues that software should evolve in the way that science evolves, through the free exchange of information, for free software information should always be free (although as Stallman repeatedly points out the freedom he talks of is that of “free speech rather than free beer”). Despite

these differences, their common methodology is in direct conflict with that practiced by Microsoft. Indeed, the color of the rhetoric the latter has used to describe OS indicates the threat this model represents; thus, Steve Ballmer of Microsoft has described it as “un-American” and a “cancer.” Such pathological metaphors reveal the magnitude of the stakes involved, as do the infamous Halloween documents, a series of internal reports produced by Microsoft that describe free software as “long term credible” and a direct threat to Microsoft’s revenues (<http://www.opensource.org/halloween/links.php>). The crux of the contention is the question of source code. Microsoft and a range of other software developers uphold a proprietorial model in which the codes that underpin their software are unavailable to its users or rivals.

The core principles to which both factions of the free software movement subscribe and that have provoked such strong reactions can be summarized as follows (see Cramer, 2000):

Free Software may be freely copied.

Not only the executable binary code, but also the program source code, are freely available.

The source code may be modified and used for other programs by anyone.

There are no restrictions on the use of Free Software. Even if Free Software is used for commercial purposes, no license fees have to be paid.

There are no restrictions on the distribution of Free Software. Free Software may be sold for money even without paying the programmers.

Free software is not freeware or shareware; that is to say, it can be sold. However, even if this is the case, the source code remains available and open to modification by the user or other programmers. These principles, known collectively as copyleft, have rapidly evolved within the context of the Internet and accommodate its open architecture into the very process of software design. Indeed, much of this architecture was written as free software, not for ideological reasons but because it predates the commodification of code that took place in the 1980s. Free software emerged as a response to this process, and attempted to preserve within a legislative framework (the GNU License) the freedoms threatened by this model. In this manner the open architecture of the Internet, constructed in part from nonproprietary code, created an environment that facilitated the collaborative production of software. Thus the GNU/Linux system has been developed entirely online through the medium of e-mail and bulletin boards. In Microsoft’s words “the ability of the OSS [open-source software] process to collect and harness the collective IQ of thousands of individuals across the Internet is simply amazing.” In OS development, a multitude of unpaid console cowboys participate in a vast collaborative project, a system of cybernetic feedback in which the divisions between work and play and between user and consumer are continually transgressed for the sake of the product. This collectivism challenges both the self-serving mythos of the free market and the lone hacker, as well as the dictatorial hierarchy of conventional

project development. Moreover, as Cramer (2000) notes, it constitutes an archive that cannot be erased: the code, once written, is in the public realm and can be drawn upon by anyone. In this respect it offers an intimation of collective intelligence or, in Microsoft’s phrase, a “mindshare.”

The relation of open source to wider political questions is complex. Terranova (2000) argues that its breakdown of the distinction between consumer and producer reflects an extension of the market into every aspect of contemporary existence. DeLanda (2001) argues that despite its insistence on freedom, “the very fact that the [GNU] license acts as an ‘enforcement mechanism’ for openness shows how far its function is from one of just promoting ‘freedom’ (that is, Stallman’s original intention)” (para. 7). Eric Raymond (n.d.) argues for open source as gift economy, but as Richard Barbrook notes this economy exists within an inescapable relation to a commodity economy: “money commodity and gift relations are not just in conflict with each other, but also co-exist in symbiosis” (Barbrook, 1997, p. 137). Similarly, Stefan Merten, one of the organizers of the Wizards of OS conferences that have been held on a yearly basis in Berlin since the late 1990s, argues for the emergence of a General Public License society in which “immaterial,” intellectual, or “affective” labor would be exchanged along an open-source model (Merten, 2001). This immateriality and free software’s association with it has been the source of critique regarding the ultimate significance of open source. According to Matteo Pasquinelli,

Softwares are immaterial machines... Free Software... [in] its immateriality... often fails to clash with the real world. Even if we know that it is a good and right thing, we ask polemically: what will change when all the computers in the world will run free software? The most interesting aspect of the free software model is the immense cooperative network that was created by programmers on a global scale, but which other concrete examples can we refer to in proposing new forms of action in the real world and not only in the digital realm? (Pasquinelli, 2004, p. 3)

The supposed immateriality of contemporary labor is the product of a Western myopia that fails to see that material labor, rather than having disappeared, has merely been outsourced to number of developing countries. In these regions, the division between producer and consumer remains firmly entrenched, because many of the goods manufactured by the coolies of global economy remain beyond the economic reach of their producers. However, it is worth pointing out that free software (for sound economic reasons) has found a welcome in developing countries, for instance India, where a large number of skilled programmers are contributing to a range of OS projects (Moody, 2002, p. 317).

Such contradictions might suggest that open source, like the politicized hacking of the 1970s, is too mired in the contradictions of its milieu to constitute a viable challenge to the values of late capitalism. But, to the extent that it exists and produces a technically superior product

using methods that implicitly challenge the dominant values of contemporary economic thought, it stands as an index of possibilities. It demonstrates that the Internet can indeed support new productive relations and thus offers a positive model for movements such as hacktivism.

## ALL THAT IS SOLID MELTS INTO AIR

Marx and Engels famously declared in the *Communist Manifesto* that under capitalism:

All fixed, fast-frozen relations, with their train of ancient and venerable prejudices and opinions, are swept away, all new-formed ones become antiquated before they can ossify. All that is solid melts into air, all that is holy is profaned, and men at last are forced to face . . . the real conditions of their lives and their relations with their fellow men (Marx & Engels, 1977, p. 46).

This prophetic articulation of the dematerializing qualities of commodity culture has recently found its echo in the titles of a spate of pro-business books that celebrate the putative weightlessness of the digital economy. For example, business books such as *Living on Thin Air*, *The Weightless World*, and *The Empty Rain Coat* are all premised upon an acceptance of, if not excitement about, the spatial disorientation created by globalization, and the new information technologies that have brought about these conditions. As stated previously, radical protest movements have sometimes been suspicious of too close an involvement with the technologies of their perceived enemies. The hacktivist groups and activities highlighted in this chapter represent a much more positive engagement with the realities of an increasingly networked world. Rather than rail against the enframing and circumscribing qualities of global systems, these movements have recognized, in Lash's words, that "there is no escaping from the information order, [and] thus the critique of information will have to come from inside the information itself" (Lash, 2002, p. vii). There is thus a growing recognition among new social movements that any desire for change to the social order will have to make use of, but also change the nature of, its present communication channels. They have chosen to concentrate upon the concluding part of Marx and Engel's pellucid assertion, that is, a recognition with "sober senses" of the "real conditions of their lives and their relations with their fellow men."

From the critical antiglobalization perspective, the increased efficiency of communication flows enabled by the new information technologies is part of both the problem and the solution. The same trends that result in the phenomenon of the *maquiladoras* (swallow factories—named after the way the fast-moving bird touches down momentarily before swooping off again) also provide such opportunities for global cooperation as that practiced by the EDT and their high-tech support for otherwise fragmented and globally disparate groups of people. What is important here is the to-and-fro movement of co-optation and counterresponse that takes place between corporate and anticorporate philosophies. Just as the hacker

ethic became co-opted for the corporate requirements of Microsoft, so those wishing to oppose commercial forces do so in an adopt-and-adapt element of a system they oppose: free software is at once outside capitalism and within, where hacktivists in detouring the tools of economic globalization both challenge and acknowledge the reality of the system. In this light, Pasquinielli's (2004) dichotomy between the immateriality of cyberspace and the harsher conditions of the material world is too bald; it is a question not of testing one against the other, but of discovering the shifting and unstable alliances and the sudden conversions and adaptations that take place between the two.

## CONCLUSION

This chapter has provided a brief overview of the main features, protagonists, and underlying philosophy of a number of emergent technologically orientated challenges to the current informational hegemony. Perhaps it was only a matter of time before anticorporate protestors saw globalization as an opportunity as well as a threat, but as much as its techniques involve new high-tech means they are essentially in keeping with both the original hacker ethic and conventional Marxist analysis of capitalism in which it is asserted that commercial power contains the seeds of its own downfall. In less polemical terms, more mainstream economic analysis also recognizes some of the inherent tensions created in the increasingly immaterial new economy that has spawned hacktivism. The fact that commodities are becoming increasingly immaterial means that it can be difficult to assert proprietary rights over them. This is a problem that both the music and the film industries are presently grappling with as they attempt to deal with the implications of the growth of online file sharing. Yet the sublimation of fixed values described by Marx and Engels a century and a half ago has still not resulted in capital's downfall: the market's powers of recuperation are robust. The basic situation faced by commercial and radical groups alike is that the online world creates conditions of flux. The "space of flows" of the information society (Castells, 2000) creates opportunities and challenges for resistance and capital alike, and in the case of open source these two vectors meet in a single praxis. This chapter has shown that, in contrast, hacktivism's most striking feature is not so much its imaginative reappropriation of technological methods and infrastructures, but its determination to apply such techniques for a social, rather than merely a technical, end. In the past, protest movements have been ill-equipped to do little more than reactively berate the worst aspects of changing social conditions whereas their corporate opponents have surfed the wave of change. The various generations of hackers have produced resources for different beasts; new sharks may now be in the water.

## GLOSSARY

**Antiglobalization/Anticapitalism Movements** A new generation of protest movements that challenge the current neoliberal hegemony and attempt to draw attention to the intrinsically exploitative reality of free

- trade. They are distinguished by their decentralization, a lack of coherent ideology beyond what they oppose, and a willingness to engage in new methods of political protest.
- Culture Jamming** An attempt to overturn or expose the hidden agenda of cultural products by subverting their messages through low-tech means; rather than an external critique, it operates immanently at the level of specific cultural artifacts.
- Free Software** Software that includes its source code, which is available to all users who in principle can modify or contribute to its development. It is free as in “free speech” and not “free beer.” This freedom is ensured by the use of licenses, which preserve the freedom of the code.
- Hacker Ethic** The belief that information sharing and technical innovation is in itself a positive act and that it should not be constrained or artificially delimited.
- Hacking** The ingenuity-driven activity of manipulating or modifying technologies without respect to their original functions, which should be distinguished from *cracking*, a more destructive or transgressive form of hacking.
- Hactivism** The adoption of various procedures drawn from hacking for explicitly political ends; more generally, a recognition that political struggle in the 21st century necessarily includes information technologies.
- Microserfs** Term adopted from Douglas Coupland’s eponymous novel, which describes the lives and frustrations of Microsoft employees in the mid-1990s.
- Open-Source Movement** A faction of the free software movement, that embraces the distribution of source code, but that views this freedom in terms of market choice and a rejection of centralized state control in favor of a free-market model. The most vocal proponent of this vision is Eric S. Raymond.
- Source Code** Source code is written in the higher programming languages that allow programmers to manipulate and assemble binary codes. This source code is not necessary for computers to run programs.
- Virtual Sit-in** A virtual sit in, like its physical counterpart, aims to immobilize a target by obstructing its services. The coordinated deployment by numerous users to bring down Web sites by accessing them several times a minute until the site collapses is an example of a virtual sit-in.

## INTRODUCTION

When we think of spying, we think of James Bond or the characters in a John LeCarre novel. It is always covert. Its justifications are found in global national concerns and values. However, spying in the most traditional sense is no longer confined to covert operations between nations. Our government under the rubric of national security and the Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism (USA PATRIOT) Act is empowered to and does spy on its citizens, in their private and business lives. And we, its citizens, spy on each other.

The world searches for intelligence. Constantly. Governments pursue intelligence to better serve and protect their constituents. For-profit organizations seek intelligence to create better mousetraps, provide better services, and, in any event, enhance the balance sheet and shareholder value. Individuals seek intelligence to help themselves or others, to fend off or perpetrate an injustice, or simply to satisfy curiosity. The reasons people want to know would take a congressional library to catalog.

Business intelligence has many levels. Businesses need to understand the regulatory environment in which they must operate. They also must continuously develop and refine the kinds of products and services they offer to targeted consumers or customers. Enterprises also need

fully to understand how to create and maintain workplace environments that motivate employees to work hard and stay focused on the company's interests. And in this world of competition, knowing thy opponent is as good as knowing thyself, so millions of dollars are spent each year in the quest to learn everything about one's competitors. Much of the intelligence referred to here is called research and involves gathering information from diverse sources within the public record or that can be accessed once appropriate authority is obtained. Information begets databases that become profiles, are used to plot trends, and are mined for comparisons and potential advantages, all as part of determining a business' potential strategies and courses of action.

Spying, in fact, is the search for intelligence overtly as well as covertly. Although we tend to think of corporate spying as that which occurs on a business-to-business (B2B) level, B2B competitive intelligence is only one aspect of corporate spying. Businesses that spy on their employees by gathering information on computer usage, Internet access, Web sites visited, and e-mails sent and received. Some businesses also keep track of employees who access sensitive company information. Conversely, employees spy on their employers, sometimes secreting information about company operations for use as a whistleblower (a form of spying that is encouraged by public policy because it serves a greater

good) or to aid the company's competitors (which, more often than not, also serves the personal interest of the employee who shares company information with the competition).

There are many consequences of corporate spying. There are, of course, the fundamental ethical concerns. Legitimacy concerns, which arise from those ethical ones, may limit the deployment of spying in the individual and business community. Whether those legitimacy concerns will hold as our society increasingly becomes more global and less personal is an open question and beyond the scope of this chapter. We know that spying occurs. As a practical matter, companies spend vast sums of money erecting barriers to unauthorized access to sensitive information. We can expect that such expenditures will also increase. We can also expect that as a countermeasure to spying, like the flotsam and jetsam used by aircraft to misdirect guidance systems, companies will disseminate misinformation—at what societal cost? Spying becomes more personal as it targets individuals and invades our sense of, and right to, privacy. Where, if at all, does privacy exist in the corporate environment? Under what circumstances, if at all, is it permissible to read the private communications between an employee and family members or medical care providers? When can someone listen to your phone calls?

These are not easy questions to answer. Without ignoring the fundamental philosophical and ethical issues that are raised, we must ask first what parameters are permitted by the law. As a practical matter, the law sets the stage for whatever drama may unfold. The purpose of this chapter is to acquaint the reader with the law as it pertains to each type of spying so that the reader can have a better idea of what is permissible and what plainly is not, and help the reader decide whether there are some forms of spying that may not be spying after all. The authors hope that this knowledge of the law will help inform the reader's choices including the reader's decisions about what safeguards or defenses he or she may wish to erect.

## A SERIES OF QUESTIONS AND A HYPOTHETICAL

A Harvard law professor, who later was to become a federal judge, was fond of teaching the law by asking his students the following question: "ask yourself what your mother would have done and that is probably what the law requires." There are problems of course with this question, not only because it is an oversimplification, but also because it assumes an objective reasonable mother who may or may not exist for any of us. It does, however, show that the law is often rooted in our own visceral sense of right and wrong. Answering a few hypothetical questions will help you grapple, in real terms, with the kinds of circumstances in which the law will be applied.

Everyone today uses the Internet to research and gather information. When, however, does that use become spying? Let's test out your views with the following questions. Keep track of your answers.

Question	Yes	No
1. Is it spying to gather information using software that searches the Internet?		
2. Does your answer change if the search software gains access to an area of a Web site by cracking a protected code?		
3. Does your answer change if the information is not publicly available on the site?		
4. Is it spying when a company's Web site inserts a cookie in the computer of each visitor to the Web site for the purpose of gathering personal identifying information about each visitor?		
5. Is it corporate spying to create a mirror image of the data in a Web site and the code that is used to create the Web site when those data and code are released publicly?		
6. Does your answer to the last question change if the company that is copying the data and code is a direct competitor of the owner and host of the Web site?		

As discussed in the Introduction, corporate intrusion on an individual's entitlement to privacy is a paramount issue. Let's explore that issue and your views with a hypothetical fact pattern, pieced together from actual events.

Lorraine works for a company that tracks, retrieves, warehouses, and returns consumer goods. Its operations include a call center that makes and receives calls from the customers of its clients for a variety of reasons, including tracking defective inventory. Lorraine signs a nondisclosure agreement when she begins her employment and, over the course of 2 years, develops casual relationships with employees of her employer's customers as well as some retail customers from whom goods have been retrieved. Lorraine's attitude about her employment and her employer begins to sour; coincidentally, she takes an extended sick leave.

One morning she attempts to return to work, staying less than 2 hours. During that time, however, she copies to a disk the contact information for some of the people with whom she began developing casual relationships. She also sent this same information by e-mail from her computer in the office to her personal e-mail address accessible from her home computer. Lorraine never returns to work. In the days immediately after her departure, Lorraine's supervisor reviews the log of Lorraine's e-mails and the content of Lorraine's voice mail messages and discovers that the company's contact information has been taken by Lorraine for personal use. In response, the company sends two supervisors to Lorraine's house, demanding immediate access to Lorraine's home computer to search for any information belonging to the company, which Lorraine refuses.

When can companies monitor employees? When can information accessible to an employee while on the job become usable by the employee outside of work? Can employees give away their right to keep certain communications private?

We will attempt to answer all of these as well as other questions in this chapter.

## THE COMMON LAW REMEDIES AND APPROACHES

The law in the United States has evolved over time. We act against a backdrop of judicial decisions that extend back hundreds of years. These decisions form a body of law known as the common law. It differs from statutes in that there is often no legislative enactment that describes the boundaries of rightful or wrongful conduct. The common law, although there are consistent trends and approaches, varies in nuance from state to state. Accordingly, what is set forth in this chapter are the broad strokes of the common law as they pertain to the issue of corporate spying.

### The Concept of Proprietary Rights: Trade Secrets

For many years, unless an idea was patentable, the primary protection for internal business data, confidential or proprietary information, and computer code was through the common law doctrine of trade secrets (*Kewanee Oil Co. v. Bicron Corp.*, 1974). Generally, a trade secret might be considered any internal, nonpublished manufacturing know-how, drawings, formulas, or sales information used in a trade or business that has commercial applicability and that provides a business with some strategic advantage. Such information, so long as it was (a) not published or disseminated to others who were not obligated to maintain its confidentiality,<sup>1</sup> and (b) maintained in confidence with the protecting organization, could be protected as a trade secret.

The law of trade secret thus recognized a business's ownership or proprietary interest in such information, data, or processes. There are, however, important practical limitations on the application of trade secret protection. First and foremost, for any product sold in the market the law does not protect against a competitor seeing the product and then using it to figuring out how to manufacture like or similar items. Competitors are therefore free to *reverse engineer* a product so long as the reverse engineering is done wholly independently.

The second caveat is that an organization has to prove not only that the information qualifies for trade secret protection, but also that it protected the secrecy of the information as required by the law of the applicable jurisdiction. This means that ownership will be a matter not of record but of case-by-case proof, making enforcement of trade secret protection time consuming and expensive later on. Generally, the proof required consists of showing that there was an active security program in place that was sufficient to protect the information as confidential. Various programs may be deemed adequate, depending on the circumstances, but usually such programs have the following in common:

- An inventory of trade secret information that is periodically updated
- A security program to protect the technology at issue, often on a need-to-know basis with clear marking of information as confidential, access restricted
- A written description of the security program that is provided to all employees
- An enforcement officer or oversight procedure
- An enforcement program, including litigation, if necessary, to enjoin unauthorized access or distribution

In the field of computing, these principles often mean that source code or other readable formats should be secured in a locked file and marked confidential. All representations of the code as stored on magnetic or other medium should be marked confidential and secured. Computerized information should be password protected with restrictions on circulation of the password and periodic password changes.<sup>2</sup> A notice of confidentiality should be displayed as soon as access to the program is obtained, with appropriate warnings on limitation of use. Levels of access should be controlled so that privileges to copy, read, and write are appropriately restricted. Surveillance of entries and log-on should be routinely conducted to verify that there has been no unauthorized entry. Finally, periodic audits should be conducted to test and substantiate the security procedures.

Security and trade secret law are forever linked together. A trade secret cannot exist without such security. The watchwords "Eternal vigilance is the price of liberty," which have often been attributed to Thomas Jefferson, in the context of business information protection should be restated as "Eternal vigilance is the price of trade secret protection." It is not as catchy a phrase, but it is the price each business must pay if it relies in whole or in part on trade secret law for protection.

### The Employee and the Concept of Fiduciary Duty

#### An Employee's Fiduciary Duty

Mobility of employees is a hallmark of today's business world. Job expectations are defined not in years, but in months. Employees may be hired for specific projects in which employment is a form a consulting, lasting only as long as the special assignment. But it was not always so. Out of a different era came the notion that an employee owes to his or her employer the fiduciary duty of utmost loyalty. As part of that fiduciary duty, an employee was prohibited from using any property that belonged to his or her employer in competition with the employer or for personal gain. An employee, however, was entitled to retain and use for whatever purpose his or her own skill and knowledge, which arguably could include contacts that he or she developed over the course of his or her employment if such contacts were not trade secrets.

Although the doctrine of fiduciary duty is a starting point, the limits of the doctrine can spawn endless

<sup>1</sup> The need to protect the information from general dissemination is what, in part, has given rise to the practice of nondisclosure agreements.

<sup>2</sup> Given the increasing use of outsourcing, protecting computer information and databases as trade secrets calls for even more elaborate programs. One should be especially careful regarding access to passwords.

arguments and lawsuits. The first step to giving the concept of fiduciary duty real teeth is to educate one's employees about what is protected information, what is treated as confidential, what is a trade secret, and the security measures that the employee must observe. The education process should begin with an employee handbook or a manual that is dedicated to the topic of the company's confidentiality and security program.

### Contractual Additions

But education alone is not enough. Especially when we are dealing with technology, a system of contractual system of checks and balances needs to be built in. On its simplest level, an employee who creates a product for a company can be motivated to maintain the proprietary nature of that product by rewarding the employee for its financial success. But what of other employees, who have access to the same proprietary data in the ordinary course of their employment but do not directly share in the rewards from the success of the product? And what of the first employee who, while creating the first product, also learned of ways to develop another competing product that will accomplish the same task but cheaper or quicker?

The answer to these concerns has been to require an employee, when he or she is most highly motivated at the start of any employment, to sign an agreement to maintain the confidentiality of business information and not to compete for some agreed on period of time on the termination of his or her employment. Such restrictive covenants usually have to be supported by consideration—some quid pro quo. When people are first hired, employment is normally sufficient consideration. Because these covenants are viewed as anticompetitive, some states will not enforce covenants not to compete and others will blue pencil them, lining out provisions that a judge views as unreasonable. Particularly for significant employees, an employer should consider augmenting the consideration to strengthen the enforceability of the restrictive covenants. The most commonly used devices are bonuses tied to the restrictive covenants or posttermination severance that is also paid in exchange for the employee honoring the covenants.

Although most of these types of restrictive covenants focus on protection of the employer's information, that is, the obligation not to disclose the information to anyone who is not authorized by the employer to receive it, one commonly overlooked clause is disgorgement of employee generated information. This is especially important for technology-driven business. Such clauses generally require that the employee (a) disclose to the employer all discoveries, know-how, improvements, inventions, and the like during the term of his or her employment (and sometimes after if his or her employment served as a springboard) and (b) assign over to the employer all rights to the ownership of such intellectual property.<sup>3</sup> Any provisions that seek to reach beyond the term of employment must be reasonable in scope

and thus must clearly relate to the employee's activities and the work assignments during the employee's employment.

### Trespass

Trespass is a common law concept that we are all familiar with when applied to land. We've all seen and probably at some point in our youth violated the no-trespassing signs that were posted on an unfriendly neighbor's property. Trespass is also a concept that can apply to computers and informational databases. Courts have been taking older concepts and reapplying them to new situations.

In *eBay, Inc. v. Bidder's Edge, Inc.* (2000), the federal district court granted eBay an injunction forbidding Bidder's Edge from using a software robot to scrape information from eBay's Web site. The court based the injunction on its finding that accessing the Web site in a manner that was beyond eBay's posted notice (there were actual letters of objection) constituted a trespass. The court reasoned that the "electronic signals sent by Bidder's Edge to retrieve information from eBay's computer system [were] sufficiently tangible to support a trespass cause of action." The court further viewed the ongoing violation of eBay's fundamental right to exclude others from its computer system as creating sufficient irreparable harm to warrant an injunction. Thus, it was not necessary that eBay prove that the access actually interfered with the operation of the Web site. Rather, proof of the "intermeddling with or use of another's personal property" was sufficient to establish the cause of action for trespass. What is significant here is that eBay did permit others to access its Web site under license, and the court viewed conduct that exceeded the licensed use, on notice to the violator, to be a trespass.

However, the applicability of trespass to unauthorized computer activity is not settled. Where trespass involves an object, rather than land, there must not only be improper use, but also some harm to the physical condition or value of the object or the misuse must deprive the rightful owner of the use of the object for a substantial period of time. The two must be causally related. In *Intel v. Hamidi* (2003), the California Supreme Court reversed a lower court's banning a former employee from sending unsolicited e-mails on the grounds of trespass. The court thought that the reach of the doctrine had been extended too far, concluding that bad analogies (i.e., viewing servers as houses and electronic waves as intrusions) create bad law. The court declined to view computers as real property. Rather, finding that they were like other personal property, the court found that this communication was no different than a letter delivered by mail or a telephone call. In short, the court declined to find a trespass because there was an "unwelcome communication, electronic or otherwise" that had fictitiously caused an "injury to a communication system." Here there was no injury to the computer system, although Intel claimed injury to its business.

<sup>3</sup> One should also be aware of the concept of a *work for hire* as it applies in the field of copyrights to works that are created within the scope of employment and that are specially commissioned. The corollary doctrine is that of shop rights. The shop right doctrine usually applies to works

made within the scope of employment or to products created using the resources, such as facilities, of the employer. The effect of the shop rights doctrine is to give the employer a nonexclusive license, but not ownership, to use the employee's work.

*Intel v. Hamidi* (2003) simply warns against overbreadth of application of the concept of trespass. If injury to the computer system can be demonstrated, then the concept of trespass does lie as a tool in the arsenal of remedies assuming that the trespasser can be identified.

## Terms of Use

Terms of use can constitute a contract with respect to Web site usage. Thus, in any situation where electronic access is requested or permitted, the terms and conditions of use, together with an acknowledgement that such terms have been seen and consented to, can be enforced as restricting usage. In *Register.com, Inc. v. Verio, Inc.* (2004), the Second Circuit upheld an order enjoining Web site access primarily on the issue of contract. There, as described by the Second Circuit, the defendant Verio, against whom the preliminary injunction was issued, was engaged in the business of selling a variety of Web site design, development, and operation services. In the sale of such services, Verio competes with Register's Web site development business. To facilitate its pursuit of customers, Verio undertook to obtain daily updates of the WHOIS information relating to newly registered domain names. To achieve this, Verio devised an automated software program, or robot, which each day would submit multiple successive WHOIS queries through the port 43 accesses of various registrars. Upon acquiring the WHOIS information of new registrants, Verio would send them marketing solicitations by e-mail, telemarketing, and direct mail. To the extent that Verio's solicitations were sent by e-mail, the practice was inconsistent with the terms of the restrictive legend Register attached to its responses to Verio's queries.

Register at first complained to Verio about this use and then adopted a new restrictive legend on its Web site that undertook to bar mass solicitation "via direct mail, electronic mail, or by telephone." The court concluded that Verio's conduct formed a contract, like buying an apple at a roadside fruit stand, which Verio breached:

We recognize that contract offers on the Internet often require the offeree to click on an "I agree" icon. And no doubt, in many circumstances, such a statement of agreement by the offeree is essential to the formation of a contract. But not in all circumstances. While new commerce on the Internet has exposed courts to many new situations, it has not fundamentally changed the principles of contract. It is standard contract doctrine that when a benefit is offered subject to stated conditions, and the offeree makes a decision to take the benefit with knowledge of the terms of the offer, the taking constitutes an acceptance of the terms, which accordingly become binding on the offeree. See, e.g., Restatement (Second) of Contracts §69 (1)(a) (1981) ("Silence and inaction operate as an acceptance . . . where an offeree takes the benefit of offered services with reasonable opportunity to reject them and reason to know that they were offered with the expectation of compensation.")

\*\*\*\*

Returning to the apple stand, the visitor, who sees apples offered for 50 cents apiece and takes an apple, owes 50 cents, regardless whether he did or did not say, "I agree." The choice offered in such circumstances is to take the apple on the known terms of the offer or not to take the apple. As we see it, the defendant in Ticketmaster and Verio in this case had a similar choice. Each was offered access to information subject to terms of which they were well aware. Their choice was either to accept the offer of contract, taking the information subject to the terms of the offer, or, if the terms were not acceptable, to decline to take the benefits

*Id.*, at 403; and was also a trespass because

The district court found that Verio's use **[\*\*31]** of search robots, consisting of software programs performing multiple automated successive queries, consumed a significant portion of the capacity of Register's computer systems. While Verio's robots alone would not incapacitate Register's systems, the court found that if Verio were permitted to continue to access Register's computers through such robots, it was "highly probable" that other Internet service providers would devise similar programs to access Register's data, and that the system would be overtaxed and would crash. We cannot say these findings were unreasonable.

*Id.*, at 405. The court declined to reach the issue if such conduct also violated the Computer Fraud and Abuse Act.

Similarly, although in a different setting, in *ProCD v. Zeidenberg* (1996), ProCD sold a compact disk with non-copyrightable data. Access to the data, however, was controlled by a license agreement; if there was no acceptance, there was also no access. The license agreement prohibited the use of the data for any commercial use. Zeidenberg took the data and posted it on a Web site that he used commercially to sell advertising. Thus, the data were being used to attract visitors. The court found the license limitation on use enforceable.

The importance of this decision is that so long as the owner prominently specifies the limitations, the restrictions can become a contract that is accepted by accepting the benefits of access and be one safeguard against misuse of the access.

## THE WIRETAP ACT

When we think about spying of any kind, we think about listening to or reading communications transmitted between people whom we believe are conveying information that we need. The question is whether, and to what extent, government agencies, corporations, and individuals can intercept those communications while they are being transmitted or retrieve them from either a temporary or a permanent destination. The answer to this

question is influenced substantially by federal laws concerning wiretaps.

## Electronic Communications

The Omnibus Crime Control and Safe Streets Act of 1968, generally referred to as the federal Wiretap Act, established the general parameters for permitted interception of communications by law enforcement. As originally crafted, the Wiretap Act covered only “wire and oral communications.” In 1986, Congress enacted the Electronic Communications Privacy Act (ECPA), which amended the Wiretap Act and created the Stored Communications Act (SCA) to “update and clarify federal privacy protections and standards in light of changes in computers and telecommunication technologies” (Senate Report No. 99-541, 1986).

The critical update for our current purposes extended the Wiretap Act’s coverage to include “electronic communications,” which is defined as “any transfer of signs, signals, writing, images, sounds, data, or intelligence of any nature transmitted in whole or in part by a wire, radio, electromagnetic, photo-electronic or photo-optical system” (Wiretap Act, 1968, §2510(12)). “Intercept” is defined as “the aural or other acquisition of the contents of any wire, electronic, or oral communication through the use of any electronic, mechanical, or other device” (Wiretap Act, §2510(4)). Consequently, the Wiretap Act now makes it an offense to “intentionally intercept . . . any wire, oral, or electronic communication” (Wiretap Act, §2511(1)(a), emphasis added; *Konop v. Hawaiian Airlines, Inc.*, 2002).<sup>4</sup>

For corporate and governmental spies, all was not lost. Under the consent of a party exception, it is permissible to intercept communications where “one of the parties to the communication has given prior consent to such interception” (Wiretap Act, 1968, §2511(2)(d)).<sup>5</sup> The requisite consent may be express or implied from the surrounding circumstances.<sup>6</sup> Furthermore, an employer may obtain consent by informing the employee of the monitoring practices in an employment contract or an employee handbook.<sup>7</sup>

<sup>4</sup> Noting the legislative history of the ECPA indicates that Congress wanted to protect electronic communications that are configured to be private, such as e-mail and private electronic bulletin boards.

<sup>5</sup> One should note, however, that as a result of the USA PATRIOT Act, an order from a U.S. or state attorney general is sufficient to permit the government to install a device to record electronic transmissions for up to 60 days where related to an ongoing criminal investigation. The Federal Bureau of Investigation (FBI) has in its arsenal a program known as Carnivore that essentially tracks a target’s online activity. Recently, freedom of information inquiries by the Electronic Privacy Information Center suggests that the FBI has discontinued use of Carnivore because Internet service providers, in light of the USA PATRIOT Act, may be providing information regarding a user’s Internet traffic directly to the government.

<sup>6</sup> According to *Griggs-Ryan v. Smith* (1990), holding consent may be implied where the individual is on notice of monitoring of all telephone calls.

<sup>7</sup> Federal law allows states to enact their own wiretapping statutes provided that the state statutes are at least as strict as the federal counterpart. Bernabei (2003) notes that most states have adopted statutes that mirror the federal statutes and that at least 10 states, including Massachusetts, require the consent of both parties before the employer can record a conversation.

Under the provider exception, a provider of electronic communication services “whose facilities are used in the transmission of a wire or electronic communication, [may] intercept, disclose or use that communication in the normal course of his employment while engaged in any activity which is a necessary incident . . . to the protection of the rights or property of the provider of that service” (Wiretap Act, 1968, §2511(2)(a)(i) (Supp. 2003)). This exception may allow an employer to lawfully intercept communications to detect an employee’s unauthorized disclosure of trade secrets to third parties.<sup>8</sup>

## The Contemporaneous Transmission Requirement

The Wiretap Act only prohibits interceptions of electronic communications” (Wiretap Act, 1968, §2511(1)(a)), a term that has been more narrowly defined by the courts than the definition in the act might suggest. The definition of interception provides that an individual intercepts a wire, oral, or electronic communication “merely by *acquiring* its contents, regardless of when or under what circumstances the acquisition occurs” (*Konop v. Hawaiian Airlines, Inc.*, 2002, 302 F.3d at 876, emphasis added). In the context of this section, a serious question arose about the legality of intercepting electronic communications as they were being transmitted and once they were stored, either temporarily or permanently. Although “Congress intended to liberalize one’s ability to monitor wire communications while it sought to make the monitoring of electronic communications more difficult” (*Konop v. Hawaiian Airlines, Inc.* 2002, 302 F.3d at 876), courts have consistently held that Congress intended to make acquisitions of electronic communications unlawful under the Wiretap Act “*only if they occur contemporaneously with their transmissions.*”<sup>9</sup>

In recent years, the courts have attempted to apply the contemporaneous transmission requirement to various situations. For example, cookies used to recover personal data from visitors to a Web site constitute an interception of a contemporaneous electronic communication and a violation of the Wiretap Act (*In re Pharmatrac, Inc.*, 2003). Noting that electronic communications are generally in transit and in storage simultaneously, the court reasoned that users communicated simultaneously with the pharmaceutical client’s Web server and with the software company’s Web server and, thus, the information was acquired contemporaneously with its transmission.

<sup>8</sup> According to *Briggs v. Am. Air Filter Co.* (1980), a holding employer could monitor employee’s communication “when [the] employee’s supervisor [had] particular suspicions about confidential information being disclosed to a business competitor, [had] warned the employee not to disclose such information, [had] reason to believe that the employee is continuing to disclose the information, and [knew] that a particular phone call is with an agent of the competitor.”

<sup>9</sup> See, for example, *Wesley Coll. v. Pitts* (1997); holding that the act criminalizes only the interception of electronic communications contemporaneously with their transmission, not once they have been stored); *Payne v. Norwest Corp.* (1995); holding the appropriation of voice mail or a similar stored electronic message does not constitute an interception under the Wiretap Act); *Steve Jackson Games, Inc. v. United States Secret Service* (1994); holding that the government’s acquisition of e-mail messages stored on an electronic bulletin board system, but not yet retrieved by the intended recipients, was not an interception under the Wiretap Act).

Where electronic transmissions are found in random access memory or on the hard drive, they are stored communications and can be retrieved because they are outside the Wiretap Act.<sup>10</sup> Similarly, an e-mail that is recovered after it has been sent and received does not satisfy the contemporaneous transmission requirement and therefore has not been intercepted under the Wiretap Act (*Eagle Investment Systems, Corp. v. Tamm*, 2001). Perhaps in response to these and other decisions, in 2001 Congress amended the Wiretap Act to apply the contemporary transmission requirement to wire communications that could not be retrieved, thereby permitting the recovery of stored wire communications.<sup>11</sup>

### ***Konop v. Hawaiian Airlines, Inc.***

The *Konop* decision appears to be the most oft-cited case on the issue of interception under the Wiretap Act. Konop, the plaintiff, was an airline pilot who created and maintained a Web site where he posted bulletins critical of his employer, Hawaiian Airlines, Inc., and the airline union. Konop controlled access to his Web site by requiring visitors to log in with a user name and password and by creating a list of authorized users.

An officer of Hawaiian Airlines asked one such authorized user for permission to use his name to access the Web site. The officer logged on several times, and another officer, using the same technique, also logged on to view the information posted on Konop's bulletin. Konop eventually filed suit against Hawaiian Airlines, alleging that it violated the Wiretap Act when its officer gained unauthorized access to Konop's Web site.

The court first reiterated that the act only prohibits interceptions of electronic communications. Interception, the court held, requires that the party acquire the information contemporaneous with its transmission and not while it is in electronic storage. In this case, the court concluded that the employer did not violate the Wiretap Act because the officers accessed an electronic communication located on an idle Web site, which did not satisfy the contemporaneous transmission requirement.

## **THE STORED COMMUNICATIONS ACT**

Unlike the Wiretap Act, the SCA, as its name suggests, establishes the limitations of access to stored communications (i.e., communications accessed *after* their transmission) (Bernabei, 2003, p. 2). Specifically, the SCA makes it unlawful to "intentionally access...without authorization a facility through which an electronic communication service is provided...and thereby obtain..., alter..., or prevent...authorized access to a wire or electronic communication while it is in *electronic storage*" (18 U.S.C. §§2701(a)(1), 2707(a); emphasis added). The SCA defines "electronic storage" as "(A) any temporary,

intermediate storage of a wire or electronic communication incidental to the electronic transmission thereof; and (B) any storage of such communication by an electronic communication service provider for purposes of backup protection of such communication" (18 U.S.C. §2510(17), incorporated by 18 U.S.C. §2711(1)). The SCA exempts from liability conduct "authorized...by the person or entity providing a wire or electronic communications service" (18 U.S.C. §2701(c)(1)) or "by a user of that service with respect to a communication of or intended for that user" (18 U.S.C. §2701(c)(2)).

### **Electronic Storage: Backup Files**

The essential element that separates the SCA from the Wiretap Act is that the accessed communications reside in electronic storage. Therefore, the first question is what constitutes electronic storage. In *Theofel v. Farey-Jones* (2004), the U.S. Court of Appeals for the Ninth Circuit attempted to answer this question.

In *Theofel*, overzealous lawyers for Farey-Jones secured, through a subpoena issued to an Internet service provider (ISP), e-mails sent and received by their opponents in the lawsuit, a company called Integrated Capital Associates (ICA). The subpoena requested from the ISP virtually every e-mail ever sent or received by ICA and its employees. In response, the ISP posted a smattering of the e-mails on a Web site accessible to Farey-Jones and its lawyers. When ICA learned of these activities, they sued Farey-Jones for, among other things, violation of the SCA.

According to the court in *Theofel*, Congress recognized that users of ISPs have a legitimate interest in protecting the confidentiality of communications in electronic storage at a communications facility. Moreover, this legitimate interest cannot be overcome by fraud or by someone who knowingly exploits a mistake that permits him or her access to what is otherwise protected. The court found that the use of the subpoena to access ICA's e-mails when it was reasonably plain, at least to counsel, that the subpoena was invalid, negated any apparent authority that Farey-Jones and its lawyers may have had to view ICA's e-mails.

Farey-Jones claimed that the ICA e-mails were not in electronic storage and therefore no violation of the SCA occurred. The court disagreed. As stated above, electronic storage exists when messages are stored on a temporary, intermediate basis as part of the process of transmitting the message to the recipient and when messages are stored as part of a backup process. In this instance, the court found that the e-mails, which had apparently been delivered to their recipients, were stored by the ISP as part of its backup process for retrieval after initial receipt. Access to those e-mails was therefore protected by the SCA, which Farey-Jones and its lawyers violated.

### **Electronic Storage: Temporarily Stored Communications**

Recent cases interpreting the meaning of "temporary, intermediate storage...incidental to" transmission of the communication have adhered to the letter of the law more than its spirit. In two cases involving the installation of cookies that were subsequently accessed by software

<sup>10</sup> In *United States v. Councilman* (2003), a Wiretap Act count was dismissed against an e-mail service provider who was charged with attempting to use electronic communications passing through his service for commercial gain.

<sup>11</sup> USA PATRIOT Act §209, 115 Stat. at 283 (2001); *Konop v. Hawaiian Airlines, Inc.*, 302 F.3d at 876-878 (2002); "The purpose of the recent amendment was to reduce the protection of voice mail messages to the lower level of protection provided other electronically stored communications."

companies for commercial gain, the courts have held that cookies are permanently (or at least indefinitely) installed in the consumer's hard drive and therefore cannot be considered "temporary, intermediate storage" (*In re DoubleClick, Inc. Privacy Litigation*, 2001; *In re Toys R US, Inc. Privacy Litigation*, 2001). The *DoubleClick* decision also emphasized that the temporary, intermediate storage element of the SCA means what it says, that is, that the prohibited conduct involves only the unauthorized access to communications while they are being temporarily stored by an intermediate and does not include access to stored messages after they have been received. In the context of an employer's right to examine an employee's e-mails, the employee will have no claim that his or her employer has violated the SCA when the employer opens e-mails sent or received by the employee once the e-mail has been either received or discarded (*Fraser v. Nationwide Mut. Ins. Co.*, 2003).

## THE COMPUTER FRAUD AND ABUSE ACT

### Prohibited Behavior and Damages

In 1984, Congress passed the original version of the Computer Fraud and Abuse Act (CFAA). The general purpose was to protect federal interest computers by criminalizing intentional and unauthorized access to those computers that resulted in damage to the computers or the data stored on them. The statute was substantially amended in 1986 (Pub. L. 99-474) and again in 1996 (National Information Infrastructure Protection Act of 1996, Pub. L. 104-294) and now contains both criminal and private civil enforcement provisions.

The statute proscribes the following activities:

- (a) Knowingly accessing a computer without authority or in excess of authority, thereafter obtaining U.S. government data to which access is restricted and delivering, or attempting to deliver, the data to someone not entitled to receive them
- (b) Intentionally accessing a computer without authority or in excess of authority and thereby obtaining protected consumer financial data
- (c) Intentional and unauthorized access of a U.S. government computer that affects the use of the computer by or for the U.S. government
- (d) Accessing a computer used in interstate commerce knowingly and with the intent to defraud and, as a result of the access, fraudulently obtaining something valued in excess of \$5,000
- (e) Causing damage to computers used in interstate commerce by (i) knowingly transmitting a program, code, and so forth that intentionally causes such damage, or (ii) intentionally accessing the computer without authority and causing such damage<sup>12</sup>
- (f) Knowingly, and with the intent to defraud, trafficking in computer passwords for computers used in interstate commerce or by the U.S. government

- (g) Transmitting threats to cause damage to a protected computer with the intent to extort money or anything of value

The lynchpin among the relevant decisions concerning access to data under the CFAA is whether the access is without authority or in excess of authority. The factors considered by the courts include the steps taken by the owner of the information to protect against disclosure or use, the extent of the defendants' knowledge regarding their authority to access or use the data, and the use(s) made of the data after gaining access. The legislative history indicates that the statute was intended to "punish those who illegally use computers for commercial advantage" (S. Rep. No. 104-357, pp. 7-8).

Broadly speaking, there are two sets of circumstances to consider. In the first instance, is the actual access authorized either expressly or impliedly? In the Internet context, in which there is a presumption of open access, the site or data owners must show that they took some steps to protect the contents of their site and to limit access to the data at issue (*Register.com, Inc. v. Verio, Inc.*, 2000). Once those steps are taken, the protection constitutes a wall through which even automated search retrieval systems may not go without express permission. Without the wall, there must be some evidence of an intent to access for an impermissible purpose, as when Intuit inserted cookies into the hard drives of home computers.<sup>13</sup>

Second, has the authorized access been improperly exceeded? Generally speaking, those who use their permitted access for an unauthorized purpose to the detriment of the site or data owner have violated the CFAA. Examples include employees who obtain trade secret information and transmit it via the employer's e-mail system to a competitor for which the employee is about to begin work (*Shurgard Storage Centers, Inc. v. Safeguard Self Storage, Inc.*, 2000); using an ISP subscription membership to gain access to and harvest e-mail addresses of other subscribers to transmit unsolicited bulk emails (*America Online, Inc. v. LCGM, Inc.*, 1998); and using access to an employer's email system to alter and delete company files (*U.S. v. Middleton*, 2000).

The criminal penalties range from fines to imprisonment for up to 20 years for multiple offenses. As discussed in the Piracy section below, the CFAA has become a prominent element of claims by the U.S. government and private parties seeking to protect data that are not always protected by other statutory schemes.

## Its Application to WebCrawling and Bots

Web robots or *bots* have become widespread to scrape data from Web sites. All of those data are generally available to the public. That is, any individual can access the same information but not with the speed or accuracy of

<sup>12</sup> See *Hotmail Corporation v. Van\$ Money Pie, Inc.*, 1998.

<sup>13</sup> *In Re Intuit Privacy Litigation* (2001). But see *U.S. v. Czubinski* (1997), where the Court of Appeals found that an Internal Revenue Service (IRS) employee who accessed private tax information in violation of IRS rules but did not disclose the accessed information could not be prosecuted under 18 U.S.C. 1030(a)(4) because he lacked an intent to deprive the affected taxpayers of their right to privacy.

a Web spider. But when does such scraping run afoul of the CFAA? To what extent does the law protect site operators or company data from penetration by an outside third party?

The key to the analysis under the CFAA is to ask whether the data are in fact publicly available. Are there technical barriers such as passwords or codes that have to be circumvented? Do the terms of use prohibit access or use other than by an individual consumer? These questions are critical to making a determination whether the access either exceeds authority or is without authority under the CFAA.

If the answer to either one of these questions (or similar questions) is yes, one needs to consider access carefully because such access and downloading of data are likely to violate the CFAA. In *EF Cultural Travel v. Zefer Corporation*, Zefer designed a Web bot to scrape trip and pricing information from the Web site of EF Cultural Travel (EF) for use by a competitive travel Web site. The bot, designed by Zefer, downloaded the information by calling repetitive uniform resource locators on which each separate trip and pricing information was stored, reading the source code for the key features, and storing the information on a spreadsheet. The bot did so in a fashion not to burden or interfere with EF's Web site. Once gathered, the information was turned over to a competitor who used the information to adjust price and trip information it offered. Zefer's scraping did not occur continuously, but only on two dedicated occasions. EF sued, claiming that a violation of the CFAA had occurred. The First Circuit Court of Appeals disagreed, refusing to read into what is or is not authorized under some "reasonable expectations" standard, instead requiring the Web site operator to expressly state any limitations on access in its terms and conditions. On remand to the Federal District Court, the court, following the First Circuit, granted summary judgment for Zefer.

### Simple Preventive Measures

Not surprisingly, there are several methods for preventing unauthorized access in the first instance and, if unsuccessful nonetheless, prevailing in any subsequent claim arising under the CFAA. Perhaps the most obvious measure, and one that the First Circuit Court of Appeals underscored, is to make sure that each visitor to a Web site is adequately notified that the owner of the site intends only limited use or access to the data on the site. The notice can take many forms.

For example, a detectable message easily identifiable on a home page warning visitors that the posted information is available only for viewing and not for use in any manner adverse to the host's interests would do the trick. Understandably, most Web hosts are reluctant to post such a blatant limitation—it's not necessarily good for business. For those interested in an equally effective but less direct message, an increasingly common practice is to compel site visitors to register before gaining access to links and other pages available through the home page. The more difficult the registration process, the greater the host's apparent intent to restrict access to and use of the information that will be accessible after registration is completed.

Those hosts that require the payment of money, some kind of membership, or an access agreement before providing access establish what, for purposes of statutes such as the CFAA that criminalize unauthorized access, will most often be seen as providing sufficient notice of the limits of authorized access. In the case of membership sites, the presumption is that each registrant is prequalified and therefore authorized to view and use the more restricted data, at least for purposes consistent with the terms of access. Enforceable click-wrap access agreements establish not only notice of access limitations, but they also secure each visitor's agreement to use the Web site and the data therein within the stated limitations.

Securing Web-based data against unauthorized use or users is, in some sense, antithetical to the information-sharing intent and purpose of the Web. In this regard, however, the decision to post information on the Web differs little from each organization's decision to facilitate its business at the risk of allowing competitors or adversaries to use our proprietary information against its interests. The greater the concern, the more likely that each host will have to either limit the data posted on the Web or increase each visitor's awareness of the rules of access.

### ECONOMIC ESPIONAGE ACT OF 1996

Prior to 1996, the Trade Secrets Act (TSA) was the only federal statute prohibiting trade secret misappropriation. The TSA, however, was of limited utility because it did not apply to private sector employees and provided only limited criminal sanctions.<sup>14</sup> To combat an increase in computer crimes, Congress enacted the Economic Espionage Act (EEA) of 1996, which provided greater protection for the proprietary and economic information of both corporate and governmental entities against foreign and domestic theft.<sup>15</sup>

The EEA criminalizes two principal categories of corporate espionage: economic espionage and theft of trade secrets. Section 1831 punishes those who steal trade secrets "to benefit a foreign government, foreign instrumentality, or foreign agent." Section 1832 is the general criminal trade secret provision. The EEA criminalizes stealing, concealing, destruction, sketching, copying, transmitting, or receiving trade secrets without authorization or with knowledge that the trade secrets have been misappropriated, as well attempts to and conspiring to do any of these acts.

### What Are Trade Secrets?

The EEA defines trade secret as

all forms and types of financial, business, scientific, technical, economic or engineering information, including patterns, plans, compilations,

<sup>14</sup> See Trade Secrets Act; see also Chamblee (2003). Other federal statutes, such as the National Stolen Property Act, were likewise of marginal utility in combating the rising problem of economic espionage. See Chamblee, p. 2.

<sup>15</sup> Uhrich (2000/2001) observes that the FBI investigated over 200% more economic espionage cases in 1996 than it had in 1994.

program devices, formulas, designs, prototypes, methods, techniques, processes, procedures, programs, or codes, whether tangible or intangible, and whether or how stored, compiled, or memorialized physically, electronically, graphically, photographically, or in writing if—(A) the owner thereof has taken reasonable measures to keep such information secret; and (B) the information derives independent economic value, actual or potential, from not being generally known to, and not being readily ascertainable through proper means by the public. (18 U.S.C. §1839(3))<sup>16</sup>

Although one might assume that this definition is relatively straight forward, not everything is as it appears. In a case of domestic trade secret theft, the Court of Appeals for the Seventh Circuit examined what the EEA means when it says that the data or material “derives independent economic value, actual or potential, from not being generally known to, and not being readily ascertainable through proper means by, the public” (*United States v. Lange*, 2002; emphasis added). Noting that others had assumed that the word *public* meant the general public, the court in *Lange* astutely observed that this was not, in fact, the case. Moreover, the standard for measuring the persons who might readily ascertain the economic value of (in this case) the design and composition of airplane brake assemblies is not the average person in the street, for this assumes (as the court mentions) that not any person can understand and apply something as arcane as Avogadro’s number. Instead, the definition of the term *the public* should take into account the segment of the population that would be interested in and understand the nature of that which has allegedly been misappropriated.

### What About Multinationals?

The international reach of the EEA is limited, extending outside of the United States only if

(1) the offender is a natural person who is a citizen or permanent resident alien of the United States, or an organization organized under the laws of the United States or a State or political subdivision . . . or (2) an act in furtherance of the offense was committed in the United States. (18 U.S.C. §1839)

Few defendants have been charged under the act since its passage in 1996, so the precise reach has yet to be tested. Having said this, the language of the EEA makes it clear that corporations with headquarters or operations subject to U.S. jurisdiction can be prosecuted or sued under the EEA. Similarly, some of the few existing decisions

involve the prosecution of agents of “foreign instrumentalities” who took steps in the United States in furtherance of their attempt or conspiracy to steal or transfer a trade secret can be prosecuted here (*United States v. Hsu*, 1998; *United States v. Yang*, 2002). Subsequent editions of this work will undoubtedly benefit from further developments in this area.

## THE DIGITAL MILLENNIUM COPYRIGHT ACT

In 1998, Congress passed the Digital Millennium Copyright Act (DMCA) to address concerns raised by the Internet and copyright issues in the context of our increasingly technological society. The DMCA creates a civil remedy for its violation, as well as criminal penalties starting after October 2000. One of the purposes of the DMCA is to protect the integrity of copyright information. Removal of copyright notice, or distribution knowing that such copyright has been removed, is now actionable. Both civil and criminal remedies also now exist if one circumvents “a technological measure that effectively controls access to a work protected” by the Copyright Act (17 U.S.C. §1201(a)).

The criminal penalties for violation of the DMCA can be quite severe. If the violation is willful for commercial gain, the first offense bears a fine of up to half a million dollars or 5 years imprisonment. Subsequent violations bear fines of up to \$1 million or 10 years imprisonment. Civil remedies include an order to restrain the violation, damages for lost profits, damages for recovery of the infringer’s profits, or statutory damages for each violation. Depending on the section of the DMCA at issue, each violation can generate fines of up to \$2,500 or \$25,000. Because each act of infringement can constitute a violation, the statutory fines can become quite substantial.

### Circumventing Technology Measures

As mentioned above, efforts to circumvent access limitations on copyrighted software are now punishable under the DMCA. In addition, it is a civil violation and a crime to “manufacture, import, offer to the public, provide or otherwise traffic in any technology, product, service, device, component, or part thereof,” that “is primarily designed or produced for the purpose of circumventing a technological measure that effectively controls access to a work protected” under the Copyright Act (17 U.S.C. §1201(a)(2)).

A technological measure effectively controls access to a work if the measure, “in the ordinary course of its operation, requires the application of information or a process or a treatment, with the authority of the copyright owner, to gain access to the work” (DMCA, 1998, 17 U.S.C. §1201(a)(3)). One circumvents such a technology measure if one uses a means “to descramble a scrambled work, to decrypt an encrypted work, or otherwise to avoid, bypass, remove, deactivate, or impair a technological measure,” without the authority of the copyright owner (DMCA, 1998, 17 U.S.C. §1201(a)(3)).

A spate of recent legal actions demonstrates that this legislation will be strictly enforced by the courts and that the technologically savvy will be in no better position

<sup>16</sup> This definition protects a wider variety of information than most federal and state civil laws. In *United States v. Hsu* (1998), “the EEA defines a ‘trade secret’ to expressly extend protection to the misappropriation of intangible information for the first time under federal law.”

to gain access to protected technology than anyone else. In *RealNetworks, Inc. v. Streambox, Inc.* (2000), Streambox distributed software that enabled users to bypass the authentication process employed by RealNetworks, which distributes audio and video content over the Internet. Thus, Streambox users could get the benefit of the RealNetworks streaming audio and video content without compensating the copyright owners. The U.S. District Court in Washington State found that the Streambox software has a technological measure that was designed to circumvent the access and copy control measures intended to protect the copyright owners.

In a case involving DVD encryption, a U.S. District Court in New York found that posting links to sites where visitors may download the decryption program was trafficking in circumvention technology, and was a violation of the DMCA (*Universal City Studios, Inc. v. Reimerdes*). In *Universal City Studios, Inc. v. Reimerdes*, the court rejected an argument that the use of the decryption software constituted free expression protected by the First Amendment of the U.S. Constitution.<sup>17</sup> And in a direct challenge to the constitutionality of the statute, several professors who responded to an open invitation from the Secure Digital Music Initiative Foundation (SDMIF) to find ways to penetrate copyright protection measures have sued for the right to publish the results of their work (*Edward Felten, et al v. Recording Industry Association of America, Inc., et al*, 2001). Edward Felten, Bede Liu, and others accepted SDMIF's invitation and successfully cracked the copyright security measures employed to protect digital music files. When the professors attempted to deliver a paper describing their success, SDMIF and others threatened litigation based on the anticircumvention provisions of the DMCA. The *Felten* lawsuit challenges the constitutionality of the DMCA in these circumstances.

## Exceptions to the Prohibitions on Technology Circumvention

### Fair Use and Reverse Engineering

The DMCA, however, explicitly carves out all defenses to copyright infringement, including the doctrine of fair use, as being unaffected by the passage of the DMCA. In some circumstances fair use can include reverse engineering.

Within the field of computer software, recent cases have considered whether dissection to reverse engineer the program is a violation of the copyright. To those involved in protecting software programs, the answer appears to be that reverse engineering in the form of disassembly does not constitute an infringement, because of the doctrine of fair use.<sup>18</sup> The Ninth Circuit in *Sega*

*Enterprises Ltd. V. Accolade, Inc.* (1992) found as a matter of law that

where disassembly is the only way to gain access to the ideas and functional elements embodied in a copyrighted computer program and where there is a legitimate reason for seeking such access, disassembly is a fair use of the copyrighted work. (977 F.2d at 1527-28)

The Ninth Circuit is not the only circuit that has upheld reverse engineering against a copyright claim. The federal circuit reached a similar conclusion regarding reverse engineering of object code to discern the ideas behind the program in *Atari Games Corp. v. Nintendo of America, Inc.* (1992). The fair use rationale of *Sega* was also adopted by the Eleventh Circuit in *Bateman v. Mnemonics, Inc.* (1996) on the grounds that it advanced the sciences. Thus, one can spy through reverse engineering still without running afoul of copyright protection or the DMCA.

However (and there usually is a however in the law), in *Bowers v. Baystate Technologies, Inc.* (2003), a split federal Circuit Court of Appeals found that a shrink-wrap license prohibiting reverse engineering was enforceable against the licensee who had reverse engineered Bowers' CAD Designer's Toolkit to develop a competing product. The Bowers court found that the contractual language trumped the fair use permitted under the Copyright Act. The Fifth Circuit reached the opposite result in the earlier decision of *Vault Corp. v. Quaid Software, Ltd.* (1988), specifically finding that the copyright act preempts state law that attempts to prohibit disassembly and holding a mass distribution license agreement unenforceable.

Thus, the extent to which *Bowers* may be followed is still unclear but it suggests a course business, can at least attempt to follow to curtail reverse engineering. If *Bowers* becomes widely accepted, the United States will be in conflict with the European Union on this issue. In its 1991 Software Directive, the European Union set forth a right to reverse engineer that is consonant with fair use under the Copyright Act. The Software Directive also provided that the right cannot be waived by contract. So, until *Bowers* is settled, if a shrink-wrap license prohibits reverse engineering, it would be best to consider having it done abroad.

### Other Exceptions

The DMCA also creates an important exception that recognizes the right to reverse engineer if (a) the person has lawfully obtained the right to use a copy of a computer program or (b) the sole purpose of circumventing the technology measure is to identify and analyze "those elements of the program that are necessary to achieve interoperability of an independently created computer program with other programs" (17 U.S.C. §1201(f)(1)). The DMCA creates a similar exemption for circumvention for the purpose of "enabling the interoperability of an independently created computer program with other programs, if such means are necessary to achieve such interoperability" (17 U.S.C. §1201(f)(2)). The term "interoperability" is defined to encompass the "ability of computer programs to

<sup>17</sup> *Reimerdes* is currently on appeal to the Second Circuit Court of Appeals, which has heard oral argument and requested additional briefing.

<sup>18</sup> There is an open issue as to whether copyright protects the format for interfacing between application and data. Competitors particularly in the area of gaming look to reverse engineer the interface format to make new modules compatible with existing hardware. Such reverse engineering has been held not to violate the copyright laws, so long as the new product does not display copyrighted images or other copyrightable expressions. Thus, the nonprotectable interface may be protected if such copyrighted images or expressions are embedded in the display.

exchange information and of such programs mutually to use the information which has been exchanged” (17 U.S.C. §1201(f)(4)). The information acquired through these permitted acts of circumvention may also be provided to third parties so long as it is solely used for the same purposes.

Exempt from the DMCA, as well, are good faith acts of circumvention for which the purpose is encryption research. A permissible act of encryption research requires that (a) the person lawfully have obtained a copy, (b) the act is necessary to the research, (c) there was a good faith effort to obtain authorization before the circumvention, and (d) such act does not constitute an infringement under a different section of the Copyright Act or under the Computer Fraud and Abuse Act of 1986. With the caveat that it must be an act of good faith encryption research, the technological means for circumvention can be provided to others who are working collaboratively on such research. The issue of good faith encryption research looks to what happened to the information derived from the research. If it was disseminated in a manner that was likely to assist infringement, as opposed to reasonably calculated to advance the development of encryption technology, then the act still falls outside the exemption. Other factors that go into the determination of good faith are whether the person conducting the research is trained, experienced, or engaged in the field of encryption research and whether the researcher provides the copyright owner with a copy of the findings.

The DMCA also has a bias against the collection or dissemination of personally identifying information. Thus, it is not a violation of the DMCA to circumvent a technology measure that essentially protects, collects, or disseminates personally identifying information, provided that the circumvention has no other effect and provided that the program itself does not contain a conspicuous notice warning of the collection of such information and a means to prevent or restrict such collection.

Finally, insofar as relevant to this chapter, the DMCA also excludes security testing from its scope. The DMCA grants permission to engage in security testing that, but for that permission, would violate the terms of the DMCA. If the security testing, for some reason, violated some other provision of the Copyright Act or the Computer Fraud and Abuse Act of 1986, then it is still an act of infringement. The DMCA, in part, considers whether a violation occurred by how the information was used. The factors to be considered include if the information was used to promote the security of the owner or operator of the computer network or system, was shared with the developer, and was used in a manner that would not facilitate infringement. For purposes of the DMCA, security testing means accessing either an individual computer or network for the purpose of “good faith testing, investigating, or correcting, a security flaw or vulnerability, with the authorization of the owner or operator” (17 U.S.C. §1201(j)(1)).

### Impact of Recent RIAA and Other Litigation

The primary drafters of and advocates for passage of the DMCA were media companies and their industry trade associations, including the Recording Industry Association

of America (RIAA) and the Motion Picture Industry Association of America. Their motivation was the perceived need to combat the technology that made free transfer of copyrighted work easier to accomplish. Advances in technology provided the entertainment industry with the incentive to propose and support some of the changes to the DMCA referred to above. Using the ample tools, Congress graciously provided and armed with claims that they were losing billions of dollars in sales revenues to the free sharing of electronic music files over the Internet, the RIAA and various individual recording industry giants have gone to court.

The initial target of their enmity was Napster, which created and made freely available the software that made music file transfers easy. In response to lawsuits filed by A&M Music and the RIAA, against the backdrop of the DCMA, federal trial and appellate courts found that the software and centralized internet-based distribution system offered by Napster violated the copyright law by, among other things, transferring copyrighted work for other than personal use. The first result of this litigation was the demise, by court injunction and later by acquisition by one of the media companies, of Napster.

To avoid a similar fate, other peer-to-peer file sharing companies, such as KaZaA and Morpheus, distributed software that enabled users to directly access the computer files of other users rather than offering a central library of protected work for each user to download. Efforts by the RIAA and others to prevent this kind of file sharing met with a different result in court. As a result, the RIAA decided to pursue users directly.

Beginning in late 2003, the RIAA opened a four-pronged approach to reduce unauthorized file sharing. First, it worked with Apple, Microsoft, and other software and hardware manufacturers and distributors to create a system for electronically distributing music to hardware that permitted the download of individual songs from extensive online libraries on a price-per-song basis. This spawned Apple’s iPod and iTunes, among others.

Second, the RIAA began investigating and pursuing unauthorized music downloads by individuals. Using the powers provided by the DMCA, the RIAA obtained and served subpoenas on ISPs to secure the personal identification information of people sharing music files over the Internet. The RIAA has met with mixed success in this effort; a recent appeal by Verizon seeking to quash the RIAA’s subpoena was successful (*Recording Industry Association of America, Inc. v. Verizon Internet Services, Inc.*, 2003).

Third, using the information gathered from various sources about the identity of file sharers, it has filed lawsuits against hundreds of individuals alleging violations of the DMCA and seeking damages, sometimes in the thousands of dollars. The defendants have included teenagers and people in their 60s, as well as occasional and prolific file sharers from all walks of life. Some of the cases were settled using written agreements in which the users promised not to violate the DMCA in the future. As long as the RIAA and media companies believe that electronic file sharing is diminishing industry revenues, there is reason to believe that lawsuits against individual file sharers will continue.

Finally, the RIAA has engaged in a public awareness campaign that portrays the artists as the victims of unauthorized file sharing. Interestingly, the response to this campaign generally and within the entertainment industry has been mixed. For example, a growing number of famous and fledgling musicians who object to the control of their work and their industry by the record publishing companies are supporting the use of the Internet for free file sharing as the best method for publicizing their work without relinquishing control of the work to the record publishers.

## CORPORATE SPYING ON THE INDIVIDUAL

### Competing Interests: Businesses and Individuals

Within today's corporate environment, employers' and employees' interests in protecting information are simultaneously harmonious and conflicting. Companies, with help from their employees, protect trade secrets, financial data (at least for companies whose stock is not publicly traded), customer lists, customer data, marketing strategies, intellectual property (computer source code, inventions), and information about mergers and acquisitions. They also work together to protect sensitive employee data concerning medical insurance, medical care, bank account numbers, social security payments, unemployment, marital and custodial issues, and sometimes employee credit information.

Conversely, there are data that employers and employees believe ought to be beyond the reach and dissemination of the other. When tobacco companies knowingly violate state and federal law concerning deceptive trade practices, the companies want to avoid disclosure of their knowledge that they violate those laws, whereas some employees may see it as their civic duty to expose that conduct. Not surprisingly, the tobacco companies have a different view of the disclosure of such sensitive information. On the other hand, employees believe that communications regarding intimate relationships either with other employees or persons outside the company are of no concern to their employers. Employers take the position that their communication equipment is intended for use solely in furtherance of the company's business interests and cannot and should not be used for intimate personal communications.

E-mail, Internet access, and voice mail are facts of life in any business. As useful as these technologies are, the possibilities of misuse are endless. Unmonitored Internet access (usually from points outside of the office firewall) can pick up viruses that will breach the security of the office system. Data can readily be transmitted to unauthorized recipients. Employees can broadcast libelous statements using a company Internet address to thousands of recipients. Intellectual property can be copied and distributed almost without detection. The question is where do the inviolable rights of employers and employees begin and end?

In a different context, businesses seek to understand the buying patterns and other habits of existing and

prospective consumers. One way to secure this information without asking for it directly is to use spyware, which has been defined as everything from hacker's software to programs that merely track consumer patterns through keystroke monitoring. A more formal definition of spyware might be "any software that covertly gathers information about a user while he/she navigates the Internet and transmits the information to an individual or company that uses it for marketing or other purposes" ([www.dictionary.com](http://www.dictionary.com)).

A growing number of consumers seeking to protect themselves against the wave of promotional information that permeates their mailboxes have raised a hue and cry about spyware and lawmakers have responded. In California, the Consumer Protection Against Spyware Act took effect on January 1, 2005. The CPASA outlaws software that secretly steals personal information such as user names and passwords, sends viruses, or takes control of infected systems as part of a distributed denial-of-service attack. Nationally, the House of Representatives has twice considered and once passed the SPY ACT, which prohibits a whole range of spyware- and adware-style activities, including keyboard logging, home page hijacking, and persistent on-screen ads. This legislation would require user permission before data collection could occur, among other things. Violators could face civil fines up to \$3 million and, according to a follow-on bill, would criminalize the use of software, including spyware, to commit a crime including logging keystrokes or stealing confidential information.

### Electronic Surveillance and Privacy: Reasonable Expectations

The definition and scope of the modern right of privacy emanates from several decisions by the U.S. Supreme Court over the past 40 years. In *Griswold v. Connecticut* (1965), the Supreme Court was asked to decide whether states had the authority to outlaw the private use of contraceptives, even among married couples. Declaring the existence of a zone of personal activity that even the framers of the Constitution would have deemed beyond the reach of governmental control, the Court held that consenting married adults had a reasonable expectation that certain activities would be private, among them the use of contraceptives in the privacy of their bedrooms.

In the famous case of *Roe v. Wade*, the Supreme Court extended the notion of a reasonable expectation of privacy to a woman's decision to abort a pregnancy, at least in the first trimester. Most recently, in *Lawrence v. Texas* (2003), the Court held that consenting male adults may not be charged with violation of antisodomy laws when they engage in such acts in the privacy of their own home. In these and other cases, the Court has focused on the liberties underlying the founding of this country and that such liberties import some protection against invasion by the government.

The reasonable expectation is not absolute in all circumstances and is certainly limited in its application in the workplace. Any e-mail can be monitored where consent is given and consent can be a condition of employment. Alternatively, an employer has the right to

reasonably monitor electronic communications if it can show a business reason for doing so. Such reasons abound in today's environment, from prevention of theft of information to simple system misuse.

But employees nonetheless view such efforts by employers as spying. They view their electronic communications by e-mail in the same way as telephone calls—sacrosanct from third-party eavesdropping. Several states have considered requiring that employees be notified of any monitoring.<sup>19</sup> Many states have now enacted privacy statutes that make invasion of privacy a civil wrong. Our home state of Massachusetts, for example, has a statute that protects against substantial interference with a person's privacy. But is there in fact a reasonable expectation of privacy in today's environment?

The answer appears to be "no." In *Garrity v. John Hancock Mutual Life Insurance Co.* (2002 U.S. Dist. LEXIS 8343 (D. Mass. 2003)), the employer fired employees who shared sexual material through the company's e-mail system. The employer knew by reviewing the e-mail messages stored in the employer's computer system. The Court concluded that there was no invasion of privacy because there was no expectation of privacy. The employees knew of Hancock's electronic communications policy and Hancock's retention of the right to review e-mails. In an earlier case, *Smyth v. Pillsbury Co.* (1996), the Court ruled that no expectation of privacy exists for employees using the company's e-mail system and made such a finding even although there was no company policy manual in place.

Looking at these two results, the conservative approach for businesses wanting to spy on their employees is to put a policy in place that permits inspection and monitoring of employee e-mails, especially given the vagaries of state law on the subject. Other judicial decisions uphold employer monitoring where such a policy is in place. *TBG Insurance Services Corp v. Superior Court* (2002) found no reasonable expectation of privacy as the employee had consented to having his home computer monitored by signing the company's electronic communications policy. *Muick v. Glenayre Electronics* 280 (2002)<sup>20</sup> reached the same conclusion where the issue was the employee's reasonable expectation of privacy in a laptop computer in light of the employer's policy permitting the employer to inspect at any time. A contrasting result was reached in *United States v. Slanina* (2002), where in the absence of such a policy, an employee was found to have a reasonable expectation of privacy because the employer had no policy in place and did not otherwise inform the employee that employees' computers were routinely accessed.

## GOVERNMENT SPYING AND BUSINESSES: THE USA PATRIOT ACT

The USA PATRIOT Act was conceived, drafted, revised, and signed into law 45 days after 9/11 and alters at least

15 federal statutes. Some contend—perhaps correctly—that this mammoth legislation is merely an instinctive reaction to the events of 9/11: a natural response to an act of war. The USA PATRIOT Act responds in several ways to the kinds of activities likely to support acts of terrorism. First, it enhances the government's ability to investigate domestic criminal and foreign intelligence activity, broadening the scope and nature of communications that can be seized and reducing the barriers to seizing those communications. It also increases the likelihood of receiving assistance from corporate and individual citizens that may lead to arrests and convictions by, among other things, protecting those who provide that assistance. Whether, and to what extent, the heightened intrusion into our business and personal lives will withstand scrutiny by the Courts is the untold but unfolding story.

### Terrorism and Financial Institutions

Title III of the USA PATRIOT Act, also known as the International Money Laundering Abatement and Anti-Terrorist Financing Act of 2001, expands the already considerable ability of the federal government to control money laundering, which is the flow of cash or other valuables derived from or intended to facilitate the commission of a crime. Among other things, the USA PATRIOT Act expands the list of businesses that are required to file reports with the government noting suspicious activities involving the flow of money. The expanded list now includes securities brokers and dealers, commodity merchants, advisors, and pool operators. These reports must be filed with the U.S. Treasury Department and, in some cases, the Internal Revenue Service. Because the vast majority of these transactions are electronic, there is a direct impact on the monitoring and reporting obligations of information technology departments in these companies.

Due diligence requirements also have been imposed on all domestic financial institutions concerning the opening and use of financial accounts. The USA PATRIOT Act requires financial institutions to verify the identity of any person seeking to open an account, maintain verification records, and consult published lists of known and suspected terrorists to determine if any person seeking to open an account appears on those lists. This means that all new customers and existing customers opening new accounts must be screened by the bank, presumably through the use of electronic databases. In addition, the act imposes strict time limits for responding to Justice and Treasury Department subpoenas.

The consequences of failing to adequately monitor and report such activity, as well as failing to adhere to the proscription against transmitting funds derived from illegal activities, were realized by PayPal, the online payment system owned by eBay, which was charged by the U.S. Attorney for the Eastern District of Missouri with transmitting funds received from online gambling. In the indictment, the government is seeking all revenues realized by PayPal from online gambling during the preceding 9 months, plus interest. PayPal may also

<sup>19</sup> This is the flip side of consent and is generally a good idea regardless of statutory requirements.

<sup>20</sup> Noting that intrusive surveillance might infringe the right of privacy.

receive criminal penalties. Presumably, PayPal would not have engaged in such activity had it adequately monitored the sources of the funds being transmitted over its system.

### Compulsory and Voluntary Cooperation Between Business and Government

The Electronic Communications Privacy Act of 1986 was implemented to create some protections against the overzealous use of wiretaps on telephones. As part of that framework, the protections were extended to network services and a few exceptions were established. The authority necessary to obtain a wiretap depended on the level of content to be intercepted. An administrative agency order, which required a minimal showing of cause by law enforcement, did not permit law enforcement to obtain message content, while a court-authorized subpoena, which required a court's acknowledgment of the existence of probable cause, permitted the recovery of much wider scope of information.

The USA PATRIOT Act changes the ECPA in several ways. First, it permits law enforcement to obtain routing information—such as the information appearing in the header of an e-mail—with a lower level of judicial scrutiny and based only on a certification by the government that the information is related to a criminal investigation. For example, the subject line of an e-mail, which might otherwise appear content oriented, may now be open to law enforcement without the usual demonstration of probable cause.

In addition, the USA PATRIOT Act clarifies the ECPA by permitting law enforcement to collect content traffic information (i.e., more than just a telephone number or Internet protocol address) from multiple forms of electronic communications—specifically the Internet—through the use of pen registers and the so-called trace and trap statute. Prior law permitted government access to the content of e-mails and communications records in the possession of third parties that have been stored for more than 180 days; the act adds government access to credit card and bank account numbers.

Further, the USA PATRIOT Act provides for the voluntary disclosure of certain electronic communications when a provider of electronic communications to the public (an ISP, for example) determines with its reasonable judgment that an emergency involving death or serious physical injury requires disclosure without delay. This permits disclosure of e-mails that appear serious to the service provider whether or not they are in fact serious (e.g., bad jokes sent by e-mail). Similarly, communications network owners who believe that a computer trespass (defined as accessing a protected computer without authority) has occurred may request an investigation by law enforcement, whether or not the network owner's concern is well founded. In this context, it has been suggested that government investigators who believe they need access to a computer network are free to initiate calls to network owners on the pretext of investigating a crime or a potential terrorist act for the purpose of gaining access to the network.

## CONCLUSION

In today's world, we can all be spies and are all subject to being spied upon. The issue of what is fair game and what is private or protected personal property has become increasingly complex. The gray world of the spy now intrudes open all of our lives. Boundaries have become difficult to define. Information flows seamlessly and globally. What is good and what is bad—even when asking whether your mother would approve—is not always easily discernable. There is a real bramble of legal regulations within the United States. Add on another layer of complexity for global transactions.

As complicated as the subject is today, it is only going to become more complex in the future. Large corporations have the luxury of creating a new position—the corporate privacy officer—who is the hired specialist. Individuals can only read chapters such as this one and utilize Web sites such as [http://www.epic.org/privacy/privacy\\_resources\\_faq.html](http://www.epic.org/privacy/privacy_resources_faq.html) to find resources that speak to their particular issues or concerns. Both help for the routine issues but not for the novel ones or for those that are factually complex where the real concerns may not be readily apparent.

The concerns about, and behind, corporate spying lie at the heart of the issues that confront us in the 21st century. We all need our “007” to help us put things rights. But in this context, it is to act as a guide to let us know what is permissible and what simply is not. This chapter is only a start. It should not be read as legal advice because all legal advice ultimately depends on the facts and individual or corporate goals. Rather, it should be read as raising questions that need to be considered as each of us works our way through issues that are pivotal to our rights as individuals as well as to corporate survival. We recognized the limitations in this chapter when we began the task of writing it. We hope it has prompted a concern to investigate and define these issues as they affect each of our lives and business. To that end, we would be glad to help the reader in the search for answers to the questions that affect their lives and futures.

## GLOSSARY

**Common Law** The common law refers to the evolution of the law through cases and appellate decision, which establish the law through precedent and respected judicial reasoning and thought, as opposed to statutes, which are legislative enactments.

**Computer Fraud and Abuse Act (CFAA)** The Computer Fraud and Abuse Act, originally passed in 1984 and amended in 1986 and 1996, has civil penalties for unauthorized access to computers and is a major weapon in prosecuting theft of computer data.

**Contract** An agreement, usually in writing, which is demonstrated by some form of mutual assent to the terms and conditions.

**Digital Millennium Copyright Act (DMCA)** The Digital Millennium Copyright Act was enacted by Congress in 1998 and created civil and criminal penalties to enhance the protection of copyright information in the

context of the Internet and to update protections in light of new technologies.

**Economic Espionage Act (EEA)** The Economic Espionage Act of 1996 applies to corporate and governmental entities and creates criminal penalties for corporate espionage that involves either economic espionage or theft of trade secrets.

**Electronic Communications Privacy Act (ECPA)** The Electronic Communications Privacy Act became law in 1986 and is codified in Title 18 of the United States Code. It created the Stored Communications Act to state as a matter of legislation federal privacy protections and standards as applied to computers and telecommunication technologies.

**Fiduciary Duty** A duty that arises out of a relationship of trust and is generally described as imposing the utmost good faith and fair dealing.

**Terms of Use** Terms of use are terms posted on a Web site that attempt to define the conditions under which a user can have access to the site. Some terms of use actually require a user to accept them before entry is permitted to that portion of the Web site. They may be viewed as akin to signage on property.

**Trade Secrets** The concept of trade secrets has developed through the common law and describes proprietary business information usually that has some commercial usage.

**Trespass** The concept of trespass is part of the common law of torts or civil wrongs and connotes entry onto property without right and without permission.

**Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism Act (USA PATRIOT Act)** The USA PATRIOT Act was conceived after September 11, 2001, and passed without too much consideration of its effect. The USA PATRIOT Act, while giving the government a freer hand to investigate terrorism, may have vitiated key protections against unwarranted governmental intrusion and is likely to be a subject of growing debate as its erosion of civil liberties has united libertarians, whether of the left or right persuasion.

## INTRODUCTION

In the context of democratic societies, policing always involves a delicate task to provide security while also maintaining liberty. With the rapid expansion of computerized technologies and the Internet, this problem is posed even more acutely, for communication methods have not only expanded sharply, but the development of Internet technology has also brought about increased anonymity and freedom in communications. This situation creates a significant law enforcement problem as the same technologies that guarantee anonymity in legitimate transactions also provide new means to violate laws and to hide the identities of lawbreakers. Because of the cross-border nature of computers linked through networks, also, threats against computer security are often global in nature. By the very nature of the Internet as a border-transcending phenomenon, cybercrimes know no geographic boundaries.

From a legal and law enforcement viewpoint, measures against computer security threats pose problems of jurisdictional authority. National legal systems and their enforcement agencies are formally bound to nationally defined borders, whereas even a single transmission of computerized information over a network may pass through a dozen or more types of carriers, such as telephone companies, satellite networks, and Internet service providers, thereby crossing numerous territorial borders and legal systems (Aldesco, 2002). The cross-border nature of threats to computer security justifies the need for international cooperation and the development of global frameworks of law and law enforcement. In this chapter, we review the most important law enforcement efforts that have been taken at selected national and international levels to respond to the challenges affecting computer security.

## COMPUTER SECURITY, THE INTERNET, AND CYBERCRIMES

With the advent and the exponential growth of the Internet and computerized transactions, the modern world has witnessed not only an expansion of new means of communication and the creation of virtual communities among people in disparate geographical locales, but it has also brought about new and unprecedented opportunities for illegitimate conduct (Ditzion, Geddes, & Rhodes, 2003; Maher & Thompson, 2002; Sinrod & Reilly 2000; Sussman, 1999; Wall 2001a). Cybercrimes have become a permanent factor in the current era of the globalization of information and communications. The negative implications of such crimes can be far-reaching in economic and other respects. The total amount of money involved with credit card theft, for example, is estimated at \$400 million annually, whereas stolen patents and trademarks involve \$250 billion a year (Aldesco, 2002; Baron, 2002).

Cybercrimes are relatively easy to execute and require little technical expertise. Toolkits and handbooks to commit cybercrimes are available on the Internet. Estimates show that nearly 50% of all U.S. companies were attacked by a computer virus, worm, or other Internet-related means in 2001. The computers of the Pentagon are attacked about 22,000 times a year. By 2000, intellectual property theft was already estimated to cause American companies losses in excess of \$ 1 trillion (Barr, Beiting, & Grezeskinski, 2003). The so-called Love Bug worm that spread via e-mails to millions of computers in the spring of 2000 led to an estimated \$8.7 billion in damages and may have cost as much as \$10 billion in lost productivity (Bellia, 2001). The U.S. Defense Department reported that the worm had contaminated at least four classified U.S. military computer systems. The Philippine-based college dropout who caused the havoc could not be prosecuted in

the United States as there was no applicable cybercrime law in the Philippines at that time, for which reasons he could also not be extradited (Cesare, 2001).

At least two types of crimes involving computer security can be distinguished (Goodman & Brenner, 2002). In a first category of offenses, the computer is the target of the crime by means of attacks on network confidentiality, integrity, and availability. Among the examples are unauthorized access to and illicit tampering with systems, programs, or computer data. In a second category of cybercrimes, traditional offenses, such as fraud, theft, and forgery, are committed by means of computers, networks, and other information and communications technology. The latter category of offenses is not novel or unique to the era of the Internet, yet it has qualitatively altered in kind by means of the use of advanced technologies, with important implications for legal policy and law enforcement practices.

Besides the high-tech nature of cybercrimes and the anonymity that the Internet affords, the border-transcending nature of the cyberworld is another outstanding characteristic of computer security since the late 20th century. "An international element is often present, not only when a computer system is the target of a crime," Bellia argues, "but also when a system merely facilitates online forms of traditional crimes or serves as a repository for evidence of a crime" (2001, p. 38). The targets of cybercrime, likewise, can be varied in nature, ranging from illicit gambling to the conveying of threats, the transmission of pornography, and attempts to lure children into sexual conduct to fraud and violations of intellectual property. The Internet has also grown in popularity across the globe and is affecting people of various ages, ethnic backgrounds, and class structures. As a result, the potential impact of cybercrimes can be exploited in a more organized manner that is akin to the existing traditional forms of organized crime, enabling the emergence of so-called cybercrime Mafias (Brenner, 2002). The complexity of cybercrime necessitates the development of new legal frameworks at the national and international levels.

## ESTABLISHING COMPUTER SECURITY THROUGH NATIONAL LAWS

The appearance of new social ills in society will typically invoke the passing of new laws designed to prevent or treat the consequences of such problems. Until recently, the spread of computer crimes was unmatched by the development of proper criminal law statutes (Barr et al., 2003; Rustad, 2001). But the sharp rise in intellectual property crimes over the Internet and other crimes related to information in a highly computerized society has led the governments of many nations across the world to enact new criminal statutes specifically tailored to adequately respond to the changing conditions. This chapter will review these legal developments, focusing primarily on the United States and a selection of other nations.

In the United States, laws to protect computer security are primarily based on two pieces of legislation: the

Economic Espionage Act of 1996 and the National Stolen Property Act, which dates as far back as 1934 (Barr et al., 2003). These laws were invoked with renewed vigor because intellectual property crimes by means of the Internet were rising sharply. As the threat of civil action was an insufficient deterrent to thwart the theft of trade secrets and the infringement of trademarks, patents, and copyrights, U.S. Congress passed the Economic Espionage Act in 1996 to criminalize the theft of trade secrets. Other acts have been passed to adequately respond to specific nature of crimes committed in cyberspace. For instance, in 1997, the No Electronic Theft Act was passed to broaden criminal liability for copyright infringement even when no financial gain is involved (Rustad, 2001). The act was passed after an Massachusetts Institute of Technology student had been acquitted for distributing copyrighted software on the Internet because he had received no financial gain from his distribution activities.

The National Stolen Property Act provides criminal sanctions for the transmission of goods and moneys that are known to have been stolen or taken by fraud. Although the act was not designed to apply to theft by computerized means, U.S. federal courts have held that the act can be applied in this circumstance. Originally, the stolen item had to be physically removed for an offense to be prosecutable under the act, but more recently some courts ruled that electronic transmission may be sufficient.

Legal responses at the national level toward the protection of computer security are sometimes only of limited value, because their application and enforcement is limited to jurisdictional borders (whereas cybercrimes are not). The U.S. Copyright Felony Act, the No Electronic Theft Act, and the Digital Millennium Copyright Act, for example, all distinctly focus on computerized information, but they cannot be applied in an extrajurisdictional context. The Economic Espionage Act, however, also applies to economic espionage that occurs overseas, at least when it involves an offender who is a U.S. citizen or corporation or as long as some part of the illegitimate activity is connected to the United States (Barr et al., 2003, pp. 777-778).

The cross-border nature of many computer crimes need not necessarily be addressed by extending national laws to apply to extrajurisdictional territories. Providing there is some degree of coordination among national legal systems, an option toward effective criminalization is provided by cooperation across nation-state borders (Brenner & Schwerha, 2002). Such cooperation is legally secured through mutual legal assistance treaties among nations. The United States, for example, maintains some 40 bilateral mutual legal assistance treaties with foreign nations. These treaties provide both legal and practical means by which one country can seek or provide legal assistance from or to another country (Department of Justice, 2001). Legal cooperation across nations, however, requires that all participating countries have developed similar statutes.

A discussion of all national legal frameworks on computer security is beyond the scope of this chapter. But by reviewing a useful selection, it can be noted that many nations have developed explicit criminal codes against cybercrimes (Schjolberg, 2003). In the Americas, the Mexican

penal code specifies that anyone who destroys or causes loss of information contained in computer systems or computer equipment protected by security measures shall be liable to punishments involving imprisonment or fines. Brazil has since July 2000 criminalized the entry of false data into information systems. Other Latin American countries, such as Venezuela and Chile, have passed similar legislation.

The Canadian Criminal Code criminalizes any attempts to fraudulently obtain a computer service or intercept any function of a computer system. In Australia, federal legislation was enacted with the Cybercrime Act of 2001, which criminalizes unauthorized access to, or modification of, data held in a computer to which access is restricted. Among the first nations to enact new laws to protect computer security, the United Kingdom passed a Computer Misuse Act in 1990 to penalize unauthorized access to computer materials. Also in Europe, the French penal code that went into effect in March 1993 provided for the criminalization of attacks on systems for automated data processing. The code criminalizes fraudulent access to an automated data processing system, as well as hindering the functioning of such systems and the fraudulent introduction or modification of data therein. Italy's penal code includes articles on the unauthorized access into computer or telecommunication systems. Similar regulations to protect data were introduced in Germany, Greece, and other European countries. In Belgium, for example, the national parliament in November 2000 adopted legal articles on computer crimes such as computer forgery, computer fraud, computer hacking, and sabotage.

Outside of Europe, China passed new legislation as early as 1994, when regulations were enacted concerning measures to protect the safety of computer information. India passed the Information Technology Act of 2000 that specifies regulations against the hacking of computer systems. Similarly, Japan introduced an Unauthorized Computer Access Law that went into effect in February 2000. In 2002, South Africa enacted an Electronic Communications and Transactions Act, which penalizes cybercrime as the unauthorized access to, interception of, or interference with computerized data.

## THE ENFORCEMENT OF NATIONAL LAWS CONCERNING COMPUTER SECURITY

Passing appropriate laws is a necessary step to respond to crimes, but without effective police operations, such laws would remain inconsequential (Rustad, 2001). The policing of laws related to computer security poses several special problems, not least of all because of the enormous popularity of the Internet and the widespread use of computers. Already by the late 1990s, it was estimated that a global population of some 19 million computer users would have the necessary skills to mount a cyberattack should they choose to use their proficiency for such illegitimate purposes (Cilluffo, Pattak, & Salmoiraghi, 1999). The expansion of the Internet itself has contributed to the growing availability of the tools and skills necessary

to carry out a cybercrime. Moreover, the relative lack of technological expertise among enforcement agencies—at least until recently—initially posed serious limitations to the adequate implementation of any law enforcement plans (O'Neill, 2000). The technological characteristics of cybercrimes also affect the nature of appropriate police actions. The anonymity of the communicator and the methods used to shield one's true identity create considerable problems for the enforcement of any law concerning information and identity theft (Davis, 2003).

The strategies to police cyberspace that were implemented in recent years in the United States provide a good example of the value and limitations of jurisdictionally confined enforcement (Ditzion et al., 2003). Police actions to enforce laws concerning computer security were first stepped up during the Clinton administration. U.S. Congress expanded the scope of the Computer Fraud and Abuse Act, originally passed in 1986 in response to the so-called war games epidemic, to lower the punishable standard of criminal intent in cases of unauthorized computer access, ensuring that a broad class of hackers would be accountable under the statute and broadening the category of protected computers.

In the United States, a leading role in computer-related law enforcement efforts has been adopted by the Federal Bureau of Investigation (FBI), which established so-called computer crime teams in its various field offices across the U.S. states (Wolf, 2000). The FBI also set up the National Infrastructure Protection Center to function as a national law enforcement investigation and response entity for critical infrastructure threat assessment, warning, and vulnerability (Gravell, 1999). These activities have not been without consequences, as many prosecutions of computer criminals evolved from FBI stings operations (Barr et al., 2003).

Besides the operations by the FBI, relevant criminal enforcement strategies in the United States are also undertaken by a host of other agencies. The Central Intelligence Agency (CIA) is involved in securing computer communications through the monitoring of communications (Baron, 2002). In the Justice Department, the Computer and Telecommunication Coordinator (CTC) Program has been set up since 1995 at the recommendation of the Computer Crime Unit, now called the Computer Crime and Intellectual Property Section (CCIPS) in the Criminal Division (<http://www.cybercrime.org>). Every U.S. attorney's office has designated at least one CTC and over 35 districts have two or more. A total of 137 U.S. attorneys are presently working in the CTC Program. The CTCs have responsibility to prosecute computer crimes, serve as technical advisors to other U.S. attorneys, act in liaison with attorneys in other districts, and provide training and guidance to other attorneys and to federal and local agencies in their districts. More recently, since July 2001, additional Computer Hacking and Intellectual Property (CHIP) units of prosecutors have been established to work in collaboration with the FBI and other agencies. Likewise, the FBI organized a cyberbanking initiative in cooperation with the Departments of Justice and the Treasury as well as financial regulatory agencies to examine the risks associated with electronic banking technology (*Cyber Crime*, 1998).

Also established by the U.S. Department of Justice was the National Cybercrime Training Partnership (NCTP) to collaborate with all levels of law enforcement and develop a long-range strategy for high-tech police work, including interagency cooperation, networking, and training (Williams, 1999). At present, NCTP activities are in hiatus pending the formation and initial meeting of a new body, the Cybercrime Advisory Board, under the direction of the National White Collar Crime Center (NW3C). The latter center also runs the Internet Fraud Complaint Center (IFCC) in partnership with the FBI to address fraud committed over the Internet. The IFCC acts as a central repository of fraud complaints for the law enforcement community and provides an easy-to-use reporting mechanism for fraud victims. Another way for citizens to get involved in computer security is through the Cyber Citizen Partnership, a program set up by the Department of Justice and the Information Technology Association of America that involves a Web site to teach children about the right ways to use the Internet.

As is the case in matters of national legal systems, law enforcement measures on computer security have been implemented in many countries across the world. In Canada, a Tech Crime Unit has been established in the Royal Canadian Mounted Police. The Federal Police in Australia has Electronic Forensic Support Teams in most of the country's major cities. In the United Kingdom, a National Hi-Tech Crime Unit was established in 2001. By 2003, the unit's investigations had led to more than 100 arrests in over 40 operations. Special attention is paid to the unit's collaboration with the cybercrime police in other countries. Other countries in Europe, indeed, have similar specialized units set up in their respective police forces. Outside of Europe, the situation is no different as specialized "cybercop" teams are set up in many countries across the globe. For example, the Central Bureau of Investigation in India has established a unit to police Internet communications and cooperate with Indian portals to safeguard against cyberattacks. Special emphasis is placed on the training of officers to serve in such units, as their skills are very different from those needed in a more traditional police role.

## BUILDING A GLOBAL LEGAL ORDER TO PROTECT COMPUTER SECURITY

Similar to the problems associated with legal frameworks, enforcement activities are especially affected by the cross-border nature of computer security-related activities in cyberspace (Calkins, 2000). Yet, among legal scholars there is disagreement on the value of international legal systems in the case of computer security and related Internet activities (Bellia, 2001; Berman, 2002). Some argue that laws regulating online activities crossing national borders are always ineffective because they are to be implemented in nations with limited jurisdiction. Other, however, suggest that the Internet is no less subject to extraterritorial authority than other forms of international activities that had already been regulated by international law for many years before the advent of the Internet. The reality is that the development of cyberspace

as a decidedly global phenomenon has instigated a host of legal initiatives at the international level. Mirroring the development of international police cooperation from the 19th century onward (Deflem 2002a, 2002b), technological advances are typically addressed at overcoming barriers of space and time, and criminal law and law enforcement respond in kind to internationalize their range and activities.

The history of the regulation of illegitimate conduct in cyberspace shows a steady expansion of applicable laws and an increasing involvement of various international bodies to tackle the cross-border nature of cybercrime (Goodman & Brenner, 2002; Grabosky & Smith, 2001; Norman, 2001; Wall, 2001b). Among the key players are the Organization for Economic Cooperation and Development (OECD), the Council of Europe, the European Union, and the United Nations.

Pertinent activities of the OECD date back to 1983 when the organization was assigned to secure a harmonization of European computer crime legislation. In the mid-1980s, the Select Committee of Experts on Computer-Related Crime of the Council of Europe thereupon drafted a recommendation to provide for an adequate and quick response to cybercrime by harmonizing existing legislation in the EU countries and improving international legal cooperation. By the mid-1990s, the Council of Europe had issued several reports detailing appropriate surveillance activities and methods of investigation in the realm of information technology.

Many international bodies were involved in developing an international regulation of cyberspace. In 1990, the United Nations first addressed some of the international legal issues associated with cybercrime. The U.N. Congress then urged the world's nations to step up their efforts to legally respond to computer crime and promote the development of an international legal framework. Also during the 1990s, international agreements were reached that specifically concerned trade secrets and the manner in which business information is to be protected. In 1994, the Uruguay Round Agreement presented Trade-Related Aspects of Intellectual Property Rights (TRIPs), and the OECD stipulated Guidelines on Security and Information Systems in 1992 and Guidelines for Cryptography Policy in 1997. Under the TRIPs agreement, enforcement of intellectual property rights can be obligated, whereas the OECD agreements are guidelines that do not attach binding obligations.

In 1997, the Justice and Interior Ministers of the Group of Eight (G8) met in Washington, D.C., and adopted a set of principles to combat high-tech crimes as well as an Action Plan to Combat High-Tech Crime (Bellia, 2001). The G8 agreement provides for national governments to pass legislation that enables international cooperation to keep pace with the development of technology and its use for illegitimate purposes.

The G8 action plan was a significant development in the internationalization of computer security law, for it inspired the Council of Europe to prepare a Convention on Cyber-Crime that has been favorably received in many countries since the convention was complete in 2001 (Aldesco, 2002; Baron, 2002; Davis, 2003; see also Brenner, 2002; Keyser, 2003; Marler, 2002). The primary goal of

the convention is to pursue a cross-national policy against the threat of cybercrime by developing appropriate legislation and enhancing international cooperation (Aldesco, 2002, p. 93). The convention includes a harmonization of laws to prevent and suppress computer(-related) crimes by establishing a common standard of offenses. This legislation should cover a variety of related areas such as the illegal interception of and interference with computer data, computer-related forgery and fraud, child pornography, and violations of copyright.

The Convention on Cyber-Crime was the first formalized international treaty on criminal offenses conducted against or by means of a computer and computer networks. With initial preparations going back to the late 1980s, the convention was formally signed in November 2001 by 26 member states of the Council of Europe as well as by the United States, Canada, Japan, and South Africa. The United States had been involved in the elaboration of the convention in its capacity as an observer at the Council of Europe. Not all of the signing countries ratified the convention, although the convention finds broad support. Heralded as the only multilateral treaty to address the problems of computer-related crime and electronic evidence gathering, U.S. President Bush in November 2003 asked the U.S. Senate to ratify the convention. These and other international legal frameworks have distinct implications for law enforcement.

## COMPUTER SECURITY AND INTERNATIONAL POLICING

From an international policing viewpoint, potential threats against computer security relate intimately to the specific means and object matter of computerized information. Computer security threats often concern multiple national jurisdictions. Police activities, in response, have to concentrate on locating the source of the communication to connect the traces of a cybercrime with a real person in the physical world. The infrastructure of the Internet does not provide a ready mechanism for tracing this "electronic trail" (Aldesco, 2002) that leads from the effects of a crime back to its perpetrator. Special strategies at an international level are needed to police threats against computers in a manner that is both effective and appropriate relative to applicable laws. Three basic models can be identified in the international policing of cybercrime: trans-border police actions involving unilaterally conducted investigations abroad, bilateral agreements among countries or their law enforcement agencies, and the establishment of multilateral regimes (Deflem, 2002a; see also Bellia, 2001).

### Variations of Global Policing

In the case of transnational police activities on foreign soil, it is striking to note that the legal systems of some nations allow for extraterritorial police activities, even without a corresponding legal system in the country in which cross-border activities take place. Such transnational police activities often take place without the knowledge or consent of the host country. Some states assert a legal right to conduct "remote cross-border searches" (Bellia, 2001, p. 39) by using computers located within their jurisdiction

to examine data that are stored outside of their jurisdiction. For example, in 2000, FBI agents downloaded data from Russian computers as part of an investigation of a ring of Russian hackers who had been targeting several U.S. companies.

International cooperation among police agencies can occur without explicit legal agreements, instead relying on an autonomously developed professional police culture among security and intelligence agencies across national borders (Deflem, 2002a). Law enforcement agencies in the United States and other countries can independently cooperate and undertake joint efforts in the policing of cyberspace. For instance, the Cybersmuggling Center operated by the U.S. Customs Service has been involved in cyberinvestigations concerning money laundering and child pornography distribution in cooperation with police from Germany, Indonesia, Italy, Honduras, Thailand, and Russia (President's Working Group, 2000).

When computer security-related crimes are subject to laws in one country but not in another, cooperation to investigate pertinent crimes may be hampered and extradition may be unlikely. Yet this limitation is not always in place, because some mutual legal assistance treaties among countries allow for assistance when illegitimate conduct is considered a crime in the state that requests extradition even though that conduct is not criminalized in the state from which assistance is requested (President's Working Group, 2000). Most often, however, especially in the more sensitive area of searches and seizures, a condition of dual criminality must exist whereby a particular type of conduct is considered a crime in both countries involved in a bilateral cooperation agreement.

Bilateral cooperation among nations is precarious, not only because each country involved in cooperation would have to develop similar laws, but also because each country would have to entertain agreements with all other nations of the world. As a perfect consensus about international policing of computer security among all of the world's nations is unlikely, the planning and implementation of multilateral strategies can be a more effective way to develop adequate global law enforcement. Because the Internet now connects virtually every country in the world, the law enforcement challenges posed by this global communication system also have to respond globally. Thus, the international legal frameworks that have been developed on matters of cybercrime carry implications for international law enforcement, especially at the level of each participating nation state and how its law enforcement agencies cooperate with one another. The Council of Europe's Convention on Cyber-Crime, most clearly, has distinct implications for international policing activities. As the convention seeks to harmonize procedures of mutual assistance among nations, special provisions are accorded to law enforcement to aid the investigation of cybercrimes (Aldesco, 2002). The nations that have signed the convention are required to ensure that special police measures are available, such as the realtime collection of traffic data and the interception of content data. The convention also enables police agencies of one nation to collect evidence related to cybercrimes for the police agency of another country and to establish a permanent communications network to provide international

assistance with ongoing investigations. Under the provisions of the convention, also, police in a country are now authorized to request “that their counterparts abroad collect an individual’s computer data, [and] have the individual arrested and extradited to serve a prison sentence abroad” (Aldesco, 2002, p. 95).

### The Role of Interpol and Europol

The international dimensions of law enforcement also include multilateral organizations that have been set up among police agencies. Such international police organizations enable participating agencies to cooperate in the form of direct police-to-police information exchange, even when no formal intergovernmental accords have been reached (Deflem, 2002a). Among the most important of these organizations are the International Criminal Police Organization, better known under its abbreviation Interpol, and the European Police Office, called Europol.

Interpol is an international organization aimed at providing and promoting mutual assistance among criminal police agencies within the limits of their respective national laws and the Universal Declaration of Human Rights (Deflem, 2002a). Originally formed in Vienna in 1923, Interpol is not a supranational police agency, but a collaborative structure among law enforcement agencies from various nations that are linked via specialized national bureaus with a central headquarters in Lyon, France. Presently, Interpol involves police agencies from 181 national states. Interpol has been involved in efforts to combat information technology-related crime for a number of years through a system of so-called working parties on information technology crime that have been set up in various regions of the world (Goodman & Brenner, 2002; *Interpol’s contribution*, n.d.). The European Working Party on Information Technology Crime was the first to be set up under this provision in 1990. It compiles a computer crime manual, organizes training courses in Internet-related crimes, and has set up a rapid information exchange system to transmit relevant information swiftly among the member agencies. The other working parties, which have been set up in the Americas, Africa, and Southern Asia, similarly work toward increasing the flow of information on computer security-related matters among its various agencies.

At a global level including all of its member agencies, Interpol has also instigated a number of activities. The Steering Committee for Information Technology Crime has been established to coordinate and harmonize the initiatives of the various regional working parties. Interpol also organizes international conferences on computer crime to share relevant information among its members (Goodman & Brenner, 2002). Initiatives have also been taken to secure coordination with private ventures geared at securing information. In 2000, for instance, Interpol agreed to provide intelligence to the private Web site Atomic Tangerine, which in return would pass on to Interpol information gathered from its monitoring of the Internet. Atomic Tangerine operates a Net Rader service that had on earlier occasions informed police authorities of a Pakistani Internet service provider that had been hacked into as a base to launch other Web site attacks.

Establishment of Europol was agreed upon in the Maastricht Treaty on the European Union in 1992 (Europol website; Rauchs & Koenig, 2001). Based in The Hague, The Netherlands, Europol started limited operations in January 1994 in the form of the Europol Drugs Unit (EDU). After the Europol Convention was ratified by all member states, Europol commenced the full scope of its activities in July 1999. The aim of Europol is to improve the effectiveness and cooperation among the competent authorities of the member states in preventing and combating serious international organized crime. Europol’s areas of investigation include illicit drug trafficking, terrorism, child pornography, financial crimes, and cybercrime.

In matters of computer security and cybercrime in the European Union, Europol is involved only when an organized criminal structure is involved and two or more member states are affected (Computer Fraud and Security 2002; Europol website). Europol has set up a network of cybercrime units among its participating agencies, a centralized monitoring center at Europol headquarters, and a working group to establish cooperation with the private sector. In October 2002, Europol formed a High Tech Crime Center, a task force that has as its mission the coordination of cross-border cybercrime investigations in the European Union. In 2003, Europe’s policing activities against cybercrimes were stepped up by the creation of a European-wide rapid reaction force against attacks on vital computer networks in the form of a single round-the-clock information exchange system against cyberattacks.

## COMPUTER SECURITY, LAW ENFORCEMENT, AND THE BALANCE OF ORDER AND LIBERTY

With respect to the law enforcement aspects of computer security, a number of interesting issues and problems are revealed. The cross-border nature of computerized information exchange highlights the limits of national laws and law enforcement strategies and reveals the need for a coordination of law and law enforcement across jurisdictions. At the same time, continued efforts have to be made to protect liberty, privacy, and other democratic values that are promoted in an open and free society.

### The Coordination of Law and Law Enforcement

A central concern with the existence of diverse national legal systems on computer security is that for national laws to be enforceable, the jurisdictional authority of a nation has to be recognized by other states (Berman, 2002; Speer, 2000). Consensus among the standards of law across nations would alleviate this problem, but there are difficulties with harmonizing various approaches to computer security issues such as copyright infringement and intellectual property theft. International treaties are surely a worthwhile ideal (Weber, 2003), but they cannot be effective unless the participating nations already resemble one another in social, cultural, and economic respects and it is precisely this condition of egalitarianism that is often not

met. The cultures of nations, for instance, differ widely in terms of the emphasis they place on privacy, appropriate law enforcement strategies, and the very notion of jurisdictional sovereignty (Davis, 2003; Fischer-Hubner, 2000; Mayer-Schonberger, 2003).

An ironic consequence of the difficulties to establish a global legal order in matters of computer security (and other important legal issues) is that the lack of formal international agreements increases the likelihood of certain countries trying to exert extraterritorial jurisdiction on other countries (Podgor, 2002). Federal U.S. agencies, in particular, have often sought to assert federal extraterritorial jurisdiction in the prosecution of computer fraud activities that take place or originate from outside the borders of the United States. However, other countries might in turn resist such intrusive attempts that are seen as interfering with the national jurisdictional authority (Deflem, 2001, 2004a). Conflicts over extraterritorial claims cannot aid toward the development of coordinated legal and law enforcement strategies.

Some of the concerns that have been raised surrounding the European Convention on Cyber-Crime nicely illustrate the difficulties that international treaties on computer security face. Some members of the U.S. Congress, for instance, have criticized the European Convention because its widespread implementation would ultimately mean that the European data protection laws, which are considered too strict, might become the world's unitary privacy standard (Davis, 2003). As such, the convention raises resentment from nations on whose support it must ultimately rely. Related concerns have been expressed against the chilling effect the provisions of the convention might have against business enterprises, based in the United States or in other countries, whose commercial interests reach well beyond their respective national home bases.

More countries agreeing to the provisions of the European convention might lead other countries to also join in this international effort (Oddis, 2002). Yet, it can also be argued that adherence to the convention will violate jurisdictional and constitutional authority problems, because the individual states of the United States would not be allowed to create any conflicting or superceding laws to an agreed upon international treaty (Fisher, 2001; Hopkins, 2003). Even if such jurisdictional issues are cleared, there would still be a considerable problem with the fact that the enforcement and prosecution of the agreed upon international laws are left to the various participating states (Mayer-Schonberger, 2003). As Bellia (2001, p. 59) argues, an international agreement still leaves "in the hands of the state where the data is physically stored the power to search or seize the data in question."

### **Policing Technology, Maintaining Liberty**

Some cybercrimes involve criminal offenses that also exist in "realspace" (O'Neill, 2000) but that can now be executed with more speed and efficiency. The technological sophistication of threats to computer security change the nature of appropriate law enforcement activities, as detection and prosecution become considerably more difficult. As such, the policing of computer security relates

intimately to the ever-evolving relationship between technology and law and the continued need to find the most efficient and appropriate way to handle concerns of law and law enforcement in a technologically advanced world. Because of the speed with which technological advances are made and the intrinsic complexity of modern technologies, existing systems of law and law enforcement are often outdated soon after they have been planned and implemented (Skibell, 2003).

The technologically sophisticated nature of computer crimes means that law enforcement must recruit and train computer specialists and place priority on cooperation and intelligence sharing (McFarlane, 2001). But the technological nature of computer security might also imply that a strategy of law enforcement is needed that shifts the burden of protection of the technology to the manufacturer. This burden-shifting approach would target the design flaws that can lead to security-related failures (Katyal, 2003; Pinkney, 2002). Although not everybody will agree with this strategy, it is clear that cooperation between the government and its agencies, on the one hand, and the private sector, on the other, is needed (Coleman & Sapte, 2003). The fact that attacks against computer security also create economic damage provides at least a commercial incentive for active cooperation from the private sector. Strategies of security are not free, but neither are the consequences of insecurity (Hinde, 2003).

Debates surrounding the protection of privacy rights are virtually concomitant with the rise of new technologies. In matters of computer-related crimes, civil libertarians have argued that police actions should always remain mindful of the legitimate transactions that are conducted over the Internet and other technological communication systems (Brenner, 2003; Huie, Larabee, & Hogan 2002; Tountas, 2003). Aldesco (2002), for instance, argues that law enforcement has a legitimate interest in combating computer crimes, but that government agencies should not invade the privacy of legitimate communications. Although the anonymity afforded by the Internet can be abused, it is also an important value in a society committed to the free development of communications (Marx, 2001).

Newly developed law enforcement methods to ensure computer security are often less concerned with protecting the liberties granted in a democratic constitutional state (Kennedy, 2002). The European Convention on Cyber-Crime, for instance, empowers law enforcement agencies with the authority to search and seize information that is stored on computer systems, at least when such activities are part of a particular investigation into a cybercrime. By giving new powers to law enforcement to investigate cybercrimes, even outside of their respective jurisdictions, an imbalance may be created when there are no increasing protections for personal privacy. It is to be noted that such issues of individual rights are also important to consider relative to foreign nationals who commit cybercrimes and who are then subject to computer searches and other investigative procedures by law enforcement (Young, 2003). Given the disparity in the recognition of liberty and civil rights across the world, the inhabitants of some countries will be more likely to face dire consequences than will others (Huie et al., 2002), further enhancing inequality on an international scale.

## CONCLUSION

Law enforcement is an important and necessary component among the efforts to maintain computer security. Because of the rapid and widespread expansion of computerized technologies and because of the border-transcending nature of computers linked through networks, the policing of threats against computer security presents a challenge to traditional means of crime detection and investigation on an international scale. Existing notions of jurisdictional authority have to be redefined to meet the global needs of information security. Trying to avert cybercrimes and the economic and social harm they can cause, many nations across the world have developed new legislation. Extending these legislative efforts are international systems of law, such as the European Convention on Cyber-Crime, to respond to the need for international legal cooperation and more adequately address cybercrimes and related cross-borders threats against computer security.

Without adequate law enforcement, laws remain ineffective. In the case of computer security, law enforcement agencies have instituted specialized computer crime teams to focus on the ways in which crimes can be perpetrated against or with the aid of computers. As with their accompanying legal systems, pertinent law enforcement activities often extend beyond the reach of jurisdictional boundaries, whether via cooperation among the police forces of different nations or through unilaterally enacted police actions abroad. International police operations pose special problems of coordination among the law enforcement agencies of various countries and they also lead us to rethink the need for police to preserve liberty and legitimate computer transactions while seeking to police computer crimes effectively.

Law enforcement efforts against threats to computer security do not respond merely to technological developments, but also take shape in specific sociohistorical circumstances. Since the terrorist attacks of September 11, 2001, many dimensions of law enforcement have undergone considerable changes, not only in terms of counterterrorism strategies but also with respect to other aspects of crime and crime control (Deflem, 2004b). The policing of computer security issues has also been altered since 9/11 because scores of systems relating to security, means of transportation and communication, and other public facilities rely heavily on computerized systems (Birnhack & ElkinKoren, 2003; Brenner & Goodman, 2002; Raghavan, 2003). Given contemporary society's heavy reliance on computers, it is possible, for instance, for a terrorist group or individual to hack into the computers that oversee the subway system of a city or the railway network of a country. Following the attacks of 9/11, interest in and concern for computer security has skyrocketed, especially in connection with cyberterrorism. To be sure, cyberterrorism does not fully equate with cybercrime, but there is some overlap. For example, the initial stages of the offenses may be similar (e.g., sending out a computer virus), so that the response from a law enforcement viewpoint can be similar as well. But cybercrime and cyberterrorism differ in the harm they may cause and the motivation that is involved. In practice, however, the legislative responses—on both

the national level and the international level—often confuse between the two offenses and have thus sped up the development of new means to police cybercrimes.

The strongest indicator of the changes affecting cyber-related matters in the post-9/11 era is the Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism (USA PATRIOT) Act in the United States (Berkeley Technology Law Journal, 2004; Copeland, 2004). Among other provisions, the act gives authorities new powers by means of expanded options for wiretaps and technological systems of cybersurveillance (Ventura, Miller, & Deflem, in press). Relatedly, also, the National Cyber Security Division was created in the Department of Homeland Security in June 2003 as part of the National Strategy to Secure Cyberspace. Similar such new laws and the means to enforce them are now being set up in many other countries. Cyberlaw and law enforcement are a rapidly expanding reality. Ongoing developments indicate that, after several years of slowly responding to the threat of cybercrime, the events of 9/11 have served as an important catalyst to step up efforts to provide computer security through law and law enforcement. Although most cybercrimes do not relate to terrorism, the terrorist events of 9/11 may have provided the strongest impulse to develop new coordinated means against all types of cybercrime.

## GLOSSARY

**Computer Security Threats** Potential and actual violations of law that either involve attacks on the security of computers or that use a computer to commit an illegal act.

**Convention on Cyber-Crime** An international treaty initiated by the Council of Europe that involves a harmonization of legislation and an enhancing of international cooperation to prevent and suppress computer-related crimes.

**Cross-Border Law Enforcement** Activities of law enforcement agencies that transcend the jurisdictional authority of national states.

**Cybercop Units** Popular term for specialized units in law enforcement agencies that deal with cybercrimes and criminal activities associated with computerized information systems.

**Cybercrimes** Criminal activities involving the use of the Internet, including such criminal acts as fraud, identity theft, and cyberterrorism.

**International Policing** Police activities that involve citizens of other national states by means of international cooperation with foreign police, transnational police operations in foreign countries, or supranational crime developments affecting police in more than one country.

**Law Enforcement** The formal institutions of national states, and the functions that are associated with them, to enforce compliance to laws and investigate violations of law.

**Legal Systems** The whole of laws formally enacted by governing bodies, including the governments of national states and international governing agencies. Legal systems are accompanied by enforcement agencies and typically comprise civil and criminal laws.

## INTRODUCTION

The rapid development of computer connectivity and the role of the Internet in the emergence of new e-commerce markets are key generators of the processes of globalization and have compelled national governments and international agencies to address the need for regulation and safety on the information superhighways. These astonishing tools have eroded the traditional barriers to communication, compressed our concepts of time and place, and changed the way a large part of the world does business. Although the process of globalization continues to accelerate, a fully global response to the problems of security in the digital age has yet to emerge and efforts to secure cyberspace have been reactive rather than proactive.

The convergence of computing and communications and the exponential growth of digital technology have brought enormous benefits, but with these new benefits come greater risks. The new opportunities created in cyberspace have also enhanced the capacity for criminal enterprises to operate more efficiently and effectively both domestically and across borders. Law enforcement agencies in many jurisdictions have been unable to respond effectively and even in the most advanced nations, 'play catch-up' with cybersavvy criminals (Sussmann, 1999). As never before and at little cost, a single offender can inflict catastrophic loss or damage on individuals, companies, and governments from the other side of the world. With these risks has come the awareness that information security is no longer a matter for the technical and computer specialist, but for millions of people who now engage these new media every day for business, communications and leisure. The basic issue of how to police this new arena, cyberspace, is the focus in this chapter (for related discussion of cybersecurity systems for military purposes or asymmetric warfare see chapters "Online

Stalking," "Wireless Information Warfare," and "Information Assurance").

The role of digital and information technologies in the generation of national wealth now means that the new risks associated with these changes require continued attention on all fronts: national, regional, and international. At the international level, two new treaty instruments provide a sound basis for the essential cross-border law enforcement cooperation required to combat cybercrime and are briefly discussed. The first is the purpose-built Council of Europe's (CoE) Cybercrime Convention, which, although it was designed as a regional mechanism, has global significance. The second is the United Nations Convention against Transnational Organized Crime (TOC Convention), which is global in scope but indirectly deals with cybercrime when carried out by criminal networks in relation to serious crime. A further UN draft resolution in 2003 "Cybersecurity and the Protection of Critical Information Infrastructures," cosponsored by Argentina, Bulgaria, Canada, Ethiopia, and the United States, was presented at the 58th session of the General Assembly. If adopted, it invites member states and all relevant international organizations to take into account the need to protect critical information structures from possible misuses, including tracing attacks and, where appropriate, the disclosure of tracing information to other nations (Redo, 2004).

At the international level, the role of agencies such as the United Nations Office of Drug Control and Crime Prevention (UNDCP), Interpol, the Organization for Economic Cooperation and Development (OECD), and the G8 group of nations and regional bodies such as the European Union (EU), Organization of American States (OAS), Association of South East Asian Nations (ASEAN), and the Asia Pacific Economic Council (APEC) provide the political and technical expertise necessary to effect

cross-border cooperation in policing. As digital technology becomes more pervasive and interconnected, ordinary crime scenes will contain some form of digital evidence. Crucially many cybercrimes take place across jurisdictional boundaries with offenders routing attacks through various jurisdictions that can only be countered by a cross-border and international policing response.

The digital divide between nation states is growing rapidly and the role of advanced information technology-based economies in bridging this divide is essential. Most developing countries do not have a telecommunications sector capable of supporting information and communication technologies (ICT). In 2000, the United Nations reported that only about 4.5% of the global population had network access, but that 44% of North Americans and 10% of Europeans did, whereas rates for Africa, Asia, and South America ranged from 0.3 to 1.6%. Currently, more than 98% of global Internet protocol bandwidth, at the regional level, connects to and from North America. Fifty-five countries account for 99% of worldwide spending on information technology production. A fifth of the world's people living in the highest-income countries have 86% of the world's gross domestic product (GDP) and 93% of Internet users, whereas the bottom fifth have 1% of GDP and only 0.2% of Internet users (United Nations, 2003, as cited in Redo, 2004—see also volume II, chapter 88).

The need for reliable and efficient mechanisms for international cooperation in law enforcement matters has never been more urgent. As noted, the international community has taken a number of significant steps to facilitate cross-border cooperation in criminal matters, including in the investigation and prosecution of cybercrime. This chapter considers some of the avenues for cooperation. However rapid the growth of ICT may be, it is unlikely to continue its apparently exponential trajectory unless the digital divide is broken and poorer nations and neighbors are included.

There is also growing concern about the potential for misuse of information technology (IT) by terrorists. This has made cyberterrorism a major strategic issue in the prevention of terrorism because the technologies themselves may be attacked and can also be used to support terrorism in the same way ITs are used by predatory cybercriminals. The use of computers by terrorists to plan, organize, and communicate is well documented and counterterrorism agencies have commonly identified high-tech media such as cellular and satellite telephones and Internet-based communications. Cases have also been reported in which hacking, physical thefts, or the corruption of officials have been used to gain access to sensitive law enforcement information (see International Narcotics Control Board, 2001). The global reach of terrorism prompted the UN General Assembly in its resolution 51/210, to note the risk of terrorists using electronic or wire communication systems to carry out criminal acts (Redo, 2000, 2004).

## CRIMINALITY AND COMPUTER CRIME

With government, industries, markets, and consumers increasingly dependent on computer connectivity, they are

prone to an array of threats. The most notable have been the widely publicized computer viruses, which have increased in both virulence and velocity since 2000. The beginning of 2004 saw the development of increasingly complex malicious code in the form of the MyDoom or Norvag worm. It combined the effects of a worm, spreading rapidly across the Internet, with that of a distributed denial of service attack in which computing power is directed at a target system with a view toward shutting it down. In other words, infected computers were remotely commandeered and directed against the target computer. The risks now posed by the release of malicious codes of increasing complexity (often specifically targeted against either a significant commercial or government site) were substantial and could threaten the viability of e-commerce (Moore, Shannon, Voelker, & Savage, 2003; Semple, 2004; Staniford, Paxson, & Weaver, 2002; see also volume III, part 1).

The U.S. Federal Bureau of Investigation (FBI) has also stressed that critical infrastructure protection is a priority in the United States. Given that most elements of critical infrastructure such as power generation, telecommunications, transport, and financial institutions are owned by the private sector, cooperation between law enforcement and the private sector is obvious. To help bridge the public-private gap, the FBI has introduced its Infraguard Program with over 4,000 members (Iden, 2003). There is also a crucial role for the communications and IT industries in designing products that are resistant to crime and that facilitate detection and investigation.

## What Is Computer Crime?

The scope of criminal activities and their social consequences can be summarized by a typology of computer-related crime that comprises the following: conventional crimes in which computers are instrumental to the offense, such as child pornography and intellectual property theft; attacks on computer networks; and conventional criminal cases in which evidence exists in digital form. The kinds of criminality encompass the following list (by no means exhaustive—see Part 2 for further details):

- Interference with lawful use of a computer: cyber-vandalism and terrorism; denial of service; insertion of viruses, worms, and other malicious code.
- Dissemination of offensive materials: pornography or child pornography, online gaming or betting, racist content, treasonous or sacrilegious content.
- Threatening communications: extortion, cyber-stalking.
- Forgery or counterfeiting: ID theft; internet protocol (IP) offenses; software, CD, DVD piracy; copyright breaches; and so forth.
- Fraud: payment card fraud and e-funds transfer fraud; theft of Internet and telephone services; auction house and catalog fraud; consumer fraud and direct sales (e.g., virtual snake oils); online securities fraud.
- Other: Illegal interception of communications, commercial or corporate espionage, communications in

furtherance of criminal conspiracies, electronic money laundering.

Many of these risks appear to mimic traditional criminal exploitation, albeit often executed with unprecedented ease, speed, and impact across jurisdictions and thus the appropriate response is guided by new technological disciplines. The tasks of identifying cybercriminals and bringing them to justice pose challenges to law enforcement agencies across the globe and require a degree and timeliness of cooperation that has been until only recently regarded as impossible to achieve. However, computer intrusion is now more likely a predicate to a more serious offense. Forensic computing and evidence preservation protocols are essential to effective investigation and prosecution, especially given the trans-border nature of evidence collection (Pollitt, 2003; and see volume II, part 3, chapters 124–129). In most cases it is unlikely that a computer expert will be available at the crime scene and the risks of contaminating the evidence are high. Consequently, as with other types of crime, the emphasis is on following the traditional chain-of-evidence rules and ensuring that command and control assigns the relevant expertise promptly to the task at hand. Frequently this will require drawing on expertise in the private sector or academia.

Leading crime prevention scholars Newman and Clarke (2003) provide a review of crime prevention in the e-commerce context. In online situations, the theft of information and the manipulation of identity and trust are the key. In their approach, crime is an *opportunity* that occurs when the following conditions combine in time and place: the presence of motivated and tempted offenders and attractive and tempting targets in the absence of effective guardians. When this situation arises, crime will occur providing the offenders also have appropriate resources to undertake the crime. Consequently, efforts to reduce online offenses and e-commerce crime need to recognize these basic ingredients and the numerous pathways or opportunities for crime in the online rather than face-to-face environment. A crucial factor is how trust is acquired and maintained when merchants must be more intrusive about their (unseen) customers' identity and credit risk and the apparent ease in which trust is manipulated by fraudsters and others operating online. Risk-averse systems of e-commerce therefore needed to be far more integrated than conventional environments and require more than passing attention to what the information security engineers like to call social engineering (see also volume III, part 2).

## TRANSNATIONAL POLICING AND CYBERCRIME

The transnational nature of cybercrime reflects the process of globalization, which has intensified over the past two decades. The emergence of e-commerce, as well as the social dimension of the Internet and associated cybercrimes, is a striking example of the challenges to the independent capability of nation states to regulate social and economic order within their territories. Radical versions

of globalization go further and suggest that the nation-state system of international relations no longer provides an effective methodology for regulating either domestic or transnational activity, especially international trade. In either version of globalization, substate actors, such as large commercial institutions, play a crucial role in the emergence of what Sheptycki (2000) terms a transnational-state system. Consequently the role of public-private police partnerships in the marketplace and the emergence of civil society on the Internet combined with public awareness are essential to contain cybercrime among ordinary users.

Although there now exist international conventions and treaties expressly designed to inhibit serious criminal networks or offenders operating across borders, the reach of these instruments is limited by the speed and scale of domestic ratification and consequential enabling laws. In dealing with IT crime, law enforcement is at a disadvantage because of the remarkable speed in which cybercrimes unfold against the typically low-speed cooperation offered by traditional forms of mutual legal assistance. The role of multinational agencies such as Interpol and the United Nations has never been more essential. Yet globally the results fall far short of creating a seamless web of bilateral or multilateral agreements and enforcement that would ensure a hostile environment for cybercriminals. The compatibility of criminal activity with these global changes is illustrated by the expansion and convergence of the profitable business of smuggling of humans, narcotics, or other illicit commodities with the development of communication infrastructure and trade.

The passage of the Council of Europe's Cybercrime Convention in December 2001 and its activation in July 2004 provides an international legal mechanism for cooperation in law enforcement and harmonization of laws (see Cross, 2003; Csonka, 2005; Esposito, 2004, Sato 2004), although 37 states have signed the convention and the "First Additional Protocol to the Convention on Cybercrime on the Criminalisation of Acts of a Racist or Xenophobic Nature Committed through Computer Systems" has been signed by 22 states but is yet to be ratified (see "Additional Protocol to the Convention on Cybercrime," 2003).

The convention, apart from enhancing mutual legal assistance (MLA), provides comprehensive powers to expedite preservation of stored computer data and partial disclosure of traffic data, to make production orders, to search computer systems, to seize stored computer data, to enable the real-time collection of traffic data, and to intercept the content of questionable electronic data. A number of countries outside the Council of Europe (United States, Mexico, Japan, Canada, and South Africa) were involved from the outset and have signed the convention, and many other countries, notably in South America, are considering similar model legislation (see OAS, n.d., for recommendations on an inter-American cybercrime instrument). The convention is also open to any non-member state wishing to join (via a request to the Committee of Ministers of the Council of Europe). Given the pressing need for a broader multilateral structure for cross-border cooperation in the computer crime area,

every effort should be made to open up the convention for accession by a wide number of signatories as soon as is practicable (Bullwinkel, 2005). Indeed many jurisdictions in the Asian region, Thailand in particular, have looked at the convention for guidance in formulating national laws.

These developments are mirrored by the increasing transnational activities of corporate and private security. Indeed, given the role of (self-) regulatory approaches by corporations, especially multinational enterprises, the role for transnational private policing is already significant and widespread (Johnston, 2000). For example, private security is the major provider in the payment card industry, intellectual property investigations, and airline security. The sheer volume of potential global cybercrime activity compels police partnerships with banks, telecommunication providers, and corporations. Partnerships also raise real issues of shared intelligence in environments of trust. Thus, the mobilization of so-called private police and non-governmental organizations in partnership with public police are essential if cybercrime is to be contained. Crime exploits the gaps in the sovereign state system of international relations and unless that is recognized in communities of shared fate, coordinated forms of regulatory endeavor (free, for example, from unduly strict or pedantic definitions of dual criminality) may be the only means to curtail cybercrime and its inevitable cross-border dimension.

### United Nations Convention against Transnational Organized Crime

Since the early 1990s, beginning with the Eighth UN Congress on the Prevention of Crime and the Treatment of Offenders (1990), the United Nations, with its network of institutes on crime prevention and criminal justice, has been actively involved in addressing problems of transnational crime and cybercrime. The scope of computer-related crime affects every country in the United Nations, and the UN General Assembly in 2001 promoted new international efforts to assist member states in dealing with computer-related crime. The General Assembly, in the "Plans of Action for the Implementation of the Vienna Declaration on Crime and Justice: Meeting the Challenges of the Twenty-first Century" (General Assembly resolution 56/261), devoted a special section to "Action against High-Technology and Computer-Related Crime," in which it provided action-oriented policy recommendations for the prevention and control of these crimes. In 2002, the General Assembly again addressed the Vienna Plan of Action (General Assembly resolution 57/170) and through the Commission on Crime Prevention and Criminal Justice recommended that the Eleventh United Congress on Crime Prevention and Criminal Justice consider the plan. In 2001, the UN secretary-general explored various options for further work on high-technology and computer-related crime and considered the following four questions: whether a global treaty, if any, should be normative or legally binding; what relationship, if any, this would have to the UN Convention against Transnational Organized Crime; how a treaty, once concluded, could be kept up to date; and how it may accommodate issues such as privacy,

freedom of expression, and other human rights and commercial interests (Redo, 2004).

Although not specifically directed at cybercrime, the complementary role of the TOC Convention is a highly relevant global instrument for addressing some of the more nefarious aspects of cybercrime. The TOC Convention was introduced in December 2000 in Palermo, Italy. The TOC Convention has been signed by 147 states (and 82 parties) and came into force on September 23, 2003 (see "United Nations Convention," n.d.). The TOC Convention significantly extends the reach of the 1988 Vienna Convention against Illicit Traffic in Narcotics and Psychotropic Substances. The TOC Convention enables MLA between states and establishes several offense categories: participation in an organized criminal group, money laundering, corruption and obstruction of justice, as well as protocols in respect to trafficking in women and children (117 states and 64 parties with effect from December 25, 2003); illicit manufacturing and trafficking in firearms (52 states and 22 parties but not yet in force); and smuggling of migrants (112 states and 57 parties with effect January 28, 2004). Serious crime is defined broadly (conduct attracting punishment of four or more years' imprisonment). The basis of the framework is one that yields such flexibility in the definitions of both organized and transnational crime that it may serve as a generic legislative model across diverse common law and continental systems. In addition, the TOC Convention expressly refers (Article 29(2)) to methods for combating the misuse of computers and telecommunications networks; refers to provisions for training and materials, especially assistance for developing countries; and places obligations on capable states. The convention also establishes a number of principles and arrangements for international cooperation, which may be taken as an example of a potent global instrument against cybercrime, in line with Article 13.1(a) of the UN Charter emphasizing the progressive development of international law. They include regulations limiting the rule of double criminality for mutual assistance purposes and introduce enterprise responsibility.

The scope of the TOC Convention includes particular offenses signatories are obliged to criminalize (Articles 5, 6, 8, and 23) as well as serious crime (as defined in the Convention), "where the offence is transnational in nature and involves an organized criminal group" (see Article 3(1)). Importantly, the definitions of *serious crime* and *organized criminal group* reflect an understanding that organized criminal activity is no longer confined to a relatively narrow range of offenses traditionally associated with organizations such as Triads and the Cosa Nostra. The TOC Convention defines an offense as "transnational" if it is (a) committed in more than one state; (b) committed in a single state but planned, prepared, directed, or controlled in another state; (c) committed in one state but involving an organized group whose activities cross national boundaries; or (d) committed in a single state but has "substantial effects" in another state (see Article 3(2)). Many of the most common forms of cybercrime therefore qualify as serious crime because such offenses usually affect more than a single jurisdiction, often involve at least three or more actors, and are

committed with the aim of achieving some financial or material benefit.

Article 27 deals with police-to-police cooperation and reflects the types of assistance routinely provided among police officials in the absence of a formal agreement and reflects international consensus on the need for close coordination between law enforcement authorities and to achieve this goal, states are encouraged to promote the exchange of personnel and other experts, including liaison officers. Additionally, signatories are required to “make full use of agreements or arrangements, including international or regional organisations, to enhance the cooperation between their law enforcement agencies” (Article 27(2)). With respect to formal MLA, Article 18 contains provisions nearly as lengthy and detailed as a comprehensive bilateral MLA treaty. States may seek assistance in connection with taking evidence or statements from persons, executing searches and seizures, obtaining business or government records, and identifying and tracing the proceeds of crime. A requested state has the discretion to decline assistance on the ground of the absence of dual criminality—a potentially significant limitation in the cybercrime context, as many countries do not have fully developed legislation in this area. The TOC Convention also provides for extradition (Article 16) even where a state party makes extradition conditional on the existence of a bilateral treaty. Article 16 represents a major step forward because its effect is to incorporate into existing bilateral treaty relationships the numerous offenses covered by the convention (Article 16(3)). Thus, where two states’ parties have relied on outdated and narrow extradition agreements (such as a list-based treaty providing for extradition only in relation to a specified list of offenses), the TOC Convention will substantially expand the range of extraditable offenses between them (Bullwinkel, 2005; Cross, 2003).

## THE COUNCIL OF EUROPE CYBERCRIME CONVENTION

The Council of Europe, founded in 1949, comprises 45 countries, including the members of the European Union (a distinctly separate entity), as well as countries from Central and Eastern Europe. Headquartered in Strasbourg, France, the CoE was formed as a vehicle for integration in Europe, and its aims include agreements and common actions in economic, social, cultural, legal, and administrative matters. As one of the two principal supranational organizations in Europe (the other being the European Union), the CoE is responsible for creating and implementing a wide variety of measures aimed at international crime and has adopted a number of widely used conventions on interstate cooperation in penal matters. In 1996, the CoE’s European Committee on Crime Problems established a committee of experts to address cybercrime, which completed its work late in 2001.

The resulting Cybercrime Convention has three aims: to lay down common definitions of certain criminal offenses—nine are mentioned in the convention—thus enabling relevant legislation to be harmonized at national

level; to define common types of investigative powers better suited to the information technology environment, thus enabling criminal procedures to be brought into line between countries; and to determine both traditional and new types of international cooperation, thus enabling cooperating countries to rapidly implement the arrangements for investigation and prosecution advocated by the convention in concert, for example by using a network of permanent contacts. The convention has received strong support from lawmakers and practitioners throughout Europe and beyond. But both the convention and its additional protocol have been criticized on various grounds by a number of associations, particularly those active in the protection of freedom of expression and also by industry elements (Csonka, 2005).

The CoE Convention on Cybercrime obligates signatories to criminalise a minimum list of specific offenses for which there was consensus and thus harmonized offenses to eliminate problems of dual criminality. The basic structure and content of the convention is outlined below.

## Computer-Related Offenses

Title 1 addresses offenses against the confidentiality, integrity, and availability of computer data such as (1) illegal access of a computer system; (2) interception of non-public transmissions of computer data to, from, or within a computer system; (3) interference with computer data; (4) interference with computer systems, such as computer sabotage; and (5) the misuse of computer-related devices (e.g., hacker tools), including the production, sale, procurement for use, import, or distribution of such devices. Criminalizing illegal access, that is, hacking, cracking, or computer trespass, sends a clear signal that this conduct is illegal in itself and will be prosecuted: such intrusions may give access to confidential data (including passwords and information about the targeted system) and secrets or to free use of the system and might encourage hackers to commit more dangerous forms of computer-related offenses, such as computer-related fraud or forgery. The criminalization of illegal interception protects the privacy rights of data communication, seeks to deter the tapping and recording of communications between persons, and applies this principle to all forms of electronic data transfer, whether by telephone, fax, e-mail, or file transfer. The provision on data interference aims at providing computer data and computer programs with protection similar to that enjoyed by corporeal objects against intentional infliction of damage. Conduct such as damaging, deteriorating, or deleting computer data reduces the integrity or content of data and programs and also captures malicious codes and viruses (e.g., Trojan horses).

The convention criminalizes acts of computer sabotage and covers the intentional hindering of the lawful use of computer systems, including telecommunications facilities, by using or influencing computer data (system interference). The section covering misuse of devices establishes a separate criminal offense including some specific conduct (production, distribution, sale, etc.) involving access devices, which were primarily designed or adapted for misuse. Devices that are designed and used for legal

purposes are not included. This offense therefore requires a particular purpose: that is, committing any of the other offenses against the confidentiality, integrity, and availability of computer systems or data.

Title 2 covers the traditional offenses of fraud and forgery when carried out through a computer system. For forgery, the intent of this provision is to protect computer data in the same manner as tangible documents, where such data may be acted upon or used for legal purposes (Esposito, 2004). Chapter 5 obliges signatories to criminalize the attempt to commit certain offenses on which the convention imposes a criminalization obligation, as well as aiding and abetting the commission of offenses, and also provides for the liability of legal persons.

### Content-Related Offenses

Title 3 seeks to control the use of computer systems as a vehicle for the sexual exploitation of children and acts of a racist or xenophobic nature. This category of offenses concerns the subject or contents of computer communications and focuses on offenses related to children. The convention makes various acts (from the possession to the intentional distribution of child pornography) criminal offenses, thus covering all links in the chain. This provision criminalizes various aspects of the electronic production, possession, and distribution of child pornography. Most states already criminalize the traditional production and physical distribution of child pornography, but with increasing use of the Internet as the main method to distribute such material specific provisions were essential to combat this new form of exploitation. Other types of illegal content, such as racist propaganda, have also been included but in the form of an additional protocol criminalizing racist propaganda. Esposito (2004) notes that cybercrime is now defined as crimes committed against and through computer systems. The CoE's Cybercrime Convention was originally intended to cover only the first category, although there is a growing consensus, at least in Europe, of the need to address the second category (e.g., Article 9 of the Cybercrime Convention on cyber-pedopornography and the additional protocol on the fight against racism and xenophobia on the Internet).

### Offenses Related to Copyright Infringement

Title 4 criminalizes willful infringements of copyright and related rights when such infringements have been committed by means of a computer system and on a commercial scale. This section targets the large-scale distribution of illegal copies of works protected by intellectual property rights (IPR). Infringements of IPR, in particular of copyright, are among the most commonly committed offenses on the Internet and cause concern both to copyright holders and to those who work professionally with computer networks.

### Jurisdiction

Among the various important matters addressed by the convention was the question of jurisdiction in relation

to information technology offenses, for example to determine the place where the offense was committed and which law should accordingly apply, including the case of multiple jurisdictions and the question of how to solve jurisdictional conflicts. This provision establishes criteria under which contracting parties are obliged to establish jurisdiction over the criminal offenses in the convention. The provision concerning jurisdiction also requires states exercising jurisdiction to coordinate when victims are located in different countries.

### Procedural Powers

The procedural part of the convention, which also applies to the additional protocol, aims to enable the prosecution of computer crime by establishing common procedural rules and adapting traditional measures such as search and seizure and creating new measures, such as expedited preservation of data, to remain effective in the volatile technological environment. As data in the IT environment is dynamic, other evidence collection relevant to telecommunications (such as real-time collection of traffic data and interception of content data) has also been adapted to permit the collection of electronic data in the process of communication.

## GLOBAL AND REGIONAL COOPERATION

Cybercrime creates an unprecedented need for concerted action from government and industry, but also unprecedented challenges to effective international cooperation. As noted, it is not always clear where computer-related offenses take place for the purpose of determining criminal jurisdiction. An offense may produce victims in many countries, as in cases involving virus attacks, copyright violations, and other offenses carried out globally through the Internet. This in turn may result in cross-border conflicts regarding which jurisdiction(s) should prosecute the offender and how such prosecutions can be carried out to avoid inconvenience to witnesses, duplication of effort, and unnecessary competition among law enforcement officials (Bullwinkel, 2005, and see volume II, part 2, chapters 92 and 93).

Most countries have domestic statutes relating to legal assistance and extradition and these sometimes enable extensive cross-border cooperation even in the absence of a formal treaty relationship. However, domestic legislation, while helpful for certain types of cooperation, is not a substitute for well-developed bilateral (or multilateral) agreements. For example, in the absence of a treaty establishing a direct relationship between legal authorities, requests for legal assistance must often be transmitted through the cumbersome and time-consuming diplomatic channel and this method is too slow to meet the challenges of cybercrime. Bilateral agreements such as MLA treaties and extradition treaties are more reliable means for international cooperation in criminal matters. Extradition treaties fall into two general categories: so-called list treaties and more modern dual criminality treaties.

In the case of list treaties, the contracting parties are bound to extradite only those offenses specified in the agreement. This may be a significant limitation, particularly in cases involving newer forms of crime (including many cybercrimes). The trend in modern treaty practice is to provide for extradition for offenses punished by imprisonment for more than a year under the laws of both parties. These dual criminality extradition treaties are as broad as the criminal laws of the requesting state but extradition for cyberoffences may prove difficult, because some jurisdictions have not yet criminalized the conduct. When this occurs the requested state should follow the practice, accepted in international law, of interpreting the treaty in favor of extradition. The advantages of a bilateral treaty are that they limit the requested state's discretion to refuse assistance. In bilateral MLA treaties, the parties will in most cases be required to execute the request unless the request relates to a political offense or to an offense under military law that would not be an offense under ordinary criminal law or when the request would prejudice the requested state's security or similar essential interests. Subject to limited exceptions and the overall scope of the agreement, bilateral treaties ordinarily oblige the signatories to provide a wide measure of assistance and often the requested assistance must be provided even in the absence of dual criminality (Bullwinkel, 2005).

The various measures now operating within the European Union, the Council of Europe's convention, the establishment of Europol, and a European Judicial Network provide examples of greater law harmonization and fewer opportunities for transnational criminals to exploit jurisdictional and legal loopholes between nations. Thus international law enforcement has shifted from a peripheral to a central role within otherwise domestically focused law enforcement agencies. In addition, the lines between the policing function and national security appear less distinct, and considerable overlap now routinely occurs between the agencies countering threats such as cybercrime, low-intensity warfare, and terrorism.

Regional efforts outside of Europe are also underway via OAS, ASEAN and the APEC forum. Such developments have yet to evolve into fully institutionalized forms of cross-border legal cooperation or to determine the response of states within the region. There are now significant regional forums for police and other law enforcement officials and there is routine exchange of consular police liaison officers (Aiziwa, 2001). The leading organizations, apart from the United Nations and the Council of Europe, involved in developing international and regional efforts against cybercrime are briefly described in the following sections.

### **G8 Senior Experts Group on Transnational Organized Crime**

The Group of Eight (comprising Canada, Germany, France, Italy, Japan, the United Kingdom, the United States and, since 1995, Russia), although originally established to coordinate economic policy, has also developed initiatives to combat international crime. At the

Halifax Summit in 1995, G8 heads of state established a cross-disciplinary group of senior government experts (the Lyon Group) to address methods of combating transnational organized crime. In 1996, the Lyon Group devised 40 recommendations aimed at increasing the efficiency of collective action against transnational organized crime via two interrelated goals: strengthened capacity in the investigation and prosecution of high-tech crime and more effective regimes for cross-border cooperation in criminal matters.

The 40 recommendations cover a range of issues and emphasized the need to eliminate delay in respect to traditional forms of cross-border assistance (such as informal police cooperation, mutual legal assistance, and extradition) and a coordinated approach in tackling high-tech crime. As a consequence of these recommendations, the Lyon Group's High-Tech Crime Subgroup was established and quickly thereafter the 24/7 computer security network, which has now expanded to countries outside the G8. As of 2004, 39 countries participated in the global 24/7 cybercrime response network. Later, G8 ministers endorsed a set of principles and an action plan to respond to transnational cybercrime cases that included provision of adequate personnel and training to fight high-tech crime; domestic laws that criminalized cybercrime and ensure that relevant evidence, including traffic data, could be preserved and obtained expeditiously; and coordination with industry to ensure that new technologies are developed in a way that will facilitate law enforcement action against cybercriminals. The 1999 Moscow meeting later endorsed principles on transborder access to stored computer data and called for a comprehensive response to Internet fraud and more industry coordination. Most recently, a joint communiqué of the G8 home affairs ministers meeting in Washington on May 10, 2004, noted, given the activation of the Council of Europe's Convention on Cybercrime, that action was required "to encourage the adoption of the legal standards it contains on a broad basis" and "all countries must continue to improve laws that criminalize misuses of computer networks and that allow for faster cooperation on Internet-related investigations" (G8 Justice and Home Affairs Communiqué 2004).

### **ASEAN**

ASEAN comprises 10 nations: Brunei Darussalam, Cambodia, Indonesia, Laos, Malaysia, Myanmar, Philippines, Singapore, Thailand, and Vietnam. Although ASEAN has provided a limited pan-Asian approach, it does form a basis for developing a wider regional forum for considering matters of MLA. Its approach, even given the developing nature of the region, mirrors the methodology of the European Union, but the cultural and economic diversity of Asia makes the process of multilateralism fraught with difficulty (Khoo, 2003). Yet understanding the different capacities and perspectives of how each state could contribute was an essential first step. The endorsement in October 2000 of the action plan of the ASEAN and China Cooperative Operations in Response to Dangerous Drugs in partnership with the UNDCP illustrates

the quickening of MLA responses to transnational crime such as cybercrime. ASEAN has conducted four ministerial meetings on problems of transnational crime (Manila 1997, Yangon 1999, Singapore 2001, and Bangkok 2003). These meetings oversee the work of the Annual Senior Officials Meeting on Transnational Crime and consider the deliberations of meetings of the ASEAN National Chiefs of Police (ASEANAPOL) and their cooperative efforts to combat transnational crime. At the Second ASEAN Ministerial Meeting on Transnational Crime (held in Myanmar in 1999), ASEAN ministers issued another ambitious communiqué outlining a broad plan of action to enhance collective efforts against the many forms of organized criminality in the region. A group of senior government officials (referred to as the Senior Officials Meeting on Transnational Crime, or SOMTC) has been tasked to assist in the execution of ministerial initiatives and directives.

The theme of greater cooperation carried over to the Third and Fourth ASEAN Ministerial Meetings on Transnational Crime, at which ASEAN ministers reiterated their commitment to collaborate further in the battle against computer-related crime and called for a stronger partnership between ASEAN and other partners and agencies, including Interpol and the United Nations ("Joint Communiqué of the Third ASEAN Ministerial Meeting," 2001). As noted, the ASEAN anticrime institutions, particularly SOMTC, mimics the G8's Lyon Group, indicating the relevance of such frameworks for collective government action. Particularly significant is that ASEAN's law enforcement experts group reports directly to ministers and thus, like the G8's Lyon Group, has the capacity to develop policies with support at the highest levels.

### The European Union and Europol

The 1957 Treaty of Rome established the European Economic Community, which in turn evolved into the European Union, established under the Treaty of Maastricht in 1992. The European Union has 28 member states and recently completed the accession of 13 countries in eastern and southern Europe (with some new members joining on May 1, 2004). It includes supranational institutions that address international crime by adopting joint positions, directives, and other instruments addressing a wide variety of criminal activities. Among the most important in respect to the coordination of law enforcement are the adoption of a common position on negotiations relating to the CoE Cybercrime Convention and EU conventions on mutual assistance in criminal matters and extradition (see European Union, *Judicial Cooperation in Criminal Matters*, 1998 and see generally <http://europa.eu.int/scadplus/leg/en/s22004.htm> visited May 9, 2005), the establishment of a European Judicial Network consisting of liaison magistrates and representatives responsible for international judicial cooperation, and tasked with facilitating cross-border cooperation (Decision establishing Eurojust, 2002). Further strengthening of MLA is contained in the April 19, 2002, "Proposal for a Council Framework Decision on

Attacks against Information Systems", adopted in June 2003 (European Union, 2003)

Included within the EU is the European Police Office or Europol, dedicated to increasing the efficiency of cooperation among the police agencies of EU member states, with an emphasis on targeting organized crime. Based in Brussels, Europol is accountable to the EU's Council of Ministers for Justice and Home Affairs. The organization is comprised of European liaison officers (who represent national law enforcement agencies across the European Union, including police, customs, and immigration officials) and Europol staff officers. Like Interpol, Europol's primary function is to support the operational activities of national law enforcement officials and was recently extended to include the fight against cybercrime. In furtherance of this, its representatives facilitate the exchange of information, provide analyses of criminal intelligence, generate strategic reports on trends and patterns of criminal activity, and provide technical expertise for ongoing investigations within the European Union. In addition, it is likely Europol will eventually assume a greater investigative and operational role.

### The Organization for Economic Cooperation and Development

Established in Paris in 1960 by 20 countries (now 30 members), the OECD aims to promote economic and social welfare throughout the OECD by helping member states to coordinate their efforts to aid less developed nations. The OECD has established a presence in law enforcement, for example, by establishing the Bribery Working Group, whose efforts ultimately led to the adoption of a convention against commercial bribery. The OECD has been active in the area of cybercrime and online security, especially in regard to encryption technology, evaluating the balance between law enforcement and privacy concerns, and the means by which member states can coordinate encryption policy and in 1997 issued a series of guidelines addressing these issues. More recently, in the wake of the terrorist attacks of September 11, 2001, OECD governments developed a series of guidelines designed to counter cyber-terrorism, computer viruses, hacking, and related threats ("OECD Governments Launch Drive," 2002). Although the recommendations are not legally binding, they reflect consensus among key jurisdictions on issues affecting the security of the online environment.

A highly effective approach to intergovernmental law enforcement coordination that offers a template for transnational cooperation against cybercrime is the Financial Action Task Force (FATF) established at the G7 Paris Summit in 1989 and based in the OECD. FATF is a policy-making body whose aim is the implementation of legislative and regulatory reforms needed to combat money laundering. In 1990, FATF issued a series of 40 recommendations addressing ways to combat and deter money laundering. The recommendations are grouped into three broad categories (criminal law, banking law, and international cooperation) and serve as the basis for its activities. As a result of awareness-raising activities

undertaken by FATF, a number of FATF-style organizations have also developed at the regional level including, in the Asian-Pacific region, the Asia/Pacific Group on Money Laundering, established in 1997, which operates in a manner similar to FATF and, in 2000, began to undertake a FATF-style mutual evaluation. A novel feature of FATF is that members are subject to peer review, a two-part process by which the group assesses implementation of the 40 recommendations. First, each FATF member conducts an annual self-assessment using a standard questionnaire. Second, periodically members are subject to a process of mutual evaluation, involving a site visit by three or four experts from other member governments. Mutual evaluation has proved effective in persuading governments to take steps to fill gaps in anti-money laundering (see generally [http://www.oecd.org/fatf/AboutFATF\\_en.htm](http://www.oecd.org/fatf/AboutFATF_en.htm)).

## Interpol

The International Criminal Police Organization, or Interpol, consists of 181 member states. Headquartered in Lyon, France, Interpol coordinates its activities through national central bureaus in individual countries. Its mission is to support law enforcement organizations throughout the world, in particular by facilitating the exchange of information, coordinating joint operational activities of member states, and developing and sharing expertise and best practices covering a wide range of criminal offences (see generally <http://www.interpol.int/Public/icpo/Guide>). Nearly half of Interpol's member countries lack the infrastructure for online communication (Noble, 2003) and thus in respect to IT crime, Interpol has recognized the need for law enforcement officials to acquire specialized knowledge and has developed international training courses and manuals providing useful guidance for investigators working on computer-related crime (see <http://www.interpol.int/Public/TechnologyCrime/WorkingParties/Default.asp#steeringCom>).

Interpol's General Secretariat has also supported the formation of regionally organized working groups comprising local experts in computer-related crime who meet periodically to share experiences and develop best practices (Noble, 2003). An example is the Asia-South Pacific Working Party on Information Technology Crime that currently meets annually and has undertaken projects relating to the handling of digital evidence, forensic tools, and training. Interpol has also endeavored to build close ties to existing regional structures in Asia, including ASEANAPOL, in an effort to build on regional cooperation by facilitating the development of regional intelligence databases and the wide dissemination of data through Interpol's extensive telecommunications network. Interpol has also stressed financial and high-technology crime as two of Interpol's top five priorities (along with drugs, terrorism, people smuggling, and organized crime). In addition, Interpol has increased its focus on intellectual property-related crime, because sophisticated and well-financed organized criminal groups increasingly carry out these offenses on a global scale. Interpol hosted an initial meeting of its Intellectual Property Crime Action Group in July 2002 (see generally [\[interpol.int/Public/FinancialCrime/IntellectualProperty/Default/.asp\]\(http://www.interpol.int/Public/FinancialCrime/IntellectualProperty/Default/.asp\)\).](http://www.</a></p></div><div data-bbox=)

Generic problems of forgery and counterfeiting were the focus of Interpol's exemplary efforts in establishing a Universal Classification System for Counterfeit Payment Cards secure Web site. This secure site provides up-to-date information on trends and techniques with respect to the forgery of payment cards and fraud and enables law enforcement officials around the world to retrieve forensic data as well as general intelligence. Payment card industry representatives working in the anti-fraud area will also have access to the otherwise closed system. Apart from illustrating how Interpol's unique clearing-house function can be adapted to meet new problems, it showed that with support from the payment card industry the law enforcement community can be better trained and equipped. This cooperation strengthens police capacity to respond to the theft of payment cards and other computer-related crimes that reduce the integrity of the market and limit the social benefits of Internet communications. As well as serving as an example of how international agencies can assist with essential tasks such as secure shared intelligence, it also exemplifies the role of private non-state actors in the prevention of crime (Newton, 2004).

## APEC

Founded in 1989 in Canberra, Australia, for the purpose of promoting economic growth among member states, APEC now consists of 21 member economies. APEC is a consensus body that meets annually at the ministerial level and historically has focused on trade, but increasingly its members look to it as a vehicle for cross-border police cooperation. APEC's work over the past several years has also evolved (as with the G8 and OECD) into a number of areas relevant to cybercrime enforcement, including an Intellectual Property Rights Working Group, an Electronic Commerce Steering Group (ECSG; see generally <http://www.apecsec.org.sg/workgroup/e-commerce.html>) and the work of the Council for Security Cooperation Asia and Pacific (2004). The objective of the ECSG, established in 1999, is to coordinate APEC-related activities in the area of e-commerce. Thus far, the ECSG has not directly addressed law enforcement issues in an e-commerce environment, but enforcement also connects to APEC's general interest in improving consumer trust and confidence in e-commerce. Further, the ECSG's increasingly detailed work in the areas of privacy and security in the online environment implicates law enforcement concerns.

At their meeting in Los Cabos, Mexico, in October 2002, APEC leaders noted the threat of global terrorism and the importance of increasing the protection of global infrastructures and that global communications are only as secure as its weakest link, and collectively committed to enact comprehensive cybersecurity laws, on a par with existing international standards, particularly the CoE Cybercrime Convention and UN General Assembly Resolution 55/63 of 2000; identify or create national cybercrime units and international high-technology assistance contact points; and establish computer emergency response teams that exchange threat and vulnerability

assessments and information. They also called for closer cooperation between law enforcement officials and businesses in the field of information security and fighting computer crime by endorsing the APEC Cyber-security Strategy. The elements of the strategy cover legal developments, information sharing and cooperation, security and technical guidelines, public awareness, training and education, and wireless security. APEC's Telecommunications and Infrastructure Working Group has been most active in sponsoring projects to increase the ability of APEC member economies to more effectively address cybercrime, including through greater intergovernmental and public-private sector cooperation (see <http://www.apectelwg.org/apecdata/telwg/28tel/estg/telwg28-ESTG-09.htm>).

Urbas (2005) observed, in concluding an overview of legislation in Asia, that the development of legislation designed to counter intellectual property offenses and cybercrime showed that although some states had enacted new laws, many remained ill-equipped to deal with the cross-border nature of these offenses. Orłowski (2004) also reported an APEC cybercrime legislation survey involving 14 nations that found all had some legislative provisions to address cybercrime and to support law enforcement (see <http://www.apectel28.com.tw/document/webword/estg/telwg28-ESTG-07.doc>). However, mutual legal assistance, extradition arrangements, and provision of cross-border information in respect of computer offenses were found in only half the countries surveyed. The survey noted that the main concerns related to the difficulties in requesting the collection and preservation of evidence in real time, issues relating to jurisdiction for offenses and offenders, and lack of, or limitations in, mutual assistance and extradition arrangements. APEC has called for further work to develop laws and procedures that facilitate the investigation and prosecution of cross-jurisdictional cybercrime. As noted above, it is essential to continually monitor progress and where necessary provide assistance and encouragement to ensure that MLA is not impeded.

### Summary of Measures for Regional Cooperation

Given the diversity of the above activities aimed at improving regional and international cooperation, the basic ingredients for a global approach can be deduced. Grabosky and Broadhurst (2005) outlined the basic elements of an effective regime for regional cooperation in combating cybercrime that include the following:

- Improve security awareness by providing adequate resources to secure transactions and equip system operators and administrators
- Improve coordination and collaboration by enabling systematic exchanges between the private sector and law enforcement including joint operations
- Take steps to ensure that technology does not outpace the ability of law enforcement to investigate and enact substantive and procedural laws adequate to cope with current and anticipated manifestations of cybercrime

- Broadly criminalize the conduct (including juvenile offenders) and focus on all violators big and small
- Strengthen international initiatives by updating existing treaties and agreements to recognize the existence, threats, and transnational nature of high-tech computer-related crimes and strive for legal harmonization
- The development of forensic computing skills by law enforcement and investigative personnel and mechanisms for operational cooperation between law enforcement agencies from different countries, that is, 24/7 points of contact for investigators.

In the future, organized crime may be expected to recruit IT specialists, intimidate corporate insiders to obtain access to IT systems, and use anonymizers and encryption in furtherance of cybercrime. In addition, there is evidence of the deployment of intelligent malicious software designed to elude detection by antivirus software. Automated intelligent computer and network attack capabilities allow remote initiation of attacks to be directed at any computer or network on the Internet while making it more difficult to identify the actual source of the attack. These advanced forms of intrusion code enable users to gain competitive advantage by extracting sensitive economic data from competitors and provide data (such as customers' records) for extortion and denial-of-service offenses. Most significant, attacks are instantaneous and often remote, disregarding national sovereignty. Whether they are the work of a 14-year-old, a terrorist, a foreign intelligence service, or an organized criminal may not be immediately apparent; all must be investigated. However, digital technology also affords new opportunities for individual citizens to communicate efficiently with police. An example is the Internet Fraud Complaint Center, which operates in the United States and receives online information from members of the public relating to questionable online activities that are evaluated and referred to the appropriate agency or jurisdiction.

Digital footprints are fragile or ephemeral, so swift action is often required. This becomes very difficult when an attack transits multiple jurisdictions with different regimes for preserving evidence. Traditional methods of law enforcement are therefore no longer adequate. A slow formal process risks losing evidence, and multiple countries may be implicated. Following and preserving a chain of evidence is a great challenge. Among the challenges faced by investigators is the enormous increase in storage capacity in today's computers and the challenge to effective and efficient searches that this entails. Almost every case will soon require computer forensics, and evidence will be located in multiple places. The challenge faced by investigators will be one of *information management* (Pollitt, 2003). Even local crimes may have an international dimension, and assistance may be required from all countries through which an attack was routed.

Many nations and regional bodies such as the Council of Europe have addressed the problem of cybercrime and laws exist that criminalize the unauthorized access and unlawful use of computers, but such laws are neither universal nor uniform. Concerns remain focused on the

weakest links in the supposedly seamless security chain necessary to prevent cybercrime by predatory criminal groups. Comity thus can only be ensured if wealthy states and affected industries are prepared to extend aid to those less capable states or agencies. Consensus is the best strategy, for the suppression of computer-related crime entails a mixture of law enforcement, technological, and market-based solutions. It can be argued, however, that a strict enforcement agenda is usually not feasible because of the limited capacity of the state. It is also feared that overregulation could stifle commercial and technological development. Those skeptical of a heavily interventionist approach also argue that the marketplace may at times be able to provide more efficient solutions than the state to the problems of computer-related crime.

Although there is consensus about the risks of computer-related crime, apart from criminalizing the conduct at a global level, there is much less consensus about what might be done to prevent it. There is concern that the technological solution to information security is a mirage, more hope than reality, and that dependence on the promise of a technology fix is an approach fated to fail. So also is the faith in a deterrence-based approach in which the criminal law is deployed as the principal instrument of prevention. Deterrence is unlikely to succeed in all or even some circumstances, and experience with conventional crime suggests that overreliance on the law, as a deterrent or moral educator alone, is unlikely to help substantially even if legitimately supported by the community.

Fundamentally systems can be designed to lessen their vulnerability to criminal exploitation. Cybercrime is often facilitated by vulnerable software, much of which is designed with user-friendliness and convenience in mind rather than security. The common industry response is for manufacturers to structure their licence conditions to avoid potential liability and then to make patches available as vulnerabilities become apparent later on. Whether market forces will eventually drive the widespread development of truly secure software remains to be seen. Commercial enterprises may be in a position to achieve more protection than poorly resourced law enforcement agencies could deliver. Microsoft Corporation has now, it seems, reflected on its failure to lead the market in respect to consumer safety and to recognize that the market demands a secure and trusted environment if computers and information technology are to realize their full potential.

In conclusion, controlling crime involving digital technology and computer networks will require a variety of new networks: networks between police and other agencies within government, networks between police and private institutions, and networks of police across national borders. Over the past five years, considerable progress has been made within and between nations to develop the capacity of police to respond to cybercrime. But the pace of technological change will continue unabated and the adaptability of cybercriminals will continue to pose challenges for law enforcement. The extent of transnational law enforcement cooperation achieved thus far, promising though it may be, can only be regarded as a beginning.

## GLOSSARY

**Comity** An association of civility and mutual benefit among nations, especially in regard to the recognition of the laws and customs of other nations.

**Dual Criminality** A rule governing or limiting the reach of a bilateral or multilateral treaty or convention, or a cross-border law enforcement that authorizes assistance only if the offense is criminalized in the law of both states.

**Extradition** The formal arrangements between nations that allow fugitives, suspects, or witnesses in one country to be transported to the country in which the crime was committed.

**List Treaty** A bilateral or multilateral treaty providing extradition or other legal assistance such as the seizure and preservation of evidence that is limited to the list of offenses.

**Mutual Legal Assistance** The general term for all informal and official forms of police, legal, and criminal justice cooperation between states usually provided on a reciprocal basis.

**Social Engineering** The manipulation of human behavior for the purposes of revealing passwords, source code, and other confidential information without recourse to unauthorized access to a computer system by means of exploiting or intrusion software.

## WHAT IS DIGITAL IDENTITY?

As an emerging technology, the meaning of *digital identity* depends to a large extent on who is talking about it. In general, the term refers to the class of technologies, standards, services, and applications that enable a real-world identity to be represented digitally on a network, manage the data related to the identity (its *attributes*), and control access to various network resources. Technically, any addressable resource on a network has identity; in many circles, though, the term is most meaningful when describing how an individual user's personal identity and personally identifiable data are modeled, represented, controlled, and shared on the network.

Digital identity touches on issues of trust, privacy, security, and interoperability that are becoming vital to the evolving Internet. As e-commerce and e-business become everyday realities, consumers want to control information about themselves, while at the same time being able to share it with trusted parties. For their part, businesses want to serve consumers better by knowing more about them, while at the same time being required to respect consumer privacy concerns and comply with regulations. And from a technology standpoint, the rapidly growing Web services infrastructure requires a way to authenticate users that is not tied to network location or device. The solutions to these problems are all aspects of digital identity.

## DIGITAL IDENTITY AND PRIVACY

Public awareness of privacy issues has been steadily increasing over the past decade, in large part to the increasing use of the Internet and its ability to permit data sharing on a scale never possible before. Telemarketing, junk faxes, and unsolicited bulk e-mail (spam) are small but annoying signs of the growing erosion of privacy. Consumers have begun to reject this erosion, not only by calling for legislation (e.g., in the United States, 2003's Controlling the Assault of Non-Solicited Pornography and Marketing (CAN-SPAM) Act and the Federal

Trade Commission's Do Not Call list), but also by demanding products and services to protect their privacy. A good example is telephone services. Phone companies used to offer only one privacy service (an unlisted phone number). Now most offer caller ID, which lets subscribers see who is calling before picking up the phone; caller ID blocking, which lets subscribers keep people who have caller ID from finding out who they are; and finally anonymous call blocking, which automatically rejects calls from people who use caller ID blocking. There are plans afoot to bring something similar to the caller ID model to e-mail.

In the United States, civil libertarians have long been sounding the alarm about the amount of personal data stored in databases owned by corporations and the government. After September 11, 2001, many Americans have said they are willing to sacrifice some privacy to feel more secure, but to others, the existence of government surveillance systems such as Carnivore and Echelon point to an Orwellian future. What worth is security, they argue, echoing Franklin, if it comes at the cost of important constitutional protections? Some fear that safeguards against misuse of information are insufficient. They warn that employers, for example, might eventually use medical records to deny employment to those with unfavorable health conditions (or, as DNA testing becomes more precise, even to those with the *potential* to develop such conditions) by partnering with health insurers and hospitals to share this information.

These concerns have spurred a flurry of legislative action internationally. In the United States, the Gramm-Leach-Bliley Act (GLBA) makes financial institutions provide their customers with a written privacy policy, regulates how they can share their customers' personal data for marketing purposes, and requires them to allow consumers to opt out of marketing from non-affiliated third parties. Also in the United States, the Health Insurance Portability and Accountability Act is intended to guarantee the security and privacy of personally identifiable health information, while requiring that standard data formats be used to allow these data

to move with the patient among health care and insurance providers. In the United Kingdom, the Data Protection Act requires firms to tell consumers on request exactly what personal data about them they have in their files and also establishes guidelines for collecting, storing, and sharing this information. The European Data Directive establishes a clear and stable regulatory framework for the movement and framework of personal data for the entire European Union.

What impact will digital identity technology have on privacy issues? The long-term effects of any new technology are impossible to predict, of course, but there are reasons to believe that many of the effects will be positive. Digital identity technologies allow individual users to set the terms under which their personal data can be shared with others and for what purpose these data may be used. Unless the requester of the data agrees to respect these terms, the protocol does not allow the data to be shared. In this scenario, digital identity provides a way for organizations to demonstrate compliance with emerging privacy regulations. In fact, in the coming years, the authors believe that a key role of government will be to make agreements between digital identities legally binding, which has the potential to strengthen consumer privacy significantly.

The other, potentially more troubling, side of the digital identity coin is the technology's ability to link data stored in numerous databases into a coherent virtual view of an entity. Corporations and governments have, collectively, amassed thousands of pieces of information about every customer and citizen. Currently, this information is in thousands of separate databases, which makes it a limited threat to privacy. Digital identity has the potential to unify these databases not just within a single organization, but also across organizational boundaries—meaning that the data kept about consumers by different companies might eventually be compared and coordinated. The technical and business challenges involved in this kind of consolidation of personal data are not trivial, given the competitive nature of business, and digital identity is hardly a silver bullet for solving them; the threat is not necessarily imminent. Clearly, though, there is a vital role for government here, with a *minimum* requirement being legislation requiring companies to tell consumers on request what personal data they keep, where it comes from, and who else it will be shared with. A stronger solution would be to require corporations to disclose any data held by a corporation about an individual to that individual on request, much as mandated by the U.K.'s Data Protection Act. This is an area in which consumer lobbies and civil liberties watchdog groups could have significant leverage by educating the public on the issues—and now is the time to start.

The government, in addition to regulating digital identity, will also become a significant user of this new technology. In the United States, the federal government alone maintains thousands of databases in its hundreds of agencies; each of the 50 states (plus territories) also has a government, and there are thousands of county and municipal governments below them, each with their own databases about the citizenry. Consolidating all these bits of data could save billions of taxpayer dollars and enable

a new level of government effectiveness and service. The United States' new Department of Homeland Security is also interested in digital identity technology as a means of allowing the country's various local, state, and federal intelligence, law enforcement, and emergency response agencies to aggregate the data each agency has, until now, maintained separately. Until relatively recently, it was routine for wanted criminals to be able to renew a driver's license or even receive public assistance without catching the eye of the police, because each government agency had its own database. Linking some of these records has made law enforcement efforts dramatically more effective and has helped many agencies become more responsive to their constituency's needs, and this trend will only be accelerated by digital identity.

But there's a darker side as well. Homeland Security has already expressed its intent to also aggregate information collected by other parties (e.g., library checkout records, credit histories, travel itineraries). There is no serious technical barrier to doing so. Certainly this would be of tremendous value in identifying and locating criminals, but it also carries obvious potential for abuse. Generally speaking, post-9/11 America is significantly more receptive to such ideas than it was just a few years ago, and there is a real danger that fear will permit unwise policy to be made and to stand unchallenged. Civil libertarians point to some of the provisions of the Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and Obstruct Terrorism (USA PATRIOT) Act as examples.

Once information about citizens has been aggregated, it can be mined to look for patterns deemed suspicious by the authorities, and any individuals identified could then be subjected to closer scrutiny. Of course, this can be (and is being) done to an extent without digital identity technology, but because the entire purpose of digital identity is to model individuals and aggregate their data, digital identity makes data mining much easier and more effective. Any intelligence-gathering technique based on data mining will inevitably result in innocent people being put under surveillance, even if the information gathered never reaches human eyes. This possibility should concern us deeply.

Law enforcement is, to be fair, involved in an ever-escalating information arms race. Criminals are becoming more and more sophisticated in their use of technology. There have already been reports, for example, of organized crime using data mining to identify and assassinate informants in their ranks. Must we as a society deny the police techniques that may be the only way to root out the worst criminals and terrorists? By analogy, few Americans would dream of barring police from carrying firearms, even though a gun is also a tool ripe for abuse. When criminals are heavily armed, the public recognizes that the police require equal firepower if society is not to be overrun by criminals. Thus, the authors believe that law enforcement and intelligence-gathering organizations will, in the end, be allowed to use data mining, although we likewise expect that this use will be strictly controlled and limited. Citizens must continue to demand due process and accountability from their governments and must remain vigilant for even the possibility of abuse.

At minimum, data mining should be held to the same legal standards and privacy expectations as other permitted forms of surveillance, such as wiretapping, although due to the nature of the technology, even stricter controls may be appropriate.

## DIGITAL IDENTITY AND IDENTITY THEFT

In identity theft, an individual's personal information (often stolen from a wallet or snatched from the mail) is used to impersonate that person for the purposes of fraud. For example, an identity thief might obtain enough personal information to obtain credit or write bad checks in another person's name. Victims of identity theft often face years of frustrating harassment from creditors as they try to clear their record.

Identity theft has become a problem due to the fact that most people simply do not know the people with whom they do business very well. Indeed, this is utterly impractical in modern society. The cashier at the local grocery store must trust that the customer's identification is valid before accepting her check. Similarly, the customer must trust that the grocery store clerk will not steal her identity using the information on her check and driver's license. Anyone who can copy identity credentials can pretend to be someone else, taking advantage of the victim's good reputation to obtain lines of credit, pass bad checks, and commit other forms of fraud. In recent years, the situation has been aggravated by the Internet, where it is trivial to assume a fictitious identity and fraud of all types has flourished.

Before 1998, the year in which identity theft was made a federal crime in the United States, it was difficult to prosecute identity theft cases. The U.S. Department of Justice's identity theft Web site recounts the case of one notorious fraudster who ran up \$100,000 worth of credit card debt, obtained a mortgage, and bought homes, motorcycles, and handguns using a stolen identity—and then called the victim to taunt him. This brazen scammer eventually declared bankruptcy in the victim's name. The identity thief, who had a previous felony conviction, served a brief sentence for violating firearms laws, but was not made to pay restitution to the victim, whereas the victim and his wife spent more than 4 years and \$15,000 of their own money to rehabilitate their damaged credit and reputation.

Although identity thieves can now be punished, the authorities still have to catch them. Meanwhile, the victim's credit report rapidly accumulates negative information, affecting his or her ability to obtain not just loans but also utility service, insurance, and housing. Due to their artificially poor credit scores, identity theft victims must pay more for many things or are forced to make larger deposits or down payments and may even find it more difficult to find employment.

Thanks to the Internet, credit ratings are only one way scammers wreak havoc. If an identity thief obtains illegitimate access to a victim's eBay auction account, for example, the thief can use the account's reputation to defraud dozens of buyers before enough negative feedback

accumulates to make buyers reluctant to bid. If a thief obtains the password to an online brokerage or banking account, the victim's finances are put directly at risk.

Often, Internet identity credentials are obtained using a technique called *phishing*, in which the criminal sends an official-looking e-mail to hundreds of potential victims claiming to be from, say, eBay or their bank and telling them that their password has expired. A link in the message directs them to a Web page that also looks official but is run by the scammer; if the victim falls into the trap and enters his or her credentials on this bogus Web page, they are sent directly to the identity thief.

Beyond the possible financial consequences are social ones, which can be no less disastrous. When someone learns another user's password and impersonates him or her in an online forum, where people know him or her only by the words he or she has typed, the impersonator can quickly ruin a hard-won reputation, and the legitimate user could lose his or her account or even, in extreme cases, be sued for libel. Even e-mail is not immune; the technique of sending out bulk e-mail with a victim's address in forged reply headers (such that the victim receives all the bounces and complaints and gains a reputation as a spammer) is common enough to have its own jargon name among mail administrators: the "Joe job."

Another new technological threat to identity is hacking. The businesses with which customers share personal information often keep it on file. Even assuming that access to this information is properly controlled and that the employees who do have access are trustworthy, both big assumptions, it is still possible that personal information could be compromised by a security breach. Sadly, bank computers do not seem to be nearly as secure as bank vaults; in one widely reported incident, a hacker obtained 8 million credit card numbers from a credit card processor.

Although identity fraud cases resulting in financial loss are crimes and can be prosecuted, the consequences even in nonfinancial cases are such a hassle that it makes sense to avoid becoming a victim. Here are some commonsense things you can do to protect your identity from being stolen:

- It should go without saying, but keep a close eye on your wallet or purse—these are still the most common vectors of identity theft. When traveling, take only the cards needed for the trip and keep them in a place where they will be hard for a pickpocket to get to, such as a front pocket.
- Check the mailbox regularly so sensitive information (such as financial documents) does not sit waiting for identity thieves. When going on vacation, have the mail held. If mail suddenly stops coming, check to make sure a fraudulent change of address has not been filed with the post office or the bank. Drop off sensitive mail in a locked mailbox or at the post office rather than leaving it out for the letter carrier.
- Keep vital documents with your social security number (SSN), driver's license number, credit card number, and other sensitive information in a safe place—preferably *literally* in a safe—especially if you have roommates or

- have hired help, such as a maid service, in your home on a regular basis.
- Use a crosscut shredder to destroy documents with sensitive personal information, including expired credit cards, before throwing them away.
  - Never write down personal identification number (PIN) codes or other passwords. Avoid using the same passwords for more than one thing (e.g., do not use the same PIN for voice mail and an ATM card), and avoid using easily guessed passwords. Change passwords regularly.
  - Guard your SSN carefully, as it is an important identity credential. With legitimate exceptions such as your employer and creditors, always ask why the person who is requesting it needs it. The SSN is not intended as a general-purpose identification number, and companies should not use it as one. Avoid doing business with companies that ask for a SSN but do not actually need it, and never have it printed on checks.
  - Sign up for a credit monitoring service, and check your credit report and your bank statements regularly for errors and signs of fraud.
  - Ask the companies you do business with not to keep personal details on file and ask for a reason if they insist on doing so. Prefer businesses that are willing to respect your wishes in this regard.
  - Do not give out any personal information on the phone to anyone who calls, even if they say they are with your bank or another company with which you do business. (Be especially suspicious if they say they are from “the bank” or “the phone company” but do not identify which one by name.) If you are interested in buying a product or service offered by phone, ask that the offer be sent in the mail, or request a phone number at which to call the seller, and check the company’s reputation with the Better Business Bureau before proceeding.
  - Many banks ask for your mother’s maiden name when you open an account, so that later they can ask you for it as a means of confirming your identity. Don’t use your mother’s *real* maiden name, as it is easily obtained from public records.
  - Use encryption to secure the personal information and Web passwords stored on a computer, especially if you use a laptop. Do not set up the computer to log in automatically to this program when it is turned on. This way, if your computer is hacked or stolen, the intruder or thief will get only gibberish rather than the information needed to steal your identity.
  - Use a firewall program to keep the computer from being hacked and antivirus software to protect you from malicious e-mail attachments that attempt to steal personal information and send it elsewhere. Do not open e-mail attachments sent by unknown senders. Use the computer’s update feature regularly to obtain security updates as they become available.
  - Be wary of any e-mail or other electronic message that claims you need to reset your password or enter a new credit card number, even if it looks official. Call the company or go to their Web site by typing in the uniform

resource locator (URL), rather than using the link provided in the e-mail.

- When submitting sensitive information to a Web site, look for the small lock icon in the browser that indicates a secure connection. This icon not only means that information will be transmitted securely, but it also means that the site is the one it claims to be in the URL. Be suspicious if the browser displays a message about an expired or invalid certificate or if the URL does not begin with “https” or has an @ sign in it.
- Be aware of the privacy policies of the companies you deal with so as to know who will have access to your personal information. If it is unclear, ask. Most legitimate companies have privacy policies posted on their Web sites.
- Shield the keyboard when entering a PIN or password, or make sure no one is close enough to see what you enter.
- Before selling or disposing of a computer or a hard disk, be sure to remove all personal information from it. Simply deleting the files or reformatting is not enough; use a “wipe” or “secure delete” program that overwrites the disk several times with gibberish and then reformat and do a fresh install of the programs that came with the computer.

The role of digital identity in combating identity theft is a supporting one. One important feature of digital identity technology is that all personal information is under the owner’s control and is only shared with others under contract. Links allow companies access to your information when they need it, without requiring that this information be stored in their systems; this makes it much more difficult for a hacker to, for example, obtain millions of credit card numbers by breaking into one card processor’s computer. Identity service providers may offer logging features that record exactly who accessed your personal information, and when, which will help to keep tabs on its use.

From the other side, identity technology will help large companies secure their systems by allowing them to require explicit contracts between customer data and the employees and departments that access it, helping to protect personal information from misappropriation by employees and business partners of the company. As mentioned earlier, businesses are already under regulatory pressure to protect customer information and ensure privacy, but the mishmash of systems in a typical large business makes it difficult to demonstrate compliance. By enforcing permissions at a protocol level, digital identity makes it possible to prove the security of a company’s systems and implement rigorous privacy controls throughout an organization.

In the United States, the Fair and Accurate Credit Transactions Act of 2003 provides some additional measures to help prevent identity theft. For example, merchants are now prohibited from printing more than five digits of your credit card number on a receipt, and consumers are entitled to a free credit report every year to check it for signs of fraud. Financial institutions are now mandated to look for patterns common to identity theft and credit reporting agencies must flag credit files whose

owners have reported identity theft. But as before, vigilance will remain the most important component of any strategy to avoid becoming a victim of identity theft. Tools for monitoring access to private consumer data will not help if consumers do not use them; technology to help businesses become more accountable will not help unless businesses are actually held accountable. Ultimately, everyone pays the price for identity fraud losses, so it is everyone's responsibility to minimize them.

## DIGITAL IDENTITY AND WEB SERVICES

The increasing prominence of Web services as a new way to achieve cross-application and cross-domain data integration also highlights the need for digital identity. Because Web services are almost as new as digital identity, it is worth taking a brief look at the technology now.

Unfortunately, the term *Web services* has caused a lot of confusion among the uninitiated. Most Internet users have bought something at Amazon.com, searched the Web using Google, or used their bank's Web site to check their checking account balance. These are services available on the Web, but they are not Web services. *Web services* is a technical term that applies in a very specific way to automated application-to-application communications—it is an extension of the similar use of the term *services* in a local computing environment. Many operating systems offer services that applications can call on for messaging, checking spelling, displaying Web pages, and so forth. Web services are a way to use another computer's services using Web protocols.

To further explain the difference between the Web and Web services, we will compare the two directly. A Web site is designed to be used by humans, and it includes site-specific formatting and graphics for, among other things, branding purposes. For example, Bank of America's Web site looks nothing like Citibank's, and neither looks anything like Bank One's. This is inconvenient if a computer program, rather than a person, wants to access a service offered by a Web site. Suppose, for example, a user of a personal finance program wants to automatically import a checking register into the program from a bank's Web site. To do this, the personal finance program would need to know how to find that information on every bank's Web site. That would require the developers of personal finance programs to provide a different interface module for every bank in the world, and this is completely impractical. A much better answer is a standard interface for all bank Web sites that lets personal finance software, once properly authenticated, retrieve a customer's checking register.

The Web services paradigm is an attempt to address this problem and others like it, which are legion. Four key standards are involved. First, the extensible markup language (XML) is an established World Wide Web Consortium (W3C) format for data representation. The simple object access protocol (SOAP) is a W3C specification that defines how programs running on one computer can request that certain operations be performed on another. The Web services description language (WSDL) is an XML schema for describing a Web services interface in a standard, machine-readable format. Lastly,

Universal Description, Discovery, and Integration (UDDI) allows a Web site to automatically discover which services are available from a given provider and determine how they should be accessed. All of these are either already open standards or are in the process of being standardized, and an overwhelming number of major industry players (including IBM, Microsoft, Sun Microsystems, Hewlett-Packard, and BEA Systems) have thrown their weight behind the concept.

With Web services, applications and portable devices can access specific information and services over the Internet without a full-fledged Web browser. When a harried traveler is checking a flight departure time on his cellular phone, he or she does not want the whole American Airlines Web site, and he or she does not want to try to use Internet Explorer on his or her phone's tiny screen. He or she just wants to punch in the flight number and find out whether he or she is going to make his or her flight or not. This is a perfect application for Web services. At the same time, Web services allow services on the Internet to begin communicating directly with each other, as well as with users. For example, a Web portal might use Web services to retrieve top headlines from a news site and then format them according to the portal's own look and feel before displaying them on the site.

As with Web sites, some Web services are public, whereas others are accessible by subscription only or only to certain users (e.g., a company might operate some Web services only for its employees). It is necessary to authenticate users before allowing them to use these restricted services. Requiring separate credentials for each service quickly becomes a headache, especially when a single user might access the service from a mobile device, from one or more Web portals, and from a desktop application. What is needed is some way to ascertain the identity of users no matter how they access a given Web service, to model users as independent digital entities rather than only representing the devices they use. This is digital identity.

To complete the circle, digital identity services can themselves be provided as one or more Web services, making them widely available to users everywhere.

## DIGITAL IDENTITY ILLUSTRATED

A simple example will serve to illustrate the basic model of digital identity. When modeling an information system, a common object-oriented methodology involves thinking of the system in terms of actors who engage in transactions with each other. For example, when a customer withdraws money from an ATM, there are three actors: the customer, the ATM, and the bank mainframe with which the ATM communicates to verify the customer's balance before dispensing money. The actors and the actions between them can be represented using a sequence diagram like that in Figure 1.

In this scenario, the ATM has interactions with the user in which it asks for information such as a PIN and the amount to be withdrawn. The ATM also has interactions with the bank mainframe, asking it to verify the account's current balance and telling it to record the withdrawal. (For simplicity, this diagram does not show exceptions,

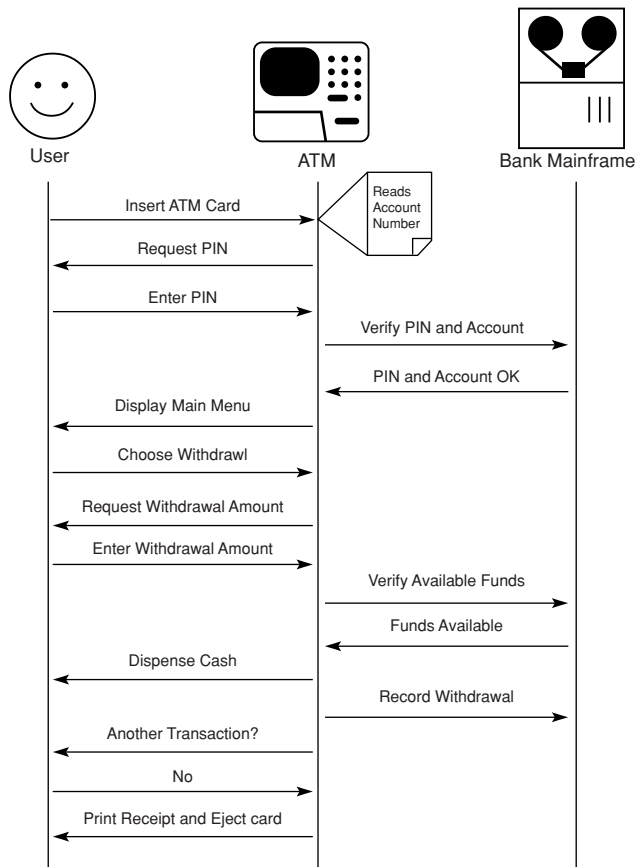

Figure 1: Sequence diagram for ATM withdrawal.

such as what happens when there is not enough money in an account to fulfill a request.) These various interactions are possible because the bank owns all the data involved in the transaction. The bank balance is stored in its computer (along with a PIN), and although the account number is stored on the ATM card that the customer carries, that number is issued by, and thus in that sense belongs to, the bank.

The bank has plenty of other information on its customers, too: their mailing addresses for statements, their SSNs for reporting interest income to the Internal Revenue Service, and their complete transaction histories. Though it describes customers, this information, too, belongs to the bank in the sense that customers do not have the authority to change it, even though they are the source of much of it. If a customer wants to change the address to which his or her statements are mailed, for example, the customer must provide the new address to the bank so it can be entered into its systems.

The ATM system works because all the actors involved in ATM transactions trust each other, and they trust each other because the bank controls all the information involved. The ATM knows that it can trust the balance data, because it knows it is connected to the bank's mainframe and not to some other computer. The bank's mainframe knows that it can trust the ATM, because it has provided credentials that prove it is an ATM owned by the same bank. And the ATM and bank know that they can trust

the customer, because the customer has inserted a card with an account number issued by the bank and entered the correct PIN for that account. In digital identity terminology, the bank's ATM system comprises a single *trust domain*. All the information in the system is owned by a single entity, and all the components of the system are deemed trustworthy. The bank considers the other information customers have given them (such as mailing address and SSN) to be trustworthy as well, because it is in their systems and thus under their control.

To keep the above scenario simple, it was assumed that the bank that owns the ATM is the bank at which the customer has an account. In the real world, of course, banks join ATM networks; customers can use their card at any ATM in a network that their bank is a member of (although the bank that owns the ATM may charge a fee). To achieve this, the member banks have had to agree on a common protocol for exchanging data. Each bank has had to decide what credentials they will accept from other banks' ATMs to verify that they are in fact legitimate ATMs and which credentials the users of these ATMs will have to provide. They have also had to agree on what data will be provided over the network, and they have taken steps to protect the security and integrity of the data as they flow from point to point. In doing so, the banks have enlarged their trust domain to encompass all banks on the network, at least for ATM-related transactions.

With digital identity standards, trust domains can be expanded even further. In other words, what if not just banks but *every person and business in the world* could communicate and exchange their data with anyone, just like the member banks of an ATM network? What is necessary to establish trust between all these entities? And what will such a world be like?

## DIGITAL IDENTITY AND THE CONSUMER

Consumer digital identity applications are the obvious place to start exploring digital identity, as these have received the lion's share of media attention. Microsoft Passport, the Liberty Alliance, and the Extensible Name Service (XNS) from the XNS Public Trust Organization (XNSORG), all initially led with consumer-facing applications.

The digital wallet is perhaps the most common example. A typical digital wallet contains a customer's mailing address, preferred shipping addresses, and information about the credit cards frequently used for online purchases. When using a digital wallet to check out at an electronic storefront, the customer simply chooses the address and credit card to be used for the order from a pop-up list, rather than being forced to enter this information at each new store. Even more conveniently, when the customer moves or is issued a different credit card number, he or she simply changes the appropriate fields in the wallet—once. The simpler a site makes the purchase process, the more likely it is to close the sale (Amazon's patented One-Click ordering is a case in point), so the digital wallet is potentially a big win for both consumers and

merchants—as well as for banks, who earn a fee on credit card transactions.

Single sign-on (or SSO) is another consumer service. SSO lets users log on, or *authenticate*, at one Web site and then use that authentication at other participating Web sites. For example, after users log into a Microsoft Passport account, they can get access to Hotmail, the Microsoft Network, Expedia, eBay, and other Web sites without having to enter their password again. It is particularly convenient to combine this with the digital wallet feature, making the wallet even more attractive for users.

Microsoft Passport is the most widely deployed single sign-on and digital wallet service at present, although adoption by consumers, vendors, and content providers has been slower than Microsoft had hoped, and a large percentage of the sites that accept Passport are owned by or affiliated with Microsoft. Part of the reason for the slow uptake is that Passport was designed as a centralized service. Microsoft stores all Passport data, including transaction records, on its own servers. Early technology adopters tend to be just the sorts of users who will insist on the privacy and security of their personal information, and Microsoft will have to provide more than convenience to win their trust. (Microsoft settled with the Federal Trade Commission in 2002 over complaints about the privacy and security of Passport subscriber data.)

The Liberty Alliance specifications and XNS both support a feature called *federation*, where users can choose from a number of hosts for their personal data and cooperating sites can share authentication seamlessly, much like an ATM network. Microsoft has announced that Passport will also move to this model.

But while digital wallets and SSO are part of digital identity, they are by no means the whole picture. It is, in fact, possible to implement these sorts of applications without even really modeling the underlying identity. A more robust conception of digital identity provides an infrastructure for a wide variety of applications.

## THE IDENTITY WEB

To better understand the emerging vision of digital identity, we will look at the characteristics of a hypothetical full global identity infrastructure. Keep in mind that no such thing exists yet, and no one organization will build it. Instead, people and companies will begin using smaller identity-related applications as these applications become compelling. In fact, at first, users might not even realize they are using something called *digital identity*. But as more and more people use identity services, they will naturally want these services to work together, further increasing their value in a classic network effect. This in turn makes additional identity applications more and more compelling, which brings more users into the identity fold, which further increases the network effect. This eventually results in the *identity web*—a global interlinked digital identity community, the virtual world in which, with the proper permissions, everyone can share anything with anyone.

To benefit from the network effect, naturally, identity applications must be interoperable, which means that a standard identity protocol must be adopted by all players.

As of this writing there are two key digital identity standards emerging: extensible resource identifier (XRI) and XRI data interchange (XDI) and Liberty Alliance Project. Both are open public standards. XRI and XDI are two separate but related standards being developed by technical committees at the Organization for the Advancement of Structured Information Standards (OASIS), a global not-for-profit consortium that already maintains many of the key XML interoperability standards. These two standards are the successors to XNS, an early identity technology; key players in the development of XNS are also involved in XRI and XDI.

The Liberty Alliance is currently publishing its own specifications, though it may eventually contribute its work to another established standards body (some public reports have mentioned OASIS). Liberty's 65 members include American Express, MasterCard, Visa, America Online, Intuit, RSA Security, Sony, Sun Microsystems, Verisign, Fidelity Investments, Novell, Citigroup, Hewlett-Packard, Nokia, Vodafone, General Motors, Cisco Systems, Bank of America, PriceWaterhouseCoopers, EDS, Cisco Systems, Earthlink, OneName, and many others. This impressive array of members demonstrates the importance of interoperability to major corporations and provides enterprise customers with the assurance that Liberty standards will be viable from both a technical and a business standpoint.

The following sections draw on concepts from both of these emerging standards, with a particular focus on XNS, XRI, and XDI—largely because the authors are coauthors of the XNS specifications, but also because XNS reflects the broadest vision of digital identity available in the marketplace to date.

## IDENTITY DOCUMENTS AND ADDRESSING

The core concept of digital identity is the *identity document*, an XML document that stores the data for which any given real-world entity is authoritative. People own their name and address, for instance, so this information would best be stored in an individual's personal identity document. An identity document can represent a person, a corporation or other organization, a software application, a server, or a directory category. Applications can query an identity document for just the attributes they are interested in; it is not necessary to retrieve and parse an entire document.

The identity document is hosted by an *identity service provider* on an *identity server*. As with Web hosting services, in the identity web there would be a multitude of identity service providers a user could choose to host his or her identity. Strong encryption would be used to ensure that only authorized users have access to the information in the identity document. Because digital identity is by its nature peer to peer (any identity can talk to any other identity), particularly savvy users could even choose to host their identity on their own computer for additional peace of mind.

To access the identity document itself and link to the information stored in it, an addressing scheme is needed.

Standard uniform resource identifiers (URIs) such as hypertext transfer protocol (HTTP) URLs, which are used to address documents on the Web, do not have the full range of functionality required by digital identity infrastructure. For example, links between identities should continue to work even if a digital identity moves to another host. (The details of how links are used to share data will be revealed shortly, but for now it suffices to note that broken links would render some shared data inaccessible, limiting the utility of sharing data in the first place.) To provide this higher level of functionality, XNS introduced a new addressing scheme that can contain identity IDs or identity names. An *identity ID* is a string of numbers and other characters that forms a permanent address for an identity. An identity ID resolves to the URI where the given identity is hosted, and although the identity ID never changes, the URI it resolves to can change if the identity is moved to a different host. Each attribute stored in an identity document, as well as the identity document itself, has an ID, and this ID, too, is the same as long as the object exists. In XNS, document and attributed IDs are assigned and resolved by the ID service.

Identity IDs, however, are assigned more or less arbitrarily and are structural rather than semantic. Typically, they are not very user friendly. Just as the domain name system (DNS) was invented to allow human-friendly host names to be assigned to computer-friendly Internet protocol (IP) addresses, so digital identity needs a way to make identity IDs easier for people to use. Enter the *identity name*. The XNS name service allows any object with an identity ID (i.e., an identity document or an attribute stored in it) to be assigned any number of names, which can be changed at the identity owner's whim. The naming service also allows an identity owner to organize the attributes stored in his or her identity document into categories or folders. For instance, phone numbers could be stored in a collection called "phone," allowing a cellular phone number to be named something like "= JohnSmith/phone/mobile." It is important to remember that although an identity document or an attribute might be located by name initially, when a link is established, it always uses the unbreakable ID.

The XRI builds on the concepts introduced in XNS addressing, while making addresses more like URIs. Version 1.0 of the XRI specification divides an address into two parts: the *authority portion* and the *local access portion*. The authority portion is analogous to the hostname portion of a URI (although the XRI specification does not specify what the authority portion points to, typically in identity applications it points to an identity document or to an identity host). Within each portion, an XRI can contain persistent segments (analogous to XNS's IDs), reassignable segments (analogous to XNS's names), or a mixture of both. Once the authority segment has been resolved, the identified authority can be passed to the local access segment to retrieve the desired resource. The authority identified by the authority segment does not need to be given the local access segment, and vice versa, enhancing privacy.

In the beginning, it is likely that organizations will operate their own resolution services for customers and partners. For example, a bank might offer identity services

to its customers, which would work with the bank's merchants but with no one else. In other words, the bank would provide resolution services only for its customers and merchants. The identities that can be located through a single resolution service are referred to as a *community*. Using the process of federation, mentioned earlier, communities can agree to share these services and thereby merge their smaller communities into larger ones. As identity services become more popular, a demand will eventually arise for *global community services* that, like the global Internet's DNS, allow any identity in the world to be found by its XRI or similar address.

## IDENTITY LINKING

Once attributes have been stored in identity documents that can find each other by ID, name, or XRI, the stage is set for letting these identities share data. *Linking* is the way information from one identity is shared with another. Links are almost always made using persistent identifiers such as XNS IDs, and because IDs never change over the life of an object, links between IDs never break while the linked object exists. When one identity needs information that is controlled by another identity, the first identity simply links to the data in the second. Then the two identities agree as to how those shared data will be kept current in the second identity—that is, how they will be synchronized.

An example will make the linking concept clearer. A person's mailing address, for all practical purposes, belongs to the person. (Street addresses are actually assigned by the city, but the city rarely changes them. More commonly, people change their own addresses—by moving. Thus, a mailing address can reasonably be treated as an attribute of an individual's identity.) The bank needs a mailing address to send statements, so the customer gives them this information, and the bank puts it into its system. As noted earlier, however, the bank controls that copy of the address. When customers move, they must ask the bank to change it—even though it is *their* address! Change-of-address forms are so unremarkable that it barely seems that this is a problem worthy of solving. But just envision all the copies of information that people and companies keep about other people and companies; a vast amount of storage is used for redundant copies of all this information, and an equally vast amount of effort is expended on keeping all the copies current.

In the identity web, the bank would simply link to a mailing address stored in the customer's identity document, using the address's immutable ID. To the bank's systems, it looks just like a copy of the customer's mailing address is stored in their database. However, the customer's copy of his or her mailing address, stored in the customer's identity document, is *authoritative*, meaning the customer can change it and the bank has to go along. When the customer moves, he or she simply updates the address stored in his or her identity document, and the customer's identity service provider would then send a digitally signed copy of the updated address to his or her bank. Their system would verify the digital signature to make sure the update was genuine and then automatically store the new address in the customer database. In essence, by eliminating

redundancy, digital identity turns the world into an object-oriented, distributed, well-normalized database.

Of course, some of the technical details have been glossed over here. The XNS protocol actually gives the bank in this scenario several options for synchronizing with a customer's identity data. For example, instead of having updates pushed to them, the bank could retrieve a copy from the customer's identity document any time they needed it by sending a digitally signed request. Or the bank could just be notified that the address has changed and use some other method to update its database (for example, mailing a change-of-address form to the new address to verify that it is correct). The exact details of how the updates are handled are implementation specific, but regardless of how they are accomplished, linking of identity data is arguably the most important concept in the sphere of digital identity.

Linking also provides the means to consolidate multiple digital identities that represent the same real-world entity. For example, a bank maintains a digital representation of each customer's account balance and activity. This information actually is part of an individual person's identity—it is the customer's account, and the customer's money, and the customer's transactions—but, for security reasons, the bank must maintain the authoritative copy. (It just wouldn't do to let people change their own account balances!) In an identitycentric world, the bank might do this by creating an identity document on its identity server for each of its customers. The attributes of these documents would be customers' various accounts, and each account would have a balance and a transaction history associated with it, among other things. So an individual's bank-hosted identity represents the real-world person just as much as that person's personal identity, hosted elsewhere, that contains his or her mailing address. One is a person's financial identity and the other is a household identity. By creating a link between a person's financial identity and his or her household identity, this customer can create a single *virtual* identity document that allows him or her to view all personal information (including the portions maintained by the customer, the customer's bank and doctor, and other parties) in one place. Any number of third-party digital representations of a single real-world identity may be linked in this fashion.

A final application for linking is to intentionally split a single identity's attributes into two or more locations for security reasons, for much the same reason the bank maintains account balances rather than allowing customers to do so. For example, using linking, a cellular phone can become a digital wallet. By storing credit card numbers on a smart card inside the phone and configuring the phone to require its owner to unlock it using a PIN before it releases a credit card number, users can enjoy increased security for online shopping. To complete an online purchase, the phone must be turned on, it must have the user's (encrypted) smart card installed, and the user must approve the purchase by entering the PIN. This makes it very difficult for anyone but the legitimate owner to use a digital wallet for purchases without the owner's knowledge or approval. Using linking, however, users could still see this information as part of their main

identity and update it as easily as any other information in their profile.

## DATA SHARING PERMISSIONS AND CONTRACTS

As described so far, digital identity is a framework for sharing everyone's identity data freely with everyone else. Most people, however, simply are not willing to share all of their personal data with everyone who might want them. Indeed, people are very discriminating with their personal information. They only give out their credit card information to stores they feel are trustworthy. They only give out their direct e-mail addresses to others if they believe they will not get more junk mail by doing so. They pay extra to have their telephone number not listed in the white pages. Therefore, one of the central principles of digital identity is to give control of private data to the people and organizations to whom it belongs. A digital identity infrastructure must support flexible privacy control at the protocol level to gain the trust of users (Figure 2).

XNS's digital identity infrastructure handles privacy through a data structure called a *contract* that defines the terms under which data may be shared. For example, a contract between a personal identity and a merchant identity might specify that the following:

- The shipping address stored in the identity document will be used only to fulfill the current order and not to mail advertising
- The merchant will not retain the address in its systems any longer than is necessary for the purposes of shipping the order
- The merchant may not share the address with any other parties without customer consent

How are contracts established? Generally, they are negotiated automatically. The XNS Negotiation service, which is used to establish contracts, is an implementation of the Privacy Framework developed by the International Security, Trust, and Privacy Alliance (ISTPA). In a transaction between a customer and a merchant, the merchant identity would present to the customer identity a proposed contract indicating what information is needed, what it will be used for, how long it will be kept, and whom it may be shared with. If the customer has previously told his or her identity service provider what terms are acceptable and provided preferred values for the kinds of data the merchant wants, negotiation could be completed entirely without human intervention. More commonly, the customer would insist on having the opportunity to review and approve the terms and select the data to be shared before finalizing the transaction. The resulting contract records the mutually agreed-on terms and governs the links between the two identity documents between which the data will be shared. When a permission requirement has been established on a data attribute stored in an identity document, it becomes impossible for other identities to access that data without first agreeing to a contract.

Because the resulting data structure is called a *contract*, the obvious next question is whether it is legally binding. The law in most countries is moving steadily toward

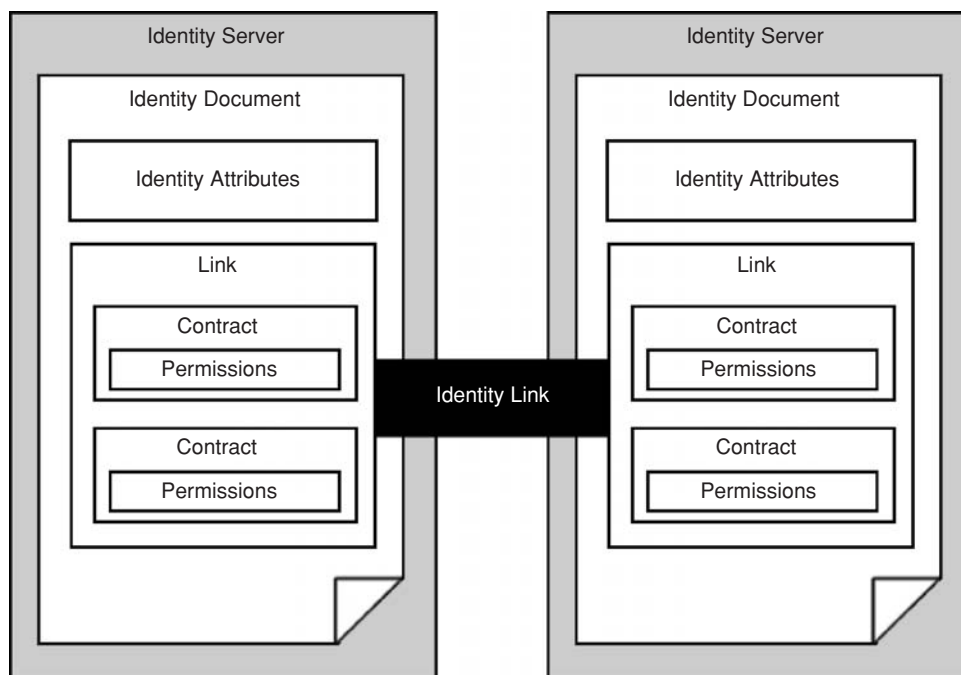

Figure 2: Identity link between two identity documents.

accepting digital signatures as legal proof of assent. The United States passed the Electronic Signatures in Global and National Commerce Act (popularly known as E-Sign) in 2000. Using established cryptographic techniques, it is possible to provide reasonable proof of the identities of the parties agreeing to the contract and to prevent repudiation. Still open, however, is the question of whether contracts automatically negotiated by software agents on behalf of the signers are legally binding. The authors expect such contracts to be affirmed in the coming years.

Even without the weight of the law behind them, data-sharing contracts make it easier for consumers to access and update the personal information that businesses keep about them, as well as allowing consumers to hold businesses more accountable for the ways they use their customers' data. Although some companies might not care for this level of accountability at first, eventually businesses will embrace it wholeheartedly, because contract-based data sharing provides a foundation of trust for building closer, more profitable relationships with customers, employees, suppliers, and partners.

## OTHER DIGITAL IDENTITY SERVICES

Being able to locate identity documents and forge permission-protected data-sharing links between them makes a wide variety of digital identity applications possible. This is the foundation of XNS and XDI and also of Liberty Phase 2. Indeed, analysts predict that data sharing will be the single largest purpose for which digital identity technology will be used in the near term. Beyond sharing, however, digital identity enables other services that will make the Internet and many common communications functions safer, easier, and faster.

Many of these are *trust services*—services that make it easier to perform trusted digital transactions. For

example, an *authentication* service is needed to prove that a digital identity represents a real-world principal and to assert that real-world identity across trust domains. Once a user logs into his or her digital identity, in other words, other services can tell that person is the same person who created the identity, and therefore they can be assured that they are dealing with a single individual at all times. This enables single sign-on and customization features and also supports the creation of contracts between identities.

*Certification* service allows digital identities to make assertions about the truth of the data stored in them. A third party, called a *certifying authority*, provides a cryptographic signature that essentially claims that it has inspected the data in question and found them to be complete and accurate. A real-world example is a driver's license. It would be much better to keep a digitally signed version of a driver's license in an identity document rather than just including the raw data the license contains; the digital signature from the issuing government would allow this credential to be used as proof of age, for instance. Certification supports the mapping of real-world identity credentials into the digital realm and thus gives digital contracts their force.

A *session* service combines authentication and certification to support a browser-based SSO solution. The third party in this case is a *session server*, which issues a cryptographic token certifying that acceptable credentials were presented to begin a session. This *session token* is then either accepted by various Web resources in place of traditional credentials (such as a user ID and password) or is transparently mapped to acceptable local credentials. The Liberty Alliance version 1.0 protocols are essentially a federated session service.

A *hosting* service allows one identity to host another. When an identity document is hosted by an identity server, the hosting service is the service responsible for

establishing the new identity's persistent address. In XNS, the identity server itself is represented by an identity document. Identities hosted by a server are registered with the server's *host identity* so that they can be located by name, ID, or XRI.

Finally, in an extensible identity protocol, some way must be provided for applications to discover new identity services they do not know about. In XNS, this is accomplished with the discovery service, which designates a *publishing identity* for each service's definition and allows the service's data formats and message descriptions to be retrieved in standard formats including XML Schema (XSD) and WSDL. The discovery service allows anyone to define new identity services that are completely interoperable with existing identity applications.

In XNS 1.0, the 10 services ID, name, discovery, hosting, data, folder, authentication, certification, session, and negotiation—plus the core service, which defines data formats and an abstract base class for messages—comprise the base services. These are, in the authors' estimation, the absolute minimum requirements for a fully functional identity infrastructure. Other potentially useful services include the following:

- *Reputation* service to allow the trustworthiness of an unknown identity to be evaluated based on the opinions of other identities
- *Introduction* service to allow two identities that currently link to a third identity to cut out the intermediary and link directly—essentially a three-way negotiation or friend-of-a-friend service
- *Directory* service to provide the ability to register and locate participating identities not just by name and ID but by certain attributes (e.g., locating all identities at a specific company or in a particular area)
- *Address translation* services allow popular identifiers such as e-mail addresses and phone numbers to be used as identifiers for identity documents, with full delegation capability

## DIGITAL IDENTITY AND ENTERPRISE APPLICATION INTEGRATION

Large companies contain vast repositories of identity data. A lightweight directory access protocol directory server contains identity data; so does a customer relationship management system, an accounting system, or an order processing system. Even a network management tool, an e-mail server, or a collaboration server could be viewed as containing identity data. (Anything that stores and manages data about entities can be considered as an identity application in a loose sense.) None of these tools are designed to talk to each other, even though the benefits of doing so might be enormous.

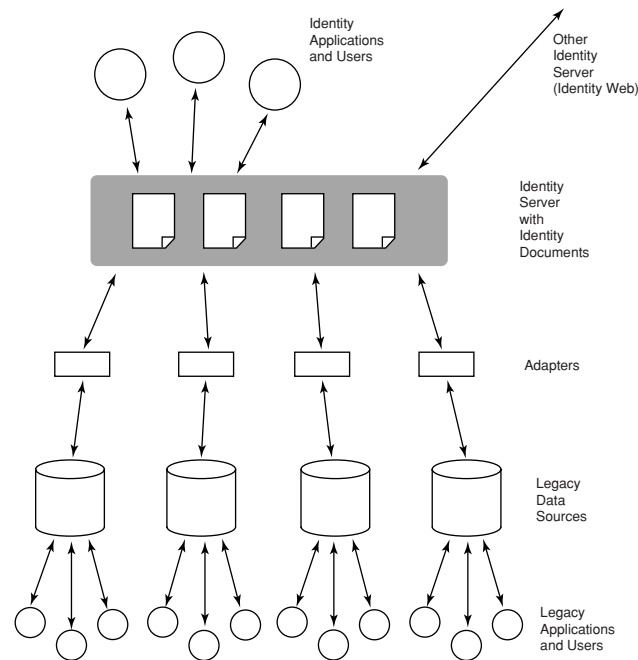

The problem is compounded in obvious ways when companies join forces; it is not uncommon for a large enterprise to have several separate, incompatible information systems performing the same functions for its various divisions, like a fossil record of the company's merger history. It is the redundancy problem from this chapter's very first example—the same information stored

in many places, wasting vast amounts of storage and requiring enormous effort to keep in sync—writ *very* large. The biggest corporate giants have hundreds or even thousands of different mission-critical databases stored in mutually incompatible systems around the world.

Addressing these issues in a comprehensive way all at once can be mind-bogglingly expensive and time consuming. Designing, implementing, and testing just data format conversions can take thousands of engineer-hours. Then there is the expense of replacing the legacy systems with more modern software and the inevitable headaches that come with trying to tie it all together, not to mention the additional time required for retraining employees on the new systems.

Reenvisioning digital identity as an integration layer on top of existing enterprise information systems makes it possible to undertake enterprise data integration in small, easily managed pieces. The legacy systems are kept intact and remain authoritative, with the data needed for a given application transparently mapped into identity documents using *adapters*, software modules that serve as a bridge between the identity server and the legacy systems. Using this approach, new integration applications can be built on top of the identity layer rather than talking directly to the enterprise layer and can be developed with modern object-oriented methodologies, with the legacy systems treated more or less as black boxes. Companies can begin with the proverbial low-hanging fruit—the most obvious enterprise integration projects with the clearest potential for substantial return on investment (ROI) or the best chance to achieve a new competitive edge (Figure 3). As these projects prove themselves out, more projects can be undertaken with increasing confidence, until at some point the network effect comes into play and the ROI of identity solutions already implemented increases exponentially by allowing new connections to be made. In the coming identitycentric world, it will eventually become a competitive disadvantage to store identity-related data in places where it cannot be shared (given appropriate permissions) with others.

An example will serve to illustrate how digital identity can be used for integration. Suppose two mail-order companies merge into one bigger company that now has two separate systems for processing orders and for mailing catalogs. An identity-based approach to integrating these systems, to allow customer service representatives to access all data stored in both systems without even having to know that there *are* two separate systems, would be to create an identity document to represent each customer. By means of adapters, individual data elements in these identity documents would be retrieved from the existing systems. The identity document stores any record keys necessary for finding the appropriate data in the two systems. When an application asks the identity server for the catalog mailing address from a customer's identity document, the identity server retrieves this data on the fly from the mailing list application. Requesting the last order date causes the identity server to query the order processing system for this bit of information. If the customer's entire identity document were requested, all the information needed from all systems involved would be retrieved behind the scenes, by means of adapters, and stitched

**Figure 3:** Digital identity as an enterprise integration layer.

together into an identity document conforming to the syntax required by the standard (e.g., XML). When an application changes something in the identity document, the adapters write the changes back out to the legacy systems. Adapters can also take care of any necessary protocol details (e.g., interfacing with the desired network stack), do encoding conversions (e.g., Extended Binary-Coded Decimal Interchange Code to Unicode), and provide caching services and even encryption and decryption.

The application never needs to know or care that any of this is happening; it uses the same simple, standardized object-oriented methods to read or write data regardless of where it is stored and how it must be accessed. Existing applications that are used with the legacy data systems can remain authoritative or can even be run simultaneously with the identity-based applications. In fact, if desired, the legacy systems can even be switched out from under the identity layer—suppose they need to be upgraded for other reasons—and, assuming the appropriate adapters have been written for the new systems, the identity-based applications will never notice. The adapter approach makes it possible for system integrators to build generic solutions for common integration problems; for each installation, they need only to write adapters and perform the specific customization necessary to get the new applications running on top of whatever legacy data stores a particular client has installed.

Once a data source becomes identity enabled, it is easy to add functionality incrementally. The first step might be to integrate the order processing and mailing list systems of two merged companies, as described above, so that customer data are more accurate and customer service staff can work more efficiently. The next step might be to add a Web interface to the system so that customers can

access and update this information on their own, reducing staffing needs for the call center. Next, the accounting system might be integrated to allow customers to see and pay their invoices online. Then the company might offer to integrate its order processing system with its identity-savvy institutional customers' inventory systems, so that their stock can automatically be replenished when it runs low. Each step adds real value, each has measurable ROI, and each can be accomplished in a relatively short time with relatively few development resources thanks to the standardized identity programming interface.

Stunning feats of integration such as these can be accomplished without digital identity—Wal-Mart's integration of its suppliers into its own data-processing operations is a textbook example. However, doing it the old-fashioned way requires expenditures of money and development resources in direct proportion to the amount of data already stored in legacy silos, and it is difficult for enterprises to justify the expense of many such projects on an ROI basis. Identity-oriented development promises to do for enterprise systems integration what object-oriented programming did for software engineering: make it simpler, quicker, less error prone, and less resource intensive. Suddenly, many projects that did not originally make financial sense look feasible, and they look even more attractive in light of the network effect made possible by open standards.

Our prediction is that the enterprise is where most identity-related development will occur over the next few years. Consumers will come to rely on identity-based services provided by these companies more and more, often without knowing (or needing to know) that these services are in fact founded on digital identity technologies. For example, companies will start allowing customers

to share their account information with their strategic partners. Meanwhile, grass roots understanding of privacy issues will slowly but inexorably lead to consumer demand for identity applications and for true control over their own data. Consumer protection legislation and regulations will drive enterprises to adopt technologies with strong privacy safeguards, lending additional weight to the benefits of digital identity. Network effects will, finally, lead to the identity web, a global hyperlinked collection of personal data shared, by mutual agreement, between entities. By the end of this decade, the most compelling reason to use identity-based solutions in the enterprise will be that customers, vendors, partners, and competitors are already using them.

## THE IDENTITY PLAYERS

This chapter has already touched on the efforts of XNSORG, OASIS, and the Liberty Alliance in the realm of digital identity, as well as Microsoft's Passport. We can characterize these efforts as pure identity plays.

XNSORG, having launched XNS, turned over the reins to OASIS, where the XRI and XDI standards are the successors to XNS. Version 1.0 of the XRI specification is already available, and XDI is under development.

Liberty's Phase I specification defines an SSO service based on the security assertion markup language, wherein existing accounts at multiple sites that have agreed to share authentication can be linked. Sun Microsystems is already supporting Liberty Phase 1 in its directory server. Phase 2, released early in 2003, is a more sophisticated protocol that allows any Liberty-compliant service to federate with any other—without preexisting partnerships—and to share more attributes between accounts.

Microsoft's Trustworthy Computing initiative, popularly known by its code name Palladium, aims to add permissions to document sharing of all kinds through a combination of security and identity technologies. The industry perceives Trustworthy Computing as being driven in large part by the desire of content providers (e.g., the music and motion picture industries) to control how their content is being used and protect it from piracy, but Microsoft recognizes that consumers will not use a system with such restrictions unless it also provides compelling benefits for them as well. The carrot Microsoft offers with Palladium is to give *everyone* the ability to apply the same industrial-grade restrictions to information *they* create. As part of Palladium, Microsoft will also provide wider access to their Passport technology—including, in an unusual move for Redmond, sharing Passport Manager source code with selected partners and customers. (Passport Manager is the software module that allows a Web site to join the Passport network and access shared user data.) The next Passport will support federation.

These three are not the only players, though—only the most visible. Enterprise software vendors are also moving into digital identity. Much of the identity data in the enterprise is housed in directory servers, which are used to control access to corporate network resources as well as to store contact information. Manufacturers of

directory and access management products have a natural interest, therefore, in providing their customers with the integration and data-sharing tools they will need in an identity centric world. Not surprisingly, vendors of access-control products—including IBM, Microsoft, Netegrity, Novell, Oblix, and Sun—are already beginning to tout digital identity functionality and interoperability for their products.

Current directory products do not scale well across trust domains—meaning that they are better suited to controlling access within an enterprise than across multiple enterprises—but some vendors already offer *metadirectory* products that can consolidate enterprise directories into one virtual directory. This monolithic approach does not offer the advantages of the Web architecture that will eventually evolve with digital identity; however, enterprises will continue to turn to these working solutions in the short term while identity standards shake out. At that point, it would be natural for these vendors to begin adding support for standards-based distributed identity.

As described earlier, digital identity has the potential to introduce a major paradigm shift in the enterprise integration category. Where the traditional integration approach is monolithic and expensive, the digital identity approach offers low upfront cost and incremental deployment. These are such powerful advantages that it is likely that vendors such as BEA, SeeBeyond, TIBCO, and webMethods will eventually be compelled to use this approach and may in time become leading vendors of identity solutions.

## THE FUTURE OF DIGITAL IDENTITY

This chapter has presented the authors' vision of how digital identity will, through links between identities that share data, eventually form an identity web similar to the current World Wide Web (WWW) of documents. The initial growth of the identity web will be driven, like the early stages of the WWW, by early adopters, though early on, more businesses than consumers will see and exploit the potential of digital identity.

As digital identity infrastructure grows, it will have progressively wider applications in many product categories. For example, e-mail vendors could use digital identity protocols to provide permission-based mail filtering. Senders of mail would have to prove their identity and agree to a privacy contract before being permitted to send mail to a given address, potentially putting an end to spam once and for all. By the end of the decade, any product category that involves sharing information is likely to include digital identity features, particularly if it involves digital rights management.

Despite the possible privacy and civil liberties pitfalls, which continue to require vigilance, the concepts embodied by digital identity have the potential to have enormous net positive social and technological impact in the coming years. It is unfortunate that the word *revolutionary* has been tarnished by its application to so many lackluster technologies, because if ever a new technology deserved that adjective, it is digital identity.

## GLOSSARY

**Adapter** In Enterprise Data Integration, a software module that serves as a bridge between an integration layer and legacy systems.

**Authentication** The process of proving that a user is an authorized user of a network resource by presenting credentials such as a user ID and password (colloquially known as logging in).

**Community** The group of identities that can be located through a given address resolution service.

**Contract** A list of mutually agreed permissions for sharing data between identities via an identity link.

**Digital Identity** An emerging technology and application category that revolves around the logical modeling of real-world actors (e.g., people and companies) and their attributes and the permission-based sharing of these attributes between actors on a network.

**Extensible Name Service (XNS)** An open, extensible markup language-based digital identity protocol licensed by the not-for-profit XNS Public Trust Organization (XNSORG).

**Extensible Resource Identifier (XRI)** A new type of standard identifier that provides the functionality necessary for addressing identity documents.

**Federation** The process whereby separate communities share address resolution services, thus merging two or more communities into a larger one and giving users a choice of which provider to use.

**Global Community Services** A publicly accessible address resolution service that allows any digital identity to be located by any other, like the domain name service.

**Host Identity** The identity that represents the identity service and is responsible for hosting other identities.

**Identity Document** A document, stored on an identity server, which stores the attributes of some real-world actor (e.g., a person, a company, a device, or an application).

**Identity ID** An immutable, machine-readable identifier that resolves to the network endpoint where an identity document is stored; identity IDs never change as long as the document exists and are the foundation of identity links.

**Identity Link** A pipe between two identities for the two-way synchronization of shared attributes.

**Identity Name** A human-readable semantic identifier for an identity document that can be resolved to an identity ID.

**Identity Server** Software that stores identity documents and provides identity services for those documents.

**Identity Service Provider** An organization that provides storage for identity documents.

**Identity Web** The global interlinked digital identity community (see *Community*).

**Liberty Alliance** An industry consortium founded by Sun Microsystems to deliver and support federated network identity solutions for the Internet.

**Negotiation** The process of agreeing on a contract for sharing data between identities via an identity link.

**Passport** Microsoft's consumer digital identity service based on the Kerberos authentication protocol.

**Publishing Identity** The identity that makes available the definition of an identity service so that the service can be discovered by identity-savvy applications.

**Trust Domain** Technically, a set of network resources, the access to which is controlled by a given directory server; in practice, the network resources a user can access with a single set of credentials; more generally, a set of network resources that trust each other, such as an ATM network.

**Trust Services** Identity services that make it easier to perform trusted digital transactions; examples include authentication and certification.

**Web Services** A new model for interapplication communication over the Internet using standardized protocols (XML, SOAP, WSDL, UDDI); the extension of the concept of local computing services to the Web.

**XRI Data Interchange (XDI)** An effort to develop a protocol for permission-based data exchange based on extensible resource identifiers.

## INTRODUCTION

While the origin of the term “digital divide” is difficult to determine, by the mid-1990s conversations about the issues that define it were present at the highest levels of the U.S. federal government. On October 10, 1996, President Bill Clinton and Vice President Al Gore addressed the public at the Knoxville Auditorium Coliseum (Clinton & Gore, 1996). The main topic of their presentation was the government’s effort to build “a bridge to the 21st century.” During the conversation, they address the existing digital divide, referring to varying levels of access to the Internet available to different demographic groups in the United States. During this same federal administration, several reports were published by the National Telecommunications and Information Administration that quantified these differences. In addition, important federal programs were put in place with the goal of guaranteeing access to the Internet to all members of U.S. society.

By 2002, under a new federal administration, reports published by the same agency announced that the gap between the “haves” and the “have-nots” was quickly closing, and predicted that it would only be a matter of (short) time before the differences disappeared altogether. Almost at the same time, a number of researchers working with the Internet from various perspectives described a new type of digital divide, which went further than simple access to machines connected to the network; factors such as absence of adequate literacy levels, the nonexistence of relevant content, lack of ability to become creators of content (and not only “consumers of content”) were placing demographic groups at risk of being unable to take advantage of the medium.

This chapter discusses how the meaning of the term “digital divide” has changed through time. It also explores new dimensions of the problem actively being studied and

argues that even the original definitions of the problem are far from being solved.

## THE ORIGINAL DEFINITION

The National Telecommunications and Information Administration (NTIA), a branch of the U.S. Department of Commerce, originally published data and analysis of who was using the Internet in 1996 and 1998. Under the title of *Falling Through the Net*, these reports outlined how typically disenfranchised groups were lacking connectivity to the Internet. White people were more connected than people of color, member of high income brackets were more connected than the poor, and so on. The problem was thought to be important enough to warrant direct governmental intervention. In 1996, the U.S. federal government created the E-rate program. Under this program, taxes were to be added to telephone bills to fund projects providing connectivity at schools and libraries. Although the government was not expecting to provide a connected computer to each household, access would be provided for all at places of public access. Table 1 presents the percent of households with online service for several important demographic groups in 1997 (NTIA, 1998).

## “PROBLEM SOLVED”

By the beginning of the 21st century, many researchers and government officials declared that the problem of the digital divide had practically disappeared. The U.S. federal government, after changing from a Democratic to a Republican administration, reflected this attitude by changing the title of its recent findings from *Falling Through the Net* to *A Nation Online* (NTIA, 1999b). There were two main arguments for this position: first, that online connectivity was penetrating into general society slowly (but surely), in what is typically known as an

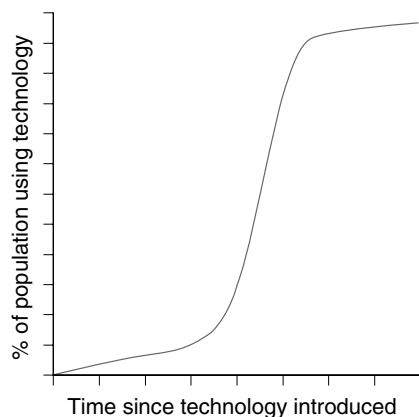

**Table 1** Internet Use for Different Demographic Groups

Group	Percent Online
<b>Race</b>	
White, not Hispanic	21.2
Black, not Hispanic	7.7
Hispanic	8.7
<b>Income</b>	
Under \$5,000	7.2
\$5,000–9,999	3.9
\$10,000–14,999	4.9
\$15,000–19,999	7.0
\$20,000–24,999	9.0
\$25,000–34,999	13.9
\$35,000–49,000	20.8

Bachelor's degree or higher	38.4

S-curve pattern of diffusion; second, that many Americans were gaining access to the Internet from places other than their households. Although these arguments are important (and presented here for a complete understanding of the digital divide problem and the dialogue around it), later sections of this chapter present data that contradict both of these arguments.

### The S-curve Pattern of Diffusion

The theory of the S-curve pattern of technology diffusion argues that new technologies are never adopted with equal speed by all members of society. Early on, only a few try the new technology. Later, once the technology starts to become popular, it is quickly adopted by a greater number of people. Finally, after reaching a saturation point, the number of participants remains close to constant, ideally including a high percentage of the population. Figure 1

**Figure 1:** Typical technology adoption curve.

shows a typical technology adoption curve. Such trends have been seen for many technological innovations, including televisions, VCRs, microwave ovens, automobiles, and others. Internet penetration has moved faster than any recent technology, reaching 25% of the U.S. population in only 7 years. This is faster than the rate of diffusion for technologies that have reached close to 100% penetration, such as radio, television, and electricity (National Center for Policy Analysis, 1998). If the S-curve for Internet adoption is steep enough, the argument goes, soon everyone who wants to be connected, will be connected, making any current demographic difference a temporary part of the diffusion process (see, for example, Compaine, 2001).

### Access Outside of Homes

In 2001, the year that *A Nation Online* was published by the NTIA, access to the Internet was defined as being able to connect to this medium from home, work, or school. This, in part, continued the idea introduced by the previous administration, which created the E-Rate program to facilitate people gaining access to the Internet from publicly accessible spaces. Defined in that way, connectivity numbers are as presented in Table 2, which includes numbers from 1997 to facilitate a comparison (1997 numbers are still defined in terms of access at home).

### “A Problem Among Many”

Although it is not a claim of Internet diffusion, social scientists present at least one more rationale for not allocating great amounts of money to ameliorate the digital divide. This rationale argues that not being connected to the Internet is only one of many problems that affect those who are disenfranchised from fully participating in what society has to offer. In addition, not being connected is not one of the most serious problems, which warrants placing more attention elsewhere. Others question why society should pay so much attention to this one problem in light of so many others (Compaine, 2001). This issue is reexamined later in this chapter.

## NEW DEFINITIONS

Parallel to reports that the whole nation was online, social scientists identified necessary requisites for taking advantage of the Internet, other than simply having access to connected machines. Broadly speaking, these have to do with each user's preparation and the context in which the Internet is used. This section explores some of those requirements more closely.

### Literacy

Carvin (2000) identified six types of literacy skills needed by a user to take full advantage of the Internet: basic literacy (the ability to read and write), functional literacy (the ability to apply basic literacy to everyday tasks), occupational literacy (the skills necessary to succeed in a professional setting), technological literacy (the ability to use technological tools), information literacy (the ability to determine the quality of informational sources), and adaptive literacy (the ability to develop new skills). Some

**Table 2** Reported Internet Connectivity

Group	Percent Online (1997)	Percent Online (2001)
<b>Race</b>		
White not Hispanic	21.2	59.9
Black not Hispanic	7.7	39.8
Hispanic	8.7	31.6
<b>Income/year</b>		
Under \$5,000	7.2	25% for those earning
\$5,000–9,999	3.9	\$15,000/year or less
\$10,000–14,999	4.9	
\$15,000–19,999	7.0	33.4% for those earning between
\$20,000–24,999	9.0	15,000–25,000
\$25,000–34,999	13.9	44.1
\$35,000–49,000	20.8	57.1
\$50,000–74,999	32.4	67.3
75000+	49.2	78.9
<b>Education</b>		
Elementary	1.8%	12.8% for those with
Some high school	3.1%	< high school
High school or general educational development diploma	9.6%	39.8%
Some College	21.9%	62.4%
Bachelor's or more	38.4%	80.8%

of these types of literacy depend on or facilitate each other. For example, technological literacy is easier to acquire for those with adequate functional and adaptive literacy. Functional literacy, at the same time, strongly depends on basic literacy. These relationships point toward basic academic skills as a prerequisite of taking advantage of the Internet. They also point toward the need for proper training on how to use technology. All of these types of literacy are crucial for effective participation. As an example, Lazarus and Mora (2000) found that although 22% of the population of the United States does not have proper “everyday” literacy skills, most of the text available online is written assuming that the audience has at least an average level of literacy.

Data analysis also indicates that college-educated individuals derive greater occupational and educational benefit from the Internet (Robinson, DiMaggio, & Hargittai, 2003). This places in question the claim that the Internet can serve as a social equalizer, instead rendering it an exacerbating force for social inequalities.

## Relevance

The Internet is heralded as an important communication medium because of its ability to facilitate flow of information. Therefore, for this new medium to be useful to all citizens, the information flowing has to be of relevance and interest to all. If the information available online turns out to be of little relevance to disenfranchised citizens, they will be less likely to participate with the medium. An audit performed by the Children's Partnership revealed that technologically underserved U.S. citizens found the Internet lacking in local information and cultural diversity (Lazarus & Mora, 2000). Servon (2002) argued that this is caused in part by the fact that the Internet was

originally “populated” by White, middle- and upper-class males who created the type of content that would interest them (Servon, 2002). This can lead to a dangerous cycle of exclusion: some demographic groups fail to connect because of the lack of information available online that interests them, and information they are interested in is not created because there is no present demand for it.

## Ability to Create Content

Because of the Internet's power as a communication tool, those who can generate content for it are able to project their message in new and powerful ways. Therefore, being left out of the opportunity to generate Internet content is another way that population groups can be marginalized by this new technology. The Pew Internet Project, through a national phone survey, found great discrepancies in the levels of Internet content that had been created by various demographic groups. This included content creation through Web site creation, Web cams, weblogs, file sharing, and newsgroups. Table 3 summarizes their findings.

## The Disabled

Serious consideration should be given to the way in which disabled people access the Internet. Those who are visually impaired or who have problems working with a mouse as an interface device, for example, can have great difficulty navigating and taking advantage of the opportunities offered by technology as a communication medium. In 2000, the NTIA reported that although 56.7% of U.S. citizens accessed the Internet (either from inside or outside their homes), only 28.4% of people with disabilities did. Only 22.5% of people with difficulty using their hands and 21.1% of people with vision problems used the Internet. In

**Table 3** Web Content Creators

September 2000, President Clinton assigned \$16 million to the Department of Education to promote technology programs for the disabled, and an additional \$9 million to Americorps volunteers working with Internet for the disabled. In addition, modifications made to the U.S. Rehabilitation Act now require government Web pages to meet certain criteria to make them more accessible to people with disabilities (CNN, 2000). At the same time, government Web sites do not, in fact, fully satisfy these requirements. In a study commissioned by the Benton Foundation and the New York State *Forum of the Rockefeller Institute of Government*, Darell West (2003) reported that only 22% of federal Web sites, 24% of state government sites, and 13% of city sites complied with Section 508 of the U.S. Rehabilitation Act.

## Broadband

Although, in theory, information available on the Internet is not dependent on the connection speed, some Web sites are designed to be accessed via high-speed connections. Many of these sites are rich on graphics and multimedia, suggesting that they are oriented more toward entertainment and less toward vital information. At the same time, a recent study by the Pew Internet Project found that access to high-speed Internet connectivity allows users to engage in the following three online patterns: content creation, wide ranging queries, and multiple Internet activities on a daily basis (Horrihan, 2002). The study also found discrepancies in the access that different groups have to high-speed Internet connections, as summarized in Table 4.

As can be seen by this data, discrepancies exist based on almost every category reported, with the possible exception of age.

**Table 4** Percent of Internet Users With Access to Broadband Versus Dialup

## A LOOK AT RECENT DATA

Although most people now agree that efficient access to the Internet involves more than simply access to a connected computer, the question of who has access to connected computers is still valid. To restate arguments discussed earlier, many consider that at least part of the digital divide problem has been solved, mostly because of access in public spaces and the quick diffusion that the Internet has shown. Recent data fail to back up these arguments. A study published by the Pew Internet Project in 2003 indicates that 63% of Americans make use of the Internet. Taken together with the 41.5% and 50.5% reported for 2001 and 2002, respectively, it might seem like the nation is still on the upswing of the diffusion curve (NTIA, 2002). In reality, each NTIA report uses numbers obtained in the previous year, and most of the access growth occurred in 2000 and early 2001 (Madden, 2003). We seem to have reached the flat upper part of the diffusion curve at around 60% to 65% penetration. If this is the case, we should not expect the number of Internet users to increase much more. More important, data suggest that we have reached this point of the S-curve for all demographic groups (Madden, 2003). That is, it does not seem to be the case that the number of White people online is now constant while the number of people of color is increasing on a separate S-curve. Table 5 summarizes who currently has

**Table 5** Internet Use by Group, vs. Percent of U.S. Population

Suburban	52	48
Rural	21	26

access to the Internet, compared with their percentages in the general population. Differences based on race, gender, and geographic location have either shrunk or disappeared, but those based on income and education are still very much present. Smaller sets of data seem to suggest that Blacks and Whites have close to the same level of Internet knowledge and sophistication (Alvarez, 2003). With regard to disabilities, 38% of U.S. citizens with disabilities use the Internet, as opposed to around 60% of all Americans who do (Lenhart et al., 2003).

The hope that access at public spaces would provide for those unable to connect from their households has fallen short of the goal. Internet access at public spaces has grown, but this has not managed to provide efficient connectivity to the economically disadvantaged. Although most of the people who say they depend on libraries to connect to the Internet live in households making less than \$30,000 per year, they are infrequent users of the medium (Harwood & Rainie, 2004).

## THE INTERNATIONAL DIVIDE

A look at international data clearly shows dramatic differences in level of access to the Internet in different nations. The number of Internet users per 10,000 inhabitants is as low as 5.64 for Myanmar and as high as 6,747 for

Iceland (International Telecommunications Union, 2004). The United Nations, during a World Summit on the Information Society held in 2003, declared its intent to harness technology to improve the human condition around the globe (United Nations, 2003a). UNCTAD, the United Nations Conference on Trade and Development, looked at data gathered and reported by several other agencies and developed a ranking methodology that measures not only current connectivity, but also the existence of infrastructure and political climate considered optimal for future growth. The following section lists the criteria used for this ranking and discusses them in light of research done by others regarding this topic.

## Definition of United Nations Technology and Communications Index

The Information and Communication Technologies Task Force of the United Nations has designed an information and communications index to describe national conditions with regard to technology and communications (United Nations, 2003a). This index takes into account not only the number of people using the Internet, but also broader characteristics that describe how well each nation has taken advantage of technology and how much of the needed infrastructure for future development has been established. These characteristics are divided into connectivity, access, and policy environment.

## Connectivity

The United Nations consideration of connectivity includes four components. PCs (personal computers) per capita, telephone lines per capita, mobile subscriber per capita, and Internet hosts per capita. In many countries, we see a close correlation between the number of computers per person and the number of people accessing the Internet. On one end of the spectrum are nations such as the United States and Sweden, with 65.89 and 62.13 computers per 100 inhabitants. On the other end are regions such as Africa, where there are 1.38 computers and .14 people connected per 100 inhabitants (International Telecommunications Union, 2003).

In many nations, a strong correlation is found between access to the Internet and access to telephone lines. In the United States, there are 62.13 telephone lines per 100 inhabitants. Canada has 65.84 per 100 inhabitants, and Sweden 72.16 per 100 inhabitants. Ethiopia, which has only 1.1 Internet users per 10,000 citizens, has only 0.63 telephone lines per 100 inhabitants (International Telecommunications Union, 2003).

Mobile subscribers per capita are included as a reflection of connection methods that might increase in importance in the future.

Internet hosts per capita looks at how many computers have an assigned IP (Internet protocol) address assigned to it. This includes both full- and part-time connections (such as the ones typically used by dial-up connections). Obtaining an accurate number for this variable is not always simple or possible, given that there is no necessary correlation between host names and the nations where they are located.

## Access

The United Nations' model defines access in terms of number of Internet users per capita, literacy, gross domestic product (GDP) per capita, and cost of placing local calls.

In countries where telephone calls are accrued on a per-minute basis, the cost of placing local calls become part of the cost of connecting to the Internet. The Organization for Economic Cooperation and Development (2001) has found strong correlations between the price per minute for telephone calls and the number of Internet hosts in different countries.

## Policy

The last indicator used by the United Nations in its indices is policy environment, which tries to document a general national framework conducive to the integration of technology into everyday life. This indicator includes the presence of Internet exchanges, competition in the telecommunications field, and competition in the ISP (Internet service provider) market.

Internet exchanges are defined as installations capable of exchanging traffic among Internet providers. The United Nations includes this indicator because it believes the existence of such an installation diminishes the dependency on international links and might reflect a proactive policy outlook.

Competition among telecommunication providers and among ISPs is desirable as a market force to increase quality and decrease the cost to consumers.

## Quantitative National Differences

Based on the factors just outlined, great discrepancies are evident in national levels of technology preparedness. National indices go from as high as 1 for the United States to as low as 171 for Eritrea (these values are normalized based on the best performing nation and grow higher with decreasing performance). Although there are individual success stories of nations advancing in their ranking (such as Costa Rica and China), rankings seem to be consistent over time. Regional analysis also reveals that those nations at the extremes of the Internet connectivity distribution curve are in fact moving further apart from each other. Although Organization for Economic Cooperation and Development countries continue to improve, sub-Saharan African countries continue to fall behind. Not surprisingly, nations in the "high-income" grouping had an average connectivity ranking 77 places higher than "middle-income" nations. Finally, it is important to point that the UNCTAD study found correlations between local policies and national connectivity.

## Other Potential Factors of the International Digital Divide

Norris (2001) analyzed data on Internet usage for Portugal, Greece, Germany, Spain, France, Belgium, Austria, Ireland, Italy, the United Kingdom, Luxembourg, Holland, Finland, Denmark, and Sweden. In all these countries, income, educational level, gender, age, and type of occupation (managerial vs. manual work) was a

strong indicator of Internet connectivity. The problem of a gender-based digital divide, now mostly absent in the United States, is a major problem in countries outside Europe. Of the total number of people connected to the Internet, only 22%, 38%, and 6% are women from the regions of Asia, Latin America, and the Middle East, respectively (Hafkin & Taggart, 2001).

There are also drastic domestic differences within developing countries. Income, education, geographic location, and gender all seem to influence connectivity (Grace, Kenny, & Qiang, 2001).

## THE IMPORTANCE OF CLOSING THE DIGITAL DIVIDE

The advantages provided by the Internet are many, but they can be generalized to the ability to acquire and communicate information. How these advantages are put to use vary depending on the user and his or her location. In the United States, for example, 53.9% of unemployed people who use the Internet from their homes and 29.8% of unemployed people who use the Internet from outside their homes use it to look for new jobs (NTIA, 1999a). Additionally, between 36% and 38% of people who use the Internet from any location are either taking online courses or doing academic research.

For countries around the world, taking advantage of new technological opportunities can be crucial for national economic development. Campbell (2001) found a strong correlation between the number of technology users and the percentage of growth in employment.

Citizens of a connected nation can follow the work of their elected representatives more closely. Many elected government officials, at both the state and federal levels, can be contacted via the Internet. Web sites not only provide information, they also allow for easier contact with elected officials. Information about government rules, regulations, and benefits can be found online. In fact, the chief executive officer of the U.S. Government Printing Office recently commented that within 5 years, 95% of all documents that are part of the Federal Depository Library Program would be available online (James, 2003). This depository includes all of the information published by U.S. federal government agencies.

Local governments have implemented Web sites through which a number of clerical tasks can be satisfied. For example, in Massachusetts citizens can renew their drivers licenses or car registrations from any computer with access to the Web, and all across the United States people can fill out and submit their income taxes electronically, receiving valuable guiding information for a process usually classified as arduous and complicated. Although the subject of e-government is discussed elsewhere in this encyclopedia, it should be clear from these examples that the Internet is making it easier for connected citizens to participate in governmental discussions and fulfill standard paperwork requirements.

Labor unions now use the Internet to inform and organize their members (CNN, 2000b). Union members are thus kept better informed and are in closer contact with the people they elect to act as their representatives.

As of 2002, the Pew Internet Project reported that 73 million Americans have looked for health information online, and 63 million had done education related research (Madden, 2003). High school technology education programs are training young programmers living in urban neighborhoods, allowing them to enter the workforce and command salaries of up to \$150 per hour (Clewley, 2001). This offers a group of typically disenfranchised citizens skills that are in high demand, turning technology into an engine capable of propelling people into higher income jobs. In Sierra Leone, a local entrepreneur created a program in which young rebel soldiers were able to trade their arms for computer training, with the goal of turning them into the center of a software outsourcing business within 3 years (Hermida, 2002). In China, citizens successfully used the Internet to change the course of political action. After a wealthy car driver received what was considered to be an extremely soft sentence for killing a poor farmer with her car, massive online protests led to government officials reopening the case (Ni, 2004).

Examples such as these are too numerous to list all of them here. Although each has a different flavor and approach, what they and others like them have in common is their use of the Internet as a powerful communication mechanism. As such, they can serve as tools for increasing equality, bringing new opportunities to disadvantaged communities. If the divide between those who have access to the Internet and those who do not is not closed, it may well serve as a mechanism to exacerbate economic and social differences between the haves and the have-nots. Although many social scientists argue that access to the Internet is not the most pressing social problem to be addressed, others argue that so-called second-order resources such as the Internet are required to assist those in need to accumulate assets that allow them to exit from and remain out of poverty (Servon, 2002).

## COMPLEX SOLUTIONS FOR A COMPLEX PROBLEM

The digital divide has proved to be a hard problem to solve, and with good reason. It includes many dimensions, and effective solutions will need to be multidimensional as well. Although defining a complete solution for this problem is outside the context of this chapter, we can point toward elements that such a solution must incorporate.

Solutions to the digital divide cannot be based simply on providing machines connected to the Internet, as was demonstrated by the "hole in the wall" experiment in New Delhi; computer kiosks were installed in a poor neighborhood, and no instructions were provided. With unrestricted 24-hour access, children learned rudimentary manipulation of the equipment (clicking and dragging with a mouse, etc.), but they spent most of their time playing computer games or using painting programs (Warschauer, 2003). Absent of guidance and purpose, connected machines fail to provide users with much of a chance to better their social positions.

It is not sufficient to place computers in schools, or even in coursework. Warschauer (2000) documented the different educational outcome of two classrooms in

Hawaii where technology was being used. Although both schools used technology to improve the educational opportunities available to their students, differences were evident. The school in the more economically affluent community used computers to develop academic and scientific skills, whereas the students in the poorer school were involved with tasks directed more toward the workforce. This difference was matched by a series of goals and expectations set by the teachers at each of the schools. The context where the technology was used clearly affected the way in which it was experienced, integrated, and used.

Many Americans from disenfranchised groups experience technology within communal settings. The type of activity these experiences take place has implications for the impact and success of these exposures to technology. Based in local communities, community technology centers (CTCs) have the ability to integrate use of the Internet with other activities of high relevance to this population. Organized technology projects, as opposed to individualized access points, can serve as a focal point for the common efforts of a community group. Technology can also serve as a source of information and resources for the group, as well as a method to establish communications with other groups with common interests in different geographic locations (Warschauer, 2003). These centers typically offer programs that not only teach their participants how to access the Internet, but also teach them how to create content and how to develop their employability (Servon, 2002).

Although in theory, libraries and schools can both create programs that involve citizens in technology projects similar to the ones offered by CTCs, this is not their main mission. Frequently sparse economic resources and different central agendas make it more difficult for this type of institution to be as effective as CTCs in providing efficient Internet connectivity to the disadvantaged. If enough funds are allocated to design and implement proper technology projects, these public spaces can assist in providing access to those that cannot gain it from within their households.

Government participation needs to be strong to close the divide. As outlined earlier, governments are key players in establishing many of the prerequisites for strong e-readiness. The E-rate program in the United States has helped wire public spaces for access to the Internet. This is a good start, but the program does not provide for any type of training or programmatic support. It also makes funds available only to libraries and schools, and not to CTCs or other types of community groups.

Governments are also central in establishing economic incentives for e-commerce and in making sure infrastructure elements such as telephones lines are widely available. Public and private institutions can also be strong collaborators in training programs at different levels. Partnerships between communities and the information technology sector can both make useful skills available to participants, and provide a well-trained workforce to employers. In Seattle, for example, programs between community groups and Microsoft, Boeing, Cisco, and AT&T have all helped make technology available to typically marginalized groups (Servon, 2002).

Various national governments have implemented a variety of plans to reduce their domestic digital divide. The one common thread among all of them is their signaling that access to the Internet is an important national issue. In 2000, President Clinton presented a budget that included several key items designed to increase Internet access across the nation. Among other things, his proposal called for \$2 billion in tax incentives for private companies donating hardware and training to technology centers; \$150 million to train new teachers in the best ways to use technology; \$100 million to create community technology centers; \$25 million to encourage the private installation of Internet connectivity to underserved communities; and \$10 million to train native Americans for careers in information technologies. In Brazil, the government put into place aggressive programs to provide Internet terminals at post offices in cities with 6 million or more habitants, and to provide Internet-ready home computers for as little as \$15 per month. The Australian government has put in place a series of initiatives to bring both connectivity and training to all of its population, at a total cost of close to \$426 million.

Potential Internet users need to understand what they have to gain from using the medium, and they need to know how to access its features. Both national governments and private institutions can play important parts in delivering this knowledge to citizens. Many of these types of initiatives share the common thread of being partnerships between public, private, and educational institutions.

A final characteristic for successful national Internet inclusion is the ease with which companies can establish electronic commerce and transactions. Murasoli Maran, secretary-general for the Asian Productivity Organization, argues that this benefits nations in three ways: It provides additional avenues for job creation and national economic development; it stimulates local and international entrepreneurs to assist with other items necessary for generalized Internet participation because they gain from an increase in online customers, and it provides incentives for citizens to acquire training in information technologies, because companies will now require a trained workforce (Maran, 2000).

Solving the international digital divide will require participation from players across national borders. The United Nations has called for national environments that encourage international cooperation and direct foreign investment. This will require efforts to "correct market failures, . . . to maximize economic and social benefits, and to serve national priorities" (United Nations, 2003b).

In this way, then, connectivity, government leadership, computer infrastructure, a trained local workforce, and a positive electronic commerce climate form the cornerstones of Internet development for any country. All these factors feed off each other in a systemic process. For example, local governments have the primary responsibility of providing connectivity, but they usually come into partnerships with private industries to facilitate the rigorous task of wiring a nation. Private industries, at the same time, take advantage of government subsidies in exchange for providing hardware and training to the general population.

## CONCLUSION

The digital divide is a problem that threatens to leave a considerable portion of the potential users of the Internet disconnected. Given the Internet's potential as a tool for social change and improvement, aggressive steps should be put in place to close this divide. While the digital divide has changed in nature and complexity since it was identified, the original problem is still present. Community groups, national and local governments, private industry, international bodies, and individual citizens will all need to come together in carefully crafted plans to design and implement effective solutions.

## GLOSSARY

**Broadband** Normally understood to refer Internet connections faster than those provided by standard telephone lines. The Federal Communications Commission defines broadband as a medium that provides for communication faster than 200 Kb in each direction. Current examples include ISDN (integrated services digital network), cable, ADSL (asymmetric digital subscriber line), satellite, local wireless, and power broadband.

**Community Technology Centers (CTC)** Facilities and programs designed to provide free or low-cost computer access as well as training. Usually located in public housing developments, libraries, or other types of public access places.

**Federal Communications Commission (FCC)** It is the branch of the U.S. federal government that oversees the telecommunications and media industries.

**General Educational Development (GED)** The GED test measures how well someone has mastered the knowledge expected of a high school graduate.

## INTRODUCTION

Use of the networked world has resulted in many social and individual benefits. The World Wide Web, for example, makes it possible for people to access a wealth of information from the comfort of their own homes. E-mail capabilities enable individuals to communicate information from one country to another at a fraction of what it would cost to do so by making an international telephone call. Bulletin boards and discussion lists provide large groups of like-minded persons with a forum in which they can exchange ideas. All of these media are fully available to the user at any time of the day.

The unique capabilities of these new technologies, however, have also given rise to novel legal, social, and ethical problems. The ability to communicate information to potentially millions of people facilitates socially desirable expression, but it also facilitates expression of questionable morality and legality. Because, for example, the harm to an individual's reputation caused by defamation is a function of how many people receive the defamatory material, the capabilities of the Web increase a user's potential for causing harm by publishing defamatory material. Similarly, because the economic loss to a copyright holder caused by the unauthorized distribution of copyrighted materials is also determined by how many people receive those materials, the capabilities of the Web also increase a user's potential for causing harm by sharing copyrighted materials.

These new information technologies, then, can be used in ways that implicate a wide variety of interests of legal, social, and ethical significance. These interests include interests in privacy, free speech, security, economic well-being, and property. This chapter discusses some of the important ways in which these technologies have unfavorably implicated these interests, although it should be

emphasized that the selection of issues here, of necessity, falls well short of being complete.<sup>1</sup>

## FREE SPEECH ON THE INTERNET

While the establishment of the World Wide Web has greatly enhanced the ability of ordinary individuals to receive and communicate information and ideas, online speech also poses ethical and social problems. Unfortunately, the Internet has been used not only to seek information and truth, but also to defame, defraud, sexually exploit, and incite other people. It is not surprising, then, that such conduct is giving rise to much controversy about the scope of the right to free speech and its application to online activity.

### Legal Protection of Free Speech

There is a consensus in Western nations that citizens have a moral right to free speech that is sufficiently important to deserve legal recognition and protection. A number of nations, including Canada and the United States, have formal constitutions that explicitly create a right of free speech limiting state restrictions on the free flow of ideas. The Canadian Charter, for example, provides that "Everyone has the following fundamental freedoms: (a) freedom of conscience and religion; (b) freedom of thought, belief, opinion, and expression, including freedom of the press and other media of communication; (c) freedom of peaceful assembly; and (d) freedom of association."<sup>2</sup> The First Amendment to the U.S. Constitution provides that "Congress shall make no law . . .

<sup>1</sup> A number of important topics cannot be discussed here because of space limitations. Notable examples include e-commerce, the digital divide, data quality, and e-learning.

<sup>2</sup> Canadian Charter of Rights and Freedoms, Part I, Section 2, "Fundamental Freedoms"; available at <http://laws.justice.gc.ca/en/charter/>.

abridging the freedom of speech, or of the press; or the right of the people peaceably to assemble, and to petition the Government for a redress of grievances.”<sup>3</sup>

European nations also regard the free flow of information among individuals as a fundamental value. For example, Article 5 of the German constitution (*Grundgesetz*) guarantees the right of free speech and expressly prohibits censorship of any kind.<sup>4</sup> Similarly, a recent draft of the proposed Charter of Fundamental Rights of the European Union includes a provision establishing a right of free speech: “Everyone has a right to freedom of expression. This right shall include freedom to hold opinions and to receive and impart information and ideas without interference by public authority and regardless of frontiers.”<sup>5</sup> Free speech is also protected by the courts in many European nations as an “implied right.”

### Moral Legitimacy of Free Speech Rights

Utilitarian justifications for legal protection of speech emphasize the benefits of free speech to the common good. John Stuart Mill (1989), for example, argued that allowing people the freedom to speak their minds and express their creative abilities promotes human happiness in several ways. First, allowing speech conduces to the speaker’s well-being by facilitating the development of his or her critical faculties. Second, allowing creative expression promotes the ideological and technological betterment of humanity. Third, and most important, allowing free debate increases the likelihood that the truth will be discovered—and knowing the truth always conduces, on Mill’s view, to human well-being.

Deontological justifications argue that there are strict moral limits on the extent to which one person may justifiably interfere with the autonomy of another person. Nozick (1977) argues, for example, that every autonomous moral agent has a “natural” right to liberty that includes the right to express her views free of coercive interference. Since people have natural rights in virtue of their status as moral persons and not in virtue of their status as citizens of some state, the operation of natural rights is not limited to obligating other individuals; even the state must respect a person’s natural rights. Indeed, so important are these rights that Nozick (1977) notes that the state’s only legitimate function is to protect them.

Contractarian theorists argue that the state’s legitimate lawmaking authority depends entirely on the consent of citizens and that citizens consent only to limited restrictions on free speech. Although classical contractarian theories require that citizens *actually* consent, whether expressly or tacitly, to state authority, the most influential modern approach focuses on what citizens *would* consent to under certain counterfactual circumstances. John Rawls argues that a just state is bound by those principles that rational self-interested agents would choose if they had to select principles constraining the government without having any specific information about their

own particular preferences, abilities, and social circumstances.<sup>6</sup> On Rawls’s view, citizens behind such a “veil of ignorance” would protect themselves from oppression by choosing a principle of personal liberty that defines a right to free speech.

## Internet Issues

### Web Pornography and Children

Pornographic material on the Web is both plentiful and easy to come by. A search of the word “sex” on any mainstream search engine will produce not only links to scientifically and medically useful information on sex, but also links to pornographic Web sites. Entering <http://www.sex.com> into a Web browser will take the user to a portal that provides links to various types of pornographic material, ranging from standard sexually explicit material to material that appeals to various fetishes. As is evident, the word “sex” can be used in a variety of Web-based devices to locate Web sites specializing in graphic sexual content.

This raises the worry that children who are emotionally unprepared for pornographic content may encounter it while surfing the Web. Although it is fair to say that the effects of pornography on adults remain unclear, child development experts agree that chronic exposure to pornographic materials can have long-lasting and harmful effects on children (see, e.g., Benedek & Brown, 1999). Such materials can affect the way in which children view sex, relationships, and women; they can also diminish the prospects for successful love relationships and might even raise the likelihood of sexual violence. Richard Spinello (2000, p. 57) eloquently described the concern:

Given the power of sexuality in one’s life, the need for carefully integrating sexuality into one’s personality, and the unfortunate tendency to regard others as sexual objects of desire (rather than as human beings), there is a convincing reason for fostering a climate in which impressionable children can be raised and nurtured without being subjected to images of gross or violent sexual conduct that totally depersonalize sexuality, exalt deviant sexual behavior, and thereby distort the view of responsible sexual behavior.

The ease with which such materials can be accessed on the Web creates the possibility of such exposure in children—and its harmful consequences.

Legislators on both sides of the Atlantic share concerns about the potential impact of Web pornography on the emotional well-being of children. The European Parliament (1997), for example, strongly advocates legislation that would protect children from access to inappropriate sexual material on the Web. It formally resolved that “minors should be protected as soon as possible against access, via the new networks and services, to material which may harm their physical and psychological development.”

It is unclear, however, what sorts of restrictions on Web pornography should be enacted by legislators. Although

<sup>3</sup> United States Constitution, First Amendment; available at <http://caselaw.lp.findlaw.com/data/constitution/amendment01/>.

<sup>4</sup> For an English translation of the German constitution, see <http://www.psr.keele.ac.uk/docs/german.htm>.

<sup>5</sup> Draft of the Charter of Fundamental Rights of the European Union, Chapter 2, Article 11; available from <http://www.europarl.eu.int/charter/pdf/text.en.pdf>.

<sup>6</sup> In particular, Rawls stated that citizens would choose a principle (the Liberty Principle) that grants each agent as much freedom as is compatible with like freedom for all other agents.

the legitimacy of concerns about minors is undeniably a point in favor of legal regulation of Web pornography, there are legitimate concerns militating against it. Any restriction on Web pornography is likely to impact socially desirable forms of speech and will thereby have the effect of limiting the access of adults to legitimate content and thereby violating their moral rights to free speech. As a historical matter, censors have typically tended to err on the side of restricting too much content in the name of sexual morality, frequently attempting to censor books and paintings that are now regarded as literary and artistic masterpieces. The effect on moral rights to free speech, had such efforts been successful, would have been significant.

Part of the problem here is that any restriction on sexually explicit content on the Web will have to be couched in abstract terms that admit of varying degrees of vagueness. Terms such as “obscene,” “indecent,” “pornography,” and “sexually explicit” are all vague at the margins and admit of very different interpretations, depending on what background assumptions are incorporated into the interpretation. Some people, for example, would characterize explicit instructions about how to use a condom as “indecent” or “sexually explicit.” Indeed, it is the very vagueness of these terms that makes it likely that too much, rather than too little, material will be censored.

Complicating the difficulty of trying to balance these competing interests is the issue of how much responsibility society should collectively bear to assist parents in raising children. On one view, society bears minimal responsibility; the primary responsibility for raising children rests with parents. On another, society has much at stake in how children are raised because the social costs of poorly raised children can be significant; accordingly, citizens must be prepared to make some sacrifices to increase the likelihood that children are raised in a way that ensures they become productive, well-adapted adults.

The various positions on how to balance these competing considerations are being debated not only by citizens, but also by legislative and judicial officials. Consider, for example, the controversy in the United States attending the enactment of statutes like the Communications Decency Act (CDA). The CDA prohibited the “transmission of any comment, request, suggestion, proposal, image, or other communication which is obscene or indecent, knowing that the recipient of the communication is under 18 years of age” and the “knowing [transmission] to a specific person or persons under 18 years of age . . . [of] any comment, request, suggestion, proposal, image or other communication that, in context, depicts or describes, in terms patently offensive as measured by contemporary community standards, sexual or excretory activities or organs.” The CDA authorized a prison sentence of up to 2 years for violations.

Although the CDA struck the balance in favor of children, the U.S. Supreme Court struck the balance in favor of speech, striking down the CDA on the ground that it would restrict the constitutionally protected speech of adults (see *Reno v. ACLU*, 1997, at 2329). Crucial to the Court’s decision was the observation that the Web is entitled to greater First Amendment protection than television and radio because one must take a series of affirmative

steps to view specific content online. Children are far less likely to be exposed accidentally to sexually explicit material on the Web than on television because they cannot randomly sample Web pages simply by changing channels. Although curious children can seek out such materials, it is the “ease with which children may obtain access to broadcasts” that, according to the Court, “justifie[s] special treatment of indecent broadcasting” (see *Reno v. ACLU* at 2342).

In response, critics argue that the difference between television and broadcasting is a difference in degree that does not justify treating the two media differently—and not a difference in kind. Although the likelihood that a child will accidentally encounter inappropriate content on the Web is lower than the likelihood he or she will accidentally encounter inappropriate content on television, the likelihood of the former is still morally significant; after all, a few mistaken keystrokes (e.g., inadvertently clicking on a link from a search) will expose a child to pornographic content. If the harm associated with such content is substantial enough to justify restricting it on television, then it is also substantial enough to justify restricting it on the Web, as long as there is a theoretically significant probability of accidentally encountering it there.

Perhaps persuaded by such reasoning, Congress subsequently enacted the Child Online Protection Act (COPA), which makes it illegal for commercial Web sites to allow persons under 17 to view sexually explicit materials that are “harmful to minors.” Although the drafters of COPA deliberately attempted to avoid the constitutional problems of the CDA by restricting the speech of only commercial Web sites, a federal appeals court recently struck it down on the ground that it is unconstitutionally overbroad in two respects. First, the court held that “COPA’s definition of ‘material harmful to minors’ impermissibly places at risk a wide spectrum of speech that is constitutionally protected” (*Ashcroft v. ACLU*, 2003, at 267). Second, it held that its definition of “minor” reaches material that is clearly protected for adults and is not obscene to older minors (*Ashcroft v. ACLU*, at 268).

Whether enactments such as COPA achieve a proper balance between the speech rights of adults and the social interests in the well-being of children remains hotly debated, but this much is clear: the interests in speech and the well-being of children are both legitimate and important in the sense that they both deserve some level of governmental protection. One can expect European and American nations to continue to invest considerable resources to working out the proper balance between the two interests.

## Online Hate Speech

There are a growing number of racist, anti-Semitic, and heterosexist Web sites worldwide that advocate violent measures to achieve hate-inspired political agendas. White supremacist Web sites, for example, frequently call for “race wars.” Extremist antiabortion Web sites feature photographs of women coming to or leaving abortion clinics. The most infamous of these sites once posted a “Wanted List” of abortion doctors and currently features an editorial advocating the arrest (which it describes as

“an act of love”) of all persons with a same-sex sexual preference.<sup>7</sup>

Online hate speech creates a host of social problems. To begin with, the anonymity of online communications has emboldened racists, anti-Semites, and homophobes to create more hate sites with increasingly egregious content. Further, the worldwide availability of such content enables bigots to find one another with unprecedented ease and to more easily reach people whose educational and economic circumstances make them susceptible to content that identifies an “Other” as scapegoat. Finally, many hate sites explicitly encourage terrorism to achieve their political agendas. These considerations point in the direction of restricting online hate speech.

Yet, as was true of pornography, there are considerations militating against regulation of such speech. Some opponents argue that restrictions on hate speech will not reduce racism, anti-Semitism, or heterosexism. On this line of analysis, such restrictions simply drive bigotry underground where it can fester until it results in serious social problems that will be far more difficult to address. Restricting hate speech, then, runs the risk of chilling legitimate speech (“hate speech” is as vague as, say, “indecent”) without producing the intended desirable consequences. The best response to hate speech, as the point is sometimes put, is more speech, not less.

Reflecting the difficulties in balancing such considerations is the fact that various nations have adopted different approaches to online hate speech. (For an outstanding analysis of the social and legal issues presented by hate speech, see Stuart Biegel, 2001.) Legislation restricting hate speech is not feasible in the United States. According to prevailing interpretations of the U.S. Constitution, hate speech does not fall into the traditional categories of unprotected speech and is hence protected by the First Amendment. For this reason, laws targeting online hate sites on the basis of their content are constitutionally impermissible in the United States.

The United States is unique among Western industrial nations in this regard. Many European nations, such as Germany, have laws criminalizing certain forms of hate speech. Indeed, the Council of Europe (n.d.) is currently preparing legislation that would prohibit posting or distributing racist or xenophobic material through a computer system. For its part, Canada has already enacted extensive legislation against online hate. The Canadian Human Rights Act (n.d., Section 13) prohibits the communication over computer networks of “any matter that is likely to expose a person or persons to hatred or contempt by reason of the fact that that person or those persons are identifiable on the basis of a prohibited ground of discrimination.”

## Spam

Unsolicited mass e-mailings (“spam”) are ethically problematic because they impose significant costs on Internet users. First, spam consumes scarce network resources (e.g., time and disk space) for which recipients must pay. Second, recipients must expend time and energy to deal with unsolicited mailings; as Spinello (2000, p. 63)

points out, “If a vendor sends out 6 million messages and it takes 6 seconds to delete each one, the total cost of this one mailing is 10,000 person hours of lost time.” Third, Internet service providers (ISPs) and consumers are harmed because large quantities of spam can overload networks, slowing response rates and causing downtime. Spam raises ethical issues because these costs are typically imposed on consumers without their consent.<sup>8</sup>

Intentionally deceptive spam raises additional issues. Many senders attempt to ensure that recipients view their mailings by concealing their commercial nature. Such practices are ethically problematic not only because they are dishonest, but also because they deliberately attempt to frustrate the intent of consumers who wish to save time online by deleting spam mailings without viewing them. When such spam is of a graphically sexual nature, the risk that children and adults are exposed to unwanted and potentially harmful pornographic images is dramatically increased.

Western nations agree on the need to restrict spam but disagree on what restrictions are legitimate. The European Union recently adopted a directive requiring spammers to obtain the consumer’s consent before sending unsolicited commercial e-mail (Saunders, 2002). Although such legislation is not possible in the United States because commercial speech is protected by the First Amendment, intentionally deceptive commercial speech can be prohibited. Indeed, Congress recently enacted the CAN-SPAM Act (i.e., the Controlling the Assault of Non-Solicited Pornography and Marketing Act), which prohibits many deceptive practices that have become common among spammers. CAN-SPAM prohibits, among other things, transmitting multiple commercial e-mails with the intent to deceive and intentionally falsifying header information before transmitting multiple commercial e-mails. The act became law in the United States on January 1, 2004.<sup>9</sup>

Whether such restrictions are ultimately efficacious in reducing objectionable spam, however, remains to be seen. First, there are a variety of increasingly sophisticated techniques that enable spammers to conceal their ultimate location. An increasing amount of spam, for example, is sent from innocent agent machines to which spammers have surreptitiously gained access because owners have unwittingly downloaded programs allowing backdoor access to their machines. Second, spam received in one country frequently originates from a different country. These factors make it difficult to enforce legal restrictions on spam and hence reduce the deterrent effects on potential spammers.

<sup>8</sup> The proliferation of pop-up advertisements on the Web raises some similar issues. For example, the consumer must expend time and effort to close a pop-up ad; in this respect, pop-up ads are like spam. Even so, there is one fundamental difference between the two: to receive a particular pop-up ad, one must perform a specific cyberact—namely, direct a Web browser to retrieve the contents of a particular Web site. Receipt of spam, in contrast, does not require any specific act on the part of the user (apart from having an e-mail account).

<sup>9</sup> CAN-SPAM supplements the preexisting efforts of many states to legislate spam. In 1998, for example, the Washington State Legislature prohibited the transmission of unsolicited commercial e-mail to Washington state residents that contains false sender addresses or deceptive subject lines. Washington’s Unsolicited Commercial Electronic Mail Act was upheld by the state’s highest court in 2001.

<sup>7</sup> The infamous Nuremberg Files Web site can be found at <http://www.christiangallery.com>.

### Filtering Devices

A number of products filter objectionable content online. Individual filtering programs, for example, can be installed on a user's personal computer to block access to Web sites using certain sexually explicit terms or featuring images with a disproportionate quantity of fleshtones. Additionally, an increasing number of Web sites, although still a comparatively small percentage of total Web sites, participate in the PICS (Platform for Internet Content Selection) ratings system, which suppresses Web sites that rate themselves for mature audiences, as well as Web sites that decline to be rated.

The most contentious issue regarding such products involves their use by public libraries. Although many people believe public libraries should install such devices out of respect for the values of the communities they are intended to serve, library professionals and associations frequently oppose their use on two grounds. The first is that filtering programs are imprecise at this point in time—they sometimes fail to block access to pornographic content and sometimes block access to unobjectionable scientific or health-related content. The second is that there is a concern about whether it is ever appropriate for a library to censor content. The American Library Association, for example, takes the position that “A person's right to use a library should not be denied or abridged because of origin, age, background, or views.” On this view, any form of censorship is inconsistent with the duty of libraries to ensure the free flow of information to individuals of all ages.

The U.S. Congress recently entered the filtering controversy with the enactment of the Children's Internet Protection Act (CIPA) in 2002, which requires public libraries to use filtering devices as a condition for receiving certain federal funds. Although a federal appellate court struck down CIPA on the ground that filtering devices typically screen out protected content (*American Library Association v. United States*, 2002), the U.S. Supreme Court recently upheld CIPA. Because CIPA requires library personnel to disable filtering devices on the request of an adult, the Court held that it leaves open alternative channels for adults to receive blocked content (*United States v. American Library Association*, 2003).

### Search Engines

Search engines are an indispensable tool for sifting through the approximately 8 billion pages now on the Web (Suzukamo, 2002).<sup>10</sup> If the user knows (a) which sites contain the needed information and (b) the precise URL addresses of those particular sites, he or she can simply enter the addresses into the browser and it will call up those sites. If, as is more often the case, the user does not know where to go to find the needed information, he or she must rely on a search engine to find appropriate Web sites; navigating the Web without the use of a search engine can be a time-consuming process that fails to produce appropriate sites.

A search engine imposes order on the Web by creating a large database that contains an index of each page's URL, along with a fairly substantial list of key words describing

its contents. When the user submits particular key words to a search engine, the engine returns a ranked list of URLs containing those key words. Search engines structure the Web by, in effect, characterizing each indexed page in terms of its content (as indicated by the appropriate key words).

Search engines, then, determine which pages users are likely to visit in two ways. First, search engines make available only those pages they have indexed—and there is currently no engine that has indexed every page on the Web.<sup>11</sup> For many people, a page that is not listed on any of the search engines doesn't exist; as Introna and Nissenbaum (2000) put the matter, “to exist is to be indexed by a search engine.” Second, users are more likely to visit only highly ranked pages. Anecdotal evidence suggests that users are likely to visit only the top 10 to 20 pages (or “hits”) returned by a search engine (Introna and Nissenbaum). If a low-ranked page exists for users, its existence is far less substantial than that of a highly ranked Web site.

Insofar as the criteria that determine the inclusion and ranking of pages determine how frequently a Web site is visited, they have two consequences of ethical significance on speech rights. First, they determine to what extent a particular publisher's Web speech is received. Second, they determine what content is ultimately available to persons seeking information on the Web. Given these critical effects, it is reasonable to think that search engines ought to employ ranking and inclusion criteria that satisfy ethical and technical standards.

Most search engines employ criteria that do not *explicitly* favor any particular class of publishers over another for reasons unrelated to merit. Web sites are usually either manually submitted to search engine editors who decide whether they are suitable for indexing or are retrieved by “spiders” that crawl the Web automatically indexing pages. A page's rank is usually determined by either the number of times a particular key word appears in the page or the number of other pages that contain links to the page.<sup>12</sup>

Some search engines, however, use economic criteria that favor firms willing to pay. Some engines, for example, allow a Web site to pay for expedited indexing, a process that can otherwise take months. Some engines permit firms to buy advertising linked to key words; any search using a particular key word will turn up a screen with an advertisement from a company that sells a related product or service. Some search engines have gone so far as to allow firms to bid on their top rankings.

Although some believe that market-driven search engine criteria are no more problematic than market-driven criteria for production of any other goods, critics have objected to economic criteria on three grounds. First, economic criteria rank content on the basis of characteristics that are irrelevant with respect to the quality or utility of the information; the ability or willingness of a Web site

<sup>10</sup> In 1999, Lawrence and Giles estimated that there were 800 million Web sites. If these estimates are accurate, the number of sites on the Web was 10 times as large in 2002 (Suzukamo, 2002) as it was 3 years earlier.

<sup>11</sup> Google, one of the most comprehensive search engines, states that it has indexed approximately 3 billion Web pages. See <http://www.google.com/help/features.html> (retrieved November 1, 2003).

<sup>12</sup> Some newer search engines attempt to evaluate a page's “authority.” Teoma, for example, ranks a site based on the number of same-subject pages, as opposed to general pages, that reference it. The goal is to be able to identify pages that are regarded as “expert” among a particular subject community. See [www.teoma.com](http://www.teoma.com).

owner to pay has nothing to do with the quality of the information contained in the site. Second, as Introna and Nissenbaum (2000) put the point, economic criteria compromise the ideal of the Web as a public good insofar as the Web “fulfills some of the functions of other traditional public spaces—museums, parks, beaches, and schools” and thereby contributes to the common good. On this view, selling influence on the Web is as ethically problematic as selling influence in a museum or school; in neither case should the common good be sold to the highest bidder. Third, failure to disclose that a Web site has bought its rank may mislead search engine users to believe the site’s rank was determined by characteristics having to do with the quality and utility of the site.

## INTELLECTUAL PROPERTY

The Web impacts the intellectual product of content creators and publishers in a variety of ethically significant ways. The Web provides them with another legitimate means to distribute intellectual product to an appropriate class of persons, but it also makes it possible for persons to distribute intellectual product to large numbers of persons without the authorization of those who claim to have property rights in that product. Since mass distribution of content on the Web can obviously reduce the economic market for the product, such distribution raises issues concerning the extent to which persons have legitimate property interests in content.

### Legal Protection of Intellectual Property

Western nations generally offer three types of legal protection for intellectual property. First, patent law protects a person’s interests in his or her own inventions, which includes newly designed useful processes.<sup>13</sup> A patent protects an invention by granting the inventor a limited monopoly power over the invention. This allows a patent holder the right to prevent other firms and persons from making or marketing it. Similar protections (“design patents” in some nations, “designs” in others) are also available for various aspects of a product’s ornamental design.

Second, trademark law protects the right of a product or company owner to use marks that distinguish its goods and services from others. Trademark infringement generally occurs when a firm or individual uses a mark that is likely to confuse a reasonably intelligent consumer about the source or sponsorship of a good or service. Many nations allow a firm to establish a trademark simply by using it, but formal registration is frequently available as well.

Third, copyright law protects the original expression of ideas and facts—the particular form, language, and structure of articulated ideas, as opposed to the facts and ideas themselves, which are never protected.<sup>14</sup> Originality of expression requires the introduction of something new to the world; a person who simply copies the expression of someone else has not produced anything original that can

be protected by copyright. Copyright protection applies to original literary works (including computer programs), musical works, dramatic works, choreographic works, artistic works, sound recordings, and architectural works.

Copyright law typically defines two intellectual property rights. First, it grants to the author an exclusive right to reproduce, modify, distribute, perform, and display the protected work. Second, it grants to the author certain moral rights of authorship. Such entitlements may include the right to claim authorship in the protected work; the right to prevent someone from attributing a work to the author that he or she didn’t create; the right to prevent someone from attributing a work to the author that diverges significantly from a protected work; the right to prevent intentional distortion, mutilation, or modification of a protected work that would detract from the author’s reputation; and the right to prevent intentional or grossly negligent destruction of a protected work.

Most nations include an exception for “fair” uses.<sup>15</sup> Copyrighted material may be used for news, educational, and research purposes, provided that such material is not directly used for material gain. In determining whether a use of copyrighted material is fair or not, courts may look to the purpose of the use (e.g., whether it is commercial), the nature of the copyrighted material, the amount of material used relative to the copyrighted work as a whole, and the effect of the use on the market for the work. The last factor is especially important insofar as copyright is intended to protect an author’s right to collect the economic value of his or her expression.

### Moral Legitimacy of Intellectual Property Rights

Theorists have produced three main lines of justification for legal protection of intellectual property. The first line is grounded in the Lockean view that persons have natural moral (as opposed to merely social) property rights in their bodies and labor. Because the particular sequence of words or symbols chosen by an author to express an idea or fact is the product of his or her labor, the author acquires an exclusive property right to that particular sequence of words or symbols—as long as no one else has a prior right to that sequence. The Lockean argument can roughly be summarized as follows: he or she made it; therefore, he or she owns it.

The second line of justification for intellectual property rights is grounded in the Hegelian view that creators use symbols, words, and sounds to express their person. As an expression of personhood, an original creative work realizes and *extends* the creator’s person. Because no one but the author has a protected interest in his or her person, the author acquires a protected interest in his or her expression because such expression is, in some vague but morally significant sense, an extension of his or her person. Roughly put, this line of argument can be summarized as follows: it is part of him or her; therefore, it is his or hers.

The third principal line of justification is utilitarian in character. Protection of intellectual property rights is

<sup>13</sup> The intellectual property statutes of various English-speaking nations are available at the following Web sites: Canada—<http://strategis.gc.ca/sc.mrksv/cipo/welcome/welcom-e.html>; United States—<http://www.law.cornell.edu/topics/topic2.html>; United Kingdom—<http://www.intellectual-property.gov.uk/>.

<sup>14</sup> Thus, others are free to express the same ideas and facts as long as they do not intentionally duplicate the author’s original expression.

<sup>15</sup> See, for example, the “Fair Dealing” exception to Canadian copyright law beginning at Section 29 of the Canadian Copyright Act (R.S. 1985, c. C-42); and the “Fair Use” exception to U.S. copyright law beginning at 17 U.S.C. Section 107.

justified because such protection conduces to the common good. People will be far more likely to invest time and energy in creating the intellectual products that contribute so much to human happiness, flourishing, and well-being if they are granted an exclusive property right in their original creations. Roughly put, this line of argument is as follows: giving it to him or her benefits all of society; therefore, it is his or hers.

These justifications, however, are vulnerable to serious objections. Critics have argued, for example, that the utilitarian line of argument is problematic in a couple of important respects. First, it presupposes that the primary motivation for creation of content is material, but this presupposition is difficult to reconcile with the success of “open-source software.” Open-source software is generally characterized by two features: (a) it is available either free of charge or at a purely nominal price, and (b) the source code of such software is made readily available to users who are free to improve the software by fixing bugs as they are identified. Although proponents of open-source software agree on the undesirability of strong copyright protection for software, they disagree on the reasons. Some proponents, such as Richard Stallman (e.g., 2002), argue that ownership of software is morally illegitimate, whereas others argue that such protection is undesirable because it discourages innovation and improvement: allowing users access to the source code ultimately results in superior software. In any event, the fact that there are many high-quality open-source software products available to users (e.g., Linux) seems to refute the idea that the primary motivation for content creation is material.<sup>16</sup>

Second, the utilitarian argument assumes that the social benefits of intellectual property protection can be achieved by no less restrictive measure than granting extended exclusive rights to intellectual property. Even if the primary incentive for content creation were material in character, there are other ways to protect it: a society could, for example, pay a salary or a fee to content creators. After all, software companies have enjoyed considerable success paying employees a salary for creating software.

Opponents of strong intellectual property protection also argue that intellectual objects are different from physical objects in two ways that diminish the force of the Lockean and Hegelian natural rights arguments. First, intellectual objects, unlike physical objects, are not scarce; one person’s consumption of, say, a recipe does not reduce the supply of the recipe available for other persons. Second, intellectual objects, unlike physical objects, can be simultaneously consumed by all persons; whereas a hairbrush can be used by one person at a time, every person can simultaneously use the same recipe. Although this makes sense, on this line of reasoning, to assign exclusive rights to scarce objects that can be consumed by only one person at a time, it is problematic to assign traditional property rights to objects that can simultaneously be

consumed by every person without reducing the amount of the object potentially available to others.

Some theorists also worry that the increasing willingness of online users to infringe copyright law undermines the social legitimacy of protecting intellectual property in cyberspace. On this line of analysis, which is roughly grounded in social contract theory, the legitimacy of any particular law depends on its being acceptable to those whose behavior it purports to govern. The growing tendency, however, especially among younger online users, to reproduce and distribute copyrighted works without permission calls into question whether intellectual property protection continues to enjoy widespread acceptance and support among citizens. Insofar as there is no longer a consensus on the legitimacy of such laws, the contractual basis for protecting intellectual property is arguably deteriorating.

Finally, some critics argue that advancements in information technology have made intellectual property rights morally obsolete. For example, Barlow argues that existing intellectual property laws have no proper application in cyberspace. First, Barlow (1996) believes that cyberspace is a distinct metaphysical reality that lies beyond the proper jurisdiction of any nation: “Your legal concepts of property, expression, identity, movement, and context do not apply to us. They are all based on matter, and there is no matter here.” Second, Barlow (1992–1993) argues that information is itself a life form that, like any other life form, is entitled to some moral standing. On Barlow’s view, information has a morally protected interest in freedom: “information,” as he has notoriously put the matter, “wants to be free.”

## Internet Issues

**Domain Names.** Every computer on a network has its own Internet protocol (IP) address consisting in a unique sequence of numbers and dots (e.g., 213.57.66.938) that defines its location on the Web. When a user accesses a particular Web site, the contents of that site are sent from the host server’s IP address to the IP address of the user’s computer. In effect, then, IP addresses make it possible for networked computers to find each other, enabling users to access the contents of Web sites hosted at other locations on the network.

In most cases, users need not know a complicated IP address to access a Web site. Most Web sites have a natural language domain name (e.g., <http://www.sporting-goods.com>) assigned to their IP addresses that permits easier and more intuitive access to their contents. The user simply types in the natural language domain name, and the ISP either looks for the corresponding IP address or submits a request to a “root server” that serves as a digital directory associating IP addresses and domain names. Once the ISP has determined the corresponding IP address, the desired site is accessed.

Domain names can be valuable commodities. An intuitive domain name saves consumers time and energy; it is much easier to find a site with an intuitive domain name than with a long IP address that is difficult to find and remember. The resulting convenience to users can naturally translate into economic benefits; the easier it is to access

<sup>16</sup> It is worth noting that the open-source spirit is finding expression in other ways on the Internet. The free online encyclopedia, *Wikipedia*, for example, allows users to add and edit entries as they see fit. See <http://www.wikipedia.com>.

a commercial Web site, the more likely users are to visit and buy from that site.<sup>17</sup>

In consequence, there have been conflicts over the use and ownership of domain names. Early in the development of the Web, some people registered domain names featuring the trademarked names of large firms in the hope that the firms would buy those names whenever they decided to go online. Although a few such “cybersquatters” made a quick profit for their trouble, courts now treat the practice of speculating on domain names incorporating trademarks as actionable trademark infringement (see, e.g., *Panavision v. Toeppe*, 1998).

More commonly, a slightly modified version of a popular Web site’s domain name is used to capture some of its traffic. One commercial pornographic Web site in the United States, for example, uses the domain name “www.whitehouse.com.” Users who type “www.whitehouse.com” instead of “www.whitehouse.gov” into their browsers—a common mistake—will access sexually explicit material instead of the U.S. president’s official Web site. By such means, a person can dramatically increase traffic to his or her site.

Although such practices appear deceptive, they can facilitate legitimate purposes of free expression. A user who mistakenly types “www.gwbush.com” instead of “www.georgebush.com” will access a site criticizing George Bush’s views and policies instead of his personal Web site. While the commercial use of a domain name similar to a trademarked name can dilute the value of the trademark and is hence unethical, the politically motivated use of a domain name to express legitimate criticism is arguably unobjectionable—as long as users are not likely to be confused about the origin of the site.

### Illicit Copying Over the Internet

No case better exemplifies the clash between the intellectual property rights of copyright holders and the increasingly libertarian spirit of online users than the proliferation of MP3 file sharing over the Web. The development of the MP3 format was the first significant step in realizing the Internet’s latent potential for online dissemination of music files. Earlier technologies offered little incentive to share music files; the files were too large to be uploaded and downloaded quickly, and their sound quality was generally inconsistent. MP3 technology, however, permits the compression of nearly perfect digital reproductions of sound recordings into small files that are efficiently transmitted from one user to another.

Napster augmented MP3’s capabilities by introducing true peer-to-peer (P2P) file sharing. Whereas users of earlier file-sharing technologies had to download previously uploaded files from a central Web site or file transfer protocol (FTP) site, Napster users could simply take music files directly from the computers of other users. Although a central server was needed to keep a searchable list of all the available MP3 files, its purpose was limited to helping

Napster users find each other. Because users could share music files online without anyone needing to take the time to upload music files to some central server, Napster made it easier than ever before for large groups of users to share their sound recordings.

Napster’s P2P networking capabilities also inhibited the efforts of recording companies to stop reproduction and distribution of their copyrighted materials. When music files had to be transmitted through a central server, recording companies could demand that the server’s owner destroy copyrighted files or litigate an expensive civil suit. Because Napster eliminated the need for centralized storage of such files, however, there was no one entity that could be pressured by copyright holders. Not surprisingly, the music industry viewed Napster as a grave threat to the value of its copyrights.

The conflict came to a head when a group of music companies sued Napster for “indirect” violations of U.S. copyright law. Because Napster’s role was limited to enabling users of Napster’s MusicShare software to gain access to the hard drives of other users, the company could not be held liable for direct infringements. Instead, the plaintiffs sought to hold Napster liable for contributory infringement (i.e., knowingly assisting others in directly infringing a copyright) and vicarious infringement (i.e., benefiting financially from infringements when it has the ability to supervise and terminate users).

Although the litigation did not settle the legal issues, it resulted in a preliminary injunction forcing Napster off the Web temporarily. A U.S. federal court issued an injunction prohibiting Napster from assisting users in sharing copyrighted materials without the express permission of the owners (*A&M Records v. Napster*, 2000). The court based its injunction on a prediction (as opposed to a final judgment) that Napster would lose at trial because (a) users were deriving an unfair economic benefit from using Napster by saving the cost of the relevant recordings and (b) Napster use was decreasing CD sales among users (*Napster*, 2000 at 1017). Napster recently returned to the Web offering music downloads for sale after negotiating contract agreements with five major record labels and hundreds of independent labels (see <http://www.napster.com/about.us.html>).

Because the litigation never resulted in a final judgment on the issue of file sharing, music-sharing technologies and Web sites have continued to proliferate,<sup>18</sup> apparently cutting into industry profits by reducing CD sales (“Downloads Blamed,” 2002). In a controversial response, the Recording Industry Association of America recently started suing individuals, instead of music-sharing Web sites, for making music files available on these sites (“Recording Industry Begins Suing,” 2003; “RIAA Strikes Back,” 2003). These lawsuits have targeted not only adult users, but also the parents and grandparents of children users (RIAA Leaning on Kids’ Parents, 2003). Although such tactics have been passionately criticized, they seem to have succeeded, according to recent reports, in reducing illegal file sharing—at least temporarily (Borland, 2003).

<sup>17</sup> Compaq reportedly paid more than \$3 million to purchase the domain name [www.altavista.com](http://www.altavista.com) from the former owner of Alta Vista Technology after acquiring the company. Until Compaq purchased the domain name, it was forced to use the ungainly [www.altavista.digital.com](http://www.altavista.digital.com) (Kornblum, 1998).

<sup>18</sup> Indeed, <http://www.afternapster.com> lists 32 file-sharing Web sites, many of which improve on the P2P networking capabilities of Napster.

## Plagiarism

The availability of so much information on the Web has especially benefited students. First, students have access to far more written academic materials than ever before; the availability of academic writings on the Web is a welcome supplement to the offerings of school and public libraries. Second, student research efforts are no longer tied to the operating hours of libraries; students can access a wide range of materials at any time from wherever they happen to be with their computers. A student with a cellular modem does not even need to be near land-based telephone lines.

The Web also makes student plagiarism much more tempting, however. It not only provides easy online access to an abundance of quality writings, but also produces it in a form that is easy to plagiarize. Formerly, a plagiarist had to take the time to copy a text sentence by sentence onto a medium that could be turned in as her or his own; not infrequently, this involved hours of time typing or writing the text. Now a plagiarist can take someone else's text with a few keystrokes: one need do no more than highlight the relevant text, enter the appropriate keystrokes to copy and paste it into a word processing document, and unethically claim authorship in the work.

Student plagiarism also raises third-party ethical issues, because there are a number of Web sites offering original research papers for sale. One such Web site boasts: "Our 80 full-time researchers are available 24 hours a day, 7 days a week. Order now, and we will write your term paper within your specified deadline."<sup>19</sup> Although students must accept moral responsibility for initiating the sequence of acts that culminates in plagiarism, Web sites offering term papers for sale are not beyond ethical reproach because the operators must be aware there is a high likelihood that students will claim the work as their own.

Indeed, these sites seem to invite student plagiarism. After all, the only writing that is appropriately characterized as a "term paper" is writing that is being turned in as coursework; thus, advertising a piece of writing as a "term paper" is not unreasonably construed as a claim that the work is suitable to be turned in for a grade. If, as seems reasonable, knowingly aiding someone in committing an ethical violation is unethical, then offering term papers for sale in such a suggestive manner is also unethical.<sup>20</sup>

## INFORMATION PRIVACY

The networked world has had ethically significant impact on information privacy. Internet users have a variety of ways to produce communications that are anonymous in

principle or in effect, thereby empowering them to engage in more legitimate speech-related activities without fear of reprisal. Such anonymity also facilitates socially undesirable behavior, however: The lower the risk of being caught for criminal activity, the less effective the social consequences will be in functioning as a deterrent.<sup>21</sup> It is, for example, much easier to make anonymous threats over the Internet than by, say, telephone; whereas one can find a variety of ways to conceal one's identity in cyberspace from the comfort of one's own computer, it is virtually impossible for one to fully conceal one's identity by a telephone call made from one's home or cell phone.

## Legal Protection of Information Privacy

The various constitutions differ with respect to how much protection they provide to privacy. The Canadian Charter and U.S. Constitution both contain a number of provisions that can be construed as concerned with protecting privacy. Each contains clauses protecting freedom of speech, thought, conscience, and religious worship, as well as freedom from unreasonable searches and seizures.<sup>22</sup> Such protections are reasonably construed as being concerned to establish a zone or sphere of privacy in which a person's movements are protected against state intrusion.

Neither the Canadian Charter nor the U.S. Constitution, however, contains a provision that explicitly defines a privacy right in personal information or data. While the U.S. Supreme Court has grounded a general right of privacy in the "penumbras" of the various protections mentioned above, the constitutional right to privacy in the United States has most commonly been cited as a justification for invalidating laws that restrain reproductive freedom.<sup>23</sup> What protections there are in Canada and the United States for personal information are defined largely by statute and common law.

In contrast, a recent draft of the Charter of Fundamental Rights of the European Union provides explicit privacy protection for personal information. Article 8 provides that "(1) Everyone has a right to the protection of personal data concerning him or her [; and] (2) Such data must be processed fairly for specified purposes and on the basis of the consent of the person concerned or some other legitimate basis laid down by law. Everyone has the right of access to data which has been collected concerning him or her, and the right to have it rectified."

It is worth noting that European statutory law provides comprehensive protection of a person's interest in information privacy. The European Parliament and Council of October 24, 1995, have issued a general directive governing the processing of personal information.<sup>24</sup> Chapter 1, Article 1 provides that "Member states shall protect the

<sup>19</sup> Retrieved September 7, 2002, from <http://www.term-paper-time.com>. It should be noted that the site also states in ironically ungrammatical fashion: "We always urge them not to use the work as their own. Although the work we do is completely original and cannot be found anywhere else on the Web" (<http://www.term-paper-time.com/html/aboutus>).

<sup>20</sup> There are now a number of Web-based products that assist instructors in detecting student plagiarism. Such products can be found at [www.canexus.com/eve/index3.shtml](http://www.canexus.com/eve/index3.shtml), [www.plagiarism.com](http://www.plagiarism.com), and [www.powerresearcher.com](http://www.powerresearcher.com). Nevertheless, it should be noted that these products will assist only in detecting instances of cut-and-paste plagiarism; they will not help in detecting instances where students have purchased specially written papers.

<sup>21</sup> For an empirical and normative analysis of the positive and negative effects of the anonymizing capabilities of the Internet, see Kling, Lee, Teich, & Frankel, 1999; Teich, Frankel, Kling, & Lee, 1999.

<sup>22</sup> See the First, Third, Fourth, Fifth, and Ninth Amendments to the U.S. Constitution; see Sections 2, 7, 8, 9, 11, and 13 of the Canadian Charter of Rights and Freedoms.

<sup>23</sup> See, for example, *Griswold v. Connecticut*, 381 U.S. 479 (1965); and *Roe v. Wade*, 410 U.S. 113 (1973).

<sup>24</sup> The full text of the directive is available from [http://www.privacy.org/pi/intl\\_orgs/ec/final\\_EU\\_Data\\_Protection.html](http://www.privacy.org/pi/intl_orgs/ec/final_EU_Data_Protection.html).

fundamental rights and freedoms of natural persons, and in particular their right to privacy, with respect to the processing of personal data.”<sup>25</sup> Among other things, the directive limits the purposes for which personal information on an individual may be collected to “specified, explicit and legitimate purposes” and guarantees a right of access of the individual to such data.

In contrast, the U.S. approach to protecting information privacy has been somewhat uneven. On the one hand, pursuant to the Health Insurance Portability and Accountability Act (HIPAA; 1996), the U.S. Department of Health and Human Services (2000) promulgated the first federal standards for protecting the privacy of medical records. On the otherhand, the U.S. PATRIOT Act, which was enacted in response to the terrorist attacks of September 11, 2001,<sup>26</sup> expands the surveillance capacities of the government in a number of ways. Section 213, for example, allows the government to conduct a search without notifying the subject that a warrant has been executed if “the court finds reasonable cause to believe that providing immediate notification of the execution of the warrant may have an adverse result.” Similarly, Section 216 allows the government to monitor an individual’s movements on the Web upon a showing that “the information likely to be obtained . . . is relevant to an ongoing criminal investigation.” If the expansion of such investigative capacities arguably promotes citizens’ security interests, it does so at some (possibly justified) cost to privacy interests.

### Moral Legitimacy of Information Privacy Rights

Consequentialist theories justify privacy rights as necessary for a person’s happiness and well-being. James Rachels (1975) argued, for example, that protection of privacy rights is justified by our need to control the structure of our social relationships: “If we cannot control who has access to us, sometimes including and sometimes excluding various people, then we cannot control the patterns of behavior we need to adopt . . . or the kinds of relations with other people we will have.” Moreover, it is commonly believed that protection of privacy rights is justified by a concern to prevent the embarrassment or offense that would be caused to a person by disclosure of certain facts.

Deontological theories of privacy, in contrast, take the position that private facts about a person are “nobody else’s business,” regardless of what the consequences of disclosure might be. Privacy should be respected, on this line of reasoning, not just because it conduces to well-being, but also because persons are intrinsically valuable beings entitled to be treated as autonomous ends in themselves. The intrinsic value of each person, then, requires that certain facts be treated as private and subject to the

control of that person, even if those facts turn out to be extremely useful to other people.

Some theorists, however, caution that legal protection of privacy should be narrowly crafted to avoid unnecessarily restricting the free flow of information. Singleton (1998), for example, argued that the collection and dissemination of consumer information from business to business should not be restricted by privacy protections. Business dissemination of consumer information, on her view, is not morally distinguishable from ordinary gossip. Inasmuch as a legal ban on ordinary gossip would violate the right to free speech, so, too, would a ban on the dissemination of ordinary consumer information. Thus, she concludes, “[any] country that takes the freedom of information seriously cannot properly prohibit one business from communicating information about real events and real people to other businesses.”<sup>27</sup>

### Public and Private Information

The general claim that personal information ought to be protected by law does not, by itself, tell us much about how to determine what information about a person deserves legal privacy protection. For example, the altogether plausible consequentialist claim that protection of information is justified by a personal need to control the structure of various social relationships says little as to what information about a person ought to be protected by the law. For this reason, general justifications of privacy rights, such as those discussed in the last section, represent only a starting point in determining what content privacy law ought to have.

It is reasonable to think that whether a person ought to have a protected privacy right in a piece of information depends in part on the character of that information. Some facts about a person are generally accepted as private facts in which a person has a legitimate expectation of privacy. Because, for example, I am entitled to draw my drapes to prevent people from viewing what is going on in my home, the facts about what is going on my home are private—at least when the drapes are drawn<sup>28</sup> and my behavior is lawful. Thus, I have a legitimate expectation of privacy in aspects of my behavior that I may rightfully prevent people from viewing; these aspects of my behavior define private facts.

Some facts, however, should be regarded as private in virtue of their intimate character. It is almost universally accepted that certain physical functions, such as those involving the sexual and excretory organs, express private facts because of their felt intimate character. Information regarding a person’s physical and emotional health is also widely regarded as private information that he or she should be entitled to control; indeed, so intimately vital

<sup>25</sup> “Processing of personal data” includes “collection, recording, organization, storage, adaptation or alteration, retrieval, consultation, use, disclosure by transmission, dissemination or otherwise making available, alignment or combination, blocking, erasure or destruction.” Chapter 1, Article 2(b).

<sup>26</sup> The text of the USA PATRIOT Act is available from [http://www.eff.org/Privacy/Surveillance/Terrorism\\_militias/20011025\\_hr3162\\_usa\\_patriot\\_bill.html](http://www.eff.org/Privacy/Surveillance/Terrorism_militias/20011025_hr3162_usa_patriot_bill.html). For a critical evaluation of the implication of the act on information privacy, see [http://www.eff.org/Privacy/Surveillance/Terrorism\\_militias/20011031\\_eff\\_usa\\_patriot\\_analysis.html](http://www.eff.org/Privacy/Surveillance/Terrorism_militias/20011031_eff_usa_patriot_analysis.html).

<sup>27</sup> Nevertheless, it should be noted that the U.S. Financial Services Modernization Act (Pub. L. 106–102) requires financial institutions (a) to inform customers of their policies regarding the collection, use, and dissemination of customer information and (b) to honor customers’ requests not to have their information disseminated to third-party businesses. Although this, of course, does not amount to a ban on such practices, it significantly restricts what Singleton characterizes as the privacy equivalent of gossip.

<sup>28</sup> I can, of course, always voluntarily make private facts public by leaving my drapes open.

are these facts that medical professionals are charged with a legal duty of confidentiality.

Although many privacy issues concern private facts, others are concerned with information of a significantly different character. Some information contained in public records concerns matters that most individuals would regard as sensitive. For example, many people are reluctant to make their debt history readily available to anyone who happens to be curious about it—and this is especially so if that history includes a bankruptcy. Likewise, many people who have paid their debt for criminal offenses are reluctant to make their criminal records easily available out of a concern that such information would be used to discriminate against them.

The issue of whether a person has a moral right to control a particular piece of information that ought to be protected by the law thus depends on a variety of considerations. It will depend not only on broad theoretical arguments regarding the general justification of information privacy, but also on the character of the particular piece of information and how that information might be used by other persons. Such determinations present difficult issues of policy and ethics.

## Internet Issues

### Corporate Use of Personal Information

Many commercial firms collect information from visitors to their Web sites, which is stored in small data files called “cookies” and deposited on the visitors’ own computers. These files typically contain information—such as passwords, on-site searches, dates of previous visits, and site preferences—that can be used by the firm to customize the user’s experience when revisiting its site. For example, a bookselling Web site might store a list of previous searches on the user’s computer so it can be accessed by the site on subsequent visits to generate a list of books to recommend to the user. This enables the site to provide what it considers to be better service by tailoring the user’s Web environment to his or her preferences as expressed in previous visits to the site.

Although the use of cookies thus has a plausible business rationale, it raises ethical issues. Typically, cookies are transmitted from the user’s hard drive to the site and retransmitted (possibly with modifications) from the site to the user’s hard drive in a way that does not interrupt the user’s browsing experience. This means that, in many cases, the user’s hard drive—that is, his or her physical (as opposed to intellectual) property—is being modified without his or her consent. Although the legitimacy of intellectual property rights may be controversial, the legitimacy of personal property rights in physical objects is not (at least not in mainstream theorizing). The idea that someone else can, in essence, modify the user’s physical property without his or her consent raises, to begin with, ethical issues concerning the user’s property rights over the contents of his or her computer.

Moreover, some theorists worry that the use of cookies to keep information on the consumer raises privacy issues. As Spinello (2000, p. 111) puts the matter, “cookie technology is analogous to having someone follow you through the mall with a video camera.” In both cases, the

technology keeps information on where you have gone, what you have looked at, and what you have purchased. To the extent that one has a legitimate expectation that one’s movements in a public mall not be recorded, it can reasonably be argued that one also has a legitimate expectation that one’s movements in cyberspace not be recorded.

Although it is possible for users to set up their browsers to refuse cookies or to alert them whenever a site attempts to store a cookie, this can cause inconvenience to the user. Refusing all cookies restricts the user’s options in cyberspace because some Web sites cannot be viewed without accepting cookies. Setting a browser to ask before accepting cookies can result in frequent interruptions that radically change the quality of the browsing experience. Many users who restrict cookies find that the disutility associated with such frequent interruptions outweighs, at least in the short run, their privacy concerns and restore their browsers to the default setting that allows for unrestricted cookies.

There is thus a sense in which users who decline to configure their browsers to refuse cookies can be presumed to consent to cookies, but such consent is of questionable ethical significance. If the initial choice between A and B is not an ethically acceptable one, then the fact that a person voluntarily chooses A does not *logically imply* consent to A. For example, the fact that I voluntarily choose giving a robber my money if my only other choice is being shot does not entail that I have, in any ethically significant way, consented to give the robber my money. Consent is ethically significant only to the extent that it is rendered in an antecedent choice situation that is ethically acceptable. Thus, *if* the choice between accepting cookies and not being able to browse a Web site efficiently is not an ethically acceptable choice to impose unilaterally on a user, then the user’s choice to accept cookies does not entail ethically meaningful consent. For this reason, the issue of whether accepting cookies amounts to meaningful consent depends on the issue of whether the choice to accept cookies or accept an inferior browsing experience can permissibly be imposed on users.

More troubling to privacy advocates than the data kept by any one firm, however, is the possibility that it could be combined with the information of other firms to create a comprehensive file about a user. To continue Spinello’s analogy, this is analogous to having your movements in every store and mall recorded by a video camera and then keeping all those recordings in one central location that can be accessed by other persons. The more information about an individual that is centrally located and available for use by other persons and firms, the more likely it is to strike individuals as involving a breach of their privacy.

Notably, there are economic forces pushing in that direction. Businesses realize that consumer information is a valuable commodity and have evinced a growing willingness to sell it. Information about a consumer’s buying and browsing habits can be used to tailor advertisements and mailings to his or her particular tastes and preferences, arguably serving both the consumer and the firm. It is not surprising, then, that trading in information itself is becoming an increasingly profitable venture—not only for firms specializing in information commerce, but

also for ordinary firms specializing in other areas, and hence increases the likelihood that businesses will compile comprehensive files of personal information on individuals.<sup>29</sup>

### State Databases

State databases raise a different set of issues because they contain only information that is “public” in an ethically meaningful sense. In most cases, what is at issue is the disposition of information that the public has a right to collect through its official state representatives. Thus, the information contained in state databases, if there legitimately, is information to which the public has some sort of antecedent claim. This distinguishes privacy issues involving state information from privacy issues involving corporate use of information that is not public in this sense.

Although state information is a matter of public record, privacy advocates believe that governments should take strong steps to protect the privacy of driver’s license numbers, birthdates, official identification numbers (e.g., social security numbers), and other identifying information frequently used to access sensitive information about a person. This kind of information is uniquely subject to abuse: all that an identity thief in the United States, for example, needs to obtain credit cards in another person’s name is her social security number and date of birth. With those two pieces of information, an identity thief can inflict long-term damage to a person’s financial health and credit record.

The online dissemination of information already available to the public also raises privacy concerns. As noted earlier, privacy advocates are opposed to posting a person’s public records online on the ground that such information can be used for discriminatory purposes. The availability of criminal records on the Web, for example, increases the likelihood that employers will discriminate against persons with criminal histories who have paid their debts to society.<sup>30</sup> Indeed, even a person’s marital history can be used to discriminate against her or him. A landlord might refuse to rent to an older person who has never been married out of a suspicion that he or she might be gay. It is the possibility of such discrimination that, on this line of reasoning, requires granting a protected privacy interest in information that is admittedly public in one sense.

Such records have always been available to the public, but the risk of misuse increases with the ease with which these records can be obtained. As a general matter, most persons are not willing to incur the inconvenience of visiting a courthouse and asking for a person’s criminal or marital records. Because posting such information on the Web eliminates such inconvenience, it dramatically increases the likelihood that people will seek such information and, *a fortiori*, the likelihood that people will

abuse it. For this reason, privacy advocates oppose posting this sort of public information on the Web.

These concerns are exacerbated by the amount of information that might be made available online. When it comes to privacy, the qualitative difference between what is and isn’t ethical is sometimes a matter of quantity. As Spinello’s mall analogy suggests, many people believe it would violate a person’s legitimate interests in privacy to have his or her movements in a mall recorded and publicized. In relating this analogy to the issue of whether public records should be made available on the Web, it is crucial to emphasize that information about a person’s movements around a mall is, in some sense, “public” information that is freely available to whoever might happen to be there.

Such worries are further increased by the ease with which various records might be obtainable on the Web. Indeed, some companies sell software that purports to enable people to obtain, among other things, public records that include criminal history, debt history, real property acquisitions, and marital records.<sup>31</sup> The idea that so much sensitive information about an individual can be obtained with just a few keystrokes makes many people rightly uncomfortable because of its susceptibility to being misused. Accordingly, privacy advocates argue that the easy availability of such information poses a significant threat to an individual’s legitimate interests in information privacy.

### Encryption Programs and Public Policy

A user’s privacy can be violated online in yet another way. Ordinary means of communicating over the Internet are surprisingly insecure. E-mail messages are typically routed through many servers en route to their final destination. This raises the possibility that such messages could be intercepted and read by persons other than the intended recipient. For example, hackers or even system administrators could breach a user’s privacy rights by reading his or her confidential e-mail.

One means for preventing these violations of privacy is the use of encryption programs. The most popular encryption programs function by means of an electronic binary “key” that maps strings of linguistic symbols into unintelligible code that can be deciphered only by someone who has the key. Senders and recipients who share a viable key, then, can communicate privately by means of encrypted messages.

Although encryption programs vary in sophistication, some programs enable encryption that is impossible to decode without the appropriate key. Although programmers have enjoyed considerable success in breaking even more sophisticated encryption programs, a “strong encryption” program incorporating a 128-bit algorithm (i.e., 2<sup>128</sup> possible values) is, at least at this juncture, virtually unbreakable. For all practical purposes, then, an e-mail communication encrypted with a 128-bit algorithm cannot be deciphered and understood by anyone lacking the

<sup>29</sup> Online privacy services, such as Trust-E and BBB Online Privacy Program, rate various Web sites according to whether they agree to disclose their policies regarding the collection and dissemination of personal information by businesses. Trust-E is located at <http://www.truste.org/>; BBB Online is located at <http://www.bbbonline.org/>.

<sup>30</sup> Indeed, the ready availability of such information on the Web could increase the probability of recidivism. If employers unfairly refuse to hire persons with criminal records, they are likely to reoffend.

<sup>31</sup> One Web site boasts of a program, which it calls “the Internet’s best selling spy software,” that will allow persons to find “driver’s records, lawsuits, criminal records, asset identification, . . . tax liens, . . . and court documents.” <http://www.oddworldz.com/landoh34/learn.html?> Other Web sites offering spy software include <http://www.spy-patrol.com> and <http://www.spectorsoft.com>.

key. Such communications are, given existing technologies, perfectly secure.

Some U.S. legislators and citizens favor legislation that restricts the export of such sophisticated encryption programs employing 128-bit keys. There have been a number of proposals, ranging from outright bans to restrictions that allow the state some sort of access to the keys. For example, the so-called Clipper computer chip, which was originally intended for encrypting telephone communications, came encoded with an algorithm enabling law enforcement agencies to decode encrypted communications. One half of the decryption key was given to each of two law enforcement agencies, thus requiring that one obtain the consent of the other to decrypt communications.

Supporters of such regulations have stressed security interests. On this line of reasoning, the interest in, or right to, security is the most important interest or right in the moral hierarchy and hence trumps other interests and rights in the event of a direct conflict. Supporters argue that restrictions on strong encryption are morally legitimate because they are necessary to ensure that intelligence and law enforcement agencies have sufficient resources to protect the public's security interests against the serious threat posed by the activities of terrorists and international criminals.

Opponents have stressed both privacy and speech interests. Restrictions on encryption that allow the state access to keys chill the exercise of legitimate speech interests because, under such restrictions, citizens must worry about whether the state can eavesdrop on encrypted communications. Privacy and speech rights require, on this view, that citizens feel (and be) utterly free to communicate with selected individuals without having to worry about whether the state can listen in on their private communications. Moreover, many believe that the continuing expansion of e-commerce, and the economic growth it makes possible, also depends on consumers feeling their transactions are protected against governmental eavesdropping.

## COMPUTER SECURITY

The term "security" is something of a catch-all term. In its broadest use, the term connotes nothing more specific than "freedom from danger,"<sup>32</sup> but "danger" itself is a broad term appropriately used to characterize *any* serious threat to a morally significant interest. On this usage, then, any law that protects life, liberty, or property is fairly characterized as attempting to ensure a person's "security."

This portion of the chapter, however, is concerned only with legal and ethical issues as they arise in connection with *computer security*, "computer security" being construed to mean "freedom from unauthorized computer intrusions." Accordingly, this section is concerned with legal protections against unauthorized computer intrusions, the justification for such protection, and the challenge posed to such justifications by hackers.

<sup>32</sup> See, for example, Merriam-Webster Online Dictionary; available from <http://www.m-w.com/>.

## Legal Protection of Computer Security

Security from unauthorized computer intrusions has become a priority for lawmakers. Most, if not all, developed nations have laws prohibiting unauthorized computer intrusions. In the United States, for example, the Computer Crime and Fraud Act (18 U.S. Code Section 1030) authorizes fines and imprisonment of up to 20 years for, among other things, "knowingly caus[ing] the transmission of a program, information, code, or command, and as a result of such conduct, intentionally caus[ing] at least \$5,000 in] damage without authorization, to a protected computer." Similarly, Section 342.1 of the Canadian Consolidated Statutes and Regulations authorizes imprisonment for up to ten years for, among other things, the fraudulent and wrongful "intercept[ion], direct[] or indirect[], [of] any function of a computer system."

The European Union has also endorsed strong protections against unauthorized computer intrusions. Article 2 of the European Convention on Cybercrime requires member nations to "adopt such legislative and other measures as may be necessary to establish as criminal offences under its domestic law, when committed intentionally, the access to the whole or any part of a computer system without right."<sup>33</sup> The clear intent of Article 2 is that unauthorized intrusions be prohibited by law.

## Moral Legitimacy of Computer Security Rights

At first glance, laws prohibiting unauthorized computer intrusions seem easy to justify on ethical grounds. Although the more malicious intrusions involve serious ethical transgressions because of the harm they are intended to cause, all seem morally objectionable for two reasons. First, they appear to constitute an electronic form of trespass onto the *physical* property of another person. To obtain unauthorized entry into some other person's network or computer seems, from an ethical perspective, straightforwardly analogous to uninvited entry onto the real property of another person. Even if it turns out that there are no natural moral rights to intellectual property, it seems clear that persons have property rights in their computers and networks (which are, after all, material objects and not intellectual objects). Such trespass is widely regarded as morally wrong, regardless of whether it results in damage or harm, because it violates the property right of the owner to control the uses to which his or her property is put and hence to exclude other people from its use. Similarly, hacking into someone else's computer or network is wrong, regardless of whether it results in damage, because it violates the owner's property right to exclude others from using his or her computer or network equipment.

Second, such computer intrusions seem to violate the legitimate privacy rights of the victims. If it is true that persons have a property right in their physical hardware, then it is reasonable to think that they have privacy rights in the documents and files they store on that hardware. If I know that I may legitimately exclude you from appropriating my computer, then I have a reasonable expectation

<sup>33</sup> See <http://conventions.coe.int/Treaty/en/Reports/Html/185.htm>.

that I may exclude you from the files and documents that I store on my hard drive. On this second line of reasoning, hacking into someone else's hardware is wrong because it violates the legitimate privacy expectations of the owners. This is true regardless of whether owners actually store sensitive information on those machines: breaking into my home involves a violation of my privacy even if the perpetrator acquires no private information about me.

It is worth noting here that considerations having to do with the legitimacy of intellectual property rights do not play a general role in justifying laws prohibiting unauthorized computer intrusions. The reason for this is that unauthorized intrusions need not involve infringement on those interests protected by intellectual property law; there is nothing in the nature of such an intrusion that entails, say, the infringement of interests that are protected by a patent or by trademark law. In contrast, unauthorized computer intrusions seem, by definition, to impinge on someone's property rights in their computer hardware and hence on reasonable privacy expectations.

### Internet Issue: Hackers

There are a growing number of well-publicized incidents in which hackers obtain unauthorized entry into a firm's or state agency's servers. Some of these incidents involve comparatively innocuous exploration of a network's structure; in such cases, hackers look around and leave without altering the system. Others involve the commission of computer pranks; one such famous incident involved an insulting message left by hackers on the *New York Times* Web site (see, e.g., Nutall, 1998). Yet others involve the commission of cyberterrorism that threatens national security, as when a hacker breaks into a government network that stores classified material, or individual well-being, as when a hacker breaks into a corporate server and takes credit card and bank account numbers.<sup>34</sup>

Many hackers reject the claim that all unauthorized computer intrusions can legitimately be prohibited to protect moral interests in property and privacy, arguing that some hacking activity can be justified in terms of its social benefits, at least when it results in no damage or harm to innocent persons. These computer intrusions, they point out, contribute to increasing our technological knowledge in a number of ways. First, by gaining insight into the operations of existing networks, hackers develop a base of knowledge that can be used to improve those networks. Second, the very break-ins themselves call attention to security flaws that could be exploited by malicious hackers or, worse, terrorists. Thus, electronic trespass is distinguished, according to proponents, from other forms of trespass in that it inevitably conduces to public benefit.

Certain hacking activities have also been defended as a form of free expression in two ways. First, the permissibility of benign break-ins appears to be a consequence of the claim that "information wants to be free." If it is true, as an ethical matter, that all information should be free, then security measures designed to keep hackers out of networks are morally objectionable on the ground that they inhibit

the free flow of information.<sup>35</sup> Second, some writers have argued that benign break-ins can be defended as a form of protest or political activism ("hacktivism"). On this line of reasoning, such incidents express legitimate outrage over the increasing commercialization of the Web. Politically motivated hacking, according to these writers, should be permitted as long as it results in neither harm nor profit (Manion & Goodrum, 2000).

### E-VOTING

Central to the legitimacy of democratic governance is the right to vote. At the foundation of all democratic theories is the idea that every competent person has a right to autonomy that entitles her or him to participate actively in his or her own governance and hence has a right to participate in the political decision-making process. The right to participate protects a variety of activities other than voting; for example, it entitles competent persons to run for elected office. Its centerpiece is the right to vote in elections that determine either the content of the law or the persons who will serve as legislators or judges.

The traditional mechanism for exercising the right to vote is the paper ballot. Up until now, the vast majority of votes have been cast on paper or punch-card ballots; citizens indicate the candidate of their choice by making a physical mark of some kind on the ballot, either by writing a mark of some kind or punching a hole next to the appropriate candidate's name. Although these ballots have usually been counted by hand, a process that is highly vulnerable to abuse and error, election precincts in many countries are now using new automated technologies for counting votes.

There are a variety of new and developing technologies that fall under the rubric of e-voting. A number of companies have developed technologies enabling citizens to vote merely by touching a computer screen that is located at their precincts; votes can then be counted at the precinct by a local automated mechanism or can be transmitted via the Internet to a central location where votes from different precincts can be counted by a machine. Many proponents of e-voting envision a day when every voter can vote via his or her personal computer from the convenience of his or her own home.

These new and developing technologies implicate the right to vote in a variety of ethically significant ways. This section explores the various social and ethical issues that arise in connection with the application of these information technologies to the democratic process.

### Legal Protection of Voting

Because the right to vote is the foundation of democratic governance, it is not surprising that democratic nations typically afford strong legal protection to the right to vote. Article I of the U.S. Constitution provides that federal legislators be democratically elected by citizens according to certain prescribed procedures (which may be defined in part by the states).<sup>36</sup> Similarly, Section 3 of the

<sup>34</sup> Some people distinguish "hacking" from "cracking." Cracking, unlike hacking, involves a malicious purpose; the intent is to gain entry to a network to cause harm or damage. In contrast, hacking is motivated primarily by curiosity.

<sup>35</sup> For a critical discussion of this claim, see Spafford (1992).

<sup>36</sup> The Fifteenth and Nineteenth Amendments prohibit restricting any person's right to vote on grounds having to do with race, color, gender, or previous servitude.

Canadian Charter provides that “Every citizen of Canada has the right to vote in an election of members of the House of Commons or of a legislative assembly and to be qualified for membership therein.” Finally, Article 39 of the European Charter of Fundamental Rights states that “Every citizen of the Union has the right to vote and to stand as a candidate at election to the European Parliament.”

The centrality of the right to vote is underscored by the fact that the justification for other fundamental rights is frequently couched in terms of the contribution they make toward democratic governance. The legal right to free speech, which is protected in North America and Europe, is frequently justified in terms of its contribution toward producing an informed and responsible electorate. Without free speech, on this line of reasoning, citizens would lack information that is essential to being able to exercise the right to vote in an ethically meaningful way.

### **Moral Legitimacy of E-Voting**

The legitimacy of adopting e-voting technologies will largely depend on a number of factors. For starters, the legitimacy of such technologies depends on how accurate and how secure they are; the less accurate or secure a technology is, the less justified a state would be in adopting it. Further, the legitimacy of such technologies depends upon their effects on the voting behaviors of citizens. To the extent that adopting such technologies would result in a decrease in significant turnout among some important segment of the population, such technologies “chill” the exercise of the right to vote among members of the affected segment. For example, excessive polling taxes are illegitimate because they make it harder for less affluent citizens to exercise that right and thus violate their rights to vote. This section surveys some of the arguments that have been made on both sides of the issue.

### **Ethical Arguments for E-Voting**

**Accuracy of Technologies.** Arguments for the adoption of the new E-voting technologies usually focus on the effects of such technologies on various aspects of the election process. For example, newer technologies make it possible to determine the results of an election more quickly than is possible using hand counting or the older automated technologies, which require the physical transportation of ballots from voting box to the counting technology. Accordingly, these newer technologies dramatically reduce the waiting period associated with traditional technologies.

Proponents of e-voting technologies also argue that fully automating the voting process will improve the accuracy of the counting process by eliminating human judgment. Proponents point to the problems that arose in connection with counting ballots cast in Florida during the 2000 U.S. presidential election. Fallible and potentially biased human beings had to sort through a large number of ambiguously marked ballots and attempt to discern the voter’s intent in marking the ballot. Fully automating the process takes elections out of the hands of human beings, replacing them with a much faster and more reliable technology.

### **Effects on Voter Turnout**

These features of the new technologies, according to proponents, will help to improve turnout for elections by restoring voter confidence in the electoral system. For example, the problems with the 2000 presidential election have led to continuing debate about the legitimacy of the Bush presidency and weakened confidence among citizens in the U.S. electoral process, which presumably operates to reduce voter turnout. Because the new technologies are more securely insulated from human judgment—and hence from human fallibility and bias—citizens are more likely to trust the results and hence to participate in elections.

Proponents argue that future Web-based technologies will boost turnout by making it easier than ever for citizens to express their political views and preferences through the voting process. Citizens who own a personal computer with an Internet connection is, other things being equal, more likely to vote if they can reliably vote using the personal computer from the privacy of their home than if they can vote only by traditional means (which, it should be noted, include absentee ballots). It is true, of course, that not every citizen owns a personal computer, but this, proponents insist, is an argument for retaining other voting technologies and not an argument against adopting Web-based voting technologies as they are developed. As long as such voters are not unfairly disadvantaged by the adoption of newer technologies, it is ethically permissible and socially desirable to adopt these technologies.

Web-based technologies, on this line of reasoning, are especially likely to boost turnout among citizens who have disabilities that severely limit their ability to travel away from home. Appropriately adapted Web-based voting technologies ensure that severely disabled citizens (who own personal computers and have an Internet connection) can exercise their right to vote with far less inconvenience than is involved for them in using the traditional voting technologies.

To appreciate fully the force of these arguments, it is important to realize that the legitimacy of an election requires that all eligible citizens be in a position to meaningfully exercise their right to vote without incurring significant costs. It is clear, for example, that an election system requiring an expensive fee to vote is illegitimate because less affluent voters will be far less likely to vote. In consequence, elected officials are considerably less likely to take their wishes and needs into account in the lawmaking process. If the point of democracy is to ensure that all constituencies are fairly represented, then voting fees (or polling taxes) defeat democracy’s very point.

Putting citizens in a position to be able to participate meaningfully in elections presumably requires not only that they receive sufficient education to minimally understand the issues, positions, and candidates, but also that elections be staged in a way that enables each citizen to exercise his or her right to vote without the sort of inconvenience that is likely to deter his or her from voting. Although it may sometimes be accurate to construe a citizen’s failure to vote as indifference on his or her part, this is not necessarily true: it is reasonable to hypothesize that many persons who would like to vote are not able to do

so because of the costs or inconveniences associated with traditional voting technologies.

### **Ethical Arguments Against E-Voting**

**Discriminatory Effects on Poor.** There are a number of arguments against the adoption of e-voting technologies. Some opponents have grounded arguments against the adoption of technologies that would allow Internet-based voting in considerations having to do with economic justice. On this line of reasoning, the adoption of such technologies discriminates against people who cannot afford a personal computer and broadband access. Although the adoption of such technologies is likely to increase turnout among wealthier (and hence technologically savvy) voters, they are also likely to have the effect of reducing turnout among less affluent persons. Even if less affluent persons can still vote by traditional means or by using computers in public schools and libraries, the use of such means could be stigmatized (in much the same way, for example, that inhabitants of public housing projects are stigmatized), thereby reducing voter turnout among less affluent voters who do not have a personal computer. As a matter of economic justice, such discrimination is unfair.

Such disproportionate effects on turnout are objectionable from the standpoint of democratic principles as well. In theory (if not in practice), full voter turnout ensures that the interests of all persons will be adequately represented in the lawmaking process and hence that the content of the law will protect and advance those interests; a lack of participation, then, by any theoretically significant constituency makes it far less likely that the content of the law will adequately protect the interests of that constituency. If the adoption of Internet-based e-voting technologies is likely to increase turnout among wealthy voters but decrease turnout among less affluent voters, then the adoption of such technologies is objectionable on democratic principles as well as on principles of economic justice. By diminishing turnout among the poor, the adoption of these technologies would operate to ensure that their interests are not fairly represented in the lawmaking process.

### **Unreliability of Existing E-Voting Technologies**

Although e-voting proponents believe that automating voting procedures is likely to increase the accuracy of results, opponents can point to a number of instances in which existing e-voting technologies produced inaccurate results.<sup>37</sup> In a 2002 election primary in Clay County, Kansas, for example, an automated counting technology falsely indicated that a candidate for county commissioner had lost by a slim margin of 4 percentage points, when a hand recount showed that he had actually won by a landslide with 76% of the votes (Harris, 2004; "Mayo Won by a Landslide," 2002). A "bad chip" was apparently to blame for a mistaken win by two Republican candidates for county commissioner in Scurry County, Texas; a recount using a new chip indicated that the Democratic candidates had won by a large margin ("Ballot glitches," 1998; Harris, 2004).

Mistaken election results are ethically problematic for at least two reasons. First, undiscovered mistakes can result in a losing candidate's holding a legislative office to which he or she was not elected and hence not entitled to hold. In such instances, the official's acts are politically illegitimate and not, strictly speaking, binding as a matter of law, but are nonetheless treated as being legally binding, something that is especially problematic when the acts involve paradigmatic lawmaking activities. Second, the proliferation of such errors is likely to diminish the confidence of citizens in the voting system procedures and is hence likely to reduce voter turnout in elections.

### **Security Concerns**

Perhaps the most significant concern with adopting Internet-based e-voting technologies has to do with the insecurity of networks on the Internet. Hackers are continually becoming more sophisticated and better able to find gaps in even the most secure Internet-based systems. Not only can the best hackers find ways to circumvent the most sophisticated security technologies, they are also becoming better at minimizing the likelihood that they will be detected during an intrusion and subsequently apprehended. It is probably true that it is not possible to break into a system without leaving some physical trace (or record) of the intrusion, but it is also true that a more sophisticated hacker can take steps to diminish the number of traces he or she leaves.

For this reason, it is reasonable to worry about the security of Internet-based e-voting technologies. One concern is, of course, the worst-case scenario in which a highly sophisticated hacker changes the results of an election without ever being detected. Another concern is that the mere possibility of such a scenario is enough to significantly diminish the electorate's confidence in election results and the integrity of the voting process. The potential consequences of such a decrease in confidence range from widespread suspicion among citizens about closely contested elections to a dramatic reduction in voter turnout.

Although many reasonable persons believe that, at this point, the security problems outweigh the potential benefits of Internet-based e-voting technologies, it is important to keep in mind that this need not always be the case. The magnitude of the relevant security risks of e-voting is a function of both the state of the security technologies intended to protect the process and the state of the technologies available to hackers. As the states of both these technologies evolve over time, we should expect that an assessment of the relevant risks and benefits will vary over time. At any given time, then, an assessment of the risks and benefits will require an empirical analysis of the states of all the relevant technologies. This leaves open the possibility that if it is true, as opponents believe, that Internet-based e-voting technologies are not yet secure enough, they might someday be.

## **CONCLUSION**

Although the advent of the Internet age has empowered ordinary citizens in novel ways, it has also created a number of equally novel ethical and social problems. Indeed, as is generally true, the very capabilities that increase a

<sup>37</sup> For a detailed account of many of these incidents involving elections in the United States, see chapter 2 of Harris (2004).

person's ability to promote public and private interests also increase his or her ability to harm other people. To the extent that, for example, the Internet enables the ordinary citizen to reach a worldwide audience, it dramatically improves his or her ability to propagate unethical and dangerous ideas.

We should expect that the social and ethical issues of the Internet are no less complicated than the remarkable technology that engenders them. For every argument that invokes traditional ethical and social values in defending a position about online behavior, there is a countervailing argument that resists the application of these values to a technology that seems so radically different from what has preceded it. The debates on these fascinating issues will fill the pages of academic and popular publications for the foreseeable future.

## GLOSSARY

**Consequentialism** The class of ethical theories that determine the moral goodness or badness of an action entirely in terms of its consequences.

**Cookies** Small files deposited by a Web site on a user's computer for the purpose of enabling the Web site to track the user's preferences.

**Copyright** Legal device that grants an exclusive right to the holder to reproduce and distribute fixed, original expression.

**Cyberterrorism** Hacking activity that attempts to harm innocent persons and thereby create a general sense of fear or terror among the general population for the purpose of achieving a political agenda.

**Deontologism** Ethical theories that take the position that the moral goodness or badness of some actions is determined, not by their consequences, but by their intrinsic features.

**Domain Names** Natural language phrase (e.g., [www.sportinggoods.com](http://www.sportinggoods.com)) that is associated with a Web site's Internet protocol address.

**Encryption** The translation of data (including that transmitted in e-mail messages) into code that cannot be deciphered and read by unintended recipients.

**File Transfer Protocol (FTP)** A device that allows a user to transfer files from his or her personal computer to a central network server and conversely.

**Filters** Programs designed to prevent a user from accessing Web sites with content that is deemed inappropriate.

**Hackers** Persons who attempt to gain unauthorized entry to network servers or other computers. Hacking is usually distinguished from "cracking" in that the latter, unlike hacking activity, is intended to cause harm to innocent persons.

**Hactivism** Hacking activity motivated by a desire to express a political view or agenda. For example, a hactivist might target a corporate Web site as a means of protesting the increasingly commercial character of the Web.

**Intellectual Property** Mental and abstract entities considered as property. Intellectual property includes music, expression of ideas, and designs.

**MP3 Files** Digital files using a format that permits the compression of nearly perfect digital reproductions of

sound recordings into small files that can efficiently be transmitted from one user to another.

**Patent** Legal device that grants an inventor monopoly power over the design of his or her invention.

**Peer-to-Peer (P2P) File Sharing** A file-sharing device that allows Web users to directly access files that are stored on the computers of other Web users.

**Spam** E-mail sent indiscriminately without the recipient's consent or against the recipient's wishes.

**Trademark** Legal device that grants a firm an exclusive right to use a mark that distinguishes its goods and services from those of other firms.

**Utilitarianism** A consequentialist moral theory that holds that the goodness or badness of an action is determined entirely by its consequences on well-being, happiness, the number of preferences satisfied, or pleasure in the community.

## INTRODUCTION

The loose structure of the Internet dictates that it is somewhat difficult to determine a user's true identity; correspondingly, a weak degree of anonymity is easily available. Complete anonymity, or a high level of assurance of the identity of another user, both require work. Technical solutions exist to help with both problems. U.S. constitutional law and common law precedents show a high degree of reverence for anonymous discourse, which has played a significant role in the British and U.S. political systems. The Supreme Court has repeatedly referred to this history in affirming, in recent years, the right of U.S. citizens to speak anonymously on political and social matters. Cases involving anonymity on the Internet began with the passage of a Georgia law banning anonymous email. Most of the case law since then has involved public companies suing anonymous individuals who posted messages accusing the companies of stock fraud or poor management. These court decisions all have held that the same protections apply to anonymity online as apply to the authors of pamphlets, people obtaining signatures on campaign petitions, or distributing religious material door to door. Nonetheless, there is a vocal minority of law professors and other commentators calling for a change in the Internet's architecture to require that a sender's identity be associated with his message.

The Internet's architecture is very supportive of anonymous discourse—and, correspondingly, very unconcerned about verifying the identity of any communicator. Optimized for ease of messaging and widespread, rapid distribution, the Internet does not care very much about the source of a message. Originally based on an easygoing philosophy of trust not enforced by the architecture, the early Internet community relied highly on people being, at least approximately, who they said they were.

Of course, from the earliest years of the Internet community, tricksters, con artists and criminals delighted in exploiting the system's open architecture. In 1985, Joan, mute and crippled as a result of a terrible automobile accident, built a worldwide community of supporters online, whose sympathy turned to venom and rage when Joan was revealed to be Alex, a male psychiatrist who was not crippled (Rheingold, 1993). Such spectacles are still

reenacted routinely today; it is a truism that anyone flirting with strangers in e-mail or chat should be (but often is not) highly suspicious as to whether any correspondent is actually the gender that the e-mail name indicates.

Sociologists and other social commentators have seen in the ambiguities of Internet identity a healthy opportunity for the human persona to develop, exploring alternative pathways and even genders in an atmosphere of healthy play. Virtual identities, says Massachusetts Institute of Technology (MIT) psychologist Sherry Turkle (1994), are "evocative objects for thinking about the self. . . experiences in virtual space" that compel us "to pay greater attention to what [we] take for granted in the real." The flip side, of course, is the huge mistaken investment of time, energy, friendship, and even money others may make based on the false representations of an alternate, "playful" identity.

Although it was never safe in e-mail to assume that anyone was exactly who they said they were, in the first years of Internet communication you could at least get a significant level of comfort from an e-mail address. "Tom@mit.edu" was at least *probably* involved with MIT in some capacity, as a student, professor, staff member, or alumnus.

Today such assumptions are completely untenable. With viruses and spammers routinely spoofing the e-mail addresses of unwitting third parties, Internet users, to protect themselves effectively, should assume that any message, regardless of who it appears to be from, is unwanted or actively dangerous. The offline equivalent would be if you needed to call the bomb squad to investigate every time you received an envelope from anyone—friend or stranger—in the mail.

## MECHANICS OF ANONYMITY AND IDENTITY ON THE NET

For e-mail users, the Web provides a significant level of functional anonymity at the entry level. Anyone can open an account with a mass service such as Hotmail, using any available name on that system. Suppose you receive an e-mail from someone calling himself brickchurch@hotmail.com. For starters, you do not know whether this is actually

a person's name or a variation (maybe Frank Church whose nickname is Brick?) or a hobbyist (who travels the world photographing brick churches everywhere) or someone who picked a name out of thin air. The Hotmail architecture is easygoing and does not care whether the e-mail address you pick has anything to do with your name.

Loose identity is true of most systems that are geared toward, or encourage, use for personal, nonbusiness purposes. These systems, however, fall into two major categories: Internet service providers (ISPs) that are relaxed about *apparent identity* but have stricter rules tracking *real identity* and nonISPs (such as Hotmail) that don't care about either.

If you receive e-mail from YouGoGirl@aol.com, you may have no idea who this is, but the chances are good that AOL knows (they have to bill her [or his?] credit card every month for the use of the system). Because Hotmail, as a free service at the entry level, has little concern for user identity, it will rarely (if ever) have verified knowledge about the identity of a nonpaying user. However, unless he takes measures to obtain a higher degree of anonymity (discussed later), the user may still leave some personal information on the Hotmail site, such as his originating IP address.

Another class of users with stronger identity rules are large corporations. Most Fortune 500 companies have internal company rules mandating the format of an e-mail address, along the lines of `firstname.lastname@fortunecompany.com`. The Internet is oblivious to these rules, however, and therefore, the most this kind of self-policing does these days is to tell you that, *if the message actually came from fortunecompany.com*, it is likely from an employee with the name given in the e-mail header. These days, however, the message could just as easily be a virus or spam with a spoofed header, and not actually have passed anywhere near the fortunecompany.com mail server.

Entry-level anonymity is not highly resistant to attempts to determine the user's real identity. If Tracey Smith, who is YouGoGirl@aol.com, opened the brickchurch@hotmail.com account and always accesses it from that address, law enforcement authorities looking into the use of the Hotmail account for a confidence scheme will not have too much trouble tracing Tracey. If Tracey only accessed the Hotmail account from Internet cafes, where she (or he) paid cash or used a stolen credit card, determining the real identity of brickchurch@hotmail.com may be difficult or impossible.

When it comes to maintaining anonymity, surfing the Web presents a different problem than the mere sending of e-mail. An Internet user visiting a Web site leaves behind a record of the user's IP address. A user whose ISP assigns a permanent IP address may change his or her proper name in the header. The permanent IP address will follow him everywhere he goes.

Some ISPs do not assign users a permanent IP but give the user one of a collection of available IP addresses just as he or she sets out from the home network to surf the Internet. In this case, the trail again becomes much more difficult to follow; the same IP address may have been used by Tracey Smith at 1 p.m., John Adams at 3, and Jane Goodloe at 5 p.m., for example.

## HOW DO WE KNOW WHO ANYONE IS ON THE NET?

It is difficult to know who anyone is on the Net. If you receive e-mail from `britney_spears@hotmail.com`, chances are good that you haven't just heard from the singer. If your correspondent, a stranger, claims to be a mining expert, or a professor of engineering, or a person looking for a long-term romantic relationship, how do you know what his or her bona fides are?

Little in the nature of e-mail or in the architecture of the Internet helps us in this attempt. Most of us probably use the same instincts to make these determinations that we do offline. Does a stranger claiming to be an engineering professor look like the real thing (insofar as we have an image of the real thing with which to compare him in our minds)? Does he or she sound knowledgeable about the field? Does your correspondent remember, from conversation to conversation, the information he or she relayed previously, such as education, state of birth, the names of siblings? Are there unexplained gaps in the information? Does the correspondent have anything to gain in a relationship or transaction with you by claiming to be something he or she is not? Are there revealing body language cues, such as an unusual nervousness or eagerness when certain topics come up?

In an e-mail exchange we can evaluate much of the same information, although we are deprived of important visual cues. This lack is offset to some extent, however, by the fact that the data is all there in writing. We are not challenged by possible inaccuracies of memory ("Didn't she say she was from Ohio last time?")

In an age of spam and viruses, the majority of the e-mail that many of us receive is automatically assigned to a "useless or dangerous" category and deleted. Several categories of correspondents send mail that is important, or potentially important, to us. The first, and the easiest to verify the identity of, are our offline friends and relatives. Years ago, your brother told you his new e-mail address was `brickchurch@hotmail.com` (the name he acquired playing football in high school). You are comfortable that whenever you send e-mail to, or receive e-mail from, that address, you are communicating with your brother.

Every once in a while, though, a virus spoofs your brother's e-mail address, and you get a communication apparently from him with a tagline such as, "Is that you naked in the picture!!!!?????" and an attachment. You immediately know this is a virus and did not originate from Brick because Brick wouldn't ask you a question like this, eschews the use of exclamation points and multiple question marks, and never sends you attachments.

A much higher level of difficulty arises when we receive unsolicited e-mail. The famous Nigerian scams (so called because most originate from that country) involve an e-mail that purports to be from the financial manager, wife, or son of a dead African politician or businessman. He or she has 10 or 15 million dollars in an account that the corrupt authorities of his country will steal if it is not expeditiously transferred out of the country. Will you help, in return for a fat commission? At some point along the way, you will be asked to put up some money of your own, as an

earnest of your good faith. That money will, of course, disappear, and you will never receive the multimillion-dollar transfer. These con artists succeed if you allow your greed to overcome your suspicion. Each of these mails relies on a plausible-sounding story and e-mail address but probably would not resist much offline investigation. (Of course, the effect is diluted when you find yourself receiving 10 or 15 similar messages a day—what are the odds that the grieving relatives and business associates of 10 different African public figures would all be contacting you?)

The Internet does not only routinely confound expectations as to identity; its open architecture also startles people who think they have achieved anonymity. For example, an author who had written a progressive political essay published on the Web recently received an aggressive, insulting unsigned e-mail. A Google search disclosed that the correspondent had a minimal Internet footprint—only five or six messages left on a Web site devoted to guns.

Based on the original e-mail and this extremely minimal footprint, it was possible to develop a significant profile of the writer. His ISP was located in Colorado, and his e-mail address was the name of the adjacent town to the one where his ISP was based. His messages on the Web site were signed with a nickname (which probably referred to a physical feature of the individual) and disclosed that he was a military veteran who had served in a war, probably Vietnam, that he had been a sniper, and that he owned a particular kind of sniper rifle, favored a particular bullet, and prepared his own black powder for the rifle. All of this information—which the writer would most likely have been shocked to discover was so easy to gather in a few minutes of searching—would probably be sufficient to identify this individual in the real world.

## TECHNICAL SOLUTIONS TO IDENTITY AND ANONYMITY

Approaches to verifying identity on the Internet fall into three basic categories (Kent & Millett, 2003): the user offers proof of something the user *knows* (such as a password or his mother's maiden name), something the user *is* (a fingerprint or signature), or something he or she *has* (a smart card or digital token).

The venerable password has, since the Internet's inception, been the entry-level guarantee that a user is who he or she claims to be. The inconvenience of remembering numerous passwords for different systems, plus the ease of guessing, reverse-engineering, or simply stealing passwords has always made this approach a necessary but insufficient condition for identity verification.

Digital signatures and public encryption keys allow the recipient to feel a high level of security that a message comes from the same person who communicated with his previously using that signature or key. That's all these measures ensure, however: They communicate nothing about the original bona fides of the sender, which the recipient must have obtained by other means. If the sender is your brother, "Brick" Church, then a key or a signature helps to assure you that your brother really sent the most

recent message. If a Nigerian con artist is using strong encryption to communicate with you, the key will only assure you that you are dealing with the same con artist as before. In the last analysis, digital assurances of identity must still be backed up by instinct and offline inquiries or by reputation systems such as credit reports or the evaluation system used by Ebay.

Smart cards and digital tokens represent assets that can be stolen and therefore are often used in conjunction with passwords or other means of verifying identity. Biometric approaches using fingerprints or retinal patterns are expensive, require sophisticated hardware, and are somewhat inconsistent with the Internet's governing philosophy of speed and ease of communication.

Because of the serious problem of fraud in online transactions, the e-commerce industry has developed a variety of solutions to make transactions more secure, using SSL (secure sockets layer), Web site authentication certificates, and ways of verifying the identity of customers via passwords, signatures, specialized information or tokens. The reputation solution pioneered by Ebay, of allowing the users of a commerce system to evaluate each other, provides a high (but not infallible) level of confidence that a particular seller will not cheat you because he has dealt fairly with others. In a case currently being prosecuted by the Justice Department, however, a man sold \$150,000 worth of electronics at very low prices, acquiring a host of favorable evaluations. He then leveraged his new reputation to sell another \$700,000 of equipment that he never delivered.

Solutions to anonymity have taken two basic forms, one for e-mail and the other for Web surfing. In the 1990s, there were a number of anonymous remailers, Web sites from which you could send a message that would reach the recipient stripped of any identifying information whatever. The flaw in the design was that the Web site itself was a single point of vulnerability on which law enforcement and disturbed e-mail recipients could exert pressure. Virtually all of these remailers, led by the famous anon.penet.fi, had shut down by the end of the decade, after being raided by police, subpoenaed, or sued. They have been replaced by a new generation of remailers, such as dizum.com, which, used together with encryption software and front-end software such as Quicksilver and Mixmaster, all but eliminate the traceability of a message. These front-end anonymity solutions code your message in multiple layers of encryption, then send them through a series of remailers.

Messages are multiply encrypted and formatted so as to appear identical to other Mixmaster messages. Messages are sent through chains of remailers. Each remailer removes one layer of encryption, and forwards the message. When the final remailer delivers the decrypted message to the recipient, it is impossible to find out where it came from, even if part of the remailers in the chain are dishonest. (Dizum.com Remailer)

Although the new generation of remailers has introduced a level of complexity that their predecessors lacked, somewhere in the chain there is still presumably at

least one remailer that knows the identity of the sender—and that is therefore vulnerable to law enforcement pressure.

There are many solutions, commercial and free, to the problem of anonymous surfing. Sites such as The Anonymizer ([www.anonymizer.com](http://www.anonymizer.com)) present you with a form, or browser-within-a-browser, in which you enter the URL (uniform resource locator) of the site you wish to visit anonymously. The site comes up on your screen, but the Internet protocol (IP) address left in its log is that of the intermediary site, not yours. Anonymity-supporting sites such as these are routinely blocked by software filters (“censorware”) because they represent an easy method of bypassing the filter’s list of banned sites.

One ISP recently offered a well-received anonymous DSL (digital subscriber line) service. The user is assigned a dynamic IP address, of which the company keeps no record. A spokesman for the ISP is quoted as saying, “[we] cannot supply information we do not possess” (Bange-man, 2004). A Google search on “Internet Anonymity” produces sponsored links (ads) for numerous other commercial sites that promise anonymous surfing via an untraceable IP address.

A 2001 (Greene, 2001) article on “do it yourself anonymity,” widely circulated on the Internet, suggests setting up an account using wholly fictitious information with a free ISP such as NetZero, masking caller ID on your home phone, and then identifying a Socks proxy server in a remote country through which you can send e-mail and surf. With the Socks software, the originating IP address on your e-mail, or recorded by the sites you visit, should be that of the proxy. Socks servers also do not keep cached copies of the sites you visit. For extra protection, the article recommends accessing the Anonymizer with all these measures in place.

Free software available from a German university project rather inauspiciously named JAP uses a variation on dynamic IP (JAP Project Web site: [http://anon.inf.tu-dresden.de/index\\_en.html](http://anon.inf.tu-dresden.de/index_en.html)). All users share a single IP address, so it is impossible to determine which user accessed which site. Users access the service via an encrypted link, shared with other users, which passes through a series of intermediary sites. The project’s coordinators warn, however, that “this version does not yet achieve the full security and anonymity that we strive for. It does not protect you against an adversary who has the capability to observe all communication links on the Internet.”

As with e-mail, anonymous surfing is available through effective “low-tech” solutions, such as paying cash to surf in an Internet café.

## A Reverence for Anonymity in U.S. Political Tradition

Anonymity in Internet discourse is founded in an old and honorable tradition of anonymous political communication. As such, online anonymity is entitled to the full protection of the First Amendment.

Anonymous speech on controversial political and moral topics was a common phenomenon in 18th- and 19th-century Great Britain and in pre-Revolutionary America. In 1720, two British men, John Trenchard and

Thomas Gordon, published a highly influential series of political essays under the name Cato. Their work was reprinted by Benjamin Franklin and cited by John Adams and Thomas Jefferson.

The famous John Peter Zenger trial, in New York in 1735, involved Zenger’s prosecution for publishing pseudonymous essays attacking the British-appointed governor of the colony. (Zenger had also republished several of Cato’s essays.) Zenger’s defense attorney asked the jury to protect the right of “exposing and opposing arbitrary power. . . . by speaking and writing truth.” Zenger’s subsequent acquittal helped to end the arbitrary prosecutions of American publishers and writers under British common law.

Thomas Paine’s *Common Sense*, which was the touchstone for intense American feeling in support of separation from Great Britain, was first published under the pseudonym “An Englishman.” The *Federalist Papers*, in which Alexander Hamilton, John Jay and James Madison laid out, and defended, the structure of the proposed U.S. Constitution, was jointly published by the three men under the single name, Publius. The Anti-Federalists replied with essays attributed to “Candidus,” another “Cato,” and “A Federal Farmer.”

The inception of the American republic did not end the need for anonymity to protect the circulation of controversial speech. Before the Civil War, many abolitionists, aware of the unpopularity of their views and the possibility of severe physical danger to themselves, wrote under names such as “A Colored Baltimorean,” “Communipaw,” “Magawisca,” and “Zillah.”

When members of political administrations wish to float new ideas without triggering the assumption that they are speaking officially on behalf of the administration—or losing their jobs because the boss disagrees—they have frequently utilized anonymity in U.S. political life. In other cases, an elected politician may wish to send out a trial balloon without being held accountable for it. In 1947, George Kennan, an official in the Truman administration, published an essay titled “The Sources of Soviet Power.” This work, which became the blueprint for the Cold War strategy of containment, was signed “X.”

During the McCarthy era, blacklisted screenwriters frequently continued to work under pseudonyms. In 199\_, the best-selling novel *Primary Colors* was published attributable only to Anonymous, although the author was shortly after revealed to be journalist Joe Klein. In 2004, the nonfiction work *Imperial Hubris* was published pseudonymously by a CIA case officer, critiquing U.S. intelligence gathering activities. Today hardly a day goes by without an article in the *New York Times*, *Washington Post*, *Chicago Tribune*, or other pillar of the mainstream press attributing a significant assertion to “a senior State Department official” or “White House staffer” (Wallace, 1994).

## THE SUPREME COURT SPEAKS

The United States Supreme Court has repeatedly affirmed that anonymous communication is protected by the First Amendment. Starting in the 1950s, the Court held that

the National Association for the Advancement of Colored People could keep its membership list secret from state investigators. In the following decade, reviewing a remarkable history of state harassment and dirty tricks directed at the Socialist Workers' Party, the Court exempted it from an Ohio requirement that it disclose its list of contributors. In *Talley v. California*, the Court invalidated a Los Angeles ordinance prohibiting distribution of anonymous leaflets. It held that "Anonymous pamphlets, leaflets, brochures and even books have played an important role in the progress of mankind."

In the 1995 case of *McIntyre v. Ohio Elections Commission*, Margaret McIntyre had been fined for handing out anonymous leaflets during a local school board campaign. Citing its holding in *Talley* about the importance of anonymous works in human progress, the Court noted that speakers may seek anonymity for a number of valid reasons: "The decision in favor of anonymity may be motivated by fear of economic or official retaliation, by concern about social ostracism, or merely by a desire to preserve as much of one's privacy as possible."

The Court recalled the newspaper right-of-reply law it had invalidated in the 1974 case of *Miami Herald Publishing Co. v. Tornillo*. Like the Ohio ordinance under review, that law had required speakers to add their names to their work. "The identity of the speaker," said the Court, "is no different from other components of the document's content that the author is free to include or exclude." They noted that anonymity "provides a way for a writer who may be personally unpopular to ensure that readers will not prejudge her message simply because they do not like its proponent."

The Court concluded that under the Constitution, "anonymous pamphleteering is not a pernicious, fraudulent practice, but an honorable tradition of advocacy and of dissent. Anonymity is a shield from the tyranny of the majority."

Since 1995, the Supreme Court has issued two more opinions elucidating the law pertaining to anonymous communications. In *Buckley v. American Constitutional Law Foundation*, the court examined a Colorado requirement that the circulators of political petitions wear an identification badge. Justice Ruth Bader Ginsburg delivered the majority opinion. The Court began by noting that the state did not require individuals collecting signatures on political nominating petitions to wear badges. Those advocating for ballot initiatives alone were singled out for this requirement.

The Court was impressed by trial testimony about harassment of signature seekers and the chilling effect of having to wear a badge, which made some people afraid to participate. The Court found the Colorado requirement even more onerous than the Ohio ordinance it struck down in *McIntyre*. The Court noted that the signature of a petition requires more sustained one-on-one interaction than the handing out of a leaflet. "[T]he badge requirement compels personal name identification at the precise moment when the circulator's interest in anonymity is greatest." Citing *McIntyre*, the Court struck down the Colorado law, holding that the badge requirement "discourages participation in the petition circulation process by forcing name identification without sufficient cause."

In *Watchtower Bible and Tract Society v. Village of Stratton*, the court reviewed an Ohio village ordinance requiring anyone soliciting door-to-door to obtain a permit. Among the various disturbing aspects of the practice, the Court, citing *McIntyre* and *Buckley*, noted the impact on the right of anonymity:

First, as our cases involving distribution of unsigned handbills demonstrate, there are a significant number of persons who support causes anonymously. The requirement that a canvasser must be identified in a permit application filed in the mayor's office and available for public inspection necessarily results in a surrender of that anonymity. . . . The badge requirement that we invalidated in *Buckley* applied to petition circulators seeking signatures in face-to-face interactions. The fact that circulators revealed their physical identities did not foreclose our consideration of the circulators' interest in maintaining their anonymity. In the Village, strangers to the resident certainly maintain their anonymity, and the ordinance may preclude such persons from canvassing for unpopular causes. [citations omitted]

The Court did, however, recently set a significant limit to anonymity: It held that an individual stopped by the police during the investigation of a crime cannot refuse to give the police his name (*Hiibel v. Sixth Judicial Circuit Court of Nevada*, 2004).

## INTERNET ANONYMITY AND THE LAW

Courts deciding on the law pertaining to new technologies must work by analogy. Is the telephone a new type of telegraph or something different? Are records like sheet music or unrelated to them? Strong analogies make for strong decisions; cases in which the courts disregard or veer away from analogies tend to result in confused law.

The key question in deciding on the level of constitutional protection for anonymity in cyberspace is whether an e-mail message is fundamentally similar in its nature to Mrs. McIntyre's pamphlet. So far courts have cautiously answered this question in the affirmative.

In 1996, the Georgia legislature, apparently oblivious to the *McIntyre* decision of the year before, passed H.B. 1630, an amendment to the state's computer security law, making it a misdemeanor to "knowingly transmit any data through a computer network [using] any individual name . . . to falsely identify the person . . . transmitting such data." The American Civil Liberties Union (ACLU), acting on behalf of a group of Web publishing plaintiffs including the author of this chapter, brought the case of *ACLU v. Miller* (1997) in U.S. district court challenging the law as an infringement of the freedom of speech. The court granted a preliminary injunction preventing enforcement of the new law pending the trial. It held that "the statute's prohibition of Internet transmissions which 'falsely identify' the sender constitutes a presumptively invalid content-based restriction" under *McIntyre*. The court

concluded that the statute was unconstitutionally overbroad because it was

not drafted with the precision necessary for laws regulating speech. On its face, the act prohibits such protected speech as the use of false identification to avoid social ostracism, to prevent discrimination and harassment, and to protect privacy[,] . . . a prohibition with well-recognized First Amendment problems.

Georgia decided not to appeal the ruling, and therefore H.B. 1630 was ripped from the law books without more litigation or any utterance by a higher court. Presumably, someone in authority read *McIntyre* and decided the case was a lost cause.

## ANONYMITY DURING WARTIME

Even before September 11, 2001, a climate of fear of terrorism, coinciding with law enforcement's fear of the Internet as a medium for hard-to-trace communication, led to several U.S. legal initiatives with the potential for undoing the less complex levels of anonymity.

In 1994, Congress passed the Communications Assistance for Law Enforcement Act (CALEA), which mandated that the telephone companies design their digital networks in a manner that would explicitly permit and support surveillance of electronic communications including e-mail. The new law allowed federal investigators to obtain addressee information more easily (addresses of the recipients of e-mail) and the contents of e-mail. In a recent "Notice of Proposed Rulemaking," the government has now signaled its intention of expanding CALEA to cover broadband transmissions and certain Voice over Internet Protocol (VoIP) communications as well. CALEA had always excluded data in the custody of "information service" providers or traveling on the Internet; e-mail was only vulnerable under the law when residing, or arriving, on the phone company's server. However, because many broadband and VoIP providers are ISPs, not phone companies, civil libertarians fear that adoption of the proposed CALEA rules will blur the distinction and lead to widespread law enforcement interference with ISPs.

CALEA is unique because it requires the system architecture to be designed with surveillance in mind. The Electronic Freedom Foundation (n.d.) states that a carrier receiving a court order or subpoena, must be able to "quickly isolate all wire and electronic communications to and from a targeted person. . . . quickly isolate call-identifying information (numbers they've called and calls they've received) of a targeted person" and "carry out intercepts unobtrusively, so targets are not made aware of the electronic surveillance."

In 2000, the Federal Bureau of Investigation (FBI) announced its use of Carnivore, specialized servers that could be attached to an ISP's server to monitor communications. The existence of Carnivore caused great concern in the civil liberties community because Internet communications are not segregated in the same way as phone calls. Although a surveillance device can easily trace one phone call from among hundreds of others, e-mail is sent

divided into multiple individual packets that are mingled with packets from thousands or millions of other unrelated communications. To capture all of the packets of a particular suspect communication, the FBI would have to filter through all the other innocent packets being transmitted at the same time. Civil libertarians feared this would lead to wide-scale illegal monitoring of innocent communications. The FBI compounded these fears by refusing to release the source code of, or even a lot of specific information about, Carnivore (Captain, 2000; Harrison, 2000).

The author of a Carnivore FAQs (frequently asked questions), drawing some inferences about the likely functioning of the system, maintains that Carnivore is likely to be easy to defeat with more advanced levels of anonymous communication. Because Carnivore searches for the suspect's name and e-mail address in the "From:" line of a communication, the system may be thrown off the track by simple forgery of the message header: "When sending e-mail, simply change your name. Since Carnivore will never see your e-mail address go across the wire, it cannot capture the e-mail nor record the fact that it was even sent." Similarly, the use of multiple remailers, coupled with encryption software such as Quicksilver, should be sufficient to evade Carnivore.

After September 11, Congress passed the Patriot Act (H. R. 3162), containing numerous provisions intended to facilitate the investigation and apprehension of suspected terrorists. Under the Patriot Act, federal authorities could obtain information on a subscriber's e-mail merely by serving an ISP with a document called a National Security Letter (NSL). In a lengthy decision issued in September 2004, a federal district court sitting in New York City invalidated this use of NSLs, partly on the ground that they violate users' constitutionally protected rights of anonymity.

Every court that has addressed the issue has held that individual internet subscribers have a right to engage in anonymous internet speech. . . . No court has adopted the Government's argument here that anonymous internet speech or associational activity ceases to be protected because a third party ISP is in possession of the identifying information. . . . the Court rejects the invitation to permit the right of internet anonymity and association to be placed at such grave risk. (*Doe v. Ashcroft*, 2004)

## SUBPOENAS SEEKING THE IDENTITY OF ANONYMOUS SPEAKERS

The majority of the litigation pertaining to online anonymity has dealt with several closely related scenarios. A party, usually a corporation, is claiming it has been harmed by the accusations made by anonymous participants in online forums. In some cases, a company is seeking to blame these speakers for a drop in its stock price. In others, it is defending itself against a lawsuit, government investigation, or administrative proceeding and claims that the anonymous speakers are in a position to provide it with useful evidence for its defense.

Matters come to a head when the litigant serves an ISP with a subpoena requiring it to disclose the identity

of a subscriber. Although some ISPs routinely give out this information without notifying the subscriber (and even sometimes without a subpoena), others have resisted disclosing the information or have given the subscriber enough notice to permit him to do so.

In *Doe v. 2themart.com Inc.* (2001), the corporate defendant in a shareholders' derivative suit served Infospace, a Seattle ISP, with a subpoena seeking the identity of John Doe, an anonymous poster on the "Silicon Investor" bulletin board. Infospace notified Doe of the subpoena's existence, and he contested it in court. The parties stipulated that Doe would be permitted to proceed anonymously while fighting the subpoena. The court said, "When an individual wishes to protect their First Amendment right to speak anonymously, he or she must be entitled to vindicate that right without disclosing their identity." The court first recognized that a subpoena, although issued by a private party, is governmental action because it is backed by the contempt power of the court. Therefore, the subpoena power is subject to the limitations of the First Amendment.

The court acknowledged that the "right to speak anonymously was of fundamental importance to the establishment of our Constitution." On the Internet, the right to speak anonymously "facilitates the rich, diverse and far-ranging exchange of ideas." If Internet users can be "stripped of that anonymity by a civil subpoena enforced under the liberal rules of civil discovery, this would have a significant chilling effect on Internet communications and thus on basic First Amendment rights."

The court then created a series of tests to be applied to determine the circumstances under which the identity of an anonymous communicant must be disclosed:

1. whether the subpoena has been issued "in good faith and not for any improper purpose";
2. whether the information sought relates to the core claim or defense of the party seeking the information;
3. whether the identifying information is "directly and materially relevant" to the claim or defense; and
4. whether information sufficient to establish or disprove that claim or defense "is unavailable from any other source."

The court then applied this test to the facts before it, holding that the information sought by 2themart did not relate to a core defense, and that the identity of the speakers (as opposed to their statements) was not of great importance either. "[T]heir identity is not needed to allow the litigation to proceed." Their statements on Silicon Investor were a matter of public record and, if in fact they had affected the company's stock price, they had done so anonymously. Their identities, unknown to the public at the time they made their statements, were not relevant now.

2themart argued that it wanted to correlate the statements on Silicon Investor to stock trades made by the individual speakers to determine whether they had profited from changes in the stock price caused by their allegations. The court responded that such innuendos of stock manipulation "do not suffice to overcome the First Amendment rights of the Internet users."

The court, granting Doe's motion to quash the subpoena, concluded that "the constitutional rights of Internet users, including the First Amendment right to speak anonymously, must be carefully safeguarded."

In *Global Telemedia International Inc. v. Doe1* (2001), the plaintiff corporation was publicly traded over the counter. The defendants were anonymous individuals who had posted derogatory statements about the plaintiff on the Raging Bull Web site. Plaintiff sued for libel, and the case was removed by the anonymous defendants to federal court. Defendants moved to dismiss the case under the California SLAPP (Strategic Lawsuit Against Public Participation) law. The court held that the SLAPP law was applicable because the plaintiff had made itself a matter of public interest "by means of numerous press releases issued since 1999."

The court noted that "Unlike many traditional media, there are no controls on the postings. . . . No special expertise, knowledge or status is required to post a message or to respond." This lack of status militated in favor of the defendants, by making their postings clearly their own opinions, rather than statements of verifiable fact. Only a false fact statement can be libelous; opinions cannot be. The court stated: "Given the general context of the postings, the colorful and figurative language of the individual postings, the inability to prove the statements true or false. . . . the postings are opinions." The court found that the anonymous defendants' postings were "an exercise of their free speech in connection with a public issue." Although the decision vindicates the right of anonymous Internet communication, it is a less than complete victory, because (in contrast to the result in *Doe v. 2themart*) the defendants' identities were disclosed in the course of the proceedings.

## AN ANONYMOUS DOMAIN REGISTRANT

In *Columbia Insurance Inc. v. Seescandy.com* (1999), the plaintiff was the assignee of various trademarks pertaining to See's Candies. The defendant was an anonymous individual who had registered the seescandy.com domain. Plaintiff sued for trademark infringement, seeking an injunction against use of the See's Candies mark and also sought cancellation of the domain registration. The plaintiff was unable to serve the complaint because it couldn't identify the defendant.

The court began by recognizing a substantial, First Amendment-protected interest in anonymous communication, which it described as

a legitimate and valuable right to participate in online forums anonymously or pseudonymously. . . . This ability to speak one's mind without the burden of the other party knowing all the facts about one's identity can foster open communication and robust debate.

The court simultaneously recognized that with the advent of the Internet, there came the ability to commit old torts, such as trademark infringement, in new ways: entirely online. The court then balanced the interests of

the parties by creating a standard for determining when an anonymous litigant would be required to disclose its identity. It held that the plaintiff must identify the defendant with “sufficient specificity” to determine the “real person or entity who could be sued in federal court.” The plaintiff must also describe all the steps it has taken on its own to identify the defendant, before invoking the court’s power to do so. Finally, the plaintiff must establish to the court’s satisfaction that the complaint would withstand a motion to dismiss to prevent the bringing of frivolous or groundless actions to force defendants to reveal their identity.

The court held that there was actual confusion here because potential customers visited the *seescandy.com* domain and attempted to order candy. It found that the plaintiff had accordingly met all three branches of the test—described the defendant adequately, made serious attempts to locate him, and established the merits of its trademark infringement claim. Accordingly, the court ordered the defendant to come forward and identify himself.

*Dendrite International Inc. v. John Doe no. 3* (2001), closely followed *Seescandy*. Like *Global Media* and *2themarkart*, the case involved anonymous statements about a publicly traded company, made on an Internet message board. Plaintiff Dendrite was a software developer and publisher, with a specialty in pharmaceutical applications. John Doe no. 3 posted to a Yahoo! Message board dedicated to Dendrite and its stock. Like so many anonymous posters, John Doe no. 3 was extremely skeptical of the company’s good faith and future prospects. Objecting to a change in Dendrite’s revenue recognition procedure, Doe wrote:

John’s [ (Dendrite president John Bailye) ] got h is contracts salted away to buy another year of earnings—and note how they’re changing revenue recognition accounting to help it. . . . Bailye has his established contracts structured to provide a nice escalation in revenue. And then he’s been changing his revenue—recognition accounting to further boost his earnings.

Doe also alleged that Dendrite was looking for a larger company to acquire it. “[Dendrite] simply does not appear to be competitively moving forward. John knows it and is shopping hard. But Siebel and SAP already have turned him down. Hope Oracle doe s want in bad. . . .”

Dendrite brought suit for libel, alleging that Doe’s statements were false and harmed the company by driving down its stock price. The company then moved to conduct limited discovery for the purpose of determining John Doe no. 3’s identity. The trial court denied the motion and the New Jersey Superior Court, Appellate Division, then considered the proper standard for deciding such a motion.

The trial court followed the *Seescandy* test, which as one of its prongs asks whether the plaintiff’s case would survive a motion to dismiss. The court held that Dendrite had not made the minimum showing necessary to survive such a motion. The appeal court zeroed in on a conflict between the law applicable to motions to dismiss, and the strong First Amendment protection for anonymity. It pointed out that New Jersey procedure, like that of most

states, leans against the dismissal of cases at a preliminary stage, prior to the conduct of discovery. Therefore, a minimal showing of merit is required to defeat a motion to dismiss. However, if the same standard was applied to motions intended to identify anonymous speakers, the latter might find themselves too easily stripped of constitutional protections in cases which proved not to be very meritorious. Therefore, the appellate court favored a standard for anonymity determinations that was stronger and more demanding than that applied to motions to dismiss.

The appellate court found that Dendrite’s complaint would have survived a motion to dismiss. To deny the motion to disclose Doe’s identity, the trial court—although it never acknowledged it was doing so—properly applied a stricter standard, considering whether Dendrite would be able to prove any damages, a matter not usually considered on a motion to dismiss (where the court typically asks whether the plaintiff has properly alleged damage, not whether it will be able to prove it).

The appeals court agreed that Dendrite failed to show damage. Stock records

indicate Dendrite experienced gains on 32 days, losses on 40 days, and no change on two days during that period, which overlaps the period when John Doe No. 3 was posting his statements on the Yahoo! bulletin board. Dendrite’s total loss during this period was 29/3 2 of a point. Moreover, John Doe No. 3 made nine postings, two on the same day. On three of the days that immediately followed a posting by John Doe No. 3, Dendrite’s stock value decreased. However, on five of the days that immediately followed a posting by John Doe No. 3, Dendrite’s stock value increased. The net change in Dendrite’s stock value over those seven days was actually an increase of 3 and 5/8 points.

Accordingly, the court affirmed the dismissal of the motion, leaving John Doe’s identity unknown. An interesting sidelight to the case is that the trial court allowed Dendrite to discover the identity of two other John Does, who did not come into court to defend themselves. John Doe no. 3 was the only defendant who appeared. The moral of the story is that people who wish to communicate anonymously must be willing to defend their right to do so.

## Contrarians

Despite the lack of a court case at any level holding that *McIntyre* does not apply in cyberspace, there has been no shortage of commentators calling for limitations on online anonymity. Some of them have advanced legal arguments, and others have called for structural solutions (changes in the architecture of the Internet). The one thing all have in common is a failure to address *McIntyre* and the lack of a persuasive argument as to why Mrs. McIntyre’s pamphlet should be treated one way if printed on paper and another if embodied in an e-mail or a Web page.

“[T]o achieve a civilized form of cyberspace,” wrote David Johnson, “we have to limit the use of anonymous communications” (Johnson, 1994). In a student

note published in the *Columbia Law Review* the year of the *McIntyre* decision, Noah Levine called for a “simple statute . . . requiring administrators of anonymous remailers to maintain records of users in a manner which allows for the identification of the senders of specific messages” (Levine, 1996).

In interpreting the First Amendment’s simple words, “Congress shall make no law . . . abridging the freedom of speech, or of the press,” the Supreme Court established a default rule of little permissible regulation for anything that comes from the printing press or which it finds analogous to printed matter. The Court has had to make a much broader analogous jump to find (for example) that movies are like print than to hold that the same exact essay, on the screen of your computer, should be treated the same way it would be in the pages of a magazine. In the seminal case of *Reno v. ACLU* (1997), the first time it considered the First Amendment’s applicability to the Internet, the Court (without promising always to follow this analogy, as indeed it has not) held evocatively that the Net allows any user to “become a pamphleteer.”

Over the years, the court has created a couple of loopholes allowing other communications technologies to receive more restrictive treatment than print media. The best established of these is the “scarcity” doctrine, which states that, because there are a limited number of broadcast television and radio frequencies available, speech over these can be regulated to a higher degree than in the “nonscarce” print media. Later, in the *Pacifica* (“Seven Dirty Words”) decision, the Court created an apparently independent justification for censorship that could (although the case involved radio) potentially be applied to a nonscarce medium: It held that there could be stronger regulation of “pervasive” media (which come into the house uninvited).

Although the pervasiveness doctrine, never fully explained, has continued to have a sort of half-life (Wallace, 1998), the Court boldly held in *Reno* that the Internet is neither scarce nor pervasive, cutting the legs out from under the proponents of Internet censorship, who have had to turn to other arguments that have received less Supreme Court attention. An important and particularly insidious argument made by some critics of Net speech is that the latter is more dangerous than Mrs. McIntyre’s leaflet because it reaches much larger audiences. Cass Sunstein (1996), a respected law professor and frequent commentator on First Amendment issues, is a leading proponent of the idea that the Internet is dangerous because it reaches more people. A speech advocating an act of violence, said Sunstein, may not motivate anyone among a small number of listeners to act, but of the millions of people who can imaginably read the speech on the Internet, “one, or two, or ten, may well be provoked to act.” This idea, that controversial speech is acceptable as long as it reaches only a few people, flies in the face of Justice Oliver Wendell Holmes’s (in dissent; *Abrams v. United States*, 1919) governing metaphor for the First Amendment that “the best test of truth is the power of the thought to get itself accepted in the competition of the market.” Sunstein argued the opposite, that is, if a “bad” thought is about to succeed in the market by reaching a wide audience, the government and courts should intervene to stop it.

A related argument is that anonymous speech is more dangerous on the Internet because of the lack of gatekeepers such as publishers, editors, or television producers who presumably will know the anonymous speaker’s identity and in any event will refuse to publish really bad speech. This is a highly antidemocratic argument insofar as it holds that speech is only acceptable when prescreened by an informed elite. Attorney Lee Tien, in an article about the applicability of *McIntyre* to cyberspace, wrote that “Such an elitist attitude should not be part of modern free speech philosophy” (Tien, 1996). After all, no gatekeeper stood between Mrs. McIntyre and her intended audience. To reconcile *McIntyre* with the “gatekeeper” argument, it is necessary to drag Sunstein’s “volume” argument back into the debate: Mrs. McIntyre’s anonymous speech is acceptable only because her audience was very small. Now you have a doubly undemocratic gloss on the modern philosophy of freedom of speech. The Supreme Court has not as of yet given any credence to the gatekeeper or volume arguments.

## CONCLUSION

The architecture of the Internet by its nature offers users weak proof of identity and also weak anonymity. Technological and practical solutions allow users higher assurances both of correct identity and of complete anonymity. Both are a good thing. Sometimes the most routine business cannot be safely transacted without some assurances of identity. The *Seescandy* case illustrates the difficulties caused by the defendant’s ability to register a domain without proving his own identity to the registration authority. On the other hand, anonymous political speech has a long and honorable history and should be not simply permitted, but encouraged.

## GLOSSARY

**Anonymous DSL** A DSL (digital subscriber line) connection provided by an Internet service provider that assigns the user a “dynamic” (temporary) Internet protocol address and then keeps no records of which user has been assigned which address.

**Anonymous Surfing Site** A Web site, such as The Anonymizer, that allows users to view other sites remotely while leaving in their logs only the identifying information of the intermediate site, rather than that of the user.

**Digital Signature** An unforgeable electronic “watermark” added to an e-mail message to assure the recipient of the identity of the sender.

**Encryption Key** A distinguishing digital feature of a message encrypted under certain software systems such as “pretty good privacy” (PGP). “Public keys” can be distributed by the sender to recipients of his mail and allow them to decrypt messages encrypted with the sender’s “private key,” which is known only to him or her. This approach incidentally provides a high degree of assurance that the sender is, at least, the same person who previously sent the mail using the same key.

**Remailer** A system, usually a Web site, set up to receive mail, strip it of its identifying elements, and forward it to its ultimate recipient as an anonymous message.

**Remailer Software** Software, such as Mixmaster, that works by encrypting a message and then sending it through a random series of remailers, each of which remove one layer of encryption. The last remailer in the chain forwards the message to the ultimate recipient. In theory, the path of the message across the Internet is untraceable.

**Secure Sockets Layer (SSL)** A protocol for the encryption of Internet communications, widely used in electronic commerce applications.

**Socks Server** Web proxy server software that promotes anonymity via features including a lack of logs identifying users who have used the system to send messages or to access other sites.

## INTRODUCTION

### Spam and “Junk Mail”

Businesses, charitable organizations, politicians, special interest groups, and many others send millions of unsolicited “junk mail” pieces every month to your postal mailbox—cards, letters, leaflets, or almost anything they want. It’s legal. Companies make money with it. You may have done it yourself.

Internet e-mail has become the new frontier of junk mail, with offers of every kind—sometimes hundreds per day—going to almost every e-mail address in the world. Businesses, charitable organizations, politicians, and special interest groups send it. Unsolicited e-mail is similar to postal junk mail, except it arrives in your e-mail box. Most people call it “spam” and most people hate it.

Ronald Scelson (2004)—known as the “Cajun Spammer”—is a high-volume spammer. On May 21, 2003, testifying before the United States Senate Commerce Committee, he boasted to the senators, “I send out between 120 million and 180 million e-mails every 12 hours.” He added, “I’m probably the most hated person in this room” (Krim, 2003). Scelson reportedly earns \$30,000 to \$40,000 “in a good month” (Swartz, 2003a).

The volume is substantial. In January 2004, one report said that 700 billion unsolicited e-mail messages were sent—more than three per day for every person on the planet (Ray, 2004). In 2003, eMarketer estimated that 2.3 billion spam messages were sent daily (Powell, 2003). At the end of 2004, one report said that “spam accounted for 88% of e-mail sent in November (Rodgers, 2004).

Not only do unsolicited and unwanted messages clog up incoming e-mail boxes, they drive up prices for

everyone who communicates with e-mail, costs that are passed through to consumers. Spam costs money for businesses to process and sort. It takes valuable resources from Internet service providers. It takes time from individuals; it lowers their trust in legitimate marketers who may have products they want or need; it harms economic growth.

E-mail, once “the next new thing” that would revolutionize ubiquitous low-cost communication, is threatened by its own technical magic in the hands of unscrupulous marketers, porn purveyors, political hucksters, and others with self-interests in communicating with you and me.

A new term, “spam rage,” has evolved. On November 24, 2003, Reuters reported that Silicon Valley programmer Charles Booher said his computer “had been rendered almost unusable for about two months by a barrage of pop-up advertising and e-mail.” Booher was arrested for “threatening to torture and kill employees of the company he blames for bombarding his computer with Web ads promising to enlarge his penis” (Reuters, 2003c).

In Paddy Chayefsky’s classic film *Network*, a frustrated Howard Beale shouts, “I want you to get up right now, and go to the window, open it, and stick your head out, and yell: ‘I’m as mad as hell, and I’m not going to take this anymore!’” As technology moved into the New Millennium, “There oughta be a law!” rang loudly through state and federal congressional chambers. Howard Beale, welcome to spam!

### Costs of Spam

Business, government, not-for-profit organizations, and individuals are being battered by spam that lowers

productivity and costs money in several other ways. The estimates vary widely, but regardless of who is counting, all are agreed that the lost productivity is substantial.

In November 2004, CNN reported that Bill Gates was the “world’s most spammed person,” receiving some 4 million e-mails per day, most of them spam. The company CEO said, “Microsoft has special technology that just filters spam intended for Gates,” and “practically an entire department [is] dedicated to ensuring that nothing unwanted gets into his inbox” (CNN, 2004a).

Some high-profile companies suffer overall spam rates as high as 79%, according to a July 2003 CyberAtlas survey (Greenspan, 2003). Pressing the delete key may only take a second—much quicker than saying “no” to a telemarketer—but judgments about message validity, origin, and other factors soak up valuable time and energy in processing the messages.

Workers may sift through hundreds of e-mails per day in search of vital information. The survey listed 36% of respondents who spend between 10 and 30 minutes per day dealing with unwanted e-mail and another 32% spending between 30 and 60 minutes. At 60 minutes per day, an employee would be giving up 12.5% of the normal workday. Counting 5 days per week, it calculates to an annual loss of up to six 40-hour workweeks.

CyberAtlas calculated that 79% of respondents think unwanted e-mail should be legally limited or banned; 74% say there should be a federal “do not e-mail” list; and 59% would like to see spammers punished. In the survey, unwanted e-mail was rated equally with telemarketing as the most annoying marketing practice (Greenspan, 2003).

The Radicati Group says spam cost U.S. companies \$20.5 billion in 2003; by 2007, the figure is expected to reach nearly \$200 billion, or about \$180 for every American. BellSouth says spam will add \$3 to \$5 to each customer’s monthly bill (Sullivan, 2003a; Swartz, 2003b).

A 2004 American Management Association survey found that “e-mail and inbox management has become the number-one office task. The average employee now spends 25% of the workday on e-mail” (Swartz, 2004c).

A 2004 Nucleus Research survey said spam will cost large U.S. companies nearly \$2,000 per employee in lost production. According to the United Nations, spam and antispam protection cost computer users \$25 billion worldwide in 2003 (Swartz, 2004b).

A Ferris Research study determined that the overall cost to U.S. business in 2003 was \$8.9 billion, including additional costs generated by requiring more powerful servers, more bandwidth, and “help desk support to annoyed users.” On the average, it concluded, it takes 4.4 seconds to deal with a message (Swartz, 2003a).

A spam-costs calculator on the Web shows that for a company of 100 employees who spend 4.4 seconds per message dealing with 50 spam a day, nearly 59 workdays would be lost per year. If the average salary is \$25 per hour, it totals over \$35,000 in lost productivity (iHateSpam, 2004).

Spam creates other problems that cost business—and ultimately consumers—money. Sometimes legitimate communications are mistakenly screened out and deleted. Jupiter Research reported that the cost of “mistakenly

blocked permission-based e-mails” will increase 82.2% between 2003 and 2008 (“Around the Block,” 2004).

These “false positives” can have devastating consequences for vital account management or customer service. If the client interprets them as being ignored by the company, whole chunks of revenue and profit can disappear. Consequently, companies are reluctant to use automated filters or other technology to screen out spam. Someone needs to read and delete each message, much as “practically an entire department” does at Microsoft.

Spam costs legitimate marketers money in other ways, too. In 2004, Gratton, in an overview of global spam, reported a survey finding that “52% of respondents are shopping less on the Internet or not at all because of concerns about receiving spam” (p. 3)

Storage is another cost. “Between one-third and one-half of all electronic communication kept in company storage systems are irrelevant. Most of these communications are personal mails and spam. Companies have a tendency to store everything in the fear that not doing so will put them in breach of regulations” (Swartz, 2004a).

Leaving monetary cost aside, most users consider spam a serious problem simply because of the annoyance. There are strong opinions on all sides.

## A Balanced Viewpoint

The polarized opinions about spam include those who would prohibit it entirely, those who would allow it without limits, and the in-between. Interested parties include the spammer, who believes it is a right to send unsolicited mail; the consumer who may or may not want to receive that mail; the Internet service provider who finds its valuable bandwidth consumed by unwanted messages; the information technology (IT) professional who may be called on to control spam; organizations polarized around or advocating for or against unlimited e-mail or tight restrictions; law enforcement; and legitimate businesses that want to communicate with prospects.

From a public policy point of view, accommodating the myriad viewpoints is an example of the classic “macro-micro dilemma,” where what is good for the individual or firm may be in conflict with what is good for society.

Government has a legitimate interest in controlling activities that are harmful to consumers, but it is also concerned with allowing businesses reasonable access to potential customers. The Federal Trade Commission (FTC) has concluded that “spam poses a serious threat to electronic commerce because deception and fraud characterize the vast majority of spam” (Privacy/Internet, 2004a). The dispute arises about the degree to which the government should limit such activity and where to draw the boundaries in a legal counterattack. The FTC has announced that it “planned to be largely hands-off, market driven,” but aggressively prosecute spammers under existing laws (Porcelli, Selby, Bagner, & Sonu, 2002, p. 24).

This chapter is focused on the legal counterattack against spam. Although the chapter discusses freedom of speech, due process, abuse or trespass of chattels, the Commerce Clause, and enforcement problems, it is not intended to be a detailed legal review but simply presents perspectives on the issues in a way that a reader of

scholarly texts can understand and use to make intelligent decisions about the role of a legal counterattack on spam in an information-based society. In the framework of rapidly changing legislation, it focuses on providing a foundation for understanding the issues in the legal counterattack of state and federal laws, including the federal CAN-SPAM Act that became effective January 1, 2004.

The legal counterattack is only one component in bringing spam under control. IT professionals working in colleges and universities at every level help make marketers, government, and organizations more aware of spam and its supporting technologies. The San Diego Super Computer Center at the University of California at San Diego, for example, publishes data on antispam databases used by “black lists.” The United States Computer Emergency Readiness Team (US-CERT) center at Carnegie Mellon University monitors hacking techniques used in cyberterrorism and makes recommendations about making the communication infrastructure more secure (Jaeger, 2003). Many hacking techniques are used in spamming, and technical solutions help support a legal counterattack on spam. Laurence Lessig’s (1999) classic article, “The Law of the Horse: What Cyberlaw Might Teach,” from the *Harvard Law Review* is cited to illustrate a multidimensional approach that includes markets, social norms, and architecture, or “code,” which may regulate interaction with cyberspace.

Specialized legal training is beginning to receive attention. Cyberspace is so new that it is difficult to keep up with its progress. In the summer of 2003, Chicago’s John Marshall Law School offered “the first law school course devoted to the subject of unsolicited commercial e-mail” to “investigate legal and policy issues raised by e-mail marketing and spam” (Festa, 2003). Many more will come.

Scholarly research about spam is relatively scarce. This chapter supplements material from peer reviewed sources with up-to-date news and other media reports. The latter are sometimes inconsistent or even contradictory, but in the fast-moving world of cyberspace, they are essential to establishing an understanding of current issues.

The chapter concludes that the legal counterattack may not be effective on its own, but it will provide a foundation of rules to complement other approaches, including technology that individuals, companies, higher education institutions, Internet service providers (ISPs), special interest groups, and advertisers can use to control spam at their respective levels.

## “SPAM” AND “SPAM”

The uppercase SPAM is a registered trademark for the world’s leading canned meat product, made of spicy pork and ham. It is popular in some areas (e.g., parts of Hawaii), yet despised in others. The lowercase spam refers to e-mail messages.

It is widely believed that the first use of the term “spam” came about as a result of the Monty Python comedy skit in a restaurant that describes the frustration a woman endures while trying to order a meal. The restaurant serves SPAM with everything, and she wants none of it! Subsequently, a group of Vikings sing a chorus of “SPAM, SPAM, SPAM” in an increasing crescendo, drowning out

other conversation. The analogy to e-mail spam is the drowning out of normal discourse on the Internet and the strong feelings on both sides of the issue (the skit and discussion can be found at <http://www.detrutus.org/spam/skit.html>; also see [http://www.uselessmoviequotes.com/umq\\_n001.htm](http://www.uselessmoviequotes.com/umq_n001.htm); <http://www.museum.tv>; <http://www.webopedia.com/TERM/s/spam.html>).

The first reported case of blatant e-mail abuse appears to have occurred on May 2, 1978, where a user of Arpanet (which preceded the Internet) distributed a message about an open house at Digital Equipment Corporation (DEC). The user typed in the e-mail address of every known person on the Arpanet and sent the identical message to all. By most contemporary definitions, this e-mail broadcast to large numbers in a commercial format would be spam (details of the message can be found at <http://www.templetons.com/brad/spamreact.html>; discussions of definitions are later in this chapter).

Prior to the early 1990s, for-profit use of the Internet was generally banned (except for membership bulletin boards and other content services). Military, government, or education personnel occasionally engaged in mass e-mails to groups of colleagues, and there was little incentive for abuse. Once money became part of the equation, with the development of the dot-com suffix, people began to see that it was a fast and inexpensive way to reach large numbers of users. It costs about the same for a mailing to 10 or 1,000 people, so some marketers just sent it to everybody.

A popular Web dictionary likens spam to SPAM with three statements: “Nobody wants it or ever asks for it. No one ever eats it; it is the first item to be pushed to the side when eating the entrée. [However], sometimes it is actually tasty, like 1% of junk mail that is really useful to some people” (see <http://www.webopedia.com/TERM/s/spam.html>). Even a low 1% response rate can make spam profitable.

## Why Do They Spam?

### Closed Loop Marketing

In their landmark book, *The One to One Future*, Peppers and Rogers (1993) show how businesses, organizations, or government can establish a “closed loop” using directly addressable media—postal mail, telemarketing, fax, or personal visits—to build ongoing relationships that benefit customers.

E-mail is one of the most cost-effective elements in the communication mix and removes many of the time and space constraints of other interactive media. The direct feedback improves a company’s ability to satisfy individual wants and needs and builds positive relationships with millions of individuals. Customers can send e-mail responses in a fraction of the time it takes to write or telephone—so they do it more often.

Organizations communicate their missions and attract donations and volunteer support. Governments keep their constituents informed and get information back to help improve policy. Retailers invite prospects to their stores and build community with current customers. Business-to-business transactions are increasingly online, lowering supply chain and distribution costs. Consumers get e-mail

information about new products and services that satisfy their needs and wants.

A Jupiter Research overview of e-mail marketing reported that “The evolution of e-mail as a cost-efficient marketing medium, coupled with the desire for improved capabilities, has driven 64% of marketers to deploy e-mail marketing systems” (Daniels, 2003).

As postal mail became more expensive and other direct marketing came under increasing regulation, e-mail became more attractive. When telemarketing was restricted by the “no call” list, new rules restricted fax, and postage rates rose, advertisers could turn to e-mail. It’s fast, easy, and cheap.

### Spammers

A new breed of advertisers—spammers—discovered e-mail, too. By eliminating the cost of postal stamps, telephone lines, and call centers, or banks of fax machines, they could send out millions of messages. Because incremental mailings cost almost nothing, they could advertise almost anything to millions for almost the same cost as to thousands. Deceptive or fraudulent operators were difficult to find and prosecute. At the same time, spam was relatively new, and the law had not had time to catch up to the problem. Spam multiplied exponentially in this “perfect storm.”

Some spammers have a political or social agenda, using e-mail for idea advertising, advocacy, or solicitation. Some social interest groups who complain loudly about spam use it liberally themselves. Politicians exempted themselves from most regulation.

With mailings in the millions, even less than 1% interest can add up to a lot of money. In fact, enough people read and respond to spam that spammers make money. Indiscriminate mailings with very low response rates can yield good profits—it works for the few, while everybody else suffers. At the end of 2003, CNN reported that Internet and e-commerce jumped into the top 10 areas for the most consumer complaints (CNN, 2003). Most spammers are driven by money. If spammers stopped making money, most spam would end almost overnight.

A 2003 consumer survey found that 4% “read suspected spam to see if it might interest them” (Morrissey, 2003). Other surveys range widely, but using this figure, it is easy to see how spammers and their clients make money. Four percent of 120 million messages equals 4.8 million readers. If these generate just 400 responses who “click-through” to an affiliated mortgage lender—a tiny .00033% inquiry rate—and the lender pays \$10 per inquiry, the spammer just earned \$4,000 for 12 hours of work. The lender, who makes an average profit of \$500 on each transaction and “converts” just 10% of the click-through inquiries, clears \$16,000.

How is that different from traditional direct-response media: direct mail, fax, or telemarketing? With these, care is usually taken to eliminate the names least likely to be interested in the offer (an application of the Pareto curve, which the Italian economist Vilfredo Pareto developed to model resource allocation). The cost of contacting the entire list is prohibitive, so the traditional direct mailer may eliminate the 9 out of 10 who have the least interest in the offer. If only the 12 million names received the e-mail (the

1 out of 10), the other 108 million would be spared the message.

The spammer simply sends out 120 million e-mails at about the same cost of sending only 12 million. The cost of editing the list outweighs the benefits. Because the spammer does not edit the list, it is almost guaranteed that most of the likely uninterested 108 million recipients will simply be annoyed.

### “No Spam in Heaven” Marketing

Wouldn’t it be a better world if you and I never—*ever!*—received another piece of junk mail, or telemarketing call, or spam that did not in some way interest or potentially benefit us? Of course!

The idea that “there is no junk mail in heaven” is the ultimate goal in direct marketing (Roberts & Berger, 1999). If senders had perfect information about everyone and perfect systems to implement mailings, they would e-mail only to interested parties. “Information security” would be meaningless, and everyone would use best practices because, of course, in heaven only legitimate organizations with benevolent motives exist. The concept applies equally to e-mail marketing. There would be no spam in heaven!

Because we are not in heaven, this scenario has problems. First, notorious spammers don’t care. Unlike postal mail, it’s just cheaper to send spam messages to everyone. No qualification. No filters. Second, perfect information about you and me is fundamentally in conflict with privacy concerns, because unscrupulous parties with other motives use it against us.

Defining the limits of privacy in relation to spam will be one of the landmark issues of the new millennium. Some privacy advocates argue against collecting any personal information. Marketers would disagree. Under the current system, most legitimate organizations maintain some control over their prospect lists and make reasonable attempts to send messages only to interested parties. Onerous prohibitions on information, marketers would argue, will simply lead to higher costs (likely passed through to consumers), loss of jobs, and economic harm.

### A SMALL SHADOWY GROUP OF PROS

The FTC believes that it is approximately 300 prolific spammers who leave ordinary e-mail users drowning in unwanted e-mail. John Mozena, cofounder of the spam-fighting Coalition Against Unsolicited Commercial E-mail (CAUCE), puts the figure at 200 spammers who generate 90% of the spam (Schwartz, 2003, p. 39).

Ronald Scelson (discussed earlier) represents one of these prolific spammers. Other spammers have produced equivalent amounts of spam, or more. Alan Ralsky reportedly can send up to 1 billion e-mails per hour (Powell, 2003). Scelson is included in this chapter because he has been visible, and he has articulated the spammers’ point of view, both before and after new federal legislation (more about this later).

He does it for money—and he is unapologetic. He thinks he should be allowed to broadcast his messages just as do speakers on street-corner soap boxes and junk mailers. He asks, is there a difference between junk mail

and spam? Both use a communication channel with addressable media.

Much of his argument revolves around First Amendment issues. He wants his freedom of speech—a common defense by spammers—and complains that others are sending spam, so he should be able to do it, too. It's harmless, he argues. If you receive something that you do not want, you can ignore it, just as the person on the street is free to ignore a soap box speaker or a postal recipient is free to discard junk mail.

He maintains that AOL, MSN, and other ISPs are even bigger spammers. They continually send e-mail to their own members, and they promote affiliate products for which they earn a commission. When it is in their financial interest, he maintains, the ISPs look the other way.

Scelson and others claim that many legitimate marketers and other respected entities profit from spam, including some of the very companies that publicly condemn it. This is changing as the Internet matures, but it is useful to look at the details.

## The Money Trail

There is money in spam—and it is not all being made by spammers. There has developed a collision of two forces: those who would control spam, versus those who continue to develop technology that can make more spam, protect and hide spammers, and frustrate efforts at control. Sometimes, the money trail is described by the “iceberg principle,” with much more activity below the surface.

Big companies, ISPs, Web hosting companies, data providers, software vendors, and even the U.S. Postal Service have an interest in spam. In discussing “White Collar Spam,” Lieb (2003) listed Kraft Foods, Palm, AT&T, and “countless major banks and lenders” as regular spammers. She says they insulate their name and brands, but “tend to engage henchmen (list outfits, renegade affiliates) to do the dirty work.”

Sullivan (2003c) investigated a spam trail that led “from Alabama to Argentina... and right through big-name companies like Ameriquest, Quicken Loans, and LoanWeb.” He traced through 15 layers to companies who claimed to be legitimate e-mail marketers—or even spam fighters—and uncovered names purchased from “lead generators,” “affiliates,” and other third-party spam facilitators. He concluded, “While the dirty work is done by secretive, faceless computer jockeys who are constantly evading authorities, lots of companies with names you know profit at least tangentially, from their efforts.”

Scelson testified that “pink contracts” and other sweetheart arrangements protect known spammers who are sending bulk e-mail through ISPs. The big operators are simply on-the-take for extra profit, he says. Favored pink-list spammers pay rates higher than other commercial clients and are terminated only when the ISP is threatened by a lawsuit or “blacklisting” from an antispam organization.

In November 2000, Festa reported that a large ISP, PSINet, had signed a contract with Cajunnet that “would permit Cajunnet to send unsolicited e-mail ‘in mass quantity’ through PSINet’s lines... for a nonrefundable, up-front payment of \$27,000 ‘for PSINet’s increased risks.’”

The person who handled the account for PSINet said, “If the complaints were too much, we would discontinue the arrangement” (Festa, 2000).

An antispam blog participant (Web log of informal postings), listed 12 of the biggest ISPs who have accepted these contracts and summarized:

Internet Service Providers pretend to be on your side in the fight against intrusive spam, but in reality, many of them are only too willing to sell out your in-box for a buck. And at the same time that they’re contributing to the spam problem, two to five dollars of your monthly ISP bill goes towards fighting spam in the form of abusive desk staff and filtering systems. It seems they can have their cake and eat it too. (Suespammers, 2001)

When Ronald Scelson filed for bankruptcy in 2003, court records reportedly showed that he owed \$56,463 to Bell South for “circuits” and another \$4,407 to Cable & Wireless as his “Internet provider.” These same firms were reported entering into “pink contracts” with spammers some three years earlier (Sullivan, 2003c).

Today, pink contract arrangements are not as popular as they were earlier this decade, when these practices were exposed. Antispammers argue that abuses have declined markedly with the cooperation of ISPs and should not be used as an argument supporting spam. Spammers, in contrast, complain that a “wink and a nod” or other subtle arrangements have the same effect, and ISPs are still on the take.

If the major ISPs are getting out of the business, smaller firms seem ready to take up the slack. E-mail and web sites work together, or the spammer doesn’t get paid.

That’s why spammers pay hundreds, and sometimes thousands of dollars a month for what’s known as ‘bullet-proof’ hosts, ... sites that won’t get pulled down, even in the face of a deluge of complaints. Commonly advertised... as ‘bulk e-mail friendly Web hosting services,’ many... operate offshore. (Sullivan, 2003b)

In *America Online, Inc. versus Hawke*, AOL alleged, “Defendants also offered ‘bulk friendly hosting’ on servers located in China, Latin America, or other foreign countries.” This is discussed later in the chapter.

Software vendors also profit from spam by developing utilities and tools to fight it. Microsoft is no longer supporting Windows 9x, and users are advised to upgrade to XP—at a price—partly because of hacking and spam. In November 2003, Microsoft unveiled SmartScreen, a new antispam engine for their exchange servers and e-mail programs, leading to the conclusion that “almost 85 percent of e-mail gateways will have been replaced between the beginning of 2003 and the end of 2004” (Kuchinkas, 2003b).

The big data providers such as Experian also have a financial interest in e-mail. Marketers use these firms to enhance their mailing list data with e-mail “append” services to better differentiate customers and increase the effectiveness of their mailings, just as they did with traditional

interactive media (Peppers & Rogers, 1993 Roberts & Burger, 1999).

Direct mail is one of the biggest revenue generators for the U.S. Postal Service (USPS). The millions of pieces of postal mail sent to consumers and businesses fund many of the USPS programs and allow them to keep the costs of first class mail lower. The USPS might have an interest in stopping spam to increase marketers' reliance on postal mail for ordering, but the USPS gains other revenue through shipping products sold by direct marketers. Postal mail and e-mail can be complementary, and the USPS has explored developing cyberspace products of its own.

Law enforcement, too, has an interest in spam. Funding through grants and spam-fighting programs add to their overall budgets. The FTC estimates that "nearly one in eight U.S. adults has had their credit card hijacked, identity co-opted or credit rating pockmarked by identity thieves over the last five years." Working with hackers, spammers increasingly are using cyberspace for these purposes (Reuters, 2003a).

## SPAM AND CRIME

Three relatively recent practices combine to make spammers an especially potent threat: spoofing, phishing, and using hijacked, or "zombie," computers. Often, this is facilitated by sending dangerous viruses, worms, spyware, and adware to local computers. Sometimes, it includes sabotage spam as a competitive business weapon. Much of this criminal activity is coming from offshore, complicating apprehension and prosecution. Dan Larkin, chief of the Federal Bureau of Investigation's (FBI's) Internet Crime Complaint Center, says, "United States citizens and businesses are very attractive targets for the world. We're getting clobbered" (Sullivan, 2004).

"Spoofing" uses a form of identity theft to seek sales, contributions, or confidential information by fraudulently claiming to be a known entity. Often, the message looks completely authentic, including company logos and trademarks. "Real-life spoofs" reported by *The Washington Post* include fraudulent messages purportedly from flowers.com, Sony, Microsoft, PayPal, and the FBI (Lieb, 2002). In January 2005, an unemployed painter from Pennsylvania was arrested for sending out more than 800,000 e-mail spoofs fraudulently soliciting donations for victims of the December 26 Asian tsunami (Betteridge, 2005).

With "phishing," the spoofing message elicits confidential information such as social security numbers, account numbers and balances, or other confidential information such as passwords into a stock trading or airline miles site. These are used by the spammer or sold to others. In 2005, it was reported that "phishing attacks have reached 57 million U.S. adults and compromised at least 122 well-known brands" through increasingly sophisticated methods, spyware, malicious code redirects, and attacks on company domain name servers (Reuters, 2005).

"Zombie" computers are another factor. Hackers working with spammers open "backdoors" to "hijack" computers connected to the Internet. They may read everyone in that computer's address book. Then, using those

addresses, they send spam from that computer, making it appear that the owner is the sender and increasing the likelihood of the message being opened and read. Messages attributed to the wrong person are difficult to track and prosecute.

In February 2004, Bloomberg News reported that "as much as 15% [of spam] come from [hijacked] home PCs infected with computer viruses" (Ray, 2004). Hijacked computers are in government entities, organizations, and homes, and educational institutions, particularly colleges. Many are set as "open relays," which are sometimes used by legitimate companies in their networks. Bick (2004a) offered a complete discussion of the issue and how legitimate senders can maintain open relays and still comply with new laws described in this chapter.

## The Legal Counterattack

### War on Spam

Governments, politicians, businesses, organizations, and many individuals have mounted a "War on Spam." Some want unsolicited e-mail stopped entirely.

Feelings are passionate on both sides. Some free speech advocates—and spammers—argue there should be no limitation. The Cajun Spammer says, "I'm willing to die for what I believe in. Look at Martin Luther King, Jr. When they assassinated him, that's when everything changed" (Brunker, 2003). (The connection is obscure.)

However, the courts have ruled that freedom of speech has limits. Telephone and fax solicitations are already controlled by legislation, so why not e-mail? Like postal mail, telemarketing, and fax, e-mail costs the sender money, but unlike these traditional media, the cost burden shifts to the recipient. It costs the spammer almost nothing to send 120 million messages, but the recipients, ISPs, and everyone else in the communication channel must spend time, bandwidth, or other resources dealing with those messages.

Economic interests argue that legislation needs to take reasonable use into consideration. Business—or anyone, they argue—should be allowed to send you unsolicited e-mails if reasonable conditions are met, but once you tell them to stop, they should respect your wishes. If every unsolicited message is spam, and organizations are completely barred from sending unsolicited messages, they say it will have a profoundly detrimental effect on jobs and economic activity.

Legitimate businesses want at least one opportunity to contact prospects by e-mail (the "one bite" approach). Marketers contend that is minimally intrusive and gives consumers information they may want or need. Small businesses, in particular, who often lack resources to pay for traditional direct-mail advertising, say they would be hurt by overly restrictive regulation.

## State and Local Legislation

Shortly after the Internet became commercial, states began writing legislation about commercial e-mail. In 1997, Nevada was the first state to enact specific legislation. By the end of 2003, some 37 states had enacted antispam laws ranging from relatively mild to highly restrictive.

Washington passed an antispam measure in 1998 and has been diligent in finding a legislative formula that satisfies the courts on interstate commerce issues and the limitation that most e-mail addresses do not have identifying geographic characteristics (compared with postal zip codes and telephone area codes). California, which had a previous law, enacted new legislation in 2003, with fines and other civil penalties designed to put spammers out of business. Virginia has been a leader in applying criminal penalties to computer crimes that use fraud or deception.

Johnson (2003) gave a broad overview of the various state attempts to regulate unsolicited commercial e-mail (UCE), or spam, from an Internet law point of view. Topics include current or prior relationship with sender, consent or request of recipient, advertisements in exchange for free use of an e-mail service, transmission to organizations, and misrepresentation, nondisclosure, and falsification. A summary table details laws and codes related to major provisions of 34 state statutes. He concluded, "There is little uniformity among these statutes in terms of the definition of UCE, the conduct regulated, or the remedies or penalties that may be imposed."

Culberg (2002) offers a similar overview of combating spam at the state level. In 2000, Sinrod and Reyna (2000) gave a comprehensive account of several state laws. Kelin (2001) is another source on state law issues.

Virginia's antispam legislation includes criminal penalties directed primarily at senders of "fraudulent claims." It "allows authorities to seize the assets of spammers and carries penalties of up to five years in prison." A person could be prosecuted for sending over 10,000 unsolicited, deceptive e-mails per day or 100,000 in a month. It defined "deceptive" as altering an e-mail header or other routing information.

California's new law was to take effect January 1, 2004. Highly restrictive with tough penalties, the law made it illegal for marketers to e-mail California residents (or California ISP subscribers, regardless of their location), unless the recipient had provided "direct consent" or had a "preexisting or current business relationship." Ignorance of a recipient's location was not an excuse. The California law set fines of \$1,000 per spam message, up to \$1 million, and unlike most laws, included fines for e-mail sent by mistake. An important provision empowered individuals to sue, which many business and trade associations viewed as a formula for chaos. Overall, marketers considered the law a substantial threat to the emerging field of e-commerce.

Legitimate marketers believed that the tough provisions of the California law would make it difficult to do business and that irresponsible spammers—the source of most spam—would continue to abuse the system. Consumers would be deprived of legitimate messages and convenient shopping, they argued, while still being inundated with spam. They contended that the California law—and others like it—would create more problems than it solved.

## The Federal CAN-SPAM Act

The new California antispam law had just been enacted when federal legislators passed the Controlling the Assault

of Non-Solicited Pornography and Marketing Act of 2003, commonly known as the "CAN-SPAM" Act.

The CAN-SPAM Act largely supersedes the hodgepodge of more-or-less-restrictive state laws, which although similar in many respects, placed the burden on direct marketers to interpret and comply with 37 state jurisdictions. Given the diversity of laws, an ever-shifting regulatory mix, and different methods of defining and enforcing, businesses had complained that confusion and uncertainty was inhibiting economic growth and progress—and they were fearful that the tough California law would become a model for other legislation.

Pink (2002, p. 11) reviewed other problems of state regulation, concluding "fundamental problems of states regulating activity on the Internet, which is a global communications network that transcends state borders and, in many cases, is more appropriately regulated at the federal level."

The CAN-SPAM Act was signed into federal law on December 16, 2003, and went into effect on January 1, 2004. Some antispammers complain that it was simply a "sellout" to marketing lobbyists, and most legitimate marketers hope it will allow them to conduct responsible, straightforward, honest marketing campaigns that benefit consumers.

### Provisions of the CAN-SPAM Act

The act preempts all state laws that expressly regulate commercial e-mail, except to the extent that they prohibit falsity or deception. State laws not specific to e-mail, such as antifraud laws, are unaffected. Under the Act, unsolicited commercial e-mail follows the basic ground rules shown in Table 1.

Additional prohibitions include harvesting e-mail addresses obtained by "automated means," use of e-mail addresses created automatically by random substitution, and using unauthorized "zombie" computers for fraudulent or deceptive messages. The act recognizes "carve outs" that allow states wider discretion in enacting additional legislation to pursue spammers who use fraud or other illegal or deceptive practices.

The CAN-SPAM Act empowers the FTC to fine violators up to \$11,000 per violation. The Department of Justice can charge up to \$2 million in fines, and judges can triple that to \$6 million if the violation is willful or meets other conditions. Violators could face up to five years in jail. FTC Chairman Tim Muris has predicted that "the criminal enforcement of the CAN-SPAM Act will ultimately prove to be more effective than civil enforcement" (Privacy/Internet, 2004b).

Commercial electronic mail message(s) are defined in the act as "any electronic mail message the primary purpose of which is the commercial advertisement or promotion of a commercial product or service." Although most definitions of spam include "bulk" e-mail, the CAN-SPAM Act does not. Even a single message can be spam, with *each* e-mail address counted as one violation. The number of messages sent is used only to set penalties.

The CAN-SPAM Act permits the "one bite" approach that allows legitimate marketers to contact prospects at least once. It allows most transactional or relationship messages arising from a preexisting or current business

**Table 1** Major Provisions of the CAN-SPAM Act That Went into Effect on January 1, 2004, Superseding Most State Antispam Laws

Rule	Description
Header Information	The sender organization must not be disguised; "spoofers" who deceive recipients into sending confidential information to credit company imposters and the like are prohibited.
Subject Headings	Prohibits deceptive subject headings in the e-mail; pornographic spammers must include "sexually explicit" in the subject line.
Return Address	Sending address must remain active for 30 days to allow processing of remove requests and other responses.
Remove Request	Requests for removal from the list must be honored within 10 calendar days; \$250 fine per e-mail for not complying; removal systems must remain active for 30 days after a mailing.
Identifier Inclusion; Opt-Out Opportunity; Physical Address	Advertising must be identified; pornographic spammers are required to label advertisements clearly; must give notice and opportunity to decline further mailings (e.g., "click here to remove my name from the list"); must include valid physical address of company (P.O. box is allowed)

relationship. These include first, the "transactional or relationship message," further defined as e-mails that would "facilitate, complete, or confirm a commercial transaction that the recipient has previously agreed to enter into with the sender," and second, e-mail that simply references the sender's company, Web site, or other commercial entity. The use of "proxy" computers is allowed, as long as they are not used for fraudulent purposes and clear identification of the sender is given through other means. Bick (2004a) offered an in-depth discussion of these issues from a legal perspective, including discussing some of the implementation questions yet to be addressed.

### Implementation Questions

Implementation and codification of the act is evolving. The FTC will make detailed rulings on the definition of "commercial electronic mail message," language such as "misleading," and ambiguities in other issues. It will issue regulations "to determine the criteria to establish the 'primary purpose' of an electronic mail message" (Rembert, 2004, p. 8).

Fingerman (2004, p. 12), in a lengthy legal overview of the act, pointed out that the language relating to subject lines "is rather vague; it is hard to say, for example, whether a coy or humorous subject line would trigger liability as misleading."

Raysman and Brown (2004) asked whether e-mail newsletters are commercial e-mails and whether a friend could be referred?

Kuchinkas asked (2003c), if an advertiser has 10 days to remove a name that has opted out, how would the e-mail service or list provider report that back to the advertiser, and who would be responsible from removing the name? What about "viral marketing," a recent trend where the recipient is asked to forward the message to another person? Will the advertiser need to run that name through their filter first? If a customer asks an advertiser to stop sending a newsletter, does that mean that their billing cannot be e-mailed? What about two different business units

in the same company, or a wholesaler who pays retailers to advertise their goods?

Soltoff (2004) noted that the act holds not just advertisers liable, but "all parties involved in sending e-mail." He raises questions about how advertisers, affiliates, and e-mailers will be able to suppress names with consistency. Also, there is some question whether the required "valid postal address" would be that of the advertiser or some other member of the e-mail sending chain. The FTC has ruled that post office boxes are valid for the purpose of physical address identification.

Nettleton (2004) asked whether a message advertising Viagra addressed to an individual within a company is really sent to the individual, or to the company, which may have a prior relationship with the marketer?

### Do-Not-Spam Lists

The CAN-SPAM Act directs the FTC to implement detailed regulations to address these and other questions, and it tells them to investigate a do-not-spam list, similar to the do-not-call list for telemarketers and the do-not-fax list.

Spam fighters ask, why not just implement a do-not-spam-list? Direct Marketing Association (DMA) members match their outbound postal mailings through the do-not-mail list, purging out names who do not want to receive mail. Telemarketers are required by law to check their telephone dialing lists against the federal do-not-call list. The FTC requires fax marketers to obtain a recipient's permission before sending faxes.

In December 2003, it was reported that "The majority of Americans [83%] would sign up for a do-not-spam list, were the Federal Trade Commissioner to launch one" (Parker, 2003). However, spam is fundamentally different from other direct-response media, and notorious spammers have little incentive to comply.

The FTC has ruled that a do-not-spam list is impractical to implement under current conditions and would "do little or nothing" to halt unsolicited commercial e-mail. In contrast to the telemarketing list, a do-not-spam registry "would be ineffective because spammers can constantly

create new e-mail addresses and identities, and because it costs virtually nothing for a spammer to clog consumers' inboxes" (Mark, 2003a).

Investigators would be able to track down and close e-commerce sites maintained by legitimate marketers who have physical facilities, much as they can do with telephone and fax call centers, but prolific spammers would fight back. First, spammers could simply ignore the list. They are difficult to track and apprehend, and jurisdiction issues are complex. Second, given the global nature of the Internet, it is easy for them to pack up and move to a new location—frequently offshore in another country. Consumers would still get the spam, but would be deprived of legitimate marketing messages they may want or need.

In addition, a do-not-e-mail-list could be dangerous. Technically, it may be possible to prevent hacking and theft of a list, but human error—or payoffs—could open the door to spammers. An industry expert said, "[It] scares the hell out of me. If I were a spammer, it would be like the holy grail . . . millions of valid e-mail addresses. I can't think of a model the FTC would use that could prevent spammers from just getting a copy of it and going to town" (Mara, 2004b).

The FTC agrees. "Spammers would stop at nothing to obtain this list and misuse it to the detriment of consumers," it concluded (FTC, 2004).

Other problems would frustrate enforcement. Most people have multiple e-mail addresses. Compared with postal mail or telephone numbers, it is easy to change e-mail addresses, making list maintenance difficult. The length of the list would be enormous—and growing.

Instead of a do-not-e-mail list, the FTC recommended that "anti-spam efforts should instead focus on creating a robust e-mail authentication system" (Swartz, 2004b). These options are discussed in the conclusion of this chapter and in other chapters of this book.

### List Restrictions

The European Union has enacted highly restrictive legislation on selling and trading names in traditional postal mail and telephone lists. Some U.S. antispam advocates argue for similar restrictions on selling or trading names, but legitimate marketers argue that only they would be hurt. The notorious spammers operate with an underground economy and network of their own that ignores or circumvents such restrictions. Severe penalties, they say, would simply drive more spammer activities offshore, with little reduction in spam.

Companies doing direct marketing in the European Union have contests and other promotions that encourage consumers to submit names. Given similar restrictions, legitimate marketers in the United States say they would build their own house lists, too, and in the long-term, marketing messages would ultimately reach nearly equivalent levels. Meantime, they maintain, it would be time-consuming and expensive, resulting in higher costs to consumers.

Legitimate marketers argue that although some regulation is essential, excessive regulation prevents businesses from being free to innovate and offer new goods

and services. Consumers would lose, they say, and restrictions on list sharing would result in an immediate loss of jobs. Let the government demonstrate that they can enforce current laws, they say, before enacting new ones that would stifle business. Most legitimate marketers prefer to regulate through trade association restrictions that can be adapted more quickly to meet changing conditions. Antispammers say trade groups will not do enough to limit spam.

### Industry Self-Regulation

Trade associations apply association regulations and a code of ethics to their member companies. They support restrictions on direct marketing, but they argue that government regulation, once enacted, is inflexible and stifles creativity, causing job losses and economic dislocations—and ultimately lowering benefits for consumers. In the narrow sense, trade association regulation is not part of the "legal" counterattack, but the restrictions have much the same effect.

The DMA represents the majority of legitimate catalog, mail, and telephone marketers. Part of their mission is public education, keeping consumers from adopting negative attitudes. They have had a "do-not-mail" list for years and cooperate in reducing unnecessary postal junk mail. Their members are bound to observe do-not-call and do-not-fax lists. They publish guidelines for their members to observe responsible e-mail practices that minimize needless and annoying spam.

They maintain that most legitimate business, government, and not-for-profit organizations are not interested in harassing people. Members are given guidance not to send unsolicited e-mail to those who are unlikely to have an interest in or benefit from the goods, services, or ideas. Many antispammers and politically active groups concerned with commercialization in cyberspace argue that industry self-regulation simply allows the profit motive to define cyberspace.

In 1998, the DMA merged with the Association for Interactive Marketing (AIM), a newer, smaller organization that represents electronic commerce. Founded in 1993, the AIM describes itself as "a non-profit trade organization devoted to helping marketers use interactive opportunities to reach their respective marketplaces" (AIM, 2003). In 1999, the DMA absorbed the Internet Alliance, a similar organization.

In 2003, AIM, working through the organization's Council for Responsible E-mail, created a "best practices" document for legitimate e-mail marketers. The draft was designed to "help facilitate and distinguish permission-based e-mail communications sent by legitimate marketers from spam." It included recommendations for six major topics: consent, delivery, content, hygiene and suppression, education, and dispute resolution. Permission marketing is a small part of e-mail marketing. The DMA adopted a broader policy focusing on fraudulent e-mail.

In 2003, the DMA announced "Operation Slam Spam," targeting the 300 or so notorious spammers whom they contend send the majority of fraudulent e-mails. Soliciting its approximately 4,700 members to work with the

FBI, regulators, and ISPs, the DMA hoped to “terminate distributors of spam” (Khan, 2003).

## ENFORCEMENT AND PROSECUTION

### Issues with CAN-SPAM and State Legislation

The CAN-SPAM Act passed the U.S. Senate without a single dissenting vote. The House of Representatives passed it 392 to 5. One representative voting against it said, “While Congress has spent literally years grappling with the definition of spam, too little time has been spent considering enforcement of whatever framework is adopted” (Mark, 2003c).

Fraudulent or deceptive advertising regulations logically extend into cyberspace on both federal and state levels, but the CAN-SPAM Act gives the federal government a new set of weapons to pursue spammers. However, the FTC, state prosecutors, and ISPs were pursuing spammers even before the act, especially where the activity involved deception or fraud.

Efforts at regulation raise several issues in both state and federal jurisdictions: freedom of speech, jurisdictional issues, due process, the Commerce Clause regulating interstate commerce, trespass on chattels, and practical aspects of the mechanics of implementation and enforcement. The definition of “place” takes on an entirely new meaning in cyberspace, one that case law is only beginning to address. As the decade proceeds, we can expect to see case law more clearly defined.

### First Amendment

Should freedom of speech apply to e-mail? Anyone can stand on a street corner soap box and broadcast messages. Passersby can choose to listen or ignore it. Spammers and civil libertarians argue that spam is free speech, and restrictive legislation infringes on freedoms guaranteed by the First Amendment of the Bill of Rights. Direct marketers have almost no restrictions on postal mail. Why should e-mail be different?

It is commonly believed that “U.S. businesses have a First Amendment right to distribute unsolicited e-mail advertisements” (Swartz, 2003b, p. 20). However, anti-spammers can argue that e-mail shifts the burden of cost away from the sender and onto the consumer. Unlike other forms of direct marketing, spam costs almost nothing to the sender, but cumulatively more to the recipients. Under these conditions, they can say, free speech should give way.

In a commercial context, the freedom of speech issue is frequently seen as having unwarranted importance. Restrictions on direct marketing and other commercial messages already exist. In most jurisdictions, it is unlawful to sell or make sales pitches on the street without appropriate licenses or permissions. In February 2004, the federal do-not-call list was upheld by the 10th Circuit Court of Appeals. The do-not-fax list also has been upheld. Restricting e-mail, anti-spammers can conclude, is a reasonable extension to these regulations.

In 1997, *CompuServe versus Cyber Promotions, Inc.*, the U.S. District Court, citing case law, held that the First Amendment to the U.S. Constitution “provides no defense” for intentional unauthorized use of proprietary

computer equipment. This is discussed further in Chats, later in the chapter.

Specific content areas may be more problematical. For example, Fingerman (2004, p. 12; citing *Reno versus American Civil Liberties Union*, 521 U.S. 844 [1997]) observes that “the sexually oriented material provision [of the CAN-SPAM Act] may be difficult to defend if challenged under the First Amendment. It is content-based regulation of speech, which triggers strict scrutiny.”

In December 2004, Microsoft filed seven lawsuits against “John Doe” spammers, alleging that they did not use “Sexually Explicit” in the subject line, sometimes called the “brown paper wrapper” rule (Naraine, 2004). In January 2005, the FTC filed suit against one individual and six companies who allegedly did not follow that rule (Associated Press, 2005a, 2005b). It will be interesting to see how those cases proceed through the legal system, with potential First Amendment and other challenges.

### Jurisdiction and Due Process

If limits can be put on e-mail, what jurisdiction should do it? In the 1945 *International Shoe* decision, the U.S. Supreme Court determined that “To have proper jurisdiction, a defendant must have purposely availed itself of the privilege of doing business (i.e., traveling, selling, advertising, and so on) in a state, and these “connections” to that state must meet minimum levels of due process” (Powers, 2002, p. 129).

How do you determine “where” a company operates? In the United States and most of the world, laws are often based on physical presence: a “place” that is identifiable, physical, and addressable. Jurisdiction usually resides there. For example, where a car accident takes place or a descendent resides, the rules are fairly straightforward.

Today, case law avoids the notion that a physical presence is necessary for jurisdiction, but is based on “purposeful availing” of the benefits of the forum state. The jurisdictional standard of purposefully availing oneself of the privilege of doing business is met, for purposes of claims arising from the defendant’s activities in a state, where there are numerous transactions with residents of the state. Thus, for example, in 2002, where a domain name registrant allegedly engaged in some 5,000 transactions with Ohio residents and its site was accessible in Ohio, the Sixth Circuit held in *Bird versus Parsons* that it was subject to Ohio’s jurisdiction.

Still, the question has become more complex. The boundaries of cyberspace do not have the usual physical characteristics. A company may have its headquarters in Delaware, their sales office in Florida, their Web server in Virginia, and their e-mail server in California. Signals divided into packets travel to their destination through multiple routes, which can be anywhere. In 1945, in contrast, it was relatively easy to determine whether a company was doing business “in” a state.

The courts have held that “even if both sender and recipient are in the same state, the spam may still cross state lines before it reaches its destination and thus qualify as interstate commerce” (Kelin, 2001). In *American Libraries Association versus Pataki*, the judge addressed the position that such commerce might remain in-state and ruled that “no intrastate communications exist” in that matter.

Another issue in state law is whether jurisdiction would apply to residents in unusual circumstances. For example, would it apply when a resident opens his or her e-mail out-of-state? In two challenges to the Commerce Clause (discussed next), the court found that to be a “jurisdictional question not at issue in this case” (Pink, 2002, p. 13).

Additional citations for jurisdiction issues are given at the end of this chapter under “Additional Reading.”

### The Commerce Clause

The biggest challenge to states enforcing their antispam laws probably has been the Commerce Clause in the U.S. Constitution (U.S. Const., art. I, §8, cl. 3), which says, “Congress shall have power . . . to regulate commerce . . . among the several states.” Because spam is commerce and interstate commerce is regulated by federal law, to what extent can it be regulated by the states?

The Commerce Clause generally prohibits states from legislating beyond their borders or enforcing laws and regulations on entities operating beyond their boundaries. The limitation is implied, and so it is commonly called the “dormant” Commerce Clause.

Several state laws recognize spam restrictions that have been held in case law to be compatible with the dormant Commerce Clause. The courts have looked at two factors: First, does the state law discriminate against interstate commerce? Second, does the legislation impose a burden on interstate commerce that is excessive in relation to the local benefits?

Most of the 37 states that have enacted antispam legislation have attempted to control fraud or deceptive practices—regardless of where they originated. In formulating their laws, for example, both Virginia and California employed a similar provision: It applied state law to spammers who live outside the state. In *State of Washington versus Heckel*, Washington’s law, which carried the provision, was challenged and carried to the Washington Supreme Court in 2001.

The Washington Supreme Court upheld the state’s antispam law, and the U.S. Supreme Court refused to hear an appeal, effectively returning the matter to the lower court for trial. The finding was that the dormant Commerce Clause “implicitly operates as a limitation on state laws when such laws unduly burden interstate commerce.” However, “The law is not unconstitutional if it regulates evenhandedly to effectuate a legitimate local public interest, its effects on interstate commerce are only incidental, and the burden it imposes on interstate commerce is not clearly excessive in relation to its putative local benefits.”

On the topic of consumer protection, it was held in *Heckel* that “a requirement that an advertiser transmitting advertising directly to consumers in their homes or offices be truthful about the source of the advertising and does not burden commerce so much as facilitate it, by eliminating fraud and deception.” In responding to the complaint that e-mail addresses generally do not identify the physical address of recipients, the court found that a public registry of e-mail addresses maintained by Washington, defining what e-mail addresses belong to Washington residents, was acceptable. Thus, states considering drafting new antispam legislation may consider *Heckel* a

blueprint for what has worked in applying laws and regulations compatible with the Commerce Clause.

A 2002 California antispam case also gives guidance on the requirements for states passing laws that can apply against out-of-state spammers. In *Ferguson versus Friendfinders* the Court found, “The state has a substantial legitimate interest in protecting its citizens from the harmful effects of deceptive UCE” (unsolicited commercial e-mail); and “A regulation serving an important public interest is upheld unless its benefits are outweighed by the burden imposed on interstate commerce.”

Pink (2002) and others (“California Anti-Spam Law,” 2002) give more details of the explanation in both *State of Washington versus Heckel* and *Ferguson versus Friendfinders*, and the issue has also been decided at the federal level.

In December 2003, a federal judge dismissed an action by America Online (AOL) against a Florida group on a jurisdiction technicality but allowed AOL to overcome the objection by refiling an amended complaint within the bounds of the Commerce Clause (Reuters, 2003b).

In March 2004, AOL filed two suits in the U.S. District Court for the Eastern District of Virginia alleging violations of Virginia’s Computer Crimes Act. The defendants, Davis Wolfgang Hawke, his associates, and numerous John Does, were charged with sending millions of deceptive and fraudulent unsolicited bulk e-mails. In *America Online, Inc. versus Hawke, et al; America Online, Inc. versus Does*, AOL alleged that the defendants were responsible for “triggering hundreds of thousands of Member complaints,” by using fraud or deception.

The solicitation included mortgage leads, business opportunities, subscriptions to adult content Web sites, penis enlargement pills, weight loss supplements, handheld devices advertised as “personal lie detectors,” and a product called “The Banned CD.”

The complaint alleged that the defendants used “header information that was materially false or materially misleading,” failed to include a “From” line “that accurately identified any person who transmitted or procured the transmission of the message, . . . contained subject headings that defendants knew, or should have known, were likely to mislead a recipient, . . . with the intent to falsify or forge electronic mail transmission information or other routing information,” and intended to “sell, give, or distribute software that is primarily designed or produced for the purpose of facilitating or enabling the falsification of electronic mail transmission information or other routing information.”

### Trespass and Nuisance Claims

ISPs have challenged spammers on several grounds, including trespass to chattels, conversion, service mark infringement or dilution, fraud, unfair trade practices, and unfair competition. Of these, chattel claims have been most receptive to the courts (Sinrod and Reyna, 2000).

In 1997, in *CompuServe versus Cyber Promotions*, the court addressed whether the defendants were trespassing on CompuServe’s personal property and held, “Trespass to chattels has evolved from its original common law application, concerning primarily the asportation of another’s tangible property, to include the unauthorized use of personal property.”

"Its chief importance now," it continued, "is that there may be recovery . . . for interferences with the possession of chattels which are not sufficiently important to be classed as conversion" (the Court called it "a little brother of conversion"). Further, "electronic signals sent by computer have been held to be sufficiently physically tangible to support a trespass cause of action." Thus, "Plaintiff has a viable claim for trespass to personal property and is entitled to injunctive relief to protect its property."

A source at the Internet Law Group, in a 2003 review of legal counterattacks, believes indiscriminate e-mail is "already illegal in all 50 states" and should be prosecuted based on chattels law (Schwartz, 2003).

In 1999, in *Intel versus Hamidi*, a California trial court extended the reach of chattel claims to noncommercial bulk e-mail. A former employee, Kourosh Hamidi, allegedly sent e-mails critical of Intel to some 35,000 employees through Intel's systems. In 2004, the California Supreme Court overturned the trial court, holding that "Hamidi did not commit trespass because Hamidi did not damage the computers" (Oriez, 2004b, p. 2). Because commercial spam does not damage computers, this ruling seems inconsistent with the CompuServe ruling, and it demonstrates the intricacies of relying on chattels claims.

Mossoff (2004, p. 625) took the position that ISPs and others should sue the spammers for creating a nuisance.

Nuisance doctrine is superior to the currently favored "trespass to chattels" because it does not require courts to engage in unnecessary legal fictions or doctrinal somersaults in finding that spam has "dispossessed" a plaintiff from its computer network [through] unreasonably and substantially interfering with an ISPs commercial operations—a paradigmatic nuisance injury.

Citations for additional case law relating to trespass to chattels, trademark infringement and dilution, and breach of contract claims by ISPs are given at the end of this chapter under "Additional Reading."

### Other Prosecutions

On December 10, 2003, two Florida mortgage scam operators—who were *not* national mortgage lenders, but were advertising "3.95% 30 Year Mortgages"—were required to post \$1 million bonds before sending any more unsolicited commercial e-mail. In addition, they were barred from using or benefiting from personal information that was deceptively collected from consumers (Mark, 2003b). Their real purpose was to collect consumer information, including social security numbers, income, and assets—information that could be sold. This is a variation of "phishing," discussed earlier in this chapter.

In late 2003, the FTC brought action against a software company accused of spamming PC users with pop-up ads and e-mails promoting its spam-blocker software. "In essence, defendants bombard an individual consumer with a stream of repeated, unwanted pop up spam in an attempt to induce the consumer to pay defendants to stop the bombardment." The FTC called it "nothing short of extortion" (Callaghan, 2003; Saunders, 2003). In 2004, the company agreed to stop the practice and submit to FTC monitoring for 5 years.

The pop-ups exploited a "feature" in Microsoft Windows called Messenger Service (subsequently addressed in XP Service Pack 2). The company "allegedly claimed it could send pop-ups to as many as 135,000 Internet addresses each hour and had a database of 2 billion addresses" (Manning, 2004). On July 31, 2004, the company reached a settlement in U.S. District Court in Maryland specifying that the company "will no longer send pop-up ads using the Windows Messenger Service or sell software that blocks such ads." The company also was restricted from sending e-mail solicitations.

New York has relied on standard consumer protection laws to prosecute spammers. In late 2003, New York Attorney General Eliot Spitzer, who has aggressively pursued securities fraud and antitrust issues, teamed up with his old nemesis Microsoft to file \$38 million in lawsuits, with a mission "to put [fraudulent] spammers out of business for good." Spitzer maintained, "We want to prove to others who are spammers that the penalties will make it financially unviable. When we catch you, we'll drive you into bankruptcy" (Naraine, 2003).

Sampling 8,000 e-mails between May 13 and June 13, 2003, Spitzer's team detected 40,000 fraudulent statements in "separate marketing campaigns that passed through 514 IP addresses around the world," including hijacked computers "belonging to a foreign government's defense ministry, . . . a hospital, and . . . elementary and high schools." The spam messages "used other people's sender names, false subject lines, fake server names, inaccurate and misrepresented sender addresses, or obscured transmission paths, all in violation of New York and Washington state law" (Naraine, 2004; Sears, 2003).

AOL has been active in pursuing spammers, with successful lawsuits against spammers in *Verizon versus Ralsky*, *AOL versus CN Productions*, and others. Recent AOL lawsuits have been part of a coordinated action by members of the Anti-Spam Coalition, formed in April 2003, including AOL, Earthlink, Microsoft, and Yahoo! The Coalition filed legal complaints in federal courts in California, Georgia, Virginia, and Washington State alleging that the defendants sent "a combined total of hundreds of millions of bulk spam e-mail messages" seeking deceptive solicitations (Business Wire, 2004). An AOL spokesman said, "Congress gave us the necessary tools to pursue spammers with stiff penalties, and we in the industry didn't waste a moment moving with speed and resolve to take advantage of the new law" (CNN, 2004b).

A list and description of AOL cases has been active at <http://legal.web.aol.com/email/jeaol/index.html>. Cases involving other ISPs may be found at <http://www.jmls.edu/cyber/cases/spam.html#cs-cp>.

In April 2004, FTC authorities filed criminal charges under the CAN-SPAM Act against four alleged spammers who were arrested in Detroit and accused of disguising their identities in sales pitches for fraudulent weight-loss products. The FTC also announced legal actions against an Australian company. It was reported that FTC Chairman Timothy Muris said, "These cases should send a strong signal to spammers that we are watching their operations and working together to enforce the law" (Associated Press, 2004).

## Defining Spam

The ultimate interpretation of laws and regulations in the legal counterattack—and the basis for enforcement—resides in the courts. The system has served the United States well over the past 200+ years and is a model for democracy everywhere.

The legal system was designed in an era when things moved slowly. Fast-moving new events such as spam have not always fared well in a traditional court environment. Spam is so new that many of our legal institutions are learning as they go. Definitions are crafted laboriously, but inconsistently in different jurisdictions. Months or even years of delay are normal in deliberating and handing disputes.

With global communication at lightening speed, prolific spammers spite the slower moving court system, setting up shell corporations in far-flung locations and finding definitional loopholes to put them back in business. They use protections designed for an earlier, slower moving era or operate with untested methods that have not been codified into law. They push the limits of what is legal and ethical. Many simply ignore the law, hoping to evade apprehension and enforcement.

Enforcement requires definition. The CAN-SPAM Act leaves much of the implementation to the FTC, which will be tested in the courts. In the courtroom, laws and regulations rest on definitions in determining prosecution and conviction, a process that exposes grey areas. As case law related to spam progresses, definitions will be clarified. In the broader sense, how spam is defined will have enormous implications in the New Millennium for both consumers and marketers, as it creates standards against which ethical, moral, and legal behavior is judged.

### Commonly Used Definitions

A definition can be restrictive or permissive. In November 2003, the Pew Internet & American Life Project (2003) reported that “92% of e-mail users agree that spam is ‘unsolicited commercial e-mail from a sender they do not know or cannot identify,’” and 32% extend this to a sender with whom they “have already done business.” E-mail is an invasion of privacy, they say. Let’s allow e-mailing *only* to people who have specifically requested it. Businesses and freedom of speech advocates can counter that if consumers understood the economic implications, they would approve responsible, legitimate commercial messages—at least a “one bite” approach.

Let us consider four definitions of spam commonly used in legal counterattacks (Sullivan, 2003b). Two include *single* unsolicited e-mails, and the others specify “bulk.”

1. UCE: *unsolicited commercial e-mail*, usually excluding unsolicited political messages
2. UBE: *unsolicited bulk e-mail*
3. UCBE: *unsolicited commercial bulk e-mail*
4. UEMS: *unsolicited electronic mail solicitations*

UBE is identified in AOL’s 2004 filings (*America Online, Inc. versus Hawke, et al.* and *America Online, Inc. versus Does*). UCE and UBE have been used by courts in making

spam rulings (*State of Washington versus Hecke*; see also *Verizon versus Ralsky*). UCE is compatible with the CAN-SPAM Act and avoids some interpretation questions.

For example, what is the numeric definition of “bulk?” Would it matter if the same e-mails were sent in smaller, multiple batches? How many could be sent within any hour or twenty-four-hour period, regardless if batch or individual? What is “unsolicited?” “Commercial?” Must it be selling a product? What about lead generation, or surveys, contests, service bulletins, electronic magazines and newsletters, news services, and other content? What about sending a message asking parents in your child’s school to donate to the athletic fund? When does e-mail “misrepresent” an offer or the “originator” or attempt to “confuse” or “defraud” people? Each of these terms requires its own specification.

Is spam only e-mail? Pop-up ads, banners, animated graphics, voice messages, spyware, required forms or registration, and other Web clutter is electronic, unsolicited, and a lot like spam. What is their relationship to e-mail spam? Should these be included in legal definitions of spam? Privacy advocates can argue that all of these—and other undiscovered techniques and devices—are similar to an unwanted guest walking through a home’s front door: an invasion of privacy.

It is not in the scope of this chapter to resolve these questions, but it is useful to present them. Under the CAN-SPAM Act, the Federal Trade Commission will formulate appropriate regulations, and states will add compatible provisions. It will be interesting to see how the court system deals with the issues discussed here in applying case law.

### Restrictive Definitions

Restrictive definitions include the so-called zero-tolerance policy—“*any* unsolicited e-mail,” or “*any* e-mail that is not relevant or interesting.” This, it can be argued, effectively would prohibit *any* unsolicited communications, even the “one-bite” approach.

The operational deficiency is obvious: If I find Susan Kathleen in the white pages and send her an innocent e-mail to ask if she is the same person I dated in high school, oops! That’s spam. To remedy this, some would include “any e-mail that is not relevant or interesting,” again an unworkable solution (How will I know if the recipient will find it relevant or interesting?). Definitions that include “unwanted” would have similar problems. Because senders cannot know individual responses ahead of time, they would surely send spam.

Gratton (2004) reported on a suggestion from Australia’s National Office for the Information Economy that would define spam as “a communication that could not be reasonably assumed to be wanted or expected by a recipient.” The ambiguous language used for this judgment would likely be perplexing to and unevenly applied by courts, as penalties were to be applied.

Highly restrictive definitions are sometimes used to generate statistics quoted by the mass media. Companies that sell filtering software benefit from copy such as, “The bad news is that the tipping point has been reached, as [our filters] classified 50% of all measured e-mail as

unwanted messages” (Greenspan, 2003). The definition being used is seldom reported in a media “sound bite.”

### Permissive Definitions

Free-speech advocates may argue that they want *no* restrictions beyond outright fraud. They would argue for permissive definitions, where people can ignore unwanted e-mail and decide for themselves what is objectionable. People, they can point out, sometimes want information about things they claim to despise.

In January 2004, half of the top ten affiliate program “clickthroughs” (*voluntarily* clicking on an ad to go to a Web site) were for health, dating, or vitamin sites, including an herbal Viagra alternative—commonly objects of spam e-mail (CyberAtlas, 2004).

Some users publicly denounce spam, but privately open the unsolicited commercial messages voluntarily—and the products sell. In June 2003, *USA Today* reported, “Commercial e-mail ads produce more than \$7.1 billion in sales annually” (Swartz, 2003a). The October 2003 Pew Internet & American Life Project (2003) poll found that 7% of e-mailers, more than 8 million people, reported ordering a product or service originating in spam.

Some users want spam. The *Wall Street Journal* noted, “If everyone hated spam, it would disappear,” and reported on Orlando Soto, who “routinely comes home to some 150 e-mail pitches, and he loves getting them all” (Mangalindan, 2004). Mr. Soto, the article said, buys aromatherapy oils, pharmaceuticals, mystery novels, home games, and other items. Spam, it seems, “helps him ‘unwind’ and ‘lose the stress of the day.’ . . . Good spam, he says, leaves him feeling blessed.” Others, of course, feel cursed.

### Opt In, Opt Out: Four Alternatives

Implementing any definition usually considers four alternatives. You may be prohibited from contacting anyone. At the other extreme—probably Mr. Soto’s preference—you are free to contact everybody. Opt-in and opt-out are the two middle cases.

*Opt in* says that a marketer may only contact people who have expressed an interest in their product and given explicit permission to contact them. This means that marketers must have some initial contact and secured their permission prior to sending any e-mail messages. The “double confirmed opt in” is more restrictive. A user must opt in, and then after receiving an e-mail message, opt in again confirming the first opt in.

*Opt out* means that marketers may send unsolicited e-mail messages to prospects without prior permission. They may continue to do so until the recipient explicitly denies permission for more mailings. This is sometimes called the “one bite” approach. It is less restrictive than opt in, but more restrictive than free access.

### Permission Marketing

In the past several years, “permission marketing,” a special case of opt in, has become a buzzword. Consumers volunteer to receive product information. Otherwise, they are not contacted. Seminars, articles, and books have extolled the virtues of marketing only to individuals who

have explicitly expressed an interest and given their permission to be sent e-mail messages. In 2003, eMarketer estimated that “76 billion messages are sent out annually through legitimate opt-in marketing campaigns” (Powell, 2003).

In practice, most people do not opt in to permission marketing lists, but almost everyone unknowingly ends up on them. They seldom know they are subscribed or how to be removed.

Many offers, contracts, and terms-of-use agreements have obscure passages buried within them allowing the list owner to interpret “permission.” Technically, a user may have “agreed” to receive e-mail at some time in the past from “associated organizations” or “affiliates,” which can mean almost anything. Some opt-in arrangements mean that *any* future offers are thereby “solicited.” These “opt-in” lists are sold or rented out by list compilers and brokers.

In addition, many are fraudulent. Lieb (2003) described “black hat developers [who] write bots that can opt you in again and again,” using robotic crawler software to harvest e-mail addresses. Once a list is sold or otherwise passed on, it is difficult to trace how a person was placed on it.

Until the CAN-SPAM Act, there was no nationwide requirement for an opt-out button or a sender’s address, so recipients couldn’t get off the lists. When those buttons did appear, they were often used only to validate the address, and many e-mail users still are reluctant to try to opt out.

## EFFECT OF THE LEGISLATIVE COUNTERATTACK

The CAN-SPAM Act is the beginning of what is likely to become a continual effort at regulation at the federal level. Like most legislation, the act is unlikely to please those with strong opinions on either side. It does not put an end to all unsolicited e-mail, and it puts limits on spammers and legitimate marketers.

### The Government Perspective

A White House spokesman said that spam is “annoying to consumers and costly to our economy,” and the act will curb abuses by “establishing a framework of technological [and] administrative civil and criminal tools” (Associated Press, 2004).

Senator Charles Schumer (D-N.Y.), who maintains that 250 spammers are responsible for 90% of the e-mail being sent said, “We are saying to those 250, no matter where you are, or how you try to hide your spam, we will find you. This bill gives the FTC and the Justice Department the tools to go after you” (Gaudin, 2003).

### The Spammer Perspective

In May 2004, at the invitation of Senator John McCain, Ronald Scelson, the Cajun Spammer, returned to the U.S. Senate to testify about the new regulations. Scelson (2004), who claimed to be following the law, said, “The act that is to curtail fraud is in fact curtailing our ability to

engage in free enterprise.” [It] “begins to look like small business against big business.” Other spammers have similar complaints.

After working diligently to become “white listed” by AOL, Scelson says WorldCom, his ISP, worked behind his back to convince AOL to revoke that status based on a count of undeliverable e-mails. These “bounce-backs,” he said, were from an old list, and “the only way to get the bad addresses out of the list was to deliver into AOL and pick up their nondeliverable reports back to us. . . . WorldCom stepped in and tried to shut me down even after AOL sent proof of our white list classification.”

Scelson also complained that “blacklist” organizations have disregarded the CAN-SPAM Act, saying they “act like vigilantes now more than ever before. These groups will not remove the blacklist even if you prove to them that you are compliant with the new legislation. . . . They do not identify themselves like we do so pursuing legal action against them is nearly impossible. Many of these groups are not even on U.S. soil.” Further, he says, they “use automated systems to generate multiple complaints to the Internet service providers.”

### The Antispammer Perspective

In mid-2004, Swartz (2004d) reported that e-mail users “have seen little reprieve in the amount of unsolicited e-mails that fill their inboxes each day.” Advocates of the act say there has not been adequate time to change spammer behavior. Several lawsuits filed against alleged spammers by large ISPs have yet to work their way through the system.

Many antispammers call the CAN-SPAM Act a “flop.” Often, these are advocates of a much more restrictive definition of spam. Although the Act permits ISPs to sue, it prevents individuals from suing spammers—a provision in the California law that legitimate marketers maintained would result in legal chaos. Ray Everett-Church of the ePrivacy Group said, “This is a pretty bad bill. . . . It actually legitimizes most forms of spam” (Gaudin, 2003). He assumed a restrictive definition.

Antispammers are concerned that relatively liberal access to prospects through list sharing and the CAN-SPAM Act’s failure to allow individuals to sue leads to a “slippery slope” that will encourage reckless e-mail spam.

### The Business Perspective

Legitimate marketers have welcomed a nationwide universal standard that they can observe, and they are “happy to comply with” the CAN-SPAM Act (Kuchinskas, 2003a). The act provides consistency and—what they believe Congress intended—a consideration for the concerns of both consumers and legitimate businesses that depend on communicating with customers.

Marketers maintain, “Laws against unwanted e-mails will have little effect on the real culprits—the mass spammers—[while] keeping track of e-mail addresses, permissions, and the documentation required to fend off lawsuits could become a major overhead headache for firms deploying e-mail” (Oliva, 2004).

Some businesses complain that the CAN-SPAM Act gives legitimacy to the argument that companies have

an obligation to protect employees from spam. Oriez reported that “there have been a number of suits against employers by employees who allege that failing to block pornography created a hostile work environment” and discussed several cases (Oriez, 2004b, p. 3).

Established marketers and trade groups such as the DMA see overregulation as the “slippery slope” to be avoided. Although legitimate marketers may reduce or eliminate some mailings, most of them are expected to implement the act’s legal provisions and continue what they consider to be ethical practices.

### The States’ Perspective

The 37 states that enacted legislation before 2004—and others such as New York that rely on conventional fraud and deceptive business practice law—have been upstaged by the CAN-SPAM Act. Although many of the states recognize the advantages in uniformity, lawmakers in states such as California that envisioned more restrictive measures have been disappointed. They have an opportunity to work with federal officials to strengthen the act, or they may devise additional provisions that are not in conflict with the act (“carve-outs,” discussed elsewhere in this chapter), but their constituents are primarily bound by the federal rules.

## THE GLOBAL PERSPECTIVE

While this chapter has focused primarily on the legal counterattack against spam in the United States, spam has a global presence. Consumers worldwide are receiving more and more unwanted spam, and many spammers have moved outside the United States to avoid laws, regulations, and enforcement.

### The Movement Offshore

As the CAN-SPAM Act and state legislation has become more restrictive, many spammers simply ignore it or move offshore, outside the jurisdiction of federal and state courts. Even if they can be found, they usually do not comply with the dispute resolution methods. An industry insider said, “The law won’t affect true e-mail abusers, against whom it was written” (Soltoff, 2004).

A February 2004 article quotes the director of the FTC’s Bureau of Consumer Protection: “There certainly hasn’t been any significant reduction in the number of spams that have been forwarded to our mail boxes” and concluded that “Spammers have already figured out quick ways to get around the rules” (Fox News, 2004).

After the act became law, a *Washington Post* article reported that AOL’s spam fighting group determined the following: “Of the roughly 2.4 billion pieces of spam AOL blocks a day, there has been a roughly 10 percent shift in their origins to overseas-based Internet addresses” (Krim, 2004). That percentage is increasing.

Industry analyst Sara Radicati concluded, “The worst spam is being sent from offshore. It’s malicious and there’s tons of it. . . . This is going to have absolutely no effect on the most disruptive, the most offensive, the most hard to deal with spam” (Gaudin, 2003).

## European Legislation

Spam in Europe has risen dramatically, prompting one writer to conclude, "Europe has overtaken North America as the most digitally attacked continent" (Greenspan, 2003). A 2003 study found that spam cost European businesses \$2.5 billion (Swartz, 2003a). In response, the European Union has increased enforcement of cyberspace.

The European Union issued a Directive on Privacy and Electronic Communications 2002/58/EC requiring all member nations to enact antispam laws by October 31, 2003 (although only six complied on time). The regulations also cover direct marketing by telephone and fax, lists, Internet cookies, and other means and generally are more restrictive than in the United States. Europe is blaming "weak" U.S. laws for most of the spam in Europe (Gratton, 2004).

In December 2003, based on the Directive, the United Kingdom enacted antispam legislation (see Stokes & Bramwell, 2004, for details of the law). The tighter rules were found to have done little to control spam, and the U.K. compliance officer "received complaints in the hundreds from annoyed e-mail users disillusioned by the buildup to the law's enactment." An observer is quoted, "Unless there is a globally ratified act it is never going to be very effective" (Bishara, 2004).

Nettleton offered an in-depth analysis of problems in the U.K. implementation, including the statement that "the vast majority of spam originates from the USA and Asia, and hence the implementation of the Directive is likely to do little to cut down its volume" (Nettleton, 2004).

A journal report supports Nettleton's figures. "Several studies have revealed that at least 50% of all unsolicited e-mails originate in the United States" (Swartz, 2004c).

In January 2004, a report said the European Union Commission determined that "the new Directive... in many cases, is ineffective... [and] admitted that further action was needed to combat the problem of junk e-mail." Measures being considered include additional investigatory powers, allowing victims to claim damages, aggressive filtering, and international cooperation (Bennett, 2004).

The European Coalition Against Unsolicited Commercial E-mail (EuroCAUCE) is an outspoken advocate of making e-mail adhere to the same standards as postal, telephone, and fax marketing, including the bias toward opt in. It has helped the European Union develop opt-in regulations similar to those for their postal mail (EuroCAUCE, 2003).

EuroCAUCE published a proposed timeline of regulation extending through 2006 that includes a do-not-e-mail list. However, EuroCAUCE does not effectively address the widely debated differences between those media and e-mail that lead many to conclude that such a list will be ineffective or even dangerous (discussed earlier in this chapter).

## Growing International Action

As definitions and enforcement become tighter in the highly developed nations, spammers are moving offshore, operating anywhere in the world. An April, 2004, Com-

touch study reported that 71% of spammers' Web sites are hosted in China, and 60.5% of the global spam is sent from the United States, demonstrating that "spam is a global problem" ("China—Main Source of Spam E-mail," 2004, p.1).

Countries across the globe have been active in investigating or enacting new legislation, including Singapore, Taiwan, Thailand, and China. Korea reportedly is testing a fee-for-e-mail, based on the number of sent messages, which has resulted in a decline of spam (Charron, 2003).

In 2002, ISPs in China agreed to form a coalition to counter the distribution of spam and computer viruses over their servers, prompted by "press reports that, over the past year, servers in both North America and Europe have blocked all e-mail from China" (Fishman, Josephberg, Linn, Pollack, & Victoriano, 2002, p. 31). The coalition also proposed the establishment of the "China Anti Junk Mail Association" that would "disseminate information regarding servers that accommodate spammers."

In 2004, spam-blocking organizations reported that China and Korea each accounted for approximately 10% of spam traffic that could be identified by country of origin. Argentina and Brazil "seem to have fallen into disuse recently," perhaps because ISPs there are taking action (Oriez, 2004a, p. 29).

Canadian policy, in 1999, suggested that "specific anti-spam legislation was not needed," instead relying on existing fraud and consumer protections. As spam volume has risen, however, Canada is considering additional legislation (Gratton, 2004).

Effective January 1, 2001, e-mail addresses were defined as "personal information" under Canada's existing Personal Information Protection and Electronic Documents Act (PIPEDA). Swartz (2003b, p. 22) reported that under these rules, "Computer mischief offenses could apply in cases where spamming would interfere with or obstruct a person's access to data or use of a computer system and the sender was reckless in that he or she understood that this would likely occur." Punishment could be up to 10 years in prison.

Many observers feel that without multinational agreement, it is "unclear whether national laws will stop spam" (Raysman & Brown, 2004). Spammers can set up almost anywhere in the world. A legal newsletter concludes, "International measures may be necessary to truly eradicate fraudulent spam" (Bick, 2004b).

Kelin (2001, p. 435) observed,

Spam is a nationwide, even worldwide, problem. Even if spam were outlawed in an entire country, it could still be sent into that country from elsewhere. Thus, outlawing spam in the United States may simply result in spam being sent via foreign ISPs that are not subject to U.S. laws.

The United Nations has announced that it would attempt to "standardize legislation to make it easier to prosecute senders of junk e-mail" (Swartz, 2004b). International action would include some form of defining and enforcing prohibitions. One of the barriers to agreement will be the difference of opinion on whether opt out or opt

in will become the standard. The United States favors opt out, whereas Europe and much of the rest of the world prefer opt in (Swartz, 2003b).

In July 2004, an international conference in Geneva, sponsored by the United Nations International Telecommunication Union (ITU), was attended by UN officials and representatives from 60 countries. The need for legislation, new technology to control unsolicited e-mail, phishing and other forms of electronic fraud, and closer international cooperation and support from ISPs and other industry sources were included on the agenda. At the meeting, the UN agency said it would present “examples of anti-spam legislation that countries can adopt to make cross-border cooperation easier” (Lemke, 2004). Reportedly, part of the ITU solution involves “fundamentally changing the nature of the Internet and SMTP” (the technical specifications for simple mail transfer protocol; Wagner, 2004).

The Organization for Economic Cooperation and Development, which has attempted to regulate international handling of personal information since 1980 through the Code of Fair Information Practices, has published new “suggested guidelines” for dealing with spammers and “protecting consumers from cross-border fraud” (Gratton, 2004).

Currently, there is no effective international law or court system to deal with individual entities in commercial matters. It may be possible to approach spam through the World Trade Organization, IMF, or World Bank, where it would be in the economic interests of nations to participate in spam reduction or face sanctions.

## CONCLUSION

Discussing what he calls “The Tragedy of E-mail,” Charron (2003) cited Garrett Hardin’s 1968 article titled “The Tragedy of the Commons.” For assets shared in common (such as cyberspace), “The individual benefit of utilizing that asset always outweighs the more remote long-term harm in destroying the asset as a whole.” With spam, “The cost of using the asset is zero, and individual benefits seem to outweigh the incremental destruction to the asset as a whole.” In other words, the spammer takes short-term benefits, and society ultimately suffers.

The Internet evolved out of its military origin into a cooperative, loosely administered collection of collegial users who, for the most part, followed etiquette and reasonable rules designed to benefit all of the users. Primary domain names (.mil, .edu, .net, .gov) were designed to quickly identify types of users. Second-level domain names (.adv, .porn, etc.), if observed as intended, would make it easy for users to filter out unwanted communications. As the Internet became more mature, however, spammers and others with personal gain motives have ignored the informal conventions and codes of conduct. Instead, they exploit it to the detriment of the larger community.

Spam is a problem that took a relatively short time to develop, but may take considerable time to control. One observer notes, “While spammers are on the run, they are still winning the race against corporations and government officials trying to shut them down. For every spam-

mer put out of business by a lawsuit, probably hundreds of newbies are being trained in secretive ‘spam clubs’ around the Internet. For every account shut down for illegal activity, thousands more open up” (Sullivan, 2003b). The legal counterattack can help.

The legal counterattack on spam sets out a legislative game plan to mitigate the potential degradation of our collective cyberspace commons. The CAN-SPAM Act establishes, for the first time, a relatively consistent set of rules for senders of commercial e-mail. It standardizes, it sets a foundation, and it leaves room for legitimate marketing in cyberspace. It attempts to balance the macro-micro dilemma, although it is unlikely to satisfy extremes on either end of the issue. Other nations and economic unions have taken similar action, more or less restrictive.

Legislation is only one piece of the mosaic in the evolving counterattack on spam that will define society’s interface to cyberspace. It is not a perfect world, and those who demand “There oughta be a law!” sometimes are chasing the chimera of a perfect legislative solution, which does not exist. As the evolution of opposing points of view and society’s experience with cyberspace becomes more mature, a series of measured responses will reconcile the divergent interests of antisammers, commercial marketers, Mr. Skelson, Mr. Soto, privacy advocates, and others.

The legal counterattack is only one means of dealing with spam. Stanford law professor Lawrence Lessig, in his 1999 classic, “The Law of the Horse: What Cyberlaw Might Teach,” said, “[of] the collection of tools that a society has at hand for affecting constraints upon behavior, . . . law . . . is just one of these tools.” Lessig offered four interdependent “modalities of regulation in real space and cyberspace” that include law, social norms, markets, and architecture.

Today, the notorious spammers flout the Net’s social norms. And, until profit is taken out of spamming, the market modality can make them money. By architecture, Lessig meant the physical world, including cyberspace structures. The architecture, or “code,” he argues, can be changed. That would include “the software and hardware that make cyberspace the way it is.” Government can “take steps to alter the Internet’s design. It can take steps, that is, to affect the regulability of the Internet.”

Just because the laws are written as they are, and understanding that the laws often lag technology, does not mean we have to wait for a legal counterattack to catch up. We can be proactive in other ways. Combating spam can be a unified goal, with many entities collaborating to accomplish the desired end result. For example, the law says that port scanning is legal (*Moulton versus VC3*), but we do not have to allow that activity to take place in our networks. Similarly, we know that looking at pornography is legal for adults, yet most companies have established rules (codes) about no pornography at work. Network administrators need effective processes to keep up with filtering on the border (of the local network), users need to notify administrators when spam comes through and when other e-mails do not, and the administrators need to notify the FCC and law enforcement who can track down spammers.

In September 2003, Lessig suggested that technologists be given more input into the debate. “We should be

embarrassed by how extraordinarily poorly our legal system works” (Coffee, 2003). In January 2004, at the National Spam and the Law conference in San Francisco, Lessig said, “The [CAN-SPAM] Act won’t stem the tide of spam” (Mara, 2004a). The legal counterattack game plan needs execution and control, but it needs technology, human-user actions, and other complementary solutions to help bring spam under control.

Schwartz (2003) outlined seven technology solutions, but says “technology alone will never win the war.” He concluded that the legal counterattack needs to be coordinated with technology solutions and other means of controlling spam.

Technology solutions may include authentication, sophisticated filters that can use artificial intelligence and other learning techniques to reduce the false positives, better virus checking, more effective closing of “backdoor” access to computer intruders, more secure operating systems, and better service bureau tools. Webber (2004) offered several practical solutions along these lines that ordinary users can implement (Webber, 2004). A broad discussion of technology solutions is beyond the scope of this chapter, but they are promising in complementing the legal counter attack.

In 2004, the BBC News reported that an IBM scientist had developed an antispam filter inspired by the way scientists analyze generic sequence “that automatically learns patterns of spam vocabulary with a proven 96.5% success rate” (News Track, 2004). There will be other new developments, as yet undiscovered.

Better “data mining” technology—especially on an international basis—would allow faster and more effective detection and tracing of spammers, although these solutions are controversial. The Terrorism Information Awareness program, for example, may be a model for effectively tracking down notorious spammers, but it was stopped because of privacy concerns. Many provisions of the Patriot Act will be under review in 2005 for similar reasons.

If money is a motivator, it may also be a deterrent. Bill Gates, in a talk show interview January 27, 2004, “predicted a spam-free world by 2006,” and a Microsoft spokesperson said, “We as a company believe that by a couple of years from now spam will be down to a very manageable level. It will be almost an afterthought” (Mara, 2004c). Gates mentioned several methods, including an electronic version of postage and authentication.

Competing proposals that shift costs to the sender are on the table from AOL, Earthlink, Yahoo, and others. ISPs could charge subscribers based on the bandwidth they use, a small per e-mail cost might be assessed, or bulk mailers might be required to post a bond that would include a “micropayment.” The other side argues that these schemes are a tax in disguise and would create more problems than they solve. In May 2004, Microsoft reportedly agreed to “merge its [authentication] proposal” with AOL (Swartz, 2004b). Such agreements, although promising, are notoriously unstable.

The Internet probably has been the vehicle for the most fast-moving adoption and diffusion of new technology in human history. Many argue that the phenomenal growth of the Internet since the mid-1990s has resulted largely

from the fact that it is not regulated or taxed, giving individuals and companies the freedom to find creative ways to use its still-to-be-discovered full potential. Many who are strongly opposed to spam also are against placing restrictions or taxation on Internet usage. Counterattacks that make senders of e-mail pay often are opposed as leading to too much central control.

Meantime, spammers will continue to challenge the legislative counterattack. New legislation and case law for issues relating to cyberspace are developing on a regular basis (see additional reading suggestions at the end of this chapter). The next generation is likely to address spam in libraries and other public meeting places, children’s protection, e-mail and spam on cell phones and other wireless networks, and other issues that have only begun to be recognized—or are still undiscovered. Spam over instant messaging (spim) reportedly reached 500 million items in 2003 (Swartz, 2004d). Software engineers recently succeeded in spamming Internet telephone systems (voice over Internet Protocol), sending “voice messages to 1,000 targets per minute . . . the first known demonstration of . . . (spit)” (Jonietz, 2004).

Controlling new technology will involve strategic political decisions, legislation, and some implementation of Lessig’s code architecture, social norms, and markets. There is a cyclical nature to the counterattack. We will need to ask ourselves, what is the vision of the future? What are people willing to give up in the way of personal and collective liberties to protect the commons? Will it be effective?

For the moment, at least, the balance may be shifting. At the end of 2004, AOL reported that a combination of the legal counterattack and technical measures had resulted in “a sharp decline in the amount of spam received and reported by members” (Rodgers, 2004). The decline was attributed to “improved security and spam blocking features, as well as the company’s well-publicized legal action against spammers.”

Progress in controlling spam will be measured objectively and subjectively in this changing environment. Perception is affected by expectations. Five years ago, spam was not much of a problem. Now, if it can be cut in half, most consumers will be pleased—even if the spam is still bad. Almost everyone hopes Bill Gates’s prediction will be fulfilled.

## GLOSSARY

**Blacklist** A list of e-mail addresses, domain names, or other identifiers in cyberspace that is used to identify and block spammers and potential spam activity.

**Bots** Robotic software crawlers that methodically seek Web pages and other areas of cyberspace to find key words and other information, including e-mail addresses that can be harvested and used by spammers.

**Bounce** E-mail messages that have been returned as undeliverable; useful in differentiating legitimate marketers from spammers, and sometimes used to determine whether an entity should be blacklisted.

**CAN-SPAM Act** Legislation in the United States that sets out rules for sending unsolicited commercial

e-mail messages; formally the Controlling the Assault of Non-Solicited Pornography and Marketing Act of 2003; the full text of the law is available at <http://www.congress.gov/cgi-bin/bdquery/z?d108:S.877>.

**Data Mining** Searching through data to find patterns of interest, for example, xxxx@yyyyyy.com, a pattern for an e-mail address.

**False Negative** Failure to identify spam e-mail.

**False Positive** Misidentifying legitimate e-mail as spam.

**Hijacked Computer** See zombie computer.

**One Bite Approach** An approach that allows one commercial message to be sent to an e-mail address; the recipient may opt out of future messages.

**Open Relays** Mail servers that have been carelessly configured so that anyone on the Internet can send mail through them without needing a password; the messages appear to have come from an Internet service provider, not a spammer.

**Opt In** A recipient must specifically agree to receiving e-mail before any is sent.

**Opt Out** Messages may be sent; recipient must request removal from the mailing list.

**Phishers** Spammers who send fraudulent e-mail asking for confidential information such as social security numbers, bank accounts, or credit card numbers; often combined with spoofing to make it appear that the request is from a legitimate agency or business.

**Pink Contracts** An Internet service provider arrangement with e-mailers to permit borderline spam through payment of an extra charge.

**Preview Window** A window enabling a user to see into an inbound e-mail message without opening it; often used by spammers to present pornographic images or register validated e-mail addresses.

**Spoofers** Spammers who forge a sender's identity to make it appear that a message is from a different sender, often a friend or trusted company or agent; it can damage a company's brand or image; it can be used to deceive a spam filter.

**UCE, UBE, UCBE, UEMS** Acronyms for definitions of spam commonly used in legal proceedings. Further defined in the Commonly Used Definitions section.

**White List** A list of e-mail addresses, domain names, or other identifiers in cyberspace that is used to identify specific users and allow them to pass e-mail messages through the Internet and World Wide Web.

**Zombie Computer** A computer that has been "hijacked" or otherwise entered by hackers or spammers who use it to send out spam messages, often from the computer's e-mail address book; sometimes politely called "open proxies," which, if not hijacked, can perform valuable functionality in delivering legitimate Internet messages.

- Hotmail Corp. versus Van\$ Money Pie Inc., 47 U.S.P.Q. 2d

1020 (N.D. Cal. 1998) (finding likelihood of success on trespass claim against spammer).

## Trademark Infringement and Dilution Claims

- America Online, Inc. versus IMS, 24 F. Supp. 2d 548, 551 (E.D. Va. 1998).
- America Online, Inc. versus LCGM, Inc., 46 F. Supp. 2d 444, 449-50 (E.D. Va. 1998).
- America Online, Inc. versus Prime Data Systems Inc, 1998 WL 34016692 (E.D. Va. 1998)
- Classified Ventures, L.L.C. versus Softcell Marketing, Inc., 109 F. Supp. 2d 898 (N.D. Ill. 2000).
- Classified Ventures, L.L.C. versus Softcell Marketing, Inc., 109 F. Supp. 2d 898, 900-01 (N.D. Ill. 2000).
- Hotmail Corp. versus Van\$ Money Pie Inc., 47 U.S.P.Q. 2d 1020, 1023-24 (N.D. Cal. 1998).

## Breach of Contract Claims by ISPs

- Hotmail Corp. versus Van\$ Money Pie Inc., 47 U.S.P.Q. 2d 1020 (N.D. Cal. 1998).

## Jurisdictional Claims and "Purposeful Availment" of the Benefits of the Forum State

- Bird versus Parsons, 289 F.3d 865 (6th Cir. 2002); Neogen Corp. versus Neo Gen Screening, Inc., 282 F. 3d 883 (6th Cir. 2002) (passive web site available in Michigan, that also let Michigan residents use passwords to view blood test results, with at least 14 transactions with Michigan residents, constituted purposeful availment sufficient for jurisdiction; citing Zippo Mfg. Co, *infra*).
- Gorman versus Ameritrade Holding Corp., 293 F.3d 506 (D.C. Cir. 2002) (a defendant's web site allowed Washington, D.C., residents to form contracts with it to buy securities and brokerage services).
- Additional citations: Optinrealbig.com, LLC versus Ironport Systems, Inc., 323 F.Supp.2d 1037 (N.D. Cal. 2004) (sender tort action against ISPs where preliminary injunction is denied).
- FTC versus Phoenix Avatar, LLC., 2004 WL 1746698 (N.D. Ill. July 30, 2004) (FTC CAN-SPAM enforcement action, one of many cases available online).
- White Buffalo Ventures, LLC versus Univ. of Texas at Austin, 2004 WL 1854168 (W. D. Tex. Mar. 22, 2004) (discusses CAN-SPAM and 1st Amendment commercial speech claim);
- In re Uhrig, 306 B.R. 687 (M.D. Fla. Bankr. 2004) (cites to \$1.9 million judgment for wrongful transmission of spam emails).
- "E-Nuisance: Unsolicited Bulk Email at the Boundaries of Common Law Property Rights," 78 So. Cal. Law Review 363 (Nov. 2004) (available on WESTLAW at 78 SCALR 363).

## INTRODUCTION

As the number of Internet users, Web connections, and personal computers increased exponentially, controversies and legal problems also accelerated in cyberspace without any specific statutes or case law at first to govern the inevitable conflicts. Despite solid preexisting legal foundation, no information medium ever had such an enormous appetite to leapfrog geographic territories and laws, in turn creating intense pressures on that system.

If somebody “ripped off” another’s slogan or logo in “pre-Net” California, it was possible that a business located in Chicago would never know the difference. If one person wrote a defamatory article in a local Florida newspaper about someone in Oregon, the defamed person at that time could have died before reading that particular printed statement. Once the Internet came into existence, however, anyone with an Internet connection—whether living in Florida or in France—could stumble across that slogan or posting. Large organizations were caught napping when more nimble entrepreneurs registered their trademarks as domain names, and then offered to sell those registrations back for outrageous sums of money. Who could ever have predicted the rise of mass-copying technology such as Napster and Kazaa that bypassed the copyrights of the musicians, composers, and recording studios? Not to mention the countless rogue programmer attacks and security failures of information systems throughout the world.

The wide differences among the laws of wide numbers of states and other countries became quickly evident. Whether entered into by e-mail or not, a contract under certain facts could be fine in Georgia but void in

California, and a copyright claim upheld in Japan but not in the United States, with its differing laws and “fair use” exception. Over time, court decisions confirmed that existing legal concepts were applicable to cyberspace, and legislatures enacted specific statutes to fill in the gaps. These basic legal concepts with later refinements proved adaptable to the Internet technology of the new millennium, just as they had during the dawning of new technologies in the past century, and as unfolds during the course of this chapter.

## INTELLECTUAL PROPERTY

The rise of the Internet and its conflicts highlighted the entire subject of intellectual property. Although important in pre-Internet property matters, intellectual property considerations became dominant in protecting one’s rights to their creations and the value of a site, its creations, and processes—whether by copyrights, trademarks, or patents.

### Copyright Law

Your computer is a worldwide copying machine, and the Internet made it extraordinarily easy for nearly anything to be instantly copied, e-mailed, and printed out anywhere, regardless of the true copyright holder’s rights. In response, the United States took the lead to enact legislation that complemented the basic law of copyrights and met this tension between competing interests.

The first major step taken was its enactment of the U.S. Digital Millennium Copyright Act of 1998 (DMCA). The online service provider section of the DMCA establishes the procedures for copyright owners to contact service providers with their complaints over a subscriber’s

improper online use of copyrighted material. This act mandates providers to remove materials used improperly once they reasonably determine there are, in fact, copyright infringements as alleged. If the subscriber files a counterprotest, however, then the provider must repost the material unless the complainant files a lawsuit against the infringer for copyright infringement over the offending use.

In effect, this legislation grants copyright owners an administrative tool to remove infringing material without having to litigate the problem, as well as a “safe harbor” against liability for U.S. online service providers. The definition of “service providers” is broad and includes not only Internet service providers (ISPs), Web hosting companies, wire and fiber transmission entities, and router services, but also corporations, universities, municipalities, governmental agencies, and other entities that “provide” online services. To receive the protection of this federal statute, an organization must register under the act with the U.S. Copyright Office and follow the DMCA’s removal provisions. Check out <http://www.loc.gov/copyright> for the details on the DMCA.

The United States was the first country to enact DMCA legislation, and this statute took it into compliance with an international copyright treaty (the WIPO Copyright Treaty, 1996). As other countries imitate this general approach, the ability to cause infringing material to be removed without using expensive litigation will begin to become globally codified. For more information, please see the chapter on the Global Aspects of Cyberlaw in this *Handbook*. Another significant U.S. legislative enactment was the No Electronic Theft Act of 1997 (NET). Under the NET, criminal penalties can be imposed on people who exchange or barter unauthorized copies of software, videos, clips, or music, whether or not they receive money for it. The only requirement is that the value of the pirated material exceed \$2,500 (for felonies) in a given 6-month period. Although enforcement of the NET Act has been limited to high-profile cases thus far, all users should be aware of its provisions.

Among other important copyright areas, cases have held that publishers must pay additional fees for pre-Net work completed by freelancers, including a U.S. Court of Appeals ruling that the National Geographic Society made an unauthorized use of pictures taken by a freelance photographer back in 1961 when it issued a CD-ROM years later of its back issues (*Greenberg v. National Geographic Society*, 2001). It was ordered to pay license fees for that use. The U.S. Supreme Court decided the issue when it later ruled that media companies must obtain the consent of their freelance writers and creators (as employees create “works for hire,” their employers typically gain those copyrights) before any pre-Net text, picture, or creation could be posted or sold online, thus forcing royalties to be paid for that use (*New York Times v. Tasini*, 2001).

In the late 1990s, music lovers using a Website and software program called Napster began file-sharing music by swapping digital copies of recordings with one another. After lawsuits by recording industry groups effectively shut down Napster (*A&M Records v. Napster*, 2001), Internet users began sharing music files by using programs that allow them to search the computer libraries of other

users. Rather than providing a centralized server where swappers could trade copyrighted material directly ala Napster, this technology allowed users to download software from sites such as Grokster and trade copyrighted music between themselves in an environment that didn’t involve a central server. In 2004, the U.S. Court of Appeals for the Ninth Circuit in *MGM Studios v. Grokster* (2004) held that Grokster’s use of such a decentralized environment was not a violation of applicable copyright laws as was Napster. On appeal, the U.S. Supreme Court heard oral arguments in 2005 on this case with its decision expected later in the year.

In addition to these aspects, other developments occurred as to the online copyright infringement issue, whether concerning books or music. The U.S. Supreme Court held in *Eldredge v. Ashcroft* (2003) that Congress had acted constitutionally in 1998 when it extended copyright protection for most works through the Sonny Bono Copyright Term Extension Act (Supp. 1999), retroactively increasing the copyright protection term from 50 years after an author’s life by another 20 years to 70 in total. Various cases upheld the constitutionality of the DMCA, including its safe-harbor provisions for ISPs.

The federal courts also have apparently answered the issue as to whether the DMCA mandates ISPs to turn over customer information to the recording industry of those suspected of illegally trading music files. In *Recording Industry Association of America (RIAA) v. Verizon Internet Services* (2003), the U.S. Court of Appeals in Washington, D.C., overturned the District Court’s decision and ruled that the RIAA could not use just subpoenas or simple notices under the DMCA to force ISPs to supply it with user names that it could only identify by their computer’s online addresses. The RIAA would have to file a formal lawsuit, then after that filing of its “John Doe” complaint, request a subpoena to secure the identity from the ISP. Immediately after the decision, the RIAA filed four new lawsuits naming 532 “John Does” to show that this added cost to its litigation policy would not deter it. The Supreme Court refused to grant certiorari and rejected the appeal without comment.

Whether the situation concerns Napster imitators, video downloading, or copying overseas, the legal wrangling between copyright holders and the public over “fair use” considerations will continue unabated. As other countries enact their own cyber copyright and intellectual property laws, the likelihood of global jurisdictional disputes increases. Please consult the chapter on Copyright Law in this *Handbook* for an extensive treatment of these copyright areas.

## Domain Names and Trademark Law

### Trademark Law and Domain Names

For decades before the emergence of the Internet, trademark law was relatively straightforward. Trademarks and service marks abound, simply arising from a company’s use of marks identifying certain products or services as being theirs (e.g., Apple with its rainbow apple and eBay’s stylized logo). The concept of trade and service marks came about to keep businesses from “passing off” their products as being those of their competitors or of

rightful owners, and the ownership of marks is another important intangible property right.

Then along came the Internet, domain names, and new Web sites that had registered the addresses of bona fide trademark and service-mark holders (i.e., Burger King vs. the “burgerking.com” registered by an individual). They knew that the domain name used to access any site was an important asset of identification, just as an entity’s mark was important in the decision to purchase a product (or domain name selection). Because domain names must be registered to have any validity and registrars don’t conduct background checks over an applicant’s representations as to who owns the legitimate trademark rights, registration even today can be a race to the swiftest on a “first come, first serve” basis.

In the early and mid-1990s, “entrepreneurs” recognized this grand opportunity. In a style reminiscent of the old Gold Rush days, they raced to tie up as many of those good corporate names as they could, whether it was “harvard.net” or “burgerking.com.” Later, they would send a demand letter to those entities and offer to sell their domain names back—at a tidy profit. Or the new owners would sit on their names and wait for that interest, conjuring up the concepts of “cybersquatting” and “cyberpirating.” When one adds to this equation the various classifications (i.e., from “.com” and “.org” to the later introduced “.biz” and “.info”) with the different country designations that are possible, it is easy to see the large opportunities created to tie up good corporate names at a good profit.

A brisk market in the buying and selling of domain names started—just hit the key word “domain name” in your search engines and see what arises. The people who registered general names, such as “business.com” or “loans.com,” made excellent business decisions. One Houston businessman paid \$150,000 in 1997 for the rights to “business.com,” then sold that to a California company for a cool \$7.5 million 2 years later. In 2000, mortgage.com was sold for \$1.8 million and loans.com for \$3 million.

Without any statutory guidance, the courts handed down mixed decisions as to when a mark holder would prevail, if at all, over a cybersquatter and a given domain name. The reason: The law was clear at the time that domain-name registrations and trademarks and service marks, whether registered or not, were two different concepts. Because there was no right by itself to use a mark as a domain name, owning one didn’t necessarily convey any ownership rights to the other.

### **Anticybersquatting Consumer Protection Act (ACPA; 1999)**

Before the passage of the ACPA, the Federal Trademark Dilution Act (FTDA, 1995) was the statutory alternative that trademark holders used to fight cybersquatters. The FTDA did not require proving a likelihood of confusion on the part of consumers on the use of a disputed mark, but that there was a “dilution” of that mark. This act provided a mark owner with injunctive relief against another’s commercial use of one that diluted the distinctive quality of that distinctive mark. Dilution occurred when an unauthorized use lessened the ability of others to distinguish goods or services from the other, including if those actions cheapened that mark (i.e., one Billy Nike

establishes a bar called “Nike’s Sleazy Palace” to which the sporting goods manufacturer, Nike, takes exception). The FTDA’s effect was to protect famous marks—such as McDonald’s or Goodyear—from the use of others that would “dilute” their value. *Panavision v. Toeppen* (1998) was one of the first cases to expand the FTDA’s dilution protection of trademarks to domain names. In *Panavision*, the appellate court held that the defendant’s actions diluted the value of Panavision’s trademark because his registration of “panavision.com” (and attempts to sell that back to the company) weakened the ability of its potential customers to find Panavision on the Internet. So long as the defendant held the Internet registrations, he curtailed, or diluted, Panavision’s value of its trademarks on the Internet, and the court upheld the injunction against that use. The problem was that entities had to prove that their trademark value had been diluted under the FTDA, as well as that this action could be ineffective and costly, when all that they wanted was to get their domain name back. Some states laws, in fact, were stronger than the FTDA. (Later, in *Moseley v. Secret Catalogue* (2003), the U.S. Supreme Court affirmed that actual harm must be proven before even FTDA injunctive relief can be obtained.)

In response, the United States passed its Anticybersquatting Consumer Protection Act, or ACPA, in late 1999. This act allows civil lawsuits to be brought for trademark and service mark violations against anyone, who with a “bad faith” intent to profit from a mark, registers, uses, or attempts to sell a domain name that’s identical or confusingly similar to that protected mark. Factors indicating bad faith are whether the name owner actually diverted the trademark owner’s customers, offered the registered name for sale without having used it, or registered multiple names. Under the Anticybersquatting Act, the courts can cancel a “pirated” domain name, assess attorney fees and costs, and levy penalties up to \$100,000 against an infringer (depending on the level of bad faith and the actual damages). This act gave broad legal weapons for any mark holder to protect its trade or service mark, as well as more remedies and damages for any unauthorized use.

This legislation also made it illegal to register the name of any living person without that person’s consent, while intending to profit by that action. Actors Brad Pitt and Kenny Rogers immediately filed suit on this provision alone, Kenny Rogers objecting to the “kennyrogers.com” registered to the Web site of a California wedding service. Both celebrities, among others, retrieved their “names.”

### **ICANN’s Dispute Resolution Process**

ICANN instituted a procedure for resolving domain-name disputes. Under an agreement called the Uniform Domain-Name Dispute-Resolution Policy (UDRP), those with a dispute over a registered domain name involving their trademark or service mark have the alternative to file a complaint with an ICANN approved dispute-resolution service. Pursuant to these procedures, the service provides an arbitration panel that then rules which party has the legitimate right to that name, and if either party disagrees with the handed-down ruling, then that party can litigate the disputed matter further in court. The judge in the court case can review all of the facts and isn’t necessarily bound by the review board’s determination. Once

a final decision is reached, the registrar then transfers the domain name as the court or administrative panel decided; for further details on this policy, see ICANN's site at <http://www.icann.org>.

Whether marks are registered or not, legitimate holders can take their case to different alternative dispute resolution centers under this process, and the United Nations' World Intellectual Property Organization (WIPO) hears most of these cases. (For more details, see its site at <http://www.wipo.int/>.) Basically, the claimant must prove (a) that the domain name very closely resembles a trademark registered or owned by that entity, (b) that the party that registered the domain name has no rights or legitimate interest in that name, and (c) that the domain name was registered and used for illicit purposes or in bad faith. This is an inexpensive process (a one-person panel for a case involving up to five domain names at the time of this publication costs the complainant \$1,500, and a three-person panel costs \$4,000); fast (the arbitrators' decision is normally rendered within 60 days); convenient (there is no hearing to attend; the arbitrator or panel reviews only the complaint, response, and supporting documents); and the decisions typically favor the trademark holder (some four fifths of the determinations favor the mark owner).

The initial decisions on domain names reached conclusions in favor of companies with recognizable names, such as the World Wrestling Federation, Stella D'Oro Biscuits (a Nabisco affiliate), and Telstra (the Australian telecom company), ordering their domain names transferred back to them. WIPO arbitration panels handed back the Web addresses bearing the names of the Corinthians (Brazilian soccer team), Dan Marino, Julia Roberts, Kevin Spacey, Yahoo!, ESPN, and Wal-Mart. However, Sting, Bruce Springsteen, the Reverend Dr. Jerry Falwell, and Ted Turner failed to prove that their personal names had been used in a trademark sense as a label of particular goods or services and did not prevail in their UDRP proceedings. ICANN's dispute-resolution policy, however, does not apply to all registrars—it applies to the TLDs (top level domains of “.com,” “.net,” “.biz,” etc.) and not directly to the “ccTLDs” (individual country domains, such as “.cn” for China), unless that country agrees or has established its own dispute resolution board. A number of the ccTLDs have done so.

### The Legal Weapon Tradeoffs

Entities with U.S.-based domain name/trademark conflicts must decide between using the Anticybersquatting Act, an ICANN proceeding, or both. ICANN gives a fast resolution, whereas ACPA litigation can take up to 2 years or more for a decision. Although the federal statutory-authorized lawsuit allows for a preliminary injunction, the opportunity to be awarded good damages, and transfer back of the domain name (which is all that an ICANN-UDRP procedure can do), this alternative is highly expensive with much more downtime, complexity, and legal dollars required. The ACPA is a final determination, whereas the extent to which an ICANN decision can be litigated further is currently being determined.

The rest of the world is not as restrictive as the United States or other developed countries, and the game is still being played in some fashion. Countries in Asia, the former Soviet Union, Eastern Europe, and others have not

yet tightened their laws, although over time, they likely will. It may still be possible in small nations such as Moldavia (until they change) for cybersquatters to purchase domain names that aren't already reserved, and the question of conflicting laws always seems to rear up when lawsuits are brought to challenge ICANN administrative rulings.

For international protection, entities need to register their mark with the U.S. Patent and Trademark Office (PTO), and U.S. concerns need to file that registration with the appropriate agency of the foreign countries in which they operate. Although the granting of a registration by the PTO is not conclusive on the issue of who owns a mark, it is prima facie evidence of that ownership (see the PTO at <http://www.uspto.gov> for the details). Given the estimated numbers of domain names (escalating from present numbers to more than 100 million in 2 years by various estimates), the number of permutations, and various country designations, the volumes of conflicts, arguments, and opportunities for these disputes can only increase over time.

For more on this subject, see the chapter on Trademark Law in the *Handbook*.

## Patent

Through patents, the United States by its Patent and Trademark Office grants an inventor the exclusive right to make, use, or sell an invention for 14 years (design patents) or 20 years (inventions). To obtain a patent, the inventor must meet certain requirements, such as novelty, usefulness, and nonobviousness. Computer hardware (i.e., the design of electronic components, handwriting recognition systems, and so on) is patentable, but software typically isn't brought into the process, because of the time it takes for a patent to be granted and contrary regulations in a few cases. The number of patent applications for Internet applications increased in recent years owing to court decisions (beginning with *State Street Bank v. Signature Financial Group*, 1998) upholding patents issued for Web site business processes and operating methods. Amazon.com (its “one-click” online purchasing system), Onsale (operating auctions), Cybersettle (its “double-blind bid” dispute resolution procedure), Priceline.com (conducting an online “reverse” auction), Microsoft (online shopping and merchandising), Sun Microsystems (Internet bill processing), Tumbleweed Communications (online greeting card delivery), E-Data Corporation (online selling to any point of sale location), and other e-commerce entities have received patents on their specific business or operational models. As expected, the court challenges from competitors over these patents have also increased, as competing entities battle over controlling important operational methods. The chapter on Patent Law in this *Handbook* goes into the details.

## DEFAMATION

Cyberspace creates an inordinate ability to post defamatory comments quickly that injure another person's reputation and can be seen around the world. Those who post libelous comments, however, do not enjoy the anonymity in cyberspace that one might first expect. A cyber-defamation lawsuit is typically filed in the city

where the chatroom provider or ISP is located and lists various “John Does” or “Jane Does.” This is legal jargon for naming unknown parties to the lawsuit, whose actual names will be added later after discovering their true identities. The lawyer then files a subpoena (demanding that the desired information be released) against the provider to gain the identity of the particular John or Jane Doe who posted the inflammatory remarks.

Lawyers serve subpoenas daily on CompuServe, AOL, Yahoo, Microsoft, and others to retrieve some poster’s identity. If the ISP doesn’t turn over the demanded information, the attorney then goes to court to ask the judge to force the ISP to divulge the required data. The judge balances the right to protect someone’s anonymity versus the injured party’s right to be protected from harm. The plaintiff, or injured party, usually must prove that there’s no other way to obtain relief without securing this specific information. If multiple servers are involved, the attorneys will follow the e-mail address back through that chain with multiple subpoenas.

A doctor at the Emory University School of Medicine in Atlanta, Georgia, came across a posting on a Yahoo message board. It falsely suggested that he had taken kickbacks from a urology company to give his department’s pathology business to the company and had been forced to resign over this conflict of interest. The message was from “fbiinformant,” who later was discovered to be a former employee at the urology company who disliked the doctor. In what was believed to be the first Internet defamation case to reach trial, a U.S. District Court judge awarded \$675,000 to that doctor, all because of this one “anonymous” Internet message (see *Graham v. Openheimer*, 2000). Litigating defamatory e-mails, postings, and communications continued on unabated from there.

As to the online service providers, the court decisions have consistently upheld that there is no liability on their part for defamatory postings made by third parties. The Communications Decency Act of 1996 (CDA) bars tort-based claims or lawsuits against ISPs for defamatory, obscene, or other objectionable postings, provided there is no complicity by the ISP with that third party over those postings or other unreasonable behavior (the provider also must “actively” remove the objectionable material). Although portions of the CDA were later held to be unconstitutional (see *Reno v. American Civil Liberties Union*, 1997), these provisions continued in their legal validity and effect.

## PRIVACY CONCERNS

At this time, there is no general, sweeping U.S. law regulating or requiring entities to disclose how they use sensitive financial and other personal information gained from their customers or users, nor how they gather that data. Notwithstanding recent U.S. Federal Trade Commission (FTC) high-profile proceedings against companies over their information practices, the FTC has had, in effect, a “self-policing” policy, promoting industry self-regulation in the fields of data collection and customer profiling. Congress did enact legislation as to the online privacy protection of children, however; when it enacted the Children’s Online Privacy Protection Act (COPPA) in 1998. This statute requires that Web sites “earmarked” for

children, or who knowingly collect data on users under age 13, need to (a) obtain verifiable parental consent for any collection or use of their children’s information (i.e., “no consent, no collection”) and (b) on request, provide the parent with the ability to review any personal information that has been so collected. The FTC has issued administrative rules on COPPA to guide these “kiddie” Web sites on their compliance with this legislation (see <http://www.ftc.gov> for more on this subject). Additionally, the FTC has charged entities with violating COPPA and reached settlement with several of those Web sites.

Congress also passed the Gramm–Leach–Bliley Act (GLBA), known also as the Financial Services Modernization Act of 1999 and which applies to Internet transmissions and electronic data collection. This legislation basically requires that financial institutions (a) inform consumers of their privacy policies and (b) notify consumers before acquiring, transferring, or selling their private data to third parties, giving them the opportunity to “opt out” of such data-transfer practices.

Additionally, various states have passed privacy legislation both in the financial area and in preserving the confidentiality of sensitive medical records, including diagnosis, treatment, and prognosis. As with most state laws, these acts are not uniform—for example, depending on the subject area, some states require opt-in conditions before data can be collected or used, whereas others establish opt-out standards. Rules have also been enacted under the Health Insurance Portability and Accountability Act (HIPAA) of 1996 in this area (see the U.S. Dept. of Health and Human Services at <http://www.os.dhhs.gov> for more), and the court challenges on its implementation are underway.

The differences between the United States and other countries, such as Canada and the European Union (EU), couldn’t be more pronounced than in the rights of privacy area. Canada’s Personal Information Protection and Electronic Documents Act (S.C., 2000) implements a wide array of data protection, including a phase-in of “opt-in” provisions for its citizens. The EU’s Data Protection Act came into effect in 1998, also using a completely different approach from that of the United States. Citizens there gained enhanced rights to prohibit their private data from being released, including requiring entities to secure “opt-in” permission in various situations before personal data can be acquired, sold, or shared. For further information, including on the “safe harbor” guidelines for U.S. companies with subsidiaries operating under the more stringent EU privacy laws, see the U.S. Department of Commerce Web site at <http://www.commerce.gov>, as well as the chapter on Privacy Law and the Internet in this *Handbook*.

## CENSORSHIP

The First Amendment places strong limitations on the government’s ability to censor, or unduly regulate, the rights to basic freedoms such as those of speech and expression, and the Internet is no exception. For example, Congress passed the Communications Decency Act of 1996 (CDA) which, among various provisions, essentially made it a crime for anyone to knowingly distribute obscene material for sale in cyberspace. Later in 1997, the U.S. Supreme Court in *Reno v. American Civil Liberties*

*Union* declared that most of the important provisions of the CDA dealing with obscenity were unconstitutional, holding that these provisions were so vague as to be void on their face. The fact that statutes applied to cyberspace didn't mean the constitutional tests applied were any less strict, and later legal battles over subsequent pornographic statutes have applied the same strict construction tests of the offline world.

For example, Congress in 1998 passed the Child Online Protection Act (COPA) as a successor to the struck-down CDA provisions in another attempt to stop children from gaining access to sexually explicit materials on the Internet. In 2002, the U.S. Supreme Court reviewed COPA and partially upheld it, adding further legal uncertainty. In *Ashcroft v. ACLU* (2002), the court ruled that the act's reliance on community standards to identify "material that is harmful to minors" did not by itself render the statute unconstitutional. The divided court kept alive the fight over whether the measure was unconstitutional, however, by affirming the appellate court's ban against COPA's enforcement, then returning the issue for further review on free-speech questions that the court felt had been left unresolved. Subsequently affirming the preliminary injunction on COPA's use, the U.S. Court of Appeals for the 3d Circuit in its decision, *Ashcroft v. ACLU* (2003), then rejected the U.S. Supreme Court's reasoning, finding that the law was not the least restrictive way to achieve the government's interest in protecting children. This panel of circuit judges said that the law was "vague, overbroad, and puritanical," and violated the First Amendment. The Justice Department again appealed. The U.S. Supreme Court then agreed with the appellate court in *Ashcroft v. ACLU* (2004) that enforcement of COPA should be enjoined because the statute likely violates the First Amendment, and that employing filters were a less restrictive way than COPA's mandated use of credit cards or other measures employed to restrict access. Yet, the Supreme Court remanded the case again to the lower court for consideration whether there are less restrictive ways to achieve the government's objectives. Whether in cyberspace or not, the complexities of First Amendment case law continue.

The U.S. Supreme Court in *United States et al v. American Library Association* (2003) held by a 6-3 majority that Congress could require public libraries to install mandatory filters on Internet computers as a condition of receiving federal technology grants and "e-rate" discounts, upholding the constitutionality of the Children's Internet Protection Act (CIPA, 2000). The Supreme Court later declined to review the "Nuremberg Files" case, in which an 11-judge U.S. Court of Appeals panel voted 6-5 in *Planned Parenthood v. American Coalition of Life Activists* (2002) to uphold a 1999 trial verdict against an antiabortion Web site that disclosed the names, addresses, and family information of physicians who performed abortions. The trial jury awarded punitive damages of \$107 million against the coalition of activists, but the appellate panel remanded the damage amount back to the trial court to determine whether the award was excessive or not.

In a case in which the judge described was a dispute between the protection of trade secrets versus freedom of speech, a federal judge ruled a Web site operator

could continue posting confidential Ford Motor Company documents on new car designs and other internal data (see *Ford Motor Co. v. Lane*, 1999). Lawsuits over employer Internet-use policies, however, provided the policies are reasonable with notice given to the employees, have generally been upheld in the employer's favor. An employer's use of Web filtering software (where worker e-mails are subject to scrutiny) also is under challenge, but most legal scholars believe that these challenges generally won't be sustained. Moreover, the courts so far have not been receptive to employee claims that work done on an employer's computer system is personal and entitled to constitutional protection. Please see the chapter on E-Mail and Internet Use Policies for more on this subject.

Courts have generally upheld the right of "suck.com" Web sites to criticize the operations of major businesses (e.g., "<http://www.ballysucks.net>"; see *Bally v. Faber*, 1998), although the complaining companies have had more luck in challenging these sites under ICANN domain name proceedings. For example, the Salvation Army filed an ICANN-UDRP proceeding over the name "salvationarmysucks.com", and the arbitrators ruled in favor of it, when evidence of offers to sell the name back to the Salvation Army came to light. Generally, provided the posted allegations are basically true or represent protectable opinion rather than false facts, the cases hold these expressions to be protected by the First Amendment. If you use a search engine with the descriptive word "suck.com" or type your favorite company name with a "suck.com" after it, watch the complaint Web sites surface that already are in existence.

Another growing First Amendment consideration involves its application in disputes where software sites collide with commercial trade interests. For example, the DVD Copy Control Association (DVDCCA) attempted to shut down Web sites, including that of California resident Andrew Bunner, which provided a link to DeCSS software code that unscrambled encrypted DVDs and allowed them to be played on unlicensed computers. A California Court of Appeals court (*DVDCCA v. Bunner*, 2001) overturned the trial judge's temporary injunction against Bunner's site as an unconstitutional prior restraint protected by the First Amendment. In reversing the appellate court, however, the California Supreme Court (*DVDCCA v. Bunner*, 2003) decided that computer source code is a form of speech that can be constitutionally protected, but that this injunction was appropriate because it was not based on the content of Bunner's speech—it was only protecting the DVDCCA's trade secrets. The court sent the issue back to the appellate court for a ruling on whether the injunction was warranted under the state's trade secret laws. The California Court of Appeal (*DVDCCA v. Bunner*, 2004) held that the facts did not support the injunction because the DeCSS software was so widely distributed before the injunction was requested. For more on the subject of censorship, please see the chapter on Internet Censorship in this *Handbook*.

## CYBERFRAUD

Cyberfraud is a major problem on the Internet, owing to its anonymity, commercial reach, and speed in exchanging

credit card data. Hackers abound, trying to exploit any weakness in a site's systems and database. The ease of entry onto the Internet makes it even easier for "fly by night" firms to race in, skim off money, and quickly disappear without leaving a trace. No matter where you live, the Web has indeed become global in when and how the unwary are fleeced. In the United States, the FTC is the federal agency charged with prohibiting unfair or deceptive commercial acts, including misleading advertising (fraudulent investments are handled by the Securities and Exchange Commission, or SEC). The FTC's rules and regulations against unfair or deceptive business practices specifically cover Internet transactions, and its Web site (<http://www.ftc.gov>) has pages with information about Internet fraud, complaints, and its fight against this problem.

The FTC has brought countless numbers of fraud and misleading advertising complaints to stop such unfair practices, both online and offline. In 2001, the FTC opened a Web site with statistics and information on primarily U.S. Internet fraud and identity theft. The site is called "Consumer Sentinel" (see <http://www.consumer.gov/sentinel>), and it started with a database of more than 300,000 complaints lodged with the FTC over the last several years. The site provides data on fraudulent transaction trends, as well as the ability to submit online complaints (as does the FTC with its Web site). From year to year, identity fraud is the overall top consumer fraud complaint from all sources received by the FTC and by a wide margin, followed by Internet auctions and Internet services/computer complaints. If you find online fraud problems involving different countries, then head to "econsumer" at <http://www.econsumer.gov/>, which has in place direct links to consumer fraud agencies in various countries and represents a coordinated world effort to work together on this global problem. This site also allows for the filing of international fraud complaints.

The Internet is an excellent tool both for investors with easy access to research sources, as well as for the shysters, hipsters, and con artists to get to the investors' and other people's money. Because anyone with a computer and modem can reach tens of thousands of potential investors simply by creating an attractive Web site and spamming, the U.S. SEC has had to become active on the Internet. It established a national cyberforce of attorneys, accountants, and analysts specifically trained to watch out for fraudulent online security transactions (see <http://www.sec.gov> for more information, including its reported Internet fraud cases).

For example, one case involved a company that used spam e-mail to announce an initial public offering (nearly all of us have received junk e-mail of this type), stating that it had been approved by the SEC and would realize at least \$1 billion in eyewear sales. In fact, it had never been approved by the SEC and didn't even own an office or inventory. The owner of the company used the "invested" money for restaurants (eating meals), casinos (gambling), and adult entertainment clubs. The investors lost everything that they had invested—the usual and unfortunate result with fraudulent investments, regardless of whether the FTC or SEC intervenes later.

Regardless of the state or country, the law is clear with regard to cyberfraud: (a) any Web advertisement of illegal

transactions under a particular country's or state's laws (e.g., gambling or usury) will be illegal there; (b) fraudulent, false, or materially misleading statements are illegal and unenforceable, no matter where you live; and (c) the regulatory agencies in different states and countries vary widely in their ability to crack down on misleading advertising, even when the customers or investors have lost all of their money. Remember: If the advertised "return" is too good to be true, then it usually is; and investors must be quite careful when reviewing potential investments of any kind, whether online or offline. (For more information, see the chapter on cyber crime and fraud.)

## E-COMMERCE LAW

### "Click" Contracts

Given the ease with which online contracts can be made, the tearing down of geographic barriers, and E-mail "proof" that lasts forever, basic contract law is even more important on the Net. From what is needed for a legitimate contract (i.e., mutual assent, consideration, capacity, and no legal defenses) to how duties are delegated and determining damages, all of the fundamental contract laws apply in cyberspace. (For an excellent discussion on this area, see *Cyberlaw, Text and Cases, Second Edition* by Ferrera, Lichtenstein, Reder, Bird, & Schiano, 2003.) As expected, e-contracts do have important aspects that stand out from offline contracts.

You can't discuss and then sign an e-contract with your handwritten name, as you can when you're in a face-to-face meeting with the other party. In place of this "personal touch," the law basically allows that you can agree to the terms and conditions of an electronic agreement when you click the "I agree," "I'll buy," or "Subscribe" button. The mouse click on that agreement button sets the approval to the conditions of your e-contract.

The courts generally have upheld these "click" contracts as being as valid as if you signed a written agreement on the dotted line. (See, for example, *Crispi v. The Microsoft Network*, 1999, and *Geoff v. AOL, Inc.*, 1998.) Any on-screen click, no matter where it's located (but provided it's reasonably identified as the "click" agreement button), will do. The legal premise is that the medium in which a signature or contract is created shouldn't affect its validity, and the transaction is enforceable, whether that medium is paper or electronic. There are limitations on when click contracts will be enforced, however, and this is discussed later in this section.

### E-Signatures, Taxation, and Spam

The U.S. government and nearly all of the states have enacted a version of an electronic signature statute. The federal act (Electronic Signature in Global and National Commerce Act, 2000) ensures that electronic records, signatures, and contracts have the same legal effect as their ink-and-paper counterparts (including that electronic records satisfy statutes mandating that records be kept in writing), validating online commerce and allowing for the eventual recordation of documents such as deeds, mortgages, and bills of sale by accepting digital notarization. Along with its state counterparts, this legislation

mandates that an e-signature is enforceable if both parties agree to its technological format (whether signature verification is based on encryption software, smart cards, mouse-pad technology, or whatever), and it provides that a signature may not be denied legal effect simply because it is in electronic form. It is an enabling statute that sets down standards that can be followed and allows states to enact their own but generally consistent legislation within this umbrella, prohibiting laws that limit permissible electronic signatures to one single technology. The states differ widely in their authorizations because numbers are applicable to all electronic transactions, whereas others can be more limited in their scope and effect. Internationally, many countries (from Brazil and Taiwan to the individual members of the EU) have enacted e-signature and e-commerce laws, simply because it is in their best interests to do so.

In 1998, the United States' Internet Tax Freedom Act capped taxes on online sales with a 3-year moratorium on any *new* state, local, or federal Internet taxes (as defined) to October 20, 2001; after an interim delay, the moratorium was extended for an additional 2-year period that then expired on November 1, 2003. It is a misnomer, however, that this statute generally ended Internet taxation. Among other allowed taxes (including "grandfathered" Internet taxes and taxes on Internet access) when the "moratorium" expired, 45 states charged sales tax on tangible products bought online, given that the seller had some form of a physical presence or "nexus" (i.e., a warehouse, retail store, office, or sales representatives) in that state—all as permitted under already existing tax law (see *National Bellas Hess v. State of Illinois*, 1976).

What was held in abeyance was the legal ability to tax an online purchase from a resident in a state where no such nexus or connection to the selling site's state was present. In late 2004, Congress finally approved the extension of these federal restrictions against taxing online sales transactions to November 1, 2007, and President Bush signed this legislation into law. Notwithstanding this, it is expected that the states and non-Internet merchants will continue to make the pleas to Congress to tax online sales as never before—and the lobbying will continue well past any further legislation that's enacted, whether the ban is made permanent or another short-term "moratorium" ensues.

As e-commerce expanded, huge increases in unwanted electronic solicitations (otherwise known as spam and junk e-mail) have also taken place. Given the Net's anonymity, enforcement difficulties, jurisdictional issues, and that more serious crimes are usually in line for prosecution, controlling spam legally will not be possible until the U.S. and the international community in general pass federal laws with strong enforcement mechanisms. Although the U.S. federal government passed an antispam bill, the CAN-SPAM Act of 2003, critics believe that this law doesn't go far enough. For example, there is no requirement of an "opt-in" provision, because the act allows e-marketers to continue spamming until the recipient responds with a required "opt-out" message (which also confirms that e-mail address). Further, this legislation legitimizes unsolicited e-mail as a marketing tool and is

ineffective on those spammers who increasingly operate outside U.S. jurisdictional limits; this act also supersedes conflicting state antispamming laws that are stricter in cases. (Even given that nearly all U.S. states have enacted laws regulating spam, including fines and jail time as penalties, these laws are rarely or difficult to enforce. In numbers of states, no one has yet been prosecuted under those statutes.) In contrast to the U.S.'s position, countries from Australia to the European Union have passed strict antispam laws with "opt-in" provisions and varying effective dates. For the latest on antispam legislation and developments, see <http://www.spamlaws.com>.

For more on e-commerce law, taxation, and spam, please see the applicable chapters in this *Handbook*. Although beyond the scope of this chapter, the global e-commerce legal aspects are considerable and ever changing; please see the treatment of these international areas throughout this treatise.

### "Terms of Use" Provisions

Many Web sites separate out the necessary purchasing information from their legal Terms of Use and Privacy policies. Although the general areas treated are similar, each site's provisions are different, depending on whether a particular location sells products, provides services, gives information, or some combination. Nonetheless, the general concepts covered are basically the same.

Given that the basic contract business terms (e.g., quantity, price, time for delivery, delivery mode, and so on) are present, what was once "just legal boilerplate" has now become more important: disclaimers of liability, limitations of warranty, indemnity, handling of disputes, applicable law, and dispute resolution, among other areas—and this is especially true when distant localities become involved.

The disclaimer-of-liability provisions typically limit a seller's liability for injury or loss incurred by the buyer to exchanging the product or a refund of the purchase price, all at the seller's option. This refund policy is usually coupled with a disclaimer of liability, such as the following: "Seller disclaims all liabilities and warranties, express or implied, including the warranties of merchantability and fitness for a particular purpose, and this Web company shall not be liable for any damages, whether consequential or incidental."

The intent of these provisions is for the seller to "duck away" from liability, leaving the manufacturer on the hook. Although not unanimous in their decisions, the courts generally uphold limitations on consequential damages (for example, a site's loss of data that results in a further loss to its users or customers) in business transactions, and it is well-settled law that two contractual parties in commercial situations can negotiate arms-length the extent to which either party's damages will be limited, given equal bargaining power (see *Robotic Vision Systems v. Cybo Systems, Inc.*, 1998). These provisions usually are not upheld if a personal injury is involved with an individual, however, such as when a customer is injured using a defective product that caused those injuries.

As a basic legal concept, no one can contract against the effects of strict product liability or one's own negligence,

unless separately negotiated between two contracting businesses. If that were the case, then there could never be any product liability, because every manufacturer and retailer in the world would be contractually providing, “Sorry, if there’s a problem with our product, even if it’s entirely our fault, we don’t accept that liability—you do.” Depending on the circumstances, Web sites can be held completely responsible for a customer’s damages, notwithstanding these one-sided contract provisions. For example, if a pharmacy Web site erroneously fills a prescription for high-blood pressure medication that severely worsens the problem, that Net retailer typically will have to compensate that injured person for his or her damages from those bad pills, regardless of any Terms of Use limitations to the contrary.

Standard Terms of Use agreements also provide for “tight” indemnity provisions (i.e., that the user is responsible for any damages), as well as favorable provisions on applicable law (typically the site’s state law, if favorable), dispute location (the Web-site’s hometown and state), copyright use (i.e., one must gain their written consent to any copying), privacy policies, and the like. Although courts tend to uphold these one-sided provisions, sites cannot be totally unfair in them, nor limit what the law already allows. For example, the United States provides for a “fair use” exception for copyrights, and the courts will generally not allow any such one-sided, restrictive statements to erode this long-standing doctrine. Just because a Web site operator says it’s true doesn’t necessarily make it legally so. However, any user must be aware that all Terms of Use provisions, including privacy policies, are agreements of legal significance and that it will take a successful court challenge to overturn their application. If possible with larger companies, it’s better to negotiate out ahead of time the legal provisions, or boilerplate, that aren’t in your favor.

## Validity

Most courts uphold “take it or leave it,” click e-agreements, provided (a) the terms are written in understandable English with readable print and not hidden from the user’s view; (b) the user has the opportunity to read and understand these terms, all before having to make any purchase or use decision; (c) the provisions are reasonable; and (d) the user has to take some affirmative action to agree (such as clicking an “I agree” button). Because courts tend to enforce software shrink-wrap agreements (where the act of opening the software package is deemed to be acceptance of the included terms), they’re doing the same with Web site Terms of Use “click” provisions, provided these elements are present.

If, however, the language used is hidden or not conspicuous, in small print, or wholly unreasonable in effect (e.g., “This Web site is not responsible for any of your damages, regardless of how much we are at fault”), then courts will generally not uphold them. There must be some knowledge (the terms are easily located and understood), prior decision-making (the user can decide before having to order), and facts showing at least mutual assent or an implied agreement (e.g., clicking on an icon to show your assent).

A leading Second U.S. Circuit Court of Appeals case, *Specht v. Netscape Communications Corp.* (2002), reviewed the standard terms and provisions applied when a user downloaded software. The standard terms provided that all provisions came into legal effect when any user simply downloaded or installed the software. However, users could directly download this software before coming or scrolling down to the “I agree” icon and any inspection of the terms of use that bound their decision. Applying standard contract law on mutuality of assent, the court upheld a lower court’s decision and refused to enforce an arbitration clause in the Web site’s forum state, holding that the required mutuality for contract assent was not present.

When the requisite criteria is present, courts will uphold these terms on a general, conceptual basis, provided additionally there is no blatant unreasonableness in those provisions. Based upon the Uniform Commercial Code’s Section 2-302 (basic to most states’ laws) that codifies the traditional common law doctrine of unconscionability, courts still have the ability to set aside those standard terms. The intentional misuse of a Web site by a user, however, can negate provisions that don’t meet these standards. For example, in *Register.Com, Inc. v. Verio* (2000), a court held that when Internet users intentionally misuse a site’s content, there is an implicit agreement to any terms of the Web site’s legal notice that would prohibit that action.

A recent Northern California Federal District Court case, *Cairo v. Crossmedia Services* (2005), consistently applied both *Specht* and *Register* to a Web site’s terms-of-use provisions that involved a forum-selection clause. Contrary to Crossmedia Services (CMS) forum clause that required lawsuits to be filed in Illinois, plaintiff Cairo filed a declaratory relief action in California. The federal court found that Cairo’s use of CMS’s Web pages in allegedly copying promotional materials was such an “actual or imputed knowledge” of those terms as to effectively bind Cairo to the forum selection clause mandating Illinois as the proper venue. CMS’s motion to dismiss was granted.

## INFORMATION SECURITY LEGAL LIABILITIES

Whether owing to electrical brownouts, software errors, or hacker interference, systems crash every minute with loss of data, inoperable equipment, and frozen software. Along with the reported cases, there are general rules of law that apply in deciding how and where liability for damages will reside. Basically, liability sits with the computer software and hardware manufacturers for their products’ “inability to perform as promised,” along with a growing Web operator liability when users lose data or incur damages—but along distinct legal lines.

### Computer Software and Hardware Manufacturer Liabilities

The great majority of cases involving computer software or hardware defects are brought usually on contract, breach of warranty, fraud, and recession grounds, not on general tort grounds such as negligence or strict liability

theories. As basic law, courts apply contract law to contract situations such as the purchase of computer software, errors, and breach of warranty problems, with tort law applied to noncontract situations (see, for example, *Grynberg v. Agri Tech, Inc.*, 2000).

Owing to an apparent general acquiescence of system malfunctions, vendor responses in solving their user's problems, insurance coverage, continuing technological improvements, responsive security safeguards (i.e., stronger firewalls, backing-up data, internal security procedures, etc.), and limitation of damage clauses, only a tiny fraction of security-related problems come to court and then most settle before trial. Two issues are common in these contractual disputes (and see the earlier discussion on "Terms of Use" and "Validity"): (a) Whether shrink-wrap (physically opening the plastic wrapping of a software box) or clickwrap (digital clicking on an Internet "I Agree" icon) acts are present, was there a valid contract entered into that included the standard Terms of Use provisions? (b) If so, was there a legally enforceable disclaimer of liabilities and/or damages?

Various courts have concluded that shrink-wrap and clickwrap licenses are a valid form of contracting, that a vendor may propose a contract of sale be formed, not in the store or over the phone, but after the customer has had a chance to inspect both the item and the terms in the box (or after "clicking" an "I Agree" button) as to standard, unchangeable terms. For example, see *ProCD, Inc. v. Zeidenberg* (1996); *Brower v. Gateway 2000, Inc.* (1998); *Mortenson Co. Inc. v. Timberline Software Corp.* (2000); *i.LAN Systems v. NetScout Service Level Corp.* (2002). Basically, if a shrink-wrap license agreement is enforceable with implicit contractual assent, then it is also correct to enforce a clickwrap agreement on the Internet.

Typically, these agreements contain limitation on liabilities, such as limiting any damages to a refund of the software price (or replacement of the hardware within a certain period) with no compensation for any out-of-pocket losses or ensuing damages. As mentioned in the previous section on e-commerce Terms of Use provisions, exclusionary clauses in purely commercial transactions—especially where the parties are of equal bargaining power and specifically negotiate their contractual terms—are generally upheld.

For example, in *Mortenson v. Timberline*, plaintiff Mortenson purchased a bid-analysis software package from defendant Timberline. After Mortenson used the software to prepare a bid that erroneously turned out to be nearly \$2 million less than it should have been, Mortenson sued on breach of warranty grounds. The Washington Supreme Court affirmed the lower courts' holding that the limitation of damages contained in the vendor's shrink-wrap package was valid. Mortenson was limited to a refund of the cost of the software with no provision for the much larger damages it had incurred due to that software error.

Other courts, however, have gone in different directions on this issue. In *Amsan LLC v. Prophet 21 Inc.* (2001), for example, a federal judge in Pennsylvania ruled that the software licensee could avoid the limitation-of-liability clause in its license agreement and pursue its remedies under the UCC, holding that because the warranty had

failed in its essential purpose, that the limitation clause had to also fail.

Except for the outstanding issue of these limiting provisions, however, it is clear there can be contractual liability if a software manufacturer warrants to anyone that its product will specifically perform in some way (i.e., "calculate mortgage payments to the penny") and doesn't. When a system crashes owing to no fault of the software provider (i.e., a hacker cracks through the site) at this time, the great majority of users generally seem to accept their fate. However, when an employee is responsible for that loss of data or security problem, the liability issues are clear.

### Security-Related Liabilities (Employee)

Liability against others for security-related breaches and damages is dependent mainly on whether an employee or outside third party is responsible for creating the security breach. Employee-created liabilities, even if the intentional act or tort of that employee, creates liability for his or her employer based on common-law liability standards—regardless as to whether the Internet, information security, or online operations are involved. Under the doctrine of respondeat superior, an employer is held accountable for the damages created by its employee, provided that employee was operating at the time within the scope of the employment relationship.

When an intentional tort is involved, as opposed to just being negligent or at fault, liability is still found on various grounds, including that the particular employee's acts would have normally been furthering the employer's business or was within their job responsibilities—even given that the intentional act would not have been condoned by the employer (see also Bick, 2003). Employees can create this vicarious liability for their employers, whether it's hacking into confidential databanks, disabling protective software programs, or sending sexually harassing e-mail messages. In fact, as Continental Airlines found in *Blakey v. Continental Airlines* (2000), businesses have liability for the individual online harassing acts of their employees; in this case, other pilots posted sufficient harassing gender-based messages on the pilots' bulletin board (and only accessible by them) that the court found the employer liable for a hostile work environment.

When hackers and viruses unexpectedly show up, however, whether it's cracking passwords, exploiting software design flaws, or coordinating attacks on target computers and Web sites, the issue becomes expectedly more complicated.

### Hackers, Crackers, and Viruses

Several large Web sites, such as Yahoo, Amazon.com, eBay, CNN, and Dell, in February 2000 were severely disrupted by distributed denial-of-service (DDoS) attacks. Later estimates of the lost business, data, and operational downtime ranged from \$1.2 to \$1.7 billion dollars. A 15-year-old teenager (known online as "Mafiaboy") living with his parents in Montreal, Canada, was responsible for the attacks. Despite the large-scale damages, Mafiaboy (Canadian law protects the anonymity of juveniles) received a sentence of 8 months in juvenile detention and a

\$250 fine to charity. If a teenager could do this, think what a dedicated hacker might be able to do. Or an experienced cracker on subscriber passwords.

Just 3 months later, the “I Love You” virus infected 45 million computers around the world. This hacker virus imbedded itself in a computer’s system files, causing system crashes and freezing, then ordered the “host” computer to forward an infected electronic mail attachment to all addressees in the user’s e-mail address book. Depending on the estimate—and including nearly 30 copycat viruses that came into being in the next weeks, the “I Love You” virus cost between \$6 and \$10 billion in lost productivity. There were no reported major U.S. cases decided regarding these security-related breaches, although claims and litigation with insurers over their coverage occurred.

Newspapers still report all too frequently the disruption caused by worldwide Internet attacks by hackers on computers and, given its market domination, on Microsoft operating systems in the main, such as the 2003 ‘LovSan’ virus. Given massive losses of data, or stolen identities, the question becomes just who is legally responsible for these problems—the software manufacturer(s), their Web site operator—customers, or the individual site users—and to what extent?

Clearly, hackers are subject to a variety of criminal and civil law sanctions (see generally Jacobson & Greene, 2002). Yet as seen so clearly in the Mafiaboy case, hackers—if they can be located at all—don’t have the money to pay for damages. The problem escalates when the virus or attack is terrorist inspired, and it will be years before any final court decisions are handed down on the myriad legal questions inherent in the September 11, 2001, tragedy (i.e., the extent to which the victim, such as the airlines, can be held liable for the intentional and criminal acts by others).

Regardless of cause, Web site operators work hard to recreate lost data and mitigate damage to their users—or risk losing their customers. When users can’t access a particular site or lose data, compensation is rarely given, however, and it isn’t cost-effective in the great majority of cases to litigate over limiting damage provisions. In high damage cases, users look toward the software manufacturer or Web operator (or both) with insurance coverage on both sides playing a dominant role (see also the next section, “Insurance Law”). The tendency by all players is to “downplay” any system malfunctions, reporting little, if anything, to the authorities or their users, preferring to negotiate with their vendors over any business losses or with their insurance carriers.

However, lack of information-security practices, record-retention policies, or backup procedures can create numerous headaches with state and federal regulatory agencies (see generally Bick, 2001). For example, the SEC penalizes organizations that it deems not to be in compliance with its record-keeping directives. In 2003, the SEC announced in a settlement agreement that it had fined five large, reputable businesses with broker-dealer operations—Deutsche Bank, Goldman Sachs, Morgan Stanley, Salomon Smith Barney, and U.S. Bancorp Piper Jaffray—a total of \$8.25 million (\$1.65 million each) for failing to have in place adequate procedures to retain e-mails and keep them accessible, all in violation of

record-keeping procedures (*Deutsche Bank*, 2002). Not having generally reasonable procedures for storing data, backup systems, or online and offline storage facilities can create problems when in litigation; courts are not accepting of excuses when discovery requests are thwarted by lack of data, and this violation can lose you a lawsuit (Buford, 2003). Further, state professional ethics bodies can and will intervene if, for example, a law firm or physicians group doesn’t adequately protect its electronic records with backup files.

## To What Extent Is the Victim Liable?

The question then becomes to what extent is the victim liable to its own customers? Generally speaking, an organization or individual is not liable to its customers for the unanticipated, independent tort of a third party. Presently, Web sites and their users seem to generally accept their losses from hackers and viruses, whether the software manufacturer could have anticipated the rogue programming or not—even when a protecting software patch against the computer virus was available and the site operator didn’t quite get around to employing it.

Legal experts maintain (for example, see Pinkney, 2002, and de Villiers, 2003) that common-law negligence and strict-liability grounds should be available, whether a patch was actually in existence or not. The theory of negligence involves proving four separate elements: a duty to a third party, the breach of that duty, proximate cause (or some “connection” or foreseeability between the breach and any ensuing damages), and damages that occur. Strict product liability is where liability is basically imposed regardless of fault on any merchant who introduces into commerce a good or product that is “unreasonably dangerous” when in a “defective condition.” To the extent that the software manufacturer and Web operator are not completely at fault, an offset to any user damages could be available. In both cases, end users can be compensated to the extent that any resulting losses are not their fault. By applying a standard of reasonableness or not being “unreasonably dangerous” with strict product liability, this line of reasoning implies that there is a duty or standard on the part of Web operators and the software and hardware manufacturers to create “information-secure” sites.

Victims of a computer virus infection, consequently, under current negligence theory and these arguments can sue the providers, distributors, and operators of infected software for their damages. Proof of specific negligence can be straightforward when the circumstances involve a familiar virus strain that could have been cost-effectively prevented. In cases involving complex and novel strains, however, these evidentiary standards may not be available and such direct proof not exist. Even in these cases, circumstantial evidence based on the doctrine of “res ipsa loquitur” (and see further, de Villiers, 2003) can be used to prove one’s case. (The theory of res ipsa loquitur, or “the thing speaks for itself,” allows an inference of negligence based on the mere occurrence of an accident and its surrounding circumstances, not requiring the proof of specific negligence.) Another de Villiers’ article (de Villiers, 2004) analyses the use of a negligence cause of action in the inadvertent transmission of a computer virus and

discusses these liability parameters within a virus infection context.

The same line of reasoning can be applied in hacker attacks that involve multiple computers. When DDoS attacks take place, the hacker typically has accessed a “master” computer that enslaves multiple numbers of other “zombie” computers in marshalling their systems to act in concert and flood the target system with massive amounts of e-mails, requests, and traffic, in an attempt to cause that system to crash or deny service to legitimate users. If a patch is available to protect these computers from being so enslaved, then using a negligence or strict liability standard can conceivably bring even these outside systems into the sphere of liability (Radin, 2001, 2002).

To do this, the courts will need to carve an exception to the general rule that disappointed expectations and economic damages (i.e., lost business profits, customers, and personnel downtime) under a “sour” contract are not recoverable, as well as the application of limiting Terms of Use liability and damage provisions, because negligence or strict product liability concepts in the great number of cases are not applied to these factual situations that don’t involve tortuous physical harm to persons or property (see *Springfield Hydroelectric Company v. Copp*, 2001; *Gus’ Catering, Inc. v. Menusoft Systems*, 2000).

When basic contract law and the UCC is applied instead of torts or strict liability, as we have seen, there is a much higher likelihood that limitation-of-liability and damage clauses will be upheld. In tort actions, courts go the other way and generally disregard these limitations (i.e., those providing that any damages are limited to just a refund of the product’s purchase price), holding that as a general policy individuals and organizations should not be allowed to contract against their own negligence.

Contractually, larger companies and entities with greater bargaining power negotiate with their software providers to insert protective language into their licenses in place of these limiting damage provisions. For example, their contracts may directly provide that the software companies are liable for any costs of security breaches and hacker attacks that exploit software weaknesses (i.e., the costs of data replacement, cleanup, and lost business). If the software provider wants the business, then it may very well accept this different language.

Smaller users are typically protected, if a hacker or thief steals a credit card number and uses this to charge for goods, whether online or offline: The customer is protected under current law for losses exceeding \$50, provided he or she doesn’t unreasonably delay in their notification of the credit card company after learning of the loss. In response, Mastercard, Visa, and American Express, among others, are understandably working with their banks and merchants to increase online information security with time lines to institute safeguards or else the participating institutions bear the cost of any chargebacks for purchases made from stolen credit cards and identities.

As leading court decisions are awaited, state agencies and legislatures are beginning to make the first inroads. In 2003, the New York attorney general’s office cited Ziff Davis (“ZD”), the New York-based print and online publisher of computer magazines such as *PC Week*, for failing

to provide reasonable computer security standards. In an offering of free limited subscriptions to a computer gaming magazine, ZD and its Web host failed to take precautions to protect consumer data, including leaving unencrypted subscriber data in the open on a publicly accessible server with no authentication controls. Hackers immediately gained access to the subscriber list, soon gaining the credit card information of 50 holders and posting the names and e-mail addresses of some 12,000 of its readers. Ziff Davis agreed to pay a \$100,000 fine to the states of New York, California, and Vermont, along with \$500 to each of the 50 subscribers whose credit card information was so accessed. Additionally, the settlement agreement provided that ZD would store data on protected servers, encrypt data in protected files, and use automated security tools (i.e., firewalls and intrusion detection systems), in addition to undertaking other safeguards. Organizations that fail to implement reasonable security systems and procedures are at risk for similar governmental action should a hacker break in.

Additionally, companies risk needing to call in the Federal Bureau of Investigation (FBI) or Justice Department under the Homeland Security Act (2002), if a hacker intrudes into sensitive information. For example, Data Processors International (DPI) is a U.S. firm that processes credit card information for Visa, MasterCard, American Express, and Discover. To its chagrin, DPI discovered that a hacker in February 2003 had accessed some 8 million credit card numbers. DPI called in the FBI to conduct a criminal investigation.

On July 1, 2003, California became the first state to pass a database privacy and antihacker act. This legislation requires that state agencies and companies with databases must notify their California customers when user personal information is illegally accessed from that computer network (California Legislative Service, 2002). If they don’t so notify their users or customers quickly and without unreasonable delay, then the company assumes the damages incurred by its users. Californians can bring civil actions for damages and injunctive relief. The law is intended to help consumers protect against identity theft by requiring businesses, wherever located, to disclose quickly any breach in their security system of personal information that is not encrypted. At this time, there is no comparable federal law. Unlike the California law, however, the federal U.S. Homeland Security Act makes the disclosure of these breaches voluntary.

The present lack of statutory and court direction will change, however, when a massive hacker attack involves a nuclear power plant, worldwide identity thefts, airline controller traffic, or some terrible act of injury. The resulting damage and noninsured liabilities will create an unfortunate climate mandating the standards as to who will pay for those liabilities and under what circumstances. Courts then will hand down decisions on negligence, strict liability, and the comparative negligence parameters. Legislatures will be forced to get down to business.

## INSURANCE LAW

With the technological sophistication of rogue programmers, the risks of operating on the Internet can be

substantial. Whether hackers or employees destroy data systems, intercept stored or transmitted personal information (identity loss), commit computer fraud, or order DDoS attacks, there are multiple risks of data loss and damages. Where a loss is uninsured, the risks increase that affected sites will need to compensate, one way or another, a large user's losses or accept that loss of business or even a lawsuit. A critical issue is whether Internet insurance risk coverage is present, and several basic considerations need to be analyzed first.

Unless a special rider or policy is purchased, the typical homeowner's policy does *not* cover an individual's losses for loss of data or other Internet damages, although it will generally cover the destruction of that computer. If you're running a business, then your personal insurance policies (whether fire, homeowner's, or car) in nearly all cases will not insure against loss when you're conducting your business operations—whether your activities are online or offline. You will need business or commercial insurance generally for such commercial protection.

Two basic insurance areas for any business are first-party property coverage (i.e., insuring your buildings and personal property against loss) and third-party liability coverage (i.e., lawsuits brought by third parties against you due to your operations). A separate commercial general liability (CGL) insurance policy typically covers third-party customer or user claims. CGL, excess liability, and other liability policies protect the policyholder against liability, including outside claims of "property damage" or "physical damage to the tangible property of others" from your acts.

Pre-cyberspace, the notion of "direct physical loss" was easy to recognize because this involved specific identified risks such as fire, slip-and-fall incident, or an automobile accident. The legal question was whether a given policy covered the submitted asset loss or third-party liability claim. The problem then came about when these decades-defined incidents under standard policy provisions now involved the loss of electronic data, as the Internet Age created new forms of loss. The question was just how "physical" were these intangible, millions of bits of information.

Insurance companies understandably took the position that their standard commercial CGL, E & O (errors and omissions), BPP (business owner's package policy), and other policies did not cover most Internet risks, arguing generally that loss of access, data, and the use of information systems was not the equivalent of a direct physical loss. Although the majority of cases held that these pre-Net policies did *not* cover electronic data losses from hacker attacks or crashed sites (see *Lucker Manufacturing v. Home Insurance Co.*, 1994), a few courts have taken a broad policy look at the issue and held for the insured (see *American Guarantee & Liability Insurance Co. v. Ingram Micro, Inc.*, 2000). In *Ingram Micro*, an Arizona federal district court made a basic policy decision that coverage "must exist" for these type of losses in the light of the realities of the modern Internet world.

In very specific areas other than loss of data, standard umbrella and CGL insurance policies can provide some small Internet insurance coverage—but discuss these provisions with your insurance agent or manager in detail. For example, claims stemming from a policyholder's

online advertising activities that, in turn, involve defamation, libel, slander, violation of privacy rights, or copyright infringement can generally be covered (provided the insurer didn't change that language later). CGL policies also generally provide coverage for the "oral or written publication of material that slanders or libels a person or organization (including product disparagement)," including the "publication of material that violates a person's privacy." Although some professionals recommend that businesses review their CGL policy for such coverage or negotiate with their insurer, legal experts believe that the better approach is to purchase specific Internet policies (i.e., media Internet operations)—and to be sure there is stated, definite coverage for your particular Net operations and risks.

Insurance companies then developed specific Internet data loss and third-party liability policies specifically covering the risks of loss from hackers, computer viruses, employee hacking, and much of the Internet privacy and intellectual property claims that clearly were not covered under traditional CGL, E & O, excess liability, and other pre-Internet policies. Supplemental e-commerce first-party property policies now can cover loss of electronic data, while digital error and omission policies can protect an insured from liability in defined areas, such as the above-mentioned advertising/personal liability, electronic data transmission, security lapses, and even copyright infringement (see, for example, Savetz, 2002). Web operators anticipating losses from Internet security problems can consider insurance coverage from their inland marine policies, fidelity policies, computer crime policies, and any other ones that have specific insurance coverage for these anticipated claims (see generally Gold, 2002). That's the good news.

The bad news is that insurance companies already are eliminating the provisions in their CGL policies that could infer coverage (such as in the advertising and privacy areas) that withstood court scrutiny and are tightening up sections to exclude Internet operations specifically. With the advent of worldwide virus attacks, such as the Code Red worm (an estimated \$2 billion in damages in 2001) and "Slammer" worm (some \$1 billion in lost global productivity in 2003), various insurance companies have raised premiums for Internet coverage or simply excluded certain Net coverage, such as that caused by computer viruses. Where reasonable coverage is possible, insurance companies are requiring that companies take strong preventive loss measures (i.e., strong firewalls, frequent backing-up of data, use of encryption, smart cards, electronic keys, and data restoration equipment plus procedures to secure their online systems), along with requiring stand-alone hacker policies—or go unprotected. The horrors of September 11 further compounded the question with the specter of terrorists unleashing viruses and the need for vulnerable industries to implement security procedures plus acquire adequate insurance to cover these risks (if affordable).

The bottom line is that it's a much better idea to discuss what Internet and security coverage is possible and at what cost with your insurance agent or risk manager before you incur an online loss. Read the policy provisions closely and, if possible, obtain a letter from your

insurer that specifically outlines your coverage. Litigating against your insurance company and agent over a denied claim—especially when that includes your customer’s or user’s complaints against you—is not a good alternative. You may be better off paying the higher premiums of specific Internet loss coverage or knowing, alternatively, that you are “self-insured”: the euphemism that in return for not paying premiums, you know you’re absorbing all of your and your users’ losses. For more on this subject, please see Security Insurance and Best Practices in this *Handbook*.

## THE CLASH OF LAWS

Given the numbers of cyberlaw conflicts, a key issue is whether a court in the plaintiff’s geographical area can hear and decide the case. Simply put, if the problem is big enough, you want your understandable laws to apply, eat and sleep in your own home, work in your office when not in court, and not have to hire an expensive attorney in a different state or foreign country. People involved in a court case don’t want jetlag, bad food, unfamiliar surroundings, a strange language, and being away from their family for weeks on end, which is why jurisdiction and conflicts of law is such a large, cyberlaw issue.

Jurisdiction over a nonresident Web site or Internet transaction in the United States is normally based on a local state’s long-arm statute. These laws provide that a state can assert jurisdiction over a nonresident defendant who commits a tort, transacts business, or has some connection with that state. When a state court asserts jurisdiction over a particular controversy to render a binding decision, for the most part it will also be constitutionally permitted to apply its laws, given sufficient connections with that dispute. (Federal courts apply the appropriate state substantive law when relevant to their decisions).

The U.S. Supreme Court’s landmark *International Shoe Company v. Washington State* (1945) decision established the law in this area. For a court to have proper jurisdiction, defendants must have purposely availed themselves of the privilege of doing business in that particular state (i.e., traveling through, selling there, advertising in, or other contacts in that state), and these “minimum contacts” must meet sufficient levels of due process so as not to offend our “traditional concepts of fair play and substantial justice.”

For example, if a Wyoming rancher died and willed his ranch to his Wyoming son, it would offend our sense of “fair play” if a second son, who happened to live in Alabama, could sue and haul that Wyoming brother into an Alabama court. There are no connections with Alabama to this case, so the only court with jurisdiction should be Wyoming—and that court would apply Wyoming law (the property is there, the decedent and his heir lived in the state, the will was probated there, and so on).

When it comes to jurisdiction on the Net, U.S. courts generally look at a Web site’s level of Internet activity, drawing distinctions between passive and active locations—and this distinction will be drawn more in foreign courts, although it is not a trend overseas. Called the “Zippo sliding scale,” this test was set down in *Zippo Manufacturing Co. v. Zippo Dot Com, Inc.* (1997).

At one end of the spectrum, Web sites that enter into contracts with out-of-state residents involving repeated contacts, e-mails or other correspondence, and selling appreciable amounts of products or services into that state are held to be “active” Web sites. These active sites can be sued in the state of their customers, or in those out-of-state residents, as various U.S. cases have held. Given the existence of these sufficient contacts, a local court could (depending on the facts) disregard a contrary Terms of Use condition of the Web site that provided it could only be sued in its home state.

On the other side of the equation, sites that only advertise or post information about their business on the Internet—not taking any orders or conducting business through that Net site—are held to be “passive” Web sites. These Internet “informational” sites generally cannot be sued out of state and dragged from their home base into foreign courts, simply because they maintain a virtual presence. To hold differently would be to subject Net operators to being sued anywhere in the world that allowed an Internet connection to be made.

In between are Net sites that provide more connections between their state and out-of-state customers—and it usually takes more than having an e-mail capability and a toll-free number to confer that jurisdiction. With these same facts, e-mailing questions about a potential purchase (without more) doesn’t suffice either, although some courts view this as borderline and “getting very close.” If a defendant Web site displays a downloadable mail-in order form, toll-free telephone number, and e-mail address but no orders are ever made there, then these facts are not normally good enough. Given a finding that a passive site was involved, the upset user then must travel to the Web site’s home state to sue. As indicated, a factual decision needs to be made in each case as to whether these minimum connections for due process reasons are present.

Some courts have developed an “effects”-based approach exception to the Zippo sliding scale. When using this approach, the court focuses its analysis on the actual effect that a Net site had in its state or the defendant’s intent, not on how interactive the Internet location was. This test derives from the U.S. Supreme Court’s *Calder v. Jones* (1984) decision, in which jurisdiction was found over a nonresident defendant newspaper, based on its intentional conduct outside the forum state that was deemed to cause defamatory injury to the plaintiff resident in that state—even though strong factual connections weren’t otherwise present. Although courts tend to apply the “effects” test in cases involving intentional torts, such as defamation or trademark infringement cases, they do differ on what conduct constitutes the kind of “express” aiming or effect that’s required to satisfy the test. Applying the “effects” test can find jurisdiction when there aren’t sufficient contacts of the type called for under the Zippo sliding scale.

In a closely followed case, the California Supreme Court in *Pavlovich v. Superior Court* (2002) overruled a Court of Appeals decision involving the application of the effects test. Pavlovich had posted his programming adaptation of DeCSS software, a technology allowing the scrambling system in DVDs to be rendered ineffective and

their contents copied. The appellate court held that California had jurisdiction over Pavlovich, a Texas resident but who was an engineering student at Purdue University in Indiana at the time. Although the defendant's actions didn't come close to meeting the *Zippo* test, the appeals court held that because there was an "effect" in California from Pavlovich's "intentional tortuous" actions, that California had jurisdiction, could apply its long-arm statute, and force the defendant to come there and defend himself. The California Supreme Court, however, reversed this decision on a 4-3 vote. It held that under the *Zippo* test, the Web site was merely an informational one and there was no evidence that the defendant had expressly hurled his activities at California. It ruled that a defendant's knowledge or foreseeability alone of harmful effects ensuing in a specific state (California) is not sufficient by itself to establish any "purposeful availment" of that state's law under the effects test. There must be more than that.

As can be seen, these can be complicated cases, whether the issue involves e-commerce differences, sales tax assessments, or defamation cases. Further, not only can a business (or wrongdoer) be a resident of one state, or even offshore from the United States, his server may be located physically in a different state, the connecting routers in others, and the end user or complaining party in another completely different one.

Keep in mind that the U.S. Supreme Court hasn't yet ruled on this area of virtual personal jurisdiction, nor what happens when a Web site's Terms of Use provisions are different from the reviewing court's laws—and courts, domestic and foreign alike, can and do give "wild" judgments that don't seem to meet any tests or analysis. For example, Australia's highest court ruled in *Dow Jones v. Gutnick* (2002) that a publisher could be sued for defamation in whatever country an individual's reputation has allegedly been harmed. This case arose when an Australian businessman, Joseph Gutnick, sued U.S.-based Dow Jones & Co. for comments made about him in an article posted on the Internet in *Barron's Online*. This court found that because damage to the plaintiff's reputation had occurred in Victoria where the article was downloaded and read, it was appropriate for Gutnick to seek damages in that Australian forum. If other countries follow the Gutnick decision, let's say Canada, then it is entirely likely that if a defamatory digital publication is read in Canada, that there can be a sufficient nexus to maintain a defamation action in Canada, regardless that the publisher and server of that entity is located entirely in the United States—not an appealing legal proposition for that publisher.

Because laws vary greatly from country to country, what's prohibited by one nation can be entirely permissible in another. Unless an international treaty governs (e.g., the United Nations' Contracts for the International Sale of Goods [CISG]), countries are free to apply their own, quite different laws. The court that feels it has the greatest "connections," or the greatest interest in protecting its citizens, can and will take charge. It is quite possible that the courts in two countries could reach two entirely different results—and this has happened numbers of times. The basic question then is the extent to which the laws of one country may be enforced against Web sites and hosts located in others.

As one example, a French judge ordered U.S.-based portal Yahoo to block Web surfers in France from an auction where Nazi memorabilia were sold, including a fine of 100,000 francs (\$13,700 U.S. dollars) for every day of noncompliance. Although Yahoo's offering sales of Nazi items was legally protected in the United States under the U.S. Constitution, it voluntarily banned the sale of these items in response. Arguing that the French court had no jurisdiction over it, however, Yahoo quickly countersued in a California Federal District Court to overturn that decision's effect in the United States.

In late 2001, the U.S. court ruled that Yahoo didn't have to comply with the French court's order (*Yahoo! v. La Ligue Contre le Racisme et L'Antisemitisme*, 2001). It held that a U.S. court cannot enforce a foreign order that violates the U.S. Constitution by "chilling protected speech that occurs simultaneously within our borders." Thus, the U.S. court held that Yahoo didn't have to comply with all the laws in other countries that conflicted with those of the United States. French civil rights groups appealed this decision to the Ninth Court of Appeals. (In 2003, a French court acquitted Yahoo of criminal charges that it had violated French criminal law by previously allowing the online sale of Nazi memorabilia from its U.S. Web servers.)

The appellate court in the United States, however, reversed the District Court's order (*Yahoo! v. La Ligue Contre le Racisme et L'Antisemitisme*, 2004), concluding that there was no basis for general jurisdiction in this case because the French groups did not have the continuous and systematic contacts with the forum state to support a finding of general personal jurisdiction. A key issue was that the French groups had never tried to collect on their judgment. Instead, Yahoo had filed a pre-emptive lawsuit against the groups, and in a split 2-1 decision the majority didn't reach the First Amendment issue, holding that Yahoo would have to wait on that question until the French litigants came to the United States to enforce their judgment. The Ninth Circuit Court of Appeals then decided to rehear the case "en banc" (the full court), but whatever its final decision, an appeal to the U.S. Supreme Court is expected.

The problem is not simple: Given other countries entering this fray, which court is right, when, and under or with what final authority? Because no international Supreme Court exists to adjudicate private disputes, there is no real way to settle this problem unless the parties later agree to those procedures. If the parties had negotiated the applicable law and forum before that dispute arose, then that agreement would control.

Fundamental differences among the various countries abound that affect basic principles, whether it's the United States and its First Amendment or EU countries with their basic consumer privacy protections. France mandates the use of the French language for numbers of documents in that country, whereas the EU and Japan have enacted strong antispy laws. Germany provides for a 2-week right of recession on online purchases, the U.S. to the contrary in this situation, as well.

One way to solve these questions is for countries to pass an international jurisdiction treaty that binds the signatory states. The Hague Conference on Private

International Law with over 60 member countries presently has established the “Hague Convention on Jurisdiction and Enforcement of Judgments in Civil and Commercial Cases.” (For more on the Hague Convention and its jurisdictional efforts, see its Web site at <http://www.hcch.net>.) The Hague’s jurisdictional treaty legislation is in the works but will take years to finalize—and this state of affairs is the reason why alternative dispute resolution is growing in e-importance. For further treatment of international cyberlaw areas, see the appropriate chapters in this *Handbook*.

## CYBERLAW DISPUTE RESOLUTION

One cyberlaw fact of life stands out: Resolving disputes arising from the Internet’s global reach through litigation is complex, expensive, and loaded with unclear results. In response, the Net community is actively pursuing alternative dispute resolution techniques (ADRs) such as mediation and arbitration—both offline and online. Given their low cost, confidentiality, limited negativity, and speed in resolving cyberdisputes, the use of ADRs is accelerating among users.

Web sites and online operators actively promote ADRs in their agreements and Terms of Use provisions. ADRs have been used to settle all types of Internet disputes, whether between Web partners, competing sites, domain name holders, ISPs and their subscribers, copyright holders and copiers, and many other Net matters. Credit card companies use an ADR form when they use “chargebacks” to end a customer’s complaint with an online seller. As discussed before, ICANN has established a worldwide arbitration procedure to resolve domain name “cybersquatting” disputes. The U.S. Digital Copyright Act basically provides for an administrative procedure in resolving copyright disputes.

One of the striking ADR advances has been the rise of online cybermediators who work primarily online. For example, one party contacts the cybermediator about the problem and the parties’ inability to solve it; the mediator then contacts the second party. If both parties agree to use a mediated approach and accept the ground rules, the online mediation begins. Typically, each party e-mails the mediator with his or her position or an acceptable settlement amount. The mediator then intercedes, shuttling back and forth electronically to reach a settlement. Although the experience has been that not having an actual presence between the mediator and parties (i.e., not experiencing body language and “real-time” emotions with words having a stronger unanticipated impact when made by e-mail) can be a drawback of online mediation, the 24/7 availability at any time, low cost, and no need to travel have proven to be advantageous.

Online resolution has particular advantages with lower monetary claims. In financial disputes, each party e-mails the amount at which they would settle their claim. In these “mediations,” the agreed rules can provide for three rounds or more of settlement offers. Each party has also agreed to lower its demands by an agreed percentage—let’s say 10%. By the third round, if the sides are close (let’s say within 20%, or by some other formula), then that difference is halved and a deal struck. This is a brilliantly

simple, mathematically oriented solution with special advantages for low-figure disputes.

The leading player in providing this “double-blind bid” procedure is Cybersettle.com, which was awarded a U.S. Patent (among other countries) for that process. Other ADR service providers in cyberspace are ClickNsettle.com, SquareTrade.com, InternetNeutral, American Arbitration Association ([adr.org](http://adr.org)), and SettleOnline, to name a few, and there are over fifty online dispute resolution Web sites at this time. Rather than being caught up in establishing expensive legal precedents over simply the issue of which law applies, where, and when—and then the main legal case must be fought—more and more parties are settling their disputes on or off the Net by using ADRs.

## THE LAW OF LINKING

The World Wide Web depends on linking for its very existence, because this makes the Internet what it is. With the Net’s maturity, however, the previous unconditional freedom to link has evolved into a framework of commonsense legal and netiquette rules that dictate limits on this freedom.

The general rule is that one doesn’t need permission to link directly to another site, provided there is no commercial gain or some competitive informational advantage brought about by that linkage (even for a nonprofit institution). It is clear, moreover, that users should receive permission when they are “deep linking” or “framing,” if only as a courtesy—and whether one should ask permission before any linking is a question of cyberethics, quite distinct from the law and any of its requirements. Clearly, any stated or implied representation by linking that another’s work is yours would be trade or service-mark infringement (e.g., using its logo in conjunction with a trade or service), unfair competition and libel (e.g., saying something is yours when it’s not), or a violation of the covenant of “good faith” that’s implied in netiquette. Linking to illegal content by itself can also be illegal; in *Universal City Studios v. Reimerdes* (2000), the court enjoined the defendants from creating links from their court-prohibited site to numbers of other “mirror” sites.

When links bypass home pages, connecting instead to a page deep within that site, additional considerations become present. Lawsuits have been filed and settled in the plaintiff’s favor in which the plaintiff complained over “deep links” bypassing the advertising on their home page, decreasing the “hit count” (users surf past the “count” page), diminishing their site’s value, and allowing the defendant to “pass off” that information as its own.

The U.S. legal community, for example, watched closely when the owners of a newspaper, the *Shetland Times* in Scotland, brought a lawsuit against the *Shetland News*, a startup news service located in the same town. The *Shetland Times* published a daily online version of its newspaper, and the *News* was the first local daily to publish solely on the Web. It linked directly into the *Times* for news, and the *Shetland Times* went to court. The court granted the *Times* a temporary restraining order against the *News* and its linking practice (*Shetland Times v. Shetland News*, 1996), and the case soon settled out of court.

One well-publicized framing case was the lawsuit brought by various media companies (CNN, Time Warner, *USA Today*, the *Washington Post*, etc.) against Total News for its framing strategy. The media argued that the use of those frames, whereby Total News showed news stories taken from the plaintiffs with only its advertising displayed, violated their copyright and trademark rights. Total News reached a settlement before trial, agreeing not to frame any content and paid to link to their sites in a separate window (*Washington Post Co., et al. v. Total News*, 1997).

An accelerating Net phenomenon has been the rise of linking agreements in which a linked site pays for the exposure. These situations occur in two ways: (a) the linkage is in reality an advertising contract or customer referral agreement (see Amazon.com's "Associate" program); (b) the linked site commercially profits or otherwise benefits from a deep link. In both cases, a written linking agreement is essential.

Commercially profiting by deep linking or sophisticated software without the other site's permission is another growing legal area. Known as "robots," "bots," "spiders," or "crawlers," these automated software systems steam past home pages deep into data banks, gathering information and transporting copies of whatever is desired back to the host site. If done frequently enough, these "hits" can create a near simultaneous look at whatever data is out there.

The largest Internet auction service, eBay, filed a lawsuit in late 1999 against Bidders Edge, one of several Net auction search services. It had been accessing eBay's site up to 125,000 times daily (as much as 1.53% of the total daily requests to eBay) in searching out what was going on specifically at eBay's auctions, and eBay promptly sued after not being able to work out a license agreement with Bidders Edge to pay for this continuing access.

The judge granted an injunction, agreeing with eBay's contention that Bidder's Edge and its robots were trespassing on eBay's site by using and diminishing the resources of eBay's computer systems without permission (*eBay v. Bidder's Edge*, 2000). Bidder's Edge quickly appealed, but just before the appellate court issued its decision, the two companies agreed to settle their lawsuit. Later, eBay reported that the settlement prohibited Bidder's Edge from sifting through its site for information and that Bidder's Edge agreed to pay an undisclosed amount of money.

Internationally, a Danish court in *Danish Newspaper Publishers Association v. Newsbooster.com* (2002) ordered an online news site, Newsbooster.com, to remove links from its site to articles on the Web sites of various newspapers, on the ground that the links violated the EU Database Directory and bypassed the newspapers' home pages—following past precedent, both U.S. and a growing international law.

The directions of the law of linking are clear: (a) The general rule is that users do not need permission to link directly to the home page of another site, provided they don't disparage, misrepresent, or misappropriate; (b) given that these facts aren't present, framing and deep linking as opposed to linking will more likely constitute a violation; and (c) deep linking in commercial situations, as opposed to

noncommercial ones, are likely to be violations in which (1) direct competitors are involved, (2) there is an advantage being taken by that linkage, and (3) there is an element of "unfairness" or bad faith on the part of the linking party. Furthermore, if data are being misappropriated, misused, or passed off by another as its own, even non-profit or noncommercial sites may have valid causes of action.

## CYBERCRIME

Cybercrime flourishes on the Internet, whether it is fraud, phony investments, hackers and poppers, pornography, rigged auctions, computer stalking, or prohibited gambling (and see <http://www.cybercrime.gov> for more). The advantages of the Net for all users can quickly turn into disadvantages for law enforcement. The ease of entry and ability to disconnect from the Web allow criminals to appear and disappear within seconds with their ill-gotten gains. Arresting criminals is further complicated by the myriad jurisdictions that cybercriminals can cross so quickly, the protection of rogue nations, and differing state or national laws that can make extradition difficult. In turn, the authorities have had to add technology patrols to their arsenal of weapons, and Net users must be ever on the alert.

Although nations add protective laws over time (e.g., the United States with its Access Device Fraud Act, 18 U.S.C. 1029 [1984]; Computer Fraud and Abuse Act, 18 U.S.C. 1030 [1986]; Trademark Counterfeit Act, 18 U.S.C. 2320 [1984]; and the various others mentioned previously), the question of jurisdiction and enforcement is always raised in this context. With criminal statutes, states and countries look at jurisdiction from the point of view of their laws and interest in protecting their citizens. For example, if gambling is illegal in State A but not State B, then a Web site in State B could be prosecuted by State A for its allowing the residents of State A to use that site. The reasoning is that every Web operator has the ability to be in compliance with State A's laws by simply refusing to allow A's residents to break their state's laws (i.e., by filtering out State A users).

Enforcement is always another question. Located in the Bahamas or other locations where activities such as gambling are legalized, just how do you enforce State A's judgment penalizing another in a foreign state or country, not to mention the inherent personal jurisdiction and conflicts of laws question (i.e., the Yahoo Nazi memorabilia decisions)? Unless there's increased cooperation among the differing authorities and criminal justice treaties agreed to, the First Amendment legal considerations by themselves will be voluminous. When property rather than an individual's freedom is concerned, courts seem to have less problems in determining rights, especially as to property that has already been seized (see, for example, *U.S. v. \$734,578.82 in U.S. Currency*, 2002).

The horrors of September 11 brought other considerations of Internet crime to the forefront, given the ability of terrorists to communicate, raise money, and transfer assets over the Net. Among various legislative proposals, the enactment of the Uniting and Strengthening America by Providing Appropriate Tools Required to Intercept and

Obstruct Terrorism Act of 2001, or the “USA PATRIOT Act,” illustrates these new thrusts. Among other provisions, the USA PATRIOT Act requires key financial sectors to implement programs that prevent their services from being used to launder money or finance terrorism. Entire new industries, such as operators of credit card systems, money transfer companies, check cashiers, security firms, insurance companies, and even casinos—whether online or not—now are encompassed by strict regulations that once included only banks. This act also amended various provisions of the U.S. Code to allow broad interceptions of electronic communications and seizure of customer records (and also controversial). Other nations have or are enacting similar legislation. Their courts, including those of the United States, are currently being asked to rule on just how legal these restraints are on individual privacy and constitutional rights. See the chapter on cybercrime and fraud, among other chapters on cyberterrorism and the criminal justice system in the U.S.

## CONCLUSION

Hold onto your hats, the Internet hurricane of change is still howling—but inside your office or study. Legally, as well as technologically, there are more vibrant areas of change coming. For example, professional associations these days face Web sites that give information out to potential patients, clients, and customers on a global basis. From medicine and accounting to lawyering and filling drug prescriptions, state licensing boards are taking issue with this “practice without a required state license.” This area continues to be well litigated.

Another area involves the ability of the Internet to “cut out the middleman.” Because this medium allows consumers to contact suppliers directly, the old ways of conducting business are being seriously challenged in the courts. Travel agents sue airlines, wine distributors litigate with wineries that sell direct (in effect, suing their own customers or suppliers), and offline textbook distributors sue online retailers, not to mention the ever-increasing numbers of other industries that are litigating these types of developments. Although the consumer has benefited, it’s clear that the legal industry also has.

A U.S. Supreme Court decision (*Granhold v. Heald*, 2005) ruled that laws dating back to post-Prohibition days were unconstitutional that allowed in-state wineries to ship directly to adult consumers within their borders, but then prohibited out-of-state wineries from shipping to the same accounts. The court ruled that restricting the ability of out-of-state wineries to ship directly to consumers in today’s Internet Age violated the Commerce Clause, despite the 21st Amendment (which repealed Prohibition) which basically established that wine entering a state typically must be sold through a three-tier system of “producer to wholesaler to retailer” before reaching the consumer. If a state chooses to allow direct shipments of wine, then it must now do so on “evenhanded terms”—and the traditional wholesaler lost economic power again.

International price competition, courtesy of the Internet, is another litigious trend. For example, the Food and Drug Administration, citing safety concerns and regulatory violations, has sued U.S. companies that solicit

drug prescriptions in the United States, then fax them to Canadian or other overseas suppliers, which then fill the orders and mail them back to their U.S. customers—at prices much lower than those available in the United States, owing to price regulations in effect overseas. These overseas Internet competitive developments will only increase over time, including the accompanying legal issues, battles, and legislative developments.

There’s no question that the megasites and huge portals (such as AOL and Yahoo) dominate the Internet, and that the question of antitrust will rear its head even higher in the future. From AOL’s acquisition of gigantic Time Warner to the Covisint cyberventure between the world’s six largest car manufacturers and their suppliers, the Web trend continues toward greater concentrations of power.

With the increase in cyberlaw actions over time, the rise and accepted use of cybercourts will also become a reality, along with more jurisdictions and courts converting to public accessible, electronic record keeping and filing. The federal government has instituted a PACER (Public Access to Court Electronic Records) system, which is an electronic public access service that allows users to obtain case and docket information from Federal Appellate, District and Bankruptcy courts, including a U.S. Party/Case Index. Links to almost all of these courts are available by registering with PACER, the judiciary’s centralized registration, and a relatively inexpensive fee is assessed for usage (see <http://pacer.psc.uscourts.gov/> for more on this). States have also instituted their own digital-access court information systems and procedures, some more advanced than others, and check out yours with a search engine.

In this direction, Michigan became the first state to create a specific cybercourt (Mich. Pub. Acts, 2001). When funded and operational, the new cybercourt under this legislation could become a model for other states. This court would have concurrent jurisdiction over commercial litigation in disputes where the amount in controversy exceeds \$25,000. All filings are to be made electronically, whereas all actions, depositions, and court appearances are by “electronic communications,” such as streaming video, audio, and Internet conferencing; the intent is that there will be no paper transmitted or physical interface between judge, litigants, or witnesses. Appeals are to be made either to a new cybercourt of appeals or through a normal appellate court. See <http://www.michigancybercourt.net> for the details and background of this approach.

Internationally, countries from England and Australia to Singapore already are experimenting with cybercourt systems and procedures. The Singapore Supreme Court, for example, has established a successful Technology Court allowing video conferencing for pre-trial conferences, ex-parte applications, and other “noncontentious” applications, thus allowing lawyers to have their applications heard and decided by the court without the need to appear personally. Further, a digital filing service, service of process, notification system, and other electronic systems are in place, making this a model for the future (and see <http://www.supcourt.gov.sg/> for more).

Regardless of the new Internet legal controversies that will rise up further in this new millennium, three real-

ities exist: (a) The legal concepts already in place have proven to be quite adaptable to these challenges; (b) the concepts of fair play, common sense, and netiquette are filling in the gaps through court decisions and statutes; and (c) the use of ADRs on the Net will continue to grow over time because of the inappropriateness of litigation to solve the cyberdisputes among the citizens of the world.

The Internet has enhanced our lives and challenged our laws. The legal system is continuing to meet the challenge, including the impact of information security issues, but our world is never again going to be the same.

## GLOSSARY

### **Anticybersquatting Consumer Protection Act (ACPA)**

A U.S. statute (15 U.S.C. 1125, 1999) that protects trademark or service mark holders (including the names of famous people) from those who register a mark's domain name or its equivalent with a bad faith intent to profit from that act (e.g., cybersquatters). It allows the trademark or service mark holder to sue for actual or statutory damages (when actual damages are difficult to prove) and force the domain name to be transferred back.

**“Click” or “Clickwrap” Contracts** An agreement whereby a party agrees to the terms and conditions of an online agreement by clicking on a space reading “I agree,” or some wording to that effect, to indicate the requisite mutual assent to those conditions and understanding.

**Communications Decency Act** Section 230 of this act (47 U.S.C. 223, 1996) provides that an online service provider is not to be treated as a publisher for purposes of liability for defamatory postings by third parties, nor liable for defamation in such cases.

**Cyberlaw** The emerging body of law that governs cyberspace transactions and disputes, otherwise known as the “Law of the Internet.”

**Cyberpirates** Persons or entities who register a domain name that is the valid trademark or service mark of another, intending to sell that registered domain name back to the legitimate mark holder at a profit. This term is similar to “cybersquatters” who register domain names ahead of such interest but wait (or “squat”) on those names until offers to buy back those names are received from others.

**Defamation** A false statement made by some person or entity about another, either orally or in writing, that is published to a third party and wrongfully harms the injured party's reputation.

**Digital Millennium Copyright Act (DMCA)** The 1998 act that amended U.S. copyright law and included (a) a section prohibiting circumvention of encryption or security protections on copyrighted software to violate its copyright (17 U.S.C. 1201–1204) and (b) a section on online service provider liability (17 U.S.C. 512). The online provider provisions set down an administrative proceeding that is used to resolve copyright disputes over third-party postings with online servers and establishes a “safe harbor” liability protection for those providers.

**Distributed Denial of Service (DDoS) Attack** A simple denial of service (“DoS”) attack typically involves one computer making repeated connection requests in trying to overpower the target system. In a DDoS attack the connection requests originate from a large number of computers, making it difficult to distinguish attacking traffic from legitimate ones. To launch a DDoS attack, a hacker accesses a computer system without authorization and inserts a software program that renders the system a “master,” able to control other computer systems. The hacker places software code then on numbers of other computer systems, causing them to operate as “agents” or “zombies” of the master system. The master system instructs its zombies to produce a flood of simultaneous requests to connect to the target system, overwhelm its capabilities, and attempt to thwart legitimate connection requests.

**Fair Use** The U.S. Copyright Act provides that the “fair use” of copyrighted works involving purposes such as criticism, comment, news reporting, teaching, scholarship, or research is not copyright infringement. Thus, some copying or copyright use is legally permissible in the United States that ordinarily would not be allowable in other countries.

**Intellectual Property** Property that the mind creates from intellectual, creative processes, whether music, books, inventions, poetry, software, trademarks, domain names, or even trade secrets. Depending on the form of intellectual creation, such property is protectable by copyrights (i.e., music, software, or a Web site's “look and feel”), trademarks (i.e., distinctive marks, whether identifying products or service), patents (i.e., inventions and Internet business-procedures), and trade secrets (i.e., customer lists, Coca-Cola's formula, and so on).

**Internet Corporation for Assigned Names and Numbers (ICANN)** The nonprofit organization that oversees a wide range of Internet functions (once the responsibility of the U.S. government) and is now managed by an international board of directors. Among other functions, ICANN promulgates policy on the registration of domain names, accreditation of new registrars, and implementation of domain-name dispute resolution policies.

**Jurisdiction** The power of a court or governmental agency to hear a case and decide the rights of the people or entities that appear before it. This jurisdiction can be *in personam* (determining the rights of people or entities, wherever they reside) or *in rem* (determining the ownership rights to property that is located within the court's territorial limits, regardless of where the disputing parties reside).

**Long-Arm Statute** U.S. state statutes that authorize a local court to assert personal jurisdiction over a non-resident defendant located outside that state, given certain factual circumstances being present, such as causing injury within that state by an act that takes place within it (i.e., a car accident).

**Netiquette** An informal, essentially noncodified doctrine of “Web manners,” courtesy, and cyberethics aimed at creating a system establishing what is or isn't acceptable conduct on the Net, regardless of what the law provides.

**No Electronic Theft Act (NET)** A U.S. act (17 U.S.C. 506(a), 1997) that provides there is an illegal infringement when pirated copyrighted material has a value of \$1,000 (a misdemeanor) or \$2,500 (a felony), even though there is no monetary gain or economic incentive on the part of the infringer.

**“Opt In” and “Opt Out”** The two distinct privacy policies used by Internet firms and Web sites, which may or may not be codified. With “opt-out” provisions, the user must take the affirmative step to say “no” or refuse permission to a Web site’s collection and transmission of financial and other sensitive consumer information. With “opt-in” policies, the Web site must take the steps to gain the positive approval of a user before it can collect, transmit, or sell such private information. Marketing firms prefer “opt-out” policies or laws, because these are less marketing restrictive and put the burden on the user, not the site.

**Prima Facie Evidence** Evidence presented that indicates a strong presumption the given fact or evidentiary assertion is factually true.

**Service Mark** A word, name, logo, mark, device, or some combination used by any person or entity to identify and distinguish services performed by it from those of another (e.g., Priceline.com’s name and logo).

**“Shrink-wrap” Agreement** An agreement whereby a party agrees to the terms and conditions of the contract, the provisions contained inside the box in which the goods are packaged, by opening the wrapper, or plastic shrink-wrap, that encloses the entire package. The act of opening the plastic, or box, indicates the requisite mutual assent to those conditions and understanding.

**Terms of Use** The legal provisions that govern anyone’s use of a particular Web site, including purchasing its product or service, and typically include disclaimers of liability, indemnity, handling of disputes, applicable law, dispute resolution, copyright and trademark notices, linking conditions, among other areas. Terms of Use provisions generally are located at the bottom of the home page with an icon of the heading, “Legal Provisions,” or some similar identification. They can also include privacy provisions, although these provisions are typically set out separately.

**Tort** The breach of a legal duty to exercise reasonable care that proximately causes injury or damage to another. This is a civil wrong that does not arise from a breach of contract.

**Trademark** A word, name, logo, mark, device, or some combination used by any person or entity to identify and distinguish its goods from those of another (e.g., McDonalds’ golden arches or Nike’s winged shoe).

**U.S. Copyright Office** The U.S. agency that oversees the registration and regulation of copyrights (see <http://www.loc.gov/copyright>).

**U.S. Patent and Trademark Office (PTO)** The U.S. agency that oversees the registration and regulation of patents and trademarks/service marks (see <http://www.uspto.gov> for further information).

**World Intellectual Property Organization (WIPO)** The specialized United Nations agency and intergovernmental organization that is responsible for promul-

gating and administering major international intellectual property conventions.

## INTRODUCTION

As we stand firmly in the 21st century, we can see that the Internet has transformed from a research network into a viable commercial marketplace. The legal framework of the Internet has also undergone significant changes from the time when John Perry Barlow declared:

Governments of the Industrial World, you weary giants of flesh and steel, I come from Cyberspace, the new home of the Mind. On behalf of the future, I ask you of the past to leave us alone. You are not welcome among us. You have no sovereignty where we gather. (Barlow, 1996)

There has been much debate as to whether national laws should apply to cyberspace, or whether a different regulatory system that better accounts for the borderless nature of the medium should be implemented. It was initially argued by some that lack of geographical borders in cyberspace turned cyberspace into its own distinct sovereignty beyond the scope of territorial law (Johnson & Post, 1996). Although this viewpoint was not universally accepted, “the belief in the virtually insurmountable legal complications created by bordered laws mapped onto a borderless Internet became a truism amongst many observers” (Geist, 2003).

During the economic prosperity of the 1990s, the Clinton administration was happy to step aside and yield development of Internet policy largely to private sector and self-regulatory initiatives. A report that outlined this policy on the Internet was set out in the Framework for Global Electronic Commerce (1997). It emphasized private sector leadership and minimal government regulation. The European Declaration, issued within one month of the Framework, also noted the special cross border

characteristics of the Internet and called for private sector dominance.

Today, spurred by business interests and as each nation seeks to protect its citizens and preserve its sovereignty, governments are taking more actions to establish the rules and regulations for cyberspace. This marks a shift in attitude and policy that can be attributed to the strengthening of national powers. This shift toward regulation through national laws has given rise to increased conflicts over which national law applies to a global Internet transaction, as well as the extent to which national laws can be applied extraterritorially.

This chapter reviews the major national and international laws in the areas of jurisdiction, privacy, electronic signatures, and encryption as well as copyrights and patents that presently affect cyberspace activity to suggest that there is an incongruence between nations in many areas. The author suggests that action be taken both in the private sector and by governments around the globe to synchronize laws in these areas. Certainty and consistency of laws are critical to the functioning of any society. The continued growth and development of the Internet will depend on whether a legal climate of predictability and reliability can be achieved.

This chapter begins by exploring the fundamental question of who, if anyone, has the legal authority to regulate the Internet. In the context of transnational law, this is, in essence, the issue of personal jurisdiction. The second section reviews the challenges that are often raised against a nation’s exercise of power beyond its borders and moves on to review the current status of jurisdiction jurisprudence for cyberspace. Concern about the protection of personal information threatens the growth of commerce on the Internet. The third section, “Privacy,” examines the national laws and international laws and treaties

that loosely form a privacy policy in cyberspace. Commerce is the major growth area on the Internet that depends on reliable contracts. The use of encryption and digital signatures to ensure the enforceability of electronic contracts is discussed in the fourth section, "Encryption and Electronic Signatures," together with an analysis of the current global status of electronic signature legislation.

Our definitions and understanding of rights to ownership in intellectual property have been challenged in response to the movement of information onto the Internet, and nations have responded to these changes in various ways. The final section, "Intellectual Property," reviews the principal international and national rules in the areas of patent and copyright infringement as they have been influenced by and have responded to the activity in cyberspace. Trademark issues are not included because this is a matter that is closely tied to the issue of registration of domain names; this has developed into its own specialty with the development of the Internet Corporation for Assigned Names and Numbers (ICANN) and is best left for a separate chapter.

The lack of uniformity in approach to legislation in many substantive areas is evident from the analysis presented in this chapter, and I suggest that policymakers remove their national blinders in order to foster e-commerce.

## JURISDICTION

### Jurisdiction—An Overview

Legal certainty and predictability is an essential element for electronic commerce to evolve profitably and efficiently. Compliance with rules is impossible without an understanding of whose law is applicable and the corollary to this is where the legal dispute, if it were to arise, will be resolved (ABA Project, 2000). These are questions of personal and prescriptive jurisdiction, which a century and a half ago were resolved easily when most people lived and died in relatively small geographic areas and the law of that place applied. Under traditional legal systems, the sovereign power of the state, which legitimizes the enforcement of its laws, is based on territoriality. There is a general correspondence between physical borders and legal borders. National borders have formed the sovereignty paradigms for regulatory authority and decision making. When parties to the action lived and the activities in dispute occurred in a single state, that state's courts and laws were the only obvious and uncontested jurisdictional choice (Mody, 2001).

Generally speaking, a state can only enforce its laws against a defendant when there is a local presence or when there are assets within the local jurisdiction (ABA Project, 2000). The Internet's architecture allows information to flow without bounds, and therefore, the individual or organization supplying the information cannot control where that content will end up. There are no physical barriers or cues to notify the provider; therefore, an activity, which may be lawful in Belize, for example, may be easily accessed in New York where it is unlawful (Mody, 2001). Individual states invest time, money, and effort to protect the welfare of its citizens and, naturally, legislate

accordingly. There is an apparent conflict between a state's sovereign interest to protect its citizens and a foreign content provider's ability to carry on its lawful activity. The main criticism that transnational cyberspace breaks jurisdictional rules is based on the notion a state may not act beyond its own territorial borders.

### Fundamental Jurisdictional Principles Under International Law

Jurisdiction can be broken down into two categories: prescriptive jurisdiction, which addresses the authority of a state to apply its own laws to regulate conduct, and enforcement jurisdiction, which is the executive's authority to compel compliance with these laws. The focus of this chapter is on prescriptive jurisdiction, although issues of enforcement jurisdiction are raised in the discussion of *Yahoo! Inc., v. La Ligue Contre le Racisme et l' Antisemitisme* (2001).

The threshold matter of "jurisdiction to prescribe" means that the substantive laws of the forum country are applicable to the particular persons and circumstances (RESTATEMENT[3rd] OF THE FOREIGN RELATIONS LAW OF THE U.S. sections, 300–450). When a country has jurisdiction to prescribe, it can appropriately apply its legal norms to conduct. Simply stated, a country has jurisdiction to prescribe law with respect to (a) conduct that, wholly or in substantial part, takes place within its territory; (b) the status of persons, or interests in things, present within its territory; (c) conduct outside its territory that has or is intended to have substantial effect within its territory; (d) the activities, interests, status, or relations of its nationals outside as well as within its territory; and (e) certain conduct outside its territory by persons who are not its nationals that is directed against the security of the country or against a limited class of other national interests (RESTATEMENT[3rd] OF THE FOREIGN RELATIONS LAW OF THE U.S. sections, 300–450).

Jurisdiction to adjudicate or to enforce means that the tribunals of a given country may resolve a dispute to enforce a judgment where the country has jurisdiction to prescribe the law. The exercise by a country of jurisdiction to enforce is subject to the requirement of reasonableness. States exercise jurisdiction to adjudicate on the basis of various links, including the defendant's presence, conduct, or, in some cases, ownership of property within the country. Exercise of judicial jurisdiction on the basis of such links is on the whole accepted as "reasonable"; reliance on other bases, such as the nationality of the plaintiff or the presence of property unrelated to the claim, is generally considered "exorbitant" (RESTATEMENT[3rd] OF THE FOREIGN RELATIONS LAW OF THE U.S. sections, 300–450).

Although historically a sovereign's power was tied to its geography, a state's power to regulate activity that originates outside the country but causes local harms has been recognized for many years. One of the first cases to recognize that a state's regulatory authority may extend to an extraterritorial activity was decided in the Permanent Court of International Justice (PCIJ) in 1927. *In the Case of S.S. Lotus* (1927), the court held that the state of Turkey could apply its criminal law to a foreigner who acted outside

of Turkey when committing the offense so charged and that prejudiced Turkey and its citizens, provided the foreigner was arrested in Turkey. This was an application of the law to a person or act outside the territory of Turkey, which had a local effect. This early case applied the “effects principle” to expand the authority of a state. This is a logical extension of control by a state outside of its territory to protect its citizens from actions taken by a defendant, which had an “effect” or impact within the state. A state’s territorial borders were no longer the sole determination of rule making authority.

In the more famous case of the *United States v. Aluminum Company of America* (ALCOA), (1945), the U.S. Second Circuit Court of Appeals considered whether the United States could apply the antitrust provisions of the Sherman Act to a Canadian company. The anticompetitive acts took place in Canada, but the material effects were experienced in the United States; the court ultimately did apply U.S. rules to this Canadian company. Thus, with the ALCOA case, the presumption of extra territoriality had been overcome.

### Classic U.S. Jurisdiction Principles

In the United States, assertion of jurisdiction over the person must satisfy the standard of constitutional due process. States enact long-arm statutes to exercise jurisdiction legitimately over nonresidents. Initially to establish personal jurisdiction over a defendant, a U.S. court will apply the relevant long-arm statute to see whether it permits the exercise of personal jurisdiction. Second, the court will apply the precepts of the Due Process Clause. A standard inquiry for whether due process has been satisfied focuses on whether the defendant has “minimal contacts” within the forum such that assertion of jurisdiction does not offend the “traditional notions of fair play and substantial justice” (*World-Wide Volkswagen Corp. v. Woodson*, 1980).

Under the Due Process Clause of the Constitution, one must look at the relationship between “the defendant, the forum and the litigation” (Aciman & VoVerde, 2002). Physical presence is not required, rather the plaintiff must show that the defendant has purposefully directed its activities toward the forum state, or otherwise “purposefully availed itself of the privilege of conducting activities within the forum State, thus invoking the benefit and protection of its laws” (*Hanson v. Denckla*, 1958).

Questions of jurisdiction in cyberspace have generated lengthy court decisions and caused much global debate because of the unique nature of Internet information dissemination. The current global jurisdictional case law though voluminous and inconsistent suggests that two principal tests are being used to ascertain jurisdiction (Rice and Gladstone, 2002). One is the “Zippo test” which is named after the case that first articulated it, *Zippo Manufacturing Co. v. Zippo Dot Com, Inc.* (1997), and the other is the “effects test,” which is based on a standard developed from a U.S. Supreme Court case that arose in the context of print media, *Calder v. Jones* (1984).

The “Zippo test” establishes jurisdiction over a non-resident defendant based on the degree of interactivity between the Web site and the forum. Mere access to

the non-resident’s Web site is the least interactive; under the “Zippo test” a passive Web site is not sufficient to establish specific jurisdiction. District Judge McLaughlin explained that whether jurisdiction could be properly asserted in a case was to be based on the nature and quality of the commercial activity that an entity conducts over the Internet. Jurisdiction cases fall somewhere on a sliding scale or spectrum on which the likelihood that personal jurisdiction can be constitutionally exercised is directly proportionate to the nature and quality of the commercial activity that an entity conducts over the Internet.

The primary difficulty that arises in applying the Zippo sliding-scale standard to jurisdiction cases in cyberspace has been in determining the degree of “interactivity.” Similar fact patterns have led to different jurisdictional findings in different courts. In addition, whether a Web site has been integral in a forum often turns more on a court’s perception than on real differences in the manner in which the user employs the Internet. For example, a judge in the Southern District of New York in 2000 found that the mere availability of the defendant’s Web site in New York made it “intuitively apparent” that defendant’s services were used by New York residents (*Cable News Network, L.P. v. GoSMS.com, Inc.*, 2000). The judge therefore found grounds for jurisdiction even though he acknowledged that plaintiff’s allegations that defendants’ mobile telephone and two-way e-mail services allegedly used in New York were “factually unsupported.”

### Jurisdiction Based on “Effects”

The first instance when “purposeful direction” arose was in the context of traditional media, and it has become the basis for all U.S. cases applying the “effects test.” In *Calder v. Jones* (1984), Florida residents who had essentially no physical contacts with California wrote and edited an article in the *National Enquirer* that defamed Shirley Jones, a well-known movie actress residing in California. The *Enquirer* had greater circulation in California than in any other state, and the material was based on California sources. The U.S. Supreme Court found jurisdiction, holding that California was the focal point both of the story and the harm suffered. The Court held that the defendants’ acts were intentional, that they were aimed at California, and that its effects took place in California.

The first use of the “effects test” in asserting jurisdiction against a defendant in an Internet context was the cybersquatting case of in *Panavision Int’l. L.P. v. Toeppen* (1998). Toeppen, an Illinois defendant, had intentionally registered the California plaintiff’s trademark as his domain name, namely Panavision. When attorneys for Panavision contacted Toeppen to demand that he stop using the name, he responded by offering to sell the name for \$13,000 and promising not to acquire any other similar names. Unwilling to be bribed, Panavision sued Toeppen in California District Court where Toeppen objected on jurisdictional grounds. The court found jurisdiction appropriate under the “effects” test because the defendant had intentionally directed its conduct toward California knowing the effect of his registering the domain name would be felt in California. The Ninth Circuit agreed, analogizing

cybersquatting to an intentional tort and found that “the brunt of the harm to Panavision was felt in California.”

In a recent Australian libel case, the “effects” test was applied to assert jurisdiction to protect a Melbourne citizen. The Victorian Supreme Court found jurisdiction over Dow Jones, a United States company, based on its *Wall Street Journal* Web site, which carried an allegedly libelous article about Joseph Gutnick, an American businessman who lived in Melbourne, Australia. The Australian Court found the publication occurred and thus had its impact whenever the article was downloaded, thereby dismissing Dow Jones’ argument that the court lacked jurisdiction because the information was not published in Australia. Again, the impact and effect was felt in Australia (*Gutnick v. Dow Jones*, 2001) VSC 305.

Several leading cyberspace commentators have suggested that the effects test is a more useful mechanism than the *Zippo* test for establishing jurisdiction in Internet cases. In fact, the effects test has been refined into two parts: a “Strict Effects” test, which looks to the intent of defendant acting outside the jurisdiction to establish a connection and a looser, and a “Soft Effects” test, which focuses more simply on the impact within the jurisdiction (Rice & Gladstone, 2002). The former has been employed mostly in tort and intellectual property cases. Indeed, cases of defamation lend themselves easily to finding jurisdiction under the Strict Effects test because intent to harm is an essential element of the underlying cause of action. At the present time, it is likely that a court dealing with the issue of jurisdiction over a nonresident based on his or her online activity will start its inquiry by using *Zippo* but continue the analysis by applying the effects test. Therefore, attorneys who advocate jurisdiction in a particular forum would be best advised to consider both tests because the effects test may apply where the *Zippo* test does not.

## Fundamental Principles of Jurisdiction Under European Law

In the European Union (EU), the primary source of law on jurisdiction, recognition and enforcement of judgments law has been the Convention on Jurisdiction and the Enforcement of Judgments in Civil and Commercial Matters September 30, 1968 (the Brussels Convention). Under the Brussels Convention, jurisdiction is based on the defendant’s domicile, Art.2. Alternative jurisdictional grounds are available so long as there is a close link between the court and the action or if the “sound administration of justice” would be facilitated. In contract matters the place of performance would govern the jurisdiction decision (Art.5.1), although there are special provisions for consumer contracts. In tort matters, jurisdiction would lie in the place where the harmful event occurred (Art.5.3).

The Brussels Convention was modified effective March 2002 as the EU issued the so-called Brussels Regulation (2000). In contrast to a convention or directive, a “regulation” of the EU becomes binding immediately after its adoption upon the 15 member states without the need for further implementation. The economic drive of electronic commerce created the need for certainty and uniformity of jurisdictional rules early on; therefore, the EU found it efficient to proceed quickly with a mere regulation.

Although the Brussels Regulation does not alter the main structure of the Brussels Convention, it effectuates certain changes that are to take account of the new technological developments that result from e-commerce. Most importantly, the Brussels Regulation is consumer-centered, establishing that the courts of the consumer’s domicile will have jurisdiction over a foreign defendant if the latter “pursues commercial or professional activities in the Member State of the consumer’s domicile or, *by any means*, directs such activities to that Member state . . . and the contract falls within the scope of such activities.” This language expands the range of situations in which the consumer can sue in his or her place of domicile.

The phrase “by any means” was included to broaden the scope of jurisdiction to reach Internet-based transactions (European Commission, 1999). The Brussels Regulation equates doing business or the offer of goods and services via the Internet with an invitation or advertising by businesses which by any means directs its activities toward that member state. In essence, the Brussels Regulation provides that an unintended effect in a member state can be the basis for jurisdiction. Because jurisdiction in European countries is not limited by U.S. Constitutional principles of due process as it is in the United States, the Brussels Regulation does not require notice or “minimum contacts.”

The Brussels Regulation was controversial; the negotiations reflected the tension between business and consumer groups. Industry groups claimed it would hinder the growth of e-commerce by making small to medium-size businesses reluctant to set up Web sites for fear of being subjected to the jurisdiction of the courts of too many countries. Alternatively, the EU Commission believed that without strong consumer protection the negative impact on consumer confidence would hurt the unified European market (European Commission, 2000). If, as a result of consumer’s reluctance to venture into the World Wide Web to shop, they were to stay within their own country, the commission believed the EU e-commerce sector would be put at a significant competitive disadvantage to the United States; this is based on the belief that the United States has stronger consumer protection laws.

The EU Parliament has also passed its Electronic Commerce Directive, which provides a more restrictive jurisdictional doctrine to legal disputes, restricting plaintiffs to a “country of origin” approach, Art.3. Under the Electronic Commerce Directive “the law of the country of origin (which is the seller’s place of business) would govern the cross-border disputes.” Although this may provide more certainty to businesses, it provides consumers with much less confidence in their business dealings (Boam, 2001). There are several exclusions from the Electronic Commerce Directive, including “contractual obligations concerning consumer contracts.” It is therefore uncertain how these exclusions will work together with the Brussels Convention as amended and will require case-by-case examination of jurisdictional issues in the short run.

## Enforcement Jurisdiction and the Yahoo! Case

The recent French lawsuit by the International League Against Racism and Anti-Semitism and the Union of

French Law Students against Yahoo! (the Yahoo! Case), which received so much attention in the popular press, summarizes many of the fundamental principles and issues that remain to be resolved in the area of international jurisdiction. In April 2000, two French groups, the Union of French Law Students and the International League Against Racism and Anti-Semitism, filed suit against Yahoo! for hosting auctions that displayed and sold Nazi propaganda. The memorabilia auctions were accessible only via the English-language site, Yahoo.com. Direct access through Yahoo.fr was not possible. Yahoo! argued in French court that the court did not have jurisdiction over Yahoo! That plea was denied, and in November 2000, a French court ruled that Yahoo! must put filtering systems in place to block users in France from access to Nazi-related goods or pay fines of approximately \$13,000 per day (Rice, 2002). Only a watered-down version of the soft effects test could be seen to apply to the French court's decision in this case, and because Yahoo! was not targeting France, which is a key element in the effects test, the assertion of jurisdiction arguably violates the due process requirement of U.S. law (Rice & Gladstone, 2002).

Yahoo! chose not to appeal the French court's judgment but rather challenged the enforcement of the order in the United States. In December 2000, Yahoo! filed a lawsuit in the U.S. District Court of Northern California, seeking a declaratory judgment that any final judgment of a French court would not be enforceable in the United States. Before the California court could address the merits of the case, in a bit of an ironic twist, the French defendants motioned the California court to dismiss the declaratory judgment suit due to lack of jurisdiction. The U.S. court denied the motion to dismiss, finding jurisdiction based on the effects theory. The court ruled that the defendant knowingly engaged in the activities and intended to have an effect on the United States citizens, for example, the use of U.S. marshals to serve Yahoo! officers in California. Clearly, the French citizens purposely availed themselves of the benefits of the United States.

A state can only enforce its laws against a defendant in a forum where the defendant can be found or where there are assets belonging to the defendant. Enforcement of a judgment rendered by another forum, however, requires its recognition by another court to enforce it. If it is the judgment of a court in a state in the United States, the Full Faith and Credit Clause of the Constitution requires that it be recognized by another state. When recognition of a judgment of a foreign court is sought in the United States, it depends on the principle of "comity" (ABA Project, 2000). Comity is not a matter of absolute obligation, but it is the recognition that one nation allows within its territory to the legislative, executive, or judicial acts of another nation (ABA Project, 2000). National procedures required for recognition and enforcement of judgments vary widely around the globe. In the United States, comity is generally upheld unless to do so would violate due process, personal jurisdiction, or some public policy.

To determine the enforcement jurisdiction of the French court over Yahoo!, the Federal District Court for the Northern District of California found the issue to be whether it was consistent with the Constitution and the Laws of the United States for another nation, namely France, through their court order, to curtail the

Yahoo! Web site. The French therefore would be regulating speech by U.S. residents within the United States on the basis that such speech could be accessed by Internet users in France. The court was mindful of the extent to which the United States is governed by the "comity of nations" but did not believe that comity was a matter of absolute obligation. The court decided the case in accordance with the Constitution, finding that the French order violated the U.S. Constitution, thereby recognizing that it was necessarily adopting the position that "certain judgments embedded within this enactment including the fundamental judgment expressed in the First Amendment that it is preferable to permit non-violent expression of offense viewpoints then to impose viewpoint based government regulation upon speech."

The court rendered judgment in favor of Yahoo! in a summary judgment motion that they requested on the declaratory judgment action to find the French order in violation of the First Amendment. This finding of a threat to constitutional rights by the court was the grounds by which it effectively rendered the order unenforceable and demonstrates the limits of perspective jurisdiction. This case suggests the disharmony that continues to exist among nations on questions of jurisdiction.

It appears that courts and legislatures have found legitimate grounds for asserting prescriptive jurisdiction over defendants based on actions taken in cyberspace, but that may have little importance when the plaintiff seeks a restorative remedy. Enforcement jurisdiction, which requires the injured party to attach either the defendant or his or her tangible assets, becomes an issue of comity or state's recognition of its obligation to enforce a law. Questions of comity have not been resolved sufficiently to ensure smooth enforcement on the Internet. Policymakers and governments will need to address this higher level of enforcement jurisdiction to foster predictability and certainty necessary for the growth of commerce on the Internet.

## PRIVACY

Society has not previously experienced the technological efficiencies that characterize the Internet—namely, transparent dissemination, collection, and aggregation of information. Although the facility of data collection has economic benefits, it compromises the individual's right to privacy. The Internet is the largest electronic infrastructure that allows public access to a nearly infinite resource of information, and as such it holds the current greatest threat to personal privacy. In recent years, many sectors of the global community have been directing time and resources to resolve the inherent tension that has developed between seeking the economic benefits from modern data collection practices and ensuring human dignity that is threatened by modern surveillance (Gladstone, 2000b).

The mechanisms used to protect that information fall into three categories: self-regulatory, statutory, and technology approaches. The self-regulatory or market-dominated approach, which is adopted in the United States, is based on industry-developed norms, policies, and contracts, rather than statutory legal rights to protect the privacy interests of its citizens. The statutory or rights-dominated approach, which is developed in the

European models and recently adopted in Asia, New Zealand, and India, relies on statutory and common laws to establish rights to information privacy (Reidenberg, 2000). Technology is used globally in varying degrees in different sectors. Data flows on the Internet are international, and these divergent data protection policies and rules confront each other with increased frequency. Attempts at harmonization have been enacted, most notably the International Safe Harbor Privacy Principles (1999), which were adopted to implement the EU Privacy Directive, but further work toward uniformity is needed.

This section begins with a description of two examples of how one's privacy is threatened on the Internet. The first example reviews data collection practices that threaten consumer privacy and is followed by a review of the laws in the United States that have been passed to prevent inadvertent exposure to pornography on the Internet. The section continues by exploring the differences that underlie the United States' versus the other nations' approaches to privacy, which suggests reasons for difficulties in finding a common ground. The *EU Privacy Directive—Explained* discusses the background and scope of the Council Directive 95/45/EC (EU Privacy Directive, 1995), including a discussion of the strategies for U.S. compliance, namely, the Safe Harbor rules, the Model Contract Terms, and derogations or exceptions allowed under national law.

The technology that drives the Internet is based on an open architecture, which has a natural default to expose information about people's actions on the Internet, whether it be the World Wide Web or e-mail. Several surveillance initiatives or technologies by the U.S. government have drawn on this open architecture to retrieve personal information about citizens. After the September 11, 2001, terrorist attacks in the United States, threats of terrorism have led the U.S. government to increase surveillance of foreigners as well as its own citizens. The passage of the USA PATRIOT Act (2001) and the Total Information Awareness Act (2003) have broadened the powers of the United States to investigate into the lives of individuals beyond the limits guaranteed by the U.S. Constitution. The expansion of privacy intrusion is developing at the same time that European initiatives to increase privacy rights and domestic proprietors who are looking to sell protective schemes are announcing the harms caused by privacy intrusions.

### Threats to Privacy Posed by the Internet

The expansion of digital computers and networking technology, with the Internet being the most prime example, has moved much of our social, educational, and commercial activities into an electronic environment. The technology that has enabled integrated global networks facilitates the creation of digital records of what an individual has spent time looking at, the time spent at a particular site, messages sent, and purchases made. This "electronic footprint" is created through a variety of processes that can be generated by simple browsing the Web (Piera, 2001). Activity of the user within the Web site provides "click stream data," which includes the time spent on each page and the information that has been retrieved. Technology is available that can collect and organize all this information

into data packets; these are referred to as *cookies* and are stored on the user's hard drive. A cookie is assigned a unique identifying code, and each time the user goes back to the Web site, the cookie is retrieved, which then tailors the second visit according to the previous behavior at the Web site. This invisible data collection is primarily conducted by business. The warehousing of transaction information and profiling of online users has become a critical component for e-commerce business models. The behavioral information enables sites to characterize users and offer them content of personal interest. Internet revenue is generated through target advertising that has become especially efficient as a consequence of the design of technological infrastructures that enable the global network.

This economic efficiency comes at the cost of lost privacy to the consumer. Studies indicate that Internet users choose not to make an online purchase due to privacy interest issues. In fact, some argue that consumers have lost total control over their personal privacy choices.

Inadvertent exposure to online pornography presents another example of how privacy is threatened by the borderless and anonymous world of cyberspace. Internet pornography is big business comprising 11% of the entire \$9 billion e-commerce sector in 1998, with industry experts projecting that e-porn will generate more than \$3 billion by 2003 (Alexander, 2002).

Many of the sites are free and serve as teasers to lure people into commercial sites; consequently children and adults alike may enter a pornographic Web site inadvertently. Such accidental exposure is common particularly because Web site addresses are often misspellings of desired Web sites. In addition, the open architecture of the Internet where all material is equally accessible means that sex-related materials are not segregated on the Internet as they may be in the material world. This exposure violates one's right to be left alone. Sexually explicit materials on the Internet range from the commonplace pornographic still frame to live broadcasts of couples losing their virginity.

The general public in the United States has voiced a desire to restrict the dissemination of pornography on the Internet, and Congress has responded with at least three major legislative reforms. Congress' top-down attempts to regulate have not been successful because in each instance a federal court has invalidated the statute based on constitutional grounds.

The first and most significant act that Congress passed to eradicate online pornography was the Communications Decency Act (CDA), which covered a wide variety of activity. The operative provisions found in Section 502(a) prohibited the "knowing transmission of obscene or indecent messages to any recipient under 18 years of age" and criminalized the "knowing, sending or displaying of patently offensive messages in a manner that is available to a person under 18 years of age." In *ACLU v. Reno* (1997), in upholding the decision of the three-judge panel the Supreme Court found that provisions of the CDA were impermissible content-based restrictions on speech. In addition, the Court found that the language was facially overbroad and vague, which would create an unacceptable chilling effect on the speech of adults using the Internet.

The subsequent two laws that Congress passed were more specifically directed toward children. The Child Online Protection Act (COPA) followed the tone of the CDA by criminalizing Web publishers who used the World Wide Web to make harmful material available to minors. COPA provided broad affirmative defenses if a Web publisher had restricted access to minors with the use of credit cards or other age verifying technology. COPA was found to be unconstitutional because of the impermissible burden placed on protected adult speech. The District Court found that COPA was neither narrowly tailored nor were the least restrictive means used to protect children from harmful materials. Finally, the Children's Internet Protection Act (CIPA) required that all public schools and libraries with Internet access install filtering software to block access to sexually explicit Web sites. A U.S. district court in Philadelphia found the CIPA unconstitutional because the filtering software would "block access to a substantial amount of speech that was both constitutionally protected and fails to meet even the filtering companies' own blocking criteria."

As of the time of this writing, the regulation of Internet pornography continues to present a challenge to Congress that remains unresolved. Access to the Internet, which is truly a unique marketplace of ideas, presents tensions among several fundamental rights. Our freedom of expression must be protected while at the same time one's right to be left alone or one's right to privacy must also be respected. To balance the right of privacy against other rights or practices such as data collection, one must first examine the much more important question: What is the value of the right to privacy?

## Views of Privacy

In the United States, the government has taken a restrained approach to protecting personal privacy, in contrast to the governments of many other nations. Since the American Revolution, many Americans have tended to fear a strong government. The U.S. Constitution gives the federal government only certain enumerated powers, leaving all others to the states. The first ten Amendments to the Constitution (the Bill of Rights) assure Americans additional freedoms, which most covet. The protection of privacy is not a fundamental right stated in the U.S. Constitution because it can impose restrictions on other fundamental rights. The First Amendment free speech guarantee limits government regulation of the flow of information including personal data. In nearly every country within the EU, the privacy right is expressly granted in the Constitution. In the entire history of the United States, the position of chief counselor for privacy was created for only 2 years, whereas in Europe there are entire parliamentary departments and "privacy czars" devoted to data protection and privacy concerns. The American reluctance to grant power to the government in this area is also reinforced by the country's *laissez-faire* market economy.

It would be inaccurate, however, to suggest that Americans desire privacy less than other members of the global community; rather they have a holistic view of their rights. This can be evidenced by the language used in the United States to describe data privacy. Americans use the term

*privacy* by which they can refer to the right to be free from the gaze of a peeping Tom or the right not to disclose one's name on a website. Europeans use the term *data protection*, which very specifically addresses information generated by an individual's overt activity.

Despite these different privacy orientations, a major international accord that addressed personal data protection, the Organisation for Economic Cooperation and Development (OECD; 1980) Privacy Guidelines of 1980 (the OECD Privacy Guidelines) was adopted in 1980. The OECD Privacy Guidelines have been adopted by all 25 member nations, and although they are not binding, they serve as suggestions for member countries and others in developing their domestic legislation. The OECD Privacy Guidelines established eight basic principles that govern the handling of personal information, referred to as *fair information principles*. They are collection limitation, data quality, purpose, specification, use limitation, security safeguards, openness, individual participation, and accountability. These are internationally accepted principles that pertain to all types of data processing by both the public and the private sector. Application of the OECD Privacy Guidelines is based on a loose reciprocity model of enforcement whereby personal data can flow freely between countries that provide equivalent protection.

## EU Privacy Directive—Explained

The most recently enacted and extensive statement of information privacy principles is the EU Privacy Directive. The EU Privacy Directive is a full-fledged system for the protection of personal data that requires the establishment of rights for data subjects and obligations for those who process personal data. It also provides monitoring by an independent body and sets out sanctions for offenders. The goal of the EU Privacy Directive is to increase the free flow of information, and it is designed to allow personal data to be sent or processed on the same terms within the EU and throughout the world. More than 15 member countries have passed their legislation to implement the EU Privacy Directive, and to date only France has not passed such laws. The EU Privacy Directive is broken into seven chapters that contain a total of 32 articles. The following overview of key provisions of the EU Privacy Directive illustrates the intensive focus on information privacy taken by the member states, which reflects a greater concern for data protection than typically found under U.S. law.

Article 2 of the EU Privacy Directive contains the operative definitions of the EU Privacy Directive, which include *personal data*, *processing of personal data*, *personal data filing system*, *controller*, *processor*, *third party*, and *recipient*. The EU Privacy Directives employs the terms *controller* and *data subject*, which creates a top-down assumption of computer networks, not necessarily personal or individual use of computers. These assumptions are less applicable or useful in a world of personal computers where people are browsing on the Internet.

Articles 6 and 7 of the EU Privacy Directive provide the general rules on the lawfulness of the processing of personal data. Article 6 establishes data quality principles by requiring that personal data must be processed

fairly and lawfully and that such data be accurate, kept up to date, and kept in a form that permits identification of data subjects for no longer than necessary. Lawful and fair processing is further defined by requiring that the data be collected for explicit, legitimate purposes. In addition, there can be no “secondary use” or “sharing” of data. Affiliate sharing or secondary use of personal data is allowed in the United States under the Financial Services Modernization Act of 1999, the U.S. law that provides the most comprehensive privacy protections for consumers to date (Gladstone, 2000b). Once again, this highlights the differences in privacy policies between the United States and Europe.

There are provisions in the EU Privacy Directive that allow data processing if the data subject “unambiguously gives consent.” A data subject can give his consent either by “opting in” or “opting out.” A data processor may disclose on its Web site that personal data disclosed by the consumer may be further distributed for purposes of research or marketing. The Web site may offer the viewer to choose not to allow the Web site to engage in this practice; this is opting out. It is unclear whether opting out satisfies the criteria of “unambiguously giving consent” or whether only an opting-in alternative whereby the Web site disseminates the data only if the viewer clicks “yes” to such a practice is sufficient (Gladstone, 2000b).

Article 7 also allows the processing of data that is needed to execute a task carried out in the public interest or for the exercise of the official authority vested in the controller. As in Article 3, the focus of the EU Privacy Directive is to protect data from abuse by private hands; the EU Privacy Directive deference to the government or an official authority is unlike the American approach, which seeks to minimize government involvement.

Articles 25 and 26 govern the transfer of personal data outside the EU to third countries such as the United States. The EU Privacy Directive bars the export of European personal data to countries that do not have “adequate” personal data protection regimes. The EU Privacy Directive sets out specific derogations whereby personal data may be exported despite adequate protection. These exemptions include where there has been consent by the subject, if it is necessary to the completion of a contract, or if it is in the public interest or for the vital interest of the subject. Information on the Internet crosses geographic and political borders on a continuous basis, and therefore all countries connected to the Internet are subject to the extraterritorial application of the EU Privacy Directive. Many U.S. companies have been concerned about the impact of the directive’s “adequacy standards” on their privacy policies and practices.

### Safe Harbor Compliance

The initial response of the United States to comply with the adequacy standards of the EU Privacy Directive resulted in the establishment of the International Safe Harbor Principles. After protracted negotiations, the United States government and the European Commission jointly agreed to principles to satisfy the “adequacy standards” of the EU Privacy Directive. Organizations that seek to benefit from the Safe Harbor Principles must self-certify

their compliance with the U.S. Department of Commerce, thereby agreeing to terms of data handling practices, compliance, and dispute settlement. The Safe Harbor mechanism allows voluntary commitment by U.S. companies, which builds on the United States-self regulatory approach to privacy. In 2003, there were 300 U.S. firms that had agreed to join the Safe Harbor program.

The Safe Harbor principles comprise two documents, list of seven “critical” elements dealing with data processing and a list several frequently asked questions (FAQs). Organizations may choose to adhere precisely to the specific provisions of the Safe Harbor Principles to obtain the benefits of the Safe Harbor and publicly declare that they do so. Alternatively, organizations may develop their own self-regulatory privacy program provided it conforms to the Safe Harbor Principles or join a self-regulatory privacy program that adheres to the Safe Harbor Principles. Organizations that have agreed to comply with the Safe Harbor principles are subject to Section 5 “unfair and deceptive” practices of the Federal Trade Commission Act or air carriers are subject to the equivalent statute of the Department of Transportation. There are several industries such as the telecommunications and financial services industries that are not eligible for the Safe Harbor or whose business practices are incompatible with the provisions.

The seven critical elements of the Safe Harbor are notice, choice, onward transfer, security, data integrity, access, and enforcement. At least five of the critical elements directly address the provisions in Articles 2 through 14 of the EU Privacy Directive. From the perspective of ensuring the same high level of privacy protection as the EU Privacy Directive, the Safe Harbor principles appear to fall short in several areas, which again reflects the trade-off between privacy and other fundamental rights in the United States. Under the Safe Harbor criteria of providing notice, individuals must be informed in clear and conspicuous language: (a) the purpose for which an organization collects and uses information, (b) the types of third parties to which an organization discloses the information; and (c) how to make inquiries or complaints. This Safe Harbor requirement follows the requirements of Articles 10 and 11 of the EU Privacy Directive, but Articles 10 and 11 require information be given to the subjects *before* the collection of personal information. The Safe Harbor notice requirement provides more leeway because such notice may be given before personal information is received or “as soon thereafter as practical.” This delayed notice was undoubtedly fashioned to encourage easy compliance with the EU Privacy Directive, but abuse of this option could effectively negate one of the key privacy protection mechanisms of the EU Privacy Directive. If an organization finds that prior notice is too costly, under Safe Harbor Principles it may routinely opt for giving notice after the fact. In addition, the Safe Harbor notice requirement does not require that data subjects be explicitly informed of their right of access to personal data (Gladstone, 2000). This is another disparity with the EU Privacy Directive, and it diminishes the underlying goals of the EU Privacy Directive.

Article 14 of the directive grants the data subject rights to object to the processing of data that the controller anticipates as being processed for direct marketing and

is incompatible with the purpose for which it was collected. The Safe Harbor gives individuals the opportunity to choose, opt out, in deciding whether and how personal information will be disclosed to third parties for a purpose other than that for which it was originally collected. Under EU Privacy Directive, the data subject must be given the opportunity to object before the data is disclosed for the first time to a third party. The Safe Harbor opt-out “choice falls short of the prior choice requirements in Article 14 of the EU Privacy Directive (Gladstone, 2000b). Article 6 of the EU Privacy Directive sets out the principle of the quality of the data, which may be collected and prohibits further processing of that personal data in a way that is incompatible with “legitimate purpose for which it was collected.” The parallel provision of Safe Harbor Principles, titled “Data Integrity,” once again allows an organization more freedom in collecting and maintaining data because an organization is not prohibited from further processing data as long as it takes “reasonable steps to ensure the data is accurate, complete and current.”

Article 25 of the EU Privacy Directive prohibits the transfer of personal data to a third country that lacks an adequate level of protection, and Article 26 offers certain limited exceptions to this prohibition. The onward transfer provision of the Safe Harbor requires that disclosure of personal information to a third party be consistent with the principles of notice and choice; an organization is liable if it knows or has reason to know that a third party will process the information improperly. Under the Safe Harbor Principles, however, an organization is in compliance when transferring data to a third party, even if the third party does not subscribe to the Safe Harbor Principles or the EU Privacy Directive, as long as that third party signs an agreement to protect the data. This flexibility could easily create a data haven and effectively subvert the EU Privacy Directive even if one were to comply with the Safe Harbor, thereby essentially frustrating the purpose of the EU Privacy Directive (Reidenberg, 2000).

### Model Contract Clauses

In an effort to offer more flexibility for compliance with the EU Privacy Directive, in December 2001 the EU Commission adopted Commission Decision 2002/16 (Contract Clause Decision), which sets out standard contract clauses for the transfer of personal data to processors in non-EU countries that have not been recognized as providing “adequate protection” for data. Under these standardized contract clauses, an EU company exporting data can and must treat the data with the full respect of the EU data protection requirements. The terms of these standard privacy contract clauses can be appended to existing licenses or contracts and offer a guarantee that the necessary security measures for privacy protection are in place.

The companies that choose to comply with the Safe Harbor provisions are subject to the enforcement jurisdiction of the U.S. Federal Trade Commission. Under the standard contract clauses, an entity becomes subject to the European Data Authority, and the standard contract creates a private right of action in Europe. In addition, the terms of the standard contract are rigid and may impose criminal penalties.

The EU Privacy Directive, which has set the standard for privacy protection for international transfer of data, can be satisfied in several ways. The means of compliance that varies from joining the Safe Harbor to drafting model contract clauses will depend on the nature of one’s organization and how one’s data are collected.

### Technological Responses to Privacy Protection

The legal and self-regulatory instruments just described have legitimately received substantial public support in their effort to protect privacy. The fundamental flaw with these privacy programs or legislation is a lack of understanding of the premise underlying the technological structure of computer networks, in particular the Internet. Loss of control over one’s personal data or relinquishment of one’s privacy is a direct result of the technology or infrastructure of the Internet. Network computer systems are designed to have identifiable transactions; every time one logs on to the Internet, an electronic record is created (Lessig, 1991).

The ease with which privacy is sacrificed as a result of the openness of the infrastructure of the Internet has recently been brought to the attention of the public as the Federal Bureau of Investigation (FBI) has widely implemented Carnivore, an efficient surveillance technology that captures Internet conversations. Carnivore is a software technology that was developed to intercept e-mail messages based on code words (Electronic Privacy Information Center, 2000). Carnivore is the term used for an entire system, which is a computer running on Microsoft’s Windows 2000 operating system and software that scans and captures packets, the standard unit of Internet traffic as they travel through an Internet service provider’s (ISP’s) network.

The FBI can install a Carnivore unit at an ISP’s network station and configure it to capture e-mail going to or from the person under investigation. Under the USA PATRIOT Act, discussed later, to obtain a court order to install Carnivore, a law enforcement agent must simply certify to a judge that the information is “relevant to an ongoing criminal investigation.” In addition to the fact that the warrant requirements are lowered under the USA PATRIOT Act, the packet-switching technology that drives the Internet has allowed the FBI to gather more information than a prescribed search warrant would allow. This compromises the privacy of all persons who have any interaction with the targeted suspect. Questions have been raised regarding the mechanics of the Carnivore system. When the Electronic Privacy Information Center filed a Freedom of Information Act (1999) request for Carnivore’s source code, the inner workings of how the device functioned, the FBI refused to disclose this information. This persistent refusal for full disclosure has led to several lawsuits against the FBI, which has created the impression in the eyes of the public that law enforcement is taking away rights rather than protecting them (Van Bergen, 2002).

Any discussion of privacy recognizes that a balance must be struck between the interests of privacy and security. The U.S. Department of Justice has been arguing with civil liberties groups and privacy advocates for several

years over amendments to federal statutes that would expand law enforcement wire tapping and electronic surveillance operations. Congress had been reluctant to expand law enforcement surveillance activities with respect to the Internet, citing privacy concerns. After the September 11 terrorist attacks, the USA PATRIOT Act passed through Congress swiftly; Congressional reluctance and public opposition, as measured by consumer polls, to expanded surveillance diminished.

The USA PATRIOT Act is a long and complex statute that made changes to more than 15 U.S. statutes, several of which directly affect Internet communications. Section 216 of the act addresses pen/trap orders, which were initially defined under the Electronic Communications Privacy Act as including a device attached to a telephone line to trace and trap telephone numbers. Since about September 2000, the FBI had been routinely applying pen/trap devices to computer communications, and thus under the USA PATRIOT Act, the pen/trap provisions apply to computer communications so that all e-mail addresses, Web addresses visited by a target, Internet protocol addresses, and other routing information can be obtained. The contents of the message has never been retrievable under a pen/trap order, but telephone numbers can be easily separated from telephone message; e-mail addresses are not so easily separated from e-mail contents or e-mail subject headings in particular.

The USA PATRIOT Act amends the Foreign Intelligence Surveillance Act (FISA), which historically had separated domestic criminal investigations from foreign investigations. Domestic surveillance was governed by Title III of the Omnibus Crime Control and Safe Streets Act of 1968, which provided for adequate safeguards for basic constitutional rights such as the Fourth Amendment probable cause requirements and judicial review. Foreign intelligence, which was governed by FISA, grants the attorney general the power to treat an alien as an agent of a foreign power, and therefore that person is not entitled to constitutional rights. The boundaries between these two laws are blurred under the USA PATRIOT Act, a fact that is most evident from the expanded definitions of *terrorist*. Consequently, under the USA PATRIOT Act's pen/trap provisions, an ISP must respond to a court order as long as the law enforcement agent certifies that the surveillance "is relevant to an ongoing investigation." The Fourth Amendment requirements of probable cause when conducting wiretaps have been lowered. In addition, pursuant to the same lowered standard, any business may now be served with an order for the production of "any tangible thing," not just a business record. Clearly ISPs, cable subscribers, and businesses in general ought to review their privacy policies and confidentiality agreements to ensure that they accurately reflect their new obligations under the USA PATRIOT Act.

There are significant differences in the regulations surrounding the protection of personal information in the United States and in Europe. These differences will likely impede global e-commerce and international agreements, and negotiations are needed to enable nation states' policies to develop in harmony. Joel Reidenberg (2001) suggested the promotion of negotiations of a General Agreement on Information Privacy (GAIP) in connection with

the World Trade Organization (WTO). Reidenberg recommends this type of a treaty organization because it places data protection in a trade arena rather than a political arena; by placing GAIP within the WTO, it would add social protection norms to a trade treaty. The GAIP would include many signatory countries and focus on an institutional process of norm development to facilitate near-term standards for informational privacy. The WTO could define cost standards for data protection that could be incorporated into a multilateral trade agreement (Reidenberg, 2001).

## ENCRYPTION AND ELECTRONIC SIGNATURES

The expansion of Internet technology has allowed people to use the Internet as a platform for worldwide business, and therefore contracts are being formed among parties with no prior relationships. Parties want to rely exclusively on online communications; thus, a reliable system of authentication is needed to ensure the success of e-commerce (Winn, 2001). The ability to transmit information secretly over distances has been accomplished using cryptography for decades. Digital signatures and encryption are the two key aspects of cryptography that have been recognized as essential tools for security and trust for electronic commerce. This section begins with an explanation of the current global regulation regarding the control of exportation of encryption. The most popular form of encryption in use today is public key asymmetric cryptography (private key infrastructure; PKI), which is used in digital signatures. *Electronic Signatures-Technical Overview* distinguishes digital signatures from electronic signatures before offering an overview of the PKI technology. *Regulatory Models* explains the three legislative models that have been developed for the regulation of electronic signatures.

Cryptography is the art of using code to keep information secret and encryption is the technique to encode or scramble communications. Most nations regulate the exportation of encryption technology because of the fear that abuse of the technology by terrorists or criminals would impede the ability of national security and law enforcement to do their jobs. Privacy advocates and free speech proponents in the United States agree that restrictions on exports of encryption infringe on individuals rights to informational privacy and on Fourth Amendment and First Amendment rights. Members of the high-tech and software industries complain that such restrictions are anticompetitive vis-à-vis foreign nationals.

### Encryption Exportation Regulation; United States Law and International Treaties

Under the Arms Export Control Act of 1978 (2000), the U.S. State Department decides whether an item is dual purpose, which is a category that includes commercial products with military application. Control over the licensing and export of dual-purpose products is transferred to the Department of Commerce (DOC; Paik, 2000). The DOC under the EAA now regulates the export of all general-purpose encryption devices and software. The

DOC Export Administration Regulations 15 C.F.R. 730-74 (2000) include source code and object code in the definition of software subject to regulation and exportation which includes “downloading or causing the downloading of such software . . . or making such software available from electronic bulletin boards” (Paik, 2000). During the years of the Clinton administration, there was significant discussion regarding the requirement that software companies create key recovery systems, one which was recommended by the government was known as the Clipper Chip. That requirement was not adopted, and current regulations allow U.S. citizens to ship any retail encryption product around the world to commercial concerns after a one-time technical review by an interagency panel (Paik, 2000).

The Wassenaar Agreement is an international agreement that addresses controls on encryption exports to which 33 countries, including the United States, subscribe (“What Is the Wassenaar Arrangement,” n.d.). The agreement, which was designed to promote cooperation among its members, was amended in 1998 to impose export control on export software for keys above 64 bits and to eliminate record keeping for low-level encryption. Several countries, including Israel, South Africa, India, and China, however, are not members. Therefore, there is not harmonization in the global encryption export market (Paik, 2000).

## Electronic Signatures—Technical Overview

An electronic signature is any method that logically associates an electronic representation of the identity of a person with the content of an electronic document or record. It implies acknowledged authorship or agreement, but there are times, with e-mail programs, for instance, when an electronic signature can be applied automatically. Generally, with electronic records the goal is to protect the integrity of the content, and a generic electronic signature provides little assurance that documents have not been altered. Digital signatures are a special subset of electronic signatures which can provide this assurance (Ballon, 2001).

Digital signatures serve three essential functions: authentication, integrity, and nonrepudiation. Authentication means that the party is who he or she claims to be. Integrity means that the communication has not been tampered with (i.e., it is in its original form), and nonrepudiation prevents the party from retreating from the transaction in the event a dispute arises. A digital signature denotes an electronic imprint that is created using public key encryption (PKI). Public key encryption is also referred to as asymmetric encryption because two keys are used, a private key and a public key. The two keys are mathematically related so that when the message is encrypted with the private key and sent off to the recipient, the recipient must use the sender’s public key to decrypt it. Each user has a different public–private key pair (Berman, 2001).

A digital signature is not a digitized version of a person’s handwritten signature, but a “message digest” of the document that is being encrypted or sent. The message digest is created by processing the document through a unique computer generated code known as a *hash*. Once

the hash is created, the signer types in a personal identification number (PIN) that allows the private key to generate a long series of numbers and letters, which is the digital signature. The sender uses a one-way hash function to encrypt the message he or she wants to sign and then sends it off. The computer generated signature and the hash result are unique to the message. Every time the message passes through the hash function, the same message digest is produced. To verify the signature of a digitally signed message, the receiver reverses the process with the public key.

For a digital signature system to function, the parties must be assured that the public keys that they obtain actually belong to the person he or she purports to be and not to a forger. The way to achieve this confidence is with a CA, which is an entity, either public or private, that attests to the integrity of the system. CAs issue certificates of authenticity as to the ownership of the keys. There have been several proposals as to the best solution to the problem of authentication (Zemmick, 2001). At the present time, several banks offer this service.

The intention in all jurisdictions that have enacted electronic signature laws is to encourage the development of e-commerce, but there is a large disparity in their treatment of electronic signatures. According to Smedinghoff and Ruth (1999), “predictability is a watch word for the growth of commerce and law can play a role in providing this valuable commodity,” and yet the most striking feature of the various electronic signature laws enacted around the world is their lack of uniformity (Fischer, 2001). As we saw with the various privacy policies, failure of policymakers to remove national barriers will hinder successful global e-commerce and possibly widen the digital divide.

## Regulatory Models

Electronic signature legislation can be seen as based on one of three models. The first is known as the *mandatory* or *prescriptive model* because it mandates a specific technology (Fischer, 2001). Alternatively, the *minimalist legislative approach* is technology neutral; and the third *hybrid approach* suggests a favored technology that affords presumptions under the law. Proponents of the prescriptive model, which include Germany, Italy, Malaysia, and Russia, mandate specific technology when authorizing electronic signatures as an alternative to pen and paper. PKI, the digital signature that is currently the most sophisticated technology, is required. In addition, this mandatory or prescriptive approach often outlines specific criteria for the trusted third party or CA. The rationale given for this approach is that the requisite security for e-commerce can only be obtained with these constraints. In addition, it is believed that these requirements will ensure legal certainty, which is essential for public trust. Critics of this approach point out that this not only grants economic advantages for a particular existing technology, it is short-sighted because although the “best” technology in 2002 may be PKI, better, more sophisticated techniques may become available.

In addition, this mandatory or prescriptive approach often outlines specific criteria for the trusted third party

(CA) and usually overly limits the liability of the CA. Typical prescriptive digital signature laws place the burden for loss or theft of a private key on the consumer if there was a failure to exercise reasonable care. The consumer will bear the entire loss, thus insulating the CA from any liability. This structure of liability seems to burden the consumer unfairly in an effort to create a less risky role for the CA in which the CA could more efficiently protect itself.

The hybrid model, which was adopted under the E.U. Signature Directive of 1999 (European Parliament and Council Directive, 2000) by the European Union, is often referred to as a two-tier model because it grants basic validity to all electronic signatures but provides special treatment to certain advanced signatures. Under this hybrid approach, an electronic signature cannot be denied legal effectiveness solely because it is electronic, but some technologies are given presumptions of authenticity if the signature meets certain requirements. At the present time, the only technology that meets these heightened standards is PKI.

The rights and duties set out for the parties to an electronic transaction under the hybrid model reflect a market driven philosophy. Unlike under the prescriptive approach, CAs will be found liable in damages for harm caused to someone that has reasonably relied on a certificate for the accuracy of the information unless it can be proven that the CA was not negligent. The presumption is in favor of the consumer. CAs under the hybrid approach can limit their liability by contract, however, before entering into the transaction.

The minimalist, wholly technology-neutral approach provides that no electronic signature of whatever type may be denied legal effect, validity, or enforceability because it is in electronic form. The United States Electronic Signatures in Global and National Commerce Act of 2000 (E-SIGN) endorses this approach. Australia and the United Kingdom have also enacted minimalist legislation, and New Zealand is considering a law similar to that of Australia (Fischer, 2001). The philosophical principles on which it is based foster technological advancements by allowing the market to decide which technology is best. It also allows several systems to be developed simultaneously. E-SIGN was drafted and enacted swiftly in the United States, in part as a response to the factious division among the several states in adopting various versions of electronic signature legislation.

The major criticism of E-SIGN is that it is too vague, and its lack of certainty will hamper electronic commercial growth. Critics of E-SIGN suggest that the nonrestrictive legislation might lead to parties being held liable for contracts that they did not actually authorize (e.g., if a party somehow failed to protect the security of his or her signature device). Although the liability may be severe, the "liberty to contract" concept prevails, which leaves the parties free to be bound or reject the contract.

The electronic signature legislation that has been passed in countries around the world reflects the contrasting views of minimalist and the prescriptive approach. The global initiative by the United Nations Commission on International Trade Law (UNCITRAL) working group on electronic commerce is not expected to have a

significant impact on existing or proposed legislation because business lost confidence in the proposal during negotiations due to the parties' insistence on a prescriptive approach mandating a PKI (Fischer, 2001). The future of commerce will not take place on paper, and it is important for the law to grow to facilitate the development of e-commerce. Attention needs to be given to harmonize the differences among nations that exist in the area of electronic signatures, possibly through revision of the work produced by UNCITRAL.

## INTELLECTUAL PROPERTY

Technology has had a profound impact on the perception of intellectual property and the appropriate distribution of the rights traditionally attached to trademark, patent, and copyright in the global context. Although technological advances have created unprecedented opportunities for economic prosperity in the area of intellectual property, legal systems have had to adapt to maintain firm standards while fostering financial growth. Consistency in legal paradigms across national borders, which is crucial to establish the Internet as a reliable conduit for successful global commerce, has been relatively successful in the area of intellectual property. International intellectual property conventions have been consolidated under the auspices of Convention Establishing the World Intellectual Property Organization (WIPO). The Agreement on Trade Related Aspects of Intellectual Property (TRIPs) has formed a WTO-WIPO union by integrating much of WIPO's law into WTO's trade regime (Mort, 1997). Trends in practice also suggest a tendency toward uniformity. This section reviews substantive provisions of the WIPO Copyright Treaty (1996), key terms of the Digital Millennium Copyright Act (DMCA), the European Copyright Directive, and the Electronic Commerce Directive, particularly as they reflect the guidelines for ISP copyright liability.

Digital transmissions allow infringers to obtain and disseminate information quickly without being detected. The Internet presents difficult challenges for copyright owners to identify and stop infringement. Locating a financially sound ISP to end the copying activity is the surest route for the copyright owner. This section also examines the discrepancies that exist between the U.S. and the EU approaches to database protection and business method software protection.

### ISP Liability for Third-Party Copyright Infringement

Intellectual property conventions that predated WIPO's creation in 1967 historically operated independently without institutional oversight (Mort, 1997). WIPO, which was designed as a specialized agency to administer major international conventions under the leadership of the United Nations director general secretariat, had difficulty enforcing rights and resolving conflicts. Serving as the sole international authority for more than two decades, WIPO lacked the necessary enforcement powers to eliminate piracy of intellectual property. In 1986, as part of the Uruguay Round Negotiations, intellectual property

protections were integrated into the General Agreement on Tariffs and Trade (1947) in 1994. TRIPs was established and a symbiotic institutional relationship between the WTO and WIPO was formed (Mort, 1997). There was a simple integration of intellectual property protection into a trade based sanction regime. In 1995, a cooperative agreement was signed between the two bodies to coordinate their efforts.

In 1996, WIPO concluded two treaties covering the protection of copyright and rights in digital environments, the WIPO Copyright Treaty and WIPO Performances and Phonograms Treaty. The WIPO Copyright Treaty established a distribution, rental, and communication right in creative works to the public. This distribution right under the WIPO Copyright Treaty may be accomplished through sale or other means of transferring ownership, but the right is limited to fixed tangible copies capable of circulation (Soma & Norman, 2000). There was no agreement between the delegates on the scope of the doctrine of exhaustion for “first sale” rights, so this was left to be defined by each adopting nation. Another important provision of the WIPO Copyright Treaty related to the exhaustion of rights is that the right of public communication permits copyright holders to make their works available by wire or wireless means. Included in this right is the ability to make works available to the public so that they can access them as they choose. In the event communication permits recipients to reproduce a tangible copy, national law must define liability for infringement.

The implications of this broad access right is that ISPs could be liable for direct and contributory copyright infringement causes of action that may be brought by the copyright owner against the ultimate recipient. The right created in the WIPO Copyright Treaty leaves details about liability for third-party copyright infringement to the contracting parties. This has caused much concern among telecommunications companies and ISPs, because such a broad interpretation of the treaty could lead to lawsuits from copyright owners (Mort, 1997).

Under case law in the United States, the issue of determining ISP liability for third-party copyright infringement starts with an examination of the type of service the ISP provides in relationship to the infringement claim. The categorization of the ISP is based on the level of knowledge the ISP had of infringing activity, the control of the ISP, the length of time the material is stored on the ISP server, and any financial benefit received by the ISP. When defined according to function, one will analyze and apply liability to the ISP based on the traditional common carrier versus publisher or distributor model (Soma & Norman 2000).

In the United States, the DMCA limits ISP liability for third-party copyright infringement when the ISP complies with a detailed system of notice and removal. When an ISP acts as a mere conduit for data, the DMCA will limit liability of the ISP relating to these transitory communications.

The recently passed EU Copyright Directive follows a similar logic as the DMCA in that it exempts ISPs from liability when they play a passive role as a mere conduit of information from third parties. An ISP cannot modify the work in any manner; the ISP must comply with industry standards for transmission and storage and must remove

infringing materials expeditiously to avoid copyright infringement liability. A third-party copyright infringement case would not be successful unless the ISP had been warned to remove it and did not do so (McDonald, 2001). Finally, the Electronic Commerce Directive, which is similar to the DMCA and the EU Copyright Directive, sets out guidelines for liability for ISPs where they play a passive role as a mere conduit of information from third parties. Similarly, the Electronic Commerce Directive limits ISPs from liability for other intermediary activities such as storage of information or caching.

## Databases

Database protection presents a controversial area of legislation in the global arena. A database, which is a compilation of information, is not protected under copyright law in the United States unless the arrangement or selection rises to a sufficiently high level of originality or uniqueness in its selection or arrangement. Database protection was limited by the U.S. Supreme Court in *Feist Publications Inc. v. Rural Tel. Serv. Co.* (1991) in which the court held that a white pages telephone directory, which consisted of preexisting factual material, lacked the requisite originality in selection coordination and arrangement of data to garner copyright protection. The simple listing of subscribers in alphabetical order by surname lacked originality, despite the excessive time, effort, and energy expended to organize it. Feist struck down the “sweat of the brow” doctrine, which some U.S. courts had used to find copyright protection. Opponents of greater legal protection for databases believe that the balance between control over information and allowing information into the public domain is best met with few legal restrictions imposed. “Information is meant to be free” is the ideology expressed in support of a reduced role of government.

The European countries believe that there are sound economic justifications for affording protection to owners of databases based on the “sweat of the brow” theory and in 1996 passed the EC Directive No. 96/9, on the Legal Protection of Databases (the Database Directive). The *sui generis* protection granted to databases under the Database Directive is based on a property concept, which bestows exclusive rights of ownership to the database compiler. The provisions to afford database protection was dropped from the WIPO Copyright Treaty over objections by members of the academic and scientific community, but debate over this issue remains in the United States. Several legislative bills have been introduced in Congress based on the belief that such protection would make the United States more competitive in foreign markets. None of these bills have passed as of the time of the writing of this chapter.

## Software Patents

The topic of patenting software and, in particular, business methods has received a lot of attention from the public because of the economic success of several e-commerce entrepreneurs (Gladstone, 2002). The EU and American approaches to protection of software have traditionally been reported as divergent but, on closer examination, the two policies appear to be converging,

particularly in light of the decline of the heated electronic commerce boom. Historically, intellectual property and software was limited to copyright protection on the grounds that it was written in code, thus it was a literary work, and hence copyright protection was appropriate. In *Diamond v. Diehr* (1981), however, the U.S. Supreme Court held that a process for monitoring the temperature inside a synthetic rubber mold using a computer and the Arrhenius equation for measuring cure time as a function of temperature and other variables was patentable subject matter. The court focused on the "postsolution activity" that resulted from the computer program (Cohen & Lemley, 2001). The lesson from the *Diehr* decision was to include a physical element or step in any future patent application that might recite a "mental process." This theory was adopted and clarified by the federal circuit in *In re: Alappat* (1994), which established that an "otherwise statutory process or apparatus requirement may be satisfied by drafting claims to include a general purpose computer or standard hardware or memory element that would be necessary for any useful application of the algorithm." The logic of these cases did not include claims reading on computer programs themselves, as opposed to programs implemented in a machine or system (McDonald, 2001). This obstacle was overcome in the *In re: Boureguard* (1995); while an appeal was pending, the U.S. Patent and Trade Office established that software stored in memory media is patentable as an article of manufacture.

Article 52 of the Convention on the Grant of European Patents of the European Patent Convention (EPC) indicates that computer programs "as such" are not patentable and that programs for computers shall not be regarded as inventions. The European Patent Office, estimates, however, that they have issued more than 20,000 patents on computer programs. In late 2000, there was a Diplomatic Conference to revise the EPC to change Article 52, bringing it in line with actual practice and with TRIPs, making it clear that patent protection would be available to technical inventions of all kinds (McDonald, 2001). This measure did not pass, however. The reversal and decision to hold on to the old position is interesting in that it reflects a rebellion against the rushed commercialization reflected in the e-commerce boom.

Critical in any discussion of intellectual property rights is finding the correct balance between creating incentives to encourage innovation by inventors and the public's right to access to information and knowledge. The trend in the United States to grant exclusive patent rights to software involving Internet technology continued unabated to the point where the U.S. Patent Office was granting patents on "how to get a business method patent." Beginning with the case of *State Street Bank & Trust vs. Signature Financial* (1998) in which Signature Financial was granted a patent for a data processing system to implement an investment structure, the court endorsed business methods providing they comply with other requirements for a patent, thus laying to rest "the ill conceived exception to the law" that business methods were not patentable. U.S. patents have been issued on numerous technological processes; the "single click" patent covering a method and system for placing purchase orders via a commercial network that was granted to Amazon.com

and contested by Barnesandnoble.com is one of the more controversial and publicly known cases to be litigated. Although Amazon.com initially was granted an injunction to prevent Barnesandnoble.com from using the process, the patent is still being challenged (Shulman, 2000).

The U.S. trend to grant patents on software for business methods informed the discussion within the Diplomatic Conference of the European Commission regarding their policy toward granting patents on software. It is likely that the concern over the inseparability of business methods from software patents in general may have encouraged no change in the EPC. Proponents of LINUX, the open-source software that encourages sharing of ideas to promote innovation, began campaigning against software patents in general in Europe in the late 1990s. This development may also have influenced the change in the EPC outcome (McDonald, 2000).

The economic downturn of the late 1990s, which hit technology companies and Internet startups particularly harshly, likely also contributed to the slowdown in Internet-related business method patent filings. Nonetheless, the curtailment of the public's endorsement of companies whose sole or main asset was a business method patent was a key factor. Empirical evidence which demonstrates the withdrawal of funds from these "idea factories" (Shulman, 2000) suggests that the flurry of business method patents may not have been based on solid economic grounds. The multibillionaire entrepreneur Jay Walker, whose company Walker Digital claimed 70 business method patents with 400 pending before the U.S. Patent Office, had to lay off 80% of its workforce within a few short years of establishing itself (Shulman, 2000). The profusion of new software business method patents was exciting but, in fact, it had a chilling effect on e-commerce; when put to the Wall Street test, most of these companies did not fare well. Although parties are still applying for business method patents, often these are an offensive or a defensive act taken to prevent others from gaining market share rather than with an expectation of employing the patent. The recent decline in enthusiasm of business method software patents in the United States suggests that the EU position to proceed cautiously before modifying laws to broaden individuals' rights at the expense of the public's access to information may be the better approach (Gladstone, 2002).

## CONCLUSION

The Internet reaches around the globe, and it may be unrealistic to expect symmetry between nations. Nonetheless, policymakers must continue to strive for a common ground. There is sufficient legal and empirical evidence to support a nation's asserting jurisdiction and enforcing its laws beyond its borders, but enforcement jurisdiction and questions of comity present additional difficulties, as seen recently with the internationally recognized Yahoo! case. In the areas of privacy and electronic signatures, discrepancies between countries remain apparent, and these variances are rooted in fundamental cultural, social, and philosophical differences. The Internet has become a medium for widespread commercial activity, but continued expansion will require agreement regarding

mechanisms to regulate in all areas of human activity. Global consensus to limit ISP liability for copyright infringement, the reduction in the business method patent application surge, and the reluctance in the United States to pass a *sui generis* database protection law suggest a concerted global effort not to limit public access to information and to allow the Internet to serve as a conduit of knowledge dissemination. There is clearly a trend toward common ground in several areas of intellectual property law in cyberspace. Harmonization in all areas of the law is the goal to strive for, because without seamless predictable systems, businesses and consumers will be reluctant to enter into transactions.

## GLOSSARY

**Cyberspace** Functionally, cyberspace is where messages and Web pages are posted for everyone in the world to see. In *Reno v. ACLU* (1997) the first opinion about the Internet by the U.S. Supreme Court, it was stated that “Taken together, these tools constitute a unique medium—known to its users as ‘cyberspace’—located in no particular geographical location but available to anyone, anywhere in the world, with access to the internet.”

**Cybersquatting** The practice in which a person or an entity registers a domain name with no intention to use the name for a useful purpose; rather, the sole purpose is to thwart the ability of the rightful owner or trademark holder to obtain the name.

**Data Protection** The right provided for under the Council Directive 95/45/EC of the European Parliament and of the Council of the European Union of Oct. 24, 1995, also known as the EU Privacy Directive.

**Electronic Signatures in Global and National Commerce Act (E-SIGN)** A U.S. law that was passed in 2000 that recognizes the legal effect of an electronic signature in whatever form it is made.

**Encryption** The conversion of data into a form, called ciphertext, that cannot be easily understood by unauthorized people.

**International Safe Harbor Principles** The regulatory response of the United States government to the “adequacy standards” of the EU Privacy Directive, agreed on by the European Commission.

**Privacy** The right to be left alone

## INTRODUCTION

Understanding privacy is a true challenge, in no small part due the difficulty in defining the concept of privacy itself. The textbook definition of privacy only begins to scratch the surface of a deeply complex issue, made all the more complex because of the strong personal feelings evoked by privacy breaches. Accounting for privacy concerns can be a daunting task, especially when one is building Internet-based services and technologies whose success can depend on not offending consumers' mercurial sensibilities about the value of their privacy versus the value of those services that depend on free-flowing personal data.

This chapter discusses the roots of privacy law, including the different ways privacy matters are dealt with under constitutional law, statutes, and common law. With the fundamentals established, the rest of this chapter will discuss how many of those principles have come to be applied in today's Internet-oriented privacy terrain, and how businesses must prepare for doing business in this new environment.

## PRIVACY LAW BASICS

### Privacy Defined

The Merriam-Webster Dictionary of Law defines **privacy** as "freedom from unauthorized intrusion; state of being let alone and able to keep certain especially personal matters to oneself." Within this broad "state of being let alone," particular types of privacy intrusion have been recognized under law. How one defends themselves against intrusions differs, however, based on who it is doing the intruding.

## Constitutional Privacy

Even though you will find no trace of the word "privacy" in the U.S. Constitution, a series of Supreme Court decisions beginning in the 1920s began to identify the modern concept of privacy. As the Court refined its views on privacy, it found the idea of privacy within the spirit of the Constitution's protections, if not in the plain language of the document. In 1928, in a landmark wiretapping case *Olmstead v. United States*, 277 U.S. 438 (1928), Supreme Court Justice Louis Brandeis articulated these ideas in some of the most important words ever written about privacy:

"The makers of our Constitution undertook to secure conditions favorable to the pursuit of happiness. They recognized the significance of man's spiritual nature, of his feelings and of his intellect. They knew that only a part of the pain, pleasure and satisfactions of life are to be found in material things. They sought to protect Americans in their beliefs, their thoughts, their emotions, and their sensations. They conferred, as against the Government, the right to be let alone—the most comprehensive of rights and the right most valued by civilized men" (Brandeis dissenting, *Olmstead* at 478).

Brandeis's phrase, "the right to be let alone," is one of the most often-repeated ideas in privacy and has influenced the court's inquiry beyond the plain words of the Bill of Rights to find other privacy rights that are logical extensions of the meaning contained in the original words, including

- The First Amendment right of free speech has been read to include the right to speak anonymously. Free speech has also been interpreted in reverse: you have the right to not be forced to say certain things.

- The First Amendment right of free association means that you can join clubs and affiliate yourself with anyone you choose. Inherent in that right, according to the court, is the right not to say whom you're associating with.
- The Fourth Amendment prohibits the government from searching your home and property and from seizing your papers or possessions, except under very specific circumstances. The Fourth Amendment has also been read to give certain rights against government wiretaps and surveillance.
- The Fifth Amendment includes various rights of due process, which means that if the government is interested in depriving you of any of your rights—throwing you in jail, for example—it must first follow strict procedures designed to protect your rights. Among those is the right against being forced to incriminate yourself.
- The equal protection clause of the Fourteenth Amendment requires that both sexes, all races, and all religions be given equal protection under all the laws of the United States and all the laws of every state. This protection comes despite other amendments that can be read to permit some types of discrimination.

But these rights aren't absolute, for example:

- The government can set up wiretaps, perform surveillance, and perform searches and seizures if they have the reasonable belief ("probable cause") that a crime has been committed and if given permission (a "warrant") by a judge;
- The government can establish secret wiretaps and surreptitiously search your home or car, without a normal warrant, if you are suspected of being a terrorist or an "agent of a foreign power;"
- It can be illegal to keep certain materials in your home, such as drugs or child pornography;
- Certain public organizations (like the Jaycees, which was the subject of a lawsuit that established this precedent) cannot use the First Amendment right of free association to exclude protected classes of people, such as women or certain minorities. On the other hand, at the time this book was written, the Boy Scouts could discriminate against gay people.

But the Constitution only affects privacy issues involving the government. What are your rights against people who are not part of the government, such as individuals and corporations? That's where a patchwork of common law privacy protections and several statutes comes into play.

### Common Law Privacy

The common law is a set of rights and obligations first recognized by courts rather than by legislatures. Just because it is "judge-made" law, though, one cannot discount the common law as being less forceful. In fact, many common-law rights have been enforced for centuries and are some of the most powerful precedents in our legal system. They are rarely overturned by legislatures, and

many state and federal laws are simply codifications of common-law ideas that have been around for hundreds of years.

In a groundbreaking law review article in 1960, William Prosser set out four broad categories of common law that underlie privacy-related torts:

- Intrusion into one's seclusion;
- Disclosure of private facts;
- Publicizing information that unreasonably places one in a false light; and,
- Appropriation of one's name or likeness. (Prosser, 1960)

**Intrusion.** The tort of intrusion recognizes the value of having your own private space, and provides relief from those who would seek to violate it. Eavesdroppers and "peeping toms" are two examples of activities considered intrusion.

**Disclosure.** The tort of disclosure recognizes that making public certain private facts can cause harm to an individual. For example, disclosures about someone's health status, financial records, personal correspondence, and other kinds of sensitive personal information can cause harm if made public.

**False Light.** The tort of false light is similar to libel in that it involves publicizing falsehoods about someone, but it is subtly different. One famous case of false light, *Cantrell v. Forest City Publishing Co.*, 419 U.S. 245 (1974), involved a family who was inaccurately portrayed in a news article in a humiliating fashion that brought shame and embarrassment. Another, *Douglass v. Hustler Magazine*, 769 F.2d 1128 (1985), involved a model who posed nude for a popular pornographic magazine, which were instead published with embarrassing captions by a notoriously vulgar magazine instead.

**Appropriation.** This tort involves using the name or likeness of someone for an unauthorized purpose, such as claiming a commercial endorsement by publishing someone's image (or even that of a look-alike impersonator) in an advertisement.

In this age of modern technology, there appear to be many new ways of violating these centuries-old privacy torts. The prevalence of miniature "Web-cams," highly sophisticated digital photo editing applications, and the vigorous online trade in pornographic imagery, have each added to the ways in which individual privacy can be violated.

## PRIVACY LAWS IN THE UNITED STATES AND ABROAD

In a 1973 report to Congress, the U.S. Department of Health, Education and Welfare (HEW) outlined four tenets of fair information practices. These guidelines were groundbreaking in that they set forth four characteristics that any fair policy regarding the collection and use of personal information had to take into account. The four tenets were

**Notice.** Details of information practices and policies should be disclosed to data subjects.

**Choice.** Data subjects should be given the ability to exercise choices about how data may be used or disclosed.

**Access.** Data subjects should be permitted access to data gathered and stored about them.

**Security.** Holders of personal data should be responsible for providing reasonable levels of security protection for data in their possession (HEW, 1973).

Since then, there have been a number of laws enacted in the United States dealing with individual privacy. The standard U.S. approach is, however, to focus on particular types of information used by or about specific sectors:

**Banking Records.** Your personal banking information is protected by law, up to a point, including under provisions of a new law called the Financial Services Modernization Act (also known by its authors as the Gramm-Leach-Bliley Act).

**Credit Reports.** The Fair Credit Reporting Act (FCRA) requires that credit bureaus handle your data in certain ways.

**Medical and Health Insurance Records.** Laws and regulations governing how medical records can be used have been in place for several decades, and provisions of a new law called the Health Insurance Portability and Accountability Act (HIPAA) are creating new rights for patients to protect and access their own health information (HHS 2002).

**Government Records.** The Privacy Act of 1974, which included the original tenets outlined in the HEW report, sets limits on how government agencies can collect and use personal information, while laws like the Freedom of Information Act of 1966 require government to give all citizens access to certain government records, provided that the government also take precautions not to breach privacy when making that information public.

**Children's Privacy.** While not limited to one business sector, a law called the Children's Online Privacy Protection Act (COPPA) places restrictions on online organizations that seek to collect data from one sector of the public: children under the age of 13. COPPA requires the publication of a privacy policy to explain data practices relating to children's information, requires verifiable parental consent before any personally identifiable information may be collected from children over the Internet, and limits companies ability to share children's information with third parties.

## International Privacy Law

The recognition of privacy rights in international law goes back to December 10, 1948, when the United Nations adopted the Universal Declaration of Human Rights. Article 12 of that document says: "No one shall be subjected

to arbitrary interference with his privacy, family, home or correspondence, nor to attacks upon his honour and reputation. Everyone has the right to the protection of the law against such interference or attacks" (UN, 1948).

Building on that foundation, and applying the four tenets articulated in 1973 by the U.S. government, in 1980 the multinational Organization for Economic Cooperation and Development (OECD), of which the United States is a member, issued its eight Principles of Fair Information Practices. These principles consisted of:

**Collection Limitation.** There should be limits to the collection of personal data, and any such data should be obtained by lawful and fair means and, where appropriate, with the knowledge or consent of the data subject.

**Data Quality.** Collection of personal data should be relevant to the purposes for which they are to be used, and, to the extent necessary for those purposes, should be accurate, complete and kept up to date.

**Purpose Specification.** The purposes for which personal data are collected should be specified not later than at the time of data collection and the subsequent use limited to the fulfillment of those purposes or such others as are not incompatible with those purposes and as are specified on each occasion of change of purpose.

**Use Limitation.** Personal data should not be disclosed made available or otherwise used for purposes other than those specified in accordance with principle of purpose specification, unless done with the consent of the data subject or by authority of law.

**Security Safeguards.** Personal data should be protected by reasonable security safeguards against such risks as loss or unauthorized access, destruction, use, modification, or disclosure of data.

**Openness.** There should be a general policy of openness about developments, practices and policies with respect to personal data. Means should be readily available of establishing the existence and nature of personal data, and the main purposes of their use, as well as the identity and usual residence of the data controller.

**Individual Participation.** An individual should have the right to obtain from a data controller confirmation of whether data are held about the individual, to be given access to the data in an intelligible form, and to have the data erased, rectified, completed, or amended.

## Accountability

A data controller should be accountable for complying with measures which give effect to the principles (OECD, 1980).

The European Union has taken the OECD principles and incorporated them into a sweeping Data Privacy Directive that establishes these principles in law. The directive mandates the following minimum standards in all countries that are members of the European Union:

- Companies can only collect information needed to complete the transaction, and must delete it after the transaction is over, unless they have explicit permission.
- Consumer's personal information must be kept up to date, or deleted.
- The purpose for collecting data must be given at the time that data are collected.
- An individual's personal information cannot be used for any other purpose (e.g., mailing catalogs or coupons) unless they have explicit permission.
- Companies must have appropriate security safeguards in place to guarantee privacy of any data in their possession.
- Companies must keep consumers advised in a clear and open manner about their data practices and how consumer's privacy will be impacted by any changes.
- Consumers must be permitted to see any information a company has on file about them, must be permitted to correct any errors, and must be allowed to delete data unless there's a legally mandated reason for keeping it.
- Companies who keep consumer information must have someone in the company accountable for assuring that the privacy laws are being adhered to.
- Companies may not transfer data outside the E.U. unless the country to which the data is being transferred has privacy laws as strict as those in the E.U. (EC, 1995)

It should also be noted that these restrictions apply to all data in a company's possession, whether customer data or employee data. And these are minimum standards; individual member countries can—and have—enacted laws that are even stricter.

To enforce their privacy laws, many E.U. member countries have established data protection authorities—government agencies whose mandate is the policing of data practices within, and crossing, national borders. These authorities often require corporations who possess personally identifiable information about any citizen of their nation to register with the agency and file detailed statements of what data are collected and how it is utilized.

In addition, while U.S. law focuses on certain categories of information, such as financial or healthcare data, holders of the data such as credit bureaus, or categories of data subjects such as children, the E.U. law gives special consideration to data about:

- Race
- Religious Affiliation
- Membership in Political Parties and Trade Unions
- Criminal Records

These topics are of particular concern to Europeans, in part because of how records containing information about race, religion, and trade union memberships were gathered and used by the Nazi regime in Germany and in their occupied countries to decide who should be shipped off to concentration camps. For Europeans, the threat of private information being misused is more than a test of wills between marketers and consumers, but meant
